Compounding rate for which the input zero rates are compounded when annualized, specified as one of the following scalar integers. Compounding determines the formula for the discount factors (`Disc`):

- If `Compounding` = `0` for simple interest:
  - `Disc = 1/(1 + Z * T)`, where `T` is time in years and simple interest assumes annual times `F = 1`.
- If `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`:
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units, for example, `T = F` is one year.
- If `Compounding` = `365`:
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = `-1`:
  - `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

`Disc` — Discounts

matrix

Discounts, specified as a number of points `(NPOINTS)` by number of curves (`NCURVES`) matrix of discounts. `Disc` are unit bond prices over investment intervals from `StartTimes`, when the cash flow is valued, to `EndTimes`, when the cash flow is received.

Data Types: `double`

EndTimes — End times
serial date number | date character vector | numeric

End times, specified as a scalar or an NPOINTS-by-1 column vector using serial date numbers or date character vectors, or times in periodic units ending the interval to discount over. When EndTimes is not a date, the value for EndTimes is T computed from SIA semi-annual time factors, Tsemi, by the formula T = Tsemi/2 * F, where F is the compounding frequency. F is set to 1 for continuous compounding.

Note When ValuationDate is not passed, EndTimes is interpreted as times. If Compounding = 365 (daily), EndTimes is measured in days.

Data Types: double | char

StartTimes — Start times
serial date number | date character vector | numeric

Start times, specified a scalar or an NPOINTS-by-1 column vector using serial date numbers or date character vectors, or times in periodic units starting the interval to discount over. StartDates must be earlier than EndDates. When StarTimes is not a date, the value for StartTimes is T computed from SIA semi-annual time factors, Tsemi, by the formula T = Tsemi/2 * F, where F is the compounding frequency. F is set to 1 for continuous compounding.

Note When ValuationDate is not passed, StartTimes is interpreted as times. If Compounding = 365 (daily), StartTimes is measured in days.

Data Types: double | char

ValuationDate — Observation date of the investment horizons entered in StartTimes and EndTimes
serial date number | date character vector

Observation date of the investment horizons entered in StartTimes and EndTimes, specified as scalar serial date number or date character vector.

Note You can specify the investment intervals either with input times or with input dates. Entering ValuationDate invokes the date interpretation; omitting ValuationDate invokes the default time interpretations.

Data Types: double | char

Basis — Day-count basis
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument when using dates for StartTimes and EndTimes, specified as a scalar or an NINST-by-1 vector of integers..

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag when using dates for `StartTimes` and `EndTimes`, specified as a scalar or an `NINST`-by-`1` vector of nonnegative integers. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Rates` — Rates
vector

Rates, returned as an `NPOINTS`-by-`NCURVES` column vector of in decimal form over `NPOINTS` time intervals.

`EndTimes` — Times ending the interval to discount over
vector

Times ending the interval to discount over, returned as an `NPOINTS`-by-`1` column vector, measured in periodic units.

`StartTimes` — Times starting the interval to discount over
vector

Times starting the interval to discount over, returned as an `NPOINTS`-by-`1` column vector, measured in periodic units.

eqpprice

Instrument prices from Equal Probabilities binomial tree

Syntax

```
[Price,PriceTree] = eqpprice(EQPTree,InstSet)
[Price,PriceTree] = eqpprice( ___ ,Options)
```

Description

`[Price,PriceTree] = eqpprice(EQPTree,InstSet)` computes stock option prices using an EQP binomial tree created with `eqptree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`eqpprice` handles instrument types: `'Asian'`, `'Barrier'`, `'Compound'`, `'CBond'`, `'Lookback'`, `'OptStock'`. See `instadd` to construct defined types.

`[Price,PriceTree] = eqpprice( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Price the Put Options Contained in the Instrument Set

Load the EQP tree and instruments from the data file `deriv.mat`. Price the put options contained in the instrument set.

```
load deriv.mat;
EQPSubSet = instselect(EQPInstSet, 'FieldName', 'OptSpec', ...
'Data', 'put')
```

```
EQPSubSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {5x1 cell}
     FieldName: {5x1 cell}
    FieldClass: {5x1 cell}
     FieldData: {5x1 cell}
```

```
instdisp(EQPSubSet)
```

```
Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt Name  Quantity
1     OptStock put     105    01-Jan-2003    01-Jan-2006    0           Put1   5

Index Type  OptSpec Strike Settle         ExerciseDates  AmericanOpt AvgType    AvgPrice AvgDate
2     Asian put     110    01-Jan-2003    01-Jan-2006    0           arithmetic NaN      NaN
3     Asian put     110    01-Jan-2003    01-Jan-2007    0           arithmetic NaN      NaN
```

Price the put options.

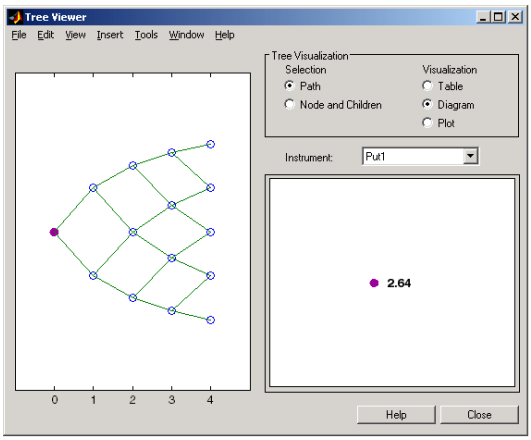
```
[Price, PriceTree] = eqpprice(EQPTree, EQPSubSet)

Price = 3×1

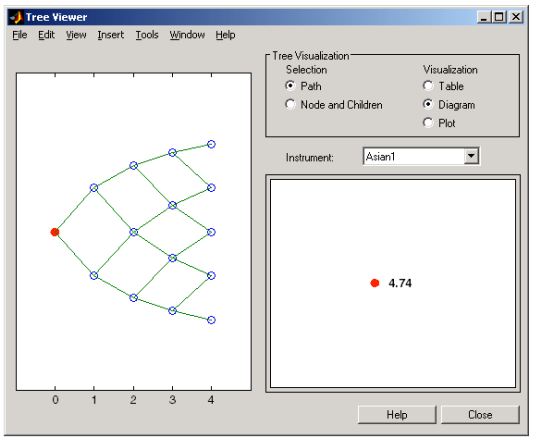
    2.6375
    4.7444
    3.9178

PriceTree = struct with fields:
    FinObj: 'BinPriceTree'
     PTree: {1x5 cell}
      tObs: [0 1 2 3 4]
      dObs: [731582 731947 732313 732678 733043]
```

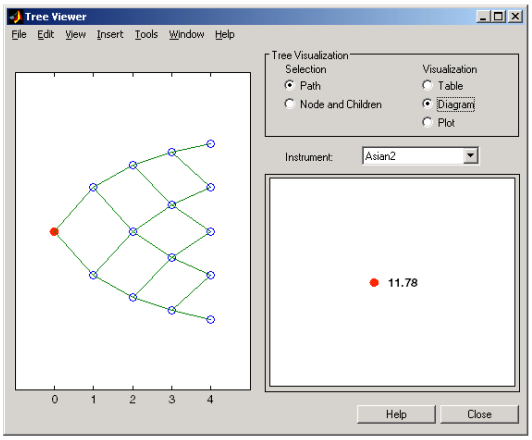
You can use `treeviewer` to see the prices of these three instruments along the price tree.



Put1



Asian11



Asian2

Input Arguments

`EQPTree` — Stock price tree structure

structure

Stock price tree structure, specified by using `eqptree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Price for each instrument

vector

Price for each instrument, returned as a `NINST`-by-1 vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Related single-type pricing functions are:

- `asianbyeqp`: Price an Asian option from an EQP tree.
- `barrierbyeqp`: Price a barrier option from an EQP tree.
- `cbondbyeqp`: Price convertible bonds from an EQP tree.
- `compoundbyeqp`: Price a compound option from an EQP tree.
- `lookbackbyeqp`: Price a lookback option from an EQP tree.
- `optstockbyeqp`: Price an American, Bermuda, or European option from an EQP tree.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

- `PriceTree.dObs` contains the observation dates.

eqpsens

Instrument prices and sensitivities from Equal Probabilities binomial tree

Syntax

```
[Delta,Gamma,Vega,Price] = eqpsens(EQPTree,InstSet)
[Delta,Gamma,Vega,Price] = eqpsens(___,Options)
```

Description

`[Delta,Gamma,Vega,Price] = eqpsens(EQPTree,InstSet)` computes instrument sensitivities and prices for instruments using a binomial tree created with the `eqptree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`eqpsens` handles instrument types: `'Asian'`, `'Barrier'`, `'Compound'`, `'CBond'`, `'Lookback'`, and `'OptStock'`. See `instadd` for information on instrument types.

`[Delta,Gamma,Vega,Price] = eqpsens(___,Options)` adds an optional input argument for `Options`.

Examples

Compute Sensitivities for Instruments Using an eqptree

Load the EQP tree and instruments from the data file `deriv.mat`. Compute the `Delta` and `Gamma` sensitivities of the put options contained in the instrument set.

```
load deriv.mat;

EQPSubSet = instselect(EQPInstSet, 'FieldName', 'OptSpec', ...
'Data', 'put')
```

```
EQPSubSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {5x1 cell}
     FieldName: {5x1 cell}
    FieldClass: {5x1 cell}
     FieldData: {5x1 cell}
```

```
instdisp(EQPSubSet)
```

```
Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt Name  Quantity
1     OptStock put     105    01-Jan-2003    01-Jan-2006    0           Put1   5

Index Type  OptSpec Strike Settle         ExerciseDates  AmericanOpt AvgType    AvgPrice AvgDate
2     Asian put     110    01-Jan-2003    01-Jan-2006    0           arithmetic NaN      NaN
```

```
3     Asian put     110    01-Jan-2003    01-Jan-2007    0           arithmetic NaN      NaN
```

Obtain the `Delta` and `Gamma` for the put options contained in the instrument set.

```
[Delta, Gamma] = eqpsens(EQPTree, EQPSubSet)
```

```
Delta = 3×1

   -0.2336
   -0.5443
   -0.4516

Gamma = 3×1

    0.0218
    0.0000
    0.0000
```

Input Arguments

`EQPTree` — Stock tree structure

structure

Stock tree structure, specified by using `eqptree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in the stock price

vector

Rate of change of instruments prices with respect to changes in the stock price, returned as a `NINST`-by-`1` vector of deltas.

For path-dependent options (`'Lookback'` and `'Asian'`), `Delta` and `Gamma` are computed by finite differences in calls to `eqpprice`. For the rest of the options (`'OptStock'`, `'Barrier'`, `'CBond'`,

and 'Compound'), Delta and Gamma are computed from the EQPTree and the corresponding option price tree.

Gamma — Rate of change of instruments deltas with respect to changes in stock price
vector

Rate of change of instruments deltas with respect to changes in the stock price, returned as a NINST-by-1 vector of gammas.

For path-dependent options ('Lookback' and 'Asian'), Delta and Gamma are computed by finite differences in calls to eqpprice. For the rest of the options ('OptStock', 'Barrier', 'CBond', and 'Compound'), Delta and Gamma are computed from the EQPTree and the corresponding option price tree.

Vega — Rate of change of instruments prices with respect to changes in volatility of the stock
vector

Rate of change of instruments prices with respect to changes in the volatility of the stock, returned as a NINST-by-1 vector of vegas. Vega is computed by finite differences in calls to eqptree.

Price — Price of each instrument
vector

Price of each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

Version History

Introduced before R2006a

eqptimespec

Specify time structure for Equal Probabilities binomial tree

Syntax

```
TimeSpec = eqptimespec(ValuationDate,Maturity,NumPeriods)
```

Description

`TimeSpec = eqptimespec(ValuationDate,Maturity,NumPeriods)` sets the number of levels and node times for an equal probabilities tree (`eqptree`).

Examples

Set the Number of Levels and Node Times for an EQP Tree

This example shows how to set the number of levels and node times for an EQP tree by specifying a four-period tree with time steps of 1 year.

```
ValuationDate = datetime(2002,7,1);
Maturity = datetime(2006,7,1);
TimeSpec = eqptimespec(ValuationDate, Maturity, 4)
```

```
TimeSpec = struct with fields:
           FinObj: 'BinTimeSpec'
    ValuationDate: 731398
         Maturity: 732859
       NumPeriods: 4
            Basis: 0
     EndMonthRule: 1
             tObs: [0 1 2 3 4]
             dObs: [731398 731763 732128 732493 732859]
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the `eqptree`, specified as a scalar datetime, string, or date character vector.

To support existing code, `eqptimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Date marking the depth of the EQP stock tree

datetime scalar | string scalar | date character vector

Date marking the depth of the `eqptree` binomial tree, specified as scalar datetime, string, or date character vector.

To support existing code, `eqptimespec` also accepts serial date numbers as inputs, but they are not recommended.

`NumPeriods` — Number of time steps in the EQP tree
integer

Number of time steps in the `eqptree` binomial tree, specified as scalar integer value.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `eqptree`
structure

Specification for the time layout for `eqptree`, returned as a structure.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `eqptimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

eqptree

Build Equal Probabilities stock tree

Syntax

```
EQPTree = eqptree(StockSpec,RateSpec,TimeSpec)
```

Description

`EQPTree = eqptree(StockSpec,RateSpec,TimeSpec)` builds an Equal Probabilities stock tree.

Examples

Create an EQP Tree

Using the data provided, create a stock specification (`StockSpec`), rate specification (`RateSpec`), and tree time layout specification (`TimeSpec`). Then use these specifications to create an EQP stock tree with `eqptree`.

```
Sigma = 0.20;
AssetPrice = 50;
DividendType = 'cash';
DividendAmounts = [0.50; 0.50; 0.50; 0.50];
ExDividendDates = {'03-Jan-2003'; '01-Apr-2003'; '05-July-2003';
'01-Oct-2003'};

StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates);

RateSpec = intenvset('Rates', 0.05, 'StartDates',...
'01-Jan-2003', 'EndDates', '31-Dec-2003');

ValuationDate = '1-Jan-2003';
Maturity = '31-Dec-2003';
TimeSpec = eqptimespec(ValuationDate, Maturity, 4);

EQPTree = eqptree(StockSpec, RateSpec, TimeSpec)
```

```
Warning: RateSpec was not created with continuous compounding. Compounding will
be set to continuous while leaving discount factors unaltered. This will result
in the recalculation of the interest rates.

EQPTree =

  struct with fields:

       FinObj: 'BinStockTree'
       Method: 'EQP'
    StockSpec: [1×1 struct]
     TimeSpec: [1×1 struct]
     RateSpec: [1×1 struct]
```

```
         tObs: [0 0.2493 0.4986 0.7479 0.9972]
         dObs: [731582 731673 731764 731855 731946]
        STree: {1×5 cell}
      UpProbs: [0.5000 0.5000 0.5000 0.5000]]
```

Use `treeviewer` to observe the tree you have created.

Input Arguments

`StockSpec` — Stock specification

structure

Stock specification, specified by the `StockSpec` obtained from `stockspec`. See `stockspec` for information on creating a stock specification.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Note The standard equal probabilities tree assumes a constant interest rate, but `RateSpec` allows you to specify an interest-rate curve with varying rates. If you specify variable interest rates, the resulting tree is not a standard equal probabilities tree.

Data Types: `struct`

`TimeSpec` — Tree time layout specification

structure

Tree time layout specification, specified by the `TimeSpec` obtained from `eqptimespec`. The `TimeSpec` defines the observation dates of the EQP stock tree. See `eqptimespec` for information on the tree structure.

Data Types: `struct`

Output Arguments

`EQPTree` — EQP stock tree

structure

EQP stock tree, returned as a structure specifying the time layout for the tree.

Version History

Introduced before R2006a

fixedbybdt

Price fixed-rate note from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = fixedbybdt(BDTTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = fixedbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = fixedbybdt(BDTTree,CouponRate,Settle,Maturity)` prices a fixed-rate note from a Black-Derman-Toy interest-rate tree.

Note Alternatively, you can use the `FixedBond` object to price fixed-rate bond instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[Price,PriceTree] = fixedbybdt( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a 10% Fixed-Rate Note Using a BDT Interest-Rate Tree

This example shows how to price a 10% fixed-rate note using a BDT interest-rate tree by loading the file `deriv.mat`, which provides `BDTTree`. The `BDTTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat

CouponRate = 0.10;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
FixedReset = 1;

Price = fixedbybdt(BDTTree, CouponRate, Settle, Maturity, FixedReset)
```

```
Price = 92.9974
```

Input Arguments

BDTTree — Interest-rate structure

structure

Interest-rate tree structure, created by `bdttree`

Data Types: `struct`

`CouponRate` — Coupon annual rate
decimal

Coupon annual rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbybdt` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every fixed-rate note is set to the `ValuationDate` of the BDT Tree. The fixed-rate note argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = fixedbybdt(BDTTree,CouponRate,Settle,Maturity,'FixedReset',4)`

`FixedReset` — Frequency of payments per year
`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FixedReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Output Arguments

`Price` — Expected fixed-rate note prices at time 0
vector

Expected fixed-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.

- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fixedbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fixedbybk

Price fixed-rate note from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = fixedbybk(BKTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = fixedbybk(___,Name,Value)
```

Description

`[Price,PriceTree] = fixedbybk(BKTree,CouponRate,Settle,Maturity)` prices a fixed-rate note from a Black-Karasinski interest-rate tree.

Note Alternatively, you can use the `FixedBond` object to price fixed-rate bond instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[Price,PriceTree] = fixedbybk(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a 5% Fixed-Rate Note Using a Black-Karasinski Interest-Rate Tree

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
CouponRate = 0.05;
Settle = datetime(2004,1,1);
Maturity = datetime(2006,1,1);
```

Use `fixedbybk` to compute the price of the note.

```
Price = fixedbybk(BKTree, CouponRate, Settle, Maturity)
```

```
Price = 103.5126
```

Input Arguments

BKTree — Interest-rate structure

structure

Interest-rate tree structure, created by `bktree`

Data Types: `struct`

`CouponRate` — Coupon annual rate
decimal

Coupon annual rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbybk` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every fixed-rate note is set to the `ValuationDate` of the BK Tree. The fixed-rate note argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each fixed-rate note.

To support existing code, `fixedbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = fixedbybk(BKTree,CouponRate,Settle,Maturity,'FixedReset',4)`

`FixedReset` — Frequency of payments per year
`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FixedReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 vector of logicals with values of 0 (false) or 1 (true).

Data Types: logical

Holidays — Holidays used in computing business days
if not specified, the default is to use holidays.m (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB dates using a NHolidays-by-1 vector.

Data Types: datetime

BusinessDayConvention — Business day conventions
actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- actual — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- follow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- modifiedfollow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- previous — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- modifiedprevious — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

Output Arguments

Price — Expected fixed-rate note prices at time 0
vector

Expected fixed-rate note prices at time 0, returned as a NINST-by-1 vector.

PriceTree — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within PriceTree:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

fixedbycir

Price fixed rate note from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = fixedbycir(CIRTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = fixedbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = fixedbycir(CIRTree,CouponRate,Settle,Maturity)` prices a fixed-rate note from a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = fixedbycir( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Fixed-Rate Note Using a CIR Interest-Rate Tree

Define the `CouponRate` for a fixed-rate note.

```
CouponRate = 0.03;
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
```

```
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the 3% fixed-rate note.

```
[Price,PriceTree] = fixedbycir(CIRT,CouponRate,Settle,Maturity)
```

```
Price = 92.1422
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 1 2 3 4]
       dObs: [736696 737061 737426 737791 738157]
      PTree: {1x5 cell}
     AITree: {[0]  [0 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [0 0 0 0 0 0 0]}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `cirtree`

Data Types: `struct`

`CouponRate` — Coupon annual rate

decimal

Coupon annual rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbycir` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every fixed-rate note is set to the `ValuationDate` of the CIR tree. The fixed-rate note argument `Settle` is ignored.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each fixed-rate note.

To support existing code, `fixedbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = fixedbycir(CIRTree,CouponRate,Settle,Maturity,'FixedReset',4)`

`FixedReset` — Frequency of payments per year

`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FixedReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules

`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.

- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Output Arguments

`Price` — Expected fixed-rate note prices at time 0

vector

Expected fixed-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.
- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fixedbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fixedbyhjm

Price fixed-rate note from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = fixedbyhjm(HJMTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = fixedbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = fixedbyhjm(HJMTree,CouponRate,Settle,Maturity)` prices a fixed-rate note from a Heath-Jarrow-Morton interest-rate tree.

`[Price,PriceTree] = fixedbyhjm( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a 4% Fixed-Rate Note Using an HJM Forward-Rate Tree

This example shows how to price a 4% fixed-rate note using an HJM forward-rate tree by loading the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and forward-rate information needed to price the note.

```
load deriv.mat

CouponRate = 0.04;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);

Price = fixedbyhjm(HJMTree, CouponRate, Settle, Maturity)
```

```
Price = 98.7159
```

Input Arguments

`HJMTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `hjmtree`

Data Types: `struct`

`CouponRate` — Coupon annual rate

decimal

Coupon annual rate, specified as a `NINST`-by-1 vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every fixed-rate note is set to the `ValuationDate` of the HJM tree. The fixed-rate note argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each fixed-rate note.

To support existing code, `fixedbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = fixedbyhjm(HJMTree,CouponRate,Settle,Maturity,'FixedReset',4)`

`FixedReset` — Frequency of payments per year
`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FixedReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Output Arguments

`Price` — Expected fixed-rate note prices at time 0
vector

Expected fixed-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fixedbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fixedbyhw

Price fixed-rate note from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = fixedbyhw(HWTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = fixedbyhw(___,Name,Value)
```

Description

`[Price,PriceTree] = fixedbyhw(HWTree,CouponRate,Settle,Maturity)` prices a fixed-rate note from a Hull-White interest-rate tree.

Note Alternatively, you can use the `FixedBond` object to price fixed-rate bond instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[Price,PriceTree] = fixedbyhw(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a 5% Fixed-Rate Note Using a Hull-White Interest-Rate Tree

Load the file `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
CouponRate = 0.05;
Settle = datetime(2004,1,1);
Maturity = datetime(2006,1,1);
```

Use `fixedbyhw` to compute the price of the note.

```
Price = fixedbyhw(HWTree, CouponRate, Settle, Maturity)
```

```
Price = 103.5126
```

Input Arguments

HWTree — Interest-rate structure

structure

Interest-rate tree structure, created by `hwtree`

Data Types: `struct`

`CouponRate` — Coupon annual rate
decimal

Coupon annual rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbyhw` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every fixed-rate note is set to the `ValuationDate` of the HW tree. The fixed-rate note argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each fixed-rate note.

To support existing code, `fixedbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = fixedbyhw(HWTree,CouponRate,Settle,Maturity,'FixedReset',4)`

`FixedReset` — Frequency of payments per year
`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FixedReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Output Arguments

`Price` — Expected fixed-rate note prices at time 0
vector

Expected fixed-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fixedbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

fixedbyzero

Price fixed-rate note from set of zero curves

Syntax

```
[Price,DirtyPrice,CFlowAmounts,CFlowDates] = fixedbyzero(RateSpec,CouponRate,
Settle,Maturity)
[Price,DirtyPrice,CFlowAmounts,CFlowDates] = fixedbyzero( ___ ,Name,Value)
```

Description

`[Price,DirtyPrice,CFlowAmounts,CFlowDates] = fixedbyzero(RateSpec,CouponRate, Settle,Maturity)` prices a fixed-rate note from a set of zero curves.

Note Alternatively, you can use the `FixedBond` object to price fixed-rate bond instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,DirtyPrice,CFlowAmounts,CFlowDates] = fixedbyzero( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a 4% Fixed-Rate Note Using a Set of Zero Curves

This example shows how to price a 4% fixed-rate note using a set of zero curves by loading the file `deriv.mat`, which provides `ZeroRateSpec`, the interest-rate term structure needed to price the note.

```
load deriv.mat

CouponRate = 0.04;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);

Price = fixedbyzero(ZeroRateSpec, CouponRate, Settle, Maturity)
```

```
Price = 98.7159
```

Pricing a Fixed-Fixed Cross Currency Swap

Assume that a financial institution has an existing swap with three years left to maturity where they are receiving 5% per year in yen and paying 8% per year in USD. The reset frequency for the swap is annual, the principals for the two legs are 1200 million yen and $10 million USD, and both term structures are flat.

```
Settle = datetime(2015,8,15);
Maturity = datetime(2018,8,15);
Reset = 1;

r_d = .09;
r_f = .04;

FixedRate_d = .08;
FixedRate_f = .05;

Principal_d = 10000000;
Principal_f = 1200000000;

S0 = 1/110;
```

Construct term structures.

```
RateSpec_d = intenvset('StartDate',Settle,'EndDate',Maturity,'Rates',r_d,'Compounding',-1);
RateSpec_f = intenvset('StartDate',Settle,'EndDate',Maturity,'Rates',r_f,'Compounding',-1);
```

Use fixedbyzero:

```
B_d = fixedbyzero(RateSpec_d,FixedRate_d,Settle,Maturity,'Principal',Principal_d,'Reset',Reset);
B_f = fixedbyzero(RateSpec_f,FixedRate_f,Settle,Maturity,'Principal',Principal_f,'Reset',Reset);
```

Compute swap price. Based on Hull (see References), a cross currency swap can be valued with the following formula `V_swap = S0*B_f − B_d`.

```
V_swap = S0*B_f - B_d
```

```
V_swap = 1.5430e+06
```

Input Arguments

`RateSpec` — Annualized zero rate term structure

structure

Annualized zero rate term structure, specified using `intenvset` to create a `RateSpec`.

Data Types: `struct`

`CouponRate` — Annual rate

decimal

Annual rate, specified as `NINST`-by-`1` decimal annual rate or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array and the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `fixedbyzero` also accepts serial date numbers as inputs, but they are not recommended.

`Settle` must be earlier than `Maturity`.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each fixed-rate note.

To support existing code, `fixedbyzero` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,DirtyPrice,CFlowAmounts,CFlowDates] = fixedbyzero(RateSpec,CouponRate,Settle,Maturity,'Principal',Principal)`

`FixedReset` — Frequency of payments per year
`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FixedReset'` and a `NINST`-by-1 vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Output Arguments

`Price` — Fixed-rate note prices
matrix

Floating-rate note prices, returned as a (`NINST`) by number of curves (`NUMCURVES`) matrix. Each column arises from one of the zero curves.

`DirtyPrice` — Dirty bond price
matrix

Dirty bond price (clean + accrued interest), returned as a `NINST`- by-`NUMCURVES` matrix. Each column arises from one of the zero curves.

`CFlowAmounts` — Cash flow amounts
matrix

Cash flow amounts, returned as a `NINST`- by-`NUMCFS` matrix of cash flows for each bond.

`CFlowDates` — Cash flow dates
matrix

Cash flow dates, returned as a `NINST`- by-`NUMCFS` matrix of payment dates for each bond.

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `fixedbyzero` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatbybdt

Price floating-rate note from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = floatbybdt(BDTTree,Spread,Settle,Maturity)
[Price,PriceTree] = floatbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = floatbybdt(BDTTree,Spread,Settle,Maturity)` prices a floating-rate note from a Black-Derman-Toy interest-rate tree.

`floatbybdt` computes prices of vanilla floating-rate notes, amortizing floating-rate notes, capped floating-rate notes, floored floating-rate notes and collared floating-rate notes.

Note Alternatively, you can use the `FloatBond` object to price floating-rate bond instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = floatbybdt( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floating-Rate Note Using a BDT Tree

Price a 20-basis point floating-rate note using a BDT interest-rate tree.

Load the file `deriv.mat`, which provides `BDTTree`. The `BDTTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat;
```

Define the floating-rate note using the required arguments. Other arguments use defaults.

```
Spread = 20;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
```

Use `floatbybdt` to compute the price of the note.

```
Price = floatbybdt(BDTTree, Spread, Settle, Maturity)
```

```
Price = 100.4865
```

Price an Amortizing Floating-Rate Note

Price an amortizing floating-rate note using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
          EndTimes: [5x1 double]
        StartTimes: [5x1 double]
          EndDates: [5x1 double]
        StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Create the floating-rate instrument using the following data:

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Spread = 15;
```

Define the floating-rate note amortizing schedule.

```
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Build the BDT tree and assume volatility is 10%.

```
MatDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
Volatility = 0.10;
BDTVolSpec = bdtvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Compute the price of the amortizing floating-rate note.

```
Price = floatbybdt(BDTT, Spread, Settle, Maturity, 'Principal', Principal)
```

```
Price = 100.3059
```

Price a Collar with a Floating-Rate Note

Price a collar with a floating-rate note using the `CapRate` and `FloorRate` input argument to define the collar pricing.

Create the `RateSpec`.

```
Rates = [0.0287; 0.03024; 0.03345; 0.03861; 0.04033];
ValuationDate = datetime(2012,4,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build the BDT tree and assume volatility is 5%.

```
MatDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
Volatility = 0.05;
BDTVolSpec = bdtvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Create the floating rate note instrument.

```
Settle = datetime(2012,4,1);
Maturity = datetime(2016,4,1);
Spread = 10;
Principal = 100;
```

Compute the price of a collared floating-rate note.

```
CapStrike = {{datetime(2013,4,1) 0.03;datetime(2015,4,1) 0.055}};
FloorStrike = {{datetime(2013,4,1) 0.025;datetime(2015,4,1) 0.04}};

Price = floatbybdt(BDTT, Spread, Settle, Maturity, 'CapRate',...
CapStrike, 'FloorRate', FloorStrike)
```

```
Price = 101.2414
```

Pricing a Floating-Rate Note When the Reset Dates Are Not Tree Level Dates

When using `floatbybdt` to price floating-rate notes, there are cases where the dates specified in the BDT tree `TimeSpec` are not aligned with the cash flow dates.

Price floating-rate notes using the following data:

```
ValuationDate = datetime(2013,9,1);
Rates = [0.0235; 0.0239; 0.0311; 0.0323];
EndDates = [datetime(2014,9,1);datetime(2015,9,1);datetime(2016,9,1);datetime(2017,9,1)];
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',...
ValuationDate,'EndDates',EndDates,'Rates',Rates,'Compounding', 1);
```

Build the BDT tree.

```
VolCurve = [.10; .11; .11; .12];

BDTVolatilitySpec = bdtvolspec(RateSpec.ValuationDate, EndDates,...
                               VolCurve);

BDTTimeSpec = bdttimespec(RateSpec.ValuationDate, EndDates, 1);

BDTT = bdttree(BDTVolatilitySpec, RateSpec, BDTTimeSpec);
```

Compute the price of the floating-rate note using the following data:

```
Spread = 5;
Settle = datetime(2013,9,1);
Maturity = datetime(2013,12,1);
Reset = 2;

Price = floatbybdt(BDTT, Spread, Settle, Maturity, 'FloatReset', Reset)

Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In floatengbybdt at 204
  In floatbybdt at 123
Error using floatengbybdt (line 299)
Instrument '1 ' has cash flow dates that span across tree nodes.

Error in floatbybdt (line 123)
[Price, PriceTree, CFTree, TLPpal] = floatengbybdt(BDTTree, Spread, Settle, Maturity, OArgs{:});
```

This error indicates that it is not possible to determine the applicable rate used to calculate the payoff at the reset dates, given that the applicable rate needed cannot be calculated (the information was lost due to the recombination of the tree nodes). Note, if the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates. The simplest solution is to place the tree levels at the cash flow dates of the instrument, which is done by specifying `BDTTimeSpec`. It is also acceptable to have reset dates between tree levels, as long as there are reset dates on the tree levels.

To recover from this error, build a tree that lines up with the instrument.

```
Basis = intenvget(RateSpec, 'Basis');
EOM = intenvget(RateSpec, 'EndMonthRule');
resetDates = cfdates(ValuationDate, Maturity, Reset ,Basis, EOM);
BDTTimeSpec = bdttimespec(RateSpec.ValuationDate,resetDates,Reset);
BDTT = bdttree(BDTVolatilitySpec, RateSpec, BDTTimeSpec);

Price = floatbybdt(BDTT, Spread, RateSpec.ValuationDate, ...
                   Maturity, 'FloatReset', Reset)

Price =

  100.1087
```

Input Arguments

`BDTTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `bdttree`

Data Types: `struct`

Spread — Number of basis points over the reference rate
vector

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: double

Settle — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, floatbybdt also accepts serial date numbers as inputs, but they are not recommended.

The Settle date for every floating-rate note is set to the ValuationDate of the BDT tree. The floating-rate note argument Settle is ignored.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, floatbybdt also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = floatbybdt(BDTTree,Spread,Settle,Maturity,'Basis',3)

FloatReset — Frequency of payments per year
1 (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

Data Types: double

Basis — Day count basis
0 (actual/actual) (default) | integer from 0 to 13

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer `[0, 1]` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 vector of logicals with values of 0 (false) or 1 (true).

Data Types: logical

Holidays — Holidays used in computing business days
if not specified, the default is to use holidays.m (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB dates using a NHolidays-by-1 vector.

Data Types: datetime

BusinessDayConvention — Business day conventions
actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- actual — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- follow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- modifiedfollow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- previous — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- modifiedprevious — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

CapRate — Annual cap rate
decimal

Annual cap rate, specified as the comma-separated pair consisting of 'CapRate' and a NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.

Data Types: double | cell

`FloorRate` — Annual floor rate
decimal

Annual floor rate, specified as the comma-separated pair consisting of `'FloorRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data Types: `double` | `cell`

Output Arguments

`Price` — Expected floating-rate note prices at time 0
vector

Expected floating-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `floatbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatbybk

Price floating-rate note from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = floatbybk(BKTree,Spread,Settle,Maturity)
[Price,PriceTree] = floatbybk(___,Name,Value)
```

Description

`[Price,PriceTree] = floatbybk(BKTree,Spread,Settle,Maturity)` prices a floating-rate note from a Black-Karasinski interest-rate tree.

`floatbybk` computes prices of vanilla floating-rate notes, amortizing floating-rate notes, capped floating-rate notes, floored floating-rate notes and collared floating-rate notes.

Note Alternatively, you can use the `FloatBond` object to price floating-rate bond instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = floatbybk(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floating-Rate Note Using a Black-Karasinski Tree

Price a 20-basis point floating-rate note using a Black-Karasinski interest-rate tree.

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat;
```

Define the floating-rate note using the required arguments. Other arguments use defaults.

```
Spread = 20;
Settle = datetime(2005,1,1);
Maturity = datetime(2006,1,1);
```

Use `floatbybk` to compute the price of the note.

```
Price = floatbybk(BKTree, Spread, Settle, Maturity)
```

```
Warning: Floating range notes are valued at Tree ValuationDate rather than Settle.
```

```
Price = 100.3825
```

Price an Amortizing Floating-Rate Note

Price an amortizing floating-rate note using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Create the floating-rate instrument using the following data:

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Spread = 15;
```

Define the floating-rate note amortizing schedule.

```
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Build the BK tree and assume the volatility is 10%.

```
VolDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
VolCurve = 0.1;
AlphaDates = datetime(2017,11,15);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Compute the price of the amortizing floating-rate note.

```
Price = floatbybk(BKT, Spread, Settle, Maturity, 'Principal', Principal)
```

```
Price = 100.3059
```

Price a Collar with a Floating-Rate Note

Price a collar with a floating-rate note using the `CapRate` and `FloorRate` input argument to define the collar pricing.

Price a portfolio of collared floating-rate notes using the following data:

```
Rates = [0.0287; 0.03024; 0.03345; 0.03861; 0.04033];
ValuationDate = datetime(2012,4,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build the BK tree and assume the volatility to be 5%.

```
VolDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
VolCurve = 0.05;
AlphaDates = datetime(2018,11,15);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Create the floating-rate note instrument.

```
Settle = datetime(2012,4,1);
Maturity = datetime(2016,4,1);
Spread = [15;10];
Principal = 100;
```

Compute the price of the two vanilla floaters.

```
Price = floatbybk(BKT, Spread, Settle, Maturity)
```

```
Price = 2×1

  100.5519
  100.3680
```

Compute the price of the collared floating-rate notes.

```
CapStrike = {{datetime(2013,4,1) 0.045;datetime(2014,4,1) 0.05;...
datetime(2015,4,1) 0.06}; 0.06};

FloorStrike = {{datetime(2013,4,1) 0.035; datetime(2014,4,1) 0.04;...
datetime(2015,4,1) 0.05}; 0.03};
PriceCollared = floatbybk(BKT, Spread, Settle, Maturity,...
'CapRate', CapStrike,'FloorRate', FloorStrike)
```

```
PriceCollared = 2×1
```

```
  102.8537
  100.4918
```

Pricing a Floating-Rate Note When the Reset Dates Are Not Tree Level Dates

When using `floatbybk` to price floating-rate notes, there are cases where the dates specified in the BK tree Time Specs are not aligned with the cash flow dates.

Price floating-rate notes using the following data:

```
ValuationDate      = datetime(2013,9,13);
ForwardRatesVector = [ 0.0001; 0.0001; 0.0010; 0.0015];
EndDatesVector     = [datetime(2013,12,13);datetime(2014,3,14);datetime(2014,6,13);datetime(2014,9,13)];
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',...
ValuationDate,'EndDates',EndDatesVector,'Rates',ForwardRatesVector,'Compounding', 1);
```

Build the BK tree.

```
Volcurve         = 0.1;
Alpha            = 0.01;
BKVolatilitySpec = bkvolspec(RateSpec.ValuationDate, ...
                   EndDatesVector, Volcurve,...
                   EndDatesVector, Alpha);

BKTimeSpec = bktimespec(RateSpec.ValuationDate, EndDatesVector, 1);

BKT = bktree(BKVolatilitySpec, RateSpec, BKTimeSpec);
```

Create the floating-rate note instrument using the following data;

```
Spread      = 0;
Maturity    = datetime(2014,6,13);
reset = 4;
```

Compute the price of the floating-rate note.

```
Price = floatbybk(BKT, Spread, RateSpec.ValuationDate,...
Maturity, 'FloatReset', reset)

Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In floatengbytrintree at 214
  In floatbybk at 136
Error using floatengbytrintree (line 319)
Instrument '1 ' has cash flow dates that span across tree nodes.

Error in floatbybk (line 136)
[Price, PriceTree, CFTree] = floatengbytrintree(BKTree, Spread, Settle, Maturity, OArgs{:});
```

This error indicates that it is not possible to determine the applicable rate used to calculate the payoff at the reset dates, given that the applicable rate needed cannot be calculated (the information was lost due to the recombination of the tree nodes). Note, if the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates. The simplest solution is to place the tree levels at the cash flow dates of the instrument, which is done by specifying `BKTimeSpec`. It is also acceptable to have reset dates between tree levels, as long as there are reset dates on the tree levels.

To recover from this error, build a tree that lines up with the instrument.

```
Basis = intenvget(RateSpec, 'Basis');
EOM = intenvget(RateSpec, 'EndMonthRule');
resetDates = cfdates(ValuationDate, Maturity,reset,Basis,EOM);
BKTimeSpec = bktimespec(RateSpec.ValuationDate,resetDates,reset);
BKT        = bktree(BKVolatilitySpec, RateSpec, BKTimeSpec);

Price      = floatbybk(BKT, Spread, RateSpec.ValuationDate, ...
             Maturity, 'FloatReset', reset)
```

```
Price =

  100.0004
```

Input Arguments

`BKTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `bktree`

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

vector

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floatbybk` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every floating-rate note is set to the `ValuationDate` of the BK tree. The floating-rate note argument `Settle` is ignored.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, `floatbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = floatbybk(BKTree,Spread,Settle,Maturity,'Basis',3)`

FloatReset — Frequency of payments per year
1 (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

Data Types: double

Basis — Day count basis
0 (actual/actual) (default) | integer from 0 to 13

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Principal — Notional principal amounts or principal value schedules
100 (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of 'Principal' and a vector or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array, where each element of the cell array is a NumDates-by-2 cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.

- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`CapRate` — Annual cap rate
decimal

Annual cap rate, specified as the comma-separated pair consisting of `'CapRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.

Data Types: `double` | `cell`

`FloorRate` — Annual floor rate
decimal

Annual floor rate, specified as the comma-separated pair consisting of `'FloorRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data Types: `double` | `cell`

Output Arguments

`Price` — Expected floating-rate note prices at time 0
vector

Expected floating-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floatbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatbycir

Price floating-rate note from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = floatbycir(CIRTree,Spread,Settle,Maturity)
[Price,PriceTree] = floatbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = floatbycir(CIRTree,Spread,Settle,Maturity)` prices a floating-rate note from a Cox-Ingersoll-Ross (CIR) interest-rate tree.

`floatbycir` computes prices of vanilla floating-rate notes, amortizing floating-rate notes, capped floating-rate notes, floored floating-rate notes, and collared floating-rate notes using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = floatbycir( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floating-Rate Note Using a CIR Interest-Rate Tree

Define a `Spread` of 20-basis points for a floating-rate note.

```
Spread = 20;
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
```

```
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the 20-basis point floating-rate note.

```
[Price,PriceTree] = floatbycir(CIRT,Spread,Settle,Maturity)
```

```
Price = 100.7143
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
      PTree: {1x5 cell}
     AITree: {[0]  [0 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [0 0 0 0 0 0 0]}
       tObs: [0 1 2 3 4]
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
      Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, created by `cirtree`

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

vector

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floatbycir` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every floating-rate note is set to the `ValuationDate` of the CIR tree. The floating-rate note argument `Settle` is ignored.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, floatbycir also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = floatbycir(CIRTree,Spread,Settle,Maturity,'Basis',3)

FloatReset — Frequency of payments per year

1 (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

Data Types: double

Basis — Day count basis

0 (actual/actual) (default) | integer from 0 to 13

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array, and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`CapRate` — Annual cap rate
decimal

Annual cap rate, specified as the comma-separated pair consisting of `'CapRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.

Data Types: `double` | `cell`

`FloorRate` — Annual floor rate
decimal

Annual floor rate, specified as the comma-separated pair consisting of `'FloorRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array.

For the `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array, where the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data Types: `double` | `cell`

Output Arguments

`Price` — Expected floating-rate note prices at time 0
vector

Expected floating-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.

- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

floatbyhjm

Price floating-rate note from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = floatbyhjm(HJMTree,Spread,Settle,Maturity)
[Price,PriceTree] = floatbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = floatbyhjm(HJMTree,Spread,Settle,Maturity)` prices a floating-rate note from a Heath-Jarrow-Morton interest-rate tree.

`floatbyhjm` computes prices of vanilla floating-rate notes, amortizing floating-rate notes, capped floating-rate notes, floored floating-rate notes and collared floating-rate notes.

`[Price,PriceTree] = floatbyhjm( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floating-Rate Note Using an HJM Tree

Price a 20-basis point floating-rate note using an HJM forward-rate tree.

Load the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat;
```

Define the floating-rate note using the required arguments. Other arguments use defaults.

```
Spread = 20;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
```

Use `floatbyhjm` to compute the price of the note.

```
Price = floatbyhjm(HJMTree, Spread, Settle, Maturity)
```

```
Price = 100.5529
```

Price an Amortizing Floating-Rate Note

Price an amortizing floating-rate note using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
          EndTimes: [5x1 double]
        StartTimes: [5x1 double]
          EndDates: [5x1 double]
        StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Create the floating-rate instrument using the following data:

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Spread = 15;
```

Define the floating-rate note amortizing schedule.

```
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Build the HJM tree using the following data:

```
MatDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
HJMTimeSpec = hjmtimespec(RateSpec.ValuationDate, MatDates);
Volatility = [.10; .08; .06; .04];
CurveTerm = [ 1; 2; 3; 4];
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec,RateSpec,HJMTimeSpec);
```

Compute the price of the amortizing floating-rate note.

```
Price = floatbyhjm(HJMT, Spread, Settle, Maturity, 'Principal', Principal)
```

```
Price = 100.3059
```

Price a Collar with a Floating-Rate Note

Price a collar with a floating-rate note using the `CapRate` and `FloorRate` input argument to define the collar pricing.

Price a portfolio of collared floating-rate notes using the following data:

```
Rates = [0.0287; 0.03024; 0.03345; 0.03861; 0.04033];
ValuationDate = datetime(2012,4,1);
```

```
StartDates = ValuationDate;
EndDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build the HJM tree with the following data:

```
MatDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
HJMTimeSpec = hjmtimespec(RateSpec.ValuationDate, MatDates);
Volatility = [.10; .08; .06; .04];
CurveTerm = [ 1; 2; 3; 4];
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec,RateSpec,HJMTimeSpec);
```

Create the floating-rate note instrument.

```
Settle = datetime(2012,4,1);
Maturity = datetime(2016,4,1);
Spread = 10;
Principal = 100;
```

Compute the price of two capped collared floating-rate notes.

```
CapStrike = [0.04;0.055];
PriceCapped = floatbyhjm(HJMT, Spread, Settle, Maturity,...
'CapRate', CapStrike)
```

```
PriceCapped = 2×1

   98.9986
  100.2051
```

Compute the price of two collared floating-rate notes.

```
FloorStrike = [0.035;0.040];
PriceCollared = floatbyhjm(HJMT, Spread, Settle, Maturity,...
'CapRate', CapStrike, 'FloorRate', FloorStrike)
```

```
PriceCollared = 2×1

   99.9246
  102.2321
```

Input Arguments

`HJMTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `hjmtree`

Data Types: `struct`

Spread — Number of basis points over the reference rate
vector

Number of basis points over the reference rate, specified as a NINST-by-1 vector.

Data Types: double

Settle — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, floatbyhjm also accepts serial date numbers as inputs, but they are not recommended.

The Settle date for every floating-rate note is set to the ValuationDate of the HJM tree. The floating-rate note argument Settle is ignored.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, floatbyhjm also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = floatbyhjm(HJMTree,Spread,Settle,Maturity,'Basis',3)

FloatReset — Frequency of payments per year
1 (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

Data Types: double

Basis — Day count basis
0 (actual/actual) (default) | integer from 0 to 13

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer `[0, 1]` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 vector of logicals with values of 0 (false) or 1 (true).

Data Types: logical

Holidays — Holidays used in computing business days
if not specified, the default is to use holidays.m (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and MATLAB dates using a NHolidays-by-1 vector.

Data Types: datetime

BusinessDayConvention — Business day conventions
actual (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a character vector or a N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- actual — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- follow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- modifiedfollow — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- previous — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- modifiedprevious — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | cell

CapRate — Annual cap rate
decimal

Annual cap rate, specified as the comma-separated pair consisting of 'CapRate' and a NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.

Data Types: double | cell

`FloorRate` — Annual floor rate
decimal

Annual floor rate, specified as the comma-separated pair consisting of `'FloorRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data Types: `double` | `cell`

Output Arguments

`Price` — Expected floating-rate note prices at time 0
vector

Expected floating-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.AIBush` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `floatbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatbyhw

Price floating-rate note from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = floatbyhw(HWTree,Spread,Settle,Maturity)
[Price,PriceTree] = floatbyhw( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = floatbyhw(HWTree,Spread,Settle,Maturity)` prices a floating-rate note from a Hull-White interest-rate tree.

`floatbyhw` computes prices of vanilla floating-rate notes, amortizing floating-rate notes, capped floating-rate notes, floored floating-rate notes and collared floating-rate notes.

Note Alternatively, you can use the `FloatBond` object to price floating-rate bond instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = floatbyhw( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floating-Rate Note Using a Hull-White Tree

Price a 20-basis point floating-rate note using a Hull-White interest-rate tree.

Load the file `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and interest-rate information needed to price the note.

```
load deriv.mat;
```

Define the floating-rate note using the required arguments. Other arguments use defaults.

```
Spread = 20;
Settle = datetime(2004,1,1);
Maturity = datetime(2007,1,1);
```

Use `floatbyhw` to compute the price of the note.

```
Price = floatbyhw(HWTree, Spread, Settle, Maturity)
```

```
Price = 100.5618
```

Price an Amortizing Floating-Rate Note

Price an amortizing floating-rate note using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Create the floating-rate instrument using the following data:

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Spread = 15;
```

Define the floating-rate note amortizing schedule.

```
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Build the HW tree and assume the volatility is 10%.

```
VolDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
VolCurve = 0.1;
AlphaDates = datetime(2017,11,15);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Compute the price of the amortizing floating-rate note.

```
Price = floatbyhw(HWT, Spread, Settle, Maturity, 'Principal', Principal)
```

```
Price = 100.3059
```

Price a Collar with a Floating-Rate Note

Price a collar with a floating-rate note using the `CapRate` and `FloorRate` input argument to define the collar pricing.

Price two collared floating-rate notes using the following data:

```
Rates = [0.0287; 0.03024; 0.03345; 0.03861; 0.04033];
ValuationDate = datetime(2012,4,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build the HW tree and assume the volatility to be 5%.

```
VolDates = [datetime(2013,4,1) ; datetime(2014,4,1) ; datetime(2015,4,1) ; datetime(2016,4,1) ; d
VolCurve = 0.05;
AlphaDates = datetime(2018,11,15);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Create the floating-rate note instrument.

```
Settle = datetime(2012,4,1);
Maturity = datetime(2016,4,1);
Spread = 10;
Principal = 100;
```

Compute the price of a vanilla floater.

```
Price = floatbyhw(HWT, Spread, Settle, Maturity)
```

```
Price = 100.3680
```

Compute the price of the collared floating-rate notes.

```
CapStrike = {{datetime(2014,4,1) 0.045;datetime(2015,4,1) 0.05;...
 datetime(2016,4,1) 0.06}; 0.06};

FloorStrike = {{datetime(2014,4,1) 0.035;datetime(2015,4,1)  0.04;...
 datetime(2016,4,1) 0.05}; 0.03};
PriceCollared = floatbyhw(HWT, Spread, Settle, Maturity,....
'CapRate', CapStrike,'FloorRate', FloorStrike)
```

```
PriceCollared = 2×1

  102.0458
  100.9299
```

Pricing a Floating-Rate Note When the Reset Dates Are Not Tree Level Dates

When using `floatbyhw` to price floating-rate notes, there are cases where the dates specified in the HW tree `TimeSpec` are not aligned with the cash flow dates.

Price floating-rate notes using the following data:

```
ValuationDate = datetime(2013,9,1);
Rates = [0.0001; 0.0001; 0.0010; 0.0015];
EndDates = [datetime(2013,12,1);datetime(2014,3,1);datetime(2014,6,1);datetime(2014,9,1)];
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',...
ValuationDate,'EndDates',EndDates,'Rates',Rates,'Compounding', 1);
```

Build the HW tree.

```
Volcurve = 0.1;
Alpha = 0.01;
HWVolatilitySpec = hwvolspec(RateSpec.ValuationDate, ...
                             EndDates, Volcurve,...
                             EndDates, Alpha);

HWTimeSpec = hwtimespec(RateSpec.ValuationDate, EndDates, 1);

HWT = hwtree(HWVolatilitySpec, RateSpec, HWTimeSpec);
```

Compute the price of the floating-rate note using the following data.

```
Spread = 10;
Settle = datetime(2013,9,1);
Maturity = datetime(2014,6,1);
Reset = 2;

Price = floatbyhw(HWT, Spread, Settle, Maturity, 'FloatReset', Reset)

Error using floatengbytrintree (line 318)
Instrument '1 ' has cash flow dates that span across tree nodes.

Error in floatbyhw (line 136)
        [Price, PriceTree, CFTree] = floatengbytrintree(HWTree, Spread, Settle, Maturity, OArgs{:});
```

This error indicates that it is not possible to determine the applicable rate used to calculate the payoff at the reset dates, given that the applicable rate needed cannot be calculated (the information was lost due to the recombination of the tree nodes). Note, if the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates. The simplest solution is to place the tree levels at the cash flow dates of the instrument, which is done by specifying `HWTimeSpec`. It is also acceptable to have reset dates between tree levels, as long as there are reset dates on the tree levels.

To recover from this error, build a tree that lines up with the instrument.

```
Basis = intenvget(RateSpec, 'Basis');
EOM = intenvget(RateSpec, 'EndMonthRule');
resetDates = cfdates(ValuationDate, Maturity, Reset, Basis, EOM);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate,resetDates, Reset);
HWT = hwtree(HWVolatilitySpec, RateSpec, HWTimeSpec);

Price = floatbyhw(HWT, Spread, RateSpec.ValuationDate, ...
                  Maturity, 'FloatReset', Reset)
```

```
Price =

  100.0748
```

Input Arguments

`HWTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `hwtree`

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

vector

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every floating-rate note is set to the `ValuationDate` of the HW tree. The floating-rate note argument `Settle` is ignored.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, `floatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = floatbyhw(HWTree,Spread,Settle,Maturity,'Basis',3)`

`FloatReset` — Frequency of payments per year

1 (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMOnthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`CapRate` — Annual cap rate
decimal

Annual cap rate, specified as the comma-separated pair consisting of `'CapRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.

Data Types: `double` | `cell`

`FloorRate` — Annual floor rate
decimal

Annual floor rate, specified as the comma-separated pair consisting of `'FloorRate'` and a `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data Types: `double` | `cell`

Output Arguments

`Price` — Expected floating-rate note prices at time 0
vector

Expected floating-rate note prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floatbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floatbyzero

Price floating-rate note from set of zero curves

Syntax

```
[Price,DirtyPrice,CFlowAmounts,CFlowDates] = floatbyzero(RateSpec,Spread,
Settle,Maturity)
[Price,DirtyPrice,CFlowAmounts,CFlowDates] = floatbyzero( ___ ,Name,Value)
```

Description

`[Price,DirtyPrice,CFlowAmounts,CFlowDates] = floatbyzero(RateSpec,Spread, Settle,Maturity)` prices a floating-rate note from a set of zero curves.

`floatbyzero` computes prices of vanilla floating-rate notes and amortizing floating-rate notes.

Note Alternatively, you can use the `FloatBond` object to price floating-rate bond instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,DirtyPrice,CFlowAmounts,CFlowDates] = floatbyzero( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floating-Rate Note Using a Set of Zero Curves

Price a 20-basis point floating-rate note using a set of zero curves.

Load `deriv.mat`, which provides `ZeroRateSpec`, the interest-rate term structure, needed to price the bond.

```
load deriv.mat;
```

Define the floating-rate note using the required arguments. Other arguments use defaults.

```
Spread = 20;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
```

Use `floatbyzero` to compute the price of the note.

```
Price = floatbyzero(ZeroRateSpec, Spread, Settle, Maturity)
```

```
Price = 100.5529
```

Price an Amortizing Floating-Rate Note

Price an amortizing floating-rate note using the `Principal` input argument to define the amortization schedule.

Create the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
          EndTimes: [5x1 double]
        StartTimes: [5x1 double]
          EndDates: [5x1 double]
        StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Create the floating-rate instrument using the following data:

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Spread = 15;
```

Define the floating-rate note amortizing schedule.

```
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Compute the price of the amortizing floating-rate note.

```
Price  = floatbyzero(RateSpec, Spread, Settle, Maturity, 'Principal', Principal)
```

```
Price = 100.3059
```

Specify the Rate at the Instrument's Starting Date When It Cannot Be Obtained from the RateSpec

If `Settle` is not on a reset date of a floating-rate note, `floatbyzero` attempts to obtain the latest floating rate before `Settle` from `RateSpec` or the `LatestFloatingRate` parameter. When the reset date for this rate is out of the range of `RateSpec` (and `LatestFloatingRate` is not specified), `floatbyzero` fails to obtain the rate for that date and generates an error. This example shows how to use the `LatestFloatingRate` input parameter to avoid the error.

Create the error condition when a floating-rate instrument's `StartDate` cannot be determined from the `RateSpec`.

```
load deriv.mat;

Spread = 20;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,12,1);

Price = floatbyzero(ZeroRateSpec, Spread, Settle, Maturity)

Error using floatbyzero (line 256)
The rate at the instrument starting date cannot be obtained from RateSpec.
 Its reset date (01-Dec-1999) is out of the range of dates contained in RateSpec.
 This rate is required to calculate cash flows at the instrument starting date.
 Consider specifying this rate with the 'LatestFloatingRate' input parameter.
```

Here, the reset date for the rate at `Settle` was 01-Dec-1999, which was earlier than the valuation date of `ZeroRateSpec` (01-Jan-2000). This error can be avoided by specifying the rate at the instrument's starting date using the `LatestFloatingRate` name-value pair argument.

Define `LatestFloatingRate` and calculate the floating-rate price.

```
Price = floatbyzero(ZeroRateSpec, Spread, Settle, Maturity, 'LatestFloatingRate', 0.03)

Price =

  100.0285
```

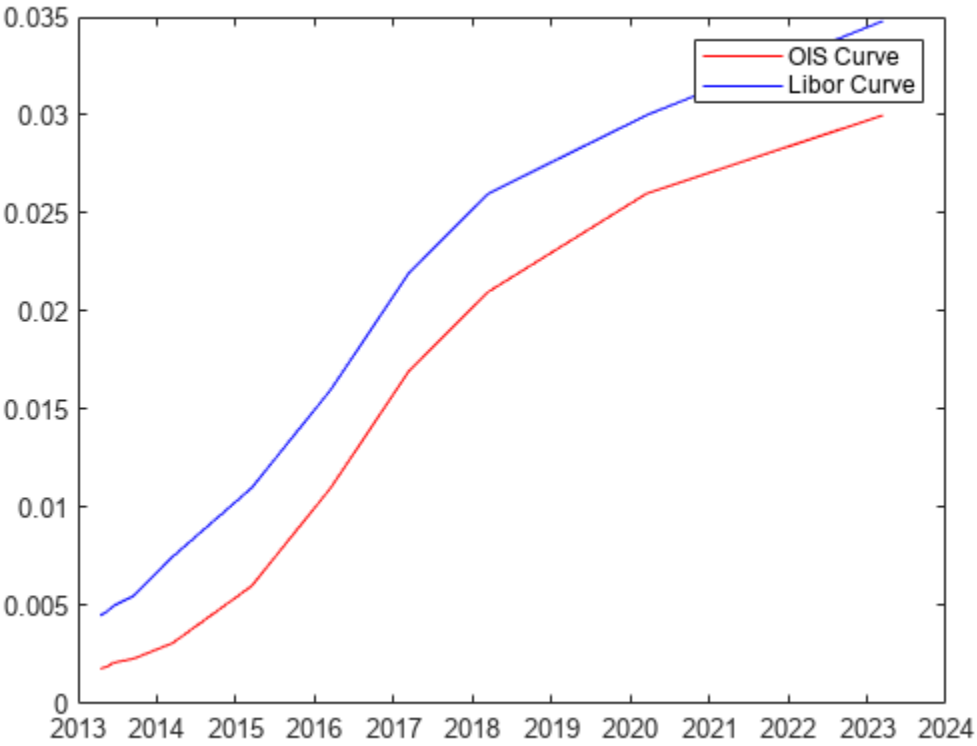
Price a Floating-Rate Note Using a Different Curve to Generate Floating Cash Flows

Define the OIS and Libor rates.

```
Settle = datetime(2013,3,15);
CurveDates = daysadd(Settle,360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10],1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006  .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .011 .016 .022 .026 .030 .0348]';
```

Plot the dual curves.

```
figure,plot(CurveDates,OISRates,'r');hold on;plot(CurveDates,LiborRates,'b')
datetick
legend({'OIS Curve', 'Libor Curve'})
```



Create an associated `RateSpec` for the OIS and Libor curves.

```
OISCurve = intenvset('Rates',OISRates,'StartDate',Settle,'EndDates',CurveDates);
LiborCurve = intenvset('Rates',LiborRates,'StartDate',Settle,'EndDates',CurveDates);
```

Define the floating-rate note.

```
Maturity = datetime(2018,3,15);
```

Compute the price for the floating-rate note. The `LiborCurve` term structure will be used to generate the floating cash flows of the floater instrument. The `OISCurve` term structure will be used for discounting the cash flows.

```
Price = floatbyzero(OISCurve,0,Settle,Maturity,'ProjectionCurve',LiborCurve)
```

```
Price = 102.4214
```

Some instruments require using different interest-rate curves for generating the floating cash flows and discounting. This is when the `ProjectionCurve` parameter is useful. When you provide both `RateSpec` and `ProjectionCurve`, `floatbyzero` uses the `RateSpec` for the purpose of discounting and it uses the `ProjectionCurve` for generating the floating cash flows.

Input Arguments

`RateSpec` — Annualized zero rate term structure
structure

Annualized zero rate term structure, specified using `intenvset` to create a `RateSpec`.

Data Types: `struct`

`Spread` — Number of basis points over the reference rate
vector

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floatbyzero` also accepts serial date numbers as inputs, but they are not recommended.

`Settle` must be earlier than `Maturity`.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, `floatbyzero` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,DirtyPrice,CFlowAmounts,CFlowDates] = floatbyzero(RateSpec,Spread,Settle,Maturity,'Principal',Principal)`

`FloatReset` — Frequency of payments per year
`1` (default) | vector

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

Notional principal amounts, specified as the comma-separated pair consisting of `'Principal'` and a vector or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`LatestFloatingRate` — Rate for the next floating payment
if not specified, the floating rate at the previous reset date is computed from `RateSpec` (default) | numeric

Rate for the next floating payment set at the last reset date, specified as the comma-separated pair consisting of `'LatestFloatingRate'` and a `NINST`-by-`1`.

Data Types: `double`

`ProjectionCurve` — Rate curve used in generating future forward rates
if not specified, then `RateSpec` is used both for discounting cash flows and projecting future forward rates (default) | structure

The rate curve to be used in generating the future forward rates, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a structure created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `struct`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

Output Arguments

`Price` — Floating-rate note prices

matrix

Floating-rate note prices, returned as a (`NINST`) by number of curves (`NUMCURVES`) matrix. Each column arises from one of the zero curves.

`DirtyPrice` — Dirty note price

matrix

Dirty note price (clean + accrued interest), returned as a `NINST`- by-`NUMCURVES` matrix. Each column arises from one of the zero curves.

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, returned as a `NINST`- by-`NUMCFS` matrix of cash flows for each note. If there is more than one curve specified in the `RateSpec` input, then the first `NCURVES` rows correspond to the first note, the second `NCURVES` rows correspond to the second note, and so on.

`CFlowDates` — Cash flow dates

matrix

Cash flow dates, returned as a `NINST`- by-`NUMCFS` matrix of payment dates for each note.

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floatbyzero` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floorbybdt

Price floor instrument from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = floorbybdt(BDTTree,Strike,Settle,Maturity)
[Price,PriceTree] = floorbybdt( ___ ,FloorReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = floorbybdt(BDTTree,Strike,Settle,Maturity)` computes the price of a floor instrument from a Black-Derman-Toy interest-rate tree. `floorbybdt` computes prices of vanilla floors and amortizing floors.

Note Alternatively, you can use the `Floor` object to price floor instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = floorbybdt( ___ ,FloorReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 10% Floor Instrument Using a BDT Interest-Rate Tree

Load the file `deriv.mat`, which provides `BDTTree`. `BDTTree` contains the time and interest-rate information needed to price the floor instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.10;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
```

Use `floorbybdt` to compute the price of the floor instrument.

```
Price = floorbybdt(BDTTree, Strike, Settle, Maturity)
```

```
Price = 0.2428
```

Price a 10% Floor Instrument Using a Newly Created BDT Interest-Rate Tree

First set the required arguments for the three needed specifications.

```
Compounding = 1;
ValuationDate = datetime(2000,1,1);
StartDate = ValuationDate;
EndDates = [datetime(2001,1,1) ; datetime(2002,1,1) ; datetime(2003,1,1) ; datetime(2004,1,1) ;da
Rates = [.1; .11; .12; .125; .13];
Volatility = [.2; .19; .18; .17; .16];
```

Create the specifications.

```
RateSpec = intenvset('Compounding', Compounding,...
'ValuationDate', ValuationDate,...
'StartDates', StartDate,...
'EndDates', EndDates,...
'Rates', Rates);
BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility);
```

Create the BDT tree from the specifications.

```
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [730486 730852 731217 731582 731947]
        TFwd: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [4]}
      CFlowT: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [5]}
     FwdTree: {1x5 cell}
```

Set the floor arguments. Remaining arguments will use defaults.

```
FloorStrike = 0.10;
Settlement = ValuationDate;
Maturity = datetime(2002,1,1);
FloorReset = 1;
```

Use `floorbybdt` to find the price of the floor instrument.

```
Price= floorbybdt(BDTTree, FloorStrike, Settlement, Maturity,...
FloorReset)
```

```
Price = 0.0863
```

Compute the Price of an Amortizing Floor Using the BDT Model

Define the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,1
Compounding = 1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Define the floor instrument.

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Strike = 0.039;
Reset = 1;
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Build the BDT Tree.

```
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
Volatility = 0.10;
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility*ones(1,length(EndDates))');
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [734822 735188 735553 735918 736283]
        TFwd: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [4]}
      CFlowT: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [5]}
     FwdTree: {1x5 cell}
```

Price the amortizing floor.

```
Basis = 0;
Price = floorbybdt(BDTTree, Strike, Settle, Maturity, Reset, Basis, Principal)
```

```
Price = 0.3060
```

Input Arguments

BDTTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`Strike` — Rate at which floor is exercised
decimal

Rate at which the floor is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for floor
datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every floor is set to the `ValuationDate` of the BDT tree. The floor argument `Settle` is ignored.

To support existing code, `floorbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor
datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`FloorReset` — Reset frequency payment per year
`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing floor.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of floor at time 0
vector

Expected price of the floor at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of floor at each node
vector

Tree structure with values of the floor at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.PTree` contains floor prices.
- `PriceTree.tObs` contains the observation times.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floorbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floorbybk

Price floor instrument from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = floorbybk(BKTree,Strike,Settle,Maturity)
[Price,PriceTree] = floorbybk( ___ ,Reset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = floorbybk(BKTree,Strike,Settle,Maturity)` computes the price of a floor instrument from a Black-Karasinski interest-rate tree. `floorbybk` computes prices of vanilla floors and amortizing floors.

Note Alternatively, you can use the `Floor` object to price floor instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = floorbybk( ___ ,Reset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Floor Instrument Using a Black-Karasinski Interest-Rate Tree

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and interest rate information needed to price the floor instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.03;
Settle = datetime(2004,1,1);
Maturity = datetime(2007,1,1);
```

Use `floorbybk` to compute the price of the floor instrument.

```
Price = floorbybk(BKTree, Strike, Settle, Maturity)
```

```
Price = 0.2061
```

Compute the Price of an Amortizing and Vanilla Floors Using the BK Model

Load `deriv.mat` to specify the `BKTree` and then define the floor instrument.

```
load deriv.mat;
Settle = datetime(2004,1,1);
Maturity = datetime(2008,1,1);
Strike = 0.045;
Reset = 1;
Principal ={{datetime(2005,1,1) 100;datetime(2006,1,1) 60;datetime(2007,1,1) 30;datetime(2008,1,1
            100};
```

Price the amortizing and vanilla floors.

```
Basis = 1;
Price = floorbybk(BKTree, Strike, Settle, Maturity, Reset, Basis, Principal)
```

```
Price = 2×1

    2.2000
    2.5564
```

Input Arguments

BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

Strike — Rate at which cap is exercised

decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

Settle — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every floor is set to the `ValuationDate` of the BK tree. The floor argument `Settle` is ignored.

To support existing code, `floorbybk` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for floor

datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbybk` also accepts serial date numbers as inputs, but they are not recommended.

Reset — Reset frequency payment per year

1 (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing floor.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of floor at time 0
vector

Expected price of the floor at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of floor at each node
vector

Tree structure with values of the floor at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.PTree` contains floor prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

floorbycir

Price floor instrument from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = floorbycir(CIRTree,Strike,Settle,Maturity)
[Price,PriceTree] = floorbycir(___,Name,Value)
```

Description

`[Price,PriceTree] = floorbycir(CIRTree,Strike,Settle,Maturity)` computes the price of a floor instrument from a Cox-Ingersoll-Ross (CIR) interest-rate tree. `floorbycir` computes prices of vanilla floors and amortizing floors using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = floorbycir(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Floor Using a CIR Interest-Rate Tree

Define the `Strike` for a floor.

```
Strike = 0.02;
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
```

```
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the 2% floor.

```
[Price,PriceTree] = floorbycir(CIRT,Strike,Settle,Maturity)
```

```
Price = 1.4211e-14
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 1 2 3 4]
      PTree: {1x5 cell}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
      Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised

decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every floor is set to the `ValuationDate` of the CIR tree. The floor argument `Settle` is ignored.

To support existing code, `floorbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor

datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = floorbycir(CIRTree,CouponRate,Settle,Maturity,'Basis',3)`

`FloorReset` — Reset frequency payment per year

`1` (default) | numeric

Reset frequency payment per year, specified as the comma-separated pair consisting of `'FloorReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount

`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array.

For the NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates, and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use Principal to pass a schedule to compute the price for an amortizing floor.

Data Types: double | cell

Output Arguments

Price — Expected price of floor at time 0

vector

Expected price of the floor at time 0, returned as a NINST-by-1 vector.

PriceTree — Tree structure with values of floor at each node

vector

Tree structure with values of the floor at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- PriceTree.PTree contains floor prices.
- PriceTree.tObs contains the observation times.
- PriceTree.Connect contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are NumNodes elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- PriceTree.Probs contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although floorbycir supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floorbyblk

Price floors using Black option pricing model

Syntax

```
[FloorPrice,Floorlets] = floorbyblk(RateSpec,Strike,Settle,Maturity,
Volatility)
[FloorPrice,Floorlets] = floorbyblk( ___ ,Name,Value)
```

Description

`[FloorPrice,Floorlets] = floorbyblk(RateSpec,Strike,Settle,Maturity, Volatility)` price floors using the Black option pricing model. `floorbyblk` computes prices of vanilla floors and amortizing floors.

Note Alternatively, you can use the `Floor` object to price floor instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[FloorPrice,Floorlets] = floorbyblk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Floor Using the Black Option Pricing Model

This example shows how to price a floor using the Black option pricing model. Consider an investor who gets into a contract that floors the interest rate on a $100,000 loan at 6% quarterly compounded for 3 months, starting on January 1, 2009. Assuming that on January 1, 2008 the zero rate is 6.9394% continuously compounded and the volatility is 20%, use this data to compute the floor price.

```
ValuationDate = datetime(2008,1,1);
EndDates = datetime(2010,4,1);
Rates = 0.069394;
Compounding = -1;
Basis = 1;

% calculate the RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding,'Basis', Basis);

Settle = datetime(2009,1,1); % floor starts in a year
Maturity = datetime(2009,4,1);
Volatility = 0.20;
FloorRate = 0.06;
FloorReset = 4;
Principal=100000;
```

```
FloorPrice = floorbyblk(RateSpec, FloorRate, Settle, Maturity, Volatility,...
'Reset',FloorReset,'ValuationDate',ValuationDate,'Principal', Principal,...
'Basis', Basis)
```

```
FloorPrice = 37.4864
```

Price a Floor Using a Different Curve to Generate the Future Forward Rates

Define the OIS and Libor rates.

```
Settle = datetime(2013,3,15);
CurveDates = daysadd(Settle,360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10],1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006  .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .0109  .0162 .0216 .0262 .0309 .0348]';
```

Create an associated `RateSpec` for the OIS and Libor curves.

```
OISCurve = intenvset('Rates',OISRates,'StartDate',Settle,'EndDates',CurveDates,'Compounding',2,'
LiborCurve = intenvset('Rates',LiborRates,'StartDate',Settle,'EndDates',CurveDates,'Compounding'
```

Define the Floor instruments.

```
Maturity = [datetime(2018,3,15) ; datetime(2020,3,15)];
Strike = [.04;.05];
BlackVol = .2;
```

Price the floor instruments using the term structure `OISCurve` both for discounting the cash flows and generating future forward rates.

```
[Price, Floorlets] = floorbyblk(OISCurve, Strike, Settle, Maturity, BlackVol)
```

```
Price = 2×1

    9.9808
   16.9057

Floorlets = 2×7

    3.6783    3.0706    1.8275    0.7280    0.6764       NaN       NaN
    4.6753    4.0587    2.7921    1.4763    1.3442    1.4130    1.1462
```

Price the floor instruments using the term structure `LiborCurve` to generate future forward rates. The term structure `OISCurve` is used for discounting the cash flows.

```
[PriceLC, FloorletsLC] = floorbyblk(OISCurve, Strike, Settle, Maturity, BlackVol,'ProjectionCurve
```

```
PriceLC = 2×1

    8.0524
   14.3184

FloorletsLC = 2×7
```

```
    3.2385    2.5338    1.2895    0.5889    0.4017       NaN       NaN
    4.2355    3.5219    2.2286    1.2751    0.9169    1.1698    0.9706
```

Compute the Price of an Amortizing Floor Using the Black Model

Define the RateSpec.

```
Rates = [0.0358; 0.0421; 0.0473; 0.0527; 0.0543];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
             'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
          EndTimes: [5x1 double]
        StartTimes: [5x1 double]
          EndDates: [5x1 double]
        StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Define the floor instrument.

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Strike = 0.05;
Reset = 2;
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Price the amortizing floor.

```
Volatility = 0.20;
Price = floorbyblk(RateSpec, Strike, Settle, Maturity, Volatility,...
'Reset',Reset,'Principal', Principal)
```

```
Price = 1.9315
```

Price a Floor Using the Shifted Black Model

Create the RateSpec.

```
ValuationDate = datetime(2016,3,1);
EndDates = [datetime(2017,3,1) ; datetime(2018,3,1) ; datetime(2019,3,1) ; datetime(2020,3,1) ; d
Rates = [-0.21; -0.12; 0.01; 0.10; 0.20]/100;
```

```
Compounding = 1;
Basis = 1;

RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding,'Basis',Basis)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 736390
    ValuationDate: 736390
            Basis: 1
     EndMonthRule: 1
```

Price the floor with a negative strike using the Shifted Black model.

```
Settle = datetime(2016,6,1); % Floor starts in 3 months.
Maturity = datetime(2016,9,1);
ShiftedBlackVolatility = 0.31;
FloorRate = -0.001;  % -0.1 percent strike.
FloorReset = 4;
Principal = 100000;
Shift = 0.01; % 1 percent shift.

FloorPrice = floorbyblk(RateSpec,FloorRate,Settle,Maturity,ShiftedBlackVolatility,...
'Reset',FloorReset,'ValuationDate',ValuationDate,'Principal',Principal,...
'Basis',Basis,'Shift',Shift)

FloorPrice = 31.2099
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

Strike — Rate at which floor is exercised

decimal

Rate at which floor is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

Settle — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor
datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`Volatility` — Volatilities values
numeric

Volatilities values, specified as a `NINST`-by-`1` vector of numeric values.

The `Volatility` input is not intended for volatility surfaces or cubes. If you specify a matrix for the `Volatility` input, `floorbyblk` internally converts it into a vector. `floorbyblk` assumes that the volatilities specified in the `Volatility` input are flat volatilities, which are applied equally to each of the floorlets.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[FloorPrice,Floorlets] = floorbyblk(RateSpec,Strike,Settle,Maturity,Volatility,'Reset',CapReset,'Principal',100000,'Basis',7)`

`Reset` — Reset frequency payment per year
`1` (default) | numeric

Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array. When `Principal` is a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array, where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing floor.

Data Types: `double` | `cell`

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate, specified as a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

ProjectionCurve — Rate curve used in generating future forward rates
if ProjectionCurve is not specified, then RateSpec is used both for discounting cash flows and projecting future forward rates (default) | structure

The rate curve to be used in generating the future forward rates. This structure must be created using intenvset. Use this optional input if the forward curve is different from the discount curve.

Data Types: struct

Shift — Shift in decimals for shifted Black model
0 (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified using a scalar or NINST-by-1 vector of rate shifts in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate. For example, a Shift of 0.01 is equal to a 1% shift.

Data Types: double

Output Arguments

FloorPrice — Expected price of floor
vector

Expected price of the floor, returned as a NINST-by-1 vector.

`Floorlets` — Floorlets
array

Floorlets, returned as a `NINST`-by-`NCF` array of floorlets, padded with `NaN`s.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$$\max(FloorRate - CurrentRate, 0)$$

Shifted Black

The Shifted Black model is essentially the same as the Black's model, except that it models the movements of (F + $Shift$) as the underlying asset, instead of F (which is the forward rate in the case of floorlets).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of Black's model has been shifted.

Algorithms

Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-\gamma T}[FN(d_1) - KN(d_2)]$$

$$put = e^{-\gamma T}[KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B{}^2}{2}\right)T}{\sigma_B\sqrt{T}}, \quad d_2 = d_1 - \sigma_B\sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Where F is the forward value and K is the strike.

Shifted Black Model

$$dF = \sigma_{Shifted\_Black}(F + Shift)dw$$

$$call = e^{-\gamma T}[(F + Shift)N(d_{s1}) - (K + Shift)N(d_{s2})]$$

$$put = e^{-\gamma T}[(K + Shift)N(-d_{s2}) - (F + Shift)N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + Shift}{K + Shift}\right) + \left(\frac{\sigma_{sB}{}^2}{2}\right)T}{\sigma_{sB}\sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB}\sqrt{T}$$

$$\sigma_{sB} = \sigma_{Shifted\_Black}$$

Where *F+Shift* is the forward value and *K+Shift* is the strike for the shifted version.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floorbyblk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

floorbyhjm

Price floor instrument from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = floorbyhjm(HJMTree,Strike,Settle,Maturity)
[Price,PriceTree] = floorbyhjm( ___ ,FloorReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = floorbyhjm(HJMTree,Strike,Settle,Maturity)` computes the price of a floor instrument from a Heath-Jarrow-Morton interest-rate tree. `floorbyhjm` computes prices of vanilla floors and amortizing floors.

`[Price,PriceTree] = floorbyhjm( ___ ,FloorReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Floor Instrument Using an HJM Forward-Rate Tree

This example shows how to price a 3% floor instrument using an HJM forward-rate tree by loading the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and forward-rate information needed to price the floor instrument.

```
load deriv.mat;

Strike = 0.03;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);

Price = floorbyhjm(HJMTree, Strike, Settle, Maturity)
```

```
Price = 0.0486
```

Compute the Price of an Amortizing Floor Using the HJM Model

Load `deriv.mat` to specify the `HJMTree` and then define the floor instrument.

```
load deriv.mat;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
Strike = 0.05;
FloorReset = 1;
Principal ={{datetime(2001,1,1) 100;datetime(2002,1,1) 80;datetime(2003,1,1) 70;datetime(2004,1,1
```

Price the amortizing floor.

```
Price = floorbyhjm(HJMTree, Strike, Settle, Maturity, FloorReset, Principal)

Price = 2.8215
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`Strike` — Rate at which floor is exercised

decimal

Rate at which the floor is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every floor is set to the `ValuationDate` of the HJM tree. The floor argument `Settle` is ignored.

To support existing code, `floorbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor

datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`FloorReset` — Reset frequency payment per year

`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing floor.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of floor at time 0
vector

Expected price of the floor at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of floor at each node
vector

Tree structure with values of the floor at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PBush` contains the clean prices.

More About

floorbyhw

Price floor instrument from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = floorbyhw(HWTree,Strike,Settle,Maturity)
[Price,PriceTree] = floorbyhw( ___ ,FloorReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = floorbyhw(HWTree,Strike,Settle,Maturity)` computes the price of a floor instrument from a Hull-White interest-rate tree. `capbyhw` computes prices of vanilla floors and amortizing floors.

Note Alternatively, you can use the `Floor` object to price floor instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = floorbyhw( ___ ,FloorReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Floor Instrument Using a Hull-White Interest-Rate Tree

Load the file `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and interest rate information needed to price the floor instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.03;
Settle = datetime(2004,1,1);
Maturity = datetime(2007,1,1);
```

Use `floorbyhw` to compute the price of the floor instrument.

```
Price = floorbyhw(HWTree, Strike, Settle, Maturity)
```

```
Price = 0.4186
```

Compute the Price of an Amortizing and Vanilla Floors Using the HW Model

Define the `RateSpec`.

```
Rates = [0.035; 0.042; 0.047; 0.052; 0.054];
ValuationDate = datetime(2014,4,1);
StartDates = ValuationDate;
EndDates = datetime(2019,4,1);
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: 737516
       StartDates: 735690
    ValuationDate: 735690
            Basis: 0
     EndMonthRule: 1
```

Define the floor instruments.

```
Settle = datetime(2014,4,1);
Maturity = datetime(2018,4,1);
Strike = 0.05;
FloorReset = 1;
Principal ={{datetime(2015,4,1) 100;datetime(2016,4,1) 60;datetime(2017,4,1) 40;datetime(2018,4,1
            100};
```

Build the HW Tree.

```
VolDates = [datetime(2015,4,1) ; datetime(2016,4,1) ; datetime(2017,4,1) ; datetime(2018,4,1)];
VolCurve = 0.05;
AlphaDates = datetime(2018,4,1);
AlphaCurve = 0.10;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
                      AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec)

HWTree = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [735690 736055 736421 736786]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

Price the amortizing and vanilla floors.

```
Basis = 0;
Price  = floorbyhw(HWTree, Strike, Settle, Maturity, FloorReset, Basis, Principal)
```

```
Price = 2×1

    4.8675
   10.3881
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`Strike` — Rate at which floor is exercised

decimal

Rate at which the floor is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every floor is set to the `ValuationDate` of the HW tree. The floor argument `Settle` is ignored.

To support existing code, `floorbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor

datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`FloorReset` — Reset frequency payment per year

`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing floor.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of floor at time 0
vector

Expected price of the floor at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of floor at each node
vector

Tree structure with values of the floor at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.PTree` contains floor prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

floorbylg2f

Price floor using Linear Gaussian two-factor model

Syntax

```
FloorPrice = floorbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,Maturity)
FloorPrice = floorbylg2f( ___ ,Name,Value)
```

Description

`FloorPrice = floorbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,Maturity)` returns the floor price for a two-factor additive Gaussian interest-rate model.

Note Alternatively, you can use the `Floor` object to price floor instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`FloorPrice = floorbylg2f( ___ ,Name,Value)` adds optional name-value pair arguments.

Note Use the optional name-value pair argument, `Notional`, to pass a schedule to compute the price for an amortizing floor.

Examples

Price a Floor Using a Linear Gaussian Two-Factor Model

Define the `ZeroCurve`, `a`, `b`, `sigma`, `eta`, and `rho` parameters to compute the floor price.

```
Settle = datetime(2007,12,15);

ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';
CurveDates = daysadd(Settle,360*ZeroTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

FloorMaturity = daysadd(Settle,360*[1:5 7 10 15 20 25 30],1);

Strike = [0.035 0.037 0.038 0.039 0.040 0.042 0.044 0.046 0.047 0.047 0.047]';

Price = floorbylg2f(irdc,a,b,sigma,eta,rho,Strike,FloorMaturity)
```

```
Price = 11×1

```

Input Arguments

`ZeroCurve` — Zero curve for Linear Gaussian two-factor model
structure

Zero curve for the Linear Gaussian two-factor model, specified using `IRDataCurve` or `RateSpec`.

Data Types: `struct`

`a` — Mean reversion for first factor for Linear Gaussian two-factor model
scalar

Mean reversion for the first factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `double`

`b` — Mean reversion for second factor for Linear Gaussian two-factor model
scalar

Mean reversion for the second factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `double`

`sigma` — Volatility for first factor for Linear Gaussian two-factor model
scalar

Volatility for the first factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `double`

`eta` — Volatility for second factor for Linear Gaussian two-factor model
scalar

Volatility for the second factor for the Linear Gaussian two-factor model, specified as a scalar.

Data Types: `double`

`rho` — Scalar correlation of factors
scalar

Scalar correlation of the factors, specified as a scalar.

Data Types: `double`

`Strike` — Floor strike price
nonnegative integer | vector of nonnegative integers

Floor strike price specified, as a nonnegative integer using a `NumFloors`-by-`1` vector of floor strike prices.

Data Types: `double`

`Maturity` — Floor maturity date
datetime array | string array | date character vector

Floor maturity date, specified using a `NumFloors`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbylg2f` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = floorbylg2f(irdc,a,b,sigma,eta,rho,Strike,FloorMaturity,'Reset',1,'Notional',100)`

`Reset` — Frequency of floor payments per year
`2` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of floor payments per year, specified as the comma-separated pair consisting of `'Reset'` and positive integers for the values `[1,2,4,6,12]` in a `NumFloors`-by-`1` vector.

Data Types: `double`

`Notional` — Notional value of floor
`100` (default) | nonnegative integer | vector of nonnegative integers

`NINST`-by-`1` of notional principal amounts or `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double`

Output Arguments

`FloorPrice` — Floor price
scalar | vector

Floor price, returned as a scalar or a `NumFloors`-by-`1` vector.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

Algorithms

The following defines the two-factor additive Gaussian interest-rate model, given the `ZeroCurve`, `a`, `b`, `sigma`, `eta`, and `rho` parameters:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -a(x)(t)dt + \sigma(dW_1(t), x(0) = 0$$

$$dy(t) = -b(y)(t)dt + \eta(dW_2(t), y(0) = 0$$

where $dW_1(t)dW_2(t) = \rho dt$ is a two-dimensional Brownian motion with correlation ρ and ϕ is a function chosen to match the initial zero curve.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floorbylg2f` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

floorbynormal

Price floors using Normal or Bachelier pricing model

Syntax

```
[FloorPrice,Floorlets] = floorbynormal(RateSpec,Strike,Settle,Maturity,
Volatility)
[FloorPrice,Floorlets] = floorbynormal( ___ ,Name,Value)
```

Description

`[FloorPrice,Floorlets] = floorbynormal(RateSpec,Strike,Settle,Maturity, Volatility)` prices floors using the Normal (Bachelier) pricing model for negative rates. `floorbynormal` computes prices of vanilla floors and amortizing floors.

Note Alternatively, you can use the `Floor` object to price floor instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[FloorPrice,Floorlets] = floorbynormal( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Floor Using Normal Model for Negative Rates

Consider an investor who gets into a contract that floors the interest rate on a $100,000 loan at –.6% quarterly compounded for 3 months, starting on January 1, 2009. Assuming that on January 1, 2008 the zero rate is .69394% continuously compounded and the volatility is 20%, use this data to compute the floor price. First, calculate the `RateSpec`, and then use `floorbynormal` to compute the `FloorPrice`.

```
ValuationDate = datetime(2008,1,1);
EndDates = datetime(2010,1,1);
Rates = 0.0069394;
Compounding = -1;
Basis = 1;

% calculate the RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding,'Basis', Basis);

Settle = datetime(2009,1,1); % floor starts in a year
Maturity = datetime(2009,4,1);
Volatility = 0.20;
FloorRate = -0.006;
FloorReset = 4;
```

```
Principal=100000;

FloorPrice = floorbynormal(RateSpec, FloorRate, Settle, Maturity, Volatility,...
'Reset',FloorReset,'ValuationDate',ValuationDate,'Principal', Principal,...
'Basis', Basis)

FloorPrice = 1.8212e+03
```

Price a Floor Using `floorbynormal` and Compare to `floorbyblk`

Define the `RateSpec`.

```
Settle = datetime(2016,1,20);
ZeroTimes = [.5 1 2 3 4 5 7 10 20 30]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = datemnth(Settle,12*ZeroTimes);
RateSpec = intenvset('StartDate',Settle,'EndDates',ZeroDates,'Rates',ZeroRates)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [10x1 double]
            Rates: [10x1 double]
         EndTimes: [10x1 double]
       StartTimes: [10x1 double]
         EndDates: [10x1 double]
       StartDates: 736349
    ValuationDate: 736349
            Basis: 0
     EndMonthRule: 1
```

Define the floor instrument and price with `floorbyblk`.

```
ExerciseDate = datetime(2026,1,20);

[~,ParSwapRate] = swapbyzero(RateSpec,[NaN 0],Settle,ExerciseDate)

ParSwapRate = 0.0216

Strike = .01;
BlackVol = .3;
NormalVol = BlackVol*ParSwapRate;

Price = floorbyblk(RateSpec,Strike,Settle,ExerciseDate,BlackVol)

Price = 1.2297
```

Price the floor instrument using `floorbynormal`.

```
Price_Normal = floorbynormal(RateSpec,Strike,Settle,ExerciseDate,NormalVol)

Price_Normal = 1.9099
```

Price the floor instrument using `floorbynormal` for a negative strike.

```
 Price_Normal = floorbynormal(RateSpec,-.005,Settle,ExerciseDate,NormalVol)
```

```
Price_Normal = 0.0857
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`Strike` — Rate at which floor is exercised

decimal

Rate at which floor is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbynormal` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor

datetime array | string array | date character vector

Maturity date for the floor, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorbynormal` also accepts serial date numbers as inputs, but they are not recommended.

`Volatility` — Normal volatilities values

numeric

Normal volatilities values, specified as a `NINST`-by-`1` vector of numeric values.

For more information on the Normal model, see “Work with Negative Interest Rates Using Functions” on page 2-18.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[FloorPrice,Floorlets] = floorbynormal(RateSpec,Strike,Settle,Maturity,Volatility,'Reset',CapReset,'Principal',100000,'Basis',7)`

`Reset` — Reset frequency payment per year
`1` (default) | numeric

Reset frequency payment per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array. Each element in the `NINST`-by-`1` cell array is a `NumDates`-by-`2` cell array, where the first column is dates, and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing cap.

Data Types: `double` | `cell`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of instrument representing the basis used when annualizing the input forward rate, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`ValuationDate` — Observation date of investment horizon
if `ValuationDate` is not specified, then `Settle` is used (default) | datetime scalar | string scalar | date character vector

Observation date of the investment horizon, specified as the comma-separated pair consisting of `'ValuationDate'` and a scalar datetime, string, or date character vector.

To support existing code, `floorbynormal` also accepts serial date numbers as inputs, but they are not recommended.

`ProjectionCurve` — Rate curve used in generating future cash flows
if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting cash flows and projecting future cash flows (default) | structure

The rate curve to be used in projecting the future cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a rate curve structure. This structure must be created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `struct`

Output Arguments

`FloorPrice` — Expected price of floor
vector

Expected price of the floor, returned as a `NINST`-by-`1` vector.

`Floorlets` — Floorlets
array

Floorlets, returned as a `NINST`-by-`NCF` array of caplets, padded with `NaN`s.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

Version History

Introduced in R2017a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `floorbynormal` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

floorvolstrip

Strip floorlet volatilities from flat floor volatilities

Syntax

```
[FloorletVols,FloorletPaymentDates,FloorStrikes] = floorvolstrip(ZeroCurve,
FloorSettle,FloorMaturity,FloorVolatility)
[FloorletVols,FloorletPaymentDates,FloorStrikes] = floorvolstrip( ___ ,
Name,Value)
```

Description

`[FloorletVols,FloorletPaymentDates,FloorStrikes] = floorvolstrip(ZeroCurve, FloorSettle,FloorMaturity,FloorVolatility)` strips floorlet volatilities from the flat floor volatilities by using the bootstrapping method. The function interpolates the cap volatilities on each floorlet payment date before stripping the floorlet volatilities.

`[FloorletVols,FloorletPaymentDates,FloorStrikes] = floorvolstrip( ___ , Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Stripping Floorlet Volatilities from At-The-Money (ATM) Floors

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2015,8,10);
ZeroRates = [0.12 0.24 0.40 0.73 1.09 1.62]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
             Type: Zero
           Settle: 736186 (10-Aug-2015)
      Compounding: 2
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [6x1 double]
             Data: [6x1 double]
```

Define the ATM floor volatility data.

```
FloorSettle = datetime(2015,8,12);
FloorMaturity = [datetime(2016,8,12) ; datetime(2017,8,14) ; datetime(2018,8,13) ; datetime(2019
FloorVolatility = [0.31;0.39;0.43;0.42;0.40];
```

Strip floorlet volatilities from ATM floors.

```
[FloorletVols, FloorletPaymentDates, ATMFloorStrikes] = floorvolstrip(ZeroCurve,...
    FloorSettle, FloorMaturity, FloorVolatility);
```

```
PaymentDates = cellstr(datestr(FloorletPaymentDates));
format;
table(PaymentDates, FloorletVols, ATMFloorStrikes)
```

```
ans=9×3 table
     PaymentDates      FloorletVols    ATMFloorStrikes

    {'20-May-2019'}      0.39831           0.01
    {'19-Nov-2019'}       0.3524           0.01
    {'19-May-2020'}      0.32765           0.01
```

Stripping Floorlet Volatilities from Floors Using the Shifted Black Model

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2016,5,3);
ZeroRates = [-0.31 -0.21 -0.15 -0.10 0.009 0.19]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
            Type: Zero
          Settle: 736453 (03-May-2016)
     Compounding: 2
           Basis: 0 (actual/actual)
    InterpMethod: linear
           Dates: [6x1 double]
            Data: [6x1 double]
```

Define the floor volatility (Shifted Black) data.

```
FloorSettle = datetime(2016,5,3);
FloorMaturity = [datetime(2017,5,3) ; datetime(2018,5,3) ; datetime(2019,5,3) ; datetime(2020,5,
FloorVolatility = [0.42;0.45;0.43;0.40;0.36]; % Shifted Black volatilities
Shift = 0.01; % 1 percent shift.
FloorStrike = -0.001; % -0.1 percent strike.
```

Strip floorlet volatilities from floors using the Shifted Black Model.

```
[FloorletVols, FloorletPaymentDates, FloorStrikes] = floorvolstrip(ZeroCurve, ...
FloorSettle,FloorMaturity,FloorVolatility,'Strike',FloorStrike,'Shift',Shift);

PaymentDates = string(datestr(FloorletPaymentDates));
format;
table(PaymentDates,FloorletVols,FloorStrikes)
```

Stripping Floorlet Volatilities from Floors Using Normal Model

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2018,5,1);
ZeroRates = [-0.31 -0.27 -0.18 -0.05 0.015 0.22]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
             Type: Zero
           Settle: 737181 (01-May-2018)
      Compounding: 2
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [6x1 double]
             Data: [6x1 double]
```

Define the normal floor volatility data.

```
FloorSettle = datetime(2018,5,1);
FloorMaturity = [datetime(2019,5,1) ; datetime(2020,5,1) ; datetime(2021,5,3) ; datetime(2022,5,2
FloorVolatility = [0.0065;0.0067;0.0064;0.0058;0.0055]; % Normal volatilities
FloorStrike = -0.005; % -0.5 percent strike.
```

Strip floorlet volatilities from floors using the Normal (Bachelier) model.

```
[FloorletVols, FloorletPaymentDates, FloorStrikes] = floorvolstrip(ZeroCurve, ...
    FloorSettle,FloorMaturity,FloorVolatility,'Strike',FloorStrike,'Model','normal');

PaymentDates = string(datestr(FloorletPaymentDates));
format;
table(PaymentDates,FloorletVols,FloorStrikes)
```

```
ans=9×3 table
    PaymentDates     FloorletVols    FloorStrikes

```

Input Arguments

`ZeroCurve` — Zero rate curve

`RateSpec` object | `IRDataCurve` object

Zero rate curve, specified using a `RateSpec` or `IRDataCurve` object containing the zero rate curve for discounting according to its day count convention. If you do not specify the optional argument `ProjectionCurve`, the function uses `ZeroCurve` to compute the underlying forward rates as well. The observation date of the `ZeroCurve` specifies the valuation date. For more information on creating a `RateSpec`, see `intenvset`. For more information on creating an `IRDataCurve` object, see `IRDataCurve`.

Data Types: `struct`

`FloorSettle` — Common floor settle date

datetime scalar | string scalar | date character vector

Common floor settle date, specified as a scalar datetime, string, or date character vector. The `FloorSettle` date cannot be earlier than the `ZeroCurve` valuation date.

To support existing code, `floorvolstrip` also accepts serial date numbers as inputs, but they are not recommended.

`FloorMaturity` — Floor maturity dates

datetime array | string array | date character vector

Floor maturity dates, specified as an `NFloor`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorvolstrip` also accepts serial date numbers as inputs, but they are not recommended.

`FloorVolatility` — Flat floor volatilities

vector of positive decimals

Flat floor volatilities, specified as an `NFloor`-by-`1` vector of positive decimals.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[FloorletVols,FloorletPaymentDates,FloorStrikes] = floorvolstrip(ZeroCurve,FloorSettle,FloorMaturity,FloorVolatility,'Strike',.2)`

Strike — Floor strike rate
if not specified, all floors are at-the-money and the function computes the ATM strike for each floor maturing on each floorlet payment date (default) | scalar decimal | vector

Floor strike rate, specified as the comma-separated pair consisting of `'Strike'` and a scalar decimal value or an `NFloorletVols`-by-`1` vector. Use `Strike` as a scalar to specify a single strike that applies equally to all floors. Or, specify an `NCapletVols`-by-`1` vector of strikes for the floors.

Data Types: `double`

FloorletDates — Floorlet reset and payment dates
If not specified, the default is to automatically generate periodic floorlet dates (default) | datetime array | string array | date character vector

Floorlet reset and payment dates, specified as the comma-separated pair consisting of `'FloorletDates'` and an `NFloorletDates`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `floorvolstrip` also accepts serial date numbers as inputs, but they are not recommended.

Use `FloorletDates` to manually specify all floorlet reset and payment dates. For example, some date intervals may be quarterly while others may be semiannual. All dates must be later than `FloorSettle` and cannot be later than the last `FloorMaturity` date. Dates are adjusted according to the `BusDayConvention` and `Holidays` inputs.

If `FloorletDates` is not specified, the default is to automatically generate periodic floorlet dates after `FloorSettle` based on the last `FloorMaturity` date as the reference date, using the following optional inputs: `Reset`, `EndMonthRule`, `BusDayConvention`, and `Holidays`.

Reset — Frequency of periodic payments per year within a floor
2 (default) | positive scalar integer with values 1,2, 3, 4, 6, or 12

Frequency of periodic payments per year within a floor, specified as the comma-separated pair consisting of `'Reset'` and a positive scalar integer with values 1,2, 3, 4, 6, or 12.

Note If you specify `FloorletDates`, the function ignores the input for `Reset`.

Data Types: `double`

EndMonthRule — End-of-month rule flag for generating floorlet dates
1 (in effect) (default) | scalar nonnegative integer `[0,1]`

End-of-month rule flag for generating floorlet dates, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`].

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

BusinessDayConvention — Business day conventions
`'modifiedfollow'` (default) | character vector with values `'actual'`, `'follow'`, `'modifiedfollow'`, `'previous'`, `'modifiedprevious'`

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector. Use this argument to specify how the function treats non-business days, which are days on which businesses are not open (such as weekends and statutory holidays).

- `'actual'` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `'follow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `'modifiedfollow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `'previous'` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `'modifiedprevious'` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | vector of MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and `NHolidays`-by-`1` vector of MATLAB dates.

Data Types: `datetime`

`ProjectionCurve` — Rate curve for computing underlying forward rates
if not specified, the default is to use the `ZeroCurve` input for computing the underlying forward rates (default) | `RateSpec` object | `IRDatCurve` object

Rate curve for computing underlying forward rates, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a `RateSpec` object or `IRDatCurve` object. For more information on creating a `RateSpec`, see `intenvset`. For more information on creating an `IRDataCurve` object, see `IRDataCurve`.

Data Types: `struct`

`MaturityInterpMethod` — Method for interpolating floor volatilities on each floorlet maturity date before stripping floorlet volatilities
`'linear'` (default) | character vector with values: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'spline'`, `'pchip'`

Method for interpolating the floor volatilities on each floorlet maturity date before stripping the floorlet volatilities, specified as the comma-separated pair consisting of `'MaturityInterpMethod'` and a character vector with values: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'spline'`, or `'pchip'`.

- `'linear'` — Linear interpolation. The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.
- `'nearest'` — Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample grid point.

- `'next'` — Next neighbor interpolation. The interpolated value at a query point is the value at the next sample grid point.
- `'previous'` — Previous neighbor interpolation. The interpolated value at a query point is the value at the previous sample grid point.
- `'spline'` — Spline interpolation using not-a-knot end conditions. The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension.
- `'pchip'` — Shape-preserving piecewise cubic interpolation. The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.

For more information on interpolation methods, see `interp1`.

Note The function uses constant extrapolation to calculate volatilities falling outside the range of user-supplied data.

Data Types: `char`

`Limit` — Upper bound of implied volatility search interval
`10` (or 1000% per annum) (default) | positive scalar decimal

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar decimal.

Data Types: `double`

`Tolerance` — Implied volatility search termination tolerance
`1e-5` (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

Data Types: `double`

`OmitFirstFloorlet` — Flag to omit the first floorlet payment in the floors
`true` always omit the first floorlet (default) | logical

Flag to omit the first floorlet payment in the floors, specified as the comma-separated pair consisting of `'OmitFirstFloorlet'` and a scalar logical.

If the floors are spot-starting, the first floorlet payment is omitted. If the floors are forward-starting, the first floorlet payment is included. Regardless of the status of the floors, if you set this logical to `false`, then the function includes the first floorlet payment.

In general, “spot lag” is the delay between the fixing date and the effective date for LIBOR-like indices. "Spot lag" determines whether a floor is spot-starting or forward-starting (Corb, 2012). Floors are considered to be spot-starting if they settle within “spot lag” business days after the valuation date. Those that settle later are considered to be forward-starting. The first floorlet is omitted if floors are spot-starting, while it is included if they are forward-starting (Tuckman, 2012).

Data Types: `logical`

`Shift` — Shift in decimals for shifted SABR model
`0` (no shift) (default) | positive scalar decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), specified as the comma-separated pair consisting of `'Shift'` and a positive scalar decimal value. Set this parameter to a positive shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate and strike. For example, a `Shift` value of 0.01 is equal to a 1% shift.

Data Types: `double`

`Model` — Model used for implied volatility
`'lognormal'` (default) | character vector with value of `'lognormal'` or `'normal'` | string scalar with value of `"lognormal"` or `"normal"`

Model used for the implied volatility calculation, specified as the comma-separated pair consisting of `'Model'` and a scalar character vector or string scalar with one of the following values:

- `'lognormal'` - Implied Black (no shift) or Shifted Black volatility.
- `'normal'` - Implied Normal (Bachelier) volatility. If you specify `'normal'`, `Shift` must be zero.

The `floorvolstrip` function supports three volatility types.

'Model' Value	'Shift' Value	Volatility Type
`'lognormal'`	`Shift = 0`	Black
`'lognormal'`	`Shift > 0`	Shifted Black
`'normal'`	`Shift = 0`	Normal (Bachelier)

Data Types: `char` | `string`

Output Arguments

`FloorletVols` — Stripped floorlet volatilities
vector of decimals

Stripped floorlet volatilities, returned as a `NFloorletVols`-by-`1` vector of decimals.

Note `floorvolstrip` can output `NaN`s for some caplet volatilities. You might encounter this output if no volatility matches the caplet price implied by the user-supplied cap data.

`FloorletPaymentDates` — Payment dates
vector of date numbers

Payment dates (in date numbers), returned as an `NFloorletVols`-by-`1` vector of date numbers corresponding to `FloorletVols`.

`FloorStrikes` — Floor strikes
vector of decimals

Floor strikes, returned as a `NFloorletVols`-by-`1` vector of strikes in decimals for floors maturing on the corresponding `FloorletPaymentDates`.

Limitations

When bootstrapping the floorlet volatilities from ATM floors, the function reuses the floorlet volatilities stripped from the shorter maturity floors in the longer maturity floors without adjusting for the difference in strike. `floorvolstrip` follows the simplified approach described in Gatarek, 2006.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

At-The-Money

A cap or floor is at-the-money (ATM) if its strike is equal to the forward swap rate.

The forward swap rate is the fixed rate of a swap that makes the present value of the floating leg equal to that of the fixed leg. In comparison, a caplet or floorlet is ATM if its strike is equal to the forward rate (not the forward swap rate). In general (except over a single period), the forward rate is not equal to the forward swap rate. So, to be precise, the individual caplets in an ATM cap have slightly different moneyness and are only approximately ATM (Alexander, 2003).

In addition, the swap rate changes with swap maturity. Similarly, the ATM cap strike also changes with cap maturity, so the ATM cap strikes are computed for each cap maturity before stripping the caplet volatilities. As a result, when stripping the caplet volatilities from the ATM caps with increasing maturities, the ATM strikes of consecutive caps are different.

Version History

Introduced in R2016a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `floorvolstrip` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

gapbybls

Determine price of gap digital options using Black-Scholes model

Syntax

```
Price = gapbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
StrikeThreshold)
```

Description

`Price = gapbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, StrikeThreshold)` calculates gap European digital option prices using the Black-Scholes option pricing model.

Examples

Compute Gap Option Prices Using the Black-Scholes Option Pricing Model

This example shows how to compute gap option prices using the Black-Scholes option pricing model. Consider a gap call and put options on a nondividend paying stock with a strike of 57 and expiring on January 1, 2008. On July 1, 2008 the stock is trading at 50. Using this data, compute the price of the option if the risk-free rate is 9%, the strike threshold is 50, and the volatility is 20%.

```
Settle = datetime(2008,1,1);
Maturity = datetime(2008,7,1);
Compounding = -1;
Rates = 0.09;
% calculate the RateSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', 1);
% define the StockSpec
AssetPrice = 50;
Sigma = .2;
StockSpec = stockspec(Sigma, AssetPrice);
% define the call and put options
OptSpec = {'call'; 'put'};
Strike = 57;
StrikeThreshold = 50;
% calculate the price
Pgap = gapbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec,...
Strike, StrikeThreshold)
```

```
Pgap = 2×1

   -0.0053
    4.4866
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `gapbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `gapbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` vector.

Data Types: `char` | `cell`

`Strike` — Pay-off strike value

vector

Pay-off strike value, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`StrikeThreshold` — Strike values that determine if the option pays off

vector

Strike values that determine if the option pays off, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices for gap option

vector

Expected prices for gap option, returned as a `NINST`-by-`1` vector.

More About

Gap Option

A gap option is a digital option in which one strike decides if the option is in or out of money and another strike decides the size the size of the payoff.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `gapbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

gapsensbybls

Determine price or sensitivities of gap digital options using Black-Scholes model

Syntax

```
PriceSens = gapsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
StrikeThreshold)
PriceSens = gapsensbybls( ___ ,Name,Value)
```

Description

`PriceSens = gapsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, StrikeThreshold)` calculates gap European digital option prices or sensitivities using the Black-Scholes option pricing model.

`PriceSens = gapsensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Gap Option Prices and Sensitivities Using the Black-Scholes Option Pricing Model

This example shows how to compute gap option prices and sensitivities using the Black-Scholes option pricing model. Consider a gap call and put options on a nondividend paying stock with a strike of 57 and expiring on January 1, 2008. On July 1, 2008 the stock is trading at 50. ```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `gapsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `gapsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` vector.

Data Types: `char` | `cell`

`Strike` — Pay-off strike value
vector

Pay-off strike value, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`StrikeThreshold` — Strike values that determine if the option pays off
vector

Strike values that determine if the option pays off, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Gamma,Delta] = gapsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,StrikeThreshold,'OutSpec',{'gamma'; 'delta'})`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities for gap option
vector

Expected prices or sensitivities (defined using `OutSpec`) for gap option, returned as a `NINST`-by-`1` vector.

More About

Gap Option

A gap option is a digital option in which one strike decides if the option is in or out of money and another strike decides the size the size of the payoff.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `gapsensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

hedgeopt

Allocate optimal hedge for target costs or sensitivities

Syntax

```
[PortSens,PortCost,PortHolds] = hedgeopt(Sensitivities,Price,CurrentHolds)
[PortSens,PortCost,PortHolds] = hedgeopt( ___ ,FixedInd,NumCosts,TargetCost,
TargetSensConSet)
```

Description

`[PortSens,PortCost,PortHolds] = hedgeopt(Sensitivities,Price,CurrentHolds)` allocates an optimal hedge by one of two criteria:

- Minimize portfolio sensitivities (exposure) for a given set of target costs.
- Minimize the cost of hedging a portfolio given a set of target sensitivities.

Hedging involves the fundamental tradeoff between portfolio insurance and the cost of insurance coverage. This function lets investors modify portfolio allocations among instruments to achieve either of the criteria. The chosen criterion is inferred from the input argument list. The problem is cast as a constrained linear least-squares problem.

`[PortSens,PortCost,PortHolds] = hedgeopt( ___ ,FixedInd,NumCosts,TargetCost, TargetSensConSet)` adds additional optional arguments.

Examples

Allocate Optimal Hedge for Target Costs

To illustrate the hedging facility, consider the portfolio `HJMInstSet` obtained from the example file `deriv.mat`. The portfolio consists of eight instruments: two bonds, one bond option, one fixed-rate note, one floating-rate note, one cap, one floor, and one swap.

In this examples, portfolio target sensitivities are treated as equality constraints during the optimization process. You can use `hedgeopt` to specify what sensitivities you want, and `hedgeopt` computes what what it will cost to get those sensitivities.

```
load deriv.mat;
```

Compute the price and sensitivities

```
warning('off')
[Delta, Gamma, Vega, Price] = hjmsens(HJMTree, HJMInstSet)
```

```
Delta = 8×1

 -272.6462
 -347.4315
   -8.0781
 -272.6462
```

```
   -1.0445
  294.9700
  -47.1629
 -282.0465

Gamma = 8×1
10^3 ×

    1.0299
    1.6227
    0.6434
    1.0299
    0.0033
    6.8526
    8.4600
    1.0597

Vega = 8×1

    0.0000
   -0.0397
   34.0746
    0.0000
         0
   93.6946
   93.6946
    0.0000

Price = 8×1

   98.7159
   97.5280
    0.0486
   98.7159
  100.5529
    6.2831
    0.0486
    3.6923
```

Extract the current portfolio holdings.

```
warning('on')
Holdings = instget(HJMInstSet, 'FieldName', 'Quantity')

Holdings = 8×1

    50
   -50
    80
     8
    30
    40
    10
```

For convenience place the `delta`, `gamma`, and `vega` sensitivity measures into a matrix of sensitivities.

```
Sensitivities = [Delta Gamma Vega];
```

Each row of the `Sensitivities` matrix is associated with a different instrument in the portfolio, and each column with a different sensitivity measure.

Summarize the portfolio information.

```
disp([Price  Holdings  Sensitivities])
```

```
   1.0e+03 *

    0.0987    0.1000   -0.2726    1.0299    0.0000
    0.0975    0.0500   -0.3474    1.6227   -0.0000
    0.0000   -0.0500   -0.0081    0.6434    0.0341
    0.0987    0.0800   -0.2726    1.0299    0.0000
    0.1006    0.0080   -0.0010    0.0033         0
    0.0063    0.0300    0.2950    6.8526    0.0937
    0.0000    0.0400   -0.0472    8.4600    0.0937
    0.0037    0.0100   -0.2820    1.0597    0.0000
```

The first column above is the dollar unit price of each instrument, the second is the holdings of each instrument (the quantity held or the number of contracts), and the third, fourth, and fifth columns are the dollar `delta`, `gamma`, and `vega` sensitivities, respectively.

The current portfolio sensitivities are a weighted average of the instruments in the portfolio.

```
TargetSens  = Holdings' * Sensitivities
```

```
TargetSens = 1×3
10^5 ×

   -0.6191    7.8895    0.0485
```

Maintaining Existing Allocations

To illustrate using `hedgeopt`, suppose that you want to maintain your existing portfolio. `hedgeopt` minimizes the cost of hedging a portfolio given a set of target sensitivities. If you want to maintain your existing portfolio composition and exposure, you should be able to do so without spending any money. To verify this, set the target sensitivities to the current sensitivities.

```
FixedInd = [1 2 3 4 5 6 7 8];
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,Holdings, FixedInd, [], [], TargetSens)
```

```
Sens = 1×3
10^5 ×

   -0.6191    7.8895    0.0485

Cost = 0

Quantity = 1×8

   100    50   -50    80     8    30    40    10
```

Portfolio composition and sensitivities are unchanged, and the cost associated with doing nothing is zero. The cost is defined as the change in portfolio value. This number cannot be less than zero because the rebalancing cost is defined as a nonnegative number.

If `Value0` and `Value1` represent the portfolio value before and after rebalancing, respectively, the zero cost can also be verified by comparing the portfolio values.

```
Value0 = Holdings' * Price
```

```
Value0 = 2.3675e+04
```

```
Value1 = Quantity * Price
```

```
Value1 = 2.3675e+04
```

Partially Hedged Portfolio

Building on this example, suppose you want to know the cost to achieve an overall portfolio dollar sensitivity of `[-23000 -3300 3000]`, while allowing trading only in instruments 2, 3, and 6 (holding the positions of instruments 1, 4, 5, 7, and 8 fixed). To find the cost, first set the target portfolio dollar sensitivity.

```
TargetSens = [-23000 -3300 3000];
```

Specify the instruments to be fixed.

```
FixedInd = [1 4 5 7 8];
```

Use `hedgeopt`:

```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,Holdings, FixedInd, [], [], TargetSens)
```

```
Sens = 1×3
10^4 ×

   -2.3000   -0.3300    0.3000

Cost = 1.9174e+04

Quantity = 1×8

  100.0000 -141.0267  137.2638   80.0000    8.0000  -57.9606   40.0000   10.0000
```

Recompute `Value1`, the portfolio value after rebalancing.

```
Value1 = Quantity * Price
```

```
Value1 = 4.5006e+03
```

As expected, the cost, $19174.02, is the difference between `Value0` and `Value1`, $23674.62 — $4500.60. Only the positions in instruments 2, 3, and 6 are changed.

Fully Hedged Portfolio

The example has illustrated a partial hedge, but perhaps the most interesting case involves the cost associated with a fully hedged portfolio (simultaneous `delta`, `gamma`, and `vega` neutrality). In this case, set the target sensitivity to a row vector of `0`s and call `hedgeopt` again.

```
TargetSens = [0 0 0];
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price, Holdings, FixedInd, [], [], TargetSens)
```

```
Sens = 1×3
10^-10 ×

    0.1091    0.5821    0.0045

Cost = 2.3056e+04

Quantity = 1×8

  100.0000 -182.3615  -19.5501   80.0000    8.0000  -32.9674   40.0000   10.0000
```

Examining the outputs reveals that you have obtained a fully hedged portfolio but at an expense of over $20,000 and `Quantity` defines the positions required to achieve a fully hedged portfolio.

The resulting new portfolio value is

```
Value1 = Quantity * Price
```

```
Value1 = 618.7168
```

Input Arguments

`Sensitivities` — Sensitivities of each instrument

matrix

Sensitivities of each instrument, specified as a number of instruments (`NINST`) by number of sensitivities (`NSENS`) matrix of dollar sensitivities. Each row represents a different instrument. Each column represents a different sensitivity.

Data Types: `double`

`Price` — Instrument prices

vector

Instrument prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CurrentHolds` — Contracts allocated to each instrument

vector

Contracts allocated to each instrument, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`FixedInd` — Number of fixed instruments

`[ ]` (default) | vector

(Optional) Number of fixed instruments, specified as an `NFIXED`-by-`1` vector of indices of instruments to hold fixed. For example, to hold the first and third instruments of a 10 instrument portfolio unchanged, set `FixedInd = [1 3]`. Default = `[]`, no instruments held fixed.

Data Types: `double`

NumCosts — Number of points generated along the cost frontier
10 (default) | integer

(Optional) Number of points generated along the cost frontier when a vector of target costs (TargetCost) is not defined, specified as an integer. The default is 10 equally spaced points between the point of minimum cost and the point of minimum exposure. When specifying TargetCost, enter NumCosts as an empty matrix [].

Data Types: double

TargetCost — Target cost values along the cost frontier
[ ] (default) | vector

(Optional) Target cost values along the cost frontier, specified as a vector. If TargetCost is empty, or not entered, hedgeopt evaluates NumCosts equally spaced target costs between the minimum cost and minimum exposure. When specified, the elements of TargetCost should be positive numbers that represent the maximum amount of money the owner is willing to spend to rebalance the portfolio.

Data Types: double

TargetSens — Target sensitivity values of the portfolio
[ ] (default) | vector

(Optional) Target sensitivity values of the portfolio, specified as a 1-by-NSENS vector containing the target sensitivity values of the portfolio. When specifying TargetSens, enter NumCosts and TargetCost as empty matrices [].

Data Types: double

ConSet — Additional conditions on the portfolio reallocations
[ ] (default) | matrix

(Optional) Additional conditions on the portfolio reallocations, specified as a number of constraints (NCONS) by number of instruments (NINST) matrix of additional conditions on the portfolio reallocations. An eligible NINST-by-1 vector of contract holdings, PortWts, satisfies all the inequalities A*PortWts <= b, where A = ConSet(:,1:end-1) and b = ConSet(:,end).

Note The user-specified constraints included in ConSet may be created with the functions pcalims or portcons. However, the portcons default PortHolds positivity constraints are typically inappropriate for hedging problems since short-selling is usually required.

NPOINTS, the number of rows in PortSens and PortHolds and the length of PortCost , is inferred from the inputs. When the target sensitivities, TargetSens, is entered, NPOINTS = 1; otherwise NPOINTS = NumCosts, or is equal to the length of the TargetCost vector.

Not all problems are solvable (for example, the solution space may be infeasible or unbounded, or the solution may fail to converge). When a valid solution is not found, the corresponding rows of PortSens, PortHolds, and the elements of PortCost are padded with NaNs as placeholders.

Data Types: double

Output Arguments

`PortSens` — Portfolio dollar sensitivities

matrix

Portfolio dollar sensitivities, returned as a number of points (`NPOINTS`-by-`NSENS`) matrix. When a perfect hedge exists, `PortSens` is zeros. Otherwise, the best hedge possible is chosen.

Note Not all problems are solvable (for example, the solution space may be infeasible, unbounded, or insufficiently constrained), or the solution may fail to converge. When a valid solution is not found, the corresponding rows of `PortSens` and `PortHolds` and elements of `PortCost` are padded with `NaN`'s as placeholders. In addition, the solution may not be unique.

`PortCost` — Total portfolio costs

vector

Total portfolio costs, returned as a `1`-by-`NPOINTS` vector.

`PortHolds` — Contracts allocated to each instrument

matrix

Contracts allocated to each instrument, returned as an `NPOINTS`-by-`NINST` matrix. These are the reallocated portfolios.

Version History

Introduced before R2006a

hedgeslf

Self-financing hedge

Syntax

```
[PortSens,PortValue,PortHolds] = hedgeslf(Sensitivities,Price,CurrentHolds)
[PortSens,PortValue,PortHolds] = hedgeslf( ___ ,FixedInd,ConSet)
```

Description

`[PortSens,PortValue,PortHolds] = hedgeslf(Sensitivities,Price,CurrentHolds)` allocates a self-financing hedge among a collection of instruments. `hedgeslf` finds the reallocation in a portfolio of financial instruments that hedges the portfolio against market moves and that is closest to being self-financing (maintaining constant portfolio value). By default the first instrument entered is hedged with the other instruments.

`hedgeslf` attempts to find the allocations of the portfolio that will make it closest to being self-financing, while reducing the sensitivities to zero. If no solution is found, `hedgeslf` finds the allocations that will minimize the sensitivities. If the resulting portfolio is self-financing, `PortValue` is equal to the value of the original portfolio.

`[PortSens,PortValue,PortHolds] = hedgeslf( ___ ,FixedInd,ConSet)` adds additional optional arguments.

Examples

Pricing and Hedging a Portfolio Using the Black-Karasinski Model

This example illustrates how MATLAB® can be used to create a portfolio of interest-rate derivatives securities, and price it using the Black-Karasinski interest-rate model. The example also shows some hedging strategies to minimize exposure to market movements.

Create the Interest-Rate Term Structure Based on Reported Data

The structure `RateSpec` is an interest-rate term structure that defines the initial rate specification from which the tree rates are derived. Use the information of annualized zero coupon rates in the table below to populate the `RateSpec` structure.

```
  From             To           Rate
27 Feb 2007    27 Feb 2008      0.0493
27 Feb 2007    27 Feb 2009      0.0459
27 Feb 2007    27 Feb 2010      0.0450
27 Feb 2007    27 Feb 2012      0.0446
27 Feb 2007    27 Feb 2014      0.0445
27 Feb 2007    27 Feb 2017      0.0450
27 Feb 2007    27 Feb 2027      0.0473
```

This data could be retrieved from the Federal Reserve Statistical Release page by using the Datafeed Toolbox™. In this case, the Datafeed Toolbox™ will connect to FRED® and pull back the rates of the following treasury notes.

```
 Terms    Symbol
=======   ======
   1   =  DGS1
   2   =  DGS2
   3   =  DGS3
   5   =  DGS5
   7   =  DGS7
   10  =  DGS10
   20  =  DGS20
```

Create the connection object:

```
c = fred;
```

Create the symbol fetch list:

```
FredNames   = { ...
  'DGS1'; ...      % 1  Year
  'DGS2'; ...      % 2  Year
  'DGS3'; ...      % 3  Year
  'DGS5'; ...      % 5  Year
  'DGS7'; ...      % 7  Year
  'DGS10'; ...     % 10 Year
  'DGS20'};        % 20 Year
```

Define the Terms:

```
Terms = [ 1; ...      % 1  Year
          2; ...      % 2  Year
          3; ...      % 3  Year
          5; ...      % 5  Year
          7; ...      % 7  Year
         10; ...      % 10 Year
         20];         % 20 Year
```

Set the `StartDate` to Feb 27, 2007:

```
StartDate = datenum('Feb-27-2007');

FredRet = fetch(c,FredNames,StartDate);
```

Set the `ValuationDate` based on the `StartDate`:

```
ValuationDate = StartDate;

EndDates = [];

Rates =[];
```

Create the `EndDates`:

```
for idx = 1:length(FredRet)

 %Pull the rates associated with Feb 27, 2007. All the Fred Rates come
 %back as percents
 Rates = [Rates; ...
     FredRet(idx).Data(1,2) / 100];

  %Determine the EndDates by adding the Term to the year of the
  %StartDate
```

```
    EndDates = [EndDates; ...
       round(datenum(...
           year(StartDate)+ Terms(idx,1), ...
           month(StartDate),...
           day(StartDate)))];

  end
```

Use the function `intenvset` to create the `RateSpec` with the following data:

```
Compounding = 1;
StartDate = datetime(2007,2,27);
Rates = [0.0493; 0.0459; 0.0450; 0.0446; 0.0446; 0.0450; 0.0473];
EndDates = [datetime(2008,2,27); datetime(2009,2,27) ; datetime(2010,2,27) ; datetime(2012,2,27)
ValuationDate = StartDate;

RateSpec = intenvset('Compounding',Compounding,'StartDates', StartDate,...
                     'EndDates', EndDates, 'Rates', Rates,'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [7x1 double]
            Rates: [7x1 double]
          EndTimes: [7x1 double]
        StartTimes: [7x1 double]
          EndDates: [7x1 double]
       StartDates: 733100
    ValuationDate: 733100
            Basis: 0
     EndMonthRule: 1
```

Specify the Volatility Model

Create the structure `VolSpec` that specifies the volatility process with the following data.

```
Volatility = [0.011892; 0.01563; 0.02021; 0.02125; 0.02165; 0.02065; 0.01803];
Alpha = [0.0001];
VolSpec = bkvolspec(ValuationDate, EndDates, Volatility, EndDates(end), Alpha)
```

```
VolSpec = struct with fields:
             FinObj: 'BKVolSpec'
      ValuationDate: 733100
            VolDates: [7x1 double]
            VolCurve: [7x1 double]
          AlphaCurve: 1.0000e-04
          AlphaDates: 740405
    VolInterpMethod: 'linear'
```

Specify the Time Structure of the Tree

The structure `TimeSpec` specifies the time structure for an interest-rate tree. This structure defines the mapping between the observation times at each level of the tree and the corresponding dates.

```
TimeSpec = bktimespec(ValuationDate, EndDates)
```

```
TimeSpec = struct with fields:
           FinObj: 'BKTimeSpec'
```

```
    ValuationDate: 733100
         Maturity: [7x1 double]
      Compounding: -1
            Basis: 0
     EndMonthRule: 1
```

Create the BK Tree

Use the previously computed values for `RateSpec`, `VolSpec`, and `TimeSpec` to create the BK tree.

```
BKTree = bktree(VolSpec, RateSpec, TimeSpec)
```

```
BKTree = struct with fields:
      FinObj: 'BKFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 5 7 10]
        dObs: [733100 733465 733831 734196 734926 735657 736753]
      CFlowT: {1x7 cell}
       Probs: {1x6 cell}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]  [2 3 3 4 5 5 6]  [2 3 4 5 6 7 8]  [2 2 ... ]}
     FwdTree: {1x7 cell}
```

Visualize the interest rate evolution along the tree by looking at the output structure `BKTree`. The function `bktree` returns an inverse discount tree, which you can convert into an interest rate tree with the `cvtree` function.

```
BKTreeR = cvtree(BKTree)
```

```
BKTreeR = struct with fields:
      FinObj: 'BKRateTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 5 7 10]
        dObs: [733100 733465 733831 734196 734926 735657 736753]
      CFlowT: {1x7 cell}
       Probs: {1x6 cell}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]  [2 3 3 4 5 5 6]  [2 3 4 5 6 7 8]  [2 2 ... ]}
    RateTree: {1x7 cell}
```

Look at the upper, middle and lower branch paths of the tree.

```
OldFormat = get(0, 'format');
format short

%Rate at root node:
RateRoot      = trintreepath(BKTreeR, 0)
```

```
RateRoot = 0.0481
```

```
%Rates along upper branch:
RatePathUp    = trintreepath(BKTreeR, [1 1 1 1 1 1])
```

```
RatePathUp = 7×1

    0.0481
    0.0425
    0.0446
    0.0478
    0.0510
    0.0555
    0.0620
```

```
%Rates along middle branch:
RatePathMiddle = trintreepath(BKTreeR, [2 2 2 2 2 2])

RatePathMiddle = 7×1

    0.0481
    0.0416
    0.0423
    0.0430
    0.0436
    0.0449
    0.0484
```

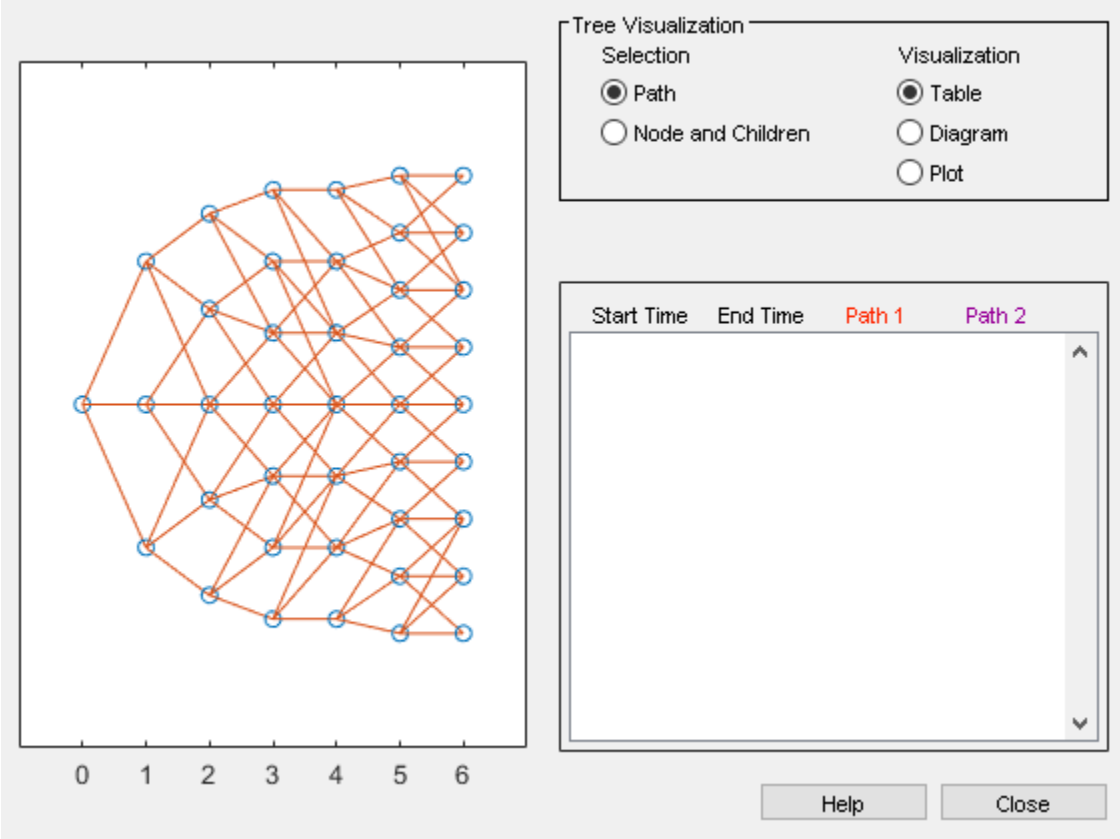
```
%Rates along lower branch:
RatePathDown = trintreepath(BKTreeR, [3 3 3 3 3 3])

RatePathDown = 7×1

    0.0481
    0.0408
    0.0401
    0.0388
    0.0373
    0.0363
    0.0378
```

You can also display a graphical representation of the tree to examine interactively the rates on the nodes of the tree until maturity. The function `treeviewer` displays the structure of the rate tree in the left window. The tree visualization in the right window is blank, but by selecting **Table/Diagram** and clicking on the nodes you can examine the rates along the paths.

```
treeviewer(BKTreeR);
```



Create an Instrument Portfolio

Create a portfolio consisting of two bonds instruments and an option on the 5% bond.

```
% Two Bonds
CouponRate = [0.04;0.05];
Settle = datetime(2007,2,27);
Maturity = [datetime(2009,2,27) ; datetime(2010,2,27) ];
Period = 1;

% American Option on the 5% Bond
OptSpec = {'call'};
Strike = 98;
ExerciseDates = datetime(2010,2,27);
AmericanOpt = 1;

InstSet = instadd('Bond', CouponRate, Settle,  Maturity, Period);
InstSet = instadd(InstSet,'OptBond', 2, OptSpec, Strike, ExerciseDates, AmericanOpt);

% Assign Names and Holdings
Holdings = [10; 15;3];
Names = {'4% Bond'; '5% Bond'; 'Option 98'};

InstSet = instsetfield(InstSet, 'Index',1:3, 'FieldName', {'Quantity'}, 'Data', Holdings );
InstSet = instsetfield(InstSet, 'Index',1:3, 'FieldName', {'Name'}, 'Data', Names );
```

Examine the set of instruments contained in the variable `InstSet`.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.04       27-Feb-2007    27-Feb-2009    1      0     1            NaN       NaN
2     Bond 0.05       27-Feb-2007    27-Feb-2010    1      0     1            NaN       NaN

Index Type    UnderInd OptSpec Strike ExerciseDates  AmericanOpt Quantity Name
3     OptBond 2        call    98     27-Feb-2010    1           3        Option 98
```

Price the Portfolio Using the BK Model

Calculate the price of each instrument in the portfolio.

```
[Price, PTree] = bkprice(BKTree, InstSet)
```

```
Price = 3×1

   98.8841
  101.3470
    3.3470

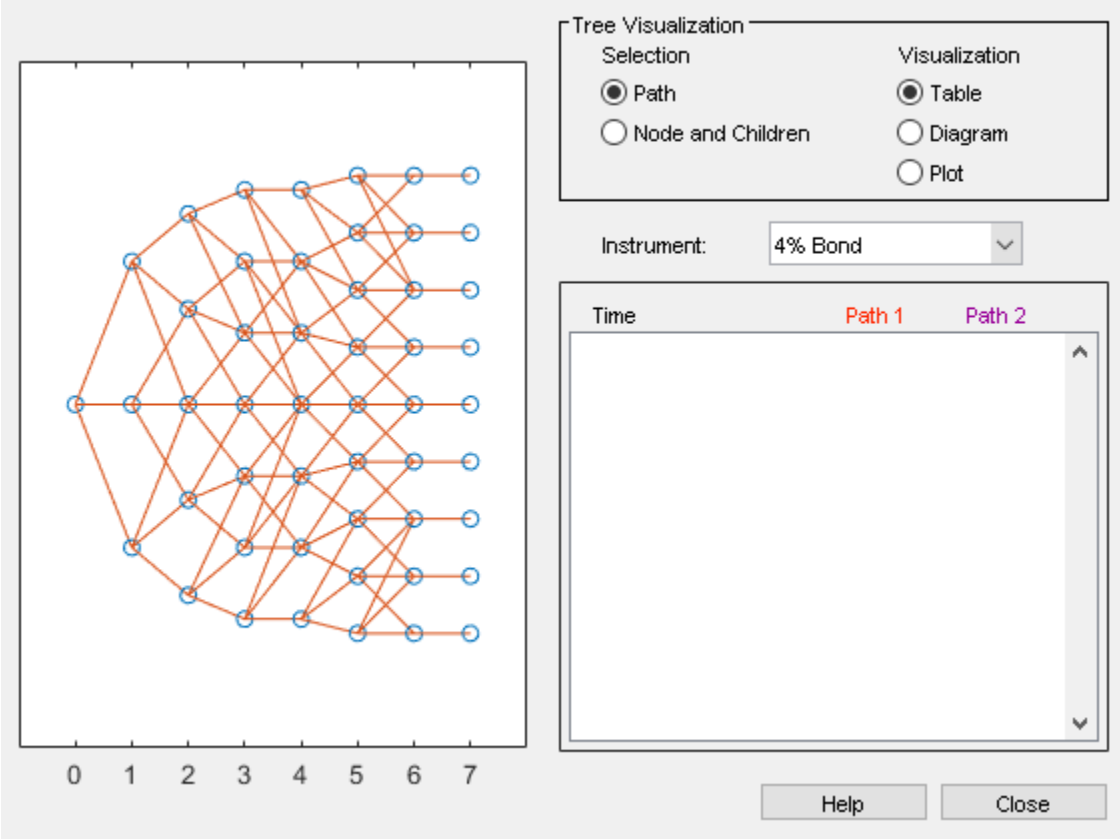
PTree = struct with fields:
     FinObj: 'BKPriceTree'
      PTree: {1x8 cell}
     AITree: {1x8 cell}
     ExTree: {1x8 cell}
       tObs: [0 1 2 3 5 7 10 20]
    Connect: {[2]  [2 3 4]  [2 3 4 5 6]  [2 3 3 4 5 5 6]  [2 3 4 5 6 7 8]  [2 2 3 ... ]}
      Probs: {1x6 cell}
```

The prices in the output vector `Price` correspond to the prices at observation time zero (`tObs = 0`), which is defined as the Valuation Date of the interest-rate tree.

In the `Price` vector, the first element, 98.884, represents the price of the first instrument (4% Bond); the second element, 101.347, represents the price of the second instrument (5% Bond), and 3.347 represents the price of the American call option.

You can also display a graphical representation of the price tree to examine the prices on the nodes of the tree until maturity.

```
treeviewer(PTree,InstSet);
```



Add More Instruments to the Existing Portfolio

Add instruments to the existing portfolio: cap, floor, floating rate note, vanilla swap and a puttable and callable bond.

```
% Cap
StrikeC =0.035;
InstSet = instadd(InstSet,'Cap', StrikeC, Settle, datetime(2010,2,27));

% Floor
StrikeF =0.05;
InstSet = instadd(InstSet,'Floor', StrikeF, Settle, datetime(2009,2,27));

% Floating Rate Note
InstSet = instadd(InstSet,'Float', 30, Settle, datetime(2009,2,27));

% Vanilla Swap
 LegRate =[0.04 5];
 InstSet = instadd(InstSet,'Swap', LegRate, Settle, datetime(2010,2,27));

% Puttable and Callable Bonds
InstSet = instadd(InstSet,'OptEmBond', CouponRate, Settle,datetime(2010,2,27), {'put';'call'},..
                  Strike, datetime(2010,2,27),'AmericanOpt', 1, 'Period', 1);

% Process Names and Holdings
Holdings = [15 ;5 ;8; 7; 9; 4];
Names = {'3.5% Cap';'5% Floor';'30BP Float';'4%/5BP Swap'; 'PuttBond'; 'CallBond' };
```

```
InstSet = instsetfield(InstSet, 'Index',4:9, 'FieldName', {'Quantity'}, 'Data', Holdings );
InstSet = instsetfield(InstSet, 'Index',4:9, 'FieldName', {'Name'}, 'Data', Names );
```

Examine the set of instruments contained in the variable `InstSet`.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCoup

```

Hedging

The idea behind hedging is to minimize exposure to market movements. As the underlying changes, the proportions of the instruments forming the portfolio may need to be adjusted to keep the sensitivities within the desired range.

Calculate sensitivities using the BK model.

```
[Delta, Gamma, Vega, Price] = bksens(BKTree, InstSet);
```

Get the current portfolio holdings.

```
Holdings = instget(InstSet, 'FieldName', 'Quantity');
```

Create a matrix of sensitivities.

```
Sensitivities = [Delta Gamma Vega];
```

Each row of the `Sensitivities` matrix is associated with a different instrument in the portfolio, and each column with a different sensitivity measure.

```
format bank
disp([Price  Holdings  Sensitivities])
```

```
         98.88         10.00       -185.47        528.47             0
        101.35         15.00       -277.51       1045.05             0
          3.35          3.00       -223.52      11843.32             0
```

```
          2.77         15.00        250.04       2921.11         -0.00
          0.75          5.00       -132.97      11566.69             0
        100.56          8.00         -0.80          2.02             0
         -1.53          7.00       -272.08       1027.85          0.00
         98.60          9.00       -168.92      21712.82             0
         98.00          4.00        -53.99     -10798.27             0
```

The first column above is the dollar unit price of each instrument, the second column is the number of contracts of each instrument, and the third, fourth, and fifth columns are the dollar delta, gamma, and vega sensitivities.

The current portfolio sensitivities are a weighted average of the instruments in the portfolio.

```
TargetSens  = Holdings' * Sensitivities
```

```
TargetSens = 1×3

      -7249.21     317573.92         -0.00
```

Obtain a Neutral Sensitivity Portfolio Using `hedgeslf`

Suppose you want to obtain a delta, gamma and vega neutral portfolio. The function `hedgeslf` finds the reallocation in a portfolio of financial instruments closest to being self-financing (maintaining constant portfolio value).

```
[Sens, Value1, Quantity]= hedgeslf(Sensitivities, Price,Holdings)
```

```
Sens = 3×1

         -0.00
         -0.00
         -0.00

Value1 =
       4637.54

Quantity = 9×1

         10.00
          5.26
         -5.11
          7.06
         -3.05
         12.45
         -7.36
          8.47
         10.37
```

The function `hedgeslf` returns the portfolio dollar sensitivities (`Sens`), the value of the rebalanced portfolio (`Value1`) and the new allocation for each instrument (`Quantity`). If `Value0` and `Value1` represent the portfolio value before and after rebalancing, you can verify the cost by comparing the portfolio values.

```
Value0 = Holdings' * Price
```

```
Value0 =
       4637.54
```

In this example, the portfolio is fully hedged (simultaneous delta, gamma, and vega neutrality) and self-financing (the values of the portfolio before and after balancing (`Value0` and `Value1`) are the same.

Adding Constraints to Hedge a Portfolio

Suppose that you want to place upper and lower bounds on the individual instruments in the portfolio. Let's say that you want to bound the position of all instruments to within +/- 11 contracts.

Applying these constraints disallows the current positions in the fifth and eighth instruments. All other instruments are currently within the upper/lower bounds.

```
% Specify the lower and upper bounds
LowerBounds = [-11  -11  -11  -11  -11  -11  -11  -11  -11];
UpperBounds = [ 11   11   11   11   11   11   11   11   11];

% Use the function portcons to build the constraints
ConSet = portcons('AssetLims', LowerBounds, UpperBounds);

% Apply the constraints to the portfolio
[Sens, Value, Quantity1] = hedgeslf(Sensitivities, Price, Holdings, [], ConSet)
```

```
Sens = 3×1

             0
             0
             0

Value =
             0

Quantity1 = 9×1

             0
             0
             0
             0
             0
             0
             0
             0
             0
```

Observe that the `hedgeslf` function enforces the bounds on the fifth and eighth instruments, and the portfolio continues to be fully hedged and self-financing.

```
set(0, 'format', OldFormat);
```

Input Arguments

`Sensitivities` — Sensitivities of each instrument

matrix

Sensitivities of each instrument, specified as a number of instruments (`NINST`) by number of sensitivities (`NSENS`) matrix of dollar sensitivities. Each row represents a different instrument. Each column represents a different sensitivity.

Data Types: `double`

`Price` — Instrument prices

vector

Instrument prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CurrentHolds` — Contracts allocated to each instrument

vector

Contracts allocated to each instrument, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`FixedInd` — Number of fixed instruments

`1` (default) | vector

(Optional) Number of fixed instruments, specified as an `NFIXED`-by-`1` vector of indices of instruments to hold fixed. For example, to hold the first and third instruments of a 10 instrument portfolio unchanged, set `FixedInd = [1 3]`. The default is `FixedInd = 1`; the holdings in the first instrument are held fixed. If no instruments are to be held fixed, enter `FixedInd = [ ]`.

Data Types: `double`

`ConSet` — Additional conditions on the portfolio reallocations

`[ ]` (default) | matrix

(Optional) Additional conditions on the portfolio reallocations, specified as a number of constraints (`NCONS`) by number of instruments (`NINST`) matrix of additional conditions on the portfolio reallocations. An eligible `NINST`-by-`1` vector of contract holdings, `PortWts`, satisfies all the inequalities `A*PortWts <= b`, where `A = ConSet(:,1:end-1)` and `b = ConSet(:,end)`.

Note Constraints `PortHolds(FixedInd) = CurrentHolds(FixedInd)` are appended to any constraints passed in `ConSet`. Pass `FixedInd = [ ]` to specify all constraints through `ConSet`. The default constraints generated by `portcons` are inappropriate, since they require the sum of all holdings to be positive and equal to `1`.

Data Types: `double`

Output Arguments

`PortSens` — Portfolio dollar sensitivities
vector

Portfolio dollar sensitivities, returned as a number of points `NSENS`-by-`1` vector. When a perfect hedge exists, `PortSens` is zeros. Otherwise, the best hedge possible is chosen.

`PortValue` — Total portfolio value
numeric

Total portfolio value, returned as a scalar value. When a perfectly self-financing hedge exists, `PortValue` is equal to the value `dot(Price,CurrentHolds)` of the initial portfolio.

`PortHolds` — Contracts allocated to each instrument
vector

Contracts allocated to each instrument, returned as an `NINST`-by-`1` vector. This is the reallocated portfolio.

Version History

Introduced before R2006a

hjmprice

Instrument prices from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = hjmprice(HJMTree,InstSet)
[Price,PriceTree] = hjmprice(___,Options)
```

Description

`[Price,PriceTree] = hjmprice(HJMTree,InstSet)` computes arbitrage-free prices for instruments using an interest-rate tree created with `hjmtree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`hjmprice` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` to construct defined types.

`[Price,PriceTree] = hjmprice(___,Options)` adds an optional input argument for `Options`.

Examples

Price the Cap and Bond Instruments Contained in an Instrument Set

Load the HJM tree and instruments from the data file `deriv.mat`.

```
load deriv.mat;
HJMSubSet = instselect(HJMInstSet,'Type', {'Bond', 'Cap'});

instdisp(HJMSubSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCouponDate LastCouponDate StartDate Face Na
1     Bond 0.04       01-Jan-2000    01-Jan-2003    1      NaN   NaN          NaN       NaN             NaN            NaN       NaN  4%
2     Bond 0.04       01-Jan-2000    01-Jan-2004    2      NaN   NaN          NaN       NaN             NaN            NaN       NaN  4%

Index Type Strike Settle         Maturity       CapReset Basis Principal Name   Quantity
3     Cap  0.03   01-Jan-2000    01-Jan-2004    1        NaN   NaN       3% Cap 30
```

Use `hjmprice` to price the instruments.

```
[Price, PriceTree] = hjmprice(HJMTree, HJMSubSet)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In checktree (line 289)
  In hjmprice (line 85)

Price =

   98.7159
   97.5280
    6.2831

PriceTree =

    FinObj: 'HJMPriceTree'
     PBush: {[3x1 double]  [3x1x2 double]  [3x2x2 double]  [3x4x2 double]  [3x8 double]}

Price Multi-Stepped Coupon Bonds

The data for the interest-rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;
```

Create a `RateSpec`.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create a portfolio of stepped coupon bonds with different maturities.

```
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2011';'01-Jan-2012';'01-Jan-2013';'01-Jan-2014'};
CouponRate = {{'01-Jan-2011' .042;'01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};

ISet = instbond(CouponRate, Settle, Maturity, 1);
instdisp(ISet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCoup
1     Bond [Cell]     01-Jan-2010    01-Jan-2011    1      0     1            NaN       NaN
2     Bond [Cell]     01-Jan-2010    01-Jan-2012    1      0     1            NaN       NaN
3     Bond [Cell]     01-Jan-2010    01-Jan-2013    1      0     1            NaN       NaN
4     Bond [Cell]     01-Jan-2010    01-Jan-2014    1      0     1            NaN       NaN
```

Build the tree with the following data:

```
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1;  2;   3;   4];
HJMTimeSpec = hjmtimespec(ValuationDate, EndDates);

Price a Portfolio of Stepped Callable Bonds and Stepped Vanilla Bonds

The data for the interest-rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;
```

Create a RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create an instrument portfolio of three stepped callable bonds and three stepped vanilla bonds and display the instrument portfolio.

```
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2012';'01-Jan-2013';'01-Jan-2014'};
CouponRate = {{'01-Jan-2011' .042;'01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};
OptSpec='call';
Strike=100;
ExerciseDates='01-Jan-2011'; %Callable in one year

% Bonds with embedded option
ISet = instoptembnd(CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1);

% Vanilla bonds
ISet = instbond(ISet, CouponRate, Settle, Maturity, 1);

instdisp(ISet)
```

```
Index Type      CouponRate Settle         Maturity       OptSpec Strike ExerciseDates  Period Bas
1     OptEmBond [Cell]     01-Jan-2010    01-Jan-2012    call    100    01-Jan-2011    1      0

    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734139 734504 734869 735235]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

Price the instrument set using `hjmprice`.

```
PHJM = hjmprice(HJMT, ISet)
```

```
PHJM = 6×1

  100.3682
  100.1557
   99.9232
  100.7368
  100.9266
  101.0115
```

The first three rows correspond to the price of the stepped callable bonds and the last three rows correspond to the price of the stepped vanilla bonds.

Compute the Price of a Portfolio of Instruments

The data for the interest-rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;
```

Create a `RateSpec`.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create an instrument portfolio with two range notes and a floating rate note with the following data and display the results:

```
Spread = 200;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';

% First Range Note
RateSched(1).Dates = {'Jan-1-2012'; 'Jan-1-2013'  ; 'Jan-1-2014'};
RateSched(1).Rates  = [0.045 0.055; 0.0525  0.0675; 0.06 0.08];

% Second Range Note
RateSched(2).Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched(2).Rates  = [0.048 0.059; 0.055  0.068 ; 0.07 0.09];

% Create an InstSet
InstSet = instadd('RangeFloat', Spread, Settle, Maturity, RateSched);

% Add a floating-rate note
InstSet = instadd(InstSet, 'Float', Spread, Settle, Maturity);

% Display the portfolio instrument
instdisp(InstSet)
```

```
Index Type       Spread Settle         Maturity       RateSched FloatReset Basis Principal EndMo
1     RangeFloat 200    01-Jan-2011    01-Jan-2014    [Struct]  1          0     100       1
2     RangeFloat 200    01-Jan-2011    01-Jan-2014    [Struct]  1          0     100       1

Index Type  Spread Settle         Maturity       FloatReset Basis Principal EndMonthRule CapRate
3     Float 200    01-Jan-2011    01-Jan-2014    1          0     100       1            Inf
```

The data to build the tree is as follows:

```
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1;  2;   3;   4];
MaTree = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
HJMTS = hjmtimespec(ValuationDate, MaTree);
HJMVS = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVS, RS, HJMTS)
```

```
HJMT = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734504 734869 735235 735600]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

Price the portfolio.

```
Price = hjmprice(HJMT, InstSet)
```

```
Price = 3×1
```

```
   91.1555
   90.6656
  105.5147
```

Create a Float-Float Swap and Price with `hjmprice`

Use `instswap` to create a float-float swap and price the swap with `hjmprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.02 .03],today,datemnth(today,60),[], [], [], [1 1]);
VolSpec = hjmvolspec('Constant', .2);
TimeSpec = hjmtimespec(today,cfdates(today,datemnth(today,60),1));
HJMTree = hjmtree(VolSpec,RateSpec,TimeSpec);
hjmprice(HJMTree,IS)
```

```
ans = -4.3220
```

Price Multiple Swaps with `hjmprice`

Use `instswap` to create multiple swaps and price the swaps with `hjmprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.03 .02],today,datemnth(today,60),[], [], [], [1 1]);
IS = instswap(IS,[200 300],today,datemnth(today,60),[], [], [], [0 0]);
IS = instswap(IS,[.08 300],today,datemnth(today,60),[], [], [], [1 0]);
VolSpec = hjmvolspec('Constant', .2);
TimeSpec = hjmtimespec(today,cfdates(today,datemnth(today,60),1));
HJMTree = hjmtree(VolSpec,RateSpec,TimeSpec);
hjmprice(HJMTree,IS)
```

```
ans = 3×1

    4.3220
   -4.3220
   -0.2701
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of NINST instruments, specified using instadd. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: struct

Options — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, created using derivset.

Data Types: struct

Output Arguments

Price — Price for each instrument
vector

Price for each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a NaN is returned in that entry.

Related single-type pricing functions are:

- bondbyhjm — Price a bond from an HJM tree.
- capbyhjm — Price a cap from an HJM tree.
- cfbyhjm — Price an arbitrary set of cash flows from an HJM tree.
- fixedbyhjm — Price a fixed-rate note from an HJM tree.
- floatbyhjm — Price a floating-rate note from an HJM tree.
- floorbyhjm — Price a floor from an HJM tree.
- optbndbyhjm — Price a bond option from an HJM tree.
- optembndbyhjm — Price a bond with embedded option by an HJM tree.
- optfloatbybdt — Price a floating-rate note with an option from an HJM tree.
- optemfloatbybdt — Price a floating-rate note with an embedded option from an HJM tree.
- rangefloatbyhjm — Price range floating note using an HJM tree.
- swapbyhjm — Price a swap from an HJM tree.
- swaptionbyhjm — Price a swaption from an HJM tree.

PriceTree — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within PriceTree:

- PriceTree.PTree contains the clean prices.
- PriceTree.AITree contains the accrued interest.
- PriceTree.tObs contains the observation times.

Version History

Introduced before R2006a

hjmsens

Instrument prices and sensitivities from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Delta,Gamma,Vega,Price] = hjmsens(HJMTree,InstSet)
[Delta,Gamma,Vega,Price] = hjmsens(___,Options)
```

Description

`[Delta,Gamma,Vega,Price] = hjmsens(HJMTree,InstSet)` computes instrument sensitivities and prices for instruments using an interest-rate tree created with the `hjmtree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`hjmsens` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` for information on instrument types.

`[Delta,Gamma,Vega,Price] = hjmsens(___,Options)` adds an optional input argument for `Options`.

Examples

Compute Instrument Sensitivities Using an HJM Interest-Rate Tree

Load the tree and instruments from the `deriv.mat` data file. Compute `Delta` and `Gamma` for the cap and bond instruments contained in the instrument set.

```
load deriv.mat;
HJMSubSet = instselect(HJMInstSet,'Type', {'Fixed', 'Cap'});
instdisp(HJMSubSet)
```

```
Index Type  CouponRate Settle         Maturity       FixedReset Basis Principal Name     Quantity
1     Fixed 0.04       01-Jan-2000    01-Jan-2003    1          NaN   NaN       4% Fixed 80

Index Type Strike Settle         Maturity       CapReset Basis Principal Name   Quantity
2     Cap  0.03   01-Jan-2000    01-Jan-2004    1        NaN   NaN       3% Cap 30
```

Compute the `Delta` and `Gamma` for the cap and bond instruments.

```
[Delta, Gamma] = hjmsens(HJMTree, HJMSubSet)
```

```
Delta = 2×1

 -272.6462
  294.9700

Gamma = 2×1
10^3 ×
```

```
    1.0299
    6.8526
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in interest rate

vector

Rate of change of instruments prices with respect to changes in the interest rate, returned as a `NINST`-by-`1` vector of deltas. `Delta` is computed by finite differences in calls to `hjmtree`.

Note `Delta` is calculated based on yield shifts of 100 basis points.

`Gamma` — Rate of change of instruments deltas with respect to changes in interest rate

vector

Rate of change of instruments deltas with respect to changes in the interest rate, returned as a `NINST`-by-`1` vector of gammas. `Gamma` is computed by finite differences in calls to `hjmtree`.

Note `Gamma` is calculated based on yield shifts of 100 basis points.

`Vega` — Rate of change of instruments prices with respect to changes in volatility

vector

Rate of change of instruments prices with respect to changes in the volatility, returned as a `NINST`-by-`1` vector of vegas. Volatility is $\sigma(t, T)$ of the interest rate. `Vega` is computed by finite differences in calls to `hjmtree`. For information on the volatility process, see `hjmvolspec`.

Note `Vega` is calculated based on 1% shift in the volatility process.

`Price` — Price of each instrument

vector

Price of each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

hjmtimespec

Specify time structure for Heath-Jarrow-Morton interest-rate tree

Syntax

```
TimeSpec = hjmtimespec(ValuationDate,Maturity)
TimeSpec = hjmtimespec( ___ ,Compounding)
```

Description

`TimeSpec = hjmtimespec(ValuationDate,Maturity)` sets the number of levels and node times for a `hjmtree` and determines the mapping between dates and time for rate quoting.

`TimeSpec = hjmtimespec( ___ ,Compounding)` adds the optional argument `Compounding`.

Examples

Set the Number of Levels and Node Times for an HJM Tree

This example shows how to specify an eight-period tree with semiannual nodes (every six months) and use exponential compounding to report rates.

```
Compounding = -1;
ValuationDate = datetime(1999,1,15);
Maturity = datemnth(ValuationDate, 6*(1:8)');
TimeSpec = hjmtimespec(ValuationDate, Maturity, Compounding)
```

```
TimeSpec = struct with fields:
           FinObj: 'HJMTimeSpec'
    ValuationDate: 730135
         Maturity: [8x1 double]
      Compounding: -1
            Basis: 0
     EndMonthRule: 1
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the tree, specified as a scalar datetime, string, or date character vector.

To support existing code, `hjmtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Dates marking the cash flow dates of the tree

datetime array | string array | date character vector

Dates marking the cash flow dates of the tree, specified as `NLEVELS`-by-`1` vector using a datetime array, string array, or date character vectors. Cash flows with these maturities fall on tree nodes. `Maturity` should be in increasing order.

To support existing code, `hjmtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Compounding` — Rate at which the input zero rates were compounded when annualized
1 (default) | integer with value of 1, 2, 3, 4, 6, 12, 365, or -1

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If `Compounding` = 1, 2, 3, 4, 6, 12:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units; for example, `T = F` is one year.
- If `Compounding` = 365:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = −1:

  `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `hjmtree`
structure

Specification for the time layout for `hjmtree`, returned as a structure. The state observation dates are `[ValuationDate; Maturity(1:end-1)]`. Because a forward rate is stored at the last observation, the tree can value cash flows out to `Maturity(end)`.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `hjmtimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

hjmtree

Build Heath-Jarrow-Morton interest-rate tree

Syntax

```
HJMTree = hjmtree(VolSpec,RateSpec,TimeSpec)
```

Description

`HJMTree = hjmtree(VolSpec,RateSpec,TimeSpec)` creates a structure containing time and forward-rate information on a bushy tree.

Examples

Create a HJMTree

Using the data provided, create a HJM volatility specification (using `hjmvolspec`), rate specification (using `intenvset`), and tree time layout specification (using `hjmtimespec`). Then use these specifications to create a HJM tree using `hjmtree`.

```
Compounding = 1;
ValuationDate = '01-01-2000';
StartDate = ['01-01-2000'; '01-01-2001'; '01-01-2002'; '01-01-2003'; '01-01-2004'];
EndDates = ['01-01-2001'; '01-01-2002'; '01-01-2003'; '01-01-2004'; '01-01-2005'];
Rates = [.1; .11; .12; .125; .13];
Volatility = [.2; .19; .18; .17; .16];
CurveTerm = [1; 2; 3; 4; 5];

HJMVolSpec = hjmvolspec('Stationary', Volatility , CurveTerm);

RateSpec = intenvset('Compounding', Compounding,...
                     'ValuationDate', ValuationDate,...
                     'StartDates', StartDate,...
                     'EndDates', EndDates,...
                     'Rates', Rates);

HJMTimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(HJMVolSpec, RateSpec, HJMTimeSpec)

HJMTree = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]

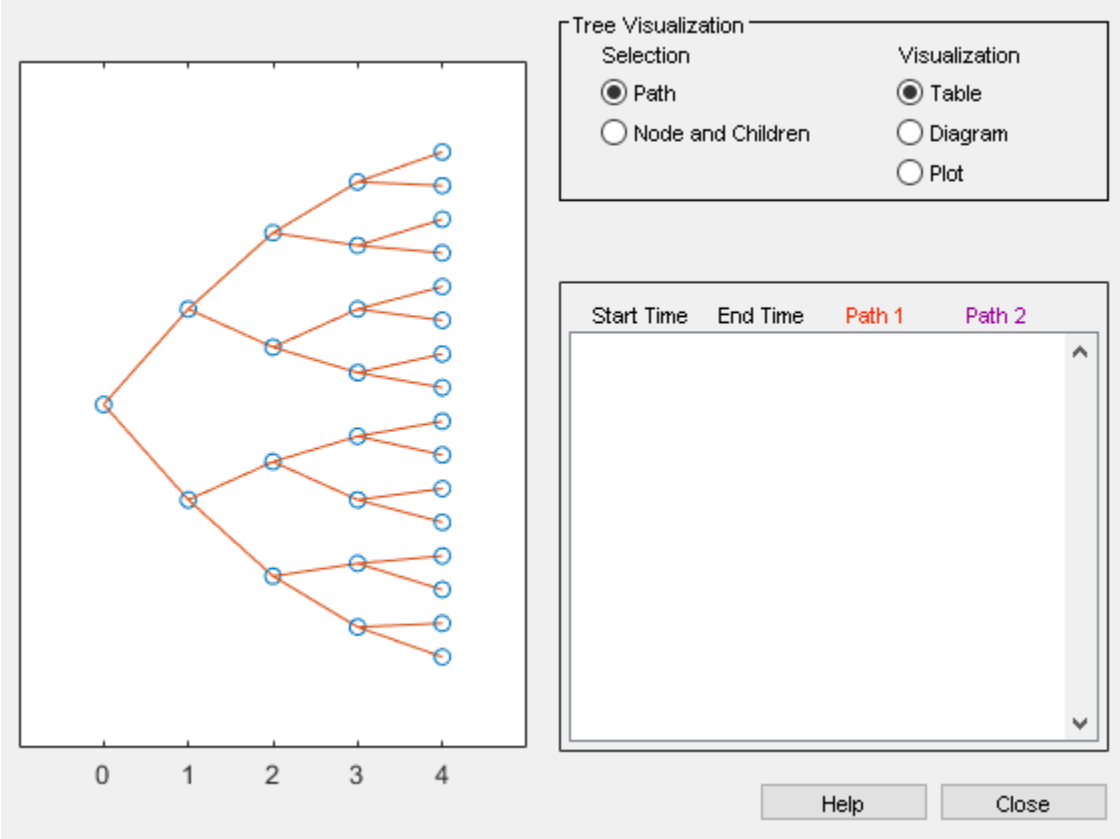
```

Use `treeviewer` to observe the tree you have created.

```
treeviewer(HJMTree)
```



Input Arguments

`VolSpec` — Volatility process specification

structure

Volatility process specification, specified using the `VolSpec` output obtained from `hjmvolspec`. `VolSpec` sets the number of factors and the rules for computing the volatility $\sigma(t, T)$ for each factor.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Time tree layout specification

structure

Time tree layout specification, specified using the `TimeSpec` output obtained from `hjmtimespec`. The TimeSpec defines the observation dates of the HJM tree and the `Compounding` rule for date to time mapping and price-yield formulas.

Data Types: `struct`

Output Arguments

`HJMTree` — Time and interest-rate information of a bushy tree

structure

Time and interest-rate information of a bushy tree, returned as a structure.

Version History

Introduced before R2006a

hjmvolspec

Specify Heath-Jarrow-Morton interest-rate volatility process

Syntax

```
VolSpec = hjmvolspec(Factor,Sigma_0)
VolSpec = hjmvolspec(Factor,CurveVol,CurveTerm)
VolSpec = hjmvolspec(Factor,Sigma_0,Lambda)
VolSpec = hjmvolspec(Factor,Sigma_0,CurveDecay,CurveTerm)
VolSpec = hjmvolspec(Factor,CurveProp,CurveTerm,MaxSpot)
```

Description

`VolSpec = hjmvolspec(Factor,Sigma_0)` creates a Constant volatility (Ho-Lee) structure for `hjmtree` by specifying the `Factor` as `'Constant'`.

`VolSpec = hjmvolspec(Factor,CurveVol,CurveTerm)` creates a Stationary volatility structure for `hjmtree` by specifying the `Factor` as `'Stationary'`.

`VolSpec = hjmvolspec(Factor,Sigma_0,Lambda)` creates an Exponential volatility structure for `hjmtree` by specifying the `Factor` as `'Exponential'`.

`VolSpec = hjmvolspec(Factor,Sigma_0,CurveDecay,CurveTerm)` creates a Vasicek, Hull-White volatility structure for `hjmtree` by specifying the `Factor` as `'Vasicek'`.

`VolSpec = hjmvolspec(Factor,CurveProp,CurveTerm,MaxSpot)` creates a Nearly proportional stationary volatility structure for `hjmtree` by specifying the `Factor` as `'Proportional'`.

Examples

Compute the VolSpec Structure to Specify a Proportional Volatility Model for HJMTree

This example shows how to compute the `VolSpec` structure to specify the volatility model for `hjmtree` when volatility is single-factor proportional.

```
CurveProp = [0.11765; 0.08825; 0.06865];
CurveTerm = [1; 2; 3];
VolSpec = hjmvolspec('Proportional', CurveProp, CurveTerm, 1e6)
```

```
VolSpec = struct with fields:
          FinObj: 'HJMVolSpec'
    FactorModels: {'Proportional'}
      FactorArgs: {{1x3 cell}}
      SigmaShift: 0
      NumFactors: 1
       NumBranch: 2
         PBranch: [0.5000 0.5000]
     Fact2Branch: [-1 1]
```

Compute the VolSpec Structure to Specify an Exponential Volatility Model for HJMTree

This example shows how to compute the `VolSpec` structure to specify the volatility model for `hjmtree` when volatility is two-factor exponential and constant.

```
VolSpec = hjmvolspec('Exponential', 0.1, 1, 'Constant', 0.2)
```

```
VolSpec = struct with fields:
          FinObj: 'HJMVolSpec'
    FactorModels: {'Exponential'  'Constant'}
      FactorArgs: {{1x2 cell}  {1x1 cell}}
      SigmaShift: 0
      NumFactors: 2
       NumBranch: 3
         PBranch: [0.2500 0.2500 0.5000]
     Fact2Branch: [2x3 double]
```

Input Arguments

Factor — Volatility factor

character vector with value of `'Constant'`, `'Stationary'`, `'Exponential'`, `'Vasicek'`, or `'Proportional'`

Volatility factor, specified as a character vector with one of the following values:

- `'Constant'`

  $\sigma(t,T)$ = `Sigma_0`
- `'Stationary'`

  $\sigma(t,T)$ = `Vol(T- t)` = `Vol(Term)`
- `'Exponential'`

  $\sigma(t,T)$ = `Sigma_0*exp(-Lambda*(T-t))`
- `'Vasicek'`

  $\sigma(t,T)$ = `Sigma_0*exp(-Decay(T-t))`
- `'Proportional'`

  $\sigma(t,T)$ = `Prop(T-t)*max(SpotRate(t),MaxSpot)`

Note You can specify more than one `Factor` by concatenating Factor names and their associated parameters.

Data Types: `char`

Sigma_0 — Base volatility over a unit time

numeric

Base volatility over a unit, specified as a scalar numeric value.

Data Types: `double`

`Lambda` — Decay factor
numeric

Decay factor, specified as a scalar numeric value.

Data Types: `double`

`CurveVol` — Number of curve `Vol` values at sample points
numeric vector

Number of curve `Vol` values at sample points, specified as a `NCURVES`-by`1` vector.

Data Types: `double`

`CurveTerm` — Number of curve `Term` values at sample points
numeric vector

Number of curve `Term` values at sample points, specified as a `NCURVES`-by-`1` vector.

Data Types: `double`

`CurveDecay` — Number of curve `Decay` values at sample points
numeric vector

Number of curve `Decay` values at sample points, specified as a `NPOINTS`-by-`1` vector.

Data Types: `double`

`CurveProp` — Number of curve `Prop` values at sample points
numeric vector

Number of curve `Prop` values at sample points, specified as a `NCURVES`-by-`1` vector.

Data Types: `double`

`MaxSpot` — Maximum spot rate
numeric

Maximum spot rate, specified as a scalar numeric value.

Data Types: `double`

Output Arguments

`VolSpec` — Specification for the volatility model for `bktree`
structure

Structure specifying the volatility model for `bktree`. `hjmvolspec` defines an HJM forward-rate volatility process based on the specified input `Factor`.

More About

Volatility Process

The volatility process is $\sigma(t, T)$, where t is the observation time and T is the starting time of a forward rate.

In a stationary process, the volatility term is $T–t$. Multiple factors can be specified sequentially.

The time values T, t, and `Term` are in coupon interval units specified by the `Compounding` input of `hjmtimespec`. For instance if `Compounding = 2`, `Term = 1` is a semiannual period (six months).

HullWhite1F

Create Hull-White one-factor model

Description

The Hull-White one-factor model is specified using the zero curve, alpha, and sigma parameters.

Specifically, the HullWhite1F model is defined using the following equations:

$$dr = [\theta(t) - a(t)r]dt + \sigma(t)dW$$

where:

dr is the change in the short-term interest rate over a small interval.

r is the short-term interest rate.

$\Theta(t)$ is a function of time determining the average direction in which r moves, chosen such that movements in r are consistent with today's zero coupon yield curve.

α is the mean reversion rate.

dt is a small change in time.

σ is the annual standard deviation of the short rate.

W is the Brownian motion.

Creation

Syntax

```
HW1F = HullWhite1F(ZeroCurve,Alpha,Sigma)
```

Description

`HW1F = HullWhite1F(ZeroCurve,Alpha,Sigma)` creates a `HullWhite1F` (`HW1F`) object using the required arguments to set the Properties on page 11-717.

Properties

`ZeroCurve` — Zero curve
`IRDataCurve` object | `RateSpec`

Zero curve, specified as an output from `IRDataCurve` or a `RateSpec` that is obtained from `intenvset`. This is the zero curve used to evolve the path of future interest rates.

Data Types: `object` | `struct`

Alpha — Mean reversion
numeric

Mean reversion, specified either as a scalar or function handle which takes time as input and returns a scalar mean reversion value.

Data Types: double

Sigma — Volatility
numeric

Volatility, specified either as a scalar or function handle which takes time as input and returns a scalar mean volatility.

Data Types: double

Object Functions

simTermStructs Simulate term structures for Hull-White one-factor model

Examples

Create a Hull-White One-Factor Model Using an IRDataCurve

Create a Hull-White one-factor model using an IRDataCurve.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

alpha = .1;
sigma = .01;

HW1F = HullWhite1F(irdc,alpha,sigma)
```

```
HW1F =
  HullWhite1F with properties:

    ZeroCurve: [1x1 IRDataCurve]
        Alpha: @(t,V)inAlpha
        Sigma: @(t,V)inSigma
```

Use the simTermStructs method with the HullWhite1F model to simulate term structures.

```
SimPaths = simTermStructs(HW1F, 10,'nTrials',100);
```

Create a Hull-White One-Factor Model Using a RateSpec

Create a Hull-White one-factor model using a RateSpec.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

RateSpec = intenvset('Rates',ZeroRates,'EndDates',CurveDates,'StartDate',Settle);

alpha = .1;
sigma = .01;

HW1F = HullWhite1F(RateSpec,alpha,sigma)

HW1F =
  HullWhite1F with properties:

    ZeroCurve: [1x1 IRDataCurve]
        Alpha: @(t,V)inAlpha
        Sigma: @(t,V)inSigma
```

Use the `simTermStructs` method with the `HullWhite1F` model to simulate term structures.

```
SimPaths = simTermStructs(HW1F, 10,'nTrials',100);
```

Simulate the Price of a Bond Using a Hull-White One-Factor Model Until the Bond's Maturity

Define the zero curve data.

```
Settle = datetime(2016,4,4);
ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';
ZeroDates = datemnth(Settle,ZeroTimes*12);
RateSpec = intenvset('StartDates', Settle,'EndDates', ZeroDates, 'Rates', ZeroRates)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [8x1 double]
            Rates: [8x1 double]
         EndTimes: [8x1 double]
       StartTimes: [8x1 double]
         EndDates: [8x1 double]
       StartDates: 736424
    ValuationDate: 736424
            Basis: 0
     EndMonthRule: 1
```

Define the bond parameters.

```
Maturity = datemnth(Settle,12*5);
CouponRate = 0;
```

Define the Hull-White parameters.

```
alpha = .1;
sigma = .01;
HW1F = HullWhite1F(RateSpec,alpha,sigma)

HW1F =
  HullWhite1F with properties:

    ZeroCurve: [1x1 IRDataCurve]
        Alpha: @(t,V)inAlpha
        Sigma: @(t,V)inSigma
```

Define the simulation parameters.

```
nTrials = 100;
nPeriods = 12*5;
deltaTime = 1/12;
SimZeroCurvePaths = simTermStructs(HW1F, nPeriods,'nTrials',nTrials,'deltaTime',deltaTime);
SimDates = datemnth(Settle,1:nPeriods);
```

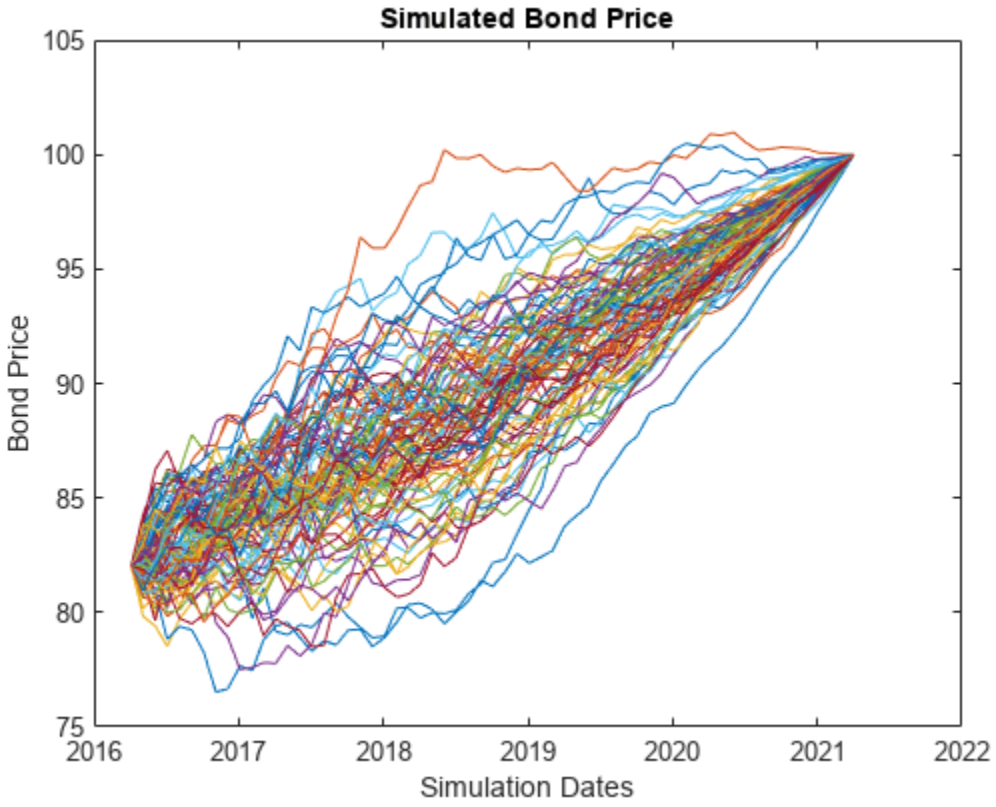
Preallocate and initialize for the simulation.

```
SimBondPrice = zeros(nPeriods+1,nTrials);
SimBondPrice(1,:,:) = bondbyzero(RateSpec,CouponRate,Settle,Maturity);
SimBondPrice(end,:,:) = 100;
```

Compute the bond values for each simulation date and path, note that you can vectorize over the trial dimension.

```
for periodidx=1:nPeriods-1
    simRateSpec = intenvset('StartDate',SimDates(periodidx),'EndDates',...
        datemnth(SimDates(periodidx),ZeroTimes*12),'Rates',squeeze(SimZeroCurvePaths(periodidx+1
    SimBondPrice(periodidx+1,:) = bondbyzero(simRateSpec,CouponRate,SimDates(periodidx),Maturity
end

plot([Settle SimDates],SimBondPrice)
datetick
ylabel('Bond Price')
xlabel('Simulation Dates')
title('Simulated Bond Price')
```



Simulate the Total Return of a Bond Portfolio Until Maturity

Define the zero curve data.

```
Settle = datetime(2016,4,4);
ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [-0.01 -0.009 -0.0075 -0.003 -0.002 -0.001 0.002 0.0075]';
ZeroDates = datemnth(Settle,ZeroTimes*12);
RateSpec = intenvset('StartDates', Settle,'EndDates', ZeroDates, 'Rates', ZeroRates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [8x1 double]
            Rates: [8x1 double]
          EndTimes: [8x1 double]
        StartTimes: [8x1 double]
          EndDates: [8x1 double]
        StartDates: 736424
    ValuationDate: 736424
            Basis: 0
     EndMonthRule: 1
```

Define the bond parameters for the five bonds in the portfolio.

```
Maturity = datemnth(Settle,12*5);  % All bonds have the same maturity
CouponRate = [0.035;0.04;0.02;0.015;0.042];  % Different coupon rates for the bonds
nBonds = length(CouponRate);
```

Define the Hull-White parameters.

```
alpha = .1;
sigma = .01;
HW1F = HullWhite1F(RateSpec,alpha,sigma)
```

```
HW1F =
  HullWhite1F with properties:

    ZeroCurve: [1x1 IRDataCurve]
        Alpha: @(t,V)inAlpha
        Sigma: @(t,V)inSigma
```

Define the simulation parameters.

```
nTrials = 1000;
nPeriods = 12*5;
deltaTime = 1/12;
SimZeroCurvePaths = simTermStructs(HW1F, nPeriods,'nTrials',nTrials,'deltaTime',deltaTime);
SimDates = datemnth(Settle,1:nPeriods);
```

Preallocate and initialize for the simulation.

```
SimBondPrice = zeros(nPeriods+1,nBonds,nTrials);
SimBondPrice(1,:,:) = repmat(bondbyzero(RateSpec,CouponRate,Settle,Maturity)',[1 1 nTrials]);
SimBondPrice(end,:,:) = 100;

[BondCF,BondCFDates,~,CFlowFlags] = cfamounts(CouponRate,Settle,Maturity);
BondCF(CFlowFlags == 4) = BondCF(CFlowFlags == 4) - 100;
SimBondCF = zeros(nPeriods+1,nBonds,nTrials);
```

Compute bond values for each simulation date and path. Note that you can vectorize over the trial dimension.

```
for periodidx=1:nPeriods
    if periodidx < nPeriods
        simRateSpec = intenvset('StartDate',SimDates(periodidx),'EndDates',...
            datemnth(SimDates(periodidx),ZeroTimes*12),'Rates',squeeze(SimZeroCurvePaths(periodic
        SimBondPrice(periodidx+1,:,:) = bondbyzero(simRateSpec,CouponRate,SimDates(periodidx),Ma
    end

    simidx = SimDates(periodidx) == BondCFDates;
    SimCF = zeros(1,nBonds);
    SimCF(any(simidx,2)) = BondCF(simidx);
    ReinvestRate = 1 + SimZeroCurvePaths(periodidx+1,1,:);
    SimBondCF(periodidx+1,:,:) = bsxfun(@times,bsxfun(@plus,SimBondCF(periodidx,:,:),SimCF),Reinv
end
```

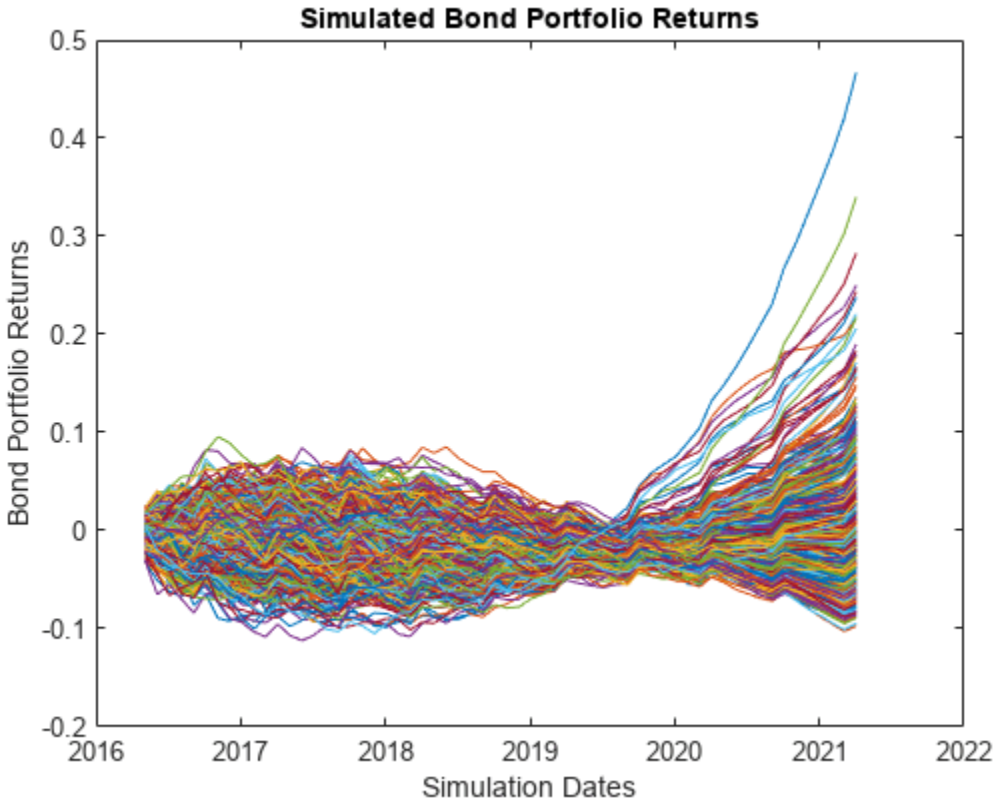
Compute the total return series.

```
TotalCF = SimBondPrice + SimBondCF;
```

Assume the bond portfolio is equally weighted and plot the simulated bond portfolio returns.

```
TotalCF = squeeze(sum(TotalCF,2));

TotRetSeries = bsxfun(@rdivide,TotalCF(2:end,:),TotalCF(1,:)) - 1;
plot(SimDates,TotRetSeries)
datetick
ylabel('Bond Portfolio Returns')
xlabel('Simulation Dates')
title('Simulated Bond Portfolio Returns')
```



More About

Hull-White One-Factor Model

The Hull-White model is a single-factor, no-arbitrage yield curve model in which the short-term rate of interest is the random factor or state variable.

No-arbitrage means that the model parameters are consistent with the bond prices implied in the zero coupon yield curve.

Version History

Introduced in R2013a

simTermStructs

Simulate term structures for Hull-White one-factor model

Syntax

```
[ZeroRates,ForwardRates] = simTermStructs(HW1F,nPeriods)
[ZeroRates,ForwardRates] = simTermStructs(___,Name,Value)
```

Description

`[ZeroRates,ForwardRates] = simTermStructs(HW1F,nPeriods)` simulates future zero curve paths using a specified `HullWhite1F` object.

`[ZeroRates,ForwardRates] = simTermStructs(___,Name,Value)` adds optional name-value pair arguments.

Examples

Simulate Term Structures for the HullWhite1F Model

Create a `HW1F` object.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

alpha = .1;
sigma = .01;

HW1F = HullWhite1F(irdc,alpha,sigma)
```

```
HW1F =
  HullWhite1F with properties:

    ZeroCurve: [1x1 IRDataCurve]
        Alpha: @(t,V)inAlpha
        Sigma: @(t,V)inSigma
```

Simulate the term structures for the specified `HW1F` object.

```
SimPaths = simTermStructs(HW1F, 10,'nTrials',100);
```

Input Arguments

`HW1F` — `HullWhite1F` object
object

`HullWhite1F` object, specified using the `HW1F` object created using `HullWhite1F`.

Data Types: `object`

`nPeriods` — Number of simulation periods
numeric

Number of simulation periods, specified as a numeric value. For example, to simulate 12 years with an annual spacing, specify `12` as the `nPeriods` input and `1` as the optional `deltaTime` input (note that the default value for `deltaTime` is `1`).

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[ZeroRates,ForwardRates] = simTermStructs(HW1F,NPeriods,'nTrials',100,'deltaTime',dt)`

`deltaTime` — Time step between `nPeriods`
`1` (default) | numeric

Time step between `nPeriods` measured in years, specified as the comma-separated pair consisting of `'deltaTime'` and a scalar numeric value. For example, to simulate 12 years with an annual spacing, specify `12` as the `nPeriods` input and `1` as the optional `deltaTime` input (note that the default value for `deltaTime` is `1`).

Data Types: `double`

`nTrials` — Number of simulated trials
`1` (default) | positive integer

Number of simulated trials (sample paths), specified as the comma-separated pair consisting of `'nTrials'` and a positive scalar integer value of `nPeriods` observations each. If you do not specify a value for this argument, the default is `1`, indicating a single path of correlated state variables.

Data Types: `double`

`antithetic` — Flag indicating whether antithetic sampling is used to generate Gaussian random variates
`false` (default) | positive integer

Flag indicating whether antithetic sampling is used to generate the Gaussian random variates that drive the zero-drift, unit-variance rate Brownian vector $dW(t)$, specified as the comma-separated pair consisting of `'antithetic'` and a Boolean scalar flag. For details, see `simBySolution`.

Data Types: `logical`

`Z` — Direct specification of dependent random noise process
Gaussian variates generated by `simBySolution` function (default) | numeric

Direct specification of the dependent random noise process, specified as the comma-separated pair consisting of `'Z'` and a numeric value. The `Z` value is used to generate the zero-drift, unit-variance

rate Brownian vector *dW*(*t*) that drives the simulation. For details, see `simBySolution` for the HWV model. If you do not specify a value for `Z`, `simBySolution` generates Gaussian variates.

Data Types: `double`

`Tenor` — Maturities to compute at each time step
tenor of `HullWhite1F` object zero curve (default) | numeric vector

Maturities to compute at each time step, specified as the comma-separated pair consisting of `'Tenor'` and a numeric vector.

`Tenor` enables you to choose a different set of rates to output than the underlying rates. For example, you may want to simulate quarterly data but only report annual rates; this can be done by specifying the optional input `Tenor`.

Data Types: `double`

Output Arguments

`ZeroRates` — Simulated zero-rate term structures
matrix

Simulated zero-rate term structures, returned as a `nPeriods+1`-by-`nTenors`-by-`nTrials` matrix.

`ForwardRates` — Simulated forward-rate term structures
matrix

Simulated zero-rate term structures, returned as a `nPeriods+1`-by-`nTenors`-by-`nTrials` matrix. The `ForwardRates` output is computed using the simulated short rates and by using the model definition to recover the entire yield curve at each simulation date.

hwcalbycap

Calibrate Hull-White tree using caps

Syntax

```
[Alpha,Sigma,OptimOut] = hwcalbycap(RateSpec,MarketStrikeMarketMaturity,
MarketVolatility)
[Alpha,Sigma,OptimOut = hwcalbycap(RateSpec,MarketStrikeMarketMaturity,
MarketVolatility,Strike,Settle,Maturity)
[Alpha,Sigma,OptimOut] = hwcalbycap( ___ ,Name,Value)
```

Description

`[Alpha,Sigma,OptimOut] = hwcalbycap(RateSpec,MarketStrikeMarketMaturity, MarketVolatility)` calibrates the `Alpha` (mean reversion) and `Sigma` (volatility) using cap market data and the Hull-White model using the entire cap surface.

The Hull-White calibration functions (`hwcalbycap` and `hwcalbyfloor`) support three models: Black (default), Bachelier or Normal, and Shifted Black. For more information, see the optional arguments for `Shift` and `Model`.

`[Alpha,Sigma,OptimOut = hwcalbycap(RateSpec,MarketStrikeMarketMaturity, MarketVolatility,Strike,Settle,Maturity)` estimates the `Alpha` (mean reversion) and `Sigma` (volatility) using cap market data and the Hull-White model to price a cap at a particular maturity/volatility using the additional optional input arguments for `Strike`, `Settle`, and `Maturity`.

`Strike`, `Settle`, and `Maturity` arguments are specified to calibrate to a specific point on the market volatility surface. If omitted, the calibration is performed across all the market instruments

For an example of calibrating using the Hull-White model with `Strike`, `Settle`, and `Maturity` input arguments, see “Calibrating Hull-White Model Using Market Data” on page 2-92.

`[Alpha,Sigma,OptimOut] = hwcalbycap( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calibrate Hull-White Model from Market Data Using the Entire Cap Volatility Surface

This example shows how to use `hwcalbycap` input arguments for `MarketStrike`, `MarketMaturity`, and `MarketVolatility` to calibrate the HW model using the entire cap volatility surface.

Cap market volatility data covering two strikes over 12 maturity dates.

```
Reset = 4;
MarketStrike = [0.0590; 0.0790];

MarketMaturity = {'21-Mar-2008'; '21-Jun-2008'; '21-Sep-2008'; '21-Dec-2008';
    '21-Mar-2009'; '21-Jun-2009'; '21-Sep-2009'; '21-Dec-2009';
    '21-Mar-2010'; '21-Jun-2010'; '21-Sep-2010'; '21-Dec-2010'};
```

```
MarketMaturity = datenum(MarketMaturity);

MarketVolaltility = [0.1533 0.1731 0.1727 0.1752 0.1809 0.1800 0.1805 0.1802...
    0.1735 0.1757 0.1755 0.1755;

Calibrating Caplets Using the Normal (Bachelier) Model

This example shows how to use `hwcalbycap` to calibrate market data with the Normal (Bachelier) model to price caplets. Use the Normal (Bachelier) model to perform calibrations when working with negative interest rates, strikes, and normal implied volatilities.

Consider a cap with these parameters:

```
Settle = datetime(2016,12,30);
Maturity = datetime(2019,12,30);
Strike = -0.001075;
Reset = 2;
Principal = 100;
Basis = 0;
```

The caplets and market data for this example are defined as:

```
capletDates = cfdates(Settle, Maturity, Reset, Basis);
datestr(capletDates')
```

```
ans = 6x11 char array
    '30-Jun-2017'
    '30-Dec-2017'
    '30-Jun-2018'
    '30-Dec-2018'
    '30-Jun-2019'
    '30-Dec-2019'
```

```
% Market data information
MarketStrike = [-0.0013; 0];
MarketMat =  [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12
```

```
MarketVol = [0.184 0.2329 0.2398 0.2467 0.2906 0.3348;   % First row in table corresponding to St
             0.217 0.2707 0.2760 0.2814 0.3160 0.3508];  % Second row in table corresponding to S
```

Define the `RateSpec` using `intenvset`.

```
Rates= [-0.002210;-0.002020;-0.00182;-0.001343;-0.001075];
ValuationDate = datetime(2016,12,30);
EndDates =  [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12
Compounding = 2;
Basis = 0;

RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);
```

Use `hwcalbycap` to find values for the volatility parameters `Alpha` and `Sigma` using the Normal (Bachelier) model.

```
format short
o=optimoptions('lsqnonlin','TolFun',100*eps);
warning ('off','fininst:hwcalbycapfloor:NoConverge')
[Alpha, Sigma, OptimOut] = hwcalbycap(RateSpec, MarketStrike, MarketMat,...
MarketVol, Strike, Settle, Maturity, 'Reset', Reset, 'Principal', Principal,...
'Basis', Basis, 'OptimOptions', o, 'model', 'normal')
```

```
Local minimum possible.
lsqnonlin stopped because the size of the current step is less than
the value of the step size tolerance.

Alpha = 1.0000e-06

Sigma = 0.3384

OptimOut = struct with fields:
     resnorm: 1.5181e-04
    residual: [5x1 double]
    exitflag: 2
      output: [1x1 struct]
      lambda: [1x1 struct]
    jacobian: [5x2 double]
```

The `OptimOut.residual` field of the `OptimOut` structure is the optimization residual. This value contains the difference between the Normal (Bachelier) caplets and those calculated during the optimization. Use the `OptimOut.residual` value to calculate the percentual difference (error) compared to Normal (Bachelier) caplet prices, and then decide whether the residual is acceptable. There is almost always some residual, so decide if it is acceptable to parameterize the market with a single value of `Alpha` and `Sigma`.

Price the caplets using the market data and Normal (Bachelier) model to obtain the reference caplet values. To determine the effectiveness of the optimization, calculate reference caplet values using the Normal (Bachelier) formula and the market data. Note, you must first interpolate the market data to obtain the caplets for calculation.

```
MarketMatNum = datenum(MarketMat);
[Mats, Strikes] = meshgrid(MarketMatNum, MarketStrike);
FlatVol = interp2(Mats, Strikes, MarketVol, datenum(Maturity), Strike, 'spline');
```

```
[CapPrice, Caplets] = capbynormal(RateSpec, Strike, Settle, Maturity, FlatVol,...
'Reset', Reset, 'Basis', Basis, 'Principal', Principal);
Caplets = Caplets(2:end)'
```

```
Caplets = 5×1

    4.7392
    6.7799
    8.2609
    9.6136
   10.6455
```

Compare the optimized values and Normal (Bachelier) values, and display the results graphically. After calculating the reference values for the caplets, compare the values analytically and graphically to determine whether the calculated single values of `Alpha` and `Sigma` provide an adequate approximation.

```
OptimCaplets = Caplets+OptimOut.residual;

disp('   ');

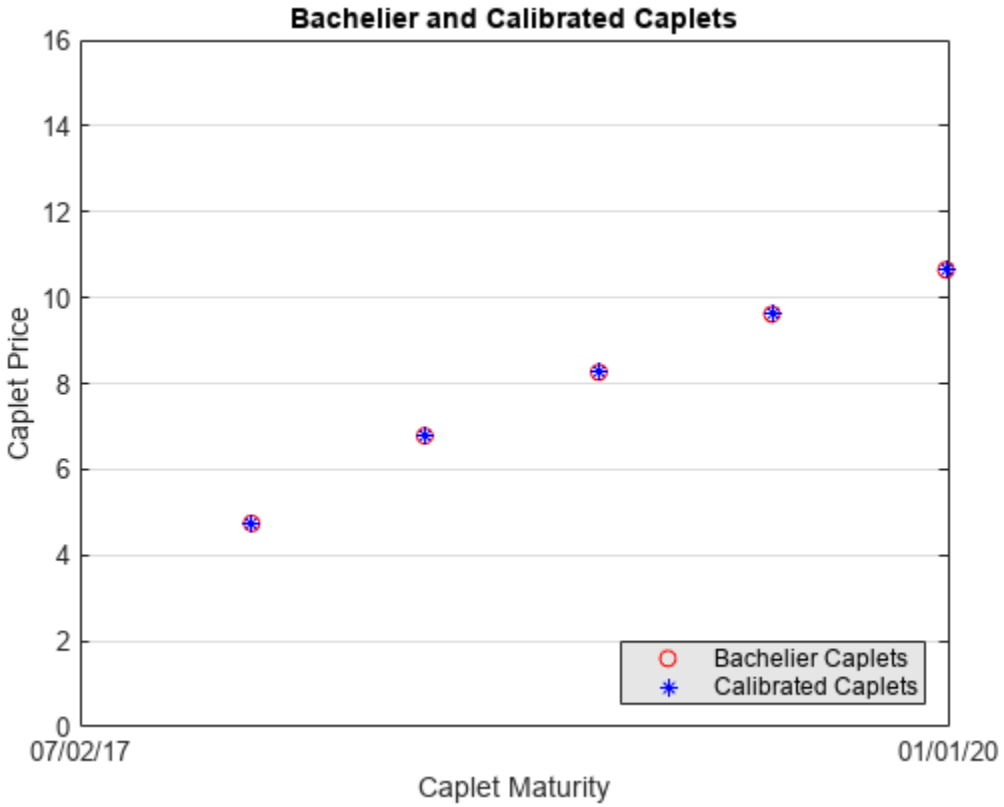
disp(' Bachelier   Calibrated Caplets');
```

```
 Bachelier   Calibrated Caplets
```

```
disp([Caplets        OptimCaplets])
```

```
    4.7392    4.7453
    6.7799    6.7851
    8.2609    8.2657
    9.6136    9.6112
   10.6455   10.6379
```

```
plot(MarketMatNum(2:end), Caplets, 'or', MarketMatNum(2:end), OptimCaplets, '*b');
datetick('x', 2)
xlabel('Caplet Maturity');
ylabel('Caplet Price');
ylim ([0 16]);
title('Bachelier and Calibrated Caplets');
h = legend('Bachelier Caplets', 'Calibrated Caplets');
set(h, 'color', [0.9 0.9 0.9]);
set(h, 'Location', 'SouthEast');
set(gcf, 'NumberTitle', 'off')
grid on
```



Input Arguments

`RateSpec` — Interest-rate specification for initial rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`MarketStrike` — Market cap strike

vector

Market cap strike, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`MarketMaturity` — Market cap maturity date

datetime array | string array | date character vector

Market cap maturity dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `hwcalbycap` also accepts serial date numbers as inputs, but they are not recommended.

`MarketVolatility` — Market flat volatilities
matrix

Market flat volatilities, specified as a `NSTRIKES`-by-`NMATS` matrix of market flat volatilities, where `NSTRIKES` is the number of caplet strikes from `MarketStrike` and `NMATS` is the caplet maturity dates from `MarketMaturity`.

Data Types: `double`

`Strike` — Rate at which cap is exercised
decimal scalar

(Optional) Rate at which the cap is exercised, specified as a decimal scalar value.

Data Types: `single`

`Settle` — Settlement date of the cap
datetime scalar | string scalar | date character vector

(Optional) Settlement date of the cap, specified as a datetime, string, or data character vector.

To support existing code, `hwcalbycap` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date of the cap
datetime scalar | string scalar | date character vector

(Optional) Maturity date of the cap, specified as scalar datetime, string, or data character vector.

To support existing code, `hwcalbycap` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Alpha,Sigma,OptimOut] = hwcalbycap(RateSpec,MarketStrike,MarketMaturity,MarketVolaltility,'Reset',2,'Principal',100000,'Basis',3,'OptimOptions',o)`

`Reset` — Frequency of payments per year
`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a scalar numeric value.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | nonnegative integer

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a scalar nonnegative integer.

Data Types: `double`

`Basis` — Day-count basis used when annualizing the input forward rate
`0` (actual/actual) (default) | integers of the set `[0...13]`

Day-count basis used when annualizing the input forward rate, specified as the comma-separated pair consisting of `'Basis'` and a scalar value. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`LB` — Lower bounds
`[0;0]` (default) | numeric vector

Lower bounds, specified as the comma-separated pair consisting of `'LB'` and a 2-by-1 vector of the lower bounds, defined as `[LBSigma; LBAlpha]`, used in the search algorithm function. For more information, see `lsqnonlin`.

Data Types: `double`

`UB` — Upper bounds
`[ ]` (unbound) (default) | numeric vector

Upper bounds, specified as the comma-separated pair consisting of `'UB'` and a 2-by-1 vector of the upper bounds, defined as `[UBSigma; LBAlpha]`, used in the search algorithm function. For more information, see `lsqnonlin`.

Data Types: `double`

`X0` — Initial values
`[0.5;0.5]` (default) | numeric vector

Initial values, specified as the comma-separated pair consisting of `'X0'` and a 2-by-1 vector of the initial values, defined as `[Sigma0; Alpha0]`, used in the search algorithm function. For more information, see `lsqnonlin`.

Data Types: `double`

`OptimOptions` — Optimization parameters
structure

Optimization parameters, specified as the comma-separated pair consisting of `'OptimOptions'` and a structure defined by using `optimoptions`.

Data Types: `struct`

`Shift` — Shift in decimals for shifted Black model
`0` (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of `'Shift'` and a scalar positive decimal value. Set this parameter to a positive shift in decimals to add a positive shift to forward rate and `Strike`, which effectively sets a negative lower bound for forward rate and `Strike`. For example, a `Shift` value of `0.01` is equal to a 1% shift.

Data Types: `double`

`Model` — Indicator for model used for calibration routine
`lognormal` (Black model) (default) | values are `normal` and `lognormal`

Indicator for model used for calibration routine, specified as the comma-separated pair consisting of `'Model'` and a scalar character vector with a value of `normal` or `lognormal`.

Data Types: `char`

Output Arguments

`Alpha` — Mean reversion value obtained from calibrating the cap using market information
scalar numeric

Mean reversion value obtained from calibrating the cap using market information, returned as a scalar value.

`Sigma` — Volatility value obtained from calibrating cap using market information
scalar numeric

Volatility value obtained from calibrating the cap using market information, returned as a scalar.

`OptimOut` — Optimization results
numeric structure

Optimization results, returned as a structure.

Version History

Introduced in R2009a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `hwcalbycap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

hwcalbyfloor

Calibrate Hull-White tree using floors

Syntax

```
[Alpha,Sigma,OptimOut] = hwcalbyfloor(RateSpec,MarketStrikeMarketMaturity,
MarketVolatility)
[Alpha,Sigma,OptimOut = hwcalbyfloor(RateSpec,MarketStrikeMarketMaturity,
MarketVolatility,Strike,Settle,Maturity)
[Alpha,Sigma,OptimOut] = hwcalbyfloor( ___ ,Name,Value)
```

Description

`[Alpha,Sigma,OptimOut] = hwcalbyfloor(RateSpec,MarketStrikeMarketMaturity, MarketVolatility)` calibrates the `Alpha` (mean reversion) and `Sigma` (volatility) using floor market data and the Hull-White model using the entire floor surface.

The Hull-White calibration functions (`hwcalbyfloor` and `hwcalbycap`) support three models: Black (default), Bachelier or Normal, and Shifted Black. For more information, see the optional arguments for `Shift` and `Model`.

`[Alpha,Sigma,OptimOut = hwcalbyfloor(RateSpec,MarketStrikeMarketMaturity, MarketVolatility,Strike,Settle,Maturity)` estimates the `Alpha` (mean reversion) and `Sigma` (volatility) using floor market data and the Hull-White model to price a floor at a particular maturity/volatility using the additional optional input arguments for `Strike`, `Settle`, and `Maturity`.

`Strike`, `Settle`, and `Maturity` arguments are specified to calibrate to a specific point on the market volatility surface. If omitted, the calibration is performed across all the market instruments

For an example of calibrating using the Hull-White model with `Strike`, `Settle`, and `Maturity` input arguments, see “Calibrating Hull-White Model Using Market Data” on page 2-92.

`[Alpha,Sigma,OptimOut] = hwcalbyfloor( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calibrate Hull-White Model from Market Data Using the Entire Floor Volatility Surface

This example shows how to use `hwcalbyfloor` input arguments for `MarketStrike`, `MarketMaturity`, and `MarketVolatility` to calibrate the HW model using the entire floor volatility surface.

Floor market volatility data covering two strikes over 12 maturity dates.

```
Reset = 4;
MarketStrike = [0.0590; 0.0790];

MarketMaturity = {'21-Mar-2008'; '21-Jun-2008'; '21-Sep-2008'; '21-Dec-2008';
    '21-Mar-2009'; '21-Jun-2009'; '21-Sep-2009'; '21-Dec-2009';
    '21-Mar-2010'; '21-Jun-2010'; '21-Sep-2010'; '21-Dec-2010'};
```

```
MarketMaturity = datenum(MarketMaturity);

MarketVolaltility = [0.1533 0.1731 0.1727 0.1752 0.1809 0.1800 0.1805 0.1802...
    0.1735 0.1757 0.1755 0.1755;
    0.1526 0.1730 0.1726 0.1747 0.1808 0.1792 0.1797 0.1794...
    0.1733 0.1751 0.1750 0.1745];
```

Plot market volatility surface.

```
[AllMaturities,AllStrikes] = meshgrid(MarketMaturity,MarketStrike);
figure;
surf(AllMaturities,AllStrikes,MarketVolaltility)
datetick
xlabel('Maturity')
ylabel('Strike')
zlabel('Volatility')

Calibrating Floorlets Using the Normal (Bachelier) Model

This example shows how to use `hwcalbyfloor` to calibrate market data with the Normal (Bachelier) model to price floorlets. Use the Normal (Bachelier) model to perform calibrations when working with negative interest rates, strikes, and normal implied volatilities.

Consider a floor with these parameters:

```
Settle = datetime(2016,12,30);
Maturity = datetime(2019,12,30);
Strike = -0.004075;
Reset = 2;
Principal = 100;
Basis = 0;
```

The floorlets and market data for this example are defined as:

```
floorletDates = cfdates(Settle, Maturity, Reset, Basis);
datestr(floorletDates')
```

```
ans = 6x11 char array
    '30-Jun-2017'
    '30-Dec-2017'
    '30-Jun-2018'
    '30-Dec-2018'
    '30-Jun-2019'
    '30-Dec-2019'
```

```
% Market data information
MarketStrike = [-0.00595; 0];
```

```
MarketMat = [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12
MarketVol = [0.184 0.2329 0.2398 0.2467 0.2906 0.3348;   % First row in table corresponding to St
             0.217 0.2707 0.2760 0.2814 0.3160 0.3508];  % Second row in table corresponding to S
```

Define the `RateSpec` using `intenvset`.

```
Rates= [-0.003210;-0.003020;-0.00182;-0.001343;-0.001075];
ValuationDate = datetime(2016,12,30);
EndDates = [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12,3
Compounding = 2;
Basis = 0;

RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);
```

Use `hwcalbyfloor` to find values for the volatility parameters `Alpha` and `Sigma` using the Normal (Bachelier) model.

```
format short
o=optimoptions('lsqnonlin','TolFun',100*eps);
warning ('off','fininst:hwcalbycapfloor:NoConverge')
[Alpha, Sigma, OptimOut] = hwcalbyfloor(RateSpec, MarketStrike, MarketMat,...
MarketVol, Strike, Settle, Maturity, 'Reset', Reset, 'Principal', Principal,...
'Basis', Basis, 'OptimOptions', o, 'model', 'normal')
```

```
Local minimum possible.
lsqnonlin stopped because the size of the current step is less than
the value of the step size tolerance.

Alpha = 1.0000e-06

Sigma = 0.3410

OptimOut = struct with fields:
     resnorm: 1.9233e-04
    residual: [5x1 double]
    exitflag: 2
      output: [1x1 struct]
      lambda: [1x1 struct]
    jacobian: [5x2 double]
```

The `OptimOut.residual` field of the `OptimOut` structure is the optimization residual. This value contains the difference between the Normal (Bachelier) floorlets and those calculated during the optimization. Use the `OptimOut.residual` value to calculate the percentual difference (error) compared to Normal (Bachelier) floorlet prices, and then decide whether the residual is acceptable. There is almost always some residual, so decide if it is acceptable to parameterize the market with a single value of `Alpha` and `Sigma`.

Price the floorlets using the market data and Normal (Bachelier) model to obtain the reference floorlet values. To determine the effectiveness of the optimization, calculate reference floorlet values using the Normal (Bachelier) formula and the market data. Note, you must first interpolate the market data to obtain the floorlets for calculation.

```
MarketMatNum = datenum(MarketMat);
[Mats, Strikes] = meshgrid(MarketMatNum, MarketStrike);
FlatVol = interp2(Mats, Strikes, MarketVol, datenum(Maturity), Strike, 'spline');
```

```
[FloorPrice, Floorlets] = floorbynormal(RateSpec, Strike, Settle, Maturity, FlatVol,...
'Reset', Reset, 'Basis', Basis, 'Principal', Principal);
Floorlets = Floorlets(2:end)'
```

```
Floorlets = 5×1

    4.7637
    6.7180
    8.1833
    9.5825
   10.6090
```

Compare the optimized values and Normal (Bachelier) values, and display the results graphically. After calculating the reference values for the floorlets, compare the values analytically and graphically to determine whether the calculated single values of `Alpha` and `Sigma` provide an adequate approximation.

```
OptimFloorlets = Floorlets+OptimOut.residual;

disp('   ');

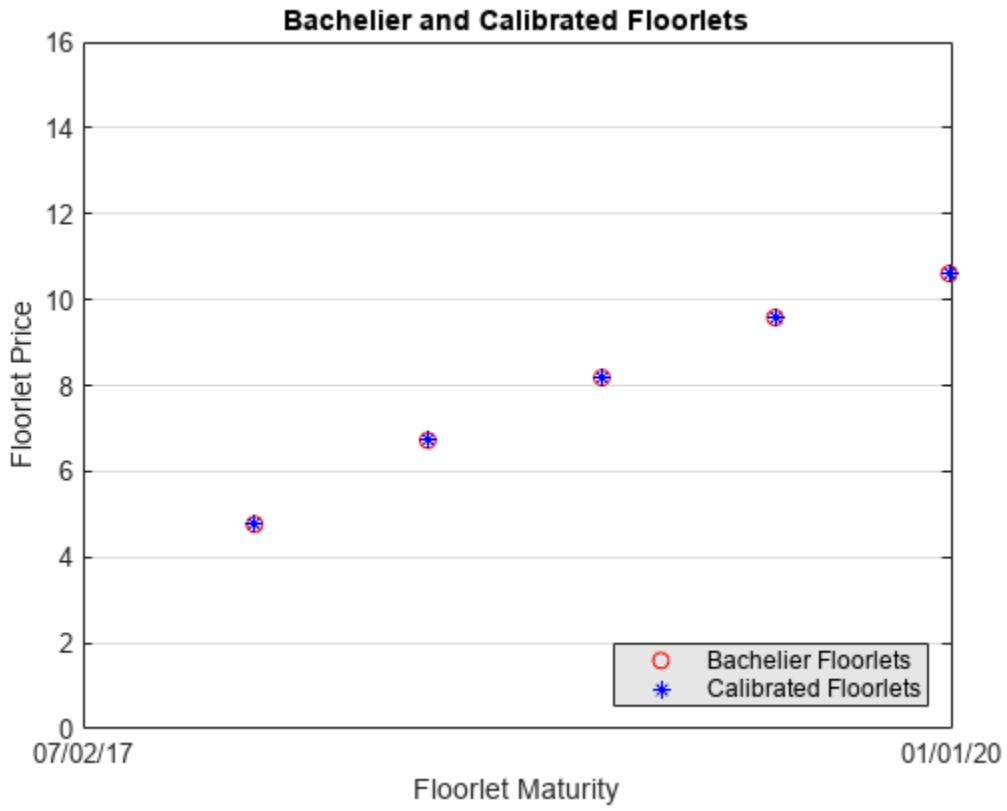
disp(' Bachelier   Calibrated Floorlets');
```

```
 Bachelier   Calibrated Floorlets
```

```
disp([Floorlets        OptimFloorlets])
```

```
    4.7637    4.7685
    6.7180    6.7263
    8.1833    8.1878
    9.5825    9.5795
   10.6090   10.6007
```

```
plot(MarketMatNum(2:end), Floorlets, 'or', MarketMatNum(2:end), OptimFloorlets, '*b');
datetick('x', 2)
xlabel('Floorlet Maturity');
ylabel('Floorlet Price');
ylim ([0 16]);
title('Bachelier and Calibrated Floorlets');
h = legend('Bachelier Floorlets', 'Calibrated Floorlets');
set(h, 'color', [0.9 0.9 0.9]);
set(h, 'Location', 'SouthEast');
set(gcf, 'NumberTitle', 'off')
grid on
```



Input Arguments

`RateSpec` — Interest-rate specification for initial rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`MarketStrike` — Market floor strike

vector

Market floor strike, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`MarketMaturity` — Market floor maturity date

datetime array | string array | date character vector

Market floor maturity dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `hwcalbyfloor` also accepts serial date numbers as inputs, but they are not recommended.

`MarketVolatility` — Market flat volatilities
matrix

Market flat volatilities, specified as a `NSTRIKES`-by-`NMATS` matrix of market flat volatilities, where `NSTRIKES` is the number of caplet strikes from `MarketStrike` and `NMATS` is the caplet maturity dates from `MarketMaturity`.

Data Types: `double`

`Strike` — Rate at which floor is exercised
decimal scalar

(Optional) Rate at which the floor is exercised, specified as a decimal scalar value.

Data Types: `double`

`Settle` — Settlement date of the floor
datetime scalar | string scalar | date character vector

(Optional) Settlement date of the floor, specified as a scalar datetime, string, or data character vector.

To support existing code, `hwcalbyfloor` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date of the floor
datetime scalar | string scalar | date character vector

(Optional) Maturity date of the floor, specified as scalar datetime, string, or data character vector.

To support existing code, `hwcalbyfloor` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Alpha,Sigma,OptimOut] = hwcalbyfloor(RateSpec,MarketStrike,MarketMaturity,MarketVolaltility,'Reset',2,'Principal',100000,'Basis',3,'OptimOptions',o)`

`Reset` — Frequency of payments per year
`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a scalar numeric value.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | nonnegative integer

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a scalar nonnegative integer.

Data Types: `double`

`Basis` — Day-count basis used when annualizing the input forward rate
`0` (actual/actual) (default) | integers of the set `[0...13]`

Day-count basis used when annualizing the input forward rate, specified as the comma-separated pair consisting of `'Basis'` and a scalar value. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`LB` — Lower bounds
`[0;0]` (default) | numeric vector

Lower bounds, specified as the comma-separated pair consisting of `'LB'` and a 2-by-1 vector of the lower bounds, defined as `[LBSigma; LBAlpha]`, used in the search algorithm function. For more information, see `lsqnonlin`.

Data Types: `double`

`UB` — Upper bounds
`[ ]` (unbound) (default) | numeric vector

Upper bounds, specified as the comma-separated pair consisting of `'UB'` and a 2-by-1 vector of the upper bounds, defined as `[UBSigma; LBAlpha]`, used in the search algorithm function. For more information, see `lsqnonlin`.

Data Types: `double`

`X0` — Initial values
`[0.5;0.5]` (default) | numeric vector

Initial values, specified as the comma-separated pair consisting of `'X0'` and a 2-by-1 vector of the initial values, defined as `[Sigma0; Alpha0]`, used in the search algorithm function. For more information, see `lsqnonlin`.

Data Types: `double`

`OptimOptions` — Optimization parameters
structure

Optimization parameters, specified as the comma-separated pair consisting of `'OptimOptions'` and a structure defined by using `optimoptions`.

Data Types: `struct`

`Shift` — Shift in decimals for shifted Black model
`0` (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of `'Shift'` and a scalar positive decimal value. Set this parameter to a positive shift in decimals to add a positive shift to forward rate and `Strike`, which effectively sets a negative lower bound for forward rate and `Strike`. For example, a `Shift` value of `0.01` is equal to a 1% shift.

Data Types: `double`

`Model` — Indicator for model used for calibration routine
`lognormal` (Black model) (default) | values are `normal` and `lognormal`

Indicator for model used for calibration routine, specified as the comma-separated pair consisting of `'Model'` and a scalar character vector with a value of `normal` or `lognormal`.

Data Types: `char`

Output Arguments

`Alpha` — Mean reversion value obtained from calibrating the floor using market information
scalar numeric

Mean reversion value obtained from calibrating the floor using market information, returned as a scalar value.

`Sigma` — Volatility value obtained from calibrating floor using market information
scalar numeric

Volatility value obtained from calibrating the floor using market information, returned as a scalar.

`OptimOut` — Optimization results
numeric structure

Optimization results, returned as a structure.

Version History

Introduced in R2009a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `hwcalbyfloor` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

hwprice

Instrument prices from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = hwprice(HWTree,InstSet)
[Price,PriceTree] = hwprice( ___ ,Options)
```

Description

`[Price,PriceTree] = hwprice(HWTree,InstSet)` computes arbitrage-free prices for instruments using an interest-rate tree created with `hwtree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`hwprice` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` to construct defined types.

`[Price,PriceTree] = hwprice( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Price the Cap and Bond Instruments Contained in an Instrument Set

Load the HW tree and instruments from the data file `deriv.mat`.

```
load deriv.mat;
HWSubSet = instselect(HWInstSet,'Type', {'Bond', 'Cap'});

instdisp(HWSubSet)
```

```
instdisp(HWSubSet)
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCouponDate LastCouponDate StartDate Face Na
1     Bond 0.04       01-Jan-2004    01-Jan-2007    1      0     1            NaN       NaN             NaN            NaN       100  4%
2     Bond 0.04       01-Jan-2004    01-Jan-2008    1      0     1            NaN       NaN             NaN            NaN       100  4%

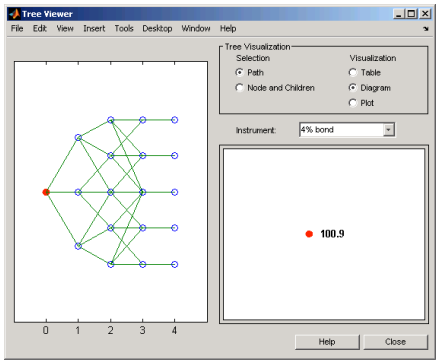
Index Type Strike Settle         Maturity       CapReset Basis Principal Name   Quantity
3     Cap  0.06   01-Jan-2004    01-Jan-2008    1        0     100       6% Cap 10
```

Price the cap and bond instruments.

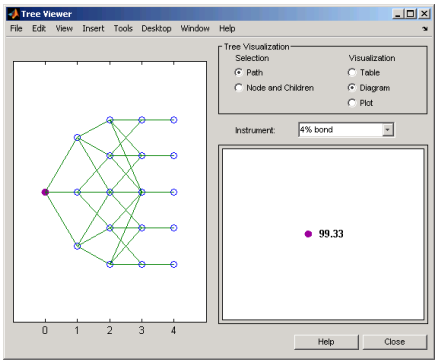
```
[Price, PriceTree] = hwprice(HWTree, HWSubSet);
```

```
100.9188
 99.3296
  0.5837
```

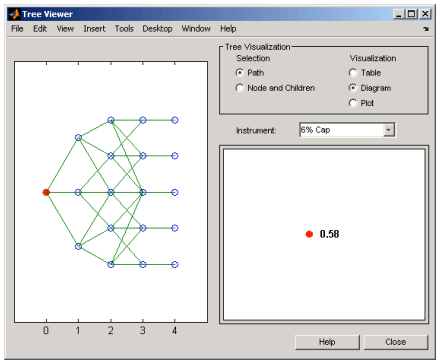
You can use `treeviewer` to see the prices of these three instruments along the price tree.



First 4% Bond (Maturity 2007)



Second 4% Bond (Maturity 2008)



6% Cap

Price Multi-Stepped Coupon Bonds

The data for the interest-rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;
```

Create the `RateSpec`.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734139
    ValuationDate: 734139
```

```
           Basis: 0
     EndMonthRule: 1
```

Create a portfolio of stepped coupon bonds with different maturities.

```
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2011';'01-Jan-2012';'01-Jan-2013';'01-Jan-2014'};
CouponRate = {{'01-Jan-2011' .042;'01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};

ISet = instbond(CouponRate, Settle, Maturity, 1);
instdisp(ISet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond [Cell]     01-Jan-2010    01-Jan-2011    1      0     1            NaN       NaN
2     Bond [Cell]     01-Jan-2010    01-Jan-2012    1      0     1            NaN       NaN
3     Bond [Cell]     01-Jan-2010    01-Jan-2013    1      0     1            NaN       NaN
4     Bond [Cell]     01-Jan-2010    01-Jan-2014    1      0     1            NaN       NaN
```

Build the tree with the following data:

```
VolDates = ['1-Jan-2011'; '1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'];
VolCurve = 0.01;
AlphaDates = '01-01-2014';
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec)
```

```
HWT = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734139 734504 734869 735235]

       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

Compute the price of the stepped coupon bonds.

```
PHW = hwprice(HWT, ISet)
```

```
PHW = 4×1

  100.6763
  100.7368
  100.9266
  101.0115
```

Price a Portfolio of Stepped Callable Bonds and Stepped Vanilla Bonds

The data for the interest-rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;
```

Create a RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create an instrument portfolio of three stepped callable bonds and three stepped vanilla bonds.

```
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2012';'01-Jan-2013';'01-Jan-2014'};
CouponRate = {{'01-Jan-2011' .042;'01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};
OptSpec='call';
Strike=100;
ExerciseDates='01-Jan-2011'; %Callable in one year
```

Bonds with embedded option.

```
ISet = instoptembnd(CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1);
```

Vanilla bonds.

```
ISet = instbond(ISet, CouponRate, Settle, Maturity, 1);
```

Display the instrument portfolio.

```
instdisp(ISet)
```

```
Index Type      CouponRate Settle         Maturity       OptSpec Strike ExerciseDates  Period Bas
1     OptEmBond [Cell]     01-Jan-2010    01-Jan-2012    call    100    01-Jan-2011    1      0
2     OptEmBond [Cell]     01-Jan-2010    01-Jan-2013    call    100    01-Jan-2011    1      0
3     OptEmBond [Cell]     01-Jan-2010    01-Jan-2014    call    100    01-Jan-2011    1      0

Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCoup
4     Bond [Cell]     01-Jan-2010    01-Jan-2012    1      0     1            NaN       NaN
5     Bond [Cell]     01-Jan-2010    01-Jan-2013    1      0     1            NaN       NaN
```

```
6     Bond [Cell]     01-Jan-2010    01-Jan-2014    1      0     1            NaN       NaN
```

Build the tree with the following data:

```
VolDates = ['1-Jan-2011'; '1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'];
VolCurve = 0.01;
AlphaDates = '01-01-2014';
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec)
```

```
HWT = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734139 734504 734869 735235]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

Compute the price of the stepped callable bonds and the stepped vanilla bonds.

```
PHW = hwprice(HWT, ISet)
```

```
PHW = 6×1

  100.4089
  100.2043
  100.0197
  100.7368
  100.9266
  101.0115
```

The first three rows correspond to the price of the stepped callable bonds and the last three rows correspond to the price of the stepped vanilla bonds.

Compute the Price of a Portfolio of Instruments

The data for the interest-rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2011';
StartDates = ValuationDate;
EndDates = {'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'};
Compounding = 1;
```

Create a `RateSpec`.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)

RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create an instrument portfolio with two range notes and a floating rate note with the following data:

```
Spread = 200;
Settle = 'Jan-1-2011';
Maturity = 'Jan-1-2014';

% First Range Note
RateSched(1).Dates = {'Jan-1-2012'; 'Jan-1-2013'  ; 'Jan-1-2014'};
RateSched(1).Rates  = [0.045 0.055; 0.0525  0.0675; 0.06 0.08];

% Second Range Note
RateSched(2).Dates = {'Jan-1-2012'; 'Jan-1-2013' ; 'Jan-1-2014'};
RateSched(2).Rates  = [0.048 0.059; 0.055  0.068 ; 0.07 0.09];
```

Create `InstSet`, add a floating-rate note, and display the portfolio instruments.

```
InstSet = instadd('RangeFloat', Spread, Settle, Maturity, RateSched);

% Add a floating-rate note
InstSet = instadd(InstSet, 'Float', Spread, Settle, Maturity);

% Display the portfolio instrument
instdisp(InstSet)

Index Type       Spread Settle         Maturity       RateSched FloatReset Basis Principal EndMo
1     RangeFloat 200    01-Jan-2011    01-Jan-2014    [Struct]  1          0     100       1
2     RangeFloat 200    01-Jan-2011    01-Jan-2014    [Struct]  1          0     100       1

Index Type  Spread Settle         Maturity       FloatReset Basis Principal EndMonthRule CapRate
3     Float 200    01-Jan-2011    01-Jan-2014    1          0     100       1            Inf
```

The data to build the tree is as follows:

```
VolDates = ['1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014';'1-Jan-2015'];
VolCurve = 0.01;
AlphaDates = '01-01-2015';
AlphaCurve = 0.1;

HWVS = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
```

```
HWTS = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVS, RS, HWTS)
```

```
HWT = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734504 734869 735235 735600]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

Price the portfolio.

```
Price = hwprice(HWT, InstSet)
```

```
Price = 3×1

   99.3327
   98.1580
  105.5147
```

Create a Float-Float Swap and Price with `hwprice`

Use `instswap` to create a float-float swap and price the swap with `hwprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.02 .03],today,datemnth(today,60),[], [], [], [1 1]);
VolSpec = hwvolspec(today,datemnth(today,60),.01,datemnth(today,60),.1);
TimeSpec = hwtimespec(today,cfdates(today,datemnth(today,60),1));
HWTree = hwtree(VolSpec,RateSpec,TimeSpec);
hwprice(HWTree,IS)
```

```
ans = -4.3220
```

Price Multiple Swaps with `hwprice`

Use `instswap` to create multiple swaps and price the swaps with `hwprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.03 .02],today,datemnth(today,60),[], [], [], [1 1]);
IS = instswap(IS,[200 300],today,datemnth(today,60),[], [], [], [0 0]);
IS = instswap(IS,[.08 300],today,datemnth(today,60),[], [], [], [1 0]);
VolSpec = hwvolspec(today,datemnth(today,60),.01,datemnth(today,60),.1);
TimeSpec = hwtimespec(today,cfdates(today,datemnth(today,60),1));
HWTree = hwtree(VolSpec,RateSpec,TimeSpec);
hwprice(HWTree,IS)
```

```
ans = 3×1

    4.3220
   -4.3220
   -0.2701
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Price for each instrument

vector

Price for each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Related single-type pricing functions are:

- `bondbyhw`: Price a bond from a Hull-White tree.
- `capbyhw`: Price a cap from a Hull-White tree.
- `cfbyhw`: Price an arbitrary set of cash flows from a Hull-White tree.
- `fixedbyhw`: Price a fixed-rate note from a Hull-White tree.
- `floatbyhw`: Price a floating-rate note from a Hull-White tree.
- `floorbyhw`: Price a floor from a Hull-White tree.
- `optbndbyhw`: Price a bond option from a Hull-White tree.
- `optembndbyhw`: Price a bond with embedded option by a Hull-White tree.

- `optfloatbybdt`: Price a floating-rate note with an option from a Hull-White tree.
- `optemfloatbybdt`: Price a floating-rate note with an embedded option from a Hull-White tree.
- `rangefloatbyhw`: Price range floating note using a Hull-White tree.
- `swapbyhw`: Price a swap from a Hull-White tree.
- `swaptionbyhw`: Price a swaption from a Hull-White tree.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

Version History

Introduced before R2006a

hwsens

Instrument prices and sensitivities from Hull-White interest-rate tree

Syntax

```
[Delta,Gamma,Vega,Price] = hwsens(HWTree,InstSet)
[Delta,Gamma,Vega,Price] = hwsens( ___ ,Options)
```

Description

`[Delta,Gamma,Vega,Price] = hwsens(HWTree,InstSet)` computes instrument sensitivities and prices for instruments using an interest-rate tree created with the `hwtree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`hwsens` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` for information on instrument types.

`[Delta,Gamma,Vega,Price] = hwsens( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Compute Instrument Sensitivities Using an HW Interest-Rate Tree

Load the tree and instruments from the `deriv.mat` data file. Compute `Delta` and `Gamma` for the cap and bond instruments contained in the instrument set.

```
load deriv.mat;
HWSubSet = instselect(HWInstSet,'Type', {'Bond', 'Cap'});

instdisp(HWSubSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.04       01-Jan-2004    01-Jan-2007    1      0     1            NaN       NaN
2     Bond 0.04       01-Jan-2004    01-Jan-2008    1      0     1            NaN       NaN

Index Type Strike Settle         Maturity       CapReset Basis Principal Name   Quantity
3     Cap  0.06   01-Jan-2004    01-Jan-2008    1        0     100       6% Cap 10
```

Compute the `Delta` and `Gamma` for the cap and bond instruments.

```
[Delta, Gamma] = hwsens(HWTree, HWSubSet)
```

```
Delta = 3×1

 -291.2580
 -374.6368
```

```
   60.9580

Gamma = 3×1
10^3 ×

    0.8584
    1.4609
    5.5994
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in interest rate

vector

Rate of change of instruments prices with respect to changes in the interest rate, returned as a `NINST`-by-1 vector of deltas. `Delta` is computed by finite differences in calls to `hwtree`.

Note `Delta` is calculated based on yield shifts of 100 basis points.

`Gamma` — Rate of change of instruments deltas with respect to changes in interest rate

vector

Rate of change of instruments deltas with respect to changes in the interest rate, returned as a `NINST`-by-1 vector of gammas. `Gamma` is computed by finite differences in calls to `hwtree`.

Note `Gamma` is calculated based on yield shifts of 100 basis points.

`Vega` — Rate of change of instruments prices with respect to changes in volatility

vector

Rate of change of instruments prices with respect to changes in the volatility, returned as a `NINST`-by-`1` vector of vegas. Volatility is $\sigma(t, T)$ of the interest rate. `Vega` is computed by finite differences in calls to `hwtree`. For information on the volatility process, see `hwvolspec`.

Note `Vega` is calculated based on 1% shift in the volatility process.

`Price` — Price of each instrument

vector

Price of each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Version History

Introduced before R2006a

hwtimespec

Specify time structure for Hull-White interest-rate tree

Syntax

```
TimeSpec = hwtimespec(ValuationDate,Maturity)
TimeSpec = hwtimespec( ___ ,Compounding)
```

Description

`TimeSpec = hwtimespec(ValuationDate,Maturity)` sets the number of levels and node times for a `hwtree` and determines the mapping between dates and time for rate quoting.

`TimeSpec = hwtimespec( ___ ,Compounding)` adds the optional argument `Compounding`.

Examples

Set the Number of Levels and Node Times for a Hull-White Tree

This example shows how to specify a four-period tree with annual nodes and use annual compounding to report rates.

```
ValuationDate = datetime(2004,1,1);
Maturity = [datetime(2004,12,31) ; datetime(2005,12,31) ; datetime(2006,12,31) ; datetime(2007,12
Compounding = 1;
TimeSpec = hwtimespec(ValuationDate, Maturity, Compounding)
```

```
TimeSpec = struct with fields:
           FinObj: 'HWTimeSpec'
    ValuationDate: 731947
         Maturity: [4x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the tree, specified as a scalar datetime, string, or data character vector.

To support existing code, `hwtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Dates marking the cash flow dates of the tree

datetime array | string array | date character vector

Dates marking the cash flow dates of the tree, specified as `NLEVELS`-by-`1` vector using a datetime array, string array, or date character vectors. Cash flows with these maturities fall on tree nodes. `Maturity` should be in increasing order.

To support existing code, `hwtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Compounding` — Rate at which the input zero rates were compounded when annualized
1 (default) | integer with value of 1, 2, 3, 4, 6, 12, 365, or -1

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units; for example, `T = F` is one year.
- If `Compounding` = `365`:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = `−1`:

  `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `hwtree`
structure

Specification for the time layout for `hwtree`, returned as a structure. The state observation dates are `[ValuationDate; Maturity(1:end-1)]`. Because a forward rate is stored at the last observation, the tree can value cash flows out to `Maturity(end)`.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `hwtimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

hwtree

Build Hull-White interest-rate tree

Syntax

```
HWTree = hwtree(VolSpec,RateSpec,TimeSpec)
HWTree = hwtree( ___ ,Name,Value)
```

Description

`HWTree = hwtree(VolSpec,RateSpec,TimeSpec)` builds a Hull-White interest-rate tree.

`HWTree = hwtree( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Create an HWTree

Using the data provided, create a Hull-White volatility specification (`VolSpec`), rate specification (`RateSpec`), and tree time layout specification (`TimeSpec`). Then, use these specifications to create a Hull-White tree using `hwtree`.

```
Compounding = -1;
ValuationDate = '01-01-2004';
StartDate = ValuationDate;
VolDates = ['12-31-2004'; '12-31-2005'; '12-31-2006';
'12-31-2007'];
VolCurve = 0.01;
AlphaDates = '01-01-2008';
AlphaCurve = 0.1;
Rates = [0.0275; 0.0312; 0.0363; 0.0415];

HWVolSpec = hwvolspec(ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);

RateSpec = intenvset('Compounding', Compounding,...
                     'ValuationDate', ValuationDate,...
                     'StartDates', ValuationDate,...
                     'EndDates', VolDates,...
                     'Rates', Rates);

HWTimeSpec = hwtimespec(ValuationDate, VolDates, Compounding);
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec)
```

```
HWTree = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.9973 1.9973 2.9973]
        dObs: [731947 732312 732677 733042]
```

```
 CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [3.9973]}
  Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
FwdTree: {1x4 cell}
```

Use `treeviewer` to observe the tree you have created.

Input Arguments

`VolSpec` — Volatility process specification

structure

Volatility process specification, specified using the `VolSpec` obtained from `hwvolspec`. See `hwvolspec` for information on the volatility process.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Time layout specification

structure

Time layout specification, specified using the `TimeSpec` obtained from `hwtimespec`. The `TimeSpec` defines the observation dates of the HW tree and the compounding rule for date to time mapping and price-yield formulas. See `hwtimespec` for information on the tree structure.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `HWTree = hwtree(VolSpec,RateSpec,TimeSpec,'Method','HW1996')`

`Method` — Hull-White method upon which tree-node connectivity algorithm is based

`HW2000` (default) | character vector with values of `HW1996` or `HW2000`

Hull-White method upon which the tree-node connectivity algorithm is based, specified a character vector with a value of `HW1996` or `HW2000`.

Note `hwtree` supports two tree-node connectivity algorithms. `HW1996` is based on the original paper published in the *Journal of Derivatives*, and `HW2000` is the general version of the algorithm, as specified in the paper published in August 2000.

Data Types: `char`

Output Arguments

`HWTree` — Hull-White interest-rate tree

structure

Hull-White interest-rate tree, returned as a structure containing time and interest rate information of a trinomial recombining tree.

The `HWTree` structure returned contains all the information necessary to propagate back any cash flows occurring during the time span of the tree. The main fields of `HWTree` are:

- `HWTree.tObs` contains the time factor of each level of the tree.
- `HWTree.dObs` contains the date of each level of the tree.
- `HWTree.Probs` contains a cell array of `3`-by-`N` numeric arrays with the up/mid/down probabilities of each node of the tree except for the last level. The cells in the cell array are ordered from root node. The arrays are `3`-by-`N` with the first row corresponding to an up-move, the mid row to a mid-move and so on. Each column of the array represents a node starting from the top node of a given level.
- `HWTree.Connect` contains a cell array with connectivity information for each node of the tree. The arrangement is similar to `HWTree.Probs`, with the exception that it has only one row in each cell. The number represents the node in the next level to which the middle branch connects to. The top branch connects to the value above (minus one) and the lower branch connects to the value below (plus one).
- `HWTree.FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.

Version History

Introduced before R2006a

hwvolspec

Specify Hull-White interest-rate volatility process

Syntax

```
VolSpec = hwvolspec(ValuationDate,VolDates,VolCurve,AlphaDates,AlphaCurve)
VolSpec = hwvolspec( ___ ,InterpMethod)
```

Description

`VolSpec = hwvolspec(ValuationDate,VolDates,VolCurve,AlphaDates,AlphaCurve)` creates a structure specifying the volatility for `hwtree`.

The volatility process is such that the variance of $r(t + dt) - r(t)$ is defined as follows: `V = (Volatility.^2 .* (1 - exp(-2*Alpha .* dt))) ./ (2 * Alpha)`. For more information on using Hull-White interest rate trees, see “Hull-White (HW) and Black-Karasinski (BK) Modeling” on page B-2.

`VolSpec = hwvolspec( ___ ,InterpMethod)` adds the optional argument `InterpMethod`.

Examples

Create a Structure Specifying the Volatility for `hwtree`

This example shows how to create a Hull-White volatility specification (`VolSpec`) using the following data.

```
ValuationDate = '01-01-2004';
StartDate = ValuationDate;
VolDates = ['12-31-2004'; '12-31-2005'; '12-31-2006';
'12-31-2007'];
VolCurve = 0.01;
AlphaDates = '01-01-2008';
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve)

HWVolSpec = struct with fields:
             FinObj: 'HWVolSpec'
      ValuationDate: 731947
           VolDates: [4x1 double]
           VolCurve: [4x1 double]
         AlphaCurve: 0.1000
         AlphaDates: 733408
    VolInterpMethod: 'linear'
```

Input Arguments

`ValuationDate` — Observation date of the investment horizon
datetime scalar | string scalar | date character vector

Observation date of the investment horizon, specified as a scalar datetime, string, or data character vector.

To support existing code, `hwvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`VolDates` — Number of points of yield volatility end dates
datetime array | string array | date character vector

Number of points of yield volatility end dates, specified as a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `hwvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`VolCurve` — Yield volatility values
decimal

Yield volatility values, specified as a `NPOINTS`-by-`1` vector of decimal values. The term structure of `VolCurve` is the yield volatility represented by the value of the volatility of the yield from time `t` = 0 to time `t` + *i*, where *i* is any point within the volatility curve.

Note The number of points in `VolCurve` and `AlphaCurve` do not have to be the same.

Data Types: `double`

`AlphaDates` — Mean reversion end dates
datetime array | string array | date character vector

Mean reversion end dates, specified as a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `hwvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`AlphaCurve` — Positive mean reversion values
positive decimal

Positive mean reversion values, specified as a `NPOINTS`-by-`1` vector of positive decimal values.

Note The number of points in `VolCurve` and `AlphaCurve` do not have to be the same.

Data Types: `double`

`InterpMethod` — Interpolation method
`'linear'` (default) | character vector with values supported by `interp1`

(Optional) Interpolation method, specified as a character vector with values supported by `interp1`.

Data Types: `char`

Output Arguments

`VolSpec` — Specification for the volatility model for `hwtree`

structure

Structure specifying the volatility model for `hwtree`.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `hwvolspec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

impvbybaw

Calculate implied volatility using Barone-Adesi and Whaley option pricing model

Syntax

```
Volatility = impvbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
OptPrice)
Volatility = impvbybaw( ___ ,Name,Value)
```

Description

`Volatility = impvbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, OptPrice)` calculates implied volatility using the Barone-Adesi and Whaley option pricing model.

`Volatility = impvbybaw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Implied Volatility for an American Option Using the Barone-Adesi and Whaley Option Pricing Model

This example shows how to compute implied volatility using the Barone-Adesi and Whaley option pricing model. Consider three American call options with exercise prices of $100 that expire on July 1, 2017. The underlying stock is trading at $100 on January 1, 2017 and pays a continuous dividend yield of 10%. The annualized continuously compounded risk-free rate is 10% per annum, and the option prices are $4.063, $6.77 and $9.46. Using this data, calculate the implied volatility of the stock using the Barone-Adesi and Whaley option pricing model.

```
AssetPrice = 100;
Settle = datetime(2017,1,1);
Maturity = datetime(2017,6,1);
Strike = 100;
DivAmount = 0.1;
Rate = 0.05;
```

Define the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9794
            Rates: 0.0500
        EndTimes: 0.4167
       StartTimes: 0
         EndDates: 736847
       StartDates: 736696
    ValuationDate: 736696
```

```
           Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
StockSpec = stockspec(NaN, AssetPrice, {'continuous'}, DivAmount)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: NaN
         AssetPrice: 100
       DividendType: {'continuous'}
    DividendAmounts: 0.1000
    ExDividendDates: []
```

Define the American option.

```
OptSpec = {'call'};
OptionPrice = [4.063;6.77;9.46];
```

Compute the implied volatility for the American option.

```
ImpVol =  impvbybaw(RateSpec, StockSpec, Settle, Maturity, OptSpec,...
Strike, OptionPrice)
```

```
ImpVol = 3×1

    0.1916
    0.3010
    0.4093
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbybaw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbybaw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors or string arrays with values `'call'` or `'put'`.

Data Types: `char` | `string`

`Strike` — American option strike price value
nonnegative scalar | nonnegative vector

American option strike price value, specified as a nonnegative scalar or `NINST`-by-`1` matrix of strike price values. Each row is the schedule for one option.

Data Types: `single` | `double`

`OptPrice` — American option price
nonnegative scalar | nonnegative vector

American option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or `NINST`-by-`1` matrix of strike price values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Volatility = impvbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,OptionPrice)`

`Limit` — Lower and upper bound of implied volatility search interval
`[0.1 10]` (or 10% to 1000% per annum) (default) | positive value

Lower and upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a 1-by-2 positive vector.

Data Types: `double`

`Tolerance` — Implied volatility search termination tolerance
`1e-6` (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

Data Types: `double`

Output Arguments

`Volatility` — Expected implied volatility values
matrix

Expected implied volatility values, returned as a `NINST`-by-`1` matrix. If no solution can be found, a `NaN` is returned.

Version History

Introduced in R2017a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `impvbybaw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

impvbybjs

Determine implied volatility using Bjerksund-Stensland 2002 option pricing model

Syntax

```
Volatility = impvbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
OptPrice)
Volatility = impvbybjs( ___ ,Name,Value)
```

Description

`Volatility = impvbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, OptPrice)` computes implied volatility using the Bjerksund-Stensland 2002 pricing model.

Note `impvbybjs` computes implied volatility of American options with continuous dividend yield using the Bjerksund-Stensland option pricing model.

`Volatility = impvbybjs( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Implied Volatility Using the Bjerksund-Stensland 2002 Option Pricing Model

This example shows how to compute implied volatility using the Bjerksund-Stensland 2002 option pricing model. Consider three American call options with exercise prices of $100 that expire on July 1, 2008. The underlying stock is trading at $100 on January 1, 2008 and pays a continuous dividend yield of 10%. The annualized continuously compounded risk-free rate is 10% per annum and the option prices are $4.063, $6.77 and $9.46. Using this data, calculate the implied volatility of the stock using the Bjerksund-Stensland 2002 option pricing model.

```
AssetPrice = 100;
Settle = datetime(2008,1,1);
Maturity = datetime(2008,6,1);
Strike = 100;
DivAmount = 0.1;
Rate = 0.1;

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 1);

StockSpec = stockspec(NaN, AssetPrice, {'continuous'}, DivAmount);

OptSpec = {'call'};
OptionPrice = [4.063;6.77;9.46];

ImpVol =  impvbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec,...
Strike, OptionPrice)
```

```
ImpVol = 3×1

    0.1633
    0.2723
    0.3810
```

The implied volatility is 15% for the first call, and 25% and 35% for the second and third call options.

Input Arguments

`RateSpec` — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'`

Definition of the option from which the implied volatility is derived, specified as a `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or `NINST`-by-`1` vector of strike price values. Each row is the schedule for one option.

Data Types: `double`

`OptPrice` — American option price
nonnegative scalar | nonnegative vector

American option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Volatility = impvbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,OptPrice,'Limit',[0.2 20],'Tolerance',1e-5)`

`Limit` — Lower and upper bound of implied volatility search interval
`[0.1 10]` (10% to 1000% per annum) (default) | positive vector

Lower and upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a `1`-by-`2` positive vector.

Data Types: `double`

`Tolerance` — Implied volatility search termination tolerance
`1e-6` (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

Data Types: `double`

Output Arguments

`Volatility` — Expected implied volatility values
vector

Expected implied volatility values, returned as a `NINST`-by-`1` vector. If no solution can be found, a `NaN` is returned.

Version History

Introduced in R2008b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `impvbybjs` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

impvbyblk

Determine implied volatility using Black option pricing model

Syntax

```
Volatility = impvbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
OptPrice)
Volatility = impvbyblk( ___ ,Name,Value)
```

Description

`Volatility = impvbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, OptPrice)` computes implied volatility using the Black option pricing model.

`Volatility = impvbyblk( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Implied Volatility Using the Black Option Pricing Model

This example shows how to compute the implied volatility using the Black option pricing model. Consider a European call and put options on a futures contract with exercise prices of $30 for the put and $40 for the call that expire on September 1, 2008. Assume that on May 1, 2008 the contract is trading at $35. The annualized continuously compounded risk-free rate is 5% per annum. Find the implied volatilities of the stock, if on that date, the call price is $1.14 and the put price is $0.82.

```
AssetPrice = 35;
Strike = [30; 40];
Rates = 0.05;
Settle = datetime(2008,5,1);
Maturity = datetime(2008,9,1);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(NaN, AssetPrice);

% define the options
OptSpec = {'put';'call'};

Price = [1.14;0.82];
Volatility = impvbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec,...
Strike, Price,'Method','jackel2016')
```

```
Volatility = 2×1

    0.4052
    0.3021
```

The implied volatility is 41% and 30%.

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'`

Definition of the option from which the implied volatility is derived, specified as a `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or `NINST`-by-`1` vector of strike prices. Each row is the schedule for one option.

Data Types: double

OptPrice — European option price
nonnegative scalar | nonnegative vector

European option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or NINST-by-1 vector.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Volatility = impvbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,OptPrice,'Limit',5,'Tolerance',1e-5)

Limit — Upper bound of implied volatility search interval
10 (1000% per annum) (default) | positive value

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of 'Limit' and a positive scalar.

Note If you are using Method with a value of 'jackel2016', the Limit argument is ignored.

Data Types: double

Tolerance — Implied volatility search termination tolerance
1e-6 (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of 'Tolerance' and a positive scalar.

Note If you are using Method with a value of 'jackel2016', the Tolerance argument is ignored.

Data Types: double

Method — Method for computing implied volatility
'jackel2016' (default) | character vector with values 'search' or 'jackel2016' | string with values "search" or "jackel2016"

Method for computing implied volatility, specified as the comma-separated pair consisting of 'Method' and a character vector with a value of 'search' or 'jackel2016' or a string with a value of "search" or "jackel2016".

Data Types: char | string

Output Arguments

`Volatility` — Expected implied volatility values
vector

Expected implied volatility values, returned as a `NINST`-by-`1` vector. If no solution can be found, a `NaN` is returned.

Version History

Introduced in R2008b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `impvbyblk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

impvbybls

Determine implied volatility using Black-Scholes option pricing model

Syntax

```
Volatility = impvbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
OptPrice)
Volatility = impvbybls( ___ ,Name,Value)
```

Description

`Volatility = impvbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, OptPrice)` computes implied volatility using the Black-Scholes option pricing model.

`Volatility = impvbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Implied Volatility Using the Black-Scholes Option Pricing Model

This example shows how to compute the implied volatility using the Black-Scholes option pricing model. Consider a European call and put options with an exercise price of $40 that expires on June 1, 2008. The underlying stock is trading at $45 on January 1, 2008 and the risk-free rate is 5% per annum. The option price is $7.10 for the call and $2.85 for the put. Using this data, calculate the implied volatility of the European call and put using the Black-Scholes option pricing model.

```
AssetPrice = 45;
Settlement = 'Jan-01-2008';
Maturity = 'June-01-2008';
Strike = 40;
Rates = 0.05;
OptionPrice = [7.10; 2.85];
OptSpec = {'call';'put'};

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settlement, 'StartDates', Settlement,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

StockSpec = stockspec(NaN, AssetPrice);

ImpvVol =  impvbybls(RateSpec, StockSpec, Settlement, Maturity, OptSpec,...
Strike, OptionPrice,'Method','jackel2016')
```

```
ImpvVol = 2×1

    0.3175
    0.4878
```

The implied volatility is 31.75% for the call and 48.78% for the put.

Input Arguments

RateSpec — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the RateSpec obtained from intenvset. For information on the interest-rate specification, see intenvset.

Data Types: struct

StockSpec — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see stockspec.

stockspec handles several types of underlying assets. For example, for physical commodities the price is StockSpec.Asset, the volatility is StockSpec.Sigma, and the convenience yield is StockSpec.DividendAmounts.

Data Types: struct

Settle — Settlement date
datetime array | string array | date character vector

Settlement date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, impvbybls also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date for the American option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, impvbybls also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
character vector with values 'call' or 'put'

Definition of the option from which the implied volatility is derived, specified as a NINST-by-1 cell array of character vectors with a value of 'call' or 'put'.

Data Types: char | cell

Strike — Option strike price
nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or NINST-by-1 vector of strike prices. Each row is the schedule for one option.

Data Types: double

`OptPrice` — European option price

nonnegative scalar | nonnegative vector

European option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Volatility = impvbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,OptPrice,'Limit',5,'Tolerance',1e-5)`

`Limit` — Upper bound of implied volatility search interval

`10` (1000% per annum) (default) | positive value

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar.

Note If you are using `Method` with a value of `'jackel2016'`, the `Limit` argument is ignored.

Data Types: `double`

`Tolerance` — Implied volatility search termination tolerance

`1e-6` (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

Note If you are using `Method` with a value of `'jackel2016'`, the `Tolerance` argument is ignored.

Data Types: `double`

`Method` — Method for computing implied volatility

`'jackel2016'` (default) | character vector with values `'search'` or `'jackel2016'` | string with values `"search"` or `"jackel2016"`

Method for computing implied volatility, specified as the comma-separated pair consisting of `'Method'` and a character vector with a value of `'search'` or `'jackel2016'` or a string with a value of `"search"` or `"jackel2016"`.

Data Types: `char` | `string`

Output Arguments

`Volatility` — Expected implied volatility values

vector

Expected implied volatility values, returned as a `NINST`-by-`1` vector. If no solution can be found, a `NaN` is returned.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `impvbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

impvbyrgw

Determine implied volatility using Roll-Geske-Whaley option pricing model for American call option

Syntax

```
Volatility = impvbyrgw(RateSpec,StockSpec,Settle,Maturity,Strike,OptPrice)
Volatility = impvbyrgw( ___ ,Name,Value)
```

Description

`Volatility = impvbyrgw(RateSpec,StockSpec,Settle,Maturity,Strike,OptPrice)` computes implied volatility using Roll-Geske-Whaley option pricing model for American call option.

Note `impvbyrgw` computes implied volatility of American calls with a single cash dividend using the Roll-Geske-Whaley option pricing model.

`Volatility = impvbyrgw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Implied Volatility Using the Roll-Geske-Whaley Option Pricing Model

This example shows how to compute the implied volatility using the Roll-Geske-Whaley option pricing model. Assume that on July 1, 2008 a stock is trading at $13 and pays a single cash dividend of $0.25 on November 1, 2008. The American call option with a strike price of $15 expires on July 1, 2009 and is trading at $1.346. The annualized continuously compounded risk-free rate is 5% per annum. Calculate the implied volatility of the stock using the Roll-Geske-Whaley option pricing model.

```
AssetPrice = 13;
Strike = 15;
Rates = 0.05;
Settle = datetime(2008,7,1);
Maturity = datetime(2009,7,1);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
 'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(NaN, AssetPrice, {'cash'}, 0.25, {'Nov 1,2008'});

Price = [1.346];
Volatility = impvbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike, Price)

Volatility = 0.3539
```

Input Arguments

`RateSpec` — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbyrgw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `impvbyrgw` also accepts serial date numbers as inputs, but they are not recommended.

`Strike` — Option strike price value
nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or `NINST`-by-`1` vector of strike price values. Each row is the schedule for one option.

Data Types: `double`

`OptPrice` — American option price
nonnegative scalar | nonnegative vector

American option prices from which the implied volatility of the underlying asset is derived, specified as a nonnegative scalar or `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Volatility = impvbyrgw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,OptPrice,'Limit',5,'Tolerance',1e-5)`

`Limit` — Upper bound of implied volatility search interval

`10` (1000% per annum) (default) | positive value

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar.

Data Types: `double`

`Tolerance` — Implied volatility search termination tolerance

`1e-6` (default) | positive scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive scalar.

Data Types: `double`

Output Arguments

`Volatility` — Expected implied volatility values

vector

Expected implied volatility values, returned as a `NINST`-by-`1` vector. If no solution can be found, a `NaN` is returned.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `impvbyrgw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instadd

Add types to instrument collection

Syntax

```
InstSetNew = instadd(InstSetOld,TypeString,Data)
```

Description

`InstSetNew = instadd(InstSetOld,TypeString,Data)` adds instruments to an existing instrument set `InstSet`. The output `InstSetNew` is a new instrument set containing the input data.

`InstSetNew` and `InstSetOld` store instruments of types `'Asian'`, `'Barrier'`, `'Bond'`, `'CBond'`, `'Cap'`, `'CashFlow'`, `'Compound'`, `'Fixed'`, `'Float'`, `'Floor'`, `'Lookback'`, `'OptBond'`, `'OptEmBond'`, `'OptEmFloat'`, `'RangeFloat'`,`'OptStock'`, `'Swap'`, or `'Swaption'`. Financial Instruments Toolbox provides pricing and sensitivity routines for these instruments.

Examples

Create a Portfolio with Two Cap Instruments and a 4% Bond

Define the bond:

```
Strike = [0.06; 0.07];
CouponRate = 0.04;
Settle = '06-Feb-2000';
Maturity = '15-Jan-2003';
```

Create a portfolio with two cap instruments and a 4% bond and then display the portfolio:

```
InstSet = instadd('Cap', Strike, Settle, Maturity);
InstSet = instadd(InstSet, 'Bond', CouponRate, Settle, Maturity);
instdisp(InstSet)
```

```
Index Type Strike Settle         Maturity       CapReset Basis Principal
1     Cap  0.06   06-Feb-2000    15-Jan-2003    1        0     100
2     Cap  0.07   06-Feb-2000    15-Jan-2003    1        0     100

Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
3     Bond 0.04       06-Feb-2000    15-Jan-2003    2      0     1            NaN       NaN
```

Input Arguments

`InstSetOld` — Existing instrument variable

structure

Existing instrument variable, specified as an `InstSet` structure.

`InstSetOld` can contain instruments of types `'Asian'`, `'Barrier'`, `'Bond'`, `'CBond'`, `'Cap'`, `'CashFlow'`, `'Compound'`, `'Fixed'`, `'Float'`, `'Floor'`, `'Lookback'`, `'OptBond'`, `'OptEmBond'`, `'OptEmFloat'`, `'RangeFloat'`, `'OptStock'`, `'Swap'`, or `'Swaption'`.

Data Types: `struct`

`TypeString` — Instrument type
character vector

Instrument type, specified as a character vector. The supported instrument types are:

- `'Asian'`
- `'Barrier'`
- `'Bond'`
- `'CBond'`
- `'Cap'`
- `'CashFlow'`
- `'Compound'`
- `'Fixed'`
- `'Float'`
- `'Floor'`
- `'Lookback'`
- `'OptBond'`
- `'OptEmBond'`
- `'OptEmFloat'`
- `'RangeFloat'`
- `'OptStock'`
- `'Swap'`
- `'Swaption'`

Note Each instrument type can have different `Data` fields.

Data Types: `char`

`Data` — Instrument data fields
vector

Instrument data fields, specified as a row vector or character vector for each instrument.

- `'Asian'` — For example:

  ```
  InstSet = instadd('Asian',OptSpec,Strike,Settle,ExerciseDates)
  ```

  For more information on Asian instrument arguments, see `instasian`.
- `'Barrier'` — For example:

  ```
  InstSet = instadd('Barrier',OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,BarrierType,Barrie
  ```

For more information on the Barrier instrument arguments, see `instbarrier`.

- `'Bond'` — For example:

  ```
  InstSet = instadd('Bond',CouponRate,Settle,Maturity,Period,Basis,EndMonthRule,IssueDate,FirstC
  ```

  For more information on the Bond instrument arguments , see `instbond`.

- `'CBond'` — For example:

  ```
  InstSet = instadd('CBond',CouponRate,Settle,Maturity,ConvRatio'CallStrike',CallStrike,'CallExD
  'PutExDates',PutExDates,'AmericanPut',AmericanPut,'Period',Period,'Face',Face,'Spread',Spread,
  LastCouponDate,'StartDate',StartDate)
  ```

  For more information on the CBond instrument arguments , see `instcbond`.

- `'Cap'` — For example:

  ```
  InstSet = instadd('Cap',Strike,Settle,Maturity,Reset,Basis,Principal)
  ```

  For more information on the Cap instrument arguments , see `instcap`.

- `'CashFlow'` — For example:

  ```
  InstSet = instadd('CashFlow',CFlowAmounts,CFlowDates,Settle,Basis)
  ```

  For more information on the Cash Flow instrument arguments , see `instcf`.

- `'Compound'` — For example:

  ```
  InstSet = instadd('Compound',UOptSpec,UStrike,USettle,UExerciseDates,UAmericanOpt,COptSpec,CSt
  ```

  For more information on the Compound instrument arguments , see `instcompound`.

- `'Fixed'` — For example:

  ```
  InstSet = instadd('Fixed',CouponRate,Settle,Maturity,Reset,Basis,Principal,EndMonthRule)
  ```

  For more information on the Fixed instrument arguments , see `instfixed`.

- `'Float'` — For example:

  ```
  InstSet = instadd('Float',Spread,Settle,Maturity,Reset,Basis,Principal,EndMonthRule,CapRate,Fl
  ```

  For more information on the Fixed instrument arguments , see `instfloat`.

- `'Floor'` — For example:

  ```
  InstSet = instadd('Floor',Strike,Settle,Maturity,Reset,Basis,Principal)
  ```

  For more information on the Floor instrument arguments , see `instfloor`.

- `'Lookback'` — For example:

  ```
  InstSet = instadd('Lookback',OptSpec,Strike,Settle,ExerciseDates,AmericanOpt)
  ```

  For more information on the Lookback instrument arguments , see `instlookback`.

- `'OptBond'` — For example:

  ```
  InstSet = instadd('OptBond',BondIndex,OptSpec,Strike,ExerciseDates,AmericanOpt)
  ```

  For more information on the Bond Option instrument arguments , see `instoptbnd`.

- `'OptStock'` — For example:

  ```
  InstSet = instadd('OptStock',OptSpec,Strike,Settle,Maturity,AmericanOpt)
  ```

  For more information on the Stock Option instrument arguments , see `instoptstock`.
- `'OptEmBond'` — For example:

  ```
  InstSet = instoptembnd(CouponRate, Settle, Maturity, OptSpec, Strike, ...
  ExerciseDates,'AmericanOpt', AmericanOpt, 'Period', Period)
  ```

  For more information on the Bond with embedded option instrument arguments , see `instoptembnd`.
- `'OptemFloat'` — For example:

  ```
  InstSet = instoptemfloat(Spread, Settle, Maturity, OptSpec, Strike, ...
  ExerciseDates,'FloatReset', Reset)
  ```

  For more information on the Floating Rate Note with an embedded option instrument arguments , see `instoptemfloat`.
- `'RangeFloat'` — For example:

  ```
  InstSet = instrangefloat(Spread, Settle, Maturity, RateSched)
  ```

  For more information on the Range Note instrument arguments , see `instrangefloat`.
- `'Swap'` — For example:

  ```
  InstSet = instadd('Swap',LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType,EndMonthRule
  ```

  For more information on the Swap instrument arguments , see `instswap`.
- `'Swaption'` — For example:

  ```
  InstSet = instadd('Swap',LegRate,Settle,Maturity,LegReset,Basis,Principal,LegType,EndMonthRule
  ```

  For more information on the Swaption instrument arguments , see `instswaption`.

Data Types: `char`

Output Arguments

`InstSetNew` — Instrument set containing the new input data

structure

`InstSetNew` is an instrument set containing the new input data, returned as a structure.

Version History

Introduced before R2006a

instaddfield

Add new instruments to instrument collection

Syntax

```
InstSetNew = instaddfield(InstSet,Name,Value)
InstSet = instaddfield(Name,Value)
```

Description

`InstSetNew = instaddfield(InstSet,Name,Value)` adds instruments to an existing instrument set `InstSet`. The output `InstSetNew` is a new instrument set containing the input data.

`InstSet = instaddfield(Name,Value)` creates an instrument variable `InstSet`.

Examples

Add New Instruments to Instrument Collection

Build a portfolio around the following July options.

```
Strike = (95:5:105)'
```

```
Strike = 3×1

    95
   100
   105
```

```
CallP = [12.2; 9.2; 6.8]
```

```
CallP = 3×1

   12.2000
    9.2000
    6.8000
```

Enter three call options with data fields `Strike`, `Price`, and `Opt`.

```
InstSet = instaddfield('Type','Option','FieldName',...
{'Strike','Price','Opt'}, 'Data',{ Strike, CallP, 'Call'});
instdisp(InstSet)
```

```
Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call
```

Add a futures contract and set the input parsing class.

```
InstSet = instaddfield(InstSet,'Type','Futures',...
'FieldName',{'Delivery','F'},'FieldClass',{'date','dble'},...
'Data' ,{'01-Jul-99',104.4 });
instdisp(InstSet)

Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4
```

Add a put option.

```
FN = instfields(InstSet,'Type','Option')

FN = 3x1 cell
    {'Strike'}
    {'Price' }
    {'Opt'   }

InstSet = instaddfield(InstSet,'Type','Option',...
'FieldName',FN, 'Data',{105, 7.4, 'Put'});
instdisp(InstSet)

Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4

Index Type   Strike Price Opt
5     Option 105     7.4  Put
```

Make a placeholder for another put.

```
InstSet = instaddfield(InstSet,'Type','Option',...
'FieldName','Opt','Data','Put')

InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {2x1 cell}
     FieldName: {2x1 cell}
    FieldClass: {2x1 cell}
     FieldData: {2x1 cell}

instdisp(InstSet)

Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
```

```
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4

Index Type   Strike Price Opt
5     Option 105     7.4  Put
6     Option NaN     NaN  Put
```

Add a cash instrument.

```
InstSet = instaddfield(InstSet, 'Type', 'TBill',...
'FieldName','Price','Data',99)

InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {3x1 cell}
     FieldName: {3x1 cell}
    FieldClass: {3x1 cell}
     FieldData: {3x1 cell}

instdisp(InstSet)

Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4

Index Type   Strike Price Opt
5     Option 105     7.4  Put
6     Option NaN     NaN  Put

Index Type  Price
7     TBill 99
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `InstSet = instaddfield('Type','Option','FieldName', {'Strike','Price','Opt'},'Data',{Strike,CallP,'Call'})`

`FieldName` — Name of each data field for instrument
cell array of character vectors

Name of each data field for an instrument, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Data` — Data contents for each field
array | cell array

Data contents for each field, specified as the comma-separated pair consisting of `'Data'` and an `NINST`-by-`M` array or `NFIELDS`-by-`1` cell array.

Data Types: `double` | `cell`

`FieldClass` — Data class of each field
vector

Data class of each field, specified as the comma-separated pair consisting of `'FieldClass'` and an `NFIELDS`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Type` — Type of instrument added
character vector

Type of instrument added, specified as the comma-separated pair consisting of `'Type'` and a character vector. Instruments of different types can have different `FieldName` collections.

Data Types: `char`

Output Arguments

`InstSetNew` — Instrument set variable containing new input data added to existing `InstSet`
structure

Instrument set variable containing the new input data added to an existing `InstSet` , returned as a structure.

`InstSet` — New Instrument set variable containing input data
structure

New Instrument set variable containing input data, returned as a structure.

Version History

Introduced before R2006a

instasian

Construct Asian option

Syntax

```
InstSet = instasian(OptSpec,Strike,Settle,ExerciseDates)
InstSet = instasian(InstSet,OptSpec,Strike,Settle,ExerciseDates)
InstSet = instasian( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)
[FieldList,ClassList,TypeString = instasian
```

Description

`InstSet = instasian(OptSpec,Strike,Settle,ExerciseDates)` creates a new instrument set containing Asian instruments.

`InstSet = instasian(InstSet,OptSpec,Strike,Settle,ExerciseDates)` adds Asian instruments to an existing instrument set.

`InstSet = instasian( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)` adds optional arguments.

`[FieldList,ClassList,TypeString = instasian` lists field meta-data for the Asian instrument.

Examples

Create an Asian Option Instrument

Load the example instrument set, `deriv.mat`, and set the required values for an asian option instrument.

```
load deriv.mat
```

Create a subportfolio with barrier and lookback options.

```
CRRSubSet = instselect(CRRInstSet,'Type',{'Barrier', 'Lookback'});
```

Define the asian instrument.

```
OptSpec = 'put';
Strike = NaN;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2004,1,1);
```

Add a floating strike asian option to the instrument set.

```
InstSet = instasian(CRRSubSet, OptSpec, Strike, Settle, ExerciseDates);
instdisp(InstSet)
```

```
Index Type    OptSpec Strike Settle         ExerciseDates  AmericanOpt BarrierSpec Barrier Rebate
1     Barrier call    105    01-Jan-2003    01-Jan-2006    1           ui          102     0
```

```
Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt Name      Quantity
2     Lookback call    115    01-Jan-2003    01-Jan-2006    0           Lookback1 7
3     Lookback call    115    01-Jan-2003    01-Jan-2007    0           Lookback2 9

Index Type  OptSpec Strike Settle         ExerciseDates  AmericanOpt AvgType    AvgPrice AvgDate
4     Asian put     NaN    01-Jan-2003    01-Jan-2004    0           arithmetic NaN      NaN
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding asian instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a scalar character vector or an `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price value

nonnegative integer | vector of nonnegative integer

Option strike price value, specified with a scalar nonnegative integer or an `NINST`-by-`1` vector of strike price values.

Data Types: `double`

`Settle` — Settlement dates or trade dates

datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instasian` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instasian` also accepts serial date numbers as inputs, but they are not recommended.

For a European option (when `AmericanOpt = 0`):

NINST-by-1 vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.

For an American option (when AmericanOpt = 1):

NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is an NINST-by-1, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.

AmericanOpt — Indicator for American option
0 (default) | integer value 0 or 1

(Optional) Indicator for American option, specified as a scalar or an NINST-by-1 vector.

If AmericanOpt = 0, NaN, or is unspecified, the option is a European option. If AmericanOpt = 1, the option is an American option.

Data Types: double

AvgType — Averaging type
'arithmetic' (default) | character vector with value 'arithmetic' or 'geometric'

(Optional) Averaging type, specified as a character vector with a value of 'arithmetic' for arithmetic average or 'geometric' for geometric average.

Data Types: char

AvgPrice — Average price of underlying asset at the Settle date
current stock price of the underlying asset (default) | numeric

(Optional) Average price of underlying asset at the Settle date, specified as a scalar numeric.

Note Use AvgPrice when AvgDate < Settle.

Data Types: double

AvgDate — Date averaging period begins
Settle date (default) | datetime array | string array | date character vector

(Optional) Date averaging period begins, specified as a scalar datetime, string, or date character vector.

To support existing code, instasian also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

InstSet — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the InstSet variable, see instget.

`FieldList` — Name of each data field for Asian instrument
cell array of character vectors

Name of each data field for an Asian instrument, returned as an `NFIELDS`-by-1 cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-1 cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For an Asian option instrument, `TypeString = 'Asian'`.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instasian` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instbarrier

Construct barrier option

Syntax

```
InstSet = instbarrier(OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,
BarrierSpec,Barrier,Rebate)
InstSet = instbarrier(InstSetOld,OptSpec,Strike,Settle,ExerciseDates,
AmericanOpt,BarrierSpec,Barrier,Rebate)
[FieldList,ClassList,TypeString] = instbarrier
```

Description

`InstSet = instbarrier(OptSpec,Strike,Settle,ExerciseDates,AmericanOpt, BarrierSpec,Barrier,Rebate)` constructs a barrier instrument.

Data arguments are `NINST`-by-`1` vectors, scalar, or empty. Fill in unspecified entries vectors with `NaN`. Only one data argument is required to create the instrument. The others can be omitted or passed as empty matrices `[]`.

`InstSet = instbarrier(InstSetOld,OptSpec,Strike,Settle,ExerciseDates, AmericanOpt,BarrierSpec,Barrier,Rebate)` adds barrier options to an existing instrument variable `InstSetOld`).

`[FieldList,ClassList,TypeString] = instbarrier` lists field metadata for the barrier instrument.

Examples

Create Two Barrier Option Instruments

Create an instrument set of two barrier options with the following data:

```
OptSpec = {'put';'call'};
Strike = 112;
Settle = datetime(2012,1,1);
ExerciseDates = datetime(2015,1,1);
BarrierSpec = {'do';'ui'};
Barrier = [101;102];
AmericanOpt = 0;
```

Create the instrument set (`InstSet`) for the two barrier options.

```
InstSet = instbarrier(OptSpec, Strike, Settle, ExerciseDates,AmericanOpt, BarrierSpec, Barrier);
```

Display the instrument set.

```
instdisp(InstSet)
```

```
Index Type    OptSpec Strike Settle         ExerciseDates  AmericanOpt BarrierSpec Barrier Rebate
1     Barrier put     112    01-Jan-2012    01-Jan-2015    0           do          101     0
```

```
2     Barrier call    112    01-Jan-2012    01-Jan-2015    0           ui          102     0
```

Input Arguments

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'`

Definition of an option as `'call'` or `'put'`, specified as a `NINST`-by-`1` list of character vector values.

Data Types: `char`

`Strike` — Option strike price value

integer

Option strike price value, specified as an `NINST`-by-`1` vector of strike values. Each row is the schedule for one option.

Data Types: `double`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement date for the barrier option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instbarrier` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option (`AmericanOpt = 0`), specified as a `NINST`-by-`1` matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one exercise date, the option expiry date.
- For an American option (`AmericanOpt = 1`), specified as a `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between the valuation date of the stock tree and the single listed exercise date.

To support existing code, `instbarrier` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Flag for American option

integer with values `0` or `1`

Flag for American option, specified as an integer with values `0` or `1`. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European option. If `AmericanOpt = 1`, the option is an American option.

Data Types: `logical`

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector with the following values:

- `'UI'` — Up Knock In

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.
- `'UO'` — Up Knock Out

  This option gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.
- `'DI'` — Down Knock In

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option.
- `'DO'` — Down Knock Up

  This option gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char`

`Barrier` — Barrier value
integer

Barrier value, specified as a vector of values.

Data Types: `double`

`Rebate` — Rebate value
integer

(Optional) Rebate value, specified as a vector of values.

Data Types: `double`

`InstSetOld` — Instrument variable
structure

(Optional) Instrument variable, this argument is specified only when adding barrier instruments to an existing instrument set. See `instget` for more information on the `InstSet` variable.

Data Types: `struct`

Output Arguments

`InstSet` — Instrument variable for barrier option
structure

Instrument variable for barrier option, returned as a structure. See `instget` for more information on the `InstSet` variable.

`FieldList` — Fields in `InstSet` instrument
cell array of character vectors

Fields in `InstSet` instrument are returned as a (`NFIELDS`-by-`1`) cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` — Data class of each field in `InstSet` instrument
cell array of character vectors

Data class of each field in `InstSet` instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument added to `InstSet` instrument
character vector

Type of instrument added to `InstSet` instrument, returned as a character vector specifying the type of instrument added. For a barrier option instrument, `TypeString = 'Barrier'`.

More About

Barrier Option

A barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `instbarrier` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instbond

Construct bond instrument

Syntax

```
InstSet = instbond(CouponRate,Settle,Maturity)
InstSet = instbond(InstSet,CouponRate,Settle,Maturity)
InstSet = instbond( ___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate,
LastCouponDate,StartDate,Face)
[FieldList,ClassList,TypeString] = instbond
```

Description

`InstSet = instbond(CouponRate,Settle,Maturity)` creates a new instrument set containing Bond instruments.

`InstSet = instbond(InstSet,CouponRate,Settle,Maturity)` adds Bond instruments to an existing instrument set.

`InstSet = instbond( ___ ,Period,Basis,EndMonthRule,IssueDate,FirstCouponDate, LastCouponDate,StartDate,Face)` adds optional arguments.

`[FieldList,ClassList,TypeString] = instbond` lists field meta-data for the Bond instrument.

Examples

Create a Bond Instrument

Create a new instrument variable with the following information:

```
CouponRate= [0.035;0.04];
Settle= datetime(2013,11,1);
Maturity = datetime(2014,11,1);
Period =1;

InstSet = instbond(CouponRate, Settle, Maturity, ...
Period)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Bond'}
     FieldName: {{11x1 cell}}
    FieldClass: {{11x1 cell}}
     FieldData: {{11x1 cell}}
```

Display the instrument set.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.035      01-Nov-2013    01-Nov-2014    1      0     1            NaN       NaN
2     Bond 0.04       01-Nov-2013    01-Nov-2014    1      0     1            NaN       NaN
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Bond instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`CouponRate` — Coupon rate indicating the annual percentage rate

decimal

Coupon rate indicating the annual percentage rate, specified as an `NINST`-by-`1` vector or an `NINST`-by-`1` cell array of decimal annual rates, or decimal annual rate schedules. For the latter case of a variable coupon schedule, each element of the cell array is a `NumDates`-by-`2` cell array, where the first column is dates and the second column is its associated rate. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement dates

datetime array | string array | date character vector

Settlement dates, specified as scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note `Settle` must be earlier than `Maturity`.

To support existing code, `instbond` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity dates

datetime array | string array | date character vector

Maturity dates, specified as scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instbond` also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Coupons per year

2 per year (default) | vector

(Optional) Coupons per year, specified as a scalar or an `NINST`-by-`1` vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as scalar or an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as a scalar or a nonnegative integer [`0`, `1`] using an `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond's coupon payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

(Optional) Bond issue date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instbond` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

(Optional) Irregular first coupon date, specified as a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instbond also accepts serial date numbers as inputs, but they are not recommended.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

(Optional) Irregular last coupon date, specified as a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instbond also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
Settle date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instbond also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as a scalar or an NINST-by-1 vector of nonnegative face values or an NINST-by-1 cell array of face values or face value schedules. For the latter case, each element of the cell array is a NumDates-by-2 cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid.

Data Types: cell | double

Output Arguments

InstSet — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the InstSet variable, see instget.

`FieldList` — Name of each data field for Bond instrument
cell array of character vectors

Name of each data field for a Bond instrument, returned as an `NFIELDS`-by-1 cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-1 cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Bond instrument, `TypeString = 'Bond'`.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `instbond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instcap

Construct cap instrument

Syntax

```
InstSet = instcap(Strike,Settle,Maturity)
InstSet = instcap(InstSet,Strike,Settle,Maturity)
InstSet = instcap( ___ ,CapReset,Basis,Principal)
[FieldList,ClassList,TypeString] = instcap
```

Description

`InstSet = instcap(Strike,Settle,Maturity)` creates a new instrument set containing Cap instruments.

`InstSet = instcap(InstSet,Strike,Settle,Maturity)` adds Cap instruments to an existing instrument set.

`InstSet = instcap( ___ ,CapReset,Basis,Principal)` adds optional arguments.

`[FieldList,ClassList,TypeString] = instcap` lists field meta-data for the Cap instrument.

Examples

Create Two Cap Instruments

Create a new instrument variable with the following information:

```
Strike = [0.035; 0.045];
Settle= datetime(2013,1,1);
Maturity = datetime(2043,1,1);
Reset = 1;
Basis = 1;
Principal = 1000;
```

Create the new cap instruments.

```
InstSet = instcap(Strike, Settle, Maturity, Reset, Basis, Principal)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Cap'}
     FieldName: {{6x1 cell}}
    FieldClass: {{6x1 cell}}
     FieldData: {{6x1 cell}}
```

Display the cap instruments.

```
instdisp(InstSet)
```

```
Index Type Strike Settle         Maturity       CapReset Basis Principal
1     Cap  0.035  01-Jan-2013    01-Jan-2043    1        1     1000
2     Cap  0.045  01-Jan-2013    01-Jan-2043    1        1     1000
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Cap instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised

decimal

Rate at which the Cap is exercised, specified as a scalar or an `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement dates

datetime array | string array | date character vector

Settlement dates, specified as scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note `Settle` must be earlier than `Maturity`.

To support existing code, `instcap` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity dates

datetime array | string array | date character vector

Maturity dates, specified as scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instcap` also accepts serial date numbers as inputs, but they are not recommended.

`CapReset` — Reset frequency payment per year

`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a scalar or an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as scalar or an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a scalar or an `NINST`-by-`1` of notional principal amounts, or an `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing Cap.

Data Types: `double` | `cell`

Output Arguments

`InstSet` — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Cap instrument
cell array of character vectors

Name of each data field for a Cap instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Cap option instrument, `TypeString = 'Cap'`.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

max(*CurrentRate* − *CapRate*, 0)

For more information, see “Cap” on page 2-12.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `instcap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instcbond

Construct CBond instrument for convertible bond

Syntax

```
ISet = instcbond(CouponRate,Settle,Maturity,ConvRatio)
ISet = instcbond( ___ ,Name,Value)

ISet = instcbond(ISet,CouponRate,Settle,Maturity,ConvRatio)
ISet = instcbond( ___ ,Name,Value)

[FieldList,ClassList,TypeString] = instcbond
```

Description

`ISet = instcbond(CouponRate,Settle,Maturity,ConvRatio)` creates a `CBond` instrument variable from data arrays.

`ISet = instcbond( ___ ,Name,Value)` creates a `CBond` instrument variable from data arrays using optional name-value pair arguments.

`ISet = instcbond(ISet,CouponRate,Settle,Maturity,ConvRatio)` adds a `CBond` to an existing instrument set.

`ISet = instcbond( ___ ,Name,Value)` adds a `CBond` instrument to an existing instrument set using optional name-value pair arguments.

`[FieldList,ClassList,TypeString] = instcbond` lists the field metadata for the `CBond` instrument.

Examples

Create a CBond Instrument

Create a `CBond` instrument.

```
CouponRate = 0.03;
Settle = datetime(2014,1,1);
Maturity = datetime(2016,1,1);
CallStrike = 125;
CallExDates = [datetime(2015,1,1) datetime(2016,1,1)];

ConvRatio = 1.5;
Spread = 0.045;

InstSet = instcbond(CouponRate,Settle,Maturity,ConvRatio,...
'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,...
'AmericanCall', 1);
```

Display the `InstSet` for the convertible bond.

```
instdisp(InstSet)
```

```
Index Type  CouponRate Settle         Maturity       ConvRatio Period IssueDate FirstCouponDate
1     CBond 0.03       01-Jan-2014    01-Jan-2016    1.5       2      NaN       NaN
```

Add a CBond Instrument to an Existing Portfolio Set

Create a bond instrument using `instbond`.

```
CouponRate= [0.035;0.04];
Settle= 'Nov-1-2013';
Maturity = 'Nov-1-2014';
Period =1;

InstSet = instbond(CouponRate,Settle,Maturity, ...
Period);
```

Add a `CBond` instrument to the existing portfolio set.

```
ConvRatio = 1.5;
InstSet = instadd(InstSet,'CBond',CouponRate,Settle,Maturity,ConvRatio);
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCoup
1     Bond 0.035      01-Nov-2013    01-Nov-2014    1      0     1            NaN       NaN
2     Bond 0.04       01-Nov-2013    01-Nov-2014    1      0     1            NaN       NaN

Index Type  CouponRate Settle         Maturity       ConvRatio Period IssueDate FirstCouponDate
3     CBond 0.035      01-Nov-2013    01-Nov-2014    1.5       2      NaN       NaN
4     CBond 0.04       01-Nov-2013    01-Nov-2014    1.5       2      NaN       NaN
```

```
[FieldList,ClassList,TypeString] = instcbond
```

```
FieldList = 20x1 cell
    {'CouponRate'        }
    {'Settle'            }
    {'Maturity'          }

    {'dble'}
    {'dble'}

TypeString =
'CBond'
```

Input Arguments

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` positive decimal annual rate or an `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every convertible bond is set to the `ValuationDate` of the stock tree. The bond argument, `Settle`, is ignored.

To support existing code, `instcbond` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instcbond also accepts serial date numbers as inputs, but they are not recommended.

ConvRatio — Number of shares convertible to one bond
nonnegative scalar

Number of shares convertible to one bond, specified as an NINST-by-1 nonnegative vector.

Data Types: double

ISet — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, specified as a structure. Use thus argument to add a CBond (convertible bond) to an existing instrument set (ISet). Instruments within ISet are broken down by type, and each type can have different data fields. For more information on theISet variable, see instget.

Data Types: struct

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: InstSet = instcbond(CouponRate,Settle,Maturity,ConvRatio,'Spread',Spread,'CallExDates', CallExDates,'CallStrike',CallStrike,'AmericanCall', 1)

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instcbond also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-1 vector using a datetime array, string array, or date character vectors

To support existing code, `instcbond` also accepts serial date numbers as inputs, but they are not recommended.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `instcbond` also accepts serial date numbers as inputs, but they are not recommended.

`Face` — Face value
`100` (default) | scalar of nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-1 scalar of nonnegative face values or an `NINST`-by-1 cell array, where each element is a `NumDates`-by-2 cell array. The first column of the `NumDates`-by-2 cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`Spread` — Number of basis points over the reference rate
`0` (default) | vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of `'Spread'` and a `NINST`-by-1 vector.

Data Types: `double`

`CallStrike` — Call strike price for European, Bermuda, or American option
nonnegative integer | vector of nonnegative integers

Call strike price for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallStrike'` and one of the following values:

- For a European call option — `NINST`-by-1 vector of nonnegative integers
- For a Bermuda call option — `NINST`-by-`NSTRIKES` matrix of strike price values, where each row is the schedule for one call option. If a call option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American call option — `NINST`-by-1 vector of strike price values for each call option.

Data Types: `double`

`CallExDates` — Call exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Call exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallExDates'` and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — NINST-by-1 vector of date character vectors.
- For a Bermuda option — NINST-by-NSTRIKES matrix of exercise dates, where each row is the schedule for one call option. For a European option, there is only one CallExDate on the option expiry date.
- For an American option — NINST-by-1 or NINST-by-2 matrix of exercise date boundaries. For each instrument, the call option can be exercised on any tree date between or including the pair of dates on that row. If CallExDates is NINST-by-1, the call option can be exercised between the ValuationDate of the stock tree and the single listed CallExDate.

To support existing code, instcbond also accepts serial date numbers as inputs, but they are not recommended.

AmericanCall — Call option type indicator
0 if AmericanCall is NaN or not entered (default) | scalar | vector of positive integers[0,1]

Call option type, specified as the comma-separated pair consisting of 'AmericanCall' and a NINST-by-1 vector with positive integer flags with values 0 or 1.

- For a European or Bermuda option — AmericanCall is 0 for each European or Bermuda option.
- For an American option — AmericanCall is 1 for each American option. The AmericanCall argument is required to invoke American exercise rules.

Data Types: double

PutStrike — Put strike values for European, Bermuda, or American option
scalar | vector of positive integers[0,1]

Put strike values for a European, Bermuda, or American option, specified as the comma-separated pair consisting of 'PutStrike' and one of the following values:

- For a European put option — NINST-by-1 vector of nonnegative integers
- For a Bermuda put option — NINST-by-NSTRIKES matrix of strike price values, where each row is the schedule for one put option. If a put option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American put option — NINST-by-1 vector of strike price values for each put option.

Data Types: double

PutExDates — Put exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Put exercise date for a European, Bermuda, or American option, specified as the comma-separated pair consisting of 'PutExDates' and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — NINST-by-1 vector date character vectors.
- For a Bermuda option — NINST-by-NSTRIKES matrix of exercise dates, where each row is the schedule for one put option. For a European option, there is only one PutExDate on the option expiry date.
- For an American option — NINST-by-1 or NINST-by-2 matrix of exercise date boundaries. For each instrument, the put option can be exercised on any tree date between or including the pair of dates on that row. If PutExDates is NINST-by-1, the put option can be exercised between the ValuationDate of the stock tree and the single listed PutExDate.

To support existing code, `instcbond` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanPut` — Put option type indicator
`0` if `AmericanPut` is `NaN` or not entered (default) | scalar | vector of positive integers`[0,1]`

Put option type, specified as the comma-separated pair consisting of `'AmericanPut'` and a `NINST`-by-`1` vector with positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanPut` is `0` for each European or Bermuda option.
- For an American option — `AmericanPut` is `1` for each American option. The `AmericanPut` argument is required to invoke American exercise rules.

Data Types: `double`

`ConvDates` — Convertible dates
`MaturityDate` (default) | datetime array | string array | date character vector

Convertible dates, specified as the comma-separated pair consisting of `'ConvDates'` and a `NINST`-by-`1` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors. If `ConvDates` is not specified, the bond is always convertible until maturity.

To support existing code, `instcbond` also accepts serial date numbers as inputs, but they are not recommended.

For each instrument, the bond can be converted on any tree date between or including the pair of dates on that row.

If `ConvDates` is `NINST`-by-`1`, the bond can be converted between the `ValuationDate` of the stock tree and the single listed `ConvDates`.

Output Arguments

`ISet` — Variable containing a collection of instruments
character vector | row vector

Variable containing a collection of instruments, returned as a row vector or character vector for each instrument. Instruments are broken down by type and each type can have different data fields. For more information on the`ISet` variable, see `instget`.

`FieldList` — Name of each data field for instrument type
cell array of character vectors

Name of each data field for instrument type, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class of each field
cell array of character vectors with valid values of `'dble'`, `'date'`, and `'char'`

Data class of each field, returned as an `NFIELDS`-by-`1` cell array of character vectors with valid character vector values of `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument added
character vector

Type of instrument added, returned as character vector. When adding a `CBond`, the `TypeString = 'CBond'`.

Version History

Introduced in R2015a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instcbond` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Convertible Bond” on page 2-4

instcf

Construct cash flow instrument

Syntax

```
InstSet = instcf(CFlowAmounts,CFlowDates,Settle)
InstSet = instcf(InstSet,CFlowAmounts,CFlowDates,Settle)
InstSet = instcf( ___ ,Basis)
[FieldList,ClassList,TypeString] = instcf
```

Description

`InstSet = instcf(CFlowAmounts,CFlowDates,Settle)` creates a new instrument set containing CashFlow instruments.

`InstSet = instcf(InstSet,CFlowAmounts,CFlowDates,Settle)` adds CashFlow instruments to an existing instrument set.

`InstSet = instcf( ___ ,Basis)` adds an optional argument.

`[FieldList,ClassList,TypeString] = instcf` lists field meta-data for the CashFlow instrument.

Examples

Create Two Cash Flow Instruments

Create a new instrument variable with the following information:

```
CFlowAmounts =[5 NaN 5.5 105; 5 0 6 105];
CFlowDates = [732678, NaN, 733408,733774;
              732678, 733034, 733408, 734774];
Settle= 'Jan-1-2015';
Basis = 1;
```

Create the new cash flow instruments.

```
InstSet = instcf(CFlowAmounts,CFlowDates,Settle,Basis)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'CashFlow'}
     FieldName: {{4x1 cell}}
    FieldClass: {{4x1 cell}}
     FieldData: {{4x1 cell}}
```

Display the cash flow instruments.

```
instdisp(InstSet)
```

```
Index Type     CFlowAmounts                                CFlowDates
1     CashFlow 5           NaN           5.5           105 01-Jan-2006      NaN        01-Jan-200
2     CashFlow 5             0             6           105 01-Jan-2006   23-Dec-2006   01-Jan-200
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding CashFlow instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, specified as a number of instruments (`NINST`) by maximum number of cash flows (`MOSTCFS`) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

serial date number

Cash flow dates, specified as an `NINST`-by-`MOSTCFS` vector using serial date numbers. Each entry contains the date of the corresponding cash flow in `CFlowAmounts`.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date on which the cash flows are priced, specified as a scalar serial date number or date character vector.

Data Types: `double` | `char`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as scalar or an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`InstSet` — Variable containing a collection of instruments

structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for CashFlow instrument

cell array of character vectors

Name of each data field for a CashFlow instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field

cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument

character vector

Type of instrument, returned as a character vector. For a CashFlow instrument, `TypeString = 'CashFlow'`.

Version History

Introduced before R2006a

“Supported Interest-Rate Instrument Functions” on page 2-3

instcompound

Construct compound option

Syntax

```
InstSet = instcompound(UOptSpec,UStrike,USettle,UExerciseDates,UAmericanOpt,
COptSpec,CStrike,CSettle,CExerciseDates,CAmericanOpt)
InstSet = instcompound(InstSet,UOptSpec,UStrike,USettle,UExerciseDates,
UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates,CAmericanOpt)
[FieldList,ClassList,TypeString] = instcompound
```

Description

`InstSet = instcompound(UOptSpec,UStrike,USettle,UExerciseDates,UAmericanOpt, COptSpec,CStrike,CSettle,CExerciseDates,CAmericanOpt)` creates a new instrument set containing Compound option instruments.

`InstSet = instcompound(InstSet,UOptSpec,UStrike,USettle,UExerciseDates, UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates,CAmericanOpt)` adds Compound option instruments to an existing instrument set.

`[FieldList,ClassList,TypeString] = instcompound` lists field meta-data for the Compound option instrument.

Examples

Create a Compound Option Instrument

Define a compound option instrument with the following data:

```
UOptSpec = 'Call';
UStrike = 130;
USettle = datetime(2012,1,1);
UExerciseDates = datetime(2015,1,1);
UAmericanOpt = 0;
COptSpec = 'Put';
CStrike = 5;
CSettle = datetime(2012,1,1);
CExerciseDates = datetime(2014,1,1);
CAmericanOpt = 0;

InstSet = instcompound(UOptSpec, UStrike, USettle,UExerciseDates, ...
UAmericanOpt, COptSpec, CStrike, CSettle,CExerciseDates, CAmericanOpt)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Compound'}
     FieldName: {{10x1 cell}}
    FieldClass: {{10x1 cell}}
```

```
     FieldData: {{10x1 cell}}
```

```
InstSet = instcompound(UOptSpec, UStrike, USettle,UExerciseDates, ...
UAmericanOpt, COptSpec, CStrike, CSettle,CExerciseDates)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Compound'}
     FieldName: {{10x1 cell}}
    FieldClass: {{10x1 cell}}
     FieldData: {{10x1 cell}}
```

Display the instrument set.

```
instdisp(InstSet)
```

```
Index Type     UOptSpec UStrike USettle        UExerciseDates UAmericanOpt COptSpec CStrike CSet
1     Compound Call     130     01-Jan-2012    01-Jan-2015    0            Put      5       01-Ja
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Compound option instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`UOptSpec` — Definition of underlying option

character vector with value `'call'` or `'put'`

Definition of underlying option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`UStrike` — Underlying option strike price value

nonnegative integer

Underlying option strike price value, specified with a nonnegative integer using a 1-by-1 vector.

Data Types: `double`

`USettle` — Underlying option settlement date or trade date

datetime array | string array | date character vector

Underlying option settlement date or trade date, specified as a 1-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `instcompound` also accepts serial date numbers as inputs, but they are not recommended.

`UExerciseDates` — Underlying option exercise date
datetime array | string array | date character vector

Underlying option exercise date, specified as a datetime array, string array, or date character vectors:

- For a European option, use a `1`-by-`1` vector of the underlying exercise date. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `1`-by-`2` vector of the underlying exercise date boundaries. The option can be exercised on any tree date. If only one non-`NaN` date is listed, or if `ExerciseDates` is `1`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `instcompound` also accepts serial date numbers as inputs, but they are not recommended.

`UAmericanOpt` — Underlying option type
`0` European (default) | scalar with values `0` or `1`

Underlying option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

If `UAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

`COptSpec` — Definition of compound option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of compound option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`CStrike` — Compound option strike price values
nonnegative integers

Compound option strike price values for a European and American option, specified with a nonnegative integer using a `NINST`-by-`1` matrix. Each row is the schedule for one option.

Data Types: `double`

`CSettle` — Compound option settlement date or trade date
datetime array | string array | date character vector

Compound option settlement date or trade date, specified as a `1`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instcompound` also accepts serial date numbers as inputs, but they are not recommended.

`CExerciseDates` — Compound option exercise dates
datetime array | string array | date character vector

Compound option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of the compound exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of the compound exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `instcompound` also accepts serial date numbers as inputs, but they are not recommended.

`CAmericanOpt` — Compound option type
`0` European (default) | scalar with values `0` or `1`

(Optional) Compound option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

If `CAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

Output Arguments

`InstSet` — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Compound option instrument
cell array of character vectors

Name of each data field for a Compound option instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Compound option instrument, `TypeString = 'Compound'`.

More About

Compound Option

A compound option is basically an option on an option; it gives the holder the right to buy or sell another option.

With a compound option, a vanilla stock option serves as the underlying instrument. Compound options thus have two strike prices and two exercise dates. For more information, see “Compound Option” on page 3-23.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instcompound` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instdelete

Complement of instrument set by matching conditions

Syntax

```
ISubSet = instdelete(InstSet,Name,Value)
```

Description

`ISubSet = instdelete(InstSet,Name,Value)` deletes instruments are from `ISubSet` if all the name-value pairs `Field`, `Index`, and `Type` conditions are met. An instrument meets an individual `Field` condition if the stored data matches any of the rows listed in the `Data`.

Examples

Remove Instrument from Instrument Set

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. The variable contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Create a new variable, `ISet`, with all `Options` deleted.

```
ISet = instdelete(ExampleInst, 'Type','Option');
instdisp(ISet)
```

```
Index Type    Delivery       F     Contracts
1     Futures 01-Jul-1999    104.4 -1000

Index Type  Price Maturity       Contracts
2     TBill 99    01-Jul-1999    6
```

Input Arguments

`InstSet` — Instrument variable for collection of instruments

structure

Instrument variable for a collection of instruments, specified as an instrument set structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ISet = instdelete(ExampleInst,'Type','Option')`

`FieldName` — Number of fields

vector

Number of fields, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-`1` cell array of character vectors listing the name of each data field to match with data values.

Data Types: `char` | `cell`

`Data` — Number of values

vector

Number of values, specified as the comma-separated pair consisting of `'Data'` and a `NVALUES`-by-`M` array or `NFIELDS`-by-`1` cell array of acceptable data values for each field. Each row lists a data row value to search for in the corresponding `FieldName`. The number of columns is arbitrary and matching ignores trailing `NaN`s or spaces.

Data Types: `char` | `cell`

`Index` — Number of instruments

vector

Number of instruments, specified as the comma-separated pair consisting of `'Index'` and a `NINST`-by-`1` vector restricting positions of instruments to check for matches. The default is all indices available in the instrument variable.

Data Types: `char` | `cell`

`Type` — Number of types

vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments to match one of types. The default is all types in the instrument variable.

Data Types: `char` | `cell`

Output Arguments

`ISubSet` — Updated variable containing a collection of instruments

structure

Updated variable containing a collection of instruments, returned as an instrument set structure. `ISubSet` contains instruments *not* matching the input criteria. Instruments are deleted from `ISubSet` if all the `Field`, `Index`, and `Type` conditions are met. An instrument meets an individual `Field` condition if the stored data matches any of the rows listed in the `Data`. See `instfind` for more examples on matching criteria.

instdisp

Display instruments

Syntax

```
CharTable = instdisp(InstSet)
```

Description

`CharTable = instdisp(InstSet)` creates a character array displaying the contents of an instrument collection `InstSet`. If `instdisp` is called without an output argument, the table is displayed in the Command Window.

Note When using `instdisp`, a value of `NaN` in one of the columns for an instrument indicates that the default value for that parameter will be used in the instrument's pricing function.

Examples

Retrieve Instrument from Instrument Set

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Create a swap instrument and use `instdisp` to display the instrument. Notice that value of `NaN` in two columns for this instrument indicates that the default values for `LegReset` and `LegType` parameters will be used in the swap instrument's pricing function.

```
LegRate1 = [0.065, 0];
Settle1 = datetime(2007,1,1);
Maturity1 = datetime(2012,1,1);
```

```
ISet = instswap(LegRate1, Settle1, Maturity1);
instdisp(ISet)

Index Type LegRate    Settle         Maturity       LegReset Basis Principal LegType EndMonthRule
1     Swap [0.065  0] 01-Jan-2007    01-Jan-2012    [NaN]    0     100       [NaN]   1
```

Input Arguments

`InstSet` — Instrument variable for collection of instruments

structure

Instrument variable for a collection of instruments, specified as an instrument set structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Output Arguments

`CharTable` — Table of instruments

array

Table of instruments, returned as a character array. For each instrument row, the `Index` and `Type` are printed along with the field contents. Field headers are printed at the tops of the columns.

instfields

List field names

Syntax

```
FieldList = instfields(InstSet,Name,Value)
```

Description

`FieldList = instfields(InstSet,Name,Value)` retrieves the list of fields stored in an instrument variable for the name-value pair argument `Type`.

Examples

Obtain Field Information for Instrument in Instrument Set

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Get the fields listed for type `'Option'`.

```
[FieldList, ClassList] = instfields(ExampleInst, 'Type','Option')
```

```
FieldList = 4x1 cell
    {'Strike'   }
    {'Price'    }
    {'Opt'      }
    {'Contracts'}

ClassList = 4x1 cell
    {'dble'}
    {'dble'}
```

```
    {'char'}
    {'dble'}
```

Get the fields listed for types `'Option'` and `'TBill'`.

```
FieldList = instfields(ExampleInst, 'Type', {'Option', 'TBill'})
```

```
FieldList = 5x1 cell
    {'Strike'   }
    {'Opt'      }
    {'Price'    }
    {'Maturity' }
    {'Contracts'}
```

Get all the fields listed in any type in the variable.

```
FieldList = instfields(ExampleInst)
```

```
FieldList = 7x1 cell
    {'Delivery' }
    {'F'        }
    {'Strike'   }
    {'Opt'      }
    {'Price'    }
    {'Maturity' }
    {'Contracts'}
```

Input Arguments

`InstSet` — Instrument variable for collection of instruments

structure

Instrument variable for a collection of instruments, specified as an instrument set structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `FieldList = instfields(ExampleInst,'Type','Option')`

Type — Number of types

vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments to match one of the types. The default is all types in the instrument variable.

Data Types: `char` | `cell`

Output Arguments

`FieldList` — Number of fields

structure

Number of fields, returned as an `NFIELDS`-by-`1` cell array of character vectors listing the name of each data field corresponding to the listed `Type`.

Version History

Introduced before R2006a

instfind

Search instruments for matching conditions

Syntax

```
IndexMatch = instfind(InstSet,'Field','Data')
IndexMatch = instfind( ___ ,Name,Value)
```

Description

`IndexMatch = instfind(InstSet,'Field','Data')` returns indices of instruments matching name-value pair arguments for `'Field'` and `'Data'`.

`IndexMatch = instfind( ___ ,Name,Value)` adds optional name-value pair arguments for `Index` and `Type`.

Examples

Search Instruments in Instrument Set for Matching Information

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Make a vector, `Opt95`, containing the indexes within `ExampleInst` of the options struck at `95`.

```
Opt95 = instfind(ExampleInst, 'FieldName','Strike','Data','95')
```

```
Opt95 = 2×1

     1
     6
```

Locate the futures and Treasury bill instruments within `ExampleInst`.

```
Types = instfind(ExampleInst,'Type',{'Futures';'TBill'})
```

```
Types = 2×1

     4
     7
```

Input Arguments

`InstSet` — Instrument variable for collection of instruments

structure

Instrument variable for a collection of instruments, specified as an instrument set structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `IndexMatch = instfind(ExampleInst,'Type',{'Futures';'TBill'})`

`Field` — Number of fields

vector

Number of fields, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-`1` cell array of character vectors listing the name of each data field to match with data values.

Data Types: `char` | `cell`

`Data` — Number of values

vector

Number of values, specified as the comma-separated pair consisting of `'Data'` and a `NVALUES`-by-`M` array or `NFIELDS`-by-`1` cell array of acceptable data values for each field. Each row lists a data row value to search for in the corresponding `FieldName`. The number of columns is arbitrary and matching ignores trailing `NaN`s or spaces.

Data Types: `char` | `cell`

`Index` — Number of instruments

vector

Number of instruments, specified as the comma-separated pair consisting of `'Index'` and a `NINST`-by-`1` vector restricting positions of instruments to check for matches. The default is all indices available in the instrument variable.

Data Types: `char` | `cell`

Type — Number of types
vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments to match one of types. The default is all types in the instrument variable.

Data Types: `char` | `cell`

Output Arguments

`IndexMatch` — Positions of instruments matching the input criteria
structure

Positions of instruments matching the input criteria, returned as an `NINST`-by-`1` vector of positions of instruments matching the input criteria. Instruments are returned in `IndexMatch` if all the `Field`, `Index`, and `Type` conditions are met.

Version History

Introduced before R2006a

instfixed

Construct fixed-rate instrument

Syntax

```
InstSet = instfixed(CouponRate,Settle,Maturity)
InstSet = instfixed(InstSet,CouponRate,Settle,Maturity)
InstSet = instfixed( ___ ,FixedReset,Basis,Principal,EndMonthRule)
[FieldList,ClassList,TypeString] = instfixed
```

Description

`InstSet = instfixed(CouponRate,Settle,Maturity)` creates a new instrument set containing Fixed-Rate instruments.

`InstSet = instfixed(InstSet,CouponRate,Settle,Maturity)` adds Fixed-Rate instruments to an existing instrument set.

`InstSet = instfixed( ___ ,FixedReset,Basis,Principal,EndMonthRule)` adds optional arguments.

`[FieldList,ClassList,TypeString] = instfixed` lists field meta-data for the Fixed-Rate instrument.

Examples

Create a Fixed-Rate Instrument

Define the characteristics of the fixed-rate instrument.

```
CouponRate = .03;
Settle = datetime(2013,3,15);
Maturity = datetime(2018,3,15);
FixedReset = 4;
Basis = 1;
Principal = 1000;
EndMonthRule = 1;
```

Create the new cap instrument.

```
ISet = instfixed(CouponRate, Settle, Maturity, FixedReset, Basis, Principal,EndMonthRule)
```

```
ISet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Fixed'}
     FieldName: {{7x1 cell}}
    FieldClass: {{7x1 cell}}
     FieldData: {{7x1 cell}}
```

Display the fixed-rate instrument.

```
instdisp(ISet)
```

```
Index Type  CouponRate Settle         Maturity       FixedReset Basis Principal EndMonthRule
1     Fixed 0.03       15-Mar-2013    15-Mar-2018    4          1     1000      1
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Cap instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`CouponRate` — Coupon annual rate

decimal

Coupon annual rate, specified as a scalar or an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the fixed-rate instrument, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instfixed` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each fixed-rate note.

To support existing code, `instfixed` also accepts serial date numbers as inputs, but they are not recommended.

`FixedReset` — Frequency of payments per year

`1` (default) | vector

(Optional) Frequency of payments per year, specified as a scalar or an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day count basis, specified as a scalar or an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

(Optional) Notional principal amounts, specified as a scalar, vector, or cell array.

`Principal` accepts a `NINST`-by-`1` vector or `NINST`-by-`1` cell array, where each element of the cell array is a `NumDates`-by-`2` cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as a nonnegative integer `0` or `1` using a scalar or an `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`InstSet` — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Fixed-Rate instrument
cell array of character vectors

Name of each data field for a Fixed-Rate instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Fixed-Rate instrument, `TypeString = 'Fixed'`.

More About

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-9.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instfixed` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instfloat

Construct floating-rate instrument

Syntax

```
InstSet = instfloat(Spread,Settle,Maturity)
InstSet = instfloat(InstSet,Spread,Settle,Maturity)
InstSet = instfloat( ___ ,FloatReset,Basis,Principal,EndMonthRule,CapRate,
FloorRate)
[FieldList,ClassList,TypeString] = instfixed
```

Description

`InstSet = instfloat(Spread,Settle,Maturity)` creates a new instrument set containing Float instruments.

`InstSet = instfloat(InstSet,Spread,Settle,Maturity)` adds Float instruments to an existing instrument set.

`InstSet = instfloat( ___ ,FloatReset,Basis,Principal,EndMonthRule,CapRate, FloorRate)` adds optional arguments.

`[FieldList,ClassList,TypeString] = instfixed` lists field meta-data for the Float instrument.

Examples

Create a Floating-Rate Instrument

Define the characteristics of the floating-rate instrument.

```
Spread = 2;
Settle = datetime(2013,3,15);
Maturity = datetime(2013,3,18);
FloatReset = 4;
Basis = 1;
Principal = 1000;
EndMonthRule = 1;
CapRate = 0.35;
FloorRate = 0.27;
```

Create the new floating-rate instrument.

```
ISet = instfloat(Spread, Settle, Maturity, FloatReset, Basis, Principal, ...
EndMonthRule, CapRate, FloorRate)
```

```
ISet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Float'}
```

```
     FieldName: {{9x1 cell}}
    FieldClass: {{9x1 cell}}
     FieldData: {{9x1 cell}}
```

Display the floating-rate instrument.

```
instdisp(ISet)
```

```
Index Type  Spread Settle         Maturity       FloatReset Basis Principal EndMonthRule CapRate
1     Float 2      15-Mar-2013    18-Mar-2013    4          1     1000      1            0.35
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Float instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

vector

Number of basis points over the reference rate, specified as a scalar or an `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instfloat` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each floating-rate note.

To support existing code, `instfloat` also accepts serial date numbers as inputs, but they are not recommended.

`FloatReset` — Frequency of payments per year

`1` (default) | vector

(Optional) Frequency of payments per year, specified as a scalar or an `NINST`-by-`1` vector.

Data Types: `double`

Basis — Day count basis
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day count basis, specified as a scalar or an NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Principal — Notional principal amounts or principal value schedules
100 (default) | vector or cell array

(Optional) Notional principal amounts, specified as a scalar, vector, or cell array.

Principal accepts a NINST-by-1 vector or NINST-by-1 cell array, where each element of the cell array is a NumDates-by-2 cell array and the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: cell | double

EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days
1 (in effect) (default) | nonnegative integer [0,1]

(Optional) End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified a scalar nonnegative integer 0 or 1 or an NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

CapRate — Annual cap rate
decimal

(Optional) Annual cap rate, specified as a scalar or an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated cap rates. The date indicates the last day that the cap rate is valid.

Data Types: `double` | `cell`

`FloorRate` — Annual floor rate
decimal

(Optional) Annual floor rate, specified as a scalar or an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array, and the cell array first column is dates, and the second column is associated floor rates. The date indicates the last day that the floor rate is valid.

Data Types: `double` | `cell`

Output Arguments

`InstSet` — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Float instrument
cell array of character vectors

Name of each data field for a Float instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Float instrument, `TypeString = 'Float'`.

More About

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Version History

Introduced in R2012b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instfloat` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instfloor

Construct floor instrument

Syntax

```
InstSet = instfloor(Strike,Settle,Maturity)
InstSet = instfloor(InstSet,Strike,Settle,Maturity)
InstSet = instfloor( ___ ,FloorReset,Basis,Principal)
[FieldList,ClassList,TypeString] = instfloor
```

Description

`InstSet = instfloor(Strike,Settle,Maturity)` creates a new instrument set containing Floor instruments.

`InstSet = instfloor(InstSet,Strike,Settle,Maturity)` adds Floor instruments to an existing instrument set.

`InstSet = instfloor( ___ ,FloorReset,Basis,Principal)` adds optional arguments.

`[FieldList,ClassList,TypeString] = instfloor` lists field meta-data for the Floor instrument.

Examples

Create a Floor Instrument

Define the characteristics of the floor instrument.

```
Strike = 0.22;
Settle = datetime(2013,3,15);
Maturity = datetime(2018,3,15);
FloorReset = 4;
Basis = 1;
Principal = 1000;
```

Create the new floor instrument.

```
ISet = instfloor(Strike, Settle, Maturity, FloorReset, Basis, Principal)
```

```
ISet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Floor'}
     FieldName: {{6x1 cell}}
    FieldClass: {{6x1 cell}}
     FieldData: {{6x1 cell}}
```

Display the floor instrument.

```
instdisp(ISet)

Index Type  Strike Settle         Maturity       FloorReset Basis Principal
1     Floor 0.22   15-Mar-2013    15-Mar-2018    4          1     1000
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Floor instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`Strike` — Rate at which floor is exercised

decimal

Rate at which the floor is exercised, specified as a scalar or an `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for floor

datetime array | string array | date character vector

Settlement date for the floor, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instfloor` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floor

datetime array | string array | date character vector

Maturity date for the floor, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instfloor` also accepts serial date numbers as inputs, but they are not recommended.

`FloorReset` — Reset frequency payment per year

`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a scalar or an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as a scalar or an `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a scalar or an `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing floor.

Data Types: `double` | `cell`

Output Arguments

`InstSet` — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Floor instrument
cell array of character vectors

Name of each data field for a Floor instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

TypeString — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Floor instrument, `TypeString = 'Floor'`.

More About

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

Version History

instget

Data from instrument variable

Syntax

```
Data = instget(InstSet,Name,Value)
```

Description

`Data = instget(InstSet,Name,Value)` retrieves `Data` from an instrument variable.

Examples

Retrieve Data Arrays From Instrument Variable

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Extract the price from all instruments.

```
P = instget(ExampleInst,'FieldName','Price')
```

```
P = 7×1

   12.2000
    9.2000
    6.8000
       NaN
    7.4000
    2.9000
   99.0000
```

Get all the prices and the number of contracts held.

```
[P,C] = instget(ExampleInst, 'FieldName', {'Price', 'Contracts'})
```

```
P = 7×1

   12.2000
    9.2000
    6.8000
       NaN
    7.4000
    2.9000
   99.0000

C = 7×1

           0
           0
        1000
       -1000
       -1000
           0
           6
```

Compute a value V. Create a new variable `ISet` that appends V to `ExampleInst`.

```
V = P.*C
```

```
V = 7×1

           0
           0
        6800
         NaN
       -7400
           0
         594
```

```
ISet = instsetfield(ExampleInst, 'FieldName', 'Value', 'Data',V);
instdisp(ISet)
```

```
Index Type   Strike Price Opt  Contracts Value
1     Option  95    12.2  Call     0         0
2     Option 100     9.2  Call     0         0
3     Option 105     6.8  Call  1000      6800

Index Type    Delivery       F     Contracts Value
4     Futures 01-Jul-1999    104.4 -1000     NaN

Index Type   Strike Price Opt  Contracts Value
5     Option 105     7.4  Put  -1000     -7400
6     Option  95     2.9  Put      0         0

Index Type  Price Maturity       Contracts Value
7     TBill 99    01-Jul-1999    6         594
```

Look at only the instruments that have nonzero `Contracts`.

```
Ind = find(C ~= 0)
```

```
Ind = 4×1

     3
     4
     5
     7
```

Get the `Type` and `Opt` parameters from those instruments. (Only options have a stored `'Opt'` field.)

```
[T,O] = instget(ExampleInst, 'Index', Ind, 'FieldName',{'Type', 'Opt'})
```

```
T = 4x7 char array
    'Option '
    'Futures'
    'Option '
    'TBill  '

O = 4x4 char array
    'Call'
    '    '
    'Put '
    '    '
```

Create a report of holdings `Type`, `Opt`, and `Value`.

```
rstring = [T, O, num2str(V(Ind))]
```

```
rstring = 4x16 char array
    'Option Call 6800'
    'Futures      NaN'
    'Option Put -7400'
    'TBill        594'
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Data = instget(ExampleInst,'FieldName','Price')`

`FieldName` — Name of each data field for instrument
all fields available for returned set of instruments (default) | cell array of character vectors

Name of each data field for an instrument, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-`1` cell array of character vectors. `FieldName` entries can also be either `Type` or `Index`; these return type strings and index numbers respectively.

Data Types: `char` | `cell`

`Index` — Number of instruments
all indices available in instrument variable (default) | vector

Number of instruments, specified as the comma-separated pair consisting of `'Index'` and an `NINST`-by-`1` vector of positions of instruments to work on. If `Type` is also entered, instruments referenced must be one of the types and contained in `Index`.

Data Types: `double`

`Type` — Number of types
all types in the instrument variable (default) | character vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments worked on to match one of `Type` types.

Data Types: `char` | `cell`

Output Arguments

`Data` — Data contents
array

Data content, returned as an `NINST`-by-`M` array of data contents for the first field in `FieldName`. Each row corresponds to a separate instrument in the specified `Index`. Unavailable data is returned as `NaN` or as spaces.

Version History

Introduced before R2006a

instgetcell

Data and context from instrument variable

Syntax

```
[DataList,FieldList,ClassList,IndexSet,TypeSet] = instgetcell(InstSet,
Name,Value)
```

Description

`[DataList,FieldList,ClassList,IndexSet,TypeSet] = instgetcell(InstSet, Name,Value)` retrieves data and context from an instrument variable.

Note `instgetcell` is best used for programming where the structure of the instrument variable is not known. `instget` gives more direct access to the data in a variable.

Examples

Retrieve Data and Context from Instrument Variable

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Get the prices and contracts from all instruments.

```
FieldList = {'Price'; 'Contracts'}
```

```
FieldList = 2x1 cell
    {'Price'    }
    {'Contracts'}
```

```
DataList = instgetcell(ExampleInst, 'FieldName', FieldList )
```

```

        1000
       -1000
           0
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `DataList = instgetcell(ExampleInst,'FieldName',FieldList)`

`FieldName` — Name of each data field for instrument
all fields available for returned set of instruments (default) | cell array of character vectors

Name of each data field for an instrument, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-`1` cell array of character vectors. `FieldName` entries can also be either `Type` or `Index`; these return type strings and index numbers respectively.

Data Types: `char` | `cell`

`Index` — Number of instruments
all indices available in instrument variable (default) | vector

Number of instruments, specified as the comma-separated pair consisting of `'Index'` and an `NINST`-by-`1` vector of positions of instruments to work on. If `Type` is also entered, instruments referenced must be one of the types and contained in `Index`.

Data Types: `double`

`Type` — Number of types
all types in the instrument variable (default) | character vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments worked on to match one of `Type` types.

Data Types: `char` | `cell`

Output Arguments

`DataList` — Data contents for each field
cell array

Data content for each field, returned as an `NFIELDS`-by-`1` cell array of data contents for each field. Each cell is an `NINST`-by-`M` array, where each row corresponds to a separate instrument in `IndexSet`. Any data which is not available is returned as `NaN` or as spaces.

`FieldList` — Name of each field in `DataList`
cell array

Name of each field in `DataList`, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class of each field
array

Data class of each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`IndexSet` — Positions of instruments
cell array

Positions of instruments, returned as an `NINST`-by-`1` vector of positions of instruments returned in `DataList`.

`TypeSet` — Type of each instrument
cell array

Type of each instrument, returned as an `NINST`-by-`1` cell array of character vectors listing the type of each instrument row returned in `DataList`.

Version History

Introduced before R2006a

instlength

Count instruments

Syntax

```
NInst = instlength(InstSet)
```

Description

`NInst = instlength(InstSet)` computes `NInst`, the number of instruments contained in the variable `InstSet`.

Examples

Count Instruments in Instrument Variable

Retrieve the instrument set `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Count the number of instruments contained in the variable `ExampleInst`.

```
NInst = instlength(ExampleInst)
```

```
NInst = 7
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Output Arguments

`NInst` — Number of instruments in `InstSet`

numeric

Number of instruments in `InstSet`, returned as a numeric value.

Version History

Introduced before R2006a

instlookback

Construct lookback option

Syntax

```
InstSet = instlookback(OptSpec,Strike,Settle,ExerciseDates)
InstSet = instlookback(InstSet,OptSpec,Strike,Settle,ExerciseDates)
InstSet = instlookback(___,AmericanOpt)
[FieldList,ClassList,TypeString] = instlookback
```

Description

`InstSet = instlookback(OptSpec,Strike,Settle,ExerciseDates)` creates a new instrument set containing Lookback instruments.

`InstSet = instlookback(InstSet,OptSpec,Strike,Settle,ExerciseDates)` adds Lookback instruments to an existing instrument set.

`InstSet = instlookback(___,AmericanOpt)` adds an optional argument.

`[FieldList,ClassList,TypeString] = instlookback` lists field meta-data for the Lookback instrument.

Examples

Create a Lookback Option Instrument

Define a floating strike lookback instrument with the following data:

```
OptSpec = 'call';
Strike = NaN;
Settle = datetime(2012,1,1);
ExerciseDates = datetime(2015,1,1);
```

Create the instrument set.

```
InstSet = instlookback(OptSpec, Strike, Settle, ExerciseDates);
```

Display the lookback instrument.

```
instdisp(InstSet)
```

```
Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt
1     Lookback call    NaN    01-Jan-2012    01-Jan-2015    0
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Lookback instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a scalar `'call'` or `'put'` using a character vector or an `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value

matrix of nonnegative integers

Option strike price value, specified as a scalar nonnegative integer or an `NINST`-by-`1` matrix of strike price values. Each row is the schedule for one option.

Data Types: `double`

`Settle` — Settlement date or trade date

datetime array | string array | date character vector

Settlement date or trade date for the lookback option, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instlookback` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a scalar or a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors:

- For a European option, use an `NINST`-by-`1` vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector of dates, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `instlookback` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type

`0` European (default) | integer with values `0` or `1`

(Optional) Option type, specified as a scalar or an `NINST`-by-`1` integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

Output Arguments

`InstSet` — Variable containing a collection of instruments

structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Lookback instrument

cell array of character vectors

Name of each data field for a Lookback instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field

cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument

character vector

Type of instrument, returned as a character vector. For a Lookback instrument, `TypeString = 'Lookback'`.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instlookback` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instoptbnd

Construct bond option

Syntax

```
InstSet = instoptbnd(BondIndex,OptSpec,Strike,ExerciseDates)
InstSet = instoptbnd(InstSet,BondIndex,OptSpec,Strike,ExerciseDates)
InstSet = instoptbnd(___,AmericanOpt)
[FieldList,ClassList,TypeString] = instoptbnd
```

Description

`InstSet = instoptbnd(BondIndex,OptSpec,Strike,ExerciseDates)` creates a new instrument set containing Bond option instruments.

`InstSet = instoptbnd(InstSet,BondIndex,OptSpec,Strike,ExerciseDates)` adds Bond option instruments to an existing instrument set.

`InstSet = instoptbnd(___,AmericanOpt)` adds an optional argument.

`[FieldList,ClassList,TypeString] = instoptbnd` lists field meta-data for the Bond option instrument.

Examples

Create a Bond Option Instrument

Create a new instrument variable with the following information:

```
BondIndex = 1;
OptSpec = 'call';
Strike= 85;
ExerciseDates = datetime(2014,11,1);
AmericanOpt = 1;
CouponRate= [0.035;0.04];
Settle= datetime(2013,11,1);
Maturity = datetime(2014,11,1);
Period =1;
```

Create the instrument portfolio with two bonds.

```
InstSet = instbond(CouponRate, Settle, Maturity, ...
Period)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Bond'}
     FieldName: {{11x1 cell}}
    FieldClass: {{11x1 cell}}
```

```
     FieldData: {{11x1 cell}}
```

Create an option on the first bond

```
InstSet = instoptbnd(InstSet, BondIndex, OptSpec, Strike, ExerciseDates, AmericanOpt)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {2x1 cell}
     FieldName: {2x1 cell}
    FieldClass: {2x1 cell}
     FieldData: {2x1 cell}
```

Display the instrument set.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.035      01-Nov-2013    01-Nov-2014    1      0     1            NaN       NaN
2     Bond 0.04       01-Nov-2013    01-Nov-2014    1      0     1            NaN       NaN

Index Type    UnderInd OptSpec Strike ExerciseDates  AmericanOpt
3     OptBond 1        call    85     01-Nov-2014    1
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Bond option instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`BondIndex` — Number of Bond instruments

vector

Number of Bond instruments, specified as a scalar or an `NINST`-by-`1` vector of indices pointing to underlying instruments of Type `'Bond'` which are stored in `InstSet`. See `instbond` for information on specifying the bond data.

Data Types: `double`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a scalar `'call'` or `'put'` using a character vector or an `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `char` | `cell`

Strike — Option strike price value
matrix of nonnegative integers | vector of nonnegative integers

Option strike price value, specified as a scalar nonnegative integer or an NINST-by-1 vector of strike price values for a European option, an NINST by number of strikes (NSTRIKES) matrix of strike price values for a Bermuda option, or an NINST-by-1 vector of strike price values for each American option. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.

Note The interpretation of the Strike and ExerciseDates depends upon the setting of the AmericanOpt. If AmericanOpt = 0, NaN, or is unspecified, the option is a European or Bermuda option. If AmericanOpt = 1, the option is an American option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a scalar or an NINST-by-2 vector using a datetime array, string array, or date character vectors of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying bond Settle and the single listed exercise date.

To support existing code, instoptbnd also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as a scalar or an NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

Data Types: single | double

Output Arguments

InstSet — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the InstSet variable, see instget.

FieldList — Name of each data field for Bond option instrument
cell array of character vectors

Name of each data field for a Bond option instrument, returned as an NFIELDS-by-1 cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-1 cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Bond option instrument, `TypeString = 'OptBond'`.

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-6.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instoptbnd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instoptembnd

Construct bond with embedded option

Syntax

```
InstSet = instoptembnd(CouponRate,Settle,Maturity,OptSpec,Strike,
ExerciseDates)
InstSet = instoptembnd(InstSet,CouponRate,Settle,Maturity,OptSpec,Strike,
ExerciseDates)
InstSet = instoptembnd( ___ ,Name,Value)
[FieldList,ClassList,TypeString] = instoptembnd
```

Description

`InstSet = instoptembnd(CouponRate,Settle,Maturity,OptSpec,Strike, ExerciseDates)` creates a new instrument set containing Bond with embedded option instruments.

`InstSet = instoptembnd(InstSet,CouponRate,Settle,Maturity,OptSpec,Strike, ExerciseDates)` adds Bond with embedded option instruments to an existing instrument set.

`InstSet = instoptembnd( ___ ,Name,Value)` uses additional name-value pairs in addition to the required arguments in the previous syntax.

`[FieldList,ClassList,TypeString] = instoptembnd` lists field meta-data for the Bond option instrument.

Examples

Create a Bond With an Embedded Option

This example shows how to create a bond with an embedded option using the following data.

```
Settle = datetime(2007,1,1);
Maturity   = datetime(2010,1,1);
CouponRate = 0.07;
OptSpec = 'call';
Strike= 100;
ExerciseDates= [datetime(2008,1,1) datetime(2010,1,1)];
AmericanOpt=1;
Period = 1;

InstSet = instoptembnd(CouponRate, ...
Settle, Maturity, OptSpec, Strike,  ExerciseDates,'AmericanOpt', AmericanOpt, ...
'Period', Period);

% display the instrument
 instdisp(InstSet)
```

```
Index Type      CouponRate Settle         Maturity       OptSpec Strike ExerciseDates
1     OptEmBond 0.07       01-Jan-2007    01-Jan-2010    call    100    01-Jan-2008   01-Jan-2010
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Bond embedded option instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as a scalar or an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instoptembnd` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instoptembnd` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a scalar or an `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified as a scalar or an `NINST`-by-`1` or an `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.

- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as scalar or an NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row.

To support existing code, instoptembnd also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: InstSet = instoptembnd(InstSet,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates, 'Period',1,'AmericanOp',1)

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar or an NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a scalar or an NINST-by-1 vector.

Data Types: double

Basis — Day-count basis
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar or an NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

EndMonthRule — End-of-month rule flag
1 (in effect) (default) | nonnegative integer with values 0 or 1

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar nonnegative integer or an NINST-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar or an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instoptembnd also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instoptembnd` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instoptembnd` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `StartDate` is the date when a bond actually starts (that is, the date from which a bond's cash flows can be considered). To make an option embedded bond instrument forward starting, specify this date as a future date.

To support existing code, `instoptembnd` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a scalar or an `NINST`-by-`1` vector or an `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Note Instruments without a `Face` schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

Data Types: `double`

Output Arguments

`InstSet` — Variable containing a collection of instruments

structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Bond embedded option instrument

cell array of character vectors

Name of each data field for a Bond embedded option instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field

cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument

character vector

Type of instrument, returned as a character vector. For a Bond embedded option instrument, `TypeString = 'OptEmBond'`.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2008a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instoptembnd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Choose Instruments, Models, and Pricers” on page 1-53

instoptfloat

Create option instrument on floating-rate note or add instrument to current portfolio

Syntax

```
InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates)
InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates,AmericanOpt)

InstSet = instoptfloat(InstSetOld,___)

[FieldList,ClassList,TypeString] = instoptfloat
```

Description

`InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates)` to specify a European option for a floating-rate note.

`InstSet = instoptfloat(FloatIndex,OptSpec,Strike,ExerciseDates,AmericanOpt)` to specify an American or Bermuda option for a floating-rate note.

`InstSet = instoptfloat(InstSetOld,___)` to add instruments to an existing portfolio.

`[FieldList,ClassList,TypeString] = instoptfloat` lists the field metadata for the `'OptFloat'` instrument.

Examples

Create an Instrument Portfolio with a Call Option for a Floating-Rate Note

Define the floating-rate note:

```
Settle = datetime(2012,11,1);
Maturity   = datetime(2015,11,1);
Spread = 50;
Reset = 1;
```

Create `InstSet`:

```
InstSet = instfloat(Spread, Settle, Maturity, Reset)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Float'}
     FieldName: {{9x1 cell}}
    FieldClass: {{9x1 cell}}
     FieldData: {{9x1 cell}}
```

Display the instrument:

```
instdisp(InstSet)
```

```
Index Type  Spread Settle         Maturity       FloatReset Basis Principal EndMonthRule CapRate
1     Float 50     01-Nov-2012    01-Nov-2015    1          0     100       1            Inf
```

Add a European call option to the instrument portfolio:

```
OptSpec = 'call';
Strike = 100;
ExerciseDates = 'Nov-1-2015';
```

Create `InstSet`:

```
InstSet = instoptfloat(InstSet, 1, OptSpec, Strike, ExerciseDates)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {2x1 cell}
     FieldName: {2x1 cell}
    FieldClass: {2x1 cell}
     FieldData: {2x1 cell}
```

Display the instrument:

```
instdisp(InstSet)
```

```
Index Type  Spread Settle         Maturity       FloatReset Basis Principal EndMonthRule CapRate
1     Float 50     01-Nov-2012    01-Nov-2015    1          0     100       1            Inf

Index Type     UnderInd OptSpec Strike ExerciseDates  AmericanOpt
2     OptFloat 1        call    100    01-Nov-2015    0
```

Input Arguments

`FloatIndex` — Indices pointing to underlying instruments

vector of nonnegative integers

Indices pointing to underlying instruments of `Type 'Float'` specified by a `NINST`-by-`1` vector. The instruments of `Type 'Float'` are also stored in the `InstSet` variable. For more information, see `instfloat`.

Data Types: `double`

`OptSpec` — Definition of option

character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price values for European, Bermuda, or American option

nonnegative integer | vector of nonnegative integers

Option strike price values for option (European, Bermuda, or American) specified as nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

- For a European or Bermuda option — NINST-by-NSTRIKES matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American Option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American), specified as a NINST-by-NSTRIKES or NINST-by-2 vector using a datetime array, string array, or date character vectors, depending on the option type.

- For a European or Bermuda option — NINST-by-NSTRIKES matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDate on the option expiry date
- For an American option — NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying bond Settle date and the single listed ExerciseDate.

To support existing code, instoptfloat also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 if AmericanOpt is NaN or not entered (default) | scalar | vector of positive integers[0,1]

Option type specified as NINST-by-1 positive integer scalar flags with values.

- For a European or Bermuda option — AmericanOpt is 0 for each European or Bermuda option.
- For an American option — AmericanOpt is 1 for each American option. The AmericanOpt argument is required to invoke American exercise rules.

Data Types: single | double

InstSetOld — Variable containing an existing collection of instruments
struct

Variable containing an existing collection of instruments, specified as a struct. For more information on the InstSet variable, see instget.

Data Types: struct

Output Arguments

InstSet — Variable containing a collection of instruments
scalar | vector

Variable containing a collection of instruments returned as a scalar or vector with the instruments broken down by type and each type can have different data fields. Each stored data field has a row

vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Data field for instrument type
character vector | cell array of character vectors

Data field for instrument type returned as a `NFIELDS`-by-`1` cell array of character vectors listing the name of each data field for this instrument type.

`ClassList` — Data class of each field
character vector with value: `'dble'`, `'date'`, `'char'` | cell array of character vectors with values: `'dble'`, `'date'`, `'char'`

Data class of each field returned as a`NFIELDS`-by-`1` cell array of character vectors listing the data class of each field. The class determines how arguments are parsed.

`TypeString` — Type of instrument added
character vector with value `'OptFloat'`

Type of instrument added returned as a character vector. The character vector for a floating-rate option instrument is `TypeString = 'OptFloat'`.

Version History

Introduced in R2013a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `instoptfloat` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instoptemfloat

Create embedded option instrument on floating-rate note or add instrument to current portfolio

Syntax

```
InstSet = instopemtfloat(Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)
InstSet = instopemtfloat( ___ ,Name,Value)

InstSet = instopemtfloat(InstSetOld,Spread,Settle,Maturity,OptSpec,Strike,
ExerciseDates)
[FieldList,ClassList,TypeString] = instoptemfloat
```

Description

`InstSet = instopemtfloat(Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)` creates an embedded option instrument for a floating-rate note.

`InstSet = instopemtfloat( ___ ,Name,Value)` adds optional name-value pair arguments.

`InstSet = instopemtfloat(InstSetOld,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)` to add `'OptEmFloat'` instruments to an instrument variable.

`[FieldList,ClassList,TypeString] = instoptemfloat` lists field metadata for the `'OptEmFloat'` instrument.

Examples

Create an Instrument Portfolio with a Embedded Option Floating-Rate Note

Define the embedded call option:

```
Settle = 'Nov-1-2012';
Maturity   = 'Nov-1-2015';
Spread = 25;
OptSpec = 'call';
Strike= 100;
ExerciseDates = 'Nov-1-2015';
Reset = 1;
```

Create `InstSet`:

```
InstSet = instoptemfloat(Spread, Settle, Maturity, OptSpec,...
Strike,  ExerciseDates,'FloatReset', Reset)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'OptEmFloat'}
     FieldName: {{13x1 cell}}
    FieldClass: {{13x1 cell}}
```

```
    FieldData: {{13x1 cell}}
```

Display the instrument:

```
instdisp(InstSet)
```

```
Index Type       Spread Settle         Maturity       OptSpec Strike ExerciseDates  FloatReset Ba
1     OptEmFloat 25     01-Nov-2012    01-Nov-2015    call    100    01-Nov-2015    1          0
```

Input Arguments

Spread — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: double

Settle — Settlement dates of floating-rate note

ValuationDate of HW Tree (default) | datetime array | string array | date character vector | serial date number

Settlement dates of floating-rate note, specified as a NINST-by-1 vector using a datetime array, string array, date character vectors, or serial date numbers.

Data Types: double | char | string | datetime

Maturity — Floating-rate note maturity date

datetime array | string array | date character vector | serial date number

Floating-rate note maturity date, specified as a NINST-by-1 vector using a datetime array, string array, date character vectors, or serial date numbers.

Data Types: double | char | string | datetime

OptSpec — Definition of option

character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

Strike — Embedded option strike price values

nonnegative integer | vector of nonnegative integers

Embedded option strike price values for option specified as nonnegative integers using as NINST-by-NSTRIKES or NINST-by-1 vector of strike price values, depending on the type of option.

- For a European or Bermuda Option — NINST-by-NSTRIKES matrix of strike price values where each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.

- For an American Option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Exercise date for embedded option
datetime array | string array | date character vector | serial date number

Exercise date for embedded option, specified as a NINST-by-NSTRIKES or NINST-by-2 vector using a datetime array, string array, date character vectors, or serial date numbers, depending on the type of option.

- For a European or Bermuda Option — NINST-by-NSTRIKES of exercise dates where each row is the schedule for one option. For a European option, there is only one ExerciseDate on the option expiry date.
- For an American Option — NINST-by-2 vector of exercise date boundaries. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying bond Settle date and the single listed ExerciseDate.

Data Types: double | char | string | datetime

InstSetOld — Variable containing an existing collection of instruments
struct

Variable containing an existing collection of instruments, specified as a struct. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on instrument data parameters, see the reference entries for individual instrument types. For example, see instfloat for additional information on the float instrument.

Data Types: struct

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: InstSet = instoptemfloat(Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'FloatReset',Reset)

AmericanOpt — Embedded option type
0 if AmericanOpt is NaN or not entered (default) | scalar | vector of positive integers[0,1]

Embedded option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 positive integer scalar flags with values:

- For a European or Bermuda option — AmericanOpt is 0 for each European or Bermuda option. The default is 0 if AmericanOpt is NaN or not entered.
- For an American option — AmericanOpt is 1 for each American option. The AmericanOpt argument is required to invoke American exercise rules.

Data Types: single | double

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set`[1,2,3,4,6, 12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `1,2,4,6,12]` in a `NINST`-by-`1` vector.

Data Types: `single` | `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `single` | `double`

`Principal` — Principal values
`100` (default) | nonnegative integer | vector of nonnegative integers | cell array of nonnegative integers

Principal values, specified as the comma-separated pair consisting of `'Principal'` and a nonnegative integer using a `NINST`-by-`1` vector of notional principal amounts.

Data Types: `single` | `double`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure using `derivset`.

Data Types: `struct`

EndMonthRule — End-of-month rule flag
1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `single` | `double`

Output Arguments

InstSet — Variable containing a collection of instruments
scalar | vector

Variable containing a collection of instruments returned as a scalar or vector with the instruments broken down by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

FieldList — Name of each data field
character vector | cell array of character vectors

`NFIELDS`-by-`1` cell array of character vectors listing the name of each data field for this instrument type.

ClassList — Determines how arguments are parsed
character vector with value: `'dble'`, `'date'`, or `'char'` | cell array of character vectors with values: `'dble'`, `'date'`, or `'char'`

`NFIELDS`-by-`1` cell array of character vectors listing the data class of each field.

TypeString — Type of instrument added
character vector with value `'OptEmFloat'`

Character vector specifying the type of instrument added where `TypeString = 'OptEmFloat'`.

Version History
Introduced in R2013a

“Supported Interest-Rate Instrument Functions” on page 2-3

instoptstock

Construct stock option

Syntax

```
InstSet = instoptstock(OptSpec,Strike,Settle,ExerciseDates)
InstSet = instoptstock(InstSet,OptSpec,Strike,Settle,ExerciseDates)
InstSet = instoptstock( ___ ,AmericanOpt)
[FieldList,ClassList,TypeString] = instoptstock
```

Description

`InstSet = instoptstock(OptSpec,Strike,Settle,ExerciseDates)` creates a new instrument set containing stock option instruments.

`InstSet = instoptstock(InstSet,OptSpec,Strike,Settle,ExerciseDates)` adds stock option instruments to an existing instrument set.

`InstSet = instoptstock( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

`[FieldList,ClassList,TypeString] = instoptstock` lists field meta-data for the stock option instrument.

Examples

Create a Stock Option Instrument

Create an instrument set of two stock options with the following data:

```
OptSpec = {'put';'call'};
Strike = [95;98];
Settle = datetime(2012,5,1);
ExerciseDates = [datetime(2014,5,1) ; datetime(2015,5,1)];
AmericanOpt = [0;1];
```

Create the stock option instruments.

```
InstSet = instoptstock(OptSpec, Strike,Settle, ExerciseDates, AmericanOpt)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'OptStock'}
     FieldName: {{5x1 cell}}
    FieldClass: {{5x1 cell}}
     FieldData: {{5x1 cell}}
```

Display the instrument set.

```
instdisp(InstSet)
```

```
Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt
1     OptStock put     95     01-May-2012    01-May-2014    0
2     OptStock call    98     01-May-2012    01-May-2015    1
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding stock option instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a scalar `'call'` or `'put'` or an `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified with a scalar or an `NINST`-by-`1` or an `NINST`-by-`NSTRIKES` depending on the option type:

- For a European option, use an `NINST`-by-`1` vector of strike prices.
- For a Bermuda option, use an `NINST`-by-`NSTRIKES` matrix of strike prices. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American option, use an `NINST`-by-`1` of strike prices.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

Data Types: `double`

`Settle` — Settlement date or trade date

datetime array | string array | date character vector

Settlement date or trade date, specified as a scalar or an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instoptstock` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a scalar or an NINST-by-1,NINST-by-2, or an NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the option type:

- For a European option, use an NINST-by-1 vector of dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use an NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use an NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row.

Note The interpretation of the Strike and ExerciseDates arguments depends upon the setting of the AmericanOpt argument. If AmericanOpt = 0, NaN, or is unspecified, the option is a European or Bermuda option. If AmericanOpt = 1, the option is an American option.

To support existing code, instoptstock also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type

0 European or Bermuda (default) | integer with values of 0 or 1

(Optional) Option type, specified as a scalar or an NINST-by-1 vector of integer flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: double

Output Arguments

InstSet — Variable containing a collection of instruments

structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the InstSet variable, see instget.

FieldList — Name of each data field for stock option instrument

cell array of character vectors

Name of each data field for a stock option instrument, returned as an NFIELDS-by-1 cell array of character vectors.

ClassList — Data class for each field

cell array of character vectors

Data class for each field, returned as an NFIELDS-by-1 cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are 'dble', 'date', and 'char'.

TypeString — Type of instrument

character vector

Type of instrument, returned as a character vector. For a stock option instrument, `TypeString = 'OptStock'`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instoptstock` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instrangefloat

Construct range note instrument

Syntax

```
InstSet = instrangefloat(Spread,Settle,Maturity,RateSched,Reset,Basis,
Principal,EndMonthRule)
InstSet = instrangefloat( ___ ,Reset,Basis,Principal,EndMonthRule)
InstSet = instrangefloat(InstSet, ___ )
```

Description

`InstSet = instrangefloat(Spread,Settle,Maturity,RateSched,Reset,Basis, Principal,EndMonthRule)` creates a range instrument from data arrays.

`InstSet = instrangefloat( ___ ,Reset,Basis,Principal,EndMonthRule)` creates a range instrument from data arrays using optional arguments.

`InstSet = instrangefloat(InstSet, ___ )` adds new range set instrument to an existing instrument set.

Examples

Create a Range Note Instrument

Create an instrument portfolio with a range note.

```
Spread = 100;
Settle = datetime(2011,1,1);
Maturity = datetime(2014,1,1);

RateSched.Dates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
RateSched.Rates  = [0.045 0.055; 0.0525  0.0675; 0.06 0.08];

% Create InstSet
InstSet = instrangefloat(Spread, Settle, Maturity, RateSched);

% Display the portfolio instrument
instdisp(InstSet)
```

```
Index Type       Spread Settle         Maturity       RateSched FloatReset Basis Principal EndMon
1     RangeFloat 100    01-Jan-2011    01-Jan-2014    [Struct]  1          0     100       1
```

Add a second range note instrument to the portfolio. Second Range Note:

```
Spread2 = 200;
Settle2 = datetime(2011,1,1);
Maturity2 = datetime(2013,1,1);
RateSched2.Dates = [datetime(2012,1,1) ; datetime(2013,1,1)];
RateSched2.Rates  = [0.048 0.059; 0.055  0.068];
```

```
InstSet = instrangefloat(InstSet, Spread2, Settle2, Maturity2, RateSched2);

% Display the portfolio instrument
instdisp(InstSet)

Index Type       Spread Settle         Maturity       RateSched FloatReset Basis Principal EndMo
1     RangeFloat 100    01-Jan-2011    01-Jan-2014    [Struct]  1          0     100       1
2     RangeFloat 200    01-Jan-2011    01-Jan-2013    [Struct]  1          0     100       1
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding stock option instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

numeric

Number of basis points over the reference rate, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement date of floating-rate note

datetime array | string array | date character vector

Settlement date of floating-rate note, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instrangefloat` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date of floating-rate note

datetime array | string array | date character vector

Maturity date of floating-rate note, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instrangefloat` also accepts serial date numbers as inputs, but they are not recommended.

`RateSched` — Range of dates within which cash flows are nonzero

date character vector

Range of dates within which cash flows are nonzero, specified as an `NINST`-by-`1` structure where each element of the structure array contains two fields:

- `RateSched.Dates` — `NDates`-by-`1` cell array of dates corresponding to the range schedule.
- `RateSched.Rates` —`NDates`-by-`2` array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date

`RateSched.Dates`(*n*) is nonzero for rates in the range `RateSched.Rates`(*n*,1) < `Rate` < `RateSched.Rate` (*n*,2).

To support existing code, `instrangefloat` also accepts serial date numbers as inputs, but they are not recommended.

`Reset` — Frequency of payments per year
`1` (default) | integer

(Optional) Frequency of payments per year, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day count basis, specified as an `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amounts, specified and an `NINST`-by-`1` vector.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as an `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`InstSet` — Variable containing a collection of instruments

structure

Variable containing a collection of instruments, returned as a structure. Instruments are divided by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. Values are:

- `FieldList` — `NFIELDS`-by-1 cell array of character vectors listing the name of each data field for this instrument type.
- `ClassList` — `NFIELDS`-by-1 cell array of character vectors listing the data class of each field. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.
- `TypeString` — Character vector specifying the type of instrument added. `TypeString = 'RangeFloat'`.

For more information on the `InstSet` variable, see `instget`.

More About

Range Note Instrument

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes.

Version History

Introduced in R2012a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instrangefloat` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instselect

Create instrument subset by matching conditions

Syntax

```
InstSubSet = instselect(InstSet,Name,Value)
```

Description

`InstSubSet = instselect(InstSet,Name,Value)` returns a variable containing a collection of instruments matching the input criteria.

Examples

Create Instrument Subset

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Make a new portfolio containing only options struck at 95.

```
Opt95 = instselect(ExampleInst, 'FieldName', 'Strike','Data', '95')
```

```
Opt95 = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {3x1 cell}
     FieldName: {3x1 cell}
    FieldClass: {3x1 cell}
     FieldData: {3x1 cell}
```

```
instdisp(Opt95)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option  95     2.9  Put      0
```

Make a new portfolio containing only futures and Treasury bills.

```
FutTBill = instselect(ExampleInst,'Type',{'Futures';'TBill'})
```

```
FutTBill = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {3x1 cell}
     FieldName: {3x1 cell}
    FieldClass: {3x1 cell}
     FieldData: {3x1 cell}
```

```
instdisp(FutTBill)
```

```
Index Type    Delivery       F     Contracts
1     Futures 01-Jul-1999    104.4 -1000

Index Type  Price Maturity       Contracts
2     TBill 99    01-Jul-1999    6
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Opt95 = instselect(ExampleInst,'FieldName','Strike','Data','95')`

`FieldName` — Name of each data field for instrument

cell array of character vectors

Name of each data field for an instrument, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-1 cell array of character vectors.

Data Types: `char` | `cell`

`Data` — Data values for field
cell array of character vectors

Data values for field, specified as the comma-separated pair consisting of `'Data'` and an `NVALUES`-by-`M` array or `NFIELDS`-by-`1` cell array of acceptable data values for each field. Each row lists a data row value to search for in the corresponding `FieldName`. The number of columns is arbitrary and matching ignores trailing `NaN`s or spaces.

Data Types: `double` | `cell`

`Index` — Number of instruments
all types in the instrument variable (default) | vector

Number of instruments, specified as the comma-separated pair consisting of `'Index'` and an `NINST`-by-`1` vector restricting positions of instruments to check for matches. The default is all indices available in the instrument variable.

Data Types: `double`

`Type` — Number of types
all types in the instrument variable (default) | character vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments to match one of `Type` types. The default is all types in the instrument variable.

Data Types: `char` | `cell`

Output Arguments

`InstSubSet` — Variable containing a collection of instruments matching input criteria
structure

Variable containing a collection of instruments matching the input criteria, returned as a structure. Instruments are returned in `InstSubSet` if all the `FieldName`, `Index`, and `Type` conditions are met. An instrument meets an individual `FieldName` condition if the value matches any of the rows listed in the `Data` for that `FieldName`. See `instfind` for examples on matching criteria.

Version History

Introduced before R2006a

instsetfield

Add or reset data for existing instruments

Syntax

```
InstSet = instsetfield(InstSet,Name,Value)
```

Description

`InstSet = instsetfield(InstSet,Name,Value)` resets or adds fields to every instrument.

Examples

Add or Reset Data for Existing Instruments

Retrieve the instrument set `ExampleInstSF` from the data file `InstSetExamples.mat`. `ExampleInstSF` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
ISet = ExampleInstSF;
instdisp(ISet)
```

```
Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4

Index Type   Strike Price Opt
5     Option 105     7.4  Put
6     Option NaN     NaN  Put

Index Type  Price
7     TBill 99
```

Enter data for the option in Index 6: `Price` `2.9` for a `Strike` of `95`.

```
ISet = instsetfield(ISet, 'Index',6,...
'FieldName',{'Strike','Price'}, 'Data',{ 95 , 2.9 });
instdisp(ISet)
```

```
Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4
```

```
Index Type   Strike Price Opt
5     Option 105     7.4  Put
6     Option  95     2.9  Put

Index Type  Price
7     TBill 99
```

Create a field `Maturity` for the cash instrument.

```
MDate = datetime(1999,7,1);
ISet = instsetfield(ISet, 'Type', 'TBill', 'FieldName',...
'Maturity','FieldClass', 'date', 'Data', MDate);
instdisp(ISet)
```

```
Index Type   Strike Price Opt
1     Option  95    12.2  Call
2     Option 100     9.2  Call
3     Option 105     6.8  Call

Index Type    Delivery       F
4     Futures 01-Jul-1999    104.4

Index Type   Strike Price Opt
5     Option 105     7.4  Put
6     Option  95     2.9  Put

Index Type  Price Maturity
7     TBill 99    01-Jul-1999
```

Create a field `Contracts` for all instruments.

```
ISet = instsetfield(ISet, 'FieldName', 'Contracts', 'Data', 0);
instdisp(ISet)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call 0
2     Option 100     9.2  Call 0
3     Option 105     6.8  Call 0

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 0

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  0
6     Option  95     2.9  Put  0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    0
```

Set the `Contracts` fields for some instruments.

```
ISet = instsetfield(ISet,'Index',[3; 5; 4; 7],...
'FieldName','Contracts',  'Data', [1000; -1000; -1000; 6]);
instdisp(ISet)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ISet = instsetfield(ISet,'Index',6,'FieldName',{'Strike','Price'},'Data',{ 95 , 2.9 })`

`FieldName` — Name of each data field for instrument

cell array of character vectors

Name of each data field for an instrument, specified as the comma-separated pair consisting of `'FieldName'` and an `NFIELDS`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Data` — Data values for field

cell array of character vectors

Data values for field, specified as the comma-separated pair consisting of `'Data'` and an `NVALUES`-by-`M` array or `NFIELDS`-by-`1` cell array of acceptable data values for each field. Each row in a data array corresponds to a separate instrument. Single rows are copied to apply to all instruments to be worked on. The number of columns is arbitrary and data is padded along columns.

Data Types: `double` | `cell`

`Index` — Number of instruments
all types in the instrument variable (default) | vector

Number of instruments, specified as the comma-separated pair consisting of `'Index'` and an `NINST`-by-`1` vector of positions of instruments to work on. If `Type` is also entered, instruments referenced must be one of `Type` types contained in `Index`.

Data Types: `double`

`Type` — Number of types
all types in the instrument variable (default) | character vector

Number of types, specified as the comma-separated pair consisting of `'Type'` and a `NTYPES`-by-`1` cell array of character vectors restricting instruments worked on to match one of `Type` types.

Data Types: `char` | `cell`

Output Arguments

`InstSet` — Instrument set variable containing the input data
structure

Instrument set variable containing the input data, returned as a structure.

instswap

Construct swap instrument

Syntax

```
InstSet = instswap(LegRate,Settle,Maturity)
InstSet = instswap(InstSet,LegRate,Settle,Maturity)
InstSet = instswap( ___ ,LegReset,Basis,Principal,LegType,EndMonthRule,
StartDate)
[FieldList,ClassList,TypeString] = instswap
```

Description

`InstSet = instswap(LegRate,Settle,Maturity)` creates a new instrument set containing Swap instruments.

`InstSet = instswap(InstSet,LegRate,Settle,Maturity)` adds Swap instruments to an existing instrument set.

`InstSet = instswap(___ ,LegReset,Basis,Principal,LegType,EndMonthRule,
StartDate)` adds optional arguments for `LegReset`, `Basis`, `Principal`, `LegType`, `EndMonthRule`, and `StartDate`.

`[FieldList,ClassList,TypeString] = instswap` lists field meta-data for the Swap instrument.

Examples

Create a Vanilla Swap Instrument

Create a vanilla swap using market data.

Use the following market data to create a swap instrument.

```
LegRate = [0.065, 0]
```

```
LegRate = 1×2

    0.0650         0
```

```
Settle = datetime(2007,1,1);
Maturity = datetime(2012,1,1);
LegReset = [1, 1];
Basis = 0
```

```
Basis = 0
```

```
Principal = 100
```

```
Principal = 100
```

```
LegType = [1, 0]
```

```
LegType = 1×2

     1     0
```

```
InstSet = instswap(LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Swap'}
     FieldName: {{9x1 cell}}
    FieldClass: {{9x1 cell}}
     FieldData: {{9x1 cell}}
```

View the swap instrument using `instdisp`.

```
instdisp(InstSet)
```

```
Index Type LegRate    Settle         Maturity       LegReset Basis Principal LegType EndMonthRule
1     Swap [0.065  0] 01-Jan-2007    01-Jan-2012    [1  1]   0     100       [1  0]  1
```

Create a Float-Float Swap and Price with `intenvprice`

Use `instswap` to create a float-float swap and price the swap with `intenvprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([40 20],today,datemnth(today,60),[], [], [], [0 0]);
intenvprice(RateSpec,IS)
```

```
ans = 0.8644
```

Create Float-Float, Fixed-Fixed, and Float-Fixed Swaps and Price with `intenvprice`

Use `instswap` to create swaps and price the swaps with `intenvprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.03 .02],today,datemnth(today,60),[], [], [], [1 1]);
IS = instswap(IS,[200 300],today,datemnth(today,60),[], [], [], [0 0]);
IS = instswap(IS,[300 .07],today,datemnth(today,60),[], [], [], [0 1]);
intenvprice(RateSpec,IS)
```

```
ans = 3×1

    4.3220
   -4.3220
    4.5921
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable, specified only when adding Swap instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

`LegRate` — Leg rate

matrix

Leg rate, specified as a scalar or an `NINST`-by-2 matrix, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

`CouponRate` is the decimal annual rate. `Spread` is the number of basis points over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `instswap` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a scalar or an `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each swap.

To support existing code, `instswap` also accepts serial date numbers as inputs, but they are not recommended.

`LegReset` — Reset frequency per year for each swap

`[1 1]` (default) | vector

(Optional) Reset frequency per year for each swap, specified as an `NINST`-by-2 vector.

Data Types: `double`

`Basis` — Day-count basis representing the basis for each leg

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis for each leg, specified as an `NINST`-by-1 array (or `NINST`-by-2 if `Basis` is different for each leg).

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amounts or principal value schedules
`100` (default) | vector or cell array

(Optional) Notional principal amounts or principal value schedules, specified as a vector or cell array.

`Principal` accepts an `NINST`-by-`1` vector or an `NINST`-by-`1` cell array (or `NINST`-by-`2` if `Principal` is different for each leg) of the notional principal amounts or principal value schedules. For schedules, each element of the cell array is a `NumDates`-by-`2` array where the first column is dates and the second column is its associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: `cell` | `double`

`LegType` — Leg type
`[1 0]` for each instrument (default) | matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float)

(Optional) Leg type, specified as an `NINST`-by-`2` matrix with values `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float). Each row represents an instrument. Each column indicates if the corresponding leg is fixed (`1`) or floating (`0`). This matrix defines the interpretation of the values entered in `LegRate`. `LegType` allows `[1 1]` (fixed-fixed), `[1 0]` (fixed-float), `[0 1]` (float-fixed), or `[0 0]` (float-float) swaps

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as a nonnegative integer `0` or `1`using an `NINST`-by-`1` (or `NINST`-by-`2` if `EndMonthRule` is different for each leg).

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`StartDate` — Date swap actually starts
`Settle` date (default) | datetime array | string array | date character vector

(Optional) Date swap actually starts, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `instswap` also accepts serial date numbers as inputs, but they are not recommended.

Use this argument to price forward swaps, that is, swaps that start in a future date

Output Arguments

`InstSet` — Variable containing a collection of instruments
structure

Variable containing a collection of instruments, returned as a structure. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or string for each instrument. For more information on the `InstSet` variable, see `instget`.

`FieldList` — Name of each data field for Swap instrument
cell array of character vectors

Name of each data field for a Swap instrument, returned as an `NFIELDS`-by-`1` cell array of character vectors.

`ClassList` — Data class for each field
cell array of character vectors

Data class for each field, returned as an `NFIELDS`-by-`1` cell array of character vectors. The class determines how arguments are parsed. Valid character vectors are `'dble'`, `'date'`, and `'char'`.

`TypeString` — Type of instrument
character vector

Type of instrument, returned as a character vector. For a Swap instrument, `TypeString = 'Swap'`.

More About

Amortizing Swap

In an amortizing swap, the notional principal decreases periodically because it is tied to an underlying financial instrument with a declining (amortizing) principal balance, such as a mortgage.

Forward Swap

Agreement to enter into an interest-rate swap arrangement on a fixed date in future.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `instswap` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

instswaption

Construct swaption instrument

Syntax

```
InstSet = instswaption(OptSpec,Strike,ExerciseDates,Spread,Settle,Maturity)
InstSet = instswaption( ___ ,AmericanOpt,SwapReset,Basis,Principal)
InstSet = instswaption(InstSetOld, ___ )
[FieldList,ClassList,TypeString] = instswaption
```

Description

`InstSet = instswaption(OptSpec,Strike,ExerciseDates,Spread,Settle,Maturity)` to specify a European swaption.

Fill in unspecified entries vectors with the value `NaN`. Only one data argument is required to create the instruments; the others may be omitted or passed as empty matrices `[]`.

`InstSet = instswaption( ___ ,AmericanOpt,SwapReset,Basis,Principal)` to specify an American swaption.

`InstSet = instswaption(InstSetOld, ___ )` to add swaption instruments to an instrument variable.

`[FieldList,ClassList,TypeString] = instswaption` to list field metadata for the swaption instrument.

Examples

Create Two Swaption Instruments

This example shows how to create two European swaption instruments using the following data.

```
OptSpec = {'Call'; 'Put'};
Strike = .05;
ExerciseDates = datetime(2011,1,1);
Spread=0;
Settle = datetime(2007,1,1);
Maturity = datetime(2012,1,1);
AmericanOpt = 0;

InstSet = instswaption(OptSpec, Strike, ExerciseDates, Spread, Settle, Maturity, ...
 AmericanOpt);

% view the European swaption instruments using instdisp
instdisp(InstSet)
```

```
Index Type     OptSpec Strike ExerciseDates  Spread Settle         Maturity       AmericanOpt Swa
1     Swaption Call    0.05   01-Jan-2011    0      01-Jan-2007    01-Jan-2012    0           1
2     Swaption Put     0.05   01-Jan-2011    0      01-Jan-2007    01-Jan-2012    0           1
```

Create Two European Swaption Instruments with Receiving and Paying Legs

This example shows how to create two European swaption instruments with receiving and paying legs using the following data.

```
OptSpec = {'Call'; 'Put'};
Strike = .05;
ExerciseDates = datetime(2011,1,1);
Spread=0;
Settle = datetime(2007,1,1);
Maturity = datetime(2012,1,1);
AmericanOpt = 0;
SwapReset = [2 4]; % 1st column represents receiving leg, 2nd column represents paying leg
Basis = [1 3];     % 1st column represents receiving leg, 2nd column represents paying leg

InstSet = instswaption(OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle,Maturity, ...
SwapReset,Basis);
```

View the European swaption instruments using `instdisp`.

```
instdisp(InstSet)
```

```
Index Type     OptSpec Strike ExerciseDates  Spread Settle Maturity       AmericanOpt SwapReset E
1     Swaption Call    0.05   01-Jan-2011    0      0      01-Jan-2007    NaN         2  4      1
2     Swaption Put     0.05   01-Jan-2011    0      0      01-Jan-2007    NaN         2  4      1
```

Input Arguments

`OptSpec` — Definition of option

cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`. A `'call'` swaption entitles the buyer to pay the fixed rate. A `'put'` swaption entitles the buyer to receive the fixed rate.

Data Types: `char` | `cell`

`Strike` — Strike swap rate values

vector

Strike swap rate values, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a vector using a datetime array, string array, or date character vectors, where each row is the schedule for one option and the last element of each row must be the same as the maturity of the tree.

- For a European option, use a `NINST`-by-`1` vector of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDate` on the option expiry date.

- For an American option, use a NINST-by-2 vector of exercise dates. For each instrument, the option can be exercised on any coupon date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is NINST-by-1, the option can be exercised between the underlying swap Settle and the single listed ExerciseDate.

To support existing code, instswaption also accepts serial date numbers as inputs, but they are not recommended.

Spread — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate, specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: double

Settle — Settle date for each swap
datetime array | string array | date character vector

Settle date for each swap, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instswaption also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for each swap
datetime array | string array | date character vector

Maturity date for each swap, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, instswaption also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

The AmericanOpt argument is required to invoke American exercise rules.

Data Types: double

SwapReset — Reset frequency per year for each leg
1 (default) | numeric

(Optional) Reset frequency per year for each leg, specified as a NINST-by-1 vector or NINST-by-2 matrix. If SwapReset is NINST-by-2, the first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of the instrument, specified as a `NINST`-by-`1` vector or `NINST`-by-`2` matrix representing the basis for each leg. If `Basis` is `NINST`-by-`2`, the first column represents the receiving leg, while the second column represents the paying leg.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`InstSetOld` — Variable containing an existing collection of instruments
struct

Variable containing an existing collection of instruments, specified as a struct. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. The `InstSetOld` argument is specified only when adding swaption instruments to an existing instrument set. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Output Arguments

`InstSet` — Variable containing collection of instruments
vector

(Optional) Variable containing a collection of instruments. Instruments are broken down by type and each type can have different data fields. Each stored data field has a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `double`

FieldList — Name of each data field for this instrument type
cell array of character vectors

Name of each data field for this instrument type, returned as a NFIELDS-by-1 cell array of character vectors.

Data Types: char | cell

ClassList — Data class of each field
character vector with value: 'dble', 'date', or 'char'.

Data class of each field, returned as a NFIELDS-by-1 cell array of character vectors. Valid character vectors are 'dble', 'date', and 'char'.

Data Types: char | cell

TypeString — Type of instrument added
character vector

Type of instrument added, returned as a character vector (for a swaption, TypeString = 'Swaption').

Data Types: char

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although instswaption supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

insttypes

List types

Syntax

```
TypeList = insttypes(InstSet)
```

Description

`TypeList = insttypes(InstSet)` retrieves a list of types stored in an instrument variable.

Examples

List Instrument Types

Retrieve the instrument set variable `ExampleInst` from the data file `InstSetExamples.mat`. `ExampleInst` contains three types of instruments: `Option`, `Futures`, and `TBill`.

```
load InstSetExamples;
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

List all of the types included in `ExampleInst`.

```
TypeList = insttypes(ExampleInst)
```

```
TypeList = 3x1 cell
    {'Futures'}
    {'Option' }
    {'TBill'  }
```

Input Arguments

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of instruments, specified as `InstSet` structure. Instruments are classified by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument. For more information on the `InstSet` variable, see `instget`.

Data Types: `struct`

Output Arguments

`TypeList` — Types of instrument

cell array of character vectors

Types of instruments, returned as an `NTYPES`-by-`1` cell array of character vectors listing the `Type` of instruments contained in the `InstSet` variable.

Version History

Introduced before R2006a

intenvget

Properties of interest-rate structure

Syntax

```
ParameterValue = intenvget(RateSpec,ParameterName)
```

Description

`ParameterValue = intenvget(RateSpec,ParameterName)` obtains the value of the named parameter `ParameterName` extracted from the `RateSpec`.

Examples

Extract Values from a RateSpec

Use `intenvset` to set the interest-rate structure.

```
RateSpec = intenvset('Rates',0.05,'StartDates',...
'20-Jan-2000','EndDates','20-Jan-2001')
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: 0.9518
            Rates: 0.0500
         EndTimes: 2
       StartTimes: 0
         EndDates: 730871
       StartDates: 730505
    ValuationDate: 730505
            Basis: 0
     EndMonthRule: 1
```

Use `intenvget` to extract values from the `RateSpec`.

```
[R, RateSpec] = intenvget(RateSpec,'Rates')
```

```
R = 0.0500
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: 0.9518
            Rates: 0.0500
         EndTimes: 2
       StartTimes: 0
         EndDates: 730871
       StartDates: 730505
    ValuationDate: 730505
            Basis: 0
```

```
    EndMonthRule: 1
```

Input Arguments

RateSpec — Interest-rate specification

structure

Interest-rate specification, specified by the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: `struct`

ParameterName — Parameter name to be accessed

character vector

Parameter name to be accessed, specified as a character vector. The value of the named parameter is extracted from the structure `RateSpec`. It is sufficient to type only the leading characters that uniquely identify the parameter. Case is ignored for parameter names.

Data Types: `char`

Output Arguments

ParameterValue — Value of the named parameter ParameterName extracted from RateSpec

scalar

Value of the named parameter `'ParameterName'` extracted from `RateSpec`, returned as a scalar value.

Version History

Introduced before R2006a

intenvprice

Price instruments from set of zero curves

Syntax

```
Price = intenvprice(RateSpecInstSet)
```

Description

`Price = intenvprice(RateSpecInstSet)` computes arbitrage-free prices for instruments against a set of zero coupon bond rate curves.

`intenvprice` handles the following instrument types: `'Bond'`, `'CashFlow'`, `'Fixed'`, `'Float'`, `'Swap'`. See `instadd` for information about constructing defined types.

Examples

Load Zero Curves and Instruments from Data File

Load the zero curves and instruments.

```
load deriv.mat
instdisp(ZeroInstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou

Input Arguments

RateSpec — Interest-rate specification

structure

(Optional) Interest-rate specification, specified by the RateSpec obtained previously from intenvset or toRateSpec for an IRDataCurve or toRateSpec for an IRFunctionCurve.

Data Types: struct

InstSet — Instrument variable containing a collection of instruments

structure

Instrument variable containing a collection of instruments, specified using instadd. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: struct

Output Arguments

Price — Prices of each instrument

matrix

Prices of each instrument, returned as a number of instruments (NINST) by number of curves (NUMCURVES) matrix. If an instrument cannot be priced, a NaN is returned in that entry.

For single-type pricing functions to retrieve pricing information, see the following:

bondbyzero	Price bonds from a set of zero curves.
cfbyzero	Price arbitrary cash flow instrument from a set of zero curves.
fixedbyzero	Fixed-rate note prices from a set of zero curves.
floatbyzero	Floating-rate note prices from a set of zero curves.
swapbyzero	Swap prices from a set of zero curves.

Version History

Introduced before R2006a

intenvsens

Instrument price and sensitivities from set of zero curves

Syntax

```
[Delta,Gamma,Price] = intenvprice(RateSpecInstSet)
```

Description

`[Delta,Gamma,Price] = intenvprice(RateSpecInstSet)` computes dollar prices and price sensitivities for instruments that use a zero coupon bond rate structure.

`intenvsens` handles the following instrument types: `'Bond'`, `'CashFlow'`, `'Fixed'`, `'Float'`, `'Swap'`. See `instadd` for information about constructing defined types.

Examples

Compute Prices Sensitivities for Instruments Using a Zero Coupon Bond Rate Structure

Load the tree and instruments from the `deriv.mat` data file and use `intenvprice` to compute dollar prices and sensitivities for instruments that use a zero coupon bond rate structure.

```
load deriv.mat
instdisp(ZeroInstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.04       01-Jan-2000    01-Jan-2003    1      NaN   NaN          NaN       NaN
2     Bond 0.04       01-Jan-2000    01-Jan-2004    2      NaN   NaN          NaN       NaN

Index Type  CouponRate Settle         Maturity       FixedReset Basis Principal Name     Quantity
3     Fixed 0.04       01-Jan-2000    01-Jan-2003    1          NaN   NaN       4% Fixed 80

Index Type  Spread Settle         Maturity       FloatReset Basis Principal Name       Quantity
4     Float 20     01-Jan-2000    01-Jan-2003    1          NaN   NaN       20BP Float 8

Index Type LegRate    Settle         Maturity       LegReset Basis Principal LegType Name

```

Input Arguments

`RateSpec` — Interest-rate specification

structure

(Optional) Interest-rate specification, specified by the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: `struct`

`InstSet` — Instrument variable containing a collection of instruments

structure

Instrument variable containing a collection of instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instrument prices with respect to shifts in the observed zero curve

vector

Rate of change of instrument prices with respect to shifts in the observed zero curve, returned as a number of instruments (`NINST`) by number of curves (`NUMCURVES`) matrix. `Delta` is computed by finite differences.

Note `Delta` sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`Gamma` — Rate of change of instrument deltas with respect to shifts in the observed zero curve

vector

Rate of change of instrument deltas with respect to shifts in the observed zero curve, returned as a number of instruments (`NINST`) by number of curves (`NUMCURVES`) matrix. `Gamma` is computed by finite differences.

Note `Gamma` sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

Price — Prices of each instrument
vector

Prices of each instrument, returned as a number of instruments (NINST) by number of curves (NUMCURVES) matrix. If an instrument cannot be priced, a NaN is returned in that entry.

Version History

Introduced before R2006a

Topics

“Pricing Using Interest-Rate Term Structure” on page 2-61
“Understanding the Interest-Rate Term Structure” on page 2-48

intenvset

Set properties of interest-rate structure

Syntax

```
RateSpec = intenvset(Name,Value)
[RateSpec,RateSpecOld] = intenvset(RateSpec,Name,Value)
[RateSpec,RateSpecOld] = intenvset
```

Description

`RateSpec = intenvset(Name,Value)` creates an interest-rate term structure (`RateSpec`) where the input argument list is specified as name-value pairs.

Note When creating a new `RateSpec`, the set of arguments passed to `intenvset` must include `StartDates`, `EndDates`, and either `Rates` or `Disc`.

Alternatively, you can create a `RateSpec` using the Financial Instruments Toolbox object framework to construct a `ratecurve` object. For more information on converting a `RateSpec` object to a `ratecurve` object, see “Convert RateSpec to a ratecurve Object” on page 1-49.

`[RateSpec,RateSpecOld] = intenvset(RateSpec,Name,Value)` creates an interest-rate term structure (`RateSpec`) where the input argument list is specified as name-value pairs along with the optional argument `RateSpec`. If the optional argument `RateSpec` is specified, `intenvset` modifies the existing interest-rate term structure `RateSpec` by changing the named argument to the specified values and recalculating the arguments dependent on the new values.

`[RateSpec,RateSpecOld] = intenvset` creates an interest-rate term structure `RateSpec` with all fields set to `[ ]`.

Examples

Create a RateSpec for a Zero Curve

Use `intenvset` to create a `RateSpec` for a zero curve.

```
RateSpec = intenvset('Rates', 0.05, 'StartDates',...
datetime(2000,1,20), 'EndDates', datetime(2021,1,20))
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: 0.3545
            Rates: 0.0500
         EndTimes: 42
       StartTimes: 0
         EndDates: 738176
       StartDates: 730505
```

```
    ValuationDate: 730505
            Basis: 0
     EndMonthRule: 1
```

Now change the `Compounding` argument to `1` (annual).

```
RateSpec = intenvset(RateSpec, 'Compounding', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.3545
            Rates: 0.0506
          EndTimes: 21
        StartTimes: 0
          EndDates: 738176
        StartDates: 730505
    ValuationDate: 730505
            Basis: 0
     EndMonthRule: 1
```

Calling `intenvset` with no input or output arguments displays a list of argument names and possible values.

```
intenvset
```

```
            Compounding: [ 0 | 1 | {2} | 3 | 4 | 6 | 12 | 365 | -1 ]
                   Disc: [ scalar | vector (NPOINTS x 1) ]
                  Rates: [ scalar | vector (NPOINTS x 1) ]
               EndDates: [ scalar | vector (NPOINTS x 1) ]
             StartDates: [ scalar | vector (NPOINTS x 1) ]
          ValuationDate: [ scalar ]
                  Basis: [ {0} | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 ]
           EndMonthRule: [ 0 | {1} ]
```

Create a RateSpec for a Forward Curve

Use `intenvset` to create a `RateSpec` for a forward curve.

```
RateSpec = intenvset('Rates', 0.05, 'StartDates',...
datetime(2001,1,20), 'EndDates', datetime(2022,1,20), 'ValuationDate',datetime(2000,1,20))
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: 0.3545
            Rates: 0.0500
          EndTimes: 44
        StartTimes: 2
          EndDates: 738541
        StartDates: 730871
    ValuationDate: 730505
            Basis: 0
```

```
     EndMonthRule: 1
```

Now change the `Compounding` argument to `1` (annual).

```
RateSpec = intenvset(RateSpec, 'Compounding', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.3545
            Rates: 0.0506
         EndTimes: 22
       StartTimes: 1
         EndDates: 738541
       StartDates: 730871
    ValuationDate: 730505
            Basis: 0
     EndMonthRule: 1
```

Create a RateSpec Using Two Curves

Define data for the interest-rate term structure and use `intenvset` to create a `RateSpec`.

```
StartDates = datetime(2011,11,1);
EndDates = [datetime(2012,11,1) ; datetime(2013,11,1) ; datetime(2014,11,1) ; datetime(2015,11,1
Rates = [[0.0356;0.041185;0.04489;0.047741],[0.0325;0.0423;0.0437;0.0465]];
RateSpec = intenvset('Rates', Rates, 'StartDates',StartDates,...
'EndDates', EndDates, 'Compounding', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x2 double]
            Rates: [4x2 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734808
    ValuationDate: 734808
            Basis: 0
     EndMonthRule: 1
```

To look at the `Rates` for the two interest-rate curves:

```
RateSpec.Rates
```

```
ans = 4×2

    0.0356    0.0325
    0.0412    0.0423
    0.0449    0.0437
    0.0477    0.0465
```

Create a RateSpec to Price Multi-Stepped Coupon Bonds

Price the following multi-stepped coupon bonds using the following data:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;

% Create RateSpec using intenvset
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Create a portfolio of stepped coupon bonds with different maturities
Settle = datetime(2010,1,1);
Maturity = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2011,1,1) .042;datetime(2012,1,1) .05;datetime(2013,1,1) .06;datetime(201

% Display the instrument portfolio
ISet = instbond(CouponRate, Settle, Maturity, 1);
instdisp(ISet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCoup
1     Bond [Cell]     01-Jan-2010    01-Jan-2011    1      0     1            NaN       NaN
2     Bond [Cell]     01-Jan-2010    01-Jan-2012    1      0     1            NaN       NaN
3     Bond [Cell]     01-Jan-2010    01-Jan-2013    1      0     1            NaN       NaN
4     Bond [Cell]     01-Jan-2010    01-Jan-2014    1      0     1            NaN       NaN
```

Build a `BDTTree` to price the stepped coupon bonds. Assume the volatility to be 10%

```
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RS, BDTTimeSpec);

% Compute the price of the stepped coupon bonds
PBDT = bdtprice(BDTT, ISet)
```

```
PBDT = 4×1

  100.6763
  100.7368
  100.9266
  101.0115
```

Input Arguments

RateSpec — Interest-rate specification for initial risk-free rate curve
structure

(Optional) Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `RateSpec = intenvset('Rates',0.05,'StartDates','20-Jan-2001','EndDates','20-Jan-2002','ValuationDate','20-Jan-2000')`

`Compounding` — Rate at which the input zero rates were compounded when annualized
`2` (default) | integer with value of `0`,`1`, `2`, `3`, `4`, `6`, `12`, `365`, or `-1`

Rate at which the input zero rates were compounded when annualized, specified as the comma-separated pair consisting of `'Compounding'` and a scalar integer value. The `Compounding` argument determines the formula for the discount factors (`Disc`):

- `Compounding` = `0` for simple interest
  - `Disc = 1/(1 + Z * T)`, where `T` is time in years and simple interest assumes annual times `F = 1`.
- `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units, for example, `T = F` is one year.
- `Compounding` = `365`
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- `Compounding` = `-1`
  - `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

`Disc` — Unit bond prices over investment intervals
`[ ]` (default) | matrix

Unit bond prices over investment intervals from `StartDates` (when the cash flow is valued) to `EndDates` (when the cash flow is received), specified as the comma-separated pair consisting of `'Disc'` and a number of points (`NPOINTS`) by number of curves (`NCURVES`) matrix.

Data Types: `double`

`Rates` — Interest rates
matrix of decimal values

Interest rates, specified as the comma-separated pair consisting of `'Rates'` and a number of points (`NPOINTS`) by number of curves (`NCURVES`) matrix of decimal values. `Rates` can only contain

negative decimal values if the resulting `RateSpec` is used with a Normal (Bachelier) model, shifted Black model, or a shifted SABR model.

Data Types: `double`

`EndDates` — Maturity dates ending the interval to discount over
datetime array | string array | date character vector

Maturity dates ending the interval to discount over, specified as the comma-separated pair consisting of `'EndDates'` and a scalar or a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `intenvset` also accepts serial date numbers as inputs, but they are not recommended.

`StartDates` — Dates starting the interval to discount over
datetime array | string array | date character vector

Dates starting the interval to discount over, specified as the comma-separated pair consisting of `'StartDates'` and a scalar or a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors. `StartDates` must be earlier than `EndDates`.

To support existing code, `intenvset` also accepts serial date numbers as inputs, but they are not recommended.

`ValuationDate` — Observation date of the investment horizons entered in `StartDates` and `EndDates`
`min(StartDates)` (default) | datetime array | string array | date character vector

Observation date of the investment horizons entered in `StartDates` and `EndDates`, specified as the comma-separated pair consisting of `'ValuationDate'` and a specified as a scalar datetime, string, or date character vector.

To support existing code, `intenvset` also accepts serial date numbers as inputs, but they are not recommended.

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer value.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar integer with a value of `0` or `1`. This rule applies only when `EndDates` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`RateSpec` — Interest-rate specification for initial rate curve
structure

Interest-rate specification for initial rate curve, returned as a structure.

`RateSpecOld` — Properties of an interest-rate structure before the changes introduced by the call to `intenvset`
structure

Properties of an interest-rate structure before the changes introduced by the call to `intenvset`, returned as a structure.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `intenvset` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

isafin

True if input argument is financial structure type or financial object class

Syntax

```
IsFinObj = isafin(Obj,ClassName)
```

Description

`IsFinObj = isafin(Obj,ClassName)` returns true (`1`) if input argument is a financial structure type or financial object class, otherwise false (`0`) is returned.

Examples

Determine if Input is Financial Structure Type or Financial Object Class

`isafin` returns true (`1`) if input argument is a financial structure type or financial object class, otherwise false (`0`) is returned.

```
load deriv.mat
IsFinObj = isafin(HJMTree, 'HJMFwdTree')
```

```
IsFinObj = logical
   1
```

Input Arguments

`Obj` — Name of a financial structure

object

Name of a financial structure, specified as an object.

Data Types: `object`

`ClassName` — Name of financial structure class

character vector

Name of a financial structure class, specified as a character vector.

Data Types: `char`

Output Arguments

`IsFinObj` — Is input argument is financial structure type or financial object class

logical

Is input argument is financial structure type or financial object class, returned as a logical. `isafin` returns true (`1`) if input argument is a financial structure type or financial object class, otherwise false (`0`).

ittprice

Price instruments using implied trinomial tree (ITT)

Syntax

```
[Price,PriceTree] = ittprice(ITTTree,InstSet)
[Price,PriceTree] = ittprice( ___ ,Options)
```

Description

`[Price,PriceTree] = ittprice(ITTTree,InstSet)` price instruments using an implied trinomial tree (ITT) created with `itttree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`ittprice` handles the following instrument types: optstock, barrier, Asian, lookback, and compound. Use `instadd` to construct the defined types.

`[Price,PriceTree] = ittprice( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Price Instruments Using Implied Trinomial Tree (ITT)

Load the ITT tree and instruments from the data file `deriv.mat`.

```
load deriv.mat
```

Display the barrier and Asian options contained in the instrument set.

```
ITTSubSet = instselect(ITTInstSet,'Type', {'Barrier', 'Asian'});

instdisp(ITTSubSet)
```

```
Index Type    OptSpec Strike Settle         ExerciseDates  AmericanOpt BarrierSpec Barrier Rebate
1     Barrier call    85     01-Jan-2006    31-Dec-2008    1           ui          115     0

Index Type  OptSpec Strike Settle         ExerciseDates  AmericanOpt AvgType    AvgPrice AvgDate
2     Asian call    55     01-Jan-2006    01-Jan-2008    0           arithmetic NaN      NaN
3     Asian call    55     01-Jan-2006    01-Jan-2010    0           arithmetic NaN      NaN
```

Price the barrier and Asian options contained in the instrument set.

```
[Price, PriceTree] = ittprice(ITTTree, ITTSubSet)
```

```
Price = 3×1

    2.4074
    3.2052
    6.6074
```

```
PriceTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x5 cell}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]
```

Input Arguments

`ITTTree` — Implied trinomial stock tree structure

structure

Implied trinomial stock tree structure, specified by using `itttree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Price for each instrument

vector

Price for each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

For information on single-type pricing functions to retrieve state-by-state pricing tree information, see the following:

- `barrierbyitt` for pricing barrier options using an ITT tree
- `optstockbyitt` for pricing American, European, or Bermuda options using an ITT tree
- `asianbyitt` for pricing Asian options using an ITT tree
- `lookbackbyitt` for pricing lookback options using an ITT tree
- `compoundbyitt` for price compound options using an ITT tree
- `cbondbyitt` for pricing convertible bonds using an ITT tree

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

Version History

Introduced in R2007a

ittsens

Instrument sensitivities and prices using implied trinomial tree (ITT)

Syntax

```
[Delta,Gamma,Vega,Price] = ittsens(ITTTree,InstSet)
[Delta,Gamma,Vega,Price] = ittsens( ___ ,Options)
```

Description

`[Delta,Gamma,Vega,Price] = ittsens(ITTTree,InstSet)` calculates instrument sensitivities and prices using an implied trinomial tree (ITT) that is created with the `itttree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`ittsens` handles the following instrument types: optstock, barrier, Asian, lookback, and compound. Use `instadd` to construct the defined types.

`[Delta,Gamma,Vega,Price] = ittsens( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Compute Instrument Sensitivities Using an Implied Trinomial Tree (ITT)

Load the ITT tree and instruments from the data file `deriv.mat` and display the vanilla options and barrier option instruments.

```
load deriv.mat
ITTSubSet = instselect(ITTInstSet,'Type', {'OptStock', 'Barrier'});

instdisp(ITTSubSet)
```

```
Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt Name  Quantity
1     OptStock call    95     01-Jan-2006    31-Dec-2008    1           Call1 10
2     OptStock put     80     01-Jan-2006    01-Jan-2010    0           Put1   4

Index Type    OptSpec Strike Settle         ExerciseDates  AmericanOpt BarrierSpec Barrier Rebate
3     Barrier call    85     01-Jan-2006    31-Dec-2008    1           ui          115     0
```

Compute the `Delta` and `Gamma` sensitivities of vanilla options and barrier option contained in the instrument set.

```
[Delta, Gamma] = ittsens(ITTTree, ITTSubSet)
```

```
Warning: The option set specified in StockOptSpec was too narrow for the generated tree.
This made extrapolation necessary. Below is a list of the options that were outside of the
range of those specified in StockOptSpec.

Option Type: 'call'   Maturity: 01-Jan-2007  Strike=67.2897
```

```
Option Type: 'put'   Maturity: 01-Jan-2007  Strike=37.1528
Option Type: 'put'   Maturity: 01-Jan-2008  Strike=27.6066
Option Type: 'put'   Maturity: 31-Dec-2008  Strike=20.5132
Option Type: 'call'   Maturity: 01-Jan-2010  Strike=164.0157
Option Type: 'put'   Maturity: 01-Jan-2010  Strike=15.2424

Delta = 3×1

    0.2387
   -0.4283
    0.3482

Gamma = 3×1

    0.0260
    0.0188
    0.0380
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in the stock price

vector

Rate of change of instruments prices with respect to changes in the stock price, returned as a `NINST`-by-`1` vector of deltas.

For path-dependent options (`'Lookback'` and `'Asian'`), `Delta` and `Gamma` are computed by finite differences in calls to `ittprice`. For the rest of the options (`'OptStock'`, `'Barrier'`, `'CBond'`,

and 'Compound'), Delta and Gamma are computed from the ITTTree and the corresponding option price tree.

Gamma — Rate of change of instruments deltas with respect to changes in stock price
vector

Rate of change of instruments deltas with respect to changes in the stock price, returned as a NINST-by-1 vector of gammas.

For path-dependent options ('Lookback' and 'Asian'), Delta and Gamma are computed by finite differences in calls to ittprice. For the rest of the options ('OptStock', 'Barrier', 'CBond', and 'Compound'), Delta and Gamma are computed from the ITTTree and the corresponding option price tree.

Vega — Rate of change of instruments prices with respect to changes in volatility of the stock
vector

Rate of change of instruments prices with respect to changes in the volatility of the stock, returned as a NINST-by-1 vector of vegas. Vega is computed by finite differences in calls to itttree.

Price — Price of each instrument
vector

Price of each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

Version History

Introduced in R2007a

itttimespec

Specify time structure using implied trinomial tree (ITT)

Syntax

```
TimeSpec = itttimespec(ValuationDate,Maturity,NumPeriods)
```

Description

`TimeSpec = itttimespec(ValuationDate,Maturity,NumPeriods)` creates the structure specifying the time layout for an ITT tree (`itttree`).

Examples

Creates the Structure Specifying the Time Layout for an ITT Tree

This example shows how to specify a four-period tree with time steps of 1 year.

```
ValuationDate = datetime(2006,7,1);
Maturity = datetime(2010,7,1);
TimeSpec = itttimespec(ValuationDate, Maturity, 4)
```

```
TimeSpec = struct with fields:
           FinObj: 'ITTTimeSpec'
    ValuationDate: 732859
         Maturity: 734320
       NumPeriods: 4
            Basis: 0
     EndMonthRule: 1
             tObs: [0 1 2 3 4]
             dObs: [732859 733224 733589 733954 734320]
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the `itttree`, specified as a scalar datetime, string, or date character vector.

To support existing code, `itttimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Date marking the depth of the EQP stock tree

datetime scalar | string scalar | date character vector

Date marking the depth of the `itttree` trinomial tree, specified as scalar datetime, string, or date character vector.

To support existing code, `itttimespec` also accepts serial date numbers as inputs, but they are not recommended.

`NumPeriods` — Number of time steps in the ITT tree
integer

Number of time steps in the `itttree` trinomial tree, specified as scalar integer value.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `itttree`
structure

Specification for the time layout for `itttree`, returned as a structure.

Version History

Introduced in R2007a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `itttimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

itttree

Build implied trinomial stock tree

Syntax

```
ITTTree = itttree(StockSpec,RateSpec,TimeSpec,StockOptSpec)
```

Description

`ITTTree = itttree(StockSpec,RateSpec,TimeSpec,StockOptSpec)` builds an implied trinomial (ITT) stock tree.

Examples

Create an ITT Tree

Assume that the interest rate is fixed at 8% annually between the valuation date of the tree (January 1, 2006) until its maturity.

```
Rate = 0.08;
ValuationDate = '01-01-2006';
EndDate = '01-01-2008';

RateSpec = intenvset('StartDates', ValuationDate, 'EndDates', EndDate, ...
    'ValuationDate', ValuationDate, 'Rates', Rate, 'Compounding', -1);
```

To build an `ITTTree`, create the `StockSpec`, `TimeSpec`, and `StockOptSpec` structures.

```
Sigma = 0.20;
AssetPrice = 50;
DividendType = 'cash';
DividendAmounts = [0.50; 0.50; 0.50; 0.50];
ExDividendDates = {'03-Jan-2007'; '01-Apr-2007'; '05-July-2007';'01-Oct-2007'}

StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates);

ValuationDate = '01-01-2006';
EndDate = '01-01-2008';
NumPeriods = 4;

TimeSpec = itttimespec(ValuationDate, EndDate, NumPeriods);
```

Build a `StockOptSpec` structure.

```
Settle =   '01/01/06';

Maturity =    ['07/01/06';
    '07/01/06';
    '07/01/06';
    '07/01/06';
```

```
    '01/01/07';
    '01/01/07';
    '01/01/07';
    '01/01/07';
    '07/01/07';
    '07/01/07';
    '07/01/07';
    '07/01/07';
    '01/01/08';
    '01/01/08';
    '01/01/08';
    '01/01/08'];

Strike = [113;
   101;
   100;
    88;
   128;
   112;
   100;
    78;
   144;
   112;
   100;
    69;
   162;
   112;
   100;
    61];

OptPrice =[                0;
   4.807905472659144;
   1.306321897011867;
   0.048039195057173;
                   0;
   2.310953054191461;
   1.421950392866235;
   0.020414826276740;
                   0;
   5.091986935627730;
   1.346534812295291;
   0.005101325584140;
                   0;
   8.047628153217246;
   1.219653432150932;
   0.001041436654748];

OptSpec = { 'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put';
    'call';
    'call';
```

```
    'put';
    'put';
    'call';
    'call';
    'put';
    'put'};

StockOptSpec = stockoptspec(OptPrice, Strike, Settle, Maturity, OptSpec);
```

Use `itttree` to build the `ITTTree` structure. Note, in this example, the extrapolation warnings are turned on. These warnings are a consequence of having to extrapolate to find the option price of the tree nodes. In this example, the set of inputs options was too narrow for the shift in the tree nodes introduced by the disturbance used to calculate the sensitivities. As a consequence extrapolation for some of the nodes was needed.

```
warning('on', 'fininst:itttree:Extrapolation');
ITTTree = itttree(StockSpec, RateSpec, TimeSpec, StockOptSpec)
```

```
Warning: The option set specified in StockOptSpec was too narrow for the generated tree.
This made extrapolation necessary. Below is a list of the options that were outside of
the range of those specified in StockOptSpec.

Option Type: 'call'   Maturity: 02-Jul-2006  Strike=60.7466
Option Type: 'put'   Maturity: 02-Jul-2006  Strike=50.0731

```

Input Arguments

`StockSpec` — Stock specification

structure

Stock specification, specified by the `StockSpec` obtained from `stockspec`. See `stockspec` for information on creating a stock specification.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Tree time layout specification

structure

Tree time layout specification, specified by the `TimeSpec` obtained from `itttimespec`. The `TimeSpec` defines the observation dates of the ITT tree. See `itttimespec` for information on the tree structure.

Data Types: `struct`

`StockOptSpec` — Option stock specification

structure

Option stock specification, specified by the `StockOptSpec` obtained from `stockoptspec`. See `stockoptspec` for information on creating a stock specification.

Data Types: `struct`

Output Arguments

`ITTTree` — ITT trinomial tree

structure

ITT trinomial tree, returned as a structure specifying the time layout for the tree.

Version History

Introduced in R2007a

LiborMarketModel

Create LIBOR Market Model

Description

The LIBOR Market Model (LMM) is an interest-rate model that differs from short rate models in that it evolves a set of discrete forward rates.

Specifically, the lognormal LMM specifies the following diffusion equation for each forward rate

$$\frac{dF_i(t)}{F_i} = -\mu_i dt + \sigma_i(t) dW_i$$

where:

W is an N-dimensional geometric Brownian motion with

$$dW_i(t) dW_j(t) = \rho_{ij}$$

The LMM relates drifts of the forward rates based on no-arbitrage arguments. Specifically, under the Spot LIBOR measure, drifts are expressed as

$$\mu_i(t) = -\sigma_i(t) \sum_{j=q(t)}^{i} \frac{\tau_j \rho_{i,j} \sigma_j(t) F_j(t)}{1 + \tau_j F_j(t)}$$

where:

$\rho_{i,j}$ represents the input argument `Correlation`.

$\sigma_j(t)$ represents the input argument `VolFunc`.

$F_j(t)$ represents the computation of the input argument for `ZeroCurve`.

τ_i is the time fraction associated with the i th forward rate

$q(t)$ is an index defined by the relation

$$T_{q(t)-1} < t < T_{q(t)}$$

and the Spot LIBOR numeraire is defined as

$$B(t) = P(t, T_{q(t)}) \prod_{n=0}^{q(t)-1} (1 + \tau_n F_n(T_n))$$

Creation

Syntax

```
LMM = LiborMarketModel(ZeroCurve,VolFunc,Correlation)
LMM = LiborMarketModel( ___ ,Name,Value)
```

Description

`LMM = LiborMarketModel(ZeroCurve,VolFunc,Correlation)` creates a `LiborMarketModel` (`LMM`) object using the required arguments for `ZeroCurve`, `VolFunc`, `Correlation`.

Note Alternatively, you can use the `SABRBraceGatarekMusiela` or `BraceGatarekMusiela` model objects to create a LIBOR market model. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`LMM = LiborMarketModel( ___ ,Name,Value)` sets Properties on page 11-964 using name-value pairs. For example, `LMM = LiborMarketModel(irdc,VolFunc,Correlation,'Period',1)`. You can specify multiple name-value pairs. Enclose each property name in single quotes.

Input Arguments

`ZeroCurve` — Zero curve used to evolve path of future interest rates

`IRDataCurve` object | `RateSpec`

Zero curve used to evolve the path of future interest rates, specified as an output from `IRDataCurve` or a `RateSpec` that is obtained from `intenvset`. The `ZeroCurve` input sets the ZeroCurve on page 11-0 property.

Data Types: `object` | `struct`

`VolFunc` — Volatility function

cell array of function handles

Volatility function, specified using a `NumRates`-by-`1` cell array of function handles and sets the VolFunc on page 11-0 property. Each function handle must take time as an input and, return a scalar volatility.

Note The number of rates to simulate using the `simTermStructs` function is determined by the size of the `VolFunc` and `Correlation` inputs which must be consistent. These can be any value and, together with the `Period` property, determines the kinds and number of rates being simulated. For example, if the `Period` is set to `4` (quarterly) and `VolFunc` has length of `120` and `Correlation` has size `120`-by-`120`, then `120` quarterly rates are simulated. In other words, 30 years of the yield curve are simulated (0-3mos, 3mos-6mos, 6mos-9mos, and so on, all the way up to 30 years). Therefore, if `VolFunc` and `Correlation` have size `120`, the output of a call to `simTermStructs` is (`nPeriods` +`1`) -by-`121`-by-`nTrials`.

Data Types: `cell`

`Correlation` — Correlation matrix

matrix

Correlation matrix, specified using a NumRates-by-NumRates correlation matrix and sets the Correlation on page 11-0 property.

Note The number of rates to simulate using the simTermStructs function is determined by the size of the VolFunc and Correlation inputs which must be consistent. These can be any value and, together with the Period property, determines the kinds and number of rates being simulated. For example, if the Period is set to 4 (quarterly) and VolFunc has length of 120 and Correlation has size 120-by-120, then 120 quarterly rates are simulated. In other words, 30 years of the yield curve are simulated (0-3mos, 3mos-6mos, 6mos-9mos, and so on, all the way up to 30 years). Therefore, if VolFunc and Correlation have size 120, the output of a call to simTermStructs is (nPeriods +1) -by-121-by-nTrials.

Data Types: double

Properties

ZeroCurve — Zero curve

IRDataCurve object | RateSpec

Zero curve, specified as an output from IRDataCurve or a RateSpec that is obtained from intenvset.

Data Types: object | struct

VolFunc — Volatility function

cell array of function handles

Volatility function, specified using a NumRates-by-1 cell array of function handles. Each function handle must take time as an input and, return a scalar volatility.

Data Types: cell

Correlation — Correlation matrix

matrix

Correlation matrix, specified using a NumRates-by-NumRates correlation matrix.

Data Types: double

NumFactors — Number of Brownian factors

NaN (default) | numeric

Number of Brownian factors, specified as a numeric value. The default is NaN, where the number of factors is equal to the number of rates.

Data Types: double

Period — Period of forward rates, specifically number of rates per year

2 (default) | numeric with value 1, 2, 4, or 12

Period of the forward rates, specifically the number of rates per year, specified as a numeric value of 1, 2, 4, or 12. The default value is 2, meaning forward rates are spaced at 0, .5, 1, 1.5, and so on.

Data Types: double

Object Functions

simTermStructs Simulate term structures for LIBOR Market Model

Examples

Create a LIBOR Market Model Using an IRDataCurve

Create a LMM object using an IRDataCurve.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = 20;
VolFunc(1:numRates,1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates)',meshgrid(1:numRates),Beta);

LMM = LiborMarketModel(irdc,VolFunc,Correlation,'Period',1)
```

```
LMM =
  LiborMarketModel with properties:

       ZeroCurve: [1x1 IRDataCurve]
    VolFunctions: {20x1 cell}
     Correlation: [20x20 double]
      NumFactors: NaN
          Period: 1
```

Simulate the term structures for the specified LMM object.

```
[ZeroRates, ForwardRates] = simTermStructs(LMM, 10,'nTrials',100);
```

Create a LIBOR Market Model Using a RateSpec

Create a LMM object using a RateSpec.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

RateSpec = intenvset('Rates',ZeroRates,'EndDates',CurveDates,'StartDate',Settle);
```

```
LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = 20;
VolFunc(1:numRates,1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates)',meshgrid(1:numRates),Beta);

LMM = LiborMarketModel(RateSpec,VolFunc,Correlation,'Period',1)

LMM =
  LiborMarketModel with properties:

       ZeroCurve: [1x1 IRDataCurve]
    VolFunctions: {20x1 cell}
     Correlation: [20x20 double]
      NumFactors: NaN
          Period: 1
```

Simulate the term structures for the specified `LMM` object.

```
[ZeroRates, ForwardRates] = simTermStructs(LMM, 10,'nTrials',100);
```

More About

LIBOR Market Model

The LIBOR Market Model, also called the BGM Model (Brace, Gatarek, Musiela Model) is a financial model of interest rates.

The quantities that are modeled are a set of forward rates (also called forward LIBORs) which have the advantage of being directly observable in the market, and whose volatilities are naturally linked to traded contracts.

Version History

Introduced in R2013a

simTermStructs

Simulate term structures for LIBOR Market Model

Syntax

```
[ZeroRates,ForwardRates] = simTermStructs(LMM,nPeriods)
[ZeroRates,ForwardRates] = simTermStructs(___,Name,Value)
```

Description

`[ZeroRates,ForwardRates] = simTermStructs(LMM,nPeriods)` simulates future zero curve paths using a specified `LiborMarketModel` object.

`[ZeroRates,ForwardRates] = simTermStructs(___,Name,Value)` adds optional name-value pair arguments.

Examples

Simulate Term Structures for a LIBOR Market Model

Create a `LMM` object.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = 20;
VolFunc(1:numRates-1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
Correlation = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),Beta);

LMM = LiborMarketModel(irdc,VolFunc,Correlation,'Period',1)
```

```
LMM =
  LiborMarketModel with properties:

       ZeroCurve: [1x1 IRDataCurve]
    VolFunctions: {1x19 cell}
     Correlation: [19x19 double]
      NumFactors: NaN
          Period: 1
```

Simulate the term structures for the specified LMM object.

```
[ZeroRates, ForwardRates] = simTermStructs(LMM, 20,'nTrials',100);
```

Input Arguments

LMM — LiborMarketModel object

object

LiborMarketModel object, specified using the LMM object created using LiborMarketModel.

Data Types: object

nPeriods — Number of simulation periods

numeric

Number of simulation periods, specified as a numeric value. The nPeriods value is determined by the swaption expiry and the periodicity of the rates of the model. For example, if you were to price a swaption expiring in 5 years with a semiannual LIBOR Market Model (LMM), then nPeriods would be 10.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [ZeroRates, ForwardRates] = simTermStructs(LMM, 20,'nTrials',100)

nTrials — Number of simulated trials

1 (default) | positive integer

Number of simulated trials (sample paths), specified as the comma-separated pair consisting of 'nTrials' and a positive scalar integer value of nPeriods observations each. If you do not specify a value for this argument, the default is 1, indicating a single path of correlated state variables.

Data Types: double

antithetic — Flag indicating whether antithetic sampling is used to generate Gaussian random variates

false (default) | positive integer

Flag indicating whether antithetic sampling is used to generate the Gaussian random variates that drive the zero-drift, unit-variance rate Brownian vector $dW(t)$, specified as the comma-separated pair consisting of 'antithetic' and a Boolean scalar flag. For details on the Brownian vector, see simBySolution.

Data Types: logical

Z — Direct specification of dependent random noise process

generated by simBySolution function (default) | numeric

Direct specification of the dependent random noise process, specified as the comma-separated pair consisting of `'Z'` and a numeric value. The `Z` value is used to generate the zero-drift, unit-variance rate Brownian vector $dW(t)$ that drives the simulation. For details, see `simBySolution` for the GBM model.

Data Types: `double`

`Tenor` — Maturities to compute at each time step
number of rates in `LiborMarketModel` object (default) | numeric vector

Maturities to compute at each time step, specified as the comma-separated pair consisting of `'Tenor'` and a numeric vector.

`Tenor` enables you to choose a different set of rates to output than the underlying rates. For example, you may want to simulate quarterly data but only report annual rates; this can be done by specifying the optional input `Tenor`.

The default for `tenor` is the number of rates in the `LiborMarketModel` object as specified by the `Correlation` and `VolFunc` input arguments for the `LiborMarketModel` object.

Data Types: `double`

Output Arguments

`ZeroRates` — Simulated zero-rate term structures
matrix

Simulated zero-rate term structures, returned as a `nPeriods+1`-by-`nTenors`-by-`nTrials` matrix.

`ForwardRates` — Simulated forward-rate term structures
matrix

Simulated zero-rate term structures, returned as a `nPeriods+1`-by-`nTenors`-by-`nTrials` matrix.

LinearGaussian2F

Create two-factor additive Gaussian interest-rate model

Description

The two-factor additive Gaussian interest rate-model is specified using the zero curve, a, b, sigma, eta, and rho parameters.

Specifically, the LinearGaussian2F model is defined using the following equations:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -a(t)x(t)dt + \sigma(t)dW_1(t), x(0) = 0$$

$$dy(t) = -b(t)y(t)dt + \eta(t)dW_2(t), y(0) = 0$$

where $dW_1(t)dW_2(t) = \rho dt$ is a two-dimensional Brownian motion with correlation ρ, and ϕ is a function chosen to match the initial zero curve.

Creation

Syntax

```
G2PP = LinearGaussian2F(ZeroCurve,a,b,sigma,eta,rho)
```

Description

`G2PP = LinearGaussian2F(ZeroCurve,a,b,sigma,eta,rho)` creates a `LinearGaussian2F` (`G2PP`) object using the required arguments to set the Properties on page 11-971.

Note Alternatively, you can use the `LinearGaussian2F` model object to create a two-factor additive Gaussian interest-rate model. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

Properties

ZeroCurve — Zero curve

`IRDataCurve` object | `RateSpec`

Zero curve, specified as an output from `IRDataCurve` or a `RateSpec` that is obtained from `intenvset`. This is the zero curve used to evolve the path of future interest rates.

Data Types: `object` | `struct`

a — Mean reversion for first factor

numeric

Mean reversion for the first factor, specified either as a scalar or function handle which takes time as input and returns a scalar mean reversion value.

Data Types: `double`

b — Mean reversion for second factor
numeric

Mean reversion for the second factor, specified either as a scalar or as a function handle which takes time as input and returns a scalar mean reversion value.

Data Types: `double`

`sigma` — Volatility for first factor
numeric

Volatility for the first factor, specified either as a scalar or function handle which takes time as input and returns a scalar mean volatility.

Data Types: `double`

`eta` — Volatility for second factor
numeric

Volatility for the second factor, specified either as a scalar or function handle which takes time as input and returns a scalar mean volatility.

Data Types: `double`

`rho` — Scalar correlation of factors
numeric

Scalar correlation of the factors, specified as a numeric value.

Data Types: `double`

Object Functions

simTermStructs Simulate term structures for two-factor additive Gaussian interest-rate model

Examples

Create a Two-Factor Additive Gaussian Interest-Rate Model Using an `IRDataCurve`

Create a two-factor additive Gaussian interest-rate model using an `IRdataCurve`.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
```

```
eta = .006;
rho = -.7;

G2PP = LinearGaussian2F(irdc,a,b,sigma,eta,rho)
```

```
G2PP =
  LinearGaussian2F with properties:

    ZeroCurve: [1x1 IRDataCurve]
            a: @(t,V)ina
            b: @(t,V)inb
        sigma: @(t,V)insigma
          eta: @(t,V)ineta
          rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` model.

```
 SimPaths = simTermStructs(G2PP, 10,'nTrials',100);
```

Create a Two-Factor Additive Gaussian Interest-Rate Model Using a RateSpec

Create a two-factor additive Gaussian interest-rate model using a `RateSpec`.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

RateSpec = intenvset('Rates',ZeroRates,'EndDates',CurveDates,'StartDate',Settle);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

G2PP = LinearGaussian2F(RateSpec,a,b,sigma,eta,rho)
```

```
G2PP =
  LinearGaussian2F with properties:

    ZeroCurve: [1x1 IRDataCurve]
            a: @(t,V)ina
            b: @(t,V)inb
        sigma: @(t,V)insigma
          eta: @(t,V)ineta
          rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` model.

```
 SimPaths = simTermStructs(G2PP, 10,'nTrials',100);
```

More About

Two-Factor Additive Gaussian Interest-Rate Model

Short-rate model based on two factors where the short rate is the sum of the two factors and a deterministic function.

In this case $\phi(t)$, which is chosen to match the initial term structure.

Version History

Introduced in R2013a

simTermStructs

Simulate term structures for two-factor additive Gaussian interest-rate model

Syntax

```
[ZeroRates,ForwardRates] = simTermStructs(G2PP,nPeriods)
[ZeroRates,ForwardRates] = simTermStructs(___,Name,Value)
```

Description

`[ZeroRates,ForwardRates] = simTermStructs(G2PP,nPeriods)` simulates future zero curve paths using a specified `LinearGaussian2F` object.

`[ZeroRates,ForwardRates] = simTermStructs(___,Name,Value)` adds optional name-value pair arguments.

Examples

Simulate Term Structures for the LinearGaussian2F Model

Create a two-factor additive Gaussian interest-rate model.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

G2PP = LinearGaussian2F(irdc,a,b,sigma,eta,rho)
```

```
G2PP =
  LinearGaussian2F with properties:

    ZeroCurve: [1x1 IRDataCurve]
            a: @(t,V)ina
            b: @(t,V)inb
        sigma: @(t,V)insigma
          eta: @(t,V)ineta
          rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` model.

```
SimPaths = simTermStructs(G2PP, 10,'nTrials',100);
```

Simulate Term Structures for the LinearGaussian2F Model Using a Vector for deltaTime

Create a two-factor additive Gaussian interest-rate model.

```
Settle = datetime(2007,12,15);
CurveTimes = [1:5 7 10 20]';
ZeroRates = [.01 .018 .024 .029 .033 .034 .035 .034]';
CurveDates = daysadd(Settle,360*CurveTimes,1);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);
a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;
G2PP = LinearGaussian2F(irdc,a,b,sigma,eta,rho)
```

```
G2PP =
  LinearGaussian2F with properties:

    ZeroCurve: [1x1 IRDataCurve]
            a: @(t,V)ina
            b: @(t,V)inb
        sigma: @(t,V)insigma
          eta: @(t,V)ineta
          rho: -0.7000
```

Use the `simTermStructs` method to simulate term structures based on the `LinearGaussian2F` object, where uneven simulation tenors are specified using the optional name-value argument `deltaTime` as a vector of length `NPeriods`.

```
NPeriods = 10;
dt = rand(NPeriods,1);
SimPaths = G2PP.simTermStructs(NPeriods,'nTrials',100,'DeltaTime',dt);
```

Input Arguments

G2PP — LinearGaussian2F object

object

`LinearGaussian2F` object, specified using the `G2PP` object created using `LinearGaussian2F`.

Data Types: `object`

nPeriods — Number of simulation periods

numeric

Number of simulation periods, specified as a numeric value. For example, to simulate 12 years with an annual spacing, specify `12` as the `nPeriods` input and `1` as the optional `deltaTime` input (note that the default value for `deltaTime` is `1`).

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[ZeroRates,ForwardRates] = simTermStructs(G2PP,NPeriods,'nTrials',100,'deltaTime',dt)`

`deltaTime` — Time step between `nPeriods`

1 (default) | numeric

Time step between `nPeriods`, specified as the comma-separated pair consisting of `'deltaTime'` and a numeric scalar or vector. For example, to simulate 12 years with an annual spacing, specify `12` as the `nPeriods` input and `1` as the optional `deltaTime` input (note that the default value for `deltaTime` is `1`).

Data Types: `double`

`nTrials` — Number of simulated trials

1 (default) | positive integer

Number of simulated trials (sample paths), specified as the comma-separated pair consisting of `'nTrials'` and a positive scalar integer value of `nPeriods` observations each. If you do not specify a value for this argument, the default is `1`, indicating a single path of correlated state variables.

Data Types: `double`

`antithetic` — Flag indicating whether antithetic sampling is used to generate Gaussian random variates

`false` (default) | positive integer

Flag indicating whether antithetic sampling is used to generate the Gaussian random variates that drive the zero-drift, unit-variance rate Brownian vector $dW(t)$, specified as the comma-separated pair consisting of `'antithetic'` and a Boolean scalar flag. For details, see `simBySolution` for the HWV model.

Data Types: `logical`

`Z` — Direct specification of dependent random noise process

Gaussian variates generated by `simBySolution` function (default) | numeric

Direct specification of the dependent random noise process, specified as the comma-separated pair consisting of `'Z'` and a numeric value. The `Z` value is used to generate the zero-drift, unit-variance rate Brownian vector $dW(t)$ that drives the simulation. For details, see `simBySolution` for the HWV model. If you do not specify a value for `Z`, `simBySolution` generates Gaussian variates.

Data Types: `double`

`Tenor` — Maturities to compute at each time step

tenor of `LinearGaussian2F` object zero curve (default) | numeric vector

Maturities to compute at each time step, specified as the comma-separated pair consisting of `'Tenor'` and a numeric vector.

`Tenor` enables you to choose a different set of rates to output than the underlying rates. For example, you may want to simulate quarterly data but only report annual rates; this can be done by specifying the optional input `Tenor`.

Data Types: `double`

Output Arguments

`ZeroRates` — Simulated zero-rate term structures

matrix

Simulated zero-rate term structures, returned as a `nPeriods+1`-by-`nTenors`-by-`nTrials` matrix.

`ForwardRates` — Simulated forward-rate term structures

matrix

Simulated zero-rate term structures, returned as a `nPeriods+1`-by-`nTenors`-by-`nTrials` matrix. The `ForwardRates` output is computed using the simulated short rates and by using the model definition to recover the entire yield curve at each simulation date.

Version History

Introduced in R2013a

lookbackbycrr

Price lookback option from Cox-Ross-Rubinstein binomial tree

Syntax

```
Price = lookbackbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbycrr( ___ ,AmericanOpt)
```

Description

`Price = lookbackbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using a Cox-Ross-Rubinstein binomial tree.

Note Alternatively, you can use the `Lookback` object to price lookback options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = lookbackbycrr( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

Examples

Price a Lookback Option Using a CRR Binomial Tree

This example shows how to price a lookback option using a CRR binomial tree by loading the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'Call';
Strike = 115;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2006,1,1);

Price = lookbackbycrr(CRRTree, OptSpec, Strike, Settle, ...
ExerciseDates)
```

```
Price = 7.6015
```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure for a Cox-Ross-Rubinstein binomial tree, specified by using `crrtree`.

Data Types: `struct`

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector or an NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

Strike — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using an NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

To compute the value of a floating-strike lookback option, Strike must be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

Settle — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the lookback option, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every lookback option is set to the ValuationDate of the stock tree. The lookback argument, Settle, is ignored.

To support existing code, lookbackbycrr also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use an NINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For an American option, use an NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is an NINST-by-1 vector of dates, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, lookbackbycrr also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as an NINST-by-1 integer flags with values:

- 0 — European

- `1` — American

Data Types: `single` | `double`

Output Arguments

`Price` — Expected prices for lookback options at time `0`

vector

Expected prices for lookback options at time 0, returned as an `NINST`-by-`1` vector. Pricing of lookback options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `lookbackbycrr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

`crrtree` | `instlookback` | `Lookback`

Topics

lookbackbycvgsg

Calculate prices of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models

Syntax

```
Price = lookbackbycvgsg(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
Price = lookbackbycvgsg( ___ ,Name,Value)
```

Description

`Price = lookbackbycvgsg(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates)` returns prices of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models. `lookbackbycvgsg` calculates prices of European fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, `Strike` must be specified as `NaN`. The Goldman-Sosin-Gatto model is used for floating-strike lookback options. The Conze-Viswanathan model is used for fixed-strike lookback options.

Note Alternatively, you can use the `Lookback` object to price lookback options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = lookbackbycvgsg( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of a Floating Lookback Option Using the Goldman-Sosin-Gatto Model

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
Rates = 0.042;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9589
            Rates: 0.0420
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
```

```
            Basis: 0
     EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 50;
Sigma = 0.36;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the floating lookback options.

```
Settle   = datetime(2013,1,1);
Maturity = datetime(2013,4,1);
OptSpec = {'put';'call'};
Strike = NaN;
```

Compute the price of the European floating lookback options.

```
Price = lookbackbycvgsg(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 2×1

    7.2581
    6.9777
```

Compute the Price of a Fixed Lookback Option Using the Conze-Viswanathan Model

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.045;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9560
            Rates: 0.0450
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
```

```
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 102;
Sigma = 0.45;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.4500
         AssetPrice: 102
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the fixed lookback options.

```
Settle   = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = {'put';'call'};
Strike = [98;101];
```

Price the European fixed lookback options.

```
Price = lookbackbycvgsg(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 2×1

   18.3130
   30.4021
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `single` | `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the lookback option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `lookbackbycvgsg` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — European option expiry date
datetime array | string array | date character vector

European option expiry date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `lookbackbycvgsg` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = lookbackbycvgsg(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'AssetMinMax',AssetMinMax)`

`AssetMinMax` — Maximum or minimum underlying asset price
if unspecified, the lookback option is newly issued, and `AssetMinMax = StockSpec.AssetPrice` (default) | nonnegative integer

Maximum or minimum underlying asset price, specified as the comma-separated pair consisting of `'AssetMinMax'` and a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices of lookback option

vector

Expected prices of the lookback option, returned as a `NINST`-by-`1` vector.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced in R2014a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `lookbackbycvgsg` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lookbacksensbycvgsg

Calculate prices or sensitivities of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models

Syntax

```
PriceSens = lookbacksensbycvgsg(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
PriceSens = lookbacksensbycvgsg( ___ ,Name,Value)
```

Description

`PriceSens = lookbacksensbycvgsg(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates)` returns prices or sensitivities of European lookback options using Conze-Viswanathan and Goldman-Sosin-Gatto models. `lookbacksensbycvgsg` calculates prices of European fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, `Strike` must be specified as `NaN`. The Goldman-Sosin-Gatto model is used for floating-strike lookback options. The Conze-Viswanathan model is used for fixed-strike lookback options.

Note Alternatively, you can use the `Lookback` object to calculate price or sensitivities for lookback options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = lookbacksensbycvgsg( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Delta of a Floating Lookback Option Using the Goldman-Sosin-Gatto Model

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
Rates = 0.41;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
 'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.6637
            Rates: 0.4100
         EndTimes: 1
       StartTimes: 0
```

```
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` with continuous dividend yield.

```
AssetPrice = 120;
Sigma = 0.3;
Yield = 0.045;
StockSpec = stockspec(Sigma, AssetPrice, 'Continuous', Yield)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 120
       DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

Define the floating lookback option.

```
Settle   = datetime(2013,1,1);
Maturity = datetime(2013,7,1);
OptSpec = 'call';
Strike = NaN;
SMinMax = 100;
```

Compute the price and delta of the European floating lookback option.

```
OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbycvgsg(RateSpec, StockSpec, OptSpec, Strike,...
Settle, Maturity,'AssetMinMax', SMinMax, 'OutSpec', OutSpec)
```

```
Price = 36.9926
```

```
Delta = 0.8659
```

Compute the Price and Delta of a Fixed Lookback Option Using the Conze-Viswanathan Model

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
```

```
             Disc: 0.8187
            Rates: 0.1000
          EndTimes: 2
        StartTimes: 0
          EndDates: 735965
        StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 103;
Sigma = 0.30;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
          AssetPrice: 103
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the fixed lookback option.

```
Settle   = datetime(2013,1,1);
Maturity = datetime(2013,7,1);
OptSpec = 'call';
Strike = 99;
```

Price and delta for the European fixed lookback option.

```
OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbyls(RateSpec, StockSpec, OptSpec,...
Strike, Settle, Maturity,'OutSpec', OutSpec)
```

```
Price = 22.7227
```

```
Delta = 1.1349
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the lookback option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `lookbacksensbycvgsg` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — European option expiry date
datetime array | string array | date character vector

European option expiry date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `lookbacksensbycvgsg` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = lookbacksensbycvgsg(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'AssetMinMax',AssetMinMax,'OutSpec',{'All'})`

`AssetMinMax` — Maximum or minimum underlying asset price
if unspecified, the lookback option is newly issued, and `AssetMinMax = StockSpec.AssetPrice` (default) | nonnegative integer

Maximum or minimum underlying asset price, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities of lookback option
vector

Expected prices or sensitivities (defined by `OutSpec`) of the lookback option, returned as a `NINST`-by-`1` vector.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced in R2014a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `lookbacksensbycvgsg` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lookbackbyeqp

Price lookback option from Equal Probabilities binomial tree

Syntax

```
Price = lookbackbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbyeqp( ___ ,AmericanOpt)
```

Description

`Price = lookbackbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using an Equal Probabilities binomial tree.

Note Alternatively, you can use the `Lookback` object to price lookback options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = lookbackbyeqp( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

Examples

Price a Lookback Option Using an EQP Equity Tree

This example shows how to price a lookback option using an EQP equity tree by loading the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat

OptSpec = 'Call';
Strike = 115;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2006,1,1);

Price = lookbackbyeqp(EQPTree, OptSpec, Strike, Settle, ...
ExerciseDates)
```

```
Price = 8.7941
```

Input Arguments

EQPTree — Stock tree structure

structure

Stock tree structure for an Equal Probabilities binomial tree, specified by using `eqptree`.

Data Types: `struct`

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector or a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: char | cell

Strike — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

To compute the value of a floating-strike lookback option, Strike must be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

Settle — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the lookback option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every lookback option is set to the ValuationDate of the stock tree. The lookback argument, Settle, is ignored.

To support existing code, lookbackbyeqp also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use aNINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 cell array of character vectors, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, lookbackbyeqp also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European

- `1` — American

Data Types: `double`

Output Arguments

`Price` — Expected prices for lookback options at time `0`

vector

Expected prices for lookback options at time 0, returned as a `NINST`-by-`1` vector. Pricing of lookback options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `lookbackbyeqp` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lookbackbyitt

Price lookback option using implied trinomial tree (ITT)

Syntax

```
Price = lookbackbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbyitt( ___ ,AmericanOpt)
```

Description

`Price = lookbackbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using an implied trinomial tree (ITT).

`Price = lookbackbyitt( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

Examples

Price a Lookback Option Using an ITT Equity Tree

This example shows how to price a lookback option using an ITT equity tree by loading the file `deriv.mat`, which provides the `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat

OptSpec = 'Call';
Strike = 85;
Settle = datetime(2006,1,1);
ExerciseDates = datetime(2008,1,1);

Price = lookbackbyitt(ITTTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 0.5426
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure for an implied trinomial tree (ITT), specified by using `itttree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector or a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: char | cell

Strike — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values. Each row is the schedule for one option.

To compute the value of a floating-strike lookback option, Strike must be specified as NaN. Floating-strike lookback options are also known as average strike options.

Data Types: double

Settle — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the lookback option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every lookback option is set to the ValuationDate of the stock tree. The lookback argument, Settle, is ignored.

To support existing code, lookbackbyitt also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use aNINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 cell array of character vectors, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, lookbackbyitt also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 integer flags with values:

- 0 — European
- 1 — American

Data Types: double

Output Arguments

`Price` — Expected prices for lookback options at time `0`

vector

Expected prices for lookback options at time 0, returned as a `NINST`-by-`1` vector. Pricing of lookback options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced in R2007a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `lookbackbyitt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lookbackbyls

Price European or American lookback options using Monte Carlo simulations

Syntax

```
[Price,Paths,Times,Z] = lookbackbyls(RateSpec,StockSpec,OptSpec,Strike,
Settle,ExerciseDates)
[Price,Paths,Times,Z] = lookbackbyls( ___ ,Name,Value)
```

Description

`[Price,Paths,Times,Z] = lookbackbyls(RateSpec,StockSpec,OptSpec,Strike, Settle,ExerciseDates)` returns prices of lookback options using the Longstaff-Schwartz model for Monte Carlo simulations. `lookbackbyls` computes prices of European and American lookback options.

For American options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

`lookbackbyls` calculates values of fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, `Strike` must be specified as `NaN`.

Note Alternatively, you can use the `Lookback` object to price lookback options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,Paths,Times,Z] = lookbackbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price for a Floating Lookback Option Using Monte Carlo Simulation

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
Rates = 0.042;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9589
            Rates: 0.0420
         EndTimes: 1
```

```
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the StockSpec.

```
AssetPrice = 50;
Sigma = 0.36;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the floating lookback option.

```
Settle   = datetime(2013,1,1);
Maturity = datetime(2013,4,1);
OptSpec = 'put';
Strike = NaN;
```

Compute the price of the European floating lookback option.

```
Price = lookbackbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 6.6471
```

Compute the Price of a Fixed Lookback Option Using Monte Carlo Simulation

Define the RateSpec.

```
StartDates = 'Jan-1-2013';
EndDates = 'Jan-1-2014';
Rates = 0.045;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9560
            Rates: 0.0450
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
```

```
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 102;
Sigma = 0.45;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.4500
         AssetPrice: 102
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the fixed lookback option.

```
Settle   = 'Jan-1-2013';
Maturity = 'July-1-2013';
OptSpec = 'call';
Strike = 98;
```

Compute the price of the European fixed lookback option.

```
Price = lookbackbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 30.2368
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `single` | `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the lookback option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `lookbackbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Exercise callable or puttable dates for European or American options
datetime array | string array | date character vector

Exercise callable or puttable dates for European or American options, specified as a datetime array, string array, or date character vectors as follows:

- European option — `NINST`-by-`1` vector of exercise dates. For a European option, there is only one exercise date which is the option expiry date.
- American option — `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option is exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector of dates, the option is exercised between `Settle` and the single listed exercise date.

To support existing code, `lookbackbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = lookbackbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,'AmericanOpt',1)`

`AmericanOpt` — Option type
`0` European (default) | scalar with value `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and an integer scalar flag with these values:

- `0` — European

- 1 — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`NumTrials` — Scalar number of independent sample paths
`1000` (default) | nonnegative scalar integer

Scalar number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a nonnegative integer.

Data Types: `double`

`NumPeriods` — Scalar number of simulation periods per trial
`100` (default) | nonnegative scalar integer

Scalar number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a nonnegative integer. `NumPeriods` is considered only when pricing European lookback options. For American lookback options, `NumPeriods` is equal to the number of exercise days during the life of the option.

Data Types: `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-1-by-`NumTrials` 3-D array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

Output Arguments

`Price` — Expected price of lookback option
scalar

Expected price of the lookback option, returned as a 1-by-1 scalar.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-`1`-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-`1`-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced in R2014a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `lookbackbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lookbacksensbyls

Calculate price and sensitivities for European or American lookback options using Monte Carlo simulations

Syntax

```
[PriceSens,Paths,Times,Z] = lookbacksensbyls(RateSpec,StockSpec,OptSpec,
Strike,Settle,ExerciseDates)
[PriceSens,Paths,Times,Z] = lookbacksensbyls( ___ ,Name,Value)
```

Description

`[PriceSens,Paths,Times,Z] = lookbacksensbyls(RateSpec,StockSpec,OptSpec, Strike,Settle,ExerciseDates)` returns prices or sensitivities of lookback options using the Longstaff-Schwartz model for Monte Carlo simulations. `lookbacksensbyls` computes prices of European and American lookback options.

For American options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

`lookbacksensbyls` calculates values of fixed- and floating-strike lookback options. To compute the value of a floating-strike lookback option, `Strike` must be specified as `NaN`.

Note Alternatively, you can use the `Lookback` object to calculate price or sensitivities for lookback options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,Paths,Times,Z] = lookbacksensbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Delta of a European Floating Lookback Option Using Monte Carlo Simulation

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
Rates = 0.41;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.6637
```

```
           Rates: 0.4100
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
           Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` with continuous dividend yield.

```
AssetPrice = 120;
Sigma = 0.3;
Yield = 0.045;
StockSpec = stockspec(Sigma, AssetPrice, 'Continuous', Yield)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 120
       DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

Define the floating lookback option.

```
Settle   = datetime(2013,1,1);
Maturity = datetime(2013,7,1);
OptSpec = 'call';
Strike = NaN;
```

Compute the price and delta of the European floating lookback option.

```
OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity,...
'OutSpec', OutSpec)
```

```
Price = 27.0768
```

```
Delta = 0.2256
```

Compute the Price and Delta of a European Fixed Lookback Option Using Monte Carlo Simulation

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
```

```
      Compounding: -1
             Disc: 0.8187
            Rates: 0.1000
          EndTimes: 2
        StartTimes: 0
          EndDates: 735965
        StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 103;
Sigma = 0.30;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.3000
          AssetPrice: 103
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the fixed lookback option.

```
Settle   = datetime(2013,1,1);
Maturity = datetime(2013,7,1);
OptSpec = 'call';
Strike = 99;
```

Compute the price and delta of the European fixed lookback option.

```
OutSpec = {'price', 'delta'};
[Price, Delta] = lookbacksensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity,...
'OutSpec', OutSpec)
```

```
Price = 22.7227
```

```
Delta = 1.1349
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` can handle several types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `single` | `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the lookback option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `lookbacksensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Matrix of exercise callable or puttable dates for European or American options
datetime array | string array | date character vector

Matrix of exercise callable or puttable dates for European or American options, specified as a datetime array, string array, or date character vectors as follows:

- European option — `NINST`-by-`1` vector of exercise dates. For a European option, there is only one exercise date which is the option expiry date.
- American option — `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option is exercised on any coupon date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector of dates, the option is exercised between `Settle` and the single listed exercise date.

To support existing code, `lookbacksensbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = lookbacksensbyls(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,Strike,Corr,'AmericanOpt',1,'OutSpec',{'All'})`

`AmericanOpt` — Option type
`0` European (default) | scalar with value `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and an integer scalar flag with these values:

- `0` — European
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`NumTrials` — Scalar number of independent sample paths
`1000` (default) | nonnegative scalar integer

Scalar number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a nonnegative integer.

Data Types: `double`

`NumPeriods` — Scalar number of simulation periods per trial
`100` (default) | nonnegative scalar integer

Scalar number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a nonnegative integer. `NumPeriods` is considered only when pricing European lookback options. For American lookback options, `NumPeriod` is equal to the number of exercise days during the life of the option.

Data Types: `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-`1`-by-`NumTrials` 3-D array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | scalar logical flag with value `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected price or sensitivities of lookback option
scalar

Expected price or sensitivities (defined by `OutSpec`) of the lookback option, returned as a `1`-by-`1` array.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-`1`-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-`1`-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

lookbackbystt

Price lookback options using standard trinomial tree

Syntax

```
Price = lookbackbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates)
Price = lookbackbystt( ___ ,AmericanOpt)
```

Description

`Price = lookbackbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates)` prices lookback options using a standard trinomial (STT) tree.

Note Alternatively, you can use the `Lookback` object to price lookback options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`Price = lookbackbystt( ___ ,AmericanOpt)` prices lookback options using a standard trinomial (STT) tree with an optional argument for `AmericanOpt`.

Examples

Price a Lookback Option Using the Standard Trinomial Tree Model

Create a `RateSpec`.

```
StartDates = datetime(2009,1,1);
EndDates = datetime(2013,1,1);
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8694
            Rates: 0.0350
         EndTimes: 4
       StartTimes: 0
         EndDates: 735235
       StartDates: 733774
    ValuationDate: 733774
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
          AssetPrice: 85
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create an STTTree.

```
NumPeriods = 4;
TimeSpec = stttimespec(StartDates, EndDates, 4);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 1 2 3 4]
         dObs: [733774 734139 734504 734869 735235]
        STree: {1x5 cell}
        Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Define the lookback option and compute the price.

```
Settle = datetime(2009,1,1);
ExerciseDates = [datetime(2012,1,1) ; datetime(2013,1,1)];
OptSpec = 'call';
Strike = [90;95];

Price= lookbackbystt(STTTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 2×1

   11.7296
   12.9120
```

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

OptSpec — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector or a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` matrix of strike price values. Each row is the schedule for one option. To compute the value of a floating-strike lookback option, `Strike` should be specified as `NaN`. Floating-strike lookback options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the lookback option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every lookback option is set to the `ValuationDate` of the stock tree. The lookback argument, `Settle`, is ignored.

To support existing code, `lookbackbystt` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` cell array of character vectors, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `lookbackbystt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European (default) | scalar with values `[0,1]`

Option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Expected prices for lookback options at time `0`

matrix

Expected prices for lookback options at time 0, returned as a `NINST`-by-`1` matrix. Pricing of lookback options is done using Hull-White (1993). Consequently, for these options there are no unique prices on the tree nodes with the exception of the root node.

More About

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-39.

Version History

Introduced in R2015b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `lookbackbystt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

lrtimespec

Specify time structure for Leisen-Reimer binomial tree

Syntax

```
TimeSpec = lrtimespec(ValuationDate,Maturity,NumPeriods)
```

Description

`TimeSpec = lrtimespec(ValuationDate,Maturity,NumPeriods)` specifies a time structure for a Leisen-Reimer stock tree (`lrtree`).

Examples

Specify the Time Structure for Leisen-Reimer Binomial Tree

This example shows how to specify a 5-period tree with time steps of 1 year.

```
ValuationDate = datetime(2010,7,1);
Maturity = datetime(2015,7,1);
TimeSpec = lrtimespec(ValuationDate, Maturity, 5)
```

```
TimeSpec = struct with fields:
           FinObj: 'BinTimeSpec'
    ValuationDate: 734320
         Maturity: 736146
       NumPeriods: 5
            Basis: 0
     EndMonthRule: 1
             tObs: [0 1 2 3 4 5]
             dObs: [734320 734685 735050 735415 735780 736146]
```

Input Arguments

`ValuationDate` — Pricing date and first observation in Leisen-Reimer stock tree
datetime scalar | string scalar | date character vector

Pricing date and first observation in the `lrtree`, specified as a scalar datetime, string, or data character vector.

To support existing code, `lrtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Date marking the depth of the Leisen-Reimer stock tree
date character vector

Date marking the depth of the Leisen-Reimer stock tree, specified as scalar datetime, string, or data character vector.

To support existing code, `lrtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`NumPeriods` — Number of time steps in the Leisen-Reimer stock tree
odd integer value

Number of time steps in the Leisen-Reimer stock tree, specified as scalar odd integer value.

Note Leisen-Reimer requires the number of steps to be an odd number.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `lrtree`
structure

Specification for the time layout for `lrtree`, returned as a structure.

Version History

lrtree

Build Leisen-Reimer stock tree

Syntax

```
LRTree = lrtree(StockSpec,RateSpec,TimeSpec,Strike)
LRTree = lrtree( ___ ,Name,Value)
```

Description

`LRTree = lrtree(StockSpec,RateSpec,TimeSpec,Strike)` builds a Leisen-Reimer stock tree.

`LRTree = lrtree( ___ ,Name,Value)` adds a name-value pair argument.

Examples

Build a Leisen-Reimer Stock Tree

This example shows how to build Leisen-Reimer stock tree. Consider a European put option with an exercise price of $30 that expires on June 1, 2010. The underlying stock is trading at $30 on January 1, 2010 and has a volatility of 30% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, create a Leisen-Reimer tree with 101 steps using the `PP1` method.

```
AssetPrice = 30;
Strike = 30;

ValuationDate = 'Jan-1-2010';
Maturity = 'June-1-2010';

% define StockSpec
Sigma = 0.3;
StockSpec = stockspec(Sigma, AssetPrice);

% define RateSpec
Rates = 0.05;
Settle = ValuationDate;
Basis = 1;
Compounding = -1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% build the Leisen-Reimer (LR) tree with 101 steps
LRTimeSpec = lrtimespec(ValuationDate, Maturity, 101);

% use the PP1 method
LRMethod  = 'PP1';

LRTree = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike, ...
'method', LRMethod)
```

```
LRTree = struct with fields:
       FinObj: 'BinStockTree'
       Method: 'LR'
    Submethod: 'PP1'
       Strike: 30
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.0041 0.0082 0.0123 0.0164 0.0205 0.0246 0.0288 ... ]
         dObs: [734139 734140 734141 734143 734144 734146 734147 734149 ... ]
        STree: {1x102 cell}
      UpProbs: [101x1 double]
```

Input Arguments

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Time tree layout specification

structure

Time tree layout specification, specified using the `TimeSpec` output obtained from `lrtimespec`.

Data Types: `struct`

`Strike` — Option strike price value

nonnegative integer

Option strike price value, specified as a scalar nonnegative integer.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `LRTree = lrtree(StockSpec,RateSpec,LRTimeSpec,Strike,'Method','PP2')`

`Method` — Computation method
`'PP1'` (default) | character vector with value `'PP1'` or `'PP2'`

Computation method, specified as the comma-separated pair consisting of `'Method'` and a character vector with a value of `'PP1'` or `'PP2'`. `'PP1'` is for Peizer-Pratt method 1 inversion and `'PP2'` is for Peizer-Pratt method 2 inversion. For more information on `'PP1'` and `'PP2'` methods, see “Leisen-Reimer Tree (LR) Modeling” on page B-3.

Data Types: `char`

Output Arguments

`LRTree` — Stock and time information for a Leisen-Reimer tree
structure

Stock and time information for a Leisen-Reimer tree, returned as a structure.

Version History

Introduced in R2010b

maxassetbystulz

Determine European rainbow option price on maximum of two risky assets using Stulz option pricing model

Syntax

```
Price = maxassetbystulz(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
```

Description

`Price = maxassetbystulz(RateSpec,StockSpec1,StockSpec2,Settle,Maturity, OptSpec,Strike,Corr)` computes option prices using the Stulz option pricing model.

Examples

Compute Rainbow Option Prices Using the Stulz Option Pricing Model

Consider a European rainbow option that gives the holder the right to buy either $100,000 worth of an equity index at a strike price of 1000 (asset 1) or $100,000 of a government bond (asset 2) with a strike price of 100% of face value, whichever is worth more at the end of 12 months. On January 15, 2008, the equity index is trading at 950, pays a dividend of 2% annually and has a return volatility of 22%. Also on January 15, 2008, the government bond is trading at 98, pays a coupon yield of 6%, and has a return volatility of 15%. The risk-free rate is 5%. Using this data, if the correlation between the rates of return is -0.5, 0, and 0.5, calculate the price of the European rainbow option.

Since the asset prices in this example are in different units, it is necessary to work in either index points (asset 1) or in dollars (asset 2). The European rainbow option allows the holder to buy the following: 100 units of the equity index at $1000 each (for a total of $100,000) or 1000 units of the government bonds at $100 each (for a total of $100,000). To convert the bond price (asset 2) to index units (asset 1), you must make the following adjustments:

- Multiply the strike price and current price of the government bond by 10 (1000/100).
- Multiply the option price by 100, considering that there are 100 equity index units in the option.

Once these adjustments are introduced, the strike price is the same for both assets ($1000). First, create the `RateSpec`:

```
Settle = 'Jan-15-2008';
Maturity = 'Jan-15-2009';
Rates = 0.05;
Basis = 1;

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
```

```
             Disc: 0.9512
            Rates: 0.0500
          EndTimes: 1
        StartTimes: 0
          EndDates: 733788
        StartDates: 733422
    ValuationDate: 733422
            Basis: 1
     EndMonthRule: 1
```

Create the two `StockSpec` definitions.

```
AssetPrice1 = 950;   % Asset 1 => Equity index
AssetPrice2 = 980;   % Asset 2 => Government bond
Sigma1 = 0.22;
Sigma2 = 0.15;
Div1 = 0.02;
Div2 = 0.06;

StockSpec1 = stockspec(Sigma1, AssetPrice1, 'continuous', Div1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2200
         AssetPrice: 950
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Sigma2, AssetPrice2, 'continuous', Div2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
         AssetPrice: 980
       DividendType: {'continuous'}
    DividendAmounts: 0.0600
    ExDividendDates: []
```

Calculate the price of the options for different correlation levels.

```
Strike = 1000 ;
Corr = [-0.5; 0; 0.5];
OptSpec = 'call';

Price = maxassetbystulz(RateSpec, StockSpec1, StockSpec2,...
Settle, Maturity, OptSpec, Strike, Corr)
```

```
Price = 3×1

  111.6683
  103.7715
   92.4412
```

These are the prices of one unit. This means that the premium is 11166.83, 10377.15, and 9244.12 (for 100 units).

Input Arguments

`RateSpec` — Annualized, continuously compounded rate term structure
structure

Annualized, continuously compounded rate term structure, specified using `intenvset`.

Data Types: `structure`

`StockSpec1` — Stock specification for asset 1
structure

Stock specification for asset 1, specified using `stockspec`.

Data Types: `structure`

`StockSpec2` — Stock specification for asset 2
structure

Stock specification for asset 2, specified using `stockspec`.

Data Types: `structure`

`Settle` — Settlement or trade dates
vector

Settlement or trade dates, specified as an `NINST`-by-`1` vector of numeric dates.

Data Types: `double`

`Maturity` — Maturity dates
vector

Maturity dates, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`OptSpec` — Option type
cell array of character vectors with a value of `'call'` or `'put'`

Option type, specified as an `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `cell`

`Strike` — Strike prices
vector

Strike prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Corr` — Correlation between the underlying asset prices
vector

Correlation between the underlying asset prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected option prices

vector

Expected option prices, returned as an `NINST`-by-`1` vector.

More About

Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

For more information, see “Rainbow Option” on page 3-27.

Version History

Introduced in R2009a

maxassetsensbystulz

Determine European rainbow option prices or sensitivities on maximum of two risky assets using Stulz pricing model

Syntax

```
PriceSens = maxassetsensbystulz(RateSpec,StockSpec1,StockSpec2,Settle,
Maturity,OptSpec,Strike,Corr)
PriceSens = maxassetsensbystulz( ___ ,Name,Value)
```

Description

`PriceSens = maxassetsensbystulz(RateSpec,StockSpec1,StockSpec2,Settle, Maturity,OptSpec,Strike,Corr)` computes option prices using the Stulz option pricing model.

`PriceSens = maxassetsensbystulz( ___ ,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Rainbow Option Prices and Sensitivities Using the Stulz Option Pricing Model

Consider a European rainbow option that gives the holder the right to buy either $100,000 of an equity index at a strike price of 1000 (asset 1) or $100,000 of a government bond (asset 2) with a strike price of 100% of face value, whichever is worth more at the end of 12 months. On January 15, 2008, the equity index is trading at 950, pays a dividend of 2% annually, and has a return volatility of 22%. Also on January 15, 2008, the government bond is trading at 98, pays a coupon yield of 6%, and has a return volatility of 15%. The risk-free rate is 5%. Using this data, calculate the price and sensitivity of the European rainbow option if the correlation between the rates of return is -0.5, 0, and 0.5.

Since the asset prices in this example are in different units, it is necessary to work in either index points (for asset 1) or in dollars (for asset 2). The European rainbow option allows the holder to buy the following: 100 units of the equity index at $1000 each (for a total of $100,000) or 1000 units of the government bonds at $100 each (for a total of $100,000). To convert the bond price (asset 2) to index units (asset 1), you must make the following adjustments:

- Multiply the strike price and current price of the government bond by 10 (1000/100).
- Multiply the option price by 100, considering that there are 100 equity index units in the option.

Once these adjustments are introduced, the strike price is the same for both assets ($1000). First, create the `RateSpec`:

```
Settle = 'Jan-15-2008';
Maturity = 'Jan-15-2009';
Rates = 0.05;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 733788
       StartDates: 733422
    ValuationDate: 733422
            Basis: 1
     EndMonthRule: 1
```

Create the two `StockSpec` definitions.

```
AssetPrice1 = 950;   % Asset 1 => Equity index
AssetPrice2 = 980;   % Asset 2 => Government bond
Sigma1 = 0.22;
Sigma2 = 0.15;
Div1 = 0.02;
Div2 = 0.06;

StockSpec1 = stockspec(Sigma1, AssetPrice1, 'continuous', Div1)
```

```
StockSpec1 = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.2200
          AssetPrice: 950
        DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Sigma2, AssetPrice2, 'continuous', Div2)
```

```
StockSpec2 = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.1500
          AssetPrice: 980
        DividendType: {'continuous'}
    DividendAmounts: 0.0600
    ExDividendDates: []
```

Calculate the price and delta for different correlation levels.

```
Strike = 1000 ;
Corr = [-0.5; 0; 0.5];
OutSpec = {'price'; 'delta'};
OptSpec = 'call';
[Price, Delta] = maxassetsensbystulz(RateSpec, StockSpec1, StockSpec2,...
Settle, Maturity, OptSpec, Strike, Corr,'OutSpec', OutSpec)
```

```
Price = 3×1
```

```
  111.6683
  103.7715
   92.4412

Delta = 3×2

    0.4594    0.3698
    0.4292    0.3166
    0.4053    0.2512
```

The output `Delta` has two columns: the first column represents the `Delta` with respect to the equity index (asset 1), and the second column represents the `Delta` with respect to the government bond (asset 2). The value 0.4595 represents `Delta` with respect to one unit of the equity index. Since there are 100 units of the equity index, the overall `Delta` would be 45.94 (100 * 0.4594) for a correlation level of -0.5. To calculate the `Delta` with respect to the government bond, remember that an adjusted price of 980 was used instead of 98. Therefore, for example, the `Delta` with respect to government bond, for a correlation of 0.5 would be 251.2 (0.2512 * 100 * 10).

Input Arguments

`RateSpec` — Annualized, continuously compounded rate term structure
structure

Annualized, continuously compounded rate term structure, specified using `intenvset`.

Data Types: `structure`

`StockSpec1` — Stock specification for asset 1
structure

Stock specification for asset 1, specified using `stockspec`.

Data Types: `structure`

`StockSpec2` — Stock specification for asset 2
structure

Stock specification for asset 2, specified using `stockspec`.

Data Types: `structure`

`Settle` — Settlement or trade dates
vector

Settlement or trade dates, specified as an `NINST`-by-`1` vector of numeric dates.

Data Types: `double`

`Maturity` — Maturity dates
vector

Maturity dates, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`OptSpec` — Option type
cell array of character vectors with a value of `'call'` or `'put'`

Option type, specified as an `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `cell`

`Strike` — Strike prices
vector

Strike prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Corr` — Correlation between the underlying asset prices
vector

Correlation between the underlying asset prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens] = maxassetsensbystulz(RateSpec, StockSpecA,StockSpecB,Settle,Maturity,OptSpec,Strike,Corr,'OutSpec',OutSpec)`

`OutSpec` — Define outputs
`{'Price'}` (default) | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities
vector

Expected prices or sensitivities, returned as an `NINST`-by-`1` or `NINST`-by-`2` vector.

More About

Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

For more information, see “Rainbow Option” on page 3-27.

Version History

Introduced in R2009a

minassetbystulz

Determine European rainbow option prices on minimum of two risky assets using Stulz option pricing model

Syntax

```
Price = minassetbystulz(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,
OptSpec,Strike,Corr)
```

Description

`Price = minassetbystulz(RateSpec,StockSpec1,StockSpec2,Settle,Maturity, OptSpec,Strike,Corr)` computes option prices using the Stulz option pricing model.

Examples

Compute Rainbow Option Prices Using the Stulz Option Pricing Model

Consider a European rainbow put option that gives the holder the right to sell either stock A or stock B at a strike of 50.25, whichever has the lower value on the expiration date May 15, 2009. On November 15, 2008, stock A is trading at 49.75 with a continuous annual dividend yield of 4.5% and has a return volatility of 11%. Stock B is trading at 51 with a continuous dividend yield of 5% and has a return volatility of 16%. The risk-free rate is 4.5%. Using this data, if the correlation between the rates of return is -0.5, 0, and 0.5, calculate the price of the minimum of two assets that are European rainbow put options. First, create the `RateSpec`:

```
Settle = datetime(2000,11,15);
Maturity = datetime(2009,5,15);
Rates = 0.045;
Basis = 1;

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.6822
            Rates: 0.0450
         EndTimes: 8.5000
       StartTimes: 0
         EndDates: 733908
       StartDates: 730805
    ValuationDate: 730805
            Basis: 1
     EndMonthRule: 1
```

Create the two `StockSpec` definitions.

```
AssetPriceA = 49.75;
AssetPriceB = 51;
SigmaA = 0.11;
SigmaB = 0.16;
DivA = 0.045;
DivB = 0.05;

StockSpecA = stockspec(SigmaA, AssetPriceA, 'continuous', DivA)
```

```
StockSpecA = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1100
         AssetPrice: 49.7500
       DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

```
StockSpecB = stockspec(SigmaB, AssetPriceB, 'continuous', DivB)
```

```
StockSpecB = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1600
         AssetPrice: 51
       DividendType: {'continuous'}
    DividendAmounts: 0.0500
    ExDividendDates: []
```

Compute the price of the options for different correlation levels.

```
Strike = 50.25;
Corr = [-0.5;0;0.5];
OptSpec = 'put';
Price = minassetbystulz(RateSpec, StockSpecA, StockSpecB, Settle,...
Maturity, OptSpec, Strike, Corr)
```

```
Price = 3×1

   10.0002
    9.1433
    8.1622
```

The values 3.43, 3.14, and 2.77 are the price of the European rainbow put options with a correlation level of -0.5, 0, and 0.5 respectively.

Input Arguments

RateSpec — Annualized, continuously compounded rate term structure

structure

Annualized, continuously compounded rate term structure, specified using `intenvset`.

Data Types: `structure`

StockSpec1 — Stock specification for asset 1

structure

Stock specification for asset 1, specified using `stockspec`.

Data Types: `structure`

`StockSpec2` — Stock specification for asset 2
structure

Stock specification for asset 2, specified using `stockspec`.

Data Types: `structure`

`Settle` — Settlement or trade dates
datetime array | string array | date character vector

Settlement or trade dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `minassetbystulz` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity dates
datetime array | string array | date character vector

Maturity dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `minassetbystulz` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Option type
cell array of character vectors with a value of `'call'` or `'put'`

Option type, specified as an `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `cell`

`Strike` — Strike prices
vector

Strike prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Corr` — Correlation between the underlying asset prices
vector

Correlation between the underlying asset prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected option prices
vector

Expected option prices, returned as an `NINST`-by-`1` vector.

More About

Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

For more information, see “Rainbow Option” on page 3-27.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `minassetbystulz` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Supported Equity Derivative Functions” on page 3-19

minassetsensbystulz

Determine European rainbow option prices or sensitivities on minimum of two risky assets using Stulz option pricing model

Syntax

```
PriceSens = minassetsensbystulz(RateSpec,StockSpec1,StockSpec2,Settle,
Maturity,OptSpec,Strike,Corr)
PriceSens = minassetsensbystulz( ___ ,Name,Value)
```

Description

`PriceSens = minassetsensbystulz(RateSpec,StockSpec1,StockSpec2,Settle, Maturity,OptSpec,Strike,Corr)` computes option prices using the Stulz option pricing model.

`PriceSens = minassetsensbystulz( ___ ,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Rainbow Option Prices and Sensitivities Using the Stulz Option Pricing Model

Consider a European rainbow put option that gives the holder the right to sell either stock A or stock B at a strike of 50.25, whichever has the lower value on the expiration date May 15, 2009. On November 15, 2008, stock A is trading at 49.75 with a continuous annual dividend yield of 4.5% and has a return volatility of 11%. Stock B is trading at 51 with a continuous dividend yield of 5% and has a return volatility of 16%. The risk-free rate is 4.5%. Using this data, if the correlation between the rates of return is -0.5, 0, and 0.5, calculate the price and sensitivity of the minimum of two assets that are European rainbow put options. First, create the `RateSpec`:

```
Settle = datetime(2000,11,15);
Maturity = datetime(2009,5,15);
Rates = 0.045;
Basis = 1;

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.6822
            Rates: 0.0450
         EndTimes: 8.5000
       StartTimes: 0
         EndDates: 733908
       StartDates: 730805
    ValuationDate: 730805
            Basis: 1
     EndMonthRule: 1
```

Create the two `StockSpec` definitions.

```
AssetPriceA = 49.75;
AssetPriceB = 51;
SigmaA = 0.11;
SigmaB = 0.16;
DivA = 0.045;
DivB = 0.05;

StockSpecA = stockspec(SigmaA, AssetPriceA, 'continuous', DivA)
```

```
StockSpecA = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1100
         AssetPrice: 49.7500
       DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

```
StockSpecB = stockspec(SigmaB, AssetPriceB, 'continuous', DivB)
```

```
StockSpecB = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1600
         AssetPrice: 51
       DividendType: {'continuous'}
    DividendAmounts: 0.0500
    ExDividendDates: []
```

Calculate price and delta for different correlation levels.

```
Strike = 50.25;
Corr = [-0.5;0;0.5];
OptSpec = 'put';
OutSpec = {'Price'; 'delta'};
[P, D] = minassetsensbystulz(RateSpec, StockSpecA, StockSpecB,...
Settle, Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
P = 3×1

   10.0002
    9.1433
    8.1622

D = 3×2

   -0.2037   -0.2192
   -0.1774   -0.2101
   -0.1452   -0.2075
```

The output `Delta` has two columns: the first column represents the `Delta` with respect to the stock A (asset 1), and the second column represents the `Delta` with respect to the stock B (asset 2). The value 0.4183 represents `Delta` with respect to the stock A for a correlation level of -0.5. The `Delta` with respect to stock B, for a correlation of zero is -0.3189.

Input Arguments

`RateSpec` — Annualized, continuously compounded rate term structure
structure

Annualized, continuously compounded rate term structure, specified using `intenvset`.

Data Types: `structure`

`StockSpec1` — Stock specification for asset 1
structure

Stock specification for asset 1, specified using `stockspec`.

Data Types: `structure`

`StockSpec2` — Stock specification for asset 2
structure

Stock specification for asset 2, specified using `stockspec`.

Data Types: `structure`

`Settle` — Settlement or trade dates
datetime array | string array | date character vector

Settlement or trade dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `minassetsensbystulz` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity dates
datetime array | string array | date character vector

Maturity dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `minassetsensbystulz` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Option type
cell array of character vectors with a value of `'call'` or `'put'`

Option type, specified as an `NINST`-by-`1` cell array of character vectors with a value of `'call'` or `'put'`.

Data Types: `cell`

`Strike` — Strike prices
vector

Strike prices, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Corr` — Correlation between the underlying asset prices
vector

Correlation between the underlying asset prices, specified as an NINST-by-1 vector.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [PriceSens] = minassetsensbystulz(RateSpec, StockSpecA,StockSpecB,Settle,Maturity,OptSpec,Strike,Corr,'OutSpec',OutSpec)

OutSpec — Define outputs

{'Price'} (default) | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: cell

Output Arguments

PriceSens — Expected prices or sensitivities

vector

Expected prices or sensitivities, returned as an NINST-by-1 or NINST-by-2 vector.

More About

Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets.

A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets. Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

For more information, see “Rainbow Option” on page 3-27.

mkbush

Create bushy tree

Syntax

```
[Tree,NumStates = mkbush(NumLevels,NumChild,NumPos)
[Tree,NumStates = mkbush( ___ ,Trim,NodeVal)
```

Description

`[Tree,NumStates = mkbush(NumLevels,NumChild,NumPos)` creates a bushy tree `Tree` with initial values `NodeVal` at each node.

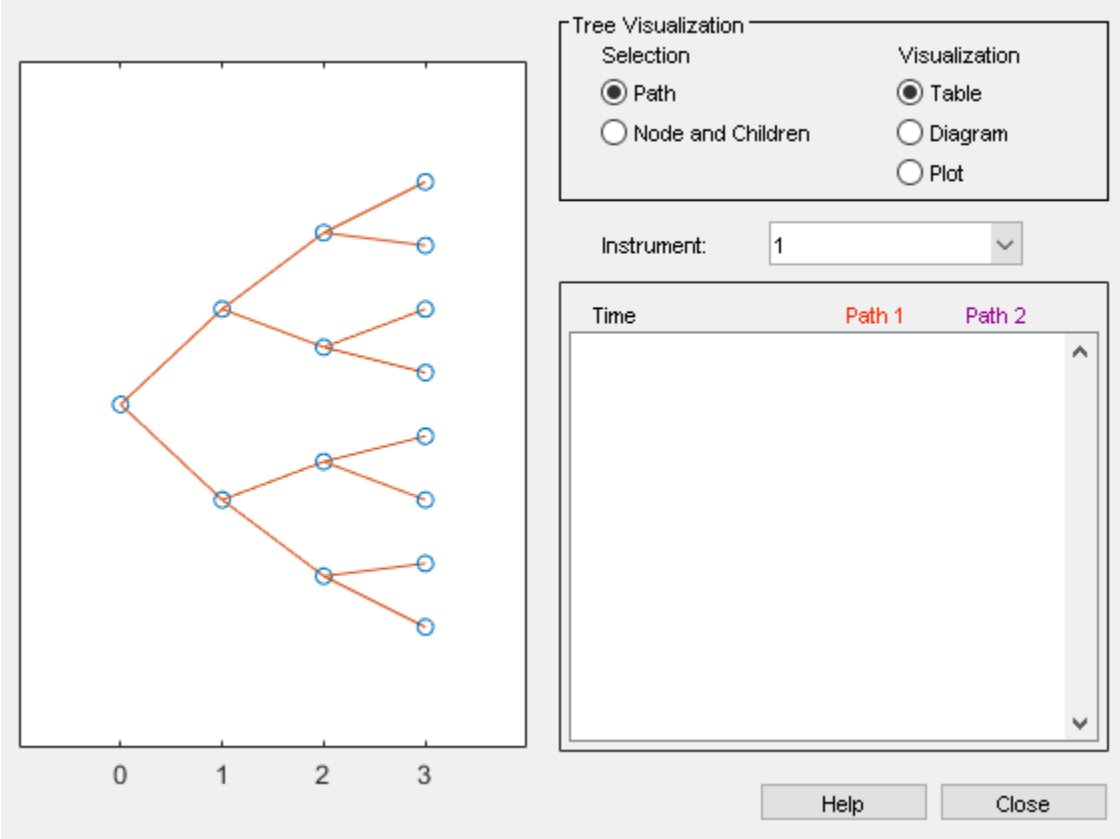
`[Tree,NumStates = mkbush( ___ ,Trim,NodeVal)` adds optional arguments for `Trim` and `NodeVal`.

Examples

Create Bushy Tree

This example shows how to create a tree with four time levels, two branches per node, and a vector of three elements in each node with each element initialized to `NaN`.

```
Tree = mkbush(4, 2, 3);
treeviewer(Tree)
```



Input Arguments

`NumLevels` — Number of time levels of the tree

numeric

Number of time levels of the tree, specified as a scalar numeric.

Data Types: `double`

`NumChild` — Number of branches (children) of the nodes in each level

vector

Number of branches (children) of the nodes in each level, specified as a 1-by- number of levels (`NUMLEVELS`) vector.

Data Types: `double`

`NumPos` — Length of the state vectors in each time level

vector

Length of the state vectors in each time level, specified as a 1-by-`NUMLEVELS` vector.

Data Types: `double`

`Trim` — Indicates movement between nodes

`0` (default) | logical

(Optional) Indicates movement between nodes, specified as a scalar `0` or `1`. If `Trim = 1`, `NumPos` decreases by `1` when moving from one time level to the next. Otherwise, if `Trim = 0`, `NumPos` does not decrease.

Data Types: `logical`

`NodeVal` — Initial value at each node of the tree
`NaN` (default) | numeric

(Optional) Initial value at each node of the tree, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`Tree` — Bushy tree
struct

Bushy tree, returned as a tree struct with initial values `NodeVal` at each node.

`NumStates` — Number of state vectors in each level
vector

Number of state vectors in each level, returned as a `1`-by-`NUMLEVELS` vector.

Version History

Introduced before R2006a

mktree

Create recombining binomial tree

Syntax

```
Tree = mktree(NumLevels,NumPos)
Tree = mktree( ___ ,NodeVal,IsPriceTree)
```

Description

`Tree = mktree(NumLevels,NumPos)` creates a recombining tree `Tree` with initial values `NodeVal` at each node.

`Tree = mktree( ___ ,NodeVal,IsPriceTree)` adds optional arguments for `NodeVal` and `IsPriceTree`.

Examples

Create Recombining Binomial Tree

Create a recombining tree of four time levels with a vector of two elements in each node and each element initialized to `NaN`.

```
Tree = mktree(4, 2)
```

```
Tree=1×4 cell array
    {2x1 double}    {2x2 double}    {2x3 double}    {2x4 double}
```

Input Arguments

`NumLevels` — Number of time levels of the tree

numeric

Number of time levels of the tree, specified as a scalar numeric.

Data Types: `double`

`NumPos` — Length of the state vectors in each time level

vector

Length of the state vectors in each time level, specified as a 1-by-`NUMLEVELS` vector.

Data Types: `double`

`NodeVal` — Initial value at each node of the tree

`NaN` (default) | numeric

(Optional) Initial value at each node of the tree, specified as a scalar numeric.

Data Types: `double`

`IsPriceTree` — Indicator if final horizontal branch is added to tree
`0` (default) | logical

(Optional) Indicator if final horizontal branch is added to tree, specified as a scalar logical value.

Data Types: `logical`

Output Arguments

`Tree` — Bushy tree
struct

Bushy tree, returned as a tree struct with initial values `NodeVal` at each node.

Version History

Introduced before R2006a

mktrintree

Create recombining trinomial tree

Syntax

```
TrinTree = mktrintree(NumLevels,NumPos,NumStates)
TrinTree = mktrintree( ___ ,NodeVal)
```

Description

`TrinTree = mktrintree(NumLevels,NumPos,NumStates)` creates a recombining tree `TrinTree` with initial values `NodeVal` at each node.

`TrinTree = mktrintree( ___ ,NodeVal)` adds an optional argument for `NodeVal`.

Examples

Create Recombining Trinomial Tree

Create a recombining trinomial tree of four time levels with a vector of two elements in each node and each element initialized to `NaN`.

```
TrinTree = mktrintree(4, [2 2 2 2], [1 3 5 7])
```

```
TrinTree=1×4 cell array
    {2x1 double}    {2x3 double}    {2x5 double}    {2x7 double}
```

Input Arguments

`NumLevels` — Number of time levels of the tree

numeric

Number of time levels of the tree, specified as a scalar numeric.

Data Types: `double`

`NumPos` — Length of the state vectors in each time level

vector

Length of the state vectors in each time level, specified as a 1-by-`NUMLEVELS` vector.

Data Types: `double`

`NumStates` — Number of state vectors in each level

vector

Number of state vectors in each level, specified as a 1-by-`NUMLEVELS` vector.

Data Types: `double`

`NodeVal` — Initial value at each node of the tree
`NaN` (default) | numeric

(Optional) Initial value at each node of the tree, specified as a scalar numeric.

Data Types: `double`

Output Arguments

`TrinTree` — Recombining trinomial tree
struct

Recombining trinomial tree, returned as a tree struct with initial values `NodeVal` at each node.

Version History

Introduced before R2006a

mmktbybdt

Create money-market tree from Black-Derman-Toy interest-rate tree

Syntax

```
MMktTree = mmktbybdt(BDTTree)
MMktTree = mmktbybdt(BDTTree)
```

Description

`MMktTree = mmktbybdt(BDTTree)` `MMktTree = mmktbybdt(BDTTree)` creates a money-market tree from an interest-rate tree structure created by `bdttree`.

Examples

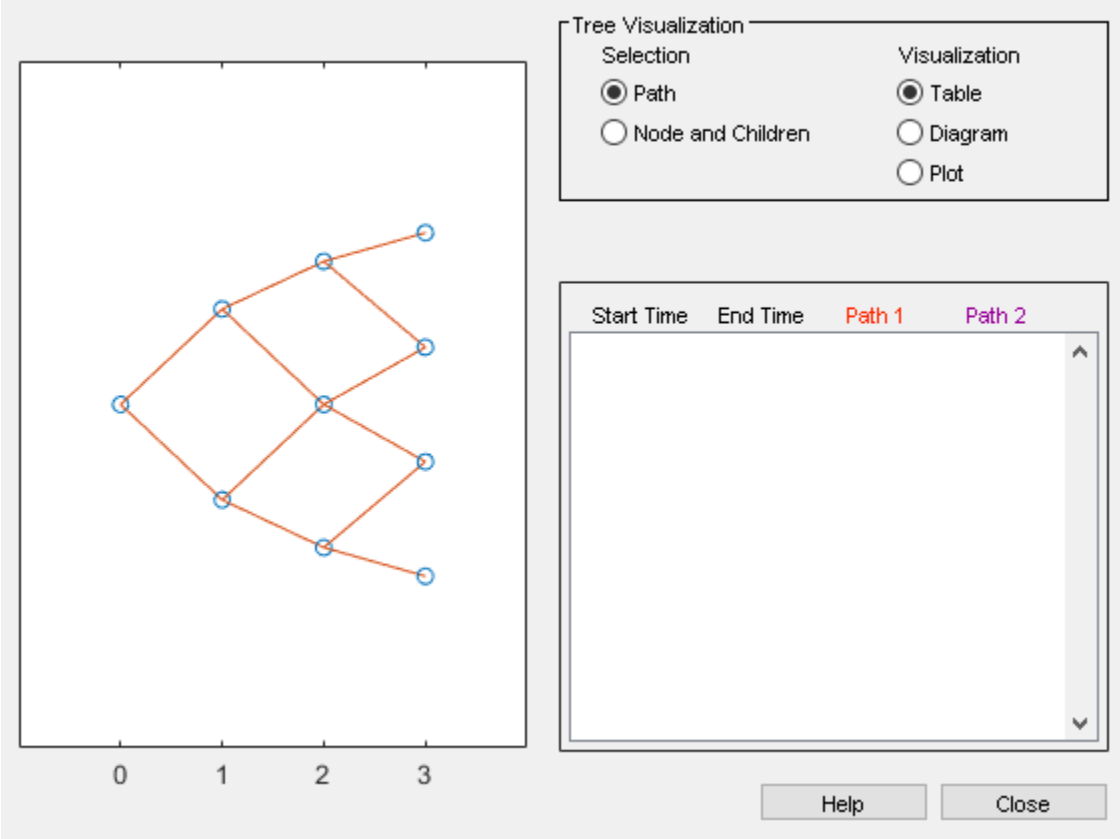
Create Money-Market Tree from Black-Derman-Toy Interest-Rate Tree

Use a `bdttree` from the `deriv.mat` and create a money-market tree from the BDT interest-rate tree.

```
load deriv.mat;
MMktTree = mmktbybdt(BDTTree)
```

```
MMktTree = struct with fields:
      FinObj: 'BDTMmktTree'
        tObs: [0 1 2 3 4]
    MMktTree: {[1]  [1.1000 1.1000]  [1.2077 1.2324 1.2575]  [1.3256 1.3633 ... ]}
```

```
treeviewer(MMktTree)
```



Input Arguments

`BDTTree` — BDT interest-rate tree structure

struct

BDT interest-rate tree structure, specified by `bdttree`.

Data Types: `struct`

Output Arguments

`MMktTree` — Money-market tree

struct

Money-market tree, returned as a tree structure.

Version History

Introduced before R2006a

Topics

mmktbyhjm

Create money-market tree from Heath-Jarrow-Morton interest-rate tree

Syntax

```
MMktTree = mmktbyhjm(HJMTree)
```

Description

`MMktTree = mmktbyhjm(HJMTree)` creates a money-market tree from an interest-rate tree structure created by `hjmtree`.

Examples

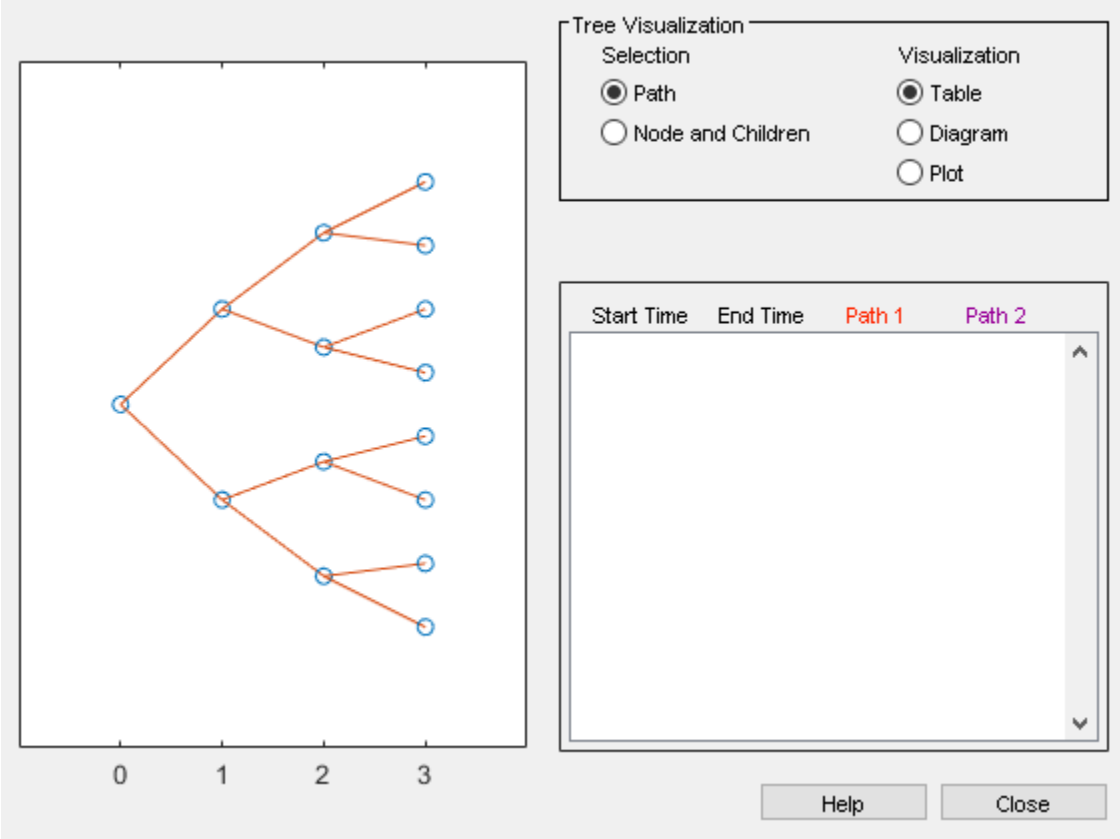
Create Money-Market Tree from Heath-Jarrow-Morton Interest-Rate Tree

Use a `hjmtree` from the `deriv.mat` and create a money-market tree from the HJM interest-rate tree.

```
load deriv.mat;
MMktTree = mmktbyhjm(HJMTree)
```

```
MMktTree = struct with fields:
      FinObj: 'HJMMmktTree'
        tObs: [0 1 2 3 4]
    MMktTree: {[1]  [1x1x2 double]  [1x2x2 double]  [1x4x2 double]}
```

```
treeviewer(MMktTree)
```



Input Arguments

`HJMTree` — HJM interest-rate tree structure

struct

HJM interest-rate tree structure, specified by `hjmtree`.

Data Types: `struct`

Output Arguments

`MMktTree` — Money-market tree

struct

Money-market tree, returned as a tree structure.

Version History

Introduced before R2006a

normalvolbysabr

Implied Normal (Bachelier) volatility by SABR model

Syntax

```
outVol = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,
Strike)
outVol = normalvolbysabr( ___ ,Name,Value)
```

Description

`outVol = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue, Strike)` calculates the implied Normal (Bachelier) volatility by using the SABR stochastic volatility model.

`outVol = normalvolbysabr( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute the Implied Normal (Bachelier) Volatility Using the SABR Model

Define the model parameters and option data.

```
ForwardValue = 0.0209;
Strike = 0.02;
Alpha = 0.041;
Beta = 0.5;
Rho = -0.2;
Nu = 0.33;

Settle = datetime(2018,2,15);
ExerciseDate = datetime(2020,2,15);
```

Compute the Normal (Bachelier) volatility using the SABR model.

```
ComputedVols = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike)
```

```
ComputedVols = 0.0059
```

Compute the Implied Normal (Bachelier) Volatility Using the Normal SABR Model

To use the Normal SABR model, set the `Beta` parameter to zero. Negative interest rates are allowed when the Normal SABR model is used in combination with Normal (Bachelier) implied volatility.

Define the model parameters and option data.

```
ForwardValue = -0.00383;
Strike = -0.003;
```

```
Alpha = 0.007;
Beta = 0;  % Set the Beta parameter to zero to use the Normal SABR model
Rho = -0.18;
Nu = 0.29;

Settle = datetime(2018,1,17);
ExerciseDate = datetime(2018,4,17);
```

Compute the Normal (Bachelier) volatility using the Normal SABR model.

```
ComputedVols = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike)
```

```
ComputedVols = 0.0070
```

Input Arguments

`Alpha` — Current SABR volatility

scalar numeric

Current SABR volatility, specified as a scalar numeric.

Data Types: `double`

`Beta` — SABR constant elasticity of variance (CEV) exponent

scalar numeric

SABR CEV exponent, specified as a scalar numeric.

Note Set the `Beta` parameter to `0` to allow a negative `ForwardValue` and `Strike`.

Data Types: `double`

`Rho` — Correlation between forward value and volatility

scalar numeric

Correlation between forward value and volatility, specified as a scalar numeric.

Data Types: `double`

`Nu` — Volatility of volatility

scalar numeric

Volatility of volatility, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `normalvolbysabr` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDate` — Option exercise date
datetime scalar | string scalar | date character vector

Option exercise date, specified as a scalar datetime, string, or date character vector.

To support existing code, `normalvolbysabr` also accepts serial date numbers as inputs, but they are not recommended.

`ForwardValue` — Current forward value of underlying asset
scalar numeric | vector

Current forward value of the underlying asset, specified as a scalar numeric or vector of size `NumVols`-by-`1`.

Data Types: `double`

`Strike` — Option strike price value
scalar numeric | vector

Option strike price value, specified as a scalar numeric or a vector of size `NumVols`-by-`1`.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `outVol = normalvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike,'Basis',2)`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer from the set `[1...13]`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`outVol` — Normal (Bachelier) volatility computed by SABR model

scalar numeric | vector

Normal (Bachelier) volatility computed by the SABR model, returned as a scalar numeric or vector of size `NumVols`-by-`1`.

Algorithms

The two general case algorithms for `normalvolbysabr` are not At-The-Money (ATM) and ATM.

For not ATM ($F \neq K$):

$$\sigma_N(\alpha,\beta,\rho,\upsilon,F,K,T) = \alpha\frac{(F-K)(1-\beta)}{F^{(1-\beta)}-K^{(1-\beta)}}\left(\frac{z}{x(z)}\right)\left\{1+\left[\frac{\beta(\beta-2)\alpha^2}{24F_{mid}^{2-2\beta}}+\frac{\rho\beta\upsilon\alpha}{4F_{mid}^{1-\beta}}+\frac{2-3\rho^2}{24}\upsilon^2\right]T\right\}$$

$$=\upsilon\frac{(F-K)}{x(z)}\left\{1+\left[\frac{\beta(\beta-2)\alpha^2}{24F_{mid}^{2-2\beta}}+\frac{\rho\beta\upsilon\alpha}{4F_{mid}^{1-\beta}}+\frac{2-3\rho^2}{24}\upsilon^2\right]T\right\}$$

$$F_{mid}=\frac{F+K}{2}$$

$$z=\frac{\upsilon}{\alpha}\left(\frac{F^{1-\beta}-K^{1-\beta}}{1-\beta}\right)\qquad x(z)=\ln\left(\frac{\sqrt{1-2\rho z+z^2}+z-\rho}{1-\rho}\right)$$

For ATM ($F = K$):

$$\sigma_{N,ATM}(\alpha,\beta,\rho,\upsilon,F,T)=\alpha F^{\beta}\left\{1+\left[\frac{\beta(\beta-2)\alpha^2}{24F^{2-2\beta}}+\frac{\rho\beta\upsilon\alpha}{4F^{1-\beta}}+\frac{2-3\rho^2}{24}\upsilon^2\right]T\right\}$$

The special case for `normalvolbysabr` where β = 0 for not ATM ($F \neq K$) is:

$$\sigma_N(\alpha,\rho,\upsilon,F,K,T)=\upsilon\frac{(F-K)}{\hat{x}(\zeta)}\left(1+\frac{2-3\rho^2}{24}\upsilon^2T\right)$$

$$\zeta=\frac{\upsilon}{\alpha}(F-K)$$

$$\hat{x}(\zeta)=\ln\left(\frac{\sqrt{1-2\rho\zeta+\zeta^2}+\zeta-\rho}{1-\rho}\right)$$

For ATM ($F = K$):

$$\sigma_{N,ATM}(\alpha,\rho,\upsilon,T)=\alpha\left(1+\frac{2-3\rho^2}{24}\upsilon^2T\right)$$

The special case for `normalvolbysabr` where β = 1 for not ATM ($F \neq K$) is:

$$\sigma_N(\alpha,\rho,\upsilon,F,K,T) = \upsilon\frac{(F-K)}{\hat{x}(\zeta)}\left\{1+\left[\frac{-\alpha^2}{24}+\frac{\rho\upsilon\alpha}{4}+\frac{2-3\rho^2}{24}\upsilon^2\right]T\right\}$$

$$\zeta = \frac{\upsilon}{\alpha}\ln\frac{F}{K}$$

$$\hat{x}(\zeta) = \ln\left(\frac{\sqrt{1-2\rho\zeta+\zeta^2}+\zeta-\rho}{1-\rho}\right)$$

For ATM ($F = K$):

$$\sigma_{N,\,ATM}(\alpha,\rho,\upsilon,F,T) = \alpha F\left\{1+\left[\frac{-\alpha^2}{24}+\frac{\rho\upsilon\alpha}{4}+\frac{2-3\rho^2}{24}\upsilon^2\right]T\right\}$$

Version History

Introduced in R2018b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `normalvolbysabr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

numerix class

Create numerix object to set up Numerix CAIL environment

Description

The `numerix` object makes the Numerix engine directly accessible from MATLAB. To use the capabilities of Numerix CAIL, you must have CAIL client software installed on your local desktop.

In addition, you must add the Numerix library file to MATLAB path to use the documentation examples:

- Add <*Numerix software package installation root*>`/lib` to <*matlabroot*>`/toolbox/local/librarypath.txt`

  or

- Place <*Numerix software package installation root*>`/lib/NxProjava.dll` in the folder <*matlabroot*>`/bin/win64`

Construction

`N = numerix(DATADIRECTORYPATH)` constructs the `numerix` object and sets up the Numerix CrossAsset Integration Layer (CAIL) environment given the path, `DATADIRECTORYPATH`.

Properties

The following properties are from the `numerix` class.

`Path` — Path for `DATADIRECTORYPATH`

character vector

Defines the path for `DATADIRECTORYPATH`, specified as a character vector. This path is the location of the templates and is created by the client installation of CAIL. A template defines the interface; it encapsulates the instructions for performing calculations, the calculation's required and optional input parameters, and the calculation's outputs.

Attributes:

`SetAccess`	`public`
`GetAccess`	`public`

`RepositoryPath` — Path for `RepositoryPath`

character vector

`RepositoryPath` defines the path location for the repository folder in a file system, specified as a character vector.

Attributes:

SetAccess	public
GetAccess	public

`Repository` — Define repositories
vector

Repositories are collections of templates and are defined as a folder in a file system, specified as a vector.

Attributes:

SetAccess	public
GetAccess	public

`Context` — CAIL application context in which to perform the calculations
vector

The calculation context manages all the CAIL information, specified as a vector. `Context` contains the location of the template repository and is responsible for creating a CAIL application context in which to perform the calculations.

Attributes:

SetAccess	public
GetAccess	public

`LookupsPath` — Path for the numeric instruments data types
character vector

Defines the path for the numeric instruments data types, specified as a character vector.

Attributes:

SetAccess	public
GetAccess	public

`MarketsPath` — Path for logical schema for naming market data
character vector

Defines a path for the logical schema for naming all the market data, specified as a character vector. `MarketsPath` enables you to provide a data dictionary to map business market data to CAIL to reduce the task of inputting market data into CAIL objects directly.

Attributes:

SetAccess	public
GetAccess	public

`FixingsPath` — Path for schema for naming historical fixing data for rates and prices
character vector

Defines the path for the schema for naming historical fixing data for rates and prices, specified as a character vector.

Attributes:

SetAccess	public
GetAccess	public

`TradesPath` — Path to trade instrument definitions

character vector

Defines the path to the trade instrument definitions, specified as a character vector.

Attributes:

SetAccess	public
GetAccess	public

`Parameters` — Calculation parameters and market data

vector

Defines the calculation parameters and market data, if available, specified as a vector.

Attributes:

SetAccess	public
GetAccess	public

Methods

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Construct a Numerix Object

Initialize Numerix CAIL environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;
```

Construct a numerix object.

```
n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =

             Path: 'i:\NumeriX_java_10_3_0\data'
   RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
       Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
          Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
      LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
      MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
      FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
```

```
    TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
    Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

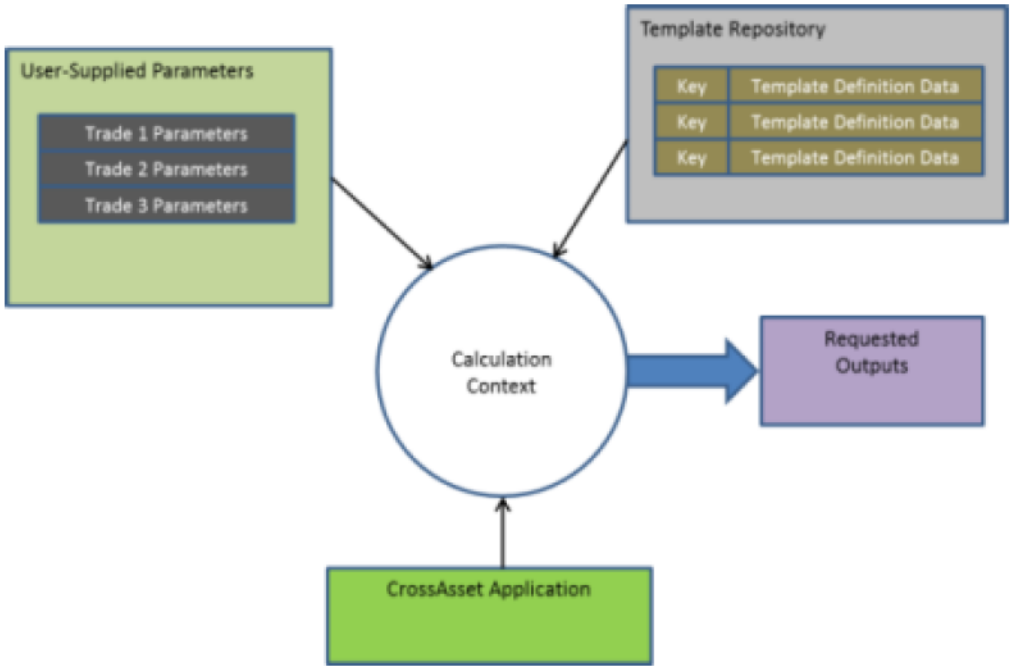
More About

CrossAsset Integration Layer (CAIL)

The CrossAsset Integration Layer (CAIL) is an application programming interface (API), which extends the data-driven approach of Numerix.

The calculation workflow of CAIL is:

1. Select a trade template for a specified deal or trade from the repository. The trade template specifies a set of inputs, a set of outputs, and the dependencies on other information (model, market data, calendar, and so on).
2. Provide the input parameters to the trade template and call the calculation context. The calculation context follows the dependency path to collect the needed information and produces the output specified by the template.



Version History

Introduced in R2013b

numerixCrossAsset class

Create `numerixCrossAsset` object to set up Numerix CROSSASSET environment for Java or C++

Description

Creating a `numerixCrossAsset` object initializes a Numerix CrossAsset object based on the Numerix data-driven CROSSASSET API. To use the Numerix engine directly from MATLAB, you must have the CROSSASSET client installed on your local desktop.

You must add the Numerix library file to MATLAB path to use the documentation examples:

- Add <*Numerix software package installation root*>`/lib` to <*matlabroot*>`/toolbox/local/librarypath.txt`

  or
- Place <*Numerix software package installation root*>`/lib/NxProjava.dll` in the folder <*matlabroot*>`/bin/win64`

In addition, when using the Java SDK API, you must add `\NumeriX_Java_12_3_0_2\lib\NxProJava.jar` to the MATLAB file `classpath.txt`.

Construction

`c = numerixCrossAsset` constructs the `numerixCrossAsset` object and sets up the Numerix CROSSASSET environment using the Java SDK API.

`c = numerixCrossAsset(true)` constructs the `numerixCrossAsset` object and sets up the Numerix CROSSASSET environment using the C++ SDK API on Windows.

Properties

`Application` — `Application` object
object

`Application` object, created when `numerixCrossAsset` object is initialized.

Example: `app = Application;`

Attributes:

`SetAccess`	`private`
`GetAccess`	`public`

`ApplicationWarning` — `ApplicationWarning` object
object

`ApplicationWarning` object, created when `numerixCrossAsset` object is initialized.

Note The `ApplicationWarning` object is `[]` when using the C++ interface.

Example: `appWarnings = ApplicationWarning;`

Attributes:

`SetAccess`	`private`
`GetAccess`	`public`

Methods

applicationCall	Create and register Numerix CROSSASSET Call object
applicationData	Create and register data with Numerix CROSSASSET Application Data object
applicationMatrix	Create and register Numerix CROSSASSET Application Matrix object
close	Close numerixCrossAsset object
getdata	Convert Numerix CROSSASSET Application object to MATLAB structure

Examples

Construct a `numerixCrossAsset` Object for Java

Construct a `numerixCrossAsset` object for the Java SDK API.

```
c = numerixCrossAsset
```

```
 c =

numerixCrossAsset with properties:

Application: [1x1 com.numerix.pro.Application]
ApplicationWarning: [1x1 com.numerix.pro.ApplicationWarning]
```

Construct a `numerixCrossAsset` Object for C++

Construct a `numerixCrossAsset` object for the C++ SDK API on Windows.

```
c = numerixCrossAsset(true)
```

```
 c =

numerixCrossAsset with properties:

Application: [1×1 fininst.internal.NumerixCAIL]
ApplicationWarning: []
```

More About

CROSSASSET

The CROSSASSET API is an application programming interface (API) for Java or C++, which extends the data-driven approach of Numerix.

Version History

Introduced in R2016b

Support for C++ interface

Use `c = numerixCrossAsset(true)` to construct the `numerixCrossAsset` object for a C++ SDK API on Windows.

applicationCall

Class: `numerixCrossAsset`

Create and register Numerix CROSSASSET Call object

Syntax

```
applicationCall(C,Headers,Name,Value)
```

Description

`applicationCall(C,Headers,Name,Value)` creates and registers the Numerix CROSSASSET Call object with additional options specified by one or more `Name,Value` pair arguments. The name-value parameters conform to the Numerix Cross Asset Integration Layer interface and are defined by `N1`, `N2`, ..., `N`*N* to the values given in `V1`, `V2`, ..., `V`*N*.

Creating and registering the Call object calculates values in the Numerix Cross Asset Integration Layer and returns the data in MATLAB.

Input Arguments

`C` — Connection object to Numerix CROSSASSET

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

`Headers` — Output names of the returned values from `numerixCrossAsset` connection object

cell array of character vectors

Output names of the returned values from `numerixCrossAsset` connection object, specified as a cell array of character vectors.

Data Types: `cell`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`N1` — Numerix name-value parameter

name-value parameter defined by Numerix

Numerix parameters, specified as a `Name,Value` argument pair.

Example: `applicationCall(c,Headers,'ID','RATESPEC','OBJECT','MARKET DATA','TYPE','YIELD','COMMENT','Comments`

```
here','SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF','CURRENCY
','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');
```

Data Types: `char` | `double` | `logical`

N2 — Numerix name-value parameters
name-value parameter defined by Numerix

Numerix parameter, specified as a `Name,Value` argument pair.

Example: `applicationCall(c,Headers,'ID','RATESPEC','OBJECT','MARKET DATA','TYPE','YIELD','COMMENT','Comments here','SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF','CURRENCY','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');`

Data Types: `char` | `double` | `logical`

Attributes

`Access`	`public`
`Static`	`false`
`Hidden`	`false`

To learn about attributes of methods, see Method Attributes.

Examples

Create and Register a Numerix CROSSASSET Call Object

Create a `datetime` object.

```
dates = datetime({'18-Feb-2014';'20-May-2014';'18-Jun-2014';'16-Jul-2014';
                  '20-Aug-2014';'17-Sep-2014';'15-Oct-2014';'19-Nov-2014';
                 '17-Dec-2014';'18-Mar-2015';'17-Jun-2015';'16-Sep-2015';
                 '16-Dec-2015';'16-Mar-2016';'15-Jun-2016';'21-Sep-2016';
                 '21-Dec-2016';'15-Mar-2017';'20-Feb-2018';'20-Feb-2019';
                 '20-Feb-2020';'22-Feb-2021';'22-Feb-2022';'21-Feb-2023';
                 '20-Feb-2024';'20-Feb-2025';'20-Feb-2026';'20-Feb-2029';
                 '21-Feb-2034';'22-Feb-2039';'22-Feb-2044';'20-Feb-2054';
                 '20-Feb-2064'});
```

Create the corresponding vector of discount factors for a 3-month LIBOR curve.

```
 discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
                     0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...
                     0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...
                     0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...
                     0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...
                     0.213809;0.152345];
```

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Add data to the Numerix Cross Asset Application Data object.

```
applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountFactors)
```

Define the `Headers` input and add the `RateSpec` Call object to the Numerix CROSSASSET Application object using name-value pairs, where `USD_3MLIBOR_CURVE` denotes the yield curve data object created previously.

```
headers = {'ID','LOCAL ID','TIMER','TIMER CPU','UPDATED'};
applicationCall(c,headers,'ID','RATESPEC','OBJECT','MARKET DATA','TYPE','YIELD','COMMENT','Comments here',...
                'SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF',...
                'CURRENCY','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');
```

Version History

Introduced in R2016b

applicationData

Class: `numerixCrossAsset`

Create and register data with Numerix CROSSASSET Application Data object

Syntax

```
applicationData(C,Desc,Name,Value)
applicationData(C,Desc,T)
applicationData(C,Desc,S)
```

Description

`applicationData(C,Desc,Name,Value)` `applicationData` creates and registers the data for Numerix CROSSASSET Application Data object with additional options specified by one or more `Name,Value` pair arguments. The name-value parameters conform to the Numerix Cross Asset Integration Layer interface and are defined by `N1`, `N2`, ..., `N`*N* to the values given in `V1`, `V2`, ..., `V`*N*.

`applicationData(C,Desc,T)` creates and registers the data for Numerix CROSSASSET Application Data object in table `T`.

`applicationData(C,Desc,S)` creates and registers the data in the structure, `S`. The structure `fieldnames` represents the property names for the values in each field.

Input Arguments

`C` — Connection object to Numerix CROSSASSET

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

`Desc` — Description of data

character vector or cell array of character vectors

Description of data, specified as a character vector or cell array of character vectors.

Data Types: `char` | `cell`

`T` — Table input

table `VariableNames` represents the property names for values in the corresponding column

Table input for data to register for the Numerix CROSSASSET Application Data object, specified using `VariableNames`.

Data Types: `table`

`S` — Structure input

structure `fieldnames` represents the property names for the values in each field

Structure input for data to register for the Numerix CROSSASSET Application Data object, specified using the `fieldnames`.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

`N1` — Numerix name-value parameter

name-value parameter defined by Numerix

Numerix parameter, specified as `Name,Value` argument pair.

Example:
`applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountFactors)`

Data Types: `char` | `double` | `logical`

`N2` — Numerix name-value parameters

name-value parameter defined by Numerix

Numerix parameter, specified as `Name,Value` argument pair.

Example:
`applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountFactors)`

Data Types: `char` | `double` | `logical`

Attributes

`Access`	`public`
`Static`	`false`
`Hidden`	`false`

To learn about attributes of methods, see Method Attributes.

Examples

Create a Numerix CROSSASSET Application Data Object

Create a `datetime` object.

```
dates = datetime({'18-Feb-2014';'20-May-2014';'18-Jun-2014';'16-Jul-2014';
                  '20-Aug-2014';'17-Sep-2014';'15-Oct-2014';'19-Nov-2014';
                 '17-Dec-2014';'18-Mar-2015';'17-Jun-2015';'16-Sep-2015';
                 '16-Dec-2015';'16-Mar-2016';'15-Jun-2016';'21-Sep-2016';
                 '21-Dec-2016';'15-Mar-2017';'20-Feb-2018';'20-Feb-2019';
                 '20-Feb-2020';'22-Feb-2021';'22-Feb-2022';'21-Feb-2023';
                 '20-Feb-2024';'20-Feb-2025';'20-Feb-2026';'20-Feb-2029';
                 '21-Feb-2034';'22-Feb-2039';'22-Feb-2044';'20-Feb-2054';
                 '20-Feb-2064'});
```

Create the corresponding vector of discount factors for a 3-month LIBOR curve.

```
discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
                       0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...
                       0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...
                       0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...
                       0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...
                       0.213809;0.152345];
```

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Create and register the data with the Numerix CROSSASSET Application Data object.

```
applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountFactors)
```

Version History

Introduced in R2016b

applicationMatrix

Class: `numerixCrossAsset`

Create and register Numerix CROSSASSET Application Matrix object

Syntax

```
applicationMatrix(C,Desc,Rdata,Cdata,Mdata)
```

Description

`applicationMatrix(C,Desc,Rdata,Cdata,Mdata)` creates the CROSSASSET Application Matrix object from the row information (`Rdata`), column information (`Cdata`), and matrix (`Mdata`).

Input Arguments

`C` — Connection object to Numerix CROSSASSET

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

`Desc` — Description of data

character vector or cell array of character vectors

Description of data, specified as a character vector or cell array of character vectors.

Data Types: `char` | `cell`

`Rdata` — Row information for Application Matrix object

numeric values

Row information for Application Matrix object, specified using numeric values.

Example: `Rdata = [41992,42020,42449,42905,43115];`

Data Types: `double`

`Cdata` — Column information for Application Matrix object

numeric values

Column information for Application Matrix object, specified as numeric values.

Example: `Cdata = [390,395,400,405];`

Data Types: `double`

`Mdata` — Volatility information for Application Matrix object

numeric values

Volatility information for Application Matrix object, specified as numeric values.

Example:
```
Mdata = [0.35778, 0.35132, 0.34394, 0.33582;...
0.33405, 0.32819, 0.32669, 0.31904;...
```

```
0.31576, 0.31235, 0.30371, 0.30261;...
0.29391, 0.29366, 0.28962, 0.28932;...
0.28787, NaN, 0.28347, NaN ];
```

Data Types: `double`

Attributes

`Access`	`public`
`Static`	`false`
`Hidden`	`false`

To learn about attributes of methods, see Method Attributes.

Examples

Create a Numerix CROSSASSET Application Matrix Object

Create a volatility matrix with dates describing the rows and strike prices describing the columns with the description `BYSTRIKEVOLDATA`. Missing values in the matrix input are denoted as `NaN`.

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Define the matrix data.

```
rowData = [41992, 42020, 42449, 42905, 43115];
colData = [390, 395, 400, 405];
volData = [0.35778, 0.35132, 0.34394, 0.33582;...
           0.33405, 0.32819, 0.32669, 0.31904;...
           0.31576, 0.31235, 0.30371, 0.30261;...
           0.29391, 0.29366, 0.28962, 0.28932;...
           0.28787, NaN,     0.28347, NaN    ];
```

Create and register a Numerix CROSSASSET Application Matrix object.

```
applicationMatrix(c,'BYSTRIKEVOLDATA',rowData,colData,volData);
```

Version History

Introduced in R2016b

close

Class: `numerixCrossAsset`

Close numerixCrossAsset object

Syntax

```
AppData = close(C)
```

Description

`AppData = close(C)` closes the `numerixCrossAsset` object (`C`).

Input Arguments

`C` — Connection object to Numerix CROSSASSET

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

Attributes

`Access`	`public`
`Static`	`false`
`Hidden`	`false`

To learn about attributes of methods, see Method Attributes.

Examples

Close the Numerix CROSSASSET Object

Construct a `numerixCrossAsset` object.

```
c = numerixCrossAsset
```

```
 c =

numerixCrossAsset with properties:

Application: [1x1 com.numerix.pro.Application]
ApplicationWarning: [1x1 com.numerix.pro.ApplicationWarning]
```

Close the `numerixCrossAsset` object.

```
close(c)
```

Version History

Introduced in R2016b

getdata

Class: `numerixCrossAsset`

Convert Numerix CROSSASSET Application object to MATLAB structure

Syntax

```
AppData = getdata(C)
```

Description

`AppData = getdata(C)` converts a Numerix CROSSASSET Application object to a MATLAB structure.

Input Arguments

`C` — Connection object to Numerix CROSSASSET

object

Connection object to Numerix CROSSASSET, specified using the `numerixCrossAsset` constructor.

Output Arguments

`AppData` — Converted Numerix CROSSASSET Application object

structure

Converted Numerix CROSSASSET Application object, returned as a MATLAB structure

Attributes

`Access`	`public`
`Static`	`false`
`Hidden`	`false`

To learn about attributes of methods, see Method Attributes.

Examples

Convert Numerix CROSSASSET Application Object to a MATLAB Structure

Create a `datetime` object.

```
dates = datetime({'18-Feb-2014';'20-May-2014';'18-Jun-2014';'16-Jul-2014';
                  '20-Aug-2014';'17-Sep-2014';'15-Oct-2014';'19-Nov-2014';
                 '17-Dec-2014';'18-Mar-2015';'17-Jun-2015';'16-Sep-2015';
                 '16-Dec-2015';'16-Mar-2016';'15-Jun-2016';'21-Sep-2016';
                 '21-Dec-2016';'15-Mar-2017';'20-Feb-2018';'20-Feb-2019';
                 '20-Feb-2020';'22-Feb-2021';'22-Feb-2022';'21-Feb-2023';
                 '20-Feb-2024';'20-Feb-2025';'20-Feb-2026';'20-Feb-2029';
```

```
                '21-Feb-2034';'22-Feb-2039';'22-Feb-2044';'20-Feb-2054';
                '20-Feb-2064'});
```

Create the corresponding vector of discount factors for a 3-month LIBOR curve.

```
discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
                    0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...
                    0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...
                    0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...
                    0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...
                    0.213809;0.152345];
```

Create a Numerix CROSSASSET object.

```
c = numerixCrossAsset;
```

Add data to the Numerix CROSSASSET Application Data object.

```
applicationData(c,'USD_3MLIBOR_CURVE','DATE',dates,'DISCOUNTFACTOR',discountFactors)
```

Add the `RATESPEC` Call object to the Numerix CROSSASSET Application object using name-value pairs, where `USD_3MLIBOR_CURVE` denotes yield curve data object created previously.

```
headers = {'ID','LOCAL ID','TIMER','TIMER CPU','UPDATED'};
 applicationCall(c,headers,'ID','RATESPEC','OBJECT','MARKET DATA','TYPE','YIELD','COMMENT','Comments here',...
                'SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF',...
                'CURRENCY','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');
```

Use `getdata` to convert the Numerix CROSSASSET Application object to a MATLAB structure.

```
APPDATA = getdata(C)
```

Version History

Introduced in R2016b

parseResults

Class: `numerix`

Converts Numerix CAIL data to MATLAB data types

Syntax

```
R = parseResults(N,Results)
```

Description

`R = parseResults(N,Results)` returns Numerix CAIL data in native MATLAB data types.

Input Arguments

`N` — Numerix object

object

Numerix object constructed using `numerix`.

`Results` — Result instances for each trade instance

Numerix CAIL trade

Result instances for each trade instance.

Output Arguments

`R` — Row information for Numerix CAIL data

character vector | numeric

Results from Numerix table output represented as MATLAB data types.

Attributes

`Access`	`public`
`Static`	`false`
`Hidden`	`false`

To learn about attributes of methods, see Method Attributes.

Examples

Return Results for Numerix CAIL API to Price a Callable Reverse Floater

Initialize Numerix environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;

n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =

             Path: 'i:\NumeriX_java_10_3_0\data'
    RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
        Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
           Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
       LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
       MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
       FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
        TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
        Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

Create a market.

```
quotes = java.util.HashMap;
quotes.put('IR.USD-LIBOR-3M.SWAP-1Y.MID', 0.0066056);
quotes.put('IR.USD-LIBOR-3M.SWAP-10Y.MID', 0.022465005);
quotes.put('IR.USD-LIBOR-3M.SWAP-20Y.MID', 0.027544995);
market = Market('EOD_14-NOV-2011', DateExtensions.date('14-Nov-2011'), quotes.entrySet);
```

Define a trade instance based on instrument template found in the `Repository`.

```
tradeDescriptor = 'TRADE.IR.CALLABLEREVERSEFLOATER';
tradeParameters = java.util.HashMap;
tradeParameters.put('Trade ID','1001');
tradeParameters.put('Quote Type', 'MID');
tradeParameters.put('Currency', 'USD');
tradeParameters.put('Notional', 1000000.0);
tradeParameters.put('Effective Date', DateExtensions.date('1-Dec-2011'));
tradeParameters.put('Termination Date', DateExtensions.date('1-Dec-2021'));
tradeParameters.put('IR Index', 'LIBOR');
tradeParameters.put('IR Index Tenor', '3M');
tradeParameters.put('Structured Freq', '3M');
tradeParameters.put('Structured Side', 'Receive');
tradeParameters.put('Structured Coupon Floor', 0.0);
tradeParameters.put('Structured Coupon UpBd', 0.08);
tradeParameters.put('StructuredCoupon Multiplier', 1.4);
tradeParameters.put('Structured Coupon Cap', 0.05);
tradeParameters.put('Structured Basis', 'ACT/360');
tradeParameters.put('Funding Freq', '3M');
tradeParameters.put('Funding Side', 'Pay');
tradeParameters.put('Funding Spread', 0.003);
tradeParameters.put('Funding Basis', 'ACT/360');
tradeParameters.put('Call Start Date', DateExtensions.date('1-Dec-2013'));
tradeParameters.put('Call End Date', DateExtensions.date('1-Dec-2020'));
tradeParameters.put('Option Side', 'Short');
tradeParameters.put('Option Type', 'Right to Terminate');
tradeParameters.put('Call Frequency', '3M');
tradeParameters.put('Model', 'IR.USD-LIBOR-3M.MID.DET');

oasbybdt

Determine option adjusted spread using Black-Derman-Toy model

Syntax

```
[OAS,OAD,OAC] = oasbybdt(BDTTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbybdt( ___ ,Name,Value)
```

Description

`[OAS,OAD,OAC] = oasbybdt(BDTTree,Price,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates option adjusted spread using a Black-Derman-Toy model.

`oasbybdt` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1450.

`[OAS,OAD,OAC] = oasbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute OAS Using the Black-Derman-Toy (BDT) Model

This example shows how to compute OAS using the Black-Derman-Toy (BDT) model with the following data.

```
ValuationDate = datetime(2010,10,1);
Rates = [0.035; 0.042; 0.047; 0.052];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;
% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding);

% specify VolSpec and TimeSpec
Sigma = 0.20;
VS = bdtvolspec(ValuationDate, EndDates, Sigma*ones(size(EndDates)));
TS = bdttimespec(ValuationDate, EndDates, Compounding);

% build the BDT tree
BDTTree = bdttree(VS, RateSpec, TS);
BDTTreenew = cvtree(BDTTree);

% instrument information
CouponRate = 0.065;
Settle = ValuationDate;
Maturity = datetime(2014,10,1);
```

```
OptSpec = 'call';
Strike = 100;
ExerciseDates = datetime(2011,10,1);
Period = 1;
Price = 101.58;

% compute the OAS
OAS = oasbybdt(BDTTree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period)

OAS = 32.7688
```

Compute OAS for an Amortizing Callable Bond Using a BDT Interest-Rate Tree Model

This example shows how to compte the OAS for an amortizing callable bond using a BDT lattice model.

Create a `RateSpec`.

```
Rates = [0.025;0.028;0.030;0.031];
ValuationDate = 'Jan-1-2018';
StartDates = ValuationDate;
EndDates = {'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'; 'Jan-1-2022'};
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);
```

Build a BDT tree and assume a volatility of 5%.

```
Sigma = 0.05;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = 'Jan-1-2018';
Maturity =  'Jan-1-2021';
Period = 1;

    Face = {
                {'Jan-1-2019'  100;
                 'Jan-1-2020'   70; ...
                  'Jan-1-2021'   50};
                };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates ={'Jan-1-2019' 'Jan-1-2020' 'Jan-1-2021'};
```

Compute the OAS for a callable amortizing bond using the BDT tree.

```
Price = 99;
BondType = 'amortizing';
```

```
OAS = oasbybdt(BDTT, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face,'BondType', BondType)
```

```
OAS = 53.0303
```

Input Arguments

`BDTTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`Price` — Market prices of bonds with embedded options

numeric

Market prices of bonds with embedded options, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond with an embedded option is set to the `ValuationDate` of the BDT tree. The bond argument `Settle` is ignored.

To support existing code, `oasbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: char | cell

Strike — Option strike price values
nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option is exercised between the underlying bond Settle date and the single listed exercise date.

To support existing code, oasbybdt also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: OAS = oasbybdt(BDTTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',4)

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda

- `1` — American

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, oasbybdt also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, oasbybdt also accepts serial date numbers as inputs, but they are not recommended.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, oasbybdt also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, oasbybdt also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first

column is dates using a datetime, string, or date character vector, and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: `double` | `string` | `char` | `datetime`

`BondType` — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`OAS` — Option adjusted spread
vector

Option adjusted spread, returned as a `NINST`-by-`1` vector.

`OAD` — Option adjusted duration
vector

Option adjusted duration, returned as a `NINST`-by-`1` vector.

`OAC` — Option adjusted convexity
vector

Option adjusted convexity, returned as a `NINST`-by-`1` vector.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2011a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `oasbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

oasbybk

Determine option adjusted spread using Black-Karasinski model

Syntax

```
[OAS,OAD,OAC] = oasbybk(BKTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbybk( ___ ,Name,Value)
```

Description

`[OAS,OAD,OAC] = oasbybk(BKTree,Price,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates option adjusted spread using a Black-Karasinski model.

`oasbybk` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1450.

`[OAS,OAD,OAC] = oasbybk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute OAS and OAD Using the Black-Karasinski (BK) Model

This example shows how to compute OAS and OAD using the Black-Karasinski (BK) model using the following data.

```
ValuationDate = datetime(2010,8,2);
Rates = [0.0355; 0.0382; 0.0427; 0.0489];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding);

% specify VolSpec and TimeSpec
Sigma = 0.10;
Alpha = 0.01;
VS = bkvolspec(ValuationDate, EndDates, Sigma*ones(size(EndDates)),...
EndDates, Alpha*ones(size(EndDates)));
TS = bktimespec(ValuationDate, EndDates, Compounding);

% build the BK tree
BKTree = bktree(VS, RateSpec, TS);

% instrument information
CouponRate = 0.045;
```

```
Settle = ValuationDate;
Maturity = datetime(2014,8,2);
OptSpec = 'put';
Strike = 100;
ExerciseDates = datetime(2013,8,2);
Period = 1;
AmericanOpt = 1;
Price = 101;

% compute OAS and OAD
[OAS, OAD] = oasbybk(BKTree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'AmericanOpt', AmericanOpt)

OAS = 9.9999e+04

OAD = 0
```

Compute OAS for an Amortizing Callable Bond Using a BK Interest-Rate Tree Model

This example shows how to compute the OAS for an amortizing callable bond using a BK lattice model.

Create a RateSpec.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build a BK tree.

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2016,1,1);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = datetime(2012,1,1);
Maturity = datetime(2016,1,1);
Period = 1;

    Face = {
                {datetime(2014,1,1)  100;
                 datetime(2015,1,1)  70;
                 datetime(2016,1,1)  50};
                };
```

```
OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates =[datetime(2014,1,1) datetime(2015,1,1)  datetime(2016,1,1)];
```

Compute OAS for a callable amortizing bond using the BK tree.

```
Price = 99;
BondType = 'amortizing';
OAS = oasbybk(BKT, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face,'BondType', BondType)
```

```
OAS = -13.7366
```

Input Arguments

`BKTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

`Price` — Market prices of bonds with embedded options

numeric

Market prices of bonds with embedded options, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond with an embedded option is set to the `ValuationDate` of the BK tree. The bond argument `Settle` is ignored.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-1 cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-1 or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-1 vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-1 vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-1, `NINST`-by-2, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a `NINST`-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates. Each row is the schedule for one option.
- For an American option, use a `NINST`-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-1 vector, the option is exercised between the underlying bond `Settle` date and the single listed exercise date.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example:
```
OAS =
oasbybk(BDTTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates
,'Period',4)
```

`AmericanOpt` — Option type
`0` European/Bermuda (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Period` — Coupons per year
`2` per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbybk` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Face — Face value
100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates using a datetime, string, or date character vector, and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: double | char | string | datetime

BondType — Type of underlying bond
'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla','amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

Options — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

Output Arguments

OAS — Option adjusted spread
vector

Option adjusted spread, returned as a NINST-by-1 vector.

OAD — Option adjusted duration
vector

Option adjusted duration, returned as a NINST-by-1 vector.

OAC — Option adjusted convexity
vector

Option adjusted convexity, returned as a NINST-by-1 vector.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2011a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `oasbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

oasbycir

Determine option adjusted spread using Cox-Ingersoll-Ross model

Syntax

```
[OAS,OAD,OAC] = oasbycir(CIRTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbycir( ___ ,Name,Value)
```

Description

`[OAS,OAD,OAC] = oasbycir(CIRTree,Price,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates the option adjusted spread from a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`oasbycir` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with embedded option. For more information, see “More About” on page 11-1450.

`[OAS,OAD,OAC] = oasbycir( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute OAS Using a CIR Interest-Rate Tree

Create a `RateSpec` using the `intenvset` function.

```
ValuationDate = datetime(2018,10,25);
Rates = [0.0355; 0.0382; 0.0427; 0.0489];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = datetime(2023,10,25);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
```

```
    RateSpec: [1x1 struct]
        tObs: [0 1.2500 2.5000 3.7500]
        dObs: [737358 737814 738271 738727]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Define the OAS instrument.

```
CouponRate = 0.045;
Settle = ValuationDate;
Maturity = '25-October-2019';
OptSpec = 'call';
Strike = 100;
ExerciseDates = {'25-October-2018','25-October-2019'};
Period = 1;
AmericanOpt = 0;
Price = 97;
```

Compute the OAS.

```
[OAS,OAD] = oasbycir(CIRT,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period'
```

```
OAS = 411.4425
```

```
OAD = 0.9282
```

Compute OAS for an Amortizing Callable Bond Using a CIR Interest-Rate Tree

his example shows how to compute the OAS for an amortizing callable bond using a CIR lattice model.

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.025; 0.032; 0.037; 0.042];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2016,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = datetime(2019,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
```

```
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.7500 1.5000 2.2500]
        dObs: [736330 736604 736878 737152]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Define the callable bond.

```
BondSettlement = datetime(2016,1,1);
BondMaturity   = datetime(2020,1,1);
CouponRate = 0.035;
Period = 1;
OptSpec = 'call';
Strike = 100;

 Face = {
                 {datetime(2018,1,1) 100;
                  datetime(2019,1,1) 70;
                  datetime(2020,1,1) 50};
                 };

ExerciseDates = [datetime(2018,1,1) ; datetime(2019,1,1)];
```

Compute OAS for a callable amortizing bond using the CIR tree.

```
Price = 99;
BondType = 'amortizing';
OAS = oasbycir(CIRT, Price, CouponRate, BondSettlement, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face,'BondType', BondType)
```

```
OAS = 2×1

   80.4801
   84.3684
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`Price` — Market prices of bonds with embedded options

numeric

Market prices of bonds with embedded options, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: double

Settle — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every bond with an embedded option is set to the ValuationDate of the CIR tree. The bond argument Settle is ignored.

To support existing code, oasbycir also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, oasbycir also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string array with values "call" or "put"

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays with values 'call' or 'put'.

Data Types: char | cell | string

Strike — Option strike price values
nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

.

To support existing code, oasbycir also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: OAS = oasbycir(CIRTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',4)

AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbycir` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbycir` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbycir` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbycir` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates using a datetime, string, or date character vector, and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: `double` | `char` | `string` | `datetime`

`BondType` — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

Output Arguments

`OAS` — Option adjusted spread

vector

Option adjusted spread, returned as a `NINST`-by-1 vector.

`OAD` — Option adjusted duration

vector

Option adjusted duration, returned as a `NINST`-by-1 vector.

`OAC` — Option adjusted convexity

vector

Option adjusted convexity, returned as a `NINST`-by-1 vector.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `oasbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

oasbyhjm

Determine option adjusted spread using Heath-Jarrow-Morton model

Syntax

```
[OAS,OAD,OAC] = oasbyhjm(HJMTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbyhjm( ___ ,Name,Value)
```

Description

`[OAS,OAD,OAC] = oasbyhjm(HJMTree,Price,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates option adjusted spread using a Heath-Jarrow-Morton model.

`oasbyhjm` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1450.

`[OAS,OAD,OAC] = oasbyhjm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute OAS Using the Heath-Jarrow-Morton (HJM) Model

This example shows how to compute OAS using the Heath-Jarrow-Morton (HJM) model using the following data.

```
ValuationDate = datetime(2010,11,1);
Rates = [0.0356; 0.0427; 0.0478; 0.0529];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding);

% specify VolSpec and TimeSpec
Sigma = 0.02;
VS = hjmvolspec('Constant', Sigma);
TS = hjmtimespec(ValuationDate, EndDates, Compounding);

% build the HJM tree
HJMTree = hjmtree(VS, RateSpec, TS);
HJMTreenew = cvtree(HJMTree);

% instrument information
CouponRate = 0.05;
Settle = ValuationDate;
```

```
Maturity = datetime(2014,11,1);
OptSpec = 'call';
Strike = 100;
ExerciseDates = datetime(2010,11,1);
Period = 1;
Price = 97.5;

% compute the OAS
OAS = oasbyhjm(HJMTree, Price, CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', Period)

OAS = 49.3289
```

Compute OAS for an Amortizing Callable Bond Using an HJM Interest-Rate Tree Model

This example shows how to compute the OAS for amortizing callable bond using an HJM lattice model.

Create a RateSpec.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build a HJM tree.

```
VolSpec = hjmvolspec('Constant', 0.01)

VolSpec = struct with fields:
          FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
      FactorArgs: {{1x1 cell}}
      SigmaShift: 0
      NumFactors: 1
       NumBranch: 2
         PBranch: [0.5000 0.5000]
     Fact2Branch: [-1 1]

TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding)

TimeSpec = struct with fields:
           FinObj: 'HJMTimeSpec'
    ValuationDate: 734869
         Maturity: [4x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1

HJMTree = hjmtree(VolSpec, RS, TimeSpec)
```

```
HJMTree = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = datetime(2012,1,1);
Maturity =  datetime(2016,1,1);
Period = 1;

    Face = {
                 {datetime(2014,1,1) 100;
                  datetime(2015,1,1) 70;
                  datetime(2016,1,1) 50};
                 };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = [datetime(2014,1,1)  datetime(2015,1,1)  datetime(2016,1,1)];
```

Compute the OAS for a callable amortizing bond using the HJM tree.

```
Price = 99;
BondType = 'amortizing';
OAS = oasbyhjm(HJMTree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face,'BondType', BondType)

OAS = -19.1325
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`Price` — Market prices of bonds with embedded options

numeric

Market prices of bonds with embedded options, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate.

Data Types: double

Settle — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every bond with an embedded option is set to the ValuationDate of the HJM tree. The bond argument Settle is ignored.

To support existing code, oasbyhjm also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, oasbyhjm also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char | cell

Strike — Option strike price values
nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option is exercised between the underlying bond Settle date and the single listed exercise date.

To support existing code, oasbyhjm also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: OAS = oasbybk(BDTTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',4)

AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates using a datetime, string, or date character vector, and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: `double` | `char` | `string` | `datetime`

`BondType` — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`OAS` — Option adjusted spread
vector

Option adjusted spread, returned as a `NINST`-by-`1` vector.

`OAD` — Option adjusted duration
vector

Option adjusted duration, returned as a `NINST`-by-`1` vector.

`OAC` — Option adjusted convexity
vector

Option adjusted convexity, returned as a `NINST`-by-`1` vector.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via

a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2011a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `oasbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

oasbyhw

Determine option adjusted spread using Hull-White model

Syntax

```
[OAS,OAD,OAC] = oasbyhw(HWTree,Price,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[OAS,OAD,OAC] = oasbyhw( ___ ,Name,Value)
```

Description

`[OAS,OAD,OAC] = oasbyhw(HWTree,Price,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates option adjusted spread using a Hull-White model.

`oasbyhw` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1450.

`[OAS,OAD,OAC] = oasbyhw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute OAS and OAD Using the Hull-White (HW) Model

This example shows how to compute OAS and OAD using the Hull-White (HW) model using the following data.

```
ValuationDate = datetime(2010,10,25);
Rates = [0.0355; 0.0382; 0.0427; 0.0489];
StartDates = ValuationDate;
EndDates = datemnth(ValuationDate, 12:12:48)';
Compounding = 1;

% define RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate,...
'StartDates', StartDates, 'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding);

% specify VolsSpec and TimeSpec
Sigma = 0.05;
Alpha = 0.01;
VS = hwvolspec(ValuationDate, EndDates, Sigma*ones(size(EndDates)),...
EndDates, Alpha*ones(size(EndDates)));
TS = hwtimespec(ValuationDate, EndDates, Compounding);

% build the HW tree
HWTree = hwtree(VS, RateSpec, TS);

% instrument information
CouponRate = 0.045;
```

```
Settle = ValuationDate;
Maturity = datetime(2014,10,25);
OptSpec = 'call';
Strike = 100;
ExerciseDates = [datetime(2010,10,25) ; datetime(2013,10,25)];
Period = 1;
AmericanOpt = 0;
Price = 97;

% compute the OAS
[OAS, OAD] = oasbyhw(HWTree, Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'AmericanOpt', AmericanOpt)

OAS = 2×1

   52.3118
  -12.8538

OAD = 2×1

    3.5507
    3.2910
```

Compute the OAS to Measure Cost of an Embedded Option Relative to a Risk-Free Curve

This example shows how to compute the price of a callable bond using a Hull-White tree.

Use the following bond data:

```
Settle = datetime(2014,8,20);

% Bond Properties
Maturity = datetime(2034,4,1);
CouponRate = .0625;
CallDates = datemnth('01-Oct-2014',6*(0:19));
CallStrikes = [102.85 102.7 102.55 102.4 102.25 102.1 101.95 101.8 ...
    101.65 101.5 101.35 101.2 101.05 100.9 100.75 100.6 100.45 100.3 ...
    100.15 100];
```

Use the following zero-curve data:

```
CurveDates = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');
ZeroRates = [.11 0.30 0.64 1.44 2.07 2.61 3.29 3.55]'/100;
```

Define the `RateSpec` and build the HW tree.

```
RateSpec = intenvset('StartDate',Settle,'EndDates',CurveDates,'Rates',ZeroRates);

% HW Model Properties
alpha = .1;
sigma = .01;

TimeSpec = hwtimespec(Settle,cfdates(Settle,Maturity,12),2);
VolSpec = hwvolspec(Settle,Maturity,sigma,Maturity,alpha);
```

```
HWTree = hwtree(VolSpec,RateSpec,TimeSpec,'method','HW2000')
```

```
HWTree = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.0652 0.2295 0.3967 0.5628 0.7283 0.8967 1.0652 1.2295 ... ]
        dObs: [735831 735843 735873 735904 735934 735965 735996 736024 ... ]
      CFlowT: {1x236 cell}
       Probs: {1x235 cell}
     Connect: {1x235 cell}
     FwdTree: {1x236 cell}
```

Compute the OAS for the bond.

```
Price = 103.25;
OAS = oasbyhw(HWTree, Price, CouponRate, Settle, Maturity, 'call', CallStrikes, CallDates)
```

```
OAS = 234.8209
```

If you want to compute an OAS that only measures the option cost, you can pass in an issuer-specific curve instead of a risk-free curve (this would be done in the `RateSpec` argument).

Compute OAS for an Amortizing Callable Bond Using an HW Interest-Rate Tree Model

This example shows how to compute the OAS for an amortizing callable bond using an HW lattice model.

Create a `RateSpec`.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2012';
StartDates = ValuationDate;
EndDates = {'Jan-1-2013'; 'Jan-1-2014'; 'Jan-1-2015'; 'Jan-1-2016'};
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build a HW tree.

```
VolDates = ['1-Jan-2013'; '1-Jan-2014'; '1-Jan-2015'; '1-Jan-2016'];
VolCurve = 0.01;
AlphaDates = '01-01-2016';
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, EndDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = 'Jan-1-2012';
```

```
Maturity =  'Jan-1-2016';
Period = 1;

    Face = {
                  {'Jan-1-2014'  100;
                   'Jan-1-2015'   70;
                   'Jan-1-2016'   50};
                  };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates ={'Jan-1-2014' 'Jan-1-2015' 'Jan-1-2016'};
```

Compute the OAS for a callable amortizing bond using the HW tree.

```
Price = 55;
BondType = 'amortizing';
OAS = oasbyhw(HWT,Price, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face,'BondType', BondType)
```

```
OAS = 2.4023e+03
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`Price` — Market prices of bonds with embedded options

numeric

Market prices of bonds with embedded options, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate.

Data Types: `double`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond with an embedded option is set to the `ValuationDate` of the HW tree. The bond argument `Settle` is ignored.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`, `NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a `NINST`-by-`1` vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates. Each row is the schedule for one option.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option is exercised between the underlying bond `Settle` date and the single listed exercise date.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `OAS = oasbybk(BDTTree,Price,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',4)`

`AmericanOpt` — Option type

`0` European/Bermuda (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Period` — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `oasbyhw` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates using a datetime, string, or date character vector, and the second column is associated face value. The date indicates the last day that the face value is valid.

Data Types: `double` | `char` | `string` | `datetime`

`BondType` — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`OAS` — Option adjusted spread
vector

Option adjusted spread, returned as a `NINST`-by-`1` vector.

`OAD` — Option adjusted duration
vector

Option adjusted duration, returned as a `NINST`-by-`1` vector.

`OAC` — Option adjusted convexity
vector

Option adjusted convexity, returned as a `NINST`-by-`1` vector.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2011a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `oasbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optbndbybdt

Price bond option from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = optbndbybdt(BDTTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbybdt( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

Description

`[Price,PriceTree] = optbndbybdt(BDTTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity)` calculates the price for a bond option from a Black-Derman-Toy interest-rate tree.

Note Alternatively, you can use the `FixedBondOption` object to price fixed-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optbndbybdt( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options)` adds optional arguments.

Examples

Price a European Call and Put Option on a Bond

Using the BDT interest-rate tree in the `deriv.mat` file, price a European call and put option on a 10% bond with a strike of 95. The exercise date for the option is Jan. 01, 2002. The settle date for the bond is Jan. 01, 2000, and the maturity date is Jan. 01, 2003.

Load the file `deriv.mat`, which provides `BDTTree`. The `BDTTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbondbybdt` to compute the price of the `'Call'` option.

```
[Price,PriceTree] = optbndbybdt(BDTTree,'Call',95,'01-Jan-2002',...
0,0.10,datetime(2000,1,1),datetime(2003,1,1),1)
```

```
Price = 1.7657
```

```
PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
      tObs: [0 1 2 3 4]
     PTree: {[1.7657]  [3.1458 0.7387]  [5.2187 1.6890 0]  [0 0 0 0]  [0 0 0 0]}
    ExTree: {[0]  [0 0]  [1 1 0]  [0 0 0 0]  [0 0 0 0]}
```

Now use `optbndbybdt` to compute the price of a `'Put'` option on the same bond.

```
[Price,PriceTree] = optbndbybdt(BDTTree,'Put',95,'01-Jan-2002',...
0,0.10,datetime(2000,1,1),datetime(2003,1,1),1)
```

```
Price = 0.5740
```

```
PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
      tObs: [0 1 2 3 4]
     PTree: {[0.5740]  [0 1.2628]  [0 0 2.8871]  [0 0 0 0]  [0 0 0 0]}
    ExTree: {[0]  [0 0]  [0 0 1]  [0 0 0 0]  [0 0 0 0]}
```

The `PriceTree.ExTree` output for the `'Call'` and `'Put'` option contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

Input Arguments

`BDTTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`, `NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optbndbybdt also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

CouponRate — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

Settle — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every bond is set to the ValuationDate of the BDT tree. The bond argument Settle is ignored.

To support existing code, optbndbybdt also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optbndbybdt also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Coupons per year
2 per year (default) | vector

(Optional) Coupons per year, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

(Optional) End-of-month rule flag is specified as a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

(Optional) Bond issue date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

(Optional) Irregular first coupon date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

(Optional) Irregular last coupon date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an`NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of bond option at time `0`

matrix

Expected price of the bond option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and accrued interest for each node

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-6.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optbndbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optbndbybk

Price bond option from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = optbndbybk(BKTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbybk( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

Description

`[Price,PriceTree] = optbndbybk(BKTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity)` calculates the price for a bond option from a Black-Karasinski interest-rate tree.

Note Alternatively, you can use the `FixedBondOption` object to price fixed-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optbndbybk( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options)` adds optional arguments.

Examples

Price a European Call and Put Option on a Bond

Using the BK interest rate tree in the `deriv.mat` file, price a European call and put option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2006. The settle date for the bond is Jan. 01, 2005, and the maturity date is Jan. 01, 2009.

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbondbybk` to compute the price of the `'Call'` option.

```
[Price,PriceTree] = optbndbybk(BKTree,'Call',96,'01-Jan-2006',...
0,0.04,datetime(2005,1,1),datetime(2009,1,1))
```

```
Warning: OptBonds are valued at Tree ValuationDate rather than Settle.
> In optbndbytrintree (line 40)
  In optbndbybk (line 92)
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbytrintree (line 151)
  In optbndbybk (line 92)
```

```

     ExTree: {[0]  [0 0 0]  [1 1 0 0 0]  [0 0 0 0 0]  [0 0 0 0 0]}
```

The `PriceTree.ExTree` output for the `'Call'` and `'Put'` option contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

Input Arguments

BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`, `NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a `NINST`-by-`1` vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European/Bermuda (default) | integer with values `0` or `1`

(Optional) Option type, specified as `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`CouponRate` — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates

and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the BK tree. The bond argument `Settle` is ignored.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Coupons per year
`2` per year (default) | vector

(Optional) Coupons per year, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

(Optional) End-of-month rule flag is specified as a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

(Optional) Bond issue date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

(Optional) Irregular first coupon date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

(Optional) Irregular last coupon date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`,

regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbybk` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an`NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of bond option at time `0`
matrix

Expected price of the bond option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and accrued interest for each node
structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-6.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optbndbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optbndbycir

Price bond option from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = optbndbycir(CIRTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optbndbycir(CIRTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity)` calculates the price for a bond option from a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = optbndbycir( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a European Call and Put Option on a Bond Using a CIR Interest-Rate Tree

Compute the price for a European call option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2018. The settle date for the bond is Jan. 01, 2017, and the maturity date is Jan. 01, 2020.

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2019,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
```

```
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.5000 1 1.5000]
        dObs: [736696 736878 737061 737243]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the `'Call'` option.

```
[Price,PriceTree] = optbndbycir(CIRT,'Call',96,datetime(2018,1,1),...
0,0.04,datetime(2017,1,1),datetime(2020,1,1))
```

```
Price = 2.6827

PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 0.5000 1 1.5000 2]
      PTree: {1x5 cell}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
     ExTree: {[0]  [0 0 0]  [0 0 1 1 1]  [0 0 0 0 0 0 0]  [0 0 0 0 0 0 0]}
```

Price the `'Put'` option.

```
[Price,PriceTree] = optbndbycir(CIRT,'Put',96,datetime(2018,1,1),...
0,0.04,datetime(2017,1,1),datetime(2020,1,1))
```

```
Price = 0.6835

PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 0.5000 1 1.5000 2]
      PTree: {1x5 cell}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
     ExTree: {[0]  [0 0 0]  [1 1 0 0 0]  [0 0 0 0 0 0 0]  [0 0 0 0 0 0 0]}
```

The `PriceTree.ExTree` output for the `'Call'` and `'Put'` option contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'` | string arrays with values `"call"` or `"put"`

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays.

Data Types: char | cell | string

Strike — Option strike price values
nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optbndbycir also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

CouponRate — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the CIR tree. The bond argument `Settle` is ignored.

To support existing code, `optbndbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optbndbycir(CIRTree,OptSpec, Strike,ExerciseDates,AmericanOpt,CouponRate,Settle,Maturity,'Period'6,'Basis' ,7,'Face',1000)`

`Period` — Coupons per year
2 per year (default) | possible values include: `0`, `1`, `2`, `3`, `4`, `6`, `12`.

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
date character vector | string array | datetime

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbycir` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbycir` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbycir` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbycir` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices of bond option at time `0`
matrix

Expected price of the bond option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and accrued interest for each node
structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PTree` contains the clean prices.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-6.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optbndbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optbndbyhjm

Price bond option from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = optbndbyhjm(HJMTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbyhjm( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

Description

`[Price,PriceTree] = optbndbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity)` calculates the price for a bond option from a Black-Karasinski interest-rate tree.

`[Price,PriceTree] = optbndbyhjm( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options)` adds optional arguments.

Examples

Price a European Call and Put Option on a Bond

Using the HJM forward-rate tree in the `deriv.mat` file, price a European call and put option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2003. The settle date for the bond is Jan. 01, 2000, and the maturity date is Jan. 01, 2004.

Load the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbndbyhjm` to compute the price of the `'Call'` option.

```
[Price,PriceTree] = optbndbyhjm(HJMTree,'Call',96,datetime(2003,1,1),...
0,0.04,datetime(2000,1,1),datetime(2004,1,1))
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbyhjm (line 223)

Price =

    2.2410

PriceTree =

  struct with fields:

    FinObj: 'HJMPriceTree'
```

```
      tObs: [0 1 2 3 4]
     PBush: {[2.2410]  [1×1×2 double]  [1×2×2 double]  [1×4×2 double]  [0 0 0 0 0 0 0 0]}
    ExBush: {[0]  [1×1×2 double]  [1×2×2 double]  [1×4×2 double]  [0 0 0 0 0 0 0 0]}
```

Now use `optbndbyhjm` to compute the price of a `'Put'` option on the same bond.

```
[Price,PriceTree] = optbndbyhjm(HJMTree,'Put',96,datetime(2003,1,1),...
0,0.04,datetime(2000,1,1),datetime(2004,1,1))
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbyhjm (line 223)

Price =

    0.0446

PriceTree =

  struct with fields:

    FinObj: 'HJMPriceTree'
      tObs: [0 1 2 3 4]
     PBush: {[0.0446]  [1×1×2 double]  [1×2×2 double]  [1×4×2 double]  [0 0 0 0 0 0 0 0]}
    ExBush: {[0]  [1×1×2 double]  [1×2×2 double]  [1×4×2 double]  [0 0 0 0 0 0 0 0]}
```

The `PriceTree.ExBush` output for the `'Call'` and `'Put'` option contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.

- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optbndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

(Optional) Option type, specified as NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

CouponRate — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

Settle — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every bond is set to the ValuationDate of the HJM tree. The bond argument Settle is ignored.

To support existing code, optbndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Coupons per year
2 per year (default) | vector

(Optional) Coupons per year, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

(Optional) End-of-month rule flag is specified as a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

IssueDate — Bond issue date
datetime array | string array | date character vector

(Optional) Bond issue date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optbndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

(Optional) Irregular first coupon date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optbndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

(Optional) Irregular last coupon date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optbndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
datetime array | string array | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optbndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as anNINST-by-1 vector.

Data Types: double

`Options` — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of bond option at time `0`
matrix

Expected price of the bond option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and accrued interest for each node
structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExBush` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-6.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `optbndbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

“Supported Interest-Rate Instrument Functions” on page 2-3

optbndbyhw

Price bond option from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = optbndbyhw(HWTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,CouponRate,Settle,Maturity)
[Price,PriceTree] = optbndbyhw( ___ ,Period,Basis,EndMonthRule,IssueDate,
FirstCouponDate,LastCouponDate,StartDate,Face,Options)
```

Description

`[Price,PriceTree] = optbndbyhw(HWTree,OptSpec,Strike,ExerciseDates, AmericanOpt,CouponRate,Settle,Maturity)` calculates the price for a bond option from a Hull-White interest-rate tree.

Note Alternatively, you can use the `FixedBondOption` object to price fixed-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optbndbyhw( ___ ,Period,Basis,EndMonthRule,IssueDate, FirstCouponDate,LastCouponDate,StartDate,Face,Options)` adds optional arguments.

Examples

Price a European Call and Put Option on a Bond

Using the HW interest rate tree in the `deriv.mat` file, price a European call option on a 4% bond with a strike of 96. The exercise date for the option is Jan. 01, 2006. The settle date for the bond is Jan. 01, 2005, and the maturity date is Jan. 01, 2009.

Load the file `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and forward-rate information needed to price the bond.

```
load deriv.mat;
```

Use `optbndbyhw` to compute the price of the `'Call'` option.

```
[Price,PriceTree] = optbndbyhw(HWTree,'Call',96,datetime(2006,1,1),...
0,0.04,datetime(2005,1,1),datetime(2009,1,1))
```

```
Warning: OptBonds are valued at Tree ValuationDate rather than Settle.
> In optbndbytrintree (line 40)
  In optbndbyhw (line 92)
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbytrintree (line 151)
  In optbndbyhw (line 92)
```

```
Price =

    1.1556

PriceTree =

  struct with fields:

     FinObj: 'HWPriceTree'
      PTree: {[1.1556]  [0.0150 0.8509 3.7085]  [0 0 0.0722 4.9980 3.8429]  [0 0 0 0 0]  [0 0 0 0
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3×1 double]  [3×3 double]  [3×5 double]}
     ExTree: {[0]  [0 0 0]  [0 0 1 1 1]  [0 0 0 0 0]  [0 0 0 0 0]}
```

Now use `optbndbyhw` to compute the price of a `'Put'` option on the same bond.

```
[Price,PriceTree] = optbndbyhw(HWTree,'Put',96,datetime(2006,1,1),...
0,0.04,datetime(2005,1,1),datetime(2009,1,1))
```

```
Warning: OptBonds are valued at Tree ValuationDate rather than Settle.
> In optbndbytrintree (line 40)
  In optbndbyhw (line 92)
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In optbndbytrintree (line 151)
  In optbndbyhw (line 92)

Price =

    1.0150

PriceTree =

  struct with fields:

     FinObj: 'HWPriceTree'
      PTree: {[1.0150]  [3.2945 0.7413 0]  [3.5551 4.6060 0 0 0]  [0 0 0 0 0]  [0 0 0 0 0]}
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3×1 double]  [3×3 double]  [3×5 double]}
     ExTree: {[0]  [0 0 0]  [1 1 0 0 0]  [0 0 0 0 0]  [0 0 0 0 0]}
```

The `PriceTree.ExTree` output for the `'Call'` and `'Put'` option contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`, `NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a `NINST`-by-`1` vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European/Bermuda (default) | integer with values `0` or `1`

Option type, specified as `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`CouponRate` — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates

and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the HW tree. The bond argument `Settle` is ignored.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Period` — Coupons per year
2 per year (default) | vector

(Optional) Coupons per year, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

(Optional) End-of-month rule flag is specified as a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

(Optional) Bond issue date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

(Optional) Irregular first coupon date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

(Optional) Irregular last coupon date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`,

regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

(Optional) Forward starting date of payments (the date from which a bond cash flow is considered), specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optbndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

(Optional) Face or par value, specified as an`NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of bond option at time `0`
matrix

Expected price of the bond option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and accrued interest for each node
structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

More About

Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

For more information, see “Bond Options” on page 2-6.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optbndbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByBatesFD

Option price by Bates model using finite differences

Syntax

```
[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD(Rate,AssetPrice,
Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,
JumpVol,JumpFreq)
[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD(Rate,AssetPrice, Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ, JumpVol,JumpFreq)` computes a vanilla European or American option price by the Bates model, using the alternating direction implicit (ADI) method.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceGrid,AssetPrices,Variances,Times] = optByBatesFD( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Price an American Option Using the Bates Model

Define the option variables and Bates model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.03;
Settle = datetime(2018,1,10);
ExerciseDates = datetime(2018,7,2);

V0 = 0.04;
ThetaV = 0.04;
Kappa = 2;
SigmaV = 0.25;
RhoSV = -0.5;
JumpVol = 0.4;
MeanJ = exp(-0.5+JumpVol.^2/2)-1;
JumpFreq = 0.2;
```

Compute the American put option price using the finite differences method.

```
OptSpec = 'Put';
Price = optByBatesFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike, ...
V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'AmericanOpt', 1)
```

```
Price = 11.4925
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: `double`

`AssetPrice` — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Option settlement date

datetime scalar | string scalar | date character vector

Option settlement date, specified as a scalar datetime, string, or data character vector.

To support existing code, `optByBatesFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a scalar datetime, string, or data character vector. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of dates to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

To support existing code, `optByBatesFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with value of `'call'` or `'put'` | string with value of `"call"` or `"put"`

Definition of the option, specified as a scalar using a character vector or string with a value of `'call'` or `'put'`.

Data Types: `cell` | `string`

`Strike` — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`V0` — Initial variance of underlying asset
scalar numeric

Initial variance of the underling asset, specified as a scalar numeric.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
scalar numeric

Long-term variance of the underling asset, specified as a scalar numeric.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
scalar numeric

Mean revision speed for the underlying asset, specified as a scalar numeric.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
scalar numeric

Volatility of the variance of the underling asset, specified as a scalar numeric.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: `double`

`MeanJ` — Mean of random percentage jump size
scalar decimal

Mean of the random percentage jump size (J), specified as a scalar decimal where `log`(1+J) is normally distributed with the mean (`log`(1+`MeanJ`)-0.5*`JumpVol^`2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+J)
scalar decimal

Standard deviation of `log`(1+J) where `J` is the random percentage jump size, specified as a scalar decimal.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
scalar numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceGrid] = optByBatesFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument

`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield

`0` (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates` = `[ ]` or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield` = `0`.

Data Types: double

DividendAmounts — Cash dividend amounts
[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and an NDIV-by-1 vector.

Note Each dividend amount must have a corresponding ex-dividend date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

Data Types: double

ExDividendDates — Ex-dividend dates
[ ] (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optByBatesFD also accepts serial date numbers as inputs, but they are not recommended.

AssetPriceMax — Maximum price for price grid boundary
if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar numeric.

Data Types: double

VarianceMax — Maximum variance for variance grid boundary
1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Data Types: double

AssetGridSize — Size of asset grid for finite difference grid
400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar numeric.

Data Types: double

VarianceGridSize — Number of nodes of variance grid for finite difference grid
200 (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

Data Types: double

`TimeGridSize` — Number of nodes of time grid for finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with value of `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of these values:

- `0` — European
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Option price
scalar numeric

Option price, returned as a scalar numeric.

`PriceGrid` — Grid containing prices calculated by the finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `AssetGridSize` × `TimeGridSize`. The number of columns is not necessarily equal to the `TimeGridSize` because exercise the function adds exercise and ex-dividend dates to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of the asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Variances` — Variances
vector

Variances corresponding to the second dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to the third dimension of `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Bates Stochastic Volatility Jump Diffusion Model

The Bates model [1] extends the Heston model by including stochastic volatility and (similar to Merton) jump diffusion parameters in the modeling of sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J)S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$
$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$
$$\mathrm{E}\left[dW_t dW_t^v\right] = pdt$$
$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

where:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

where:

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByBatesFD` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByBatesFD

Option price and sensitivities by Bates model using finite differences

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optSensByBatesFD(Rate,
AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,
MeanJ,JumpVol,JumpFreq)
[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optSensByBatesFD( ___ ,
Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optSensByBatesFD(Rate, AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV, MeanJ,JumpVol,JumpFreq)` computes a vanilla European or American option price and sensitivities by the Bates model, using the alternating direction implicit (ADI) method.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optSensByBatesFD( ___ , Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Price and Sensitivities for an American Option Using the Bates Model

Define the option variables and Bates model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.03;
Settle = datetime(2018,1,1);
ExerciseDates = datetime(2018,6,2);

V0 = 0.04;
ThetaV = 0.04;
Kappa = 2;
SigmaV = 0.25;
RhoSV = -0.5;
JumpVol = 0.4;
MeanJ = exp(-0.5+JumpVol.^2/2)-1;
JumpFreq = 0.2;
```

Compute the American put option price and sensitivities using the finite differences method.

```
OptSpec = 'Put';
[Price, Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByBatesFD(Rate, AssetPrice, Settle, Exe
OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'AmericanOpt', 1,..
'OutSpec', ["Price" "Delta" "Gamma" "Rho" "Theta" "Vega" "VegaLT"])

Price = 11.2164

Delta = -0.6988

Gamma = 0.0391

Rho = -17.1376

Theta = -4.7656

Vega = 13.3283

VegaLT = 6.1456
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: `double`

`AssetPrice` — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Option settlement date

datetime scalar | string scalar | date character vector

Option settlement date, specified as a scalar datetime, string, or data character vector.

To support existing code, `optSensByBatesFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a scalar date. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of dates to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

To support existing code, `optSensByBatesFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value of `'call'` or `'put'` | string with value of `"call"` or `"put"`

Definition of the option, specified as a scalar using a character vector or string with a value of `'call'` or `'put'`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`V0` — Initial variance of underlying asset
scalar numeric

Initial variance of the underling asset, specified as a scalar numeric.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
scalar numeric

Long-term variance of the underling asset, specified as a scalar numeric.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
scalar numeric

Mean revision speed for the underlying asset, specified as a scalar numeric.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
scalar numeric

Volatility of the variance of the underling asset, specified as a scalar numeric.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: `double`

`MeanJ` — Mean of random percentage jump size
scalar decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal where `log`(1+*J*) is normally distributed with the mean (`log`(1+`MeanJ`)-0.5*`JumpVol^`2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+J)`
scalar decimal

Standard deviation of `log(1+J)` where `J` is the random percentage jump size, specified as a scalar decimal.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
scalar numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens,PriceGrid] = optSensByBatesFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7,'OutSpec','delta')`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

DividendYield — Continuously compounded underlying asset yield
0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

Note If you enter a value for DividendYield, then set DividendAmounts and ExDividendDates = [ ] or do not enter them. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

Data Types: double

DividendAmounts — Cash dividend amounts
[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and an NDIV-by-1 vector.

Note Each dividend amount must have a corresponding ex-dividend date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

Data Types: double

ExDividendDates — Ex-dividend dates
[ ] (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of 'ExDividendDates' and an NDIV-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optSensByBatesFD also accepts serial date numbers as inputs, but they are not recommended.

AssetPriceMax — Maximum price for price grid boundary
if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar numeric.

Data Types: double

VarianceMax — Maximum variance for variance grid boundary
1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

Data Types: double

AssetGridSize — Size of asset grid for finite difference grid
400 (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a scalar numeric.

Data Types: `double`

`VarianceGridSize` — Number of nodes of variance grid for finite difference grid
`200` (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of `'VarianceGridSize'` and a scalar numeric.

Data Types: `double`

`TimeGridSize` — Number of nodes of time grid for finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with value of `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of these values:

- `0` — European
- `1` — American

Data Types: `double`

`OutSpec` — Define outputs
`['price']` (default) | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'rho'`, `'theta'`, and `'vegalt'` | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, `"theta"`, and `"vegalt"`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` string array or cell array of character vectors with supported values.

Note `'vega'` is the sensitivity with respect to the initial volatility sqrt(`V0`). In contrast, `'vegalt'` is the sensitivity with respect to the long-term volatility sqrt(`ThetaV`).

Example: `OutSpec = ['price','delta','gamma','vega','rho','theta','vegalt']`

Data Types: `string` | `cell`

Output Arguments

`PriceSens` — Option price or sensitivities
numeric

Option price or sensitivities, returned as a numeric. The name-value pair argument `OutSpec` determines the types and order of the outputs.

`PriceGrid` — Grid containing prices calculated by the finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `AssetGridSize` × `TimeGridSize`. The number of columns is not necessarily equal to the `TimeGridSize` because the function adds exercise and ex-dividend dates to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of the asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Variances` — Variances
vector

Variances corresponding to the second dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to the third dimension of `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Bates Stochastic Volatility Jump Diffusion Model

The Bates model [1] extends the Heston model by including stochastic volatility and (similar to Merton) jump diffusion parameters in the modeling of sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + J S_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

where:

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where `ln`(1+J) is normally distributed with mean $\ln(1+\mu_J)-\frac{\delta^2}{2}$ and the standard deviation δ, and (1+J) has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J)-\left(\ln(1+\mu_J)-\frac{\delta^2}{2}\right]\right]^2}{2\delta^2}\right\}$$

where:

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of `ln`(1+J) for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

optByBatesFFT

Option price by Bates model using FFT and FRFT

Syntax

```
[Price,StrikeOut] = optByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,
Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
[Price,StrikeOut] = optByBatesFFT( ___ ,Name,Value)
```

Description

`[Price,StrikeOut] = optByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec, Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price by Bates model, using Carr-Madan FFT and Chourdakis FRFT methods.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,StrikeOut] = optByBatesFFT( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Price Surface Using the Bates Model

Use `optByBatesFFT` to calibrate the FFT strike grid, compute option prices, and plot an option price surface.

Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying `Strike`

Compute option prices and also output the corresponding strikes. If the `Strike` input is empty (`[]`), option prices will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid

is determined as `exp(log-strike grid)`, where each column of the log-strike grid has `NumFFT` points with `LogStrikeStep` spacing that are roughly centered around each element of `log(AssetPrice)`. The default value for `NumFFT` is `2^12`. In addition to the prices in the first output, the optional last output contains the corresponding strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option prices for the entire FFT strike grid
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield);

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option prices
Range = (2046:2052);
[Kout(Range) Call(Range)]

ans = 7×2

   50.4929   29.4990
   58.8640   21.4545
   68.6231   12.8544
   80.0000    5.3484
   93.2631    1.2404
  108.7251    0.1648
  126.7505    0.0152
```

Change the Number of FFT (or FRFT) Points and Compare with optByBatesNI

Try a different number of FFT (or FRFT) points, and compare the results with direct numerical integration. Unlike `optByBatesFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optByBatesNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optByBatesNI` can serve as a benchmark for adjusting the settings for `optByBatesFFT`.

```
% Try a smaller number of FFT (or FRFT) points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
```

```
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7×4 table
    Strike     CallFFT       CallNI         Error
    ______    _________    ___________    _________

```

Make Further Adjustments to FFT (or FRFT)

If the values in the output `CallFFT` are significantly different from those in `CallNI`, try making adjustments to `optByBatesFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` * `CharacteristicFcnStep`) is 2*pi / `NumFFT`, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001);

% Compare with numerical integration method
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7×4 table
    Strike    CallFFT    CallNI      Error
    ______    _______    ______    __________

    79.76     5.4682     5.4682    1.5355e-08
    79.84     5.4281     5.4281    1.4833e-08

    80.24       5.23       5.23    1.1272e-08
```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of |Strike| inputs for
% which the FFT (or FRFT) operation is valid.
```

```
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

Compute the Option Price for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes (rather than providing an empty array). If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)
```

```
Call = 5.3484
```

Compute the Option Prices for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)
```

```
Call = 5×1

    7.5765
    6.4020
    5.3484
    4.4173
    3.6073
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes
```

```
Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001) % Five values in vector output
```

```
Call = 5×1

    9.7516
   10.3931
   10.8865
   11.2990
   11.6491
```

Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes`-by-`NMaturities` matrices. In this case, they are square matrices.

```
[Call, Kout] = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 5) matrix output
```

```
Call = 5×5

    9.7516   11.4387   12.8395   14.0588   15.1361
    8.6554   10.3931   11.8344   13.0890   14.1980
    7.6432    9.4149   10.8865   12.1693   13.3046
    6.7153    8.5035    9.9952   11.2990   12.4553
    5.8705    7.6581    9.1594   10.4771   11.6491

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84
```

Compute Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular).

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 6) matrix output
```

```
Call = 5×6

    7.5765    9.7516   11.4387   12.8395   14.0588   15.1361
```

```
    6.4020    8.6554   10.3931   11.8344   13.0890   14.1980
    5.3484    7.6432    9.4149   10.8865   12.1693   13.3046
    4.4173    6.7153    8.5035    9.9952   11.2990   12.4553
    3.6073    5.8705    7.6581    9.1594   10.4771   11.6491
```

Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByBatesFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 4) matrix output
```

```
Call = 5×4

    4.2033    6.6918    9.7516   13.2808
    3.5558    5.8112    8.6554   11.9993
    2.9906    5.0181    7.6432   10.7934
    2.5018    4.3096    6.7153    9.6652
    2.0825    3.6818    5.8705    8.6158
```

Plot an Option Price Surface

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to `"true"` to output the surface as a `NStrikes`-by-`NMaturities` matrix.

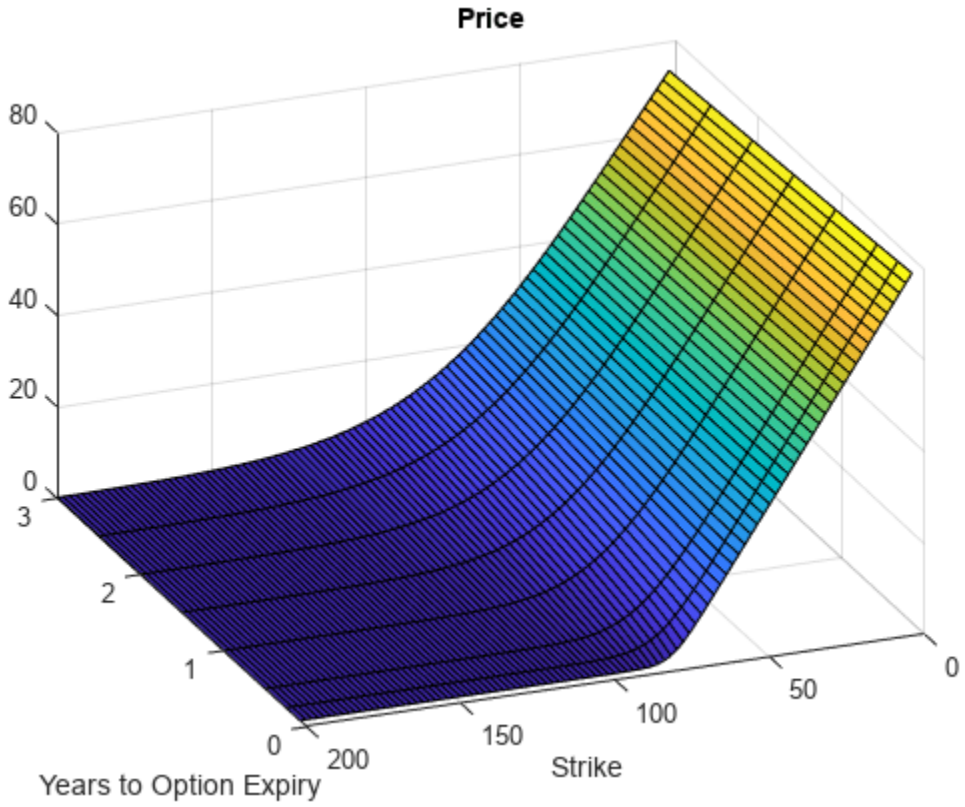
```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase |NumFFT| to support a wider range of strikes
NumFFT = 2^13;

Call = optByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV,  MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);
```



Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optByBatesFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByBatesFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has `'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

Kappa — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol^`2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+*J*)
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price, StrikeOut] = optByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa, SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of `'DampingFactor'` and a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`"simpson"` (default) | character vector with values: `'simpson'` or `'trapezoidal'` | string array with values: `"simpson"` or `"trapezoidal"`

Type of quadrature, specified as the comma-separated pair consisting of `'Quadrature'` and a single character vector or string array with a value of `'simpson'` or `'trapezoidal'`.

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-`1` vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-`1` vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-`1` vectors.

- `false` — If `false`, the outputs are `NINST`-by-`1` vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-`1` vectors.

Data Types: `logical`

Output Arguments

`Price` — Option prices

numeric

Option prices, returned as a `NINST`-by-`1`, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

`StrikeOut` — Strikes corresponding to `Price`

numeric

Strikes corresponding to `Price`, returned as a `NINST`-by-`1`, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + J S_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where `ln`(1+J) is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and (1+J) has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2}\right\}$$

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of `ln`(1+J) for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

The characteristic function $f_{Bates_j(\phi)}$ for $j = 1$ (asset price mean measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t)\exp\left(\lambda_p \tau(1+\mu_J)^{m_j + \frac{1}{2}}\left[(1+\mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1\right] - \lambda_p \tau \mu_j i\phi\right)$$

$$m_j = \begin{Bmatrix} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{Bmatrix}$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity for ($\tau = T - t$).

i is the unit imaginary number for ($i^2 = -1$).

The definitions for C_j and D_j under "The Little Heston Trap" by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^{\infty} \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u-(\alpha+1)i))}{\alpha^2+\alpha-u^2+iu(2\alpha+1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number (i^2= -1)

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where ϕ = (u - (α+1)i).

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration, u, is discretized into `NumFFT`(N) points with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration, u_j(for j = 1,2,3,...,N), has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid, k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iuj\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

Δu is the step size of discretized characteristic function variable for integration.

Δk is the step size of discretized log-strike.

N is the number of FFT/FRFT points

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByBatesFFT` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByBatesFFT

Option price and sensitivities by Bates model using FFT and FRFT

Syntax

```
[PriceSens,StrikeOut] = optSensByBatesFFT(Rate,AssetPrice,Settle,Maturity,
OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
[PriceSens,StrikeOut] = optSensByBatesFFT( ___ ,Name,Value)
```

Description

`[PriceSens,StrikeOut] = optSensByBatesFFT(Rate,AssetPrice,Settle,Maturity, OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price and sensitivities by Bates model, using Carr-Madan FFT and Chourdakis FRFT methods.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,StrikeOut] = optSensByBatesFFT( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Sensitivity Surface Using the Bates Model

Use `optSensByBatesFFT` to calibrate the FFT strike grid for sensitivities, compute option sensitivities, and plot option sensitivity surfaces.

Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Sensitivities for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option sensitivities and also output the corresponding strikes. If the `Strike` input is empty (`[]`), option sensitivities will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as `exp(log-strike grid)`, where each column of the log-strike grid has `NumFFT` points with `LogStrikeStep` spacing that are roughly centered around each element of `log(AssetPrice)`. The default value for `NumFFT` is `2^12`. In addition to the sensitivities in the first output, the optional last output contains the corresponding strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option sensitivities for the entire FFT strike grid
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta");

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option sensitivities
Range = (2046:2052);
[Kout(Range) Delta(Range)]

ans = 7×2

   50.4929    0.9846
   58.8640    0.9585
   68.6231    0.8498
   80.0000    0.5630
   93.2631    0.1955
  108.7251    0.0319
  126.7505    0.0033
```

Change the Number of FFT (or FRFT) Points and Compare with optSensByBatesNI

Try a different number of FFT (or FRFT) points, and compare the results with numerical integration. Unlike `optSensByBatesFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optSensByBatesNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optSensByBatesNI` can serve as a benchmark for adjusting the settings for `optSensByBatesFFT`.

```
% Try a smaller number of FFT points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
```

```
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)

ans=7×4 table
    Strike     DeltaFFT      DeltaNI        Error
    ______    __________    __________    __________

    12.696       0.9265       0.99002      0.063524
    23.449      0.95153       0.99002      0.038497
    43.312      0.95928       0.98928      0.029994
        80       0.5355       0.56303      0.027531
    147.76    0.0016267    0.00025691     0.0013698
    272.93    0.00058267    1.8942e-09    0.00058267
    504.11    0.00017752    8.7099e-10    0.00017752
```

Make Further Adjustments to FFT (or FRFT)

If the values in the output `DeltaFFT` are significantly different from those in `DeltaNI`, try making adjustments to `optSensByBatesFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` * `CharacteristicFcnStep`) is 2*pi/ `NumFFT`, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);

% Compare with numerical integration method
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)

ans=7×4 table
    Strike    DeltaFFT    DeltaNI      Error
    ______    ________    _______    __________

```

```
    80.24     0.55564     0.55564    1.0847e-08
```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

Compute the Option Sensitivity for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Delta = 0.5630
```

Compute the Option Sensitivities for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Delta = 5×1

    0.6807
    0.6234
    0.5630
    0.5011
    0.4392
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001) % Five values in vector output
```

```
Delta = 5×1

    0.6625
    0.6232
    0.5958
    0.5748
    0.5577
```

Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes`-by-`NMaturities` matrices. In this case, they are square matrices.

```
[Delta, Kout] = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5

    0.6625    0.6556    0.6515    0.6483    0.6455
    0.6222    0.6232    0.6239    0.6241    0.6238
    0.5805    0.5900    0.5958    0.5996    0.6019
    0.5381    0.5564    0.5674    0.5748    0.5798
    0.4954    0.5225    0.5389    0.5499    0.5577

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByBatesFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

```
Delta = 5×6

    0.6807    0.6625    0.6556    0.6515    0.6483    0.6455
    0.6234    0.6222    0.6232    0.6239    0.6241    0.6238
    0.5630    0.5805    0.5900    0.5958    0.5996    0.6019
    0.5011    0.5381    0.5564    0.5674    0.5748    0.5798
    0.4392    0.4954    0.5225    0.5389    0.5499    0.5577
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByBatesFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, ...
    Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 4) matrix output
```

```
Delta = 5×4

    0.4350    0.5579    0.6625    0.7457
    0.3881    0.5124    0.6222    0.7120
    0.3432    0.4670    0.5805    0.6763
    0.3010    0.4223    0.5381    0.6390
    0.2619    0.3789    0.4954    0.6002
```

Plot Option Sensitivity Surfaces

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to `"true"` to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

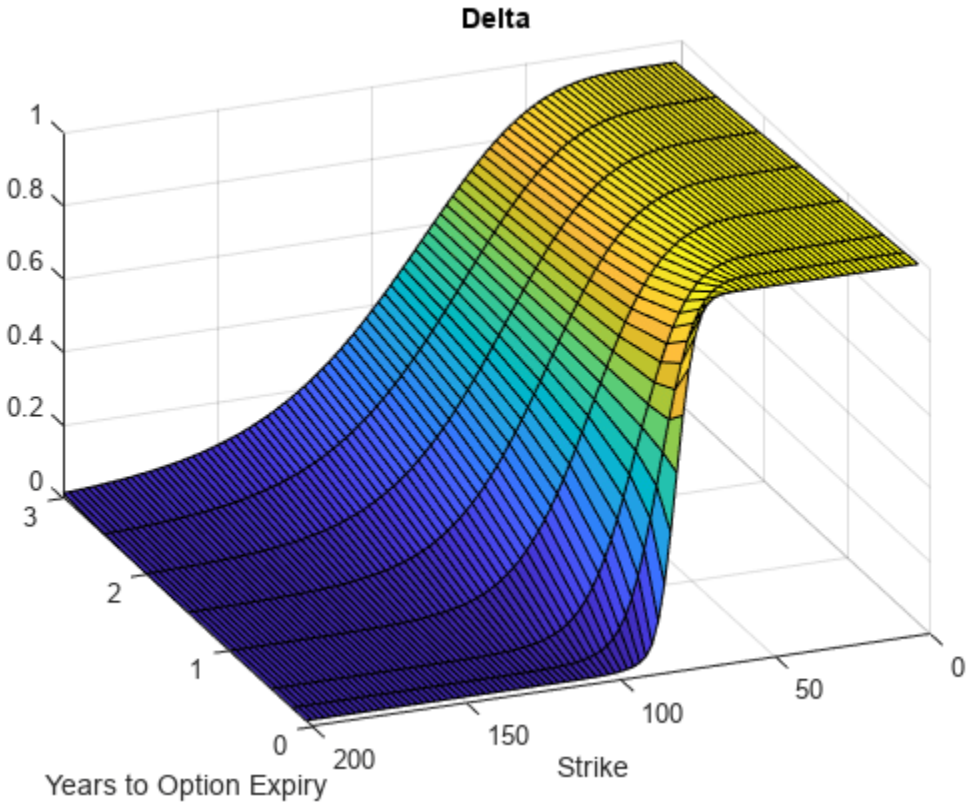
```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;
```

```
[Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByBatesFFT(...
    Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega", "vegalt"], ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
```



```

```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optSensByBatesFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByBatesFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has `'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

Kappa — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol^`2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+*J*)
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens,StrikeOut] = optSensByBatesFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`OutSpec` — Define outputs
`["price"]` (default) | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, `"theta"`, and `"vegalt"` | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'rho'`, `'theta'`, and `'vegalt'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` string array or cell array of character vectors with supported values.

Note `"vega"` is the sensitivity with respect the initial volatility sqrt(`V0`). In contrast, `"vegalt"` is the sensitivity with respect to the long-term volatility sqrt(`ThetaV`).

Example: `OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]`

Data Types: `string` | `cell`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of `'DampingFactor'` and a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`"simpson"` (default) | character vector with values:`'simpson'` or `'trapezoidal'` | string array with values: `"simpson"` or `"trapezoidal"`

Type of quadrature, specified as the comma-separated pair consisting of `'Quadrature'` and a single character vector or string array with a value of `'simpson'` or `'trapezoidal'`.

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`PriceSens` — Option prices or sensitivities
numeric

Option prices or sensitivities, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`. The name-value pair argument `OutSpec` determines the types and order of the outputs.

`StrikeOut` — Strikes corresponding to `Price`
numeric

Strikes corresponding to `Price`, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J)S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$
$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$
$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$
$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where `ln`$(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of `ln`$(1+J)$ for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

The characteristic function $f_{Bates_j(\phi)}$ for $j = 1$ (asset price mean measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t)\exp\left(\lambda_p \tau(1+\mu_J)^{m_j} + \frac{1}{2}\left[(1+\mu_j)^{i\phi} e^{\delta^2\left(m_j i\phi + \frac{(i\phi)^2}{2}\right)} - 1\right] - \lambda_p \tau \mu_J i\phi\right)$$

$$m_j = \begin{Bmatrix} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{Bmatrix}$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity for ($\tau = T - t$).

i is the unit imaginary number for ($i^2 = -1$).

The definitions for C_j and D_j under "The Little Heston Trap" by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^\infty \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u-(\alpha+1)i))}{\alpha^2+\alpha-u^2+iu(2\alpha+1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where ϕ = (u - (α+1)i).

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration, u, is discretized into `NumFFT`(N) points with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration, u_j(for j = 1,2,3,...,N), has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid, k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2}-1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iuj\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

Δu is the step size of discretized characteristic function variable for integration.

Δk is the step size of discretized log-strike.

N is the number of FFT/FRFT points

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByBatesFFT` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByBatesNI

Option price by Bates model using numerical integration

Syntax

```
Price = optByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,
ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
Price = optByBatesNI( ___ ,Name,Value)
```

Description

`Price = optByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0, ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price by Bates model, using numerical integration methods.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = optByBatesNI( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Price Surface Using the Bates Model

`optByBatesNI` uses numerical integration to compute option prices and then plot an option price surface.

Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Price for a Single Strike

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield)

Call = 5.3484
```

Compute the Option Prices for a Vector of Strikes

The `Strike` input can be a vector.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield)

Call = 5×1

    7.5765
    6.4020
    5.3484
    4.4173
    3.6073
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield) % Five values in vector output

Call = 5×1

    9.7516
   10.3931
   10.8865
   11.2990
   11.6491
```

Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes`-by-`NMaturities` matrix. In this case, it is a square matrix.

```
Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true) % (5 x 5) matrix output

Call = 5×5

    9.7516   11.4387   12.8395   14.0588   15.1361
    8.6554   10.3931   11.8344   13.0890   14.1980
    7.6432    9.4149   10.8865   12.1693   13.3046
    6.7153    8.5035    9.9951   11.2990   12.4553
    5.8705    7.6581    9.1594   10.4771   11.6491
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular).

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true) % (5 x 6) matrix output

Call = 5×6

    7.5765    9.7516   11.4387   12.8395   14.0588   15.1361
    6.4020    8.6554   10.3931   11.8344   13.0890   14.1980
    5.3484    7.6432    9.4149   10.8865   12.1693   13.3046
    4.4173    6.7153    8.5035    9.9951   11.2990   12.4553
    3.6073    5.8705    7.6581    9.1594   10.4771   11.6491
```

Compute Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByBatesNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true) % (5 x 4) matrix output

Call = 5×4

    4.2033    6.6918    9.7516   13.2808
    3.5558    5.8111    8.6554   11.9993
    2.9906    5.0181    7.6432   10.7934
    2.5018    4.3096    6.7153    9.6651
    2.0825    3.6818    5.8705    8.6158
```

Plot an Option Price Surface

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to `"true"` to output the surface as a `NStrikes`-by-`NMaturities` matrix.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

Call = optByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

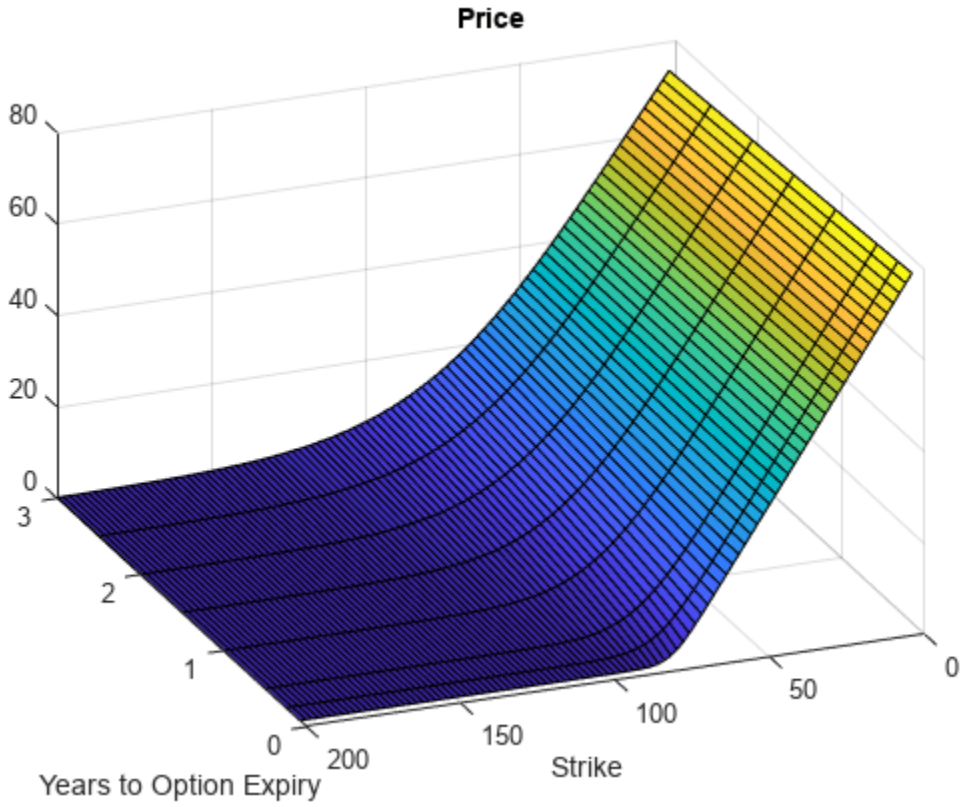
zlim([0 80]);
```



Input Arguments

Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

AssetPrice — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

Settle — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optByBatesNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByBatesNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol^2`) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+`*`J`*`)`
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating "Little Heston Trap" formulation
`true` (default) | logical with values `true` or `false`

Flag indicating "Little Heston Trap" formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`AbsTol` — Absolute error tolerance for numerical integration
`1e-10` (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of `'AbsTol'` and a scalar numeric value.

Data Types: `double`

`RelTol` — Relative error tolerance for numerical integration
`1e-6` (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of `'RelTol'` and a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, specified as the comma-separated pair consisting of `'IntegrationRange'` and a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with values `"heston1993"` or `"lewis2001"` | character vector with values `'heston1993'` or `'lewis2001'`

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of `'Framework'` and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`Price` — Option prices

numeric

Option prices, returned as a `NINST`-by-`1`, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + J S_t dP_t$$
$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$
$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$
$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where `ln`$(1+J)$ is normally distributed with mean $\ln(1+\mu_J)-\frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J)-\left(\ln(1+\mu_J)-\frac{\delta^2}{2}\right]\right]^2}{2\delta^2}\right\}$$

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of `ln`$(1+J)$ for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

The characteristic function $f_{Bates_j(\phi)}$ for $j = 1$ (asset price mean measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t)\exp\left(\lambda_p \tau(1+\mu_J)^{m_j+\frac{1}{2}}\left[(1+\mu_j)^{i\phi}e^{\delta^2(m_j i\phi+\frac{(i\phi)^2}{2})}-1\right]-\lambda_p\tau\mu_J i\phi\right)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1-g_j e^{d_j\tau}}{1-g_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1-e^{d_j\tau}}{1-g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity for ($\tau = T - t$).

i is the unit imaginary number for ($i^2 = -1$).

The definitions for C_j and D_j under "The Little Heston Trap" by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau}P_1 - Ke^{-r\tau}P_2$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \mathrm{Re}\left[\frac{e^{-i\phi\ln(K)}f_j(\phi)}{i\phi}\right]d\phi$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity ($\tau = T$-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number ($i^2 = -1$)

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j (j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

This framework is chosen with the default value "`Heston1993`" for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K}e^{-\tau t}}{\pi}\int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right)\frac{1}{u^2 + \frac{1}{4}}\right]du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity ($\tau = T\text{-}t$).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number ($i^2 = -1$)

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

This framework is chosen with the value "`Lewis2001`" for the `Framework` name-value pair argument.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByBatesNI` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByBatesNI

Option price or sensitivities by Bates model using numerical integration

Syntax

```
PriceSens = optSensByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,
V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)
PriceSens = optSensByBatesNI( ___ ,Name,Value)
```

Description

`PriceSens = optSensByBatesNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike, V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price and sensitivities by Bates model, using numerical integration methods.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`PriceSens = optSensByBatesNI( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Sensitivity Surface Using the Bates Model

`optSensByBatesNI` uses numerical integration to compute option sensitivities and then to plot option sensitivity surfaces.

Define Option Variables and Bates Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Sensitivity for a Single Strike

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 0.5630
```

Compute the Option Sensitivities for a Vector of Strikes

The `Strike` input can be a vector.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 5×1

    0.6807
    0.6234
    0.5630
    0.5011
    0.4392
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta  = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta") % Five values in vector output
```

```
Delta = 5×1

    0.6625
    0.6232
    0.5958
    0.5748
    0.5577
```

Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes`-by-`NMaturities` matrix. In this case, it is a square matrix.

```
Delta  = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
```

```
    'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5

    0.6625    0.6556    0.6515    0.6483    0.6455
    0.6222    0.6232    0.6239    0.6241    0.6238
    0.5805    0.5900    0.5958    0.5996    0.6019
    0.5381    0.5564    0.5674    0.5748    0.5798
    0.4954    0.5225    0.5389    0.5499    0.5577
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes` -by- `NMaturities` matrix can be rectangular.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta  = optSensByBatesNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'ExpandOutput', true)  % (5 x 6) matrix output
```

```
Delta = 5×6

    0.6807    0.6625    0.6556    0.6515    0.6483    0.6455
    0.6234    0.6222    0.6232    0.6239    0.6241    0.6238
    0.5630    0.5805    0.5900    0.5958    0.5996    0.6019
    0.5011    0.5381    0.5564    0.5674    0.5748    0.5798
    0.4392    0.4954    0.5225    0.5389    0.5499    0.5577
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta  = optSensByBatesNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, MeanJ, JumpVol, JumpFreq, ...
    'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'ExpandOutput', true) % (5 x 4) matrix output
```

```
Delta = 5×4

    0.4350    0.5579    0.6625    0.7457
    0.3881    0.5124    0.6222    0.7120
    0.3432    0.4670    0.5805    0.6763
    0.3010    0.4223    0.5381    0.6390
    0.2619    0.3789    0.4954    0.6002
```

Plot Option Sensitivity Surfaces

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to `"true"` to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = optSensByBatesNI(...
    Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ThetaV, Kappa, ...

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optSensByBatesNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByBatesNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol^2`) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+`*`J`*`)`
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = optSensByBatesNI(Rate,AssetPrice,Settle,Maturity, OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`OutSpec` — Define outputs
`["price"]` (default) | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, `"theta"`, and `"vegalt"` | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'rho'`, `'theta'`, and `'vegalt'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` string array or cell array of character vectors with supported values.

Note `"vega"` is the sensitivity with respect the initial volatility sqrt(`V0`). In contrast, `"vegalt"` is the sensitivity with respect to the long-term volatility sqrt(`ThetaV`).

Example: `OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]`

Data Types: `string` | `cell`

`AbsTol` — Absolute error tolerance for numerical integration
`1e-10` (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of `'AbsTol'` and a scalar numeric value.

Data Types: `double`

`RelTol` — Relative error tolerance for numerical integration
`1e-6` (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of `'RelTol'` and a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, specified as the comma-separated pair consisting of `'IntegrationRange'` and a `1`-by-`2` vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with values `"heston1993"` or `"lewis2001"` | character vector with values `'heston1993'` or `'lewis2001'`

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of `'Framework'` and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-`1` vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-`1` vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-`1` vectors.
- `false` — If `false`, the outputs are `NINST`-by-`1` vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-`1` vectors.

Data Types: `logical`

Output Arguments

`PriceSens` — Option prices

numeric

Option prices or sensitivities, returned as a `NINST`-by-`1`, or `NRows`-by-`NColumns`, depending on `ExpandOutput`. The name-value pair argument `OutSpec` determines the types and order of the outputs.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates (1996)) is an extension of the Heston model, where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) were also added to model sudden asset price movements.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + J S_t dP_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

$$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

J is the random percentage jump size conditional on the jump occurring, where `ln`$(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2}\right\}$$

v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for ($\kappa > 0$).

σ_v is the volatility of variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of `ln`$(1+J)$ for ($\delta \ge 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).

The characteristic function $f_{Bates_j(\phi)}$ for $j = 1$ (asset price mean measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t)\exp\left(\lambda_p \tau (1+\mu_J)^{m_j + \frac{1}{2}}\left[(1+\mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1\right] - \lambda_p \tau \mu_J i\phi\right)$$

$$m_j = \begin{Bmatrix} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{Bmatrix}$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1-g_j e^{d_j\tau}}{1-g_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1-e^{d_j\tau}}{1-g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity for ($\tau = T - t$).

i is the unit imaginary number for ($i^2 = -1$).

The definitions for C_j and D_j under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Numerical Integration method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \mathrm{Re}\left[\frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j (j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

This framework is chosen with the default value `"Heston1993"` for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-\tau t}}{\pi} \int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right) \frac{1}{u^2 + \frac{1}{4}} \right] du$$

$$Put(K) = Call(K) = K e^{-\tau t} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

This framework is chosen with the value "`Lewis2001`" for the `Framework` name-value pair argument.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByBatesNI` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByHestonFD

Option price by Heston model using finite differences

Syntax

```
[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD(Rate,
AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD(Rate, AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)` computes a vanilla European or American option price by the Heston model, using the alternating direction implicit (ADI) method.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Price an American Option Using the Heston Model

Define the option variables and Heston model parameters.

```
AssetPrice = 10;
Strike = 10;
Rate = 0.1;
Settle = datetime(2017,1,1);
ExerciseDates = datetime(2017,4,2);

V0 = 0.0625;
ThetaV = 0.16;
Kappa = 5.0;
SigmaV = 0.9;
RhoSV = 0.1;
```

Compute the American put option price.

```
OptSpec = 'Put';
Price = optByHestonFD(Rate, AssetPrice, Settle, ...
ExerciseDates, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'AmericanOpt', 1)
```

```
Price = 0.5188
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate
scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: `double`

`AssetPrice` — Current underlying asset price
scalar numeric

Current underlying asset price, specified as numeric value using a scalar numeric.

Data Types: `double`

`Settle` — Option settlement date
datetime scalar | string scalar | date character vector

Option settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optByHestonFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, the option can be exercised between the `Settle` date and the single listed `ExerciseDate`.

To support existing code, `optByHestonFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
cell array of character vectors with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a scalar using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`V0` — Initial variance of underlying asset
scalar numeric

Initial variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
scalar numeric

Long-term variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`Kappa` — Mean revision speed for variance of underlying asset
scalar numeric

Mean revision speed for the variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`SigmaV` — Volatility of variance of underlying asset
scalar numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceGrid,AssetPrices,Variances,Times] = optByHestonD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, `10`, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`DividendAmounts` — Cash dividend amounts
`[ ]` (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of `'DividendAmounts'` and a `NDIV`-by-`1` vector.

Note Each dividend amount must have a corresponding ex-dividend date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`ExDividendDates` — Ex-dividend dates
`[ ]` (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of `'ExDividendDates'` and an `NDIV`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByHestonFD` also accepts serial date numbers as inputs, but they are not recommended.

`AssetPriceMax` — Maximum price for price grid boundary
if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a positive scalar.

Data Types: `single` | `double`

`VarianceMax` — Maximum variance to use for variance grid boundary
`1.0` (default) | scalar numeric

Maximum variance to use for the variance grid boundary, specified as the comma-separated pair consisting of `'VarianceMax'` as a scalar numeric.

Data Types: `double`

`AssetGridSize` — Size of asset grid for finite difference grid
`400` (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a scalar numeric.

Data Types: `double`

`VarianceGridSize` — Number of nodes for variance grid for finite difference grid
`200` (default) | scalar numeric

Number of nodes for the variance grid for finite difference grid, specified as the comma-separated pair consisting of `'VarianceGridSize'` and a scalar numeric.

Data Types: `double`

`TimeGridSize` — Number of nodes of time grid for finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with value of `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of these values:

- `0` — European
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Option price
numeric

Option price, returned as a scalar numeric.

`PriceGrid` — Grid containing prices calculated by the finite difference method
numeric

Grid containing prices calculated by the finite difference method, returned as a three-dimensional grid with size `AssetGridSize` × `VarianceGridSize` × `TimeGridSize`. The depth is not necessarily equal to the `TimeGridSize`, because exercise and ex-dividend dates are added to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of the asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Variances` — Variances
vector

Variances corresponding to the second dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to the third dimension of `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = \rho dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and W^v_t for ($-1 \le p \le 1$).

Version History

Introduced in R2018b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByHestonFD` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByHestonFD

Option price and sensitivities by Heston model using finite differences

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD(Rate,
AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD( ___ ,
Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD(Rate, AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)` computes a vanilla European or American option price and sensitivities by the Heston model, using the alternating direction implicit (ADI) method.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optByHestonFD( ___ , Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute an American Option Price and Sensitivities Using the Heston Model

Define the option variables and Heston model parameters.

```
AssetPrice = 10;
Strike = 10;
Rate = 0.1;
Settle = datetime(2017,1,1);
ExerciseDates = datetime(2017,4,2);

V0 = 0.0625;
ThetaV = 0.16;
Kappa = 5.0;
SigmaV = 0.9;
RhoSV = 0.1;
```

Compute the American put option price and sensitivities.

```
OptSpec = 'Put';
[Price,Delta,Gamma,Rho,Theta,Vega,VegaLT] = optSensByHestonFD(Rate, AssetPrice, Settle, ExerciseD
OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV, 'AmericanOpt', 1, ...
'OutSpec', ["Price" "Delta" "Gamma" "Rho" "Theta" "Vega" "VegaLT"])
```

```
Price = 0.5188

Delta = -0.4472

Gamma = 0.2822

Rho = -0.9234

Theta = -1.1614

Vega = 0.8998

VegaLT = 1.0921
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal.

Data Types: `double`

`AssetPrice` — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Option settlement date

datetime scalar | string scalar | date character vector

Option settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optSensByHestonFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, the option can be exercised between the `Settle` date and the single listed `ExerciseDate`.

To support existing code, `optSensByHestonFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a scalar using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`V0` — Initial variance of underlying asset
scalar numeric

Initial variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
scalar numeric

Long-term variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
scalar numeric

Mean revision speed for the variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
scalar numeric

Volatility of the variance of the underlying asset, specified as a scalar numeric.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
scalar numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens,PriceGrid,AssetPrices,Variances,Times] = optSensByHestonFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,'Basis',7)`

Basis — Day-count basis of instrument
0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

DividendYield — Continuously compounded underlying asset yield
0 (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric.

Note If you enter a value for DividendYield, then set DividendAmounts and ExDividendDates = [ ] or do not enter them. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

Data Types: double

DividendAmounts — Cash dividend amounts
[ ] (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of 'DividendAmounts' and a NDIV-by-1 vector.

Note Each dividend amount must have a corresponding ex-dividend date. If you enter values for DividendAmounts and ExDividendDates, then set DividendYield = 0.

Data Types: double

`ExDividendDates` — Ex-dividend dates
`[]` (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of `'ExDividendDates'` and a `NDIV`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByHestonFD` also accepts serial date numbers as inputs, but they are not recommended.

`AssetPriceMax` — Maximum price for price grid boundary
if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a positive scalar.

Data Types: `single` | `double`

`VarianceMax` — Maximum variance to use for variance grid boundary
`1.0` (default) | scalar numeric

Maximum variance to use for variance grid boundary, specified as the comma-separated pair consisting of `'VarianceMax'` as a scalar numeric.

Data Types: `double`

`AssetGridSize` — Size of asset grid for finite difference grid
`400` (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a scalar numeric.

Data Types: `double`

`VarianceGridSize` — Number of nodes for variance grid for finite difference grid
`200` (default) | scalar numeric

Number of nodes for the variance grid for finite difference grid, specified as the comma-separated pair consisting of `'VarianceGridSize'` and a scalar numeric.

Data Types: `double`

`TimeGridSize` — Number of nodes of time grid for finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of these values:

- `0` — European

- 1 — American

Data Types: double

OutSpec — Define outputs
["price"] (default) | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt' | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT- by-1 or a 1-by-NOUT string array or cell array of character vectors with the supported values.

Note 'vega' is the sensitivity with respect to the initial volatility sqrt(V0). In contrast, 'vegalt' is the sensitivity with respect to the long-term volatility sqrt(ThetaV).

Example: OutSpec = {'price','delta','gamma','vega','rho','theta','vegalt'}

Data Types: string | cell

Output Arguments

PriceSens — Option price and sensitivities
scalar numeric

Option price and sensitivities, returned as a scalar numeric. OutSpec determines the types and order of the outputs.

PriceGrid — Grid containing prices calculated by the finite difference method
numeric

Grid containing prices calculated by the finite difference method, returned as a three-dimensional grid with size AssetGridSize VarianceGridSize TimeGridSize. The depth is not necessarily equal to the TimeGridSize, because exercise and ex-dividend dates are added to the time grid. PriceGrid(:, :, end) contains the price for $t = 0$.

AssetPrices — Prices of the asset
vector

Prices of the asset corresponding to the first dimension of PriceGrid, returned as a vector.

Variances — Variances
vector

Variances corresponding to the second dimension of PriceGrid, returned as a vector.

Times — Times
vector

Times corresponding to the third dimension of PriceGrid, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

optByHestonFFT

Option price by Heston model using FFT and FRFT

Syntax

```
[Price,StrikeOut] = optByHestonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,
Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[Price,StrikeOut] = optByHestonFFT( ___ ,Name,Value)
```

Description

`[Price,StrikeOut] = optByHestonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec, Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)` computes vanilla European option price by Heston model, using Carr-Madan FFT and Chourdakis FRFT methods.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,StrikeOut] = optByHestonFFT( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Price Surface Using the Heston Model

Use `optByHestonFFT` to calibrate a FFT strike grid and then compute option prices and plot an option price surface.

Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

Compute the Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option prices and also output the corresponding strikes. If the `Strike` input is empty (`[]`), option prices will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as `exp(log-strike grid)`, where each column of the log-strike grid has `NumFFT`

points with `LogStrikeStep` spacing that are roughly centered around each element of log(`AssetPrice`). The default value for `NumFFT` is 2^12. In addition to the prices in the first output, the optional last output contains the corresponding strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option prices for the entire FFT strike grid
[Call, Kout] =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield);

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid
```

```
MinStrike = 2.9205e-135
```

```
MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid
```

```
MaxStrike = 1.8798e+138
```

```
% Show a subset of the strikes and corresponding option prices
Range = (2046:2052);
[Kout(Range) Call(Range)]
```

```
ans = 7×2

   50.4929   29.4843
   58.8640   21.3767
   68.6231   12.5614
   80.0000    4.7008
   93.2631    0.6496
  108.7251    0.0144
  126.7505    0.0001
```

Change the Number of FFT (or FRFT) Points, and Compare with optByHestonNI

Try a different number of FFT (or FRFT) points, and compare the results with direct numerical integration. Unlike `optByHestonFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optByHestonNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optByHestonNI` can serve as a benchmark for adjusting the settings for `optByHestonFFT`.

```
% Try a smaller number of FFT (or FRFT) points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Call, Kout] = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
```

```
    ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7×4 table
    Strike     CallFFT       CallNI         Error
    ______    _________    ___________    _________

    12.696       66.066          66.696      0.62964
    23.449       55.766          56.103      0.33672
    43.312       36.359          36.539      0.17974
        80       4.7727          4.7007     0.071928
    147.76     0.066156     2.3472e-08     0.066156
    272.93     0.013271    -2.5036e-09     0.013271
    504.11    0.0034504    -3.0876e-07    0.0034508
```

Make Further Adjustments to FFT (or FRFT)

If the values in the output `CallFFT` are significantly different from those in `CallNI`, try making adjustments to `optByHestonFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` * `CharacteristicFcnStep`) is 2*pi/ `NumFFT`, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Call, Kout] = optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);

% Compare with numerical integration method
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, V0, ...
    ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7×4 table
    Strike    CallFFT    CallNI      Error
    ______    _______    ______    __________

    79.76      4.826      4.826    2.7708e-08
    79.84     4.7841     4.7841    3.0111e-08
    79.92     4.7423     4.7423    3.2376e-08
       80     4.7007     4.7007    3.4496e-08
    80.08     4.6593     4.6593    3.6457e-08
    80.16     4.6181     4.6181    3.8253e-08
    80.24      4.577      4.577    3.9872e-08
```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

Compute the Option Price for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Call =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Call = 4.7007
```

Compute the Option Prices for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Call = 5×1

    7.0401
    5.8053
    4.7007
    3.7316
    2.8991
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001) % Five values in vector output
```

```
Call = 5×1

    8.9560
```

```
    9.3419
    9.6240
    9.8560
   10.0500
```

Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes`-by `NMaturities` matrices. In this case, they are square matrices.

```
[Call, Kout] =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 5) matrix outputs
```

```
Call = 5×5

    8.9560   10.4543   11.7058   12.8009   13.7728
    7.7946    9.3419   10.6337   11.7644   12.7685
    6.7244    8.3028    9.6240   10.7828   11.8134
    5.7475    7.3379    8.6771    9.8560   10.9074
    4.8645    6.4474    7.7930    8.9840   10.0500

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular).

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

```
Call = 5×6

    7.0401    8.9560   10.4543   11.7058   12.8009   13.7728
    5.8053    7.7946    9.3419   10.6337   11.7644   12.7685
    4.7007    6.7244    8.3028    9.6240   10.7828   11.8134
    3.7316    5.7475    7.3379    8.6771    9.8560   10.9074
    2.8991    4.8645    6.4474    7.7930    8.9840   10.0500
```

Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call =  optByHestonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 4) matrix output
```

```
Call = 5×4

    3.2944    5.8047    8.9560   12.6052
    2.6413    4.8810    7.7946   11.2507
    2.0864    4.0575    6.7244    9.9738
    1.6230    3.3325    5.7475    8.7783
    1.2429    2.7028    4.8645    7.6676
```

Plot an Option Price Surface

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to `"true"` to output the surface as a `NStrikes`-by-`NMaturities` matrix.

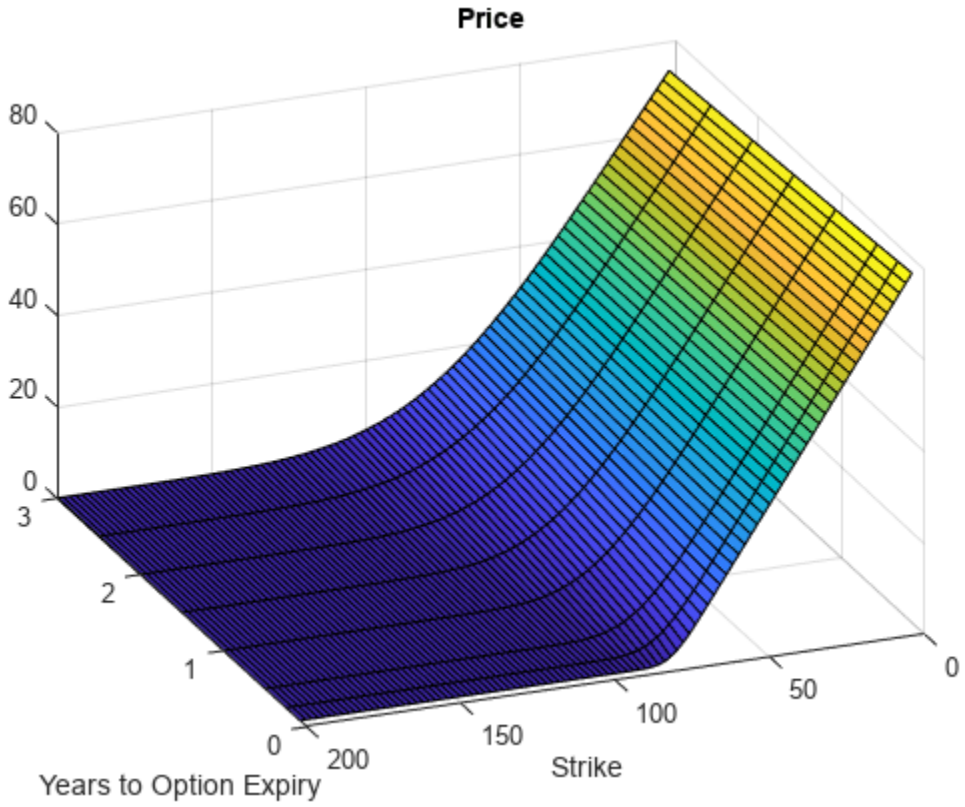
```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

Call =  optByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);
```



Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optByHestonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByHestonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `"call"` or `"put"`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has `'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

Kappa — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,StrikeOut] = optByHestonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of `'DampingFactor'` and a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`"simpson"` (default) | character vector with values: `'simpson'` or `'trapezoidal'` | string array with values: `"simpson"` or `"trapezoidal"`

Type of quadrature, specified as the comma-separated pair consisting of `'Quadrature'` and a single character vector or string array with a value of `'simpson'` or `'trapezoidal'`.

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`Price` — Option prices
numeric

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

`StrikeOut` — Strikes corresponding to `Price`
numeric

Strikes corresponding to `Price`, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and $W^v{}_t$ for ($-1 \le p \le 1$).

The characteristic function $f_{Heston_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right)\right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

The definitions for C_j and D_j under "The Little Heston Trap" by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^{\infty} \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u-(\alpha+1)i))}{\alpha^2+\alpha-u^2+iu(2\alpha+1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

τ is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number (i^2= -1)

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where ϕ = (u - (α+1)i).

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration, u, is discretized into `NumFFT`(N) points with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration, u_j(for j = 1,2,3,...,N), has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid, k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iuj\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

Δu is the step size of discretized characteristic function variable for integration.

Δk is the step size of discretized log-strike.

N is the number of FFT or FRFT points.

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByHestonFFT` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByHestonFFT

Option price and sensitivities by Heston model using FFT and FRFT

Syntax

```
[PriceSens,StrikeOut] = optSensByHestonFFT(Rate,AssetPrice,Settle,Maturity,
OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)
[PriceSens,StrikeOut] = optSensByHestonFFT( ___ ,Name,Value)
```

Description

`[PriceSens,StrikeOut] = optSensByHestonFFT(Rate,AssetPrice,Settle,Maturity, OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV)` computes vanilla European option price and sensitivities by Heston model, using Carr-Madan FFT and Chourdakis FRFT methods.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,StrikeOut] = optSensByHestonFFT( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Sensitivity Surface Using the Heston Model

Use `optSensByHestonFFT` to calibrate the FFT strike grid for sensitivities, compute option sensitivities, and plot option sensitivity surfaces.

Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

Compute the Option Sensitivities for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option sensitivities and also output the corresponding strikes. If the `Strike` input is empty (`[]`), option sensitivities will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as `exp(log-strike grid)`, where each column of the log-strike

grid has NumFFT points with LogStrikeStep spacing that are roughly centered around each element of log(AssetPrice). The default value for NumFFT is 2^12. In addition to the sensitivities in the first output, the optional last output contains the corresponding strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option sensitivities for the entire FFT strike grid
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta");

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option sensitivities
Range = (2046:2052);
[Kout(Range) Delta(Range)]

ans = 7×2

   50.4929    0.9866
   58.8640    0.9671
   68.6231    0.8724
   80.0000    0.5775

  108.7251    0.0059
  126.7505    0.0000
```

Change the Number of FFT (or FRFT) Points, and Compare With optSensByHestonNI

Try a different number of FFT (or FRFT) points, and compare the results with numerical integration. Unlike optSensByHestonFFT, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the optSensByHestonNI function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by optSensByHestonNI can serve as a benchmark for adjusting the settings for optSensByHestonFFT.

```
% Try a smaller number of FFT points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
```

```
DeltaFFT = Delta(Range);
DeltaNI = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)
```

```
ans=7×4 table
    Strike     DeltaFFT      DeltaNI        Error
    ______    __________    __________    _________

    12.696       0.90066       0.99002       0.08936
    23.449       0.93635       0.99002      0.053677
    43.312       0.94796        0.9896      0.041645

```

Make Further Adjustments to FFT (or FRFT)

If the values in the output `DeltaFFT` are significantly different from those in `DeltaNI`, try making adjustments to `optSensByHestonFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` * `CharacteristicFcnStep`) is 2*pi/ `NumFFT`, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)

% Compare with numerical integration method
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)
```

```
ans=7×4 table

```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437

MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike

MaxStrike = 133.3566
```

Compute the Option Sensitivity for a Single Strike

Once you determine FFT (or FRFT) settings, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)

Delta = 0.5775
```

Compute the Option Sensitivities for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001)

Delta = 5×1

    0.7043
    0.6433
    0.5775
    0.5083
    0.4377
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
```

```
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001) % Five values in vector output
```

```
Delta = 5×1

    0.6848
    0.6413
    0.6095
    0.5841
    0.5631
```

Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes`-by-`NMaturities` matrices. In this case, they are square matrices.

```
[Delta, Kout] = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5

    0.6848    0.6762    0.6703    0.6654    0.6609
    0.6416    0.6413    0.6404    0.6390    0.6372
    0.5960    0.6048    0.6095    0.6119    0.6129
    0.5485    0.5671    0.5776    0.5841    0.5882
    0.4997    0.5286    0.5452    0.5559    0.5631

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular).

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 6) matrix output
```

```
Delta = 5×6

    0.7043    0.6848    0.6762    0.6703    0.6654    0.6609
    0.6433    0.6416    0.6413    0.6404    0.6390    0.6372
```

```
    0.5775    0.5960    0.6048    0.6095    0.6119    0.6129
    0.5083    0.5485    0.5671    0.5776    0.5841    0.5882
    0.4377    0.4997    0.5286    0.5452    0.5559    0.5631
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 4) matrix output
```

```
Delta = 5×4

    0.4293    0.5708    0.6848    0.7705
    0.3737    0.5193    0.6416    0.7364
    0.3200    0.4668    0.5960    0.6994
    0.2693    0.4143    0.5485    0.6597
    0.2226    0.3628    0.4997    0.6177
```

Plot Option Sensitivity Surfaces

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to `"true"` to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = ...
    optSensByHestonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...

```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optSensByHestonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByHestonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has `'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

Kappa — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

RhoSV — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens,StrikeOut] = optSensByHestonFFT(Rate, AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa,SigmaV,RhoSV,'Basis',7,'OptSpec',"vega")`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'` and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`OutSpec` — Define outputs
`["price"]` (default) | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, `"theta"`, and `"vegalt"` | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'rho'`, `'theta'`, and `'vegalt'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` string array or cell array of character vectors with supported values.

Note `"vega"` is the sensitivity with respect the initial volatility sqrt(`V0`). In contrast, `"vegalt"` is the sensitivity with respect to the long-term volatility sqrt(`ThetaV`).

Example: `OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]`

Data Types: `string` | `cell`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of `'DampingFactor'` and a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`simpson` (default) | character vector with values:`simpson` or `trapezoidal` | string array with values: `simpson` or `trapezoidal`

Type of quadrature, specified as the comma-separated pair consisting of `'Quadrature'` and a single character vector or string array with a value of `simpson` or `trapezoidal`.

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-`1` vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-`1` vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-`1` vectors.
- `false` — If `false`, the outputs are `NINST`-by-`1` vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-`1` vectors.

Data Types: `logical`

Output Arguments

`PriceSens` — Option prices or sensitivities

numeric

Option prices or sensitivities, returned as a `NINST`-by-`1`, or `NRows`-by-`NColumns`, depending on `ExpandOutput`. The name-value pair argument `OutSpec` determines the types and order of the outputs.

`StrikeOut` — Strikes corresponding to `Price`

numeric

Strikes corresponding to `Price`, returned as a `NINST`-by-`1`, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = \rho dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and $W^v{}_t$ for ($-1 \le p \le 1$).

The characteristic function $f_{Heston_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right)\right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

The definitions for C_j and D_j under “The Little Heston Trap” by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v{}^2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1-\varepsilon_j e^{-d_j\tau}}{1-\varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1-e^{-d_j\tau}}{1-\varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^\infty \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u-(\alpha+1)i))}{\alpha^2+\alpha-u^2+iu(2\alpha+1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where ϕ = (u - (α+1)i).

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration, u, is discretized into `NumFFT`(N) points with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration, u_j(for j = 1,2,3,...,N), has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid, k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

Δu is the step size of discretized characteristic function variable for integration.

Δk is the step size of discretized log-strike.

N is the number of FFT or FRFT points.

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

Version History

Introduced in R2018a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `optSensByHestonFFT` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByHestonNI

Option price by Heston model using numerical integration

Syntax

```
Price = optByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,
ThetaV,Kappa,SigmaV,RhoSV)
Price = optByHestonNI( ___ ,Name,Value)
```

Description

`Price = optByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0, ThetaV,Kappa,SigmaV,RhoSV)` computes vanilla European option price by Heston model, using numerical integration methods.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = optByHestonNI( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Price Surface Using the Heston Model

`optByHestonNI` uses numerical integration to compute option prices and then to plot an option price surface.

Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

Compute the Option Price for a Single Strike

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield)
```

```
Call = 4.7007
```

Compute the Option Prices for a Vector of Strikes

The `Strike` input can be a vector.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield)
```

```
Call = 5×1

    7.0401
    5.8053
    4.7007
    3.7316
    2.8991
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield)
```

```
Call = 5×1

    8.9560
    9.3419
    9.6240
    9.8560
   10.0500

    % Five values in vector output
```

Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes`-by-`NMaturities` matrix. In this case, it is a square matrix.

```
Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

```
Call = 5×5

    8.9560   10.4543   11.7058   12.8009   13.7728
```

```
    7.7946    9.3419   10.6337   11.7644   12.7685
    6.7244    8.3028    9.6240   10.7828   11.8134
    5.7474    7.3378    8.6771    9.8560   10.9074
    4.8645    6.4474    7.7930    8.9840   10.0500
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular).

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

```
Call = 5×6

    7.0401    8.9560   10.4543   11.7058   12.8009   13.7728
    5.8053    7.7946    9.3419   10.6337   11.7644   12.7685
    4.7007    6.7244    8.3028    9.6240   10.7828   11.8134
    3.7316    5.7474    7.3378    8.6771    9.8560   10.9074
    2.8991    4.8645    6.4474    7.7930    8.9840   10.0500
```

Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByHestonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 4) matrix output
```

```
Call = 5×4

    3.2944    5.8047    8.9560   12.6052
    2.6413    4.8810    7.7946   11.2507
    2.0864    4.0575    6.7244    9.9738
    1.6230    3.3325    5.7474    8.7783
    1.2429    2.7028    4.8645    7.6676
```

Plot an Option Price Surface

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to `"true"` to output the surface as a `NStrikes`-by-`NMaturities` matrix.

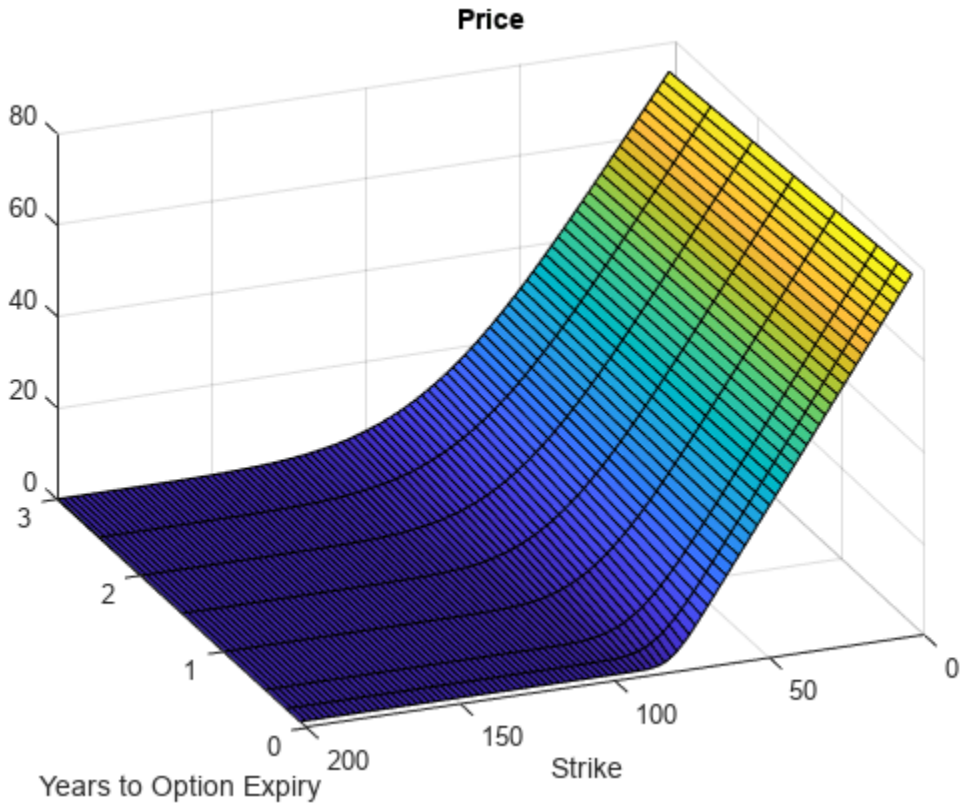
```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
```

```
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

Call = optByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);
```



Input Arguments

Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

AssetPrice — Current underlying asset price
numeric

Current underlying asset price, specified as numeric value using a scalar or a NINST-by-1 or NColumns-by-1 vector.

For more information on the proper dimensions for AssetPrice, see the name-value pair argument ExpandOutput.

Data Types: double

Settle — Option settlement date
datetime array | string array | date character vector

Option settlement date, specified as a NINST-by-1 or NColumns-by-1 vector using a datetime array, string array, or date character vectors. The Settle date must be before the Maturity date.

To support existing code, optByHestonNI also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for Settle, see the name-value pair argument ExpandOutput.

Maturity — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a NINST-by-1 or NColumns-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optByHestonNI also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for Maturity, see the name-value pair argument ExpandOutput.

OptSpec — Definition of option
cell array of character vector with values 'call' or 'put' | string array with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 or NColumns-by-1 vector using a cell array of character vectors or string arrays with values "call" or "put".

For more information on the proper dimensions for OptSpec, see the name-value pair argument ExpandOutput.

Data Types: cell | string

Strike — Option strike price value
numeric

Option strike price value, specified as a NINST-by-1, NRows-by-1, NRows-by-NColumns vector of strike prices.

For more information on the proper dimensions for Strike, see the name-value pair argument ExpandOutput.

Data Types: double

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,V0,ThetaV,Kappa, SigmaV,RhoSV,'Basis',7,'Framework',"lewis2001")`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`VolRiskPremium` — Volatility risk premium
`0` (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of `'VolRiskPremium'` and a scalar numeric value.

Data Types: `double`

`LittleTrap` — Flag indicating Little Heston Trap formulation
`true` (default) | logical with values `true` or `false`

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of `'LittleTrap'`and a logical:

- `true` — Use the Albrecher *et al* formulation.
- `false` — Use the original Heston formation.

Data Types: `logical`

`AbsTol` — Absolute error tolerance for numerical integration
`1e-10` (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of `'AbsTol'` and a scalar numeric value.

Data Types: `double`

`RelTol` — Relative error tolerance for numerical integration
`1e-6` (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of `'RelTol'` and a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, specified as the comma-separated pair consisting of `'IntegrationRange'` and a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with values `"heston1993"` or `"lewis2001"` | character vector with values `'heston1993'` or `'lewis2001'`

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of `'Framework'` and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`Price` — Option prices
numeric

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and $W^v{}_t$ for ($-1 \le p \le 1$).

The characteristic function $f_{Heston_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right)\right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

The definitions for C_j and D_j under "The Little Heston Trap" by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v 2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \mathrm{Re}\left[\frac{e^{-i\phi\ln(K)} f_j(\phi)}{i\phi}\right] d\phi$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j(j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

This framework is chosen with the default value "`Heston1993`" for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K}e^{-\tau t}}{\pi}\int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right)\frac{1}{u^2 + \frac{1}{4}}\right]du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

Call(*K*) is the call price at strike *K*.

Put(*K*) is the put price at strike *K*.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

This framework is chosen with the value "`Lewis2001`" for the `Framework` name-value pair argument.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByHestonNI` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByHestonNI

Option price and sensitivities by Heston model using numerical integration

Syntax

```
PriceSens = optSensByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,
V0,ThetaV,Kappa,SigmaV,RhoSV)
PriceSens = optSensByHestonNI( ___ ,Name,Value)
```

Description

`PriceSens = optSensByHestonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike, V0,ThetaV,Kappa,SigmaV,RhoSV)` computes vanilla European option price and sensitivities by Heston model, using numerical integration methods.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optSensByHestonNI( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Sensitivity Surface Using the Heston Model

`optSensByHestonNI` uses numerical integration to compute option sensitivities and then to plot option sensitivity surfaces.

Define Option Variables and Heston Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;
```

Compute the Option Sensitivity for a Single Strike

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;
```

```
Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 0.5775
```

Compute the Option Sensitivities for a Vector of Strikes

The `Strike` input can be a vector.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, 'OutSpec', "delta")
```

```
Delta = 5×1

    0.7043
    0.6433
    0.5775
    0.5083
    0.4377
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta") % Five values in vector output
```

```
Delta = 5×1

    0.6848
    0.6413
    0.6095
    0.5841
    0.5631
```

Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes`-by-`NMaturities` matrix. In this case, it is a square matrix.

```
Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5
```

```
    0.6848    0.6762    0.6703    0.6654    0.6609
    0.6416    0.6413    0.6404    0.6390    0.6372
    0.5960    0.6048    0.6095    0.6119    0.6129
    0.5485    0.5671    0.5776    0.5841    0.5882
    0.4997    0.5286    0.5452    0.5559    0.5631
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities` (that is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular).

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true)  % (5 x 6) matrix output
```

```
Delta = 5×6

    0.7043    0.6848    0.6762    0.6703    0.6654    0.6609
    0.6433    0.6416    0.6413    0.6404    0.6390    0.6372
    0.5775    0.5960    0.6048    0.6095    0.6119    0.6129
    0.5083    0.5485    0.5671    0.5776    0.5841    0.5882
    0.4377    0.4997    0.5286    0.5452    0.5559    0.5631
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByHestonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 4) matrix output
```

```
Delta = 5×4

    0.4293    0.5708    0.6848    0.7705
    0.3737    0.5193    0.6416    0.7364
    0.3200    0.4668    0.5960    0.6994
    0.2693    0.4143    0.5485    0.6597
    0.2226    0.3628    0.4997    0.6177
```

Plot Option Sensitivity Surfaces

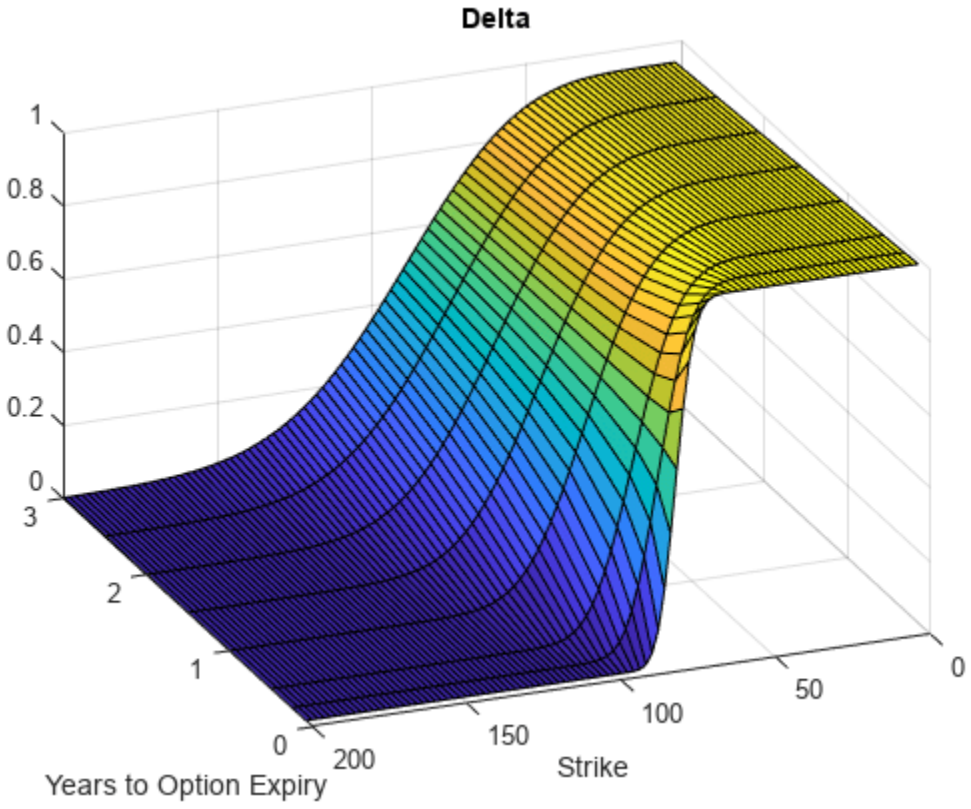
The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to `"true"` to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

[Delta, Gamma, Rho, Theta, Vega, VegaLT] = ...
    optSensByHestonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    V0, ThetaV, Kappa, SigmaV, RhoSV, 'DividendYield', DividendYield, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega", "vegalt"], ...
    'ExpandOutput', true);

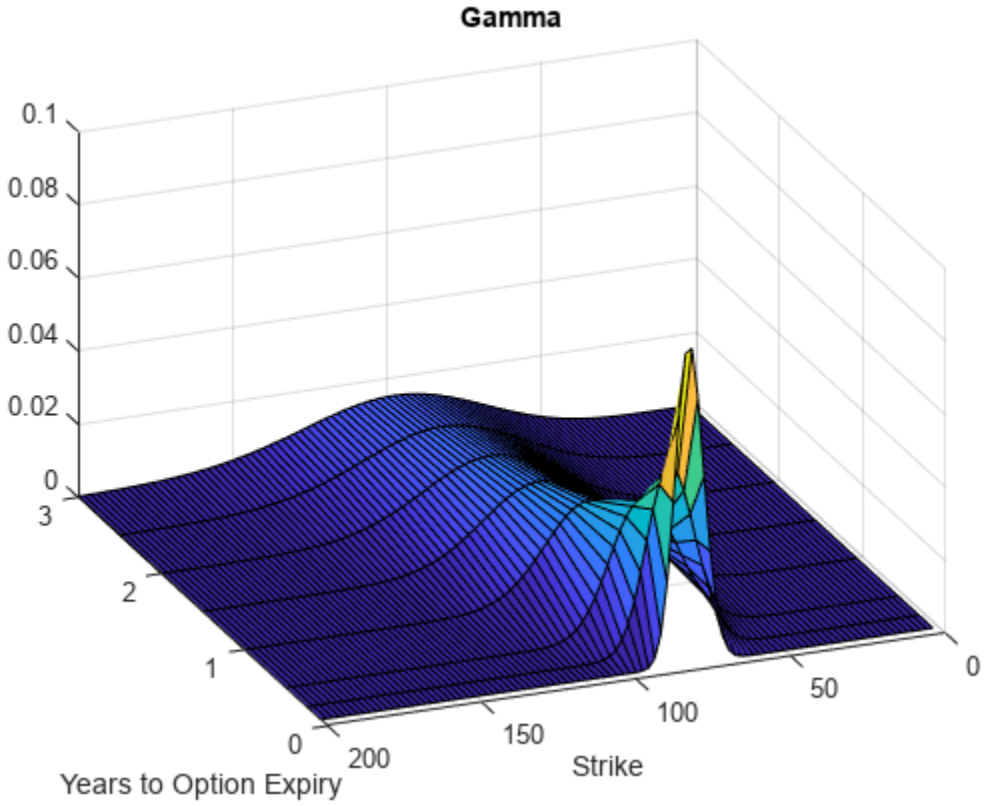
[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
```

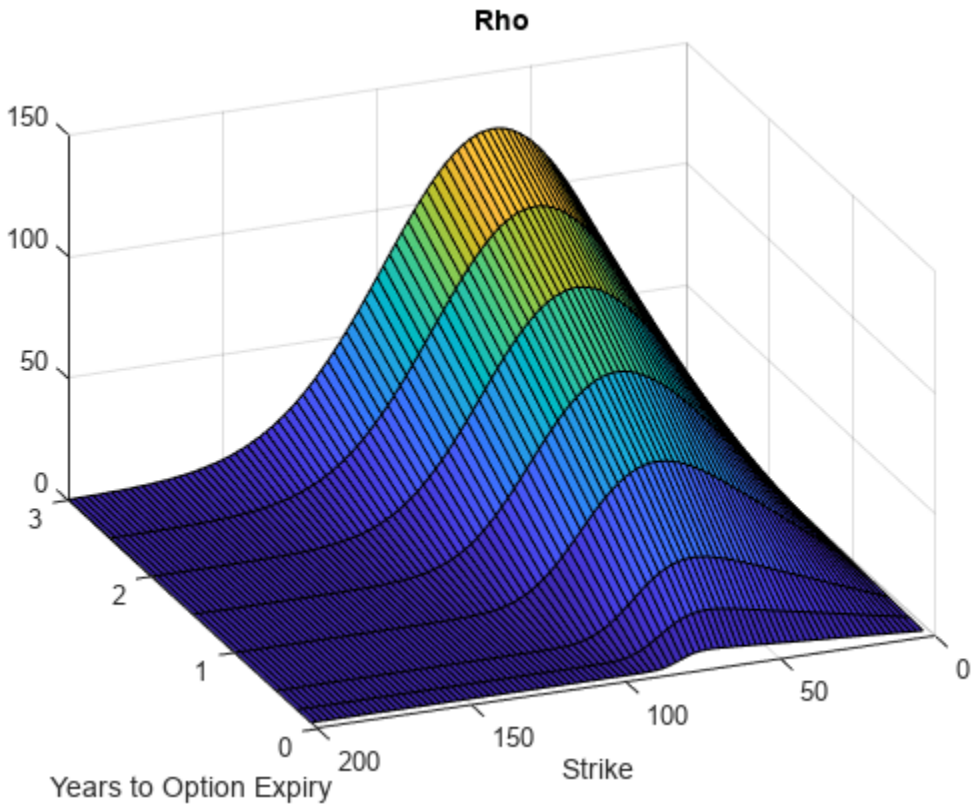


```
figure;
surf(X,Y,Gamma)
title('Gamma')
xlabel('Years to Option Expiry')
ylabel('Strike')
```

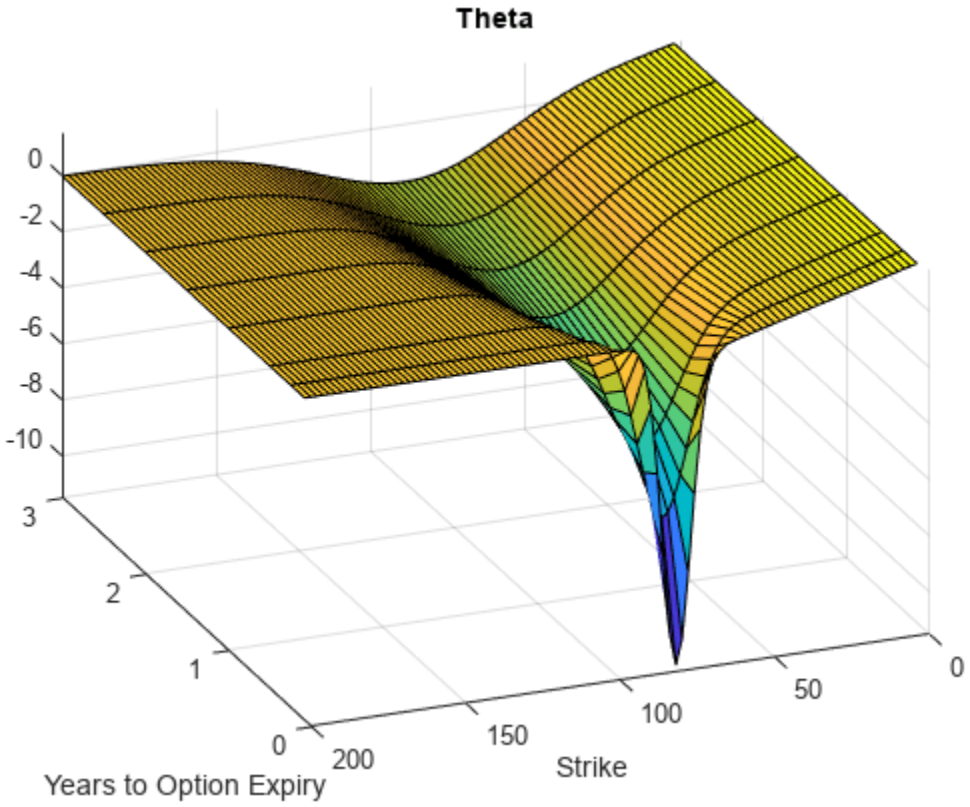
```
view(-112,34);
xlim([0 Times(end)]);
```



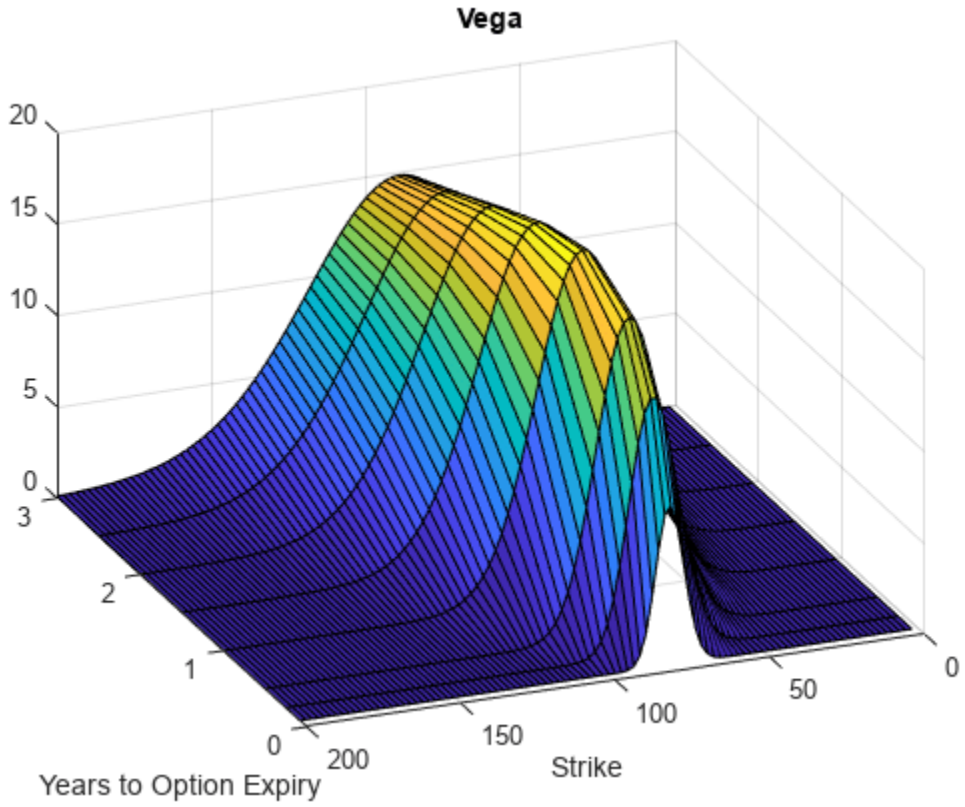
```
figure;
surf(X,Y,Rho)
title('Rho')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



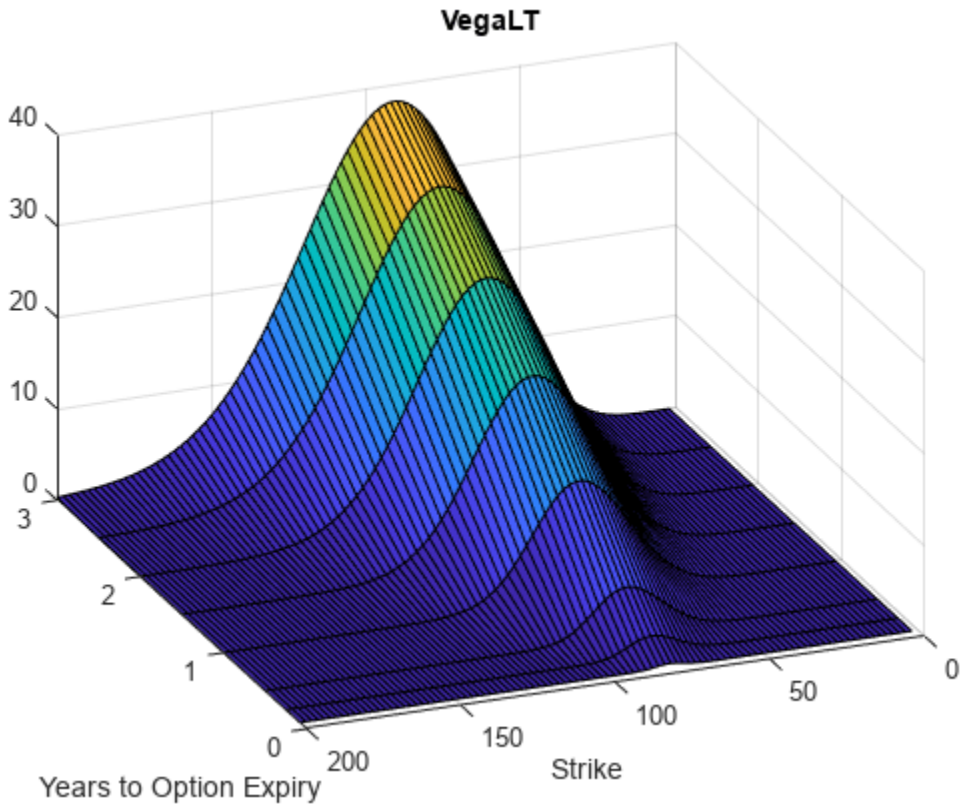
```
figure;
surf(X,Y,Theta)
title('Theta')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



```
figure;
surf(X,Y,Vega)
title('Vega')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



```
figure;
surf(X,Y,VegaLT)
title('VegaLT')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optSensByHestonNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByHestonNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`V0` — Initial variance of underlying asset
numeric

Initial variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`ThetaV` — Long-term variance of underlying asset
numeric

Long-term variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`Kappa` — Mean revision speed for the variance of underlying asset
numeric

Mean revision speed for the underling asset, specified as a scalar numeric value.

Data Types: `double`

`SigmaV` — Volatility of the variance of underlying asset
numeric

Volatility of the variance of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`RhoSV` — Correlation between Weiner processes for underlying asset and its variance
numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = optSensByHestonFFT(Rate, AssetPrice, Settle,Maturity, OptSpec, Strike, V0, ThetaV, Kappa, SigmaV, RhoSV,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

DividendYield — Continuously compounded underlying asset yield
0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

VolRiskPremium — Volatility risk premium
0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

LittleTrap — Flag indicating Little Heston Trap formulation
true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher *et al*, specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher *et al* formulation.
- false — Use the original Heston formation.

Data Types: logical

OutSpec — Define outputs
["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", "theta", and "vegalt" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', 'theta', and 'vegalt'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

Note "vega" is the sensitivity with respect the initial volatility sqrt(V0). In contrast, "vegalt" is the sensitivity with respect to the long-term volatility sqrt(ThetaV).

Example: OutSpec = ["price","delta","gamma","vega","rho","theta","vegalt"]

Data Types: string | cell

AbsTol — Absolute error tolerance for numerical integration
1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

RelTol — Relative error tolerance for numerical integration
1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of `'RelTol'` and a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, specified as the comma-separated pair consisting of `'IntegrationRange'` and a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with values `"heston1993"` or `"lewis2001"` | character vector with values `'heston1993'` or `'lewis2001'`

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of `'Framework'` and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`PriceSens` — Option prices or sensitivities
numeric

Option prices or sensitivities, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`. The name-value pair argument `OutSpec` determines the types and order of the outputs.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is:

$$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

v_t is the asset price variance at time t.

v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).

θ is the long-term variance level for ($\theta > 0$).

κ is the mean reversion speed for the variance for ($\kappa > 0$).

σ_v is the volatility of the variance for ($\sigma_v > 0$).

p is the correlation between the Weiner processes W_t and $W^v{}_t$ for ($-1 \le p \le 1$).

The characteristic function $f_{Heston_j}(\phi)$ for $j = 1$ (asset price measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2}\left[\left(b_j - p\sigma_v i\phi + d_j\right)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right)\right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2}\left(\frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}}\right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{\left(b_j - p\sigma_v i\phi\right)^2 - \sigma_v^2\left(2u_j i\phi - \phi^2\right)}$$

where for $j = 1, 2$:

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

where

ϕ is the characteristic function variable.

$\lambda_{VolRisk}$ is the volatility risk premium.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

The definitions for C_j and D_j under "The Little Heston Trap" by Albrecher et al. (2007) are:

$$C_j = (r-q)i\phi\tau + \frac{\kappa\theta}{\sigma_v 2}\left[\left(b_j - p\sigma_v i\phi - d_j\right)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right)\right]$$

$$Dj = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2}\left(\frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}}\right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \mathrm{Re}\left[\frac{e^{-i\phi\ln(K)} f_j(\phi)}{i\phi}\right] d\phi$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j(j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

This framework is chosen with the default value "`Heston1993`" for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K}e^{-\tau t}}{\pi}\int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right)\frac{1}{u^2 + \frac{1}{4}}\right]du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

Call(*K*) is the call price at strike *K*.

Put(*K*) is the put price at strike *K*.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

This framework is chosen with the value "`Lewis2001`" for the `Framework` name-value pair argument.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByHestonNI` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByLocalVolFD

Option price by local volatility model, using finite differences

Syntax

```
[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD(Rate,AssetPrice,Settle,
ExerciseDates,OptSpec,Strike,ImpliedVolData)
[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD(Rate,AssetPrice,Settle, ExerciseDates,OptSpec,Strike,ImpliedVolData)` compute a Vanilla European or American option price by the local volatility model, using the Crank-Nicolson method.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceGrid,AssetPrices,Times] = optByLocalVolFD( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Price a European Option Using the Local Volatility Model

Define the option variables.

```
AssetPrice = 590;
Strike = 590;
Rate = 0.06;
DividendYield = 0.0262;
Settle = '01-Jan-2018';
ExerciseDates = '01-Jan-2020';
```

Define the implied volatility surface data.

```
Maturity = ["06-Mar-2018" "05-Jun-2018" "12-Sep-2018" "10-Dec-2018" "01-Jan-2019" ...
"02-Jul-2019" "01-Jan-2020" "01-Jan-2021" "01-Jan-2022" "01-Jan-2023"];
Maturity = repmat(Maturity,10,1);
Maturity = Maturity(:);

ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];
ExercisePrice = repmat(ExercisePrice,1,10)';

ImpliedVol = [...
    0.190; 0.168; 0.133; 0.113; 0.102; 0.097; 0.120; 0.142; 0.169; 0.200; ...
```

```
    0.177; 0.155; 0.138; 0.125; 0.109; 0.103; 0.100; 0.114; 0.130; 0.150; ...
    0.172; 0.157; 0.144; 0.133; 0.118; 0.104; 0.100; 0.101; 0.108; 0.124; ...
    0.171; 0.159; 0.149; 0.137; 0.127; 0.113; 0.106; 0.103; 0.100; 0.110; ...
    0.171; 0.159; 0.150; 0.138; 0.128; 0.115; 0.107; 0.103; 0.099; 0.108; ...
    0.169; 0.160; 0.151; 0.142; 0.133; 0.124; 0.119; 0.113; 0.107; 0.102; ...
    0.169; 0.161; 0.153; 0.145; 0.137; 0.130; 0.126; 0.119; 0.115; 0.111; ...
    0.168; 0.161; 0.155; 0.149; 0.143; 0.137; 0.133; 0.128; 0.124; 0.123; ...
    0.168; 0.162; 0.157; 0.152; 0.148; 0.143; 0.139; 0.135; 0.130; 0.128; ...
    0.168; 0.164; 0.159; 0.154; 0.151; 0.147; 0.144; 0.140; 0.136; 0.132];

ImpliedVolData = table(Maturity, ExercisePrice, ImpliedVol);
```

Compute the European call option price.

```
OptSpec = 'Call';
Price = optByLocalVolFD(Rate, AssetPrice, ...
Settle, ExerciseDates, OptSpec, Strike, ImpliedVolData, 'DividendYield',DividendYield)
```

```
Price = 65.1319
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

scalar numeric

Continuously compounded risk-free interest rate, specified by a scalar numeric.

Data Types: `double`

`AssetPrice` — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optByLocalVolFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` value and this is the option expiry date.
- For an American option, use a 1-by-2 vector of dates. The American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `optByLocalVolFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a character vector or string array with values `'call'` or `'put'`.

Data Types: `char` | `string`

`Strike` — Option strike price value
nonnegative scalar

Option strike price value, specified as a nonnegative scalar.

Data Types: `double`

`ImpliedVolData` — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities
table

Table of maturity dates, strike or exercise prices, and their corresponding implied volatilities,specified as a `NVOL`-by-`3` table.

Data Types: `table`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optByLocalVolFD(Rate,AssetPrice,Settle, ExerciseDates,OptSpec,Strike,ImpliedVolData,'AssetGridSize',1000)`

`Basis` — Day-count basis
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar using one of the supported values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`DividendAmounts` — Cash dividend amounts
`[ ]` (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of `'DividendAmounts'` and a `NDIV`-by-`1` vector.

For each dividend amount, there must be a corresponding `ExDividendDates` date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them.

Data Types: `double`

`ExDividendDates` — Ex-dividend dates
`[ ]` (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of `'ExDividendDates'` and a `NDIV`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByLocalVolFD` also accepts serial date numbers as inputs, but they are not recommended.

`AssetPriceMax` — Maximum price for price grid boundary
if unspecified, `AssetPriceMax` values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a positive scalar.

Data Types: `double`

`AssetGridSize` — Size of asset grid for finite difference grid
`400` (default) | positive scalar

Size of the asset grid for a finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a positive scalar.

Data Types: `double`

`TimeGridSize` — Size of time grid for finite difference grid
`100` (default) | positive scalar

Size of the time grid for a finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a positive integer scalar flag with one of these values:

- `0` — European
- `1` — American

Data Types: `double`

`InterpMethod` — Method of interpolation for estimating the implied volatility surface from `ImpliedVolData`
`'linear'` (default) | character vector with values `'linear'`, `'makima'`, `'spline'`, or `'tpaps'` | string with values `"linear"`, `"makima"`, `"spline"`, or `"tpaps"`

Method of interpolation for estimating the implied volatility surface from `ImpliedVolData`, specified as the comma-separated pair consisting of `'InterpMethod'` and a character vector or string array with one of the following values:

- `'linear'` — Linear interpolation
- `'makima'` — Modified Akima cubic Hermite interpolation
- `'spline'` — Cubic spline interpolation
- `'tpaps'` — Thin-plate smoothing spline interpolation

Note The `'tpaps'` method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The `'makima'` and `'spline'` methods work only for gridded data. For scattered data, use the `'linear'` or `'tpaps'` methods.

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” and “Interpolating Gridded Data”.

Data Types: `char` | `string`

Output Arguments

`Price` — Option price
scalar numeric

Option price, returned as a scalar numeric.

`PriceGrid` — Grid containing prices calculated by finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size `AssetGridSize` × `TimeGridSize`. The number of columns does not have to be equal to the `TimeGridSize`, because `ExerciseDates` and `ExDividendDates` are added to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to second dimension of the `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K,\tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + \left((\tau - d) + \sigma_{imp}^2/2\right)\tau}{\sigma_{imp}\sqrt{\tau}}$$

Version History

Introduced in R2018b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByLocalVolFD` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByLocalVolFD

Option price and sensitivities by local volatility model, using finite differences

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD(Rate,
AssetPrice,Settle,ExerciseDates,OptSpec,Strike,ImpliedVolData)
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD( ___ ,Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD(Rate, AssetPrice,Settle,ExerciseDates,OptSpec,Strike,ImpliedVolData)` compute option price and sensitivities by the local volatility model, using the Crank-Nicolson method.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,PriceGrid,AssetPrices,Times] = optSensByLocalVolFD( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute European Option Price and Sensitivities Using the Local Volatility Model

Define the option variables.

```
AssetPrice = 590;
Strike = 590;
Rate = 0.06;
DividendYield = 0.0262;
Settle = datetime(2018,1,1);
ExerciseDates = datetime(2020,1,1);
```

Define the implied volatility surface data.

```
Maturity = [datetime(2018,3,6) datetime(2018,6,5) datetime(2018,9,12) datetime(2018,12,10) dateti
Maturity = repmat(Maturity,10,1);
Maturity = Maturity(:);

ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];
ExercisePrice = repmat(ExercisePrice,1,10)';

ImpliedVol = [...

Delta = 0.5519

Gamma = 0.0091

Lambda = 4.9994

Theta = -20.9529

Price = 65.1319
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

scalar numeric

Continuously compounded risk-free interest rate, specified by a scalar numeric.

Data Types: `double`

`AssetPrice` — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optSensByLocalVolFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` value and this is the option expiry date.
- For an American option, use a 1-by-2 vector dates. The American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `optSensByLocalVolFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value of `'call'` or `'put'` | string array with value of `"call"` or `"put"`

Definition of the option, specified as a character vector or string array with a value of `'call'` or `'put'`.

Data Types: `char` | `string`

`Strike` — Option strike price value
nonnegative scalar

Option strike price value, specified as a nonnegative scalar.

Data Types: `double`

`ImpliedVolData` — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities
table

A table of maturity dates, strike or exercise prices, and their corresponding implied volatilities,specified as a `NVOL`-by-3 table.

Data Types: `table`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = Price = optByLocalVolFD(Rate,AssetPrice,Settle, ExerciseDates,OptSpec,Strike,ImpliedVolData,'AssetGridSize',1000,'OutSpec', {'delta','gamma','vega','lambda','rho','theta','price'})`

`Basis` — Day-count basis
`0` (default) | numeric values: `0`,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar using one of these supported values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`DividendAmounts` — Cash dividend amounts
`[ ]` (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of `'DividendAmounts'` and a `NDIV`-by-`1` vector.

For each dividend amount, there must be a corresponding `ExDividendDates` date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them.

Data Types: `double`

`ExDividendDates` — Ex-dividend dates
`[ ]` (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of `'ExDividendDates'` and a `NDIV`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByLocalVolFD` also accepts serial date numbers as inputs, but they are not recommended.

AssetPriceMax — Maximum price for price grid boundary
if unspecified, AssetPriceMax values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' and a positive scalar.

Data Types: double

AssetGridSize — Size of asset grid for finite difference grid
400 (default) | positive scalar

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a positive scalar.

Data Types: double

TimeGridSize — Size of time grid for finite difference grid
100 (default) | positive scalar

Size of the time grid for finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive scalar.

Data Types: double

AmericanOpt — Option type
0 (European) (default) | scalar with values [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a positive integer scalar flag with one of these values:

- 0 — European
- 1 — American

Data Types: double

InterpMethod — Method of interpolation for estimating the implied volatility surface from ImpliedVolData
'linear' (default) | character vector with values 'linear', 'makima', 'spline', or 'tpaps' | string with values "linear", "makima", "spline", or "tpaps"

Method of interpolation for estimating the implied volatility surface from ImpliedVolData, specified as the comma-separated pair consisting of 'InterpMethod' and a character vector or string with one of the following values:

- 'linear' — Linear interpolation
- 'makima' — Modified Akima cubic Hermite interpolation
- 'spline' — Cubic spline interpolation
- 'tpaps' — Thin-plate smoothing spline interpolation

Note The 'tpaps' method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The 'makima' and 'spline' methods work only for gridded data. For scattered data, use the 'linear' or 'tpaps' methods.

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” and “Interpolating Gridded Data”.

Data Types: `char` | `string`

`OutSpec` — Define outputs
`{'price'}` (default) | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'lambda'`, `'rho'`, `'theta'` | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, `"theta"`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and an `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'lambda'`, `'rho'`, and `'theta'`.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `cell` | `string`

Output Arguments

`PriceSens` — Option price and sensitivities
scalar numeric

Option price and sensitivities, returned as a scalar numeric. `OutSpec` determines the types and order of the output.

`PriceGrid` — Grid containing prices calculated by finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size `AssetGridSize` × `TimeGridSize`. The number of columns does not have to be equal to the `TimeGridSize`, because `ExerciseDates` and `ExDividendDates` are added to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to second dimension of the `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K,\tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + \left((\tau - d) + \sigma_{imp}^2/2\right)\tau}{\sigma_{imp}\sqrt{\tau}}$$

Version History

Introduced in R2018b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByLocalVolFD` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByMertonFD

Option price by Merton76 model using finite differences

Syntax

```
[Price,PriceGrid,AssetPrices,Times] = optByMertonFD(Rate,AssetPrice,Settle,
ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[Price,PriceGrid,AssetPrices,Times] = optByMertonFD( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Times] = optByMertonFD(Rate,AssetPrice,Settle, ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)` computes a vanilla European or American option price by the Merton76 model, using the Crank-Nicolson Adams-Bashforth (CNAB) IMEX method.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceGrid,AssetPrices,Times] = optByMertonFD( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Price for an American Option Using the Merton Model

Define the option variables and Merton model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.06;
DividendYield = 0.1;
Settle = datetime(2018,1,1);
ExerciseDates = datetime(2018,4,2);

Sigma = 0.40;
MeanJ = -0.10;
JumpVol = 0.01;
JumpFreq = 1.00;
```

Compute the American call option price using the finite differences method.

```
OptSpec = 'Call';

Price = optSensByMertonFD(Rate, AssetPrice, Settle, ExerciseDates, OptSpec, Strike,...
Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'AmericanOpt', 1)
```

```
Price = 3.4551
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

scalar decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

scalar numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Option settlement date

datetime scalar | string scalar | date character vector

Option settlement date, specified as a scalar datetime, string, or data character vector.

To support existing code, `optByMertonFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a scalar date. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of dates to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

To support existing code, `optByMertonFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with value of `'call'` or `'put'` | string array with value of `"call"` or `"put"`

Definition of the option, specified as a scalar using a character vector or string array with a value of `'call'` or `'put'`.

Data Types: `cell` | `string`

`Strike` — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

Sigma — Volatility of underlying asset
scalar numeric

Volatility of the underling asset, specified as a scalar numeric.

Data Types: double

MeanJ — Mean of the random percentage jump size
scalar decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where log(1+*J*) is normally distributed with the mean (log(1+MeanJ)-0.5*JumpVol^2) and the standard deviation JumpVol.

Data Types: double

JumpVol — Standard deviation of log(1+*J*)
scalar decimal

Standard deviation of log(1+*J*) where J is the random percentage jump size, specified as a scalar decimal.

Data Types: double

JumpFreq — Annual frequency of Poisson jump process
numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceGrid] = optByMertonFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,MeanJ,JumpVol,JumpFreq,'Basis',7)

Basis — Day-count basis of instrument
0 (default) | numeric values: 0,1, 2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`DividendAmounts` — Cash dividend amounts
`[ ]` (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of `'DividendAmounts'` and an `NDIV`-by-`1` vector.

Note Each dividend amount must have a corresponding ex-dividend date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`ExDividendDates` — Ex-dividend dates
`[ ]` (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of `'ExDividendDates'` and an `NDIV`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByMertonFD` also accepts serial date numbers as inputs, but they are not recommended.

`AssetPriceMax` — Maximum price for price grid boundary
if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a positive scalar numeric.

Data Types: `double`

`AssetGridSize` — Size of asset grid for finite difference grid
`400` (default) | scalar numeric

Size of the asset grid for the finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a scalar numeric.

Data Types: `double`

`TimeGridSize` — Number of nodes of time grid for finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with value of `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of these values:

- `0` — European
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Option price
scalar numeric

Option price, returned as a scalar numeric.

`PriceGrid` — Grid containing prices calculated by the finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `AssetGridSize` × `TimeGridSize`. The number of columns is not necessarily equal to the `TimeGridSize` because exercise and ex-dividend dates are added to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of the asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to the second dimension of `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Merton Jump Diffusion Model

The Merton jump diffusion model [2] extends the Black-Scholes model by using the Poisson process to include jump diffusion parameters in the modeling of sudden asset price movements (both up and down).

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where:

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

where:

μ_J is the mean of J for (μ_J > -1).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByMertonFD` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByMertonFD

Option price and sensitivities by Merton76 model using finite differences

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD(Rate,AssetPrice,
Settle,ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD( ___ ,Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD(Rate,AssetPrice, Settle,ExerciseDates,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)` computes a vanilla European or American option price and sensitivities by the Merton76 model, using the Crank-Nicolson Adams-Bashforth (CNAB) IMEX method.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,PriceGrid,AssetPrices,Times] = optSensByMertonFD( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Price and Sensitivities for an American Option Using the Merton Model

Define the option variables and Merton model parameters.

```
AssetPrice = 90;
Strike = 100;
Rate = 0.06;
DividendYield = 0.1;
Settle = datetime(2018,1,1);
ExerciseDates = datetime(2018,4,2);

Sigma = 0.40;
MeanJ = -0.10;
JumpVol = 0.01;
JumpFreq = 1.00;
```

Compute the American call option price and sensitivities using the finite differences method.

```
OptSpec = 'Call';

[Price, Delta, Gamma, Rho, Theta, Vega] = optSensByMertonFD(Rate, AssetPrice, Settle, ExerciseDa
Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'AmericanOpt', 1,...
'OutSpec', ["Price" "Delta" "Gamma" "Rho" "Theta" "Vega"])
```

```
Price = 3.4551

Delta = 0.3211

Gamma = 0.0195

Rho = 5.6610

Theta = -11.9877

Vega = 15.5156
```

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as a scalar numeric.

Data Types: `double`

`Settle` — Option settlement date

datetime scalar | string scalar | date character vector

Option settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optSensByMertonFD` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a scalar date. For a European option, `ExerciseDates` contains only one value: the option expiry date.
- For an American option, use a 1-by-2 vector of dates to specify the exercise date boundaries. An American option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, then the option can be exercised between `Settle` date and the single listed value in `ExerciseDates`.

  To support existing code, `optSensByMertonFD` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with value of `'call'` or `'put'` | string array with value of `"call"` or `"put"`

Definition of the option, specified as a scalar using a character vector or string array with a value of `'call'` or `'put'`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`Sigma` — Volatility of underlying asset
scalar numeric

Volatility of the underling asset, specified as a scalar numeric.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
scalar decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with the mean (`log`(1+`MeanJ`)-0.5*`JumpVol`^2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+*J*)
scalar decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
scalar numeric

Annual frequency of the Poisson jump process, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceGrid] = optByMertonFD(Rate,AssetPrice,Settle,ExerciseDates,OptSpec,Strike,MeanJ,JumpVol,JumpFreq,'Basis',7,'OutSpec','delta')`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | scalar numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric.

Note If you enter a value for `DividendYield`, then set `DividendAmounts` and `ExDividendDates = [ ]` or do not enter them. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`DividendAmounts` — Cash dividend amounts
`[ ]` (default) | vector

Cash dividend amounts, specified as the comma-separated pair consisting of `'DividendAmounts'` and an `NDIV`-by-`1` vector.

Note Each dividend amount must have a corresponding ex-dividend date. If you enter values for `DividendAmounts` and `ExDividendDates`, then set `DividendYield = 0`.

Data Types: `double`

`ExDividendDates` — Ex-dividend dates
`[]` (default) | datetime array | string array | date character vector

Ex-dividend dates, specified as the comma-separated pair consisting of `'ExDividendDates'` and an `NDIV`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByMertonFD` also accepts serial date numbers as inputs, but they are not recommended.

`AssetPriceMax` — Maximum price for price grid boundary
if unspecified, value is calculated based on asset price distribution at maturity (default) | positive scalar numeric

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a positive scalar numeric.

Data Types: `double`

`AssetGridSize` — Size of asset grid for the finite difference grid
`400` (default) | scalar numeric

Size of the asset grid for finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a scalar numeric.

Data Types: `double`

`TimeGridSize` — Number of nodes of time grid for the finite difference grid
`100` (default) | positive numeric scalar

Number of nodes of the time grid for finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive numeric scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European) (default) | scalar with value of `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of these values:

- `0` — European
- `1` — American

Data Types: `double`

`OutSpec` — Define outputs
`['price']` (default) | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'rho'`, and `'theta'` | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, and `"theta"`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` string array or cell array of character vectors with supported values.

Example: `OutSpec = ['price','delta','gamma','vega','rho','theta']`

Data Types: `string` | `cell`

Output Arguments

`PriceSens` — Option price or sensitivities
numeric

Option price or sensitivities, returned as a numeric. The name-value pair argument `OutSpec` determines the types and order of the outputs.

`PriceGrid` — Grid containing prices calculated by the finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `AssetGridSize` × `TimeGridSize`. The number of columns is not necessarily equal to the `TimeGridSize` because exercise and ex-dividend dates are added to the time grid. `PriceGrid(:, :, end)` contains the price for $t = 0$.

`AssetPrices` — Prices of the asset
vector

Prices of the asset corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times
vector

Times corresponding to the second dimension of `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Merton Jump Diffusion Model

The Merton jump diffusion model [2] extends the Black-Scholes model by using the Poisson process to include jump diffusion parameters in the modeling of sudden asset price movements (both up and down).

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where:

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where `ln`$(1+J)$ is normally distributed with mean $\ln(1+\mu_J)-\frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}}\exp\left\{\frac{-\left[\ln(1+J)-\left(\ln(1+\mu_J)-\frac{\delta^2}{2}\right]\right]^2}{2\delta^2}\right\}$$

where:

μ_J is the mean of J for $(\mu_J > -1)$.

δ is the standard deviation of `ln`$(1+J)$ for $(\delta \geq 0)$.

λ_p is the annual frequency (intensity) of Poisson process $P_t$for $(\lambda_p \geq 0)$.

σ is the volatility of the asset price for $(\sigma > 0)$.

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByMertonFD` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByMertonFFT

Option price by Merton76 model using FFT and FRFT

Syntax

```
[Price,StrikeOut] = optByMertonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,
Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[Price,StrikeOut] = optByMertonFFT( ___ ,Name,Value)
```

Description

`[Price,StrikeOut] = optByMertonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec, Strike,Sigma,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price by Merton76 model, using Carr-Madan FFT and Chourdakis FRFT methods.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,StrikeOut] = optByMertonFFT( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Price Surface Using the Merton76 Model

Use `optByMertonFFT` to calibrate the FFT strike grid, compute option prices, and plot an option price surface.

Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option prices and also output the corresponding strikes. If the `Strike` input is empty (`[]`), option prices will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as `exp(log-strike grid)`, where each column of the log-strike grid has `NumFFT` points with `LogStrikeStep` spacing that are roughly centered around each element of

log(AssetPrice). The default value for NumFFT is 2^12. In addition to the prices in the first output, the optional last output contains the corresponding strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified (will use the entire FFT strike grid)

% Compute option prices for the entire FFT strike grid
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);

% Show the lowest and highest strike values on the FFT strike grid
format
MinStrike = Kout(1) % Lowest possible strike in the current FFT strike grid

MinStrike = 2.9205e-135

MaxStrike = Kout(end) % Highest possible strike in the current FFT strike grid

MaxStrike = 1.8798e+138

% Show a subset of the strikes and corresponding option prices
Range = (2046:2052);
[Kout(Range) Call(Range)]

ans = 7×2

   50.4929   29.4645
   58.8640   21.2601
   68.6231   12.2218
   80.0000    4.5600
   93.2631    0.9579
  108.7251    0.1236
  126.7505    0.0113
```

Change the Number of FFT (or FRFT) Points and Compare with optByMertonNI

Try a different number of FFT(or FRFT) points, and compare the results with direct numerical integration. Unlike optByMertonFFT, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the optByMertonNI function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by optByMertonNI can serve as a benchmark for adjusting the settings for optByMertonFFT.

```
% Try a smaller number of FFT (or FRFT) points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
```

```
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7×4 table
    Strike     CallFFT       CallNI         Error
    ______    _________    ___________    _________

    12.696       66.328         66.696      0.36786
    23.449       55.922         56.103      0.18071
    43.312       36.481         36.536     0.055233
        80       4.7387           4.56      0.17867
    147.76     0.046602      0.0008089     0.045793
    272.93    0.0092842    -7.0709e-08    0.0092842
    504.11    0.0024041    -2.4515e-07    0.0024044
```

Make Further Adjustments to FFT (or FRFT)

If the values in the output `CallFFT` are significantly different from those in `CallNI`, try making adjustments to `optByMertonFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` * `CharacteristicFcnStep`) is 2*pi/ `NumFFT`, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);

% Compare with numerical integration method
Strike = Kout(Range);
CallFFT = Call(Range);
CallNI = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield);
Error = abs(CallFFT-CallNI);
table(Strike, CallFFT, CallNI, Error)
```

```
ans=7×4 table
    Strike    CallFFT    CallNI      Error
    ______    _______    ______    __________

    79.76      4.674      4.674    4.9664e-10
    79.84     4.6358     4.6358    4.9651e-10
    79.92     4.5978     4.5978    4.9642e-10
       80       4.56       4.56    4.9641e-10
    80.08     4.5224     4.5224    4.9642e-10
    80.16      4.485      4.485     4.965e-10
    80.24     4.4478     4.4478     4.966e-10
```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

Compute Option Price for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Call = 4.5600
```

Compute the Option Prices for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Call = 5×1

    6.7411
    5.5762
    4.5600
    3.6891
    2.9551
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001) % Five values in vector output
```

```
Call = 5×1

    8.5589
    8.9439
    9.2316
```

```
    9.4653
    9.6565
```

Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes`-by-`NMaturities` matrices. In this case, they are square matrices.

```
[Call, Kout] = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

```
Call = 5×5

    8.5589    9.9675   11.1343   12.1492   13.0464
    7.4844    8.9439   10.1481   11.1939   12.1181
    6.5125    8.0023    9.2316   10.2999   11.2449
    5.6401    7.1402    8.3827    9.4653   10.4249
    4.8630    6.3545    7.5990    8.6881    9.6565

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

```
Call = 5×6

    6.7411    8.5589    9.9675   11.1343   12.1492   13.0464
    5.5762    7.4844    8.9439   10.1481   11.1939   12.1181
    4.5600    6.5125    8.0023    9.2316   10.2999   11.2449
    3.6891    5.6401    7.1402    8.3827    9.4653   10.4249
    2.9551    4.8630    6.3545    7.5990    8.6881    9.6565
```

Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByMertonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'ExpandOutput', true) % (5 x 4) matrix output
```

```
Call = 5×4

    3.4187    5.6579    8.5589   12.0417
    2.8538    4.8401    7.4844   10.7343
    2.3718    4.1205    6.5125    9.5230
    1.9635    3.4922    5.6401    8.4090
    1.6198    2.9476    4.8630    7.3921
```

Plot an Option Price Surface

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to `"true"` to output the surface as a `NStrikes`-by-`NMaturities` matrix.

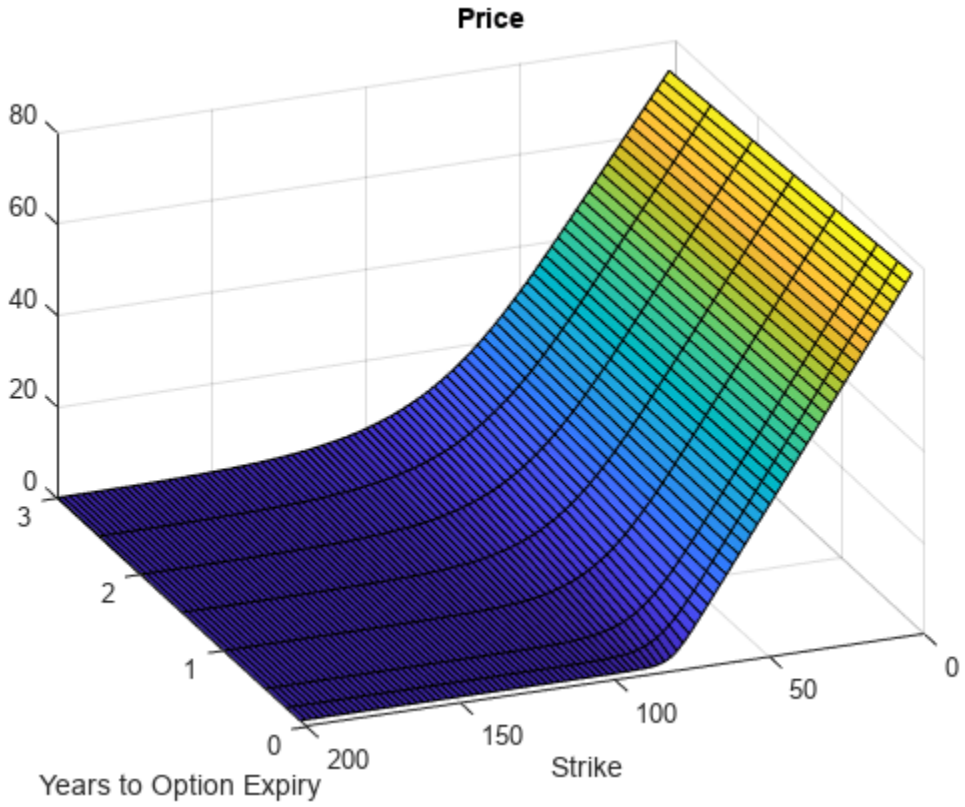
```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

Call = optByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'NumFFT', NumFFT, ...
    'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, 'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);
```



Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optByMertonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optByMertonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has`'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Sigma` — Volatility of underlying asset
numeric

Volatility of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol`^2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log`(1+*J*)
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,StrikeOut] = optByMertonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: `double`

`DampingFactor` — Damping factor for Carr-Madan formulation
`1.5` (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of `'DampingFactor'` and a scalar numeric value.

Data Types: `double`

`Quadrature` — Type of quadrature
`"simpson"` (default) | character vector with values: `'simpson'` or `'trapezoidal'` | string array with values: `"simpson"` or `"trapezoidal"`

Type of quadrature, specified as the comma-separated pair consisting of `'Quadrature'` and a single character vector or string array with a value of `'simpson'` or `'trapezoidal'`.

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. If `Strike` is empty, `NRows` is equal to `NumFFT`. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`Price` — Option prices
numeric

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

`StrikeOut` — Strikes corresponding to `Price`
numeric

Strikes corresponding to `Price`, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

μ_J is the mean of J for (μ_J > -1).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

The characteristic function $f_{Merton76_j}(\phi)$ for $j = 1$ (asset prices measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau \left(1 + \mu_j\right)^{m_j + \frac{1}{2}} \left[\left(1 + \mu_j\right)^{i\phi} e^{\delta^2 \left(m_j i\phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i\phi \right)$$

where for $j = 1, 2$:

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2}{2} \tau \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

ϕ is the characteristic function variable.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^\infty \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity ($\tau = T-t$).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number ($i^2 = -1$)

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where $\phi = (u - (\alpha+1)i)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration, u, is discretized into `NumFFT`(N) points with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration, u_j(for $j = 1,2,3,\ldots,N$), has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid, k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

Δu is the step size of discretized characteristic function variable for integration.

Δk is the step size of discretized log-strike.

N is the number of FFT or FRFT points.

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByMertonFFT` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByMertonFFT

Option price and sensitivities by Merton76 model using FFT and FRFT

Syntax

```
[PriceSens,StrikeOut] = optSensByMertonFFT(Rate,AssetPrice,Settle,Maturity,
OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)
[PriceSens,StrikeOut] = optSensByMertonFFT( ___ ,Name,Value)
```

Description

`[PriceSens,StrikeOut] = optSensByMertonFFT(Rate,AssetPrice,Settle,Maturity, OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price and sensitivities by Merton76 model, using Carr-Madan FFT and Chourdakis FRFT methods.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,StrikeOut] = optSensByMertonFFT( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Sensitivity Surface Using the Merton76 Model

Use `optSensByMertonFFT` to calibrate the FFT strike grid for sensitivities, compute option sensitivities, and plot option sensitivity surfaces.

Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Prices for the Entire FFT (or FRFT) Strike Grid, Without Specifying "Strike"

Compute option sensitivities and also output the corresponding strikes. If the `Strike` input is empty (`[]`), option sensitivities will be computed on the entire FFT (or FRFT) strike grid. The FFT (or FRFT) strike grid is determined as `exp(log-strike grid)`, where each column of the log-strike grid has `NumFFT` points with `LogStrikeStep` spacing that are roughly centered around each

element of `log(AssetPrice)`. The default value for `NumFFT` is 2^12. In addition to the sensitivities in the first output, the optional last output contains the corresponding strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = []; % Strike is not specified

[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta");

% Show the lowest and highest strike values on the FFT strike grid
format
[Kout(1) Kout(end)]
```

```
ans = 1×2
10^138 ×

    0.0000    1.8798
```

```
% Show a subset of the strikes and corresponding option sensitivities
Range = (2046:2052);
[Kout(Range) Delta(Range)]
```

```
ans = 7×2

   50.4929    0.9895
   58.8640    0.9801
   68.6231    0.8816
   80.0000    0.5283
   93.2631    0.1551
  108.7251    0.0241
  126.7505    0.0025
```

Change the Number of FFT (or FRFT) Points and Compare with optSensByMertonNI

Try a different number of FFT (or FRFT) points, and compare the results with numerical integration. Unlike `optSensByMertonFFT`, which uses FFT (or FRFT) techniques for fast computation across the whole range of strikes, the `optSensByMertonNI` function uses direct numerical integration and it is typically slower, especially for multiple strikes. However, the values computed by `optSensByMertonNI` can serve as a benchmark for adjusting the settings for `optSensByMertonFFT`.

```
% Try a smaller number of FFT points
% (e.g. for faster performance or smaller memory footprint)
NumFFT = 2^10; % Smaller than the default value of 2^12
Strike = []; % Strike is not specified (will use the entire FFT strike grid)
[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT);

% Compare with numerical integration method
Range = (510:516);
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
```

```
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)
```

```
ans=7×4 table
    Strike     DeltaFFT      DeltaNI        Error
    ______    __________    __________    _________

    12.696       0.89726       0.99002      0.092766
    23.449       0.93421       0.99002       0.05581
    43.312       0.94691       0.99001      0.043093
        80       0.50983       0.52827      0.018446
    147.76      0.004147    0.00019101      0.003956
    272.93      0.001071     1.547e-09      0.001071
    504.11    0.00030521    5.7578e-10    0.00030521
```

Make Further Adjustments to FFT (or FRFT)

If the values in the output `DeltaFFT` are significantly different from those in `DeltaNI`, try making adjustments to `optSensByMertonFFT` settings, such as `CharacteristicFcnStep`, `LogStrikeStep`, `NumFFT`, `DampingFactor`, and so on. Note that if (`LogStrikeStep` * `CharacteristicFcnStep`) is 2*pi/ `NumFFT`, FFT is used. Otherwise, FRFT is used.

```
Strike = []; % Strike is not specified (will use the entire FFT or FRFT strike grid)
[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001);

% Compare with numerical integration method
Strike = Kout(Range);
DeltaFFT = Delta(Range);
DeltaNI = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta");
Error = abs(DeltaFFT-DeltaNI);
table(Strike, DeltaFFT, DeltaNI, Error)
```

```
ans=7×4 table
    Strike    DeltaFFT    DeltaNI      Error
    ______    ________    _______    __________

    79.76     0.53701     0.53701    5.6407e-12
    79.84      0.5341      0.5341    5.3257e-12
    79.92     0.53119     0.53119    5.0099e-12
       80     0.52827     0.52827    4.6956e-12

    80.16     0.52245     0.52245    4.0653e-12
    80.24     0.51953     0.51953    3.7503e-12
```

```
% Save the final FFT (or FRFT) strike grid for future reference. For
% example, it provides information about the range of Strike inputs for
% which the FFT (or FRFT) operation is valid.
FFTStrikeGrid = Kout;
MinStrike = FFTStrikeGrid(1) % Strike cannot be less than MinStrike
```

```
MinStrike = 47.9437
```

```
MaxStrike = FFTStrikeGrid(end) % Strike cannot be greater than MaxStrike
```

```
MaxStrike = 133.3566
```

Compute the Option Sensitivity for a Single Strike

Once the desired FFT (or FRFT) settings are determined, use the `Strike` input to specify the strikes rather than providing an empty array. If the specified strikes do not match a value on the FFT (or FRFT) strike grid, the outputs are interpolated on the specified strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Delta = 0.5283
```

Compute the Option Sensitivities for a Vector of Strikes

Use the `Strike` input to specify the strikes.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001)
```

```
Delta = 5×1

    0.6727
    0.6013
    0.5283
    0.4565
    0.3883
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001) % Five values in vector output
```

```
Delta = 5×1
```

```
    0.6419
    0.5907
    0.5565
    0.5311
    0.5110
```

Expand the Outputs for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the outputs into `NStrikes`-by-`NMaturities` matrices. In this case, they are square matrices.

```
[Delta, Kout] = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 5) matrix output
```

```
Delta = 5×5

    0.6419    0.6305    0.6245    0.6204    0.6173
    0.5922    0.5907    0.5905    0.5905    0.5905
    0.5422    0.5507    0.5565    0.5607    0.5637
    0.4927    0.5112    0.5229    0.5311    0.5372
    0.4447    0.4725    0.4898    0.5020    0.5110

Kout = 5×5

    76    76    76    76    76
    78    78    78    78    78
    80    80    80    80    80
    82    82    82    82    82
    84    84    84    84    84
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonFFT(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 6) matrix output
```

```
Delta = 5×6

    0.6727    0.6419    0.6305    0.6245    0.6204    0.6173
    0.6013    0.5922    0.5907    0.5905    0.5905    0.5905
    0.5283    0.5422    0.5507    0.5565    0.5607    0.5637
    0.4565    0.4927    0.5112    0.5229    0.5311    0.5372
    0.3883    0.4447    0.4725    0.4898    0.5020    0.5110
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonFFT(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, 'OutSpec', "delta", ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, ...
    'LogStrikeStep', 0.001, 'ExpandOutput', true) % (5 x 4) matrix output
```

```
Delta = 5×4

    0.3796    0.5157    0.6419    0.7472
    0.3315    0.4637    0.5922    0.7043
    0.2874    0.4137    0.5422    0.6592
    0.2474    0.3664    0.4927    0.6128
    0.2117    0.3224    0.4447    0.5657
```

Plot Option Sensitivity Surfaces

Use the `Strike` input to specify the strikes. Increase the value for `NumFFT` to support a wider range of strikes. Also, the `Maturity` input can be a vector. Set `ExpandOutput` to `"true"` to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

% Increase 'NumFFT' to support a wider range of strikes
NumFFT = 2^13;

[Delta, Gamma, Rho, Theta, Vega] = optSensByMertonFFT(...
    Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'NumFFT', NumFFT, 'CharacteristicFcnStep', 0.065, 'LogStrikeStep', 0.001, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega"], ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optSensByMertonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByMertonFFT` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

If this input is an empty array (`[]`), option prices are computed on the entire FFT (or FRFT) strike grid, which is determined as `exp(log-strike grid)`. Each column of the log-strike grid has`'NumFFT'` points with `'LogStrikeStep'` spacing that are roughly centered around each element of `log(AssetPrice)`.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Sigma` — Volatility of underlying asset
numeric

Volatility of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol^2`) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+J)`
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[PriceSens,StrikeOut] = optSensByMertonFFT(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`OutSpec` — Define outputs
`["price"]` (default) | string array with values `"price"`, `"delta"`, `"gamma"`, `"vega"`, `"rho"`, and `"theta"` | cell array of character vectors with values `'price'`, `'delta'`, `'gamma'`, `'vega'`, `'rho'`, and `'theta'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` string array or cell array of character vectors with supported values.

Note `"vega"` is the sensitivity with respect the initial volatility sqrt(`V0`).

Example: `OutSpec = ["price","delta","gamma","vega","rho","theta"]`

Data Types: `string` | `cell`

`NumFFT` — Number of grid points in the characteristic function variable
`4096` (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of `'NumFFT'` and a scalar numeric value.

Data Types: `double`

`CharacteristicFcnStep` — Characteristic function variable grid spacing
`0.01` (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of `'CharacteristicFcnStep'` and a scalar numeric value.

Data Types: `double`

`LogStrikeStep` — Log-strike grid spacing
`2*pi/NumFFT/CharacteristicFcnStep` (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of `'LogStrikeStep'` and a scalar numeric value.

Note If (`LogStrikeStep*CharacteristicFcnStep`) is `2*pi/NumFFT`, FFT is used. Otherwise, FRFT is used.

Data Types: double

DampingFactor — Damping factor for Carr-Madan formulation
1.5 (default) | numeric

Damping factor for Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

Quadrature — Type of quadrature
"simpson" (default) | character vector with values: 'simpson' or 'trapezoidal' | string array with values: "simpson" or "trapezoidal"

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a single character vector or string array with a value of 'simpson' or 'trapezoidal'.

Data Types: char | string

ExpandOutput — Flag to expand the outputs
false (outputs are NINST-by-1 vectors) (default) | logical with value of true or false

Flag to expand the outputs, specified as the comma-separated pair consisting of 'ExpandOutput' and a logical:

- true — If true, the outputs are NRows-by- NColumns matrices. NRows is the number of strikes for each column and it is determined by the Strike input. For example, Strike can be a NRows-by-1 vector, or a NRows-by-NColumns matrix. If Strike is empty, NRows is equal to NumFFT. NColumns is determined by the sizes of AssetPrice, Settle, Maturity, and OptSpec, which must all be either scalar or NColumns-by-1 vectors.
- false — If false, the outputs are NINST-by-1 vectors. Also, the inputs Strike, AssetPrice, Settle, Maturity, and OptSpec must all be either scalar or NINST-by-1 vectors.

Data Types: logical

Output Arguments

PriceSens — Option prices or sensitivities
numeric

Option prices or sensitivities, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput. The name-value pair argument OutSpec determines the types and order of the outputs.

StrikeOut — Strikes corresponding to Price
numeric

Strikes corresponding to Price, returned as a NINST-by-1, or NRows-by-NColumns, depending on ExpandOutput.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j)S_t dt + \sigma S_t dW_t + JS_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

μ_J is the mean of J for ($\mu_J > -1$).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process $P_t$for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

The characteristic function $f_{Merton76_j}(\phi)$ for $j = 1$ (asset prices measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j}\exp\left(\lambda_p\tau\left(1+\mu_j\right)^{m_j} + \frac{1}{2}\left[\left(1+\mu_j\right)^{i\phi}e^{\delta^2\left(m_j i\phi + \frac{(i\phi)^2}{2}\right)} - 1\right] - \lambda_p\tau\mu_j i\phi\right)$$

where for $j = 1, 2$:

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS2}(\phi) = \exp\left(i\phi\left[\ln S_t + \left(r - q - \frac{\sigma^2}{2}\right)\tau\right] - \frac{\phi^2\sigma^2}{2}\tau\right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

ϕ is the characteristic function variable.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

Carr-Madan Formulation

The Carr and Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities P_1 and P_2 as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi}\int_0^\infty \mathrm{Re}\left[e^{-iuk}\psi(u)\right]du$$

$$\psi(u) = \frac{e^{-r\tau}f_2(\phi = (u - (\alpha+1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha+1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

τ is time to maturity ($\tau = T - t$).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number ($i^2 = -1$).

ϕ is the characteristic function variable.

α is the damping factor.

u is the characteristic function variable for integration, where $\phi = (u - (\alpha+1)i)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration, u, is discretized into `NumFFT`(N) point with the step size `CharacteristicFcnStep` (Δu), and the log-strike k is discretized into N points with the step size `LogStrikeStep`(Δk).

The discretized characteristic function variable for integration, u_j(for j = 1,2,3,...,N), has a minimum value of 0 and a maximum value of (N-1) (Δu), and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid, k_n(for n = 1, 2, 3, N) is approximately centered around `ln`(S_t), with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^{N} \mathrm{Re}\left[e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iuj\left[\frac{N\Delta k}{2} - \ln(S_t)\right]} \psi(u_j)\right] w_j$$

where

Δu is the step size of discretized characteristic function variable for integration.

Δk is the step size of discretized log-strike.

N is the number of FFT or FRFT points.

w_j is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if Δk and Δu are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

otherwise, the functions use the FRFT method described in Chourdakis (2005).

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByMertonFFT` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optByMertonNI

Option price by Merton76 model using numerical integration

Syntax

```
Price = optByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,
MeanJ,JumpVol,JumpFreq)
Price = optByMertonNI( ___ ,Name,Value)
```

Description

`Price = optByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma, MeanJ,JumpVol,JumpFreq)` computes vanilla European option price by the Merton76 model, using numerical integration.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = optByMertonNI( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Price Surface Using the Merton76 Model

`optByMertonNI` uses numerical integration to compute option prices and then plot an option price surface.

Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Price for a Single Strike

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield)
```

```
Call = 4.5600
```

Compute the Option Prices for a Vector of Strikes

The `Strike` input can be a vector.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield)
```

```
Call = 5×1

    6.7410
    5.5762
    4.5600
    3.6891
    2.9551
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield)
```

```
Call = 5×1

    8.5589
    8.9439
    9.2316
    9.4653
    9.6565

    % Five values in vector output
```

Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes`-by-`NMaturities` matrix. In this case, it is a square matrix.

```
Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 5) matrix output
```

```
Call = 5×5

    8.5589    9.9675   11.1343   12.1492   13.0464
```

```
    7.4844    8.9439   10.1481   11.1939   12.1181
    6.5125    8.0023    9.2316   10.2999   11.2449
    5.6401    7.1402    8.3827    9.4653   10.4249
    4.8630    6.3545    7.5990    8.6881    9.6565
```

Compute the Option Prices for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 6) matrix output
```

```
Call = 5×6

    6.7410    8.5589    9.9675   11.1343   12.1492   13.0464
    5.5762    7.4844    8.9439   10.1481   11.1939   12.1181
    4.5600    6.5125    8.0023    9.2316   10.2999   11.2449

```

Compute the Option Prices for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Call = optByMertonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true) % (5 x 4) matrix output
```

```
Call = 5×4

    3.4186    5.6579    8.5589   12.0417
    2.8538    4.8401    7.4844   10.7343
    2.3718    4.1205    6.5125    9.5230
    1.9635    3.4922    5.6401    8.4090
    1.6198    2.9476    4.8630    7.3921
```

Plot an Option Price Surface

The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to `"true"` to output the surface as a `NStrikes`-by-`NMaturities` matrix.

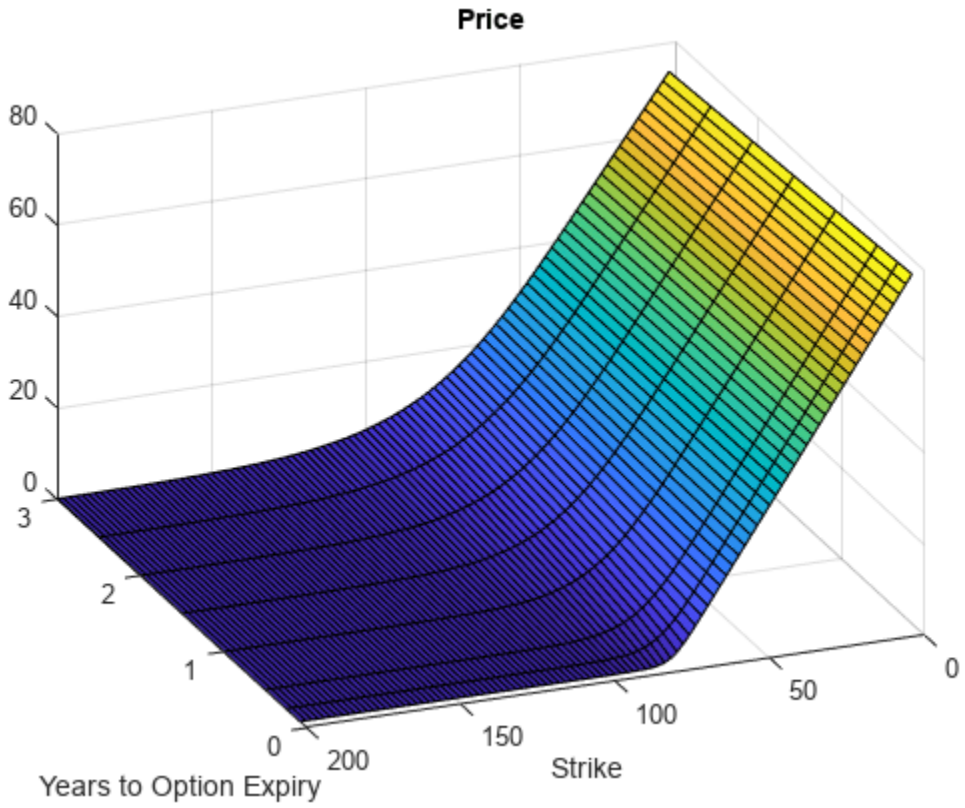
```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
```

```
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

Call = optByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'ExpandOutput', true);

[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Call);
title('Price');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
zlim([0 80]);
```



Input Arguments

Rate — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

AssetPrice — Current underlying asset price
numeric

Current underlying asset price, specified as numeric value using a scalar or a NINST-by-1 or NColumns-by-1 vector.

For more information on the proper dimensions for AssetPrice, see the name-value pair argument ExpandOutput.

Data Types: double

Settle — Option settlement date
datetime array | string array | date character vector

Option settlement date, specified as a NINST-by-1 or NColumns-by-1 vector using a datetime array, string array, or date character vectors. The Settle date must be before the Maturity date.

To support existing code, optByMertonNI also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for Settle, see the name-value pair argument ExpandOutput.

Maturity — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a NINST-by-1 or NColumns-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optByMertonNI also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for Maturity, see the name-value pair argument ExpandOutput.

OptSpec — Definition of option
cell array of character vector with values 'call' or 'put' | string array with values "call" or "put"

Definition of the option, specified as a NINST-by-1 or NColumns-by-1 vector using a cell array of character vectors or string arrays with values 'call' or 'put'.

For more information on the proper dimensions for OptSpec, see the name-value pair argument ExpandOutput.

Data Types: cell | string

Strike — Option strike price value
numeric

Option strike price value, specified as a NINST-by-1, NRows-by-1, NRows-by-NColumns vector of strike prices.

For more information on the proper dimensions for Strike, see the name-value pair argument ExpandOutput.

Data Types: double

`Sigma` — Volatility of underlying asset

numeric

Volatility of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size

decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol^2`) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+`*J*`)`

decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process

numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ,JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument

`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`DividendYield` — Continuously compounded underlying asset yield
`0` (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of `'DividendYield'` and a scalar numeric value.

Data Types: `double`

`AbsTol` — Absolute error tolerance for numerical integration
`1e-10` (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of `'AbsTol'` and a scalar numeric value.

Data Types: `double`

`RelTol` — Relative error tolerance for numerical integration
`1e-6` (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of `'RelTol'` and a scalar numeric value.

Data Types: `double`

`IntegrationRange` — Numerical integration range used to approximate continuous integral over `[0 Inf]`
`[1e-9 Inf]` (default) | vector

Numerical integration range used to approximate the continuous integral over `[0 Inf]`, specified as the comma-separated pair consisting of `'IntegrationRange'` and a 1-by-2 vector representing `[LowerLimit UpperLimit]`.

Data Types: `double`

`Framework` — Framework for computing option prices and sensitivities using numerical integration of models
`"heston1993"` (default) | string with values `"heston1993"` or `"lewis2001"` | character vector with values `'heston1993'` or `'lewis2001'`

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of `'Framework'` and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`Price` — Option prices
numeric

Option prices, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

μ_J is the mean of J for (μ_J > -1).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

The characteristic function $f_{Merton76_j}(\phi)$ for $j = 1$ (asset prices measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau \left(1 + \mu_j\right)^{m_j + \frac{1}{2}} \left[\left(1 + \mu_j\right)^{i\phi} e^{\delta^2 \left(m_j i\phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i\phi \right)$$

where for $j = 1, 2$:

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2}{2} \tau \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

ϕ is the characteristic function variable

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \mathrm{Re}\left[\frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity ($\tau = T - t$).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number ($i^2 = -1$)

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j (j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

This framework is chosen with the default value “`Heston1993`” for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K}e^{-\tau t}}{\pi}\int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right)\frac{1}{u^2 + \frac{1}{4}}\right]du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K

i is a unit imaginary number (i^2= -1)

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

This framework is chosen with the value “`Lewis2001`” for the `Framework` name-value pair argument.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optByMertonNI` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optSensByMertonNI

Option price and sensitivities by Merton76 model using numerical integration

Syntax

```
PriceSens = optSensByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,
Sigma,MeanJ,JumpVol,JumpFreq)
PriceSens = optSensByMertonNI( ___ ,Name,Value)
```

Description

`PriceSens = optSensByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike, Sigma,MeanJ,JumpVol,JumpFreq)` computes vanilla European option price and sensitivities by the Merton76 model, using numerical integration.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optSensByMertonNI( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Workflow for Plotting an Option Sensitivity Surface Using the Merton76 Model

`optSensByMertonNI` uses numerical integration to compute option sensitivities and then plot option sensitivity surfaces.

Define Option Variables and Merton76 Model Parameters

```
AssetPrice = 80;
Rate = 0.03;
DividendYield = 0.02;
OptSpec = 'call';

Sigma = 0.16;
MeanJ = 0.02;
JumpVol = 0.08;
JumpFreq = 2;
```

Compute the Option Sensitivity for a Single Strike

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = 80;

Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
```

```
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta")

Delta = 0.5283
```

Compute the Option Sensitivities for a Vector of Strikes

The `Strike` input can be a vector.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 6);
Strike = (76:2:84)';

Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta")

Delta = 5×1

    0.6727
    0.6013
    0.5283
    0.4565
    0.3883
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of the Same Lengths

Use the `Strike` input to specify the strikes. Also, the `Maturity` input can be a vector, but it must match the length of the `Strike` vector if the `ExpandOutput` name-value pair argument is not set to `"true"`.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, [12 18 24 30 36]); % Five maturities
Strike = [76 78 80 82 84]'; % Five strikes

Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta")

Delta = 5×1

    0.6419
    0.5907
    0.5565
    0.5311
    0.5110

    % Five values in vector output
```

Expand the Output for a Surface

Set the `ExpandOutput` name-value pair argument to `"true"` to expand the output into a `NStrikes`-by-`NMaturities` matrix. In this case, it is a square matrix.

```
Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 5) matrix output

Delta = 5×5

    0.6419    0.6305    0.6245    0.6204    0.6173
    0.5922    0.5907    0.5905    0.5905    0.5905
    0.5422    0.5507    0.5565    0.5607    0.5637
    0.4927    0.5112    0.5229    0.5311    0.5372
    0.4447    0.4725    0.4898    0.5020    0.5110
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Dates of Different Lengths

When `ExpandOutput` is `"true"`, `NStrikes` do not have to match `NMaturities`. That is, the output `NStrikes`-by-`NMaturities` matrix can be rectangular.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*(0.5:0.5:3)'); % Six maturities
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonNI(Rate, AssetPrice, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true)  % (5 x 6) matrix output

Delta = 5×6

    0.6727    0.6419    0.6305    0.6245    0.6204    0.6173
    0.6013    0.5922    0.5907    0.5905    0.5905    0.5905
    0.5283    0.5422    0.5507    0.5565    0.5607    0.5637
    0.4565    0.4927    0.5112    0.5229    0.5311    0.5372
    0.3883    0.4447    0.4725    0.4898    0.5020    0.5110
```

Compute the Option Sensitivities for a Vector of Strikes and a Vector of Asset Prices

When `ExpandOutput` is `"true"`, the output can also be a `NStrikes`-by-`NAssetPrices` rectangular matrix by accepting a vector of asset prices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12); % Single maturity
ManyAssetPrices = [70 75 80 85]; % Four asset prices
Strike = (76:2:84)'; % Five strikes

Delta = optSensByMertonNI(Rate, ManyAssetPrices, Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', "delta", 'ExpandOutput', true) % (5 x 4) matrix output

Delta = 5×4

    0.3796    0.5157    0.6419    0.7472
    0.3315    0.4637    0.5922    0.7043
    0.2874    0.4137    0.5422    0.6592
    0.2474    0.3664    0.4927    0.6128
    0.2117    0.3224    0.4447    0.5657
```

Plot Option Sensitivity Surfaces

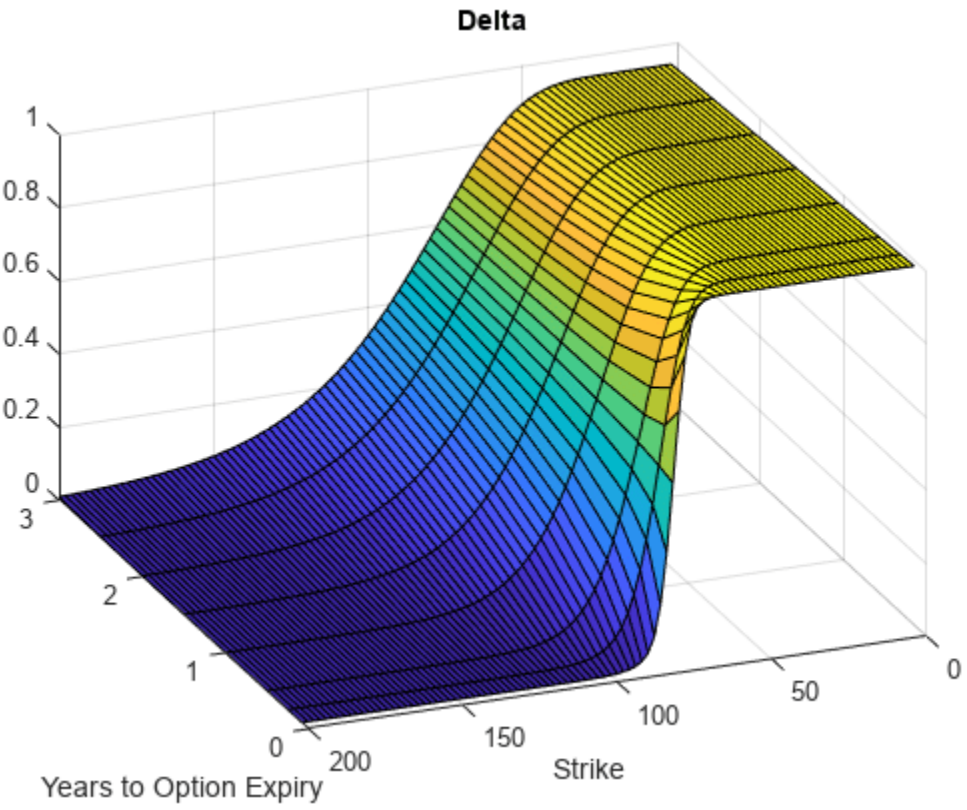
The `Strike` and `Maturity` inputs can be vectors. Set `ExpandOutput` to `"true"` to output the surfaces as `NStrikes`-by-`NMaturities` matrices.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle, 12*[1/12 0.25 (0.5:0.5:3)]');
Times = yearfrac(Settle, Maturity);
Strike = (2:2:200)';

[Delta, Gamma, Rho, Theta, Vega] = optSensByMertonNI(...
    Rate, AssetPrice,Settle, Maturity, OptSpec, Strike, ...
    Sigma, MeanJ, JumpVol, JumpFreq, 'DividendYield', DividendYield, ...
    'OutSpec', ["delta", "gamma", "rho", "theta", "vega"], ...
    'ExpandOutput', true);

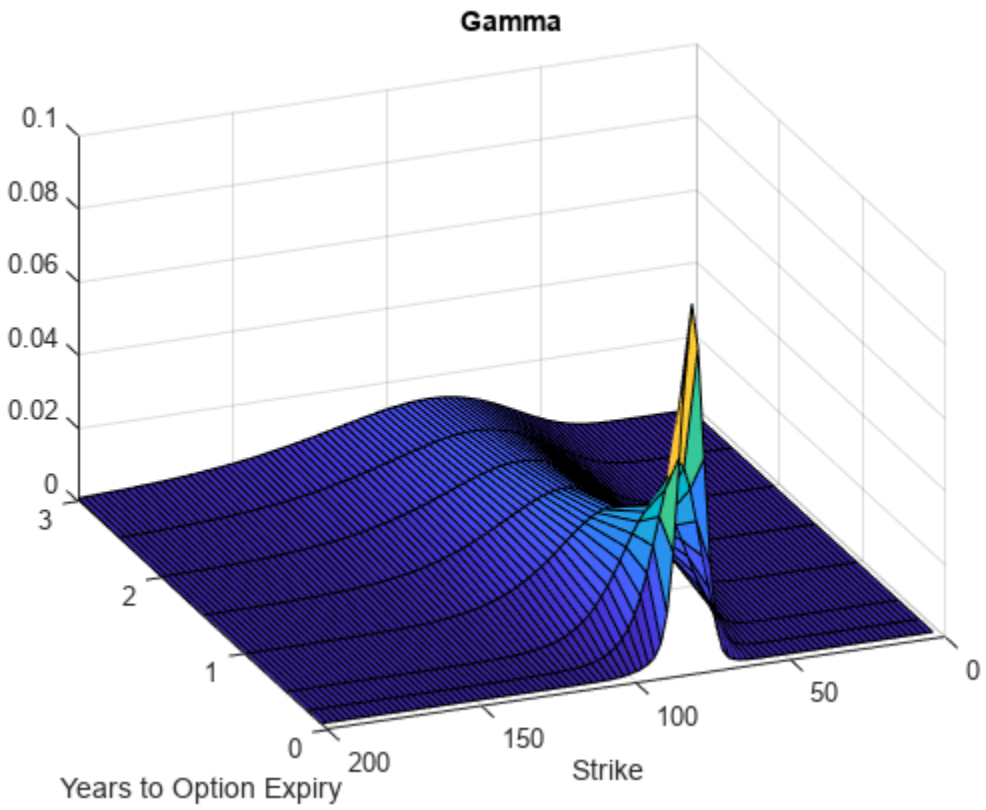
[X,Y] = meshgrid(Times,Strike);

figure;
surf(X,Y,Delta);
title('Delta');
xlabel('Years to Option Expiry');
ylabel('Strike');
view(-112,34);
xlim([0 Times(end)]);
```

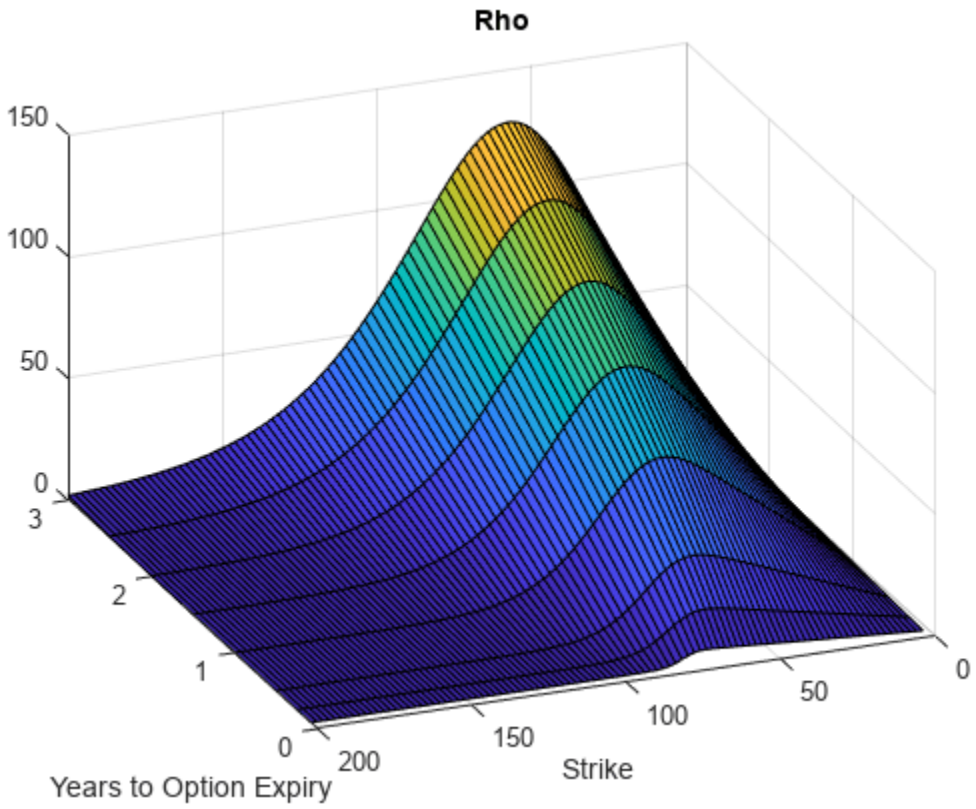


```
figure;
```

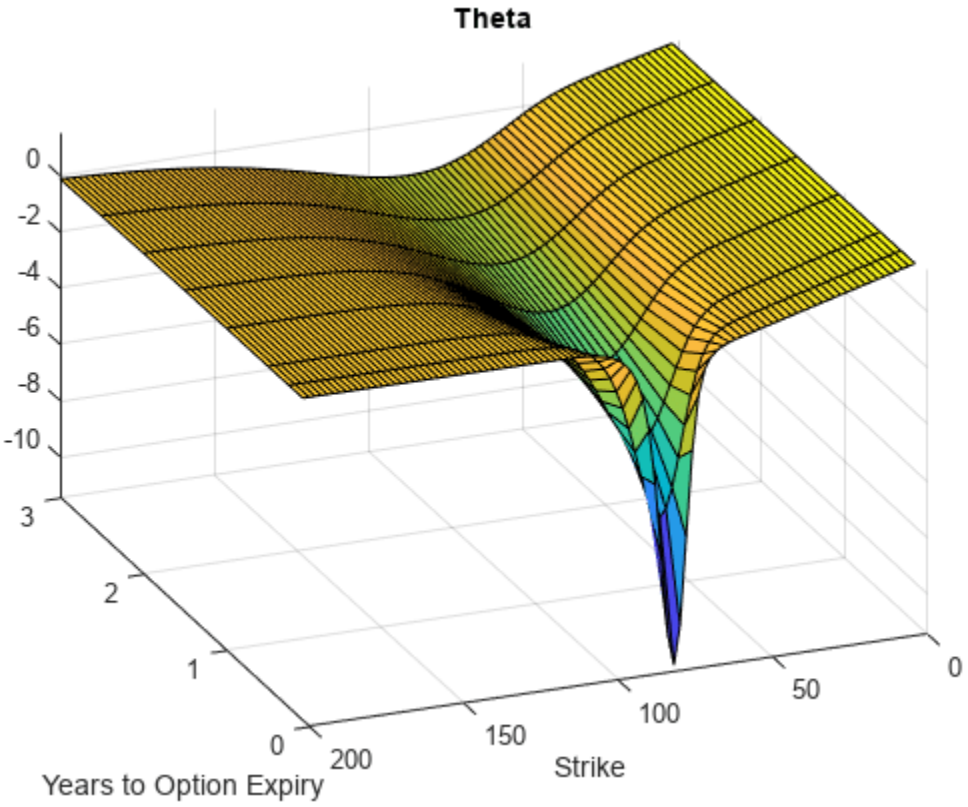
```
surf(X,Y,Gamma)
title('Gamma')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



```
figure;
surf(X,Y,Rho)
title('Rho')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



```
figure;
surf(X,Y,Theta)
title('Theta')
xlabel('Years to Option Expiry')
ylabel('Strike')
view(-112,34);
xlim([0 Times(end)]);
```



```
figure;

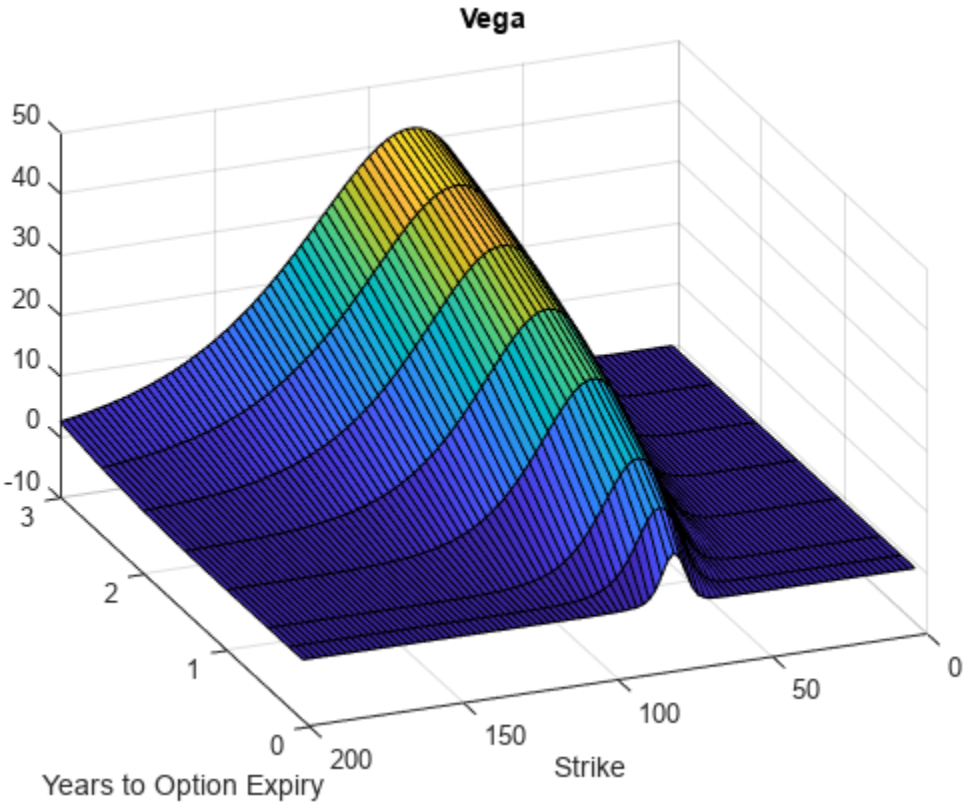
xlim([0 Times(end)]);
```



Input Arguments

`Rate` — Continuously compounded risk-free interest rate

decimal

Continuously compounded risk-free interest rate, specified as a scalar decimal value.

Data Types: `double`

`AssetPrice` — Current underlying asset price

numeric

Current underlying asset price, specified as numeric value using a scalar or a `NINST`-by-`1` or `NColumns`-by-`1` vector.

For more information on the proper dimensions for `AssetPrice`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Settle` — Option settlement date

datetime array | string array | date character vector

Option settlement date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date must be before the `Maturity` date.

To support existing code, `optSensByMertonNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Settle`, see the name-value pair argument `ExpandOutput`.

`Maturity` — Option maturity date
datetime array | string array | date character vector

Option maturity date, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optSensByMertonNI` also accepts serial date numbers as inputs, but they are not recommended.

For more information on the proper dimensions for `Maturity`, see the name-value pair argument `ExpandOutput`.

`OptSpec` — Definition of option
cell array of character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option, specified as a `NINST`-by-`1` or `NColumns`-by-`1` vector using a cell array of character vectors or string arrays with values `'call'` or `'put'`.

For more information on the proper dimensions for `OptSpec`, see the name-value pair argument `ExpandOutput`.

Data Types: `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a `NINST`-by-`1`, `NRows`-by-`1`, `NRows`-by-`NColumns` vector of strike prices.

For more information on the proper dimensions for `Strike`, see the name-value pair argument `ExpandOutput`.

Data Types: `double`

`Sigma` — Volatility of underlying asset
numeric

Volatility of the underling asset, specified as a scalar numeric value.

Data Types: `double`

`MeanJ` — Mean of the random percentage jump size
decimal

Mean of the random percentage jump size (*J*), specified as a scalar decimal value where `log`(1+*J*) is normally distributed with mean (`log`(1+`MeanJ`)-0.5*`JumpVol`^2) and the standard deviation `JumpVol`.

Data Types: `double`

`JumpVol` — Standard deviation of `log(1+`*`J`*`)`
decimal

Standard deviation of `log`(1+*J*) where `J` is the random percentage jump size, specified as a scalar decimal value.

Data Types: `double`

`JumpFreq` — Annual frequency of Poisson jump process
numeric

Annual frequency of Poisson jump process, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optSensByMertonNI(Rate,AssetPrice,Settle,Maturity,OptSpec,Strike,Sigma,MeanJ, JumpVol,JumpFreq,'Basis',7)`

`Basis` — Day-count basis of instrument
`0` (default) | numeric values: `0`,`1`, `2`, `3`, `4`, `6`, `7`, `8`, `9`, `10`, `11`, `12`, `13`

Day-count of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a scalar using a supported value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

DividendYield — Continuously compounded underlying asset yield
0 (default) | numeric

Continuously compounded underlying asset yield, specified as the comma-separated pair consisting of 'DividendYield' and a scalar numeric value.

Data Types: double

OutSpec — Define outputs
["price"] (default) | string array with values "price", "delta", "gamma", "vega", "rho", and "theta" | cell array of character vectors with values 'price', 'delta', 'gamma', 'vega', 'rho', and 'theta'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or a 1-by-NOUT string array or cell array of character vectors with supported values.

Note "vega" is the sensitivity with respect the initial volatility sqrt(V0).

Example: OutSpec = ["price","delta","gamma","vega","rho","theta"]

Data Types: string | cell

AbsTol — Absolute error tolerance for numerical integration
1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

RelTol — Relative error tolerance for numerical integration
1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]
[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

Framework — Framework for computing option prices and sensitivities using numerical integration of models
"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- `"heston1993"` or `'heston1993'` — Method used in Heston (1993)
- `"lewis2001"` or `'lewis2001'` — Method used in Lewis (2001)

Data Types: `char` | `string`

`ExpandOutput` — Flag to expand the outputs
`false` (outputs are `NINST`-by-1 vectors) (default) | logical with value of `true` or `false`

Flag to expand the outputs, specified as the comma-separated pair consisting of `'ExpandOutput'` and a logical:

- `true` — If `true`, the outputs are `NRows`-by- `NColumns` matrices. `NRows` is the number of strikes for each column and it is determined by the `Strike` input. For example, `Strike` can be a `NRows`-by-1 vector, or a `NRows`-by-`NColumns` matrix. `NColumns` is determined by the sizes of `AssetPrice`, `Settle`, `Maturity`, and `OptSpec`, which must all be either scalar or `NColumns`-by-1 vectors.
- `false` — If `false`, the outputs are `NINST`-by-1 vectors. Also, the inputs `Strike`, `AssetPrice`, `Settle`, `Maturity`, and `OptSpec` must all be either scalar or `NINST`-by-1 vectors.

Data Types: `logical`

Output Arguments

`PriceSens` — Option prices or sensitivities
numeric

Option prices or sensitivities, returned as a `NINST`-by-1, or `NRows`-by-`NColumns`, depending on `ExpandOutput`. The name-value pair argument `OutSpec` determines the types and order of the outputs.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Merton Jump Diffusion Model

The Merton jump diffusion model (Merton (1976)) is a different extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is:

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + J S_t dP_t$$
$$\text{prob}(dP_t = 1) = \lambda_p dt$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

W_t is the Weiner process.

J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

$$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

μ_J is the mean of J for (μ_J > -1).

δ is the standard deviation of $\ln(1+J)$ for ($\delta \geq 0$).

λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \geq 0$).

σ is the volatility of the asset price for ($\sigma > 0$).

The characteristic function $f_{Merton76_j}(\phi)$ for $j = 1$ (asset prices measure) and $j = 2$ (risk-neutral measure) is:

$$f_{Merton76_j} = f_{BS_j} \exp\left(\lambda_p \tau \left(1 + \mu_j\right)^{m_j + \frac{1}{2}} \left[\left(1 + \mu_j\right)^{i\phi} e^{\delta^2 \left(m_j i\phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i\phi \right)$$

where for $j = 1, 2$:

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2}{2} \tau \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

where

ϕ is the characteristic function variable.

τ is the time to maturity ($\tau = T - t$).

i is the unit imaginary number ($i^2 = -1$).

Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions:

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \mathrm{Re}\left[\frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity ($\tau = T - t$).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number ($i^2 = -1$).

ϕ is the characteristic function variable.

$f_j(\phi)$ is the characteristic function for $P_j (j = 1,2)$.

P_1 is the probability of $S_t > K$ under the asset price measure for the model.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

Where $j = 1,2$ so that $f_1(\phi)$ and $f_2(\phi)$ are the characteristic functions for probabilities P_1 and P_2, respectively.

This framework is chosen with the default value “`Heston1993`” for the `Framework` name-value pair argument.

Numerical Integration Method Under Lewis (2001) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K}e^{-\tau t}}{\pi}\int_0^{\infty} \mathrm{Re}\left[K^{-iu} f_2\left(\phi = \left(u - \frac{i}{2}\right)\right)\frac{1}{u^2 + \frac{1}{4}}\right]du$$

$$Put(K) = Call(K) = Ke^{-\tau t} - S_t e^{-q\tau}$$

where

r is the continuous risk-free rate.

q is the continuous dividend yield.

S_t is the asset price at time t.

K is the strike.

τ is time to maturity (τ = T-t).

$Call(K)$ is the call price at strike K.

$Put(K)$ is the put price at strike K.

i is a unit imaginary number (i^2= -1).

ϕ is the characteristic function variable.

u is the characteristic function variable for integration, where $\phi = \left(u - \frac{i}{2}\right)$.

$f_2(\phi)$ is the characteristic function for P_2.

P_2 is the probability of $S_t > K$ under the risk-neutral measure for the model.

This framework is chosen with the value “`Lewis2001`” for the `Framework` name-value pair argument.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optSensByMertonNI` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optembndbybdt

Price bonds with embedded options by Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = optembndbybdt(BDTTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optembndbybdt(BDTTree,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates price for bonds with embedded options from a Black-Derman-Toy interest-rate tree and returns exercise probabilities in `PriceTree`.

`optembndbybdt` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1450.

Note Alternatively, you can use the `OptionEmbeddedFixedBond` object to price embedded fixed-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optembndbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Callable Bond Using a BDT Interest-Rate Tree Model

Create a `BDTTree` with the following data:

```
ZeroRates = [ 0.035;0.04;0.045];
Compounding = 1;
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = 'jan-1-2007';
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [3x1 double]
            Rates: [3x1 double]
```

```
         EndTimes: [3x1 double]
       StartTimes: [3x1 double]
         EndDates: [3x1 double]
       StartDates: 733043
    ValuationDate: 733043
            Basis: 0
     EndMonthRule: 1
```

Create a `VolSpec`.

```
Volatility = 0.10 * ones (3,1);
VolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
VolSpec = struct with fields:
             FinObj: 'BDTVolSpec'
      ValuationDate: 733043
           VolDates: [3x1 double]
           VolCurve: [3x1 double]
    VolInterpMethod: 'linear'
```

Create a `TimeSpec`.

```
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
```

Build the `BDTTree`.

```
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2]
        dObs: [733043 733408 733774]
        TFwd: {[3x1 double]  [2x1 double]  [2]}
      CFlowT: {[3x1 double]  [2x1 double]  [3]}
     FwdTree: {[1.0350]  [1.0406 1.0495]  [1.0447 1.0546 1.0667]}
```

To compute the price of an American callable bond that pays a 5.25% annual coupon, matures in Jan-1-2010, and is callable on Jan-1-2008 and 01-Jan-2010.

```
BondSettlement = datetime(2007,1,1);
BondMaturity   = datetime(2010,1,1);
CouponRate = 0.0525;
Period = 1;
OptSpec = 'call';
Strike = [100];
ExerciseDates = [datetime(2008,1,1) datetime(2010,1,1)];
AmericanOpt = 1;

PriceCallBond = optembndbybdt(BDTTree, CouponRate, BondSettlement, BondMaturity,...
OptSpec, Strike, ExerciseDates, 'Period', 1,'AmericanOp', 1)
```

```
PriceCallBond = 101.4750
```

Obtain Callable Bond Exercise Information Using a BDT Interest-Rate Tree Model

Create a `BDTTree` with the following data:

```
ZeroRates = [ 0.025;0.03;0.045];
Compounding = 1;
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = datetime(2007,1,1);
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate);
```

Build the BDT tree with the following data.

```
Volatility = 0.10 * ones (3,1);
VolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
VolSpec = struct with fields:
             FinObj: 'BDTVolSpec'
      ValuationDate: 733043
           VolDates: [3x1 double]
           VolCurve: [3x1 double]
    VolInterpMethod: 'linear'
```

```
TimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2]
        dObs: [733043 733408 733774]
        TFwd: {[3x1 double]  [2x1 double]  [2]}
      CFlowT: {[3x1 double]  [2x1 double]  [3]}
     FwdTree: {[1.0250]  [1.0315 1.0385]  [1.0614 1.0750 1.0917]}
```

Define the callable bond instruments.

```
Settle = datetime(2007,1,1);
Maturity = [datetime(2008,1,1) datetime(2010,1,1)];
CouponRate = {{datetime(2008,1,1) .0425;datetime(2010,1,1) .0450}};
OptSpec='call';
Strike= [86;90];
ExerciseDates= [datetime(2008,1,1) ; datetime(2010,1,1)];
```

Price the instruments.

```
[Price, PriceTree]= optembndbybdt(BDTTree, CouponRate,  Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1,'AmericanOp', 1)
```

```
Price = 2×1

    86
    90

PriceTree = struct with fields:
                FinObj: 'BDTPriceTree'
                  tObs: [0 1 2 3]
                 PTree: {1x4 cell}
              ProbTree: {[1]  [0.5000 0.5000]  [0.2500 0.5000 0.2500]  [1x3 double]}
                 ExTree: {1x4 cell}
            ExProbTree: {1x4 cell}
    ExProbsByTreeLevel: [2x4 double]
```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

```
PriceTree.ExTree{4}
```

```
ans = 2×3

     0     0     0
     1     1     1
```

There is no exercise for instrument 1 and instrument 2 is exercised at all nodes.

```
PriceTree.ExTree{3}
```

```
ans = 2×3

     0     0     0
     0     0     0
```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2×2

     1     1
     1     0
```

There is exercise for instrument 1 at all nodes and instrument 2 is exercised at some nodes.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×2

    0.5000    0.5000
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×3

    0.2500    0.5000    0.2500
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×3

    0.2500    0.5000    0.2500
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{4}
```

```
ans = 2×3

         0         0         0
    0.2500    0.5000    0.2500
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×3

     0     0     0
     0     0     0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×2

    0.5000    0.5000
    0.5000         0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2×4

    1.0000    1.0000         0         0
    1.0000    0.5000         0    1.0000
```

Price Single Stepped Callable Bonds Using a BDT Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = datetime(2010,1,1);
Maturity =[datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{'01-Jan-2012' .0425;'01-Jan-2014' .0750}};
OptSpec='call';
Strike=100;
ExerciseDates= datetime(2012,1,1);  %Callable in two years

% Build the tree
% Assume the volatility to be 10%
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RS, BDTTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable bond
% with maturity of four years.
PBDT=  optembndbybdt(BDTT, CouponRate, Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1)
```

```
PBDT = 2×1

  100.0945
  100.0297

Price a Sinking Fund Bond Using a BDT Interest-Rate Tree Model

A corporation issues a three year bond with a sinking fund obligation requiring the company to sink 1/3 of face value after the first year and 1/3 after the second year. The company has the option to buy the bonds in the market or call them at $98. The following data describes the details needed for pricing the sinking fund bond:

```
Rates = [0.1;0.1;0.1;0.1];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;

% Create RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% Build the BDT tree
```

```
% Assume the volatility to be 10%
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);

% Instrument
% The bond has a coupon rate of 9%, a period of one year and matures in
% 1-Jan-2014. Face decreases 1/3 after the first year and 1/3 after the
% second year.
CouponRate = 0.09;
Settle = datetime(2011,1,1);
Maturity = datetime(2014,1,1);
Period = 1;
Face = { ...
            {datetime(2012,1,1) 100; ...
             datetime(2013,1,1) 66.6666; ...
             datetime(2014,1,1) 33.3333};
        };

% Option provision
OptSpec = 'call';
Strike = [98 98];
ExerciseDates = [datetime(2012,1,1) , datetime(2013,1,1)];

% Price of non-sinking fund bond.
PNSF = bondbybdt(BDTT, CouponRate, Settle, Maturity, Period)
```

```
PNSF = 97.5131
```

Price of the bond with the option sinking provision.

```
PriceSF = optembndbybdt(BDTT, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates,'Period', Period, 'Face', Face)
```

```
PriceSF = 96.8364
```

Price an Amortizing Callable Bond Using a BDT Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using a BDT lattice model.

Create a `RateSpec`.

```
Rates = [0.025;0.028;0.030;0.031];
ValuationDate = datetime(2018,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2019,1,1) ; datetime(2020,1,1) ; datetime(2021,1,1) ; datetime(2022,1,1)];
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);
```

Build a BDT tree and assume a volatility of 5%.

```
Sigma = 0.05;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
```

```
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = datetime(2018,1,1);
Maturity = datetime(2021,1,1);
Period = 1;

    Face = {
                {datetime(2019,1,1) 100;
                 datetime(2020,1,1) 70; ...
                 datetime(2021,1,1) 50};
                };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = [datetime(2019,1,1) datetime(2020,1,1) datetime(2021,1,1)];
```

Price a callable amortizing bond using the BDT tree.

```
BondType = 'amortizing';
Pcallbonds = optembndbybdt(BDTT, CouponRate, Settle, Maturity, OptSpec, Strike, ExerciseDates, '
```

```
Pcallbonds = 99.5122
```

Input Arguments

`BDTTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the BDT tree. The bond argument `Settle` is ignored.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`, `NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a `NINST`-by-`1` vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optembndbybdt(BDTTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',1,'AmericanOp',1)`

`AmericanOpt` — Option type

`0` European/Bermuda (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Period` — Coupons per year

`2` per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybdt` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Note Instruments without a `Face` schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

Data Types: `double`

`BondType` — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of embedded option at time `0`

matrix

Expected price of the embedded option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and exercise probabilities for each node

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.
- `PriceTree.ProbTree` contains the probability of reaching each node from root node.
- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2008a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optembndbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optembndbybk

Price bonds with embedded options by Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = optembndbybk(BKTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbybk( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optembndbybk(BKTree,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates price for bonds with embedded options from a Black-Karasinski interest-rate tree and returns exercise probabilities in `PriceTree`.

`optembndbybk` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1463.

Note Alternatively, you can use the `OptionEmbeddedFixedBond` object to price embedded fixed-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optembndbybk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Callable Bond Using a BK Interest-Rate Tree Model

Create a `BKTree` with the following data:

```
ZeroRates = [ 0.035;0.04;0.045];
Compounding = 1;
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = datetime(2007,1,1);
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [3x1 double]
            Rates: [3x1 double]
```

```
         EndTimes: [3x1 double]
       StartTimes: [3x1 double]
         EndDates: [3x1 double]
       StartDates: 733043
    ValuationDate: 733043
            Basis: 0
     EndMonthRule: 1
```

Create a `VolSpec`.

```
VolDates = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2010,1,1);
AlphaCurve = 0.1;
BKVolSpec = bkvolspec(ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve)
```

```
BKVolSpec = struct with fields:
             FinObj: 'BKVolSpec'
      ValuationDate: 733043
           VolDates: [3x1 double]
           VolCurve: [3x1 double]
         AlphaCurve: 0.1000
         AlphaDates: 734139
    VolInterpMethod: 'linear'
```

Create a `TimeSpec`.

```
BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
```

Build the `BKTree`.

```
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec)
```

```
BKTree = struct with fields:
      FinObj: 'BKFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2]
        dObs: [733043 733408 733774]
      CFlowT: {[3x1 double]  [2x1 double]  [3]}
       Probs: {[3x1 double]  [3x3 double]}
     Connect: {[2]  [2 3 4]}
     FwdTree: {[1.0350]  [1.0458 1.0450 1.0442]  [1.0571 1.0561 1.0551 ... ]}
```

To compute the price of an American puttable bond that pays an annual coupon of 5.25% , matures on January 1, 2010, and is callable on January 1, 2008 and January 1, 2010.

```
BondSettlement = datetime(2007,1,1);
BondMaturity   = datetime(2010,1,1);
CouponRate = 0.0525;
Period = 1;
OptSpec = 'put';
Strike = [100];
ExerciseDates = [datetime(2008,1,1) datetime(2010,1,1)];
AmericanOpt = 1;
```

```
PricePutBondBK = optembndbybk(BKTree, CouponRate, BondSettlement, BondMaturity,...
OptSpec, Strike, ExerciseDates,'Period', 1, 'AmericanOpt', 1)

PricePutBondBK = 102.3820
```

Obtain Callable Bond Exercise Information Using a BK Interest-Rate Tree Model

Create a `BKTree` with the following data:

```
ZeroRates = [ 0.025;0.03;0.045];
Compounding = 1;
StartDates = [datetime(2007,1,1); datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1); datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = datetime(2007,1,1);
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate);
```

Build the BK tree with the following data.

```
VolDates = [datetime(2008,1,1); datetime(2009,1,1) ; datetime(2010,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2010,1,1);
AlphaCurve = 0.1;
BKVolSpec = bkvolspec(ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve);

BKTimeSpec = bktimespec(ValuationDate, EndDates, Compounding);
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Define the callable bond instruments.

```
Settle = datetime(2007,1,1);
Maturity = [datetime(2008,1,1) ; datetime(2010,1,1)];
CouponRate = {{datetime(2008,1,1) .0315;datetime(2010,1,1) .0350}};
OptSpec='call';
Strike= [86;90];
ExerciseDates= [datetime(2008,1,1) ; datetime(2010,1,1)];
```

Price the instruments.

```
[Price, PriceTree]= optembndbybk(BKTree, CouponRate,  Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1,'AmericanOp', 1)

Price = 2×1

   86.0000
   88.3060

PriceTree = struct with fields:
                FinObj: 'BKPriceTree'
                  tObs: [0 1 2 3]
                 PTree: {1x4 cell}
```

```
            ProbTree: {1x4 cell}
              ExTree: {1x4 cell}
           ExProbTree: {1x4 cell}
    ExProbsByTreeLevel: [2x4 double]
              Connect: {[2]  [2 3 4]}
```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

```
PriceTree.ExTree{4}
```

```
ans = 2×5

     0     0     0     0     0
     1     1     1     1     1
```

There is no exercise for instrument 1 and instrument 2 is exercised at all nodes.

```
PriceTree.ExTree{3}
```

```
ans = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2×3

     1     1     1
     0     0     0
```

There is exercise for instrument 1 at all nodes and instrument 2 is not exercised.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×3

    0.1667    0.6667    0.1667
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×5

    0.0203    0.2206    0.5183    0.2206    0.0203
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×5
```

```
    0.0203    0.2206    0.5183    0.2206    0.0203
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{4}
```

```
ans = 2×5

         0         0         0         0         0
    0.0203    0.2206    0.5183    0.2206    0.0203
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×3

    0.1667    0.6667    0.1667
         0         0         0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2×4

    1.0000    1.0000         0         0
         0         0         0    1.0000
```

Price Single Stepped Callable Bonds Using a BK Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
```

```
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = datetime(2010,1,1);
Maturity = [datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
OptSpec='call';
Strike=100;
ExerciseDates= datetime(2012,1,1);  %Callable in two years

% Build the tree with the following data
VolDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ;datetime(2014,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2014,1,1);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable bond
% with maturity of four years.
PBK= optembndbybk(BKT, CouponRate,  Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

PBK = 2×1

  100.0945
  100.0945
```

Price an Amortizing Callable Bond Using a BK Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using a BK lattice model.

Create a RateSpec.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build a BK tree.

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2016,1,1);
AlphaCurve = 0.1;
```

```
BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = datetime(2012,1,1);
Maturity =  datetime(2016,1,1);
Period = 1;

    Face = {
                {datetime(2014,1,1) 100;
                 datetime(2015,1,1) 70;
                 datetime(2016,1,1) 50};
                };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = [datetime(2014,1,1) datetime(2015,1,1) datetime(2016,1,1)];
```

Price a callable amortizing bond using the BDT tree.

```
BondType = 'amortizing';
Pcallbonds = optembndbybk(BKT, CouponRate,  Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1,'Face',Face,'BondType', BondType)

Pcallbonds = 98.7475
```

Input Arguments

BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

Settle — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the BK tree. The bond argument `Settle` is ignored.

To support existing code, `optembndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — `NINST`-by-`1` vector of strike price values.
- Bermuda option — `NINST` by number of strikes (`NSTRIKES`) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- American option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`, `NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a `NINST`-by-`1` vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `optembndbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optembndbybk(BKTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',1,'AmericanOp',1)`

`AmericanOpt` — Option type
`0` European/Bermuda (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybk` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybk` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbybk` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optembndbybk also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector or a NINST-by-1 cell array where each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Note Instruments without a Face schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

Data Types: double

BondType — Type of underlying bond
'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla','amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

Options — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

Output Arguments

`Price` — Expected prices of embedded option at time `0`

matrix

Expected price of the embedded option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and exercise probabilities for each node

structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.
- `PriceTree.ProbTree` contains the probability of reaching each node from root node.
- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2008a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optembndbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optembndbycir

Price bonds with embedded options by Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = optembndbycir(CIRTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optembndbycir(CIRTree,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates price for bonds with embedded options from a Cox-Ingersoll-Ross (CIR) interest-rate tree and returns exercise probabilities in `PriceTree`.

`optembndbycir` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option using a CIR++ model with the Nawalka-Beliaeva (NB) approach. For more information, see “More About” on page 11-1474.

`[Price,PriceTree] = optembndbycir( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Callable Bond Using a CIR Interest-Rate Tree

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.025; 0.032; 0.037; 0.042];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Maturity = '01-Jan-2018';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
```

```
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.2500 0.5000 0.7500]
        dObs: [736696 736787 736878 736969]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Define the bond with embedded option instrument.

```
BondSettlement = datetime(2017,1,1);
BondMaturity   = datetime(2020,1,1);
CouponRate = 0.035;
Period = 1;
OptSpec = 'put';
Strike = 100;
ExerciseDates = [datetime(2018,1,1) datetime(2019,1,1)];
```

Price the bond.

```
[Price,PriceTree] = optembndbycir(CIRT,CouponRate,BondSettlement,BondMaturity,OptSpec,...
Strike,ExerciseDates,'AmericanOpt',1,'Period',1)
```

```
Price = 103.3099
```

```
PriceTree = struct with fields:
                FinObj: 'CIRPriceTree'
                  tObs: [0 0.2500 0.5000 0.7500 1]
                 PTree: {1x5 cell}
               ProbTree: {1x5 cell}
                 ExTree: {[0]  [0 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [1 1 1 0 0 0 0]}
            ExProbTree: {[0]  [0 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [0.0222 ... ]}
    ExProbsByTreeLevel: [0 0 0 0 0.3089]
               Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Obtain Callable Bond Exercise Information Using a CIR Interest-Rate Tree Model

Create a CIR`Tree` with the following data:

```
Rates = [0.025; 0.027; 0.028; 0.03];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
```

Create a `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
'Rates', Rates, 'Compounding', Compounding);
```

Build the CIR tree with the following data.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
```

```
Theta = 0.02;
Sigma = 0.1;
Maturity = datetime(2018,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);
CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec);
```

Define the callable bond instruments.

```
Settle = datetime(2017,1,1);
Maturity = [datetime(2018,1,1) ; datetime(2020,1,1)];
CouponRate = {{datetime(2019,1,1) .0325;datetime(2020,1,1) .0375}};
OptSpec='call';
Strike= [100;110];
ExerciseDates= [datetime(2018,1,1) ; datetime(2020,1,1)];
```

Price the instruments.

```
[Price, PriceTree]= optembndbycir(CIRT, CouponRate,  Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1,'AmericanOpt',1)
```

```
Price = 2×1

   98.1718
  102.6458

PriceTree = struct with fields:
                FinObj: 'CIRPriceTree'
                  tObs: [0 0.2500 0.5000 0.7500 1]
                 PTree: {1x5 cell}
              ProbTree: {1x5 cell}
                 ExTree: {1x5 cell}
            ExProbTree: {1x5 cell}
    ExProbsByTreeLevel: [2x5 double]
               Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

```
PriceTree.ExTree{4}
```

```
ans = 2×7

     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{3}
```

```
ans = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

There is no exercise for instrument 1 or instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2×3

     0     0     0
     0     0     0
```

There is exercise for instrument 1 or instrument 2.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×3

    0.2794    0.3750    0.3456
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×5

    0.0786    0.2095    0.3318    0.2592    0.1209
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×7

    0.0222    0.0885    0.1982    0.2678    0.2442    0.1360    0.0432
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{4}
```

```
ans = 2×7

     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×3

     0     0     0
```

```
     0     0     0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2×5

     0     0     0     0     0
     0     0     0     0     0
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the CIR tree. The bond argument `Settle` is ignored.

To support existing code, `optembndbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbycir` also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string array with value "call" or "put"

Definition of option, specified as a NINST-by-1 cell array of character vectors or string arrays with a value of 'call' or 'put'.

Data Types: char | cell | string

Strike — Option strike price values
nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optembndbycir also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = optembndbycir(BDTTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',1,'AmericanOpt',1)

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and an `NINST`-by-`1` positive integer flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.

- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optembndbycir also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optembndbycir also accepts serial date numbers as inputs, but they are not recommended.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optembndbycir also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optembndbycir also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | NINST-by-1 vector | NINST-by-1 cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Note Instruments without a `Face` schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

Data Types: `double`

BondType — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

Output Arguments

`Price` — Expected prices of embedded option at time `0`
matrix

Expected price of the embedded option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and exercise probabilities for each node
structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PTree` contains the clean prices.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

- `PriceTree.ProbTree` contains the probability of reaching each node from root node.
- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (calls and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optembndbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optembndbyhjm

Price bonds with embedded options by Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = optembndbyhjm(HJMTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optembndbyhjm(HJMTree,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates price for bonds with embedded options from a Heath-Jarrow-Morton interest-rate tree and returns exercise probabilities in `PriceTree`.

`optembndbyhjm` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1490.

`[Price,PriceTree] = optembndbyhjm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Callable Bond Using an HJM Interest-Rate Tree Model

Create a `HJMTree` with the following data:

```
Rates = [0.05;0.06;0.07];
Compounding = 1;
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = datetime(2007,1,1);
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [3x1 double]
            Rates: [3x1 double]
         EndTimes: [3x1 double]
       StartTimes: [3x1 double]
         EndDates: [3x1 double]
       StartDates: 733043
    ValuationDate: 733043
            Basis: 0
```

```
     EndMonthRule: 1
```

Create a `VolSpec`.

```
VolSpec = hjmvolspec('Constant', 0.01)
```

```
VolSpec = struct with fields:
          FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
      FactorArgs: {{1x1 cell}}
      SigmaShift: 0
      NumFactors: 1
       NumBranch: 2
         PBranch: [0.5000 0.5000]
     Fact2Branch: [-1 1]
```

Create a `TimeSpec`.

```
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding)
```

```
TimeSpec = struct with fields:
           FinObj: 'HJMTimeSpec'
    ValuationDate: 733043
         Maturity: [3x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Build the `HJMTree`.

```
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)
```

```
HJMTree = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2]
        dObs: [733043 733408 733774]
        TFwd: {[3x1 double]  [2x1 double]  [2]}
      CFlowT: {[3x1 double]  [2x1 double]  [3]}
     FwdTree: {[3x1 double]  [2x1x2 double]  [1x2x2 double]}
```

To compute the price of an American callable bond that pays a 6% annual coupon and matures and is callable on January 1, 2010.

```
BondSettlement = datetime(2007,1,1);
BondMaturity   = datetime(2010,1,1);
CouponRate = 0.06;
Period = 1;
OptSpec = 'call';
Strike = [98];
ExerciseDates = datetime(2010,1,1);
AmericanOpt = 1;
```

```
[PriceCallBond,PT] = optembndbyhjm(HJMTree, CouponRate, BondSettlement, BondMaturity,...
OptSpec, Strike, ExerciseDates, 'Period', 1,'AmericanOp',1)

PriceCallBond = 95.9492

PT = struct with fields:
                FinObj: 'HJMPriceTree'
                  tObs: [0 1 2 3]
                 PBush: {[95.9492]  [1x1x2 double]  [1x2x2 double]  [98 ... ]}
              ProbBush: {[1]  [1x1x2 double]  [1x2x2 double]  [0.2500 ... ]}
                ExBush: {[0]  [1x1x2 double]  [1x2x2 double]  [1 1 1 1]}
            ExProbBush: {[0]  [1x1x2 double]  [1x2x2 double]  [0.2500 ... ]}
    ExProbsByBushLevel: [0 0 0 1]
```

Obtain Callable Bond Exercise Information Using a HJM Interest-Rate Tree Model

Create a HJMTree with the following data:

```
Rates = [0.05;0.06;0.07];
Compounding = 1;
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = 'jan-1-2007';
```

Create a RateSpec.

```
RateSpec = intenvset('Rates', Rates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate);
```

Build the HJM tree with the following data.

```
VolSpec = hjmvolspec('Constant', 0.01);
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec);
```

Define the callable bond instruments.

```
Settle = datetime(2007,1,1);
Maturity = [datetime(2009,1,1) ; datetime(2010,1,1)];
CouponRate = {{datetime(2009,1,1) .0325;datetime(2010,1,1) .0375}};
OptSpec='call';
Strike= [90;92];
ExerciseDates= [datetime(2009,1,1) ; datetime(2010,1,1)];
```

Price the instruments.

```
[Price, PriceTree]= optembndbyhjm(HJMTree, CouponRate,  Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1,'AmericanOpt',1)

Price = 2×1

   86.0874
   84.1482
```

```
PriceTree = struct with fields:
                FinObj: 'HJMPriceTree'
                  tObs: [0 1 2 3]
                 PBush: {1x4 cell}
              ProbBush: {[1]  [1x1x2 double]  [1x2x2 double]  [0.2500 ... ]}
                ExBush: {1x4 cell}
            ExProbBush: {1x4 cell}
    ExProbsByBushLevel: [2x4 double]
```

Examine the output `PriceTree.ExBush`. `PriceTree.ExBush` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

```
PriceTree.ExBush{4}
```

```
ans = 2×4

     0     0     0     0
     1     1     1     1
```

There is no exercise for instrument 1 and instrument 2 is exercised at all nodes.

```
PriceTree.ExBush{3}
```

```
ans =
ans(:,:,1) =

     1     1
     0     0

ans(:,:,2) =

     1     1
     0     0
```

There is exercise for instrument 1 at all nodes and no exercise for instrument 2.

```
PriceTree.ExBush{2}
```

```
ans =
ans(:,:,1) =

     0
     0

ans(:,:,2) =

     0
     0
```

There is no exercise for instrument 1 or instrument 2.

Next view the probability of reaching each node from the root node using `PriceTree.ProbBush`.

```
PriceTree.ProbBush{2}

ans =
ans(:,:,1) =

    0.5000

ans(:,:,2) =

    0.5000
```

```
PriceTree.ProbBush{3}

ans =
ans(:,:,1) =

    0.2500    0.2500

ans(:,:,2) =

    0.2500    0.2500
```

```
PriceTree.ProbBush{4}

ans = 1×4

    0.2500    0.2500    0.2500    0.2500
```

View the exercise probabilities using `PriceTree.ExProbBush`. `PriceTree.ExProbBush` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbBush{4}

ans = 2×4

         0         0         0         0
    0.2500    0.2500    0.2500    0.2500
```

```
PriceTree.ExProbBush{3}

ans =
ans(:,:,1) =

    0.2500    0.2500
         0         0

ans =
ans(:,:,1) =

     0
     0

ans(:,:,2) =

     0
     0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByBushLevel`. `PriceTree.ExProbsByBushLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByBushLevel

ans = 2×4

     0     0     1     0
     0     0     0     1
```

Price Single Stepped Callable Bonds Using an HJM Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = datetime(2010,1,1);
Maturity = [datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
OptSpec = 'call';
Strike = 100;
ExerciseDates = datetime(2012,1,1);  %Callable in two years

% Build the tree with the following data
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1;  2;   3;   4];
HJMTimeSpec = hjmtimespec(ValuationDate, EndDates);
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
```

```
HJMT = hjmtree(HJMVolSpec, RS, HJMTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable
% bond with maturity of four years.
PHJM=  optembndbyhjm(HJMT, CouponRate, Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

PHJM = 2×1

  100.0484
   99.8009
```

Price a Sinking Fund Bond Using an HJM Interest-Rate Tree Model

A corporation issues a three year bond with a sinking fund obligation requiring the company to sink 1/3 of face value after the first year and 1/3 after the second year. The company has the option to buy the bonds in the market or call them at $99. The following data describes the details needed for pricing the sinking fund bond:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Build the HJM tree.

```
Sigma = 0.1;
HJMTimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding);
HJMVolSpec = hjmvolspec('Constant', Sigma);
HJMT = hjmtree(HJMVolSpec, RateSpec, HJMTimeSpec)

HJMT = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
```

```
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734504 734869 735235 735600]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

Define the sinking fund instrument. The bond has a coupon rate of 4.5%, a period of one year and matures in 1-Jan-2013. Face decreases 1/3 after the first year.

```
CouponRate = 0.045;
Settle = datetime(2011,1,1);
Maturity =  datetime(2013,1,1);
Period = 1;
Face = { {datetime(2012,1,1) 100; ...
          datetime(2013,1,1) 66.6666}};
```

Define the option provision.

```
OptSpec = 'call';
Strike = 99;
ExerciseDates = datetime(2012,1,1);
```

Price of non-sinking fund bond.

```
PNSF = bondbyhjm(HJMT, CouponRate, Settle, Maturity, Period)
```

```
PNSF = 100.5663
```

Price of the bond with the option sinking provision.

```
PriceSF = optembndbyhjm(HJMT, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face)
```

```
PriceSF = 98.8736
```

Price an Amortizing Callable Bond Using an HJM Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using an HJM lattice model.

Create a `RateSpec`.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ;datetime(2016,1,1)];
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build a HJM tree.

```
VolSpec = hjmvolspec('Constant', 0.01)
```

```
VolSpec = struct with fields:
          FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
      FactorArgs: {{1x1 cell}}
      SigmaShift: 0
      NumFactors: 1
       NumBranch: 2
         PBranch: [0.5000 0.5000]
     Fact2Branch: [-1 1]
```

```
TimeSpec = hjmtimespec(ValuationDate, EndDates, Compounding)
```

```
TimeSpec = struct with fields:
           FinObj: 'HJMTimeSpec'
    ValuationDate: 734869
         Maturity: [4x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

```
HJMTree = hjmtree(VolSpec, RS, TimeSpec)
```

```
HJMTree = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = datetime(2012,1,1);
Maturity =  datetime(2016,1,1);
Period = 1;

    Face = {
                 {datetime(2014,1,1) 100;
                  datetime(2015,1,1) 70;
                  datetime(2016,1,1) 50};
                 };

OptSpec = 'call';
Strike = [97 95 93];
ExerciseDates = [datetime(2014,1,1) datetime(2015,1,1) datetime(2016,1,1)];
```

Price a callable amortizing bond using the HJM tree.

```
BondType = 'amortizing';
Pcallbonds = optembndbyhjm(HJMTree, CouponRate,  Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1,'Face',Face,'BondType', BondType)
```

```
Pcallbonds = 98.6000
```

Input Arguments

`HJMTree` — Interest-rate tree structure
structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the HJM tree. The bond argument `Settle` is ignored.

To support existing code, `optembndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char`

`Strike` — Option strike price values
nonnegative integer

Option strike price value, specified as a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optembndbyhjm also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = optembndbyhjm(HJMTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',1,'AmericanOp',1)

AmericanOpt — Option type
0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Face — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Note Instruments without a `Face` schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

Data Types: `double`

BondType — Type of underlying bond
'vanilla' for scalar Face values, 'callablesinking' for scheduled Face values (default) | cell array of character vectors with values 'vanilla','amortizing', or 'callablesinking' | string array with values "vanilla", "amortizing", or "callablesinking"

Type of underlying bond, specified as the comma-separated pair consisting of 'BondType' and a NINST-by-1 cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- 'vanilla' is a standard callable or puttable bond with a scalar Face value and a single coupon or stepped coupons.
- 'callablesinking' is a bond with a schedule of Face values and a sinking fund call provision with a single or stepped coupons.
- 'amortizing' is an amortizing callable or puttable bond with a schedule of Face values with single or stepped coupons.

Data Types: char | string

Options — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

Output Arguments

Price — Expected prices of embedded option at time 0
matrix

Expected price of the embedded option at time 0, returned as a NINST-by-1 matrix.

PriceTree — Structure containing trees of vectors of instrument prices and exercise probabilities for each node
structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- PriceTree.ExBush contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.
- PriceTree.tObs contains the observation times.
- PriceTree.ProbBush contains the probability of reaching each node from root node.
- PriceTree.ExProbBush contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- PriceTree.ExProbsByBushLevel is an array with each row holding the exercise probability for a given option at each tree observation time.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2008a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optembndbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optembndbyhw

Price bonds with embedded options by Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = optembndbyhw(HWTree,CouponRate,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optembndbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optembndbyhw(HWTree,CouponRate,Settle,Maturity,OptSpec, Strike,ExerciseDates)` calculates price for bonds with embedded options from a Hull-White interest-rate tree and returns exercise probabilities in `PriceTree`.

`optembndbyhw` computes prices of vanilla bonds with embedded options, stepped coupon bonds with embedded options, amortizing bonds with embedded options, and sinking fund bonds with call embedded option. For more information, see “More About” on page 11-1505.

Note Alternatively, you can use the `OptionEmbeddedFixedBond` object to price embedded fixed-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optembndbyhjm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Callable Bond Using an HW Interest-Rate Tree Model

Create a `HWTree` with the following data:

```
ZeroRates = [ 0.035;0.04;0.045];
Compounding = 1;
StartDates = [datetime(2007,1,1) ; datetime(2008,1,1) ; datetime(2009,1,1)];
EndDates   = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
ValuationDate = datetime(2007,1,1);
```

Create a `RateSpec`.

```
RateSpec = intenvset('Rates', ZeroRates, 'StartDates', ValuationDate, 'EndDates', ...
EndDates, 'Compounding', Compounding, 'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [3x1 double]
            Rates: [3x1 double]
```

```
         EndTimes: [3x1 double]
       StartTimes: [3x1 double]
         EndDates: [3x1 double]
       StartDates: 733043
    ValuationDate: 733043
            Basis: 0
     EndMonthRule: 1
```

Create a `VolSpec`.

```
VolDates = [datetime(2008,1,1) ; datetime(2009,1,1) ; datetime(2010,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2010,1,1);
AlphaCurve = 0.1;
HWVolSpec = hwvolspec(ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve)
```

```
HWVolSpec = struct with fields:
             FinObj: 'HWVolSpec'
      ValuationDate: 733043
           VolDates: [3x1 double]
           VolCurve: [3x1 double]
         AlphaCurve: 0.1000
         AlphaDates: 734139
    VolInterpMethod: 'linear'
```

Create a `TimeSpec`.

```
HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding)
```

```
HWTimeSpec = struct with fields:
           FinObj: 'HWTimeSpec'
    ValuationDate: 733043
         Maturity: [3x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Build the `HWTree`.

```
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec)
```

```
HWTree = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2]
        dObs: [733043 733408 733774]
      CFlowT: {[3x1 double]  [2x1 double]  [3]}
       Probs: {[3x1 double]  [3x3 double]}
     Connect: {[2]  [2 3 4]}
     FwdTree: {[1.0350]  [1.0633 1.0451 1.0271]  [1.0925 1.0737 1.0553 ... ]}
```

Compute the price of an American puttable bond that pays an annual coupon of 5.25%, matures on January 1, 2010, and is puttable from January 1, 2008 to January 1, 2010.

```
BondSettlement = datetime(2007,1,1);
BondMaturity   = datetime(2010,1,1);
CouponRate = 0.0525;
Period = 1;
OptSpec = 'put';
Strike = [100];
ExerciseDates = [datetime(2008,1,1) datetime(2010,1,1)];
AmericanOpt = 1;

PricePutBondHW = optembndbyhw(HWTree, CouponRate, BondSettlement, BondMaturity,...
OptSpec, Strike, ExerciseDates,'Period', 1, 'AmericanOpt', 1)

PricePutBondHW = 102.9127
```

Obtain Callable Bond Exercise Information Using an HW Interest-Rate Tree Model

Create a `HWTree` with the following data:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2019,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2020,1,1) ; datetime(2021,1,1) ; datetime(2022,1,1) ; datetime(2023,1,1)];
Compounding = 1;
```

Create a `RateSpec`.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Define the callable bond instruments.

```
Settle = datetime(2019,1,1);
Maturity = [datetime(2022,1,1) ; datetime(2023,1,1)];
CouponRate = {{datetime(2021,1,1) .0425 ; datetime(2023,1,1) .0450}};
OptSpec='call';
Strike= [98;95];
ExerciseDates= [datetime(2021,1,1) ; datetime(2022,1,1)];
```

Build the HW tree with the following data.

```
VolDates = [datetime(2020,1,1) ; datetime(2021,1,1) ; datetime(2022,1,1) ; datetime(2023,1,1)];
VolCurve = 0.05;
AlphaDates = datetime(2023,1,1);
AlphaCurve = 0.05;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);
```

Price the instruments.

```
[Price, PriceTree]= optembndbyhw(HWT, CouponRate,  Settle, Maturity,OptSpec, Strike,...
ExerciseDates, 'Period', 1)
```

```
Price = 2×1

   96.4131
   92.9341

PriceTree = struct with fields:
                FinObj: 'HWPriceTree'
                  tObs: [0 1 2 3 4]
                 PTree: {1x5 cell}
              ProbTree: {1x5 cell}
                 ExTree: {1x5 cell}
            ExProbTree: {1x5 cell}
    ExProbsByTreeLevel: [2x5 double]
               Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
```

Examine the output `PriceTree.ExTree`. `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it is not.

```
PriceTree.ExTree{5}
```

```
ans = 2×7

     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
```

There is no exercise for instrument 1 or 2.

```
PriceTree.ExTree{4}
```

```
ans = 2×7

     0     0     0     0     0     0     0
     0     0     0     1     1     1     1
```

There is no exercise for instrument 1 and instrument 2 is exercised at some nodes.

```
PriceTree.ExTree{3}
```

```
ans = 2×5

     0     0     1     1     1
     0     0     0     0     0
```

There is the exercise for instrument 1 at some node and no exercise for instrument 2.

```
PriceTree.ExTree{2}
```

```
ans = 2×3

     0     0     0
     0     0     0
```

There is no exercise for instrument 1 or 2.

Next view the probability of reaching each node from the root node using `PriceTree.ProbTree`.

```
PriceTree.ProbTree{2}
```

```
ans = 1×3

    0.1667    0.6667    0.1667
```

```
PriceTree.ProbTree{3}
```

```
ans = 1×5

    0.0238    0.2218    0.5087    0.2218    0.0238
```

```
PriceTree.ProbTree{4}
```

```
ans = 1×7

    0.0029    0.0473    0.2374    0.4247    0.2374    0.0473    0.0029
```

```
PriceTree.ProbTree{5}
```

```
ans = 1×7

    0.0029    0.0473    0.2374    0.4247    0.2374    0.0473    0.0029
```

Then view the exercise probabilities using `PriceTree.ExProbTree`. `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceTree.ExProbTree{5}
```

```
ans = 2×7

     0     0     0     0     0     0     0
     0     0     0     0     0     0     0
```

```
PriceTree.ExProbTree{4}
```

```
ans = 2×7

         0         0         0         0         0         0         0
         0         0         0    0.4247    0.2374    0.0473    0.0029
```

```
PriceTree.ExProbTree{3}
```

```
ans = 2×5

         0         0    0.5087    0.2218    0.0238
         0         0         0         0         0
```

```
PriceTree.ExProbTree{2}
```

```
ans = 2×3

     0     0     0
     0     0     0
```

View the exercise probabilities at each tree level using `PriceTree.ExProbsByTreeLevel`. `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2×5

         0         0    0.7544         0         0
         0         0         0    0.7124         0
```

Price Single Stepped Callable Bonds Using an HW Interest-Rate Tree Model

Price the following single stepped callable bonds using the following data: The data for the interest rate term structure is as follows:

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1); datetime(2014,1,1)];
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Instrument
Settle = datetime(2010,1,1);
Maturity = [datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
OptSpec = 'call';
Strike = 100;
ExerciseDates = datetime(2012,1,1);  %Callable in two years

% Build the tree with the following data
VolDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2014,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);

% The first row corresponds to the price of the callable bond with maturity
% of three years. The second row corresponds to the price of the callable
```

```
% bond with maturity of four years.

PHW= optembndbyhw(HWT, CouponRate,  Settle, Maturity,OptSpec, Strike,...
ExerciseDates, 'Period', 1)

PHW = 2×1

  100.0326
   99.7987
```

Price a Sinking Fund Bond Using an HW Interest-Rate Tree Model

A corporation issues a two year bond with a sinking fund obligation requiring the company to sink 1/3 of face value after the first year. The company has the option to buy the bonds in the market or call them at $99. The following data describes the details needed for pricing the sinking fund bond:

```
Rates = [0.1;0.1;0.1;0.1];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;

% Create RateSpec
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Build the HW tree
% The data to build the tree is as follows:
VolDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2015,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);

% Instrument
% The bond has a coupon rate of 9%, a period of one year and matures in
% 1-Jan-2013. Face decreases 1/3 after the first year.
CouponRate = 0.09;
Settle = datetime(2011,1,1);
Maturity =  datetime(2013,1,1);
Period = 1;
Face = { ...
            {datetime(2012,1,1) 100; ...
             datetime(2013,1,1) 66.6666}; ...
        };

% Option provision
OptSpec = 'call';
Strike = 99;
```

```
ExerciseDates = datetime(2012,1,1);

% Price of non-sinking fund bond.
PNSF = bondbyhw(HWT, CouponRate, Settle, Maturity, Period)

PNSF = 98.2645
```

Price of the bond with the option sinking provision.

```
PriceSF = optembndbyhw(HWT, CouponRate, Settle, Maturity,...
OptSpec, Strike, ExerciseDates, 'Period', Period, 'Face', Face)

PriceSF = 98.1553
```

Price an Amortizing Callable Bond Using an HW Interest-Rate Tree Model

This example shows how to price an amortizing callable bond and a vanilla callable bond using an HW lattice model.

Create a `RateSpec`.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Build a HW tree.

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2016,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, EndDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);
```

Define the callable bond.

```
CouponRate = 0.05;
Settle = datetime(2012,1,1);
Maturity = datetime(2016,1,1);
Period = 1;

    Face = {
                {datetime(2014,1,1) 100;
                 datetime(2015,1,1) 70;
                 datetime(2016,1,1) 50};
                };

OptSpec = 'call';
```

```
Strike = [97 95 93];
ExerciseDates = [datetime(2014,1,1) datetime(2015,1,1) datetime(2016,1,1) ];
```

Price a callable amortizing bond using the HW tree.

```
BondType = 'amortizing';
Pcallbonds = optembndbyhw(HWT, CouponRate,  Settle, Maturity ,OptSpec, Strike,...
ExerciseDates, 'Period', 1,'Face',Face,'BondType', BondType)
```

```
Pcallbonds = 98.6554
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date for the bond option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every bond is set to the `ValuationDate` of the HW tree. The bond argument `Settle` is ignored.

To support existing code, `optembndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as a NINST-by-1 cell array of character vectors.

Data Types: char

Strike — Option strike price values

nonnegative integer

Option strike price value, specified as a NINST-by-1 or NINST-by-NSTRIKES depending on the type of option:

- European option — NINST-by-1 vector of strike price values.
- Bermuda option — NINST by number of strikes (NSTRIKES) matrix of strike price values. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- American option — NINST-by-1 vector of strike price values for each option.

Data Types: double

ExerciseDates — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1, NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the type of option:

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optembndbyhw also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = optembndbyhw(HWTree,CouponRate,Settle,Maturity,OptSpec,Strike,ExerciseDates,'Period',1,'AmericanOp',1)

AmericanOpt — Option type

0 European/Bermuda (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer flags with values:

- 0 — European/Bermuda

- `1` — American

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date,specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optembndbyhw` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | `NINST`-by-`1` vector | `NINST`-by-`1` cell array

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector or a `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first

column is dates and the second column is associated face value. The date indicates the last day that the face value is valid.

Note Instruments without a `Face` schedule are treated as either vanilla bonds or stepped coupon bonds with embedded options.

Data Types: `double`

`BondType` — Type of underlying bond
`'vanilla'` for scalar `Face` values, `'callablesinking'` for scheduled `Face` values (default) | cell array of character vectors with values `'vanilla'`,`'amortizing'`, or `'callablesinking'` | string array with values `"vanilla"`, `"amortizing"`, or `"callablesinking"`

Type of underlying bond, specified as the comma-separated pair consisting of `'BondType'` and a `NINST`-by-`1` cell array of character vectors or string array specifying if the underlying is a vanilla bond, an amortizing bond, or a callable sinking fund bond. The supported types are:

- `'vanilla'` is a standard callable or puttable bond with a scalar `Face` value and a single coupon or stepped coupons.
- `'callablesinking'` is a bond with a schedule of `Face` values and a sinking fund call provision with a single or stepped coupons.
- `'amortizing'` is an amortizing callable or puttable bond with a schedule of `Face` values with single or stepped coupons.

Data Types: `char` | `string`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of embedded option at time `0`
matrix

Expected price of the embedded option at time `0`, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure containing trees of vectors of instrument prices and exercise probabilities for each node
structure

Structure containing trees of vectors of instrument prices, a vector of observation times for each node, and exercise probabilities. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing `1`'s where an option is exercised and `0`'s where it isn't.

- `PriceTree.ProbTree` contains the probability of reaching each node from root node.
- `PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing `0`'s where there is no exercise, or the probability of reaching that node where exercise happens.
- `PriceTree.ExProbsByTreeLevel` is an array with each row holding the exercise probability for a given option at each tree observation time.

More About

Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

Stepped Coupon Bond with Callable and Puttable Features

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

Sinking Fund Bond with Call Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision.

This provision obligates the issuer to amortize portions of the principal prior to maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity.

The bond may have a sinking fund call option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper. If interest rates are high, then the issuer buys back the requirement amount of bonds from the market since bonds are cheap, but if interest rates are low (bond prices are high), then most likely the issuer is buying the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund call option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a non-sinking fund bond.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Version History

Introduced in R2008a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optembndbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optemfloatbybdt

Price embedded option on floating-rate note for Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = optemfloatbybdt(BDTTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optemfloatbybdt(BDTTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates)` prices embedded options on floating-rate notes from a Black-Derman-Toy interest rate tree. `optemfloatbybdt` computes prices of vanilla floating-rate notes with embedded options.

Note Alternatively, you can use the `OptionEmbeddedFloatBond` object to price embedded floating-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optemfloatbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price Callable Embedded Option for Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
```

```
      StartDates: 734869
  ValuationDate: 734869
          Basis: 0
   EndMonthRule: 1
```

Build the BDT tree and assume a volatility of 10%.

```
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Define the floater instruments with the embedded call option.

```
Spread = 10;
Settle = datetime(2012,1,1);
Maturity =  [datetime(2015,1,1) ; datetime(2016,1,1)];
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = datetime(2015,1,1);
```

Compute the price of the floaters with the embedded call.

```
Price= optemfloatbybdt(BDTT, Spread, Settle, Maturity, OptSpec, Strike,...
ExerciseDates)
```

```
Price = 2×1

  100.2800
  100.3655
```

Input Arguments

BDTTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bdttree`.

Data Types: `struct`

Spread — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`)-by-1).

Data Types: `double`

Settle — Settlement dates of floating-rate note

`ValuationDate` of BDT Tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the BDT tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optemfloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors of dates.

To support existing code, `optemfloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optemfloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optemfloatbybdt(BDTTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'AmericanOpt',1,'FloatReset',6,'Basis',8)`

`AmericanOpt` — Option type
scalar | vector of positive integers `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0
scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node
tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains option prices.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-11.

Version History

optemfloatbybk

Price embedded option on floating-rate note for Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = optemfloatbybk(BKTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbybk( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optemfloatbybk(BKTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates)` prices embedded options on floating-rate notes from a Black-Karasinski interest rate tree. `optemfloatbybk` computes prices of vanilla floating-rate notes with embedded options.

Note Alternatively, you can use the `OptionEmbeddedFloatBond` object to price embedded floating-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optemfloatbybk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price European Callable Embedded Option for Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
```

```
       StartDates: 734869
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build the BK tree.

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2016,1,1);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
            AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec)
```

```
BKT = struct with fields:
      FinObj: 'BKFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

The floater instrument has a spread of 15, a period of one year, and matures and is callable on Jan-1-2015.

```
Spread = 15;
Settle = datetime(2012,1,1);
Maturity =  datetime(2015,1,1);
Period = 1;
OptSpec = {'call'};
Strike =101;
ExerciseDates = datetime(2015,1,1);
```

Compute the price of the floater with the embedded call.

```
Price= optemfloatbybk(BKT, Spread, Settle, Maturity,...
OptSpec, Strike, ExerciseDates)
```

```
Price = 100.4201
```

Input Arguments

BKTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bktree`.

Data Types: `struct`

Spread — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

Settle — Settlement dates of floating-rate note
ValuationDate of BDT Tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every floating-rate note with an embedded option is set to the ValuationDate of the BK tree. The floating-rate note argument Settle is ignored.

To support existing code, optemfloatbybk also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optemfloatbybk also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
character vector | cell array of character vectors

Definition of option as 'call' or 'put' specified as a NINST-by-1 cell array of character vectors for 'call' or 'put'.

Data Types: cell | char

Strike — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as NINST-by-NSTRIKES vector of strike price values.

Data Types: single | double

ExerciseDates — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a NINST-by-NSTRIKES or NINST-by-2 vector using a datetime array, string array, or date character vectors.

To support existing code, optemfloatbybk also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = optemfloatbybk(BKTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'AmericanOpt',1,'FloatReset',6,'Basis',8)

AmericanOpt — Option type

scalar | vector of positive integers [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

FloatReset — Frequency of payments per year

1 (default) | positive integer from the set [1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1,2,3,4,6,12] in a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: double

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains option prices.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optemfloatbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optemfloatbycir

Price embedded option on floating-rate note for Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = optemfloatbycir(CIRTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optemfloatbycir(CIRTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates)` prices embedded options on floating-rate notes from a Cox-Ingersoll-Ross (CIR) interest rate tree. `optemfloatbycir` computes prices of vanilla floating-rate notes with embedded options using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = optemfloatbycir( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price European Callable Embedded Option for a Floating-Rate Note Using a CIR Interest-Rate Tree

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2020,1,1);
CIRTimeSpec = cirtimespec(Settle, Maturity, 3);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
```

```
        tObs: [0 1 2]
        dObs: [736696 737061 737426]
     FwdTree: {[1.0350]  [1.0790 1.0500 1.0298]  [1.1275 1.0887 1.0594 ... ]}
     Connect: {[3x1 double]  [3x3 double]}
       Probs: {[3x1 double]  [3x3 double]}
```

Define the floater instruments with the embedded call option.

```
Spread = 10;
Settle = datetime(2017,1,1);
Maturity =  [datetime(2019,1,1) ; datetime(2020,1,1)];
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = datetime(2019,1,1);
```

Compute the price of the floaters with the embedded call.

```
[Price,PriceTree] = optemfloatbycir(CIRT,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates)
```

```
Price = 2×1

  100.1887
  100.2757

PriceTree = struct with fields:
    FinObj: 'CIRPriceTree'
      tObs: [0 1 2 3]
     PTree: {[2x1 double]  [2x3 double]  [2x5 double]  [2x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree specified as a structure by using `cirtree`.

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`-by-1).

Data Types: `double`

`Settle` — Settlement dates of floating-rate note

`ValuationDate` of CIR tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the CIR tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optemfloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optemfloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with value of `'call'` or `'put'` | cell array of character vectors with value of `'call'` or `'put'` | string array with value of `"call"` or `"put"`

Definition of option, specified as a `NINST`-by-`1` cell array of character vectors or string arrays with a value of `'call'` or `'put'`.

Data Types: `cell` | `char` | `string`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or an `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

- For a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, the `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDates`.

To support existing code, `optemfloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optemfloatbycir(CIRTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'AmericanOpt',1,'FloatReset',6,'Basis',8)`

`AmericanOpt` — Option type
scalar | vector of positive integers `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` vector of flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)

- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts.

When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates, and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and the output from `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0
scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node
tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PTree` contains option prices.

More About

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

optemfloatbyhjm

Price embedded option on floating-rate note for Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = optemfloatbyhjm(HJMTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optemfloatbyhjm(HJMTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates)` prices embedded options on floating-rate notes from a Heath-Jarrow-Morton interest rate tree. `optemfloatbybk` computes prices of vanilla floating-rate notes with embedded options.

`[Price,PriceTree] = optemfloatbyhjm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price European Callable Embedded Option for a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.035;0.040;0.045];
ValuationDate = datetime(2012,1,1);
StartDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
EndDates =[datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: [4x1 double]
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build the HJM tree.

```
VolSpec = hjmvolspec('Constant', 0.01);
TimeSpec = hjmtimespec(RateSpec.ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)
```

```
HJMTree = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

The floater instrument has a spread of 15, a period of one year, and matures and is callable on Jan-1-2016.

```
Spread = 15;
Settle = datetime(2012,1,1);
Maturity = datetime(2016,1,1);
Period = 1;
OptSpec = {'call'};
Strike = 95;
ExerciseDates = datetime(2016,1,1);
```

Compute the price of the floater with the embedded call.

```
Price = optemfloatbyhjm(HJMTree, Spread, Settle, Maturity,...
OptSpec, Strike, ExerciseDates)
```

```
Price = 96.2355
```

Input Arguments

`HJMTree` — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `hjmtree`.

Data Types: `struct`

`Spread` — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`)-by-1).

Data Types: `double`

`Settle` — Settlement dates of floating-rate note

`ValuationDate` of BDT Tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the HJM tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optemfloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optemfloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optemfloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optemfloatbyhjm(HJMTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'AmericanOpt',1,'FloatReset',6,'Basis',8)`

`AmericanOpt` — Option type
scalar | vector of positive integers `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)

- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0
scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node
tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optemfloatbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optemfloatbyhw

Price embedded option on floating-rate note for Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = optemfloatbyhw(HWTree,Spread,Settle,Maturity,OptSpec,
Strike,ExerciseDates)
[Price,PriceTree] = optemfloatbyhw( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optemfloatbyhw(HWTree,Spread,Settle,Maturity,OptSpec, Strike,ExerciseDates)` prices embedded options on floating-rate notes from a Hull-White interest rate tree. `optemfloatbybk` computes prices of vanilla floating-rate notes with embedded options.

Note Alternatively, you can use the `OptionEmbeddedFloatBond` object to price embedded floating-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optemfloatbyhw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price European Callable Embedded Option for Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates',...
StartDates, 'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734869
    ValuationDate: 734869
```

```
            Basis: 0
     EndMonthRule: 1
```

Build the HW tree using the following:

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2016,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
            AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec)
```

```
HWT = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

Define the floater instruments with the embedded call option.

```
Spread = 10;
Settle = datetime(2012,1,1);
Maturity =  [datetime(2015,1,1) ; datetime(2016,1,1)];
Period = 1;
OptSpec = {'call'};
Strike = 101;
ExerciseDates = datetime(2015,1,1);
```

Compute the price of the floaters with the embedded call.

```
Price= optemfloatbyhw(HWT, Spread, Settle, Maturity, OptSpec, Strike,...
ExerciseDates)
```

```
Price = 2×1

  100.2800
  100.3655
```

Input Arguments

HWTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `hwtree`.

Data Types: `struct`

`Spread` — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`)-by-`1`).

Data Types: `double`

`Settle` — Settlement dates of floating-rate note
`ValuationDate` of BDT Tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note with an embedded option is set to the `ValuationDate` of the HW tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optemfloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optemfloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optemfloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- If an American option, then ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = optemfloatbyhw(HWTree,Spread,Settle,Maturity,OptSpec,Strike,ExerciseDates,'AmericanOpt',1,'FloatReset',6,'Basis',8)

AmericanOpt — Option type

scalar | vector of positive integers [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

FloatReset — Frequency of payments per year

1 (default) | positive integer from the set [1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1,2,3,4,6,12] in a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: double

Basis — Day-count basis of the instrument

0 (actual/actual) (default) | positive integers of the set [1...13] | vector of positive integers of the set [1...13]

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a positive integer using a NINST-by-1 vector. The Basis value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 are returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains embedded option prices.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optemfloatbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optfloatbybdt

Price options on floating-rate notes for Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = optfloatbybdt(BDTTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optfloatbybdt(BDTTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity)` prices options on floating-rate notes from a Black-Derman-Toy interest rate tree. `optfloatbybdt` computes prices of options on vanilla floating-rate notes.

Note Alternatively, you can use the `FloatBondOption` object to price floating-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optfloatbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of American Call and Put Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
```

```
       StartDates: 734869
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build the BDT tree and assume a volatility of 10%.

```
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTT = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[1.0300]  [1.0342 1.0418]  [1.0374 1.0456 1.0558]  [1.0337 ... ]}
```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2016.

```
Spread = 10;
Settle = datetime(2012,1,1);
Maturity =  datetime(2016,1,1);
Period = 1;
```

Define the option for the floating-rate note.

```
OptSpec = {'call'; 'put'};
Strike = [100;101];
ExerciseDates = datetime(2015,1,1);
AmericanOpt = 1;
```

Compute the price of the call and put options.

```
Price= optfloatbybdt(BDTT,  OptSpec, Strike, ExerciseDates,AmericanOpt, Spread,...
Settle, Maturity)
```

```
Price = 2×1

    0.3655
    0.8087
```

Input Arguments

BDTTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bdttree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

`AmericanOpt` — Option type
scalar | vector of positive integers `[0,1]`

Option type specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Spread` — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`)-by-`1`).

Data Types: `single` | `double`

`Settle` — Settlement dates of floating-rate note
`ValuationDate` of BDT Tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note is set to the `ValuationDate` of the BDT tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optfloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example:
`[Price,PriceTree]=optfloatbybdt(BDTTree,OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle,Maturity,'FloatReset',4,'Basis',7)`

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an `NINST`-by-1 vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains option prices.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optfloatbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optfloatbybk

Price options on floating-rate notes for Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = optfloatbybdt(BKTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optfloatbybdt(BKTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity)` prices options on floating-rate notes from a Black-Karasinski interest rate tree. `optfloatbybk` computes prices of options on vanilla floating-rate notes.

Note Alternatively, you can use the `FloatBondOption` object to price floating-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optfloatbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of American and European Call Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',StartDates,...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'

      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2016.

```
Spread = 10;
Settle = datetime(2012,1,1);
Maturity =  datetime(2016,1,1);
Period = 1;
```

Define the option for the floating-rate note.

```
OptSpec = {'call'};
Strike = 95;
ExerciseDates = datetime(2016,1,1);
AmericanOpt = [0;1];
```

Compute the price of the call options.

```
Price = optfloatbybk(BKT,OptSpec,Strike,ExerciseDates,AmericanOpt,...
Spread,Settle,Maturity)
```

```
Price = 2×1

    4.2740
    5.3655
```

Input Arguments

`BKTree` — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `bktree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values

nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)

datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbybk` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

`AmericanOpt` — Option type

scalar | vector of positive integers`[0,1]`

Option type specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Spread` — Number of basis points over the reference rate

nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: single | double

Settle — Settlement dates of floating-rate note
ValuationDate of BK tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every floating-rate note is set to the ValuationDate of the BK tree. The floating-rate note argument Settle is ignored.

To support existing code, optfloatbybk also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optfloatbybk also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = optfloatbybk(BKTree,OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle,Maturity,'FloatReset',4,'Basis',7)

FloatReset — Frequency of payments per year
1 (default) | positive integer from the set[1,2,3,4,6,12] | vector of positive integers from the set [1,2,3,4,6,12]

Frequency of payments per year, specified as the comma-separated pair consisting of 'FloatReset' and positive integers for the values [1,2,3,4,6,12] in a NINST-by-1 vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: double

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optfloatbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optfloatbycir

Price options on floating-rate notes for Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = optfloatbycir(CIRTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optfloatbycir(CIRTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity)` prices options on floating-rate notes from a Cox-Ingersoll-Ross (CIR) interest-rate tree. `optfloatbycir` computes prices of options on vanilla floating-rate notes using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = optfloatbycir( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of American and European Call Options on a Floating-Rate Note Using a CIR Interest-Rate Tree

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
CIRTimeSpec = cirtimespec(Settle, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
```

```
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2018.

```
Spread = 10;
Settle = datetime(2017,1,1);
Maturity = datetime(2019,1,1);
Period = 1;
```

Define the option for the floating-rate note.

```
OptSpec = {'call'};
Strike = 95;
ExerciseDates = datetime(2018,1,1);
AmericanOpt = [0;1];
```

Compute the price of the call options.

```
[Price,PriceTree] = optfloatbycir(CIRT, OptSpec,Strike,ExerciseDates,AmericanOpt,...
Spread, Settle, Maturity)
```

```
Price = 2×1

    4.9230
    5.1887

PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
      PTree: {1x5 cell}
     AITree: {1x5 cell}
       tObs: [0 1 2 3 4]
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
      Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree specified as a structure by using `cirtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values of `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of option, specified as a `NINST`-by-1 cell array of character vectors or string arrays with values of `'call'` or `'put'`.

Data Types: cell | char | string

Strike — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values, specified as nonnegative integers using an NINST-by-NSTRIKES vector of strike price values.

Data Types: double

ExerciseDates — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a NINST-by-NSTRIKES or NINST-by-2 vector using a datetime array, string array, or date character vectors.

To support existing code, optfloatbycir also accepts serial date numbers as inputs, but they are not recommended.

- For a European or Bermuda option, the ExerciseDates is a 1-by-1 (European) or 1-by-NSTRIKES (Bermuda) vector of exercise dates. For a European option, there is only one ExerciseDate on the option expiry date.
- For an American option, the ExerciseDates is a 1-by-2 vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-NaN date, or if ExerciseDates is 1-by-1, the option exercises between the Settle date and the single listed ExerciseDate.

AmericanOpt — Option type
scalar | vector of positive integers[0,1]

Option type specified as NINST-by-1 positive integer scalar flags with values:

- 0 — European/Bermuda
- 1 — American

Data Types: double

Spread — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (NINST)-by-1).

Data Types: double

Settle — Settlement dates of floating-rate note
ValuationDate of CIR tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every floating-rate note is set to the ValuationDate of the CIR tree. The floating-rate note argument Settle is ignored.

To support existing code, `optfloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optfloatbybk(CIRTree,OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle,Maturity,'FloatReset',4,'Basis',7)`

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts.

When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates, and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and the output from `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

optfloatbyhjm

Price options on floating-rate notes for Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = optfloatbyhjm(HJMTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbyhjm( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optfloatbyhjm(HJMTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity)` prices options on floating-rate notes from a Heath-Jarrow-Morton interest rate tree. `optfloatbyhjm` computes prices of options on vanilla floating-rate notes.

`[Price,PriceTree] = optfloatbyhjm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of American and European Call Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.035;0.040;0.045];
ValuationDate = datetime(2012,1,1);
StartDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)]
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: [4x1 double]
    ValuationDate: 734869
            Basis: 0
     EndMonthRule: 1
```

Build the HJM tree.

```
VolSpec = hjmvolspec('Constant', 0.01);
TimeSpec = hjmtimespec(RateSpec.ValuationDate, EndDates, Compounding);
HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)
```

```
HJMTree = struct with fields:
      FinObj: 'HJMFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[4x1 double]  [3x1x2 double]  [2x2x2 double]  [1x4x2 double]}
```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2015.

```
Spread = 10;
Settle = datetime(2012,1,1);
Maturity = datetime(2015,1,1);
Period = 1;
```

Define the option for the floating-rate note.

```
OptSpec = {'call'};
Strike = 95;
ExerciseDates = datetime(2015,1,1);
AmericanOpt = [0;1];
```

Compute the price of the call options.

```
Price= optfloatbyhjm(HJMTree,  OptSpec, Strike, ExerciseDates,AmericanOpt,...
Spread, Settle, Maturity)
```

```
Price = 2×1

    4.5098
    5.2811
```

Input Arguments

`HJMTree` — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `hjmtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

`AmericanOpt` — Option type
scalar | vector of positive integers `[0,1]`

Option type specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Spread` — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`)-by-`1`).

Data Types: `double`

`Settle` — Settlement dates of floating-rate note
`ValuationDate` of HJM tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note is set to the `ValuationDate` of the HJM tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optfloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date

datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optfloatbyhjm(HJMTree,OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle, Maturity,'FloatReset',4,'Basis',7)`

`FloatReset` — Frequency of payments per year

`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument

`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0
scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node
tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.AIBush` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optfloatbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optfloatbyhw

Price options on floating-rate notes for Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = optfloatbyhw(HWTree,OptSpec,Strike,ExerciseDates,
AmericanOpt,Spread,Settle,Maturity)
[Price,PriceTree] = optfloatbyhw( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optfloatbyhw(HWTree,OptSpec,Strike,ExerciseDates, AmericanOpt,Spread,Settle,Maturity)` prices options on floating-rate notes from a Hull-White interest rate tree. `optfloatbyhw` computes prices of options on vanilla floating-rate notes.

Note Alternatively, you can use the `FloatBondOption` object to price floating-rate bond option instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optfloatbyhw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of American and European Call Options on a Floating-Rate Note

Define the interest-rate term structure.

```
Rates = [0.03;0.034;0.038;0.04];
ValuationDate = datetime(2012,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 734869
    ValuationDate: 734869
```

```
           Basis: 0
     EndMonthRule: 1
```

Build the HW tree using the following:

```
VolDates = [datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2016,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
            AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec)
```

```
HWT = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734869 735235 735600 735965]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

The floater instrument has a spread of 10, a period of one year, and matures on Jan-1-2016.

```
Spread = 10;
Settle = datetime(2012,1,1);
Maturity =  datetime(2016,1,1);
Period = 1;
```

Define the option for the floating-rate note.

```
OptSpec = {'call'};
Strike = 95;
ExerciseDates = datetime(2016,1,1);
AmericanOpt = [0;1];
```

Compute the price of the call options.

```
Price= optfloatbyhw(HWT,  OptSpec, Strike, ExerciseDates,AmericanOpt,...
Spread, Settle, Maturity)
```

```
Price = 2×1

    4.2740
    5.3655
```

Input Arguments

HWTree — Interest-rate tree structure

binomial tree structure

Interest-rate tree specified as a structure by using `hwtree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector | cell array of character vectors

Definition of option as `'call'` or `'put'` specified as a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `cell` | `char`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values specified nonnegative integers using as `NINST`-by-`NSTRIKES` vector of strike price values.

Data Types: `double`

`ExerciseDates` — Exercise date for option (European, Bermuda, or American)
datetime array | string array | date character vector

Exercise date for option (European, Bermuda, or American) specified as a `NINST`-by-`NSTRIKES` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

- If a European or Bermuda option, the `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- If an American option, then `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between or including the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

`AmericanOpt` — Option type
scalar | vector of positive integers `[0,1]`

Option type specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

`Spread` — Number of basis points over the reference rate
nonnegative integer | vector of nonnegative integers

Number of basis points over the reference rate specified as a vector of nonnegative integers for the number of instruments (`NINST`)-by-`1`).

Data Types: `double`

`Settle` — Settlement dates of floating-rate note
`ValuationDate` of HW tree (default) | datetime array | string array | date character vector

Settlement dates of floating-rate note specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every floating-rate note is set to the `ValuationDate` of the HW tree. The floating-rate note argument `Settle` is ignored.

To support existing code, `optfloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Floating-rate note maturity date
datetime array | string array | date character vector

Floating-rate note maturity date specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optfloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example:
`[Price,PriceTree]=optfloatbyhw(HWTree,OptSpec,Strike,ExerciseDates,AmericanOpt,Spread,Settle,Maturity,'FloatReset',4,'Basis',7)`

`FloatReset` — Frequency of payments per year
`1` (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of payments per year, specified as the comma-separated pair consisting of `'FloatReset'` and positive integers for the values `[1,2,3,4,6,12]` in a `NINST`-by-`1` vector.

Note Payments on floating-rate notes (FRNs) are determined by the effective interest-rate between reset dates. If the reset period for an FRN spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there will be more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of the instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]` | vector of positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer using a `NINST`-by-`1` vector. The `Basis` value represents the basis used when annualizing the input forward-rate tree.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Principal values
`100` (default) | vector of nonnegative values | cell array of nonnegative values

Principal values, specified as the comma-separated pair consisting of `'Principal'` and nonnegative values using a `NINST`-by-`1` vector or `NINST`-by-`1` cell array of notional principal amounts. When using a `NINST`-by-`1` cell array, each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `double` | `cell`

`Options` — Structure containing derivatives pricing options
structure

Structure containing derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Price` — Expected prices of the floating-rate note option at time 0

scalar | vector

Expected prices of the floating-rate note option at time 0 is returned as a scalar or an `NINST`-by-`1` vector.

`PriceTree` — Structure of trees containing vectors of option prices at each node

tree structure

Structure of trees containing vectors of instrument prices and accrued interest and a vector of observation times for each node returned as:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Floating-Rate Note Options

A floating-rate note option is a put or call option on a floating-rate note.

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

For more information, see “Floating-Rate Note Options” on page 2-11.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optfloatbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)

y =

        2021
```

There are no plans to remove support for serial date number inputs.

optsensbysabr

Calculate option sensitivities using SABR model

Syntax

```
Sens = optsensbysabr(ZeroCurve,Alpha,Beta,Rho,Nu,Settle,ExerciseDate,
ForwardValue,Strike,OptSpec)
Sens = optsensbysabr( ___ ,Name,Value)
```

Description

`Sens = optsensbysabr(ZeroCurve,Alpha,Beta,Rho,Nu,Settle,ExerciseDate, ForwardValue,Strike,OptSpec)` returns the sensitivities of an option value by using the SABR stochastic volatility model.

`Sens = optsensbysabr( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate the Sensitivity Values for an Interest-Rate Swaption

Define the interest rate and the model parameters.

```
SwapRate = 0.0357;
Strike = 0.03;
Alpha = 0.036;
Beta = 0.5;
Rho = -0.25;
Nu = 0.35;
Rates = 0.05;
```

Define the `Settle`, `ExerciseDate`, and `OptSpec` for an interest-rate swaption.

```
Settle = datetime(2013,9,15);
ExerciseDate = datetime(2015,9,15);
OptSpec = 'call';
```

Define the `RateSpec` for the interest-rate curve.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', ExerciseDate, 'Rates', Rates, 'Compounding', -1, 'Basis', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9048
            Rates: 0.0500
        EndTimes: 2
       StartTimes: 0
         EndDates: 736222
```

```
       StartDates: 735492
    ValuationDate: 735492
            Basis: 1
     EndMonthRule: 1
```

Calculate the `Delta` and `Vega` sensitivity values for the interest-rate swaption.

```
[SABRDelta, SABRVega] = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, Settle, ...
ExerciseDate, SwapRate, Strike, OptSpec, 'OutSpec',  {'Delta', 'Vega'})

SABRDelta = 0.7025

SABRVega = 0.0772
```

Calculate the Sensitivity Values for a Swaption Using the Shifted SABR Model

Define the interest rate and the model parameters.

```
SwapRate = 0.0002;
Strike = -0.001;  % -0.1% strike.
Alpha = 0.01;
Beta = 0.5;
Rho = -0.1;
Nu = 0.15;
Shift = 0.005;  % 0.5 percent shift
Rates = 0.0002;
```

Define the `Settle`, `ExerciseDate`, and `OptSpec` for the swaption.

```
Settle = datetime(2016,3,1);
ExerciseDate = datetime(2017,3,1);
OptSpec = 'call';
```

Define the `RateSpec` for the interest-rate curve.

```
RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle, ...
'EndDates',ExerciseDate,'Rates',Rates,'Compounding',-1,'Basis', 1)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9998
            Rates: 2.0000e-04
         EndTimes: 1
       StartTimes: 0
         EndDates: 736755
       StartDates: 736390
    ValuationDate: 736390
            Basis: 1
     EndMonthRule: 1
```

Calculate the `Delta` and `Vega` sensitivity values for the swaption.

```
[ShiftedSABRDelta,ShiftedSABRVega] = optsensbysabr(RateSpec, ...
Alpha,Beta,Rho,Nu,Settle,ExerciseDate,SwapRate,Strike,OptSpec, ...
'OutSpec',{'Delta','Vega'},'Shift',Shift)

ShiftedSABRDelta = 0.9628

ShiftedSABRVega = 0.0060
```

Calculate the Sensitivity Values for an Interest-Rate Swaption with Normal (Bachelier) Implied Volatility

This example shows how to use `optsensbysabr` to calculate sensitivities for an interest-rate swaption using the Normal model for the case where the `Beta` parameter is `> 0` and where `Beta = 0`.

For the case where the `Beta` parameter is `> 0`, select the Normal (Bachelier) implied volatility model in `optsensbysabr`, specify the `'Model'` name-value pair to `'normal'`.

```
% Define the interest rate and the model parameters.

SwapRate = 0.025;
Strike = 0.02;
Alpha = 0.044;
Beta = 0.5;
Rho = -0.21;
Nu = 0.31;
Rates = 0.028;

% Define the Settle, ExerciseDate, and OptSpec for the swaption.

Settle = datetime(2018,3,7);
ExerciseDate = datetime(2020,3,7);
OptSpec = 'call';

% Define the RateSpec for the interest-rate curve.

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', ExerciseDate, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

% Calculate the Delta and Vega sensitivity values for the swaption. Set the
% 'Model' name-value pair to 'normal' in order to select the Normal
% (Bachelier) implied volatility model.

[SABRDelta, SABRVega] = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, ...
    Settle, ExerciseDate, SwapRate, Strike, OptSpec, ...
    'OutSpec',  {'Delta', 'Vega'}, 'Model', 'normal')

SABRDelta = 0.7171

SABRVega = 0.0686
```

Calculate Sensitivities for a Swaption with Normal Implied Volatility Using the Normal SABR Model

When the `Beta` parameter is set to zero, the SABR model becomes the Normal SABR model. Negative interest rates are allowed when the Normal SABR model is used in combination with Normal

(Bachelier) implied volatility. To select the Normal (Bachelier) implied volatility model in `optsensbysabr`, specify the 'Model' name-value pair to 'normal'.

```
% Define the interest rate and the model parameters.

SwapRate = -0.00254;
Strike = -0.002;
Alpha = 0.0047;
Beta = 0;  % Set the Beta parameter to zero to use the Normal SABR model
Rho = -0.20;
Nu = 0.28;
Rates = 0.0001;

% Define the Settle, ExerciseDate, and OptSpec for the swaption.

Settle = datetime(2018,4,11);
ExerciseDate = datetime(2019,4,11);
OptSpec = 'call';

% Define the RateSpec for the interest-rate curve.

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', ExerciseDate, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

% Calculate the Delta and Vega sensitivity values for the swaption. Set the
% 'Model' name-value pair to 'normal' in order to select the Normal
% (Bachelier) implied volatility model.

[SABRDelta, SABRVega] = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, ...
    Settle, ExerciseDate, SwapRate, Strike, OptSpec, ...
    'OutSpec',  {'Delta', 'Vega'}, 'Model', 'normal')
```

```
SABRDelta = 0.4644
```

```
SABRVega = 0.3987
```

Input Arguments

`ZeroCurve` — Annualized interest-rate term structure for zero-coupon bonds

structure

Annualized interest-rate term structure for zero-coupon bonds, specified by using the `RateSpec` obtained from `intenvset` or an `IRDataCurve` with multiple rates using the `IRDataCurve` constructor.

Data Types: `struct`

`Alpha` — Current SABR volatility

scalar numeric

Current SABR volatility, specified as a scalar numeric.

Data Types: `double`

`Beta` — SABR constant elasticity of variance (CEV) exponent

scalar numeric

SABR CEV exponent, specified as a scalar numeric.

Data Types: `double`

`Rho` — Correlation between forward value and volatility
scalar numeric

Correlation between forward value and volatility, specified as a scalar numeric.

Data Types: `double`

`Nu` — Volatility of volatility
scalar numeric

Volatility of volatility, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement date
datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optsensbysabr` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDate` — Option exercise date
datetime scalar | string scalar | date character vector

Option exercise date, specified as a scalar datetime, string, or date character vector.

To support existing code, `optsensbysabr` also accepts serial date numbers as inputs, but they are not recommended.

`ForwardValue` — Current forward value of underlying asset
scalar numeric | vector

Current forward value of the underlying asset, specified as a scalar numeric or vector of size `NINST`-by-`1`.

Data Types: `double`

`Strike` — Option strike price values
scalar numeric | vector

Option strike price values, specified as a scalar numeric or a vector of size `NINST`-by-`1`.

Data Types: `double`

`OptSpec` — Definition of option
character vector with value of `'call'` or `'put'`

Definition of the option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `ModifiedSABRDelta = optsensbysabr(RateSpec,Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike,OptSpec,'OutSpec','ModifiedDelta')`

`OutSpec` — Sensitivity outputs

`'Delta'` (default) | character vector with values `'Delta'`, `'Vega'`, `'ModifiedDelta'`, `'ModifiedVega'`, `'dSigmadF'`, `'dSigmadAlpha'` | cell array of character vectors with values `'Delta'`, `'Vega'`, `'ModifiedDelta'`, `'ModifiedVega'`, `'dSigmadF'`, `'dSigmadAlpha'`

Sensitivity outputs, specified as the comma-separated pair consisting of `'OutSpec'` and an `NOUT`-by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Delta'`, `'Vega'`, `'ModifiedDelta'`, `'ModifiedVega'`, `'dSigmadF'`, and `'dSigmadAlpha'` where:

- `'Delta'` is SABR Delta by Hagan et al. (2002).
- `'Vega'` is SABR Vega by Hagan et al. (2002).
- `'ModifiedDelta'` is SABR Delta modified by Bartlett (2006).
- `'ModifiedVega'` is SABR Vega modified by Bartlett (2006).
- `'dSigmadF'` is the sensitivity of implied volatility with respect to the underlying current forward value, *F*. The implied volatility type depends on `Shift` and `Model`.
- `'dSigmadAlpha'` is the sensitivity of implied volatility with respect to the `Alpha` parameter. The implied volatility type depends on `Shift` and `Model`.

Example: `OutSpec = {'Delta','Vega','ModifiedDelta','ModifiedVega','dSigmadF','dSigmadAlpha'}`

Data Types: `char` | `cell`

`Shift` — Shift in decimals for shifted SABR model

`0` (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), specified as the comma-separated pair consisting of `'Shift'` and a scalar positive decimal value. Set this parameter to a positive shift in decimals to add a positive shift to `ForwardValue` and `Strike`, which effectively sets a negative lower bound for `ForwardValue` and `Strike`. For example, a `Shift` value of `0.01` is equal to a 1% positive shift.

Note If the `Model` is set to `'normal'`, the `Shift` parameter must be `0`.

Data Types: `double`

`Model` — Model used by the implied volatility sigma

`'lognormal'` (default) | character vector with value `'lognormal'` or `'normal'` | string with value `"lognormal"` or `"normal"`

Model used by the implied volatility sigma, specified as the comma-separated pair consisting of `'Model'` and a character vector with a value of `'lognormal'` or `'normal'`, or a string with a value of `"lognormal"` or `"normal"`.

Note The setting for `Model` affects the interpretation of the implied volatility "sigma". Depending on the setting for `Model`, the "sigma" has the following interpretations:

- If `Model` is `'lognormal'` (default), "sigma" can be either Implied Black (no shift) or Implied Shifted Black volatility.
- If `Model` is `'normal'`, "sigma" is the Implied Normal (Bachelier) volatility and `Shift` must be zero.

Data Types: `char` | `string`

Output Arguments

Sens — Sensitivity values

array

Sensitivity values, returned as an `NINST`-by-`1` array as defined by the `OutSpec`.

Algorithms

In the SABR model, an option with value V is defined by the modified Black formula B, where σ_B is the SABR implied Black volatility.

$$V = B(F, K, T, \sigma_B(\alpha, \beta, \rho, \nu, F, K, T))$$

The `Delta` and `Vega` sensitivities under the SABR model are expressed in terms of partial derivatives in the original paper by Hagan (2002).

$$\text{SABR } Delta = \frac{\partial V}{\partial F} = \frac{\partial B}{\partial F} + \frac{\partial B}{\partial \sigma_B}\frac{\partial \sigma_B}{\partial F}$$

$$\text{SABR } Vega = \frac{\partial V}{\partial \alpha} = \frac{\partial B}{\partial \sigma_B}\frac{\partial \sigma_B}{\partial \alpha}$$

Later, Bartlett (2006) made better use of the model dynamics by incorporating the correlated changes between F and α

$$\text{Modified SABR } Delta = \frac{\partial B}{\partial F} + \frac{\partial B}{\partial \sigma_B}\left(\frac{\partial \sigma_B}{\partial F} + \frac{\partial \sigma_B}{\partial \alpha}\frac{\rho \upsilon}{F^{\beta}}\right)$$

$$\text{Modified SABR } Vega = \frac{\partial B}{\partial \sigma_B}\left(\frac{\partial \sigma_B}{\partial \alpha} + \frac{\partial \sigma_B}{\partial F}\frac{\rho F^{\beta}}{\upsilon}\right)$$

where $\frac{\partial B}{\partial F}$ is the classic Black `Delta` and $\frac{\partial B}{\partial \sigma_B}$ is the classic Black `Vega`. The Black implied volatility σ_B is computed internally by calling `blackvolbysabr`, while its partial derivatives $\frac{\partial \sigma_B}{\partial F}$ and $\frac{\partial \sigma_B}{\partial \alpha}$ are computed using closed-form expressions by `optsensbysabr`.

Similar expressions apply to the implied Normal volatility σ_N. For more information, see `normalvolbysabr`.

Version History

Introduced in R2014b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optsensbysabr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

optstockbybaw

Calculate American options prices using Barone-Adesi and Whaley option pricing model

Syntax

```
Price = optstockbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

Description

`Price = optstockbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)` calculates American options prices using the Barone-Adesi and Whaley option pricing model.

Examples

Compute American Option Prices Using the Barone-Adesi and Whaley Option Pricing Model

Consider an American call option with an exercise price of $120. The option expires on Jan 1, 2018. The stock has a volatility of 14% per annum, and the annualized continuously compounded risk-free rate is 4% per annum as of Jan 1, 2016. Using this data, calculate the price of the American call, assuming the price of the stock is $125 and pays a dividend of 2%.

```
StartDate  = datetime(2016,1,1);
EndDate = datetime(2018,1,1);
Basis = 1;
Compounding = -1;
Rates = 0.04;
```

Define the `RateSpec`.

```
RateSpec = intenvset('ValuationDate',StartDate,'StartDate',StartDate,'EndDate',EndDate, ...
'Rates',Rates,'Basis',Basis,'Compounding',Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9231
            Rates: 0.0400
         EndTimes: 2
       StartTimes: 0
         EndDates: 737061
       StartDates: 736330
    ValuationDate: 736330
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
Dividend = 0.02;
AssetPrice = 125;
Volatility = 0.14;
```

```
StockSpec = stockspec(Volatility,AssetPrice,'Continuous',Dividend)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1400
         AssetPrice: 125
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Define the American option.

```
OptSpec = 'call';
Strike = 120;
Settle = datetime(2016,1,1);
Maturity = datetime(2018,1,1);
```

Compute the price for the American option.

```
Price = optstockbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

```
Price = 14.5180
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement date

datetime array | string array | date character vector

Settlement date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbybaw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbybaw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors or string arrays with values `'call'` or `'put'`.

Data Types: `char` | `cell` | `string`

`Strike` — American option strike price value
nonnegative scalar | nonnegative vector

American Option strike price value, specified as a nonnegative scalar or `NINST`-by-`1` matrix of strike price values. Each row is the schedule for one option.

Data Types: `single` | `double`

Output Arguments

`Price` — Expected prices for American options
vector

Expected prices for American options, returned as a `NINST`-by-`1` vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2017a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstockbybaw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstocksensbybaw

Calculate American options prices and sensitivities using Barone-Adesi and Whaley option pricing model

Syntax

```
PriceSens = optstocksensbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,
Strike)
PriceSens = optstocksensbybaw( ___ ,Name,Value)
```

Description

`PriceSens = optstocksensbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec, Strike)` calculates American options prices using the Barone-Adesi and Whaley option pricing model.

`PriceSens = optstocksensbybaw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute an American Option Price and Sensitivities Using the Barone-Adesi and Whaley Option Pricing Model

Consider an American call option with an exercise price of $120. The option expires on Jan 1, 2018. The stock has a volatility of 14% per annum, and the annualized continuously compounded risk-free rate is 4% per annum as of Jan 1, 2016. Using this data, calculate the price of the American call, assuming the price of the stock is $125 and pays a dividend of 2%.

```
StartDate  = datetime(2016,1,1);
EndDate = datetime(2018,1,1);
Basis = 1;
Compounding = -1;
Rates = 0.04;

Dividend = 0.02;
AssetPrice = 125;
Volatility = 0.14;

StockSpec = stockspec(Volatility,AssetPrice,'Continuous',Dividend)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1400
         AssetPrice: 125
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Define the American option.

```
OptSpec = 'call';
Strike = 120;
Settle = datetime(2016,1,1);
Maturity = datetime(2018,1,1);
```

Compute the price and sensitivities for the American option.

```
OutSpec = {'price';'delta';'theta'};

[Price,Delta,Theta] = optstocksensbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpe
```

```
Price = 14.5180

Delta = 0.6672

Theta = -3.1861
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbybaw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the American option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbybaw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors or string arrays with values `'call'` or `'put'`.

Data Types: `char` | `string`

`Strike` — American option strike price value
nonnegative scalar | nonnegative vector

American option strike price value, specified as a nonnegative scalar or `NINST`-by-`1` matrix of strike price values. Each row is the schedule for one option.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,Delta,Theta] = optstocksensbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',OutSpec)`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities for American options
matrix

Expected prices or sensitivities for American options, returned as a `NINST`-by-`1` matrix.

Note All sensitivities are evaluated by computing a discrete approximation of the partial derivative. This means that the option is revalued with a fractional change for each relevant parameter. The change in the option value divided by the increment is the approximated sensitivity value.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

optstockbybjs

Price American options using Bjerksund-Stensland 2002 option pricing model

Syntax

```
Price = optstockbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

Description

`Price = optstockbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)` computes American option prices with continuous dividend yield using the Bjerksund-Stensland 2002 option pricing model.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute the American Option Prices With Continuous Dividend Yield Using the Bjerksund-Stensland 2002 Option Pricing Model

This example shows how to compute the American option prices with continuous dividend yield using the Bjerksund-Stensland 2002 option pricing model. Consider two American stock options (a call and a put) with an exercise price of $100. The options expire on April 1, 2008. Assume the underlying stock pays a continuous dividend yield of 4% as of January 1, 2008. The stock has a volatility of 20% per annum and the annualized continuously compounded risk-free rate is 8% per annum. Using this data, calculate the price of the American call and put, assuming the following current prices of the stock: $90 (for the call) and $120 (for the put).

```
Settle = datetime(2008,1,1);
Maturity = datetime(2008,4,1);
Strike = 100;
AssetPrice = [90;120];
DivYield = 0.04;
Rate = 0.08;
Sigma = 0.20;

% define the RateSpec and StockSpec
StockSpec = stockspec(Sigma, AssetPrice, {'continuous'}, DivYield);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1);

% define the option type
OptSpec = {'call'; 'put'};

Price = optstockbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price = 2×1

    0.8420
    0.1108
```

The first element of the `Price` vector represents the price of the call ($0.84); the second element represents the price of the put option ($0.11).

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for option

datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option

cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected option prices
vector

Expected option prices, returned as a `NINST`-by-`1` vector.

Data Types: `double`

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2008b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `optstockbybjs` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbyblk

Price options on futures and forwards using Black option pricing model

Syntax

```
Price = optstockbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
Price = optstockbyblk( ___ ,Name,Value)
```

Description

`Price = optstockbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)` computes option prices on futures or forward using the Black option pricing model.

Note `optstockbyblk` calculates option prices on futures and forwards. If `ForwardMaturity` is not passed, the function calculates prices of future options. If `ForwardMaturity` is passed, the function computes prices of forward options. This function handles several types of underlying assets, for example, stocks and commodities. For more information on the underlying asset specification, see `stockspec`.

`Price = optstockbyblk( ___ ,Name,Value)` adds an optional name-value pair argument for `ForwardMaturity` to compute option prices on forwards using the Black option pricing model.

Examples

Compute Option Prices on Futures Using the Black Option Pricing Model

This example shows how to compute option prices on futures using the Black option pricing model. Consider two European call options on a futures contract with exercise prices of $20 and $25 that expire on September 1, 2008. Assume that on May 1, 2008 the contract is trading at $20, and has a volatility of 35% per annum. The risk-free rate is 4% per annum. Using this data, calculate the price of the call futures options using the Black model.

```
Strike = [20; 25];
AssetPrice = 20;
Sigma = .35;
Rates = 0.04;
Settle = datetime(2008,5,1);
Maturity = datetime(2008,9,1);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
 'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(Sigma, AssetPrice);

% define the call options
OptSpec = {'call'};
```

```
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity,...
OptSpec, Strike)
```

```
Price = 2×1

    1.5903
    0.3037
```

Compute Option Prices on a Forward

This example shows how to compute option prices on forwards using the Black pricing model. Consider two European options, a call and put on the Brent Blend forward contract that expires on January 1, 2015. The options expire on October 1, 2014 with an exercise price of $200 and $90 respectively. Assume that on January 1, 2014 the forward price is at $107, the annualized continuously compounded risk-free rate is 3% per annum and volatility is 28% per annum. Using this data, compute the price of the options.

Define the `RateSpec`.

```
ValuationDate = datetime(2014,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.03;
Compounding = -1;
Basis = 1;
RateSpec  = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate, 'EndDates', EndDates, 'Rates', Rates,....
'Compounding', Compounding, 'Basis', Basis')
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9704
            Rates: 0.0300
         EndTimes: 1
       StartTimes: 0
         EndDates: 735965
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 107;
Sigma = 0.28;
StockSpec  = stockspec(Sigma, AssetPrice);
```

Define the options.

```
Settle = datetime(2014,1,1);
Maturity = datetime(2014,10,1);  %Options maturity
Strike = [200;90];
OptSpec = {'call'; 'put'};
```

Price the forward call and put options.

```
ForwardMaturity = 'Jan-1-2015';  % Forward contract maturity
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike,...
'ForwardMaturity', ForwardMaturity)
```

```
Price = 2×1

    0.0535
    3.2111
```

Compute the Option Price on a Future

Consider a call European option on the Crude Oil Brent futures. The option expires on December 1, 2014 with an exercise price of $120. Assume that on April 1, 2014 futures price is at $105, the annualized continuously compounded risk-free rate is 3.5% per annum and volatility is 22% per annum. Using this data, compute the price of the option.

Define the `RateSpec`.

```
ValuationDate = datetime(2014,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.035;
Compounding = -1;
Basis = 1;
RateSpec  = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis')
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 735965
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 105;
Sigma = 0.22;
StockSpec  = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2200
         AssetPrice: 105
       DividendType: []
    DividendAmounts: 0
```

```
    ExDividendDates: []
```

Define the option.

```
Settle = datetime(2014,4,1);
Maturity = datetime(2014,12,1);
Strike = 120;
OptSpec = {'call'};
```

Price the futures call option.

```
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price = 2.5847
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for option

datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbyblk` also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
cell array of character vectors with values 'call' or 'put'

Definition of the option as 'call' or 'put', specified as a NINST-by-1 cell array of character vectors with values 'call' or 'put'.

Data Types: cell

Strike — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = optstockbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'ForwardMaturity',ForwardMaturity)

ForwardMaturity — Maturity date or delivery date of forward contract
Maturity of option (default) | date character vector

Maturity date or delivery date of forward contract, specified as the comma-separated pair consisting of 'ForwardMaturity' and a NINST-by-1 vector using date character vectors.

To support existing code, optstockbyblk also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

Price — Expected option prices
vector

Expected option prices, returned as a NINST-by-1 vector.

More About

Futures Option

A futures option is a standardized contract between two parties to buy or sell a specified asset of standardized quantity and quality for a price agreed upon today (the futures price) with delivery and payment occurring at a specified future date, the delivery date.

The futures contracts are negotiated at a futures exchange, which acts as an intermediary between the two parties. The party agreeing to buy the underlying asset in the future, the "buyer" of the contract, is said to be "long," and the party agreeing to sell the asset in the future, the "seller" of the contract, is said to be "short."

A futures contract is the delivery of item J at time T and:

- There exists in the market a quoted price $F(t,T)$, which is known as the futures price at time t for delivery of J at time T.
- The price of entering a futures contract is equal to zero.
- During any time interval $[t,s]$, the holder receives the amount $F(s,T) - F(t,T)$ (this reflects instantaneous marking to market).
- At time T, the holder pays $F(T,T)$ and is entitled to receive J. Note that $F(T,T)$ should be the spot price of J at time T.

For more information, see “Futures Option” on page 3-32.

Forwards Option

A forwards option is a non-standardized contract between two parties to buy or to sell an asset at a specified future time at a price agreed upon today.

The buyer of a forwards option contract has the right to hold a particular forward position at a specific price any time before the option expires. The forwards option seller holds the opposite forward position when the buyer exercises the option. A call option is the right to enter into a long forward position and a put option is the right to enter into a short forward position. A closely related contract is a futures contract. A forward is like a futures in that it specifies the exchange of goods for a specified price at a specified future date.

The payoff for a forwards option, where the value of a forward position at maturity depends on the relationship between the delivery price (K) and the underlying price (S_T) at that time, is:

- For a long position: $f_T = S_T - K$
- For a short position: $f_T = K - S_T$

For more information, see “Forwards Option” on page 3-31.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstockbyblk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbybls

Price options using Black-Scholes option pricing model

Syntax

```
Price = optstockbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

Description

`Price = optstockbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)` returns option prices using the Black-Scholes option pricing model.

Note When using `StockSpec` with `optstockbybls`, you can modify `StockSpec` to handle other types of underliers when pricing instruments that use the Black-Scholes model.

When pricing Futures (Black model), enter the following in `StockSpec`:

```
DivType = 'Continuous';
DivAmount = RateSpec.Rates;
```

For example, see “Compute Option Prices Using the Black-Scholes Option Pricing Model” on page 11-1603.

When pricing Foreign Currencies (Garman-Kohlhagen model), enter the following in `StockSpec`:

```
DivType = 'Continuous';
DivAmount = ForeignRate;
```

where `ForeignRate` is the continuously compounded, annualized risk free interest rate in the foreign country. For example, see “Compute Option Prices on Foreign Currencies Using the Garman-Kohlhagen Option Pricing Model” on page 11-1604.

Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute Option Prices Using the Black-Scholes Option Pricing Model

This example shows how to compute option prices using the Black-Scholes option pricing model. Consider two European options, a call and a put, with an exercise price of $29 on January 1, 2008. The options expire on May 1, 2008. Assume that the underlying stock for the call option provides a cash dividend of $0.50 on February 15, 2008. The underlying stock for the put option provides a continuous dividend yield of 4.5% per annum. The stocks are trading at $30 and have a volatility of 25% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, compute the price of the options using the Black-Scholes model.

```
Strike = 29;
AssetPrice = 30;
Sigma = .25;
Rates = 0.05;
Settle = datetime(2008,1,1);
Maturity = datetime(2008,5,1);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding', -1);

DividendType = {'cash';'continuous'};
DividendAmounts = [0.50; 0.045];
ExDividendDates = {datetime(2008,2,15);NaN};

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts,...
ExDividendDates);

OptSpec = {'call'; 'put'};

Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price = 2×1

    2.2030
    1.2025
```

Compute Option Prices on Foreign Currencies Using the Garman-Kohlhagen Option Pricing Model

This example shows how to compute option prices on foreign currencies using the Garman-Kohlhagen option pricing model. Consider a European put option on a currency with an exercise price of $0.50 on October 1, 2015. The option expires on June 1, 2016. Assume that the current exchange rate is $0.52 and has a volatility of 12% per annum. The annualized continuously compounded domestic risk-free rate is 4% per annum and the foreign risk-free rate is 8% per annum. Using this data, compute the price of the option using the Garman-Kohlhagen model.

```
Settle = datetime(2015,10,1);
Maturity = datetime(2016,6,1);
AssetPrice = 0.52;
Strike = 0.50;
Sigma = .12;
Rates = 0.04;
ForeignRate = 0.08;
```

Define the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding', -1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9737
```

```
           Rates: 0.0400
         EndTimes: 0.6667
       StartTimes: 0
         EndDates: 736482
       StartDates: 736238
    ValuationDate: 736238
           Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
DividendType = 'Continuous';
DividendAmounts = ForeignRate;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1200
         AssetPrice: 0.5200
       DividendType: {'continuous'}
    DividendAmounts: 0.0800
    ExDividendDates: []
```

Price the European put option.

```
OptSpec = {'put'};
Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price = 0.0162
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for option
datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected option prices
vector

Expected option prices, returned as a `NINST`-by-`1` vector.

Data Types: `double`

optstockbycrr

Price stock option from Cox-Ross-Rubinstein tree

Syntax

```
[Price,PriceTree] = optstockbycrr(CRRTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbycrr( ___ ,AmericanOpt)
```

Description

`[Price,PriceTree] = optstockbycrr(CRRTree,OptSpec,Strike,Settle, ExerciseDates)` returns the price of a European, Bermuda, or American stock option from a Cox-Ross-Rubinstein tree.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optstockbycrr( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

Examples

Price an American Stock Option Using a CRR Binomial Tree

This example shows how to price an American stock option using a CRR binomial tree by loading the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the American option.

```
load deriv.mat;

OptSpec = 'Call';
Strike = 105;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2005,1,1);
AmericanOpt = 1;

Price = optstockbycrr(CRRTree, OptSpec, Strike, Settle, ...
ExerciseDates, AmericanOpt)

Price = 8.2863
```

Price a Bermudan Stock Option Using a CRR Binomial Tree

Load the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the Bermudan option.

```
load deriv.mat;

% Option
OptSpec = 'Call';
Strike = [110,111,112,113]
```

```
Strike = 1×4

   110   111   112   113
```

```
Settle = datetime(2003,1,1);
ExerciseDatesBerm= [datetime(2004,1,1)  datetime(2005,1,1)  datetime(2006,1,1)  datetime(2007,1,1
```

Price the Bermudan option.

```
Price = optstockbycrr(CRRTree, OptSpec, Strike, Settle, ExerciseDatesBerm)
```

```
Price = 11.6017
```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a `NINST`-by-1 cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified with a `NINST`-by-1 or `NINST`-by-`NSTRIKES` depending on the option type:

- For a European option, use a `NINST`-by-1 vector of strike prices.
- For a Bermuda option, use a`NINST`-by-`NSTRIKES` matrix of strike prices. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American option, use a `NINST`-by-1 of strike prices.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every option is set to the `ValuationDate` of the stock tree. The option argument `Settle` is ignored.

To support existing code, `optstockbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`,`NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the option type:

- For a European option, use a `NINST`-by-`1` vector of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates. Each row is the schedule for one option.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

To support existing code, `optstockbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European or Bermuda (default) | integer with values of `0` or `1`

(Optional) Option type, specified as `NINST`-by-`1` vector of integer flags with values:

- `0` — European or Bermuda
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Expected price of option at time `0`

vector

Expected price of the vanilla option at time `0`, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure containing trees of vectors of instrument prices for each node

structure

Structure containing trees of vectors of instrument prices and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstockbycrr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbyeqp

Price stock option from Equal Probabilities binomial tree

Syntax

```
[Price,PriceTree] = optstockbyeqp(EQPTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbyeqp( ___ ,AmericanOpt)
```

Description

`[Price,PriceTree] = optstockbyeqp(EQPTree,OptSpec,Strike,Settle, ExerciseDates)` returns the price of a European, Bermuda, or American stock option from an Equal Probabilities binomial tree.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optstockbyeqp( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

Examples

Price an American Stock Option Using an EQP Equity Tree

This example shows how to price an American stock option using an EQP equity tree by loading the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the American option.

```
load deriv.mat

OptSpec = 'Call';
Strike = 105;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2006,1,1);
AmericanOpt = 1;

Price = optstockbyeqp(EQPTree, OptSpec, Strike, Settle, ...
ExerciseDates, AmericanOpt)

Price = 12.2632
```

Price a Bermudan Stock Option Using a EQP Equity Tree

Load the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the Bermudan option.

```
load deriv.mat;

% Option
OptSpec = 'Call';
Strike = 105;
Settle = datetime(2003,1,1);
ExerciseDatesBerm= [datetime(2004,1,15) , datetime(2005,6,15) , datetime(2005,1,15) , datetime(20
```

Price the Bermudan option.

```
Price= optstockbyeqp(EQPTree, OptSpec, Strike, Settle, ExerciseDatesBerm)
```

```
Warning: Some ExerciseDates are not aligned with tree nodes. Result will be approximated.
```

```
Price = 10.0335
```

Input Arguments

`EQPTree` — Stock tree structure

structure

Stock tree structure, specified by using `eqptree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified with a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the option type:

- For a European option, use a `NINST`-by-`1` vector of strike prices.
- For a Bermuda option, use a`NINST`-by-`NSTRIKES` matrix of strike prices. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American option, use a `NINST`-by-`1` of strike prices.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every option is set to the `ValuationDate` of the stock tree. The option argument `Settle` is ignored.

To support existing code, `optstockbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`,`NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the option type:

- For a European option, use a `NINST`-by-`1` vector of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates. Each row is the schedule for one option.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

To support existing code, `optstockbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European or Bermuda (default) | integer with values of `0` or `1`

(Optional) Option type, specified as `NINST`-by-`1` vector of integer flags with values:

- `0` — European or Bermuda
- `1` — American

Data Types: `single` | `double`

Output Arguments

`Price` — Expected price of option at time `0`
vector

Expected price of the vanilla option at time `0`, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure containing trees of vectors of instrument prices for each node
structure

Structure containing trees of vectors of instrument prices and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

optstockbyfd

Calculate vanilla option prices using finite difference method

Syntax

```
[Price,PriceGrid,AssetPrices,Times] = optstockbyfd(RateSpec,StockSpec,
OptSpec,Strike,Settle,ExerciseDates)
[Price,PriceGrid,AssetPrices,Times] = optstockbyfd( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Times] = optstockbyfd(RateSpec,StockSpec, OptSpec,Strike,Settle,ExerciseDates)` calculates vanilla option prices using the finite difference method.

`[Price,PriceGrid,AssetPrices,Times] = optstockbyfd( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Vanilla Call Option Using Finite Difference Method

Create a `RateSpec`.

```
AssetPrice = 50;
Strike = 45;
Rate = 0.035;
Volatility = 0.30;
Settle = datetime(2015,1,1);
Maturity = datetime(2016,1,1);
Basis = 1;

RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',...
Maturity,'Rates',Rate,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 736330
       StartDates: 735965
    ValuationDate: 735965
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
StockSpec = stockspec(Volatility,AssetPrice)

StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price of a European vanilla call option using the finite difference method.

```
ExerciseDates = datetime(2015,5,1);
OptSpec = 'Call';
Price = optstockbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)

Price = 6.7352
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a character vector or string array with values `'call'` or `'put'`.

Data Types: `char` | `string`

`Strike` — Option strike price value

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or vector.

- For a European option, use a scalar of strike price.

- For a Bermuda option, use a 1-by-NSTRIKES vector of strike prices.
- For an American option, use a scalar of strike price.

Data Types: double

Settle — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, optstockbyfd also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a 1-by-1 vector of dates. For a Bermuda option, use a 1-by-NSTRIKES vector of dates.
- For an American option, use a 1-by-2 vector of dates. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a 1-by-1 vector dates, the option can be exercised between Settle and the single listed date in ExerciseDates.

To support existing code, optstockbyfd also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = optstockbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'AssetGridSize',1000)

AssetGridSize — Size of asset grid used for finite difference grid
400 (default) | positive scalar

Size of the asset grid used for a finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a positive scalar.

Data Types: double

AssetPriceMax — Maximum price for price grid boundary
if unspecified, StockSpec values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of 'AssetPriceMax' as a positive scalar.

Data Types: `single` | `double`

`TimeGridSize` — Size of time grid used for finite difference grid
`100` (default) | positive scalar

Size of the time grid used for a finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European/Bermuda) (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Expected prices for vanilla options
scalar

Expected prices for vanilla options, returned as a `1`-by-`1` matrix.

`PriceGrid` — Grid containing prices calculated by finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size `PriceGridSize*length(Times)`. The number of columns does not have to be equal to the `TimeGridSize`, because ex-dividend dates in the `StockSpec` are added to the time grid. The price for `t = 0` is contained in `PriceGrid(:, end)`.

`AssetPrices` — Prices of asset defined by `StockSpec`
vector

Prices of the asset defined by the `StockSpec` corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to second dimension of `PriceGrid`
vector

Times corresponding to second dimension of the `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstockbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstocksensbyfd

Calculate vanilla option prices or sensitivities using finite difference method

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd(RateSpec,
StockSpec,OptSpec,Strike,Settle,ExerciseDates)
[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd( ___ ,Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd(RateSpec, StockSpec,OptSpec,Strike,Settle,ExerciseDates)` calculates vanilla option prices or sensitivities using the finite difference method.

`[PriceSens,PriceGrid,AssetPrices,Times] = optstocksensbyfd( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate the Price and Sensitivities for a Vanilla Call Option Using Finite Difference Method

Create a `RateSpec`.

```
AssetPrice = 50;
Strike = 45;
Rate = 0.035;
Volatility = 0.30;
Settle = datetime(2015,1,1);
Maturity = datetime(2016,1,1);
Basis = 1;

RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',...
Maturity,'Rates',Rate,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
          EndTimes: 1
        StartTimes: 0
          EndDates: 736330
        StartDates: 735965
    ValuationDate: 735965
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
StockSpec = stockspec(Volatility,AssetPrice)

StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price and sensitivities for of a European vanilla call option using the finite difference method.

```
ExerciseDates = datetime(2015,5,1);
OptSpec = 'Call';
OutSpec = {'price'; 'delta'; 'theta'};
[PriceSens, Delta, Theta] = optstocksensbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,...
ExerciseDates,'OutSpec',OutSpec)

PriceSens = 6.7352

Delta = 0.7765

Theta = -4.9999
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a character vector or string array with values `'call'` or `'put'`.

Data Types: `char` | `string`

`Strike` — Option strike price value

nonnegative scalar | nonnegative vector

Option strike price value, specified as a nonnegative scalar or vector.

- For a European option, use a scalar of strike price.
- For a Bermuda option, use a 1-by-`NSTRIKES` vector of strike prices.
- For an American option, use a scalar of strike price.

Data Types: `double`

`Settle` — Settlement or trade date

datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `optstocksensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors as follows:

- For a European option, use a 1-by-1 vector of dates. For a Bermuda option, use a 1-by-`NSTRIKES` vector of dates.
- For an American option, use a 1-by-2 vector of dates. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a 1-by-1 cell array of date character vectors, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `optstocksensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = optstocksensbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',{'All'},'AssetGridSize',1000)`

`OutSpec` — Define outputs

`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-1 or a 1-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

`AssetGridSize` — Size of asset grid used for finite difference grid
`400` (default) | positive scalar

Size of asset grid used for finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a positive scalar.

Data Types: `double`

`AssetPriceMax` — Maximum price for price grid boundary
if unspecified, `StockSpec` values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for price grid boundary, specified as the comma-separated pair consisting of `'AssetPriceMax'` and a positive scalar.

Data Types: `single` | `double`

`TimeGridSize` — Size of time grid used for finite difference grid
`100` (default) | positive scalar

Size of the time grid used for a finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive scalar.

Data Types: `double`

`AmericanOpt` — Option type
`0` (European/Bermuda) (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Data Types: `double`

Output Arguments

`PriceSens` — Expected prices or sensitivities for vanilla options
scalar

Expected price or sensitivities (defined by `OutSpec`) of the vanilla option, returned as a `1`-by-`1` array.

`PriceGrid` — Grid containing prices calculated by finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `PriceGridSize*length(Times)`. The number of columns does not have to be equal to the `TimeGridSize`, because ex-dividend dates in the `StockSpec` are added to the time grid. The price for `t = 0` is contained in `PriceGrid(:, end)`.

`AssetPrices` — Prices of asset defined by `StockSpec`
vector

Prices of the asset defined by the `StockSpec` corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to second dimension of `PriceGrid`
vector

Times corresponding to second dimension of the `PriceGrid`, returned as a vector.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstocksensbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbyitt

Price options on stocks using implied trinomial tree (ITT)

Syntax

```
[Price,PriceTree] = optstockbyitt(ITTTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbyitt( ___ ,AmericanOpt)
```

Description

`[Price,PriceTree] = optstockbyitt(ITTTree,OptSpec,Strike,Settle, ExerciseDates)` returns the price of a European, Bermuda, or American stock option from an implied trinomial tree (ITT).

`[Price,PriceTree] = optstockbyitt( ___ ,AmericanOpt)` adds an optional argument for `AmericanOpt`.

Examples

Price an American Stock Option Using an ITT Equity Tree

This example shows how to price an American stock option using an ITT equity tree by loading the file `deriv.mat`, which provides the `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the American option.

```
load deriv.mat

OptSpec = 'Put';
Strike = 30;
Settle = datetime(2006,1,1);
ExerciseDates = datetime(2010,1,1);
AmericanOpt = 1;

Price = optstockbyitt(ITTTree, OptSpec, Strike, Settle,ExerciseDates, AmericanOpt)
```

```
Price = 0.1271
```

Price a Bermudan Stock Option Using an ITT Equity Tree

Load the file `deriv.mat`, which provides an `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the Bermudan option.

```
load deriv.mat;

% Option
OptSpec = 'Put';
Strike = 30;
Settle = datetime(2006,1,1);
ExerciseDatesBerm = [datetime(2007,1,1) , datetime(2007,6,1) , datetime(2008,1,1) , datetime(2008,6,1)];
```

Price the Bermudan option.

```
Price = optstockbyitt(ITTTree, OptSpec, Strike, Settle, ExerciseDatesBerm)
```

```
Warning: Some ExerciseDates are not aligned with tree nodes. Result will be approximated.
> In procoptions at 171
  In optstockbystocktree at 22
  In optstockbyitt at 68

Price =

    0.0664
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values

nonnegative integer

Option strike price value, specified with a `NINST`-by-`1` or `NINST`-by-`NSTRIKES` depending on the option type:

- For a European option, use a `NINST`-by-`1` vector of strike prices.
- For a Bermuda option, use a`NINST`-by-`NSTRIKES` matrix of strike prices. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American option, use a `NINST`-by-`1` of strike prices.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

Data Types: `double`

`Settle` — Settlement date or trade date

datetime array | string array | date character vector

Settlement date or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every option is set to the `ValuationDate` of the stock tree. The option argument `Settle` is ignored.

To support existing code, `optstockbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1`,`NINST`-by-`2`, or `NINST`-by-`NSTRIKES` vector using a datetime array, string array, or date character vectors, depending on the option type:

- For a European option, use a `NINST`-by-`1` vector of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of dates. Each row is the schedule for one option.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

Note The interpretation of the `Strike` and `ExerciseDates` arguments depends upon the setting of the `AmericanOpt` argument. If `AmericanOpt = 0`, `NaN`, or is unspecified, the option is a European or Bermuda option. If `AmericanOpt = 1`, the option is an American option.

To support existing code, `optstockbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European or Bermuda (default) | integer with values of `0` or `1`

(Optional) Option type, specified as `NINST`-by-`1` vector of integer flags with values:

- `0` — European or Bermuda
- `1` — American

Data Types: `single` | `double`

Output Arguments

`Price` — Expected price of option at time `0`
vector

Expected price of the vanilla option at time `0`, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure containing trees of vectors of instrument prices for each node
structure

Structure containing trees of vectors of instrument prices and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

- `PriceTree.dObs` contains the observation dates.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

optstockbylr

Price options on stocks using Leisen-Reimer binomial tree model

Syntax

```
[Price,PriceTree] = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates)
[Price,PriceTree] = optstockbylr( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates)` computes option prices on stocks using the Leisen-Reimer binomial tree model.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optstockbylr( ___ ,Name,Value)` adds an optional name-value pair argument for `AmericanOpt`.

Examples

Price Options on Stocks Using the Leisen-Reimer Binomial Tree Model

This example shows how to price options on stocks using the Leisen-Reimer binomial tree model. Consider European call and put options with an exercise price of $95 that expire on July 1, 2010. The underlying stock is trading at $100 on January 1, 2010, provides a continuous dividend yield of 3% per annum and has a volatility of 20% per annum. The annualized continuously compounded risk-free rate is 8% per annum. Using this data, compute the price of the options using the Leisen-Reimer model with a tree of 15 and 55 time steps.

```
AssetPrice  = 100;
Strike = 95;

ValuationDate = datetime(2010,1,1);
Maturity = datetime(2010,6,1);

% define StockSpec
Sigma = 0.2;
DividendType = 'continuous';
DividendAmounts = 0.03;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);

% define RateSpec
Rates = 0.08;
Settle = ValuationDate;
Basis = 1;
```

```
Compounding = -1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% build the Leisen-Reimer (LR) tree with 15 and 55 time steps
LRTimeSpec15  = lrtimespec(ValuationDate, Maturity, 15);
LRTimeSpec55  = lrtimespec(ValuationDate, Maturity, 55);

% use the PP2 method
LRMethod  = 'PP2';

LRTree15 = lrtree(StockSpec, RateSpec, LRTimeSpec15, Strike, 'method', LRMethod);
LRTree55 = lrtree(StockSpec, RateSpec, LRTimeSpec55, Strike, 'method', LRMethod);

% price the call and the put options using the LR model:
OptSpec = {'call'; 'put'};

PriceLR15 = optstockbylr(LRTree15, OptSpec, Strike, Settle, Maturity);
PriceLR55 = optstockbylr(LRTree55, OptSpec, Strike, Settle, Maturity);

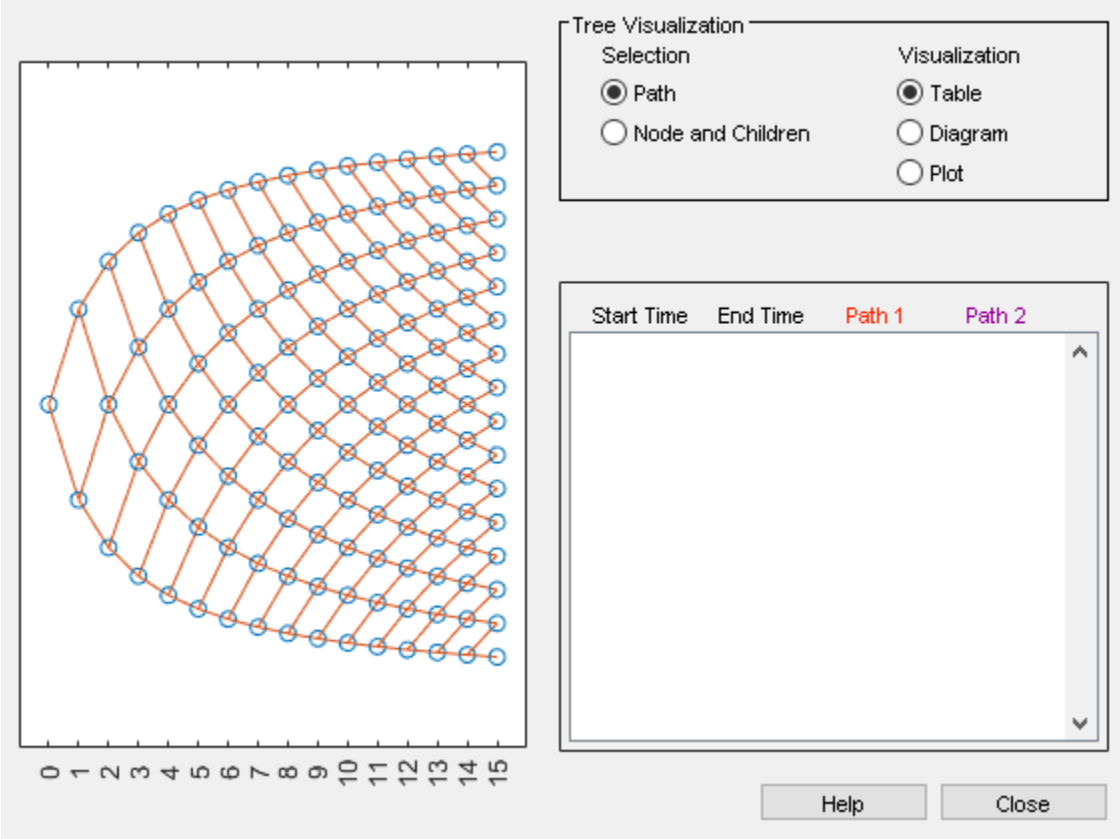
% calculate price using the Black-Scholes model (BLS) to compare values with
% the LR model:
PriceBLS = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike);

% compare values of BLS and LR
[PriceBLS PriceLR15 PriceLR55]

ans = 2×3

    9.0870    9.0826    9.0831
    2.2148    2.2039    2.2044

% use treeviewer to display LRTree of 15 time steps
treeviewer(LRTree15)
```



Input Arguments

`LRTree` — Stock tree structure

structure

Stock tree structure, specified by `lrtree`.

Data Types: `struct`

`OptSpec` — Definition of option

cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price values

vector of nonnegative integers

Option strike price value, specified with nonnegative integer:

- For a European option, use a `NINST`-by-`1` vector of strike prices.
- For a Bermuda option, use a `NINST`-by-`NSTRIKES` vector of strike prices. Each row is the schedule for one option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.

- For an American option, use a `NINST`-by-`1` vector of strike prices.

Data Types: `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbylr` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors, where each row is the schedule for one option and the last element of each row must be the same as the maturity of the tree.

- For a European option, use a `NINST`-by-`1` vector of dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- For a Bermuda option, use a `NINST`-by-`NSTRIKEDATES` vector of dates.
- For an American option, use a `NINST`-by-`1` vector of exercise dates. For the American type, the option can be exercised on any tree data between the `ValuationDate` and tree maturity.

To support existing code, `optstockbylr` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates,'AmericanOpt','1')`

`AmericanOpt` — Option type
`0` European or Bermuda (default) | values: `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` vector of flags with values:

- `0` — European or Bermuda
- `1` — American

Data Types: `double`

Output Arguments

`Price` — Expected prices at time 0
vector

expected prices at time 0, returned as a `NINST`-by-1 vector.

`PriceTree` — Tree structure
structure

Tree structure, returned as a vector of instrument prices at each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2010b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstockbylr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbyls

Price European, Bermudan, or American vanilla options using Monte Carlo simulations

Syntax

```
Price = optstockbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
Price = optstockbyls( ___ ,Name,Value)

[Price,Path,Times,Z] = optstockbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
[Price,Path,Times,Z] = optstockbyls( ___ ,Name,Value)
```

Description

`Price = optstockbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns vanilla option prices using the Longstaff-Schwartz model. `optstockbyls` computes prices of European, Bermudan, and American vanilla options.

For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = optstockbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

`[Price,Path,Times,Z] = optstockbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns vanilla option prices using the Longstaff-Schwartz model.

`[Price,Path,Times,Z] = optstockbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of a Vanilla Option

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.05;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
```

```
             Disc: 0.9060
            Rates: 0.0500
          EndTimes: 4
        StartTimes: 0
          EndDates: 735965
        StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 100;
Sigma = 0.1;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1000
         AssetPrice: 100
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the vanilla option.

```
OptSpec = 'put';
Settle = datetime(2013,1,1);
ExerciseDates = datetime(2015,1,1);
Strike = 105;
```

Compute the vanilla option price using the Longstaff-Schwartz model.

```
Antithetic = true;
Price = optstockbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ...
ExerciseDates, 'Antithetic', Antithetic)
```

```
Price = 3.2292
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`Strike` — Option strike price values
nonnegative scalar integer

Option strike price value, specified with nonnegative scalar integer:

- For a European option, use a scalar of strike price.
- For a Bermuda option, use a 1-by-`NSTRIKES` vector of strike prices.
- For an American option, use a scalar of strike price.

Data Types: `single` | `double`

`Settle` — Settlement date or trade date
datetime scalar | string scalar | date character vector

Settlement date or trade date for the vanilla option, specified as a scalar datetime, string, or date character vector.

To support existing code, `optstockbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors as follows:

- For a European option, use a 1-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a 1-by-`NSTRIKES` vector of dates.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a 1-by-1 cell array of character vectors, the option can be exercised between `Settle` and the single listed `ExerciseDates`.

To support existing code, `optstockbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optstockbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'AmericanOpt','1','NumTrials','2000')`

`AmericanOpt` — Option type
`0` European or Bermuda (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and positive integer scalar flags with values:

- `0` — European or Bermuda
- `1` — American

Note For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`NumTrials` — Simulation trials
`1000` (default) | scalar

Simulation trials, specified as a scalar number of independent sample paths.

Data Types: `double`

`NumPeriods` — Simulation periods per trial
`100` (default) | scalar

Simulation periods per trial, specified as a scalar number. `NumPeriods` is considered only when pricing European vanilla options. For American and Bermuda vanilla options, `NumPeriod` is equal to the number of `Exercise` days during the life of the option.

Data Types: `double`

`Z` — Dependent random variates
scalar | nonnegative integer

Dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation, specified as a be `NumPeriods`-by-`1`-by-`NumTrials` 3-D time series array.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified with a value of `true` or `false`.

Data Types: `logical`

Output Arguments

`Price` — Expected price of vanilla option

scalar

Expected price of the vanilla option, returned as a 1-by-1 scalar.

`Path` — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a (`NumPeriods` + 1) -by-1-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a (`NumPeriods` + 1)-by-1 column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates

vector

Dependent random variates, if `Z` is specified as an optional input argument, the same value is returned. Otherwise, `Z` contains the random variates generated internally.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstockbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstocksensbyls

Calculate price and sensitivities for European, Bermudan, or American vanilla options using Monte Carlo simulations

Syntax

```
PriceSens = optstocksensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
PriceSens = optstocksensbyls( ___ ,Name,Value)

[PriceSens,Path,Times,Z] = optstocksensbyls(RateSpec,StockSpec,OptSpec,
Strike,Settle,ExerciseDates)
[PriceSens,Path,Times,Z] = optstocksensbyls( ___ ,Name,Value)
```

Description

`PriceSens = optstocksensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns vanilla option prices or sensitivities using the Longstaff-Schwartz model. `optstocksensbyls` computes prices or sensitivities of European, Bermudan, and American vanilla options.

For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optstocksensbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

`[PriceSens,Path,Times,Z] = optstocksensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns vanilla option prices or sensitivities using the Longstaff-Schwartz model.

`[PriceSens,Path,Times,Z] = optstocksensbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Sensitivities of a Vanilla Option

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.05;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates, 'Rates', Rates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: 0.9060
            Rates: 0.0500
         EndTimes: 4
       StartTimes: 0
         EndDates: 735965
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 100;
Sigma = 0.1;
DivType = 'continuous';
DivAmounts = 0.04;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmounts)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1000
         AssetPrice: 100
       DividendType: {'continuous'}
    DividendAmounts: 0.0400
    ExDividendDates: []
```

Define the vanilla option.

```
OptSpec = 'call';
Settle = datetime(2013,1,1);
ExerciseDates = datetime(2015,1,1);
Strike = 105;
```

Compute the `Delta` sensitivity for the vanilla option using the Longstaff-Schwartz model.

```
Antithetic = true;
OutSpec = {'Delta'};
PriceSens = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, ...
Settle, ExerciseDates,'Antithetic', Antithetic, 'OutSpec', OutSpec)
```

```
PriceSens = 0.3945
```

To display the output for `Price`, `Delta`, `Path`, and `Times`, use the following:

```
OutSpec = {'Price','Delta'};
[Price, Delta, Path, Times] = optstocksensbyls(RateSpec, StockSpec, OptSpec, Strike, ...
Settle, ExerciseDates,'Antithetic', Antithetic, 'OutSpec', OutSpec);
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities.

Data Types: `struct`

`OptSpec` — Definition of option
character vector values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`Strike` — Option strike price value
nonnegative scalar integer

Option strike price value, specified with a nonnegative scalar integer:

- For a European option, use a scalar of strike price.
- For a Bermuda option, use a 1-by-`NSTRIKES` vector of strike price.
- For an American option, use a scalar of strike price.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime scalar | string scalar | date character vector

Settlement date or trade date for the vanilla option, specified as a scalar datetime, string, or date character vector.

To support existing code, `optstocksensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise date
datetime array | string array | date character vector

Option exercise date, specified using a datetime array, string array, or date character vectors as follows:

- For a European option, use a 1-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For a Bermuda option, use a 1-by-`NSTRIKES` vector of dates.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a 1-by-1 cell array of character vectors, the option can be exercised between `Settle` and the single listed `ExerciseDates`.

To support existing code, `optstocksensbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optstocksensbyls(RateSpec,StockSpec, OptSpec,Strike,Settle,ExerciseDates,'AmericanOpt','1','NumTrials','2000','OutSpec',{'Price','Delta','Gamma'})`

`AmericanOpt` — Option type

`0` European or Bermuda (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a positive integer scalar flag with values:

- `0` — European or Bermuda
- `1` — American

Note For American and Bermudan options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `single` | `double`

`NumTrials` — Simulation trials

`1000` (default) | scalar

Simulation trials, specified as the comma-separated pair consisting of `'NumTrials'` and a scalar number of independent sample paths.

Data Types: `double`

`NumPeriods` — Simulation periods per trial

`100` (default) | scalar

Simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar number. `NumPeriods` is considered only when pricing European vanilla options. For American and Bermuda vanilla options, `NumPeriod` is equal to the number of `Exercise` days during the life of the option.

Data Types: `double`

`Z` — Dependent random variates

scalar | nonnegative integer

Dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-`1`-by-`NumTrials` 3-D time series array.

Data Types: `single` | `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected price or sensitivities of vanilla option
scalar

Expected price or sensitivities (defined by `OutSpec`) of the vanilla option, returned as a `1`-by-`1` array.

`Path` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a (`NumPeriods` + `1`)-by-`1`-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a (`NumPeriods` + `1`)-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates
vector

Dependent random variates, if `Z` is specified as an optional input argument, the same value is returned. Otherwise, `Z` contains the random variates generated internally.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstocksensbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbyrgw

Determine American call option prices using Roll-Geske-Whaley option pricing model

Syntax

```
Price = optstockbyrgw(RateSpec,StockSpec,Settle,Maturity,Strike)
```

Description

`Price = optstockbyrgw(RateSpec,StockSpec,Settle,Maturity,Strike)` computes the American call option prices using the Roll-Geske-Whaley option pricing model. `optstockbyrgw` computes prices of American calls with a single cash dividend using the Roll-Geske-Whaley option pricing model.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Determine American Call Option Prices Using Roll-Geske-Whaley Option Pricing Model

This example shows how to determine American call option prices using Roll-Geske-Whaley option pricing model. Consider an American call option with an exercise price of $22 that expires on February 1, 2009. The underlying stock is trading at $20 on June 1, 2008 and has a volatility of 20% per annum. The annualized continuously compounded risk-free rate is 6.77% per annum. The stock pays a single dividend of $2 on September 1, 2008. Using this data, compute price of the American call option using the Roll-Geske-Whaley option pricing model.

```
Settle = datetime(2008,6,1);
Maturity = datetime(2009,2,1);
AssetPrice = 20;
Strike = 22;
Sigma  = 0.2;
Rate = 0.0677;
DivAmount = 2;
DivDate = datetime(2008,9,1);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 0);

StockSpec = stockspec(Sigma, AssetPrice, {'cash'}, DivAmount, DivDate);

Price  = optstockbyrgw(RateSpec, StockSpec, Settle, Maturity,Strike)

Price = 0.3359
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbyrgw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for option

datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstockbyrgw` also accepts serial date numbers as inputs, but they are not recommended.

`Strike` — Option strike price value

nonnegative vector

Option strike price value, specified as a nonnegative `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected call option prices

vector

Expected call option prices, returned as a `NINST`-by-`1` vector.

Data Types: `double`

optstocksensbybjs

Determine American option prices or sensitivities using Bjerksund-Stensland 2002 option pricing model

Syntax

```
PriceSens = optstocksensbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,
Strike)
PriceSens = optstocksensbybjs( ___ ,Name,Value)
```

Description

`PriceSens = optstocksensbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec, Strike)` computes American option prices or sensitivities using the Bjerksund-Stensland 2002 option pricing model.

`optstocksensbybjs` computes prices of American options with continuous dividend yield using the Bjerksund-Stensland option pricing model. All sensitivities are evaluated by computing a discrete approximation of the partial derivative. This means that the option is revalued with a fractional change for each relevant parameter, and the change in the option value divided by the increment, is the approximated sensitivity value.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optstocksensbybjs( ___ ,Name,Value)` adds an optional name-value pair argument for `OutSpec`.

Examples

Compute American Option Prices and Sensitivities Using the Bjerksund-Stensland 2002 Option Pricing Model

This example shows how to compute American option prices and sensitivities using the Bjerksund-Stensland 2002 option pricing model. Consider four American put options with an exercise price of $100. The options expire on October 1, 2008. Assume the underlying stock pays a continuous dividend yield of 4% and has a volatility of 40% per annum. The annualized continuously compounded risk-free rate is 8% per annum. Using this data, calculate the `delta`, `gamma`, and `price` of the American put options, assuming the following current prices of the stock on July 1, 2008: $90, $100, $110 and $120.

```
Settle = datetime(2008,6,1);
Maturity = datetime(2008,10,1);
Strike = 100;
AssetPrice = [90;100;110;120];
Rate = 0.08;
```

```
Sigma = 0.40;
DivYield = 0.04;

% define the RateSpec and StockSpec
StockSpec = stockspec(Sigma, AssetPrice, {'continuous'}, DivYield);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1);

% define the option type
OptSpec = {'put'};

OutSpec = {'Delta', 'Gamma', 'Price'};

[Delta, Gamma, Price] = optstocksensbybjs(RateSpec, StockSpec, Settle, Maturity,...
OptSpec, Strike, 'OutSpec', OutSpec)
```

```
Delta = 4×1

   -0.6236
   -0.4351
   -0.2794
   -0.1673

Gamma = 4×1

    0.0196
    0.0176
    0.0134
    0.0091

Price = 4×1

   13.7594
    8.4830
    4.9451
    2.7475
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for option
datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Delta,Gamma,Price] = optstocksensbybjs(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',OutSpec)`

`OutSpec` — Define outputs
`{'Price'}` (default) | cell array of character vectors with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected future prices or sensitivities values

vector

Expected future prices or sensitivities values, returned as a `NINST`-by-`1` vector.

Data Types: `double`

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

optstocksensbyblk

Determine option prices or sensitivities on futures and forwards using Black option pricing model

Syntax

```
PriceSens = optstocksensbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,
Strike)
PriceSens = optstocksensbyblk( ___ ,Name,Value)
```

Description

`PriceSens = optstocksensbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec, Strike)` computes option prices on futures and forwards using the Black option pricing model.

Note `optstocksensbyblk` calculates option prices or sensitivities on futures and forwards. If `ForwardMaturity` is not passed, the function calculates prices or sensitivities of future options. If `ForwardMaturity` is passed, the function computes prices or sensitivities of forward options. This function handles several types of underlying assets, for example, stocks and commodities. For more information on the underlying asset specification, see `stockspec`.

`PriceSens = optstocksensbyblk( ___ ,Name,Value)` adds optional name-value pair arguments for `ForwardMaturity` and `OutSpec` to compute option prices or sensitivities on forwards using the Black option pricing model.

Examples

Compute Option Prices and Sensitivities on Futures Using the Black Pricing Model

This example shows how to compute option prices and sensitivities on futures using the Black pricing model. Consider a European put option on a futures contract with an exercise price of $60 that expires on June 30, 2008. On April 1, 2008 the underlying stock is trading at $58 and has a volatility of 9.5% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, compute `delta`, `gamma`, and the `price` of the put option.

```
AssetPrice = 58;
Strike = 60;
Sigma = .095;
Rates = 0.05;
Settle = datetime(2008,4,1);
Maturity = datetime(2008,6,30);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);

StockSpec = stockspec(Sigma, AssetPrice);

% define the options
```

```
OptSpec = {'put'};

OutSpec = {'Delta','Gamma','Price'};
[Delta, Gamma, Price] = optstocksensbyblk(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike,'OutSpec', OutSpec)

Delta = -0.7469

Gamma = 0.1130

Price = 2.3569
```

Compute Forward Option Prices and Delta Sensitivities

This example shows how to compute option prices and sensitivities on forwards using the Black pricing model. Consider two European call options on the Brent Blend forward contract that expires on January 1, 2015. The options expire on October 1, 2014 and Dec 1, 2014 with an exercise price % of $120 and $150 respectively. Assume that on January 1, 2014 the forward price is at $107, the annualized continuously compounded risk-free rate is 3% per annum and volatility is 28% per annum. Using this data, compute the price and delta of the options.

Define the `RateSpec`.

```
ValuationDate = datetime(2014,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.03;
Compounding = -1;
Basis = 1;
RateSpec  = intenvset('ValuationDate', ValuationDate, 'StartDates', ...
ValuationDate, 'EndDates', EndDates, 'Rates', Rates, ...
'Compounding', Compounding, 'Basis', Basis');
```

Define the `StockSpec`.

```
AssetPrice = 107;
Sigma = 0.28;
StockSpec  = stockspec(Sigma, AssetPrice);
```

Define the options.

```
Settle = datetime(2014,1,1);
Maturity = [datetime(2014,10,1) ; datetime(2014,12,1)]; %Options maturity
Strike = [120;150];
OptSpec = {'call'; 'call'};
```

Price the forward call options and return the `Delta` sensitivities.

```
ForwardMaturity = 'Jan-1-2015'; % Forward contract maturity
OutSpec = {'Delta'; 'Price'};
[Delta, Price] = optstocksensbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, ...
Strike, 'ForwardMaturity', ForwardMaturity, 'OutSpec', OutSpec)

Delta = 2×1

    0.3518
```

```
    0.1262

Price = 2×1

    5.4808
    1.6224
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbyblk` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for option

datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbyblk` also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option

cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

Strike — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative NINST-by-1 vector.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Delta,Gamma,Price] = optstocksensbyblk(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',OutSpec)

ForwardMaturity — Maturity date or delivery date of forward contract
Maturity of option (default) | date character vector

Maturity date or delivery date of forward contract, specified as the comma-separated pair consisting of 'ForwardMaturity' and a NINST-by-1 vector using date character vectors.

To support existing code, optstocksensbyblk also accepts serial date numbers as inputs, but they are not recommended.

OutSpec — Define outputs
{'Price'} (default) | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

Output Arguments

PriceSens — Expected future prices or sensitivities values
vector

Expected future prices or sensitivities values, returned as a NINST-by-1 vector.

Data Types: double

More About

Futures Option

A futures option is a standardized contract between two parties to buy or sell a specified asset of standardized quantity and quality for a price agreed upon today (the futures price) with delivery and payment occurring at a specified future date, the delivery date.

The futures contracts are negotiated at a futures exchange, which acts as an intermediary between the two parties. The party agreeing to buy the underlying asset in the future, the "buyer" of the contract, is said to be "long," and the party agreeing to sell the asset in the future, the "seller" of the contract, is said to be "short."

A futures contract is the delivery of item J at time T and:

- There exists in the market a quoted price $F(t, T)$, which is known as the futures price at time t for delivery of J at time T.
- The price of entering a futures contract is equal to zero.
- During any time interval $[t,s]$, the holder receives the amount $F(s, T) - F(t, T)$ (this reflects instantaneous marking to market).
- At time T, the holder pays $F(T, T)$ and is entitled to receive J. Note that $F(T, T)$ should be the spot price of J at time T.

For more information, see “Futures Option” on page 3-32.

Forwards Option

A forwards option is a non-standardized contract between two parties to buy or to sell an asset at a specified future time at a price agreed upon today.

The buyer of a forwards option contract has the right to hold a particular forward position at a specific price any time before the option expires. The forwards option seller holds the opposite forward position when the buyer exercises the option. A call option is the right to enter into a long forward position and a put option is the right to enter into a short forward position. A closely related contract is a futures contract. A forward is like a futures in that it specifies the exchange of goods for a specified price at a specified future date.

The payoff for a forwards option, where the value of a forward position at maturity depends on the relationship between the delivery price (K) and the underlying price (S_T) at that time, is:

- For a long position: $f_T = S_T - K$
- For a short position: $f_T = K - S_T$

For more information, see “Forwards Option” on page 3-31.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstocksensbyblk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstocksensbybls

Determine option prices or sensitivities using Black-Scholes option pricing model

Syntax

```
PriceSens = optstocksensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,
Strike)
PriceSens = optstocksensbybls( ___ ,Name,Value)
```

Description

`PriceSens = optstocksensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec, Strike)` computes option prices or sensitivities using the Black-Scholes option pricing model.

Note When using `StockSpec` with `optstocksensbybls`, you can modify `StockSpec` to handle other types of underliers when pricing instruments that use the Black-Scholes model.

When pricing Futures (Black model), enter the following in `StockSpec`:

```
DivType = 'Continuous';
DivAmount = RateSpec.Rates;
```

When pricing Foreign Currencies (Garman-Kohlhagen model), enter the following in `StockSpec`:

```
DivType = 'Continuous';
DivAmount = ForeignRate;
```

where `ForeignRate` is the continuously compounded, annualized risk free interest rate in the foreign country.

Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optstocksensbybls( ___ ,Name,Value)` adds an optional name-value pair argument for `OutSpec`.

Examples

Compute Option Prices and Sensitivities Using the Black-Scholes Option Pricing Model

This example shows how to compute option prices and sensitivities using the Black-Scholes option pricing model. Consider a European call and put options with an exercise price of $30 that expires on June 1, 2008. The underlying stock is trading at $30 on January 1, 2008 and has a volatility of 30% per annum. The annualized continuously compounded risk-free rate is 5% per annum. Using this data, compute the `delta`, `gamma`, and `price` of the options using the Black-Scholes model.

```
AssetPrice = 30;
Strike = 30;
```

```
Sigma = .30;
Rates = 0.05;
Settle = datetime(2008,1,1);
Maturity = datetime(2008,6,1);

% define the RateSpec and StockSpec
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding',-1, 'Basis', 1);

StockSpec = stockspec(Sigma, AssetPrice);

% define the options
OptSpec = {'call', 'put'};

OutSpec = {'Delta','Gamma','Price'};
[Delta, Gamma, Price] = optstocksensbybls(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike,'OutSpec', OutSpec)
```

```
Delta = 2×1

    0.5810
   -0.4190

Gamma = 2×1

    0.0673
    0.0673

Price = 2×1

    2.6126
    1.9941
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for option
datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Delta,Gamma,Price] = optstocksensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',OutSpec)`

`OutSpec` — Define outputs
`{'Price'}` (default) | cell array of character vectors with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected future prices or sensitivities values

vector

Expected future prices or sensitivities values, returned as a `NINST`-by-`1` vector.

Data Types: `double`

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstocksensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstocksensbylr

Determine option prices or sensitivities using Leisen-Reimer binomial tree model

Syntax

```
PriceSens = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates)
PriceSens = optstockbylr( ___ ,Name,Value)
```

Description

`PriceSens = optstockbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates)` calculates option prices or sensitivities using a Leisen-Reimer binomial tree model.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optstockbylr( ___ ,Name,Value)` adds optional name-value pair arguments for `AmericanOpt` and `OutSpec`.

Examples

Compute Option Prices and Sensitivities Using a Leisen-Reimer Binomial Tree Model

This example shows how to compute option prices and sensitivities using a Leisen-Reimer binomial tree model. Consider European call and put options with an exercise price of $100 that expire on December 1, 2010. The underlying stock is trading at $100 on June 1, 2010 and has a volatility of 30% per annum. The annualized continuously compounded risk-free rate is 7% per annum. Using this data, compute the price, delta and gamma of the options using the Leisen-Reimer model with a tree of 25 time steps and the `PP2` method.

```
AssetPrice  = 100;
Strike = 100;

ValuationDate = datetime(2010,6,1);
Maturity = datetime(2010,12,1);

% define StockSpec
Sigma = 0.3;

StockSpec = stockspec(Sigma, AssetPrice);

% define RateSpec
Rates = 0.07;
Settle = ValuationDate;
Basis = 1;
Compounding = -1;
```

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);

% build the Leisen-Reimer (LR) tree with 25 time steps
LRTimeSpec  = lrtimespec(ValuationDate, Maturity, 25);

% use the PP2 method
LRMethod  = 'PP2';

TreeLR = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike, 'method', LRMethod);

% compute prices and sensitivities using the LR model:
OptSpec = {'call'; 'put'};
OutSpec = {'Price', 'Delta', 'Gamma'};

[Price, Delta, Gamma] = optstocksensbylr(TreeLR, OptSpec, Strike, Settle, ...
Maturity, 'OutSpec', OutSpec)
```

```
Price = 2×1

   10.1332
    6.6937

Delta = 2×1

    0.6056
   -0.3944

Gamma = 2×1

    0.0185
    0.0185
```

Input Arguments

LRTree — Stock tree structure

structure

Stock tree structure, specified by `lrtree`.

Data Types: `struct`

OptSpec — Definition of option

cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

Strike — Option strike price values

vector of nonnegative integers

Option strike price value, specified with nonnegative integer:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American option, use a NINST-by-1 vector of strike prices.

Data Types: double

Settle — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, optstocksensbylr also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1 or NINST-by-NSTRIKEDATES vector using a datetime array, string array, or date character vectors, where each row is the schedule for one option and the last element of each row must be the same as the maturity of the tree.

- For a European option, use a NINST-by-1 vector of dates. For a European option, there is only one ExerciseDate on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKEDATES vector of dates.
- For an American option, use a NINST-by-1 vector of exercise dates. For the American type, the option can be exercised on any tree data between the ValuationDate and tree maturity.

To support existing code, optstocksensbylr also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,Delta,Gamma] = optstocksensbylr(LRTree,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',OutSpec)

AmericanOpt — Option type
0 European or Bermuda (default) | values: [0,1]

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a NINST-by-1 vector of flags with values:

- 0 — European or Bermuda
- 1 — American

Data Types: `double`

`OutSpec` — Define outputs
`{'Price'}` (default) | cell array of character vectors with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected future prices or sensitivities values
vector

Expected future prices or sensitivities values, returned as a `NINST`-by-`1` vector.

Data Types: `double`

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2010b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `optstocksensbylr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstocksensbyrgw

Determine American call option prices or sensitivities using Roll-Geske-Whaley option pricing model

Syntax

```
PriceSens = optstocksensbyrgw(RateSpec,StockSpec,Settle,Maturity,OptSpec,
Strike)
PriceSens = optstocksensbyrgw( ___ ,Name,Value)
```

Description

`PriceSens = optstocksensbyrgw(RateSpec,StockSpec,Settle,Maturity,OptSpec, Strike)` computes American call option prices or sensitivities using the Roll-Geske-Whaley option pricing model.

`optstocksensbyrgw` computes prices of American calls with a single cash dividend using the Roll-Geske-Whaley option pricing model. All sensitivities are evaluated by computing a discrete approximation of the partial derivative. This means that the option is revalued with a fractional change for each relevant parameter, and the change in the option value divided by the increment, is the approximated sensitivity value.

Note Alternatively, you can use the `Vanilla` object to calculate price or sensitivities for vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = optstocksensbyrgw( ___ ,Name,Value)` adds an optional name-value pair argument for `OutSpec`.

Examples

Compute American Call Option Prices and Sensitivities Using the Roll-Geske-Whaley Option Pricing Model

This example shows how to compute American call option prices and sensitivities using the Roll-Geske-Whaley option pricing model. Consider an American stock option with an exercise price of $82 on January 1, 2008 that expires on May 1, 2008. Assume the underlying stock pays dividends of $4 on April 1, 2008. The stock is trading at $80 and has a volatility of 30% per annum. The risk-free rate is 6% per annum. Using this data, calculate the price and the value of `delta` and `gamma` of the American call using the Roll-Geske-Whaley option pricing model.

```
AssetPrice = 80;
Settle = datetime(2008,1,1);
Maturity = datetime(2008,5,1);
Strike = 82;
Rate = 0.06;
Sigma  = 0.3;
DivAmount = 4;
```

```
DivDate = datetime(2008,4,1);

% define the RateSpec and StockSpec
StockSpec = stockspec(Sigma, AssetPrice, {'cash'}, DivAmount, DivDate);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1, 'Basis', 1);

% define the OutSpec
OutSpec = {'Price', 'Delta', 'Gamma'};

[Price, Delta, Gamma]  = optstocksensbyrgw(RateSpec, StockSpec, Settle,...
Maturity, Strike,'OutSpec', OutSpec)

Price = 4.3860

Delta = 0.5022

Gamma = 0.0336
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbyrgw` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for option

datetime array | string array | date character vector

Maturity date for option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `optstocksensbyrgw` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — Option strike price value
nonnegative vector

Option strike price value, specified as a nonnegative `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Delta,Gamma,Price] = optstocksensbyrgw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec',OutSpec)`

`OutSpec` — Define outputs
`{'Price'}` (default) | cell array of character vectors with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected future prices or sensitivities values
vector

Expected future prices or sensitivities values, returned as a `NINST`-by-`1` vector.

Data Types: `double`

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

For more information, see “Vanilla Option” on page 3-27.

Version History

Introduced in R2008b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optstocksensbyrgw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

optstockbystt

Price vanilla options on stocks using standard trinomial tree

Syntax

```
[Price,PriceTree] = optstockbystt(STTTree,OptSpec,Strike,Settle,
ExerciseDates)
[Price,PriceTree] = optstockbystt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = optstockbystt(STTTree,OptSpec,Strike,Settle, ExerciseDates)` returns vanilla option (American, European, or Bermudan) prices on stocks using a standard trinomial (STT) tree.

Note Alternatively, you can use the `Vanilla` object to price vanilla options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = optstockbystt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price Call and Put Stock Options Using the Standard Trinomial Tree Model

Create a `RateSpec`.

```
StartDates = datetime(2009,1,1);
EndDates = datetime(2013,1,1);
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8694
            Rates: 0.0350
         EndTimes: 4
       StartTimes: 0
         EndDates: 735235
       StartDates: 733774
    ValuationDate: 733774
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
         AssetPrice: 85
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create an `STTTree`.

```
NumPeriods = 4;
TimeSpec = stttimespec(StartDates, EndDates, 4);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 1 2 3 4]
         dObs: [733774 734139 734504 734869 735235]
        STree: {1x5 cell}
        Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Define the call and put options and compute the price.

```
Settle = datetime(2009,1,1);
ExerciseDates = [datetime(2011,1,1) ; datetime(2012,1,1)];
OptSpec =  {'call';'put'};
Strike =[100;80];

Price = optstockbystt(STTTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 2×1

    4.5025
    3.0603
```

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector.

Data Types: char | cell

Strike — Option strike price values
nonnegative integer

Option strike price value, specified with a NINST-by-1 or NINST-by-NSTRIKES depending on the option type:

- For a European option, use a NINST-by-1 vector of strike prices.
- For a Bermuda option, use aNINST-by-NSTRIKES matrix of strike prices. Each row is the schedule for one option. If an option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American option, use a NINST-by-1 of strike prices.

Data Types: double

Settle — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the vanilla option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note The Settle date for every vanilla option is set to the ValuationDate of the stock tree. The vanilla option argument Settle is ignored.

To support existing code, optstockbystt also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a NINST-by-1,NINST-by-2, or NINST-by-NSTRIKES vector using a datetime array, string array, or date character vectors, depending on the option type:

- For a European option, use a NINST-by-1 vector of dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For a Bermuda option, use a NINST-by-NSTRIKES vector of dates. Each row is the schedule for one option.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

To support existing code, optstockbystt also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optstockbystt(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'AmericanOpt','1')`

`AmericanOpt` — Option type

`0` European or Bermuda (default) | integer with values of `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` vector of integer flags with values:

- `0` — European or Bermuda
- `1` — American

Data Types: `single` | `double`

Output Arguments

`Price` — Expected price of vanilla option at time `0`

vector

Expected price of the vanilla option at time `0`, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure containing trees of vectors of instrument prices and accrued interest for each node

structure

Structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

More About

Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$

- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

optpricebysim

Price option given simulated underlying values

Syntax

```
Price = optpricebysim(RateSpec,SimulatedPrices,Times,OptSpec,Strike,
ExerciseTimes)
Price = optpricebysim( ___ ,Name,Value)
```

Description

`Price = optpricebysim(RateSpec,SimulatedPrices,Times,OptSpec,Strike, ExerciseTimes)` calculates the price of European, American, and Berumdan call/put options based on risk-neutral simulation of the underlying asset. For American and Bermudan options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

`Price = optpricebysim( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of an American Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S0 = 100; % Initial price of underlying asset
Sigma = .2; % Volatility of underlying asset
Strike = 110; % Strike
OptSpec = 'call'; % Call option
Settle = datetime(2013,1,1); % Settlement date of option
Maturity = datetime(2014,1,1); % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the `gbm` object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
'NTRIALS',NTRIALS, 'DeltaTime',dt,'Antithetic',true);
```

Create the interest-rate term structure to define `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
           'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
           'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Price an American option.

```
SimulatedPrices = squeeze(Paths);
OptPrice = optpricebysim(RateSpec, SimulatedPrices, Times, OptSpec, ...
           Strike, T, 'AmericanOpt', 1)
```

```
OptPrice = 5.8172
```

Compute the Price of an American Asian Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S0 = 100; % Initial price of underlying asset
Sigma = .2; % Volatility of underlying asset
Strike = 110; % Strike
OptSpec = 'call'; % Call option
Settle = datetime(2013,1,1); % Settlement date of option
Maturity = datetime(2014,1,1); % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the `gbm` object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
'NTRIALS',NTRIALS, 'DeltaTime',dt,'Antithetic',true);
```

Create the interest-rate term structure to define `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
           'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
           'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
```

```
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Price an American Asian option (arithmetic mean) by finding the average price over periods.

```
AvgPrices = zeros(NPERIODS+1, NTRIALS);
    for i = 1:NPERIODS+1
        AvgPrices(i,:) = mean(squeeze(Paths(1:i,:,:)));
    end
    AsianPrice = optpricebysim(RateSpec, AvgPrices, Times, OptSpec, ...
        Strike, T, 'AmericanOpt', 1)
```

```
AsianPrice = 1.8221
```

Compute the Price of an American Lookback Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S0 = 100; % Initial price of underlying asset
Sigma = .2; % Volatility of underlying asset
Strike = 110; % Strike
OptSpec = 'call'; % Call option
Settle = datetime(2013,1,1); % Settlement date of option
Maturity = datetime(2014,1,1); % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the `gbm` object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
'NTRIALS',NTRIALS, 'DeltaTime',dt,'Antithetic',true);
```

Create the interest-rate term structure to define `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
           'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
           'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
```

```
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Price an American lookback option by finding the maximum price over periods.

```
MaxPrices = zeros(NPERIODS+1, NTRIALS);
    LastPrice = squeeze(Paths(1,:,:))';
    for i = 1:NPERIODS+1;
        MaxPrices(i,:) = max([LastPrice; Paths(i,:)]);
        LastPrice = MaxPrices(i,:);
    end
    LookbackPrice = optpricebysim(RateSpec, MaxPrices, Times, OptSpec, ...
        Strike, T, 'AmericanOpt', 1)
```

```
LookbackPrice = 10.4410
```

Compute the Price of a Bermudan Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S0 = 80; % Initial price of underlying asset
Sigma = .3; % Volatility of underlying asset
Strike = 75; % Strike
OptSpec = 'put'; % Put option
Settle = datetime(2013,1,1); % Settlement date of option
Maturity = datetime(2014,1,1); % Maturity date of option
ExerciseDates = [datetime(2013,1,1) , datetime(2014,1,1)]; % Exercise dates of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
ExerciseTimes = yearfrac(Settle, ExerciseDates, Basis); % Exercise times
```

Set up the `gbm` object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
OptionGBM = gbm(r, Sigma, 'StartState', S0);
[Paths, Times, Z] = simBySolution(OptionGBM, NPERIODS, ...
'NTRIALS',NTRIALS, 'DeltaTime',dt,'Antithetic',true);
```

Create the interest-rate term structure to define `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
           'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
           'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Price the Bermudan option.

```
SimulatedPrices = squeeze(Paths);
BermudanPrice = optpricebysim(RateSpec, SimulatedPrices, Times, ...
OptSpec, Strike, ExerciseTimes)
```

```
BermudanPrice = 4.9889
```

Compute the Price of an American Spread Option Using Monte Carlo Simulation Based on Geometric Brownian Motion

Define the option.

```
S1 = 110; % Price of first underlying asset
S2 = 100; % Price of second underlying asset
Sigma1 = .1;  % Volatility of first underlying asset
Sigma2 = .15; % Volatility of second underlying asset
Strike = 15; % Strike
Rho = .3; % Correlation between underlyings
OptSpec = 'put'; % Put option
Settle = datetime(2013,1,1); % Settlement date of option
Maturity = datetime(2014,1,1); % Maturity date of option
r = .05; % Risk-free rate (annual, continuous compounding)
Compounding = -1; % Continuous compounding
Basis = 0; % Act/Act day count convention
T = yearfrac(Settle, Maturity, Basis); % Time to expiration in years
```

Set up the `gbm` object and run the Monte Carlo simulation based on Geometric Brownian Motion (GBM) using the `simBySolution` method from Financial Toolbox™.

```
NTRIALS = 1000;
NPERIODS = daysact(Settle, Maturity);
dt = T/NPERIODS;
SpreadGBM = gbm(r*eye(2), diag([Sigma1;Sigma2]),'Correlation',...
[1 Rho;Rho 1],'StartState',[S1;S2]);
[Paths, Times, Z] = simBySolution(SpreadGBM, NPERIODS,'NTRIALS',NTRIALS,...
'DeltaTime',dt,'Antithetic',true);
```

Create the interest-rate term structure to define RateSpec.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
           'EndDates', Maturity, 'Rate', r, 'Compounding', Compounding, ...
           'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Price the American spread option.

```
Spread = squeeze(Paths(:,1,:) - Paths(:,2,:));
SpreadPrice = optpricebysim(RateSpec, Spread, Times, OptSpec, Strike, ...
T, 'AmericanOpt', 1)
```

```
SpreadPrice = 9.0007
```

Input Arguments

RateSpec — Interest-rate term structure of risk-free rates

structure

Interest-rate term structure of risk-free rates (annualized and continuously compounded), specified by the RateSpec obtained from intenvset. The valuation date must be at the settlement date of the option, and the day-count basis and end-of-month rule must be the same as those used to calculate the Times input. For information on the interest-rate specification, see intenvset.

Data Types: struct

SimulatedPrices — Simulated prices

matrix

Simulated prices, specified using a (NumPeriods + 1)-by-NumTrials matrix of risk-neutral simulated prices. The first element of SimulatedPrices is the initial value at time 0.

Data Types: double

Times — Annual time factors associated with simulated prices

vector

Annual time factors associated with simulated prices, specified using a (NumPeriods + 1)-by-1 column vector. Each element of Times is associated with the corresponding row of SimulatedPrices. The first element of Times must be 0 (current time).

Data Types: double

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'`

Definition of option as `'call'` or `'put'`, specified as a character vector.

Data Types: `char`

`Strike` — Option strike price values
scalar | function handle

Option strike price values, specified as a scalar value `Strike` price. `Strike` for Bermudan options can be specified as a `1`-by-`NSTRIKES` vector or a function handle that returns the value of the strike given the time of the strike.

Data Types: `double` | `function_handle`

`ExerciseTimes` — Exercise time for option
datetime array | string array | date character vector

Exercise time for the option, specified as a datetime array, string array, or date character vectors, as follows:

- For a European or Bermudan option, `ExerciseTimes` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermudan) vector of exercise times. For a European option, there is only one `ExerciseTimes` on the option expiry date.
- For an American option, `ExerciseTimes` is a `1`-by-`2` vector of exercise time boundaries. The option exercises on any date between, or including, the pair of times on that row. If `ExerciseTimes` is `1`-by-`1`, the option exercises between time `0` and the single listed `ExerciseTimes`.

To support existing code, `optpricebysim` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = optpricebysim(RateSpec,Prices,Times,OptSpec,Settle,Strike,ExerciseTimes,'AmericanOpt',1)`

`AmericanOpt` — Option type
`0` European or Bermudan (default) | scalar flag with value `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and an integer scalar flag with values:

- `0` — European or Bermudan
- `1` — American

For American options, the Longstaff-Schwartz least squares method calculates the early exercise premium.

Data Types: `double`

Output Arguments

`Price` — Price of option

scalar

Price of the option, returned as a scalar value.

Version History

Introduced in R2014a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `optpricebysim` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

rangefloatbybdt

Price range floating note using Black-Derman-Toy tree

Syntax

```
[Price,PriceTree] = rangefloatbybdt(BDTTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbybdt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = rangefloatbybdt(BDTTree,Spread,Settle,Maturity,RateSched)` prices range floating note using a Black-Derman-Toy tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

`[Price,PriceTree] = rangefloatbybdt( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of a Range Note Using a Black-Derman-Toy Tree

This example shows how to compute the price of a range note using a Black-Derman-Toy tree with the following interest-rate term structure data.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = datetime(2011,1,1);
Maturity = datetime(2014,1,1);
RateSched(1).Dates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
RateSched(1).Rates = [0.045 0.055 ; 0.0525  0.0675; 0.06 0.08];

% data to build the tree is as follows:
% assume the volatility is 10%.
Sigma = 0.1;
BDTTS = bdttimespec(ValuationDate, EndDates, Compounding);
```

```
BDTVS = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVS, RS, BDTTS);

% price the instrument
Price = rangefloatbybdt(BDTT, Spread, Settle, Maturity, RateSched)

Price = 97.5267
```

Input Arguments

BDTTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

Spread — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

Settle — Settlement date for floating range note

datetime array | string array | date character vector

Settlement date for the floating range note, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the BDT tree. The floating range note argument `Settle` is ignored.

To support existing code, `rangefloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for floating range note

datetime array | string array | date character vector

Maturity date for the floating-rate note, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `rangefloatbybdt` also accepts serial date numbers as inputs, but they are not recommended.

RateSched — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a `NINST`-by-`1` vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — `NDates`-by-`1` cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — `NDates`-by-`2` array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates`(*n*) is nonzero for rates in the range `RateSched.Rates`(*n*,1) < `Rate` < `RateSched.Rate` (*n*,2).

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = rangefloatbybdt(BDTTree,Spread,Settle,Maturity,RateSched,'Reset',4,'Basis',5,'Principal',10000)`

`Reset` — Frequency payment per year

`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount

`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating caplet dates
`1` (in effect) (default) | nonnegative integer with value `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer with a value of `0` or `1` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`Price` — Expected prices of range floating notes at time 0
vector

Expected prices of the range floating notes at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Range Note

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, like vanilla floating notes. For more information, see “Range Note” on page 2-13.

Version History

Introduced in R2012a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `rangefloatbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

rangefloatbybk

Price range floating note using Black-Karasinski tree

Syntax

```
[Price,PriceTree] = rangefloatbybk(BKTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbybk( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = rangefloatbybk(BKTree,Spread,Settle,Maturity,RateSched)` prices range floating note using a Black-Karasinski tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

`[Price,PriceTree] = rangefloatbybk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = datetime(2011,1,1);
Maturity = datetime(2014,1,1);
RateSched(1).Dates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
RateSched(1).Rates = [0.045 0.055 ; 0.0525  0.0675; 0.06 0.08];

% data to build the tree is as follows:
VolDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2015,1,1);
```

```
AlphaCurve = 0.1;

BKVS = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTS = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVS, RS, BKTS);

% price the instrument
Price = rangefloatbybk(BKT, Spread, Settle, Maturity, RateSched)

Price = 96.8542
```

Input Arguments

BKTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

Spread — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

Settle — Settlement date for floating range note

datetime array | string array | date character vector

Settlement date for the floating range note, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the BK tree. The floating range note argument `Settle` is ignored.

To support existing code, `rangefloatbybk` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date for floating range note

datetime array | string array | date character vector

Maturity date for the floating-rate note, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `rangefloatbybk` also accepts serial date numbers as inputs, but they are not recommended.

RateSched — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a `NINST`-by-`1` vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — `NDates`-by-`1` cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — `NDates`-by-`2` array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date

`RateSched.Dates`(*n*) is nonzero for rates in the range `RateSched.Rates`(*n*,1) < `Rate` < `RateSched.Rate` (*n*,2).

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = rangefloatbybk(BKTree,Spread,Settle,Maturity,RateSched,'Reset',4,'Basis',5,'Principal',10000)`

`Reset` — Frequency payment per year
`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating caplet dates
`1` (in effect) (default) | nonnegative integer with value `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer with a value of `0` or `1` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`Price` — Expected prices of range floating notes at time 0
vector

Expected prices of the range floating notes at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

rangefloatbycir

Price range floating note using Cox-Ingersoll-Ross tree

Syntax

```
[Price,PriceTree] = rangefloatbycir(CIRTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbycir( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = rangefloatbycir(CIRTree,Spread,Settle,Maturity,RateSched)` prices range floating note with a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = rangefloatbycir( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Range Floating-Rate Note Using a CIR Interest-Rate Tree

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2020';
CIRTimeSpec = cirtimespec(Settle, Maturity, 3);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2]
        dObs: [736696 737061 737426]
     FwdTree: {[1.0350]  [1.0790 1.0500 1.0298]  [1.1275 1.0887 1.0594 ... ]}
```

```
     Connect: {[3x1 double]  [3x3 double]}
       Probs: {[3x1 double]  [3x3 double]}
```

Define the range note instrument that matures in Jan-1-2014 and has the following RateSchedule:

```
Spread = 100;
Settle = 'Jan-1-2017';
Maturity = 'Jan-1-2020';
RateSched(1).Dates = {'Jan-1-2018'; 'Jan-1-2019'  ; 'Jan-1-2020'};
RateSched(1).Rates = [0.045 0.055 ; 0.0525  0.0675; 0.06 0.08];
```

Compute the price of the range floating note.

```
[Price,PriceTree] = rangefloatbycir(CIRT,Spread,Settle,Maturity,RateSched)
```

```
Price = 91.6849
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
      PTree: {1x4 cell}
     AITree: {[0]  [0 0 0]  [0 0 0 0 0]  [0 0 0 0 0]}
       tObs: [0 1 2 3]
    Connect: {[3x1 double]  [3x3 double]}
      Probs: {[3x1 double]  [3x3 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`Spread` — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Settle` — Settlement date for floating range note

datetime array | string array | date character vector

Settlement date for the floating range note, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the CIR tree. The floating range note argument `Settle` is ignored.

To support existing code, `rangefloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floating range note

datetime array | string array | date character vector

Maturity date for the floating-rate note, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `rangefloatbycir` also accepts serial date numbers as inputs, but they are not recommended.

`RateSched` — Range of rates within which cash flows are nonzero
structure

Range of rates within which cash flows are nonzero, specified as a `NINST`-by-`1` vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — `NDates`-by-`1` cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — `NDates`-by-`2` array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates`(*n*) is nonzero for rates in the range `RateSched.Rates`(*n*,1) < `Rate` < `RateSched.Rate` (*n*,2).

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = rangefloatbycir(CIRTree,Spread,Settle,Maturity,RateSched,'Reset',4,'Basis',5,'Principal',10000)`

`Reset` — Frequency payment per year
`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Note Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual

- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating caplet dates
`1` (in effect) (default) | nonnegative integer with value `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer with a value of `0` or `1` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`Price` — Expected prices of range floating notes at time 0
vector

Expected prices of the range floating notes at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Range Note

A range note is a structured (market-linked) security whose coupon rate is equal to the reference rate as long as the reference rate is within a certain range.

If the reference rate is outside of the range, the coupon rate is `0` for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest rate and are floored to be positive. The note holder gets direct exposure to the reference rate. In return for the drawback that no interest is paid for the time the range is left, they offer higher coupon rates than comparable standard products, vanilla floating notes. For more information, see “Range Note” on page 2-13.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `rangefloatbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

rangefloatbyhjm

Price range floating note using Heath-Jarrow-Morton tree

Syntax

```
[Price,PriceTree] = rangefloatbyhjm(HJMTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbyhjm(___,Name,Value)
```

Description

`[Price,PriceTree] = rangefloatbyhjm(HJMTree,Spread,Settle,Maturity,RateSched)` prices range floating note using a Heath-Jarrow-Morton tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

`[Price,PriceTree] = rangefloatbyhjm(___,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of a Range Note Using a Heath-Jarrow-Morton Tree

This example shows how to compute the price of a range note using a Heath-Jarrow-Morton tree with the following interest-rate term structure data.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = datetime(2011,1,1);
Maturity = datetime(2014,1,1);
RateSched(1).Dates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
RateSched(1).Rates = [0.045 0.055 ; 0.0525  0.0675; 0.06 0.08];

% data to build the tree is as follows:
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1;  2;   3;   4];
MaTree = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
```

```
HJMTS = hjmtimespec(ValuationDate, MaTree);
HJMVS = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVS, RS, HJMTS);

% price the instrument
Price = rangefloatbyhjm(HJMT, Spread, Settle, Maturity, RateSched)

Price = 90.2348
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`Spread` — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a `NINST`-by-1 vector.

Data Types: `double`

`Settle` — Settlement date for floating range note

datetime array | string array | date character vector

Settlement date for the floating range note, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the HJM tree. The floating range note argument `Settle` is ignored.

To support existing code, `rangefloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floating range note

datetime array | string array | date character vector

Maturity date for the floating-rate note, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `rangefloatbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`RateSched` — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a `NINST`-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — `NDates`-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — `NDates`-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date `RateSched.Dates`(*n*) is nonzero for rates in the range `RateSched.Rates`(*n*,1) < `Rate` < `RateSched.Rate` (*n*,2).

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = rangefloatbyhjm(HJMTree,Spread,Settle,Maturity,RateSched,'Reset',4,'Basis',5,'Principal',10000)`

`Reset` — Frequency payment per year

`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount

`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating caplet dates
`1` (in effect) (default) | nonnegative integer with value `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer with a value of `0` or `1` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`Price` — Expected prices of range floating notes at time 0
vector

Expected prices of the range floating notes at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

rangefloatbyhw

Price range floating note using Hull-White tree

Syntax

```
[Price,PriceTree] = rangefloatbyhw(HWTree,Spread,Settle,Maturity,RateSched)
[Price,PriceTree] = rangefloatbyhw( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = rangefloatbyhw(HWTree,Spread,Settle,Maturity,RateSched)` prices range floating note using a Hull-White tree.

Payments on range floating notes are determined by the effective interest-rate between reset dates. If the reset period for a range spans more than one tree level, calculating the payment becomes impossible due to the recombining nature of the tree. That is, the tree path connecting the two consecutive reset dates cannot be uniquely determined because there is more than one possible path for connecting the two payment dates.

`[Price,PriceTree] = rangefloatbyhw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
Compounding = 1;

% define RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding);

% range note instrument matures in Jan-1-2014 and has the following RateSchedule:
Spread = 100;
Settle = datetime(2011,1,1);
Maturity = datetime(2014,1,1);
RateSched(1).Dates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
RateSched(1).Rates = [0.045 0.055 ; 0.0525  0.0675; 0.06 0.08];

% data to build the tree is as follows:
VolDates = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2015,1,1);
```

```
AlphaCurve = 0.1;

HWVS = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTS = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVS, RS, HWTS);

% price the instrument
Price = rangefloatbyhw(HWT, Spread, Settle, Maturity, RateSched)

Price = 96.6107
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`Spread` — Number of basis points over reference rate

numeric

Number of basis points over the reference rate, specified as a `NINST`-by-1 vector.

Data Types: `double`

`Settle` — Settlement date for floating range note

datetime array | string array | date character vector

Settlement date for the floating range note, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors. The `Settle` date for every range floating instrument is set to the `ValuationDate` of the HW tree. The floating range note argument `Settle` is ignored.

To support existing code, `rangefloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for floating range note

datetime array | string array | date character vector

Maturity date for the floating-rate note, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `rangefloatbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`RateSched` — Range of rates within which cash flows are nonzero

structure

Range of rates within which cash flows are nonzero, specified as a `NINST`-by-1 vector of structures. Each element of the structure array contains two fields:

- `RateSched.Dates` — `NDates`-by-1 cell array of dates corresponding to the range schedule.
- `RateSched.Rates` — `NDates`-by-2 array with the first column containing the lower bound of the range and the second column containing the upper bound of the range. Cash flow for date

`RateSched.Dates`(*n*) is nonzero for rates in the range `RateSched.Rates`(*n*,1) < `Rate` < `RateSched.Rate` (*n*,2).

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = rangefloatbyhw(HWTree,Spread,Settle,Maturity,RateSched,'Reset',4,'Basis',5,'Principal',10000)`

`Reset` — Frequency payment per year
`1` (default) | numeric

Frequency of payments per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate tree, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

Derivatives pricing options structure, specified as the comma-separated pair consisting of `'Options'` and a structure obtained from using `derivset`.

Data Types: `struct`

`EndMonthRule` — End-of-month rule flag for generating caplet dates
`1` (in effect) (default) | nonnegative integer with value `0` or `1`

End-of-month rule flag, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer with a value of `0` or `1` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`Price` — Expected prices of range floating notes at time 0
vector

Expected prices of the range floating notes at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a structure containing trees of vectors of instrument prices and accrued interest, and a vector of observation times for each node. Values are:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

rate2disc

Discount factors from interest rates

Syntax

```
Disc = rate2disc(Compounding,Rates,EndTimes,StartTimes)
[Disc,EndTimes,StartTimes] = rate2disc(Compounding,Rates,EndTimes,StartTimes,
ValuationDate,Basis,EndMonthRule)
```

Description

`Disc = rate2disc(Compounding,Rates,EndTimes,StartTimes)` computes discount factors from interest rates where interval points are input as times in periodic units.

The `rate2disc` function computes the discounts over a series of `NPOINTS` time intervals given the annualized yield over those intervals. `NCURVES` different rate curves can be translated at once if they have the same time structure. The time intervals can represent a zero curve or a forward curve.

The output `Disc` is an `NPOINTS`-by-`NCURVES` column vector of discount factors in decimal form representing the value at time `StartTimes` of a unit cash flow received at time `EndTimes`.

`[Disc,EndTimes,StartTimes] = rate2disc(Compounding,Rates,EndTimes,StartTimes, ValuationDate,Basis,EndMonthRule)` computes discount factors from interest rates where `ValuationDate` is passed and interval points are input as dates.

You can specify the investment intervals either with input times or with input dates. Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

Examples

Compute Discount Factors From Interest Rates

This example shows the two uses of `rate2disc`.

Interval Points Are Input as Times in Periodic Units

Compute discounts from a zero curve at 6 months, 12 months, and 24 months. The times to the cash flows are 1, 2, and 4. Use `rate2disc` to compute the present value (at time 0) of the cash flows.

```
Compounding = 2;
Rates = [0.05; 0.06; 0.065];
EndTimes   = [1; 2; 4];
Disc = rate2disc(Compounding, Rates, EndTimes)
```

```
Disc = 3×1

    0.9756
    0.9426
```

```
    0.8799
```

Interval Points Are Input as Dates

Compute discounts from a zero curve at 6 months, 12 months, and 24 months. Use dates to specify the ending time horizon.

```
Compounding = 2;
Rates = [0.05; 0.06; 0.065];
EndDates = ['10/15/97'; '04/15/98'; '04/15/99'];
ValuationDate = '4/15/97';
Disc = rate2disc(Compounding, Rates, EndDates, [], ValuationDate)
```

```
Disc = 3×1

    0.9756
    0.9426
    0.8799
```

Input Arguments

`Compounding` — Compounding rate

integer with value of `0`, `1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

Compounding rate for which the input zero rates are compounded when annualized, specified as one of the following scalar integers. Compounding determines the formula for the discount factors (`Disc`):

- If `Compounding` = `0` for simple interest:
  - `Disc = 1/(1 + Z * T)`, where `T` is time in years and simple interest assumes annual times `F = 1`.
- If `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`:
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units, for example, `T = F` is one year.
- If `Compounding` = `365`:
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = `-1`:
  - `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

`Rates` — Rates

decimal

Rates, specified as a number of points (`NPOINTS`) by number of curves (`NCURVES`) matrix of rates in decimal form. `Rates` are the yields over investment intervals from `StartTimes`, when the cash flow is valued, to `EndTimes`, when the cash flow is received. For example, 5% is `0.05` in `Rates`.

Data Types: `double`

`EndTimes` — End times

serial date number | date character vector | numeric

End times, specified as a scalar or an `NPOINTS`-by-`1` column vector using serial date numbers or date character vectors, or with times in periodic units ending the interval to discount over. When `EndTimes` is not a date, the value for `EndTimes` is `T` computed from SIA semi-annual time factors, `Tsemi`, by the formula `T = Tsemi/2 * F`, where `F` is the compounding frequency. `F` is set to `1` for continuous compounding.

Note When `ValuationDate` is not passed, `EndTimes` is interpreted as times. If `Compounding = 365` (daily), `EndTimes` is measured in days.

Data Types: `double` | `char`

`StartTimes` — Start times

serial date number | date character vector | numeric

Start times, specified a scalar or an `NPOINTS`-by-`1` column vector using serial date numbers or date character vectors, or with times in periodic units starting the interval to discount over. `StartDates` must be earlier than `EndDates`. When `StarTimes` is not a date, the value for `StartTimes` is `T` computed from SIA semi-annual time factors, `Tsemi`, by the formula `T = Tsemi/2 * F`, where `F` is the compounding frequency. `F` is set to `1` for continuous compounding.

Note When `ValuationDate` is not passed, `StartTimes` is interpreted as times. If `Compounding = 365` (daily), `StartTimes` is measured in days.

Data Types: `double` | `char`

`ValuationDate` — Observation date of the investment horizons entered in `StartTimes` and `EndTimes`

serial date number | date character vector

Observation date of the investment horizons entered in `StartTimes` and `EndTimes`, specified as scalar serial date number or date character vector.

Note You can specify the investment intervals either with input times or with input dates. Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

Data Types: `double` | `char`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of the instrument when using dates for `StartTimes` and `EndTimes`, specified as a scalar or an `NINST`-by-`1` vector of integers..

- 0 = actual/actual
- 1 = 30/360 (SIA)

- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag
`1` (in effect) (default) | nonnegative integer with values `0` or `1`

End-of-month rule flag when using dates for `StartTimes` and `EndTimes`, specified as a scalar or an `NINST`-by-`1` vector of nonnegative integers. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days.

- `0` = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: `double`

Output Arguments

`Disc` — Discount factors
vector

Discount factors, returned as an `NPOINTS`-by-`NCURVES` column vector of in decimal form representing the value at time `StartTimes` of a unit cash flow received at time `EndTimes`.

`EndTimes` — Times ending the interval to discount over
vector

Times ending the interval to discount over, returned as an `NPOINTS`-by-`1` column vector, measured in periodic units.

`StartTimes` — Times starting the interval to discount over
vector

Times starting the interval to discount over, returned as an `NPOINTS`-by-`1` column vector, measured in periodic units.

Version History

Introduced before R2006a

ratetimes

Change time intervals defining interest-rate environment

Syntax

```
[Rates,EndTimes,StartTimes] = ratetimes(Compounding,RefRates,RefEndTimes,
RefStartTimes,EndTimes,StartTimes)
[Rates,EndTimes,StartTimes] = ratetimes(Compounding,RefRates,RefEndTimes,
RefStartTimes,EndTimes,StartTimes,ValuationDate)
```

Description

`[Rates,EndTimes,StartTimes] = ratetimes(Compounding,RefRates,RefEndTimes, RefStartTimes,EndTimes,StartTimes)` change time intervals defining an interest-rate environment where interval points are input as times in periodic units.

`ratetimes` takes an interest-rate environment defined by yields over one collection of time intervals and computes the yields over another set of time intervals. The zero rate is assumed to be piecewise linear in time.

`[Rates,EndTimes,StartTimes] = ratetimes(Compounding,RefRates,RefEndTimes, RefStartTimes,EndTimes,StartTimes,ValuationDate)` change time intervals defining an interest-rate environment where `ValuationDate` is passed and interval points are input as dates.

Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

Examples

Change Time Intervals Defining Interest-Rate Environment

`ratetimes` takes an interest-rate environment defined by yields over one collection of time intervals and computes the yields over another set of time intervals. The zero rate is assumed to be piecewise linear in time.

The reference environment is a collection of zero rates at 6, 12, and 24 months. Create a collection of 1-year forward rates beginning at `0`, `6`, and `12` months.

```
RefRates = [0.05; 0.06; 0.065];
RefEndTimes = [1; 2; 4];
StartTimes = [0; 1; 2];
EndTimes   = [2; 3; 4];
Rates = ratetimes(2, RefRates, RefEndTimes, 0, EndTimes,StartTimes)
```

```
Rates = 3×1

    0.0600
    0.0688
    0.0700
```

Interpolate a zero yield curve to different dates. Zero curves start at the default date of `ValuationDate`.

```
RefRates = [0.04; 0.05; 0.052];
RefDates = [729756; 729907; 730121];
Dates    = [730241; 730486];
ValuationDate   = 729391;
Rates = ratetimes(2, RefRates, RefDates, [], Dates, [], ValuationDate)
```

```
Rates = 2×1

    0.0520
    0.0520
```

Input Arguments

`Compounding` — Compounding rate

integer with value of `0`, `1`, `2`, `3`, `4`, `6`, `12`, `365`, `-1`

Compounding rate for which the input zero rates are compounded when annualized, specified as one of the following scalar integers. Compounding determines the formula for the discount factors (`Disc`):

- If `Compounding` = `0` for simple interest:
  - `Disc = 1/(1 + Z * T)`, where `T` is time in years and simple interest assumes annual times `F = 1`.
- If `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`:
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units, for example, `T = F` is one year.
- If `Compounding` = `365`:
  - `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = `-1`:
  - `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

`RefRates` — Reference rates

decimal

Reference rates, specified as an `NREFPTS`-by-`NCURVES` matrix in decimal form. `RefRates` are the yields over investment intervals from `RefStartTimes`, when the cash flow is valued, to `RefEndTimes`, when the cash flow is received.

Data Types: `double`

`RefEndTimes` — End times

serial date number | date character vector

End times, specified as a scalar or an NREFPTS-by-1 vector using serial date numbers or date character vectors, or with times in periodic units ending the intervals corresponding to RefRates. When RefEndTimes is not a date, the value for RefEndTimes is T computed from SIA semi-annual time factors, Tsemi, by the formula T = Tsemi/2 * F, where F is the compounding frequency. F is set to 1 for continuous compounding.

Note When ValuationDate is not passed, RefEndTimes is interpreted as times. If Compounding = 365 (daily), RefEndTimes is measured in days.

Data Types: double | char

RefStartTimes — Start times
0 (default) | serial date number | date character vector

(Optional) Start times, specified a scalar or an NREFPTS-by-1 vector using serial date numbers or date character vectors, or with times in periodic units starting the intervals corresponding to RefRates. RefStartDates must be earlier than RefEndDates. When RefStarTimes is not a date, the value for RefStartTimes is T computed from SIA semi-annual time factors, Tsemi, by the formula T = Tsemi/2 * F, where F is the compounding frequency. F is set to 1 for continuous compounding.

Note When ValuationDate is not passed, RefStartTimes is interpreted as times. If Compounding = 365 (daily), RefStartTimes is measured in days.

(Optional) NREFPTS-by-1 vector or scalar of times in periodic units starting the intervals corresponding to RefRates. Default = 0.

Data Types: double | char

EndTimes — End of interval where rates are desired
serial date number | date character vector

End of interval where rates are desired, specified as a scalar or NPOINTS-by-1 vector using serial date numbers or date character vectors.

Note You can specify the investment intervals either with input times or with input dates. Entering ValuationDate invokes the date interpretation; omitting ValuationDate invokes the default time interpretations.

Data Types: double | char

StartTimes — Starting new interval where rates are desired
0 (default) | serial date number | date character vector

(Optional) Starting new interval where rates are desired, specified as a scalar or NPOINTS-by-1 vector using serial date numbers or date character vectors.

Note You can specify the investment intervals either with input times or with input dates. Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

Data Types: `double` | `char`

`ValuationDate` — Observation date of the investment horizons entered in `RefStartTimes` and `RefEndTimes`
serial date number | date character vector

(Optional) Observation date of the investment horizons entered in `RefStartTimes` and `RefEndTimes`, specified as a serial date number or data character vector.

Note You can specify the investment intervals either with input times or with input dates. Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

Data Types: `double` | `char`

Output Arguments

`Rates` — Rates implied by reference interest-rate structure and sampled at new intervals
matrix

Rates implied by the reference interest-rate structure and sampled at new intervals, returned as an `NPOINTS`-by-`NCURVES`.

`EndTimes` — Times ending the new intervals
vector

Times ending the new intervals, returned as an `NPOINTS`-by-`1` column vector, measured in periodic units.

`StartTimes` — Times starting the new intervals where rates are desired
vector

Times starting the new intervals where rates are desired, returned as an `NPOINTS`-by-`1` column vector, measured in periodic units.

spreadbykirk

Price European spread options using Kirk pricing model

Syntax

```
Price = spreadbykirk(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,
Strike,Corr)
```

Description

`Price = spreadbykirk(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec, Strike,Corr)` returns the price for a European spread option using the Kirk pricing model.

Note Alternatively, you can use the `Spread` object to price spread options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute the Price of a Spread Option Using the Kirk Model

Define the spread option dates.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2012,4,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
   Price1gallon = 2.85;          % $/gallon
   Price1 = Price1gallon * 42;   % $/barrel
   Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
  Price2 = 93.20;         % $/barrel
  Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
```

```
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
         EndTimes: 0.2500
       StartTimes: 0
         EndDates: 734960
       StartDates: 734869
    ValuationDate: 734869
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2900
         AssetPrice: 119.7000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
         AssetPrice: 93.2000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the European spread option price based on the Kirk model.

```
Price = spreadbykirk(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr)
```

```
Price = 11.1904
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec1` — Stock specification for underlying asset 1
structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`StockSpec2` — Stock specification for underlying asset 2
structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement dates for spread option
datetime array | string array | date character vector

Settlement dates for the spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadbykirk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for spread option
datetime array | string array | date character vector

Maturity date for spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadbykirk` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `cell` | `char`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

If `Strike` is equal to `0`, the function computes the price of an exchange option.

Data Types: `double`

`Corr` — Correlation between underlying asset prices
integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices of spread option
vector

Expected prices of the spread option, returned as a `NINST`-by-`1` vector.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `spreadbykirk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

spreadbybjs

Price European spread options using Bjerksund-Stensland pricing model

Syntax

```
Price = spreadbybjs(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec,
Strike,Corr)
```

Description

`Price = spreadbybjs(RateSpec,StockSpec1,StockSpec2,Settle,Maturity,OptSpec, Strike,Corr)` returns the price for a European spread option using the Bjerksund-Stensland pricing model.

Note Alternatively, you can use the `Spread` object to price spread options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute the Price of a Spread Option Using the Bjerksund-Stensland Model

Define the spread option dates.

```
Settle = datetime(2012,1,1);
Maturity = datetime(2012,4,1);
```

Define asset 1. Price and volatility of RBOB gasoline

```
  Price1gallon = 2.85;          % $/gallon
  Price1 = Price1gallon * 42;   % $/barrel
  Vol1 = 0.29;
```

Define asset 2. Price and volatility of WTI crude oil

```
   Price2 = 93.20;         % $/barrel
   Vol2 = 0.36;
```

Define the correlation between the underlying asset prices of asset 1 and asset 2.

```
Corr = 0.42;
```

Define the spread option.

```
OptSpec = 'call';
Strike = 20;
```

Define the `RateSpec`.

```
rates = 0.05;
Compounding = -1;
```

```
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
'EndDates', Maturity, 'Rates', rates, ...
'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9876
            Rates: 0.0500
         EndTimes: 0.2500
       StartTimes: 0
         EndDates: 734960
       StartDates: 734869
    ValuationDate: 734869
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the two assets.

```
StockSpec1 = stockspec(Vol1, Price1)
```

```
StockSpec1 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2900
         AssetPrice: 119.7000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

```
StockSpec2 = stockspec(Vol2, Price2)
```

```
StockSpec2 = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3600
         AssetPrice: 93.2000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Compute the European spread option price based on the Bjerksund-Stensland model.

```
Price = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
Maturity, OptSpec, Strike, Corr)
```

```
Price = 11.2000
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec1` — Stock specification for underlying asset 1
structure

Stock specification for underlying asset 1. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`StockSpec2` — Stock specification for underlying asset 2
structure

Stock specification for underlying asset 2. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, for physical commodities the price is represented by `StockSpec.Asset`, the volatility is represented by `StockSpec.Sigma`, and the convenience yield is represented by `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement dates for spread option
datetime array | string array | date character vector

Settlement dates for the spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for spread option
datetime array | string array | date character vector

Maturity date for spread option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `spreadbybjs` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
integer | vector of integers

Option strike price values, specified as an integer using a `NINST`-by-`1` vector of strike price values.

If `Strike` is equal to zero, the function computes the price of an exchange option.

Data Types: `double`

`Corr` — Correlation between underlying asset prices

integer | vector of integers

Correlation between underlying asset prices, specified as an integer using a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices of spread option

vector

Expected prices of the spread option, returned as a `NINST`-by-`1` vector.

More About

Spread Option

A spread option is an option written on the difference of two underlying assets.

For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

For more information, see “Spread Option” on page 3-30.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `spreadbybjs` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.
