Financial Instruments Toolbox Product Description

Design, price, and hedge complex financial instruments

Financial Instruments Toolbox provides functions for pricing, modeling, hedging, and analyzing cash flows, fixed-income securities, and derivative instruments (including equity, interest-rate, credit, and energy instruments). For interest-rate instruments, you can calculate price, yield, spread, and sensitivity values for various instrument types, including convertible bonds, mortgage-backed securities, treasury bills, bonds, swaps, caps, floors, and floating-rate notes. For derivative instruments, you can compute price, implied volatility, and Greeks using binomial trees, trinomial trees, Shifted SABR, Heston, Monte Carlo simulation, and other models. You can also connect to Numerix® CrossAsset Integration Layer for the valuation and risk management of fixed-income securities, OTC derivatives, structured products, and variable annuity products.

Interest-Rate-Based Derivatives

The toolbox provides functionality that supports the creation on page 1-6 and management on page 1-15 of these interest-rate-based instruments:

- Bonds
- Bond options (puts and calls)
- Bond with embedded options
- Caps
- Convertible bonds
- Fixed-rate notes
- Floating-rate notes
- Floors
- Swaps
- Swaption

Additionally, the toolbox provides functions to create *arbitrary cash flow instruments*. The toolbox provides pricing and sensitivity routines for these instruments. For more information, see “Pricing Using Interest-Rate Term Structure” on page 2-61,“Pricing Using Interest-Rate Tree Models” on page 2-81, and“Interest-Rate Derivatives Using Closed-Form Solutions” on page 2-99.

Equity-Based Derivatives

The toolbox also provides functions to create and manage various equity-based derivatives, including the following:

- Asian options
- Barrier options
- Basket options
- Compound options
- Convertible bonds
- Digital options
- Lookback options
- Rainbow options
- Vanilla stock options (put and call options)

The toolbox also provides pricing and sensitivity routines for these instruments. (See “Pricing Equity Derivatives Using Trees” on page 3-64, “Equity Derivatives Using Closed-Form Solutions” on page 3-79, and “Basket Option” on page 3-22.)

Expected Users

In general, this guide assumes experience working with financial derivatives and some familiarity with the underlying models.

In designing Financial Instruments Toolbox documentation, we assume that your title is similar to one of these:

- Analyst, quantitative analyst
- Risk manager
- Portfolio manager
- Fund manager, asset manager
- Financial engineer
- Trader
- Student, professor, or other academic

We also assume that your background, education, training, and responsibilities match some aspects of this profile:

- Finance, economics, perhaps accounting
- Engineering, mathematics, physics, other quantitative sciences
- Bachelor's degree minimum; MS or MBA likely; Ph.D. perhaps; CFA
- Comfortable with probability theory, statistics, and algebra
- Understand linear or matrix algebra, calculus, and differential equations
- Previously done traditional programming (C, Fortran, and so on)
- Responsible for instruments or analyses involving large sums of money
- Perhaps new to MATLAB®

Portfolio Creation Using Functions

In this section...

Introduction

The `instadd` function creates a set of instruments (portfolio) or adds instruments to an existing instrument collection. The `TypeString` argument specifies the type of the investment instrument. For interest-rate-based derivatives, the types are: `Bond`, `OptBond`, `CashFlow`, `Fixed`, `Float`, `Cap`, `Floor`, and `Swap`. For equity derivatives, the types are `Asian`, `Barrier`, `Compound`, `Lookback`, and `OptStock`.

The input arguments following `TypeString` are specific to the type of investment instrument. Thus, the `TypeString` argument determines how the remainder of the input arguments is interpreted. For example, `instadd` with the type character vector for `Bond` creates a portfolio of bond instruments.

```
InstSet = instadd('Bond', CouponRate, Settle, Maturity, Period,
Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate,
StartDate, Face)
```

Interest-Rate-Based Derivatives

In addition to the bond instrument already described, the toolbox can create portfolios containing the following set of functions for interest-rate-based derivatives:

- Bond option

  ```
  InstSet = instadd('OptBond', BondIndex, OptSpec, Strike, ExerciseDates, AmericanOpt)
  ```

- Arbitrary cash flow instrument

  ```
  InstSet = instadd('CashFlow', CFlowAmounts, CFlowDates, Settle, Basis)
  ```

- Fixed-rate note instrument

  ```
  InstSet = instadd('Fixed', CouponRate, Settle, Maturity, FixedReset, Basis, Principal)
  ```

- Floating-rate note instrument

  ```
  InstSet = instadd('Float', Spread, Settle, Maturity, FloatReset, Basis, Principal)
  ```

- Cap instrument

  ```
  InstSet = instadd('Cap', Strike, Settle, Maturity, CapReset, Basis, Principal)
  ```

- Convertible bond instrument

  ```
  InstSet = instcbond(CouponRate,Settle,Maturity,ConvRatio)
  ```

- Floor instrument

  ```
  InstSet = instadd('Floor', Strike, Settle, Maturity, FloorReset, Basis, Principal)
  ```

- Swap instrument

  ```
  InstSet = instadd('Swap', LegRate, Settle, Maturity, LegReset, Basis, Principal, LegType)
  ```

- Swaption instrument

```
InstSet = instadd('Swaption', OptSpec, Strike, ExerciseDates, Spread, ...
Settle, Maturity, AmericanOpt, SwapReset, Basis, Principal)
```

- Bond with embedded option instrument

```
InstSet = instadd('OptEmBond', CouponRate, Settle, Maturity, OptSpec, Strike, ...
ExerciseDates, 'AmericanOpt', AmericanOpt, 'Period', Period,'Basis', Basis, ...
'EndMonthRule', EndMonthRule,'Face',Face,'IssueDate', IssueDate, 'FirstCouponDate', ...
FirstCouponDate, 'LastCouponDate', LastCouponDate,'StartDate', StartDate)
```

Equity Derivatives

The toolbox can create portfolios containing the following set of functions for equity derivatives:

- Asian instrument

```
InstSet = instadd('Asian', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt, ...
AvgType, AvgPrice, AvgDate)
```

- Barrier instrument

```
InstSet = instadd('Barrier', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt, ...
BarrierType, Barrier, Rebate)
```

- Compound instrument

```
InstSet = instadd('Compound', UOptSpec, UStrike, USettle, UExerciseDates, UAmericanOpt, ...
COptSpec, CStrike, CSettle, CExerciseDates, CAmericanOpt)
```

- Convertible bond instrument

```
InstSet = instcbond(CouponRate,Settle,Maturity,ConvRatio)
```

- Lookback instrument

```
InstSet = instadd('Lookback', OptSpec, Strike, Settle, ExerciseDates, AmericanOpt)
```

- Stock option instrument

```
InstSet = instadd('OptStock', OptSpec, Strike, Settle, Maturity, AmericanOpt)
```

Adding Instruments to an Existing Portfolio Using Functions

To use the `instadd` function to add additional instruments to an existing instrument portfolio, provide the name of an existing portfolio as the first argument to the `instadd` function.

Consider, for example, a portfolio containing two cap instruments only:

```
Strike = [0.06; 0.07];
Settle = '08-Feb-2000';
Maturity = '15-Jan-2003';

Port_1 = instadd('Cap', Strike, Settle, Maturity);
```

These commands create a portfolio containing two cap instruments with the same settlement and maturity dates, but with different strikes. In general, the input arguments describing an instrument can be either a scalar, or a number of instruments (`NumInst`)-by-`1` vector in which each element corresponds to an instrument. Using a scalar assigns the same value to all instruments passed in the call to `instadd`.

Use the `instdisp` command to display the contents of the instrument set:

```
instdisp(Port_1)

Index Type Strike Settle      Maturity    CapReset Basis Principal
1     Cap  0.06   08-Feb-2000 15-Jan-2003 1        0     100
2     Cap  0.07   08-Feb-2000 15-Jan-2003 1        0     100
```

Now add a single bond instrument to `Port_1`. The bond has a 4.0% coupon and the same settlement and maturity dates as the cap instruments.

```
CouponRate = 0.04;
Port_1 = instadd(Port_1, 'Bond', CouponRate, Settle, Maturity);
```

Use `instdisp` again to see the resulting instrument set:

```
instdisp(Port_1)

Index Type Strike Settle         Maturity       CapReset Basis Principal
1     Cap  0.06   08-Feb-2000    15-Jan-2003    1        0     100
2     Cap  0.07   08-Feb-2000    15-Jan-2003    1        0     100

Index Type CouponRate Settle         Maturity     Period Basis EndMonthRule IssueDate ... Face
3     Bond 0.04       08-Feb-2000    15-Jan-2003  2      0     1            NaN       ... 100
```

Pricing a Portfolio Using the Black-Derman-Toy Model

This example illustrates how the Financial Instruments Toolbox™ is used to create a Black-Derman-Toy (BDT) tree and price a portfolio of instruments using the BDT model.

Create the Interest Rate Term Structure

The structure `RateSpec` is an interest-rate term structure that defines the initial forward-rate specification from which the tree rates are derived. Use the information of annualized zero coupon rates in the table below to populate the `RateSpec` structure.

```
From To Rate

01 Jan 2005 01 Jan 2006 0.0275

01 Jan 2005 01 Jan 2007 0.0312

01 Jan 2005 01 Jan 2008 0.0363

01 Jan 2005 01 Jan 2009 0.0415

01 Jan 2005 01 Jan 2010 0.0458
```

```
StartDates = ['01 Jan 2005'];

EndDates =   ['01 Jan 2006';
              '01 Jan 2007';
              '01 Jan 2008';
              '01 Jan 2009';
              '01 Jan 2010'];

ValuationDate = ['01 Jan 2005'];
Rates = [0.0275; 0.0312; 0.0363; 0.0415; 0.0458];
Compounding = 1;

RateSpec = intenvset('Compounding',Compounding,'StartDates', StartDates,...
                     'EndDates', EndDates, 'Rates', Rates,'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 732313
    ValuationDate: 732313
            Basis: 0
     EndMonthRule: 1
```

Specify the Volatility Model

Create the structure `VolSpec` that specifies the volatility process with the following data.

```
Volatility = [0.005; 0.0055; 0.006; 0.0065; 0.007];
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
BDTVolSpec = struct with fields:
             FinObj: 'BDTVolSpec'
      ValuationDate: 732313
           VolDates: [5x1 double]
           VolCurve: [5x1 double]
    VolInterpMethod: 'linear'
```

Specify the Time Structure of the Tree

The structure `TimeSpec` specifies the time structure for an interest-rate tree. This structure defines the mapping between the observation times at each level of the tree and the corresponding dates.

```
Maturity = EndDates;
BDTTimeSpec = bdttimespec(ValuationDate, Maturity, Compounding)
```

```
BDTTimeSpec = struct with fields:
           FinObj: 'BDTTimeSpec'
    ValuationDate: 732313
         Maturity: [5x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Create the BDT Tree

Use the previously computed values for `RateSpec`, `VolSpec`, and `TimeSpec` to create the `BDTTree`.

```
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [732313 732678 733043 733408 733774]
        TFwd: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [4]}
      CFlowT: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [5]}
     FwdTree: {1x5 cell}
```

Observe the Interest Rate Tree

Visualize the interest-rate evolution along the tree by looking at the output structure `BDTTree`. `BDTTree` returns an inverse discount tree, which you can convert into an interest-rate tree with the `cvtree` function.

```
BDTTreeR = cvtree(BDTTree);
```

Look at the upper branch and lower branch paths of the tree:

```
%Rate at root node:
RateRoot      = treepath(BDTTreeR.RateTree, [0])
```

```
RateRoot = 0.0275

%Rates along upper branch:
RatePathUp    = treepath(BDTTreeR.RateTree, [1 1 1 1])

RatePathUp = 5×1

    0.0275
    0.0347
    0.0460
    0.0560
    0.0612

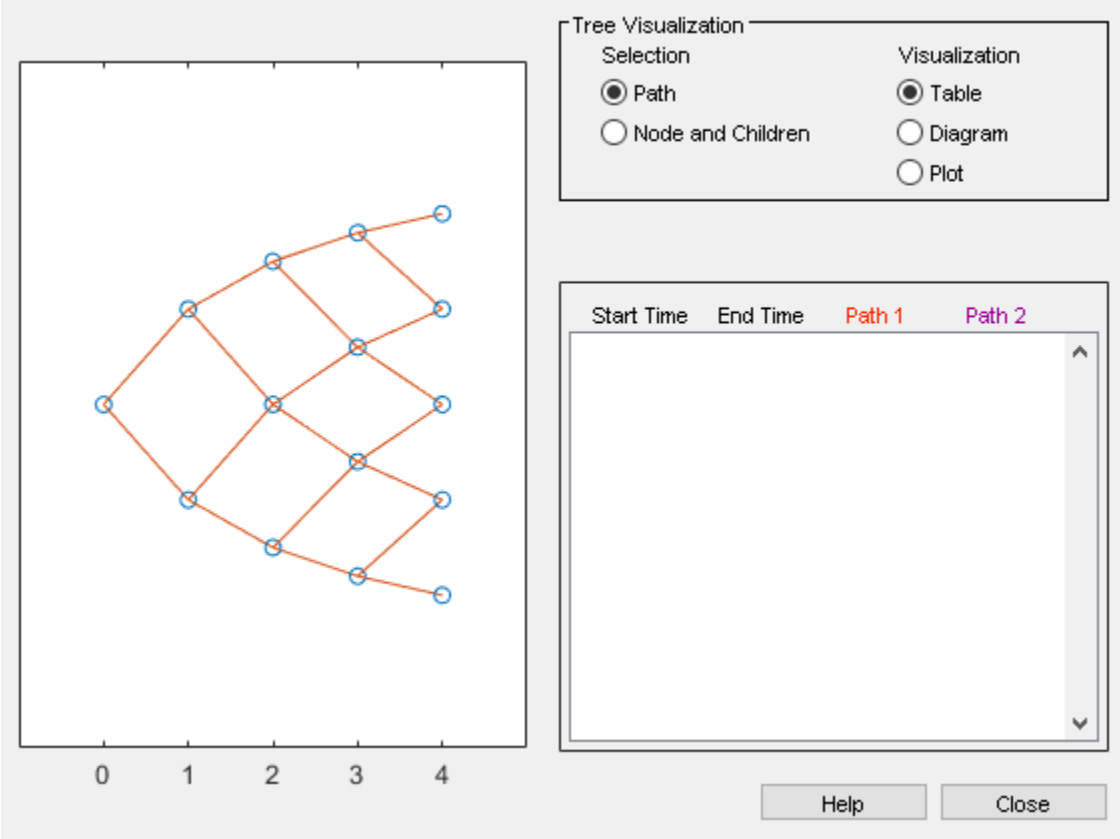
%Rates along lower branch:
RatePathDown = treepath(BDTTreeR.RateTree, [2 2 2 2])

RatePathDown = 5×1

    0.0275
    0.0351
    0.0472
    0.0585
    0.0653
```

You can also display a graphical representation of the tree to examine interactively the rates on the nodes of the tree until maturity. The function `treeviewer` displays the structure of the rate tree in the left pane. The tree visualization in the right pane is blank, but by selecting `Diagram` and clicking on the nodes you can examine the rates along the paths.

```
treeviewer(BDTTreeR)
```



Create an Instrument Portfolio

Create a portfolio consisting of two bond instruments and a option on the 5% Bond.

```
% Bonds
CouponRate = [0.04;0.05];
Settle = '01 Jan 2005';
Maturity = ['01 Jan 2009';'01 Jan 2010'];
Period = 1;

% Option
OptSpec = {'call'};
Strike = 98;
ExerciseDates = ['01 Jan 2010'];
AmericanOpt = 1;

InstSet = instadd('Bond',CouponRate, Settle,  Maturity, Period);
InstSet = instadd(InstSet,'OptBond', 2, OptSpec, Strike, ExerciseDates, AmericanOpt);
```

Examine the set of instruments contained in the variable `InstSet`.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.04       01-Jan-2005    01-Jan-2009    1      0     1            NaN       NaN
2     Bond 0.05       01-Jan-2005    01-Jan-2010    1      0     1            NaN       NaN

Index Type    UnderInd OptSpec Strike ExerciseDates  AmericanOpt
```

```
3     OptBond 2        call    98     01-Jan-2010    1
```

Price the Portfolio Using a BDT Tree

Calculate the price of each instrument in the instrument set (`InstSet`) using `bdtprice`.

```
Price = bdtprice(BDTTree, InstSet)
```

```
Price = 3×1

   99.6374
  102.2460
    4.2460
```

The prices in the output vector `Price` correspond to the prices at observation time zero (`tObs = 0`), which is defined as the Valuation Date of the interest-rate tree.

In the `Price` vector, the first element, `99.6374`, represents the price of the first instrument (4% Bond); the second element, `102.2460`, represents the price of the second instrument (5% Bond), and `4.2460` represents the price of the Option.

Instrument Construction and Portfolio Management Using Functions

In this section...

Instrument Constructors

The toolbox provides constructors for the most common financial instruments. A *constructor* is a function that builds a structure dedicated to a certain type of object; in this toolbox, an *object* is a type of market instrument.

The instruments and their constructor functions are listed below.

Instrument	Constructor Function
Asian option	`instasian`
Barrier option	`instbarrier`
Bond	`instbond`
Bond option	`instoptbnd`
Arbitrary cash flow	`instcf`
Compound option	`instcompound`
Convertible bond	`instcbond`
Fixed-rate note	`instfixed`
Floating-rate note	`instfloat`
Cap	`instcap`
Floor	`instfloor`
Lookback option	`instlookback`
Stock option	`instoptstock`
Swap	`instswap`
Swaption	`instswaption`

Each instrument has parameters (fields) that describe the instrument. The toolbox functions let you do the following:

- Create an instrument or portfolio of instruments.
- Enumerate stored instrument types and information fields.
- Enumerate instrument field data.
- Search and select instruments.

The instrument structure consists of various fields according to instrument type. A *field* is an element of data associated with the instrument. For example, a bond instrument contains the fields:

`CouponRate`, `Settle`, `Maturity`. Also, each instrument has a field that identifies the investment type (bond, cap, floor, and so on).

In reality, the set of parameters for each instrument is not fixed. You have the ability to add additional parameters. These additional fields are ignored by the toolbox functions. They may be used to attach additional information to each instrument, such as an internal code describing the bond.

Parameters not specified when *creating* an instrument default to `NaN`, which, in general, means that the functions using the instrument set (such as `intenvprice` or `hjmprice`) will use default values. At the time of *pricing*, an error occurs if any of the required fields is missing, such as `Strike` in a cap or `CouponRate` in a bond.

Creating Instruments or Properties

Use the `instaddfield` function to create a kind of instrument or to add new properties to the instruments in an existing instrument collection.

To create a kind of instrument with `instaddfield`, you must specify three arguments:

- `Type`
- `FieldName`
- `Data`

`Type` defines the type of the new instrument, for example, `Future`. `FieldName` names the fields uniquely associated with the new type of instrument. `Data` contains the data for the fields of the new instrument.

An optional fourth argument is `ClassList`. `ClassList` specifies the data types of the contents of each unique field for the new instrument.

Use either syntax to create a kind of instrument using `instaddfield`:

```
InstSet = instaddfield('FieldName', FieldList, 'Data', DataList,...
'Type', TypeString)
InstSet = instaddfield('FieldName', FieldList, 'FieldClass',...
ClassList, 'Data' , DataList, 'Type', TypeString)
```

To add new instruments to an existing set, use:

```
InstSetNew = instaddfield(InstSetOld, 'FieldName', FieldList,...
'Data', DataList, 'Type', TypeString)
```

As an example, consider a futures contract with a delivery date of July 15, 2000, and a quoted price of $104.40. Since Financial Instruments Toolbox software does not directly support this instrument, you must create it using the function `instaddfield`. Use these parameters to create instruments:

- Type: `Future`
- Field names: `Delivery` and `Price`
- Data: Delivery is July 15, 2000, and price is $104.40.

Enter the data into MATLAB software:

```
Type = 'Future';
FieldName = {'Delivery', 'Price'};
Data = {'Jul-15-2000', 104.4};
```

Finally, create the portfolio with a single instrument:

```
Port = instaddfield('Type', Type, 'FieldName', FieldName,...
'Data', Data);
```

Now use the function `instdisp` to examine the resulting single-instrument portfolio:

```
instdisp(Port)

Index Type   Delivery    Price
1     Future Jul-15-2000 104.4
```

Because your portfolio `Port` has the same structure as those created using the function `instadd`, you can combine portfolios created using `instadd` with portfolios created using `instaddfield`. For example, you can now add two cap instruments to `Port` with `instadd`.

```
Strike = [0.06; 0.07];
Settle = '08-Feb-2000';
Maturity = '15-Jan-2003';

Port = instadd(Port, 'Cap', Strike, Settle, Maturity);
```

View the resulting portfolio using `instdisp`.

```
instdisp(Port)

Index   Type   Delivery      Price
1       Future 15-Jul-2000   104.4

Index Type Strike Settle      Maturity    CapReset  Basis Principal
2     Cap  0.06   08-Feb-2000 15-Jan-2003 1         0     100
3     Cap  0.07   08-Feb-2000 15-Jan-2003 1         0     100
```

Searching or Subsetting a Portfolio

Financial Instruments Toolbox provides functions that enable you to:

- Find specific instruments within a portfolio.
- Create a subset portfolio consisting of instruments selected from a larger portfolio.

The `instfind` function finds instruments with a specific parameter value; it returns an instrument index (position) in a large instrument set. The `instselect` function, on the other hand, subsets a large instrument set into a portfolio of instruments with designated parameter values; it returns an instrument set (portfolio) rather than an index.

instfind

The general syntax for `instfind` is

```
IndexMatch = instfind(InstSet, 'FieldName', FieldList, 'Data',...
DataList, 'Index', IndexSet, 'Type', TypeList)
```

`InstSet` is the instrument set to search. Within `InstSet` instruments categorized by type, each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

The `FieldList`, `DataList`, and `TypeList` arguments indicate values to search for in the `FieldName`, `Data`, and `Type` data fields of the instrument set. `FieldList` is a cell array of field names specific to the instruments. `DataList` is a cell array or matrix of acceptable values for one or

more parameters specified in `FieldList`. `FieldName` and `Data` (therefore, `FieldList` and `DataList`) parameters must appear together or not at all.

`IndexSet` is a vector of integer indexes designating positions of instruments in the instrument set to check for matches; the default is all indices available in the instrument set. `TypeList` is a character vector or cell array of character vectors restricting instruments to match one of the `TypeList` types; the default is all types in the instrument set.

`IndexMatch` is a vector of positions of instruments matching the input criteria. Instruments are returned in `IndexMatch` if all the `FieldName`, `Data`, `Index`, and `Type` conditions are met. An instrument meets an individual field condition if the stored `FieldName` data matches any of the rows listed in the `DataList` for that `FieldName`.

instfind Examples

The examples use the provided MAT-file `deriv.mat`.

The MAT-file contains an instrument set, `HJMInstSet`, that contains eight instruments of seven types.

```
load deriv.mat
instdisp(HJMInstSet)
```

```
Index Type CouponRate Settle       Maturity     Period Basis ...  Name      Quantity
1    Bond 0.04       01-Jan-2000  01-Jan-2003    1     NaN   ... 4% bond     100
2    Bond 0.04       01-Jan-2000  01-Jan-2004    2     NaN   ... 4% bond      50

Index Type    UnderInd OptSpec Strike ExerciseDates  AmericanOpt Name        Quantity
3     OptBond 2        call    101    01-Jan-2003    NaN         Option 101   -50

Index Type  CouponRate Settle      Maturity     FixedReset Basis Principal Name     Quantity
4     Fixed 0.04       01-Jan-2000 01-Jan-2003    1        NaN    NaN     4% Fixed   80

Index Type  Spread Settle      Maturity   FloatReset  Basis Principal Name        Quantity
5     Float 20     01-Jan-2000 01-Jan-2003 1           NaN   NaN       20BP Float   8

Index Type Strike Settle         Maturity      CapReset Basis Principal Name     Quantity
6     Cap  0.03   01-Jan-2000    01-Jan-2004    1        NaN   NaN       3% Cap   30

Index Type  Strike Settle      Maturity     FloorReset Basis Principal Name       Quantity
7     Floor 0.03 01-Jan-2000 01-Jan-2004    1          NaN   NaN         3% Floor   40

Index Type LegRate   Settle     Maturity     LegReset Basis Principal LegType  Name   Quantity

8     Swap [0.06 20] 01-Jan-2000  01-Jan-2003  [1  1]   NaN   NaN     [NaN]  6%/20BP Swap  10
```

Find all instruments with a maturity date of January 01, 2003.

```
Mat2003 = ...
instfind(HJMInstSet,'FieldName','Maturity','Data','01-Jan-2003')

Mat2003 =

     1
     4
     5
     8
```

Find all cap and floor instruments with a maturity date of January 01, 2004.

```
CapFloor = instfind(HJMInstSet,...
'FieldName','Maturity','Data','01-Jan-2004', 'Type',...
{'Cap';'Floor'})
```

```
CapFloor =

     6
     7
```

Find all instruments where the portfolio is long or short a quantity of 50.

```
Pos50 = instfind(HJMInstSet,'FieldName',...
'Quantity','Data',{'50';'-50'})

Pos50 =

     2
     3
```

instselect

The syntax for `instselect` is the same syntax as for `instfind`. `instselect` returns a full portfolio instead of indexes into the original portfolio. Compare the values returned by both functions by calling them equivalently.

Previously you used `instfind` to find all instruments in `HJMInstSet` with a maturity date of January 01, 2003.

```
Mat2003 = ...
instfind(HJMInstSet,'FieldName','Maturity','Data','01-Jan-2003')

Mat2003 =

     1
     4
     5
     8
```

Now use the same instrument set as a starting point, but execute the `instselect` function instead, to produce a new instrument set matching the identical search criteria.

```
Select2003 = ...
instselect(HJMInstSet,'FieldName','Maturity','Data',...
'01-Jan-2003')

instdisp(Select2003)

Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCouponDate LastCouponDate StartDate Face Na
1     Bond 0.04       01-Jan-2000    01-Jan-2003    1      NaN   NaN          NaN       NaN             NaN            NaN       NaN  4%

Index Type  CouponRate Settle         Maturity       FixedReset Basis Principal Name     Quantity
2     Fixed 0.04       01-Jan-2000    01-Jan-2003    1          NaN   NaN       4% Fixed 80

3     Float 20     01-Jan-2000    01-Jan-2003    1          NaN   NaN       20BP Float 8

Index Type LegRate    Settle         Maturity       LegReset Basis Principal LegType Name         Quantity
4     Swap [0.06  20] 01-Jan-2000    01-Jan-2003    [1  1]   NaN   NaN       [NaN]   6%/20BP Swap 10
```

instselect Examples

These examples use the portfolio `ExampleInst` provided with the MAT-file `InstSetExamples.mat`.

```
load InstSetExamples.mat
instdisp(ExampleInst)
```

```
Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option 100     9.2  Call     0
3     Option 105     6.8  Call  1000

Index Type    Delivery       F     Contracts
4     Futures 01-Jul-1999    104.4 -1000

Index Type   Strike Price Opt  Contracts
5     Option 105     7.4  Put  -1000
6     Option  95     2.9  Put      0

Index Type  Price Maturity       Contracts
7     TBill 99    01-Jul-1999    6
```

The instrument set contains three instrument types: `Option`, `Futures`, and `TBill`. Use `instselect` to make a new instrument set containing only options struck at `95`. In other words, select all instruments containing the field `Strike` *and* with the data value for that field equal to `95`.

```
InstSet = instselect(ExampleInst,'FieldName','Strike','Data',95);

instdisp(InstSet)

Index Type   Strike Price Opt  Contracts
1     Option  95    12.2  Call     0
2     Option  95     2.9  Put      0
```

You can use all the various forms of `instselect` and `instfind` to locate specific instruments within this instrument set.

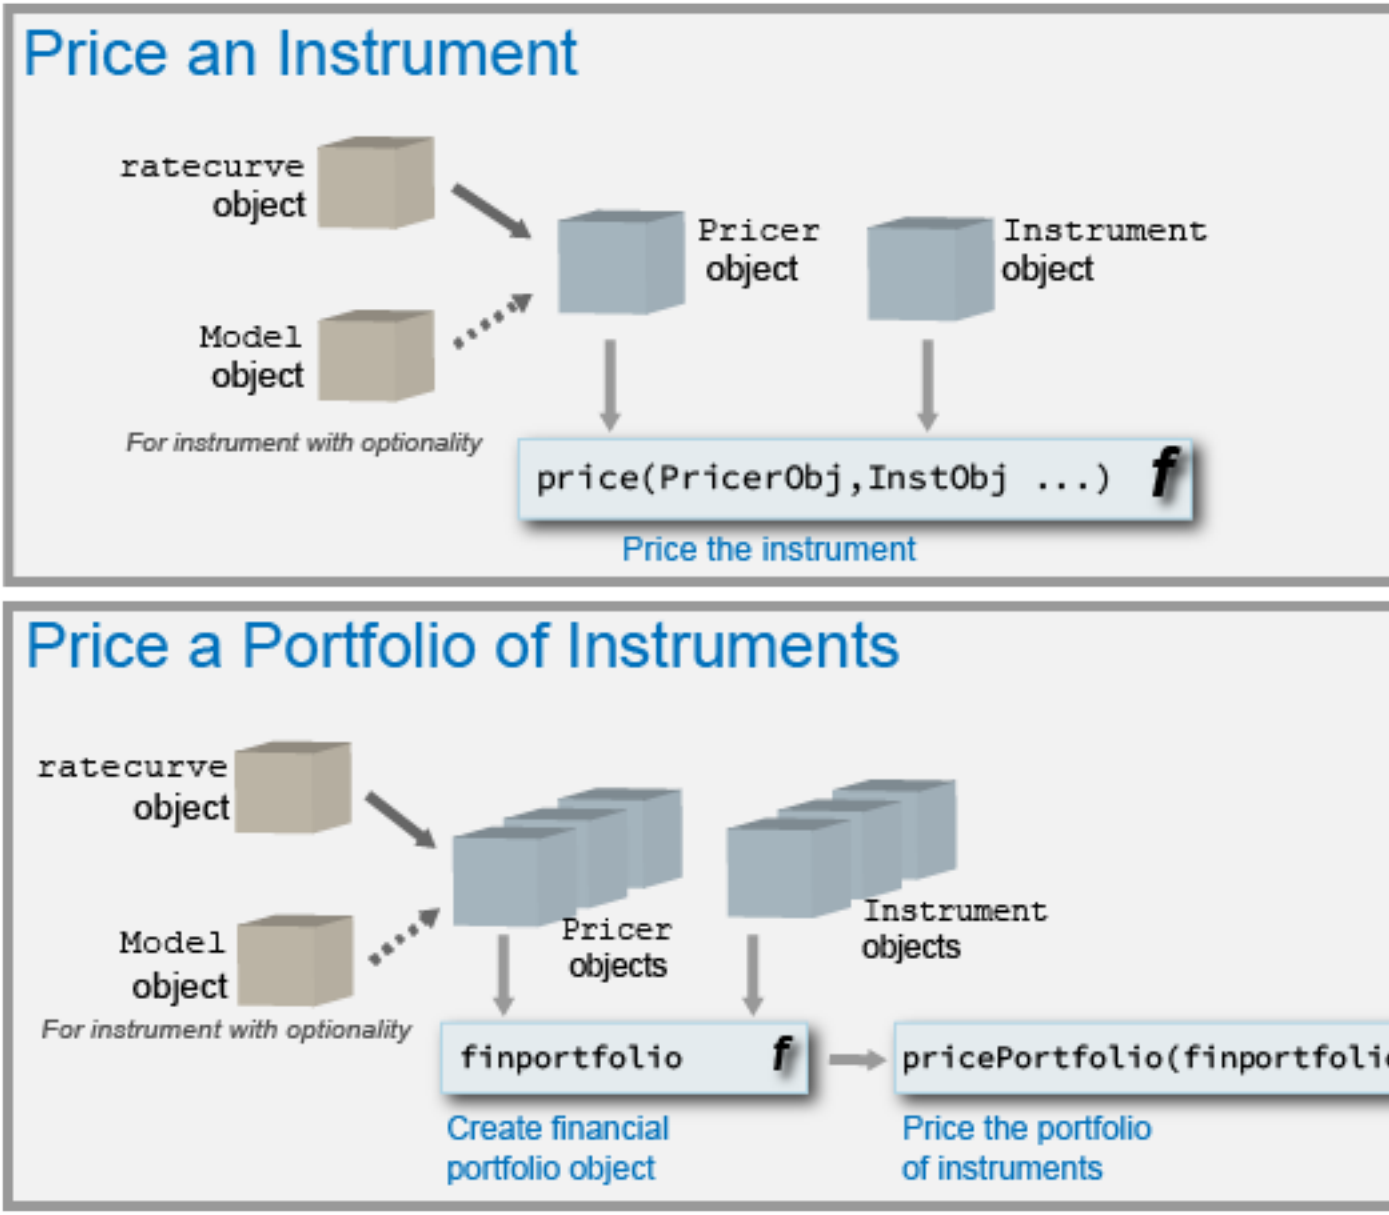
Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments



Object-Based Framework Workflow

Financial Instruments Toolbox supports an object framework for pricing financial instruments. There are three types of object constructors in the framework: `fininstrument` to create an instrument object, `finmodel` to create a model object, and `finpricer` to create a pricer object. The canonical workflow to price an instrument is:

1 Create an instrument object using `fininstrument`.

```
myInst = fininstrument(InstType,…)
```

2. Create a model object using `finmodel`.

   ```
   myModel = finmodel(ModelType,…)
   ```

3. Create a `ratecurve` object using `ratecurve`.

   ```
   myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
   ```

4. Create a pricer object using `finpricer`.

   ```
   myPricer = finpricer(PricerType,myModel,myRC,...)
   ```

5. Price the instrument using an associated `price` function.

   ```
   [Price, PriceResult] = price(myPricer, myInst,…)
   ```

For examples showing how to use this workflow to create different types of instruments, see:

- “Workflow to Price an Interest-Rate Instrument” on page 1-25
- “Workflow to Price an Inflation Instrument” on page 1-28
- “Workflow to Price an Equity, Commodity, or FX Instrument” on page 1-37
- “Workflow to Price a Credit Derivative Instrument” on page 1-40
- “Workflow for Creating and Analyzing a ratecurve and parametercurve” on page 1-46

You can also price an entire portfolio. After creating instrument objects and pricer objects, you can add the instrument and pricer objects to a `finportfolio` object and then price the portfolio using this workflow:

1. Create instrument objects using `fininstrument`.

   ```
   myInst1 = fininstrument(InstType,…)
   myInst2 = fininstrument(InstType,…)
   ```

2. Create model objects using `finmodel`.

   ```
   myModel = finmodel(ModelType,…)
   myModel2 = finmodel(ModelType,…)
   ```

3. Create one or more `ratecurve` objects using `ratecurve`.

   ```
   myRC1 = ratecurve('zero',Settle,ZeroDates,ZeroRates)
   myRC2 = ratecurve('zero',Settle,ZeroDates,ZeroRates)
   ```

4. Create a pricer object using `finpricer`.

   ```
   myPricer1 = finpricer(PricerType,myModel,myRC1,...)
   myPricer2 = finpricer(PricerType,myModel,myRC2,...)
   ```

5. Create a portfolio object using `finportfolio`.

   ```
   IP = finportfolio([MyInst1,MyInst2],[MyPricer1,MyPricer2],...)
   ```

6. Price the portfolio using `pricePortfolio`.

   ```
   [portPrice, portSens, instPrice, instSens] = price(IP)
   ```

For an example showing how to use this workflow to create a portfolio, see “Workflow to Create and Price a Portfolio of Instruments” on page 1-42.

Workflow to Price an Interest-Rate Instrument

Price a financial instrument with a zero curve. Such an instrument has no embedded optionality, in other words, the cash flows are deterministic and valuing the instrument is simply a matter of generating the cash flows and then computing the present value of the cash flows by generating corresponding discount factors from the zero curve. For more information on the supported interest-rate instruments, see “Choose Instruments, Models, and Pricers” on page 1-53.

Price Vanilla Fixed Bond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a vanilla `FixedBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

Create `FixedBond` Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond",'Maturity',datetime(2022,9,15),'CouponRate',0.021,'Period',2,'Ba
```

```
FixB =
  FixedBond with properties:

                 CouponRate: 0.0210
                     Period: 2
                      Basis: 1
                EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Sep-2022
                        Name: "fixed_bond_instrument"
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                 Type: "zero"
```

```
          Compounding: -1
                Basis: 0
                Dates: [10x1 datetime]
                Rates: [10x1 double]
               Settle: 15-Sep-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Discount` Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```
outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]
```

Price `FixedBond` Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, FixB,["all"])
```

```
Price = 104.5679

outPR =
  priceresult with properties:

       Results: [1x2 table]
    PricerData: []

outPR.Results

ans=1×2 table
    Price       DV01
    ______    ________

    104.57    0.040397
```

Workflow to Price an Inflation Instrument

When pricing inflation derivatives and building inflation curves, incorporating seasonality can be a critical factor. The zero-coupon inflation swap rates typically have maturities that increase in whole number of years. As a result, the inflation curve is typically built from zero-coupon inflation swap rates on an annual basis. For more information on the supported inflation instruments, see “Choose Instruments, Models, and Pricers” on page 1-53.

Analyze Inflation-Indexed Instruments

This example shows how to analyze inflation-indexed instruments using Financial Toolbox™ and Financial Instruments Toolbox™.

Compute Real Prices and Yields for Inflation-Indexed Bonds

While inflation-indexed bonds have a great deal of variation in the design, for example, the length of the indexation lag, the majority of inflation-indexed bonds now have a three month lag. They are also capital-indexed, that is, the principal of the bond is indexed to inflation. Therefore, the coupon rate of the bond is constant, but the actual coupon payments vary as the principal of the bond is indexed to inflation.

Specifically, the indexation is done with the following ratio:

$$IndexRatio = \frac{CPI_{Ref}}{CPI_{Base}}$$

where CPI_{Base} is the level of the consumer price index (or equivalent price measure) at the time of the bond's issue and CPI_{Ref} is the reference CPI.

Typically, you compute the CPI_{Ref} by interpolating between the index data of a known inflation-index curve. To compute the cash flows for an inflation-indexed bond, you simply compute the appropriate reference CPI and Index Ratio.

The market convention for inflation-indexed bonds is to quote the price and yield using the actual (that is, unadjusted) coupon, which means that your quote is a real price and yield. To get a real price and yield, you can use the Financial Toolbox™ functions `bndprice` and `bndyield`. For example:

```
Price = 124 + 9/32;
Settle = datetime(2009,9,28);
Coupon = .03375;
Maturity = datetime(2032,4,15);

RealYield = bndyield(Price,Coupon,Settle,Maturity);
disp(['Real Yield: ', num2str(RealYield*100) '%'])
```

```
Real Yield: 2.0278%
```

Construct Nominal, Real, and Inflation Curves

With the advent of the inflation-indexed bond market, real curves can be constructed in a similar fashion to nominal curves. Using the available market data, you can construct the real curve and compare it to the nominal curve.

Note that one issue relates to the indexation lag of the bonds. As stated previously, typically the indexation lag is three months, which means that the inflation compensation is not actually matched up with the maturity or the coupon payments of the bond. While Anderson and Sleath [1] discuss an approach to resolving this discrepancy, for this example, the lag is simply noted.

You can use the `fitNelsonSiegel` and `fitSvensson` functions in the Financial Instruments Toolbox™ to create `parametercurve` objects that fit Nelson-Siegel and Svensson models to real and nominal yield curves in the US. The Nelson-Siegel model typically places restrictions on the model parameters to ensure that the interest rates are always positive. However, real interest rates can be negative, which means that these Nelson-Siegel restrictions are not used in the case below.

```
% Load the data.
load usbond_02Sep2008
Settle = datetime(2008, 9, 2);
NominalTimeToMaturity = yearfrac(Settle,NominalMaturity);
TIPSTimeToMaturity = yearfrac(Settle,TIPSMaturity);

% Compute the yields.
NominalYield = bndyield(NominalPrice,NominalCoupon,Settle,NominalMaturity);
TIPSYield = bndyield(TIPSPrice,TIPSCoupon,Settle,TIPSMaturity);

% Plot the yields.
scatter(NominalTimeToMaturity,NominalYield*100,'r');
hold on;
scatter(TIPSTimeToMaturity,TIPSYield*100,'b');

% Fit the real yield curve using fitNelsonSiegel.
nInst = numel(TIPSCoupon);
TIPSBonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    TIPSBonds(ii) = fininstrument("FixedBond",'Maturity',TIPSMaturity(ii),...
        'CouponRate',TIPSCoupon(ii));
end

TIPSNelsonSiegel = fitNelsonSiegel(Settle,TIPSBonds,TIPSPrice);

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

% Fit the nominal yield curve using fitSvensson.
nInst = numel(NominalCoupon);
NominalBonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    NominalBonds(ii) = fininstrument("FixedBond",'Maturity',NominalMaturity(ii),...
        'CouponRate',NominalCoupon(ii));
end

NominalSvensson = fitSvensson(Settle,NominalBonds,NominalPrice);

Solver stopped prematurely.

lsqnonlin stopped because it exceeded the function evaluation limit,
options.MaxFunctionEvaluations = 6.000000e+02.

% Plot the nominal and real yield curves.
PlotDates = (Settle+calmonths(1):calmonths(1):Settle+calyears(30)-1)';
```

```
PlotTimeToMaturity = yearfrac(Settle,PlotDates);

TIPSNelsonSiegelZeroRates = zerorates(TIPSNelsonSiegel,PlotDates);
TIPSNelsonSiegelParYields = zero2pyld(TIPSNelsonSiegelZeroRates,PlotDates,Settle, ...
    'InputCompounding', -1, 'OutputCompounding', 2);

NominalSvenssonZeroRates = zerorates(NominalSvensson,PlotDates);
NominalSvenssonParYields = zero2pyld(NominalSvenssonZeroRates,PlotDates,Settle, ...
    'InputCompounding', -1, 'OutputCompounding', 2);

plot(PlotTimeToMaturity,NominalSvenssonParYields*100,'r')
plot(PlotTimeToMaturity,TIPSNelsonSiegelParYields*100,'b')
hold off;

```

Constructing Inflation Curves from Zero-Coupon Inflation Swaps

Inflation-linked derivatives have also experienced growth in the market. Some of the most liquidly traded inflation derivatives are zero coupon inflation swaps (`ZeroCouponInflationSwap`) and year-on-year inflation swaps (`YearYearInflationSwap`).

In a zero-coupon inflation swap, the inflation payer agrees to pay the rate of inflation at maturity (lagged by a certain amount) compounded by the number of years. The inflation receiver typically pays a fixed rate, again compounded by the tenor of the instrument. At the inception of the zero-coupon inflation swap, the fixed rate is set to the projected inflation rate for the life of the swap. This rate is called the "breakeven inflation swap rate" and it is quoted in the market [6].

Using the notation from Hurd and Relleen, you compute the rate as:

$$(1 + Rate_{swap})^T = (1 + Inflation_{t-L,\,t+T-L})^T$$

where t is the current time, T is the tenor, and L is the lag. [5]

At maturity, the actual cash flows of the zero-coupon inflation swap are:

$$FixedLeg = N \times [(1 + k)^M - 1]$$

$$InflationLeg = N \times \left[\frac{I(T_M)}{I_0} - 1\right]$$

where

- $N$is the reference notional of the swap.
- k is the fixed inflation rate.
- $M$is the number of years for the life of the swap.
- $I(T_M)$is the inflation index at the maturity date with some lag (for example, three months).
- I_0 is the inflation index at the start date with some lag (for example, three months).

While the fixed-leg cash flow might be different from the actual inflation-leg cash flow at maturity, the fixed breakeven inflation swap rate of the zero-coupon inflation swap represents the projected inflation rate for the tenor of the swap at inception. You can build an inflation curve from a series of breakeven zero-coupon inflation swap rates starting on the same date and maturing on different dates. Here, the dates are already adjusted with the appropriate indexation lag to simplify the notation:

$$I(0, T_{1Y}) = I(T_0)(1 + b(0; T_0, T_{1Y}))^{T_{1Y} - T_0}$$

$$I(0, T_{2Y}) = I(T_0)(1 + b(0; T_0, T_{2Y}))^{T_{2Y} - T_0}$$

$$I(0, T_{3Y}) = I(T_0)(1 + b(0; T_0, T_{3Y}))^{T_{3Y} - T_0}$$

. . .

$$I(0, T_i) = I(T_0)(1 + b(0; T_0, T_i))^{T_i - T_0}$$

where

- $I(0, T_i)$ is the breakeven inflation index reference number for maturity date T_i.
- $I(T_0)$ is the base inflation index value for the starting date T_0.
- $b(0; T_0, T_i)$ is the breakeven inflation rate for the zero-coupon inflation swap maturing on T_i.

You can get your inflation curve this by using the `inflationbuild` function to create an `inflationcurve` object. To build an `inflationcurve` from zero-coupon inflation swap rates, first define the base inflation date and the corresponding base inflation-index value.

```
% Define the base inflation date and index value for the inflation-index
% curve.
BaseDate = datetime(2020,6,1);
BaseIndexValue = 100;
```

Then, define the zero-coupon inflation swap rates and the corresponding maturity dates already adjusted with the appropriate indexation lag.

```
% Define the zero-coupon inflation swap rates and maturity dates.
ZCISTimes = (calyears([1 2 3 4 5 7 10 20 30]))';
ZCISRates = [0.42 0.54 0.76 0.87 0.92 1.39 1.71 2.01 2.46]'./100
```

```
ZCISRates = 9×1

    0.0042
    0.0054
    0.0076
    0.0087
    0.0092
    0.0139
    0.0171
    0.0201
    0.0246
```

```
ZCISDates = BaseDate + ZCISTimes
```

```
ZCISDates = 9x1 datetime
   01-Jun-2021
   01-Jun-2022
   01-Jun-2023
   01-Jun-2024
   01-Jun-2025
   01-Jun-2027
   01-Jun-2030
   01-Jun-2040
   01-Jun-2050
```

In pricing inflation derivatives and building inflation curves, incorporating seasonality can be a critical factor. The zero-coupon inflation swap rates typically have maturities that increase in whole number of years. As a result, the inflation curve is typically built from zero-coupon inflation swap rates on an annual basis. However, when computing inflation-index values for monthly periods that are not whole number of years, you can make seasonal adjustments to reflect the seasonal patterns of inflation within the year. These 12 monthly seasonal rates are annualized and they add up to zero to ensure that the cumulative seasonal adjustments are reset to zero every year. In the `inflationbuild` function and the `inflationcurve` object, you define these seasonal rates using the `'Seasonality'` name-value pair argument and they are internally corrected to ensure that they add to zero.

```
% Define the 12 monthly seasonal rates.
%
% Months:
%    Jan   Feb   Mar   Apr   May   Jun   Jul   Aug   Sep   Oct   Nov   Dec
%     1     2     3     4     5     6     7     8     9    10    11    12
% Seasonal Rates (percent):
%   -6.34 -3.00 -1.34  3.34  5.34  3.66  8.66  5.66 -2.34 -2.66 -4.66 -6.32
SeasonalRates = [-6.34 -3.00 -1.34 3.34 5.34 3.66 8.66 5.66 -2.34 -2.66 -4.66 -6.32]./100
```

```
SeasonalRates = 1×12

   -0.0634   -0.0300   -0.0134    0.0334    0.0534    0.0366    0.0866    0.0566   -0.0234   -0.0
```

```
% Build an inflation-index curve from zero-coupon inflation swap rates.
myInflationCurve = inflationbuild(BaseDate, BaseIndexValue, ...
    ZCISDates, ZCISRates, 'Seasonality', SeasonalRates)
```

```
myInflationCurve =
  inflationcurve with properties:
```

```
                Basis: 0
                Dates: [10x1 datetime]
 InflationIndexValues: [10x1 double]
ForwardInflationRates: [9x1 double]
          Seasonality: [12x1 double]
```

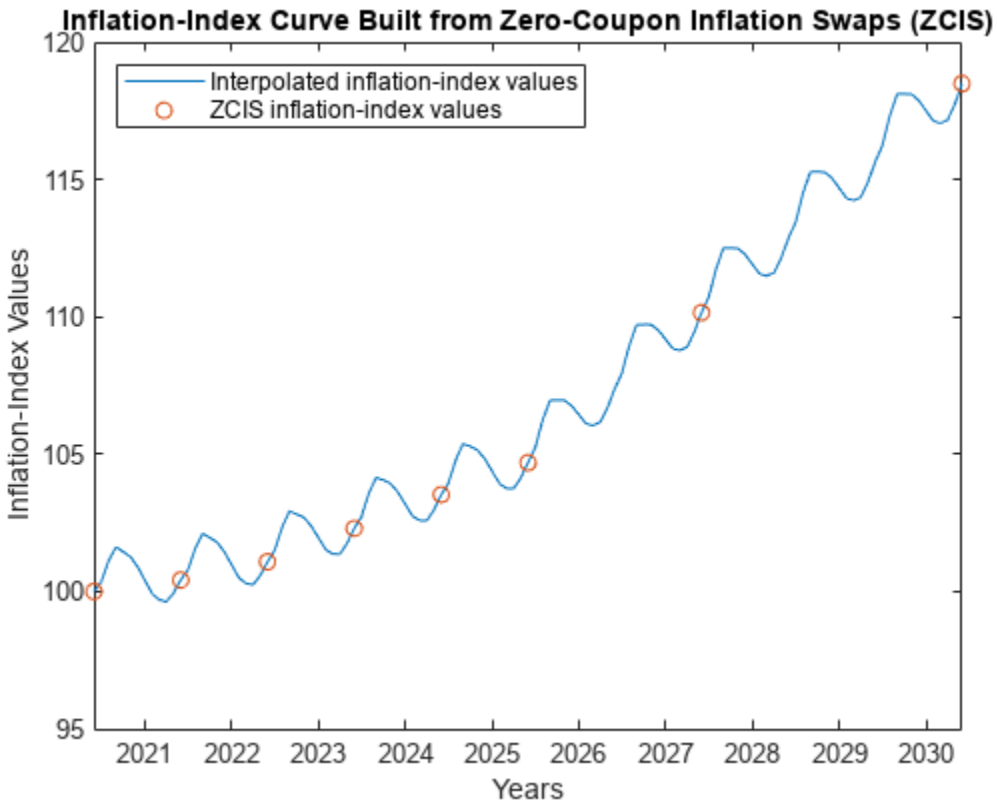
Once you have created the `inflationcurve` object, compute the inflation-index values for each month using `indexvalues`.

```
% Compute the inflation-index values.
IndexPlotDates = (BaseDate:calmonths(1):BaseDate+calyears(10))';
IndexPlotValues = indexvalues(myInflationCurve, IndexPlotDates);
```

To visualize the seasonal patterns of inflation that occur within each year, plot the computed inflation-index values.

```
% Plot the inflation-index curve.
figure; plot(IndexPlotDates, IndexPlotValues)
hold on;
plot(myInflationCurve.Dates(1:8), myInflationCurve.InflationIndexValues(1:8), 'o')
hold off;

title('Inflation-Index Curve Built from Zero-Coupon Inflation Swaps (ZCIS)')
xlabel('Years')
ylabel('Inflation-Index Values')
legend({'Interpolated inflation-index values','ZCIS inflation-index values'},'location','northwes
```



Price Inflation-Indexed Instruments Using an Inflation Curve

With the `inflationcurve` object created, you can price inflation-indexed instruments such as zero-coupon inflation swaps (`ZeroCouponInflationSwap`), year-on-year inflation swaps (`YearYearInflationSwap`), and inflation-indexed bonds (`InflationBond`).

First, create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,25);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0043 0.0051 0.0062 0.0072 0.0096 0.0121 0.0172 0.0241 0.0302 0.0308]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 25-Sep-2020
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Using the `ratecurve` and `inflationcurve` objects as inputs, create an `Inflation` pricer object using `finpricer`.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

    DiscountCurve: [1x1 ratecurve]
   InflationCurve: [1x1 inflationcurve]
```

Create an `InflationBond` instrument using `fininstrument`.

```
IssueDate = datetime(2020,9,20);
Maturity = datetime(2025,9,20);
CouponRate = 0.023;

InflationBond = fininstrument("InflationBond",'IssueDate',IssueDate,'Maturity',Maturity,'CouponRa
```

```
InflationBond =
  InflationBond with properties:

                 CouponRate: 0.0230
                     Period: 2
                      Basis: 0
                  Principal: 100
   DaycountAdjustedCashFlow: 0
                        Lag: 3
```

```
BusinessDayConvention: "actual"
              Holidays: NaT
          EndMonthRule: 1
             IssueDate: 20-Sep-2020
       FirstCouponDate: NaT
        LastCouponDate: NaT
              Maturity: 20-Sep-2025
                  Name: ""
```

Here, the default indexation lag is three months and the bond issue date is `20-Sep-2020`. The first date on the inflation curve of the pricer must be on or before `20-Jun-2020` to price this instrument. In this example, the first date on the inflation curve of the pricer is `01-Jun-2020`.

Price the `InflationBond` instrument by using the `price` function for the `Inflation` pricer.

```
InflationBondPrice = price(outPricer, InflationBond)
```

```
InflationBondPrice = 110.1314
```

Workflow to Price an Equity, Commodity, or FX Instrument

Price a Vanilla option with the Black-Scholes closed form formula. For more information on the supported equity, commodity, or FX instruments, see “Choose Instruments, Models, and Pricers” on page 1-53.

Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla",'ExerciseDate',datetime(2018,5,1),'Strike',29,'OptionType','
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "put"
    ExerciseStyle: "european"
     ExerciseDate: 01-May-2018
           Strike: 29
             Name: "vanilla_option"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes",'Volatility',0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

     Volatility: 0.2500
    Correlation: 1
```

Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
        Compounding: -1
```

```
                Basis: 1
                Dates: 01-Jan-2019
                Rates: 0.0500
               Settle: 01-Jan-2018
         InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic",'DiscountCurve',myRC,'Model',BlackScholesModel,'SpotPrice',30,'D
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 30
    DividendValue: 0.0450
     DividendType: "continuous"
```

Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer,VanillaOpt,["all"])
```

```
Price = 1.2046

outPR =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1×7 table
    Price      Delta       Gamma      Lambda      Vega       Rho       Theta
    ______    ________    ________    _______    ______    _______    _______

    1.2046    -0.36943    0.086269    -9.3396    6.4702    -4.0959    -2.3107
```

Workflow to Price a Credit Derivative Instrument

Price and analyze a credit default swap. For more information on the supported credit derivative instruments, see “Choose Instruments, Models, and Pricers” on page 1-53.

Price CDS Instrument Using Default Probability Curve and Credit Pricer

This example shows the workflow to price a `CDS` instrument when you use a `defprobcurve` model and a `Credit` pricing method.

Create `CDS` Instrument Object

Use `fininstrument` to create a `CDS` instrument object.

```
CDS = fininstrument("CDS",'Maturity',datetime(2021,9,15),'ContractSpread',15,'Notional',20000,'Pe
```

```
CDS =
  CDS with properties:

           ContractSpread: 15
                 Maturity: 15-Sep-2021
                   Period: 4
                    Basis: 3
             RecoveryRate: 0.4000
    BusinessDayConvention: "follow"
                 Holidays: NaT
        PayAccruedPremium: 1
                 Notional: 20000
                     Name: "CDS_instrument"
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 20-Sep-2020
                   Basis: 5
                   Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `Credit` Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("credit",'DefaultProbabilityCurve',DefaultProbCurve,'DiscountCurve',myRC)
```

```
outPricer =
  Credit with properties:

             DiscountCurve: [1x1 ratecurve]
                  TimeStep: 10
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

Price `CDS` Instrument

Use `price` to compute the price for the `CDS` instrument.

```
Price = price(outPricer,CDS)
```

```
Price = 52.7426
```

Workflow to Create and Price a Portfolio of Instruments

Price a portfolio of instruments — each with their own associated pricer. This workflow is common in risk situations where you may have a portfolio of securities that need to be valued.

Create and Price Portfolio of Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio of interest-rate and equity instruments. The portfolio contains a vanilla `FixedBond`, an `OptionEmbeddedFixedBond`, a `Vanilla` European call option, a `Vanilla` American call option, and an `Asian` call option.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates);
```

Create the Instrument Objects

Use `fininstrument` to create the instrument objects.

```
% Vanilla FixedBond
CouponRate = 0.0325;
Maturity = datetime(2038,3,15);
Period = 1;
VanillaBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,...
    'Period',Period,'Name',"VanillaBond")
```

```
VanillaBond =
  FixedBond with properties:

                 CouponRate: 0.0325
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Mar-2038
                        Name: "VanillaBond"
```

```
% OptionEmbeddedBond
Maturity = datetime(2024,9,15);
CouponRate = 0.035;
Strike = 100;
```

```
ExerciseDates = datetime(2023,9,15);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;
CallableBond = fininstrument("OptionEmbeddedFixedBond", "Maturity",Maturity,...
    'CouponRate',CouponRate,'Period',Period, ...
    'CallSchedule',CallSchedule,...
    'Name',"CallableBond");

% Vanilla European call option
ExerciseDate = datetime(2022,1,1);
Strike = 96;
OptionType = 'call';
CallOpt = fininstrument("Vanilla",'ExerciseDate',ExerciseDate,'Strike',Strike,...
    'OptionType',OptionType, 'Name',"EuropeanCallOption")

CallOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 01-Jan-2022
           Strike: 96
             Name: "EuropeanCallOption"

% Vanilla American call option
ExerciseDate = datetime(2023,1,1);
Strike = 97;
OptionType = 'call';
CallOpt_American = fininstrument("Vanilla",'ExerciseDate',ExerciseDate,'Strike',Strike,...
    'OptionType',OptionType, 'ExerciseStyle', "american", ...
    'Name',"AmericanCallOption")

CallOpt_American =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2023
           Strike: 97
             Name: "AmericanCallOption"

% Asian call option
ExerciseDate = datetime(2023,1,1);
Strike = 102;
OptionType = 'call';
CallOpt_Asian = fininstrument("Asian",'ExerciseDate',ExerciseDate,'Strike',Strike,...
    'OptionType',OptionType,'Name',"AsianCall")

CallOpt_Asian =
  Asian with properties:

         OptionType: "call"
             Strike: 102
        AverageType: "arithmetic"
       AveragePrice: 0
```

```
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 01-Jan-2023
                Name: "AsianCall"
```

Create Model Objects

Use `finmodel` to create `HullWhite` and `BlackScholes` model objects.

```
% Create Hull-White model
Vol = 0.01;
Alpha = 0.1;
HWModel = finmodel("hullwhite",'alpha',Alpha,'sigma',Vol);

% Create Black-Scholes model
Vol = .1;
SpotPrice = 95;
BlackScholesModel = finmodel("BlackScholes",'Volatility',Vol);
```

Create Pricer Objects

Use `finpricer` to create `Discount`, `IRTree`, `BlackScholes`, `Levy`, and `BjerksundStensland` pricer objects and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
% Create Discount pricer
DiscPricer = finpricer("Discount","DiscountCurve",ZeroCurve);

% Create Hull-White tree pricer
TreeDates = Settle + calyears(1:30);
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,...
    'TreeDates',TreeDates');

% Create BlackScholes, Levy, and BjerksundStensland pricers
BLSPricer = finpricer("analytic",'DiscountCurve',ZeroCurve,'Model',BlackScholesModel,'SpotPrice'
LevyPricer = finpricer("analytic",'DiscountCurve',ZeroCurve,'Model',BlackScholesModel,...
                       'SpotPrice',SpotPrice,'PricingMethod',"Levy");
BJSpricer = finpricer("analytic",'DiscountCurve',ZeroCurve,'Model',BlackScholesModel,...
                       'SpotPrice',SpotPrice,'PricingMethod',"BjerksundStensland");
```

Create `finportfolio` Object

Create a `finportfolio` object that contains all of the instrument and pricer objects using `finportfolio`.

```
myPort = finportfolio([VanillaBond CallableBond CallOpt CallOpt_American CallOpt_Asian]',...
                           [DiscPricer HWTreePricer BLSPricer BJSpricer LevyPricer]')
```

```
myPort =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
        Pricers: [5x1 finpricer.FinPricer]
    PricerIndex: [5x1 double]
       Quantity: [5x1 double]
```

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myPort)
```

```
PortPrice = 237.3275

InstPrice = 5×1

  107.4220
  110.8389

Workflow for Creating and Analyzing a ratecurve and parametercurve

Use `ratecurve` or `irbootstrap` to create a `ratecurve` object.

```
% Create a ratecurve
Settle = datetime(2019,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =

  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10×1 datetime]
               Rates: [10×1 double]
              Settle: 15-Sep-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Use `zerorates`, `forwardrates`, or `discountfactors` with the `ratecurve` object.

```
CurveSettle = datetime(2019,9,15);

% zerorates
outZeroRates = zerorates(myRC,CurveSettle+30:30:CurveSettle+720)

% forwardrates
outForwardRates = forwardrates(myRC,datetime(2019,12,15),datetime(2021,9,15),6,7)

% discountfactors
outDiscountFactors = discountfactors(myRC,CurveSettle+30:30:CurveSettle+720)
```

```
outZeroRates =

  Columns 1 through 14

    0.0052    0.0052    0.0052    0.0052    0.0052    0.0052    0.0052    0.0053    0.0053    0.0

  Columns 15 through 24

    0.0056    0.0057    0.0057    0.0058    0.0058    0.0059    0.0059    0.0060    0.0060    0.0

outForwardRates =

    0.0062

outDiscountFactors =

```

Convert RateSpec to a ratecurve Object

You can create a `RateSpec` using `intenvset` or `toRateSpec` from an `IRDataCurve` object. Then, you can covert this previously created `RateSpec` to a `ratecurve` object.

```
% Assume there is a RateSpec
Settle = datetime('01-Oct-2019');
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Basis = 1;
RateSpec = intenvset('StartDates', Settle, 'EndDates', ZeroDates, ...
    'Rates', ZeroRates, 'Basis', Basis)

RateSpec =

  struct with fields:

          FinObj: 'RateSpec'
     Compounding: 2
            Disc: [10×1 double]
           Rates: [10×1 double]
       EndTimes: [10×1 double]
      StartTimes: [10×1 double]
        EndDates: [10×1 double]
      StartDates: 737699
    ValuationDate: 737699
           Basis: 1
     EndMonthRule: 1

% Convert the RateSpec to a ratecurve
myRC = ratecurve("zero",RateSpec.ValuationDate,RateSpec.EndDates,RateSpec.Rates,...
"Compounding",RateSpec.Compounding,"Basis",RateSpec.Basis)

myRC =

  ratecurve with properties:

                Type: "zero"
         Compounding: 2
               Basis: 1
               Dates: [10×1 datetime]
               Rates: [10×1 double]
              Settle: 01-Oct-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"

% Check the discount factors
OldDF = intenvget(intenvset(RateSpec,'EndDates',datetime('01-Oct-2024')),'Disc')
NewDF = discountfactors(myRC,datetime('01-Oct-2024'))

OldDF =

    0.9424
```

```
NewDF =

    0.9424
```

In this case, the `RateSpec` and `ratecurve` are identical. This may not always be the case because `yearfrac` is used to compute times in `ratecurve` while `date2time` is used in computing a `RateSpec`. For more information, see “Difference Between yearfrac and date2time”.

Workflow for Creating and Analyzing a defprobcurve

You can use `defprobcurve` or `defprobstrip` to create a `defprobcurve` object.

```
% defprobcurve
Settle = datetime(2019,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)
```

```
DefaultProbCurve =

  defprobcurve with properties:

                 Settle: 20-Sep-2019
                  Basis: 2
                  Dates: [10×1 datetime]
    DefaultProbabilities: [10×1 double]
```

You can then use the `defprobcurve` object with `survprobshazardrates`.

```
% hazardrates
hazardrates(DefaultProbCurve)
```

```
ans =

    0.0099
    0.0039
    0.0030
    0.0050
    0.0111
    0.0142
    0.0194
    0.0057
    0.0064
    0.0060
```

```
% survprobs
Settle = datetime(2019,9,20);
SurvProbTimes = [calmonths([6 12 18])];
SurvProbDates = Settle + SurvProbTimes;
outSurvProb = survprobs(DefaultProbCurve, SurvProbDates)
```

```
outSurvProb =

    0.9950
    0.9930
    0.9915
```

Choose Instruments, Models, and Pricers

The object-based framework supports a workflow for creating instruments, models, and pricer objects to price financial instruments. Using these objects, you can price interest-rate instruments; inflation instruments; equity, commodity, or FX instruments; or credit derivative instruments.

Interest-Rate Instruments with Associated Models and Pricers

The following table lists the interest-rate instrument objects with models and pricers.

Interest-Rate Instrument Type	Available Models	Available Pricers
`Cap`	• `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `Black` • `Normal` • `BraceGatarekMusiela` • `SABRBraceGatarekMusiela` • `LinearGaussian2F`	• `HullWhite` for `HullWhite` model • `Black` for `Black` model • `Normal` for `Normal` model • `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models
`Floor`	• `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `Black` • `Normal` • `BraceGatarekMusiela` • `SABRBraceGatarekMusiela` • `LinearGaussian2F`	• `HullWhite` for `HullWhite` model • `Black` for `Black` model • `Normal` for `Normal` model • `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models

Interest-Rate Instrument Type	Available Models	Available Pricers
`Swaption`	• `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `Black` • `SABR` • `Normal` • `LinearGaussian2F`	• `HullWhite` for `HullWhite` model • `Black` for `Black` model • `SABR` for `SABR` model • `Normal` for `Normal` model • `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, or `LinearGaussian2F` models
`FixedBondOption`	• `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `BraceGatarekMusiela` • `SABRBraceGatarekMusiela` • `LinearGaussian2F`	• `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models
`OptionEmbeddedFixedBond`	• `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `BraceGatarekMusiela` • `SABRBraceGatarekMusiela` • `LinearGaussian2F`	• `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models
`OptionEmbeddedFloatBond`	• `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `BraceGatarekMusiela` • `SABRBraceGatarekMusiela` • `LinearGaussian2F`	• `IRTree` for `HullWhite`, `BlackKarasinski`, `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models

Interest-Rate Instrument Type	Available Models	Available Pricers
Swap	• `ratecurve` object • `HullWhite` • `BlackKarasinski` • `BlackDermanToy` • `LinearGaussian2F`	• `Discount` • `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models • `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, or `LinearGaussian2F` models

`FixedBond`	• Use a `ratecurve` object for a `Discount` pricer.
	• Use one of the following models:
	  • `HullWhite`
	  • `BlackDermanToy`
	  • `BlackKarasinski`
	  • `BraceGatarekMusiela`
	  • `SABRBraceGatarekMusiela`
	  • `LinearGaussian2F`
		• `Discount`
		• `IRTree` for `HullWhite`, `BlackDermanToy`, or `BlackKarasinski` models
		• `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models

`FloatBond`	• Use a object for a `Discount` pricer.
	• Use one of the following models:
	  • `HullWhite`
	  • `BlackDermanToy`
	  • `BlackKarasinski`
	  • `BraceGatarekMusiela`
	  • `SABRBraceGatarekMusiela`
	  • `LinearGaussian2F`
		• `Discount`
		• `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models
		• `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models

Interest-Rate Instrument Type	Available Models	Available Pricers

`FloatBondOption`	• Use a `ratecurve` object for a `Discount` pricer.
	• Use one of the following models:
	  • `HullWhite`
	  • `BlackDermanToy`
	  • `BlackKarasinski`
	  • `BraceGatarekMusiela`
	  • `SABRBraceGatarekMusiela`
	  • `LinearGaussian2F`
		• `Discount`
		• `IRTree` for `HullWhite`, `BlackKarasinski`, or `BlackDermanToy` models
		• `IRMonteCarlo` for `HullWhite`, `BlackKarasinski`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models

`ConvertibleBond`	• `BlackScholes`	• `FiniteDifference` for `BlackScholes` model
`Deposit`	Use a `ratecurve` object.	• `Discount`
`FRA`	Use a `ratecurve` object.	• `Discount`
`OvernightIndexedSwap`	Use a `ratecurve` object.	• `Discount` • `irbootstrap` for curve construction
`STIRFuture`	Use a `ratecurve` object.	• `Discount` • `irbootstrap` for curve construction
`OISFuture`	Use a `ratecurve` object.	• `Discount` • `irbootstrap` for curve construction
`BondFuture`	Use a `ratecurve` object.	• `Future`

Equity, Commodity, FX, and Energy Instruments with Associated Models and Pricers

The following table lists the equity, commodity, FX , and energy instrument objects with models and pricers.

Equity, Commodity, FX Instrument Type	Available Models	Available Pricers
`Asian`	• `BlackScholes` • `Heston` • `Merton` • `Bates`	• `Levy` for `BlackScholes` model • `AssetTree` for a Cox-Ross-Rubinstein (CRR), equal-probability (EQP), Leisen-Reimer (LR), or Standard Trinomial (ST) lattice tree using a `BlackScholes` model • `KemnaVorst` for `BlackScholes` model • `TurnbullWakeman` or `BlackScholes` model • `AssetMonteCarlo` for `BlackScholes`, `Heston`, `Merton`, `Bates` models
`Barrier`	• `BlackScholes` • `Heston` • `Merton` • `Bates`	• `BlackScholes` for `BlackScholes` model • `AssetTree` for a Cox-Ross-Rubinstein (CRR), equal-probability (EQP), Leisen-Reimer (LR), or Standard Trinomial (ST) lattice tree using a `BlackScholes` model • `VannaVolga` for `BlackScholes` model • `FiniteDifference` for `BlackScholes`, `Heston`, `Merton`, `Bates` models • `AssetMonteCarlo` for `BlackScholes`, `Heston`, `Merton`, `Bates` models
`DoubleBarrier`	• `BlackScholes` • `Heston` • `Merton` • `Bates`	• `IkedaKunitomo` for `BlackScholes` model • `VannaVolga` for `BlackScholes` model • `FiniteDifference` for `BlackScholes`, `Heston`,,`Merton`, or `Bates` model • `AssetMonteCarlo` for `BlackScholes`, `Heston`, `Merton`, `Bates` models

Equity, Commodity, FX Instrument Type	Available Models	Available Pricers
Lookback	• BlackScholes • Heston • Merton • Bates	• ConzeViswanathan for BlackScholes model • AssetTree for a Cox-Ross-Rubinstein (CRR), equal-probability (EQP), Leisen-Reimer (LR), or Standard Trinomial (ST) lattice tree using a BlackScholes model • GoldmanSosinGatto for BlackScholes model • AssetMonteCarlo for BlackScholes, Heston, Merton, Bates models
PartialLookback	• BlackScholes • Heston • Merton • Bates	• HeynenKat for BlackScholes model • AssetMonteCarlo for BlackScholes, Heston, Merton, Bates models
Spread	• BlackScholes • Bachelier	For BlackScholes model: • Kirk • BjerksundStensland • AssetMonteCarlo For Bachelier model: • AssetMonteCarlo
VarianceSwap	• ratecurve object • Heston	For ratecurve object: • ReplicatingVarianceSwap For Heston model: • Heston

Equity, Commodity, FX Instrument Type	Available Models	Available Pricers
`Vanilla`	• `BlackScholes` • `Bachelier` • `Heston` • `Merton` • `Bates` • `Dupire`	For `BlackScholes` model: • `BlackScholes` • `VannaVolga` • `BjerksundStensland` • `RollGeskeWhaley` • `FiniteDifference` • `AssetMonteCarlo` • `AssetTree` for a Cox-Ross-Rubinstein (CRR), equal-probability (EQP), Leisen-Reimer (LR), or Standard Trinomial (ST) lattice tree For `Heston` model: • `FFT` • `FiniteDifference` • `NumericalIntegration` • `AssetMonteCarlo` For `Merton` model: • `FFT` • `FiniteDifference` • `NumericalIntegration` • `AssetMonteCarlo` For `Bates` model: • `FFT` • `FiniteDifference` • `NumericalIntegration` • `AssetMonteCarlo` For `Dupire` model: • `FiniteDifference` For `Bachelier` model: • `AssetMonteCarlo`

Equity, Commodity, FX Instrument Type	Available Models	Available Pricers
Touch	• BlackScholes • Heston • Merton • Bates	• BlackScholes for BlackScholes model • VannaVolga for BlackScholes model • AssetMonteCarlo for Bachelier model
DoubleTouch	• BlackScholes • Heston • Merton • Bates	• BlackScholes for BlackScholes model • VannaVolga for BlackScholes model • AssetMonteCarlo for BlackScholes, Heston, Merton, or Bates models
Cliquet	• BlackScholes • Heston • Merton • Bates	• Rubinstein for BlackScholes model • AssetMonteCarlo for BlackScholes, Heston, Merton, or Bates models
Binary	• BlackScholes • Bachelier • Heston • Merton • Bates	• BlackScholes for BlackScholes model • AssetMonteCarlo for BlackScholes, Heston, Merton, Bachelier, or Bates models
CommodityFuture	Use a ratecurve object.	• Future
FXFuture	Use a ratecurve object.	• Future
EquityIndexFuture	Use a ratecurve object.	• Future
ConvertibleBond	• BlackScholes	• FiniteDifference for BlackScholes model

Inflation Instruments with Associated Models and Pricers

The following table lists the inflation instrument objects with models and pricers.

Inflation Instrument Type	Available Models	Available Pricers
InflationBond	Use an inflationcurve object and a ratecurve object.	• Inflation
YearYearInflationSwap	Use an inflationcurve object and a ratecurve object.	• Inflation
ZeroCouponInflationSwap	Use an inflationcurve object and a ratecurve object.	• Inflation

Credit Derivative Instruments with Associated Models and Pricers

The following table lists the credit derivative instrument objects with models and pricers.

Credit Derivative Instrument Type	Available Models	Available Pricers
`CDS`	Use a `defprobcurve` object and a `ratecurve` object.	• `Credit`
`CDSOption`	`CDSBlack`	• `CDSBlack`

Supported Exercise Styles

The following table lists the interest-rate instrument objects with their associated models and pricers and supported `Exercise` styles.

Interest-Rate Instrument Type	Exercise Styles
`Swaption`	• `"European"` — `HullWhite` pricer for `HullWhite` model • `"European"` — `Black` pricer for `Black` model • `"European"` — `SABR` pricer for `SABR` model • `"European"` — `Normal` pricer for `Normal` model • `"European"` or `"American"` — `IRTree` pricer for `HullWhite` or `BlackKarasinski` models • `"European"` or `"American"` — `IRMonteCarlo` pricer for `HullWhite`, or `LinearGaussian2F` models
`FixedBondOption`	• `"European"`, `"American"`, or `"Bermudan"` — `IRTree` pricer for `HullWhite` or `BlackKarasinski` models • `"European"`, `"American"`, or `"Bermudan"` — `IRMonteCarlo` pricer for `HullWhite`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models
`FloatBondOption`	• `"European"`, `"American"`, or `"Bermudan"` — `IRTree` pricer for `HullWhite` or `BlackKarasinski` models • `"European"`, `"American"`, or `"Bermudan"` — `IRMonteCarlo` pricer for `HullWhite`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models
`OptionEmbeddedFixedBond`	• `"European"`, `"American"`, or `"Bermudan"` — `IRTree` pricer for `HullWhite` or `BlackKarasinski` models • `"European"`, `"American"`, or `"Bermudan"` — `IRMonteCarlo` pricer for `HullWhite`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models

Interest-Rate Instrument Type	Exercise Styles
`OptionEmbeddedFloatBond`	• `"European"`, `"American"`, or `"Bermudan"` — `IRTree` pricer for `HullWhite` or `BlackKarasinski` models • `"European"`, `"American"`, or `"Bermudan"` — `IRMonteCarlo` pricer for `HullWhite`, `BraceGatarekMusiela`, `SABRBraceGatarekMusiela`, or `LinearGaussian2F` models
`ConvertibleBond`	For `BlackScholes` model: • `"European"`, `"American"`, or `"Bermudan"` — `FiniteDifference` pricer

The following table lists the equity, commodity, or FX instrument objects with their associated models and pricers and the supported `Exercise` styles.

Equity, Commodity, FX Instrument Type	Exercise Styles
`Asian`	For `BlackScholes` model: • `"European"` — `Levy` pricer • `"European"` — `KemnaVorst` pricer • `"European"` — `TurnbullWakeman` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer • `"European"` or `"American"` — `AssetTree` pricer For `Bates` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Merton` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Heston` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer

Equity, Commodity, FX Instrument Type	Exercise Styles
`Barrier`	For `BlackScholes` model: • `"European"` — `BlackScholes` pricer • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer • `"European"` or `"American"` — `AssetTree` pricer For `Bates` model: • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Merton` model: • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Heston` model: • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer

Equity, Commodity, FX Instrument Type	Exercise Styles
`DoubleBarrier`	For `BlackScholes` model: • `"European"` — `IkedaKunitomo` pricer • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Bates` model: • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Merton` model: • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Heston` model: • `"European"` or `"American"` — `FiniteDifference` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer

Equity, Commodity, FX Instrument Type	Exercise Styles
`Lookback`	For `BlackScholes` model: • `"European"` — `ConzeViswanathan` pricer • `"European"` — `GoldmanSosinGatto` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer • `"European"` or `"American"` — `AssetTree` pricer For `Bates` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Merton` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Heston` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer
`PartialLookback`	For `BlackScholes` model: • `"European"` — `HeynenKat` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Bates` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Merton` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Heston` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer

Equity, Commodity, FX Instrument Type	Exercise Styles
`Spread`	For `BlackScholes` model: • `"European"` — `Kirk` pricer • `"European"` — `BjerksundStensland` pricer • `"European"` or `"American"` — `AssetMonteCarlo` pricer For `Bachelier` model: • `"European"` or `"American"` — `AssetMonteCarlo` pricer

Equity, Commodity, FX Instrument Type	Exercise Styles
`Vanilla`	For `BlackScholes` model: • `"European"` — `BlackScholes` pricer • `"American"` — `BjerksundStensland` pricer • `"American"` — `RollGeskeWhaley` pricer • `"European"`, `"American"`, or `"Bermudan"` —`FiniteDifference` pricer • `"European"`, `"American"`, or `"Bermudan"` — `AssetMonteCarlo` pricer • `"European"`, `"American"`, or `"Bermudan"` — `AssetTree` pricer For `Heston` model: • `"European"` — `FFT` pricer • `"European"`, `"American"`, or `"Bermudan"` — `FiniteDifference` pricer • `"European"` — `NumericalIntegration` pricer • `"European"`, `"American"`, or `"Bermudan"` — `AssetMonteCarlo` pricer For `Merton` model: • `"European"` — `FFT` pricer • `"European"`, `"American"`, or `"Bermudan"` — `FiniteDifference` pricer • `"European"` — `NumericalIntegration` pricer • `"European"`, `"American"`, or `"Bermudan"` — `AssetMonteCarlo` pricer For `Bates` model: • `"European"` — `FFT` pricer • `"European"`, `"American"`, or `"Bermudan"` — `FiniteDifference` pricer • `"European"` — `NumericalIntegration` pricer • `"European"`, `"American"`, or `"Bermudan"` — `AssetMonteCarlo` pricer For `Dupire` model: • `"European"`, `"American"`, or `"Bermudan"` — `FiniteDifference` pricer For `Bachelier` model:

Equity, Commodity, FX Instrument Type	Exercise Styles
	• `"European"`, `"American"`, `"Bermudan"` — `AssetMonteCarlo` pricer
`Binary`	For `BlackScholes` model: • `"European"` — `BlackScholes` pricer For `Heston`, `Bates`, and `Merton` models: • `"European"` — `AssetMonteCarlo` pricer For `Bachelier` model: • `"European"` — `AssetMonteCarlo` pricer
`Cliquet`	For `BlackScholes` model: • `"European"` — `Rubinstein` pricer For `BlackScholes`, `Heston`, `Bates`, and `Merton` models: • `"European"` — `AssetMonteCarlo` pricer
`ConvertibleBond`	For `BlackScholes` model: • `"European"`, `"American"`, or `"Bermudan"` — `FiniteDifference` pricer

Mapping Financial Instruments Toolbox Functions to Object-Based Framework for Instruments, Models, and Pricers

Financial Instruments Toolbox allows you to use either a function-based framework or an alternative object-based framework to price financial instruments.

In the function-based framework, a typical workflow to price a bond with embedded options is as follows.

1 Create a `RateSpec` instrument using `intenvset`.

```
% Zero Data
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = -1;
Basis = 1;

% Instrument parameters
Maturity = datetime(2024,9,15);
CouponRate = 0.035;
Strike = 100;
ExerciseDates = datetime(2022,9,15);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

% HW Parameters
Vol = 0.01;
Alpha = 0.1;
TreeDates = Settle + calyears(1:10);

RateSpec = intenvset('Compounding', Compounding,'StartDates', Settle,...
    'EndDates', ZeroDates,'Rates', ZeroRates,'Basis',Basis);
```

2 Create a Hull-White tree object using `hwvolspec`, `hwtimespec`, and `hwtree`.

```
HWVolSpec = hwvolspec(Settle, TreeDates, Vol,TreeDates, Alpha);
HWTimeSpec = hwtimespec(Settle, TreeDates, 1);
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
OldPrice = optembndbyhw(HWTree,CouponRate,Settle,Maturity,'call',Strike,ExerciseDates,'Perioc
```

3 Price the bond with embedded options using an Hull-White interest-rate tree with `optembndbyhw`.

```
OldPrice = optembndbyhw(HWTree,CouponRate,Settle,Maturity,'call',Strike,ExerciseDates,'Perioc
```

```
OldPrice =

  109.4814
```

By contrast, in the Financial Instruments Toolbox object-based workflow, you price an instrument using instrument, model, and pricer objects:

1 Create an `OptionEmbeddedFixedBond` instrument using `OptionEmbeddedFixedBond`.

```
% Zero Data
Settle = datetime(2018,9,15);
```

```
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = -1;
Basis = 1;

% Instrument parameters
Maturity = datetime(2024,9,15);
CouponRate = 0.035;
Strike = 100;
ExerciseDates = datetime(2022,9,15);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

% HW Parameters
Vol = 0.01;
Alpha = 0.1;
TreeDates = Settle + calyears(1:10);

CallableBond = fininstrument("OptionEmbeddedFixedBond", "Maturity",Maturity,...
    'CouponRate',CouponRate,'Period',Period, ...
    'CallSchedule',CallSchedule,'Name',"CallableBond",'Basis',Basis);
```

2 Create a `ratecurve` object using `ratecurve`.

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Basis',Basis);
```

3 Create a `HullWhite` model object using `HullWhite`.

```
HWModel = finmodel("HullWhite","Alpha",Alpha,"Sigma",Vol);
```

4 Create an `IRTree` pricer object using `IRTree`.

```
HWPricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',myRC,'TreeDates',TreeDates');
```

5 Price the bond instrument using `price`.

```
NewPrice = price(HWPricer, CallableBond)
```

```
NewPrice =

  109.4814
```

Note The function-based and object-based workflows can return different instrument prices even if you use the same data. The difference is because the existing Financial Instruments Toolbox functions internally use `datetime` and the object-based framework use `yearfrac` for date handling.

For a mapping of function-based instrument pricing to the object-based instrument pricing, see:

Mapping Financial Instruments Toolbox Functions for Interest-Rate Instrument Objects

The following table lists the Financial Instruments Toolbox functions for interest-rate instruments mapped to the associated workflow using the object-based framework for instruments, models, and pricers.

Financial Instruments Toolbox Function	Object-Based Workflow
`capbyblk`	Create the following objects: 1 `Cap` instrument 2 `Black` model 3 `ratecurve` 4 `Black` pricer Compute the price of the `Cap` instrument using `price`.
`capbynormal`	Create the following objects: 1 `Cap` instrument 2 `Normal` model 3 `ratecurve` 4 `Normal` pricer Compute the price of the `Cap` instrument using `price`.
`capbybk`	Create the following objects: 1 `Cap` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Cap` instrument using `price`.
`capbybdt`	Create the following objects: 1 `Cap` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Cap` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`capbyhw`	Create the following objects: 1 `Cap` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Cap` instrument using `price`.
`capbylg2f`	Create the following objects: 1 `Cap` instrument 2 `LinearGaussian2F` model 3 `ratecurve` 4 `IRMonteCarlo` pricer Compute the price of the `Cap` instrument using `price`.
`floorbyblk`	Create the following objects: 1 `Floor` instrument 2 `Black` model 3 `ratecurve` 4 `Black` pricer Compute the price of the `Floor` instrument using `price`.
`floorbynormal`	Create the following objects: 1 `Floor` instrument 2 `Normal` model 3 `ratecurve` 4 `Normal` pricer Compute the price of the `Floor` instrument using `price`.
`floorbybk`	Create the following objects: 1 `Floor` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Floor` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`floorbybdt`	Create the following objects: 1 `Floor` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Floor` instrument using `price`.
`floorbyhw`	Create the following objects: 1 `Floor` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Floor` instrument using `price`.
`floorbylg2f`	Create the following objects: 1 `Floor` instrument 2 `LinearGaussian2F` model 3 `ratecurve` 4 `IRMonteCarlo` pricer Compute the price of the associated instrument using `price`.
`swaptionbyblk`	Create the following objects: 1 `Swaption` instrument 2 `Black` model 3 `ratecurve` 4 `Black` pricer Compute the price of the `Swaption` instrument using `price`.
`swaptionbynormal`	Create the following objects: 1 `Swaption` instrument 2 `Normal` model 3 `ratecurve` 4 `Normal` pricer Compute the price of the `Swaption` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`swaptionbybk`	Create the following objects: 1 `Swaption` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Swaption` instrument using `price`.
`swaptionbybdt`	Create the following objects: 1 `Swaption` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Swaption` instrument using `price`.
`swaptionbyhw`	Create the following objects: 1 `Swaption` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Swaption` instrument using `price`.
`swaptionbylg2f`	Create the following objects: 1 `Swaption` instrument 2 `LinearGaussian2F` model 3 `ratecurve` 4 `IRMonteCarlo` pricer Compute the price of the associated instrument using `price`.
`fixedbyzero`	Create the following objects: 1 `FixedBond` instrument 2 `ratecurve` 3 `Discount` pricer Compute the price of the `FixedBond` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`fixedbybk`	Create the following objects: 1 `FixedBond` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FixedBond` instrument using `price`.
`fixedbybdt`	Create the following objects: 1 `FixedBond` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FixedBond` instrument using `price`.
`fixedbyhw`	Create the following objects: 1 `FixedBond` instrument 2 `HullWhite` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FixedBond` instrument using `price`.
`bondbyzero`	Create the following objects: 1 `FixedBond` instrument 2 `ratecurve` 3 `Discount` pricer Compute the price of the `FixedBond` instrument using `price`.
`tfutbyprice`	Create the following objects: 1 `BondFuture` instrument 2 `ratecurve` 3 `Future` pricer Compute the price of the `BondFuture` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`floatbyzero`	Create the following objects: 1 `FloatBond` instrument 2 `ratecurve` 3 `Discount` pricer Compute the price of the `FloatBond` instrument using `price`.
`floatbybk`	Create the following objects: 1 `FloatBond` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FloatBond` instrument using `price`.
`floatbybdt`	Create the following objects: 1 `FloatBond` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FloatBond` instrument using `price`.
`floatbyhw`	Create the following objects: 1 `FloatBond` instrument 2 `HullWhite` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FloatBond` instrument using `price`.
`optbndbyhw`	Create the following objects: 1 `FixedBondOption` instrument 2 `HullWhite` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `FixedBondOption` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`optbndbybk`	Create the following objects: **1** `FixedBondOption` instrument **2** `BlackKarasinski` model **3** `ratecurve` **4** `IRTree` pricer Compute the price of the `FixedBondOption` instrument using `price`.
`optbndbybdt`	Create the following objects: **1** `FixedBondOption` instrument **2** `BlackDermanToy` model **3** `ratecurve` **4** `IRTree` pricer Compute the price of the `FixedBondOption` instrument using `price`.
`optfloatbybk`	Create the following objects: **1** `FloatBondOption` instrument **2** `BlackKarasinski` model **3** `ratecurve` **4** `IRTree` pricer Compute the price of the `FloatBondOption` instrument using `price`.
`optfloatbybdt`	Create the following objects: **1** `FloatBondOption` instrument **2** `BlackDermanToy` model **3** `ratecurve` **4** `IRTree` pricer Compute the price of the `FloatBondOption` instrument using `price`.
`optfloatbyhw`	Create the following objects: **1** `FloatBondOption` instrument **2** `BlackKarasinski` model **3** `ratecurve` **4** `IRTree` pricer Compute the price of the `FloatBondOption` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`optembndbyhw`	Create the following objects: 1 `OptionEmbeddedFixedBond` instrument 2 `HullWhite` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFixedBond` instrument using `price`.
`optembndbybk`	Create the following objects: 1 `OptionEmbeddedFixedBond` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFixedBond` instrument using `price`.
`optembndbybdt`	Create the following objects: 1 `OptionEmbeddedFixedBond` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFixedBond` instrument using `price`.
`optemfloatbybk`	Create the following objects: 1 `OptionEmbeddedFloatBond` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFloatBond` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`optembndbybdt`	Create the following objects: 1 `OptionEmbeddedFloatBond` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFloatBond` instrument using `price`.
`optemfloatbybk`	Create the following objects: 1 `OptionEmbeddedFloatBond` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFloatBond` instrument using `price`.
`optemfloatbyhw`	Create the following objects: 1 `OptionEmbeddedFloatBond` instrument 2 `HullWhite` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFloatBond` instrument using `price`.
`optemfloatbybdt`	Create the following objects: 1 `OptionEmbeddedFloatBond` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `OptionEmbeddedFloatBond` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`swapbyzero`	Create the following objects: 1 `Swap` instrument 2 `ratecurve` 3 `Discount` pricer Compute the price of the `Swap` instrument using `price`.
`swapbybk`	Create the following objects: 1 `Swap` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Swap` instrument using `price`.
`swapbybdt`	Create the following objects: 1 `Swap` instrument 2 `BlackDermanToy` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Swap` instrument using `price`.
`swapbyhw`	Create the following objects: 1 `Swap` instrument 2 `BlackKarasinski` model 3 `ratecurve` 4 `IRTree` pricer Compute the price of the `Swap` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`LiborMarketModel`	Create the following objects: **1** `Cap`, `Floor`, `FixedBond`, `FloatBond`, `FloatBondOption` `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument **2** `SABRBraceGatarekMusiela` or `BraceGatarekMusiela` model **3** `ratecurve` **4** `IRMonteCarlo` pricer Compute the price of the associated instrument using `price`.
`LinearGaussian2F`	Create the following objects: **1** `Cap`, `Floor`, `Swap`, `Swaption`, `FixedBond`, `FloatBond`, `FloatBondOption` `FixedBondOption`, `OptionEmbeddedFixedBond`, or `OptionEmbeddedFloatBond` instrument **2** `LinearGaussian2F` model **3** `ratecurve` **4** `IRMonteCarlo` pricer Compute the price of the associated instrument using `price`.

Mapping Financial Instruments Toolbox Functions for Equity, Commodity, FX Instrument Objects

The following table lists the Financial Instruments Toolbox functions for equity, FX, or commodity instruments mapped to the associated workflow using the object-based framework for instruments, models, and pricers.

Financial Instruments Toolbox Function	Object-Based Workflow
`asianbycrr`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Asian` instrument using `price`.
`asianbyeqp`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Asian` instrument using `price`.
`asianbykv` and `asiansensbykv`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `KemnaVorst` pricer Compute the price of the `Asian` instrument using `price`.
`asianbylevy` and `asiansensbylevy`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `Levy` pricer Compute the price of the `Asian` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`asianbytw` and `asiansensbytw`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `TurnbullWakeman` pricer Compute the price of the `Asian` instrument using `price`.
`asianbyls` and `asiansensbyls`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes`, `Merton`, `Bates`, or `Heston` model 3 `ratecurve` 4 `AssetMonteCarlo` pricer Compute the price of the `Asian` instrument using `price`.
`asianbystt`	Create the following objects: 1 `Asian` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Asian` instrument using `price`.
`barrierbycrr`	Create the following objects: 1 `Barrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Barrier` instrument using `price`.
`barrierbyeqp`	Create the following objects: 1 `Barrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Barrier` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`barrierbybls` and `barriersensbybls`	Create the following objects: 1 `Barrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer Compute the price of the `Barrier` instrument using `price`.
`barrierbyfd` and `barriersensbyfd`	Create the following objects: 1 `Barrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `Barrier` instrument using `price`.
`barrierbyls` and `barriersensbyls`	Create the following objects: 1 `Barrier` instrument 2 `BlackScholes`, `Merton`, `Bates`, or `Heston` model 3 `ratecurve` 4 `AssetMonteCarlo` pricer Compute the price of the `Barrier` instrument using `price`.
`barrierbystt`	Create the following objects: 1 `Barrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Barrier` instrument using `price`.
`dblbarrierbybls` and `dblbarriersensbybls`	Create the following objects: 1 `DoubleBarrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer Compute the price of the `DoubleBarrier` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`dblbarrierbyfd` and `dblbarriersensbyfd`	Create the following objects: 1 `DoubleBarrier` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `DoubleBarrier` instrument using `price`.
`touchbybls` and `touchsensbybls`	Create the following objects: 1 `Touch` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer Compute the price of the `Touch` instrument using `price`.
`dbltouchbybls` and `dbltouchsensbybls`	Create the following objects: 1 `DoubleTouch` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer Compute the price of the `DoubleTouch` instrument using `price`.
`cashbybls` and `cashsensbybls`	Create the following objects: 1 `Binary` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer
`assetbybls` and `assetsensbybls`	Create the following objects: 1 `Binary` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer

Financial Instruments Toolbox Function	Object-Based Workflow
`lookbackbycrr`	Create the following objects: 1 `Lookback` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Lookback` instrument using `price`.
`lookbackbyeqp`	Create the following objects: 1 `Lookback` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Lookback` instrument using `price`.
`lookbackbycvgsg` and `lookbacksensbycvgsg`	Create the following objects: 1 `Lookback` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `ConzeViswanathan` or `GoldmanSosinGatto` pricer Compute the price of the `Lookback` instrument using `price`.
`lookbackbyls` and `lookbacksensbyls`	Create the following objects: 1 `Lookback` instrument 2 `BlackScholes`, `Merton`, `Bates`, or `Heston` model 3 `ratecurve` 4 `AssetMonteCarlo` pricer Compute the price of the `Lookback` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`lookbackbystt`	Create the following objects: 1 `Lookback` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Lookback` instrument using `price`.
`spreadbykirk` and `spreadsensbykirk`	Create the following objects: 1 `Spread` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `Kirk` pricer Compute the price of the `Spread` instrument using `price`.
`spreadbybjs` and `spreadsensbybjs`	Create the following objects: 1 `Spread` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BjerksundStensland` pricer Compute the price of the `Spread` instrument using `price`.
`spreadbyls` and `spreadsensbyls`	Create the following objects: 1 `Spread` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetMonteCarlo` pricer Compute the price of the `Spread` instrument using `price`.
`optstockbycrr`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Vanilla` instrument using `price`

Financial Instruments Toolbox Function	Object-Based Workflow
`optstockbyeqp`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Vanilla` instrument using `price`
`optstockbylr` and `optstocksensbylr`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Vanilla` instrument using `price`
`optstockbybls` and `optstocksensbybls`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BlackScholes` pricer Compute the price of the `Vanilla` instrument using `price`.
`optstockbybjs` and `optstocksensbybjs`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `BjerksundStensland` pricer Compute the price of the `Vanilla` instrument using `price`.
`optstockbyrgw` and `optstocksensbyrgw`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `RollGeskeWhaley` pricer Compute the price of the `Vanilla` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`optstockbyfd` and `optstocksensbyfd`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `Vanilla` instrument using `price`.
`optstockbyls` and `optstocksensbyls`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes`, `Merton`, `Bates`, or `Heston` model 3 `ratecurve` 4 `AssetMonteCarlo` pricer Compute the price of the `Vanilla` instrument using `price`.
`optstockbystt`	Create the following objects: 1 `Vanilla` instrument 2 `BlackScholes` model 3 `ratecurve` 4 `AssetTree` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByHestonFFT` and `optSensByHestonFFT`	Create the following objects: 1 `Vanilla` instrument 2 `Heston` model 3 `ratecurve` 4 `FFT` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByHestonFD` and `optSensByHestonFD`	Create the following objects: 1 `Vanilla` instrument 2 `Heston` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `Vanilla` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`optByHestonNI` and `optSensByHestonNI`	Create the following objects: 1 `Vanilla` instrument 2 `Heston` model 3 `ratecurve` 4 `NumericalIntegration` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByBatesFFT` and `optSensByBatesFFT`	Create the following objects: 1 `Vanilla` instrument 2 `Bates` model 3 `ratecurve` 4 `FFT` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByBatesFD` and `optSensByBatesFD`	Create the following objects: 1 `Vanilla` instrument 2 `Bates` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByBatesNI` and `optSensByBatesNI`	Create the following objects: 1 `Vanilla` instrument 2 `Bates` model 3 `ratecurve` 4 `NumericalIntegration` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByMertonFFT` and `optSensByMertonFFT`	Create the following objects: 1 `Vanilla` instrument 2 `Merton` model 3 `ratecurve` 4 `FFT` pricer Compute the price of the `Vanilla` instrument using `price`.

Financial Instruments Toolbox Function	Object-Based Workflow
`optByMertonFD` and `optSensByMertonFD`	Create the following objects: 1 `Vanilla` instrument 2 `Merton` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByMertonNI` and `optSensByMertonNI`	Create the following objects: 1 `Vanilla` instrument 2 `Merton` model 3 `ratecurve` 4 `NumericalIntegration` pricer Compute the price of the `Vanilla` instrument using `price`.
`optByLocalVolFD` and `optSensByLocalVolFD`	Create the following objects: 1 `Vanilla` instrument 2 `Dupire` model 3 `ratecurve` 4 `FiniteDifference` pricer Compute the price of the `Vanilla` instrument using `price`.

Mapping Financial Instruments Toolbox Curve Functions to Object-Based Framework

Financial Instruments Toolbox allows you to use either a function-based framework or an alternative object-based framework to create and analyze financial curves.

In the function-based framework, a typical workflow to create an interest-rate curve uses `intenvset` or `IRDataCurve`.

```
CurveSettle = datetime(2016,3,2);
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data)
```

```
irdc =

             Type: Zero
           Settle: 736391 (02-Mar-2016)
      Compounding: 2
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [8x1 double]
             Data: [8x1 double]
```

By contrast, in the Financial Instruments Toolbox object-based workflow, you create a `ratecurve` object:

```
Settle = datetime(2017,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =

  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10×1 datetime]
               Rates: [10×1 double]
              Settle: 15-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Note The function-based and object-based workflows can return different prices even if you use the same data. This is because the existing Financial Instruments Toolbox curve functions use `date2time` and the object-based framework use `yearfrac` for date handling.

The following table lists the Financial Instruments Toolbox curve functions mapped to the associated object-based framework.

Financial Instruments Toolbox Curve Function	Object-Based Framework
`IRDataCurve`	`ratecurve`
`getForwardRates`	`forwardrates`
`getZeroRates`	`zerorates`
`getDiscountFactors`	`discountfactors`
`bootstrap`	`irbootstrap`
`IRFunctionCurve`	`parametercurve`
`getForwardRates`	`forwardrates`
`getZeroRates`	`zerorates`
`getDiscountFactors`	`discountfactors`
`fitNelsonSiegel`	`fitNelsonSiegel`
`fitSvensson`	`fitSvensson`
`cdsbootstrap`	`defprobstrip`
Not supported	`defprobcurve`
Not supported	`survprobs`
Not supported	`hazardrates`
Not supported	`STIRFuture` using `irbootstrap` to create `ratecurve` object
Not supported	`OISFuture` using `irbootstrap` to create `ratecurve` object
Not supported	`OvernightIndexedSwap` using `irbootstrap` to create `ratecurve` object

Price European Vanilla Call Options Using Black-Scholes Model and Different Equity Pricers

This example shows how to compare European `Vanilla` instrument call option prices using a `BlackScholes` model and different pricing methods. The pricing methods for this comparison are the Cox-Ross-Rubinstein, Leisen-Reimer, finite difference, and the Black-Scholes analytical formula.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,01,01);
Maturity = datetime(2022,01,01);
Rate = 0.0111;
Compounding = -1;
ZeroCurve = ratecurve('zero',Settle,Maturity,Rate,'Compounding',Compounding);
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
Volatility = .35;
BSModel = finmodel("BlackScholes",'Volatility',Volatility);
```

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
ExerciseDates = datetime(2019,09,01);
Strike = 30;
OptionType = 'call';

EuropeanCallOption = fininstrument("Vanilla",'ExerciseDate',ExerciseDates,'Strike',Strike,...
    'OptionType',OptionType,'Name',"vanilla_call_option");
```

Create `Analytic`, `AssetTree`, and `FiniteDifference` Pricer Objects

Create two scenarios for the Vanilla option. In the first scenario, the option is out of the money (OTM). In the second scenario the option is at the money (ATM).

```
% Define the number of levels of the tree for AssetTree pricer
NumPeriods = 55;
```

Calculate Vanilla Option Price for OTM Option

Use `finpricer` to create an `BlackScholes`, `AssetTree`, and `FiniteDifference` pricer objects for the OTM option and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SpotPriceOTM = 25;

% Analytic Pricer
AnalyticPricerOTM = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', SpotPriceOTM, 'DiscountC
PriceBLSOTM = price(AnalyticPricerOTM, EuropeanCallOption);

% AssetTree Pricer
```

```
CRRPricerOTM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',SpotP
                         'PricingMethod',"CoxRossRubinstein",'NumPeriods', NumPeriods, 'Maturity
PriceCRROTM = price(CRRPricerOTM, EuropeanCallOption);

LRPricerOTM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',SpotPr
                        'PricingMethod',"LeisenReimer",'NumPeriods', NumPeriods, 'Maturity', Exer
PriceLROTM = price(LRPricerOTM, EuropeanCallOption);

% FiniteDifference Pricer
FDPricerOTM = finpricer('FiniteDifference', 'Model', BSModel, 'SpotPrice', SpotPriceOTM, 'Discou
PriceFDOTM = price(FDPricerOTM, EuropeanCallOption);
```

Calculate Vanilla Option Price for ATM Option

Use `finpricer` to create an `BlackScholes`, `AssetTree`, and `FiniteDifference` pricer objects for the ATM option and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SpotPriceATM = 30;

% Analytic Pricer
AnalyticPricerATM = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', SpotPriceATM, 'DiscountC
PriceBLSATM = price(AnalyticPricerATM, EuropeanCallOption);

% AsetTree Pricer
CRRPricerATM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',SpotP
                         'PricingMethod',"CoxRossRubinstein",'NumPeriods', NumPeriods, 'Maturity
PriceCRRATM = price(CRRPricerATM, EuropeanCallOption);

LRPricerATM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',SpotPr
                        'PricingMethod',"LeisenReimer",'NumPeriods', NumPeriods, 'Maturity', Exer
PriceLRATM = price(LRPricerATM, EuropeanCallOption);

% FiniteDifference Pricer
FDPricerATM = finpricer('FiniteDifference', 'Model', BSModel, 'SpotPrice', SpotPriceATM, 'Discou
PriceFDATM = price(FDPricerATM, EuropeanCallOption);
```

Vanilla Option Price Comparison When Option Is OTM

Use the `displayPricesVanillaCallOption` in Local Functions on page 1-101 to compare the Vanilla call prices for OTM.

```
displayPricesVanillaCallOption("OTM", PriceBLSOTM, PriceCRROTM, PriceLROTM, PriceFDOTM)
```

```
Comparison of Vanilla Call Option Prices OTM:

Black-Scholes:        1.280591
Cox-Ross-Rubinstein:  1.278306
Leisen-Reimer:        1.280651
Finite-Difference:    1.280599
```

Vanilla Option Price Comparison When Option Is ATM

Use the `displayPricesVanillaCallOption` in Local Functions on page 1-101 to compare the Vanilla call prices for ATM.

```
displayPricesVanillaCallOption("ATM", PriceBLSATM, PriceCRRATM, PriceLRATM, PriceFDATM)
```

```
Comparison of Vanilla Call Option Prices ATM:

Black-Scholes:        3.505323
Cox-Ross-Rubinstein:  3.520559
Leisen-Reimer:        3.505377
Finite-Difference:    3.505452
```

Analyze Effect of Number of Tree Levels on Price of Options When Using `AssetTree` Pricer

Create graphs to visualize how convergence changes as the number of steps in the binomial calculation increases for the Cox-Ross-Rubinstein and Leisen-Reimer tree models, as well as the impact on convergence to changes to the asset price.

```
% Define the number of time steps of the tree
NPoints = 240;

% Cox-Ross-Rubinstein
NumPeriodCRR  = 5 : 1 : NPoints;
NbStepCRR     = length(NumPeriodCRR);
PriceOTMCRR = nan(NbStepCRR, 1);
PriceATMCRR = PriceOTMCRR;

for i = 1 : NbStepCRR

    PricerCRROTM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',S
                   'PricingMethod',"CoxRossRubinstein",'NumPeriods', NumPeriodCRR(i), 'Maturity'
    PriceOTMCRR(i) = price(PricerCRROTM, EuropeanCallOption);

    PricerCRRATM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',S
                   'PricingMethod',"CoxRossRubinstein",'NumPeriods', NumPeriodCRR(i), 'Maturity'
    PriceATMCRR(i) = price(PricerCRRATM, EuropeanCallOption);

end

% Leisen-Reimer
NumPeriodLR  = 5 : 2 : NPoints;
NbStepLR     = length(NumPeriodLR);
PriceOTMLR = nan(NbStepLR, 1);
PriceATMLR = PriceOTMLR;

for i = 1 : NbStepLR
    PricerLROTM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',Sp
                   'PricingMethod',"LeisenReimer",'NumPeriods', NumPeriodLR(i), 'Maturity', Exerc
    PriceOTMLR(i) = price(PricerLROTM, EuropeanCallOption);

    PricerLRATM = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',Sp
                   'PricingMethod',"LeisenReimer",'NumPeriods', NumPeriodLR(i), 'Maturity', Exerc
    PriceATMLR(i) = price(PricerLRATM, EuropeanCallOption);
end
```

First Scenario: OTM Vanilla Call Option

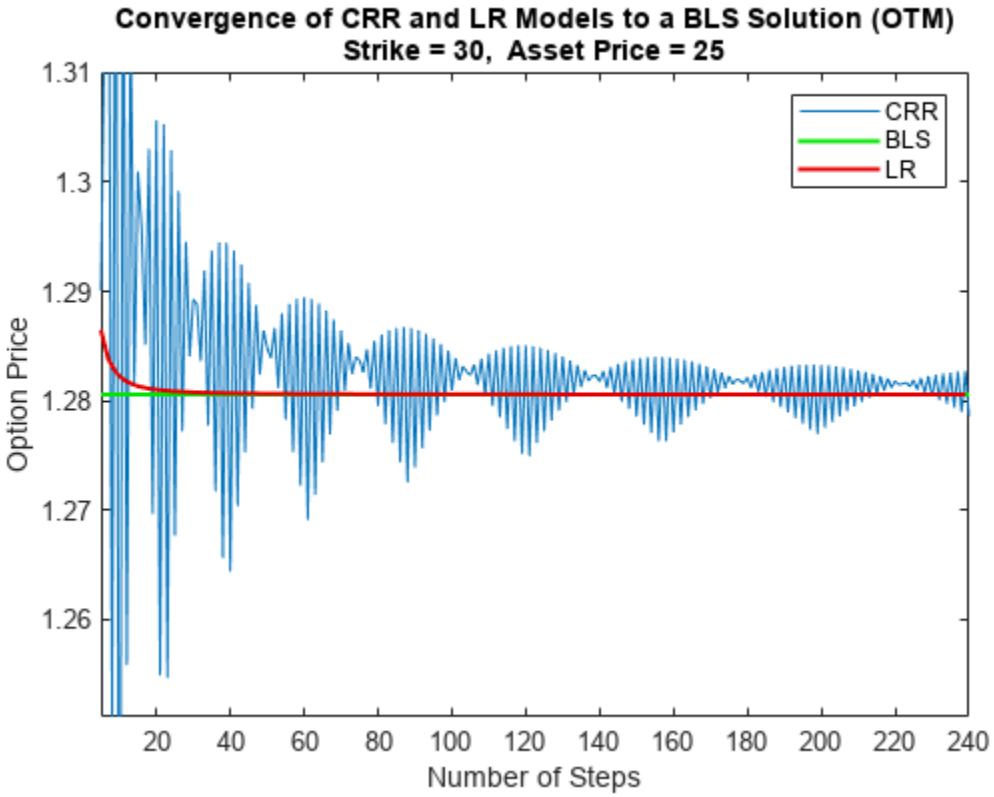
Plot the convergence of CRR and LR models to a Black-Scholes solution for an OTM option.

```
% Cox-Ross-Rubinstein
plot(NumPeriodCRR, PriceOTMCRR);
hold on;
plot(NumPeriodCRR, PriceBLSOTM*ones(NbStepCRR,1),'Color',[0 0.9 0], 'linewidth', 1.5);
```

```
% Leisen-Reimer
plot(NumPeriodLR, PriceOTMLR, 'Color',[0.9 0 0], 'linewidth', 1.5);

% Concentrate the area of interest by clipping on the Y axis at five times the
% LR price:
YLimDelta = 5*abs(PriceOTMLR(1) - PriceBLSOTM);
ax = gca;
ax.YLim = [PriceBLSOTM - YLimDelta PriceBLSOTM + YLimDelta];
ax.XLim = [5 NPoints];

% Annotate plot
titleString = sprintf('\nConvergence of CRR and LR Models to a BLS Solution (OTM)\nStrike = %d,
title(titleString)
ylabel('Option Price')
xlabel('Number of Steps')
legend('CRR', 'BLS', 'LR', 'Location', 'NorthEast')
```



Observe that the Leisen-Reimer model removes the oscillation and produces estimates close to the Black-Scholes model using only a small number of steps.

Second Scenario: ATM Vanilla Call Option

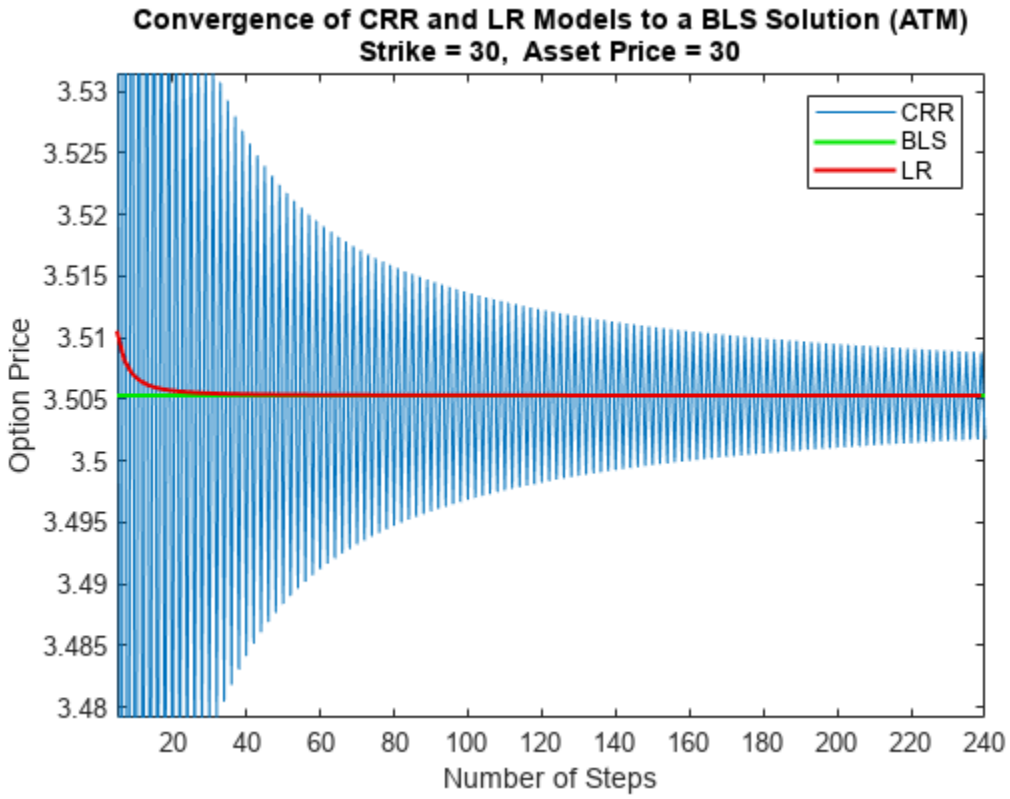
Plot the convergence of CRR and LR models to a Black-Scholes solution for an ATM option.

```
% Cox-Ross-Rubinstein
figure;
plot(NumPeriodCRR, PriceATMCRR);
```

```
hold on;
plot(NumPeriodCRR, PriceBLSATM*ones(NbStepCRR,1),'Color',[0 0.9 0], 'linewidth', 1.5);

% Leisen-Reimer
plot(NumPeriodLR, PriceATMLR, 'Color',[0.9 0 0], 'linewidth', 1.5);

% Concentrate the area of interest by clipping on the Y axis at five times the
% LR price:
YLimDelta = 5*abs(PriceATMLR(1) - PriceBLSATM);
ax = gca;
ax.YLim = [PriceBLSATM - YLimDelta PriceBLSATM + YLimDelta];
ax.XLim = [5 NPoints];
% Annotate plot
titleString = sprintf('\nConvergence of CRR and LR Models to a BLS Solution (ATM)\nStrike = %d,
title(titleString)
ylabel('Option Price')
xlabel('Number of Steps')
legend('CRR', 'BLS', 'LR', 'Location', 'NorthEast')
```



While the CRR binomial model and the Black-Scholes model converge as the number of time steps increases, this convergence, except for the at-the-money options, is anything but smooth or uniform.

Local Functions

```
function displayPricesVanillaCallOption(type, PriceBLS, PriceCRR, PriceLR, PriceFD)
fprintf('Comparison of Vanilla Call Option Prices %s:\n', type);
fprintf('\n');
fprintf('Black-Scholes:        %f\n', PriceBLS);
```

```
fprintf('Cox-Ross-Rubinstein:  %f\n', PriceCRR);
fprintf('Leisen-Reimer:        %f\n', PriceLR);
fprintf('Finite-Difference:    %f\n', PriceFD);
fprintf('\n');
end
```

Price Weather Derivatives

This example demonstrates a workflow for pricing weather derivatives based on historically observed temperature data.

The workflow for pricing call and put options for weather derivatives includes these steps:

1. Get raw temperature data on page 1-104.
2. Load and process observed termperature data on page 1-105.
3. Visualize temperatures on page 1-106.
4. Analyze of seasonality on page 1-106.
5. Estimate deterministic trends in a time series on page 1-107.
6. Create and fit ARIMA/GARCH models on page 1-109.
7. Perform Monte Carlo simulation from a model on page 1-110.
8. Evaluate the number of heating degree days from simulation on page 1-111.
9. Price sample call and put options on page 1-113.

The techniques used in this example are based on the approach described in Alaton [1 on page 1-114].

What Is a Weather Derivative?

A weather derivative is a financial instrument used by companies or individuals to hedge against the risk of weather-related losses. Weather derivatives are index-based instruments that use observed weather data at a weather station to create an index on which a payout is based. The seller of a weather derivative agrees to bear the risk of disasters in return for a premium. If no damages occur before the expiration of the contract, the seller makes a profit—and in the event of unexpected or adverse weather, the buyer of the derivative claims the agreed amount.

How to Price Weather Derivatives

A number of different contracts for weather derivatives are traded on the over-the-counter (OTC) market. This example explores a simple option (call or put) based on the accumulation of heating degree days (HDD), which are the number of degrees that the temperature deviates from a reference level on a given day.

$$H_n = \sum_{i=1}^{n} \max\{18 - T_i, 0\}$$

There is no standard model for valuing weather derivatives similar to the Black-Scholes formula for pricing European equity options and similar derivatives. The underlying asset of the weather derivative is not tradeable, which violates a number of key assumptions of the Black-Scholes model. In this example, you price the option using the following formula from Alaton [1 on page 1-114]:

$$\chi = \alpha \max\{H_n - K, 0\} \qquad K = \text{strike level} \qquad \alpha = \text{tick size}$$

In general, the process of pricing weather derivative options is: obtain temperature data, clean the temperature data, and model the temperature to forecast the option price.

Get Raw Temperature Data

All data in this example is obtained from NOAA. Use `getGHCNData` in Local Functions on page 1-114 to extract the data, given a `stationID` and start and end dates. A REST API is also available for extracting data from NOAA. For more information on using a REST API, see https://github.com/mathworks/Climate-IAM-Explorer/tree/master/examples/Pricing%20Weather%20Derivatives.

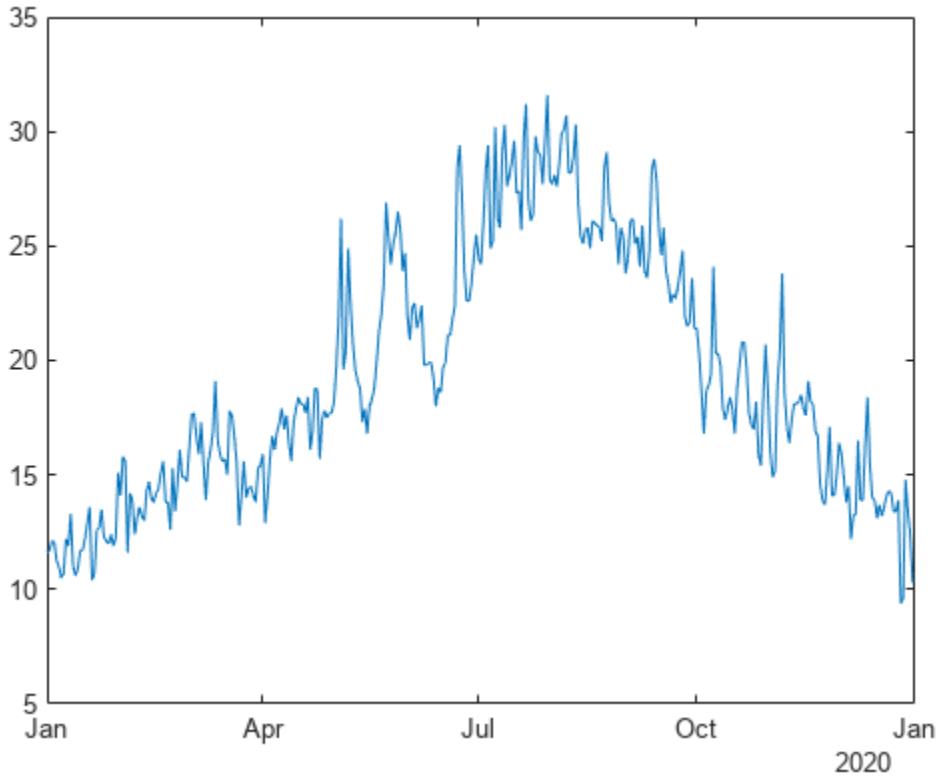
To obtain the full temperature data for one year and plot the results, use `getGHCNData` in Local Functions on page 1-114.

```
stationID = 'SPE00119783';
Element = 'TAVG';
startDate = datetime(2020,1,1);
endDate = datetime(2020,12,31);
T = getGHCNData(stationID,Element,startDate,endDate);
head(T)
```

```
       Date        TAVG
    ___________    ____

    01-Jan-2020    11.6
    02-Jan-2020    11.7
    03-Jan-2020    12.1
    04-Jan-2020    12.1
    05-Jan-2020    11.3
    06-Jan-2020      11
    07-Jan-2020    10.5
    08-Jan-2020    10.7
```

```
figure
plot(T.Date, T.TAVG)
```



Load and Process Observed Temperature Data

This example uses data containing temperatures from 1978 to the end of 2020 near Stockholm. You can obtain this data by using `getGHCNData` in Local Functions on page 1-114.

```
stationID = 'SW000008525';
Element = 'TMAX';
startDate = datetime(1978,1,1);
endDate = datetime(2020,12,31);
Temp = getGHCNData(stationID,Element,startDate,endDate)
```

```
Temp=15706×1 timetable
       Date        TMAX
    ___________    ____

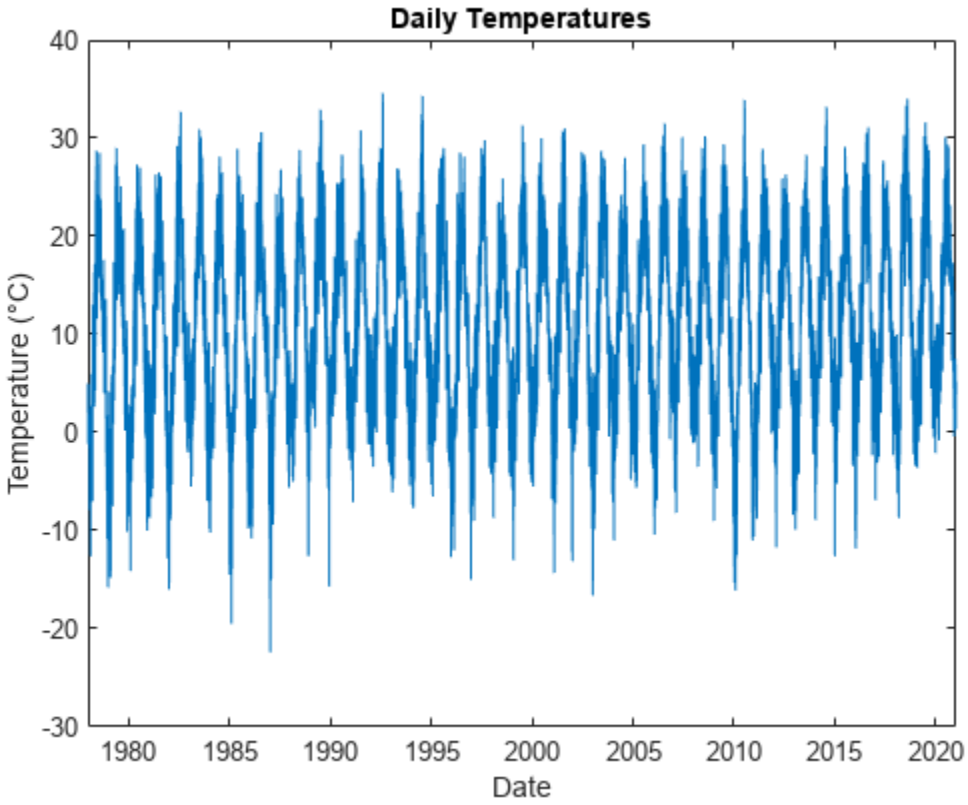
    01-Jan-1978     4.7
    02-Jan-1978       5
    03-Jan-1978     3.1
    04-Jan-1978    -0.5
    05-Jan-1978    -1.2
    06-Jan-1978     2.7
    07-Jan-1978     4.5
    08-Jan-1978     4.9
    09-Jan-1978     1.8
    10-Jan-1978     3.2
    11-Jan-1978     1.5
    12-Jan-1978    -0.5
    13-Jan-1978     0.6
```

```
14-Jan-1978       2
15-Jan-1978     2.5
16-Jan-1978     2.4
   ⋮
```

Visualize Temperatures

Use `plotTemperature` in Local Functions on page 1-114 to visualize the daily temperatures.

```
figure
plot( Temp.Date, Temp.TMAX)
xlabel("Date")
ylabel("Temperature (" + char(176) + "C)")
title("Daily Temperatures")
```



In the remaining sections of this example, you model the temperature and then evalauate sample option prices.

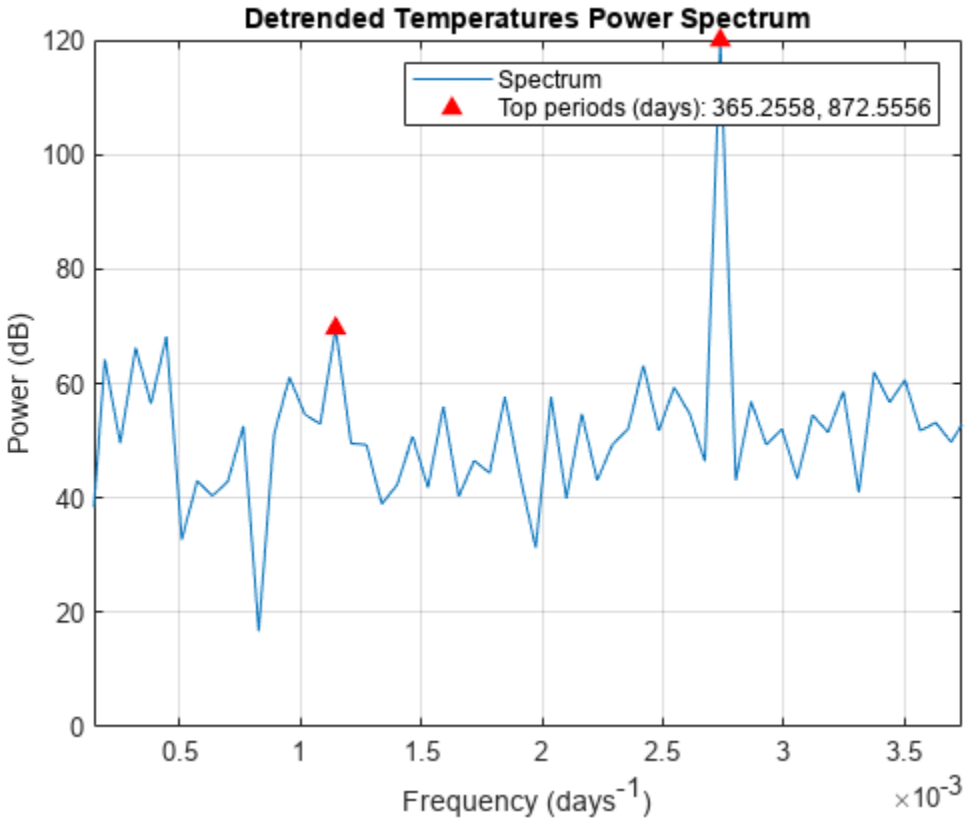
Determine Seasonality in Data

Assume that the deterministic component of the temperature model comprises a linear trend and seasonal terms. To estimate the main frequencies present in the time series, apply the Fourier transform.

Use `determineSeasonality` in Local Functions on page 1-114 to remove the linear trend by subtracting the best-fit line. Then, use the `periodogram` (Signal Processing Toolbox) function to

compute the spectrum (with a sample rate of one observation per day), and to visualize the spectrum. In addition, the `determineSeasonality` function identifies the top two component frequencies and periods in the data and adds these to the power spectrum.

```
determineSeasonality(Temp)
```



The plot illustrates that the dominant seasonal components in the data are the annual and 6-monthly cycles.

Fit Deterministic Trend

Based on the previous results, fit the following function for the temperature using the `fitlm` function.

$$\text{TemperatureFcn} = A + B\,t + C\sin(2\pi\,t) + D\cos(2\pi\,t) + E\cos(4\pi\,t)$$

```
elapsedTime = years(Temp.Date - Temp.Date(1));
designMatrix = @(t) [t, cos( 2 * pi * t ), sin( 2 * pi * t ), cos( 4 * pi * t )];
trendPreds = ["t", "cos(2*pi*t)", "sin(2*pi*t)", "cos(4*pi*t)"];
trendModel = fitlm(designMatrix(elapsedTime), Temp.TMAX, "VarNames", [trendPreds, "Temperature"])
```

```
trendModel =
Linear regression model:
    Temperature ~ 1 + t + cos(2*pi*t) + sin(2*pi*t) + cos(4*pi*t)

Estimated Coefficients:
                   Estimate       SE         tStat       pValue
```

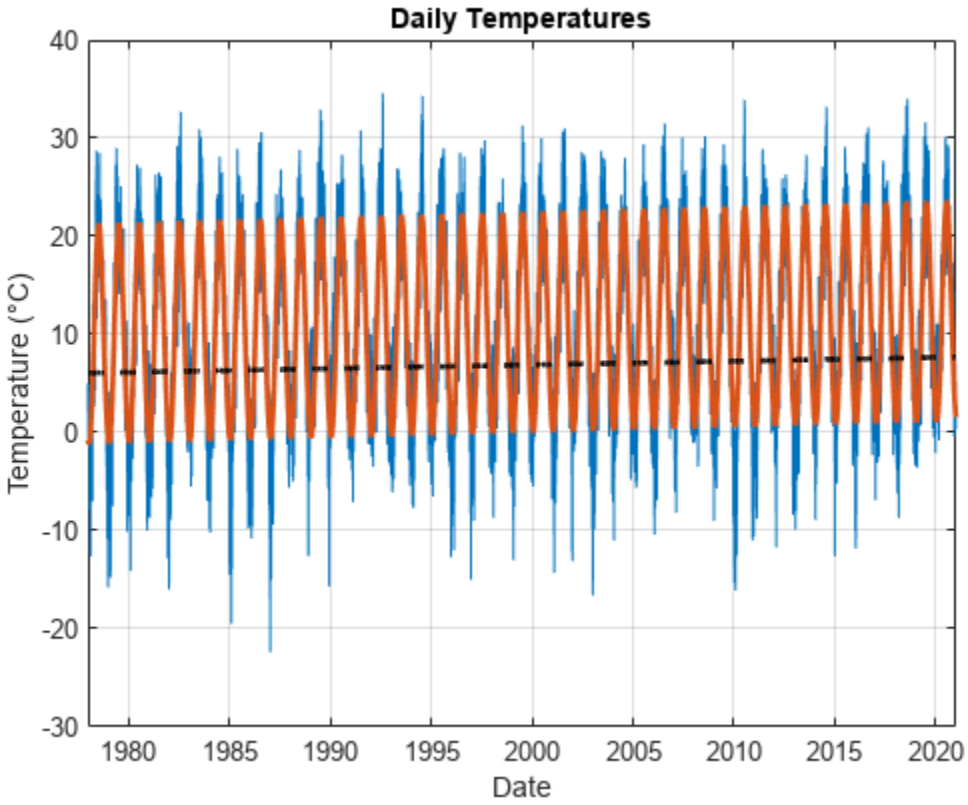
```
                    ________    _________    _______    __________

    (Intercept)       9.7095     0.064138     151.39             0
    t                0.054648    0.0025836     21.152    6.1629e-98
    cos(2*pi*t)       -10.909     0.045348    -240.56             0
    sin(2*pi*t)        -2.772     0.045357    -61.115             0
    cos(4*pi*t)       0.39298     0.045348     8.6659    4.9102e-18

Number of observations: 15706, Error degrees of freedom: 15701
Root Mean Squared Error: 4.02
R-squared: 0.798,  Adjusted R-Squared: 0.798
F-statistic vs. constant model: 1.55e+04, p-value = 0
```

Use the `plotDeterministicTrend` in Local Functions on page 1-114 to visualize the fitted trend.

```
trendModel = plotDeterministicTrend(Temp, trendModel, 1978, 2020)
```



```
trendModel =
Linear regression model:
    Temperature ~ 1 + t + cos(2*pi*t) + sin(2*pi*t) + cos(4*pi*t)

Estimated Coefficients:
                    Estimate       SE          tStat       pValue
                    ________    _________    _______    __________

    (Intercept)       9.7095     0.064138     151.39             0
    t                0.054648    0.0025836     21.152    6.1629e-98
```

```
    cos(2*pi*t)     -10.909     0.045348    -240.56             0
    sin(2*pi*t)      -2.772     0.045357    -61.115             0
    cos(4*pi*t)     0.39298     0.045348     8.6659    4.9102e-18

Number of observations: 15706, Error degrees of freedom: 15701
Root Mean Squared Error: 4.02
R-squared: 0.798,  Adjusted R-Squared: 0.798
F-statistic vs. constant model: 1.55e+04, p-value = 0
```

The coefficient of the *t* term is significant with a value of `0.038`. This value suggests that this geographic location has a warming trend of approximately `0.038`°C per year.

Analyze and Fit Model Residuals

Create an ARIMA/GARCH model for the residuals using `arima` (Econometrics Toolbox).

Based on the preceding results, create a separate time-series model for the regression model residuals using the following workflow:

1. Create an `arima` (Econometrics Toolbox) object and use the ARMA terms help to model the autocorrelation in the residual series.
2. Set the constant term to `0`, since the regression model above already includes a constant.
3. Use a *t*-distribution for the innovation series.
4. Use a `garch` (Econometrics Toolbox) model for the variance of the residuals to model the autocorrelation in the squared residuals.

```
trendRes = trendModel.Residuals.Raw;

resModel = arima( "ARLags", 1, ...
    "MALags", 1, ...
    "Constant", 0, ...
    "Distribution", "t", ...
    "Variance", garch( 1, 1 ) );
resModel = estimate(resModel,trendRes);

    ARIMA(1,0,1) Model (t Distribution):

                 Value      StandardError    TStatistic      PValue
                ________    _____________    __________    __________

    Constant          0               0           NaN             NaN
    AR{1}       0.76851       0.0063873        120.32               0
    MA{1}      0.075023        0.010201        7.3545       1.9168e-13
    DoF          10.369         0.75567        13.722       7.4771e-43

    GARCH(1,1) Conditional Variance Model (t Distribution):

                 Value      StandardError    TStatistic      PValue
                ________    _____________    __________    __________

    Constant    0.67469        0.091761        7.3527       1.9426e-13
```

```
    GARCH{1}     0.82015       0.019319        42.453              0
    ARCH{1}     0.070964      0.0069394        10.226      1.5119e-24
    DoF           10.369        0.75567        13.722      7.4771e-43
```

The residuals are not normally distributed or independent. Also, the residuals show evidence of GARCH effects.

Simulate Future Temperature Scenarios

Now that you have a calibrated temperature model, you can use it to simulate future temperature paths.

Prepare the simulation time.

```
nDays = 730;
simDates = Temp.Date(end) + caldays(1:nDays).';
simTime = years(simDates - Temp.Date(1));
```

Use `predict` to predict the deterministic trend.

```
trendPred = predict(trendModel, designMatrix(simTime));
```

Simulate from the ARIMA/GARCH model using `simulate` (Econometrics Toolbox).

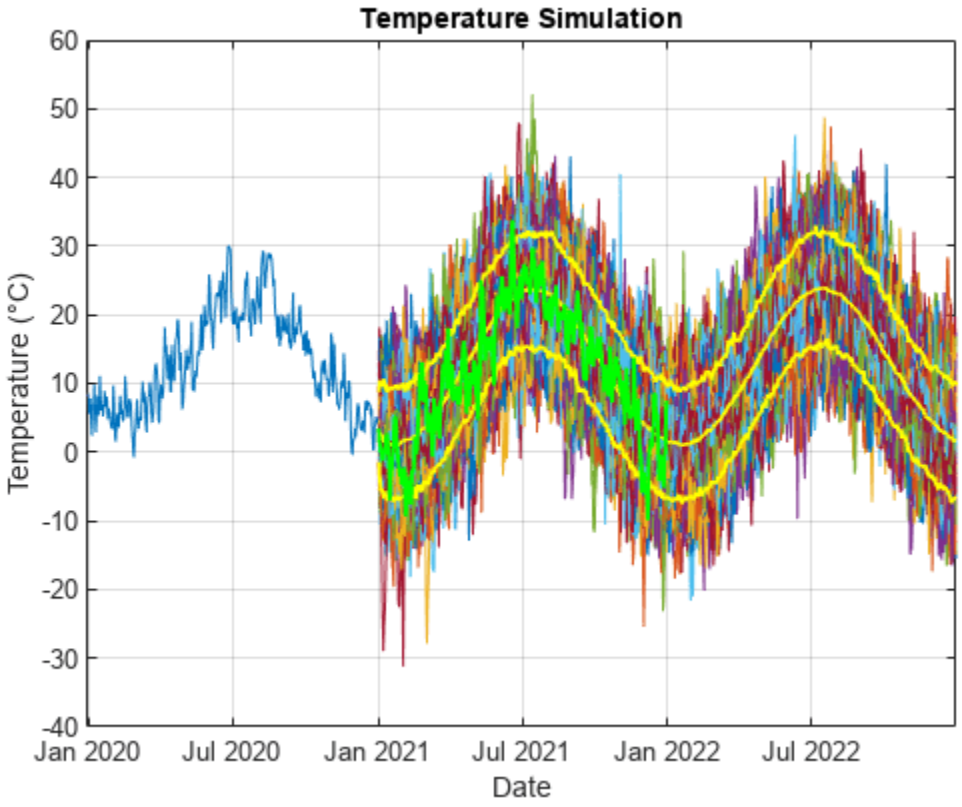
```
simRes = simulate(resModel, nDays, "NumPaths", 1000, "Y0", trendRes);
```

Add the deterministic trend to the simulated residuals.

```
simTemp = simRes + trendPred;
```

Use `visualizeScenarios` in Local Functions on page 1-114 to visualize the temperature scenarios.

```
visualizeScenarios(Temp, simTemp, simDates)
```

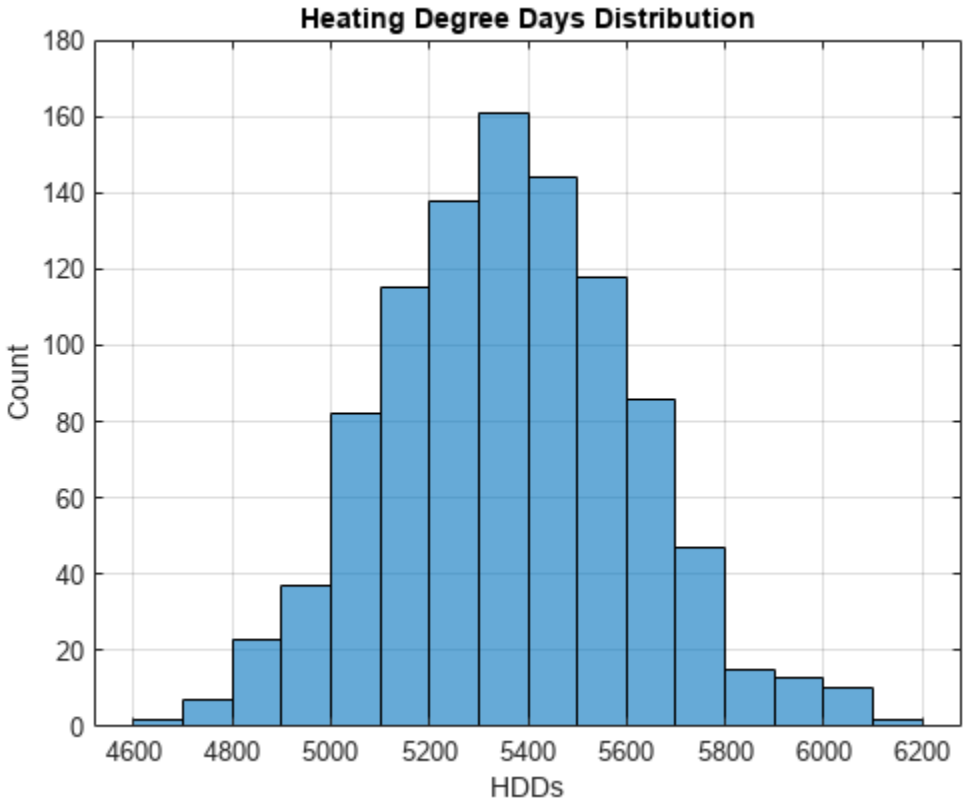


Evaluate Number of Heating Degree Days from Simulation

The number of heating degree days is given by $H = \sum_{i=1}^{n} \max(18 - T_i, 0)$, where $T_1, T_2, \ldots, T_n$ are the simulated temperatures.

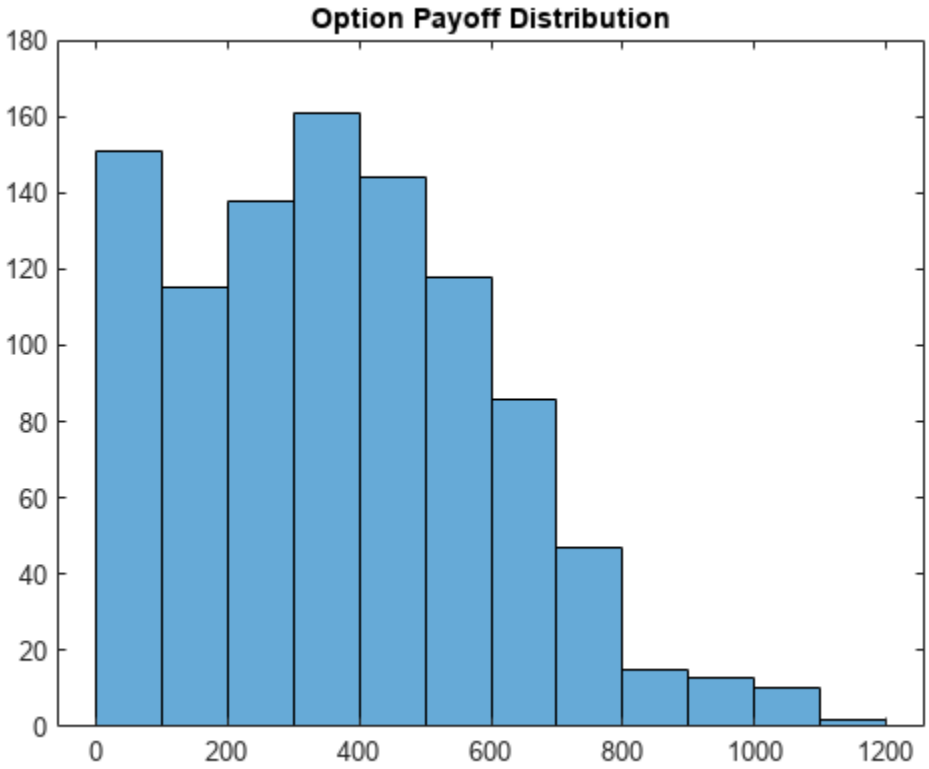
```
H = sum(max(18 - simTemp, 0));

figure
histogram(H)
xlabel("HDDs")
ylabel("Count")
title("Heating Degree Days Distribution")
grid on
```



Using the original formula $\chi = \alpha \max\{H_n - K, 0\}$ from Alaton [1 on page 1-114], you can obtain a payoff distribution. When `K = 7400`, the `max` of `H_n-K` and `0` is always `0` for the set of simulation results in this example. Consequently, the histogram shows the distribution of 1000 zeros, that is, a single bar centered at `0` with a height of `1000`. As `K` decreases to `5000`, `H_n-K` has more opportunities to be positive, so the histogram changes shape.

```
K =    5000                          ;
figure
alpha = 1;
chi = alpha*max(H-K, 0); % Payoff of option
histogram(chi)
title("Option Payoff Distribution")
```



Price Sample Call and Put Options

The weather derivative option pricing calculation is based on H (the number of heating degree days) which is defined in the Evaluate Number of Heating Degree Days From Simulation on page 1-111 section.

First, compute the mean and standard deviation of H.

```
muH = mean(H);
sigmaH = std(H);
```

Define the sample option parameters.

```
r = 0.01; % Risk-free interest rate
K = 5000; % Strike value
TTM = 0.25; % Expiry time
```

Evaluate α.

```
a = (K - muH) / sigmaH;
```

Compute the price of the call and put options.

```
call_option = exp(-r*TTM) * ((muH - K) * normcdf(-a) + (sigmaH / sqrt(2*pi) * exp(-0.5*a^2)))
```

```
call_option = 371.9754
```

```
put_option = exp(-r*TTM) * ((K - muH) * (normcdf(a) - normcdf(-muH / sigmaH)) + sigmaH / sqrt(2*p
```

```
put_option = 8.5494
```

Interest-Rate Derivatives

Supported Interest-Rate Instrument Functions

In this section...

Bond

A bond is a long-term debt security with a preset interest-rate and maturity. At maturity, you must pay the principal and interest.

The price or value of a bond is determined by discounting the expected cash flows of the bond to the present, using the appropriate discount rate. The following equation represents the relationship of the expected cash flows and discount rate:

$$B_0 = \frac{C}{2}\left[\frac{1-\left(1+\frac{r}{2}\right)^{-2t}}{\frac{r}{2}}\right] + \frac{F}{\left(1+\frac{r}{2}\right)^{2t}}$$

where:

B_0 is the bond value.

C is the annual coupon payment.

F is the face value of the bond.

r is the required return on the bond.

t is the number of years remaining until maturity.

Financial Instruments Toolbox supports the following for pricing and specifying a bond.

Function	Purpose
`bondbybdt`	Price a bond using a BDT interest-rate tree.
`bondbyhw`	Price a bond using an HW interest-rate tree.
`bondbybk`	Price a bond using a BK interest-rate tree.
`bondbyhjm`	Price a bond using an HJM interest-rate tree.
`bondbycir`	Price bonds using a CIR tree model.
`bondbyzero`	Price a bond using a set of zero curves.
`instbond`	Construct a bond instrument.

Convertible Bond

A convertible bond is a financial instrument that combines equity and debt features. It is a bond with the embedded option to turn it into a fixed number of shares. The holder of a convertible bond has the right, but not the obligation, to exchange the convertible security for a predetermined number of equity shares at a preset price. The debt component is derived from the coupon payments and the principal. The equity component is provided by the conversion feature.

Convertible bonds have several defining features:

- Coupon — The coupon in convertible bonds are typically lower than coupons in vanilla bonds since investors are willing to take the lower coupon for the opportunity to participate in the company's stock via the conversion.
- Maturity — Most convertible bonds are issued with long-stated maturities. Short-term maturity convertible bonds usually do not have call or put provisions.
- Conversion ratio — Conversion ratio is the number of shares that the holder of the convertible bond receives from exercising the call option of the convertible bond:

  ```
  Conversion ratio = par value convertible bond/conversion price of equity
  ```

  For example, a conversion ratio of 25 means a bond can be exchanged for 25 shares of stock. This also implies a conversion price of $40 (1000/25). This, $40, would be the price at which the owner would buy the shares. This can be expressed as a ratio or as the conversion price and is specified in the contract along with other provisions.
- Option type:
  - Callable Convertible: a convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder. Upon call, the bondholder can either convert the bond or redeem at the call price.

This option enables the issuer to control the price of the convertible bond and if necessary refinance the debt with a new cheaper one.

- Puttable Convertible: a convertible bond with a put feature that allows the bondholder to sell back the bond at a premium on a specific date. This option protects the holder against rising interest rates by reducing the year to maturity.

Function	Purpose
`cbondbycrr`	Price convertible bonds using a CRR binomial tree with the Tsiveriotis and Fernandes model.
`cbondbyeqp`	Price convertible bonds using an EQP binomial tree with the Tsiveriotis and Fernandes model.
`cbondbyitt`	Price convertible bonds using an implied trinomial tree with the Tsiveriotis and Fernandes model.
`cbondbystt`	Price convertible bonds using a standard trinomial tree with the Tsiveriotis and Fernandes model.
`instcbond`	Construct a `cbond` instrument for a convertible bond.

Stepped Coupon Bonds

A step-up and step-down bond is a debt security with a predetermined coupon structure over time. With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. For more information on options features (call and puts), see “Stepped Coupon Bonds with Calls and Puts” on page 2-8. The following functions have a modified `CouponRate` argument to support a new variable coupon schedule allowing pricing of stepped coupon bonds.

Function	Purpose
`bondbyzero`	Price bonds using a term structure model.
`bondbybdt`	Price bonds using a BDT tree model.
`bondbyhjm`	Price bonds using an HJM tree model.
`bondbyhw`	Price bonds using an HW tree model.
`bondbybk`	Price bonds using a BK tree model.
`bondbycir`	Price bonds using a CIR tree model.
`instbond`	Construct a bond instrument.
`instoptbnd`	Construct a bond option instrument.
`instdisp`	Display instruments stored in a variable.

Sinking Fund Bonds

A sinking fund bond is a coupon bond with a sinking fund provision. This provision obligates the issuer to amortize portions of the principal before maturity, affecting bond prices since the time of the principal repayment changes. This means that investors receive the coupon and a portion of the principal paid back over time. These types of bonds reduce credit risk, since it lowers the probability of investors not receiving their principal payment at maturity. For more information on options support for sinking fund bonds, see “Sinking Fund Bonds with an Embedded Option” on page 2-8. The following functions have a modified `Face` argument to support a variable face schedule for pricing bonds with a sinking provisions.

Function	Purpose
`bondbyzero`	Price bonds using a term structure model.
`bondbybdt`	Price bonds using a BDT tree model.
`bondbyhjm`	Price bonds using an HJM tree model.
`bondbyhw`	Price bonds using an HW tree model.
`bondbybk`	Price bonds using a BK tree model.
`bondbycir`	Price bonds using a CIR tree model.
`instoptbnd`	Construct a bond option instrument.
`instbond`	Construct a bond instrument.
`instdisp`	Display instruments stored in a variable.

Bonds with an Amortization Schedule

A bond with an amortization schedule repays part of the principal (face value) along with the coupon payments. An amortizing bond is a special case of a sinking fund bond when there is no market purchase option and no call provision. The following functions have a modified `Face` argument to support an amortization schedule.

Function	Purpose
`bondbyzero`	Price bonds using a term structure model.
`bondbybdt`	Price bonds using a BDT tree model.
`bondbyhjm`	Price bonds using an HJM tree model.
`bondbyhw`	Price bonds using an HW tree model.
`bondbybk`	Price bonds using a BK tree model.
`bondbycir`	Price bonds using a CIR tree model.

Bond Options

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option: An option that you exercise any time until its expiration date.
- European option: An option that you exercise only on its expiration date.
- Bermuda option: A Bermuda option resembles a hybrid of American and European options. You can exercise it on predetermined dates only, usually monthly.

Financial Instruments Toolbox supports the following for pricing and specifying a bond option.

Function	Purpose
`optbndbybdt`	Price a bond option price using a BDT interest-rate tree.
`optbndbyhw`	Price a bond option price using an HW interest-rate tree.
`optbndbybk`	Price a bond option price using a BK interest-rate tree.
`optbndbyhjm`	Price a bond option price using an HJM interest-rate tree.

Function	Purpose
`optbndbycir`	Price a bond option price using a CIR interest-rate tree.
`instoptbnd`	Construct a bond option instrument.

Bond with Embedded Options

A bond with embedded options allows the issuer to buy back (callable) or redeem (puttable) the bond at a predetermined price at specified future dates. Financial Instruments Toolbox supports American, European, and Bermuda callable and puttable bonds.

The pricing for a bond with embedded options is as follows:

- For a callable bond:*PriceCallableBond* = *BondPrice* − *BondCallOption*

  In the callable case, the holder bought a bond and sold a call option to the issuer. For example, if interest rates go down by the time of the call date, the issuer is able to refinance its debt at a cheaper level and can call the bond.
- For a puttable bond: *PricePuttableBond* = *PriceBond* + *PricePutOption*

  In the puttable case, the holder bought a bond and a put option. For example, if interest rates rise, the future value of coupon payments becomes less valuable. Therefore, the investor can sell the bond back to the issuer and then lend proceeds elsewhere at a higher rate.

In addition, Option Adjusted Spread (OAS) is a useful way to value and compare securities with embedded options, like callable or puttable bonds. For more information on OAS, see “OAS for Callable and Puttable Bonds” on page 2-64.

Financial Instruments Toolbox supports the following for pricing and specifying a bond with embedded options.

Function	Purpose
`optembndbybdt`	Price a bond with embedded options using a BDT interest-rate tree.
`optembndbyhw`	Price a bond with embedded options using an HW interest rate tree.
`optembndbybk`	Price a bond with embedded options using a BK interest-rate tree.
`optembndbyhjm`	Price a bond with embedded options using an HJM interest-rate tree.
`optembndbycir`	Price a bond with embedded options using a CIR interest-rate tree.
`instoptembnd`	Construct a bond-with-embedded-options instrument.
`oasbybdt`	Determine an option adjusted spread using Black-Derman-Toy model.
`oasbybk`	Determine an option adjusted spread using Black-Karasinski model.

Function	Purpose
oasbyhjm	Determine an option adjusted spread using Heath-Jarrow-Morton model.
oasbyhw	Determine an option adjusted spread using Hull-White model.
oasbycir	Determine an option adjusted spread using Cox-Ingersoll-Ross model.
agencyoas	Compute the OAS of the callable bond using the Agency OAS model.
agencyprice	Price the callable bond OAS using the Agency OAS model.

Stepped Coupon Bonds with Calls and Puts

A step-up and step-down bond is a debt security with a predetermined coupon structure over time. For more information on stepped coupon bonds, see “Stepped Coupon Bonds” on page 2-5. Stepped coupon bonds can have options features (call and puts). The following functions have a modified `CouponRate` argument to support a new variable coupon schedule allowing pricing stepped coupon bonds with callable and puttable features:

Function	Purpose
optembndbybdt	Price bonds with embedded options using a BDT model tree.
optembndbyhjm	Price bonds with embedded options using an HJM model tree.
optembndbybk	Price bonds with embedded options using a BK model tree.
optembndbyhw	Price bonds with embedded options using an HW model tree.
optembndbycir	Price bonds with embedded options using a CIR model tree.
instbond	Construct a bond instrument.
instoptbnd	Construct a bond option instrument.
instoptembnd	Construct a bond with an embedded option instrument.
instdisp	Display instruments stored in a variable.

Sinking Fund Bonds with an Embedded Option

A sinking fund bond is a coupon bond with a sinking fund provision. For more information on sinking fund bonds, see “Sinking Fund Bonds” on page 2-5. The sinking fund bond can have a sinking fund option provision allowing the issuer to retire the sinking fund obligation either by purchasing the bonds to be redeemed from the market or by calling the bond via a sinking fund call, whichever is cheaper.

If interest rates are high, then the issuer buys back the required amount of bonds from the market since bonds are cheap. But if interest rates are low (bond prices are high), then most likely the issuer buys the bonds at the call price. Unlike a call feature, however, if a bond has a sinking fund option provision, it is an obligation, not an option, for the issuer to buy back the increments of the issue as stated. Because of this, a sinking fund bond trades at a lower price than a nonsinking fund bond. The following functions have a modified `Face` argument to support a variable face schedule for pricing bonds with a sinking fund option provision.

Function	Purpose
optembndbybdt	Price bonds with embedded options using a BDT model tree.
optembndbyhjm	Price bonds with embedded options using an HJM model tree.
optembndbybk	Price bonds with embedded options using a BK model tree.
optembndbyhw	Price bonds with embedded options using an HW model tree.
optembndbycir	Price bonds with embedded options using a CIR model tree.
instbond	Construct a bond instrument.
instoptbnd	Construct a bond option instrument.
instdisp	Display instruments stored in a variable.

Amortizing Callable or Puttable Bond

Amortizing callable or puttable bonds work under a scheduled `Face` input argument. An amortizing callable bond give the issuer the right to call back the bond, but instead of paying the `Face` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

Function	Purpose
optembndbybdt	Price bonds with embedded options using a BDT model tree.
optembndbyhjm	Price bonds with embedded options using an HJM model tree.
optembndbybk	Price bonds with embedded options using a BK model tree.
optembndbyhw	Price bonds with embedded options using an HW model tree.
optembndbycir	Price bonds with embedded options using a CIR model tree.
oasbybdt	Determine an option adjusted spread using Black-Derman-Toy model.
oasbybk	Determine an option adjusted spread using Black-Karasinski model.
oasbyhjm	Determine an option adjusted spread using Heath-Jarrow-Morton model.
oasbyhw	Determine an option adjusted spread using Hull-White model.
oasbycir	Determine an option adjusted spread using Cox-Ingersoll-Ross model.

Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid. The principal may or may not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity.

Function	Purpose
fixedbybdt	Price a fixed-rate note using a BDT interest-rate tree.
fixedbyhw	Price a fixed-rate note using an HW interest-rate tree.
fixedbybk	Price a fixed-rate note using a BK interest-rate tree.
fixedbyhjm	Price a fixed-rate note using an HJM interest-rate tree.

Function	Purpose
`fixedbycir`	Price a fixed-rate note using a CIR interest-rate tree.
`fixedbyzero`	Price a fixed-rate note using a set of zero curves.
`instfixed`	Construct a fixed-rate instrument.

Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

Function	Purpose
`floatbybdt`	Price a floating-rate note using a BDT interest-rate tree.
`floatbyhw`	Price a floating-rate note using an HW interest-rate tree.
`floatbybk`	Price a floating-rate note using a BK interest-rate tree.
`floatbyhjm`	Price a floating-rate note using an HJM interest-rate tree.
`floatbycir`	Price a floating-rate note using a CIR interest-rate tree.
`floatbyzero`	Price a floating-rate note using a set of zero curves.
`instfloat`	Construct a floating-rate note instrument.

Floating-Rate Note with an Amortization Schedule

A floating-rate note with an amortization schedule repays part of the principal (face value) along with the coupon payments. The following functions have a `Principal` argument to support an amortization schedule.

Function	Purpose
`floatbyzero`	Price floating-rate note from set of zero curves.
`floatbybdt`	Price floating-rate note from Black-Derman-Toy interest-rate tree.
`floatbyhjm`	Price floating-rate note from Heath-Jarrow-Morton interest-rate tree.
`floatbyhw`	Price floating-rate note from Hull-White interest-rate tree.
`floatbybk`	Price floating-rate note from Black-Karasinski interest-rate tree.
`floatbycir`	Price a floating-rate note using a CIR interest-rate tree.

Floating-Rate Note with Caps, Collars, and Floors

A floating-rate note with caps, collars, and floors. This type of instrument can carry restrictions on the maximum (cap) or minimum (floor) coupon rate paid. A cap is an unattractive feature for an investor, since they constrain the coupon rates from increasing. A floor is an attractive feature, since it allows investors to get a minimum coupon rate when market rates decrease below a certain level. Also, a floating-rate note can have a collar which is a combination of a cap and a floor together. The following functions have a `CapRate` and `FloorRate` argument to support a capped, collared, or floored floating-rate note.

Function	Purpose
`floatbybdt`	Price a capped floating-rate note from a Black-Derman-Toy interest-rate tree.
`floatbyhjm`	Price a capped floating-rate note from a Heath-Jarrow-Morton interest-rate tree.
`floatbyhw`	Price a capped floating-rate note from a Hull-White interest-rate tree.
`floatbybk`	Price a capped floating-rate note from a Black-Karasinski interest-rate tree.
`floatbycir`	Price a floating-rate note using a CIR interest-rate tree.
`instfloat`	Create a capped floating-rate note instrument.
`instadd`	Add a capped floating-rate note instrument to a portfolio.

Floating-Rate Note Options

Financial Instruments Toolbox supports three types of put and call options on floating-rate notes:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly.

Financial Instruments Toolbox supports the following for pricing and specifying a floating-rate note option:

Function	Purpose
`optfloatbybdt`	Price an option for floating-rate note using a Black-Derman-Toy interest-rate tree.
`optfloatbyhjm`	Price an option for floating-rate note using a Heath-Jarrow-Morton interest-rate tree.
`optfloatbyhw`	Price an option for floating-rate note using a Hull-White interest-rate tree.
`optfloatbycir`	Price an option for floating-rate note using a Cox-Ingersoll-Ross interest-rate tree.
`optfloatbybk`	Price an option for floating-rate note using a Black-Karasinski interest-rate tree.
`instoptfloat`	Define the option instrument for floating-rate note.

Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features. An FRN with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

Financial Instruments Toolbox supports the following for pricing and specifying a floating-rate note with an embedded option:

Function	Purpose
`optemfloatbybdt`	Price an embedded option for floating-rate note using a Black-Derman-Toy interest-rate tree.
`optemfloatbybk`	Price an embedded option for floating-rate note using a Black-Karasinski interest-rate tree.
`optemfloatbyhjm`	Price an embedded option for floating-rate note using a Heath-Jarrow-Morton interest-rate tree.
`optemfloatbyhw`	Price an embedded option for floating-rate note using a Hull-White interest-rate tree.
`optemfloatbycir`	Price an embedded option for floating-rate note using a Cox-Ingersoll-Ross interest-rate tree.
`instoptemfloat`	Define the floating-rate note with embedded option instrument.

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate. The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

Function	Purpose
`capbybdt`	Price a cap instrument using a BDT interest-rate tree.
`capbyhw`	Price a cap instrument using an HW interest-rate tree.
`capbybk`	Price a cap instrument using a BK interest-rate tree.
`capbyhjm`	Price a cap instrument using an HJM interest-rate tree.
`capbycir`	Price a cap instrument using a CIR interest-rate tree.
`capbyblk`	Price a cap instrument using the Black option pricing model.
`capbylg2f`	Price a cap using Linear Gaussian two-factor model.
`capbynormal`	Price a cap instrument with negative rates using the Normal (Bachelier) option pricing model.
`capvolstrip`	Strip caplet volatilities from flat cap volatilities.
`instcap`	Construct a cap instrument.

Floor

A floor is a contract that includes a guarantee setting the minimum interest rate to be received by the holder, based on an otherwise floating interest rate. The payoff for a floor is:

$\max(FloorRate - CurrentRate, 0)$

Function	Purpose
`floorbybdt`	Price a floor instrument using a BDT interest-rate tree.
`floorbyhw`	Price a floor instrument using an HW interest-rate tree.
`floorbybk`	Price a floor instrument using a BK interest-rate tree.
`floorbyhjm`	Price a floor instrument using an HJM interest-rate tree.
`floorbycir`	Price a floor instrument using a CIR interest-rate tree.
`floorbyblk`	Price a floor instrument using the Black option pricing model.
`floorbylg2f`	Price a floor using Linear Gaussian two-factor model.
`floorbynormal`	Price a floor instrument with negative rates using the Normal (Bachelier) option pricing model.
`floorvolstrip`	Strip floorlet volatilities from flat floor volatilities.
`instfloor`	Construct a floor instrument.

Range Note

A range note is a structured (market-linked) security whose coupon-rate is equal to the reference rate as long as the reference rate is within a certain range. If the reference rate is outside of the range, the coupon-rate is 0 for that period. This type of instrument entitles the holder to cash flows that depend on the level of some reference interest-rate that is floored to be positive and gives the holder of the note direct exposure to the reference rate. This type of instrument is useful for cases where you believe that interest rates will stay within a certain range. In return for the drawback that no interest is paid for the time the range is left, a range note offers higher coupon rates than comparable standard products, like vanilla floating notes.

Function	Purpose
`instrangefloat`	Create a range note instrument.
`rangefloatbybdt`	Price range floating note using a BDT tree.
`rangefloatbybk`	Price range floating note using a BK tree.
`rangefloatbyhjm`	Price range floating note using an HJM tree.
`rangefloatbyhw`	Price range floating note using an HW tree.
`rangefloatbycir`	Price range floating note using a CIR tree.

Swap

A swap is contract between two parties obligating the parties to exchange future cash flows. A vanilla swap is composed of a floating-rate leg and a fixed-rate leg.

Function	Purpose
`swapbybdt`	Price a swap instrument using a BDT interest-rate tree.
`swapbyhw`	Price a swap instrument using an HW interest-rate tree.
`swapbybk`	Price a swap instrument using a BK interest-rate tree.
`swapbyhjm`	Price a swap instrument using an HJM interest-rate tree.

Function	Purpose
`swapbycir`	Price a swap instrument using a CIR interest-rate tree.
`swapbyzero`	Price a swap instrument using a set of zero curves and price cross currency swaps.
`instswap`	Construct a swap instrument.

Swap with an Amortization Schedule

A swap with an amortization schedule repays part of the principal (face value) along with the coupon payments. A swap with an amortization schedule is used to manage interest rate risk and serve as a cash flow management tool. For this particular type of swap, the notional amount decreases over time. This means that interest payments decrease not only on the floating leg but also on the fixed leg. The following swap functions have a `Principal` argument to support an amortization schedule.

Function	Purpose
`swapbyzero`	Price swap instrument from set of zero curves.
`swapbybdt`	Price swap instrument from Black-Derman-Toy interest-rate tree.
`swapbyhjm`	Price swap instrument from Heath-Jarrow-Morton interest-rate tree.
`swapbyhw`	Price swap instrument from Hull-White interest-rate tree.
`swapbybk`	Price swap instrument from Black-Karasinski interest-rate tree.
`swapbycir`	Price a swap instrument using a CIR interest-rate tree.
`instswap`	Construct swap instrument.

Forward Swap

In a forward interest-rate swap, a fixed interest-rate loan is exchanged for a floating interest-rate loan at a future specified date. The following functions have a `StartDate` argument to support the future date for the forward swap.

Function	Purpose
`swapbyzero`	Price a forward swap from a zero curve.
`swapbybdt`	Price a forward swap from a Black-Derman-Toy interest-rate tree.
`swapbyhjm`	Price a forward swap from a Heath-Jarrow-Morton interest-rate tree.
`swapbyhw`	Price a forward swap from a Hull-White interest-rate tree.
`swapbybk`	Price a forward swap from a Black-Karasinski interest-rate tree.
`swapbycir`	Price a swap instrument using a CIR interest-rate tree.
`instswap`	Create a forward swap instrument.
`instadd`	Add a capped floating-rate note instrument to a portfolio.

Swaption

A swaption is an option to enter into an interest-rate swap contract. A call swaption allows the option buyer to enter into an interest-rate swap where the buyer of the option pays the fixed-rate and

receives the floating-rate. A put swaption allows the option buyer to enter into an interest-rate swap where the buyer of the option receives the fixed-rate and pays the floating-rate.

Function	Purpose
`swaptionbybdt`	Price a swaption instrument using a BDT interest-rate tree.
`swaptionbyhw`	Price a swaption instrument using an HW interest-rate tree.
`swaptionbybk`	Price a swaption instrument using a BK interest-rate tree.
`swaptionbyhjm`	Price a swaption instrument using an HJM interest-rate tree.
`swaptionbycir`	Price a swaption instrument using a CIR interest-rate tree.
`swaptionbyblk`	Price swaptions using the Black model with a forward on a swap.
`swaptionbylg2f`	Price European swaptions using Linear Gaussian two-factor model.
`swaptionbynormal`	Price swaptions for negative rates using the Normal (Bachelier) model with a forward on a swap.
`instswaption`	Construct a swaption instrument.

Use `swaptionbyblk` to price a swaption using the Black model. The Black model is standard model used in the swaption market when pricing European swaptions. This type of model is widely used by when speed is important to quickly obtain a price at settlement date, even if the price is less accurate than other swaption pricing models based on interest-rate tree models.

Bond Futures

Bond futures are futures contracts where the commodity for delivery is a government bond. There are established global markets for government bond futures. Bond futures provide a liquid alternative for managing interest-rate risk.

In the US market, the Chicago Mercantile Exchange (CME) offers futures on Treasury bonds and notes with maturities of 2, 5, 10, and 30 years. Typically, the following bond future contracts from the CME have maturities of 3, 6, 9, and 12 months:

- 30-year U.S. Treasury bond
- 10-year U.S. Treasury bond
- 5-year U.S. Treasury bond
- 2-year U.S. Treasury bond

The short position in a Treasury bond or note future contract must deliver to the long position in one of many possible existing Treasury bonds. For example, in a 30-year Treasury bond future, the short position must deliver a Treasury bond with at least 15 years to maturity. Because these bonds have different values, the bond future contract is standardized by computing a conversion factor. The conversion factor normalizes the price of a bond to a theoretical bond with a coupon of 6%. The price of a bond future contract is represented as:

$InvoicePrice = FutPrice \times CF + AI$

where:

FutPrice is the price of the bond future.

CF is the conversion factor for a bond to deliver in a futures contract.

AI is the accrued interest.

The short position in a futures contract has the option of which bond to deliver and, in the US bond market, when in the delivery month to deliver the bond. The short position typically chooses to deliver the bond known as the Cheapest to Deliver (CTD). The CTD bond most often delivers on the last delivery day of the month.

Financial Instruments Toolbox supports the following bond futures:

- US Treasury bonds and notes
- German Bobl, Bund, Buxl, and Schatz
- UK gilts
- Japanese government bonds (JGBs)

The functions supporting all bond futures are:

Function	Purpose
`convfactor`	Calculates bond conversion factors for US Treasury bonds, German Bobl, Bund, Buxl, and Schatz, UK gilts, and JGBs.
`bndfutprice`	Prices bond future given repo rates.
`bndfutimprepo`	Calculates implied repo rates for a bond future given price.

The functions supporting US Treasury bond futures are:

Function	Purpose
`tfutbyprice`	Calculates future prices of Treasury bonds given the spot price.
`tfutbyyield`	Calculates future prices of Treasury bonds given current yield.
`tfutimprepo`	Calculates implied repo rates for the Treasury bond future given price.
`tfutpricebyrepo`	Calculates Treasury bond futures price given the implied repo rates.
`tfutyieldbyrepo`	Calculates Treasury bond futures yield given the implied repo rates.

For more information on bond futures, see “Bond Futures” on page 7-10.

Work with Negative Interest Rates Using Functions

Interest-Rate Modeling Options for Negative Rates

Financial Instruments Toolbox computes prices for caps, floors, and swaptions when modeling for negative interest-rates using a Normal volatility model, shifted Black model, or shifted SABR model:

- Normal volatility model (Bachelier model) for interest-rate options to handle negative rates with the following:
  - `swaptionbynormal`
  - `capbynormal`
  - `floorbynormal`
  - `normalvolbysabr`
- Shifted Black model and the shifted SABR model for interest-rate options using an optional `Shift` argument to handle negative rates with the following:
  - `blackvolbysabr` (Shifted SABR)
  - `optsensbysabr` (Shifted SABR)
  - `swaptionbyblk` (Shifted Black)
  - `capbyblk` (Shifted Black)
  - `floorbyblk` (Shifted Black)
  - `capvolstrip` (Shifted Black)
  - `floorvolstrip` (Shifted Black)

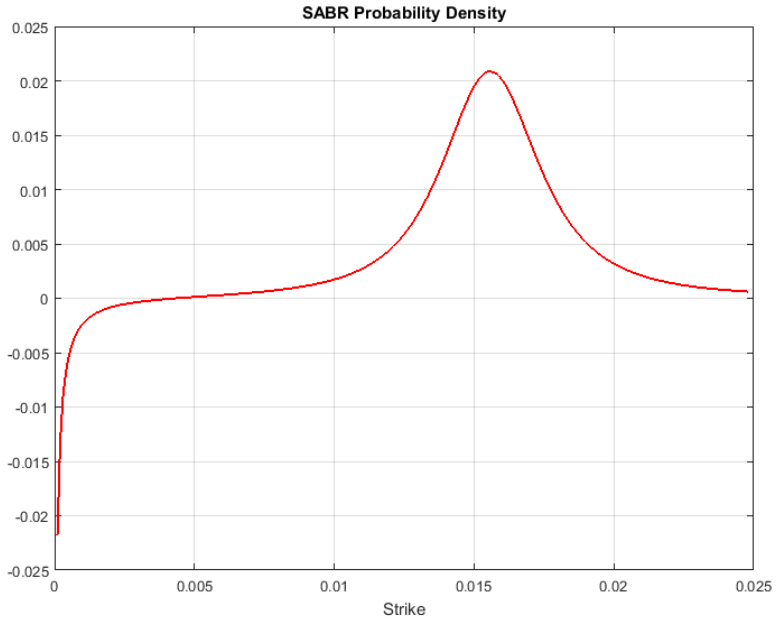
Modeling Negative Rates

The original authors of the SABR model provided a closed form approximation of the implied Black volatility in terms of the SABR model parameters (known as “Hagan’s formula”), so that the option price could be computed by inserting the computed SABR Black volatility into the Black formula:

$$Call(K,T) = Black_{call}(F,K,r,T,\sigma_{Black}(\alpha,\beta,\rho,\nu,F,K,T))$$

However, these methods started to break down with the introduction of negative interest rates, due to the assumption of the Black model that the underlying rates are lognormally distributed (and therefore cannot be negative).

In addition, even when the underlying rate is positive, the closed form approximation of the SABR implied Black volatility (Hagan et al., 2002) is known to become increasingly inaccurate as the strike approaches zero. Even without crossing the zero strike boundary, the implied probability density of the underlying rate at option expiry can become negative at low positive strikes, although probability densities clearly should not be negative:



Options with negative strikes cannot be represented by Black volatilities. To work around this problem, the market started to quote the cap, floor, and swaption prices also in terms of either Normal volatilities or Shifted Black volatilities. Instead of the Black model, both types of volatilities come from alternative models that allow negative rates.

Normal Model

The Normal volatilities are associated with the Normal model (also known as the Bachelier model):

$$dF = \sigma_{Normal} dW$$

where the underlying rates are assumed to be normally distributed. Unlike in a lognormal model (where rates have a lower bound), the rates in the Normal model can be both infinitely positive and infinitely negative.

Shifted Black

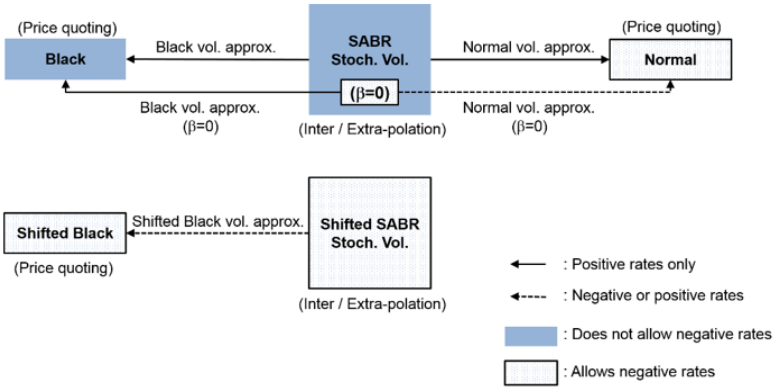
The Shifted Black volatilities are associated with the Shifted Black model (also known as “Displaced Diffusion” or “Shifted Lognormal” model):

$$dF = \sigma_{Shifted\_Black}(F + Shift) dW$$

The Shifted Black model is essentially the same as the Black model, except that it models the movements of (F + $Shift$) as the underlying asset, instead of F (where F is the forward swap rate in the case of swaptions, and the forward rate in the case of caplets and floorlets). So, the Shifted Black model allows negative rates, with a fixed negative lower bound defined by the amount of shift, that is, the zero lower bound of the Black model has been shifted.

Shifted SABR

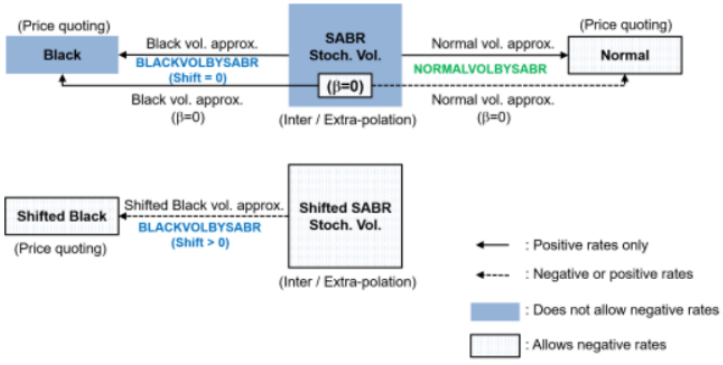
The introduction of negative interest rates also called for an update in the method for interpolating the volatilities quoted in the market. The following shows the connections between the volatilities and the SABR models:



As shown, the Black and Normal volatility approximations allow you to use the SABR model with the Black and Normal model option pricing formulas. However, although the Normal model itself allows negative rates and the SABR model has an implied Normal volatility approximation, the underlying dynamics of the SABR model do not allow negative rates, unless $\beta = 0$. In the Shifted SABR model, the Shifted Black volatility approximation can be used to allow negative rates with a fixed negative lower bound defined by the amount of shift.

Implied Normal Volatility and SABR

You can compute the implied Normal volatility in terms of the SABR model parameters, for either $\beta = 0$ (Normal SABR), or any other value of β allowed by the SABR model ($0 \le \beta \le 1$) using `normalvolbysabr`.



`normalvolbysabr`computes the implied Normal volatility σ_N in terms of the SABR model parameters. Using `normalvolbysabr` to compute σ_N, you can then you this with other functions for Normal model pricing (for example, `capbynormal`, `floorbynormal`, and `swaptionbyblk`).

Work with Negative Interest Rates Using Objects

Interest-Rate Modeling Options for Negative Rates

Financial Instruments Toolbox computes prices for a `Cap`, `Floor`, or `Swaption` instrument when modeling for negative interest-rates using a Normal volatility model, shifted Black model, or shifted SABR model:

- Normal volatility model (Bachelier model) for interest-rate options to handle negative rates with the following:
  - `Normal` model object
  - `Normal` pricer object
  - `SABR` model object
  - `SABR` pricer object
- Shifted Black model and the shifted SABR model for interest-rate options to handle negative rates with the following:
  - `Black` model object (Shifted Black model, specified by the `'Shift'` name-value argument set to a positive value.)
  - `Black` pricer object (Shifted Black model, specified by the `'Shift'` name-value argument set to a positive value.)
  - `SABR` model object (Shifted SABR model, specified by the `'VolatilityType'` name-value argument set to `"Black"` and the `'Shift'` name-value argument set to a positive value.)
  - `SABR` pricer object (Shifted SABR model, specified by the `'VolatilityType'` name-value argument set to `"Black"` and the `'Shift'` name-value argument set to a positive value.)

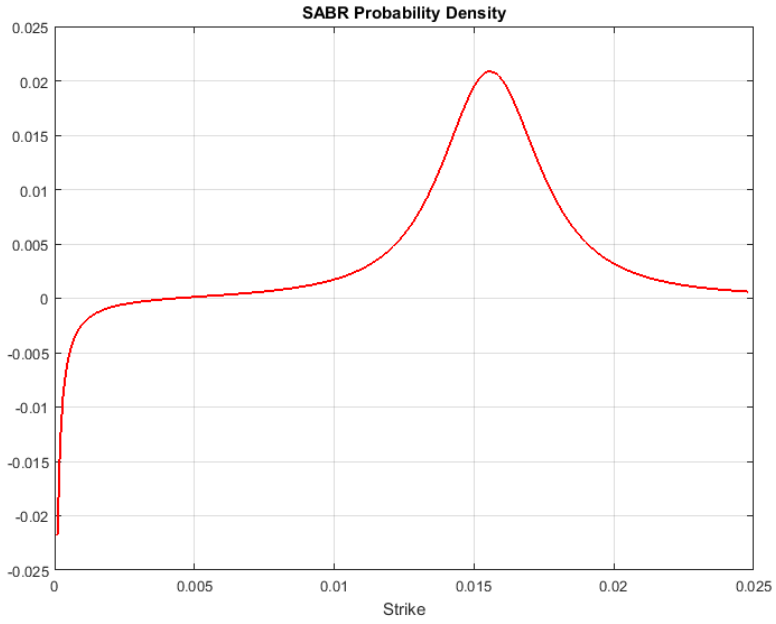
Modeling Negative Rates

The original authors of the SABR model provided a closed form approximation of the implied Black volatility in terms of the SABR model parameters (known as “Hagan’s formula”), so that the option price could be computed by inserting the computed SABR Black volatility into the Black formula:

$$Call(K,T) = Black_{call}(F,K,r,T,\sigma_{Black}(\alpha,\beta,\rho,\nu,F,K,T))$$

However, these methods started to break down with the introduction of negative interest rates, due to the assumption of the Black model that the underlying rates are lognormally distributed (and therefore cannot be negative).

In addition, even when the underlying rate is positive, the closed form approximation of the SABR implied Black volatility (Hagan et al., 2002) is known to become increasingly inaccurate as the strike approaches zero. Even without crossing the zero strike boundary, the implied probability density of the underlying rate at option expiry can become negative at low positive strikes, although probability densities clearly should not be negative:



Options with negative strikes cannot be represented by Black volatilities. To work around this problem, the market started to quote the cap, floor, and swaption prices also in terms of either Normal volatilities or Shifted Black volatilities. Instead of the Black model, both types of volatilities come from alternative models that allow negative rates.

Normal Model

The Normal volatilities are associated with the Normal model (also known as the Bachelier model):

$$dF = \sigma_{Normal} dW$$

where the underlying rates are assumed to be normally distributed. Unlike in a lognormal model (where rates have a lower bound), the rates in the Normal model can be both infinitely positive and infinitely negative.

Shifted Black

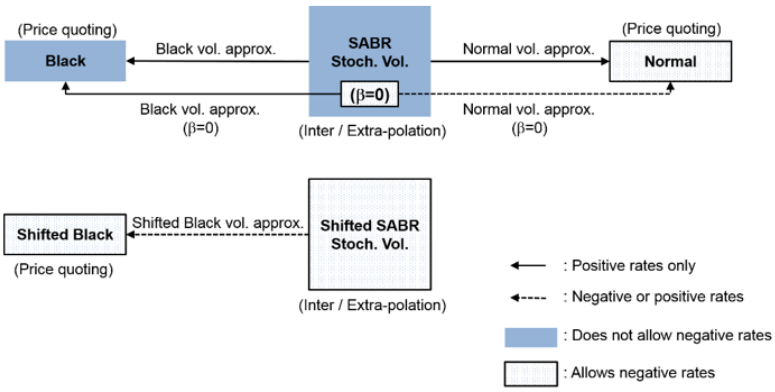
The Shifted Black volatilities are associated with the Shifted Black model (also known as “Displaced Diffusion” or “Shifted Lognormal” model):

$$dF = \sigma_{Shifted\_Black}(F + Shift)dW$$

The Shifted Black model is essentially the same as the Black model, except that it models the movements of (F + $Shift$) as the underlying asset, instead of F (where F is the forward swap rate in the case of swaptions, and the forward rate in the case of caplets and floorlets). So, the Shifted Black model allows negative rates, with a fixed negative lower bound defined by the amount of shift, that is, the zero lower bound of the Black model has been shifted.

Normal SABR and Shifted SABR

The introduction of negative interest rates also called for an update in the method for interpolating the volatilities quoted in the market. The following shows the connections between the volatilities and the SABR models:



As shown, the Black and Normal volatility approximations allow you to use the SABR model with the Black and Normal model option pricing formulas. However, although the Normal model itself allows negative rates and the SABR model has an implied Normal volatility approximation, the underlying dynamics of the SABR model do not allow negative rates, unless $\beta = 0$. When the β (Beta) parameter of the SABR model is set to zero, the model is a Normal SABR model, which allows computing the implied Normal volatilities for negative rates.

In the Shifted SABR model, the Shifted Black volatility approximation can be used to allow negative rates with a fixed negative lower bound defined by the amount of shift. This is achieved by setting the `'Shift'` name-value argument of the SABR model to a positive value.

Implied Volatilities and SABR

You can compute the implied volatilities in terms of the SABR model parameters, for either $\beta = 0$ (Normal SABR), or any other value of β allowed by the SABR model ($0 \le \beta \le 1$) using the `volatilities` function for the SABR analytic pricer.

The following three types of implied volatilities are supported by the SABR analytic pricer, and the type of implied volatilities computed by the `volatilities` function depends on the parameters of the SABR model when using the SABR analytic pricer:

- Implied Black volatilities — The SABR model `'VolatilityType'` name-value argument is set to `"Black"` and the `'Shift'` name-value argument is set to zero. Negative rates are not allowed.
- Implied Sifted Black volatilities — The SABR model `'VolatilityType'` name-value argument is set to `"Black"` and the `'Shift'` name-value argument is set to a positive value. Negative rates are allowed with lower bound defined by the amount of shift.
- Implied Normal (Bachelier) volatilities — The SABR model `'VolatilityType'` name-value argument is set to `"Black"` and the `'Shift'` name-value argument is set to zero. Negative rates are allowed when the `Beta` input argument is set to zero.

Price Swaptions with Negative Strikes Using the Shifted SABR Model

This example shows how to price swaptions with negative strikes by using the Shifted SABR model. The market Shifted Black volatilities are used to calibrate the Shifted SABR model parameters. The calibrated Shifted SABR model is then used to compute the Shifted Black volatilities for negative strikes.

The swaptions with negative strikes are then priced using the computed Shifted Black volatilities and the `swaptionbyblk` function with the `'Shift'` parameter set to the prespecified shift. Similarly, Shifted SABR Greeks can be computed by using the `optsensbysabr` function by setting the `'Shift'` parameter. Finally, from the swaption prices, the probability density of the underlying asset is computed to show that the swaption prices imply positive probability densities for some negative strikes.

Load the market data.

First, load the market interest rates and swaption volatility data. The market swaption volatilities are quoted in terms of Shifted Black volatilities with a `0.8` percent shift.

Define `RateSpec`.

```
ValuationDate = '5-Apr-2016';
EndDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]])';
ZeroRates = [-0.34 -0.29 -0.25 -0.13 -0.07 -0.02 0.010 0.025 ...
    0.031 0.040 0.052 0.090 0.190 0.290 0.410 0.520]'/100;
Compounding = 1;
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',ZeroRates,'Compounding',Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [16x1 double]
            Rates: [16x1 double]
         EndTimes: [16x1 double]
       StartTimes: [16x1 double]
          EndDates: [16x1 double]
       StartDates: 736425
    ValuationDate: 736425
            Basis: 0
     EndMonthRule: 1
```

Define the swaption.

```
SwaptionSettle = '5-Apr-2016';
SwaptionExerciseDate = '5-Apr-2017';
SwapMaturity = '5-Apr-2022';
Reset = 1;
OptSpec = 'call';
TimeToExercise = yearfrac(SwaptionSettle,SwaptionExerciseDate);
```

Use `swapbyzero` to compute the forward swap rate.

```
LegRate = [NaN 0];  % To compute the forward swap rate, set the fixed rate to NaN.
[~, CurrentForwardValue] = swapbyzero(RateSpec,LegRate,SwaptionSettle,SwapMaturity,...
'StartDate',SwaptionExerciseDate)
```

```
CurrentForwardValue = 6.6384e-04
```

Specify amount of shift in decimals for Shifted Black and Shifted SABR models.

```
Shift = 0.008;  % 0.8 percent shift
```

Load the market implied Shifted Black volatility data for swaptions.

```
MarketShiftedBlackVolatilities = [21.1; 15.3; 14.0; 14.6; 16.0; 17.7; 19.8; 23.9; 26.2]/100;
StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = CurrentForwardValue + StrikeGrid;
ATMShiftedBlackVolatility = MarketShiftedBlackVolatilities(StrikeGrid==0);
```

Calibrate the Shifted SABR model parameters.

To better represent the market at-the-money volatility, the `Alpha` parameter value is implied by the market at-the-money volatility. This is similar to the "Method 2" in “Calibrate the SABR Model” on page 2-33. However, note the addition of `Shift` to `CurrentForwardValue` and the use of the `'Shift'` parameter with `blackvolbysabr`. The `Beta` parameter is predetermined at `0.5`.

```
Beta = 0.5;
```

This function solves the Shifted SABR at-the-money volatility equation as a polynomial of `Alpha`. Note the addition of `Shift` to `CurrentForwardValue`.

```
alpharoots = @(Rho,Nu) roots([...
    (1 - Beta)^2*TimeToExercise/24/(CurrentForwardValue + Shift)^(2 - 2*Beta) ...
    Rho*Beta*Nu*TimeToExercise/4/(CurrentForwardValue + Shift)^(1 - Beta) ...
    (1 + (2 - 3*Rho^2)*Nu^2*TimeToExercise/24) ...
    -ATMShiftedBlackVolatility*(CurrentForwardValue + Shift)^(1 - Beta)]);
```

This function converts at-the-money volatility into `Alpha` by picking the smallest positive real root.

```
atmVol2ShiftedSabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
    x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharoots(Rho,Nu))));
```

Fit `Rho` and `Nu` (while converting at-the-money volatility into `Alpha`). Note the `'Shift'` parameter of `blackvolbysabr` is set to the prespecified shift.

```
objFun = @(X) MarketShiftedBlackVolatilities - ...
    blackvolbysabr(atmVol2ShiftedSabrAlpha(X(1), X(2)), ...
    Beta, X(1), X(2), SwaptionSettle, SwaptionExerciseDate, CurrentForwardValue, ...
    MarketStrikes, 'Shift', Shift);

options = optimoptions('lsqnonlin','Display','none');
X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf], options);
Rho = X(1);
Nu = X(2);
```

Get the final `Alpha` from the calibrated parameters.

```
Alpha = atmVol2ShiftedSabrAlpha(Rho, Nu)
```

```
Alpha = 0.0133
```

Show the calibrated Shifted SABR parameters.

```
CalibratedPrameters = array2table([Shift Alpha Beta Rho Nu],...
    'VariableNames',{'Shift' 'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'1Y into 5Y'})
```

```
CalibratedPrameters=1×5 table
                  Shift     Alpha      Beta      Rho        Nu
                  _____    ________    ____    _______    _______

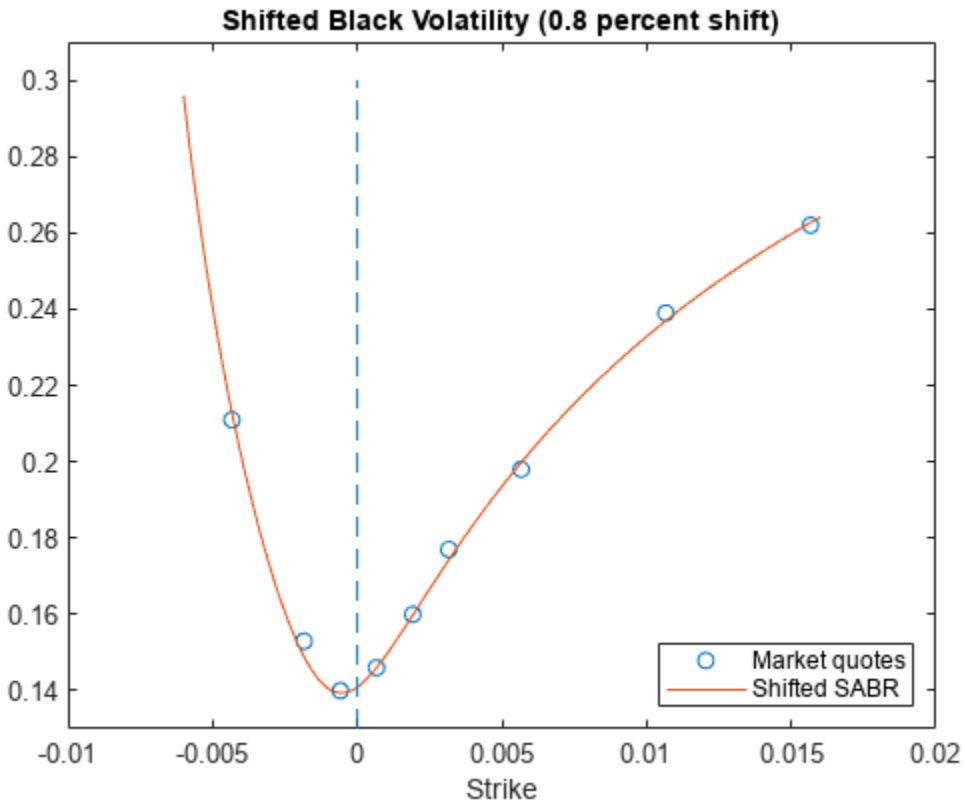
    1Y into 5Y    0.008    0.013345    0.5     0.46698    0.49816
```

Compute the swaption volatilities using the calibrated Shifted SABR model.

Use `blackvolbysabr` with the `'Shift'` parameter.

```
Strikes = (-0.6:0.01:1.6)'/100; % Include negative strikes.
SABRShiftedBlackVolatilities = blackvolbysabr(Alpha, Beta, Rho, Nu, SwaptionSettle, ...
    SwaptionExerciseDate, CurrentForwardValue, Strikes, 'Shift', Shift);

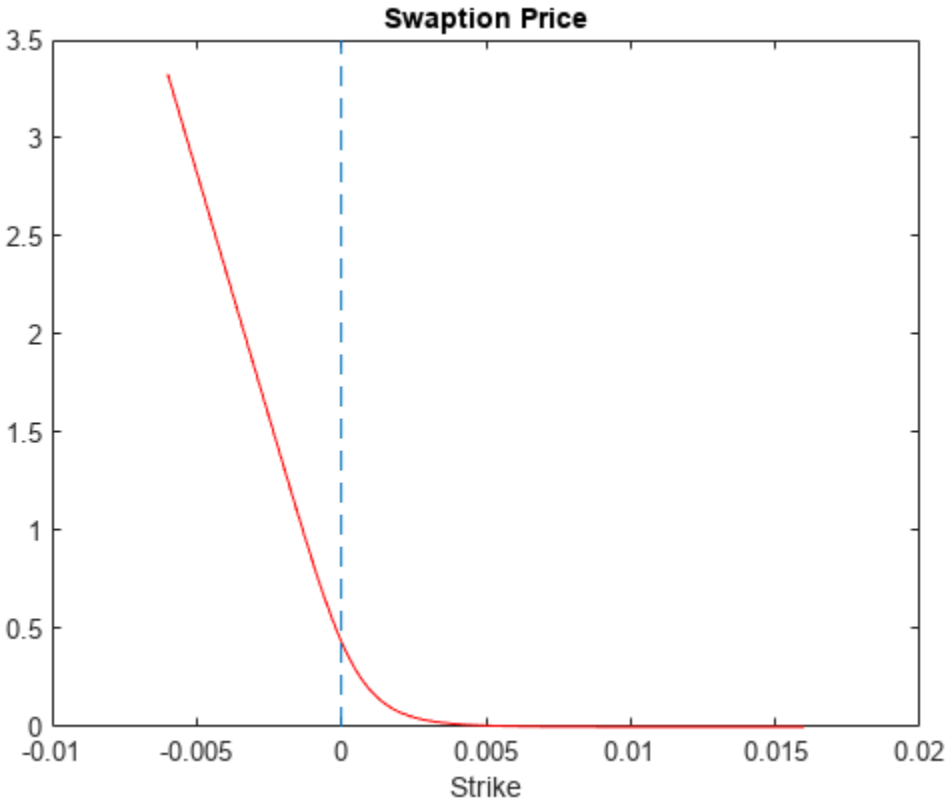
figure;
plot(MarketStrikes, MarketShiftedBlackVolatilities, 'o', ...
    Strikes, SABRShiftedBlackVolatilities);
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
ylim([0.13 0.31])
xlabel('Strike');
legend('Market quotes','Shifted SABR', 'location', 'southeast');
title (['Shifted Black Volatility (',num2str(Shift*100),' percent shift)']);
```



Price the swaptions, including those with negative strikes.

Use `swaptionbyblk` with the `'Shift'` parameter to compute swaption prices using the Shifted Black model.

```
SwaptionPrices = swaptionbyblk(RateSpec, OptSpec, Strikes, SwaptionSettle, SwaptionExerciseDate,
    SwapMaturity, SABRShiftedBlackVolatilities, 'Reset', Reset, 'Shift', Shift);
figure;
plot(Strikes, SwaptionPrices, 'r');
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
xlabel('Strike');
title ('Swaption Price');
```

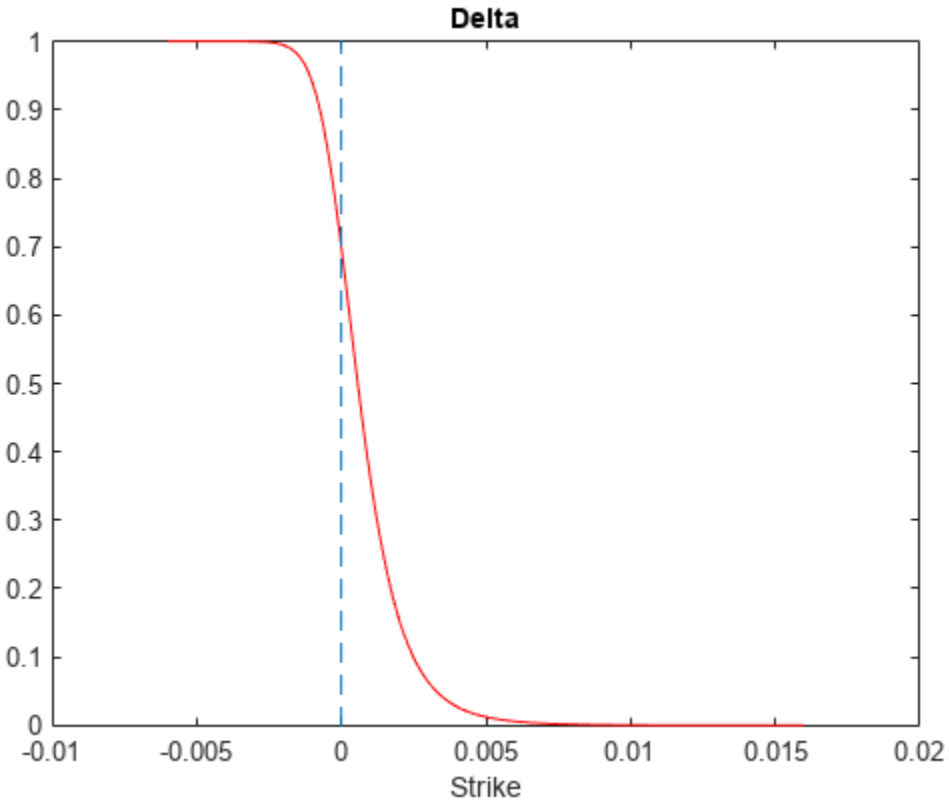


Compute Shifted SABR Delta.

Use `optsensbysabr` with the `'Shift'` parameter to compute `Delta` using the Shifted SABR model.

```
ShiftedSABRDelta = optsensbysabr(RateSpec, Alpha, Beta, Rho, Nu, SwaptionSettle, ...
SwaptionExerciseDate, CurrentForwardValue, Strikes, OptSpec, 'Shift', Shift);

figure;
plot(Strikes,ShiftedSABRDelta,'r-');
ylim([-0.002 1.002]);
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
xlabel('Strike');
title ('Delta');
```



Compute the probability density.

The risk-neutral probability density of the terminal underlying asset prices can be approximated as the second derivative of swaption prices with respect to strike (Breeden and Litzenberger, 1978). As can be seen in the plot below, the computed probability density is positive for some negative rates above -0.8 percent (the lower bound determined by `'Shift'`).

```
NumGrids = length(Strikes);
ProbDensity = zeros(NumGrids-2,1);
dStrike = mean(diff(Strikes));

for k = 2:(NumGrids-1)
    ProbDensity(k-1) = (SwaptionPrices(k-1) - 2*SwaptionPrices(k) + SwaptionPrices(k+1))/dStrike^
end

ProbDensity = ProbDensity./sum(ProbDensity);
ProbStrikes = Strikes(2:end-1);

figure;
plot(ProbStrikes,ProbDensity,'r-');
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
xlabel('Strike');
title ('Probability Density');
```

Calibrate the SABR Model

This example shows how to use two different methods to calibrate the SABR stochastic volatility model from market implied Black volatilities. Both approaches use `blackvolbysabr`.

In this section...

Load Market Implied Black Volatility Data

This example shows how to set up hypothetical market implied Black volatilities for European swaptions over a range of strikes before calibration. The swaptions expire in three years from the `Settle` date and have 10-year swaps as the underlying instrument. The rates are expressed in decimals. (Changing the units affect the numerical value and interpretation of the `Alpha` input parameter to the function `blackvolbysabr`.)

Load the market implied Black volatility data for swaptions expiring in three years.

```
Settle = '12-Jun-2013';
ExerciseDate = '12-Jun-2016';

MarketStrikes = [2.0 2.5 3.0 3.5 4.0 4.5 5.0]'/100;
MarketVolatilities = [45.6 41.6 37.9 36.6 37.8 39.2 40.0]'/100;
```

At the time of `Settle`, define the underlying forward rate and the at-the-money volatility.

```
CurrentForwardValue = MarketStrikes(4)
ATMVolatility = MarketVolatilities(4)
```

```
CurrentForwardValue =

    0.0350

ATMVolatility =

    0.3660
```

Method 1: Calibrate Alpha, Rho, and Nu Directly

This example shows how to calibrate the `Alpha`, `Rho`, and `Nu` input parameters directly. The value of `Beta` is predetermined either by fitting historical market volatility data or by choosing a value deemed appropriate for that market [1].

Define the predetermined `Beta`.

```
Beta1 = 0.5;
```

After fixing the value of β (`Beta`), the parameters α (`Alpha`), ρ (`Rho`), and υ(`Nu`) are all fitted directly. The Optimization Toolbox™ function `lsqnonlin` generates the parameter values that minimize the squared error between the market volatilities and the volatilities computed by `blackvolbysabr`.

```
% Calibrate Alpha, Rho, and Nu
objFun = @(X) MarketVolatilities - ...
    blackvolbysabr(X(1), Beta1, X(2), X(3), Settle, ...
    ExerciseDate, CurrentForwardValue, MarketStrikes);

X = lsqnonlin(objFun, [0.5 0 0.5], [0 -1 0], [Inf 1 Inf]);

Alpha1 = X(1);
Rho1 = X(2);
Nu1 = X(3);
```

```
Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the default value of the function tolerance.
```

Method 2: Calibrate Rho and Nu by Implying Alpha from At-The-Money Volatility

This example shows how to use an alternative calibration method where the value of β (`Beta`) is again predetermined as in Method 1.

Define the predetermined `Beta`.

```
Beta2 = 0.5;
```

However, after fixing the value of β (`Beta`), the parameters ρ (`Rho`), and υ (`Nu`) are fitted directly while α (`Alpha`) is implied from the market at-the-money volatility. Models calibrated using this method produce at-the-money volatilities that are equal to market quotes. This approach is widely used in swaptions, where at-the-money volatilities are quoted most frequently and are important to match. To imply α (`Alpha`) from market at-the-money volatility (σ_{ATM}), the following cubic polynomial is solved for α (`Alpha`), and the smallest positive real root is selected [2].

$$\frac{(1-\beta)^2 T}{24F^{(2-2\beta)}}\alpha^3 + \frac{\rho\beta\upsilon T}{4F^{(1-\beta)}}\alpha^2 + \left(1 + \frac{2-3\rho^2}{24}\upsilon^2 T\right)\alpha - \sigma_{ATM}F^{(1-\beta)} = 0$$

where:

- F is the current forward value.
- T is the year fraction to maturity.

To accomplish this, define an anonymous function as:

```
% Year fraction from Settle to option maturity
T = yearfrac(Settle, ExerciseDate, 1);

% This function solves the SABR at-the-money volatility equation as a
% polynomial of Alpha
alpharoots = @(Rho,Nu) roots([...
    (1 - Beta2)^2*T/24/CurrentForwardValue^(2 - 2*Beta2) ...
    Rho*Beta2*Nu*T/4/CurrentForwardValue^(1 - Beta2) ...
```

```
    (1 + (2 - 3*Rho^2)*Nu^2*T/24) ...
    -ATMVolatility*CurrentForwardValue^(1 - Beta2)]);

% This function converts at-the-money volatility into Alpha by picking the
% smallest positive real root
atmVol2SabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
    x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharoots(Rho,Nu))));
```

The function `atmVol2SabrAlpha` converts at-the-money volatility into α (`Alpha`) for a given set of ρ (`Rho`) and υ (`Nu`). This function is then used in the objective function to fit parameters ρ (`Rho`) and υ (`Nu`).

```
% Calibrate Rho and Nu (while converting at-the-money volatility into Alpha
% using atmVol2SabrAlpha)
objFun = @(X) MarketVolatilities - ...
    blackvolbysabr(atmVol2SabrAlpha(X(1), X(2)), ...
    Beta2, X(1), X(2), Settle, ExerciseDate, CurrentForwardValue, ...
    MarketStrikes);

X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf]);

Rho2 = X(1);
Nu2 = X(2);
```

```
Local minimum found.

Optimization completed because the size of the gradient is less than
the default value of the function tolerance.
```

The calibrated parameter α (`Alpha`) is computed using the calibrated parameters ρ (`Rho`) and υ (`Nu`).

```
% Obtain final Alpha from at-the-money volatility using calibrated parameters
Alpha2 = atmVol2SabrAlpha(Rho2, Nu2);

% Display calibrated parameters
C = {Alpha1 Beta1 Rho1 Nu1;Alpha2 Beta2 Rho2 Nu2};
CalibratedPrameters = cell2table(C,...
    'VariableNames',{'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'Method 1';'Method 2'})
```

```
CalibratedPrameters =

                Alpha      Beta      Rho        Nu
               ________    ____    _______    _______

    Method 1    0.060277    0.5      0.2097    0.75091
    Method 2    0.058484    0.5     0.20568    0.79647
```

Use the Calibrated Models

This example shows how to use the calibrated models to compute new volatilities at any strike value.

Compute volatilities for models calibrated using Method 1 and Method 2 and plot the results.

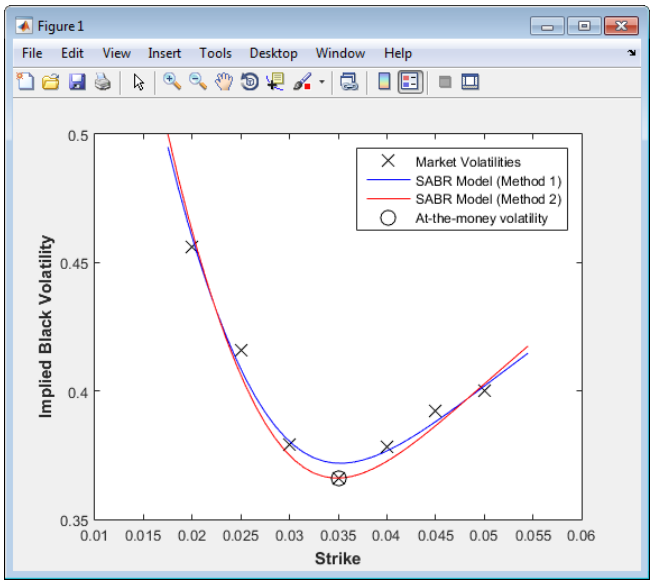
```
PlottingStrikes = (1.75:0.1:5.50)'/100;

% Compute volatilities for model calibrated by Method 1
ComputedVols1 = blackvolbysabr(Alpha1, Beta1, Rho1, Nu1, Settle, ...
```

```
    ExerciseDate, CurrentForwardValue, PlottingStrikes);

% Compute volatilities for model calibrated by Method 2
ComputedVols2 = blackvolbysabr(Alpha2, Beta2, Rho2, Nu2, Settle, ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes);

figure;
plot(MarketStrikes,MarketVolatilities,'xk',...
    PlottingStrikes,ComputedVols1,'b', ...
    PlottingStrikes,ComputedVols2,'r', ...
    CurrentForwardValue,ATMVolatility,'ok',...
    'MarkerSize',10);
xlim([0.01 0.06]);
ylim([0.35 0.5]);
xlabel('Strike', 'FontWeight', 'bold');
ylabel('Implied Black Volatility', 'FontWeight', 'bold');
legend('Market Volatilities', 'SABR Model (Method 1)',...
    'SABR Model (Method 2)', 'At-the-money volatility');
```



The model calibrated using Method 2 reproduces the market at-the-money volatility (marked with a circle) exactly.

Price a Swaption Using the SABR Model

This example shows how to price a swaption using the SABR model. First, a swaption volatility surface is constructed from market volatilities. This is done by calibrating the SABR model parameters separately for each swaption maturity. The swaption price is then computed by using the implied Black volatility on the surface as an input to the `swaptionbyblk` function.

Step 1. Load market swaption volatility data.

Load the market implied Black volatility data for swaptions.

```
Settle = '12-Jun-2013';
ExerciseDates = {'12-Sep-2013';'12-Jun-2014';'12-Jun-2015';...
    '12-Jun-2016';'12-Jun-2017';'12-Jun-2018';'12-Jun-2020';...
    '12-Jun-2023'};

YearsToExercise = yearfrac(Settle, ExerciseDates, 1);
NumMaturities = length(YearsToExercise);

MarketVolatilities = [ ...
   57.6 53.7 49.4 45.6 44.1 41.1 35.2 32.0

```

```
CurrentForwardValues = 1×8

    0.0250    0.0275    0.0318    0.0350    0.0376    0.0391    0.0408    0.0412
```

```
ATMVolatilities = MarketVolatilities(4,:)
```

```
ATMVolatilities = 1×8

    0.3410    0.3650    0.3780    0.3660    0.3500    0.3190    0.2810    0.2660
```

The current underlying forward rates and the corresponding at-the-money volatilities across the eight swaption maturities are represented in the fourth rows of the two matrices.

Step 2. Calibrate the SABR model parameters for each swaption maturity.

Using a model implemented in the function `blackvolbysabr`, a static SABR model, where the model parameters are assumed to be constant with respect to time, the parameters are calibrated separately for each swaption maturity (years to exercise) in a `for` loop. To better represent market at-the-money volatilities, the `Alpha` parameter values are implied by the market at-the-money volatilities (see "Method 2" for “Calibrate the SABR Model” on page 2-33).

Define the predetermined `Beta`, calibrate SABR model parameters for each swaption maturity and display calibrated parameters in a table.

```
Beta = 0.5;
Betas = repmat(Beta, NumMaturities, 1);
Alphas = zeros(NumMaturities, 1);
Rhos = zeros(NumMaturities, 1);
Nus = zeros(NumMaturities, 1);

options = optimoptions('lsqnonlin','Display','none');

for k = 1:NumMaturities
    % This function solves the SABR at-the-money volatility equation as a
    % polynomial of Alpha
    alpharoots = @(Rho,Nu) roots([...
        (1 - Beta)^2*YearsToExercise(k)/24/CurrentForwardValues(k)^(2 - 2*Beta) ...
        Rho*Beta*Nu*YearsToExercise(k)/4/CurrentForwardValues(k)^(1 - Beta) ...
        (1 + (2 - 3*Rho^2)*Nu^2*YearsToExercise(k)/24) ...
        -ATMVolatilities(k)*CurrentForwardValues(k)^(1 - Beta)]);

    % This function converts at-the-money volatility into Alpha by picking the
    % smallest positive real root
    atmVol2SabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
        x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharoots(Rho,Nu))));

    % Fit Rho and Nu (while converting at-the-money volatility into Alpha)
    objFun = @(X) MarketVolatilities(:,k) - ...
        blackvolbysabr(atmVol2SabrAlpha(X(1), X(2)), ...
        Beta, X(1), X(2), Settle, ExerciseDates(k), CurrentForwardValues(k), ...
        MarketStrikes(:,k));

    X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf], options);
    Rho = X(1);
    Nu = X(2);

    % Get final Alpha from the calibrated parameters
    Alpha = atmVol2SabrAlpha(Rho, Nu);

    Alphas(k) = Alpha;
    Rhos(k) = Rho;
    Nus(k) = Nu;
end

CalibratedPrameters = array2table([Alphas Betas Rhos Nus],...
    'VariableNames',{'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'3M into 10Y';'1Y into 10Y';...
    '2Y into 10Y';'3Y into 10Y';'4Y into 10Y';...
    '5Y into 10Y';'7Y into 10Y';'10Y into 10Y'})
```

```
CalibratedPrameters=8×4 table
                      Alpha      Beta      Rho         Nu
                    _________    ____    ________    _______

    3M into 10Y      0.051947    0.5      0.39572     1.4146
    1Y into 10Y      0.054697    0.5       0.2955     1.1257
    2Y into 10Y      0.058433    0.5      0.24175    0.93463
    3Y into 10Y      0.058484    0.5      0.20568    0.79647
    4Y into 10Y      0.056054    0.5      0.13685    0.76993
    5Y into 10Y      0.051072    0.5     0.060285    0.73595
    7Y into 10Y       0.04475    0.5     0.083385    0.66341
    10Y into 10Y     0.044548    0.5      0.02261    0.49487
```

Step 3. Construct a volatility surface.

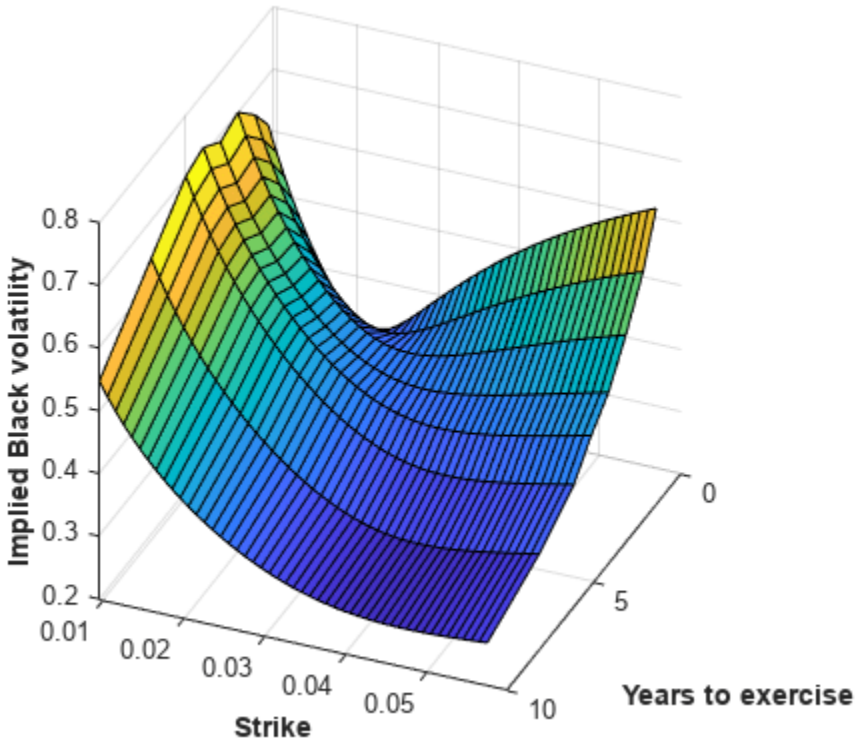
Use the calibrated model to compute new volatilities at any strike value to produce a smooth smile for a given maturity. This can be repeated for each maturity to form a volatility surface

Compute volatilities using the calibrated models for each maturity and plot the volatility surface.

```
PlottingStrikes = (0.95:0.1:5.8)'/100;
ComputedVols = zeros(length(PlottingStrikes), NumMaturities);

for k = 1:NumMaturities
ComputedVols(:,k) = blackvolbysabr(Alphas(k), Betas(k), Rhos(k), Nus(k), Settle, ...
    ExerciseDates(k), CurrentForwardValues(k), PlottingStrikes);
end

figure;
surf(YearsToExercise, PlottingStrikes, ComputedVols);
xlim([0 10]); ylim([0.0095 0.06]); zlim([0.2 0.8]);
view(113,32);
set(gca, 'Position', [0.13 0.11 0.775 0.815], ...
    'PlotBoxAspectRatioMode', 'manual');
xlabel('Years to exercise', 'Fontweight', 'bold');
ylabel('Strike', 'Fontweight', 'bold');
zlabel('Implied Black volatility', 'Fontweight', 'bold');
```



Note, in this volatility surface, the smiles tend to get flatter for longer swaption maturities (years to exercise). This is consistent with the `Nu` parameter values tending to decrease with swaption maturity, as shown previously in the table for `CalibratedPrameters`.

Step 4. Use `swaptionbyblk` to price a swaption.

Use the volatility surface to price a swaption that matures in five years. Define a swaption (for a 10-year swap) that matures in five years and use the interest-rate term structure at the time of the swaption `Settle` date to define the `RateSpec`. Use the `RateSpec` to compute the current forward swap rate using the `swapbyzero` function. Compute the SABR implied Black volatility for this swaption using the `blackvolbysabr` function (and it is marked with a red arrow in the figure that follows). Price the swaption using the SABR implied Black volatility as an input to the `swaptionbyblk` function.

```
% Define the swaption
SwaptionSettle = '12-Jun-2013';
SwaptionExerciseDate = '12-Jun-2018';
SwapMaturity = '12-Jun-2028';
Reset = 1;
OptSpec = 'call';
Strike = 0.0263;

% Define RateSpec
ValuationDate = '12-Jun-2013';
EndDates = {'12-Jul-2013';'12-Sep-2013';'12-Dec-2013';'12-Jun-2014';...
    '12-Jun-2015';'12-Jun-2016';'12-Jun-2017';'12-Jun-2018';...
    '12-Jun-2019';'12-Jun-2020';'12-Jun-2021';'12-Jun-2022';...
```

```
    '12-Jun-2023';'12-Jun-2025';'12-Jun-2028';'12-Jun-2033'};
Rates = [0.2 0.3 0.4 0.7 0.5 0.7 1.0 1.4 1.7 1.9 ...
    2.1 2.3 2.5 2.8 3.1 3.3]'/100;
Compounding = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, ...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

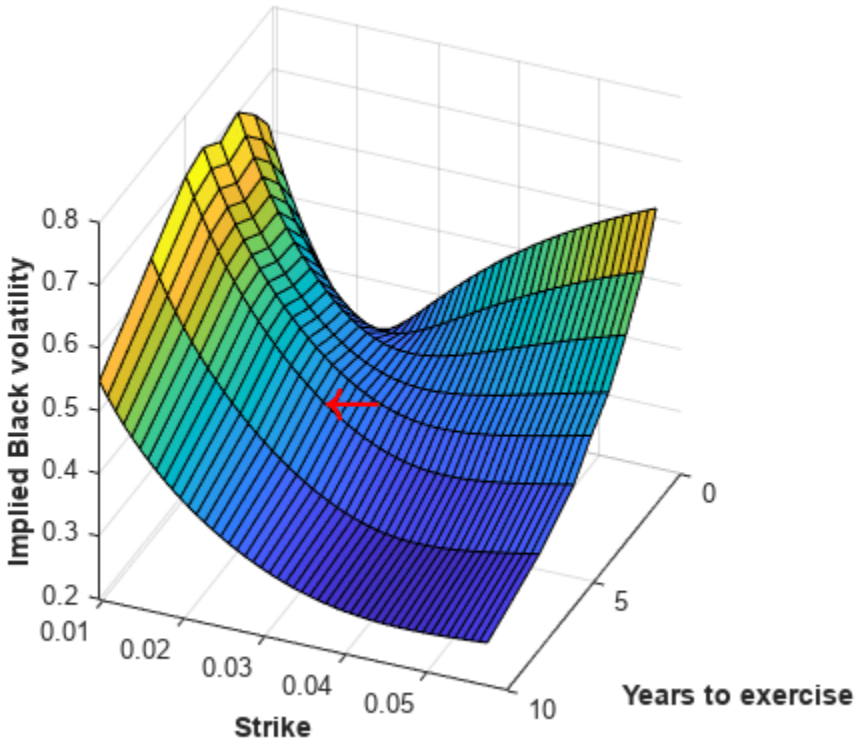
```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [16x1 double]
            Rates: [16x1 double]
         EndTimes: [16x1 double]
       StartTimes: [16x1 double]
         EndDates: [16x1 double]
       StartDates: 735397
    ValuationDate: 735397
            Basis: 0
     EndMonthRule: 1
```

```
% Use swapbyzero
LegRate = [NaN 0]; % To compute the forward swap rate, set the coupon rate to NaN.
[~, CurrentForwardSwapRate] = swapbyzero(RateSpec, LegRate, SwaptionSettle, SwapMaturity,...
'StartDate', SwaptionExerciseDate);

% Use blackvolbysabr
SABRBlackVolatility = blackvolbysabr(Alphas(6), Betas(6), Rhos(6), Nus(6), SwaptionSettle, ...
    SwaptionExerciseDate, CurrentForwardSwapRate, Strike)
```

```
SABRBlackVolatility = 0.3932
```

```
text (YearsToExercise(6), Strike, SABRBlackVolatility, '\leftarrow',...
    'Color', 'r', 'FontWeight', 'bold', 'FontSize', 22);
```



```
% Use swaptionbyblk
Price = swaptionbyblk(RateSpec, OptSpec, Strike, SwaptionSettle, SwaptionExerciseDate, ...
SwapMaturity, SABRBlackVolatility, 'Reset', Reset)

Price = 14.2403
```

Overview of Interest-Rate Tree Models

In this section...

Interest-Rate Modeling

Financial Instruments Toolbox computes prices and sensitivities of interest-rate contingent claims based on several methods of modeling changes in interest rates over time:

- The interest-rate term structure

  This model uses sets of zero-coupon bonds to predict changes in interest rates. A zero-coupon bond is a bond that, instead of carrying a coupon, is sold at a discount from its face value, pays no interest during its life, and pays the principal only at maturity.
- Heath-Jarrow-Morton (HJM) model

  The HJM model considers a given initial term structure of interest rates and a specification of the volatility of forward rates to build a tree representing the evolution of the interest rates, based on a statistical process.
- Black-Derman-Toy (BDT) model

  In the BDT model, all security prices and rates depend on the short rate (annualized one-period interest rate). The model uses long rates (the yield on a zero-coupon Treasury bond) and their volatilities to construct a tree of possible future short rates. The resulting tree can then be used to determine the value of interest-rate sensitive securities from this tree.
- Hull-White (HW) model

  The Hull-White model incorporates the initial term structure of interest rates and the volatility term structure to build a trinomial recombining tree of short rates. The resulting tree is used to value interest-rate dependent securities. The implementation of the HW model in Financial Instruments Toolbox is limited to one factor.
- Black-Karasinski (BK) model

  The BK model is a single-factor, log-normal version of the HW model.

For detailed information about interest-rate models, see:

- “Pricing Using Interest-Rate Term Structure” on page 2-61 for a discussion of price and sensitivity based on portfolios of zero-coupon bonds
- “Pricing Using Interest-Rate Tree Models” on page 2-81 for a discussion of price and sensitivity based on the HJM and BDT interest-rate models

---

Note Historically, the initial version of Financial Instruments Toolbox provided only the HJM interest-rate model. A later version added the BDT model. The current version adds both the HW and BK models. This section provides extensive examples of using the HJM and BDT models to compute prices and sensitivities of interest-rate based financial derivatives.

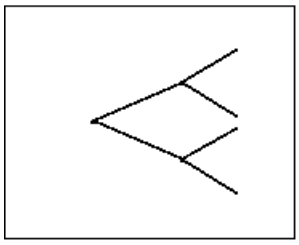
The HW and BK tree structures are similar to the BDT tree structure. To avoid needless repetition throughout this section, documentation is provided only where significant deviations from the BDT structure exist. Specifically, “HW and BK Tree Structures” on page 2-77 explains the few noteworthy differences among the various formats.

Rate and Price Trees

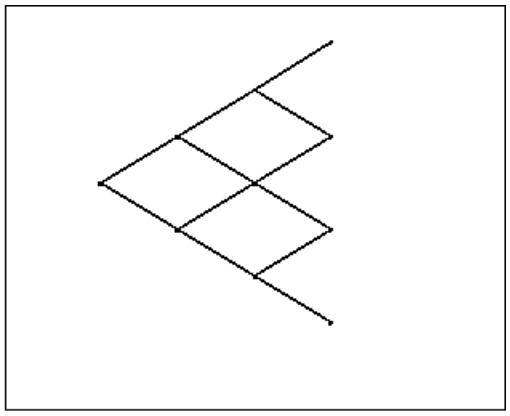
The interest-rate or price trees can be either binomial (two branches per node) or trinomial (three branches per node). Typically, binomial trees assume that underlying interest rates or prices can only either increase or decrease at each node. Trinomial trees allow for a more complex movement of rates or prices. With trinomial trees, the movement of rates or prices at each node is unrestricted (for example, up-up-up or unchanged-down-down). At any time step, the price or rate direction can be upward, neutral, or downward.

Types of Trees

Financial Instruments Toolbox trees can be classified as *bushy* or *recombining*. A bushy tree is a tree in which the number of branches increases exponentially relative to observation times; branches never recombine. In this context, a recombining tree is the opposite of a bushy tree. A recombining tree has branches that recombine over time. From any given node, the node reached by taking the path up-down is the same node reached by taking the path down-up. A bushy tree and a recombining binomial tree are illustrated next.



Bushy Tree



Recombining Binomial Tree

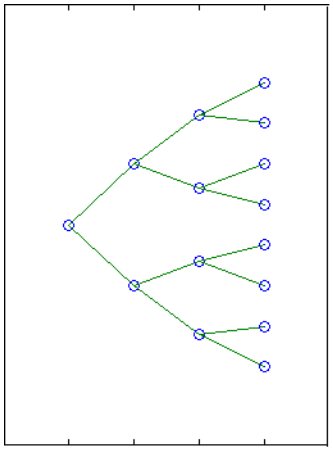
The Heath-Jarrow-Morton model works with bushy trees. The Black-Derman-Toy model, on the other hand, works with recombining binomial trees. The Hull-White and Black-Karasinsk interest-rate models work with recombining trinomial trees.

Viewing Rate or Price Movement

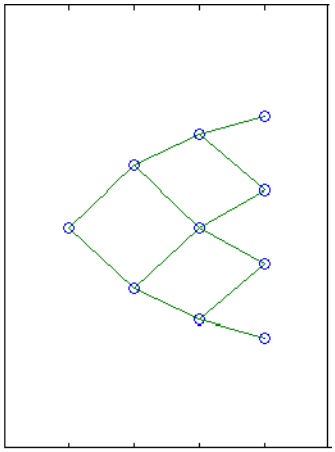
This toolbox provides the data file `deriv.mat` that contains four interest-rate based trees:

- `HJMTree` — A bushy binomial tree
- `BDTTree` — A recombining binomial tree
- `HWTree` and `BKTree` — Recombining trinomial trees

The toolbox also provides the `treeviewer` function, which graphically displays the shape and data of price, interest rate, and cash flow trees. Viewed with `treeviewer`, the bushy shape of an HJM tree and the recombining shape of a BDT tree are apparent.

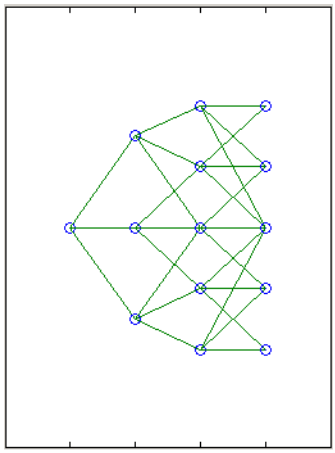


HJMTree (bushy)



BDTTree (recombining)

With `treeviewer`, you can also see the recombining shape of HW and BK trinomial trees.



HWTree and BKTree (recombining)

Understanding the Interest-Rate Term Structure

In this section...

Introduction

The *interest-rate term structure* represents the evolution of interest rates through time. In MATLAB, the interest-rate environment is encapsulated in a structure called `RateSpec` (*rate specification*). This structure holds all information required to completely identify the evolution of interest rates. Several functions included in Financial Instruments Toolbox software are dedicated to the creating and managing of the `RateSpec` structure. Many others take this structure as an input argument representing the evolution of interest rates.

Before looking further at the `RateSpec` structure, examine three functions that provide key functionality for working with interest rates: `disc2rate`, its opposite, `rate2disc`, and `ratetimes`. The first two functions map between discount factors and interest rates. The third function, `ratetimes`, calculates the effect of term changes on the interest rates.

Interest Rates Versus Discount Factors

Discount factors are coefficients commonly used to find the current value of future cash flows. As such, there is a direct mapping between the rate applicable to a period of time, and the corresponding discount factor. The function `disc2rate` converts discount factors for a given term (period) into interest rates. The function `rate2disc` does the opposite; it converts interest rates applicable to a given term (period) into the corresponding discount factors.

Calculating Discount Factors from Rates

As an example, consider these annualized zero-coupon bond rates.

From	To	Rate
15 Feb 2000	15 Aug 2000	0.05
15 Feb 2000	15 Feb 2001	0.056
15 Feb 2000	15 Aug 2001	0.06
15 Feb 2000	15 Feb 2002	0.065
15 Feb 2000	15 Aug 2002	0.075

To calculate the discount factors corresponding to these interest rates, call `rate2disc` using the syntax

```
Disc = rate2disc(Compounding, Rates, EndDates, StartDates,
ValuationDate)
```

where:

- `Compounding` represents the frequency at which the zero rates are compounded when annualized. For this example, assume this value to be 2.

- `Rates` is a vector of annualized percentage rates representing the interest rate applicable to each time interval.
- `EndDates` is a vector of dates representing the end of each interest-rate term (period).
- `StartDates` is a vector of dates representing the beginning of each interest-rate term.
- `ValuationDate` is the date of observation for which the discount factors are calculated. In this particular example, use February 15, 2000 as the beginning date for all interest-rate terms.

Next, set the variables in MATLAB.

```
StartDates = ['15-Feb-2000'];
EndDates  = ['15-Aug-2000'; '15-Feb-2001'; '15-Aug-2001';...
'15-Feb-2002'; '15-Aug-2002'];
Compounding = 2;
ValuationDate = ['15-Feb-2000'];
Rates = [0.05; 0.056; 0.06; 0.065; 0.075];
```

Finally, compute the discount factors.

```
Disc = rate2disc(Compounding, Rates, EndDates, StartDates,...
ValuationDate)
```

```
Disc =

    0.9756
    0.9463
    0.9151
    0.8799
    0.8319
```

By adding a fourth column to the rates table (see “Calculating Discount Factors from Rates” on page 2-48) to include the corresponding discounts, you can see the evolution of the discount factors.

From	To	Rate	Discount
15 Feb 2000	15 Aug 2000	0.05	0.9756
15 Feb 2000	15 Feb 2001	0.056	0.9463
15 Feb 2000	15 Aug 2001	0.06	0.9151
15 Feb 2000	15 Feb 2002	0.065	0.8799
15 Feb 2000	15 Aug 2002	0.075	0.8319

Optional Time Factor Outputs

The function `rate2disc` optionally returns two additional output arguments: `EndTimes` and `StartTimes`. These vectors of time factors represent the start dates and end dates in discount periodic units. The scale of these units is determined by the value of the input variable `Compounding`.

To examine the time factor outputs, find the corresponding values in the previous example.

```
[Disc, EndTimes, StartTimes] = rate2disc(Compounding, Rates,...
EndDates, StartDates, ValuationDate);
```

Arrange the two vectors into a single array for easier visualization.

```
Times = [StartTimes, EndTimes]
```

```
Times =

     0     1
     0     2
     0     3
     0     4
     0     5
```

Because the valuation date is equal to the start date for all periods, the `StartTimes` vector is composed of 0s. Also, since the value of `Compounding` is 2, the rates are compounded semiannually, which sets the units of periodic discount to six months. The vector `EndDates` is composed of dates separated by intervals of six months from the valuation date. This explains why the `EndTimes` vector is a progression of integers from 1 to 5.

Alternative Syntax (rate2disc)

The function `rate2disc` also accommodates an alternative syntax that uses periodic discount units instead of dates. Since the relationship between discount factors and interest rates is based on time periods and not on absolute dates, this form of `rate2disc` allows you to work directly with time periods. In this mode, the valuation date corresponds to 0, and the vectors `StartTimes` and `EndTimes` are used as input arguments instead of their date equivalents, `StartDates` and `EndDates`. This syntax for `rate2disc` is:

```
Disc = rate2disc(Compounding, Rates, EndTimes, StartTimes)
```

Using as input the `StartTimes` and `EndTimes` vectors computed previously, you should obtain the previous results for the discount factors.

```
Disc = rate2disc(Compounding, Rates, EndTimes, StartTimes)

Disc =

    0.9756
    0.9463
    0.9151
    0.8799
    0.8319
```

Calculating Rates from Discounts

The function `disc2rate` is the complement to `rate2disc`. It finds the rates applicable to a set of compounding periods, given the discount factor in those periods. The syntax for calling this function is:

```
Rates = disc2rate(Compounding, Disc, EndDates, StartDates, ValuationDate)
```

Each argument to this function has the same meaning as in `rate2disc`. Use the results found in the previous example to return the rate values you started with.

```
Rates = disc2rate(Compounding, Disc, EndDates, StartDates,ValuationDate)

Rates =

    0.0500
    0.0560
    0.0600
    0.0650
    0.0750
```

Alternative Syntax (disc2rate)

As in the case of `rate2disc`, `disc2rate` optionally returns `StartTimes` and `EndTimes` vectors representing the start and end times measured in discount periodic units. Again, working with the same values as before, you should obtain the same numbers.

```
[Rates, EndTimes, StartTimes] = disc2rate(Compounding, Disc,...
EndDates, StartDates, ValuationDate);
```

Arrange the results in a matrix convenient to display.

```
Result = [StartTimes, EndTimes, Rates]
```

```
Result =

         0    1.0000    0.0500
         0    2.0000    0.0560
         0    3.0000    0.0600
         0    4.0000    0.0650
         0    5.0000    0.0750
```

As with `rate2disc`, the relationship between rates and discount factors is determined by time periods and not by absolute dates. So, the alternate syntax for `disc2rate` uses time vectors instead of dates, and it assumes that the valuation date corresponds to time = 0. The time-based calling syntax is:

```
Rates = disc2rate(Compounding, Disc, EndTimes, StartTimes);
```

Using this syntax, you again obtain the original values for the interest rates.

```
Rates = disc2rate(Compounding, Disc, EndTimes, StartTimes)
```

```
Rates =

    0.0500
    0.0560
    0.0600
    0.0650
    0.0750
```

Interest-Rate Term Conversions

Interest-rate evolution is typically represented by a set of interest rates, including the beginning and end of the periods the rates apply to. For zero rates, the start dates are typically at the valuation date, with the rates extending from that valuation date until their respective maturity dates.

Spot Curve to Forward Curve Conversion

Frequently, given a set of rates including their start and end dates, you may be interested in finding the rates applicable to different terms (periods). This problem is addressed by the function `ratetimes`. This function interpolates the interest rates given a change in the original terms. The syntax for calling `ratetimes` is

```
[Rates, EndTimes, StartTimes] = ratetimes(Compounding, RefRates, ...
RefEndDates, RefStartDates, EndDates, StartDates, ValuationDate);
```

where:

- `Compounding` represents the frequency at which the zero rates are compounded when annualized.
- `RefRates` is a vector of initial interest rates representing the interest rates applicable to the initial time intervals.
- `RefEndDates` is a vector of dates representing the end of the interest rate terms (period) applicable to `RefRates`.
- `RefStartDates` is a vector of dates representing the beginning of the interest rate terms applicable to `RefRates`.
- `EndDates` represent the maturity dates for which the interest rates are interpolated.
- `StartDates` represent the starting dates for which the interest rates are interpolated.
- `ValuationDate` is the date of observation, from which the `StartTimes` and `EndTimes` are calculated. This date represents time = 0.

The input arguments to this function can be separated into two groups:

- The initial or reference interest rates, including the terms for which they are valid
- Terms for which the new interest rates are calculated

As an example, consider the rate table specified in “Calculating Discount Factors from Rates” on page 2-48.

From	To	Rate
15 Feb 2000	15 Aug 2000	0.05
15 Feb 2000	15 Feb 2001	0.056
15 Feb 2000	15 Aug 2001	0.06
15 Feb 2000	15 Feb 2002	0.065
15 Feb 2000	15 Aug 2002	0.075

Assuming that the valuation date is February 15, 2000, these rates represent zero-coupon bond rates with maturities specified in the second column. Use the function `ratetimes` to calculate the forward rates at the beginning of all periods implied in the table. Assume a compounding value of 2.

```
% Reference Rates.
RefStartDates = ['15-Feb-2000'];
RefEndDates  = ['15-Aug-2000'; '15-Feb-2001'; '15-Aug-2001';...
'15-Feb-2002'; '15-Aug-2002'];
Compounding = 2;
ValuationDate = ['15-Feb-2000'];
RefRates = [0.05; 0.056; 0.06; 0.065; 0.075];

% New Terms.
StartDates = ['15-Feb-2000'; '15-Aug-2000'; '15-Feb-2001';...
'15-Aug-2001'; '15-Feb-2002'];
EndDates =   ['15-Aug-2000'; '15-Feb-2001'; '15-Aug-2001';...
'15-Feb-2002'; '15-Aug-2002'];
% Find the new rates.
Rates = ratetimes(Compounding, RefRates, RefEndDates,...
RefStartDates, EndDates, StartDates, ValuationDate)
```

```
Rates =

    0.0500
    0.0620
    0.0680
    0.0801
    0.1155
```

Place these values in a table like the previous one. Observe the evolution of the forward rates based on the initial zero-coupon rates.

From	To	Rate
15 Feb 2000	15 Aug 2000	0.0500
15 Aug 2000	15 Feb 2001	0.0620
15 Feb 2001	15 Aug 2001	0.0680
15 Aug 2001	15 Feb 2002	0.0801
15 Feb 2002	15 Aug 2002	0.1155

Alternative Syntax (ratetimes)

The `ratetimes` function can provide the additional output arguments `StartTimes` and `EndTimes`, which represent the time factor equivalents to the `StartDates` and `EndDates` vectors. The `ratetimes` function uses time factors for interpolating the rates. These time factors are calculated from the start and end dates, and the valuation date, which are passed as input arguments. `ratetimes` can also use time factors directly, assuming time = 0 as the valuation date. This alternate syntax is:

```
[Rates, EndTimes, StartTimes] = ratetimes(Compounding, RefRates, RefEndTimes,
RefStartTimes, EndTimes, StartTimes);
```

Use this alternate version of `ratetimes` to find the forward rates again. In this case, you must first find the time factors of the reference curve. Use `date2time` for this.

```
RefEndTimes = date2time(ValuationDate, RefEndDates, Compounding)
```

```
RefEndTimes =
```

```
     1
     2
     3
     4
     5

RefStartTimes = date2time(ValuationDate, RefStartDates, ...
Compounding)

RefStartTimes =

     0
```

These are the expected values, given semiannual discounts (as denoted by a value of 2 in the variable `Compounding`), end dates separated by six-month periods, and the valuation date equal to the date marking beginning of the first period (time factor = 0).

Now call `ratetimes` with the alternate syntax.

```
StartDates = ['15-Feb-2000'];
EndDates  = ['15-Aug-2000'; '15-Feb-2001'; '15-Aug-2001';...
'15-Feb-2002'; '15-Aug-2002'];
Compounding = 2;
ValuationDate = ['15-Feb-2000'];
Rates = [0.05; 0.056; 0.06; 0.065; 0.075];
[Disc, EndTimes, StartTimes] = rate2disc(Compounding, Rates,...
EndDates, StartDates, ValuationDate);

[Rates, EndTimes, StartTimes] = ratetimes(Compounding,...
RefRates, RefEndTimes, RefStartTimes, EndTimes, StartTimes)

Rates =

    0.0500
    0.0560
    0.0600
    0.0650
    0.0750

EndTimes =

     1
     2
     3
     4
     5

StartTimes =

     0
     0
     0
     0
     0
```

`EndTimes` and `StartTimes` have, as expected, the same values they had as input arguments.

```
Times = [StartTimes, EndTimes]

Times =

     0     1
     1     2
     2     3
     3     4
     4     5
```

Modeling the Interest-Rate Term Structure

Financial Instruments Toolbox includes a set of functions to encapsulate interest-rate term information into a single structure. These functions present a convenient way to package all information related to interest-rate terms into a common format, and to resolve interdependencies when one or more of the parameters is modified. For information, see:

- "Creating or Modifying (intenvset)" on page 2-57 for a discussion of how to create or modify an interest-rate term structure (`RateSpec`) using the `intenvset` function
- "Obtaining Specific Properties (intenvget)" on page 2-58 for a discussion of how to extract specific properties from a `RateSpec`

Creating or Modifying (intenvset)

The main function to create or modify an interest-rate term structure `RateSpec` (rates specification) is `intenvset`. If the first argument to this function is a previously created `RateSpec`, the function modifies the existing rate specification and returns a new one. Otherwise, it creates a `RateSpec`.

When using `RateSpec` to specify the rate term structure to price instruments based on yields (zero coupon rates) or forward rates, specify zero rates or forward rates as the input argument. However, the `RateSpec` structure is not limited or specific to this problem domain. `RateSpec` is an encapsulation of rates-times relationships; `intenvset` acts as either a constructor or a modifier, and `intenvget` as an accessor. The interest rate models supported by the Financial Instruments Toolbox software work either with zero coupon rates or forward rates.

The other `intenvset` arguments are name-value pairs. The name-value pair arguments that can be specified or modified are:

- `Basis`
- `Compounding`
- `Disc`
- `EndDates`
- `EndMonthRule`
- `Rates`
- `StartDates`
- `ValuationDate`

For more information on `Basis`, see "Basis" on page 2-228.

Consider again the original table of interest rates (see "Calculating Discount Factors from Rates" on page 2-48).

From	To	Rate
15 Feb 2000	15 Aug 2000	0.05
15 Feb 2000	15 Feb 2001	0.056
15 Feb 2000	15 Aug 2001	0.06
15 Feb 2000	15 Feb 2002	0.065

From	To	Rate
15 Feb 2000	15 Aug 2002	0.075

Use the information in this table to populate the RateSpec structure.

```
StartDates = ['15-Feb-2000'];
EndDates =   ['15-Aug-2000';
              '15-Feb-2001';
              '15-Aug-2001';
              '15-Feb-2002';
              '15-Aug-2002'];
Compounding = 2;
ValuationDate = ['15-Feb-2000'];
Rates = [0.05; 0.056; 0.06; 0.065; 0.075];

rs = intenvset('Compounding',Compounding,'StartDates',...
StartDates, 'EndDates', EndDates, 'Rates', Rates,...
'ValuationDate', ValuationDate)

rs =

       FinObj:    'RateSpec'
  Compounding:    2
         Disc:    [5x1 double]
        Rates:    [5x1 double]
     EndTimes:    [5x1 double]
   StartTimes:    [5x1 double]
     EndDates:    [5x1 double]
   StartDates:    730531
ValuationDate:    730531
        Basis: 0
 EndMonthRule: 1
```

Some of the properties filled in the structure were not passed explicitly in the call to RateSpec. The values of the automatically completed properties depend on the properties that are explicitly passed. Consider for example the StartTimes and EndTimes vectors. Since the StartDates and EndDates vectors are passed in, and the ValuationDate, intenvset has all the information required to calculate StartTimes and EndTimes. Hence, these two properties are read-only.

Obtaining Specific Properties (intenvget)

The complementary function to intenvset is intenvget, which gets function-specific properties from the interest-rate term structure. Its syntax is:

```
ParameterValue = intenvget(RateSpec, 'ParameterName')
```

To obtain the vector EndTimes from the RateSpec structure, enter:

```
EndTimes = intenvget(rs, 'EndTimes')

EndTimes =

     1
     2
     3
```

```
     4
     5
```

To obtain `Disc`, the values for the discount factors that were calculated automatically by `intenvset`, type:

```
Disc = intenvget(rs, 'Disc')
```

```
Disc =

    0.9756
    0.9463
    0.9151
    0.8799
    0.8319
```

These discount factors correspond to the periods starting from `StartDates` and ending in `EndDates`.

Caution Although you can directly access these fields within the structure instead of using `intenvget`, it is advised not to do so. The format of the interest-rate term structure could change in future versions of the toolbox. Should that happen, any code accessing the `RateSpec` fields directly would stop working.

Now use the `RateSpec` structure with its functions to examine how changes in specific properties of the interest-rate term structure affect those depending on it. As an exercise, change the value of `Compounding` from 2 (semiannual) to 1 (annual).

```
rs = intenvset(rs, 'Compounding', 1);
```

Since `StartTimes` and `EndTimes` are measured in units of periodic discount, a change in `Compounding` from 2 to 1 redefines the basic unit from semiannual to annual. This means that a period of six months is represented with a value of `0.5`, and a period of one year is represented by `1`. To obtain the vectors `StartTimes` and `EndTimes`, enter:

```
StartTimes = intenvget(rs, 'StartTimes');
EndTimes = intenvget(rs, 'EndTimes');
Times = [StartTimes, EndTimes]
```

```
Times =

         0    0.5000
         0    1.0000
         0    1.5000
         0    2.0000
         0    2.5000
```

Since all the values in `StartDates` are the same as the valuation date, all `StartTimes` values are 0. On the other hand, the values in the `EndDates` vector are dates separated by six-month periods. Since the redefined value of compounding is 1, `EndTimes` becomes a sequence of numbers separated by increments of 0.5.

Pricing Using Interest-Rate Term Structure

In this section...

Introduction

The instruments can be presented to the functions as a portfolio of different types of instruments or as groups of instruments of the same type. The current version of the toolbox can compute price and sensitivities for five instrument types of using interest-rate curves:

- Bonds
- Fixed-rate notes
- Floating-rate notes
- Swaps
- OAS for callable and puttable bonds
- Agency OAS

In addition to these instruments, the toolbox also supports the calculation of price and sensitivities of arbitrary sets of cash flows.

Options and interest-rate floors and caps are absent from the above list of supported instruments. These instruments are not supported because their pricing and sensitivity function require a stochastic model for the evolution of interest rates. The interest-rate term structure used for pricing is treated as deterministic, and as such is not adequate for pricing these instruments.

Financial Instruments Toolbox also contains functions that use the Heath-Jarrow-Morton (HJM) and Black-Derman-Toy (BDT) models to compute prices and sensitivities for financial instruments. These models support computations involving options and interest-rate floors and caps. See “Pricing Using Interest-Rate Tree Models” on page 2-81 for information on computing price and sensitivities of financial instruments using the HJM and BDT models.

Computing Instrument Prices

The main function used for pricing portfolios of instruments is `intenvprice`. This function works with the family of functions that calculate the prices of individual types of instruments. When called, `intenvprice` classifies the portfolio contained in `InstSet` by instrument type, and calls the appropriate pricing functions. The map between instrument types and the pricing function `intenvprice` calls is

`bondbyzero`:	Price a bond by a set of zero curves
`fixedbyzero`:	Price a fixed-rate note by a set of zero curves
`floatbyzero`:	Price a floating-rate note by a set of zero curves

`swapbyzero`:	Price a swap by a set of zero curves

You can use each of these functions individually to price an instrument. Consult the reference pages for specific information on using these functions.

`intenvprice` takes as input an interest-rate term structure created with `intenvset`, and a portfolio of interest-rate contingent derivatives instruments created with `instadd`.

The syntax for using `intenvprice` to price an entire portfolio is

```
Price = intenvprice(RateSpec, InstSet)
```

where:

- `RateSpec` is the interest-rate term structure.
- `InstSet` is the name of the portfolio.

Example: Pricing a Portfolio of Instruments

Consider this example of using the `intenvprice` function to price a portfolio of instruments supplied with Financial Instruments Toolbox software.

The provided MAT-file `deriv.mat` stores a portfolio as an instrument set variable `ZeroInstSet`. The MAT-file also contains the interest-rate term structure `ZeroRateSpec`. You can display the instruments with the function `instdisp`.

```
load deriv.mat;
instdisp(ZeroInstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis...
1     Bond 0.04       01-Jan-2000    01-Jan-2003    1      NaN...
2     Bond 0.04       01-Jan-2000    01-Jan-2004    2      NaN...

Index Type  CouponRate Settle      Maturity    FixedReset Basis...
3     Fixed 0.04       01-Jan-2000 01-Jan-2003 1          NaN...

Index Type  Spread Settle         Maturity       FloatReset Basis...
4     Float 20     01-Jan-2000    01-Jan-2003    1          NaN...

Index Type LegRate    Settle         Maturity       LegReset Basis...
5     Swap [0.06 20]  01-Jan-2000    01-Jan-2003    [1  1]   NaN...
```

Use `intenvprice` to calculate the prices for the instruments contained in the portfolio `ZeroInstSet`.

```
format bank
Prices = intenvprice(ZeroRateSpec, ZeroInstSet)
```

```
Prices =

         98.72
         97.53
         98.72
        100.55
          3.69
```

The output `Prices` is a vector containing the prices of all the instruments in the portfolio in the order indicated by the `Index` column displayed by `instdisp`. So, the first two elements in `Prices` correspond to the first two bonds; the third element corresponds to the fixed-rate note; the fourth to the floating-rate note; and the fifth element corresponds to the price of the swap.

Computing Instrument Sensitivities

In general, you can compute sensitivities either as dollar price changes or as percentage price changes. The toolbox reports all sensitivities as dollar sensitivities.

Using the interest-rate term structure, you can calculate two types of derivative price sensitivities, delta and gamma. *Delta* represents the dollar sensitivity of prices to shifts in the observed forward yield curve. *Gamma* represents the dollar sensitivity of delta to shifts in the observed forward yield curve.

The `intenvsens` function computes instrument sensitivities and instrument prices. If you need both the prices and sensitivity measures, use `intenvsens`. A separate call to `intenvprice` is not required.

Here is the syntax

```
[Delta, Gamma, Price] = intenvsens(RateSpec, InstSet)
```

where, as before:

- `RateSpec` is the interest-rate term structure.
- `InstSet` is the name of the portfolio.

Example: Sensitivities and Prices

Here is an example that uses `intenvsens` to calculate both sensitivities and prices.

```
format bank
load deriv.mat;
[Delta, Gamma, Price] = intenvsens(ZeroRateSpec, ZeroInstSet);
```

Display the results in a single matrix in bank format.

```
All = [Delta Gamma Price]
```

```
All =

       -272.64       1029.84         98.72
       -347.44       1622.65         97.53
       -272.64       1029.84         98.72
         -1.04          3.31        100.55
       -282.04       1059.62          3.69
```

To view the per-dollar sensitivity, divide the first two columns by the last one.

```
[Delta./Price, Gamma./Price, Price]
```

```
ans =

         -2.76         10.43         98.72
         -3.56         16.64         97.53
         -2.76         10.43         98.72
         -0.01          0.03        100.55
        -76.39        286.98          3.69
```

OAS for Callable and Puttable Bonds

Option Adjusted Spread (OAS) is a useful way to value and compare securities with embedded options, like callable or puttable bonds. Basically, when the constant or flat spread is added to the interest-rate curve/rates in the tree, the pricing model value equals the market price. Financial Instruments Toolbox supports pricing American, European, and Bermuda callable and puttable bonds using different interest rate models. The pricing for a bond with embedded options is:

- For a callable bond, where the holder has bought a bond and sold a call option to the issuer:

  `Price callable bond = Price Option free bond − Price call option`
- For a puttable bond, where the holder has bought a bond and a put option:

  `Price puttable bond = Price Option free bond + Price put option`

There are two additional sensitivities related to OAS for bonds with embedded options: Option Adjusted Duration and Option Adjusted Convexity. These are similar to the concepts of modified duration and convexity for option-free bonds. The measure Duration is a general term that describes how sensitive a bond's price is to a parallel shift in the yield curve. Modified Duration and Modified Convexity assume that the bond's cash flows do not change when the yield curve shifts. This is not true for OA Duration or OA Convexity because the cash flows may change due to the option risk component of the bond.

Function	Purpose
`oasbybdt`	Compute OAS using a BDT model.
`oasbybk`	Compute OAS using a BK model.
`oasbyhjm`	Compute OAS using an HJM model.
`oasbyhw`	Compute OAS using an HW model.

Agency OAS

Often bonds are issued with embedded options, which then makes standard price/yield or spread measures irrelevant. For example, a municipality concerned about the chance that interest rates may fall in the future might issue bonds with a provision that allows the bond to be repaid before the bond's maturity. This is a call option on the bond and must be incorporated into the valuation of the bond. Option-adjusted spread (OAS), which adjusts a bond spread for the value of the option, is the standard measure for valuing bonds with embedded options. Financial Instruments Toolbox supports computing option-adjusted spreads for bonds with single embedded options using the agency model.

The Securities Industry and Financial Markets Association (SIFMA) has a simplified approach to compute OAS for agency issues (Government Sponsored Entities like Fannie Mae and Freddie Mac) termed "Agency OAS." In this approach, the bond has only one call date (European call) and uses Black's model (see *The BMA European Callable Securities Formula* at https://www.sifma.org) to value the bond option. The price of the bond is computed as follows:

$\texttt{Price}_{\text{Callable}} = \texttt{Price}_{\text{NonCallable}} - \texttt{Price}_{\text{Option}}$

where

$\texttt{Price}_{\text{Callable}}$ is the price of the callable bond.

$\texttt{Price}_{\text{NonCallable}}$ is the price of the noncallable bond, that is, price of the bond using `bndspread`.

$Price_{Option}$ is the price of the option, that is, price of the option using Black's model.

The Agency OAS is the spread, when used in the previous formula, yields the market price. Financial Instruments Toolbox supports these functions:

Agency OAS

Agency OAS Functions	Purpose
`agencyoas`	Compute the OAS of the callable bond using the Agency OAS model.
`agencyprice`	Price the callable bond OAS using the Agency OAS model.

For more information on agency OAS, see "Agency Option-Adjusted Spreads" on page 6-2.

Understanding Interest-Rate Tree Models

In this section...

Introduction

Financial Instruments Toolbox supports the following interest-rate trees:

- Black-Derman-Toy (BDT)
- Black-Karasinski (BK)
- Heath-Jarrow-Morton (HJM)
- Hull-White (HW)
- Cox-Ingersoll-Ross (CIR)

The Heath-Jarrow-Morton model is one of the most widely used models for pricing interest-rate derivatives. The model considers a given initial term structure of interest rates and a specification of the volatility of forward rates to build a tree representing the evolution of the interest rates, based on a statistical process. For further explanation, see the book *Modelling Fixed Income Securities and Interest Rate Options* by Robert A. Jarrow.

The Black-Derman-Toy model is another analytical model commonly used for pricing interest-rate derivatives. The model considers a given initial zero rate term structure of interest rates and a specification of the yield volatilities of long rates to build a tree representing the evolution of the interest rates. For further explanation, see the paper "A One Factor Model of Interest Rates and its Application to Treasury Bond Options" by Fischer Black, Emanuel Derman, and William Toy.

The Hull-White model incorporates the initial term structure of interest rates and the volatility term structure to build a trinomial recombining tree of short rates. The resulting tree is used to value interest rate-dependent securities. The implementation of the Hull-White model in Financial Instruments Toolbox software is limited to one factor.

The Black-Karasinski model is a single factor, log-normal version of the Hull-White model.

For further information on the Hull-White and Black-Karasinski models, see the book *Options, Futures, and Other Derivatives* by John C. Hull.

Building a Tree of Forward Rates

The tree of forward rates is the fundamental unit representing the evolution of interest rates in a given period of time. This section explains how to create a forward-rate tree using Financial Instruments Toolbox.

Note To avoid needless repetition, this document uses the HJM and BDT models to illustrate the creation and use of interest-rate trees. The HW and BK models are similar to the BDT model. Where specific differences exist, they are documented in “HW and BK Tree Structures” on page 2-77.

The MATLAB functions that create rate trees are `hjmtree` and `bdttree`. The `hjmtree` function creates the structure, `HJMTree`, containing time and forward-rate information for a bushy tree. The `bdttree` function creates a similar structure, `BDTTree`, for a recombining tree.

This structure is a self-contained unit that includes the tree of rates (found in the `FwdTree` field of the structure) and the volatility, rate, and time specifications used in building this tree.

These functions take three structures as input arguments:

- The volatility model `VolSpec`. (See “Specifying the Volatility Model (VolSpec)” on page 2-68.)
- The interest-rate term structure `RateSpec`. (See “Specifying the Interest-Rate Term Structure (RateSpec)” on page 2-70.)
- The tree time layout `TimeSpec`. (See “Specifying the Time Structure (TimeSpec)” on page 2-70.)

An easy way to visualize any trees you create is with the `treeviewer` function, which displays trees in a graphical manner. See “Graphical Representation of Trees” on page 2-219 for information about `treeviewer`.

Calling Sequence

The calling syntax for `hjmtree` is `HJMTree = hjmtree(VolSpec, RateSpec, TimeSpec)`.

Similarly, the calling syntax for `bdttree` is `BDTTree = bdttree(VolSpec, RateSpec, TimeSpec)`.

Each of these functions requires `VolSpec`, `RateSpec`, and `TimeSpec` input arguments:

- `VolSpec` is a structure that specifies the forward-rate volatility process. You create `VolSpec` using either of the functions `hjmvolspec` or `bdtvolspec`.

  The `hjmvolspec` function supports the specification of up to three factors. It handles these models for the volatility of the interest-rate term structure:

  - Constant
  - Stationary
  - Exponential
  - Vasicek
  - Proportional

  A one-factor model assumes that the interest term structure is affected by a single source of uncertainty. Incorporating multiple factors allows you to specify different types of shifts in the shape and location of the interest-rate structure. See `hjmvolspec` for details.

  The `bdtvolspec` function supports only a single volatility factor. The volatility remains constant between pairs of nodes on the tree. You supply the input volatility values in a vector of decimal values. See `bdtvolspec` for details.
- `RateSpec` is the interest-rate specification of the initial rate curve. You create this structure with the function `intenvset`. (See “Modeling the Interest-Rate Term Structure” on page 2-57.)

- `TimeSpec` is the tree time layout specification. You create this variable with the functions `hjmtimespec` or `bdttimespec`. It represents the mapping between level times and level dates for rate quoting. This structure indirectly determines the number of levels in the tree.

Specifying the Volatility Model (VolSpec)

Because HJM supports multifactor (up to 3) volatility models while BDT (also, BK and HW) supports only a single volatility factor, the `hjmvolspec` and `bdtvolspec` functions require different inputs and generate slightly different outputs. For examples, see “Creating an HJM Volatility Model” on page 2-68. For BDT examples, see “Creating a BDT Volatility Model” on page 2-69.

Creating an HJM Volatility Model

The function `hjmvolspec` generates the structure `VolSpec`, which specifies the volatility process $\sigma(t, T)$ used in the creation of the forward-rate trees. In this context capital T represents the starting time of the forward rate, and t represents the observation time. The volatility process can be constructed from a combination of factors specified sequentially in the call to function that creates it. Each factor specification starts with a character vector specifying the name of the factor, followed by the pertinent parameters.

HJM Volatility Specification Example

Consider an example that uses a single factor, specifically, a constant-sigma factor. The constant factor specification requires only one parameter, the value of σ. In this case, the value corresponds to 0.10.

```
HJMVolSpec = hjmvolspec('Constant', 0.10)
```

```
HJMVolSpec =

      FinObj: 'HJMVolSpec'
FactorModels: {'Constant'}
  FactorArgs: {{1x1 cell}}
  SigmaShift: 0
  NumFactors: 1
   NumBranch: 2
     PBranch: [0.5000 0.5000]
 Fact2Branch: [-1 1]
```

The `NumFactors` field of the `VolSpec` structure, `VolSpec.NumFactors = 1`, reveals that the number of factors used to generate `VolSpec` was one. The `FactorModels` field indicates that it is a `Constant` factor, and the `NumBranches` field indicates the number of branches. As a consequence, each node of the resulting tree has two branches, one going up, and the other going down.

Consider now a two-factor volatility process made from a proportional factor and an exponential factor.

```
% Exponential factor
Sigma_0 = 0.1;
Lambda = 1;
% Proportional factor
CurveProp = [0.11765; 0.08825; 0.06865];
CurveTerm = [   1   ;    2   ;    3   ];
% Build VolSpec
HJMVolSpec = hjmvolspec('Proportional', CurveProp, CurveTerm,...
1e6,'Exponential', Sigma_0, Lambda)
```

```
HJMVolSpec =
```

```
      FinObj: 'HJMVolSpec'
FactorModels: {'Proportional'  'Exponential'}
  FactorArgs: {{1x3 cell}  {1x2 cell}}
  SigmaShift: 0
  NumFactors: 2
   NumBranch: 3
     PBranch: [0.2500 0.2500 0.5000]
 Fact2Branch: [2x3 double]
```

The output shows that the volatility specification was generated using two factors. The tree has three branches per node. Each branch has probabilities of 0.25, 0.25, and 0.5, going from top to bottom.

Creating a BDT Volatility Model

The function `bdtvolspec` generates the structure `VolSpec`, which specifies the volatility process. The function requires three input arguments:

- The valuation date `ValuationDate`
- The yield volatility end dates `VolDates`
- The yield volatility values `VolCurve`

An optional fourth argument `InterpMethod`, specifying the interpolation method, can be included.

The syntax used for calling `bdtvolspec` is:

```
BDTVolSpec = bdtvolspec(ValuationDate, VolDates, VolCurve,... InterpMethod)
```

where:

- `ValuationDate` is the first observation date in the tree.
- `VolDates` is a vector of dates representing yield volatility end dates.
- `VolCurve` is a vector of yield volatility values.
- `InterpMethod` is the method of interpolation to use. The default is `linear`.

BDT Volatility Specification Example

Consider the following example:

```
ValuationDate = datetime(2000,1,1);
EndDates = [datetime(2001,1,1) ; datetime(2002,1,1) ; datetime(2003,1,1) ;datetime(2004,1,1) ; da
Volatility = [.2; .19; .18; .17; .16];
```

Use `bdtvolspec` to create a volatility specification. Because no interpolation method is explicitly specified, the function uses the `linear` default.

```
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
BDTVolSpec =
             FinObj: 'BDTVolSpec'
      ValuationDate: 730486
           VolDates: [5x1 double]
           VolCurve: [5x1 double]
    VolInterpMethod: 'linear'
```

Specifying the Interest-Rate Term Structure (RateSpec)

The structure `RateSpec` is an interest term structure that defines the initial forward-rate specification from which the tree rates are derived. “Modeling the Interest-Rate Term Structure” on page 2-57 explains how to create these structures using the function `intenvset`, given the interest rates, the starting and ending dates for each rate, and the compounding value.

Rate Specification Creation Example

Consider the following example:

```
Compounding = 1;
Rates = [0.02; 0.02; 0.02; 0.02];
StartDates = ['01-Jan-2000';
              '01-Jan-2001';
              '01-Jan-2002';
              '01-Jan-2003'];
EndDates =   ['01-Jan-2001';
              '01-Jan-2002';
              '01-Jan-2003';
              '01-Jan-2004'];
ValuationDate = '01-Jan-2000';

RateSpec = intenvset('Compounding',1,'Rates', Rates,...
'StartDates', StartDates, 'EndDates', EndDates,...
'ValuationDate', ValuationDate)
```

```
RateSpec =

        FinObj: 'RateSpec'
   Compounding: 1
          Disc: [4x1 double]
         Rates: [4x1 double]
       EndTimes: [4x1 double]
     StartTimes: [4x1 double]
       EndDates: [4x1 double]
     StartDates: [4x1 double]
 ValuationDate: 730486
         Basis: 0
  EndMonthRule: 1
```

Use the function `datedisp` to examine the dates defined in the variable `RateSpec`. For example:

```
datedisp(RateSpec.ValuationDate)
```

```
01-Jan-2000
```

Specifying the Time Structure (TimeSpec)

The structure `TimeSpec` specifies the time structure for an interest-rate tree. This structure defines the mapping between the observation times at each level of the tree and the corresponding dates.

`TimeSpec` is built using either the `hjmtimespec` or `bdttimespec` function. These functions require three input arguments:

- The valuation date `ValuationDate`

- The maturity date `Maturity`
- The compounding rate `Compounding`

For example, the syntax used for calling `hjmtimespec` is

```
TimeSpec = hjmtimespec(ValuationDate, Maturity, Compounding)
```

where:

- `ValuationDate` is the first observation date in the tree.
- `Maturity` is a vector of dates representing the cash flow dates of the tree. Any instrument cash flows with these maturities fall on tree nodes.
- `Compounding` is the frequency at which the rates are compounded when annualized.

Creating a Time Specification

Calling the time specification creation functions with the same data used to create the interest-rate term structure, `RateSpec` on page 2-70 builds the structure that specifies the time layout for the tree.

HJM Time Specification Example

Consider the following example:

```
Maturity = EndDates;
HJMTimeSpec = hjmtimespec(ValuationDate, Maturity, Compounding)

HJMTimeSpec =

       FinObj: 'HJMTimeSpec'
ValuationDate: 730486
     Maturity: [4x1 double]
  Compounding: 1
        Basis: 0
 EndMonthRule: 1
```

Maturities specified when building `TimeSpec` need not coincide with the `EndDates` of the rate intervals in `RateSpec`. Since `TimeSpec` defines the time-date mapping of the tree, the rates in `RateSpec` are interpolated to obtain the initial rates with maturities equal to those in `TimeSpec`.

Creating a BDT Time Specification

Consider the following example:

```
Maturity = EndDates;
BDTTimeSpec = bdttimespec(ValuationDate, Maturity, Compounding)

BDTTimeSpec =

           FinObj: 'BDTTimeSpec'
    ValuationDate: 730486
         Maturity: [4x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Creating Trees

Use the `VolSpec`, `RateSpec`, and `TimeSpec` you have previously created as inputs to the functions used to create HJM and BDT trees.

Creating an HJM Tree

```
% Reset the volatility factor to the Constant case
HJMVolSpec = hjmvolspec('Constant', 0.10);

HJMTree = hjmtree(HJMVolSpec, RateSpec, HJMTimeSpec)
```

```
HJMTree =

  FinObj: 'HJMFwdTree'
 VolSpec: [1x1 struct]
TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    TFwd: {[4x1 double] [3x1 double] [2x1 double] [3]}
  CFlowT: {[4x1 double] [3x1 double] [2x1 double] [4]}
 FwdTree:{[4x1 double][3x1x2 double][2x2x2 double][1x4x2 double]}
```

Creating a BDT Tree

Now use the previously computed values for `VolSpec`, `RateSpec`, and `TimeSpec` as input to the function `bdttree` to create a BDT tree.

```
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree =

  FinObj: 'BDTFwdTree'
 VolSpec: [1x1 struct]
TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
    tObs: [0 1.00 2.00 3.00]
    TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3.00]}
  CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4.00]}
 FwdTree: {[1.02] [1.02 1.02] [1.01 1.02 1.03] [1.01 1.02 1.02 1.03]}
```

Examining Trees

When working with the models, Financial Instruments Toolbox uses trees to represent forward rates, prices, and so on. At the highest level, these trees have structures wrapped around them. The structures encapsulate information required to interpret completely the information contained in a tree.

Consider this example, which uses the interest rate and portfolio data in the MAT-file `deriv.mat` included in the toolbox.

Load the data into the MATLAB workspace.

```
load deriv.mat
```

Display the list of the variables loaded from the MAT-file.

```
whos
```

```
 Name             Size           Bytes  Class     Attributes
```

```
  BDTInstSet       1x1            15956  struct
  BDTTree          1x1             5138  struct
  BKInstSet        1x1            15946  struct
  BKTree           1x1             5904  struct
  CRRInstSet       1x1            12434  struct
  CRRTree          1x1             5058  struct
  EQPInstSet       1x1            12434  struct
  EQPTree          1x1             5058  struct
  HJMInstSet       1x1            15948  struct
  HJMTree          1x1             5838  struct
  HWInstSet        1x1            15946  struct
  HWTree           1x1             5904  struct
  ITTInstSet       1x1            12438  struct
  ITTTree          1x1             8862  struct
  ZeroInstSet      1x1            10282  struct
  ZeroRateSpec     1x1             1580  struct
```

HJM Tree Structure

You can now examine in some detail the contents of the `HJMTree` structure contained in this file.

```
HJMTree
```

```
HJMTree =

  FinObj: 'HJMFwdTree'
 VolSpec: [1x1 struct]
TimeSpec: [1x1 struct]
RateSpec: [1x1 struct]
    tObs: [0 1 2 3]
    TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
  CFlowT: {[4x1 double]  [3x1 double]  [2x1 double] [4]}
 FwdTree:{[4x1 double][3x1x2 double][2x2x2 double][1x4x2 double]}
```

`FwdTree` contains the actual forward-rate tree. MATLAB represents it as a cell array with each cell array element containing a tree level.

The other fields contain other information relevant to interpreting the values in `FwdTree`. The most important are `VolSpec`, `TimeSpec`, and `RateSpec`, which contain the volatility, time structure, and rate structure information respectively.

First Node

Observe the forward rates in `FwdTree`. The first node represents the valuation date, `tObs = 0`.

```
HJMTree.FwdTree{1}
```

```
ans =

   1.0356
   1.0468
   1.0523
   1.0563
```

Note Financial Instruments Toolbox uses *inverse discount* notation for forward rates in the tree. An inverse discount represents a factor by which the current value of an asset is multiplied to find its future value. In general, these forward factors are reciprocals of the discount factors.

Look closely at the `RateSpec` structure used in generating this tree to see where these values originate. Arrange the values in a single array.

```
[HJMTree.RateSpec.StartTimes HJMTree.RateSpec.EndTimes...
HJMTree.RateSpec.Rates]
```

```
ans =

         0    1.0000    0.0356
    1.0000    2.0000    0.0468
    2.0000    3.0000    0.0523
    3.0000    4.0000    0.0563
```

If you find the corresponding inverse discounts of the interest rates in the third column, you have the values at the first node of the tree. You can turn interest rates into inverse discounts using the function `rate2disc`.

```
Disc = rate2disc(HJMTree.TimeSpec.Compounding,...
HJMTree.RateSpec.Rates, HJMTree.RateSpec.EndTimes,...
HJMTree.RateSpec.StartTimes);
FRates = 1./Disc
```

```
FRates =
    1.0356
    1.0468
    1.0523
    1.0563
```

Second Node

The second node represents the first-rate observation time, `tObs = 1`. This node displays two states: one representing the branch going up and the other representing the branch going down.

Note that `HJMTree.VolSpec.NumBranch = 2`.

```
HJMTree.VolSpec
```

```
ans =

          FinObj: 'HJMVolSpec'
    FactorModels: {'Constant'}
      FactorArgs: {{1x1 cell}}
      SigmaShift: 0
      NumFactors: 1
       NumBranch: 2
         PBranch: [0.5000 0.5000]
     Fact2Branch: [-1 1]
```

Examine the rates of the node corresponding to the up branch.

```
HJMTree.FwdTree{2}(:,:,1)
```

```
ans =

    1.0364
    1.0420
    1.0461
```

Now examine the corresponding down branch.

```
HJMTree.FwdTree{2}(:,:,2)
```

```
ans =

    1.0574
```

```
    1.0631
    1.0672
```

Third Node

The third node represents the second observation time, `tObs = 2`. This node contains a total of four states, two representing the branches going up and the other two representing the branches going down. Examine the rates of the node corresponding to the up states.

```
HJMTree.FwdTree{3}(:,:,1)
```

```
ans =

    1.0317    1.0526
    1.0358    1.0568
```

Next examine the corresponding down states.

```
HJMTree.FwdTree{3}(:,:,2)
```

```
ans =

    1.0526    1.0738
    1.0568    1.0781
```

Isolating a Specific Node

Starting at the third level, indexing within the tree cell array becomes complex, and isolating a specific node can be difficult. The function `bushpath` isolates a specific node by specifying the path to the node as a vector of branches taken to reach that node. As an example, consider the node reached by starting from the root node, taking the branch up, then the branch down, and then another branch down. Given that the tree has only two branches per node, branches going up correspond to a 1, and branches going down correspond to a 2. The path up-down-down becomes the vector `[1 2 2]`.

```
FRates = bushpath(HJMTree.FwdTree, [1 2 2])
```

```
FRates =

    1.0356
    1.0364
    1.0526
    1.0674
```

`bushpath` returns the spot rates for all the nodes tapped by the path specified in the input argument, the first one corresponding to the root node, and the last one corresponding to the target node.

Isolating the same node using direct indexing obtains

```
HJMTree.FwdTree{4}(:, 3, 2)
```

```
ans =

    1.0674
```

As expected, this single value corresponds to the last element of the rates returned by `bushpath`.

You can use these techniques with any type of tree generated with Financial Instruments Toolbox, such as forward-rate trees or price trees.

BDT Tree Structure

You can now examine in some detail the contents of the BDTTree structure.

```
BDTTree
```

```
BDTTree =

      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1.00 2.00 3.00]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3.00]}
     CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4.00]}
    FwdTree: {[1.10]  [1.10 1.14]  [1.10 1.14 1.19]  [1.09 1.12 1.16 1.22]}
```

FwdTree contains the actual rate tree. MATLAB represents it as a cell array with each cell array element containing a tree level.

The other fields contain other information relevant to interpreting the values in FwdTree. The most important are VolSpec, TimeSpec, and RateSpec, which contain the volatility, time structure, and rate structure information respectively.

Look at the RateSpec structure used in generating this tree to see where these values originate. Arrange the values in a single array.

```
[BDTTree.RateSpec.StartTimes BDTTree.RateSpec.EndTimes...
BDTTree.RateSpec.Rates]
```

```
ans =

         0    1.0000    0.1000
         0    2.0000    0.1100
         0    3.0000    0.1200
         0    4.0000    0.1250
```

Look at the rates in FwdTree. The first node represents the valuation date, tObs = 0. The second node represents tObs = 1. Examine the rates at the second, third, and fourth nodes.

```
BDTTree.FwdTree{2}
```

```
ans =

      1.0979    1.1432
```

The second node represents the first observation time, tObs = 1. This node contains a total of two states, one representing the branch going up (1.0979) and the other representing the branch going down (1.1432).

Note The convention in this document is to display *prices* going up on the upper branch. So, when displaying *rates*, rates are falling on the upper branch and increasing on the lower branch.

```
BDTTree.FwdTree{3}
```

```
ans =

    1.0976    1.1377    1.1942
```

The third node represents the second observation time, t`Obs = 2`. This node contains a total of three states, one representing the branch going up (`1.0976`), one representing the branch in the middle (`1.1377`) and the other representing the branch going down (`1.1942`).

```
BDTTree.FwdTree{4}
```

```
ans =

    1.0872    1.1183    1.1606    1.2179
```

The fourth node represents the third observation time, `tObs = 3`. This node contains a total of four states, one representing the branch going up (`1.0872`), two representing the branches in the middle (`1.1183` and `1.1606`), and the other representing the branch going down (`1.2179`).

Isolating a Specific Node

The function `treepath` isolates a specific node by specifying the path to the node as a vector of branches taken to reach that node. As an example, consider the node reached by starting from the root node, taking the branch up, then the branch down, and finally another branch down. Given that the tree has only two branches per node, branches going up correspond to a 1, and branches going down correspond to a 2. The path up-down-down becomes the vector `[1 2 2]`.

```
FRates = treepath(BDTTree.FwdTree, [1 2 2])
```

```
FRates =

    1.1000
    1.0979
    1.1377
    1.1606
```

`treepath` returns the short rates for all the nodes tapped by the path specified in the input argument, the first one corresponding to the root node, and the last one corresponding to the target node.

HW and BK Tree Structures

The HW and BK tree structures are similar to the BDT tree structure. You can see this if you examine the sample HW tree contained in the file `deriv.mat`.

```
load deriv.mat;
HWTree
```

```
HWTree =

      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1.00 2.00 3.00]
        dObs: [731947.00 732313.00 732678.00 733043.00]
     CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4.00]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2.00]  [2.00 3.00 4.00]  [2.00 2.00 3.00 4.00 4.00]}
     FwdTree: {[1.03]  [1.05 1.04 1.02]  [1.08 1.07 1.05 1.03 1.01]  [1.09 1.08 1.06 1.04 1.02]
```

All fields of this structure are similar to their BDT counterparts. There are two additional fields not present in BDT: `Probs` and `Connect`. The `Probs` field represents the occurrence probabilities at each branch of each node in the tree. The `Connect` field describes the connectivity of the nodes of a given tree level to nodes to the next tree level.

Probs Field

While BDT and one-factor HJM models have equal probabilities for each branch at a node, HW and BK do not. For HW and BK trees, the `Probs` field indicates the likelihood that a particular branch will be taken in moving from one node to another node on the next level.

The `Probs` field consists of a cell array with one cell per tree level. Each cell is a 3-by-`NUMNODES` array with the top row representing the probability of an up movement, the middle row representing the probability of a middle movement, and the last row the probability of a down movement.

As an illustration, consider the first two elements of the `Probs` field of the structure, corresponding to the first (root) and second levels of the tree.

```
HWTree.Probs{1}
```

```
0.16666666666667
0.66666666666667
0.16666666666667
```

```
HWTree.Probs{2}
```

```
0.12361333418768   0.16666666666667   0.21877591615172
0.65761074966060   0.66666666666667   0.65761074966060
0.21877591615172   0.16666666666667   0.12361333418768
```

Reading from top to bottom, the values in `HWTree.Probs{1}` correspond to the up, middle, and down probabilities at the root node.

`HWTree.Probs{2}` is a 3-by-3 matrix of values. The first column represents the top node, the second column represents the middle node, and the last column represents the bottom node. As with the root node, the first, second, and third rows hold the values for up, middle, and down branching off each node.

As expected, the sum of all the probabilities at any node equals 1.

```
sum(HWTree.Probs{2})
```

```
1.0000    1.0000    1.0000
```

Connect Field

The other field that distinguishes HW and BK tree structures from the BDT tree structure is `Connect`. This field describes how each node in a given level connects to the nodes of the next level. The need for this field arises from the possibility of nonstandard branching in a tree.

The `Connect` field of the HW tree structure consists of a cell array with one cell per tree level.

```
HWTree.Connect
```

```
ans =

    [2]    [1x3 double]    [1x5 double]
```

Each cell contains a 1-by-`NUMNODES` vector. Each value in the vector relates to a node in the corresponding tree level and represents the index of the node in the next tree level that the middle branch of the node connects to.

If you subtract 1 from the values contained in `Connect`, you reveal the index of the nodes in the next level that the up branch connects to. If you add `1` to the values, you reveal the index of the corresponding down branch.

As an illustration, consider `HWTree.Connect{1}`:

```
HWTree.Connect{1}

ans =

     2
```

This indicates that the middle branch of the root node connects to the second (from the top) node of the next level, as expected. If you subtract `1` from this value, you obtain `1`, which tells you that the up branch goes to the top node. If you add `1`, you obtain `3`, which points to the last node of the second level of the tree.

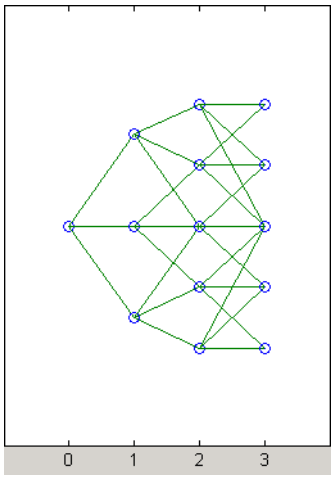
Now consider level 3 in this example:

```
HWTree.Connect{3}

2     2     3     4     4
```

On this level, there is nonstandard branching. This can be easily recognized because the middle branch of two nodes is connected to the same node on the next level.

To visualize this, consider the following illustration of the tree.



Here it becomes apparent that there is nonstandard branching at the third level of the tree, on the top and bottom nodes. The first and second nodes connect to the same trio of nodes on the next level. Similar branching occurs at the bottom and next-to-bottom nodes of the tree.

Pricing Using Interest-Rate Tree Models

In this section...

Introduction

For purposes of illustration, this section relies on the HJM and BDT models. The HW and BK functions that perform price and sensitivity computations are not explicitly shown here. Functions that use the HW and BK models operate similarly to the BDT model.

Computing Instrument Prices

The portfolio pricing functions `hjmprice` and `bdtprice` calculate the price of any set of supported instruments, based on an interest-rate tree. The functions are capable of pricing these instrument types:

- Bonds
- Bond options
- Bond with embedded options
- Arbitrary cash flows
- Fixed-rate notes
- Floating-rate notes
- Floating-rate notes with options or embedded options
- Caps
- Floors
- Range Notes
- Swaps
- Swaptions

For example, the syntax for calling `hjmprice` is:

```
[Price, PriceTree] = hjmprice(HJMTree, InstSet, Options)
```

Similarly, the calling syntax for `bdtprice` is:

```
[Price, PriceTree] = bdtprice(BDTTree, InstSet, Options)
```

Each function requires two input arguments: the interest-rate tree and the set of instruments, `InstSet`. An optional argument, `Options`, further controls the pricing and the output displayed. (See “Pricing Options Structure” on page A-2 for information about the `Options` argument.)

`HJMTree` is the Heath-Jarrow-Morton tree sampling of a forward-rate process, created using `hjmtree`. `BDTTree` is the Black-Derman-Toy tree sampling of an interest-rate process, created using `bdttree`. See “Building a Tree of Forward Rates” on page 2-66 to learn how to create these structures.

`InstSet` is the set of instruments to be priced. This structure represents the set of instruments to be priced independently using the model.

`Options` is an options structure created with the function `derivset`. This structure defines how the tree is used to find the price of instruments in the portfolio, and how much additional information is displayed in the command window when calling the pricing function. If this input argument is not specified in the call to the pricing function, a default Options structure is used. The pricing options structure is described in “Pricing Options Structure” on page A-2.

The portfolio pricing functions classify the instruments and call the appropriate instrument-specific pricing function for each of the instrument types. The HJM instrument-specific pricing functions are `bondbyhjm`, `cfbyhjm`, `fixedbyhjm`, `floatbyhjm`, `optbndbyhjm`, `rangefloatbyhjm`, `swapbyhjm`, and `swaptionbyhjm`. A similarly named set of functions exists for BDT models. You can also use these functions directly to calculate the price of sets of instruments of the same type.

HJM Pricing Example

Consider the following example, which uses the portfolio and interest-rate data in the MAT-file `deriv.mat` included in the toolbox. Load the data into the MATLAB workspace.

```
load deriv.mat
```

Use the MATLAB `whos` command to display a list of the variables loaded from the MAT-file.

```
whos
```

```
Name              Size            Bytes  Class     Attributes

  BDTInstSet        1x1             15956  struct
  BDTTree           1x1              5138  struct
  BKInstSet         1x1             15946  struct

```

There are eight instruments in this portfolio set: two bonds, one bond option, one fixed-rate note, one floating-rate note, one cap, one floor, and one swap. Each instrument has a corresponding index that identifies the instrument prices in the price vector returned by `hjmprice`.

Now use `hjmprice` to calculate the price of each instrument in the instrument set.

```
Price = hjmprice(HJMTree, HJMInstSet)
```

```
Warning: Not all cash flows are aligned with the tree. Result will
be approximated.

Price =

   98.7159
   97.5280
    0.0486
   98.7159
  100.5529
    6.2831
    0.0486
    3.6923
```

Note The warning shown above appears because some of the cash flows for the second bond do not fall exactly on a tree node.

BDT Pricing Example

Load the MAT-file `deriv.mat` into the MATLAB workspace.

```
load deriv.mat
```

Use the MATLAB `whos` command to display a list of the variables loaded from the MAT-file.

```
whos
```

```

  HWTree            1x1             5904  struct
  ITTInstSet        1x1            12438  struct
  ITTTree           1x1             8862  struct
  ZeroInstSet       1x1            10282  struct
  ZeroRateSpec      1x1             1580  struct
```

`BDTTree` and `BDTInstSet` are the input arguments required to call the function `bdtprice`.

Use the function `instdisp` to examine the set of instruments contained in the variable `BDTInstSet`.

```
instdisp(BDTInstSet)
```

```

```

There are eight instruments in this portfolio set: two bonds, one bond option, one fixed-rate note, one floating-rate note, one cap, one floor, and one swap. Each instrument has a corresponding index that identifies the instrument prices in the price vector returned by `bdtprice`.

Now use `bdtprice` to calculate the price of each instrument in the instrument set.

```
Price = bdtprice(BDTTree, BDTInstSet)
```

```
Warning: Not all cash flows are aligned with the tree. Result will
be approximated.

Price =

   95.5030
   93.9079
    1.7657
   95.5030
  100.4865
    1.4863
    0.0245
    7.4222
```

Price Vector Output

The prices in the output vector `Price` correspond to the prices at observation time zero `(tObs = 0)`, which is defined as the valuation date of the interest-rate tree. The instrument indexing within `Price` is the same as the indexing within `InstSet`.

In the HJM example, the prices in the `Price` vector correspond to the instruments in this order.

```
InstNames = instget(HJMInstSet, 'FieldName','Name')
```

```
InstNames =

4% bond
4% bond
Option 101
4% Fixed
20BP Float
3% Cap
3% Floor
6%/20BP Swap
```

So, in the `Price` vector, the fourth element, 98.7159, represents the price of the fourth instrument (4% fixed-rate note); the sixth element, 6.2831, represents the price of the sixth instrument (3% cap).

In the BDT example, the prices in the `Price` vector correspond to the instruments in this order.

```
InstNames = instget(BDTInstSet, 'FieldName','Name')
```

```
InstNames =

10% Bond
10% Bond
Option 95
10% Fixed
20BP Float
15% Cap
9% Floor
15%/10BP Swap
```

So, in the `Price` vector, the fourth element, 95.5030, represents the price of the fourth instrument (10% fixed-rate note); the sixth element, 1.4863, represents the price of the sixth instrument (15% cap).

Price Tree Structure Output

If you call a pricing function with two output arguments, for example,

```
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In checktree (line 292)
In hjmprice (line 85)

Price =

   98.7159
   97.5280
    0.0486
```

```
   98.7159
  100.5529
    6.2831
    0.0486
    3.6923

PriceTree =

  struct with fields:

    FinObj: 'HJMPriceTree'
     PBush: {[8×1 double]  [8×1×2 double]  [8×2×2 double]  [8×4×2 double]  [8×8 double]}
    AIBush: {[8×1 double]  [8×1×2 double]  [8×2×2 double]  [8×4×2 double]  [8×8 double]}
    ExBush: {[8×1 double]  [8×1×2 double]  [8×2×2 double]  [8×4×2 double]  [8×8 double]}
      tObs: [0 1 2 3 4]
```

you generate a price tree along with the price information.

The optional output price tree structure `PriceTree` holds all the pricing information.

HJM Price Tree

In the HJM example, the first field of this structure, `FinObj`, indicates that this structure represents a price tree. The second field, `PBush`, is the tree holding the price of the instruments in each node of the tree. The third field, `AIBush`, is the tree holding the accrued interest of the instruments in each node of the tree. Finally, the fourth field, `tObs`, represents the observation time of each level of `PBush` and `AIBush`, with units in terms of compounding periods.

In this example, the price tree looks like this:

```
FinObj: 'HJMPriceTree'
 PBush: {[8x1 double]  [8x1x2 double]  ...[8x8 double]}
AIBush: {[8x1 double]  [8x1x2 double] ... [8x8 double]}
  tObs: [0 1 2 3 4]
```

Both `PBush` and `AIBush` are `1`-by-`5` cell arrays, consistent with the five observation times of `tObs`. The data display has been shortened here to fit on a single line.

Using the command-line interface, you can directly examine `PriceTree.PBush`, the field within the `PriceTree` structure that contains the price tree with the price vectors at every state. The first node represents `tObs = 0`, corresponding to the valuation date.

```
PriceTree.PBush{1}

ans =

   98.7159
   97.5280
    0.0486
   98.7159
  100.5529
    6.2831
    0.0486
    3.6923
```

With this interface, you can observe the prices for *all* instruments in the portfolio at *a specific time*.

BDT Price Tree

The BDT output price tree structure `PriceTree` holds all the pricing information. The first field of this structure, `FinObj`, indicates that this structure represents a price tree. The second field, `PTree`, is the tree holding the price of the instruments in each node of the tree. The third field, `AITree`, is the tree holding the accrued interest of the instruments in each node of the tree. The fourth field, `tObs`, represents the observation time of each level of `PTree` and `AITree`, with units in terms of compounding periods.

You can directly examine the field within the `PriceTree` structure, which contains the price tree with the price vectors at every state. The first node represents `tObs = 0`, corresponding to the valuation date.

```
[Price, PriceTree] = bdtprice(BDTTree, BDTInstSet)

PriceTree.PTree{1}

ans =

   95.5030
   93.9079
    1.7657
   95.5030
  100.4865
    1.4863
    0.0245
    7.4222
```

Computing Instrument Sensitivities

Sensitivities can be reported either as dollar price changes or percentage price changes. The delta, gamma, and vega sensitivities that the toolbox computes are dollar sensitivities.

The functions `hjmsens` and `bdtsens` compute the delta, gamma, and vega sensitivities of instruments using an interest-rate tree. They also optionally return the calculated price for each instrument. The sensitivity functions require the same two input arguments used by the pricing functions (`HJMTree` and `HJMInstSet` for HJM; `BDTTree` and `BDTInstSet` for BDT).

Sensitivity functions calculate the dollar value of delta and gamma by shifting the observed forward yield curve by 100 basis points in each direction, and the dollar value of vega by shifting the volatility process by 1%. To obtain the per-dollar value of the sensitivities, divide the dollar sensitivity by the price of the corresponding instrument.

HJM Sensitivities Example

The calling syntax for the function is:

```
[Delta, Gamma, Vega, Price] = hjmsens(HJMTree, HJMInstSet)
```

Use the previous example data to calculate the price of instruments.

```
load deriv.mat
[Delta, Gamma, Vega, Price] = hjmsens(HJMTree, HJMInstSet);
```

```
Warning: Not all cash flows are aligned with the tree. Result will
be approximated.
```

Note The warning appears because some of the cash flows for the second bond do not fall exactly on a tree node.

You can conveniently examine the sensitivities and the prices by arranging them into a single matrix.

```
All = [Delta, Gamma, Vega, Price]
```

```
All =

       -272.65       1029.90          0.00         98.72
       -347.43       1622.69         -0.04         97.53
         -8.08        643.40         34.07          0.05
       -272.65       1029.90          0.00         98.72
         -1.04          3.31             0        100.55
        294.97       6852.56         93.69          6.28
        -47.16       8459.99         93.69          0.05
       -282.05       1059.68          0.00          3.69
```

As with the prices, each row of the sensitivity vectors corresponds to the similarly indexed instrument in `HJMInstSet`. To view the *per-dollar sensitivities*, divide each dollar sensitivity by the corresponding instrument price.

BDT Sensitivities Example

The calling syntax for the function is:

```
[Delta, Gamma, Vega, Price] = bdtsens(BDTTree, BDTInstSet);
```

Arrange the sensitivities and prices into a single matrix.

```
All = [Delta, Gamma, Vega, Price]
```

```
All =

     -232.67       803.71      -0.00       95.50
     -281.05      1181.93      -0.01       93.91
      -50.54       246.02       5.31        1.77

Calibrating Hull-White Model Using Market Data

The pricing of interest-rate derivative securities relies on models that describe the underlying process. These interest rate models depend on one or more parameters that you must determine by matching the model predictions to the existing data available in the market. In the Hull-White model, there are two parameters related to the short rate process: mean reversion and volatility. Calibration is used to determine these parameters, such that the model can reproduce, as close as possible, the prices of caps or floors observed in the market. The calibration routines find the parameters that minimize the difference between the model price predictions and the market prices for caps and floors.

For a Hull-White model, the minimization is two dimensional, with respect to mean reversion (α) and volatility (σ). That is, calibrating the Hull-White model minimizes the difference between the model's predicted prices and the observed market prices of the corresponding caplets or floorlets.

Hull-White Model Calibration Example

Use market data to identify the implied volatility (σ) and mean reversion (α) coefficients needed to build a Hull-White tree to price an instrument. The ideal case is to use the volatilities of the caps or floors used to calculate `Alpha` (α) and `Sigma` (σ). This will most likely not be the case, so market data must be interpolated to obtain the required values.

Consider a cap with these parameters:

```
Settle = ' Jan-21-2008';
Maturity = 'Mar-21-2011';
Strike = 0.0690;
Reset = 4;
Principal = 1000;
Basis = 0;
```

The caplets for this example would fall in:

```
capletDates = cfdates(Settle, Maturity, Reset, Basis);
datestr(capletDates')
```

```
ans =

21-Mar-2008
21-Jun-2008
21-Sep-2008
21-Dec-2008
21-Mar-2009
21-Jun-2009
21-Sep-2009
21-Dec-2009
21-Mar-2010
21-Jun-2010
21-Sep-2010
21-Dec-2010
21-Mar-2011
```

In the best case, look up the market volatilities for caplets with a `Strike = 0.0690`, and maturities in each reset date listed, but the likelihood of finding these exact instruments is low. As a consequence, use data that is available in the market and interpolate to find appropriate values for the caplets.

Based on the market data, you have the cap information for different dates and strikes. Assume that instead of having the data for `Strike = 0.0690`, you have the data for `Strike1 = 0.0590` and `Strike2 = 0.0790`.

Maturity	Strike1 = 0.0590	Strike2 = 0.0790
21-Mar-2008	0.1533	0. 1526
21-Jun-2008	0.1731	0. 1730
21-Sep-2008	0. 1727	0. 1726
21-Dec-2008	0. 1752	0. 1747
21-Mar-2009	0. 1809	0. 1808
21-Jun-2009	0. 1809	0. 1792
21-Sep-2009	0. 1805	0. 1797
21-Dec-2009	0. 1802	0. 1794
21-Mar-2010	0. 1802	0. 1733
21-Jun-2010	0. 1757	0. 1751
21-Sep-2010	0. 1755	0. 1750
21-Dec-2010	0. 1755	0. 1745
21-Mar-2011	0. 1726	0. 1719

The nature of this data lends itself to matrix nomenclature, which is perfect for MATLAB. `hwcalbycap` requires that the dates, the strikes, and the actual volatility be separated into three variables: `MarketStrike`, `MarketMat`, and `MarketVol`.

```
MarketStrike = [0.0590; 0.0790];
MarketMat = {'21-Mar-2008';
'21-Jun-2008';
'21-Sep-2008';
'21-Dec-2008';
'21-Mar-2009';
'21-Jun-2009';
'21-Sep-2009';
'21-Dec-2009';
'21-Mar-2010';
'21-Jun-2010';
'21-Sep-2010';
'21-Dec-2010';
'21-Mar-2011'};

MarketVol = [0.1533 0.1731 0.1727 0.1752 0.1809 0.1800 0.1805 0.1802 0.1735 0.1757 ...
             0.1755 0.1755 0.1726; % First row in table corresponding to Strike1
             0.1526 0.1730 0.1726 0.1747 0.1808 0.1792 0.1797 0.1794 0.1733 0.1751 ...
             0.1750 0.1745 0.1719]; % Second row in table corresponding to Strike2
```

Complete the input arguments using this data for `RateSpec`:

```
Rates = [0.0627;
0.0657;
0.0691;
0.0717;
0.0739;
0.0755;

```

Call the calibration routine to find values for volatility parameters Alpha and Sigma

Use `hwcalbycap` to calculate the values of `Alpha` and `Sigma` based on market data. Internally, `hwcalbycap` calls the function `lsqnonlin`. You can customize `lsqnonlin` by passing an optimization options structure created by `optimoptions` and then this can be passed to `hwcalbycap` using the name-value pair argument for `OptimOptions`. For example, `optimoptions` defines the target objective function tolerance as `100*eps` and then calls `hwcalbycap`:

```
o=optimoptions('lsqnonlin','TolFun',100*eps);

[Alpha, Sigma] = hwcalbycap(RateSpec, MarketStrike, MarketMat, MarketVol,...
Strike, Settle, Maturity, 'Reset', Reset, 'Principal', Principal, 'Basis',...
Basis, 'OptimOptions', o)

Local minimum possible.

lsqnonlin stopped because the size of the current step is less than
the default value of the step size tolerance.

Warning: LSQNONLIN did not converge to an optimal solution. It exited with exitflag = 2.

> In hwcalbycapfloor at 93
  In hwcalbycap at 75

Alpha =

   1.0000e-06

Sigma =

    0.0127
```

The previous warning indicates that the conversion was not optimal. The search algorithm used by the Optimization Toolbox™ function `lsqnonlin` did not find a solution that conforms to all the constraints. To discern whether the solution is acceptable, look at the results of the optimization by specifying a third output (`OptimOut`) for `hwcalbycap`:

```
[Alpha, Sigma, OptimOut] = hwcalbycap(RateSpec, MarketStrike, MarketMat,...
MarketVol, Strike, Settle, Maturity, 'Reset', Reset, 'Principal', Principal,...
'Basis', Basis, 'OptimOptions', o);
```

The `OptimOut.residual` field of the `OptimOut` structure is the optimization residual. This value contains the difference between the Black caplets and those calculated during the optimization. You can use the `OptimOut.residual` value to calculate the percentual difference (error) compared to Black caplet prices and then decide whether the residual is acceptable. There is almost always some residual, so decide if it is acceptable to parameterize the market with a single value of `Alpha` and `Sigma`.

Price caplets using market data and Black's formula to obtain reference caplet values

To determine the effectiveness of the optimization, calculate reference caplet values using Black's formula and the market data. Note, you must first interpolate the market data to obtain the caplets for calculation:

```
MarketMatNum = datenum(MarketMat);
[Mats, Strikes] = meshgrid(MarketMatNum, MarketStrike);
FlatVol = interp2(Mats, Strikes, MarketVol, datenum(Maturity), Strike, 'spline');
```

Compute the price of the cap using the Black model:

```
[CapPrice, Caplets] = capbyblk(RateSpec, Strike, Settle, Maturity, FlatVol,...
'Reset', Reset, 'Basis', Basis, 'Principal', Principal);
Caplets = Caplets(2:end)';
```

```
Caplets =

    0.3210
    1.6355
    2.4863
    3.1903
    3.4110
    3.2685
    3.2385
    3.4803
    3.2419
    3.1949
    3.2991
    3.3750
```

Compare optimized values and Black values and display graphically

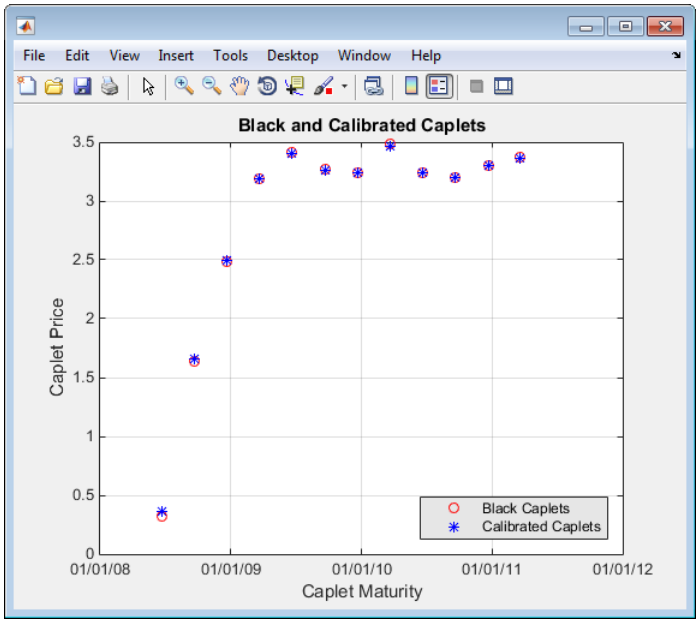
After calculating the reference values for the caplets, compare the values, analytically and graphically, to determine whether the calculated single values of `Alpha` and `Sigma` provide an adequate approximation:

```
OptimCaplets = Caplets+OptimOut.residual;

disp('   ');
disp('    Black76   Calibrated Caplets');
disp([Caplets                  OptimCaplets])

plot(MarketMatNum(2:end), Caplets, 'or', MarketMatNum(2:end), OptimCaplets, '*b');
datetick('x', 2)
xlabel('Caplet Maturity');
ylabel('Caplet Price');
title('Black and Calibrated Caplets');
h = legend('Black Caplets', 'Calibrated Caplets');
set(h, 'color', [0.9 0.9 0.9]);
set(h, 'Location', 'SouthEast');
set(gcf, 'NumberTitle', 'off')
grid on
```

```
Black76   Calibrated Caplets
   0.3210    0.3636
   1.6355    1.6603
   2.4863    2.4974
   3.1903    3.1874
   3.4110    3.4040
   3.2685    3.2639
   3.2385    3.2364
   3.4803    3.4683
   3.2419    3.2408
   3.1949    3.1957
   3.2991    3.2960
   3.3750    3.3663
```



Compare cap prices using the Black, HW analytical, and HW tree models

Using the calculated caplet values, compare the prices of the corresponding cap using the Black model, Hull-White analytical, and Hull-White tree models. To calculate a Hull-White tree based on `Alpha` and `Sigma`, use these calibration routines:

- Black model:

  ```
  CapPriceBLK = CapPrice;
  ```

- HW analytical model:

  ```
  CapPriceHWAnalytical = sum(OptimCaplets);
  ```

- HW tree model to price the cap derived from the calibration process:

  1. Create `VolSpec` from the calibration parameters `Alpha` and `Sigma`:

     ```
     VolDates    = EndDates;
     VolCurve    = Sigma*ones(14,1);
     AlphaDates  = EndDates;
     AlphaCurve  = Alpha*ones(14,1);
     HWVolSpec = hwvolspec(ValuationDate, VolDates, VolCurve,AlphaDates, AlphaCurve);
     ```

  2. Create the `TimeSpec`:

```
HWTimeSpec = hwtimespec(ValuationDate, EndDates, Compounding);
```

3. Build the HW tree using the `HW2000` method:

```
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec, 'Method', 'HW2000');
```

4. Price the cap:

```
Price = capbyhw(HWTree, Strike, Settle, Maturity, Reset, Basis, Principal);

disp('   ');
disp(['  CapPrice Black76 ..................:  ', num2str(CapPriceBLK,'%15.5f')]);
disp(['  CapPrice HW analytical..........:  ', num2str(CapPriceHWAnalytical,'%15.5f')]);
disp(['  CapPrice HW from capbyhw ..:  ', num2str(Price,'%15.5f')]);
disp('   ');
```

```
CapPrice Black76 ...........: 34.14220
CapPrice HW analytical.....: 34.18008
CapPrice HW from capbyhw ..: 34.14192
```

Price a portfolio of instruments using the calibrated HW tree

After building a Hull-White tree, based on parameters calibrated from market data, use `HWTree` to price a portfolio of these instruments:

- Two bonds

```
CouponRate = [0.07; 0.09];
Settle = ' Jan-21-2008';
Maturity = {'Mar-21-2010';'Mar-21-2011'};
Period = 1;
Face = 1000;
Basis = 0;
```

- Bond with an embedded American call option

```
CouponRateOEB = 0.08;
SettleOEB = ' Jan-21-2008';
MaturityOEB = 'Mar-21-2011';
OptSpec = 'call';
StrikeOEB = 950;
ExerciseDatesOEB = 'Mar-21-2011';
AmericanOpt = 1;
Period = 1;
Face = 1000;
Basis = 0;
```

To price this portfolio of instruments using the calibrated `HWTree`:

1. Use `instadd` to create the portfolio `InstSet`:

```
InstSet = instadd('Bond', CouponRate, Settle,  Maturity, Period, Basis, [], [], [], [], [], Face);
InstSet = instadd(InstSet,'OptEmBond',  CouponRateOEB, SettleOEB, MaturityOEB, OptSpec,...
StrikeOEB,   ExerciseDatesOEB, 'AmericanOpt', AmericanOpt, 'Period', Period,...
'Face',Face,  'Basis', Basis);
```

2. Add the cap instrument used in the calibration:

```
SettleCap = ' Jan-21-2008';
MaturityCap = 'Mar-21-2011';
StrikeCap = 0.0690;
Reset = 4;
Principal = 1000;

InstSet = instadd(InstSet,'Cap', StrikeCap, SettleCap, MaturityCap, Reset, Basis, Principal);
```

3. Assign names to the portfolio instruments:

```
Names = {'7% Bond'; '8% Bond'; 'BondEmbCall'; '6.9% Cap'};
InstSet = instsetfield(InstSet, 'Index',1:4, 'FieldName', {'Name'}, 'Data', Names );
```

4 Examine the set of instruments contained in `InstSet`:

```
instdisp(InstSet)
```

```
IdxType CoupRate Settle Mature Period Basis EOMRule IssueDate 1stCoupDate LastCoupDate StartDate Face Name

1 Bond 0.07       21-Jan-2008    21-Mar-2010    1  0  NaN  NaN     NaN   NaN  NaN  1000    7% Bond
2 Bond 0.09       21-Jan-2008    21-Mar-2011    1  0  NaN  NaN     NaN   NaN  NaN  1000    8% Bond

IdxType CoupRate Settle Mature OptSpec Stke ExDate Per Basis EOMRule IssDate 1stCoupDate LstCoupDate StrtDate Face AmerOpt Name
3 OptEmBond 0.08 21-Jan-2008 21-Mar-2011 call 950  21-Jan-2008  21-Mar-2011  1  0  1  NaN  NaN NaN  NaN  1000 1 BondEmbCall

Index Type Strike Settle     Maturity   CapReset Basis Principal Name
4 Cap  0.069  21-Jan-2008    21-Mar-2011    4      0     1000    6.9% Cap
```

5 Use `hwprice` to price the portfolio using the calibrated `HWTree`:

```
format bank
PricePortfolio = hwprice(HWTree, InstSet)
```

```
PricePortfolio =
         980.45
        1023.05
         945.73
          34.14
```

Interest-Rate Derivatives Using Closed-Form Solutions

Pricing Caps and Floors Using the Black Option Model

Caps and floors are contracts that allow the holder to be protected if interest rates rise or decrease. The Black model uses a forward price as an underlier in place of a spot price. The assumption is that the forward price at maturity of the option is log-normally distributed.

Closed-form solutions for pricing caps and floors using the Black model support the following tasks:

Task	Function
Price the interest rate caps using the Black option pricing model.	`capbyblk`
Price the interest rate floors using the Black option pricing model.	`floorbyblk`

Price Swaptions with Interest-Rate Models Using Simulation

In this section...

Introduction

This example shows how to price European swaptions using interest-rate models in Financial Instruments Toolbox. Specifically, a Hull-White one factor model, a Linear Gaussian two-factor model, and a LIBOR Market Model are calibrated to market data and then used to generate interest-rate paths using Monte Carlo simulation.

The following sections set up the data that is then used with examples for “Simulate Interest-Rate Paths Using the Hull-White One-Factor Model” on page 2-103, “Simulate Interest-Rate Paths Using the Linear Gaussian Two-Factor Model” on page 2-106, and “Simulate Interest-Rate Paths Using the LIBOR Market Model” on page 2-108:

- “Construct a Zero Curve” on page 2-100
- “Define Swaption Parameters” on page 2-102
- “Compute the Black Model and the Swaption Volatility Matrix” on page 2-102
- “Select Calibration Instruments” on page 2-102
- “Compute Swaption Prices Using Black's Model” on page 2-102
- “Define Simulation Parameters” on page 2-103

Construct a Zero Curve

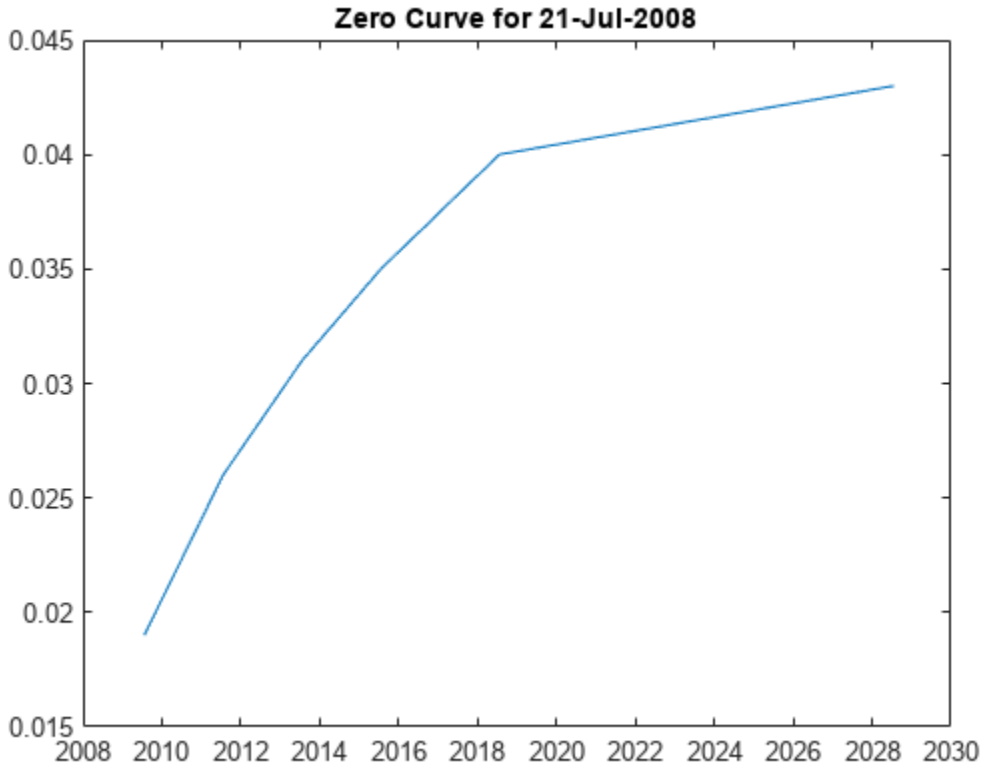
This example shows how to use `ZeroRates` for a zero curve that is hard-coded. You can also create a zero curve by bootstrapping the zero curve from market data (for example, deposits, futures/forwards, and swaps)

The hard-coded data for the zero curve is defined as:

```
Settle = datetime(2008,7,21);
```

```
% Zero Curve
CurveDates = daysadd(Settle,360*([1 3 5 7 10 20]),1);
ZeroRates = [1.9 2.6 3.1 3.5 4 4.3]'/100;

plot(CurveDates,ZeroRates)
datetick
title(['Zero Curve for ' datestr(Settle)]);
```



Construct an `IRDataCurve` object.

```
irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);
```

Create the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('Rates',ZeroRates,'EndDates',CurveDates,'StartDate',Settle)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [6x1 double]
            Rates: [6x1 double]
         EndTimes: [6x1 double]
       StartTimes: [6x1 double]
         EndDates: [6x1 double]
       StartDates: 733610
    ValuationDate: 733610
            Basis: 0
```

```
      EndMonthRule: 1
```

Define Swaption Parameters

While Monte Carlo simulation is typically used to value more sophisticated derivatives (for example, Bermudan swaptions), in this example, the price of a European swaption is computed with an exercise date of five years and an underlying swap of five years.

```
InstrumentExerciseDate = datenum('21-Jul-2013');
InstrumentMaturity = datenum('21-Jul-2018');
InstrumentStrike = .045;
```

Compute the Black Model and the Swaption Volatility Matrix

Black's model is often used to price and quote European exercise interest-rate options, that is, caps, floors and swaptions. In the case of swaptions, Black's model is used to imply a volatility given the current observed market price. The following matrix shows the Black implied volatility for a range of swaption exercise dates (columns) and underlying swap maturities (rows).

```
SwaptionBlackVol = [22 21 19 17 15 13 12
    21 19 17 16 15 13 11
    20 18 16 15 14 12 11
    19 17 15 14 13 12 10
    18 16 14 13 12 11 10
    15 14 13 12 12 11 10
    13 13 12 11 11 10 9]/100;
ExerciseDates = [1:5 7 10];
Tenors = [1:5 7 10];

EurExDatesFull = repmat(daysadd(Settle,ExerciseDates*360,1)',...
    length(Tenors),1);
EurMatFull = reshape(daysadd(EurExDatesFull,...
    repmat(360*Tenors,1,length(ExerciseDates)),1),size(EurExDatesFull));
```

Select Calibration Instruments

Selecting the instruments to calibrate the model to is one of the tasks in calibration. For Bermudan swaptions, it is typical to calibrate to European swaptions that are co-terminal with the Bermudan swaption to be priced. In this case, all swaptions having an underlying tenor that matures before the maturity of the swaption to be priced (21-Jul-2018) are used in the calibration.

```
% Find the swaptions that expire on or before the maturity date of the
% sample swaption
relidx = find(EurMatFull <= InstrumentMaturity);
```

Compute Swaption Prices Using Black's Model

This example shows how to compute swaption prices using Black's Model. The swaption prices are then used to compare the model’s predicted values that are obtained from the calibration process.

To compute the swaption prices using Black's model:

```
SwaptionBlackPrices = zeros(size(SwaptionBlackVol));
SwaptionStrike = zeros(size(SwaptionBlackVol));

for iSwaption=1:length(ExerciseDates)
    for iTenor=1:length(Tenors)
        [~,SwaptionStrike(iTenor,iSwaption)] = swapbyzero(RateSpec,[NaN 0], Settle, EurMatFull(iTenor,iSwaption),...
            'StartDate',EurExDatesFull(iTenor,iSwaption),'LegReset',[1 1]);
```

```
        SwaptionBlackPrices(iTenor,iSwaption) = swaptionbyblk(RateSpec, 'call', SwaptionStrike(iTenor,iSwaption),Settle, ...
            EurExDatesFull(iTenor,iSwaption), EurMatFull(iTenor,iSwaption), SwaptionBlackVol(iTenor,iSwaption));
    end
end
```

Define Simulation Parameters

This example shows how to use the `simTermStructs` method with `HullWhite1F`, `LinearGaussian2F`, and `LiborMarketModel` objects.

To demonstrate using the `simTermStructs` method with `HullWhite1F`, `LinearGaussian2F`, and `LiborMarketModel` objects, use the following simulation parameters:

```
nPeriods = 5;
DeltaTime = 1;
nTrials = 1000;

Tenor = (1:10)';

SimDates = daysadd(Settle,360*DeltaTime*(0:nPeriods),1)
SimTimes = diff(yearfrac(SimDates(1),SimDates))

% For 1 year periods and an evenly spaced tenor, the exercise row will be
% the 5th row and the swaption maturity will be the 5th column
exRow = 5;
endCol = 5;
```

```
SimDates =

      733610
      733975
      734340
      734705
      735071
      735436

SimTimes =

    1.0000
    1.0000
    1.0000
    1.0027
    1.0000
```

Simulate Interest-Rate Paths Using the Hull-White One-Factor Model

This example shows how to simulate interest-rate paths using the Hull-White one-factor model. Before beginning this example that uses a `HullWhite1F` model, make sure that you have set up the data as described in:

- “Construct a Zero Curve” on page 2-100
- “Define Swaption Parameters” on page 2-102
- “Compute the Black Model and the Swaption Volatility Matrix” on page 2-102
- “Select Calibration Instruments” on page 2-102
- “Compute Swaption Prices Using Black's Model” on page 2-102
- “Define Simulation Parameters” on page 2-103

The Hull-White one-factor model describes the evolution of the short rate and is specified using the zero curve, *alpha*, and *sigma* parameters for the equation

$$dr = [\theta(t) - a(t)r]dt + \sigma(t)dW$$

where:

dr is the change in the short-term interest rate over a small interval, dt.

r is the short-term interest rate.

$\Theta(t)$ is a function of time determining the average direction in which r moves, chosen such that movements in r are consistent with today's zero coupon yield curve.

α is the mean reversion rate.

dt is a small change in time.

σ is the annual standard deviation of the short rate.

W is the Brownian motion.

The Hull-White model is calibrated using the function `swaptionbyhw`, which constructs a trinomial tree to price the swaptions. Calibration consists of minimizing the difference between the observed market prices (computed above using the Black's implied swaption volatility matrix, see “Compute the Black Model and the Swaption Volatility Matrix” on page 2-102) and the model's predicted prices.

In this example, the Optimization Toolbox function `lsqnonlin` is used to find the parameter set that minimizes the difference between the observed and predicted values. However, other approaches (for example, simulated annealing) may be appropriate. Starting parameters and constraints for α and σ are set in the variables `x0`, `lb`, and `ub`; these could also be varied depending upon the particular calibration approach.

Calibrate the set of parameters that minimize the difference between the observed and predicted values using `swaptionbyhw` and `lsqnonlin`.

```
TimeSpec = hwtimespec(Settle,daysadd(Settle,360*(1:11),1), 2);
HW1Fobjfun = @(x) SwaptionBlackPrices(relidx) - ...
    swaptionbyhw(hwtree(hwvolspec(Settle,'11-Aug-2015',x(2),'11-Aug-2015',x(1)), RateSpec, TimeSpec), 'call', SwaptionStrike(relidx),...
    EurExDatesFull(relidx), 0, EurExDatesFull(relidx), EurMatFull(relidx));
options = optimset('disp','iter','MaxFunEvals',1000,'TolFun',1e-5);

% Find the parameters that minimize the difference between the observed and
% predicted prices
x0 = [.1 .01];
lb = [0 0];
ub = [1 1];
HW1Fparams = lsqnonlin(HW1Fobjfun,x0,lb,ub,options);

HW_alpha = HW1Fparams(1)
HW_sigma = HW1Fparams(2)
```

```
                                    Norm of      First-order
 Iteration  Func-count     f(x)          step          optimality
     0          3        0.953772                         20.5
     1          6        0.142828      0.0169199           1.53
     2          9        0.123022      0.0146705           2.31
     3         12        0.122222      0.0154098          0.482
     4         15        0.122217     0.00131297        0.00409

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the selected value of the function tolerance.

HW_alpha =

    0.0967

HW_sigma =

    0.0088
```

Construct the `HullWhite1F` model using the `HullWhite1F` constructor.

```
HW1F = HullWhite1F(RateSpec,HW_alpha,HW_sigma)
```

```
HW1F =

  HullWhite1F with properties:

    ZeroCurve: [1x1 IRDataCurve]
        Alpha: @(t,V)inAlpha

Simulate Interest-Rate Paths Using the Linear Gaussian Two-Factor Model

This example shows how to simulate interest-rate paths using the Linear Gaussian two-factor model. Before beginning this example that uses a `LinearGaussian2F` model, make sure that you have set up the data as described in:

- “Construct a Zero Curve” on page 2-100
- “Define Swaption Parameters” on page 2-102
- “Compute the Black Model and the Swaption Volatility Matrix” on page 2-102
- “Select Calibration Instruments” on page 2-102
- “Compute Swaption Prices Using Black's Model” on page 2-102
- “Define Simulation Parameters” on page 2-103

The Linear Gaussian two-factor model (called the G2++ by Brigo and Mercurio, see “Interest-Rate Modeling Using Monte Carlo Simulation” on page B-4) is also a short rate model, but involves two factors. Specifically:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -a(t)x(t)dt + \sigma(t)dW_1(t), x(0) = 0$$

$$dy(t) = -b(t)y(t)dt + \eta(t)dW_2(t), y(0) = 0$$

where $dW_1(t)dW_2(t) = \rho dt$ is a two-dimensional Brownian motion with correlation ρ, and ϕ is a function chosen to match the initial zero curve.

The function `swaptionbylg2f` is used to compute analytic values of the swaption price for model parameters, and therefore can be used to calibrate the model. Calibration consists of minimizing the difference between the observed market prices (computed above using the Black's implied swaption volatility matrix, see “Compute the Black Model and the Swaption Volatility Matrix” on page 2-102) and the model’s predicted prices.

In this example, the approach is similar to “Simulate Interest-Rate Paths Using the Hull-White One-Factor Model” on page 2-103 and the Optimization Toolbox function `lsqnonlin` is used to minimize the difference between the observed swaption prices and the predicted swaption prices. However, other approaches (for example, simulated annealing) may also be appropriate. Starting parameters and constraints for a, b, η, ρ, and σ are set in the variables `x0`, `lb`, and `ub`; these could also be varied depending upon the particular calibration approach.

Calibrate the set of parameters that minimize the difference between the observed and predicted values using `swaptionbylg2f` and `lsqnonlin`.

```
G2PPobjfun = @(x) SwaptionBlackPrices(relidx) - swaptionbylg2f(irdc,x(1),x(2),x(3),x(4),x(5),SwaptionStrike(relidx),...
    EurExDatesFull(relidx),EurMatFull(relidx),'Reset',1);

options = optimset('disp','iter','MaxFunEvals',1000,'TolFun',1e-5);
x0 = [.2 .1 .02 .01 -.5];
lb = [0 0 0 0 -1];
ub = [1 1 1 1 1];
LG2Fparams = lsqnonlin(G2PPobjfun,x0,lb,ub,options)
```

```

Simulate Interest-Rate Paths Using the LIBOR Market Model

This example shows how to simulate interest-rate paths using the LIBOR market model. Before beginning this example that uses a `LiborMarketModel`, make sure that you have set up the data as described in:

- “Construct a Zero Curve” on page 2-100
- “Define Swaption Parameters” on page 2-102
- “Compute the Black Model and the Swaption Volatility Matrix” on page 2-102
- “Select Calibration Instruments” on page 2-102
- “Compute Swaption Prices Using Black's Model” on page 2-102
- “Define Simulation Parameters” on page 2-103

The LIBOR Market Model (LMM) differs from short rate models in that it evolves a set of discrete forward rates. Specifically, the lognormal LMM specifies the following diffusion equation for each forward rate

$$\frac{dF_i(t)}{F_i} = -\mu_i dt + \sigma_i(t) dW_i$$

where:

W is an N-dimensional geometric Brownian motion with

$$dW_i(t)dW_j(t) = \rho_{ij}$$

The LMM relates the drifts of the forward rates based on no-arbitrage arguments. Specifically, under the Spot LIBOR measure, the drifts are expressed as

$$\mu_i(t) = -\sigma_i(t)\sum_{j=q(t)}^{i}\frac{\tau_j\rho_{i,j}\sigma_j(t)F_j(t)}{1+\tau_jF_j(t)}$$

where:

τ_i is the time fraction associated with the ith forward rate

$q(t)$ is an index defined by the relation

$$T_{q(t)-1} < t < T_{q(t)}$$

and the Spot LIBOR numeraire is defined as

$$B(t) = P(t,T_{q(t)})\prod_{n=0}^{q(t)-1}(1+\tau_nF_n(T_n))$$

The choice with the LMM is how to model volatility and correlation and how to estimate the parameters of these models for volatility and correlation. In practice, you may use a combination of historical data (for example, observed correlation between forward rates) and current market data. For this example, only swaption data is used. Further, many different parameterizations of the volatility and correlation exist. For this example, two relatively straightforward parameterizations are used.

One of the most popular functional forms in the literature for volatility is:

$$\sigma_i(t) = \varphi_i(a(T_i-t)+b)e^{c(T_i-t)}+d$$

where ϕ adjusts the curve to match the volatility for the i th forward rate. For this example, all of the ϕ's are taken to be 1. For the correlation, the following functional form is used:

$$\rho_{i,j} = e^{-\beta|i-j|}$$

Once the functional forms have been specified, these parameters must be estimated using market data. One useful approximation, initially developed by Rebonato, is the following, which relates the Black volatility for a European swaption, given a set of volatility functions and a correlation matrix

$$(v_{\alpha,\beta}^{LFM})^2 = \sum_{i,j=\alpha+1}^{\beta}\frac{w_i(0)w_j(0)F_i(0)F_j(0)\rho_{i,j}}{S_{\alpha,\beta}(0)^2}\int_0^{T_\alpha}\sigma_i(t)\sigma_j(t)dt$$

where:

$$w_i(t) = \frac{\tau_iP(t,T_i)}{\sum_{k=\alpha+1}^{\beta}\tau_kP(t,t_k)}$$

This calculation is done using the function `blackvolbyrebonato` to compute analytic values of the swaption price for model parameters, and therefore, is then used to calibrate the model. Calibration consists of minimizing the difference between the observed implied swaption Black volatilities and the predicted Black volatilities.

In this example, the approach is similar to “Simulate Interest-Rate Paths Using the Hull-White One-Factor Model” on page 2-103 and “Simulate Interest-Rate Paths Using the Linear Gaussian Two-Factor Model” on page 2-106 where the Optimization Toolbox function `lsqnonlin` is used to minimize the difference between the observed swaption prices and the predicted swaption prices. However, other approaches (for example, simulated annealing) may also be appropriate. Starting parameters and constraints for a, b, d, and β are set in the variables `x0`, `lb`, and `ub`; these could also be varied depending upon the particular calibration approach.

Calibrate the set of parameters that minimize the difference between the observed and predicted values using `blackvolbyrebonato` and `lsqnonlin`.

```
nRates = 10;

Pricing Bermudan Swaptions with Monte Carlo Simulation

This example shows how to price Bermudan swaptions using interest-rate models in Financial Instruments Toolbox™. Specifically, a Hull-White one factor model, a Linear Gaussian two-factor model, and a LIBOR Market Model are calibrated to market data and then used to generate interest-rate paths using Monte Carlo simulation.

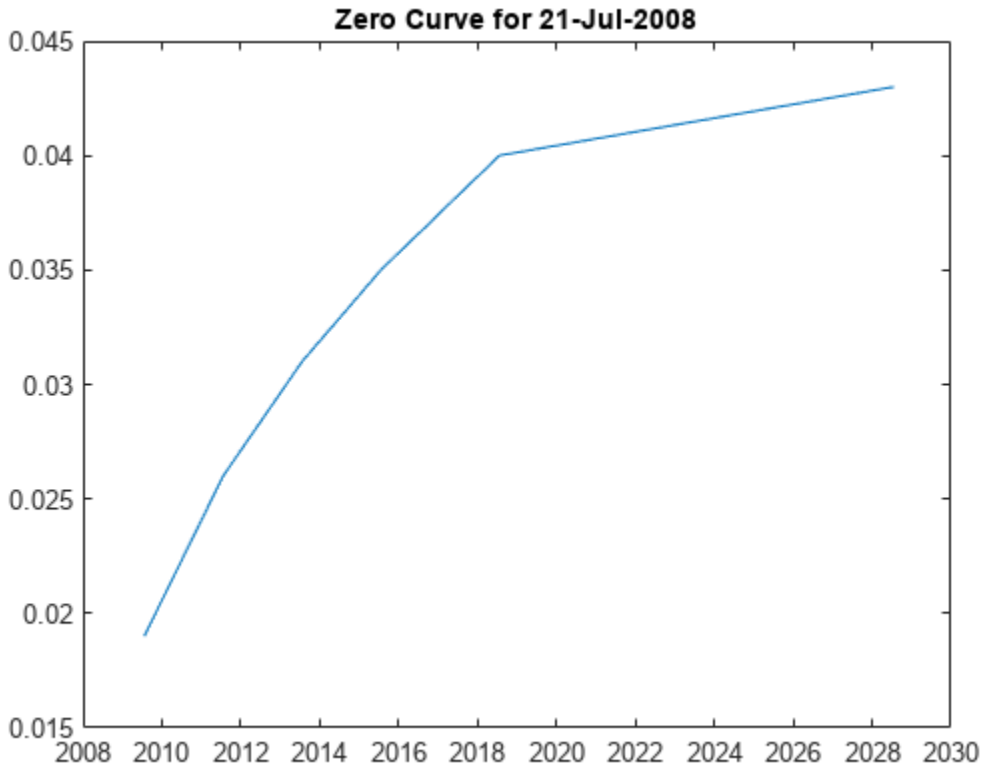
Zero Curve

In this example, the `ZeroRates` for a zero curve is hard-coded. You can also create a zero curve by bootstrapping the zero curve from market data (for example, deposits, futures/forwards, and swaps). The hard-coded data for the zero curve is defined as:

```
Settle = datetime(2008,7,21);

% Zero Curve
CurveDates = daysadd(Settle,360*([1 3 5 7 10 20]),1);
ZeroRates = [1.9 2.6 3.1 3.5 4 4.3]'/100;

plot(CurveDates,ZeroRates)
datetick
title(['Zero Curve for ' datestr(Settle)]);
```



```
RateSpec = intenvset('Rates',ZeroRates,'EndDates',CurveDates,'StartDate',Settle);
```

Define Swaption Parameters

For this example, you compute the price of a 10-no-call-1 Bermudan swaption.

```
BermudanExerciseDates = daysadd(Settle,360*(1:9),1);
BermudanMaturity = datetime(2018,7,21);
BermudanStrike = .045;
```

Black's Model and the Swaption Volatility Matrix

Black's model is often used to price and quote European exercise interest-rate options, that is, caps, floors, and swaptions. In the case of swaptions, Black's model is used to imply a volatility given the current observed market price. The following matrix shows the Black implied volatility for a range of swaption exercise dates (columns) and underlying swap maturities (rows).

```
SwaptionBlackVol = [22 21 19 17 15 13 12
    21 19 17 16 15 13 11
    20 18 16 15 14 12 11
    19 17 15 14 13 12 10
    18 16 14 13 12 11 10
    15 14 13 12 12 11 10
    13 13 12 11 11 10 9]/100;
ExerciseDates = [1:5 7 10];
Tenors = [1:5 7 10];

EurExDatesFull = repmat(daysadd(Settle,ExerciseDates*360,1)',...
    length(Tenors),1);
EurMatFull = reshape(daysadd(EurExDatesFull,...
    repmat(360*Tenors,1,length(ExerciseDates)),1),size(EurExDatesFull));
```

Selecting the Calibration Instruments

Selecting the instruments to calibrate the model to is one of the tasks in calibration. For Bermudan swaptions, it is typical to calibrate to European swaptions that are co-terminal with the Bermudan swaption that you want to price. In this case, all swaptions having an underlying tenor that matures before the maturity of the swaption to be priced are used in the calibration.

```
% Find the swaptions that expire on or before the maturity date of the
% sample swaption
relidx = find(EurMatFull <= BermudanMaturity);
```

Compute Swaption Prices Using Black's Model

Swaption prices are computed using Black's Model. You can then use the swaption prices to compare the model's predicted values. To compute the swaption prices using Black's model:

```
% Compute Swaption Prices using Black's model
SwaptionBlackPrices = zeros(size(SwaptionBlackVol));
SwaptionStrike = zeros(size(SwaptionBlackVol));

for iSwaption=1:length(ExerciseDates)
    for iTenor=1:length(Tenors)
        [~,SwaptionStrike(iTenor,iSwaption)] = swapbyzero(RateSpec,[NaN 0], Settle, EurMatFull(i
            'StartDate',EurExDatesFull(iTenor,iSwaption),'LegReset',[1 1]);
        SwaptionBlackPrices(iTenor,iSwaption) = swaptionbyblk(RateSpec, 'call', SwaptionStrike(i

    end
end
```

Simulation Parameters

The following parameters are used where each exercise date is a simulation date.

```
nPeriods = 9;
DeltaTime = 1;
nTrials = 1000;

Tenor = (1:10)';

SimDates = daysadd(Settle,360*DeltaTime*(0:nPeriods),1);
SimTimes = diff(yearfrac(SimDates(1),SimDates));
```

Hull White 1 Factor Model

The Hull-White one-factor model describes the evolution of the short rate and is specified by the following:

$$dr = [\theta(t) - \alpha r]dt + \sigma dW$$

The Hull-White model is calibrated using the function `swaptionbyhw`, which constructs a trinomial tree to price the swaptions. Calibration consists of minimizing the difference between the observed market prices (computed above using the Black's implied swaption volatility matrix) and the model's predicted prices.

This example uses the Optimization Toolbox™ function `lsqnonlin` to find the parameter set that minimizes the difference between the observed and predicted values. However, other approaches (for example, simulated annealing) may be appropriate. Starting parameters and constraints for α and σ are set in the variables `x0` , `lb`, and `ub`; these could also be varied depending upon the particular calibration approach.

```
warnId = 'fininst:swaptionbyirtree:IgnoredSettle';
warnStruct = warning('off',warnId); % Turn warning off

```

Linear Gaussian 2 Factor Model

The Linear Gaussian two-factor model (called the G2++ by Brigo and Mercurio) is also a short rate model, but involves two factors. Specifically:

$$r(t) = x(t) + y(t) + \varphi(t)$$

$$dx(t) = -ax(t)dt + \sigma dW_1(t)$$

$$dy(t) = -by(t)dt + \eta dW_2(t)$$

where $dW_1(t)dW_2(t)$ is a two-dimensional Brownian motion with correlation ρ

$$dW_1(t)dW_2(t) = \rho$$

and φ is a function chosen to match the initial zero curve.

You can use the function `swaptionbylg2f` to compute analytic values of the swaption price for model parameters and to calibrate the model. Calibration consists of minimizing the difference between the observed market prices and the model's predicted prices.

```
% Calibrate the set of parameters that minimize the difference between the
% observed and predicted values using swaptionbylg2f and lsqnonlin.

LIBOR Market Model

The LIBOR Market Model (LMM) differs from short rate models in that it evolves a set of discrete forward rates. Specifically, the lognormal LMM specifies the following diffusion equation for each forward rate

$$\frac{dF_i(t)}{F_i} = -\mu_i dt + \sigma_i(t) dW_i$$

where

σ_i is the volatility function for each rate and dW is an `N` dimensional geometric Brownian motion with:

$$dW_i(t)dW_j(t) = \rho_{ij}$$

The LMM relates the drifts of the forward rates based on no-arbitrage arguments.

The choice with the LMM is how to model volatility and correlation and how to estimate the parameters of these models for volatility and correlation. In practice, you might use a combination of historical data (for example, observed correlation between forward rates) and current market data. For this example, only swaption data is used. Furthermore, many different parameterizations of the volatility and correlation exist. This example uses two relatively straightforward parameterizations.

One of the most popular functional forms in the literature for volatility is:

$$\sigma_i(t) = \phi_i(a(T_i - t) + b)e^{c(T_i - t)} + d$$

where ϕ adjusts the curve to match the volatility for the i^{th} forward rate. For this example, all of the Phi's will be taken to be `1`.

For the correlation, the following functional form is used:

$$\rho_{i,\,j} = e^{-\beta|i - j|}$$

Once the functional forms are specified, the parameters need to be estimated using market data. One useful approximation, initially developed by Rebonato, is the following, which computes the Black volatility for a European swaption, given a LMM with a set of volatility functions and a correlation matrix.

$$(v_{\alpha,\beta}^{LFM})^2 = \sum_{i,\,j\,=\,\alpha\,+\,1}^{\beta} \frac{w_i(0)w_j(0)F_i(0)F_j(0)\rho_{i,\,j}}{S_{\alpha,\beta}(0)^2}\int_0^{T\alpha}\sigma_i(t)\sigma_j(t)dt$$

where

$$w_i(t) = \frac{\tau_i P(t, T_i)}{\sum_{k\,=\,\alpha\,+\,1}^{\beta}\tau_k P(t, t_k)}$$

This calculation is done using `blackvolbyrebonato` to compute analytic values of the swaption price for model parameters and also to calibrate the model. Calibration consists of minimizing the difference between the observed implied swaption Black volatilities and the predicted Black volatilities.

Managing Interest-Rate Risk with Bond Futures

This example shows how to hedge the interest-rate risk of a portfolio using bond futures.

Modifying the Duration of a Portfolio with Bond Futures

In managing a bond portfolio, you can use a benchmark portfolio to evaluate performance. Sometimes a manager is constrained to keep the portfolio's duration within a particular band of the duration of the benchmark. One way to modify the duration of the portfolio is to buy and sell bonds, however, there may be reasons why a portfolio manager wishes to maintain the existing composition of the portfolio (for example, the current holdings reflect fundamental research/views about future returns). Therefore, another option for modifying the duration is to buy and sell bond futures.

Bond futures are futures contracts where the commodity to be delivered is a government bond that meets the standard outlined in the futures contract (for example, the bond has a specified remaining time to maturity). Since often many bonds are available, and each bond may have a different coupon, you can use a conversion factor to normalize the payment by the long to the short.

There exist well developed markets for government bond futures. Specifically, the Chicago Board of Trade offers futures on the following:

- 2 Year Note
- 3 Year Note
- 5 Year Note
- 10 Year Note
- 30 Year Bond

https://www.cmegroup.com/trading/interest-rates/

Eurex offers futures on the following:

- Euro-Schatz Futures 1.75 to 2.25
- Euro-Bobl Futures 4.5 to 5.5
- Euro-Bund Futures 8.5 to 10.5
- Euro-Buxl Futures 24.0 to 35

https://www.eurex.com/ex-en/

Bond futures can be used to modify the duration of a portfolio. Since bond futures derive their value from the underlying instrument, the duration of a bond futures contract is related to the duration of the underlying bond.

There are two challenges in computing this duration:

- Since there are many available bonds for delivery, the short in the contract has a choice in which bond to deliver.
- Some contracts allow the short flexibility in choosing the delivery date.

Typically, the bond used for analysis is the bond that is cheapest for the short to deliver (CTD). One approach is to compute duration measures using the CTD's duration and the conversion factor.

For example, the Present Value of a Basis Point (PVBP) can be computed from the following:

$$PVBP_{Futures} = \frac{PVBP_{CTD}}{ConversionFactor_{CTD}}$$

$$PVBP_{CTD} = \frac{Duration_{CTD} * Price_{CTD}}{100}$$

Note that these definitions of duration for the futures contract are approximate, and do not account for the value of the delivery options for the short.

If the goal is to modify the duration of a portfolio, use the following:

$$NumContracts = \frac{(Dur_{Target} - Dur_{Initial}) * Value_{Portfolio}}{Dur_{CTD} * Price_{CTD} * ContractSize} * ConvFactor_{CTD}$$

Note that the contract size is typically for 100,000 face value of a bond -- so the contract size is typically 1000, as the bond face value is 100.

The following example assumes an initial duration, portfolio value, and target duration for a portfolio with exposure to the Euro interest rate. The June Euro-Bund Futures contract is used to modify the duration of the portfolio. Note that typically futures contracts are offered for March, June, September and December.

```
% Assume the following for the portfolio and target
PortfolioDuration = 6.4;
PortfolioValue = 100000000;
BenchmarkDuration = 4.8;

% Deliverable Bunds -- note that these conversion factors may also be
% computed with the MATLAB(R) function convfactor
BondPrice = [106.46;108.67;104.30];
BondMaturity = datenum({'04-Jan-2018','04-Jul-2018','04-Jan-2019'});
BondCoupon = [.04;.0425;.0375];
ConversionFactor = [.868688;.880218;.839275];

% Futures data -- found from http://www.eurex.com
FuturesPrice = 122.17;
FuturesSettle = '23-Apr-2009';
FuturesDelivery = '10-Jun-2009';

% To find the CTD bond we can compute the implied repo rate
ImpliedRepo = bndfutimprepo(BondPrice,FuturesPrice,FuturesSettle,...
    FuturesDelivery,ConversionFactor,BondCoupon,BondMaturity);

% Note that the bond with the highest implied repo rate is the CTD
[CTDImpRepo,CTDIndex] = max(ImpliedRepo);

% Compute the CTD's Duration -- note the period and basis for German Bunds
Duration = bnddurp(BondPrice,BondCoupon,FuturesSettle,BondMaturity,1,8);

ContractSize = 1000;

% Use the formula above to compute the number of contracts to sell
NumContracts = (BenchmarkDuration - PortfolioDuration)*PortfolioValue./...
    (BondPrice(CTDIndex)*ContractSize*Duration(CTDIndex))*ConversionFactor(CTDIndex);
```

```
disp(['To achieve the target duration, ' num2str(abs(round(NumContracts))) ...
    ' Euro-Bund Futures must be sold.'])
```

```
To achieve the target duration, 180 Euro-Bund Futures must be sold.
```

Modifying the Key Rate Durations of a Portfolio with Bond Futures

One of the shortcomings of using duration as a risk measure is that it assumes parallel shifts in the yield curve. While many studies have shown that this explains roughly 85% of the movement in the yield curve, changes in the slope or shape of the yield curve are not captured by duration, and therefore, hedging strategies are not successful at addressing these dynamics. One approach is to use key rate duration -- this is particularly relevant when using bond futures with multiple maturities, like Treasury futures.

The following example uses 2, 5, 10 and 30 year Treasury Bond futures to hedge the key rate duration of a portfolio. Computing key rate durations requires a zero curve. This example uses the zero curve published by the Treasury and found at the following location:

https://www.treasury.gov/resource-center/data-chart-center/interest-rates/Pages/TextView.aspx?data=yield

Note that this zero curve could also be derived using the Interest-Rate Curve functionality found in `IRDataCurve` and `IRFunctionCurve`.

```
% Assume the following for the portfolio and target, where the duration
% vectors are key rate durations at 2, 5, 10, and 30 years.
PortfolioDuration = [.5 1 2 6];
PortfolioValue = 100000000;
BenchmarkDuration = [.4 .8 1.6 5];

% The following are the CTD Bonds for the 30, 10, 5 and 2 year futures
% contracts -- these were determined using the procedure outlined in the
% previous section.
CTDCoupon = [4.75 3.125 5.125 7.5]'/100;
CTDMaturity = datenum({'3/31/2011','08/31/2013','05/15/2016','11/15/2024'});
CTDConversion = [0.9794 0.8953 0.9519 1.1484]';
CTDPrice = [107.34 105.91 117.00 144.18]';

ZeroRates = [0.07 0.10 0.31 0.50 0.99 1.38 1.96 2.56 3.03 3.99 3.89]'/100;
ZeroDates = daysadd(FuturesSettle,[30 360 360*2 360*3 360*5 ...
    360*7 360*10 360*15 360*20 360*25 360*30],1);

% Compute the key rate durations for each of the CTD bonds.
CTDKRD = bndkrdur([ZeroDates ZeroRates], CTDCoupon,FuturesSettle,...
    CTDMaturity,'KeyRates',[2 5 10 30]);

% Note that the contract size for the 2 Year Note Future is $200,000
ContractSize = [2000;1000;1000;1000];

NumContracts = (bsxfun(@times,CTDPrice.*ContractSize./CTDConversion,CTDKRD))\...
    (BenchmarkDuration - PortfolioDuration)'*PortfolioValue;

sprintf(['To achieve the target duration, \n' ...
    num2str(-round(NumContracts(1))) ' 2 Year Treasury Note Futures must be sold, \n' ...
    num2str(-round(NumContracts(2))) ' 5 Year Treasury Note Futures must be sold, \n' ...
    num2str(-round(NumContracts(3))) ' 10 Year Treasury Note Futures must be sold, \n' ...
    num2str(-round(NumContracts(4))) ' Treasury Bond Futures must be sold, \n'])
```

```
ans =
    'To achieve the target duration,
     24 2 Year Treasury Note Futures must be sold,
     47 5 Year Treasury Note Futures must be sold,
     68 10 Year Treasury Note Futures must be sold,
     120 Treasury Bond Futures must be sold,
     '
```

Improving the Performance of a Hedge with Regression

An additional component to consider in hedging interest-rate risk with bond futures, again related to movements in the yield curve, is that typically the yield curve moves more at the short end than at the long end.

Therefore, if a position is hedged with a future where the CTD bond has a maturity that is different than the portfolio this could lead to a situation where the hedge under- or over-compensates for the actual interest-rate risk of the portfolio One approach is to perform a regression on historical yields at different maturities to determine a Yield Beta, which is a value that represents how much more the yield changes for different maturities.

This example shows how to use this approach with UK Long Gilt futures and historical data on Gilt Yields.

Market data on Gilt futures is found at the following:

https://www.euronext.com

Historical data on gilts is found at the following;

https://www.dmo.gov.uk

Note that while this approach does offer the possibility of improving the performance of a hedge, any analysis using historical data depends on historical relationships remaining consistent.

Also note that an additional enhancement takes into consideration the correlation between different maturities. While this approach is outside the scope of this example, you can use this to implement a minimum variance hedge.

```
% Assume the following for the portfolio and target
PortfolioDuration = 6.4;
PortfolioValue = 100000000;
BenchmarkDuration = 4.8;

% This is the CTD Bond for the Long Gilt Futures contract
CTDBondPrice = 113.40;
CTDBondMaturity = datenum('7-Mar-2018');
CTDBondCoupon = .05;
CTDConversionFactor = 0.9325024;

% Market data for the Long Gilt Futures contract
FuturesPrice = 120.80;
FuturesSettle = '23-Apr-2009';
FuturesDelivery = '10-Jun-2009';

CTDDuration = bnddurp(CTDBondPrice,CTDBondCoupon,FuturesSettle,CTDBondMaturity);
```

```
ContractSize = 1000;

NumContracts = (BenchmarkDuration - PortfolioDuration)*PortfolioValue./...
    (CTDBondPrice*ContractSize*CTDDuration)*CTDConversionFactor;

disp(['To achieve the target duration with a conventional hedge ' ...
    num2str(-round(NumContracts)) ...
    ' Long Gilt Futures must be sold.'])
```

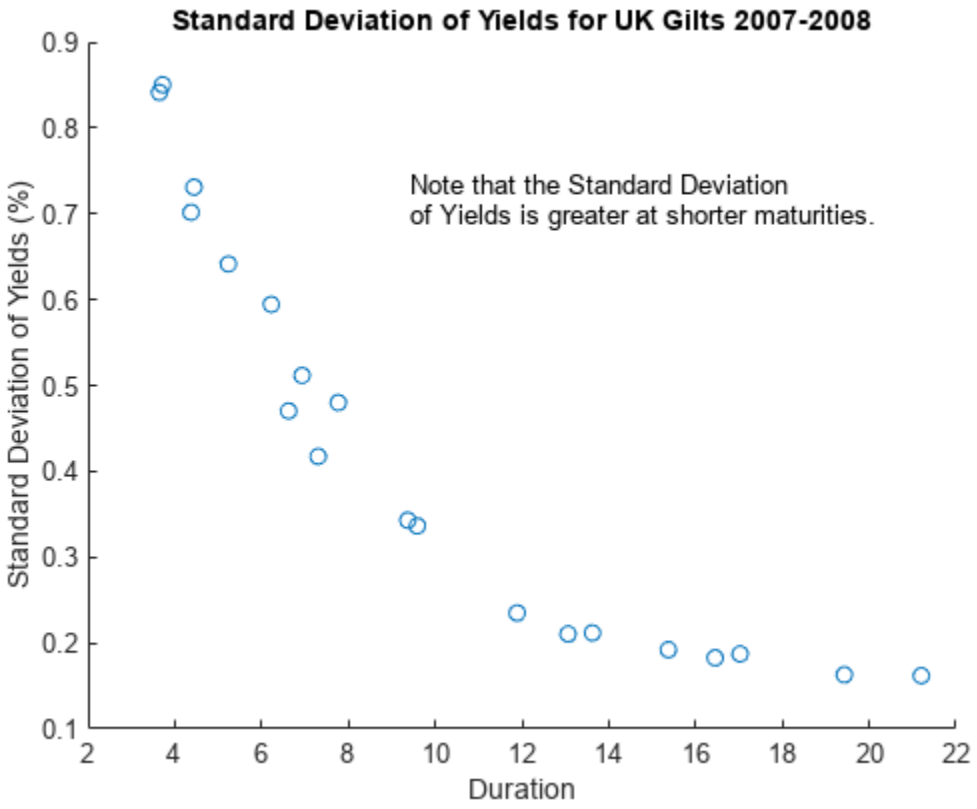
```
To achieve the target duration with a conventional hedge 182 Long Gilt Futures must be sold.
```

To improve the accuracy of this hedge, historical data is used to determine a relationship between the standard deviation of the yields. Specifically, standard deviation of yields is plotted and regressed vs bond duration. This relationship is then used to compute a Yield Beta for the hedge.

```
% Load data from XLS spreadsheet
load ukbonddata_20072008

Duration = bnddury(Yield(1,:)',Coupon,Dates(1,:),Maturity);

scatter(Duration,100*std(Yield))
title('Standard Deviation of Yields for UK Gilts 2007-2008')
ylabel('Standard Deviation of Yields (%)')
xlabel('Duration')
annotation(gcf,'textbox',[0.4067 0.685 0.4801 0.0989],...
    'String',{'Note that the Standard Deviation',...
    'of Yields is greater at shorter maturities.'},...
    'FitBoxToText','off',...
    'EdgeColor','none');
```



```
stats = regstats(std(Yield),Duration);
YieldBeta = (stats.beta'*[1 PortfolioDuration]')./(stats.beta'*[1 CTDDuration]');
```

Now the Yield Beta is used to compute a new value for the number of contracts to be sold. Note that since the duration of the portfolio was less than the duration of the CTD Gilt, the number of futures to sell is actually greater than in the first case.

```
NumContracts = (BenchmarkDuration - PortfolioDuration)*PortfolioValue./...
    (CTDBondPrice*ContractSize*CTDDuration)*CTDConversionFactor*YieldBeta;

disp(['To achieve the target duration using a Yield Beta-modified hedge, ' ...
    num2str(abs(round(NumContracts))) ...
    ' Long Gilt Futures must be sold.'])
```

```
To achieve the target duration using a Yield Beta-modified hedge, 193 Long Gilt Futures must be s
```

Analyze Inflation-Indexed Instruments

This example shows how to analyze inflation-indexed instruments using Financial Toolbox™ and Financial Instruments Toolbox™.

Compute Real Prices and Yields for Inflation-Indexed Bonds

While inflation-indexed bonds have a great deal of variation in the design, for example, the length of the indexation lag, the majority of inflation-indexed bonds now have a three month lag. They are also capital-indexed, that is, the principal of the bond is indexed to inflation. Therefore, the coupon rate of the bond is constant, but the actual coupon payments vary as the principal of the bond is indexed to inflation.

Specifically, the indexation is done with the following ratio:

$$IndexRatio = \frac{CPI_{Ref}}{CPI_{Base}}$$

where CPI_{Base} is the level of the consumer price index (or equivalent price measure) at the time of the bond's issue and CPI_{Ref} is the reference CPI.

Typically, you compute the CPI_{Ref} by interpolating between the index data of a known inflation-index curve. To compute the cash flows for an inflation-indexed bond, you simply compute the appropriate reference CPI and Index Ratio.

The market convention for inflation-indexed bonds is to quote the price and yield using the actual (that is, unadjusted) coupon, which means that your quote is a real price and yield. To get a real price and yield, you can use the Financial Toolbox™ functions `bndprice` and `bndyield`. For example:

```
Price = 124 + 9/32;
Settle = datetime(2009,9,28);
Coupon = .03375;
Maturity = datetime(2032,4,15);

RealYield = bndyield(Price,Coupon,Settle,Maturity);
disp(['Real Yield: ', num2str(RealYield*100) '%'])
```

```
Real Yield: 2.0278%
```

Construct Nominal, Real, and Inflation Curves

With the advent of the inflation-indexed bond market, real curves can be constructed in a similar fashion to nominal curves. Using the available market data, you can construct the real curve and compare it to the nominal curve.

Note that one issue relates to the indexation lag of the bonds. As stated previously, typically the indexation lag is three months, which means that the inflation compensation is not actually matched up with the maturity or the coupon payments of the bond. While Anderson and Sleath [1] discuss an approach to resolving this discrepancy, for this example, the lag is simply noted.

You can use the `fitNelsonSiegel` and `fitSvensson` functions in the Financial Instruments Toolbox™ to create `parametercurve` objects that fit Nelson-Siegel and Svensson models to real and nominal yield curves in the US. The Nelson-Siegel model typically places restrictions on the model

parameters to ensure that the interest rates are always positive. However, real interest rates can be negative, which means that these Nelson-Siegel restrictions are not used in the case below.

```
% Load the data.
load usbond_02Sep2008
Settle = datetime(2008, 9, 2);
NominalTimeToMaturity = yearfrac(Settle,NominalMaturity);
TIPSTimeToMaturity = yearfrac(Settle,TIPSMaturity);

% Compute the yields.
NominalYield = bndyield(NominalPrice,NominalCoupon,Settle,NominalMaturity);
TIPSYield = bndyield(TIPSPrice,TIPSCoupon,Settle,TIPSMaturity);

% Plot the yields.
scatter(NominalTimeToMaturity,NominalYield*100,'r');
hold on;
scatter(TIPSTimeToMaturity,TIPSYield*100,'b');

% Fit the real yield curve using fitNelsonSiegel.
nInst = numel(TIPSCoupon);
TIPSBonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    TIPSBonds(ii) = fininstrument("FixedBond",'Maturity',TIPSMaturity(ii),...
        'CouponRate',TIPSCoupon(ii));
end

TIPSNelsonSiegel = fitNelsonSiegel(Settle,TIPSBonds,TIPSPrice);

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

% Fit the nominal yield curve using fitSvensson.
nInst = numel(NominalCoupon);
NominalBonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    NominalBonds(ii) = fininstrument("FixedBond",'Maturity',NominalMaturity(ii),...
        'CouponRate',NominalCoupon(ii));
end

NominalSvensson = fitSvensson(Settle,NominalBonds,NominalPrice);

Solver stopped prematurely.

lsqnonlin stopped because it exceeded the function evaluation limit,
options.MaxFunctionEvaluations = 6.000000e+02.

% Plot the nominal and real yield curves.

Constructing Inflation Curves from Zero-Coupon Inflation Swaps

Inflation-linked derivatives have also experienced growth in the market. Some of the most liquidly traded inflation derivatives are zero coupon inflation swaps (`ZeroCouponInflationSwap`) and year-on-year inflation swaps (`YearYearInflationSwap`).

In a zero-coupon inflation swap, the inflation payer agrees to pay the rate of inflation at maturity (lagged by a certain amount) compounded by the number of years. The inflation receiver typically pays a fixed rate, again compounded by the tenor of the instrument. At the inception of the zero-coupon inflation swap, the fixed rate is set to the projected inflation rate for the life of the swap. This rate is called the "breakeven inflation swap rate" and it is quoted in the market [6].

Using the notation from Hurd and Relleen, you compute the rate as:

$$(1 + Rate_{swap})^T = (1 + Inflation_{t-L,\,t+T-L})^T$$

where t is the current time, T is the tenor, and L is the lag. [5]

At maturity, the actual cash flows of the zero-coupon inflation swap are:

$$FixedLeg = N \times [(1 + k)^M - 1]$$

$$InflationLeg = N \times \left[\frac{I(T_M)}{I_0} - 1\right]$$

where

- $N$is the reference notional of the swap.
- k is the fixed inflation rate.
- $M$is the number of years for the life of the swap.
- $I(T_M)$is the inflation index at the maturity date with some lag (for example, three months).
- I_0 is the inflation index at the start date with some lag (for example, three months).

While the fixed-leg cash flow might be different from the actual inflation-leg cash flow at maturity, the fixed breakeven inflation swap rate of the zero-coupon inflation swap represents the projected inflation rate for the tenor of the swap at inception. You can build an inflation curve from a series of breakeven zero-coupon inflation swap rates starting on the same date and maturing on different dates. Here, the dates are already adjusted with the appropriate indexation lag to simplify the notation:

$$I(0,T_{1Y}) = I(T_0)(1 + b(0;T_0,T_{1Y}))^{T_{1Y} - T_0}$$

$$I(0,T_{2Y}) = I(T_0)(1 + b(0;T_0,T_{2Y}))^{T_{2Y} - T_0}$$

$$I(0,T_{3Y}) = I(T_0)(1 + b(0;T_0,T_{3Y}))^{T_{3Y} - T_0}$$

. . .

$$I(0,T_i) = I(T_0)(1 + b(0;T_0,T_i))^{T_i - T_0}$$

where

- $I(0,T_i)$ is the breakeven inflation index reference number for maturity date T_i.
- $I(T_0)$ is the base inflation index value for the starting date T_0.
- $b(0;T_0,T_i)$ is the breakeven inflation rate for the zero-coupon inflation swap maturing on T_i.

You can get your inflation curve this by using the `inflationbuild` function to create an `inflationcurve` object. To build an `inflationcurve` from zero-coupon inflation swap rates, first define the base inflation date and the corresponding base inflation-index value.

```
% Define the base inflation date and index value for the inflation-index
% curve.
BaseDate = datetime(2020,6,1);
BaseIndexValue = 100;
```

Then, define the zero-coupon inflation swap rates and the corresponding maturity dates already adjusted with the appropriate indexation lag.

```
% Define the zero-coupon inflation swap rates and maturity dates.
ZCISTimes = (calyears([1 2 3 4 5 7 10 20 30]))';
ZCISRates = [0.42 0.54 0.76 0.87 0.92 1.39 1.71 2.01 2.46]'./100
```

```
ZCISRates = 9×1

    0.0042
    0.0054
    0.0076
    0.0087
```

```
    0.0092
    0.0139
    0.0171
    0.0201
    0.0246
```

```
ZCISDates = BaseDate + ZCISTimes
```

```
ZCISDates = 9x1 datetime
   01-Jun-2021
   01-Jun-2022
   01-Jun-2023
   01-Jun-2024
   01-Jun-2025
   01-Jun-2027
   01-Jun-2030
   01-Jun-2040
   01-Jun-2050
```

In pricing inflation derivatives and building inflation curves, incorporating seasonality can be a critical factor. The zero-coupon inflation swap rates typically have maturities that increase in whole number of years. As a result, the inflation curve is typically built from zero-coupon inflation swap rates on an annual basis. However, when computing inflation-index values for monthly periods that are not whole number of years, you can make seasonal adjustments to reflect the seasonal patterns of inflation within the year. These 12 monthly seasonal rates are annualized and they add up to zero to ensure that the cumulative seasonal adjustments are reset to zero every year. In the `inflationbuild` function and the `inflationcurve` object, you define these seasonal rates using the `'Seasonality'` name-value pair argument and they are internally corrected to ensure that they add to zero.

```
% Define the 12 monthly seasonal rates.
%
% Months:
%    Jan   Feb   Mar   Apr   May   Jun   Jul   Aug   Sep   Oct   Nov   Dec
%     1     2     3     4     5     6     7     8     9    10    11    12
% Seasonal Rates (percent):
%   -6.34 -3.00 -1.34  3.34  5.34  3.66  8.66  5.66 -2.34 -2.66 -4.66 -6.32
SeasonalRates = [-6.34 -3.00 -1.34 3.34 5.34 3.66 8.66 5.66 -2.34 -2.66 -4.66 -6.32]./100
```

```
SeasonalRates = 1×12

   -0.0634   -0.0300   -0.0134    0.0334    0.0534    0.0366    0.0866    0.0566   -0.0234   -0.0
```

```
% Build an inflation-index curve from zero-coupon inflation swap rates.
myInflationCurve = inflationbuild(BaseDate, BaseIndexValue, ...
    ZCISDates, ZCISRates, 'Seasonality', SeasonalRates)
```

```
myInflationCurve =
  inflationcurve with properties:

                   Basis: 0
                   Dates: [10x1 datetime]
     InflationIndexValues: [10x1 double]
    ForwardInflationRates: [9x1 double]
```

```
            Seasonality: [12x1 double]
```

Once you have created the `inflationcurve` object, compute the inflation-index values for each month using `indexvalues`.

```
% Compute the inflation-index values.
IndexPlotDates = (BaseDate:calmonths(1):BaseDate+calyears(10))';
IndexPlotValues = indexvalues(myInflationCurve, IndexPlotDates);
```

To visualize the seasonal patterns of inflation that occur within each year, plot the computed inflation-index values.

```
% Plot the inflation-index curve.
figure; plot(IndexPlotDates, IndexPlotValues)
hold on;
plot(myInflationCurve.Dates(1:8), myInflationCurve.InflationIndexValues(1:8), 'o')
hold off;

title('Inflation-Index Curve Built from Zero-Coupon Inflation Swaps (ZCIS)')
xlabel('Years')
ylabel('Inflation-Index Values')
legend({'Interpolated inflation-index values','ZCIS inflation-index values'},'location','northwes
```

Price Inflation-Indexed Instruments Using an Inflation Curve

With the `inflationcurve` object created, you can price inflation-indexed instruments such as zero-coupon inflation swaps (`ZeroCouponInflationSwap`), year-on-year inflation swaps (`YearYearInflationSwap`), and inflation-indexed bonds (`InflationBond`).

First, create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,25);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0043 0.0051 0.0062 0.0072 0.0096 0.0121 0.0172 0.0241 0.0302 0.0308]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 25-Sep-2020
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Using the `ratecurve` and `inflationcurve` objects as inputs, create an `Inflation` pricer object using `finpricer`.

```
outPricer = finpricer("Inflation",'DiscountCurve',ZeroCurve,'InflationCurve',myInflationCurve)
```

```
outPricer =
  Inflation with properties:

     DiscountCurve: [1x1 ratecurve]
    InflationCurve: [1x1 inflationcurve]
```

Create an `InflationBond` instrument using `fininstrument`.

```
IssueDate = datetime(2020,9,20);
Maturity = datetime(2025,9,20);
CouponRate = 0.023;

InflationBond = fininstrument("InflationBond",'IssueDate',IssueDate,'Maturity',Maturity,'CouponRa
```

```
InflationBond =
  InflationBond with properties:

                  CouponRate: 0.0230
                      Period: 2
                       Basis: 0
                   Principal: 100
    DaycountAdjustedCashFlow: 0
                         Lag: 3
```

```
BusinessDayConvention: "actual"
              Holidays: NaT
          EndMonthRule: 1
             IssueDate: 20-Sep-2020
       FirstCouponDate: NaT
        LastCouponDate: NaT
              Maturity: 20-Sep-2025
                  Name: ""
```

Here, the default indexation lag is three months and the bond issue date is `20-Sep-2020`. The first date on the inflation curve of the pricer must be on or before `20-Jun-2020` to price this instrument. In this example, the first date on the inflation curve of the pricer is `01-Jun-2020`.

Price the `InflationBond` instrument by using the `price` function for the `Inflation` pricer.

```
InflationBondPrice = price(outPricer, InflationBond)
```

```
InflationBondPrice = 110.1314
```

Bootstrapping a Swap Curve

This example shows how to bootstrap an interest-rate curve, often referred to as a swap curve, using the `IRDataCurve` object. The static `bootstrap` method takes as inputs a cell array of market instruments (which can be deposits, interest-rate futures, swaps, and bonds) and bootstraps an interest-rate curve of either the forward or the zero curve. It is also possible to specify multiple interpolation methods, including piecewise constant, linear, and Piecewise Cubic Hermite Interpolating Polynomial (PCHIP).

Obtain Data

A curve is bootstrapped from market data. In this example, you bootstrap a swap curve from deposits, Eurodollar Futures, and swaps.

For this example, the input market data is hard-coded and specified as 2 cell arrays of data, one which indicates the type of instrument and a second cell array containing the `Settle`, `Maturity`, and Market Quote for the instrument. For deposits and swaps, the quote is a rate, and for the EuroDollar Futures, the quote is a price. Although bonds are not used in this example, a bond would be quoted with a price.

```
InstrumentTypes = {'Deposit';'Deposit';'Deposit';'Deposit';'Deposit'; ...
    'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Swap';'Swap';'Swap';'Swap';'Swap';'Swap';'Swap'};

Instruments = [datenum('08/10/2007'),datenum('08/17/2007'),.0532063; ...

    datenum('08/08/2007'),datenum('08/08/2037'),.0566];
```

Construct the Curve Using Bootstrapping

The `bootstrap` method is called as a static method of the `IRDataCurve` class. Inputs to this method include the curve type (Zero or Forward), settle date, instrument types, instrument data, and optional arguments including an interpolation method, compounding, and an options structure for bootstrapping. Note that in this example, you pass in an `IRBootstrapOptions` object which includes information for the convexity adjustment to forward rates.

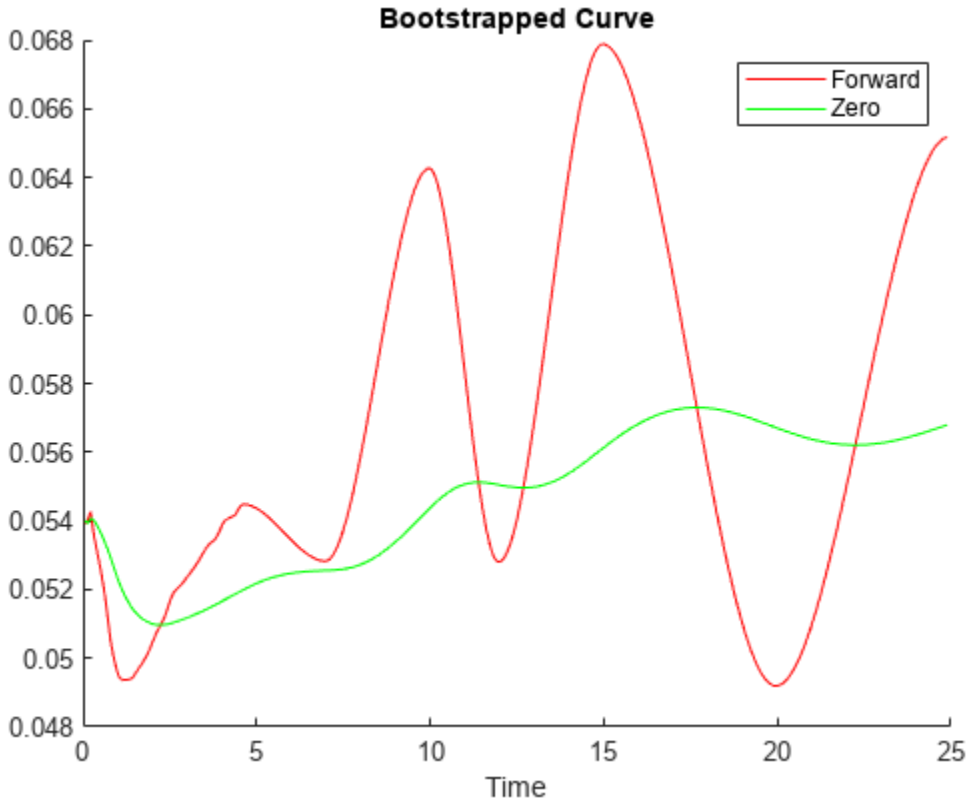
```
IRsigma = .01;
CurveSettle = datenum('08/10/2007');
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
    InstrumentTypes, Instruments,'InterpMethod','pchip',...
    'Compounding',-1,'IRBootstrapOptions',...
    IRBootstrapOptions('ConvexityAdjustment',@(t) .5*IRsigma^2.*t.^2));
```

Plot Curves

Plot both the forward and zero curves.

```
PlottingDates = (CurveSettle+20:30:CurveSettle+365*25)';
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
BootstrappedForwardRates = bootModel.getForwardRates(PlottingDates);
BootstrappedZeroRates = bootModel.getZeroRates(PlottingDates);

figure
hold on
plot(TimeToMaturity,BootstrappedForwardRates,'r')
plot(TimeToMaturity,BootstrappedZeroRates,'g')
title('Bootstrapped Curve')
xlabel('Time')
legend({'Forward','Zero'})
```



Bibliography

This example draws from the following papers and journal articles:

[2] Ron, Uri (2000). "A Practical Guide to Swap Curve Construction." Working Papers 00-17, Bank of Canada.

Fitting Interest-Rate Curve Functions

This example shows how to use `IRFunctionCurve` objects to model the term structure of interest rates (also referred to as the yield curve). This can be contrasted with modeling the term structure with vectors of dates and data and interpolating between the points (which can currently be done with the function `prbyzero`). The term structure can refer to at least three different curves: the discount curve, zero curve, or forward curve.

The `IRFunctionCurve` object allows you to model an interest-rate curve as a function.

This example explores using an `IRFunctionCurve` object to model the default-free term structure of interest rates in the United Kingdom. Three different forms for the term structure are implemented and are discussed in more detail later:

- Nelson-Siegel
- Svensson
- Smoothing Cubic Spline with a so-called Variable Roughness Penalty (VRP)

Choosing the Data

The first question in modeling the yield curve is what data should be used. To model a default-free yield curve, default-free, option-free market instruments must be used. The most significant component of the data is UK Government Bonds (known as Gilts). Historical data is retrieved from the following site:

https://www.dmo.gov.uk

Repo data is used to construct the short end of the yield curve. Repo data is retrieved from the following site:

https://www.ukfinance.org.uk/

Note also that the data must be specified as a matrix where the columns are `Settle`, `Maturity`, `CleanPrice`, and `CouponRate` and that instruments must be bonds or synthetically converted to bonds.

Market data for a close date of April 30, 2008, has been downloaded and saved to the following data file (`ukdata20080430`), which is loaded into MATLAB® with the following command:

```
% Load the data
load ukdata20080430

% Convert repo rates to be equivalent zero coupon bonds
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);

% Aggregate the data
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
```

```
CurveSettle = datenum('30-Apr-2008');
```

Fit Nelson-Siegel Model to Market Data

The Nelson-Siegel model proposes that the instantaneous forward curve can be modeled with the following:

$$f = \beta_0 + \beta_1 e^{\frac{-m}{\tau}} + \beta_2 e^{\frac{-m}{\tau}} \frac{m}{\tau}$$

This can be integrated to derive an equation for the zero curve (see [6] for more information on the equations and the derivation):

$$s = \beta_0 + (\beta_1 + \beta_2)\frac{\tau}{m}(1 - e^{\frac{-m}{\tau}}) - \beta_2 e^{\frac{-m}{\tau}}$$

See [1 on page 2-148] for more information.

The `IRFunctionCurve` object provides the capability to fit a Nelson Siegel curve to observed market data with the `fitNelsonSiegel` method. The fitting is done by calling the Optimization Toolbox™ function `lsqnonlin`.

The `fitNelsonSiegel` function has required inputs for Curve `Type`, Curve `Settle`, and a matrix of instrument data.

Optional input arguments, specified in name-value pair argument, are:

- `IRFitOptions` structure: Provides the capability to choose which quantity to be minimized (price, yield, or duration weighted price) and other optimization parameters (for example, upper and lower bounds for parameters).
- Curve `Compounding` and `Basis` (day-count convention)
- Additional instrument parameters, `Period`, `Basis`, `FirstCouponDate`, and so on.

```
NSModel = IRFunctionCurve.fitNelsonSiegel('Zero',CurveSettle,...
    Instruments,'InstrumentPeriod',InstrumentPeriod);
```

Fit Svensson Model

A very similar model to the Nelson-Siegel model is the Svensson model, which adds two additional parameters to account for greater flexibility in the term structure. This model proposes that the forward rate can be modeled with the following form:

$$f = \beta_0 + \beta_1 e^{\frac{-m}{\tau_1}} + \beta_2 e^{\frac{-m}{\tau_1}} \frac{m}{\tau_1} + \beta_3 e^{\frac{-m}{\tau_2}} \frac{m}{\tau_2}$$

As above, this can be integrated to derive an equation for the zero curve:

$$s = \beta_0 + \beta_1(1 - e^{\frac{-m}{\tau_1}})(-\frac{\tau_1}{m}) + \beta_2((1 - e^{\frac{-m}{\tau_1}})\frac{\tau_1}{m} - e^{\frac{m}{\tau_1}}) + \beta_3((1 - e^{\frac{-m}{\tau_2}})\frac{\tau_2}{m} - e^{\frac{m}{\tau_2}})$$

See [2 on page 2-148] for more information.

Fitting the parameters to this model proceeds in a similar fashion to the Nelson-Siegel model using the `fitSvensson` function.

```
SvenssonModel = IRFunctionCurve.fitSvensson('Zero',CurveSettle,...
    Instruments,'InstrumentPeriod',InstrumentPeriod);
```

Fit Smoothing Spline

The term structure can also be modeled with a spline, specifically, one way to model the term structure is by representing the forward curve with a cubic spline. To ensure that the spline is sufficiently smooth, a penalty is imposed relating to the curvature (second derivative) of the spline:

$$\sum_{i=1}^{N}[\frac{P_i - \widehat{P}_i(f)}{D_i}]^2 + \int_0^M \lambda_t(m)[f''(m)]^2 dm$$

where the first term is the difference between the observed price *P* and the predicted price, *P_hat*, (weighted by the bond's duration, *D*) summed over all bonds in the data set, and the second term is the penalty term (where *lambda* is a penalty function and *f* is the spline).

See [3 on page 2-148], [4 on page 2-148], [5 on page 2-149] below.

There have been different proposals for the specification of the penalty function *lambda*. One approach, advocated by [4 on page 2-148], and currently used by the UK Debt Management Office, is a penalty function of the following form:

$$log(\lambda(m)) = L - (L - S)e^{\frac{-m}{\mu}}$$

The parameters *L*, *S*, and *mu* are typically estimated from historical data.

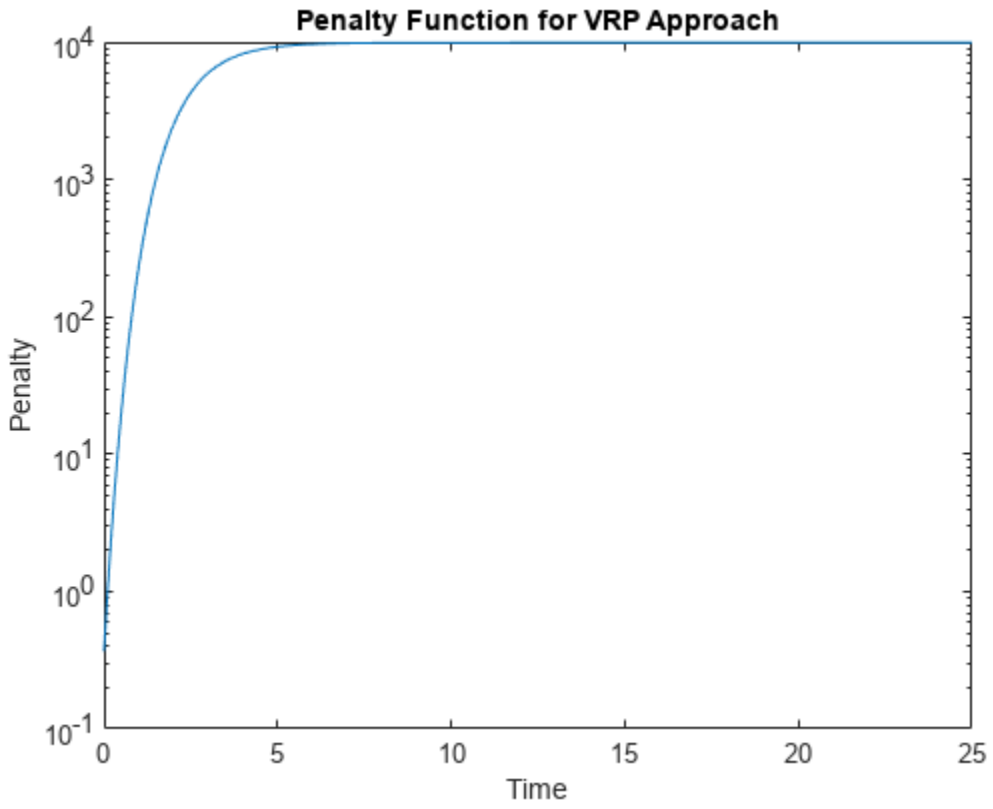
The `IRFunctionCurve` object can be used to fit a smoothing spline representation of the forward curve with a penalty function using the function `fitSmoothingSpline`.

Required inputs, like for the functions above, are a `CurveType`, Curve`Settle`, `Instruments` matrix, and a function handle (`Lambdafun`) containing the penalty function.

The optional parameters are similar to `fitNelsonSiegel` and `fitSvensson`.

```
% Parameters chosen to be roughly similar to [4] below.
L = 9.2;
S = -1;
mu = 1;

lambdafun = @(t) exp(L - (L-S)*exp(-t/mu)); % Construct penalty function
t = 0:.1:25; % Construct data to plot penalty function
y = lambdafun(t);
figure
semilogy(t,y);
title('Penalty Function for VRP Approach')
ylabel('Penalty')
xlabel('Time')
```



```
VRPModel = IRFunctionCurve.fitSmoothingSpline('Forward',CurveSettle,...
    Instruments,lambdafun,'Compounding',-1,...
    'InstrumentPeriod',InstrumentPeriod);
```

Use Fitted Curves and Plot Results

Once a curve is created, functions are used to extract the Forward and Zero Rates and the Discount Factors. This curve can also be converted into a `RateSpec` structure using the `toRateSpec` function. The `RateSpec` can then be used with many other functions in the Financial Instruments Toolbox™

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);

NSForwardRates = NSModel.getForwardRates(PlottingDates);
SvenssonForwardRates = SvenssonModel.getForwardRates(PlottingDates);
VRPForwardRates = VRPModel.getForwardRates(PlottingDates);

figure
hold on
plot(TimeToMaturity,NSForwardRates,'r')
plot(TimeToMaturity,SvenssonForwardRates,'g')
plot(TimeToMaturity,VRPForwardRates,'b')
title('UK Instantaneous Nominal Forward Curve')
xlabel('Years Ahead')
legend({'Nelson Siegel','Svensson','VRP'})
```

Fitting the Diebold Li Model

This example shows how to construct a Diebold Li model of the US yield curve for each month from 1990 to 2010. This example also demonstrates how to forecast future yield curves by fitting an autoregressive model to the time series of each parameter.

The paper can be found here:

https://www.nber.org/papers/w10048

Load the Data

The data used are monthly Treasury yields from 1990 through 2010 for tenors of 1 Mo, 3 Mo, 6 Mo, 1 Yr, 2 Yr, 3 Yr, 5 Yr, 7 Yr, 10 Yr, 20 Yr, 30 Yr.

Daily data can be found here:

https://www.treasury.gov/resource-center/data-chart-center/interest-rates/Pages/TextView.aspx?data=yieldAll

Data is stored in a MATLAB® data file as a MATLAB `dataset` object.

```
load Data_USYieldCurve

% Extract data for the last day of each month
MonthYearMat = repmat((1990:2010)',1,12)';
EOMDates = lbusdate(MonthYearMat(:),repmat((1:12)',21,1));
MonthlyIndex = find(ismember(Dataset.Properties.ObsNames,datestr(EOMDates)));
Estimationdataset = Dataset(MonthlyIndex,:);
EstimationData = double(Estimationdataset);
```

Diebold Li Model

Diebold and Li start with the Nelson Siegel model

$$y = \beta_0 + (\beta_1 + \beta_2)\frac{\tau}{m}(1 - e^{\frac{-m}{\tau}}) - \beta_2 e^{\frac{-m}{\tau}}$$

and rewrite it to be the following:

$$y_t(\tau) = \beta_{1t} + \beta_{2t}\left(\frac{1 - e^{-\lambda_t\tau}}{\lambda_t\tau}\right) + \beta_{3t}\left(\frac{1 - e^{-\lambda_t\tau}}{\lambda_t\tau} - e^{-\lambda_t\tau}\right)$$

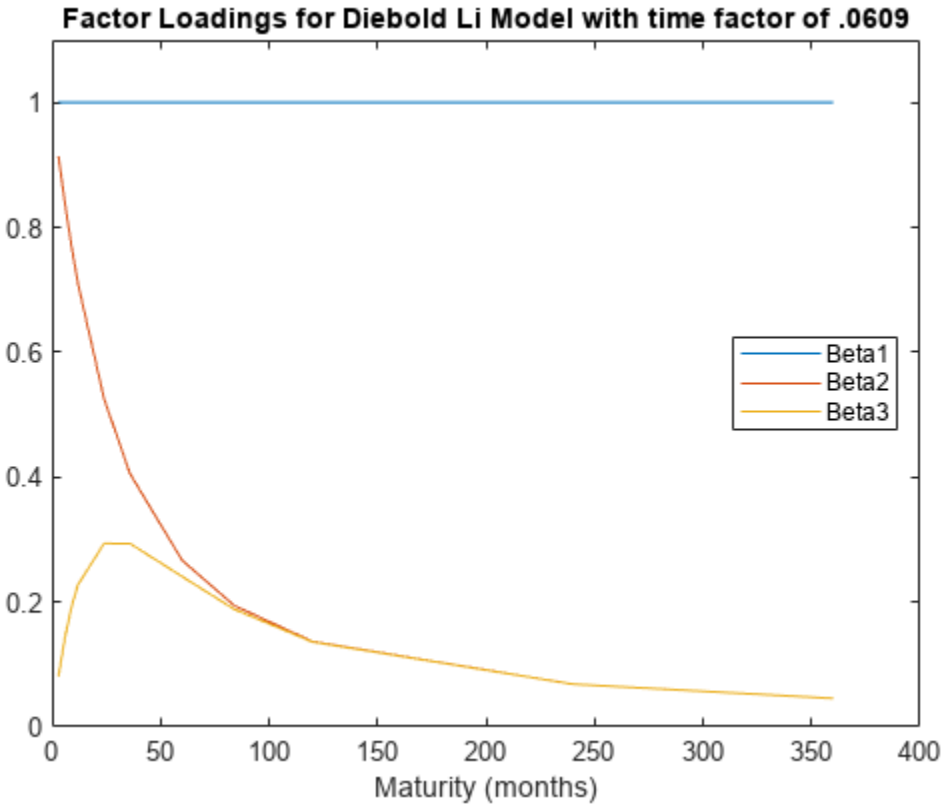
The above model allows the factors to be interpreted in the following way: Beta1 corresponds to the long term/level of the yield curve, Beta2 corresponds to the short term/slope, and Beta3 corresponds to the medium term/curvature. λ determines the maturity at which the loading on the curvature is maximized, and governs the exponential decay rate of the model.

Diebold and Li advocate setting λ to maximize the loading on the medium term factor, Beta3, at 30 months. This also transforms the problem from a nonlinear fitting to a simple linear regression.

```
% Explicitly set the time factor lambda
lambda_t = .0609;
```

```
% Construct a matrix of the factor loadings
% Tenors associated with data
TimeToMat = [3 6 9 12 24 36 60 84 120 240 360]';
X = [ones(size(TimeToMat)) (1 - exp(-lambda_t*TimeToMat))./(lambda_t*TimeToMat) ...
    ((1 - exp(-lambda_t*TimeToMat))./(lambda_t*TimeToMat) - exp(-lambda_t*TimeToMat))];

% Plot the factor loadings
plot(TimeToMat,X)
title('Factor Loadings for Diebold Li Model with time factor of .0609')
xlabel('Maturity (months)')
ylim([0 1.1])
legend({'Beta1','Beta2','Beta3'},'location','east')
```



Fit the Model

A `DieboldLi` object is developed to facilitate fitting the model from yield data. The `DieboldLi` object inherits from the `IRCurve` object, so the `getZeroRates`, `getDiscountFactors`, `getParYields`, `getForwardRates`, and `toRateSpec` methods are all implemented. Additionally, the method `fitYieldsFromBetas` is implemented to estimate the Beta parameters given a lambda parameter for observed market yields.

The `DieboldLi` object is used to fit a Diebold Li model for each month from 1990 through 2010.

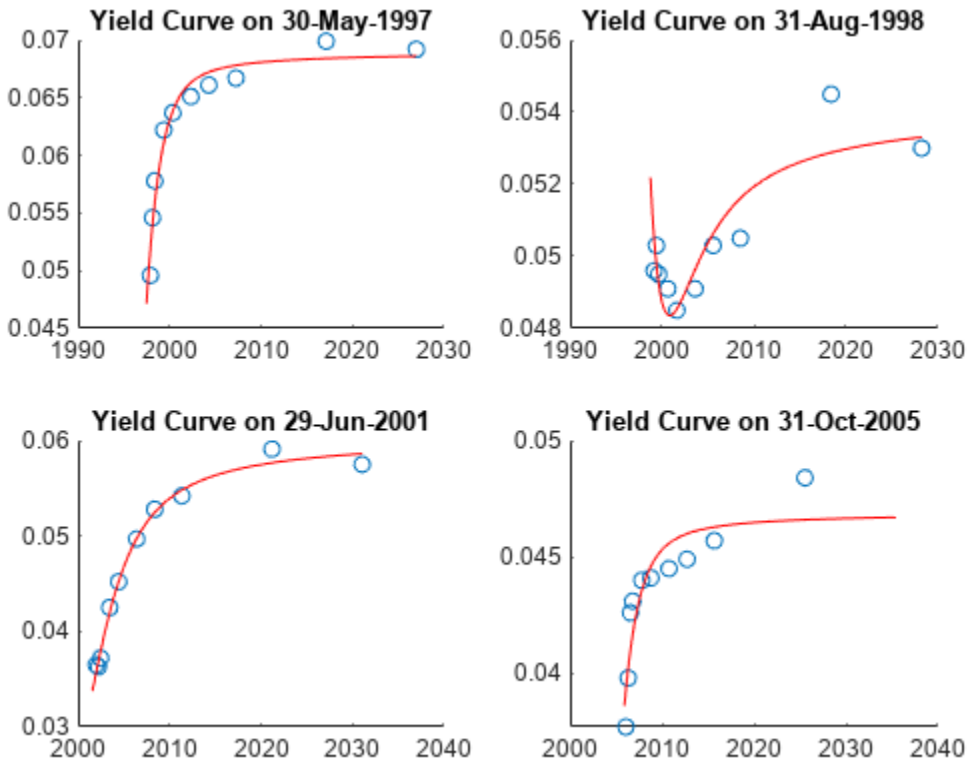
```
% Preallocate the Betas
Beta = zeros(size(EstimationData,1),3);

% Loop through and fit each end of month yield curve
```

```
for jdx = 1:size(EstimationData,1)
    tmpCurveModel = DieboldLi.fitBetasFromYields(EOMDates(jdx),lambda_t*12,daysadd(EOMDates(jdx)
    Beta(jdx,:) = [tmpCurveModel.Beta1 tmpCurveModel.Beta2 tmpCurveModel.Beta3];
end
```

The Diebold Li fits on selected dates are included here

```
PlotSettles = [datetime(1997,5,30) , datetime(1998,8,31) , datetime(2001,6,29) , datetime(2005,10
figure
for jdx = 1:length(PlotSettles)
    subplot(2,2,jdx)
    tmpIdx = find(strcmpi(Estimationdataset.Properties.ObsNames,datestr(PlotSettles(jdx))));
    tmpCurveModel = DieboldLi.fitBetasFromYields(PlotSettles(jdx),lambda_t*12,...
        daysadd(PlotSettles(jdx),30*TimeToMat),EstimationData(tmpIdx,:)');
    scatter(daysadd(PlotSettles(jdx),30*TimeToMat),EstimationData(tmpIdx,:))
    hold on
    PlottingDates = (PlotSettles(jdx)+30:30:PlotSettles(jdx)+30*360)';
    plot(PlottingDates,tmpCurveModel.getParYields(PlottingDates),'r-')
    title(['Yield Curve on ' datestr(PlotSettles(jdx))])
    datetick
end
```



Forecasting

The Diebold Li model can be used to forecast future yield curves. Diebold and Li propose fitting an AR(1) model to the time series of each Beta parameter. This fitted model can then be used to forecast future values of each parameter, and by extension, future yield curves.

For this example the MATLAB function `regress` is used to estimate the parameters for an AR(1) model for each Beta.

The confidence intervals for the regression fit are also used to generate two additional yield curve forecasts that serve as additional possible scenarios for the yield curve.

The `MonthsLag` variable can be adjusted to make different period ahead forecasts. For example, changing the value from `1` to `6` would change the forecast from a 1 month ahead to 6 month ahead forecast.

```
MonthsLag = 1;

[tmpBeta,bint] = regress(Beta(MonthsLag+1:end,1),[ones(size(Beta(MonthsLag+1:end,1))) Beta(1:end
ForecastBeta(1,1) = [1 Beta(end,1)]*tmpBeta;
ForecastBeta_Down(1,1) = [1 Beta(end,1)]*bint(:,1);
ForecastBeta_Up(1,1) = [1 Beta(end,1)]*bint(:,2);
[tmpBeta,bint]  = regress(Beta(MonthsLag+1:end,2),[ones(size(Beta(MonthsLag+1:end,2))) Beta(1:en
ForecastBeta(1,2) = [1 Beta(end,2)]*tmpBeta;
ForecastBeta_Down(1,2) = [1 Beta(end,2)]*bint(:,1);
ForecastBeta_Up(1,2) = [1 Beta(end,2)]*bint(:,2);
[tmpBeta,bint]  = regress(Beta(MonthsLag+1:end,3),[ones(size(Beta(MonthsLag+1:end,3))) Beta(1:en
ForecastBeta(1,3) = [1 Beta(end,3)]*tmpBeta;
ForecastBeta_Down(1,3) = [1 Beta(end,3)]*bint(:,1);
ForecastBeta_Up(1,3) = [1 Beta(end,3)]*bint(:,2);

% Forecasted yield curve
figure
Settle = daysadd(EOMDates(end),30*MonthsLag);
DieboldLi_Forecast = DieboldLi('ParYield',Settle,[ForecastBeta lambda_t*12]);
DieboldLi_Forecast_Up = DieboldLi('ParYield',Settle,[ForecastBeta_Up lambda_t*12]);
DieboldLi_Forecast_Down = DieboldLi('ParYield',Settle,[ForecastBeta_Down lambda_t*12]);
PlottingDates = (Settle+30:30:Settle+30*360)';
plot(PlottingDates,DieboldLi_Forecast.getParYields(PlottingDates),'b-')
hold on
plot(PlottingDates,DieboldLi_Forecast_Up.getParYields(PlottingDates),'r-')
plot(PlottingDates,DieboldLi_Forecast_Down.getParYields(PlottingDates),'r-')
title(['Diebold Li Forecasted Yield Curves on ' datestr(EOMDates(end)) ' for '  datestr(Settle)]
legend({'Forecasted Curve','Additional Scenarios'},'location','southeast')
datetick
```

Calibrating Caplets Using the Normal (Bachelier) Model

This example shows how to use `hwcalbycap` to calibrate market data with the Normal (Bachelier) model to price caplets. Use the Normal (Bachelier) model to perform calibrations when working with negative interest rates, strikes, and normal implied volatilities.

Consider a cap with these parameters:

```
Settle = datetime(2016,12,30);
Maturity = datetime(2019,12,30);
Strike = -0.001075;
Reset = 2;
Principal = 100;
Basis = 0;
```

The caplets and market data for this example are defined as:

```
capletDates = cfdates(Settle, Maturity, Reset, Basis);
datestr(capletDates')
```

```
ans = 6x11 char array
    '30-Jun-2017'
    '30-Dec-2017'
    '30-Jun-2018'
    '30-Dec-2018'
    '30-Jun-2019'
    '30-Dec-2019'
```

```
% Market data information
MarketStrike = [-0.0013; 0];
MarketMat =  [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12
MarketVol = [0.184 0.2329 0.2398 0.2467 0.2906 0.3348;   % First row in table corresponding to St
             0.217 0.2707 0.2760 0.2814 0.3160 0.3508];  % Second row in table corresponding to S
```

Define the `RateSpec` using `intenvset`.

```
Rates= [-0.002210;-0.002020;-0.00182;-0.001343;-0.001075];
ValuationDate = datetime(2016,12,30);
EndDates =  [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12
Compounding = 2;
Basis = 0;

RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);
```

Use `hwcalbycap` to find values for the volatility parameters `Alpha` and `Sigma` using the Normal (Bachelier) model.

```
format short
o=optimoptions('lsqnonlin','TolFun',100*eps);
warning ('off','fininst:hwcalbycapfloor:NoConverge')
[Alpha, Sigma, OptimOut] = hwcalbycap(RateSpec, MarketStrike, MarketMat,...
MarketVol, Strike, Settle, Maturity, 'Reset', Reset, 'Principal', Principal,...
'Basis', Basis, 'OptimOptions', o, 'model', 'normal')
```

```
Local minimum possible.
lsqnonlin stopped because the size of the current step is less than
the value of the step size tolerance.

Alpha = 1.0000e-06

Sigma = 0.3384

OptimOut = struct with fields:
     resnorm: 1.5181e-04
    residual: [5x1 double]
    exitflag: 2
      output: [1x1 struct]
      lambda: [1x1 struct]
    jacobian: [5x2 double]
```

The `OptimOut.residual` field of the `OptimOut` structure is the optimization residual. This value contains the difference between the Normal (Bachelier) caplets and those calculated during the optimization. Use the `OptimOut.residual` value to calculate the percentual difference (error) compared to Normal (Bachelier) caplet prices, and then decide whether the residual is acceptable. There is almost always some residual, so decide if it is acceptable to parameterize the market with a single value of `Alpha` and `Sigma`.

Price the caplets using the market data and Normal (Bachelier) model to obtain the reference caplet values. To determine the effectiveness of the optimization, calculate reference caplet values using the Normal (Bachelier) formula and the market data. Note, you must first interpolate the market data to obtain the caplets for calculation.

```
MarketMatNum = datenum(MarketMat);
[Mats, Strikes] = meshgrid(MarketMatNum, MarketStrike);
FlatVol = interp2(Mats, Strikes, MarketVol, datenum(Maturity), Strike, 'spline');

[CapPrice, Caplets] = capbynormal(RateSpec, Strike, Settle, Maturity, FlatVol,...
'Reset', Reset, 'Basis', Basis, 'Principal', Principal);
Caplets = Caplets(2:end)'
```

```
Caplets = 5×1

    4.7392
    6.7799
    8.2609
    9.6136
   10.6455
```

Compare the optimized values and Normal (Bachelier) values, and display the results graphically. After calculating the reference values for the caplets, compare the values analytically and graphically to determine whether the calculated single values of `Alpha` and `Sigma` provide an adequate approximation.

```
OptimCaplets = Caplets+OptimOut.residual;

disp('   ');

disp(' Bachelier   Calibrated Caplets');

Calibrating Floorlets Using the Normal (Bachelier) Model

This example shows how to use `hwcalbyfloor` to calibrate market data with the Normal (Bachelier) model to price floorlets. Use the Normal (Bachelier) model to perform calibrations when working with negative interest rates, strikes, and normal implied volatilities.

Consider a floor with these parameters:

```
Settle = datetime(2016,12,30);
Maturity = datetime(2019,12,30);
Strike = -0.004075;
Reset = 2;
Principal = 100;
Basis = 0;
```

The floorlets and market data for this example are defined as:

```
floorletDates = cfdates(Settle, Maturity, Reset, Basis);
datestr(floorletDates')
```

```
ans = 6x11 char array
    '30-Jun-2017'
    '30-Dec-2017'
    '30-Jun-2018'
    '30-Dec-2018'
    '30-Jun-2019'
    '30-Dec-2019'
```

```
% Market data information
MarketStrike = [-0.00595; 0];
MarketMat = [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12
MarketVol = [0.184 0.2329 0.2398 0.2467 0.2906 0.3348;   % First row in table corresponding to St
             0.217 0.2707 0.2760 0.2814 0.3160 0.3508];  % Second row in table corresponding to S
```

Define the `RateSpec` using `intenvset`.

```
Rates= [-0.003210;-0.003020;-0.00182;-0.001343;-0.001075];
ValuationDate = datetime(2016,12,30);
EndDates = [datetime(2017,6,30) ; datetime(2017,12,30) ; datetime(2018,6,30) ; datetime(2018,12,3
Compounding = 2;
Basis = 0;

RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate, 'EndDates', EndDates, ...
'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);
```

Use `hwcalbyfloor` to find values for the volatility parameters `Alpha` and `Sigma` using the Normal (Bachelier) model.

```
format short
o=optimoptions('lsqnonlin','TolFun',100*eps);
warning ('off','fininst:hwcalbycapfloor:NoConverge')
[Alpha, Sigma, OptimOut] = hwcalbyfloor(RateSpec, MarketStrike, MarketMat,...
MarketVol, Strike, Settle, Maturity, 'Reset', Reset, 'Principal', Principal,...
'Basis', Basis, 'OptimOptions', o, 'model', 'normal')
```

```
Local minimum possible.
lsqnonlin stopped because the size of the current step is less than
the value of the step size tolerance.

Alpha = 1.0000e-06

Sigma = 0.3410

OptimOut = struct with fields:
     resnorm: 1.9233e-04
    residual: [5x1 double]
    exitflag: 2
      output: [1x1 struct]
      lambda: [1x1 struct]
    jacobian: [5x2 double]
```

The `OptimOut.residual` field of the `OptimOut` structure is the optimization residual. This value contains the difference between the Normal (Bachelier) floorlets and those calculated during the optimization. Use the `OptimOut.residual` value to calculate the percentual difference (error) compared to Normal (Bachelier) floorlet prices, and then decide whether the residual is acceptable. There is almost always some residual, so decide if it is acceptable to parameterize the market with a single value of `Alpha` and `Sigma`.

Price the floorlets using the market data and Normal (Bachelier) model to obtain the reference floorlet values. To determine the effectiveness of the optimization, calculate reference floorlet values using the Normal (Bachelier) formula and the market data. Note, you must first interpolate the market data to obtain the floorlets for calculation.

```
MarketMatNum = datenum(MarketMat);
[Mats, Strikes] = meshgrid(MarketMatNum, MarketStrike);
FlatVol = interp2(Mats, Strikes, MarketVol, datenum(Maturity), Strike, 'spline');

[FloorPrice, Floorlets] = floorbynormal(RateSpec, Strike, Settle, Maturity, FlatVol,...
'Reset', Reset, 'Basis', Basis, 'Principal', Principal);
Floorlets = Floorlets(2:end)'
```

```
Floorlets = 5×1

    4.7637
    6.7180
    8.1833
    9.5825
   10.6090
```

Compare the optimized values and Normal (Bachelier) values, and display the results graphically. After calculating the reference values for the floorlets, compare the values analytically and graphically to determine whether the calculated single values of `Alpha` and `Sigma` provide an adequate approximation.

```
OptimFloorlets = Floorlets+OptimOut.residual;

disp('   ');

disp(' Bachelier   Calibrated Floorlets');
```

```
 Bachelier   Calibrated Floorlets
```

```
disp([Floorlets        OptimFloorlets])

Calibrate the SABR Model Using Normal (Bachelier) Volatilities with Negative Strikes

This example shows how to use two different methods to calibrate the SABR stochastic volatility model from market implied Normal (Bachelier) volatilities with negative strikes. Both approaches use `normalvolbysabr`, which computes the implied Normal volatilities by using the SABR model. When the `Beta` parameter of the SABR model is set to zero, the model is a Normal SABR model, which allows computing the implied Normal volatilities for negative strikes.

Load the Market Implied Normal (Bachelier) Volatility Data

Set up hypothetical market implied Normal volatilities for European swaptions over a range of strikes before calibration. The swaptions expire in one year from the `Settle` date and have two-year swaps as the underlying instrument. The rates are expressed in decimals. The market implied Normal volatilities are converted from basis points to decimals. (Changing the units affects the numerical value and interpretation of the `Alpha` parameter input to the function `normalvolbysabr`.)

```
% Load the market implied Normal volatility data for swaptions expiring in one year.
Settle = '20-Sep-2017';
ExerciseDate = '20-Sep-2018';
Basis = 1;

ATMStrike = -0.174/100;
MarketStrikes = ATMStrike + ((-0.5:0.25:1.5)')./100;
MarketVolatilities = [20.58 17.64 16.93 18.01 20.46 22.90 26.11 28.89 31.91]'/10000;

% At the time of Settle, define the underlying forward rate and the at-the-money volatility.
CurrentForwardValue = MarketStrikes(3)
```

```
CurrentForwardValue = -0.0017
```

```
ATMVolatility = MarketVolatilities(3)
```

```
ATMVolatility = 0.0017
```

Method 1: Calibrate `Alpha`, `Rho`, and `Nu` Directly

This section demonstrates how to calibrate the `Alpha`, `Rho`, and `Nu` parameters directly. The value of the `Beta` parameter is set to zero in order to allow negative rates in the SABR model (Normal SABR). After fixing the value of β(`Beta`), the parameters α (`Alpha`), ρ (`Rho`), and ν (`Nu`) are all fitted directly. The Optimization Toolbox™ function `lsqnonlin` generates the parameter values that minimize the squared error between the market volatilities and the volatilities computed by `normalvolbysabr`.

```
% Define the predetermined Beta
Beta1 = 0; % Setting Beta to zero allows negative rates for Normal volatilities

% Calibrate Alpha, Rho, and Nu
objFun = @(X) MarketVolatilities - ...
    normalvolbysabr(X(1), Beta1, X(2), X(3), Settle, ...
    ExerciseDate, CurrentForwardValue, MarketStrikes, 'Basis', Basis);

% If necessary, tolerances and stopping criteria can be adjusted for lsqnonlin
X = lsqnonlin(objFun, [ATMVolatility 0 0.5], [0 -1 0], [Inf 1 Inf]);
```

```
Local minimum found.
```

```
Optimization completed because the size of the gradient is less than
the value of the optimality tolerance.
```

```
Alpha1 = X(1);
Rho1 = X(2);
Nu1 = X(3);
```

Method 2: Calibrate Rho and Nu by Implying Alpha from At-The-Money Volatility

This section demonstrates how to use an alternative calibration method where the value of β is again predetermined to be zero in order to allow negative rates. However, after fixing the value of β (`Beta`), the parameters ρ (`Rho`), and ν (`Nu`) are fitted directly while α (`Alpha`) is implied from the market at-the-money volatility. Models calibrated using this method produce at-the-money volatilities that are equal to market quotes. This approach can be useful when at-the-money volatilities are quoted most frequently and are important to match. In order to imply α (`Alpha`) from market at-the-money Normal volatility ($\sigma_{Normal,\,ATM}$), the following cubic polynomial is solved for α (`Alpha`), and the smallest positive real root is selected. This is similar to the approach used for implying α (`Alpha`) from market at-the-money Black volatility [2]. However, note that the following expression that is used for Normal volatilities is different from another expression that is used for Black volatilities.

$$\frac{\beta(\beta-2)T}{24F^{(2-2\beta)}}\alpha^3+\frac{\rho\beta\nu T}{4F^{(1-\beta)}}\alpha^2+\left(1+\frac{2-3\rho^2}{24}\nu^2T\right)\alpha-\sigma_{Normal,\,ATM}F^{-\beta}=0$$

```
% Define the predetermined Beta
Beta2 = 0; % Setting Beta to zero allows negative rates for Normal volatilities

% Year fraction from Settle to option maturity
T = yearfrac(Settle, ExerciseDate, Basis);

% This function solves the SABR at-the-money volatility equation as a
% polynomial of Alpha
alpharootsNormal = @(Rho,Nu) roots([...
    Beta2.*(Beta2 - 2)*T/24/CurrentForwardValue^(2 - 2*Beta2) ...
    Rho*Beta2*Nu*T/4/CurrentForwardValue^(1 - Beta2) ...
    (1 + (2 - 3*Rho^2)*Nu^2*T/24) ...
    -ATMVolatility*CurrentForwardValue^(-Beta2)]);

% This function converts at-the-money volatility into Alpha by picking the
% smallest positive real root
atmNormalVol2SabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
    x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharootsNormal(Rho,Nu))));

% Calibrate Rho and Nu (while converting at-the-money volatility into Alpha
% using atmVol2NormalSabrAlpha)
objFun = @(X) MarketVolatilities - ...
    normalvolbysabr(atmNormalVol2SabrAlpha(X(1), X(2)), ...
    Beta2, X(1), X(2), Settle, ExerciseDate, CurrentForwardValue, ...
    MarketStrikes, 'Basis', Basis);

% If necessary, tolerances and stopping criteria can be adjusted for lsqnonlin
X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf]);
```

```
Local minimum found.

Optimization completed because the size of the gradient is less than
the value of the optimality tolerance.
```

```
Rho2 = X(1);
Nu2 = X(2);

% Obtain final Alpha from at-the-money volatility using calibrated parameters
Alpha2 = atmNormalVol2SabrAlpha(Rho2, Nu2);

% Display calibrated parameters
C = {Alpha1 Beta1 Rho1 Nu1;Alpha2 Beta2 Rho2 Nu2};
format;
CalibratedPrameters = cell2table(C,...
    'VariableNames',{'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'Method 1';'Method 2'})
```

```
CalibratedPrameters=2×4 table
                Alpha      Beta       Rho         Nu
              _________    ____    _________    _______

    Method 1    0.0016332     0      -0.034233    0.45877
    Method 2    0.0016652     0        -0.0318    0.44812
```

Use the Calibrated Models

Use the calibrated models to compute new volatilities at any strike value, including negative strikes.

Compute volatilities for models calibrated using Method 1 and Method 2, then plot the results. The model calibrated using Method 2 reproduces the market at-the-money volatility (marked with a circle) exactly.

```
PlottingStrikes = (min(MarketStrikes)-0.0025:0.0001:max(MarketStrikes)+0.0025)';

% Compute volatilities for model calibrated by Method 1
ComputedVols1 = normalvolbysabr(Alpha1, Beta1, Rho1, Nu1, Settle, ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes, 'Basis', Basis);

% Compute volatilities for model calibrated by Method 2
ComputedVols2 = normalvolbysabr(Alpha2, Beta2, Rho2, Nu2, Settle, ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes, 'Basis', Basis);

figure;
plot(MarketStrikes,MarketVolatilities*10000,'xk',...
    PlottingStrikes,ComputedVols1*10000,'b', ...
    PlottingStrikes,ComputedVols2*10000,'r', ...
    CurrentForwardValue,ATMVolatility*10000,'ok',...
    'MarkerSize',10);

h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');

xlabel('Strike', 'FontWeight', 'bold');
ylabel('Implied Normal Volatility (bps)', 'FontWeight', 'bold');
legend('Market Volatilities', 'Normal SABR Model (Method 1)', ...
    'Normal SABR Model (Method 2)', 'At-the-money volatility', ...
    'Location', 'northwest');
```

Calibrate Shifted SABR Model Parameters for Swaption Instrument

Calibrate model parameters for a `Swaption` instrument when you use a `SABR` pricing method.

Load Market Data

```
% Zero curve
ValuationDate = datetime("5-Mar-2016", 'Locale', 'en_US');
ZeroDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]])';
ZeroRates = [-0.33 -0.28 -0.24 -0.12 -0.08 -0.03 0.015 0.028 ...
    0.033 0.042 0.056 0.095 0.194 0.299 0.415 0.525]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",ValuationDate,ZeroDates,ZeroRates,'Compounding',Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
               Basis: 0
               Dates: [16x1 datetime]
               Rates: [16x1 double]
              Settle: 05-Mar-2016
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

```
% Define the swaptions
SwaptionSettle = datetime("5-Mar-2016", 'Locale', 'en_US');
SwaptionExerciseDate = datetime("5-Mar-2017", 'Locale', 'en_US');
SwaptionStrikes = (-0.6:0.01:1.6)'/100; % Include negative strikes
SwapMaturity = datetime("5-Mar-2022", 'Locale', 'en_US'); % Maturity of underlying swap
OptSpec = 'call';
```

Compute Forward Swap Rate by Creating Swap Instrument

Use `fininstrument` to create a `Swap` instrument object.

```
LegRate = [0 0];
Swap = fininstrument("Swap", 'Maturity', SwapMaturity, 'LegRate', LegRate, "LegType",["fixed" "f
    "ProjectionCurve", ZeroCurve, "StartDate", SwaptionExerciseDate)
```

```
Swap =
  Swap with properties:

                   LegRate: [0 0]
                   LegType: ["fixed"    "float"]
                     Reset: [2 2]
                     Basis: [0 0]
                  Notional: 100
         LatestFloatingRate: [NaN NaN]
                ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
```

```
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: 05-Mar-2017
                    Maturity: 05-Mar-2022
                        Name: ""
```

```
ForwardValue = parswaprate(Swap,ZeroCurve)
```

```
ForwardValue = 7.3271e-04
```

Load the Market Implied Volatility Data

The market swaption volatilities are quoted in terms of shifted Black volatilities with a `0.8` percent shift.

```
StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = ForwardValue + StrikeGrid;
Shift = 0.008;  % 0.8 percent shift
MarketShiftedBlackVolatilities = [21.1; 15.3; 14.0; 14.6; 16.0; 17.7; 19.8; 23.9; 26.2]/100;
ATMShiftedBlackVolatility = MarketShiftedBlackVolatilities(StrikeGrid==0);
```

Calibrate Shifted SABR Model Parameters

The `Beta` parameter is predetermined at `0.5`. Use `volatilities` to compute the implied volatility.

```
Beta = 0.5;

% Calibrate Alpha, Rho, and Nu
objFun = @(X) MarketShiftedBlackVolatilities - volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', X(1), 'Beta', Beta, 'Rho', X(2), 'Nu', X(3), 'Shift', Shift), ...
    'DiscountCurve', ZeroCurve), SwaptionExerciseDate, ForwardValue, MarketStrikes);

X = lsqnonlin(objFun, [0.5 0 0.5], [0 -1 0], [Inf 1 Inf]);
```

```
Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.
```

```
Alpha = X(1);
Rho = X(2);
Nu = X(3);
```

Create SABR Model Using the Calibrated Parameters

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR",'Alpha',Alpha,'Beta',Beta,'Rho',Rho,'Nu',Nu,'Shift',Shift)
```

```
SABRModel =
  SABR with properties:

             Alpha: 0.0135
              Beta: 0.5000
               Rho: 0.4654
                Nu: 0.4957
```

```
             Shift: 0.0080
    VolatilityType: "black"
```

Create SABR Pricer Using Calibrated SABR Model and Compute Volatilities

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SABRPricer = finpricer("Analytic", 'Model', SABRModel, 'DiscountCurve', ZeroCurve)
```

```
SABRPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

```
SABRShiftedBlackVolatilities = volatilities(SABRPricer, SwaptionExerciseDate, ForwardValue, Swapt
```

```
SABRShiftedBlackVolatilities = 221×1

    0.2978
    0.2911
    0.2848

Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instruments using an `IRTree` pricing method.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
 ZeroTimes = calyears(1:4)';
 ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
 ZeroDates = Settle + ZeroTimes;
 Compounding = 1;
 ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: 1
               Basis: 0
               Dates: [4x1 datetime]
               Rates: [4x1 double]
              Settle: 01-Jan-2018
        InterpMethod: "linear"
   ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

Create Bond and Option Instruments

Use `fininstrument` to create a `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;

% Vanilla FixedBond
VBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',0.0425,'Period',Period,'Name'
```

```
VBond =
  FixedBond with properties:

                 CouponRate: 0.0425
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
```

```
                    Holidays: NaT
                   IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "vanilla_fixed"
```

```
 % Stepped coupon bond
SBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,'Period',Period,'Na
```

```
SBond =
  FixedBond with properties:

                CouponRate: [2x1 timetable]
                    Period: 1
                     Basis: 0
               EndMonthRule: 1
                  Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "stepped_coupon_bond"
```

```
% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond",'Maturity',Maturity,'Spread',Spread,'Reset', Reset,...
                      'ProjectionCurve',ZeroCurve,'Name',"floatbond")
```

```
Float =
  FloatBond with properties:

                     Spread: 0
              ProjectionCurve: [1x1 ratecurve]
                  ResetOffset: 0
                        Reset: 1
                        Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
          LatestFloatingRate: NaN
                    Holidays: NaT
                   IssueDate: NaT
              FirstCouponDate: NaT
               LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                        Name: "floatbond"
```

```
% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType ='call';
Period = 1;
CallOption = fininstrument("FixedBondOption",'Strike',Strike,'ExerciseDate',ExerciseDates,...
                  'OptionType',OptionType,'ExerciseStyle',"american",'Bond', VBond,'Name',"fixed
```

```
CallOption =
  FixedBondOption with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2020
           Strike: 100
             Bond: [1x1 fininstrument.FixedBond]
             Name: "fixed_bond_option"
```

```
% Option for embedded bond (callable bond)
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule =  timetable(ExerciseDatesOE,StrikeOE,'VariableNames',{'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
                             'CouponRate',CouponRate,'Period', Period, ...
                             'CallSchedule',CallSchedule,'Name',"option_embedded_fixedbond")
```

```
CallableBond =
  OptionEmbeddedFixedBond with properties:

                 CouponRate: [2x1 timetable]
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                  Principal: 100
   DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
                   Holidays: NaT
                  IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 01-Jan-2022
                   CallDates: [2x1 datetime]
                    PutDates: [0x1 datetime]
                CallSchedule: [2x1 timetable]
                 PutSchedule: [0x0 timetable]
           CallExerciseStyle: "american"
            PutExerciseStyle: [0x0 string]
                        Name: "option_embedded_fixedbond"
```

Create HullWhite Model

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("hullwhite",'alpha',AlphaCurve,'sigma',VolCurve)
```

```
HWModel =
  HullWhite with properties:

    Alpha: 0.1000
    Sigma: 0.0100
```

Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an `IRTree` pricer object for a `HullWhite` model and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates
```

```
HWTreePricer =
  HWBKTree with properties:

            Tree: [1x1 struct]
       TreeDates: [4x1 datetime]
           Model: [1x1 finmodel.HullWhite]
   DiscountCurve: [1x1 ratecurve]
```

Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```
myportfolio = finportfolio([VBond,SBond,Float,CallOption],HWTreePricer, [1,2,2,1])
```

```
myportfolio =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FinInstrument]
        Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [4x1 double]
       Quantity: [4x1 double]
```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```
myportfolio = addInstrument(myportfolio,CallableBond,HWTreePricer,1)
```

```
myportfolio =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
        Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [5x1 double]
       Quantity: [5x1 double]
```

```
myportfolio.PricerIndex
```

```
ans = 5×1

     1
     1
     1
     1
     1
```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =
        600.55

InstPrice = 5×1

         96.59
        204.14
        200.00
          0.05
         99.77

PortSens=1×4 table
    Price      Delta       Gamma      Vega
    ______    ________    _______    ______

    600.55    -1297.48    5759.65    -63.40

InstSens=5×4 table
                                Price      Delta      Gamma      Vega
                                ______    _______    _______    ______

    vanilla_fixed                96.59    -344.81    1603.49     -0.00
    stepped_coupon_bond         204.14    -725.96    3364.60      0.00
    floatbond                   200.00       0.00      -0.00     -0.00
    fixed_bond_option             0.05      -3.69      24.15     12.48

```

Calibrate SABR Model Using Normal (Bachelier) Volatilities with Analytic Pricer

This example shows how to use two different methods to calibrate the SABR stochastic volatility model from market implied Normal (Bachelier) volatilities with negative strikes. Both approaches use the SABR analytic pricer. When the Beta parameter of the SABR model is set to zero, the model is a Normal SABR model, which allows computing the implied Normal volatilities for negative strikes.

Load Market Implied Normal (Bachelier) Volatility Data

Set up hypothetical market implied Normal volatilities for European swaptions over a range of strikes before calibration. The swaptions expire in one year from the Settle date and have two-year swaps as the underlying instrument. The rates are expressed in decimals. The market implied Normal volatilities are converted from basis points to decimals. (Changing the units affects the numerical value and interpretation of the Alpha parameter in the SABR model.)

```
% Load the market implied Normal volatility data for swaptions expiring in one year.
Settle = datetime(2020, 4, 24);
ExerciseDate = datetime(2021, 4, 24);
Basis = 1;
ZeroDates = Settle + [calmonths([3 6 9]) calyears([1 2 3 4 5 ...
    6 7 10 15 20])]';
ZeroRates = [-.54 -.57 -.60 -.62 -.67 -.67 -.65 -.61 ...
    -.56 -.51 -.36 -.19 -.10]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',Compounding);

ATMStrike = -0.70/100;
MarketStrikes = ATMStrike + ((-0.5:0.25:1.5)')./100;
MarketVolatilities = [29.89 25.47 23.21 26.17 29.59 33.12 37.81 41.88 46.24]'/10000;

% At the time of Settle, define the underlying forward rate and the at-the-money volatility.
CurrentForwardValue = MarketStrikes(3)
```

```
CurrentForwardValue = -0.0070
```

```
ATMVolatility = MarketVolatilities(3)
```

```
ATMVolatility = 0.0023
```

Method 1: Calibrate Alpha, Rho, and Nu Directly

You can calibrate the Alpha, Rho, and Nu parameters directly. Set the value of the Beta parameter to zero in order to allow negative rates in the SABR model (Normal SABR). After you fix the value of β (Beta), you fit the parameters α (Alpha), ρ (Rho), and ν (Nu) directly. The Optimization Toolbox™ function lsqnonlin generates the parameter values that minimize the squared error between the market volatilities and the volatilities computed by the SABR analytic pricer.

```
% Define the predetermined Beta
Beta1 = 0; % Setting Beta to zero allows negative rates for Normal volatilities

% Calibrate Alpha, Rho, and Nu
objFun = @(X) MarketVolatilities - ...
    volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', X(1), 'Beta', Beta1, 'Rho', X(2), ...
```

```
    'Nu', X(3), 'VolatilityType', 'Normal'), 'DiscountCurve', ZeroCurve), ...
    ExerciseDate, CurrentForwardValue, MarketStrikes);

% If necessary, adjust the tolerances and stopping criteria for lsqnonlin
X = lsqnonlin(objFun, [ATMVolatility 0 0.5], [0 -1 0], [Inf 1 Inf]);

Local minimum found.

Optimization completed because the size of the gradient is less than
the value of the optimality tolerance.

Alpha1 = X(1);
Rho1 = X(2);
Nu1 = X(3);
```

Method 2: Calibrate Rho and Nu by Implying Alpha from At-The-Money Volatility

Another method is to use an alternative calibration method. As in the first method, you set the value of β (`Beta`) to zero to allow negative rates. However, after fixing the value of β (`Beta`), you fit the parameters ρ (`Rho`) and ν (`Nu`) directly while α (`Alpha`) is implied from the market at-the-money volatility. Models calibrated using this method produce at-the-money volatilities that are equal to market quotes. This approach can be useful when at-the-money volatilities are quoted most frequently and are important to match. To imply α (`Alpha`) from market at-the-money Normal volatility ($\sigma_{Normal,\,ATM}$), solve the following cubic polynomial for α (`Alpha`), and select the smallest positive real root. This is similar to the approach used for implying α (`Alpha`) from market at-the-money Black volatility [2 on page 2-180]. However, note that the following expression that is used for Normal volatilities is different from the expression that is used for Black volatilities.

$$\frac{\beta(\beta-2)T}{24F^{(2-2\beta)}}\alpha^3+\frac{\rho\beta\nu T}{4F^{(1-\beta)}}\alpha^2+\left(1+\frac{2-3\rho^2}{24}\nu^2T\right)\alpha-\sigma_{Normal,\,ATM}F^{-\beta}=0$$

```
% Define the predetermined Beta
Beta2 = 0; % Setting Beta to zero allows negative rates for Normal volatilities

% Year fraction from Settle date to option maturity
T = yearfrac(Settle, ExerciseDate, Basis);

% This function solves the SABR at-the-money volatility equation as a
% polynomial of Alpha
alpharootsNormal = @(Rho,Nu) roots([...
    Beta2.*(Beta2 - 2)*T/24/CurrentForwardValue^(2 - 2*Beta2) ...
    Rho*Beta2*Nu*T/4/CurrentForwardValue^(1 - Beta2) ...
    (1 + (2 - 3*Rho^2)*Nu^2*T/24) ...
    -ATMVolatility*CurrentForwardValue^(-Beta2)]);

% This function converts at-the-money volatility into Alpha by picking the
% smallest positive real root
atmNormalVol2SabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
    x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharootsNormal(Rho,Nu))));

% Calibrate Rho and Nu (while converting at-the-money volatility into Alpha
% using atmNormalVol2SabrAlpha)
objFun = @(X) MarketVolatilities - ...
    volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', atmNormalVol2SabrAlpha(X(1), X(2)), ...
    'Beta', Beta2, 'Rho', X(1), 'Nu', X(2), 'VolatilityType', 'Normal'), ...
    'DiscountCurve', ZeroCurve), ...
```

```
    ExerciseDate, CurrentForwardValue, MarketStrikes);

% If necessary, adjust the tolerances and stopping criteria for lsqnonlin
X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf]);

Local minimum found.

Optimization completed because the size of the gradient is less than
the value of the optimality tolerance.

Rho2 = X(1);
Nu2 = X(2);

% Obtain final Alpha from at-the-money volatility using calibrated parameters
Alpha2 = atmNormalVol2SabrAlpha(Rho2, Nu2);

% Display calibrated parameters
C = {Alpha1 Beta1 Rho1 Nu1;Alpha2 Beta2 Rho2 Nu2};
format;
CalibratedPrameters = cell2table(C,...
    'VariableNames',{'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'Method 1';'Method 2'})

CalibratedPrameters=2×4 table
                 Alpha      Beta       Rho         Nu
               _________    ____    _________    _______

    Method 1    0.0023279     0      -0.010078    0.63538
    Method 2    0.0022389     0      -0.019029    0.66368
```

Use the Calibrated Models

Use the calibrated models to compute new volatilities at any strike value, including negative strikes.

Compute volatilities for models calibrated using Method 1 and Method 2, then plot the results. The model calibrated using Method 2 reproduces the market at-the-money volatility (marked with a circle) exactly.

```
PlottingStrikes = (min(MarketStrikes)-0.0025:0.0001:max(MarketStrikes)+0.0025)';

% Compute volatilities for model calibrated by Method 1
SABR_Model_Method_1 = finmodel("SABR", ...
    'Alpha', Alpha1, 'Beta', Beta1, 'Rho', Rho1, 'Nu', Nu1, ...
    'VolatilityType', 'Normal');

ComputedVols1 = volatilities(finpricer("Analytic", ...
    'Model', SABR_Model_Method_1, 'DiscountCurve', ZeroCurve), ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes);

% Compute volatilities for model calibrated by Method 2
SABR_Model_Method_2 = finmodel("SABR", ...
    'Alpha', Alpha2, 'Beta', Beta2, 'Rho', Rho2, 'Nu', Nu2, ...
    'VolatilityType', 'Normal');

ComputedVols2 = volatilities(finpricer("Analytic", ...
    'Model', SABR_Model_Method_2, 'DiscountCurve', ZeroCurve), ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes);
```

```
figure;
plot(MarketStrikes,MarketVolatilities*10000,'xk',...
    PlottingStrikes,ComputedVols1*10000,'b', ...
    PlottingStrikes,ComputedVols2*10000,'r', ...
    CurrentForwardValue,ATMVolatility*10000,'ok',...
    'MarkerSize',10);

h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');

xlabel('Strike', 'FontWeight', 'bold');
ylabel('Implied Normal Volatility (bps)', 'FontWeight', 'bold');
legend('Market Volatilities', 'Normal SABR Model (Method 1)', ...
    'Normal SABR Model (Method 2)', 'At-the-money volatility', ...
    'Location', 'northwest');
```

Calibrate SABR Model Using Analytic Pricer

This example shows how to use two different methods to calibrate a SABR stochastic volatility model from market implied Black volatilities. Both approaches use the SABR analytic pricer.

Load Market Implied Black Volatility Data

This example sets up hypothetical market implied Black volatilities for European swaptions over a range of strikes before calibration. The swaptions expire in three years from the `Settle` date and have five-year swaps as the underlying instrument. The rates are expressed in decimals. (Changing the units affects the numerical value and interpretation of the `Alpha` parameter in the SABR model.)

Load the market implied Black volatility data for swaptions expiring in three years.

```
Settle = datetime(2013, 7, 10);
ZeroDates = Settle + [calmonths([1 2 3 6 9]) calyears([1 2 3 4 5 6 7 8 9 10 12])]';
ZeroRates = [0.25 0.3 0.33 0.42 0.8 0.9 1.1 1.2 ...
    1.8 2.2 2.4 2.71 2.95 3.02 3.24 3.58]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',Compounding);
ExerciseDate = datetime(2016, 7, 10);
MarketStrikes = [2.46 2.96 3.46 3.96 4.46 4.96 5.46]'/100;
MarketVolatilities = [44.3 40.2 36.7 35.7 37.2 38.1 39.8]'/100;
```

At the time of `Settle`, define the underlying forward rate and the at-the-money volatility.

```
CurrentForwardValue = MarketStrikes(4)
```

```
CurrentForwardValue = 0.0396
```

```
ATMVolatility = MarketVolatilities(4)
```

```
ATMVolatility = 0.3570
```

Method 1: Calibrate `Alpha`, `Rho`, and `Nu` Directly

You can calibrate the `Alpha`, `Rho`, and `Nu` model parameters directly. Set the value of `Beta` either by fitting historical market volatility data or by choosing a value appropriate for the market [1 on page 2-184]. For this example, use the value `0.5`.

```
% Define the predetermined Beta.
Beta1 = 0.5;
```

After fixing the value of β (`Beta`), fit the parameters α (`Alpha`), ρ (`Rho`), and ν (`Nu`) directly. The Optimization Toolbox™ function `lsqnonlin` generates the parameter values that minimize the squared error between the market volatilities and the volatilities computed by the SABR analytic pricer.

```
% Calibrate Alpha, Rho, and Nu.
objFun = @(X) MarketVolatilities - ...
    volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', X(1), 'Beta', Beta1, 'Rho', X(2), 'Nu', X(3)), ...
    'DiscountCurve', ZeroCurve), ExerciseDate, CurrentForwardValue, MarketStrikes);

X = lsqnonlin(objFun, [0.5 0 0.5], [0 -1 0], [Inf 1 Inf]);
```

```
Local minimum found.

Optimization completed because the size of the gradient is less than
the value of the optimality tolerance.
```

```
Alpha1 = X(1);
Rho1 = X(2);
Nu1 = X(3);
```

Method 2: Calibrating Rho and Nu by Implying Alpha from At-The-Money Volatility

You can also use an alternative calibration method. Set the value of β (`Beta`) as in the first method.

```
Beta2 = 0.5;
```

Next you fit the parameters ρ (`Rho`) and ν (`Nu`) directly while α (`Alpha`) is implied from the market at-the-money volatility. Models calibrated using this method produce at-the-money volatilities that are equal to market quotes. This approach is widely used in swaptions, where at-the-money volatilities are quoted most frequently and are important to match. To imply α (`Alpha`) from market at-the-money volatility (σ_{ATM}), the following cubic polynomial is solved for α (`Alpha`), and the smallest positive real root is selected [2 on page 2-184].

$$\frac{(1-\beta)^2 T}{24F^{(2-2\beta)}}\alpha^3 + \frac{\rho\beta\nu T}{4F^{(1-\beta)}}\alpha^2 + \left(1 + \frac{2-3\rho^2}{24}\nu^2 T\right)\alpha - \sigma_{ATM}F^{(1-\beta)} = 0$$

Here:

F is the current forward value

T is the year fraction to maturity.

Fit the parameters by defining an anonymous function.

```
% Year fraction from Settle to option maturity.
T = yearfrac(Settle, ExerciseDate, 1);

% This function solves the SABR at-the-money volatility equation as a
% polynomial of Alpha.
alpharoots = @(Rho,Nu) roots([...
    (1 - Beta2)^2*T/24/CurrentForwardValue^(2 - 2*Beta2) ...
    Rho*Beta2*Nu*T/4/CurrentForwardValue^(1 - Beta2) ...
    (1 + (2 - 3*Rho^2)*Nu^2*T/24) ...
    -ATMVolatility*CurrentForwardValue^(1 - Beta2)]);

% This function converts at-the-money volatility into Alpha by picking the
% smallest positive real root.
atmVol2SabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
    x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharoots(Rho,Nu))));
```

The function `atmVol2SabrAlpha` converts at-the-money volatility into α (`Alpha`) for a given set of ρ (`Rho`) and ν (`Nu`). This function is then used in the objective function to fit the parameters ρ (`Rho`) and ν (`Nu`).

```
% Calibrate Rho and Nu (while converting at-the-money volatility into Alpha
% using atmVol2SabrAlpha).

objFun = @(X) MarketVolatilities - ...
```

```
    volatilities(finpricer("Analytic", 'Model', finmodel("SABR", ...
    'Alpha', atmVol2SabrAlpha(X(1), X(2)), 'Beta', Beta2, 'Rho', X(1), 'Nu', X(2)), ...
    'DiscountCurve', ZeroCurve), ExerciseDate, CurrentForwardValue, MarketStrikes);

X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf]);

Local minimum found.

Optimization completed because the size of the gradient is less than
the value of the optimality tolerance.

Rho2 = X(1);
Nu2 = X(2);
```

The calibrated parameter α (`Alpha`) is computed using the calibrated parameters ρ (`Rho`) and ν (`Nu`).

```
% Obtain final Alpha from at-the-money volatility using calibrated
% parameters.
Alpha2 = atmVol2SabrAlpha(Rho2, Nu2);

% Display calibrated parameters.
C = {Alpha1 Beta1 Rho1 Nu1;Alpha2 Beta2 Rho2 Nu2};
CalibratedPrameters = cell2table(C,...
    'VariableNames',{'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'Method 1';'Method 2'})

CalibratedPrameters=2×4 table
                Alpha      Beta      Rho        Nu
              ________    ____    _______    _______

    Method 1    0.060203    0.5     0.19131    0.85327
    Method 2    0.058851    0.5     0.18901    0.88627
```

Use Calibrated Models

Use the calibrated models to compute new volatilities at any strike value.

Compute volatilities for models calibrated using Method 1 and Method 2 and plot the results.

```
PlottingStrikes = (1.75:0.1:5.50)'/100;

% Compute volatilities for model calibrated by Method 1.
SABR_Model_Method_1 = finmodel("SABR", ...
    'Alpha', Alpha1, 'Beta', Beta1, 'Rho', Rho1, 'Nu', Nu1);

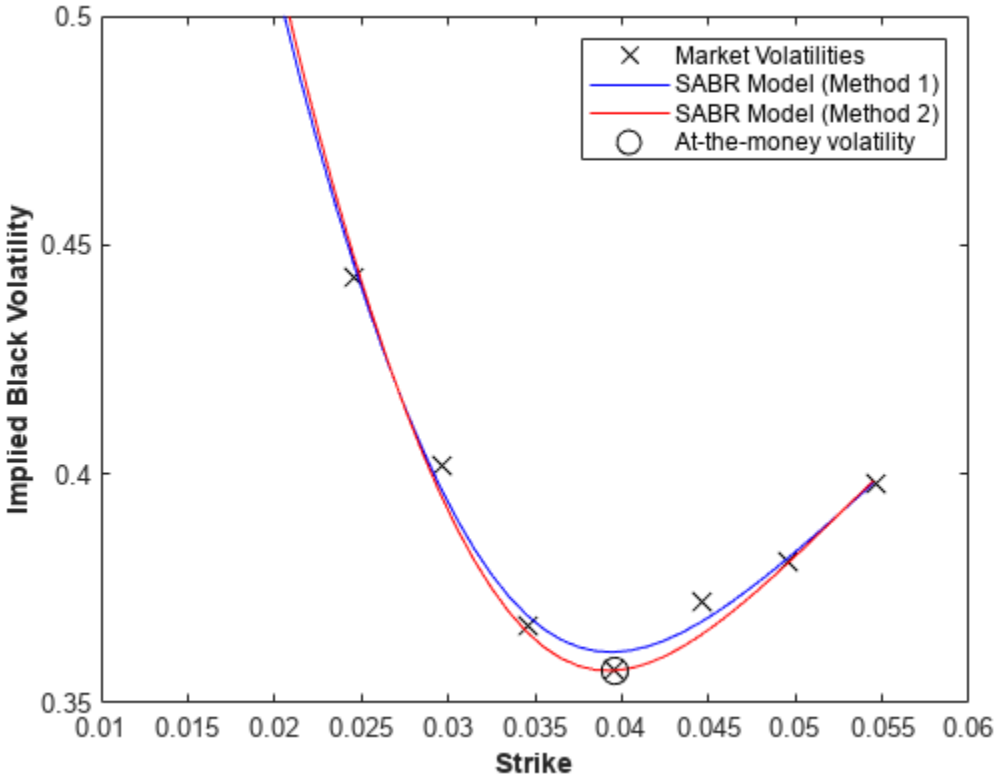
ComputedVols1 = volatilities(finpricer("Analytic", ...
    'Model', SABR_Model_Method_1, 'DiscountCurve', ZeroCurve), ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes);

% Compute volatilities for model calibrated by Method 2.
SABR_Model_Method_2 = finmodel("SABR", ...
    'Alpha', Alpha2, 'Beta', Beta2, 'Rho', Rho2, 'Nu', Nu2);

ComputedVols2 = volatilities(finpricer("Analytic", ...
    'Model', SABR_Model_Method_2, 'DiscountCurve', ZeroCurve), ...
    ExerciseDate, CurrentForwardValue, PlottingStrikes);

figure;
```

```
plot(MarketStrikes,MarketVolatilities,'xk',...
    PlottingStrikes,ComputedVols1,'b', ...
    PlottingStrikes,ComputedVols2,'r', ...
    CurrentForwardValue,ATMVolatility,'ok',...
    'MarkerSize',10);
xlim([0.01 0.06]);
ylim([0.35 0.5]);
xlabel('Strike', 'FontWeight', 'bold');
ylabel('Implied Black Volatility', 'FontWeight', 'bold');
legend('Market Volatilities', 'SABR Model (Method 1)',...
    'SABR Model (Method 2)', 'At-the-money volatility');
```



The model calibrated using Method 2 reproduces the market at-the-money volatility (marked with a circle) exactly.

Price a Swaption Using SABR Model and Analytic Pricer

This example shows how to price a swaption using the SABR model. First, you construct a swaption volatility surface from market volatilities by calibrating the SABR model parameters separately for each swaption maturity using the SABR analytic pricer. You then compute the swaption price by using the implied Black volatility on the surface with the SABR analytic pricer.

Step 1. Load market swaption volatility data.

Load the zero curve and market implied Black volatility data for swaptions.

```
Settle = datetime(2013, 6, 14);
ZeroDates = Settle + [calmonths([1 3 6]) calyears([1 2 3 4 5 6 7 8 9 10 12 15 20])]';
ZeroRates = [0.22 0.31 0.45 0.73 0.54 0.72 1.22 1.54 1.83 1.92 ...
    2.16 2.32 2.52 2.93 3.12 3.36]'/100;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',1);
ExerciseDates =  Settle + [calmonths(3) calyears([1 2 3 4 5 7 10])]';
YearsToExercise = yearfrac(Settle,ExerciseDates,1);
NumMaturities = length(YearsToExercise);

MarketVolatilities = [ ...
   56.5 52.7 49.1 44.9 43.5 40.5 34.8 32.2

```

The current underlying forward rates and the corresponding at-the-money volatilities across the eight swaption maturities are represented in the fourth rows of the two matrices.

Step 2. Calibrate the SABR model parameters for each swaption maturity.

When you use a static SABR model, where the model parameters are assumed to be constant with respect to time, the parameters are calibrated separately for each swaption maturity (years to exercise) in a `for` loop using the SABR analytic pricer. To better represent market at-the-money volatilities, the `Alpha` parameter values are implied by the market at-the-money volatilities (for details, see Method 2 in "Calibrate SABR Model Using Analytic Pricer" on page 2-181).

```
% Define the predetermined Beta, calibrate SABR model parameters for each
% swaption maturity, and display the calibrated parameters in a table.
Beta = 0.5;
Betas = repmat(Beta, NumMaturities, 1);
Alphas = zeros(NumMaturities, 1);
Rhos = zeros(NumMaturities, 1);
Nus = zeros(NumMaturities, 1);

options = optimoptions('lsqnonlin','Display','none');

for k = 1:NumMaturities
    % This function solves the SABR at-the-money volatility equation as a
    % polynomial of Alpha.
    alpharoots = @(Rho,Nu) roots([...
        (1 - Beta)^2*YearsToExercise(k)/24/CurrentForwardValues(k)^(2 - 2*Beta) ...
        Rho*Beta*Nu*YearsToExercise(k)/4/CurrentForwardValues(k)^(1 - Beta) ...
        (1 + (2 - 3*Rho^2)*Nu^2*YearsToExercise(k)/24) ...
        -ATMVolatilities(k)*CurrentForwardValues(k)^(1 - Beta)]);

    % This function converts at-the-money volatility into Alpha by picking the
    % smallest positive real root.
    atmVol2SabrAlpha = @(Rho,Nu) min(real(arrayfun(@(x) ...
        x*(x>0) + realmax*(x<0 || abs(imag(x))>1e-6), alpharoots(Rho,Nu))));

    % Fit Rho and Nu (while converting at-the-money volatility into Alpha).
    objFun = @(X) MarketVolatilities(:,k) - ...
    volatilities(finpricer("Analytic", 'Model', finmodel("SABR", ...
    'Alpha', atmVol2SabrAlpha(X(1), X(2)), 'Beta', Beta, 'Rho', X(1), 'Nu', X(2)), ...
    'DiscountCurve', ZeroCurve), ExerciseDates(k), CurrentForwardValues(k), MarketStrikes(:,k));

    X = lsqnonlin(objFun, [0 0.5], [-1 0], [1 Inf], options);
    Rho = X(1);
    Nu = X(2);

    % Get final Alpha from the calibrated parameters.
    Alpha = atmVol2SabrAlpha(Rho, Nu);

    Alphas(k) = Alpha;
    Rhos(k) = Rho;
    Nus(k) = Nu;
end

CalibratedParameters = array2table([Alphas Betas Rhos Nus],...
    'VariableNames',{'Alpha' 'Beta' 'Rho' 'Nu'},...
    'RowNames',{'3M into 10Y';'1Y into 10Y';...
    '2Y into 10Y';'3Y into 10Y';'4Y into 10Y';...
    '5Y into 10Y';'7Y into 10Y';'10Y into 10Y'})
```

```
CalibratedParameters=8×4 table
                     Alpha      Beta      Rho         Nu
```

```
                  ________    ____    ________    _______

    3M into 10Y     0.051895    0.5      0.40869     1.4054
    1Y into 10Y     0.054381    0.5      0.28066     1.1234
    2Y into 10Y     0.057325    0.5       0.2166    0.97407
    3Y into 10Y     0.057243    0.5      0.19837    0.82932
    4Y into 10Y     0.053387    0.5      0.17304    0.81441
    5Y into 10Y      0.04673    0.5      0.11618    0.80138
    7Y into 10Y     0.046986    0.5       0.1554    0.63377
    10Y into 10Y     0.04443    0.5     0.080169    0.52515
```

Step 3. Construct a volatility surface.

Use the calibrated SABR model to compute new volatilities at any strike value to produce a smooth smile for a given maturity. This can be repeated for each maturity to form a volatility surface.

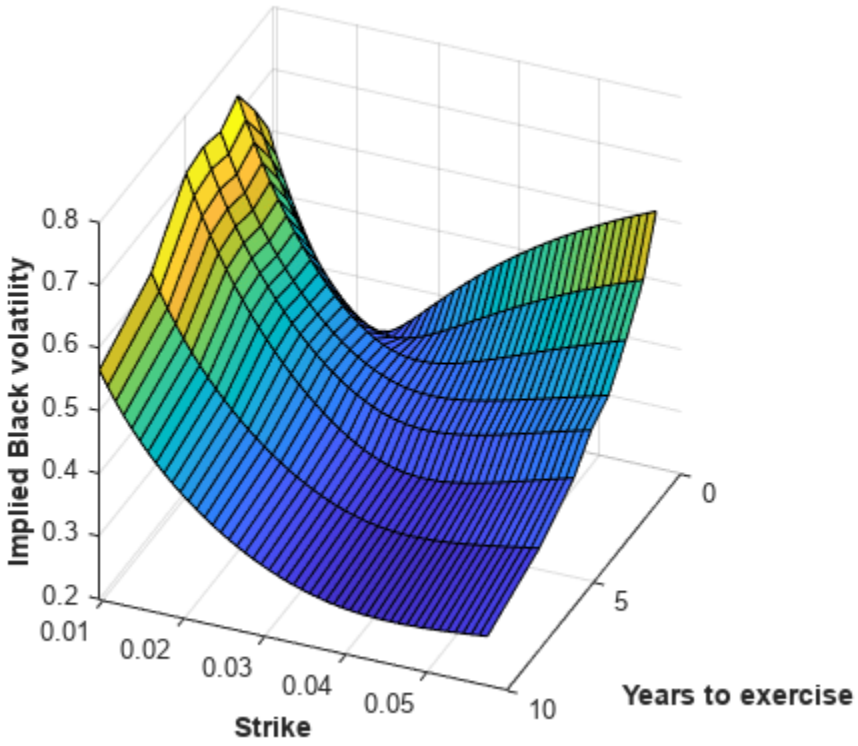
Compute volatilities using the calibrated models for each maturity and plot the volatility surface.

```
PlottingStrikes = (0.95:0.1:5.8)'/100;
ComputedVols = zeros(length(PlottingStrikes), NumMaturities);

for k = 1:NumMaturities
    SABRModel = finmodel("SABR", ...
        'Alpha', Alphas(k), 'Beta', Betas(k), 'Rho', Rhos(k), 'Nu', Nus(k));

    ComputedVols(:,k) = volatilities(finpricer("Analytic", ...
        'Model', SABRModel, 'DiscountCurve', ZeroCurve), ...
        ExerciseDates(k), CurrentForwardValues(k), PlottingStrikes);
end

figure;
surf(YearsToExercise, PlottingStrikes, ComputedVols);
xlim([0 10]); ylim([0.0095 0.06]); zlim([0.2 0.8]);
view(113,32);
set(gca, 'Position', [0.13 0.11 0.775 0.815], ...
    'PlotBoxAspectRatioMode', 'manual');
xlabel('Years to exercise', 'Fontweight', 'bold');
ylabel('Strike', 'Fontweight', 'bold');
zlabel('Implied Black volatility', 'Fontweight', 'bold');
```



Note that in this volatility surface, the smiles tend to get flatter for longer swaption maturities (years to exercise). This is consistent with the Nu parameter values tending to decrease with swaption maturity, as shown in the table for `CalibratedParameters`.

Step 4. Use the SABR analytic pricer to price a swaption.

Use the SABR analytic pricer to price a swaption that matures in five years. First, create the underlying 10-year swap instrument starting in five years and create the `Swaption` instrument for this underlying `Swap`. Then create the SABR model for this swaption maturing in five years, which is used for creating the SABR analytic pricer.

```
% Create the underlying 10-year swap starting in 5 years.
MaturityIdx = 6;
SwapStartDate = ExerciseDates(MaturityIdx);
SwapMaturity = SwapStartDate + calyears(10);
Swap = fininstrument("Swap", 'Maturity', SwapMaturity, ...
    'LegRate', [0 0], "LegType",["fixed" "float"],...
    "ProjectionCurve", ZeroCurve, "StartDate", SwapStartDate)
```

```
Swap =
  Swap with properties:

                    LegRate: [0 0]
                    LegType: ["fixed"    "float"]
                      Reset: [2 2]
                      Basis: [0 0]
                   Notional: 100
```

```
          LatestFloatingRate: [NaN NaN]
                 ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
             ProjectionCurve: [1x2 ratecurve]
       BusinessDayConvention: ["actual"    "actual"]
                    Holidays: NaT
                EndMonthRule: [1 1]
                   StartDate: 14-Jun-2018
                    Maturity: 14-Jun-2028
                        Name: ""
```

```
% Create the swaption (for the underlying 10-year swap) maturing in five
% years.
SwaptionExerciseDate = SwapStartDate;
Reset = 1;
OptSpec = 'call';
Strike = 0.0272;
Swaption = fininstrument("Swaption", 'Strike', Strike, ...
    'ExerciseDate', SwaptionExerciseDate, 'Swap', Swap, 'OptionType', OptSpec)
```

```
Swaption =
  Swaption with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 14-Jun-2018
           Strike: 0.0272
             Swap: [1x1 fininstrument.Swap]
             Name: ""
```

```
% Create the SABR model for the swaption maturing in five years.
SABRModel = finmodel("SABR", ...
        'Alpha', Alphas(MaturityIdx), 'Beta', Betas(MaturityIdx), ...
        'Rho', Rhos(MaturityIdx), 'Nu', Nus(MaturityIdx))
```

```
SABRModel =
  SABR with properties:

            Alpha: 0.0467
             Beta: 0.5000
              Rho: 0.1162
               Nu: 0.8014
            Shift: 0
    VolatilityType: "black"
```

```
% Create the SABR analytic pricer.
SABRPricer = finpricer("Analytic", 'Model', SABRModel, 'DiscountCurve', ZeroCurve)
```

```
SABRPricer =
  SABR with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.SABR]
```

To visualize the SABR implied Black volatility used in pricing the swaption, first compute the current forward swap rate by using the `parswaprate` function.

```
CurrentForwardSwapRate = parswaprate(Swap,ZeroCurve)
```

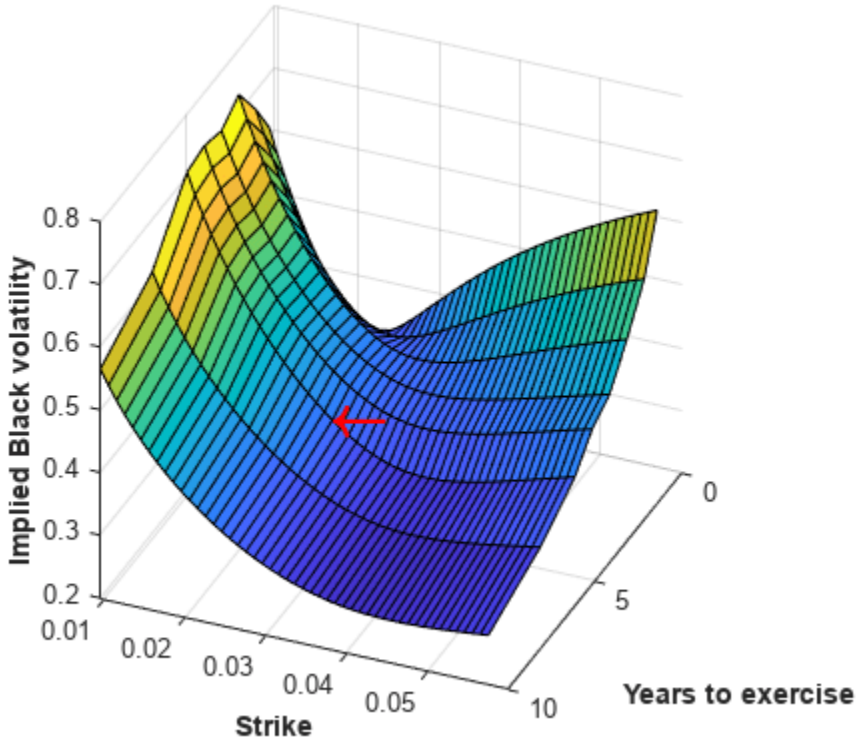
```
CurrentForwardSwapRate = 0.0384
```

Next, compute the SABR implied Black volatility for this `Swaption` by using the `volatilities` function, and it is marked with a red arrow in the figure at the bottom.

```
SABRBlackVolatility = volatilities(SABRPricer, ...
         SwaptionExerciseDate, CurrentForwardSwapRate, Strike)
```

```
SABRBlackVolatility = 0.3665
```

```
text (YearsToExercise(MaturityIdx), Strike, SABRBlackVolatility, ...
    '\leftarrow', 'Color', 'r', 'FontWeight', 'bold', 'FontSize', 22);
```



Finally, price the swaption using the `price` function of the `SABR` analytic pricer.

```
SwaptionPrice = price(SABRPricer, Swaption)
```

```
SwaptionPrice = 13.0141
```

Compute LIBOR Fallback

This example shows how to compute a USD LIBOR fallback. Regulators and industry groups have recommended that firms transition away from the London inter-bank offered rate (LIBOR) and prepare to replace them with overnight Alternative Reference Rates (ARRs). What happens to contracts with a notional value of trillions of dollars if they refer to a benchmark that no longer exists? If the LIBOR benchmark is no longer published, references to that benchmark rate must change and benchmark rates “fall back” to a new benchmark in contracts. For example, if a 30-year floating-rate instrument with a three-month coupon based on the LIBOR rate is created in 2008 and expires in 2038, then the rate will need to change in 2023 because in 2023, the publication of a LIBOR rate permanently ceases. To calculate three-month coupon payments after 2023, you must use a LIBOR fallback. This example is based on the ISDA® 2020 IBOR Fallbacks Protocol.

Spread Adjustments

Use spread adjustments from the ISDA® website at LIBOR Cessation and the Impact on Fallbacks Protocol.

```
Adjustment = [.00644 .03839 .11448 .18456 .26161 .42826 .71513]'/100;
TenorLabel = ["ON","1W","1M","2M","3M","6M","12M]';
Tenors = [caldays(1) calweeks(1) calmonths([1 2 3 6 12])];
SpreadAdjustmentTable = table(TenorLabel,Adjustment);
nTenors = height(SpreadAdjustmentTable);
```

Example Data

Run this example using the following example data.

```
RateRecordDate = datetime(2021,2,26);
RateTenor = "1M";
ARR_DC = 360;
```

Obtain Calculation Date

Use `RateRecordDate` and `Tenors` to calculate `CalculationDate`.

```
CalculationDate = RateRecordDate + Tenors(RateTenor == TenorLabel);
if ~isbusday(CalculationDate)
    CalculationDate = busdate(CalculationDate);
end
```

Obtain Historical Data

For this example, the historical data is hard-coded. However, you can also use Datafeed Toolbox™ with Federal Reserve Economic Data (FRED®) to obtain the historical data.

```
getFredData = false;
if getFredData
    ARR_ID = 'SOFR';
    c = fred;
    c.DataReturnFormat = 'timetable';
    c.DatetimeType = 'datetime';
    FredData = fetch(c,ARR_ID,RateRecordDate,CalculationDate);
    SOFRData = FredData.Data{1};
    SOFRData(isnan(SOFRData{:,1}),:) = [];
else
```

```
    SOFRRates = [0.01 0.02 0.04 0.04 0.02 0.02 0.02 0.02 0.02 0.01 ...
        0.01 0.01 0.01 0.01 0.01 0.01 0.01 0.01 0.01 0.01 0.01]';
    SOFRDates = busdays(RateRecordDate,CalculationDate);
    SOFRData = timetable(SOFRDates,SOFRRates);
end
```

Compute Spread Adjustment

Obtain the spread adjustment from `SpreadAdjustmentTable`.

```
SpreadAdj = Adjustment(RateTenor == TenorLabel);
```

Compute ARR

Compute the alternative reference rate (ARR) using the relevant reference rate data.

```
tau = days(diff(SOFRData.Properties.RowTimes))/ARR_DC;
relRate = SOFRData{1:end-1,1};
CompRate = prod(1 + tau.*1/100.*relRate) - 1;
ARR = ARR_DC/days(CalculationDate - RateRecordDate)*CompRate;
ARR = round(ARR,7);
```

Compute Fallback Rate

`FallbackRate` is the sum of `ARR` and `SpreadAdj`.

```
FallbackRate = ARR + SpreadAdj
```

```
FallbackRate = 0.0013
```

Use treeviewer to Examine HWTree and PriceTree When Pricing European Callable Bond

This example demonstrates how to use `treeviewer` to examine tree information for a Hull-White tree when you price a European callable bond.

Specify Input Parameters

Define the interest-rate curve information.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2019';
EndDates = {'Jan-1-2020'; 'Jan-1-2021'; 'Jan-1-2022'; 'Jan-1-2023'};
Compounding = 1;
```

Define the callable bond instruments. The first instrument is the first entry in the arrays. So, for example, the first instrument has a strike price of $98 and a maturity of January 1, 2022.

```
Settle = '01-Jan-2019';
Maturity = {'01-Jan-2022'; '01-Jan-2023'};
CouponRate = {{'01-Jan-2021' .0425; '01-Jan-2023' .0450}};
OptType = 'call';
Strike = [98; 95];
ExerciseDates= {'01-Jan-2021'; '01-Jan-2022'};
Basis = 1;
```

Define the volatility information and HW one-factor parameters.

```
VolDates = ['1-Jan-2020'; '1-Jan-2021'; '1-Jan-2022'; '1-Jan-2023'];
VolCurve = 0.05;
AlphaDates = '01-01-2023';
AlphaCurve = 0.05;
```

Build Hull-White One-Factor Tree

Use `hwtree` to build a one-factor tree.

```
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis);
HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve, AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWTimeSpec.Basis = Basis;

HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Price Both Callable Instruments

Use `optembndbyhw` to price the callable bond with embedded options.

```
[Price, PriceTree] = optembndbyhw(HWT, CouponRate,  Settle, Maturity, OptType, Strike,...
ExerciseDates, 'Period', 1, 'Basis', Basis)
```

```
Price = 2×1

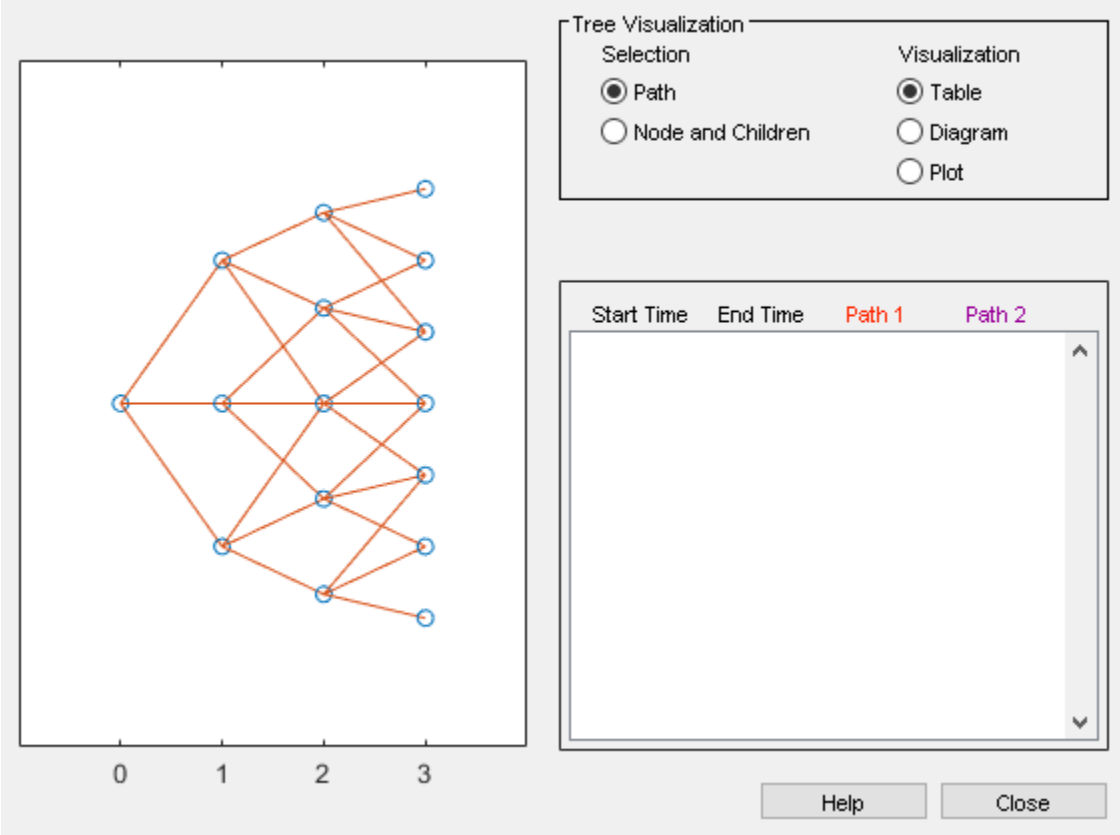
   96.4131
   92.9341
```

```
PriceTree = struct with fields:
                FinObj: 'HWPriceTree'
                  tObs: [0 1 2 3 4]
                 PTree: {1x5 cell}
               ProbTree: {1x5 cell}
                 ExTree: {1x5 cell}
             ExProbTree: {1x5 cell}
    ExProbsByTreeLevel: [2x5 double]
               Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
```

Examine Hull-White Tree Structure

Use `treeviewer` to examine the Hull-White interest-rate tree that is the input for the embedded option pricer.

```
treeviewer(HWT)
```



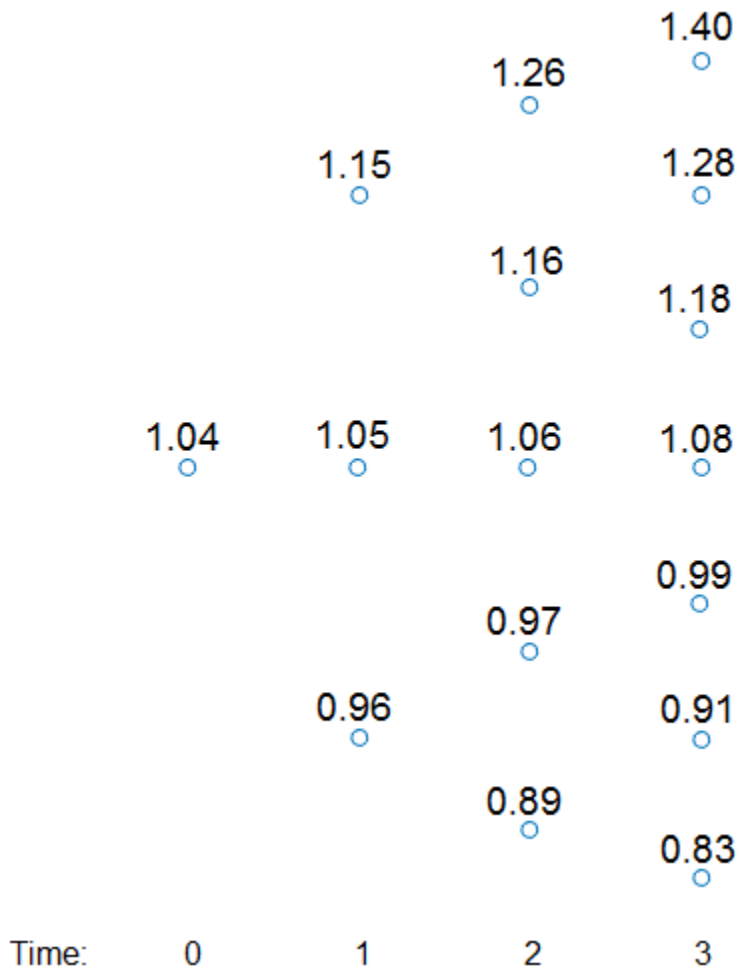
The Hull-White tree has 4 levels of nodes. The root node is at $t = 0$, three nodes are at $t = 1$, five nodes are at $t = 2$, and seven nodes are at $t = 3$. Each node represents a particular state. In this case, the state is defined by the forward interest-rate curve, `HWT.FwdTree`. The combination of `HWT.FwdTree` and `HWT.Connect` defines the tree structure. `FwdTree` contains the values of the forward interest rate at each node. The other fields contain other information relevant to interpreting the values in `FwdTree`. The most important are `VolSpec`, `TimeSpec`, and `RateSpec`, which contain the volatility, time structure, and rate structure information, respectively.

For example, `HWT.FwdTree` is:

```
HWT.FwdTree
```

```
ans=1×4 cell array
    {[1.0350]}    {[1.1457 ... ]}    {[1.2639 ... ]}    {[1.4003 ... ]}
```

If you display the nodes graphically with the forward rates superimposed it looks like:



You can use the `treeviewer` function to visualize the rates in the tree with `treeviewer(HWT)`. This function displays the structure of a Hull-White tree (`HWT`) in the left pane. The tree visualization in the right pane is blank. Visualize the actual interest-rate tree:

1. In the **Tree Visualization** pane, click **Path** and **Diagram**.

2. Select the first path by clicking the first node of the up branch at $t = 1$.

3. Continue by clicking the up branch at the next node at $t = 2$.

The following figures show the `treeviewer` path diagrams for these selections.

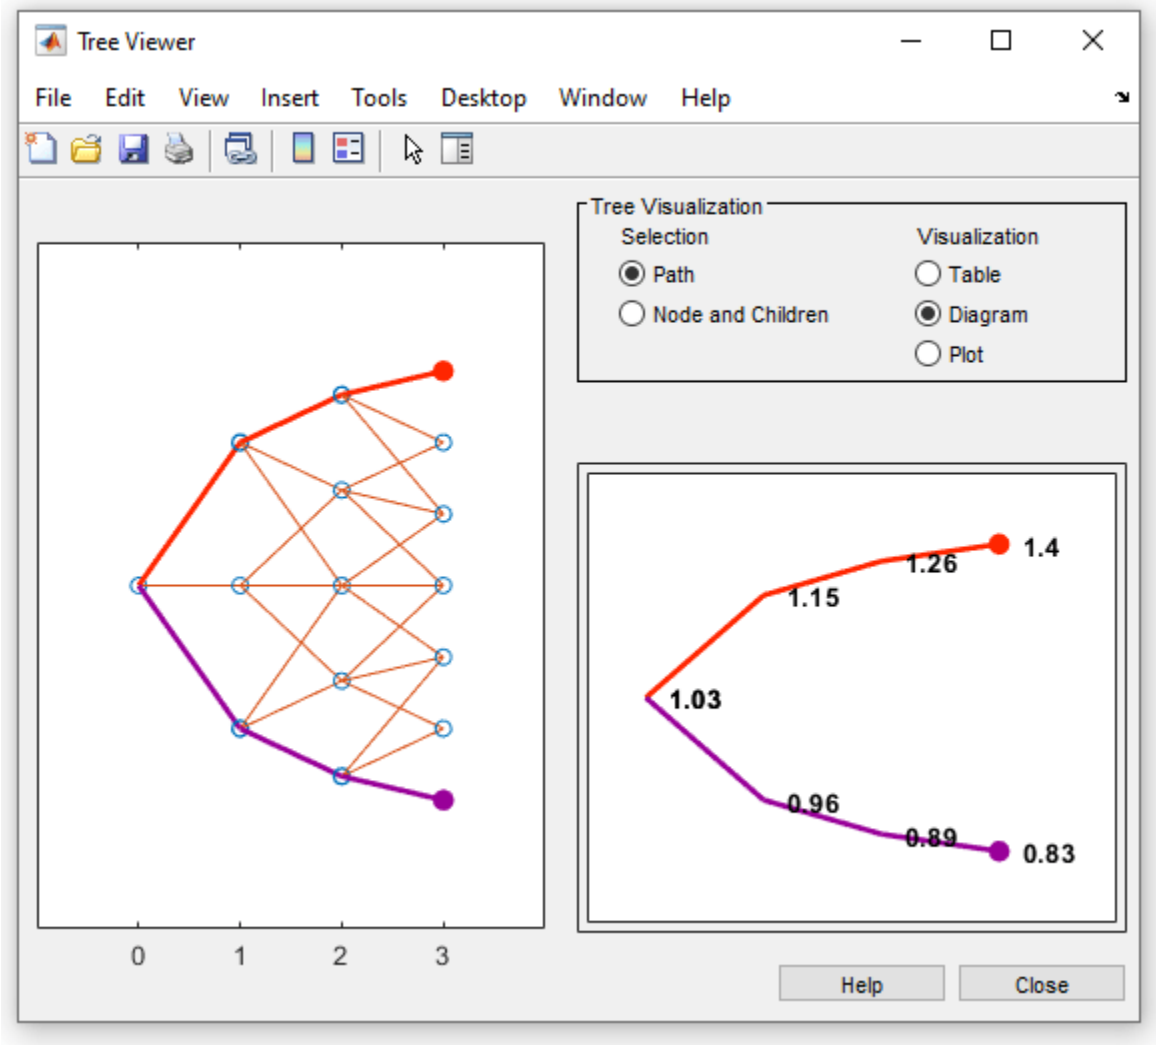
4. Continue clicking all nodes in succession until you reach the end of the branch. The entire path you selected is highlighted in red.

5. Select a second path by clicking the first node of the lower branch at $t = 1$. Continue clicking lower nodes as you did on the first branch. The second branch is highlighted in purple.



Hull-White trees have two additional properties called `Probs` and `Connect`. The `Probs` property represents the transition probabilities and the `Connect` property defines how the nodes are connected together.

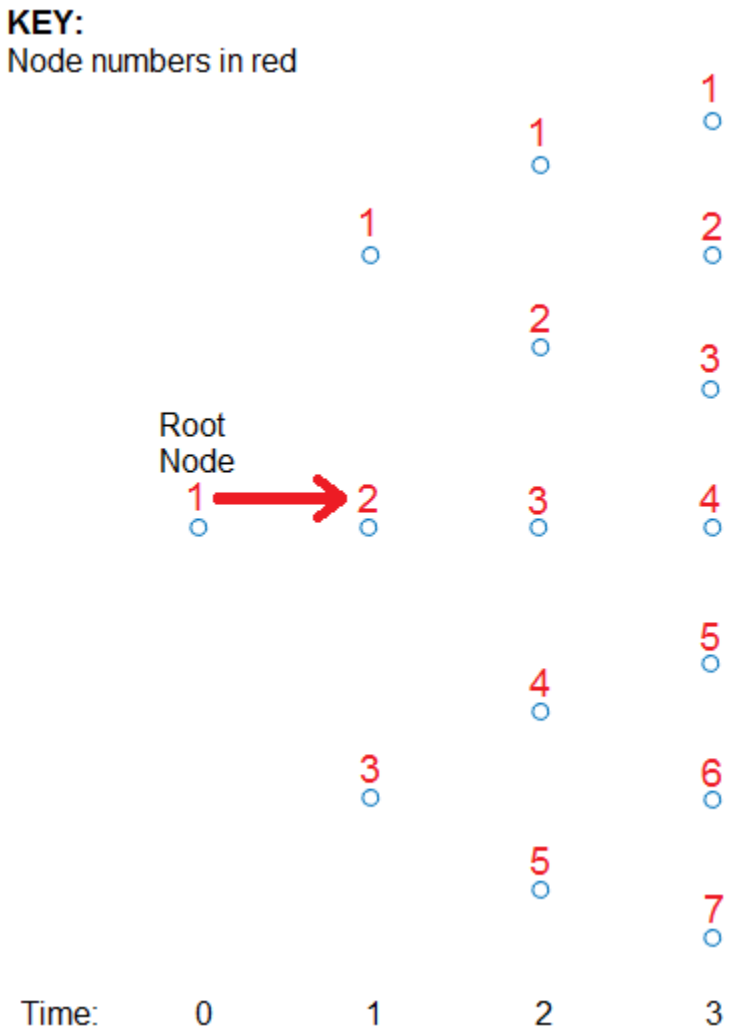
`Connect` Field

`HWT.Connect` describes the connectivity of the nodes of a given tree level to the nodes at the next tree level.

```
HWT.Connect
```

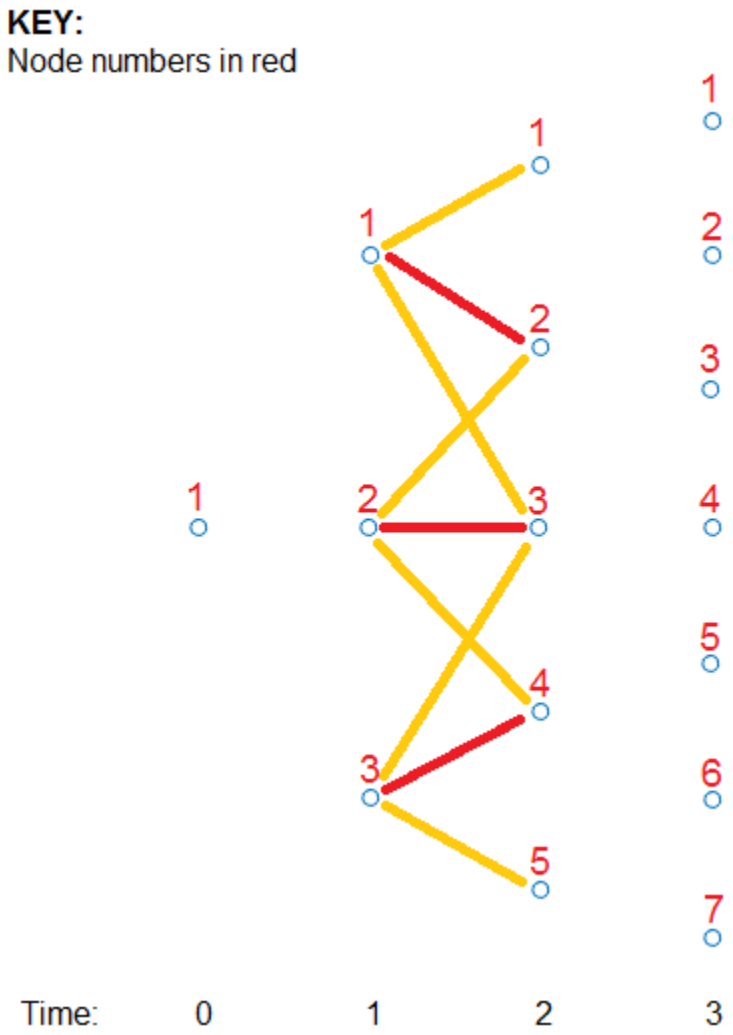
```
ans=1×3 cell array
    {[2]}    {[2 3 4]}    {[2 3 4 5 6]}
```

The first value of `HWT.Connect` corresponds to $t = 0$ for the root node and indicates that the root node connects to node 2 of the next level at $t = 1$. To visualize this, consider the following connection illustration of the tree, where the node numbers have been superimposed above each node.

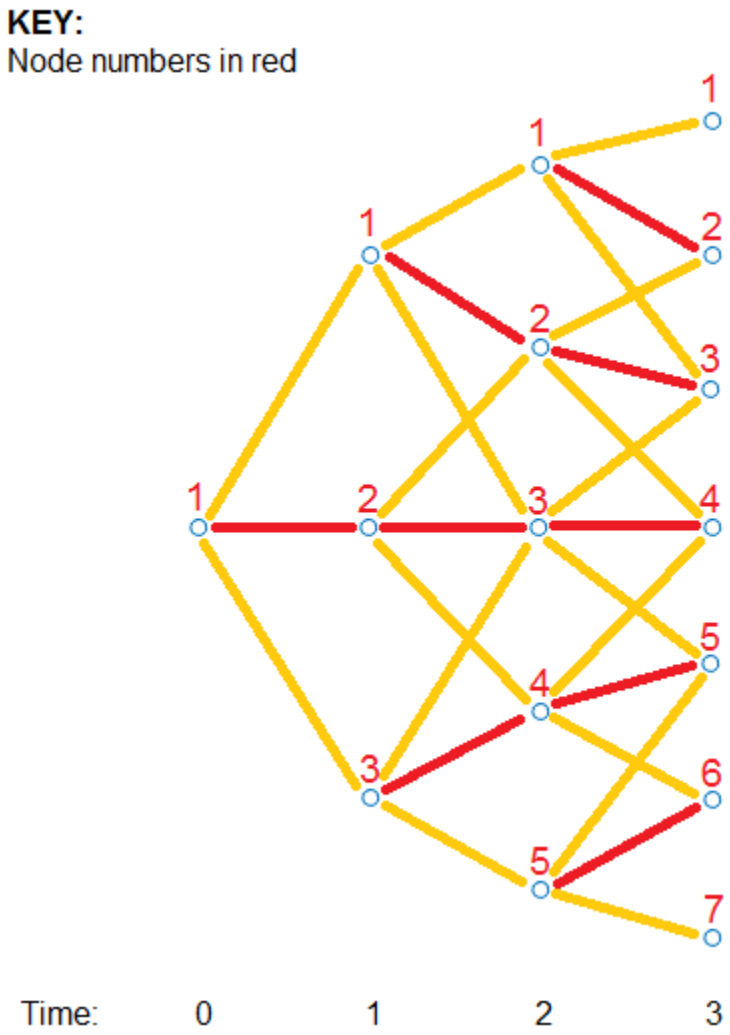


Specifically, `HWT.Connect` represents the index of the node in the next tree level ($t + 1$) that the middle branch of the node connects to.

The next entry in `HWT.Connect` at $t = 1$ is `[2,3,4]`. This means that node 1 at $t = 1$ has a middle branch with node 2 at $t = 2$, node 2 at $t = 1$ has a middle branch with node 3 at $t = 2$, and node 3 at $t = 1$ has a middle branch with node 4 at $t = 2$. A graphic representation follows.



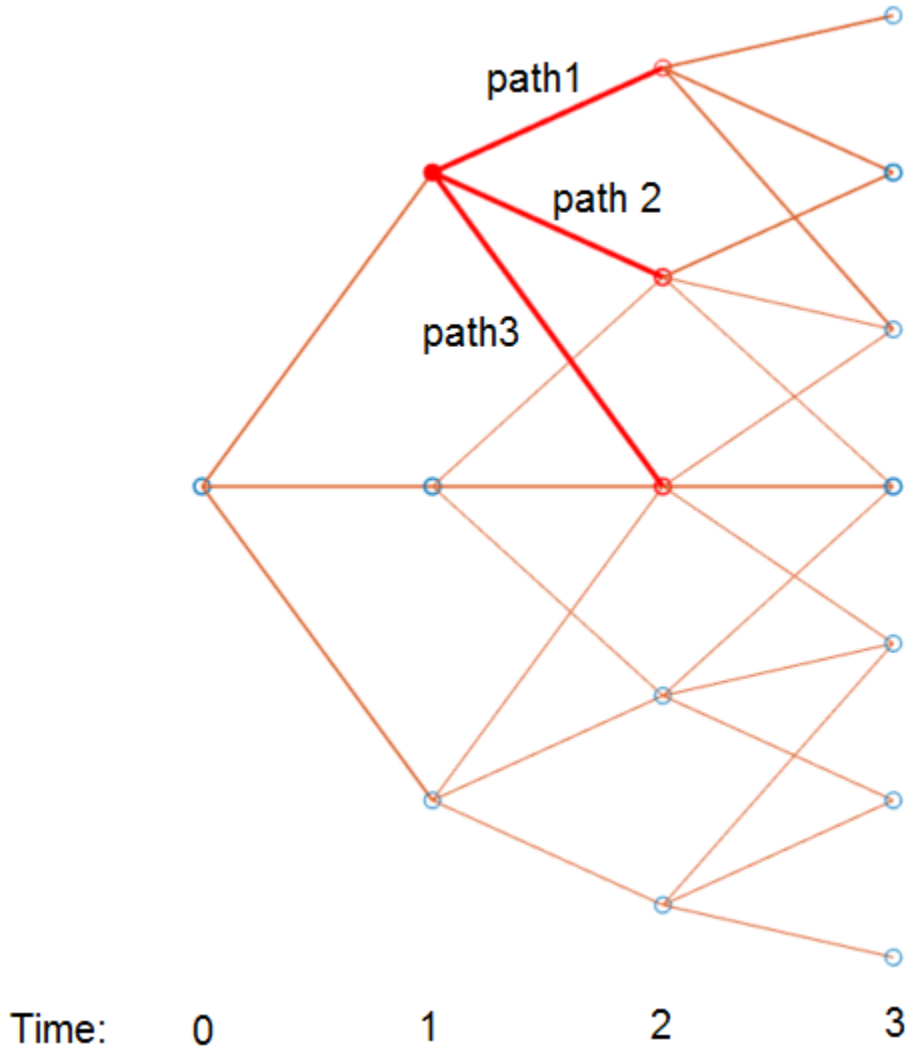
The middle branch path, as explicitly defined in `HWT.Connect`, is colored red and the implicit upper and lower branch paths are colored yellow. Overlaying all paths defined in `HWT.Connect` as red and the implicit upper and lower branches as yellow produces the following tree structure.



The shape in the figure is the same shape obtained by running the function `treeviewer(HWT)`.

`Probs` Field

Using the following illustration, consider that you want to know the probability at $t = 1$ (second level of the tree) that the top node takes of one of the three paths.



`HWT.Probs` gives the probabilities that a particular branch has of moving from a given node to a node on the next level of the tree.

```
HWT.Probs
```

```
ans=1×3 cell array
    {3x1 double}    {3x3 double}    {3x5 double}
```

The `Probs` field consists of a cell array with one cell per level of the tree. Find the probabilities of all three nodes at $t = 1$, which corresponds to the second level of the tree.

```
HWT.Probs{2}
```

```
ans = 3×3

    0.1429    0.1667    0.1929
    0.6642    0.6667    0.6642
```

```
    0.1929    0.1667    0.1429
```

Each column represents a different node. The first node at $t = 1$ corresponds to the first column and the probabilities are 14.29%, 66.42%, and 19.30%.

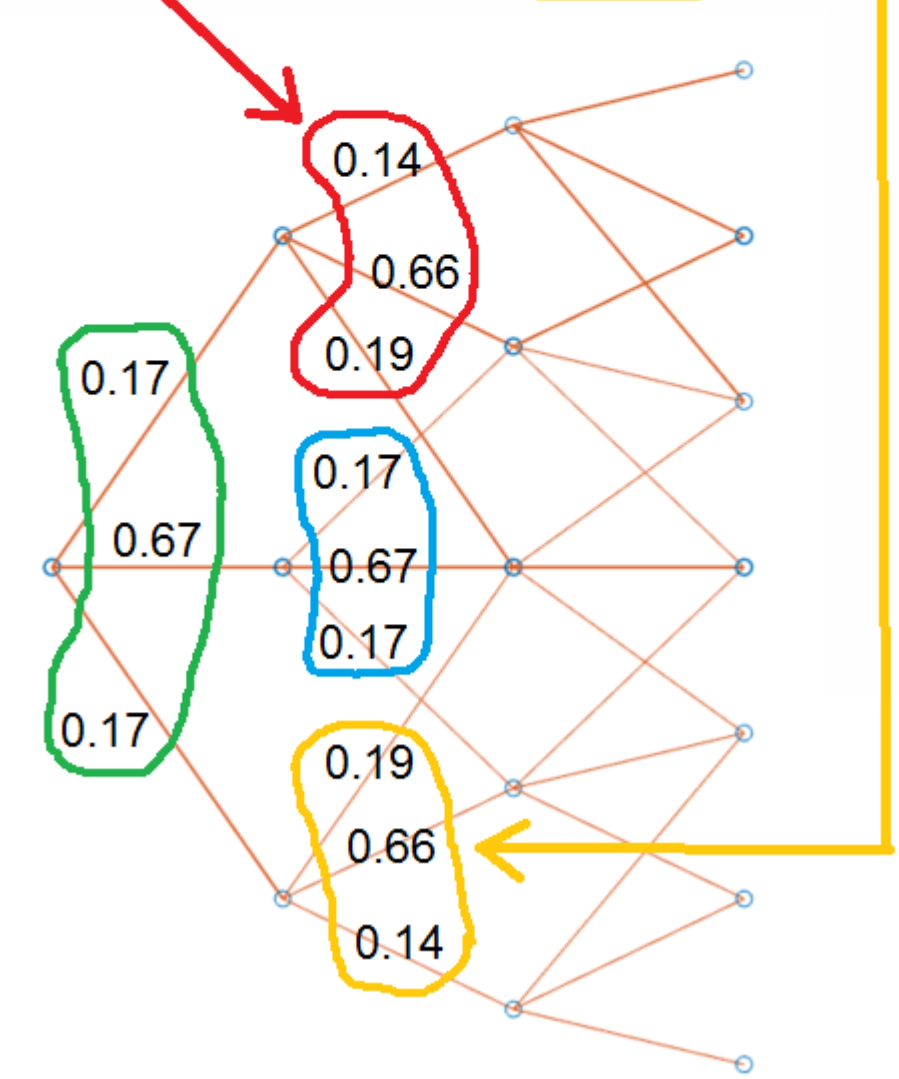
The probability of moving up (path 1) is the top value (14.29%), the middle path is the middle value (66.42%), and the path going down (path 3) is the bottom value in the array (19.30%). The following diagram summarizes this information.

```
HWT.Probs{1}
```

```
ans = 3×1
    0.16667
    0.66667
    0.16667
```

```
HWT.Probs{2}
```

```
ans = 3×3
    0.14292    0.16667    0.19292
    0.66417    0.66667    0.66417
    0.19292    0.16667    0.14292
```



Examine the PriceTree Structure

The output of the pricing function is `PriceTree`. `PriceTree` has the following fields.

- `PriceTree.PTree` — contains the clean prices of each instrument.
- `PriceTree.ExTree` — contains the exercise indicator arrays where a value of `1` indicates the option has been exercised and a value of `0` indicates the option has not been exercised.
- `PriceTree.ExProbTree` — contains the exercise probabilities. A value of 0 indicates there was no exercise and a nonzero value gives the probability of reaching that node where the exercise happens.
- `PriceTree.ProbTree` — contains the probability tree indicating how likely any node is reached from the root node.
- `PriceTree.ExProbsByTreeLevel` — contains the exercise probability for a given option at each tree observation time. This is an aggregated view of `PriceTree.ExProbTree` that sums the values along all nodes at a particular time.

Note that for `ProbTree`, `PTree`, `ExTree`, and `ExProbTree`, each cell represents a different time in the tree, and inside each cell is an array. Each column in the array represents a different node on the tree at that particular tree level. This structure is the same as in `HWT.Probs`. However, for `PTree`, `ExTree`, and `ExProbTree` each row represents a different instrument. Because this example prices two instruments, there are only two rows. `ProbTree` contains only one row as the probability of reaching a particular node is independent of the instrument being priced.

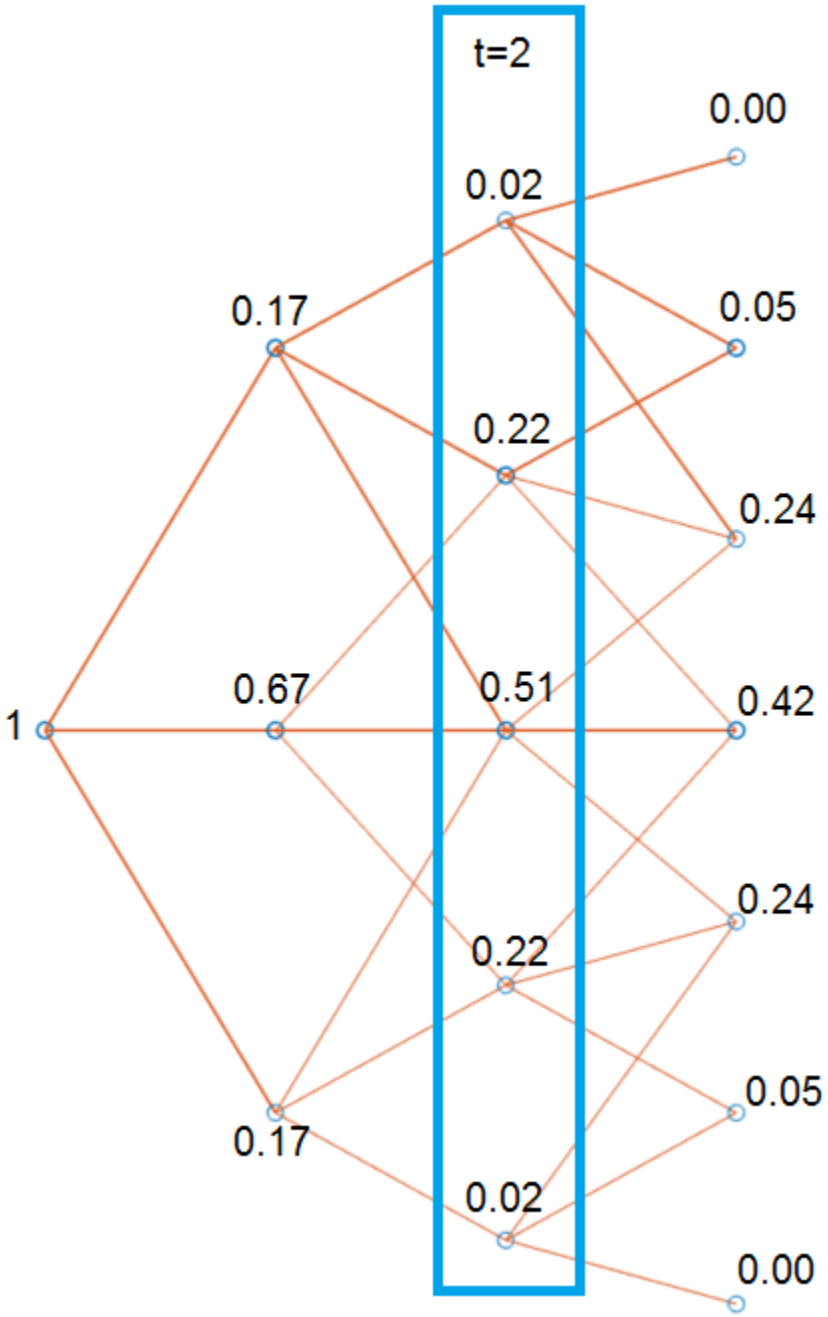
Looking at `PriceTree.ProbTree`, examine the probabilities of reaching each of the five nodes from the root node at $t = 2$, which is the third level of the tree.

```
PriceTree.ProbTree{3}
```

```
ans = 1×5

    0.0238    0.2218    0.5087    0.2218    0.0238
```

These results are displayed in the following diagram, where all nodes are overlayed with their probabilities. The root node at $t = 0$ always has a probability of being reached, hence, it has a value of `1`.



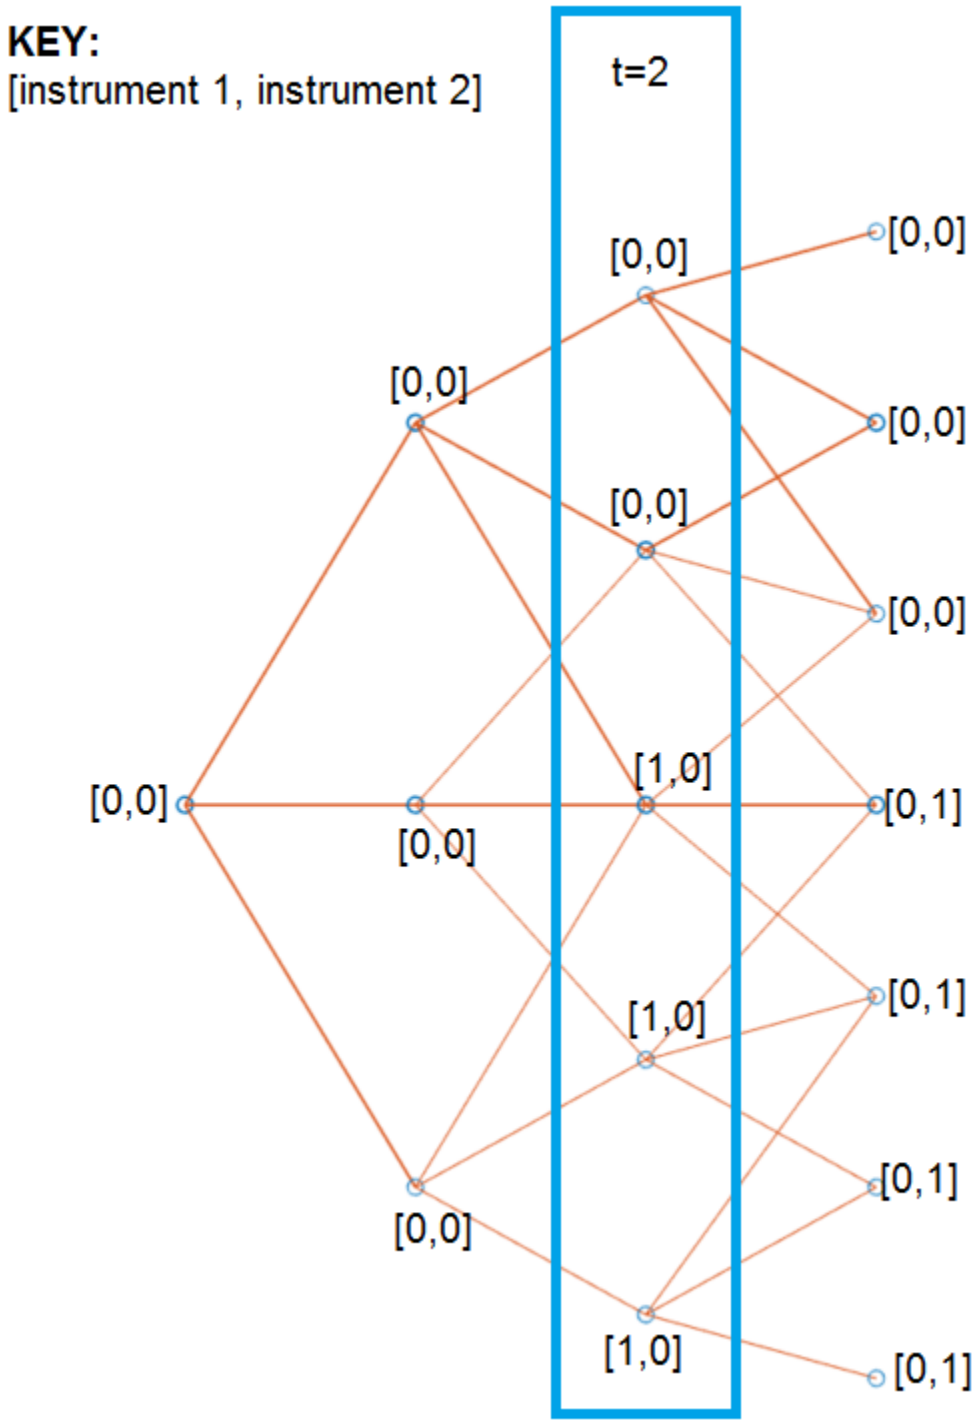
By looking at `PriceTree.ExTree`, you can determine if the options are exercised. If either of the two instruments has options exercised at $t = 2$, which is the third level of the tree, the values in `ExTree` are `1`; otherwise, the value is `0`.

```
PriceTree.ExTree{3}
```

```
ans = 2×5
```

```
     0     0     1     1     1
     0     0     0     0     0
```

At $t = 2$, the first instrument has its option exercised at some nodes, while there is no exercise for the second instrument. The following diagram summarizes the exercise indicators on the tree.

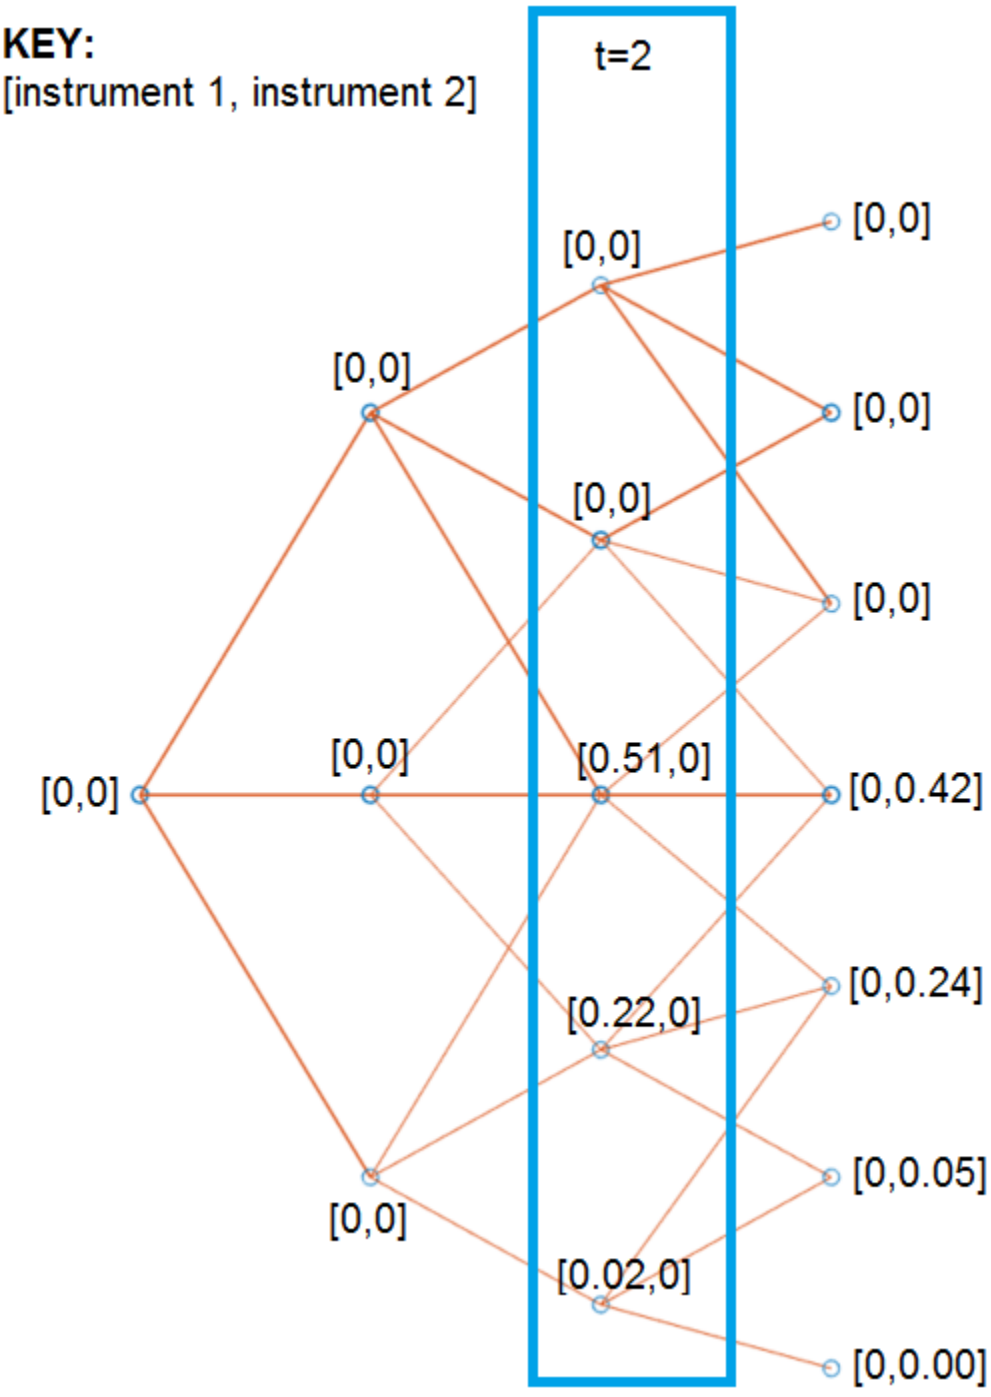


Examine `ExProbTree`, which contains the exercise probabilities. These values indicate the probability of exercising the option.

```
PriceTree.ExProbTree{3}
```

```
ans = 2×5

         0         0    0.5087    0.2218    0.0238
         0         0         0         0         0
```



`ExProbsByTreeLevel` is an aggregated view of `ExProbTrees`. Examine the exercise probabilities for the two options at each tree observation time.

```
PriceTree.ExProbsByTreeLevel
```

```
ans = 2×5

         0         0    0.7544         0         0
         0         0         0    0.7124         0
```

The first row corresponds to instrument 1, and the second row corresponds to instrument 2.

You can use `treeviewer` to examine the `tree` and `PriceTree` structures for any of the following tree types:

- `bdttree`
- `bktree`
- `hjmtree`
- `hwtree`
- `cirtree`
- `crrtree`
- `itttree`
- `stttree`
- `lrtree`
- `eqptree`

Select Cheapest-to-Deliver Bond Using BondFuture Instrument

This example shows how to select the cheapest-to-deliver (CTD) bond for Treasury bond future contracts using a `BondFuture` instrument. It demonstrates two workflows for selecting the CTD bond:

- Select the CTD bond at the time of delivery on page 2-212.
- Select the CTD bond months before the delivery date on page 2-215.

When a Treasury bond future contract matures, the party that is in the short position of the contract can deliver the underlying bond to the party that is in the long position of the contract. Typically, there can be many different bonds that satisfy the terms of the contract during the delivery month. For example, you can meet the delivery obligation for a 30-year US Treasury bond future contract with any US Treasury bond that has at least 15 years to maturity at the time of delivery. Furthrermore, these deliverable bonds can have different coupons and maturities. Since the party in the short position has the option to choose which bond to deliver from these deliverable bonds, it is in the interest of that party to select the CTD bond that minimizes the delivery cost. You can select the CTD bond at the time of delivery during the delivery month of the future contract using the current market prices. Alternatively, you can predict the CTD bond several months before the delivery month based on the current zero curve.

Select CTD Bond at Time of Delivery

In this workflow, you determine the delivery cost by comparing the invoice price that the short position receives from the long position against the price of the deliverable bond. For a particular deliverable bond, the invoice price that the short position receives from the long position is:

```
InvoicePrice = (QuotedFuturePrice x ConversionFactor + AccruedInterest)/BondPrincipal x FutureNo
```

For example, in the 30-year US Treasury bond futures market, typically, `BondPrincipal` is $100 and `FutureNotional` is $100,000. In return, the short position delivers the bond to the long position by buying the deliverable bond that has the following purchase cost in the market:

```
PurchaseCost = (SpotPrice + AccruedInterest)/BondPrincipal x FutureNotional
```

Here, `SpotPrice` is the clean market price of the bond at the time of delivery. From this purchase cost, subtracting the invoice amount to be received by the short position from the long position gives the following formula for the overall delivery cost:

```
OverallDeliveryCost = (SpotPrice - QuotedFuturePrice x ConversionFactor)/BondPrincipal x FutureN
```

You can compute the delivery cost for every deliverable bond and determine the CTD bond by selecting the bond with the lowest delivery cost. The `OverallDeliveryCost` formula applies only at the time of delivery. This method is equivalent to using the `cashsettle` method of the `BondFuture` instrument at the time of delivery. To demonstrate this workflow, the following example uses fictitious data, and selects the CTD bond using the `BondFuture` instrument on the delivery day of a hypothetical 30-year US Treasury bond future contract maturing in December 2021.

```
% Create a zero curve.
Settle = datetime(2021,12,21);
ZeroDates = Settle + [calmonths([1 2 3 6]) calyears([1 2 3 5 7 10 20 30])]';
ZeroRates = [0.06 0.04 0.06 0.07 0.21 0.60 0.95 1.34 1.60 1.69 2.15 2.05]'./100;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);
```

```
% Define the data for the deliverable bonds.
ReferenceDate = datetime(2021,12,1);
BondMaturity = datetime(datevec(["2/15/2045","2/15/2037","8/15/2040",...
    "5/15/2041","5/15/2037","2/15/2042","11/15/2043","11/15/2044",...
    "5/15/2038","2/15/2041"],'mm/dd/yyyy'));
CouponRate = [2.5 4.75 3.875 2.25 5.0 3.125 3.75 3.0 4.5 4.75]'/100;
IssueDate = datetime(datevec(["2/17/2015","2/15/2007","8/16/2010",...
    "6/1/2021","8/15/2007","2/15/2012","11/15/2013","11/17/2014",...
    "8/15/2008","2/15/2011"],'mm/dd/yyyy'));
SpotPrice = [109.06;140.78;130.60;104.04;144.02;119.03;131.05;118.23;138.08;145.25];
NumBonds = length(BondMaturity);
BondID = (1:NumBonds)';

% Use convfactor to compute the conversion factors.

```

Once you have computed the delivery costs for all of the deliverable bonds, you can determine the CTD bond by selecting the bond with the lowest delivery cost.

```
% Determine the CTD bond with the lowest delivery cost.
[~,CTDBondIdx] = min(DeliverableBondTable.DeliveryCost);
CTDBondTableDecember2021 = DeliverableBondTable(CTDBondIdx,:)
```

```
CTDBondTableDecember2021=1×7 table
    BondID    BondMaturity     IssueDate     CouponRate    SpotPrice    ConversionFactor    Deliv
    ______    ____________    ___________    __________    _________    ________________    _____
```

```
      5       15-May-2037     15-Aug-2007       0.05        144.02          0.9009            29
```

```
BondFutureContracts(CTDBondIdx)
```

```
ans =
  BondFuture with properties:

           Maturity: 21-Dec-2021
       QuotedPrice: 159.5300
              Bond: [1x1 fininstrument.FixedBond]
    ConversionFactor: 0.9009
           Notional: 100000
               Name: ""
```

Among the ten deliverable bonds, the CTD bond with the lowest delivery cost for the December 2021 future contract is the bond with a 5% coupon rate maturing on May 15, 2037. This CTD bond is determined at the time of delivery on December 21, 2021.

Since the delivery costs in this example are computed at the time of delivery, the delivery costs computed by the `cashsettle` method of the `BondFuture` instrument for this future contract are in agreement with those computed using the following formula for the overall delivery cost at delivery:

```
OverallDeliveryCost = (SpotPrice - QuotedFuturePrice x ConversionFactor)/BondPrincipal x FutureNo
```

```
% Compare calculated delivery cost using cashsettle with the delivery cost formula.
DeliveryCostFormula = ...
    (SpotPrice - QuotedFuturePrice.*ConversionFactor)/BondPrincipal*FutureNotional;
table(DeliveryCostFormula, DeliveryCost)
```

```
ans=10×2 table

          8146.4              8146.4
```

Select CTD Bond Months Before Delivery Month

The previous overall delivery cost formula on page 2-215 applies only at the time of delivery. However, if a current zero curve is available, you can still compute the estimated delivery cost using the `cashsettle` method of the `BondFuture` instrument, even when it is several months before the delivery month. In the following example, you select the CTD bond using the `BondFuture` instrument in November 2021 for a hypothetical 30-year US Treasury bond future contract maturing several months later in June 2022. The overall workflow is similar to the workflow in Select CTD Bond at Time of Delivery on page 2-212, except that you select the CTD bond several months before the delivery month and the overall delivery cost formula no longer applies.

```
% Create a zero curve.
Settle = datetime(2021,11,22);
ZeroDates = Settle + [calmonths([1 2 3 6]) calyears([1 2 3 5 7 10 20 30])]';
ZeroRates = [0.07 0.04 0.05 0.07 0.20 0.63 0.95 1.34 1.57 1.65 2.09 2.01]'./100;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,Compounding=2);

% Define the data for the deliverable bonds.

Graphical Representation of Trees

In this section...

Introduction

You can use the function `treeviewer` to display a graphical representation of a tree, allowing you to examine interactively the prices and rates on the nodes of the tree until maturity. To get started with this process, first load the data file `deriv.mat` included in this toolbox.

```
load deriv.mat
```

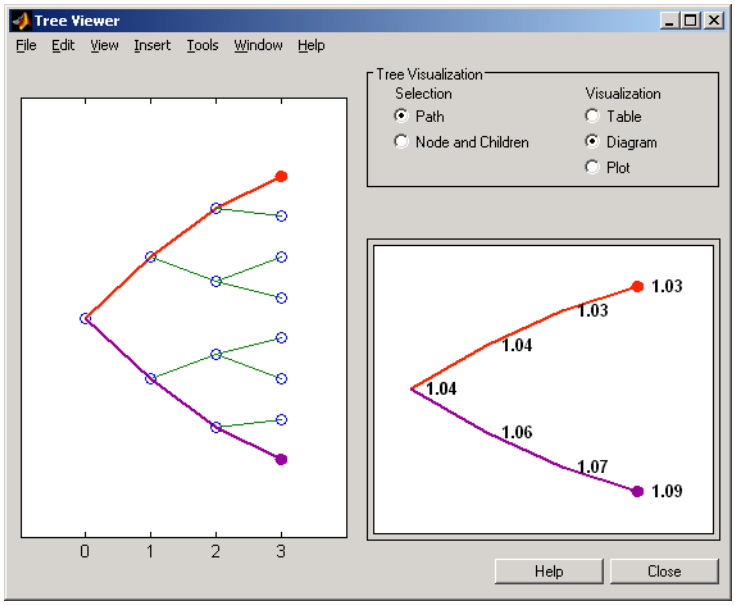
Note `treeviewer` price tree diagrams follow the convention that increasing prices appear on the upper branch of a tree and, consequently, decreasing prices appear on the lower branch. Conversely, for interest rate displays, *decreasing* interest rates appear on the upper branch (prices are rising) and *increasing* interest rates on the lower branch (prices are falling).

For information on the use of `treeviewer` to observe interest rate movement, see “Observing Interest Rates” on page 2-219. For information on using `treeviewer` to observe the movement of prices, see “Observing Instrument Prices” on page 2-222.

Observing Interest Rates

If you provide the name of an interest rate tree to the `treeviewer` function, it displays a graphical view of the path of interest rates. For example, here is the `treeviewer` representation of all the rates along both the up and down branches of `HJMTree`.

```
treeviewer(HJMTree)
```



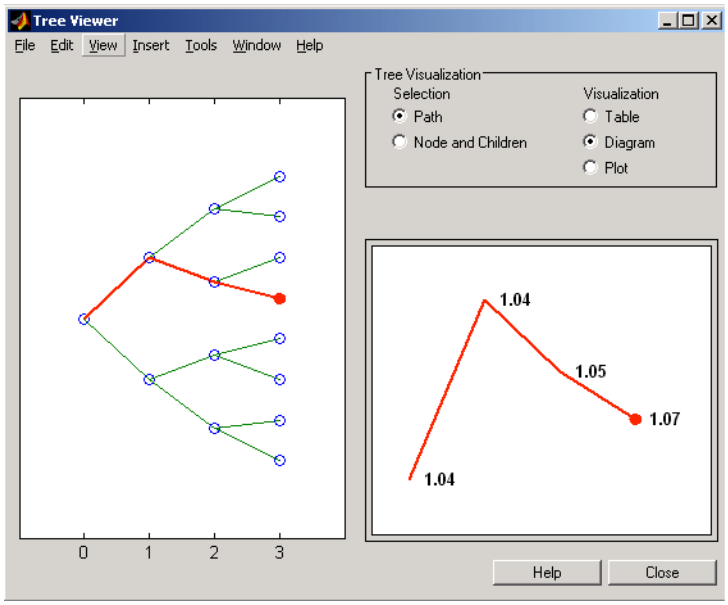
The example in “Isolating a Specific Node” on page 2-75 used `bushpath` to find the path of forward rates along an HJM tree by taking the first branch up and then two branches down the rate tree.

```
FRates = bushpath(HJMTree.FwdTree, [1 2 2])
```

```
FRates =

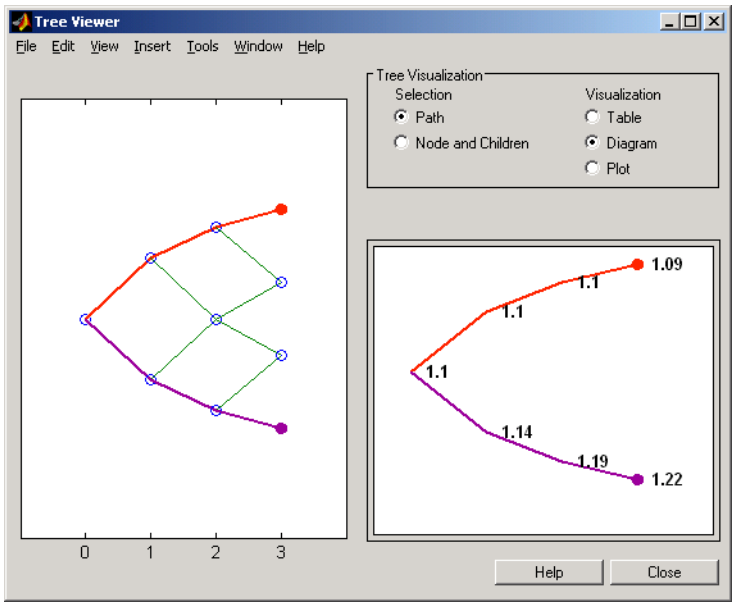
    1.0356
    1.0364
    1.0526
    1.0674
```

With the `treeviewer` function you can display the identical information by clicking along the same sequence of nodes, as shown next.



Next is a `treeviewer` representation of interest rates along several branches of `BDTTree`.

```
treeviewer(BDTTree)
```



Note When using `treeviewer` with recombining trees, such as BDT, BK, and HW, you must click each node in succession from the beginning to the end. Because these trees can recombine, `treeviewer` is unable to complete the path automatically.

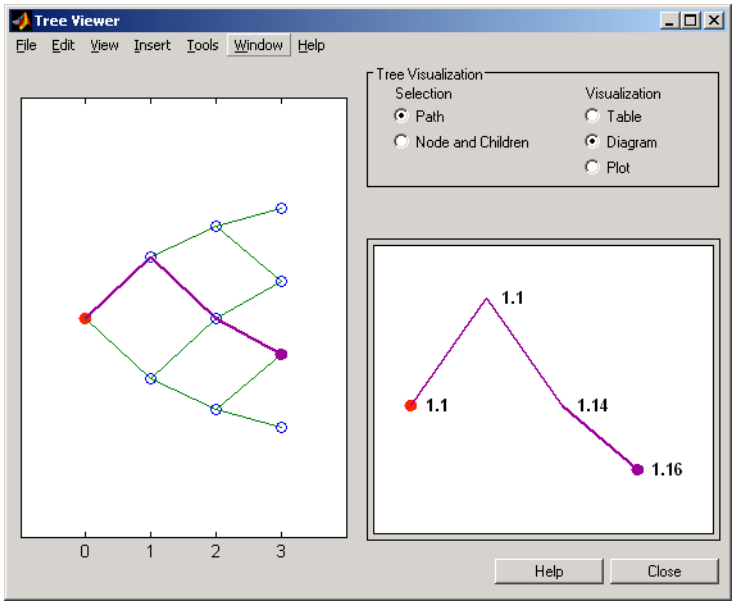
The example in “Isolating a Specific Node” on page 2-75 used `treepath` to find the path of interest rates taking the first branch up and then two branches down the rate tree.

```
FRates = treepath(BDTTree.FwdTree, [1 2 2])
```

```
FRates =

    1.1000
    1.0979
    1.1377
    1.1606
```

You can display the identical information by clicking along the same sequence of nodes, as shown next.

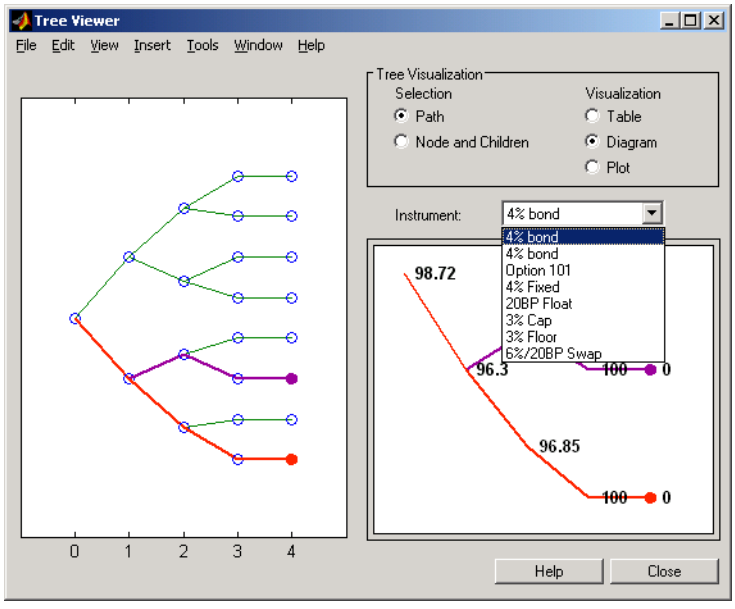


Observing Instrument Prices

To use `treeviewer` to display a tree of instrument prices, provide the name of an instrument set along with the name of a price tree in your call to `treeviewer`, for example:

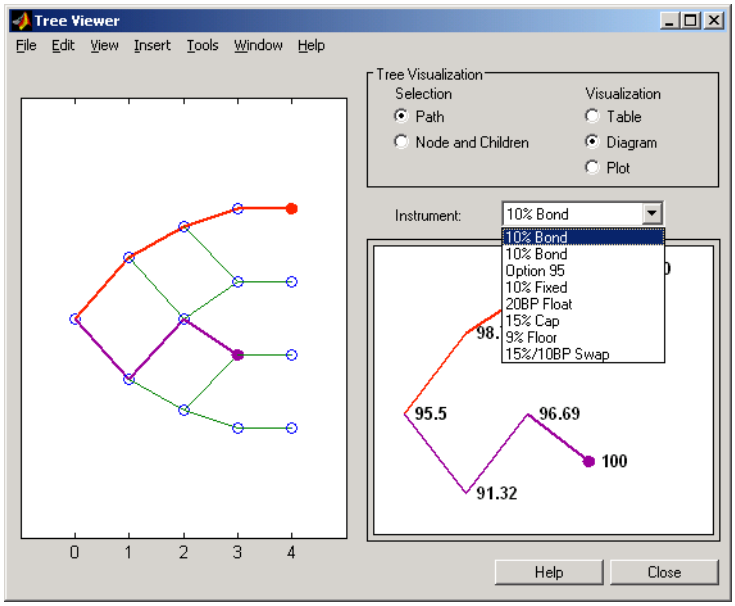
```
load deriv.mat
[Price, PriceTree] = hjmprice(HJMTree, HJMInstSet);
treeviewer(PriceTree, HJMInstSet)
```

With `treeviewer` you select *each instrument individually* in the instrument portfolio for display.



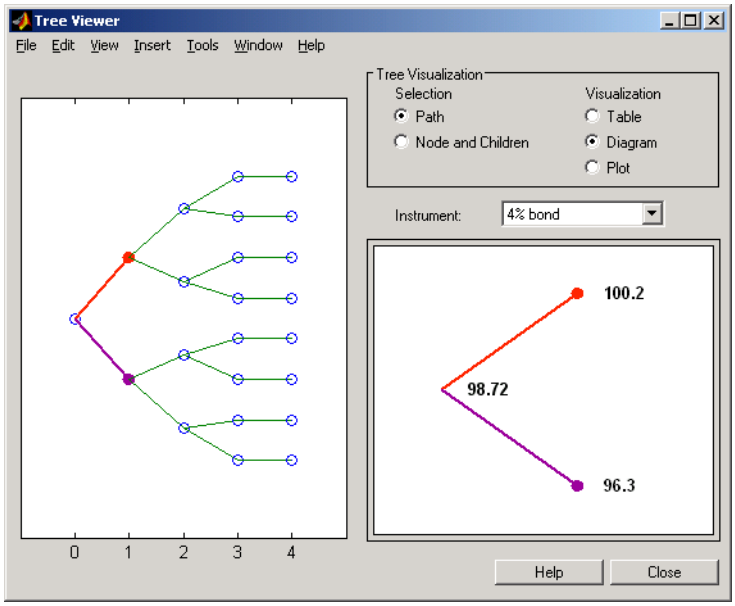
You can use an analogous process to view instrument prices based on the BDT interest rate tree included in `deriv.mat`.

```
load deriv.mat
[BDTPrice, BDTPriceTree] = bdtprice(BDTTree, BDTInstSet);
treeviewer(BDTPriceTree, BDTInstSet)
```

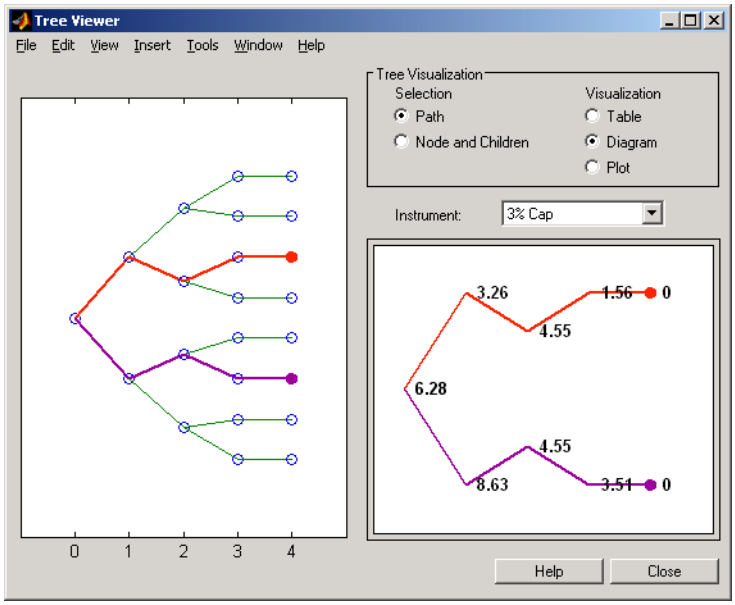


Valuation Date Prices

You can use `treeviewer` instrument-by-instrument to observe instrument prices through time. For the first 4% bond in the HJM instrument portfolio, `treeviewer` indicates a valuation date price of 98.72, the same value obtained by accessing the `PriceTree` structure directly.



As a further example, look at the sixth instrument in the price vector, the 3% cap. At the valuation date, its value obtained directly from the structure is 6.2831. Use `treeviewer` on this instrument to confirm this price.



Additional Observation Times

The second node represents the first-rate observation time, `tObs = 1`. This node displays two states, one representing the branch going up and the other one representing the branch going down.

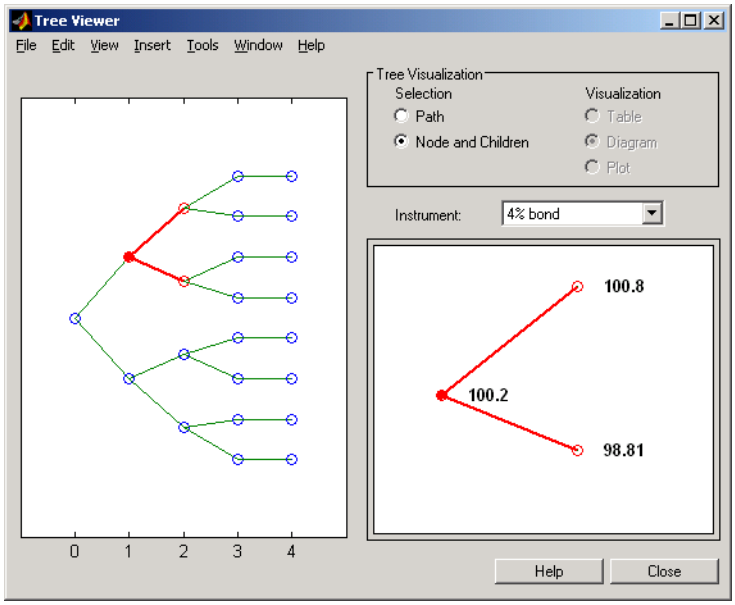
Examine the prices of the node corresponding to the up branch.

```
PriceTree.PBush{2}(:,:,1)
```

```
ans =

  100.1563
   99.7309
    0.1007
  100.1563
  100.3782
    3.2594
    0.1007
    3.5597
```

As before, you can use `treeviewer`, this time to examine the price for the 4% bond on the up branch. `treeviewer` displays a price of 100.2 for the first node of the up branch, as expected.



Now examine the corresponding down branch.

```
PriceTree.PBush{2}(:,:,2)
```

```
ans =

   96.3041
   94.1986
         0
   96.3041
  100.3671
    8.6342
         0
   -0.3923
```

Use `treeviewer` once again, now to observe the price of the 4% bond on the down branch. The displayed price of 96.3 conforms to the price obtained from direct access of the `PriceTree` structure. You may continue this process as far along the price tree as you want.

Basis

Day count basis determines how interest accrues over time for various instruments and the amount transferred on interest payment dates. The calculation of accrued interest for dates between payments also uses day count basis. Day count basis is a fraction of `Number of interest accrual days` / `Days in the relevant coupon period`. Supported day count conventions and basis values are:

Basis Value	Day Count Convention
`0`	actual/actual (default) — Number of days in both a period and a year is the actual number of days.
`1`	30/360 SIA — Year fraction is calculated based on a 360 day year with 30-day months, after applying the following rules: If the first date and the second date are the last day of February, the second date is changed to the 30th. If the first date falls on the 31st or is the last day of February, it is changed to the 30th. If after the preceding test, the first day is the 30th and the second day is the 31st, then the second day is changed to the 30th.
`2`	actual/360 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360.
`3`	actual/365 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year).
`4`	30/360 PSA — Number of days in every month is set to 30 (including February). If the start date of the period is either the 31st of a month or the last day of February, the start date is set to the 30th, while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.
`5`	30/360 ISDA — Number of days in every month is set to 30, except for February where it is the actual number of days. If the start date of the period is the 31st of a month, the start date is set to the 30th while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.
`6`	30E /360 — Number of days in every month is set to 30 except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360.
`7`	actual/365 Japanese — Number of days in a period is equal to the actual number of days, except for leap days (29th February) which are ignored. The number of days in a year is 365 (even in a leap year).
`8`	actual/actual ICMA — Number of days in both a period and a year is the actual number of days and the compounding frequency is annual.
`9`	actual/360 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360 and the compounding frequency is annual.
`10`	actual/365 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year) and the compounding frequency is annual.
`11`	30/360 ICMA — Number of days in every month is set to 30, except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360 and the compounding frequency is annual.

Basis Value	Day Count Convention
12	actual/365 ISDA — The day count fraction is calculated using the following formula: `(Actual number of days in period that fall in a leap year / 366) + (Actual number of days in period that fall in a normal year / 365 ).`
13	bus/252 — The number of days in a period is equal to the actual number of business days. The number of business days in a year is 252.

Equity Derivatives

Understanding Equity Trees

In this section...

Introduction

Financial Instruments Toolbox supports five types of recombining tree models to represent the evolution of stock prices:

- Cox-Ross-Rubinstein (CRR) model
- Equal probabilities (EQP) model
- Leisen-Reimer (LR) model
- Implied trinomial tree (ITT) model
- Standard trinomial tree (STT) model

For a discussion of recombining trees, see “Rate and Price Trees” on page 2-45.

The CRR, EQP, LR, STT, and ITT models are examples of discrete time models. A discrete time model divides time into discrete bits; prices can only be computed at these specific times.

The CRR model is one of the most common methods used to model the evolution of stock processes. The strength of the CRR model lies in its simplicity. It is a good model when dealing with many tree levels. The CRR model yields the correct expected value for each node of the tree and provides a good approximation for the corresponding local volatility. The approximation becomes better as the number of time steps represented in the tree is increased.

The EQP model is another discrete time model. It has the advantage of building a tree with the exact volatility in each tree node, even with small numbers of time steps. It also provides better results than CRR in some given trading environments, for example, when stock volatility is low and interest rates are high. However, this additional precision causes increased complexity, which is reflected in the number of calculations required to build a tree.

The LR model is another discrete time model. It has the advantage of producing estimates close to the Black-Scholes model using only a few steps, while also minimizing the oscillation.

The ITT model is a CRR-style implied trinomial tree which takes advantage of prices quoted from liquid options in the market with varying strikes and maturities to build a tree that more accurately represents the market. An ITT model is commonly used to price exotic options in such a way that they are consistent with the market prices of standard options.

The STT model is another discrete time model. It is considered to produce more accurate results than the binomial model when fewer time steps are modeled. The STT model is sometimes more stable and accurate than the binomial model when pricing exotic options.

Building Equity Binary Trees

The tree of stock prices is the fundamental unit representing the evolution of the price of a stock over a given period of time. The MATLAB functions `crrtree`, `eqptree`, and `lrtree` create CRR trees, EQP trees, and LR trees, respectively. These functions create an output tree structure along with information about the parameters used for creating the tree.

The functions `crrtree`, `eqptree`, and `lrtree` take three structures as input arguments:

- The stock parameter structure `StockSpec`
- The interest-rate term structure `RateSpec`
- The tree time layout structure `TimeSpec`

Calling Sequence for Equity Binary Trees

The calling syntax for `crrtree` is:

```
CRRTree = crrtree (StockSpec, RateSpec, TimeSpec)
```

Similarly, the calling syntax for `eqptree` is:

```
EQPTree = eqptree (StockSpec, RateSpec, TimeSpec)
```

And, the calling syntax for `lrtree` is:

```
LRTree = lrtree(StockSpec, RateSpec, TimeSpec, Strike)
```

All three functions require the structures `StockSpec`, `RateSpec`, and `TimeSpec` as input arguments:

- `StockSpec` is a structure that specifies parameters of the stock whose price evolution is represented by the tree. This structure, created using the function `stockspec`, contains information such as the stock's original price, its volatility, and its dividend payment information.
- `RateSpec` is the interest-rate specification of the initial rate curve. Create this structure with the function `intenvset`.
- `TimeSpec` is the tree time layout specification. Create these structures with the functions `crrtimespec`, `eqptimespec`, and `lrtimespec`. The structures contain information regarding the mapping of relevant dates into the tree structure, plus the number of time steps used for building the tree.

Specifying the Stock Structure for Equity Binary Trees

The structure `StockSpec` encapsulates the stock-specific information required for building the binary tree of an individual stock's price movement.

You generate `StockSpec` with the function `stockspec`. This function requires two input arguments and accepts up to three additional input arguments that depend on the existence and type of dividend payments.

The syntax for calling `stockspec` is:

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates)
```

where:

- `Sigma` is the decimal annual volatility of the underlying security.
- `AssetPrice` is the price of the stock at the valuation date.
- `DividendType` is a character vector specifying the type of dividend paid by the stock. Allowed values are `cash`, `constant`, or `continuous`.
- `DividendAmounts` has a value that depends on the specification of `DividendType`. For `DividendType` `cash`, `DividendAmounts` is a vector of cash dividends. For `DividendType` `constant`, it is a vector of constant annualized dividend yields. For `DividendType` `continuous`, it is a scalar representing a continuously annualized dividend yield.
- `ExDividendDates` also has a value that depends on the nature of `DividendType`. For `DividendType` `cash` or `constant`, `ExDividendDates` is vector of dividend dates. For `DividendType` `continuous`, `ExDividendDates` is ignored.

Stock Structure Example Using a Binary Tree

Consider a stock with a price of $100 and an annual volatility of 15%. Assume that the stock pays three cash $5.00 dividends on dates January 01, 2004, July 01, 2005, and January 01, 2006. You specify these parameters in MATLAB as:

```
Sigma = 0.15;
AssetPrice = 100;
DividendType = 'cash';
DividendAmounts = [5; 5; 5];
ExDividendDates = {'jan-01-2004', 'july-01-2005', 'jan-01-2006'};

StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates)
```

```
StockSpec =

               FinObj: 'StockSpec'
                Sigma: 0.1500
           AssetPrice: 100
         DividendType: 'cash'
      DividendAmounts: [3x1 double]
      ExDividendDates: [3x1 double]
```

Specifying the Interest-Rate Term Structure for Equity Binary Trees

The `RateSpec` structure defines the interest rate environment used when building the stock price binary tree. “Modeling the Interest-Rate Term Structure” on page 2-57 explains how to create these structures using the function `intenvset`, given the interest rates, the starting and ending dates for each rate, and the compounding value.

Specifying the Tree-Time Term Structure for Equity Binary Trees

The `TimeSpec` structure defines the tree layout of the binary tree:

- It maps the valuation and maturity dates to their corresponding times.
- It defines the time of the levels of the tree by dividing the time span between valuation and maturity into equally spaced intervals. By specifying the number of intervals, you define the granularity of the tree time structure.

The syntax for building a `TimeSpec` structure is:

```
TimeSpec = crrtimespec(ValuationDate, Maturity, NumPeriods)
TimeSpec = eqptimespec(ValuationDate, Maturity, NumPeriods)
```

```
TimeSpec = lrtimespec(ValuationDate, Maturity, NumPeriods)
```

where:

- `ValuationDate` is a scalar date marking the pricing date and first observation in the tree (location of the root node). You enter `ValuationDate` either as a datetime or a date character vector.
- `Maturity` is a scalar date marking the maturity of the tree, entered as a serial date number or a date character vector.
- `NumPeriods` is a scalar defining the number of time steps in the tree; for example, `NumPeriods = 10` implies 10 time steps and 11 tree levels (0, 1, 2, ..., 9, 10).

TimeSpec Example Using a Binary Tree

Consider building a CRR tree, with a valuation date of January 1, 2003, a maturity date of January 1, 2008, and 20 time steps. You specify these parameters in MATLAB as:

```
ValuationDate = datetime(2003,1,1);
Maturity = datetime(2008,1,1);
NumPeriods = 20;
TimeSpec = crrtimespec(ValuationDate, Maturity, NumPeriods)
```

```
TimeSpec =

           FinObj: 'BinTimeSpec'
    ValuationDate: 731582
         Maturity: 733408
       NumPeriods: 20
            Basis: 0
     EndMonthRule: 1
             tObs: [1x21 double]
             dObs: [1x21 double]
```

Two vector fields in the `TimeSpec` structure are of particular interest: `dObs` and `tObs`. These two fields represent the observation times and corresponding dates of all tree levels, with `dObs(1)` and `tObs(1)`, respectively, representing the root node (`ValuationDate`), and `dObs(end)` and `tObs(end)` representing the last tree level (`Maturity`).

Note There is no relationship between the dates specified for the tree and the implied tree level times, and the maturities specified in the interest-rate term structure. The rates in `RateSpec` are interpolated or extrapolated as required to meet the time distribution of the tree.

Examples of Binary Tree Creation

You can now use the `StockSpec` and `TimeSpec` structures described previously to build an equal probability tree (`EQPTree`), a CRR tree (`CRRTree`), or an LR tree (`LRTree`). First, you must define the interest-rate term structure. For this example, assume that the interest rate is fixed at 10% annually between the valuation date of the tree (January 1, 2003) until its maturity.

```
ValuationDate = datetime(2003,1,1);
Maturity = datetime(2008,1,1);
Rate = 0.1;
RateSpec = intenvset('Rates', Rate, 'StartDates', ...
ValuationDate, 'EndDates', Maturity, 'Compounding', -1);
```

To build a CRRTree, enter:

```
CRRTree = crrtree(StockSpec, RateSpec, TimeSpec)
```

```
CRRTree =

       FinObj: 'BinStockTree'
       Method: 'CRR'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [1x21 double]
         dObs: [1x21 double]
        STree: {1x21 cell}
      UpProbs: [1x20 double]
```

To build an EQPTree, enter:

```
EQPTree = eqptree(StockSpec, RateSpec, TimeSpec)
```

```
EQPTree =

       FinObj: 'BinStockTree'
       Method: 'EQP'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [1x21 double]
         dObs: [1x21 double]
        STree: {1x21 cell}
      UpProbs: [1x20 double]
```

Building Implied Trinomial Trees

The tree of stock prices is the fundamental unit representing the evolution of the price of a stock over a given period of time. The function `itttree` creates an output tree structure along with the information about the parameters used to create the tree.

The function `itttree` takes four structures as input arguments:

- The stock parameter structure `StockSpec`
- The interest-rate term structure `RateSpec`
- The tree time layout structure `TimeSpec`
- The stock option specification structure `StockOptSpec`

Calling Sequence for Implied Trinomial Trees

The calling syntax for `itttree` is:

```
ITTTree = itttree (StockSpec,RateSpec,TimeSpec,StockOptSpec)
```

- `StockSpec` is a structure that specifies parameters of the stock whose price evolution is represented by the tree. This structure, created using the function `stockspec`, contains information such as the stock's original price, its volatility, and its dividend payment information.
- `RateSpec` is the interest-rate specification of the initial rate curve. Create this structure with the function `intenvset`.

- `TimeSpec` is the tree time layout specification. Create these structures with the function `itttimespec`. This structure contains information regarding the mapping of relevant dates into the tree structure, plus the number of time steps used for building the tree.
- `StockOptSpec` is a structure containing parameters of European stock options instruments. Create this structure with the function `stockoptspec`.

Specifying the Stock Structure for Implied Trinomial Trees

The structure `StockSpec` encapsulates the stock-specific information required for building the trinomial tree of an individual stock's price movement.

You generate `StockSpec` with the function `stockspec`. This function requires two input arguments and accepts up to three additional input arguments that depend on the existence and type of dividend payments.

The syntax for calling `stockspec` is:

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates)
```

where:

- `Sigma` is the decimal annual volatility of the underlying security.
- `AssetPrice` is the price of the stock at the valuation date.
- `DividendType` is a character vector specifying the type of dividend paid by the stock. Allowed values are `cash`, `constant`, or `continuous`.
- `DividendAmounts` has a value that depends on the specification of `DividendType`. For `DividendType cash`, `DividendAmounts` is a vector of cash dividends. For `DividendType constant`, it is a vector of constant annualized dividend yields. For `DividendType continuous`, it is a scalar representing a continuously annualized dividend yield.
- `ExDividendDates` also has a value that depends on the nature of `DividendType`. For `DividendType cash` or `constant`, `ExDividendDates` is vector of dividend dates. For `DividendType continuous`, `ExDividendDates` is ignored.

Stock Structure Example Using an Implied Trinomial Tree

Consider a stock with a price of $100 and an annual volatility of 12%. Assume that the stock is expected to pay a dividend yield of 6%. You specify these parameters in MATLAB as:

```
So = 100;
DividendYield = 0.06;
Sigma = .12;

StockSpec = stockspec(Sigma, So, 'continuous', DividendYield)

StockSpec =

             FinObj: 'StockSpec'
              Sigma: 0.1200
         AssetPrice: 100
       DividendType: 'continuous'
    DividendAmounts: 0.0600
    ExDividendDates: []
```

Specifying the Interest-Rate Term Structure for Implied Trinomial Trees

The structure `RateSpec` defines the interest rate environment used when building the stock price binary tree. “Modeling the Interest-Rate Term Structure” on page 2-57 explains how to create these structures using the function `intenvset`, given the interest rates, the starting and ending dates for each rate, and the compounding value.

Specifying the Tree-Time Term Structure for Implied Trinomial Trees

The `TimeSpec` structure defines the tree layout of the trinomial tree:

- It maps the valuation and maturity dates to their corresponding times.
- It defines the time of the levels of the tree by dividing the time span between valuation and maturity into equally spaced intervals. By specifying the number of intervals, you define the granularity of the tree time structure.

The syntax for building a `TimeSpec` structure is:

```
TimeSpec = itttimespec(ValuationDate, Maturity, NumPeriods)
```

where:

- `ValuationDate` is a scalar date marking the pricing date and first observation in the tree (location of the root node). You enter `ValuationDate` either as a datetime or a date character vector.
- `Maturity` is a scalar date marking the maturity of the tree, entered as a serial date number or a date character vector.
- `NumPeriods` is a scalar defining the number of time steps in the tree; for example, `NumPeriods = 10` implies 10 time steps and 11 tree levels (0, 1, 2, ..., 9, 10).

TimeSpec Example Using an Implied Trinomial Tree

Consider building an ITT tree, with a valuation date of January 1, 2006, a maturity date of January 1, 2008, and four time steps. You specify these parameters in MATLAB as:

```
ValuationDate = datetime(2006,1,1);
EndDate = datetime(2008,1,1);
NumPeriods = 4;

TimeSpec = itttimespec(ValuationDate, EndDate, NumPeriods)
```

```
TimeSpec =

           FinObj: 'ITTTimeSpec'
    ValuationDate: 732678
         Maturity: 733408
       NumPeriods: 4
            Basis: 0
     EndMonthRule: 1
             tObs: [0 0.5000 1 1.5000 2]
             dObs: [732678 732860 733043 733225 733408]
```

Two vector fields in the `TimeSpec` structure are of particular interest: `dObs` and `tObs`. These two fields represent the observation times and corresponding dates of all tree levels, with `dObs(1)` and `tObs(1)`, respectively, representing the root node (`ValuationDate`), and `dObs(end)` and `tObs(end)` representing the last tree level (`Maturity`).

Specifying the Option Stock Structure for Implied Trinomial Trees

The `StockOptSpec` structure encapsulates the option-stock-specific information required for building the implied trinomial tree. You generate `StockOptSpec` with the function `stockoptspec`. This function requires five input arguments. An optional sixth argument `InterpMethod`, specifying the interpolation method, can be included. The syntax for calling `stockoptspec` is:

```
[StockOptSpec] = stockoptspec(OptPrice, Strike, Settle, Maturity, OptSpec)
```

where:

- `Optprice` is a `NINST`-by-`1` vector of European option prices.
- `Strike` is a `NINST`-by-`1` vector of strike prices.
- `Settle` is a scalar date marking the settlement date.
- `Maturity` is a `NINST`-by-`1` vector of maturity dates.
- `OptSpec` is a `NINST`-by-`1` cell array of character vectors for the values `'call'` or `'put'`.

Option Stock Structure Example Using an Implied Trinomial Tree

Consider the following data quoted from liquid options in the market with varying strikes and maturity. You specify these parameters in MATLAB as:

```
Settle =   '01/01/06';

Maturity =    ['07/01/06';
    '07/01/06';
    '07/01/06';
    '07/01/06';
    '01/01/07';
    '01/01/07';
    '01/01/07';
    '01/01/07';
    '07/01/07';
    '07/01/07';
    '07/01/07';
    '07/01/07';
    '01/01/08';
    '01/01/08';
    '01/01/08';
    '01/01/08'];

Strike = [113;
   101;
   100;
    88;
   128;
   112;
   100;
    78;
   144;
   112;
   100;
    69;
   162;
   112;
   100;
    61];

OptPrice = [                0;
   4.807905472659144;
   1.306321897011867;
   0.048039195057173;
                    0;
   2.310953054191461;
   1.421950392866235;
```

```
   0.020414826276740;
                   0;
   5.091986935627730;
   1.346534812295291;
   0.005101325584140;
                   0;
   8.047628153217246;
   1.219653432150932;
   0.001041436654748];

OptSpec = { 'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put';
    'call';
    'call';
    'put';
    'put'};

StockOptSpec = stockoptspec(OptPrice, Strike, Settle, Maturity, OptSpec)

StockOptSpec =

          FinObj: 'StockOptSpec'
        OptPrice: [16x1 double]
          Strike: [16x1 double]
          Settle: 732678
        Maturity: [16x1 double]
         OptSpec: {16x1 cell}
    InterpMethod: 'price'
```

Note The algorithm for building the ITT tree requires specifying option prices for all tree nodes. The maturities of those options correspond to those of the tree levels, and the strike to the prices on the tree nodes. The types of option are `Calls` for the nodes above the central nodes, and `Puts` for those below and including the central nodes.

Clearly, all these options will not be available in the market, hence making interpolation, and extrapolation necessary to obtain the node option prices. The degree to which the tree reflects the market will unavoidably be tied to the results of these interpolations and extrapolations. Keeping in mind that extrapolation is less accurate than interpolation, and more so the further away the extrapolated points are from the data points, the function `itttree` issues a warning with a list of the options for which extrapolation was necessary.

Sometimes, it may be desirable to view a list of ideal option prices to form an idea of the ranges needed. This can be achieved by calling the function `itttree` specifying only the first three input arguments. The second output argument is a structure array containing the list of ideal options needed.

Creating an Implied Trinomial Tree

You can now use the `StockSpec`, `TimeSpec`, and `StockOptSpec` structures described in “Stock Structure Example Using an Implied Trinomial Tree” on page 3-7, “TimeSpec Example Using an

Implied Trinomial Tree” on page 3-8, and “Option Stock Structure Example Using an Implied Trinomial Tree” on page 3-9 to build an implied trinomial tree (ITT). First, you must define the interest rate term structure. For this example, assume that the interest rate is fixed at 8% annually between the valuation date of the tree (January 1, 2006) until its maturity.

```
Rate = 0.08;
ValuationDate = datetime(2006,1,1);
EndDate = datetime(2008,1,1);

RateSpec = intenvset('StartDates', ValuationDate, 'EndDates', EndDate, ...
    'ValuationDate', ValuationDate, 'Rates', Rate, 'Compounding', -1)
```

```
RateSpec =

  struct with fields:

           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8521
            Rates: 0.0800
         EndTimes: 2
       StartTimes: 0
         EndDates: 733408
       StartDates: 732678
    ValuationDate: 732678
            Basis: 0
     EndMonthRule: 1
```

To build an `ITTTree`, enter:

```
ITTTree = itttree(StockSpec, RateSpec, TimeSpec, StockOptSpec)
```

```
ITTTree =

          FinObj: 'ITStockTree'
       StockSpec: [1x1 struct]
    StockOptSpec: [1x1 struct]
        TimeSpec: [1x1 struct]
        RateSpec: [1x1 struct]
            tObs: [0 0.500000000000000 1 1.500000000000000 2]
            dObs: [732678 732860 733043 733225 733408]
           STree: {1x5 cell}
           Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Building Standard Trinomial Trees

The tree of stock prices is the fundamental unit representing the evolution of the price of a stock over a given period of time. The function `stttree` creates an output tree structure along with the information about the parameters used to create the tree.

The function `stttree` takes three structures as input arguments:

- The stock parameter structure `StockSpec`
- The interest-rate term structure `RateSpec`
- The tree time layout structure `TimeSpec`

Calling Sequence for Standard Trinomial Trees

The calling syntax for `stttree` is:

```
STTTree = stttree (StockSpec,RateSpec,TimeSpec)
```

- `StockSpec` is a structure that specifies parameters of the stock whose price evolution is represented by the tree. This structure, created using the function `stockspec`, contains information such as the stock's original price, its volatility, and its dividend payment information.
- `RateSpec` is the interest-rate specification of the initial rate curve. Create this structure with the function `intenvset`.
- `TimeSpec` is the tree time layout specification. Create these structures with the function `stttimespec`. This structure contains information regarding the mapping of relevant dates into the tree structure, plus the number of time steps used for building the tree.

Specifying the Stock Structure for Standard Trinomial Trees

The structure `StockSpec` encapsulates the stock-specific information required for building the trinomial tree of an individual stock's price movement.

You generate `StockSpec` with the function `stockspec`. This function requires two input arguments and accepts up to three additional input arguments that depend on the existence and type of dividend payments.

The syntax for calling `stockspec` is:

```
StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates)
```

where:

- `Sigma` is the decimal annual volatility of the underlying security.
- `AssetPrice` is the price of the stock at the valuation date.
- `DividendType` is a character vector specifying the type of dividend paid by the stock. Allowed values are `cash`, `constant`, or `continuous`.
- `DividendAmounts` has a value that depends on the specification of `DividendType`. For `DividendType cash`, `DividendAmounts` is a vector of cash dividends. For `DividendType constant`, it is a vector of constant annualized dividend yields. For `DividendType continuous`, it is a scalar representing a continuously annualized dividend yield.
- `ExDividendDates` also has a value that depends on the nature of `DividendType`. For `DividendType cash` or `constant`, `ExDividendDates` is vector of dividend dates. For `DividendType continuous`, `ExDividendDates` is ignored.

Stock Structure Example Using a Standard Trinomial Tree

Consider a stock with a price of $100 and an annual volatility of 12%. Assume that the stock is expected to pay a dividend yield of 6%. You specify these parameters in MATLAB as:

```
So = 100;
DividendYield = 0.06;
Sigma = .12;

StockSpec = stockspec(Sigma, So, 'continuous', DividendYield)

StockSpec =

             FinObj: 'StockSpec'
              Sigma: 0.1200
         AssetPrice: 100
       DividendType: 'continuous'
```

```
    DividendAmounts: 0.0600
    ExDividendDates: []
```

Specifying the Interest-Rate Term Structure for Standard Trinomial Trees

The structure `RateSpec` defines the interest rate environment used when building the stock price binary tree. “Modeling the Interest-Rate Term Structure” on page 2-57 explains how to create these structures using the function `intenvset`, given the interest rates, the starting and ending dates for each rate, and the compounding value.

Specifying the Tree-Time Term Structure for Standard Trinomial Trees

The `TimeSpec` structure defines the tree layout of the trinomial tree:

- It maps the valuation and maturity dates to their corresponding times.
- It defines the time of the levels of the tree by dividing the time span between valuation and maturity into equally spaced intervals. By specifying the number of intervals, you define the granularity of the tree time structure.

The syntax for building a `TimeSpec` structure is:

```
TimeSpec = stttimespec(ValuationDate, Maturity, NumPeriods)
```

where:

- `ValuationDate` is a scalar date marking the pricing date and first observation in the tree (location of the root node). You enter `ValuationDate` either as a datetime or a date character vector.
- `Maturity` is a scalar date marking the maturity of the tree, entered as a serial date number or a date character vector.
- `NumPeriods` is a scalar defining the number of time steps in the tree; for example, `NumPeriods = 10` implies 10 time steps and 11 tree levels (0, 1, 2, ..., 9, 10).

TimeSpec Example Using a Standard Trinomial Tree

Consider building an STT tree, with a valuation date of January 1, 2006, a maturity date of January 1, 2008, and four time steps. You specify these parameters in MATLAB as:

```
ValuationDate = datetime(2006,1,1);
EndDate = datetime(2008,1,1);
NumPeriods = 4;

TimeSpec = stttimespec(ValuationDate, EndDate, NumPeriods)
```

```
TimeSpec =

           FinObj: 'STTTimeSpec'
    ValuationDate: 732678
         Maturity: 733408
       NumPeriods: 4
            Basis: 0
     EndMonthRule: 1
             tObs: [0 0.5000 1 1.5000 2]
             dObs: [732678 732860 733043 733225 733408]
```

Two vector fields in the `TimeSpec` structure are of particular interest: `dObs` and `tObs`. These two fields represent the observation times and corresponding dates of all tree levels, with `dObs(1)` and

`tObs(1)`, respectively, representing the root node (`ValuationDate`), and `dObs(end)` and `tObs(end)` representing the last tree level (`Maturity`).

Creating a Standard Trinomial Tree

You can now use the `StockSpec`, `TimeSpec` structures described in "Stock Structure Example Using an Implied Trinomial Tree" on page 3-7 and "TimeSpec Example Using an Implied Trinomial Tree" on page 3-8, to build a standard trinomial tree (STT). First, you must define the interest rate term structure. For this example, assume that the interest rate is fixed at 8% annually between the valuation date of the tree (January 1, 2006) until its maturity.

```
Rate = 0.08;
ValuationDate = datetime(2006,1,1);
EndDate = datetime(2008,1,1);

RateSpec = intenvset('StartDates', ValuationDate, 'EndDates', EndDate, ...
    'ValuationDate', ValuationDate, 'Rates', Rate, 'Compounding', -1)
```

```
RateSpec =

  struct with fields:

           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8521
            Rates: 0.0800
         EndTimes: 2
       StartTimes: 0
         EndDates: 733408
       StartDates: 732678
    ValuationDate: 732678
            Basis: 0
     EndMonthRule: 1
```

To build an `STTTree`, enter:

```
STTTree = sttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree =

       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.5000 1 1.5000 2]
         dObs: [732678 732860 733043 733225 733408]
        STree: {1x5 cell}
        Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Examining Equity Trees

Financial Instruments Toolbox uses equity binary and trinomial trees to represent prices of equity options and of underlying stocks. At the highest level, these trees have structures wrapped around them. The structures encapsulate information required to interpret information in the tree.

To examine an equity, binary, or trinomial tree, load the data in the MAT-file `deriv.mat` into the MATLAB workspace.

```
load deriv.mat
```

Display the list of variables loaded from the MAT-file with the `whos` command.

```
Name              Size            Bytes  Class     Attributes

  STTInstSet        1x1             21070  struct
  STTTree           1x1              7782  struct
  ZeroInstSet       1x1             17458  struct
  ZeroRateSpec      1x1              2152  struct
```

Examining a CRRTree

You can examine in some detail the contents of the `CRRTree` structure contained in this file.

```
CRRTree
```

```
CRRTree =

       FinObj: 'BinStockTree'
       Method: 'CRR'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 1 2 3 4]
         dObs: [731582 731947 732313 732678 733043]
        STree: {[100]  [110.5171 90.4837]  [122.1403 100 81.8731]  [1x4 double]  [1x5 double]}
      UpProbs: [0.7309 0.7309 0.7309 0.7309]
```

The `Method` field of the structure indicates that this is a CRR tree, not an EQP tree.

The fields `StockSpec`, `TimeSpec`, and `RateSpec` hold the original structures passed into the function `crrtree`. They contain all the context information required to interpret the tree data.

The fields `tObs` and `dObs` are vectors containing the observation times and dates, that is, the times and dates of the levels of the tree. In this particular case, `tObs` reveals that the tree has a maturity of four years (`tObs(end) = 4`) and that it has four time steps (the length of `tObs` is five).

The field `dObs` shows the specific dates for the tree levels, with a granularity of one day. This means that all values in `tObs` that correspond to a given day from 00:00 hours to 24:00 hours are mapped to the corresponding value in `dObs`. You can use the function `datestr` to convert these MATLAB serial dates into their character vector representations.

The field `UpProbs` is a vector representing the probabilities for up movements from any node in each level. This vector has one element per tree level. All nodes for a given level have the same probability of an up movement. In the specific case being examined, the probability of an up movement is 0.7309 for all levels, and the probability for a down movement is 0.2691 (1 − 0.7309).

Finally, the field `STree` contains the actual stock tree. It is represented in MATLAB as a cell array with each cell array element containing a vector of prices corresponding to a tree level. The prices are in descending order, that is, `CRRTree.STree{3}(1)` represents the topmost element of the third level of the tree, and `CRRTree.STree{3}(end)` represents the bottom element of the same level of the tree.

Examining an ITTTree

You can examine in some detail the contents of the `ITTTree` structure contained in this file.

```
ITTTree
```

```
ITTTree =

          FinObj: 'ITStockTree'
       StockSpec: [1x1 struct]
    StockOptSpec: [1x1 struct]
        TimeSpec: [1x1 struct]
        RateSpec: [1x1 struct]
            tObs: [0 1 2 3 4]
            dObs: [732678 733043 733408 733773 734139]
           STree: {1x5 cell}
           Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

The fields `StockSpec`, `StockOptSpec`, `TimeSpec`, and `RateSpec` hold the original structures passed into the function `itttree`. They contain all the context information required to interpret the tree data.

The fields `tObs` and `dObs` are vectors containing the observation times and dates and the times and dates of the levels of the tree. In this particular case, `tObs` reveals that the tree has a maturity of four years (`tObs(end) = 4`) and that it has four time steps (the length of `tObs` is five).

The field `dObs` shows the specific dates for the tree levels, with a granularity of one day. This means that all values in `tObs` that correspond to a given day from 00:00 hours to 24:00 hours are mapped to the corresponding value in `dObs`. You can use the function `datestr` to convert these MATLAB serial dates into their character vector representations.

The field `Probs` is a vector representing the probabilities for movements from any node in each level. This vector has three elements per tree node. In the specific case being examined, at `tObs= 1`, the probability for an up movement is 0.4675, and the probability for a down movement is 0.1934.

Finally, the field `STree` contains the actual stock tree. It is represented in MATLAB as a cell array with each cell array element containing a vector of prices corresponding to a tree level. The prices are in descending order, that is, `ITTTree.STree{4}(1)` represents the top element of the fourth level of the tree, and `ITTTree.STree{4}(end)` represents the bottom element of the same level of the tree.

Isolating a Specific Node for a CRRTree

The function `treepath` can isolate a specific set of nodes of a binary tree by specifying the path used to reach the final node. As an example, consider the nodes tapped by starting from the root node, then following a down movement, then an up movement, and finally a down movement. You use a vector to specify the path, with `1` corresponding to an up movement and `2` corresponding to a down movement. An up-down-up path is then represented as `[2 1 2]`. To obtain the values of all nodes tapped by this path, enter:

```
SVals = treepath(CRRTree.STree, [2 1 2])
```

```
SVals =

  100.0000
   90.4837
  100.0000
   90.4837
```

The first value in the vector `SVals` corresponds to the root node, and the last value corresponds to the final node reached by following the path indicated.

Isolating a Specific Node for an ITTTree

The function `trintreepath` can isolate a specific set of nodes of a trinomial tree by specifying the path used to reach the final node. As an example, consider the nodes tapped by starting from the root node, then following an up movement, then a middle movement, and finally a down movement. You use a vector to specify the path, with `1` corresponding to an up movement, `2` corresponding to a middle movement, and `3` corresponding to a down movement. An up-down-middle-down path is then represented as `[1 3 2 3]`. To obtain the values of all nodes tapped by this path, enter:

```
pathSVals = trintreepath(ITTTree, [1 3 2 3])
```

```
pathSVals =

   50.0000
   66.3448
   50.0000
   50.0000
   37.6819
```

The first value in the vector `pathSVals` corresponds to the root node, and the last value corresponds to the final node reached by following the path indicated.

Differences Between CRR and EQP Tree Structures

In essence, the structures representing CRR trees and EQP trees are similar. If you create a CRR or an EQP tree using identical input arguments, only a few of the tree structure fields differ:

- The `Method` field has a value of `'CRR'` or `'EQP'` indicating the method used to build the structure.
- The prices in the `STree` cell array have the same structure, but the prices within the cell array are different.
- For EQP, the structure field `UpProb` always holds a vector with all elements set to 0.5, while for CRR, these probabilities are calculated based on the input arguments passed when building the tree.

Supported Equity Derivative Functions

In this section...

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option. They are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option.

There are four Asian option types, each with its own characteristic payoff formula:

- Fixed call (average price option): $\max(0, S_{av} - X)$
- Fixed put (average price option): $\max(0, X - S_{av})$
- Floating call (average strike option): $\max(0, S - S_{av})$
- Floating put (average strike option): $\max(0, S_{av} - S)$

where:

S_{av} is the average price of underlying asset.

S is the price of the underlying asset.

X is the strike price (applicable only to fixed Asian options).

S_{av} is defined using either a geometric or an arithmetic average.

The following functions support Asian options.

Function	Purpose
asianbycrr	Price Asian options from a CRR binomial tree.
asianbyeqp	Price Asian options from an EQP binomial tree.
asianbyitt	Price Asian options using an implied trinomial tree (ITT).
asianbystt	Price Asian options using a standard trinomial tree (STT).
instasian	Construct an Asian option.
asianbyls	Price European or American Asian options using the Longstaff-Schwartz model.
asiansensbyls	Calculate prices and sensitivities of European or American Asian options using the Longstaff-Schwartz model.
asianbykv	Price European geometric Asian options using the Kemna Vorst model.
asiansensbykv	Calculate prices and sensitivities of European geometric Asian options using the Kemna Vorst model.
asianbylevy	Price European arithmetic Asian options using the Levy model.
asiansensbylevy	Calculate prices and sensitivities of European arithmetic Asian options using the Levy model.
asianbyhhm	Calculate prices of European discrete arithmetic fixed Asian options using the Haug, Haug, Margrabe model.
asiansensbyhhm	Calculate prices and sensitivities of European discrete arithmetic fixed Asian options using the Haug, Haug, Margrabe model
asianbytw	Calculate prices of European arithmetic fixed Asian options using the Turnbull Wakeman model.
asiansensbytw	Calculate prices and sensitivities of European arithmetic fixed Asian options using the Turnbull Wakeman model.

Barrier Option

A barrier option is similar to a vanilla put or call option, but its life either begins or ends when the price of the underlying stock passes a predetermined barrier value. There are four types of barrier options.

Up Knock-In

This option becomes effective when the price of the underlying stock passes above a barrier that is above the initial stock price. Once the barrier has knocked in, it will not knock out even if the price of the underlying instrument moves below the barrier again.

Up Knock-Out

This option terminates when the price of the underlying stock passes above a barrier that is above the initial stock price. Once the barrier has knocked out, it will not knock in even if the price of the underlying instrument moves below the barrier again.

Down Knock-In

This option becomes effective when the price of the underlying stock passes below a barrier that is below the initial stock price. Once the barrier has knocked in, it will not knock out even if the price of the underlying instrument moves above the barrier again.

Down Knock-Out

This option terminates when the price of the underlying stock passes below a barrier that is below the initial stock price. Once the barrier has knocked out, it will not knock in even if the price of the underlying instrument moves above the barrier again.

Rebates

If a barrier option fails to exercise, the seller may pay a rebate to the buyer of the option. Knock-outs may pay a rebate when they are knocked out, and knock-ins may pay a rebate if they expire without ever knocking in.

The following functions support barrier options.

Function	Purpose
`barrierbycrr`	Price barrier options from a CRR binomial tree.
`barrierbyeqp`	Price barrier options from an EQP binomial tree.
`barrierbyitt`	Price barrier options using an implied trinomial tree (ITT).
`barrierbystt`	Price barrier options using a standard trinomial tree (STT).
`barrierbyfd`	Price barrier option using finite difference method.
`barriersensbyfd`	Calculate barrier option price and sensitivities using finite difference method.
`barrierbybls`	Price a European barrier option using Black-Scholes option pricing model.
`barriersensbybls`	Calculate price and sensitivities for a European barrier option using Black-Scholes option pricing model.
`barrierbyls`	Price a barrier option using Longstaff-Schwartz model.
`barriersensbyls`	Calculate price and sensitivities for a barrier option using Longstaff-Schwartz model.
`instbarrier`	Construct a barrier option.

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that they have two barrier levels: a lower barrier (LB) and an upper barrier (UB). The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as the probability of being knocked out is higher. Because of this, double barrier options allow investors to achieve reduction in the option premiums as and match an investor’s belief about the future movement of the underlying price process.

There are two types of double barrier options:

- Double Knock-in

  This option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder, the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.

- Double Knock-out

  This option gives the option holder, the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

The following functions support double barrier options.

Function	Purpose
`dblbarrierbybls`	Price European double barrier options using the Black-Scholes option pricing model.
`dblbarriersensbybls`	Calculate the price and sensitivities for a European double barrier options using the Black-Scholes option pricing model.
`dblbarrierbyfd`	Price double barrier option prices using the finite difference method.
`dblbarriersensbyfd`	Calculate the price and sensitivities for a double barrier option using the finite difference method.

Basket Option

A basket option is an option on a portfolio of several underlying equity assets. Payout for a basket option depends on the cumulative performance of the collection of the individual assets. A basket option tends to be cheaper than the corresponding portfolio of plain vanilla options for these reasons:

- If the basket components correlate negatively, movements in the value of one component neutralize opposite movements of another component. Unless all the components correlate perfectly, the basket option is cheaper than a series of individual options on each of the assets in the basket.
- A basket option minimizes transaction costs because an investor has to purchase only one option instead of several individual options.

The payoff for a basket option is as follows:

- For a call: $\max(\sum Wi * Si - K; 0)$
- For a put: $\max(\sum K - Wi * Si; 0)$

where:

Si is the price of asset i in the basket.

Wi is the quantity of asset i in the basket.

K is the strike price.

Financial Instruments Toolbox software supports Longstaff-Schwartz and Nengiu Ju models for pricing basket options. The Longstaff-Schwartz model supports both European, Bermuda, and American basket options. The Nengiu Ju model only supports European basket options. If you want to price either an American or Bermuda basket option, use the functions for the Longstaff-Schwartz model. To price a European basket option, use either the functions for the Longstaff-Schwartz model or the Nengiu Ju model.

Function	Purpose
`basketbyls`	Price basket options using the Longstaff-Schwartz model.
`basketsensbyls`	Calculate price and sensitivities for basket options using the Longstaff-Schwartz model.
`basketbyju`	Price European basket options using the Nengjiu Ju approximation model.
`basketsensbyju`	Calculate European basket options price and sensitivity using the Nengjiu Ju approximation model.
`basketstockspec`	Specify a basket stock structure.

Chooser Option

A chooser option enables the holder to decide before the option expiration date whether the option is a call or put.

A chooser option has a specified decision time t_1 where the holder has to make the decision whether the option is a call or put. At the expiration time t_2 the option expires. If the holder chooses a call option, the payout is $max\ (\ S - K\ ,\ 0)$. For the choice of a put option, the payout is $max\ (\ K - S\ ,\ 0)$ where K is the strike price of the option and S is the equity price at expiry.

Function	Purpose
`chooserbybls`	Price a European simple chooser options using Black-Scholes model.

Compound Option

A compound option is basically an option on an option; it gives the holder the right to buy or sell another option. With a compound option, a vanilla stock option serves as the underlying instrument. Compound options thus have two strike prices and two exercise dates.

There are four types of compound options:

- Call on a call
- Put on a put
- Call on a put
- Put on a call

> **Note** The payoff formulas for compound options are too complex for this discussion. If you are interested in the details, consult the paper by Mark Rubinstein entitled “Double Trouble,” published in *Risk 5* (1991).

Consider the third type, a call on a put. It gives the holder the right to buy a put option. In this case, on the first exercise date, the holder of the compound option pay the first strike price and receives a

put option. The put option gives the holder the right to sell the underlying asset for the second strike price on the second exercise date.

The following functions support compound options.

Function	Purpose
`compoundbycrr`	Price compound options from a CRR binomial tree.
`compoundbyeqp`	Price compound options from an EQP binomial tree.
`compoundbyitt`	Price compound options using an implied trinomial tree (ITT).
`compoundbystt`	Price compound options using a standard trinomial tree (STT).
`instcompound`	Construct a compound option.

Convertible Bond

A convertible bond is a financial instrument that combines equity and debt features. It is a bond with the embedded option to turn it into a fixed number of shares. The holder of a convertible bond has the right, but not the obligation, to exchange the convertible security for a predetermined number of equity shares at a preset price. The debt component is derived from the coupon payments and the principal. The equity component is provided by the conversion feature.

Convertible bonds have several defining features:

- Coupon — The coupon in convertible bonds are typically lower than coupons in vanilla bonds since investors are willing to take the lower coupon for the opportunity to participate in the company's stock via the conversion.
- Maturity — Most convertible bonds are issued with long-stated maturities. Short-term maturity convertible bonds usually do not have call or put provisions.
- Conversion ratio — Conversion ratio is the number of shares that the holder of the convertible bond will receive from exercising the call option of the convertible bond:

  ```
  Conversion ratio = par value convertible bond/conversion price of equity
  ```

  For example, a conversion ratio of 25 means a bond can be exchanged for 25 shares of stock. This also implies a conversion price of $40 (1000/25). This, $40, would be the price at which the owner would buy the shares. This can be expressed as a ratio or as the conversion price and is specified in the contract along with other provisions.
- Option type:
  - Callable Convertible: a convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder. Upon call, the bondholder can either convert the bond or redeem at the call price. This option enables the issuer to control the price of the convertible bond and if necessary refinance the debt with a new cheaper one.
  - Puttable Convertible: a convertible bond with a put feature that allows the bondholder to sell back the bond at a premium on a specific date. This option protects the holder against rising interest rates by reducing the year to maturity.

Function	Purpose
`cbondbycrr`	Price convertible bonds using a CRR binomial tree with the Tsiveriotis and Fernandes model.
`cbondbyeqp`	Price convertible bonds using an EQP binomial tree with the Tsiveriotis and Fernandes model.
`cbondbyitt`	Price convertible bonds using an implied trinomial tree with the Tsiveriotis and Fernandes model.
`cbondbystt`	Price convertible bonds using a standard trinomial tree with the Tsiveriotis and Fernandes model.
`instcbond`	Construct a `cbond` instrument for a convertible bond.

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. So, there are a total of four lookback option types, each with its own characteristic payoff formula:

- Fixed call: $\max(0, S_{\max} - X)$
- Fixed put: $\max(0, X - S_{\min})$
- Floating call: $\max(0, S - S_{\min})$
- Floating put: $\max(0, S_{\max} - S)$

where:

$S_{\max}$ is the maximum price of underlying stock found along the particular path followed to the node.

$S_{\min}$ is the minimum price of underlying stock found along the particular path followed to the node.

S is the price of the underlying stock on the node.

X is the strike price (applicable only to fixed lookback options).

The following functions support lookback options.

Function	Purpose
`lookbackbycrr`	Price lookback options from a CRR binomial tree.
`lookbackbyeqp`	Price lookback options from an EQP binomial tree.
`lookbackbyitt`	Price lookback options using an implied trinomial tree (ITT).
`lookbackbystt`	Price lookback options using standard trinomial tree.
`instlookback`	Construct a lookback option based on an equity tree model.

Function	Purpose
`lookbackbycvgsg`	Calculate prices of European lookback fixed and floating strike options using the Conze-Viswanathan and Goldman-Sosin-Gatto models. For more information, see “Lookback Option” on page 3-39.
`lookbacksensbycvgsg`	Calculate prices and sensitivities of European fixed and floating strike lookback options using the Conze-Viswanathan and Goldman-Sosin-Gatto models. For more information, see “Lookback Option” on page 3-39.
`lookbackbyls`	Calculate prices of lookback fixed and floating strike options using the Longstaff-Schwartz model. For more information, see “Lookback Option” on page 3-39.
`lookbacksensbyls`	Calculate prices and sensitivities of lookback fixed and floating strike options using the Longstaff-Schwartz model. For more information, see “Lookback Option” on page 3-39.

Digital Option

A digital option is an option whose payoff is characterized as having only two potential values: a fixed payout, when the option is in the money or a zero payout otherwise. This is the case irrespective of how far the asset price at maturity is above (call) or below (put) the strike.

Digital options are attractive to sellers because they guarantee a known maximum loss when the option is exercised. This overcomes a fundamental problem with the vanilla options, where the potential loss is unlimited. Digital options are attractive to buyers because the option payoff is a known constant amount, and this amount can be adjusted to provide the exact quantity of protection required.

Financial Instruments Toolbox supports four types of digital options:

- Cash-or-nothing option — Pays some fixed amount of cash if the option expires in the money.
- Asset-or-nothing option — Pays the value of the underlying security if the option expires in the money.
- Gap option — One strike decides if the option is in or out of money; another strike decides the size of the payoff.
- Supershare — Pays out a proportion of the assets underlying a portfolio if the asset lies between a lower and an upper bound at the expiry of the option.
- One-touch and double one-touch — (also known as binary barrier options or American digitals) are path-dependent options in which the existence and payment of the options depend on the movement of the underlying spot through their option life. For more information, see “One-Touch and Double One-Touch Options” on page 3-30.

The following functions calculate pricing and sensitivity for digital options.

Function	Purpose
`cashbybls`	Calculate the price of cash-or-nothing digital options using the Black-Scholes model.
`assetbybls`	Calculate the price of asset-or-nothing digital options using the Black-Scholes model.

Function	Purpose
`gapbybls`	Calculate the price of gap digital options using the Black-Scholes model.
`supersharebybls`	Calculate the price of supershare digital options using the Black-Scholes model.
`cashsensbybls`	Calculate the price and sensitivities of cash-or-nothing digital options using the Black-Scholes model.
`assetsensbybls`	Calculate the price and sensitivities of asset-or-nothing digital options using the Black-Scholes model.
`gapsensbybls`	Calculate the price and sensitivities of gap digital options using the Black-Scholes model.
`supersharesensbybls`	Calculate the price and sensitivities of supershare digital options using the Black-Scholes model.

Rainbow Option

A rainbow option payoff depends on the relative price performance of two or more assets. A rainbow option gives the holder the right to buy or sell the best or worst of two securities, or options that pay the best or worst of two assets.

Rainbow options are popular because of the lower premium cost of the structure relative to the purchase of two separate options. The lower cost reflects the fact that the payoff is generally lower than the payoff of the two separate options.

Financial Instruments Toolbox supports two types of rainbow options:

- Minimum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth less.
- Maximum of two assets — The option holder has the right to buy(sell) one of two risky assets, whichever one is worth more.

The following rainbow options speculate/hedge on two equity assets.

Function	Purpose
`minassetbystulz`	Calculate the European rainbow option price on minimum of two risky assets using the Stulz option pricing model.
`minassetsensbystulz`	Calculate the European rainbow option prices and sensitivities on minimum of two risky assets using the Stulz pricing model.
`maxassetbystulz`	Calculate the European rainbow option price on maximum of two risky assets using the Stulz option pricing model.
`maxassetsensbystulz`	Calculate the European rainbow option prices and sensitivities on maximum of two risky assets using the Stulz pricing model.

Vanilla Option

A vanilla option is a category of options that includes only the most standard components. A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

The following functions support specifying or pricing a vanilla option.

Function	Purpose
`optstockbybaw`	Calculate the American options prices using the Barone-Adesi-Whaley option pricing model.
`optstocksensbybaw`	Calculate the American options prices and sensitivities using the Barone-Adesi-Whaley option pricing model.
`optstockbycrr`	Calculate the price of a European, Bermuda, or American stock option using a CRR tree.
`optstockbyeqp`	Calculate the price of a European, Bermuda, or American stock option using an EQP tree.
`optstockbyfd`	Calculate vanilla option prices using finite difference method.
`optstocksensbyfd`	Calculate vanilla option prices and sensitivities using finite difference method.
`optByLocalVolFD`	Calculate vanilla option price by local volatility model, using finite differences.
`optSensByLocalVolFD`	Calculate vanilla option price or sensitivities by local volatility model, using finite differences.
`optByHestonFD`	Calculate vanilla option price by Heston model using finite differences.
`optSensByHestonFD`	Calculate vanilla option price and sensitivities by Heston model using finite differences.
`optByBatesFD`	Calculates vanilla European option price by Bates model using finite differences.
`optSensByBatesFD`	Calculates vanilla European option price and sensitivities by Bates model using finite differences.
`optByMertonFD`	Calculates vanilla European option price by Merton76 model using finite differences.
`optSensByMertonFD`	Calculates vanilla European option price and sensitivities by Merton76 model using finite differences.
`optstockbyitt`	Calculate the price of a European, Bermuda, or American stock option using an ITT tree.
`optstockbystt`	Calculate the price of a European, Bermuda, or American stock option using an STT tree.
`optstockbylr`	Calculate the price of a European, Bermuda, or American stock option using the Leisen-Reimer (LR) binomial tree model.

Function	Purpose
optstocksensbylr	Calculate the price and sensitivities of a European, Bermuda, or American stock option using the Leisen-Reimer (LR) binomial tree model.
optstockbybls	Price options using the Black-Scholes option pricing model.
optstocksensbybls	Calculate option prices and sensitivities using the Black-Scholes option pricing model.
optstockbyrgw	Calculate American call option prices using the Roll-Geske-Whaley option pricing model.
optstocksensbyrgw	Calculate American call option prices and sensitivities using the Roll-Geske-Whaley option pricing model.
optstockbybjs	Price American options using the Bjerksund-Stensland 2002 option pricing model.
optstocksensbybjs	Calculate American option prices and sensitivities using the Bjerksund-Stensland 2002 option pricing model.
optstockbyls	Price vanilla options using the Longstaff-Schwartz model.
optstocksensbyls	Calculate vanilla option prices and sensitivities using the Longstaff-Schwartz model.
optByHestonFFT	Calculate option price by Heston model using FFT and FRFT.
optSensByHestonFFT	Calculate option price and sensitivities by Heston model using FFT and FRFT.
optByHestonNI	Calculate option price by Heston model using numerical integration.
optSensByHestonNI	Calculate option price and sensitivities by Heston model using numerical integration.
optByBatesFFT	Calculate option price by Bates model using FFT and FRFT.
optSensByBatesFFT	Calculate option price and sensitivities by Bates model using FFT and FRFT.
optByBatesNI	Calculate option price by Bates model using numerical integration.
optSensByBatesNI	Calculate option price or sensitivities by Bates model using numerical integration.
optByMertonFFT	Calculate option price by Merton76 model using FFT and FRFT.
optSensByMertonFFT	Calculate option price and sensitivities by Merton76 model using FFT and FRFT.
optByMertonNI	Calculate option price by Merton76 model using numerical integration.
optSensByMertonNI	Calculate option price and sensitivities by Merton76 model using numerical integration.
instoptstock	Specify a European or Bermuda option.

Bermuda Put and Call Schedule

A Bermuda option resembles a hybrid of American and European options. You exercise it on predetermined dates only, usually monthly. In Financial Instruments Toolbox software, you indicate the relevant information for a Bermuda option in two input matrices:

- `Strike` — Contains the strike price values for the option.
- `ExerciseDates` — Contains the schedule when you can exercise the option.

Spread Option

A spread option is an option written on the difference of two underlying assets. For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

The following functions support spread options.

Function	Purpose
`spreadbykirk`	Price European spread options using the Kirk pricing model.
`spreadsensbykirk`	Calculate European spread option prices and sensitivities using the Kirk pricing model.
`spreadbybjs`	Price European spread options using the Bjerksund-Stensland pricing model.
`spreadsensbybjs`	Calculate European spread option prices and sensitivities using the Bjerksund-Stensland pricing model.
`spreadbyfd`	Price European or American spread options using the Alternate Direction Implicit (ADI) finite difference method.
`spreadsensbyfd`	Calculate price and sensitivities of European or American spread options using the Alternate Direction Implicit (ADI) finite difference method.
`spreadbyls`	Price European or American spread options using Monte Carlo simulations.
`spreadsensbyls`	Calculate price and sensitivities for European or American spread options using Monte Carlo simulations.

One-Touch and Double One-Touch Options

A touch option (also known as binary barrier options or American digitals) are path-dependent options in which the existence and payment of the options depend on the movement of the underlying spot through their option life.

There are two types of touch options:

- One-Touch

The one-touch (no-touch) option provides a payoff if the underlying spot ever (never) trades at or beyond the barrier level and zero otherwise.

- Double One-Touch

  The double one-touch and double no-touch option works the same way as a one-touch option, but has two barriers. A double one-touch (double no-touch) option provides a payoff if the underlying spot ever (never) touches either the upper or lower barriers levels.

The following functions support touch options.

Function	Purpose
`touchbybls`	Price one-touch and no-touch binary options using the Black-Scholes option pricing model.
`touchsensbybls`	Calculate price and sensitivities for one-touch and no-touch binary options using the Black-Scholes option pricing model.
`dbltouchbybls`	Price double one-touch and double no-touch binary options using the Black-Scholes option pricing model
`dbltouchsensbybls`	Calculate price and sensitivities for double one-touch and double no-touch binary options using the Black-Scholes option pricing model

Forwards Option

A forward option is a non-standardized contract between two parties to buy or to sell an asset at a specified future time at a price agreed upon today. The buyer of a forward option contract has the right to hold a particular forward position at a specific price any time before the option expires. The forward option seller holds the opposite forward position when the buyer exercises the option. A call option is the right to enter into a long forward position and a put option is the right to enter into a short forward position. A closely related contract is a futures contract. A forward is like a futures in that it specifies the exchange of goods for a specified price at a specified future date. The table below displays some of the characteristics of forward and futures contracts.

Forwards	Futures
Customized contracts	Standardized contracts
Over the counter traded	Exchange traded
Exposed to default risk	Clearing house reduces default risk
Mostly used for hedging	Mostly used by hedgers and speculators
Settlement at the end of contract (no Margin required)	Daily changes are settled day by day (Margin required)
Delivery usually takes place	Delivery usually never happens

The payoff for a forward option, where the value of a forward position at maturity depends on the relationship between the delivery price (K) and the underlying price (S_T) at that time, is:

- For a long position: $f_T = S_T - K$
- For a short position: $f_T = K - S_T$

The following functions support pricing a forwards option.

Function	Purpose
optstockbyblk	Price options on forwards using the Black option pricing model.
optstocksensbyblk	Determine option prices and sensitivities on forwards using the Black pricing model.

Futures Option

A future option is a standardized contract between two parties to buy or sell a specified asset of standardized quantity and quality for a price agreed upon today (the futures price) with delivery and payment occurring at a specified future date, the delivery date. The contracts are negotiated at a futures exchange, which acts as an intermediary between the two parties. The party agreeing to buy the underlying asset in the future, the "buyer" of the contract, is said to be "long", and the party agreeing to sell the asset in the future, the "seller" of the contract, is said to be "short."

Forwards	Futures
Customized contracts	Standardized contracts
Over the counter traded	Exchange traded
Exposed to default risk	Clearing house reduces default risk
Mostly used for hedging	Mostly used by hedgers and speculators
Settlement at the end of contract (no Margin required)	Daily changes are settled day by day (Margin required)
Delivery usually takes place	Delivery usually never happens

A futures contract is the delivery of item J at time T and:

- There exists in the market a quoted price $F(t,T)$, which is known as the futures price at time t for delivery of J at time T.
- The price of entering a futures contract is equal to zero.
- During any time interval $[t,s]$, the holder receives the amount $F(s,T) - F(t,T)$ (this reflects instantaneous marking to market).
- At time T, the holder pays $F(T,T)$ and is entitled to receive J. Note that $F(T,T)$ should be the spot price of J at time T.

The following functions support pricing a futures option.

Function	Purpose
optstockbyblk	Price options on futures using the Black option pricing model.
optstocksensbyblk	Determine option prices and sensitivities on futures using the Black pricing model.

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option. They are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option.

There are four Asian option types, each with its own characteristic payoff formula:

- Fixed call (average price option): $\max(0, S_{av} - X)$
- Fixed put (average price option): $\max(0, X - S_{av})$
- Floating call (average strike option): $\max(0, S - S_{av})$
- Floating put (average strike option): $\max(0, S_{av} - S)$

where:

S_{av} is the average price of underlying asset.

S is the price of the underlying asset.

X is the strike price (applicable only to fixed Asian options).

S_{av} is defined using either a geometric or an arithmetic average.

The following functions support Asian options.

Function	Purpose
`asianbyls`	Price European or American Asian options using the Longstaff-Schwartz model.
`asiansensbyls`	Calculate prices and sensitivities of European or American Asian options using the Longstaff-Schwartz model.
`asianbykv`	Price European geometric Asian options using the Kemna Vorst model.

Function	Purpose
asiansensbykv	Calculate prices and sensitivities of European geometric Asian options using the Kemna Vorst model.
asianbylevy	Price European arithmetic Asian options using the Levy model.
asiansensbylevy	Calculate prices and sensitivities of European arithmetic Asian options using the Levy model.
asianbyhhm	Calculate prices of European discrete arithmetic fixed Asian options using the Haug, Haug, Margrabe model.
asiansensbyhhm	Calculate prices and sensitivities of European discrete arithmetic fixed Asian options using the Haug, Haug, Margrabe model
asianbytw	Calculate prices of European arithmetic fixed Asian options using the Turnbull Wakeman model.
asiansensbytw	Calculate prices and sensitivities of European arithmetic fixed Asian options using the Turnbull Wakeman model.
asianbycrr	Price an Asian option from a Cox-Ross-Rubinstein binomial tree.
asianbyeqp	Price an Asian option from an Equal Probabilities binomial tree.
asianbyitt	Price an Asian option using an implied trinomial tree (ITT).
asianbystt	Price an Asian option using a standard trinomial tree.
instasian	Construct an Asian option.

Barrier Option

A barrier option is similar to a vanilla put or call option, but its life either begins or ends when the price of the underlying asset passes a predetermined barrier value. There are four types of barrier options.

Up Knock-In

This option becomes effective when the price of the underlying asset passes above a barrier that is above the initial asset price. Once the barrier has knocked in, it will not knock out even if the price of the underlying instrument moves below the barrier again.

Up Knock-Out

This option terminates when the price of the underlying asset passes above a barrier that is above the initial stock price. Once the barrier has knocked out, it will not knock in even if the price of the underlying instrument moves below the barrier again.

Down Knock-In

This option becomes effective when the price of the underlying asset passes below a barrier that is below the initial stock price. Once the barrier has knocked in, it will not knock out even if the price of the underlying instrument moves above the barrier again.

Down Knock-Out

This option terminates when the price of the underlying asset passes below a barrier that is below the initial stock price. Once the barrier has knocked out, it will not knock in even if the price of the underlying instrument moves above the barrier again.

Rebates

If a barrier option fails to exercise, the seller may pay a rebate to the buyer of the option. Knock-outs may pay a rebate when they are knocked out, and knock-ins may pay a rebate if they expire without ever knocking in.

The following functions support barrier options.

Function	Purpose
`barrierbyfd`	Price barrier option using finite difference method.
`barriersensbyfd`	Calculate barrier option price and sensitivities using finite difference method.
`barrierbyls`	Price European or American barrier options using Monte Carlo simulations.
`barrierbybls`	Price European barrier options using Black-Scholes option pricing model.
`barrierbycrr`	Price a barrier option from a Cox-Ross-Rubinstein binomial tree.
`barrierbyeqp`	Price a barrier option from an Equal Probabilities binomial tree.
`barrierbyitt`	Price a barrier option using an implied trinomial tree (ITT).
`barrierbystt`	Price a barrier options using a standard trinomial tree.

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that they have two barrier levels: a lower barrier (LB) and an upper barrier (UB). The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as the probability of being knocked out is higher. Because of this, double barrier options allow investors to achieve reduction in the option premiums as and match an investor’s belief about the future movement of the underlying price process.

There are two types of double barrier options:

- Double Knock-in

  This option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder, the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.
- Double Knock-out

  This option gives the option holder, the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

The following functions support double barrier options.

Function	Purpose
`dblbarrierbybls`	Price European double barrier options using the Black-Scholes option pricing model.
`dblbarriersensbybls`	Calculate the price and sensitivities for a European double barrier options using the Black-Scholes option pricing model.
`dblbarrierbyfd`	Price double barrier option prices using the finite difference method.
`dblbarriersensbyfd`	Calculate the price and sensitivities for a double barrier option using the finite difference method.

Vanilla Option

A vanilla option is a category of options that includes only the most standard components. A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call: $\max(St - K, 0)$
- For a put: $\max(K - St, 0)$

where:

St is the price of the underlying asset at time t.

K is the strike price.

The following functions support specifying or pricing a vanilla option.

Function	Purpose
`optstockbyls`	Price European, Bermudan, or American vanilla options using the Longstaff-Schwartz model.
`optstocksensbyls`	Calculate European, Bermudan, or American vanilla option prices and sensitivities using the Longstaff-Schwartz model.
`optstockbyfd`	Calculate vanilla option prices using finite difference method.
`optstocksensbyfd`	Calculate vanilla option prices and sensitivities using finite difference method.
`optstockbybaw`	Calculate American options prices using Barone-Adesi and Whaley option pricing model.
`optstocksensbybaw`	Calculate American options prices and sensitivities using Barone-Adesi and Whaley option pricing model.
`optstockbyrgw`	Calculate American call option prices using Roll-Geske-Whaley option pricing model.
`optstocksensbyrgw`	Calculate American call option prices or sensitivities using Roll-Geske-Whaley option pricing model.
`optByLocalVolFD`	Calculate vanilla option price by local volatility model, using finite differences.

Function	Purpose
optstockbybjs	Price American options using Bjerksund-Stensland 2002 option pricing model.
optstocksensbybjs	Determine American option prices or sensitivities using Bjerksund-Stensland 2002 option pricing model.
optSensByLocalVolFD	Calculate vanilla option price or sensitivities by local volatility model, using finite differences.
optByHestonFD	Calculate vanilla option price by Heston model using finite differences.
optSensByHestonFD	Calculate vanilla option price and sensitivities by Heston model using finite differences.
optByBatesFD	Calculates vanilla European option price by Bates model using finite differences.
optSensByBatesFD	Calculates vanilla European option price and sensitivities by Bates model using finite differences.
optByMertonFD	Calculates vanilla European option price by Merton76 model using finite differences.
optSensByMertonFD	Calculates vanilla European option price and sensitivities by Merton76 model using finite differences.
optByBatesFFT	Calculate option price by Bates model using FFT and FRFT.
optByHestonFFT	Calculate option price by Heston model using FFT and FRFT.
optByMertonFFT	Calculate option price by Merton76 model using FFT and FRFT.
optstockbycrr	Price an option from a Cox-Ross-Rubinstein binomial tree.
optstockbyeqp	Price an option from an Equal Probabilities binomial tree.
optstockbyitt	Price an option using an implied trinomial tree (ITT).
optstockbystt	Price an option using a standard trinomial tree.

Spread Option

A spread option is an option written on the difference of two underlying assets. For example, a European call on the difference of two assets *X1* and *X2* would have the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

where:

K is the strike price.

The following functions support spread options.

Function	Purpose
spreadbykirk	Price European spread options using the Kirk pricing model.
spreadsensbykirk	Calculate European spread option prices and sensitivities using the Kirk pricing model.

Function	Purpose
`spreadbybjs`	Price European spread options using the Bjerksund-Stensland pricing model.
`spreadsensbybjs`	Calculate European spread option prices and sensitivities using the Bjerksund-Stensland pricing model.
`spreadbyfd`	Price European or American spread options using the Alternate Direction Implicit (ADI) and Crank-Nicolson finite difference methods.
`spreadsensbyfd`	Calculate price and sensitivities of European or American spread options using the Alternate Direction Implicit (ADI) and Crank-Nicolson finite difference methods.
`spreadbyls`	Price European or American spread options using Monte Carlo simulations.
`spreadsensbyls`	Calculate price and sensitivities for European or American spread options using Monte Carlo simulations.

For more information on using spread options, see “Pricing European and American Spread Options” on page 3-97.

Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset (e.g. electricity, stock) achieves during the entire life of the option. Basically the holder of the option can ‘look back’ over time to determine the payoff. This type of option provides price protection over a selected period, reduces uncertainties with the timing of market entry, moderates the need for the ongoing management, and therefore, is usually more expensive than vanilla options.

Lookback call options give the holder the right to buy the underlying asset at the lowest price. Lookback put options give the right to sell the underlying asset at the highest price.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. The difference is related to how the strike price is set in the contract. Fixed lookback options have a specified strike price and the option pays out the maximum of the difference between the highest (lowest) observed price of the underlying during the life of the option and the strike. Floating lookback options have a strike price determined at maturity, and it is set at the lowest (highest) price of the underlying reached during the life of the option. This means that for a floating strike lookback call (put), the holder has the right to buy (sell) the underlying asset at its lowest (highest) price observed during the life of the option. So, there are a total of four lookback option types, each with its own characteristic payoff formula:

- Fixed call: $\max(0, S_{\max} - X)$
- Fixed put: $\max(0, X - S_{\min})$
- Floating call: $\max(0, S - S_{\min})$
- Floating put: $\max(0, S_{\max} - S)$

where:

$S_{\max}$ is the maximum price of underlying asset.

S_{min} is the minimum price of underlying asset.

S is the price of the underlying asset at maturity.

X is the strike price.

The following functions support lookback options.

Function	Purpose
`lookbackbycvgsg`	Calculate prices of European lookback fixed and floating strike options using the Conze-Viswanathan and Goldman-Sosin-Gatto models.
`lookbacksensbycvgsg`	Calculate prices and sensitivities of European fixed and floating strike lookback options using the Conze-Viswanathan and Goldman-Sosin-Gatto models.
`lookbackbyls`	Calculate prices of lookback fixed and floating strike options using the Longstaff-Schwartz model.
`lookbacksensbyls`	Calculate prices and sensitivities of lookback fixed and floating strike options using the Longstaff-Schwartz model.
`lookbackbycrr`	Price a lookback option from a Cox-Ross-Rubinstein binomial tree.
`lookbackbyeqp`	Price a lookback option from an Equal Probabilities binomial tree.
`lookbackbyitt`	Price a lookback option using an implied trinomial tree (ITT).
`lookbackbystt`	Price a lookback option using a standard trinomial tree.

Lookback options and Asian options are instruments used in the electricity market to manage purchase timing risk. Electricity purchasers cover part of their expected electricity consumption on the forward market to avoid the volatility and limited liquidity of the spot market. Using Asian options as a hedging tool is a passive approach to solving the purchase timing problem. An Asian option instrument diminishes the wrong timing risk but it also reduces any potential benefit to the buyer from falling prices. On the other hand, lookback options allow the purchasers to buy electricity at the lowest price, but as mentioned before, this instrument is more expensive than Asian and vanilla options.

Forwards Option

A forward option is a non-standardized contract between two parties to buy or to sell an asset at a specified future time at a price agreed upon today. The buyer of a forward option contract has the right to hold a particular forward position at a specific price any time before the option expires. The forward option seller holds the opposite forward position when the buyer exercises the option. A call option is the right to enter into a long forward position and a put option is the right to enter into a short forward position. A closely related contract is a futures contract. A forward is like a futures in that it specifies the exchange of goods for a specified price at a specified future date. The following table displays some of the characteristics of forward and futures contracts.

Forwards	Futures
Customized contracts	Standardized contracts
Over the counter traded	Exchange traded
Exposed to default risk	Clearing house reduces default risk

Forwards	Futures
Mostly used for hedging	Mostly used by hedgers and speculators
Settlement at the end of contract (no Margin required)	Daily changes are settled day by day (Margin required)
Delivery usually takes place	Delivery usually never happens

The payoff for a forward option, where the value of a forward position at maturity depends on the relationship between the delivery price (K) and the underlying price (S_T) at that time, is:

- For a long position: $f_T = S_T - K$
- For a short position: $f_T = K - S_T$

The following functions support pricing a forwards option.

Function	Purpose
`optstockbyblk`	Price options on forwards using the Black option pricing model.
`optstocksensbyblk`	Determine option prices and sensitivities on forwards using the Black pricing model.

Futures Option

A future option is a standardized contract between two parties to buy or sell a specified asset of standardized quantity and quality for a price agreed upon today (the futures price) with delivery and payment occurring at a specified future date, the delivery date. The contracts are negotiated at a futures exchange, which acts as an intermediary between the two parties. The party agreeing to buy the underlying asset in the future, the "buyer" of the contract, is said to be "long", and the party agreeing to sell the asset in the future, the "seller" of the contract, is said to be "short."

Forwards	Futures
Customized contracts	Standardized contracts
Over the counter traded	Exchange traded
Exposed to default risk	Clearing house reduces default risk
Mostly used for hedging	Mostly used by hedgers and speculators
Settlement at the end of contract (no Margin required)	Daily changes are settled day by day (Margin required)
Delivery usually takes place	Delivery usually never happens

A futures contract is the delivery of item J at time T and:

- There exists in the market a quoted price $F(t, T)$, which is known as the futures price at time t for delivery of J at time T.
- The price of entering a futures contract is equal to zero.
- During any time interval $[t,s]$, the holder receives the amount $F(s, T) - F(t, T)$ (this reflects instantaneous marking to market).
- At time T, the holder pays $F(T, T)$ and is entitled to receive J. Note that $F(T, T)$ should be the spot price of J at time T.

The following functions support pricing a futures option.

Function	Purpose
`optstockbyblk`	Price options on futures using the Black option pricing model.
`optstocksensbyblk`	Determine option prices and sensitivities on futures using the Black pricing model.

Pricing Swing Options Using the Longstaff-Schwartz Method

This example shows how to price a swing option using a Monte Carlo simulation and the Longstaff-Schwartz method. A risk-neutral simulation of the underlying natural gas price is conducted using a mean-reverting model. The simulation results are used to price a swing option based on the Longstaff-Schwartz method [6 on page 3-51]. This approach uses a regression technique to approximate the continuation value of the option. A comparison is made between a polynomial and spline basis to fit the regression. Finally, the resulting prices are analyzed against lower and upper price boundaries derived from standard European and American options.

Overview of Swing Options

Swing options are popular financial instruments in the energy market, which provide flexibility in the volume of the delivered asset. In order for energy consumers to protect themselves against fluctuations in energy prices, they want to lock in a price by purchasing a forward contract, called the *baseload forward contract*. However, consumers do not know exactly how much energy will be used in the future, and energy commodities such as electricity and gas cannot easily be stored. Therefore, the consumer wants the flexibility to change the amount of energy that is delivered at each delivery date. Swing options provide this flexibility. Thus, the full contract is composed of two parts: the baseload forward contract, and the swing option component.

Swing options are generally over-the-counter (OTC) contracts that can be highly customized. Therefore, there are many different types of constraints and penalties (see [5 on page 3-51] for more details). In this example, a swing option is priced where the only constraint is the daily volume, which is known as the Daily Contract Quantity (DCQ). When a swing right is exercised, the volume cannot go below the minimum DCQ (`minDCQ`), or go above the maximum DCQ (`maxDCQ`).

There are several methods to price swing options, such as finite differences, simulation, and dynamic programming based on trees [5 on page 3-51]. This example uses the simulation-based approach with the Longstaff-Schwartz method. The benefit of the simulation-based approach is that the dynamics used to simulate the underlying asset price are separated from the pricing algorithm. In the finite difference and tree based methods, the pricing algorithm must be changed in order to consider pricing with a different underlying price dynamic.

Risk-Neutral Simulation of Natural Gas Price

In this example, natural gas is used as the underlying asset with the following mean-reverting dynamic [8]:

$$dS_t = \kappa(\mu - \log(S_t))S_t dt + \sigma S_t dW_t$$

where W_t is a standard Brownian motion. Applying Ito's Lemma to the logarithm of the price leads to an Orstein-Uhlenbeck process:

$$dX_t = \kappa(\theta - X_t)dt + \sigma dW_t$$

where $X_t = \log(S_t)$, $\kappa > 0$, and θ is defined as:

$$\theta = \mu - \frac{\sigma^2}{2\kappa}$$

θ is the mean-reversion level that determines the value at which the simulated values will revert to in the long run. κ is the mean-reversion speed that determines how fast this reversion occurs. σ is the

volatility of X. We first proceed by simulating the logarithm of the price. Afterwards, the exponential of the simulated values are taken to obtain the prices.

The length of the simulation is for a one year period, with the initial price of 3.9 dollars per MMBtu. The Monte Carlo simulation is conducted for 1,000 trials, with daily periods. In practice, these parameters are calibrated against market data. In this example, $\kappa = 1.2$, $\theta = 1.7$, and $\sigma = 59\%$. The `hwv` object from the Financial Toolbox™ is used to simulate the mean-reverting dynamics of the natural gas price.

```
% Settlement date
Settle = '01-Jun-2014';

% Maturity Date
Maturity = '01-Jun-2015';

% Actual/Actual basis
Basis = 0;

% Initial log(price in $/MMBtu)
X0 = log(3.9);

% Volatility of log(price)
Sigma = 0.59;

% Number of trials in the Monte Carlo simulation
NumTrials =1000;

% Number of periods (daily)
NumPeriods = daysdif(Settle, Maturity, Basis);

% Daily time step
dt = 1/NumPeriods;

% Mean reversion speed of log(price)
Kappa = 1.2;

% Mean reversion level of log(price)
Theta = 1.7;

% Create HWV object
hwvobj = hwv(Kappa, Theta, Sigma, 'StartState', X0);
```

The simulation is run and plotted.

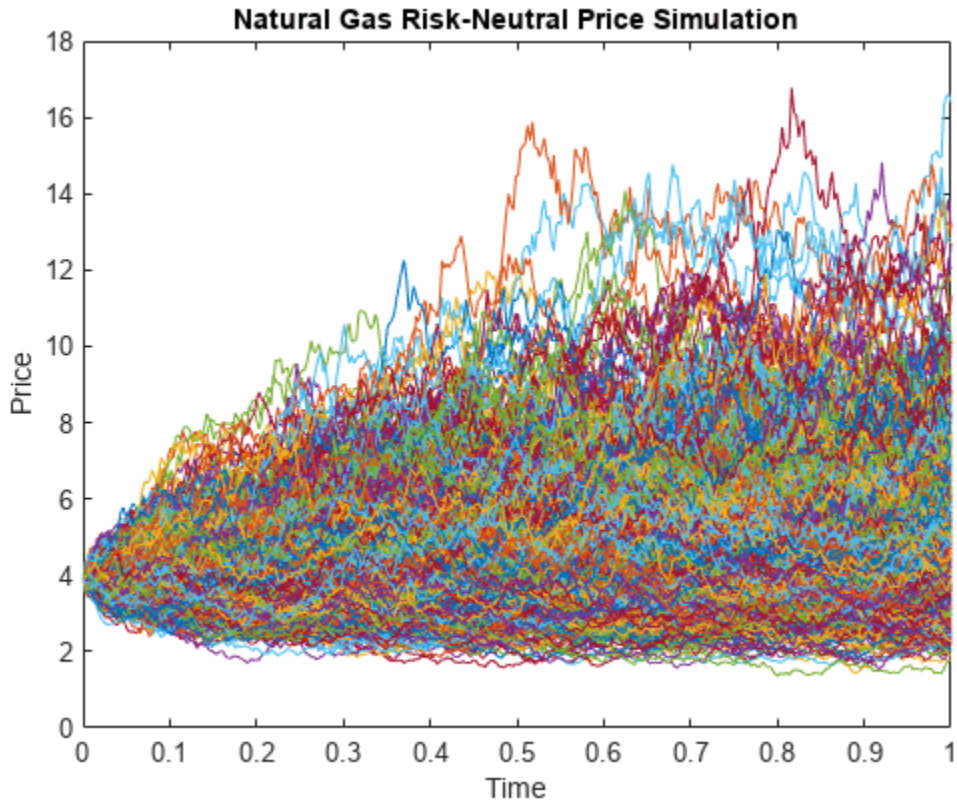
```
% Set random number generator seed
savedState = rng(0, 'twister');

% Simulate gas prices
[Paths, Times] = hwvobj.simBySolution(NumPeriods, 'NTRIALS', NumTrials, ...
    'DeltaTime', dt);
Paths = squeeze(exp(Paths));

% Restore random number generator state
rng(savedState);

% Plot paths
figure;
plot(Times, Paths);
```

```
title('Natural Gas Risk-Neutral Price Simulation');
xlabel('Time');
ylabel('Price');
```



In this example, natural gas is used as the underlying asset with a mean-reverting dynamic. However, the Longstaff-Schwartz algorithm can be used for other underlying assets, such as electricity, with any underlying price dynamic.

Pricing the Swing Option

We consider a swing option with five swing rights at the strike of $4.69/MMBtu, which can be exercised daily between the day after the settlement date and the maturity date. The Daily Contract Quantity (DCQ) is 10,000 MMBtu, which is the average amount of natural gas that the consumer expects to purchase on a given day. The consumer has the flexibility to reduce the purchase amount (downswing) in one day to the minimum DCQ of 2,500 MMBtu, or increase the purchase (upswing) to 15,000 MMBtu. The continuously compounded annual risk-free rate is 1%.

`RateSpec` is used to represent the interest-rate term structure. For the sake of simplicity, we consider a flat interest-rate term structure in this example. The values of `RateSpec` can be modified to accommodate any interest-rate curve. The function `hswingbyls` in this example assumes a daily exercise if the `ExerciseDates` input is empty.

```
% Define RateSpec
rfrate = 0.01;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
                     'EndDates', Maturity, 'Rates', rfrate, ...
```

```
                    'Compounding', Compounding, 'Basis', Basis);

% Daily exercise
% hswingbyls assumes daily exercise for empty ExerciseDates
ExerciseDates = [];

% Number of swings
NumSwings = 5;

% Daily Contract Quantity in MMBtu
DCQ = 10000;

% Minimum DCQ constraint in MMBtu
minDCQ = 2500;

% Maximum DCQ constraint in MMBtu
maxDCQ = 15000;

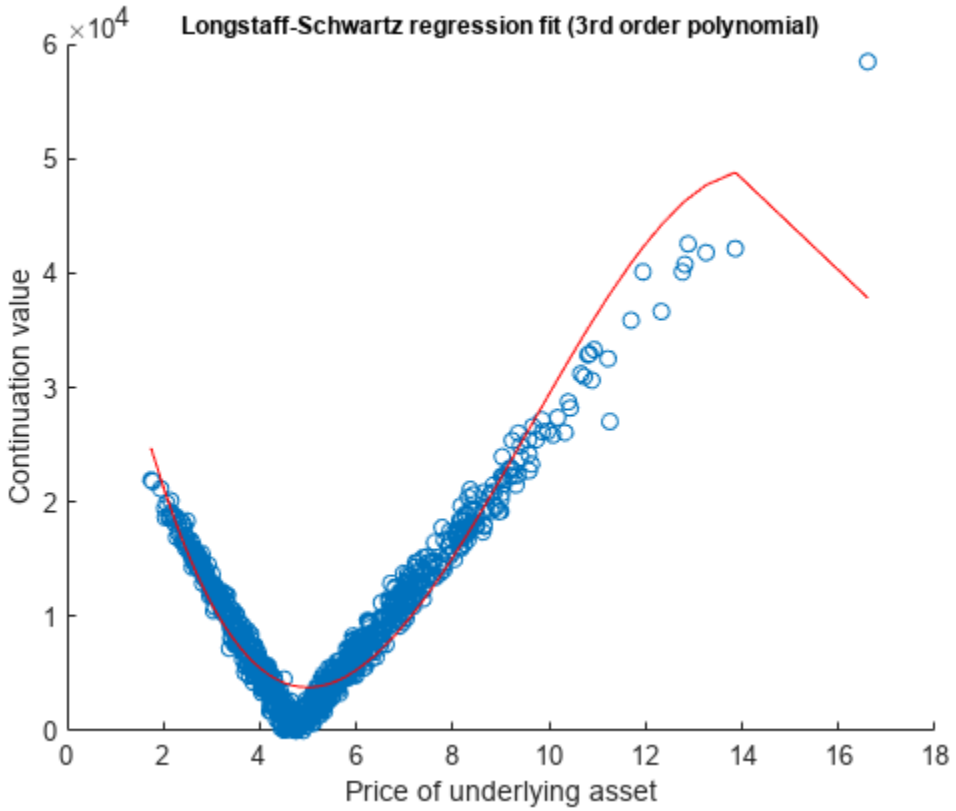
% Strike
Strike = 4.69;
```

The Longstaff-Schwartz method is a backward iteration algorithm, which steps backward in time from the maturity date. At each exercise date, the algorithm approximates the continuation value, which is the value of the option if it is not exercised. This is done by fitting a regression against the values of the simulated prices and the discounted future value of the option at the next exercise date. The future value of the option is known as the algorithm moves backward in time. The continuation value is compared to the sum of the payoff from immediate exercise (a downswing or upswing) and the continuation value of a swing option with one less swing right. If this sum is smaller, the option holder's optimal strategy is to not exercise on that date. The function `hswingbyls` in this example uses this method to determine the optimal exercise strategy and the price for swing options [1 on page 3-50,2 on page 3-50,7 on page 3-51].

As discussed earlier, the only constraint considered in this example is the minimum and maximum DCQ. In this case, the optimal early exercise strategy is of a "bang-bang" type. This means that when it is optimal to upswing or downswing at a certain exercise date, the option holder should always exercise at the maximum or minimum DCQ to maximize profit. The "bang-bang" exercise would not be the optimal strategy if, for example, there is a terminal penalty based on volume. The pricing algorithm would then need to additionally keep track of all possible volume levels, which significantly adds to the runtime performance cost.

First, the swing option is priced using a third order polynomial to fit the regression of the Longstaff-Schwartz method. The function `hswingbyls` also generates a plot of the regression between the underlying price and the continuation value at the exercise date before maturity.

```
% Price swing option using 3rd order polynomial to fit Longstaff-Schwartz
% regression
tic;
useSpline = false;
SwingPrice = hswingbyls(Paths, Times, RateSpec, Settle, Maturity, ...
    Strike, ExerciseDates, NumSwings, DCQ, minDCQ, maxDCQ, useSpline, ...
    [], true)
```

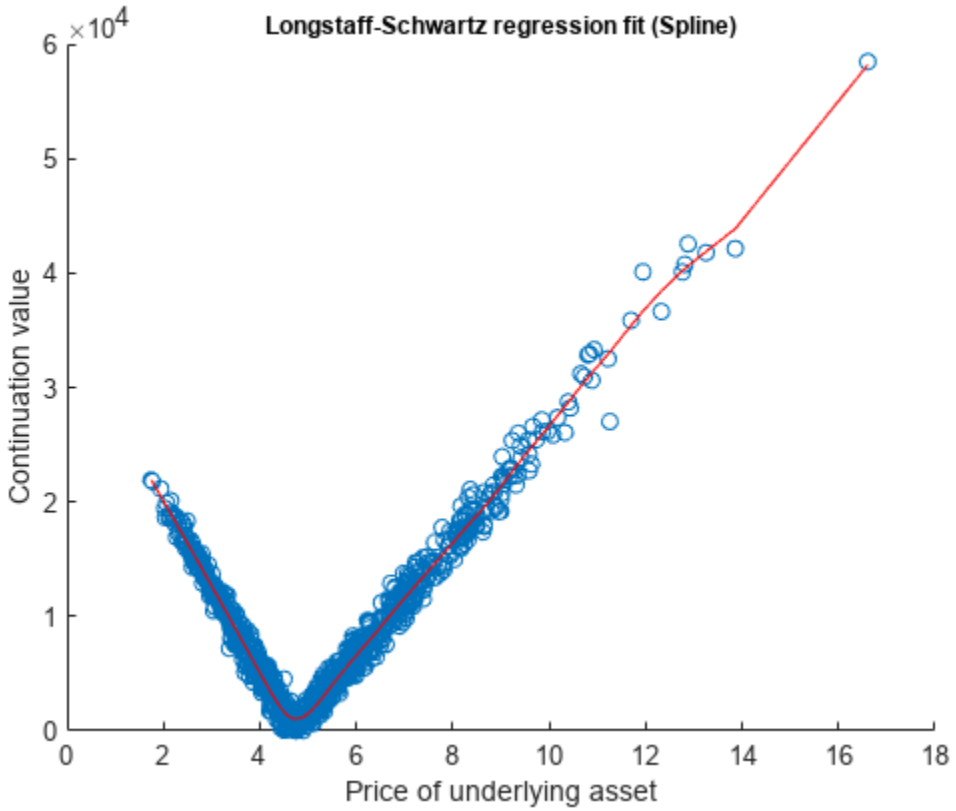


```
SwingPrice = 5.6943e+04
```

```
lsPolyTime = toc;
```

The above plot of the regression fit shows that the third order polynomial does not fit the continuation value perfectly, especially near the hinge and at the extreme points. Use the `csaps` function to fit the regression using a cubic smoothing spline with a smoothing parameter of 0.7. The Curve Fitting Toolbox™ is required to run the remainder of the example.

```
% Price swing option using smoothed splines to fit Longstaff-Schwartz
% regression
tic;
useSpline = true;
smoothingParam = 0.7;
SwingPriceSpline = hswingbyls(Paths, Times, RateSpec, Settle, Maturity, ...
    Strike, ExerciseDates, NumSwings, DCQ, minDCQ, maxDCQ, useSpline, ...
    smoothingParam, true)
```



```
SwingPriceSpline = 6.0729e+04
```

```
lsSplineTime = toc;
```

The plot of the regression shows that the cubic smoothing spline has a better fit against the data, thus obtaining a more accurate value for the continuation values. However, the comparison below shows that using a cubic smoothing spline takes longer than a third order polynomial.

```
% Print comparison of running times
displayRunningTimes(lsPolyTime, lsSplineTime)
```

```
Comparison of running times:

3rd order polynomial: 6.29 sec
Spline              : 20.44 sec
```

Also, it is important to note that the price represents solely the optionality component. Hence, the price of the baseload forward contract is not included in the above calculated price. Because we used a fixed strike price, the baseload contract has a non-zero value, which can be calculated by:

$$BaseLoadPrice = \sum_{i=1}^{N} e^{-rt_i} E(S_{t_i} - K)$$

where $t_i, i = 1, \ldots, N$, are the exercise dates (see [3 on page 3-50] for more details). The full price of the contract, including the baseload and the swing option, is calculated below using the swing option price from the smoothed cubic spline.

```
% Obtain discount factors
RS2 = intenvset(RateSpec, 'StartTimes', 0, 'EndTimes', Times(2:end));
D = intenvget(RS2,'Disc');

% Calculate baseload price
BaseLoadPrice = DCQ.*mean(Paths(2:end,:)-Strike,2)'*D;

% Calculate full contract price, based on results from cubic spline LS
FullContractPrice = BaseLoadPrice + SwingPriceSpline

FullContractPrice = 1.2479e+05
```

Price Bounds

A lower bound for the swing option is a strip of European options, and the upper bound is a strip of American options [4 on page 3-50]. Compared to European options, swing options have an early exercise premium at each exercise date, thus the price should be higher. The price is lower than the American option strips, because only a single swing right can be exercised at each exercise date. More than one strip can be exercised in a single day using American options.

The prices for the strips of the lower and upper bounds are calculated below to check that the swing option prices are within these bounds. The European strip prices are calculated against the last five exercise dates.

```
% Obtain discount factor for the last NumSwings exercise dates
D = D(end-NumSwings+1:end);

% European lower bound
idx = size(Paths, 1):-1:(size(Paths, 1) - NumSwings + 1);
putEuro = D'*mean(max(Strike - Paths(idx,:), 0),2);
callEuro = D'*mean(max(Paths(idx,:) - Strike, 0),2);
lowerBound = ((DCQ-minDCQ).*putEuro+(maxDCQ-DCQ).*callEuro);

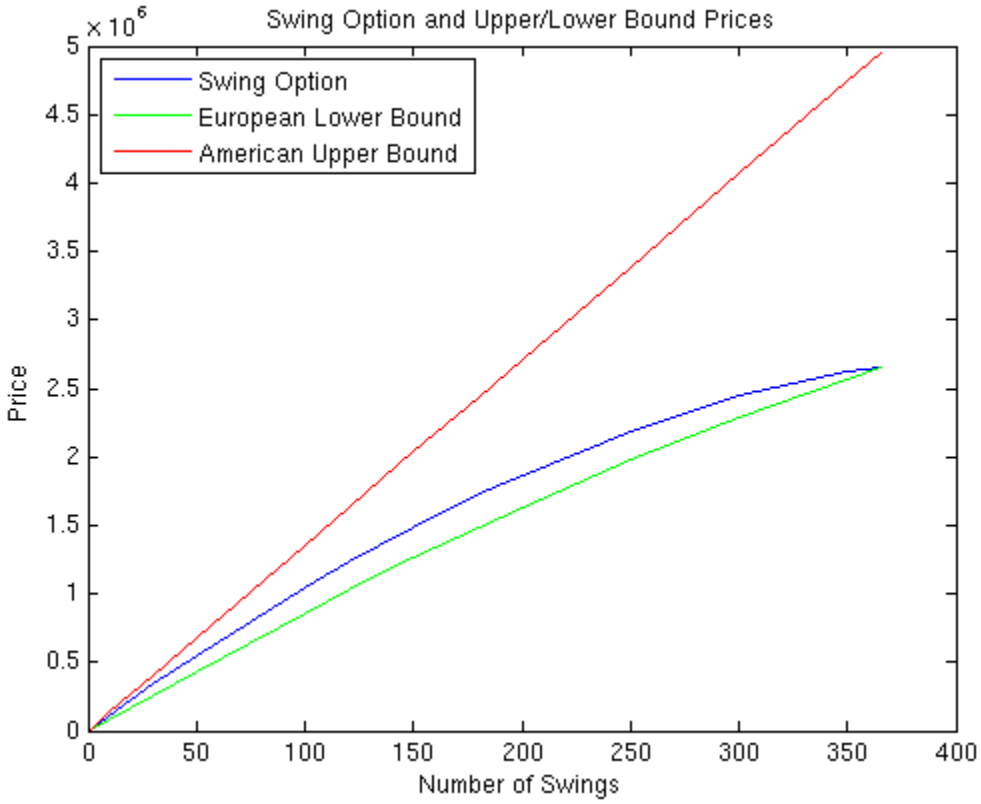
% American upper bound
[putAmer, callAmer] = hamericanPrice(Paths, Times, RateSpec, Strike);
upperBound = NumSwings.*((DCQ-minDCQ).*putAmer+(maxDCQ-DCQ).*callAmer);

% Print price and lower/upper bounds
displaySummary(SwingPriceSpline, lowerBound, upperBound);

Comparison to lower and upper bounds:

Lower bound (European) : 44412.14
Swing Option Price     : 60729.00
Upper bound (American) : 68181.42
```

The prices calculated using the Longstaff-Schwartz algorithm are within the lower and upper bounds. The plot below shows a comparison between the swing option and the upper and lower bounds as the number of swings increases. When the number of swings is 1, the swing option is equivalent to an American option. In the case of daily exercise opportunity (`NumSwings = 365`), the swing option is equivalent to the strip of European options with daily maturity.



Conclusion

The example shows the use of the Longstaff-Schwartz method to price a swing option where the underlying asset follows a mean-reverting dynamic. A 3rd order polynomial and a smoothed cubic spline are used to fit the regression in the Longstaff-Schwartz algorithm to approximate the continuation value. It was shown that the smoothed cubic spline fits the data better at the cost of slower performance. Finally, the resulting swing option prices were checked against the lower bound of a strip of European options and an upper bound of a strip of American options.

Simulating Electricity Prices with Mean-Reversion and Jump-Diffusion

This example shows how to simulate electricity prices using a mean-reverting model with seasonality and a jump component. The model is calibrated under the real-world probability using historical electricity prices. The market price of risk is obtained from futures prices. A risk-neutral Monte Carlo simulation is conducted using the calibrated model and the market price of risk. The simulation results are used to price a Bermudan option with electricity prices as the underlying.

Overview of the Model

Electricity prices exhibit jumps in prices at periods of high demand when additional, less efficient electricity generation methods, are brought on-line to provide a sufficient supply of electricity. In addition, they have a prominent seasonal component, along with reversion to mean levels. Therefore, these characteristics should be incorporated into a model of electricity prices [2 on page 3-62].

In this example, electricity price is modeled as:

$$log(P_t) = f(t) + X_t$$

where P_t is the spot price of electricity. The logarithm of electricity price is modeled with two components: $f(t)$ and X_t. The component $f(t)$ is the deterministic seasonal part of the model, and X_t is the stochastic part of the model. Trigonometric functions are used to model $f(t)$ as follows [3]:

$$f(t) = s_1\sin(2\pi t) + s_2\cos(2\pi t) + s_3\sin(4\pi t) + s_4\cos(4\pi t) + s_5$$

where $s_i, i = 1, \ldots, 5$ are constant parameters, and t is the annualized time factors. The stochastic component X_t is modeled as an Ornstein-Uhlenbeck process (mean-reverting) with jumps:

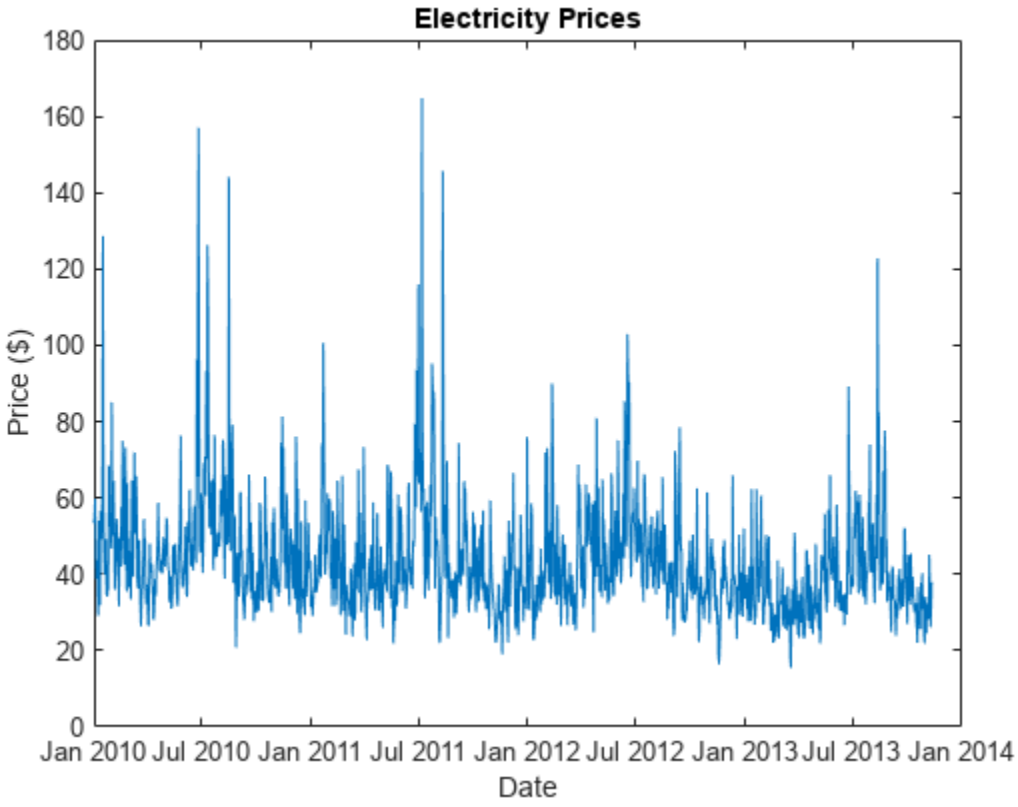
$$dX_t = (\alpha - \kappa X_t)dt + \sigma dW_t + J(\mu_J, \sigma_J)d\Pi(\lambda)$$

The parameters α and κ are the mean-reversion parameters. Parameter σ is the volatility, and W_t is a standard Brownian motion. The jump size is $J(\mu_J, \sigma_J)$, with a normally distributed mean μ_J, and a standard deviation σ_J. The Poisson process $\Pi(\lambda)$ has a jump intensity of λ.

Electricity Prices

Sample electricity prices from January 1, 2010 to November 11, 2013 are loaded and plotted below. `Prices` contain the electricity prices, and `PriceDates` contain the dates associated with the prices. The logarithm of the prices and annual time factors are calculated.

```
% Load the electricity prices and futures prices.
load('electricity_prices.mat');
PriceDates = datetime(PriceDates,'ConvertFrom','datenum');
FutExpiry = datetime(FutExpiry,'ConvertFrom','datenum');
FutValuationDate = datetime(FutValuationDate,'ConvertFrom','datenum');
% Plot the electricity prices.
figure;
plot(PriceDates, Prices);
title('Electricity Prices');
xlabel('Date');
ylabel('Price ($)');
```



```
% Obtain the log of prices.
logPrices = log(Prices);

% Obtain the annual time factors from dates.
PriceTimes = yearfrac(PriceDates(1), PriceDates);
```

Calibration

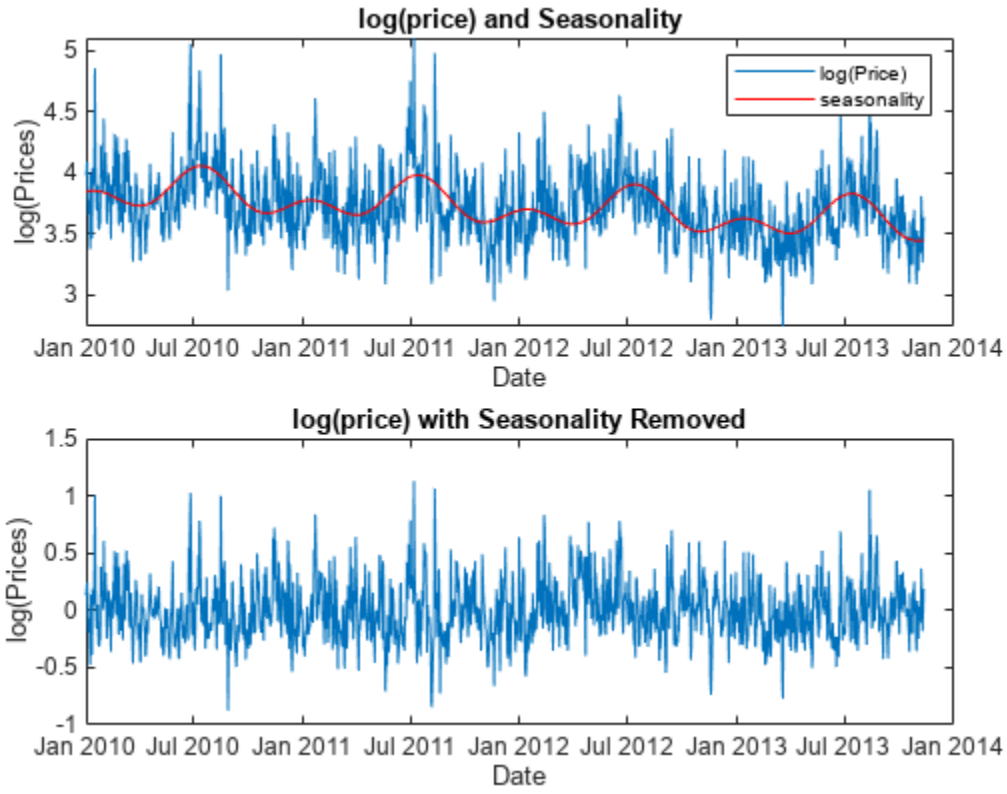
First, the deterministic seasonality part is calibrated using the least squares method. Since the seasonality function is linear with respect to the parameters s_i, the backslash operator (`mldivide`) is used. After the calibration, the seasonality is removed from the logarithm of price. The logarithm of price and seasonality trends are plotted below. Also, the de-seasonalized logarithm of price is plotted.

```
% Calibrate parameters for the seasonality model.
seasonMatrix = @(t) [sin(2.*pi.*t) cos(2.*pi.*t) sin(4.*pi.*t) ...
    cos(4.*pi.*t) t ones(size(t, 1), 1)];
C = seasonMatrix(PriceTimes);
seasonParam = C\logPrices;

% Plot the log price and seasonality line.
figure;
subplot(2, 1, 1);
plot(PriceDates, logPrices);
title('log(price) and Seasonality');
xlabel('Date');
ylabel('log(Prices)');
```

```
hold on;
plot(PriceDates, C*seasonParam, 'r');
hold off;
legend('log(Price)', 'seasonality');

% Plot de-seasonalized log price
X = logPrices-C*seasonParam;
subplot(2, 1, 2);
plot(PriceDates, X);
title('log(price) with Seasonality Removed');
xlabel('Date');
ylabel('log(Prices)');
```



The second stage is to calibrate the stochastic part. The model for X_t needs to be discretized to conduct the calibration. To discretize, assume that there is a Bernoulli process for the jump events. That is, there is at most one jump per day since this example is calibrating against daily electricity prices. The discretized equation is:

$$X_t = \alpha\Delta t + \phi X_{t-1} + \sigma\xi$$

with probability $(1 - \lambda\Delta t)$ and,

$$X_t = \alpha\Delta t + \phi X_{t-1} + \sigma\xi + \mu_J + \sigma_J\xi_J$$

with probability $\lambda\Delta t$, where ξ and ξ_J are independent standard normal random variables, and $\phi = 1 - \kappa\Delta t$. The density function of X_t given X_{t-1} is [1 on page 3-62,4 on page 3-62]:

$$f(X_t|X_{t-1}) = (\lambda\Delta t)N_1(X_t|X_{t-1}) + (1-\lambda\Delta t)N_2(X_t|X_{t-1})$$

$$N_1(X_t|X_{t-1}) = (2\pi(\sigma^2+\sigma_J^2))^{-\frac{1}{2}}\exp(\frac{-(X_t-\alpha\Delta t-\phi X_{t-1}-\mu_J)^2}{2(\sigma^2+\sigma_J^2)})$$

$$N_2(X_t|X_{t-1}) = (2\pi\sigma^2)^{-\frac{1}{2}}\exp(\frac{-(X_t-\alpha\Delta t-\phi X_{t-1})^2}{2\sigma^2})$$

The parameters $\theta = \{\alpha, \phi, \mu_J, \sigma^2, \sigma_J^2, \lambda\}$ can be calibrated by minimizing the negative log likelihood function:

$$min_\theta - \sum_{t=1}^{T}\log(f(X_t|X_{t-1}))$$

$$subject\ to\ \phi < 1, \sigma^2 > 0, \sigma_J^2 > 0, 0 \le \lambda\Delta t \le 1$$

The first inequality constraint, $\phi < 1$, is equivalent to $\kappa > 0$. The volatilities σ and σ_J must be positive. In the last inequality, $\lambda\Delta t$ is between 0 and 1, because it represents the probability of a jump occurring in Δt time. In this example, assume that Δt is one day. Therefore, there is at most 365 jumps in one year. The `mle` function from the Statistics and Machine Learning Toolbox™ is well suited to solve the above maximum likelihood problem.

```
% Prices at t, X(t).
Pt = X(2:end);

% Prices at t-1, X(t-1).
Pt_1 = X(1:end-1);

% Discretization for the daily prices.
dt = 1/365;

% PDF for the discretized model.
mrjpdf = @(Pt, a, phi, mu_J, sigmaSq, sigmaSq_J, lambda) ...
    lambda.*exp((-(Pt-a-phi.*Pt_1-mu_J).^2)./ ...
    (2.*(sigmaSq+sigmaSq_J))).* (1/sqrt(2.*pi.*(sigmaSq+sigmaSq_J))) + ...
    (1-lambda).*exp((-(Pt-a-phi.*Pt_1).^2)/(2.*sigmaSq)).* ...
    (1/sqrt(2.*pi.*sigmaSq));

% Constraints:
% phi < 1 (k > 0)
% sigmaSq > 0
% sigmaSq_J > 0
% 0 <= lambda <= 1
lb = [-Inf -Inf -Inf 0 0 0];

sigma_J = sqrt(params(5))
```

```
sigma_J = 0.2659
```

```
lambda = params(6)/dt
```

```
lambda = 98.3358
```

Monte Carlo Simulation

The calibrated parameters and the discretized model allow us to simulate electricity prices under the real-world probability. The simulation is conducted for approximately 2 years with 10,000 trials. It exceeds 2 years to include all the dates in the last month of simulation. This is because the expected simulation prices for the futures contract expiry date is required in the next section to calculate the market price of risk. The seasonality is added back on the simulated paths. A plot for a single simulation path is plotted below.

```
rng default;

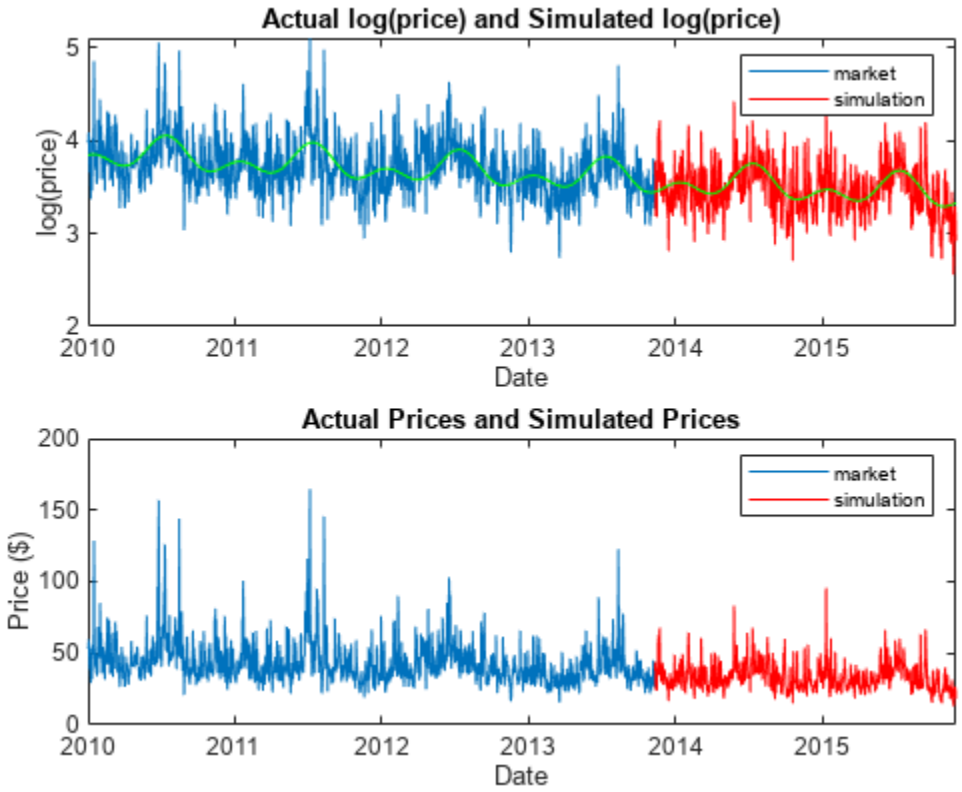
% Simulate for about 2 years.
nPeriods = 365*2+20;
nTrials = 10000;
n1 = randn(nPeriods,nTrials);
n2 = randn(nPeriods, nTrials);
j = binornd(1, lambda*dt, nPeriods, nTrials);
SimPrices = zeros(nPeriods, nTrials);
SimPrices(1,:) = X(end);
for i=2:nPeriods
    SimPrices(i,:) = alpha*dt + (1-kappa*dt)*SimPrices(i-1,:) + ...
                sigma*sqrt(dt)*n1(i,:) + j(i,:).*(mu_J+sigma_J*n2(i,:));
end

% Add back seasonality.
SimPriceDates = PriceDates(end) + days(0:(nPeriods-1))';
SimPriceTimes = yearfrac(PriceDates(1), SimPriceDates);
CSim = seasonMatrix(SimPriceTimes);
logSimPrices = SimPrices + repmat(CSim*seasonParam,1,nTrials);

% Plot the logarithm of Prices and simulated logarithm of Prices.
figure;
subplot(2, 1, 1);
plot(PriceDates, logPrices);
hold on;
plot(SimPriceDates(2:end), logSimPrices(2:end,1), 'red');
seasonLine = seasonMatrix([PriceTimes; SimPriceTimes(2:end)])*seasonParam;
```

```
plot([PriceDates; SimPriceDates(2:end)], seasonLine, 'green');
hold off;
title('Actual log(price) and Simulated log(price)');
xlabel('Date');
ylabel('log(price)');
legend('market', 'simulation');

% Plot the prices and simulated prices.
PricesSim = exp(logSimPrices);
subplot(2, 1, 2);
plot(PriceDates, Prices);
hold on;
plot(SimPriceDates, PricesSim(:,1), 'red');
hold off;
title('Actual Prices and Simulated Prices');
xlabel('Date');
ylabel('Price ($)');
legend('market', 'simulation');
```



Calibration of the Market Price of Risk

Up to this point, the parameters were calibrated under the real-world probability. However, to price options, you need the simulation under the risk-neutral probability. To obtain this, calculate the market price of risk from futures prices to derive the risk-neutral parameters. Suppose that there are monthly futures contracts available on the market, which are settled daily during the contract month. For example, such futures for the PJM electricity market are listed on the Chicago Mercantile Exchange [5 on page 3-62].

The futures are settled daily during the contract month. Therefore, you can obtain daily futures values by assuming the futures value is constant for the contract month. The expected futures prices from the real-world measure are also needed to calculate the market price of risk. This can be obtained from the simulation conducted in the previous section.

```
% Obtain the daily futures prices.
FutPricesDaily = zeros(size(SimPriceDates));
for i=1:nPeriods
    idx = find(year(SimPriceDates(i)) == year(FutExpiry) & ...
        month(SimPriceDates(i)) == month(FutExpiry));
    FutPricesDaily(i) = FutPrices(idx);
end

% Calculate the expected futures price under real-world measure.
SimPricesExp = mean(PricesSim, 2);
```

To calibrate the market price of risk against market futures values, use the following equation:

$$\log(\frac{F_t}{E_t}) = -\sigma e^{-kt}\int_0^t e^{ks} m_s ds$$

where F_t is the observed futures value at time t, and E_t is the expected value under the real-world measure at time t. The equation was obtained using the same methodology as described in [3 on page 3-62]. This example assumes that the market price of risk is fully driven by the Brownian motion. The market price of risk, m_t, can be solved by discretizing the above equation and solving a system of linear equations.

```
% Setup system of equations.
t0 = yearfrac(PriceDates(1), FutValuationDate);
tz = SimPriceTimes-t0;
b = -log(FutPricesDaily(2:end) ./ SimPricesExp(2:end)) ./ ...
    (sigma.*exp(-kappa.*tz(2:end)));
A = (1/kappa).*(exp(kappa.*tz(2:end)) - exp(kappa.*tz(1:end-1)));
A = tril(repmat(A', size(A,1), 1));

% Precondition to stabilize numerical inversion.
P = diag(1./diag(A));
b = P*b;
A = P*A;

% Solve for the market price of risk.
riskPremium = A\b;
```

Simulation of Risk-Neutral Prices

Once m_t is obtained, risk-neutral simulation can be conducted using the following dynamics:

$$X_t = \alpha\Delta t + \phi X_{t-1} - \sigma m_{t-1}\Delta t + \sigma\xi$$

with probability $(1 - \lambda\Delta t)$ and

$$X_t = \alpha\Delta t + \phi X_{t-1} - \sigma m_{t-1}\Delta t + \sigma\xi + \mu_J + \sigma_J\xi_J$$

with probability $\lambda\Delta t$.

```
nTrials = 10000;
n1 = randn(nPeriods, nTrials);
```

```
n2 = randn(nPeriods, nTrials);
j = binornd(1, lambda*dt, nPeriods, nTrials);

SimPrices = zeros(nPeriods, nTrials);
SimPrices(1,:) = X(end);
for i=2:nPeriods
    SimPrices(i,:) = alpha*dt + (1-kappa*dt)*SimPrices(i-1,:) + ...
        sigma*sqrt(dt)*n1(i,:) - sigma*dt*riskPremium(i-1) + ...
        j(i,:).*(mu_J+sigma_J*n2(i,:));
end

% Add back seasonality.
CSim = seasonMatrix(SimPriceTimes);
logSimPrices = SimPrices + repmat(CSim*seasonParam,1,nTrials);

% Convert the log(Price) to Price.
PricesSim = exp(logSimPrices);
```

The expected values from the risk-neutral simulation are plotted against the market futures values. This confirms that the risk-neutral simulation closely reproduces the market futures values.

```
% Obtain expected values from the risk-neutral simulation.
SimPricesExp = mean(PricesSim,2);
fexp = zeros(size(FutExpiry));
for i = 1:size(FutExpiry,1)
    idx = SimPriceDates == FutExpiry(i);
    if sum(idx)==1
        fexp(i) = SimPricesExp(idx);
    end
end

% Plot expected values from the simulation against market futures prices.
figure;
subplot(2,1,1);

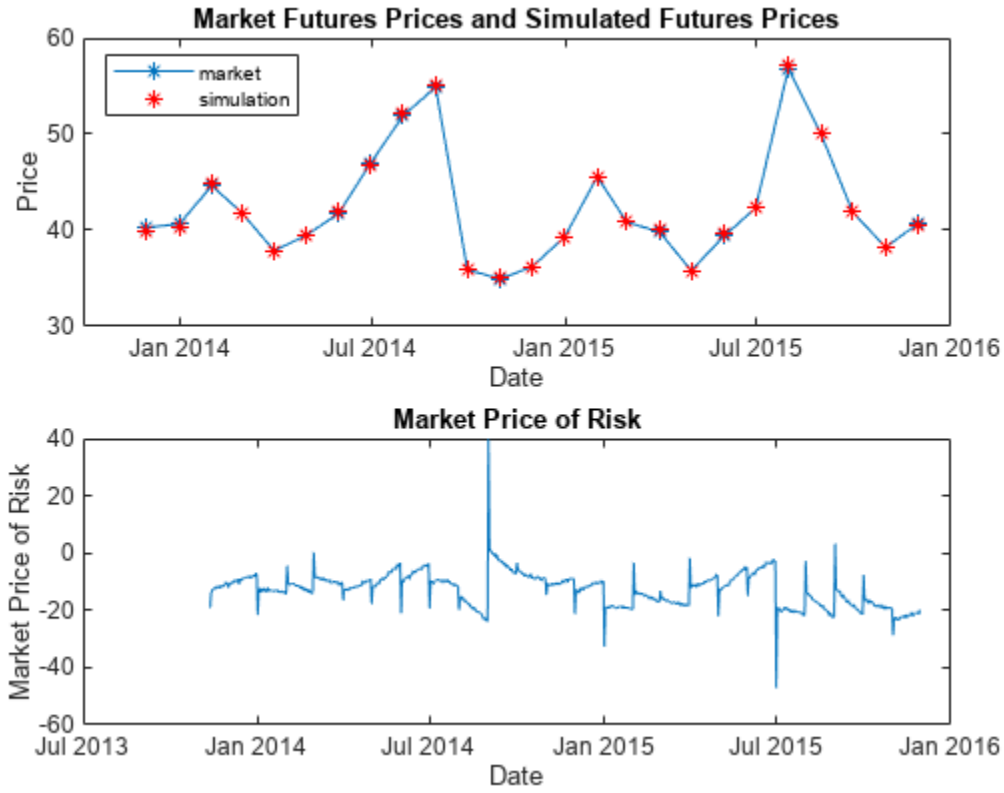
plot(SimPriceDates(2:end), riskPremium);
title('Market Price of Risk');
xlabel('Date');
ylabel('Market Price of Risk');
```



Pricing a Bermudan Option

The risk-neutral simulated values are used as input into the function `optpricebysim` in the Financial Instruments Toolbox™ to price a European, Bermudan, or American option on electricity prices. Below, the price is calculated for a two-year Bermudan call option with two exercise opportunities. The first exercise is after one year, and the second is at the maturity of the option.

```
% Settle, maturity of option.
Settle = FutValuationDate;
Maturity = FutValuationDate + calyears(2);

% Create the interest-rate term structure.
riskFreeRate = 0.01;
Basis = 0;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rate', riskFreeRate, 'Compounding', ...
    Compounding, 'Basis', Basis);

% Cutoff the simulation at maturity.
endIdx = find(SimPriceDates == Maturity);
SimPrices = PricesSim(1:endIdx,:);
Times = SimPriceTimes(1:endIdx) - SimPriceTimes(1);

% Bermudan call option with strike 60, two exercise opportunities, after
% one year and at maturity.
OptSpec = 'call';
```

```
Strike = 60;
ExerciseTimes = [Times(366) Times(end)];
Price = optpricebysim(RateSpec, SimPrices, Times, OptSpec, Strike, ...
    ExerciseTimes)
```

```
Price = 1.1085
```

Pricing Equity Derivatives Using Trees

In this section...

Computing Instrument Prices

The portfolio pricing functions `crrprice`, `eqpprice`, and `ittprice` calculate the price of any set of supported instruments based on a binary equity price tree, an implied trinomial price tree, or a standard trinomial tree. These functions are capable of pricing the following instrument types:

- Vanilla stock options
  - American and European puts and calls
- Exotic options
  - Asian
  - Barrier
  - Compound
  - Lookback
  - Stock options (Bermuda put and call schedules)

The syntax for calling the function `crrprice` is:

```
[Price, PriceTree] = crrprice(CRRTree, InstSet, Options)
```

The syntax for `eqpprice` is:

```
[Price, PriceTree] = eqpprice(EQPTree, InstSet, Options)
```

The syntax for `ittprice` is:

```
Price = ittprice(ITTTree, ITTInstSet, Options)
```

The syntax for `sttprice` is:

```
[Price, PriceTree] = sttprice(STTTree, InstSet, Name, Value)
```

These functions require two input arguments: the equity price tree and the set of instruments, `InstSet`, and allow a third optional argument.

Required Arguments

`CRRTree` is a CRR equity price tree created using `crrtree`. `EQPTree` is an equal probability equity price tree created using `eqptree`. `ITTTree` is an ITT equity price tree created using `itttree`.

`STTTree` is a standard trinomial equity price tree created using `stttree`. See “Building Equity Binary Trees” on page 3-3 and “Building Implied Trinomial Trees” on page 3-6 to learn how to create these structures.

`InstSet` is a structure that represents the set of instruments to be priced independently using the model.

Optional Argument

You can enter a third optional argument, `Options`, used when pricing barrier options. For more specific information, see “Pricing Options Structure” on page A-2.

These pricing functions internally classify the instruments and call the appropriate individual instrument pricing function for each of the instrument types. The CRR pricing functions are `asianbycrr`, `barrierbycrr`, `compoundbycrr`, `lookbackbycrr`, and `optstockbycrr`. A similar set of functions exists for EQP, ITT, and STT pricing. You can also use these functions directly to calculate the price of sets of instruments of the same type. See the reference pages for these individual functions for further information.

Computing Prices Using CRR

Consider the following example, which uses the portfolio and stock price data in the MAT-file `deriv.mat` included in the toolbox. Load the data into the MATLAB workspace.

```
load deriv.mat
```

Use the MATLAB `whos` command to display a list of the variables loaded from the MAT-file.

```

8     Asian put     110    01-Jan-2003    01-Jan-2007    0           arithmetic NaN      NaN     Asian2 6
```

Note Because of space considerations, the compound option above (`Index 4`) has been condensed to fit the page. The `instdisp` command displays all compound option fields on your computer screen.

The instrument set contains eight instruments:

- Two vanilla options (`Call1`, `Put1`)
- One barrier option (`Barrier1`)
- One compound option (`Compound1`)
- Two lookback options (`Lookback1`, `Lookback2`)
- Two Asian options (`Asian1`, `Asian2`)

Each instrument has a corresponding index that identifies the instrument prices in the price vector returned by `crrprice`.

Now use `crrprice` to calculate the price of each instrument in the instrument set.

```
Price = crrprice(CRRTree, CRRInstSet)
```

```
Price =

    8.2863
    2.5016
   12.1272
    3.3241
    7.6015
   11.7772
    4.1797
    3.4219
```

Computing Prices Using EQP

Load the data into the MATLAB workspace.

```
load deriv.mat
```

Use the MATLAB `whos` command to display a list of the variables loaded from the MAT-file.

```

```

The instrument set contains eight instruments:

- Two vanilla options (`Call1`, `Put1`)
- One barrier option (`Barrier1`)
- One compound option (`Compound1`)
- Two lookback options (`Lookback1`, `Lookback2`)
- Two Asian options (`Asian1`, `Asian2`)

Each instrument has a corresponding index that identifies the instrument prices in the price vector returned by `ittprice`.

Now use `ittprice` to calculate the price of each instrument in the instrument set.

```
Price = ittprice(ITTTree, ITTInstSet)
```

```
Price =

    1.6506
   10.6832
    2.4074
    3.2294
    0.5426
    6.1845
    3.2052
    6.6074
```

Computing Prices Using STT

Consider the following example, which uses the portfolio and stock price data in the MAT-file `deriv.mat` included in the toolbox. Load the data into the MATLAB workspace.

```
load deriv.mat
```

Use the MATLAB `whos` command to display a list of the variables loaded from the MAT-file.

```
 Name              Size            Bytes  Class     Attributes

  BDTInstSet        1x1             27344  struct
  BDTTree           1x1              7322  struct
  BKInstSet         1x1             27334  struct

```

The instrument set contains eight instruments:

- Two vanilla options (`Call1`, `Put1`)
- One barrier option (`Barrier1`)
- One compound option (`Compound1`)
- Two lookback options (`Lookback1`, `Lookback2`)
- Two Asian options (`Asian1`, `Asian2`)

Each instrument has a corresponding index that identifies the instrument prices in the price vector returned by `sttprice`.

Now use `sttprice` to calculate the price of each instrument in the instrument set.

```
Price = sttprice(STTTree, STTInstSet)
```

```
Price =

    4.5025
    3.0603
    3.7977
    1.7090
   11.7296
   12.9120
    1.6905
    2.6203
```

Examining Output from the Pricing Functions

The prices in the output vector `Price` correspond to the prices at observation time zero (`tObs = 0`), which is defined as the valuation date of the equity tree. The instrument indexing within `Price` is the same as the indexing within `InstSet`.

In the CRR example, the prices in the `Price` vector correspond to the instruments in this order.

```
InstNames = instget(CRRInstSet, 'FieldName','Name')
```

```
InstNames =

Call1
Put1
Barrier1
Compound1
```

```
Lookback1
Lookback2
Asian1
Asian2
```

So, in the `Price` vector, the fourth element, `3.3241`, represents the price of the fourth instrument (`Compound1`), and the sixth element, `11.7772`, represents the price of the sixth instrument (`Lookback2`).

In the ITT example, the prices in the `Price` vector correspond to the instruments in this order.

```
InstNames = instget(ITTInstSet, 'FieldName','Name')
```

```
InstNames =

Call1
Put1
Barrier1
Compound1
Lookback1
Lookback2
Asian1
Asian2
```

So, in the `Price` vector, the first element, 1.650, represents the price of the first instrument (`Call1`), and the eighth elements, 6.607, represents the price of the eighth instrument (`Asian2`).

Price Tree Output for CRR

If you call a pricing function with two output arguments, for example:

```
[Price, PriceTree] = crrprice(CRRTree, CRRInstSet)
```

you generate a price tree structure along with the price information.

This price tree structure `PriceTree` holds all pricing information.

```
PriceTree =
FinObj: 'BinPriceTree'
PTree: {[8x1 double] [8x2 double] [8x3 double] [8x4 double] [8x5 double]}
tObs: [0 1 2 3 4]
dObs: [731582 731947 732313 732678 733043]
```

The first field of this structure, `FinObj`, indicates that this structure represents a price tree. The second field, `PTree`, is the tree holding the prices of the instruments in each node of the tree. Finally, the third and fourth fields, `tObs` and `dObs`, represent the observation time and date of each level of `PTree`, with `tObs` using units in terms of compounding periods.

Using the command-line interface, you can directly examine `PriceTree.PTree`, the field within the `PriceTree` structure that contains the price tree with the price vectors at every state. The first node represents `tObs = 0`, corresponding to the valuation date.

```
PriceTree.PTree{1}
```

```
ans =
8.2863
2.5016
12.1272
3.3241
```

```
7.6015
11.7772
4.1797
3.4219
```

With this interface, you can observe the prices for all instruments in the portfolio at a specific time.

The function `eqpprice` also returns a price tree that you can examine in the same way.

Price Tree Output for ITT

If you call a pricing function with two output arguments, for example:

```
[Price, PriceTree] = ittprice(ITTTree, ITTInstSet)
```

you generate a price tree structure along with the price information.

This price tree structure `PriceTree` holds all pricing information.

```
PriceTree =

    FinObj: 'TrinPriceTree'
     PTree: {[8x1 double]  [8x3 double]  [8x5 double]  [8x7 double]  [8x9 double]}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]
```

The first field of this structure, `FinObj`, indicates that this structure represents a trinomial price tree. The second field, `PTree` is the tree holding the prices of the instruments in each node of the tree. Finally, the third and fourth fields, `tObs` and `dObs`, represent the observation time and date of each level of `PTree`, with `tObs` using units in terms of compounding periods.

Using the command-line interface, you can directly examine `PriceTree.PTree`, the field within the `PriceTree` structure that contains the price tree with the price vectors at every state. The first node represents `tObs = 0`, corresponding to the valuation date.

```
PriceTree.PTree{1}

ans =

    1.6506
   10.6832
    2.4074
    3.2294
    0.5426
    6.1845
    3.2052
    6.6074
```

With this interface, you can observe the prices for all instruments in the portfolio at a specific time.

Prices for Lookback and Asian Options for Equity Trees

Lookback options and Asian options are path-dependent, and, as such, there are no unique prices for any node except the root node. So, the corresponding values for lookback and Asian options in the price tree are set to `NaN`, the only exception being the root node. This becomes apparent if you examine the prices in the second node (`tobs = 1`) of the CRR price tree:

```
PriceTree.PTree{2}

ans =
```

```
   11.9176         0
    0.9508    7.1914
   16.4600    2.6672
    2.5896    5.0000
       NaN       NaN
       NaN       NaN
       NaN       NaN
       NaN       NaN
```

Examining the prices in the second node (`tobs = 1`) of the ITT price tree displays:

```
PriceTree.PTree{2}
```

```
 ans =

    3.9022         0         0
    6.3736   13.3743   22.1915
    5.6914         0         0
    2.7663    3.8594    5.0000
       NaN       NaN       NaN
       NaN       NaN       NaN
       NaN       NaN       NaN
       NaN       NaN       NaN
```

Graphical Representation of Equity Derivative Trees

You can use the function `treeviewer` to display a graphical representation of a tree, allowing you to examine interactively the prices and rates on the nodes of the tree until maturity. The graphical representations of CRR, EQP, and LR trees are equivalent to Black-Derman-Toy (BDT) trees, given that they are all binary recombining trees. The graphical representations of ITT and STT trees are equivalent to Hull-White (HW) trees, given that they are all trinomial recombining trees. See “Graphical Representation of Trees” on page 2-219 for an overview on the use of `treeviewer` with CRR trees, EQP trees, LR trees, ITT trees, and STT trees and their corresponding option price trees. Follow the instructions for BDT trees.

Computing Equity Instrument Sensitivities

Sensitivities can be reported either as dollar price changes or percentage price changes. The delta, gamma, and vega sensitivities that the toolbox computes are dollar sensitivities.

The functions `crrsens`, `eqpsens`, `ittsens`, and `sttsens` compute the delta, gamma, and vega sensitivities of instruments using a stock tree. They also optionally return the calculated price for each instrument. The sensitivity functions require the same two input arguments used by the pricing functions (`CRRTree` and `CRRInstSet` for CRR, `EQPTree` and `EQPInstSet` for EQP, `ITTTree` and `ITTInstSet` for ITT, and `STTTree` and `STTInstSet` for STT).

As with the instrument pricing functions, the optional input argument `Options` is also allowed. You would include this argument if you want a sensitivity function to generate a price for a barrier option as one of its outputs and want to control the method that the toolbox uses to perform the pricing operation. See “Pricing Options Structure” on page A-2 or the `derivset` function for more information.

For path-dependent options (lookback and Asian), delta and gamma are computed by finite differences in calls to `crrprice`, `eqpprice`, `ittprice`, and `sttprice`. For the other options (stock option, barrier, and compound), delta and gamma are computed from the CRR, EQP, ITT, and STT trees and the corresponding option price tree. (See Chriss, Neil, *Black-Scholes and Beyond*, pp. 308–312.)

CRR Sensitivities Example

The calling syntax for the sensitivity function is:

```
[Delta, Gamma, Vega, Price] = crrsens(CRRTree, InstSet, Options)
```

Using the example data in `deriv.mat`, calculate the sensitivity of the instruments.

```
load deriv.mat
[Delta, Gamma, Vega, Price] = crrsens(CRRTree, CRRInstSet);
```

You can conveniently examine the sensitivities and the prices by arranging them into a single matrix.

```
format bank
All = [Delta, Gamma, Vega, Price]
```

```
All =

       0.59            0.04       53.45          8.29
      -0.31            0.03       67.00          2.50
       0.69            0.03       67.00         12.13
      -0.12           -0.01      -98.08          3.32
      -0.40       -45926.32       88.18          7.60
      -0.42      -112143.15      119.19         11.78
       0.60        45926.32       49.21          4.18
       0.82       112143.15       41.71          3.42
```

As with the prices, each row of the sensitivity vectors corresponds to the similarly indexed instrument in `CRRInstSet`. To view the per-dollar sensitivities, divide each dollar sensitivity by the corresponding instrument price.

```
All = [Delta ./ Price, Gamma ./ Price, Vega ./ Price, Price]
```

```
All =

       0.07         0.00         6.45         8.29
      -0.12         0.01        26.78         2.50
       0.06         0.00         5.53        12.13
      -0.04        -0.00       -29.51         3.32
      -0.05     -6041.77        11.60         7.60
      -0.04     -9522.02        10.12        11.78
       0.14     10987.98        11.77         4.18
       0.24     32771.92        12.19         3.42
```

ITT Sensitivities Example

The calling syntax for the sensitivity function is:

```
[Delta, Gamma, Vega, Price] = ittsens(ITTTree, ITTInstSet, Options)
```

Using the example data in `deriv.mat`, calculate the sensitivity of the instruments.

```
load deriv.mat
```

```
warning('off', 'fininst:itttree:Extrapolation');
[Delta, Gamma, Vega, Price] = ittsens(ITTTree, ITTInstSet);
```

You can conveniently examine the sensitivities and the prices by arranging them into a single matrix.

```
format bank
All = [Delta, Gamma, Vega, Price]
```

```
All =

          0.24          0.03         19.35          1.65
         -0.43          0.02         49.69         10.68
          0.35          0.04         12.29          2.41
         -0.07          0.00          6.73          3.23
          0.63     142945.66         38.90          0.54
          0.60      22703.21         68.92          6.18
          0.32    -142945.66         18.48          3.21
          0.67     -22703.21         17.75          6.61
```

As with the prices, each row of the sensitivity vectors corresponds to the similarly indexed instrument in `ITTInstSet`.

Note In this example, the extrapolation warnings are turned off before calculating the sensitivities to avoid displaying many warnings on the Command Window as the sensitivities are calculated.

If the extrapolation warnings are turned on

```
warning('on', 'fininst:itttree:Extrapolation');
```

and `ittsens` is rerun, the extrapolation warnings scroll as the command executes:

```
[Delta, Gamma, Vega, Price] = ittsens(ITTTree, ITTInstSet)
```

```
Warning: The option set specified in StockOptSpec was too narrow for the
generated tree.
This made extrapolation necessary. Below is a list of the options that were
```

```
outside of the
range of those specified in StockOptSpec.

Vega =

         19.35
         49.69
         12.29
          6.73
         38.90
         68.92
         18.48
         17.75

Price =

          1.65
         10.68
          2.41
          3.23
          0.54
          6.18
          3.21
          6.61
```

These warnings are a consequence of having to extrapolate to find the option price of the tree nodes. In this example, the set of inputs options was too narrow for the shift in the tree nodes introduced by the disturbance used to calculate the sensitivities. As a consequence extrapolation for some of the nodes was needed. Since the input data is quite close the extrapolated data, the error introduced by extrapolation is fairly low.

STT Sensitivities Example

The calling syntax for the sensitivity function is:

```
[Delta, Gamma, Vega, Price] = sttsens(STTTree, InstSet, Name, Value)
```

Using the example data in `deriv.mat`, calculate the sensitivity of the instruments.

```
load deriv.mat
[Delta, Gamma, Vega, Price] = sttsens(STTTree, STTInstSet);
```

You can conveniently examine the sensitivities and the prices by arranging them into a single matrix.

```
format bank
All = [Delta, Gamma, Vega, Price]

All =

          0.53          0.02         52.90          4.50
         -0.09          0.00         42.44          3.06
          0.47          0.03         25.98          3.80
         -0.06          0.00         -9.53          1.71
          0.23    -186495.25         70.38         11.73
          0.33    -191186.43         92.92         12.91
          0.57     186495.25         25.81          1.69
          0.66     191186.43         37.88          2.62
```

Equity Derivatives Using Closed-Form Solutions

In this section...

Introduction

Financial Instruments Toolbox supports four types of closed-form solutions and analytical approximations to calculate price and sensitivities (greeks) of vanilla options:

- Black-Scholes model
- Black model
- Roll-Geske-Whaley model
- Bjerksund-Stensland 2002 model

Black-Scholes Model

The Black-Scholes model is one of the most commonly used models to price European calls and puts. It serves as a basis for many closed-form solutions used for pricing options. The standard Black-Scholes model is based on the following assumptions:

- There are no dividends paid during the life of the option.
- The option can only be exercised at maturity.
- The markets operate under a Markov process in continuous time.
- No commissions are paid.
- The risk-free interest rate is known and constant.
- Returns on the underlying stocks are log-normally distributed.

Note The Black-Scholes model implemented in Financial Instruments Toolbox software allows dividends. The following three dividend methods are supported:

- Cash dividend

- Continuous dividend yield
- Constant dividend yield

However, not all Black-Scholes closed-form pricing functions support all three dividend methods. For more information on specifying the dividend methods, see `stockspec`.

Closed-form solutions based on a Black-Scholes model support the following tasks.

Task	Function
Price European options with different dividends using the Black-Scholes option pricing model.	`optstockbybls`
Calculate European option prices and sensitivities using the Black-Scholes option pricing model.	`optstocksensbybls`
Calculate implied volatility on European options using the Black-Scholes option pricing model.	`impvbybls`
Price European simple chooser options using Black-Scholes model.	`chooserbybls`

For an example using the Black-Scholes model, see “Pricing Using the Black-Scholes Model” on page 3-82.

Black Model

Use the Black model for pricing European options on physical commodities, forwards or futures. The Black model supported by Financial Instruments Toolbox software is a special case of the Black-Scholes model. The Black model uses a forward price as an underlier in place of a spot price. The assumption is that the forward price at maturity of the option is log-normally distributed.

Closed-form solutions for a Black model support the following tasks.

Task	Function
Price European options on futures using the Black option pricing model.	`optstockbyblk`
Calculate European option prices and sensitivities on futures using the Black option pricing model.	`optstocksensbyblk`
Calculate implied volatility for European options using the Black option pricing model.	`impvbyblk`

For an example using the Black model, see “Pricing Using the Black Model” on page 3-83.

Roll-Geske-Whaley Model

Use the Roll-Geske-Whaley approximation method to price American call options paying a single cash dividend. This model is based on the modification of the observed stock price for the present value of the dividend and also supports a compound option to account for the possibility of early exercise. The Roll-Geske-Whaley model has drawbacks due to an escrowed dividend price approach which may lead to arbitrage. For further explanation, see *Options, Futures, and Other Derivatives* by John Hull.

Closed-form solutions for a Roll-Geske-Whaley model support the following tasks.

Task	Function
Price American call options with a single cash dividend using the Roll-Geske-Whaley option pricing model.	`optstockbyrgw`
Calculate American call prices and sensitivities using the Roll-Geske-Whaley option pricing model.	`optstocksensbyrgw`
Calculate implied volatility for American call options using the Roll-Geske-Whaley option pricing model.	`impvbyrgw`

For an example using the Roll-Geske-Whaley model, see “Pricing Using the Roll-Geske-Whaley Model” on page 3-84.

Bjerksund-Stensland 2002 Model

Use the Bjerksund-Stensland 2002 model for pricing American puts and calls with continuous dividend yield. This model works by dividing the time to maturity of the option in two separate parts, each with its own flat exercise boundary (trigger price). The Bjerksund-Stensland 2002 method is a generalization of the Bjerksund and Stensland 1993 method and is considered to be computationally efficient. For further explanation, see *Closed Form Valuation of American Options* by Bjerksund and Stensland.

Closed-form solutions for a Bjerksund-Stensland 2002 model support the following tasks.

Task	Function
Price American options with continuous dividend yield using the Bjerksund-Stensland 2002 option pricing model.	`optstockbybjs`
Calculate American options prices and sensitivities using the Bjerksund-Stensland 2002 option pricing model.	`optstocksensbybjs`
Calculate implied volatility for American options using the Bjerksund-Stensland 2002 option pricing model.	`impvbybjs`

For an example using the Bjerksund-Stensland 2002 model, see “Pricing Using the Bjerksund-Stensland Model” on page 3-84.

Barone-Adesi-Whaley Model

The Barone-Adesi-Whaley model is used for pricing American vanilla options. Closed-form solutions for a Barone-Adesi-Whaley model support the following tasks.

Task	Function
Calculate the prices of an American call and put options using the Barone-Adesi-Whaley approximation model.	`optstockbybaw`
Calculate the prices and sensitivities of an American call and put options using the Barone-Adesi-Whaley approximation model.	`optstocksensbybaw`
Calculate the implied volatility for American options using the Barone-Adesi-Whaley model.	`impvbybaw`

For an example using the Barone-Adesi-Whaley model, see “Compute American Option Prices Using the Barone-Adesi and Whaley Option Pricing Model” on page 3-86.

Pricing Using the Black-Scholes Model

Consider a European stock option with an exercise price of $40 on January 1, 2008 that expires on July 1, 2008. Assume that the underlying stock pays dividends of $0.50 on March 1 and June 1. The stock is trading at $40 and has a volatility of 30% per annum. The risk-free rate is 4% per annum. Using this data, calculate the price of a call and a put option on the stock using the Black-Scholes option pricing model:

```
Strike = 40;
AssetPrice = 40;
Sigma = .3;
Rates = 0.04;
Settle = 'Jan-01-08';
Maturity = 'Jul-01-08';

Div1 = 'March-01-2008';
Div2 = 'Jun-01-2008';
```

Create `RateSpec` and `StockSpec`:

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates',...
Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(Sigma, AssetPrice, {'cash'}, 0.50,{Div1,Div2});
```

Define two options, one call and one put:

```
OptSpec = {'call'; 'put'};
```

Calculate the price of the European options:

```
Price = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price =

    3.2063
    3.4027
```

The first element of the `Price` vector represents the price of the call ($3.21); the second is the price of the put ($3.40). Use the function `optstocksensbybls` to compute six sensitivities for the Black-Scholes model: `delta`, `gamma`, `vega`, `lambda`, `rho`, and `theta` and the `price` of the option.

The selection of output parameters and their order is determined by the optional input parameter `OutSpec`. This parameter is a cell array of character vectors, each one specifying a desired output parameter. The order in which these output parameters are returned by the function is the same as the order of the character vectors contained in `OutSpec`.

As an example, consider the same options as the previous example. To calculate their `Delta`, `Rho`, `Price`, and `Gamma`, build the cell array `OutSpec` as follows:

```
OutSpec = {'delta', 'rho', 'price', 'gamma'};

[Delta, Rho, Price, Gamma] = optstocksensbybls(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike, 'OutSpec', OutSpec)
```

```
Delta =

    0.5328
   -0.4672
```

```
Rho =

    8.7902
  -10.8138

Price =

    3.2063
    3.4027

Gamma =

    0.0480
    0.0480
```

Pricing Using the Black Model

Consider two European call options on a futures contract with exercise prices of $20 and $25 that expire on September 1, 2008. Assume that on May 1, 2008 the contract is trading at $20 and has a volatility of 35% per annum. The risk-free rate is 4% per annum. Using this data, calculate the price of the call futures options using the Black model:

```
Strike = [20; 25];
AssetPrice = 20;
Sigma = .35;
Rates = 0.04;
Settle = 'May-01-08';
Maturity = 'Sep-01-08';
```

Create `RateSpec` and `StockSpec`:

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', -1);

StockSpec = stockspec(Sigma, AssetPrice);
```

Define the call option:

```
OptSpec = {'call'};
```

Calculate price and all sensitivities of the European futures options:

```
OutSpec = {'All'}

[Delta, Gamma, Vega, Lambda, Rho, Theta, Price] = optstocksensbyblk(RateSpec,...
StockSpec, Settle, Maturity, OptSpec, Strike, 'OutSpec', OutSpec);
```

```
Price =

    1.5903
    0.3037
```

The first element of the `Price` vector represents the price of the call with an exercise price of $20 ($1.59); the second is the price of the call with an exercise price of $25 ($2.89).

The function `impvbyblk` is used to compute the implied volatility using the Black option pricing model. Assuming that the previous European call futures are trading at $1.5903 and $0.3037, you can calculate their implied volatility:

```
Volatility = impvbyblk(RateSpec, StockSpec, Settle, Maturity,...
OptSpec,  Strike, Price);
```

As expected, you get volatilities of 35%. If the call futures were trading at $1.50 and $0.50 in the market, the implied volatility would be 33% and 42%:

```
Volatility = impvbyblk(RateSpec, StockSpec, Settle, Maturity,...
OptSpec,  Strike, [1.50;0.5])

Volatility =

    0.3301
    0.4148
```

Pricing Using the Roll-Geske-Whaley Model

Consider two American call options, with exercise prices of $110 and $100 on June 1, 2008, that expire on June 1, 2009. Assume that the underlying stock pays dividends of $0.001 on December 1, 2008. The stock is trading at $80 and has a volatility of 20% per annum. The risk-free rate is 6% per annum. Using this data, calculate the price of the American calls using the Roll-Geske-Whaley option pricing model:

```
AssetPrice = 80;
Settle = 'Jun-01-2008';
Maturity = 'Jun-01-2009';
Strike = [110; 100];

Rate = 0.06;
Sigma  = 0.2;

DivAmount = 0.001;
DivDate = 'Dec-01-2008';
```

Create `RateSpec` and `StockSpec`:

```
StockSpec = stockspec(Sigma, AssetPrice, {'cash'}, DivAmount, DivDate);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1);
```

Calculate the call prices:

```
Price  = optstockbyrgw(RateSpec, StockSpec, Settle, Maturity, Strike)

Price =

    0.8398
    2.0236
```

The first element of the `Price` vector represents the price of the call with an exercise price of $110 ($0.84); the second is the price of the call with an exercise price of $100 ($2.02).

Pricing Using the Bjerksund-Stensland Model

Consider four American stock options (two calls and two puts) with an exercise price of $100 that expire on July 1, 2008. Assume that the underlying stock pays a continuous dividend yield of 4% as of January 1, 2008. The stock has a volatility of 20% per annum and the risk-free rate is 8% per annum.

Using this data, calculate the price of the American calls and puts assuming the following current prices of the stock: $80, $90 (for the calls) and $100 and $110 (for the puts):

```
Settle = 'Jan-1-2008';
Maturity = 'Jul-1-2008';
Strike = 100;
AssetPrice = [80; 90; 100; 110];
DivYield = 0.04;

Rate = 0.08;
Sigma = 0.20;
```

Create `RateSpec` and `StockSpec`:

```
StockSpec = stockspec(Sigma, AssetPrice, {'continuous'}, DivYield);

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the option type:

```
OptSpec = {'call'; 'call'; 'put'; 'put'};
```

Compute the option prices:

```
Price = optstockbybjs(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price =

    0.4144
    2.1804
    4.7253
    1.7164
```

The first two elements of the `Price` vector represent the price of the calls ($0.41 and $2.18), the last two elements represent the price of the put options ($4.72 and $1.72). Use the function `optstocksensbybjs` to compute six sensitivities for the Bjerksund-Stensland model: `delta`, `gamma`, `vega`, `lambda`, `rho`, and `theta` and the `price` of the option. The selection of output parameters and their order is determined by the optional input parameter `OutSpec`. This parameter is a cell array of character vectors, each one specifying a desired output parameter. The order in which these output parameters are returned by the function is the same as the order of the character vectors contained in `OutSpec`. As an example, consider the same options as the previous example. To calculate their `delta`, `gamma`, and `price`, build the cell array `OutSpec` as follows:

```
OutSpec = {'delta', 'gamma', 'price'};
```

The outputs of `optstocksensbybjs` are in the same order as in `OutSpec`.

```
[Delta, Gamma, Price] = optstocksensbybjs(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike, 'OutSpec', OutSpec)
```

```
Delta =

    0.0843
    0.2912
    0.4803
    0.2261

Gamma =
```

```
    0.0136
    0.0267
    0.0304
    0.0217

Price =

    0.4144
    2.1804
    4.7253
    1.7164
```

For more information on the Bjerksund-Stensland model, see “Closed-Form Solutions Modeling” on page B-3.

Compute American Option Prices Using the Barone-Adesi and Whaley Option Pricing Model

Consider an American call option with an exercise price of $120. The option expires on Jan 1, 2018. The stock has a volatility of 14% per annum, and the annualized continuously compounded risk-free rate is 4% per annum as of Jan 1, 2016. Using this data, calculate the price of the American call, assuming the price of the stock is $125 and pays a dividend of 2%.

```
StartDate  = datetime(2016,1,1);
EndDate = datetime(2018,1,1);
Basis = 1;
Compounding = -1;
Rates = 0.04;
```

Define the `RateSpec`.

```
RateSpec = intenvset('ValuationDate',StartDate,'StartDate',StartDate,'EndDate',EndDate, ...
'Rates',Rates,'Basis',Basis,'Compounding',Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9231
            Rates: 0.0400
         EndTimes: 2
       StartTimes: 0
         EndDates: 737061
       StartDates: 736330
    ValuationDate: 736330
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
Dividend = 0.02;
AssetPrice = 125;
Volatility = 0.14;

StockSpec = stockspec(Volatility,AssetPrice,'Continuous',Dividend)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1400
         AssetPrice: 125
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Define the American option.

```
OptSpec = 'call';
Strike = 120;
Settle = datetime(2016,1,1);
Maturity = datetime(2018,1,1);
```

Compute the price for the American option.

```
Price = optstockbybaw(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

```
Price = 14.5180
```

Pricing European Call Options Using Different Equity Models

This example illustrates how the Financial Instruments Toolbox™ is used to price European vanilla call options using different equity models.

The example compares call option prices using the Cox-Ross-Rubinstein model, the Leisen-Reimer model and the Black-Scholes closed formula.

Define the Call Instrument

Consider a European call option, with an exercise price of $30 on January 1, 2010. The option expires on Sep 1, 2010. Assume that the underlying stock provides no dividends. The stock is trading at $25 and has a volatility of 35% per annum. The annualized continuously compounded risk-free rate is 1.11% per annum.

```
% Option
Settle = 'Jan-01-2010';
Maturity = 'Sep-01-2010';
Strike = 30;
OptSpec = 'call';

% Stock
AssetPrice = 25;
Sigma = .35;
```

Create the Interest Rate Term Structure

```
StartDates = '01 Jan 2010';
EndDates =   '01 Jan 2013';
Rates = 0.0111;
ValuationDate = '01 Jan 2010';
Compounding = -1;

RateSpec = intenvset('Compounding',Compounding,'StartDates', StartDates,...
                     'EndDates', EndDates, 'Rates', Rates,'ValuationDate', ValuationDate);
```

Create the Stock Structure

Suppose we want to create two scenarios. The first one assumes that `AssetPrice` is currently $25, the option is out of the money (OTM). The second scenario assumes that the option is at the money (ATM), and therefore `AssetPriceATM = 30`.

```
AssetPriceATM = 30;

StockSpec = stockspec(Sigma, AssetPrice);
StockSpecATM = stockspec(Sigma, AssetPriceATM);
```

Price the Options Using the Black-Scholes Closed Formula

Use the function `optstockbybls` in the Financial Instruments Toolbox to compute the price of the European call options.

```
% Price the option with AssetPrice = 25
PriceBLS = optstockbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike);
```

```
% Price the option with AssetPrice = 30
PriceBLSATM = optstockbybls(RateSpec, StockSpecATM, Settle, Maturity, OptSpec, Strike);
```

Build the Cox-Ross-Rubinstein Tree

```
% Create the time specification of the tree
NumPeriods = 15;

CRRTimeSpec = crrtimespec(ValuationDate, Maturity, NumPeriods);

% Build the tree
CRRTree = crrtree(StockSpec, RateSpec, CRRTimeSpec);
CRRTreeATM = crrtree(StockSpecATM, RateSpec, CRRTimeSpec);
```

Build the Leisen-Reimer Tree

```
% Create the time specification of the tree
LRTimeSpec = lrtimespec(ValuationDate, Maturity, NumPeriods);

% Use the default method 'PP1' (Peizer-Pratt method 1 inversion)to build
% the tree
LRTree = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike);
LRTreeATM = lrtree(StockSpecATM, RateSpec, LRTimeSpec, Strike);
```

Price the Options Using the Cox-Ross-Rubinstein (CRR) Model

```
PriceCRR = optstockbycrr(CRRTree, OptSpec, Strike, Settle, Maturity);
PriceCRRATM = optstockbycrr(CRRTreeATM, OptSpec, Strike, Settle, Maturity);
```

Price the Options Using the Leisen-Reimer (LR) Model

```
PriceLR = optstockbylr(LRTree, OptSpec, Strike, Settle, Maturity);
PriceLRATM = optstockbylr(LRTreeATM, OptSpec, Strike, Settle, Maturity);
```

Compare BLS, CRR and LR Results

```
sprintf('PriceBLS: \t%f\nPriceCRR: \t%f\nPriceLR:\t%f\n', PriceBLS, ...
    PriceCRR, PriceLR)

ans =
    'PriceBLS:     1.275075
     PriceCRR:     1.294979
     PriceLR:    1.275838
     '

sprintf('\t== ATM ==\nPriceBLS ATM: \t%f\nPriceCRR ATM: \t%f\nPriceLR ATM:\t%f\n', PriceBLSATM,
    PriceCRRATM,   PriceLRATM)

ans =
    '    == ATM ==
     PriceBLS ATM:     3.497891

     '
```

Convergence of CRR and LR Models to a BLS Solution

The following tables compare call option prices using the CRR and LR models against the results obtained with the Black-Scholes formula.

While the CRR binomial model and the Black-Scholes model converge as the number of time steps gets large and the length of each step gets small, this convergence, except for at the money options, is anything but smooth or uniform.

The tables below show that the Leisen-Reimer model reduces the size of the error with even as few steps of 45.

```
Strike = 30, Asset Price = 30

-------------------------------------

#Steps LR CRR

15 3.4986 3.5539

25 3.4981 3.5314

45 3.4980 3.5165

65 3.4979 3.5108

85 3.4979 3.5077

105 3.4979 3.5058

201 3.4979 3.5020

501 3.4979 3.4996

999 3.4979 3.4987

Strike = 30, Asset Price = 25

-------------------------------------

#Steps LR CRR

15 1.2758 1.2950

25 1.2754 1.2627

45 1.2751 1.2851

65 1.2751 1.2692

85 1.2751 1.2812

105 1.2751 1.2766

201 1.2751 1.2723

501 1.2751 1.2759
```

```
999 1.2751 1.2756
```

Analyze the Effect of the Number of Periods on the Price of the Options

The following graphs show how convergence changes as the number of steps in the binomial calculation increases, as well as, the impact on convergence to changes to the stock price. Observe that the Leisen-Reimer model removes the oscillation and produces estimates close to the Black-Scholes model using only a small number of steps.

```
NPoints = 300;

% Cox-Ross-Rubinstein
NumPeriodCRR  = 5 : 1 : NPoints;
NbStepCRR     = length(NumPeriodCRR);
PriceCRR = nan(NbStepCRR, 1);
PriceCRRATM = PriceCRR;

for i = 1 : NbStepCRR
    CRRTimeSpec = crrtimespec(ValuationDate, Maturity, NumPeriodCRR(i));
    CRRT = crrtree(StockSpec, RateSpec, CRRTimeSpec);
    PriceCRR(i) = optstockbycrr(CRRT, OptSpec, Strike,ValuationDate, Maturity) ;

    CRRTATM = crrtree(StockSpecATM, RateSpec, CRRTimeSpec);
    PriceCRRATM(i) = optstockbycrr(CRRTATM, OptSpec, Strike,ValuationDate, Maturity) ;
end

% Now with Leisen-Reimer
NumPeriodLR  = 5 : 2 : NPoints;
NbStepLR     = length(NumPeriodLR);
PriceLR = nan(NbStepLR, 1);
PriceLRATM = PriceLR;

for i = 1 : NbStepLR
    LRTimeSpec = lrtimespec(ValuationDate, Maturity, NumPeriodLR(i));
    LRT = lrtree(StockSpec, RateSpec, LRTimeSpec, Strike);
    PriceLR(i) = optstockbylr(LRT, OptSpec, Strike,ValuationDate, Maturity) ;

    LRTATM = lrtree(StockSpecATM, RateSpec, LRTimeSpec, Strike);
    PriceLRATM(i) = optstockbylr(LRTATM, OptSpec, Strike,ValuationDate, Maturity) ;
end
```

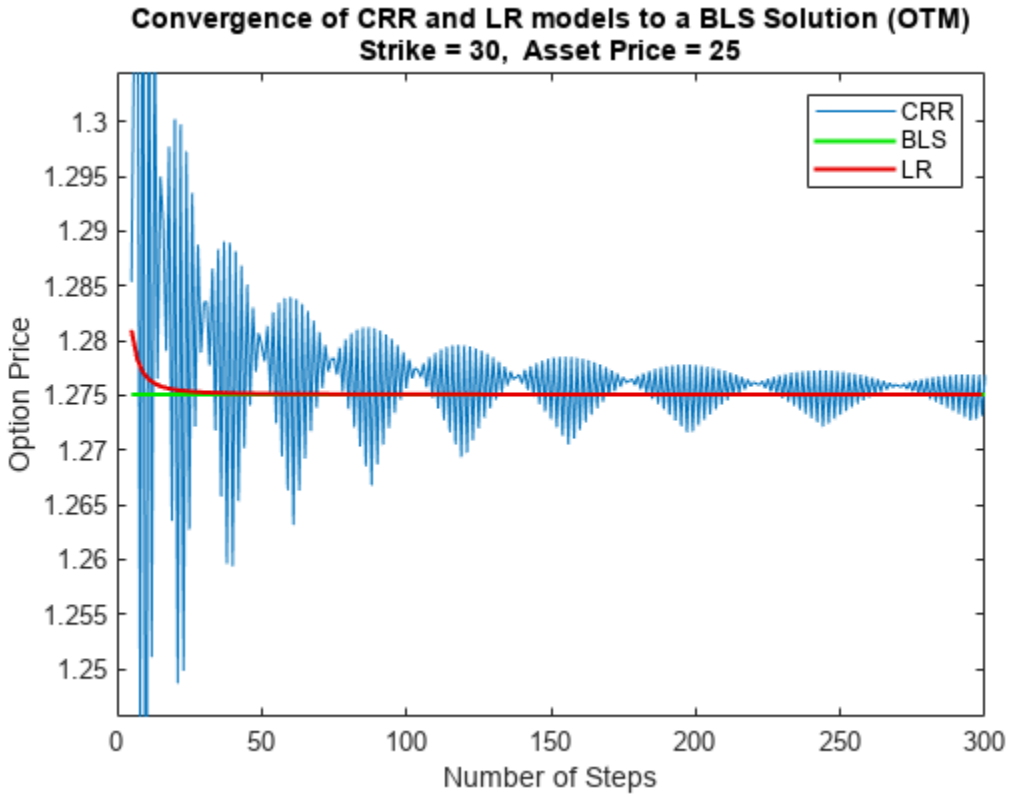
First scenario: Out of the Money call option

```
% For Cox-Ross-Rubinstein
plot(NumPeriodCRR, PriceCRR);
hold on;
plot(NumPeriodCRR, PriceBLS*ones(NbStepCRR,1),'Color',[0 0.9 0], 'linewidth', 1.5);

% For Leisen-Reimer
plot(NumPeriodLR, PriceLR, 'Color',[0.9 0 0], 'linewidth', 1.5);

% Concentrate in the area of interest by clipping on the Y axis at 5x the
% LR Price:
YLimDelta = 5*abs(PriceLR(1) - PriceBLS);
ax = gca;
ax.YLim = [PriceBLS-YLimDelta PriceBLS+YLimDelta];
```

```
% Annotate Plot
titleString = sprintf('\nConvergence of CRR and LR models to a BLS Solution (OTM)\nStrike = %d,
title(titleString)
ylabel('Option Price')
xlabel('Number of Steps')
legend('CRR', 'BLS', 'LR', 'Location', 'NorthEast')
```



Second scenario: At the Money call option

```
% For Cox-Ross-Rubinstein
figure;
plot(NumPeriodCRR, PriceCRRATM);
hold on;
plot(NumPeriodCRR, PriceBLSATM*ones(NbStepCRR,1),'Color',[0 0.9 0], 'linewidth', 1.5);

% For Leisen-Reimer
plot(NumPeriodLR, PriceLRATM, 'Color',[0.9 0 0], 'linewidth', 1.5);

% Concentrate in the area of interest by clipping on the Y axis at 5x the
% LR Price:
YLimDelta = 5*abs(PriceLRATM(1) - PriceBLSATM);
ax = gca;
ax.YLim = [PriceBLSATM-YLimDelta PriceBLSATM+YLimDelta];
% Annotate Plot

Compute the Option Price on a Future

Consider a call European option on the Crude Oil Brent futures. The option expires on December 1, 2014 with an exercise price of $120. Assume that on April 1, 2014 futures price is at $105, the annualized continuously compounded risk-free rate is 3.5% per annum and volatility is 22% per annum. Using this data, compute the price of the option.

Define the `RateSpec`.

```
ValuationDate = datetime(2014,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.035;
Compounding = -1;
Basis = 1;
RateSpec  = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate,...
'EndDates', EndDates, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis')
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 735965
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 105;
Sigma = 0.22;
StockSpec  = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2200
         AssetPrice: 105
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the option.

```
Settle = datetime(2014,4,1);
Maturity = datetime(2014,12,1);
Strike = 120;
OptSpec = {'call'};
```

Price the futures call option.

```
Price = optstockbyblk(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Price = 2.5847
```

Pricing European and American Spread Options

This example shows how to price and calculate sensitivities for European and American spread options using various techniques. First, the price and sensitivities for a European spread option is calculated using closed form solutions. Then, price and sensitivities for an American spread option is calculated using finite difference and Monte Carlo simulations. Finally, further analysis is conducted on spread options with a different range of inputs.

Spread options are options on the difference of two underlying asset prices. For example, a call option on the spread between two assets has the following payoff at maturity:

$$max(X_1 - X_2 - K, 0)$$

where X_1 is the price of the first underlying asset, X_2 is the price of the second underlying asset, and K is the strike price. At maturity, if the spread $X_1 - X_2$ is greater than the strike price K, the option holder exercises the option and gains the difference between the spread and the strike price. If the spread is less than 0, the option holder does not exercise the option, and the payoff is 0. Spread options are frequently traded in the energy market. Two examples are:

- *Crack spreads*: Options on the spread between refined petroleum products and crude oil. The spread represents the refinement margin made by the oil refinery by "cracking" the crude oil into a refined petroleum product.
- *Spark spreads*: Options on the spread between electricity and some type of fuel. The spread represents the margin of the power plant, which takes fuel to run its generator to produce electricity.

Overview of the Pricing Methods

There are several methods to price spread options, as discussed in [1 on page 3-107]. This example uses the closed form, finite difference, and Monte Carlo simulations to price spread options. The advantages and disadvantages of each method are discussed below:

- Closed form solutions and approximations of partial differential equations (PDE) are advantageous because they are very fast, and extend well to computing sensitivities (Greeks). However, closed form solutions are not always available, for example for American spread options.
- The finite difference method is a numerical procedure to solve PDEs by discretizing the price and time variables into a grid. A detailed analysis of this method can be found in [2 on page 3-107]. It can handle cases where closed form solutions are not available. Also, finite difference extends well to calculating sensitivities because it outputs a grid of option prices for a range of underlying prices and times. However, it is slower than the closed form solutions.
- Monte Carlo simulation uses random sampling to simulate movements of the underlying asset prices. It handles cases where closed solutions do not exist. However, it usually takes a long time to run, especially if sensitivities are calculated.

Pricing a European Spread Option

The following example demonstrates the pricing of a crack spread option.

A refiner is concerned about its upcoming maintenance schedule and needs to protect against decreasing crude oil prices and increasing heating oil prices. During the maintenance the refiner needs to continue providing customers with heating oil to meet their demands. The refiner's strategy is to use spread options to manage its hedge.

On January 2013, the refiner buys a 1:1 crack spread option by purchasing heating oil futures and selling crude oil futures. CLF14 WTI crude oil futures is at $100 per barrel and HOF14 heating oil futures contract is at $2.6190 per gallon.

```
clear;

% Price, volatility, and dividend of heating oil
Price1gallon = 2.6190;       % $/gallon
Price1 = Price1gallon*42;    % $/barrel
Vol1 = 0.10;
Div1 = 0.03;

% Price, volatility, and dividend of WTI crude oil
Price2 = 100;     % $/barrel
Vol2 = 0.15;
Div2 = 0.02;

% Correlation of underlying prices
Corr = 0.3;

% Option type
OptSpec = 'call';

% Strike
Strike = 5;

% Settlement date
Settle = '01-Jan-2013';

% Maturity
Maturity = '01-Jan-2014';

% Risk free rate
RiskFreeRate = 0.05;
```

The pricing functions take an interest-rate term structure and stock structure as inputs. Also, you need to specify which outputs are of interest.

```
% Define RateSpec
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', RiskFreeRate, 'Compounding', ...
    Compounding, 'Basis', Basis);

% Define StockSpec for the two assets
StockSpec1 = stockspec(Vol1, Price1, 'Continuous', Div1);
StockSpec2 = stockspec(Vol2, Price2, 'Continuous', Div2);

% Specify price and sensitivity outputs
OutSpec = {'Price', 'Delta', 'Gamma'};
```

The Financial Instruments Toolbox™ contains two types of closed form approximations for calculating price and sensitivities of European spread options: the Kirk's approximation (`spreadbykirk`, `spreadsensbykirk`) and the Bjerksund and Stensland model (`spreadbybjs`, `spreadsensbybjs`) [3 on page 3-107].

The function `spreadsensbykirk` calculates prices and sensitivities for a European spread option using the Kirk's approximation.

```
% Kirk's approximation
[PriceKirk, DeltaKirk, GammaKirk] = ...
    spreadsensbykirk(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
PriceKirk = 8.3636

DeltaKirk = 1×2

    0.6108   -0.5590

GammaKirk = 1×2

    0.0225    0.0249
```

The function `spreadsensbybjs` calculates the prices and sensitivities for a European spread option using the Bjerksund and Stensland model. In [3 on page 3-107], Bjerksund and Stensland explains that the Kirk's approximation tends to underprice the spread option when the strike is close to zero, and overprice when the strike is further away from zero. In comparison, the model by Bjerksund and Stensland has higher precision.

```
% Bjerksund and Stensland model
[PriceBJS, DeltaBJS, GammaBJS] = ...
    spreadsensbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec)
```

```
PriceBJS = 8.3662

DeltaBJS = 1×2

    0.6115   -0.5597

GammaBJS = 1×2

    0.0225    0.0248
```

A comparison of the calculated prices show that the two closed form models produce similar results for price and sensitivities. In addition to delta and gamma, the functions can also calculate theta, vega, lambda, and rho.

```
displayComparison('Kirk', 'BJS', PriceKirk, PriceBJS, DeltaKirk, DeltaBJS, GammaKirk, GammaBJS)
```

```
Comparison of prices:

Kirk:    8.363641
BJS :    8.366158

Comparison of delta:

Kirk:    0.610790     -0.558959
BJS :    0.611469     -0.559670
```

```
Comparison of gamma:

Kirk:    0.022533      0.024850
BJS :    0.022495      0.024819
```

Pricing an American Spread Option

Although the closed form approximations are fast and well suited for pricing European spread options, they cannot price American spread options. Using the finite difference method and the Monte Carlo method, an American spread option can be priced. In this example, an American spread option is priced with the same attributes as the above crack spread option.

The finite difference method numerically solves a PDE by discretizing the underlying price and time variables into a grid. The Financial Instrument Toolbox™ contains the functions `spreadbyfd` and `spreadsensbyfd`, which calculate prices and sensitivities for European and American spread options using the finite difference method. For the finite difference method, the composition of the grid has a large impact on the quality of the output and the execution time. Generally, a finely discretized grid will result in outputs that are closer to the theoretical value, but it comes at the cost of longer execution times. The composition of the grid is controlled using optional parameters `PriceGridSize`, `TimeGridSize`, `AssetPriceMin` and `AssetPriceMax`.

To indicate pricing an American option, add an optional input of `AmericanOpt` with a value of `1` to the argument of the function.

```
% Finite difference method for American spread option
[PriceFD, DeltaFD, GammaFD, PriceGrid, AssetPrice1, ...
    AssetPrice2] = ...
    spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec, ...
    'PriceGridSize', [500 500], 'TimeGridSize', 100, ...
    'AssetPriceMin', [0 0], 'AssetPriceMax', [2000 2000], ...
    'AmericanOpt', 1);

% Display price and sensitivities
PriceFD

PriceFD = 8.5463

DeltaFD

DeltaFD = 1×2

    0.6306   -0.5777

GammaFD

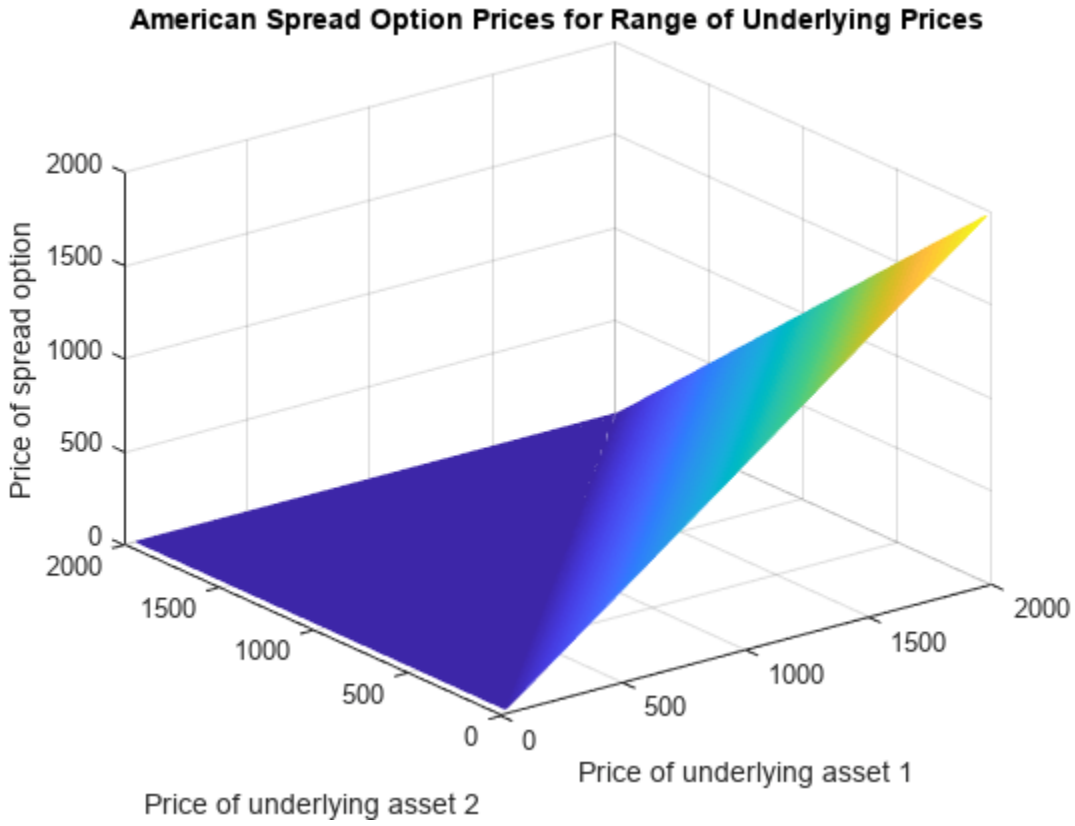
GammaFD = 1×2

    0.0233    0.0259
```

The function `spreadsensbyfd` also returns a grid that contains the option prices for a range of underlying prices and times. The grid of option prices at time zero, which is the option prices at the settle date, can be plotted for a range of underlying prices.

```
% Plot option prices
figure;
```

```
mesh(AssetPrice1, AssetPrice2, PriceGrid(:, :, 1)');
title('American Spread Option Prices for Range of Underlying Prices');
xlabel('Price of underlying asset 1');
ylabel('Price of underlying asset 2');
zlabel('Price of spread option');
```



An American style option can be priced by Monte Carlo methods using the least square method of Longstaff and Schwartz [4 on page 3-107]. The Financial Instruments Toolbox™ contains the functions `spreadbyls` and `spreadsensbyls`, that calculate prices and sensitivities of European and American options using simulations. The Monte Carlo simulation method in `spreadsensbyls` generates multiple paths of simulations according to a geometric Brownian motion (GBM) for the two underlying asset prices. Similar to the finite difference method where the granularity of the grid determined the quality of the output and the execution time, the quality of output and execution time of the Monte Carlo simulation depends on the number of paths (`NumTrials`) and the number of time periods per path (`NumPeriods`). Also, the results obtained by Monte Carlo simulations are not deterministic. Each run will have different results depending on the simulation outcomes.

```
% To indicate that we are pricing an American option using the Longstaff
% and Schwartz method, add an optional input of |AmericanOpt| with a value
% of |1| to the argument of the function.

% Monte Carlo method for American spread option
[PriceMC, DeltaMC, GammaMC] = ...
    spreadsensbyls(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec, ...
    'NumTrials', 1000, 'Antithetic', true, 'AmericanOpt', 1)
```

```
PriceMC = 8.4999

DeltaMC = 1×2

    0.6325   -0.5931

GammaMC = 1×2

   -0.0873    0.0391
```

The results of the two models are compared. The prices and sensitivities calculated by the Longstaff and Schwartz method will vary at each run, depending on the outcome of the simulations. It is important to note that the quality of the results from the finite difference method and the Monte Carlo simulation depend on the optional input parameters. For example, increasing the number of paths (`NumTrials`) for the `spreadsensbyls` function will result in more precise results at the cost of longer execution times.

```
displayComparison('Finite Difference', 'Monte Carlo', PriceFD, PriceMC, DeltaFD, DeltaMC, GammaFD
```

```
Comparison of prices:

Finite Difference:    8.546285
Monte Carlo      :    8.499894

Comparison of delta:

Finite Difference:    0.630606     -0.577686
Monte Carlo      :    0.632549     -0.593106

Comparison of gamma:

Finite Difference:    0.023273      0.025852
Monte Carlo      :   -0.087340      0.039120
```

Comparing Results for a Range of Strike Prices

As discussed earlier, the Kirk's approximation tends to overprice spread options when the strike is further away from zero. To confirm this, a spread option is priced with the same attributes as before, but for a range of strike prices.

```
% Specify outputs
OutSpec = {'Price', 'Delta'};

% Range of strike prices
Strike = [-25; -15; -5; 0; 5; 15; 25];
```

The results from the Kirk's approximation and the Bjerksund and Stensland model are compared against the numerical approximation from the finite difference method. Since `spreadsensbyfd` can only price one option at a time, it is called in a loop for each strike value. The Monte Carlo simulation (`spreadsensbyls`) with a large number of trial paths can also be used as a benchmark, but the finite difference is used for this example.

```
% Kirk's approximation
[PriceKirk, DeltaKirk] = ...
    spreadsensbykirk(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec);
```

```
% Bjerksund and Stensland model
[PriceBJS, DeltaBJS] = ...
    spreadsensbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec);

% Finite difference
PriceFD = zeros(numel(Strike), 1);
DeltaFD = zeros(numel(Strike), 2);
for i = 1:numel(Strike)
    [PriceFD(i), DeltaFD(i,:)] = ...
    spreadsensbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike(i), Corr, 'OutSpec', OutSpec, ...
    'PriceGridSize', [500 500], 'TimeGridSize', 100, ...
    'AssetPriceMin', [0 0], 'AssetPriceMax', [2000 2000]);
end

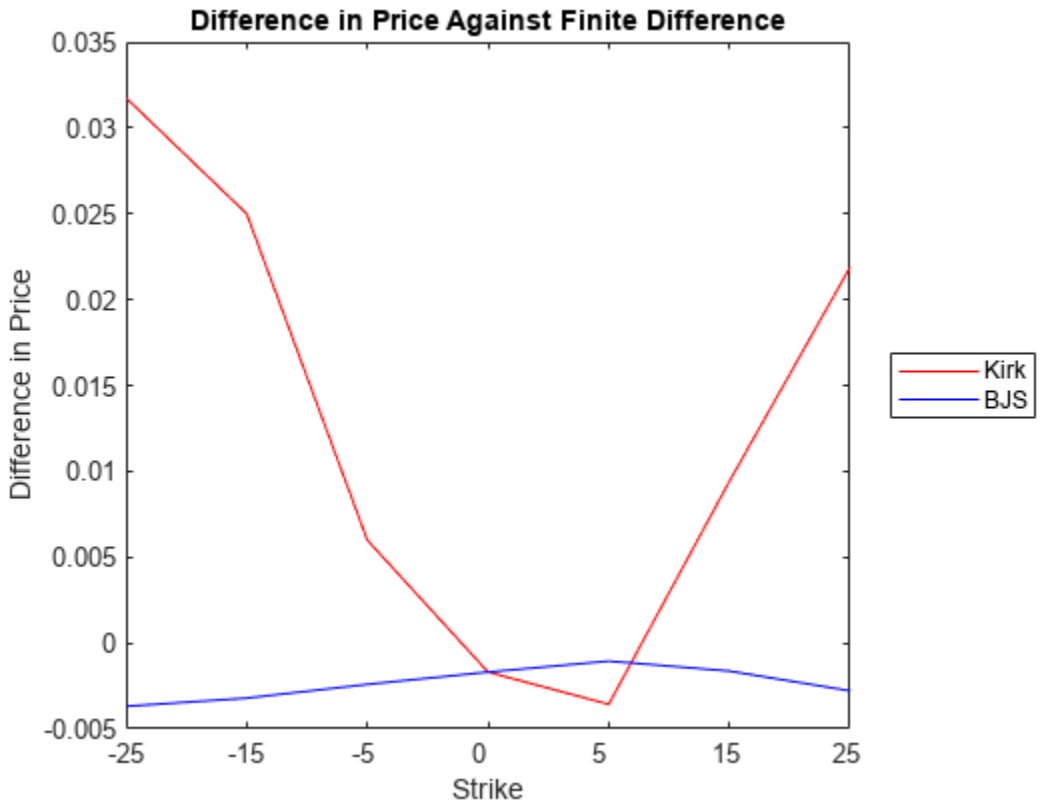
displayComparisonPrices(PriceKirk, PriceBJS, PriceFD, Strike)
```

```
Prices for range of strikes:

Kirk         BJS          FD
32.707787    32.672353    32.676040
23.605307    23.577099    23.580307
15.236908    15.228510    15.230919
11.560332    11.560332    11.562023
8.363641    8.366158    8.367212
3.689909    3.678862    3.680493
1.243753    1.219079    1.221866
```

The difference in prices between the closed form and finite difference method is plotted below. It is clear that as the strike moves further away from 0, the difference between the Kirk's approximation and finite difference (red line) increases, while the difference between the Bjerksund and Stensland model and finite difference (blue line) stays at the same level. As stated in [3 on page 3-107], the Kirk's approximation is overpricing the spread option when the strike is far away from 0.

```
% Plot of difference in price against the benchmark
figure;
plot(PriceKirk-PriceFD, 'Color', 'red');
hold on;
plot(PriceBJS-PriceFD, 'Color', 'blue');
hold off;
title('Difference in Price Against Finite Difference');
legend('Kirk', 'BJS', 'Location', 'EastOutside');
xlabel('Strike');
ax = gca;
ax.XTickLabel = Strike;
ylabel('Difference in Price');
```

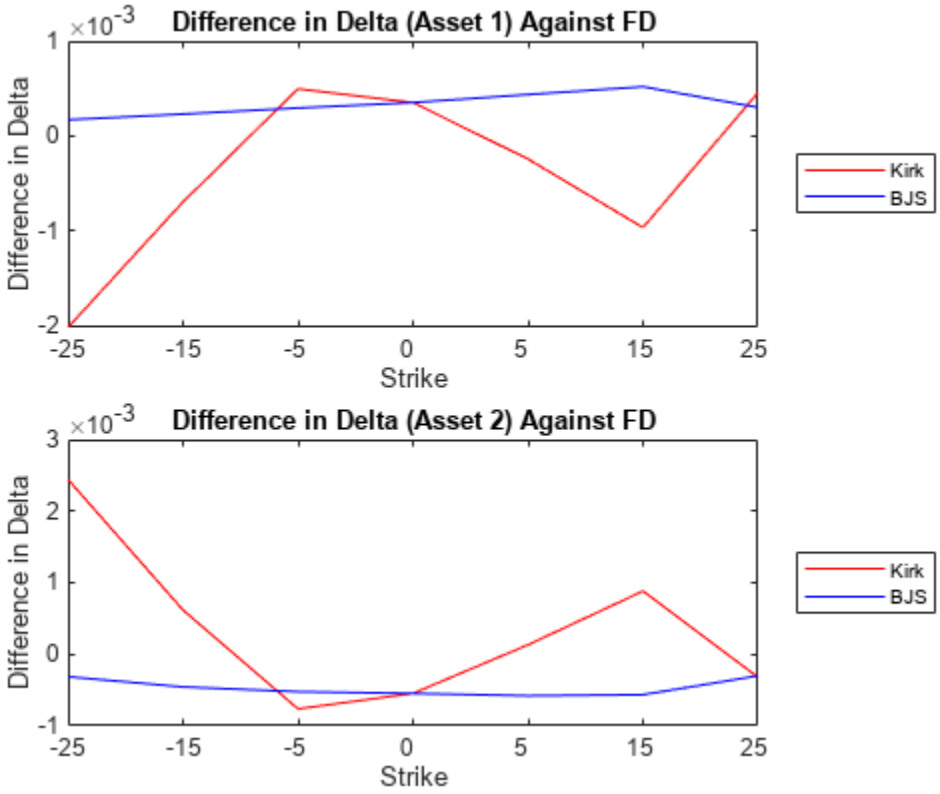


Next, the difference in delta between the closed form models and finite difference is plotted. The top plot shows the difference in delta for the first asset, and the bottom plot shows the difference in delta for the second asset. As seen from the small increments in the y-axis of the order 10e-3, it can be seen that all three models (Kirk, BJS, finite difference) produce similar values for delta.

```
% Plot of difference in delta of first asset against the benchmark
figure;
subplot(2, 1, 1);
plot(DeltaKirk(:,1)-DeltaFD(:,1), 'Color', 'red');
hold on;
plot(DeltaBJS(:,1)-DeltaFD(:,1), 'Color', 'blue');
hold off;
title('Difference in Delta (Asset 1) Against FD');
legend('Kirk', 'BJS', 'Location', 'EastOutside');
xlabel('Strike');
ax = gca;
ax.XTickLabel = Strike;
ylabel('Difference in Delta');

% Plot of difference in delta of second asset against the benchmark
subplot(2, 1, 2);
plot(DeltaKirk(:,2)-DeltaFD(:,2), 'Color', 'red');
hold on;
plot(DeltaBJS(:,2)-DeltaFD(:,2), 'Color', 'blue');
hold off;
title('Difference in Delta (Asset 2) Against FD');
legend('Kirk', 'BJS', 'Location', 'EastOutside');
```

```
xlabel('Strike');
ax = gca;
ax.XTickLabel = Strike;
ylabel('Difference in Delta');
```



Analyzing Prices and Vega at Different Levels of Volatility

To further show the type of analysis that can be conducted using these models, the above spread option is priced at different levels of volatility for the first asset. The price and vega are compared at three levels of volatility for the first asset: `0.1`, `0.3`, and `0.5`. The Bjerksund and Stensland model is used for this analysis.

```
% Strike
Strike = 5;

% Specify output
OutSpec = {'Price', 'Vega'};

% Different levels of volatility for asset 1
Vol1 = [0.1, 0.3, 0.5];

StockSpec1 = stockspec(Vol1, Price1, 'Continuous', Div1);

% Bjerksund and Stensland model
[PriceBJS, VegaBJS] = ...
    spreadsensbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
    Maturity, OptSpec, Strike, Corr, 'OutSpec', OutSpec);
```

```
displaySummary(Vol1, PriceBJS, VegaBJS)
```

```
Prices for different vol levels in asset 1:

8.366158
14.209112
21.795746

Asset 1 vega for different vol levels in asset 1:

15.534849
36.212192
38.794348

Asset 2 vega for different vol levels in asset 1:

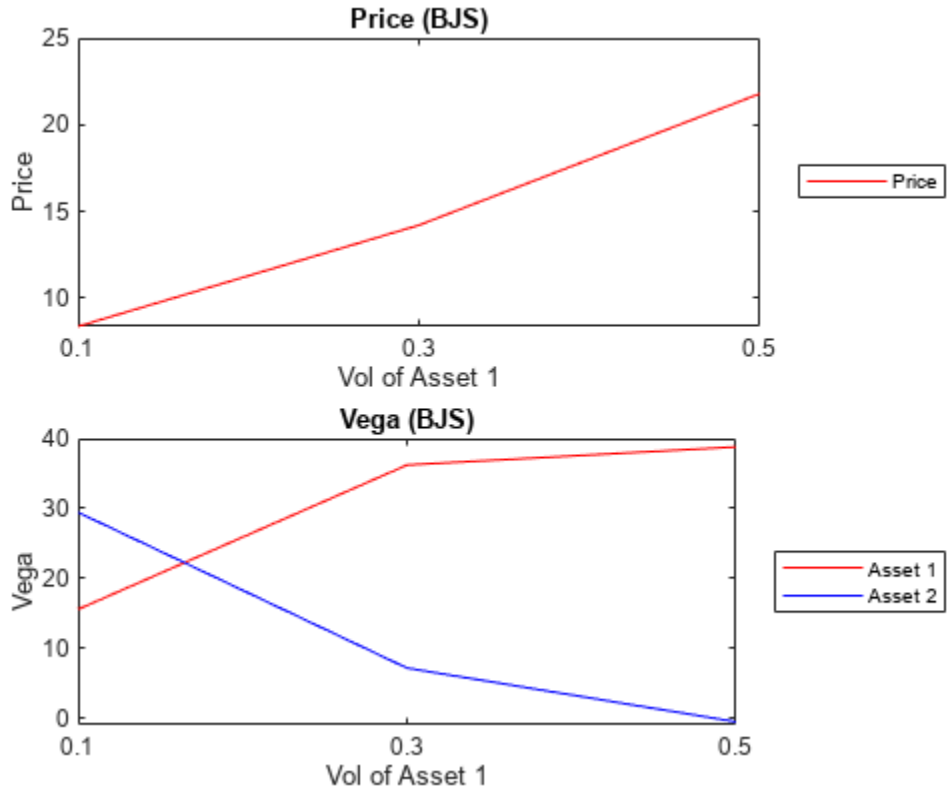
29.437036
7.133657
-0.557852
```

The change in the price and vega with respect to the volatility of the first asset is plotted below. You can observe that as the volatility of the first asset increases, the price of the spread option also increases. Also, the changes in vega indicate that the price of the spread option becomes more sensitive to the volatility of the first asset and less sensitive to the volatility of the second asset.

```
figure;

% Plot price for BJS model
subplot(2, 1, 1);
plot(PriceBJS, 'Color', 'red');
title('Price (BJS)');
legend('Price', 'Location', 'EastOutside');
xlabel('Vol of Asset 1');
ax = gca;
ax.XTick = 1:3;
ax.XTickLabel = Vol1;
ylabel('Price');

% Plot of vega for BJS model
subplot(2, 1, 2);
plot(VegaBJS(:,1), 'Color', 'red');
hold on;
plot(VegaBJS(:,2), 'Color', 'blue');
hold off;
title('Vega (BJS)');
legend('Asset 1', 'Asset 2', 'Location', 'EastOutside');
xlabel('Vol of Asset 1');
ax = gca;
ax.XTick = 1:3;
ax.XTickLabel = Vol1;
ax.YLim = [-1 40];
ylabel('Vega');
```



Summary

In this example, European and American spread options are priced and analyzed using various techniques. The Financial Instruments Toolbox™ provides functions for two types of closed form solutions (Kirk, BJS), the finite difference method, and the Monte Carlo simulation method. The closed form solutions are well suited for pricing and sensitivity calculation of European spread options because they are fast. However, they cannot price American spread options. The finite difference method and Monte Carlo method can price both European and American options. However, they are not as fast in pricing European spread options as compared to closed form solutions.

Pricing Asian Options

This example shows how to price a European Asian option using six methods in the Financial Instruments Toolbox™. This example demonstrates four closed form approximations (Kemna-Vorst, Levy, Turnbull-Wakeman, and Haug-Haug-Margrabe), a lattice model (Cox-Ross-Rubinstein), and Monte Carlo simulation. All these methods involve some tradeoffs between numerical accuracy and computational efficiency. This example also demonstrates how variations in spot prices, volatility, and strike prices affect option prices on European Vanilla and Asian options.

Overview of Asian Options

Asian options are securities with payoffs that depend on the average value of an underlying asset over a specific period of time. Underlying assets can be stocks, commodities, or financial indices.

Two types of Asian options are found in the market: average price options and average strike options. Average price options have a fixed strike value and the average used is the asset price. Average strike options have a strike equal to the average value of the underlying asset.

The payoff at maturity of an average price European Asian option is:

$max(0, Savg - K)$ for a call

$max(0, K - Savg)$ for a put

The payoff at maturity of an average strike European Asian option is:

$max(0, St - Savg)$ for a call

$max(0, Savg - St)$ for a put

where $Savg$ is the average price of underlying asset, St is the price at maturity of underlying asset, and K is the strike price.

The average can be arithmetic or geometric.

Pricing Asian Options Using Closed Form Approximations

The Financial Instruments Toolbox™ supports four closed form approximations for European Average Price options. The Kemna-Vorst method is based on the geometric mean of the price of the underlying during the life of the option [1]. The Levy and Turnbull-Wakeman models provide a closed form pricing solution to continuous arithmetic averaging options [2,3 on page 3-120]. The Haug-Haug-Margrabe approximation is used for pricing discrete arithmetic averaging options [4].

All the pricing functions `asianbykv`, `asianbylevy`, `asianbytw`, and `asianbyhhm` take an interest-rate term structure and stock structure as inputs.

Consider the following example:

```
% Create RateSpec from the interest rate term structure
StartDates = '12-March-2014';
EndDates = '12-March-2020';
Rates = 0.035;
Compounding = -1;
Basis = 1;
```

```
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
    'EndDates', EndDates, 'Rates', Rates, 'Compounding', ...
    Compounding, 'Basis', Basis);

% Define StockSpec with the underlying asset information
Sigma = 0.20;
AssetPrice = 100;

StockSpec = stockspec(Sigma, AssetPrice);

% Define the Asian option
Settle = '12-March-2014';
ExerciseDates = '12-March-2015';
Strike = 90;
OptSpec = 'call';

% Kemna-Vorst closed form model
PriceKV = asianbykv(RateSpec, StockSpec, OptSpec, Strike, Settle,...
    ExerciseDates);

% Levy model approximation
PriceLevy = asianbylevy(RateSpec, StockSpec, OptSpec, Strike, Settle,...
    ExerciseDates);

% Turnbull-Wakeman approximation
PriceTW = asianbytw(RateSpec, StockSpec, OptSpec, Strike, Settle,...
    ExerciseDates);

% Haug-Haug-Margrabe approximation
PriceHHM = asianbyhhm(RateSpec, StockSpec, OptSpec, Strike, Settle,...
    ExerciseDates);

% Comparison of calculated prices for the geometric and arithmetic options
% using different closed form algorithms.
displayPricesClosedForm(PriceKV, PriceLevy, PriceTW, PriceHHM)

Comparison of Asian Arithmetic and Geometric Prices:

Kemna-Vorst:        11.862580
Levy:               12.164734
Turnbull-Wakeman:   12.164734
Haug-Haug-Margrabe: 12.108746
```

Computing Asian Options Prices Using the Cox-Ross-Rubinstein Model

In addition to closed form approximations, the Financial Instruments Toolbox™ supports pricing European Average Price options using CRR trees via the function `asianbycrr`.

The lattice pricing function `asianbycrr` takes an interest-rate tree (`CRRTree`) and stock structure as inputs. You can price the previous options by building a `CRRTree` using the interest-rate term structure and stock specification from the example above.

```
% Create the time specification of the tree
NPeriods = 20;
TreeValuationDate = '12-March-2014';
TreeMaturity = '12-March-2024';
TimeSpec = crrtimespec(TreeValuationDate, TreeMaturity, NPeriods);
```

```
% Build the tree
CRRTree =  crrtree(StockSpec, RateSpec, TimeSpec);

% Price the European Asian option using the CRR lattice model.
% The function 'asianbycrr' computes prices of arithmetic and geometric
% Asian options.
AvgType = {'arithmetic';'geometric'};
AmericanOpt = 0;
PriceCRR20 = asianbycrr(CRRTree, OptSpec, Strike, Settle, ExerciseDates,...
                        AmericanOpt, AvgType);

% Increase the numbers of periods in the tree and compare results
NPeriods = 40;
TimeSpec = crrtimespec(TreeValuationDate, TreeMaturity, NPeriods);
CRRTree =  crrtree(StockSpec, RateSpec, TimeSpec);

PriceCRR40 = asianbycrr(CRRTree, OptSpec, Strike, Settle, ExerciseDates,...
                        AmericanOpt, AvgType);

% Display prices
displayPricesCRR(PriceCRR20, PriceCRR40)

Asian Prices using the CRR lattice model:

PriceArithmetic(CRR20): 11.934380
PriceArithmetic(CRR40): 12.047243
PriceGeometric (CRR20): 11.620899
PriceGeometric (CRR40): 11.732037
```

The results above compare the findings from calculating both geometric and arithmetic Asian options, using CRR trees with 20 and 40 levels. As the number of levels increases, the results approach the closed form solutions.

Calculating Prices of Asian Options Using Monte Carlo Simulation

Another method to price European Average Price options with the Financial Instruments Toolbox™ is via Monte Carlo simulations.

The pricing function `asianbyls` takes an interest-rate term structure and stock structure as inputs. The output and execution time of the Monte Carlo simulation depends on the number of paths (`NumTrials`) and the number of time periods per path (`NumPeriods`).

You can price the same options of previous examples using Monte Carlo.

```
% Simulation Parameters
NumTrials = 500;
NumPeriods = 200;

% Price the arithmetic option
PriceAMC = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                     ExerciseDates,'NumTrials', NumTrials, ...
                     'NumPeriods', NumPeriods);

% Price the geometric option
PriceGMC = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                     ExerciseDates,'NumTrials', NumTrials, ...
                     'NumPeriods', NumPeriods, 'AvgType', AvgType(2));
```

```
% Use the antithetic variates method to value the options
Antithetic = true;
PriceAMCAntithetic = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                    ExerciseDates,'NumTrials', NumTrials, 'NumPeriods',...
                    NumPeriods, 'Antithetic', Antithetic);

PriceGMCAntithetic = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                    ExerciseDates,'NumTrials', NumTrials, 'NumPeriods',...
                    NumPeriods, 'Antithetic', Antithetic,'AvgType', AvgType(2));

% Display prices
displayPricesMonteCarlo(PriceAMC, PriceAMCAntithetic, PriceGMC, PriceGMCAntithetic)

Asian Prices using Monte Carlo Method:

Arithmetic Asian
Standard Monte Carlo:           12.304046
Variate Antithetic Monte Carlo: 12.304046

Geometric Asian
Standard Monte Carlo:           12.048434
Variate Antithetic Monte Carlo: 12.048434
```

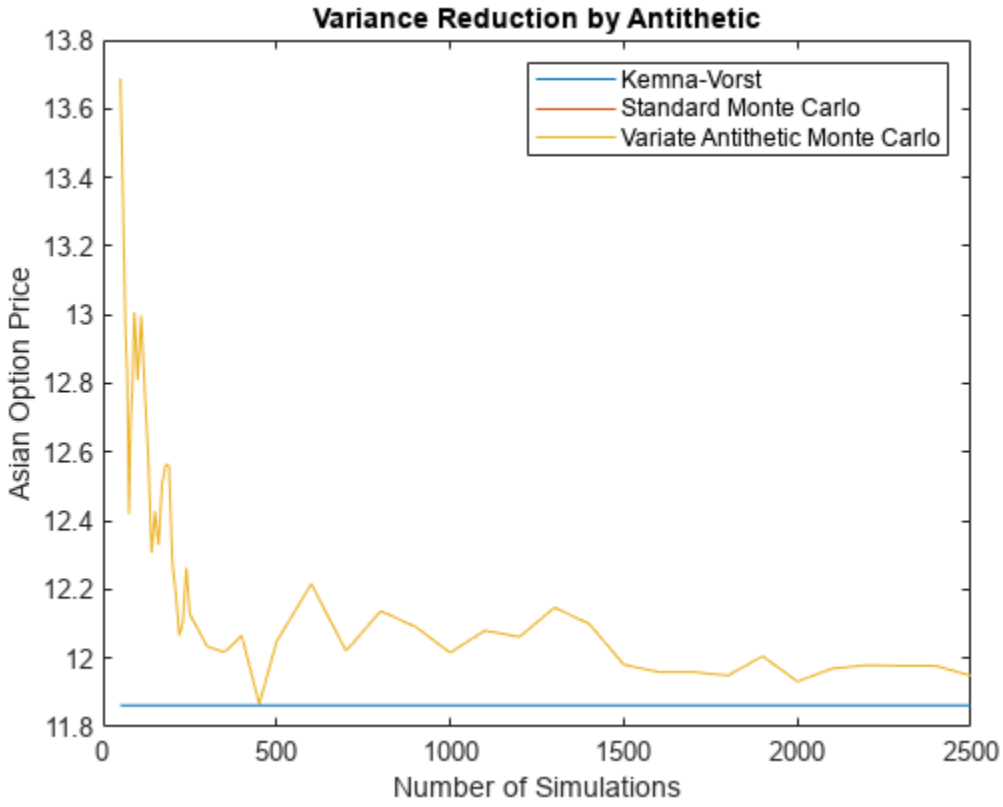
The use of variate antithetic accelerates the conversion process by reducing the variance.

You can create a plot to display the difference between the geometric Asian price using the Kemna-Vorst model, standard Monte Carlo, and antithetic Monte Carlo.

```
nTrials = [50:5:100 110:10:250 300:50:500 600:100:2500]';
PriceKVVector = PriceKV * ones(size(nTrials));
PriceGMCVector = nan(size(nTrials));
PriceGMCAntitheticVector = nan(size(nTrials));
TimeGMCAntitheticVector = nan(length(nTrials),1);
TimeGMCVector = nan(length(nTrials),1);
idx = 1;
for iNumTrials = nTrials'
    PriceGMCVector(idx) = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                        ExerciseDates,'NumTrials', iNumTrials, 'NumPeriods',...
                        NumPeriods,'AvgType', AvgType(2));

    PriceGMCAntitheticVector(idx) = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                        ExerciseDates,'NumTrials', iNumTrials, 'NumPeriods',...
                        NumPeriods, 'Antithetic', Antithetic,'AvgType', AvgType(2));
    idx = idx+1;
end

figure('menubar', 'none', 'numbertitle', 'off')
plot(nTrials, [PriceKVVector PriceGMCVector PriceGMCAntitheticVector]);
title 'Variance Reduction by Antithetic'
xlabel 'Number of Simulations'
ylabel 'Asian Option Price'
legend('Kemna-Vorst', 'Standard Monte Carlo', 'Variate Antithetic Monte Carlo ', 'location', 'no
```



The graph above shows how oscillation in simulated price is reduced by using variate antithetic.

Compare Pricing Model Results

Prices calculated by the Monte Carlo method varies depending on the outcome of the simulations. Increase `NumTrials` and analyze the results.

```
NumTrials = 2000;

PriceAMCAntithetic2000 = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates,.
         'NumTrials', NumTrials, 'NumPeriods', NumPeriods, 'Antithetic', Antithetic);

PriceGMCAntithetic2000 = asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                    ExerciseDates,'NumTrials', NumTrials, 'NumPeriods',...
                    NumPeriods, 'Antithetic', Antithetic,'AvgType', AvgType(2));

% Comparison of calculated Asian call prices
displayComparisonAsianCallPrices(PriceLevy, PriceTW, PriceHHM, PriceCRR40, PriceAMCAntithetic, P

Comparison of Asian call prices:

Arithmetic Asian
Levy:                     12.164734
Turnbull-Wakeman:         12.164734
Haug-Haug-Margrabe:       12.108746
Cox-Ross-Rubinstein:      12.047243
Monte Carlo(500 trials):  12.304046
Monte Carlo(2000 trials): 12.196848
```

```
Geometric Asian
Kemna-Vorst:              11.862580
Cox-Ross-Rubinstein:      11.732037
Monte Carlo(500 trials):  12.048434
Monte Carlo(2000 trials): 11.932017
```

The table above contrasts the results from closed approximation models against price simulations implemented via CRR trees and Monte Carlo.

Asian and Vanilla Call Options

Asian options are popular instruments since they tend to be less expensive than comparable Vanilla calls and puts. This is because the volatility in the average value of an underlier tends to be lower than the volatility of the value of the underlier itself.

The Financial Instruments Toolbox™ supports several algorithms for pricing vanilla options. Let us compare the price of Asian options against their Vanilla counterpart.

First, compute the price of a European Vanilla Option using the Black Scholes model.

```
PriceBLS = optstockbybls(RateSpec, StockSpec, Settle, ExerciseDates,...
                         OptSpec, Strike);

% Comparison of calculated call prices.
displayComparisonVanillaAsian('Prices', PriceBLS, PriceKV, PriceLevy, PriceTW, PriceHHM)

Comparison of Vanilla and Asian Prices:

Vanilla BLS:              15.743809
Asian Kemna-Vorst:        11.862580
Asian Levy:               12.164734
Asian Turnbull-Wakeman:   12.164734
Asian Haug-Haug-Margrabe: 12.108746
```

Both geometric and arithmetic Asians price lower than their Vanilla counterpart.

You can analyze options prices at different levels of the underlying asset. Using the Financial Instruments Toolbox™, it is possible to observe the effect of different parameters on the price of the options. Consider for example, the effect of variations in the price of the underlying asset.

```
StockPrices = (50:5:150)';
PriceBLS = nan(size(StockPrices));
PriceKV = nan(size(StockPrices));
PriceLevy = nan(size(StockPrices));
PriceTW = nan(size(StockPrices));
PriceHHM = nan(size(StockPrices));
idx = 1;
for So = StockPrices'
    SP = stockspec(Sigma, So);
    PriceBLS(idx) = optstockbybls(RateSpec, SP, Settle, ExerciseDates,...
                                  OptSpec, Strike);

    PriceKV(idx) = asianbykv(RateSpec, SP, OptSpec, Strike, Settle,...
                             ExerciseDates);

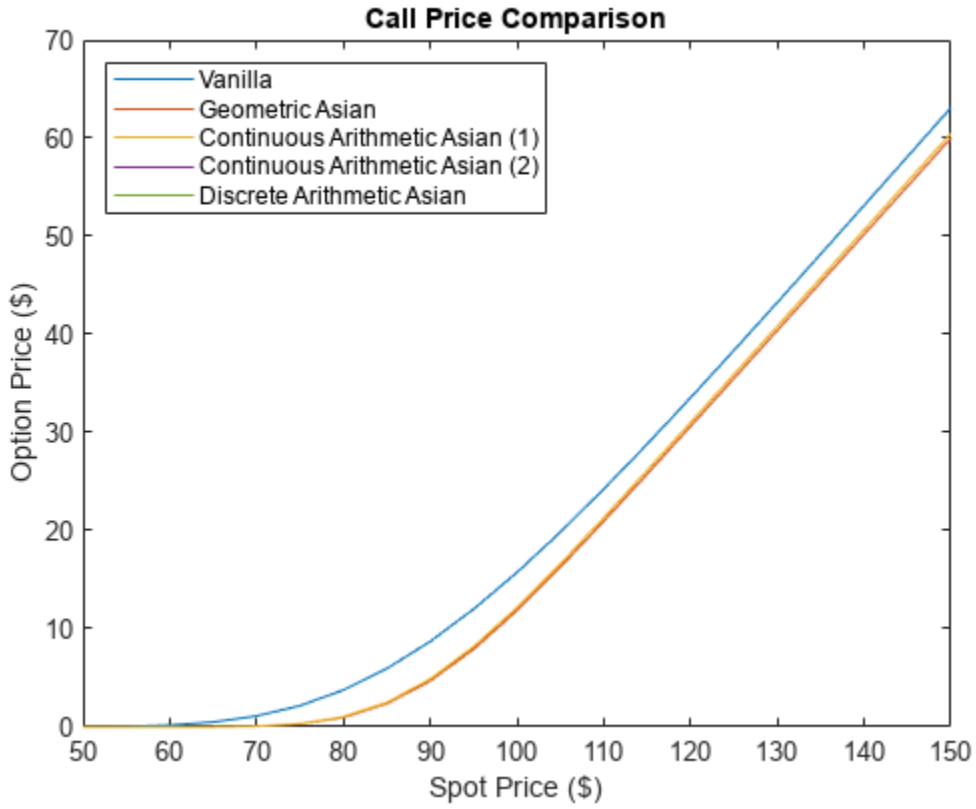
    PriceLevy(idx) = asianbylevy(RateSpec, SP, OptSpec, Strike, Settle,...
                                 ExerciseDates);
```

```
    PriceKV(idx) = asianbykv(RateSpec, SP, OptSpec, Strike, Settle,...
                             ExerciseDates);

    PriceKV(idx) = asianbykv(RateSpec, SP, OptSpec, Strike, Settle,...
                             ExerciseDates);

    idx = idx+1;
end

figure('menubar', 'none', 'numbertitle', 'off')
plot(StockPrices, [PriceBLS PriceKV PriceLevy PriceTW PriceHHM]);
xlabel 'Spot Price ($)'
ylabel 'Option Price ($)'
title 'Call Price Comparison'
legend('Vanilla', 'Geometric Asian', 'Continuous Arithmetic Asian (1)', 'Continuous Arithmetic As
```



It can be observed that the price of the Asian option is cheaper than the price of the Vanilla option.

Also, it is possible to observe the effect of changes in the volatility of the underlying asset. The table below shows what happens to Asian and Vanilla option prices when the constant volatility changes.

```
Call Option (ITM)

Strike = 90 AssetPrice = 100

------------------------------------------------------------------------------
--------
```

```
Volatility Haug-Haug-Margrabe Turnbull-Wakeman Levy Kemna-Vorst BLS

10% 11.3946 11.3987 11.3987 11.3121 13.4343

20% 12.1087 12.1647 12.1647 11.8626 15.7438

30% 13.5374 13.6512 13.6512 13.0338 18.8770

40% 15.2823 15.4464 15.4464 14.4086 22.2507
```

A comparison of the calculated prices show that Asian options are less sensitive to volatility changes, since averaging reduces the volatility of the value of the underlying asset. Also, Asian options that use arithmetic average are more expensive than those that use geometric average.

Now, examine the effect of strike on option prices.

```
Strikes = (90:5:120)';
NStrike = length(Strikes);
PriceBLS = nan(size(Strikes));
PriceKV = nan(size(Strikes));
PriceLevy = nan(size(Strikes));
PriceTW = nan(size(Strikes));
PriceHHM = nan(size(Strikes));
idx = 1;
for ST = Strikes'
    SP = stockspec(Sigma, AssetPrice);
    PriceBLS(idx) = optstockbybls(RateSpec, SP, Settle, ExerciseDates,...
                                  OptSpec, ST);

    PriceKV(idx) = asianbykv(RateSpec, SP, OptSpec, ST, Settle,...
                             ExerciseDates);

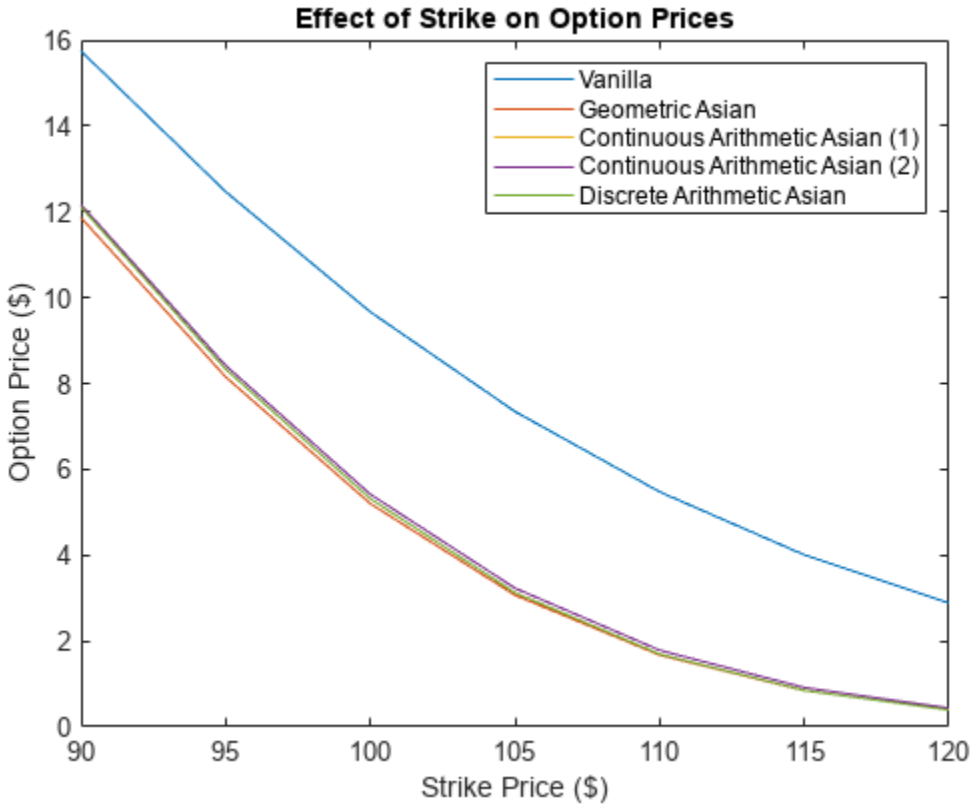
    PriceLevy(idx) = asianbylevy(RateSpec, SP, OptSpec, ST, Settle,...
                                 ExerciseDates);

    PriceTW(idx) = asianbytw(RateSpec, SP, OptSpec, ST, Settle,...
                             ExerciseDates);

    PriceHHM(idx) = asianbyhhm(RateSpec, SP, OptSpec, ST, Settle,...
                             ExerciseDates);

    idx = idx+1;
end

figure('menubar', 'none', 'numbertitle', 'off')
plot(Strikes, [PriceBLS PriceKV PriceLevy PriceTW PriceHHM]);
xlabel 'Strike Price ($)'
ylabel 'Option Price ($)'
title 'Effect of Strike on Option Prices'
legend('Vanilla', 'Geometric Asian', 'Continuous Arithmetic Asian (1)', 'Continuous Arithmetic As
```



The figure above displays the option price with respect to strike price. Since call option value decreases as strike price increases, the Asian call curve is under the Vanilla call curve. It can be observed that the Asian call option is less expensive than the Vanilla call.

Hedging

Hedging is an insurance to minimize exposure to market movements on the value of a position or portfolio. As the underlying changes, the proportions of the instruments forming the portfolio may need to be adjusted to keep the sensitivities within the desired range. `Delta` measures the option price sensitivity to changes in the price of the underlying.

Assume that you have a portfolio of two options with the same strike and maturity. You can use the Financial Instruments Toolbox™ to compute `Delta` for the Vanilla and Average Price options.

```
OutSpec = 'Delta';

% Vanilla option using Black Scholes
DeltaBLS = optstocksensbybls(RateSpec, StockSpec, Settle, ExerciseDates,...
                             OptSpec, Strike, 'OutSpec', OutSpec);

% Asian option using Kemna-Vorst method
DeltaKV = asiansensbykv(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                        ExerciseDates,  'OutSpec', OutSpec);

% Asian option using Levy model
DeltaLevy = asiansensbylevy(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                            ExerciseDates,  'OutSpec', OutSpec);
```

```
% Asian option using Turnbull-Wakeman model
DeltaTW = asiansensbytw(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                        ExerciseDates,  'OutSpec', OutSpec);

% Asian option using Haug-Haug-Margrabe model
DeltaHHM = asiansensbyhhm(RateSpec, StockSpec, OptSpec, Strike, Settle,...
                        ExerciseDates,  'OutSpec', OutSpec);

% Delta Comparison
displayComparisonVanillaAsian('Delta', DeltaBLS, DeltaKV, DeltaLevy, DeltaTW, DeltaHHM)

Comparison of Vanilla and Asian Delta:

Vanilla BLS:              0.788666
Asian Kemna-Vorst:        0.844986
Asian Levy:               0.852806
Asian Turnbull-Wakeman:   0.852806
Asian Haug-Haug-Margrabe: 0.857864
```

The following graph demonstrates the behavior of `Delta` for the Vanilla and Asian options as a function of the underlying price.

```
StockPrices = (40:5:120)';
NStockPrices = length(StockPrices);
DeltaBLS = nan(size(StockPrices));
DeltaKV = nan(size(StockPrices));
DeltaLevy = nan(size(StockPrices));
DeltaTW = nan(size(StockPrices));
DeltaHHM = nan(size(StockPrices));

idx = 1;
for SPrices = StockPrices'
    SP = stockspec(Sigma, SPrices);
    DeltaBLS(idx) = optstocksensbybls(RateSpec, SP, Settle, ...
                    ExerciseDates, OptSpec, Strike, 'OutSpec', OutSpec);

    DeltaKV(idx) = asiansensbykv(RateSpec, SP, OptSpec, Strike, ...
                   Settle, ExerciseDates,'OutSpec', OutSpec);

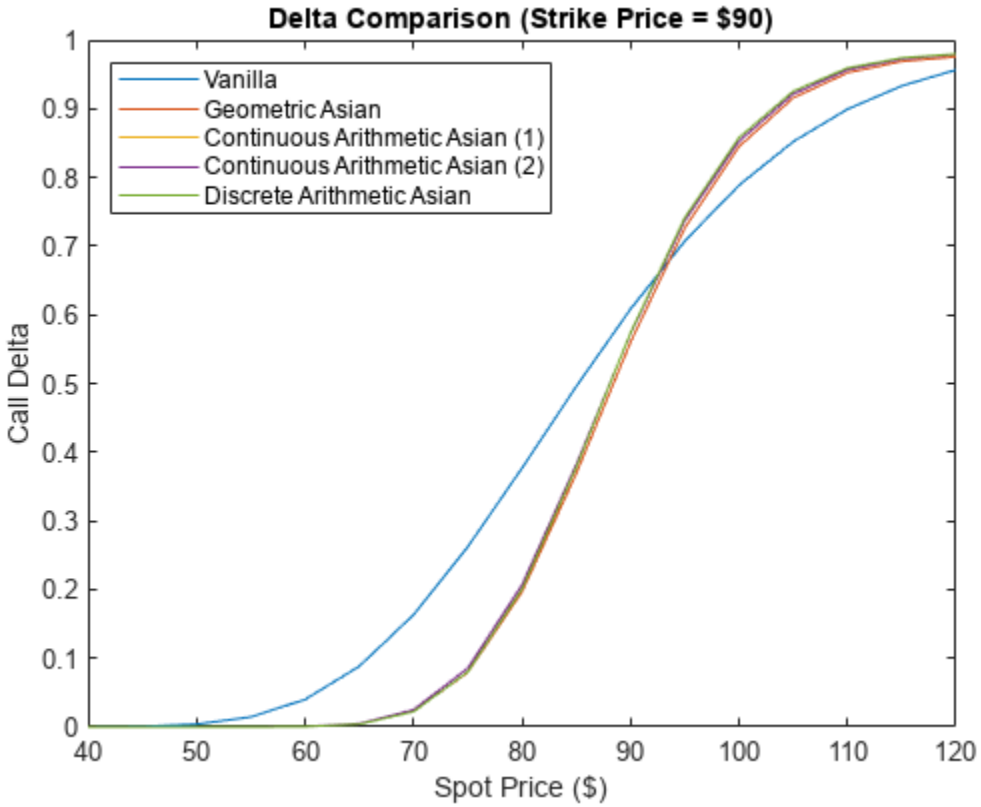
legend('Vanilla', 'Geometric Asian', 'Continuous Arithmetic Asian (1)', 'Continuous Arithmetic As
```



A Vanilla, or Asian, in the money (ITM) call option is more sensitive to price movements than an out of the money (OTM) option. If the asset price is deep in the money, then it is more likely to be exercised. The opposite occurs for an out of the money option. Asian delta is lower for out of the money options and is higher for in the money options than its Vanilla European counterpart. The geometric Asian delta is lower than the arithmetic Asian delta.

Price Spread Instrument for a Commodity Using Black-Scholes Model and Analytic Pricers

This example shows the workflow to price a commodity `Spread` instrument when you use a `BlackScholes` model and `Kirk` and `BjerksundStensland` analytic pricing methods.

Understanding Crack Spread Options

In the petroleum industry, refiners are concerned about the difference between their input costs (crude oil) and output prices (refined products — gasoline, heating oil, diesel fuel, and so on). The differential between these two underlying commodities is referred to as a *crack spread*. It represents the profit margin between crude oil and the refined products.

A *spread option* is an option on the spread where the holder has the right, but not the obligation, to enter into a spot or forward spread contract. Crack spread options are often used to protect against declines in the crack spread or to monetize volatility or price expectations on the spread.

Define the Commodity

Assume that current gasoline prices are strong, and you want to model a crack spread option strategy to protect the gasoline margin. A crack spread option strategy is used to maintain profits for the following season. The WTI crude oil futures are at $93.20 per barrel and RBOB gasoline futures contract are at $2.85 per gallon.

```
Strike = 20;
Rate = 0.05;

Settle = datetime(2020,1,1);
Maturity = datemnth(Settle,3);

% Price and volatility of RBOB gasoline
PriceGallon1 = 2.85;          % Dollars per gallon
Price1 = PriceGallon1 * 42;   % Dollars per barrel
Vol1 = 0.29;

% Price and volatility of WTI crude oil
Price2 = 93.20;         % Dollars per barrel
Vol2 = 0.36;

% Correlation between the prices of the commodities
Corr = 0.42;
```

Create Spread Instrument Object

Use `fininstrument` to create a `Spread` instrument object.

```
SpreadOpt = fininstrument("Spread", 'ExerciseDate', Maturity, 'Strike', Strike,'ExerciseStyle',"e
```

```
SpreadOpt =
  Spread with properties:

       OptionType: "call"
           Strike: 20
    ExerciseStyle: "european"
     ExerciseDate: 01-Apr-2020
```

```
            Name: "spread_instrument"
```

Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [Vol1,Vol2], 'Correlation', [1 Corr; C
```

Create ratecurve Object

Create a flat `ratecurve` object using `ratecurve`.

```
ZeroCurve = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1);
```

Create BjerksundStensland Pricer Object

Use `finpricer` to create a `BjerksundStensland` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BJSPricer = finpricer("Analytic", 'Model', BlackScholesModel, 'SpotPrice', [Price1 , Price2], 'Di
```

Create Kirk Pricer Object

Use `finpricer` to create a `Kirk` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
KirkPricer = finpricer("Analytic", 'Model', BlackScholesModel,'SpotPrice', [Price1 , Price2], 'Di
```

Price Spread Instrument Using BjerksundStensland and Kirk Analytic Pricing Methods

Use `price` to compute the price and sensitivities for the commodity `Spread` instrument.

```
[PriceKirk, outPR_Kirk] = price(KirkPricer, SpreadOpt, "all");
[PriceBJS,  outPR_BJS]  = price(BJSPricer,  SpreadOpt, "all");

[outPR_Kirk.Results; outPR_BJS.Results]
```

```

Price Vanilla Instrument Using Heston Model and Multiple Different Pricers

This example shows the workflow to price a `Vanilla` instrument when you use a `Heston` model and various pricing methods.

Create `Vanilla` Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle,6);
Strike = 80;
VanillaOpt = fininstrument('Vanilla','ExerciseDate',Maturity,'Strike',Strike,'Name',"vanilla_opti
```

```
VanillaOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 29-Dec-2017
           Strike: 80
             Name: "vanilla_option"
```

Create `Heston` Model Object

Use `finmodel` to create a `Heston` model object.

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;

HestonModel = finmodel("Heston",'V0',V0,'ThetaV',ThetaV,'Kappa',Kappa,'SigmaV',SigmaV,'RhoSV',Rho
```

```
HestonModel =
  Heston with properties:

         V0: 0.0400
    ThetaV: 0.0500
     Kappa: 1
    SigmaV: 0.2000
     RhoSV: -0.7000
```

Create `ratecurve` object

Create a `ratecurve` object using `ratecurve`.

```
Rate = 0.03;
ZeroCurve = ratecurve('zero',Settle,Maturity,Rate);
```

Create NumericalIntegration, FFT, and FiniteDifference Pricer Objects

Use `finpricer` to create a `NumericalIntegration`, `FFT`, and `FiniteDifference` pricer objects and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SpotPrice = 80;
Strike = 80;
DividendYield = 0.02;

NIPricer = finpricer("NumericalIntegration",'Model', HestonModel,'SpotPrice',SpotPrice,'DiscountC
```

```
NIPricer =
  NumericalIntegration with properties:

                Model: [1x1 finmodel.Heston]
        DiscountCurve: [1x1 ratecurve]
            SpotPrice: 80
         DividendType: "continuous"
        DividendValue: 0.0200
               AbsTol: 1.0000e-10
               RelTol: 1.0000e-10
     IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnHeston
            Framework: "heston1993"
       VolRiskPremium: 0
           LittleTrap: 1
```

```
FFTPricer = finpricer("FFT",'Model',HestonModel, ...
    'SpotPrice',SpotPrice,'DiscountCurve',ZeroCurve, ...
    'DividendValue',DividendYield,'NumFFT',8192)
```

```
FFTPricer =
  FFT with properties:

                    Model: [1x1 finmodel.Heston]
            DiscountCurve: [1x1 ratecurve]
                SpotPrice: 80
             DividendType: "continuous"
            DividendValue: 0.0200
                   NumFFT: 8192
    CharacteristicFcnStep: 0.0100
            LogStrikeStep: 0.0767
        CharacteristicFcn: @characteristicFcnHeston
            DampingFactor: 1.5000
               Quadrature: "simpson"
           VolRiskPremium: 0
               LittleTrap: 1
```

```
FDPricer = finpricer("FiniteDifference",'Model',HestonModel,'SpotPrice',SpotPrice,'DiscountCurve
```

```
FDPricer =
  FiniteDifference with properties:

     DiscountCurve: [1x1 ratecurve]
             Model: [1x1 finmodel.Heston]
         SpotPrice: 80
    GridProperties: [1x1 struct]
```

```
      DividendType: "continuous"
     DividendValue: 0.0200
```

Price `Vanilla` Instrument

Use the following sensitivities when pricing the `Vanilla` instrument.

```
InpSensitivity = ["delta", "gamma", "theta", "rho", "vega", "vegalt"];
```

Use `price` to compute the price and sensitivities for the `Vanilla` instrument that uses the `NumericalIntegration` pricer.

```
[PriceNI,  outPR_NI]  = price(NIPricer,VanillaOpt,InpSensitivity)
```

```
PriceNI = 4.7007

outPR_NI =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

Use `price` to compute the price and sensitivities for the `Vanilla` instrument that uses the `FFT` pricer.

```
[PriceFFT, outPR_FFT] = price(FFTPricer,VanillaOpt,InpSensitivity)
```

```
PriceFFT = 4.7007

outPR_FFT =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: []
```

Use `price` to compute the price and sensitivities for the `Vanilla` instrument that uses the `FiniteDifference` pricer.

```
[PriceFD,  outPR_FD]  = price(FDPricer,VanillaOpt,InpSensitivity)
```

```
PriceFD = 4.7003

outPR_FD =
  priceresult with properties:

       Results: [1x7 table]
    PricerData: [1x1 struct]
```

Aggregate the price results.

```
[outPR_NI.Results;outPR_FFT.Results;outPR_FD.Results]
```

```
ans=3×7 table

Create and Price Portfolio of Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio of interest-rate and equity instruments. The portfolio contains a vanilla `FixedBond`, an `OptionEmbeddedFixedBond`, a `Vanilla` European call option, a `Vanilla` American call option, and an `Asian` call option.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates);
```

Create the Instrument Objects

Use `fininstrument` to create the instrument objects.

```
% Vanilla FixedBond
CouponRate = 0.0325;
Maturity = datetime(2038,3,15);
Period = 1;
VanillaBond = fininstrument("FixedBond",'Maturity',Maturity,'CouponRate',CouponRate,...
    'Period',Period,'Name',"VanillaBond")
```

```
VanillaBond =
  FixedBond with properties:

                 CouponRate: 0.0325
                     Period: 1
                      Basis: 0
                EndMonthRule: 1
                   Principal: 100
    DaycountAdjustedCashFlow: 0
       BusinessDayConvention: "actual"
                    Holidays: NaT
                   IssueDate: NaT
             FirstCouponDate: NaT
              LastCouponDate: NaT
                   StartDate: NaT
                    Maturity: 15-Mar-2038
                        Name: "VanillaBond"
```

```
% OptionEmbeddedBond
Maturity = datetime(2024,9,15);
CouponRate = 0.035;
Strike = 100;
ExerciseDates = datetime(2023,9,15);
CallSchedule =  timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;
CallableBond = fininstrument("OptionEmbeddedFixedBond", "Maturity",Maturity,...
    'CouponRate',CouponRate,'Period',Period, ...
    'CallSchedule',CallSchedule,...
```

```
    'Name',"CallableBond");

% Vanilla European call option
ExerciseDate = datetime(2022,1,1);
Strike = 96;
OptionType = 'call';
CallOpt = fininstrument("Vanilla",'ExerciseDate',ExerciseDate,'Strike',Strike,...
    'OptionType',OptionType, 'Name',"EuropeanCallOption")

CallOpt =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 01-Jan-2022
           Strike: 96
             Name: "EuropeanCallOption"

% Vanilla American call option
ExerciseDate = datetime(2023,1,1);
Strike = 97;
OptionType = 'call';
CallOpt_American = fininstrument("Vanilla",'ExerciseDate',ExerciseDate,'Strike',Strike,...
    'OptionType',OptionType, 'ExerciseStyle', "american", ...
    'Name',"AmericanCallOption")

CallOpt_American =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2023
           Strike: 97
             Name: "AmericanCallOption"

% Asian call option
ExerciseDate = datetime(2023,1,1);
Strike = 102;
OptionType = 'call';
CallOpt_Asian = fininstrument("Asian",'ExerciseDate',ExerciseDate,'Strike',Strike,...
    'OptionType',OptionType,'Name',"AsianCall")

CallOpt_Asian =
  Asian with properties:

         OptionType: "call"
             Strike: 102
        AverageType: "arithmetic"
       AveragePrice: 0
   AverageStartDate: NaT
      ExerciseStyle: "european"
       ExerciseDate: 01-Jan-2023
               Name: "AsianCall"
```

Create Model Objects

Use `finmodel` to create `HullWhite` and `BlackScholes` model objects.

```
% Create Hull-White model
Vol = 0.01;
Alpha = 0.1;
HWModel = finmodel("hullwhite",'alpha',Alpha,'sigma',Vol);

% Create Black-Scholes model
Vol = .1;
SpotPrice = 95;
BlackScholesModel = finmodel("BlackScholes",'Volatility',Vol);
```

Create Pricer Objects

Use `finpricer` to create `Discount`, `IRTree`, `BlackScholes`, `Levy`, and `BjerksundStensland` pricer objects and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
% Create Discount pricer
DiscPricer = finpricer("Discount","DiscountCurve",ZeroCurve);

% Create Hull-White tree pricer
TreeDates = Settle + calyears(1:30);
HWTreePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,...
    'TreeDates',TreeDates');

% Create BlackScholes, Levy, and BjerksundStensland pricers
BLSPricer = finpricer("analytic",'DiscountCurve',ZeroCurve,'Model',BlackScholesModel,'SpotPrice'
LevyPricer = finpricer("analytic",'DiscountCurve',ZeroCurve,'Model',BlackScholesModel,...
                       'SpotPrice',SpotPrice,'PricingMethod',"Levy");
BJSpricer = finpricer("analytic",'DiscountCurve',ZeroCurve,'Model',BlackScholesModel,...
                       'SpotPrice',SpotPrice,'PricingMethod',"BjerksundStensland");
```

Create `finportfolio` Object

Create a `finportfolio` object that contains all of the instrument and pricer objects using `finportfolio`.

```
myPort = finportfolio([VanillaBond CallableBond CallOpt CallOpt_American CallOpt_Asian]',...
                           [DiscPricer HWTreePricer BLSPricer BJSpricer LevyPricer]')
```

```
myPort =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
        Pricers: [5x1 finpricer.FinPricer]
    PricerIndex: [5x1 double]
       Quantity: [5x1 double]
```

Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myPort)
```

```
PortPrice = 237.3275
```

```
InstPrice = 5×1

Use Black-Scholes Model to Price Asian Options with Several Equity Pricers

This example shows how to compare arithmetic and geometric Asian option prices using the `BlackScholes` model and various pricing methods. The pricing methods are: the Kemna-Vorst, Levy, Turnbull-Wakeman, and Cox-Ross-Rubinstein methods and Monte Carlo simulation. This example also demonstrates how variations in spot prices affect option and delta sensitivity values on European vanilla and Asian options.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,01,01);
Maturity = datetime(2025,01,01);
Rate = 0.035;
Compounding = -1;
Basis = 1;
ZeroCurve = ratecurve('zero',Settle,Maturity,Rate,'Compounding',Compounding,'Basis', Basis)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 1
               Dates: 01-Jan-2025
               Rates: 0.0350
              Settle: 01-Jan-2019
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
Volatility = .20;
BSModel = finmodel("BlackScholes",'Volatility',Volatility)
```

```
BSModel =
  BlackScholes with properties:

     Volatility: 0.2000
    Correlation: 1
```

Create `Asian` Instrument Objects

Use `fininstrument` to create two `Asian` instrument objects, one using an arithmetic average and the other using a geometric average.

```
ExerciseDates = datetime(2020,01,01);
Strike = 90;
OptionType = 'call';
```

```
AverageType = 'geometric';

AsianOptArith = fininstrument("Asian",'ExerciseDate',ExerciseDates,'Strike',Strike,...
                              'OptionType',OptionType,'Name',"CallAsianArith")

AsianOptArith =
  Asian with properties:

          OptionType: "call"
              Strike: 90
         AverageType: "arithmetic"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 01-Jan-2020
                Name: "CallAsianArith"

AsianOptGeo = fininstrument("Asian",'ExerciseDate',ExerciseDates,'Strike',Strike,...
                            'OptionType',OptionType,'AverageType', AverageType,'Name',"CallAsian

AsianOptGeo =
  Asian with properties:

          OptionType: "call"
              Strike: 90
         AverageType: "geometric"
        AveragePrice: 0
    AverageStartDate: NaT
       ExerciseStyle: "european"
        ExerciseDate: 01-Jan-2020
                Name: "CallAsianGeo"
```

Create `Analytic`, `AssetTree`, and `AssetMonteCarlo` Pricer Objects

Use `finpricer` to create `BlackScholes`, `AssetTree`, and `AssetMonteCarlo` pricer objects and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
SpotPrice = 100;
InpSensitivity = "delta";

% Analytic Pricers
LevyPricer = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', SpotPrice, ...
                       'DiscountCurve', ZeroCurve, 'PricingMethod', "Levy");

TWPricer = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', SpotPrice, ...
                     'DiscountCurve', ZeroCurve, 'PricingMethod', "TurnbullWakeman");

KVPricer = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', SpotPrice, ...
                       'DiscountCurve', ZeroCurve, 'PricingMethod', "KemnaVorst");

% AssetTree Pricer
% Define the number of levels of the tree
NumPeriods = 50;
CRRPricer = finpricer("AssetTree",'DiscountCurve',ZeroCurve,'Model',BSModel, 'SpotPrice',SpotPric
                      'PricingMethod',"CoxRossRubinstein",'NumPeriods', NumPeriods,...
                      'Maturity', ExerciseDates);
```

```
% AssetMonteCarlo Pricer
% Define the number of simulation trials
NumTrials = 2000;
SimDates =[Settle:days(2):ExerciseDates ExerciseDates];

MCPricer = finpricer("AssetMonteCarlo", 'Model', BSModel, 'SpotPrice', SpotPrice, 'DiscountCurve
                     'SimulationDates',  SimDates, 'NumTrials', NumTrials);
```

Calculate the Price of the Arithmetic and Geometric Asian Options Using Different Pricers

Calculate the Asian option prices using the `price` function for the `Analytic`, `AssetTree`, and `AssetMonetCarlo` pricing methods.

```
% Analytic
[LevyPrice,LevyoutPR] = price(LevyPricer, AsianOptArith,InpSensitivity);

[TWPrice, TWoutPR] = price(TWPricer, AsianOptArith, InpSensitivity);

[KVPrice, KVoutPR] = price(KVPricer, AsianOptGeo, InpSensitivity);

% Cox-Ross-Rubinstein
[CRRArithPrice, CRRArithoutPR] = price(CRRPricer, AsianOptArith, InpSensitivity);

[CRRGeoPrice, CRRGeooutPR] = price(CRRPricer, AsianOptGeo, InpSensitivity);

% Monte Carlo
[MCArithPrice, MCArithoutPR] = price(MCPricer, AsianOptArith, InpSensitivity);

[MCGeoPrice, MCGeooutPR] = price(MCPricer, AsianOptGeo, InpSensitivity);
```

Compare Asian Option Prices

Compare the Asian option call prices using the `displayPricesAsianCallOption` function defined in Local Functions on page 3-141.

```
displayPricesAsianCallOption(KVPrice,LevyPrice,TWPrice,CRRArithPrice,CRRGeoPrice,MCArithPrice,MC
```

```
Comparison of Asian prices:

Arithmetic Asian
Levy:                    12.164734
Turnbull-Wakeman:        12.164734
Cox-Ross-Rubinstein:     12.126509
Monte Carlo:             12.102669

Geometric Asian
Kemna-Vorst:             11.862580
Cox-Ross-Rubinstein:     11.852462
Monte Carlo:             11.988051
```

The table contrasts the results from closed approximation models against price simulations implemented using the Cox-Ross-Rubinstein binomial tree and Monte Carlo pricing methods. Observe that arithmetic average Asian options are more expensive than their geometric average counterparts.

Compare Asian and Vanilla Options

Asian options are popular instruments since they tend to be less expensive than comparable vanilla calls and puts. This is because the volatility in the average value of an underlier tends to be lower

than the volatility of the value of the underlier itself. You can compare the price and delta sensitivity values of Asian options against their vanilla counterparts.

Create Vanilla Instrument Object

Use `fininstrument` to create a `Vanilla` instrument object with same Maturity and Strike as the two Asian options.

```
EuropeanCallOption = fininstrument("Vanilla",'ExerciseDate',ExerciseDates,'Strike',Strike,...
                                   'OptionType',OptionType,'Name',"CallVanilla")
```

```
EuropeanCallOption =
  Vanilla with properties:

       OptionType: "call"
    ExerciseStyle: "european"
     ExerciseDate: 01-Jan-2020
           Strike: 90
             Name: "CallVanilla"
```

Create `Analytic` Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
BLSPricer = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', SpotPrice, 'DiscountCurve', Zero
```

```
BLSPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0
     DividendType: "continuous"
```

Compute price and delta sensitivity.

```
[BLSPrice, BLSoutPR] = price(BLSPricer, EuropeanCallOption, InpSensitivity);
```

Compare Prices for Asian and Vanilla Options

Compare option prices using the `displayVanillaAsianComparison` function defined in Local Functions on page 3-141.

```
displayVanillaAsianComparison('Prices', BLSPrice, KVPrice,LevyPrice,TWPrice)
```

```
Comparison of Vanilla and Asian Option Prices:

Vanilla BLS:              15.743809
Asian Kemna-Vorst:        11.862580
Asian Levy:               12.164734
Asian Turnbull-Wakeman:   12.164734
```

Observe that both the geometric and arithmetic Asian option prices are lower than their vanilla counterparts.

Compare Delta Sensitivity for Asian and Vanilla Options

The delata value measures the option price sensitivity to changes in the price of the underlying asset. As the underlier changes, the proportions of the instruments forming the portfolio might need to be adjusted to keep the sensitivities within the desired range.

```
displayVanillaAsianComparison('Delta', BLSoutPR.Results.Delta, KVoutPR.Results.Delta, LevyoutPR.R
```

```
Comparison of Vanilla and Asian Option Delta:

Vanilla BLS:              0.788666
Asian Kemna-Vorst:        0.844986
Asian Levy:               0.852806
Asian Turnbull-Wakeman:   0.852806
```

The table shows the delta values for both the vanilla and arithmetic and geometric Asian options. Observe that the geometric Asian delta value is lower than the delta value for the arithmetic Asian option.

Analyze Effect of Variations of Underlying Asset on Option Prices

Examine the effect of changes of underlying asset prices. Create a plot to show the effect of variations in the price of the underlying asset on the vanilla and Asian option prices.

```
StockPrices = (50:5:120)';
PriceBLS = nan(size(StockPrices));
PriceKV = PriceBLS;
PriceLevy = PriceBLS;
PriceTW = PriceBLS;
DeltaBLS = PriceBLS;
DeltaLevy = PriceBLS;
DeltaTW = PriceBLS;
DeltaKV = PriceBLS;
InpSensitivity = "delta";
idx = 1;
for AssetPrice = StockPrices'

    PricerBLS = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', AssetPrice,...
                          'DiscountCurve', ZeroCurve);
    [PriceBLS(idx), outPRBLS] = price(PricerBLS, EuropeanCallOption, InpSensitivity);
    DeltaBLS(idx) = outPRBLS.Results.Delta;

    PricerLevy = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', AssetPrice, ...
                           'DiscountCurve', ZeroCurve, 'PricingMethod', "Levy");
    [PriceLevy(idx), outPRLevy] = price(PricerLevy, AsianOptArith, InpSensitivity);
    DeltaLevy(idx) = outPRLevy.Results.Delta;

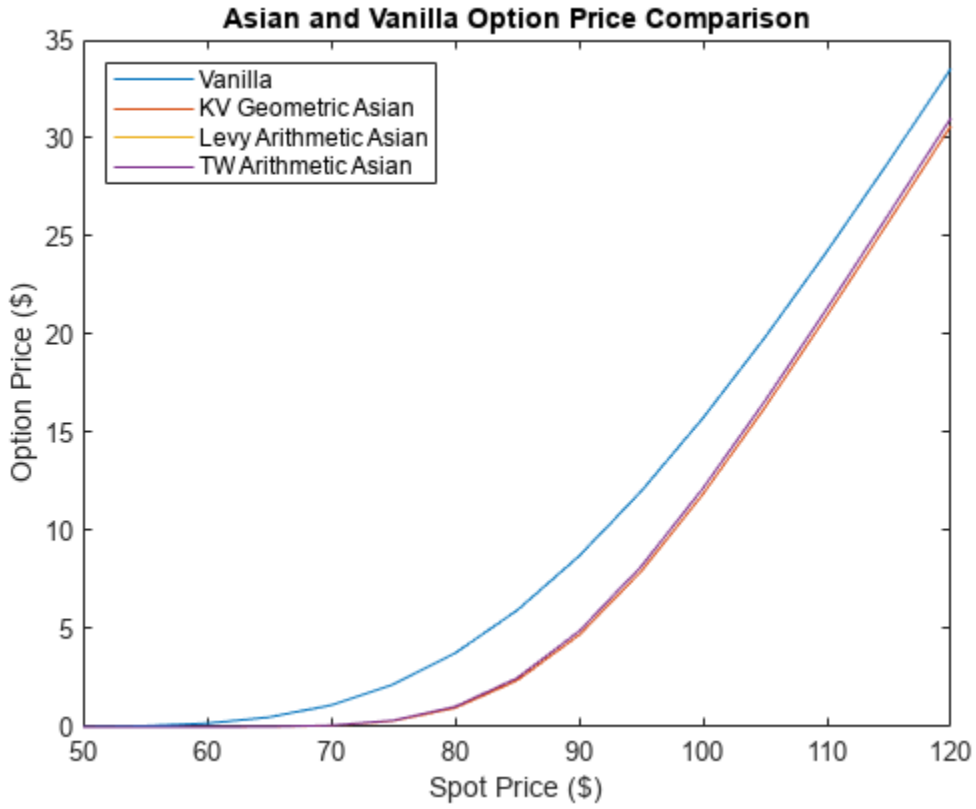
    PricerTW = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', AssetPrice, ...
        'DiscountCurve', ZeroCurve, 'PricingMethod', "TurnbullWakeman");
    [PriceTW(idx), outPRBTW] = price(PricerTW, AsianOptArith, InpSensitivity);
    DeltaTW(idx) = outPRBTW.Results.Delta;

    PricerKV = finpricer('Analytic', 'Model', BSModel, 'SpotPrice', AssetPrice, ...
        'DiscountCurve', ZeroCurve, 'PricingMethod', "KemnaVorst");
    [PriceKV(idx), outPRKV] = price(PricerKV, AsianOptGeo, InpSensitivity);
    DeltaKV(idx) = outPRKV.Results.Delta;

    idx = idx+1;
```

```
end

figure('menubar', 'none', 'numbertitle', 'off')
plot(StockPrices, [PriceBLS PriceKV PriceLevy PriceTW]);
xlabel 'Spot Price ($)'
ylabel 'Option Price ($)'
title 'Asian and Vanilla Option Price Comparison'
legend('Vanilla', 'KV Geometric Asian', 'Levy Arithmetic Asian', 'TW Arithmetic Asian', 'locatio
```

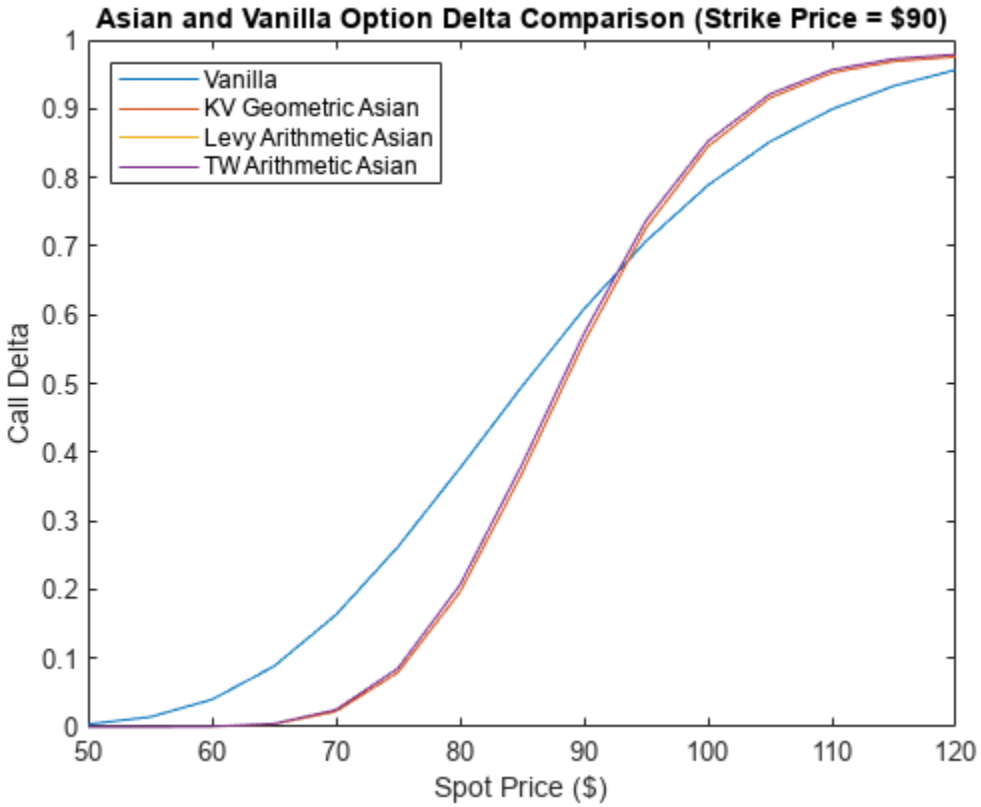


The plot displays vanilla and Asian option prices with respect to the underlying asset price. Observe that the price of the Asian options is cheaper than the price of the vanilla option.

Analyze Effect of Variations of the Underlying Asset on the Options Delta

Examine the effect of changes of underlying asset prices on delta sensitivity. The following plot demonstrates the behavior of the delta value for the Vanilla and Asian options as a function of the underlying price.

```
figure('menubar', 'none', 'numbertitle', 'off')
plot(StockPrices, [DeltaBLS DeltaKV DeltaLevy DeltaTW]);
xlabel 'Spot Price ($)'
ylabel 'Call Delta'
title 'Asian and Vanilla Option Delta Comparison (Strike Price = $90)'
legend('Vanilla', 'KV Geometric Asian', 'Levy Arithmetic Asian', 'TW Arithmetic Asian', 'locatio
```



The plot displays the vanilla and Asian delta sensitivity values with respect to the underlying asset price. A vanilla or Asian in-the-money (ITM) call option is more sensitive to price movements than an out-of-the-money (OTM) option. If the asset price is deep in the money, then it is more likely to be exercised. The opposite is the case for an out-of-the-money option. Observe that the Asian delta value is lower for out-of-the-money options and higher for in-the-money options compared with the vanilla European counterpart.

Local Functions

```

Calibrate Option Pricing Model Using Heston Model

This example shows how to use the **Calibrate Pricing Model** Live Editor task to calibrate a `Heston` pricing model to call option prices from the market. After calibration, use the Financial Instruments Toolbox™ object-based workflow to price an American option for a `Barrier` instrument using the calibrated parameter values for the `Heston` model with an `AssetMonteCarlo` pricing method.

Define Pricing Data

Define the data.

```
Settle = datetime(2015,7,10);
SpotPrice = 123.28;
Rate = -0.001;
MaturityDates = datetime([2015,8,21; 2015,9,18; 2015,12,18; 2016,4,15; 2016,6,17; 2017,1,20]);

Strikes = [115 120 125 130 135 140 145]';

Prices = [9.95 10.63 12.84 15.10 15.95 20.00; ...
    6.30 7.20 9.90 12.30 13.57 17.50; ...
    3.60 4.55 7.30 9.70 11.15 15.20; ...
    1.82 2.68 5.30 7.70 9.00 13.20; ...
    0.82 1.45 3.70 5.85 7.20 11.27; ...
    0.36 0.77 2.50 4.48 5.76 9.65; ...
    0.15 0.38 1.70 3.44 4.54 8.10];

ZeroCurve = ratecurve("zero", Settle, MaturityDates(end), Rate)
```

```
ZeroCurve =
  ratecurve with properties:

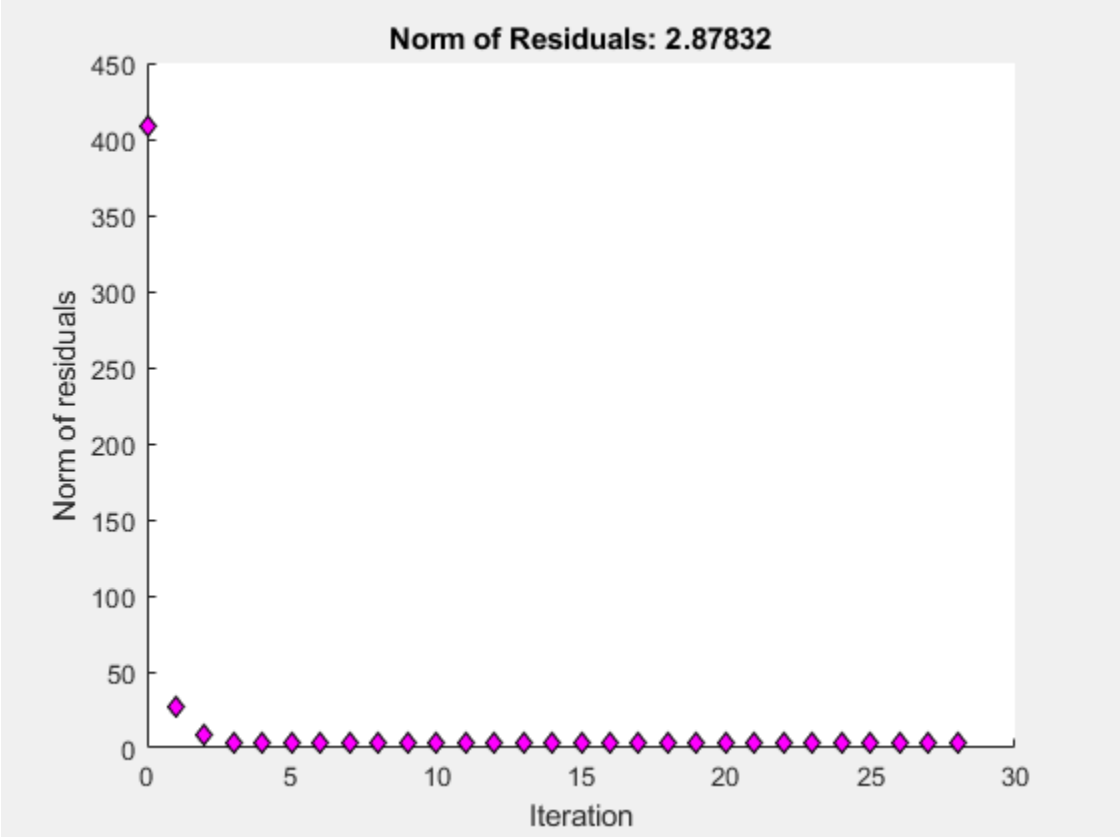
                Type: "zero"
       Compounding: -1
             Basis: 0
             Dates: 20-Jan-2017
             Rates: -1.0000e-03
            Settle: 10-Jul-2015
      InterpMethod: "linear"
  ShortExtrapMethod: "next"
   LongExtrapMethod: "previous"
```

Use the Calibrate Pricing Model live task to interactively select the data, model, parameter constraints, and the optimization and solver options to generate a volatility surface plot.

```
% Create fininstrument objects
[MAT, STR] = meshgrid(MaturityDates', Strikes);
Inst = fininstrument('Vanilla', 'ExerciseDate', MAT(:), ...
    'Strike', STR(:), 'OptionType', 'Call');

% Construct objective function
objectiveFcn = @(Param) Prices(:) - price(finpricer('FFT', 'Model', ...
    finmodel('Heston', 'V0', Param(1), 'ThetaV', Param(2), ...
    'Kappa', Param(3), 'SigmaV', Param(4), 'RhoSV', Param(5)), ...
    'SpotPrice', 123.28, 'DiscountCurve', ZeroCurve), Inst);
```

```
% Estimate model parameters
options = optimoptions('lsqnonlin', 'FunctionTolerance', 0.0001, ...
    'Display', 'final', 'PlotFcn', 'optimplotresnorm');
Param = lsqnonlin(objectiveFcn, [0.1 0.4 0.2 0.6 -0.1], [0 0 0 0 -1], ...
    [1 1 10 2 1], options);
```



```
Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.

HestonModel = finmodel('Heston', 'V0', Param(1), 'ThetaV', Param(2), ...
    'Kappa', Param(3), 'SigmaV', Param(4), 'RhoSV', Param(5))

HestonModel =
  Heston with properties:

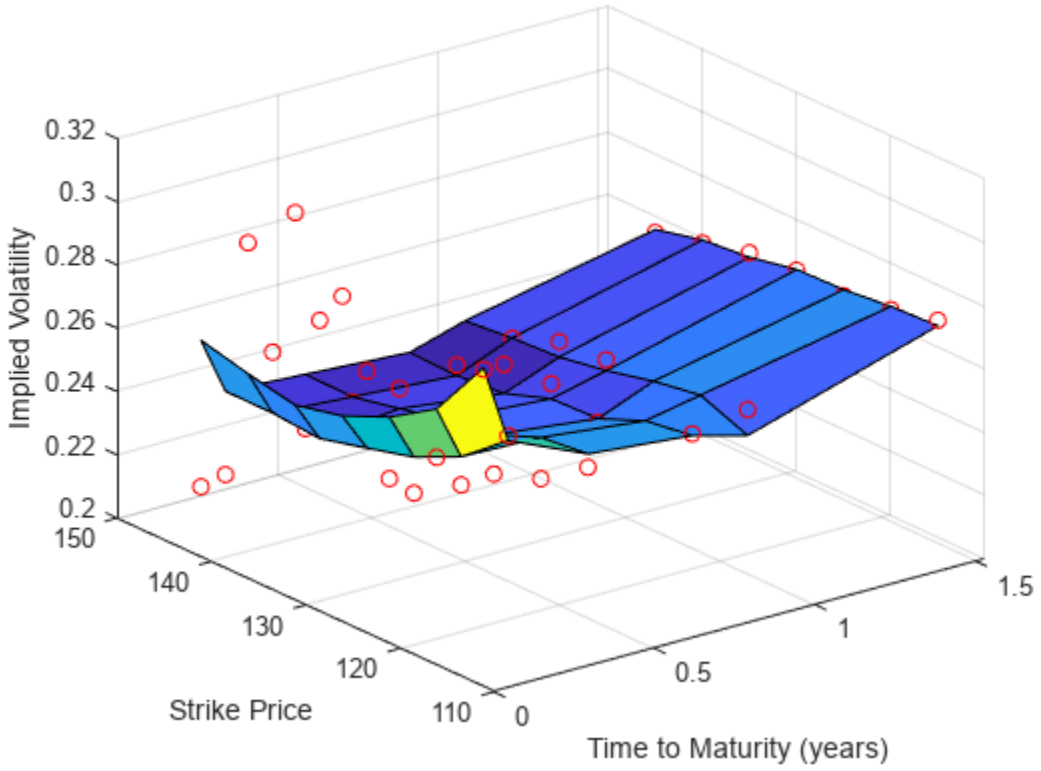
        V0: 0.0448
    ThetaV: 0.1625
     Kappa: 0.3317
    SigmaV: 0.0776
     RhoSV: -0.8401

% Calculate implied volatilities for market and model prices
TMAT = yearfrac(ZeroCurve.Settle, MAT);
```

```
MKTVOL = blsimpv(123.28, STR, ZeroCurve.Rates(1), TMAT, Prices);

ModelPrice = price(finpricer('FFT', 'Model', HestonModel, 'SpotPrice', 123.28, ...
    'DiscountCurve', ZeroCurve), Inst);
ModelVol = blsimpv(123.28, STR(:), ZeroCurve.Rates(1), TMAT(:), ModelPrice);

% Plot implied volatility surface
figure
surf(TMAT, STR, MKTVOL)
hold on
scatter3(TMAT(:), STR(:), ModelVol, 'ro')
xlabel('Time to Maturity (years)')
ylabel('Strike Price')
zlabel('Implied Volatility')
hold off
grid on
```



```
clearvars TMAT MKTVOL ModelPrice ModelVol
clearvars STR MAT Inst Param options objectiveFcn
```

Continue with this workflow to price an American option for a `Barrier` instrument using the calibrated parameter values for a `Heston` model with an `AssetMonteCarlo` pricing method.

Create `Barrier` Instrument Object

Use `fininstrument` to create a `Barrier` instrument object.

```
ExerciseDate = datetime(2016,1,1);
BarrierOpt = fininstrument("Barrier",Strike=90,ExerciseDate=ExerciseDate,OptionType="call",Exerci

BarrierOpt =
  Barrier with properties:

       OptionType: "call"
           Strike: 90
      BarrierType: "do"
     BarrierValue: 40
           Rebate: 0
    ExerciseStyle: "american"
     ExerciseDate: 01-Jan-2016
             Name: "barrier_option"
```

Create `AssetMonteCarlo` Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object `ZeroCurve` for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",DiscountCurve=ZeroCurve,Model=HestonModel,SpotPrice=100,S

outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
          SpotPrice: 100
    SimulationDates: [11-Jul-2015    16-Jul-2015    21-Jul-2015    ...    ]
          NumTrials: 1000
      RandomNumbers: []
              Model: [1x1 finmodel.Heston]
       DividendType: "continuous"
      DividendValue: 0
```

Price `Barrier` Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price,outPR] = price(outPricer,BarrierOpt,"all")

Price = 12.4688

outPR =
  priceresult with properties:

       Results: [1x8 table]
    PricerData: [1x1 struct]

outPR.Results

ans=1×8 table
    Price      Delta      Gamma      Lambda      Rho       Theta       Vega      VegaLT
    ______    _______    ________    ______    ______    ________    ______    ______

Related Examples

- “Use Deep Learning to Approximate Barrier Option Prices with Heston Model” on page 3-148

Use Deep Learning to Approximate Barrier Option Prices with Heston Model

This example shows how to use Deep Learning Toolbox™ to train a network and obtain predictions on barrier option prices with a Heston model.

Barrier Option

The barrier option is an option where the payoff depends on whether the underlying asset crosses the predetermined trigger value (barrier level) during the life of the option. Barrier options are attractive because they are less expensive than the corresponding vanilla options.

Heston Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance follows a stochastic (CIR) process. The Heston model allows modeling the implied volatility smiles observed in the market where options with identical expiration dates show increasing volatility as the options become more in-the-money (ITM) or out-of-the-money (OTM).

The stochastic differential equation is:

$$dS_t = rS_t dt + \sqrt{v_t} S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

where

r — Continuous risk-free rate

S_t — Asset price at time t

v_t — Asset price variance at time t

v_0 — Initial variance of the asset price at $t = 0$

θ — Long-term variance level

κ — Mean reversion speed for the variance

σ_v — Volatility of the variance

ρ — Correlation between the Wiener processes W_t and W_t^v

Barrier option prices are usually computed using Monte Carlo simulation in the Heston setting since there is no closed-form solution available. However, a Monte Carlo simulation is computationally expensive, and when pricing instruments for financial markets, pricing speed is crucial. This example demonstrates using a vanilla neural network to speed up the barrier option pricing by learning the results from a Monte Carlo simulation. The neural network provides a highly efficient approximation technique. Although the off-line training is time consuming, the on-line pricing is fast.

Define Parameters

Focusing on a barrier-up, knock-out call option, start by deciding on the ranges for the pricing parameters. Consider a scaled spot price (moneyness) instead of two separate parameters S_0 (asset spot price) and K(strike). The barrier level is also scaled by strike value.

```
% Option parameter ranges.
% The first value defines the lower bound
% and the second value is the upper bound.
moneyness = [0.6 1.2]; % S0/K
maturity = [0.05 2];
upBarrier = [0.6 1.3]; % Up barrier/K

% Model parameter ranges
rate = [0 0.05];
kappa = [0.3 2];
theta = [0.05 0.2];
sigma = [0.05 0.5];
v0 = [0.05 0.2];
rho = [-0.9 -0.1];

% Call option parameters
optSpec = "call";
exerciseStyle = "european";
barriertype = "uo";

% Simulation parameter
nTrials = 1000;

% Set the random generator seed for reproducibility.
%rng('default')
```

Gather Data

Sample the parameter combinations by using a quasi-Monte Carlo sampling method (`sobolset`) that is based on Sobol sequences which possess good uniformity properties. A Sobol sequence uses a base of 2 to form successively finer uniform partitions of the unit interval, and then reorders the coordinates in each dimension.

```
Quasi = sobolset(9,'Skip',1024);
Quasi = scramble(Quasi,'MatousekAffineOwen');
inputs = Quasi(1:24e4, :); % Initial 240000 samples

% Column number for each parameter in the inputs array.
iMoneyness = 1;iTime = 2;iRate = 3;iCorr = 4;iKappa = 5;iTheta = 6;iSigma = 7;iV0 = 8;iBarrier =

inputs(:,iMoneyness) = inputs(:,iMoneyness)*(moneyness(2)-moneyness(1))+moneyness(1);   % Moneyne
inputs(:,iTime)      = inputs(:,iTime)*(maturity(2)-maturity(1))+maturity(1);           % Maturi
inputs(:,iRate)      = inputs(:,iRate)*(rate(2)-rate(1))+rate(1);                       % rate
inputs(:,iCorr)      = inputs(:,iCorr)*(rho(2)-rho(1))+rho(1);                          % Correla
inputs(:,iKappa)     = inputs(:,iKappa)*(kappa(2)-kappa(1))+kappa(1);                   % Mean re
inputs(:,iTheta)     = inputs(:,iTheta)*(theta(2)-theta(1))+theta(1);                   % Long-te
inputs(:,iSigma)     = inputs(:,iSigma)*(sigma(2)-sigma(1))+sigma(1);                   % Volati
inputs(:,iV0)        = inputs(:,iV0)*(v0(2)-v0(1))+v0(1);                               % Initia
inputs(:,iBarrier)   = inputs(:,iBarrier)*(upBarrier(2)-upBarrier(1))+upBarrier(1);     % UPbarri
```

Remove the parameter combinations where the barrier levels are not greater than the initial spot prices.

```
% Barrier level should be higher than the initial spot price.
invalid = inputs(:,iBarrier)<=inputs(:,iMoneyness);
inputs(invalid,:) = [];
```

Calculate Barrier Option Prices Using Monte Carlo Simulation

After you create the parameter space, calculate the prices of the `Barrier` option by Monte Carlo simulation using the object-based pricing framework in Financial Instrument Toolbox™. Specifically, use `ratecurve`, `Heston`, `Barrier`, and `AssetMonteCarlo` to create the objects required to price the `Barrier` option. To avoid waiting for the Monte Carlo simulation, load the calculated prices for the example by setting the `doMCPricing` flag to `false`.

```
doMCPricing = false;

if doMCPricing
    % Calculate the prices using the AssetMonteCarlo pricer.
    Settle = datetime(2021,2,1);
    Price = nan(size(inputs,1),1);

    for i = 1:size(inputs,1)
        AssetPrice = inputs(i,iMoneyness);
        Strike = 1;
        Barrier = inputs(i,iBarrier);

        V0 = inputs(i,iV0);
        ThetaV = inputs(i,iTheta);
        Kappa = inputs(i,iKappa);
        SigmaV = inputs(i,iSigma);
        RhoSV = inputs(i,iCorr);

        Rates = inputs(i,iRate);
        ExerciseDate = daysadd(Settle,round(inputs(i,iTime)*365),0);
        ZeroCurve = ratecurve('zero',Settle,ExerciseDate,Rates);

        hestonModel = finmodel("Heston",V0=V0,ThetaV=ThetaV,Kappa=Kappa,SigmaV=SigmaV,RhoSV=RhoS

        MCPricer = finpricer("AssetMonteCarlo",DiscountCurve=ZeroCurve,Model=hestonModel,SpotPri
            SimulationDates=[Settle:days(2):ExerciseDate, ExerciseDate],numTrials=nTrials);

        CallBarrier = fininstrument("Barrier",ExerciseDate=ExerciseDate,Strike=Strike,OptionType=
            Barriertype=barriertype,Barriervalue=Barrier,ExerciseStyle=exerciseStyle);

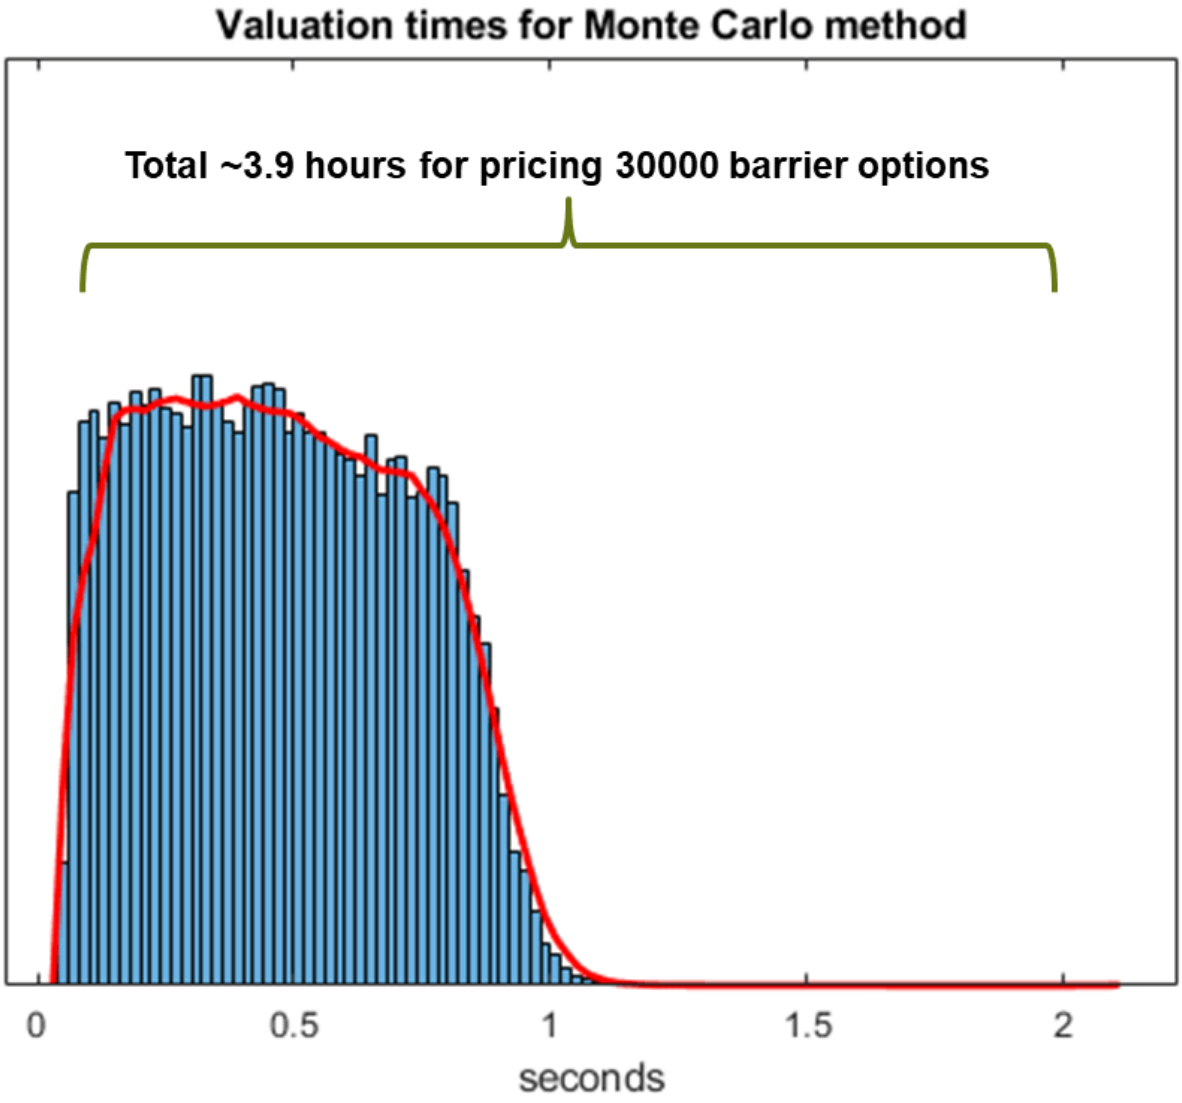
        Price(i) = price(MCPricer,CallBarrier);

    end

else
    % Load the calculated prices for the example.
    load('DeepLearningBarrierHeston.mat','inputs','Price')
end
```

If you do not use the calculated prices for the example by setting the `doMCPricing` flag to `false`, the following histogram shows the distribution of valuation times for *each individual* barrier option using a Monte Carlo method. This histogram demonstrates that it takes approximately 0.46 seconds to compute a single barrier option price. In this example, `nTrials` is set to `1e3` which is the number of trials in the Monte Carlo simulation to compute a single option price. The total time to compute

prices for the sample size of 30,000 barrier options is approximately 3.9 hours, depending on the processor speed.



Define Neural Network

Different network architectures can help with the task of pricing barrier options using a Heston model. Choosing a neural network architecture requires balancing computation time against accuracy. This example uses multiple, fully-connected layers and Leaky ReLU activations.

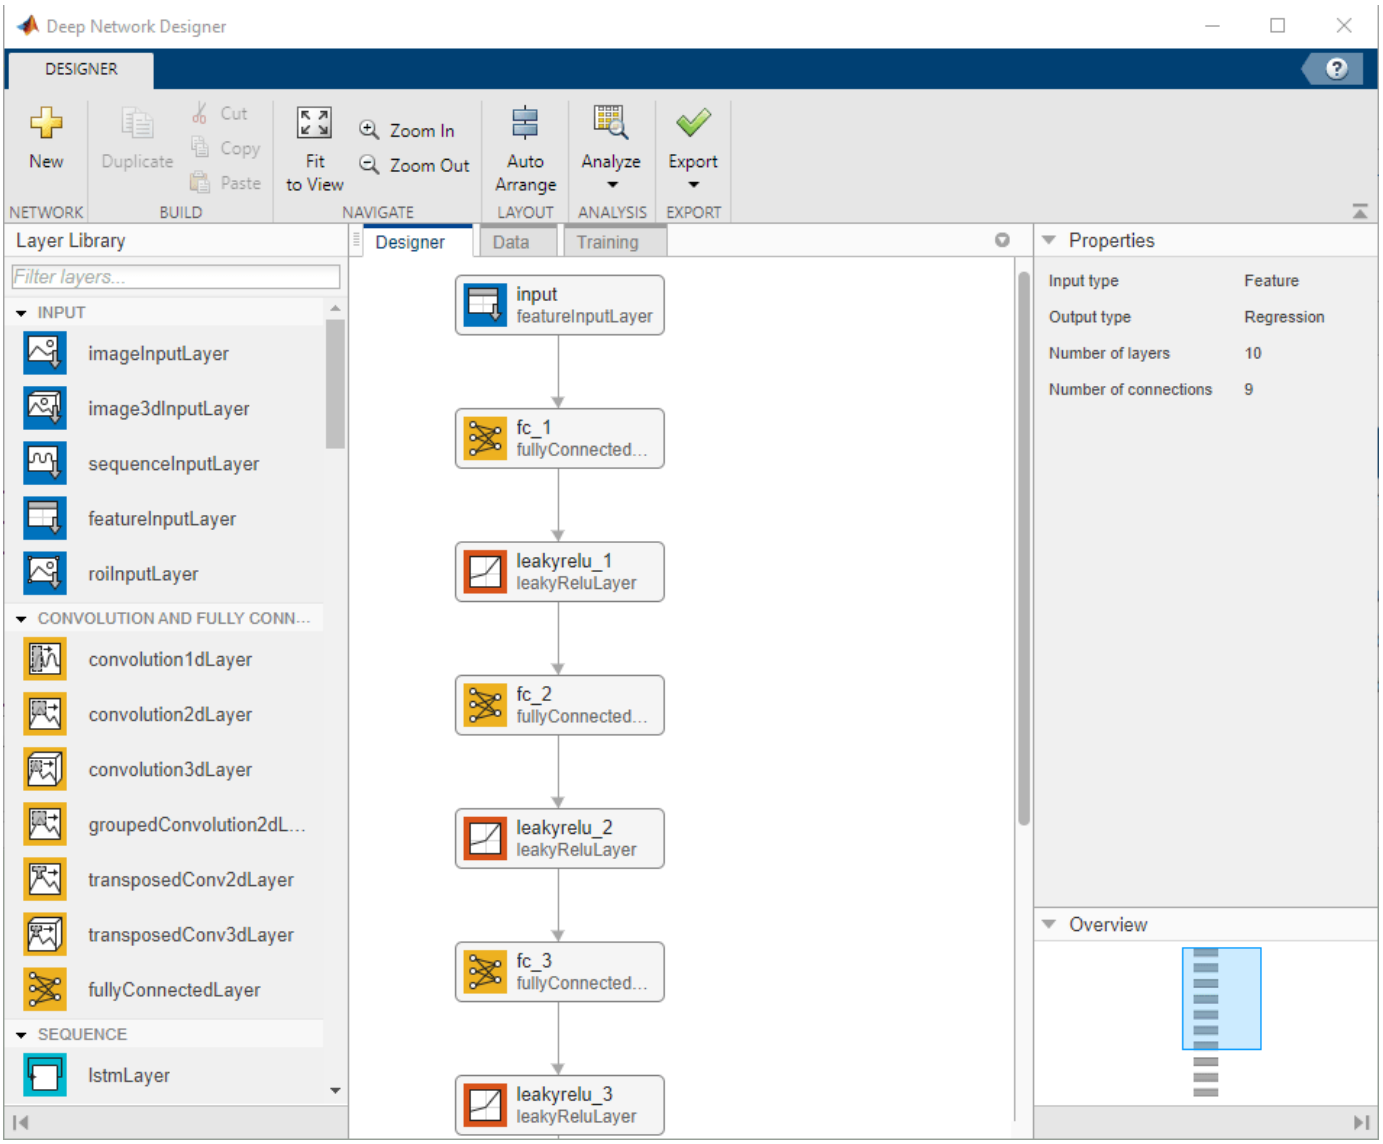
```
numFeatures = size(inputs,2);
layers = [
    featureInputLayer(numFeatures,Normalization='zscore')
    fullyConnectedLayer(32,WeightsInitializer='he')
    leakyReluLayer
    fullyConnectedLayer(32,WeightsInitializer='he')
    leakyReluLayer
    fullyConnectedLayer(32,WeightsInitializer='he')
    leakyReluLayer
```

```
    fullyConnectedLayer(1,WeightsInitializer='he')
    leakyReluLayer
    regressionLayer];
```

Visualize Network

You can visualize the network using the Deep Network Designer (Deep Learning Toolbox) app or the `analyzeNetwork` (Deep Learning Toolbox) function.

```
deepNetworkDesigner(layerGraph(layers))
```



Train Network

Train the neural network by using the `trainNetwork` (Deep Learning Toolbox) function. The function creates a hold-out set to test the trained network and allocates a validation set to monitor the overfitting during the training. By default, `trainNetwork` uses a GPU if one is available; otherwise, it uses a CPU. Training on a GPU requires Parallel Computing Toolbox™ and a supported

GPU device. For information, see “Deep Learning with MATLAB on Multiple GPUs” (Deep Learning Toolbox).

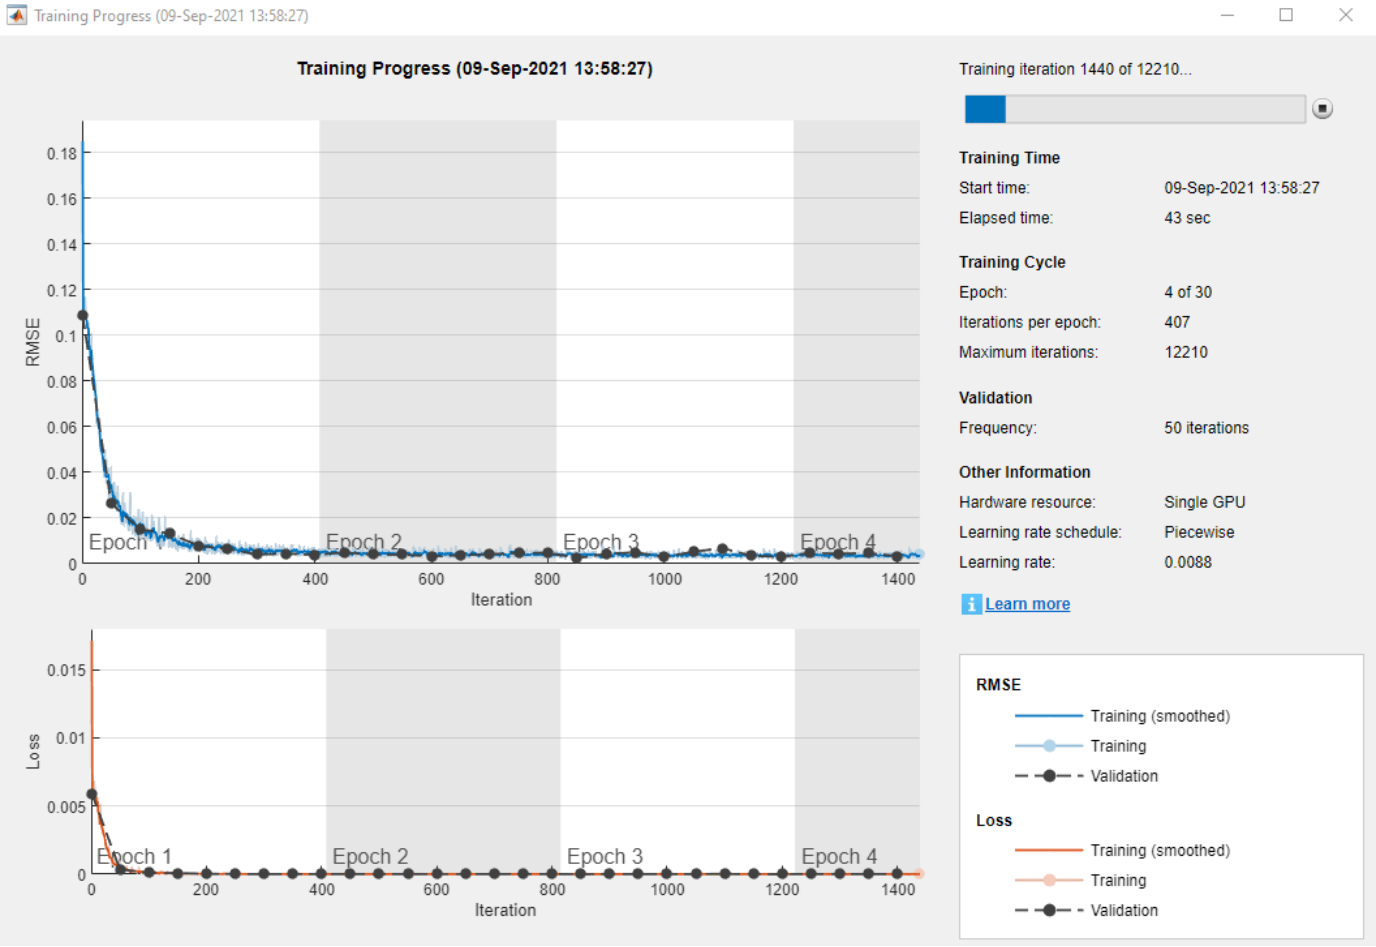
```
n = size(Price,1);
c = cvpartition(n,Holdout=1/5);     % Hold out 1/5 of the data set for testing
XTrain = inputs(training(c),:);     % 4/5 of the input for training
YTrain = Price(training(c),:);      % 4/5 of the target for training
XTest = inputs(test(c),:);          % 1/5 of the input for testing
YTest = Price(test(c),:);           % 1/5 of the target for testing

nTrain = size(XTrain,1);
idx = randperm(nTrain,floor(nTrain*0.1)); % 10% validation data
XValidation = XTrain(idx,:);
XTrain(idx,:) = [];
YValidation = YTrain(idx,:);
YTrain(idx,:) = [];

opts = trainingOptions('adam', ...
    MaxEpochs=30, ...
    Shuffle='every-epoch', ...
    Plots='none', ...
    Verbose=false, ...
    VerboseFrequency=50, ...
    MiniBatchSize=265, ...
    ValidationData={XValidation,YValidation}, ...
    ValidationFrequency=50, ...
    ValidationPatience=Inf, ...
    L2Regularization=1.9e-7, ...
    InitialLearnRate=8.8e-3, ...
    LearnRateSchedule='piecewise', ...
    LearnRateDropPeriod=4, ...
    LearnRateDropFactor=0.128, ...
    SquaredGradientDecayFactor=0.55, ...
    GradientDecayFactor=0.62);
%opts.ExecutionEnvironment = "gpu";  % When using GPU

doTraining = false;
if doTraining
    % Train the network.
    net = trainNetwork(XTrain,YTrain,layers,opts);
else
    % Load the pretrained network for the example.
    load('DeepLearningBarrierHeston.mat','net')
end
```

To avoid waiting for the training, load the pretrained network by setting the `doTraining` flag to `false`. To train the networks using `analyzeNetwork` (Deep Learning Toolbox), set the `doTraining` flag to `true`. The **Training Progress** window displays progress when `Plots` in `trainingOptions` is set as `training-progress`.



Test Network

After training the network model, you can use the `predict` (Deep Learning Toolbox) function to evaluate the test data set containing 30,000 barrier options on this trained network. Compared to the histogram in Calculate Barrier Option Prices Using MonteCarlo Simulation on page 3-150 where Monte Carlo simulation takes 0.46 seconds to price each barrier option (3.9 hours to price 30,000 barrier options), after the network model is trained, a data set containing 30,000 barrier option is evaluated in seconds.

```
% If testing on a GPU, then convert data to a gpuArray.
if opts.ExecutionEnvironment == "gpu" && canUseGPU
    XTest = gpuArray(XTest);
end

YPred = predict(net,XTest);
```

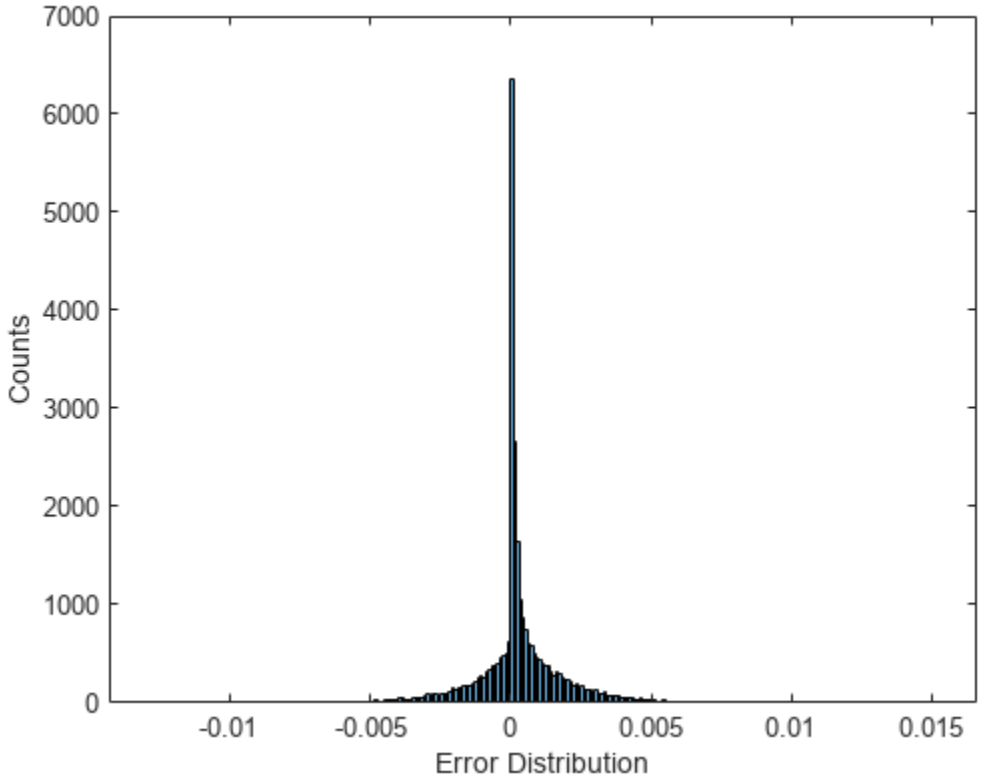
To assess the performance of the network, calculate the mean-squared error (MSE) value.

```
mseTest = mean((YTest - YPred).^2)

mseTest = single
    2.9402e-06
```

The following histogram shows the error distribution for the predicted barrier option price using Deep Learning Toolbox™ with respect to the calculated barrier option price using Financial Instrument Toolbox™.

```
figure
histogram(YTest - YPred, Binwidth=1e-4)
xlabel('Error Distribution')
ylabel('Counts')
```



A plot of the calculated prices and predicted prices shows the performance of the network for the Heston model using the test data.

```
figure
plot(YTest,YPred,'.',[min(YTest),max(YTest)],[min(YTest),max(YTest)],'r')
xlabel('Scaled Actual Price')
ylabel('Scaled Predicted Price')
title('Predictions on Test Data')
```

Hedging Portfolios

Hedging

Hedging is an important consideration in modern finance. Whether or not to hedge, how much portfolio insurance is adequate, and how often to rebalance a portfolio are important considerations for traders, portfolio managers, and financial institutions alike.

If there were no transaction costs, financial professionals would prefer to rebalance portfolios continually, thereby minimizing exposure to market movements. However, in practice, the transaction costs associated with frequent portfolio rebalancing may be expensive. Therefore, traders and portfolio managers must carefully assess the cost required to achieve a particular portfolio sensitivity (for example, maintaining delta, gamma, and vega neutrality). Thus, the hedging problem involves the fundamental tradeoff between portfolio insurance and the cost of such insurance coverage.

Hedging Functions

In this section...

Introduction

Hedging is an investment to reduce the risk of adverse price movements in an asset. Financial Instruments Toolbox offers two functions for assessing the fundamental hedging tradeoff, `hedgeopt` and `hedgeslf`.

The first function, `hedgeopt`, addresses the most general hedging problem. It allocates an optimal hedge to satisfy either of two goals:

- Minimize the cost of hedging a portfolio given a set of target sensitivities.
- Minimize portfolio sensitivities for a given set of maximum target costs.

`hedgeopt` allows investors to modify portfolio allocations among instruments according to either of the goals. The problem is cast as a constrained linear least-squares problem. For additional information about `hedgeopt`, see “Hedging with hedgeopt” on page 4-4.

The second function, `hedgeslf`, attempts to allocate a self-financing hedge among a portfolio of instruments. In particular, `hedgeslf` attempts to maintain a constant portfolio value consistent with reduced portfolio sensitivities (that is, the rebalanced portfolio is hedged against market moves and is closest to being self-financing). If `hedgeslf` cannot find a self-financing hedge, it rebalances the portfolio to minimize overall portfolio sensitivities. For additional information on `hedgeslf`, see “Self-Financing Hedges with hedgeslf” on page 4-9.

The examples in this section consider the *delta*, *gamma*, and *vega* sensitivity measures. In this toolbox, when you work with *interest-rate derivatives*, delta is the price sensitivity measure of shifts in the forward yield curve, gamma is the delta sensitivity measure of shifts in the forward yield curve, and vega is the price sensitivity measure of shifts in the volatility process. See `bdtsens` or `hjmsens` for details on the computation of sensitivities for interest-rate derivatives.

For *equity exotic options*, the underlying instrument is the stock price instead of the forward yield curve. So, delta now represents the price sensitivity measure of shifts in the stock price, gamma is the delta sensitivity measure of shifts in the stock price, and vega is the price sensitivity measure of shifts in the volatility of the stock. See `crrsens`, `eqpsens`, `ittsens`, or `sttsens` for details on the computation of sensitivities for equity derivatives.

For examples showing the computation of sensitivities for interest-rate based derivatives, see “Computing Instrument Sensitivities” on page 2-63. Likewise, for examples showing the computation of sensitivities for equity exotic options, see “Computing Equity Instrument Sensitivities” on page 3-75.

Note The delta, gamma, and vega sensitivities that the toolbox calculates are dollar sensitivities.

Hedging with hedgeopt

Note The numerical results in this section are displayed in the MATLAB bank format. Although the calculations are performed in floating-point double precision, only two decimal places are displayed.

To illustrate the hedging facility, consider the portfolio `HJMInstSet` obtained from the example file `deriv.mat`. The portfolio consists of eight instruments: two bonds, one bond option, one fixed-rate note, one floating-rate note, one cap, one floor, and one swap.

Both hedging functions require some common inputs, including the current portfolio holdings (allocations), and a matrix of instrument sensitivities. To create these inputs, load the example portfolio into memory

```
load deriv.mat;
```

compute price and sensitivities

```
[Delta, Gamma, Vega, Price] = hjmsens(HJMTree, HJMInstSet);
```

```
Warning: Not all cash flows are aligned with the tree. Result will
be approximated.
```

and extract the current portfolio holdings.

```
Holdings = instget(HJMInstSet, 'FieldName', 'Quantity');
```

For convenience place the delta, gamma, and vega sensitivity measures into a matrix of sensitivities.

```
Sensitivities = [Delta Gamma Vega];
```

Each row of the `Sensitivities` matrix is associated with a different instrument in the portfolio, and each column with a different sensitivity measure.

To summarize the portfolio information

```
disp([Price  Holdings  Sensitivities])
```

```
 98.72      100.00      -272.65      1029.90       0.00
 97.53       50.00      -347.43      1622.69      -0.04
  0.05      -50.00        -8.08       643.40      34.07
 98.72       80.00      -272.65      1029.90       0.00
100.55        8.00        -1.04         3.31          0
  6.28       30.00       294.97      6852.56      93.69
  0.05       40.00       -47.16      8459.99      93.69
  3.69       10.00      -282.05      1059.68       0.00
```

The first column above is the dollar unit price of each instrument, the second is the holdings of each instrument (the quantity held or the number of contracts), and the third, fourth, and fifth columns are the dollar delta, gamma, and vega sensitivities, respectively.

The current portfolio sensitivities are a weighted average of the instruments in the portfolio.

```
TargetSens  = Holdings' * Sensitivities
```

```
TargetSens =

     -61910.22     788946.21       4852.91
```

Maintaining Existing Allocations

To illustrate using `hedgeopt`, suppose that you want to maintain your existing portfolio. The first form of `hedgeopt` minimizes the cost of hedging a portfolio given a set of target sensitivities. If you want to maintain your existing portfolio composition and exposure, you should be able to do so without spending any money. To verify this, set the target sensitivities to the current sensitivities.

```
FixedInd = [1 2 3 4 5 6 7 8];
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,Holdings, FixedInd, [], [], TargetSens)
```

```
Holdings =

        100.00
         50.00
        -50.00
         80.00
          8.00
         30.00
         40.00
         10.00

Sens =

     -61910.22     788946.21       4852.91

Cost =

             0

Quantity =

  Columns 1 through 6

       100.00         50.00        -50.00         80.00          8.00         30.00

  Columns 7 through 8

        40.00         10.00
```

Portfolio composition and sensitivities are unchanged, and the cost associated with doing nothing is zero. The cost is defined as the change in portfolio value. This number cannot be less than zero because the rebalancing cost is defined as a nonnegative number.

If `Value0` and `Value1` represent the portfolio value before and after rebalancing, respectively, the zero cost can also be verified by comparing the portfolio values.

```
Value0 = Holdings' * Price
```

```
Value0 =

     23674.62
```

```
Value1 = Quantity * Price
```

```
Value1 =

     23674.62
```

Partially Hedged Portfolio

Building on the example in “Maintaining Existing Allocations” on page 4-5, suppose you want to know the cost to achieve an overall portfolio dollar sensitivity of `[-23000 -3300 3000]`, while allowing trading only in instruments 2, 3, and 6 (holding the positions of instruments 1, 4, 5, 7, and 8 fixed). To find the cost, first set the target portfolio dollar sensitivity.

```
TargetSens = [-23000 -3300 3000];
```

Then, specify the instruments to be fixed.

```
FixedInd = [1 4 5 7 8];
```

Finally, call `hedgeopt`

```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [], [], TargetSens);
```

and again examine the results.

```
Sens =

     -23000.00      -3300.00       3000.00

Cost =

      19174.02

Quantity' =

        100.00
       -141.03
        137.26
         80.00
          8.00
        -57.96
         40.00
         10.00
```

Recompute `Value1`, the portfolio value after rebalancing.

```
Value1 = Quantity * Price

Value1 =

      4500.60
```

As expected, the cost, $19174.02, is the difference between `Value0` and `Value1`, $23674.62 — $4500.60. Only the positions in instruments 2, 3, and 6 have been changed.

Fully Hedged Portfolio

The example in “Partially Hedged Portfolio” on page 4-6 illustrates a partial hedge, but perhaps the most interesting case involves the cost associated with a fully hedged portfolio (simultaneous delta,

gamma, and vega neutrality). In this case, set the target sensitivity to a row vector of 0s and call `hedgeopt` again. The following example uses data from “Hedging with hedgeopt” on page 4-4.

```
TargetSens = [0 0 0];
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price, ...
Holdings, FixedInd, [], [], TargetSens);
```

Examining the outputs reveals that you have obtained a fully hedged portfolio

```
Sens =

         -0.00          -0.00          -0.00
```

but at an expense of over $20,000.

```
Cost =

      23055.90
```

The positions required to achieve a fully hedged portfolio

```
Quantity' =

        100.00
       -182.36
        -19.55
         80.00
          8.00
        -32.97
         40.00
         10.00
```

result in the new portfolio value

```
Value1 = Quantity * Price

Value1 =

      618.72
```

Minimizing Portfolio Sensitivities

The examples in “Fully Hedged Portfolio” on page 4-6 illustrate how to use `hedgeopt` to determine the minimum cost of hedging a portfolio given a set of target sensitivities. In these examples, portfolio target sensitivities are treated as equality constraints during the optimization process. You tell `hedgeopt` what sensitivities you want, and it tells you what it will cost to get those sensitivities.

A related problem involves minimizing portfolio sensitivities for a given set of maximum target costs. For this goal, the target costs are treated as inequality constraints during the optimization process. You tell `hedgeopt` the most you are willing spend to insulate your portfolio, and it tells you the smallest portfolio sensitivities you can get for your money.

To illustrate this use of `hedgeopt`, compute the portfolio dollar sensitivities along the entire cost frontier. From the previous examples, you know that spending nothing replicates the existing portfolio, while spending $23,055.90 completely hedges the portfolio.

Assume, for example, you are willing to spend as much as $50,000, and want to see what portfolio sensitivities will result along the cost frontier. Assume that the same instruments are held fixed, and that the cost frontier is evaluated from $0 to $50,000 at increments of $1000.

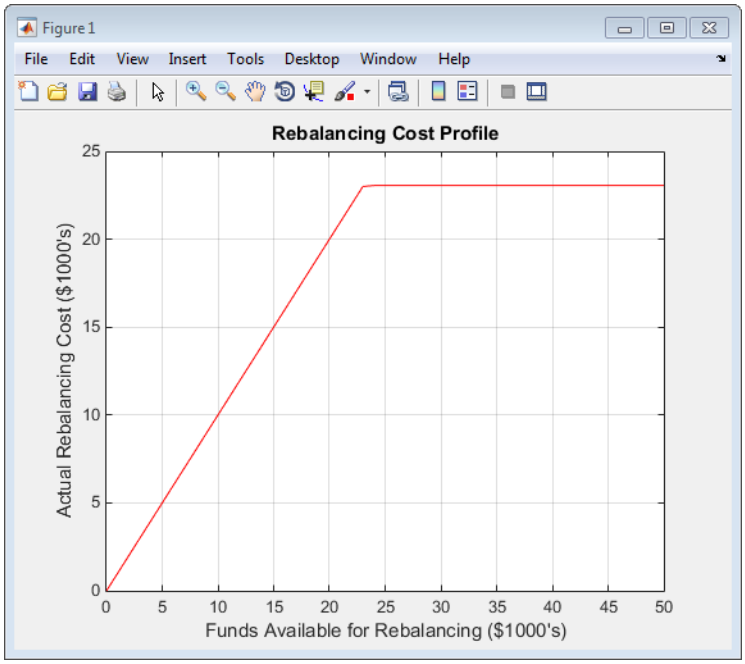
```
MaxCost = [0:1000:50000];
```

Now, call `hedgeopt`.

```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price, ...
Holdings, FixedInd, [], MaxCost);
```

With this data, you can plot the required hedging cost versus the funds available (the amount you are willing to spend)

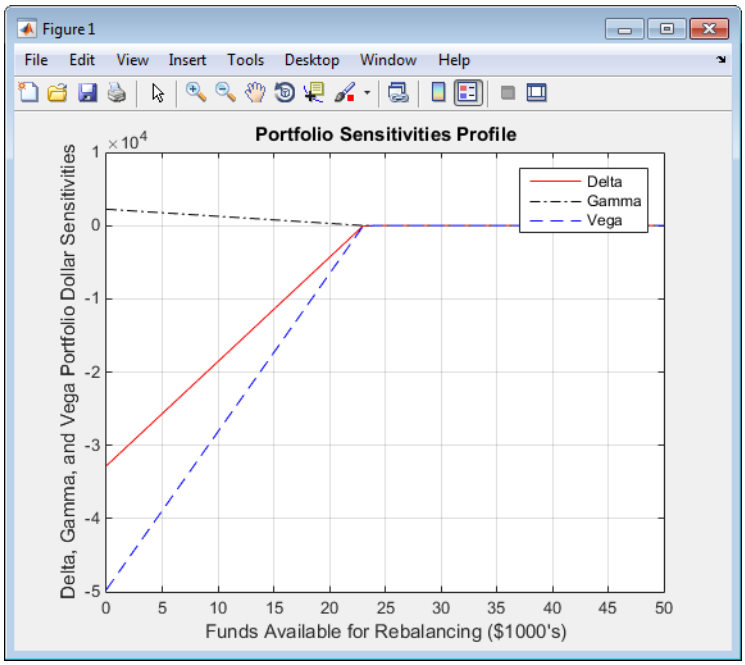
```
plot(MaxCost/1000, Cost/1000, 'red'), grid
xlabel('Funds Available for Rebalancing ($1000''s)')
ylabel('Actual Rebalancing Cost ($1000''s)')
title ('Rebalancing Cost Profile')
```



Rebalancing Cost Profile

and the portfolio dollar sensitivities versus the funds available.

```
figure
plot(MaxCost/1000, Sens(:,1), '-red')
hold('on')
plot(MaxCost/1000, Sens(:,2), '-.black')
plot(MaxCost/1000, Sens(:,3), '--blue')
grid
xlabel('Funds Available for Rebalancing ($1000''s)')
ylabel('Delta, Gamma, and Vega Portfolio Dollar Sensitivities')
title ('Portfolio Sensitivities Profile')
legend('Delta', 'Gamma', 'Vega', 0)
```



Funds Available for Rebalancing

Self-Financing Hedges with hedgeslf

The figures “Rebalancing Cost Profile” on page 4-8 and “Funds Available for Rebalancing” on page 4-9 indicate that there is no benefit because the funds available for hedging exceed $23,055.90, the point of maximum expense required to obtain simultaneous delta, gamma, and vega neutrality. You can also find this point of delta, gamma, and vega neutrality using `hedgeslf`.

```
[Sens, Value1, Quantity] = hedgeslf(Sensitivities, Price,...
Holdings, FixedInd);

Sens =

         -0.00
         -0.00
         -0.00

Value1 =

      618.72

Quantity =

        100.00
       -182.36
        -19.55
         80.00
          8.00
        -32.97
         40.00
         10.00
```

Similar to `hedgeopt`, `hedgeslf` returns the portfolio dollar sensitivities and instrument quantities (the rebalanced holdings). However, in contrast, the second output parameter of `hedgeslf` is the value of the rebalanced portfolio, from which you can calculate the rebalancing cost by subtraction.

```
Value0 - Value1

ans =

       23055.90
```

In this example, the portfolio is clearly not self-financing, so `hedgeslf` finds the best possible solution required to obtain zero sensitivities.

There is, in fact, a third calling syntax available for `hedgeopt` directly related to the results shown above for `hedgeslf`. Suppose, instead of directly specifying the funds available for rebalancing (the most money you are willing to spend), you want to simply specify the number of points along the cost frontier. This call to `hedgeopt` samples the cost frontier at 10 equally spaced points between the point of minimum cost (and potentially maximum exposure) and the point of minimum exposure (and maximum cost).

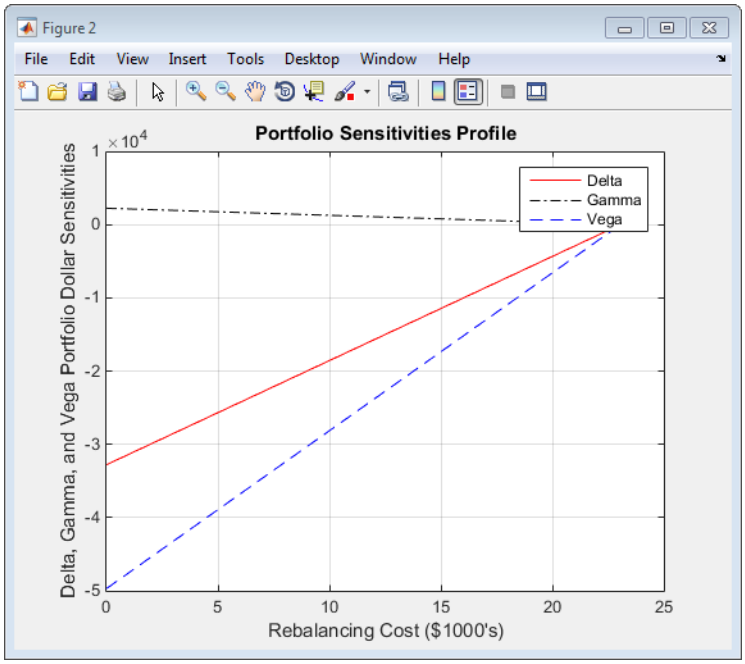
```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, 10)

Sens =
     -32784.46       2231.83     -49694.33
     -29141.74       1983.85     -44172.74
     -25499.02       1735.87     -38651.14
     -21856.30       1487.89     -33129.55
     -18213.59       1239.91     -27607.96
     -14570.87        991.93     -22086.37
     -10928.15        743.94     -16564.78
      -7285.43        495.96     -11043.18
      -3642.72        247.98      -5521.59
          0.00         -0.00          0.00

Cost =
          0.00
       2561.77
       5123.53
       7685.30
      10247.07
      12808.83
      15370.60
      17932.37
      20494.14
      23055.90
```

Now plot this data.

```
figure
plot(Cost/1000, Sens(:,1), '-red')
hold('on')
plot(Cost/1000, Sens(:,2), '-.black')
plot(Cost/1000, Sens(:,3), '--blue')
grid
xlabel('Rebalancing Cost ($1000''s)')
ylabel('Delta, Gamma, and Vega Portfolio Dollar Sensitivities')
title ('Portfolio Sensitivities Profile')
legend('Delta', 'Gamma', 'Vega', 0)
```



Rebalancing Cost

In this calling form, `hedgeopt` calls `hedgeslf` internally to determine the maximum cost needed to minimize the portfolio sensitivities ($23,055.90), and evenly samples the cost frontier between $0 and $23,055.90.

Both `hedgeopt` and `hedgeslf` cast the optimization problem as a constrained linear least squares problem. Depending on the instruments and constraints, neither function is guaranteed to converge to a solution. In some cases, the problem space may be unbounded, and additional instrument equality constraints, or user-specified constraints, may be necessary for convergence. See “Hedging with Constrained Portfolios” on page 4-28 for additional information.

Pricing and Hedging a Portfolio Using the Black-Karasinski Model

This example illustrates how MATLAB® can be used to create a portfolio of interest-rate derivatives securities, and price it using the Black-Karasinski interest-rate model. The example also shows some hedging strategies to minimize exposure to market movements.

Create the Interest-Rate Term Structure Based on Reported Data

The structure `RateSpec` is an interest-rate term structure that defines the initial rate specification from which the tree rates are derived. Use the information of annualized zero coupon rates in the table below to populate the `RateSpec` structure.

```
  From             To           Rate
27 Feb 2007    27 Feb 2008      0.0493
27 Feb 2007    27 Feb 2009      0.0459
27 Feb 2007    27 Feb 2010      0.0450
27 Feb 2007    27 Feb 2012      0.0446
27 Feb 2007    27 Feb 2014      0.0445
27 Feb 2007    27 Feb 2017      0.0450
27 Feb 2007    27 Feb 2027      0.0473
```

This data could be retrieved from the Federal Reserve Statistical Release page by using the Datafeed Toolbox™. In this case, the Datafeed Toolbox™ will connect to FRED® and pull back the rates of the following treasury notes.

```
  Terms    Symbol
 =======   ======
    1   =  DGS1
    2   =  DGS2
    3   =  DGS3
    5   =  DGS5
    7   =  DGS7
    10  =  DGS10
    20  =  DGS20
```

Create the connection object:

```
  c = fred;
```

Create the symbol fetch list:

```
FredNames   = { ...
  'DGS1'; ...      % 1  Year
  'DGS2'; ...      % 2  Year
  'DGS3'; ...      % 3  Year
  'DGS5'; ...      % 5  Year
  'DGS7'; ...      % 7  Year
  'DGS10'; ...     % 10 Year
  'DGS20'};        % 20 Year
```

Define the Terms:

```
Terms = [ 1; ...      % 1  Year
          2; ...      % 2  Year
```

```
          3; ...      % 3  Year
          5; ...      % 5  Year
          7; ...      % 7  Year
         10; ...      % 10 Year
         20];         % 20 Year
```

Set the `StartDate` to Feb 27, 2007:

```
StartDate = datenum('Feb-27-2007');

FredRet = fetch(c,FredNames,StartDate);
```

Set the `ValuationDate` based on the `StartDate`:

```
ValuationDate = StartDate;

EndDates = [];

Rates =[];
```

Create the `EndDates`:

```
for idx = 1:length(FredRet)

 %Pull the rates associated with Feb 27, 2007. All the Fred Rates come
 %back as percents
 Rates = [Rates; ...
     FredRet(idx).Data(1,2) / 100];

  %Determine the EndDates by adding the Term to the year of the
  %StartDate
  EndDates = [EndDates; ...
     round(datenum(...
         year(StartDate)+ Terms(idx,1), ...
         month(StartDate),...
         day(StartDate)))];

end
```

Use the function `intenvset` to create the `RateSpec` with the following data:

```
Compounding = 1;
StartDate = datetime(2007,2,27);
Rates = [0.0493; 0.0459; 0.0450; 0.0446; 0.0446; 0.0450; 0.0473];
EndDates = [datetime(2008,2,27); datetime(2009,2,27) ; datetime(2010,2,27) ; datetime(2012,2,27)
ValuationDate = StartDate;

RateSpec = intenvset('Compounding',Compounding,'StartDates', StartDate,...
                     'EndDates', EndDates, 'Rates', Rates,'ValuationDate', ValuationDate)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [7x1 double]
            Rates: [7x1 double]
         EndTimes: [7x1 double]
       StartTimes: [7x1 double]
         EndDates: [7x1 double]
       StartDates: 733100
    ValuationDate: 733100
```

```
            Basis: 0
     EndMonthRule: 1
```

Specify the Volatility Model

Create the structure `VolSpec` that specifies the volatility process with the following data.

```
Volatility = [0.011892; 0.01563; 0.02021; 0.02125; 0.02165; 0.02065; 0.01803];
Alpha = [0.0001];
VolSpec = bkvolspec(ValuationDate, EndDates, Volatility, EndDates(end), Alpha)
```

```
VolSpec = struct with fields:
             FinObj: 'BKVolSpec'
      ValuationDate: 733100
           VolDates: [7x1 double]
           VolCurve: [7x1 double]
         AlphaCurve: 1.0000e-04
         AlphaDates: 740405
    VolInterpMethod: 'linear'
```

Specify the Time Structure of the Tree

The structure `TimeSpec` specifies the time structure for an interest-rate tree. This structure defines the mapping between the observation times at each level of the tree and the corresponding dates.

```
TimeSpec = bktimespec(ValuationDate, EndDates)
```

```
TimeSpec = struct with fields:
           FinObj: 'BKTimeSpec'
    ValuationDate: 733100
         Maturity: [7x1 double]
      Compounding: -1
            Basis: 0
     EndMonthRule: 1
```

Create the BK Tree

Use the previously computed values for `RateSpec`, `VolSpec`, and `TimeSpec` to create the BK tree.

```
BKTree = bktree(VolSpec, RateSpec, TimeSpec)
```

```
BKTree = struct with fields:
      FinObj: 'BKFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 5 7 10]
        dObs: [733100 733465 733831 734196 734926 735657 736753]
      CFlowT: {1x7 cell}
       Probs: {1x6 cell}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]  [2 3 3 4 5 5 6]  [2 3 4 5 6 7 8]  [2 2 ... ]}
     FwdTree: {1x7 cell}
```

Visualize the interest rate evolution along the tree by looking at the output structure `BKTree`. The function `bktree` returns an inverse discount tree, which you can convert into an interest rate tree with the `cvtree` function.

```
BKTreeR = cvtree(BKTree)
```

```
BKTreeR = struct with fields:
      FinObj: 'BKRateTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 5 7 10]
        dObs: [733100 733465 733831 734196 734926 735657 736753]
      CFlowT: {1x7 cell}
       Probs: {1x6 cell}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]  [2 3 3 4 5 5 6]  [2 3 4 5 6 7 8]  [2 2 ... ]}
    RateTree: {1x7 cell}
```

Look at the upper, middle and lower branch paths of the tree.

```
OldFormat = get(0, 'format');
format short

%Rate at root node:
RateRoot      = trintreepath(BKTreeR, 0)
```

```
RateRoot = 0.0481
```

```
%Rates along upper branch:
RatePathUp    = trintreepath(BKTreeR, [1 1 1 1 1 1])
```

```
RatePathUp = 7×1

    0.0481
    0.0425
    0.0446
    0.0478
    0.0510
    0.0555
    0.0620
```

```
%Rates along middle branch:
RatePathMiddle = trintreepath(BKTreeR, [2 2 2 2 2 2])
```

```
RatePathMiddle = 7×1

    0.0481
    0.0416
    0.0423
    0.0430
    0.0436
    0.0449
    0.0484
```

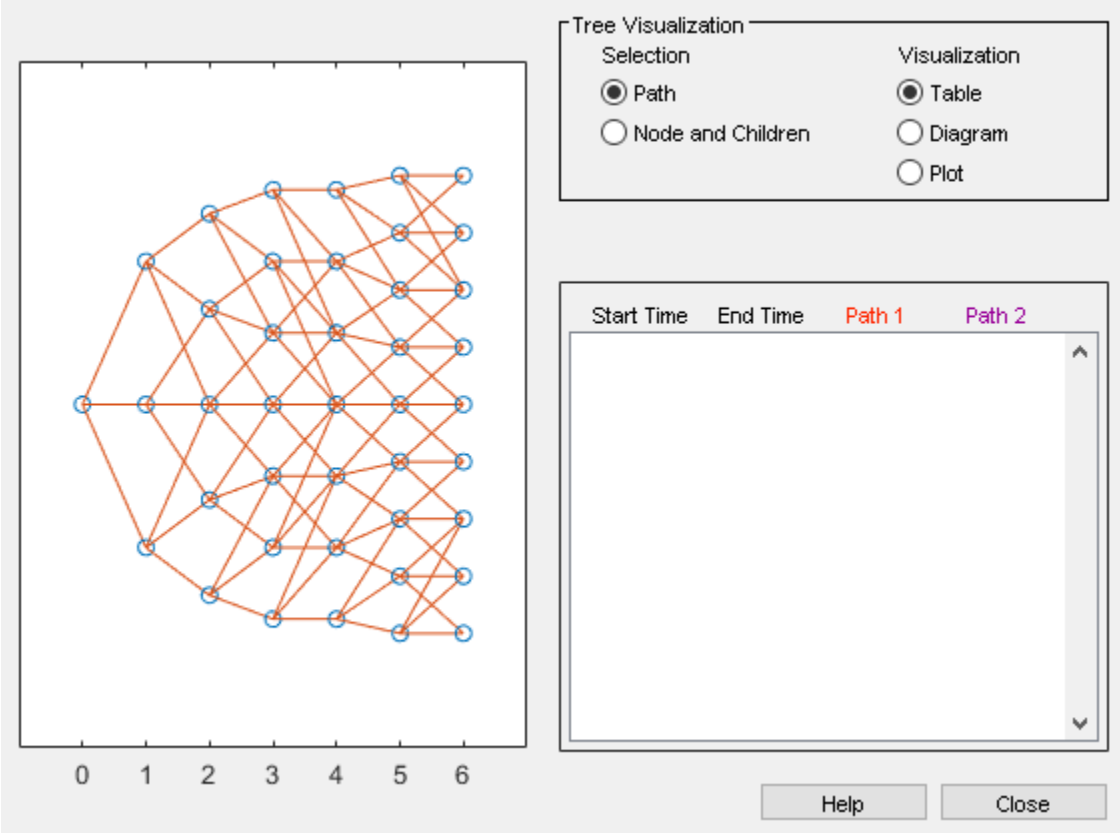
```
%Rates along lower branch:
RatePathDown = trintreepath(BKTreeR, [3 3 3 3 3 3])
```

```
RatePathDown = 7×1

    0.0481
    0.0408
    0.0401
    0.0388
    0.0373
    0.0363
    0.0378
```

You can also display a graphical representation of the tree to examine interactively the rates on the nodes of the tree until maturity. The function `treeviewer` displays the structure of the rate tree in the left window. The tree visualization in the right window is blank, but by selecting **Table/Diagram** and clicking on the nodes you can examine the rates along the paths.

```
treeviewer(BKTreeR);
```



Create an Instrument Portfolio

Create a portfolio consisting of two bonds instruments and an option on the 5% bond.

```
% Two Bonds
CouponRate = [0.04;0.05];
```

```
Settle = datetime(2007,2,27);
Maturity = [datetime(2009,2,27) ; datetime(2010,2,27) ];
Period = 1;

% American Option on the 5% Bond
OptSpec = {'call'};
Strike = 98;
ExerciseDates = datetime(2010,2,27);
AmericanOpt = 1;

InstSet = instadd('Bond', CouponRate, Settle,  Maturity, Period);
InstSet = instadd(InstSet,'OptBond', 2, OptSpec, Strike, ExerciseDates, AmericanOpt);

% Assign Names and Holdings
Holdings = [10; 15;3];
Names = {'4% Bond'; '5% Bond'; 'Option 98'};

InstSet = instsetfield(InstSet, 'Index',1:3, 'FieldName', {'Quantity'}, 'Data', Holdings );
InstSet = instsetfield(InstSet, 'Index',1:3, 'FieldName', {'Name'}, 'Data', Names );
```

Examine the set of instruments contained in the variable `InstSet`.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.04       27-Feb-2007    27-Feb-2009    1      0     1            NaN       NaN
2     Bond 0.05       27-Feb-2007    27-Feb-2010    1      0     1            NaN       NaN

Index Type    UnderInd OptSpec Strike ExerciseDates  AmericanOpt Quantity Name
3     OptBond 2        call    98     27-Feb-2010    1           3        Option 98
```

Price the Portfolio Using the BK Model

Calculate the price of each instrument in the portfolio.

```
[Price, PTree] = bkprice(BKTree, InstSet)
```

```
Price = 3×1

   98.8841
  101.3470
    3.3470

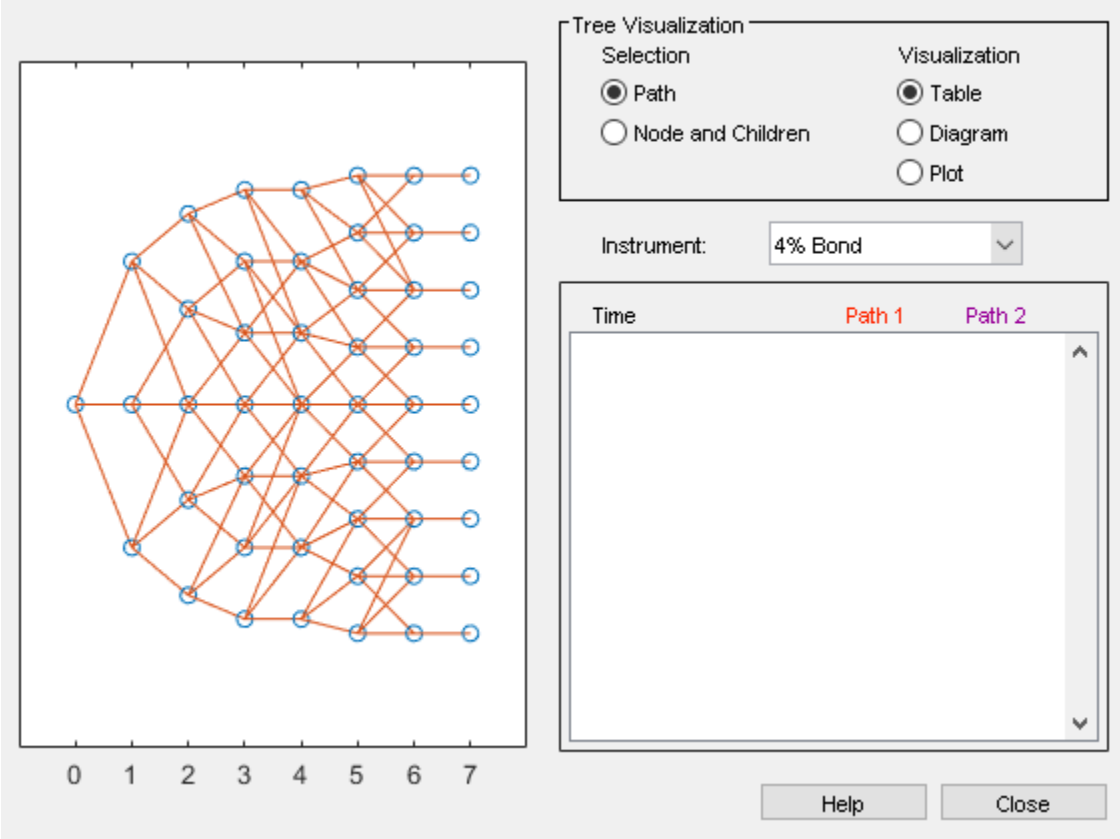
PTree = struct with fields:
     FinObj: 'BKPriceTree'
      PTree: {1x8 cell}
     AITree: {1x8 cell}
     ExTree: {1x8 cell}
       tObs: [0 1 2 3 5 7 10 20]
    Connect: {[2]  [2 3 4]  [2 3 4 5 6]  [2 3 3 4 5 5 6]  [2 3 4 5 6 7 8]  [2 2 3 ... ]}
      Probs: {1x6 cell}
```

The prices in the output vector `Price` correspond to the prices at observation time zero (`tObs = 0`), which is defined as the Valuation Date of the interest-rate tree.

In the `Price` vector, the first element, 98.884, represents the price of the first instrument (4% Bond); the second element, 101.347, represents the price of the second instrument (5% Bond), and 3.347 represents the price of the American call option.

You can also display a graphical representation of the price tree to examine the prices on the nodes of the tree until maturity.

```
treeviewer(PTree,InstSet);
```



Add More Instruments to the Existing Portfolio

Add instruments to the existing portfolio: cap, floor, floating rate note, vanilla swap and a puttable and callable bond.

```
% Cap
StrikeC =0.035;
InstSet = instadd(InstSet,'Cap', StrikeC, Settle, datetime(2010,2,27));

% Floor
StrikeF =0.05;
InstSet = instadd(InstSet,'Floor', StrikeF, Settle, datetime(2009,2,27));

% Floating Rate Note
InstSet = instadd(InstSet,'Float', 30, Settle, datetime(2009,2,27));

% Vanilla Swap
 LegRate =[0.04 5];
```

```
 InstSet = instadd(InstSet,'Swap', LegRate, Settle, datetime(2010,2,27));

% Puttable and Callable Bonds
InstSet = instadd(InstSet,'OptEmBond', CouponRate, Settle,datetime(2010,2,27), {'put';'call'},..
                  Strike, datetime(2010,2,27),'AmericanOpt', 1, 'Period', 1);

% Process Names and Holdings
Holdings = [15 ;5 ;8; 7; 9; 4];
Names = {'3.5% Cap';'5% Floor';'30BP Float';'4%/5BP Swap'; 'PuttBond'; 'CallBond' };

InstSet = instsetfield(InstSet, 'Index',4:9, 'FieldName', {'Quantity'}, 'Data', Holdings );
InstSet = instsetfield(InstSet, 'Index',4:9, 'FieldName', {'Name'}, 'Data', Names );
```

Examine the set of instruments contained in the variable `InstSet`.

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou

```

Hedging

The idea behind hedging is to minimize exposure to market movements. As the underlying changes, the proportions of the instruments forming the portfolio may need to be adjusted to keep the sensitivities within the desired range.

Calculate sensitivities using the BK model.

```
[Delta, Gamma, Vega, Price] = bksens(BKTree, InstSet);
```

Get the current portfolio holdings.

```
Holdings = instget(InstSet, 'FieldName', 'Quantity');
```

Create a matrix of sensitivities.

```
Sensitivities = [Delta Gamma Vega];
```

Each row of the `Sensitivities` matrix is associated with a different instrument in the portfolio, and each column with a different sensitivity measure.

```
format bank
disp([Price  Holdings  Sensitivities])
```

```
         98.88         10.00       -185.47        528.47             0
        101.35         15.00       -277.51       1045.05             0
          3.35          3.00       -223.52      11843.32             0

          0.75          5.00       -132.97      11566.69             0
        100.56          8.00         -0.80          2.02             0
         -1.53          7.00       -272.08       1027.85          0.00
         98.60          9.00       -168.92      21712.82             0
         98.00          4.00        -53.99     -10798.27             0
```

The first column above is the dollar unit price of each instrument, the second column is the number of contracts of each instrument, and the third, fourth, and fifth columns are the dollar delta, gamma, and vega sensitivities.

The current portfolio sensitivities are a weighted average of the instruments in the portfolio.

```
TargetSens  = Holdings' * Sensitivities
```

```
TargetSens = 1×3

      -7249.21     317573.92         -0.00
```

Obtain a Neutral Sensitivity Portfolio Using `hedgeslf`

Suppose you want to obtain a delta, gamma and vega neutral portfolio. The function `hedgeslf` finds the reallocation in a portfolio of financial instruments closest to being self-financing (maintaining constant portfolio value).

```
[Sens, Value1, Quantity]= hedgeslf(Sensitivities, Price,Holdings)
```

```
Sens = 3×1

         -0.00
         -0.00
         -0.00

Value1 =
       4637.54

Quantity = 9×1

         10.00
          5.26
         -5.11
          7.06
         -3.05
         12.45
         -7.36
          8.47
```

```
         10.37
```

The function `hedgeslf` returns the portfolio dollar sensitivities (`Sens`), the value of the rebalanced portfolio (`Value1`) and the new allocation for each instrument (`Quantity`). If `Value0` and `Value1` represent the portfolio value before and after rebalancing, you can verify the cost by comparing the portfolio values.

```
Value0 = Holdings' * Price
```

```
Value0 =
       4637.54
```

In this example, the portfolio is fully hedged (simultaneous delta, gamma, and vega neutrality) and self-financing (the values of the portfolio before and after balancing (`Value0` and `Value1`) are the same.

Adding Constraints to Hedge a Portfolio

Suppose that you want to place upper and lower bounds on the individual instruments in the portfolio. Let's say that you want to bound the position of all instruments to within +/- 11 contracts.

Applying these constraints disallows the current positions in the fifth and eighth instruments. All other instruments are currently within the upper/lower bounds.

```
% Specify the lower and upper bounds
LowerBounds = [-11  -11  -11  -11  -11  -11  -11  -11  -11];
UpperBounds = [ 11   11   11   11   11   11   11   11   11];

% Use the function portcons to build the constraints
ConSet = portcons('AssetLims', LowerBounds, UpperBounds);

% Apply the constraints to the portfolio
[Sens, Value, Quantity1] = hedgeslf(Sensitivities, Price, Holdings, [], ConSet)
```

```
Sens = 3×1

             0
             0
             0

Value =
             0

Quantity1 = 9×1

             0
             0
             0
             0
             0
             0
             0
             0
             0
```

Observe that the `hedgeslf` function enforces the bounds on the fifth and eighth instruments, and the portfolio continues to be fully hedged and self-financing.

```
set(0, 'format', OldFormat);
```

Specifying Constraints with ConSet

In this section...

Introduction

Both `hedgeopt` and `hedgeslf` accept an optional input argument, `ConSet`, that allows you to specify a set of linear inequality constraints for instruments in your portfolio. The examples in this section are brief. For additional information regarding portfolio constraint specifications, refer to “Analyzing Portfolios”.

Setting Constraints

For the first example of setting constraints, return to the fully hedged portfolio example that used `hedgeopt` to determine the minimum cost of obtaining simultaneous delta, gamma, and vega neutrality (target sensitivities all `0`). Recall that when `hedgeopt` computes the cost of rebalancing a portfolio, the input target sensitivities you specify are treated as equality constraints during the optimization process. The situation is reproduced next for convenience.

```
TargetSens = [0 0 0];
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [], [], TargetSens);
```

The outputs provide a fully hedged portfolio

```
Sens =
         -0.00          -0.00          -0.00
```

at an expense of over $23,000.

```
Cost =
      23055.90
```

The positions required to achieve this fully hedged portfolio are

```
Quantity' =

        100.00
       -182.36
        -19.55
         80.00
          8.00
        -32.97
         40.00
         10.00
```

Suppose now that you want to place some upper and lower bounds on the individual instruments in your portfolio. You can specify these constraints, along with a variety of general linear inequality constraints, with function `portcons`.

As an example, assume that, in addition to holding instruments 1, 4, 5, 7, and 8 fixed as before, you want to bound the position of all instruments to within +/- 180 contracts (for each instrument, you cannot short or long more than 180 contracts). Applying these constraints disallows the current position in the second instrument (short 182.36). All other instruments are currently within the upper/lower bounds.

You can generate these constraints by first specifying the lower and upper bounds vectors and then calling `portcons`.

```
LowerBounds = [-180 -180 -180 -180 -180 -180 -180 -180];
UpperBounds = [ 180  180   180 180  180  180  180  180];
ConSet = portcons('AssetLims', LowerBounds, UpperBounds);
```

To impose these constraints, call `hedgeopt` with `ConSet` as the last input.

```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [], [], TargetSens, ConSet);
```

Examine the outputs and see that they are all set to `NaN`, indicating that the problem, given the constraints, is not solvable. Intuitively, the results mean that you cannot obtain simultaneous delta, gamma, and vega neutrality with these constraints at any price.

To see how close you can get to portfolio neutrality with these constraints, call `hedgeslf`.

```
[Sens, Value1, Quantity] = hedgeslf(Sensitivities, Price,...
Holdings, FixedInd, ConSet);

Sens =

       -352.43
         21.99
       -498.77

Value1 =

      855.10

Quantity =

        100.00
       -180.00
        -37.22
         80.00
          8.00
        -31.86
         40.00
         10.00
```

`hedgeslf` enforces the lower bound for the second instrument, but the sensitivity is far from neutral. The cost to obtain this portfolio is

```
Value0 - Value1

ans =

      22819.52
```

Portfolio Rebalancing

As a final example of user-specified constraints, rebalance the portfolio using the second hedging goal of `hedgeopt`. Assume that you are willing to spend as much as $20,000 to rebalance your portfolio, and you want to know what minimum portfolio sensitivities you can get for your money. In this form, recall that the target cost ($20,000) is treated as an inequality constraint during the optimization process.

For reference, start up `hedgeopt` without any user-specified linear inequality constraints.

```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [], 20000);

Sens =

      -4345.36        295.81      -6586.64
Cost =

      20000.00

Quantity' =

        100.00
       -151.86
       -253.47
         80.00
          8.00
        -18.18
         40.00
         10.00
```

This result corresponds to the $20,000 point along the Portfolio Sensitivities Profile shown in the figure “Rebalancing Cost” on page 4-11.

Assume that, in addition to holding instruments 1, 4, 5, 7, and 8 fixed as before, you want to bound the position of all instruments to within +/- 150 contracts (for each instrument, you cannot short more than 150 contracts and you cannot long more than 150 contracts). These bounds disallow the current position in the second and third instruments (-151.86 and -253.47). All other instruments are currently within the upper/lower bounds.

As before, you can generate these constraints by first specifying the lower and upper bounds vectors and then calling `portcons`.

```
LowerBounds = [-150 -150 -150 -150 -150 -150 -150 -150];
UpperBounds = [ 150  150  150  150  150  150  150  150];
ConSet = portcons('AssetLims', LowerBounds, UpperBounds);
```

To impose these constraints, again call `hedgeopt` with `ConSet` as the last input.

```
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings,FixedInd, [], 20000, [], ConSet);

Sens =

      -8818.47        434.43      -4010.79

Cost =
```

```
      19876.89

Quantity' =

        100.00
       -150.00
       -150.00
         80.00
          8.00
        -28.32
         40.00
         10.00
```

With these constraints, `hedgeopt` enforces the lower bound for the second and third instruments. The cost incurred is $19,876.89.

Hedging with Constrained Portfolios

In this section...

Overview

Both hedging functions cast the optimization as a constrained linear least-squares problem. (See the function `lsqlin` for details.) In particular, `lsqlin` attempts to minimize the constrained linear least squares problem

$$\min_x \frac{1}{2}\|Cx - d\|_2^2 \text{ such that } \quad A \cdot x \le b$$
$$Aeq \cdot x = beq$$
$$lb \le x \le ub$$

where C, A, and Aeq are matrices, and d, b, beq, lb, and ub are vectors. For Financial Instruments Toolbox software, x is a vector of asset holdings (contracts).

Depending on the constraint and the number of assets in the portfolio, a solution to a particular problem may or may not exist. Furthermore, if a solution is found, it may not be unique. For a unique solution to exist, the least squares problem must be sufficiently and appropriately constrained.

Example: Fully Hedged Portfolio

Recall that `hedgeopt` allows you to allocate an optimal hedge by one of two goals:

- Minimize the cost of hedging a portfolio given a set of target sensitivities.
- Minimize portfolio sensitivities for a given set of maximum target costs.

As an example, reproduce the results for the fully hedged portfolio example.

```
TargetSens = [0 0 0];
FixedInd   = [1 4 5 7 8];
[Sens,Cost,Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [], [], TargetSens);
```

```
Sens =

         -0.00          -0.00          -0.00

Cost =

       23055.90

Quantity' =
```

```
   98.72
 -182.36
  -19.55
   80.00
    8.00
  -32.97
   40.00
   10.00
```

This example finds a unique solution at a cost of just over $23,000. The matrix `C` (formed internally by `hedgeopt` and passed to `lsqlin`) is the asset `Price` vector expressed as a row vector.

```
C = Price' == [98.72 97.53 0.05 98.72 100.55 6.28 0.05 3.69]
```

The vector `d` is the current portfolio value `Value0 = 23674.62`. The example maintains, as closely as possible, a constant portfolio value subject to the specified constraints.

Additional Constraints

In the absence of any additional constraints, the least squares objective involves a single equation with eight unknowns. This is an under-determined system of equations. Because such systems generally have an infinite number of solutions, you need to specify additional constraints to achieve a solution with practical significance.

The additional constraints can come from two sources:

- User-specified equality constraints
- Target sensitivity equality constraints imposed by `hedgeopt`

The example in “Fully Hedged Portfolio” on page 4-6 specifies five equality constraints associated with holding assets 1, 4, 5, 7, and 8 fixed. This reduces the number of unknowns from eight to three, which is still an under-determined system. However, when combined with the first goal of `hedgeopt`, the equality constraints associated with the target sensitivities in `TargetSens` produce an additional system of three equations with three unknowns. This additional system guarantees that the weighted average of the delta, gamma, and vega of assets 2, 3, and 6, together with the remaining assets held fixed, satisfy the overall portfolio target sensitivity needs in `TargetSens`.

Combining the least-squares objective equation with the three portfolio sensitivity equations provides an overall system of four equations with three unknown asset holdings. This is no longer an under-determined system, and the solution is as shown.

If the assets held fixed are reduced, for example, `FixedInd = [1 4 5 7]`, `hedgeopt` returns a no cost, fully hedged portfolio (`Sens = [0 0 0]` and `Cost = 0`).

If you further reduce `FixedInd` (for example, `[1 4 5]`, `[1 4]`, or even `[]`), `hedgeopt` always returns a no cost, fully hedged portfolio. In these cases, insufficient constraints result in an under-determined system. Although `hedgeopt` identifies no cost, fully hedged portfolios, there is nothing unique about them. These portfolios have little practical significance.

Constraints must be *sufficient* and *appropriately defined*. Additional constraints having no effect on the optimization are called *dependent constraints*. As a simple example, assume that parameter Z is constrained such that $Z \le 1$. Furthermore, assume that you somehow add another constraint that effectively restricts $Z \le 0$. The constraint $Z \le 1$ now has no effect on the optimization.

Example: Minimize Portfolio Sensitivities

To illustrate using `hedgeopt` to minimize portfolio sensitivities for a given maximum target cost, specify a target cost of $20,000 and determine the new portfolio sensitivities, holdings, and cost of the rebalanced portfolio.

```
MaxCost = 20000;
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, [1 4 5 7 8], [], MaxCost);

Sens =

      -4345.36        295.81      -6586.64

Cost =

       20000.00

Quantity' =

        100.00
       -151.86
       -253.47
         80.00
          8.00
        -18.18
         40.00
         10.00
```

This example corresponds to the $20,000 point along the cost axis in the figures “Rebalancing Cost Profile” on page 4-8, “Funds Available for Rebalancing” on page 4-9, and “Rebalancing Cost” on page 4-11.

When minimizing sensitivities, the maximum target cost is treated as an inequality constraint; in this case, `MaxCost` is the most you are willing to spend to hedge a portfolio. The least-squares objective matrix `C` is the matrix transpose of the input asset sensitivities

```
C = Sensitivities'
```

a 3-by-8 matrix in this example, and `d` is a 3-by-1 column vector of zeros, `[0 0 0]'`.

Without any additional constraints, the least-squares objective results in an under-determined system of three equations with eight unknowns. By holding assets 1, 4, 5, 7, and 8 fixed, you reduce the number of unknowns from eight to three. Now, with a system of three equations with three unknowns, `hedgeopt` finds the solution shown.

Example: Under-Determined System

Reducing the number of assets held fixed creates an under-determined system with meaningless solutions. For example, see what happens with only four assets constrained.

```
FixedInd = [1 4 5 7];
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [], MaxCost);
```

```
Sens =

         -0.00          -0.00          -0.00

Cost =

      20000.00

Quantity' =

        100.00
        -149.31
        -14.91
         80.00
          8.00
        -34.64
         40.00
        -32.60
```

You have spent $20,000 (all the funds available for rebalancing) to achieve a fully hedged portfolio.

With an increase in available funds to $50,000, you still spend all available funds to get another fully hedged portfolio.

```
MaxCost  = 50000;
[Sens, Cost, Quantity] = hedgeopt(Sensitivities, Price,...
Holdings, FixedInd, [],MaxCost);

Sens =

         -0.00          0.00          0.00
Cost =

      50000.00

Quantity' =

        100.00
       -473.78
        -60.51
         80.00
          8.00
        -18.20
         40.00
        385.60
```

All solutions to an under-determined system are meaningless. You buy and sell various assets to obtain zero sensitivities, spending all available funds every time. If you reduce the number of fixed assets any further, this problem is insufficiently constrained, and you find no solution (the outputs are all `NaN`).

Note also that no solution exists whenever constraints are *inconsistent*. Inconsistent constraints create an infeasible solution space; the outputs are all `NaN`.

Example: Portfolio Constraints with hedgeslf

The other hedging function, `hedgeslf`, attempts to minimize portfolio sensitivities such that the rebalanced portfolio maintains a constant value (the rebalanced portfolio is hedged against market

moves and is closest to being self-financing). If a self-financing hedge is not found, `hedgeslf` tries to rebalance a portfolio to minimize sensitivities.

From a least-squares systems approach, `hedgeslf` first attempts to minimize cost in the same way that `hedgeopt` does. If it cannot solve this problem (a no cost, self-financing hedge is not possible), `hedgeslf` proceeds to minimize sensitivities like `hedgeopt`. Thus, the discussion of constraints for `hedgeopt` is directly applicable to `hedgeslf` as well.

To illustrate this hedging facility using equity exotic options, consider the portfolio `CRRInstSet` obtained from the example MAT-file `deriv.mat`. The portfolio consists of eight option instruments: two stock options, one barrier, one compound, two lookback, and two Asian.

The hedging functions require inputs that include the current portfolio holdings (allocations) and a matrix of instrument sensitivities. To create these inputs, start by loading the example portfolio into memory

```
load deriv.mat;
```

Next, compute the prices and sensitivities of the instruments in this portfolio.

```
[Delta, Gamma, Vega, Price] = crrsens(CRRTree, CRRInstSet);
```

Extract the current portfolio holdings (the quantity held or the number of contracts).

```
Holdings = instget(CRRInstSet, 'FieldName', 'Quantity');
```

For convenience place the delta, gamma, and vega sensitivity measures into a matrix of sensitivities.

```
Sensitivities = [Delta Gamma Vega];
```

Each row of the `Sensitivities` matrix is associated with a different instrument in the portfolio and each column with a different sensitivity measure.

```
disp([Price  Holdings  Sensitivities])
```

```
    8.29   10.00    0.59    0.04   53.45
    2.50    5.00   -0.31    0.03   67.00
   12.13    1.00    0.69    0.03   67.00
    3.32    3.00   -0.12   -0.01  -98.08
    7.60    7.00   -0.40  -45926.32   88.18
   11.78    9.00   -0.42  -112143.15  119.19
    4.18    4.00    0.60   45926.32   49.21
    3.42    6.00    0.82   112143.15   41.71
```

The first column contains the dollar unit price of each instrument, the second contains the holdings of each instrument, and the third, fourth, and fifth columns contain the delta, gamma, and vega dollar sensitivities, respectively.

Suppose that you want to obtain a delta, gamma, and vega neutral portfolio using `hedgeslf`.

```
[Sens, Value1, Quantity]= hedgeslf(Sensitivities, Price, ...
Holdings)
```

```
Sens =

    0.00
   -0.00
    0.00

Value1 =
```

```
        313.93

Quantity =

         10.00
          7.64
         -1.56
         26.13
          9.94
          3.73
         -0.75
          8.11
```

`hedgeslf` returns the portfolio dollar sensitivities (`Sens`), the value of the rebalanced portfolio (`Value1`) and the new allocation for each instrument (`Quantity`).

If `Value0` and `Value1` represent the portfolio value before and after rebalancing, respectively, you can verify the cost by comparing the portfolio values.

```
Value0= Holdings' * Price

Value0 =

        313.93
```

In this example, the portfolio is fully hedged (simultaneous delta, gamma, and vega neutrality) and self-financing (the values of the portfolio before and after balancing (`Value0` and `Value1`) are the same.

Suppose now that you want to place some upper and lower bounds on the individual instruments in your portfolio. By using function `portcons`, you can specify these constraints, along with various general linear inequality constraints.

As an example, assume that, in addition to holding instrument 1 fixed as before, you want to bound the position of all instruments to within +/- 20 contracts (for each instrument, you cannot short or long more than 20 contracts). Applying these constraints disallows the current position in the fourth instrument (long 26.13). All other instruments are currently within the upper/lower bounds.

You can generate these constraints by first specifying the lower and upper bounds vectors and then calling `portcons`.

```
LowerBounds = [-20  -20  -20  -20  -20  -20  -20  -20];
UpperBounds = [20  20  20  20  20  20  20  20];
ConSet = portcons('AssetLims', LowerBounds, UpperBounds);
```

To impose these constraints, call `hedgeslf` with `ConSet` as the last input.

```
[Sens, Cost, Quantity1] = hedgeslf(Sensitivities, Price, ...
Holdings, 1, ConSet)

Sens =

         -0.00
          0.00
          0.00

Cost =
```

```
        313.93

Quantity1 =

         10.00
          5.28
         10.98
         20.00
         20.00
         -6.99
        -20.00
          9.39
```

Observe that `hedgeslf` enforces the upper bound on the fourth instrument, and the portfolio continues to be fully hedged and self-financing.

Hedging Strategies Using Spread Options

This example shows different hedging strategies to minimize exposure in the Energy market using Crack Spread Options.

Understanding Crack Spread Options

In the petroleum industry, refiners are concerned about the difference between their input costs (crude oil) and output prices (refined products - gasoline, heating oil, diesel fuel, and so on). The differential between these two underlying commodities is referred to as a *Crack Spread*. It represents the profit margin between crude oil and the refined products.

A *Spread option* is an option on the spread where the holder has the right, but not the obligation, to enter into a spot or forward spread contract. Crack Spread Options are often used to protect against declines in the crack spread or to monetize volatility or price expectations on the spread.

Example 1: Protecting Margins using a 1:1 Crack Spread Option

A marketer is interested in protecting his gasoline margin since current prices are strong. A crack spread option strategy is used to maintain profits for the following season. In March the June WTI crude oil futures are at $91.10 per barrel and RBOB gasoline futures contract are at $2.72 per gallon. The marketer's strategy is a long crack call involving purchasing RBOB gasoline futures and selling crude oil futures.

```
OldFormat = get(0, 'format');
format bank

% Price and volatility of RBOB gasoline
Price1gallon = 2.72;          % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Vol1 = 0.39;

% Price and volatility of WTI crude oil
Price2 = 91.10;         % $/barrel
Vol2 = 0.34;

% Assume the following data
% Spread Option
Strike = 20;
OptSpec = 'call';
Settle =   '01-March-2013';
Maturity = '01-June-2013';
Corr = 0.45;     % Correlation of underlying commodities
```

Define the `RateSpec` and `StockSpec`.

```
% Define RateSpec
Rate = 0.035;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rate, 'Compounding', ...
    Compounding, 'Basis', Basis);

% Define StockSpec for the two assets
```

```
StockSpec1 = stockspec(Vol1, Price1);
StockSpec2 = stockspec(Vol2, Price2);
```

Price the Crack Spread Option

Use the function `spreadbybjs` in the Financial Instruments Toolbox™ to price the spread option using the Bjerksund and Stensland model.

```
Price = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
                      Maturity, OptSpec, Strike, Corr)
```

```
Price =
          9.91
```

The 1:1 implied current crack spread between these two underlyings is $23.14 per barrel.

```
CrackSpread = Price1 - Price2    % $/barrel
```

```
CrackSpread =
         23.14
```

Suppose that by expiration day, June crude oil prices decrease to $90.34 per barrel and gasoline prices rise to $2.89 per gallon. The price changes cause the marketer's profit margin (the new implied crack spread) to increase from $23.14/barrel to $31.04/barrel:

```
NewCrackSpread = (2.89 * 42) - 90.34
```

```
NewCrackSpread =
         31.04
```

Since the marketer purchased a long crack call on the $20 call, the option is now in the money by $11.04.

```
(NewCrackSpread - Strike)
```

```
ans =
         11.04
```

The marketer paid $9.91 from the long crack call, this protects the margin by $1.13.

```
(NewCrackSpread - Strike - Price)
```

```
ans =
          1.13
```

This strategy provides the marketer protection during spread increase scenarios.

Example 2: Creating a Floor with Crack Spread Options

A refiner is interested in covering its fixed and operating costs, but still profit from a favorable move in the market. In March the May WTI crude oil futures are at $99.43 per barrel and RBOB gasoline futures contract are at $3.04 per gallon. The refiner believes that the spread between those commodities of $28.25 per barrel is favorable. Of this, $11 corresponds to operating and fixed costs,

and $17.25 is the net refining margin. The refiner's strategy is to sell the crack spread by selling 10 RBOB gasoline futures and buying 10 crude oil futures.

```
% Price and volatility of RBOB gasoline
Price1gallon = 3.04;          % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Vol1 = 0.35;
Div1 = 0.0783;

% Price and volatility of WTI crude oil
Price2 = 99.43;         % $/barrel
Vol2 = 0.38;
Div2 = 0.0571;
```

The refiner purchases 10 May RBOB gasoline crack spread puts with a strike price of $25.

```
% Spread Option
Strike = 25;
OptSpec = 'put';
Settle =   '01-March-2013';
Maturity = '01-May-2013';
Corr = 0.30;      % Correlation of underlying commodities
```

Define the `RateSpec` and `StockSpec`.

```
% Define RateSpec
Rate = 0.035;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rate, 'Compounding', ...
    Compounding, 'Basis', Basis);

% Define StockSpec for the two assets
StockSpec1 = stockspec(Vol1, Price1, 'Continuous', Div1);
StockSpec2 = stockspec(Vol2, Price2, 'Continuous', Div2);
```

Price the Crack Spread Option

Use the function `spreadbyfd` in the Financial Instruments Toolbox™ to price the American spread option using the finite difference method.

```
Price = spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
                   Maturity, OptSpec, Strike, Corr, 'AmericanOpt', 1)
```

```
Price =
          6.61
```

By expiration, if the option is exercised, the refiner would have hedged the cost of purchasing 10000 barrels of crude oil with the revenue of selling 10000 barrels of RBOB gasoline. The futures contract represents 1000 barrels of crude oil and 42000 gallons of gasoline.

```
CostOfHedge = Price * 10000   % Option premium
```

```
CostOfHedge =
      66122.24
```

The hedge cost is $66386 to implement and guarantee that neither a fall in RBOB gasoline prices or an increase in WTI crude oil prices will diminish the refining margin below $25.

```
ProfitMargin = 14 * 10000   %$
```

```
ProfitMargin =
     140000.00
```

```
CrackingMargin = ProfitMargin - CostOfHedge
```

```
CrackingMargin =
      73877.76
```

This strategy allows a cracking margin of $73613.

Another strategy for the refiner could be to buy the $22 puts at a price of $5.38.

```
StrikeNew = 22;

PriceNew = spreadbyfd(RateSpec, StockSpec1, StockSpec2, Settle, ...
                      Maturity, OptSpec, StrikeNew, Corr, 'AmericanOpt', 1)
```

```
PriceNew =
          5.36
```

This time the hedge would have cost $53823, but it also guarantees a $11 per barrel or a $56176 cracking margin.

```
NewCostOfHedge = PriceNew * 10000   % Option premium
```

```
NewCostOfHedge =
      53570.97
```

```
NewProfitMargin = 11 * 10000
```

```
NewProfitMargin =
     110000.00
```

```
CrackingMargin = NewProfitMargin - NewCostOfHedge
```

```
CrackingMargin =
      56429.03
```

Example 3: Using Collars to Reduce the Cost of Hedging

A refiner is concerned about its cost of hedging and decides to use a collar strategy. In April the crack spread is trading at $4.23 per barrel. The refiner is not convinced to lock in this margin, but also

wants to protect against price changes causing the refinery margin to decrease less than $4 per barrel.

```
% Price and volatility of heating oil
Price1gallon = 2.52;          % $/gallon
Price1 = Price1gallon * 42;   % $/barrel
Vol1 = 0.38;
Div1 = 0.0762;

% Price and volatility of WTI crude oil
Price2 = 101.61;         % $/barrel
Vol2 = 0.34;
Div2 = 0.1169;
```

To accomplish the collar strategy the refiner sells a call spread option with a strike of $4.50 and uses the premium income to offset the cost of purchasing a put spread option with a strike of $4. This allows the refiner to benefit if market prices move up, and protects it if market prices move down.

```
% Assume the following data
Strike = [4.50;4];
OptSpec = {'call';'put'};
Settle =   '01-April-2013';
Maturity = '01-June-2013';
Corr = 0.35;       % Correlation of underlying commodities
```

Define the `RateSpec` and `StockSpec`.

```
% Define RateSpec
Rate = 0.035;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, ...
    'EndDates', Maturity, 'Rates', Rate, 'Compounding', ...
    Compounding, 'Basis', Basis);

% Define StockSpec for the two assets
StockSpec1 = stockspec(Vol1, Price1, 'Continuous', Div1);
StockSpec2 = stockspec(Vol2, Price2, 'Continuous', Div2);
```

Price the Crack Spread Options

Use the function `spreadbybjs` in the Financial Instruments Toolbox™ to price the spread options using the Bjerksund and Stensland model.

```
Price = spreadbybjs(RateSpec, StockSpec1, StockSpec2, Settle, ...
                      Maturity, OptSpec, Strike, Corr)
```

```
Price = 2×1

          7.06
          6.43
```

The collar strategy allows the refiner to reduce the cost of the hedge to $0.63.

```
% CostOfHedge = Premium of Call - Premium of Put
CostOfHedge = Price(1) - Price(2)
```

```
CostOfHedge =
          0.63
```

The refiner is protected if the crack spread narrows to less than $4. If the crack spread widens to more than $4.50, the refiner will not benefit over this amount if he has hedged 100% of all its market exposure.

```
set(0, 'format', OldFormat);
```

Mortgage-Backed Securities

What Are Mortgage-Backed Securities?

Mortgage-backed securities (MBSs) are a type of investment that represents ownership in a group of mortgages. Principal and interest from the individual mortgages are used to pay principal and interest on the MBS.

Ownership in a group of mortgages is typically represented by a *pass-through certificate* (PC). Most pass-through certificates are issued by the Government National Mortgage Agency, a branch of the United States government, or by one of two private corporations: Fannie Mae or Freddie Mac. With these certificates, homeowners' payments pass from the originating bank through the issuing agency to holders of the certificates. These agencies also frequently guarantee that the certificate holder receives timely payment of principal and interest from the PCs.

Fixed-Rate Mortgage Pool

In this section...

Introduction

Financial Instruments Toolbox software supports calculations involved with generic fixed-rate mortgage pools and balloon mortgages. Generic fixed-rate mortgage pools and balloon mortgages have pass-through certificates (PC) that typically have embedded call options in the form of prepayment. Prepayment is an excess payment applied to the principal of a PC. These accelerated payments reduce the effective life of a PC.

The toolbox comes with a standard Bond Market Association (PSA) prepayment model and can generate multiples of standard prepayment speeds. The Public Securities Association provides a set of uniform practices for calculating the characteristics of mortgage-backed securities when there is an assumed prepayment function.

Alternatively, aside from the standard PSA implementation in this toolbox, you can supply your own projected prepayment vectors. Currently, however, custom prepayment functionality that incorporates pool-specific information and interest rate forecasts are not available in this toolbox. If you plan to use custom prepayment vectors in your calculations, you presumably already own such a suite in MATLAB.

Inputs to Functions

Because of the generic, all-purpose nature of the toolbox pass-through functions, you can fine-tune them to conform to a particular mortgage. Most functions require at least this set of inputs:

- Gross coupon rate
- Settlement date
- Issue (effective) date
- Maturity date

Typical optional inputs include standard prepayment speed (or customized vector), net coupon rate (if different from gross coupon rate), and payment delay in number of days.

All calculations are based on expected payment dates and actual cash flow to the investor. For example, when `GrossRate` and `CouponRate` differ as inputs to `mbsdurp`, the function returns a modified duration based on `CouponRate`. (A notable exception is `mbspassthrough`, which returns interest quantities based on the `GrossRate`.)

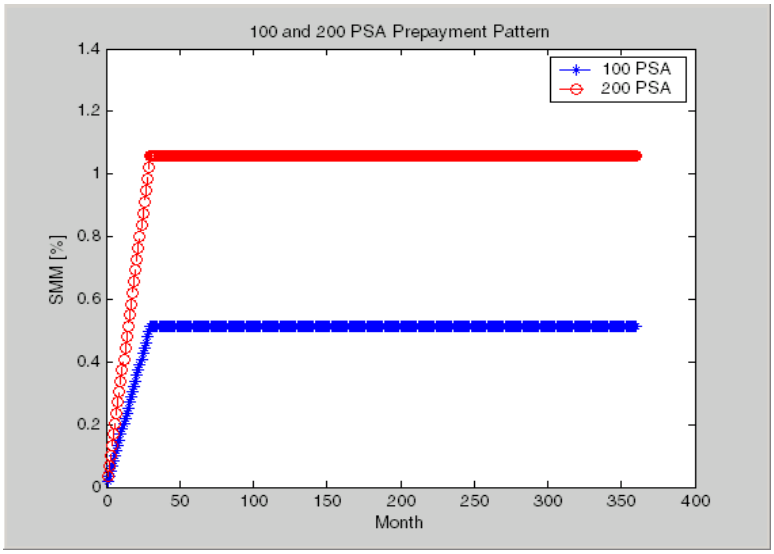
Generating Prepayment Vectors

You can generate PSA multiple prepayment vectors quickly. To generate prepayment vectors of 100 and 200 PSA, type

```
PSASpeed = [100, 200];
[CPR, SMM] = psaspeed2rate(PSASpeed)
```

This function computes two prepayment values: conditional prepayment rate (CPR) and single monthly mortality (SMM) rate. CPR is the percentage of outstanding principal prepaid in one year. SMM is the percentage of outstanding principal prepaid in one month. In other words, CPR is an annual version of SMM.

Since the entire 360-by-2 array is too long to show in this document, observe the SMM (100 and 200 PSA) plots, spaced one month apart, instead.



Prepayment assumptions form the basis upon which far more comprehensive MBS calculations are based. As an illustration, observe the following example, which shows the use of the function `mbscfamounts` to generate cash flows and timings based on a set of standard prepayments.

Consider three mortgage pools that were sold on the issue date (which starts unamortized). The first two pools "balloon out" in 60 months, and the third is regularly amortized to the end. The prepayment speeds are assumed to be 100, 200, and 200 PSA, respectively.

```
Settle     = [datetime(2000,2,1) ; datetime(2000,2,1) ; datetime(2000,2,1) ;datetime(2000,2,1)];

Maturity   = datetime(2030,2,1);

IssueDate  = datetime(2000,2,1);
GrossRate  = 0.08125;
CouponRate = 0.075;
Delay = 14;

PSASpeed = [100, 200];
[CPR, SMM] = psaspeed2rate(PSASpeed);

PrepayMatrix = ones(360,3);
```

```
PrepayMatrix(1:60,1:2) = SMM(1:60,1:2);
PrepayMatrix(:,3) = SMM(:,2);

[CFlowAmounts, CFlowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, [], PrepayMatrix);
```

The fourth output argument, `Factors`, indicates the fraction of the balance still outstanding at the beginning of each month. A snapshot of this argument in the MATLAB Variables editor illustrates the 60-month life of the first two of the mortgages with balloon payments and the continuation of the third mortgage until the end (360 months).

	59	60	61	62	63
1	0.7627	0.7580	0.7533	0	0
2	0.6021	0.5951	0.5882	0	0
3	0.6021	0.5951	0.5882	0.5813	0.5746

You can readily see that `mbscfamounts` is the building block of most fixed-rate and balloon pool cash flows.

Mortgage Prepayments

Prepayment is beneficial to the pass-through owner when a mortgage pool has been purchased at discount. The next example compares mortgage yields (compounded monthly) versus the purchase clean price with constant prepayment speed. The example illustrates that when you have purchased a pool at a discount, prepayment generates a higher yield with decreasing purchase price.

```
Price = [85; 90; 95];
Settle = datetime(2002,4,15);
Maturity = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;
```

Compute the mortgage and bond-equivalent yields.

```
[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Speed)

MYield =

    0.1018
    0.0918
    0.0828

BEMBSYield =

    0.1040
```

```
    0.0936
    0.0842
```

If for this same pool of mortgages, there was no prepayment (`Speed = 0`), the yields would decline to

```
MYield =

    0.0926
    0.0861
    0.0802

BEMBSYield =

    0.0944
    0.0877
    0.0815
```

Likewise, if the rate of prepayment doubled (`Speed = 200`), the yields would increase to

```
MYield =

    0.1124
    0.0984
    0.0858

BEMBSYield =

    0.1151
    0.1004
    0.0873
```

For the same prepayment vector, deeper discount pools earn higher yields. For more information, see `mbsprice` and `mbsyield`.

Risk Measurement

Financial Instruments Toolbox provides the most basic risk measures of a pool portfolio:

- Modified duration
- Convexity
- Average life of pool

Consider the following example, which calculates the Macaulay and modified durations given the price of a mortgage pool.

```
Price = [95; 100; 105];
Settle = datetime(2002,4,15);
Maturity = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

[YearDuration, ModDuration] = mbsdurp(Price, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, Speed)
```

```
YearDuration =

    6.1341
    6.3882
    6.6339

ModDuration =

    5.8863
    6.1552
    6.4159
```

Using Financial Instruments Toolbox functions, you can obtain modified duration and convexity from either price or yield, as long as you specify a prepayment vector or an assumed prepayment speed. The toolbox risk-measurement functions (`mbsdurp`, `mbsdury`, `mbsconvp`, `mbsconvy`, and `mbswal`) adhere to the guidelines listed in the *PSA Uniform Practices* manual.

Mortgage Pool Valuation

For accurate valuation of a mortgage pool, you must generate interest-rate paths and use them with mortgage pool characteristics to properly value the pool. A widely used methodology is the option-adjusted spread (OAS). OAS measures the yield spread that is not directly attributable to the characteristics of a fixed-income investment.

Calculating OAS

Prepayment alters the cash flows of an otherwise regularly amortizing mortgage pool. A comprehensive option-adjusted spread calculation typically begins with the generation of a set of paths of spot rates to predict prepayment. A path is collection of i spot-rate paths, with corresponding j cash flows on each of those paths.

The effect of the OAS on pool pricing is shown mathematically in the following equation, where K is the option-adjusted spread.

$$PoolPrice = \frac{1}{NumberofPaths} \times \sum_{i}^{NumberofPaths} \sum_{j}^{CF_{ij}} \frac{CF_{ij}}{(1 + zerorates_{ij} + K)^{T_{ij}}}$$

Calculating Effective Duration

Alternatively, if you are more interested in the sensitivity of a mortgage pool to interest rate changes, use effective duration, which is a more appropriate measure. Effective duration is defined mathematically with the following equation.

$$Effective\ Duration = \frac{P(y + \Delta y) - P(y - \Delta y)}{2P(y)\Delta y}$$

Calculating Market Price

The toolbox has all the components required to calculate OAS and effective duration if you supply prepayment vectors or assumptions. For OAS, given a prepayment vector, you can generate a set of cash flows with `mbscfamounts`. Discounting these cash flows with the reference curve and then adding OAS produces the market price. See “Computing Option-Adjusted Spread” on page 5-9 for a discussion on the computation of option-adjusted spread.

Effective duration is a more difficult issue. While modified duration changes the discounting process (by changing the yield used to discount cash flows), effective duration must account for the change in cash flow because of the change in yield. A possible solution is to recompute prices using `mbsprice` for a small change in yield, in both the upwards and downwards directions. In this case, you must recompute the prepayment input. Internally, this alters the cash flows of the mortgage pool. Assuming that the OAS stays constant in all yield environments, you can apply a set of discounting factors to the cash flows in up and down yield environments to find the effective duration.

Computing Option-Adjusted Spread

The option-adjusted spread (OAS) is an amount of extra interest added above (or below if negative) the reference zero curve. To compute the OAS, you must provide the zero curve as an extra input. You can specify the zero curve in any intervals and with any compounding method. (To minimize any error due to interpolation, keep the intervals as regular and frequent as possible.) You must supply a prepayment vector or specify a speed corresponding to a standard PSA prepayment vector.

One way to compute the appropriate zero curve for an agency is to look at its bond yields and bootstrap them from the shortest maturity onwards. You can do this with Financial Toolbox™ functions `zbtprice` and `zbtyield`.

The following example shows how to calculate an appropriate zero curve followed by computation of the pool's OAS. This example calculates the OAS of a 30-year fixed rate mortgage with about a 28-year weighted average maturity left, given an assumption of 0, 50, and 100 PSA prepayment speeds.

Create curve for `zerorates`.

```
Bonds = [datenum('11/21/2002')   0        100    0    2    1;
         datenum('02/20/2003')   0        100    0    2    1;
         datenum('07/31/2004')   0.03     100    2    3    1;
         datenum('08/15/2007')   0.035    100    2    3    1;
         datenum('08/15/2012')   0.04875  100    2    3    1;
         datenum('02/15/2031')   0.05375  100    2    3    1];

Yields = [0.0162;
          0.0163;
          0.0211;
          0.0328;
          0.0420;
          0.0501];
```

Since the above is Treasury data and not selected agency data, a term structure of spread is assumed. In this example, the spread declines proportionally from a maximum of 250 basis points at the shortest maturity.

```
Yields = Yields + 0.025 * (1./[1:6]')
```

```
Yields =

    0.0412
    0.0288
    0.0294
    0.0391
    0.0470
    0.0543
```

Get parameters from `Bonds` matrix.

```
Settle = datetime(2002,8,20);
Maturity = Bonds(:,1);
CouponRate = Bonds(:,2);
Face = Bonds(:,3);
Period = Bonds(:,4);
Basis = Bonds(:,5);
EndMonthRule = Bonds(:,6);

[Prices, AccruedInterest] = bndprice(Yields, CouponRate, ...
Settle, Maturity, Period, Basis, EndMonthRule, [], [], [], [], ...
Face)
```

```
Prices =
```

```
   98.9747
   98.5804
  100.1040
   98.1802
  101.3808
   99.2535

AccruedInterest =

         0
         0
    0.1644
    0.0479
    0.0668
    0.0736
```

Use `zbtprice` to solve for zero rates.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCompounding = 2*ones(size(ZeroRatesP));
ZeroMatrix = [CurveDatesP, ZeroRatesP, ZeroCompounding]

ZeroMatrix =

   1.0e+05 *

    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Use output from `zbtprice` to calculate the OAS.

```
Price = 95;
Settle = datenum('20-Aug-2002');
Maturity = datenum('2-Jan-2030');
IssueDate = datenum('2-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Interpolation = 1;
PrepaySpeed = [0; 50; 100];

OAS = mbsprice2oas(ZeroMatrix, Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)

OAS =

    26.0502
    28.6348
    31.2222
```

This example shows that one cash flow set is being discounted and solved for its OAS, as contrasted with the `NumberOfPaths` set of cash flows as shown in “Mortgage Pool Valuation” on page 5-7.

Averaging the sets of cash flows resulting from all simulations into one average cash flow vector and solving for the OAS, discounts the averaged cash flows to have a present value of today's (average) price.

While this example uses the mortgage pool price (`mbsprice2oas`) to determine the OAS, you can also use yield to resolve it (`mbsyield2oas`). Also, there are reverse OAS functions that return prices and yields given OAS (`mbsoas2price` and `mbsoas2yield`).

The example also restates earlier examples that show discount securities benefit from higher level of prepayment, keeping everything else unchanged. The relation is reversed for premium securities.

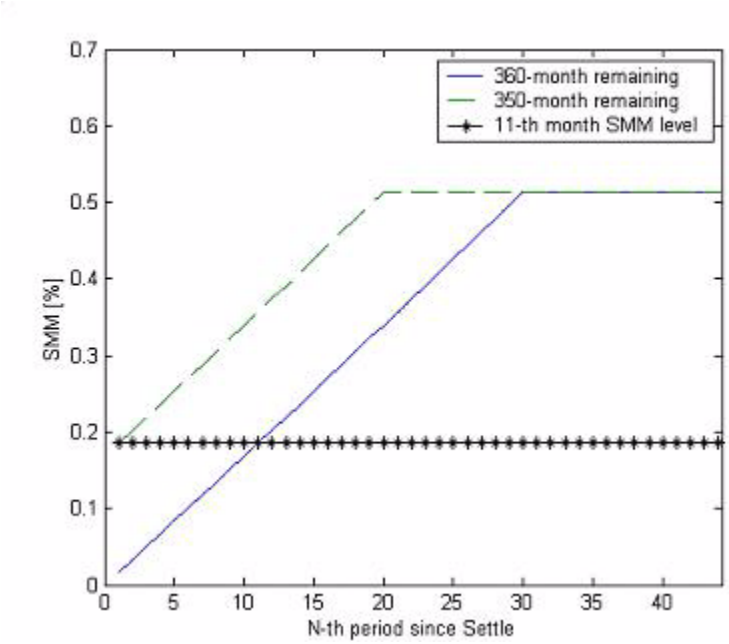
Prepayments with Fewer Than 360 Months Remaining

When fewer than 360 months remain in the pool, the applicable PSA prepayment vector is "seasoned" by the pool's age. (Elements in the 360-element prepayment vector that represent past payments are skipped. For example, on a 30-year mortgage that is 10 months old, only the final 350 prepayments are applied.)

Assume, for example, that you have two 30-year loans, one new and another 10 months old. Both have the same PSA speed of 100 and prepay using the vectors plotted below.



Still within the scope of relative valuation, you could also solve for the percentage of the standard PSA prepayment vector given the pool's arbitrary, user-supplied prepayment vector, such that the PSA speed gives the same Macaulay duration as the user-supplied prepayment vector.

If you supply a custom prepayment vector, you must account for the number of months remaining.

```
Price = 101;
Settle = datetime(2001,1,1);
Maturity = datetime(2030,1,1);
IssueDate = datetime(2000,1,1);
GrossRate = 0.08125;
PrepayMatrix = 0.005*ones(348,1);
CouponRate   = 0.075;
Delay = 14;

ImpliedSpeed = mbsprice2speed(Price, Settle, Maturity, ...
IssueDate, GrossRate, PrepayMatrix, CouponRate, Delay)

ImpliedSpeed =

  104.2543
```

Examine the prepayment input. The remaining 29 years require 348 monthly elements in the prepayment vector. Suppose then, keeping everything the same, you change `Settle` to February 14, 2003.

```
Settle = datetime(2003,2,14);
```

You can use `cpncount` to count all incoming coupons received after `Settle` by invoking

```
NumCouponsRemaining = cpncount(Settle, Maturity, 12, 1, [], ...
IssueDate)
```

```
NumCouponsRemaining =
323
```

The input `12` defines the monthly payment frequency, `1` defines the 30/360 basis, and `IssueDate` defines aging and determination-of-holder date. Thus, you must supply a 323-element vector to account for a prepayment corresponding to each monthly payment.

Pools with Different Numbers of Coupons Remaining

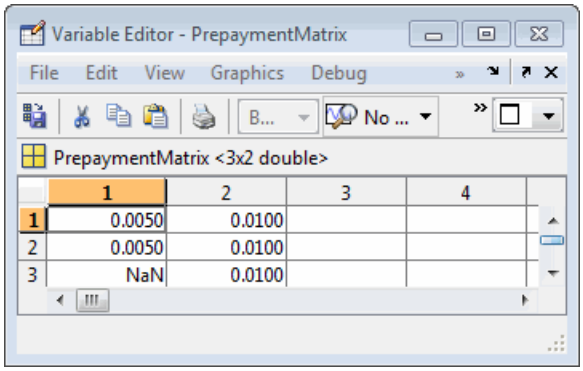
Suppose that one pool has two remaining coupons, and the other has three. MATLAB expects the prepayment matrix to be in the following format:

```
V11       V21
V12       V22
NaN       V23
```

V_{ij} denotes the single monthly mortality (SMM) rate for pool `i` during the `j`th coupon period since `Settle`.

The use of `NaN` to pad the prepayment matrix is necessary because MATLAB cannot concatenate vectors of different lengths into a matrix. Also, it can serve as an error check against any unintended operation (any MATLAB operation that would return `NaN`).

For example, assume that the 2-month pool has a constant SMM of 0.5% and the 3-month pool has a constant SMM of 1% in every period. The prepayment matrix you would create is depicted below.



Create this input in whatever manner is best for you.

Summary of Prepayment Data Vector Representation

- When you specify a PSA prepayment speed, MATLAB "seasons" the pool according to its age.
- When you specify your own prepayment matrix, identify the maximum number of coupons remaining using `cpncount`. Then supply the matrix elements up to the point when cash flow ceases to exist.
- When different length pools must exist in the same matrix, pad the shorter one(s) with `NaN`. Each column of the prepayment matrix corresponds to a specific pool.

Prepayment Modeling with a Two Factor Hull White Model and a LIBOR Market Model

This example shows how to model prepayment in MATLAB® using functionality from the Financial Instruments Toolbox™. Specifically, a variation of the Richard and Roll prepayment model is implemented using a two factor Hull-White interest-rate model and a LIBOR Market Model to simulate future interest-rate paths. A mortgage-backed security is priced with both the custom and default prepayment models.

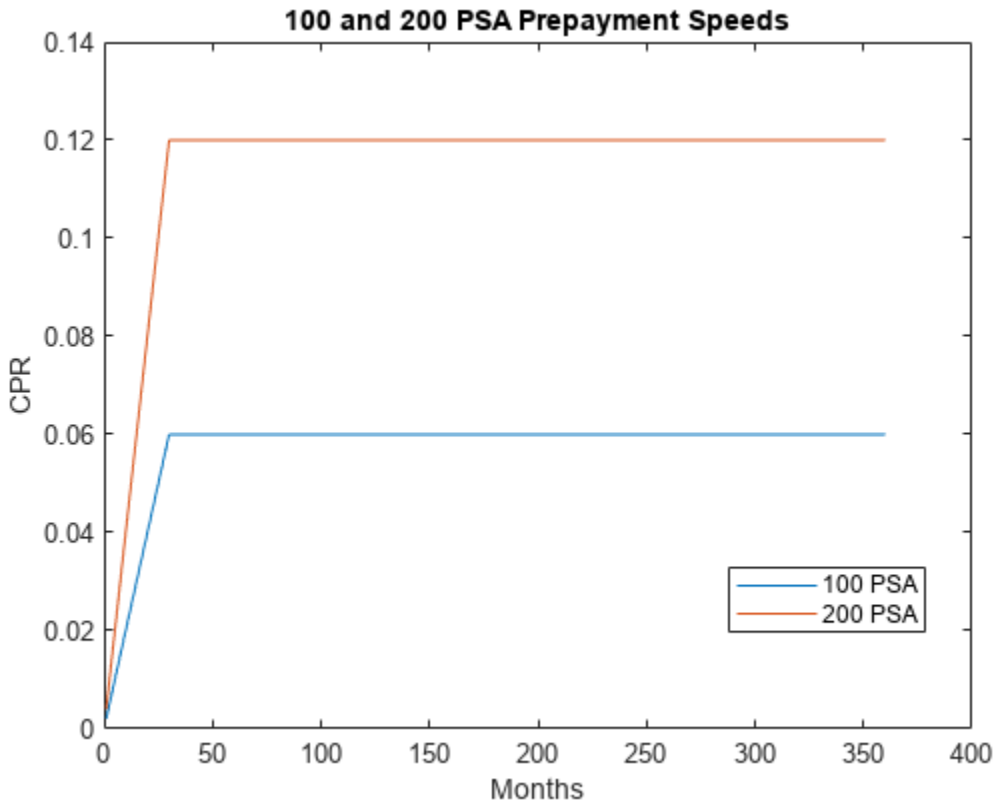
Introduction

Prepayment modeling is crucial to the analysis of mortgage-backed securities (MBS). Prepayments by individual mortgage holders affect both the amount and timing of cash flows and for collateralized mortgage obligations (for example, interest-only securities), prepayment can greatly affect the value of the securities.

PSA Model

The most basic prepayment model is the Public Securities Association (PSA) model, which assumes a ramp-up phase and then a constant conditional prepayment rate (CPR). The PSA model can be generated in MATLAB using the Financial Instruments Toolbox function `psaspeed2rate`.

```
G2PP_CPR = psaspeed2rate([100 200]);
figure
plot(G2PP_CPR)
title('100 and 200 PSA Prepayment Speeds')
xlabel('Months')
ylabel('CPR')
ylim([0 .14])
legend({'100 PSA','200 PSA'}, 'Location', 'Best')
```



Mortgage-Backed Security

The MBS analyzed in this example matures in 2020 and has the properties outlined in this section. Cash flows are generated for PSA prepayment speeds simply by entering the PSA speed as an input argument.

```
% Parameters for MBS passthrough to be priced
Settle = datetime(2007,12,15);
Maturity = datetime(2020,12,15);
IssueDate = datetime(2000,12,15);
GrossRate = .0475;
CouponRate = .045;
Delay = 14;
Period = 12;
Basis = 4;

% Generate cash flows and dates for baseline case using 100 PSA
[CFlowAmounts, CFlowDates] = mbscfamounts(Settle,Maturity, IssueDate,...
    GrossRate, CouponRate, Delay,100);
CFlowTimes = yearfrac(Settle,CFlowDates);
NumCouponsRemaining = cpncount(Settle, Maturity, Period,Basis, 1, IssueDate);
```

Richard and Roll Model

While prepayment modeling often involves complex and sophisticated modeling, often at the loan level, this example uses a slightly modified approach based on the model proposed by Richard and Roll [6 on page 5-32].

The Richard and Roll prepayment model involves the following factors:

- Refinancing incentive
- Seasonality (month of the year)
- Seasoning or age of the mortgage
- Burnout

Richard and Roll propose a multiplicative model of the following:

$$CPR = RefiIncentive * SeasoningMultiplier * SeasonalityMultiplier * BurnoutMultiplier$$

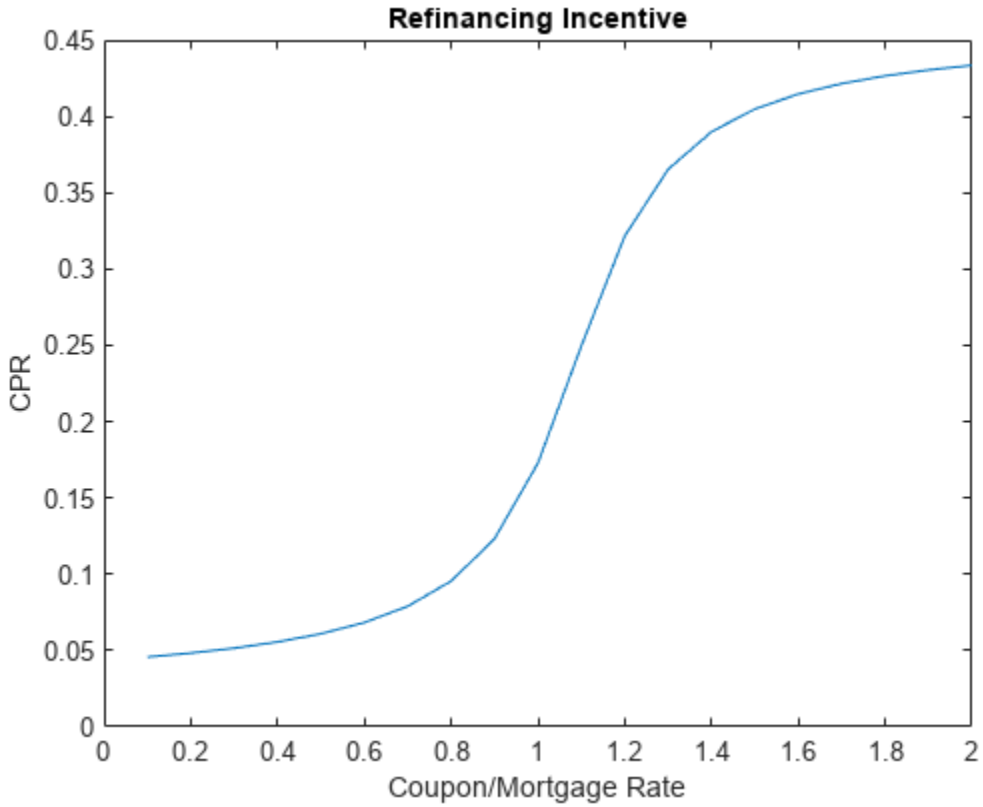
For the custom model in this example, the *Burnout Multiplier*, which describes the tendency of prepayment to slow when a significant number of homeowners have already refinanced, is ignored and the first three terms are used.

The refinancing incentive is a function of the ratio of the coupon-rate of the mortgage to the available mortgage rate at that particular point in time. For example, the Office of Thrift Supervision (OTS) proposes the following model:

$$Refi = .2406 - .1389 * arctan(5.952 * (1.089 - \frac{CouponRate}{MortgageRate}))$$

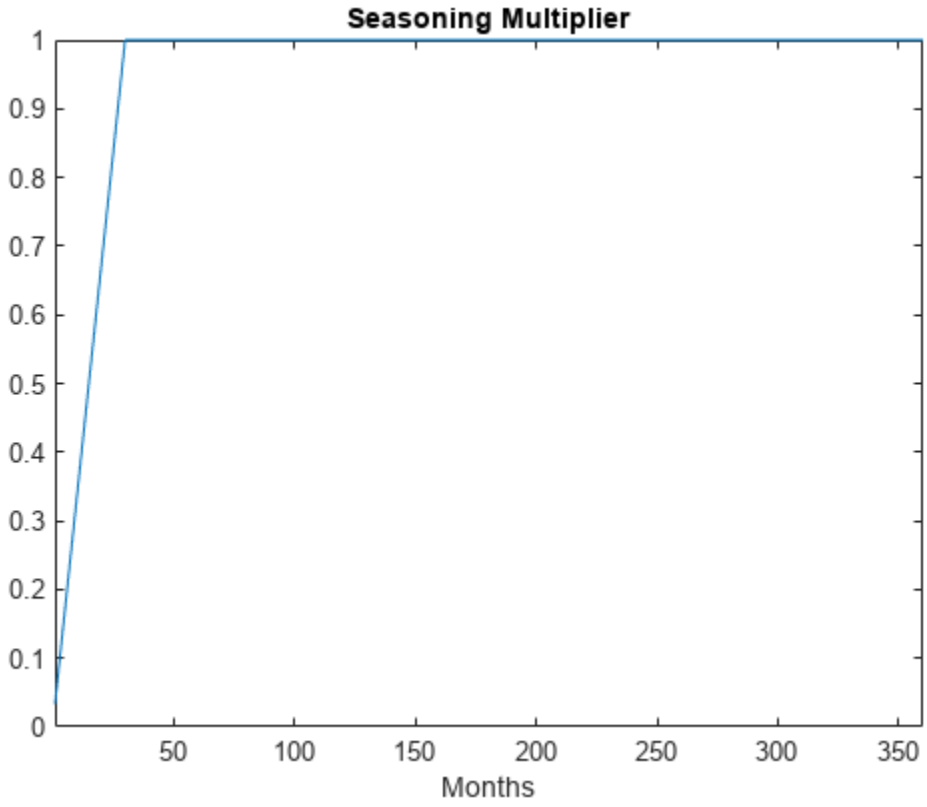
The refinancing incentive requires a simulation of future interest rates. This will be discussed later in this example.

```
C_M = .1:.1:2;
G2PP_Refi = .2406 - .1389 * atan(5.952*(1.089 - C_M));
figure
plot(C_M,G2PP_Refi)
xlabel('Coupon/Mortgage Rate')
ylabel('CPR')
title('Refinancing Incentive')
```



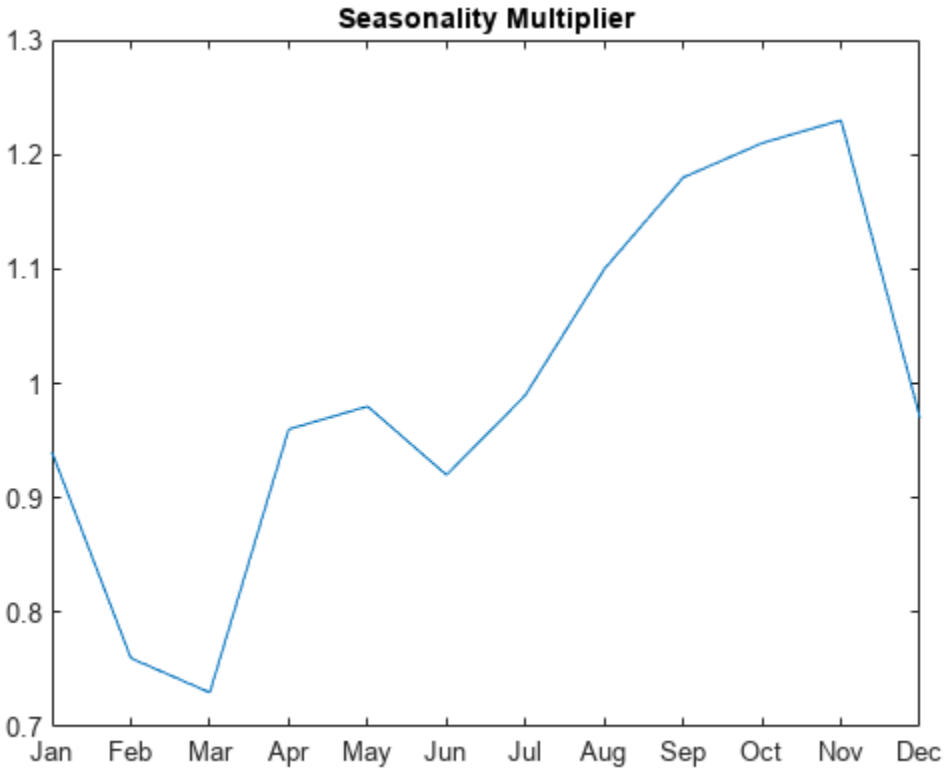
Seasoning captures the tendency of prepayment to ramp up at the beginning of a mortgage before leveling off. The OTS models the seasoning multiplier as follows:

```
Seasoning = ones(360,1);
Seasoning(1:29) = (1:29)/30;
figure
plot(Seasoning)
xlim([1 360])
title('Seasoning Multiplier')
xlabel('Months')
```



The seasonality multiplier simply models the seasonal behavior of prepayments -- this data is based on Figure 3 of [6 on page 5-32], which applies to the behavior of Ginnie Mae 30-year, single-family MBSs.

```
Seasonality = [.94 .76 .73 .96 .98 .92 .99 1.1 1.18 1.21 1.23 .97];
figure
plot(Seasonality)
xlim([1 12])
ax = gca;
ax.XTick = 1:12;
ax.XTickLabel = {'Jan','Feb','Mar','Apr','May','Jun','Jul','Aug', ...
    'Sep','Oct','Nov','Dec'};
title('Seasonality Multiplier')
```



G2++ Interest-Rate Model

Since the refinancing incentive requires a simulation of future interest rates, an interest-rate model must be used. One choice is a two-factor additive Gaussian model, referred to as G2++ by Brigo and Mercurio [2 on page 5-32].

The G2++ Interest Rate Model is:

$$r(t) = x(t) + y(t) + \varphi(t)$$

$$dx(t) = -ax(t)dt + \sigma dW_1(t)$$

$$dy(t) = -by(t)dt + \eta dW_2(t)$$

where $dW_1(t)dW_2(t)$ is a two-dimensional Brownian motion with correlation ρ

$$dW_1(t)dW_2(t) = \rho dt$$

$$\varphi(T) = f^M(0,T) + \frac{\sigma^2}{2a^2}(1-e^{-aT})^2 + \frac{\eta^2}{2b^2}(1-e^{-bT})^2 + \rho\frac{\sigma\eta}{ab}(1-e^{-aT})(1-e^{-bT})$$

and $r(t)$ is the short rate, a and b are mean reversion constants and σ and η are volatility constants, and $f^M(0,T)$ is the market forward rate, or the forward rate observed on the Settle date.

LIBOR Market Model

The LIBOR Market Model (LMM) differs from short-rate models in that it evolves a set of discrete forward rates. Specifically, the lognormal LMM specifies the following diffusion equation for each forward rate:

$$\frac{dF_i(t)}{F_i} = -\mu_i dt + \sigma_i(t) dW_i$$

where

dW is an N dimensional geometric Brownian motion with:

$$dW_i(t) dW_j(t) = \rho_{i,j} dt$$

The LMM relates the drifts of the forward rates based on no-arbitrage arguments. Specifically, under the Spot LIBOR measure, the drifts are expressed as the following:

$$\mu_i(t) = -\sigma_i(t) \sum_{j=q(t)}^{i} \frac{\tau_j \rho_{i,j} \sigma_j(t) F_j(t)}{1 + \tau_j F_j(t)}$$

where

τ_i is the time fraction associated with the ith forward rate

$q(t)$ is an index function defined by the relation $T_{q(t)-1} < t < T_{q(t)}$

and the Spot LIBOR numeraire is defined as the following:

$$B(t) = P(t, T_{q(t)}) \prod_{n=0}^{q(t)-1} (1 + \tau_n F_n(T_n))$$

Given the above, the choice with the LMM is how to model volatility and correlation.

The volatility of the rates can be modeled with a stochastic volatility, but for this example a deterministic volatility is used, and so a functional form needs to be specified. One of the most popular functional forms in the literature is the following:

$$\sigma_i(t) = \phi_i(a(T_i - t) + b)e^{c(T_i - t)} + d$$

where ϕ adjusts the curve to match the volatility for the i^{th} forward rate.

Similarly, the correlation between the forward rates needs to be specified. This can be estimated from historical data or fitted to option prices. For this example, the following functional form will be used:

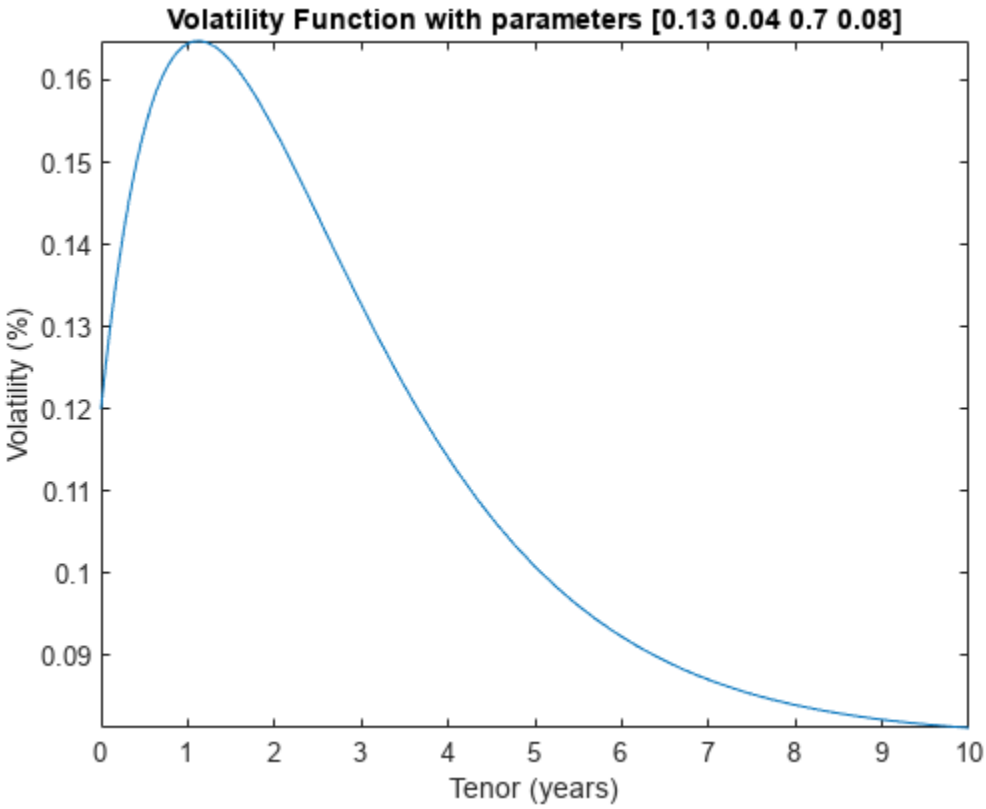
$$\rho_{i,j} = e^{-\beta |i-j|}$$

Once the volatility and correlation are specified, the parameters need to be calibrated -- this can be done with historical or market data, typically swaptions or caps and floors. For this example, we simply use reasonable estimates for the correlation and volatility parameters.

```
% The volatility function to be used -- and one choice for the parameters
LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
```

```
LMMVolParams = [.13 .04 .7 .08];

% Volatility specification
fplot(@(t) LMMVolFunc(LMMVolParams,t),[0 10])
title(['Volatility Function with parameters ' mat2str(LMMVolParams)])
ylabel('Volatility (%)')
xlabel('Tenor (years)')
```



Calibration to Market Data

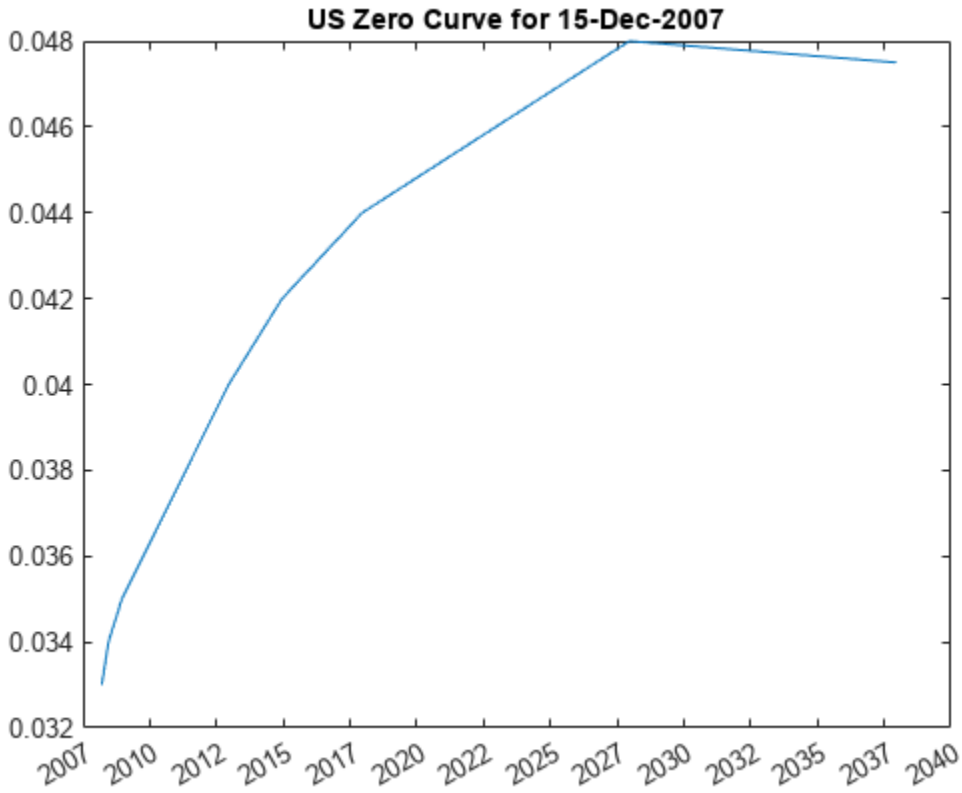
The parameters in the G2++ model can be calibrated to market data. Typically, the parameters are calibrated to observed interest-rate cap, floor and/or swaption data. For now, market cap data is used for calibration.

This data is hardcoded but could be imported into MATLAB with the Database Toolbox™ or Datafeed Toolbox™.

```
% Zero Curve -- this data is hardcoded for now, but could be bootstrapped
% using the bootstrap method of IRDataCurve.
ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';
ZeroDates = daysadd(Settle,360*ZeroTimes,1);
DiscountRates = zero2disc(ZeroRates,ZeroDates,Settle);
irdc = IRDataCurve('Zero',Settle,ZeroDates,ZeroRates);

figure
plot(ZeroDates,ZeroRates)
```

```
datetick
title(['US Zero Curve for ' datestr(Settle)])
```

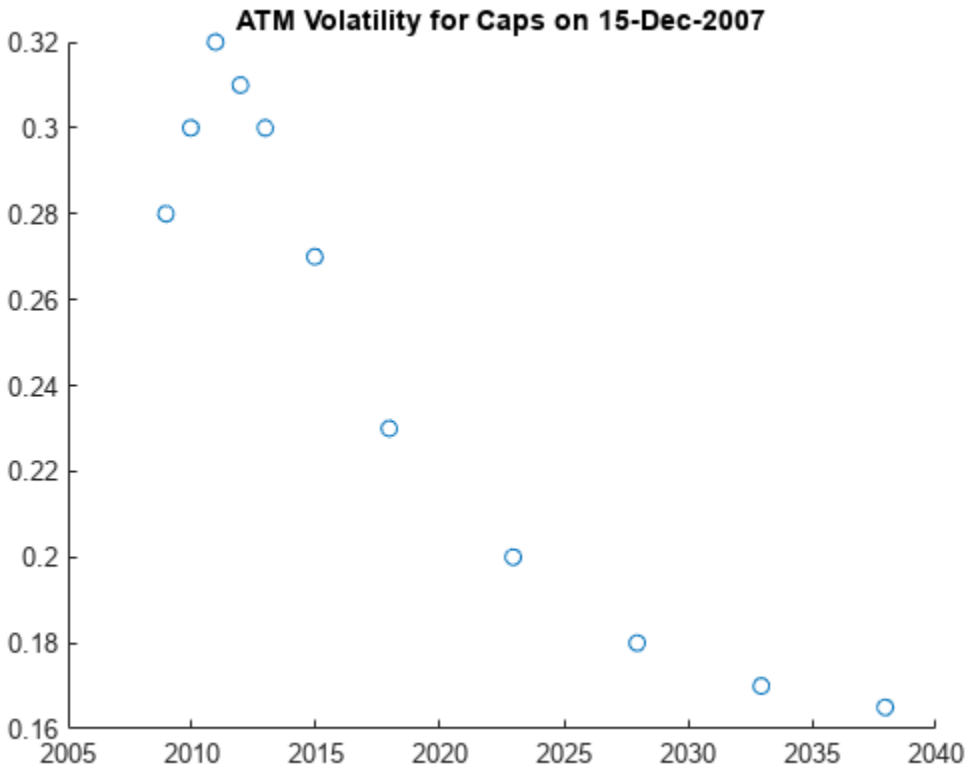


```
% Cap Data
Reset = 2;
Notional = 100;
CapMaturity = daysadd(Settle,360*[1:5 7 10 15 20 25 30],1);
CapVolatility = [.28 .30 .32 .31 .30 .27 .23 .2 .18 .17 .165]';

% ATM strikes could be computed with swapbyzero
Strike = [0.0353 0.0366 0.0378 0.0390 0.0402 0.0421 0.0439 ...
    0.0456 0.0471 0.0471 0.0471]';

% This could be computed with capbyblk
BlackCapPrices = [0.1532 0.6416 1.3366 2.0290 2.7366 4.2960 6.5992 ...
    9.6787 12.2580 14.0969 15.7873]';

figure
scatter(CapMaturity,CapVolatility)
datetick
title(['ATM Volatility for Caps on ' datestr(Settle)])
```



To calibrate the model parameters, a parameter set will be found that minimizes the sum of the squared differences between the G2++ predicted Cap values and the observed Black Cap values. The Optimization Toolbox™ function `lsqnonlin` is used in this example, although other approaches (for example, Global Optimization) may also be applicable. The function `capbylg2f` computes the analytic values for the caps given parameter values.

Upper and lower bounds for the model parameters are set to be relatively constrained. As Brigo and Mercurio discuss, the correlation parameter, *rho*, can often be close to `-1` when fitting a G2++ model to interest-rate cap prices. Therefore, *rho* is constrained to be between `-.7` and `.7` to ensure that the parameters represent a truly two-factor model. The remaining mean reversion and volatility parameters are constrained to be between `0` and `.5`. Calibration remains a complex task, and while the plot below indicates that the best fit parameters seem to do a reasonably good job of reproducing the Cap prices, it should be noted that the procedure outlined here simply represents one approach.

```
% Call to lsqnonlin to calibrate parameters
objfun = @(x) BlackCapPrices - capbylg2f(irdc,x(1),x(2),x(3),x(4),x(5),Strike,CapMaturity);
x0 = [.5 .05 .1 .01 -.1];
lb = [0 0 0 0 -.7];
ub = [.5 .5 .5 .5 .7];

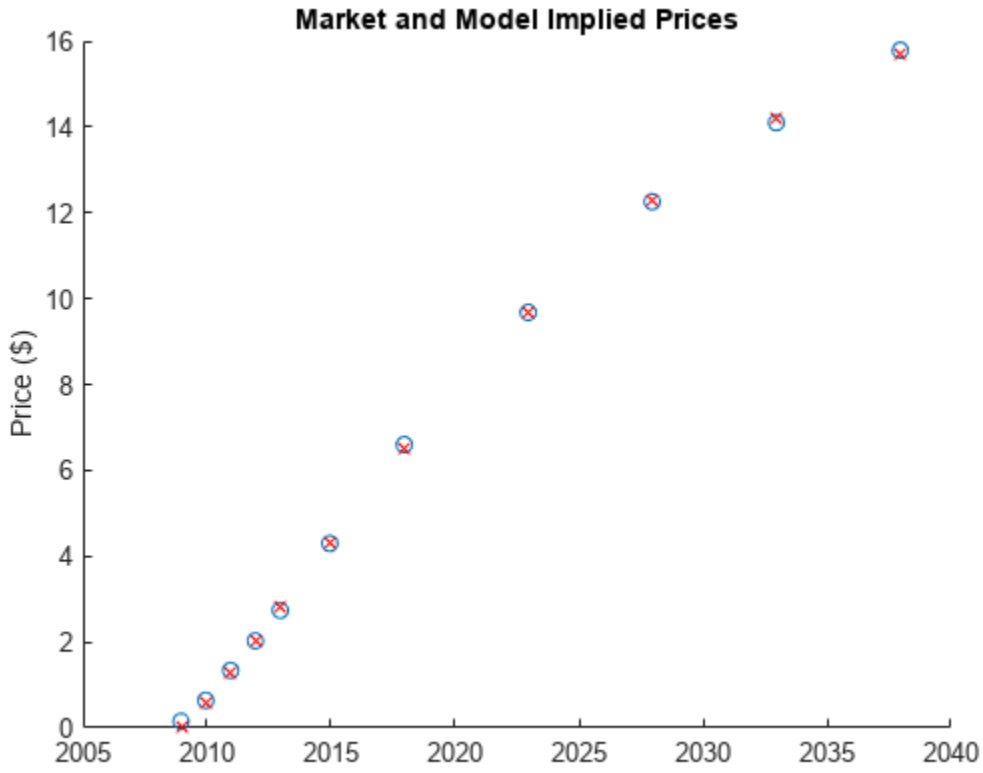
G2PP_Params = lsqnonlin(objfun,x0,lb,ub);

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the value of the function tolerance.
```

```
a = G2PP_Params(1);
b = G2PP_Params(2);
sigma = G2PP_Params(3);
eta = G2PP_Params(4);
rho = G2PP_Params(5);

% Compare the results
figure
scatter(CapMaturity,BlackCapPrices)
hold on
scatter(CapMaturity,capbylg2f(irdc,a,b,sigma,eta,rho,Strike,CapMaturity),'rx')
datetick
title('Market and Model Implied Prices')
ylabel('Price ($)')
```



G2++ Model Implementation

The `LinearGaussian2F` model can be used to specify the G2++ model and simulate future paths interest rates.

```
% G2++ model from Brigo and Mercurio with time homogeneous volatility
% parameters
G2PP = LinearGaussian2F(irdc,a,b,sigma,eta,rho);
```

LIBOR Market Model Implementation

After the volatility and correlation have been calibrated, Monte Carlo simulation is used to evolve the rates forward in time. The `LiborMarketModel` object is used to simulate the forward rates.

While factor reduction is often used with the LMM to reduce computational complexity, there is no factor reduction in this example.

6M LIBOR rates are chosen to be evolved in this simulation. Since a monthly prepayment vector must be computed, interpolation is used to generate the intermediate rates. Simple linear interpolation is used.

```
numForwardRates = 46;

% Instead of being fit, VolPhi is simply hard-coded  --
% representative of a declining volatility over time.
VolPhi = linspace(1.2,.8,numForwardRates-1)';

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
CorrMat = CorrFunc(meshgrid(1:numForwardRates-1)',meshgrid(1:numForwardRates-1),Beta);

VolFunc = cell(length(VolPhi),1);
for jdx = 1:length(VolPhi)
    VolFunc(jdx) = {@(t) VolPhi(jdx)*ones(size(t)).*(LMMVolParams(1)*t + ...
        LMMVolParams(2)).*exp(-LMMVolParams(3)*t) + LMMVolParams(4)};
end

LMM = LiborMarketModel(irdc,VolFunc,CorrMat);
```

G2++ Monte Carlo Simulation

The various interest-rate paths can be simulated by calling the `simTermStructs` method.

One limitation to two-factor Gaussian models like this one is that it does permit negative interest rates. This is a concern, particularly in low interest-rate environments. To handle this possibility, any interest-rate paths with negative rates are simply rejected.

```
nPeriods = NumCouponsRemaining;
nTrials = 100;
DeltaTime = 1/12;

% Generate factors and short rates
Tenor = [1/12 1 2 3 4 5 7 10 15 20 30];
G2PP_SimZeroRates = G2PP.simTermStructs(nPeriods,'NTRIALS',nTrials,...
    'Tenor',Tenor,'DeltaTime',DeltaTime);

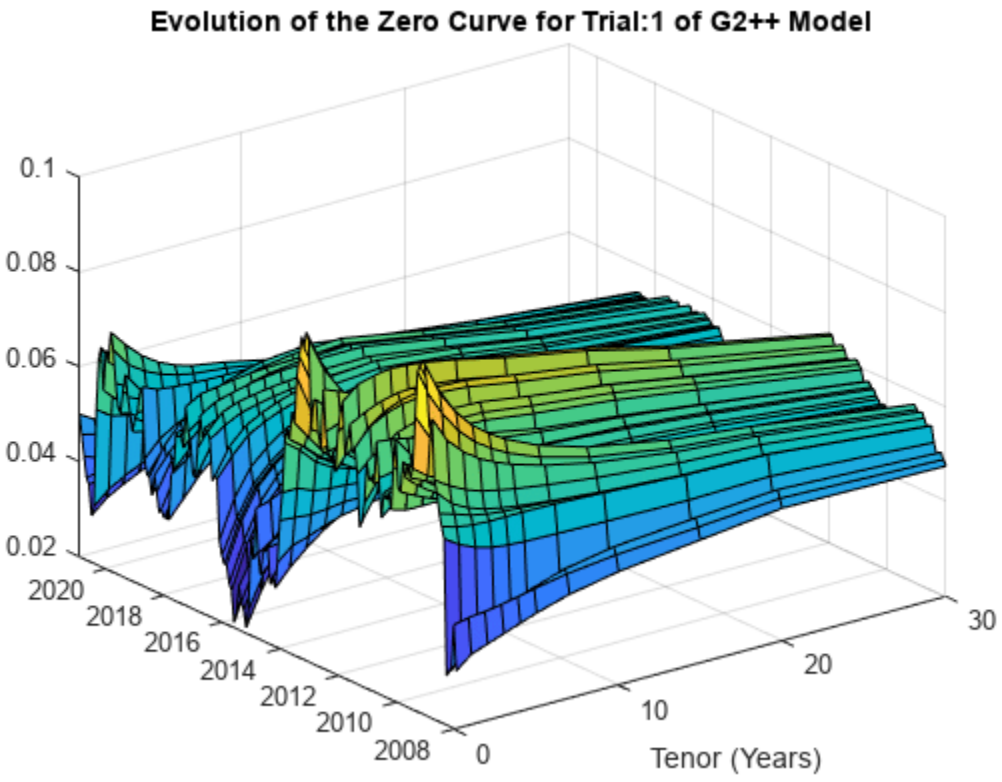
SimDates = daysadd(Settle,360*DeltaTime*(0:nPeriods),1);

% Tenors that will be recovered for each simulation date. The stepsize is
% included here to facilitate computing a discount factor for each
% simulation path.

% Remove any paths that go negative
NegIdx = squeeze(any(any(G2PP_SimZeroRates < 0,1),2));
G2PP_SimZeroRates(:,:,NegIdx) = [];
nTrials = size(G2PP_SimZeroRates,3);

% Plot evolution of one sample path
trialIdx = 1;
figure
surf(Tenor,SimDates,G2PP_SimZeroRates(:,:,trialIdx))
datetick y keepticks keeplimits
```

```
title(['Evolution of the Zero Curve for Trial:' num2str(trialIdx) ' of G2++ Model'])
xlabel('Tenor (Years)')
```



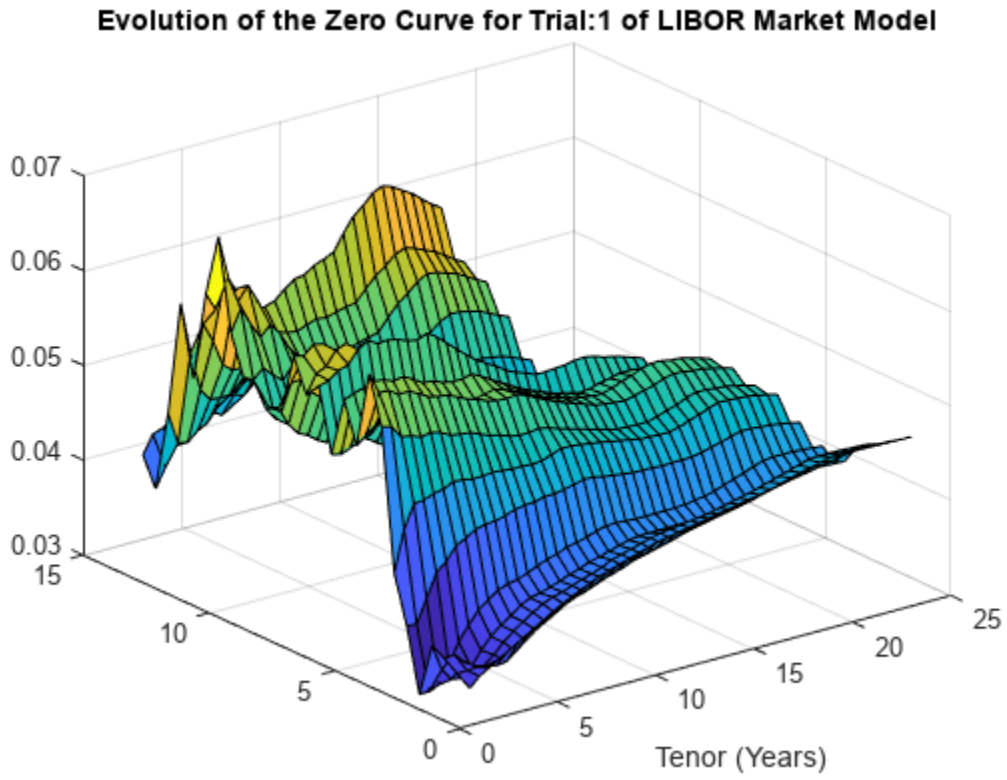
LIBOR Market Model Simulation

The various interest-rate paths can be simulated by calling the `simTermStructs` method of the `LiborMarketModel` object.

```
LMMPeriod = 2; % Semiannual rates
LMMNumPeriods = NumCouponsRemaining/12*LMMPeriod; % Number of semiannual periods
LMMDeltaTime = 1/LMMPeriod;
LMMNTRIALS = 100;

% Simulate
[LMMZeroRates, LMMForwardRates] = LMM.simTermStructs(LMMNumPeriods,'nTrials',LMMNTRIALS,'DeltaTi
ForwardTimes = 1/2:1/2:numForwardRates/2;
LMMSimTimes = 0:1/LMMPeriod:LMMNumPeriods/LMMPeriod;

% Plot evolution of one sample path
trialIdx = 1;
figure
tmpPlotData = LMMZeroRates(:,:,trialIdx);
tmpPlotData(tmpPlotData == 0) = NaN;
surf(ForwardTimes,LMMSimTimes,tmpPlotData)
title(['Evolution of the Zero Curve for Trial:' num2str(trialIdx) ' of LIBOR Market Model'])
xlabel('Tenor (Years)')
```



Compute Mortgage Rates from Simulation

Once the interest-rate paths have been simulated, the mortgage rate needs to be computed -- one approach, discussed by [7 on page 5-32], is to compute the mortgage rate from a combination of the 2-year and 10-year rates.

For this example, the following is used:

$$MortgageRate = .024 + .2*TwoYearRate + .6*TenYearRate$$

```
% Compute mortgage rates from interest rate paths
TwoYearRates = squeeze(G2PP_SimZeroRates(:,Tenor == 2,:));
TenYearRates = squeeze(G2PP_SimZeroRates(:,Tenor == 7,:));
G2PP_MortgageRates = .024 + .2*TwoYearRates + .6*TenYearRates;

LMMMortgageRates = squeeze(.024 + .2*LMMZeroRates(:,4,:) + .6*LMMZeroRates(:,20,:));
LMMDiscountFactors = squeeze(cumprod(1./(1 + LMMZeroRates(:,1,:)*.5)));

% Interpolate to get monthly mortgage rates
MonthlySimTimes = 0:1/12:LMMNumPeriods/LMMPeriod;
LMMMonthlyMortgageRates = zeros(nPeriods+1,LMMNTRIALS);
LMMMonthlyDF = zeros(nPeriods+1,LMMNTRIALS);
for trialidx = 1:LMMNTRIALS
   LMMMonthlyMortgageRates(:,trialidx) = interp1(LMMSimTimes,LMMMortgageRates(:,trialidx),Monthly
   LMMMonthlyDF(:,trialidx) = interp1(LMMSimTimes,LMMDiscountFactors(:,trialidx),MonthlySimTimes
end
```

Computing CPR and Generating and Valuing Cash Flows

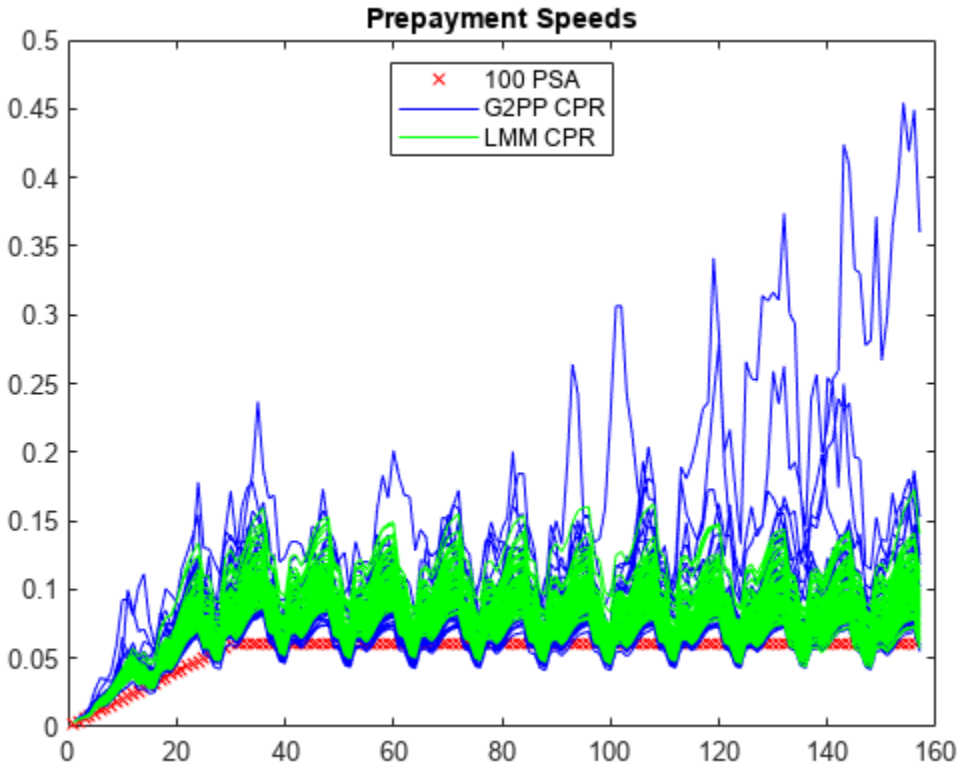
Once the Mortgage Rates have been simulated, the CPR can be computed from the multiplicative model for each interest-rate path.

```
% Compute Seasoning and Refinancing Multipliers
Seasoning = ones(nPeriods+1,1);
Seasoning(1:30) = 1/30*(1:30);
G2PP_Refi = .2406 - .1389 * atan(5.952*(1.089 - CouponRate./G2PP_MortgageRates));
LMM_Refi = .2406 - .1389 * atan(5.952*(1.089 - CouponRate./LMMMonthlyMortgageRates));

% CPR is simply computed by evaluating the multiplicative model
G2PP_CPR = bsxfun(@times,G2PP_Refi,Seasoning.*(Seasonality(month(CFlowDates))'));
LMM_CPR = bsxfun(@times,LMM_Refi,Seasoning.*(Seasonality(month(CFlowDates))'));

% Compute single monthly mortality (SMM) from CPR
G2PP_SMM = 1 - (1 - G2PP_CPR).^(1/12);
LMM_SMM = 1 - (1 - LMM_CPR).^(1/12);

% Plot CPR's against 100 PSA
CPR_PSA100 = psaspeed2rate(100);
figure
PSA_handle = plot(CPR_PSA100(1:nPeriods),'rx');
hold on
G2PP_handle = plot(G2PP_CPR,'b');
LMM_handle = plot(LMM_CPR,'g');
title('Prepayment Speeds')
legend([PSA_handle(1) G2PP_handle(1) LMM_handle(1)],{'100 PSA','G2PP CPR','LMM CPR'},'Location',
```



Generate Cash Flows and Compute Present Value

With a vector of single monthly mortalities (SMM) computed for each interest-rate path, cash flows for the MBS can be computed and discounted.

```
% Compute the baseline zero rate at each cash flow time
CFlowZero = interp1(ZeroTimes,ZeroRates,CFlowTimes,'linear','extrap');

% Compute DF for each cash flow time
CFlowDF_Zero = zero2disc(CFlowZero,CFlowDates,Settle);

% Compute the price of the MBS using the zero curve
Price_Zero = CFlowAmounts*CFlowDF_Zero';

% Generate the cash flows for each IR Path
G2PP_CFlowAmounts = mbscfamounts(Settle, ...
    repmat(Maturity,1,nTrials), IssueDate, GrossRate, CouponRate, Delay, [], G2PP_SMM(2:end,:));

% Compute the DF for each IR path
G2PP_CFlowDFSim = cumprod(exp(squeeze(-G2PP_SimZeroRates(:,1,:).*DeltaTime)));

% Present value the cash flows for each MBS
G2PP_Price_Ind = sum(G2PP_CFlowAmounts.*G2PP_CFlowDFSim',2);
G2PP_Price = mean(G2PP_Price_Ind);

% Repeat for LMM
LMM_CFlowAmounts = mbscfamounts(Settle, ...
```

```
    repmat(Maturity,1,LMMNTRIALS), IssueDate, GrossRate, CouponRate, Delay, [], LMM_SMM(2:end,:))

% Present value the cash flows for each MBS
LMM_Price_Ind = sum(LMM_CFlowAmounts.*LMMMonthlyDF',2);
LMM_Price = mean(LMM_Price_Ind);
```

The results from the different approaches can be compared. The number of trials for the G2++ model will typically be less than 100 due to the filtering out of any paths that produce negative interest rates.

Additionally, while the number of trials for the G2++ model in this example is set to be 100, it is often the case that a larger number of simulations need to be run to produce an accurate valuation.

```
fprintf('                     # of Monte Carlo Trials: %8d\n'    , nTrials)
```

```
                    # of Monte Carlo Trials:       72
```

```
fprintf('                     # of Time Periods/Trial: %8d\n\n'  , nPeriods)
```

```
                    # of Time Periods/Trial:      156
```

```
fprintf('                      MBS Price with PSA 100: %8.4f\n'  , Price_Zero)
```

```
                     MBS Price with PSA 100:   1.0187
```

```
fprintf(' MBS Price with Custom G2PP Prepayment Model: %8.4f\n\n', G2PP_Price)
```

```
 MBS Price with Custom G2PP Prepayment Model:   0.9884
```

```
fprintf(' MBS Price with Custom LMM Prepayment Model: %8.4f\n\n', LMM_Price)
```

```
 MBS Price with Custom LMM Prepayment Model:   0.9993
```

Conclusion

This example shows how to calibrate and simulate a G2++ interest-rate model and how to use the generated interest-rate paths in a prepayment model loosely based on the Richard and Roll model. This example also provides a useful starting point to using the G2++ and LMM interest-rate models in other financial applications.

Pricing Mortgage Backed Securities Using the Black-Derman-Toy Model

This example illustrates how the Financial Toolbox™ and Financial Instruments Toolbox™ are used to price a level mortgage backed security using the BDT model.

Load the BDT Tree Stored in the Data File

```
load mbsexample.mat
```

Observe the Interest-Rate Tree

Visualize the interest rate evolution along the tree by looking at the output structure `BDTTree`. `BDTTree` returns an inverse discount tree, which you can convert into an interest-rate tree with the `cvtree` function.

```
BDTTreeR = cvtree(BDTTree);
```

Look at the upper branch and lower branch paths of the tree:

```
OldFormat = get(0, 'format');
format short

%Rate at root node:
RateRoot      = treepath(BDTTreeR.RateTree, 0)

RateRoot = 0.0399

%Rates along upper branch:
RatePathUp    = treepath(BDTTreeR.RateTree, [1 1 1 1 1])

RatePathUp = 6×1

    0.0399
    0.0397
    0.0391
    0.0383
    0.0373
    0.0360

%Rates along lower branch:
RatePathDown = treepath(BDTTreeR.RateTree, [2 2 2 2 2])

RatePathDown = 6×1

    0.0399
    0.0470
    0.0550
    0.0638
    0.0734
    0.0841
```

Compute the Price Tree for the Non-Prepayable Mortgage

Let's say that we have a three year $10000 level prepayable loan, with a mortgage interest rate of 4.64% semi-annually compounded.

```
MortgageAmount = 10000;
CouponRate = 0.0464;
Period = 2;
Settle='01-Jan-2007';
Maturity='01-Jan-2010';
Compounding = BDTTree.TimeSpec.Compounding;

format bank
```

Use the function `amortize` in the Financial Toolbox™ to calculate the mortgage payment of the loan (MP), the interest and principal components, and the outstanding principal balance.

```
NumPeriods = date2time(Settle,Maturity, Compounding)';

[Principal, InterestPayment, OutstandingBalance, MP] = amortize(CouponRate/Period, NumPeriods, M

% Display Principal, Interest and Outstanding balances
PrincipalAmount = Principal'
```

```
PrincipalAmount = 6×1

       1572.59
       1609.07
       1646.40
       1684.60
       1723.68
       1763.67
```

```
InterestPaymentAmount = InterestPayment'
```

```
InterestPaymentAmount = 6×1

        232.00
        195.52
        158.19
        119.99
         80.91
         40.92
```

```
OutstandingBalanceAmount = OutstandingBalance'
```

```
OutstandingBalanceAmount = 6×1

       8427.41
       6818.34
       5171.94
       3487.35
       1763.67
          0.00
```

```
CFlowAmounts = MP*ones(1,NumPeriods);
% The CFlowDates are the same as the tree level dates
```

```
CFlowDates= {'01-Jul-2007' ,'01-Jan-2008' ,'01-Jul-2008' , '01-Jan-2009' , '01-Jul-2009' , '01-Ja

Using Collateralized Mortgage Obligations (CMOs)

What Are CMOs?

Financial Instruments Toolbox supports collateralized mortgage obligations (CMOs) to provide investors with a greater range of risk and return characteristics than mortgage-backed securities (MBS). In contrast to an MBS, which simply redirects principal and interest cash flows to investors on a pro rata basis, a CMO structures cash flows to different tranches, or slices, to create securities that are better tailored to specific investors.

For example, banks might be primarily concerned with extension risk, or the risk that their investment lengthens in time due to increasing interest rates, given that they typically have short-term deposits as liabilities. Insurance companies and pension funds might be concerned primarily with contraction risk, or the risk that their investment will pay off too soon, with liabilities that have much longer lives. A CMO structure addresses the interest-rate risk of extension or contraction with a blend of short-term and long-term CMO securities, called tranches.

Prepayment Risk

Prepayment risk is the risk that the term of the security varies according to differing rates of repayment of principal by borrowers (repayments from refinancings, sales, curtailments, or foreclosures). In a CMO, you can structure the principal (and associated coupon) stream from the underlying mortgage pool collateral to allocate prepayment risk. If principal is prepaid faster than expected (for example, if mortgage rates fall and borrowers refinance), then the overall term of the mortgage pool collateral shortens.

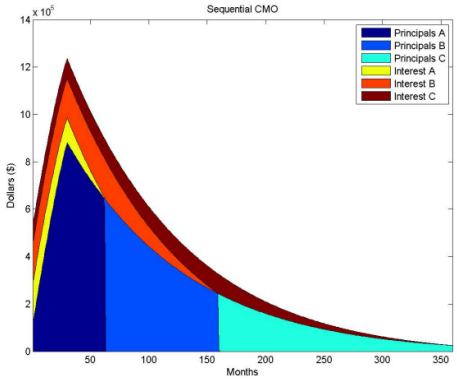
You cannot remove prepayment risk, but you can reallocate it among CMO tranches so that some tranches have some protection against this risk, and other tranches will absorb more of this risk. To facilitate this allocation of prepayment risk, CMOs are structured such that prepayments are allocated among tranches using a fixed set of rules. The most common schemes for prepayment tranching are:

- Sequential tranching, with or without, Z-bond tranching
- Schedule bond tranching
  - Planned amortization class (PAC) bonds
  - Target amortization class (TAC) bonds

Financial Instruments Toolbox supports these schemes for prepayment tranching for CMOs and tools for pricing and scheduling cash flows between the tranches, as well as analyzing the price and yield for CMOs. Financial Instruments Toolbox functionality for CMOs does not model credit risk. Therefore, this functionality is most appropriate for CMOs where credit risk is not an issue (for example, agency CMOs where the underlying mortgage pool collateral is insured for default by the agency Government-Sponsored Enterprises (GSEs), such as Fannie Mae and Freddie Mac).

Sequential Tranches Without a Z-Bond

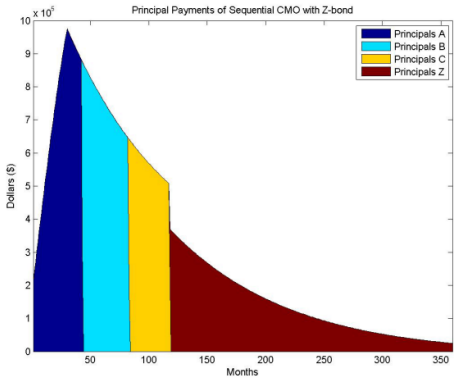
All available principal and interest payments go to the first sequential tranche, until its balance decrements to zero, then to the second, and so on. For example, consider the following example where all principal and interest from the underlying mortgage pool is repaid on tranche A first, then tranche B, then tranche C. Interest is paid on each tranche as long as the principal for the tranche has not been retired.



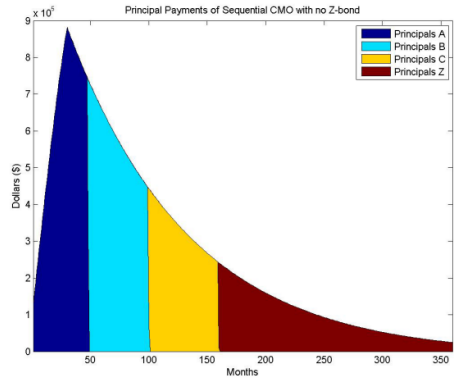
Sequential Tranches with a Z-Bond

The Z-bond, also called an accrual bond, is a type of interest and principal pay rule. The Z-bond tranche supports other sequential pay tranches by not receiving an interest payment. The interest payment that would have accrued to the Z-bond tranche pays off the principal of other bonds, and the principal of the Z-bond tranche increases. The Z-bond tranche starts receiving interest and principal payments only after the other tranches in the CMO have been fully paid. The Z-bond tranche is used in a sequential-pay structure to accelerate the principal repayments of the sequential-pay bonds.

A Z-bond differs from other CMO instruments because it is not tranching principal but interest. The Z-bond receives no cash flows until all other securities have been paid off. In the interim, the interest that is owed to the Z-bond is accrued to its principal. The following chart demonstrates the difference between a Z-bond and a normal sequential pay tranche. The C tranche pays off sooner with the Z-bond, because the interest cash flows to the Z-bond are being used to pay down the principal of the C tranche.



For comparison, the following graphic is the same sequential CMO with no Z-bond.



PAC Tranches

Planned amortization class (PAC) bonds help reduce the effects of prepayment risk. They are designed to produce more stable cash flows by redirecting prepayments from the underlying mortgage collateral to other classes (tranches) called companion or support classes. PAC bonds have a principal payment rate over a predetermined period of time. The PAC bond payment schedule is

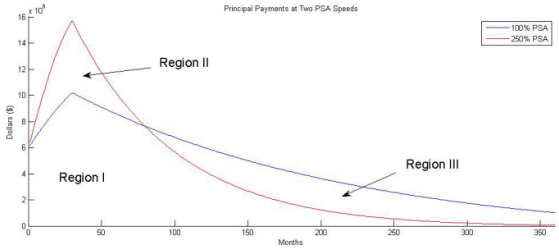
determined by two different prepayment rates, which together form a band (also called a collar). Early in the life of the CMO, the prepayment at the lower PSA yields a lower prepayment. Later in its life, the principal in the higher PSA declines enough that it yields a lower prepayment. The PAC tranche receives whichever rate is lower, so it will change prepayment at one PSA for the first part of its life, then switch to the other rate. The ability to stay on this schedule is maintained by a support bond, which absorbs excess prepayments, and receives fewer prepayments to prevent extension of average life.

However, the PAC is only protected from extension to the amount that prepayments are made on the underlying MBSs. If there is a sustained period of fast prepayments, then that might completely eliminate a PAC bond's outstanding support class. When the principal of the associated PAC bond is exhausted, the CMO is called a "busted PAC", or "busted collar". Alternatively, in times of slow prepayments, amortization of the support bonds is delayed if there is not enough principal for the currently paying PAC bond. This extends the average life of the class.

A PAC bond protects against both extension and contraction risk by:

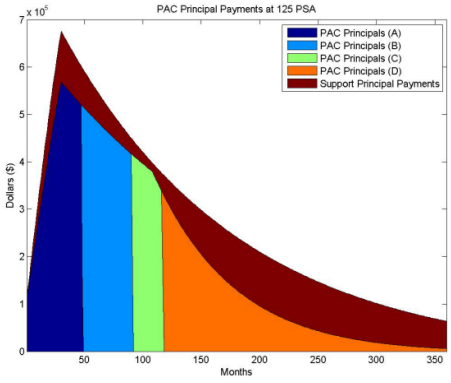
- Specifying a schedule of principal payments for the PAC bond
- Including support tranches that are allocated prepayments inside a specified prepayment band

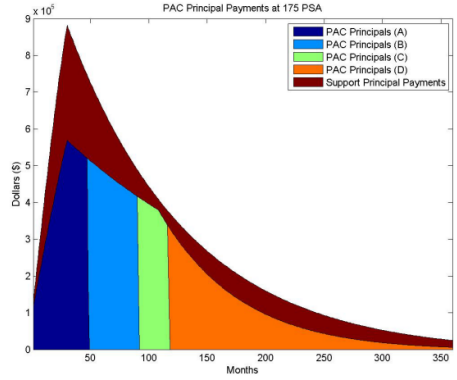
PAC bonds typically specify a band expressed using the PSA model. A PAC bond with a range of 100–250% has this principal schedule.

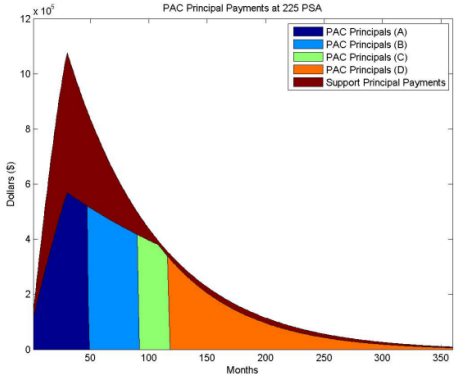


The principal repayment schedule is the minimum principal payment as Region 1 shows. This is the principal payment schedule as long as the actual prepayment stays within the prepayment band of 100–250% PSA.

For example, for different prepayment speeds of 125%, 175%, and 225% PSA, the actual principal payments are shown in the following graphs. At higher prepayment speeds, the support tranche is allocated principal earlier while the principal timing for the other tranches remains constant.



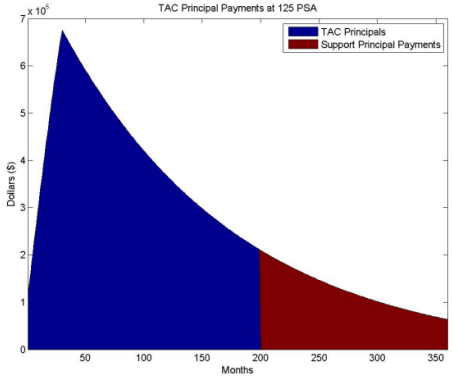


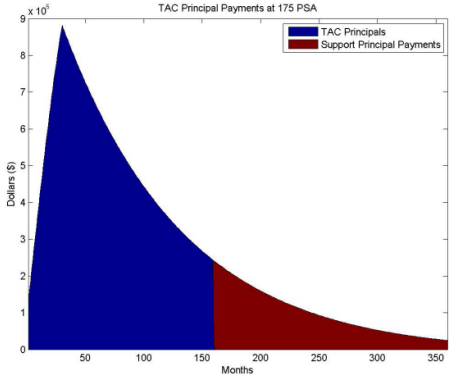


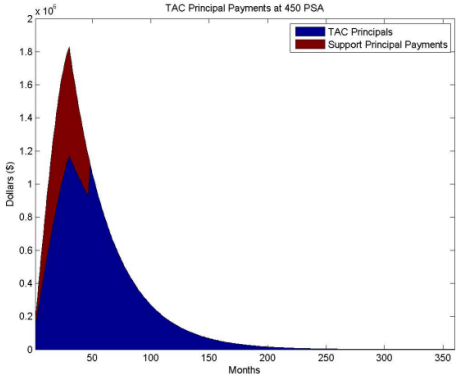
TAC Tranches

Target amortization class (TAC) bonds are similar to PAC bonds, but they do not provide protection against extension of average life. Create the schedule of principal payments by using just a single PSA. TAC bonds pay a “targeted” principal payment schedule at a single, constant prepayment speed. As long as the underlying mortgage collateral does not prepay at a rate slower than this speed, the TAC bond payment schedule is met. TAC bonds can protect against increasing prepayments and early retirement of the TAC bond investment. If the principal cash flow from the mortgage collateral exceeds the TAC schedule, the excess is allocated to TAC companion (support) classes. Alternatively, if prepayments fall below the speed necessary to maintain the TAC schedule, the weighted average life of the TAC is extended. The TAC bond does not protect against low prepayment rates.

For example, here is a TAC structure rated for 125%, 175%, and 450% PSA.







For prepayments below 175% PSA, the TAC bond extends like a normal sequential pay CMO. TAC bonds are appealing because they offer higher yields than comparable PAC bonds. The unaddressed risk from low prepayment rates generally does not concern investors as much as risk from high prepayment rates.

CMO Workflow

In general, the CMO workflow is:

1. Calculate underlying mortgage cash flows.
2. Define CMO tranches
3. If using a PAC or TAC CMO, calculate the principal schedule.
4. Calculate cash flows for each tranche.
5. Analyze the CMO by computing price, yield, spread of CMO cash flows.

Calculate Underlying Mortgage Cash Flows

Underlying mortgage pool pass-through cash flows are calculated by the existing function `mbspassthrough`. The CMO cash flow functions require the principal payments (including prepayments) calculated from existing functions `mbspassthrough` or `mbscfamounts`.

```
principal = 10000000;
coupon = 0.06;
terms = 360;
psa = 150;

[principal_balance, monthly_payments, sched_principal_payments,...
interest_payments, prepayments] = mbspassthrough(principal,...
coupon, terms, terms, psa, []);

principal_payments = sched_principal_payments.' + prepayments.';
```

After determining principal payments for the underlying mortgage collateral, you can generate cash flows for a sequential CMO, with or without a Z-bond, by using `cmoseqcf`. For a PAC or TAC CMO, the cash flows are generated using `cmoschedcf`

Define CMO Tranches

Define CMO tranche; for example, define a CMO with two tranches:

```
TranchePrincipals = [500000; 500000];
TrancheCoupons = [0.06; 0.06];
```

If Using a PAC or TAC CMO, Calculate Principal Schedule

Calculate the PAC/TAC principal balance schedule based on a band of PSA speeds. For scheduled CMOs (PAC/TAC), the CMO cash flow functions additionally take in the principal balance schedule calculated by the CMO schedule function `cmosched`.

```
terms = 360;
coupon = 0.06;
principal = 10000000;
speed = [100 300];
[balanceSchedule, initialBalance] = cmosched(principal, coupon,...
terms, terms, speed, TranchePrincipals(1));
```

Calculate Cash Flows for Each Tranche

You can reuse the output from the cash flow generation functions to further divide the cash flows into tranches. For example, the output from `cmoschedcf` for a PAC tranche can be divided into sequential

tranches by passing the principal cash flows of the PAC tranche into the `cmoschedcf` function. The outputs of the CMO cash flow functions are the principal and interest cash flows, and the principal balance.

```
[principal_balances, principal_cashflows, interest_cashflows] = cmoschedcf(principal_payments,...
TranchePrincipals, TrancheCoupons, balanceSchedule);
```

Analyze CMO by Computing Price, Yield, and Spread of CMO Cash Flows

The outputs from the CMO functions (`cmoseqcf` and `cmoschedcf`) are cash flows. The functions used to analyze a CMO are based on these cash flows. To that end, you can use `cfbyzero`, `cfspread`, `cfyield`, and `cfprice` to compute prices, yield, and spreads for the CMO cash flows. In addition, using the following, you can calculate a weighted average life (WAL) for each tranche in the CMO:

$$WAL = \sum_{i=1}^{n} \frac{P_i}{P} t_i$$

where:

P is the total principal.

P_i is the principal repayment of the coupon i.

$\frac{P_i}{P}$ is the fraction of the principal repaid in coupon i.

t_i is the time in years from the start to coupon i.

Create PAC and Sequential CMO

This example shows how to use an underlying mortgage-backed security (MBS) pool for a 30-year fixed-rate mortgage of 6% to define a PAC bond, and then define a sequential CMO from the PAC bond. Analyze the CMO by comparing the CMO spread to a zero-rate curve for a 30-year Treasury bond and then calculate the weighted-average life (WAL) for the PAC bond.

Step 1. Define the underlying mortgage pool.

```
principal = 100000000;
grossrate = 0.06;
coupon = 0.05;
originalTerm = 360;
termRemaining = 360;
speed = 100;
delay = 14;

Settle      = datenum('1-Jan-2011');
IssueDate   = datenum('1-Jan-2011');
Maturity    = addtodate(IssueDate, 360, 'month');
```

Step 2. Calculate underlying pool cash flow.

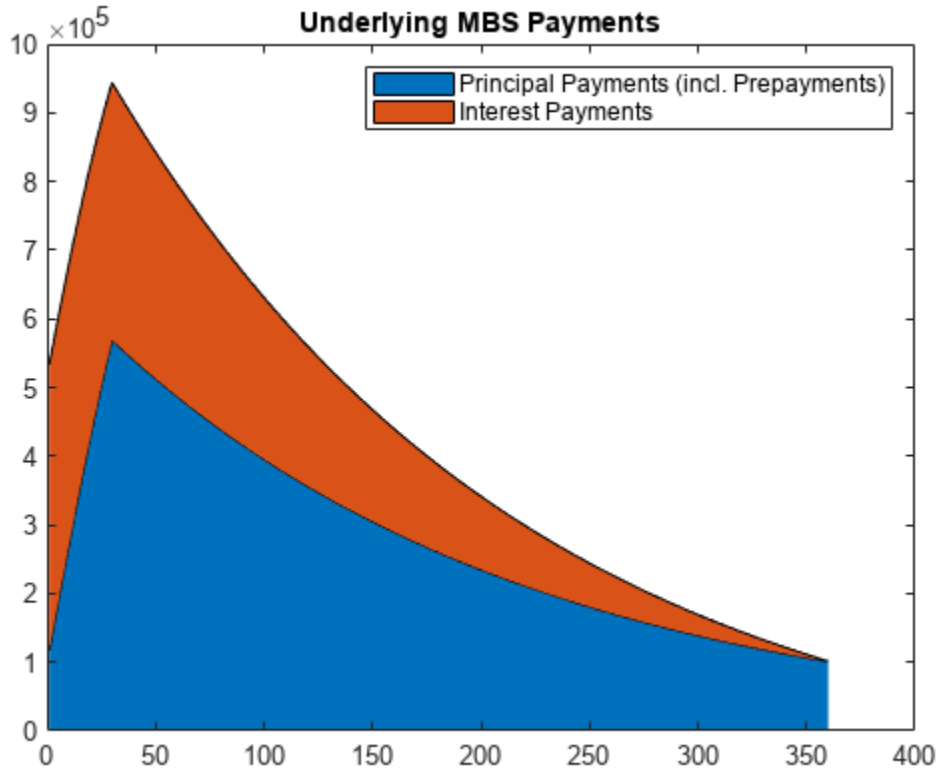
```
[CFlowAmounts, CFlowDates, ~, ~, ~, UnitPrincipal, UnitInterest, ...
UnitPrepayment] = mbscfamounts(Settle, Maturity, IssueDate, grossrate, ...
coupon, delay, speed, []);
```

Step 3. Calculate prepayments.

```
principalPayments = UnitPrincipal * principal;
netInterest = UnitInterest * principal;
prepayments = UnitPrepayment * principal;
dates = CFlowDates' + delay;
```

Step 4. Generate a plot for underlying MBS payments.

```
area([principalPayments'+prepayments', netInterest'])
title('Underlying MBS Payments');
legend('Principal Payments (incl. Prepayments)', 'Interest Payments')
```

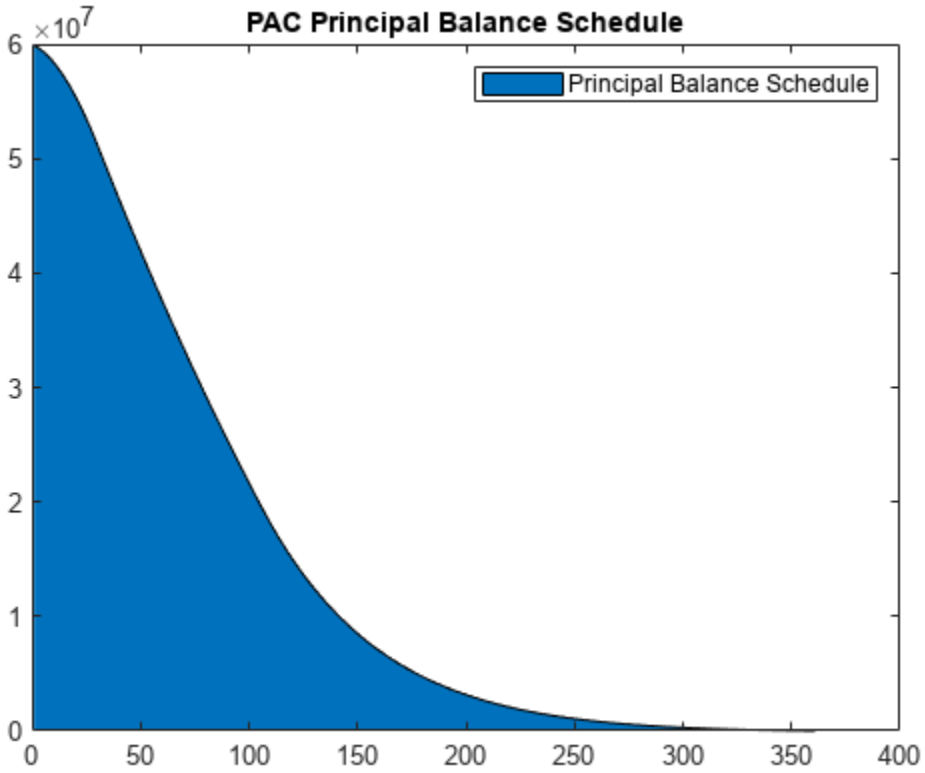


Step 5. Calculate the PAC schedule.

```
pacSpeed = [80 300];
[balanceSchedule, pacInitBalance] = ...
cmosched(principal, grossrate, originalTerm, termRemaining, ...
pacSpeed, []);
```

Step 6. Generate a plot for the PAC principal balance schedule.

```
figure;
area([pacInitBalance'; balanceSchedule'])
title('PAC Principal Balance Schedule');
legend('Principal Balance Schedule');
```



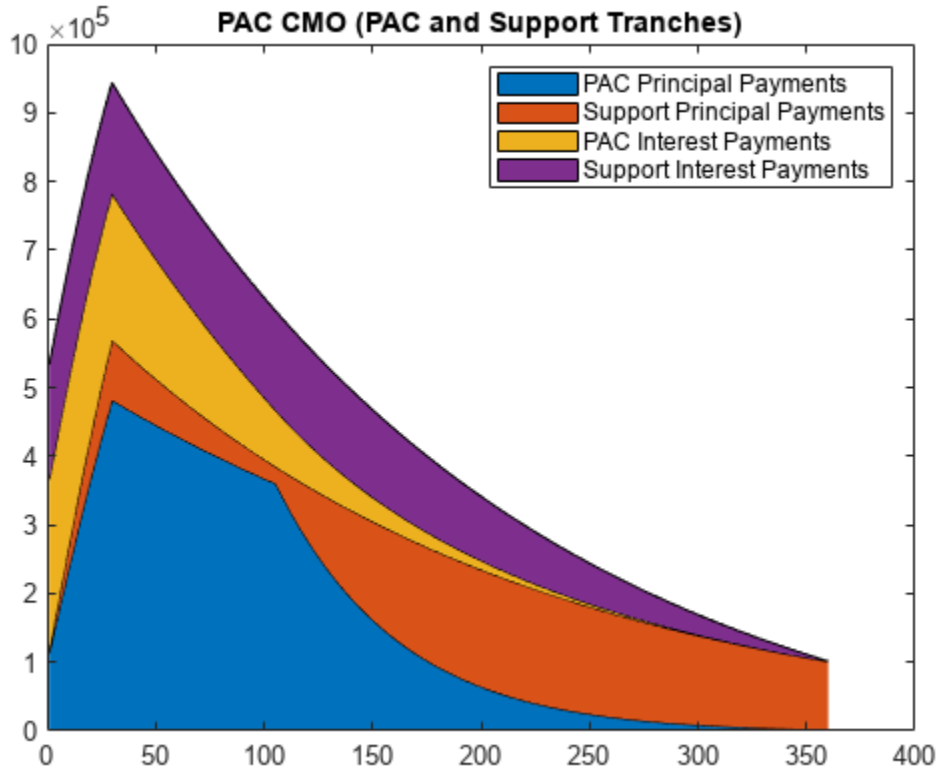
Step 7. Calculate PAC cash flow.

```
pacTranchePrincipals = [pacInitBalance; principal-pacInitBalance];
pacTrancheCoupons = [0.05; 0.05];
[pacBalances, pacPrincipals, pacInterests] = ...
cmoschedcf(principalPayments+prepayments, ...
pacTranchePrincipals, pacTrancheCoupons, balanceSchedule);
```

Step 8. Generate a plot for the PAC CMO tranches.

Generate a plot for the PAC CMO tranches:

```
figure;
area([pacPrincipals' pacInterests']);
title('PAC CMO (PAC and Support Tranches)');
legend('PAC Principal Payments', 'Support Principal Payments', ...
'PAC Interest Payments', 'Support Interest Payments');
```



Step 9. Create sequential CMO from the PAC bond.

CMO tranches, A, B, C, and D

```
seqTranchePrincipals = ...
[20000000; 20000000; 10000000; pacInitBalance-50000000];
seqTrancheCoupons = [0.05; 0.05; 0.05; 0.05];
```

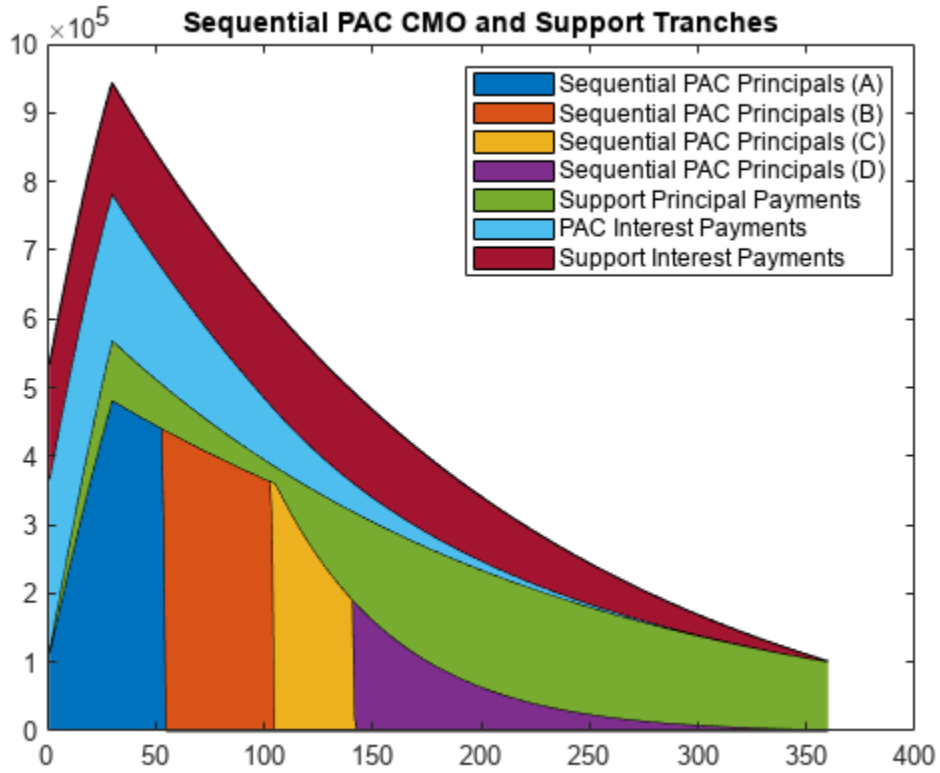
Step 10. Calculate cash flows for each tranche.

```
[seqBalances, seqPrincipals, seqInterests] = ...
cmoseqcf(pacPrincipals(1, :), seqTranchePrincipals, ...
seqTrancheCoupons, false);
```

Step 11. Generate a plot for the sequential PAC CMO.

Generate a plot for the sequential PAC CMO:

```
figure
area([seqPrincipals' pacPrincipals(2, :)' pacInterests']);
title('Sequential PAC CMO and Support Tranches');
legend('Sequential PAC Principals (A)', 'Sequential PAC Principals (B)', ...
'Sequential PAC Principals (C)', 'Sequential PAC Principals (D)', ...
'Support Principal Payments', 'PAC Interest Payments', ...
'Support Interest Payments');
```



Step 12. Create the discount curve.

```
CurveSettle = datenum('1-Jan-2011');
ZeroRates = [0.01 0.03 0.10 0.19 0.45 0.81 1.76 2.50 3.18 4.09 4.38]'/100;
CurveTimes = [1/12 3/12 6/12 1 2 3 5 7 10 20 30]';
CurveDates = daysadd(CurveSettle, 360 * CurveTimes, 1);
zeroCurve = intenvset('Rates', ZeroRates, 'StartDates', CurveSettle, ...
'EndDates', CurveDates);
```

Step 13. Price the CMO cash flows.

The cash flow for the sequential PAC principal A tranche is calculated using the cash flow functions `cfbyzero`, `cfyield`, `cfprice`, and `cfspread`.

```
cflows = seqPrincipals(1, :)+seqInterests(1, :);
cfdates = dates(2:end)';
price1 = cfbyzero(zeroCurve, cflows, cfdates, Settle, 4)
```

```
price1 = 2.2109e+07
```

```
yield = cfyield(cflows, cfdates, price1, Settle, 'Basis', 4)
```

```
yield = 0.0090
```

```
price2 = cfprice(cflows, cfdates, yield, Settle, 'Basis', 4)
```

```
price2 = 2.2109e+07
```

```
spread = cfspread(zeroCurve, price2, cflows, cfdates, Settle, 'Basis', 4)
```

```
spread = 5.5084e-12
```

```
WAL = sum(cflows .* yearfrac(Settle, cfdates, 4)) / sum(cflows)
```

```
WAL = 2.5408
```

The weighted average life (WAL) for the sequential PAC principal A tranche is `2.54` years.

Debt Instruments

Agency Option-Adjusted Spreads

Often bonds are issued with embedded options, which then makes standard price/yield or spread measures irrelevant. For example, a municipality concerned about the chance that interest rates may fall in the future might issue bonds with a provision that allows the bond to be repaid before the bond's maturity. This is a call option on the bond and must be incorporated into the valuation of the bond. Option-adjusted spread (OAS), which adjusts a bond spread for the value of the option, is the standard measure for valuing bonds with embedded options. Financial Instruments Toolbox software supports computing option-adjusted spreads for bonds with single embedded options using the agency model.

The Securities Industry and Financial Markets Association (SIFMA) has a simplified approach to compute OAS for agency issues (Government Sponsored Entities like Fannie Mae and Freddie Mac) termed "Agency OAS". In this approach, the bond has only one call date (European call) and uses Black's model (a variation on Black Scholes, `http://en.wikipedia.org/wiki/Black_model`) to value the bond option. The price of the bond is computed as follows:

$$\texttt{Price}_{\text{Callable}} = \texttt{Price}_{\text{NonCallable}} - \texttt{Price}_{\text{Option}}$$

where

$\texttt{Price}_{\text{Callable}}$ is the price of the callable bond.

$\texttt{Price}_{\text{NonCallable}}$ is the price of the noncallable bond, that is, price of the bond using `bndspread`.

$\texttt{Price}_{\text{Option}}$ is the price of the option, that is, price of the option using Black's model.

The Agency OAS is the spread, when used in the previous formula, yields the market price. Financial Instruments Toolbox software supports these functions:

Agency OAS

Agency OAS Functions	Purpose
`agencyoas`	Compute the OAS of the callable bond using the Agency OAS model.
`agencyprice`	Price the callable bond OAS using Agency using the OAS model.

Computing the Agency OAS for Bonds

To compute the Agency OAS using `agencyoas`, you must provide the zero curve as the input `ZeroData`. You can specify the zero curve in any intervals and with any compounding method. You can do this using Financial Toolbox™ functions `zbtprice` and `zbtyield`. Or, you can use `IRDataCurve` to construct an `IRDataCurve` object, and then use the `getZeroRates` to convert to dates and data for use in the `ZeroData` input.

After creating the `ZeroData` input for `agencyoas`, you can then:

1. Assign parameters for `CouponRate`, `Settle`, `Maturity`, `Vol`, `CallDate`, and `Price`.
2. Compute the option-adjusted spread using `agencyoas` to derive the `OAS` output.

   If you have the Agency OAS for the callable bond, you can use the `OAS` value as an input to `agencyprice` to determine the price for a callable bond.

In the following example, the Agency OAS is computed using `agencyoas` for a range of bond prices and the spread of an identically priced noncallable bond is calculated using `bndspread`.

```
%% Data
% Bond data -- note that there is only 1 call date
Settle = datetime(2010,1,20);
Maturity = datetime(2013,12,30);
Coupon = .022;
Vol = .5117;
CallDate = datetime(2010,12,30);
Period = 2;
Basis = 1;
Face = 100;

% Zero Curve data
ZeroTime = [.25 .5 1 2 3 4 5 7 10 20 30]';
ZeroDates = daysadd(Settle,360*ZeroTime,1);
ZeroRates = [.0008 .0017 .0045 .0102 .0169 .0224 .0274 .0347 .0414 .0530 .0740]';
ZeroData = [ZeroDates ZeroRates];
CurveCompounding = 2;
CurveBasis = 1;

Price = 94:104;
OAS = agencyoas(ZeroData, Price', Coupon, Settle,Maturity, Vol, CallDate,'Basis',Basis)
Spread = bndspread(ZeroData, Price', Coupon, Settle, Maturity)
plot(OAS,Price)
hold on
plot(Spread,Price,'r')
xlabel('Spread (bp)')
ylabel('Price')
title('AOAS and Spread for an Agency and Equivalent Noncallable Bond')
legend({'Callable Issue','Noncallable Issue'})
```

```
OAS =

  163.4942
  133.7306
  103.8735
   73.7505
   43.1094
   11.5608
  -21.5412
  -57.3869
  -98.5675
 -152.5226
 -239.6462

Spread =

  168.1412
  139.7047
  111.6123
   83.8561
   56.4286
   29.3227
    2.5314
  -23.9523
  -50.1348
  -76.0226
 -101.6218
```

The following plot demonstrates as the price increases, the value of the embedded option in the Agency issue increases, and the value of the issue itself does not increase as much as it would for a noncallable bond, illustrating the negative convexity of this issue:

Using Zero-Coupon Bonds

In this section...

Introduction

A zero-coupon bond is a corporate, Treasury, or municipal debt instrument that pays no periodic interest. Typically, the bond is redeemed at maturity for its full face value. It is a security issued at a discount from its face value, or it may be a coupon bond stripped of its coupons and repackaged as a zero-coupon bond.

Financial Instruments Toolbox software provides functions for valuing zero-coupon debt instruments. These functions supplement existing coupon bond functions such as `bndprice` and `bndyield` that are available in Financial Toolbox software.

Measuring Zero-Coupon Bond Function Quality

Zero-coupon function quality is measured by how consistent the results are with coupon-bearing bonds. Because the zero coupon's yield is bond-equivalent, comparisons with coupon-bearing bonds are possible.

In the textbook case, where time (t) is measured continuously and the rate (r) is continuously compounded, the value of a zero bond is the principal multiplied by e^{-rt}. In reality, the rate quoted is continuous and the basis can be variable, requiring a more consistent approach to meet the stricter demands of accurate pricing.

The following two examples

- “Pricing Treasury Notes” on page 6-5
- “Pricing Corporate Bonds” on page 6-7

show how the zero functions are consistent with supported coupon bond functions.

Pricing Treasury Notes

A Treasury note can be considered to be a package of zeros. The toolbox functions that price zeros require a coupon bond equivalent yield. That yield can originate from any type of coupon paying bond, with any periodic payment, or any accrual basis. The next example shows the use of the toolbox to price a Treasury note and compares the calculated price with the actual price quotation for that day.

```
Settle = datetime(2003,2,3);
MaturityCpn = datetime(2009,5,15);
Period = 2;
Basis = 0;
```

```
% Quoted yield.
QYield = 0.03342;

% Quoted price.
QPriceACT = 112.127;

CouponRate = 0.055;
```

Extract the cash flow and compute price from the sum of zeros discounted.

```
[CFlows, CDates] = cfamounts(CouponRate, Settle, MaturityCpn, ...
Period, Basis);
MaturityofZeros = CDates;
```

Compute the price of the coupon bond identically as a collection of zeros by multiplying the discount factors to the corresponding cash flows.

```
PriceofZeros = CFlows * zeroprice(QYield, Settle, ...
MaturityofZeros, Period, Basis)/100;
```

The following table shows the intermediate calculations.

Cash Flows	Discount Factors		Discounted Cash Flows
-1.2155	1.0000		-1.2155
2.7500	0.9908		2.7246
2.7500	0.9745		2.6799
2.7500	0.9585		2.6359
2.7500	0.9427		2.5925
2.7500	0.9272		2.5499
2.7500	0.9120		2.5080
2.7500	0.8970		2.4668
2.7500	0.8823		2.4263
2.7500	0.8678		2.3864
2.7500	0.8535		2.3472
2.7500	0.8395		2.3086
2.7500	0.8257		2.2706
102.7500	0.8121		83.4451
		Total	112.1263

Compare the quoted price and the calculated price based on zeros.

```
[QPriceACT PriceofZeros]

ans =

112.1270   112.1263
```

This example shows that `zeroprice` can satisfactorily price a Treasury note, a semiannual actual/actual basis bond, as if it were a composed of a series of zero-coupon bonds.

Pricing Corporate Bonds

You can similarly price a corporate bond, for which there is no corresponding zero-coupon bond, as opposed to a Treasury note, for which corresponding zeros exist. You can create a synthetic zero-coupon bond and arrive at the quoted coupon-bond price when you later sum the zeros.

```
Settle = datetime(2003,2,5);
MaturityCpn = datetime(2009,1,14);
Period = 2;
Basis = 1;
% Quoted yield.
QYield = 0.05974;
% Quoted price.
QPrice30 = 99.382;
CouponRate = 0.05850;
```

Extract cash flow and compute price from the sum of zeros.

```
[CFlows, CDates] = cfamounts(CouponRate, Settle, MaturityCpn, ...
Period, Basis);

Maturity = CDates;
```

Compute the price of the coupon bond identically as a collection of zeros by multiplying the discount factors to the corresponding cash flows.

```
Price30 = CFlows * zeroprice(QYield, Settle, Maturity, Period, ...
Basis)/100;
```

Compare quoted price and calculated price based on zeros.

```
[QPrice30 Price30]

ans =

99.3820   99.3828
```

As a test of fidelity, intentionally giving the wrong basis, say actual/actual (`Basis = 0`) instead of 30/360, gives a price of 99.3972. Such a systematic error, if recurring in a more complex pricing routine, quickly adds up to large inaccuracies.

In summary, the zero functions in MATLAB software facilitate extraction of present value from virtually any fixed-coupon instrument, up to any period in time.

Stepped-Coupon Bonds

In this section...

Introduction

A stepped-coupon bond has a fixed schedule of changing coupon amounts. Like fixed coupon bonds, stepped-coupon bonds could have different periodic payments and accrual bases.

The functions `stepcpnprice` and `stepcpnyield` compute prices and yields of such bonds. An accompanying function `stepcpncfamounts` produces the cash flow schedules pertaining to these bonds.

Cash Flows from Stepped-Coupon Bonds

Consider a bond that has a schedule of two coupons. Suppose that the bond starts out with a 2% coupon that steps up to 4% in 2 years and onward to maturity. Assume that the issue and settlement dates are both March 15, 2003. The bond has a 5-year maturity. Use `stepcpncfamounts` to generate the cash flow schedule and times.

```
Settle      = datenum('15-Mar-2003');
Maturity    = datenum('15-Mar-2008');
ConvDates   = [datenum('15-Mar-2005')];
CouponRates = [0.02, 0.04];

[CFlows, CDates, CTimes] = stepcpncfamounts(Settle, Maturity, ...
ConvDates, CouponRates)

CFlows =

     0     1     1     1     1     2     2     2     2     2   102

CDates =

      731655      731839      732021      732205      732386      732570      732751      732935      733116      733300

CTimes =

     0     1     2     3     4     5     6     7     8     9    10
```

Notably, `ConvDates` has one less element than `CouponRates` because MATLAB software assumes that the first element of `CouponRates` indicates the coupon schedule between `Settle` (March 15, 2003) and the first element of `ConvDates` (March 15, 2005), shown diagrammatically below.

	Pay 2% from March 15, 2003		Pay 4% from March 15, 2003
Effective 2% on March 15, 2003		Effective 4% on March 15, 2005	

Coupon Dates	Semiannual Coupon Payment
15-Mar-03	0
15-Sep-03	1
15-Mar-04	1
15-Sep-04	1
15-Mar-05	1
15-Sep-05	2
15-Mar-06	2
15-Sep-06	2
15-Mar-07	2
15-Sep-07	2
15-Mar-08	102

The payment on March 15, 2005 is still a 2% coupon. Payment of the 4% coupon starts with the next payment, September 15, 2005. March 15, 2005 is the end of first coupon schedule, not to be confused with the beginning of the second.

In summary, MATLAB takes user input as the end dates of coupon schedules and computes the next coupon dates automatically.

The payment due on settlement (zero in this case) represents the accrued interest due on that day. It is negative if such amount is nonzero. Comparison with `cfamounts` in Financial Toolbox shows that the two functions operate identically.

Price and Yield of Stepped-Coupon Bonds

The toolbox provides two basic analytical functions to compute price and yield for stepped-coupon bonds. Using the above bond as an example, you can compute the price when the yield is known.

You can estimate the yield to maturity as a number-of-year weighted average of coupon rates. For this bond, the estimated yield is:

$$\frac{(2 \times 2) + (4 \times 3)}{5}$$

.

or 3.33%. While definitely not exact (due to nonlinear relation of price and yield), this estimate suggests close to par valuation and serves as a quick first check on the function.

```
Yield = 0.0333;

[Price, AccruedInterest] = stepcpnprice(Yield, Settle, ...
Maturity, ConvDates, CouponRates)
```

```
Price =

   99.2237

AccruedInterest =
```

```
     0
```

The price returned is 99.2237 (per $100 notional), and the accrued interest is zero, consistent with our earlier assertions.

To validate that there is consistency among the stepped-coupon functions, you can use the above price and see if indeed it implies a 3.33% yield by using `stepcpnyield`.

```
YTM = stepcpnyield(Price, Settle, Maturity, ConvDates, ...
CouponRates)
```

```
YTM =

    0.0333
```

Term Structure Calculations

In this section...

Introduction

So far, a more formal definition of "yield" and its application has not been developed. In many situations when cash flow is available, discounting factors to the cash flows may not be immediately apparent. In other cases, what is relevant is often a *spread*, the difference between curves (also known as the term structure of spread).

All these calculations require one main ingredient, the Treasury spot, par-yield, or forward curve. Typically, the generation of these curves starts with a series of on-the-run and selected off-the-run issues as inputs.

MATLAB software uses these bonds to find spot rates one at a time, from the shortest maturity onwards, using bootstrap techniques. All cash flows are used to construct the spot curve, and rates between maturities (for these coupons) are interpolated linearly.

Computing Spot and Forward Curves

For an illustration of how this works, observe the use of `zbtyield` (or equivalently `zbtprice`) on a portfolio of six Treasury bills and bonds.

Bills	Maturity Date	Current Yield
3 month	4/17/03	1.15
6 month	7/17/03	1.18

Notes/Bonds	Coupon	Maturity Date	Current Yield
2 year	1.750	12/31/04	1.68
5 year	3.000	11/15/07	2.97
10 year	4.000	11/15/12	4.01
30 year	5.375	2/15/31	4.92

You can specify prices or yields to the bonds above to infer the spot curve. The function `zbtyield` accepts yields (bond-equivalent yield, to be exact).

To proceed, first assemble the above table into a variable called `Bonds`. The first column contains maturities, the second contains coupons, and the third contains notionals or face values of the bonds. (Note that bills have zero coupons.)

```
Bonds = [datenum('04/17/2003')    0        100;
         datenum('07/17/2003')    0        100;
         datenum('12/31/2004')    0.0175   100;
         datenum('11/15/2007')    0.03     100;
```

```
         datenum('11/15/2012')    0.04     100;
         datenum('02/15/2031')    0.05375  100];
```

Then specify the corresponding yields.

```
Yields  = [0.0115;
           0.0118;
           0.0168;
           0.0297;
           0.0401;
           0.0492];
```

You are now ready to compute the spot curve for each of these six maturities. The spot curve is based on a settlement date of January 17, 2003.

```
Settle = datenum('17-Jan-2003');
[ZeroRates, CurveDates] = zbtyield(Bonds, Yields, Settle)
```

```
ZeroRates =

    0.0115
    0.0118
    0.0168
    0.0302
    0.0418
    0.0550

CurveDates =

      731688
      731779
      732312
      733361
      735188
      741854
```

This gets you the Treasury spot curve for the day.

You can compute the forward curve from this spot curve with `zero2fwd`.

```
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, ...
Settle)
```

```
ForwardRates =

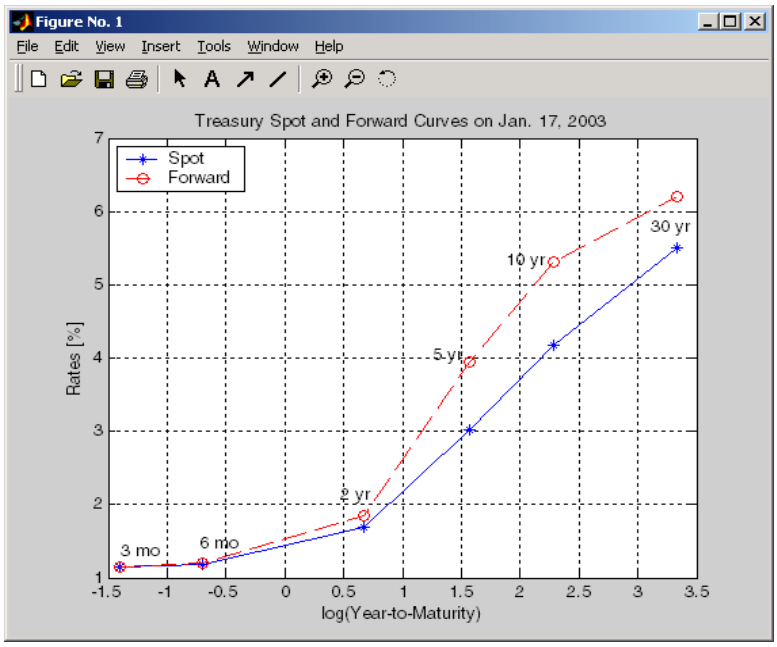
    0.0115
    0.0121
    0.0185
    0.0394
    0.0530
    0.0621

CurveDates =

      731688
      731779
      732312
```

```
733361
735188
741854
```

Here the notion of forward rates refers to rates between the maturity dates shown above, not to a certain period (forward 3-month rates, for example).



Computing Spreads

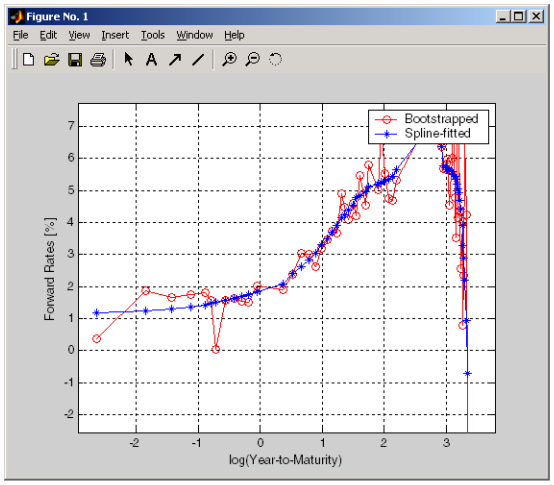
Calculating the spread between specific, fixed forward periods (such as the Treasury-Eurodollar spread) requires an extra step. Interpolate the zero rates (or zero prices, instead) for the corresponding maturities on the interval dates. Then use the interpolated zero rates to deduce the forward rates, and thus the spread of Eurodollar forward curve segments versus the relevant forward segments from Treasury bills.

Additionally, the variety of curve functions (including `zero2fwd`) helps to standardize such calculations. For instance, by making both rates quoted with quarterly compounding and on an actual/360 basis, the resulting spread structure is fully comparable. This avoids the small inconsistency that occurs when directly comparing the bond-equivalent yield of a Treasury bill to the quarterly forward rates implied by Eurodollar futures.

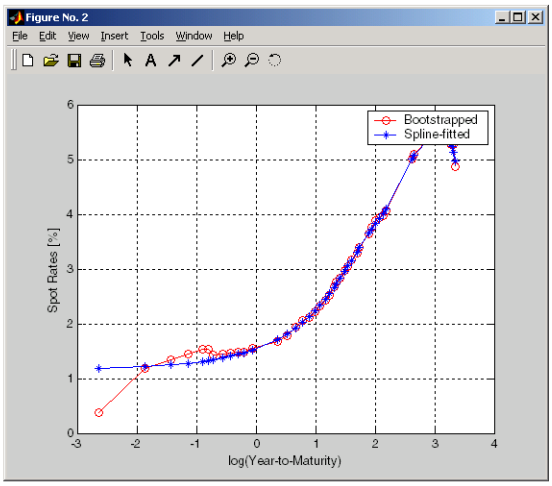
Noise in Curve Computations

When introducing more bonds in constructing curves, noise may become a factor and may need some “smoothing” (with splines, for example); this helps obtain a smoother forward curve.

The following spot and forward curves are constructed from 67 Treasury bonds. The fitted and bootstrapped spot curve (bottom right figure) displays comparable stability. The forward curve (upper-left figure) contains significant noise and shows an improbable forward rate structure. The noise is not necessarily bad; it could uncover trading opportunities for a relative-value approach. Yet, a more balanced approach is desired when the bootstrapped forward curve oscillates this much and contains a negative rate as large as -10% (not shown in the plot because it is outside the limits).



Implied Forward Curves. The jagged curve comes from direct bootstrapping. The smooth curve shows the effect of smoothing with splines.



Implied Spot Rate Curves. These curves correspond to the forward curve above.

This example uses `termfit`, an example function from Financial Toolbox software that also requires the use of Curve Fitting Toolbox™ software.

Interest Rate Swaps

In this section...

Swap Pricing Assumptions

Financial Instruments Toolbox contains the function `liborfloat2fixed`, which computes a fixed-rate par yield that equates the floating-rate side of a swap to the fixed-rate side. The solver sets the present value of the fixed side to the present value of the floating side without having to line up and compare fixed and floating periods.

Assumptions on Floating-Rate Input

- Rates are quarterly, for example, that of Eurodollar futures.
- Effective date is the first third Wednesday after the settlement date.
- All delivery dates are spaced 3 months apart.
- All periods start on the third Wednesday of delivery months.
- All periods end on the same dates of delivery months, 3 months after the start dates.
- Accrual basis of floating rates is actual/360.
- Applicable forward rates are estimated by interpolation in months when forward-rate data is not available.

Assumptions on Fixed-Rate Output

- Design allows you to create a bond of any coupon, basis, or frequency, based on the floating-rate input.
- The start date is a valuation date, that is, a date when an agreement to enter into a contract by the settlement date is made.
- Settlement can be on or after the start date. If it is after, a forward fixed-rate contract results.
- Effective date is assumed to be the first third Wednesday after settlement, the same date as that of the floating rate.
- The end date of the bond is a designated number of years away, on the same day and month as the effective date.
- Coupon payments occur on anniversary dates. The frequency is determined by the period of the bond.
- Fixed rates are not interpolated. A fixed-rate bond of the same present value as that of the floating-rate payments is created.

Swap Pricing Example

This example shows the use of the functions in computing the fixed rate applicable to a series of 2-, 5-, and 10-year swaps based on Eurodollar market data. According to the Chicago Mercantile Exchange (`https://www.cmegroup.com`), Eurodollar data on Friday, October 11, 2002, was as shown in the following table.

Note This example illustrates swap calculations in MATLAB software. Timing of the data set used was not rigorously examined and was assumed to be the proxy for the swap rate reported on October 11, 2002.

Eurodollar Data on Friday, October 11, 2002

6	2011	93.56
9	2011	93.515
12	2011	93.47
3	2012	93.445
6	2012	93.41
9	2012	93.39

Using this data, you can compute 1-, 2-, 3-, 4-, 5-, 7-, and 10-year swap rates with the toolbox function `liborfloat2fixed`. The function requires you to input only Eurodollar data, the settlement date, and tenor of the swap. MATLAB software then performs the required computations.

To illustrate how this function works, first load the data contained in the supplied Excel® worksheet `EDdata.xls`.

```
[EDRawData, textdata] = xlsread('EDdata.xls');
```

Extract the month from the first column and the year from the second column. The rate used as proxy is the arithmetic average of rates on opening and closing.

```
Month = EDRawData(:,1);
Year  = EDRawData(:,2);
IMMData = (EDRawData(:,4)+EDRawData(:,6))/2;
EDFutData = [Month, Year, IMMData]
```

```
EDFutData =

   1.0e+03 *

    0.0120    2.0110    0.0935
    0.0030    2.0120    0.0934
    0.0060    2.0120    0.0934
    0.0090    2.0120    0.0934
```

Next, input the current date.

```
Settle = datetime(2002,10,11);
```

To compute for the 2-year swap rate, set the tenor to 2.

```
Tenor = 2;
```

Finally, compute the swap rate with `liborfloat2fixed`.

```
[FixedSpec, ForwardDates, ForwardRates] = ...
liborfloat2fixed(EDFutData, Settle, Tenor)
```

MATLAB returns a par-swap rate of 2.23% using the default setting (quarterly compounding and 30/360 accrual), and forward dates and rates data (quarterly compounded).

```
FixedSpec =

       Coupon: 0.0223
       Settle: '16-Oct-2002'
     Maturity: '16-Oct-2004'
       Period: 4
        Basis: 1

ForwardDates =

      731505
      731596
      731687
      731778
      731869
      731967
      732058
      732149

ForwardRates =
```

```
0.0178
0.0168
0.0171
0.0189
0.0216
0.0250
0.0280
0.0306
```

In the `FixedSpec` output, note that the swap rate actually goes forward from the third Wednesday of October 2002 (October 16, 2002), 5 days after the original `Settle` input (October 11, 2002). This, however, is still the best proxy for the swap rate on `Settle`, as the assumption merely starts the swap's effective period and does not affect its valuation method or its length.

The correction suggested by Hull and White improves the result by turning on convexity adjustment as part of the input to `liborfloat2fixed`. (See Hull, J., *Options, Futures, and Other Derivatives*, 4th Edition, Prentice-Hall, 2000.) For a long swap, for example, five years or more, this correction could prove to be large.

The adjustment requires additional parameters:

- `StartDate`, which you make the same as `Settle` (the default) by providing an empty matrix `[]` as input.
- `ConvexAdj` to tell `liborfloat2fixed` to perform the adjustment.
- `RateParam`, which provides the parameters `a` and `S` as input to the Hull-White short rate process.
- Optional parameters `InArrears` and `Sigma`, for which you can use empty matrices `[]` to accept the MATLAB defaults.
- `FixedCompound`, with which you can facilitate comparison with values cited in Table H15 of *Federal Reserve Statistical Release* by turning the default quarterly compounding into semiannual compounding, with the (default) basis of 30/360.

```
StartDate = [];
Interpolation = [];
ConvexAdj = 1;
RateParam = [0.03; 0.017];
FixedCompound = 2;
[FixedSpec, ForwardDaates, ForwardRates] = ...
liborfloat2fixed(EDFutData, Settle, Tenor, StartDate, ...
Interpolation, ConvexAdj, RateParam, [], [], FixedCompound)
```

This returns 2.21% as the 2-year swap rate, quite close to the reported swap rate for that date.

Analogously, the following table summarizes the solutions for 1-, 3-, 5-, 7-, and 10-year swap rates (convexity-adjusted and unadjusted).

Calculated and Market Average Data of Swap Rates on Friday, October 11, 2002

Swap Length (Years)	Unadjusted	Adjusted	Table H15	Adjusted Error (Basis Points)
1	1.80%	1.79%	1.80%	-1
2	2.24%	2.21%	2.22%	-1
3	2.70%	2.66%	2.66%	0
4	3.12%	3.03%	3.04%	-1
5	3.50%	3.37%	3.36%	+1
7	4.16%	3.92%	3.89%	+3
10	4.87%	4.42%	4.39%	+3

Portfolio Hedging

You can use these results further, such as for hedging a portfolio. The `liborduration` function provides a duration-hedging capability. You can isolate assets (or liabilities) from interest-rate risk exposure with a swap arrangement.

Suppose that you own a bond with these characteristics:

- $100 million face value
- 7% coupon paid semiannually
- 5% yield to maturity
- Settlement on October 11, 2002
- Maturity on January 15, 2010
- Interest accruing on an actual/365 basis

Use of the `bnddury` function from Financial Toolbox software shows a modified duration of 5.6806 years.

To immunize this asset, you can enter into a pay-fixed swap, specifically a swap in the amount of notional principal (*Ns*) such that *Ns***SwapDuration* + $100M*5.6806 = 0 (or *Ns* = -100*5.6806/ *SwapDuration*).

Suppose again, you choose to use a 5-, 7-, or 10-year swap (3.37%, 3.92%, and 4.42% from the previous table) as your hedging tool.

```
SwapFixRate = [0.0337; 0.0392; 0.0442];
Tenor = [5; 7; 10];
Settle = '11-Oct-2002';
PayFixDuration = liborduration(SwapFixRate, Tenor, Settle)
```

```
PayFixDuration =

   -3.6835
   -4.7307
   -6.0661
```

This gives a duration of -3.6835, -4.7307, and -6.0661 years for 5-, 7-, and 10-year swaps. The corresponding notional amount is computed by

```
Ns = -100*5.6806./PayFixDuration

Ns =

  154.2163
  120.0786
   93.6443
```

The notional amount entered in pay-fixed side of the swap instantaneously immunizes the portfolio.

Bond Futures

Bond futures are futures contracts where the commodity for delivery is a government bond. There are established global markets for government bond futures. Bond futures provide a liquid alternative for managing interest-rate risk.

In the U.S. market, the Chicago Mercantile Exchange (CME) offers futures on Treasury bonds and notes with maturities of 2, 5, 10, and 30 years. Typically, the following bond future contracts from the CME have maturities of 3, 6, 9, and 12 months:

- 30-year U.S. Treasury bond
- 10-year U.S. Treasury bond
- 5-year U.S. Treasury bond
- 2-year U.S. Treasury bond

The short position in a Treasury bond or note future contract must deliver to the long position in one of many possible existing Treasury bonds. For example, in a 30-year Treasury bond future, the short position must deliver a Treasury bond with at least 15 years to maturity. Because these bonds have different values, the bond future contract is standardized by computing a conversion factor. The conversion factor normalizes the price of a bond to a theoretical bond with a coupon of 6%. The price of a bond future contract is represented as:

$$InvoicePrice = FutPrice \times CF + AI$$

where:

FutPrice is the price of the bond future.

CF is the conversion factor for a bond to deliver in a futures contract.

AI is the accrued interest.

The short position in a futures contract has the option of which bond to deliver and, in the U.S. bond market, when in the delivery month to deliver the bond. The short position typically chooses to deliver the bond known as the Cheapest to Deliver (CTD). The CTD bond most often delivers on the last delivery day of the month.

Financial Instruments Toolbox software supports the following bond futures:

- U.S. Treasury bonds and notes
- German Bobl, Bund, Buxl, and Schatz
- UK gilts
- Japanese government bonds (JGBs)

The functions supporting all bond futures are:

Function	Purpose
`convfactor`	Calculates bond conversion factors for U.S. Treasury bonds, German Bobl, Bund, Buxl, and Schatz, U.K. gilts, and JGBs.
`bndfutprice`	Prices bond future given repo rates.

Function	Purpose
`bndfutimprepo`	Calculates implied repo rates for a bond future given price.

The functions supporting U.S. Treasury bond futures are:

Function	Purpose
`tfutbyprice`	Calculates future prices of Treasury bonds given the spot price.
`tfutbyyield`	Calculates future prices of Treasury bonds given current yield.
`tfutimprepo`	Calculates implied repo rates for the Treasury bond future given price.
`tfutpricebyrepo`	Calculates Treasury bond futures price given the implied repo rates.
`tfutyieldbyrepo`	Calculates Treasury bond futures yield given the implied repo rates.

Analysis of Bond Futures

The following example demonstrates analyzing German Euro-Bund futures traded on Eurex. However, `convfactor`, `bndfutprice`, and `bndfutimprepo` apply to bond futures in the U.S., U.K., Germany, and Japan. The workflow for this analysis is:

1. Calculate bond conversion factors.
2. Calculate implied repo rates to find the CTD bond.
3. Price the bond future using the term implied repo rate.

Calculating Bond Conversion Factors

Use conversion factors to normalize the price of a particular bond for delivery in a futures contract. When using conversion factors, the assumption is that a bond for delivery has a 6% coupon. Use `convfactor` to calculate conversion factors for all bond futures from the U.S., Germany, Japan, and U.K.

For example, conversion factors for Euro-Bund futures on Eurex are listed at `www.eurexchange.com`. The delivery date for Euro-Bund futures is the 10th day of the month, as opposed to bond futures in the U.S., where the short position has the option of choosing when to deliver the bond.

For the 4% bond, compute the conversion factor with:

```
CF1 = convfactor('10-Sep-2009','04-Jul-2018', .04,.06,3)
```

```
CF1 =

     0.8659
```

This syntax for `convfactor` works fine for bonds with standard coupon periods. However, some deliverable bonds have long or short first coupon periods. Compute the conversion factors for such bonds using the optional input parameters `StartDate` and `FirstCouponDate`. Specify all optional input arguments for `convfactor` as parameter/value pairs:

```
CF2 = convfactor(datetime(2009,9,10),datetime(2019,1,4), .0375,'Convention',3,'startdate',...
datetime(2008,11,14))
```

```
CF2 =

    0.8426
```

Calculating Implied Repo Rates to Find the CTD Bond

To determine the availability of the cheapest bond for deliverable bonds against a futures contract, compute the implied repo rate for each bond. The bond with the highest repo rate is the cheapest because it has the lowest initial value, thus yielding a higher return, provided you deliver it with the stated futures price. Use `bndfutimprepo` to calculate repo rates:

```
% Bond Properties
CouponRate = [.0425;.0375;.035];
Maturity = [datenum('04-Jul-2018');datenum('04-Jan-2019');datenum('04-Jul-2019')];
CF = [0.882668;0.842556;0.818193];
Price = [105.00;100.89;98.69];

% Futures Properties
FutSettle = '09-Jun-2009';
```

```
FutPrice = 118.54;
Delivery = '10-Sep-2009';

% Note that the default for BNDFUTIMPREPO is for the bonds to be
% semi-annual with a day count basis of 0.  Since these are German
% bonds, we need to have a Basis of 8 and a Period of 1
ImpRepo = bndfutimprepo(Price, FutPrice, FutSettle, Delivery, CF, ...
CouponRate, Maturity,'Basis',8,'Period',1)
```

```
ImpRepo =

    0.0261
   -0.0022
   -0.0315
```

Pricing Bond Futures Using the Term Implied Repo Rate

Use `bndfutprice` to perform price calculations for all bond futures from the U.S., Germany, Japan, and U.K. To price the bond, given a term repo rate:

```
% Assume a term repo rate of .0091;
RepoRate = .0091;
[FutPrice,AccrInt] = bndfutprice(RepoRate, Price(1), FutSettle,...
Delivery, CF(1), CouponRate(1), Maturity(1),...
'Basis',8,'Period',1)
```

```
FutPrice =

  118.0126

AccrInt =

    0.7918
```

Managing Present Value with Bond Futures

The Present Value of a Basis Point (PVBP) is used to manage interest-rate risk. PVBP is a measure that quantifies the change in price of a bond given a one-basis point shift in interest rates. The PVBP of a bond is computed with the following:

$$PVBPBond = \frac{Duration \times MarketValue}{100}$$

The PVBP of a bond futures contract can be computed with the following:

$$PVBPFutures = \frac{PVBPCTDBond}{CTDConversionFactor}$$

Use `bnddurp` and `bnddury` from Financial Toolbox software to compute the modified durations of CTD bonds. For more information, see “Managing Interest-Rate Risk with Bond Futures” on page 2-125 and “Fitting the Diebold Li Model” on page 7-15.

Fitting the Diebold Li Model

This example shows how to construct a Diebold Li model of the US yield curve for each month from 1990 to 2010. This example also demonstrates how to forecast future yield curves by fitting an autoregressive model to the time series of each parameter.

The paper can be found here:

https://www.nber.org/papers/w10048

Load the Data

The data used are monthly Treasury yields from 1990 through 2010 for tenors of 1 Mo, 3 Mo, 6 Mo, 1 Yr, 2 Yr, 3 Yr, 5 Yr, 7 Yr, 10 Yr, 20 Yr, 30 Yr.

Daily data can be found here:

https://www.treasury.gov/resource-center/data-chart-center/interest-rates/Pages/TextView.aspx?data=yieldAll

Data is stored in a MATLAB® data file as a MATLAB `dataset` object.

```
load Data_USYieldCurve

% Extract data for the last day of each month
MonthYearMat = repmat((1990:2010)',1,12)';
EOMDates = lbusdate(MonthYearMat(:),repmat((1:12)',21,1));
MonthlyIndex = find(ismember(Dataset.Properties.ObsNames,datestr(EOMDates)));
Estimationdataset = Dataset(MonthlyIndex,:);
EstimationData = double(Estimationdataset);
```

Diebold Li Model

Diebold and Li start with the Nelson Siegel model

$$y = \beta_0 + (\beta_1 + \beta_2)\frac{\tau}{m}(1 - e^{\frac{-m}{\tau}}) - \beta_2 e^{\frac{-m}{\tau}}$$

and rewrite it to be the following:

$$y_t(\tau) = \beta_{1t} + \beta_{2t}\left(\frac{1 - e^{-\lambda_t\tau}}{\lambda_t\tau}\right) + \beta_{3t}\left(\frac{1 - e^{-\lambda_t\tau}}{\lambda_t\tau} - e^{-\lambda_t\tau}\right)$$

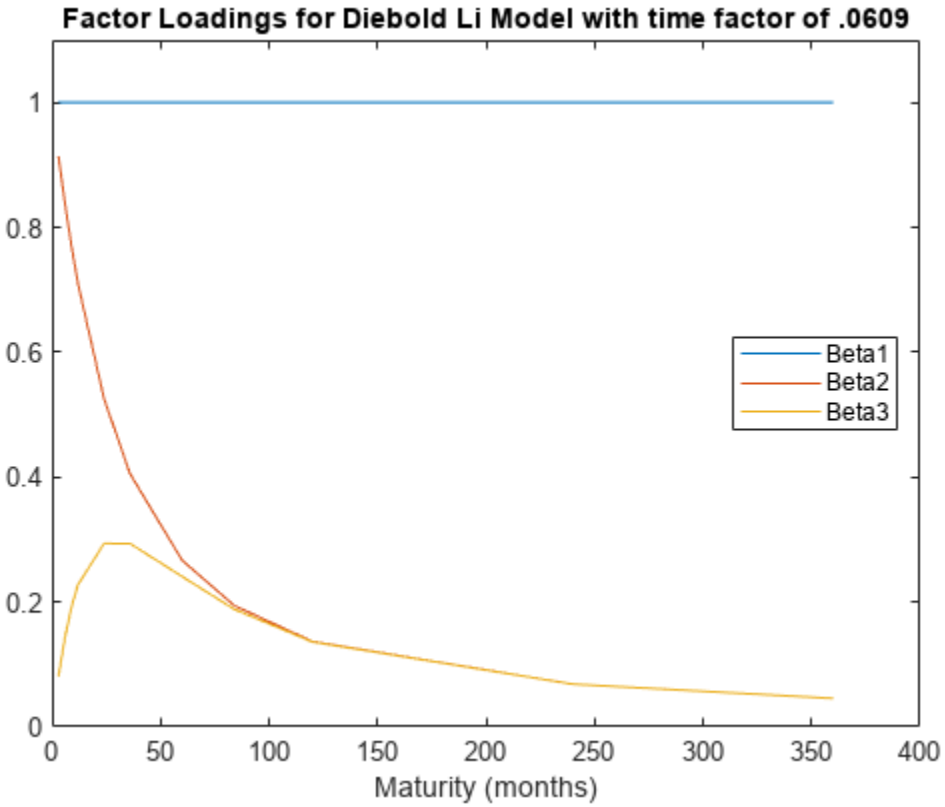
The above model allows the factors to be interpreted in the following way: Beta1 corresponds to the long term/level of the yield curve, Beta2 corresponds to the short term/slope, and Beta3 corresponds to the medium term/curvature. λ determines the maturity at which the loading on the curvature is maximized, and governs the exponential decay rate of the model.

Diebold and Li advocate setting λ to maximize the loading on the medium term factor, Beta3, at 30 months. This also transforms the problem from a nonlinear fitting to a simple linear regression.

```
% Explicitly set the time factor lambda
lambda_t = .0609;
```

```
% Construct a matrix of the factor loadings
% Tenors associated with data
TimeToMat = [3 6 9 12 24 36 60 84 120 240 360]';
X = [ones(size(TimeToMat)) (1 - exp(-lambda_t*TimeToMat))./(lambda_t*TimeToMat) ...
    ((1 - exp(-lambda_t*TimeToMat))./(lambda_t*TimeToMat) - exp(-lambda_t*TimeToMat))];

% Plot the factor loadings
plot(TimeToMat,X)
title('Factor Loadings for Diebold Li Model with time factor of .0609')
xlabel('Maturity (months)')
ylim([0 1.1])
legend({'Beta1','Beta2','Beta3'},'location','east')
```



Fit the Model

A `DieboldLi` object is developed to facilitate fitting the model from yield data. The `DieboldLi` object inherits from the `IRCurve` object, so the `getZeroRates`, `getDiscountFactors`, `getParYields`, `getForwardRates`, and `toRateSpec` methods are all implemented. Additionally, the method `fitYieldsFromBetas` is implemented to estimate the Beta parameters given a lambda parameter for observed market yields.

The `DieboldLi` object is used to fit a Diebold Li model for each month from 1990 through 2010.

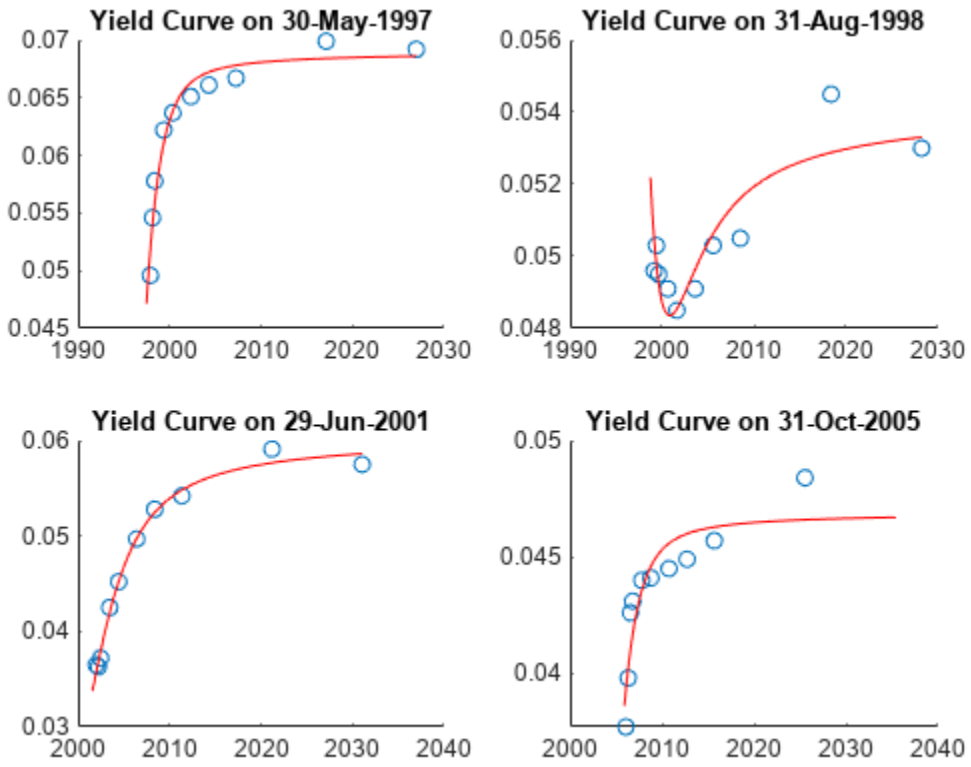
```
% Preallocate the Betas
Beta = zeros(size(EstimationData,1),3);

% Loop through and fit each end of month yield curve
```

```
for jdx = 1:size(EstimationData,1)
    tmpCurveModel = DieboldLi.fitBetasFromYields(EOMDates(jdx),lambda_t*12,daysadd(EOMDates(jdx)
    Beta(jdx,:) = [tmpCurveModel.Beta1 tmpCurveModel.Beta2 tmpCurveModel.Beta3];
end
```

The Diebold Li fits on selected dates are included here

```
PlotSettles = [datetime(1997,5,30) , datetime(1998,8,31) , datetime(2001,6,29) , datetime(2005,10
figure
for jdx = 1:length(PlotSettles)
    subplot(2,2,jdx)
    tmpIdx = find(strcmpi(Estimationdataset.Properties.ObsNames,datestr(PlotSettles(jdx))));
    tmpCurveModel = DieboldLi.fitBetasFromYields(PlotSettles(jdx),lambda_t*12,...
        daysadd(PlotSettles(jdx),30*TimeToMat),EstimationData(tmpIdx,:)');
    scatter(daysadd(PlotSettles(jdx),30*TimeToMat),EstimationData(tmpIdx,:))
    hold on
    PlottingDates = (PlotSettles(jdx)+30:30:PlotSettles(jdx)+30*360)';
    plot(PlottingDates,tmpCurveModel.getParYields(PlottingDates),'r-')
    title(['Yield Curve on ' datestr(PlotSettles(jdx))])
    datetick
end
```



Forecasting

The Diebold Li model can be used to forecast future yield curves. Diebold and Li propose fitting an AR(1) model to the time series of each Beta parameter. This fitted model can then be used to forecast future values of each parameter, and by extension, future yield curves.

For this example the MATLAB function `regress` is used to estimate the parameters for an AR(1) model for each Beta.

The confidence intervals for the regression fit are also used to generate two additional yield curve forecasts that serve as additional possible scenarios for the yield curve.

The `MonthsLag` variable can be adjusted to make different period ahead forecasts. For example, changing the value from `1` to `6` would change the forecast from a 1 month ahead to 6 month ahead forecast.

```
MonthsLag = 1;

[tmpBeta,bint] = regress(Beta(MonthsLag+1:end,1),[ones(size(Beta(MonthsLag+1:end,1))) Beta(1:end
ForecastBeta(1,1) = [1 Beta(end,1)]*tmpBeta;
ForecastBeta_Down(1,1) = [1 Beta(end,1)]*bint(:,1);
ForecastBeta_Up(1,1) = [1 Beta(end,1)]*bint(:,2);
[tmpBeta,bint]  = regress(Beta(MonthsLag+1:end,2),[ones(size(Beta(MonthsLag+1:end,2))) Beta(1:en
ForecastBeta(1,2) = [1 Beta(end,2)]*tmpBeta;
ForecastBeta_Down(1,2) = [1 Beta(end,2)]*bint(:,1);
ForecastBeta_Up(1,2) = [1 Beta(end,2)]*bint(:,2);
[tmpBeta,bint]  = regress(Beta(MonthsLag+1:end,3),[ones(size(Beta(MonthsLag+1:end,3))) Beta(1:en

Credit Derivatives

Counterparty Credit Risk and CVA

This example shows how to compute the unilateral credit value (valuation) adjustment (CVA) for a bank holding a portfolio of vanilla interest-rate swaps with several counterparties. CVA is the expected loss on an over-the-counter contract or portfolio of contracts due to counterparty default. The CVA for a particular counterparty is defined as the sum over all points in time of the discounted expected exposure at each moment multiplied by the probability that the counterparty defaults at that moment, all multiplied by 1 minus the recovery rate. The CVA formula is:

$$CVA = (1 - R)\int_0^T discEE(t)dPD(t)$$

Where `R` is the recovery, `discEE` the discounted expected exposure at time t, and `PD` the default probability distribution.

The expected exposure is computed by first simulating many future scenarios of risk factors for the given contract or portfolio. Risk factors can be interest rates, as in this example, but will differ based on the portfolio and can include FX rates, equity or commodity prices, or anything that will affect the market value of the contracts. Once a sufficient set of scenarios has been simulated, the contract or portfolio can be priced on a series of future dates for each scenario. The result is a matrix, or "cube", of contract values.

These prices are converted into exposures after taking into account collateral agreements that the bank might have in place as well as netting agreements, as in this example, where the values of several contracts may offset each other, lowering their total exposure.

The contract values for each scenario are discounted to compute the discounted exposures. The discounted expected exposures can then be computed by a simple average of the discounted exposures at each simulation date.

Finally, counterparty default probabilities are typically derived from credit default swap (CDS) market quotes and the CVA for the counterparty can be computed according to the above formula. Assume that a counterparty default is independent of its exposure (no wrong-way risk).

This example demonstrates a portfolio of vanilla interest-rate swaps with the goal of computing the CVA for a particular counterparty.

Read Swap Portfolio

The portfolio of swaps is close to zero value at time t = `0`. Each swap is associated with a counterparty and may or may not be included in a netting agreement.

```
% Read swaps from spreadsheet
swapFile = 'cva-swap-portfolio.xls';
swaps = readtable(swapFile,'Sheet','Swap Portfolio');
swaps.LegType = [swaps.LegType ~swaps.LegType];
swaps.LegRate = [swaps.LegRateReceiving swaps.LegRatePaying];
swaps.LegReset = ones(size(swaps,1),1);

numSwaps = size(swaps,1);
```

For more information on the swap parameters for `CounterpartyID` and `NettingID`, see `creditexposures`. For more information on the swap parameters for `Principal`, `Maturity`, `LegType`, `LegRate`, `LatestFloatingRate`, `Period`, and `LegReset`, see `swapbyzero`.

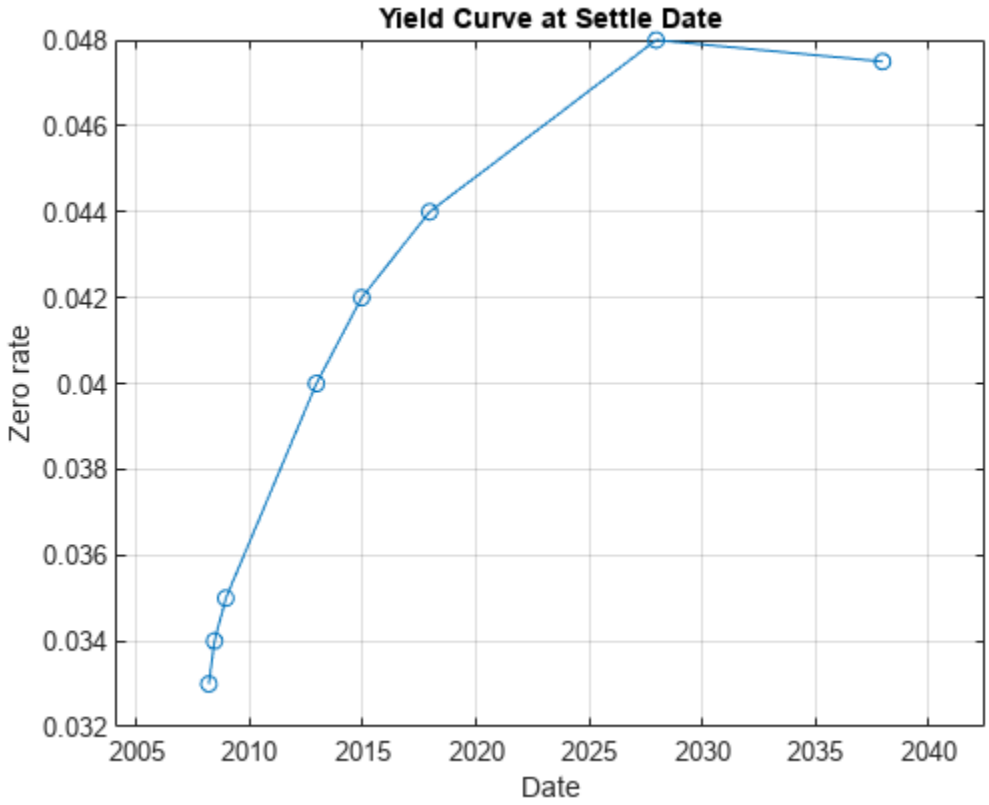
Create RateSpec from the Interest-Rate Curve

```
Settle = datenum('14-Dec-2007');

Tenor = [3 6 12 5*12 7*12 10*12 20*12 30*12]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';

ZeroDates = datemnth(Settle,Tenor);
Compounding = 2;
Basis = 0;
RateSpec = intenvset('StartDates', Settle,'EndDates', ZeroDates, ...
    'Rates', ZeroRates,'Compounding',Compounding,'Basis',Basis);

figure;
plot(ZeroDates, ZeroRates, 'o-');
xlabel('Date');
datetick('keeplimits');
ylabel('Zero rate');
grid on;
title('Yield Curve at Settle Date');
```



Set Changeable Simulation Parameters

You can vary the number of simulated interest-rate scenarios that you generate. This example sets the simulation dates to be more frequent at first, then turning less frequent further in the future.

```
% Number of Monte Carlo simulations
numScenarios = 1000;
```

```
% Compute monthly simulation dates, then quarterly dates later.
simulationDates = datemnth(Settle,0:12);
simulationDates = [simulationDates datemnth(simulationDates(end),3:3:74)]';
numDates = numel(simulationDates);
```

Compute Floating Reset Dates

For each simulation date, compute previous floating reset date for each swap.

```
floatDates = cfdates(Settle-360,swaps.Maturity,swaps.Period);
swaps.FloatingResetDates = zeros(numSwaps,numDates);
for i = numDates:-1:1
    thisDate = simulationDates(i);
    floatDates(floatDates > thisDate) = 0;
    swaps.FloatingResetDates(:,i) = max(floatDates,[],2);
end
```

Setup Hull-White Single Factor Model

The risk factor that is simulated to value the contracts is the zero curve. For this example, you model the interest-rate term structure using the one-factor Hull-White model. This is a model of the short rate and is defined as:

$$dr = [\theta(t) - ar]dt + \sigma dz$$

where

- dr: Change in the short rate after a small change in time, dt
- a: Mean reversion rate
- σ: Volatility of the short rate
- dz: A Weiner process (a standard normal process)
- $\theta(t)$: Drift function defined as:

$$\theta(t) = F_t(0,t) + aF(0,t) + \frac{\sigma^2}{2a}(1 - e^{-2at})$$

$F(0,t)$: Instantaneous forward rate at time t

$F_t(0,t)$: Partial derivative of F with respect to time

Once you have simulated a path of the short rate, generate a full yield curve at each simulation date using the formula:

$$R(t,T) = -\frac{1}{(T-t)}\ln A(t,T) + \frac{1}{(T-t)}B(t,T)r(t)$$

$$\ln A(t,T) = \ln\frac{P(0,T)}{P(0,t)} + B(t,T)F(0,t) - \frac{1}{4a^3}\sigma^2(e^{-aT} - e^{-at})^2(e^{2at} - 1)$$

$$B(t,T) = \frac{1 - e^{-a(T-t)}}{a}$$

$R(t,T)$: Zero rate at time t for a period of $T - t$

$P(t,T)$: Price of a zero coupon bond at time t that pays one dollar at time T

Each scenario contains the full term structure moving forward through time, modeled at each of our selected simulation dates.

Refer to the “Calibrating Hull-White Model Using Market Data” on page 2-92 example in the Financial Instruments Toolbox™ Users' Guide for more details on Hull-White one-factor model calibration.

```
Alpha = 0.2;
Sigma = 0.015;

hw1 = HullWhite1F(RateSpec,Alpha,Sigma);
```

Simulate Scenarios

For each scenario, simulate the future interest-rate curve at each valuation date using the Hull-White one-factor interest-rate model.

```
% Use reproducible random number generator (vary the seed to produce
% different random scenarios).
prevRNG = rng(0, 'twister');

dt = diff(yearfrac(Settle,simulationDates,1));
nPeriods = numel(dt);
scenarios = hw1.simTermStructs(nPeriods, ...
    'nTrials',numScenarios, ...
    'deltaTime',dt);

% Restore random number generator state
rng(prevRNG);

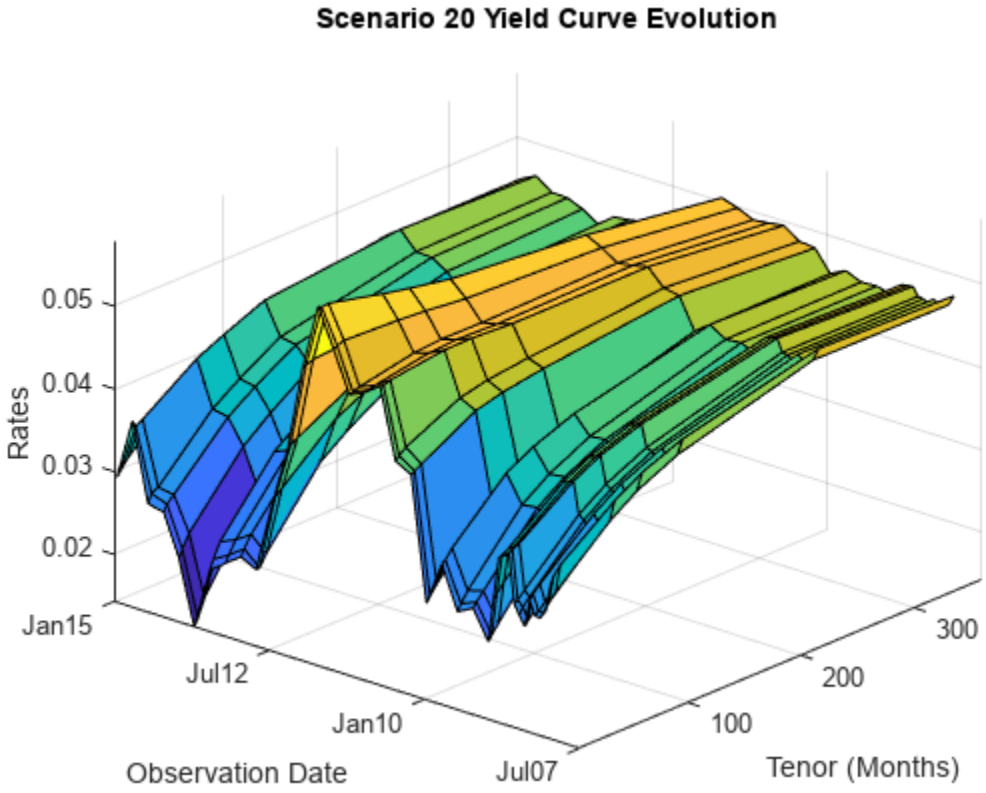
% Compute the discount factors through each realized interest rate
% scenario.
dfactors = ones(numDates,numScenarios);
for i = 2:numDates
    tenorDates = datemnth(simulationDates(i-1),Tenor);
    rateAtNextSimDate = interp1(tenorDates,squeeze(scenarios(i-1,:,:)), ...
        simulationDates(i),'linear','extrap');
    % Compute D(t1,t2)
    dfactors(i,:) = zero2disc(rateAtNextSimDate, ...
        repmat(simulationDates(i),1,numScenarios),simulationDates(i-1),-1,3);
end
dfactors = cumprod(dfactors,1);
```

Inspect a Scenario

Create a surface plot of the yield curve evolution for a particular scenario.

```
i = 20;
figure;
surf(Tenor, simulationDates, scenarios(:,:,i))
axis tight
datetick('y','mmmyy');
xlabel('Tenor (Months)');
ylabel('Observation Date');
zlabel('Rates');
ax = gca;
```

```
ax.View = [-49 32];
title(sprintf('Scenario %d Yield Curve Evolution\n',i));
```



Compute Mark to Market Swap Prices

For each scenario the swap portfolio is priced at each future simulation date. Prices are computed using a price approximation function, `hswapapprox`. It is common in CVA applications to use simplified approximation functions when pricing contracts due to the performance requirements of these Monte Carlo simulations.

Since the simulation dates do not correspond to the swaps cash flow dates (where the floating rates are reset) estimate the latest floating rate with the 1-year rate (all swaps have period 1 year) interpolated between the nearest simulated rate curves.

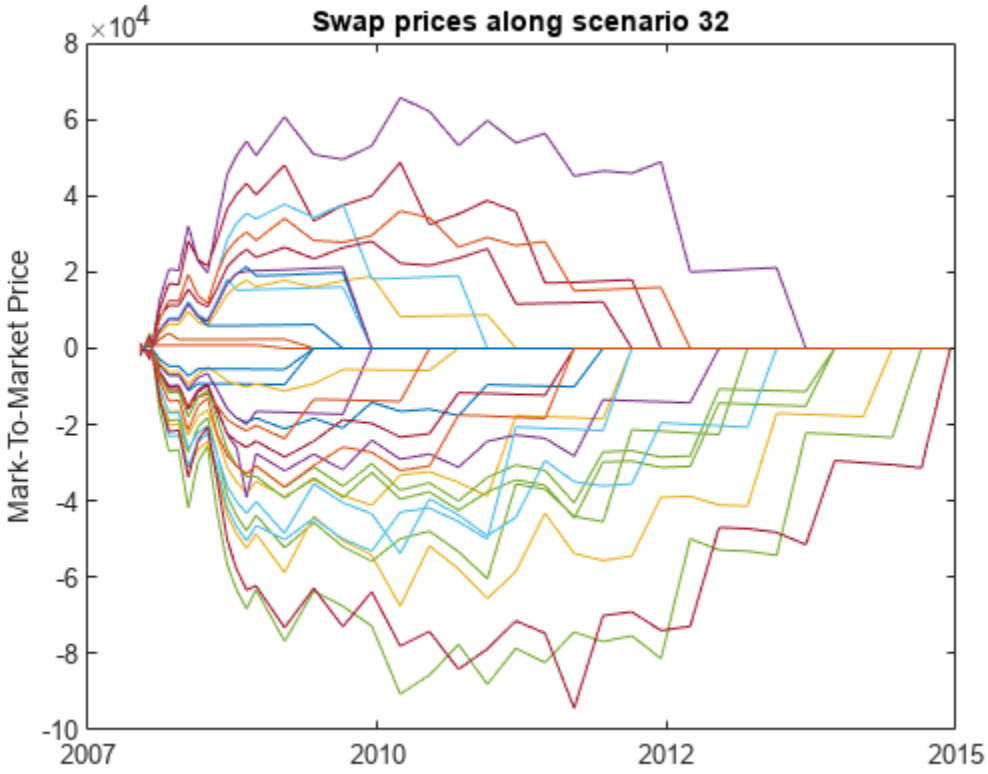
The swap prices are then aggregated into a "cube" of values which contains all future contract values at each simulation date for each scenario. The resulting cube of contract prices is a 3-dimensional matrix where each row represents a simulation date, each column a contract, and each "page" a different simulated scenario.

```
% Compute all mark-to-market values for this scenario. Use an
% approximation function here to improve performance.
values = hcomputeMTMValues(swaps,simulationDates,scenarios,Tenor);
```

Inspect Scenario Prices

Create a plot of the evolution of all swap prices for a particular scenario.

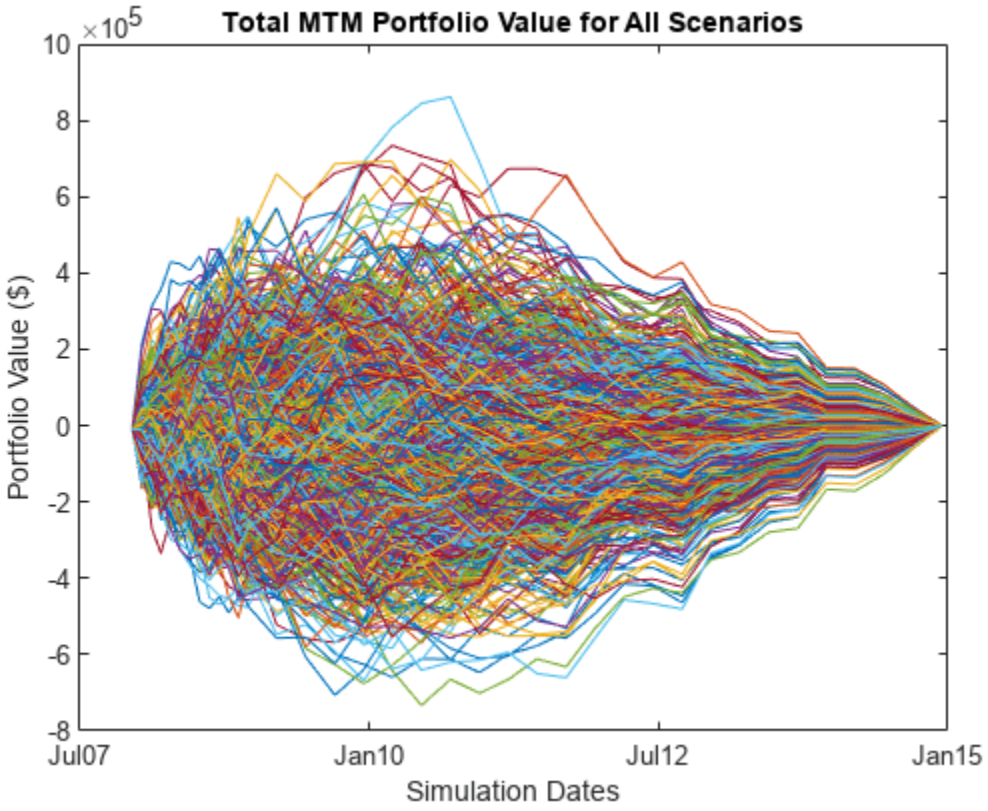
```
i = 32;
figure;
plot(simulationDates, values(:,:,i));
datetick;
ylabel('Mark-To-Market Price');
title(sprintf('Swap prices along scenario %d', i));
```



Visualize Simulated Portfolio Values

Plot the total portfolio value for each scenario of the simulation. As each scenario moves forward in time, the values of the contracts move up or down depending on how the modeled interest-rate term structure changes. As the swaps get closer to maturity, their values will begin to approach zero since the aggregate value of all remaining cash flows will decrease after each cash flow date.

```
% View portfolio value over time
figure;
totalPortValues = squeeze(sum(values, 2));
plot(simulationDates,totalPortValues);
title('Total MTM Portfolio Value for All Scenarios');
datetick('x','mmmyy')
ylabel('Portfolio Value ($)')
xlabel('Simulation Dates')
```



Compute Exposure by Counterparty

The exposure of a particular contract (i) at time t is the maximum of the contract value (Vi) and `0`:

$$E_i(t) = \max\{V_i(t), 0\}$$

And the exposure for a particular counterparty is simply a sum of the individual contract exposures:

$$E_{cp}(t) = \sum E_i(t) = \sum \max\{V_i(t), 0\}$$

In the presence of netting agreements, however, contracts are aggregated together and can offset each other. Therefore the total exposure of all contracts in a netting agreement is:

$$E_{na}(t) = \max\{\sum V_i(t), 0\}$$

Compute these exposures for the entire portfolio as well as each counterparty at each simulation date using the `creditexposures` function.

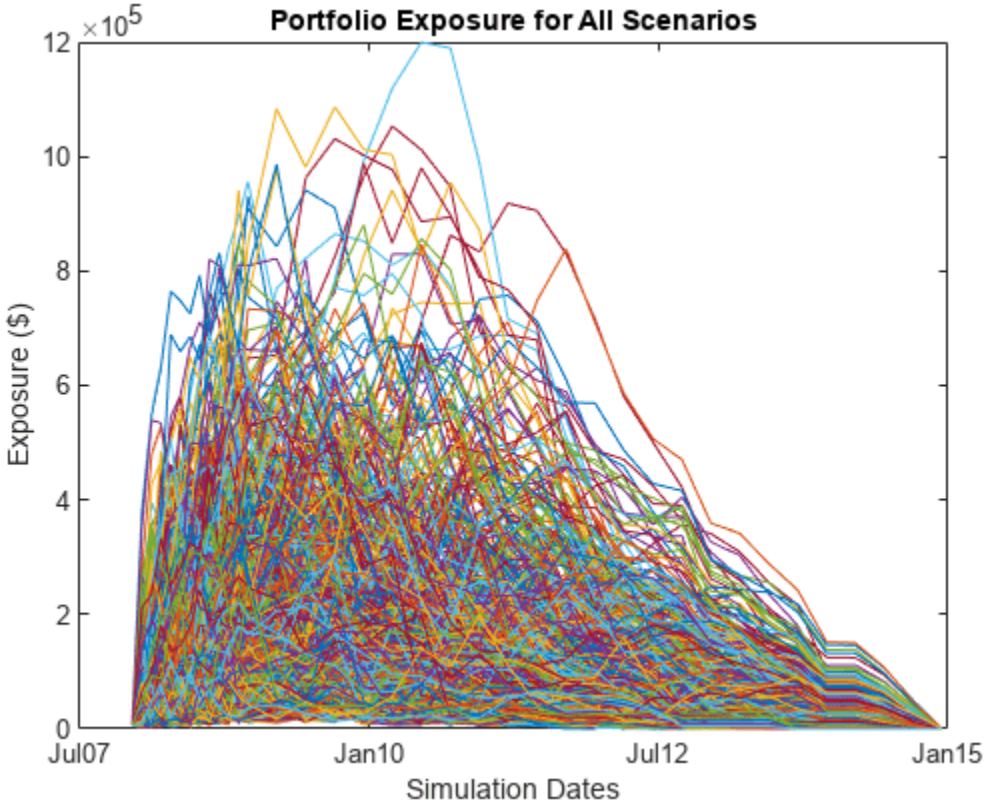
Unnetted contracts are indicated using a `NaN` in the `NettingID` vector. Exposure of an unnetted contract is equal to the market value of the contract if it has positive value, otherwise it is zero.

Contracts included in a netting agreement have their values aggregated together and can offset each other. See the references for more details on computing exposure from mark-to-market contract values.

```
[exposures, expcpty] = creditexposures(values,swaps.CounterpartyID, ...
    'NettingID',swaps.NettingID);
```

Plot the total portfolio exposure for each scenario in our simulation. Similar to the plot of contract values, the exposures for each scenario will approach zero as the swaps mature.

```
% View portfolio exposure over time
figure;
totalPortExposure = squeeze(sum(exposures,2));
plot(simulationDates,totalPortExposure);
title('Portfolio Exposure for All Scenarios');
datetick('x','mmmyy')
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Exposure Profiles

Several exposure profiles are useful when analyzing the potential future exposure of a bank to a counterparty. Here you can compute several (non-discounted) exposure profiles per counterparty, as well as, for the entire portfolio.

- `PFE` (Potential Future Exposure): A high percentile (95%) of the distribution of exposures at any particular future date (also called Peak Exposure (PE))
- `MPFE` (Maximum Potential Future Exposure): The maximum PFE across all dates
- `EE` : (Expected Exposure): The mean (average) of the distribution of exposures at each date

- `EPE` (Expected Positive Exposure): Weighted average over time of the expected exposure
- `EffEE` (Effective Expected Exposure): The maximum expected exposure at any time, *t*, or previous time
- `EffEPE` (Effective Expected Positive Exposure): The weighted average of the effective expected exposure

For further definitions, see for example the Basel II document in references.

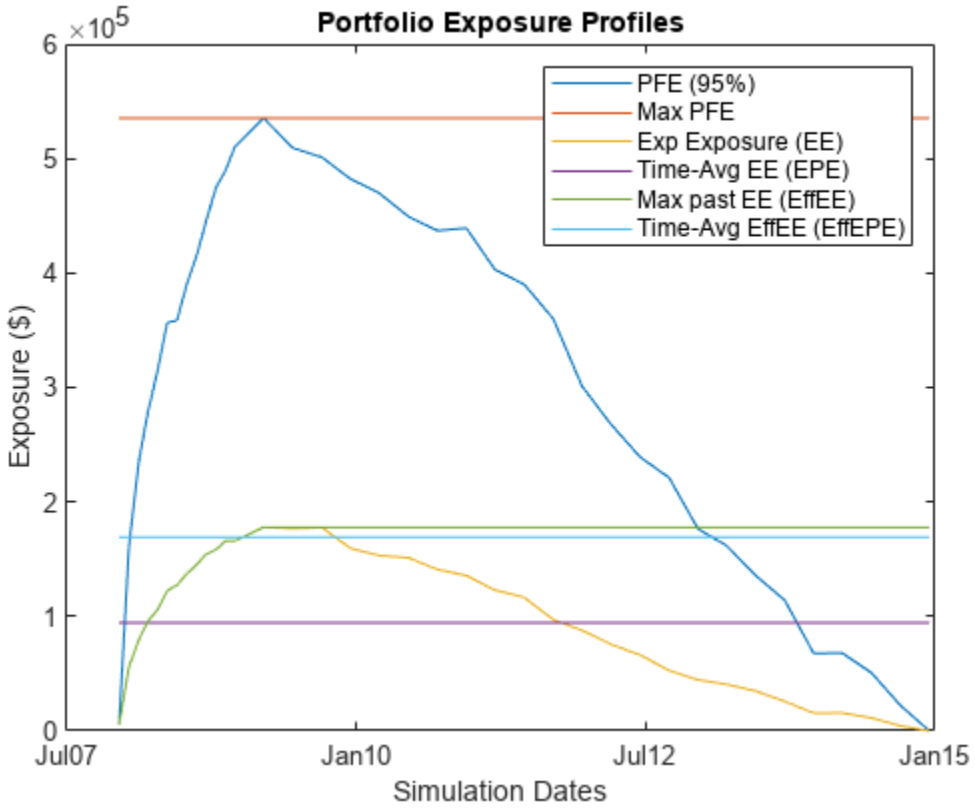
```
% Compute entire portfolio exposure
portExposures = sum(exposures,2);

% Compute exposure profiles for each counterparty and entire portfolio
cpProfiles = exposureprofiles(simulationDates,exposures);
portProfiles = exposureprofiles(simulationDates,portExposures);
```

Visualize the exposure profiles, first for the entire portfolio, then for a particular counterparty.

```
% Visualize portfolio exposure profiles
figure;
plot(simulationDates,portProfiles.PFE, ...
    simulationDates,portProfiles.MPFE * ones(numDates,1), ...
    simulationDates,portProfiles.EE, ...
    simulationDates,portProfiles.EPE * ones(numDates,1), ...
    simulationDates,portProfiles.EffEE, ...
    simulationDates,portProfiles.EffEPE * ones(numDates,1));
legend({'PFE (95%)','Max PFE','Exp Exposure (EE)','Time-Avg EE (EPE)', ...
    'Max past EE (EffEE)','Time-Avg EffEE (EffEPE)'})

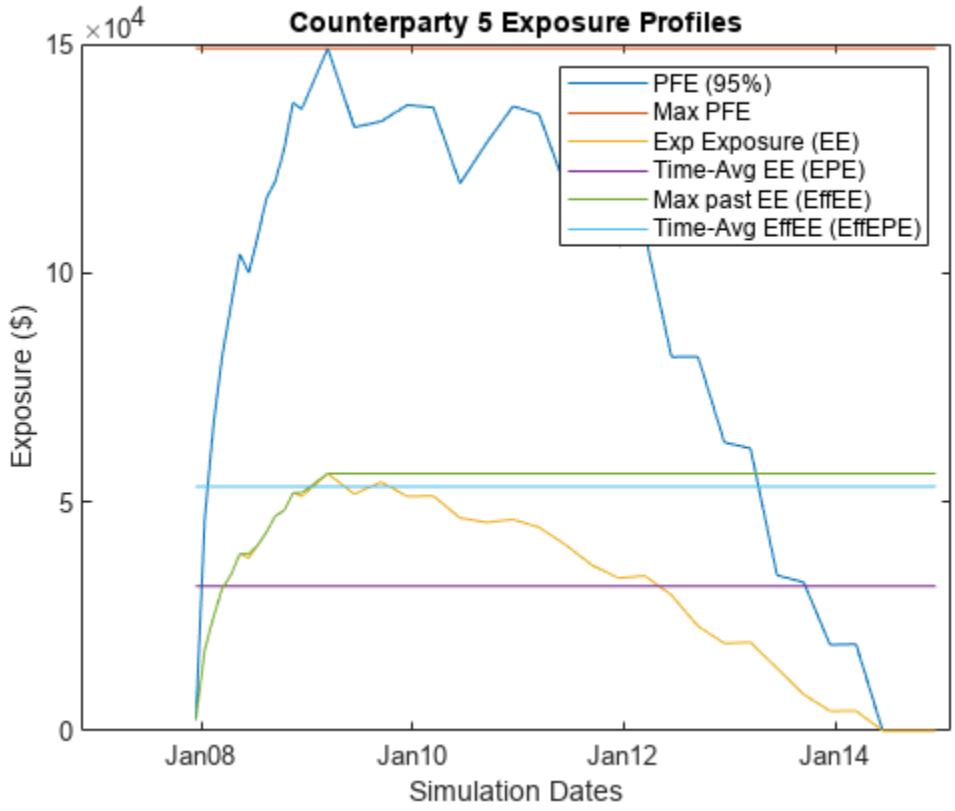
datetick('x','mmmyy')
title('Portfolio Exposure Profiles');
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Visualize exposure profiles for a particular counterparty.

```
cpIdx = find(expcpty == 5);
figure;
plot(simulationDates,cpProfiles(cpIdx).PFE, ...
    simulationDates,cpProfiles(cpIdx).MPFE * ones(numDates,1), ...
    simulationDates,cpProfiles(cpIdx).EE, ...
    simulationDates,cpProfiles(cpIdx).EPE * ones(numDates,1), ...
    simulationDates,cpProfiles(cpIdx).EffEE, ...
    simulationDates,cpProfiles(cpIdx).EffEPE * ones(numDates,1));
legend({'PFE (95%)','Max PFE','Exp Exposure (EE)','Time-Avg EE (EPE)', ...
    'Max past EE (EffEE)','Time-Avg EffEE (EffEPE)'})

datetick('x','mmmyy','keeplimits')
title(sprintf('Counterparty %d Exposure Profiles',cpIdx));
ylabel('Exposure ($)')
xlabel('Simulation Dates')
```



Discounted Exposures

Compute the discounted expected exposures using the discount factors from each simulated interest-rate scenario. The discount factor for a given valuation date in a given scenario is the product of the incremental discount factors from one simulation date to the next, along with the interest-rate path of that scenario.

```
% Get discounted exposures per counterparty, for each scenario
discExp = zeros(size(exposures));
for i = 1:numScenarios
    discExp(:,:,i) = bsxfun(@times,dfactors(:,i),exposures(:,:,i));
end

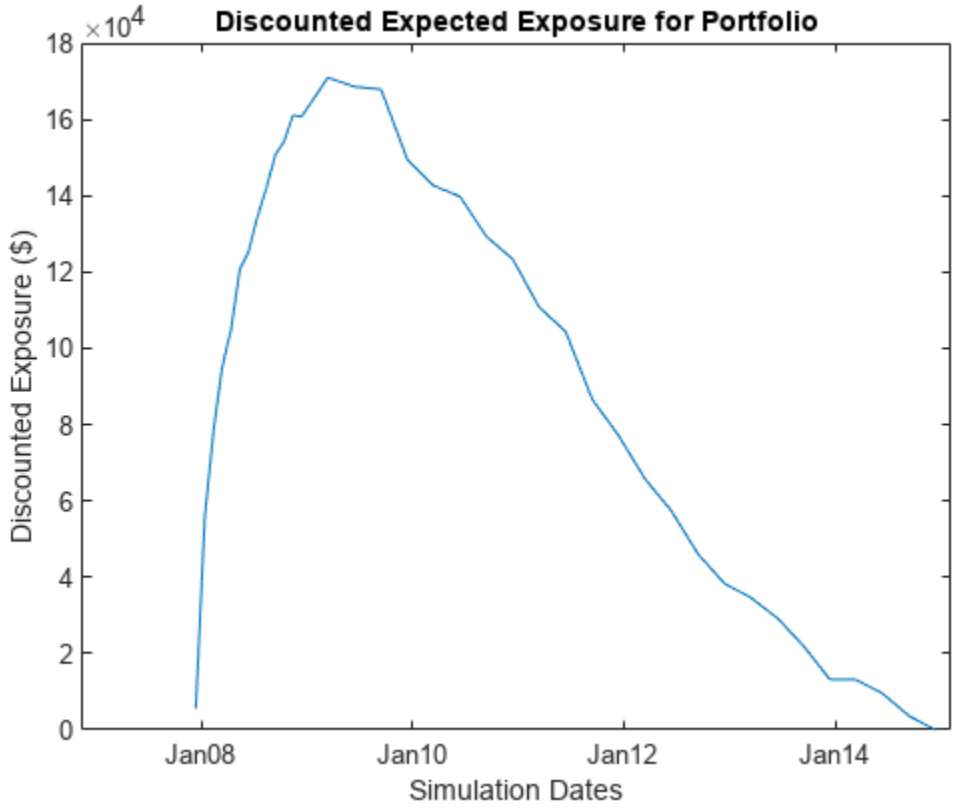
% Discounted expected exposure
discProfiles = exposureprofiles(simulationDates,discExp, ...
    'ProfileSpec','EE');
```

Plot the discounted expected exposures for the aggregate portfolio as well as for each counterparty.

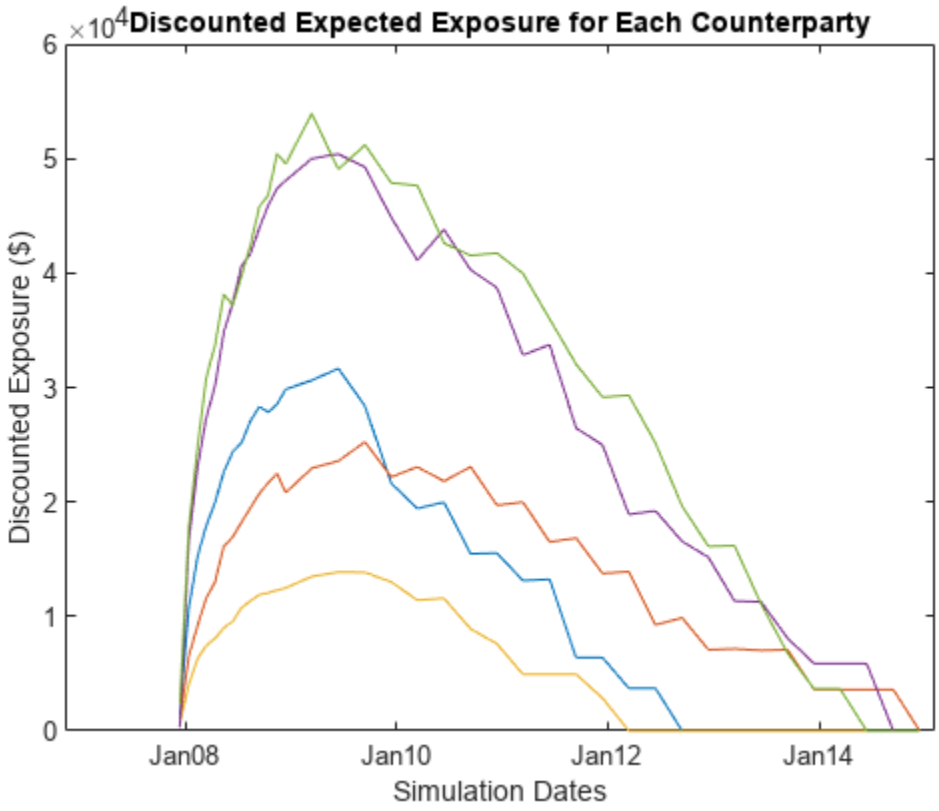
```
% Aggregate the discounted EE for each counterparty into a matrix
discEE = [discProfiles.EE];

% Portfolio discounted EE
figure;
plot(simulationDates,sum(discEE,2))
datetick('x','mmmyy','keeplimits')
title('Discounted Expected Exposure for Portfolio');
```

```
ylabel('Discounted Exposure ($)')
xlabel('Simulation Dates')
```



```
% Counterparty discounted EE
figure;
plot(simulationDates,discEE)
datetick('x','mmmyy','keeplimits')
title('Discounted Expected Exposure for Each Counterparty');
ylabel('Discounted Exposure ($)')
xlabel('Simulation Dates')
```



Calibrating Probability of Default Curve for Each Counterparty

The default probability for a given counterparty is implied by the current market spreads of the counterparty's CDS. Use the function `cdsbootstrap` to generate the cumulative probability of default at each simulation date.

```
% Import CDS market information for each counterparty
CDS = readtable(swapFile,'Sheet','CDS Spreads');
disp(CDS);
```

Date	cp1	cp2	cp3	cp4	cp5
{'3/20/2008'}	140	85	115	170	140
{'3/20/2009'}	185	120	150	205	175
{'3/20/2010'}	215	170	195	245	210
{'3/20/2011'}	275	215	240	285	265
{'3/20/2012'}	340	255	290	320	310

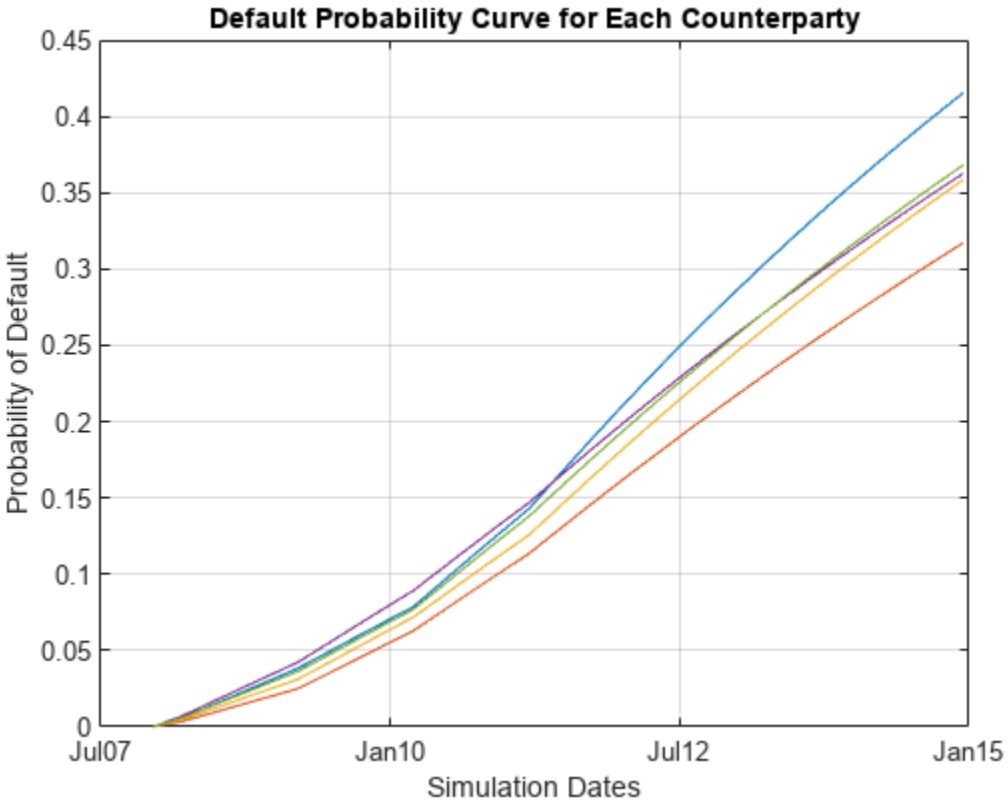
```
CDSDates = datenum(CDS.Date);
CDSSpreads = table2array(CDS(:,2:end));

ZeroData = [RateSpec.EndDates RateSpec.Rates];

% Calibrate default probabilities for each counterparty
DefProb = zeros(length(simulationDates), size(CDSSpreads,2));
for i = 1:size(DefProb,2)
    probData = cdsbootstrap(ZeroData, [CDSDates CDSSpreads(:,i)], ...
```

```
        Settle, 'probDates', simulationDates);
    DefProb(:,i) = probData(:,2);
end

% Plot of the cumulative probability of default for each counterparty.
figure;
plot(simulationDates,DefProb)
title('Default Probability Curve for Each Counterparty');
xlabel('Date');
grid on;
ylabel('Cumulative Probability')
datetick('x','mmmyy')
ylabel('Probability of Default')
xlabel('Simulation Dates')
```



CVA Computation

The Credit Value (Valuation) Adjustment (CVA) formula is:

$$CVA = (1 - R)\int_0^T discEE(t)dPD(t)$$

Where `R` is the recovery, `discEE` the discounted expected exposure at time t, and `PD` the default probability distribution. This assumes the exposure is independent of default (no wrong-way risk), and it also assumes that the exposures were obtained using risk-neutral probabilities.

Approximate the integral with a finite sum over the valuation dates as:

$$CVA(approx) = (1 - R) \sum_{i=2}^{n} discEE(t_i)(PD(t_i) - PD(t_{i-1}))$$

where `t_1` is today's date, `t_2`, ...,`t_`*n* the future valuation dates.

Assume that the CDS information corresponds to the counterparty with index `cpIdx`. The computed CVA is the present market value of our credit exposure to counterparty `cpIdx`. For this example, set the recovery rate at 40%.

```
Recovery = 0.4;
CVA = (1-Recovery) * sum(discEE(2:end,:) .* diff(DefProb));
for i = 1:numel(CVA)
    fprintf('CVA for counterparty %d = $%.2f\n',i,CVA(i));
end
```

```
CVA for counterparty 1 = $2229.38
CVA for counterparty 2 = $2498.71
CVA for counterparty 3 = $918.96
CVA for counterparty 4 = $5521.83
CVA for counterparty 5 = $5883.77
```

```
figure;
bar(CVA);
title('CVA for each counterparty');
xlabel('Counterparty');
ylabel('CVA $');
grid on;
```

First-to-Default Swaps

This example shows how to price first-to-default (FTD) swaps under the homogeneous loss assumption.

A first-to-default swap is an instrument that pays a predetermined amount when (and if) the first of a basket of credit instruments defaults. The credit instruments in the basket are usually bonds. If you assume that the loss amount following a credit event is the same for all credits in the basket, you are under the *homogeneous loss* assumption. This assumption makes models simpler because any default in the basket triggers the same payment amount. This example is an implementation of the pricing methodology for these instruments, as described in O'Kane [2 on page 8-26]. There are two steps in the methodology:

- Compute the survival probability for the basket numerically.
- Use this survival curve and standard single-name credit-default swap (CDS) functionality to find FTD spreads and to price existing FTD swaps.

Fit Probability Curves to Market Data

Given CDS market quotes for each issuer in the basket, use `cdsbootstrap` to calibrate individual default probability curves for each issuer.

```
% Interest-rate curve
ZeroDates = datenum({'17-Jan-10','17-Jul-10','17-Jul-11','17-Jul-12',...
'17-Jul-13','17-Jul-14'});
ZeroRates = [1.35 1.43 1.9 2.47 2.936 3.311]'/100;
ZeroData = [ZeroDates ZeroRates];

% CDS spreads
% Each row in MarketSpreads corresponds to a different issuer; each
% column to a different maturity date (corresponding to MarketDates)
MarketDates = datenum({'20-Sep-10','20-Sep-11','20-Sep-12','20-Sep-14',...
'20-Sep-16'});
MarketSpreads = [
   160 195 230 285 330;
   130 165 205 260 305;
   150 180 210 260 300;
   165 200 225 275 295];
% Number of issuers equals number of rows in MarketSpreads
nIssuers = size(MarketSpreads,1);

% Settlement date
Settle = datenum('17-Jul-2009');
```

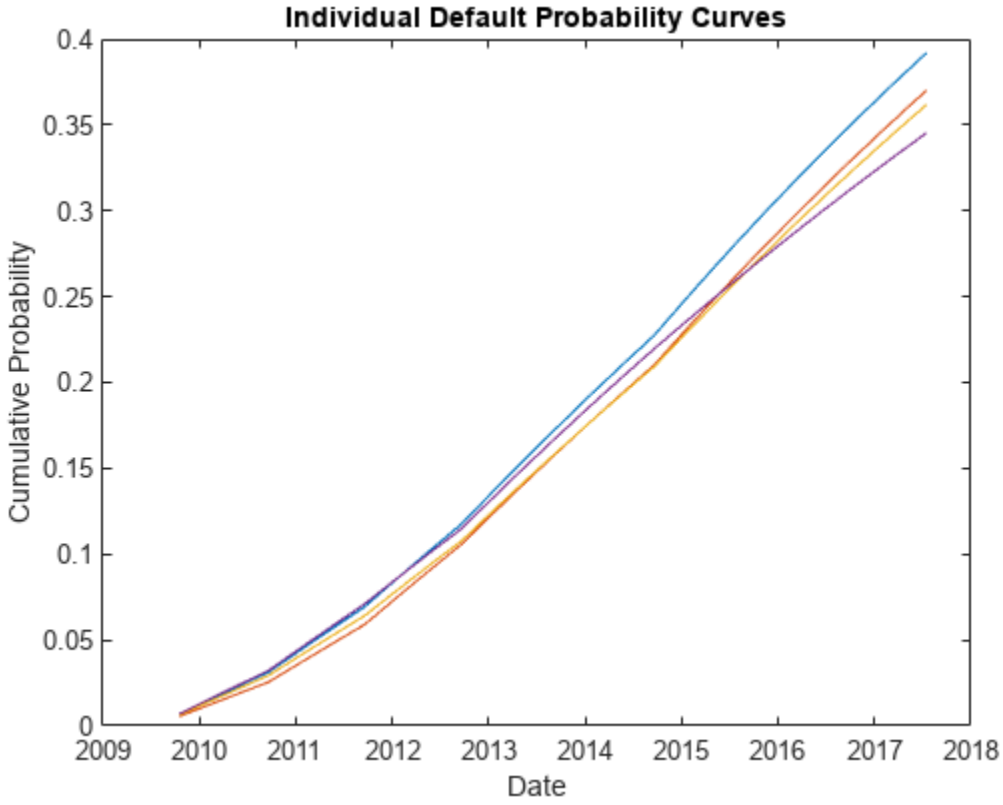
In practice, the time axis is discretized and the FTD survival curve is only evaluated at grid points. This example uses one point every three months. To request that `cdsbootstrap` returns default probability values over the specific grid points that you want, use the optional argument `'ProbDates'`. Add the original standard CDS market dates to the grid, otherwise the default probability information on those dates is interpolated using the two closest dates on the grid, and then the prices on market dates will be inconsistent with the original market data.

```
ProbDates = union(MarketDates,daysadd(Settle,360*(0.25:0.25:8),1));
nProbDates = length(ProbDates);
DefProb = zeros(nIssuers,nProbDates);
```

```
for ii = 1:nIssuers
   MarketData = [MarketDates MarketSpreads(ii,:)'];
   ProbData = cdsbootstrap(ZeroData,MarketData,Settle,...
      'ProbDates',ProbDates);
   DefProb(ii,:) = ProbData(:,2)';
end
```

Here are the calibrated default probability curves for each credit in the basket.

```
figure
plot(ProbDates',DefProb)
datetick
title('Individual Default Probability Curves')
ylabel('Cumulative Probability')
xlabel('Date')
```



Determine Latent Variable Thresholds

Latent variables are used in different credit risk contexts, with different interpretations. In some contexts, a latent variable is a proxy for a *change in the value of assets*, and the domain of this variable is binned, with each bin corresponding to a credit rating. The bins limits, or thresholds, are determined from credit migration matrices. In our context, the latent variable is associated to a *time to default*, and the thresholds determine bins in a discretized time grid where defaults may occur.

Formally, if the time to default of a particular issuer is denoted by τ, and we know its default probability function $P(t)$, a latent variable A and corresponding thresholds $C(t)$ satisfy

$$Pr(\tau \le t) = P(t) = Pr(A \le C(t))$$

or

$$Pr(s \le \tau \le t) = P(t) - P(s) = Pr(C(s) \le A \le C(t))$$

These relationships make latent variable approaches convenient for both simulations and analytical derivations. Both $P(t)$ and $C(t)$ are functions of time.

The choice of a distribution for the variable A determines the thresholds $C(t)$. In the standard latent variable model, the variable A is chosen to follow a standard normal distribution, from which

$$C(t) = \Phi^{-1}(P(t))$$

where Φ is the cumulative standard normal distribution.

Use the previous formula to determine the *default-time thresholds*, or simply *default thresholds*, corresponding to the default probabilities previously obtained for the credits in the basket.

```
DefThresh = norminv(DefProb);
```

Derive Survival Curve for the Basket

Following O'Kane [2 on page 8-26], you can use a one-factor latent variable model to derive expressions for the survival probability function of the basket.

Given parameters β_i for each issuer i, and given independent standard normal variables Z and ϵ_i, the one-factor latent variable model assumes that the latent variable A_i associated to issuer i satisfies

$$A_i = \beta_i * Z + \sqrt{1 - \beta_i^2} * \epsilon_i$$

This induces a correlation between issuers i and j of $\beta_i\beta_j$. All latent variables A_i share the common factor Z as a source of uncertainty, but each latent variable also has an idiosyncratic source of uncertainty ϵ_i. The larger the coefficient β_i, the more the latent variable resembles the common factor Z.

Using the latent variable model, you can derive an analytic formula for the survival probability of the basket. The probability that issuer i survives past time t_j, in other words, that its default time τ_i is greater than t_j is

$$Pr(\tau_i > t_j) = 1 - Pr(A_i \le C_i(t_j))$$

where $C_i(t_j)$ is the default threshold computed above for issuer i, for the j-th date in the discretization grid. Conditional on the value of the one-factor Z, the probability that all issuers survive past time t_j is

$$\begin{aligned} &Pr(\text{No defaults by time } t_j | Z) \\ &= Pr(\tau_i > t_j \text{ for all } i | Z) \\ &= \prod_i [1 - Pr(A_i \le C_i(t_j) | Z)] \end{aligned}$$

where the product is justified because all the ϵ_i's are independent. Therefore, conditional on Z, the A_i's are independent. The unconditional probability of no defaults by time t_j is the integral over all values of Z of the previous conditional probability

$$Pr(\text{No defaults by time } t_j) = \int_Z \prod_i [1 - Pr(A_i \le C_i(t_j) \mid Z)]\phi(Z)dZ$$

with $\phi(Z)$ the standard normal density.

By evaluating this one-dimensional integral for each point t_j in the grid, you get a discretization of the survival curve for the whole basket, which is the FTD survival curve.

The latent variable model can also be used to simulate default times, which is the back engine of many pricing methodologies for credit instruments. Loeffler and Posch [1 on page 8-26], for example, estimate the survival probability of a basket via simulation. In each simulated scenario a time to default is determined for each issuer. With some bookkeeping, the probability of having the first default on each bucket of the grid can be estimated from the simulation. The simulation approach is also discussed in O'Kane [2 on page 8-26]. Simulation is very flexible and applicable to many credit instruments. However, analytic approaches are preferred, when available, because they are much faster and more accurate than simulation.

To compute the FTD survival probabilities in this example, set all betas to the square root of a target correlation. Then you can loop over all dates in the time grid to compute the one-dimensional integral that gives the survival probability of the basket.

Regarding implementation, the conditional survival probability as a function of a scalar Z would be

```
condProb=@(Z)prod(normcdf((-DefThresh(:,jj)+beta*Z)./sqrt(1-beta.^2)));
```

However, the integration function requires that the function handle of the integrand accepts vectors. Although a loop around the scalar version of the conditional probability would work, it is far more efficient to vectorize the conditional probability using `bsxfun`.

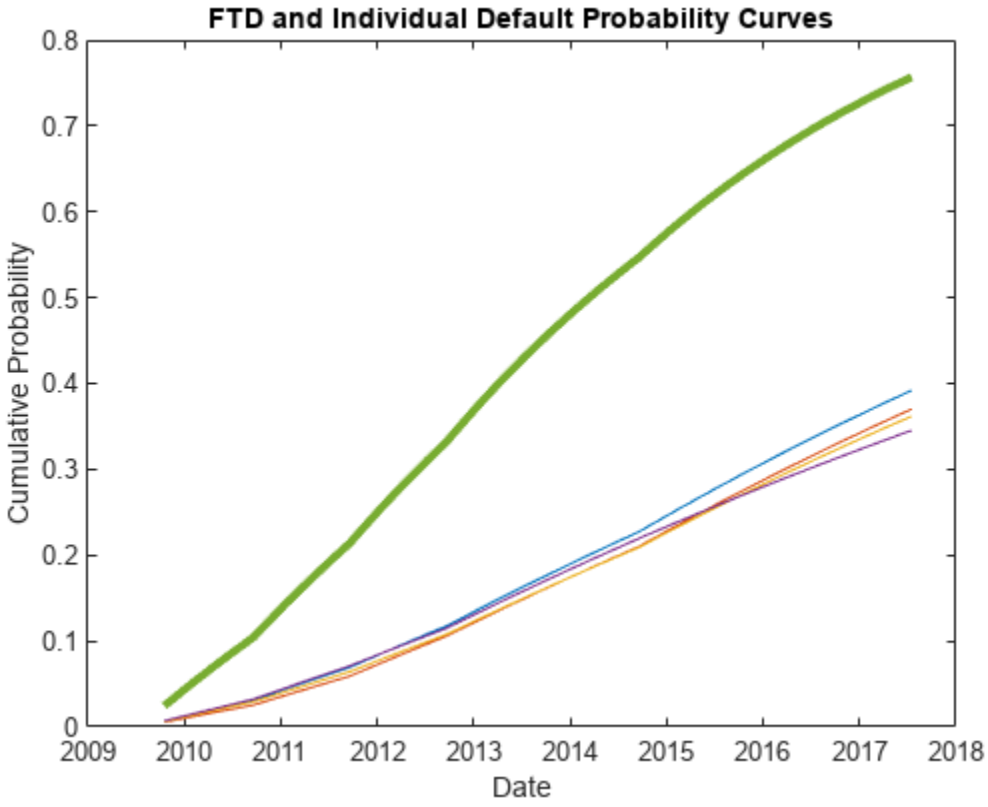
```
beta = sqrt(0.25)*ones(nIssuers,1);

FTDSurvProb = zeros(size(ProbDates));
for jj = 1:nProbDates
   % Vectorized conditional probability as a function of Z
   vecCondProb = @(Z)prod(normcdf(bsxfun(@rdivide,...
      -repmat(DefThresh(:,jj),1,length(Z))+bsxfun(@times,beta,Z),...
      sqrt(1-beta.^2))));
   % Truncate domain of normal distribution to [-5,5] interval
   FTDSurvProb(jj) = integral(@(Z)vecCondProb(Z).*normpdf(Z),-5,5);
end
FTDDefProb = 1-FTDSurvProb;
```

Compare the FTD probability to the default probabilities of the individual issuers.

```
figure
plot(ProbDates',DefProb)
datetick
hold on
plot(ProbDates,FTDDefProb,'LineWidth',3)
datetick
```

```
hold off
title('FTD and Individual Default Probability Curves')
ylabel('Cumulative Probability')
xlabel('Date')
```



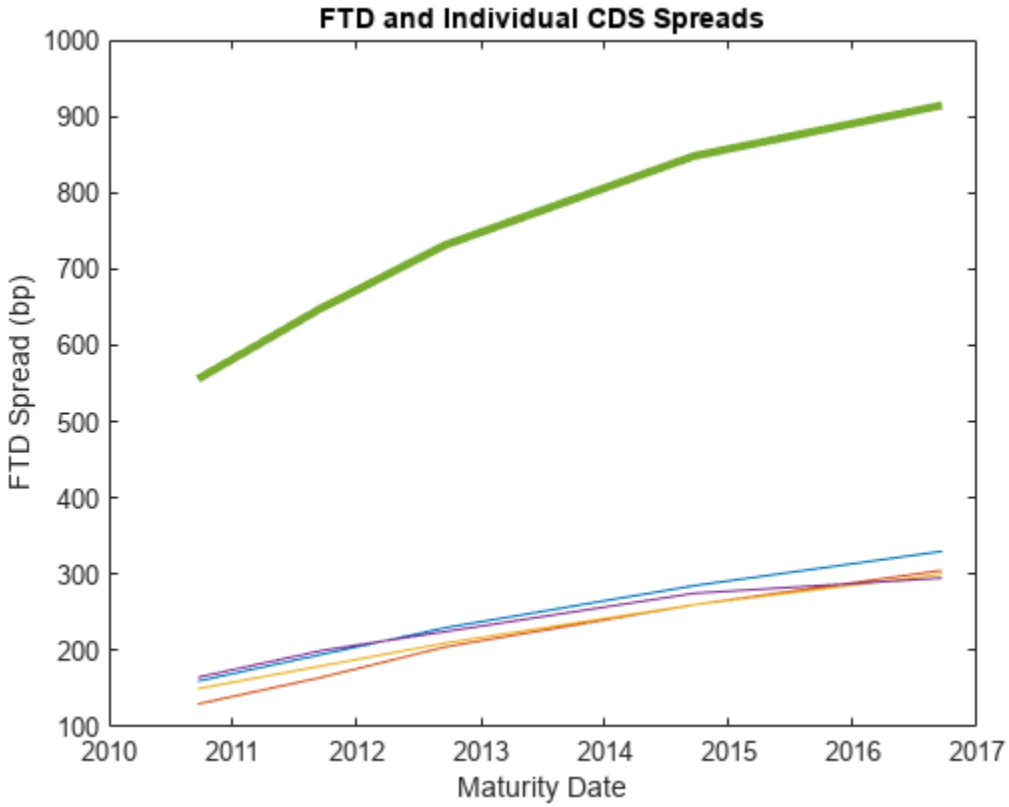
Find FTD Spreads and Price Existing FTD Swaps

Under the assumption that all instruments in the basket have the same recovery rate, or homogeneous loss assumption (see O'Kane [2 on page 8-26]), you get the spread for the FTD swap using the `cdsspread` function by passing the FTD probability data just computed.

```
Maturity = MarketDates;
ProbDataFTD = [ProbDates, FTDDefProb];
FTDSpread = cdsspread(ZeroData,ProbDataFTD,Settle,Maturity);
```

Compare the FTD spreads with the individual spreads.

```
figure
plot(MarketDates,MarketSpreads')
datetick
hold on
plot(MarketDates,FTDSpread,'LineWidth',3)
hold off
title('FTD and Individual CDS Spreads')
ylabel('FTD Spread (bp)')
xlabel('Maturity Date')
```



An existing FTD swap can be priced with `cdsprice`, using the same FTD probability.

```
Maturity0 = MarketDates(1); % Assume maturity on nearest market date
Spread0 = 540; % Spread of existing FTD contract
% Assume default values of recovery and notional
FTDPrice = cdsprice(ZeroData,ProbDataFTD,Settle,Maturity0,Spread0);
fprintf('Price of existing FTD contract: %g\n',FTDPrice)
```

```
Price of existing FTD contract: 17644.7
```

Analyze Sensitivity to Correlation

To illustrate the sensitivity of the FTD spreads to model parameters, calculate the market spreads for a range of correlation values.

```
corr = [0 0.01 0.10 0.25 0.5 0.75 0.90 0.99 1];
FTDSpreadByCorr = zeros(length(Maturity),length(corr));
FTDSpreadByCorr(:,1) = sum(MarketSpreads)';
FTDSpreadByCorr(:,end) = max(MarketSpreads)';

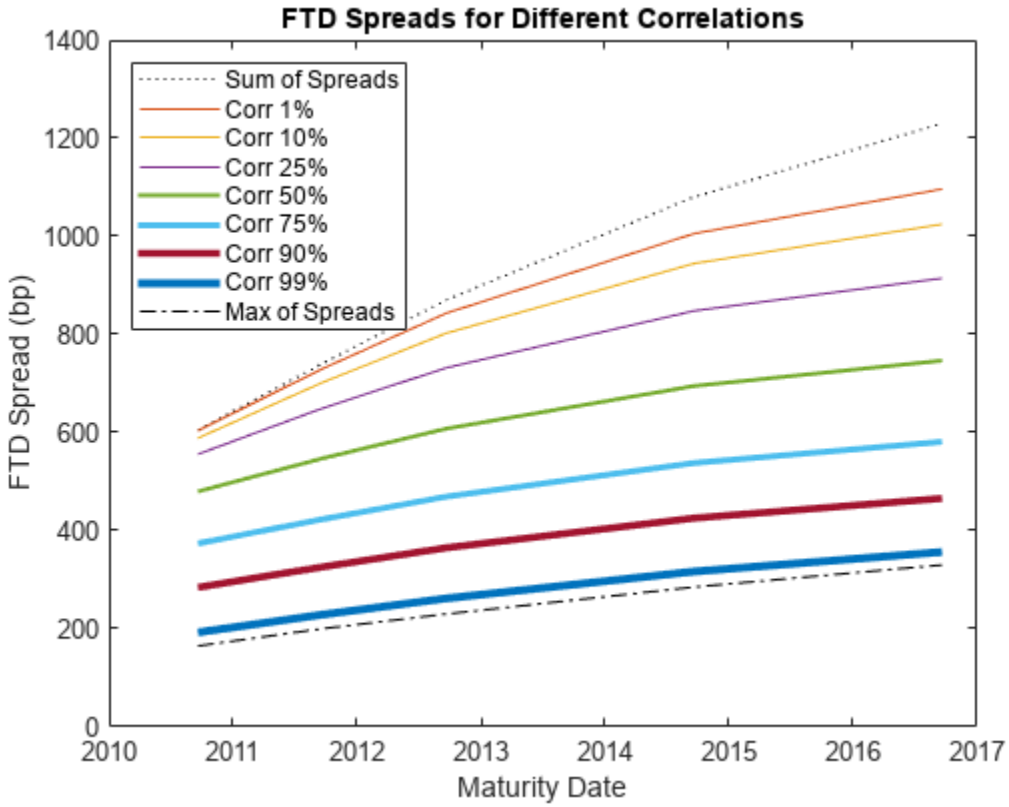
for ii = 2:length(corr)-1
   beta = sqrt(corr(ii))*ones(nIssuers,1);
   FTDSurvProb = zeros(length(ProbDates));
   for jj = 1:nProbDates
      % Vectorized conditional probability as a function of Z
      condProb = @(Z)prod(normcdf(bsxfun(@rdivide,...
         -repmat(DefThresh(:,jj),1,length(Z))+bsxfun(@times,beta,Z),...
         sqrt(1-beta.^2))));
```

```
      % Truncate domain of normal distribution to [-5,5] interval
      FTDSurvProb(jj) = integral(@(Z)condProb(Z).*normpdf(Z),-5,5);
   end
   FTDSurvProb = FTDSurvProb(:,1);
   FTDDefProb = 1-FTDSurvProb;
   ProbDataFTD = [ProbDates, FTDDefProb];
   FTDSpreadByCorr(:,ii) = cdsspread(ZeroData,ProbDataFTD,Settle,Maturity);
end
```

The FTD spreads lie in a band between the sum and the maximum of individual spreads. As the correlation increases to one, the FTD spreads decrease towards the maximum of the individual spreads in the basket (all credits default together). As the correlation decreases to zero, the FTD spreads approach the sum of the individual spreads (independent credits).

```
figure
legends = cell(1,length(corr));
plot(MarketDates,FTDSpreadByCorr(:,1),'k:')
legends{1} = 'Sum of Spreads';
datetick
hold on
for ii = 2:length(corr)-1
   plot(MarketDates,FTDSpreadByCorr(:,ii),'LineWidth',3*corr(ii))
   legends{ii} = ['Corr ' num2str(corr(ii)*100) '%'];
end
plot(MarketDates,FTDSpreadByCorr(:,end),'k-.')
legends{end} = 'Max of Spreads';

hold off
title('FTD Spreads for Different Correlations')
ylabel('FTD Spread (bp)')
xlabel('Maturity Date')
legend(legends,'Location','NW')
```



For short maturities and small correlations, the basket is effectively independent (the FTD spread is very close to the sum of individual spreads). The correlation effect becomes more significant for longer maturities.

Here is an alternative visualization of the dependency of FTD spreads on correlation.

```
figure
surf(corr,MarketDates,FTDSpreadByCorr)
datetick('y')
ax = gca;
ax.YDir = 'reverse';
view(-40,10)
title('FTD Spreads for Different Correlations and Maturities')
xlabel('Correlation')
ylabel('Maturity Date')
zlabel('FTD Spread (bp)')
```

Credit Default Swap Option

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the holder with the right, but not the obligation, to enter into a credit default swap in the future. CDS options can either be payer swaptions or receiver swaptions. If a payer swaption, the option holder has the right to enter into a CDS where they pay premiums; and, if a receiver swaption, the option holder receives premiums. Financial Instruments Toolbox software provides `cdsoptprice` or `CDSOption` for pricing payer and receiver credit default swaptions. Also, with some additional steps, `cdsoptprice` or `CDSOption` can be used for pricing multi-name CDS index options.

Pricing a Single-Name CDS Option

This example shows how to price a single-name CDS option using `cdsoptprice`. The function `cdsoptprice` is based on the Black's model as described in O'Kane (2008). The optional `knockout` argument for `cdsoptprice` supports two variations of the mechanics of a CDS option. CDS options can be knockout or non-knockout options.

- A knockout option cancels with no payments if there is a credit event before the option expiry date.
- A non-knockout option does not cancel if there is a credit event before the option expiry date. In this case, the option holder of a non-knockout payer swaption can take delivery of the underlying long protection CDS on the option expiry date and exercise the protection, delivering a defaulted obligation in return for par. This portion of protection from option initiation to option expiry is known as the front-end protection (FEP). While this distinction does not affect the receiver swaption, the price of a non-knockout payer swaption is obtained by adding the value of the FEP to the knockout payer swaption price.

Define the CDS instrument.

```
Settle = datenum('12-Jun-2012');
OptionMaturity = datenum('20-Sep-2012');
CDSMaturity = datenum('20-Sep-2017');
OptionStrike = 200;
SpreadVolatility = .4;
```

Define the zero rate.

```
Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [.5 .75 1.5 1.7 1.9 2.2]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate]
```

```
ZeroData = 6×2
10^5 ×

    7.3521    0.0000
    7.3540    0.0000
    7.3576    0.0000
    7.3613    0.0000
    7.3649    0.0000
    7.3686    0.0000
```

Define the market data.

```
Market_Time = [1 2 3 5 7 10]';
Market_Rate = [100 120 145 220 245 270]';
Market_Dates = daysadd(Settle,360*Market_Time,1);
MarketData = [Market_Dates Market_Rate];

ProbData = cdsbootstrap(ZeroData, MarketData, Settle)
```

```
ProbData = 6×2
10^5 ×
```

```
    7.3540    0.0000
    7.3576    0.0000
    7.3613    0.0000
    7.3686    0.0000
    7.3759    0.0000
    7.3868    0.0000
```

Define the CDS option.

```
[Payer,Receiver] = cdsoptprice(ZeroData, ProbData, Settle, OptionMaturity, ...
    CDSMaturity, OptionStrike, SpreadVolatility, 'Knockout', true);
fprintf('    Payer: %.0f   Receiver: %.0f  (Knockout)\n',Payer,Receiver);
```

```
    Payer: 196   Receiver: 23  (Knockout)
```

```
[Payer,Receiver] = cdsoptprice(ZeroData, ProbData, Settle, OptionMaturity, ...
    CDSMaturity, OptionStrike, SpreadVolatility, 'Knockout', false);
fprintf('    Payer: %.0f   Receiver: %.0f  (Non-Knockout)\n',Payer,Receiver);
```

```
    Payer: 224   Receiver: 23  (Non-Knockout)
```

Pricing a CDS Index Option

This example shows how to price CDS index options by using `cdsoptprice` with the forward spread adjustment. Unlike a single-name CDS, a CDS portfolio index contains multiple credits. When one or more of the credits default, the corresponding contingent payments are made to the protection buyer but the contract still continues with reduced coupon payments. Considering the fact that the CDS index option does not cancel when some of the underlying credits default before expiry, one might attempt to price CDS index options using the Black's model for non-knockout single-name CDS option. However, Black's model in this form is not appropriate for pricing CDS index options because it does not capture the exercise decision correctly when the strike spread (K) is very high, nor does it ensure put-call parity when (K) is not equal to the contractual spread (O'Kane, 2008).

However, with the appropriate modifications, Black's model for single-name CDS options used in `cdsoptprice` can provide a good approximation for CDS index options. While there are some variations in the way the Black's model is modified for CDS index options, they usually involve adjusting the forward spread F, the strike spread K, or both. Here we describe the approach of adjusting the forward spread only. In the Black's model for single-name CDS options, the forward spread F is defined as:

$$F = S(t, t_E, T) = \frac{S(t,T)RPV01(t,T) - S(t,t_E)RPV01(t,t_E)}{RPV01(t,t_E,T)}$$

where

S is the spread.

RPV01 is the risky present value of a basis point (see `cdsrpv01`).

t is the valuation date.

t_E is the option expiry date.

T is the CDS maturity date.

To capture the exercise decision correctly for CDS index options, we use the knockout form of the Black's model and adjust the forward spread to incorporate the *FEP* as follows:

$$F_{Adj} = F + \frac{FEP}{RPV01(t,t_E,T)}$$

with *FEP* defined as

$$FEP = (1 - R)Z(t,t_E)(1 - Q(t,t_E))$$

where

R is the recovery rate.

Z is the discount factor.

Q is the survival probability.

In `cdsoptprice`, forward spread adjustment can be made with the `AdjustedForwardSpread` parameter. When computing the adjusted forward spread, we can compute the spreads using `cdsspread` and the RPV01s using `cdsrpv01`.

Set up the data for the CDS index, its option, and zero curve. The underlying is a 5-year CDS index maturing on 20-Jun-2017 and the option expires on 20-Jun-2012. A flat index spread is assumed when bootstrapping the default probability curve.

```
% CDS index and option data
Recovery = .4;
Basis = 2;
Period = 4;
CDSMaturity = datenum('20-Jun-2017');
ContractSpread = 100;
IndexSpread = 140;
BusDayConvention = 'follow';
Settle = datenum('13-Apr-2012');
OptionMaturity = datenum('20-Jun-2012');
OptionStrike = 140;
SpreadVolatility = .69;

% Zero curve data
MM_Time = [1 2 3 6]';
MM_Rate = [0.004111 0.00563 0.00757 0.01053]';
MM_Dates = daysadd(Settle,30*MM_Time,1);
Swap_Time = [1 2 3 4 5 6 7 8 9 10 12 15 20 30]';
Swap_Rate = [0.01387 0.01035 0.01145 0.01318 0.01508 0.01700 0.01868 ...
    0.02012 0.02132 0.02237 0.02408 0.02564 0.02612 0.02524]';
Swap_Dates = daysadd(Settle,360*Swap_Time,1);

InstTypes = [repmat({'deposit'},size(MM_Time));repmat({'swap'},size(Swap_Time))];
Instruments = [repmat(Settle,size(InstTypes)) [MM_Dates;Swap_Dates] [MM_Rate;Swap_Rate]];

ZeroCurve = IRDataCurve.bootstrap('zero',Settle,InstTypes,Instruments);

% Bootstrap the default probability curve assuming a flat index spread.
MarketData = [CDSMaturity IndexSpread];
ProbDates = datemnth(OptionMaturity,(0:5*12)');
ProbData = cdsbootstrap(ZeroCurve, MarketData, Settle, 'ProbDates', ProbDates);
```

Compute the spot and forward RPV01s, which will be used later in the computation of the adjusted forward spread. For this purpose, we can use `cdsrpv01`.

```
% RPV01(t,T)
RPV01_CDSMaturity = cdsrpv01(ZeroCurve,ProbData,Settle,CDSMaturity)

% RPV01(t,t_E,T)
RPV01_OptionExpiryForward = cdsrpv01(ZeroCurve,ProbData,Settle,CDSMaturity,...
    'StartDate',OptionMaturity)

% RPV01(t,t_E) = RPV01(t,T) - RPV01(t,t_E,T)
RPV01_OptionExpiry = RPV01_CDSMaturity - RPV01_OptionExpiryForward
```

```
RPV01_CDSMaturity =

    4.7853

RPV01_OptionExpiryForward =

    4.5971

RPV01_OptionExpiry =

    0.1882
```

Compute the spot spreads using `cdsspread`.

```
% S(t,t_E)
Spread_OptionExpiry = cdsspread(ZeroCurve,ProbData,Settle,OptionMaturity,...
    'Period',Period,'Basis',Basis,'BusDayConvention',BusDayConvention,...
    'PayAccruedPremium',true,'recoveryrate',Recovery)

% S(t,T)
Spread_CDSMaturity = cdsspread(ZeroCurve,ProbData,Settle,CDSMaturity,...
```

```
    'Period',Period,'Basis',Basis,'BusDayConvention',BusDayConvention,...
    'PayAccruedPremium',true,'recoveryrate',Recovery)
```

```
Spread_OptionExpiry =

  139.9006

Spread_CDSMaturity =

  140.0000
```

The spot spreads and RPV01s are then used to compute the forward spread.

```
% F = S(t,t_E,T)
ForwardSpread = (Spread_CDSMaturity.*RPV01_CDSMaturity - ...
    Spread_OptionExpiry.*RPV01_OptionExpiry)./RPV01_OptionExpiryForward
```

```
ForwardSpread =

  140.0040
```

Compute the front-end protection (FEP).

```
FEP = 10000*(1-Recovery)*ZeroCurve.getDiscountFactors(OptionMaturity)*ProbData(1,2)
```

```
FEP =

   26.3108
```

Compute the adjusted forward spread.

```
AdjustedForwardSpread = ForwardSpread + FEP./RPV01_OptionExpiryForward
```

```
AdjustedForwardSpread =

  145.7273
```

Compute the option prices using `cdsoptprice` with the adjusted forward spread. Note again that the `Knockout` parameter should be set to be `true` because the FEP was already incorporated into the adjusted forward spread.

```
[Payer,Receiver] = cdsoptprice(ZeroCurve, ProbData, Settle, OptionMaturity, ...
    CDSMaturity, OptionStrike, SpreadVolatility,'Knockout',true,...
    'AdjustedForwardSpread', AdjustedForwardSpread,'PayAccruedPremium',true);
fprintf('    Payer: %.0f   Receiver: %.0f  \n',Payer,Receiver);
```

```
Payer: 92   Receiver: 66
```

Wrong Way Risk with Copulas

This example shows an approach to modeling wrong-way risk for Counterparty Credit Risk using a Gaussian copula.

A basic approach to Counterparty Credit Risk (CCR) (see “Counterparty Credit Risk and CVA” on page 8-2 example) assumes that market and credit risk factors are independent of each other. A simulation of market risk factors drives the exposures for all contracts in the portfolio. In a separate step, Credit-Default Swap (CDS) market quotes determine the default probabilities for each counterparty. Exposures, default probabilities, and a given recovery rate are used to compute the Credit-Value Adjustment (CVA) for each counterparty, which is a measure of expected loss. The simulation of risk factors and the default probabilities are treated as independent of each other.

In practice, default probabilities and market factors are correlated. The relationship may be negligible for some types of instruments, but for others, the relationship between market and credit risk factors may be too important to be ignored when computing risk measures. When the probability of default of a counterparty and the exposure resulting from particular contract tend to increase together we say that the contract has wrong-way risk (WWR).

This example demonstrates an implementation of the wrong-way risk methodology described in Garcia Cespedes et al. (see References on page 8-41).

Exposures Simulation

Many financial institutions have systems that simulate market risk factors and value all the instruments in their portfolios at given simulation dates. These simulations are used to compute exposures and other risk measures. Because the simulations are computationally intensive, reusing them for subsequent risk analyses is important.

This example uses the data and the simulation results from the “Counterparty Credit Risk and CVA” on page 8-2 example, previously saved in the `ccr.mat` file. The `ccr.mat` file contains:

- `RateSpec`: The rate spec when contract values were calculated
- `Settle`: The settle date when contract values were calculated
- `simulationDates`: A vector of simulation dates
- `swaps`: A struct containing the swap parameters
- `values`: The `NUMDATES` x `NUMCONTRACT` x `NUMSCENARIOS` cube of simulated contract values over each date/scenario

This example looks at expected losses over a one-year time horizon only, so the data is cropped after one year of simulation. Simulation dates over the first year are at a monthly frequency, so the 13th simulation date is our one-year time horizon (the first simulation date is the settle date).

```
load ccr.mat

oneYearIdx = 13;
values = values(1:oneYearIdx,:,:);
dates = simulationDates(1:oneYearIdx);

numScenarios = size(values,3);
```

The credit exposures are computed from the simulated contract values. These exposures are monthly credit exposures per counterparty from the settle date to our one-year time horizon.

Since defaults can happen at any time during the one-year time period, it is common to model the exposure at default (EAD) based on the idea of expected positive exposure (EPE). The time-averaged exposure for each scenario is computed, which is called PE (positive exposure). The average of the PE's, including all scenarios, is the EPE, which can also be obtained from the `exposureprofiles` function.

The positive exposure matrix PE contains one row per simulated scenario and one column per counterparty. This is used as the EAD in this analysis.

```
% Compute counterparty exposures
[exposures, counterparties] = creditexposures(values,swaps.Counterparty, ...
    'NettingID',swaps.NettingID);
numCP = numel(counterparties);

% Compute PE (time-averaged exposures) per scenario
intervalWeights = diff(dates) / (dates(end) - dates(1));
exposureMidpoints = 0.5 * (exposures(1:end-1,:,:) + exposures(2:end,:,:));
weightedContributions = bsxfun(@times,intervalWeights,exposureMidpoints);
PE = squeeze(sum(weightedContributions))';

% Compute total portfolio exposure per scenario
totalExp = sum(PE,2);

% Display size of PE and totalExp
whos PE totalExp
```

```
  Name             Size            Bytes  Class     Attributes

  PE            1000x5             40000  double
  totalExp      1000x1              8000  double
```

Credit Simulation

A common approach for simulating credit defaults is based on a "one-factor model", sometimes called the "asset-value approach" (see Gupton et al., 1997 on page 8-41). This is an efficient way to simulate correlated defaults.

Each company *i* is associated with a random variable *Yi*, such that

$$Y_i = \beta_i Z + \sqrt{1 - \beta_i^2}\epsilon_i$$

where *Z* is the "one-factor", a standard normal random variable that represents a systematic credit risk factor whose values affect all companies. The correlation between company *i* and the common factor is given by *beta_i*, the correlation between companies *i* and *j* is *beta_i*beta_j*. The idiosyncratic shock *epsilon_i* is another standard normal variable that may reduce or increase the effect of the systematic factor, independently of what happens with any other company.

If the default probability for company *i* is *PDi*, a default occurs when

$$\Phi(Y_i) < PD_i$$

where Φ is the cumulative standard normal distribution.

The *Yi* variable is sometimes interpreted as asset returns, or sometimes referred to as a latent variable.

This model is a Gaussian copula that introduces a correlation between credit defaults. Copulas offer a particular way to introduce correlation, or more generally, co-dependence between two random variables whose co-dependence is unknown.

Use CDS spreads to bootstrap the one-year default probabilities for each counterparty. The CDS quotes come from the swap-portfolio spreadsheet used in the “Counterparty Credit Risk and CVA” on page 8-2 example.

```
% Import CDS market information for each counterparty
swapFile = 'cva-swap-portfolio.xls';
cds = readtable(swapFile,'Sheet','CDS Spreads');
cdsDates = datenum(cds.Date);
cdsSpreads = table2array(cds(:,2:end));

% Bootstrap default probabilities for each counterparty
zeroData = [RateSpec.EndDates RateSpec.Rates];
defProb = zeros(1, size(cdsSpreads,2));
for i = 1:numel(defProb)
    probData = cdsbootstrap(zeroData, [cdsDates cdsSpreads(:,i)], ...
        Settle, 'probDates', dates(end));
    defProb(i) = probData(2);
end
```

Now simulate the credit scenarios. Because defaults are rare, it is common to simulate a large number of credit scenarios.

The sensitivity parameter *beta* is set to `0.3` for all counterparties. This value can be calibrated or tuned to explore model sensitivities. See the References on page 8-41 for more information.

```
numCreditScen = 100000;
rng('default');

% Z is the single credit factor
Z = randn(numCreditScen,1);

% epsilon is the idiosyncratic factor
epsilon = randn(numCreditScen,numCP);

% beta is the counterparty sensitivity to the credit factor
beta = 0.3 * ones(1,numCP);

% Counterparty latent variables
Y = bsxfun(@times,beta,Z) + bsxfun(@times,sqrt(1 - beta.^2),epsilon);

% Default indicator
isDefault = bsxfun(@lt,normcdf(Y),defProb);
```

Correlating Exposure and Credit Scenarios

Now that there is a set of sorted portfolio exposure scenarios and a set of default scenarios, follow the approach in Garcia Cespedes et al. and use a Gaussian copula to generate correlated exposure-default scenario pairs.

Define a latent variable *Ye* that maps into the distribution of simulated exposures. *Ye* is defined as

$$Y_e = \rho Z + \sqrt{1 - \rho^2}\epsilon_e$$

where *Z* is the systemic factor computed in the credit simulation, *epsilon_e* is an independent standard normal variable and *rho* is interpreted as a market-credit correlation parameter. By construction, *Ye* is a standard normal variable correlated with *Z* with correlation parameter *rho*.

The mapping between *Ye* and the simulated exposures requires us to order the exposure scenarios in a meaningful way, based on some sortable criterion. The criterion can be any meaningful quantity, for example, it could be an underlying risk factor for the contract values (such as an interest rate), the total portfolio exposure, and so on.

In this example, use the total portfolio exposure (`totalExp`) as the exposure scenario criterion to correlate the credit factor with the total exposure. If *rho* is negative, low values of the credit factor *Z* tend to get linked to high values of *Ye*, hence high exposures. This means negative values of *rho* introduce WWR.

To implement the mapping between *Ye* and the exposure scenarios, sort the exposure scenarios by the `totalExp` values. Suppose that the number of exposure scenarios is *S* (`numScenarios`). Given *Ye*, find the value *j* such that

$$\frac{j-1}{S} \le \Phi(Y_e) < \frac{j}{S}$$

and select the scenario *j* from the sorted exposure scenarios.

Ye is correlated to the simulated exposures and *Z* is correlated to the simulated defaults. The correlation *rho* between *Ye* and *Z* is, therefore, the correlation link between the exposures and the credit simulations.

```
% Sort the total exposure
[~,totalExpIdx] = sort(totalExp);

% Scenario cut points
cutPoints = 0:1/numScenarios:1;

% epsilonExp is the idiosyncratic factor for the latent variable
epsilonExp = randn(numCreditScen,1);

% Set a market-credit correlation value
rho = -0.75;

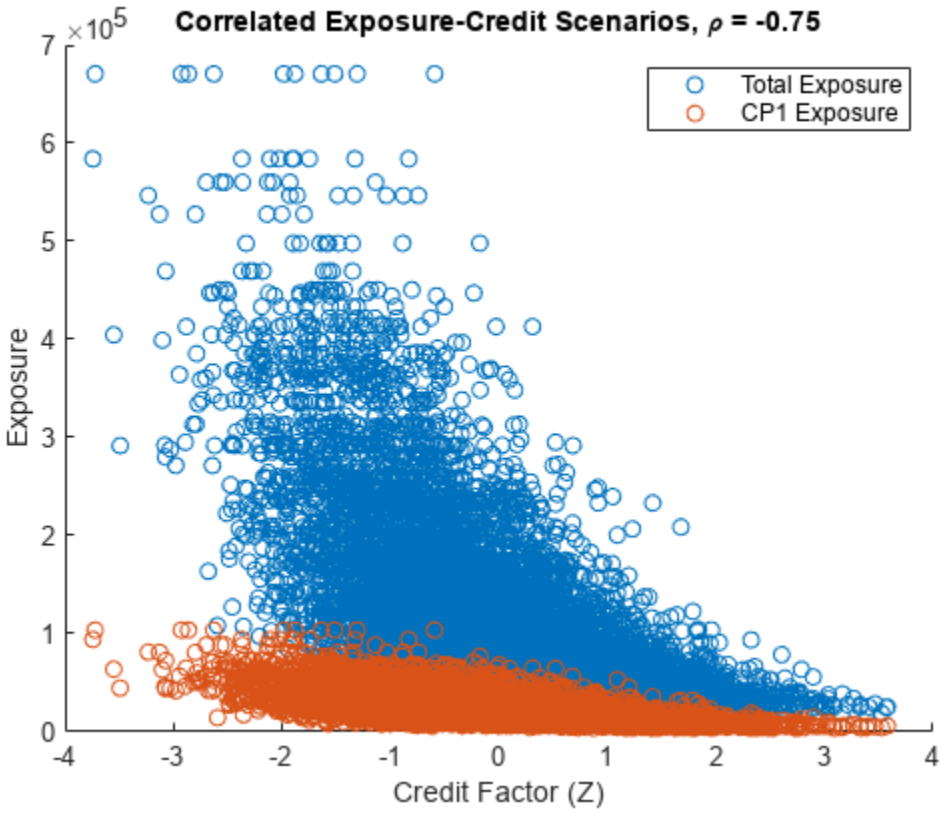
% Latent variable
Ye = rho * Z + sqrt(1 - rho^2) * epsilonExp;

% Find corresponding exposure scenario
binidx = discretize(normcdf(Ye),cutPoints);
scenIdx = totalExpIdx(binidx);
totalExpCorr = totalExp(scenIdx);
PECorr = PE(scenIdx,:);
```

The following plot shows the correlated exposure-credit scenarios for the total portfolio exposure as well as for the first counterparty. Because of the negative correlation, negative values of the credit factor *Z* correspond to high exposure levels (wrong-way risk).

```
% We only plot up to 10000 scenarios
numScenPlot = min(10000,numCreditScen);
figure;
scatter(Z(1:numScenPlot),totalExpCorr(1:numScenPlot))
```

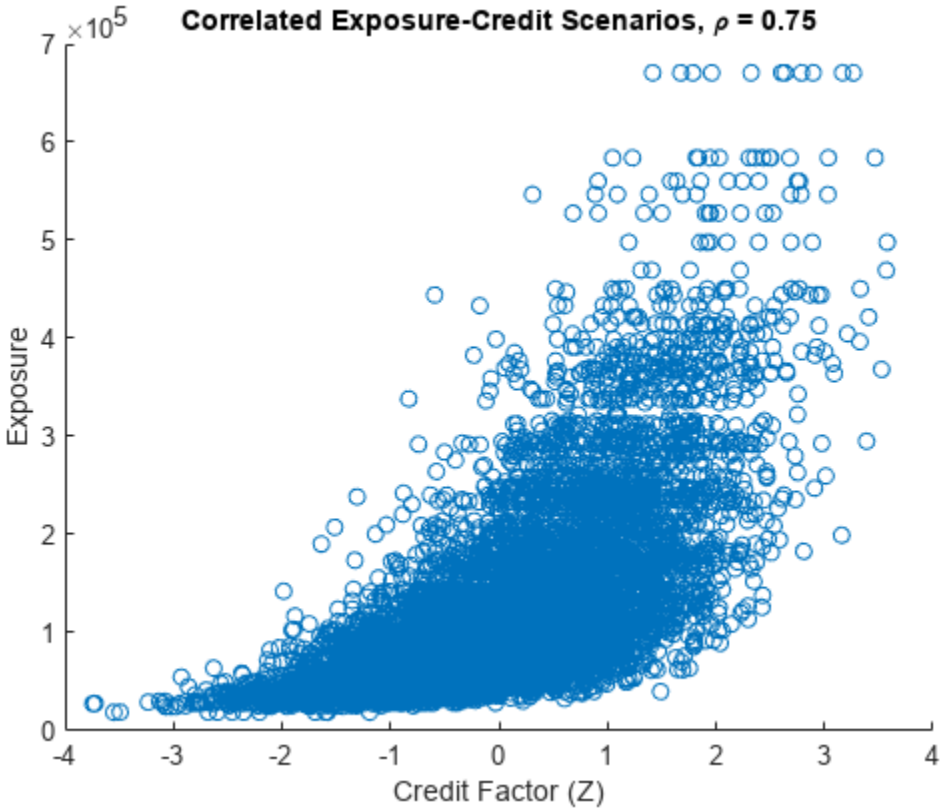
```
hold on
scatter(Z(1:numScenPlot),PECorr(1:numScenPlot,1))
xlabel('Credit Factor (Z)')
ylabel('Exposure')
title(['Correlated Exposure-Credit Scenarios, \rho = ' num2str(rho)])
legend('Total Exposure','CP1 Exposure')
hold off
```



For positive values of *rho,* the relationship between the credit factor and the exposures is reversed (right-way risk).

```
rho = 0.75;
Ye = rho * Z + sqrt(1 - rho^2) * epsilonExp;
binidx = discretize(normcdf(Ye),cutPoints);
scenIdx = totalExpIdx(binidx);
totalExpCorr = totalExp(scenIdx);

figure;
scatter(Z(1:numScenPlot),totalExpCorr(1:numScenPlot))
xlabel('Credit Factor (Z)')
ylabel('Exposure')
title(['Correlated Exposure-Credit Scenarios, \rho = ' num2str(rho)])
```



Sensitivity to Correlation

You can explore the sensitivity of the exposures or other risk measures to a range of values for *rho*.

For each value of *rho*, compute the total losses per credit scenario as well as the expected losses per counterparty. This example assumes a 40% recovery rate.

```
Recovery = 0.4;
rhoValues = -1:0.1:1;

totalLosses = zeros(numCreditScen,numel(rhoValues));
expectedLosses = zeros(numCP, numel(rhoValues));

for i = 1:numel(rhoValues)

    rho = rhoValues(i);

    % Latent variable
    Ye = rho * Z + sqrt(1 - rho^2) * epsilonExp;

    % Find corresponding exposure scenario
    binidx = discretize(normcdf(Ye),cutPoints);
    scenIdx = totalExpIdx(binidx);
    simulatedExposures = PE(scenIdx,:);

    % Compute actual losses based on exposures and default events
    losses = isDefault .* simulatedExposures * (1-Recovery);
```

```
    totalLosses(:,i) = sum(losses,2);

    % We compute the expected losses per counterparty
    expectedLosses(:,i) = mean(losses)';
end
displayExpectedLosses(rhoValues, expectedLosses)
```

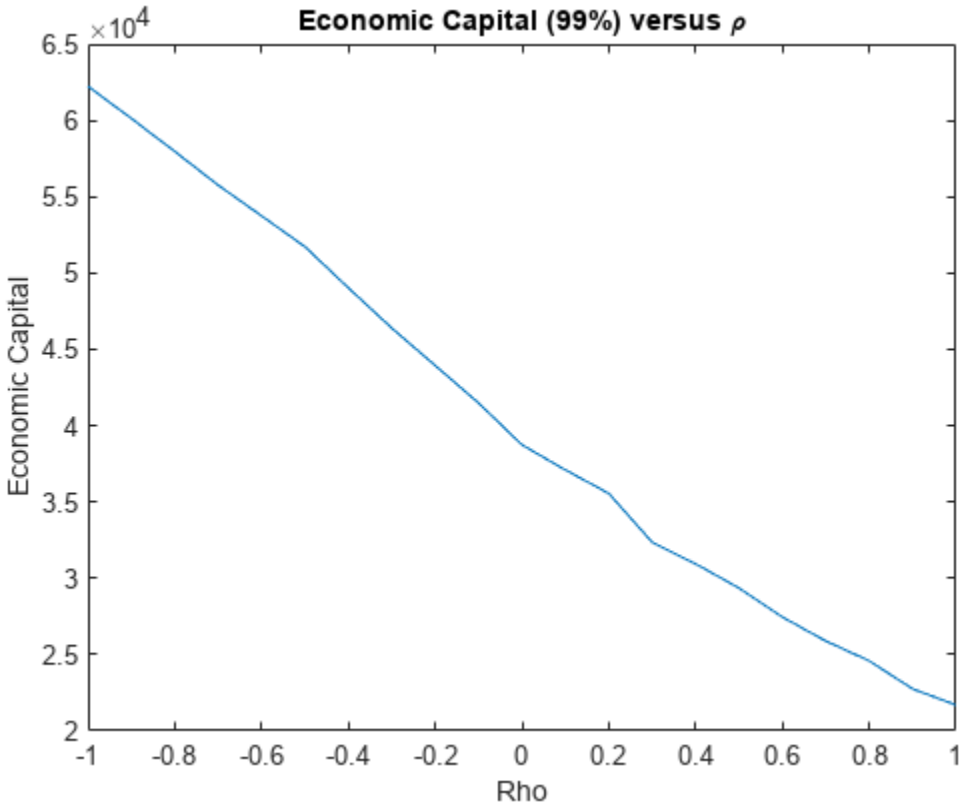
```
               Expected Losses
 Rho    CP1      CP2      CP3     CP4       CP5
-------------------------------------------------
-1.0   604.10   260.44   194.70  1234.17   925.95-0.9   583.67   250.45   189.02  1158.65   897.9
```

You can visualize the sensitivity of the Economic Capital (EC) to the market-credit correlation parameter. Define EC as the difference between a percentile q of the distribution of losses, minus the expected loss.

Negative values of *rho* result in higher capital requirements because of WWR.

```
pct = 99;
ec = prctile(totalLosses,pct) - mean(totalLosses);

figure;
plot(rhoValues,ec)
title('Economic Capital (99%) versus \rho')
xlabel('Rho');
ylabel('Economic Capital');
```



Final Remarks

This example implements a copula-based approach to WWR, following Garcia Cespedes et al. The methodology can efficiently reuse existing exposures and credit simulations, and the sensitivity to the market-credit correlation parameter can be efficiently computed and conveniently visualized for all correlation values.

The single-parameter copula approach presented here can be extended for a more thorough exploration of the WWR of a portfolio. For example, different types of copulas can be applied, and different criteria can be used to sort the exposure scenarios. Other extensions include simulating multiple systemic credit risk variables (a multi-factor model), or switching from a one-year to a multi-period framework to calculate measures such as credit value adjustment (CVA), as in Rosen and Saunders (see References on page 8-41).

Bootstrapping a Default Probability Curve from Credit Default Swaps

This example shows how to bootstrap a default probability curve for CDS instruments.

Create a ratecurve Object for a Zero Curve

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 15-Sep-2017
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Market CDS Spreads and a Vector of Market CDS Instruments

Define the market CDS spreads and use `fininstrument` to create a vector of market CDS instrument objects.

```
SpreadTimes = [1 2 3 4 5 7 10 20 30]';
Spread = [140 175 210 265 310 360 410 460 490]';
MarketDates = datemnth(Settle,12*SpreadTimes);

NumMarketInst = length(MarketDates);
ContractSpreadBP = 50.*ones(NumMarketInst,1);

MarketCDSInstruments(NumMarketInst,1) = fininstrument("cds", ...
    'ContractSpread', ContractSpreadBP(end), 'Maturity', MarketDates(end));
for k = 1:NumMarketInst
    MarketCDSInstruments(k,1) = fininstrument("cds", ...
        'ContractSpread', ContractSpreadBP(k), 'Maturity', MarketDates(k));
end
MarketCDSInstruments
```

```
MarketCDSInstruments=9×1 object
  9x1 CDS array with properties:

    ContractSpread
    Maturity
    Period
    Basis
```

```
    RecoveryRate
    BusinessDayConvention
    Holidays
    PayAccruedPremium
    Notional
    Name
```

Bootstrap a Default Probability Curve

Use `defprobstrip`, `hazardrates`,and `survprobs` to analyse a default probability curve for the market `CDS` instruments.

```
DefaultProbCurve = defprobstrip(ZeroCurve, MarketCDSInstruments, Spread)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 15-Sep-2017
                  Basis: 2
                  Dates: [9x1 datetime]
    DefaultProbabilities: [9x1 double]
```

```
HazardRates = hazardrates(DefaultProbCurve)
```

```
HazardRates = 9×1

Bootstrap Default Probability Curve from Market CDS Instruments

This example shows how to use `defprobstrip` to bootstrap a `defprobcurve` object based on market CDS instruments.

Create `ratecurve` Object for Zero-Rate Curve

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2017,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates);
```

Market CDS Spreads and Vector of Market CDS Instruments

Define the market CDS spreads and use `fininstrument` to create a vector of market CDS instrument objects.

```
SpreadTimes = [1 2 3 4 5 7 10 20 30]';
Spread = [140 175 210 265 310 360 410 460 490]';
MarketDates = datemnth(Settle,12*SpreadTimes);

NumMarketInst = length(MarketDates);
ContractSpreadBP = zeros(NumMarketInst,1);

MarketCDSInstruments(NumMarketInst,1) = fininstrument("cds", ...
      'ContractSpread', ContractSpreadBP(end), 'Maturity', MarketDates(end));
  for k = 1:NumMarketInst
      MarketCDSInstruments(k,1) = fininstrument("cds", ...
          'ContractSpread', ContractSpreadBP(k), 'Maturity', MarketDates(k));
  end
```

Use `defprobstrip` to create a `defprobcurve` object.

```
DefaultProbCurve = defprobstrip(ZeroCurve,MarketCDSInstruments, Spread)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                  Settle: 15-Sep-2017
                   Basis: 2
                   Dates: [9x1 datetime]
    DefaultProbabilities: [9x1 double]
```

Price Multiple CDS Option Instruments Using CDS Black Model and CDS Black Pricer

This example shows the workflow to price multiple `CDSOption` instruments using a `CDSBlack` model and a `CDSBlack` pricer.

Create `ratecurve` Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2021,9,20);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero", Settle, ZeroDates ,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

                Type: "zero"
         Compounding: -1
               Basis: 0
               Dates: [10x1 datetime]
               Rates: [10x1 double]
              Settle: 20-Sep-2021
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
     LongExtrapMethod: "previous"
```

Create `defprobcurve` Object

Create a `defprobcurve` object using `defprobcurve`.

```
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)
```

```
DefaultProbCurve =
  defprobcurve with properties:

                 Settle: 20-Sep-2021
                  Basis: 2
                  Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

Create `CDS` Instrument Object

Use `fininstrument` to create an underlying `CDS` instrument object.

```
ContractSpreadBP = 0; % Contractual spread is determined on ExerciseDate
CDS = fininstrument("CDS",'Maturity',datetime(2027,9,20),'ContractSpread',ContractSpreadBP)
```

```
CDS =
  CDS with properties:
```

```
          ContractSpread: 0
                Maturity: 20-Sep-2027
                  Period: 4
                   Basis: 2
            RecoveryRate: 0.4000
    BusinessDayConvention: "actual"
                Holidays: NaT
        PayAccruedPremium: 1
                Notional: 10000000
                    Name: ""
```

Create CDSOption Instrument Objects

Use `fininstrument` to create multiple `CDSOption` instrument objects.

```
ExerciseDate = datetime(2021, 12, 20);
Strikes = [30:2:90]';
PayerCDSOptions = fininstrument("CDSOption",'Strike',Strikes,'ExerciseDate',ExerciseDate,'Option
```

```
PayerCDSOptions=31×1 object
  16x1 CDSOption array with properties:

    OptionType
    Strike
    Knockout
    AdjustedForwardSpread
    ExerciseDate
    CDS
    Name
      ⋮
```

```
ReceiverCDSOptions = fininstrument("CDSOption",'Strike',Strikes,'ExerciseDate',ExerciseDate,'Opti
```

```
ReceiverCDSOptions=31×1 object
  16x1 CDSOption array with properties:

    OptionType
    Strike
    Knockout
    AdjustedForwardSpread
    ExerciseDate
    CDS
    Name
      ⋮
```

Price CDSOption Instruments

Assuming a flat volatility structure across strikes, first use `finmodel` to create a `CDSBlack` model object. Then use `finpricer` to create a `CDSBlack` pricer object. Use `price` to compute the prices for the `CDSOption` instruments.

```
SpreadVolatility = 0.3;
CDSOptionModel = finmodel("CDSBlack",'SpreadVolatility',SpreadVolatility)
```

```
CDSOptionModel =
  CDSBlack with properties:
```

```
    SpreadVolatility: 0.3000
```

```
CDSOptionpricer = finpricer("analytic",'Model',CDSOptionModel,'DiscountCurve',ZeroCurve,'DefaultP
```

```
CDSOptionpricer =
  CDSBlack with properties:

                     Model: [1x1 finmodel.CDSBlack]
             DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

```
PayerPrices = price(CDSOptionpricer,PayerCDSOptions)
```

```
PayerPrices = 31×1

  171.7269

Interest-Rate Curve Objects

Interest-Rate Curve Objects and Workflow

In this section...

Class Structure

Financial Instruments Toolbox class structure supports interest-rate curve objects. The class structure supports four classes.

Class Structure

Class Name	Description
`IRDataCurve`	Creates a representation of an interest-rate curve with dates and data. `IRDataCurve` is created directly by specifying dates and corresponding interest rates or discount factors, or you can bootstrap an `IRDataCurve` object from market data.
`IRFunctionCurve`	Creates a representation of an interest-rate curve with a function. `IRFunctionCurve` is created directly by specifying a function handle, or you can fit a function to market data using functions of the `IRFunctionCurve` object.
`IRBootstrapOptions`	The `IRBootstrapOptions` object lets you specify options relating to the bootstrapping of an `IRDataCurve` object.
`IRFitOptions`	The `IRFitOptions` object lets you specify options relating to the fitting process for an `IRFunctionCurve` object.

Workflow Using Interest-Rate Curve Objects

The supported workflow model for using interest-rate curve objects is:

1. Create an interest-rate curve based on an `IRDataCurve` object or an `IRFunctionCurve` object.
   - To create an `IRDataCurve` object:
     - Use vectors of dates and data with interpolation methods.
     - Use bootstrapping based on market instruments.

     For more information on creating an `IRDataCurve` object, see “Creating an IRDataCurve Object” on page 9-6.
   - To create an `IRFunctionCurve` object:
     - Specify a function handle.
     - Fit a function using the Nelson-Siegel model, Svensson model, or smoothing spline model.
     - Fit a custom function.
2. Use functions of the `IRDataCurve` or `IRFunctionCurve` objects to extract forward, zero, discount factor, or par yield curves for the interest-rate curve object.

3 Convert an interest-rate curve from an `IRDataCurve` or `IRFunctionCurve` object to a `RateSpec` structure. This `RateSpec` structure is identical to the `RateSpec` produced by the function `intenvset`. Using the `RateSpec` for an interest-rate curve object, you can then use Financial Instruments Toolbox functions to model an interest-rate structure and price. Alternatively, you can convert the `RateSpec` to a `ratecurve` object (see “Convert RateSpec to a ratecurve Object” on page 1-49) and then use the Financial Instruments Toolbox object-based framework for pricing instruments.

`ratecurve` | `parametercurve`

Related Examples

- “Creating Interest-Rate Curve Objects” on page 9-4

More About

- “Mapping Financial Instruments Toolbox Curve Functions to Object-Based Framework” on page 1-95

Creating Interest-Rate Curve Objects

Depending on your data and purpose for analysis, you can create an interest-rate curve object by using an `IRDataCurve` or `IRFunctionCurve` object.

To create an `IRDataCurve` object, you can:

- Use `IRDataCurve` to create an `IRDataCurve` object using vector of dates and data with interpolation methods.
- Use the object function `bootstrap` using market instruments.

For more information on creating an `IRDataCurve` object, see “Creating an IRDataCurve Object” on page 9-6.

Using an `IRDataCurve` object, you can use the following functions to determine:

- Forward rate curve — `getForwardRates`
- Zero rate curve — `getZeroRates`
- Discount rate curve — `getDiscountFactors`
- Par yield curve — `getParYields`

Alternatively, to create an `IRFunctionCurve` object, you can:

- Use `IRFunctionCurve` to create an `IRFunctionCurve` object and directly specify a function handle.
- Use `IRFunctionCurve` object functions:
  - `fitNelsonSiegel` fits a “Fitting IRFunctionCurve Object Using Nelson-Siegel Method” on page 9-16 to market data for bonds.
  - `fitSvensson` fits a “Fitting IRFunctionCurve Object Using Svensson Method” on page 9-17 to market data for bonds.
  - `fitSmoothingSpline` fits a “Fitting IRFunctionCurve Object Using Smoothing Spline Method” on page 9-19 function to market data for bonds.
  - `fitFunction` custom fits an interest-rate curve object to market data for bonds.

Using an `IRFunctionCurve` object, you can use the following functions to determine:

- Forward rate curve — `getForwardRates`
- Zero rate curve — `getZeroRates`
- Discount rate curve — `getDiscountFactors`
- Par yield curve — `getParYields`

In addition, you can convert an `IRDataCurve` object or `IRFunctionCurve` object to a `RateSpec` structure. For more information, see “Converting an IRDataCurve or IRFunctionCurve Object” on page 9-30.

Related Examples

- “Creating an IRDataCurve Object” on page 9-6

More About

- “Interest-Rate Curve Objects and Workflow” on page 9-2

Creating an IRDataCurve Object

To create an `IRDataCurve` object, see the following options:

In this section...
“Use IRDataCurve with Dates and Data” on page 9-6
“Bootstrap IRDataCurve Based on Market Instruments” on page 9-7

Use IRDataCurve with Dates and Data

Use `IRDataCurve` with vectors of dates and data to create an interest-rate curve object. When constructing the `IRDataCurve` object, you can also use optional inputs to define how the interest-rate curve is constructed from the dates and data.

Example

In this example, you create the vectors for `Dates` and `Data` for an interest-rate curve.

```
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = daysadd(today,[360 2*360 3*360 5*360 7*360 10*360 20*360 30*360],1);
```

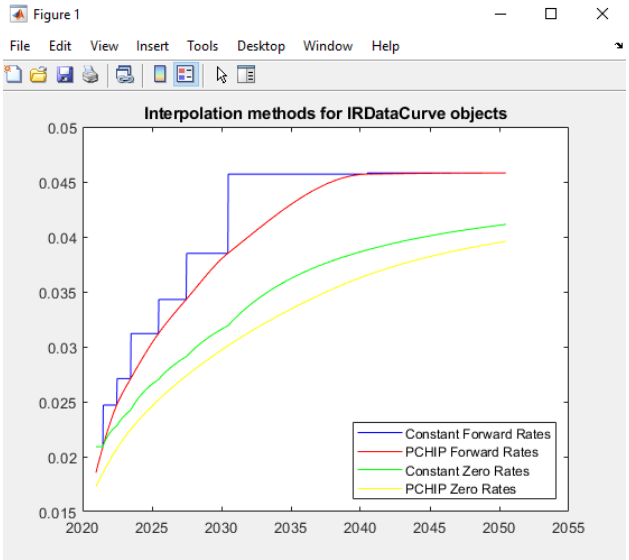
Use `IRDataCurve` to build interest-rate objects based on the `constant` and `pchip` interpolation methods.

```
irdc_const = IRDataCurve('Forward',today,Dates,Data,'InterpMethod','constant');
irdc_pchip = IRDataCurve('Forward',today,Dates,Data,'InterpMethod','pchip');
```

Plot the forward and zero rate curves for the two `IRDataCurve` objects based on `constant` and `pchip` interpolation methods.

```
PlottingDates = daysadd(today,180:10:360*30,1);
plot(PlottingDates, getForwardRates(irdc_const, PlottingDates),'b')
hold on
plot(PlottingDates, getForwardRates(irdc_pchip, PlottingDates),'r')
plot(PlottingDates, getZeroRates(irdc_const, PlottingDates),'g')
plot(PlottingDates, getZeroRates(irdc_pchip, PlottingDates),'yellow')
legend({'Constant Forward Rates','PCHIP Forward Rates','Constant Zero Rates',...
'PCHIP Zero Rates'},'location','SouthEast')
title('Interpolation methods for IRDataCurve objects')
datetick
```

The plot demonstrates the relationship of the forward and zero rate curves.



Bootstrap IRDataCurve Based on Market Instruments

Use the bootstrapping function, based on market instruments, to create an interest-rate curve object. When bootstrapping, you also have the option to define a range of interpolation methods (`linear`, `spline`, `constant`, and `pchip`).

Example 1

In this example, you bootstrap a swap curve from deposits, Eurodollar Futures and swaps. The input market data for this example is hard-coded and specified as two cell arrays of data; one cell array indicates the type of instrument and the other contains the `Settle`, `Maturity` values and a market quote for the instrument. For deposits and swaps, the quote is a rate; for the EuroDollar futures, the quote is a price. Although bonds are not used in this example, a bond would also be quoted with a price.

```
InstrumentTypes = {'Deposit';'Deposit';'Deposit';'Deposit';'Deposit'; ...
    'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Futures';'Futures';'Futures'; ...
    'Swap';'Swap';'Swap';'Swap';'Swap';'Swap';'Swap'};

Instruments = [datenum('08/10/2007'),datenum('08/17/2007'),.0532063; ...
    datenum('08/10/2007'),datenum('08/24/2007'),.0532000; ...
    datenum('08/10/2007'),datenum('09/17/2007'),.0532000; ...
    datenum('08/10/2007'),datenum('10/17/2007'),.0534000; ...
    datenum('08/10/2007'),datenum('11/17/2007'),.0535866; ...
    datenum('08/08/2007'),datenum('19-Dec-2007'),9485; ...
    datenum('08/08/2007'),datenum('19-Mar-2008'),9502; ...
    datenum('08/08/2007'),datenum('18-Jun-2008'),9509.5; ...
    datenum('08/08/2007'),datenum('17-Sep-2008'),9509; ...
    datenum('08/08/2007'),datenum('17-Dec-2008'),9505.5; ...
    datenum('08/08/2007'),datenum('18-Mar-2009'),9501; ...
    datenum('08/08/2007'),datenum('17-Jun-2009'),9494.5; ...
    datenum('08/08/2007'),datenum('16-Sep-2009'),9489; ...
    datenum('08/08/2007'),datenum('16-Dec-2009'),9481.5; ...
    datenum('08/08/2007'),datenum('17-Mar-2010'),9478; ...
    datenum('08/08/2007'),datenum('16-Jun-2010'),9474; ...
    datenum('08/08/2007'),datenum('15-Sep-2010'),9469.5; ...
```

```
    datenum('08/08/2007'),datenum('15-Dec-2010'),9464.5; ...
    datenum('08/08/2007'),datenum('16-Mar-2011'),9462.5; ...
    datenum('08/08/2007'),datenum('15-Jun-2011'),9456.5; ...
    datenum('08/08/2007'),datenum('21-Sep-2011'),9454; ...
    datenum('08/08/2007'),datenum('21-Dec-2011'),9449.5; ...
    datenum('08/08/2007'),datenum('08/08/2014'),.0530; ...
    datenum('08/08/2007'),datenum('08/08/2017'),.0545; ...
    datenum('08/08/2007'),datenum('08/08/2019'),.0551; ...
    datenum('08/08/2007'),datenum('08/08/2022'),.0559; ...
    datenum('08/08/2007'),datenum('08/08/2027'),.0565; ...
    datenum('08/08/2007'),datenum('08/08/2032'),.0566; ...
    datenum('08/08/2007'),datenum('08/08/2037'),.0566];
```

`bootstrap` is called as a function of the `IRDataCurve` object. Inputs to this function include the curve `Type` (`zero` or `forward`), `Settle` date, `InstrumentTypes`, and `Instrument` data. The `bootstrap` function also supports optional arguments, including an interpolation method, compounding, basis, and an options structure for bootstrapping. For example, you are passing in an `IRBootstrapOptions` object which includes information for the `ConvexityAdjustment` to forward rates.

```
IRsigma = .01;
CurveSettle = datenum('08/10/2007');
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments,'InterpMethod','pchip',...
'Compounding',-1,'IRBootstrapOptions',...
IRBootstrapOptions('ConvexityAdjustment',@(t) .5*IRsigma^2.*t.^2))
```

```
bootModel =

IRDataCurve

             Type: Forward
           Settle: 733264 (10-Aug-2007)
      Compounding: -1
            Basis: 0 (actual/actual)
     InterpMethod: pchip
            Dates: [29x1 double]
             Data: [29x1 double]
```

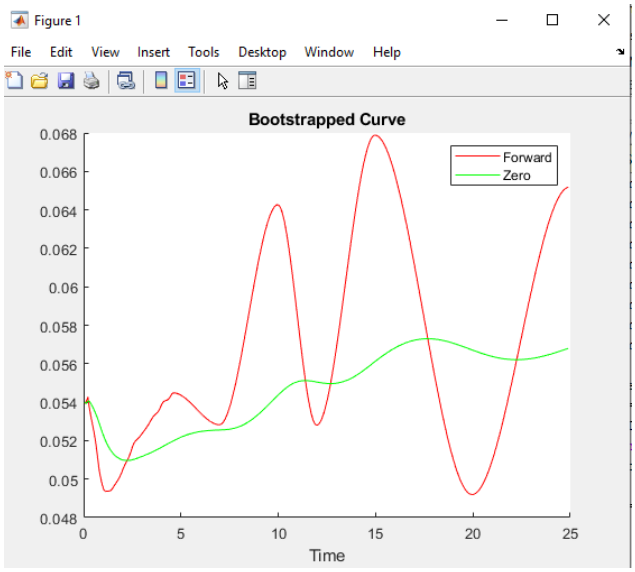
The `bootstrap` function uses an Optimization Toolbox function to solve for any bootstrapped rates.

Plot the forward and zero curves.

```
PlottingDates = (CurveSettle+20:30:CurveSettle+365*25)';
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
BootstrappedForwardRates = getForwardRates(bootModel, PlottingDates);
BootstrappedZeroRates = getZeroRates(bootModel, PlottingDates);

figure
hold on
plot(TimeToMaturity,BootstrappedForwardRates,'r')
plot(TimeToMaturity,BootstrappedZeroRates,'g')
title('Bootstrapped Curve')
xlabel('Time')
legend({'Forward','Zero'})
```

The plot demonstrates the forward and zero rate curves for the market data.



Example 2

In this example, you bootstrap a swap curve from deposits, Eurodollar futures, and swaps. The input market data for this example is hard-coded and specified as two cell arrays of data; one cell array indicates the type of instrument and the other cell array contains the `Settle`, `Maturity` values and a market quote for the instrument. This example of bootstrapping also demonstrates the use of an `InstrumentBasis` for each `Instrument` type.

```
InstrumentTypes = {'Deposit';'Deposit';...
'Futures';'Futures';'Futures';'Futures';'Futures';...
'Swap';'Swap';'Swap';'Swap';};

Instruments = [datenum('08/10/2007'),datenum('09/17/2007'),.0532000; ...
datenum('08/10/2007'),datenum('11/17/2007'),.0535866; ...
datenum('08/08/2007'),datenum('19-Dec-2007'),9485; ...
datenum('08/08/2007'),datenum('19-Mar-2008'),9502; ...
datenum('08/08/2007'),datenum('18-Jun-2008'),9509.5; ...
datenum('08/08/2007'),datenum('17-Sep-2008'),9509; ...
datenum('08/08/2007'),datenum('17-Dec-2008'),9505.5; ...
datenum('08/08/2007'),datenum('18-Mar-2009'),9501; ...
datenum('08/08/2007'),datenum('08/08/2014'),.0530; ...
datenum('08/08/2007'),datenum('08/08/2019'),.0551; ...
datenum('08/08/2007'),datenum('08/08/2027'),.0565; ...
datenum('08/08/2007'),datenum('08/08/2037'),.0566];

CurveSettle = datenum('08/10/2007');
```

The `bootstrap` function is called as a function of the `IRBootstrapOptions` object. Inputs to the `bootstrap` function include the curve `Type` (`zero` or `forward`), `Settle` date, `InstrumentTypes`, and `Instrument` data. The `bootstrap` function also supports optional arguments, including an interpolation method, compounding, basis, and an options structure for bootstrapping. In this example, you are passing an additional `Basis` value for each instrument type.

```
bootModel=IRDataCurve.bootstrap('Forward',CurveSettle,InstrumentTypes, ...
Instruments,'InterpMethod','pchip','InstrumentBasis',[repmat(2,8,1);repmat(0,4,1)])
```

```
bootModel =

    IRDataCurve

           Type: Forward
```

```
      Settle: 733264 (10-Aug-2007)
 Compounding: 2
       Basis: 0 (actual/actual)
InterpMethod: pchip
       Dates: [12x1 double]
        Data: [12x1 double]
```

The `bootstrap` function uses an Optimization Toolbox function to solve for any bootstrapped rates.

Plot the par yields curve using the `getParYields` function.

```
PlottingDates = (datenum('08/11/2007'):30:CurveSettle+365*25)';
plot(PlottingDates, getParYields(bootModel, PlottingDates),'r')
datetick
```

The plot demonstrates the par yields curve for the market data.

Dual Curve Bootstrapping

This example shows how to bootstrap a forward curve using a different curve for discounting.

Define the Data

Data is needed for both the forward and discount curve. For this particular example, it is assumed that the data is provided for EONIA (the discount curve) and EURIBOR (the forward curve). However, this approach can be used in any case where the curve to be built is different than the curve used for discounting cash flows. While the data in this example is hardcoded, it could also be imported into MATLAB with Datafeed Toolbox™ or Database Toolbox™.

```
Settle = datenum('20-Aug-2013');

% Deposit data
EONIADepositRates = [.0007 .00067]';
EONIADepositMat = datenum({'3-Sep-2013','20-Sep-2013'});
EONIADepositBasis = 2; % act/360
EONIADepositPeriod = 0;

% FRA
EONIAFRARates = [.00025 .0003 .00043 .00054]';
EONIAFRAStartDate = datenum({'11-Sep-2013','9-Oct-2013','13-Nov-2013','11-Dec-2013'});
EONIAFRAEndDate = datenum({'9-Oct-2013','13-Nov-2013','11-Dec-2013','11-Jan-2014'});
EONIAFRABasis = 2; % act/360
EONIAFRAPeriod = 0;

% Swap data
EONIASwapRates = [.0003 .001 .002 .004 .008 .012 .0155 .018 .0193 .02]';
EONIASwapMat = datemnth(Settle,12*[2:5 7 10 15 20 25 30]');
EONIASwapBasis = 5; % 30/360 ISDA
EONIASwapPeriod = 1;

% EURIBOR Deposit data
EURIBORDepositRates = [.0022 .0021 .002 .0019]';
EURIBORDepositMat = datenum({'3-Sep-2013','20-Sep-2013','21-Oct-2013','20-Nov-2013'});
EURIBORDepositBasis = 2; % act/360
EURIBORDepositPeriod = 0;

% EURIBOR Futures
EURIBORFRARates = [9982 9978 9976 9975]';
EURIBORFRAStartDate = datenum({'18-Dec-2013','19-Mar-2014','18-Jun-2014','17-Sep-2014'});
EURIBORFRAEndDate = datenum({'18-Mar-2014','19-Jun-2014','18-Sep-2014','17-Dec-2014'});
EURIBORFRABasis = 2; % act/360
EURIBORFRAPeriod = 4;

% EURIBOR Swap data
EURIBORSwapRates = [.0026 .0044 .0062 .0082 .012 .015 .018 .02 .021 .0215]';
EURIBORSwapMat = datemnth(Settle,12*[2:5 7 10 15 20 25 30]');
EURIBORSwapBasis = 5; % 30/360 ISDA
EURIBORSwapPeriod = 1;
```

Create an EONIA Discount Curve

Build the EONIA curve. This is essentially the same as the single curve case.

```
CurveType = 'zero';
CurveCompounding = 1;
CurveBasis = 3; % act/365

nEONIADeposits = length(EONIADepositMat);
nEONIAFRA = length(EONIAFRAEndDate);
nEONIASwaps = length(EONIASwapMat);

EONIAInstrumentTypes = [repmat({'deposit'},nEONIADeposits,1);
    repmat({'fra'},nEONIAFRA,1);repmat({'swap'},nEONIASwaps,1)];

EONIAPeriod = [repmat(EONIADepositPeriod,nEONIADeposits,1);
    repmat(EONIAFRAPeriod,nEONIAFRA,1);repmat(EONIASwapPeriod,nEONIASwaps,1)];

EONIABasis = [repmat(EONIADepositBasis,nEONIADeposits,1);
    repmat(EONIAFRABasis,nEONIAFRA,1);repmat(EONIASwapBasis,nEONIASwaps,1)];

EONIAInstrumentData = [[repmat(Settle,[nEONIADeposits 1]);EONIAFRAStartDate;repmat(Settle,[nEONIASwaps 1])] ...
```

```
    [EONIADepositMat;EONIAFRAEndDate;EONIASwapMat] ...
    [EONIADepositRates;EONIAFRARates;EONIASwapRates]];

EONIACurve = IRDataCurve.bootstrap(CurveType,Settle,EONIAInstrumentTypes,...
    EONIAInstrumentData,'Compounding',CurveCompounding,'Basis',CurveBasis,...
    'InstrumentPeriod',EONIAPeriod,'InstrumentBasis',EONIABasis)
```

```
EONIACurve =

             Type: zero
           Settle: 735466 (20-Aug-2013)
      Compounding: 1
            Basis: 3 (actual/365)
     InterpMethod: linear
            Dates: [16x1 double]
             Data: [16x1 double]
```

Create an EURIBOR Forward Curve

The EURIBOR forward curve is built first using a single curve approach.

```
nEURIBORDeposits = length(EURIBORDepositMat);
nEURIBORFRA = length(EURIBORFRAEndDate);
nEURIBORSwaps = length(EURIBORSwapMat);

EURIBORInstrumentTypes = [repmat({'deposit'},nEURIBORDeposits,1);
    repmat({'futures'},nEURIBORFRA,1);repmat({'swap'},nEURIBORSwaps,1)];

EURIBORPeriod = [repmat(EURIBORDepositPeriod,nEURIBORDeposits,1);
    repmat(EURIBORFRAPeriod,nEURIBORFRA,1);repmat(EURIBORSwapPeriod,nEURIBORSwaps,1)];

EURIBORBasis = [repmat(EURIBORDepositBasis,nEURIBORDeposits,1);
    repmat(EURIBORFRABasis,nEURIBORFRA,1);repmat(EURIBORSwapBasis,nEURIBORSwaps,1)];

EURIBORInstrumentData = [repmat(Settle,size(EURIBORInstrumentTypes)) ...
    [EURIBORDepositMat;EURIBORFRAEndDate;EURIBORSwapMat] ...
    [EURIBORDepositRates;EURIBORFRARates;EURIBORSwapRates]];

EURIBORCurve_Single = IRDataCurve.bootstrap(CurveType,Settle,EURIBORInstrumentTypes,...
    EURIBORInstrumentData,'Compounding',CurveCompounding,'Basis',CurveBasis,...
    'InstrumentPeriod',EURIBORPeriod,'InstrumentBasis',EURIBORBasis)
```

```
EURIBORCurve_Single =

             Type: zero
           Settle: 735466 (20-Aug-2013)
      Compounding: 1
            Basis: 3 (actual/365)
     InterpMethod: linear
            Dates: [18x1 double]
             Data: [18x1 double]
```

Build the EURIBOR Curve with the EONIA Curve

Next, build a curve using the EONIA curve as a discounting curve. To do this, specify the EONIA curve as an optional input argument.

```
EURIBORCurve = IRDataCurve.bootstrap(CurveType,Settle,EURIBORInstrumentTypes,...
    EURIBORInstrumentData,'DiscountCurve',EONIACurve,'Compounding',...
    CurveCompounding,'Basis',CurveBasis,'InstrumentPeriod',EURIBORPeriod,...
    'InstrumentBasis',EURIBORBasis)
```

```
EURIBORCurve =

             Type: zero
           Settle: 735466 (20-Aug-2013)
      Compounding: 1
            Basis: 3 (actual/365)
```

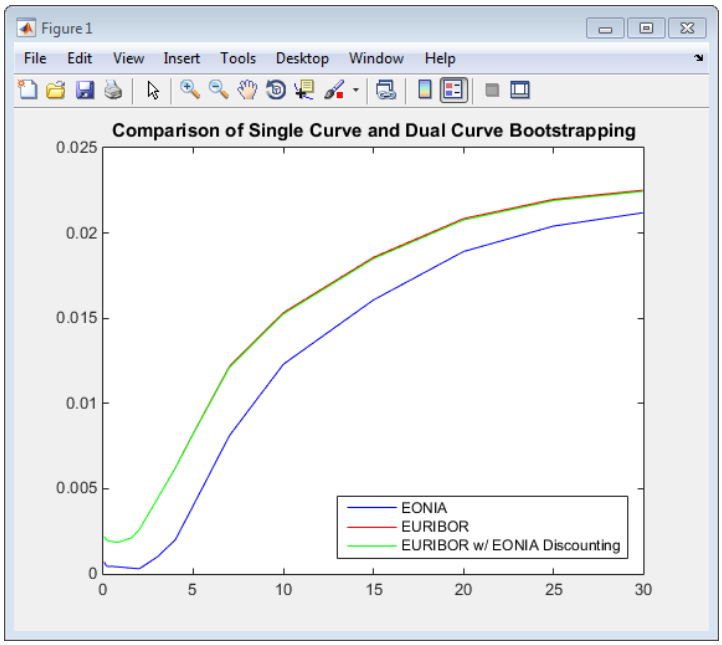
```
     InterpMethod: linear
            Dates: [18x1 double]
             Data: [18x1 double]
```

Plot the Results

Plot the results to compare the curves.

```
PlottingDates = (Settle+20:30:Settle+365*30)';
TimeToMaturity = yearfrac(Settle,PlottingDates);

figure
plot(TimeToMaturity, getZeroRates(EONIACurve, PlottingDates),'b')
hold on
plot(TimeToMaturity, getZeroRates(EURIBORCurve_Single, PlottingDates),'r')
plot(TimeToMaturity, getZeroRates(EURIBORCurve, PlottingDates),'g')
title('Comparison of Single Curve and Dual Curve Bootstrapping')
legend({'EONIA','EURIBOR','EURIBOR w/ EONIA Discounting'},'location','southeast')
```



As expected, the difference between the two different EURIBOR curves is small but nontrivial.

Creating an IRFunctionCurve Object

To create an `IRFunctionCurve` object, see the following options:

Fitting IRFunctionCurve Object Using a Function Handle

You can use `IRFunctionCurve` with a MATLAB function handle to define an interest-rate curve. For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.

Example

This example uses a `FunctionHandle` argument with a value `@(t) t.^2` to create an interest-rate curve.

```
rr = IRFunctionCurve('Zero',today,@(t) t.^2)
```

```
rr =

  Properties:
    FunctionHandle: @(t)t.^2
              Type: 'Zero'
            Settle: 733600
       Compounding: 2
             Basis: 0
```

Fitting IRFunctionCurve Object Using Nelson-Siegel Method

Use the function, `fitNelsonSiegel`, for the Nelson-Siegel model that fits the empirical form of the yield curve with a prespecified functional form of the spot rates which is a function of the time to maturity of the bonds.

The Nelson-Siegel model represents a dynamic three-factor model: level, slope, and curvature. However, the Nelson-Siegel factors are unobserved, or latent, which allows for measurement error, and the associated loadings have economic restrictions (forward rates are always positive, and the discount factor approaches zero as maturity increases). For more information, see “Zero-coupon yield curves: technical documentation,” *BIS Papers*, Bank for International Settlements, Number 25, October 2005.

Example

This example uses `IRFunctionCurve` to model the default-free term structure of interest rates in the United Kingdom.

Load the data.

```
load ukdata20080430
```

Convert repo rates to be equivalent zero-coupon bonds.

```
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);
```

Aggregate the data.

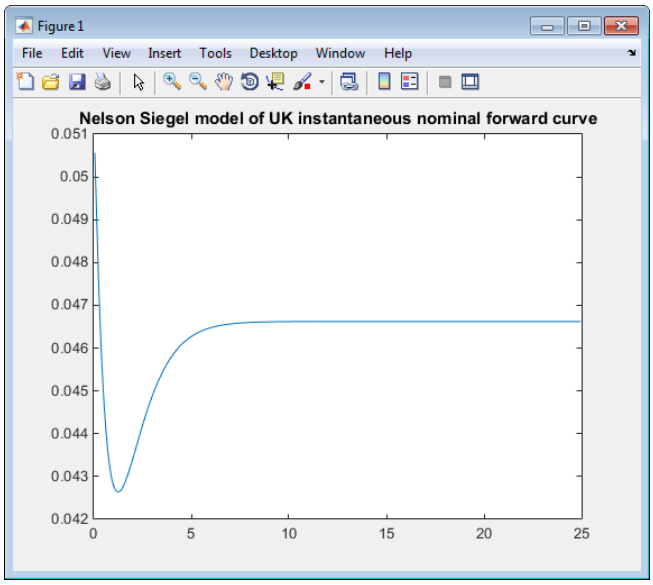
```
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
CurveSettle = datenum('30-Apr-2008');
```

The `IRFunctionCurve` object provides the capability to fit a Nelson-Siegel curve to observed market data with the `fitNelsonSiegel` function. The fitting is done by calling the function `lsqnonlin`. The `fitNelsonSiegel` function has required inputs of `Type`, `Settle`, and a matrix of instrument data.

```
NSModel = IRFunctionCurve.fitNelsonSiegel('Zero',CurveSettle,...
Instruments,'Compounding',-1,'InstrumentPeriod',InstrumentPeriod);
```

Plot the Nelson-Siegel interest-rate curve for forward rates.

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
NSForwardRates = getForwardRates(NSModel, PlottingDates);
plot(TimeToMaturity,NSForwardRates)
title('Nelson Siegel model of UK instantaneous nominal forward curve')
```



Fitting IRFunctionCurve Object Using Svensson Method

Use the function, `fitSvensson`, for the Svensson model to improve the flexibility of the curves and the fit for a Nelson-Siegel model. In 1994, Svensson extended Nelson and Siegel's function by adding a further term that allows for a second "hump." The extra precision is achieved at the cost of adding two more parameters, $\beta 3$ and $\tau 2$, which have to be estimated.

Example

In this example of using the `fitSvensson` function, an `IRFitOptions` structure, previously defined using `IRFitOptions`, is used. Thus, you must specify `FitType`, `InitialGuess`, `UpperBound`, `LowerBound`, and the `OptOptions` optimization parameters for `lsqnonlin`.

Load the data.

```
load ukdata20080430
```

Convert repo rates to be equivalent zero coupon bonds.

```
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);
```

Aggregate the data.

```
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
CurveSettle = datenum('30-Apr-2008');
```

Define `OptOptions` for `IRFitOptions`.

```
OptOptions = optimoptions('lsqnonlin','MaxFunEvals',1000);
fIRFitOptions = IRFitOptions([5.82 -2.55 -.87 0.45 3.9 0.44],...
'FitType','durationweightedprice','OptOptions',OptOptions,...
'LowerBound',[0 -Inf -Inf -Inf 0 0],'UpperBound',[Inf Inf Inf Inf Inf Inf]);
```

Fit the interest-rate curve using a Svensson model.

```
SvenssonModel = IRFunctionCurve.fitSvensson('Zero',CurveSettle,...
Instruments,'IRFitOptions', fIRFitOptions, 'Compounding',-1,...
'InstrumentPeriod',InstrumentPeriod)

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to
its initial value is less than the default value of the function tolerance.

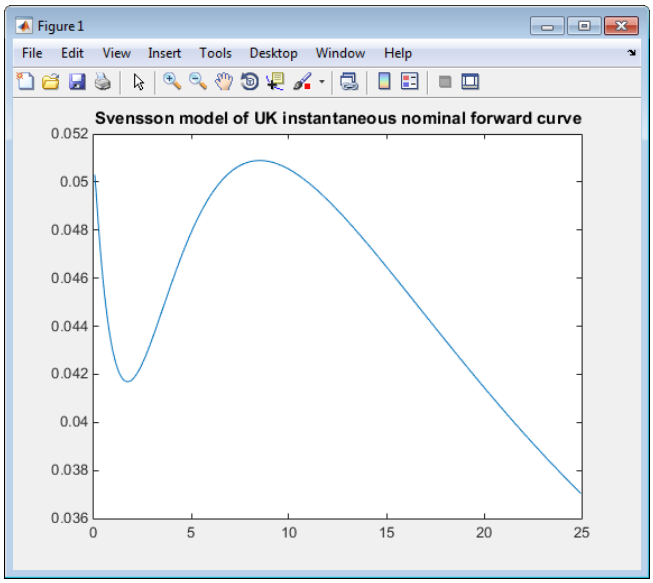
SvenssonModel =

             Type: Zero
           Settle: 733528 (30-Apr-2008)
      Compounding: -1
            Basis: 0 (actual/actual)
```

The status message, output from `lsqnonlin`, indicates that the optimization to find parameters for the Svensson equation terminated successfully.

Plot the Svensson interest-rate curve for forward rates.

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
SvenssonForwardRates = getForwardRates(SvenssonModel, PlottingDates);
plot(TimeToMaturity,SvenssonForwardRates)
title('Svensson model of UK instantaneous nominal forward curve')
```



Fitting IRFunctionCurve Object Using Smoothing Spline Method

Use the function, `fitSmoothingSpline`, to model the term structure with a spline, specifically, the term structure represents the forward curve with a cubic spline.

Note You must have a license for Curve Fitting Toolbox software to use the `fitSmoothingSpline` function.

Example

The `IRFunctionCurve` object is used to fit a smoothing spline representation of the forward curve with a penalty function. Required inputs for `fitSmoothingSpline` are `Type`, `Settle`, the matrix of `Instruments`, and `Lambdafun`, a function handle containing the penalty function

Load the data.

```
load ukdata20080430
```

Convert repo rates to be equivalent zero coupon bonds.

```
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);
```

Aggregate the data.

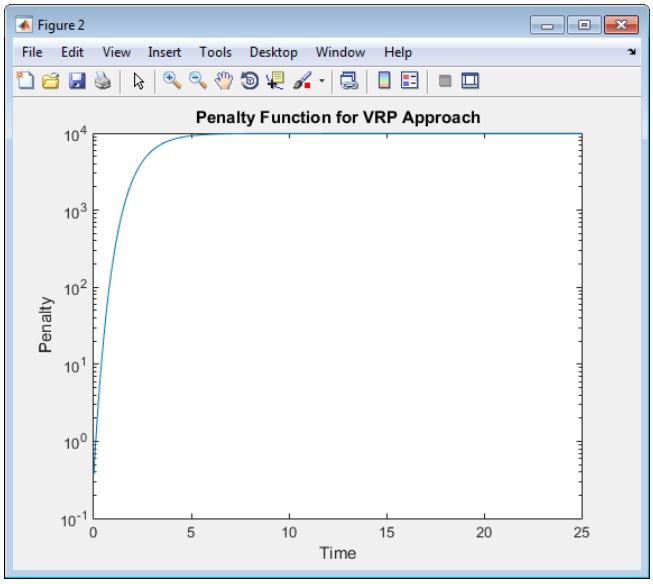
```
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
CurveSettle = datenum('30-Apr-2008');
```

Choose parameters for `Lambdafun`.

```
L = 9.2;
S = -1;
mu = 1;
```

Define the `Lambdafun` penalty function.

```
lambdafun = @(t) exp(L - (L-S)*exp(-t/mu));
t = 0:.1:25;
y = lambdafun(t);
figure
semilogy(t,y);
title('Penalty Function for VRP Approach')
ylabel('Penalty')
xlabel('Time')
```

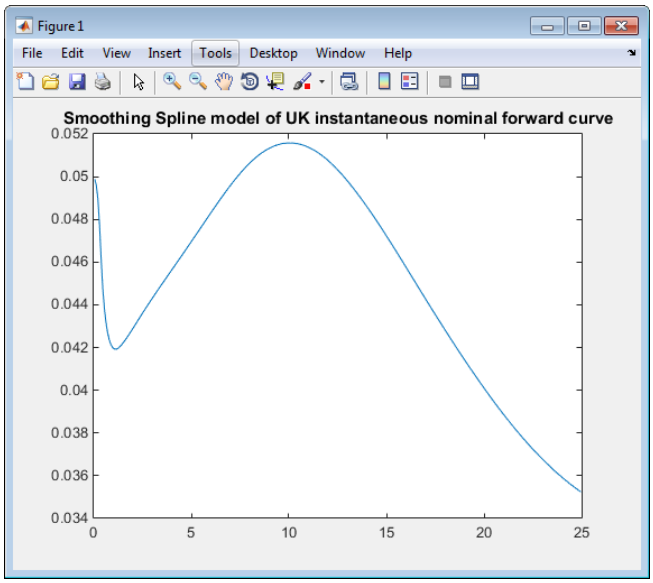


Use the `fitSmoothingSpline` function to fit the interest-rate curve and model the `Lambdafun` penalty function.

```
VRPModel = IRFunctionCurve.fitSmoothingSpline('Forward',CurveSettle,...
Instruments,lambdafun,'Compounding',-1, 'InstrumentPeriod',InstrumentPeriod);
```

Plot the smoothing spline interest-rate curve for forward rates.

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
VRPForwardRates = getForwardRates(VRPModel, PlottingDates);
plot(TimeToMaturity,VRPForwardRates)
title('Smoothing Spline model of UK instantaneous nominal forward curve')
```



Using fitFunction to Create Custom Fitting Function

When using an `IRFunctionCurve` object, you can create a custom fitting function with the `fitFunction` function. To use `fitFunction`, you must define a `FunctionHandle`. In addition, you must also use `IRFitOptions` to define an `IRFitOptions` object to support an `InitialGuess` for the parameters of the curve function.

Example

The following example demonstrates the use of `fitFunction` with a `FunctionHandle` and an `IRFitOptions` object.

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
CurveSettle = datenum('30-Apr-2008');
```

Define the `FunctionHandle`.

```
functionHandle = @(t,theta) polyval(theta,t);
```

Define the `OptOptions` for `IRFitOptions`.

```
OptOptions = optimoptions('lsqnonlin','display','iter');
```

Define `fitFunction`.

```
CustomModel = IRFunctionCurve.fitFunction('Zero', CurveSettle, ...
functionHandle,Instruments, IRFitOptions([.05 .05 .05],'FitType','price',...
'OptOptions',OptOptions));
```

```
                                        Norm of      First-order
 Iteration  Func-count     f(x)          step          optimality   CG-iterations
     0          4         38036.7                     4.92e+04
     1          8         38036.7            10       4.92e+04            0
     2         12         38036.7           2.5       4.92e+04            0
```

```

Fitting Interest-Rate Curve Functions

This example shows how to use `IRFunctionCurve` objects to model the term structure of interest rates (also referred to as the yield curve). This can be contrasted with modeling the term structure with vectors of dates and data and interpolating between the points (which can currently be done with the function `prbyzero`). The term structure can refer to at least three different curves: the discount curve, zero curve, or forward curve.

The `IRFunctionCurve` object allows you to model an interest-rate curve as a function.

This example explores using an `IRFunctionCurve` object to model the default-free term structure of interest rates in the United Kingdom. Three different forms for the term structure are implemented and are discussed in more detail later:

- Nelson-Siegel
- Svensson
- Smoothing Cubic Spline with a so-called Variable Roughness Penalty (VRP)

Choosing the Data

The first question in modeling the yield curve is what data should be used. To model a default-free yield curve, default-free, option-free market instruments must be used. The most significant component of the data is UK Government Bonds (known as Gilts). Historical data is retrieved from the following site:

https://www.dmo.gov.uk

Repo data is used to construct the short end of the yield curve. Repo data is retrieved from the following site:

https://www.ukfinance.org.uk/

Note also that the data must be specified as a matrix where the columns are `Settle`, `Maturity`, `CleanPrice`, and `CouponRate` and that instruments must be bonds or synthetically converted to bonds.

Market data for a close date of April 30, 2008, has been downloaded and saved to the following data file (`ukdata20080430`), which is loaded into MATLAB® with the following command:

```
% Load the data
load ukdata20080430

% Convert repo rates to be equivalent zero coupon bonds
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);

% Aggregate the data
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
```

```
CurveSettle = datenum('30-Apr-2008');
```

Fit Nelson-Siegel Model to Market Data

The Nelson-Siegel model proposes that the instantaneous forward curve can be modeled with the following:

$$f = \beta_0 + \beta_1 e^{\frac{-m}{\tau}} + \beta_2 e^{\frac{-m}{\tau}} \frac{m}{\tau}$$

This can be integrated to derive an equation for the zero curve (see [6] for more information on the equations and the derivation):

$$s = \beta_0 + (\beta_1 + \beta_2)\frac{\tau}{m}(1 - e^{\frac{-m}{\tau}}) - \beta_2 e^{\frac{-m}{\tau}}$$

See [1 on page 9-28] for more information.

The `IRFunctionCurve` object provides the capability to fit a Nelson Siegel curve to observed market data with the `fitNelsonSiegel` method. The fitting is done by calling the Optimization Toolbox™ function `lsqnonlin`.

The `fitNelsonSiegel` function has required inputs for Curve `Type`, Curve `Settle`, and a matrix of instrument data.

Optional input arguments, specified in name-value pair argument, are:

- `IRFitOptions` structure: Provides the capability to choose which quantity to be minimized (price, yield, or duration weighted price) and other optimization parameters (for example, upper and lower bounds for parameters).
- Curve `Compounding` and `Basis` (day-count convention)
- Additional instrument parameters, `Period`, `Basis`, `FirstCouponDate`, and so on.

```
NSModel = IRFunctionCurve.fitNelsonSiegel('Zero',CurveSettle,...
    Instruments,'InstrumentPeriod',InstrumentPeriod);
```

Fit Svensson Model

A very similar model to the Nelson-Siegel model is the Svensson model, which adds two additional parameters to account for greater flexibility in the term structure. This model proposes that the forward rate can be modeled with the following form:

$$f = \beta_0 + \beta_1 e^{\frac{-m}{\tau_1}} + \beta_2 e^{\frac{-m}{\tau_1}} \frac{m}{\tau_1} + \beta_3 e^{\frac{-m}{\tau_2}} \frac{m}{\tau_2}$$

As above, this can be integrated to derive an equation for the zero curve:

$$s = \beta_0 + \beta_1 (1 - e^{\frac{-m}{\tau_1}})(-\frac{\tau_1}{m}) + \beta_2 ((1 - e^{\frac{-m}{\tau_1}})\frac{\tau_1}{m} - e^{\frac{m}{\tau_1}}) + \beta_3 ((1 - e^{\frac{-m}{\tau_2}})\frac{\tau_2}{m} - e^{\frac{m}{\tau_2}})$$

See [2 on page 9-28] for more information.

Fitting the parameters to this model proceeds in a similar fashion to the Nelson-Siegel model using the `fitSvensson` function.

```
SvenssonModel = IRFunctionCurve.fitSvensson('Zero',CurveSettle,...
    Instruments,'InstrumentPeriod',InstrumentPeriod);
```

Fit Smoothing Spline

The term structure can also be modeled with a spline, specifically, one way to model the term structure is by representing the forward curve with a cubic spline. To ensure that the spline is sufficiently smooth, a penalty is imposed relating to the curvature (second derivative) of the spline:

$$\sum_{i=1}^{N}[\frac{P_i - \widehat{P}_i(f)}{D_i}]^2 + \int_0^M \lambda_t(m)[f''(m)]^2 dm$$

where the first term is the difference between the observed price *P* and the predicted price, *P_hat*, (weighted by the bond's duration, *D*) summed over all bonds in the data set, and the second term is the penalty term (where *lambda* is a penalty function and *f* is the spline).

See [3 on page 9-28], [4 on page 9-28], [5 on page 9-29] below.

There have been different proposals for the specification of the penalty function *lambda*. One approach, advocated by [4 on page 9-28], and currently used by the UK Debt Management Office, is a penalty function of the following form:

$$log(\lambda(m)) = L - (L - S)e^{\frac{-m}{\mu}}$$

The parameters *L*, *S*, and *mu* are typically estimated from historical data.

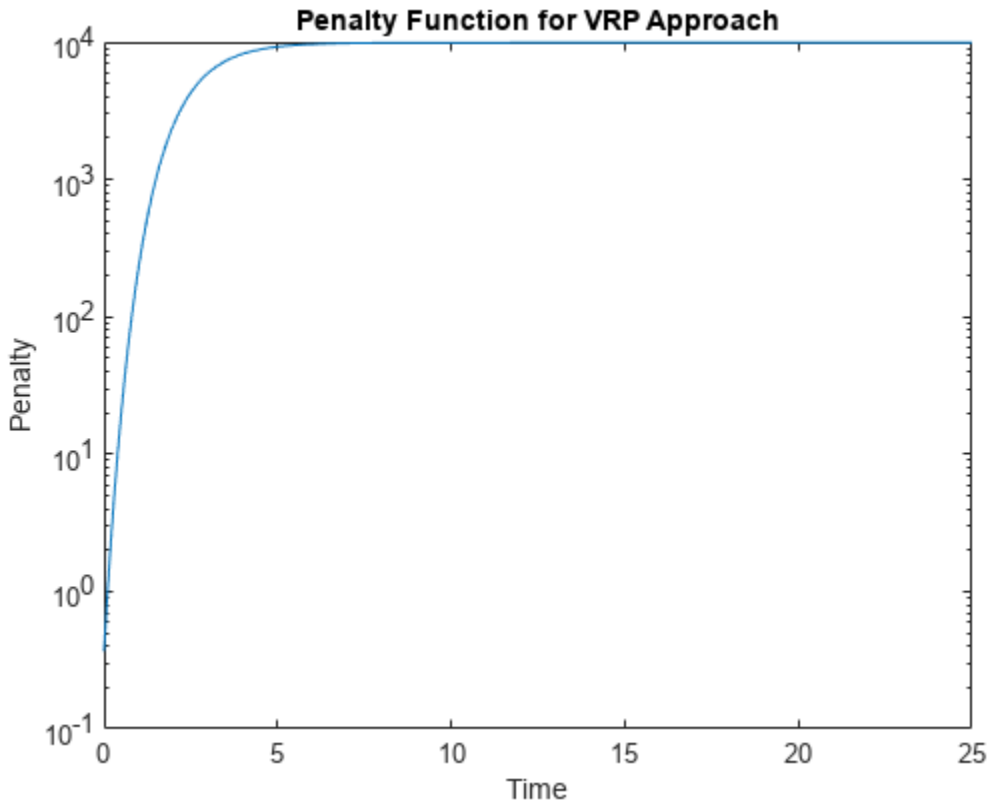
The `IRFunctionCurve` object can be used to fit a smoothing spline representation of the forward curve with a penalty function using the function `fitSmoothingSpline`.

Required inputs, like for the functions above, are a `CurveType`, Curve`Settle`, `Instruments` matrix, and a function handle (`Lambdafun`) containing the penalty function.

The optional parameters are similar to `fitNelsonSiegel` and `fitSvensson`.

```
% Parameters chosen to be roughly similar to [4] below.
L = 9.2;
S = -1;
mu = 1;

lambdafun = @(t) exp(L - (L-S)*exp(-t/mu)); % Construct penalty function
t = 0:.1:25; % Construct data to plot penalty function
y = lambdafun(t);
figure
semilogy(t,y);
title('Penalty Function for VRP Approach')
ylabel('Penalty')
xlabel('Time')
```



```
VRPModel = IRFunctionCurve.fitSmoothingSpline('Forward',CurveSettle,...
    Instruments,lambdafun,'Compounding',-1,...
    'InstrumentPeriod',InstrumentPeriod);
```

Use Fitted Curves and Plot Results

Once a curve is created, functions are used to extract the Forward and Zero Rates and the Discount Factors. This curve can also be converted into a `RateSpec` structure using the `toRateSpec` function. The `RateSpec` can then be used with many other functions in the Financial Instruments Toolbox™

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);

NSForwardRates = NSModel.getForwardRates(PlottingDates);
SvenssonForwardRates = SvenssonModel.getForwardRates(PlottingDates);
VRPForwardRates = VRPModel.getForwardRates(PlottingDates);

figure
hold on
plot(TimeToMaturity,NSForwardRates,'r')
plot(TimeToMaturity,SvenssonForwardRates,'g')
plot(TimeToMaturity,VRPForwardRates,'b')
title('UK Instantaneous Nominal Forward Curve')
xlabel('Years Ahead')
legend({'Nelson Siegel','Svensson','VRP'})
```

Converting an IRDataCurve or IRFunctionCurve Object

In this section...

Introduction

The `IRDataCurve` and `IRFunctionCurve` objects for interest-rate curves support conversion to:

- A `RateSpec` structure.

  The `RateSpec` generated from an `IRDataCurve` or `IRFunctionCurve` object, using the `toRateSpec` function, is identical to the `RateSpec` structure created with `intenvset` using Financial Instruments Toolbox software.
- A vector of dates and data from an `IRDataCurve` object

  The vector of dates and data is acceptable to `prbyzero`, `bkcall`, `bkput`, `tfutbyprice`, and `tfutbyyield` or any function that requires a term structure of interest rates.

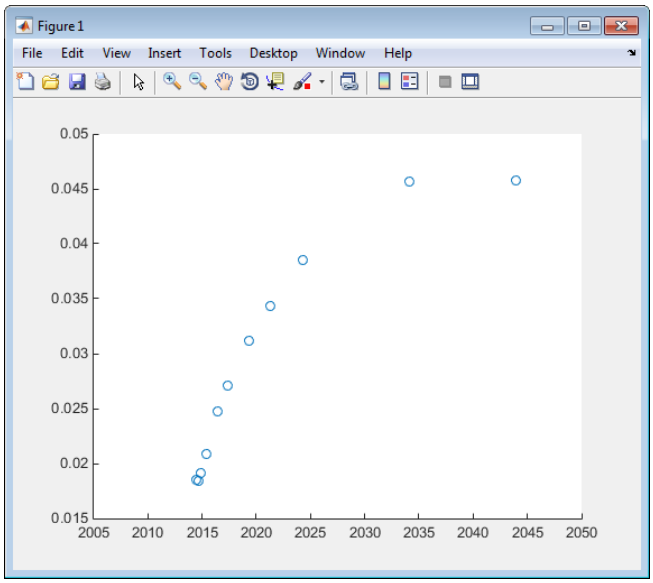
Using the toRateSpec Function

To convert an `IRDataCurve` or `IRFunctionCurve` object to a `RateSpec` structure, you must first create an interest-rate curve object. Then, use the `toRateSpec` function for an `IRDataCurve` object or the`toRateSpec` function for an `IRFunctionCurve` object.

Example

Create a data vector from the following data: `https://www.ustreas.gov/offices/domestic-finance/debt-management/interest-rate/yield.shtml`.

```
Data = [1.85 1.84 1.91 2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = daysadd(today,[30 90 180 360 2*360 3*360 5*360 7*360 10*360 20*360 30*360],2);
scatter(Dates,Data)
datetick
```



Create an `IRDataCurve` interest-rate curve object.

```
rr = IRDataCurve('Zero',today,Dates,Data);
```

Convert to a `RateSpec`.

```
toRateSpec(rr, today+30:30:today+365)
```

```
ans =
          FinObj: 'RateSpec'
      Compounding: 2
             Disc: [12x1 double]
            Rates: [12x1 double]
         EndTimes: [12x1 double]
       StartTimes: [12x1 double]
         EndDates: [12x1 double]
       StartDates: 733569
    ValuationDate: 733569
            Basis: 0
     EndMonthRule: 1
```

Using Vector of Dates and Data

You can use the `getZeroRates` function for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `prbyzero` in Financial Toolbox software and `bkcall`, `bkput`, `tfutbyprice`, and `tfutbyyield` in Financial Instruments Toolbox software.

Example

This is an example of using an `IRDataCurve` object with the `getZeroRates` function with `prbyzero`.

```
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = daysadd(today,[360 2*360 3*360 5*360 7*360 10*360 20*360 30*360],1);
irdc = IRDataCurve('Zero',today,Dates,Data,'InterpMethod','pchip');
Maturity = daysadd(today,8*360,1);
CouponRate = .055;
```

```
ZeroDates = daysadd(today,180:180:8*360,1);
ZeroRates = getZeroRates(irdc, ZeroDates);
BondPrice = prbyzero([Maturity CouponRate], today, ZeroRates, ZeroDates)
```

```
BondPrice =
  113.9250
```

Numerix Workflows

Working with Simple Numerix Trades

This example shows how to price a callable reverse floater using Numerix CROSSASSET.

Initialize Numerix environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;

n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =

              Path: 'i:\NumeriX_java_10_3_0\data'
    RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
        Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
           Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
       LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
       MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
       FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
        TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
        Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

Create a market.

```
quotes = java.util.HashMap;
quotes.put('IR.USD-LIBOR-3M.SWAP-1Y.MID', 0.0066056);
quotes.put('IR.USD-LIBOR-3M.SWAP-10Y.MID', 0.022465005);
quotes.put('IR.USD-LIBOR-3M.SWAP-20Y.MID', 0.027544995);
market = Market('EOD_14-NOV-2011', DateExtensions.date('14-Nov-2011'), quotes.entrySet);
```

Define a trade instance for a callable reverse floater based on instrument template located in the `Repository`.

```
tradeDescriptor = 'TRADE.IR.CALLABLEREVERSEFLOATER';
tradeParameters = java.util.HashMap;
tradeParameters.put('Trade ID','1001');
tradeParameters.put('Quote Type', 'MID');
tradeParameters.put('Currency', 'USD');
tradeParameters.put('Notional', 1000000.0);
tradeParameters.put('Effective Date', DateExtensions.date('1-Dec-2011'));
tradeParameters.put('Termination Date', DateExtensions.date('1-Dec-2021'));
tradeParameters.put('IR Index', 'LIBOR');
tradeParameters.put('IR Index Tenor', '3M');
tradeParameters.put('Structured Freq', '3M');
tradeParameters.put('Structured Side', 'Receive');
tradeParameters.put('Structured Coupon Floor', 0.0);
tradeParameters.put('Structured Coupon UpBd', 0.08);
tradeParameters.put('StructuredCoupon Multiplier', 1.4);
tradeParameters.put('Structured Coupon Cap', 0.05);
tradeParameters.put('Structured Basis', 'ACT/360');
tradeParameters.put('Funding Freq', '3M');
tradeParameters.put('Funding Side', 'Pay');
tradeParameters.put('Funding Spread', 0.003);
tradeParameters.put('Funding Basis', 'ACT/360');
tradeParameters.put('Call Start Date', DateExtensions.date('1-Dec-2013'));
tradeParameters.put('Call End Date', DateExtensions.date('1-Dec-2020'));
tradeParameters.put('Option Side', 'Short');
tradeParameters.put('Option Type', 'Right to Terminate');
tradeParameters.put('Call Frequency', '3M');
tradeParameters.put('Model', 'IR.USD-LIBOR-3M.MID.DET');
tradeParameters.put('Method', 'BackwardAnalytic');
```

Create the trade instance.

```
trade = RepositoryExtensions.createTradeInstance(n.Repository, tradeDescriptor, tradeParameters)
```

Price the trade.

```
results = CalculationContextExtensions.calculate(n.Context, trade, market, Request.getAll);
```

Parse the results for MATLAB and display.

```
r = n.parseResults(results)
disp([r.Name r.Category r.Currency r.Data])
```

```
r =

    Category: {13x1 cell}
    Currency: {13x1 cell}

Working with Advanced Numerix Trades

This example shows how to price multiple trades from MATLAB using Numerix CROSSASSET.

Initialize Numerix environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;

n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =

             Path: 'i:\NumeriX_java_10_3_0\data'
    RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
        Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
           Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
       LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
       MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
       FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
        TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
        Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

Specify the hybrid model for multiple trades.

```
hySpec = HybridModelSpecification;
hySpec.addHW1F('IR-USD', 'USD', 'LIBOR', '3M', 'MeanReversion(0.5),DiagonalSwaption(ATM, 10Y)');
hySpec.addHW1F('IR-EUR', 'EUR', 'EURIBOR', '6M', 'MeanReversion(0.5),DiagonalSwaption(ATM, 10Y)');
hySpec.addFXBlack('FX-USDEUR', 'USD', 'EUR', 'LIBOR', '3M', 'EURIBOR', '6M', 'StrikeFXEuropean(ATM, 10Y)');
% 5 Specify the factor correlations.
hyCorrelations = HybridModelCorrelationMatrix(hySpec);
hyCorrelations.add('IR-USD', 'IR-EUR', 0.5);
hyCorrelations.add('IR-USD', 'FX-USDEUR', 0.25);
hyCorrelations.add('IR-EUR', 'FX-USDEUR', 0.25);

% Specify the model parameters.
hybridModelParameters = java.util.HashMap;
hybridModelParameters.put('Quote Type', 'MID');
hybridModelParameters.put('Payout Currency', 'USD');
hybridModelParameters.put('Specification', hySpec);
hybridModelParameters.put('Correlations', hyCorrelations);
```

Specify exposure calculation parameters.

```
observationDates = CustomObservationSchedule;
observationDates.add(DateExtensions.date(2011, 12, 1));
for y = 2012:2013
  for m = 1:12
    observationDates.add(DateExtensions.date(y, m, 1));
  end
end

exposureParameters = java.util.HashMap;
exposureParameters.put('Model ID', 'HYBRID');
exposureParameters.put('Observation Dates', observationDates);
```

Define the first trade instance.

```
tradeParameters1 = java.util.HashMap;
tradeParameters1.put('Trade ID', 'RVFL1001');
tradeParameters1.put('Quote Type', 'MID');
tradeParameters1.put('Currency', 'USD');
tradeParameters1.put('Notional', 1000000.0);
tradeParameters1.put('Effective Date', DateExtensions.date('1-Dec-2011'));
tradeParameters1.put('Termination Date', DateExtensions.date('1-Dec-2021'));
tradeParameters1.put('IR Index', 'LIBOR');
tradeParameters1.put('IR Index Tenor', '3M');
tradeParameters1.put('Structured Freq', '3M');
tradeParameters1.put('Structured Side', 'Receive');
tradeParameters1.put('Structured Coupon Floor', 0.0);
tradeParameters1.put('Structured Coupon UpBd', 0.08);
tradeParameters1.put('StructuredCoupon Multiplier', 1.4);
tradeParameters1.put('Structured Coupon Cap', 0.05);
tradeParameters1.put('Structured Basis', 'ACT/360');
```

```
tradeParameters1.put('Funding Freq', '3M');
tradeParameters1.put('Funding Side', 'Pay');
tradeParameters1.put('Funding Spread', 0.003);
tradeParameters1.put('Funding Basis', 'ACT/360');
tradeParameters1.put('Call Start Date', DateExtensions.date('1-Dec-2013'));
tradeParameters1.put('Call End Date', DateExtensions.date('1-Dec-2020'));
tradeParameters1.put('Option Side', 'Short');
tradeParameters1.put('Option Type', 'Right to Terminate');
tradeParameters1.put('Call Frequency', '3M');
tradeParameters1.put('Model', 'HYBRID');
tradeParameters1.put('Method', 'BackwardMC');
tradeInstance1 = RepositoryExtensions.createTradeInstance(n.Repository, 'TRADE.IR.CALLABLEREVERSEFLOATER', tradeParameters1);
```

Define the second trade instance.

```
tradeParameters2 = java.util.HashMap;
tradeParameters2.put('Trade ID', 'CASHDEP1001');
tradeParameters2.put('Quote Type', 'MID');
tradeParameters2.put('Currency', 'USD');
tradeParameters2.put('Coupon Rate', 0.05);
tradeParameters2.put('Yield', 0.044);
tradeParameters2.put('Notional', 100.0);
tradeParameters2.put('Effective Date', DateExtensions.date('1-Apr-2012'));
tradeParameters2.put('Maturity', DateExtensions.date('1-Apr-2013'));
tradeParameters2.put('IR Index', 'LIBOR');
tradeParameters2.put('IR Index Tenor', '3M');
tradeParameters2.put('Model', 'HYBRID');
tradeParameters2.put('Method', 'BACKWARDMC');
tradeInstance2 = RepositoryExtensions.createTradeInstance(n.Repository, 'IR.CASHDEPOSIT', tradeParameters2);
```

Create the third trade instance.

```
tradeParameters3 = java.util.HashMap;
tradeParameters3.put('Trade ID', 'FXFWD1001');
tradeParameters3.put('Quote Type', 'MID');
tradeParameters3.put('Base Currency', 'USD');
tradeParameters3.put('Term Currency', 'EUR');
tradeParameters3.put('Delivery Date', DateExtensions.date('1-Jun-2012'));
tradeParameters3.put('Contract FX Forward Rate', 80.5);
tradeParameters3.put('Base Notional', 10000000.0);
tradeParameters3.put('Base IR Index', 'LIBOR');
tradeParameters3.put('Term IR Index', 'EURIBOR');
tradeParameters3.put('Base IR Index Tenor', '3m');
tradeParameters3.put('Term IR Index Tenor', '6m');
tradeParameters3.put('Calendar', 'NewYork Target');
tradeParameters3.put('Spot Lag', '2bd');
tradeParameters3.put('Model', 'HYBRID');
tradeParameters3.put('Method', 'BACKWARDMC');
tradeInstance3 = RepositoryExtensions.createTradeInstance(n.Repository, 'FX.FXFORWARD', tradeParameters3);
```

Set `tradeInstances` for all three trade instances.

```
tradeInstances = java.util.ArrayList;
tradeInstances.add(tradeInstance1);
tradeInstances.add(tradeInstance2);
tradeInstances.add(tradeInstance3);
n.Parameters.setInstances(tradeInstances);
```

Add a custom lookup so these trade instances reference the hybrid model.

```
n.Parameters.getLookups.add(0,ExactLookupRule('HYBRID','MODEL.HYBRID',hybridModelParameters.entrySet));
```

Add another custom lookup so that exposure report has parameters defined.

```
n.Parameters.getLookups.add(1,ExactLookupRule('RISK.REPORT.EXPOSURE','REPORT.EXPOSURE',exposureParameters.entrySet));
```

Perform the calculation.

```
results = n.Context.calculate(n.Parameters, Request.getExposure);
```

Parse the results for MATLAB and display.

```
r = n.parseResults(results)

disp([r.Trade(2) r.Market(2)])
disp([r.Results{2}.Name r.Results{2}.Category r.Results{2}.Currency r.Results{2}.Data])
```

```
disp([r.Results{2}.Name{1}])
disp([r.Results{2}.Data{1}])
```

```
r =

```

Plot the results for the second trade instance, `CASHDEP1001`, with the corresponding Exposure Discount Factors.

```
figure('Tag','NumerixAdvancedRiskExample');

for ii=1:3
   % Get dates
   dates = cell2mat(r.Results{ii}.Data{expIndex}(2:end,1));
   dates = dates(:,4:end);
   dates = floor(datenum(dates));
```

```
    % Get exposures
    mtm = cell2mat(r.Results{ii}.Data{expIndex}(2:end,2:end))';
    exposures = max(0,mtm);  % Exposure at contract level, no netting
    EE = mean(exposures);  % Expected Exposure
    PFE = prctile(exposures,95);  % Potential Future Exposure
    subplot(3,1,ii)
    plot(dates,EE,dates,PFE)
    title(r.Trade{ii})
    datetick
end
```

Use Numerix to Price Cash Deposits

This example shows how to use the Numerix CROSSASSET API to price a cash deposit from MATLAB. The trade parameters are read from the `Cashdeposit1.csv` in the `Numerix Data Trades` folder.

Initialize Numerix environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;

n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =

              Path: 'i:\NumeriX_java_10_3_0\data'
    RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
        Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
           Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
       LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
       MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
       FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
        TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
        Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

Create a market.

```
market = Market('EOD_16-APR-2012', DateExtensions.date('16-APR-2012'), []);
```

Read the `Cashdeposit1.csv` file from the `Numerix Trades` folder.

```
[~,~,tradeInfo] = xlsread([n.TradesPath '\Cashdeposit1.csv'])
```

```
tradeInfo =

    'Template'          'String'      'TRADE.IR.CASHDEPOSIT'
    'Trade ID'          'ID'          'CASHDEP1001'
    'Quote Type'        'String'      'MID'
    'Effective Date'    'Date'        '4/1/2012'
    'Maturity'          'Date'        '4/1/2013'
    'Notional'          'Double'      [                100]
    'Currency'          'Currency'    'USD'
    'Coupon Rate'       'Double'      [             0.0500]
    'Yield'             'Double'      [             0.0440]
    'IR Index'          'String'      'Libor'
    'IR Index Tenor'    'Tenor'       '3m'
```

Define a trade instance from the imported `CASHDEP1001` instrument.

```
tradeDescriptor = tradeInfo{1,3};
tradeParameters = java.util.HashMap;
numTradeInfoFields = size(tradeInfo,1);
for i = 2:numTradeInfoFields
  switch tradeInfo{i,2}
    case {'DATE','Date'}
      tradeParameters.put(tradeInfo{i,1},DateExtensions.date(datestr(tradeInfo{i,3},'dd-mmm-yyyy')));
    otherwise
      tradeParameters.put(tradeInfo{i,1},tradeInfo{i,3});
  end
end
```

Create the trade instance.

```
trade = RepositoryExtensions.createTradeInstance(n.Repository, tradeDescriptor, tradeParameters);
```

Price the trade.

```
results = CalculationContextExtensions.calculate(n.Context, trade, market, Request.getAll);
```

Parse the results for MATLAB and display.

```
r = n.parseResults(results)
disp([r.Name r.Category r.Currency r.Data])
```

```
 r =

    Category: {9x1 cell}
    Currency: {9x1 cell}
        Name: {9x1 cell}
        Data: {9x1 cell}

    'Modified Duration'     'Price'    ''       [   0.9349]
    'Accrued Interest'      'Price'    'USD'    [   0.2083]
    'Reporting Currency'    'Price'    ''       'USD'

Use Numerix for Interest-Rate Risk Assessment

This example shows how to use the Numerix CROSSASSET API for interest-rate curve stripping for risk assessment.

Initialize Numerix environment.

```
import com.numerix.integration.*;
import com.numerix.integration.implementation.*;

n = numerix('i:\NumeriX_java_10_3_0\data')
```

```
n =

             Path: 'i:\NumeriX_java_10_3_0\data'
    RepositoryPath: 'i:\NumeriX_java_10_3_0\data\Repository'
        Repository: [1x1 com.numerix.integration.implementation.FileSystemRepository]
           Context: [1x1 com.numerix.integration.implementation.LocalCalculationContext]
       LookupsPath: 'i:\NumeriX_java_10_3_0\data\Data\LookupRules'
       MarketsPath: 'i:\NumeriX_java_10_3_0\data\Data\Markets'
       FixingsPath: 'i:\NumeriX_java_10_3_0\data\Data\Fixings'
        TradesPath: 'i:\NumeriX_java_10_3_0\data\Data\Trades'
        Parameters: [1x1 com.numerix.integration.implementation.CalculationParameters]
```

Specify the current market associated with the Numerix CROSSASSET environment.

```
markets = get(n.Parameters,'Markets');
currentMarket = markets.get(0);
outInstance = RefObject(currentMarket);
```

Define the interest-rate curve key `IR.USD-LIBOR-3M.MID`.

```
n.Context.tryResolveId('IR.USD-LIBOR-3M.MID',outInstance);
currentInstance = outInstance.argvalue;
```

Set the instance and market.

```
n.Parameters.setMarkets(java.util.Arrays.asList(currentMarket));
n.Parameters.setInstances(java.util.Arrays.asList(currentInstance));
```

Calculate the interest-rate curve stripping.

```
results = n.Context.calculate(n.Parameters,Request.getAll);
```

The calculation returns the results from stripping the interest-rate curve for `IR.USD-LIBOR-3M.MID`. Parse the results for MATLAB and display.

```
% IR.USD-LIBOR-3M.MID.
r = n.parseResults(results)

disp([r.Instance r.Market])
disp([r.Results{1}.Name r.Results{1}.Category r.Results{1}.Currency r.Results{1}.Data])
disp([r.Results{1}.Name{1}])
disp([r.Results{1}.Data{1}])
```

```
r =

    Instance: {'IR.USD-LIBOR-3M.MID'}
      Market: {'EOD'}
     Results: {[1x1 struct]}

 'IR.USD-LIBOR-3M.MID'    'EOD'

'Curve Info'    ''    ''    {30x3 cell}
'Messages'      ''    ''    { 7x1 cell}

Numerix CROSSASSET Interface Workflow Example Using Matrix, Data, and Call Objects

This example shows how to use the Numerix CROSSASSET API to create and price a vanilla European option.

Construct a `numerixCrossAsset` object for Java® or C++.

For the Java SDK API:

```
c = numerixCrossAsset
```

```
 c =

numerixCrossAsset with properties:

Application: [1x1 com.numerix.pro.Application]
ApplicationWarning: [1x1 com.numerix.pro.ApplicationWarning]
```

For the C++ SDK API on Windows®:

```
c = numerixCrossAsset(true)
```

```
 c =

numerixCrossAsset with properties:

Application: [1×1 fininst.internal.NumerixCAIL]
ApplicationWarning: []
```

Create and register data as a Matrix with the Numerix Cross Asset Integration Layer Application using the `applicationMatrix` method.

```
rowData = [41992, 42020, 42449, 42905, 43115];
colData = [390, 395, 400, 405];
volData = [0.35778, 0.35132, 0.34394, 0.33582;...
           0.33405, 0.32819, 0.32669, 0.31904;...
           0.31576, 0.31235, 0.30371, 0.30261;...
           0.29391, 0.29366, 0.28962, 0.28932;...
           0.28787, NaN,     0.28347, NaN    ];
applicationMatrix(c,'BYSTRIKEVOLDATA',rowData,colData,volData);
```

Create and register the yield curve data with the Application object. Use a table for optimal display purposes. Dates must be relative to '01/01/1900' and the Numerix Cross Asset Integration Layer API supports date number representation only. MATLAB datetime's get converted automatically, otherwise date numbers must be input and based relative to '01/01/1900'.

```
dates = datetime({'18-Feb-2014';'20-May-2014';'18-Jun-2014';'16-Jul-2014';
                  '20-Aug-2014';'17-Sep-2014';'15-Oct-2014';'19-Nov-2014';
                  '17-Dec-2014';'18-Mar-2015';'17-Jun-2015';'16-Sep-2015';
                  '16-Dec-2015';'16-Mar-2016';'15-Jun-2016';'21-Sep-2016';
                  '21-Dec-2016';'15-Mar-2017';'20-Feb-2018';'20-Feb-2019';
                  '20-Feb-2020';'22-Feb-2021';'22-Feb-2022';'21-Feb-2023';
                  '20-Feb-2024';'20-Feb-2025';'20-Feb-2026';'20-Feb-2029';
                  '21-Feb-2034';'22-Feb-2039';'22-Feb-2044';'20-Feb-2054';
                  '20-Feb-2064'},'locale','en_US');
```

Define the corresponding discount factors.

```
discountFactors = [1;0.99942;0.999231;0.999037;0.998797;0.998616;0.998385;...
                   0.998122;0.997941;0.997159;0.996157;0.994825;0.993065;...
                   0.99078;0.987889;0.984092;0.979913;0.975459;0.952707;...
                   0.922223;0.888128;0.852291;0.816462;0.781228;0.746677;...
                   0.712892;0.680462;0.592285;0.474003;0.383493;0.312617;...
                   0.213809;0.152345];
```

Supported Numerix Cross Asset Integration Layer API names are `DATE` and `DISCOUNTFACTOR` for the creation of the data.

```
curveData = table(dates,discountFactors,'VariableNames',{'DATE','DISCOUNTFACTOR'});
applicationData(c,'USD_3MLIBOR_CURVE',curveData);
```

Define the headers for registering the `RATESPEC` and `DIVSPEC` call objects.

```
headers = {'ID','LOCAL ID','TIMER','TIMER CPU','UPDATED'};
```

Data is required to create dividend curve. Create and register the `DIVSPEC` call object using name-value pairs in this example.

```
applicationCall(c,headers,'ID','DIVSPEC','OBJECT','MARKET DATA','TYPE','DIVIDEND',...
                  'COMMENT','Comments here','SKIP',false,'NOWDATE',41688,...
                  'CURRENCY','USD','RATE/DIVIDEND',0,'BASIS','ACT/360');
```

Create the `EQUITYVOLSPEC` call object. `BYSTRIKEVOLDATA` denotes the volatility matrix object created previously, using an array of names and an array of values in this example.

```
applicationCall(c,headers,{'ID','OBJECT','TYPE','COMMENT','SKIP','NOWDATE','CURRENCY','VOLATILITYBASIS',...
                           'DATA','INTERPMETHOD','INTERPVARIABLE','EXTRAPOLATION'},...
                         {'EQVOLSPEC','MARKET DATA','EQ VOL','Comments here',...
                          false,41688,'USD','ACT/360','BYSTRIKEVOLDATA',...
                          'LINEAR','VOL','FLAT EXTRAPOLATION'});
```

Create the `RATESPEC` call object. `USD_3MLIBOR_CURVE` denotes yield curve data object created previously using name-value pairs.

```
applicationCall(c,headers,'ID','RATESPEC','OBJECT','MARKET DATA','TYPE','YIELD','COMMENT','Comments here',...
                  'SKIP',false,'INTERPMETHOD','LogLinear','INTERPVARIABLE','DF',...
                  'CURRENCY','USD','DATA','USD_3MLIBOR_CURVE','BASIS','ACT/360');
```

Create the `EuropeanOptionEQ` instrument. Create the `STOCKSPEC` call object using the `applicationCall` method.

```
applicationCall(c,headers,'ID','STOCKSPEC','OBJECT','INSTRUMENT','TYPE','EQ EUROPEAN',...
                  'COMMENT','Comments here','SKIP',false,'FLAVOR','PUT',...
                  'CURRENCY','USD','ENDDATE',43976,'SETTLEMENTDATE',43976,...
                  'STRIKE',112,'SIGMA1',0.2,'NOTIONAL',100);
```

Price the portfolio by creating and registering call object to run pricing analytics. Create the `OPTIONSPEC_CLOSEFORM` call object headers for registering the `OPTIONSPEC_CLOSEFORM` call object.

```
headers = {'ATM','DELTA','DELTA TRADER','FORWARD DELTA','FORWARD DELTA TRADER', ...
           'FUTURES DELTA','FUTURES DELTA TRADER','GAMMA','GAMMA TRADER', ...
           'ID','LOCAL ID','NOTIONAL','PRICE','PV','RHO','RHO TRADER', ...
           'SIGMA1','STRIKE','THETA','TIMER','TIMER CPU','UPDATED','VANNA', ...
           'VANNA TRADER','VEGA','VEGA TRADER','VOLGA','VOLGA TRADER'};

applicationCall(c,headers,'ID','OPTIONSPEC_CLOSEFORM','OBJECT','ANALYTIC',...
                  'TYPE','EUROPEAN OPTION','COMMENT','Comments here',...
                  'SKIP',false,'NOWDATE',41688,'OPTION','STOCKSPEC',...
                  'DIVIDENDCURVE','DIVSPEC','DOMESTICYIELDCURVE','RATESPEC',...
                  'SPOTPRICE',112,'SPOTDATE',41688,'MODEL','BLACK');
```

Create an output structure in MATLAB from the Application object using the `getdata` method.

```
appData = getdata(c);
```

Display the results.

```
[appData.OPTIONSPEC_CLOSEFORM.OUTPUT_HEADERS
appData.OPTIONSPEC_CLOSEFORM.OUTPUT_VALUES]
```

```
ans =

  28×2 cell array

    'PRICE'                  [            1467.24]
    'PV'                     [            1467.24]
    'DELTA'                  [             -30.54]
    'FORWARD DELTA'          [             -30.54]
    'FUTURES DELTA'          [             -26.83]
    'GAMMA'                  [               0.62]
```

Functions

Calibrate Pricing Model

Calibrate option pricing model in the Live Editor

Description

The **Calibrate Pricing Model** task lets you interactively calibrate an equity, FX, or commodity option pricing model using market data. The task automatically generates MATLAB code for your live script.

Using this task, you can:

- Select data.
- Select a model.
- Edit parameter constraints.
- Specify an optimization solver and options.
- Display the results in a volatility surface plot.

For general information about Live Editor tasks, see “Add Interactive Tasks to a Live Script”.

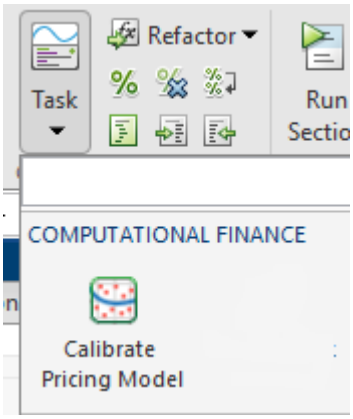
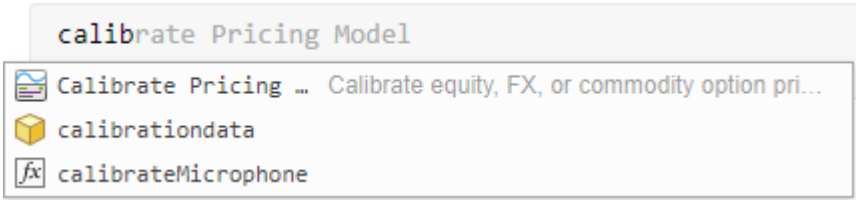
Open the Task

To add the **Calibrate Pricing Model** task to a live script in the MATLAB Editor:

- On the **Live Editor** tab, select **Task > Calibrate Pricing Model**.



- In a code block in the script, type a relevant keyword, such as `calibrate`. Select **Calibrate Pricing Model** from the suggested command completions.



Parameters

`Select data` — Data for model
matrix for **Price**, **Strike**, **Maturity** | object for **Discount Curve** | string for **Option Type** | positive numeric for **Spot Price**

Select data enables you to select the data that you want to use to calibrate your pricing model:

- **Price** — `M`-by-`N` numeric matrix for prices
- **Strike** — `M`-by-`N` numeric matrix or `M`-by-`1` column vector for strikes and `Strike` must be a nonnegative value.
- **Discount Curve** — Rate curve (`ratecurve`) for the zero curve
- **Option Type** — Put or call option type
- **Maturity** — Option maturity dates
- **Spot Price** — Current underlying asset price

`Select model` — Specify model type
object for **Heston**, **Bates**, or **Merton**

Select model enables you to select the model type that you want to use to calibrate pricing:

- **Heston** — The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This option allows modeling the implied volatility smiles observed in the market.

  The stochastic differential equation is

  $$dS_t = (r - q)S_t dt + \sqrt{v_t} S_t dW_t$$
  $$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$
  $$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$

  where

  - r is the continuous risk-free rate.
  - q is the continuous dividend yield.
  - S_t is the asset price at time t.
  - v_t is the asset price variance at time t
  - v_0 is the initial variance of the asset price at $t = 0$ for ($v_0 > 0$).
  - θ is the long-term variance level for ($\theta > 0$).
  - κ is the mean reversion speed for the variance for ($\kappa > 0$).
  - σ_v is the volatility of the variance for ($\sigma_v > 0$).
  - p is the correlation between the Weiner processes W_t and W^v_t for ($-1 \le p \le 1$).
- **Bates** — The Bates model extends the Heston model by including stochastic volatility and (similar to Merton) jump diffusion parameters in the modeling of sudden asset price movements.

  The stochastic differential equation is

  $$dS_t = (r - q - \lambda_p \mu_J)S_t dt + \sqrt{v_t} S_t dW_t + J S_t dP_t$$
  $$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t$$
  $$\mathrm{E}\left[dW_t dW_t^v\right] = p dt$$
  $$\mathrm{prob}(dP_t = 1) = \lambda_p dt$$

  where

  - r is the continuous risk-free rate.
  - q is the continuous dividend yield.
  - S_t is the asset price at time t.
  - v_t is the asset price variance at time t.
  - J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

    $$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]\right]^2}{2\delta^2} \right\}$$

where

- v_0 is the initial variance of the asset price at $t = 0$ ($v_0 > 0$).
- θ is the long-term variance level for ($\theta > 0$).
- κ is the mean reversion speed for ($\kappa > 0$).
- σ_v is the volatility of variance for ($\sigma_v > 0$).
- p is the correlation between the Weiner processes W_t and W_t^v for ($-1 \le p \le 1$).
- μ_J is the mean of J for ($\mu_J > -1$).
- λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).
- δ is the standard deviation of $\ln(1+J)$ for ($\delta \ge 0$).

- **Merton** — The Merton jump diffusion model extends the Black-Scholes model by using the Poisson process to include jump diffusion parameters in the modeling of sudden asset price movements (both up and down).

  The stochastic differential equation is

  $$dS_t = (r - q - \lambda_p \mu_j)S_t dt + \sigma S_t dW_t + JS_t dP_t$$
  $$\text{prob}(dP_t = 1) = \lambda_p dt$$

  where

  - r is the continuous risk-free rate.
  - q is the continuous dividend yield.
  - W_t is the Weiner process.
  - J is the random percentage jump size conditional on the jump occurring, where $\ln(1+J)$ is normally distributed with mean $\ln(1 + \mu_J) - \frac{\delta^2}{2}$ and the standard deviation δ, and $(1+J)$ has a lognormal distribution:

    $$\frac{1}{(1 + J)\delta\sqrt{2\pi}} \exp\left\{ \frac{-\left[\ln(1 + J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right]^2\right.}{2\delta^2} \right\}$$

    where

    - μ_J is the mean of J for ($\mu_J > -1$).
    - δ is the standard deviation of $\ln(1+J)$ for ($\delta \ge 0$).
    - λ_p is the annual frequency (intensity) of Poisson process P_t for ($\lambda_p \ge 0$).
    - σ is the volatility of the asset price for ($\sigma > 0$).

`Edit parameter constraints` — Parameter constraints for model and solver table

The parameter constraints displayed in table for editing depend on the model type that you specify from **Select model**.

- **Heston**
  - **V0** — Initial variance of the underlying asset
  - **ThetaV** — Long-term variance of underlying asset
  - **Kappa** — Mean revision speed for the variance of underlying asset
  - **SigmaV** — Volatility of the variance of underlying asset
  - **RhoSV** — Correlation between Weiner processes for underlying asset and its variance
- **Bates**
  - **V0** — Initial variance of the underlying asset
  - **ThetaV** — Long-term variance of underlying asset
  - **Kappa** — Mean revision speed for the variance of underlying asset
  - **SigmaV** — Volatility of the variance of underlying asset
  - **RhoSV** — Correlation between Weiner processes for underlying asset and its variance
  - **MeanJ** — Mean of the random percentage jump size
  - **JumpVol** — Standard deviation of `log`(1+*J*)
  - **JumpFreq** — Annual frequency of Poisson jump process
- **Merton**
  - **Volatility** — Volatility value for the underlying asset
  - **MeanJ** — Mean of the random percentage jump size
  - **JumpVol** — Standard deviation of `log`(1+*J*)
  - **JumpFreq** — Annual frequency of Poisson jump process

In addition, you can edit the table for **Lower Bounds (lb)** and **Upper Bounds (ub)**.

`Specify optimization solver and options` — Specify solver type and options
drop-down control for **Solver**, **Text Display**, and **Plot Function** | text box for **Tolerance** | text box for **Max Iterations**

Specify optimization solver and options enables you to specify the solver and options for optimization and visualizing results:

- **Solver**
  - **lsqnonlin - Non linear least squares** — For information, see `lsqnonlin`.
  - **simulannelbnd - Simulated annealing** — For information, see `simulannealbnd`.
- **Text Display**
  - **Final output**
  - **Each iteration**
  - **No display**

  For information, see “Iterative Display”.
- **Plot Function**

- **Best value**
- **Current value**
- **No plot**

For information, see “Plot Functions”.

- **Tolerance** — Termination tolerance of the objective function `lsqnonlin` or `simulannealbnd`. `Tolerance` must be a positive value.
- **Max Iterations** — Maximum number of iterations allowed. **Max Iterations** must be a positive numeric value.

`Display results` — Display optimization results
check box to toggle display of **Volatility Surface Plot**

Select the **Volatility Surface Plot** check box to display the current optimization results.

Version History

Introduced in R2022a

Support for Maximum Iterations
Behavior changed in R2022b

The **Specify optimization solver and options** section of the Live Editor task supports an option for **Max Iterations**.

asianbycrr

Price Asian option from Cox-Ross-Rubinstein binomial tree

Syntax

```
Price = asianbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbycrr( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)
```

Description

`Price = asianbycrr(CRRTree,OptSpec,Strike,Settle,ExerciseDates)` prices Asian options using a Cox-Ross-Rubinstein binomial tree.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`Price = asianbycrr( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)` adds optional arguments for `AmericanOpt`, `AvgType`, `AvgPrice`, and `AvgDate`.

Examples

Price a Floating-Strike Asian Option Using a CRR Binomial Tree

This example shows how to price a floating-strike Asian option using a CRR binomial tree using the file deriv.mat, which provides CRRTree. The CRRTree structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'put';
Strike = NaN;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2004,1,1);

Price = asianbycrr(CRRTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 1.2177
```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put'

Definition of option, specified as 'call' or 'put' using a character vector or a cell array of character vectors.

Data Types: char | cell

Strike — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 matrix of strike price values.

To compute the value of a floating-strike Asian option, Strike must be specified as NaN. Floating-strike Asian options are also known as average strike options.

Data Types: double

Settle — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a NINST-by-1 matrix of settlement or trade dates using a datetime array, string array, or date character vectors.

To support existing code, asianbycrr also accepts serial date numbers as inputs, but they are not recommended. For more information, see Version History on page 11-12.

Note The Settle date for every Asian option is set to the ValuationDate of the stock tree. The Asian argument, Settle, is ignored.

Data Types: char | string | datetime

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use aNINST-by-1 matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one ExerciseDates on the option expiry date.
- For an American option, use a NINST-by-2 vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-NaN date is listed, or if ExerciseDates is a NINST-by-1 vector, the option can be exercised between ValuationDate of the stock tree and the single listed ExerciseDates.

  To support existing code, asianbycrr also accepts serial date numbers as inputs, but they are not recommended. For more information, see Version History on page 11-12.

Data Types: char | string | datetime

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

(Optional) Option type, specified as `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`AvgType` — Average types
`arithmetic` (default) | character vector with values of `arithmetic` or `geometric`

Average types, specified as `arithmetic` for arithmetic average, or `geometric` for geometric average.

Data Types: `char`

`AvgPrice` — Average price of underlying asset at `Settle`
scalar numeric

Average price of underlying asset at `Settle`, specified as a scalar numeric.

Note Use this argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime scalar | string scalar | date character vector

Date averaging period begins, specified as a scalar datetime, string, or date character vector.

To support existing code, `asianbycrr` also accepts serial date numbers as inputs, but they are not recommended. For more information, see Version History on page 11-12.

Data Types: `char` | `string` | `datetime`

Output Arguments

`Price` — Expected prices for Asian options at time `0`
vector

Expected prices for Asian options at time 0, returned as a `NINST`-by-`1` vector. Pricing of Asian options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified

strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `asianbycrr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

asianbyeqp

Price Asian option from Equal Probabilities binomial tree

Syntax

```
Price = asianbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbyeqp( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)
```

Description

`Price = asianbyeqp(EQPTree,OptSpec,Strike,Settle,ExerciseDates)` prices Asian options using an Equal Probabilities binomial tree.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`Price = asianbyeqp( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)` adds optional arguments for `AmericanOpt`, `AvgType`, `AvgPrice`, and `AvgDate`.

Examples

Price a Floating-Strike Asian Option Using an EQP Equity Tree

This example shows how to price a floating-strike Asian option using an EQP equity tree by loading the file deriv.mat, which provides EQPTree. The EQPTree structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'put';
Strike = NaN;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2004,1,1);

Price = asianbyeqp(EQPTree, OptSpec, Strike, Settle, ...
ExerciseDates)
```

```
Price = 1.2724
```

Input Arguments

EQPTree — Stock tree structure

structure

Stock tree structure, specified by using `eqptree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` matrix of strike price values.

To compute the value of a floating-strike Asian option, `Strike` must be specified as `NaN`. Floating-strike Asian options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | scalar array | date character vector

Settlement date or trade date for the Asian option, specified as a `NINST`-by-`1` matrix of settlement or trade dates using a datetime array, string array, or date character vectors.

Note The `Settle` date for every Asian option is set to the `ValuationDate` of the stock tree. The Asian argument, `Settle`, is ignored.

To support existing code, `asianbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a `NINST`-by-`1` matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `asianbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European (default) | integer with values `0` or `1`

(Optional) Option type, specified as `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`AvgType` — Average types
`arithmetic` (default) | character vector with values of `arithmetic` or `geometric`

Average types, specified as `arithmetic` for arithmetic average, or `geometric` for geometric average.

Data Types: `char`

`AvgPrice` — Average price of underlying asset at `Settle`
scalar numeric

Average price of underlying asset at `Settle`, specified as a scalar numeric.

Note Use this argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime scalar | string scalar | date character vector

Date averaging period begins, specified as a scalar datetime, string, or date character vector.

To support existing code, `asianbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices for Asian options at time `0`
vector

Expected prices for Asian options at time 0, returned as a `NINST`-by-`1` vector. Pricing of Asian options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

How to Price Asian Options Efficiently Using MATLAB (4 min 37 sec)

asianbyitt

Price Asian options using implied trinomial tree (ITT)

Syntax

```
Price = asianbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbyitt( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)
```

Description

`Price = asianbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates)` prices Asian options using an implied trinomial tree (ITT).

`Price = asianbyitt( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)` adds optional arguments for `AmericanOpt`, `AvgType`, `AvgPrice`, and `AvgDate`.

Examples

Price a Floating-Strike Asian Option Using an ITT Equity Tree

This example shows how to price a floating-strike Asian option using an ITT equity tree by loading the file deriv.mat, which provides ITTTree. The ITTTree structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'put';
Strike = NaN;
Settle = datetime(2006,1,1);
ExerciseDates = datetime(2007,1,1);

Price = asianbyitt(ITTTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 1.0778
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` matrix of strike price values.

To compute the value of a floating-strike Asian option, `Strike` must be specified as `NaN`. Floating-strike Asian options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a `NINST`-by-`1` matrix of settlement or trade dates using a datetime array, string array, or date character vectors.

Note The `Settle` date for every Asian option is set to the `ValuationDate` of the stock tree. The Asian argument, `Settle`, is ignored.

To support existing code, `asianbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vector:

- For a European option, use a`NINST`-by-`1` matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `asianbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European (default) | integer with values `0` or `1`

(Optional) Option type, specified as `NINST`-by-`1` positive integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`AvgType` — Average types
`arithmetic` (default) | character vector with values of `arithmetic` or `geometric`

Average types, specified as `arithmetic` for arithmetic average, or `geometric` for geometric average.

Data Types: `char`

`AvgPrice` — Average price of underlying asset at `Settle`
scalar numeric

Average price of underlying asset at `Settle`, specified as a scalar numeric.

Note Use this argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime scalar | string scalar | date character vector

Date averaging period begins, specified as a scalar datetime, string, or date character vector.

To support existing code, `asianbyitt` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices for Asian options at time `0`
vector

Expected prices for Asian options at time 0, returned as a `NINST`-by-`1` vector. Pricing of Asian options is done using Hull-White (1993). Therefore, for these options there are no unique prices on the tree nodes except for the root node.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2007a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `asianbyitt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Asian Options Efficiently Using MATLAB (4 min 37 sec)

asianbyls

Price European or American Asian options using Monte Carlo simulations

Syntax

```
Price = asianbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbyls( ___ ,Name,Value)

[Price,Paths,Times,Z] = asianbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
[Price,Paths,Times,Z] = asianbyls( ___ ,Name,Value)
```

Description

`Price = asianbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns fixed- and floating-strike Asian option prices using the Longstaff-Schwartz model. `asianbyls` computes prices of European and American Asian options.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

To compute the value of a floating-strike Asian option, `Strike` should be specified as `NaN`. Fixed-strike Asian options are also known as average price options and floating-strike Asian options are also known as average strike options.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = asianbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

`[Price,Paths,Times,Z] = asianbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns fixed- and floating-strike Asian option `Price`, `Paths`, `Times`, and `Z` values using the Longstaff-Schwartz model. `asianbyls` computes prices of European and American Asian options.

`[Price,Paths,Times,Z] = asianbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price of an Asian Option Using the Longstaff-Schwartz Model

Define the `RateSpec`.

```
Rates = 0.05;
StartDate = datetime(2013,1,1);
```

```
EndDate = datetime(2014,1,1);
RateSpec = intenvset('ValuationDate', StartDate, 'StartDates', StartDate, ...
'EndDates', EndDate,'Compounding', -1, 'Rates', Rates)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 100;
Sigma = 0.2;
StockSpec = stockspec(Sigma, AssetPrice)

StockSpec = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.2000
          AssetPrice: 100
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the Asian `'call'` option.

```
Settle = datetime(2013,1,1);
ExerciseDates = datetime(2014,1,1);
Strike = 110;
OptSpec = 'call';
```

Compute the price for the European arithmetic average price for the Asian option using the Longstaff-Schwartz model.

```
NumTrials = 10000;
NumPeriods = 100;
AvgType = 'arithmetic';
Antithetic= true;
Price= asianbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, ...
'NumTrials', NumTrials, 'NumPeriods', NumPeriods,'Antithetic', Antithetic, 'AvgType', AvgType)

Price = 1.9876
```

Input Arguments

RateSpec — Interest-rate term structure
structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with a value of `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector

Data Types: `char`

`Strike` — Option strike price value
nonnegative scalar integer

Option strike price value, specified with a nonnegative scalar integer. To compute the value of a floating-strike Asian option, `Strike` should be specified as `NaN`. Floating-strike Asian options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the Asian option, specified as a scalar datetime, string, or date character vector. By default, `asianbyls` calculates the price of Asian options based on averages that start on the settlement date.

To support existing code, `asianbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a `1`-by-`1` vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `1`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `1`-by-`1` vector of dates, the option can be exercised between `Settle` and the single listed `ExerciseDates`.

To support existing code, `asianbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = asianbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'NumTrials',NumTrials,'NumPeriods',NumPeriods,'Antithetic',Antithetic,'AvgType','arithmetic')`

`AmericanOpt` — Option type

`0` European (default) | scalar with value `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `single` | `double`

`AvgType` — Average types

`arithmetic` (default) | character vector with values of `arithmetic` or `geometric`

Average types, specified as the comma-separated pair consisting of `'AvgType'` and `arithmetic` for arithmetic average, or `geometric` for geometric average.

Data Types: `char`

`AvgPrice` — Average price of underlying asset at `Settle`

scalar numeric

Average price of underlying asset at `Settle`, specified as the comma-separated pair consisting of `'AvgPrice'` and a scalar numeric value. The `AvgPrice` is assumed to be calculated in the time window starting at `AvgDate` and ending on `Settle`. In other words, the average is backward looking.

Note Use this argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins

datetime scalar | string scalar | date character vector

Date averaging period begins, specified as the comma-separated pair consisting of `'AvgDate'` and a scalar datetime, string, or date character vector.

To support existing code, `asianbyls` also accepts serial date numbers as inputs, but they are not recommended.

`NumTrials` — Simulation trials
`1000` (default) | numeric

Simulation trials, specified as the comma-separated pair consisting of `'NumTrials'` and a scalar number of independent sample paths.

Data Types: `double`

`NumPeriods` — Simulation periods per trial
`100` (default) | numeric

Simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` scalar numeric value. `NumPeriods` is considered only when pricing European Asian options. For American Asian options, `NumPeriods` is equal to the number of exercise days during the life of the option.

Data Types: `double`

`Z` — Dependent random variates
nonnegative integer

Dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-2-by-`NumTrials` 3-D time series array.

Data Types: `single` | `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | logical flag with value of `true` or `false`

Logical flag to indicate antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

Output Arguments

`Price` — Expected price of Asian option
scalar

Expected price of the Asian option, returned as a 1-by-1 scalar.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a (`NumPeriods` + 1)-by-1-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with the simulated paths, returned as a (`NumPeriods` + 1)-by-1 column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates
vector

Dependent random variates, returned, if `Z` is specified as an optional input argument, the same value is returned. Otherwise, `Z` contains the random variates generated internally.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `asianbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

asianbystt

Price Asian options using standard trinomial tree

Syntax

```
Price = asianbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbystt( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)
```

Description

`Price = asianbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates)` prices Asian options using a standard trinomial (STT) tree.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`Price = asianbystt( ___ ,AmericanOpt,AvgType,AvgPrice,AvgDate)` prices Asian options using a standard trinomial (STT) tree with optional arguments for `AmericanOpt`, `AvgType`, `AvgPrice`, and `AvgDate`.

Examples

Price an Asian Option Using the Standard Trinomial Tree Model

Create a `RateSpec`.

```
StartDates = datetime(2009,1,1);
EndDates = datetime(2013,1,1);
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8694
            Rates: 0.0350
         EndTimes: 4
       StartTimes: 0
         EndDates: 735235
       StartDates: 733774
    ValuationDate: 733774
            Basis: 1
     EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
         AssetPrice: 85
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create an STTTree.

```
NumPeriods = 4;
TimeSpec = stttimespec(StartDates, EndDates, 4);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 1 2 3 4]
         dObs: [733774 734139 734504 734869 735235]
        STree: {1x5 cell}
        Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Define the Asian option and compute the price.

```
Settle = datetime(2009,1,1);
ExerciseDates = [datetime(2012,1,1) ; datetime(2013,1,1)];
OptSpec = 'call';
Strike = 100;

Price = asianbystt(STTTree, OptSpec, Strike, Settle, ExerciseDates)
```

```
Price = 2×1

    1.6905
    2.6203
```

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using stttree.

Data Types: struct

OptSpec — Definition of option

character vector with value 'call' or 'put'

Definition of option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`Strike` — Option strike price value
matrix of nonnegative integers

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` matrix of strike price values. To compute the value of a floating-strike Asian option, `Strike` should be specified as `NaN`. Floating-strike Asian options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a `NINST`-by-`1` vector of settlement or trade dates using date character vectors, or a datetime array.

Note The `Settle` date for every Asian option is set to the `ValuationDate` of the stock tree. The Asian argument, `Settle`, is ignored.

To support existing code, `asianbystt` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or character vectors:

- For a European option, use a`NINST`-by-`1` matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` vector of dates, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `asianbystt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
`0` European (default) | scalar with values `[0,1]`

Option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Data Types: `single` | `double`

`AvgType` — Average types
`arithmetic` (default) | character vector with values of `arithmetic` or `geometric`

Average types, specified as `arithmetic` for arithmetic average, or `geometric` for geometric average.

Data Types: `char`

`AvgPrice` — Average price of underlying asset at `Settle`
scalar numeric

Average price of underlying asset at `Settle`, specified as a scalar numeric.

Note Use this argument when `AvgDate < Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime scalar | string scalar | date character vector

Date averaging period begins, specified as a scalar datetime, string, or date character vector.

To support existing code, `asianbystt` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices for Asian options at time `0`
matrix

Expected prices for Asian options at time 0, returned as a `NINST`-by-`1` matrix. Pricing of Asian options is done using Hull-White (1993). Consequently, for these options there are no unique prices on the tree nodes with the exception of the root node.

How to Price Asian Options Efficiently Using MATLAB (4 min 37 sec)

asiansensbyls

Calculate price and sensitivities for European or American Asian options using Monte Carlo simulations

Syntax

```
PriceSens = asiansensbyls(RateSpec,StockSpec,OptSpec,StrikeSettle,
ExerciseDates)
PriceSens = asiansensbyls( ___ ,Name,Value)

[PriceSens,Path,Times,Z] = asiansensbyls(RateSpec,StockSpec,OptSpec,Strike
Settle,ExerciseDates)
[PriceSens,Path,Times,Z] = asiansensbyls( ___ ,Name,Value)
```

Description

`PriceSens = asiansensbyls(RateSpec,StockSpec,OptSpec,StrikeSettle, ExerciseDates)` returns Asian option prices or sensitivities for fixed- and floating-strike Asian options using the Longstaff-Schwartz model. `asiansensbyls` supports European and American Asian options.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

To compute the value of a floating-strike Asian option, `Strike` should be specified as `NaN`. Fixed-strike Asian options are also known as average price options and floating-strike Asian options are also known as average strike options.

Note Alternatively, you can use the `Asian` object to calculate prices or sensitivities for Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = asiansensbyls( ___ ,Name,Value)` returns Asian option prices or sensitivities for fixed- and floating-strike Asian options using optional name-value pair arguments and the Longstaff-Schwartz model.

`[PriceSens,Path,Times,Z] = asiansensbyls(RateSpec,StockSpec,OptSpec,Strike Settle,ExerciseDates)` returns Asian option prices or sensitivities (`PriceSens`, `Path`, `Times`, and `Z`) for fixed- and floating-strike Asian options using the Longstaff-Schwartz model.

`[PriceSens,Path,Times,Z] = asiansensbyls( ___ ,Name,Value)` returns Asian option prices or sensitivities (`PriceSens`, `Path`, `Times`, and `Z`) for fixed- and floating-strike Asian options using optional name-value pair arguments and the Longstaff-Schwartz model.

Examples

Compute the Price and Sensitivities of an Asian Option Using the Longstaff-Schwartz Model

Define the `RateSpec`.

```
Rates = 0.05;
StartDate = datetime(2013,1,1);
EndDate = datetime(2014,1,1);
RateSpec = intenvset('ValuationDate', StartDate, 'StartDates', StartDate, ...
'EndDates', EndDate,'Compounding', -1, 'Rates', Rates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0500
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 100;
Sigma = 0.2;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2000
         AssetPrice: 100
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the Asian `'call'` option.

```
Settle = datetime(2013,1,1);
ExerciseDates = datetime(2014,1,1);
Strike = 110;
OptSpec = 'call';
```

Compute the price for the European arithmetic average price and sensitivities for the Asian option using the Longstaff-Schwartz model.

```
NumTrials = 10000;
NumPeriods = 100;
AvgType = 'arithmetic';
Antithetic= true;
OutSpec = {'Price', 'Delta', 'Gamma'};
PriceSens = asiansensbyls(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, ...
'NumTrials', NumTrials, 'NumPeriods', NumPeriods,'Antithetic', Antithetic, 'AvgType', ...
AvgType,'OutSpec',OutSpec)
```

```
PriceSens = 1.9876
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`Strike` — Option strike price value

nonnegative scalar integer

Option strike price value, specified with a nonnegative scalar integer. To compute the value of a floating-strike Asian option, `Strike` should be specified as `NaN`. Floating-strike Asian options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement date or trade date

datetime scalar | string scalar | date character vector

Settlement date or trade date for the Asian option, specified as a scalar datetime, string, or date character vector.

To support existing code, `asiansensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a 1-by-1 vector of dates. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date

is listed, or if `ExerciseDates` is a `1`-by-`1` vector of dates, the option can be exercised between `Settle` and the single listed `ExerciseDates`.

To support existing code, `asiansensbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = asiansensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'NumTrials',NumTrials,'NumPeriods', NumPeriods,'Antithetic',Antithetic,'AvgType',AvgType,'OutSpec',{'All'})`

`AmericanOpt` — Option type

`0` European (default) | scalar with values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `single` | `double`

`AvgType` — Average types

`arithmetic` (default) | character vector with values of `arithmetic` or `geometric`

Average types, specified as the comma-separated pair consisting of `'AvgType'` and `arithmetic` for arithmetic average, or `geometric` for geometric average.

Data Types: `char`

`AvgPrice` — Average price of underlying asset at `Settle`

scalar numeric

Average price of underlying asset at `Settle`, specified as the comma-separated pair consisting of `'AvgPrice'` and a scalar numeric value.

Note Use this argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime scalar | string scalar | date character vector

Date averaging period begins, specified as the comma-separated pair consisting of `'AvgDate'` and a scalar datetime, string, or data character vector.

To support existing code, `asiansensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`NumTrials` — Simulation trials
`1000` (default) | numeric

Simulation trials, specified as the comma-separated pair consisting of `'NumTrials'` and a scalar number of independent sample paths.

Data Types: `double`

`NumPeriods` — Simulation periods per trial
`100` (default) | numeric

Simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar numeric value. `NumPeriods` is considered only when pricing European Asian options. For American Asian options, `NumPeriod` is equal to the number of exercise days during the life of the option.

Data Types: `double`

`Z` — Dependent random variates
nonnegative integer

Dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-2-by-`NumTrials` 3-D time series array.

Data Types: `single` | `double`

`Antithetic` — Indicates antithetic sampling
`false` (default) | logical flag with value of `true` or `false`

Indicates antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected price or sensitivities of Asian option

scalar

Expected price or sensitivities (defined by `OutSpec`) of the Asian option, returned as a `1`-by-`1` array.

`Path` — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a (`NumPeriods` + `1`)-by-`2`-by-`NumTrials` 3-D time series array. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a (`NumPeriods` + `1`)-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Dependent random variates

vector

Dependent random variates, returned, if `Z` is specified as an optional input argument, the same value is returned. Otherwise, `Z` contains the random variates generated internally.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `asiansensbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

asianbykv

Prices European geometric Asian options using Kemna-Vorst model

Syntax

```
Price = asianbykv(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
```

Description

`Price = asianbykv(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns prices of European geometric Asian options using the Kemna-Vorst model.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute the Price of an Asian Option Using the Kemna-Vorst Model

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
Rates = 0.035;
Basis = 1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates,'Rates', Rates,  'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 100;
Sigma = 0.15;
DivType = 'continuous';
DivAmounts = 0.03;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmounts)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
         AssetPrice: 100
       DividendType: {'continuous'}
    DividendAmounts: 0.0300
    ExDividendDates: []
```

Define the Asian `'call'` and `'put'` options.

```
Strike = 102;
OptSpec = {'put'; 'call'};
Settle = datetime(2013,1,1);
Maturity = datetime(2013,4,1);
```

Compute the European geometric Average Price for the Asian option using the Kemna-Vorst model.

```
Price = asiansensbykv(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 2×1

    2.8881
    0.9210
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

The annualized continuously compounded interest-rate term structure specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors

Definition of option, specified as `'call'` or `'put'` using a `NINST`-by-`1` cell array of character vectors.

Data Types: `cell` | `char`

`Strike` — Option strike price values

nonnegative integer | vector of nonnegative integers

Option strike price values, specified with nonnegative integers using a `NINST`-by-`1` vector.

Data Types: `single` | `double`

`Settle` — Settlement dates or trade dates
datetime array | string array | date character vector

Settlement dates or trade dates for the Asian option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asianbykv` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — European option exercise dates
datetime array | string array | date character vector

European option exercise dates, specified as `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. For a European option, there is only one `ExerciseDates` on the option expiry date.

To support existing code, `asianbykv` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices of an Asian option
vector

Expected prices of the Asian option, returned as an `NINST`-by-`1` vector.

asiansensbykv

Calculate prices or sensitivities of European geometric Asian options using Kemna-Vorst model

Syntax

```
PriceSens = asiansensbykv(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
PriceSens = asiansensbykv( ___ ,Name,Value)
```

Description

`PriceSens = asiansensbykv(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates)` returns prices or sensitivities of European geometric Asian options using Kemna-Vorst model.

Note Alternatively, you can use the `Asian` object to calculate prices or sensitivities for Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = asiansensbykv( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Sensitivities of an Asian Option Using the Kemna-Vorst Model

Define the `RateSpec`.

```
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
Rates = 0.035;
Basis = 1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, ...
'EndDates', EndDates,'Rates', Rates,  'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 100;
Sigma = 0.15;
DivType = 'continuous';
DivAmounts = 0.03;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmounts)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
         AssetPrice: 100
       DividendType: {'continuous'}
    DividendAmounts: 0.0300
    ExDividendDates: []
```

Define the Asian `'call'` and `'put'` options.

```
Strike = 102;
OptSpec = {'put'; 'call'};
Settle = datetime(2013,1,1);
ExerciseDates = datetime(2014,1,1);
```

Compute the European geometric Average Price and sensitivities for the Asian option using the Kemna-Vorst model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
PriceSens = asiansensbykv(RateSpec, StockSpec, OptSpec, Strike,...
Settle, ExerciseDates,'OutSpec', OutSpec)
```

```
PriceSens = 2×1

    4.3871
    2.5163
```

Input Arguments

RateSpec — Interest-rate term structure

structure

The annualized continuously compounded interest-rate term structure specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

OptSpec — Definition of option
character vector with values 'call' or 'put' | cell array of character vectors

Definition of option, specified as 'call' or 'put' using a NINST-by-1 cell array of character vectors.

Data Types: cell | char

Strike — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values, specified with nonnegative integers using a NINST- by-1 vector.

Data Types: single | double

Settle — Settlement dates or trade dates
datetime array | string array | date character vector

Settlement dates or trade dates for the Asian option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, asiansensbykv also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — European option exercise dates
datetime array | string array | date character vector

European option exercise dates, specified as NINST-by-1 vector using a datetime array, string array, or date character vectors. For a European option, there is only one ExerciseDates on the option expiry date.

To support existing code, asiansensbykv also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: PriceSens = asiansensbykv(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',{'All'})

OutSpec — Define outputs
{'Price'} (default) | character vector with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta' and 'All'. | cell array of character vectors with values: 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta' and 'All'.

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output should be Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec as:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities of the Asian option

vector

Expected prices or sensitivities (defined by `OutSpec`) of the Asian option, returned as an `1`-by-`1` vector. If the `OutSpec` is not specified only price is returned.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. asianbylevy

Price of European arithmetic Asian options using Levy model

Syntax

```
Price = asianbylevy(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
```

Description

`Price = asianbylevy(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` returns European arithmetic average pricing for Asian options using the Levy model.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute the Price of an Asian Option Using the Levy Model

Define the `RateSpec`.

```
Rates = 0.07;
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, 'EndDates', ...
EndDates, 'Rates', Rates, 'Compounding', -1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9324
            Rates: 0.0700
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 6.8;
Sigma = 0.14;
DivType = 'continuous';
DivAmounts = 0.09;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmounts)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1400
         AssetPrice: 6.8000
       DividendType: {'continuous'}
    DividendAmounts: 0.0900
    ExDividendDates: []
```

Define two options for `'call'` and `'put'`.

```
Settle = datetime(2013,1,1);
Maturity = datetime(2013,7,1);
Strike = 6.9;
OptSpec = {'call'; 'put'};
```

Compute the European arithmetic average price for the Asian option using the Levy model.

```
Price= asianbylevy(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity)
```

```
Price = 2×1

    0.0944
    0.2237
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option, specified as `'call'` or `'put'` using a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

Strike — Option strike price values

nonnegative integer | vector of nonnegative integers

Option strike price values, specified with nonnegative integers as a `NINST`-by-`1` vector.

Data Types: `single` | `double`

`Settle` — Settlement dates or trade dates
datetime array | string array | date character vector

Settlement dates or trade dates for the Asian option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asianbylevy` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. For a European option, there is only one `ExerciseDates` on the option expiry date.

To support existing code, `asianbylevy` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices of Asian option
vector

Expected prices of the Asian option, returned as a `NINST`-by-`1` vector.

How to Price Asian Options Efficiently Using MATLAB (4 min 37 sec)

asiansensbylevy

Calculate prices or sensitivities of European arithmetic Asian options using Levy model

Syntax

```
PriceSens = asiansensbylevy(RateSpec,StockSpec,OptSpec,StrikeSettle,
ExerciseDates)
PriceSens = asiansensbylevy( ___ ,Name,Value)
```

Description

`PriceSens = asiansensbylevy(RateSpec,StockSpec,OptSpec,StrikeSettle, ExerciseDates)` returns European average pricing or sensitivities for arithmetic Asian options using the Levy model.

Note Alternatively, you can use the `Asian` object to calculate prices or sensitivities for Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = asiansensbylevy( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Price and Sensitivities of an Asian Option Using the Levy Model

Define the `RateSpec`.

```
Rates = 0.07;
StartDates = datetime(2013,1,1);
EndDates = datetime(2014,1,1);
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates, 'EndDates', ...
EndDates, 'Rates', Rates, 'Compounding', -1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9324
            Rates: 0.0700
         EndTimes: 1
       StartTimes: 0
         EndDates: 735600
       StartDates: 735235
    ValuationDate: 735235
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec` for the asset.

```
AssetPrice = 6.8;
Sigma = 0.14;
DivType = 'continuous';
DivAmounts = 0.09;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmounts)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1400
         AssetPrice: 6.8000
       DividendType: {'continuous'}
    DividendAmounts: 0.0900
    ExDividendDates: []
```

Define two options for a `'call'` and `'put'`.

```
Settle = datetime(2013,1,1);
ExerciseDates = datetime(2014,1,1);
Strike = 6.9;
OptSpec = {'call'; 'put'};
```

Compute the European arithmetic average price and sensitivities for the Asian option using the Levy model.

```
OutSpec = {'Price', 'Delta', 'Gamma'};
PriceSens = asiansensbylevy(RateSpec, StockSpec, OptSpec, Strike,...
Settle, ExerciseDates,'OutSpec', OutSpec)
```

```
PriceSens = 2×1

    0.1358
    0.2921
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors

Definition of option, specified as `'call'` or `'put'` using a `NINST`-by-`1` cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price values
nonnegative integer | vector of nonnegative integers

Option strike price values, specified with nonnegative integers using a `NINST`-by-`1` vector.

Data Types: `single` | `double`

`Settle` — Settlement dates or trade dates
datetime array | string array | date character vector

Settlement dates or trade dates for the Asian option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asiansensbylevy` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. For a European option, there is only one `ExerciseDates` on the option expiry date.

To support existing code, `asiansensbylevy` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = asiansensbylevy(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',{'All'})`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values: `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`. | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output should be `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities of Asian option

vector

Expected prices or sensitivities (defined by `OutSpec`) of the Asian option, returned as an `1`-by-`1` vector. If the `OutSpec` is not specified only the price is returned.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2013b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `asiansensbylevy` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Asian Options Efficiently Using MATLAB (4 min 37 sec)

asianbyhhm

Price European discrete arithmetic fixed Asian options using Haug, Haug, Margrabe model

Syntax

```
Price = asianbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbyhhm( ___ ,Name,Value)
```

Description

`Price = asianbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` prices European discrete arithmetic fixed Asian options using the Haug, Haug, Margrabe model.

`Price = asianbyhhm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price an Asian Option with Averaging Period Starting Before the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = datetime(2013,4,1);
Maturity = datetime(2013,10,1);
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price of the Asian option using the Haug, Haug, Margrabe approximation. Assume that the averaging period has started before the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = datetime(2013,10,1);
NumFixings = 12;
AvgDate = datetime(2013,1,1);
AvgPrice = 100;

Price = asianbyhhm(RateSpec, StockSpec, OptSpec, Strike, Settle, ExerciseDates, ...
'NumFixings', NumFixings, 'AvgDate', AvgDate, 'AvgPrice', AvgPrice)
```

```
Price = 5.8216
```

Price an Asian Option with Averaging Period Starting After the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = datetime(2013,4,1);
Maturity = datetime(2013,10,1);
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price of the Asian option using the Haug, Haug, Margrabe approximation. Assume that the averaging period starts after the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = datetime(2013,10,1);
NumFixings = 15;
AvgDate = datetime(2013,1,1);

Price = asianbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'NumFixings',NumFixings,'AvgDate',AvgDate)
```

```
Price = 1.3785e-07
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

stockspec can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in StockSpec, dividends are assumed to be 0.

Data Types: struct

OptSpec — Definition of option
character vector with value 'call' or 'put' | cell array of character vectors with values 'call' or 'put' | string array with values "call" or "put"

Definition of option, specified as 'call' or 'put' using a character vector, cell array of character vectors, or string array.

Data Types: char | cell | string

Strike — Option strike price value
nonnegative integer | vector of nonnegative integers

Option strike price value, specified with a nonnegative integer using a NINST-by-1 vector of strike price values.

Data Types: double

Settle — Settlement dates or trade dates
datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, asianbyhhm also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — European option exercise dates
datetime array | string array | date character vector

European option exercise dates, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one ExerciseDates on the option expiry date.

To support existing code, asianbyhhm also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: Price = asianbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'NumFixings',15)

`AvgPrice` — Average price of underlying asset at the `Settle` date
vector

Average price of underlying asset at the `Settle` date, specified as the comma-separated pair consisting of `'AvgPrice'` and a `NINST`-by-`1` vector.

Note Use the `AvgPrice` argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime array | string array | date character vector

Date averaging period begins, specified as the comma-separated pair consisting of `'AvgDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asianbyhhm` also accepts serial date numbers as inputs, but they are not recommended.

`NumFixings` — Total number of fixings or averaging points
`10` (default) | vector

Total number of fixings or averaging points, specified as the comma-separated pair consisting of `'NumFixings'` and a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices for fixed Asian options
vector

Expected prices for fixed Asian options, returned as a `NINST`-by-`1` vector.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2018a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `asianbyhhm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

asiansensbyhhm

Calculate price and sensitivities of European discrete arithmetic fixed Asian options using Haug, Haug, Margrabe model

Syntax

```
PriceSens = asiansensbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
PriceSens = asiansensbyhhm( ___ ,Name,Value)
```

Description

`PriceSens = asiansensbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates)` calculates prices and sensitivities for European discrete arithmetic fixed Asian options using the Haug, Haug, Margrabe model.

`PriceSens = asiansensbyhhm( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute Price and Sensitivities for Asian Option with Averaging Period Starting Before the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = datetime(2013,4,1);
Maturity = datetime(2013,10,1);
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price and sensitivities of the Asian option using the Haug, Haug, Margrabe approximation. Assume that the averaging period has started before the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = datetime(2013,10,1);
NumFixings = 12;
AvgDate = datetime(2013,1,1);
```

```
AvgPrice = 100;
OutSpec = {'Price','Delta','Gamma'};

[Price,Delta,Gamma] = asiansensbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'NumFixings',NumFixings,'AvgDate',AvgDate,'AvgPrice',AvgPrice,'OutSpec',OutSpec)

Price = 5.8216

Delta = 0.5907

Gamma = 0.0143
```

Compute Price and Sensitivities for Asian Option with Averaging Period Starting After the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = 'Apr-1-2013';
Maturity = 'Oct-1-2013';
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price and sensitivities of the Asian option using the Haug, Haug, Margrabe approximation. Assume that the averaging period started after the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = 'Oct-1-2013';
NumFixings = 15;
AvgDate = 'Jan-1-2013';
OutSpec = {'Price','Delta','Gamma'};

[Price,Delta,Gamma] = asiansensbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'NumFixings',NumFixings,'AvgDate',AvgDate,'OutSpec',OutSpec)

Price = 1.3785e-07

Delta = 1.1438e-07

Gamma = 9.0830e-08
```

Input Arguments

`RateSpec` — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of option, specified as `'call'` or `'put'` using a character vector, cell array of character vectors, or string array.

Data Types: `char` | `cell` | `string`

`Strike` — Option strike price value

nonnegative integer | vector of nonnegative integers

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `double`

`Settle` — Settlement dates or trade dates

datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asiansensbyhhm` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — European option exercise dates

datetime array | string array | date character vector

European option exercise dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDates` on the option expiry date.

To support existing code, asiansensbyhhm also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: PriceSens = asiansensbyhhm(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',{'All'},'NumFixings',15)

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | string array with values "Price", "Delta", "Gamma", "Vega", "Lambda", "Rho", "Theta", and "All"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity:

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell | string

AvgPrice — Average price of underlying asset at the Settle date
vector

Average price of underlying asset at the Settle date, specified as the comma-separated pair consisting of 'AvgPrice' and a NINST-by-1 vector.

Note Use the AvgPrice argument when AvgDate < Settle.

Data Types: double

AvgDate — Date averaging period begins
character vector | datetime | string array

Date averaging period begins, specified as the comma-separated pair consisting of 'AvgDate' and a NINST-by-1 vector using character vectors, datetimes, or string arrays.

To support existing code, asiansensbyhhm also accepts serial date numbers as inputs, but they are not recommended.

NumFixings — Total number of fixings or averaging points
10 (default) | vector

Total number of fixings or averaging points, specified as the comma-separated pair consisting of `'NumFixings'` and a `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`PriceSens` — Expected prices or sensitivities for fixed Asian options

vector

Expected prices or sensitivities for fixed Asian options, returned as a `NINST`-by-`1` vector. `asianbyhhm` calculates prices of European arithmetic fixed (average price) Asian options with discretely monitoring.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `asiansensbyhhm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Asian Options Efficiently Using MATLAB (4 min 37 sec)

asianbytw

Price European arithmetic fixed Asian options using Turnbull-Wakeman model

Syntax

```
Price = asianbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)
Price = asianbytw( ___ ,Name,Value)
```

Description

`Price = asianbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates)` prices European arithmetic fixed Asian options using the Turnbull-Wakeman model.

Note Alternatively, you can use the `Asian` object to price Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = asianbytw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price an Asian Option with Averaging Period Before the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = datetime(2013,4,1);
Maturity = datetime(2013,10,1);
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price of the Asian option using the Turnbull-Wakeman approximation. Assume that the averaging period has started before the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = datetime(2013,10,1);
```

```
AvgDate = datetime(2013,1,1);
AvgPrice = 100;

Price = asianbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'AvgDate',AvgDate,'AvgPrice',AvgPrice)

Price = 5.6731
```

Price an Asian Option with Averaging Period After the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = datetime(2013,4,1);
Maturity = datetime(2013,10,1);
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price of the Asian option using the Turnbull-Wakeman approximation. Assume that the averaging period starts after the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = datetime(2013,10,1);
AvgDate = datetime(2013,1,1);

Price = asianbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'AvgDate',AvgDate)

Price = 1.0774e-08
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of option, specified as `'call'` or `'put'` using a character vector, cell array of character vectors, or string array.

Data Types: `char` | `cell` | `string`

`Strike` — Option strike price value
nonnegative integer | vector of nonnegative integer

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `double`

`Settle` — Settlement dates or trade dates
datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asianbytw` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — European option exercise dates
datetime array | string array | date character vector

European option exercise dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDates` on the option expiry date.

To support existing code, `asianbytw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = asianbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'AvgPrice',1500)`

`AvgPrice` — Average price of underlying asset at the `Settle` date
vector

Average price of underlying asset at the `Settle` date, specified as the comma-separated pair consisting of `'AvgPrice'` and a `NINST`-by-`1` vector.

Note Use the `AvgPrice` argument when `AvgDate` < `Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins
datetime array | string array | date character vector

Date averaging period begins, specified as the comma-separated pair consisting of `'AvgDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asianbytw` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices for fixed Asian options
vector

Expected prices for Asian options, returned as a `NINST`-by-`1` vector.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2018a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `asianbytw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

asiansensbytw

Calculate price and sensitivities of European fixed arithmetic Asian options using Turnbull-Wakeman model

Syntax

```
PriceSens = asiansensbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates)
PriceSens = asiansensbytw( ___ ,Name,Value)
```

Description

`PriceSens = asiansensbytw(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates)` calculates prices and sensitivities for European fixed arithmetic Asian options using the Turnbull-Wakeman model.

Note Alternatively, you can use the `Asian` object to calculate prices or sensitivities for Asian options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = asiansensbytw( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute Price and Sensitivities for Asian Option with Averaging Period Before the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = datetime(2013,4,1);
Maturity = datetime(2013,10,1);
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price and sensitivities of the Asian option using the Turnbull-Wakeman approximation. Assume that the averaging period has started before the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = datetime(2013,10,1);
AvgDate = datetime(2013,1,1);
AvgPrice = 100;
OutSpec = {'Price','Delta','Gamma'};

[Price,Delta,Gamma] = asiansensbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'AvgDate',AvgDate,'AvgPrice',AvgPrice,'OutSpec',OutSpec)

Price = 5.6731

Delta = 0.5995

Gamma = 0.0135
```

Compute Price and Sensitivities for Asian Option with Averaging Period After the Settle Date

Define the Asian option parameters.

```
AssetPrice = 100;
Strike = 95;
Rates = 0.1;
Sigma = 0.15;
Settle = 'Apr-1-2013';
Maturity = 'Oct-1-2013';
```

Create a `RateSpec` using the `intenvset` function.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
 Maturity, 'Rates', Rates, 'Compounding', -1, 'Basis', 1);
```

Create a `StockSpec` for the underlying asset using the `stockspec` function.

```
DividendType = 'Continuous';
DividendAmounts = 0.05;

StockSpec = stockspec(Sigma, AssetPrice, DividendType, DividendAmounts);
```

Calculate the price and sensitivities of the Asian option using the Turnbull-Wakeman approximation. Assume that the averaging period starts after the `Settle` date.

```
OptSpec = 'Call';
ExerciseDates = 'Oct-1-2013';
AvgDate = 'Jan-1-2013';
OutSpec = {'Price','Delta','Gamma'};

[Price,Delta,Gamma] = asiansensbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, ...
'AvgDate',AvgDate,'OutSpec',OutSpec)

Price = 1.0774e-08

Delta = 1.0380e-08
```

```
Gamma = 9.6246e-09
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Data Types: `struct`

OptSpec — Definition of option

character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of option, specified as `'call'` or `'put'` using a character vector, cell array of character vectors, or string array.

Data Types: `char` | `cell` | `string`

Strike — Option strike price value

nonnegative integer | vector of nonnegative integers

Option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` vector of strike price values.

Data Types: `double`

Settle — Settlement dates or trade dates

datetime array | string array | date character vector

Settlement date or trade date for the Asian option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asiansensbytw` also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — European option exercise dates

datetime array | string array | date character vector

European option exercise dates, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDates` on the option expiry date.

To support existing code, `asiansensbytw` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = asiansensbytw(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,'OutSpec',{'All'})`

`OutSpec` — Define outputs

`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Lambda"`, `"Rho"`, `"Theta"`, and `"All"`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or `1`-by-`NOUT` cell array of character vectors or string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity:

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell` | `string`

`AvgPrice` — Average price of underlying asset at the `Settle` date

vector

Average price of underlying asset at the `Settle` date, specified as the comma-separated pair consisting of `'AvgPrice'` and a `NINST`-by-`1` vector.

Note Use the `AvgPrice` argument when `AvgDate < Settle`.

Data Types: `double`

`AvgDate` — Date averaging period begins

datetime array | string array | date character vector

Date averaging period begins, specified as the comma-separated pair consisting of `'AvgDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `asiansensbytw` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`PriceSens` — Expected prices or sensitivities for fixed Asian options

vector

Expected prices or sensitivities for fixed Asian options, returned as a `NINST`-by-`1` vector. `asiansensbytw` calculates prices of European arithmetic fixed (average price) Asian options.

More About

Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-34.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `asiansensbytw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

assetbybls

Determine price of asset-or-nothing digital options using Black-Scholes model

Syntax

```
Price = assetbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
```

Description

`Price = assetbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)` computes asset-or-nothing European digital options using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Binary` object to price digital options. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

Examples

Compute Asset-Or-Nothing Digital Option Prices Using the Black-Scholes Option Pricing Model

Consider two asset-or-nothing put options on a nondividend paying stock with a strike of 95 and 93 and expiring on January 30, 2009. On November 3, 2008 the stock is trading at 97.50. Using this data, calculate the price of the asset-or-nothing put options if the risk-free rate is 4.5% and the volatility is 22%. First, create the `RateSpec`.

```
Settle = datetime(2008,11,3);
Maturity = datetime(2009,1,30);
Rates = 0.045;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9893
            Rates: 0.0450
         EndTimes: 0.2391
       StartTimes: 0
         EndDates: 733803
       StartDates: 733715
    ValuationDate: 733715
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 97.50;
Sigma = .22;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2200
         AssetPrice: 97.5000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the put options.

```
OptSpec = {'put'};
Strike = [95;93];
```

Calculate the price.

```
Paon = assetbybls(RateSpec, StockSpec, Settle, Maturity, OptSpec, Strike)
```

```
Paon = 2×1

   33.7666
   26.9662
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `assetbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `assetbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` vector.

Data Types: `char` | `cell`

`Strike` — Pay-off strike value
vector

Pay-off strike value, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices for asset-or-nothing option
vector

Expected prices for asset-or-nothing option, returned as a `NINST`-by-`1` vector.

Version History

Introduced in R2009a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `assetbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

assetsensbybls

Determine price or sensitivities of asset-or-nothing digital options using Black-Scholes model

Syntax

```
PriceSens = assetsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)
PriceSens = assetsensbybls( ___ ,Name,Value)
```

Description

`PriceSens = assetsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike)` computes asset-or-nothing European digital options or sensitivities using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Binary` object to calculate price or sensitivities for digital options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = assetsensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Asset-Or-Nothing Digital Option Prices and Sensitivities Using the Black-Scholes Option Pricing Model

Consider two asset-or-nothing put options on a nondividend paying stock with a strike of 95 and 93 and expiring on January 30, 2009. On November 3, 2008 the stock is trading at 97.50. Using this data, calculate the price and sensitivity of the asset-or-nothing put options if the risk-free rate is 4.5% and the volatility is 22%. First, create the `RateSpec`.

```
Settle = datetime(2008,11,3);
Maturity = datetime(2009,1,30);
Rates = 0.045;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9893
            Rates: 0.0450
         EndTimes: 0.2391
       StartTimes: 0
         EndDates: 733803
       StartDates: 733715
    ValuationDate: 733715
```

```
            Basis: 0
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 97.50;
Sigma = .22;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2200
         AssetPrice: 97.5000
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Define the put options.

```
OptSpec = {'put'};
Strike = [95;93];
```

Calculate the delta, price, and gamma.

```
OutSpec = { 'delta';'price';'gamma'};
[Delta, Price, Gamma] = assetsensbybls(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike, 'OutSpec', OutSpec)
```

```
Delta = 2×1

   -3.0833
   -2.8337

Price = 2×1

   33.7666
   26.9662

Gamma = 2×1

    0.0941
    0.1439
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

Settle — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors

To support existing code, `assetsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `assetsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

OptSpec — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` vector.

Data Types: `char` | `cell`

Strike — Pay-off strike value
vector

Pay-off strike value, specified as an `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Gamma,Delta] = assetsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,'OutSpec', {'gamma'; 'delta'})`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities for asset-or-nothing option
vector

Expected prices or sensitivities (defined using `OutSpec`) for asset-or-nothing option, returned as a `NINST`-by-`1` vector.

Version History

Introduced in R2009a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `assetsensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barrierbycrr

Price barrier option from Cox-Ross-Rubinstein binomial tree

Syntax

```
[Price,PriceTree] = barrierbycrr(CRRTree,OptSpec,Strike,Settle,AmericanOpt,
ExerciseDates,BarrierSpec,Barrier)
[Price,PriceTree] = barrierbycrr( ___ ,Rebate,Options)
```

Description

`[Price,PriceTree] = barrierbycrr(CRRTree,OptSpec,Strike,Settle,AmericanOpt, ExerciseDates,BarrierSpec,Barrier)` calculates prices for barrier options using a Cox-Ross-Rubinstein binomial tree.

Note Alternatively, you can use the `Barrier` object to price Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = barrierbycrr( ___ ,Rebate,Options)` adds optional arguments for `Rebate` and `Options`.

Examples

Price a Barrier Option Using a CRR Binomial Tree

This example shows how to price a barrier option using a CRR binomial tree by loading the file deriv.mat, which provides CRRTree. The CRRTree structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'Call';
Strike = 105;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2006,1,1);
AmericanOpt = 1;
BarrierSpec = 'UI';
Barrier = 102;

Price = barrierbycrr(CRRTree, OptSpec, Strike, Settle, ...
ExerciseDates, AmericanOpt, BarrierSpec, Barrier)

Price = 12.1272
```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of an option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vector values.

Data Types: `char` | `cell`

`Strike` — Option strike price value

integer

Option strike price value for a European or an American Option, specified as `NINST`-by-`1` matrix of integers. Each row is the schedule for one option.

Data Types: `double`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the barrier option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every barrier is set to the `ValuationDate` of the stock tree. The barrier argument `Settle` is ignored.

To support existing code, `barrierbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vector:

- For a European option, use a `1`-by-`1` matrix of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a `1`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed date in `ExerciseDates`.

To support existing code, `barrierbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type

Option type values `0` or `1`

Option type, specified as `NINST`-by-`1` matrix of integer flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'` | cell array of character vectors with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector or an `NINST`-by-`1` cell array of character vectors with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy/sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.
- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.
- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char` | `cell`

`Barrier` — Barrier level
numeric

Barrier level, specified as a `NINST`-by-`1` matrix of numeric values.

Data Types: `double`

`Rebate` — Rebate value
`0` (default) | numeric

(Optional) Rebate value, specified as a `NINST`-by-`1` matrix of numeric values. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: `double`

`Options` — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices for barrier options at time 0
matrix

Expected prices for barrier options at time 0, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure with vector of barrier option prices at each node
tree structure

Structure with a vector of barrier option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `barrierbycrr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barrierbyeqp

Price barrier option from Equal Probabilities binomial tree

Syntax

```
[Price,PriceTree] = barrierbyeqp(EQPTree,OptSpec,Strike,Settle,AmericanOpt,
ExerciseDates,BarrierSpec,Barrier)
[Price,PriceTree] = barrierbyeqp( ___ ,Rebate,Options)
```

Description

`[Price,PriceTree] = barrierbyeqp(EQPTree,OptSpec,Strike,Settle,AmericanOpt, ExerciseDates,BarrierSpec,Barrier)` calculates prices for barrier options using an Equal Probabilities binomial tree.

Note Alternatively, you can use the `Barrier` object to price Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = barrierbyeqp( ___ ,Rebate,Options)` adds optional arguments for `Rebate` and `Options`.

Examples

Price a Barrier Option Using an EQP Equity Tree

This example shows how to price a barrier option using an EQP equity tree by loading the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'Call';
Strike = 105;
Settle = datetime(2003,1,1);
ExerciseDates = datetime(2006,1,1);
AmericanOpt = 1;
BarrierSpec = 'UI';
Barrier = 102;

Price = barrierbyeqp(EQPTree, OptSpec, Strike, Settle, ...
ExerciseDates, AmericanOpt, BarrierSpec, Barrier)

Price = 12.2632
```

Input Arguments

`EQPTree` — Stock tree structure

structure

Stock tree structure, specified by using `eqptree`.

Data Types: `struct`

`OptSpec` — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of an option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vector values.

Data Types: `char` | `cell`

`Strike` — Option strike price value

numeric

Option strike price value for a European or an American Option, specified as `NINST`-by-`1` matrix of numeric values. Each row is the schedule for one option.

Data Types: `double`

`Settle` — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the barrier option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every barrier is set to the `ValuationDate` of the stock tree. The barrier argument `Settle` is ignored.

To support existing code, `barrierbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vector:

- For a European option, use a `1`-by-`1` matrix of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a `1`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed date in `ExerciseDates`.

To support existing code, `barrierbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type

option type with values `0` or `1`

Option type, specified as `NINST`-by-`1` matrix of flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'` | cell array of character vectors with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector or an `NINST`-by-`1` cell array of character vectors with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.
- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.
- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char` | `cell`

`Barrier` — Barrier level
numeric

Barrier level, specified as a NINST-by-1 matrix of numeric values.

Data Types: double

Rebate — Rebate value
0 (default) | numeric

(Optional) Rebate value, specified as a NINST-by-1 matrix of numeric values. For Knock-in options, the Rebate is paid at expiry. For Knock-out options, the Rebate is paid when the Barrier is reached.

Data Types: double

Options — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as a structure that is created with derivset.

Data Types: struct

Output Arguments

Price — Expected prices for barrier options at time 0
matrix

Expected prices for barrier options at time 0, returned as a NINST-by-1 matrix.

PriceTree — Structure with vector of barrier option prices at each node
tree structure

Structure with a vector of barrier option prices at each node, returned as a tree structure.

PriceTree is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

PriceTree.PTree contains the prices.

PriceTree.tObs contains the observation times.

PriceTree.dObs contains the observation dates.

barrierbyfd

Calculate barrier option prices using finite difference method

Syntax

```
[Price,PriceGrid,AssetPrices,Times] = barrierbyfd(RateSpec,StockSpec,OptSpec,
Strike,Settle,ExerciseDates,BarrierSpec,Barrier)
[Price,PriceGrid,AssetPrices,Times] = barrierbyfd( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Times] = barrierbyfd(RateSpec,StockSpec,OptSpec, Strike,Settle,ExerciseDates,BarrierSpec,Barrier)` calculates European and American barrier option prices on a single underlying asset using the finite difference method. `barrierbyfd` assumes that the barrier is continuously monitored.

Note Alternatively, you can use the `Barrier` object to price Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceGrid,AssetPrices,Times] = barrierbyfd( ___ ,Name,Value)` adds optional name-value pair arguments. `barrierbyfd` assumes that the barrier is continuously monitored.

Examples

Price a Barrier Down and Out Call Option Using Finite Difference Method

Create a `RateSpec`.

```
AssetPrice = 50;
Strike = 45;
Rate = 0.035;
Volatility = 0.30;
Settle = datetime(2015,1,1);
Maturity = datetime(2016,1,1);
Basis = 1;

RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity,'Rates', Rate, 'Compounding', -1, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 736330
```

```
       StartDates: 735965
    ValuationDate: 735965
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
StockSpec = stockspec(Volatility, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price of a European Down and Out call option using Finite Difference.

```
Barrier = 40;
BarrierSpec = 'DO';
OptSpec = 'Call';
Price = barrierbyfd(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity,...
BarrierSpec, Barrier)
```

```
Price = 8.5020
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of an option as `'call'` or `'put'`, specified as a character vector or string array with values `"call"` or `"put"`.

Data Types: `char` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `barrierbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `barrierbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.
- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the

underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.

- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char`

`Barrier` — Barrier level

numeric

Barrier level, specified as a scalar numeric value.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = barrierbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,Rebate,1000)`

`Rebate` — Rebate value

`0` (default) | numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and a scalar numeric. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: `double`

`AssetGridSize` — Size of asset grid used for a finite difference grid

`400` (default) | positive numeric

Size of the asset grid used for finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a scalar positive numeric.

Data Types: `double`

`TimeGridSize` — Size of time grid used for finite difference grid
`100` (default) | positive numeric

Size of the time grid used for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a scalar positive numeric.

Data Types: `double`

`AmericanOpt` — Option type
`0` European (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of the following values:

- `0` — European
- `1` — American

Data Types: `logical`

Output Arguments

`Price` — Expected prices for barrier options
matrix

Expected prices for barrier options, returned as a `NINST`-by-`1` matrix.

`PriceGrid` — Grid containing prices calculated by finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a grid that is two-dimensional with size `PriceGridSize*length(Times)`. The number of columns does not have to be equal to the `TimeGridSize`, because ex-dividend dates in the `StockSpec` are added to the time grid. The price for `t = 0` is contained in `PriceGrid(:, end)`.

`AssetPrices` — Prices of asset defined by `StockSpec`
vector

Prices of the asset defined by the `StockSpec` corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to second dimension of `PriceGrid`
vector

Times corresponding to the second dimension of the `PriceGrid`, returned as a vector.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying

asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `barrierbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barriersensbyfd

Calculate barrier option prices or sensitivities using finite difference method

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = barriersensbyfd(RateSpec,StockSpec,
OptSpec,Strike,Settle,ExerciseDates,BarrierSpec,Barrier)
[PriceSens,PriceGrid,AssetPrices,Times] = barriersensbyfd( ___ ,Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Times] = barriersensbyfd(RateSpec,StockSpec, OptSpec,Strike,Settle,ExerciseDates,BarrierSpec,Barrier)` calculates European and American barrier option prices or sensitivities of a single underlying asset using the finite difference method. `barrierbyfd` assumes that the barrier is continuously monitored.

Note Alternatively, you can use the `Barrier` object to calculate price or sensitivities for Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,PriceGrid,AssetPrices,Times] = barriersensbyfd( ___ ,Name,Value)` adds optional name-value pair arguments. `barriersesbyfd` assumes that the barrier is continuously monitored.

Examples

Calculate Price and Sensitivities for a Barrier Down and Out Call Option Using Finite Difference Method

Create a `RateSpec`.

```
AssetPrice = 50;
Strike = 45;
Rate = 0.035;
Volatility = 0.30;
Settle = datetime(2015,1,1);
Maturity = datetime(2016,1,1);
Basis = 1;

RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',...
Maturity,'Rates',Rate,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
```

```
       StartTimes: 0
         EndDates: 736330
       StartDates: 735965
    ValuationDate: 735965
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
StockSpec = stockspec(Volatility,AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the `Price`, `Delta`, and `Theta` of a European Down and Out call option using the finite difference method.

```
Barrier = 40;
BarrierSpec = 'DO';
OptSpec = 'Call';
OutSpec = {'price';'delta';'theta'};
[Price, Delta, Theta] = barriersensbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,...
Maturity, BarrierSpec,Barrier,'Outspec',OutSpec)
```

```
Price = 8.5020

Delta = 0.8569

Theta = -1.8502
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `'call'` or `'put'`

Definition of an option as `'call'` or `'put'`, specified as a character vector or string array with values `"call"` or `"put"`.

Data Types: `char` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `barriersensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a `1`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `barriersensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the

barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.

- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.

- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price, as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char`

`Barrier` — Barrier level

numeric

Barrier level, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example:
```
PriceSens =
barriersensbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec
,Barrier,Rebate,1000,AmericanOpt,1)
```

`Rebate` — Rebate value

`0` (default) | numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and a scalar numeric. For Knock-in options, the `Rebate` is paid at expiry. For `Knock-out` options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: double

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

AssetGridSize — Size of asset grid used for finite difference grid
400 (default) | positive numeric

Size of the asset grid used for a finite difference grid, specified as the comma-separated pair consisting of 'AssetGridSize' and a scalar positive numeric.

Data Types: double

TimeGridSize — Size of time grid used for finite difference grid
100 (default) | positive numeric

Size of the time grid used for a finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a scalar positive numeric.

Data Types: double

AmericanOpt — Option type
0 European (default) | integer with values 0 or 1

Option type, specified as the comma-separated pair consisting of 'AmericanOpt' and a scalar flag with one of the following values:

- 0 — European
- 1 — American

Data Types: logical

Output Arguments

PriceSens — Expected prices or sensitivities values for barrier options
matrix

Expected prices or sensitivities (defined using OutSpec) for barrier options, returned as a NINST-by-1 matrix.

PriceGrid — Grid containing prices calculated by finite difference method
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with size `PriceGridSize*length(Times)`. The number of columns does not have to be equal to the `TimeGridSize`, because ex-dividend dates in the `StockSpec` are added to the time grid. The price for `t = 0` is contained in `PriceGrid(:, end)`.

`AssetPrices` — Prices of the asset defined by `StockSpec`
vector

Prices of the asset defined by the `StockSpec` corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to second dimension of `PriceGrid`
vector

Times corresponding to the second dimension of the `PriceGrid`, returned as a vector.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `barriersensbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

dblbarrierbyfd

Calculate double barrier option price using finite difference method

Syntax

```
[Price,PriceGrid,AssetPrices,Times] = dblbarrierbyfd(RateSpec,StockSpec,
OptSpec,Strike,Settle,ExerciseDates,BarrierSpec,Barrier)
[Price,PriceGrid,AssetPrices,Times] = dblbarrierbyfd( ___ ,Name,Value)
```

Description

`[Price,PriceGrid,AssetPrices,Times] = dblbarrierbyfd(RateSpec,StockSpec, OptSpec,Strike,Settle,ExerciseDates,BarrierSpec,Barrier)` calculates a European or American call or put double barrier option price on a single underlying asset using the finite difference method. `dblbarrierbyfd` assumes that the barrier is continuously monitored.

Note Alternatively, you can use the `DoubleBarrier` object to price double barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceGrid,AssetPrices,Times] = dblbarrierbyfd( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Price an American Double Knock-Out Call Option with Rebate

Compute the price of an American double barrier option for a double knock-out (down and out-up and out) call option with a rebate using the following data:

```
Rate = 0.05;
Settle = datetime(2018,6,1);
Maturity = datetime(2018,12,1);
Basis = 1;
```

Define a `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity,'Rates'
```

Define a `StockSpec`.

```
AssetPrice = 100;
Volatility = 0.25;
StockSpec = stockspec(Volatility, AssetPrice);
```

Define the double barrier option.

```
LBarrier = 80;
UBarrier = 130;
Barrier = [UBarrier LBarrier];
BarrierSpec = 'DKO';
OptSpec = 'Call';
Strike = 110;
Rebate = 1;
```

Compute the price of an American option using finite differences.

```
Price = dblbarrierbyfd(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity, BarrierSpec, Barr
```

```
Price = 4.0002
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | string scalar with values `"call"` or `"put"`

Definition of an option, specified as a character vector with a value of `'call'` or `'put'`, or a string scalar with values `"call"` or `"put"`.

Data Types: `char` | `string`

Strike — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

Settle — Settlement or trade date

datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `dblbarrierbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors.

- For a European option, the option expiry date has only one `ExerciseDates` value.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `dblbarrierbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Double barrier option type
character vector with value of `'DKI'` or `'DKO'` | scalar string with value of `"DKI"` or `"DKO"`

Double barrier option type, specified as a character vector or string with one of the following values:

- `'DKI'` — Double Knock-in

  The `'DKI'` option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.
- `'DKO'` — Double Knock-out

  The `'DKO'` option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-in	Standard Call/Put	Worthless
Call/Put	Double Knock-out	Worthless	Standard Call/Put

Data Types: `char` | `string`

`Barrier` — Barrier level
vector

Barrier level, specified as a 1-by-2 vector of numeric values, where the first column is the upper barrier (1)(UB) and the second column is the lower barrier (2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = dblbarrierbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec, Barrier,'Rebate',[100,100])`

`Rebate` — Rebate value

`[0 0]` for Double Knock-out or `0` for Double Knock-in (default) | vector | scalar numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and one of the following:

- For a Double Knock-out option, use a 1-by-2 vector of rebate values where the first column is the payout if the upper barrier(1)(UB) is hit and the second column is payout if the lower barrier(2) (LB) is hit. The rebate is paid when the barrier is reached.
- For a Double Knock-in option, use a scalar rebate value. The rebate is paid at expiry.

Data Types: `double`

`AssetGridSize` — Size of asset grid used for a finite difference grid

`400` (default) | positive scalar numeric

Size of the asset grid used for the finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a positive scalar numeric.

Data Types: `double`

`TimeGridSize` — Size of time grid used for finite difference grid

`100` (default) | positive scalar numeric

Size of the time grid used for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive scalar numeric.

Note The actual time grid may have a larger size because exercise and ex-dividend dates might be added to the grid from `StockSpec`.

Data Types: `double`

`AmericanOpt` — Option type

`0` European (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of the following values:

- `0` — European
- `1` — American

Data Types: `logical`

Output Arguments

`Price` — Expected prices for double barrier options

matrix

Expected prices for double barrier options, returned as a 1-by-1 matrix.

`PriceGrid` — Grid containing prices

grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with the size `AssetGridSize*TimeGridSize`. The number of columns does not have to be equal to the `TimeGridSize`, because exercise and ex-dividend dates in `StockSpec` are added to the time grid. `PriceGrid(:, end)` contains the price for `t = 0`.

`AssetPrices` — Prices of asset defined by `StockSpec`

vector

Prices of the asset defined by the `StockSpec` corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to second dimension of `PriceGrid`

vector

Times corresponding to the second dimension of `PriceGrid`, returned as a vector.

More About

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that it has two barrier levels: a lower barrier (LB) and an upper barrier (UB).

The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as they have a higher knock-out probability. Because of this, double barrier options allow investors to reduce option premiums and match an investor’s belief about the future movement of the underlying price process.

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `dblbarrierbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

dblbarriersensbyfd

Calculate double barrier option price and sensitivities using finite difference method

Syntax

```
[PriceSens,PriceGrid,AssetPrices,Times] = dblbarriersensbyfd(RateSpec,
StockSpec,OptSpec,Strike,Settle,ExerciseDates,BarrierSpec,Barrier)
[PriceSens,PriceGrid,AssetPrices,Times] = dblbarriersensbyfd( ___ ,Name,Value)
```

Description

`[PriceSens,PriceGrid,AssetPrices,Times] = dblbarriersensbyfd(RateSpec, StockSpec,OptSpec,Strike,Settle,ExerciseDates,BarrierSpec,Barrier)` calculates a European or American call or put double barrier option price and sensitivities of a single underlying asset using the finite difference method. `dblbarrierbyfd` assumes that the barrier is continuously monitored.

Note Alternatively, you can use the `DoubleBarrier` object to calculate price or sensitivities for double barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,PriceGrid,AssetPrices,Times] = dblbarriersensbyfd( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate Price and Sensitivities for an American Double Knock-Out Call Option with Rebate

Compute the price and sensitivities for an American double barrier option for a double knock-out (down and out-up and out) call option with a rebate using the following data:

```
Rate = 0.05;
Settle = datetime(2018,6,1);
Maturity = datetime(2018,12,1);
Basis = 1;
```

Define a `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity,'Rates'
```

Define a `StockSpec`.

```
AssetPrice = 100;
Volatility = 0.25;
StockSpec = stockspec(Volatility, AssetPrice);
```

Define the double barrier option.

```
LBarrier = 80;
UBarrier = 130;
Barrier = [UBarrier LBarrier];
BarrierSpec = 'DKO';
OptSpec = 'Call';
Strike = 110;
Rebate = 1;
OutSpec = {'price'; 'vega'; 'theta'};
```

Compute the price and sensitivities for an American option using finite differences.

```
[Price, Vega, Theta] = dblbarriersensbyfd(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity
```

```
Price = 4.0002
```

```
Vega = -1.9180e+03
```

```
Theta = -6.6509
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | string scalar with values `"call"` or `"put"`

Definition of an option, specified as a character vector with a value of `'call'` or `'put'`, or a string scalar with values `"call"` or `"put"`.

Data Types: `char` | `string`

Strike — Option strike price value

scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

Settle — Settlement or trade date

datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `dblbarriersensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors.

- For a European option, the option expiry date has only one `ExerciseDates` value.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `dblbarriersensbyfd` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Double barrier option type

character vector with value of `'DKI'` or `'DKO'` | scalar string with value of `"DKI"` or `"DKO"`

Double barrier option type, specified as a character vector or string with one of the following values:

- `'DKI'` — Double Knock-in

  The `'DKI'` option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.
- `'DKO'` — Double Knock-out

  The `'DKO'` option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-in	Standard Call/Put	Worthless
Call/Put	Double Knock-out	Worthless	Standard Call/Put

Data Types: `char` | `string`

`Barrier` — Barrier level

vector

Barrier level, specified as a 1-by-2 vector of numeric values, where the first column is the upper barrier (1)(UB) and the second column is the lower barrier (2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = dblbarriersensbyfd(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,'OutSpec', {'delta','gamma','vega','lambda','rho','theta','price'},'AmericanOpt',1)`

`OutSpec` — Define outputs

`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Lambda"`, `"Rho"`, `"Theta"`, and `"All"`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors or a string array with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell` | `string`

`Rebate` — Rebate value

`[0 0]` for Double Knock-out or `0` for Double Knock-in (default) | vector | scalar numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and one of the following:

- For a Double Knock-out option, use a `1`-by-`2` vector of rebate values where the first column is the payout if the upper barrier(1)(UB) is hit and the second column is payout if the lower barrier(2)(LB) is hit. The rebate is paid when the barrier is reached.
- For a Double Knock-in option, use a scalar rebate value. The rebate is paid at expiry.

Data Types: `double`

`AssetGridSize` — Size of asset grid used for finite difference grid

`400` (default) | positive scalar numeric

Size of the asset grid used for the finite difference grid, specified as the comma-separated pair consisting of `'AssetGridSize'` and a positive scalar numeric.

Data Types: `double`

`TimeGridSize` — Size of time grid used for finite difference grid

`100` (default) | positive scalar numeric

Size of the time grid used for the finite difference grid, specified as the comma-separated pair consisting of `'TimeGridSize'` and a positive scalar numeric.

Note The actual time grid may have a larger size because exercise and ex-dividend dates might be added to the grid from `StockSpec`.

Data Types: `double`

`AmericanOpt` — Option type
`0` European (default) | integer with values `0` or `1`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of the following values:

- `0` — European
- `1` — American

Data Types: `logical`

Output Arguments

`PriceSens` — Expected prices or sensitivities values for double barrier options
matrix

Expected prices or sensitivities (defined using `OutSpec`) for double barrier options, returned as a `1`-by-`NOUT` matrix.

`PriceGrid` — Grid containing prices
grid

Grid containing prices calculated by the finite difference method, returned as a two-dimensional grid with the size `AssetGridSize*TimeGridSize`. The number of columns does not have to be equal to the `TimeGridSize`, because exercise and ex-dividend dates in `StockSpec` are added to the time grid. `PriceGrid(:, end)` contains the price for `t = 0`.

`AssetPrices` — Prices of the asset defined by `StockSpec`
vector

Prices of the asset defined by the `StockSpec` corresponding to the first dimension of `PriceGrid`, returned as a vector.

`Times` — Times corresponding to second dimension of `PriceGrid`
vector

Times corresponding to the second dimension of the `PriceGrid`, returned as a vector.

More About

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that it has two barrier levels: a lower barrier (`LB`) and an upper barrier (`UB`).

The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as they have a higher knock-out probability. Because of this, double barrier options

allow investors to reduce option premiums and match an investor's belief about the future movement of the underlying price process.

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `dblbarriersensbyfd` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barrierbyls

Price European or American barrier options using Monte Carlo simulations

Syntax

```
[Price,Paths,Times,Z] = barrierbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates,BarrierSpec,Barrier)
[Price,Paths,Times,Z] = barrierbyls( ___ ,Name,Value)
```

Description

`[Price,Paths,Times,Z] = barrierbyls(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates,BarrierSpec,Barrier)` calculates barrier option prices on a single underlying asset using the Longstaff-Schwartz model. `barrierbyls` computes prices of European and American barrier options.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

Note Alternatively, you can use the `Barrier` object to price Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,Paths,Times,Z] = barrierbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price an American Barrier Down In Put Option

Compute the price of an American down in put option using the following data:

```
Rates = 0.0325;
Settle = datetime(2016,1,1);
Maturity = datetime(2017,1,1);
Compounding = -1;
Basis = 1;
```

Define a `RateSpec`.

```
 RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',Maturity, ...
     'Rates',Rates,'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9680
            Rates: 0.0325
```

```
          EndTimes: 1
        StartTimes: 0
          EndDates: 736696
        StartDates: 736330
     ValuationDate: 736330
             Basis: 1
      EndMonthRule: 1
```

Define a `StockSpec`.

```
AssetPrice = 40;
Volatility = 0.20;
StockSpec = stockspec(Volatility,AssetPrice)
```

```
StockSpec = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.2000
          AssetPrice: 40
        DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price of an American barrier down in put option.

```
Strike = 45;
OptSpec = 'put';
Barrier = 35;
BarrierSpec = 'DI';
AmericanOpt = 1;

Price = barrierbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,...
Barrier,'NumTrials',2000,'AmericanOpt',AmericanOpt)
```

```
Price = 4.7306
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as a character vector or string array with a value of `"call"` or `"put"`.

Data Types: `char` | `string`

`Strike` — Option strike price value
scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `barrierbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a `1`-by-`2` vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `barrierbyls` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the

barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.

- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option.

- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually, the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char`

`Barrier` — Barrier level

scalar numeric

Barrier level, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = barrierbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,Rebate,1000)`

`AmericanOpt` — Option type

`0` (European) (default) | values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`Rebate` — Rebate value
`0` (default) | scalar numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and a scalar numeric. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: `double`

`NumTrials` — Number of independent sample paths
`1000` (default) | nonnegative integer

Number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a scalar nonnegative integer.

Data Types: `double`

`NumPeriods` — Number of simulation periods per trial
`100` (default) | nonnegative integer

Number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar nonnegative integer.

Data Types: `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-`1`-by-`NumTrials` 3-D time series array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

Output Arguments

Price — Expected prices for barrier options

matrix

Expected prices for barrier options, returned as a NINST-by-1 matrix.

Paths — Simulated paths of correlated state variables

vector

Simulated paths of correlated state variables, returned as a NumPeriods + 1-by-1-by-NumTrials 3-D time series array of simulated paths of correlated state variables. Each row of Paths is the transpose of the state vector $X(t)$ at time t for a given trial.

Times — Observation times associated with simulated paths

vector

Observation times associated with simulated paths, returned as a NumPeriods + 1-by-1 column vector of observation times associated with the simulated paths. Each element of Times is associated with the corresponding row of Paths.

Z — Time series array of dependent random variates

vector

Time series array of dependent random variates, returned as a NumPeriods-by-1-by-NumTrials 3-D array when Z is specified as an input argument. If the Z input argument is not specified, then the Z output argument contains the random variates generated internally.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by Barrier, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although barrierbyls supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barriersensbyls

Calculate price and sensitivities for European or American barrier options using Monte Carlo simulations

Syntax

```
[PriceSens,Paths,Times,Z] = barriersensbyls(RateSpec,StockSpec,OptSpec,
Strike,Settle,ExerciseDates,BarrierSpec,Barrier)
[PriceSens,Paths,Times,Z] = barriersensbyls( ___ ,Name,Value)
```

Description

`[PriceSens,Paths,Times,Z] = barriersensbyls(RateSpec,StockSpec,OptSpec, Strike,Settle,ExerciseDates,BarrierSpec,Barrier)` calculates barrier option prices or sensitivities on a single underlying asset using the Longstaff-Schwartz model. `barriersensbyls` computes prices of European and American barrier options.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

Note Alternatively, you can use the `Barrier` object to calculate price or sensitivities for Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[PriceSens,Paths,Times,Z] = barriersensbyls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Delta and Gamma of an American Barrier Down In Put Option

Compute the price of an American down in put option using the following data:

```
Rates = 0.0325;
Settle = datetime(2016,1,1);
Maturity = datetime(2017,1,1);
Compounding = -1;
Basis = 1;
```

Define a `RateSpec`.

```
 RateSpec = intenvset('ValuationDate',Settle,'StartDates',Settle,'EndDates',Maturity, ...
     'Rates',Rates,'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9680
```

```
           Rates: 0.0325
         EndTimes: 1
       StartTimes: 0
         EndDates: 736696
       StartDates: 736330
    ValuationDate: 736330
           Basis: 1
     EndMonthRule: 1
```

Define a `StockSpec`.

```
AssetPrice = 40;
Volatility = 0.20;
StockSpec = stockspec(Volatility,AssetPrice)
```

```
StockSpec = struct with fields:
            FinObj: 'StockSpec'
             Sigma: 0.2000
         AssetPrice: 40
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the delta and gamma of an American barrier down in put option.

```
Strike = 45;
OptSpec = 'put';
Barrier = 35;
BarrierSpec = 'DI';
AmericanOpt = 1;

OutSpec = {'delta','gamma'};

[Delta,Gamma] = barriersensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,...
Maturity,BarrierSpec,Barrier,'NumTrials',2000,'AmericanOpt',AmericanOpt,'OutSpec',OutSpec)
```

```
Delta = -0.6346

Gamma = -0.3091
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as a character vector or string array with values `"call"` or `"put"`.

Data Types: `char` | `string`

`Strike` — Option strike price value
scalar numeric

Option strike price value, specified as a scalar numeric.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the barrier option, specified as a scalar datetime, string, or date character vector.

To support existing code, `barriersensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a 1-by-2 vector of exercise date boundaries. The option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, the option can be exercised between `Settle` and the single listed date in `ExerciseDates`.

To support existing code, `barriersensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.

- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.

- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option.

- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually, the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char`

`Barrier` — Barrier level

scalar numeric

Barrier level, specified as a scalar numeric.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = barriersensbyls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,Rebate,1000)`

`AmericanOpt` — Option type

`0` (European) (default) | values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a scalar flag with one of the following values:

- `0` — European
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`Rebate` — Rebate value
`0` (default) | numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and a scalar numeric. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: `double`

`NumTrials` — Number of independent sample paths
`1000` (default) | nonnegative integer

Number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a scalar nonnegative integer.

Data Types: `double`

`NumPeriods` — Number of simulation periods per trial
`100` (default) | nonnegative integer

Number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar nonnegative integer.

Data Types: `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-`1`-by-`NumTrials` 3-D time series array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a scalar value of `true` or `false`.

Data Types: `logical`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

`MonitoringFreq` — Number of days between monitoring barriers
`0` (default) | integer

Number of days between monitoring barriers, specified as a scalar integer. The default is `0` which indicates that the barrier is continuously monitored.

Data Types: `double`

Output Arguments

`PriceSens` — Expected prices or sensitivities for barrier options
matrix

Expected prices or sensitivities (defined using `OutSpec`) for barrier options, returned as a `NINST`-by-`1` matrix.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-`1`-by-`NumTrials` 3-D time series array of simulated paths of correlated state variables. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-`1`-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `barriersensbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barrierbybls

Price European barrier options using Black-Scholes option pricing model

Syntax

```
Price = barrierbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates,
BarrierSpec,Barrier)
Price = barrierbybls( ___ ,Name,Value)
```

Description

`Price = barrierbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,ExerciseDates, BarrierSpec,Barrier)` calculates European barrier option prices using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Barrier` object to price Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = barrierbybls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price an European Barrier Down Out Call Option

Compute the price of an European barrier down out call option using the following data:

```
Rates = 0.035;
Settle = datetime(2015,1,1);
Maturity = datetime(2016,1,1);
Compounding = -1;
Basis = 1;
```

Define a `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity, ...
'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 736330
       StartDates: 735965
    ValuationDate: 735965
            Basis: 1
```

```
     EndMonthRule: 1
```

Define a StockSpec.

```
AssetPrice = 50;
Volatility = 0.30;
StockSpec = stockspec(Volatility, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price of an European barrier down out call option using the Black-Scholes option pricing model.

```
Strike = 50;
OptSpec = 'call';
Barrier = 45;
BarrierSpec = 'DO';

Price = barrierbybls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
Maturity,  BarrierSpec, Barrier)
```

```
Price = 4.4285
```

Price European Barrier Down Out and Down In Call Options

Compute the price of European down out and down in call options using the following data:

```
Rates = 0.035;
Settle = datetime(2015,1,1);
Maturity = datetime(2016,1,1);
Compounding = -1;
Basis = 1;
```

Define a RateSpec.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity, ...
'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9656
            Rates: 0.0350
         EndTimes: 1
       StartTimes: 0
         EndDates: 736330
       StartDates: 735965
    ValuationDate: 735965
```

```
            Basis: 1
     EndMonthRule: 1
```

Define a `StockSpec`.

```
AssetPrice = 50;
Volatility = 0.30;
StockSpec = stockspec(Volatility, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.3000
         AssetPrice: 50
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Calculate the price of European barrier down out and down in call options using the Black-Scholes Option Pricing model.

```
Strike = 50;
OptSpec = 'Call';
Barrier = 45;
BarrierSpec = {'DO';'DI'};

Price = barrierbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity,  BarrierSpec, Barrie
```

```
Price = 2×1

    4.4285
    2.3301
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` cell array of character vectors or string array with values `'call'` or `'put'` or `"call"` or `"put"`.

Data Types: `char` | `cell` | `string`

`Strike` — Option strike price value
numeric

Option strike price value, specified as an `NINST`-by-`1` matrix of numeric values, where each row is the schedule for one option.

Data Types: `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the barrier option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `barrierbybls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.

To support existing code, `barrierbybls` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as an `NINST`-by-`1` cell array of character vectors with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying

asset passes above the barrier level. Usually with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.

- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option.

- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually, the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char` | `cell`

`Barrier` — Barrier level

numeric

Barrier level, specified as `NINST`-by-`1` matrix of numeric values.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = barrierbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,Rebate,1000)`

`Rebate` — Rebate value

`0` (default) | numeric

Rebate value, specified as the comma-separated pair consisting of `'Rebate'` and `NINST`-by-`1` matrix of numeric values. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: `double`

Output Arguments

`Price` — Expected prices for barrier options

matrix

Expected prices for barrier options at time 0, returned as a `NINST`-by-`1` matrix.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2016b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `barrierbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

barriersensbybls

Calculate price or sensitivities for European barrier options using Black-Scholes option pricing model

Syntax

```
PriceSens = barriersensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates,BarrierSpec,Barrier)
PriceSens = barriersensbybls( ___ ,Name,Value)
```

Description

`PriceSens = barriersensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates,BarrierSpec,Barrier)` calculates European barrier option prices or sensitivities using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Barrier` object to calculate price or sensitivities for Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = barriersensbybls( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Calculate Price and Sensitivities for European Barrier Down Out and Down In Call Options

Compute price of European barrier down out and down in call options using the following data:

```
Rates = 0.035;
Settle = '01-Jan-2015';
Maturity = '01-April-2015';
Compounding = -1;
Basis = 1;
```

Define a `RateSpec`.

```
 RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity, ...
     'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9913
            Rates: 0.0350
         EndTimes: 0.2500
       StartTimes: 0
         EndDates: 736055
       StartDates: 735965
    ValuationDate: 735965
            Basis: 1
```

```
     EndMonthRule: 1
```

Define a `StockSpec`.

```
AssetPrice = 19;
Volatility = 0.40;
DivType = 'Continuous';
DivAmount = 0.035;
StockSpec = stockspec(Volatility, AssetPrice, DivType, DivAmount)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.4000
         AssetPrice: 19
       DividendType: {'continuous'}
    DividendAmounts: 0.0350
    ExDividendDates: []
```

Calculate the `price`, `delta`, and `gamma` for European barrier down out and down in call options using the Black-Scholes option pricing model.

```
OptSpec = 'Call';
Strike = 20;
Barrier = 18;
BarrierSpec = {'DO';'DI'};
OutSpec = {'price', 'delta', 'gamma'};

[Price, Delta, Gamma] = barriersensbybls(RateSpec, StockSpec, OptSpec, Strike, Settle,...
Maturity,  BarrierSpec, Barrier,'OutSpec', OutSpec)
```

```
Price = 2×1

    0.6287
    0.4655

Delta = 2×1

    0.6376
   -0.2036

Gamma = 2×1

    0.0255
    0.0773
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` cell array of character vectors or string arrays with values `"call"` or `"put"`.

Data Types: `char` | `string` | `cell`

`Strike` — Option strike price value
numeric

Option strike price value, specified as an `NINST`-by-`1` matrix of numeric values.

Data Types: `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector | serial date number

Settlement or trade date for the barrier option, specified as an `NINST`-by-`1` vector using a datetime array, string array, date character vectors, or serial date numbers.

Data Types: `double` | `char` | `string` | `datetime`

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector | serial date number

Option exercise dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, date character vectors, or serial date numbers.

Note For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.

Data Types: `double` | `char` | `string` | `datetime`

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as an `NINST`-by-`1` cell array of character vectors with the following values:

- `'UI'` — Up Knock-in

This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option.

- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.

- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option.

- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually, the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char` | `cell`

`Barrier` — Barrier level

numeric

Barrier level, specified as an `NINST`-by-`1` matrix of numeric values.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = barriersensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,'Rebate',1000,'OutSpec','Delta')`

Rebate — Rebate values
0 (default) | numeric

Rebate values, specified as the comma-separated pair consisting of 'Rebate' and NINST-by-1 matrix of numeric values. For Knock-in options, the Rebate is paid at expiry. For Knock-out options, the Rebate is paid when the Barrier is reached.

Data Types: double

OutSpec — Define outputs
{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and a NOUT- by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}

Data Types: char | cell

Output Arguments

PriceSens — Expected prices or sensitivities for barrier options
matrix

Expected prices at time 0 or sensitivities (defined using OutSpec) for barrier options, returned as a NINST-by-1 matrix.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by Barrier, during the life of the option. For more information, see “Barrier Option” on page 3-20.

dblbarrierbybls

Price European double barrier options using Black-Scholes option pricing model

Syntax

```
Price = dblbarrierbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates,BarrierSpec,Barrier)
Price = dblbarrierbybls( ___ ,Name,Value)
```

Description

`Price = dblbarrierbybls(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates,BarrierSpec,Barrier)` calculates European double barrier option prices using the Black-Scholes option pricing model and the Ikeda and Kunitomo approximation.

Note Alternatively, you can use the `DoubleBarrier` object to price double barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`Price = dblbarrierbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Price a European Double Knock-Out Call Option

Compute the price of a European for a double knock-out (down and out-up and out) call option using the following data:

```
Rate = 0.05;
Settle = datetime(2018,6,1);
Maturity = datetime(2018,12,1);
Basis = 1;
```

Define a `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity,'Rates'
```

Define a `StockSpec`.

```
AssetPrice = 100;
Volatility = 0.25;
StockSpec = stockspec(Volatility, AssetPrice);
```

Define the double barrier option.

```
LBarrier = 80;
UBarrier = 130;
Barrier = [UBarrier LBarrier];
```

```
BarrierSpec = 'DKO';
OptSpec = 'Call';
Strike = 110;
```

Compute price of option using flat boundaries.

```
PriceFlat = dblbarrierbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity, BarrierSpec,
```

```
PriceFlat = 1.1073
```

Compute price of option using two curved boundaries.

```
Curvature = [0.05 -0.05];
PriceCurved = dblbarrierbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity, BarrierSpec
```

```
PriceCurved = 1.4548
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

OptSpec — Definition of option

cell array of character vectors with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors or string array with values `'call'` or `'put'` or `"call"` or `"put"`.

Data Types: `char` | `cell` | `string`

Strike — Option strike price value

matrix

Option strike price value, specified as an `NINST`-by-`1` matrix of numeric values, where each row is the schedule for one option.

Data Types: `double`

Settle — Settlement or trade date

datetime array | string array | date character vector

Settlement or trade date for the double barrier option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `dblbarrierbybls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note For a European option, the option expiry date has only one `ExerciseDates` value, which is the maturity of the instrument.

To support existing code, `dblbarrierbybls` also accepts serial date numbers as inputs, but they are not recommended.

`BarrierSpec` — Double barrier option type

cell array of character vectors with values of `'DKI'` or `'DKO'` | string array with values of `"DKI"` or `"DKO"`

Double barrier option type, specified as an `NINST`-by-`1` cell array of character vectors or string array with the following values:

- `'DKI'` — Double Knock-In

  The `'DKI'` option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.
- `'DKO'` — Double Knock-Out

  The `'DKO'` option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-in	Standard Call/Put	Worthless
Call/Put	Double Knock-out	Worthless	Standard Call/Put

Data Types: `char` | `cell` | `string`

`Barrier` — Double barrier value

numeric

Double barrier value, specified as `NINST`-by-`1` matrix of numeric values, where each element is a `1`-by-`2` vector where the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = dblbarrierbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,'Curvature',[1,5])`

`Curvature` — Curvature levels of the upper and lower barriers

`[]` (default) | matrix

Curvature levels of the upper and lower barriers, specified as the comma-separated pair consisting of `'Curvature'` and an `NINST`-by-`1` matrix, where each element is a `1`-by-`2` vector. The first column is the upper barrier curvature (*d1*) and the second column is the lower barrier curvature (*d2*).

- *d1* = *d2* = `0` corresponds to two flat boundaries.
- *d1* < 0 < *d2* corresponds to an exponentially growing lower boundary and an exponentially decaying upper boundary.
- *d1* > 0 > *d2* corresponds to a convex downward lower boundary and a convex upward upper boundary.

Data Types: `double`

Output Arguments

`Price` — Expected prices for double barrier options

matrix

Expected prices for double barrier options at time 0, returned as a `NINST`-by-`1` matrix.

More About

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that it has two barrier levels: a lower barrier (`LB`) and an upper barrier (`UB`).

The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as they have a higher knock-out probability. Because of this, double barrier options allow investors to reduce option premiums and match an investor’s belief about the future movement of the underlying price process.

Ikeda and Kunitomo Approximation

The analytical formulas of Ikeda and Kunitomo approach pricing as constrained by curved boundaries.

This approach has the advantage of covering barriers that are flat, have exponential growth or decay, or are concave. The Ikeda and Kunitomo model for pricing double barrier options focuses on calculating double knock-out barriers.

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `dblbarrierbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

dblbarriersensbybls

Calculate prices and sensitivities for European double barrier options using Black-Scholes option pricing model

Syntax

```
PriceSens = dblbarriersensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,
ExerciseDates,BarrierSpec,Barrier)
PriceSens = dblbarriersensbybls( ___ ,Name,Value)
```

Description

`PriceSens = dblbarriersensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle, ExerciseDates,BarrierSpec,Barrier)` calculates European double barrier option prices and sensitivities using the Black-Scholes option pricing model and the Ikeda and Kunitomo approximation.

Note Alternatively, you can use the `DoubleBarrier` object to calculate price or sensitivities for double barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = dblbarriersensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate Price and Sensitivities for a European Double Knock-Out Call Option

Compute the price and sensitivities for a European double knock-out (down and out-up and out) call option using the following data:

```
Rate = 0.05;
Settle = datetime(2018,6,1);
Maturity = datetime(2018,12,1);
Basis = 1;
```

Define a `RateSpec`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', Maturity,'Rates'
```

Define a `StockSpec`.

```
AssetPrice = 100;
Volatility = 0.25;
StockSpec = stockspec(Volatility, AssetPrice);
```

Define the double barrier option and sensitivities.

```
LBarrier = 80;
UBarrier = 130;
```

```
Barrier = [UBarrier LBarrier];
BarrierSpec = 'DKO';
OptSpec = 'Call';
Strike = 110;
OutSpec = {'Price', 'Delta', 'Gamma'};
```

Compute the price of the option using flat boundaries.

```
[PriceFlat, Delta, Gamma] = dblbarriersensbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, Ma
```

```
PriceFlat = 1.1073
```

```
Delta = 0.0411
```

```
Gamma = -0.0040
```

Compute the price of the option using two curved boundaries.

```
Curvature = [0.05 -0.05];
[PriceCurved, Delta, Gamma] = dblbarriersensbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, M
```

```
PriceCurved = 1.4548
```

```
Delta = 0.0620
```

```
Gamma = -0.0045
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

OptSpec — Definition of option

cell array of character vectors with values `'call'` or `'put'` | string array with values `"call"` or `"put"`

Definition of the option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vectors or string array with values `'call'` or `'put'` or `"call"` or `"put"`.

Data Types: `char` | `cell` | `string`

Strike — Option strike price value
matrix

Option strike price value, specified as an NINST-by-1 matrix of numeric values, where each row is the schedule for one option.

Data Types: double

Settle — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the double barrier option, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, dblbarriersensbybls also accepts serial date numbers as inputs, but they are not recommended.

ExerciseDates — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as an NINST-by-1 vector using a datetime array, string array, or date character vectors.

Note For a European option, the option expiry date has only one ExerciseDates value, which is the maturity of the instrument.

To support existing code, dblbarriersensbybls also accepts serial date numbers as inputs, but they are not recommended.

BarrierSpec — Double barrier option type
cell array of character vectors with values of 'DKI' or 'DKO' | string array with values of "DKI" or "DKO"

Double barrier option type, specified as an NINST-by-1 cell array of character vectors or string array with the following values:

- 'DKI' — Double Knock-in

  The 'DKI' option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.
- 'DKO' — Double Knock-out

  The 'DKO' option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-in	Standard Call/Put	Worthless

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-out	Worthless	Standard Call/Put

Data Types: `char` | `cell` | `string`

`Barrier` — Double barrier value
matrix

Double barrier value, specified as `NINST`-by-`1` matrix of numeric values, where each element is a `1`-by-`2` vector where the first column is `Barrier`(1)(`UB`) and the second column is `Barrier`(2)(`LB`). `Barrier`(1) must be greater than `Barrier`(2).

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = dblbarriersensbybls(RateSpec,StockSpec,OptSpec,Strike,Settle,Maturity,BarrierSpec,Barrier,'Curvature',[1,5],'OutSpec','Delta')`

`Curvature` — Curvature levels of the upper and lower barriers
`[]` (default) | matrix

Curvature levels of the upper and lower barriers, specified as the comma-separated pair consisting of `'Curvature'` and an `NINST`-by-`1` matrix of numeric values, where each element is a `1`-by-`2` vector. The first column is the upper barrier curvature (*d1*) and the second column is the lower barrier curvature (*d2*).

- *d1* = *d2* = `0` corresponds to two flat boundaries.
- *d1* < 0 < *d2* corresponds to an exponentially growing lower boundary and an exponentially decaying upper boundary.
- *d1* > 0 > *d2* corresponds to a convex downward lower boundary and a convex upward upper boundary.

Data Types: `double`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | string array with values `"Price"`, `"Delta"`, `"Gamma"`, `"Vega"`, `"Lambda"`, `"Rho"`, `"Theta"`, and `"All"`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities for double barrier options

matrix

Expected prices at time 0 or sensitivities (defined using `OutSpec`) for double barrier options, returned as a `NINST`-by-`1` matrix.

More About

Double Barrier Option

A double barrier option is similar to the standard single barrier option except that it has two barrier levels: a lower barrier (`LB`) and an upper barrier (`UB`).

The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as they have a higher knock-out probability. Because of this, double barrier options allow investors to reduce option premiums and match an investor's belief about the future movement of the underlying price process.

Ikeda and Kunitomo Approximation

The analytical formulas of Ikeda and Kunitomo approach pricing as constrained by curved boundaries.

This approach has the advantage of covering barriers that are flat, have exponential growth or decay, or are concave. The Ikeda and Kunitomo model for pricing double barrier options focuses on calculating double knock-out barriers.

Version History

Introduced in R2019a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `dblbarriersensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barrierbyitt

Price barrier options using implied trinomial tree (ITT)

Syntax

```
[Price,PriceTree] = barrierbyitt(ITTTree,OptSpec,Strike,Settle,AmericanOpt,
ExerciseDates,BarrierSpec,Barrier)
[Price,PriceTree] = barrierbyitt( ___ ,Rebate,Options)
```

Description

`[Price,PriceTree] = barrierbyitt(ITTTree,OptSpec,Strike,Settle,AmericanOpt, ExerciseDates,BarrierSpec,Barrier)` calculates prices for barrier options using implied trinomial tree (ITT).

`[Price,PriceTree] = barrierbyitt( ___ ,Rebate,Options)` adds optional arguments for `Rebate` and `Options`.

Examples

Price a Barrier Option Using an ITT Tree

This example shows how to price a barrier option using an ITT tree by loading the file deriv.mat, which provides ITTTree. The ITTTree structure contains the stock specification and time information needed to price the option.

```
load deriv.mat;

OptSpec = 'Call';
Strike =  85;
Settle = datetime(2006,1,1);
ExerciseDates = datetime(2008,12,31);
AmericanOpt = 1;
BarrierSpec = 'UI';
Barrier =  115;

Price = barrierbyitt(ITTTree,OptSpec,Strike,Settle,ExerciseDates,AmericanOpt,...
BarrierSpec,Barrier)
```

```
Price = 2.4074
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of an option as `'call'` or `'put'`, specified as a `NINST`-by-`1` cell array of character vector values.

Data Types: `char` | `cell`

`Strike` — Option strike price value
numeric

Option strike price value for a European or an American Option, specified as `NINST`-by-`1` matrix of numeric values. Each row is the schedule for one option.

Data Types: `double`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the barrier option, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every barrier is set to the `ValuationDate` of the stock tree. The barrier argument `Settle` is ignored.

To support existing code, `barrierbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a `NINST`-by-`1` matrix of dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date which is the maturity of the instrument.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. For each instrument, the option can be exercised on any date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is an `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed date in `ExerciseDates`.

To support existing code, `barrierbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
option type values `0` or `1`

Option type, specified as `NINST`-by-`1` flags with values:

- `0` — European
- `1` — American

Data Types: `double`

BarrierSpec — Barrier option type
character vector with values: 'UI', 'UO', 'DI', 'DO' | cell array of character vectors with values: 'UI', 'UO', 'DI', 'DO'

Barrier option type, specified as a character vector or a cell array of character vectors with the following values:

- 'UI' — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option. Note, barrierbyfd does not support American knock-in barrier options.
- 'UO' — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.
- 'DI' — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note, barrierbyfd does not support American knock-in barrier options.
- 'DO' — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: char | cell

Barrier — Barrier level
numeric

Barrier level, specified as an NINST-by-1 matrix of numeric values.

Data Types: double

`Rebate` — Rebate value
`0` (default) | numeric

(Optional) Rebate value, specified as a `NINST`-by-`1` matrix of numeric values. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the `Barrier` is reached.

Data Types: `double`

`Options` — Derivatives pricing options
structure

(Optional) Derivatives pricing options, specified as structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices for barrier options at time 0
vector

Expected prices for barrier options at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure with vector of barrier option prices at each node
tree structure

Structure with a vector of barrier option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2007a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `barrierbyitt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

barrierbystt

Price barrier options using standard trinomial tree

Syntax

```
[Price,PriceTree] = barrierbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates,
AmericanOpt,BarrierSpec,Barrier)
[Price,PriceTree] = barrierbystt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = barrierbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates, AmericanOpt,BarrierSpec,Barrier)` prices barrier options using a standard trinomial (STT) tree.

Note Alternatively, you can use the `Barrier` object to price Barrier options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = barrierbystt( ___ ,Name,Value)` prices barrier options using a standard trinomial (STT) tree with an optional name-value pair argument for `Rebate` and `Options`.

Examples

Price a Barrier Option Using the Standard Trinomial Tree Model

Create a `RateSpec`.

```
StartDates = datetime(2009,1,1);
EndDates = datetime(2013,1,1);
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8694
            Rates: 0.0350
         EndTimes: 4
       StartTimes: 0
         EndDates: 735235
       StartDates: 733774
    ValuationDate: 733774
            Basis: 1
     EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'

Barrier = 115;

Price= barrierbystt(STTTree, OptSpec, Strike, Settle, ExerciseDates,...
AmericanOpt, BarrierSpec, Barrier)
```

```
Price = 3.7977
```

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using stttree.

Data Types: struct

`OptSpec` — Definition of option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of option, specified as `'call'` or `'put'` using a character vector or a `NINST`-by-`1` cell array of character vectors for `'call'` or `'put'`.

Data Types: `char` | `cell`

`Strike` — European or American option strike price value
nonnegative numeric

European or American option strike price value, specified with a nonnegative integer using a `NINST`-by-`1` matrix of nonnegative numeric values. Each row is the schedule for one option. To compute the value of a floating-strike barrier option, `Strike` should be specified as `NaN`. Floating-strike barrier options are also known as average strike options.

Data Types: `double`

`Settle` — Settlement date or trade date
datetime array | string array | date character vector

Settlement date or trade date for the barrier option, specified as a `NINST`-by-`1` vector of settlement or trade dates using a datetime array, string array, or date character vectors.

Note The `Settle` date for every barrier option is set to the `ValuationDate` of the stock tree. The barrier argument, `Settle`, is ignored.

To support existing code, `barrierbystt` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates
datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of exercise date boundaries. The option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is a `NINST`-by-`1` cell array of character vectors, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `barrierbystt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanOpt` — Option type
scalar with values `[0,1]`

Option type, specified as an `NINST`-by-`1` matrix of flags with values:

- `0` — European
- `1` — American

Data Types: `double`

`BarrierSpec` — Barrier option type
character vector with values: `'UI'`, `'UO'`, `'DI'`, `'DO'` | cell array of character vectors with values: `'UI'`, `'UO'`, `'DI'`, `'DO'`

Barrier option type, specified as a character vector or an `NINST`-by-`1` cell array of character vectors with the following values:

- `'UI'` — Up Knock-in

  This option becomes effective when the price of the underlying asset passes above the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying asset goes above the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.
- `'UO'` — Up Knock-out

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying asset passes above the barrier level. Usually, with an up-and-out option, the rebate is paid if the spot price of the underlying reaches or exceeds the barrier level.
- `'DI'` — Down Knock-in

  This option becomes effective when the price of the underlying stock passes below the barrier level. It gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying security at the strike price if the underlying security goes below the barrier level during the life of the option. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note, `barrierbyfd` does not support American knock-in barrier options.
- `'DO'` — Down Knock-up

  This option gives the option holder the right, but not the obligation, to buy or sell (call/put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security passes below the barrier level. Usually the option holder receives a rebate amount if the option expires worthless.

Option	Barrier Type	Payoff if Barrier Crossed	Payoff if Barrier not Crossed
Call/Put	Down Knock-out	Worthless	Standard Call/Put
Call/Put	Down Knock-in	Call/Put	Worthless
Call/Put	Up Knock-out	Worthless	Standard Call/Put
Call/Put	Up Knock-in	Standard Call/Put	Worthless

Data Types: `char` | `cell`

`Barrier` — Barrier levels
numeric

Barrier levels, specified as an `NINST`-by-`1` matrix of numeric values.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = barrierbystt(STTTree,OptSpec,Strike,Settle,ExerciseDates,1,'UI',115,'Rebate',25)`

`Rebate` — Rebate values
`0` (default) | numeric

Rebate values, specified as the comma-separated pair consisting of `'Rebate'` and a `NINST`-by-`1` matrix of numeric values. For Knock-in options, the `Rebate` is paid at expiry. For Knock-out options, the `Rebate` is paid when the`Barrier` is reached.

Data Types: `double`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices for barrier options at time `0`
matrix

Expected prices for barrier options at time 0, returned as a `NINST`-by-`1` matrix.

`PriceTree` — Structure with vector of barrier option prices at each node
tree structure

Structure with a vector of barrier option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

More About

Barrier Option

A Barrier option has not only a strike price but also a barrier level and sometimes a rebate.

A rebate is a fixed amount that is paid if the option cannot be exercised because the barrier level has been reached or not reached. The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `Barrier`, during the life of the option. For more information, see “Barrier Option” on page 3-20.

Version History

Introduced in R2015b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `barrierbystt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

basketbyju

Price European basket options using Nengjiu Ju approximation model

Syntax

```
Price = basketbyju(RateSpec,BasketStockSpec,OptSpec,Strike,Settle,Maturity)
```

Description

`Price = basketbyju(RateSpec,BasketStockSpec,OptSpec,Strike,Settle,Maturity)` prices European basket options using the Nengjiu Ju approximation model.

Examples

Price European Basket Options Using Nengjiu Ju Approximation Model

Find a European call basket option of two stocks. Assume that the stocks are currently trading at $10 and $11.50 with annual volatilities of 20% and 25%, respectively. The basket contains one unit of the first stock and one unit of the second stock. The correlation between the assets is 30%. On January 1, 2009, an investor wants to buy a 1-year call option with a strike price of $21.50. The current annualized, continuously compounded interest rate is 5%. Use this data to compute the price of the call basket option with the Nengjiu Ju approximation model.

```
Settle = datetime(2009,1,1);
Maturity  = datetime(2010,1,1);

% Define the RateSpec.
Rate = 0.05;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', ...
Settle, 'EndDates', Maturity, 'Rates', Rate, 'Compounding', Compounding);

% Define the Correlation matrix. Correlation matrices are symmetric and
% have ones along the main diagonal.
Corr = [1 0.30; 0.30 1];

% Define the BasketStockSpec.
AssetPrice =  [10;11.50];
Volatility = [0.2;0.25];
Quantity = [1;1];
BasketStockSpec = basketstockspec(Volatility, AssetPrice, Quantity, Corr);

% Compute the price of the call basket option.
OptSpec = {'call'};
Strike = 21.5;
PriceCorr30 = basketbyju(RateSpec, BasketStockSpec, OptSpec, Strike, Settle, Maturity)
```

```
PriceCorr30 = 2.1221
```

Compute the price of the basket instrument for these two stocks with a correlation of 60%. Then compare this cost to the total cost of buying two individual call options.

```
Corr = [1 0.60; 0.60 1];

% Define the new BasketStockSpec.
BasketStockSpec = basketstockspec(Volatility, AssetPrice, Quantity, Corr);

% Compute the price of the call basket option with Correlation = -0.60
PriceCorr60 = basketbyju(RateSpec, BasketStockSpec, OptSpec, Strike, Settle, Maturity)

PriceCorr60 = 2.2757
```

The following table summarizes the sensitivity of the option to correlation changes. In general, the premium of the basket option decreases with lower correlation and increases with higher correlation.

Correlation	-0.60	-0.30	0	0.30	0.60
Premium	1.52830	1.76006	1.9527	2.1221	2.2756

Compute the cost of two vanilla 1-year call options using the Black-Scholes (BLS) model on the individual assets:

```
StockSpec = stockspec(Volatility, AssetPrice);
StrikeVanilla= [10;11.5];

PriceVanillaOption = optstockbybls(RateSpec, StockSpec, Settle, Maturity,...
OptSpec, StrikeVanilla)

PriceVanillaOption = 2×1

    1.0451
    1.4186
```

Find the total cost of buying two individual call options.

```
sum(PriceVanillaOption)

ans = 2.4637
```

The total cost of purchasing two individual call options is $2.4637, compared to the maximum cost of the basket option of $2.27 with a correlation of 60%.

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

BasketStockSpec — BasketStock specification

structure

`BasketStock` specification, specified using `basketstockspec`.

Data Types: `struct`

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a character vector or a 2-by-1 cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price value
scalar numeric | vector

Option strike price value, specified as one of the following:

- For a European or Bermuda option, `Strike` is a scalar (European) or 1-by-`NSTRIKES` (Bermuda) vector of strike prices.
- For an American option, `Strike` is a scalar vector of the strike price.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the basket option, specified as a scalar datetime, string, or date character vector.

To support existing code, `basketbyju` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime scalar | string scalar | date character vector

Maturity date for the basket option, specified as a scalar datetime, string, or date character vector.

To support existing code, `basketbyju` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected price for basket option
numeric

Expected price for basket option, returned as a numeric.

More About

Basket Option

A basket option is an option on a portfolio of several underlying equity assets.

Payout for a basket option depends on the cumulative performance of the collection of the individual assets. A basket option tends to be cheaper than the corresponding portfolio of plain vanilla options for these reasons:

- If the basket components correlate negatively, movements in the value of one component neutralize opposite movements of another component. Unless all the components correlate perfectly, the basket option is cheaper than a series of individual options on each of the assets in the basket.
- A basket option minimizes transaction costs because an investor has to purchase only one option instead of several individual options.

For more information, see “Basket Option” on page 3-22.

Version History

Introduced in R2009b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `basketbyju` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

basketbyls

Price European or American basket options using Monte Carlo simulations

Syntax

```
[Price,Paths,Times,Z] = basketbyls(RateSpec,BasketStockSpec,OptSpec,Strike,
Settle,ExerciseDates)
[Price,Paths,Times,Z] = basketbyls( ___ ,Name,Value)
```

Description

`[Price,Paths,Times,Z] = basketbyls(RateSpec,BasketStockSpec,OptSpec,Strike, Settle,ExerciseDates)` prices basket options using the Longstaff-Schwartz model.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

`[Price,Paths,Times,Z] = basketbyls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Prices Basket Options Using the Longstaff-Schwartz Model

Find an American call basket option of three stocks. The stocks are currently trading at $35, $40 and $45 with annual volatilities of 12%, 15% and 18%, respectively. The basket contains 33.33% of each stock. Assume the correlation between all pair of assets is 50%. On May 1, 2009, an investor wants to buy a three-year call option with a strike price of $42. The current annualized continuously compounded interest rate is 5%. Use this data to compute the price of the call basket option using the Longstaff-Schwartz model.

```
Settle = datetime(2009,5,1);
Maturity  = datetime(2012,5,1);

% Define RateSpec
Rate = 0.05;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates',...
Settle, 'EndDates', Maturity, 'Rates', Rate, 'Compounding', Compounding);

% Define the Correlation matrix. Correlation matrices are symmetric,
% and have ones along the main diagonal.
Corr = [1 0.50 0.50; 0.50 1 0.50;0.50 0.50 1];

% Define BasketStockSpec
AssetPrice =  [35;40;45];
Volatility = [0.12;0.15;0.18];
Quantity = [0.333;0.333;0.333];
BasketStockSpec = basketstockspec(Volatility, AssetPrice, Quantity, Corr);
```

```
% Compute the price of the call basket option
OptSpec = {'call'};
Strike = 42;
AmericanOpt = 1; % American option
Price = basketbyls(RateSpec, BasketStockSpec, OptSpec, Strike, Settle, Maturity,...
'AmericanOpt',AmericanOpt)

Price = 5.4687
```

Increase the number of simulation trials to 2000 to give the following results:

```
NumTrial = 2000;
Price = basketbyls(RateSpec, BasketStockSpec, OptSpec, Strike, Settle, Maturity,...
'AmericanOpt',AmericanOpt,'NumTrials',NumTrial)

Price = 5.5501
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

BasketStockSpec — BasketStock specification

structure

`BasketStock` specification, specified using `basketstockspec`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a character vector or a 2-by-1 cell array of character vectors.

Data Types: `char` | `cell`

Strike — Option strike price value

scalar numeric | vector

Option strike price value, specified as one of the following:

- For a European or Bermuda option, `Strike` is a scalar (European) or 1-by-`NSTRIKES` (Bermuda) vector of strike prices.
- For an American option, `Strike` is a scalar vector of the strike price.

Data Types: `double`

Settle — Settlement or trade date

datetime scalar | string scalar | date character vector

Settlement or trade date for the basket option, specified as a scalar datetime, string, or date character vector.

To support existing code, `basketbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European or Bermuda option, `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between, or including, the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

To support existing code, `basketbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = basketbyls(RateSpec,BasketStockSpec,OptSpec, Strike,Settle,Maturity,'AmericanOpt',AmericanOpt,'NumTrials',NumTrial)`

`AmericanOpt` — Option type

`0` (European/Bermuda) (default) | values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AmericanOpt'` and a `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda
- `1` — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`NumPeriods` — Number of simulation periods per trial

`100` (default) | nonnegative integer

Number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar nonnegative integer.

Note `NumPeriods` is considered only when pricing European basket options. For American and Bermuda basket options, `NumPeriod` equals the number of exercise days during the life of the option.

Data Types: `double`

`NumTrials` — Number of independent sample paths (simulation trials)
`1000` (default) | nonnegative integer

Number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a scalar nonnegative integer.

Data Types: `double`

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-`NINST`-by-`NumTrials` 3-D time series array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling
`false` (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

Output Arguments

`Price` — Expected prices for basket option
matrix

Expected prices for basket option, returned as a `NINST`-by-`1` matrix.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-`1`-by-`NumTrials` 3-D time series array of simulated paths of correlated state variables. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

Z — Time series array of dependent random variates

vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-`1`-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

More About

Basket Option

A basket option is an option on a portfolio of several underlying equity assets.

Payout for a basket option depends on the cumulative performance of the collection of the individual assets. A basket option tends to be cheaper than the corresponding portfolio of plain vanilla options for these reasons:

- If the basket components correlate negatively, movements in the value of one component neutralize opposite movements of another component. Unless all the components correlate perfectly, the basket option is cheaper than a series of individual options on each of the assets in the basket.
- A basket option minimizes transaction costs because an investor has to purchase only one option instead of several individual options.

For more information, see “Basket Option” on page 3-22.

Version History

Introduced in R2009b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `basketbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

basketsensbyju

Determine European basket options price or sensitivities using Nengjiu Ju approximation model

Syntax

```
PriceSens = basketsensbyju(RateSpec,BasketStockSpec,OptSpec,Strike,Settle,
Maturity)
PriceSens = basketsensbyju( ___ ,Name,Value)
```

Description

`PriceSens = basketsensbyju(RateSpec,BasketStockSpec,OptSpec,Strike,Settle, Maturity)` calculates prices or sensitivities for basket options using the Nengjiu Ju approximation model.

`PriceSens = basketsensbyju( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate Prices and Sensitivities for Basket Options Using the Nengjiu Ju Approximation Model

Find a European call basket option of five stocks. Assume that the basket contains:

- 5% of the first stock trading at $110
- 15% of the second stock trading at $75
- 20% of the third stock trading at $40
- 25% of the fourth stock trading at $125
- 35% of the fifth stock trading at $92

These stocks have annual volatilities of 20% and the correlation between the assets is zero. On May 1, 2009, an investor wants to buy a 1-year call option with a strike price of $90. The current annualized, continuously compounded interest is 5%. Use this data to compute price and delta of the call basket option with the Ju approximation model.

```
Settle = datetime(2009,5,1);
Maturity  = datetime(2010,5,1);

% Define RateSpec
Rate = 0.05;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', ...
Settle, 'EndDates', Maturity, 'Rates', Rate, 'Compounding', Compounding);

% Define the Correlation matrix. Correlation matrices are symmetric, and
% have ones along the main diagonal.
NumInst  = 5;
```

```
InstIdx = ones(NumInst,1);
Corr = diag(ones(5,1), 0);

% Define BasketStockSpec
AssetPrice =  [110; 75; 40; 125; 92];
Volatility = 0.2;
Quantity = [0.05; 0.15; 0.2; 0.25; 0.35];
BasketStockSpec = basketstockspec(Volatility, AssetPrice, Quantity, Corr);

% Compute the price of the call basket option. Calculate also the delta
% of the first stock.
OptSpec = {'call'};
Strike = 90;
OutSpec = {'Price','Delta'};
UndIdx = 1; % First element in the basket
[Price, Delta] = basketsensbyju(RateSpec, BasketStockSpec, OptSpec, Strike, Settle, ...
Maturity, 'OutSpec', OutSpec,'UndIdx', UndIdx)

Price = 5.1610

Delta = 0.0297
```

Compute `Delta` with respect to the second asset:

```
UndIdx = 2; % Second element in the basket
OutSpec = {'Delta'};
Delta = basketsensbyju(RateSpec, BasketStockSpec, OptSpec, Strike, Settle, Maturity, ...
'OutSpec',OutSpec,'UndIdx',UndIdx)

Delta = 0.0906
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

BasketStockSpec — BasketStock specification

structure

`BasketStock` specification, specified using `basketstockspec`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a character vector or a 2-by-1 cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price value
scalar numeric | vector

Option strike price value, specified as one of the following:

- For a European or Bermuda option, `Strike` is a scalar (European) or `1`-by-`NSTRIKES` (Bermuda) vector of strike prices.
- For an American option, `Strike` is a scalar vector of the strike price.

Data Types: `double`

`Settle` — Settlement or trade date
datetime scalar | string scalar | date character vector

Settlement or trade date for the basket option, specified as a scalar datetime, string, or date character vector.

To support existing code, `basketsensbyju` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime scalar | string scalar | date character vector

Maturity date for the basket option, specified as a scalar datetime, string, or date character vector.

To support existing code, `basketsensbyju` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = basketsensbyju(RateSpec,BasketStockSpec,OptSpec, Strike,Settle,Maturity,'OutSpec','delta')`

`OutSpec` — Define outputs
`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

`UndIdx` — Index of the underlying instrument to compute the sensitivity
`[]` (default) | scalar numeric

Index of the underlying instrument to compute the sensitivity, specified as the comma-separated pair consisting of `'UndIdx'` and a scalar numeric.

Data Types: `double`

Output Arguments

`PriceSens` — Expected prices or sensitivities for basket option

matrix

Expected prices or sensitivities (defined using `OutSpec`) for basket option, returned as a `NINST`-by-`1` matrix.

More About

Basket Option

A basket option is an option on a portfolio of several underlying equity assets.

Payout for a basket option depends on the cumulative performance of the collection of the individual assets. A basket option tends to be cheaper than the corresponding portfolio of plain vanilla options for these reasons:

- If the basket components correlate negatively, movements in the value of one component neutralize opposite movements of another component. Unless all the components correlate perfectly, the basket option is cheaper than a series of individual options on each of the assets in the basket.
- A basket option minimizes transaction costs because an investor has to purchase only one option instead of several individual options.

For more information, see “Basket Option” on page 3-22.

Version History

Introduced in R2009b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `basketsensbyju` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

basketsensbyls

Calculate price and sensitivities for European or American basket options using Monte Carlo simulations

Syntax

```
[PriceSens,Paths,Times,Z] = basketsensbyls(RateSpec,BasketStockSpec,OptSpec,
Strike,Settle,ExerciseDates)
[PriceSens,Paths,Times,Z] = basketsensbyls( ___ ,Name,Value)
```

Description

`[PriceSens,Paths,Times,Z] = basketsensbyls(RateSpec,BasketStockSpec,OptSpec, Strike,Settle,ExerciseDates)` calculates price and sensitivities for European or American basket options using the Longstaff-Schwartz model.

For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium.

`[PriceSens,Paths,Times,Z] = basketsensbyls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Calculate Price and Sensitivities for Basket Options Using the Longstaff-Schwartz Model

Find a European put basket option of two stocks. The basket contains 50% of each stock. The stocks are currently trading at $90 and $75, with annual volatilities of 15%. Assume that the correlation between the assets is zero. On May 1, 2009, an investor wants to buy a one-year put option with a strike price of $80. The current annualized, continuously compounded interest is 5%. Use this data to compute price and delta of the put basket option with the Longstaff-Schwartz approximation model.

```
Settle = datetime(2009,5,1);
Maturity  = datetime(2010,5,1);

% Define RateSpec
Rate = 0.05;
Compounding = -1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates',...
Settle, 'EndDates', Maturity, 'Rates', Rate, 'Compounding', Compounding);

% Define the Correlation matrix. Correlation matrices are symmetric,
% and have ones along the main diagonal.
NumInst  = 2;
InstIdx = ones(NumInst,1);
Corr = diag(ones(NumInst,1), 0);

% Define BasketStockSpec
AssetPrice =  [90; 75];
Volatility = 0.15;
```

```
Quantity = [0.50; 0.50];
BasketStockSpec = basketstockspec(Volatility, AssetPrice, Quantity, Corr);

% Compute the price of the put basket option. Calculate also the delta
% of the first stock.
OptSpec = {'put'};
Strike = 80;
OutSpec = {'Price','Delta'};
UndIdx = 1; % First element in the basket

[PriceSens, Delta] = basketsensbyls(RateSpec, BasketStockSpec, OptSpec,...
Strike, Settle, Maturity,'OutSpec', OutSpec,'UndIdx', UndIdx)

PriceSens = 0.9822

Delta = -0.0995
```

Compute the `Price` and `Delta` of the basket with a correlation of -20%:

```
NewCorr = [1 -0.20; -0.20 1];

% Define the new BasketStockSpec.
BasketStockSpec = basketstockspec(Volatility, AssetPrice, Quantity, NewCorr);

% Compute the price and delta of the put basket option.
[PriceSens, Delta] = basketsensbyls(RateSpec, BasketStockSpec, OptSpec,...
Strike, Settle, Maturity,'OutSpec', OutSpec,'UndIdx', UndIdx)

PriceSens = 0.7814

Delta = -0.0961
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

BasketStockSpec — BasketStock specification

structure

`BasketStock` specification, specified using `basketstockspec`.

Data Types: `struct`

OptSpec — Definition of option

character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as a character vector or a 2-by-1 cell array of character vectors.

Data Types: `char` | `cell`

`Strike` — Option strike price value

scalar numeric | vector

Option strike price value, specified as one of the following:

- For a European or Bermuda option, `Strike` is a scalar (European) or `1`-by-`NSTRIKES` (Bermuda) vector of strike prices.
- For an American option, `Strike` is a scalar vector of the strike price.

Data Types: `double`

`Settle` — Settlement or trade date

datetime scalar | string scalar | date character vector

Settlement or trade date for the basket option, specified as a scalar datetime, string, or date character vector.

To support existing code, `basketsensbyls` also accepts serial date numbers as inputs, but they are not recommended.

`ExerciseDates` — Option exercise dates

datetime array | string array | date character vector

Option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European or Bermuda option, `ExerciseDates` is a `1`-by-`1` (European) or `1`-by-`NSTRIKES` (Bermuda) vector of exercise dates. For a European option, there is only one `ExerciseDate` on the option expiry date.
- For an American option, `ExerciseDates` is a `1`-by-`2` vector of exercise date boundaries. The option exercises on any date between, or including, the pair of dates on that row. If there is only one non-`NaN` date, or if `ExerciseDates` is `1`-by-`1`, the option exercises between the `Settle` date and the single listed `ExerciseDate`.

To support existing code, `basketsensbyls` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `PriceSens = basketsensbyls(RateSpec,BasketStockSpec,OptSpec, Strike,Settle,Maturity,'AmericanOpt',AmericanOpt,'NumTrials',NumTrial,'OutSpec','delta')`

`AmericanOpt` — Option type

`0` (European/Bermuda) (default) | values `[0,1]`

Option type, specified as the comma-separated pair consisting of `'AnericanOpt'` and a `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European/Bermuda

- 1 — American

Note For American options, the Longstaff-Schwartz least squares method is used to calculate the early exercise premium. For more information on the least squares method, see https://people.math.ethz.ch/%7Ehjfurrer/teaching/LongstaffSchwartzAmericanOptionsLeastSquareMonteCarlo.pdf.

Data Types: `double`

`NumPeriods` — Number of simulation periods per trial

`100` (default) | nonnegative integer

Number of simulation periods per trial, specified as the comma-separated pair consisting of `'NumPeriods'` and a scalar nonnegative integer.

Note `NumPeriods` is considered only when pricing European basket options. For American and Bermuda basket options, `NumPeriod` equals the number of exercise days during the life of the option.

Data Types: `double`

`NumTrials` — Number of independent sample paths (simulation trials)

`1000` (default) | nonnegative integer

Number of independent sample paths (simulation trials), specified as the comma-separated pair consisting of `'NumTrials'` and a scalar nonnegative integer.

Data Types: `double`

`Z` — Time series array of dependent random variates

vector

Time series array of dependent random variates, specified as the comma-separated pair consisting of `'Z'` and a `NumPeriods`-by-`NINST`-by-`NumTrials` 3-D time series array. The `Z` value generates the Brownian motion vector (that is, Wiener processes) that drives the simulation.

Data Types: `double`

`Antithetic` — Indicator for antithetic sampling

`false` (default) | scalar logical flag with value of `true` or `false`

Indicator for antithetic sampling, specified as the comma-separated pair consisting of `'Antithetic'` and a value of `true` or `false`.

Data Types: `logical`

`OutSpec` — Define outputs

`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-1 or a 1-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

`UndIdx` — Index of the underlying instrument to compute the sensitivity
`[]` (default) | scalar numeric

Index of the underlying instrument to compute the sensitivity, specified as the comma-separated pair consisting of `'UndIdx'` and a scalar numeric.

Data Types: `double`

Output Arguments

`PriceSens` — Expected prices or sensitivities for basket option
matrix

Expected prices or sensitivities (defined using `OutSpec`) for basket option, returned as a `NINST`-by-`1` matrix.

`Paths` — Simulated paths of correlated state variables
vector

Simulated paths of correlated state variables, returned as a `NumPeriods + 1`-by-`1`-by-`NumTrials` 3-D time series array of simulated paths of correlated state variables. Each row of `Paths` is the transpose of the state vector $X(t)$ at time t for a given trial.

`Times` — Observation times associated with simulated paths
vector

Observation times associated with simulated paths, returned as a `NumPeriods + 1`-by-`1` column vector of observation times associated with the simulated paths. Each element of `Times` is associated with the corresponding row of `Paths`.

`Z` — Time series array of dependent random variates
vector

Time series array of dependent random variates, returned as a `NumPeriods`-by-`1`-by-`NumTrials` 3-D array when `Z` is specified as an input argument. If the `Z` input argument is not specified, then the `Z` output argument contains the random variates generated internally.

More About

Basket Option

A basket option is an option on a portfolio of several underlying equity assets.

Payout for a basket option depends on the cumulative performance of the collection of the individual assets. A basket option tends to be cheaper than the corresponding portfolio of plain vanilla options for these reasons:

- If the basket components correlate negatively, movements in the value of one component neutralize opposite movements of another component. Unless all the components correlate perfectly, the basket option is cheaper than a series of individual options on each of the assets in the basket.
- A basket option minimizes transaction costs because an investor has to purchase only one option instead of several individual options.

For more information, see “Basket Option” on page 3-22.

Version History

Introduced in R2009b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `basketsensbyls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

basketstockspec

Specify basket stock structure using Longstaff-Schwartz model

Syntax

```
BasketStockSpec = basketstockspec(Sigma,AssetPrice,Quantity,Correlation)
BasketStockSpec = basketstockspec( ___ ,Name,Value)
```

Description

`BasketStockSpec = basketstockspec(Sigma,AssetPrice,Quantity,Correlation)` creates a basket stock structure.

`BasketStockSpec = basketstockspec( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Create a Basket Stock Structure for Three Stocks

Find a basket option of three stocks. The stocks are currently trading at $56, $92 and $125 with annual volatilities of 20%, 12% and 15%, respectively. The basket option contains 25% of the first stock, 40% of the second stock, and 35% of the third. The first stock provides a continuous dividend of 1%, while the other two provide no dividends. The correlation between the first and second asset is 30%, between the second and third asset 11%, and between the first and third asset 16%. Use this data to create the `BasketStockSpec` structure:

```
AssetPrice = [56;92;125];
Sigma = [0.20;0.12;0.15];

% Create the Correlation matrix. Correlation matrices are symmetric and
% have ones along the main diagonal.
NumInst  = 3;
Corr = zeros(NumInst,1);
Corr(1,2) = .30;
Corr(2,3) = .11;
Corr(1,3) = .16;
Corr = triu(Corr,1) + tril(Corr',-1) + diag(ones(NumInst,1), 0);

% Define dividends
DivType = cell(NumInst,1);
DivType{1}='continuous';
DivAmounts = cell(NumInst,1);
DivAmounts{1} = 0.01;

Quantity = [0.25; 0.40; 0.35];

BasketStockSpec = basketstockspec(Sigma, AssetPrice, Quantity, Corr, ...
'DividendType', DivType, 'DividendAmounts', DivAmounts)
```

```
BasketStockSpec = struct with fields:
             FinObj: 'BasketStockSpec'
              Sigma: [3x1 double]
         AssetPrice: [3x1 double]
           Quantity: [3x1 double]
        Correlation: [3x3 double]
       DividendType: {3x1 cell}
    DividendAmounts: {3x1 cell}
    ExDividendDates: {3x1 cell}
```

Examine the `BasketStockSpec` structure.

```
BasketStockSpec.Correlation
```

```
ans = 3×3

    1.0000    0.3000    0.1600
    0.3000    1.0000    0.1100
    0.1600    0.1100    1.0000
```

Create a Basket Stock Structure for Two Stocks

Find a basket option of two stocks. The stocks are currently trading at $60 and $55 with volatilities of 30% per annum. The basket option contains 50% of each stock. The first stock provides a cash dividend of $0.25 on May 1, 2009 and September 1, 2009. The second stock provides a continuous dividend of 3%. The correlation between the assets is 40%. Use this data to create the structure `BasketStockSpec`:

```
AssetPrice = [60;55];
Sigma = [0.30;0.30];

% Create the Correlation matrix. Correlation matrices are symmetric and
% have ones along the main diagonal.
Correlation = [1 0.40;0.40 1];

% Define dividends
NumInst  = 2;
DivType = cell(NumInst,1);
DivType{1}='cash';
DivType{2}='continuous';

DivAmounts = cell(NumInst,1);
DivAmounts{1} = [0.25 0.25];
DivAmounts{2} = 0.03;

ExDates = cell(NumInst,1);
ExDates{1} = {'May-1-2009' 'Sept-1-2009'};

Quantity = [0.5; 0.50];

BasketStockSpec = basketstockspec(Sigma, AssetPrice, Quantity, Correlation, ...
'DividendType', DivType, 'DividendAmounts', DivAmounts, 'ExDividendDates',ExDates)
```

```
BasketStockSpec = struct with fields:
             FinObj: 'BasketStockSpec'
              Sigma: [2x1 double]
         AssetPrice: [2x1 double]
           Quantity: [2x1 double]
        Correlation: [2x2 double]
       DividendType: {2x1 cell}
    DividendAmounts: {2x1 cell}
    ExDividendDates: {2x1 cell}
```

Examine the `BasketStockSpec` structure.

```
BasketStockSpec.DividendType
```

```
ans = 2x1 cell
    {'cash'      }
    {'continuous'}
```

Input Arguments

`Sigma` — Annual price volatility of the underlying security

vector in decimals

Annual price volatility of the underlying security, specified as an `NINST`-by-1 vector in decimals.

Data Types: `double`

`AssetPrice` — Underlying asset price values at time 0

vector

Underlying asset price values at time 0, specified as a `NINST`-by-1 vector.

Data Types: `double`

`Quantity` — Quantities of the instruments contained in the basket

vector

Quantities of the instruments contained in the basket, specified as an `NINST`-by-1 vector.

Data Types: `double`

`Correlation` — Correlation values

matrix

Correlation values, specified as an `NINST`-by-1 matrix.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BasketStockSpec = basketstockspec(Sigma,AssetPrice,Quantity,Correlation,'DividendType',DivType, 'DividendAmounts',DivAmounts)`

`DividendAmounts` — Dividend amounts for basket instruments
row vector

Dividend amounts for basket instruments, specified as the comma-separated pair consisting of `'DividendAmounts'` and an `NINST`-by-`1` cell array. Each element of the cell array is a `1`-by-`NDIV` row vector of cash dividends or a scalar representing a continuous annualized dividend yield for the corresponding instrument.

Data Types: `double`

`DividendType` — Stock dividend type
cell array of character vectors

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and an `NINST`-by-`1` cell array of character vectors specifying each stock's dividend type. Dividend type must be either `cash` for actual dollar dividends or `continuous` for continuous dividend yield.

Data Types: `char` | `cell`

`ExDividendDates` — Ex-dividend dates for the basket instruments
cell array

Ex-dividend dates for the basket instruments, specified as the comma-separated pair consisting of `'ExDividendDates'` and an `NINST`-by-`1` cell array specifying the ex-dividend dates for the basket instruments. Each row is a `1`-by-`NDIV` matrix of ex-dividend dates for `cash` type. For rows that correspond to basket instruments with `continuous` dividend type, the cell is empty. If none of the basket instruments pay `continuous` dividends, do not specify `ExDividendDates`.

Data Types: `cell`

Output Arguments

`BasketStockSpec` — Structure encapsulating the properties of a basket stock structure
structure

Structure encapsulating the properties of a basket stock structure, returned as a structure.

Version History

Introduced in R2009b

bdtprice

Instrument prices from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = bdtprice(BDTTree,InstSet)
[Price,PriceTree] = bdtprice( ___ ,Options)
```

Description

`[Price,PriceTree] = bdtprice(BDTTree,InstSet)` computes arbitrage-free prices for instruments using an interest-rate tree created with `bdttree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`bdtprice` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` to construct defined types.

`[Price,PriceTree] = bdtprice( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Price a Cap and Bond Instruments Contained in an Instrument Set

Load the BDT tree and instruments from the data file `deriv.mat` to price the cap and bond instruments contained in the instrument set.

```
load deriv.mat;
BDTSubSet = instselect(BDTInstSet,'Type', {'Bond', 'Cap'});

instdisp(BDTSubSet)
```

```
instdisp(BDTSubSet)

```

Create a Float-Float Swap and Price with `bdtprice`

Use `instswap` to create a float-float swap and price the swap with `bdtprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.02 .03],today,datemnth(today,60),[], [], [], [1 1]);
VolSpec = bdtvolspec(today,datemnth(today,[10 60]),[.01 .02]);
TimeSpec = bdttimespec(today,cfdates(today,datemnth(today,60),1));
```

```
BDTTree = bdttree(VolSpec,RateSpec,TimeSpec);
bdtprice(BDTTree,IS)
```

```
ans = -4.3220
```

Price Multiple Swaps with bdtprice

Use `instswap` to create multiple swaps and price the swaps with `bdtprice`.

```
RateSpec = intenvset('Rates',.05,'StartDate',today,'EndDate',datemnth(today,60));
IS = instswap([.03 .02],today,datemnth(today,60),[], [], [], [1 1]);
IS = instswap(IS,[200 300],today,datemnth(today,60),[], [], [], [0 0]);
IS = instswap(IS,[.08 300],today,datemnth(today,60),[], [], [], [1 0]);
VolSpec = bdtvolspec(today,datemnth(today,[10 60]),[.01 .02]);
TimeSpec = bdttimespec(today,cfdates(today,datemnth(today,60),1));
BDTTree = bdttree(VolSpec,RateSpec,TimeSpec);
bdtprice(BDTTree,IS)
```

```
ans = 3×1

    4.3220
   -4.3220
   -0.2701
```

Input Arguments

BDTTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

InstSet — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Options — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

Price — Price for each instrument at time 0

vector

Price for each instrument at time 0, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Related single-type pricing functions are:

- `bondbybdt` — Price a bond from a BDT tree.
- `capbybdt` — Price a cap from a BDT tree.
- `cfbybdt` — Price an arbitrary set of cash flows from a BDT tree.
- `fixedbybdt` — Price a fixed-rate note from a BDT tree.
- `floatbybdt` — Price a floating-rate note from a BDT tree.
- `floorbybdt` — Price a floor from a BDT tree.
- `optbndbybdt` — Price a bond option from a BDT tree.
- `optfloatbybdt` — Price a floating-rate note with an option from a BDT tree.
- `optemfloatbybdt` — Price a floating-rate note with an embedded option from a BDT tree.
- `optembndbybdt` — Price a bond with embedded option by a BDT tree.
- `rangefloatbybdt` — Price range floating note using a BDT tree.
- `swapbybdt` — Price a swap from a BDT tree.
- `swaptionbybdt` — Price a swaption from a BDT tree.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

Version History

Introduced before R2006a

bdtsens

Instrument prices and sensitivities from Black-Derman-Toy interest-rate tree

Syntax

```
[Delta,Gamma,Vega,Price] = bdtsens(BDTTree,InstSet)
[Delta,Gamma,Vega,Price] = bdtsens(___,Options)
```

Description

`[Delta,Gamma,Vega,Price] = bdtsens(BDTTree,InstSet)` computes instrument sensitivities and prices for instruments using an interest-rate tree created with the `bdttree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`bdtsens` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` for information on instrument types.

`[Delta,Gamma,Vega,Price] = bdtsens(___,Options)` adds an optional input argument for `Options`.

Examples

Compute Instrument Sensitivities and Prices for Cap and Bond instruments

Load the tree and instruments from the `deriv.mat` data file.

```
load deriv.mat;
BDTSubSet = instselect(BDTInstSet,'Type', {'Bond', 'Cap'});

instdisp(BDTSubSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.1        01-Jan-2000    01-Jan-2003    1      NaN   NaN          NaN       NaN
2     Bond 0.1        01-Jan-2000    01-Jan-2004    2      NaN   NaN          NaN       NaN

```

Compute `Delta` and `Gamma` for the cap and bond instruments contained in the instrument set.

```
[Delta, Gamma] = bdtsens(BDTTree, BDTSubSet)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.

Delta = 3×1

 -232.6681
 -281.0517
```

```
   63.8102

Gamma = 3×1
10^3 ×

    0.8037
    1.1819
    1.8535
```

Input Arguments

`BDTTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in interest rate

vector

Rate of change of instruments prices with respect to changes in the interest rate, returned as a `NINST`-by-1 vector of deltas. `Delta` is computed by finite differences in calls to `bdttree`.

Note `Delta` is calculated based on yield shifts of 100 basis points.

`Gamma` — Rate of change of instruments deltas with respect to changes in interest rate

vector

Rate of change of instruments deltas with respect to changes in the interest rate, returned as a `NINST`-by-1 vector of gammas. `Gamma` is computed by finite differences in calls to `bdttree`.

Note `Gamma` is calculated based on yield shifts of 100 basis points.

`Vega` — Rate of change of instruments prices with respect to changes in volatility
vector

Rate of change of instruments prices with respect to changes in the volatility, returned as a `NINST`-by-`1` vector of vegas. Volatility is $\sigma(t, T)$ of the interest rate. `Vega` is computed by finite differences in calls to `bdttree`. For information on the volatility process, see `bdtvolspec`.

Note `Vega` is calculated based on 1% shift in the volatility process.

`Price` — Price of each instrument
vector

Price of each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Version History

bdttimespec

Specify time structure for Black-Derman-Toy interest-rate tree

Syntax

```
TimeSpec = bdttimespec(ValuationDate,Maturity)
TimeSpec = bdttimespec( ___ ,Compounding)
```

Description

`TimeSpec = bdttimespec(ValuationDate,Maturity)` sets the number of levels and node times for a `bdttree` and determines the mapping between dates and time for rate quoting.

`TimeSpec = bdttimespec( ___ ,Compounding)` adds the optional argument `Compounding`.

Examples

Specify a Five-Period Tree with Annual Nodes

This example shows how to specify a five-period tree with annual nodes and use annual compounding to report rates.

```
Compounding = 1;
ValuationDate = datetime(2000,1,1);
Maturity = [datetime(2001,1,1) ; datetime(2002,1,1) ; datetime(2003,1,1) ;
datetime(2004,1,1); datetime(2005,1,1)];

TimeSpec = bdttimespec(ValuationDate, Maturity, Compounding)
```

```
TimeSpec = struct with fields:
           FinObj: 'BDTTimeSpec'
    ValuationDate: 730486
         Maturity: [5x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the tree, specified as a scalar datetime, string, or date character vector.

To support existing code, `bdttimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Dates marking the cash flow dates of the tree
datetime array | string array | date character vector

Dates marking the cash flow dates of the tree, specified as `NLEVELS`-by-`1` vector using a datetime array, string array, or date character vectors. Cash flows with these maturities fall on tree nodes. `Maturity` should be in increasing order.

To support existing code, `bdttimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Compounding` — Rate at which the input zero rates were compounded when annualized
1 (default) | integer with value of 1, 2, 3, 4, 6, 12, 365, or -1

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If `Compounding` = 1, 2, 3, 4, 6, 12:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units; for example, `T = F` is one year.
- If `Compounding` = 365:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = −1:

  `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `bdttree`
structure

Specification for the time layout for `bdttree`, returned as a structure. The state observation dates are `[ValuationDate; Maturity(1:end-1)]`. Because a forward rate is stored at the last observation, the tree can value cash flows out to `Maturity(end)`.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `bdttimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bdttree

Build Black-Derman-Toy interest-rate tree

Syntax

```
BDTTree = bdttree(VolSpec,RateSpec,TimeSpec)
```

Description

`BDTTree = bdttree(VolSpec,RateSpec,TimeSpec)` creates a structure containing time and interest-rate information on a recombining tree.

Examples

Create a BDTTree

Using the data provided, create a BDT volatility specification (using `bdtvolspec`), rate specification (using `intenvset`), and tree time layout specification (using `bdttimespec`). Then use these specifications to create a BDT tree with `bdttree`.

```
Compounding = 1;
ValuationDate = '01-01-2000';
StartDate = ValuationDate;
EndDates = ['01-01-2001'; '01-01-2002'; '01-01-2003';
'01-01-2004'; '01-01-2005'];
Rates = [.1; .11; .12; .125; .13];
Volatility = [.2; .19; .18; .17; .16];

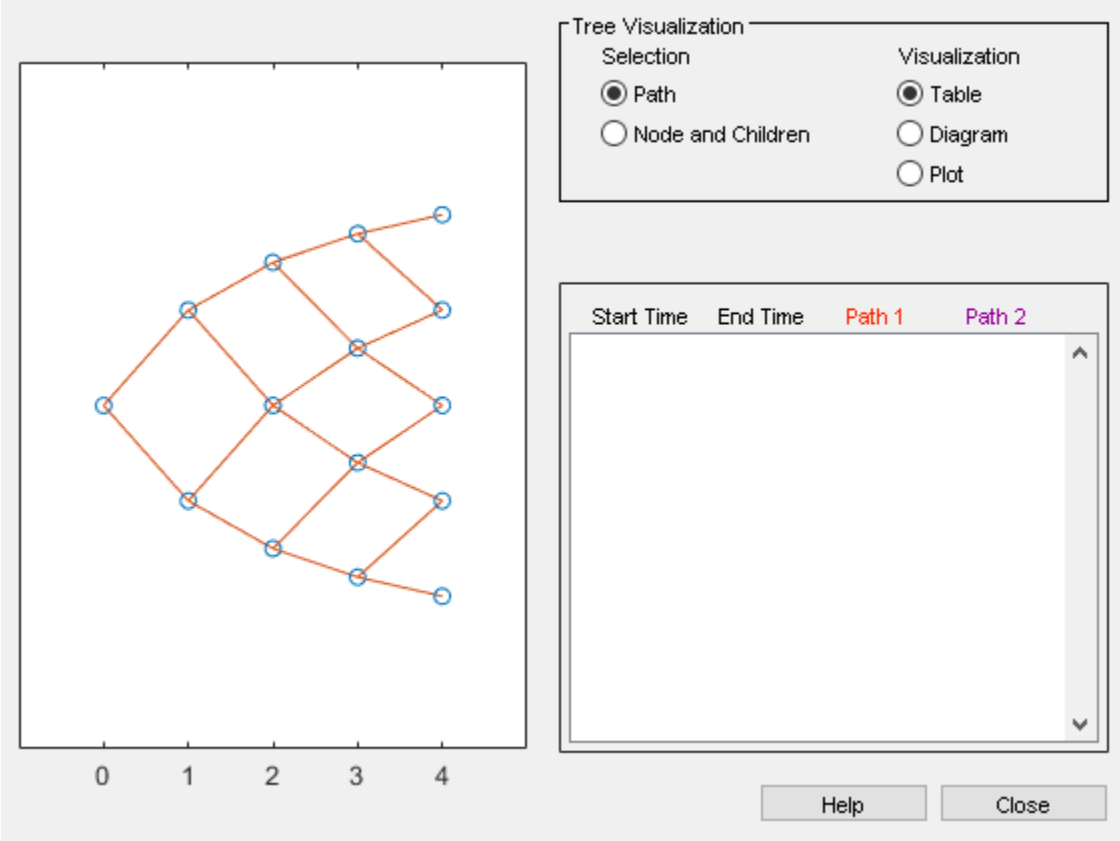
RateSpec = intenvset('Compounding', Compounding,...
             'ValuationDate', ValuationDate,...
             'StartDates', StartDate,...
             'EndDates', EndDates,...
             'Rates', Rates);

BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility);
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [730486 730852 731217 731582 731947]
        TFwd: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [4]}
      CFlowT: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [5]}
     FwdTree: {1x5 cell}
```

Use `treeviewer` to observe the tree you have created.

```
treeviewer(BDTTree)
```



Input Arguments

`VolSpec` — Volatility process specification

structure

Volatility process specification, specified using the `VolSpec` output obtained from `bdtvolspec`.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Time tree layout specification

structure

Time tree layout specification, specified using the `TimeSpec` output obtained from `bdttimespec`. The TimeSpec defines the observation dates of the BDT tree and the `Compounding` rule for date to time mapping and price-yield formulas.

Data Types: `struct`

Output Arguments

`BDTTree` — Time and interest-rate information of a recombining tree

structure

Time and interest-rate information of a recombining tree, returned as a structure.

Version History

Introduced before R2006a

bdtvolspec

Specify Black-Derman-Toy interest-rate volatility process

Syntax

```
VolSpec = bdtvolspec(ValuationDate,VolDates,VolCurve)
VolSpec = bdtvolspec( ___ ,InterpMethod)
```

Description

`VolSpec = bdtvolspec(ValuationDate,VolDates,VolCurve)` creates a structure specifying the volatility for `bdttree`.

`VolSpec = bdtvolspec( ___ ,InterpMethod)` adds the optional argument `InterpMethod`.

Examples

Create a BDT Volatility Specification

This example shows how to create a BDT volatility specification (VolSpec) using the following data.

```
ValuationDate = '01-01-2000';
EndDates = [datetime(2001,1,1) ; datetime(2002,1,1) ; datetime(2003,1,1) ;
datetime(2004,1,1); datetime(2005,1,1)];
Volatility = [.2; .19; .18; .17; .16];

BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility)
```

```
BDTVolSpec = struct with fields:
             FinObj: 'BDTVolSpec'
      ValuationDate: 730486
           VolDates: [5x1 double]
           VolCurve: [5x1 double]
    VolInterpMethod: 'linear'
```

Input Arguments

`ValuationDate` — Observation date of the investment horizon

character vector date | datetime

Observation date of the investment horizon, specified as a scalar datetime, string, or date character vector.

To support existing code, `bdtvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`VolDates` — Number of points of yield volatility end dates

datetime array | string array | date character vector

Number of points of yield volatility end dates, specified as a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bdtvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`VolCurve` — Yield volatility values
decimal

Yield volatility values, specified as a `NPOINTS`-by-`1` vector of decimal values. The term structure of `VolCurve` is the yield volatility represented by the value of the volatility of the yield from time `t` = 0 to time `t` + *i*, where *i* is any point within the volatility curve.

Data Types: `double`

`InterpMethod` — Interpolation method
`'linear'` (default) | character vector with values supported by `interp1`

(Optional) Interpolation method, specified as a character vector with values supported by `interp1`.

Data Types: `char`

Output Arguments

`VolSpec` — Specification for the volatility model for `bdttree`
structure

Structure specifying the volatility model for `bdttree`.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `bdtvolspec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bkprice

Instrument prices from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = bkprice(BKTree,InstSet)
[Price,PriceTree] = bkprice( ___ ,Options)
```

Description

`[Price,PriceTree] = bkprice(BKTree,InstSet)` computes arbitrage-free prices for instruments using an interest-rate tree created with `bktree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`bkprice` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` to construct defined types.

`[Price,PriceTree] = bkprice( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Price Cap and Bond Instruments in the Instrument Set

Load the BK tree and instruments from the data file `deriv.mat`. Price the cap and bond instruments contained in the instrument set.

```
load deriv.mat;
BKSubSet = instselect(BKInstSet,'Type', {'Bond', 'Cap'});

instdisp(BKSubSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.03       01-Jan-2004    01-Jan-2007    1      0     1            NaN       NaN
2     Bond 0.03       01-Jan-2004    01-Jan-2008    1      0     1            NaN       NaN

Index Type Strike Settle         Maturity       CapReset Basis Principal Name   Quantity
3     Cap  0.04   01-Jan-2004    01-Jan-2008    1        0     100       4% Cap 10
```

```
[Price, PriceTree] = bkprice(BKTree, BKSubSet)
```

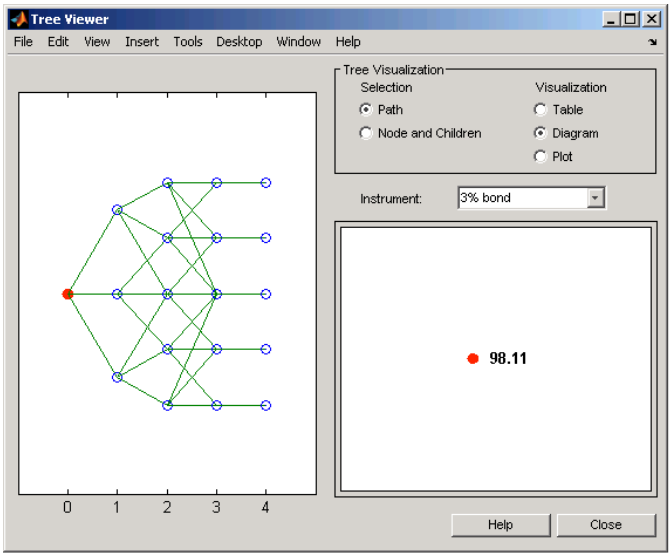
```
Price = 3×1

   98.1096
   95.6734
    2.2706

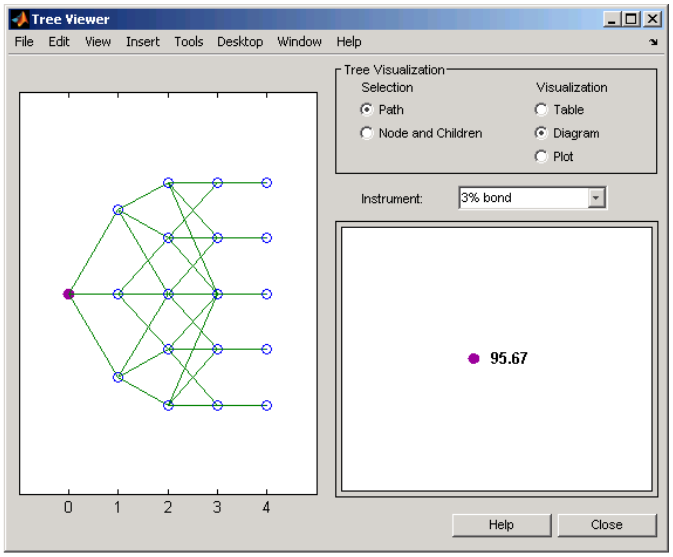
PriceTree = struct with fields:
     FinObj: 'BKPriceTree'
```

```
    PTree: {1x5 cell}
   AITree: {1x5 cell}
     tObs: [0 1 2 3 4]
  Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
    Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

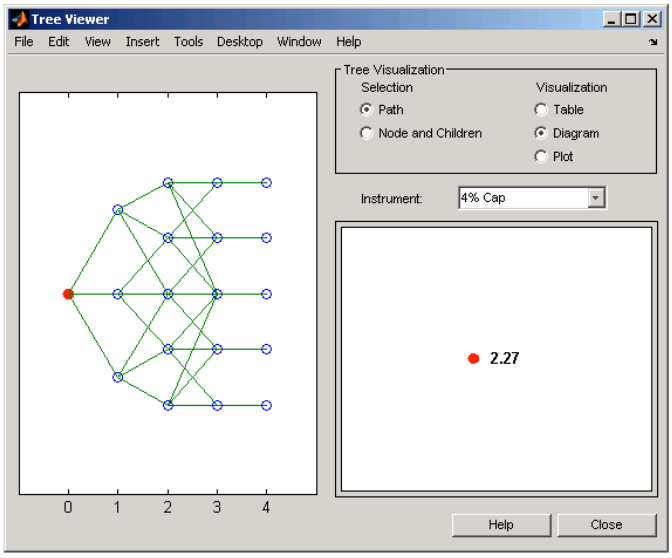
You can use `treeviewer` to see the prices of these three instruments along the price tree.



First 3% Bond (Maturity 2007)



Second 3% Bond (Maturity 2008)



4% Cap

Price Multi-Stepped Coupon Bonds

Price the following multi-stepped coupon bonds using the following data:

```
% The data for the interest rate term structure is as follows:
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Create a portfolio of stepped coupon bonds with different maturities
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2011';'01-Jan-2012';'01-Jan-2013';'01-Jan-2014'};
CouponRate = {{'01-Jan-2011' .042;'01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};

ISet = instbond(CouponRate, Settle, Maturity, 1);
instdisp(ISet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond [Cell]     01-Jan-2010    01-Jan-2011    1      0     1            NaN       NaN
2     Bond [Cell]     01-Jan-2010    01-Jan-2012    1      0     1            NaN       NaN
3     Bond [Cell]     01-Jan-2010    01-Jan-2013    1      0     1            NaN       NaN
4     Bond [Cell]     01-Jan-2010    01-Jan-2014    1      0     1            NaN       NaN
```

Build the `BKTree` with the following data:

```
VolDates = ['1-Jan-2011'; '1-Jan-2012'; '1-Jan-2013'; '1-Jan-2014'];
VolCurve = 0.01;
AlphaDates = '01-01-2014';
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);
```

Compute the price of the stepped coupon bonds.

```
PBK = bkprice(BKT, ISet)
```

```
PBK = 4×1

  100.6763
  100.7368
  100.9266
  101.0115
```

Price a Portfolio of Stepped Callable Bonds and Stepped Vanilla Bonds

Price a portfolio of stepped callable bonds and stepped vanilla bonds using the following data:

```
% The data for the interest rate term structure is as follows:
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = 'Jan-1-2010';
StartDates = ValuationDate;
EndDates = {'Jan-1-2011'; 'Jan-1-2012'; 'Jan-1-2013'; 'Jan-1-2014'};
Compounding = 1;

% Create RateSpec
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);

% Create an instrument portfolio of 3 stepped callable bonds and three
% stepped vanilla bonds
Settle = '01-Jan-2010';
Maturity = {'01-Jan-2012';'01-Jan-2013';'01-Jan-2014'};
CouponRate = {{'01-Jan-2011' .042;'01-Jan-2012' .05; '01-Jan-2013' .06; '01-Jan-2014' .07}};
OptSpec='call';
Strike=100;
ExerciseDates='01-Jan-2011'; % Callable in one year

% Bonds with embedded option
ISet = instoptembnd(CouponRate, Settle, Maturity, OptSpec, Strike,...
ExerciseDates, 'Period', 1);

% Vanilla bonds
ISet = instbond(ISet, CouponRate, Settle, Maturity, 1);

% Display the instrument portfolio
instdisp(ISet)
```

```
Index Type      CouponRate Settle         Maturity       OptSpec Strike ExerciseDates  Period Bas
1     OptEmBond [Cell]     01-Jan-2010    01-Jan-2012    call    100    01-Jan-2011    1      0

Price = 3×1

  105.5147
  101.4805
  105.5147
```

Input Arguments

`BKTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Price for each instrument at time 0

vector

Price for each instrument at time 0, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Related single-type pricing functions are:

- `bondbybk` — Price a bond from a Black-Karasinski tree.
- `capbybk` — Price a cap from a Black-Karasinski tree.
- `cfbybk` — Price an arbitrary set of cash flows from a Black-Karasinski tree.
- `fixedbybk` — Price a fixed-rate note from a Black-Karasinski tree.
- `floatbybk` — Price a floating-rate note from a Black-Karasinski tree.
- `floorbybk` — Price a floor from a Black-Karasinski tree.
- `optbndbybk` — Price a bond option from a Black-Karasinski tree.
- `optembndbybk` — Price a bond with embedded option by a Black-Karasinski tree.
- `optfloatbybk` — Price a floating-rate note with an option from a Black-Karasinski tree.
- `optemfloatbybk` — Price a floating-rate note with an embedded option from a Black-Karasinski tree.
- `rangefloatbybk` — Price range floating note from a Black-Karasinski tree.
- `swapbybk` — Price a swap from a Black-Karasinski tree.
- `swaptionbybk` — Price a swaption from a Black-Karasinski tree.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

bksens

Instrument prices and sensitivities from Black-Karasinski interest-rate tree

Syntax

```
[Delta,Gamma,Vega,Price] = bktsens(BKTree,InstSet)
[Delta,Gamma,Vega,Price] = bksens(___,Options)
```

Description

`[Delta,Gamma,Vega,Price] = bktsens(BKTree,InstSet)` computes instrument sensitivities and prices for instruments using an interest-rate tree created with the `bktree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`bksens` handles instrument types: `'Bond'`, `'CashFlow'`, `'OptBond'`, `'OptEmBond'`, `'OptEmBond'`, `'OptFloat'`, `'OptEmFloat'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'RangeFloat'`, `'Swap'`. See `instadd` for information on instrument types.

`[Delta,Gamma,Vega,Price] = bksens(___,Options)` adds an optional input argument for `Options`.

Examples

Compute Instrument Sensitivities and Prices for Cap and Bond Instruments

Load the tree and instruments from the `deriv.mat` data file.

```
load deriv.mat;
BKSubSet = instselect(BKInstSet,'Type', {'Bond', 'Cap'});

instdisp(BKSubSet)
```

```

  189.5319
```

```
Gamma = 3×1
10^3 ×

    0.8456
    1.4345
    6.9999
```

Input Arguments

`BKTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in interest rate

vector

Rate of change of instruments prices with respect to changes in the interest rate, returned as a `NINST`-by-`1` vector of deltas. `Delta` is computed by finite differences in calls to `bktree`.

Note `Delta` is calculated based on yield shifts of 100 basis points.

`Gamma` — Rate of change of instruments deltas with respect to changes in interest rate

vector

Rate of change of instruments deltas with respect to changes in the interest rate, returned as a `NINST`-by-`1` vector of gammas. `Gamma` is computed by finite differences in calls to `bktree`.

Note `Gamma` is calculated based on yield shifts of 100 basis points.

`Vega` — Rate of change of instruments prices with respect to changes in volatility

vector

Rate of change of instruments prices with respect to changes in the volatility, returned as a `NINST`-by-`1` vector of vegas. Volatility is $\sigma(t, T)$ of the interest rate. `Vega` is computed by finite differences in calls to `bktree`. For information on the volatility process, see `bkvolspec`.

Note `Vega` is calculated based on 1% shift in the volatility process.

`Price` — Price of each instrument

vector

Price of each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Version History

Introduced before R2006a

bktimespec

Specify time structure for Black-Karasinski tree

Syntax

```
TimeSpec = bktimespec(ValuationDate,Maturity)
TimeSpec = bktimespec( ___ ,Compounding)
```

Description

`TimeSpec = bktimespec(ValuationDate,Maturity)` sets the number of levels and node times for a `bktree` and determines the mapping between dates and time for rate quoting.

`TimeSpec = bktimespec( ___ ,Compounding)` adds the optional argument `Compounding`.

Examples

Specify a Four-Period Tree with Annual Nodes

This example shows how to specify a four-period tree with annual nodes using annual compounding to report rates.

```
ValuationDate = datetime(2004,1,1);
Maturity = [datetime(2004,12,31) ; datetime(2005,12,31) ; datetime(2006,12,31) ;
datetime(2007,12,31)];
Compounding = 1;
TimeSpec = bktimespec(ValuationDate,Maturity,Compounding)
```

```
TimeSpec = struct with fields:
           FinObj: 'BKTimeSpec'
    ValuationDate: 731947
         Maturity: [4x1 double]
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the tree, specified as a scalar datetime, string, or date character vector.

To support existing code, `bktimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Dates marking the cash flow dates of the tree
datetime array | string array | date character vector

Dates marking the cash flow dates of the tree, specified as `NLEVELS`-by-`1` vector using a datetime array, string array, or date character vectors. Cash flows with these maturities fall on tree nodes. `Maturity` should be in increasing order.

To support existing code, `bktimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Compounding` — Rate at which the input zero rates were compounded when annualized
`1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, `12`, `365`, or `-1`

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If `Compounding` = `1`, `2`, `3`, `4`, `6`, `12`:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the compounding frequency, `Z` is the zero rate, and `T` is the time in periodic units; for example, `T = F` is one year.
- If `Compounding` = `365`:

  `Disc = (1 + Z/F)^(-T)`, where `F` is the number of days in the basis year and `T` is a number of days elapsed computed by basis.
- If `Compounding` = `−1`:

  `Disc = exp(-T*Z)`, where `T` is time in years.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `bktree`
structure

Specification for the time layout for `bktree`, returned as a structure. The state observation dates are `[ValuationDate; Maturity(1:end-1)]`. Because a forward rate is stored at the last observation, the tree can value cash flows out to `Maturity`(`end`).

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `bktimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bktree

Build Black-Karasinski interest-rate tree

Syntax

```
BKTree = bktree(VolSpec,RateSpec,TimeSpec)
BKTree = bktree( ___ ,Name,Value)
```

Description

`BKTree = bktree(VolSpec,RateSpec,TimeSpec)` creates a structure containing time and interest-rate information on a recombining tree.

`BKTree = bktree( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Create a BKTree

Using the data provided, create a BK volatility specification (using `bkvolspec`), rate specification (using `intenvset`), and tree time layout specification (using `bktimespec`). Then use these specifications to create a BK tree using `bktree`.

```
Compounding = -1;
ValuationDate = '01-01-2004';
StartDate = ValuationDate;
VolDates = ['12-31-2004'; '12-31-2005'; '12-31-2006';
'12-31-2007'];
VolCurve = 0.01;
AlphaDates = '01-01-2008';
AlphaCurve = 0.1;
Rates = [0.0275; 0.0312; 0.0363; 0.0415];

BKVolSpec = bkvolspec(ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);

RateSpec = intenvset('Compounding', Compounding,...
             'ValuationDate', ValuationDate,...
             'StartDates', ValuationDate,...
             'EndDates', VolDates,...
             'Rates', Rates);

BKTimeSpec = bktimespec(ValuationDate, VolDates, Compounding);

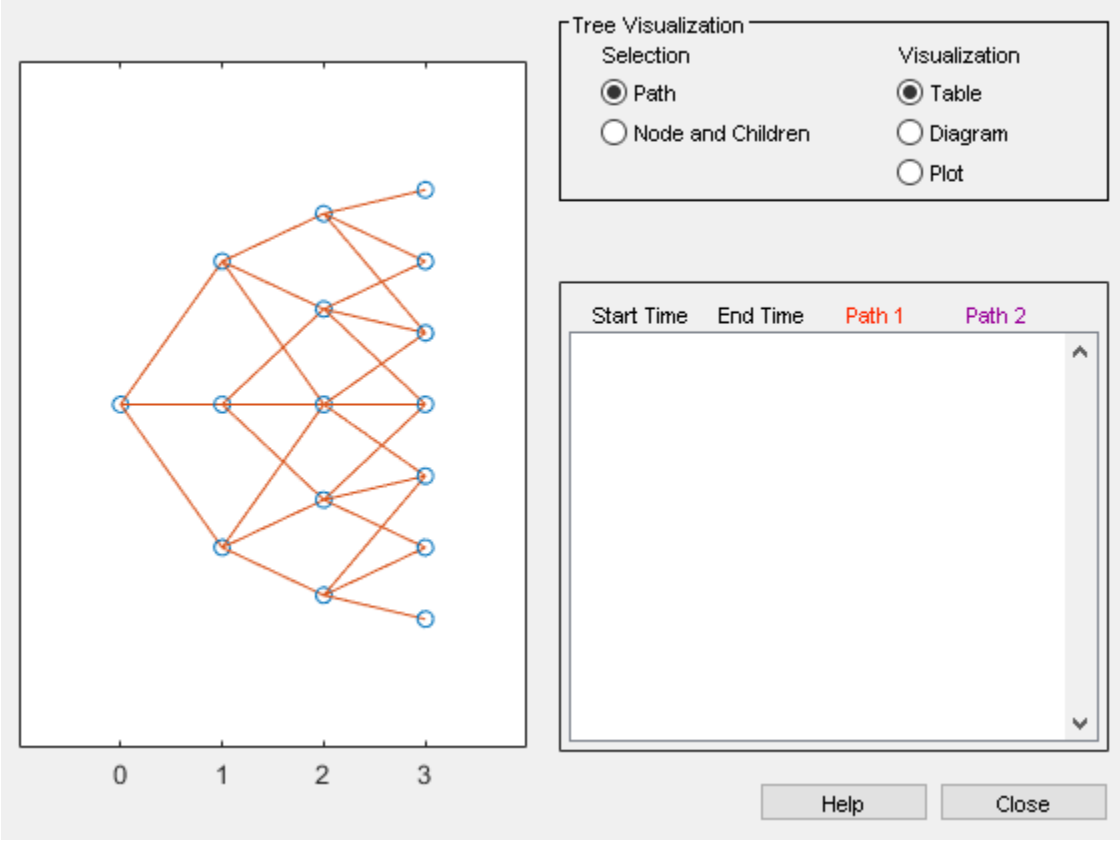
BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec)
```

```
BKTree = struct with fields:
      FinObj: 'BKFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
```

```
    tObs: [0 0.9973 1.9973 2.9973]
    dObs: [731947 732312 732677 733042]
  CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [3.9973]}
   Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
 Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
 FwdTree: {1x4 cell}
```

Use `treeviewer` to observe the tree you have created.

```
treeviewer(BKTree)
```



Input Arguments

`VolSpec` — Volatility process specification

structure

Volatility process specification, specified using the `VolSpec` output obtained from `bdtvolspec`.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Time tree layout specification
structure

Time tree layout specification, specified using the `TimeSpec` output obtained from `bdttimespec`. The TimeSpec defines the observation dates of the BK tree and the `Compounding` rule for date to time mapping and price-yield formulas.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `BKTree = bktree(BKVolSpec, RateSpec, BKTimeSpec,'Method','HW1996')`

`Method` — Hull-White method upon which the tree-node connectivity algorithm is based
`'HW2000'` (default) | character vector with values `'HW2000'` or `'HW1996'`

Hull-White method upon which the tree-node connectivity algorithm is based, specified as a character vector with a value of `'HW2000'` or `'HW1996'`.

`bktree` supports two tree-node connectivity algorithms. `HW1996` is based on the original paper published in the *Journal of Derivatives*, and `HW2000` is the general version of the algorithm, as specified in the paper published in August 2000.

Data Types: `char`

Output Arguments

`BKTree` — Time and interest-rate information of a recombining tree
structure

Time and interest-rate information of a recombining tree, returned as a structure.

Version History

Introduced before R2006a

bkvolspec

Specify Black-Karasinski interest-rate volatility process

Syntax

```
VolSpec = bdtvolspec(ValuationDate,VolDates,VolCurve,AlphaDates,AlphaCurve)
VolSpec = bdtvolspec( ___ ,InterpMethod)
```

Description

`VolSpec = bdtvolspec(ValuationDate,VolDates,VolCurve,AlphaDates,AlphaCurve)` creates a structure specifying the volatility for `bktree`.

`VolSpec = bdtvolspec( ___ ,InterpMethod)` adds the optional argument `InterpMethod`.

Examples

Create a Black-Karasinski Volatility Specification

This example shows how to create a Black-Karasinski volatility specification (VolSpec) using the following data.

```
ValuationDate = datetime(2004,1,1);
StartDate = ValuationDate;
VolDates = [datetime(2004,12,31) ; datetime(2005,12,31) ; datetime(2006,12,31) ;
datetime(2007,12,31) ];
VolCurve = 0.01;
AlphaDates = datetime(2008,1,1);
AlphaCurve = 0.1;
BKVolSpec = bkvolspec(ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve)
```

```
BKVolSpec = struct with fields:
             FinObj: 'BKVolSpec'
      ValuationDate: 731947
           VolDates: [4x1 double]
           VolCurve: [4x1 double]
         AlphaCurve: 0.1000
         AlphaDates: 733408
    VolInterpMethod: 'linear'
```

Input Arguments

`ValuationDate` — Observation date of the investment horizon

datetime scalar | string scalar | date character vector

Observation date of the investment horizon, specified as a scalar datetime, string, or date character vector.

To support existing code, `bkvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`VolDates` — Number of points of yield volatility end dates
datetime array | string array | date character vector

Number of points of yield volatility end dates, specified as a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bkvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`VolCurve` — Yield volatility values
decimal

Yield volatility values, specified as a `NPOINTS`-by-`1` vector of decimal values. The term structure of `VolCurve` is the yield volatility represented by the value of the volatility of the yield from time `t` = 0 to time `t` + *i*, where *i* is any point within the volatility curve.

Data Types: `double`

`AlphaDates` — Mean reversion end dates
datetime array | string array | date character vector

Mean reversion end dates, specified as a `NPOINTS`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bkvolspec` also accepts serial date numbers as inputs, but they are not recommended.

`AlphaCurve` — Positive mean reversion values
positive decimal

Positive mean reversion values, specified as a `NPOINTS`-by-`1` vector of positive decimal values.

Data Types: `double`

`InterpMethod` — Interpolation method
`'linear'` (default) | character vector with values supported by `interp1`

(Optional) Interpolation method, specified as a character vector with values supported by `interp1`.

Data Types: `char`

Output Arguments

`VolSpec` — Specification for the volatility model for `bktree`
structure

Structure specifying the volatility model for `bktree`.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bkvolspec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bondbybdt

Price bond from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = bondbybdt(BDTTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = bondbybdt(___,Name,Value)
```

Description

`[Price,PriceTree] = bondbybdt(BDTTree,CouponRate,Settle,Maturity)` prices bond from a Black-Derman-Toy interest-rate tree. `bondbybdt` computes prices of vanilla bonds, stepped coupon bonds and amortizing bonds.

`[Price,PriceTree] = bondbybdt(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Bond Using a BDT Tree

Price a 10% bond using a BDT interest-rate tree.

Load `deriv.mat`, which provides `BDTTree`. The `BDTTree` structure contains the time and interest-rate information needed to price the bond.

```
load deriv.mat;
```

Define the bond using the required arguments. Other arguments use defaults.

```
CouponRate = 0.10;
Settle = datetime(2000,1,1);
Maturity = datetime(2003,1,1);
Period = 1;
```

Use `bondbybdt` to compute the price of the bond.

```
Price = bondbybdt(BDTTree, CouponRate, Settle, Maturity, Period)
```

```
Price = 95.5030
```

Price a Stepped Coupon Bond

Price single stepped coupon bonds using market data.

Define the interest-rate term structure.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
```

```
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;
```

Create the RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates, 'EndDates',...
EndDates, 'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create the stepped bond instrument.

```
Settle = datetime(2010,1,1);
Maturity = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
%CouponRate = {{'01-Jan-2012' .0425;'01-Jan-2014' .0750}};
CouponRate = {{datetime(2012,1,1) .0425; datetime(2014,1,1) .0750}};
Period = 1;
```

Build the BDT tree and assume the volatility to be 10% using the following market data:

```
Sigma = 0.1;
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Sigma*ones(1, length(EndDates))');
BDTT = bdttree(BDTVolSpec, RS, BDTTimeSpec)
```

```
BDTT = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [734139 734504 734869 735235]
        TFwd: {[4x1 double]  [3x1 double]  [2x1 double]  [3]}
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
     FwdTree: {[1.0350]  [1.0444 1.0543]  [1.0469 1.0573 1.0700]  [1.0505 ... ]}
```

Compute the price of the stepped coupon bonds.

```
PBDT= bondbybdt(BDTT, CouponRate, Settle,Maturity , Period)
```

```
PBDT = 4×1

  100.7246
  100.0945
  101.5900
```

```
  102.0820
```

Price Two Bonds with Amortization Schedules

Price two bonds with amortization schedules using the `Face` input argument to define the schedule.

Define the interest-rate term structure.

```
Rates = 0.035;
ValuationDate = datetime(2011,11,1);
StartDates = ValuationDate;
EndDates = datetime(2017,11,1);
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Create the bond instrument. The bonds have a coupon rate of 4% and 3.85%, a period of one year, and mature on 1-Nov-2017.

```
CouponRate = [0.04; 0.0385];
Settle = datetime(2011,11,1);
Maturity = datetime(2017,11,1);
Period = 1;
```

Define the amortizing schedule.

```
Face = {{datetime(2015,11,1) 100; datetime(2016,11,1) 85; datetime(2017,11,1) 70};
{datetime(2015,11,1) 100; datetime(2016,11,1) 90; datetime(2017,11,1) 80}};
```

Build the BDT tree and assume the volatility to be 10%.

```
MatDates = [datetime(2012,11,1) ; datetime(2013,11,1) ; datetime(2014,11,1) ; datetime(2015,11,1
BDTTimeSpec = bdttimespec(ValuationDate, MatDates);
Volatility = 0.1;
BDTVolSpec = bdtvolspec(ValuationDate, MatDates, Volatility*ones(1,length(MatDates))');
BDTT = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec);
```

Compute the price of the amortizing bonds.

```
Price = bondbybdt(BDTT, CouponRate, Settle, Maturity, 'Period',Period,...
'Face', Face)
```

```
Price = 2×1

  102.4791
  101.7786
```

Input Arguments

BDTTree — Interest-rate structure
structure

Interest-rate tree structure, created by `bdttree`

Data Types: `struct`

CouponRate — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

Settle — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybdt` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every bond is set to the `ValuationDate` of the BDT tree. The bond argument `Settle` is ignored.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each bond.

To support existing code, `bondbybdt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = bondbybdt(BDTTree,CouponRate,Settle,Maturity,'Period',4,'Face',10000)`

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and an `NINST`-by-`1` vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybdt` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybdt` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
`Settle` date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybdt` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or an `NINST`-by-`1` cell array of face values or face value schedules. For the latter case, each element of the cell array is a `NumDates`-by-`2` cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

Output Arguments

`Price` — Expected bond prices at time 0
vector

Expected bond prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bondbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

blackvolbyrebonato

Compute Black volatility for LIBOR Market Model using Rebonato formula

Syntax

```
outVol = blackvolbyrebonato(ZeroCurve,VolFunc,CorrMat,ExerciseDate,Maturity)
outVol = blackvolbyrebonato( ___ ,Name,Value)
```

Description

`outVol = blackvolbyrebonato(ZeroCurve,VolFunc,CorrMat,ExerciseDate,Maturity)` computes the Black volatility for a swaption using a LIBOR Market Model.

`outVol = blackvolbyrebonato( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price Swaption for LIBOR Market Model Using the Rebonato Formula

Define the input maturity and tenor for a LIBOR Market Model (LMM) specified by the cell array of volatility function handles, and a correlation matrix for the LMM.

```
Settle = datetime(2004,8,11);

% Zero Curve
CurveTimes = (1:10)';
CurveDates = daysadd(Settle,360*CurveTimes,1);

ZeroRates = [0.03 0.033 0.036 0.038 0.04 0.042 0.043 0.044 0.045 0.046]';

% Construct an IRCurve
irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

LMMVolFunc = @(a,t) (a(1)*t + a(2)).*exp(-a(3)*t) + a(4);
LMMVolParams = [.3 -.02 .7 .14];

numRates = length(ZeroRates);
VolFunc(1:numRates-1) = {@(t) LMMVolFunc(LMMVolParams,t)};

Beta = .08;
CorrFunc = @(i,j,Beta) exp(-Beta*abs(i-j));
CorrMat = CorrFunc(meshgrid(1:numRates-1)',meshgrid(1:numRates-1),Beta);

ExerciseDate = datetime(2009,8,11);
Maturity = daysadd(ExerciseDate,360*[3;4],1);

Vol = blackvolbyrebonato(irdc,VolFunc,CorrMat,ExerciseDate,Maturity,'Period',1)
```

```
Vol = 2×1

    0.2210
```

```
    0.2079
```

Input Arguments

`ZeroCurve` — Zero-curve for `LiborMarketModel` model

structure

Zero-curve for the `LiborMarketModel`, specified using `IRDataCurve` or `RateSpec`.

Data Types: `struct`

`VolFunc` — Function handle for volatility

cell array of function handles

Function handle for volatility, specified by a `NumRates`-by-`1` cell array of function handles. Each function handle must take time as an input and return a scalar volatility

Data Types: `cell` | `function_handle`

`CorrMat` — Correlation matrix

vector

Correlation matrix, specified by `NumRates`-by-`NumRates`.

Data Types: `double`

`ExerciseDate` — Swaption exercise date

datetime array | string array | date character vector

Swaption exercise dates, specified by a `NumSwaptions`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `blackvolbyrebonato` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Swap maturity date

datetime array | string array | date character vector

Swap maturity dates, specified using a `NumSwaptions`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `blackvolbyrebonato` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Vol = blackvolbyrebonato(irdc,VolFunc,CorrMat,ExerciseDate,Maturity,'Period',1)`

`Period` — Compounding frequency of curve and reset of swaptions
2 (default) | positive integer from the set `[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Compounding frequency of curve and reset of swaptions, specified as the comma-separated pair consisting of `'Period'` and a positive integer for the values `1,2,4,6,12` in a `NumSwaptions`-by-`1` vector.

Data Types: `single` | `double`

Output Arguments

`outVol` — Black volatility for specified swaption
scalar | vector

Black volatility, returned as a vector for the specified swaptions.

Algorithms

The Rebonato approximation formula relates the Black volatility for a European swaption, given a set of volatility functions and a correlation matrix

$$(v_{\alpha,\beta}^{LFM})^2 = \sum_{i,\,j\,=\,\alpha+1}^{\beta} \frac{w_i(0)w_j(0)F_i(0)F_j(0)\rho_{i,\,j}}{S_{\alpha,\beta}(0)^2} \int_0^{T_\alpha} \sigma_i(t)\sigma_j(t)dt$$

where:

$$w_i(t) = \frac{\tau_i P(t,T_i)}{\sum_{k\,=\,\alpha+1}^{\beta} \tau_K P(t,t_K)}$$

Version History

Introduced in R2013a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `blackvolbyrebonato` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

blackvolbysabr

Calculate implied Black volatility using SABR model

Syntax

```
outVol = blackvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,
Strike)
outVol = blackvolbysabr( ___ ,Name,Value)
```

Description

`outVol = blackvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue, Strike)` calculates the implied Black volatility using the SABR stochastic volatility model.

`outVol = blackvolbysabr( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Compute the Implied Black Volatility Using the SABR Model

Define the model parameters and option data.

```
ForwardRate = 0.0357;
Strike = 0.03;
Alpha = 0.036;
Beta = 0.5;
Rho = -0.25;
Nu = 0.35;

Settle = datetime(2013,9,15);
ExerciseDate = datetime(2015,9,15);
```

Compute the Black volatility using the SABR model.

```
ComputedVols = blackvolbysabr(Alpha, Beta, Rho, Nu, Settle, ...
ExerciseDate, ForwardRate, Strike)
```

```
ComputedVols = 0.2122
```

Compute the Shifted Black Volatility Using the Shifted SABR Model

Define the model parameters and option data with a negative strike.

```
ForwardRate = 0.0002;
Strike = -0.001;  % -0.1% strike.
Alpha = 0.01;
Beta = 0.5;
Rho = -0.1;
```

```
Nu = 0.15;
Shift = 0.005;  % 0.5 percent shift

Settle = datetime(2016,3,1);
ExerciseDate = datetime(2017,3,1);
```

Compute the Shifted Black volatility using the Shifted SABR model.

```
ComputedVols = blackvolbysabr(Alpha, Beta, Rho, Nu, Settle, ...
ExerciseDate, ForwardRate, Strike, 'Shift', Shift)
```

```
ComputedVols = 0.1518
```

Input Arguments

`Alpha` — Current SABR volatility

scalar

Current SABR volatility, specified as a scalar.

Data Types: `double`

`Beta` — SABR constant elasticity of variance (CEV) exponent

scalar

SABR CEV exponent, specified as a scalar.

Data Types: `double`

`Rho` — Correlation between forward value and volatility

scalar

Correlation between forward value and volatility, specified as a scalar.

Data Types: `double`

`Nu` — Volatility of volatility

scalar

Volatility of volatility, specified as a scalar.

Data Types: `double`

`Settle` — Settlement date

scalar for serial nonnegative date number | scalar for date character vector

Settlement date, specified as a scalar using a serial nonnegative date number or date character vector.

Data Types: `double` | `char`

`ExerciseDate` — Option exercise date

scalar for serial nonnegative date number | scalar for date character vector

Option exercise date, specified as a scalar using a serial nonnegative date number or date character vector.

Data Types: `double` | `char`

`ForwardValue` — Current forward value of underlying asset
scalar | vector

Current forward value of the underlying asset, specified as a scalar or vector of size `NumVols`-by-`1`.

Data Types: `double`

`Strike` — Option strike price values
scalar | vector

Option strike price values, specified as a scalar value or a vector of size `NumVols`-by-`1`.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `outVol = blackvolbysabr(Alpha,Beta,Rho,Nu,Settle,ExerciseDate,ForwardValue,Strike,'Basis',2,'Model','Obloj2008')`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | positive integers of the set `[1...13]`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a positive integer of the set `[1...13]`.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Model` — Version of SABR model
`'Hagan2002'` (default) | value `'Obloj2008'`

Version of SABR model, specified as the comma-separated pair consisting of `'Model'` and one of the following values:

- `'Hagan2002'` — Original version by Hagan et al. (2002)
- `'Obloj2008'` — Version by Obloj (2008)

Data Types: `char`

`Shift` — Shift in decimals for shifted SABR model
`0` (no shift) (default) | positive decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), specified as the comma-separated pair consisting of `'Shift'` and a scalar positive decimal value. Set this parameter to a positive shift in decimals to add a positive shift to `ForwardValue` and `Strike`, which effectively sets a negative lower bound for `ForwardValue` and `Strike`. For example, a `Shift` value of 0.01 is equal to a 1% shift.

Data Types: `double`

Output Arguments

`outVol` — Implied Black volatility computed by SABR model
scalar | vector

Implied Black volatility computed by SABR model, returned as a scalar or vector of size `NumVols`-by-`1`.

Algorithms

The SABR stochastic volatility model treats the underlying forward $\widehat{F}$ and volatility $\widehat{\alpha}$ as separate random processes, which are related with correlation ρ:

$$d\widehat{F} = \widehat{\alpha}\widehat{F}^{\beta}dW_1$$
$$d\widehat{\alpha} = \nu\widehat{\alpha}dW_2$$
$$dW_1dW_2 = \rho dt$$
$$\widehat{F}(0) = F$$
$$\widehat{\alpha}(0) = \alpha$$

where

- $\widehat{F}$ is the underlying forward (a variable).
- F is the current underlying forward (a constant).
- $\widehat{\alpha}$ is the SABR volatility (a variable).
- α is the current SABR volatility (a constant).
- β is the SABR constant elasticity of variance (CEV) exponent.

- υ is the volatility of volatility.
- dW_1 is Brownian motion.
- dW_2 is Brownian motion.
- ρ is the correlation between forward value and volatility.

In contrast, Black's lognormal model assumes a constant volatility, σ_B.

$$d\widehat{F} = \sigma_B \widehat{F} dW$$

Hagan et al. (2002) derived the following closed-form approximation of implied Black lognormal volatility (σ_B) for the SABR model

$$\sigma_B(F,K) = \frac{\alpha\left\{1 + \left[\frac{(1-\beta)^2}{24}\frac{\alpha^2}{(FK)^{1-\beta}} + \frac{1}{4}\frac{\rho\beta\upsilon\alpha}{(FK)^{(1-\beta)/2}} + \frac{2-3\rho^2}{24}\upsilon^2\right]T + \ldots\right\}}{(FK)^{(1-\beta)/2}\left\{1 + \frac{(1-\beta)^2}{24}\log^2(F/K) + \frac{(1-\beta)^4}{1920}\log^4(F/K) + \ldots\right\}}\left(\frac{z}{x(z)}\right)$$

$$z = \frac{\upsilon}{\alpha}({}^{F}\log(F/K)$$

$$x(z) = \log\left\{\frac{\sqrt{1-2\rho z + z^2} + z - \rho}{1-\rho}\right\}$$

where

- F is the current forward value of the underlying.
- α is the current SABR volatility.
- K is the strike value.
- T is the time to option maturity.

Obloj (2008) advocated the following closed-form approximation of implied Black lognormal volatility for the SABR model (for $\beta < 1$)

$$\sigma_B(F,K) = \frac{\upsilon\log(F/K)}{x(z)}\left\{1 + \left[\frac{(1-\beta)^2}{24}\frac{\alpha^2}{(FK)^{1-\beta}} + \frac{1}{4}\frac{\rho\beta\upsilon\alpha}{(FK)^{(1-\beta)/2}} + \frac{2-3\rho^2}{24}\upsilon^2\right]T + \ldots\right\}$$

$$z = \frac{\upsilon}{\alpha}\frac{F^{(1-\beta)} - K^{(1-\beta)}}{1-\beta}$$

$$x(z) = \log\left\{\frac{\sqrt{1-2\rho z + z^2} + z - \rho}{1-\rho}\right\}$$

These expressions can be simplified in special situations, such as the at-the-money ($F = K$) and stochastic lognormal ($\beta = 1$) cases [1,2].

Version History

Introduced in R2014a

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

bondbybk

Price bond from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = bondbybk(BKTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = bondbybk( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = bondbybk(BKTree,CouponRate,Settle,Maturity)` prices bond from a Black-Karasinski interest-rate tree. `bondbybk` computes prices of vanilla bonds, stepped coupon bonds and amortizing bonds.

`[Price,PriceTree] = bondbybk( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Bond Using a BK Tree

Price a 4% bond using a Black-Karasinski interest-rate tree.

Load `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and interest-rate information needed to price the bond.

```
load deriv.mat;
```

Define the bond using the required arguments. Other arguments use defaults.

```
CouponRate = 0.04;
Settle = datetime(2004,1,1);
Maturity = datetime(2008,1,1);
```

Use `bondbybk` to compute the price of the bond.

```
Period = 1;
Price = bondbybk(BKTree, CouponRate, Settle, Maturity, Period)
```

```
Price = 99.3296
```

Price a Stepped Coupon Bond

Price single stepped coupon bonds using market data.

Define the interest-rate term structure.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
```

```
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ;...
datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;
```

Create the RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create the stepped bond instrument.

```
Settle = datetime(2010,1,1);
Maturity = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
Period = 1;
```

Build the BK tree using the following market data:

```
VolDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ];
VolCurve = 0.01;
AlphaDates = datetime(2014,1,1);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RS.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RS, BKTimeSpec);
```

Compute the price of the stepped coupon bonds.

```
PBK= bondbybk(BKT, CouponRate, Settle,Maturity , Period)
```

```
PBK = 4×1

  100.7246
  100.0945
  101.5900
  102.0820
```

Price a Bond with an Amortization Schedule

Price a bond with an amortization schedule using the `Face` input argument to define the schedule.

Define the interest-rate term structure.

```
Rates = 0.065;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates=  datetime(2017,1,1);
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.6853
            Rates: 0.0650
         EndTimes: 6
       StartTimes: 0
         EndDates: 736696
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create the bond instrument. The bond has a coupon rate of 7%, a period of one year, and matures on 1-Jan-2017.

```
CouponRate = 0.07;
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
Period = 1;
Face = {{datetime(2015,1,1) 100; datetime(2016,1,1) 90; datetime(2017,1,1) 80}};
```

Build the BK tree with the following market data:

```
VolDates = [datetime(2012,1,1) ; datetime(2013,1,1) ;...
datetime(2014,1,1) ; datetime(2015,1,1) ; datetime(2016,1,1) ; datetime(2017,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2017,1,1);
AlphaCurve = 0.1;

BKVolSpec = bkvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
BKTimeSpec = bktimespec(RateSpec.ValuationDate, VolDates, Compounding);
BKT = bktree(BKVolSpec, RateSpec, BKTimeSpec);
```

Compute the price of the amortizing bond.

```
Price = bondbybk(BKT, CouponRate, Settle, Maturity, 'Period', Period,...
'Face', Face)
```

```
Price = 102.3155
```

Compare the results with price of a vanilla bond.

```
PriceVanilla = bondbybk(BKT, CouponRate, Settle, Maturity, Period)
```

```
PriceVanilla = 102.4205
```

Input Arguments

`BKTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `bktree`

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybk` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every bond is set to the `ValuationDate` of the BK tree. The bond argument `Settle` is ignored.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each bond.

To support existing code, `bondbybk` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = bondbybk(BKTree,CouponRate,Settle,Maturity,'Period',4,'Face',10000)`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer `[0, 1]` using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybk` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybk` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybk` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
`Settle` date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbybk` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or an `NINST`-by-`1` cell array of face values or face value schedules. For the latter case, each element of the cell array is a `NumDates`-by-`2` cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

Output Arguments

`Price` — Expected bond prices at time 0
vector

Expected bond prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bondbybk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bondbyhjm

Price bond from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = bondbyhjm(HJMTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = bondbyhjm(___,Name,Value)
```

Description

`[Price,PriceTree] = bondbyhjm(HJMTree,CouponRate,Settle,Maturity)` prices bond from a Heath-Jarrow-Morton interest-rate tree. `bondbyhjm` computes prices of vanilla bonds, stepped coupon bonds and amortizing bonds.

`[Price,PriceTree] = bondbyhjm(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Bond Using an HJM Tree

Price a 4% bond using an HJM interest-rate tree.

Load `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and interest-rate information needed to price the bond.

```
load deriv.mat;
```

Define the bond using the required arguments. Other arguments use defaults.

```
CouponRate = 0.04;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
```

Use `bondbyhjm` to compute the price of the bond.

```
Period = 1;
Price = bondbyhjm(HJMTree, CouponRate, Settle, Maturity, Period)
```

```
Price = 97.3600
```

Price a Stepped Coupon Bond

Price single stepped coupon bonds using market data.

Define the interest-rate term structure.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
```

```
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;
```

Create the RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Create the stepped bond instrument.

```
Settle = datetime(2010,1,1);
Maturity = [ datetime(2011,1,1); datetime(2012,1,1); datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
Period = 1;
```

Build the HJM tree using the following market data:

```
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1;  2;   3;   4];
HJMTimeSpec = hjmtimespec(ValuationDate, EndDates);
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec,RS,HJMTimeSpec);
```

Compute the price of the stepped coupon bonds.

```
PHJM= bondbyhjm(HJMT, CouponRate, Settle,Maturity , Period)
```

```
PHJM = 4×1

  100.7246
  100.0945
  101.5900
  102.0820
```

Price a Bond with an Amortization Schedule

Price a bond with an amortization schedule using the Face input argument to define the schedule.

Define the interest-rate term structure.

```
Rates = 0.065;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates=  datetime(2017,1,1);
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
```

```
            Disc: 0.6853
           Rates: 0.0650
       EndTimes: 6
     StartTimes: 0
       EndDates: 736696
     StartDates: 734504
  ValuationDate: 734504
           Basis: 0
    EndMonthRule: 1
```

Create the bond instrument. The bond has a coupon rate of 7%, a period of one year, and matures on 1-Jan-2017.

```
CouponRate = 0.07;
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
Period = 1;
Face = {{datetime(2015,1,1) 100;datetime(2016,1,1) 90;datetime(2017,1,1) 80}};
```

Build the HJM tree using the following market data:

```
Volatility = [.2; .19; .18; .17];
CurveTerm = [ 1;  2;   3;   4];
MaTree = [datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1) ; datetime(2015,1,1);...
datetime(2016,1,1) ; datetime(2017,1,1)];
HJMTimeSpec = hjmtimespec(ValuationDate, MaTree);
HJMVolSpec = hjmvolspec('Proportional', Volatility, CurveTerm, 1e6);
HJMT = hjmtree(HJMVolSpec,RateSpec,HJMTimeSpec);
```

Compute the price of the amortizing bond.

```
Price = bondbyhjm(HJMT, CouponRate, Settle, Maturity, 'Period',...
Period, 'Face' , Face)
```

```
Price = 102.3155
```

Compare the results with price of a vanilla bond.

```
PriceVanilla = bondbyhjm(HJMT, CouponRate, Settle, Maturity, Period)
```

```
PriceVanilla = 102.4205
```

Input Arguments

`HJMTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `hjmtree`

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates

and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every bond is set to the `ValuationDate` of the HJM tree. The bond argument `Settle` is ignored.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each bond.

To support existing code, `bondbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = bondbyhjm(HJMTree,CouponRate,Settle,Maturity,'Period',4,'Face',10000)`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-1 vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
`Settle` date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

Face — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or an `NINST`-by-`1` cell array of face values or face value schedules. For the latter case, each element of the cell array is a `NumDates`-by-`2` cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

Options — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

BusinessDayConvention — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

Output Arguments

`Price` — Expected bond prices at time 0
vector

Expected bond prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PBush` contains the clean prices.
- `PriceTree.AIBush` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

More About

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bondbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bondbyhw

Price bond from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = bondbyhw(HWTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = bondbyhw(___,Name,Value)
```

Description

`[Price,PriceTree] = bondbyhw(HWTree,CouponRate,Settle,Maturity)` prices bond from a Hull-White interest-rate tree. `bondbyhw` computes prices of vanilla bonds, stepped coupon bonds and amortizing bonds.

`[Price,PriceTree] = bondbyhw(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Bond Using the HW Tree

Price a 4% bond using a Hull-White interest-rate tree.

Load `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and interest-rate information needed to price the bond.

```
load deriv.mat;
```

Define the bond using the required arguments. Other arguments use defaults.

```
CouponRate = 0.04;
Settle = datetime(2004,1,1);
Maturity = datetime(2006,1,1);
```

Use `bondbyhw` to compute the price of the bond.

```
Period = 1;
Price = bondbyhw(HWTree, CouponRate, Settle, Maturity, Period)
```

```
Price = 101.6002
```

Price a Stepped Coupon Bond

Price single stepped coupon bonds using market data.

Define the interest-rate term structure.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
```

```
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;
```

Create the RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create the stepped bond instrument.

```
Settle = datetime(2010,1,1);
Maturity = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
Period = 1;
```

Build the HW tree using the following market data:

```
VolDates = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
VolCurve = 0.01;
AlphaDates = datetime(2014,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RS.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RS.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RS, HWTimeSpec);
```

Compute the price of the stepped coupon bonds.

```
PHW= bondbyhw(HWT, CouponRate, Settle,Maturity , Period)
```

```
PHW = 4×1

  100.7246
  100.0945
  101.5900
  102.0820
```

Price Two Bonds with Amortization Schedules

Price two bonds with amortization schedules using the Face input argument to define the schedules.

Define the interest rate term structure.

```
Rates = 0.035;
ValuationDate = datetime(2011,11,1);
StartDates = ValuationDate;
EndDates = datetime(2017,11,1);
Compounding = 1;
```

Create the `RateSpec`.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding);
```

Create the bond instrument. The bonds have a coupon rate of 4% and 3.85%, a period of one year, and mature on 1-Nov-2017.

```
CouponRate = [0.04; 0.0385];
Settle = datetime(2011,11,1);
Maturity = datetime(2017,11,1);
Period = 1;
```

Define the amortizing schedule.

```
Face = {{datetime(2015,11,1) 100;datetime(2016,11,1) 85;datetime(2017,11,1) 70};
{datetime(2015,11,1) 100;datetime(2016,11,1) 90;datetime(2017,11,1) 80}};
```

Build the HW tree and assume the volatility to be 10%.

```
VolDates = [datetime(2012,11,1) ; datetime(2013,11,1) ; datetime(2014,11,1) ; datetime(2015,11,1
VolCurve = 0.1;
AlphaDates = datetime(2017,1,1);
AlphaCurve = 0.1;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWT = hwtree(HWVolSpec, RateSpec, HWTimeSpec);
```

Compute the price of the amortizing bonds.

```
Price = bondbyhw(HWT, CouponRate, Settle, Maturity, 'Period',Period,...
'Face', Face)
```

```
Price = 2×1

  102.4791
  101.7786
```

Input Arguments

`HWTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `hwtree`.

Data Types: `struct`

CouponRate — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an NINST-by-1 decimal annual rate or NINST-by-1 cell array, where each element is a NumDates-by-2 cell array. The first column of the NumDates-by-2 cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | cell

Settle — Settlement date
datetime array | string array | date character vector

Settlement date, specified either as a scalar or NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyhw also accepts serial date numbers as inputs, but they are not recommended.

The Settle date for every bond is set to the ValuationDate of the HW tree. The bond argument Settle is ignored.

Maturity — Maturity date
datetime array | string array | date character vector

Maturity date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each bond.

To support existing code, bondbyhw also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] =
bondbyhw(HWTree,CouponRate,Settle,Maturity,'Period',4,'Face',10000)

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector. Values for Period are 1, 2, 3, 4, 6, and 12.

Data Types: double

Basis — Day-count basis
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyhw` also accepts serial date numbers as inputs, but they are not recommended.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyhw also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a LastCouponDate, the cash flow payment dates are determined from other inputs.

StartDate — Forward starting date of payments
Settle date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyhw also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of 'Face' and a NINST-by-1 vector of nonnegative face values or an NINST-by-1 cell array of face values or face value schedules. For the latter case, each element of the cell array is a NumDates-by-2 cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid.

Data Types: cell | double

Options — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of 'Options' and a structure that is created with derivset.

Data Types: struct

AdjustCashFlowsBasis — Flag to adjust cash flows based on actual period day count
false (default) | value of 0 (false) or 1 (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'AdjustCashFlowsBasis' and a NINST-by-1 vector of logicals with values of 0 (false) or 1 (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

Output Arguments

`Price` — Expected bond prices at time 0
vector

Expected bond prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bondbyhw` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bondbycir

Price bond from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = bondbycir(CIRTree,CouponRate,Settle,Maturity)
[Price,PriceTree] = bondbycir(___,Name,Value)
```

Description

`[Price,PriceTree] = bondbycir(CIRTree,CouponRate,Settle,Maturity)` prices bond from a Cox-Ingersoll-Ross (CIR) interest-rate tree. `bondbycir` computes prices of vanilla bonds, stepped coupon bonds, and amortizing bonds using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = bondbycir(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Bond Using a CIR Interest-Rate Tree

Define the `CouponRate` for a bond.

```
CouponRate = 0.035;
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = datetime(2017,1,1);
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
       FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
```

```
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the bond.

```
[Price,PriceTree] = bondbycir(CIRT,CouponRate,Settle,Maturity)
```

```
Price = 94.0880
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 1 2 3 4]
       dObs: [736696 737061 737426 737791 738157]
      PTree: {1x5 cell}
     AITree: {[0]  [0 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [0 0 0 0 0 0 0]}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate structure

structure

Interest-rate tree structure, created by `cirtree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbycir` also accepts serial date numbers as inputs, but they are not recommended.

The `Settle` date for every bond is set to the `ValuationDate` of the CIR tree. The bond argument `Settle` is ignored.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a NINST-by-1 vector using a datetime array, string array, or date character vectors representing the maturity date for each bond.

To support existing code, bondbycir also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree] = bondbycir(CIRTree,CouponRate,Settle,Maturity,'Period',4,'Face',10000)

Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and an NINST-by-1 vector. Values for Period are 1, 2, 3, 4, 6, and 12.

Data Types: double

Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a `NINST`-by-`1` vector.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbycir` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbycir` also accepts serial date numbers as inputs, but they are not recommended.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify a `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbycir` also accepts serial date numbers as inputs, but they are not recommended.

In the absence of a specified `FirstCouponDate`, a specified `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at the `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a `LastCouponDate`, the cash flow payment dates are determined from other inputs.

`StartDate` — Forward starting date of payments
`Settle` date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of `'StartDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbycir` also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify `StartDate`, the effective start date is the `Settle` date.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face or par value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or a `NINST`-by-`1` cell array of face values or face value schedules. For the latter case, each element of the cell array is a `NumDates`-by-`2` cell array, where the first column is dates and the second column is its associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

Output Arguments

`Price` — Expected bond prices at time 0
vector

Expected bond prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.
- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.

More About

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced in R2018a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `bondbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bondbyzero

Price bond from set of zero curves

Syntax

```
[Price,DirtyPrice,CFlowAmounts,CFlowDates] = bondbyzero(RateSpec,CouponRate,
Settle,Maturity)
[Price,DirtyPrice,CFlowAmounts,CFlowDates] = bondbyzero( ___ ,Name,Value)
```

Description

`[Price,DirtyPrice,CFlowAmounts,CFlowDates] = bondbyzero(RateSpec,CouponRate, Settle,Maturity)` prices a bond from a set of zero curves. `bondbyzero` computes prices of vanilla bonds, stepped coupon bonds and amortizing bonds.

Note Alternatively, you can use the `FixedBond` object to price fixed-rate bond instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,DirtyPrice,CFlowAmounts,CFlowDates] = bondbyzero( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Vanilla Bond

Price a 4% bond using a zero curve.

Load `deriv.mat`, which provides `ZeroRateSpec`, the interest-rate term structure, needed to price the bond.

```
load deriv.mat;
CouponRate = 0.04;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
Price = bondbyzero(ZeroRateSpec, CouponRate, Settle, Maturity)
```

```
Price = 97.5334
```

Price a Stepped Coupon Bond

Price single stepped coupon bonds using market data.

Define data for the interest-rate term structure.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
ValuationDate = datetime(2010,1,1);
```

```
StartDates = ValuationDate;
EndDates = [datetime(2011,1,1) ; datetime(20102,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
Compounding = 1;
```

Create the RateSpec.

```
RS = intenvset('ValuationDate', ValuationDate, 'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RS = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x1 double]
            Rates: [4x1 double]
          EndTimes: [4x1 double]
        StartTimes: [4x1 double]
          EndDates: [4x1 double]
        StartDates: 734139
    ValuationDate: 734139
            Basis: 0
     EndMonthRule: 1
```

Create the stepped bond instrument.

```
Settle = datetime(2010,1,1);
Maturity = [datetime(2011,1,1) ; datetime(2012,1,1) ; datetime(2013,1,1) ; datetime(2014,1,1)];
CouponRate = {{datetime(2012,1,1) .0425;datetime(2014,1,1) .0750}};
Period = 1;
```

Compute the price of the stepped coupon bonds.

```
PZero= bondbyzero(RS, CouponRate, Settle, Maturity ,Period)
```

```
PZero = 4×1

  100.7246
  101.4247
  101.6442
  102.1362
```

Price a Bond with an Amortizing Schedule

Price a bond with an amortizing schedule using the Face input argument to define the schedule.

Define data for the interest-rate term structure.

```
Rates = 0.065;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates=  datetime(2017,1,1);
Compounding = 1;
```

Create the RateSpec.

```
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: 0.6853
            Rates: 0.0650
         EndTimes: 6
       StartTimes: 0
         EndDates: 736696
       StartDates: 734504
    ValuationDate: 734504
            Basis: 0
     EndMonthRule: 1
```

Create and price the amortizing bond instrument. The bond has a coupon rate of 7%, a period of one year, and matures on 1-Jan-2017.

```
CouponRate = 0.07;
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
Period = 1;
Face = {{datetime(2015,1,1) 100;datetime(2016,1,1) 90;datetime(2017,1,1) 80}};
Price = bondbyzero(RateSpec, CouponRate, Settle, Maturity, 'Period',...
Period, 'Face', Face)
```

```
Price = 102.3155
```

Compare the results with price of a vanilla bond.

```
PriceVanilla = bondbyzero(RateSpec, CouponRate, Settle, Maturity,Period)
```

```
PriceVanilla = 102.4205
```

Price both the amortizing and vanilla bonds.

```
Face = {{datetime(2015,1,1) 100;datetime(2016,1,1) 90;datetime(2017,1,1) 80};
         100};
PriceBonds = bondbyzero(RateSpec, CouponRate, Settle, Maturity, 'Period',...
               Period, 'Face', Face)
```

```
PriceBonds = 2×1

  102.3155
  102.4205
```

Price a Bond in a Holding Period

When a bond is first issued, it can be priced with `bondbyzero` on that day by setting the `Settle` date to the issue date. Later on, if the bond needs to be traded someday between the issue date and the maturity date, its new price can be computed by updating the `Settle` date, as well as the `RateSpec` input.

Note that the bond's price is determined by its remaining cash flows and the zero-rate term structure, which can both change as the bond matures. While `bondbyzero` automatically updates the bond's remaining cash flows with respect to the new `Settle` date, you must supply a new `RateSpec` input in order to reflect the new zero-rate term structure for that new `Settle` date.

Use the following Bond information.

```
IssueDate = datetime(2014,5,20);
CouponRate = 0.01;
Maturity = datetime(2019,5,20);
```

Determine the bond price on 20-May-2014.

```
Settle1 = datetime(2014,5,20);
ZeroDates1 = datemnth(Settle1,12*[1 2 3 5 7 10 20]');
ZeroRates1 = [0.23 0.63 1.01 1.60 2.01 2.27 2.79]'/100;
RateSpec1 = intenvset('StartDate',Settle1,'EndDates',ZeroDates1,'Rates',ZeroRates1);
[Price1, ~, CFlowAmounts1, CFlowDates1] = bondbyzero(RateSpec1, ...
    CouponRate, Settle1, Maturity, 'IssueDate', IssueDate);
Price1
```

```
Price1 = 97.1899
```

Determine the bond price on 10-Aug-2015.

```
Settle2 = datetime(2015,8,10);
ZeroDates2 = datemnth(Settle2,12*[1 2 3 5 7 10 20]');
ZeroRates2 = [0.40 0.73 1.09 1.62 1.98 2.24 2.58]'/100;
RateSpec2 = intenvset('StartDate',Settle2,'EndDates',ZeroDates2,'Rates',ZeroRates2);
[Price2, ~, CFlowAmounts2, CFlowDates2] = bondbyzero(RateSpec2, ...
    CouponRate, Settle2, Maturity, 'IssueDate', IssueDate);
Price2
```

```
Price2 = 98.9384
```

Price Three Bonds Using Two Different Curves

To price three bonds using two different curves, define the `RateSpec`:

```
StartDates = datetime(2016,4,1);
EndDates = [datetime(2017,4,1) ; datetime(2018,4,1) ; datetime(2019,4,1) ; datetime(2020,4,1)];
Rates = [[0.0356;0.041185;0.04489;0.047741],[0.0325;0.0423;0.0437;0.0465]];
RateSpec = intenvset('Rates', Rates, 'StartDates',StartDates,...
'EndDates', EndDates, 'Compounding', 1)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [4x2 double]
            Rates: [4x2 double]
         EndTimes: [4x1 double]
       StartTimes: [4x1 double]
         EndDates: [4x1 double]
       StartDates: 736421
    ValuationDate: 736421
            Basis: 0
```

```
    EndMonthRule: 1
```

Price three bonds with the same `Maturity` and different coupons.

```
Settle = datetime(2016,4,1);
Maturity = datetime(2020,4,1);
Price = bondbyzero(RateSpec,[0.025;0.028;0.035],Settle,Maturity)
```

```
Price = 3×2

   92.0766   92.4888
   93.1680   93.5823
   95.7145   96.1338
```

Price a Vanilla Bond Using the Optional Input Argument `AdjustCashFlowsBasis`

To adjust the cash flows according to the accrual amount, use the optional input argument `AdjustCashFlowsBasis` when calling `bondbyzero`.

Use the following data to define the interest-rate term structure and to create a `RateSpec`.

```
Rates = 0.065;
ValuationDate = datetime(2011,1,1);
StartDates = ValuationDate;
EndDates=  datetime(2017,1,1);
Compounding = 1;
RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',StartDates,...
'EndDates', EndDates,'Rates',Rates,'Compounding',Compounding);
CouponRate = 0.07;
Settle = datetime(2011,1,1);
Maturity = datetime(2017,1,1);
Period = 1;
Face = {{datetime(2015,1,1) 100;datetime(2016,1,1) 90;datetime(2017,1,1) 80}};
```

Use `cfamounts` and cycle through the `Basis` of `0` to `13`, using the optional argument `AdjustCashFlowsBasis` to determine the cash flow amounts for accrued interest due at settlement.

```
AdjustCashFlowsBasis = true;
CFlowAmounts =  cfamounts(CouponRate,Settle,Maturity,'Period',Period,'Basis',0:13,'AdjustCashFlo
```

```
CFlowAmounts = 14×7

         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0972    7.1167    7.0972    7.0972    7.0972  107.1167
         0    7.0000    7.0192    7.0000    7.0000    7.0000  107.0192
         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0000    7.0000    7.0000    7.0000    7.0000  107.0000
         0    7.0972    7.1167    7.0972    7.0972    7.0972  107.1167
    ⋮
```

Notice that the cash flow amounts have been adjusted according to `Basis`.

Price a vanilla bond using the input argument `AdjustCashFlowsBasis`.

```
PriceVanilla = bondbyzero(RateSpec,CouponRate,Settle,Maturity,'Period',Period,'Basis',0:13,'Adjus
```

```
PriceVanilla = 14×1

  102.4205
  102.4205
  102.9216
  102.4506
  102.4205
  102.4205
  102.4205

  102.4205
  102.9216
      ⋮
```

Input Arguments

`RateSpec` — Interest-rate structure

structure

Interest-rate structure, specified using `intenvset` to create a `RateSpec` for an annualized zero rate term structure.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified either as a scalar or `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `bondbyzero` also accepts serial date numbers as inputs, but they are not recommended.

`Settle` must be earlier than `Maturity`.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors representing the maturity date for each bond.

To support existing code, `bondbyzero` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = bondbyzero(RateSpec,CouponRate,Settle,Maturity,'Period',4,'Face',10000)`

`Period` — Coupons per year

`2` per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector. Values for `Period` are `1`, `2`, `3`, `4`, `6`, and `12`.

Data Types: `double`

`Basis` — Day-count basis

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of the instrument, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days
1 (in effect) (default) | nonnegative integer [0,1]

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a nonnegative integer [0, 1] using a NINST-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyzero also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyzero also accepts serial date numbers as inputs, but they are not recommended.

LastCouponDate — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyzero also accepts serial date numbers as inputs, but they are not recommended.

StartDate — Forward starting date of payments
Settle date (default) | datetime array | string array | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, bondbyzero also accepts serial date numbers as inputs, but they are not recommended.

If you do not specify StartDate, the effective start date is the Settle date.

Face — Face value
100 (default) | scalar of nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` scalar of nonnegative face values or an `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`Options` — Derivatives pricing options
structure

Derivatives pricing options, specified as the comma-separated pair consisting of `'Options'` and a structure that is created with `derivset`.

Data Types: `struct`

`AdjustCashFlowsBasis` — Flag to adjust cash flows based on actual period day count
`false` (default) | value of `0` (false) or `1` (true)

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of `'AdjustCashFlowsBasis'` and a `NINST`-by-`1` vector of logicals with values of `0` (false) or `1` (true).

Data Types: `logical`

`BusinessDayConvention` — Business day conventions
`actual` (default) | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector or a `N`-by-`1` (or `NINST`-by-`2` if `BusinessDayConvention` is different for each leg) cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- `actual` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `follow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `modifiedfollow` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `previous` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `modifiedprevious` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and MATLAB dates using a `NHolidays`-by-`1` vector.

Data Types: `datetime`

Output Arguments

`Price` — Fixed-rate note prices
matrix

Floating-rate note prices, returned as a (`NINST`) by number of curves (`NUMCURVES`) matrix. Each column arises from one of the zero curves.

`DirtyPrice` — Dirty bond price
matrix

Dirty bond price (clean + accrued interest), returned as a `NINST`- by-`NUMCURVES` matrix. Each column arises from one of the zero curves.

`CFlowAmounts` — Cash flow amounts
matrix

Cash flow amounts, returned as a `NINST`- by-`NUMCFS` matrix of cash flows for each bond.

`CFlowDates` — Cash flow dates
matrix

Cash flow dates, returned as a `NINST`- by-`NUMCFS` matrix of payment dates for each bond.

More About

Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

Stepped Coupon Bond

A step-up and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `bondbyzero` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

bushpath

Extract entries from node of bushy tree

Syntax

```
Values = bushpath(Tree,BranchList)
```

Description

`Values = bushpath(Tree,BranchList)` extracts entries of a node of a bushy tree. The node path is described by the sequence of branchings taken, starting at the root. The top branch is number 1, the second-to-top is 2, and so on. Set the branch sequence to zero to obtain the entries at the root node.

Examples

Extract Entries From Node of Bushy Tree

Create an HJM tree by loading the example file.

```
load deriv.mat;
```

Use `bushpath` to return the rates at the tree nodes located by taking the up branch, then the down branch, and finally the up branch again.

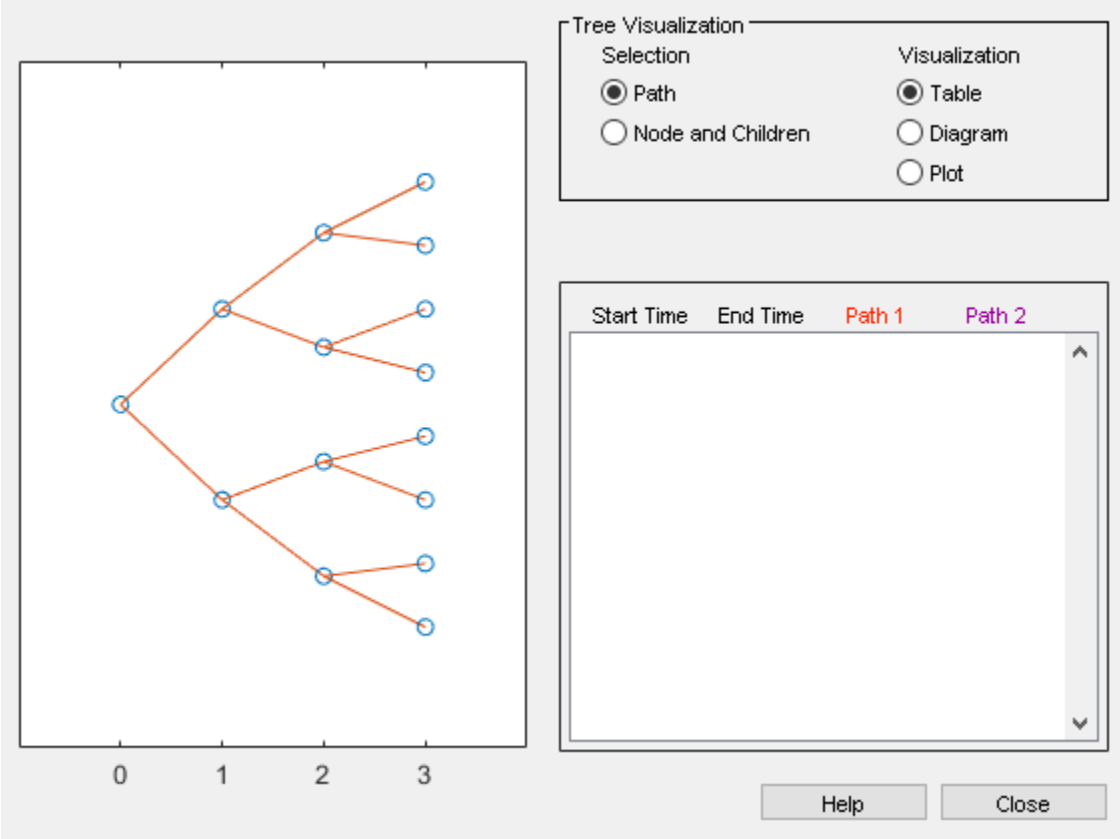
```
FwdRates = bushpath(HJMTree.FwdTree, [1 2 1])
```

```
FwdRates = 4×1

    1.0356
    1.0364
    1.0526
    1.0463
```

You can visualize this with the `treeviewer` function.

```
treeviewer(HJMTree)
```



Input Arguments

`Tree` — Bushy tree

structure

Bushy tree, specified using an HJM, BDT, HW, BK, or CIR tree.

Data Types: `struct`

`BranchList` — Sequence of branching

matrix

Sequence of branching, specified as a number of paths (`NUMPATHS`) by path length (`PATHLENGTH`) matrix.

Data Types: `double`

Output Arguments

`Values` — Retrieved entries of a bushy tree

numeric

Retrieved entries of a bushy tree, returned as a number of values (`NUMVALS`)-by-`NUMPATHS` matrix.

Version History

Introduced before R2006a

Topics

“Graphical Representation of Trees” on page 2-219

bushshape

Retrieve shape of bushy tree

Syntax

```
[NumLevels,NumChild,NumPos,NumStates,Trim] = bushshape(Tree)
```

Description

`[NumLevels,NumChild,NumPos,NumStates,Trim] = bushshape(Tree)` returns information on a bushy tree's shape.

Examples

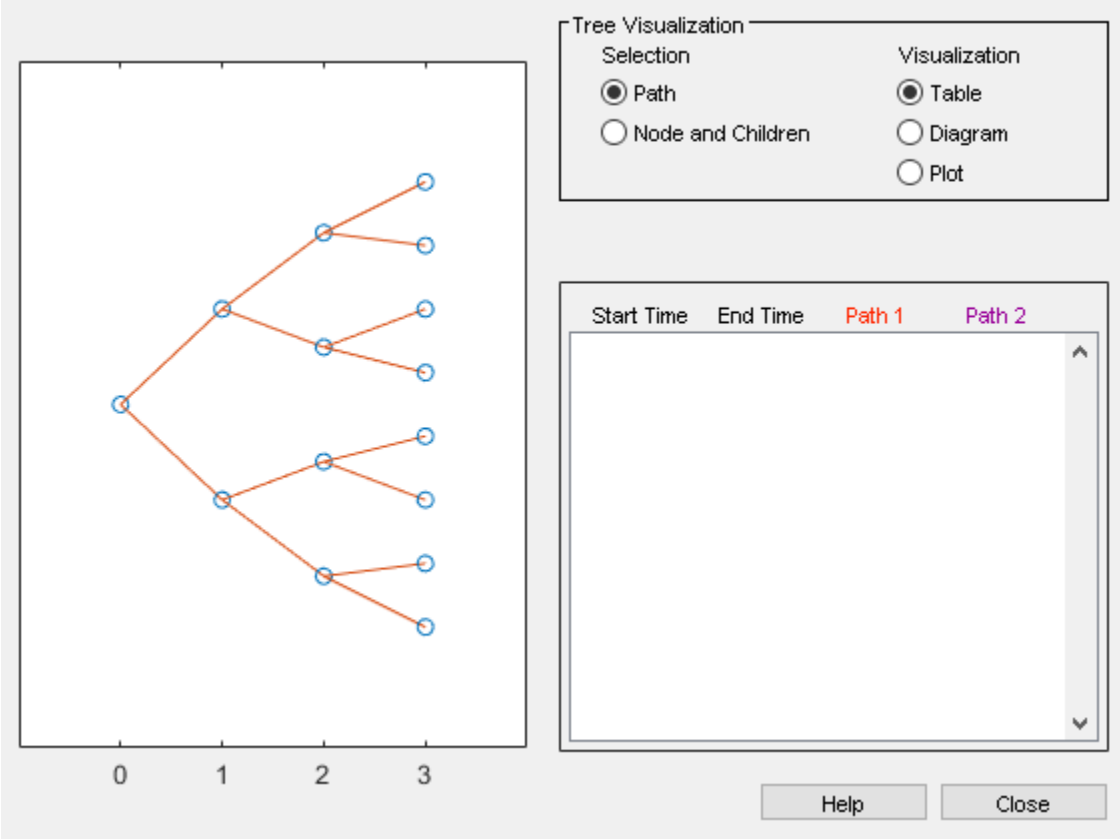
Retrieve Shape of Bushy Tree

Create an HJM tree by loading the example file.

```
load deriv.mat;
```

With `treeviewer` you can see the general shape of the HJM interest-rate tree.

```
treeviewer(HJMTree)
```



Use `bushshape` with the `HJMTree`.

```
[NumLevels, NumChild, NumPos, NumStates, Trim] = bushshape(HJMTree.FwdTree)
```

```
NumLevels = 4

NumChild = 1×4

     2     2     2     0

NumPos = 1×4

     4     3     2     1

NumStates = 1×4

     1     2     4     8

Trim = logical
   1
```

You can recreate this tree using the `mkbush` function.

```
Tree = mkbush(NumLevels, NumChild(1), NumPos(1), Trim)
```

```
Tree=1×4 cell array
    {4x1 double}    {3x1x2 double}    {2x2x2 double}    {1x4x2 double}
```

```
Tree = mkbush(NumLevels, NumChild, NumPos)
```

```
Tree=1×4 cell array
    {4x1 double}    {3x1x2 double}    {2x2x2 double}    {1x4x2 double}
```

Input Arguments

`Tree` — Bushy tree

structure

Bushy tree, specified using an HJM, BDT, HW, BK, or CIR tree.

Data Types: `struct`

Output Arguments

`NumLevels` — Number of tree levels

numeric

Number of tree levels, returned as a numeric.

`NumChild` — Number of branches of the nodes in each level

vector

Number of branches (children) of the nodes in each level, returned as a 1-by-number of levels (`NUMLEVELS`) vector.

`NumPos` — Length of the state vectors in each level

vector

Length of the state vectors in each level, returned as a 1-by-number of levels (`NUMLEVELS`) vector.

`NumStates` — Number of state vectors in each level

vector

Number of state vectors in each levels, returned as a 1-by-number of levels (`NUMLEVELS`) vector.

`Trim` — Trim

numeric

Trim, returned as a `1` if `NumPos` decreases by `1` when moving from one time level to the next. Otherwise, it is `0`.

Version History

Introduced before R2006a

capbybdt

Price cap instrument from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = capbybdt(BDTTree,Strike,Settle,Maturity)
[Price,PriceTree] = capbybdt( ___ ,CapReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = capbybdt(BDTTree,Strike,Settle,Maturity)` computes the price of a cap instrument from a Black-Derman-Toy interest-rate tree. `capbybdt` computes prices of vanilla caps and amortizing caps.

Note Alternatively, you can use the `Cap` object to price cap instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[Price,PriceTree] = capbybdt( ___ ,CapReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Cap Instrument Using a BDT Interest-Rate Tree

Load the file `deriv.mat`, which provides `BDTTree`. The `BDTTree` structure contains the time and interest-rate information needed to price the cap instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.03;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
```

Use `capbybdt` to compute the price of the cap instrument.

```
Price = capbybdt(BDTTree, Strike, Settle, Maturity)
```

```
Price = 28.4001
```

Price a 10% Cap Instrument Using a BDT Interest-Rate Tree

Set the required arguments for the three specifications required to create a BDT tree.

```
Compounding = 1;
ValuationDate = datetime(2000,1,1);
StartDate = ValuationDate;
EndDates = [datetime(2001,1,1) ; datetime(2002,1,1) ; datetime(2003,1,1) ;
datetime(2004,1,1) ; datetime(2005,1,1)];
Rates = [.1; .11; .12; .125; .13];
Volatility = [.2; .19; .18; .17; .16];
```

Create the specifications.

```
RateSpec = intenvset('Compounding', Compounding,...
'ValuationDate', ValuationDate,...
'StartDates', StartDate,...
'EndDates', EndDates,...
'Rates', Rates);
BDTTimeSpec = bdttimespec(ValuationDate, EndDates, Compounding);
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility);
```

Create the BDT tree from the specifications.

```
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [730486 730852 731217 731582 731947]
        TFwd: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [4]}
      CFlowT: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [5]}
     FwdTree: {1x5 cell}
```

Set the cap arguments. Remaining arguments will use defaults.

```
CapStrike = 0.10;
Settlement = ValuationDate;
Maturity = datetime(2002,1,1);
CapReset = 1;
```

Use `capbybdt` to find the price of the cap instrument.

```
Price= capbybdt(BDTTree, CapStrike, Settlement, Maturity,...
CapReset)
```

```
Price = 1.7169
```

Compute the Price of an Amortizing Cap Using the BDT Model

Define the `RateSpec`.

```
Rates = [0.03583; 0.042147; 0.047345; 0.052707; 0.054302];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
```

```
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
          EndTimes: [5x1 double]
        StartTimes: [5x1 double]
          EndDates: [5x1 double]
        StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Define the cap instrument.

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Strike = 0.04;
CapReset = 1;
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Build the BDT Tree.

```
BDTTimeSpec = bdttimespec(ValuationDate, EndDates);
Volatility = 0.10;
BDTVolSpec = bdtvolspec(ValuationDate, EndDates, Volatility*ones(1,length(EndDates))');
BDTTree = bdttree(BDTVolSpec, RateSpec, BDTTimeSpec)
```

```
BDTTree = struct with fields:
      FinObj: 'BDTFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3 4]
        dObs: [734822 735188 735553 735918 736283]
        TFwd: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [4]}
      CFlowT: {[5x1 double]  [4x1 double]  [3x1 double]  [2x1 double]  [5]}
     FwdTree: {1x5 cell}
```

Price the amortizing cap.

```
Basis = 0;
Price = capbybdt(BDTTree, Strike, Settle, Maturity, CapReset, Basis, Principal)
```

```
Price = 1.4042
```

Input Arguments

BDTTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised
decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for cap
datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every cap is set to the `ValuationDate` of the BDT tree. The cap argument `Settle` is ignored.

To support existing code, `capbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for cap
datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbybdt` also accepts serial date numbers as inputs, but they are not recommended.

`CapReset` — Reset frequency payment per year
`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing cap.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of cap at time 0
vector

Expected price of the cap at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of cap at each node
vector

Tree structure with values of the cap at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.PTree` contains cap prices.
- `PriceTree.tObs` contains the observation times.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

For more information, see “Cap” on page 2-12.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `capbybdt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

capbybk

Price cap instrument from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = capbybk(BKTree,Strike,Settle,Maturity)
[Price,PriceTree] = capbybk(___,CapReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = capbybk(BKTree,Strike,Settle,Maturity)` computes the price of a cap instrument from a Black-Karasinski interest-rate tree. `capbybk` computes prices of vanilla caps and amortizing caps.

Note Alternatively, you can use the `Cap` object to price cap instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`[Price,PriceTree] = capbybk(___,CapReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Cap Instrument Using a Black-Karasinski Interest-Rate Tree

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and interest-rate information needed to price the cap instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.03;
Settle = datetime(2004,1,1);
Maturity = datetime(2007,1,1);
```

Use `capbybk` to compute the price of the cap instrument.

```
Price = capbybk(BKTree, Strike, Settle, Maturity)
```

```
Price = 2.0965
```

Compute the Price of an Amortizing and Vanilla Caps Using the BK Model

Load `deriv.mat` to specify the `BKTree` and then define the cap instrument.

```
load deriv.mat;
Settle = datetime(2004,1,1);
Maturity = datetime(2008,1,1);
Strike = 0.05;
CapReset = 1;
Principal ={{datetime(2005,1,1) 100;datetime(2006,1,1) 60;datetime(2007,1,1) 30;datetime(2008,1,1
            100};
```

Price the amortizing and vanilla caps.

```
Basis = 1;
Price = capbybk(BKTree, Strike, Settle, Maturity, CapReset, Basis, Principal)
```

```
Price = 2×1

    0.2226
    0.7422
```

Input Arguments

`BKTree` — Interest-rate tree structure
structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised
decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for cap
datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every cap is set to the `ValuationDate` of the BK tree. The cap argument `Settle` is ignored.

To support existing code, `capbybk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for cap
datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbybk` also accepts serial date numbers as inputs, but they are not recommended.

`CapReset` — Reset frequency payment per year
1 (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing cap.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of cap at time 0
vector

Expected price of the cap at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of cap at each node
vector

Tree structure with values of the cap at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.PTree` contains cap prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

capbyblk

Price caps using Black option pricing model

Syntax

```
[CapPrice,Caplets] = capbyblk(RateSpec,Strike,Settle,Maturity,Volatility)
[CapPrice,Caplets] = capbyblk( ___ ,Name,Value)
```

Description

`[CapPrice,Caplets] = capbyblk(RateSpec,Strike,Settle,Maturity,Volatility)` price caps using the Black option pricing model. `capbyblk` computes prices of vanilla caps and amortizing caps.

Note Alternatively, you can use the `Cap` object to price cap instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[CapPrice,Caplets] = capbyblk( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Cap Using the Black Option Pricing Model

Consider an investor who gets into a contract that caps the interest rate on a $100,000 loan at 8% quarterly compounded for 3 months, starting on January 1, 2009. Assuming that on January 1, 2008 the zero rate is 6.9394% continuously compounded and the volatility is 20%, use this data to compute the cap price. First, calculate the `RateSpec`:

```
ValuationDate = datetime(2008,1,1);
EndDates = datetime(2010,4,1);
Rates = 0.069394;
Compounding = -1;
Basis = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding,'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8554
            Rates: 0.0694
         EndTimes: 2.2500
       StartTimes: 0
         EndDates: 734229
```

```
       StartDates: 733408
    ValuationDate: 733408
            Basis: 1
     EndMonthRule: 1
```

Compute the price of the cap.

```
Settle = datetime(2009,1,1); % cap starts in a year
Maturity = datetime(2009,4,1);
Volatility = 0.20;
CapRate = 0.08;
CapReset = 4;
Principal=100000;

CapPrice = capbyblk(RateSpec,  CapRate, Settle, Maturity, Volatility,...
'Reset',CapReset,'ValuationDate',ValuationDate,'Principal', Principal,...
'Basis', Basis)
```

```
CapPrice = 51.6125
```

Price a Cap Using a Different Curve to Generate the Future Forward Rates

Define the OIS and Libor rates.

```
Settle = datetime(2013,3,15);
CurveDates = daysadd(Settle,360*[1/12 2/12 3/12 6/12 1 2 3 4 5 7 10],1);
OISRates = [.0018 .0019 .0021 .0023 .0031 .006  .011 .017 .021 .026 .03]';
LiborRates = [.0045 .0047 .005 .0055 .0075 .0109  .0162 .0216 .0262 .0309 .0348]';
```

Create an associated `RateSpec` for the OIS and Libor curves.

```
OISCurve = intenvset('Rates',OISRates,'StartDate',Settle,'EndDates',CurveDates,'Compounding',2,'
LiborCurve = intenvset('Rates',LiborRates,'StartDate',Settle,'EndDates',CurveDates,'Compounding'
```

Define the Cap instruments.

```
Maturity = [ datetime(2018,3,15) ; datetime(2020,3,15)];
Strike = [0.04;0.05];
BlackVol = 0.2;
```

Price the cap instruments using the term structure `OISCurve` both for discounting the cash flows and generating future forward rates.

```
[Price, Caplets] = capbyblk(OISCurve, Strike, Settle, Maturity, BlackVol)
```

```
Price = 2×1

    0.7472
    0.9890

Caplets = 2×7

         0    0.0000    0.0033    0.2996    0.4443       NaN       NaN
         0    0.0000    0.0003    0.1134    0.2112    0.2292    0.4349
```

Price the cap instruments using the term structure `LiborCurve` to generate future forward rates. The term structure `OISCurve` is used for discounting the cash flows.

```
[PriceLC, CapletsLC] = capbyblk(OISCurve, Strike, Settle, Maturity, BlackVol,'ProjectionCurve',Li
```

```
PriceLC = 2×1

    1.3293
    1.6329

CapletsLC = 2×7

         0    0.0000    0.0337    0.4250    0.8706       NaN       NaN
         0    0.0000    0.0052    0.1767    0.4849    0.3663    0.5998
```

Compute the Price of Two Amortizing Caps Using the Black Model

Define the `RateSpec`.

```
Rates = [0.0358; 0.0421; 0.0473; 0.0527; 0.0543];
ValuationDate = datetime(2011,11,15);
StartDates = ValuationDate;
EndDates = [datetime(2012,11,15) ; datetime(2013,11,15) ; datetime(2014,11,15) ; datetime(2015,11
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
             'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: [5x1 double]
       StartDates: 734822
    ValuationDate: 734822
            Basis: 0
     EndMonthRule: 1
```

Define the cap instruments.

```
Settle = datetime(2011,11,15);
Maturity = datetime(2015,11,15);
Strike = [0.03;0.035];
Reset = 1;
Principal ={{datetime(2012,11,15) 100;datetime(2013,11,15) 70;datetime(2014,11,15) 40;datetime(20
```

Price the amortizing caps.

```
Volatility = 0.10;
Price = capbyblk (RateSpec, Strike, Settle, Maturity, Volatility,...
'Reset', Reset,'Principal', Principal)
```

```
Price = 2×1

    3.0339
    2.0141
```

Price a Cap Using the Shifted Black Model

Create the RateSpec.

```
ValuationDate = datetime(2016,3,1);
EndDates = [datetime(2017,3,1) ; datetime(2018,3,1) ; datetime(2019,3,1) ; datetime(2020,3,1) ; d
Rates = [-0.21; -0.12; 0.01; 0.10; 0.20]/100;
Compounding = 1;
Basis = 1;

RateSpec = intenvset('ValuationDate',ValuationDate,'StartDates',ValuationDate, ...
'EndDates',EndDates,'Rates',Rates,'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
          EndTimes: [5x1 double]
        StartTimes: [5x1 double]
          EndDates: [5x1 double]
        StartDates: 736390
    ValuationDate: 736390
            Basis: 1
     EndMonthRule: 1
```

Price the cap with a negative strike using the Shifted Black model.

```
Settle = datetime(2016,6,1); % Cap starts in 3 months.
Maturity = datetime(2016,9,1);
ShiftedBlackVolatility = 0.31;
CapRate = -0.003;  % -0.3 percent strike.
CapReset = 4;
Principal = 100000;
Shift = 0.01; % 1 percent shift.

CapPrice = capbyblk(RateSpec,CapRate,Settle,Maturity,ShiftedBlackVolatility,...
'Reset',CapReset,'ValuationDate',ValuationDate,'Principal',Principal,...
'Basis',Basis,'Shift',Shift)
```

```
CapPrice = 26.0733
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised
decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for cap
datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for cap
datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbyblk` also accepts serial date numbers as inputs, but they are not recommended.

`Volatility` — Volatilities values
numeric

Volatilities values, specified as a `NINST`-by-`1` vector of numeric values.

The `Volatility` input is not intended for volatility surfaces or cubes. If you specify a matrix for the `Volatility` input, `capbyblk` internally converts it into a vector. `capbyblk` assumes that the volatilities specified in the `Volatility` input are flat volatilities, which are applied equally to each of the caplets.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[CapPrice,Caplets] = capbyblk(RateSpec,Strike,Settle,Maturity,Volatility,'Reset',CapReset,'Principal',100000,'Basis',7)`

`Reset` — Reset frequency payment per year
`1` (default) | numeric

Reset frequency payment per year, specified as a NINST-by-1 vector.

Data Types: double

Principal — Notional principal amount
100 (default) | numeric

Notional principal amount, specified as a NINST-by-1 vector or a NINST-by-1 cell array. When Principal is a NINST-by-1 cell array, each element is a NumDates-by-2 cell array, where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use Principal to pass a schedule to compute the price for an amortizing cap.

Data Types: double | cell

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis used when annualizing the input forward rate, specified as a NINST-by-1 vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

ProjectionCurve — Rate curve used in generating future forward rates
if ProjectionCurve is not specified, then RateSpec is used both for discounting cash flows and projecting future forward rates (default) | structure

The rate curve to be used in generating the future forward rates. This structure must be created using intenvset. Use this optional input if the forward curve is different from the discount curve.

Data Types: struct

Shift — Shift in decimals for shifted Black model
0 (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified using a scalar or `NINST`-by-`1` vector of rate shifts in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate. For example, a `Shift` of `0.01` is equal to a 1% shift.

Data Types: `double`

Output Arguments

`CapPrice` — Expected price of cap

vector

Expected price of the cap, returned as a `NINST`-by-`1` vector.

`Caplets` — Caplets

array

Caplets, returned as a `NINST`-by-`NCF` array of caplets, padded with `NaN`s.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

For more information, see “Cap” on page 2-12.

Shifted Black

The Shifted Black model is essentially the same as the Black’s model, except that it models the movements of ($F + Shift$) as the underlying asset, instead of F (which is the forward rate in the case of caplets).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of Black’s model has been shifted.

Algorithms

Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-\gamma T}[FN(d_1) - KN(d_2)]$$

$$put = e^{-\gamma T}[KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B{}^2}{2}\right)T}{\sigma_B\sqrt{T}}, \quad d_2 = d_1 - \sigma_B\sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Where F is the forward value and K is the strike.

Shifted Black Model

$$dF = \sigma_{Shifted\_Black}(F + Shift)dw$$

$$call = e^{-\gamma T}[(F + Shift)N(d_{s1}) - (K + Shift)N(d_{s2})]$$

$$put = e^{-\gamma T}[(K + Shift)N(-d_{s2}) - (F + Shift)N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + Shift}{K + Shift}\right) + \left(\frac{\sigma_{sB}{}^2}{2}\right)T}{\sigma_{sB}\sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB}\sqrt{T}$$

$$\sigma_{sB} = \sigma_{Shifted\_Black}$$

Where $F+Shift$ is the forward value and $K+Shift$ is the strike for the shifted version.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `capbyblk` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

capbycir

Price cap instrument from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = capbycir(CIRTree,Strike,Settle,Maturity)
[Price,PriceTree] = capbycir(___,Name,Value)
```

Description

`[Price,PriceTree] = capbycir(CIRTree,Strike,Settle,Maturity)` computes the price of a cap instrument from a Cox-Ingersoll-Ross (CIR) interest-rate tree. `capbycir` computes prices of vanilla caps and amortizing caps using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = capbycir(___,Name,Value)` adds additional name-value pair arguments.

Examples

Price a Cap Using a CIR Interest-Rate Tree

Define the `Strike` for a cap.

```
Strike = 0.03;
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = [datetime(2017,1,1) ; datetime(2018,1,1) ; datetime(2019,1,1) ; datetime(2020,1,1) ; date
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',EndD
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
```

```
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the 3% cap.

```
[Price,PriceTree] = capbycir(CIRT,Strike,Settle,Maturity)
```

```
Price = 7.9081
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
       tObs: [0 1 2 3 4]
      PTree: {1x5 cell}
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
      Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised

decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for cap

datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every cap is set to the `ValuationDate` of the CIR tree. The cap argument `Settle` is ignored.

To support existing code, `capbycir` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for cap

datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbycir` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree] = capbycir(CIRTree,CouponRate,Settle,Maturity,'Basis',3)`

`CapReset` — Reset frequency payment per year

`1` (default) | numeric

Reset frequency payment per year, specified as the comma-separated pair consisting of `'CapReset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis representing the basis used when annualizing the input forward rate, specified as the comma-separated pair consisting of `'Basis'` and a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount

`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` of notional principal amounts or a `NINST`-by-`1` cell array.

For the NINST-by-1 cell array, each element is a NumDates-by-2 cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use Principal to pass a schedule to compute the price for an amortizing cap.

Data Types: double | cell

Output Arguments

Price — Expected price of cap at time 0

vector

Expected price of the cap at time 0, returned as a NINST-by-1 vector.

PriceTree — Tree structure with values of cap at each node

vector

Tree structure with values of the cap at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- PriceTree.PTree contains cap prices.
- PriceTree.tObs contains the observation times.
- PriceTree.Connect contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are NumNodes elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- PriceTree.Probs contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

For more information, see “Cap” on page 2-12.

Version History

Introduced in R2018a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `capbycir` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

capbyhjm

Price cap instrument from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = capbyhjm(HJMTree,Strike,Settle,Maturity)
[Price,PriceTree] = capbyhjm(___,CapReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = capbyhjm(HJMTree,Strike,Settle,Maturity)` computes the price of a cap instrument from a Heath-Jarrow-Morton interest-rate tree. `capbyhjm` computes prices of vanilla caps and amortizing caps.

`[Price,PriceTree] = capbyhjm(___,CapReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Cap Instrument Using an HJM Forward-Rate Tree

Load the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and forward-rate information needed to price the cap instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.03;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
```

Use `capbyhjm` to compute the price of the cap instrument.

```
Price = capbyhjm(HJMTree, Strike, Settle, Maturity)
```

```
Price = 6.2831
```

Compute the Price of an Amortizing Cap Using the HJM Model

Load `deriv.mat` to specify the `HJMTree` and then define the cap instrument.

```
load deriv.mat;
Settle = datetime(2000,1,1);
Maturity = datetime(2004,1,1);
Strike = 0.045;
CapReset = 1;
Principal ={{datetime(2001,1,1) 100;datetime(2002,1,1) 80;datetime(2003,1,1) 70;datetime(2004,1,1
```

Price the amortizing cap.

```
Basis = 1;
Price = capbyhjm(HJMTree, Strike, Settle, Maturity, CapReset, Basis, Principal)
```

```
Price = 1.4588
```

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised

decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for cap

datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every cap is set to the `ValuationDate` of the HJM tree. The cap argument `Settle` is ignored.

To support existing code, `capbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for cap

datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbyhjm` also accepts serial date numbers as inputs, but they are not recommended.

`CapReset` — Reset frequency payment per year

`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing cap.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of cap at time 0
vector

Expected price of the cap at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of cap at each node
vector

Tree structure with values of the cap at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PBush` contains the clean prices.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

For more information, see “Cap” on page 2-12.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `capbyhjm` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

capbyhw

Price cap instrument from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = capbyhw(HWTree,Strike,Settle,Maturity)
[Price,PriceTree] = capbyhw(___,CapReset,Basis,Principal,Options)
```

Description

`[Price,PriceTree] = capbyhw(HWTree,Strike,Settle,Maturity)` computes the price of a cap instrument from a Hull-White interest-rate tree. `capbyhw` computes prices of vanilla caps and amortizing caps.

Note Alternatively, you can use the `Cap` object to price cap instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[Price,PriceTree] = capbyhw(___,CapReset,Basis,Principal,Options)` adds optional arguments.

Examples

Price a 3% Cap Instrument Using a Hull-White Interest-Rate Tree

Load the file `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and interest-rate information needed to price the cap instrument.

```
load deriv.mat;
```

Set the required values. Other arguments will use defaults.

```
Strike = 0.03;
Settle = datetime(2004,1,1);
Maturity = datetime(2007,1,1);
```

Use `capbyhw` to compute the price of the cap instrument.

```
Price = capbyhw(HWTree, Strike, Settle, Maturity)
```

```
Price = 2.3090
```

Compute the Price of an Amortizing and Vanilla Caps Using the HW Model

Define the `RateSpec`.

```
Rates = [0.035; 0.042; 0.047; 0.052; 0.054];
ValuationDate = datetime(2014,4,1);
StartDates = ValuationDate;
EndDates = datetime(2019,4,1);
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate,'StartDates', StartDates,...
'EndDates', EndDates,'Rates', Rates, 'Compounding', Compounding)

RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 1
             Disc: [5x1 double]
            Rates: [5x1 double]
         EndTimes: [5x1 double]
       StartTimes: [5x1 double]
         EndDates: 737516
       StartDates: 735690
    ValuationDate: 735690
            Basis: 0
     EndMonthRule: 1
```

Define the cap instruments.

```
Settle = datetime(2014,4,1);
Maturity = datetime(2018,4,1);
Strike = 0.055;
CapReset = 1;
Principal ={{datetime(2015,4,1) 100;datetime(2016,4,1) 60;datetime(2017,4,1) 40;datetime(2018,4,1
            100};
```

Build the HW Tree.

```
VolDates = [datetime(2015,4,1) ; datetime(2016,4,1) ; datetime(2017,4,1) ; datetime(2018,4,1)];
VolCurve = 0.05;
AlphaDates = datetime(2018,4,1);
AlphaCurve = 0.10;

HWVolSpec = hwvolspec(RateSpec.ValuationDate, VolDates, VolCurve,...
                      AlphaDates, AlphaCurve);
HWTimeSpec = hwtimespec(RateSpec.ValuationDate, VolDates, Compounding);
HWTree = hwtree(HWVolSpec, RateSpec, HWTimeSpec)

HWTree = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [735690 736055 736421 736786]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 3 4 5 6]}
     FwdTree: {1x4 cell}
```

Price the amortizing and vanilla caps.

```
Basis = 0;
Price  = capbyhw(HWTree, Strike, Settle, Maturity, CapReset, Basis, Principal)
```

```
Price = 2×1

    1.6754
    4.6149
```

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`Strike` — Rate at which cap is exercised

decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

`Settle` — Settlement date for cap

datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. The `Settle` date for every cap is set to the `ValuationDate` of the HW tree. The cap argument `Settle` is ignored.

To support existing code, `capbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date for cap

datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbyhw` also accepts serial date numbers as inputs, but they are not recommended.

`CapReset` — Reset frequency payment per year

`1` (default) | numeric

(Optional) Reset frequency payment per year, specified as a `NINST`-by-`1` vector.

Data Types: `double`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis representing the basis used when annualizing the input forward rate, specified as a `NINST`-by-`1` vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

(Optional) Notional principal amount, specified as a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing cap.

Data Types: `double` | `cell`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected price of cap at time 0
vector

Expected price of the cap at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure with values of cap at each node
vector

Tree structure with values of the cap at each node, returned as a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node:

- `PriceTree.PTree` contains cap prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

capbylg2f

Price cap using Linear Gaussian two-factor model

Syntax

```
CapPrice = capbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,Maturity)
CapPrice = capbylg2f( ___ ,Name,Value)
```

Description

`CapPrice = capbylg2f(ZeroCurve,a,b,sigma,eta,rho,Strike,Maturity)` returns cap price for a two-factor additive Gaussian interest-rate model.

Note Alternatively, you can use the `Cap` object to price cap instruments. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`CapPrice = capbylg2f( ___ ,Name,Value)` adds optional name-value pair arguments.

Note Use the optional name-value pair argument, `Notional`, to pass a schedule to compute the price for an amortizing cap.

Examples

Price a Cap Using a Linear Gaussian Two-Factor Model

Define the `ZeroCurve`, `a`, `b`, `sigma`, `eta`, and `rho` parameters to price the cap.

```
Settle = datetime(2007,12,15);

ZeroTimes = [3/12 6/12 1 5 7 10 20 30]';
ZeroRates = [0.033 0.034 0.035 0.040 0.042 0.044 0.048 0.0475]';
CurveDates = daysadd(Settle,360*ZeroTimes);

irdc = IRDataCurve('Zero',Settle,CurveDates,ZeroRates);

a = .07;
b = .5;
sigma = .01;
eta = .006;
rho = -.7;

CapMaturity = daysadd(Settle,360*[1:5 7 10 15 20 25 30],1);

Strike = [0.035 0.037 0.038 0.039 0.040 0.042 0.044 0.046 0.047 0.047 0.047]';

Price = capbylg2f(irdc,a,b,sigma,eta,rho,Strike,CapMaturity)
```

```
Price = 11×1

    3.6963
    3.8628
      ⋮
```

Input Arguments

`ZeroCurve` — Zero-curve for Linear Gaussian two-factor model

structure

Zero-curve for the Linear Gaussian two-factor model, specified using `IRDataCurve` or `RateSpec`.

Data Types: `struct`

`a` — Mean reversion for first factor for Linear Gaussian two-factor model

scalar numeric

Mean reversion for first factor for the Linear Gaussian two-factor model, specified as a scalar numeric.

Data Types: `double`

`b` — Mean reversion for second factor for Linear Gaussian two-factor model

scalar numeric

Mean reversion for second factor for the Linear Gaussian two-factor model, specified as a scalar numeric.

Data Types: `double`

`sigma` — Volatility for first factor for Linear Gaussian two-factor model

scalar numeric

Volatility for first factor for the Linear Gaussian two-factor model, specified as a scalar numeric.

Data Types: `double`

`eta` — Volatility for second factor for Linear Gaussian two-factor model

scalar numeric

Volatility for second factor for the Linear Gaussian two-factor model, specified as a scalar numeric.

Data Types: `double`

`rho` — Scalar correlation of the factors

scalar numeric

Scalar correlation of the factors, specified as a scalar numeric.

Data Types: `double`

`Strike` — Cap strike price

nonnegative integer | vector of nonnegative integers

Cap strike price, specified as a nonnegative integer using a `NumCaps`-by-`1` vector.

Data Types: `double`

`Maturity` — Cap maturity date

datetime array | string array | date character vector

Cap maturity date, specified using a `NumCaps`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbylg2f` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = capbylg2f(irdc,a,b,sigma,eta,rho,Strike,CapMaturity,'Reset',1,'Notional',100)`

`Reset` — Frequency of cap payments per year
`2` (default) | positive integer from the set`[1,2,3,4,6,12]` | vector of positive integers from the set `[1,2,3,4,6,12]`

Frequency of cap payments per year, specified as the comma-separated pair consisting of `'Reset'` and a positive integers for the values `[1,2,4,6,12]` in a `NumCaps`-by-`1` vector.

Data Types: `single` | `double`

`Notional` — Notional value of cap
`100` (default) | nonnegative integer | vector of nonnegative integers

Notional value of cap, specified as the comma-separated pair consisting of `'Notional'` and a `NINST`-by-`1` of notional principal amounts or `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array where the first column is dates and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Data Types: `single` | `double`

Output Arguments

`CapPrice` — Cap price
scalar | vector

Expected prices of cap, returned as a scalar or an `NumCaps`-by-`1` vector.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

For more information, see “Cap” on page 2-12.

Algorithms

The following defines the two-factor additive Gaussian interest rate model, given the `ZeroCurve`, `a`, `b`, `sigma`, `eta`, and `rho` parameters:

$$r(t) = x(t) + y(t) + \phi(t)$$

$$dx(t) = -a(x)(t)dt + \sigma(dW_1(t), x(0) = 0$$

$$dy(t) = -b(y)(t)dt + \eta(dW_2(t), y(0) = 0$$

where $dW_1(t)dW_2(t) = \rho dt$ is a two-dimensional Brownian motion with correlation ρ and ϕ is a function chosen to match the initial zero curve.

Version History

Introduced in R2013a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `capbylg2f` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

capbynormal

Price caps using Normal or Bachelier pricing model

Syntax

```
[CapPrice,Caplets] = capbynormal(RateSpec,Strike,Settle,Maturity,Volatility)
[CapPrice,Caplets] = capbynormal( ___ ,Name,Value)
```

Description

`[CapPrice,Caplets] = capbynormal(RateSpec,Strike,Settle,Maturity,Volatility)` prices caps using the Normal (Bachelier) pricing model for negative rates. `capbynormal` computes prices of vanilla caps and amortizing caps.

Note Alternatively, you can use the `Cap` object to price cap instruments. For more information, see "Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments" on page 1-22.

`[CapPrice,Caplets] = capbynormal( ___ ,Name,Value)` adds optional name-value pair arguments.

Examples

Price a Cap Using Normal Model for Negative Rates

Consider an investor who gets into a contract that caps the interest rate on a $100,000 loan at –.08% quarterly compounded for 3 months, starting on January 1, 2009. Assuming that on January 1, 2008 the zero rate is .069394% continuously compounded and the volatility is 20%, use this data to compute the cap price. First, calculate the `RateSpec`, and then use `capbynormal` to compute the `CapPrice`.

```
ValuationDate = datetime(2008,1,1);
EndDates = datetime(2010,4,1);
Rates = 0.0069394;
Compounding = -1;
Basis = 1;

RateSpec = intenvset('ValuationDate', ValuationDate, ...
'StartDates', ValuationDate,'EndDates', EndDates, ...
'Rates', Rates,'Compounding', Compounding,'Basis', Basis);

Settle = datetime(2009,1,1); % cap starts in a year
Maturity = datetime(2009,4,1);
Volatility = 0.20;
CapRate = -0.008;
CapReset = 4;
Principal=100000;
```

```
CapPrice = capbynormal(RateSpec,  CapRate, Settle, Maturity, Volatility,...
'Reset',CapReset,'ValuationDate',ValuationDate,'Principal', Principal,...
'Basis', Basis)
```

```
CapPrice = 2.1682e+03
```

Price a Cap Using capbynormal and Compare to capbyblk

Define the RateSpec.

```
Settle = datetime(2016,1,20);
ZeroTimes = [.5 1 2 3 4 5 7 10 20 30]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = datemnth(Settle,12*ZeroTimes);
RateSpec = intenvset('StartDate',Settle,'EndDates',ZeroDates,'Rates',ZeroRates)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: 2
             Disc: [10x1 double]
            Rates: [10x1 double]
         EndTimes: [10x1 double]
       StartTimes: [10x1 double]
         EndDates: [10x1 double]
       StartDates: 736349
    ValuationDate: 736349
            Basis: 0
     EndMonthRule: 1
```

Define the cap instrument and price with capbyblk.

```
ExerciseDate = datetime(2026,1,20);

[~,ParSwapRate] = swapbyzero(RateSpec,[NaN 0],Settle,ExerciseDate)
```

```
ParSwapRate = 0.0216
```

```
Strike = .01;
BlackVol = .3;
NormalVol = BlackVol*ParSwapRate;

Price = capbyblk(RateSpec,Strike,Settle,ExerciseDate,BlackVol)
```

```
Price = 11.8693
```

Price the cap instrument using capbynormal.

```
Price_Normal = capbynormal(RateSpec,Strike,Settle,ExerciseDate,NormalVol)
```

```
Price_Normal = 12.5495
```

Price the cap instrument using capbynormal for a negative strike.

```
 Price_Normal = capbynormal(RateSpec,-.005,Settle,ExerciseDate,NormalVol)
```

```
Price_Normal = 24.4816
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

Strike — Rate at which cap is exercised

decimal

Rate at which cap is exercised, specified as a `NINST`-by-`1` vector of decimal values.

Data Types: `double`

Settle — Settlement date for cap

datetime array | string array | date character vector

Settlement date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbynormal` also accepts serial date numbers as inputs, but they are not recommended.

Data Types: `double` | `char` | `datetime` | `string`

Maturity — Maturity date for cap

datetime array | string array | date character vector

Maturity date for the cap, specified as a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capbynormal` also accepts serial date numbers as inputs, but they are not recommended.

Volatility — Normal volatilities values

numeric

Normal volatilities values, specified as a `NINST`-by-`1` vector of numeric values.

For more information on the Normal model, see “Work with Negative Interest Rates Using Functions” on page 2-18.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[CapPrice,Caplets] = capbynormal(RateSpec,Strike,Settle,Maturity,Volatility,'Reset',CapReset,'Principal',100000,'Basis',7)`

`Reset` — Reset frequency payment per year
`1` (default) | numeric

Reset frequency payment per year, specified as the comma-separated pair consisting of `'Reset'` and a `NINST`-by-`1` vector.

Data Types: `double`

`Principal` — Notional principal amount
`100` (default) | numeric

Notional principal amount, specified as the comma-separated pair consisting of `'Principal'` and a `NINST`-by-`1` of notional principal amounts, or a `NINST`-by-`1` cell array. Each element in the `NINST`-by-`1` cell array is a `NumDates`-by-`2` cell array, where the first column is dates, and the second column is the associated principal amount. The date indicates the last day that the principal value is valid.

Use `Principal` to pass a schedule to compute the price for an amortizing cap.

Data Types: `double` | `cell`

`Basis` — Day-count basis of instrument
`0` (actual/actual) (default) | integer from `0` to `13`

Day-count basis of instrument representing the basis used when annualizing the input forward rate, specified as the comma-separated pair consisting of `'Basis'`and a `NINST`-by-`1` vector of integers. Values are:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`ValuationDate` — Observation date of investment horizon
if `ValuationDate` is not specified, then `Settle` is used (default) | datetime scalar | string scalar | date character vector

Observation date of the investment horizon, specified as the comma-separated pair consisting of `'ValuationDate'` and a scalar datetime, string, or date character vector.

To support existing code, `capbynormal` also accepts serial date numbers as inputs, but they are not recommended.

`ProjectionCurve` — Rate curve used in generating future cash flows
if `ProjectionCurve` is not specified, then `RateSpec` is used both for discounting cash flows and projecting future cash flows (default) | structure

The rate curve to be used in projecting the future cash flows, specified as the comma-separated pair consisting of `'ProjectionCurve'` and rate curve structure. This structure must be created using `intenvset`. Use this optional input if the forward curve is different from the discount curve.

Data Types: `struct`

Output Arguments

`CapPrice` — Expected price of cap
vector

Expected price of the cap, returned as a `NINST`-by-`1` vector.

`Caplets` — Caplets
array

Caplets, returned as a `NINST`-by-`NCF` array of caplets, padded with `NaN`s.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

max(*CurrentRate* − *CapRate*, 0)

For more information, see “Cap” on page 2-12.

Version History

Introduced in R2017a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `capbynormal` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

capvolstrip

Strip caplet volatilities from flat cap volatilities

Syntax

```
[CapletVols,CapletPaymentDates,CapStrikes] = capvolstrip(ZeroCurve,CapSettle,
CapMaturity,CapVolatility)
[CapletVols,CapletPaymentDates,CapStrikes] = capvolstrip( ___ ,Name,Value)
```

Description

`[CapletVols,CapletPaymentDates,CapStrikes] = capvolstrip(ZeroCurve,CapSettle, CapMaturity,CapVolatility)` strips caplet volatilities from the flat cap volatilities by using the bootstrapping method. The function interpolates the cap volatilities on each caplet payment date before stripping the caplet volatilities.

`[CapletVols,CapletPaymentDates,CapStrikes] = capvolstrip( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Stripping Caplet Volatilities from At-The-Money (ATM) Caps

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2015,6,23);
ZeroRates = [0.01 0.09 0.30 0.70 1.07 1.71]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
             Type: Zero
           Settle: 736138 (23-Jun-2015)
      Compounding: 2
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [6x1 double]
             Data: [6x1 double]
```

Define the ATM cap volatility data.

```
CapSettle = datetime(2015,6,25);
CapMaturity = [datetime(2016,6,27) ; datetime(2017,6,26) ; datetime(2018,6,25) ; datetime(2019,6
CapVolatility = [0.29;0.38;0.42;0.40;0.38];
```

Strip caplet volatilities from ATM caps.

```
[CapletVols, CapletPaymentDates, ATMCapStrikes] = capvolstrip(ZeroCurve, ...
    CapSettle, CapMaturity, CapVolatility);
```

```
PaymentDates = cellstr(datestr(CapletPaymentDates));
format;
table(PaymentDates, CapletVols, ATMCapStrikes)
```

```
ans=9×3 table

```

Stripping Caplet Volatilities from Caps with the Same Strikes

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2015,2,17);
ZeroRates = [0.02 0.07 0.25 0.70 1.10 1.62]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
            Type: Zero
          Settle: 736012 (17-Feb-2015)
     Compounding: 2
           Basis: 0 (actual/actual)
    InterpMethod: linear
           Dates: [6x1 double]
            Data: [6x1 double]
```

Define the cap volatility data.

```
CapSettle = datetime(2015,2,19);
CapMaturity = [datetime(2016,2,19) ; datetime(2017,2,21) ; datetime(2018,2,20) ; datetime(2019,2
CapVolatility = [0.44;0.45;0.44;0.41;0.39];
CapStrike = 0.013;
```

Strip caplet volatilities from caps with the same strike.

```
[CapletVols, CapletPaymentDates, CapStrikes] = capvolstrip(ZeroCurve, ...
    CapSettle, CapMaturity, CapVolatility, 'Strike', CapStrike);

PaymentDates = cellstr(datestr(CapletPaymentDates));
format;
table(PaymentDates, CapletVols, CapStrikes)
```

```
ans=9×3 table

```

Stripping Caplet Volatilities Using Manually Specified Caplet Dates

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2015,3,6);
ZeroRates = [0.01 0.08 0.27 0.73 1.16 1.70]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
            Type: Zero
          Settle: 736029 (06-Mar-2015)
    Compounding: 2
           Basis: 0 (actual/actual)
    InterpMethod: linear
           Dates: [6x1 double]
            Data: [6x1 double]
```

Define the cap volatility data.

```
CapSettle = datetime(2015,3,6);
CapMaturity = [datetime(2016,3,7) ; datetime(2017,3,6) ; datetime(2018,3,6) ; datetime(2019,3,6)
CapVolatility = [0.43;0.44;0.44;0.43;0.41];
CapStrike = 0.011;
```

Specify quarterly and semiannual dates.

```
CapletDates = [cfdates(CapSettle, datetime(2016,3,6), 4) ...
     cfdates(datetime(2016,3,6), datetime(2020,3,6), 2)]';
CapletDates(~isbusday(CapletDates)) =  ...
    busdate(CapletDates(~isbusday(CapletDates)), 'modifiedfollow');
```

Strip caplet volatilities using specified `CapletDates`.

```
[CapletVols, CapletPaymentDates, CapStrikes] = capvolstrip(ZeroCurve, ...
    CapSettle, CapMaturity, CapVolatility, 'Strike', CapStrike, ...
    'CapletDates', CapletDates);

PaymentDates = cellstr(datestr(CapletPaymentDates));
format;
table(PaymentDates, CapletVols, CapStrikes)
```

```
ans=11×3 table
     PaymentDates      CapletVols    CapStrikes

```

Stripping Caplet Volatilities from Caps Using the Shifted Black Model

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2016,3,1);
ZeroRates = [-0.38 -0.25 -0.21 -0.12 0.01 0.2]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
            Type: Zero
          Settle: 736390 (01-Mar-2016)
     Compounding: 2
           Basis: 0 (actual/actual)
    InterpMethod: linear
           Dates: [6x1 double]
            Data: [6x1 double]
```

Define the cap volatility (Shifted Black) data.

```
CapSettle = datetime(2016,3,1);
CapMaturity = [datetime(2017,3,1); datetime(2018,3,1) ; datetime(2019,3,1) ; datetime(2020,3,2)
CapVolatility = [0.35;0.40;0.37;0.34;0.32]; % Shifted Black volatilities
Shift = 0.01; % 1 percent shift.
CapStrike = -0.001; % -0.1 percent strike.
```

Strip caplet volatilities from caps using the Shifted Black Model.

```
[CapletVols, CapletPaymentDates, CapStrikes] = capvolstrip(ZeroCurve, ...
CapSettle,CapMaturity,CapVolatility,'Strike',CapStrike,'Shift',Shift);

PaymentDates = string(datestr(CapletPaymentDates));
format;
table(PaymentDates,CapletVols,CapStrikes)
```

```
ans=9×3 table

    "01-Mar-2021"     0.25697        -0.001
```

Stripping Caplet Volatilities from Caps Using Normal Model

Compute the zero curve for discounting and projecting forward rates.

```
ValuationDate = datetime(2018,6,1);
ZeroRates = [-0.38 -0.25 -0.21 -0.12 0.01 0.2]/100;
CurveDates = datemnth(ValuationDate, [0.25 0.5 1 2 3 5]*12);
ZeroCurve = IRDataCurve('Zero',ValuationDate,CurveDates,ZeroRates)
```

```
ZeroCurve =
             Type: Zero
           Settle: 737212 (01-Jun-2018)
      Compounding: 2
            Basis: 0 (actual/actual)
     InterpMethod: linear
            Dates: [6x1 double]
             Data: [6x1 double]
```

Define the normal cap volatility data.

```
CapSettle = datetime(2018,6,1);
CapMaturity = [datetime(2019,6,3) ; datetime(2020,6,1) ; datetime(2021,6,1) ; datetime(2022,6,1)
CapVolatility = [0.0057;0.0059;0.0057;0.0053;0.0051]; % Normal volatilities
CapStrike = -0.002; % -0.2 percent strike.
```

Strip caplet volatilities from caps using the Normal (Bachelier) model.

```
[CapletVols, CapletPaymentDates, CapStrikes] = capvolstrip(ZeroCurve, ...
    CapSettle,CapMaturity,CapVolatility,'Strike',CapStrike,'Model','normal');

PaymentDates = string(datestr(CapletPaymentDates));
format;
table(PaymentDates,CapletVols,CapStrikes)
```

```

Input Arguments

`ZeroCurve` — Zero rate curve

`RateSpec` object | `IRDataCurve` object

Zero rate curve, specified using a `RateSpec` or `IRDataCurve` object containing the zero rate curve for discounting according to its day count convention. If you do not specify the optional argument `ProjectionCurve`, the function uses `ZeroCurve` to compute the underlying forward rates as well. The observation date of the `ZeroCurve` specifies the valuation date. For more information on creating a `RateSpec`, see `intenvset`. For more information on creating an `IRDataCurve` object, see `IRDataCurve`.

Data Types: `struct`

`CapSettle` — Common cap settle date

datetime scalar | string scalar | date character vector

Common cap settle date, specified as a scalar datetime, string, or date character vector. The `CapSettle` date cannot be earlier than the `ZeroCurve` valuation date.

To support existing code, `capvolstrip` also accepts serial date numbers as inputs, but they are not recommended.

`CapMaturity` — Cap maturity dates

datetime array | string array | date character vector

Cap maturity dates, specified using a `NCap`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `capvolstrip` also accepts serial date numbers as inputs, but they are not recommended.

`CapVolatility` — Flat cap volatilities

vector of positive decimals

Flat cap volatilities, specified as an `NCap`-by-`1` vector of positive decimals.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[CapletVols,CapletPaymentDates,CapStrikes] = capvolstrip(ZeroCurve,CapSettle,CapMaturity,CapVolatility,'Strike',.2)`

Strike — Cap strike rate
If not specified, all caps are at-the-money and the function computes the ATM strike for each cap maturing on each caplet payment date (default) | scalar decimal | vector

Cap strike rate, specified as the comma-separated pair consisting of `'Strike'` and a scalar decimal value or an `NCapletVols`-by-1 vector. Use `Strike` as a scalar to specify a single strike that applies equally to all caps. Or, specify an `NCapletVols`-by-1 vector of strikes for the caps.

Data Types: `double`

CapletDates — Caplet reset and payment dates
if not specified, the default is to automatically generate periodic caplet dates (default) | datetime array | string array | date character vector

Caplet reset and payment dates, specified as the comma-separated pair consisting of `'CapletDates'` and an `NCapletDates`-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `capvolstrip` also accepts serial date numbers as inputs, but they are not recommended.

Use `CapletDates` to manually specify all caplet reset and payment dates. For example, some date intervals may be quarterly, while others may be semiannual. All dates must be later than `CapSettle` and cannot be later than the last `CapMaturity` date. Dates are adjusted according to the `BusDayConvention` and `Holidays` inputs.

If `CapletDates` is not specified, the default is to automatically generate periodic caplet dates after `CapSettle` based on the last `CapMaturity` date as the reference date, using the following optional inputs: `Reset`, `EndMonthRule`, `BusDayConvention`, and `Holidays`.

Reset — Frequency of periodic payments per year within a cap
2 (default) | positive scalar integer with values 1,2, 3, 4, 6, or 12

Frequency of periodic payments per year within a cap, specified as the comma-separated pair consisting of `'Reset'` and a positive scalar integer with values 1,2, 3, 4, 6, or 12.

Note If you specify `CapletDates`, the function ignores the input for `Reset`.

Data Types: `double`

EndMonthRule — End-of-month rule flag for generating caplet dates
1 (in effect) (default) | scalar nonnegative integer `[0,1]`

End-of-month rule flag for generating caplet dates, specified as the comma-separated pair consisting of `'EndMonthRule'` and a scalar nonnegative integer [0, 1].

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

BusinessDayConvention — Business day conventions
`'modifiedfollow'` (default) | character vector with values `'actual'`, `'follow'`, `'modifiedfollow'`, `'previous'`, `'modifiedprevious'`

Business day conventions, specified as the comma-separated pair consisting of `'BusinessDayConvention'` and a character vector. Use this argument to specify how the function treats non-business days, which are days on which businesses are not open (such as weekends and statutory holidays).

- `'actual'` — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- `'follow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- `'modifiedfollow'` — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However, if the following business day is in a different month, the previous business day is adopted instead.
- `'previous'` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- `'modifiedprevious'` — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However, if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char`

`Holidays` — Holidays used in computing business days
if not specified, the default is to use `holidays.m` (default) | vector of MATLAB dates

Holidays used in computing business days, specified as the comma-separated pair consisting of `'Holidays'` and `NHolidays`-by-`1` vector of MATLAB dates.

Data Types: `datetime`

`ProjectionCurve` — Rate curve for computing underlying forward rates
if not specified, the default is to use the `ZeroCurve` input for computing the underlying forward rates (default) | `RateSpec` object | `IRDatCurve` object

Rate curve for computing underlying forward rates, specified as the comma-separated pair consisting of `'ProjectionCurve'` and a `RateSpec` object or `IRDatCurve` object. For more information on creating a `RateSpec`, see `intenvset`. For more information on creating an `IRDataCurve` object, see `IRDataCurve`.

Data Types: `struct`

`MaturityInterpMethod` — Method for interpolating the cap volatilities on each caplet maturity date before stripping the caplet volatilities
`'linear'` (default) | character vector with values: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'spline'`, `'pchip'`

Method for interpolating the cap volatilities on each caplet maturity date before stripping the caplet volatilities, specified as the comma-separated pair consisting of `'MaturityInterpMethod'` and a character vector with values: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'spline'`, or `'pchip'`.

- `'linear'` — Linear interpolation. The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.
- `'nearest'` — Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample grid point.

- `'next'` — Next neighbor interpolation. The interpolated value at a query point is the value at the next sample grid point.
- `'previous'` — Previous neighbor interpolation. The interpolated value at a query point is the value at the previous sample grid point.
- `'spline'` — Spline interpolation using not-a-knot end conditions. The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension.
- `'pchip'` — Shape-preserving piecewise cubic interpolation. The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.

For more information on interpolation methods, see `interp1`.

Note The function uses constant extrapolation to calculate volatilities falling outside the range of user-supplied data.

Data Types: `char`

`Limit` — Upper bound of implied volatility search interval
`10` (or 1000% per annum) (default) | positive scalar decimal

Upper bound of implied volatility search interval, specified as the comma-separated pair consisting of `'Limit'` and a positive scalar decimal.

Data Types: `double`

`Tolerance` — Implied volatility search termination tolerance
`1e-5` (default) | positive numeric scalar

Implied volatility search termination tolerance, specified as the comma-separated pair consisting of `'Tolerance'` and a positive numeric scalar.

Data Types: `double`

`OmitFirstCaplet` — Flag to omit the first caplet payment in the caps
`true` (always omit the first caplet) (default) | logical

Flag to omit the first caplet payment in the caps, specified as the comma-separated pair consisting of `'OmitFirstCaplet'` and a scalar logical.

If the caps are spot-starting, the first caplet payment is omitted. If the caps are forward-starting, the first caplet payment is included. Regardless of the status of the caps, if you set this logical to `false`, then the function includes the first caplet payment.

In general, “spot lag” is the delay between the fixing date and the effective date for LIBOR-like indices. "Spot lag" determines whether a cap is spot-starting or forward-starting (Corb, 2012). Caps are considered to be spot-starting if they settle within “spot lag” business days after the valuation date. Those that settle later are considered to be forward-starting. The first caplet is omitted if caps are spot-starting, while it is included if they are forward-starting (Tuckman, 2012).

Data Types: `logical`

`Shift` — Shift in decimals for shifted SABR model

`0` (no shift) (default) | positive scalar decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), specified as the comma-separated pair consisting of `'Shift'` and a positive scalar decimal value. Set this parameter to a positive shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate and strike. For example, a `Shift` value of 0.01 is equal to a 1% shift.

Data Types: `double`

`Model` — Model used for implied volatility

`'lognormal'` (default) | character vector with value of `'lognormal'` or `'normal'` | string scalar with value of `"lognormal"` or `"normal"`

Model used for the implied volatility calculation, specified as the comma-separated pair consisting of `'Model'` and a scalar character vector or string scalar with one of the following values:

- `'lognormal'` - Implied Black (no shift) or Shifted Black volatility.
- `'normal'` - Implied Normal (Bachelier) volatility. If you specify `'normal'`, `Shift` must be zero.

The `capvolstrip` function supports three volatility types.

'Model' Value	'Shift' Value	Volatility Type
`'lognormal'`	`Shift = 0`	Black
`'lognormal'`	`Shift > 0`	Shifted Black
`'normal'`	`Shift = 0`	Normal (Bachelier)

Data Types: `char` | `string`

Output Arguments

`CapletVols` — Stripped caplet volatilities

vector of decimals

Stripped caplet volatilities, returned as an `NCapletVols`-by-`1` vector of decimals.

Note `capvolstrip` can output `NaN`s for some caplet volatilities. You might encounter this output if no volatility matches the caplet price implied by the user-supplied cap data.

`CapletPaymentDates` — Payment dates

vector of date numbers

Payment dates (in date numbers), returned as an `NCapletVols`-by-`1` vector of date numbers corresponding to `CapletVols`.

`CapStrikes` — Cap strikes

vector of decimals

Cap strikes, returned as an `NCapletVols`-by-`1` vector of strikes in decimals for caps maturing on the corresponding `CapletPaymentDates`. `CapStrikes` are the same as the strikes of the corresponding caplets that have been stripped.

Limitations

When bootstrapping the caplet volatilities from ATM caps, the function reuses the caplet volatilities stripped from the shorter maturity caps in the longer maturity caps without adjusting for the difference in strike. `capvolstrip` follows the simplified approach described in Gatarek, 2006.

More About

Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate to be paid by the holder, based on an otherwise floating interest rate.

The payoff for a cap is:

$\max(CurrentRate - CapRate, 0)$

For more information, see “Cap” on page 2-12.

At-The-Money

A cap or floor is at-the-money (ATM) if its strike is equal to the forward swap rate.

The forward swap rate is the fixed rate of a swap that makes the present value of the floating leg equal to that of the fixed leg. In comparison, a caplet or floorlet is ATM if its strike is equal to the forward rate (not the forward swap rate). In general (except over a single period), the forward rate is not equal to the forward swap rate. So, to be precise, the individual caplets in an ATM cap have slightly different moneyness and are only approximately ATM (Alexander, 2003).

In addition, the swap rate changes with swap maturity. Similarly, the ATM cap strike also changes with cap maturity, so the ATM cap strikes are computed for each cap maturity before stripping the caplet volatilities. As a result, when stripping the caplet volatilities from the ATM caps with increasing maturities, the ATM strikes of consecutive caps are different.

Version History

Introduced in R2016a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `capvolstrip` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

How to Price Interest Rate Options with Negative Interest Rates (3 min 05 sec)

cashbybls

Determine price of cash-or-nothing digital options using Black-Scholes model

Syntax

```
Price = cashbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,Payoff)
```

Description

`Price = cashbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,Payoff)` computes the price for cash-or-nothing European digital options using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Binary` object to price digital options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

Examples

Compute Cash-or-Nothing Option Prices Using the Black-Scholes Option Pricing Model

Consider a European call and put cash-or-nothing options on a futures contract with and exercise strike price of $90, a fixed payoff of $10 that expires on October 1, 2008. Assume that on January 1, 2008, the contract trades at $110, and has a volatility of 25% per annum and the risk-free rate is 4.5% per annum. Using this data, calculate the price of the call and put cash-or-nothing options on the futures contract. First, create the `RateSpec`:

```
Settle = datetime(2008,1,1);
Maturity = datetime(2008,10,1);
Rates = 0.045;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9668
            Rates: 0.0450
         EndTimes: 0.7500
       StartTimes: 0
         EndDates: 733682
       StartDates: 733408
    ValuationDate: 733408
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 110;
Sigma = .25;
DivType = 'Continuous';
DivAmount = Rates;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmount)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2500
         AssetPrice: 110
       DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

Define the call and put options.

```
OptSpec = {'call'; 'put'};
Strike = 90;
Payoff = 10;
```

Calculate the prices.

```
Pcon = cashbybls(RateSpec, StockSpec, Settle,...
Maturity, OptSpec, Strike, Payoff)
```

```
Pcon = 2×1

    7.6716
    1.9965
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cashbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cashbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` vector.

Data Types: `char` | `cell`

`Strike` — Strike price value
vector

Strike price value, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Payoff` — Payoff values
vector

Payoff values (or the amount to be paid at expiration), specified as an `NINST`-by-`1` vector.

Data Types: `double`

Output Arguments

`Price` — Expected prices for cash-or-nothing option
vector

Expected prices for cash-or-nothing option, returned as a `NINST`-by-`1` vector.

Version History

Introduced in R2009a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `cashbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

cashsensbybls

Determine price or sensitivities of cash-or-nothing digital options using Black-Scholes model

Syntax

```
PriceSens = cashsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,
Payoff)
PriceSens = cashsensbybls( ___ ,Name,Value)
```

Description

`PriceSens = cashsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike, Payoff)` computes the price or sensitivities for cash-or-nothing European digital options using the Black-Scholes option pricing model.

Note Alternatively, you can use the `Binary` object to calculate price or sensitivities for digital options. For more information, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

`PriceSens = cashsensbybls( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

Examples

Compute Cash-or-Nothing Option Prices and Sensitivities Using the Black-Scholes Option Pricing Model

Consider a European call and put cash-or-nothing options on a futures contract with an exercise price of $90, and a fixed payoff of $10 that expires on October 1, 2008. Assume that on January 1, 2008 the contract trades at $110, and has a volatility of 25% per annum and the risk-free rate is 4.5% per annum. Using this data, calculate the price and sensitivity of the call and put cash-or-nothing options on the futures contract. First, create the `RateSpec`:

```
Settle = datetime(2008,1,1);
Maturity = datetime(2008,10,1);
Rates = 0.045;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle,...
'EndDates', Maturity, 'Rates', Rates, 'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9668
            Rates: 0.0450
         EndTimes: 0.7500
       StartTimes: 0
```

```
         EndDates: 733682
       StartDates: 733408
    ValuationDate: 733408
            Basis: 1
     EndMonthRule: 1
```

Define the `StockSpec`.

```
AssetPrice = 110;
Sigma = .25;
DivType = 'Continuous';
DivAmount = Rates;
StockSpec = stockspec(Sigma, AssetPrice, DivType, DivAmount)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2500
         AssetPrice: 110
       DividendType: {'continuous'}
    DividendAmounts: 0.0450
    ExDividendDates: []
```

Define the call and put options.

```
OptSpec = {'call'; 'put'};
Strike = 90;
Payoff = 10;
```

Compute the gamma, theta, and price.

```
OutSpec = { 'gamma';'theta';'price'};
[Gamma, Theta, Price] = cashsensbybls(RateSpec, StockSpec,...
Settle, Maturity, OptSpec, Strike, Payoff, 'OutSpec', OutSpec)
```

```
Gamma = 2×1

   -0.0050
    0.0050

Theta = 2×1

   -2.2489
    1.8139

Price = 2×1

    7.6716
    1.9965
```

Input Arguments

RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

`Settle` — Settlement or trade date
datetime array | string array | date character vector

Settlement or trade date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cashsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date for the basket option, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cashsensbybls` also accepts serial date numbers as inputs, but they are not recommended.

`OptSpec` — Definition of option
character vector with values `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of the option as `'call'` or `'put'`, specified as an `NINST`-by-`1` vector.

Data Types: `char` | `cell`

`Strike` — Strike price value
vector

Strike price value, specified as an `NINST`-by-`1` vector.

Data Types: `double`

`Payoff` — Payoff values
vector

Payoff values (or the amount to be paid at expiration), specified as an `NINST`-by-`1` vector.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Gamma,Theta,Price] = cashsensbybls(RateSpec,StockSpec,Settle,Maturity,OptSpec,Strike,Payoff,'OutSpec',{'gamma';'theta';'price'})`

`OutSpec` — Define outputs

`{'Price'}` (default) | character vector with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'` | cell array of character vectors with values `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`

Define outputs, specified as the comma-separated pair consisting of `'OutSpec'` and a `NOUT`- by-`1` or a `1`-by-`NOUT` cell array of character vectors with possible values of `'Price'`, `'Delta'`, `'Gamma'`, `'Vega'`, `'Lambda'`, `'Rho'`, `'Theta'`, and `'All'`.

`OutSpec = {'All'}` specifies that the output is `Delta`, `Gamma`, `Vega`, `Lambda`, `Rho`, `Theta`, and `Price`, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta','gamma','vega','lambda','rho','theta','price'}`

Data Types: `char` | `cell`

Output Arguments

`PriceSens` — Expected prices or sensitivities for cash-or-nothing option

vector

Expected prices or sensitivities (defined using `OutSpec`) for cash-or-nothing option, returned as a `NINST`-by-`1` vector.

Version History

Introduced in R2009a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `cashsensbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cbondbycrr

Price convertible bonds from CRR binomial tree

Syntax

```
Price = cbondbycrr(CRRTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree] = cbondbycrr(CRRTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree,EquityTree,DebtTree] = cbondbycrr( ___ ,Name,Value)
```

Description

`Price = cbondbycrr(CRRTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds from a CRR binomial tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree] = cbondbycrr(CRRTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds from a CRR binomial tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree,EquityTree,DebtTree] = cbondbycrr( ___ ,Name,Value)` prices convertible bonds from a CRR binomial tree using a credit spread or incorporating the risk of bond default.

To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair input argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair input arguments `DefaultProbability` and `RecoveryRate`.

Examples

Price Convertible Bond Using a CRR Tree

Price a convertible bond using the following data for the interest-rate term structure:

```
StartDates = datetime(2014,1,1);
EndDates = datetime(2015,1,1);
Rates = 0.1;
Basis = 1;
```

Create the `RateSpec` and `StockSpec`.

```
Sigma = 0.3;
Price = 50;

RateSpec = intenvset('ValuationDate',StartDates,'StartDates',StartDates,'EndDates',EndDates,...
'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9048
            Rates: 0.1000
         EndTimes: 1
```

```
       StartTimes: 0
         EndDates: 735965
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

```
StockSpec = stockspec(Sigma,Price)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'

```

Price a Convertible Bond Using a CRR Tree and Incorporate Default Risk Using `DefaultProbability` and `RecoveryRate`

Create the interest-rate term structure `RateSpec`.

```
StartDates = 'Jan-1-2014';
EndDates = 'Jan-1-2016';
Rates = 0.025;
Basis = 1;
RateSpec = intenvset('ValuationDate',StartDates,'StartDates',...
StartDates,'EndDates',EndDates,'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0250
         EndTimes: 2
       StartTimes: 0
         EndDates: 736330
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

Create the `StockSpec`.

```
AssetPrice = 110;
Sigma = 0.22;
Div = 0.02;
StockSpec = stockspec(Sigma,AssetPrice,'continuous',Div)
```

```
StockSpec = struct with fields:
              FinObj: 'StockSpec'
               Sigma: 0.2200
          AssetPrice: 110
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
```

```
    ExDividendDates: []
```

Create the CRR tree for the equity.

```
Settle = '1-Jan-2014';
Maturity = '1-Oct-2014';
NumSteps = 3;
TimeSpec = crrtimespec(Settle,Maturity,NumSteps);
CRRT = crrtree(StockSpec,RateSpec,TimeSpec)
```

```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every convertible bond is set to the `ValuationDate` of the CRR stock tree. The bond argument, `Settle`, is ignored.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`ConvRatio` — Number of shares convertible to one bond

nonnegative number

Number of shares convertible to one bond, specified as an `NINST`-by-`1` with a nonnegative number.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,EquityTree,DebtTree] = cbondbycrr(CRRT,CouponRate,Settle, Maturity, ConvRatio,'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall',1)`

Spread — Number of basis points over the reference rate

`0` (default) | vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of `'Spread'` and a `NINST`-by-`1` vector.

Note To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. Do not use `Spread` with `DefaultProbability` and `RecoveryRate`.

Data Types: `double`

Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date

datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`CallStrike` — Call strike price for European, Bermuda, or American option
nonnegative integer | vector of nonnegative integers

Call strike price for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallStrike'` and one of the following values:

- For a European call option — `NINST`-by-`1` vector of nonnegative integers
- For a Bermuda call option — `NINST`-by-`NSTRIKES` matrix of call strike price values, where each row is the schedule for one call option. If a call option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American call option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `single` | `double`

`CallExDates` — Call exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Call exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallExDates'` and a datetime array, string array, or date character vectors for the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates, where each row is the schedule for one option. For a European option, there is only one `CallExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the call option can be exercised on any tree date between or including the pair of dates on that row. If `CallExDates` is `NINST`-by-`1`, the option can be exercised between the `ValuationDate` of the CRR stock tree and the single listed `CallExDate`.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanCall` — Call option type indicator
`0` if `AmericanCall` is `NaN` or not entered (default) | scalar | vector of positive integers`[0,1]`

Call option type, specified as the comma-separated pair consisting of `'AmericanCall'` and a `NINST`-by-`1` vector of positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanCall` is `0` for each European or Bermuda option.
- For an American option — `AmericanCall` is `1` for each American option. The `AmericanCall` argument is required to invoke American exercise rules.

Data Types: `single` | `double`

`PutStrike` — Put strike values for European, Bermuda, or American option
positive integer | vector of positive integers

Put strike values for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'PutStrike'` and one of the following values:

- For a European put option — `NINST`-by-`1` vector of nonnegative integers
- For a Bermuda put option — `NINST`-by-`NSTRIKES` matrix of strike price values where each row is the schedule for one option. If a put option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American put option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `single` | `double`

`PutExDates` — Put exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Put exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'PutExDates'` and a datetime array, string array, or date character vectors for the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates where each row is the schedule for one option. For a European option, there is only one `PutExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the put option can be exercised on any tree date between or including the pair of dates on that row. If `PutExDates` is `NINST`-by-`1`, the put option can be exercised between the `ValuationDate` of the CRR stock tree and the single listed `PutExDate`.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanPut` — Put option type indicator
`0` if `AmericanPut` is `NaN` or not entered (default) | positive integer `[0,1]` | vector of positive integers `[0,1]`

Put option type, specified as the comma-separated pair consisting of `'AmericanPut'` and a `NINST`-by-`1` vector of positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanPut` is `0` for each European or Bermuda option.
- For an American option — `AmericanPut` is `1` for each American option. The `AmericanPut` argument is required to invoke American exercise rules.

Data Types: `double`

`ConvDates` — Convertible dates
`MaturityDate` (default) | datetime array | string array | date character vector

Convertible dates, specified as the comma-separated pair consisting of `'ConvDates'` and a `NINST`-by-`1` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors. If `ConvDates` is not specified, the bond is always convertible until maturity.

To support existing code, `cbondbycrr` also accepts serial date numbers as inputs, but they are not recommended.

For each instrument, the bond can be converted on any tree date between or including the pair of dates on that row.

If `ConvDates` is `NINST`-by-`1`, the bond can be converted between the `ValuationDate` of the CRR stock tree and the single listed `ConvDates`.

`DefaultProbability` — Annual probability of default rate
`0` (default) | nonnegative decimal

Annual probability of default rate, specified as the comma-separated pair consisting of `'DefaultProbability'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

`RecoveryRate` — Recovery rate
`1` (default) | nonnegative decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `NINST`-by-`1` nonnegative decimal.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

Output Arguments

`Price` — Expected price at time `0`
array

Expected price at time `0`, returned as an `NINST`-by-`1` array.

`PriceTree` — Structure with vector of convertible bond prices at each node
tree structure

Structure with a vector of convertible bond prices at each node, returned as a tree structure.

`EquityTree` — Structure with vector of convertible bond equity component at each node
tree structure

Structure with a vector of convertible bond equity component at each node, returned as a tree structure.

`DebtTree` — Structure with vector of convertible bond debt component at each node
tree structure

Structure with a vector of convertible bond debt component at each node, returned as a tree structure.

More About

Callable Convertible

A convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder.

Upon call, the bondholder can either convert the bond or redeem at the call price. This option enables the issuer to control the price of the convertible bond and, if necessary, refinance the debt with a new cheaper one.

Puttable Convertible

A convertible bond with a put feature allows the bondholder to sell back the bond at a premium on a specific date.

This option protects the holder against rising interest rates by reducing the year to maturity.

Algorithms

`cbondbycrr`, `cbondbyeqp`, `cbondbyitt`, and `cbondbysttr`eturn price information in the form of a price vector and a price tree. These functions implement the risk in the form of either a credit spread or incorporating the risk of bond default. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair arguments `DefaultProbability` and `RecoveryRate`.

Version History

Introduced in R2015a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `cbondbycrr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Convertible Bond” on page 2-4

cbondbyeqp

Price convertible bonds from EQP binomial tree

Syntax

```
Price = cbondbyeqp(EQPTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree] = cbondbyeqp(EQPTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree,EquityTree,DebtTree] = cbondbyeqp( ___ ,Name,Value)
```

Description

`Price = cbondbyeqp(EQPTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds from an EQP binomial tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree] = cbondbyeqp(EQPTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds from an EQP binomial tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree,EquityTree,DebtTree] = cbondbyeqp( ___ ,Name,Value)` prices convertible bonds from an EQP binomial tree using a credit spread or incorporating the risk of bond default.

To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair input argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair input arguments `DefaultProbability` and `RecoveryRate`.

Examples

Price Convertible Bond Using an EQP Tree

Create the interest-rate term structure `RateSpec`.

```
StartDates = datetime(2014,1,1);
EndDates = 'Jan-1-2016';
Rates = 0.025;
Basis = 1;
RateSpec = intenvset('ValuationDate',StartDates,'StartDates',StartDates,'EndDates',EndDates,...
'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0250
         EndTimes: 2
       StartTimes: 0
         EndDates: 736330
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

Create the `StockSpec`.

```
AssetPrice = 110;
Sigma = 0.22;
Div = 0.02;
StockSpec = stockspec(Sigma,AssetPrice,'continuous',Div)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.2200
         AssetPrice: 110
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Create the EQP tree for the equity.

```
NumSteps = 6;
TimeSpec = eqptimespec(StartDates,EndDates,NumSteps);
EQPTree = eqptree(StockSpec,RateSpec,TimeSpec)
```

```
EQPTree = struct with fields:
       FinObj: 'BinStockTree'
       Method: 'EQP'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.3333 0.6667 1 1.3333 1.6667 2]

      UpProbs: [0.5000 0.5000 0.5000 0.5000 0.5000 0.5000]
```

Define the convertible bond. The convertible bond can be called starting on Jan 1, 2015 with a strike price of 125.

```
Settle = datetime(2014,1,1);
Maturity = datetime(2016,1,1);
CouponRate = 0.03;
CallStrike = 125;
Period = 1;
CallExDates = [datetime(2015,1,1) ; datetime(2016,1,1)];
ConvRatio = 1.5;
```

Price the convertible bond.

```
Spread = 0.045;

[Price,PriceTree,EqtTre,DbtTree] = cbondbyeqp(EQPTree,CouponRate,Settle,...
Maturity,ConvRatio,'Period',Period,'Spread',Spread,'CallExDates',...
CallExDates,'CallStrike',CallStrike,'AmericanCall',1)
```

```
Price = 2×1

   165
   165
```

```
PriceTree = struct with fields:
    FinObj: 'BinPriceTree'
     PTree: {1x7 cell}
      tObs: [0 0.3333 0.6667 1 1.3333 1.6667 2]
      dObs: [735600 735721 735843 735965 736086 736208 736330]

EqtTre = struct with fields:
    FinObj: 'BinPriceTree'

DbtTree = struct with fields:
    FinObj: 'BinPriceTree'
     PTree: {1x7 cell}
      tObs: [0 0.3333 0.6667 1 1.3333 1.6667 2]
      dObs: [735600 735721 735843 735965 736086 736208 736330]
```

Price a Convertible Bond Using an EQP Tree and Incorporate Default Risk Using `DefaultProbability` and `RecoveryRate`

Create the interest-rate term structure `RateSpec`.

```
StartDates = datetime(2014,1,1);
EndDates = datetime(2016,1,1);
Rates = 0.025;
Basis = 1;
RateSpec = intenvset('ValuationDate',StartDates,'StartDates',...
StartDates,'EndDates',EndDates,'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.9512
            Rates: 0.0250
         EndTimes: 2
       StartTimes: 0
         EndDates: 736330
       StartDates: 735600
    ValuationDate: 735600
            Basis: 1
     EndMonthRule: 1
```

Create the `StockSpec`.

```
AssetPrice = 110;
Sigma = 0.22;
Div = 0.02;
StockSpec = stockspec(Sigma,AssetPrice,'continuous',Div)
```

```
StockSpec = struct with fields:
            FinObj: 'StockSpec'
```

```
             Sigma: 0.2200
         AssetPrice: 110
       DividendType: {'continuous'}
    DividendAmounts: 0.0200
    ExDividendDates: []
```

Create the EQP tree for the equity.

```
NumSteps = 6;
TimeSpec = eqptimespec(StartDates,EndDates,NumSteps);
EQPTree = eqptree(StockSpec,RateSpec,TimeSpec)
```

```
EQPTree = struct with fields:
       FinObj: 'BinStockTree'
       Method: 'EQP'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.3333 0.6667 1 1.3333 1.6667 2]
         dObs: [735600 735721 735843 735965 736086 736208 736330]

      UpProbs: [0.5000 0.5000 0.5000 0.5000 0.5000 0.5000]
```

Define and price the convertible bond using the optional `DefaultProbability` and `RecoveryRate` arguments.

```
Settle = datetime(2014,1,1);
Maturity = datetime(2016,1,1);
CouponRate = 0.03;
CallStrike = 125;
Period = 1;
CallExDates = [datetime(2015,1,1) ; datetime(2016,1,1)];
ConvRatio = 1.5;
DefaultProbability = .30;
RecoveryRate = .82;

[Price,PriceTree,EqtTre,DbtTree] = cbondbyeqp(EQPTree,CouponRate,Settle,...
Maturity,ConvRatio,'Period',Period,'CallExDates',...
CallExDates,'CallStrike',CallStrike,'AmericanCall',1,...
'DefaultProbability',DefaultProbability,'RecoveryRate',RecoveryRate)
```

```
Price = 2×1

```

Input Arguments

`EQPTree` — Stock tree structure
structure

Stock tree structure, specified by using `eqptree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate
positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date
datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every convertible bond is set to the `ValuationDate` of the EQP stock tree. The bond argument, `Settle`, is ignored.

To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`ConvRatio` — Number of shares convertible to one bond
nonnegative number

Number of shares convertible to one bond, specified as an NINST-by-1 with a nonnegative number.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree,EquityTree,DebtTree] = cbondbyeqp(EQPT,CouponRate,Settle, Maturity, ConvRatio,'Spread',Spread,'CallExDates',CallExDates, 'CallStrike',CallStrike,'AmericanCall',1)

Spread — Number of basis points over the reference rate

0 (default) | vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of 'Spread' and a NINST-by-1 vector.

Note To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument Spread. To incorporate default risk into the algorithm, specify the optional input arguments DefaultProbability and RecoveryRate. Do not use Spread with DefaultProbability and RecoveryRate.

Data Types: double

Period — Coupons per year

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

IssueDate — Bond issue date

datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cbondbyeqp also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date

datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or an `NINST`-by-`1` cell array where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`CallStrike` — Call strike price for European, Bermuda, or American option
nonnegative integer | vector of nonnegative integers

Call strike price for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallStrike'` and one of the following values:

- For a European call option — `NINST`-by-`1` vector of nonnegative integers
- For a Bermuda call option — `NINST`-by-`NSTRIKES` matrix of strike price values, where each row is the schedule for one call option. If an option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American call option — `NINST`-by-`1` vector of strike price values for each call option.

Data Types: `single` | `double`

`CallExDates` — Call exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Call exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallExDates'` and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates, where each row is the schedule for one call option. For a European option, there is only one `CallExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the call option can be exercised on any tree date between or including the pair of dates on that row. If `CallExDates` is `NINST`-by-`1`, the call option can be exercised between the `ValuationDate` of the EQP stock tree and the single listed `CallExDate`.

To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanCall` — Call option type indicator
`0` if `AmericanCall` is `NaN` or not entered (default) | scalar | vector of positive integers `[0,1]`

Call option type, specified as the comma-separated pair consisting of `'AmericanCall'` and a `NINST`-by-`1` vector with positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanCall` is `0` for each European or Bermuda option.
- For an American option — `AmericanCall` is `1` for each American option. The `AmericanCall` argument is required to invoke American exercise rules.

Data Types: `single` | `double`

`PutStrike` — Put strike values for European, Bermuda, or American option
positive integer | vector of positive integers

Put strike values for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'PutStrike'` and one of the following values:

- For a European put option — `NINST`-by-`1` vector of nonnegative integers
- For a Bermuda put option — `NINST`-by-`NSTRIKES` matrix of put strike price values, where each row is the schedule for one put option. If a put option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American put option — `NINST`-by-`1` vector of strike price values for each put option.

Data Types: `single` | `double`

`PutExDates` — Put exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Put exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'PutExDates'` and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates, where each row is the schedule for one put option. For a European option, there is only one `PutExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the put option can be exercised on any tree date between or including the pair of dates on that row. If `PutExDates` is `NINST`-by-`1`, the put option can be exercised between the `ValuationDate` of the EQP stock tree and the single listed `PutExDate`.

  To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanPut` — Put option type indicator
`0` if `AmericanPut` is `NaN` or not entered (default) | positive integer `[0,1]` | vector of positive integers `[0,1]`

Put option type, specified as the comma-separated pair consisting of `'AmericanPut'` and a `NINST`-by-`1` vector of positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanPut` is `0` for each European or Bermuda option.

- For an American option — `AmericanPut` is `1` for each American option. The `AmericanPut` argument is required to invoke American exercise rules.

Data Types: `single` | `double`

`ConvDates` — Convertible dates
`MaturityDate` (default) | datetime array | string array | date character vector

Convertible dates, specified as the comma-separated pair consisting of `'ConvDates'` and a `NINST`-by-`1` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors. If `ConvDates` is not specified, the bond is always convertible until maturity.

To support existing code, `cbondbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

For each instrument, the bond can be converted on any tree date between or including the pair of dates on that row.

If `ConvDates` is `NINST`-by-`1`, the bond can be converted between the `ValuationDate` of the EQP stock tree and the single listed `ConvDates`.

`DefaultProbability` — Annual probability of default rate
`0` (default) | nonnegative decimal

Annual probability of default rate, specified as the comma-separated pair consisting of `'DefaultProbability'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

`RecoveryRate` — Recovery rate
`1` (default) | nonnegative decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

Output Arguments

`Price` — Expected price at time `0`
array

Expected price at time `0`, returned as an `NINST`-by-`1` array.

`PriceTree` — Structure with vector of convertible bond prices at each node
tree structure

Structure with a vector of convertible bond prices at each node, returned as a tree structure.

`EquityTree` — Structure with vector of convertible bond equity component at each node
tree structure

Structure with a vector of convertible bond equity component at each node, returned as a tree structure.

`DebtTree` — Structure with vector of convertible bond debt component at each node
tree structure

Structure with a vector of convertible bond debt component at each node, returned as a tree structure.

More About

Callable Convertible

A convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder.

Upon call, the bondholder can either convert the bond or redeem at the call price. This option enables the issuer to control the price of the convertible bond and, if necessary, refinance the debt with a new cheaper one.

Puttable Convertible

A convertible bond with a put feature allows the bondholder to sell back the bond at a premium on a specific date.

This option protects the holder against rising interest rates by reducing the year to maturity.

Algorithms

`cbondbycrr`, `cbondbyeqp`, `cbondbyitt`, and `cbondbysttr`eturn price information in the form of a price vector and a price tree. These functions implement the risk in the form of either a credit spread or incorporating the risk of bond default. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair arguments `DefaultProbability` and `RecoveryRate`.

Version History

Introduced in R2015a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `cbondbyeqp` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Convertible Bond” on page 2-4

cbondbyitt

Price convertible bonds from ITT trinomial tree

Syntax

```
Price = cbondbyitt(ITTTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree] = cbondbyitt(ITTTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree,EquityTree,DebtTree] = cbondbyitt( ___ ,Name,Value)
```

Description

`Price = cbondbyitt(ITTTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds from an ITT trinomial tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree] = cbondbyitt(ITTTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds from an ITT trinomial tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree,EquityTree,DebtTree] = cbondbyitt( ___ ,Name,Value)` prices convertible bonds from an ITT trinomial tree using a credit spread or incorporating the risk of bond default.

To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair input argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair input arguments `DefaultProbability` and `RecoveryRate`.

Examples

Price a Convertible Bond Using an ITT Tree

Price a convertible bond using the following data for an `ITTTree` from `deriv.mat`:

```
load deriv.mat
```

Use `cbondbyitt` to price a convertible bond using an ITT trinomial tree.

```
CouponRate = 0.05;
Settle = datetime(2006,1,1);
Maturity = datetime(2008,1,1);
Period = 1;
CallStrike = 65;
CallExDates = datetime(2007,1,1);
ConvRatio = 1;
Spread = 0.015;

[Price,PriceTree,EqtTre,DbtTree] = cbondbyitt(ITTTree,CouponRate,Settle,Maturity,ConvRatio,...
'Period',Period,'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall'
```

```
Price = 58.9170
```

```
PriceTree = struct with fields:
    FinObj: 'TrinPriceTree'
```

```
     PTree: {1x5 cell}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]

EqtTre = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {[28.0629]  [66.3448 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [0 0 0 0 0 ... ]}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]

DbtTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {[30.8540]  [0 65 65]  [105 105 105 105 105]  [0 0 0 0 0 0 0]  [0 0 ... ]}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]
```

Price a Convertible Bond Using an ITT Tree and Incorporate Default Risk Using `DefaultProbability` and `RecoveryRate`

Price a convertible bond using the following data for an `ITTTree` from `deriv.mat`.

```
load deriv.mat
```

Use `cbondbyitt` to price a convertible bond using an ITT trinomial tree with the optional `DefaultProbability` and `RecoveryRate` arguments.

```
CouponRate = 0.05;
Settle = datetime(2006,1,1);
Maturity = datetime(2008,1,1);
Period = 1;
CallStrike = 65;
CallExDates = datetime(2007,1,1);
ConvRatio = 1;
DefaultProbability = .30;
RecoveryRate = .82;

[Price,PriceTree,EqtTre,DbtTree] = cbondbyitt(ITTTree,CouponRate,Settle,Maturity,ConvRatio,...
'Period',Period,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall',1,...
'DefaultProbability',DefaultProbability,'RecoveryRate',RecoveryRate)

Price = 50.6487

PriceTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x5 cell}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]

EqtTre = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {[20.7895]  [66.3448 0 0]  [0 0 0 0 0]  [0 0 0 0 0 0 0]  [0 0 0 0 0 ... ]}
      tObs: [0 1 2 3 4]
```

```
      dObs: [732678 733043 733408 733773 734139]

DbtTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {[29.8591]  [0 65 65]  [105 105 105 105 105]  [0 0 0 0 0 0 0]  [0 0 ... ]}
      tObs: [0 1 2 3 4]
      dObs: [732678 733043 733408 733773 734139]
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

`CouponRate` — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

`Settle` — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every convertible bond is set to the `ValuationDate` of the standard trinomial (STT) stock tree. The bond argument, `Settle`, is ignored.

To support existing code, `cbondbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`ConvRatio` — Number of shares convertible to one bond

nonnegative number

Number of shares convertible to one bond, specified as an `NINST`-by-`1` with a nonnegative number.

Data Types: double

Name-Value Pair Arguments

Specify optional pairs of arguments as Name1=Value1,...,NameN=ValueN, where Name is the argument name and Value is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose Name *in quotes.*

Example: [Price,PriceTree,EquityTree,DebtTree] = cbondbyitt(ITTTree,CouponRate,Settle, Maturity, ConvRatio,'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall',1)

Spread — Number of basis points over the reference rate
0 (default) | vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of 'Spread' and a NINST-by-1 vector.

Note To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument Spread. To incorporate default risk into the algorithm, specify the optional input arguments DefaultProbability and RecoveryRate. Do not use Spread with DefaultProbability and RecoveryRate.

Data Types: double

Period — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a NINST-by-1 vector.

Data Types: double

IssueDate — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cbondbyitt also accepts serial date numbers as inputs, but they are not recommended.

FirstCouponDate — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a NINST-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, cbondbyitt also accepts serial date numbers as inputs, but they are not recommended.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`CallStrike` — Call strike price for European, Bermuda, or American option
nonnegative integer | vector of nonnegative integers

Call strike price for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallStrike'` and one of the following values:

- For a European call option — `NINST`-by-`1` vector of nonnegative integers.
- For a Bermuda call option — `NINST`-by-`NSTRIKES` matrix of call strike price values, where each row is the schedule for one call option. If a call option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American call option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`CallExDates` — Call exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Call exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallExDates'` and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates, where each row is the schedule for one option. For a European option, there is only one `CallExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the call option can be exercised on any tree date between or including the pair of dates on that row. If `CallExDates` is `NINST`-by-`1`, the option can be exercised between the `ValuationDate` of the ITT stock tree and the single listed `CallExDate`.

To support existing code, `cbondbyitt` also accepts serial date numbers as inputs, but they are not recommended.

AmericanCall — Call option type indicator
0 if AmericanCall is NaN or not entered (default) | positive integer [0,1] | vector of positive integers [0,1]

Call option type, specified as the comma-separated pair consisting of 'AmericanCall' and a NINST-by-1 vector of positive integer flags with values 0 or 1.

- For a European or Bermuda option — AmericanCall is 0 for each European or Bermuda option.
- For an American option — AmericanCall is 1 for each American option. The AmericanCall argument is required to invoke American exercise rules.

Data Types: double

PutStrike — Put strike values for European, Bermuda, or American option
positive integer | vector of positive integers

Put strike values for European, Bermuda, or American option, specified as the comma-separated pair consisting of 'PutStrike' and one of the following values:

- For a European put option — NINST-by-1 vector of nonnegative integers.
- For a Bermuda put option — NINST-by-NSTRIKES matrix of strike price values where each row is the schedule for one option. If a put option has fewer than NSTRIKES exercise opportunities, the end of the row is padded with NaNs.
- For an American put option — NINST-by-1 vector of strike price values for each option.

Data Types: double

PutExDates — Put exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Put exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of 'PutExDates' and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — NINST-by-1 vector of date character vectors.
- For a Bermuda option — NINST-by-NSTRIKES matrix of exercise dates where each row is the schedule for one option. For a European option, there is only one PutExDate on the option expiry date.
- For an American option — NINST-by-1 or NINST-by-2 matrix of exercise date boundaries. For each instrument, the put option can be exercised on any tree date between or including the pair of dates on that row. If PutExDates is NINST-by-1, the put option can be exercised between the ValuationDate of the ITT stock tree and the single listed PutExDate.

To support existing code, cbondbyitt also accepts serial date numbers as inputs, but they are not recommended.

AmericanPut — Put option type indicator
0 if AmericanPut is NaN or not entered (default) | positive integer [0,1] | vector of positive integers [0,1]

Put option type, specified as the comma-separated pair consisting of 'PutExDates' and a NINST-by-1 vector of positive integer flags with values 0 or 1.

- For a European or Bermuda option — `AmericanPut` is `0` for each European or Bermuda option.
- For an American option — `AmericanPut` is `1` for each American option. The `AmericanPut` argument is required to invoke American exercise rules.

Data Types: `double`

`ConvDates` — Convertible dates
`MaturityDate` (default) | datetime array | string array | date character vector

Convertible dates, specified as the comma-separated pair consisting of `'ConvDates'` and a `NINST`-by-`1` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors. If `ConvDates` is not specified, the bond is always convertible until maturity.

To support existing code, `cbondbyitt` also accepts serial date numbers as inputs, but they are not recommended.

For each instrument, the bond can be converted on any tree date between or including the pair of dates on that row.

If `ConvDates` is `NINST`-by-`1`, the bond can be converted between the `ValuationDate` of the ITT stock tree and the single listed `ConvDates`.

`DefaultProbability` — Annual probability of default rate
`0` (default) | nonnegative decimal

Annual probability of default rate, specified as the comma-separated pair consisting of `'DefaultProbability'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

`RecoveryRate` — Recovery rate
`1` (default) | nonnegative decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

Output Arguments

`Price` — Expected price at time `0`
array

Expected price at time `0`, returned as an `NINST`-by-`1` array.

`PriceTree` — Structure with vector of convertible bond prices at each node
tree structure

Structure with a vector of convertible bond prices at each node, returned as a tree structure.

`EquityTree` — Structure with vector of convertible bond equity component at each node
tree structure

Structure with a vector of convertible bond equity components at each node, returned as a tree structure.

`DebtTree` — Structure with vector of convertible bond debt component at each node
tree structure

Structure with a vector of convertible bond debt components at each node, returned as a tree structure.

More About

Callable Convertible

A convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder.

Upon call, the bondholder can either convert the bond or redeem at the call price. This option enables the issuer to control the price of the convertible bond and, if necessary, refinance the debt with a new cheaper bond.

Puttable Convertible

A convertible bond with a put feature allows the bondholder to sell back the bond at a premium on a specific date.

This option protects the holder against rising interest rates by reducing the year to maturity.

Algorithms

`cbondbycrr`, `cbondbyeqp`, `cbondbyitt`, and `cbondbysttr`eturn price information in the form of a price vector and a price tree. These functions implement the risk in the form of either a credit spread or incorporating the risk of bond default. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair arguments `DefaultProbability` and `RecoveryRate`.

Version History

Introduced in R2015b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `cbondbyitt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

Topics

“Convertible Bond” on page 2-4

cbondbystt

Price convertible bonds from standard trinomial tree

Syntax

```
Price = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree] = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio)
[Price,PriceTree,EquityTree,DebtTree] = cbondbystt( ___ ,Name,Value)
```

Description

`Price = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds using a standard trinomial (STT) tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree] = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio)` prices convertible bonds using a standard trinomial (STT) tree using the Tsiveriotis and Fernandes method.

`[Price,PriceTree,EquityTree,DebtTree] = cbondbystt( ___ ,Name,Value)` prices convertible bonds from a standard trinomial (STT) tree using a credit spread or incorporating the risk of bond default.

To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair input argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair input arguments `DefaultProbability` and `RecoveryRate`.

Examples

Price a Convertible Bond Using a STTTree

Create a `RateSpec`.

```
StartDates = datetime(2015,1,1);
EndDates = datetime(2020,1,1);
Rates = 0.025;
Basis = 1;

RateSpec = intenvset('ValuationDate',StartDates,'StartDates',StartDates,...
'EndDates',EndDates,'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8825
            Rates: 0.0250
        EndTimes: 5
       StartTimes: 0
         EndDates: 737791
       StartDates: 735965
    ValuationDate: 735965
```

```
           Basis: 1
     EndMonthRule: 1
```

Create a StockSpec.

```
AssetPrice = 80;
Sigma = 0.12;
StockSpec = stockspec(Sigma,AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1200
         AssetPrice: 80
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create a STTTree.

```
TimeSpec = stttimespec(StartDates, EndDates, 20);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
         dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]
        STree: {1x21 cell}
        Probs: {1x20 cell}
```

Define the convertible bond. The convertible bond can be called starting on Jan 1, 2016 with a strike price of 95.

```
CouponRate = 0.03;
Settle = datetime(2015,1,1);
Maturity = datetime(2018,4,1);
Period = 1;
CallStrike = 95;
CallExDates = [datetime(2016,1,1) ; datetime(2018,1,1)];
ConvRatio = 1;
Spread = 0.025;
```

Price the convertible bond using the standard trinomial tree model.

```
[Price,PriceTree,EqtTre,DbtTree] = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio,...
'Period',Period,'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall'
```

```
Price = 2×1

   91.8885
   90.6328

PriceTree = struct with fields:
    FinObj: 'TrinPriceTree'
```

```
     PTree: {1x21 cell}
      tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
      dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]

EqtTre = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x21 cell}
      tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
      dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]

DbtTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x21 cell}
      tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
      dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]
```

Spread Effect Analysis for a Convertible Bond Using a STTTree

This example demonstrates the spread effect analysis of a 4% coupon convertible bond, callable at 110 at end of the second year, maturing in five years, with spreads of 0, 50, 100, and 150 BP.

Define the `RateSpec`.

```
StartDates = datetime(2015,4,1);
EndDates = datetime(2020,4,1);
Rates = 0.05;
Compounding = -1;
Basis = 1;
RateSpec = intenvset('StartDates',StartDates,'EndDates',EndDates,'Rates',Rates,...
'Compounding',Compounding,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.7788
            Rates: 0.0500
         EndTimes: 5
       StartTimes: 0
         EndDates: 737882
       StartDates: 736055
    ValuationDate: 736055
            Basis: 1
     EndMonthRule: 1
```

Define the convertible bond data.

```
Settle = datetime(2015,4,1);
Maturity = datetime(2020,4,1);
CouponRate = 0.04;
CallStrike = 110;
CallExDates = [datetime(2017,4,1)  datetime(2020,4,1)];
ConvRatio = 1;
```

```
AmericanCall = 1;
Sigma = 0.3;
Spreads = 0:0.005:0.015;
Prices = 40:10:140;
convprice = zeros(length(Prices),length(Spreads));
```

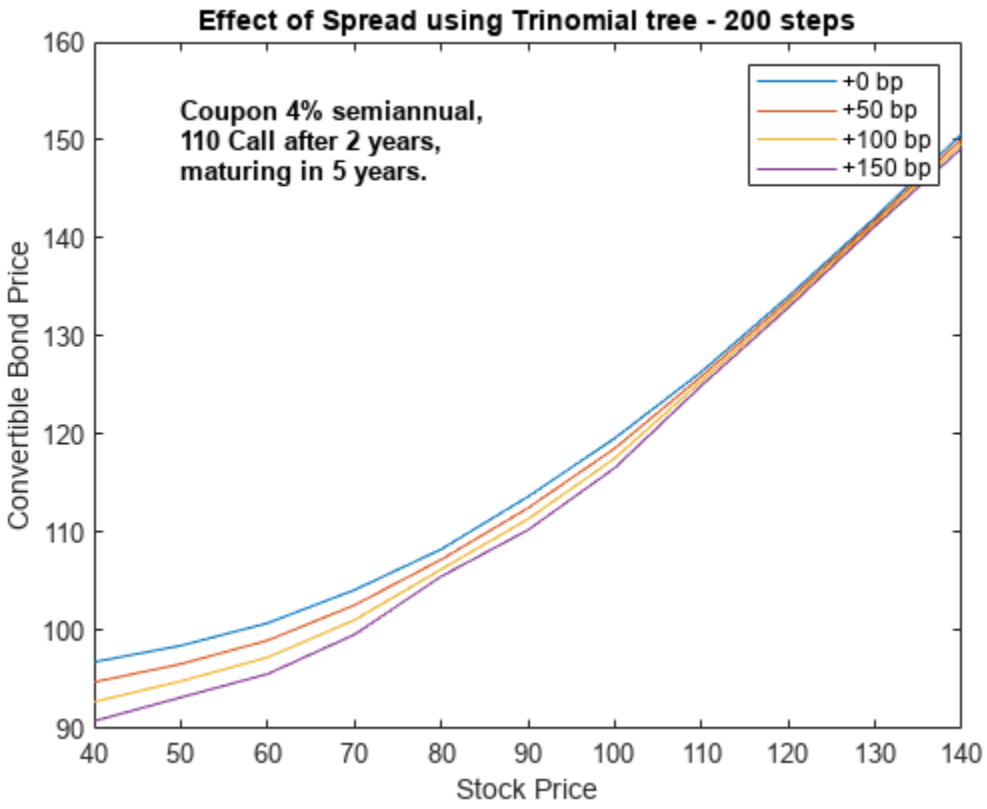
Define the `TimeSpec` for the Standard Trinomial Tree, create an `STTTree` using `stttree`, and price the convertible bond using `cbondbystt`.

```
NumSteps = 200;
TimeSpec = stttimespec(StartDates, EndDates, NumSteps);

for PriceIdx = 1:length(Prices)
    StockSpec = stockspec(Sigma, Prices(PriceIdx));
    STTT = stttree(StockSpec, RateSpec, TimeSpec);
    convprice(PriceIdx,:) = cbondbystt(STTT,  CouponRate, Settle, Maturity, ConvRatio,...
    'Spread', Spreads(:),'CallExDates', CallExDates, 'CallStrike', CallStrike,...
    'AmericanCall', AmericanCall);
end
```

Plot the spread effect analysis for the convertible bond.

```
stock = repmat(Prices',1,length(Spreads));
plot(stock,convprice);
legend({'+0 bp'; '+50 bp'; '+100 bp'; '+150 bp'});
title ('Effect of Spread using Trinomial tree - 200 steps')
xlabel('Stock Price');
ylabel('Convertible Bond Price');
text(50, 150, ['Coupon 4% semiannual,', sprintf('\n'), ...
    '110 Call after 2 years,' sprintf('\n'), ...
    'maturing in 5 years.'],'fontweight','Bold')
```



Price a Convertible Bond Using an STT Tree and Incorporate Default Risk Using `DefaultProbability` and `RecoveryRate`

Create the interest-rate term structure `RateSpec`.

```
StartDates = datetime(2015,1,1);
EndDates = datetime(2020,1,1);
Rates = 0.025;
Basis = 1;

RateSpec = intenvset('ValuationDate',StartDates,'StartDates',StartDates,...
'EndDates',EndDates,'Rates',Rates,'Compounding',-1,'Basis',Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8825
            Rates: 0.0250
        EndTimes: 5
       StartTimes: 0
         EndDates: 737791
       StartDates: 735965
    ValuationDate: 735965
            Basis: 1
```

```
     EndMonthRule: 1
```

Create the `StockSpec`.

```
AssetPrice = 80;
Sigma = 0.12;
StockSpec = stockspec(Sigma,AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1200
         AssetPrice: 80
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create the STT tree for the equity.

```
TimeSpec = stttimespec(StartDates, EndDates, 20);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
         dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]
        STree: {1x21 cell}
        Probs: {1x20 cell}
```

Define and price the convertible bond using the optional `DefaultProbability` and `RecoveryRate` arguments.

```
CouponRate = 0.03;
Settle = datetime(2015,1,1);
Maturity = datetime(2018,4,1);
Period = 1;
CallStrike = 95;
CallExDates = [datetime(2016,1,1) datetime(2018,1,1)];
ConvRatio = 1;
DefaultProbability = .30;
RecoveryRate = .82;

[Price,PriceTree,EqtTre,DbtTree] = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio,...
'Period',Period,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall',1,...
'DefaultProbability',DefaultProbability,'RecoveryRate',RecoveryRate)
```

```
Price = 80

PriceTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x21 cell}
      tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
      dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]
```

```
EqtTre = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x21 cell}
      tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
      dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]

DbtTree = struct with fields:
    FinObj: 'TrinPriceTree'
     PTree: {1x21 cell}
      tObs: [0 0.2500 0.5000 0.7500 1 1.2500 1.5000 1.7500 2 2.2500 ... ]
      dObs: [735965 736056 736147 736238 736330 736421 736512 736604 ... ]
```

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for a standard trinomial tree, specified by using `sttree`.

Data Types: `struct`

CouponRate — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an `NINST`-by-`1` decimal annual rate or `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: `double` | `cell`

Settle — Settlement date

datetime array | string array | date character vector

Settlement date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

Note The `Settle` date for every convertible bond is set to the `ValuationDate` of the standard trinomial (STT) stock tree. The bond argument, `Settle`, is ignored.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

Maturity — Maturity date

datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

`ConvRatio` — Number of shares convertible to one bond
nonnegative number

Number of shares convertible to one bond, specified as an `NINST`-by-`1` with a nonnegative number.

Data Types: `double`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `[Price,PriceTree,EquityTree,DebtTree] = cbondbystt(STTTree,CouponRate,Settle,Maturity,ConvRatio,'Spread',Spread,'CallExDates',CallExDates,'CallStrike',CallStrike,'AmericanCall',1)`

`Spread` — Number of basis points over the reference rate
`0` (default) | vector

Number of basis points over the reference rate, specified as the comma-separated pair consisting of `'Spread'` and a `NINST`-by-`1` vector.

Note To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. Do not use `Spread` with `DefaultProbability` and `RecoveryRate`.

Data Types: `double`

`Period` — Coupons per year
2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of `'Period'` and a `NINST`-by-`1` vector.

Data Types: `double`

`IssueDate` — Bond issue date
datetime array | string array | date character vector

Bond issue date, specified as the comma-separated pair consisting of `'IssueDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

`FirstCouponDate` — Irregular first coupon date
datetime array | string array | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

`LastCouponDate` — Irregular last coupon date
datetime array | string array | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

`Face` — Face value
`100` (default) | nonnegative value | cell array of nonnegative values

Face value, specified as the comma-separated pair consisting of `'Face'` and a `NINST`-by-`1` vector of nonnegative face values or a `NINST`-by-`1` cell array, where each element is a `NumDates`-by-`2` cell array. The first column of the `NumDates`-by-`2` cell array is dates and the second column is the associated face value. The date indicates the last day that the face value is valid.

Data Types: `cell` | `double`

`CallStrike` — Call strike price for European, Bermuda, or American option
nonnegative integer | vector of nonnegative integers

Call strike price for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallStrike'` and one of the following values:

- For a European call option — `NINST`-by-`1` vector of nonnegative integers
- For a Bermuda call option — `NINST`-by-`NSTRIKES` matrix of call strike price values, where each row is the schedule for one call option. If a call option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American call option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`CallExDates` — Call exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Call exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'CallExDates'` and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates, where each row is the schedule for one option. For a European option, there is only one `CallExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the call option can be exercised on any tree date between or including the pair of dates on that row. If `CallExDates` is `NINST`-by-`1`, the option can be exercised between the `ValuationDate` of the STT stock tree and the single listed `CallExDate`.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanCall` — Call option type indicator
`0` if `AmericanCall` is `NaN` or not entered (default) | positive integer `[0,1]` | vector of positive integers `[0,1]`

Call option type, specified as the comma-separated pair consisting of `'AmericanCall'` and a `NINST`-by-`1` vector of positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanCall` is `0` for each European or Bermuda option.
- For an American option — `AmericanCall` is `1` for each American option. The `AmericanCall` argument is required to invoke American exercise rules.

Data Types: `double`

`PutStrike` — Put strike values for European, Bermuda, or American option
positive integer | vector of positive integers

Put strike values for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'PutStrike'` and one of the following values:

- For a European put option — `NINST`-by-`1` vector of nonnegative integers.
- For a Bermuda put option — `NINST`-by-`NSTRIKES` matrix of strike price values where each row is the schedule for one option. If a put option has fewer than `NSTRIKES` exercise opportunities, the end of the row is padded with `NaN`s.
- For an American put option — `NINST`-by-`1` vector of strike price values for each option.

Data Types: `double`

`PutExDates` — Put exercise date for European, Bermuda, or American option
datetime array | string array | date character vector

Put exercise date for European, Bermuda, or American option, specified as the comma-separated pair consisting of `'PutExDates'` and a datetime array, string array, or date character vectors for one of the following values:

- For a European option — `NINST`-by-`1` vector of date character vectors.
- For a Bermuda option — `NINST`-by-`NSTRIKES` matrix of exercise dates where each row is the schedule for one option. For a European option, there is only one `PutExDate` on the option expiry date.
- For an American option — `NINST`-by-`1` or `NINST`-by-`2` matrix of exercise date boundaries. For each instrument, the put option can be exercised on any tree date between or including the pair of dates on that row. If `PutExDates` is `NINST`-by-`1`, the put option can be exercised between the `ValuationDate` of the STT stock tree and the single listed `PutExDate`.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

`AmericanPut` — Put option type indicator
`0` if `AmericanPut` is `NaN` or not entered (default) | positive integer `[0,1]` | vector of positive integers `[0,1]`

Put option type, specified as the comma-separated pair consisting of `'AmericanPut'` and a `NINST`-by-`1` vector of positive integer flags with values `0` or `1`.

- For a European or Bermuda option — `AmericanPut` is `0` for each European or Bermuda option.
- For an American option — `AmericanPut` is `1` for each American option. The `AmericanPut` argument is required to invoke American exercise rules.

Data Types: `double`

`ConvDates` — Convertible dates
`MaturityDate` (default) | datetime array | string array | date character vector

Convertible dates, specified as the comma-separated pair consisting of `'ConvDates'` and a `NINST`-by-`1` or `NINST`-by-`2` vector using a datetime array, string array, or date character vectors. If `ConvDates` is not specified, the bond is always convertible until maturity.

To support existing code, `cbondbystt` also accepts serial date numbers as inputs, but they are not recommended.

For each instrument, the bond can be converted on any tree date between or including the pair of dates on that row.

If `ConvDates` is `NINST`-by-`1`, the bond can be converted between the `ValuationDate` of the standard trinomial (STT) stock tree and the single listed `ConvDates`.

`DefaultProbability` — Annual probability of default rate
`0` (default) | nonnegative decimal

Annual probability of default rate, specified as the comma-separated pair consisting of `'DefaultProbability'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

`RecoveryRate` — Recovery rate
`1` (default) | nonnegative decimal

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a `NINST`-by-`1` nonnegative decimal value.

Note To incorporate default risk into the algorithm, specify the optional input arguments `DefaultProbability` and `RecoveryRate`. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional input argument `Spread`. Do not use `DefaultProbability` and `RecoveryRate` with `Spread`.

Data Types: `double`

Output Arguments

`Price` — Expected price at time `0`
array

Expected price at time `0`, returned as an `NINST`-by-`1` array.

`PriceTree` — Structure with vector of convertible bond prices at each node
tree structure

Structure with a vector of convertible bond prices at each node, returned as a tree structure.

`EquityTree` — Structure with vector of convertible bond equity component at each node
tree structure

Structure with a vector of convertible bond equity components at each node, returned as a tree structure.

`DebtTree` — Structure with vector of convertible bond debt component at each node
tree structure

Structure with a vector of convertible bond debt components at each node, returned as a tree structure.

More About

Callable Convertible

A convertible bond that is callable by the issuer. The issuer of the bond forces conversion, removing the advantage that conversion is at the discretion of the bondholder.

Upon call, the bondholder can either convert the bond or redeem at the call price. This option enables the issuer to control the price of the convertible bond and, if necessary, refinance the debt with a new cheaper bond.

Puttable Convertible

A convertible bond with a put feature allows the bondholder to sell back the bond at a premium on a specific date.

This option protects the holder against rising interest rates by reducing the year to maturity.

Algorithms

`cbondbycrr`, `cbondbyeqp`, `cbondbyitt`, and `cbondbysttreturn` price information in the form of a price vector and a price tree. These functions implement the risk in the form of either a credit spread or incorporating the risk of bond default. To incorporate the risk in the form of credit spread (Tsiveriotis-Fernandes method), use the optional name-value pair argument `Spread`. To incorporate default risk into the algorithm, specify the optional name-value pair arguments `DefaultProbability` and `RecoveryRate`.

Version History

Introduced in R2015b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `cbondbystt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cfbybdt

Price cash flows from Black-Derman-Toy interest-rate tree

Syntax

```
[Price,PriceTree] = cfbybdt(BDTTree,CFlowAmounts,CFlowDates,Settle)
[Price,PriceTree] = cfbybdt( ___ ,Basis,Options)
```

Description

`[Price,PriceTree] = cfbybdt(BDTTree,CFlowAmounts,CFlowDates,Settle)` prices cash flows from a Black-Derman-Toy interest-rate tree.

`[Price,PriceTree] = cfbybdt( ___ ,Basis,Options)` adds optional arguments.

Examples

Price a Portfolio Containing Two Cash Flow Instruments

Price a portfolio containing two cash flow instruments paying interest annually over the four-year period from January 1, 2000 to January 1, 2004.

Load the file `deriv.mat`, which provides `BDTTree`. The `BDTTree` structure contains the time and interest-rate information needed to price the instruments.

```
load deriv.mat;
```

The valuation date (settle date) specified in `BDTTree` is January 1, 2000 (date number `730486`).

```
BDTTree.RateSpec.ValuationDate
```

```
ans = 730486
```

Provide values for the other required arguments.

```
CFlowAmounts =[5 NaN 5.5 105; 5 0 6 105];
CFlowDates = [730852, NaN, 731582, 731947;
              730852, 731217, 731582, 731947];
```

Use this information to compute the prices of the two cash flow instruments.

```
[Price, PriceTree] = cfbybdt(BDTTree, CFlowAmounts, ...
CFlowDates, BDTTree.RateSpec.ValuationDate)
```

```
Price = 2×1

   74.0112
   74.3671

PriceTree = struct with fields:
    FinObj: 'BDTPriceTree'
```

```
     tObs: [0 1 2 3 4]
    PTree: {1x5 cell}
```

You can visualize the prices of the two cash flow instruments with the `treeviewer` function.

Input Arguments

`BDTTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bdttree`.

Data Types: `struct`

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, specified as a Number of instruments (`NINST`) by maximum number of cash flows (`MOSTCFS`) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

serial date number

Cash flow dates, specified as `NINST`-by-`MOSTCFS` vector using serial date numbers. Each entry contains the date of the corresponding cash flow in `CFlowAmounts`.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified as a vector using serial date numbers or date character vectors. The `Settle` date for every cash flow is set to the `ValuationDate` of the BDT tree. The cash flow argument, `Settle`, is ignored.

Data Types: `double` | `char`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices at time 0
vector

Expected prices at time 0, returned as a `NINST`-by-1 vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.

Version History

Introduced before R2006a

cfbybk

Price cash flows from Black-Karasinski interest-rate tree

Syntax

```
[Price,PriceTree] = cfbybk(BKTree,CFlowAmounts,CFlowDates,Settle)
[Price,PriceTree] = cfbybk( ___ ,Basis,Options)
```

Description

`[Price,PriceTree] = cfbybk(BKTree,CFlowAmounts,CFlowDates,Settle)` prices cash flows from a Black-Karasinski interest-rate tree.

`[Price,PriceTree] = cfbybk( ___ ,Basis,Options)` adds optional arguments.

Examples

Price a Portfolio Containing Two Cash Flow Instruments

Price a portfolio containing two cash flow instruments paying interest annually over the four-year period from January 1, 2005 to January 1, 2009.

Load the file `deriv.mat`, which provides `BKTree`. The `BKTree` structure contains the time and interest-rate information needed to price the instruments.

```
load deriv.mat;
```

The valuation date (settle date) specified in `BKTree` is January 1, 2004 (date number `731947`).

```
BKTree.RateSpec.ValuationDate
```

```
ans =

      731947
```

Provide values for the other required arguments.

```
CFlowAmounts =[5 NaN 5.5 105; 5 0 6 105];
CFlowDates = [732678, NaN, 733408,733774;
              732678, 733034, 733408, 734774];
```

Use this information to compute the prices of the two cash flow instruments.

```
[Price, PriceTree] = cfbybk(BKTree, CFlowAmounts, CFlowDates,...
BKTree.RateSpec.ValuationDate)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In cfbytrintree (line 88)
  In cfbybk (line 75)

Price =
```

```
   93.3600
   81.6218

PriceTree =

  struct with fields:

     FinObj: 'BKPriceTree'
      PTree: {[2×1 double]  [2×3 double]  [2×5 double]  [2×5 double]  [2×5 double]}
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3×1 double]  [3×3 double]  [3×5 double]}
```

You can visualize the prices of the two cash flow instruments with the `treeviewer` function.

Input Arguments

`BKTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `bktree`.

Data Types: `struct`

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, specified as a Number of instruments (`NINST`) by maximum number of cash flows (`MOSTCFS`) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

serial date number

Cash flow dates, specified as `NINST`-by-`MOSTCFS` vector using serial date numbers. Each entry contains the serial date number of the corresponding cash flow in `CFlowAmounts`.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified as a vector using serial date numbers or date character vectors. The `Settle` date for every cash flow is set to the `ValuationDate` of the BK tree. The cash flow argument, `Settle`, is ignored.

Data Types: `double` | `char`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices at time 0
vector

Expected prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

cfbycir

Price cash flows from Cox-Ingersoll-Ross interest-rate tree

Syntax

```
[Price,PriceTree] = cfbycir(CIRTree,CFlowAmounts,CFlowDates,Settle)
[Price,PriceTree] = cfbycir( ___ ,Basis)
```

Description

`[Price,PriceTree] = cfbycir(CIRTree,CFlowAmounts,CFlowDates,Settle)` prices cash flows from a Cox-Ingersoll-Ross (CIR) interest-rate tree using a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`[Price,PriceTree] = cfbycir( ___ ,Basis)` adds an optional argument for `Basis`.

Examples

Price a Portfolio Containing Two Cash Flow Instruments

Price a portfolio containing two cash flow instruments paying interest annually over the four-year period from January 1, 2017 to June 1, 2020.

Load the file `deriv.mat`, which provides `CIRTree`. The `CIRTree` structure contains the time and interest-rate information required to price the instruments.

```
load deriv.mat;
```

The valuation date (settle date) specified in the `CIRTree` is January 1, 2017 (serial date number `736696`).

```
CIRTree.RateSpec.ValuationDate
```

```
ans = 736696
```

Provide values for the other required arguments.

```
CFlowAmounts =[5 NaN 5.5 105; 5 0 6 105];
CFlowDates = [736847,NaN,737061,737212;
              737426,737577,737791,737943];
```

Compute the prices of the two cash flow instruments using `cfbycir`.

```
[Price,PriceTree] = cfbycir(CIRTree, CFlowAmounts, CFlowDates,...
CIRTree.RateSpec.ValuationDate)
```

```
Price = 2×1

  109.6845
   98.7246
```

```
PriceTree = struct with fields:
     FinObj: 'CIRPriceTree'
      PTree: {1x5 cell}
       tObs: [0 1 2 3 4]
    Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
      Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, specified as a number of instruments (`NINST`) by maximum number of cash flows (`MOSTCFS`) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

serial date number

Cash flow dates, specified as `NINST`-by-`MOSTCFS` vector using serial date numbers. Each entry contains the serial date number of the corresponding cash flow in `CFlowAmounts`.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified as a vector using serial date numbers or date character vectors. The `Settle` date for every cash flow is set to the `ValuationDate` of the CIR tree. The cash flow argument `Settle` is ignored.

Data Types: `double` | `char`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

Output Arguments

`Price` — Expected prices at time 0

vector

Expected prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

cfbyhjm

Price cash flows from Heath-Jarrow-Morton interest-rate tree

Syntax

```
[Price,PriceTree] = cfbyhjm(HJMTree,CFlowAmounts,CFlowDates,Settle)
[Price,PriceTree] = cfbyhjm( ___ ,Basis,Options)
```

Description

`[Price,PriceTree] = cfbyhjm(HJMTree,CFlowAmounts,CFlowDates,Settle)` prices cash flows from a Heath-Jarrow-Morton interest-rate tree.

`[Price,PriceTree] = cfbyhjm( ___ ,Basis,Options)` adds optional arguments.

Examples

Price a Portfolio Containing Two Cash Flow Instruments

Price a portfolio containing two cash flow instruments paying interest annually over the four-year period from January 1, 2000 to January 1, 2004.

Load the file `deriv.mat`, which provides `HJMTree`. The `HJMTree` structure contains the time and interest-rate information needed to price the instruments.

```
load deriv.mat;
```

The valuation date (settle date) specified in `HJMTree` is January 1, 2000 (date number `730486`).

```
HJMTree.RateSpec.ValuationDate
```

```
ans = 730486
```

Provide values for the other required arguments.

```
CFlowAmounts =[5 NaN 5.5 105; 5 0 6 105];
CFlowDates = [730852, NaN, 731582, 731947;
              730852, 731217, 731582, 731947];
```

Use this information to compute the prices of the two cash flow instruments.

```
[Price, PriceTree] = cfbyhjm(HJMTree, CFlowAmounts,...
CFlowDates, HJMTree.RateSpec.ValuationDate)
```

```
Price = 2×1

   96.7805
   97.2188

PriceTree = struct with fields:
    FinObj: 'HJMPriceTree'
```

```
     tObs: [0 1 2 3 4]
    PBush: {1x5 cell}
```

You can visualize the prices of the two cash flow instruments with the `treeviewer` function.

Input Arguments

`HJMTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hjmtree`.

Data Types: `struct`

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, specified as a Number of instruments (`NINST`) by maximum number of cash flows (`MOSTCFS`) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

serial date number

Cash flow dates, specified as `NINST`-by-`MOSTCFS` vector using serial date numbers. Each entry contains the serial date number of the corresponding cash flow in `CFlowAmounts`.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified as a vector using serial date numbers or date character vectors. The `Settle` date for every cash flow is set to the `ValuationDate` of the HJM tree. The cash flow argument, `Settle`, is ignored.

Data Types: `double` | `char`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)

- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices at time 0
vector

Expected prices at time 0, returned as a `NINST`-by-1 vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and observation times for each node. Within `PriceTree`:

- `PriceTree.tObs` contains the observation times.
- `PriceTree.PBush` contains the clean prices.

Version History

Introduced before R2006a

cfbyhw

Price cash flows from Hull-White interest-rate tree

Syntax

```
[Price,PriceTree] = cfbyhw(HWTree,CFlowAmounts,CFlowDates,Settle)
[Price,PriceTree] = cfbyhw( ___ ,Basis,Options)
```

Description

`[Price,PriceTree] = cfbyhw(HWTree,CFlowAmounts,CFlowDates,Settle)` prices cash flows from a Hull-White interest-rate tree.

`[Price,PriceTree] = cfbyhw( ___ ,Basis,Options)` adds optional arguments.

Examples

Price a Portfolio Containing Two Cash Flow Instruments

Price a portfolio containing two cash flow instruments paying interest annually over the four-year period from January 1, 2005 to January 1, 2009.

Load the file `deriv.mat`, which provides `HWTree`. The `HWTree` structure contains the time and interest-rate information needed to price the instruments.

```
load deriv.mat;
```

The valuation date (settle date) specified in `HWTree` is January 1, 2004 (date number `731947`).

```
HWTree.RateSpec.ValuationDate
```

```
ans =

      731947
```

Provide values for the other required arguments.

```
CFlowAmounts =[5 NaN 5.5 105; 5 0 6 105];
CFlowDates = [732678, NaN, 733408, 733774;
              732678, 733034, 733408, 734774];
```

Use this information to compute the prices of the two cash flow instruments.

```
[Price, PriceTree] = cfbyhw(HWTree, CFlowAmounts, CFlowDates,...
HWTree.RateSpec.ValuationDate)
```

```
Warning: Not all cash flows are aligned with the tree. Result will be approximated.
> In cfbytrintree (line 88)
  In cfbyhw (line 75)

Price =
```

```
   93.3789
   81.7651

PriceTree =

  struct with fields:

     FinObj: 'HWPriceTree'
      PTree: {[2×1 double]  [2×3 double]  [2×5 double]  [2×5 double]  [2×5 double]}
       tObs: [0 1 2 3 4]
    Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
      Probs: {[3×1 double]  [3×3 double]  [3×5 double]}
```

You can visualize the prices of the two cash flow instruments with the `treeviewer` function.

Input Arguments

`HWTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `hwtree`.

Data Types: `struct`

`CFlowAmounts` — Cash flow amounts

matrix

Cash flow amounts, specified as a Number of instruments (`NINST`) by maximum number of cash flows (`MOSTCFS`) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than `MOSTCFS` cash flows, the end of the row is padded with `NaN`s.

Data Types: `double`

`CFlowDates` — Cash flow dates

serial date number

Cash flow dates, specified as `NINST`-by-`MOSTCFS` vector using serial date numbers. Each entry contains the serial date number of the corresponding cash flow in `CFlowAmounts`.

Data Types: `double`

`Settle` — Settlement date

serial date number | date character vector

Settlement date, specified as a vector using serial date numbers or date character vectors. The `Settle` date for every cash flow is set to the `ValuationDate` of the HW tree. The cash flow argument, `Settle`, is ignored.

Data Types: `double` | `char`

`Basis` — Day-count basis of instrument

`0` (actual/actual) (default) | integer from `0` to `13`

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, specified using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Expected prices at time 0
vector

Expected prices at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicated where the down branch connects to.
- `PriceTree.Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.

cfbyzero

Price cash flows from set of zero curves

Syntax

```
Price = cfbyzero(RateSpec,CFlowAmounts,CFlowDates,Settle)
Price = cfbyzero( ___ ,Basis)
```

Description

`Price = cfbyzero(RateSpec,CFlowAmounts,CFlowDates,Settle)` prices cash flows from a set of zero curves.

`Price = cfbyzero( ___ ,Basis)` adds an optional argument.

Examples

Compute the Price and Sensitivity From the Interest-Rate Term Structure

This example shows how to price a portfolio containing two cash flow instruments paying interest annually over the four-year period from January 1, 2000 to January 1, 2004. Load the file `deriv.mat`, which provides `ZeroRateSpec`. The `ZeroRateSpec` structure contains the interest-rate information needed to price the instruments.

```
load deriv.mat
CFlowAmounts =[5 NaN 5.5 105;5 0 6 105];
CFlowDates = [730852, NaN, 731582,731947;
              730852, 731217, 731582, 731947];
Settle = 730486;
Price = cfbyzero(ZeroRateSpec, CFlowAmounts, CFlowDates, Settle)
```

```
Price = 2×1

   96.7804
   97.2187
```

Input Arguments

RateSpec — Annualized zero rate term structure

structure

Annualized zero rate term structure, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

CFlowAmounts — Cash flow amounts

matrix

Cash flow amounts, specified as a Number of instruments (NINST) by maximum number of cash flows (MOSTCFS) matrix of cash flow amounts. Each row is a list of cash flow values for one instrument. If an instrument has fewer than MOSTCFS cash flows, the end of the row is padded with NaNs.

Data Types: double

CFlowDates — Cash flow dates
serial date number

Cash flow dates, specified as NINST-by-MOSTCFS vector using serial date numbers. Each entry contains the serial date number of the corresponding cash flow in CFlowAmounts.

Data Types: double

Settle — Settlement date on which cash flows are priced
serial date number | date character vector

Settlement date on which the cash flows are priced, specified using a NINST-by-1 vector with serial date numbers or date character vectors of the same value which represent the settlement date for each cash flow. Settle must be earlier than Maturity.

Data Types: double | char

Basis — Day-count basis of instrument
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of the instrument, specified as a vector of integers.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: double

Output Arguments

Price — Cash flow prices
matrix

Cash flow prices, returned as a `NINST`-by-`NUMCURVES` matrix where each column arises from one of the zero curves.

Version History

Introduced before R2006a

chooserbybls

Price European simple chooser options using Black-Scholes model

Syntax

```
Price = chooserbybls(RateSpec,StockSpec,Settle,Maturity,Strike,ChooseDate)
```

Description

`Price = chooserbybls(RateSpec,StockSpec,Settle,Maturity,Strike,ChooseDate)` computes the price for European simple chooser options using the Black-Scholes model.

Examples

Price European Simple Chooser Options Using the Black-Scholes Model

Consider a European chooser option with an exercise price of $60 on June 1, 2007. The option expires on December 2, 2007. Assume the underlying stock provides a continuous dividend yield of 5% per annum, is trading at $50, and has a volatility of 20% per annum. The annualized continuously compounded risk-free rate is 10% per annum. Assume that the choice must be made on August 31, 2007. Using this data:

```
AssetPrice = 50;
Strike = 60;
Settlement = datetime(2007,1,1);
Maturity = datetime(2007,12,2);
ChooseDate = datetime(2007,8,31);
RiskFreeRate = 0.1;
Sigma = 0.20;
Yield = 0.05
```

```
Yield = 0.0500
```

Define the `RateSpec` and `StockSpec`.

```
RateSpec = intenvset('Compounding', -1, 'Rates', RiskFreeRate, 'StartDates',...
Settlement, 'EndDates', Maturity);
StockSpec = stockspec(Sigma, AssetPrice,'continuous',Yield);
```

Price the chooser option.

```
Price  = chooserbybls(RateSpec, StockSpec, Settlement, Maturity,...
Strike, ChooseDate)
```

```
Price = 9.2781
```

Input Arguments

RateSpec — Annualized zero rate term structure
structure

Annualized zero rate term structure, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`StockSpec` — Stock specification for underlying asset
structure

Stock specification for underlying asset, specified using `StockSpec` obtained from `stockspec`. For information on the stock specification, see `stockspec`.

`stockspec` can handle other types of underlying assets. For example, stocks, stock indices, and commodities. If dividends are not specified in `StockSpec`, dividends are assumed to be `0`.

Note Only dividends of type `continuous` can be considered for choosers.

Data Types: `struct`

`Settle` — Settlement or trade dates
datetime array | string array | date character vector

Settlement or trade dates, specified using an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors. `Settle` must be earlier than `Maturity`.

To support existing code, `chooserbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity date
datetime array | string array | date character vector

Maturity date, specified as an `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `chooserbybls` also accepts serial date numbers as inputs, but they are not recommended.

`Strike` — Option strike price value
nonnegative integer

Option strike price value, specified with a `NINST`-by-`1` vector of nonnegative integers.

Data Types: `double`

`ChooseDate` — Chooser dates
datetime array | string array | date character vector

Choose dates, specified with a `NINST`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `chooserbybls` also accepts serial date numbers as inputs, but they are not recommended.

Output Arguments

`Price` — Expected prices
vector

Expected prices, returned as an `NINST`-by-`1` vector.

Version History

Introduced in R2008b

Serial date numbers not recommended
Not recommended starting in R2022b

Although `chooserbybls` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

cirprice

Instrument prices from Cox-Ingersoll-Ross interest-rate model

Syntax

```
Price = cirprice(CIRTree,InstSet)
[Price,PriceTree] = cirprice(CIRTree,InstSet)
```

Description

`Price = cirprice(CIRTree,InstSet)` computes prices for instruments using a Cox-Ingersoll-Ross (CIR) interest rate tree created with `cirtree`. The CIR tree uses a CIR++ model with the Nawalka-Beliaeva (NB) approach.

`cirprice` handles the following instrument type values: `'Bond'`, `'CashFlow'`,`'OptBond'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'Swap'`,`'Swaption'`, `'RangeFloat'`, `'OptFloat'`, `'OptEmFloat'`.

`[Price,PriceTree] = cirprice(CIRTree,InstSet)` returns the optional output for `PriceTree`.

Examples

Price Bonds Using a CIR Interest-Rate Tree

Define two bond instruments.

```
CouponRate= [0.035;0.04];
Settle= 'Jan-1-2017';
Maturity = 'Jan-1-2019';
Period = 1;
InstSet = instbond(CouponRate, Settle, Maturity, Period)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Bond'}
     FieldName: {{11x1 cell}}
    FieldClass: {{11x1 cell}}
     FieldData: {{11x1 cell}}
```

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.035      01-Jan-2017    01-Jan-2019    1      0     1            NaN       NaN
2     Bond 0.04       01-Jan-2017    01-Jan-2019    1      0     1            NaN       NaN
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a CIR tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2019';
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.5000 1 1.5000]
        dObs: [736696 736878 737061 737243]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Price the bonds.

```
Price = cirprice(CIRT,InstSet)
```

```
Price = 2×1

   98.6793
   99.6228
```

Input Arguments

CIRTree — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

InstSet — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Output Arguments

`Price` — Expected floating-rate note prices at time 0

vector

Expected floating-rate note prices at time 0, returned as a `NINST`-by-1 vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

`PriceTree` — Tree structure of instrument prices

structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.AITree` contains the accrued interest.
- `PriceTree.tObs` contains the observation times.

Version History

Introduced in R2018a

cirsens

Instrument sensitivities and prices from Cox-Ingersoll-Ross interest-rate model

Syntax

```
[Delta,Gamma,Vega,Price] = cirsens(CIRTree,InstSet)
```

Description

`[Delta,Gamma,Vega,Price] = cirsens(CIRTree,InstSet)` computes dollar sensitivities and prices for instruments using a Cox-Ingersoll-Ross (CIR) interest rate tree created with `cirtree`. The CIR tree uses a CIR++ model with the Nawalka-Beliaeva (NB) approach.

Note All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`cirsens` handles the following instrument type values: `'Bond'`, `'CashFlow'`,`'OptBond'`, `'Fixed'`, `'Float'`, `'Cap'`, `'Floor'`, `'Swap'`,`'Swaption'`, `'RangeFloat'`, `'OptFloat'`, `'OptEmFloat'`.

Examples

Compute Instrument Sensitivities Using a CIR Interest-Rate Tree

Define and set up two bond instruments. Compute `Delta` and `Gamma` for the bond instruments contained in the instrument set.

```
CouponRate= [0.035;0.04];
Settle= 'Jan-1-2017';
Maturity = 'Jan-1-2019';
Period = 1;
InstSet = instbond(CouponRate, Settle, Maturity, Period)
```

```
InstSet = struct with fields:
        FinObj: 'Instruments'
    IndexTable: [1x1 struct]
          Type: {'Bond'}
     FieldName: {{11x1 cell}}
    FieldClass: {{11x1 cell}}
     FieldData: {{11x1 cell}}
```

```
instdisp(InstSet)
```

```
Index Type CouponRate Settle         Maturity       Period Basis EndMonthRule IssueDate FirstCou
1     Bond 0.035      01-Jan-2017    01-Jan-2019    1      0     1            NaN       NaN
2     Bond 0.04       01-Jan-2017    01-Jan-2019    1      0     1            NaN       NaN
```

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2019';
CIRTimeSpec = cirtimespec(Settle, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 0.5000 1 1.5000]
        dObs: [736696 736878 737061 737243]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Calculate the `Delta` and `Gamma` sensitivities for the two bonds.

```
[Delta, Gamma] = cirsens(CIRT,InstSet)
```

```
Delta = 2×1

 -186.1885
 -187.5390

Gamma = 2×1

  532.8675
  536.3132
```

Input Arguments

`CIRTree` — Interest-rate tree structure

structure

Interest-rate tree structure, specified by using `cirtree`.

Data Types: `struct`

`InstSet` — Instrument variable
structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in interest rate
vector

Rate of change of instruments prices with respect to changes in the interest rate, returned as a `NINST`-by-`1` vector of deltas. `Delta` is computed by finite differences in calls to `cirtree`.

Note `Delta` is calculated based on yield shifts of 100 basis points.

`Gamma` — Rate of change of instruments deltas with respect to changes in interest rate
vector

Rate of change of instruments deltas with respect to changes in the interest rate, returned as a `NINST`-by-`1` vector of gammas. `Gamma` is computed by finite differences in calls to `cirtree`.

Note `Gamma` is calculated based on yield shifts of 100 basis points.

`Vega` — Rate of change of instruments prices with respect to changes in volatility
vector

Rate of change of instruments prices with respect to changes in the volatility, returned as a `NINST`-by-`1` vector of vegas. Volatility is Sigma (t,T) of the interest rate. `Vega` is computed by finite differences in calls to `cirtree`. For information on the volatility process, see `cirvolspec`.

Note `Vega` is calculated based on 1% shift in the volatility process.

`Price` — Price of each instrument
vector

Price of each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the interest-rate tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Version History

Introduced in R2018a

classfin

Create financial structure or return financial structure class name

Syntax

```
Obj = classfin(ClassName)
Obj = classfin(Struct,ClassName)
ClassName = classfin(Obj)
```

Description

`Obj = classfin(ClassName)` create a financial structure of class `ClassName`.

`Obj = classfin(Struct,ClassName)` create a converted MATLAB financial structure of class `ClassName`.

`ClassName = classfin(Obj)` returns a character vector containing a financial structure's class name.

Examples

Create a Financial Structure

This example shows how to create a financial structure `HJMTimeSpec` and complete its fields. (Typically, the function `hjmtimespec` is used to create `HJMTimeSpec` structures).

```
TimeSpec = classfin('HJMTimeSpec');
TimeSpec.ValuationDate = datetime(1999,12,10);
TimeSpec.Maturity = datetime(2002,12,10);
TimeSpec.Compounding = 2;
TimeSpec.Basis = 0;
TimeSpec.EndMonthRule = 1;
TimeSpec
```

```
TimeSpec = struct with fields:
           FinObj: 'HJMTimeSpec'
    ValuationDate: 10-Dec-1999
         Maturity: 10-Dec-2002
      Compounding: 2
            Basis: 0
     EndMonthRule: 1
```

Convert an Existing MATLAB Structure into a Financial Structure

This example shows how to convert an existing MATLAB structure into a financial structure.

```
TSpec.ValuationDate = datetime(1999,12,10);
TSpec.Maturity = datetime(2002,12,10);
```

```
TSpec.Compounding = 2;
TSpec.Basis = 0;
TSpec.EndMonthRule = 0;
TimeSpec = classfin(TSpec, 'HJMTimeSpec')
```

```
TimeSpec = struct with fields:
    ValuationDate: 10-Dec-1999
         Maturity: 10-Dec-2002
      Compounding: 2
            Basis: 0
     EndMonthRule: 0
           FinObj: 'HJMTimeSpec'
```

Return a Character Vector Containing a Financial Structure's Class Name

This example shows how to obtain a character vector containing a financial structure's class name.

```
load deriv.mat
ClassName = classfin(HJMTree)
```

```
ClassName =
'HJMFwdTree'
```

Input Arguments

`ClassName` — Name of a financial structure class

character vector

Name of a financial structure class, specified by a character vector.

Data Types: `char`

`Struct` — Structure for conversion

structure

Structure for conversion, specified as a MATLAB structure

Data Types: `struct`

`Obj` — Name of a financial structure

object

Name of a financial structure, specified with an instance of an object.

Data Types: `object`

Output Arguments

`Obj` — Name of a financial structure

object

Name of a financial structure, returned as an instance of an object.

`ClassName` — Name of a financial structure class
character vector

Name of a financial structure class, specified by a character vector.

cirtimespec

Specify time structure for Cox-Ingersoll-Ross tree

Syntax

```
TimeSpec = cirtimespec(ValuationDate,Maturity,NumPeriods)
TimeSpec = cirtimespec( ___ ,Name,Value)
```

Description

`TimeSpec = cirtimespec(ValuationDate,Maturity,NumPeriods)` creates a time spec for a Cox-Ingersoll-Ross (CIR) tree.

`TimeSpec = cirtimespec( ___ ,Name,Value)` adds additional name-value pair arguments.

Examples

Set the Number of Levels and Node Times for a CIR Tree

Set the number of levels and node times for an CIR tree by specifying a four-period tree with time steps of 1 year.

```
ValuationDate = datetime(2017,1,1);
Maturity = datetime(2021,1,1);
NumPeriods = 4
```

```
NumPeriods = 4
```

```
CIRTimeSpec = cirtimespec(ValuationDate, Maturity, NumPeriods)
```

```
CIRTimeSpec = struct with fields:
           FinObj: 'CIRTimeSpec'
    ValuationDate: 736696
         Maturity: 738157
       NumPeriods: 4
      Compounding: 1
            Basis: 0
     EndMonthRule: 1
             tObs: [0 1 2 3 4]
             dObs: [736696 737061 737426 737791 738157]
```

Input Arguments

`ValuationDate` — Date marking the pricing date and first observation tree

datetime scalar | string scalar | date character vector

Date marking the pricing date and first observation in the tree, specified as a scalar datetime, string, or date character vector

To support existing code, `cirtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Date marking the depth of tree
datetime scalar | string scalar | date character vector

Date marking the depth of the tree, specified as a scalar datetime, string, or date character vector, .

To support existing code, `cirtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`NumPeriods` — Determines how many time steps are in tree
nonnegative integer

Determines how many time steps are in tree, specified as a scalar using a nonnegative integer value.

Data Types: `double`

Name-Value Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `TimeSpec = cirtimespec(Valuationdate,Maturity,NumPeriods,'Basis',3)`

`Compounding` — Frequency at which the rates are compounded when annualized
`1` (default) | integer with value of `1`, `2`, `3`, `4`, `6`, or `12`

Frequency at which the rates are compounded when annualized, specified as the comma-separated pair consisting of `'Compounding'` and a scalar value:

- `1` — Annual compounding
- `2` — Semiannual compounding
- `3` — Compounding three times per year
- `4` — Quarterly compounding
- `6` — Bimonthly compounding
- `12` — Monthly compounding

Data Types: `double`

`Basis` — Day count basis
`0` (actual/actual) (default) | integer from `0` to `13`

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar value:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

`EndMonthRule` — End-of-month rule flag for generating dates when `Maturity` is end-of-month date for month having 30 or fewer days
`1` (in effect) (default) | nonnegative integer `[0,1]`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified as the comma-separated pair consisting of `'EndMonthRule'` and a nonnegative integer [`0`, `1`] using a scalar.

- `0` = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- `1` = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

Output Arguments

`TimeSpec` — Time layout for CIR tree
structure

Time layout for the `CIRTree`, returned as a structure.

Version History

Introduced in R2018a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `cirtimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

See Also

`cirtree`

cirvolspec

Specify Cox-Ingersoll-Ross interest-rate volatility process

Syntax

```
VolSpec = cirvolspec(Sigma,Alpha,Theta)
```

Description

`VolSpec = cirvolspec(Sigma,Alpha,Theta)` creates a Cox-Ingersoll-Ross (CIR) `VolSpec`.

Examples

Create a Structure Specifying the Volatility for `cirtree`

Create a Cox-Ingersoll-Ross volatility specification (`CIRVolSpec`) using the following data.

```
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
CIRVolSpec = cirvolspec(Sigma,Alpha,Theta)
```

```
CIRVolSpec = struct with fields:
    FinObj: 'CIRVolSpec'
     Sigma: 0.1000
     Alpha: 0.0300
     Theta: 0.0200
```

Input Arguments

`Sigma` — Volatility

numeric

Volatility, specified as a scalar using a numeric value.

Data Types: `double`

`Alpha` — Mean reversion speed

numeric

Mean reversion speed, specified as a scalar using a numeric value.

Data Types: `double`

`Theta` — Mean reversion level or long-term mean of short rate

numeric

Mean reversion level or long-term mean of the short rate, specified as a scalar using a numeric value.

Data Types: `double`

Output Arguments

`VolSpec` — Volatility model for CIR tree

structure

Volatility model for the `CIRTree`, returned as a structure.

Version History

Introduced in R2018a

See Also

`cirtree`

cirtree

Build a Cox-Ingersoll-Ross interest-rate tree

Syntax

```
CIRTree = cirvolspec(VolSpec,RateSpec,TimeSpec)
```

Description

`CIRTree = cirvolspec(VolSpec,RateSpec,TimeSpec)` builds a Cox-Ingersoll-Ross (CIR) interest-rate tree. The CIR tree uses a CIR++ model with the Nawalka-Beliaeva (NB) approach.

Examples

Create a CIR Tree

Create a `RateSpec` using the `intenvset` function.

```
Rates = [0.035; 0.042147; 0.047345; 0.052707];
Dates = {'Jan-1-2017'; 'Jan-1-2018'; 'Jan-1-2019'; 'Jan-1-2020'; 'Jan-1-2021'};
ValuationDate = 'Jan-1-2017';
EndDates = Dates(2:end)';
Compounding = 1;
RateSpec = intenvset('ValuationDate', ValuationDate, 'StartDates', ValuationDate, 'EndDates',End
```

Create a `CIR` tree.

```
NumPeriods = length(EndDates);
Alpha = 0.03;
Theta = 0.02;
Sigma = 0.1;
Settle = '01-Jan-2017';
Maturity = '01-Jan-2021';
CIRTimeSpec = cirtimespec(Settle, Maturity, NumPeriods);
CIRVolSpec = cirvolspec(Sigma, Alpha, Theta);

CIRT = cirtree(CIRVolSpec, RateSpec, CIRTimeSpec)
```

```
CIRT = struct with fields:
      FinObj: 'CIRFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [736696 737061 737426 737791]
     FwdTree: {1x4 cell}
     Connect: {[3x1 double]  [3x3 double]  [3x5 double]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
```

Input Arguments

`VolSpec` — Volatility process specification
structure

Volatility process specification, specified using the `VolSpec` output obtained from `cirvolspec`.

Data Types: `struct`

`RateSpec` — Interest-rate specification for initial risk-free rate curve
structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

`TimeSpec` — Time tree layout specification
structure

Time tree layout specification, specified using the `TimeSpec` output obtained from `cirtimespec`.

Data Types: `struct`

Output Arguments

`CIRTree` — Time and interest-rate information of a recombining tree
structure

Time and interest-rate information of a recombining tree, returned as a structure.

Version History

Introduced in R2018a

compoundbycrr

Price compound option from Cox-Ross-Rubinstein binomial tree

Syntax

```
[Price,PriceTree] = compoundbycrr(CRRTree,UOptSpec,UStrike,USettle,
UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)
[Price,PriceTree] = compoundbycrr( ___ ,CAmericanOpt)
```

Description

`[Price,PriceTree] = compoundbycrr(CRRTree,UOptSpec,UStrike,USettle, UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)` prices compound options from a Cox-Ross-Rubinstein binomial tree.

`[Price,PriceTree] = compoundbycrr( ___ ,CAmericanOpt)` adds an optional argument for `CAmericanOpt`.

Examples

Price a Compound Option Using a CRR Binomial Tree

This example shows how to price a compound option using a CRR binomial tree by loading the file `deriv.mat`, which provides `CRRTree`. The `CRRTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat

UOptSpec = 'Call';
UStrike = 130;
USettle = datetime(2003,1,1);
UExerciseDates = datetime(2006,1,1);
UAmericanOpt = 1;
COptSpec = 'Put';
CStrike = 5;
CSettle = datetime(2003,1,1);
CExerciseDates = datetime(2005,1,1);

Price = compoundbycrr(CRRTree, UOptSpec, UStrike, USettle, ...
UExerciseDates, UAmericanOpt, COptSpec, CStrike, CSettle, ...
CExerciseDates)
```

```
Price = 2.8482
```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

`UOptSpec` — Definition of underlying option
character vector with value `'call'` or `'put'`

Definition of underlying option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`UStrike` — Underlying option strike price value
nonnegative integer

Underlying option strike price value, specified with a nonnegative integer using a 1-by-1 vector.

Data Types: `double`

`USettle` — Underlying option settlement date or trade date
datetime array | string array | date character vector

Underlying option settlement date or trade date, specified as a 1-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`UExerciseDates` — Underlying option exercise date
datetime array | string array | date character vector

Underlying option exercise date, specified as a datetime array, string array, or date character vectors:

- For a European option, use a1-by-1 vector of the underlying exercise date. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a 1-by-2 vector of the underlying exercise date boundaries. The option can be exercised on any tree date. If only one non-`NaN` date is listed, or if `ExerciseDates` is 1-by-1, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`UAmericanOpt` — Underlying option type
`0` European (default) | scalar with values `0` or `1`

Underlying option type, specified as `NINST`-by-1 positive integer scalar flags with values:

- `0` — European
- `1` — American

If `UAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

`COptSpec` — Definition of compound option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of compound option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`CStrike` — Compound option strike price values
nonnegative integers

Compound option strike price values for a European and American option, specified with a nonnegative integer using a `NINST`-by-`1` matrix. Each row is the schedule for one option.

Data Types: `double`

`CSettle` — Compound option settlement date or trade date
datetime array | string array | date character vector

Compound option settlement date or trade date, specified as a `1`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`CExerciseDates` — Compound option exercise dates
datetime array | string array | date character vector

Compound option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of the compound exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of the compound exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbycrr` also accepts serial date numbers as inputs, but they are not recommended.

`CAmericanOpt` — Compound option type
`0` European (default) | scalar with values `0` or `1`

(Optional) Compound option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

If `CAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

Output Arguments

`Price` — Expected prices for compound options at time `0`

vector

Expected prices for compound options at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure with vector of compound option prices at each node

tree structure

Structure with a vector of compound option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

More About

Compound Option

A compound option is basically an option on an option; it gives the holder the right to buy or sell another option.

With a compound option, a vanilla stock option serves as the underlying instrument. Compound options thus have two strike prices and two exercise dates. For more information, see “Compound Option” on page 3-23.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `compoundbycrr` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

compoundbyeqp

Price compound option from Equal Probabilities binomial tree

Syntax

```
[Price,PriceTree] = compoundbyeqp(EQPTree,UOptSpec,UStrike,USettle,
UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)
[Price,PriceTree] = compoundbyeqp( ___ ,CAmericanOpt)
```

Description

`[Price,PriceTree] = compoundbyeqp(EQPTree,UOptSpec,UStrike,USettle, UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)` prices compound options from a Equal Probabilities binomial tree.

`[Price,PriceTree] = compoundbyeqp( ___ ,CAmericanOpt)` adds an optional argument for `CAmericanOpt`.

Examples

Price a Compound Option Using an EQP Equity Tree

This example shows how to price a compound option using a EQP equity tree by loading the file `deriv.mat`, which provides `EQPTree`. The `EQPTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat
UOptSpec = 'Call';
UStrike = 130;
USettle = datetime(2003,1,1);
UExerciseDates = datetime(2006,1,1);
UAmericanOpt = 1;
COptSpec = 'Put';
CStrike = 5;
CSettle = datetime(2003,1,1);
CExerciseDates = datetime(2005,1,1);

Price = compoundbyeqp(EQPTree, UOptSpec, UStrike, USettle, ...
UExerciseDates, UAmericanOpt, COptSpec, CStrike, CSettle, ...
CExerciseDates)
```

```
Price = 3.3931
```

Input Arguments

EQPTree — Stock tree structure

structure

Stock tree structure, specified by using `eqptree`.

Data Types: `struct`

`UOptSpec` — Definition of underlying option
character vector with value `'call'` or `'put'`

Definition of underlying option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`UStrike` — Underlying option strike price value
nonnegative integer

Underlying option strike price value, specified with a nonnegative integer using a 1-by-1 vector.

Data Types: `double`

`USettle` — Underlying option settlement date or trade date
datetime array | string array | date character vector

Underlying option settlement date or trade date, specified as a 1-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`UExerciseDates` — Underlying option exercise date
datetime array | string array | date character vector

Underlying option exercise date, specified as a datetime array, string array, or date character vectors:

- For a European option, use a1-by-1 vector of the underlying exercise date. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a 1-by-2 vector of the underlying exercise date boundaries. The option can be exercised on any tree date. If only one non-`NaN` date is listed, or if `ExerciseDates` is 1-by-1, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`UAmericanOpt` — Underlying option type
`0` European (default) | scalar with values `0` or `1`

Underlying option type, specified as `NINST`-by-1 positive integer scalar flags with values:

- `0` — European
- `1` — American

If `UAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

`COptSpec` — Definition of compound option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of compound option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`CStrike` — Compound option strike price values
nonnegative integers

Compound option strike price values for a European and American option, specified with a nonnegative integer using a `NINST`-by-`1` matrix. Each row is the schedule for one option.

Data Types: `double`

`CSettle` — Compound option settlement date or trade date
datetime array | string array | date character vector

Compound option settlement date or trade date, specified as a `1`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`CExerciseDates` — Compound option exercise dates
datetime array | string array | date character vector

Compound option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of the compound exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of the compound exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbyeqp` also accepts serial date numbers as inputs, but they are not recommended.

`CAmericanOpt` — Compound option type
`0` European (default) | scalar with values `0` or `1`

(Optional) Compound option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

If `CAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

Output Arguments

`Price` — Expected prices for compound options at time `0`

vector

Expected prices for compound options at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure with vector of compound option prices at each node

tree structure

Structure with a vector of compound option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

More About

Compound Option

A compound option is basically an option on an option; it gives the holder the right to buy or sell another option.

With a compound option, a vanilla stock option serves as the underlying instrument. Compound options thus have two strike prices and two exercise dates. For more information, see “Compound Option” on page 3-23.

Version History

Introduced before R2006a

Serial date numbers not recommended

Not recommended starting in R2022b

Although `compoundbyeqp` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

compoundbyitt

Price compound option from implied trinomial tree (ITT)

Syntax

```
[Price,PriceTree] = compoundbyitt(ITTTree,UOptSpec,UStrike,USettle,
UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)
[Price,PriceTree] = compoundbyitt( ___ ,CAmericanOpt)
```

Description

`[Price,PriceTree] = compoundbyitt(ITTTree,UOptSpec,UStrike,USettle, UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)` prices compound options from a Equal Probabilities binomial tree.

`[Price,PriceTree] = compoundbyitt( ___ ,CAmericanOpt)` adds an optional argument for `CAmericanOpt`.

Examples

Price a Compound Option Using an ITT Tree

This example shows how to price a compound option using a ITT tree by loading the file `deriv.mat`, which provides `ITTTree`. The `ITTTree` structure contains the stock specification and time information needed to price the option.

```
load deriv.mat

UOptSpec = 'Call';
UStrike = 99;
USettle = datetime(2006,1,1);
UExerciseDates = datetime(2010,1,1);
UAmericanOpt = 1;
COptSpec = 'Put';
CStrike = 5;
CSettle = datetime(2006,1,1);
CExerciseDates = datetime(2010,1,1);

Price = compoundbyitt(ITTTree, UOptSpec, UStrike, USettle, ...
UExerciseDates, UAmericanOpt, COptSpec, CStrike, CSettle, ...
CExerciseDates)

Price = 2.7271
```

Input Arguments

`ITTTree` — Stock tree structure

structure

Stock tree structure, specified by using `itttree`.

Data Types: `struct`

`UOptSpec` — Definition of underlying option
character vector with value `'call'` or `'put'`

Definition of underlying option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`UStrike` — Underlying option strike price value
nonnegative integer

Underlying option strike price value, specified with a nonnegative integer using a 1-by-1 vector.

Data Types: `double`

`USettle` — Underlying option settlement date or trade date
datetime array | string array | date character vector

Underlying option settlement date or trade date, specified as a 1-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`UExerciseDates` — Underlying option exercise date
datetime array | string array | date character vector

Underlying option exercise date, specified as a datetime array, string array, or date character vectors:

- For a European option, use a1-by-1 vector of the underlying exercise date. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a 1-by-2 vector of the underlying exercise date boundaries. The option can be exercised on any tree date. If only one non-`NaN` date is listed, or if `ExerciseDates` is 1-by-1, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`UAmericanOpt` — Underlying option type
`0` European (default) | scalar with values `0` or `1`

Underlying option type, specified as `NINST`-by-1 positive integer scalar flags with values:

- `0` — European
- `1` — American

If `UAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

`COptSpec` — Definition of compound option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of compound option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`CStrike` — Compound option strike price values
nonnegative integers

Compound option strike price values for a European and American option, specified with a nonnegative integer using a `NINST`-by-`1` matrix. Each row is the schedule for one option.

Data Types: `double`

`CSettle` — Compound option settlement date or trade date
datetime array | string array | date character vector

Compound option settlement date or trade date, specified as a `1`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`CExerciseDates` — Compound option exercise dates
datetime array | string array | date character vector

Compound option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of the compound exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of the compound exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbyitt` also accepts serial date numbers as inputs, but they are not recommended.

`CAmericanOpt` — Compound option type
`0` European (default) | scalar with values `0` or `1`

(Optional) Compound option type, specified as `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

If `CAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `double`

Output Arguments

`Price` — Expected prices for compound options at time `0`

vector

Expected prices for compound options at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure with vector of compound option prices at each node

tree structure

Structure with a vector of compound option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

compoundbystt

Price compound options using standard trinomial tree

Syntax

```
[Price,PriceTree] = compoundbystt(STTTree,UOptSpec,UStrike,USettle,
UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)
[Price,PriceTree] = compoundbystt( ___ ,Name,Value)
```

Description

`[Price,PriceTree] = compoundbystt(STTTree,UOptSpec,UStrike,USettle, UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates)` prices compound options using a standard trinomial (STT) tree.

`[Price,PriceTree] = compoundbystt( ___ ,Name,Value)` adds an optional name-value pair argument for `CAmericanOpt`.

Examples

Price a Compound Option Using the Standard Trinomial Tree Model

Create a `RateSpec`.

```
StartDates = datetime(2009,1,1);
EndDates = datetime(2013,1,1);
Rates = 0.035;
Basis = 1;
Compounding = -1;
RateSpec = intenvset('ValuationDate', StartDates, 'StartDates', StartDates,...
'EndDates', EndDates, 'Rates', Rates,'Compounding', Compounding, 'Basis', Basis)
```

```
RateSpec = struct with fields:
           FinObj: 'RateSpec'
      Compounding: -1
             Disc: 0.8694
            Rates: 0.0350
         EndTimes: 4
       StartTimes: 0
         EndDates: 735235
       StartDates: 733774
    ValuationDate: 733774
            Basis: 1
     EndMonthRule: 1
```

Create a `StockSpec`.

```
AssetPrice = 85;
Sigma = 0.15;
StockSpec = stockspec(Sigma, AssetPrice)
```

```
StockSpec = struct with fields:
             FinObj: 'StockSpec'
              Sigma: 0.1500
         AssetPrice: 85
       DividendType: []
    DividendAmounts: 0
    ExDividendDates: []
```

Create an STTTree.

```
NumPeriods = 4;
TimeSpec = stttimespec(StartDates, EndDates, 4);
STTTree = stttree(StockSpec, RateSpec, TimeSpec)
```

```
STTTree = struct with fields:
       FinObj: 'STStockTree'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 1 2 3 4]
         dObs: [733774 734139 734504 734869 735235]
        STree: {1x5 cell}
        Probs: {[3x1 double]  [3x3 double]  [3x5 double]  [3x7 double]}
```

Define the compound option and compute the price.

```
USettle = datetime(2009,1,1);
UExerciseDates = datetime(2012,1,1);
UOptSpec =  'call';
UStrike = 95;
UAmericanOpt = 1;
CSettle = datetime(2009,1,1);
CExerciseDates = datetime(2011,1,1);
COptSpec = 'put';
CStrike = 5;
CAmericanOpt = 1;

Price= compoundbystt(STTTree, UOptSpec, UStrike, USettle, UExerciseDates,...
UAmericanOpt, COptSpec, CStrike, CSettle,CExerciseDates, CAmericanOpt)
```

```
Price = 1.7090
```

Input Arguments

STTTree — Stock tree structure for standard trinomial tree

structure

Stock tree structure for standard trinomial tree, specified by using `stttree`.

Data Types: `struct`

UOptSpec — Definition of underlying option

character vector with value `'call'` or `'put'`

Definition of underlying option, specified as `'call'` or `'put'` using a character vector.

Data Types: `char`

`UStrike` — Underlying option strike price value
nonnegative integer

Underlying option strike price value, specified with a nonnegative integer using a 1-by-1 vector.

Data Types: `double`

`USettle` — Underlying option settlement date or trade date
datetime array | string array | date character vector

Underlying option settlement date or trade date, specified as a 1-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbystt` also accepts serial date numbers as inputs, but they are not recommended.

`UExerciseDates` — Underlying option exercise date
datetime array | string array | date character vector

Underlying option exercise date, specified as a datetime array, string array, or date character vectors:

- For a European option, use a1-by-1 vector of the underlying exercise date. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a 1-by-2 vector of the underlying exercise date boundaries. The option can be exercised on any tree date. If only one non-`NaN` date is listed, or if `ExerciseDates` is 1-by-1, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbystt` also accepts serial date numbers as inputs, but they are not recommended.

`UAmericanOpt` — Underlying option type
`0` European (default) | scalar with values `0` or `1`

Underlying option type, specified as `NINST`-by-1 positive integer scalar flags with values:

- `0` — European
- `1` — American

If `UAmericanOpt` is a `NaN` or is unspecified, the option is a European option.

Data Types: `single` | `double`

`COptSpec` — Definition of compound option
character vector with value `'call'` or `'put'` | cell array of character vectors with values `'call'` or `'put'`

Definition of compound option, specified as `'call'` or `'put'` using a character vector or a cell array of character vectors with values `'call'` or `'put'`.

Data Types: `char` | `cell`

`CStrike` — Compound option strike price values
nonnegative integers

Compound option strike price values for a European and American option, specified with a nonnegative integer using a `NINST`-by-`1` matrix. Each row is the schedule for one option.

Data Types: `double`

`CSettle` — Compound option settlement date or trade date
datetime array | string array | date character vector

Compound option settlement date or trade date, specified as a `1`-by-`1` vector using a datetime array, string array, or date character vectors.

To support existing code, `compoundbystt` also accepts serial date numbers as inputs, but they are not recommended.

`CExerciseDates` — Compound option exercise dates
datetime array | string array | date character vector

Compound option exercise dates, specified as a datetime array, string array, or date character vectors:

- For a European option, use a`NINST`-by-`1` matrix of the compound exercise dates. Each row is the schedule for one option. For a European option, there is only one `ExerciseDates` on the option expiry date.
- For an American option, use a `NINST`-by-`2` vector of the compound exercise date boundaries. For each instrument, the option can be exercised on any tree date between or including the pair of dates on that row. If only one non-`NaN` date is listed, or if `ExerciseDates` is `NINST`-by-`1`, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDates`.

To support existing code, `compoundbystt` also accepts serial date numbers as inputs, but they are not recommended.

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Price = compoundbystt(STTTree,UOptSpec,UStrike,USettle,UExerciseDates,UAmericanOpt,COptSpec,CStrike,CSettle,CExerciseDates,'CAmericanOpt',1)`

`CAmericanOpt` — Compound option type
`0` European (default) | scalar with values `[0,1]`

Compound option type, specified as the comma-separated pair consisting of `'CAmericanOpt'` and a `NINST`-by-`1` positive integer scalar flags with values:

- `0` — European
- `1` — American

Data Types: `single` | `double`

Output Arguments

`Price` — Expected prices for compound options at time `0`

vector

Expected prices for compound options at time 0, returned as a `NINST`-by-`1` vector.

`PriceTree` — Structure with vector of compound option prices at each node

tree structure

Structure with a vector of compound option prices at each node, returned as a tree structure.

`PriceTree` is a MATLAB structure of trees containing vectors of instrument prices and a vector of observation times for each node.

`PriceTree.PTree` contains the prices.

`PriceTree.tObs` contains the observation times.

`PriceTree.dObs` contains the observation dates.

More About

Compound Option

A compound option is basically an option on an option; it gives the holder the right to buy or sell another option.

With a compound option, a vanilla stock option serves as the underlying instrument. Compound options thus have two strike prices and two exercise dates. For more information, see “Compound Option” on page 3-23.

Version History

Introduced in R2015b

Serial date numbers not recommended

Not recommended starting in R2022b

Although `compoundbystt` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

crrprice

Instrument prices from Cox-Ross-Rubinstein tree

Syntax

```
[Price,PriceTree] = crrprice(CRRTree,InstSet)
[Price,PriceTree] = crrprice( ___ ,Options)
```

Description

`[Price,PriceTree] = crrprice(CRRTree,InstSet)` computes stock option prices using a CRR binomial tree created with `crrtree`. All instruments contained in a financial instrument variable, `InstSet`, are priced.

`crrprice` handles instrument types: `'Asian'`, `'Barrier'`, `'Compound'`, `'CBond'`, `'Lookback'`, `'OptStock'`. See `instadd` to construct defined types.

`[Price,PriceTree] = crrprice( ___ ,Options)` adds an optional input argument for `Options`.

Examples

Price Barrier and Lookback Options in the Instrument Set

Load the CRR tree and instruments from the data file `deriv.mat`. Price the barrier and lookback options contained in the instrument set.

```
load deriv.mat;
CRRSubSet = instselect(CRRInstSet,'Type', ...
{'Barrier', 'Lookback'});

instdisp(CRRSubSet)
```

```
Index Type    OptSpec Strike Settle         ExerciseDates  AmericanOpt BarrierSpec Barrier Rebate
1     Barrier call    105    01-Jan-2003    01-Jan-2006    1           ui          102     0

Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt Name      Quantity
2     Lookback call    115    01-Jan-2003    01-Jan-2006    0           Lookback1 7
3     Lookback call    115    01-Jan-2003    01-Jan-2007    0           Lookback2 9
```

Price the barrier and lookback options.

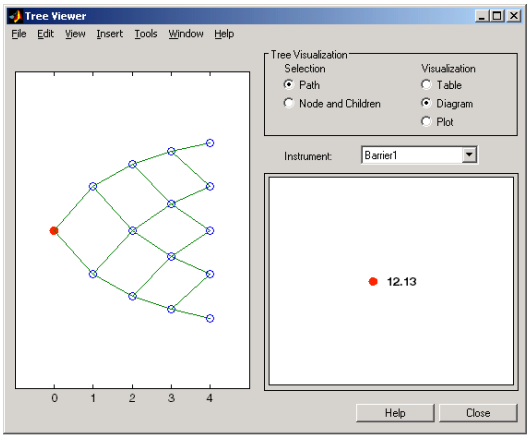
```
[Price, PriceTree] = crrprice(CRRTree,CRRSubSet)
```

```
Price = 3×1

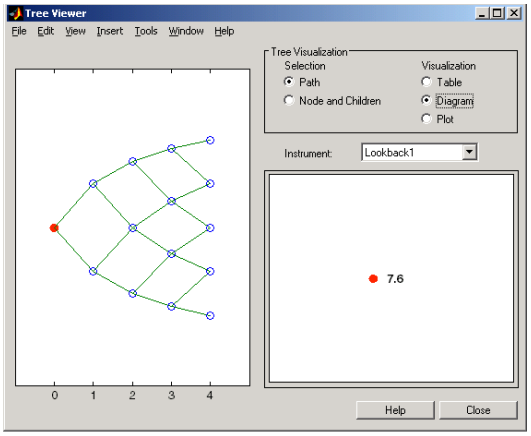
   12.1272
    7.6015
   11.7772
```

```
PriceTree = struct with fields:
    FinObj: 'BinPriceTree'
     PTree: {1x5 cell}
      tObs: [0 1 2 3 4]
      dObs: [731582 731947 732313 732678 733043]
```

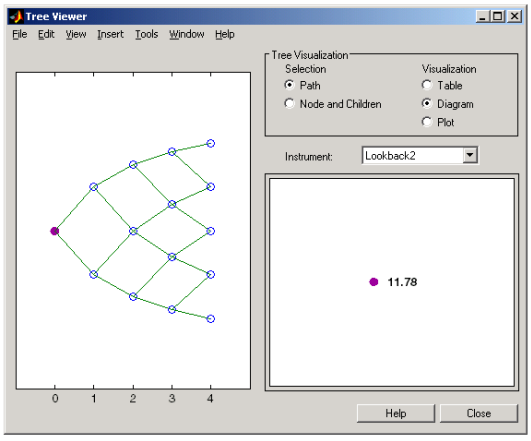
You can use `treeviewer` to see the prices of these three instruments along the price tree.



Barrier1



Lookback1



Lookback2

Input Arguments

CRRTree — Stock price tree structure

structure

Stock price tree structure, specified by using `crrtree`.

Data Types: `struct`

`InstSet` — Instrument variable
structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure
structure

(Optional) Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Price` — Price for each instrument
vector

Price for each instrument, returned as a `NINST`-by-`1` vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a `NaN` is returned in that entry.

Related single-type pricing functions are:

- `asianbycrr`: Price an Asian option from a CRR tree.
- `barrierbycrr`: Price a barrier option from a CRR tree.
- `cbondbycrr`: Price convertible bonds from a CRR tree.
- `compoundbycrr`: Price a compound option from a CRR tree.
- `lookbackbycrr`: Price a lookback option from a CRR tree.
- `optstockbycrr`: Price an American, Bermuda, or European option from a CRR tree.

`PriceTree` — Tree structure of instrument prices
structure

Tree structure of instrument prices, returned as a MATLAB structure of trees containing vectors of instrument prices and accrued interest, and a vector of observation times for each node. Within `PriceTree`:

- `PriceTree.PTree` contains the clean prices.
- `PriceTree.tObs` contains the observation times.
- `PriceTree.dObs` contains the observation dates.

Version History

Introduced before R2006a

crrsens

Instrument prices and sensitivities from Cox-Ross-Rubinstein tree

Syntax

```
[Delta,Gamma,Vega,Price] = crrsens(CRRTree,InstSet)
[Delta,Gamma,Vega,Price] = crrsens(___,Options)
```

Description

`[Delta,Gamma,Vega,Price] = crrsens(CRRTree,InstSet)` computes instrument sensitivities and prices for instruments using a binomial tree created with the `crrtree` function. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide by the respective instrument price.

`crrsens` handles instrument types: `'Asian'`, `'Barrier'`, `'Compound'`, `'CBond'`, `'Lookback'`, `'OptStock'`. See `instadd` for information on instrument types.

`[Delta,Gamma,Vega,Price] = crrsens(___,Options)` adds an optional input argument for `Options`.

Examples

Compute Sensitivities for Barrier and Lookback Instruments Using a crrtree

Load the CRR tree and instruments from the data file `deriv.mat`. Compute the `Delta` and `Gamma` sensitivities of the barrier and lookback options contained in the instrument set.

```
load deriv.mat;
CRRSubSet = instselect(CRRInstSet,'Type', ...
{'Barrier', 'Lookback'});

instdisp(CRRSubSet)
```

```
Index Type    OptSpec Strike Settle         ExerciseDates  AmericanOpt BarrierSpec Barrier Rebate
1     Barrier call    105    01-Jan-2003    01-Jan-2006    1           ui          102     0

Index Type     OptSpec Strike Settle         ExerciseDates  AmericanOpt Name      Quantity
2     Lookback call    115    01-Jan-2003    01-Jan-2006    0           Lookback1 7
3     Lookback call    115    01-Jan-2003    01-Jan-2007    0           Lookback2 9
```

Obtain the `Delta` and `Gamma` for the barrier and lookback options contained in the instrument set.

```
[Delta, Gamma] = crrsens(CRRTree, CRRSubSet)
```

```
Delta = 3×1

    0.6885
    0.6049
```

```
    0.8187

Gamma = 3×1

    0.0310
   -0.0000
         0
```

Input Arguments

`CRRTree` — Stock tree structure

structure

Stock tree structure, specified by using `crrtree`.

Data Types: `struct`

`InstSet` — Instrument variable

structure

Instrument variable containing a collection of `NINST` instruments, specified using `instadd`. Instruments are categorized by type; each type can have different data fields. The stored data field is a row vector or character vector for each instrument.

Data Types: `struct`

`Options` — Derivatives pricing options structure

structure

Derivatives pricing options structure, created using `derivset`.

Data Types: `struct`

Output Arguments

`Delta` — Rate of change of instruments prices with respect to changes in the stock price

vector

Rate of change of instruments prices with respect to changes in the stock price, returned as a `NINST`-by-`1` vector of deltas.

For path-dependent options (`'Lookback'` and `'Asian'`), `Delta` and `Gamma` are computed by finite differences in calls to `crrprice`. For the rest of the options (`'OptStock'`, `'Barrier'`, `'CBond'`, and `'Compound'`), `Delta` and `Gamma` are computed from the `CRRTree` and the corresponding option price tree.

`Gamma` — Rate of change of instruments deltas with respect to changes in stock price

vector

Rate of change of instruments deltas with respect to changes in the stock price, returned as a `NINST`-by-`1` vector of gammas.

For path-dependent options (`'Lookback'` and `'Asian'`), `Delta` and `Gamma` are computed by finite differences in calls to `crrprice`. For the rest of the options (`'OptStock'`, `'Barrier'`, `'CBond'`,

and 'Compound'), Delta and Gamma are computed from the CRRTree and the corresponding option price tree.

Vega — Rate of change of instruments prices with respect to changes in volatility of the stock
vector

Rate of change of instruments prices with respect to changes in the volatility of the stock, returned as a NINST-by-1 vector of vegas. Vega is computed by finite differences in calls to crrtree.

Price — Price of each instrument
vector

Price of each instrument, returned as a NINST-by-1 vector. The prices are computed by backward dynamic programming on the stock tree. If an instrument cannot be priced, a NaN is returned in that entry.

Version History

Introduced before R2006a

crrtimespec

Specify time structure for Cox-Ross-Rubinstein tree

Syntax

```
TimeSpec = crrtimespec(ValuationDate,Maturity,NumPeriods)
```

Description

`TimeSpec = crrtimespec(ValuationDate,Maturity,NumPeriods)` sets the number of levels and node times for a CRR binomial tree (`crrtree`).

Examples

Set the Number of Levels and Node Times for a CRR Binomial Tree

This example shows how to specify a four-period CRR tree with time steps of 1 year.

```
ValuationDate = datetime(2002,7,1);
Maturity = datetime(2006,7,1);
TimeSpec = crrtimespec(ValuationDate, Maturity, 4)
```

```
TimeSpec = struct with fields:
           FinObj: 'BinTimeSpec'
    ValuationDate: 731398
         Maturity: 732859
       NumPeriods: 4
            Basis: 0
     EndMonthRule: 1
             tObs: [0 1 2 3 4]
             dObs: [731398 731763 732128 732493 732859]
```

Input Arguments

`ValuationDate` — Pricing date and first observation in the tree

datetime scalar | string scalar | date character vector

Pricing date and first observation in the `crrtree`, specified as a scalar datetime, string, or date character vector.

To support existing code, `crrtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Date marking the depth of the CRR stock tree

datetime scalar | string scalar | date character vector

Date marking the depth of the `crrtree` binomial tree, specified as scalar datetime, string, or date character vector.

To support existing code, `crrtimespec` also accepts serial date numbers as inputs, but they are not recommended.

`NumPeriods` — Number of time steps in the CRR stock tree
integer

Number of time steps in the `crrtree` binomial tree, specified as scalar integer value.

Data Types: `double`

Output Arguments

`TimeSpec` — Specification for the time layout for `crrtree`
structure

Specification for the time layout for `crrtree`, returned as a structure.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although `crrtimespec` supports serial date numbers, `datetime` values are recommended instead. The `datetime` data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to `datetime` values, use the `datetime` function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

crrtree

Build Cox-Ross-Rubinstein stock tree

Syntax

```
CRRTree = crrtree(StockSpec,RateSpec,TimeSpec)
```

Description

`CRRTree = crrtree(StockSpec,RateSpec,TimeSpec)` builds a Cox-Ross-Rubinstein stock tree.

Examples

Create a CRR Tree

Using the data provided, create a stock specification (`StockSpec`), rate specification (`RateSpec`), and tree time layout specification (`TimeSpec`). Then use these specifications to create a CRR tree with `crrtree`.

```
Sigma = 0.20;
AssetPrice = 50;
DividendType = 'cash';
DividendAmounts = [0.50; 0.50; 0.50; 0.50];
ExDividendDates = {'03-Jan-2003'; '01-Apr-2003'; '05-July-2003';
'01-Oct-2003'};

StockSpec = stockspec(Sigma, AssetPrice, DividendType, ...
DividendAmounts, ExDividendDates);

RateSpec = intenvset('Rates', 0.05, 'StartDates',...
'01-Jan-2003', 'EndDates', '31-Dec-2003','Compounding',-1);

ValuationDate = '1-Jan-2003';
Maturity = '31-Dec-2003';
TimeSpec = crrtimespec(ValuationDate, Maturity, 4);

CRRTree = crrtree(StockSpec, RateSpec, TimeSpec)
```

```
CRRTree = struct with fields:
       FinObj: 'BinStockTree'
       Method: 'CRR'
    StockSpec: [1x1 struct]
     TimeSpec: [1x1 struct]
     RateSpec: [1x1 struct]
         tObs: [0 0.2493 0.4986 0.7479 0.9972]
         dObs: [731582 731673 731764 731855 731946]
        STree: {1x5 cell}
      UpProbs: [0.5378 0.5378 0.5378 0.5378]
```

Input Arguments

StockSpec — Stock specification

structure

Stock specification, specified by the `StockSpec` obtained from `stockspec`. See `stockspec` for information on creating a stock specification.

Data Types: `struct`

RateSpec — Interest-rate specification for initial risk-free rate curve

structure

Interest-rate specification for initial risk-free rate curve, specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Note The standard CRR tree assumes a constant interest rate, but `RateSpec` allows you to specify an interest-rate curve with varying rates. If you specify variable interest rates, the resulting tree is not a standard CRR tree.

Data Types: `struct`

TimeSpec — Tree time layout specification

structure

Tree time layout specification, specified by the `TimeSpec` obtained from `crrtimespec`. The `TimeSpec` defines the observation dates of the CRR binomial tree. See `crrtimespec` for information on the tree structure.

Data Types: `struct`

Output Arguments

CRRTree — CRR binomial tree

structure

CRR binomial tree, returned as a structure specifying the time layout for the tree.

Version History

Introduced before R2006a

cvtree

Convert inverse-discount tree to interest-rate tree

Syntax

```
RateTree = cvtree(Tree)
```

Description

`RateTree = cvtree(Tree)` converts a tree structure using inverse-discount notation to a tree structure using rate notation for forward rates.

Examples

Convert a Hull-White Tree Using Inverse-Discount Notation

Convert a Hull-White tree using inverse-discount notation to a Hull-White tree displaying interest-rate notation.

```
load deriv.mat;
HWTree
```

```
HWTree = struct with fields:
      FinObj: 'HWFwdTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [731947 732313 732678 733043]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
     FwdTree: {1x4 cell}
```

```
HWTree.FwdTree{1}
```

```
ans = 1.0279
```

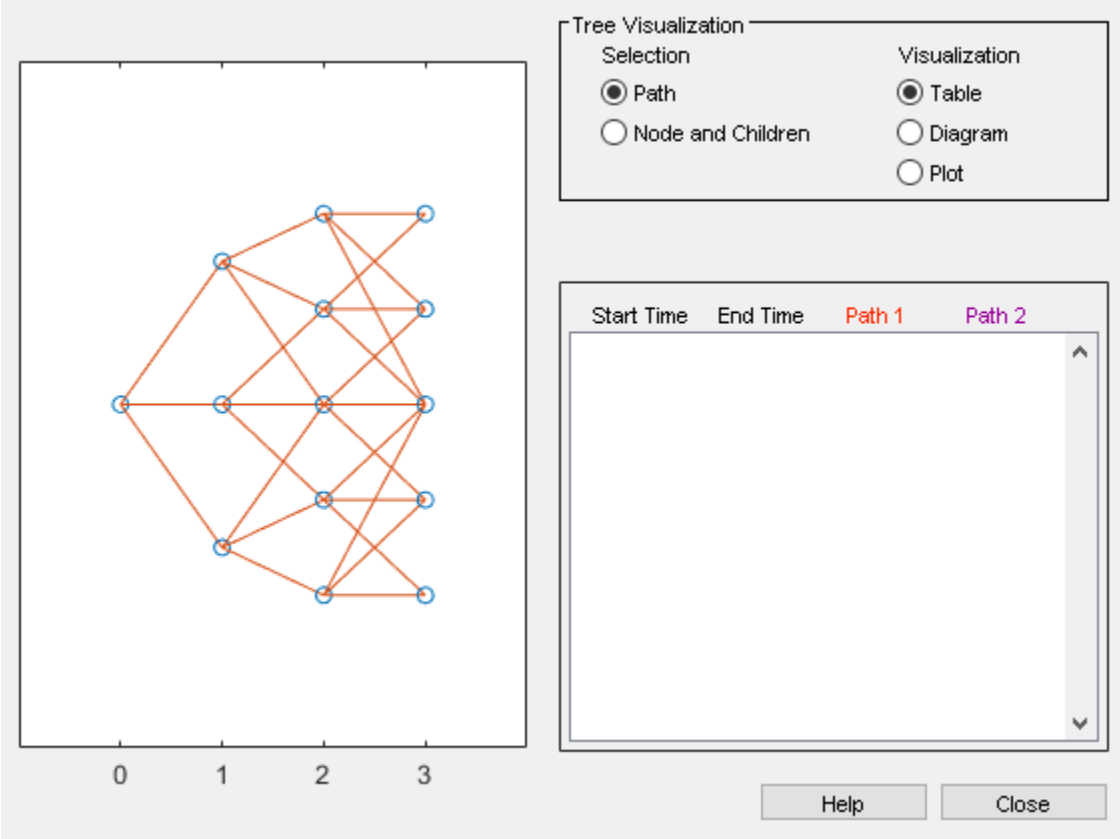
```
HWTree.FwdTree{2}
```

```
ans = 1×3

    1.0528    1.0356    1.0186
```

Use `treeviewer` to display the path of interest rates expressed in inverse-discount notation.

```
treeviewer(HWTree)
```



Use `cvtree` to convert the inverse-discount notation to interest-rate notation.

```
RTree = cvtree(HWTree)
```

```
RTree = struct with fields:
      FinObj: 'HWRateTree'
     VolSpec: [1x1 struct]
    TimeSpec: [1x1 struct]
    RateSpec: [1x1 struct]
        tObs: [0 1 2 3]
        dObs: [731947 732313 732678 733043]
      CFlowT: {[4x1 double]  [3x1 double]  [2x1 double]  [4]}
       Probs: {[3x1 double]  [3x3 double]  [3x5 double]}
     Connect: {[2]  [2 3 4]  [2 2 3 4 4]}
    RateTree: {1x4 cell}
```

```
RTree.RateTree{1}
```

```
ans = 0.0275
```

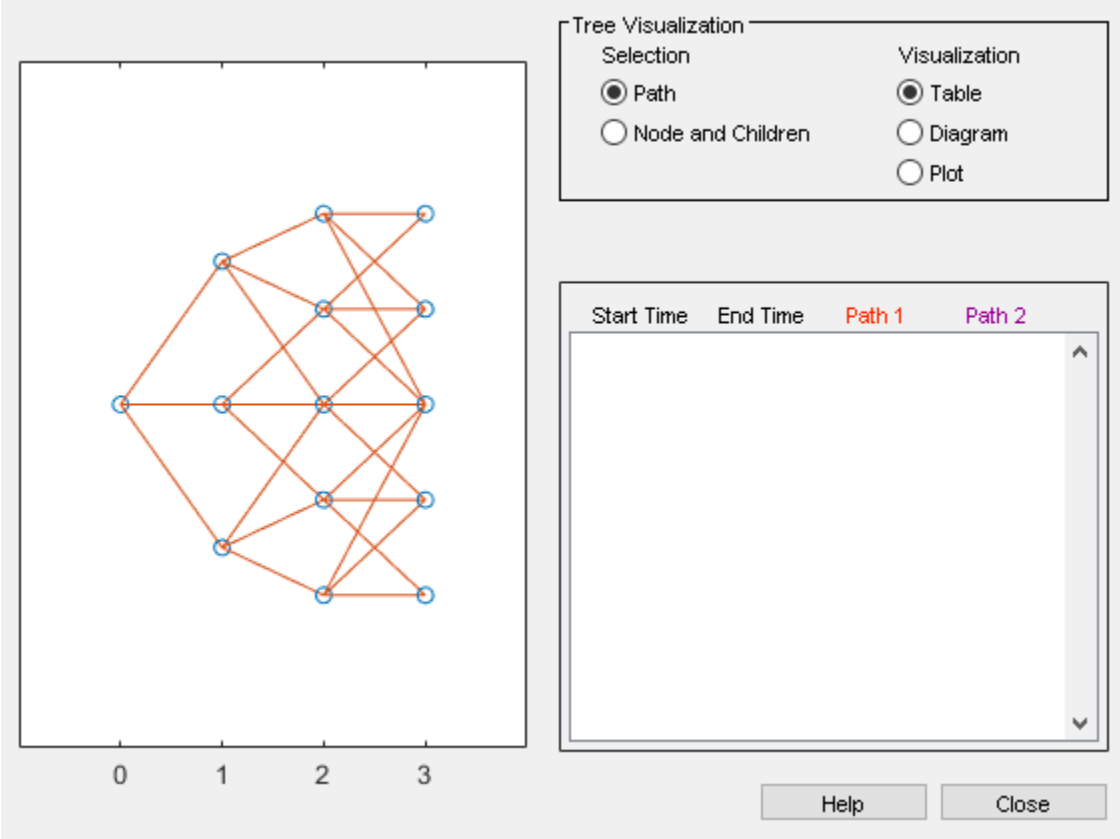
```
RTree.RateTree{2}
```

```
ans = 1×3

    0.0514    0.0349    0.0185
```

use `treeviewer` to display the converted tree, showing the path of interest rates expressed as forward rates.

```
treeviewer(RTree)
```



Input Arguments

`Tree` — Tree structure

HJM Tree | BDT Tree | HW Tree | BK Tree | CIR Tree

Tree structure, specified by Heath-Jarrow-Morton, Black-Derman-Toy, Hull-White, Black-Karasinski, or Cox-Ingersoll-Ross tree structure that uses inverse-discount notation for forward rates.

Data Types: `struct`

Output Arguments

`RateTree` — Tree structure using rate notation for forward rates

structure

Tree structure using rate notation for forward rates, returned as a tree structure.

Version History

Introduced before R2006a

date2time

Time and frequency from dates

Syntax

```
[Times,F] = date2time(Settle,Maturity)
[Times,F] = date2time( ___ ,Compounding,Basis,EndMonthRule)
```

Description

`[Times,F] = date2time(Settle,Maturity)` computes time factors appropriate to compounded rate quotes beyond the settlement date.

`[Times,F] = date2time( ___ ,Compounding,Basis,EndMonthRule)` add additional optional arguments.

Examples

Time and Frequency from Dates

This example shows how to compute time and frequency from dates.

```
Settle = datetime(2002,9,1);
Maturity = [datetime(2005,8,31) ; datetime(2006,2,28) ; datetime(2006,6,15) ; datetime(2006,12,31
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
Times = date2time(Settle, Maturity, Compounding, Basis, EndMonthRule)
```

```
Times = 4×1

    5.9945
    6.9945
    7.5738
    8.6576
```

Input Arguments

`Settle` — Settlement date

datetime scalar | string scalar | date character vector

Settlement date, specified as a scalar datetime, string, or date character vector.

To support existing code, `date2time` also accepts serial date numbers as inputs, but they are not recommended.

`Maturity` — Maturity dates

datetime array | string array | date character vector

Maturity dates, specified as a scalar or an N-by-1 vector using a datetime array, string array, or date character vectors.

To support existing code, `date2time` also accepts serial date numbers as inputs, but they are not recommended.

`Compounding` — Rate at which the input zero rates were compounded when annualized
2 (default) | integer with value of 1, 2, 3, 4, 6, 12, 365, or -1

(Optional) Rate at which the input zero rates were compounded when annualized, specified as a scalar integer value.

- If `Compounding` = 1, 2, 3, 4, 6, 12:

  `Disc = (1 + Z/F)^(-T)`, where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units; for example, `T = F` is one year.
- If `Compounding` = 365:

  `Disc = (1 + Z/F)^(-T)`, where F is the number of days in the basis year and T is a number of days elapsed computed by basis.
- If `Compounding` = −1:

  `Disc = exp(-T*Z)`, where T is time in years.

Data Types: `double`

`Basis` — Day-count basis
0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis, specified as a scalar or an N-by-1 vector using the following values:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-228.

Data Types: `double`

EndMonthRule — End-of-month rule flag
1 (in effect) (default) | nonnegative integer [0,1]

(Optional) End-of-month rule flag, specified as a scalar or an N-by-1 vector of end-of-month rules.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: logical

Output Arguments

Times — Time factors appropriate to compounded rate quotes between Settle and Maturity dates
vector

Time factors appropriate to compounded rate quotes between Settle and Maturity dates, returned as an N-by-1 vector.

F — Frequency
numeric

Frequency, returned as a scalar of related compounding frequencies.

Note To obtain accurate results from this function, the Basis and Maturity arguments must be consistent. If the Maturity argument contains months that have 31 days, Basis must be one of the values that allow months to contain more than 30 days; for example, Basis = 0, 3, or 7.

date2time is the inverse of time2date.

Version History

Introduced before R2006a

Serial date numbers not recommended
Not recommended starting in R2022b

Although date2time supports serial date numbers, datetime values are recommended instead. The datetime data type provides flexible date and time formats, storage out to nanosecond precision, and properties to account for time zones and daylight saving time.

To convert serial date numbers or text to datetime values, use the datetime function. For example:

```
t = datetime(738427.656845093,"ConvertFrom","datenum");
y = year(t)
```

```
y =

        2021
```

There are no plans to remove support for serial date number inputs.

datedisp

Display date entries

Syntax

```
datedisp(NumMat,DateForm)
CharMat = datedisp(NumMat,DateForm)
```

Description

`datedisp(NumMat,DateForm)` displays the matrix with the serial dates formatted as date character vectors, using a matrix with mixed numeric entries and serial date number entries. Integers between `datenum('01-Jan-1900')` and `datenum('01-Jan-2200')` are assumed to be serial date numbers, while all other values are treated as numeric entries.

`CharMat = datedisp(NumMat,DateForm)` displays the output matrix `CharMat`.

Examples

Display Date Entries

This example shows how to display dates for serial date numbers.

```
NumMat = [ 730730, 0.03, 1200, 730100;
           730731, 0.05, 1000, NaN]
```

```
NumMat = 2×4
10^5 ×

    7.3073    0.0000    0.0120    7.3010
    7.3073    0.0000    0.0100       NaN
```

```
datedisp(NumMat)
```

```
01-Sep-2000   0.03   1200   11-Dec-1998
02-Sep-2000   0.05   1000      NaN
```

Input Arguments

`NumMat` — Numeric matrix to display

numeric

Numeric matrix to display, specified as numeric values for serial date numbers.

Data Types: `double`

`DateForm` — date format

character vector

(Optional) Date format, specified as a character vector. See `datestr` for available and default format flags.

Data Types: `char`

Output Arguments

`CharMat` — Character array representing the matrix

array

Character array representing the matrix, returned as an array. If no output variable is assigned, `datedisp` prints the array to the display.

Tips

This function is identical to the `datedisp` function in Financial Toolbox software.

Version History

Introduced before R2006a

derivget

Get derivatives pricing options

Syntax

```
Value = derivget(Options,ParameterName)
```

Description

`Value = derivget(Options,ParameterName)` extracts the value of the specified `ParameterName` argument values from the derivative `Options` structure.

Examples

Get Derivatives Pricing Options

Enable the display of additional diagnostic information that appears when executing pricing functions

```
Options = derivset('Diagnostics','on')
```

```
Options = struct with fields:
      Diagnostics: 'on'
         Warnings: 'on'
        ConstRate: 'on'
    BarrierMethod: 'unenhanced'
```

Use `derivget` to extract the value of `Diagnostics` from the `Options` structure.

```
Value = derivget(Options, 'Diagnostics')
```

```
Value =
'on'
```

Use `derivget` to extract the value of `ConstRate`.

```
Value   = derivget(Options, 'ConstRate')
```

```
Value =
'on'
```

If the value of `'ConstRate'` is not previously set with `derivset`, the answer represents the default setting for `'ConstRate'`.

Find the value of `'BarrierMethod'` in this Options structure.

```
derivget(Options ,'BarrierMethod')
```

```
ans =
'unenhanced'
```

Input Arguments

`Options` — Existing options specification

structure

Existing options specification, specified as a structure obtained from a previous call to `derivset`.

Data Types: `struct`

`ParameterName` — Parameter name to be accessed in `Options` structure

character vector with value of `'Diagnostics'`, `'Warnings'`, `'ConstRate'`, or `'BarrierMethod'`

Parameter name to be accessed in `Options` structure, specified as a character vector for one of the following:

- `'Diagnostics'` — Print diagnostic information with a returned value of `'on'` or `'off'`. This option applies only for HJM, BDT, HW and BK pricing.
- `'Warnings'` — Display warnings with a returned value of `'on'` or `'off'`. This option applies only for HJM, BDT, HW and BK pricing.
- `'ConstRate'` — Assume constant rates between tree nodes with a returned value of `'on'` or `'off'`. This option applies only for HJM, BDT, HW and BK pricing.
- `BarrierMethod` — Method for pricing Barrier option. The returned values are either `'unenhanced'` that uses no correction calculation or `'interp'` that uses an enhanced valuation interpolating between nodes on barrier boundaries.

Data Types: `char`

Output Arguments

`Value` — Value

character vector

Value, returned as a character vector depending on the specified `ParameterName`.

Version History

Introduced before R2006a

derivset

Set or modify derivatives pricing options

Syntax

```
Options = derivset(Options,Name,Value)
Options = derivset(Name,Value)
Options = derivset(OldOptions,NewOptions)
Options = derivset
derivset
```

Description

`Options = derivset(Options,Name,Value)` modifies an existing derivatives pricing options structure `Options` by changing the specified name-value pair argument values.

`Options = derivset(Name,Value)` creates a derivatives pricing options structure `Options` using the specified name-value pair argument values. Any unspecified name-value arguments are set to default values for when the `Options` output is passed to the derivatives function.

`Options = derivset(OldOptions,NewOptions)` combines an existing options structure `OldOptions` with a new options structure `NewOptions`. Any parameters in `NewOptions` with nonempty values overwrite the corresponding old parameters in `OldOptions`.

`Options = derivset` creates an options structure `Options` where all the parameters are set to the default values.

`derivset` with no input or output arguments displays all parameter names and information about their possible values.

Examples

Set or Modify Derivatives Pricing Options

Enable the display of additional diagnostic information that appears when executing pricing functions

```
Options = derivset('Diagnostics','on')
```

```
Options = struct with fields:
      Diagnostics: 'on'
         Warnings: 'on'
        ConstRate: 'on'
    BarrierMethod: 'unenhanced'
```

Change the `ConstRate` parameter in the existing `Options` structure so that the assumption of constant rates between tree nodes no longer applies.

```
Options = derivset(Options, 'ConstRate', 'off')
```

```
Options = struct with fields:
      Diagnostics: 'on'
         Warnings: 'on'
        ConstRate: 'off'
    BarrierMethod: 'unenhanced'
```

With no input or output arguments, `derivset` displays all parameter names and information about their possible values.

```
derivset
```

```
            Diagnostics: [ on   | {off} ]
               Warnings: [ {on} | off   ]
              ConstRate: [ {on} | off   ]
          BarrierMethod: [ {unenhanced} | interp ]
```

Input Arguments

`Options` — Existing options specification

structure

Existing options specification, specified as a structure obtained from a previous call to `derivset`.

Data Types: `struct`

`OldOptions` — Existing options specification

structure

Existing options specification, specified as a structure obtained from a previous call to `derivset`.

Data Types: `struct`

`NewOptions` — New options specification

structure

New options specification, specified as a structure.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional pairs of arguments as `Name1=Value1,...,NameN=ValueN`, where `Name` is the argument name and `Value` is the corresponding value. Name-value arguments must appear after other arguments, but the order of the pairs does not matter.

Before R2021a, use commas to separate each name and value, and enclose `Name` *in quotes.*

Example: `Options = derivset(Options, 'ConstRate', 'off')`

`Diagnostics` — Print diagnostic information

character vectors with value `'on'` or `'off'`

Print diagnostic information, specified as the comma-separated pair consisting of `'Diagnostics'` and a character vector. This option applies only for HJM, BDT, HW and BK pricing.

Data Types: `char`

`Warnings` — Display warnings
character vectors with value `'on'` or `'off'`

Display warnings, specified as the comma-separated pair consisting of `'Warnings'` and a character vector. This option applies only for HJM, BDT, HW and BK pricing.

Data Types: `char`

`ConstRate` — Assume constant rates between tree nodes
character vectors with value `'on'` or `'off'`

Assume constant rates between tree nodes, specified as the comma-separated pair consisting of `'ConstRate'` and a character vector. This option applies only for HJM, BDT, HW and BK pricing.

Data Types: `char`

`BarrierMethod` — Method for pricing Barrier option
`'unenhanced'` (default) | character vector with value of `'unenhanced'` or `'interp'`

Method for pricing Barrier option, specified as the comma-separated pair consisting of `'BarrierMethod'` and a character vector. Specifying `'unenhanced'` uses no correction calculation. Specifying `'interp'` uses an enhanced valuation interpolating between nodes on barrier boundaries.

Data Types: `char`

Output Arguments

`Options` — Options specification
structure

Options specification, returned as a structure encapsulating the properties of a derivatives option.

Version History

Introduced before R2006a

disc2rate

Interest rates from cash flow discounting factors

Syntax

```
Rates = disc2rate(Compounding,Disc,EndTimes,StartTimes)
[Rates,EndTimes,StartTimes] = disc2rate(Compounding,Disc,EndTimes,StartTimes,
ValuationDate,Basis,EndMonthRule)
```

Description

`Rates = disc2rate(Compounding,Disc,EndTimes,StartTimes)` computes interest rates from discount factors where interval points are input as times in periodic units.

`disc2rate` computes the yields over a series of `NPOINTS` time intervals given the cash flow discounts over those intervals. `NCURVES` different rate curves can be translated at once if they have the same time structure. The time intervals can represent a zero or a forward curve.

The output `Rates` is an `NPOINTS`-by-`NCURVES` column vector of yields in decimal form over the `NPOINTS` time intervals.

`[Rates,EndTimes,StartTimes] = disc2rate(Compounding,Disc,EndTimes,StartTimes,
ValuationDate,Basis,EndMonthRule)` computes interest rates from discount factors where `ValuationDate` is passed and interval points are input as dates.

You can specify the investment intervals either with input times or with input dates. Entering `ValuationDate` invokes the date interpretation; omitting `ValuationDate` invokes the default time interpretations.

Examples

Compute Interest Rates from Cash Flow Discounting Factors

This example shows the two uses of `disc2rate`.

Interval Points Are Input as Times in Periodic Units

Compute rates from a zero curve at 6 months, 12 months, and 24 months, given the discount factors for these periods. The times to the cash flows are 1, 2, and 4. `disc2rate` assumes that the valuation date corresponds to time = 0.

```
Compounding = 2;
Disc = [0.9756; 0.9426; 0.8799];
EndTimes   = [1; 2; 4];
Rates = disc2rate(Compounding, Disc, EndTimes)
```

```
Rates = 3×1

    0.0500
    0.0600
```

```
    0.0650
```

Interval Points Are Input as Dates

Compute rates from a zero curve at 6 months, 12 months, and 24 months, given the discount factors for these periods. Use dates to specify the ending time horizon.

```
Compounding = 2;
Disc = [0.9756; 0.9426; 0.8799];
EndDates = ['10/15/97'; '04/15/98'; '04/15/99'];
ValuationDate = '4/15/97';
Rates = disc2rate(Compounding, Disc, EndDates, [], ValuationDate)
```

```
Rates = 3×1

    0.0500
    0.0600
    0.0650
```
