## AC Cable (Three-Phase)

Three-phase AC power cable

**Library:** Simscape / Electrical / Passive / Lines

### Description

The AC Cable (Three-Phase) block represents a three-phase AC power cable with a conducting sheath surrounding each phase. The figure shows a single-phase conductor inside a conducting sheath. The inner cylinder represents the main conductor for the phase, and the outer cylinder represents the conducting sheath.

You can model composite or expanded three-phase ports by setting the **Modeling option** parameter to either:

- **Composite three-phase ports** — Contains three-phase connection ports for the sheaths and phases and a single-phase connection port for each electrical reference node.
- **Expanded three-phase ports** — Contains single-phase connection ports for each sheath, phase, and electrical reference node.

The AC Cable (Three-Phase) block includes inductances and mutual inductances between each phase, sheath, and return path. Therefore, you can connect an ideal electrical reference block to both return ports, **g1** and **g2**, while maintaining loss modeling in the Earth- or neutral-return line.

To facilitate simulation convergence when you connect the AC Cable (Three-Phase) block to a source block, include source impedance using one of these methods:

- Configure the source block to include impedance.
- Insert a block that models impedance between the source block and the AC Cable (Three-Phase) block.

To model unbonded sheaths, connect the unbonded sheaths to an Open Circuit (Three-Phase) block. The figure shows a model of single-point bonding when you set **Modeling option** to Composite three-phase ports.

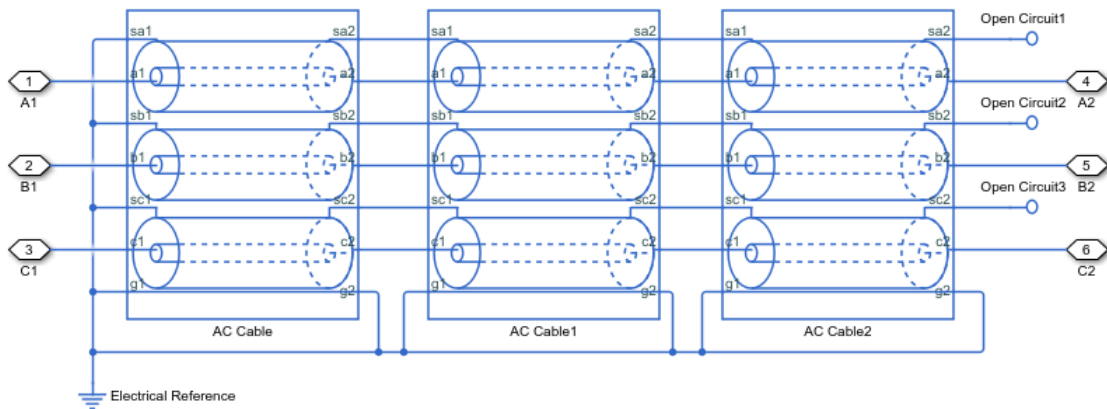

For high performance modeling, in terms of simulation speed, use a single AC Cable (Three-Phase) block. To improve model fidelity in terms of frequency behavior, connect several AC Cable (Three-Phase) blocks in series. For series-connected blocks, the sheaths and main conductors act as coupled transmission lines with perfect transposition of the phases. The number of AC Cable (Three-Phase) blocks that you use to model a particular physical length of cable must be less than the number of transpositions in the physical system that you are modeling. Types of continuous multi-segment cables that you can model include:

- Unbonded continuous cables

- Single-point bonded continuous cables

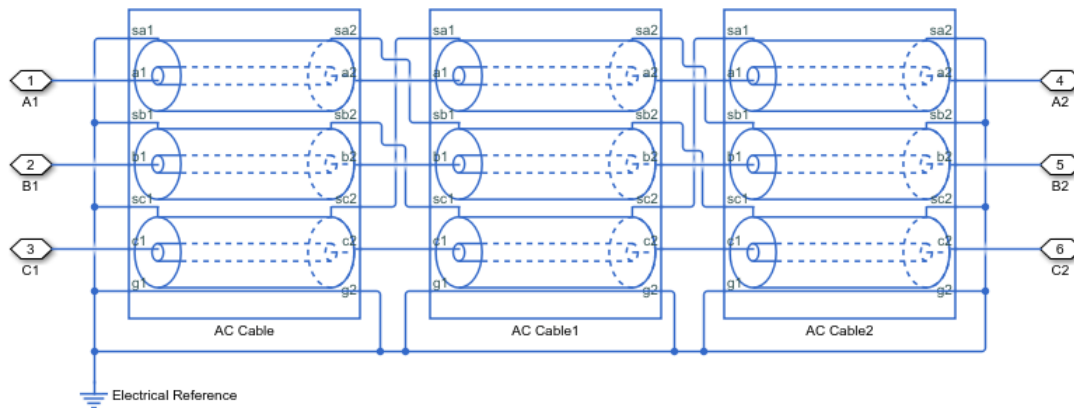

- Double-point bonded continuous cables

You can also model cross-bonded cables using the AC Cable (Three Phase) block.

This three pi-segment cable model implements cross-bonding using expanded three-phase ports and single-phase connection lines. The sheath in the model is two-point bonded.

This model of blocks with composite three-phase-ports uses Phase Permute blocks to implement cross bonding. The sheath in the model is unbonded.

For an example that allows you to choose the number of segments and type of bonding, see “AC Cable with Bonded Sheaths”.

### Three-Phase AC Cable Model

The AC Cable (Three-Phase) block uses the concept of partial inductances to calculate the inductance values. These values include the partial self-inductance of each phase, sheath, and return path and the partial mutual inductances between each:

- Phase and each other phase
- Phase and the sheath of that phase
- Phase and the sheath of neighboring phases
- Phase and the return
- Sheath and each neighboring sheath
- Sheath and the return

For three equivalent phases, the matrix that defines the resistance relationships for the vector [phase A; sheath A; phase B; sheath B; phase C; sheath C] is

$$R = \begin{bmatrix} R_a + R_g & R_g & R_g & R_g & R_g & R_g \\ R_g & R_s + R_g & R_g & R_g & R_g & R_g \\ R_g & R_g & R_a + R_g & R_g & R_g & R_g \\ R_g & R_g & R_g & R_s + R_g & R_g & R_g \\ R_g & R_g & R_g & R_g & R_a + R_g & R_g \\ R_g & R_g & R_g & R_g & R_g & R_s + R_g \end{bmatrix}$$

$$R_a = R'_a l$$

$$R_g = R'_{\text{return}} l,$$

for which  $R'_{\text{return}}$  depends on the return parameterization method such that:

- For a return parameterization based on distance and resistance  $R'_{\text{return}} = R'_g$ .
- For a return parameterization based on frequency and Earth resistivity  $R'_{\text{return}} = \pi^2 10^{-7} f$

and

$$R_s = R'_s l,$$

where:

- $R$  is the resistance matrix.
- $R_a$  is the resistance of a particular phase.
- $R_s$  is the resistance of a particular sheath.
- $R_g$  is the resistance of the Earth- or neutral-return.
- $R'_a$  is the resistance per unit length for the phase.
- $l$  is the cable length.
- $R'_s$  is the resistance per unit length for the sheath.
- $R'_{\text{return}}$  is the resistance per unit length of the return. The value of  $R'_{\text{return}}$  varies depending on the return parameterization method.
- $R'_g$  is the resistance per unit length for the Earth- or neutral return.
- $f$  is the frequency that the block uses to calculate Earth-return parameters if you parameterize the block using the frequency and Earth resistivity method.

The block uses standard expressions to calculate the capacitances between:

- Concentric or adjacent cylinders
- Each phase and its own sheath
- Each sheath and the return

The matrix that defines these capacitance relationships is

$$C = \begin{bmatrix} C_{as_a} & -C_{as_a} & 0 & 0 & 0 & 0 \\ -C_{as_a} & C_{as_a} + C_{s_ag} & 0 & 0 & 0 & 0 \\ 0 & 0 & C_{as_a} & -C_{as_a} & 0 & 0 \\ 0 & 0 & -C_{as_a} & C_{as_a} + C_{s_ag} & 0 & 0 \\ 0 & 0 & 0 & 0 & C_{as_a} & -C_{as_a} \\ 0 & 0 & 0 & 0 & -C_{as_a} & C_{as_a} + C_{s_ag} \end{bmatrix}$$

$$C_{as_a} = \frac{2\pi\epsilon_r\epsilon_0 l}{\ln\left(\frac{r_s}{r_a}\right)}$$

$$r_a = GMR \cdot e^{\frac{1}{4}}$$

$$C_{s_ag} = \frac{2\pi\epsilon_{env}\epsilon_0 l}{\ln\left(\frac{r_{cable}}{r_{s,outer}}\right)}$$

where:

- $C$  is the capacitance matrix.
- $C_{as_a}$  is the capacitance between each phase and the sheath of that phase.
- $C_{s_ag}$  is the capacitance between each sheath and return.
- $\epsilon_r$  is the permittivity of the dielectric.
- $\epsilon_0$  is the permittivity of free space.
- $r_s$  is the radius of the sheath.
- $r_a$  is the effective radius of the conductor. For a single-strand conductor,  $r_a$  is the radius of the strand.
- $r_{cable}$  is the cable radius and  $r_{cable}$  is greater than  $r_{s,outer}$ .
- $GMR$  is the geometric mean radius of the conductor. For a single-strand conductor,  $GMR = r_{strand}e^{-\frac{1}{4}}$ , where  $r_{strand}$  is the radius of the strand.
- $\epsilon_{env}$  is the permittivity of the material between the sheathed lines and the return path.

The block uses the concept of partial inductances to calculate inductance values. These values include the partial self-inductance of each phase, sheath, and return path and the partial mutual inductances between each:

- Phase and each other phase
- Phase and the sheath of that phase
- Phase and the sheath of neighboring phases
- Phase and the return
- Sheath and each neighboring sheath
- Sheath and the return

The equations that define these inductance relationships are:

$$L = \begin{bmatrix} D_a & \delta & A & \alpha & A & \alpha \\ \delta & D_s & \alpha & S & \alpha & S \\ A & \alpha & D_a & \delta & A & \alpha \\ \alpha & S & \delta & D_s & \alpha & S \\ A & \alpha & A & \alpha & D_a & \delta \\ \alpha & S & \alpha & S & \delta & D_s \end{bmatrix}$$

$$D_a = L_a - M_{ag}$$

$$L_a = 2 \times 10^{-7} l \left[ \ln\left(\frac{2l}{r_a}\right) - \frac{3}{4} \right]$$

$$M_{ag} = M_{sg} = 2 \times 10^{-7} l \left[ \ln\left(\frac{2l}{D_{\text{return}}}\right) - 1 \right]$$

for which  $D_{\text{return}}$  depends on the return parameterization method such that:

- For a return parameterization based on distance and resistance  $D_{\text{return}} = D_e$ .
- For a return parameterization based on frequency and Earth resistivity  $D_{\text{return}} = 1650 \sqrt{\frac{\rho}{2\pi f}}$ .

$$D_s = L_s - M_{sg}$$

$$L_s = M_{asa} = 2 \times 10^{-7} l \left[ \ln\left(\frac{2l}{r_s}\right) - \frac{3}{4} \right]$$

$$\delta = M_{asa} - M_{ag}$$

$$\alpha = M_{asb} - M_{ag}$$

$$M_{asb} = M_{sasb} = M_{ab} = 2 \times 10^{-7} l \left[ \ln\left(\frac{2l}{d_{ab}}\right) - 1 \right],$$

for which  $d_{ab}$  depends on the line formation parameterization method, such that:

- For a trefoil line formation parameterization  $d_{ab} = D_{ab}$ .
- For a flat line formation parameterization  $d_{ab} = D_{ab} \sqrt[3]{2}$ .

$$A = M_{ab} - M_{ag}$$

$$S = M_{sasb} - M_{sg},$$

where:

- $L$  is the inductance matrix.
- $D_a$  is the self-inductance of a single phase through its entire path and return.
- $L_a$  is the partial self-inductance of each phase.
- $M_{ag}$  is the partial mutual inductance between each phase and the Earth- or neutral-return.
- $M_{sg}$  is the partial mutual inductance between each sheath and the Earth- or neutral-return.
- The factor,  $2 \times 10^{-7}$  is equal to  $\mu_0/2\pi$ , because permeability of free space,  $\mu_0$ , is equal to  $1.257 \times 10^{-6}$  or  $4\pi \times 10^{-7}$  H/m.

- $D_s$  is the self-inductance of a single sheath through its entire path and return.
- $L_s$  is the partial self-inductance of each sheath.
- $M_{as_a}$  is the partial mutual inductance between each phase and the sheath of that phase.
- $\delta$  is the effective mutual inductance between a phase and the sheath of that phase.
- $\alpha$  is the effective mutual inductance between a phase and a neighboring sheath.
- $M_{as_b}$  is the partial mutual inductance between each phase and the sheath of each neighboring phase.
- $M_{s_a s_b}$  is the partial mutual inductance between sheaths of different phases.
- $M_{ab}$  is the partial mutual inductance between each phase and each other phase.
- $D_{return}$  is the effective distance to the return. The value of  $D_{return}$  varies if you use the distance/return parameterization method.
- $D_e$  is the effective distance to the Earth- or neutral-return.
- $\rho$  is the effective Earth resistivity for an Earth-return.
- $f$  is the frequency that is used to determine the return path properties.
- $d_{ab}$  is the effective distance between adjacent phases. The value of  $d_{ab}$  varies depending on the line parameterization method.
- $D_{ab}$  is the center-to-center distance between adjacent phases.
- $A$  is the effective mutual inductance between phases.
- $S$  is the effective mutual inductance between sheaths.

A modal transformation that is related to the Clarke transform simplifies the equivalent circuit. The six-by-six transformation,  $T$ , is

$$T = \frac{1}{\sqrt{3}} \begin{bmatrix} 1 & 0 & \sqrt{2} & 0 & 0 & 0 \\ 0 & 1 & 0 & \sqrt{2} & 0 & 0 \\ 1 & 0 & -\frac{1}{\sqrt{2}} & 0 & \frac{\sqrt{3}}{2} & 0 \\ 0 & 1 & 0 & -\frac{1}{\sqrt{2}} & 0 & \frac{\sqrt{3}}{2} \\ 1 & 0 & -\frac{1}{\sqrt{2}} & 0 & -\frac{\sqrt{3}}{2} & 0 \\ 0 & 1 & 0 & -\frac{1}{\sqrt{2}} & 0 & -\frac{\sqrt{3}}{2} \end{bmatrix}.$$

As  $T^\dagger = T^{-1}$ , applying the  $T$  transform yields the modal resistance matrix,  $R_m$ , the modal capacitance matrix,  $C_m$ , and the modal inductance matrix,  $L_m$ .

The transformed matrices are:

$$R_m = T^\dagger R T = \begin{bmatrix} R_a + 3R_g & 3R_g & 0 & 0 & 0 & 0 \\ 3R_g & R_s + 3R_g & 0 & 0 & 0 & 0 \\ 0 & 0 & R_a & 0 & 0 & 0 \\ 0 & 0 & 0 & R_s & 0 & 0 \\ 0 & 0 & 0 & 0 & R_a & 0 \\ 0 & 0 & 0 & 0 & 0 & R_s \end{bmatrix}$$

$$C_m = T^\dagger C T = \begin{bmatrix} C_{as_a} & -C_{as_a} & 0 & 0 & 0 & 0 \\ -C_{as_a} & C_{as_a} + C_{s_a g} & 0 & 0 & 0 & 0 \\ 0 & 0 & C_{as_a} & -C_{as_a} & 0 & 0 \\ 0 & 0 & -C_{as_a} & C_{as_a} + C_{s_a g} & 0 & 0 \\ 0 & 0 & 0 & 0 & C_{as_a} & -C_{as_a} \\ 0 & 0 & 0 & 0 & -C_{as_a} & C_{as_a} + C_{s_a g} \end{bmatrix} = C$$

$$L_m = T^\dagger L T = \begin{bmatrix} D_a + 2A & \delta + 2\alpha & 0 & 0 & 0 & 0 \\ \delta + 2\alpha & D_s + 2A & 0 & 0 & 0 & 0 \\ 0 & 0 & D_a - A & \delta - \alpha & 0 & 0 \\ 0 & 0 & \delta - \alpha & D_s - S & 0 & 0 \\ 0 & 0 & 0 & 0 & D_a - A & \delta - \alpha \\ 0 & 0 & 0 & 0 & \delta - \alpha & D_s - S \end{bmatrix}.$$

The transformation changes each six-by-six matrix into three uncoupled two-by-two matrices. The capacitance matrix is invariant under this transformation. The power is invariant in the transformed and untransformed domains because  $T$  is unitary.

### Assumptions and Limitations

- For resistance calculations, the phases are equivalent.
- Relative to the phase-to-sheath capacitance and the sheath-return capacitances all other capacitances, are negligible due to the shielding provided by the conducting sheaths.

**Parameters****Modeling option — Whether to model composite or expanded three-phase ports**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

Expanded three-phase ports represent the individual phases of a three-phase system using three separate electrical conserving ports.

**Cable length — Length**

120 km (default)

Length of the cable.

**Geometric mean radius of conductor — Radius**

5 mm (default)

Geometric mean radius of the conductor, which is a function of the number and type of individual strands in the conductor of the AC cable.

**Sheath radius — Radius**

10 mm (default)

Average radius of the sheath. To ensure that the sheath radius is greater than the physical radius of a single-stranded conductor with a particular GMR, the sheath radius must be greater than  $GMR * e^{\frac{1}{4}}$ .

**Outer cable radius — Outer radius**

20 mm (default)

Outer radius of the cable, in mm. The cable radius must be greater than the **Sheath radius** parameter. This ensures that the sheath and conductor are both enclosed inside an insulating outer cable layer.

**Line-line spacing (center-to-center) — Distance**

25 mm (default)

Distance between the line centers.

**Line formation — Line configuration**

Trefoil (default) | Flat

Cable line formation.

**Conductor resistance per length – Resistance**

1 Ohm/km (default)

Resistance per length of a conductor.

**Sheath resistance per length – Resistance**

10 Ohm/km (default)

Resistance per length of a sheath.

**Insulation relative permittivity – Permittivity**

2.4 (default)

Relative permittivity of the insulation.

**Relative permittivity between lines and return path – Relative permittivity**

1 (default)

Relative permittivity of the circuit.

**Return parameterization – Model**

# Accelerometer

Behavioral model of MEMS accelerometer

**Library:** Simscape / Electrical / Sensors & Transducers

## Description

The Accelerometer block implements a behavioral model of a MicroElectroMechanical Systems (MEMS) accelerometer. For the default output type `Voltage level`, the accelerometer provides an output voltage that is proportional to the acceleration rate presented at the mechanical translational physical port R. The output voltage is limited according to the values that you provide for maximum and minimum output voltage.

The block also has an alternative output type, `PWM duty cycle`. With this choice, the output of the block is a PWM signal with a duty cycle that is proportional to the measured acceleration. You can limit the variation in duty cycle to a specified range.

Optionally, you can model sensor dynamics by setting the **Dynamics** parameter to `Model sensor bandwidth`. Including dynamics adds a first-order lag between the angular rate presented at port R and the corresponding voltage applied to the electrical + and - ports.

If running your simulation with a fixed-step solver, or generating code for hardware-in-the-loop testing, MathWorks recommends that you set the **Dynamics** parameter to `No dynamics – Suitable for HIL`, because this avoids the need for a small simulation time step if the sensor bandwidth is high.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

The **Measured acceleration** variable target specifies the initial output for the sensor.

Mechanical conserving port associated with the accelerometer translational port.

#### **+ — Positive port**

electrical

Electrical conserving port associated with the accelerometer positive terminal.

#### **- — Negative port**

electrical

Electrical conserving port associated with the accelerometer negative terminal.

## Parameters

### **Output type — Block output type**

Voltage level (default) | PWM duty cycle

Select one of the following options to define the block output type:

- **Voltage level** — The amplitude of the output voltage is proportional to the measured acceleration. This is the default option.
- **PWM duty cycle** — The duty cycle (on time divided by the pulse total time) is proportional to the measured acceleration.

### **Sensitivity — Sensitivity**

1000 mV/gee (default)

Change in output voltage level per unit change in acceleration when the output is not being limited.

#### **Dependencies**

This parameter is visible only when you select **Voltage level** for the **Output type** parameter.

### **Output voltage for zero acceleration — Output voltage for zero acceleration**

2.5 V (default)

The output voltage from the sensor when the acceleration is zero.

#### **Dependencies**

This parameter is visible only when you select **Voltage level** for the **Output type** parameter.

### **Maximum output voltage — Maximum output voltage**

4 V (default)

The maximum output voltage from the sensor, which determines the sensor maximum measured positive acceleration.

#### **Dependencies**

This parameter is visible only when you select **Voltage level** for the **Output type** parameter.

### **Minimum output voltage — Minimum output voltage**

1 V (default)

The minimum output voltage from the sensor, which determines the sensor maximum measured negative acceleration. This parameter is only visible when you select `Voltage` level for the **Output type** parameter. The default value is 1 V.

**Duty cycle sensitivity (percent per unit acceleration) – Duty cycle sensitivity**  
10 1/gee (default)

The change in duty cycle per unit acceleration. Duty cycle is expressed as a percentage of the PWM period.

**Dependencies**

This parameter is visible only when you select `PWM duty cycle` for the **Output type** parameter.

**Duty cycle for zero acceleration (percent) – Duty cycle for zero acceleration**  
50 (default)

The duty cycle output by the sensor when the acceleration is zero.

**Dependencies**

This parameter is visible only when you select `PWM duty cycle` for the **Output type** parameter.

**Maximum duty cycle (percent) – Maximum duty cycle**  
75 (default)

The maximum duty cycle output by the sensor. Increasing acceleration levels beyond this point will not register an increase in duty cycle.

**Dependencies**

This parameter is visible only when you select `PWM duty cycle` for the **Output type** parameter.

**Minimum duty cycle (percent) – Minimum duty cycle**  
25 (default)

The minimum duty cycle output by the sensor. Decreasing acceleration levels beyond this point will not register a decrease in duty cycle.

**Dependencies**

This parameter is visible only when you select `PWM duty cycle` for the **Output type** parameter.

**PWM frequency – PWM frequency**  
1000 Hz (default)

The frequency of the output pulse train.

**Dependencies**

This parameter is visible only when you select `PWM duty cycle` for the **Output type** parameter.

**Output voltage amplitude – Output voltage amplitude**  
5 V (default)

The amplitude of the output pulse train when high.

### Dependencies

This parameter is visible only when you select `PWM duty cycle` for the **Output type** parameter.

### Dynamics — Dynamics

`No dynamics – Suitable for HIL (default) | Model sensor bandwidth`

Select one of the following options for modeling sensor dynamics:

- `No dynamics – Suitable for HIL` — Do not model sensor dynamics. Use this option when running your simulation fixed step or generating code for hardware-in-the-loop testing, because this avoids the need for a small simulation time step if the sensor bandwidth is high. This is the default option.
- `Model sensor bandwidth` — Model sensor dynamics with a first-order lag approximation, based on the **Bandwidth** parameter value. You can control the initial condition for the lag by specifying the **Measured acceleration** variable target.

### Bandwidth — Bandwidth

`3 kHz (default)`

Specifies the 3dB bandwidth for the measured acceleration assuming a first-order time constant.

### Dependencies

This parameter is visible only when you select `Model sensor bandwidth` for the **Dynamics** parameter.

Behavioral model of AC-DC converter

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

### Description

This block represents the behavioral model of an AC-DC converter. Use this block to model AC-DC converters without simulating individual switching events. Use the DC voltage reference input to convert the electrical energy between the AC and DC sides.

This block is compatible with time simulation mode and frequency-and-time simulation mode.

### Equations

#### DC Side

At the DC side, if you set the **Voltage dynamics at DC side** parameter to **No dynamics**, the block calculates the output voltage,  $V_{DC}$ , by using this equation:

$$V_{DC} = V_{ref} - DI_{DC},$$

where  $V_{ref}$  is the value of the input signal at the **Vref** port,  $D$  is the value of the **Output DC voltage droop with output current** parameter, and  $I_{DC}$  is the output DC current.

If you set the **Voltage dynamics at DC side** parameter to **Specify voltage regulation time constant**, the block calculates the output voltage,  $V_{DC}$ , by using this equation:

$$\tau_{DC}\dot{V}_{DC} + V_{DC} = V_{ref} - DI_{DC},$$

where  $\tau_{DC}$  is the value of the **Voltage regulation time constant at DC side** parameter.

The power at the DC side is

$$P_{DC} = V_{DC}I_{DC}.$$

#### AC Side

If you set the **Power balance dynamics** parameter to **No dynamics**, the input power at the AC side is equal to the output power at the DC side.

$$P_{AC} = P_{DC}.$$

If you set the **Power balance dynamics** parameter to **Specify power time constant**, the block calculates the input power at the AC side by using this equation:

$$\tau_P \dot{P}_{AC} + P_{AC} = P_{DC},$$

where  $\tau_P$  is the value of the **Power balance time constant** parameter.

To determine the three-phase input currents at the AC side, the block first calculates the  $dq$ -axes voltages,  $v_d$  and  $v_q$ , using the Park transform on the  $abc$ -phase voltages,  $v_a$ ,  $v_b$ , and  $v_c$ :

$$\begin{bmatrix} v_d \\ v_q \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \sin\theta & \sin(\theta - 120^\circ) & \sin(\theta + 120^\circ) \\ \cos\theta & \cos(\theta - 120^\circ) & \cos(\theta + 120^\circ) \end{bmatrix} \begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix}$$

where  $\theta = 2\pi F_{\text{rated}} \cdot t$  is the angle of the synchronously rotating reference frame.

The block then calculates the three-phase AC currents,  $i_a$ ,  $i_b$ , and  $i_c$ , by using these power equations:

$$P_{AC} = \frac{3}{2}(v_d i_d + v_q i_q)$$

$$Q_{AC} = 0 = \frac{3}{2}(v_d i_q - v_q i_d).$$

From these equations, the  $dq$ -axes currents,  $i_d$  and  $i_q$ , are

$$i_d = \frac{2}{3} \frac{P_{AC} v_{dx}}{v_{dx}^2 + v_{qx}^2}$$

$$i_q = \frac{2}{3} \frac{P_{AC} v_{qx}}{v_{dx}^2 + v_{qx}^2},$$

where  $v_{dx}$  and  $v_{qx}$  are obtained from these equations:

$$\tau_{AC} \dot{v}_{dx} + v_{dx} = v_d$$

$$\tau_{AC} \dot{v}_{qx} + v_{qx} = v_q,$$

where  $\tau_{AC}$  is the value of the **Voltage time constant at AC side** parameter.

Finally, the block calculates the three-phase AC currents that flow into the converter by using this equation:

$$\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} = \begin{bmatrix} \sin\theta & \cos\theta \\ \sin(\theta - 120^\circ) & \cos(\theta - 120^\circ) \\ \sin(\theta + 120^\circ) & \cos(\theta + 120^\circ) \end{bmatrix} \begin{bmatrix} i_d \\ i_q \end{bmatrix}.$$

## Limitations

The AC-DC Converter (Three-Phase) block does not model the power losses.

### **Parameters**

#### **Electrical connection — Electrical connection**

Composite three-phase ports (default) | Expanded three-phase ports

Option to model composite or expanded three-phase ports.

**Output DC voltage droop with output current — Voltage droop at 1 A**

1V/A (default) | nonnegative scalar

Amount of voltage that the output DC voltage drops from the set point for an output current of 1 A.

**Voltage dynamics at DC side — Dynamics model at DC side**

No dynamics (default) | Specify voltage regulation time constant

Option to include voltage regulation dynamics. If you set this parameter to `No dynamics`, the block does not consider the voltage regulation dynamics. If you set this parameter to `Specify voltage regulation time constant`, the block adds a first-order lag to the equation that defines the value of the DC voltage source.

**Voltage regulation time constant at DC side — Voltage dynamics time constant at DC side**

0.02 s (default) | positive scalar

Time constant associated with the voltage transients at the DC side when the load current at the DC side is stepped.

**Dependencies**

To enable this parameter, set **Voltage dynamics at DC side** to `Specify voltage regulation time constant`.

**Initial output voltage at DC side — Output voltage at DC side at time zero**

100 V (default) | scalar

DC side output voltage at time zero. To initialize the model with no transients when it delivers a steady-state load current, use this parameter to set the initial DC side output voltage.

**Dependencies**

To enable this parameter, set **Voltage dynamics at DC side** to `Specify voltage regulation time constant`.

**Rated electrical frequency at AC side — Rated electrical frequency at AC side**

60 Hz (default) | positive scalar

Rated electrical frequency at AC side.

**Minimum AC side voltage (phase-to-phase RMS) — Minimum AC-side voltage**

80 V (default) | positive scalar

Minimum value of the phase-to-phase RMS AC-side voltage for the converter to produce a DC output voltage.

**Voltage time constant at AC side — Voltage time constant at AC-side**

0.01 s (default) | positive scalar

Time constant associated with the voltage measurement transients at the AC side.

**Initial voltage at AC side (phase-to-phase RMS) — AC-side initial voltage**

100 V (default) | positive scalar

Phase-to-phase RMS voltage at the AC-side at time zero. The value of this parameter must be greater than the value of the **Minimum AC side voltage (phase-to-phase RMS)** parameter.

**Initial voltage angle at AC side — Initial voltage angle of a-phase at AC side**

0 deg (default) | scalar

Initial voltage angle of the *a*-phase at time zero for the AC side.

**Power balance dynamics — Option to include power balance dynamics**

Specify power time constant (default) | No dynamics

Whether to include power balance dynamics. If you set this parameter to `No dynamics`, the block does not consider power balance dynamics. If you set this parameter to `Specify power time constant`, the block adds a first-order lag to the equation that defines the AC-side power. When you enable the dynamics, a DC-side output power change results in a transient change in the input power at the AC side.

**Power balance time constant — Time constant for power balance dynamics**

0.01 s (default) | positive scalar

Time constant associated with the transients of the power balance between the AC and DC side.

**Dependencies**

To enable this parameter, set **Power balance dynamics** to `Specify power time constant`.

**Initial active power — Initial active power at AC side**

1e3 W (default) | scalar

Initial active power at time zero at the AC side.

**Dependencies**

To enable this parameter, set **Power balance dynamics** to `Specify power time constant`.

**Parasitic conductance to electrical reference — Parasitic conductance to electrical reference**

1e-6 S (default) | nonnegative scalar

Parasitic conductance to the electrical reference.

# Average-Value DC-DC Converter

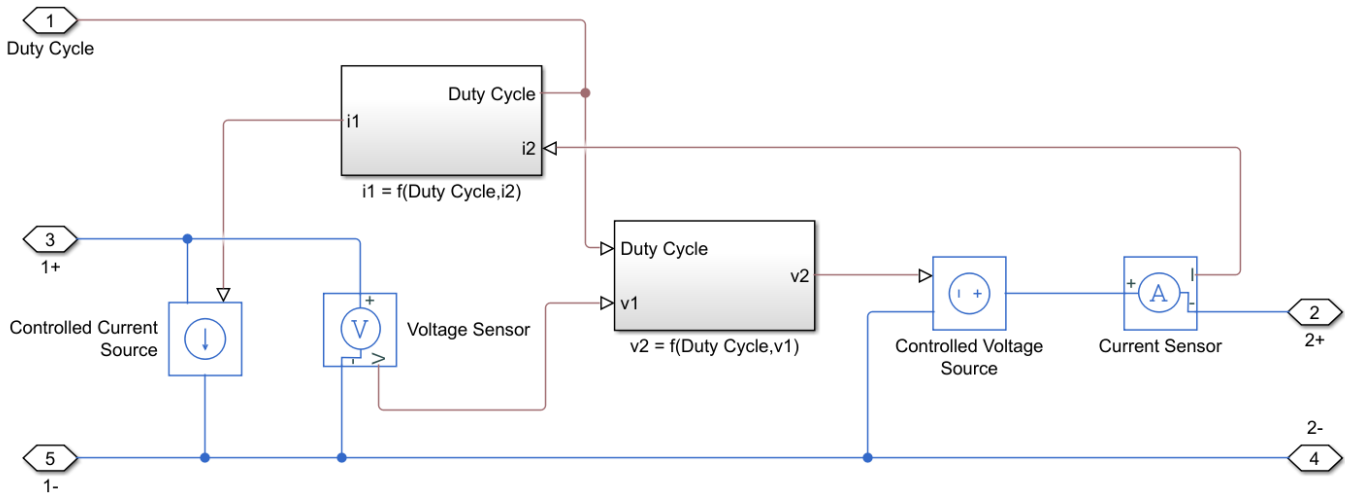

Average-value DC-DC converter

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Average-Value DC-DC Converter block represents a controlled average-value DC-DC converter. You can program the block as a buck converter, boost converter, or buck-boost converter by providing the duty cycle. The diagram shows the equivalent circuit for the block with duty cycle as input. The converter contains a controlled current source and a controlled voltage source. Use the duty cycle, the current reference, or the voltage reference ports as control input to convert the electrical energy between the connected components on either side of the converter.

## Equations

If you set the **Control input** parameter to Duty cycle, the input current and output voltage are a function of the duty cycle and depend on the converter type.

## Voltage and Current Equations

Converter Type	Output Voltage, $v_2$	Input Current, $i_1$
<b>Buck</b>	$v_2 = DutyCycle \cdot v_1$	$i_1 = DutyCycle \cdot i_2$
<b>Boost</b>	$v_2 = \frac{v_1}{1 - DutyCycle}$	$i_1 = \frac{i_2}{1 - DutyCycle}$
<b>Buck-Boost</b>	$v_2 = \frac{DutyCycle \cdot v_1}{1 - DutyCycle}$	$i_1 = \frac{DutyCycle \cdot i_2}{1 - DutyCycle}$

If you set the **Control input** parameter to `Current` reference, the converter sets the output current and it computes the voltage.

Similarly, if you set the **Control input** parameter to `Voltage` reference, the converter sets the output voltage and it computes the current.

### Limitations and Assumptions

- The input voltage is positive.
- All converter types use the same polarity for input and output.

## Average-Value Inverter (Three-Phase)

Average-value DC Voltage to three-phase AC voltage converter with fixed power loss

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

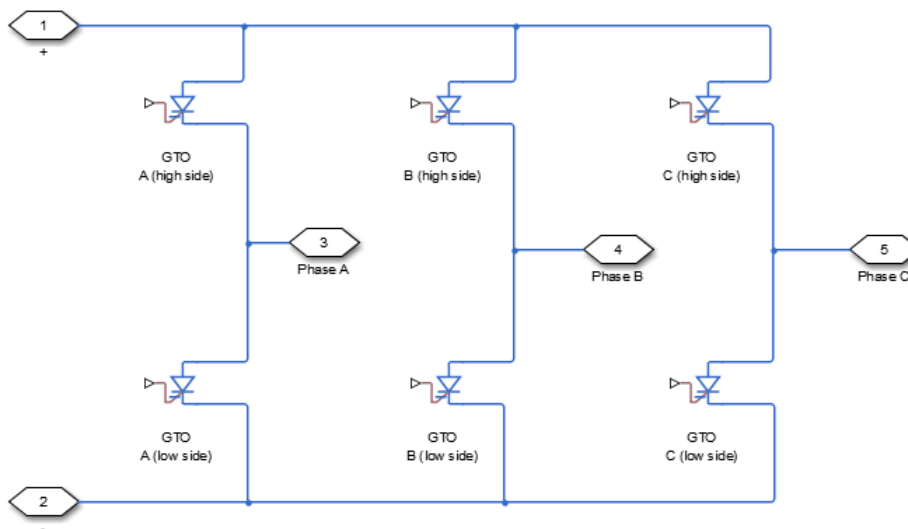

### Description

The Average-Value Inverter (Three-Phase) block models an average-value, full-wave inverter. It converts DC voltage to three-phase AC voltages and converts three-phase AC power demand to DC power demand. The corresponding DC power demand is equal to the sum of the fixed power loss and the AC power demand.

You can use the Average-Value Inverter (Three-Phase) block only as a full-wave inverter. It behaves as a DC-voltage-controlled AC voltage source. The ratio you specify determines the ratio between the DC voltage and the AC voltage.

The figure shows the equivalent circuit for the inverter as a full-wave inverter. The Average-Value Inverter (Three-Phase) block does not yield the harmonics that are typically associated with the detailed representation, however, because it performs an average-value power conversion.

### Electrical Defining Equations

The voltages are defined by

$$v_{DC} = v_p - v_n,$$

$$v_{ref} = \frac{v_p + v_n}{2},$$

$$v_{RMS} = v_{ratio}v_{DC},$$

$$V_0 = \frac{\sqrt{2}}{\sqrt{3}}V_{RMS},$$

$$v_a = V_0\sin(2\pi ft + \varphi) + v_{ref},$$

$$v_b = V_0\sin(2\pi ft + \varphi - 120^\circ) + v_{ref},$$

and

$$v_c = V_0\sin(2\pi ft + \varphi + 120^\circ) + v_{ref},$$

where:

- $v_p$  and  $v_n$  are the voltages at the positive and negative terminals of the inverter.
- $v_{DC}$  is the voltage difference between the positive and negative terminals of the inverter.
- $v_{ref}$  is the DC offset.
- $V_{ratio}$  is the ratio of rated AC voltage to rated DC voltage for the inverter. See the **Ratio of rated AC voltage to rated DC voltage** parameter in “Parameters” on page 1-34 for the  $V_{ratio}$  values for common inverter control modes.
- $V_{RMS}$  is the RMS AC line-line voltage.
- $V_0$  is the peak phase voltage.
- $f$  is the frequency.
- $t$  is the time.
- $\varphi$  is the phase shift.
- $v_a, v_b, v_c$  are the respective AC phase voltages.

The power, resistance, and currents are defined by

$$P_{AC} = -v_a i_a - v_b i_b - v_c i_c,$$

$$R_{DC} = \frac{v_{DC}^2}{P_{AC} + P_{fixed}},$$

and

$$i = \frac{v_{DC}}{R_{DC}},$$

where:

- $i_a, i_b,$  and  $i_c$  are the respective AC phase currents flowing into the inverter.
- $P_{AC}$  is the power output on the AC side.  $P_{AC}$  has a minimum limit of 0 W.
- $P_{fixed}$  is the fixed power loss that you specify on the block.
- $R_{DC}$  is the resistance on the DC side.

- $i$  is the current flowing from the positive to the negative terminals of the inverter.

The inverter starts to create an AC voltage, that is turns on, when the DC supply voltage is above the value that you specify for **DC voltage for turn on** parameter. It stops inverting, that is turns off, when the DC supply voltage falls below the value that you specify for **DC voltage for turn off** parameter. When the inverter turns off, the block sets the output AC current to zero.

## Parameters

### Electrical connection — Electrical connection

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

### Rated AC frequency — AC frequency in Hz

60Hz (default)

AC frequency, specified in Hz (where Hz is defined as 1/s). For example, kHz and MHz are valid units, but rad/s is not.

### Phase shift — Phase shift

0deg (default)

Phase shift in angular units.

### Ratio of rated AC voltage to rated DC voltage — Ratio of rated AC voltage to rated DC voltage

$\sqrt{6}/\pi$  (default)

The table shows ratios for common three-phase two-level inverter control modes. The default value is  $\sqrt{6}/\pi$ .

For 180° and 120° conduction modes, the listed voltages are the fundamental RMS values of line-line voltages. For other methods, the listed voltages are the maximum fundamental RMS values of line-line voltages.

You can control the output voltage of the inverter according to specific requirements. DPWM includes 30° DPWM, 60° DPWM, and 120° DPWM. For details, see references [3] and [4].

Control Method	$V_{RMS} (line-line)$	Ratio of $V_{RMS} (line-line)$ to $V_{DC}$
180° conduction mode [1]	$\frac{\sqrt{6}}{\pi} V_{DC}$	0.7797
120° conduction mode [1]	$\frac{3}{\sqrt{2}\pi} V_{DC}$	0.6752
Hysteresis current control [2]	$\left(\frac{\sqrt{3}}{\sqrt{2}}\right) \left(\frac{2V_{DC}}{\pi}\right)$	0.7797
Sinusoidal PWM (SPMW) [2]	$\left(\frac{\sqrt{3}}{\sqrt{2}}\right) \left(\frac{V_{DC}}{2}\right)$	0.6124
Space vector modulation (SVM) [2]	$\left(\frac{\sqrt{3}}{\sqrt{2}}\right) \left(\frac{V_{DC}}{\sqrt{3}}\right)$	0.7071
Discontinuous PWM (DPWM) [3], [4]	$\left(\frac{\sqrt{3}}{\sqrt{2}}\right) \left(\frac{V_{DC}}{\sqrt{3}}\right)$	0.7071
Convert to the original AC voltage of the average-value rectifier	$\left(\frac{\pi}{\sqrt{2}}\right) \left(\frac{V_{DC}}{3}\right)$	0.7405

**Fixed power loss — Fixed power loss**

1e3W (default)

Minimum power drawn on the DC side. The default value is 1e3.

**DC voltage for turn on — DC voltage for turn on**

100V (default)

When the DC supply voltage rises above this value, the inverter produces an AC output voltage.

**DC voltage for turn off — DC voltage for turn off**

75V (default)

When the DC supply voltage falls below this value, the inverter turns off and the block sets the output AC currents to zero.

## Average-Value Rectifier (Three-Phase)

Average-value three-phase AC voltage to DC voltage converter with fixed power loss

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

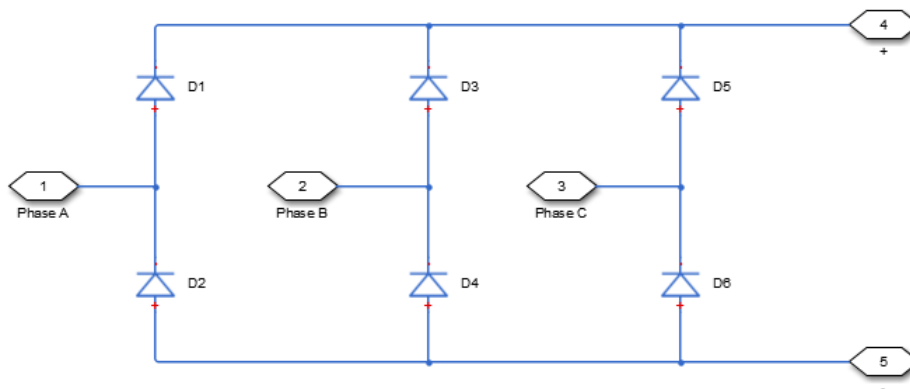

### Description

The Average-Value Rectifier (Three-Phase) block models an average-value, full-wave, six-pulse rectifier. It converts instantaneous three-phase AC voltages to DC voltage and DC power demand to three-phase AC power demand. The corresponding AC power demand is equal to the sum of the fixed power loss and the DC power demand.

You can use the Average-Value Rectifier (Three-Phase) block only as a six-pulse rectifier. You cannot combine two Average-Value Rectifier blocks to represent a twelve-pulse rectifier.

The figure shows the equivalent circuit for the rectifier as a full-wave, six-pulse rectifier. The Average-Value Rectifier (Three-Phase) block does not yield the harmonics that are typically associated with the detailed representation, however, because it performs an average-value power conversion.

This block can work in both time and frequency-and-time simulation modes. If you set the **AC frequency** parameter to **Variable**, this block works only in time simulation mode. If you select **Constant**, this block works in both time and frequency-time simulation modes. For more information, see “Frequency and Time Simulation Mode”.

### Electrical Defining Equations

The voltages are defined by:

$$v_{ref} = \frac{v_a + v_b + v_c}{3},$$

$$V_{RMS} = \sqrt{\frac{(v_a - v_b)^2 + (v_b - v_c)^2 + (v_c - v_a)^2}{3}},$$

$$v_{DC} = 3\frac{\sqrt{2}}{\pi}V_{RMS},$$

$$v_p = v_{ref} + \frac{v_{DC}}{2},$$

and

$$v_n = v_{ref} - \frac{v_{DC}}{2},$$

where:

- $v_a, v_b, v_c$  are the respective AC phase voltages.
- $v_{ref}$  is the DC offset on the AC side. In a balanced AC power system with no DC bias,  $v_{DC}$  is 0 V.
- $V_{RMS}$  is the RMS AC line-line voltage.
- $v_{DC}$  is the voltage difference between the positive and negative terminals of the rectifier.
- $3\sqrt{2}/\pi$  is the  $v_{DC}/V_{RMS}$  ratio for a full-wave, six-pulse rectifier.
- $v_p, v_n$  are the voltages at the positive and negative terminals of the rectifier.

The resistance, power, and currents are defined by

$$R_{fixed} = \frac{V_{Rated}^2}{P_{fixed}},$$

$$P_{DC} = -v_p i_p - v_n i_n,$$

$$R_{AC} = \frac{V_{RMS}^2}{P_{DC} + \frac{V_{RMS}^2}{R_{fixed}}},$$

and

$$[i_a \ i_b \ i_c] = \frac{[v_a \ v_b \ v_c] - v_{ref}}{R_{AC}},$$

where:

- $V_{Rated}$  is the rated AC voltage that you specify on the block mask.
- $P_{fixed}$  is the fixed power loss that you specify on the block mask.
- $R_{fixed}$  is the fixed per-phase series resistance in an equivalent wye-connected load.
- $i_p, i_n$  are the currents flowing into the positive and negative terminals of the rectifier.
- $P_{DC}$  is the power output on the DC side.  $P_{DC}$  has a minimum limit of 0 W.
- $R_{AC}$  is the per-phase series resistance in an equivalent wye-connected load.
- $i_a, i_b, i_c$  are the respective AC phase currents flowing into the rectifier.

## Parameters

### Electrical connection – Electrical connection

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

**AC frequency — AC frequency**

Variable (default) | Constant

Whether to have a variable or constant AC frequency:

- **Variable** — If the frequency at the AC side varies, this option only works in time simulation mode.
- **Constant** — If the frequency at the AC side is constant, this option works in both time and frequency-and-time simulation modes.

**Rated AC voltage — Rated AC voltage**

4160V (default)

Rated voltage of the AC system.

**Rated electrical frequency — Rated electrical frequency**

60 Hz | scalar

Rated electrical frequency. The value of this parameter must be equal to the value of the rated electrical frequencies of other sinusoidal sources in your model, if present.

**Dependencies**

To enable this parameter, set **AC frequency** to Constant.

**Fixed power loss — Fixed power loss**

1e3W (default)

Minimum power drawn on the AC side at rated AC voltage. When the instantaneous AC voltage is equal to the value you specify for the **Rated AC voltage**, the AC power demand equals the value you specify for the **Fixed power loss** plus DC power demand.

# Average-Value Voltage Source Converter (Three-Phase)

Average-value bidirectional AC/DC voltage source converter

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Average-Value Voltage Source Converter (Three-Phase) block converts electrical energy from AC to DC voltage or from DC to AC voltage according to an input three-phase modulation wave. The corresponding input power is equal to the sum of the fixed power loss and the output power.

This block can work in both time and frequency-and-time simulation modes. If you set the **AC frequency** parameter to **Variable**, this block works only in time simulation mode. If you select **Constant**, this block works in both time and frequency-time simulation modes. For more information, see “Frequency and Time Simulation Mode”.

## Losses Parameterization

Switching losses, conduction losses, and quiescent losses are the main heat sources for a converter.

The switching losses are defined by this equation:

$$P_{switching} = k_s v_{dc} I_{rms}$$

where:

- $k_s$  is the proportionality constant that depends on the turn-on and turn-off intervals and switching frequency. Specify this value by setting the **Switching losses coefficient, ks** parameter.

- $v_{dc}$  is the dc-link voltage.

- $I_{rms} = \frac{\sqrt{(i_a - i_{dc})^2 + (i_b - i_{dc})^2 + (i_c - i_{dc})^2}}{\sqrt{3}}$  is the root mean square (RMS) phase current, where

$$i_{dc} = \frac{i_a + i_b + i_c}{3}.$$

The conduction losses are defined by this equation:

$$P_{conduction} = k_{c1} I_{rms} + k_{c2} I_{rms}^2$$

where:

- $k_{c1}$  is the coefficient of the conduction losses that depends on the on-state zero current collector-emitter voltage of the transistor and on the forward voltage drop of the diode. Specify this value by setting the **Conduction losses coefficient, kc1** parameter.
- $k_{c2}$  is the coefficient of the conduction losses that depends on the state resistance of the transistor and on the anti-parallel diode. Specify this value by setting the **Conduction losses coefficient, kc2** parameter.

The quiescent losses are defined by the **Fixed power loss** parameter,  $P_{fixed}$ .

The sum of the switching, conduction, and quiescent losses define the total power losses of the converter:

$$P_{loss} = P_{switching} + P_{conduction} + P_{fixed}.$$

If not available, you can also obtain the  $k_s$ ,  $k_{c1}$ ,  $k_{c2}$  and  $P_{fixed}$  parameters values from the power losses profile, by setting the **Losses parameterization** parameter to **Profile: loss=f(Irms,vdc\_nom)**. The block then solves this equation and calculates the values of the parameters:

$$\begin{bmatrix} P_1 \\ \vdots \\ P_n \end{bmatrix} = \begin{bmatrix} 1 & v_{dc\_nom} I_{rms,1} & I_{rms,1} & I_{rms,1}^2 \\ \vdots & \vdots & \vdots & \vdots \\ 1 & v_{dc\_nom} I_{rms,n} & I_{rms,n} & I_{rms,n}^2 \end{bmatrix} \begin{bmatrix} P_{fixed} \\ k_s \\ k_{c1} \\ k_{c2} \end{bmatrix}$$

where  $\begin{bmatrix} P_1 \\ \vdots \\ P_n \end{bmatrix}$  is the vector of power loss values, **Converter losses**, corresponding to the **RMS current**

for **converter losses** parameter,  $\begin{bmatrix} I_{rms,1} \\ \vdots \\ I_{rms,n} \end{bmatrix}$ , and the **Nominal dc-link voltage**,  $v_{dc\_nom}$ .

### Model Thermal Effects

This block has one optional thermal port. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port.

### Electrical connection — Electrical connection

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

### AC frequency — AC frequency

Variable (default) | Constant

Whether to have a variable or constant AC frequency:

- **Variable** — If the frequency of generated AC voltage varies, this option supports both variable-voltage variable-frequency (VVVF) and variable-voltage constant-frequency (VVCF) applications but the block only works in time simulation mode.
- **Constant** — If the frequency of generated AC voltage is constant, this option supports variable-voltage constant-frequency (VVCF) application and the block works in both time and frequency-and-time simulation modes.

### Rated electrical frequency — Rated electrical frequency

60 Hz | scalar

Rated electrical frequency. The value of this parameter must be equal to the value of the rated electrical frequencies of other sinusoidal sources in your model, if present.

#### Dependencies

To enable this parameter, set **AC frequency** to Constant.

### Losses parameterization — Losses parameterization

Fixed (default) | Coefficients:  $loss = P_{fixed} + k_s \cdot v_{dc} \cdot I_{rms} + k_{c1} \cdot I_{rms} + k_{c2} \cdot I_{rms}^2$  | Profile:  $loss = f(I_{rms}, v_{dc\_nom})$

Parameterization option for the power losses. You can choose one of these options:

- **Fixed** — Power loss is fixed and equal to the value of the **Fixed power loss** parameter.
- **Coefficients**:  $loss = P_{fixed} + k_s \cdot v_{dc} \cdot I_{rms} + k_{c1} \cdot I_{rms} + k_{c2} \cdot I_{rms}^2$  — The total power losses are obtained by summing up the switching, the conduction, and quiescent losses.
- **Profile**:  $loss = f(I_{rms}, v_{dc\_nom})$  — The power loss is a function of the RMS current and the nominal dc-link voltage, and is obtained from the power losses profile.

### Fixed power loss — Power loss

1 W (default)

Fixed power loss on semiconductor components, in W. The input power is equal to the fixed power loss plus output power.

#### Dependencies

To enable this parameter, set **Losses parameterization** to either Fixed or Coefficients:  $loss = P_{fixed} + k_s \cdot v_{dc} \cdot I_{rms} + k_{c1} \cdot I_{rms} + k_{c2} \cdot I_{rms}^2$ .

### Switching losses coefficient, $k_s$ — Coefficient of switching losses

0.01 (default)

Proportionality constant that depends on the turn-on and turn-off intervals and switching frequency.

**Dependencies**

To enable this parameter, set **Losses parameterization** to Coefficients:  $\text{loss}=\text{Pfixed}+k_s*v_{dc}*I_{rms}+k_{c1}*I_{rms}+k_{c2}*I_{rms}^2$ .

**Conduction losses coefficient,  $k_{c1}$  — First coefficient of conduction losses**

1.7 V (default)

Coefficient of the conduction losses that depends on the on-state zero current collector-emitter voltage of the transistor and on the forward voltage drop of the diode.

**Dependencies**

To enable this parameter, set **Losses parameterization** to Coefficients:  $\text{loss}=\text{Pfixed}+k_s*v_{dc}*I_{rms}+k_{c1}*I_{rms}+k_{c2}*I_{rms}^2$ .

**Conduction losses coefficient,  $k_{c2}$  — Second coefficient of conduction losses**

0.01 Ohm (default)

Coefficient of the conduction losses that depends on the state resistance of the transistor and on the anti-parallel diode.

**Dependencies**

To enable this parameter, set **Losses parameterization** to Coefficients:  $\text{loss}=\text{Pfixed}+k_s*v_{dc}*I_{rms}+k_{c1}*I_{rms}+k_{c2}*I_{rms}^2$ .

**Converter losses — Converter losses vector**

[100, 800, 1870, 3250, 4900] W (default)

Vector of power losses values.

**Dependencies**

To enable this parameter, set **Losses parameterization** to Profile:  $\text{loss}=f(I_{rms},v_{dc\_nom})$ .

**RMS current for converter losses — RMS currents vector**

[10, 100, 200, 300, 400] A (default)

Vector of root mean square currents associated to the values of the **Converter losses** parameter.

**Dependencies**

To enable this parameter, set **Losses parameterization** to Profile:  $\text{loss}=f(I_{rms},v_{dc\_nom})$ .

**Nominal dc-link voltage — Nominal dc-link voltage**

300 V (default)

Nominal voltage.

**Dependencies**

To enable this parameter, set **Losses parameterization** to Profile:  $\text{loss}=f(I_{rms},v_{dc\_nom})$ .

**Thermal mass — Thermal mass**

30000 J/K (default)

Thermal mass.

### Dependencies

## Band-Limited Op-Amp

Model band-limited operational amplifier

**Library:** Simscape / Electrical / Integrated Circuits

### Description

The Band-Limited Op-Amp block models a band-limited operational amplifier. If the voltages at the positive and negative ports are  $V_p$  and  $V_m$ , respectively, the output voltage is:

$$V_{out} = \frac{A(V_p - V_m)}{\frac{s}{2\pi f} + 1} - I_{out} * R_{out}$$

where:

- $A$  is the gain.
- $R_{out}$  is the output resistance.
- $I_{out}$  is the output current.
- $s$  is the Laplace operator.
- $f$  is the 3-dB bandwidth.

The input current is:

$$\frac{V_p - V_m}{R_{in}}$$

where  $R_{in}$  is the input resistance.

The block does not use the initial condition you specify using the **Initial output voltage, V0** parameter if you select the **Start simulation from steady state** check box in the SimscapeSolver Configuration block.

# Battery

Behavioral battery model

**Library:** Simscape / Electrical / Sources  
Simscape / Battery / Cells

## Description

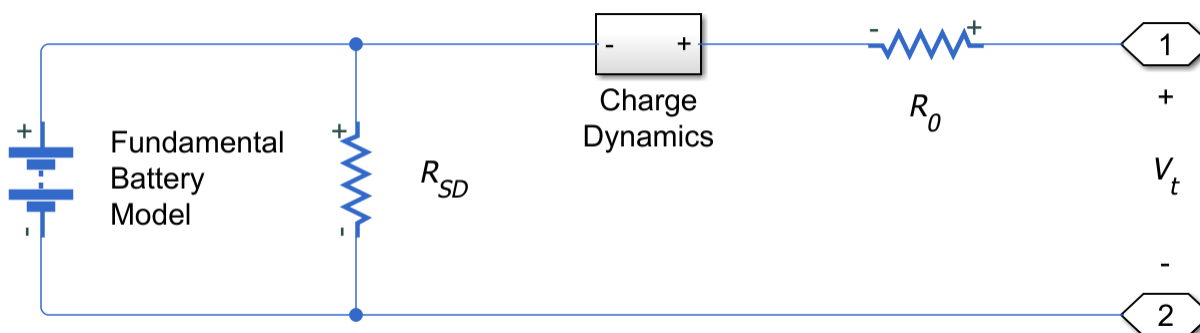

The Battery block represents a simple battery model. The block has four modeling options, accessible by setting the **Modeling option** parameter to either:

- **Uninstrumented | No thermal port** — Basic model that does not output battery charge level or simulate thermal effects.
- **Uninstrumented | Show thermal port** — Model with exposed thermal port. This model does not measure internal charge level of the battery.
- **Instrumented | No thermal port** — Model with exposed charge output port. This model does not simulate thermal effects.
- **Instrumented | Show thermal port** — Model that lets you measure internal charge level of the battery and simulate thermal effects. Both the thermal port and the charge output port are exposed.

The instrumented modeling options have an extra physical signal port that outputs the internal state of charge. Use this functionality to change load behavior as a function of state of charge, without the complexity of building a charge state estimator.

The thermal port modeling options expose a thermal port, which represents the battery thermal mass. When you select this option, provide additional parameters to define battery behavior at a second temperature. For more information, see “Modeling Thermal Effects” on page 1-53.

The battery equivalent circuit is made up of the fundamental battery model, the self-discharge resistance  $R_{SD}$ , the charge dynamics model, and the series resistance  $R_0$ .

## Battery Model

If you select **Infinite** for the **Battery charge capacity** parameter, the block models the battery as a series resistor and a constant voltage source. If you select **Finite** for the **Battery charge capacity** parameter, the block models the battery as a series resistor and a charge-dependent voltage source. In the finite case, the voltage is a function of charge and has the following relationship:

$$V = V_0 \left( \frac{\text{SOC}}{1 - \beta(1 - \text{SOC})} \right)$$

where:

- SOC (state-of-charge) is the ratio of current charge to rated battery capacity.
- $V_0$  is the voltage when the battery is fully charged at no load, as defined by the **Nominal voltage**, **Vnom** parameter.
- $\beta$  is a constant that is calculated so that the battery voltage is  $V1$  when the charge is  $AH1$ . Specify the voltage  $V1$  and cell capacity  $AH1$  using block parameters.  $AH1$  is the charge when the no-load (open-circuit) voltage is  $V1$ , and  $V1$  is less than the nominal voltage.

The equation defines an approximate relationship between voltage and remaining charge. This approximation replicates the increasing rate of voltage drop at low charge values, and ensures that the battery voltage becomes zero when the charge level is zero. The advantage of this model is that it requires few parameters, which are readily available on most datasheets.

## Modeling Battery Fade

For battery models with finite battery charge capacity, you can model battery performance deterioration depending on the number of discharge cycles. This deterioration is referred to as battery fade. To enable battery fade, set the **Battery fade** parameter to **Enabled**. This setting exposes additional parameters in the **Fade** section.

The block implements battery fade by scaling certain battery parameter values that you specify in the **Main** section, depending on the number of completed discharge cycles. The block uses multipliers  $\lambda_{AH}$ ,  $\lambda_{R0}$ , and  $\lambda_{V1}$  on the **Cell capacity (Ah rating)**, **Internal resistance**, and **Voltage V1 when charge is AH1** parameter values, respectively. These multipliers, in turn, depend on the number of discharge cycles:

$$\lambda_{AH} = 1 - k_1 N^{0.5}$$

$$\lambda_{R0} = 1 + k_2 N^{0.5}$$

$$\lambda_{V1} = 1 - k_3 N$$

$$N = N_0 + \frac{1}{AH} \int_0^t \frac{i(t) \cdot H(i(t))}{\lambda_{AH}(t)} dt$$

where:

- $\lambda_{AH}$  is the multiplier for battery nominal capacity.
- $\lambda_{R0}$  is the multiplier for battery series resistance.
- $\lambda_{V1}$  is the multiplier for voltage  $V1$ .

- $N$  is the number of discharge cycles completed.
- $N_0$  is the number of full discharge cycles completed before the start of the simulation.
- $AH$  is the rated battery capacity in ampere-hours.
- $i(t)$  is the instantaneous battery output current.
- $H(i(t))$  is the Heaviside function of the instantaneous battery output current. This function returns 0 if the argument is negative, and 1 if the argument is positive.

The block calculates the coefficients  $k_1$ ,  $k_2$ , and  $k_3$  by substituting the parameter values you provide in the **Facte** section into these battery equations. For example, the default set of block parameters corresponds to the following coefficient values:

- $k_1 = 1e-2$
- $k_2 = 1e-3$
- $k_3 = 1e-3$

You can also define a starting point for a simulation based on the previous charge-discharge history by using the high-priority variable **Discharge cycles**. For more information, see “Variables” on page 1-56.

### Modeling Thermal Effects

If you set the **Modeling option** parameter to either `Uninstrumented | Show thermal port` or `Instrumented | Show thermal port`, you provide additional parameters to define battery behavior at a second temperature. The extended equations for the voltage when the thermal port is exposed are:

$$V = V_{0T} \left( \frac{\text{SOC}}{1 - \beta_T(1 - \text{SOC})} \right)$$

$$V_{0T} = V_0(1 + \lambda_V(T - T_1))$$

where:

- $T$  is the battery temperature.
- $T_1$  is the nominal measurement temperature.
- $\lambda_V$  is the parameter temperature dependence coefficient for  $V_0$ .
- $\beta_T = \beta[1 + \lambda_\beta(T - T_1)]$ .
- $\lambda_\beta$  is the parameter temperature dependence coefficient for  $\beta$ .
- $\beta$  is calculated in the same way as “Battery Model” on page 1-52, using the temperature-modified nominal voltage  $V_{0T}$ .

The internal series resistance, self-discharge resistance, and any charge-dynamic resistances are also functions of temperature:

$$R_T = R(1 + \lambda_R(T - T_1))$$

where  $\lambda_R$  is the parameter temperature dependence coefficient.

All the temperature dependence coefficients are determined from the corresponding values you provide at the nominal and second measurement temperatures. If you include charge dynamics in the model, the time constants vary with temperature in the same way.

The battery temperature is determined from a summation of all the ohmic losses included in the model:

$$M_{th}\dot{T} = \sum_i V_{T,i}^2/R_{T,i}$$

where:

- $M_{th}$  is the battery thermal mass.
- $i$  corresponds to the  $i$ th ohmic loss contributor. Depending on how you have configured the block, the losses include:
  - Series resistance
  - Self-discharge resistance
  - First charge dynamics segment
  - Second charge dynamics segment
  - Third charge dynamics segment
  - Fourth charge dynamics segment
  - Fifth charge dynamics segment
- $V_{T,i}$  is the voltage drop across resistor  $i$ .
- $R_{T,i}$  is resistor  $i$ .

### Modeling Charge Dynamics

You can model battery charge dynamics using the **Charge dynamics** parameter:

- **No dynamics** — The equivalent circuit contains no parallel RC sections. There is no delay between terminal voltage and internal charging voltage of the battery.
- **One time-constant dynamics** — The equivalent circuit contains one parallel RC section. Specify the time constant using the **First time constant** parameter.
- **Two time-constant dynamics** — The equivalent circuit contains two parallel RC sections. Specify the time constants using the **First time constant** and **Second time constant** parameters.
- **Three time-constant dynamics** — The equivalent circuit contains three parallel RC sections. Specify the time constants using the **First time constant**, **Second time constant**, and **Third time constant** parameters.
- **Four time-constant dynamics** — The equivalent circuit contains four parallel RC sections. Specify the time constants using the **First time constant**, **Second time constant**, **Third time constant**, and **Fourth time constant** parameters.
- **Five time-constant dynamics** — The equivalent circuit contains five parallel RC sections. Specify the time constants using the **First time constant**, **Second time constant**, **Third time constant**, **Fourth time constant**, and **Fifth time constant** parameters.

This figure shows the equivalent circuit for the block configured with two time-constant dynamics.

In the diagram:

- $R_{RC1}$  and  $R_{RC2}$  are the parallel RC resistances. Specify these values with the **First polarization resistance** and **Second polarization resistance** parameters, respectively.
- $C_{RC1}$  and  $C_{RC2}$  are the parallel RC capacitances. The time constant  $\tau$  for each parallel section relates the  $R$  and  $C$  values using the relationship  $C = \tau/R$ . Specify  $\tau$  for each section using the **First time constant** and **Second time constant** parameters, respectively.
- $R_0$  is the series resistance. Specify this value with the **Internal resistance** parameter.

### Modeling Battery Aging

For battery models with finite battery charge capacity, you can model the battery performance deterioration that occurs when the battery is not used. Calendar aging affects both the internal resistance and capacity. In particular, the resistance increase depends by various mechanisms such as the creation of Solid Electrolyte Interface (SEI) at both anode and cathode and the corrosion of the current collector. These processes mainly depends on the storage temperature, the storage state of charge, and time.

This equation defines the terminal resistance increase of the battery due to calendar aging:

$$\alpha_r(T, V_{oc}) = (bV_{oc} - c)e^{-\frac{qd}{kT}},$$

$$R = R_0 \left( 1 + \sum_{i=1}^{i=n} \alpha_r(T_i, V_{oc})(t_i^a - t_{i-1}^a - 1) \right),$$

where:

- $V_{oc}$  is the **Normalized open-circuit voltage during storage, V/Vnom**.
- $R_0$  is the **Internal resistance**.
- $t_i$  is the time sample derived from the **Vector of time intervals** parameter.
- $T_i$  is derived from the **Vector of temperatures** parameter.
- $b$  is the **Linear scaling for voltage, b**.
- $c$  is the **Constant offset for voltage, c**.
- $d$  is the **Temperature-dependent exponential increase, d**.
- $a$  is the **Time exponent, a**.

- $q$  is the electron's elementary charge, in C.
- $k$  is the Boltzmann constant, in J/K.

The *R1\_age\_multiplier* variable in the **Simscape Results Explorer** stores the calendar aging of the battery in terms of resistance increase:

$$R1\_age\_multiplier = \frac{R}{R_0}.$$

For thermal modeling options of the block, if you set the **Storage condition** parameter to **Fixed open-circuit voltage**, you must specify the additional **Open-circuit voltage measurement temperature** parameter to convert the storage open-circuit voltage to the temperature-independent state of charge during storage:

$$SOC = \frac{OCV(1 - \beta(T_{OCV\_measurement}))}{1 - \beta(T_{OCV\_measurement})OCV}.$$

The open-circuit voltage according to the storage temperature is then defined by this equation:

$$OCV_{T_{storage}} = \frac{SOC}{1 - \beta(T_{storage})(1 - \beta(T_{storage})SOC)}.$$

Finally, this equation defines the terminal resistance increase of the battery due to calendar aging according to the storage temperature:

$$R = R_0 \left( 1 + \sum_{i=1}^{i=n} \alpha_r(T_{storage_i}, OCV_{T_{storage_i}})(t_i^a - t_{i-1}^a) \right).$$

### Plotting Voltage-Charge Characteristics

A quick plot feature lets you visualize the voltage-charge characteristic for the battery model parameter values. To plot the characteristics, right-click a Battery block in your model and, from the context menu, select **Electrical > Basic characteristic**. The software automatically computes a set of bias conditions, based on the block parameter values, and opens a figure window containing a plot of no-load voltage versus the state-of-charge (SOC) for the block. For more information, see “Plot Basic Characteristics for Battery Blocks”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

When you model battery fade, the **Discharge cycles** variable lets you specify the number of charge-discharge cycles completed prior to the start of simulation. If you disable battery fade modeling, this variable is not used by the block.

## Assumptions and Limitations

- The self-discharge resistance is assumed not to depend strongly on the number of discharge cycles.
- For the thermal modeling option of the battery, you provide fade data only for the reference temperature operation. The block applies the same derived  $\lambda_{AH}$ ,  $\lambda_{RO}$ , and  $\lambda_{V1}$  multipliers to parameter values corresponding to the second temperature.
- When using the thermal block modeling options, use caution when operating at temperatures outside of the temperature range bounded by the **Measurement temperature** and **Second measurement temperature** values. The block uses linear interpolation for the derived equation coefficients, and simulation results can become nonphysical outside of the specified range. The block checks that the internal series resistance, self-discharge resistance, and nominal voltage always remain positive. If there is a violation, the block issues error messages.

## Ports

### Output

#### q — Battery charge level, C

physical signal

Physical signal port that outputs the internal charge, in the units of coulomb (C). Use this output port to change load behavior as a function of charge, without the complexity of building a charge state estimator.

### Dependencies

To enable this port, set **Modeling option** to either Instrumented | No thermal port and Instrumented | Show thermal port.

### Conserving

#### + — Positive terminal

electrical

Electrical conserving port associated with the battery positive terminal.

#### - — Negative terminal

electrical

Electrical conserving port associated with the battery negative terminal.

#### H — Battery thermal mass

thermal

Thermal conserving port that represents the battery thermal mass. When you expose this port, provide additional parameters to define battery behavior at a second temperature. For more information, see “Modeling Thermal Effects” on page 1-53.

### Dependencies

To enable this port, set **Modeling option** to either Uninstrumented | Show thermal port and Instrumented | Show thermal port.

## Parameters

### **Modeling option — Whether to enable charge level and thermal ports**

Uninstrumented | No thermal port (default) | Uninstrumented | Show thermal port | Instrumented | No thermal port | Instrumented | Show thermal port

Whether to output the internal charge level of the battery and enable the thermal port.

### **Main**

### **Nominal voltage, Vnom — Output voltage when battery is fully charged**

12 V (default) | positive number

The no-load voltage across the battery when it is fully charged.

### **Current directionality — Enable direction of current**

Disabled (default) | Enabled

Whether to enable current directionality. If you set this parameter to Enabled, the terminal resistance depends on the direction of the current.

### **Internal resistance — Battery internal resistance**

2 Ohm (default) | positive number

Internal connection resistance of the battery.

### **Dependencies**

To enable this parameter, set **Current directionality** to Disabled.

### **Internal resistance during charging — Battery internal resistance during charge**

2 Ohm (default) | positive number

Internal connection resistance of the battery during charge phase.

### **Dependencies**

To enable this parameter, set **Current directionality** to Enabled.

### **Internal resistance during discharging — Battery internal resistance during discharge**

2 Ohm (default) | positive number

Internal connection resistance of the battery during discharge phase.

### **Dependencies**

To enable this parameter, set **Current directionality** to Enabled.

### **Battery charge capacity — Select battery model**

Infinite (default) | Finite

Select one of the options for modeling the charge capacity of the battery:

- **Infinite** — The battery voltage is independent of charge drawn from the battery.
- **Finite** — The battery voltage decreases as charge decreases.

**Cell capacity (Ah rating) – Nominal battery capacity when fully charged**

50 hr\*A (default) | positive number

The maximum (nominal) battery charge in ampere-hours. To specify a target value for the initial battery charge at the start of simulation, use the high-priority **Charge** variable. For more information, see “Variables” on page 1-56.

**Dependencies**

Enabled when the **Battery charge capacity** parameter is set to *Finite*.

**Voltage V1 when charge is AH1 – Output voltage at charge level AH1**

11.5 V (default) | positive number

The fundamental battery output voltage when the charge level is AH1, as specified by the **Charge AH1 when no-load voltage is V1** parameter. This parameter must be less than **Nominal voltage, Vnom**.

**Dependencies**

Enabled when the **Battery charge capacity** parameter is set to *Finite*.

**Charge AH1 when no-load voltage is V1 – Charge level when the no-load output voltage is V1**

25 hr\*A (default) | positive number

The battery charge level corresponding to the no-load output voltage specified by the **Voltage V1 when charge is AH1** parameter.

**Dependencies**

Enabled when the **Battery charge capacity** parameter is set to *Finite*.

**Self-discharge – Select whether to model the self-discharge resistance of the battery**

Disabled (default) | Enabled

Select whether to model the self-discharge resistance of the battery. The block models this effect as a resistor across the terminals of the fundamental battery model.

As temperature increases, self-discharge resistance decreases, causing self-discharge to increase. If the decrease in resistance is too fast, thermal runaway of the battery and numerical instability can occur. You can resolve this by doing any of the following:

- Decrease the thermal resistance
- Decrease the gradient of the self-discharge resistance with respect to temperature
- Increase the self-discharge resistance

**Dependencies**

Enabled when the **Battery charge capacity** parameter is set to *Finite*.

**Self-discharge resistance – Resistance that represents battery self-discharge**

2000 Ohm (default) | positive number

The resistance across the fundamental battery model that represents battery self-discharge.

**Dependencies**

Enabled when the **Self-discharge** parameter is set to Enabled.

**Measurement temperature — Temperature at which the block parameters are measured**

298.15 K (default) | positive number

Temperature  $T_1$ , at which the block parameters in the **Main** section are measured. For more information, see “Modeling Thermal Effects” on page 1-53.

**Dependencies**

Enabled for blocks with exposed thermal port.

**Dynamics****Charge dynamics — Battery charge dynamics model**

No dynamics (default) | One time-constant dynamics | Two time-constant dynamics | Three time-constant dynamics | Four time-constant dynamics | Five time-constant dynamics

Select how to model battery charge dynamics. This parameter determines the number of parallel RC sections in the equivalent circuit:

- **No dynamics** — The equivalent circuit contains no parallel RC sections. There is no delay between terminal voltage and internal charging voltage of the battery.
- **One time-constant dynamics** — The equivalent circuit contains one parallel RC section. Specify the time constant using the **First time constant** parameter.
- **Two time-constant dynamics** — The equivalent circuit contains two parallel RC sections. Specify the time constants using the **First time constant** and **Second time constant** parameters.
- **Three time-constant dynamics** — The equivalent circuit contains three parallel RC sections. Specify the time constants using the **First time constant**, **Second time constant**, and **Third time constant** parameters.
- **Four time-constant dynamics** — The equivalent circuit contains four parallel RC sections. Specify the time constants using the **First time constant**, **Second time constant**, **Third time constant**, and **Fourth time constant** parameters.
- **Five time-constant dynamics** — The equivalent circuit contains five parallel RC sections. Specify the time constants using the **First time constant**, **Second time constant**, **Third time constant**, **Fourth time constant**, and **Fifth time constant** parameters.

**First polarization resistance — First RC resistance**

0.005 Ohm (default) | positive number

The resistance of the first parallel RC section. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**First time constant — First RC time constant**

30 s (default) | positive number

The time constant of the first parallel RC section. This value is equal to  $RC$  and affects the dynamics of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Second polarization resistance — Second RC resistance**

0.005 Ohm (default) | positive number

The resistance of the second parallel RC section. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Second time constant — Second RC time constant**

30 s (default) | positive number

The time constant of the second parallel RC section. This value is equal to  $RC$  and affects the dynamics of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Third polarization resistance — Third RC resistance**

0.005 Ohm (default) | positive number

The resistance of the third parallel RC section. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Third time constant — Third RC time constant**

30 s (default) | positive number

The time constant of the third parallel RC section. This value is equal to  $RC$  and affects the dynamics of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Fourth polarization resistance — Fourth RC resistance**

0.005 Ohm (default) | positive number

The resistance of the fourth parallel RC section. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to `Four time-constant dynamics` or `Five time-constant dynamics`.

**Fourth time constant — Fourth RC time constant**

30 s (default) | positive number

The time constant of the fourth parallel RC section. This value is equal to  $RC$  and affects the dynamics of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to `Four time-constant dynamics` or `Five time-constant dynamics`.

**Fifth polarization resistance — Fifth RC resistance**

0.005 Ohm (default) | positive number

The resistance of the fifth parallel RC section. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to `Five time-constant dynamics`.

**Fifth time constant — Fifth RC time constant**

30 s (default) | positive number

The time constant of the fifth parallel RC section. This value is equal to  $RC$  and affects the dynamics of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to `Five time-constant dynamics`.

**Fade****Battery fade — Select whether to model battery performance deterioration with aging**

Disabled (default) | Enabled

Select whether to include battery fade modeling:

- **Disabled** — The battery performance is not age dependent.
- **Enabled** — The battery performance changes depending on the number of completed charge-discharge cycles. Selecting this option exposes additional parameters in this section, which define the battery performance after a certain number of discharge cycles. The block uses these parameter values to calculate the scaling coefficients  $k_1$ ,  $k_2$ , and  $k_3$ . For more information, see “Modeling Battery Fade” on page 1-52.

**Dependencies**

Enabled when the **Battery charge capacity** parameter in the **Main** section is set to `Finite`. If **Battery charge capacity** is `Infinite`, the **Fade** section is empty.

**Number of discharge cycles, N – Number of cycles that defines a second set of data points**

100 (default) | positive number

The number of charge-discharge cycles after which the other parameters in this section are measured. This second set of data points defines the scaling coefficients  $k_1$ ,  $k_2$ , and  $k_3$ , used in modeling battery fade.

**Dependencies**

Enabled when the **Battery fade** parameter is set to Enabled.

**Cell capacity after N discharge cycles – Maximum battery capacity after N discharge cycles**

45 hr\*A (default) | positive number

The maximum battery charge, in ampere-hours, after the number of discharge cycles specified by the **Number of discharge cycles, N** parameter.

**Dependencies**

Enabled when the **Battery fade** parameter is set to Enabled.

**Internal resistance after N discharge cycles – Battery internal resistance after N discharge cycles**

2.02 Ohm (default) | positive number

The battery internal resistance after the number of discharge cycles specified by the **Number of discharge cycles, N** parameter.

**Dependencies**

Enabled when the **Battery fade** parameter is set to Enabled and **Current Directionality** is set to Disabled.

**Average internal resistance after N discharge cycles – Battery average internal resistance after N discharge cycles**

2.02 Ohm (default) | positive number

Average of the battery charge and discharge internal resistance after the number of discharge cycles specified by the **Number of discharge cycles, N** parameter.

**Dependencies**

To enable this parameter, set **Battery fade** and **Current directionality** to Enabled.

**Voltage V1 at charge AH1 after N discharge cycles – Output voltage at charge level AH1 after N discharge cycles**

10.35 V (default) | positive number

The fundamental battery model output voltage, at charge level AH1, after the number of discharge cycles specified by the **Number of discharge cycles, N** parameter.

**Dependencies**

Enabled when the **Battery fade** parameter is set to Enabled.

### **Calendar Aging**

To expose these parameters, in the **Main** tab, set **Battery charge capacity** to **Finite**.

#### **Calendar aging — Calendar aging option**

Disabled (default) | Enabled

Whether to enable calendar aging of the battery.

#### **Storage condition — Storage condition**

Fixed open-circuit voltage (default) | Fixed state of charge

Whether to specify the open-circuit voltage or the state of charge during storage.

#### **Dependencies**

To enable this parameter, set **Calendar aging** to **Enabled**.

#### **Normalized open-circuit voltage during storage, $V/V_{nom}$ — Normalized open-circuit voltage during storage**

0.9 (default) | scalar

Normalized open-circuit voltage during storage.

#### **Dependencies**

To enable this parameter, set **Calendar aging** to **Enabled** and **Storage condition** to **Fixed open-circuit voltage**.

#### **Open-circuit measurement temperature — Open-circuit temperature**

298.15 K (default) | positive number

Open-circuit measurement temperature.

#### **Dependencies**

To enable this parameter, expose the block thermal port and set **Calendar aging** to **Enabled** and **Storage condition** to **Fixed open-circuit voltage**.

#### **State of charge during storage (%) — Percentage state of charge during storage**

60 (default) | positive number

State of charge during storage, in percentage.

#### **Dependencies**

To enable this parameter, set **Calendar aging** to **Enabled** and **Storage condition** to **Fixed state of charge**.

#### **Vector of time intervals — Time intervals**

[0] d (default) | scalar

Time intervals. This parameter must be equal in size to **Vector of temperatures**.

#### **Dependencies**

To enable this parameter, set **Calendar aging** to **Enabled**.

**Vector of temperatures — Storage temperatures**

[273] K (default) | scalar

Set of storage temperatures. This parameter must be equal in size to **Vector of time intervals**.

**Dependencies**

To enable this parameter, set **Calendar aging** to Enabled.

**Linear scaling for voltage, b — Voltage linear scaling**

2.2134e6 (default) | scalar

Linear scaling coefficient for open-circuit voltage.

**Dependencies**

To enable this parameter, set **Calendar aging** to Enabled.

**Constant offset for voltage, c — Voltage constant offset**

1.632e6 (default) | scalar

Constant offset for open-circuit voltage.

**Dependencies**

To enable this parameter, set **Calendar aging** to Enabled.

**Temperature-dependent exponential increase, d — Temperature-dependent exponential increase**

0.515833569 V (default) | scalar

Temperature-dependent exponential increase.

**Dependencies**

To enable this parameter, set **Calendar aging** to Enabled.

**Time exponent, a — Time exponent**

0.75 (default) | scalar

Time exponent.

**Dependencies**

To enable this parameter, set **Calendar aging** to Enabled.

**Temperature Dependence**

This section appears only for blocks with exposed thermal port. For more information, see “Modeling Thermal Effects” on page 1-53.

**Nominal voltage at second measurement temperature — Output voltage when battery is fully charged**

12 V (default) | positive number

The no-load voltage across the battery at the second measurement temperature when it is fully charged.

**Internal resistance at second measurement temperature – Battery internal resistance**

2.2 0hm (default) | positive number

Internal connection resistance of the battery at the second measurement temperature.

**Voltage V1 at second measurement temperature – Output voltage at charge level AH1**

11.4 V (default) | positive number

The fundamental battery model output voltage at the second measurement temperature and at charge level AH1, as specified by the **Charge AH1 when no-load voltage is V1** parameter.

**Dependencies**

Enabled when the **Battery charge capacity** parameter in the **Main** section is set to **Finite**.

**Self-discharge resistance at second measurement temperature – Resistance that represents battery self-discharge**

2200 0hm (default) | positive number

The resistance across the fundamental battery model at the second measurement temperature. This resistance represents the self-discharge.

**Dependencies**

Enabled when the **Self-discharge resistance** parameter in the **Main** section is set to **Enabled**.

**First polarization resistance at second measurement temperature – First RC resistance at second measurement temperature**

0.005 0hm (default) | positive number

The resistance of the first parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to **One time-constant dynamics**, **Two time-constant dynamics**, **Three time-constant dynamics**, **Four time-constant dynamics**, or **Five time-constant dynamics**.

**First time constant at second measurement temperature – First RC time constant at second measurement temperature**

30 s (default) | positive number

The time constant of the first parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to **One time-constant dynamics**, **Two time-constant dynamics**, **Three time-constant dynamics**, **Four time-constant dynamics**, or **Five time-constant dynamics**.

**Second polarization resistance at second measurement temperature – Second RC resistance at second measurement temperature**

0.005 0hm (default) | positive number

The resistance of the second parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Second time constant at second measurement temperature — Second RC time constant at second measurement temperature**

30 s (default) | positive number

The time constant of the second parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Third polarization resistance at second measurement temperature — Third RC resistance at second measurement temperature**

0.005 Ohm (default) | positive number

The resistance of the third parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Third time constant at second measurement temperature — Third RC time constant at second measurement temperature**

30 s (default) | positive number

The time constant of the third parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Fourth polarization resistance at second measurement temperature — Fourth RC resistance at second measurement temperature**

0.005 Ohm (default) | positive number

The resistance of the fourth parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics or Five time-constant dynamics.

**Fourth time constant at second measurement temperature — Fourth RC time constant at second measurement temperature**

30 s (default) | positive number

The time constant of the fourth parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics or Five time-constant dynamics.

**Fifth polarization resistance at second measurement temperature — Fifth RC resistance at second measurement temperature**

0.005 Ohm (default) | positive number

The resistance of the fifth parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics.

**Fifth time constant at second measurement temperature — Fifth RC time constant at second measurement temperature**

30 s (default) | positive number

The time constant of the fifth parallel RC section at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics.

**Second measurement temperature — Temperature at which the block parameters in this section are measured**

273.15 K (default) | positive number

Temperature  $T_2$ , at which the block parameters in the **Temperature Dependence** section are measured. For more information, see “Modeling Thermal Effects” on page 1-53.

To specify the initial temperature at the start of simulation, use the high-priority **Temperature** variable. For more information, see “Variables” on page 1-56.

**Thermal Port**

This section appears only for blocks with exposed thermal port. For more information, see “Modeling Thermal Effects” on page 1-53.

**Thermal mass — Thermal mass associated with the thermal port**

30000 J/K (default) | positive number

Thermal mass associated with the thermal port H. It represents the energy required to raise the temperature of the thermal port by one degree.

### Description

The Battery (Table-Based) block represents a high-fidelity battery model. The block calculates open-circuit voltage as a function of charge level and optional temperature using lookup tables and includes several modeling options:

- Self-discharge
- Battery fade
- Charge dynamics
- Calendar aging

---

**Note** The block can use linear or nearest interpolation and extrapolation for all the table based parameters. For rows and columns, it follows the row-column convention, whereas rows are indexed first and, subsequently, columns.

---

The plot shows a battery whose performance varies with temperature and state of charge changes, as typically found on a datasheet.

Use this block to parameterize batteries with complex open-circuit voltage behavior from datasheets or experimental results. For a simpler representation of a battery, see the Battery block.

The Battery (Table-Based) block has two optional ports that you can expose by setting the corresponding parameters. The extra physical signal port, **SOC**, outputs the internal state of charge. Use this functionality to change the load behavior as a function of state of charge, without the complexity of building a charge state estimator. To expose the **SOC** port, in the **Main** setting, set the **Expose SOC measurement port** parameter to Yes.

To expose the thermal port, in the **Thermal** setting, set the **Thermal port** parameter to Model. The thermal port represents the battery thermal mass.

You can also choose different built-in parameterizations for this block. For more information, see the “Predefined Parameterization” on page 1-77 section.

The battery equivalent circuit is made up of the fundamental battery model, the self-discharge resistance  $R_{SD}$ , the charge dynamics model, and the series resistance  $R_0$ .

### Battery Model

The block calculates the open-circuit voltage, or the voltage across the fundamental battery model by interpolation:

$$v_0 = v_0(\text{SOC}, T)$$

Where:

- $v_0$  is the open-circuit voltage of the battery. Specify the grid of lookup values using the **Open-circuit voltage, V0(SOC,T)** parameter if tabulating parameters over temperature, or **Open-circuit voltage, V0(SOC)** otherwise.
- SOC is the ratio of current charge to nominal battery capacity specified in the **Cell capacity, AH** parameter along with the effects of the temperature dependent fade percentage change in cell capacity,  $\delta_{AH}(n, T_{fade})$ , specified in the **Percentage change in cell capacity, dAH(N, Tfade)** parameter. Specify the SOC breakpoints using the **Vector of state-of-charge values, SOC** parameter. The block estimates the nominal battery capacity based on the number of cycles and the temperature of the battery by interpolating the specified temperature dependent fade characteristic and the **Cell capacity, AH** parameter.

SOC represents the normalized data with respect to  $q_{nom}$ .

For the lookup-table based fade characteristic option,

$$q_{nom}(T, n) = \left(1 + \frac{\delta_{AH}(n, T_{fade})}{100}\right) * AH \text{ Ah}.$$

For the equation-based fade characteristic option,

$$q_{nom}(T, n) = \left(1 + \frac{\delta_{AH}}{100} \sqrt{\frac{n}{N}}\right) * AH \text{ Ah}.$$

Finally, SOC is obtained from the following equation.

$$\text{SOC}(t) = \frac{1}{q_{nom}(T, n)} \int \left( i(t) - \frac{V_{open}(T, n, t)}{R_{SD}(T, n)} \right) dt$$

Where:

- $q_{nom}$  is the cell capacity of the battery. Specify this value using the **Cell capacity, AH** parameter.
- $N$  is the reference number of discharge cycles over which you specify percent change of several battery parameters. Set this value using the **Number of discharge cycles, N** parameter.
- $n$  is the present number of cycles of the battery.
- $\delta_{AH}$  is the percentage change in cell capacity of the battery after  $N$  discharge cycles.
- $T$  is the battery temperature. Specify the  $T$  breakpoints using the **Vector of temperatures, T** parameter if tabulating the parameters over temperature.

The block also models the series resistance  $R_0$  as a function of state of charge and optional temperature. Specify the grid of lookup values for the series resistance using the **Terminal resistance, R0(SOC,T)** parameter if tabulating the parameters over temperature, or **Terminal resistance, R0(SOC)** otherwise.

### Modeling Self-Discharge

When the battery terminals are open-circuit, it is still possible for internal currents to discharge the battery. This behavior is called self-discharge. To enable this effect, set the **Self-discharge** parameter to Enabled.

The block models these internal currents with a temperature-dependent resistance  $R_{SD}(T)$  across the terminals of the fundamental battery model. You can specify the lookup values for this resistance using the **Self-discharge resistance, Rleak(T)** parameter if tabulating the parameters over temperature, or **Self-discharge resistance, Rleak** otherwise.

### Modeling Charge Dynamics

Batteries are not able to respond instantaneously to load changes. They require some time to achieve a steady-state. This time-varying property is a result of battery charge dynamics and is modeled using parallel RC sections in the equivalent circuit.

You can model battery charge dynamics using the **Charge dynamics** parameter:

- **No dynamics** — The equivalent circuit contains no parallel RC sections. There is no delay between terminal voltage and internal charging voltage of the battery.
- **One time-constant dynamics** — The equivalent circuit contains one parallel RC section. Specify the time constant using the **First time constant, tau1(SOC,T)** parameter if tabulating parameters over temperature or **First time constant, tau1(SOC)** otherwise.
- **Two time-constant dynamics** — The equivalent circuit contains two parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)** and **Second time constant, tau2(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC)** and **Second time constant, tau2(SOC)** otherwise.
- **Three time-constant dynamics** — The equivalent circuit contains three parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)**, **Second time constant, tau2(SOC,T)**, and **Third time constant, tau3(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC)**, **Second time constant, tau2(SOC)**, and **Third time constant, tau3(SOC)** otherwise.
- **Four time-constant dynamics** — The equivalent circuit contains four parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)**, **Second time constant,**

**tau2(SOC,T), Third time constant, tau3(SOC,T), and Fourth time constant, tau4(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC), Second time constant, tau2(SOC), Third time constant, tau3(SOC), and Fourth time constant, tau4(SOC)** otherwise.

- Five time-constant dynamics — The equivalent circuit contains five parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T), Second time constant, tau2(SOC,T), Third time constant, tau3(SOC,T), Fourth time constant, tau4(SOC,T), and Fifth time constant, tau5(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC), Second time constant, tau2(SOC), Third time constant, tau3(SOC), Fourth time constant, tau4(SOC), and Fifth time constant, tau5(SOC)** otherwise.

This diagram shows the equivalent circuit for the block configured with two time-constant dynamics.

In the diagram:

- $R_1$  and  $R_2$  are the parallel RC resistances. Specify these values with the **First polarization resistance, R1(SOC,T)** and **Second polarization resistance, R2(SOC,T)** parameters, respectively, if tabulating parameters over temperature or **First polarization resistance, R1(SOC)** and **Second polarization resistance, R2(SOC)** otherwise.
- $C_1$  and  $C_2$  are the parallel RC capacitances. The time constant  $\tau$  for each parallel section relates the  $R$  and  $C$  values using the relationship  $C = \tau/R$ . Specify  $\tau$  for each section using the **First time constant, tau1(SOC,T)** and **Second time constant, tau2(SOC,T)** parameters, respectively, if tabulating parameters over temperature or **First time constant, tau1(SOC)** and **Second time constant, tau2(SOC)** otherwise.
- $R_0$  is the series resistance. Specify this value with the **Terminal resistance, R0(SOC,T)** parameter if tabulating parameters over temperature or **Terminal resistance, R0(SOC)** otherwise.

### Modeling Battery Fade

Battery fade is the deterioration of battery performance over repeated charge and discharge cycles. When the **Fade characteristic** parameter is set to Equations, the battery fade is modeled as follows.

The open-circuit voltage across the fundamental battery model fades proportionally with the number of discharge cycles  $n$ :

$$v_{0, \text{fade}} = v_0 \left( 1 + \frac{\delta_{v_0} n}{100 N} \right)$$

Where  $\delta_{v_0}$  is the percent change in open-circuit voltage after  $N$  discharge cycles. Specify  $\delta_{v_0}$  using the **Change in open-circuit voltage after N discharge cycles (%)** parameter.

The nominal charge, from which state of charge is calculated, fades with the square root of number of discharge cycles:

$$q_{nom, \text{fade}} = q_{nom} \left( 1 + \frac{\delta_{AH} \sqrt{n}}{100 \sqrt{N}} \right)$$

All resistances in the battery model also fade with the square root of the number of discharge cycles:

$$R_{i, \text{fade}} = R_i \left( 1 + \frac{\delta_{R_i} \sqrt{n}}{100 \sqrt{N}} \right)$$

Where:

- $R_i$  is the  $i^{\text{th}}$  resistance
- $\delta_{R_i}$  is the percent change in this resistance over  $N$  cycles

Depending on how you have configured the block, the resistances might include:

- The series resistance — Specify the percent change over  $N$  cycles using the **Change in terminal resistance after N discharge cycles (%)** parameter.
- The self-discharge resistance — Specify the percent change over  $N$  cycles using the **Change in self-discharge resistance after N discharge cycles (%)** parameter.
- The first charge dynamics resistance — Specify the percent change over  $N$  cycles using the **Change in first polarization resistance after N discharge cycles (%)** parameter.
- The second charge dynamics resistance — Specify the percent change over  $N$  cycles using the **Change in second polarization resistance after N discharge cycles (%)** parameter.
- The third charge dynamics resistance — Specify the percent change over  $N$  cycles using the **Change in third polarization resistance after N discharge cycles (%)** parameter.
- The fourth charge dynamics resistance — Specify the percent change over  $N$  cycles using the **Change in fourth polarization resistance after N discharge cycles (%)** parameter.
- The fifth charge dynamics resistance — Specify the percent change over  $N$  cycles using the **Change in fifth polarization resistance after N discharge cycles (%)** parameter.

---

**Note** You can also model the battery fade characteristic by using lookup tables (temperature independent) or lookup tables (temperature dependent). Choosing any of these two options changes the blocks parameters accordingly. For more information, see the “Fade” on page 1-87 parameters tab.

### Modeling Thermal Effects

The battery temperature is determined from a summation of all the ohmic losses included in the model:

$$M_{th}\dot{T} = \sum_i V_{T,i}^2/R_{T,i}$$

Where:

- $M_{th}$  is the battery thermal mass.
- $i$  corresponds to the  $i^{\text{th}}$  ohmic loss contributor. Depending on how you have configured the block, the losses might include:
  - The series resistance
  - The self-discharge resistance
  - The first charge dynamics segment
  - The second charge dynamics segment
  - The third charge dynamics segment
  - The fourth charge dynamics segment
  - The fifth charge dynamics segment
- $V_{T,i}$  is the voltage drop across resistor  $i$ .
- $R_{T,i}$  is resistor  $i$ .

### Modeling Battery Aging

You can model the battery performance deterioration that occurs when the battery is not used. Calendar aging affects both the internal resistance and capacity. In particular, the resistance increase depends by various mechanisms such as the creation of Solid Electrolyte Interface (SEI) at both anode and cathode and the corrosion of the current collector. These processes mainly depends on the storage temperature, the storage state of charge, and time.

You can model the calendar aging in the Battery (Table-Based) block by setting the **Modeling option** parameter to:

- Equation-based
- Tabulated: temperature
- Tabulated: time and temperature

#### Equation-based

This equation defines the terminal resistance increase of the battery due to calendar aging:

$$\alpha_r(T, V_{oc}) = (bV_{oc} - c)e^{-\frac{qd}{kT}},$$

$$R = R_0 \left( 1 + \sum_{i=1}^{i=n} \alpha_r(T_i, V_{oc})(t_i^a - t_{i-1}^a) \right),$$

where:

- $V_{oc}$  is the **Normalized open-circuit voltage during storage, V/Vnom**.
- $R_0$  is the **Internal resistance**.
- $t_i$  is the time sample derived from the **Vector of time intervals** parameter.
- $T_i$  is derived from the **Vector of temperatures, T** parameter.

- $b$  is the **Terminal resistance linear scaling for voltage, b**.
- $c$  is the **Terminal resistance constant offset for voltage, c**.
- $d$  is the **Terminal resistance temperature-dependent exponential increase, d**.
- $a$  is the **Terminal resistance time exponent, a**.
- $q$  is the electron's elementary charge, in C.
- $k$  is the Boltzmann constant, in J/K.

This equation defines the capacity decrease of the battery due to calendar aging:

$$\alpha_c(T, V_{oc}) = (bV_{oc} - c)e^{-\frac{qd}{kT}},$$

$$C = C_0 \left( 1 - \sum_{i=1}^{i=n} \alpha_c(T_i, V_{oc})(t_i^a - t_{i-1}^a) \right),$$

where:

- $C_0$  is the **initial capacity**.
- $b$  is the **Capacity linear scaling for voltage, b**.
- $c$  is the **Capacity constant offset for voltage, c**.
- $d$  is the **Capacity temperature-dependent exponential increase, d**.
- $a$  is the **Capacity time constant, a**.

If you set the **Storage condition** parameter to Specify state-of-charge during storage, the block converts the state of charge during storage into normalized open-circuit voltage using the tabulated voltage  $V_0$  against the state of charge and the temperature during storage.

**Tabulated: temperature**

The aged terminal resistance is the product between the terminal resistance,  $R_0(SOC, T)$ , the percentage resistance increase,  $dR_0$ , and the power law that describes the time dependence of the calendar aging:

$$R_0(SOC, T; t_{st}, T_{st}) = R_0(SOC, T) \left( 1 + \sum_{i=1}^n \frac{dR_0(T_{st}, i)}{100} \left( \frac{t_{st, i}^a - t_{st, i-1}^a}{t_{st, m}^a} \right) \right),$$

where:

- $T$  is the battery temperature. Specify the  $T$  breakpoints using the **Vector of temperatures, T** parameter if tabulating the parameters over temperature.
- $T_{st}$  is the **Vector of storage temperatures**.
- $t_{st, i}$  and  $t_{st, i-1}$  are the time samples derived from the **Vector of time intervals**.
- $t_0$  is assumed to be null.
- $t_{st, m}$  is the moment in time at which the resistance increase,  $dR_0$ , is measured.

The same equation applies to the calculation of the aged battery capacity.

**Tabulated: time and temperature**

The aged terminal resistance is the product between the terminal resistance,  $R_0(SOC, T)$  and  $dR_0$ :

$$R_0(SOC, T; \Delta t_{st}, T_{st}) = R_0(SOC, T) \left( 1 + \sum_{i=1}^n \frac{dR_0(\Delta t_{st,i}, T_{st,i})}{100} \right).$$

The same equation applies to the calculation of the aged battery capacity.

### Predefined Parameterization

There are multiple available built-in parameterizations for the Battery (Table-Based) block.

This pre-parameterization data allows you to set up the block to represent components by specific suppliers. The parameterizations of these batteries match the discharge curves in the manufacturer data sheets. To load a predefined parameterization, double-click the Battery (Table-Based) block, click the **<click to select>** hyperlink of the **Selected part** parameter and, in the Block Parameterization Manager window, select the part you want to use from the list of available components.

The available pre-parameterized data model steady state electrical parameters of a lithium-ion battery. The **Open-circuit voltage, V0(SOC)**, **Terminal resistance, R0(SOC, T)**, **Cell capacity, AH**, **Percentage change in cell capacity, dAH**, and **Percentage change in Open-circuit voltage, dV0(N)** parameters are parameterized from characteristics curves in the manufacture datasheets. The change in series resistance with the battery cycle life, the thermal mass, and the dynamic RC network parameters are not parameterized. Instead, the net resistance of the RC network resistors is summed to the series resistance of the specific pre-parameterized data. If you need to fill the RC parameter data, subtract the net RC network resistance from the series resistance data.

The available data is parameterized for 1C discharge current for different temperatures up to the minimum terminal voltage in the datasheet. The data below the minimum terminal voltage is extrapolated. The **Open-circuit voltage, V0(SOC)** parameter is approximated to be temperature independent. At lower temperature, in the low SOC region, the terminal resistances are constant and equal to the value of the resistance at the minimum terminal voltage. This might lead to higher thermal losses.

---

**Note** The predefined parameterizations of Simscape components use available data sources for the parameter values. Engineering judgement and simplifying assumptions are used to fill in for missing data. As a result, expect deviations between simulated and actual physical behavior. To ensure accuracy, validate the simulated behavior against experimental data and refine component models as necessary.

### Plotting Voltage-Charge Characteristics

A quick plot feature lets you visualize the voltage-charge characteristic for the battery model parameter values. To plot the characteristics, right-click a Battery (Table-Based) block in your model and, from the context menu, select **Electrical > Basic characteristics**. The software automatically computes a set of bias conditions, based on the block parameter values, and opens a figure window containing a plot of open-circuit voltage versus the state-of-charge (SOC) for the block. For more information, see “Plot Basic Characteristics for Battery Blocks”.

## Ports

### Output

#### SOC — Battery charge level, C

physical signal

Physical signal port that outputs the internal state of charge. Use this output port to change load behavior as a function of state of charge, without the complexity of building a charge state estimator. The state of charge is the normalized value estimated from the ratio of current charge with the nominal battery capacity,  $q_{nom}(T,n)$ . The block estimates the current battery charge by integrating the battery terminal output current. To convert the state of charge into actual charge, you must use the correct nominal battery capacity for each temperature.

#### Dependencies

To enable this port, in the **Main** setting, set the **Expose SOC measurement port** parameter to Yes.

### Conserving

#### + — Positive terminal

electrical

Electrical conserving port associated with the battery positive terminal.

#### - — Negative terminal

electrical

Electrical conserving port associated with the battery negative terminal.

#### H — Battery thermal mass

thermal

Thermal conserving port that represents the battery thermal mass.

#### Dependencies

To enable this port, in the **Thermal** setting, set the **Thermal port** parameter to Yes.

## Parameters

#### Selected part — Predefined parameterization option

<click to select> (default)

Whether to parameterize the block to represent components by specific suppliers. Click the **<click to select>** hyperlink to open the Block Parameterization Manager window. For more information on the Block Parameterization Manager, see “Load Predefined Parameterizations”.

### Main

#### Vector of state-of-charge values, SOC — SOC breakpoints

[0, .25, .75, 1] (default) | vector

Vector of state-of-charge breakpoints defining the points at which you specify lookup data. This vector must be strictly ascending. The state-of-charge value is calculated with respect to the nominal battery

capacity specified in the **Cell capacity, AH** parameter. SOC is the ratio of the available battery charge,  $q_{battery}$  and the nominal battery capacity,  $q_{nom}(T,n)$ . You must make sure that, for each temperature,  $SOC = 1$  represents the respective battery charge capacity specified in the **Cell capacity, AH** parameter, assuming a fresh battery with a number of cycles,  $N$ , equal to 1 and  $\delta_{AH}(n = 1, T_{fade}) = 0$ .

$$SOC = \frac{q_{battery}}{q_{nom}(T, n)}$$

for  $N = 1$  and  $\delta_{AH}(n, T_{fade}) = 0$ ,  $q_{nom}(T, n) = AH$ .

### Temperature dependent tables — Select whether to tabulate battery parameters over temperature

Yes - tabulate parameters over temperature (default) | No - do not tabulate parameters over temperature

Select whether to tabulate battery parameters over temperature.

### Current directionality — Enable direction of current

Disabled (default) | Enabled

Whether to enable current directionality. If you set this parameter to Enabled, the terminal resistance depends on the direction of the current.

### Terminal voltage operating range [Min Max] — Terminal voltage operating range

[0, inf] V (default) | vector of positive numbers

Operating range of the terminal voltage. This parameter must be a vector of size 1-by-2 that defines the minimum and maximum values of the terminal voltage.

### Vector of temperatures, T — T breakpoints

[273.15, 298.15, 323.15] K (default) | vector of positive numbers

Vector of temperature breakpoints defining the points at which you specify lookup data. This vector must be strictly ascending and greater than 0 K.

### Dependencies

This parameter is visible only when the **Temperature dependent tables** parameter is set to Yes - tabulate parameters over temperature.

### Open-circuit voltage, V0(SOC, T) — V0 lookup table with temperature breakpoint

[3.2, 3.1, 3.14; 3.25, 3.27, 3.3; 3.28, 3.31, 3.34; 3.33, 3.5, 3.59] V (default) | matrix of nonnegative numbers

Lookup data for open-circuit voltages across the fundamental battery model at the specified SOC and temperature breakpoints.

### Dependencies

This parameter is visible only when the **Temperature dependent tables** parameter is set to Yes - tabulate parameters over temperature.

### Open-circuit voltage, V0(SOC) — V0 lookup table

[3.1, 3.27, 3.31, 3.5] V (default) | matrix of nonnegative numbers

Lookup data for open-circuit voltages across the fundamental battery model at the specified SOC.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to No - do not tabulate parameters over temperature.

**Terminal resistance,  $R_0(SOC, T)$  —  $R_0$  lookup table with temperature breakpoint**

[.03, .015, .002; .04, .017, .008; .039, .012, .006; .027, .013, .021] Ohm (default) | matrix of nonnegative numbers

Lookup data for series resistance of the battery at the specified SOC and temperature breakpoints.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to Yes - tabulate parameters over temperature and the **Current directionality** parameter is set to Disabled.

**Terminal resistance during discharging,  $R_0(SOC, T)$  —  $R_0$  lookup table with temperature breakpoint during discharging phase**

[.03, .015, .002; .04, .017, .008; .039, .012, .006; .027, .013, .021] Ohm (default) | matrix of nonnegative numbers

Lookup data for series resistance of the battery at the specified SOC and temperature breakpoints during the discharging phase.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to Yes - tabulate parameters over temperature and the **Current directionality** parameter is set to Enabled.

**Terminal resistance during charging,  $R_0(SOC, T)$  —  $R_0$  lookup table with temperature breakpoint during charging phase**

[.03, .015, .002; .04, .017, .008; .039, .012, .006; .027, .013, .021] Ohm (default) | matrix of nonnegative numbers

Lookup data for series resistance of the battery at the specified SOC and temperature breakpoints during the charging phase.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to Yes - tabulate parameters over temperature and the **Current directionality** parameter is set to Enabled.

**Terminal resistance,  $R_0(SOC)$  —  $R_0$  lookup table**

[.015, .017, .012, .013] Ohm (default) | matrix of nonnegative numbers

Lookup data for series resistance of the battery at the specified SOC.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to No - do not tabulate parameters over temperature and the **Current directionality** parameter is set to Disabled.

**Terminal resistance during discharging,  $R_0(\text{SOC})$  —  $R_0$  lookup table during discharging phase**

[.015, .017, .012, .013] Ohm (default) | matrix of nonnegative numbers

Lookup data for series resistance of the battery at the specified SOC during the discharging phase.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to No - do not tabulate parameters over temperature and the **Current directionality** parameter is set to Enabled.

**Terminal resistance during charging,  $R_0(\text{SOC})$  —  $R_0$  lookup table during charging phase**

[.015, .017, .012, .013] Ohm (default) | matrix of nonnegative numbers

Lookup data for series resistance of the battery at the specified SOC during the charging phase.

**Dependencies**

This parameter is visible only when the **Temperature dependent tables** parameter is set to No - do not tabulate parameters over temperature and the **Current directionality** parameter is set to Enabled.

**Cell capacity, AH — Battery capacity when fully charged**

4.1 hr\*A (default) | nonnegative scalar

Cell capacity of the battery. The block calculates the state of charge by dividing the accumulated charge by this value. The block calculates accumulated charge by integrating the battery current.

**Self-discharge — Select whether to model the self-discharge resistance of the battery**

Disabled (default) | Enabled

Select whether to model the self-discharge resistance of the battery. The block models this effect as a resistor across the terminals of the fundamental battery model.

As temperature increases, self-discharge resistance decreases, causing self-discharge to increase. If the decrease in resistance is too fast, thermal runaway of the battery and numerical instability can occur. You can resolve this instability by making any of these changes:

- Decrease the thermal resistance
- Decrease the gradient of the self-discharge resistance with respect to temperature
- Increase the self-discharge resistance

**Self-discharge resistance,  $R_{\text{leak}}(T)$  — Resistance that represents battery self-discharge at temperature breakpoints**

[8000, 7000, 6000] Ohm (default) | vector of positive numbers

Lookup data for self-discharge resistance of the battery at the specified temperature breakpoints. This resistance acts across the terminals of the fundamental battery model.

**Dependencies**

Enabled when the **Self-discharge** parameter is set to Enabled and **Temperature dependent tables** is set to Yes - tabulate parameters over temperature.

**Self-discharge resistance, R<sub>leak</sub> — Resistance that represents battery self-discharge**  
7e3 Ohm (default) | positive scalar

Lookup data for self-discharge resistance of the battery. This resistance acts across the terminals of the fundamental battery model.

#### Dependencies

This parameter is visible only when the **Self-discharge** parameter is set to Enabled and the **Temperature dependent tables** parameter is set to No - do not tabulate parameters over temperature.

.

**Extrapolation method for all tables — Method of extrapolation for tables**  
Nearest (default) | Linear | Error

Extrapolation method for all the table based parameters:

- **Linear** — Estimates values beyond the dataset by creating a tangent line at the end of the known data and extending it beyond that limit.
- **Nearest** — Extrapolates a value at query point that is the value at the nearest sample grid point.
- **Error** — Returns an error if the value goes beyond the known dataset. If you select this option, the block does not use extrapolation.

**Expose SOC measurement port — Method of extrapolation for tables**  
No (default) | Yes

Whether to expose the state-of-charge measurement port.

#### Dynamics

**Charge dynamics — Battery charge dynamics model**

No dynamics (default) | One time-constant dynamics | Two time-constant dynamics | Three time-constant dynamics | Four time-constant dynamics | Five time-constant dynamics

Select how to model battery charge dynamics. This parameter determines the number of parallel RC sections in the equivalent circuit:

- **No dynamics** — The equivalent circuit contains no parallel RC sections. There is no delay between terminal voltage and internal charging voltage of the battery.
- **One time-constant dynamics** — The equivalent circuit contains one parallel RC section. Specify the time constant using the **First time constant, tau1(SOC,T)** parameter if tabulating parameters over temperature or **First time constant, tau1(SOC)** otherwise.
- **Two time-constant dynamics** — The equivalent circuit contains two parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)** and **Second time constant, tau2(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC)** and **Second time constant, tau2(SOC)** otherwise.
- **Three time-constant dynamics** — The equivalent circuit contains three parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)**, **Second time constant, tau2(SOC,T)**, and **Third time constant, tau3(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC)**, **Second time constant, tau2(SOC)**, and **Third time constant, tau3(SOC)** otherwise.

- **Four time-constant dynamics** — The equivalent circuit contains four parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)**, **Second time constant, tau2(SOC,T)**, **Third time constant, tau3(SOC,T)**, and **Fourth time constant, tau4(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC)**, **Second time constant, tau2(SOC)**, **Third time constant, tau3(SOC)**, and **Fourth time constant, tau4(SOC)** otherwise.
- **Five time-constant dynamics** — The equivalent circuit contains five parallel RC sections. Specify the time constants using the **First time constant, tau1(SOC,T)**, **Second time constant, tau2(SOC,T)**, **Third time constant, tau3(SOC,T)**, **Fourth time constant, tau4(SOC,T)**, and **Fifth time constant, tau5(SOC,T)** parameters if tabulating parameters over temperature or **First time constant, tau1(SOC)**, **Second time constant, tau2(SOC)**, **Third time constant, tau3(SOC)**, **Fourth time constant, tau4(SOC)**, and **Fifth time constant, tau5(SOC)** otherwise.

**First polarization resistance, R1(SOC,T) — First RC resistance at temperature breakpoints**

[.089, .076, .01; .042, .022, .099; .019, .007, .002; .051, .043, .029] Ohm (default) | matrix of positive numbers

Lookup data for the first parallel RC resistance at the specified SOC and temperature breakpoints. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**First polarization resistance, R1(SOC) — First RC resistance**

[.076, .022, .007, .043] Ohm (default) | matrix of positive numbers

Lookup data for the first parallel RC resistance at the specified SOC. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**First time constant, tau1(SOC,T) — First RC time constant at temperature breakpoints**

[44, 148, 235; 93, 110, 1000; 19, 27, 133; .5, 22, 3] s (default) | matrix of positive numbers

Lookup data for the first parallel RC time constant at the specified SOC and temperature breakpoints.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**First time constant, tau1(SOC) – First RC time constant**

[148, 110, 27, 22] s (default) | matrix of positive numbers

Lookup data for the first parallel RC time constant at the specified SOC.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Second polarization resistance, R2(SOC,T) – Second RC resistance at temperature breakpoints**

[.014, .382, .407; .028, .006, .007; .014, .007, .006; .333, .956, .912] Ohm (default) | matrix of positive numbers

Lookup data for the second parallel RC resistance at the specified SOC and temperature breakpoints. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**Second polarization resistance, R2(SOC) – Second RC resistance**

[.382, .006, .007, .956] Ohm (default) | matrix of positive numbers

Lookup data for the second parallel RC resistance at the specified SOC. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Second time constant, tau2(SOC,T) – Second RC time constant at temperature breakpoints**

[1, 44, 5644; 11, 24, 506; 2, 14, 330; 3310, 13419, 30216] s (default) | matrix of positive numbers

Lookup data for the second parallel RC time constant at the specified SOC and temperature breakpoints.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**Second time constant, tau2(SOC) – Second RC time constant**

[44, 24, 14, 13419] s (default) | matrix of positive numbers

Lookup data for the second parallel RC time constant at the specified SOC.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Third polarization resistance,  $R_3(SOC, T)$  – Third RC resistance at temperature breakpoints**

[.014, .382, .407; .028, .006, .007; .014, .007, .006; .333, .956, .912] Ohm (default) | matrix of positive numbers

Lookup data for the third parallel RC resistance at the specified SOC and temperature breakpoints. This parameter primarily affects the ohmic losses of the RC section and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics.

**Third polarization resistance,  $R_3(SOC)$  – Third RC resistance**

[.382, .006, .007, .956] Ohm (default) | matrix of positive numbers

Lookup data for the third parallel RC resistance at the specified SOC. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Third time constant,  $\tau_3(SOC, T)$  – Third RC time constant at temperature breakpoints**

[1, 44, 5644; 11, 24, 506; 2, 14, 330; 3310, 13419, 30216] s (default) | matrix of positive numbers

Lookup data for the third parallel RC time constant at the specified SOC and temperature breakpoints.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**Third time constant,  $\tau_3(SOC)$  – Third RC time constant**

[44, 24, 14, 13419] s (default) | matrix of positive numbers

Lookup data for the third parallel RC time constant at the specified SOC.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Fourth polarization resistance, R4(SOC,T) – Fourth RC resistance at temperature breakpoints**

[.014, .382, .407; .028, .006, .007; .014, .007, .006; .333, .956, .912] Ohm (default) | matrix of positive numbers

Lookup data for the fourth parallel RC resistance at the specified SOC and temperature breakpoints. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**Fourth polarization resistance, R4(SOC) – Fourth RC resistance**

[.382, .006, .007, .956] Ohm (default) | matrix of positive numbers

Lookup data for the fourth parallel RC resistance at the specified SOC. This parameter primarily affects the ohmic losses of the RC section.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Fourth time constant, tau4(SOC,T) – Fourth RC time constant at temperature breakpoints**

[1, 44, 5644; 11, 24, 506; 2, 14, 330; 3310, 13419, 30216] s (default) | matrix of positive numbers

Lookup data for the fourth parallel RC time constant at the specified SOC and temperature breakpoints.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics or Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

**Fourth time constant, tau4(SOC) – Fourth RC time constant**

[44, 24, 14, 13419] s (default) | matrix of positive numbers

Lookup data for the fourth parallel RC time constant at the specified SOC.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics or Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

**Fifth polarization resistance, R5(SOC,T) – Fifth RC resistance at temperature breakpoints**

[.014, .382, .407; .028, .006, .007; .014, .007, .006; .333, .956, .912] Ohm (default) | matrix of positive numbers

Lookup data for the fifth parallel RC resistance at the specified SOC and temperature breakpoints. This parameter primarily affects the ohmic losses of the RC section.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

#### Fifth polarization resistance, R5(SOC) – Fifth RC resistance

[.382, .006, .007, .956] Ohm (default) | matrix of positive numbers

Lookup data for the fifth parallel RC resistance at the specified SOC. This parameter primarily affects the ohmic losses of the RC section.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

#### Fifth time constant, tau5(SOC,T) – Fifth RC time constant at temperature breakpoints

[1, 44, 5644; 11, 24, 506; 2, 14, 330; 3310, 13419, 30216] s (default) | matrix of positive numbers

Lookup data for the fifth parallel RC time constant at the specified SOC and temperature breakpoints.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Temperature dependent tables** to Yes - tabulate parameters over temperature.

#### Fifth time constant, tau5(SOC) – Fifth RC time constant

[44, 24, 14, 13419] s (default) | matrix of positive numbers

Lookup data for the fifth parallel RC time constant at the specified SOC.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Temperature dependent tables** to No - do not tabulate parameters over temperature.

## Fade

### Fade characteristic – Select how to define fade characteristic

Disabled (default) | Equations | Lookup tables (temperature independent) | Lookup tables (temperature dependent)

Select how to define fade characteristic:

- **Disabled** — The block does not model fade characteristic.
- **Equations** — The cell capacity and terminal resistance will be proportional to  $\sqrt{N}$  whilst the open-circuit voltage will be proportional to  $N$ . If the self-discharge resistance or any number of the time constants are enabled, their values will be proportional to  $\sqrt{N}$ .
- **Lookup tables (temperature independent)** — Set tabulated data for the percentage change in parameters as a function of  $N$ .
- **Lookup tables (temperature dependent)** — Set tabulated data for the percentage change in parameters as a function of  $N$  and temperature.

**Number of discharge cycles, N – Reference number of cycles for percent change calculations**

100 (default) | number from 1 to Inf

The number of charge-discharge cycles over which the specified percent changes occur.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Equations.

**Change in open-circuit voltage after N discharge cycles (%) – Percent change in open-circuit voltage after N cycles**

0 (default) | scalar

Percent change in the open-circuit voltage after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Equations.

**Change in terminal resistance after N discharge cycles (%) – Percent change in series resistance after N cycles**

0 (default) | scalar

Percent change in the series resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Equations.

**Change in cell capacity after N discharge cycles (%) – Percent change in cell capacity after N cycles**

0 (default) | scalar

Percent change in the cell capacity after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Equations.

**Change in self-discharge resistance after N discharge cycles (%) – Percent change in self-discharge resistance after N cycles**

0 (default) | scalar

Percent change in the self-discharge resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Self-discharge** to Enabled and **Fade characteristic** to Equations.

**Change in first polarization resistance after N discharge cycles (%) – Percent change in first RC resistance after N cycles**

0 (default) | scalar

Percent change in the first RC resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Equations.

**Change in second polarization resistance after N discharge cycles (%) — Percent change in second RC resistance after N cycles**

0 (default) | scalar

Percent change in the second RC resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Equations.

**Change in third polarization resistance after N discharge cycles (%) — Percent change in third RC resistance after N cycles**

0 (default) | scalar

Percent change in the third RC resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Equations.

**Change in fourth polarization resistance after N discharge cycles (%) — Percent change in fourth RC resistance after N cycles**

0 (default) | scalar

Percent change in the fourth RC resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Equations.

**Change in fifth polarization resistance after N discharge cycles (%) — Percent change in fifth RC resistance after N cycles**

0 (default) | scalar

Percent change in the fifth RC resistance after the battery undergoes *N* discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Fade characteristic** to Equations.

**Vector of discharge cycle values, N — Reference vector or numbers of cycles for percent change calculations**

[100, 200, 300] (default) | number from 1 to Inf

Vector of numbers of charge-discharge cycles over which the specified percent changes occur.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature independent) or Lookuptables (temperature dependent).

**Vector of temperatures for fade data, Tfade — Vector temperatures at which fade lookup tables has been extracted**

[298.15, 323.15] K (default) | number from 1 to Inf

Vector of temperatures at which fade lookup tables has been extracted. These temperatures are completely independent of **Vectors of temperatures, T** parameter from the **Main** tab.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature dependent).

**Percentage change in open-circuit voltage, dV0(N) — Vector of percent change in open-circuit voltage after N cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent changes in the open-circuit voltage after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature independent).

**Percentage change in terminal resistance, dR0(N) — Vector of percent change in series resistance after N cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the series resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature independent).

**Percentage change in cell capacity, dAH(N) — Vector of percent change in cell capacity after N cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the cell capacity after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature independent).

**Percentage change in self-discharge resistance, dRleak(N) — Vector of percent change in self-discharge resistance after N cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the self-discharge resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Self-discharge** to Enabled and **Fade characteristic** to Lookup tables (temperature independent).

**Percentage change in first polarization resistance,  $dR1(N)$  — Vector of percent change in first RC resistance after  $N$  cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the first RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature independent).

**Percent change in second polarization resistance,  $dR2(N)$  — Vector of percent change in second RC resistance after  $N$  cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the second RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature independent).

**Percent change in third polarization resistance,  $dR3(N)$  — Vector of percent change in third RC resistance after  $N$  cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the third RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature independent).

**Percent change in fourth polarization resistance,  $dR4(N)$  — Vector of percent change in fourth RC resistance after  $N$  cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the fourth RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature independent).

**Percent change in fifth polarization resistance,  $dR5(N)$  — Vector of percent change in fifth RC resistance after  $N$  cycles**

[0, 0, 0] (default) | vector of scalars

Vector of percent change in the fifth RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature independent).

**Percentage change in open-circuit voltage,  $dV_0(N, T_{fade})$  — Matrix of percent change in open-circuit voltage after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent changes in the open-circuit voltage after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature dependent).

**Percentage change in terminal resistance,  $dR_0(N, T_{fade})$  — Matrix of percent change in series resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the series resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature dependent).

**Percentage change in cell capacity,  $dAH(N, T_{fade})$  — Matrix of percent change in cell capacity after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the cell capacity after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Fade characteristic** to Lookup tables (temperature dependent).

**Percentage change in self-discharge resistance,  $dR_{leak}(N, T_{fade})$  — Matrix of percent change in self-discharge resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the self-discharge resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Self-discharge** to Enabled and **Fade characteristic** to Lookup tables (temperature dependent).

**Percentage change in first polarization resistance,  $dR_1(N, T_{fade})$  — Matrix of percent change in first RC resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the first RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to One time-constant dynamics, Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature dependent).

**Percent change in second polarization resistance,  $dR2(N, T_{fade})$  — Matrix of percent change in second RC resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the second RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Two time-constant dynamics, Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature dependent).

**Percent change in third polarization resistance,  $dR3(N, T_{fade})$  — Matrix of percent change in third RC resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the third RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Three time-constant dynamics, Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature dependent).

**Percent change in fourth polarization resistance,  $dR4(N, T_{fade})$  — Matrix of percent change in fourth RC resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the fourth RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Four time-constant dynamics, or Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature dependent).

**Percent change in fifth polarization resistance,  $dR5(N, T_{fade})$  — Matrix of percent change in fifth RC resistance after  $N$  cycles**

[0, 0; 0, 0; 0, 0] (default) | matrix of scalars

Matrix of percent change in the fifth RC resistance after the battery undergoes  $N$  discharge cycles.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Five time-constant dynamics and **Fade characteristic** to Lookup tables (temperature dependent).

## **Calendar Aging**

### **Internal resistance calendar aging – Calendar aging for internal resistance**

Disabled (default) | Enabled

Whether to enable calendar aging of the internal resistance of the battery.

### **Capacity calendar aging – Calendar aging for capacity**

Disabled (default) | Enabled

Whether to enable calendar aging of the capacity of the battery.

### **Modeling option – Calendar aging option**

Equation-based (default) | Tabulated: temperature | Tabulated: time and temperature

Modeling option for internal resistance and capacity calendar aging.

#### **Dependencies**

To enable this parameter, set either **Internal resistance calendar aging** or **Capacity calendar aging** to Enabled.

### **Vector of time intervals – Time intervals**

[0] d (default) | scalar

Time intervals. This parameter must be equal in size to **Vector of storage temperatures**.

#### **Dependencies**

To enable this parameter, set **Modeling option** to either Equation-based, Tabulated: temperature, or Tabulated: time and temperature.

### **Vector of storage temperatures – Storage temperatures**

[273] K (default) | scalar

Set of storage temperatures. This parameter must be equal in size to **Vector of time intervals**.

#### **Dependencies**

To enable this parameter, set **Modeling option** to either Equation-based, Tabulated: temperature, or Tabulated: time and temperature.

### **Storage condition – Storage condition**

Specify open-circuit voltage during storage (default) | Specify state-of-charge during storage

Whether to specify the open-circuit voltage or the state of charge during storage.

#### **Dependencies**

To enable this parameter, set **Modeling option** to Equation-based.

### **Normalized open-circuit voltage during storage, V/Vnom – Normalized open-circuit voltage during storage**

0.9 (default) | scalar

Normalized open-circuit voltage during storage.

**Dependencies**

To enable this parameter, set **Modeling option** to Equation-based and **Storage condition** to Specify open-circuit voltage during storage.

**State of charge during storage — Percentage state of charge during storage**

60 (default) | positive number

State of charge during storage, in percentage.

**Dependencies**

To enable this parameter, set **Modeling option** to Equation-based and **Storage condition** to Specify state-of-charge during storage.

**Terminal resistance linear scaling for voltage, b — Voltage linear scaling in terminal resistance**

2.2134e6 (default) | scalar

Linear scaling coefficient in terminal resistance for open-circuit voltage.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Equation-based.

**Terminal resistance constant offset for voltage, c — Voltage constant offset in terminal resistance**

1.632e6 (default) | scalar

Constant offset in terminal resistance for open-circuit voltage.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Equation-based.

**Terminal resistance temperature-dependent exponential increase, d — Temperature-dependent exponential increase in terminal resistance**

0.515833569 V (default) | scalar

Temperature-dependent exponential increase in terminal resistance.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Equation-based.

**Terminal resistance time exponent, a — Time exponent in terminal resistance**

0.75 (default) | scalar

Time exponent in terminal resistance.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to either Equation-based or Tabulated: temperature.

**Capacity linear scaling for voltage, b — Voltage linear scaling in capacity**

1.5097e07 (default) | scalar

Linear scaling coefficient in capacity for open-circuit voltage.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Equation-based.

**Capacity constant offset for voltage, c — Voltage constant offset in capacity**

8.3625e06 (default) | scalar

Constant offset in capacity for open-circuit voltage.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Equation-based.

**Capacity temperature-dependent exponential increase, d — Temperature-dependent exponential increase in capacity**

0.6011 V (default) | scalar

Temperature-dependent exponential increase in capacity.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Equation-based.

**Capacity time exponent, a — Time exponent in capacity**

0.75 (default) | scalar

Time exponent in capacity.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to either Equation-based or Tabulated: temperature.

**Vector of sampled temperatures for terminal resistance calendar aging, T\_ar — Sampled temperatures for terminal resistance calendar aging**

[273.15, 298.15, 323.15] K (default) | vector of scalars

Vector of sampled temperatures for terminal resistance calendar aging.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to either Tabulated: temperature or Tabulated: time and temperature.

**Percentage change in terminal resistance due to calendar aging, dR0(T\_ar) — Percentage change in terminal resistance due to calendar aging**

[0, 0, 0] (default) | vector of scalars

Percentage change in terminal resistance due to calendar aging.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Tabulated: time.

**Time between terminal resistance beginning of life and  $dR(T_{ar})$  measurement — Time between terminal resistance beginning of life and  $dR(T_{ar})$  measurement**

100 d (default) | scalar

Time between the beginning of life of the terminal resistance and the  $dR(T_{ar})$  measurement.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Tabulated: time.

**Vector of sampled temperatures for capacity calendar aging,  $T_{ac}$  — Sampled temperatures for capacity calendar aging**

[273.15, 298.15, 323.15] K (default) | vector of scalars

Vector of sampled temperatures for capacity calendar aging.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to either Tabulated: temperature or Tabulated: time and temperature.

**Percentage change in capacity due to calendar aging,  $dAH(T_{ac})$  — Percentage change in capacity due to calendar aging**

[0, 0, 0] (default) | vector of scalars

Percentage change in capacity due to calendar aging.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Tabulated: time.

**Time between capacity beginning of life and  $dAH(T_{ac})$  measurement — Time between capacity beginning of life and  $dAH(T_{ac})$  measurement**

100 d (default) | scalar

Time between the beginning of life of the capacity and the  $dR(T_{ac})$  measurement.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Tabulated: time.

**Vector of sampled storage time intervals for terminal resistance calendar aging,  $t_{ar}$  — Sampled storage time intervals for terminal resistance calendar aging**

[90, 180, 270, 360] d (default) | vector of scalars

Vector of sampled storage time intervals for terminal resistance calendar aging.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Tabulated: time and temperature.

**Percentage change in terminal resistance due to calendar aging,  $dR0(t_{ar}, T_{ar})$  – Percentage change in terminal resistance due to calendar aging**

[0, 0, 0; 0, 0, 0; 0, 0, 0; 0, 0, 0] (default) | matrix of scalars

Percentage change in terminal resistance due to calendar aging.

**Dependencies**

To enable this parameter, set **Internal resistance calendar aging** to Enabled and **Modeling option** to Tabulated: time and temperature.

**Vector of sampled storage time intervals for capacity calendar aging,  $t_{ac}$  – Sampled storage time intervals for capacity calendar aging**

[90, 180, 270, 360] d (default) | vector of scalars

Vector of sampled storage time intervals for capacity calendar aging.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Tabulated: time and temperature.

**Percentage change in capacity due to calendar aging,  $dAH(t_{ac}, T_{ac})$  – Percentage change in capacity due to calendar aging**

[0, 0, 0; 0, 0, 0; 0, 0, 0; 0, 0, 0] (default) | matrix of scalars

Percentage change in capacity due to calendar aging.

**Dependencies**

To enable this parameter, set **Capacity calendar aging** to Enabled and **Modeling option** to Tabulated: time and temperature.

**Thermal**

**Thermal port – Thermal port visibility**

Omit (default) | Model

Whether to expose the thermal port.

**Simulation temperature – Battery temperature**

298.15 K (default) | positive number

Battery temperature used in lookup tables throughout simulation.

**Dependencies**

To enable this parameter, set **Thermal port** to Omit and **Temperature dependent tables** to Yes - tabulate parameters over temperature or **Fade characteristic** to Lookup tables (temperature dependent). For more information, see “Modeling Thermal Effects” on page 1-53.

**Thermal mass – Thermal mass associated with the thermal port**

30000 J/K (default)

Thermal mass associated with the thermal port H. It represents the energy required to raise the temperature of the thermal port by one degree.

**Dependencies**

To enable this parameter, set **Thermal port** to Model. For more information, see “Modeling Thermal Effects” on page 1-53.

# Bidirectional DC-DC Converter

Controller-driven bidirectional DC-DC step-up and step-down voltage regulator

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Bidirectional DC-DC Converter block represents a converter that steps up or steps down DC voltage from either side of the converter to the other as driven by an attached controller and gate-signal generator. Bidirectional DC-DC converters are useful for switching between energy storage and use, for example, in electric vehicles.

The Bidirectional DC-DC Converter block allows you to model a nonisolated converter with two switching devices, an isolated converter with six switching devices, or a dual active bridge converter with eight switching devices. Options for the type of switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

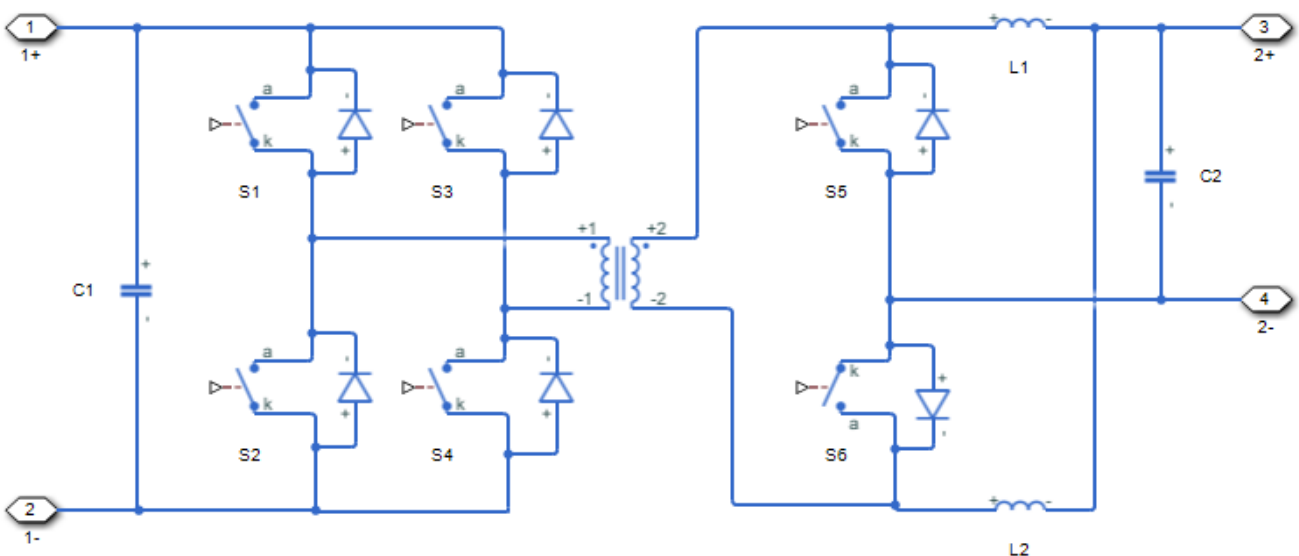

## Model

You can model three different types of bidirectional DC-DC converter. To access the different options, double-click the block and set the **Modeling option** parameter to either:

- **Nonisolated converter** — Bidirectional DC-DC converter without an electrical barrier. This converter contains an inductor, two capacitors, and two switches that are of the same device type.

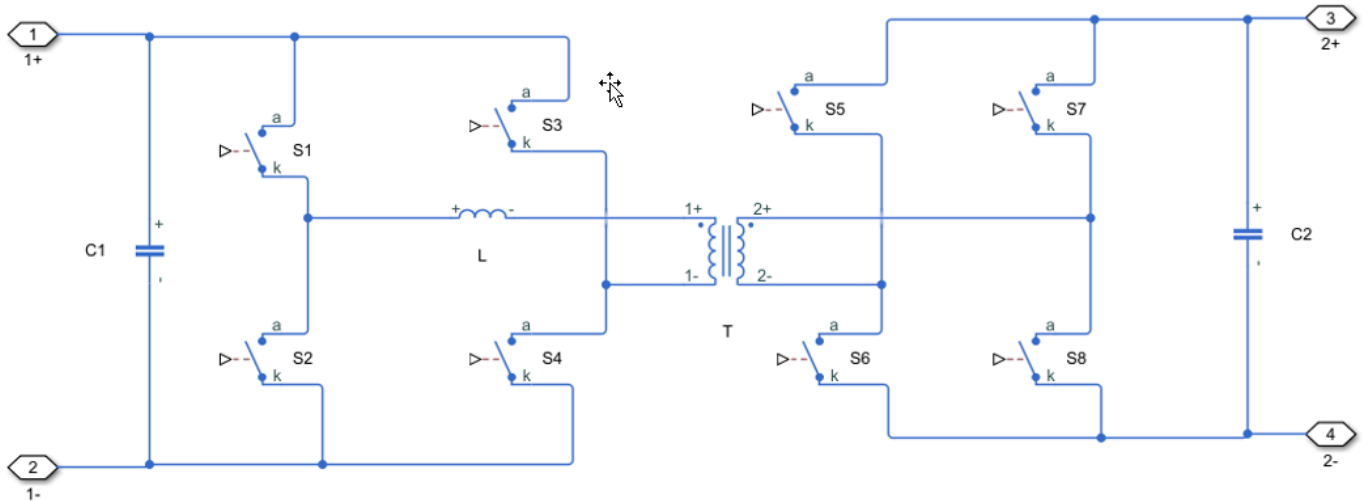

- **Isolated converter** — Bidirectional DC-DC converter with an electrical barrier. This converter contains four additional switches that form a full bridge. The full bridge is on the input or high-voltage (HV) side of the converter. The other two switches are on the output or low-voltage (LV) side of the converter. You can select different semiconductor types for the HV and LV switching devices. For example, you can use a GTO for the HV switching devices and an IGBT for the LV switching devices. To provide separation between the input and output voltages, the model uses a high-frequency transformer.

- **Dual Active Bridge converter** — This bidirectional DC-DC converter contains two full-bridges. The left bridge is the input or high-voltage (HV) side of the converter. The right bridge is the output or low-voltage (LV) side of the converter. You can select different semiconductor types for the HV and LV switching devices. For example, you can use a GTO for the HV switching

devices and an IGBT for the LV switching devices. To provide separation between the input and output voltages, the model uses a high-frequency transformer.

### Protection

The block contains an integral protection diode for each switching device. The integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

To configure the internal protection diode block, use the **Protection Diode** parameters. This table shows how to set the **Model dynamics** parameter based on your goals.

Goals	Value to Select	Integral Protection Diode
Prioritize simulation speed.	Diode with no dynamics	The Diode block
Prioritize model fidelity by precisely specifying reverse-mode charge dynamics.	Diode with charge dynamics	The dynamic model of the Diode block

You can also include a snubber circuit for each switching device. Snubber circuits contain a series-connected resistor and capacitor. They protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of current change when a switching device turns on.

To include and configure a snubber circuit for each switching device, use the **Snubbers** parameters.

### Gate Control

To connect Simulink® gate-control voltage signals to the gate ports of the switching devices:

- 1 Convert each voltage signal using a Simulink-PS Converter block.
- 2 Mux the converted gate signals into a single vector.
  - For a nonisolated converter model, use a Two-Pulse Gate Multiplexer block.
  - For an isolated converter model, use a Six-Pulse Gate Multiplexer block.

- For a dual active bridge converter model, use a Eight-Pulse Gate Multiplexer block.

3 Connect the vector signal to the **G** port.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to **Averaged switch** and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

### Assumptions

A source impedance or a nonzero equivalent-series resistance (ESR) is connected to the left side of the Bidirectional DC-DC Converter block.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Ports

### Conserving

#### **G** — Switching device gate control

electrical | vector

Electrical conserving port associated with the gate terminals of the switching devices.

Data Types: double

#### **1+** — Positive DC voltage 1

electrical | scalar

Electrical conserving port associated with the positive terminal of the first DC voltage.

Data Types: double

**1- – Negative DC voltage 1**

electrical | scalar

Electrical conserving port associated with the negative terminal of the first DC voltage.

Data Types: double

**2+ – Positive DC voltage 2**

electrical | scalar

Electrical conserving port associated with the positive terminal of the second DC voltage.

Data Types: double

**2- – Negative DC voltage 2**

electrical | scalar

## **Parameters**

**Modeling option – Converter model**

Nonisolated converter (default) | Isolated converter | Dual Active Bridge converter

Whether to model a nonisolated converter with two switching devices, an isolated converter with six switching devices, or a dual active bridge converter with eight switching devices.

### **Switching Devices**

These tables show how the visibility of **Switching Devices** parameters depends on the converter model and switching devices that you select. To learn how to read the table, see “Parameter Dependencies” on page A-2.

**Switching device – Switch type**

*Ideal Semiconductor Switch* (default) | *GTO* | *IGBT* | *MOSFET* | *Thyristor* | *Averaged Switch*

Switching device type for the nonisolated converter model.

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Forward voltage — Voltage**

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode i-v characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**On-state resistance — Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance

- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Gate trigger voltage, Vgt — Voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Gate turn-off voltage, Vgt\_off — Voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Holding current — Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Nonisolated Converter Switching Devices Parameter Dependencies table.

**Switching device HV — Switch**

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Switching device type for the high-voltage side of the isolated converter model.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Forward voltage HV — Voltage**

0.8 Ohm (default) | scalar

For the different switching device types, the **Forward voltage HV** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode i-v characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Drain-source on resistance HV — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**On-state resistance HV — Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance HV** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Off-state conductance HV — Conductance**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance HV**.

For the different switching device types, the **On-state resistance HV** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Threshold voltage HV — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Gate trigger voltage HV, Vgt\_hv — Voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Gate turn-off voltage HV, Vgt\_off\_hv — Voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Holding current HV — Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Switching device LV – Switch**

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Switching device type for the low-voltage side of the isolated converter model.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Forward voltage LV – Voltage**

0.8 Ohm (default) | scalar

For the different switching device types, the **Forward voltage LV** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode i-v characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Drain-source on resistance LV – Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**On-state resistance LV – Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance LV** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Off-state conductance LV – Conductance**

1e-5 1/0hm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance LV**.

For the different switching device types, the **On-state resistance LV** is taken as:

- GTO – Anode-cathode conductance
- Ideal semiconductor switch – Anode-cathode conductance
- IGBT – Collector-emitter conductance
- MOSFET – Drain-source conductance
- Thyristor – Anode-cathode conductance

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Threshold voltage LV – Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch – Gate-emitter voltage
- IGBT – Gate-cathode voltage
- MOSFET – Gate-source voltage

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Gate trigger voltage LV, Vgt\_lv – Voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Gate turn-off voltage LV, Vgt\_off\_lv – Voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Holding current LV – Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Isolated Converter and Dual Active Bridge Converter Switching Devices Parameter Dependencies table.

**Integer for piecewise constant approximation of gate input (0 for disabled) – Integer mode for FPGA deployment**

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

**Dependencies**

To enable this parameter, set **Switching device** to Averaged Switch.

**Protection Diode**

The visibility of **Protection Diode** parameters depends on how you configure the protection diode **Model dynamics** and **Reverse recovery time parameterization** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

**Model dynamics – Diode model**

Diode with no dynamics (default) | Diode with charge dynamics

Diode type. The options are:

- **Diode with no dynamics** — Select this option to prioritize simulation speed using the Diode block.
- **Diode with charge dynamics** — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

---

**Note** If you select Averaged Switch for the **Switching Device** parameter in the **Switching Device** setting, this parameter is not visible and Diode with no dynamics is automatically selected.

---

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Forward voltage – Voltage**

0.8 V (default) | scalar

Minimum voltage required across the positive and negative block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.**On resistance – Resistance**

0.001 Ohm (default) | scalar

Rate of change of voltage versus current above the **Forward voltage**.**Off conductance – Conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

**Junction capacitance – Capacitance**

50 nF (default) | scalar

Diode junction capacitance.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Peak reverse current,  $i_{RM}$  – Current**

-235 A (default) | scalar less than 0

Peak reverse current measured by an external test circuit.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Initial forward current when measuring  $i_{RM}$  – Current**

300 A (default) | scalar greater than 0

Initial forward current when measuring peak reverse current. This value must be greater than zero.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Rate of change of current when measuring $i_{RM}$ – Current change rate

-50 A/us (default) | scalar

Rate of change of current when measuring peak reverse current.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Reverse recovery time parameterization – Recovery-time model

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Model for parameterizing the recovery time. When you select `Specify stretch factor` or `Specify reverse recovery charge`, you can specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates  $T_M$  and  $\tau$ ” on page 1-452.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Reverse recovery time stretch factor – Stretch factor

3 (default) | scalar greater than 1

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Reverse recovery time, $t_{rr}$ – Time

15 us (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10 percent of the peak reverse current.

The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Reverse recovery charge, $Q_{rr}$ – Charge

1500 s\*uA (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

### Dependencies

See the Protection Diode Parameter Dependencies table.

### Transformer

To enable these parameters, set **Modeling option** to Isolated converter.

#### Transformer inductance L1 — Inductance

10 H (default) | positive scalar

Self-inductance of the first winding of the transformer.

### Dependencies

To enable this parameter, set **Modeling option** to Isolated converter.

#### Transformer inductance L2 — Inductance

0.1 H (default) | positive scalar

Self-inductance of the second winding of the transformer.

### Dependencies

To enable this parameter, set **Modeling option** to Isolated converter.

#### Transformer coefficient of coupling — Coupling coefficient

0.9 (default) | positive scalar greater than zero and less than 1

Defines the mutual inductance of the transformer.

### Dependencies

To enable this parameter, set **Modeling option** to Isolated converter.

### LC Parameters

#### Inductance, L — Inductance

1e-6 H (default) | positive scalar

Converter inductance. If you set the **Modeling option** parameter to Isolated converter, the two inductors are identical.

**Inductor series resistance – Inductor series resistance**

0 Ohm (default) | zero or positive scalar

Series resistance of the inductor.

**Capacitance, C1 – Capacitance**

1e-7 F (default) | positive scalar

Capacitance of the first DC terminal.

**Capacitance, C2 – Capacitance**

1e-7 F (default) | positive scalar

Capacitance of the second DC terminal.

**C1 effective series resistance – Resistance**

1e-6 Ohm (default) | zero or positive scalar

Series resistance of capacitor *C1*.**C2 effective series resistance – Resistance**

1e-6 Ohm (default) | zero or positive scalar

Series resistance of capacitor *C2*.**Snubbers**The **Snubbers** parameters tab is not visible if you set **Switching device** to Averaged Switch.The table summarizes the **Snubbers** parameter dependencies. ## BLDC

Three-winding brushless DC motor with trapezoidal flux distribution

**Library:** Simscape / Electrical / Electromechanical / Permanent Magnet

### Description

The BLDC block models a permanent magnet synchronous machine with a three-phase wye-wound stator. The block has four options for defining the permanent magnet flux distribution as a function of rotor angle. Two options allow for simple parameterization by assuming a perfect trapezoid for the back emf. For simple parameterization, you specify either the flux linkage or the rotor-induced back emf. The other two options give more accurate results using tabulated data that you specify. For more accurate results, you specify either the flux linkage partial derivative or the measured back emf constant for a given rotor speed.

The figure shows the equivalent electrical circuit for the stator windings.

### Motor Construction

This figure shows the motor construction with a single pole-pair on the rotor.

For the axes convention in the preceding figure, the *a*-phase and permanent magnet fluxes are aligned when rotor angle  $\theta_r$  is zero. The block supports a second rotor-axis definition. For the second definition, the rotor angle is the angle between the *a*-phase magnetic axis and the rotor *q*-axis.

**Trapezoidal Rate of Change of Flux**

The rotor magnetic field due to the permanent magnets create a trapezoidal rate of change of flux with rotor angle. The figure shows this rate of change of flux.

Back emf is the rate of change of flux, defined by

$$\frac{d\Phi}{dt} = \frac{\partial\Phi}{\partial\theta} \frac{d\theta}{dt} = \frac{\partial\Phi}{\partial\theta} \omega,$$

where:

- $\Phi$  is the permanent magnet flux linkage.
- $\theta$  is the rotor angle.
- $\omega$  is the mechanical rotational speed.

The height *h* of the trapezoidal rate of change of flux profile is derived from the permanent magnet peak flux.

Integrating  $\frac{\partial\Phi}{\partial\theta}$  over the range 0 to  $\pi/2$ ,

$$\Phi_{max} = \frac{h}{2}(\theta_F + \theta_W),$$

where:

- $\Phi_{max}$  is the permanent magnet flux linkage.
- $h$  is the rate of change of flux profile height.
- $\theta_F$  is the rotor angle range over which the back emf that the permanent magnet flux induces in the stator is constant.
- $\theta_W$  is the rotor angle range over which back emf increases or decreases linearly when the rotor moves at constant speed.

Rearranging the preceding equation,

$$h = 2\Phi_{max}/(\theta_F + \theta_W).$$

### Electrical Defining Equations

Voltages across the stator windings are defined by

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} R_s & 0 & 0 \\ 0 & R_s & 0 \\ 0 & 0 & R_s \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} \frac{d\psi_a}{dt} \\ \frac{d\psi_b}{dt} \\ \frac{d\psi_c}{dt} \end{bmatrix},$$

where:

- $v_a$ ,  $v_b$ , and  $v_c$  are the external voltages applied to the three motor electrical connections.
- $R_s$  is the equivalent resistance of each stator winding.
- $i_a$ ,  $i_b$ , and  $i_c$  are the currents flowing in the stator windings.
- $\frac{d\psi_a}{dt}$ ,  $\frac{d\psi_b}{dt}$ , and  $\frac{d\psi_c}{dt}$

are the rates of change of magnetic flux in each stator winding.

The permanent magnet and the three windings contribute to the total flux linking each winding. The total flux is defined by

$$\begin{bmatrix} \psi_a \\ \psi_b \\ \psi_c \end{bmatrix} = \begin{bmatrix} L_{aa} & L_{ab} & L_{ac} \\ L_{ba} & L_{bb} & L_{bc} \\ L_{ca} & L_{cb} & L_{cc} \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} \psi_{am} \\ \psi_{bm} \\ \psi_{cm} \end{bmatrix},$$

where:

- $\psi_a$ ,  $\psi_b$ , and  $\psi_c$  are the total fluxes linking each stator winding.
- $L_{aa}$ ,  $L_{bb}$ , and  $L_{cc}$  are the self-inductances of the stator windings.
- $L_{ab}$ ,  $L_{ac}$ ,  $L_{ba}$ , etc. are the mutual inductances of the stator windings.
- $\psi_{am}$ ,  $\psi_{bm}$ , and  $\psi_{cm}$  are the permanent magnet fluxes linking the stator windings.

The inductances in the stator windings are functions of rotor angle, defined by

$$L_{aa} = L_s + L_m \cos(2\theta_r),$$

$$L_{bb} = L_s + L_m \cos(2(\theta_r - 2\pi/3)),$$

$$L_{cc} = L_s + L_m \cos(2(\theta_r + 2\pi/3)),$$

$$L_{ab} = L_{ba} = -M_s - L_m \cos(2(\theta_r + \pi/6)),$$

$$L_{bc} = L_{cb} = -M_s - L_m \cos(2(\theta_r + \pi/6 - 2\pi/3)),$$

and

$$L_{ca} = L_{ac} = -M_s - L_m \cos(2(\theta_r + \pi/6 + 2\pi/3)),$$

where:

- $L_s$  is the stator self-inductance per phase — The average self-inductance of each of the stator windings.
- $L_m$  is the stator inductance fluctuation — The fluctuation in self-inductance and mutual inductance with changing rotor angle.
- $M_s$  is the stator mutual inductance — The average mutual inductance between the stator windings.

The permanent magnet flux linking each stator winding follows the trapezoidal profile shown in the figure. The block implements the trapezoidal profile using lookup tables to calculate permanent magnet flux values.

### Simplified Equations

The defining voltage and torque equations for the block are

$$\begin{bmatrix} v_d \\ v_q \\ v_0 \end{bmatrix} = P \left( \begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} - N\omega \begin{bmatrix} \frac{\partial \psi_{am}}{\partial \theta_r} \\ \frac{\partial \psi_{bm}}{\partial \theta_r} \\ \frac{\partial \psi_{cm}}{\partial \theta_r} \end{bmatrix} \right),$$

$$v_d = R_s i_d + L_d \frac{di_d}{dt} - N\omega i_q L_q$$

$$v_q = R_s i_q + L_q \frac{di_q}{dt} + N\omega i_d L_d,$$

$$v_0 = R_s i_0 + L_0 \frac{di_0}{dt}$$

and

$$T = \frac{3}{2} N (i_q i_d L_d - i_d i_q L_q) + [i_a \ i_b \ i_c] \begin{bmatrix} \frac{\partial \psi_{am}}{\partial \theta_r} \\ \frac{\partial \psi_{bm}}{\partial \theta_r} \\ \frac{\partial \psi_{cm}}{\partial \theta_r} \end{bmatrix},$$

where:

- $v_d$ ,  $v_q$ , and  $v_0$  are the  $d$ -axis,  $q$ -axis, and zero-sequence voltages.
- $P$  is Park's Transformation, defined by

$$P = 2/3 \begin{bmatrix} \cos\theta_e & \cos(\theta_e - 2\pi/3) & \cos(\theta_e + 2\pi/3) \\ -\sin\theta_e & -\sin(\theta_e - 2\pi/3) & -\sin(\theta_e + 2\pi/3) \\ 0.5 & 0.5 & 0.5 \end{bmatrix}$$

- $N$  is the number of rotor permanent magnet pole pairs.
- $\omega$  is the rotor mechanical rotational speed.
- $\frac{\partial \psi_{am}}{\partial \theta_r}$ ,  $\frac{\partial \psi_{bm}}{\partial \theta_r}$ , and  $\frac{\partial \psi_{cm}}{\partial \theta_r}$

are the partial derivatives of instantaneous permanent magnet flux linking each phase winding.

- $i_d$ ,  $i_q$ , and  $i_0$  are the  $d$ -axis,  $q$ -axis, and zero-sequence currents, defined by

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = P \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}$$

- $L_d = L_s + M_s + 3/2 L_m$ .  $L_d$  is the stator  $d$ -axis inductance.
- $L_q = L_s + M_s - 3/2 L_m$ .  $L_q$  is the stator  $q$ -axis inductance.
- $L_0 = L_s - 2M_s$ .  $L_0$  is the stator zero-sequence inductance.
- $T$  is the rotor torque. Torque flows from the motor case (block physical port C) to the motor rotor (block physical port R).

### Calculating Iron Losses

Iron losses are divided into two terms, one representing the main magnetizing path, and the other representing the cross-tooth tip path that becomes active during field weakened operation. The iron losses model, which is based on the work of Mellor [3].

The term representing the main magnetizing path depends on the induced RMS stator voltage,  $V_{m_{rms}}$ :

$$P_{OC}(V_{m_{rms}}) = \frac{a_h}{k} V_{m_{rms}} + \frac{a_j}{k^2} V_{m_{rms}}^2 + \frac{a_{ex}}{k^{1.5}} V_{m_{rms}}^{1.5}$$

This is the dominant term during no-load operation.  $k$  is the back emf constant relating RMS volts per Hz. It is defined as  $k = V_{m_{rms}}/f$ , where  $f$  is the electrical frequency. The first term on the right-hand side is the magnetic hysteresis loss, the second is the eddy current loss and the third is the excess loss. The three coefficients appearing on the numerators are derived from the values that you provide for the open-circuit hysteresis, eddy, and excess losses.

The term representing the cross-tooth tip path becomes important when a demagnetizing field is set up and can be determined from a finite element analysis short-circuit test. It depends on the RMS emf associated with the cross-tooth tip flux,  $V_{d_{rms}}^*$ :

$$P_{SC}(V_{d_{rms}}^*) = \frac{b_h}{k} V_{d_{rms}}^* + \frac{b_j}{k^2} V_{d_{rms}}^{*2} + \frac{b_{ex}}{k^{1.5}} V_{d_{rms}}^{*1.5}$$

The three numerator terms are derived from the values you provide for the short-circuit hysteresis, eddy, and excess losses.

### Predefined Parameterization

There are multiple available built-in parameterizations for the BLDC block.

This pre-parameterization data allows you to set up the block to represent components by specific suppliers. The parameterizations of these brushless DC motors match the manufacturer data sheets. To load a predefined parameterization, double-click the BLDC block, click the **<click to select>** hyperlink of the **Selected part** parameter and, in the Block Parameterization Manager window, select the part you want to use from the list of available components.

---

**Note** The predefined parameterizations of Simscape components use available data sources for the parameter values. Engineering judgement and simplifying assumptions are used to fill in for missing data. As a result, expect deviations between simulated and actual physical behavior. To ensure accuracy, validate the simulated behavior against experimental data and refine component models as necessary.

---

For more information about pre-parameterization and for a list of the available components, see “List of Pre-Parameterized Components”.

### Model Thermal Effects

You can expose thermal ports to model the effects of losses that convert power to heat. To expose the thermal ports, set the **Modeling option** parameter to either:

- **No thermal port** — The block contains expanded electrical conserving ports associated with the stator windings, but does not contain thermal ports.
- **Show thermal port** — The block contains expanded electrical conserving ports associated with the stator windings and thermal conserving ports for each of the windings and for the rotor.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Ports

### Conserving

~ — **Three-phase port**  
electrical

Expandable three-phase port.

**Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

**a – a-phase**

electrical

Electrical conserving port associated with *a*-phase.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**b – b-phase**

electrical

Electrical conserving port associated with *b*-phase.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c – c-phase**

electrical

Electrical conserving port associated with *c*-phase.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**n – Neutral phase**

electrical

Electrical conserving port associated with the neutral phase.

**Dependencies**

To enable this port, set **Winding Type** to Wye-wound and **Zero sequence** to Include.

**R – Motor rotor**

mechanical

Mechanical rotational conserving port associated with the motor rotor.

**C – Motor case**

mechanical

Mechanical rotational conserving port associated with the motor case.

**HA – Winding A thermal port**

thermal

Thermal conserving port associated with winding A.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HB — Winding B thermal port**

thermal

Thermal conserving port associated with winding B.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HC — Winding C thermal port**

thermal

Thermal conserving port associated with winding C.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HR — Rotor thermal port**

thermal

Thermal conserving port associated with the rotor.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters****Selected part — Predefined parameterization option**

<click to select> (default)

Whether to parameterize the block to represent components by specific suppliers. Click the **<click to select>** hyperlink to open the Block Parameterization Manager window. For more information on the Block Parameterization Manager, see "Load Predefined Parameterizations".

**Modeling option — Whether to enable thermal ports**

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of losses that convert power to heat.

**Rotor****Electrical connection — Electrical connection**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

**Winding type — Windings configuration**

Wye-wound (default) | Delta-wound

Select the configuration for the windings:

- Wye-wound — The windings are wye-wound.
- Delta-wound — The windings are delta-wound. The *a*-phase is connected between ports **a** and **b**, the *b*-phase between ports **b** and **c** and the *c*-phase between ports **c** and **a**.

**Back EMF profile — Back EMF profile**

Perfect trapezoid - specify maximum flux linkage (default) | Perfect trapezoid - specify maximum rotor-induced back emf | Tabulated - specify flux partial derivative with respect to rotor angle | Tabulated - specify rotor-induced back emf as a function of rotor angle

Parameterization for defining the permanent magnet flux distribution as a function of rotor angle. Choose:

- Perfect trapezoid - specify maximum flux linkage to specify the maximum flux linkage for the permanent magnet and the rotor angle where the back emf is constant. The block assumes a perfect trapezoid for the back emf. This is the default value.
- Perfect trapezoid - specify maximum rotor-induced back emf to specify the maximum rotor-induced back emf and the corresponding rotor speed. The block assumes a perfect trapezoid for the back emf.
- Tabulated - specify flux partial derivative with respect to rotor angle to specify values for the partial derivative of flux linkage and the corresponding rotor angles.
- Tabulated - specify rotor-induced back emf as a function of rotor angle to specify the measured back emf constant and the corresponding rotor speed and angles.

**Maximum permanent magnet flux linkage — Maximum permanent magnet flux linkage**  
0.03 Wb (default)

Peak permanent magnet flux linkage with any of the stator windings.

**Dependencies**

To enable this parameter, set **Back EMF profile** to Perfect trapezoid - specify maximum flux linkage.

**Rotor angle over which back emf is constant — Rotor angle over which back emf is constant**

$\pi / 12$  rad (default)

Rotor angle range over which the permanent magnet flux linking the stator winding is constant. This angle is  $\theta_F$  in the figure that shows the “Trapezoidal Rate of Change of Flux” on page 1-121.

**Dependencies**

To enable this parameter, set **Back EMF profile** to Perfect trapezoid - specify maximum flux linkage or Perfect trapezoid - specify maximum rotor-induced back emf.

**Maximum rotor-induced back emf — Maximum rotor-induced back emf**  
9.6 V (default)

Peak rotor-induced back emf into the stator windings.

**Dependencies**

To enable this parameter, set **Back EMF profile** to Perfect trapezoid - specify maximum rotor-induced back emf.

**Rotor-induced back emf — Rotor-induced back emf**

[0, -9.6, -9.6, 9.6, 9.6, 0] V (default)

Vector of values for the rotor-induced back emf as a function of rotor angle. The first and last values must be the same, and are normally both zero. For more information, see the **Corresponding rotor angles** parameter. First and last values are the same because flux is cyclic with period  $2\pi/N$ , where  $N$  is the number of permanent magnet pole pairs.

**Dependencies**

To enable this parameter, set **Back EMF profile** to Tabulated - specify rotor-induced back emf as a function of rotor angle.

**Flux linkage partial derivative with respect to rotor angle — Flux linkage partial derivative with respect to rotor angle**

[0, -.1528, -.1528, .1528, .1528, 0] Wb/rad (default)

Vector of values for the partial derivative of flux linkage (where flux linkage is flux times number of winding turns) with respect to rotor angle. The first and last values must be the same, and are normally both zero. For more information, see the **Corresponding rotor angles** parameter. First and last values are the same because flux is cyclic with period  $2\pi/N$ , where  $N$  is the number of permanent magnet pole pairs.

**Corresponding rotor angles — Corresponding rotor angles**

[0, 7.5, 22.5, 37.5, 52.5, 60] deg (default)

Vector of rotor angles where the flux linkage partial derivative or rotor-induced back emf is defined. Rotor angle is defined as the angle between the  $a$ -phase magnetic axis and the  $d$ -axis. That is, when the angle is zero, the magnetic fields due to the rotor and the  $a$ -phase winding align. This definition is used regardless of your block setting for rotor angle definition. The first value is zero, and the last value is  $2\pi/N$ , where  $N$  is the number of permanent magnet pole pairs.

**Dependencies**

To enable this parameter, set **Back EMF profile** to Tabulated - specify flux partial derivative with respect to rotor angle or Tabulated - specify rotor-induced back emf as a function of rotor angle.

**Rotor speed used for back emf measurement — Rotor speed used for back emf measurement**

600 rpm (default)

Specify the rotor speed corresponding to the maximum rotor-induced back emf.

**Dependencies**

To enable this parameter, set **Back EMF profile** to Perfect trapezoid - specify maximum rotor-induced back emf or Tabulated - specify rotor-induced back emf as a function of rotor angle.

**Number of pole pairs — Number of pole pairs**

6 (default)

Number of permanent magnet pole pairs on the rotor.

**Rotor angle definition — Reference point for the rotor angle measurement**

Angle between the a-phase magnetic axis and the d-axis (default) | Angle between the a-phase magnetic axis and the q-axis

Reference point for the rotor angle measurement. The default value is Angle between the a-phase magnetic axis and the d-axis. This definition is shown in the “Motor Construction” on page 1-120 figure. When you select this value, the rotor and a-phase fluxes are aligned when the rotor angle is zero.

The other value you can choose for this parameter is Angle between the a-phase magnetic axis and the q-axis. When you select this value, the a-phase current generates maximum torque when the rotor angle is zero.

**Stator****Modeling fidelity — Modeling fidelity**

Constant  $L_d$  and  $L_q$  (default) | Tabulated  $L_d$  and  $L_q$

Select the modeling fidelity:

- Constant  $L_d$  and  $L_q$  —  $L_d$  and  $L_q$  values are constant and defined by their respective parameters.
- Tabulated  $L_d$  and  $L_q$  —  $L_d$  and  $L_q$  values are computed online from DQ currents look-up tables as follows:

$$L_d = f_1(i_d, i_q)$$

$$L_q = f_2(i_d, i_q)$$

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify  $L_d$ ,  $L_q$ , and  $L_0$ .

**Stator parameterization — Stator parameterization**

Specify  $L_d$ ,  $L_q$ , and  $L_0$  (default) | Specify  $L_s$ ,  $L_m$ , and  $M_s$

Choose Specify  $L_d$ ,  $L_q$ , and  $L_0$  or Specify  $L_s$ ,  $L_m$ , and  $M_s$ .

**Stator d-axis inductance,  $L_d$  — Stator d-axis inductance**

0.00022 H (default)

D-axis inductance.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify  $L_d$ ,  $L_q$ , and  $L_0$  and **Modeling fidelity** to Constant  $L_d$  and  $L_q$ .

**Stator q-axis inductance,  $L_q$  — Stator q-axis inductance**

0.00022 H (default)

Q-axis inductance.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify  $L_d$ ,  $L_q$ , and  $L_0$  and **Modeling fidelity** to Constant  $L_d$  and  $L_q$ .

**Direct-axis current vector,  $i_D$  — Direct-axis current vector**

[-200, 0, 200] A (default)

Direct-axis current vector,  $i_D$ .**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ld, Lq, and L0 and **Modeling fidelity** to Tabulated Ld and Lq.

**Quadrature-axis current vector,  $i_Q$  — Quadrature-axis current vector**

[-200, 0, 200] A (default)

Quadrature-axis current vector,  $i_Q$ .**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ld, Lq, and L0 and **Modeling fidelity** to Tabulated Ld and Lq.

**Ld matrix,  $L_d(i_d, i_q)$  — Ld matrix**

0.00022 \* ones(3, 3) H (default)

Ld matrix.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ld, Lq, and L0 and **Modeling fidelity** to Tabulated Ld and Lq.

**Lq matrix,  $L_q(i_d, i_q)$  — Lq matrix**

0.00022 \* ones(3, 3) H (default)

Lq matrix.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ld, Lq, and L0 and **Modeling fidelity** to Tabulated Ld and Lq.

**Stator zero-sequence inductance,  $L_0$  — Stator zero-sequence inductance**

0.00016 H (default)

Zero-sequence inductance.

**Dependencies**

To enable this parameter either:

- Set **Winding Type** to Wye-wound, **Zero sequence** to Include, and **Stator parameterization** to Specify Ld, Lq, and L0.
- Set **Winding Type** to Delta-wound and **Stator parameterization** to Specify Ld, Lq, and L0.

**Stator self-inductance per phase,  $L_s$  — Stator self-inductance per phase**

0.0002 H (default)

Average self-inductance of each of the three stator windings.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ls, Lm, and Ms.

**Stator inductance fluctuation, Lm — Stator inductance fluctuation**

0 H (default)

Fluctuation in self-inductance and mutual inductance of the stator windings with rotor angle.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ls, Lm, and Ms.

**Stator mutual inductance, Ms — Stator mutual inductance**

0.00002 H (default)

Average mutual inductance between the stator windings.

**Dependencies**

To enable this parameter, set **Stator parameterization** to Specify Ls, Lm, and Ms.

**Stator resistance per phase, Rs — Stator resistance per phase**

0.013 Ohm (default)

Resistance of each of the stator windings.

**Zero sequence — Zero sequence option**

Include (default) | Exclude

Option to include or exclude zero-sequence terms.

- **Include** — Include zero-sequence terms. To prioritize model fidelity, use this default setting. Using this option:
  - Results in an error for simulations that use the Partitioning solver. For more information, see “Increase Simulation Speed Using the Partitioning Solver”.
  - Exposes a zero-sequence parameter in the **Impedances** settings.
- **Exclude** — Exclude zero-sequence terms. To prioritize simulation speed for desktop simulation or real-time deployment, select this option.

**Dependencies**

This parameter is visible only when you set the **Winding Type** parameter to Wye-wound.

**Iron Losses****Model — Enable iron losses computation**

None (default) | Empirical

Specify the iron losses computational model.

**Open-circuit iron losses, [P\_hysteresis P\_eddy P\_excess] — Open-circuit iron losses**

[0, 0, 0] W (default)

Row vector, of length 3, of the open-circuit iron losses due to hysteresis, Eddy, and excess losses, respectively, at the frequency specified by **Electrical frequency at which losses determined**.

#### Dependencies

To enable this parameter, set **Model** to Empirical.

#### Short-circuit iron losses, [P\_hysteresis P\_eddy P\_excess] — Short-circuit iron losses

[0, 0, 0] W (default)

Row vector, of length 3, of the short-circuit iron losses due to hysteresis, Eddy, and excess losses, respectively, at the frequency specified by **Electrical frequency at which losses determined**.

#### Dependencies

To enable this parameter, set **Model** to Empirical.

#### Electrical frequency at which losses determined — Electrical frequency at which losses determined

60 Hz (default)

Electrical frequency at which the open-circuit and short-circuit iron losses were measured.

#### Dependencies

To enable this parameter, set **Model** to Empirical.

#### Short-circuit RMS current for short-circuit iron losses — Short-circuit RMS current for short-circuit iron losses

95 A (default)

The resulting short-circuit RMS phase current when measuring the short-circuit losses.

#### Dependencies

To enable this parameter, set **Model** to Empirical.

### Mechanical

#### Rotor inertia — Rotor inertia

0.01 kg\*m<sup>2</sup> (default)

Inertia of the rotor attached to mechanical translational port **R**. The value can be zero.

#### Rotor damping — Rotor damping

0 N\*m/(rad/s) (default)

Rotary damping.

### Temperature Dependence

These parameters appear only for blocks with exposed thermal ports.

#### Measurement temperature — Measurement temperature

298.15 K (default)

The temperature for which motor parameters are quoted.

**Resistance temperature coefficient – Resistance temperature coefficient**

3.93e-3 1/K (default)

Coefficient  $\alpha$  in the equation relating resistance to temperature, as described in “Thermal Model for Actuator Blocks”. The default value is for copper.

**Permanent magnet flux temperature coefficient – Permanent magnet flux temperature coefficient**

-0.001 1/K (default)

The fractional rate of change of permanent magnet flux density with temperature. It is used to linearly reduce the torque and the induced back EMF as temperature rises.

**Thermal Port**

These parameters appear only for blocks with exposed thermal ports.

**Thermal mass for each stator winding – Thermal mass for each stator winding**

100 J/K (default)

The thermal mass value for the A, B, and C windings. The thermal mass is the energy required to raise the temperature by one degree.

**Rotor thermal mass – Rotor thermal mass**

200 J/K (default)

The thermal mass of the rotor, that is, the energy required to raise the temperature of the rotor by one degree.

**Percentage of main flux path iron losses associated with the rotor – Percentage of main flux path iron losses associated with the rotor**

90 (default)

The percentage of the main flux path iron losses associated with the magnetic path through the rotor. It determines how much of the iron loss heating is attributed to the rotor thermal port **HR**, and how much is attributed to the three winding thermal ports **HA**, **HB**, and **HC**.

**Dependencies**

To enable this parameter, set **Model** to **Empirical**.

**Percentage of cross-tooth flux path iron losses associated with the rotor – Percentage of cross-tooth flux path iron losses associated with the rotor**

30 (default)

The percentage of the cross-tooth flux path iron losses associated with the magnetic path through the rotor. It determines how much of the iron loss heating is attributed to the rotor thermal port **HR**, and how much is attributed to the three winding thermal ports **HA**, **HB**, and **HC**.

**Dependencies**

To enable this parameter, set **Model** to **Empirical**.

Switch-commutation logic for brushless DC motors

**Library:** Simscape / Electrical / Control / BLDC Control

## Description

The BLDC Commutation Logic block implements a commutation logic for brushless DC motors as part of this control algorithm.

The commutation logic is based on the Hall signals as summarized in this table.

Hall Sensors			Motor Phases		
Hall a	Hall b	Hall c	Phase a	Phase b	Phase c

Hall Sensors			Motor Phases		
0	0	0	0	0	0

## Ports

### Input

#### Hall — Hall sensor

vector

Hall sensor data.

Data Types: single | double

#### Direction — Motor direction

scalar

Direction of motor rotation.

Data Types: single | double

### Output

#### abc — Motor phase

vector

Motor phase indicated by the commutation logic.

Data Types: single | double

## Parameters

#### Sample time (-1 for inherited) — Block sample time

-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

# BLDC Current Controller

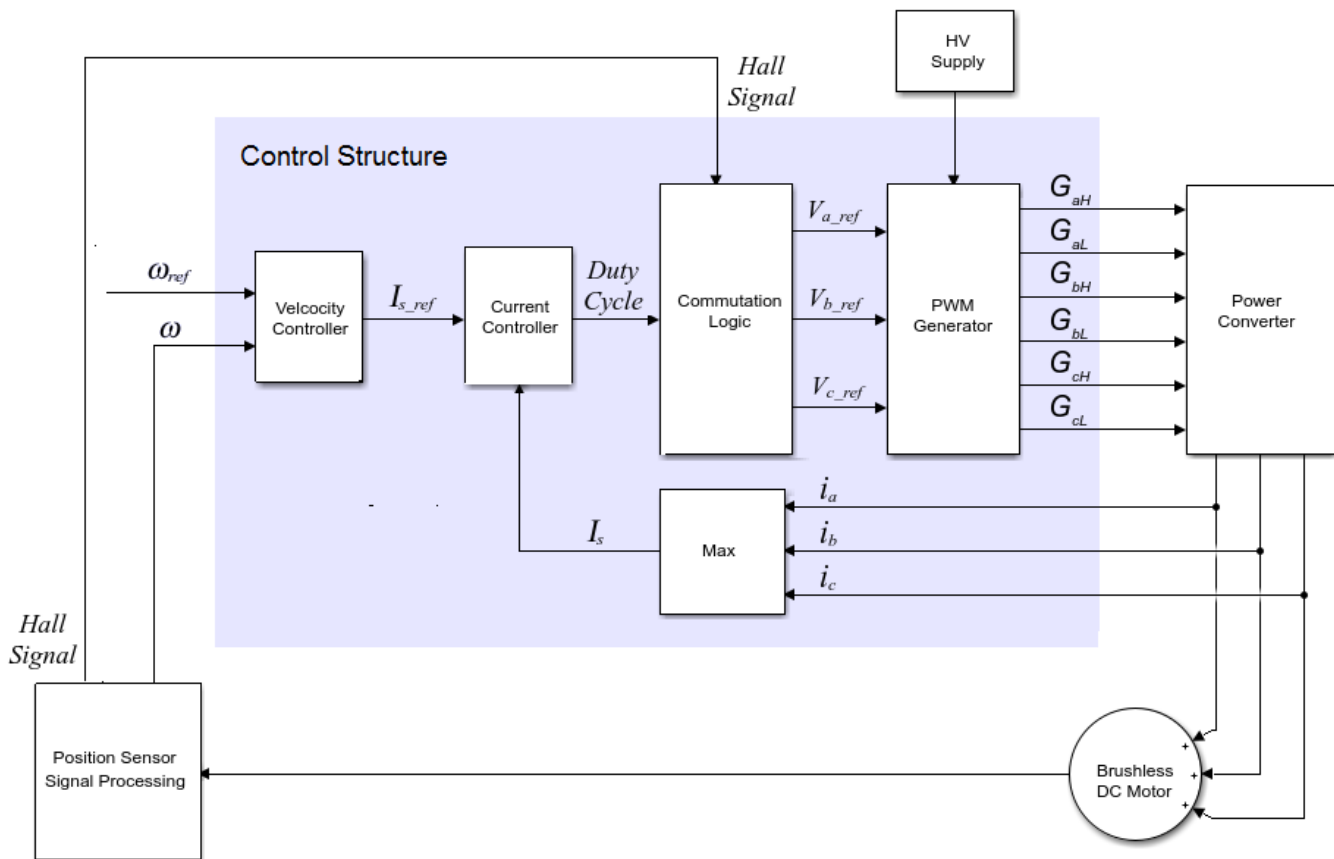

Discrete-time Brushless DC Motor current PI controller

**Library:** Simscape / Electrical / Control / BLDC Control

## Description

The BLDC Current Controller block uses this algorithm to control current in a DC brushless motor.

## Equations

The BLDC Current Controller produces the duty cycle for a BLDC block by implementing proportional-integral (PI) current control using this equation.

$$D = \left( K_p + K_i \frac{T_s z}{z-1} \right) (I_{s\_ref} - I_s)$$

Where:

- $D$  is the duty cycle.
- $K_p$  is the proportional gain.
- $K_i$  is the integral gain.
- $T_s$  is the time period.
- $I_{s\_ref}$  is the reference current.
- $I_s$  is the measured current.
- $G_{zc}$  is the zero cancellation polynomial.

The closed-loop transfer function for the PI control algorithm yields a zero that can be cancelled by using zero-cancellation in the feedforward path. The zero-cancellation transfer function in discrete-time is:

$$G_{ZC}(z) = \frac{\frac{T_s K_i}{K_p}}{z + \left( \frac{T_s - \frac{K_p}{K_i}}{\frac{K_p}{K_i}} \right)}$$

The block obtains control signals for the three phases by multiplying the duty cycle by the commutation signals. The resulting three control signals are normalized over the interval [-1, 1].

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

### **Dependencies**

If you set **Sample time (-1 for inherited)** to -1 and select the **Enable zero cancellation** option, the **Discretization sample time** parameter becomes visible.

**Discretization sample time — Sample time for discretization**

0.001 (default) | positive scalar

Time, in s, between consecutive discretizations. Discretization is required for zero cancellation.

**Dependencies**

This parameter is only visible when both these conditions are met:

- **Sample time** is set to -1.
- **Enable zero cancellation** is selected.

**Enable zero cancellation — Feedforward zero cancellation**

off (default) | on

Option to use zero cancellation on the feedforward path.

**Dependencies**

If you select the **Enable zero cancellation** option and set **Sample time (-1 for inherited)** to -1, the **Discretization sample time** parameter becomes visible.

# BLDC Current Controller with PWM Generation

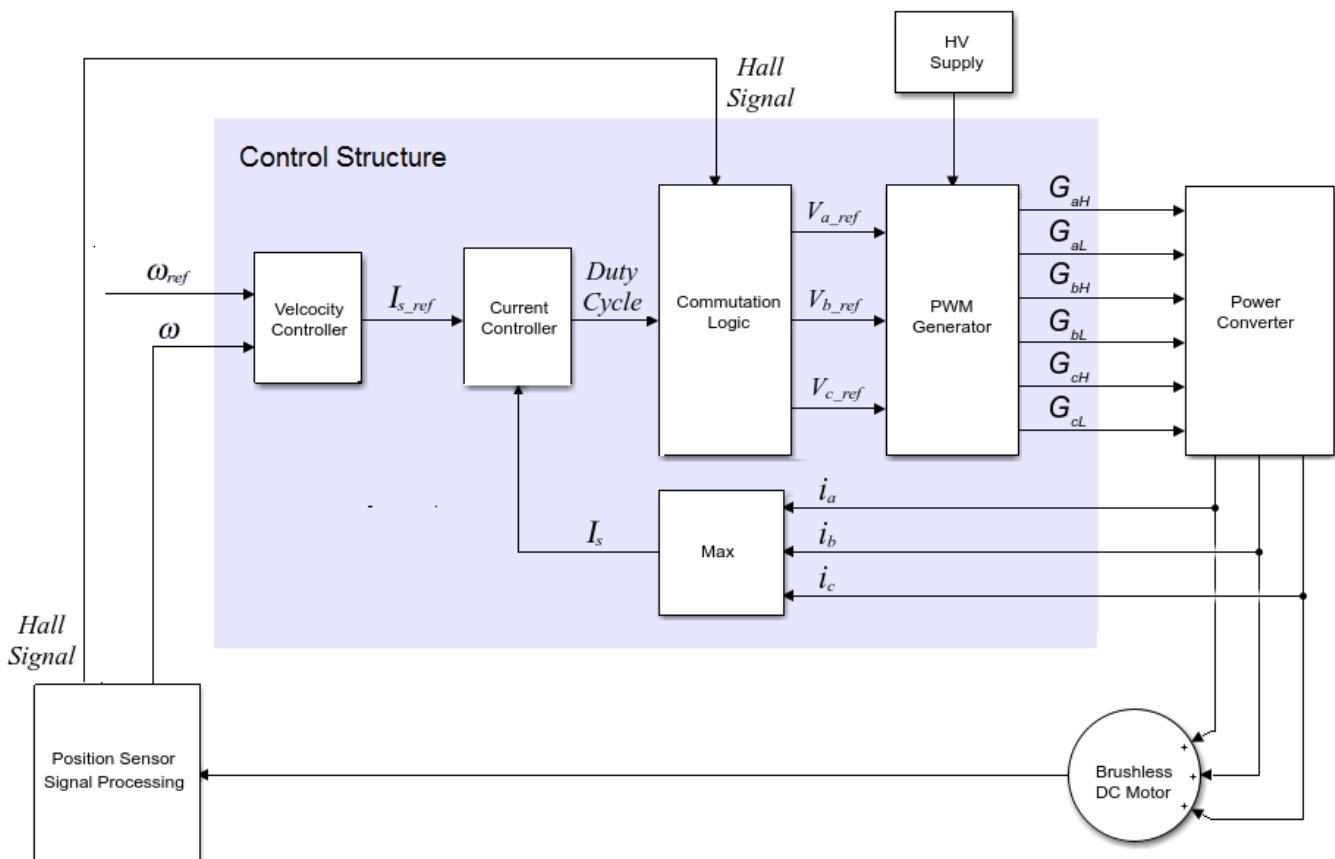

Discrete-time brushless DC Motor current PI controller with pulse width modulation generation

**Library:** Simscape / Electrical / Control / BLDC Control

## Description

The BLDC Current Controller with PWM Generation block generates a pulse width modulation (PWM) signal and controls current in a brushless DC motor. The controller uses this algorithm.

## Equations

The BLDC Current Controller with PWM Generation produces the duty cycle for a BLDC block by implementing proportional-integral (PI) current control using this equation

$$D = \left( K_p + K_i \frac{T_s z}{z-1} \right) (I_{s\_ref} - I_s)$$

where:

- $D$  is the duty cycle.
- $K_p$  is the proportional gain.
- $K_i$  is the integral gain.
- $T_s$  is the time period.
- $I_{s\_ref}$  is the reference current.
- $I_s$  is the measured current.
- $G_{zc}$  is the zero cancellation polynomial.

The closed-loop transfer function for the PI control algorithm yields a zero that can be cancelled by using zero-cancellation block in the feedforward path. The zero-cancellation transfer function in discrete-time is:

$$G_{ZC}(z) = \frac{\frac{T_s K_i}{K_p}}{z + \left( \frac{T_s - \frac{K_p}{K_i}}{\frac{K_p}{K_i}} \right)}$$

The block obtains control signals for the three phases by multiplying the duty cycle by the commutation signals. The resulting three control signals are normalized over the interval  $[-1, 1]$ .

The PWM generator outputs a 1 when the value of the control signal is greater than the carrier counter value. Otherwise, the PWM generator outputs a 0.

## Ports

### Input

#### IsRef — Reference current

scalar

Reference current for control.

Data Types: `single` | `double`

#### Is — Measured current

scalar

Actual current.

Data Types: `single` | `double`

**Reset — External reset**

scalar

External reset signal (rising edge) for the integrator.

Data Types: single | double

**Hall — Hall sensor**

vector

Hall sensor data.

Data Types: single | double

**Direction — Motor direction**

scalar

Direction of motor rotation.

Data Types: single | double

**Output****G — Gate pulses**

vector

Pulse waveforms that determine switching behavior in the attached block.

Data Types: single | double

**Parameters****Control Parameters****Proportional gain — Controller proportional gain,  $K_p$** 

1 (default) | positive scalar

Proportional gain,  $K_p$ , of the controller.**Integral gain — Integral gain,  $K_i$** 

5 (default) | positive scalar

Integral gain,  $K_i$ , of the controller.**Anti-windup gain — Anti-windup gain,  $K_{aw}$** 

1 (default) | positive scalar

Anti-windup gain,  $K_{aw}$ , of the controller.**Sample time (-1 for inherited) — Block sample time**

-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

#### Dependencies

If you set **Sample time (-1 for inherited)** to -1 and select the **Enable zero cancellation** option, the **Discretization sample time** parameter becomes visible.

#### Discretization sample time — Sample time for discretization

0.001 (default) | positive scalar

Time, in s, between consecutive discretizations. Discretization is required for zero cancellation.

#### Dependencies

This parameter is only visible when both these conditions are met:

- **Sample time** is set to -1.
- **Enable zero cancellation** is selected.

#### Enable zero cancellation — Feedforward zero cancellation

off (default) | on

Option to use zero cancellation on the feedforward path.

#### Dependencies

If you select the **Enable zero cancellation** option and set **Sample time (-1 for inherited)** to -1, the **Discretization sample time** parameter becomes visible.

### PWM Generator

#### Carrier counter — Carrier counter model

Up (default) | Down | Up-Down

Use the carrier counter strategy to change the initial behavior of the PWM output:

- Up counter — PWM output begins at the start of the on state.
- Down counter — PWM output begins at the start of the off state.
- Up-down counter — PWM output begins in the middle of the on state.

#### Timer period (s) — PWM timer period

0.001 (default) | positive scalar

Pulse width modulation timer period,  $T_{per}$ , in seconds.

#### Fundamental sample time (s) — Sample time for PWM generation

0.0001 (default) | positive scalar

Time, in s, between consecutive PWM generator executions. During execution, the block produces PWM output and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

To ensure adequate resolution in the generated PWM signal, set the fundamental sample time so that  $0 < T_{s\_pwm} \leq 10T_{per}$ , where:

- $T_{s\_pwm}$  is the **Fundamental sample time (s)**.
- $T_{per}$  is the **Timer period (s)**.

# Boost Converter

Controller-driven DC-DC step-up voltage regulator

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Boost Converter block represents a converter that steps up DC voltage as driven by an attached controller and gate-signal generator. Boost converters are also known as step-up voltage regulators because they increase voltage magnitude.

The Boost Converter block allows you to model a nonsynchronous converter with one switching device or a synchronous converter with two switching devices. Options for the type of switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

## Converter Topology

You can model this converter as a nonsynchronous converter with a physical signal gate control port or with two electrical control ports, or as a synchronous converter with an electrical control port. To select the converter topology, set the **Modeling option** parameter to either:

- Nonsynchronous converter — Nonsynchronous converter with optional physical or electrical gate control ports.
- Synchronous converter — Synchronous converter with multiplexed gate signals.

The nonsynchronous boost converter models contain an inductor, a switching device, a diode, and an output capacitor.

The synchronous boost converter model contains an inductor, two switching devices, and an output capacitor.

In each case, the capacitor smoothes the output voltage.

### Protection

For the synchronous converter model, you can include an integral protection diodes. Integral diodes protect the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

To include and configure the internal protection diodes, use the **Diode** parameters. This table shows how to set the **Model dynamics** parameter based on your goals.

Goals		Value to Select	Integral Protection Diode
Do not include protection.		None	None
Include protection.	Prioritize simulation speed.	Diode with no dynamics	The Diode block

Goals		Value to Select	Integral Protection Diode
	Prioritize model fidelity by precisely specifying reverse-mode charge dynamics.	Diode with charge dynamics	The dynamic model of the Diode block

You can also include a snubber circuit for each switching device. Snubber circuits contain a series-connected resistor and capacitor. They protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of current change when a switching device turns on.

To include and configure a snubber circuit for each switching device, use the **Snubbers** parameters.

### Gate Control

To connect gate-control voltage signals to the gate ports of the switching devices, for the:

- Nonsynchronous converter model:
  - PS control port model:
    - 1 Convert a Simulink gate-control voltage signal to a physical signal using a Simulink-PS Converter block.
    - 2 Connect the Simulink-PS Converter block to the **G** port.
  - Electrical control ports model:
    - 1 Connect a Simscape electrical-domain positive DC voltage signal to the **G+** port.
    - 2 Connect the Simscape electrical-domain negative DC voltage signal to the **G-** port.
- Synchronous converter model:
  - 1 Convert each Simulink gate-control voltage signal to a physical signal using Simulink-PS Converter blocks.
  - 2 Multiplex the converted gate-control signals into a single vector using a Two-Pulse Gate Multiplexer.
  - 3 Connect the vector signal to the **G** port.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to **Averaged switch** and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the

range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Assumptions and Limitations

Only a PWM-driven averaged switch converter captures both continuous conduction mode (CCM) and discontinuous conduction mode (DCM). A duty cycle-driven averaged switch converter captures CCM only.

## Ports

### Input

#### G – Switching device gate control

physical signal | scalar

Physical signal port associated with the gate terminals of the switching device.

#### Dependencies

To enable this port, set **Modeling option** to Nonsynchronous converter and **Gate-control port** to PS.

Data Types: double

### Conserving

#### G – Switching device gate control

electrical | vector

Electrical conserving port associated with the gate terminals of the switching devices.

#### Dependencies

To enable this port, set **Modeling option** to Synchronous converter.

Data Types: double

#### G+ – Switching device gate control positive terminal

electrical | scalar

Positive electrical conserving port associated with the positive gate terminal of the switching device.

**Dependencies**

To enable this port, set **Modeling option** to `Nonsynchronous converter` and **Gate-control port** to `Electrical`.

Data Types: `double`

**G- — Switching device gate control negative terminal**

`electrical` | `scalar`

Negative electrical conserving port associated with the negative gate terminal of the switching device.

**Dependencies**

To enable this port, set **Modeling option** to `Nonsynchronous converter` and **Gate-control port** to `Electrical`.

Data Types: `double`

**1+ — Positive DC voltage 1**

`electrical` | `scalar`

Electrical conserving port associated with the positive terminal of the first DC voltage.

Data Types: `double`

**1- — Negative DC voltage 1**

`electrical` | `scalar`

	Gate turn-off voltage, Vgt_off			Gate turn-off voltage, Vgt_off	
	Holding current			Holding current	

### Gate-control port — Whether to specify physical or electrical control port for the switching gate

PS (default) | Electrical

Whether to specify physical or electrical control port for the switching gate.

#### Dependencies

To enable this port, set **Modeling option** to Nonsynchronous converter.

### Switching device — Switch type

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Switching device type for the converter. For the synchronous model, the switches are identical.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**

- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**On-state resistance — Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate trigger voltage, $V_{gt}$ — Voltage threshold

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate turn-off voltage, $V_{gt\_off}$ — Voltage threshold

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Holding current — Current threshold

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Integer for piecewise constant approximation of gate input (0 for disabled) — Integer mode for FPGA deployment

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

#### Dependencies

To enable this parameter, set **Switching device** to Averaged Switch.

#### Diode

This table shows how the visibility of **Diode** parameters depends on how you configure the **Modeling option**, **Model dynamics**, and **Reverse recovery time parameterization** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

**Model dynamics – Diode model**

Diode with no dynamics (default) | Diode with charge dynamics | None

Diode type. The options are:

- **None** — This option is not available for the nonsynchronous converter.
- **Diode with no dynamics** — Select this option to prioritize simulation speed using the Diode block. This option is the default for the nonsynchronous converter.
- **Diode with charge dynamics** — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

---

**Note** If you select **Averaged Switch** for the **Switching Device** parameter in the **Switching Device** setting, this parameter is not visible and Diode with no dynamics is automatically selected.

---

### Dependencies

See the Diode Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

Minimum voltage required across the positive and negative block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

### On resistance — Resistance

0.001 Ohm (default) | scalar

Rate of change of voltage versus current above the **Forward voltage**.

### Off conductance — Conductance

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

### Junction capacitance — Capacitance

50 nF (default) | scalar

Diode junction capacitance.

### Dependencies

See the Diode Parameter Dependencies table.

### Peak reverse current, $i_{RM}$ — Current

-235 A (default) | scalar less than 0

Peak reverse current measured by an external test circuit.

### Dependencies

See the Diode Parameter Dependencies table.

### Initial forward current when measuring $i_{RM}$ — Current

300 A (default) | scalar greater than 0

Initial forward current when measuring peak reverse current. This value must be greater than zero.

### Dependencies

See the Diode Parameter Dependencies table.

### Rate of change of current when measuring $i_{RM}$ — Current change rate

-50 A/us (default) | scalar

Rate of change of current when measuring peak reverse current.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time parameterization – Recovery-time model**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Model for parameterizing the recovery time. When you select `Specify stretch factor` or `Specify reverse recovery charge`, you can specify a value that the block uses to derive the reverse recovery time.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time stretch factor – Stretch factor**

3 (default) | scalar greater than 1

Value that the block uses to calculate **Reverse recovery time, trr**. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time, trr – Time**

15 us (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10 percent of the peak reverse current.

The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, i<sub>RM</sub>** parameter divided by the value of the **Rate of change of current when measuring i<sub>RM</sub>** parameter.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery charge, Q<sub>rr</sub> – Charge**

1500 s\*uA (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, i<sub>RM</sub>**.

- $a$  is the value specified for **Rate of change of current when measuring iRM**.

### Dependencies

See the Diode Parameter Dependencies table.

### LC Parameters

#### Inductance – Inductance

1e-6 H (default) | positive scalar

Inductance.

#### Inductor series resistance – Inductor series resistance

0 Ohm (default) | zero or positive scalar

Series resistance of the inductor.

#### Capacitance – Capacitance

1e-7 F (default) | positive scalar

Capacitance.

#### Capacitor effective series resistance – Capacitor resistance

1e-6 Ohm (default) | zero or positive scalar

Series resistance of the capacitor.

### Snubbers

The **Snubbers** parameters tab is not visible if you set **Switching device** to Averaged Switch.

The table summarizes the **Snubbers** parameter dependencies. To learn how to read the table, see “Parameter Dependencies” on page A-2.

#### Snubbers Parameter Dependencies

Snubbers Parameter Dependencies

## Bridge Cycloconverter Voltage Controller (Three-Phase)

RMS Voltage PI control for three-phase bridge cycloconverters

**Library:** Simscape / Electrical / Control / Converter Control

### Description

The Bridge Cycloconverter Voltage Controller (Three-Phase) block implements a PI-based root-mean-square (RMS) voltage controller for three-phase bridge cycloconverters.

To convert a three-phase signal directly from a higher frequency to a lower frequency, use this block with a three-phase bridge cycloconverter. Refer to "Three-Phase Bridge Cycloconverter" for an example of such a conversion.

### Operating Principle

The controller regulates the cycloconverter line-to-neutral RMS voltage to a given value and a given electrical frequency. The structure of the cycloconverter controller is illustrated in this diagram.

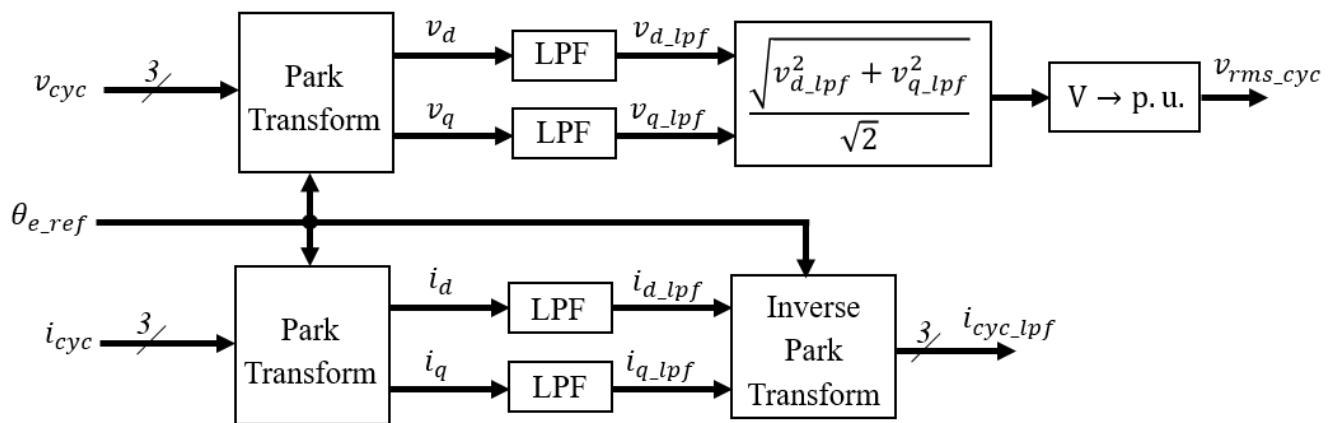

In the diagram:

- The controller integrates the desired output frequency  $f_{ref}$  to produce the reference electrical angle  $\theta_{e\_ref}$ .

- The Signal Conditioning block filters the cycloconverter line-to-neutral voltage  $v_{cyc}$  and current  $i_{cyc}$  to produce the per-unit RMS voltage  $v_{rms\_cyc}$  and smoothed current signal  $i_{cyc\_lpf}$ .
- The PI Controller generates a reference phase voltage in the  $q$ -axis from the error between the desired output RMS voltage  $V_{ref}$  and  $v_{rms\_cyc}$ .
- The Inverse Park Transform block converts the reference phase voltage in  $dq0$ -coordinates to a phase voltage  $v_{abc\_ref}$  in  $abc$ -coordinates.
- The Sinusoidal Power Measurement (PLL, Three-Phase) block estimates the phase angle  $\theta$  of the input voltage signal  $v_{abc}$ .

The Modulator and Bank Selector blocks create the 36 pulses to drive the cycloconverter using the reference phase voltage  $v_{abc\_ref}$ , estimated phase angle  $\theta$ , and filtered cycloconverter current  $i_{cyc\_lpf}$ . To generate the firing angles, the controller uses the cosine wave crossing method.

This diagram shows the signal conditioning logic.

In the diagram:

- The Park Transform blocks convert the measured cycloconverter voltage  $v_{cyc}$  and current  $i_{cyc}$  into  $d$ - and  $q$ -axis components ( $v_d, v_q, i_d, i_q$ ) using the reference electrical angle  $\theta_{e\_ref}$ .
- The Low-Pass Filter (LPF) blocks remove the high-frequency noise from each of the  $d$ - and  $q$ -axis voltage and currents to produce the filtered components ( $v_{d\_lpf}, v_{q\_lpf}, i_{d\_lpf}, i_{q\_lpf}$ ).
- The block calculates the cycloconverter per-unit RMS voltage  $v_{rms\_cyc}$  by taking the squared sum of the  $dq$  components, dividing by  $\sqrt{2}$ , and finally converting from SI to per-unit representation.
- The Inverse Park Transform converts the  $dq$  filtered current back to the  $abc$ -axis and outputs it as  $i_{cyc\_lpf}$ .

The cycloconverter reference line-to-neutral rms voltage output is given in per-unit representation.

### Visualization

The block outputs a bus containing six signals for visualization:

- The estimated phase angle  $\theta$  of the input voltage signal  $v_{abc}$
- The desired RMS voltage  $V_{ref}$  of the output signal

- The reference phase voltages  $v_{abc\_ref}$  of the desired output signal
- The filtered line-to-neutral cycloconverter RMS voltage  $v_{rms\_cyc}$
- The filtered cycloconverter phase currents  $i_{cyc\_lpf}$
- The filtered cycloconverter phase voltages  $v_{cyc\_lpf}$

## Ports

### Input

#### **VRef — Reference voltage**

scalar

Reference line-to-neutral RMS voltage, expressed in per-unit representation.

Data Types: `single` | `double`

#### **fRef — Reference frequency**

scalar

Reference electrical frequency, in Hz.

Data Types: `single` | `double`

#### **vabc — Phase voltages**

vector

Measured phase voltages of the source, in V.

Data Types: `single` | `double`

#### **Vcyc — Cycloconverter voltages**

vector

Measured cycloconverter phase voltages, in V.

Data Types: `single` | `double`

#### **Icyc — Cycloconverter currents**

vector

Measured cycloconverter phase currents, in A.

Data Types: `single` | `double`

### Output

#### **P — Pulses**

vector

Thyristor pulse vector to control a three-phase bridge cycloconverter.

Data Types: `single` | `double`

#### **Visualization — Visualization bus**

bus

Bus containing internal signals for visualization. For a full list of signals, refer to the “Visualization” on page 1-162 section.

Data Types: single | double

## Parameters

### **Rated voltage (phase-to-phase RMS) — Rated RMS voltage**

6000 (default) | positive number

Rated RMS voltage for per-unit conversion calculations, in V.

### **Loop filter proportional gain — LF proportional gain**

2 (default) | positive number

Loop filter proportional gain for the phase-locked loop (PLL) estimating the phase of the input signal. This value determines the aggressiveness of the PLL in tracking and locking to the phase angle. Increase this value to improve reaction time of the tracking to step changes in the phase angle.

### **Loop filter integral gain — LF integral gain**

20 (default) | positive number

Loop filter integral gain for the phase-locked loop (PLL) estimating the phase of the input signal. Increase this value to increase the rate at which steady-state error is eliminated in the phase angle. This value also determines the aggressiveness of the PLL in tracking and locking to the phase.

### **Filters time constant (s) — Time constant**

1e-2 (default) | positive number

Time constant of the low-pass filters in the Signal Conditioning block of the controller. These filters reduce undesired high-frequency noise in the cycloconverter phase voltage and current measurements.

### **Controller proportional gain — Proportional gain**

1 (default) | positive number

Proportional gain for the PI-controller that generates the reference phase voltage for the cycloconverter. Increase this value to increase the aggressiveness of the controller.

### **Controller integral gain — Integral gain**

12 (default) | positive number

Integral gain of the PI-controller that generates the reference phase voltage for the cycloconverter. Increase this value to increase the rate at which steady-state error is eliminated in the phase voltage signal.

### **Controller anti-windup gain — Anti-windup gain**

10 (default) | positive number

Anti-windup gain of the PI-controller that generates the reference phase voltage for the cycloconverter.

### **Thyristor pulse width (rad) — Pulse width**

5\*pi/6 (default) | positive number

Angular width of pulses sent to the cycloconverter.

**Bank selector current threshold (A) – Current threshold**

5 (default) | positive number

Current threshold for switching between positive and negative converters.

**Pulse ordering – Pulse ordering rule**

Sequential device order (default) | Natural order of commutation

Strategy used for the ordering of generated pulses.

**Sample time (-1 for inherited) – Sample time**

-1 (default) | positive number

Sample time for the block (-1 for inherited). If you use this block inside a triggered subsystem, set the sample time to -1. If you use this block in a continuous variable-step model, set the sample time explicitly.

# Buck Converter

Controller-driven DC-DC step-down voltage regulator

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Buck Converter block represents a converter that steps down DC voltage as driven by an attached controller and gate-signal generator. Buck converters are also known as step-down voltage regulators because they decrease voltage magnitude.

The Buck Converter block allows you to model a nonsynchronous converter with one switching device or a synchronous converter with two switching devices. Options for the type of switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

## Converter Topology

You can model this converter as a nonsynchronous converter with a physical signal gate control port or with two electrical control ports, or as a synchronous converter with an electrical control port. To select the converter topology, set the **Modeling option** parameter to either:

- Nonsynchronous converter — Nonsynchronous converter with optional physical or electrical gate control ports.
- Synchronous converter — Synchronous converter with multiplexed gate signals.

The nonsynchronous buck converter models contain a switching device, a diode, an inductor, and an output capacitor.

The synchronous buck converter model contains two switching devices, an inductor, and an output capacitor.

In each case, the capacitor smoothes the output voltage.

### Protection

For the synchronous converter model, you can include an integral protection diode for the S2 switching device. An integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

To include and configure the internal protection diode block, use the **Diode** parameters. This table shows how to set the **Model dynamics** parameter based on your goals.

Goals		Value to Select	Integral Protection Diode
Do not include protection.		None	None
Include protection.	Prioritize simulation speed.	Diode with no dynamics	The Diode block

Goals		Value to Select	Integral Protection Diode
	Prioritize model fidelity by precisely specifying reverse-mode charge dynamics.	Diode with charge dynamics	The dynamic model of the Diode block

You can also include a snubber circuit for each switching device. Snubber circuits contain a series-connected resistor and capacitor. They protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of current change when a switching device turns on.

To include and configure a snubber circuit for each switching device, use the **Snubbers** parameters.

### Gate Control

To connect gate-control voltage signals to the gate ports of the switching devices, for the:

- Nonsynchronous converter model:
  - PS control port model:
    - 1 Convert a Simulink gate-control voltage signal to a physical signal using a Simulink-PS Converter block.
    - 2 Connect the Simulink-PS Converter block to the **G** port.
  - Electrical control ports model:
    - 1 Connect a Simscape electrical-domain positive DC voltage signal to the **G+** port.
    - 2 Connect the Simscape electrical-domain negative DC voltage signal to the **G-** port.
- Synchronous converter model:
  - 1 Convert each Simulink gate-control voltage signal to a physical signal using Simulink-PS Converter blocks.
  - 2 Multiplex the converted gate-control signals into a single vector using a Two-Pulse Gate Multiplexer.
  - 3 Connect the vector signal to the **G** port.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to *Averaged switch* and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the

range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Assumptions and Limitations

Only a PWM-driven averaged switch converter captures both continuous conduction mode (CCM) and discontinuous conduction mode (DCM). A duty cycle-driven averaged switch converter captures CCM only.

	Gate turn-off voltage, Vgt_off			Gate turn-off voltage, Vgt_off	
	Holding current			Holding current	

### Gate-control port — Whether to specify physical or electrical control port for the switching gate

PS (default) | Electrical

Whether to specify physical or electrical control port for the switching gate.

#### Dependencies

To enable this port, set **Modeling option** to Nonsynchronous converter.

### Switching device — Switch type

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Switching device type for the converter. For the synchronous model, the switches are identical.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**

- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**On-state resistance — Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged Switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate trigger voltage, $V_{gt}$ — Voltage threshold

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate turn-off voltage, $V_{gt\_off}$ — Voltage threshold

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Holding current — Current threshold

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Integer for piecewise constant approximation of gate input (0 for disabled) — Integer mode for FPGA deployment

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

#### Dependencies

To enable this parameter, set **Switching device** to Averaged Switch.

#### Diode

This table shows how the visibility of **Diode** parameters depends on how you configure the **Modeling option**, **Model dynamics**, and **Reverse recovery time parameterization** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

**Model dynamics – Diode model**

Protection diode with no dynamics (default) | Protection diode with charge dynamics | None

Diode type. The options are:

- None — This option is not available for the nonsynchronous converter.
- Diode with no dynamics — Select this option to prioritize simulation speed using the Diode block. This option is the default for the nonsynchronous converter.

- **Diode with charge dynamics** — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

### Dependencies

See the Diode Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

Minimum voltage required across the positive and negative block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

### On resistance — Resistance

0.001 Ohm (default) | scalar

Rate of change of voltage versus current above the **Forward voltage**.

### Off conductance — Conductance

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

### Junction capacitance — Capacitance

50 nF (default) | scalar

Diode junction capacitance.

### Dependencies

See the Diode Parameter Dependencies table.

### Peak reverse current, $i_{RM}$ — Current

-235 A (default) | scalar less than 0

Peak reverse current measured by an external test circuit.

### Dependencies

See the Diode Parameter Dependencies table.

### Initial forward current when measuring $i_{RM}$ — Current

300 A (default) | scalar greater than 0

Initial forward current when measuring peak reverse current. This value must be greater than zero.

### Dependencies

See the Diode Parameter Dependencies table.

### Rate of change of current when measuring $i_{RM}$ — Current change rate

-50 A/us (default) | scalar

Rate of change of current when measuring peak reverse current.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time parameterization – Recovery-time model**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Model for parameterizing the recovery time. When you select **Specify stretch factor** or **Specify reverse recovery charge**, you can specify a value that the block uses to derive the reverse recovery time.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time stretch factor – Stretch factor**

3 (default) | scalar greater than 1

Value that the block uses to calculate **Reverse recovery time, trr**. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time, trr – Time**

15 us (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10 percent of the peak reverse current.

The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, iRM** parameter divided by the value of the **Rate of change of current when measuring iRM** parameter.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery charge, Qrr – Charge**

1500 s\*uA (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

### Dependencies

See the Diode Parameter Dependencies table.

### LC Filter

#### Inductance – Filter inductance

1e-6 H (default) | positive scalar

Inductance of the LC filter.

#### Inductor series resistance – Inductor series resistance

0 Ohm (default) | zero or positive scalar

Series resistance of the inductor.

#### Capacitance – Filter capacitance

1e-7 F (default) | positive scalar

Capacitance of the LC filter.

#### Capacitor effective series resistance – Capacitor resistance

1e-6 Ohm (default) | zero or positive scalar

Series resistance of the capacitor.

### Snubbers

The **Snubbers** parameters tab is not visible if you set **Switching device** to Averaged Switch.

The table summarizes the **Snubbers** parameter dependencies. To learn how to read the table, see “Parameter Dependencies” on page A-2.

#### Snubbers Parameter Dependencies

Snubbers Parameter Dependencies

# Buck-Boost Converter

Controller-driven DC-DC inverting or four-switch step-up or step-down voltage regulator

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Buck-Boost Converter block represents a DC-DC converter that can either step up or step down DC voltage from one side of the converter to the other as driven by an attached controller and gate-signal generator. Buck-boost converters are also known as step-up/step-down voltage regulators because they can increase or decrease voltage magnitude.

The block can also invert voltage so that the polarity of the output voltage is the opposite of the polarity of the input voltage. The magnitude of the output voltage depends on the duty cycle.

The Buck-Boost Converter block allows you to model an inverting buck-boost converter with one switching device or a buck-boost converter with four switching devices. Options for the type of switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

## Converter Topology

You can model this converter as an inverting buck-boost converter with a physical signal gate control port or with two electrical control ports, or as a four-switch buck-boost converter with an electrical control port. To select the converter topology, set the **Modeling option** parameter to either:

- Inverting converter — Inverting buck-boost converter with physical or electrical gate control port.
- Four-switch converter — Four-switch buck-boost converter with multiplexed gate signals.

The inverting converter models contain a switching device, a diode, an inductor, and an output capacitor.

The four-switch converter model contains four switching devices, an inductor, and an output capacitor.

In each case, the capacitor smoothes the output voltage.

## Protection

You can include a snubber circuit for each switching device. Snubber circuits contain a series-connected resistor and capacitor. They protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of current change when a switching device turns on.

To include and configure a snubber circuit for each switching device, use the **Snubbers** parameters.

## Gate Control

To connect gate-control voltage signals to the gate ports of the switching devices, for the:

- Inverting converter model:
  - PS control port model:
    - 1 Convert a Simulink gate-control voltage signal to a physical signal using a Simulink-PS Converter block.
    - 2 Connect the Simulink-PS Converter block to the **G** port.
  - Electrical control ports model:
    - 1 Connect a Simscape electrical-domain positive DC voltage signal to the **G+** port.
    - 2 Connect the Simscape electrical-domain negative DC voltage signal to the **G-** port.
- Synchronous converter model:
  - 1 Convert each Simulink gate-control voltage signal to a physical signal using Simulink-PS Converter blocks.
  - 2 Multiplex the converted gate-control signals into a single vector using a Four-Pulse Gate Multiplexer
  - 3 Connect the vector signal to the **G** port.

## Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to *Averaged switch* and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Assumptions and Limitations

Only a PWM-driven averaged switch converter captures both continuous conduction mode (CCM) and discontinuous conduction mode (DCM). A duty cycle-driven averaged switch converter captures CCM only.

## Switching Devices Parameter Dependencies

Parameters and Options					
Switching device					
<i>Ideal Semiconductor Switch</i>	<i>GTO</i>	<i>IGBT</i>	<i>MOSFET</i>	<i>Thyristor</i>	<i>Averaged Switch</i>
On-state resistance	Forward voltage	Forward voltage	Drain-source on resistance	Forward voltage	On-state resistance
Off-state conductance	On-state resistance	On-state resistance	Off-state conductance	On-state resistance	Integer for piecewise constant approximation of gate input (0 for disabled)
Threshold voltage	Off-state conductance	Off-state conductance	Threshold voltage	Off-state conductance	
	Gate trigger voltage, Vgt	Threshold voltage		Gate trigger voltage, Vgt	
	Gate turn-off voltage, Vgt_off			Gate turn-off voltage, Vgt_off	
	Holding current			Holding current	

### Gate-control port — Whether to specify physical or electrical control port for the switching gate

PS (default) | Electrical

Whether to specify physical or electrical control port for the switching gate.

#### Dependencies

To enable this port, set **Modeling option** to Inverting converter.

### Switching device — Switch type

*Ideal Semiconductor Switch* (default) | *GTO* | *IGBT* | *MOSFET* | *Thyristor* | *Averaged Switch*

Switching device type for the converter. For the four-switch model, the switches are identical.

model.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**On-state resistance — Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage

- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate trigger voltage, Vgt — Voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate turn-off voltage, Vgt\_off — Voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Holding current — Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Integer for piecewise constant approximation of gate input (0 for disabled) — Integer mode for FPGA deployment**

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

**Dependencies**

To enable this parameter, set **Switching device** to Averaged Switch.

**Diode**

This table shows how the visibility of **Diode** parameters depends on how you configure the **Model dynamics** and **Reverse recovery time parameterization** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

## Diode Parameter Dependencies

Parameters and Options			
<b>Model dynamics</b>			
<i>Diode with no dynamics</i>	<i>Diode with charge dynamics</i>		
Forward voltage	Forward voltage		
On resistance	On resistance		
Off conductance	Off conductance		
	Junction capacitance		
	Peak reverse current, iRM		
	Initial forward current when measuring iRM		
	Rate of change of current when measuring iRM

Reverse recovery time stretch factor	Reverse recovery time, trr	Reverse recovery charge, Qrr	

### Model dynamics — Diode model

*Diode with no dynamics (default) | Diode with charge dynamics*

Diode type. The options are:

- *Diode with no dynamics* — Select this option to prioritize simulation speed using the Diode block.
- *Diode with charge dynamics* — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

---

**Note** If you select Averaged Switch for the **Switching Device** parameter in the **Switching Device** setting, this parameter is not visible and *Diode with no dynamics* is automatically selected.

---

### Dependencies

See the Diode Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

Minimum voltage required across the positive and negative block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

### On resistance — Resistance

0.001 Ohm (default) | scalar

Rate of change of voltage versus current above the **Forward voltage**.

**Off conductance – Conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

**Junction capacitance – Capacitance**

50 nF (default) | scalar

Diode junction capacitance.

**Dependencies**

See the Diode Parameter Dependencies table.

**Peak reverse current,  $i_{RM}$  – Current**

-235 A (default) | scalar less than 0

Peak reverse current measured by an external test circuit.

**Dependencies**

See the Diode Parameter Dependencies table.

**Initial forward current when measuring  $i_{RM}$  – Current**

300 A (default) | scalar greater than 0

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

See the Diode Parameter Dependencies table.

**Rate of change of current when measuring  $i_{RM}$  – Current change rate**

-50 A/us (default) | scalar

Rate of change of current when measuring peak reverse current.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time parameterization – Recovery-time model**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Model for parameterizing the recovery time. When you select `Specify stretch factor` or `Specify reverse recovery charge`, you can specify a value that the block uses to derive the reverse recovery time.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time stretch factor – Stretch factor**

3 (default) | scalar greater than 1

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge.

The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

See the Diode Parameter Dependencies table.

#### Reverse recovery time, $t_{rr}$ – Time

15  $\mu$ s (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10 percent of the peak reverse current.

The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

#### Dependencies

See the Diode Parameter Dependencies table.

#### Reverse recovery charge, $Q_{rr}$ – Charge

1500  $\text{s} \cdot \mu\text{A}$  (default) | scalar

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current,  $i_{RM}$** .
- $a$  is the value specified for **Rate of change of current when measuring  $i_{RM}$** .

#### Dependencies

See the Diode Parameter Dependencies table.

### LC Parameters

#### Inductance – Inductance

1e-6 H (default) | positive scalar

Inductance.

#### Inductor series resistance – Inductor series resistance

0  $\Omega$  (default) | zero or positive scalar

Series resistance of the inductor.

#### Capacitance – Capacitance

1e-7 F (default) | positive scalar

Capacitance.

### Capacitor effective series resistance – Capacitor resistance

1e-6 Ohm (default) | zero or positive scalar

Series resistance of the capacitor.

### Snubbers

The **Snubbers** parameters tab is not visible if you set **Switching device** to Averaged Switch.

The table summarizes the **Snubbers** parameter dependencies. To learn how to read the table, see “Parameter Dependencies” on page A-2.

# Busbar

Load flow analysis busbar connector

**Library:** Simscape / Electrical / Connectors & References

## Description

The Busbar block is a connector for load-flow analysis. Use this block with three-phase Simscape Electrical networks that are compatible with frequency-time simulation mode. After completing simulation, the block adds an annotation showing the voltage, phase, active power, and reactive power at each of its three-phase electrical conserving ports at the time the simulation started. For the annotation to be added, Simscape logging must be enabled.

The block will simulate in time-based simulation mode, however it will not add the annotation with initial load flow results unless the network is compatible with frequency-time simulation mode and, on the Solver Configuration block, you check `Start simulation from steady state`. However, when using time-based simulation mode, the block calculates approximate values for voltage, phase, active and reactive powers. You can view these values from Simscape logging or by exposing the optional measurement ports on the block. The level of approximation depends on how balanced the system is and on the level of harmonics present.

## Ports

### Output

#### Vt — Voltage

physical signal

Physical signal port associated with the voltage measurement. The value is reported in per-unit, i.e. phase-to-phase root mean square voltage divided by the **Rated busbar voltage (phase-to-phase RMS)**.

#### Dependencies

This port is visible only when, in the **Parameters** settings, the **Measurements ports** parameter is set to Yes.

#### ph — Phase

physical signal

Physical signal port associated with the voltage phase measurement.

#### Dependencies

This port is visible only when, in the **Parameters** settings, the **Measurements ports** parameter is set to Yes.

#### P — Active power

physical signal

Physical signal port associated with the active (real) power measurement.

**Dependencies**

This port is visible only when, in the **Parameters** settings, the **Number of connections** parameter is set to 2, 3, or 4 and the **Measurements ports** parameter is set to Yes.

**Q — Reactive power**

physical signal

Physical signal port associated with the reactive (imaginary) power measurement.

**Dependencies**

This port is visible only when, in the **Parameters** settings, the **Number of connections** parameter is set to 2, 3, or 4 and the **Measurements ports** parameter is set to Yes.

**Conserving**

**~1 — Three-phase connection 1**

electrical

Composite three-phase electrical conserving port associated with the first three-phase connection.

**~2 — Three-phase connection 2**

electrical

Composite three-phase electrical conserving port associated with the second three-phase connection.

**Dependencies**

This port is visible only when, in the **Parameters** settings, the **Number of connections** parameter is set to 2, 3, or 4.

**~3 — Three-phase connection 3**

electrical

Composite three-phase electrical conserving port associated with the third three-phase connection..

**Dependencies**

This port is visible only when, in the **Parameters** settings, the **Number of connections** parameter is set to 3 or 4.

**~4 — Three-phase connection 4**

electrical

Composite three-phase electrical conserving port associated with the fourth three-phase connection.

**Dependencies**

This port is visible only when, in the **Parameters** settings, the **Number of connections** parameter is set to 4.

## Parameters

### Number of connections — Number of port connections

2 (default) | 1 | 3 | 4

Number of port connections that are exposed on the block.

The number of exposed ports on the block correlates to this parameter.

### Rated busbar voltage (phase-to-phase RMS) — Busbar rated voltage

$\sqrt{3} * 100 / \sqrt{2}$  V (default)

Rated phase-to-phase root mean square voltage of the busbar.

### Network frequency — Network frequency

60 Hz (default)

Frequency of the connected network.

### Measurement ports — Measurement port exposure

No (default) | Yes

Visibility for the voltage, phase, active power, and reactive power physical signal output measurement ports.

### Dependencies

Ports **Vt** and **ph** are visible only when this parameter is set to Yes.

Ports **P** and **Q** are visible only when this parameter is set to Yes and, in the **Parameters** settings, the **Number of connections** parameter is set to 2, 3, or 4.

electrical

Electrical conserving port associated with the fourth negative connection.

### **Dependencies**

To enable this port, in the **Parameters** settings, set the **Number of connections** parameter to 4.

## Parameters

### Number of connections — Number of port connections

2 (default) | 1 | 3 | 4

Number of port connections to expose on the block.

### Rated DC voltage — Busbar rated DC voltage

1e3 V (default) | positive scalar

Rated DC voltage of the busbar. This block uses this value to scale the per-unit voltage value.

### Measurement type — Measurement type

Instantaneous (default) | Average over a specified period

Type of measurement. In time simulation mode, you can set this parameter to either **Instantaneous** or **Average over a specified period**. In frequency-time simulation mode, you must set this parameter to **Instantaneous**.

### Averaging period — Averaging period of measurement

1e-2 s (default) | positive scalar

Period over which the voltage and power values are averaged.

### Dependencies

To enable this parameter, set **Measurement type** to **Average over a specified period**.

### Measurement ports — Measurement port exposure

No (default) | Yes

Whether to expose the **Vt** and **P** physical signal output measurement ports.

# Capacitor

Linear or nonlinear capacitor with optional tolerance, operational limits and fault behavior

**Library:** Simscape / Electrical / Passive

## Description

The Capacitor block lets you model linear, nonlinear (table-based), and frequency-dependent capacitors, including polar capacitors. Optionally, you can also model the following effects:

- “Tolerances” on page 1-199
- “Operating Limits” on page 1-200
- “Faults” on page 1-200

You can turn these modeling options on and off independently of each other. When all the additional options are turned off, the component behavior is identical to the Simscape Foundation library Capacitor block.

In its simplest form, the Capacitor block models a linear capacitor, described with the following equation:

$$I = C \frac{dV}{dt}$$

where:

- $I$  is the current.
- $C$  is the capacitance.
- $V$  is the voltage.
- $t$  is the time.

To model a nonlinear or polar capacitor, set the **Capacitance model** parameter to `Lookup table` and provide a lookup table of capacitance-voltage values:

- For polar capacitors, where this lookup table is asymmetric with respect to the applied terminal voltage, set the **Symmetric C-V table** parameter to `No - use C-V data as-is`.
- For other types of nonlinear capacitor, ensure symmetry of the capacitance with regards to the applied terminal voltage by setting the **Symmetric C-V table** parameter to `Yes - use voltage magnitude when computing C`.

To model a frequency-dependent capacitor with resistive and dielectric losses, set the **Capacitance model** parameter to `Dielectric relaxation (Debye)`. The Debye relaxation model considers a collection of noninteracting dipoles in the frequency domain. The result is in terms of a complex permittivity. The real ( $\epsilon'$ ) and imaginary ( $\epsilon''$ ) parts of the complex permittivity are given by the equations:

$$\varepsilon' = \varepsilon_{\infty} + \frac{\varepsilon_s - \varepsilon_{\infty}}{1 + \omega^2\tau^2}$$

$$\varepsilon'' = \frac{(\varepsilon_s - \varepsilon_{\infty})\omega\tau}{1 + \omega^2\tau^2},$$

where  $\omega$  is the radial frequency,  $\varepsilon_{\infty}$  is the real permittivity at very high frequency,  $\varepsilon_s$  is the real permittivity at low frequency and  $\tau$  is the relaxation time constant.

In the time-domain, the characteristic equation for a capacitor in the Debye model is

$$\tau i = -q + C_s(\alpha\tau\dot{v} + v),$$

where  $C_s$  is the low-frequency capacitance,  $q = Q/C_s$  is the charge,  $i$  is the current and  $v$  is the voltage across the capacitor.

Most datasheets do not provide explicit values for the complex permittivity nor for the relaxation time; however, often the dissipation factor is provided at two frequencies. The parameters  $\tau$  and  $\alpha$  may be derived from these values as described by the equations:

$$\tau = \frac{DF_1DF_2(\omega_2^2 - \omega_1^2) + \sqrt{DF_1^2DF_2^2(\omega_2^2 - \omega_1^2)^2 + 4\omega_1\omega_2(DF_2\omega_2 - DF_1\omega_1)(DF_1\omega_2 - DF_2\omega_1)}}{2\omega_1\omega_2(DF_2\omega_2 - DF_1\omega_1)}$$

$$\alpha = \frac{\omega_1\tau - DF_1}{\omega_1\tau(1 + DF_1\omega_1\tau)},$$

where  $\omega_1$  and  $\omega_2$  are two different frequencies, and  $DF_1$  and  $DF_2$  are the dissipation factors calculated at said frequencies, respectively.

The argument of the square root must be positive for a valid parameterization in the Debye model.

## Tolerances

You can apply tolerances to the nominal value you provide for the **Capacitance** parameter. Datasheets typically provide a tolerance percentage for a given capacitor type. The table shows how the block applies tolerances and calculates capacitance based on the selected **Tolerance application** option.

Option	Capacitance Value
None – use nominal value	$C$
Random tolerance	Uniform distribution: $C \cdot (1 - tol + 2 \cdot tol \cdot rand)$ Gaussian distribution: $C \cdot (1 + tol \cdot randn / nSigma)$
Apply maximum tolerance value	$C \cdot (1 + tol)$
Apply minimum tolerance value	$C \cdot (1 - tol)$

In the table,

- $C$  is the **Capacitance** parameter value, nominal capacitance.
- $tol$  is the fractional tolerance, **Capacitance tolerance (%)** /100.

- $nSigma$  is the value you provide for the **Number of standard deviations for quoted tolerance** parameter.
- `rand` and `randn` are standard MATLAB® functions for generating uniform and normal distribution random numbers.

---

**Note** If you choose the `Random tolerance` option and you are in "Fast Restart" mode, the random tolerance value is updated on every simulation if at least one between the fractional tolerance,  $tol$ , or the **Number of standard deviations for quoted tolerance**,  $nSigma$ , is set to Run-time and is defined with a variable (even if you do not modify that variable).

---

### Operating Limits

You can specify operating limits in terms of maximum working voltage and the maximum (instantaneous) power dissipation in the series resistance and in the parallel conductance of the capacitor.

For polar capacitors, you can define the working voltage range in such a way that the block provides a warning, or an error, if the polarity of the applied voltage becomes incorrect.

When an operating limit is exceeded, the block can either generate a warning or stop the simulation with an error. For more information, see "Operating Limits" on page 1-204.

### Faults

Instantaneous changes in capacitor parameters are unphysical. Therefore, when the Capacitor block enters the faulted state, the capacitance, resistance, and conductance transition to their faulted values over a period of time, according to the following formula:

$$CurrentValue = FaultedValue - (FaultedValue - UnfaultedValue) \cdot \operatorname{sech}(\Delta t / \tau) \quad (1-1)$$

where:

- $\Delta t$  is the time since the onset of the fault condition.
- $\tau$  is the user-defined time constant associated with the fault transition.

The block can trigger the start of fault transition:

- At a specific time
- When terminal voltage is outside the permissible voltage range for longer than a specific time interval

You can enable or disable these trigger mechanisms separately, or use them together if more than one trigger mechanism is required in a simulation. When more than one mechanism is enabled, the first mechanism to trigger the fault transition takes precedence. In other words, component fails no more than once per simulation.

You can also choose whether to issue an assertion when a fault occurs, by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Variables

Use the **Variables** section of the block interface to set the priority and initial target values for the block variables prior to simulation. For more information, see “Set Priority and Initial Target for Block Variables”.

The **Capacitor voltage** variable lets you specify a high-priority target for the initial capacitor voltage at the start of simulation.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the capacitor positive voltage.

#### - – Negative terminal

electrical

Electrical conserving port associated with the capacitor negative voltage.

## Parameters

### Main

#### Capacitance model – Capacitor type

Constant (default) | Lookup table | Dielectric relaxation (Debye)

Select the type of capacitor:

- **Constant** — Model a linear capacitor, with nominal capacitance defined by the **Capacitance** parameter value. This is the default.
- **Lookup table** — Model a nonlinear capacitor, where the nominal capacitance value changes based on the value of applied terminal voltage.
- **Dielectric relaxation (Debye)** — Model a frequency-dependent capacitor with resistive and dielectric losses.

#### Capacitance — Nominal capacitance

1e-6 F (default)

The nominal capacitance value for linear capacitor, or the low-frequency capacitance in the Debye parameterization.

### Dependencies

This parameter is visible only when you select **Constant** or **Dielectric relaxation (Debye)** for the **Capacitance model** parameter.

#### Capacitance values — Vector of capacitance values

[1e-05, 1e-06] F (default) | positive vector

The vector of capacitance values, for table lookup based on the corresponding voltage value. Capacitance values must be greater than 0. The vector length must be the same as the voltage vector length.

**Dependencies**

This parameter is visible only when you select `Lookup table` for the **Capacitance model** parameter.

**Corresponding voltage values – Input vector of voltage values**

[0, 10] V (default)

The input vector of voltage values for table-based capacitance calculation. The vector length must be greater than or equal to 2, and the values must be strictly monotonic, either increasing or decreasing.

**Dependencies**

This parameter is visible only when you select `Lookup table` for the **Capacitance model** parameter.

**Symmetric C-V table – Table data**

Yes - use voltage magnitude when computing C (default) | No - use C-V data as-is

Specify how to use the table data:

- **Yes - use voltage magnitude when computing C** — Use this option to ensure symmetry of the capacitance with regards to the applied terminal voltage. This is the default.
- **No - use C-V data as-is** — Use this option to model polar capacitors. For example, with default parameter values for table-based capacitance, applied voltage of -10 V would produce nominal capacitance of 1e-6 F. However, if you select **No - use C-V data as-is** for the **Symmetric C-V table** parameter, the resulting capacitance value is 1e-5 F, because the block uses the nearest input value for extrapolation.

**Dependencies**

This parameter is visible only when you select `Lookup table` for the **Capacitance model** parameter.

**Frequencies for specifying dissipation factors [f1 f2] – Frequencies for dissipation factors calculation**

[1, 10] kHz (default)

Frequencies at which the dissipation factors **[DF1 DF2]** are calculated, in kHz.

**Dependencies**

This parameter is visible only when you select `Dielectric relaxation (Debye)` for the **Capacitance model** parameter.

**Dissipation factors (%) at f1 and f2 [DF1 DF2] – Dissipation factors at f1 and f2**

[.8, 1.2] (default)

Ratio between the equivalent series resistance and the capacitive reactance, or the tangent of the loss angle. Dissipation factors are a common metric for capacitors.

**Dependencies**

This parameter is visible only when you select `Dielectric relaxation (Debye)` for the **Capacitance model** parameter.

**Capacitance tolerance (%) – Capacitor tolerance**

5 (default)

The capacitor tolerance as defined on the manufacturer datasheet. For table-based capacitors, this tolerance is applied to the entire table at once.

**Tolerance application – Tolerance application**

None – use nominal value (default) | Random tolerance | Apply maximum tolerance value | Apply minimum tolerance value

Select how to apply tolerance during simulation:

- `None – use nominal value` — The block does not apply tolerance, uses the nominal capacitance value. This is the default.
- `Random tolerance` — The block applies random offset to the capacitance value, within the tolerance value limit. You can choose `Uniform` or `Gaussian` distribution for calculating the random number by using the **Tolerance distribution** parameter.
- `Apply maximum tolerance value` — The capacitance is increased by the specified tolerance percent value.
- `Apply minimum tolerance value` — The capacitance is decreased by the specified tolerance percent value.

**Tolerance distribution – Tolerance distribution type**

Uniform (default) | Gaussian

Select the distribution type:

- `Uniform` — Uniform distribution. This is the default.
- `Gaussian` — Gaussian distribution.

**Dependencies**

This parameter is visible only when you select `Random tolerance` for the **Tolerance application** parameter.

**Number of standard deviations for quoted tolerance – Number of standard deviations for quoted tolerance**

4 (default)

Number of standard deviations for calculating the Gaussian random number.

**Dependencies**

This parameter is visible only when you select `Gaussian` for the **Tolerance distribution** parameter.

**Series resistance – Series resistance**

1e-6 Ohm (default)

Simulation of some circuits may require the presence of the small series resistance. Equivalent series resistance (ESR) is sometimes specified on manufacturer datasheets. If not, you can define this

resistance for a linear capacitor via the dissipation factor (DF), which is also shown on many datasheets. The relationship is  $DF = 2\pi \cdot f \cdot C \cdot ESR$ , where  $f$  is signal frequency. For a Debye capacitor, the **Dissipation factors (%) at f1 and f2 [DF1 DF2]** are corrected for this additional series resistance prior to computing  $\tan \delta$  and  $\cos \phi$ .

### **Parallel conductance — Parallel leakage path**

0 1/Ohm (default)

Parallel leakage path associated with the capacitor. For capacitors connected in series, the presence of a small parallel conductance can help with convergence.

### **Averaging period for power logging — Averaging period for power logging**

0 s (default)

Averaging period for power logging, in s.

---

**Note** If this parameter is set to 0, the output is the instantaneous power.

---

### **Dependencies**

This parameter is visible only when you select **Dielectric relaxation (Debye)** for the **Capacitance model** parameter.

### **Operating Limits**

#### **Enable operating limits — Enable operating limits**

No (default) | Yes

Select **Yes** to enable reporting when the operational limits are exceeded. The associated parameters become visible on the **Operating Limits** tab to let you select the reporting method and specify the operating limits in terms of power and working voltage.

#### **Reporting if operating limits exceeded — Report behavior**

Warn (default) | Error

Select what happens when an operating limit is exceeded:

- **Warn** — The block issues a warning. This is the default.
- **Error** — Simulation stops with an error.

#### **Working voltage range — Working voltage range**

[-25, 25] V (default)

Range of voltage values allowed for normal block operation, specified as a vector of size 2.

#### **Power rating — Maximum instantaneous power dissipation**

1 W (default)

Maximum instantaneous power dissipation in the resistance and conductance elements associated with the capacitor.

## Faults

### Enable faults — Enable faults

No (default) | Yes

Select **Yes** to enable faults modeling. The associated **Faults** parameters become visible to let you select the reporting method and specify the trigger mechanism (temporal or behavioral). You can enable these trigger mechanisms separately or use them together. The default value is **No**.

### Reporting when a fault occurs — Report behavior

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- **None** — The block does not issue an assertion. This is the default.
- **Warn** — The block issues a warning.
- **Error** — Simulation stops with an error.

### Faulted capacitance as % of unfaulted — Faulted capacitance as % of unfaulted

100 (default)

Relative change in the capacitance when the block is in the faulted state, as compared to the unfaulted state. For table-based capacitances, the relative change is applied to all elements of the vector. The default value is 100, which means that the faulted capacitance is equal to the unfaulted capacitance.

### Faulted series resistance — Faulted series resistance

1e-3 Ohm (default)

Equivalent series resistance of the capacitor when the block is in the faulted state.

### Faulted parallel conductance — Faulted parallel conductance

0 (default) | 1/0hm

Parallel leakage conductance of the capacitor when the block is in the faulted state.

### Fault transition time constant — Fault transition time constant

1e-3 s (default)

Time constant associated with the transition to the faulted state, as described in “Faults” on page 1-200.

### Enable temporal fault trigger — Time-based fault triggering

No (default) | Yes

Select **Yes** to enable time-based fault triggering.

### Simulation time for fault event — Simulation time for fault event

1 s (default)

Set the simulation time at which you want the block to start entering the fault state.

### Dependencies

This parameter is visible only when you select **Yes** for the **Enable temporal fault trigger** parameter.

**Enable behavioral fault trigger – Behavioral fault triggering**

No (default) | Yes

Select Yes to enable behavioral fault triggering.

**Permissible voltage range – Minimum and maximum permissible voltage**

[-100, 100] V (default)

Specify the minimum and maximum permissible voltage. If the voltage value is outside this range for longer than the **Time to fail when exceeding voltage range** parameter value, then the block starts entering the fault state.

**Dependencies**

This parameter is visible only when you select Yes for the **Enable behavioral fault trigger** parameter.

**Time to fail when exceeding voltage range – Time to fail when exceeding voltage range**

1 s (default)

Set the maximum length of time that the voltage can be outside the permissible voltage range without triggering the fault.

**Dependencies**

This parameter is visible only when you select Yes for the **Enable behavioral fault trigger** parameter.

# Cauer Thermal Model

Heat transfer through multiple layers of a semiconductor module

**Library:** Simscape / Electrical / Passive / Thermal

## Description

The Cauer Thermal Model block represents heat transfer through multiple layers of a semiconductor module. A Cauer Thermal Model contains multiple Cauer Thermal Model Element components. The figure shows an equivalent circuit for a Cauer Thermal Model Element.

The multiple layers of a Cauer thermal model include chip, solder, substrate, solder, and base. Other terms that describe a Cauer thermal model are:

- Continued fraction circuit
- T model
- Ladder network

This figure shows an equivalent circuit for a Cauer Thermal Model.

The temperature at **R** is equal to the absolute zero temperature.

## Equations

The defining equations for each Cauer thermal model element are

$$C_{thermal} = \frac{\tau}{R_{thermal}},$$

$$Q_{AB} = \frac{T_{AB}}{R_{thermal}},$$

and

$$Q_{AR} = C_{thermal} \frac{dT_{AR}}{dt},$$

where:

- $C_{thermal}$  is the thermal capacity.
- $\tau$  is the thermal time constant.
- $R_{thermal}$  is the thermal resistance.
- $Q_{AB}$  is the heat flow through the material.
- $T_{AB}$  is the temperature difference between the material layers.
- $Q_{AR}$  is the heat flow through the thermal capacity.
- $T_{AR}$  is the temperature drop across the thermal capacity.

### Parameterize Cauer Model from Foster Coefficients

The datasheets of semiconductor devices often use Foster coefficients to specify the thermal model. However, Cauer thermal models are more useful as you can extend them with additional thermal components such as heatsinks and radiation or convection elements.

To parameterize the Cauer Thermal Model block from Foster thermal model data, select the **Parameterize Cauer model using Foster coefficient data** parameter.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

To specify the initial temperatures of each thermal capacity, set the value of the **Vector of thermal mass temperatures** variable. The length of this vector must be equal to the number of Cauer thermal model elements. It corresponds to the temperature drop across each thermal capacity in the model.

### Ports

#### Conserving

**A — First surface of the semiconductor individual layer**  
thermal

Thermal conserving port associated with the first surface of the individual layer of the semiconductor.

### **B – Second surface of the semiconductor last layer**

thermal

Thermal conserving port associated with the second surface of the last layer of the semiconductor.

## **Parameters**

# Change Detector

Boolean signal change detector

**Library:** Simscape / Electrical / Control / General Control

## Description

The Change Detector block outputs a Boolean response of `true` when it detects a change in the Boolean input signal that meets one of these change criteria:

- Rising edge — The input goes from false to true.

- Falling edge — The input goes from true to false.

- Either edge — The input goes from true to false or from false to true.

## Ports

### Input

#### **u** — Boolean input

0 or 1

Input Boolean signal. If false, 0. If true, 1.

Data Types: Boolean

### Output

#### **y** — Change report

0 or 1

Output is true, 1, when the block detects a change that corresponds to the specified criteria (rising, falling, or either edge). Otherwise, output is false, 0.

Data Types: Boolean

## Parameters

#### **Change detection** — Change criteria

Rising edge (default) | Falling edge | Either edge

Criteria for change detection.

**Initial condition — Initial Boolean value**

0 (default) | 1

Initial value of the previous input. If the input at the start of simulation is different from the initial condition value, the block detects an edge.

**Sample time (-1 for inherited) — Block sample time**

-1 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

## Circuit Breaker (with arc)

Single-pole single-throw circuit breaker with Mayr arc representation

**Library:** Simscape / Electrical / Switches & Breakers

### Description

The Circuit Breaker (with arc) block represents a single-phase circuit breaker with Mayr arc representation controlled by an external control signal  $vT$ . If  $vT$  is less than the threshold, then the breaker is closed. If  $vT$  is greater than or equal to the threshold, then the breaker opens with an arc during the current interruption. The external signal can open and close the breaker repeatedly.

The table shows how the external signal  $vT$  controls the block behavior.

Condition	Block Behavior
$vT < \text{Threshold}$	The circuit breaker is closed. Port <b>1</b> is connected to port <b>2</b> .
$vT \geq \text{Threshold}$	The circuit breaker is either opening or open. Port <b>1</b> is connected to port <b>2</b> via a nonlinear conductance.

The Circuit Breaker (with arc) block has a higher computational overhead than the Circuit Breaker block. If the fidelity of the representation of arc current or voltage is your overriding requirement, use the Circuit Breaker (with arc) block and use a global Simulink variable-step solver. Otherwise, use the Circuit Breaker block.

### Mayr Arc Model Equations

The defining equations for the breaker are

$$x = \ln(g)$$

and

$$i = gv,$$

where:

- $g$  is the arc conductance.
- $x$  is an internal state variable.
- $v$  is the voltage across the breaker.
- $i$  is the current through the breaker.

When the breaker is closed,

$$\frac{dx}{dt} = 0.$$

When the breaker is opening or open,

$$\frac{dx}{dt} = \frac{1}{\tau} \left( \frac{gv^2}{P} - 1 \right),$$

where:

- $\tau$  is the arc time constant.
- $P$  is the cooling power.

# Clarke to Park Angle Transform

Implement  $\alpha\beta 0$  to  $dq0$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

## Description

The Clarke to Park Angle Transform block converts the alpha, beta, and zero components in a stationary reference frame to direct, quadrature, and zero components in a rotating reference frame. For balanced three-phase systems, the zero components are equal to zero.

You can configure the block to align the phase  $a$ -axis of the three-phase system to either the  $q$ - or  $d$ -axis of the rotating reference frame at time,  $t = 0$ . The figures show the direction of the magnetic axes of the stator windings in the three-phase system, a stationary  $\alpha\beta 0$  reference frame, and a rotating  $dq0$  reference frame where:

- The  $a$ -axis and the  $q$ -axis are initially aligned.

- The  $a$ -axis and the  $d$ -axis are initially aligned.

In both cases, the angle  $\theta = \omega t$ , where

- $\theta$  is the angle between the  $a$  and  $q$  axes for the  $q$ -axis alignment or the angle between the  $a$  and  $d$  axes for the  $d$ -axis alignment.
- $\omega$  is the rotational speed of the  $d$ - $q$  reference frame.
- $t$  is the time, in s, from the initial alignment.

The figures show the time-response of the individual components of equivalent balanced  $\alpha\beta 0$  and  $dq 0$  for an:

- Alignment of the  $a$ -phase vector to the  $q$ -axis

- Alignment of the  $a$ -phase vector to the  $d$ -axis

### Equations

The Clarke to Park Angle Transform block implements the transform for an  $\alpha$ -phase to  $q$ -axis alignment as

$$\begin{bmatrix} d \\ q \\ 0 \end{bmatrix} = \begin{bmatrix} \sin(\theta) & -\cos(\theta) & 0 \\ \cos(\theta) & \sin(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \\ 0 \end{bmatrix}$$

where:

- $\alpha$  and  $\beta$  are the alpha-axis and beta-axis components of the two-phase system in the stationary reference frame.
- $0$  is the zero component.
- $d$  and  $q$  are the direct-axis and quadrature-axis components of the two-axis system in the rotating reference frame.

For an  $\alpha$ -phase to  $d$ -axis alignment, the block implements the transform using this equation:

$$\begin{bmatrix} d \\ q \\ 0 \end{bmatrix} = \begin{bmatrix} \cos(\theta) & \sin(\theta) & 0 \\ -\sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \\ 0 \end{bmatrix}$$

## Ports

### Input

#### $\alpha\beta 0$ — $\alpha$ - $\beta$ axis and zero components

vector

Alpha-axis,  $\alpha$ , beta-axis,  $\beta$ , and zero components of the two-phase system in the stationary reference frame.

Data Types: single | double

#### $\theta_{abc}$ — Rotational angle

scalar | in radians

Angular position of the rotating reference frame. The value of this parameter is equal to the polar distance from the vector of the  $a$ -phase in the  $abc$  reference frame to the initially aligned axis of the  $dq0$  reference frame.

Data Types: single | double

### Output

#### $dq0$ — $d$ - $q$ axis and zero components

vector

Direct-axis and quadrature-axis components and the zero component of the system in the rotating reference frame.

Data Types: single | double

## Parameters

#### Phase-a axis alignment — $dq0$ reference frame alignment

Q-axis (default) | D-axis

Align the  $a$ -phase vector of the  $abc$  reference frame to the  $d$ - or  $q$ -axis of the rotating reference frame.

## Description

The Clarke Transform block converts the time-domain components of a three-phase system in an  $abc$  reference frame to components in a stationary  $\alpha\beta 0$  reference frame. The block can preserve the active and reactive powers with the powers of the system in the  $abc$  reference frame by implementing a power invariant version of the Clarke transform. For a balanced system, the zero component is equal to zero.

The figures show:

- The direction of the magnetic axes of the stator windings in the  $abc$  reference frame and the stationary  $\alpha\beta 0$  reference frame

- Equivalent  $\alpha$ ,  $\beta$ , and zero components in the stationary reference frame

- The time-response of the individual components of equivalent balanced  $abc$  and  $\alpha\beta 0$  systems

### Equations

The block implements the Clarke transform as

$$\begin{bmatrix} \alpha \\ \beta \\ 0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix}$$

where:

- $a$ ,  $b$ , and  $c$  are the components of the three-phase system in the  $abc$  reference frame.
- $\alpha$  and  $\beta$  are the components of the two-axis system in the stationary reference frame.
- $0$  is the zero component of the two-axis system in the stationary reference frame.

The block implements the power invariant version of the Clarke transform as

$$\begin{bmatrix} \alpha \\ \beta \\ 0 \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{1}}{\sqrt{2}} & \frac{\sqrt{1}}{\sqrt{2}} & \frac{\sqrt{1}}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix}.$$

## Ports

### Input

#### **abc** — **a-, b-, and c-phase components**

vector

Components of the three-phase system in the  $abc$  reference frame.

Data Types: single | double

### Output

#### **$\alpha\beta 0$** — **$\alpha$ - $\beta$ axis and zero components**

vector

Alpha-axis component  $\alpha$ , beta-axis component  $\beta$ , and zero component in the stationary reference frame.

Data Types: single | double

## Parameters

#### **Power Invariant** — **Power invariant transform**

off (default) | on

Preserve the active and reactive power of the system in the  $abc$  reference frame.

# CMOS AND

Behavioral model of CMOS AND gate

**Library:** Simscape / Electrical / Integrated Circuits / Logic

## Description

The CMOS AND block represents a CMOS AND logic gate behaviorally:

- The block output logic level is **HIGH** if the logic levels of both of the gate inputs are 1.
- The block output logic level is **LOW** otherwise.

The block determines the logic levels of the gate inputs as follows:

- If the gate voltage is greater than the threshold voltage, the block interprets the input as logic 1.
- Otherwise, the block interprets the input as logic 0.

The threshold voltage is the voltage value at midpoint between the **High level input voltage** parameter value and the **Low level input voltage** parameter value.

---

**Note** To improve simulation speed, the block does not model all the internal individual MOSFET devices that make up the gate. See “Assumptions and Limitations” on page 1-236 for details.

---

The block models the gate as follows:

- The gate inputs have infinite resistance and finite or zero capacitance.
- The gate output offers a selection of two models: **Linear** and **Quadratic**. For more information, see “Selecting the Output Model for Logic Blocks”. Use the **Output current-voltage relationship** parameter to specify the output model.
- You can specify propagation delay for both output models. For **Linear** output, the block sets the value of the gate output capacitor such that the resistor-capacitor time constant equals the **Propagation delay** parameter value. For **Quadratic** output, the gate input demand is lagged to approximate the **Propagation delay** parameter value.

The block initial conditions depend on the output model selected:

- For **Linear** model, the high initial condition corresponds to the **High level output voltage** parameter value,  $V_{OH}$ , and the low initial condition corresponds to the **Low level output voltage** parameter value,  $V_{OL}$ .
- For **Quadratic** model, the high initial condition is a value close to the **Supply voltage** parameter value,  $V_{CC}$ , and the low initial condition is close to 0.

The block output voltage depends on the output model selected:

- For **Linear** model, output high is the **High level output voltage** parameter value, and output low is the **Low level output voltage** parameter value.

- For **Quadratic** model, the output voltage for High and Low states is a function of the output current, as explained in “Quadratic Model Output and Parameters”. For zero load current, output high is  $V_{cc}$  (the **Supply voltage** parameter value), and output low is zero volts.

### **Voltage Plot**

To access a voltage plot for each electrical port, in your model, right-click the block and, from the context menu, select **Electrical > Basic Characteristics**.

## **Assumptions and Limitations**

The block does not model the internal individual MOSFET devices that make up the gate (except for the final MOSFET pair if you select the **Quadratic** option for the **Output current-voltage relationship** parameter). This limitation has the following implications:

- The block does not accurately model the gate's response to input noise and inputs that are around the logic threshold voltage.
- The block does not accurately model dynamic response.

Circuits that involve a feedback path around a set of logic gates may require a nonzero propagation delay to be set on one or more gates.

## **Ports**

### **Conserving**

#### **A — Input port**

electrical

Electrical conserving port associated with the CMOS AND input.

#### **B — Input port**

electrical

Electrical conserving port associated with the CMOS AND input.

#### **J — Output port**

electrical

Electrical conserving port associated with the CMOS AND output.

## **Parameters**

### **Inputs**

#### **Low level input voltage — Low level input voltage**

2 V (default)

Voltage value below which the block interprets the input voltage as logic LOW.

#### **High level input voltage — High level input voltage**

3 V (default)

Voltage value above which the block interprets the input voltage as logic HIGH.

### **Average input capacitance — Average input capacitance**

5 pF (default)

Fixed capacitance that approximates the input capacitance for a MOSFET gate. The MOSFET capacitance depends on the applied voltage. When you drive this block with another gate, the **Average input capacitance** produces a rise time similar to that of the MOSFET. You can usually find this capacitance value on a manufacturer datasheet. Setting this value to zero may result in faster simulation times.

### **Outputs**

#### **Output current-voltage relationship — Output current-voltage relationship**

Linear (default) | Quadratic

Select the output model:

- Linear - This is the default value.
- Quadratic

#### **Low level output voltage — Low level output voltage**

0 V (default)

Voltage value at the output when the output logic level is LOW.

#### **Dependencies**

This parameter is visible only when you select Linear for the **Output current-voltage relationship** parameter.

#### **High level output voltage — High level output voltage**

5 V (default)

Voltage value at the output when the output logic level is HIGH.

#### **Dependencies**

This parameter is visible only when you select Linear for the **Output current-voltage relationship** parameter.

#### **Output resistance — Output resistance**

25 Ohm (default)

Value of the series output resistor that is used to model the drop in output voltage resulting from the output current. You can derive this value from a datasheet by dividing the high-level output voltage by the maximum low-level output current.

#### **Dependencies**

This parameter is visible only when you select Linear for the **Output current-voltage relationship** parameter.

#### **Supply voltage — Supply voltage**

5 V (default)

Supply voltage value applied to the gate in your circuit.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Measurement voltage — Measurement voltage**

5 V (default)

The gate supply voltage for which mask data output resistances and currents are defined.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic HIGH output resistance at zero current and at  $I_{OH}$  — Logic HIGH output resistance at zero current and at  $I_{OH}$** 

[25, 250] Ohm

A row vector [  $R_{OH1}$   $R_{OH2}$  ] of two resistance values. The first value  $R_{OH1}$  is the gradient of the output voltage-current relationship when the gate is logic HIGH and there is no output current. The second value  $R_{OH2}$  is the gradient of the output voltage-current relationship when the gate is logic HIGH and the output current is  $I_{OH}$ .

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic HIGH output current  $I_{OH}$  when shorted to ground — Logic HIGH output current  $I_{OH}$  when shorted to ground**

63 mA (default)

The resulting current when the gate is in the logic HIGH state, but the load forces the output voltage to zero.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic LOW output resistance at zero current and at  $I_{OL}$  — Logic LOW output resistance at zero current and at  $I_{OL}$** 

[30, 800] Ohm (default)

A row vector [  $R_{OL1}$   $R_{OL2}$  ] of two resistance values. The first value  $R_{OL1}$  is the gradient of the output voltage-current relationship when the gate is logic LOW and there is no output current. The second value  $R_{OL2}$  is the gradient of the output voltage-current relationship when the gate is logic LOW and the output current is  $I_{OL}$ .

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic LOW output current I<sub>OL</sub> when shorted to V<sub>cc</sub> – Logic LOW output current I<sub>OL</sub> when shorted to V<sub>cc</sub>**

-45 mA (default)

The resulting current when the gate is in the logic LOW state, but the load forces the output voltage to the supply voltage V<sub>cc</sub>.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Propagation delay – Propagation delay**

25 ns (default)

Time it takes for the output to swing from LOW to HIGH or HIGH to LOW after the input logic levels change.

**Protection diode on resistance – Protection diode on resistance**

5 Ohm (default)

The gradient of the voltage-current relationship for the protection diodes when forward biased.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Protection diode forward voltage – Protection diode forward voltage**

0.6 V (default)

The voltage above which the protection diode is turned on.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Initial Conditions****Output initial state – Output initial state**

Low (default) | High

Specify whether the initial output state of the block is High or Low. This parameter is used for both linear and quadratic output states, provided that the **Propagation delay** parameter is greater than zero and the Solver Configuration block does not have the **Start simulation from steady state** option selected.

The block initial conditions depend on the output model selected:

- For **Linear** model, the high initial condition corresponds to the **High level output voltage** parameter value,  $V_{OH}$ , and the low initial condition corresponds to the **Low level output voltage** parameter value,  $V_{OL}$ .
- For **Quadratic** model, the high initial condition is a value close to the **Supply voltage** parameter value,  $V_{CC}$ , and the low initial condition is close to 0.

The block output voltage depends on the output model selected:

- For **Linear** model, output high is the **High level output voltage** parameter value, and output low is the **Low level output voltage** parameter value.

- For **Quadratic** model, the output voltage for High and Low states is a function of the output current, as explained in “Quadratic Model Output and Parameters”. For zero load current, output high is  $V_{cc}$  (the **Supply voltage** parameter value), and output low is zero volts.

### Voltage Plot

To access a voltage plot for each electrical port, in your model, right-click the block and, from the context menu, select **Electrical > Basic Characteristics**.

## Assumptions and Limitations

The block does not model the internal individual MOSFET devices that make up the gate (except for the final MOSFET pair if you select the **Quadratic** option for the **Output current-voltage relationship** parameter). This limitation has the following implications:

- The block does not accurately model the gate's response to input noise and inputs that are around the logic threshold voltage.
- The block does not accurately model dynamic response.

Circuits that involve a feedback path around a set of logic gates may require a nonzero propagation delay to be set on one or more gates.

Electrical conserving port associated with the CMOS NOR input.

#### B — Input port

electrical

Electrical conserving port associated with the CMOS NOR input.

#### J — Output port

electrical

Electrical conserving port associated with the CMOS NOR output.

## Parameters

### Inputs

#### Low level input voltage — Low level input voltage

2 V (default)

Voltage value below which the block interprets the input voltage as logic LOW.

#### High level input voltage — High level input voltage

3 V (default)

Voltage value above which the block interprets the input voltage as logic HIGH.

**Average input capacitance — Average input capacitance**

5 pF (default)

Fixed capacitance that approximates the input capacitance for a MOSFET gate. The MOSFET capacitance depends on the applied voltage. When you drive this block with another gate, the **Average input capacitance** produces a rise time similar to that of the MOSFET. You can usually find this capacitance value on a manufacturer datasheet. Setting this value to zero may result in faster simulation times.

**Outputs****Output current-voltage relationship — Output current-voltage relationship**

Linear (default) | Quadratic

Select the output model:

- Linear - This is the default value.
- Quadratic

**Low level output voltage — Low level output voltage**

0 V (default)

Voltage value at the output when the output logic level is LOW.

**Dependencies**

This parameter is visible only when you select Linear for the **Output current-voltage relationship** parameter.

**High level output voltage — High level output voltage**

5 V (default)

Voltage value at the output when the output logic level is HIGH.

**Dependencies**

This parameter is visible only when you select Linear for the **Output current-voltage relationship** parameter.

**Output resistance — Output resistance**

25 Ohm (default)

Value of the series output resistor that is used to model the drop in output voltage resulting from the output current. You can derive this value from a datasheet by dividing the high-level output voltage by the maximum low-level output current.

**Dependencies**

This parameter is visible only when you select Linear for the **Output current-voltage relationship** parameter.

**Supply voltage — Supply voltage**

5 V (default)

Supply voltage value applied to the gate in your circuit.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Measurement voltage — Measurement voltage**

5 V (default)

The gate supply voltage for which mask data output resistances and currents are defined.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic HIGH output resistance at zero current and at I\_OH — Logic HIGH output resistance at zero current and at I\_OH**

[25, 250] Ohm

A row vector [  $R_{OH1}$   $R_{OH2}$  ] of two resistance values. The first value  $R_{OH1}$  is the gradient of the output voltage-current relationship when the gate is logic HIGH and there is no output current. The second value  $R_{OH2}$  is the gradient of the output voltage-current relationship when the gate is logic HIGH and the output current is  $I_{OH}$ .

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic HIGH output current I\_OH when shorted to ground — Logic HIGH output current I\_OH when shorted to ground**

63 mA (default)

The resulting current when the gate is in the logic HIGH state, but the load forces the output voltage to zero.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic LOW output resistance at zero current and at I\_OL — Logic LOW output resistance at zero current and at I\_OL**

[30, 800] Ohm (default)

A row vector [  $R_{OL1}$   $R_{OL2}$  ] of two resistance values. The first value  $R_{OL1}$  is the gradient of the output voltage-current relationship when the gate is logic LOW and there is no output current. The second value  $R_{OL2}$  is the gradient of the output voltage-current relationship when the gate is logic LOW and the output current is  $I_{OL}$ .

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic LOW output current I<sub>OL</sub> when shorted to V<sub>cc</sub> — Logic LOW output current I<sub>OL</sub> when shorted to V<sub>cc</sub>**

-45 mA (default)

The resulting current when the gate is in the logic LOW state, but the load forces the output voltage to the supply voltage V<sub>cc</sub>.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Propagation delay — Propagation delay**

25 ns (default)

Time it takes for the output to swing from LOW to HIGH or HIGH to LOW after the input logic levels change.

**Protection diode on resistance — Protection diode on resistance**

5 Ohm (default)

The gradient of the voltage-current relationship for the protection diodes when forward biased.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Protection diode forward voltage — Protection diode forward voltage**

0.6 V (default)

The voltage above which the protection diode is turned on.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Initial Conditions****Output initial state — Output initial state**

Low (default) | High

Specify whether the initial output state of the block is High or Low. This parameter is used for both linear and quadratic output states, provided that the **Propagation delay** parameter is greater than zero and the Solver Configuration block does not have the **Start simulation from steady state** option selected.

## CMOS NOT

Behavioral model of CMOS NOT gate

**Library:** Simscape / Electrical / Integrated Circuits / Logic

### Description

The CMOS NOT block represents a CMOS NOT logic gate behaviorally:

- The block output logic level is HIGH if the logic level of the gate input is 0.
- The block output logic level is LOW otherwise.

The block determines the logic levels of the gate inputs as follows:

- If the gate voltage is greater than the threshold voltage, the block interprets the input as logic 1.
- Otherwise, the block interprets the input as logic 0.

The threshold voltage is the voltage value at midpoint between the **High level input voltage** parameter value and the **Low level input voltage** parameter value.

---

**Note** To improve simulation speed, the block does not model all the internal individual MOSFET devices that make up the gate. See “Assumptions and Limitations” on page 1-259 for details.

---

The block models the gate as follows:

- The gate inputs have infinite resistance and finite or zero capacitance.
- The gate output offers a selection of two models: **Linear** and **Quadratic**. For more information, see “Selecting the Output Model for Logic Blocks”. Use the **Output current-voltage relationship** parameter to specify the output model.
- You can specify propagation delay for both output models. For **Linear** output, the block sets the value of the gate output capacitor such that the resistor-capacitor time constant equals the **Propagation delay** parameter value. For **Quadratic** output, the gate input demand is lagged to approximate the **Propagation delay** parameter value.

The block initial conditions depend on the output model selected:

- For **Linear** model, the high initial condition corresponds to the **High level output voltage** parameter value,  $V_{OH}$ , and the low initial condition corresponds to the **Low level output voltage** parameter value,  $V_{OL}$ .
- For **Quadratic** model, the high initial condition is a value close to the **Supply voltage** parameter value,  $V_{CC}$ , and the low initial condition is close to 0.

The block output voltage depends on the output model selected:

- For **Linear** model, output high is the **High level output voltage** parameter value, and output low is the **Low level output voltage** parameter value.
- For **Quadratic** model, the output voltage for High and Low states is a function of the output current, as explained in “Quadratic Model Output and Parameters”. For zero load current, output high is  $V_{cc}$  (the **Supply voltage** parameter value), and output low is zero volts.

**Logic LOW output resistance at zero current and at I\_OL — Logic LOW output resistance at zero current and at I\_OL**

[30, 800] Ohm (default)

A row vector [  $R_{OL1}$   $R_{OL2}$  ] of two resistance values. The first value  $R_{OL1}$  is the gradient of the output voltage-current relationship when the gate is logic LOW and there is no output current. The second value  $R_{OL2}$  is the gradient of the output voltage-current relationship when the gate is logic LOW and the output current is  $I_{OL}$ .

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Logic LOW output current I<sub>OL</sub> when shorted to V<sub>cc</sub> — Logic LOW output current I<sub>OL</sub> when shorted to V<sub>cc</sub>**

-45 mA (default)

The resulting current when the gate is in the logic LOW state, but the load forces the output voltage to the supply voltage V<sub>cc</sub>.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Propagation delay — Propagation delay**

25 ns (default)

Time it takes for the output to swing from LOW to HIGH or HIGH to LOW after the input logic levels change.

**Protection diode on resistance — Protection diode on resistance**

5 Ohm (default)

The gradient of the voltage-current relationship for the protection diodes when forward biased.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Protection diode forward voltage — Protection diode forward voltage**

0.6 V (default)

The voltage above which the protection diode is turned on.

**Dependencies**

This parameter is visible only when you select Quadratic for the **Output current-voltage relationship** parameter.

**Initial Conditions****Output initial state — Output initial state**

Low (default) | High

Specify whether the initial output state of the block is High or Low. This parameter is used for both linear and quadratic output states, provided that the **Propagation delay** parameter is greater than zero and the Solver Configuration block does not have the **Start simulation from steady state** option selected.

# Comparator

Behavioral model of a comparator integrated circuit

**Library:** Simscape / Electrical / Integrated Circuits

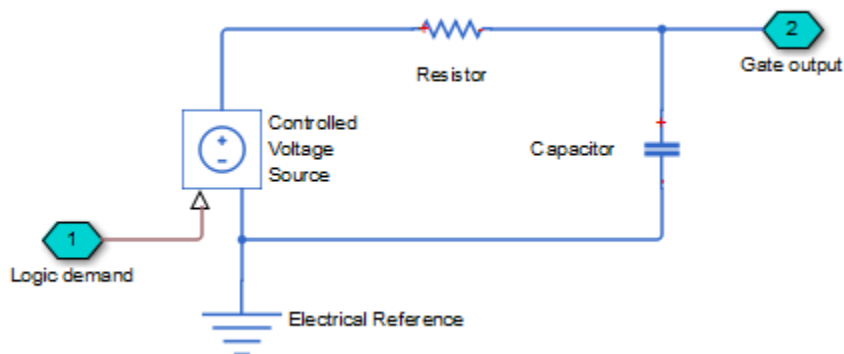

## Description

The Comparator block is an abstracted behavioral model of a comparator integrated circuit. It does not model an internal transistor-level implementation. Therefore, the block runs quickly during simulation but retains the correct I/O behavior. The block models differential inputs electrically as having infinite resistance and a finite or zero capacitance.

The block models the gate output as a voltage source driving a series resistor and a capacitor that connects to ground. The output pin connects to the resistor-capacitor connection node. If the difference in the inputs is greater than the input threshold voltage, then the output is equal to the **High level output voltage** ( $V_{OH}$ ). Otherwise, the output is equal to the **Low level output voltage** ( $V_{OL}$ ).

The output model is shown in the following illustration.

## Assumptions and Limitations

Modeling of the output as a controlled voltage source is representative of a totem-pole or push-pull output stage. To model a device with an open-collector:

- 1 Connect the output pin to the base of an NPN Bipolar Transistor or PNP Bipolar Transistor block.
- 2 Set the **Output resistance** parameter to a suitable value.

## Ports

### Conserving

#### + – Non-inverting input

electrical

Electrical conserving port associated with the comparator non-inverting input.

#### - – Inverting input

electrical

Electrical conserving port associated with the comparator inverting input.

#### OUT – Output port

electrical

Electrical conserving port associated with the comparator output

## Parameters

### Input

#### Input offset voltage – Input offset voltage

5 mV (default)

The voltage which the difference in the input voltages must be greater than so that the comparator gives a logic output 1.

#### Average input capacitance – Average input capacitance

0 pF (default)

You can usually find this capacitance value on a manufacturer datasheet. Setting this value to zero can result in faster simulation times.

### Output

#### Low level output voltage – Low level output voltage

0 V (default)

The steady-state output voltage,  $V_{OL}$ , when the voltage difference across the inputs is less than or equal to the threshold voltage, and the output current is zero.

#### High level output voltage – High level output voltage

5 V (default)

The steady-state output voltage,  $V_{OH}$ , when the voltage difference across the inputs is greater than the threshold voltage, and the output current is zero.

**Output resistance – Output resistance**

50 Ohm (default)

This parameter is the ratio of output voltage drop to output current. Set this parameter to  $(V_{OH} - V_{OH1})/I_{OH1}$ , where  $V_{OH1}$  is the reduced output high voltage when the output current is  $I_{OH1}$ .

**Propagation delay – Propagation delay**

0 s (default)

Set this value based on the high-to-low and low-to-high propagation delays.

# Compound Motor

Compound motor model with electrical and torque characteristics and fault modeling

**Library:** Simscape / Electrical / Electromechanical / Brushed Motors

## Description

The Compound Motor block represents the electrical and torque characteristics of a compound motor. This figure shows the equivalent circuit for a short-shunt compound motor:

This figure shows the equivalent circuit for a long-shunt compound motor:

where:

- $i$  is the total current.
- $i_s$  is the series field winding current.
- $i_p$  is the parallel field winding current.
- $i_a$  is the armature current.
- $V$  is the total voltage.
- $V_s$  is the series field winding voltage.
- $V_p$  is the parallel field winding voltage.
- $V_a$  is the armature voltage.
- $\omega$  is the angular velocity.
- $t_e$  is the torque.

If you set the **Steady-state parameterization** parameter to **By equivalent circuit parameters**, you can specify the equivalent circuit parameters for this model:

- $R_a$  — **Armature resistance, Ra**
- $R_s$  — **Series field winding resistance, Rs**
- $R_p$  — **Shunt field winding resistance, Rp**
- $L_{sa}$  — **Series field winding to armature back EMF constant, Lsa**
- $L_{pa}$  — **Shunt field winding to armature back EMF constant, Lpa**

### Short-Shunt Equations

When **Electrical circuit topology** is set to **Short - shunt**, the electrical dynamic equations are:

$$\begin{aligned}
V_s &= R_s i_s + L_s \frac{di_s}{dt} + L_{sp} \frac{di_p}{dt} \\
V_p &= R_p i_p + L_p \frac{di_p}{dt} + L_{sp} \frac{di_s}{dt} \\
V_{emf} &= k_v \omega = (L_{sa} i_s + L_{pa} i_p) \omega \\
V &= V_s + V_p \\
V_p &= k_v \omega + R_a i_a \\
i &= i_s \\
i_a &= i_s - i_p
\end{aligned}$$

These are the mechanical dynamic equations for the short-shunt compound motor:

$$\begin{aligned}
J \dot{\omega} + D \omega &= t_e + t_{load} \\
t_e &= k_v i_a = (L_{sa} i_s + L_{pa} i_p) i_a
\end{aligned}$$

From these dynamic equations, the block obtains the steady-state equations by making the derivatives equal to zero:

$$\begin{aligned}
V_{emf} &= L_{sa} i_s \omega + L_{pa} i_p \omega \\
t_{elec} &= k_v (i_s - i_p) = V_{emf} \frac{i_s - i_p}{\omega} \\
V &= R_s i_s + R_p i_p \\
R_p i_p &= V_{emf} + R_a (i_s - i_p)
\end{aligned}$$

Then, it computes the steady-state currents and torque as follows:

$$\begin{aligned}
t_{elec}(\omega, V) &= \frac{-V^2 (L_{pa} \omega + L_{sa} \omega - R_p) (R_a L_{pa} + R_a L_{sa} + R_p L_{sa})}{(R_a R_p + R_a R_s + R_p R_s + L_{sa} R_p \omega - L_{pa} R_s \omega)^2} \\
i &= i_s(\omega, V) = \frac{V (R_a + R_p - L_{pa} \omega)}{R_a R_p + R_a R_s + R_p R_s + L_{sa} R_p \omega - L_{pa} R_s \omega}
\end{aligned}$$

### Long-Shunt Equations

When **Electrical circuit topology** is set to Long - shunt, the electrical dynamic equations are:

$$\begin{aligned}
V_s &= R_s i_s + L_s \frac{di_s}{dt} + L_{sp} \frac{di_p}{dt} \\
V_p &= R_p i_p + L_p \frac{di_p}{dt} + L_{sp} \frac{di_s}{dt} \\
V_{emf} &= k_v \omega = (L_{sa} i_s + L_{pa} i_p) \omega \\
V &= V_p \\
V_p &= k_v \omega + R_a i_a + V_s \\
i &= i_s + i_p \\
i_a &= i_s
\end{aligned}$$

These are the mechanical dynamic equations for the long-shunt compound motor:

$$J\dot{\omega} + D\omega = t_e + t_{load}$$

$$t_e = k_v i_a = (L_{sa} i_s + L_{pa} i_p) \dot{i}_a$$

From these dynamic equations, the block obtains the steady-state equations by making the derivatives equal to zero:

$$V_{emf} = L_{sa} i_s \omega + L_{pa} i_p \omega$$

$$t_{elec} = k_v i_s = V_{emf} \frac{i_s}{\omega}$$

$$V = R_p i_p$$

$$R_p i_p = V_{emf} + (R_a + R_s) i_s$$

Then, it computes the steady-state currents and torque as follows:

$$t_{elec}(\omega, V) = \frac{V^2 (R_a - L_{pa} \omega) (R_a L_{pa} + R_s L_{pa} + R_p L_{sa})}{R_p^2 (R_a + R_s + L_{sa} \omega)^2}$$

$$i(\omega, V) = i_s + i_p = \frac{V}{R_p} + \frac{R_p V - L_{pa} V \omega}{R_p (R_a + R_s + L_{sa} \omega)}$$

## Faults

The Compound Motor block allows you to model three types of faults:

- Armature winding fault — The armature winding fails and becomes open circuit.
- Series field winding fault — The series field winding fails and becomes open circuit.
- Shunt field winding fault — The shunt field winding fails and becomes open circuit.

The block can trigger fault events:

- At a specific time (temporal fault)
- When a current limit is exceeded for longer than a specific time interval (behavioral fault)

You can enable or disable these trigger mechanisms separately.

You can choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

If you set the **Enable armature winding open-circuit fault** parameter to On, the armature fails at the time specified by the **Simulation time for armature winding fault event** parameter for a temporal fault, or when the winding currents exceeds the value of the **Maximum permissible armature winding current** parameter for a behavioral fault. When the armature fails, the voltage source connected to this block observes an open circuit for a fraction of the total motor revolution, specified by the **Fraction of revolution during which armature is open-circuit** parameter. This figure illustrates the circuit state behavior and the open-circuit state (`rev_faulted`) for a revolution period:

### Model Thermal Effects

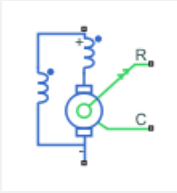

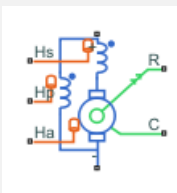

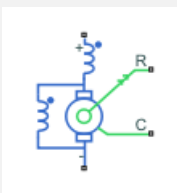

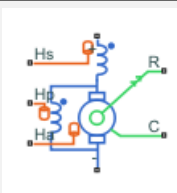

You can expose thermal ports to model the effects of losses that convert power to heat. To expose the thermal ports, set the **Modeling option** parameter to either:

- `No thermal port` — The block does not contain thermal ports.
- `Show thermal port` — The block contains thermal conserving ports for the series field winding, the shunt field winding, and the armature.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Ports

The type, visibility, and location of the block ports depend on how you configure the **Electrical circuit topology** parameter in the **Configuration** tab, and if you expose the thermal ports:

Electrical circuit topology	Thermal ports	Block
Long-shunt	Hidden	
	Visible	
Short-shunt	Hidden	
	Visible

To enable this port, set **Modeling option** to Show thermal port.

#### Hp — Shunt field winding thermal port

thermal

Thermal conserving port associated with the shunt field winding.. For more information, see “Model Thermal Effects” on page 1-1735.

#### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

#### Ha — Armature thermal port

thermal

Thermal conserving port associated with the armature. For more information, see “Model Thermal Effects” on page 1-1735.

#### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

#### Modeling option — Whether to enable thermal ports

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of losses that convert power to heat.

#### Configuration

#### Electrical circuit topology — Topology of electrical circuit

Long-shunt (default) | Short-shunt

Topology of the electrical circuit.

#### Shunt winding polarity — Shunt winding polarity

Cumulative (default) | Differential

Magnetic orientation of the shunt winding.

#### Steady-State

#### Steady-state parameterization — Block parameterization

By equivalent circuit parameters (default) | By rated, stall, and no-load datasheet parameters

Select one of the following methods for block parameterization:

- By equivalent circuit parameters — Provide electrical parameters for an equivalent circuit model of the motor.

- By rated, stall, and no-load datasheet parameters — Provide current and speed parameters that the block converts to an equivalent circuit model of the motor.

**Armature resistance,  $R_a$  — Armature resistance**

1.68 Ohm (default) | positive scalar

Resistance of the conducting portion of the motor.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By equivalent circuit parameters.

**Series field winding resistance,  $R_s$  — Series field winding resistance**

1.68 Ohm (default) | positive scalar

Resistance of the series field winding.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By equivalent circuit parameters.

**Shunt field winding resistance,  $R_p$  — Shunt field winding resistance**

303 Ohm (default) | positive scalar

Resistance of the shunt field winding.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By equivalent circuit parameters.

**Series field winding to armature back EMF constant,  $L_{sa}$  — Series field winding to armature back EMF constant**

0.69 H (default) | positive scalar

Series field winding to armature back EMF constant.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By equivalent circuit parameters.

**Shunt field winding to armature back EMF constant,  $L_{pa}$  — Shunt field winding to armature back EMF constant**

0.64 H (default) | positive scalar

Shunt field winding to armature back EMF constant.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By equivalent circuit parameters.

**Rated voltage — Rated voltage**

100 V (default) | positive scalar

Voltage at which the motor is rated to operate.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Rated speed — Rated speed**

1000 rpm (default) | positive scalar

Speed at which the motor is rated to operate.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Rated electrical power — Rated electrical power**

136 W (default) | positive scalar

Power at which the motor is rated to operate.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Rated efficiency (percent) — Rated efficiency**

85 (default) | positive scalar

Efficiency at which the motor is rated to operate, as a percentage.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Stall current — Zero speed current**

30 A (default) | positive scalar

Amount of current generated by the motor when the speed is approximately zero. This parameter must be greater than the value of the **No-load current** parameter.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**No-load speed — No-load speed**

4500 rpm (default) | positive scalar

Speed of the motor when no load is applied. This parameter must be greater than the value of the **Rated speed** parameter.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**No-load current — No-load current**

0.33 A (default) | positive scalar

Current of the motor when no load is applied.

**Dependencies**

To enable this parameter, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Ratio of shunt field winding resistance divided by series field winding resistance — Ratio of shunt field winding resistance divided by series field winding resistance**

190 (default) | nonnegative scalar

Ratio of the shunt field winding resistance divided by the series field winding resistance.

**Dependencies**

To enable this parameter, in the **Configuration** tab, set **Electrical circuit topology** to Short-shunt and, in the **Steady-state** tab, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Ratio of armature resistance divided by series field winding resistance — Ratio of armature resistance divided by series field winding resistance**

1.0 (default) | nonnegative scalar

Ratio of armature resistance divided by series field winding resistance.

**Dependencies**

To enable this parameter, in the **Configuration** tab, set **Electrical circuit topology** to Long-shunt and, in the **Steady-state** tab, set **Steady-state parameterization** to By rated, stall, and no-load datasheet parameters.

**Mechanical****Rotor inertia — Rotor inertia**

1e-4 kg\*m<sup>2</sup> (default) | scalar

Resistance of the rotor to change in motor motion. The value can be zero.

**Rotor damping — Rotor dissipated energy**

1e-6 N\*m/(rad/s) (default) | scalar

Energy dissipated by the rotor. The value can be zero.

**Dependencies**

To enable this parameter, in the **Steady-State** tab, set **Steady-state parameterization** to By equivalent circuit parameters.

**Electrical Dynamics****Series field winding inductance, L<sub>s</sub> — Series field winding inductance**

0.9 H (default) | positive scalar

Inductance of the series field winding.

**Shunt field winding inductance,  $L_p$  — Shunt field winding inductance**

0.85 H (default) | positive scalar

Inductance of the shunt field winding.

**Coefficient of mutual inductance between shunt-series windings,  $k_{sp}$  — Coefficient of mutual inductance between shunt-series windings**

0.8 (default) | nonnegative scalar between 0 and 1

Coefficient of mutual inductance between shunt-series windings.

**Thermal**

**Resistance temperature coefficient — Resistance temperature coefficient**

3.93e-3 1/K (default) | scalar

Coefficient  $\alpha$  in the equation relating resistance to temperature. The default value is for copper.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Measurement temperature — Measurement temperature**

25 degC (default) | scalar

Temperature for which motor parameters are quoted.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Thermal masses, [ $M_s$   $M_p$   $M_a$ ] — Thermal masses**

[100, 100, 100] J/K (default) | vector

1-by-3 row vector that defines the thermal mass for the series and shunt field windings and armature winding. The thermal mass is the energy required to raise the temperature by one degree.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Faults**

**Enable armature winding open-circuit fault — Whether to enable armature winding faults**

Off (default) | On

Select On to enable faults modeling and expose parameters that allow you to select the reporting method and specify the trigger mechanism.

**Fraction of revolution during which armature is open-circuit — Fraction of revolution during which armature is open-circuit**

1/3 (default) | scalar

Fraction of the revolution of the compound motor during which the armature winding is faulted and the voltage source observes an open circuit. For more information, see the “Faults” on page 1-388 section.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On.

**Faulted armature winding open-circuit conductance — Open-circuit conductance of faulted armature winding**

1e-5 S (default) | scalar

Open-circuit conductance when the armature winding is faulted.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On.

**Armature winding fault trigger — Fault trigger for armature winding**

Temporal (default) | Behavioral

Whether the trigger for the armature winding fault is temporal or behavioral.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On.

**Simulation time for armature winding fault event — Simulation time for armature winding fault event**

1 s (default) | scalar

Simulation time for the armature winding becomes faulted.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On and **Armature winding fault trigger** to Temporal.

**Maximum permissible armature winding current — Maximum permissible armature winding current**

inf A (default)

Upper load-current threshold for open-circuit armature winding faults.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On and **Armature winding fault trigger** to Behavioral.

**Time to fail when exceeding armature winding current — Time to fail when exceeding armature winding current**

1 s (default) | scalar

Amount of time that the winding current must continuously exceed the maximum permissible armature winding current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On and **Armature winding fault trigger** to Behavioral.

**Enable series field winding open-circuit fault — Whether to enable series field winding faults**

Off (default) | On

Select On to enable faults modeling and expose parameters that allow you to select the reporting method and specify the trigger mechanism.

**Faulted series field winding open-circuit conductance — Open-circuit conductance of faulted field winding**

1e-5 S (default) | scalar

Open-circuit conductance when the series field winding is faulted.

**Dependencies**

To enable this parameter, set **Enable series field winding open-circuit fault** to On.

**Series field winding fault trigger — Fault trigger for series field winding**

Temporal (default) | Behavioral

Whether the trigger for the series field winding fault is temporal or behavioral.

**Dependencies**

To enable this parameter, set **Enable series field winding open-circuit fault** to On.

**Simulation time for series field winding fault event — Simulation time for series field winding fault event**

1 s (default) | scalar

Simulation time for the series field winding becomes faulted.

**Dependencies**

To enable this parameter, set **Enable series field winding open-circuit fault** to On and **Series field winding fault trigger** to Temporal.

**Maximum permissible series field winding current — Maximum permissible series field winding current**

inf A (default)

Upper load-current threshold for open-circuit series field winding faults.

**Dependencies**

To enable this parameter, set **Enable series field winding open-circuit fault** to On and **Series field winding fault trigger** to Behavioral.

**Time to fail when exceeding series field winding current — Time to fail when exceeding series field winding current**

1 s (default) | scalar

Amount of time that the winding current must continuously exceed the maximum permissible series field winding current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Enable series field winding open-circuit fault** to On and **Series field winding fault trigger** to Behavioral.

**Enable shunt field winding open-circuit fault – Whether to enable shunt field winding faults**

Off (default) | On

Select On to enable faults modeling and expose parameters that allow you to select the reporting method and specify the trigger mechanism.

**Faulted shunt field winding open-circuit conductance – Open-circuit conductance of faulted shunt winding**

1e-5 S (default) | scalar

Open-circuit conductance when the shunt field winding is faulted.

**Dependencies**

To enable this parameter, set **Enable shunt field winding open-circuit fault** to On.

**Shunt field winding fault trigger – Fault trigger for shunt field winding**

Temporal (default) | Behavioral

Whether the trigger for the shunt field winding fault is temporal or behavioral.

**Dependencies**

To enable this parameter, set **Enable shunt field winding open-circuit fault** to On.

**Simulation time for shunt field winding fault event – Simulation time for shunt field winding fault event**

1 s (default) | scalar

Simulation time for the shunt field winding becomes faulted.

**Dependencies**

To enable this parameter, set **Enable shunt field winding open-circuit fault** to On and **Shunt field winding fault trigger** to Temporal.

**Maximum permissible shunt field winding current – Maximum permissible shunt field winding current**

inf A (default)

Upper load-current threshold for open-circuit shunt field winding faults.

**Dependencies**

To enable this parameter, set **Enable shunt field winding open-circuit fault** to On and **Shunt field winding fault trigger** to Behavioral.

**Time to fail when exceeding shunt field winding current — Time to fail when exceeding shunt field winding current**

1 s (default) | scalar

Amount of time that the winding current must continuously exceed the maximum permissible shunt field winding current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Enable shunt field winding open-circuit fault** to On and **Shunt field winding fault trigger** to Behavioral.

**Reporting when a fault occurs — Reporting when a fault occurs**

None (default) | Warn | Error

Simulation reporting when a fault occurs:

- None — Does not generate a warning or an error.
- Warn — Generates a warning.
- Error — The simulation stops and generates an error.

**Dependencies**

To enable this parameter, set at least one of these parameters to On:

- **Enable armature winding open-circuit fault**
- **Enable series field winding open-circuit fault**
- **Enable shunt field winding open-circuit fault**

## Constant Current Load

Constant current load for DC or AC supply

**Library:** Simscape / Electrical / Passive

### Description

The Constant Current Load block implements a constant current load for a DC or AC supply.

If you set the **Load type** parameter to DC:

- The consumed current of this block is equal to the value of the **Consumed current** parameter as long as the voltage from the DC supply is equal to or greater than the value specified for the **Minimum supply voltage** parameter.
- When the voltage from the DC supply drops below **Minimum supply voltage**, the load behaviour changes and the block models a resistive load. If the supply voltage becomes negative, the block models a small open-circuit conductance.

To ensure smooth transitions between these behaviours, the block uses a third-order polynomial spline with continuous derivatives. You can specify the width of this transition using the **Transition voltage width** parameter.

If you set the **Load type** parameter to AC:

- The root mean square consumed current of this block is equal to the value of the **Consumed current (RMS)** parameter as long as the voltage from the AC supply is equal to or greater than the value specified for the **Minimum supply voltage (RMS)** parameter.
- When the voltage from the AC supply drops below the **Minimum supply voltage (RMS)** parameter, the load behaviour changes and the block models a load with constant resistance.

### Equations

If you set the **Load type** parameter to AC, the block calculates the peak voltage,  $V_{pk}$ , through harmonic approximation of the instantaneous voltage by using a one-period-integrated Fourier transform:

$$\text{Re} = f_0 \int v \sin(2\pi f_0 t)$$

$$\text{Im} = f_0 \int v \sin\left(2\pi f_0 t + \frac{\pi}{2}\right)$$

$$V_{pk} = 2\sqrt{\text{Re}^2 + \text{Im}^2}$$

During the first period, the peak voltage is equal to  $\theta$  V. The current is defined by this equation:

$$i(t) = \frac{V(t)}{R_{equiv}}$$

where  $R_{equiv}$  is the equivalent resistance and depends on the value of the **Minimum supply voltage (RMS)** parameter.

If the voltage from the three-phase supply is greater than the value specified for the **Minimum supply voltage (RMS)** parameter, the equivalent resistance is defined by:

$$R_{equiv} = \frac{\frac{V_{pk}}{\sqrt{2}}}{I_{RMSconsumed}},$$

where  $V_{pk}$  is the voltage peak magnitude and  $I_{RMSconsumed}$  is the value of the **Consumed current (RMS)** parameter.

If the voltage from the three-phase supply is less than the value specified for the **Minimum supply voltage (RMS)** parameter, the equivalent resistance is defined by:

$$R_{equiv} = \frac{V_{RMSmin}}{I_{RMSconsumed}},$$

where  $V_{RMSmin}$  is the value of the **Minimum supply voltage (RMS)** parameter.

## Faults

The Constant Current Load block allows you to model an electrical fault as an open circuit. The block can trigger fault events either:

- At a specific time
- When a power limit is exceeded for longer than a specific time interval

You can also choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Load-Flow Analysis

If the block is in a network that is compatible with the frequency-time simulation mode, you can perform a load-flow analysis on the network. A load-flow analysis provides steady-state values that you can use to initialize a machine.

For more information, see “Perform a Load-Flow Analysis Using Simscape Electrical” and “Frequency and Time Simulation Mode”.

## Parameters

### Main

#### **Load type — Load type**

DC (default) | AC

Type of load. Select DC to use this load with a DC supply or AC to use this load with an AC supply.

#### **Consumed current — Current consumed**

1 A (default) | scalar

Current consumed by the block.

#### **Dependencies**

To enable this parameter, set **Load Type** to DC.

#### **Minimum supply voltage — Minimum DC supply voltage**

5 V (default) | scalar

Minimum voltage the DC supply needs to give the block to act as a constant current load.

#### **Dependencies**

To enable this parameter, set **Load Type** to DC.

#### **Reverse conductance — Reverse conductance**

1e-6 S (default) | scalar

Value of the reverse conductance when the supply voltage becomes negative.

#### **Dependencies**

To enable this parameter, set **Load Type** to DC.

#### **Transition voltage width — Transition voltage width**

1e-3 V (default) | scalar

Transition voltage width used to ensure smooth transitions between block behaviours when the supply voltage drops below the value of the **Minimum supply voltage** parameter or becomes negative.

#### **Dependencies**

To enable this parameter, set **Load Type** to DC.

#### **Consumed current (RMS) — Root mean square consumed current**

100 A (default) | scalar

Root mean square current consumed by the block.

#### **Dependencies**

To enable this parameter, set **Load Type** to AC.

#### **Rated frequency — Rated frequency**

60 Hz (default) | scalar

Rated frequency.

#### Dependencies

To enable this parameter, set **Load Type** to AC.

#### Minimum supply voltage (RMS) — Minimum AC supply voltage

200 V (default) | scalar

Minimum voltage, in RMS, that the AC supply must provide for the block to act as a constant current load.

#### Dependencies

To enable this parameter, set **Load Type** to AC.

#### Faults

#### Enable open-circuit fault — Whether to enable faults modeling

Off (default) | On

Select On to enable faults modeling and expose parameters that allow you to select the reporting method and specify the trigger mechanism.

#### Open-circuit conductance — Open-circuit conductance

1e-4 S (default) | scalar

Conductance during the open-circuit state.

#### Dependencies

To enable this parameter, set **Enable open-circuit fault** to On.

#### Reporting when a fault occurs — Whether to issue an assertion when a fault occurs

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- None — The block does not issue an assertion.
- Warn — The block issues a warning.
- Error — Simulation stops with an error.

#### Dependencies

To enable this parameter, set **Enable open-circuit fault** to On.

#### Fault trigger — Trigger mechanism

Temporal (default) | Behavioral

Whether to trigger the fault based on temporal or behavioral conditions.

#### Dependencies

To enable this parameter, set **Enable open-circuit fault** to On.

#### Simulation time for fault event — Time before entering faulted state

1 s (default) | scalar

Simulation time when the block enters the faulted state.

**Dependencies**

To enable this parameter, set **Enable open-circuit fault** to On and **Fault trigger** to Temporal.

**Maximum permissible power — Power threshold to fault transition**

inf W (default)

Maximum permissible power value. If the power exceeds this value for longer than the **Time to fail when exceeding power** parameter value, then the block enters the faulted state.

**Dependencies**

To enable this parameter, set **Enable open-circuit fault** to On and **Fault trigger** to Behavioral.

**Time to fail when exceeding power — Maximum length of time the power exceeds the threshold**

1 s (default)

Maximum length of time that the power can exceed the maximum permissible value without triggering the fault.

**Dependencies**

To enable this parameter, set **Enable open-circuit fault** to On and **Fault trigger** to Behavioral.

## Constant Current Load (Three-Phase)

Three-phase constant current load

**Library:** Simscape / Electrical / Passive

### Description

The Constant Current Load (Three-Phase) block implements a constant current load for a three-phase supply.

This block consumes a current equal to the value of the **Consumed current (RMS)** parameter as long as the voltage from the three-phase supply is equal to or greater than the value specified for the **Minimum supply voltage (phase-to-phase RMS)** parameter.

When the voltage from the three-phase supply drops below the value of **Minimum supply voltage (phase-to-phase RMS)**, the load behaviour changes and the block models a load with constant resistance.

### Equations

If the three-phase voltages are balanced, the phase-to-phase RMS voltage is defined by this equation:

$$V_{lineRMS} = \sqrt{(v_a - v_{dc})^2 + (v_b - v_{dc})^2 + (v_c - v_{dc})^2},$$

$$\text{where } v_{dc} = \frac{v_a + v_b + v_c}{3}.$$

The currents for each of the three phases are defined by this equation:

$$i_k(t) = \frac{v_k(t)}{R_{equiv}},$$

where  $R_{equiv}$  is the equivalent resistance and depends on value of the **Minimum supply voltage (phase-to-phase RMS)** parameter.

If the voltage from the three-phase supply is greater than the value specified for the **Minimum supply voltage (phase-to-phase RMS)** parameter, the equivalent resistance is defined by:

$$R_{equiv} = \frac{\frac{v_{pk}}{\sqrt{2}}}{I_{RMSconsumed}},$$

where  $v_{pk}$  is the voltage peak magnitude and  $I_{RMSconsumed}$  is the value of the **Consumed current (RMS)** parameter.

If the voltage from the three-phase supply is less than the value specified for the **Minimum supply voltage (phase-to-phase RMS)** parameter, the equivalent resistance is defined by:

$$R_{equiv} = \frac{v_{phRMSmin}}{I_{RMSconsumed}},$$

where  $v_{phRMSmin} = \frac{V_{lineRMSmin}}{\sqrt{3}}$  is the phase-to-ground RMS minimum voltage.

## Faults

The Constant Current Load (Three-Phase) block allows you to model an electrical fault as an open circuit. The block can trigger fault events either:

- At a specific time
- When a power limit is exceeded for longer than a specific time interval

You can also choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Load-Flow Analysis

If the block is in a network that is compatible with frequency-time simulation mode, you can perform a load-flow analysis on the network. A load-flow analysis provides steady-state values that you can use to initialize a machine.

For more information, see “Perform a Load-Flow Analysis Using Simscape Electrical” and “Frequency and Time Simulation Mode”.

# Constant Power Load

Constant power load for DC or AC supply

**Library:** Simscape / Electrical / Passive

## Description

The Constant Power Load block implements a constant power load for a DC or AC supply.

If you set the **Load type** parameter to DC:

- The block outputs a nominal rated power as long as the voltage from the DC supply is equal to or greater than the value specified for the **Minimum supply voltage** parameter.
- When the voltage from the DC supply drops below the **Minimum supply voltage**, the load behaviour changes and the block acts as a constant resistance. If the supply voltage becomes negative, the block acts as a constant reverse conductance.

To ensure smooth transitions between these behaviours, the block uses a third-order polynomial spline with continuous derivatives. You can specify the width of this transition using the **Transition voltage width** parameter.

If you set the **Load type** parameter to AC:

- The block outputs a nominal rated power as long as the voltage from the AC supply is equal to or greater than the value specified for the **Minimum supply voltage (RMS)** parameter.
- When the voltage from the AC supply drops below the **Minimum supply voltage (RMS)**, the load behaviour changes and the block models a load with constant impedance.

For more information about the equations for the AC load type in a three-phase system, see the “Equations” on page 1-307 section of the Constant Power Load (Three-Phase) block.

## Faults

The Constant Power Load block allows you to model an electrical fault as an open circuit. The block can trigger fault events at a specific time.

You can also choose whether to issue an assertion when a fault occurs, by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Equations

When the voltage from the three-phase supply is greater than the value specified for the **Minimum supply voltage (phase-to-phase RMS)** parameter, the block acts in constant PQ mode.

The active and reactive power are defined by:

$$P = \frac{3}{2} V_{pk} I_{pk} \cos(\varphi_V - \varphi_I)$$

$$Q = \frac{3}{2} V_{pk} I_{pk} \sin(\varphi_V - \varphi_I)$$

where:

- $V_{pk}$  is the voltage peak magnitude.
- $\varphi_I = \varphi_V - \text{atan}\left(\frac{Q}{P}\right)$  is the phase of the current.
- $I_{pk} = \frac{2}{3} \frac{P}{V_{pk} \cos(\varphi_V - \varphi_I)}$  is the current peak magnitude.

When the voltage from the three-phase supply is less than or equal to the value specified for the **Minimum supply voltage (phase-to-phase RMS)** parameter, the block acts in constant Z mode.

The active and reactive power are defined by:

$$P = \frac{3}{2} V_{pk}^2 \frac{R}{R^2 + X^2}$$

$$Q = \frac{3}{2} V_{pk}^2 \frac{X}{R^2 + X^2}$$

where:

- $R = V_{line\ RMS_{min}} \frac{P}{P^2 + Q^2}$  is the constant resistance.
- $X = V_{line\ RMS_{min}} \frac{Q}{P^2 + Q^2}$  is the constant reactance.
- $V_{line\ RMS_{min}}$  is the **Minimum supply voltage (phase-to-phase RMS)**.

## Controlled Current Source (Three-Phase)

Ideal three-phase controlled current source

**Library:** Simscape / Electrical / Sources

### Description

The Controlled Current Source (Three-Phase) block represents an ideal three-phase current source that is powerful enough to maintain the specified current through it regardless of the voltage across it. The output currents are  $[i_a \ i_b \ i_c] = S$ , where  $S$  is a vector containing the numerical values presented at the physical signal port.

The figure shows the equivalent circuit for the expanded implementation of the Controlled Current Source (Three-Phase) block.

To use the Controlled Current Source (Three-Phase) block as an abstracted current controller in an electrical drive, connect the conserving ports for the output current directly to the machine.

To choose the input type of this block, set the **Input type** parameter to Instantaneous or Sinusoidal magnitude and phase shift. If you select Instantaneous, this block works only

in time simulation mode. If you select `Sinusoidal magnitude and phase shift`, this block works in both time and frequency-time simulation modes. For more information, see “Frequency and Time Simulation Mode”.

To access the implementation with an expanded, three-phase port, double-click the block and set the **Modeling option** parameter to `Expanded three-phase ports`.

## Controlled PWM Voltage

Pulse-width modulated voltage source

**Library:** Simscape / Electrical / Integrated Circuits

### Description

The Controlled PWM Voltage block represents a pulse-width modulated (PWM) voltage source. You can model electrical or physical signal input ports by setting the **Modeling option** parameter to either:

- **Electrical input ports** — The block calculates the duty cycle based on the reference voltage across its **ref+** and **ref-** ports. This option is the default.
- **PS input** — Specify the duty cycle value directly by using an input physical signal port.

If you set **Modeling option** to **Electrical input ports**, the demanded duty cycle is

$$100 * \frac{V_{ref} - V_{min}}{V_{max} - V_{min}} \text{ percent}$$

where:

- $V_{ref}$  is the reference voltage across the **ref+** and **ref-** ports.
- $V_{min}$  is the minimum reference voltage.
- $V_{max}$  is the maximum reference voltage.

The value of the **Output voltage amplitude** parameter determines amplitude of the output voltage.

At time zero, the pulse is initialized as high, unless the **Pulse delay time** parameter is greater than zero, or the demanded duty cycle is zero.

You can use parameters **Pulse delay time** and **Pulse width offset** to add a small turn-on delay and a small turn-off advance. This can be useful when fine-tuning switching times so as to minimize switching losses.

In PWM mode, the block has two options for the type of switching event when moving between output high and output low states:

- **Asynchronous** — **Best for variable-step solvers** — Asynchronous events are better suited to variable step solvers, because they require fewer simulation steps for the same level of accuracy. In asynchronous mode the PWM switching events generate zero crossings, and therefore switching times are always determined accurately, regardless of the simulation maximum step size.
- **Discrete-time** — **Best for fixed-step solvers** — Discrete-time events are better suited to fixed-step operation, because then the switching events are always synchronized with the simulation step. Using an asynchronous implementation with fixed-step solvers may sometimes

result in events being up to one simulation step late. For more information, see “Simulating with Fixed Time Step — Local and Global Fixed-Step Solvers”.

If you use a fixed-step or local solver and the discrete-time switching event type, the following restrictions apply to the **Sample time** parameter value:

- The sample time must be a multiple of the simulation step size.
- The sample time must be small compared to the PWM period, to ensure sufficient resolution.

### Assumptions and Limitations

The model is based on the following assumptions:

- The REF output of this block is floating, it is not tied to the Electrical Reference. One consequence of this is that if you connect the PWM and REF electrical ports directly to the PWM and REF electrical ports of an H-bridge or a gate driver, you must attach an Electrical Reference block to the REF connection line.
- Do not connect the Controlled PWM block directly to a semiconductor gate, because this omits the gate driver output impedance that determines switching dynamics. Use a Gate Driver or a Half-Bridge Driver block to set the gate-source or the gate-emitter voltage.
- Do not use the Controlled PWM block to drive a motor block directly. A PWM motor driver goes open circuit in between pulses. Use the H-Bridge block to drive a motor block.
- When driving a motor via the H-Bridge block, set the **Simulation mode** parameter to **Averaged** to speed up simulations. You must also set the **Simulation mode** parameter of the H-Bridge block to **Averaged** mode. This applies the average of the demanded PWM voltage to the motor. The **Averaged** mode assumes that the impedance of the motor inductive term is small at the **PWM frequency**. To verify this assumption, run the simulation using the **PWM** mode and compare the results to those obtained from using the **Averaged** mode.
- If you are linearizing your model, set the **Simulation mode** parameter to **Averaged** and ensure that you have specified the operating point of the block correctly. You can only linearize the block for inputs corresponding to a duty cycle greater than zero and less than 100 percent.
- When you use this block in **PWM** mode with the **Use local solver option** selected in the Solver Configuration block, set the **Switching event type** parameter to **Discrete-time – Best for fixed-step solvers**. Using the **Asynchronous – Best for variable-step solvers** option in this situation may produce inaccuracies, because simulation with the local solver implies fixed step, and the PWM events will not always coincide precisely with the simulation steps. This results in PWM events sometimes occurring one simulation step late.

## Ports

### Input

#### **u** — Control signal, unitless

physical signal

Input physical signal that specifies the duty cycle.

### Dependencies

To enable this port, set **Modeling option** to **PS** input.

## Conserving

### **ref+ — Positive terminal**

electrical

Positive electrical reference voltage.

#### **Dependencies**

To enable this port, set **Modeling option** to Electrical input ports.

### **ref- — Negative terminal**

electrical

Negative electrical reference voltage

#### **Dependencies**

To enable this port, set **Modeling option** to Electrical input ports.

### **PWM — Pulse-width modulated signal**

electrical

Electrical conserving port associated with the pulse-width modulated signal.

### **REF — Floating zero volt reference**

electrical

Electrical conserving port associated with the floating zero volt reference.

## Parameters

### **Modeling option — Whether to model electrical or physical signal input ports**

Electrical input ports (default) | PS input

Whether to model electrical or physical signal input ports.

#### **PWM**

### **PWM frequency — PWM output signal frequency**

1000 Hz (default)

Frequency of the PWM output signal.

### **Pulse delay time — Turn-on delay**

0 s (default)

The pulse train does not start until the simulation time is equal to the **Pulse delay time**. You can specify a small value for **Pulse delay time** to fine-tune switching times and ensure that an off-going device is fully off before the on-going device starts to turn on. You can also use larger delay times, for example, if you need the pulse train to start only after a number of cycles. The value you provide must be greater than or equal to zero.

#### **Dependencies**

Enabled when the **Simulation mode** parameter is set to PWM.

**Pulse width offset — Lengthens or shortens the pulse**

0 s (default)

The demanded pulse width as defined by the product of the demanded duty cycle and one over the pulse frequency can be offset by the value you provide for **Pulse width offset**. A positive value acts to lengthen the pulse by a fixed amount. A negative value acts to shorten the pulse. You can use this parameter, along with the **Pulse delay time**, to fine-tune switching times so as to minimize switching losses in some circuits.

**Dependencies**

Enabled when the **Simulation mode** parameter is set to PWM.

**Minimum pulse width — Minimum length of pulse**

0 s (default)

The minimum pulse length, based on the internal clock or defined programmatically, to protect the device being driven. The value you provide must be greater than or equal to zero.

**Dependencies**

Enabled when the **Simulation mode** parameter is set to PWM.

**Simulation mode — Select type of output voltage**

PWM (default) | Averaged

Select the type of output voltage:

- **PWM** — Produces a pulse-width modulated signal.
- **Averaged** — The output is a constant whose value is equal to the average value of the PWM signal.

**Switching event type — Select type of switching event**

Asynchronous — Best for variable-step solvers (default) | Discrete-time — Best for fixed-step solvers

Select the switching event type when moving between output high and output low states:

- **Asynchronous — Best for variable-step solvers** — This option is more efficient for desktop simulation with variable-step solvers, because it requires fewer simulation steps for the same level of accuracy.
- **Discrete-time — Best for fixed-step solvers** — Use with fixed-step solvers, including the local solver. For more information, see “Simulating with Fixed Time Step — Local and Global Fixed-Step Solvers”.

**Dependencies**

Enabled when the **Simulation mode** parameter is set to PWM.

**Sample time — Discrete sampling time**

1e-6 s (default)

The time between updates of the block output state. The sample time must be a multiple of the simulation step size. In order for the PWM control to have sufficient resolution, set the sample time to less than one hundredth of the PWM period. (The PWM period is one over the PWM frequency.)

**Dependencies**

Enabled when the **Switching event type** parameter is set to Discrete-time – Best for fixed-step solvers.

**Input Scaling****Input voltage for 0% duty cycle – Vmin**

0 V (default)

Value of the input voltage at which the PWM signal has a 0% duty cycle.

**Dependencies**

To enable this parameter, set **Modeling option** to Electrical input ports.

**Input voltage for 100% duty cycle – Vmax**

5 V (default)

Value of the input voltage at which the PWM signal has a 100% duty cycle.

**Dependencies**

To enable this parameter, set **Modeling option** to Electrical input ports.

**Input value for 0% duty cycle – Minimum signal value**

0 (default)

Value of the input signal at which the PWM signal has a 0% duty cycle.

**Dependencies**

To enable this parameter, set **Modeling option** to PS input.

**Input value for 100% duty cycle – Maximum signal value**

1 (default)

Value of the input signal at which the PWM signal has a 100% duty cycle

**Dependencies**

To enable this parameter, set **Modeling option** to PS input.

**Output Voltage****Output voltage amplitude – Signal amplitude for high output**

5 V (default)

Amplitude of the PWM signal when the output is high.

# Controller LCFB1

Load controller for turbine-governor model

**Library:** Simscape / Electrical / Control / Turbine-Governors

## Description

The Controller LCFB1 block models a model LCFB1 turbine load controller. You can use this load controller with any turbine-governor model, such as the Governor Type 1 or Governor Type 3 blocks.

You can switch between continuous and discrete implementations of the block by using the **Sample time (-1 for inherited)** parameter. To configure the controller for continuous time, set the **Sample time (-1 for inherited)** property to 0. To configure the controller for discrete time, set the **Sample time (-1 for inherited)** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block.

This diagram illustrates the overall structure of the block:

## Ports

### Input

**speed\_pu** — Speed load  
scalar

Speed load, specified as a scalar.

Data Types: `single` | `double`

### **Pmwset — Power setpoint**

scalar

Power setpoint value, specified as a scalar.

Data Types: `single` | `double`

### **Pelec — Electrical power input**

scalar

Electrical power input, specified as a scalar.

Data Types: `single` | `double`

## **Output**

### **Pref — Bias**

scalar

Bias to apply to a turbine-governor speed load reference, returned as a scalar.

Data Types: `single` | `double`

## **Parameters**

### **Speed reference (pu) — Speed reference**

1 (default) | scalar

Per-unit speed reference.

### **Initial power reference, P\_ref0 (pu) — Initial power reference**

0.45 (default) | scalar

Per-unit power reference at the start of the simulation.

### **Controller deadband (pu) — Deadband of controller**

0 (default) | scalar

Per-unit deadband of the controller.

### **Maximum error, e\_max (pu) — Maximum error**

0.1 (default) | scalar

Maximum possible error.

### **Frequency bias gain, f\_b (pu) — Gain of frequency bias**

0 (default) | scalar

Per-unit gain of the frequency bias.

### **Proportional gain, K\_p (pu) — Proportional gain for PI control**

0 (default) | scalar

Per-unit proportional gain for PI control.

**Integral gain,  $K_i$  (pu/s) – Integral gain for PI control**

0.1 (default) | scalar

Per-unit integral gain for PI control.

**Power transducer time constant,  $T_{pelec}$  (s) – Time constant of power transducer**

3.5 (default) | scalar

Time constant of the power transducer, in seconds. The power transducer is represented by the block labeled "Low-Pass Filter" in the diagram.

**Maximum output,  $I_{rmax}$  (pu) – Upper limit of the output**

0.035 (default) | scalar

Per-unit upper saturation limit for the output.

**Sample time (-1 for inherited) – Block sample time**

-1 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see "What Is Sample Time?" and "Specify Sample Time".

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see "Promote Block Parameters on a Mask".

# Converter (Three-Phase)

Controller-driven bidirectional AC/DC three-arm converter

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

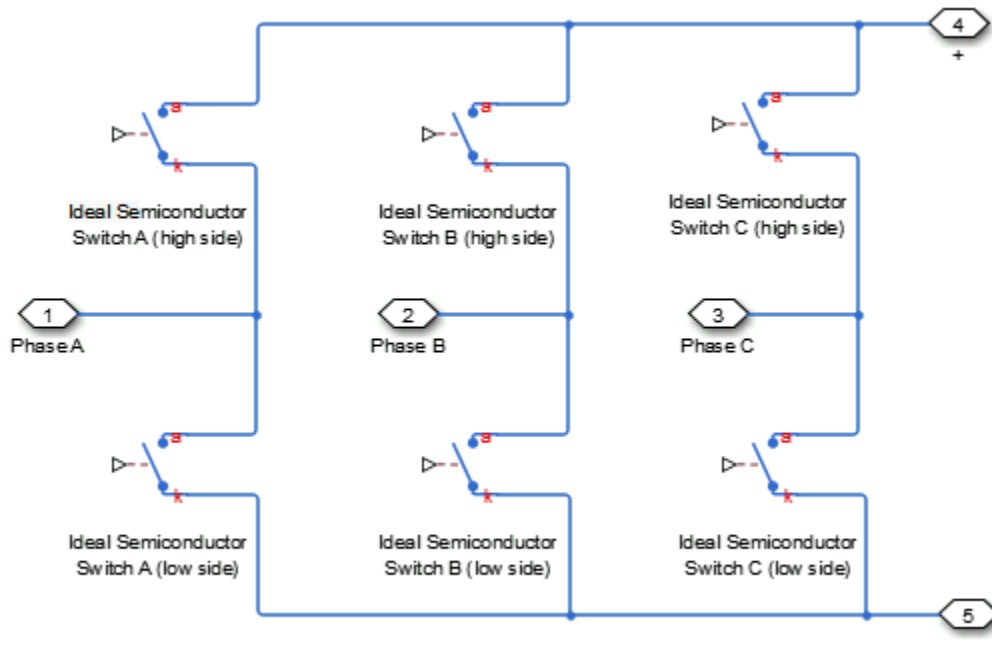

## Description

The Converter (Three-Phase) block models a three-arm converter circuit that connects a three-phase AC network to a DC network.

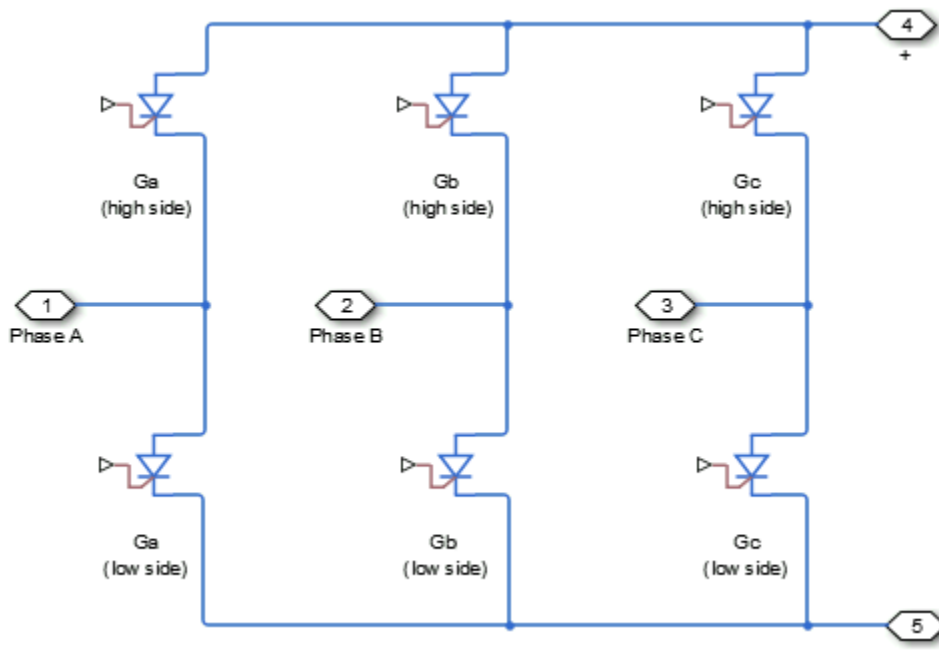

Each component in the three-arm circuit is the same switching device, which you specify using an option on the Converter (Three-Phase) block dialog box. The switching devices that you can specify are implementations of blocks in the **Simscape > Electrical > Semiconductors & Converters > Semiconductors** library:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

The figure shows the equivalent circuit for a converter with fully controlled switching devices (e.g. IGBTs, GTOs).

The figure shows the equivalent circuit for a converter with partially controlled switching devices (e.g. thyristors).

Control the gate ports of the six switching devices via an input to port **G** on the Converter (Three-Phase) block:

- 1 Multiplex all six gate signals into a single vector with a Six-Pulse Gate Multiplexer block.

- 2 Connect the output of the Six-Pulse Gate Multiplexer block to the Converter (Three-Phase) block **G** port.

You can specify an integral protection diode for each switching device. An integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

The table shows you how to set the **Integral protection diode** parameter based on your goals.

Goals	Value to Select	Integral Protection Diode
Prioritize simulation speed.	Diode with no dynamics	The Diode block
Prioritize model fidelity by precisely specifying reverse-mode charge dynamics.	Diode with charge dynamics	The dynamic model of the Diode block

You can include a snubber circuit, consisting of a resistor and capacitor connected in series, for each switching device. Snubber circuits protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of change of current when a switching device turns on.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to *Averaged switch* and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

### Assumptions and Limitations

If, in the Solver Configuration block inside your model, you set the **Solver type** parameter to *Partitioning*, the averaged switches introduce instability during dead time, when all gate inputs are set to 0. Where possible, use the open-zero state by setting all high-side switches to 0 and all low-side switches to 1.

## Ports

### Conserving

#### **G — Gate terminals**

electrical

Vector input port associated with the gate terminals of the switching devices. Connect this port to a Six-Pulse Gate Multiplexer block.

#### **~ — Three-phase port**

electrical

Expandable three-phase port

#### **Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

#### **a — a-phase**

electrical

Electrical conserving port associated with *a*-phase.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

#### **b — b-phase**

electrical

Electrical conserving port associated with *b*-phase.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

#### **c — c-phase**

electrical

Electrical conserving port associated with *c*-phase.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

#### **+ — Positive terminal**

electrical

Electrical conserving port associated with the DC positive terminal

#### **- — Negative terminal**

electrical

Electrical conserving port associated with the DC negative terminal

## Parameters

### Electrical connection — Electrical connection

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

### Switching device — Switching device

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Converter switching device. The default value is Ideal Semiconductor Switch.

The switching devices you can select are:

- “Switching Devices: GTO” on page 1-331
- “Switching Devices: Ideal Semiconductor Switch” on page 1-332
- “Switching Devices: IGBT” on page 1-332
- “Switching Devices: MOSFET” on page 1-333
- “Switching Devices: Thyristor” on page 1-333
- “Switching Devices: Averaged Switch” on page 1-334

### Dependencies

Multiple additional parameters will become visible depending on the choice of the specific switching device.

### Switching Devices: GTO

For more information, see GTO.

The parameters for this switching device will be visible only if you select it in the **Switching device** parameter.

### Forward voltage, $V_f$ — Forward voltage

0.8 V (default)

Minimum voltage required across the anode and cathode block ports for the gradient of the device i-v characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**.

### On-state resistance — On-state resistance

0.001 Ohm (default)

Rate of change of voltage versus current above the forward voltage.

### Off-state Conductance — Off-state conductance

1e-6 1/Ohm (default)

Anode-cathode conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

### Gate trigger voltage, $V_{gt}$ — Gate trigger voltage

1 V (default)

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Gate turn-off voltage, Vgt\_off – Gate turn-off voltage**

-1 V (default)

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Holding current – Holding current**

1 A (default)

Current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Switching Devices: Ideal Semiconductor Switch**

For more information, see Ideal Semiconductor Switch.

The parameters for this switching device will be visible only if you select it in the **Switching device** parameter.

**On-state resistance – On-state resistance**

0.001 Ohm (default)

Anode-cathode resistance when the device is on.

**Off-state Conductance – Off-state conductance**

1e-6 1/Ohm (default)

Anode-cathode conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

**Threshold voltage, Vth – Threshold voltage**

6 V (default)

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Switching Devices: IGBT**

For more information, see IGBT (Ideal, Switching).

The parameters for this switching device will be visible only if you select it in the **Switching device** parameter.

**Forward voltage, Vf – Forward voltage**

0.8 V (default)

Minimum voltage required across the collector and emitter block ports for the gradient of the diode  $i$ - $v$  characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**.

**On-state resistance – On-state resistance**

0.001 Ohm (default)

Collector-emitter resistance when the device is on.

**Off-state Conductance — Off-state conductance**

1e-6 1/Ohm (default)

Collector-emitter conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

**Threshold voltage,  $V_{th}$  — Threshold voltage**

6 V (default)

Gate-emitter voltage at which the device turns on.

**Switching Devices: MOSFET**

For more information, see MOSFET (Ideal, Switching).

The parameters for this switching device will be visible only if you select it in the **Switching device** parameter.

**Drain-source on resistance,  $R_{DS(on)}$  — Drain-source on resistance**

0.001 Ohm (default)

Drain-source resistance when the device is on.

**Off-state Conductance — Off-state conductance**

1e-6 1/Ohm (default)

Drain-source conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

**Threshold voltage,  $V_{th}$  — Threshold voltage**

6 V (default)

Gate-source voltage threshold. The device turns on when the gate-source voltage is above this value.

**Switching Devices: Thyristor**

The parameters for this switching device will be visible only if you select it in the **Switching device** parameter.

For more information, see Thyristor (Piecewise Linear).

**Forward voltage,  $V_f$  — Forward voltage**

0.8 V (default)

Forward voltage at which the device turns on.

**On-state resistance — On-state resistance**

0.001 Ohm (default)

Anode-cathode resistance when the device is on.

**Off-state Conductance — Off-state conductance**

1e-6 1/Ohm (default)

Anode-cathode conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

**Gate trigger voltage, Vgt – Gate trigger voltage**

1 V (default)

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Holding current – Holding current**

1 A (default)

Current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Switching Devices: Averaged Switch**

The parameters for this switching device will be visible only if you select it in the **Switching device** parameter.

---

**Note** If you select this mode, the value of the gate signals must be between 0 and 1.

---

**On-state resistance – On-state resistance**

0.001 Ohm (default)

Anode-cathode resistance when the device is on.

**Integer for piecewise constant approximation of gate input (0 for disabled) – Integer mode for FPGA deployment**

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

**Dependencies**

To enable this parameter, set **Switching device** to Averaged Switch.

**Integral Diodes****Integral protection diode – Integral protection diode**

None (default) | Diode with no dynamics | Diode with charge dynamics

Integral protection diode for each switching device.

The diodes you can select are:

- Diode with no dynamics
- Diode with charge dynamics

---

**Note** If you select Averaged Switch for the **Switching Device** parameter in the **Switching Device** setting, this parameter is not visible and Diode with no dynamics is automatically selected.

---

**Forward voltage – Forward voltage**

0.8 V (default)

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

#### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with no dynamics or Diode with charge dynamics.

#### On resistance — On resistance

0.001 Ohm (default)

Rate of change of voltage versus current above the **Forward voltage**.

#### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with no dynamics or Diode with charge dynamics.

#### Off conductance — Off conductance

1e-5 1/Ohm (default)

Conductance of the reverse-biased diode.

#### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with no dynamics or Diode with charge dynamics.

#### Junction capacitance — Junction capacitance

50e-9 F (default)

Diode junction capacitance.

#### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics.

#### Peak reverse current, $i_{RM}$ — Peak reverse current

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero. The default value is -235 A.

#### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics.

#### Initial forward current when measuring $i_{RM}$ — Initial forward current when measuring $i_{RM}$

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics.

**Rate of change of current when measuring  $i_{RM}$  — Rate of change of current when measuring  $i_{RM}$** 

-50A/ $\mu$ s (default) | negative scalar

Rate of change of current when measuring peak reverse current. This value must be less than zero.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics.

**Reverse recovery time parameterization — Reverse recovery time parameterization**

Specify reverse recovery time directly (default) | Specify stretch factor | Specify reverse recovery charge

Determines how you specify reverse recovery time in the block. The default value is Specify reverse recovery time directly.

If you select Specify stretch factor or Specify reverse recovery charge, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates  $T_M$  and  $\tau$ ” on page 1-452.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics.

**Reverse recovery time,  $t_{rr}$  — Reverse recovery time**

15  $\mu$ s (default)

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery time directly.

**Reverse recovery time stretch factor — Reverse recovery time stretch factor**

3 (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify stretch factor.

**Reverse recovery charge,  $Q_{rr}$  — Reverse recovery charge**

1500  $\mu$ As (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

### Dependencies

To enable this parameter, set **Integral protection diode** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery charge.

For more information on these parameters, see Diode.

### Snubbers

The **Snubbers** parameters tab is not visible if you set **Switching device** to Averaged Switch.

#### Snubber — Snubber

None (default) | RC snubber

Snubber for each switching device:

- None - This is the default value.
- RC snubber

#### Snubber resistance — Snubber resistance

0.1 Ohm (default)

Snubber resistance.

### Dependencies

This parameter is visible only when the **Snubber** parameter is set to RC snubber.

#### Snubber capacitance — Snubber capacitance

1e-7 F (default)

Snubber capacitance.

### Dependencies

This parameter is visible only when the **Snubber** parameter is set to RC snubber.

### Description

The Coordinate Transform (Five-Phase) block converts the time-domain components of a five-phase system in an  $abcde$  reference frame to direct, quadrature,  $x$ ,  $y$ , and zero components in a rotating reference frame.

You can configure the block to align the phase  $a$ -axis of the five-phase system to either the  $d$ -axis or  $q$ -axis of the rotating reference frame at time  $t = 0$ .

$\theta = \omega t + \text{Offset}$  is the angle between the  $a$  and  $q$  axes for the  $q$ -axis alignment or the angle between the  $a$  and  $d$  axes for the  $d$ -axis alignment, where:

- $\omega$  is the rotational speed of the rotational reference frame.
- $t$  is the time, in s, from the initial alignment.
- $\text{Offset} = \frac{\pi}{2}$ ,  $d$  - axis alignment  
0,  $q$  - axis alignment

### Equations

The Coordinate Transform (Five-Phase) block implements the transform as

$$\begin{bmatrix} d \\ q \\ x \\ y \\ 0 \end{bmatrix} = \frac{2}{5} \begin{bmatrix} \sin\theta & \sin\left(\theta - \frac{2\pi}{5}\right) & \sin\left(\theta - \frac{4\pi}{5}\right) & \sin\left(\theta + \frac{4\pi}{5}\right) & \sin\left(\theta + \frac{2\pi}{5}\right) \\ \cos\theta & \cos\left(\theta - \frac{2\pi}{5}\right) & \cos\left(\theta - \frac{4\pi}{5}\right) & \cos\left(\theta + \frac{4\pi}{5}\right) & \cos\left(\theta + \frac{2\pi}{5}\right) \\ \sin\theta & \sin\left(\theta + \frac{4\pi}{5}\right) & \sin\left(\theta - \frac{2\pi}{5}\right) & \sin\left(\theta + \frac{2\pi}{5}\right) & \sin\left(\theta - \frac{4\pi}{5}\right) \\ \cos\theta & \cos\left(\theta + \frac{4\pi}{5}\right) & \cos\left(\theta - \frac{2\pi}{5}\right) & \cos\left(\theta + \frac{2\pi}{5}\right) & \cos\left(\theta - \frac{4\pi}{5}\right) \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} a \\ b \\ c \\ d \\ e \end{bmatrix}$$

### Ports

#### Input

**abcde** —  $a$ -,  $b$ -,  $c$ -,  $d$ -, and  $e$ -phase components

vector

Components of the five-phase system in an *abcde* reference frame, specified as a vector.

Data Types: `single` | `double`

### **$\theta_{elec}$ — Rotational angle**

scalar

Angular position of the rotating reference frame, specified as a scalar.

Data Types: `single` | `double`

### **Output**

#### **$dqxy0$ — Direct, quadrature, x, y, and zero components**

vector

Direct, quadrature, x-axis, y-axis, and zero components of the system in the rotating reference frame, returned as a vector.

Data Types: `single` | `double`

### **Parameters**

#### **Phase-a axis alignment — $dqxy0$ reference frame alignment**

Q-axis (default) | D-axis

Whether to align the *a*-phase vector of the *abcde* reference frame to the *d*-axis or *q*-axis of the rotating reference frame.

# Counter

Discrete- or continuous-time counter

**Library:** Simscape / Electrical / Control / General Control

## Description

The Counter block implements an incremental counter in either discrete or continuous time. The counter increments in response to one of these criteria:

- Up — The input goes up.

- Down — The input goes down.

- Up-Down — The input goes up or down.

## Ports

### Output

#### T – Counter value

scalar

Counter value.

Data Types: single | double

## Parameters

### Counter type – Counter strategy

Up (default) | Down | Up-Down

Counter type.

### Output range – Range

[0 1] (default) | [-1 1]

Range for the output.

### Timer period (s) – Period

0.001 (default) | positive scalar

Timer period, in s.

### Phase delay (s) – Delay

0 (default) | 0 or positive scalar

Phase delay, in s. Add a phase delay to change the initial state of the counter.

### Sample time – Block sample time

0.0001 (default) | 0 or positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For discrete-time simulation, set the sample time to a positive scalar. For continuous-time simulation, set the sample time to 0.

## Coupled Lines (Pair)

Magnetically couple two lines

**Library:** Simscape / Electrical / Passive / Lines

### Description

The Coupled Lines (Pair) block models two magnetically coupled lines. Each line has a self-inductance, series resistance, and parallel conductance. In addition, there is a mutual inductance and mutual resistance between the two lines.

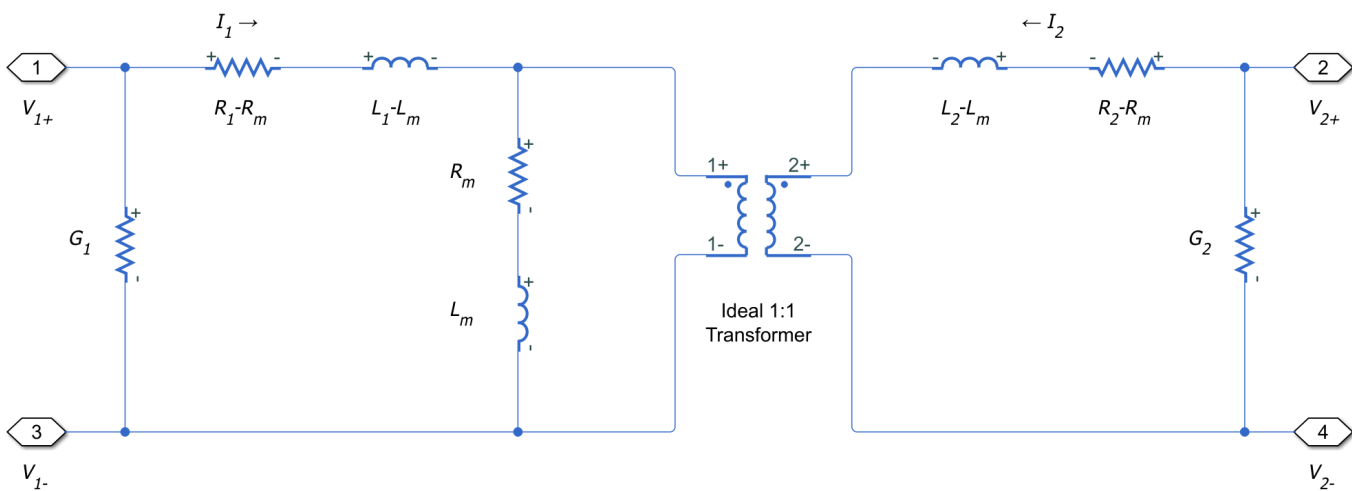

Use this block when the magnetic coupling between the two lines is nonnegligible. These effects are most prominent when:

- The lines are parallel and close together.
- The self-inductances of the lines are high.
- The AC frequency of the network is high.

To model magnetic coupling of a three-phase line, use the Coupled Lines block.

### Equivalent Circuit

The figure shows the equivalent circuit for a pair of coupled lines.

Here:

- $R_1$  and  $R_2$  are the series resistances of lines 1 and 2, respectively.

- $L_1$  and  $L_2$  are the self-inductances of lines 1 and 2, respectively.
- $R_m$  is the mutual resistance between the two lines. You can use this parameter to account for losses in a common return path.
- $L_m$  is the mutual inductance between the two lines.
- $G_1$  and  $G_2$  are the leakage conductances of lines 1 and 2, respectively.
- $V_1$  and  $V_2$  are voltage drops across lines 1 and 2, respectively.
- $I_1$  and  $I_2$  are the currents through the resistors  $R_1 - R_m$  and  $R_2 - R_m$ , respectively.

### Equations

The defining equation for this block is:

$$V = \begin{bmatrix} R_1 & R_m \\ R_m & R_2 \end{bmatrix} I + \begin{bmatrix} L_1 & L_m \\ L_m & L_2 \end{bmatrix} \frac{dI}{dt},$$

where:

$$V = \begin{bmatrix} V_1 \\ V_2 \end{bmatrix},$$

$$I = \begin{bmatrix} I_1 \\ I_2 \end{bmatrix}.$$

$I_1$  and  $I_2$  are, in general, not equal to the currents in line 1 and line 2. These terminal currents make up the vector:

$$I_{total} = I + \begin{bmatrix} G_1 & 0 \\ 0 & G_2 \end{bmatrix} V.$$

### Inductive Coupling

To quantify the strength of the coupling between the two lines, you can use a coupling factor or coefficient of coupling  $k$ . The coupling factor relates the mutual inductance to the line self-inductances:

$$L_m = k\sqrt{L_1 L_2}.$$

This coupling factor must fall in the range  $-1 < k < 1$ , where a negative coupling factor indicates a reversal in orientation of one of the coils. The magnitude of  $k$  indicates:

- $|k| = 0$  — There is no magnetic coupling between the two lines.
- $0 < |k| < 0.5$  — The two lines are loosely coupled and mutual magnetic effects are small.
- $0.5 \leq |k| < 1$  — The two lines are strongly coupled and mutual magnetic effects are large.

### Mutual Resistance

If the two lines share a common return path, you can model the resistance of this return path using the **Mutual resistance** parameter. This workflow is equivalent to setting the **Mutual resistance** to zero and explicitly modeling the return path resistance  $R_m$ , as shown in this diagram.

If the two lines do not share a common return path, set the mutual resistance parameter to zero and model each of the return resistances explicitly.

## Ports

### Conserving

#### 1+ – Line 1 positive terminal

electrical

Electrical conserving port associated with the positive terminal of line 1.

#### 1- – Line 1 negative terminal

electrical

Electrical conserving port associated with the negative terminal of line 1.

#### 2+ – Line 2 positive terminal

electrical

Electrical conserving port associated with the positive terminal of line 2.

#### 2- – Line 2 negative terminal

electrical

Electrical conserving port associated with the negative terminal of line 2.

## Parameters

### Parameters

#### Parameterization – Line impedance parameterization

Balanced impedance (default) | General impedance

Specify how to parameterize the impedance of the two lines:

#### Balanced impedance

Specify the same series resistance, series inductance, and parallel leakage conductance for both lines.

**General impedance**

Specify the series resistance, series inductance, and parallel leakage conductance separately for each line.

**Line 1 inductance — Line 1 self-inductance**

1e-3 H (default)

Self-inductance of line 1. This value must be greater than zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line 2 inductance — Line 2 self-inductance**

1e-3 H (default)

Self-inductance of line 2. This value must be greater than zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line inductance — Self-inductance**

1e-3 H (default)

Self-inductance of line 1 and line 2. This value must be greater than zero.

**Dependencies**

To enable this parameter, set **Parameterization** to Balanced impedance.

**Mutual inductance — Mutual inductance between lines**

3e-4 H (default)

Mutual inductance between line 1 and line 2. If you know the coupling factor, set this value to  $k\sqrt{L_1L_2}$ . To have a physically realizable mutual inductance, this value must satisfy:

$$-\sqrt{L_1L_2} < L_m < \sqrt{L_1L_2}.$$

**Line 1 resistance — Line 1 series resistance**

0.001 Ohm (default)

Series resistance of line 1. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line 2 resistance — Line 2 series resistance**

0.001 Ohm (default)

Series resistance of line 2. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line resistance — Series resistance**

0.001 Ohm (default)

Series resistance of line 1 and line 2. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to Balanced impedance.

**Mutual resistance — Mutual resistance between lines**

0 Ohm (default)

Mutual resistance between line 1 and line 2. This value must be greater than or equal to zero. Use this value to account for losses in a common return path.

**Line 1 leakage conductance — Line 1 parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of line 1. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line 2 leakage conductance — Line 2 parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of line 2. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line leakage conductance — Parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of line 1 and line 2. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to Balanced impedance.

Coupled Lines

## Coupled Lines (Three-Phase)

Magnetically couple three-phase lines

**Library:** Simscape / Electrical / Passive / Lines

### Description

The Coupled Lines (Three-Phase) block models three magnetically coupled lines. Each line has a self-inductance, series resistance, and parallel conductance. In addition, there is a mutual inductance and mutual resistance between each pair of lines.

Use this block when the magnetic coupling in a three-phase network is nonnegligible. These effects are most prominent when:

- The lines are parallel and close together.
- The self-inductances of the lines are high.
- The AC frequency of the network is high.

To model magnetic coupling of a single pair of lines, use the Coupled Lines (Pair) block. To model capacitive coupling between the lines, use the Transmission Line block.

### Equivalent Circuit

The equivalent circuit shows the coupling between two arbitrary phases  $i$ , and  $j$ . The block models the magnetic coupling using such an equivalent circuit between each of the three phases  $a$ ,  $b$ , and  $c$ .

Here:

- $R_i$  and  $R_j$  are the series resistances of lines  $i$  and  $j$ , respectively.
- $L_i$  and  $L_j$  are the self-inductances of lines  $i$  and  $j$ , respectively.
- $R_m$  is the mutual resistance between the two lines. You can use this parameter to account for losses in a common return path.
- $L_{m,ij}$  is the mutual inductance between lines  $i$  and  $j$ , respectively.
- $G_i$  and  $G_j$  are the leakage conductances of lines  $i$  and  $j$ , respectively.
- $V_i$  and  $V_j$  are voltage drops across lines  $i$  and  $j$ , respectively.
- $I_i$  and  $I_j$  are the currents through the resistors  $R_i-R_m$  and  $R_j-R_m$ , respectively.

### Equations

The defining equation for this block is:

$$V = \begin{bmatrix} R_a & R_m & R_m \\ R_m & R_b & R_m \\ R_m & R_m & R_c \end{bmatrix} I + \begin{bmatrix} L_a & L_{m,ab} & L_{m,ac} \\ L_{m,ab} & L_b & L_{m,bc} \\ L_{m,ac} & L_{m,bc} & L_c \end{bmatrix} \frac{dI}{dt},$$

where:

$$V = \begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix},$$

$$I = \begin{bmatrix} I_a \\ I_b \\ I_c \end{bmatrix}.$$

$I_a$ ,  $I_b$ , and  $I_c$  are, in general, not equal to the currents in lines  $a$ ,  $b$ , and  $c$ . These terminal currents make up the vector:

$$I_{total} = I + \begin{bmatrix} G_a & 0 & 0 \\ 0 & G_b & 0 \\ 0 & 0 & G_c \end{bmatrix} V.$$

### Inductive Coupling

To quantify the strength of the coupling between the two lines, you can use a coupling factor or coefficient of coupling  $k$ . The coupling factor relates the mutual inductance to the line self-inductances:

$$L_{m,ij} = k\sqrt{L_i L_j}.$$

This coupling factor must fall in the range  $-1 < k < 1$ , where a negative coupling factor indicates a reversal in orientation of one of the coils. The magnitude of  $k$  indicates:

- $|k| = 0$  — There is no magnetic coupling between the two lines.
- $0 < |k| < 0.5$  — The two lines are loosely coupled and mutual magnetic effects are small.

- $0.5 \leq |k| < 1$  — The two lines are strongly coupled and mutual magnetic effects are large.

### Mutual Resistance

If the three lines share a common return path, you can model the resistance of this return path using the **Mutual resistance** parameter  $R_m$ . This workflow is equivalent to setting the **Mutual resistance** to zero and explicitly modeling the return path resistance  $R_m$ , as shown in this diagram.

If the three lines do not share a common return path, set the mutual resistance parameter to zero and model each of the return resistances explicitly.

**Parameters****Modeling option — Whether to model composite or expanded three-phase ports**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

Expanded three-phase ports represent the individual phases of a three-phase system using three separate electrical conserving ports.

## Main

### Parameterization — Line impedance parameterization

Balanced impedance (default) | General impedance

Specify how to parameterize the impedance of the three lines:

#### Balanced impedance

Specify the same series resistance, series inductance, and parallel leakage conductance for all lines.

#### General impedance

Specify the series resistance, series inductance, and parallel leakage conductance separately for each line.

### Line a inductance — Line a self-inductance

1e-3 H (default)

Self-inductance of line *a*. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Parameterization** to General impedance.

### Line b inductance — Line b self-inductance

1e-3 H (default)

Self-inductance of line *b*. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Parameterization** to General impedance.

### Line c inductance — Line c self-inductance

1e-3 H (default)

Self-inductance of line *c*. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Parameterization** to General impedance.

### Line inductance — Self-inductance

1e-3 H (default)

Self-inductance of lines *a*, *b*, and *c*. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Parameterization** to Balanced impedance.

**Line a-b mutual inductance – Mutual inductance between a-b**

3e-4 H (default)

Mutual inductance between lines  $a$  and  $b$ . If you know the coupling factor, set this value to  $k\sqrt{L_a L_b}$ . To have a physically realizable mutual inductance, this value must satisfy:

$$-\sqrt{L_a L_b} < L_{m,ab} < \sqrt{L_a L_b}.$$

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line b-c mutual inductance – Mutual inductance between b-c**

3e-4 H (default)

Mutual inductance between lines  $b$  and  $c$ . If you know the coupling factor, set this value to  $k\sqrt{L_b L_c}$ . To have a physically realizable mutual inductance, this value must satisfy:

$$-\sqrt{L_b L_c} < L_{m,bc} < \sqrt{L_b L_c}.$$

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line a-c mutual inductance – Mutual inductance between a-c**

3e-4 H (default)

Mutual inductance between lines  $a$  and  $c$ . If you know the coupling factor, set this value to  $k\sqrt{L_a L_c}$ . To have a physically realizable mutual inductance, this value must satisfy:

$$-\sqrt{L_a L_c} < L_{m,ac} < \sqrt{L_a L_c}.$$

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Mutual inductance – Mutual inductance**

3e-4 H (default)

Mutual inductance between each pair of lines. If you know the coupling factor, set this value to  $kL$ , where  $L$  is the series inductance of each of the lines. To have a physically realizable mutual inductance, this value must satisfy:

$$-L < L_m < L.$$

**Dependencies**

To enable this parameter, set **Parameterization** to Balanced impedance.

**Resistance****Line a resistance – Line a series resistance**

0.001 Ohm (default)

Series resistance of line  $a$ . This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line b resistance — Line b series resistance**

0.001 Ohm (default)

Series resistance of line *b*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line c resistance — Line c series resistance**

0.001 Ohm (default)

Series resistance of line *c*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line resistance — Series resistance**

0.001 Ohm (default)

Series resistance of lines *a*, *b*, and *c*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to Balanced impedance.

**Mutual resistance — Mutual resistance**

0 Ohm (default)

Mutual resistance between each pair of lines. This value must be greater than or equal to zero. Use this value to account for losses in a common return path.

**Line a leakage conductance — Line a parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of line *a*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line b leakage conductance — Line b parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of line *b*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line c leakage conductance — Line c parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of line *a*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to General impedance.

**Line leakage conductance — Parallel leakage conductance**

1e-9 1/Ohm (default)

Parallel leakage conductance of lines *a*, *b*, and *c*. This value must be greater than or equal to zero.

**Dependencies**

To enable this parameter, set **Parameterization** to Balanced impedance.

# Crystal

Stable resonator

**Library:** Simscape / Electrical / Passive

## Description

The Crystal block represents the electrical characteristics of a crystal. The following figure shows the equivalent circuit model of the Crystal block.

You specify the equivalent circuit parameters for this model when you set the **Parameterization** parameter to `Equivalent circuit parameters`.

- The capacitor  $C0$  corresponds to the capacitance you specify in the **Shunt capacitance, C0** parameter.
- The capacitor  $C1$  corresponds to the capacitance you specify in the **Motional capacitance, C1** parameter.
- The inductor  $L1$  corresponds to the inductance you specify in the **Motional inductance, L1** parameter.
- The resistor  $R1$  corresponds to the resistance you specify in the **Equivalent series resistance, R1** parameter.

Most datasheets specify crystal frequency rather than inductance, so the block optionally accepts frequency data.

- When you set the **Parameterization** parameter to `Series resonance data`, the block uses the following relationship to calculate  $L1$  from the series resonant frequency:

$$f_s = \frac{1}{2\pi\sqrt{L_1 C_1}}$$

Where  $f_s$  is the **Series resonance, fs** parameter value.

- When you set the **Parameterization** parameter to `Parallel resonance data`, the block uses the following relationship to calculate  $L1$  from the parallel resonant frequency:

$$f_a = \frac{1}{2\pi\sqrt{L_1 C_1 (C_0 + C_L) / (C_1 + C_0 + C_L)}}$$

Where:

- $f_a$  is the **Parallel resonance, fa** parameter value.
- $C_L$  is the **Load capacitance, CL** parameter value.

Some datasheets specify quality factor rather than equivalent series resistance, so the block optionally accepts quality factor data. When you set the **R1 parameterization** parameter to **Quality factor Q**, the block uses the following relationship to calculate  $R1$  from the quality factor:

$$Q = \frac{2\pi f L_1}{R_1}$$

Where  $Q$  is the **Quality factor, Q** parameter value.

---

**Note** The **R1 parameterization** parameter is only visible when you select **Series resonance data** or **Parallel resonance data** for the **Parameterization** parameter.

---

## Assumptions and Limitations

## Parameters

### Parameterization – Block parameterization

Series resonance data (default) | Parallel resonance data | Equivalent circuit parameters

Select one of the following methods for block parameterization:

- **Series resonance data** — Provide series resonant frequency and capacitance data for the crystal. This method is the default.
- **Parallel resonance data** — Provide parallel resonant frequency and capacitance data for the crystal.
- **Equivalent circuit parameters** — Provide electrical parameters for an equivalent circuit model of the crystal.

**Series resonance,  $f_s$  — Crystal series resonant frequency**

32.764 kHz (default)

Crystal series resonant frequency.

**Dependencies**

This parameter is visible only when you select **Series resonance** data for the **Parameterization** parameter.

**Parallel resonance,  $f_a$  — Crystal parallel resonant frequency**

32.768 kHz (default)

Crystal parallel resonant frequency that corresponds to operating with a parallel load capacitance specified by the **Load capacitance,  $C_L$**  parameter.

**Dependencies**

This parameter is visible only when you select **Parallel resonance** data for the **Parameterization** parameter.

**Motional inductance,  $L_1$  — Motional inductance**

6742 H (default)

Inductance that represents the mechanical mass of the crystal.

**Dependencies**

This parameter is visible only when you select **Equivalent circuit** parameters for the **Parameterization** parameter.

**R1 parameterization — Series resistance parameterization**Equivalent series resistance  $R_1$  (default) | Quality factor  $Q$ 

Select one of the following methods for series resistance parameterization:

- **Equivalent series resistance  $R_1$**  — Provide the resistance value directly. This is the default method.
- **Quality factor  $Q$**  — Provide the quality factor that the block uses to calculate the resistance value.

**Dependencies**

This parameter is visible only when you select **Series resonance** data or **Parallel resonance** data for the **Parameterization** parameter.

**Quality factor,  $Q$  — Crystal quality factor**

90000 (default)

Crystal quality factor. This parameter is only visible when you make one of the following selections:

- **Series resonance** data for the **Parameterization** parameter and **Quality factor  $Q$**  for the **R1 parameterization** parameter
- **Parallel resonance** data for the **Parameterization** parameter and **Quality factor  $Q$**  for the **R1 parameterization** parameter

**Dependencies**

This parameter is visible only when you select:

- Series resonance data for the **Parameterization** parameter and Quality factor Q for the **R1 parameterization** parameter
- Parallel resonance data for the **Parameterization** parameter and Quality factor Q for the **R1 parameterization** parameter

**Equivalent series resistance, R1 — Motional damping**

15 kOhm (default)

Motional damping term. This parameter is only visible when you make one of the following selections:

- Series resonance data for the **Parameterization** parameter and Equivalent series resistance R1 for the **R1 parameterization** parameter
- Parallel resonance data for the **Parameterization** parameter and Equivalent series resistance R1 for the **R1 parameterization** parameter
- Equivalent circuit parameters for the **Parameterization** parameter

**Dependencies**

This parameter is visible only when you select:

- Series resonance data for the **Parameterization** parameter and Equivalent series resistance R1 for the **R1 parameterization** parameter

# Current-Controlled Switch

Current-controlled switch with hysteresis

**Library:** Simscape / Electrical / Additional Components / SPICE Passives

## Description

The Current-Controlled Switch block represents the electrical characteristics of a switch whose state is controlled by the current through the input ports (the controlling current).

This block models either a variable-resistance or a short-transition switch. For a variable-resistance switch, set the **Switch model** parameter to Smooth transition between  $I_{on}$  and  $I_{off}$ . For a short-transition switch, set **Switch model** to Abrupt transition after delay.

### Short-transition Switch

In a short-transition switch, the transition between the off and on states is instantaneous:

- When the controlling current is greater than or equal to the sum of the **Threshold current,  $I_T$**  and **Hysteresis current,  $I_H$**  parameter values, the switch is closed and has a resistance equal to the **On resistance,  $R_{ON}$**  parameter value.
- When the controlling current is less than the **Threshold current,  $I_T$**  parameter value minus the **Hysteresis current,  $I_H$**  parameter value, the switch is open and has a resistance equal to the **Off resistance,  $R_{OFF}$**  parameter value.
- When the controlling current is greater than or less than the **Threshold current,  $I_T$**  parameter value by an amount less than or equal to the **Hysteresis current,  $I_H$**  parameter value, the current is in the crossover region and the state of the switch remains unchanged.

---

**Note** If the **Hysteresis current,  $I_H$**  parameter value is less than 0, the block models a variable-resistance switch independently of the value you set for the **Switch model** parameter.

---

### Variable-resistance Switch

In a variable-resistance switch, the transition between the off and on states is exponential:

- When the **Control current for on state,  $I_{ON}$**  is greater than the **Control current for off state,  $I_{OFF}$** :
  - If the controlling current is greater than the **Control current for on state,  $I_{ON}$**  parameter value, the switch is closed and has a resistance equal to the **On resistance,  $R_{ON}$**  parameter value.

- If the controlling current is less than the **Control current for off state, IOFF** parameter value, the switch is open and has a resistance equal to the **Off resistance, ROFF** parameter value.
- If the controlling current is greater than the **Control current for off state, IOFF** parameter value or less than the **Control current for on state, ION** parameter value, the resistance is defined by:

$$R_s = \exp \left[ L_m + 3L_r \left( \frac{I_c - I_m}{2I_d} \right) - 2L_r \left( \frac{(I_c - I_m)^3}{I_d^3} \right) \right]$$

where:

- $R_s$  is the switch resistance.
  - $L_m = \ln \left[ (R_{ON} * R_{OFF})^{\frac{1}{2}} \right]$  is the log-mean of resistor values.
  - $L_r = \ln \left( \frac{R_{ON}}{R_{OFF}} \right)$  is the log-ratio of resistor values.
  - $I_c$  is the controlling current.
  - $I_m = \frac{I_{ON} + I_{OFF}}{2}$  is the mean of the control currents.
  - $I_d = I_{ON} - I_{OFF}$  is the difference between the control currents.
- When the **Control current for on state, ION** is less than the **Control current for off state, IOFF**:
    - If the controlling current is less than the **Control current for on state, ION** parameter value, the switch is closed and has a resistance equal to the **On resistance, RON** parameter value.
    - If the controlling current is greater than the **Control current for off state, IOFF** parameter value, the switch is open and has a resistance equal to the **Off resistance, ROFF** parameter value.
    - If the controlling current is less than the **Control current for off state, IOFF** parameter value or greater than the **Control current for on state, ION** parameter value, the resistance is defined by:

$$R_s = \exp \left[ L_m + 3L_r \left( \frac{I_c - I_m}{2I_d} \right) - 2L_r \left( \frac{(I_c - I_m)^3}{I_d^3} \right) \right]$$

## Assumptions and Limitations

The block output resistance model is discontinuous during switching. The discontinuity might cause numerical issues. Try the following actions to resolve the issues:

- Set the **On resistance, RON** and **Off resistance, ROFF** parameter values to keep  $R_{ON}$  divided by  $R_{OFF}$  as large as possible, and more than  $1e+12$ .
- Increase the **Hysteresis current, IH** parameter value to reduce switch chatter.
- If a variable-step solver is employed, decrease the **Max step size** parameter value (in the Configuration Parameters block dialog box).

---

**Note** This increases the simulation time.

---

## Parameters

### **Switch model – Switch model**

Abrupt transition after delay (default) | Smooth transition between  $I_{on}$  and  $I_{off}$

Whether the transition between on state and off state current is instantaneous or not. To model this block as a variable-resistance switch, select Smooth transition between  $I_{on}$  and  $I_{off}$ . To model this block as a short-transition switch, select Abrupt transition after delay.

### **Threshold current, IT – Threshold current**

0 A (default)

Current above which the block interprets the controlling current as HIGH.

---

**Note** The controlling current must differ from the threshold current by at least the **Hysteresis current, IH** parameter value to change the state of the switch.

---

### Dependencies

To enable this parameter, set **Switch model** to Abrupt transition after delay.

### **Hysteresis current, IH – Hysteresis current**

0 A (default)

Amount by which the controlling current must exceed or fall below the **Threshold current, IT** parameter value to change the state of the switch.

**Dependencies**

To enable this parameter, set **Switch model** to Abrupt transition after delay.

**Control current for on state, ION – Control current for on state**

1e-3 A (default)

Switch control current for the on state.

**Dependencies**

To enable this parameter, set **Switch model** to Smooth transition between Ion and Ioff.

**Control current for off state, IOFF – Control current for off state**

0 A (default)

Switch control current for the off state.

**Dependencies**

To enable this parameter, set **Switch model** to Smooth transition between Ion and Ioff.

**On resistance, RON – Closed switch resistance**

1 Ohm (default)

Resistance of the switch when it is closed.

**Use 1/GMIN as Off resistance – Whether to use 1/GMIN as off resistance**

No (default) | Yes

Whether to automatically calculate the off resistance of this switch as 1/GMIN.

---

**Note** The value of the parallel conductance, *GMIN*, depends on whether your model contains an Environment Parameters block.

By default, *GMIN* matches the **GMIN** parameter of the Environment Parameters block, whose default value is 1e-12. To change *GMIN*, add an Environment Parameters block to your model and set the **GMIN** parameter to the desired value.

---

**Dependencies**

To enable this parameter, set **Switch model** to Abrupt transition after delay.

**Off resistance, ROFF – Open switch resistance**

1e12 Ohm (default) | 1e6

Resistance of the switch when it is open.

**Dependencies**

To enable this parameter either:

- Set **Switch model** to Abrupt transition after delay and **Use 1/GMIN as Off resistance** to No. The default value is 1e12.
- Set **Switch model** to Smooth transition between Ion and Ioff. The default value is 1e6.

, .

**Time delay, TD — Time delay**

0 s (default)

Time delay after which the switch transition takes place.

**Dependencies**

To enable this parameter, set **Switch model** to Abrupt transition after delay.

# Current Limiter

Behavioral model of current limiter

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The Current Limiter block provides a behavioral model of a current limiter. Use it to represent current limiting as found in power supplies and motor drives, and also to represent components that are used to limit inrush current.

The current limiting acts for both positive and negative currents. For applications where limiting is required in only one direction, you can augment the Current Limiter block with a series diode (blocks any reverse current) or parallel diode (no limiting in the reverse direction).

The block implements current limiting by using a hyperbolic tangent function:

$$i = i_{LIM} \tanh\left(\frac{4v}{v_{LIM}}\right) + g_{LIM}v$$

where:

- $i$  is the current through the component.
- $v$  is the voltage drop across the component.
- $i_{LIM}$  is the current limit.
- $v_{LIM}$  is the approximate voltage drop across the component when the current limit becomes active.
- $g_{LIM}$  is the rate of change of current with voltage drop when on the current limit (limit-state conductance).

When  $v = v_{LIM}$ , then

$$i = i_{LIM} \tanh(4) + g_{LIM}v = 0.9993i_{LIM} + g_{LIM}v$$

Therefore the current is approximately equal to the limit. Choose the value for  $g_{LIM}$  such that  $g_{LIM}v$  is small compared to  $i_{LIM}$  for the maximum expected voltage drop. This term is included in the block equation to improve numerical properties during simulation.

When choosing the value of  $v_{LIM}$ , consider that making it too small will require tight solver tolerances and small step sizes. In practice, current limiters can be implemented using a MOSFET and series source resistor, the gate-source voltage being driven by the series resistor. This implementation does not produce a sharp limit, similar to the tanh curve used in this block. You can use a datasheet plot of current against voltage to pick a suitable value for  $v_{LIM}$ .

## Thermal Port

This block has one optional thermal port. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port.
- **Show thermal port** — The block contains one thermal conserving port.

The thermal port model contains a thermal mass. The power dissipated by the current limiter, plus the heat flow into the thermal port, drives the thermal mass differential equation:

$$m \frac{dT}{dt} = P_{loss} + Q_H$$

where:

- $m$  is the thermal mass.
- $T$  is the thermal port temperature.
- $P_{loss}$  is the electrical loss,  $v \cdot i$ .
- $Q_H$  is the heat flow from the external network into the thermal port.

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model thermal parameters.

### Parameters

#### Current limit — Current limit

1 A (default)

The maximum current magnitude.

**Voltage drop when current starts to limit – Voltage drop when current starts to limit**

0.1 V (default)

When the voltage drop is equal to this value, then the current is limited at 0.9993 times the current limit value.

**Limit-state conductance – Limit-state conductance**

1e-3 1/Ohm (default)

When the current is limited, this parameter defines the rate of change of current with voltage drop if the current is driven harder onto the limit.

**Thermal Port**

To enable these parameters, set **Modeling option** to Show thermal port.

**Thermal mass – Thermal mass**

100 J/K (default)

The heat energy required to raise the temperature by one degree.

**Initial temperature – Initial temperature**

25 C (default)

The temperature at the start of the simulation.

# Current Source

Current source with optional DC, AC, and noise components

**Library:** Simscape / Electrical / Sources

## Description

The Current Source block implements a current source with DC, AC, and noise components. The current flowing through the source from the - terminal to the + terminal is given by:

$$i = i_{DC} + i_{AC}\sin(2\pi ft + \phi) + i_N$$

where:

- $i_{DC}$  is the steady-state DC current component.
- $i_{AC}$  is the amplitude of the AC current component.
- $f$  is the frequency of the AC component.
- $\phi$  is the phase offset of the AC component.
- $i_N$  is the noise current.

You can configure your source as DC-only, AC-only, or a combination of both. By default, both AC and DC components are set to 0. Define the AC/DC current by specifying nonzero parameter values after placing the block in your model.

The noise component is also optional. If you set the **Noise mode** parameter to **Enabled**, then the added noise current is given by:

$$i_N = \sqrt{P_i/2} \frac{N(0, 1)}{\sqrt{h}}$$

where:

- $P_i$  is the single-sided noise power spectral density for a 1 ohm load, in  $A^2/Hz$ .
- $N$  is a Gaussian random number with zero mean and standard deviation of one.
- $h$  is the sampling interval.

By default, the **Noise mode** parameter is set to **Disabled**, and the current source generates no thermal noise.

## Noise Options

The block generates Gaussian noise by using the PS Random Number source in the Simscape Foundation library. You can control the random number seed by setting the **Repeatability** parameter:

- **Not repeatable** — Every time you simulate your model, the block resets the random seed using the MATLAB random number generator:

```
seed = randi(2^32-1);
```

- **Repeatable** — The block automatically generates a seed value and stores it inside the block, to always start the simulation with the same random number. This auto-generated seed value is set when you add a Current Source block from the block library to the model. When you make a new copy of the Current Source block from an existing one in a model, a new seed value is generated. The block sets the value using the MATLAB random number generator command shown above.
- **Specify seed** — If you select this option, the additional **Seed** parameter lets you directly specify the random number seed value.

## Assumptions and Limitations

- Simulating with noise enabled slows down simulation. Choose the sample time ( $h$ ) so that noise is generated only at frequencies of interest, and not higher.

## Ports

### Conserving

#### + — Positive port

electrical

Electrical conserving port associated with the current source positive terminal

#### - — Negative port

electrical

Electrical conserving port associated with the current source negative terminal

## Parameters

### DC & AC Components

#### DC current — DC current

0 A (default)

DC component of the output current. Specify a nonzero value to add a DC component to the current source.

#### AC current peak amplitude — AC current amplitude

0 A (default)

Amplitude of the AC component of the output current. Specify a nonzero value to add an AC component to the current source.

#### AC current phase shift — AC current phase offset

0 rad (default)

Phase offset of the AC component of the output current.

#### AC current frequency — AC current frequency

60 Hz (default)

Frequency of the AC component of the output current.

## Noise

### Noise mode — Noise option

Disabled (default) | Enabled

Select the noise option:

- **Disabled** — No noise is produced by the current source. This is the default.
- **Enabled** — The current source generates thermal noise, and the associated parameters become visible on the **Noise** tab.

### Power spectral density — Power spectral density

0 A<sup>2</sup>/Hz (default)

The single-sided spectrum noise power. Strictly-speaking, this is a density function for the square of the current, commonly thought of as a power into a 1 ohm load, and therefore units are A<sup>2</sup>/Hz. To avoid this unit ambiguity, some datasheets quote noise current as a noise density with units of A/√Hz. In this case, you should enter the square of the noise density quoted in the datasheet as the parameter value.

### Repeatability — Noise control option

Not repeatable (default) | Repeatable | Specify seed

Select the noise control option:

- **Not repeatable** — The random sequence used for noise generation is not repeatable. This is the default.
- **Repeatable** — The random sequence used for noise generation is repeatable, with a system-generated seed.
- **Specify seed** — The random sequence used for noise generation is repeatable, and you control the seed by using the **Seed** parameter.

### Auto-generated seed used for repeatable option — Auto-generated random number seed

3241354618 (default)

Random number seed stored inside the block to make the random sequence repeatable. The parameter value is automatically generated using the MATLAB random number generator command. You can modify this parameter value, but it gets overwritten by a new random value if you copy the block to another block in the model. Therefore, if you want to control the seed of the random sequence, use the **Specify seed** option for the **Repeatability** parameter and specify the desired seed value using the **Seed** parameter.

### Dependencies

This parameter is visible only when you select **Repeatable** for the **Repeatability** parameter.

### Seed — Random number seed

0 (default)

Random number seed used by the noise random number generator.

### Dependencies

This parameter is visible only when you select **Specify seed** for the **Repeatability** parameter.

**Sample time – Sample time**

1e-3 s (default)

Defines the rate at which the noise source is sampled. Choose it to reflect the frequencies of interest in your model. Making the sample time too small will unnecessarily slow down your simulation.

## Current Source (Three-Phase)

Ideal three-phase current source

**Library:** Simscape / Electrical / Sources

### Description

The Current Source (Three-Phase) block models an ideal three-phase current source that maintains sinusoidal currents of the specified magnitude through its terminals, independent of the voltage across the source.

The output current is defined by the following equations:

$$I_0 = \sqrt{2}i_{\text{phase\_rms}}$$

$$i_a = I_0 \sin(2\pi ft + \varphi)$$

$$i_b = I_0 \sin(2\pi ft + \varphi - 120^\circ)$$

$$i_c = I_0 \sin(2\pi ft + \varphi + 120^\circ),$$

where:

- $I_0$  is the peak phase current.
- $i_{\text{phase\_rms}}$  is the RMS phase current.
- $i_a, i_b, i_c$  are the respective phase currents.
- $f$  is the frequency.
- $\varphi$  is the phase shift.
- $t$  is the time.

The arrow indicates the positive direction of the current flow. The source has a wye configuration, and port **n** provides a connection to the center of the wye.

## DC Current Controller

Discrete-time DC current PI control with integral anti-windup

**Library:** Simscape / Electrical / Control / General Machine Control

### Description

The DC Current Controller block implements a discrete-time proportional-integral (PI) DC voltage controller. The block can implement zero cancellation in the feedforward path. To avoid saturation of the integral gain, the block can implement anti-windup gain.

### Equations

The equation that the DC Current Controller block uses to calculate the reference voltage is

$$v_{ref} = \left( K_p + K_i \frac{T_s z}{z-1} \right) (i_{ref} - i),$$

where:

- $v_{ref}$  is the reference voltage.
- $K_p$  is the proportional gain.
- $K_i$  is the integral gain.
- $T_s$  is the sample time.
- $i_{ref}$  is the reference current.
- $i$  is the measured current.

The PI control calculation yields a zero in the closed-loop transfer function. To cancel the zero, the block uses this discrete-time zero-cancellation transfer function:

$$G_{ZC}(z) = \frac{\frac{T_s K_i}{K_p}}{z + \frac{T_s - \frac{K_p}{K_i}}{\frac{K_p}{K_i}}}$$

To avoid saturation of the integrator output, the block uses an anti-windup mechanism. The integrator gain is then equal to

$$K_i + K_{aw}(v_{ref\_sat} - v_{ref\_unsat}),$$

where:

- $K_{aw}$  is the anti-windup gain.
- $v_{ref\_sat}$  is the saturated reference voltage signal, which the block calculates as  $v_{ref\_sat} = \min(\max(v_{ref\_unsat}, v_{min}), v_{max})$ ,

where:

- $v_{ref\_unsat}$  is the unsaturated reference voltage signal.
- $v_{min}$  is the lower limit for the output voltage. For positive voltage only,  $v_{min} = 0$ . For positive and negative voltage,  $v_{min} = -v_{max}$
- $v_{max}$  is the upper limit for the output voltage.

-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

### Dependencies

If you set **Sample time (-1 for inherited)** to -1 and select the **Enable zero cancellation** option, the **Discretization sample time** parameter becomes visible.

#### **Discretization sample time — Sample time for discretization**

0.001 (default) | positive scalar

Time, in s, between consecutive discretizations. Discretization is required for zero cancellation.

### Dependencies

This parameter is only visible when both these conditions are met:

- **Sample time** is set to -1.
- **Enable zero cancellation** is selected.

**Enable zero cancellation — Feedforward zero cancellation**

off (default) | on

Option to use zero cancellation on the feedforward path.

**Dependencies**

If you select the **Enable zero cancellation** option and set **Sample time (-1 for inherited)** to -1, the **Discretization sample time** parameter becomes visible.

# DC Current Source

Constant current source

**Library:** Simscape / Electrical / Additional Components / SPICE Sources

## Description

The DC Current Source block represents a constant current source whose output current value is independent of the voltage across its terminals.

The block uses a small conductance internally to prevent numerical simulation issues. The conductance connects the + and - ports of the device and has a conductance *GMIN*:

- By default, *GMIN* matches the **GMIN** parameter of the Environment Parameters block, whose default value is 1e-12.
- To change *GMIN*, add an Environment Parameters block to your model and set the **GMIN** parameter to the desired value.

## Ports

### Conserving

#### + — Positive voltage

electrical

Electrical conserving port associated with the DC current source positive voltage

#### - — Negative voltage

electrical

Electrical conserving port associated with the DC current source negative voltage

## Parameters

### Constant value, DC — DC output current

0 A (default)

Value of the DC output current, in A.

### Include parallel conductance, GMIN — Whether to include parallel conductance

Yes (default) | No

Specify if the current source includes a parallel conductance. The value of the parallel conductance, *GMIN*, depends on whether your model contains an Environment Parameters block.

This table shows the possible values of the parallel conductance, *GMIN*:

### Values of parallel conductance, *GMIN*

Include parallel conductance, <i>GMIN</i>		
Yes		No
<b>Model contains Environment Parameters block</b>	<b>Model does not contain Environment Parameters block</b>	Parallel conductance, <i>GMIN</i> , is not included and it does not affect the current source.
<i>GMIN</i> is equal to the value of the <b><i>GMIN</i></b> parameter in the Environment Parameters block.	<i>GMIN</i> = 1e-12 Ohm

## DC Motor

DC motor model with electrical and torque characteristics and fault modeling

**Library:** Simscape / Electrical / Electromechanical / Brushed Motors

### Description

The DC Motor block represents the electrical and torque characteristics of a DC motor using the following equivalent circuit model:

You specify the equivalent circuit parameters for this model when you set the **Model parameterization** parameter to *By equivalent circuit parameters*. The resistor  $R$  corresponds to the resistance you specify in the **Armature resistance** parameter. The inductor  $L$  corresponds to the inductance you specify in the **Armature inductance** parameter.

You can specify how to generate the magnetic field of the DC motor by setting the **Field type** parameter to the desired option. The permanent magnets in the motor induce the following back emf  $v_b$  in the armature:

$$v_b = k_v \omega$$

where  $k_v$  is the **Back-emf constant** and  $\omega$  is the angular velocity. The motor produces the following torque, which is proportional to the motor current  $i$ :

$$T_E = k_t i$$

where  $k_t$  is the **Torque constant**. The DC Motor block assumes that there are no electromagnetic losses. This means that mechanical power is equal to the electrical power dissipated by the back emf in the armature. Equating these two terms gives:

$$T_E \omega = v_b i$$

$$k_t i \omega = k_v \omega i$$

$$k_v = k_t$$

As a result, you specify either  $k_v$  or  $k_t$  in the block parameters.

If the magnetic field is generated from the current flowing through the windings, the **Back-emf constant** depends on the field current  $I_f$ :

$$k_v = L_{af}I_f$$

where  $L_{af}$  is the **Field-armature mutual inductance**.

The torque-speed characteristic for the DC Motor block is related to the parameters in the preceding figure. When you set the **Model parameterization** parameter to **By stall torque & no-load speed** or **By rated power, rated speed & no-load speed**, the block solves for the equivalent circuit parameters as follows:

- 1 For the steady-state torque-speed relationship,  $L$  has no effect.
- 2 Sum the voltages around the loop and rearrange for  $i$ :

$$i = \frac{V - v_b}{R} = \frac{V - k_v\omega}{R}$$

- 3 Substitute this value of  $i$  into the equation for torque:

$$T_E = \frac{k_t}{R}(V - k_v\omega)$$

When you set the **Model parameterization** parameter to **By stall torque & no-load speed**, the block uses the stall torque and no-load speed to determine values for  $R$  and  $k_t$  (and equivalently  $k_v$ ).

When you set the **Model parameterization** parameter to **By rated power, rated speed & no-load speed**, the block uses the rated speed and power to calculate the rated torque. The block uses the rated torque and no-load speed values to determine values for  $R$  and  $k_t$ .

The block models motor inertia  $J$  and damping  $\lambda$  for all values of the **Model parameterization** parameter. The resulting torque across the block is:

$$T = \frac{k_t}{R}(V - k_v\omega) - J\dot{\omega} - \lambda\omega$$

It is not always possible to measure rotor damping, and rotor damping is not always provided on a manufacturer datasheet. An alternative is to use the no-load current to infer a value for rotor damping.

For no-load, the electrically-generated mechanical torque must equal the rotor damping torque:

$$k_t i_{noload} = \lambda \omega_{noload}$$

where  $i_{noload}$  is the no-load current. If you select **By no-load current** for the **Rotor damping parameterization** parameter, then this equation is used in addition to the torque-speed equation to determine values for  $\lambda$  and the other equation coefficients.

The value for rotor damping, whether specified directly or in terms of no-load current, is taken into account when determining equivalent circuit parameters for **Model parameterization** options **By stall torque and no-load speed** and **By rated power, rated speed and no-load speed**.

When a positive current flows from the electrical **+** to **-** ports, a positive torque acts from the mechanical **C** to **R** ports.

### Faults

The DC Motor block allows you to model two types of faults:

- Armature winding fault — The armature winding fails and goes open circuit.
- Field winding fault — The field winding that creates the magnetic field fails and goes open circuit.

The block can trigger fault events:

- At a specific time (temporal fault).
- When a current limit is exceeded for longer than a specific time interval (behavioral fault).

You can enable or disable these trigger mechanisms separately.

You can choose whether to issue an assertion when a fault occurs, by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

This figure shows a generic representation of a DC motor, with brushes, armatures, commutators, and their windings:

If you set the **Enable armature winding open-circuit fault** parameter to On, the armature fails at the time specified by the **Simulation time for armature winding fault event** parameter for a temporal fault, or when the winding currents exceeds the value of the **Maximum permissible armature winding current** parameter for a behavioral fault. When the armature fails, the voltage source connected to this block observes an open circuit for a fraction of the total motor revolution, specified by the **Fraction of revolution during which armature is open-circuit** parameter, `rev_faulted`. This figure illustrates the circuit state behaviour for a certain `rev_faulted` during the entire revolution period:

### Predefined Parameterization

There are multiple available built-in parameterizations for the permanent magnet DC Motor block.

This pre-parameterization data allows you to set up the block to represent components by specific suppliers. The parameterizations of these DC motors match the manufacturer data sheets. To load a predefined parameterization, double-click the DC Motor block, click the **<click to select>** hyperlink of the **Selected part** parameter and, in the Block Parameterization Manager window, select the part you want to use from the list of available components.

---

**Note** The predefined parameterizations of Simscape components use available data sources for the parameter values. Engineering judgement and simplifying assumptions are used to fill in for missing data. As a result, expect deviations between simulated and actual physical behavior. To ensure accuracy, validate the simulated behavior against experimental data and refine component models as necessary.

---

For more information about pre-parameterization and for a list of the available components, see “List of Pre-Parameterized Components”.

## Model Thermal Effects

You can expose the thermal port to model the effects of losses that convert power to heat. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port.
- **Show thermal port** — The block contains one thermal conserving port.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

## Ports

### Conserving

#### + — Positive terminal

electrical

Electrical conserving port associated with the DC motor positive terminal.

#### - — Negative terminal

electrical

Electrical conserving port associated with the DC motor negative terminal.

#### C — Motor case

mechanical

Mechanical rotational conserving port associated with the DC motor case.

#### R — Motor rotor

mechanical

Mechanical rotational conserving port associated with the DC motor rotor.

#### F+ — Positive field

electrical

Electrical conserving port associated with the positive field winding.

### Dependencies

To enable this port, set **Field type** to Wound.

#### F- — Negative field

electrical

Electrical conserving port associated with the negative field winding.

### Dependencies

To enable this port, set **Field type** to Wound.

#### H — Thermal port

thermal

Thermal conserving port.

### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### Modeling option — Whether to enable thermal ports

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of losses that convert power to heat.

### Selected part — Predefined parameterization option

<click to select> (default)

Whether to parameterize the block to represent components by specific suppliers. Click the **<click to select>** hyperlink to open the Block Parameterization Manager window. For more information on the Block Parameterization Manager, see “Load Predefined Parameterizations”.

### Electrical Torque

#### Field type — Type of field

Permanent Magnet (default) | Wound

Select one of the following methods for field type:

- Permanent Magnet — Generate the DC Motor magnetic field using a permanent magnet.
- Wound — Generate the DC Motor magnetic field using the current flowing through the windings.

#### Model parameterization — Block parameterization

By equivalent circuit parameters (default) | By stall torque & no-load speed | By rated power, rated speed & no-load speed

Select one of the following methods for block parameterization:

- By equivalent circuit parameters — Provide electrical parameters for an equivalent circuit model of the motor.
- By stall torque & no-load speed — Provide torque and speed parameters that the block converts to an equivalent circuit model of the motor.
- By rated power, rated speed & no-load speed — Provide power and speed parameters that the block converts to an equivalent circuit model of the motor.

### Dependencies

To enable this parameter, set **Field type** to Permanent magnet.

#### Field resistance — Field resistance

100 Ohm (default)

Resistance of the magnetic field.

**Dependencies**

To enable this parameter, set **Field type** to Wound.

**Field inductance – Field inductance**

1 H (default)

Inductance of the magnetic field.

**Dependencies**

To enable this parameter, set **Field type** to Wound.

**Field-armature mutual inductance – Field-armature mutual inductance**

0.15 H (default)

Mutual inductance between the magnetic field and the conducting portion of the motor.

**Dependencies**

To enable this parameter, set **Field type** to Wound.

**Initial field current – Initial field current**

0 A (default)

Initial field current.

**Dependencies**

To enable this parameter, set **Field type** to Wound.

**Armature resistance – Armature resistance**

3.9 Ohm (default)

Resistance of the conducting portion of the motor.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to By equivalent circuit parameters.

**Armature inductance – Armature inductance**

12e-6 H (default)

Inductance of the conducting portion of the motor. If you do not have information about this inductance, set the value of this parameter to a small, nonzero number.

**Define back-emf or torque constant – Constants specification**

Specify back-emf constant (default) | Specify torque constant

Indicate whether you will specify the motor's back-emf constant or torque constant. When you specify them in SI units, these constants have the same value, so you only specify one or the other in the block dialog box.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to By equivalent circuit parameters.

**Back-emf constant — Back-emf constant**

0.072e-3 (default) | V/rpm

The ratio of the voltage generated by the motor to the speed at which the motor is spinning.

**Dependencies**

This parameter is visible only when you set the **Define back-emf or torque constant** parameter to Specify back-emf constant.

**Torque constant — Torque constant**

6.876e-4 N\*m/A (default)

The ratio of the torque generated by the motor to the current delivered to it.

**Dependencies**

This parameter is visible only when you set the **Define back-emf or torque constant** parameter to Specify torque constant.

**Stall torque — Stall torque**

0.24e-3 N\*m. (default)

The amount of torque generated by the motor when the speed is approximately zero.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to By stall torque & no-load speed.

**No-load speed — No-load speed**

19100 rpm (default)

Speed of the motor when not driving a load.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to By stall torque & no-load speed or By rated power, rated speed & no-load speed.

**Rated speed (at rated load) — Rated speed**

15000 rpm (default)

Motor speed at the rated mechanical power level.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to By rated power, rated speed & no-load speed.

**Rated load (mechanical power) — Rated load**

0.08 W (default)

The mechanical power the motor is designed to deliver at the rated speed.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to By rated power, rated speed & no-load speed.

**Rated DC supply voltage — Rated DC supply voltage**

1.5 V (default)

The voltage at which the motor is rated to operate.

**Dependencies**

This parameter is visible only when you set the **Model parameterization** parameter to **By stall torque & no-load speed** or **By rated power, rated speed & no-load speed**.

**Rotor damping parameterization — Rotor damping parameterization**

By damping value (default) | By no-load current

Select one of the following methods to specify rotor damping:

- **By damping value** — Specify a value for rotor damping directly, by using the **Rotor damping** parameter in the **Mechanical** parameters.
- **By no-load current** — The block calculates rotor damping based on the values that you specify for the **No-load current** and **DC supply voltage when measuring no-load current** parameters. If you select this option, the **Rotor damping** parameter is not available for the **Mechanical** parameters.

**No-load current — No-load current**

0 A (default)

Specify the no-load current value, to be used for calculating the rotor damping. This parameter is only visible when you select **By no-load current** for the **Rotor damping parameterization** parameter.

**Dependencies**

This parameter is visible only when you set the **Rotor damping parameterization** parameter to **By no-load current**.

**DC supply voltage when measuring no-load current — DC supply voltage when measuring no-load current**

1.5 V (default)

Specify the DC supply voltage corresponding to the no-load current value, to be used for calculating the rotor damping.

**Dependencies**

This parameter is visible only when you set the **Rotor damping parameterization** parameter to **By no-load current**.

**Mechanical****Rotor inertia — Rotor inertia**0.01 g\*cm<sup>2</sup> (default)

Resistance of the rotor to change in motor motion. The value can be zero.

**Rotor damping — Rotor dissipated energy**

0 N\*m/(rad/s) (default)

Energy dissipated by the rotor. The value can be zero.

## Dependencies

This parameter is visible only when you set the **Rotor damping parameterization** parameter in the **Electrical Torque** setting to By damping value.

## Initial rotor speed — Initial rotor speed

0 rpm (default)

Speed of the rotor at the start of the simulation.

## Temperature Dependence

This tab appears only for blocks with exposed thermal port.

## Resistance temperature coefficient — Resistance temperature coefficient

$3.93e-3$  1/K (default)

Resistance temperature coefficient.

## Measurement temperature — Measurement temperature

25 degC (default)

The temperature for which motor parameters are defined.

## Thermal Port

This tab appears only for blocks with exposed thermal port.

## Thermal mass — Thermal mass

100 J/K (default)

The thermal mass is the energy required to raise the temperature by one degree.

## Initial temperature — Initial temperature

25 degC (default)

Temperature of the thermal port at the start of simulation.

## Faults

### Enable armature winding open-circuit fault — Whether to enable armature winding faults

Off (default) | On

Select **On** to enable faults modeling and expose the associated parameters in the **Faults** section, which enables you to select the reporting method and specify the time at which the armature winding fault triggers.

### Fraction of revolution during which armature is open-circuit — Fraction of revolution during which armature is open-circuit

1/3 (default)

Fraction of the revolution of the DC motor during which the armature winding is faulted and the voltage source observes an open circuit. For more information, see the “Faults” on page 1-388 section.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On.

**Faulted armature winding open-circuit conductance — Open-circuit conductance of faulted armature winding**

1e-5 S (default)

Open-circuit conductance when the armature winding is faulted.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On.

**Armature winding fault trigger — Fault trigger for armature winding**

Temporal (default) | Behavioral

Whether the trigger for the armature winding fault is temporal or behavioral.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On.

**Simulation time for armature winding fault event — Simulation time for armature winding fault event**

1 s (default)

Time at which the armature winding becomes faulted.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On and **Armature winding fault trigger** to Temporal.

**Maximum permissible armature winding current — Maximum permissible armature winding current**

inf A (default)

Upper load-current threshold for open-circuit armature winding faults.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On and **Armature winding fault trigger** to Behavioral.

**Time to fail when exceeding armature winding current — Time to fail when exceeding armature winding current**

1 s (default)

Amount of time that the winding current must continuously exceed the maximum permissible armature winding current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Enable armature winding open-circuit fault** to On and **Armature winding fault trigger** to Behavioral.

**Enable field winding open-circuit fault — Whether to enable field winding faults**

Off (default) | On

Select On to enable field winding faults modeling and expose the associated parameters in the **Faults** section, which enables you to select the reporting method and specify the time at which the field winding fault triggers.

**Dependencies**

To enable this parameter, set **Field type** to Wound.

**Faulted field winding open-circuit conductance — Open-circuit conductance of faulted field winding**

1e-5 S (default)

Open-circuit conductance when the field winding is faulted.

**Dependencies**

To enable this parameter, set **Enable field winding open-circuit fault** to On.

**Field winding fault trigger — Fault trigger for field winding**

Temporal (default) | Behavioral

Whether the trigger for the field winding fault is temporal or behavioral.

**Dependencies**

To enable this parameter, set **Enable field winding open-circuit fault** to On.

**Simulation time for field winding fault event — Simulation time for field winding fault event**

1 s (default)

Time at which the field winding becomes faulted.

**Dependencies**

To enable this parameter, set **Enable field winding open-circuit fault** to On and **Field winding fault trigger** to Temporal.

**Maximum permissible field winding current — Maximum permissible field winding current**

inf A (default)

Upper load-current threshold for open-circuit field winding faults.

**Dependencies**

To enable this parameter, set **Enable field winding open-circuit fault** to On and **Field winding fault trigger** to Behavioral.

**Time to fail when exceeding field winding current — Time to fail when exceeding field winding current**

1 s (default)

Amount of time that the winding current must continuously exceed the maximum permissible field winding current before a behavioral fault is triggered.

### Dependencies

To enable this parameter, set **Enable field winding open-circuit fault** to On and **Field winding fault trigger** to Behavioral.

### Reporting when a fault occurs — Reporting when a fault occurs

None (default) | Warn | Error

Simulation reporting when a fault occurs:

- None — Does not generate a warning or an error.
- Warn — Generates a warning.
- Error — The simulation stops and generates an error.

### Dependencies

To enable this parameter, set **Enable armature winding open-circuit fault** or **Enable field winding open-circuit fault** to On.

# DC Voltage Controller

Discrete-time DC voltage PI control with feedforward zero cancellation and integral anti-windup

**Library:** Simscape / Electrical / Control / General Machine Control

## Description

The DC Voltage Controller block implements discrete-time PI-based DC voltage control. The block can implement zero cancellation in the feedforward path. To avoid saturation of the integral gain, the block can implement anti-windup gain.

## Equations

The equation that the DC Voltage Controller block uses to calculate the control signal is

$$control = \left( K_p + K_i \frac{T_s z}{z-1} \right) (v_{ref} - v),$$

where:

- $control$  is the control signal, which is expressed as a duty cycle or a current.
- $K_p$  is the proportional gain.
- $K_i$  is the integral gain.
- $T_s$  is the sample time.
- $v_{ref}$  is the reference voltage.
- $v$  is the measured voltage.

The PI control calculation yields a zero in the closed-loop transfer function. To cancel the zero, the block uses this discrete-time zero-cancellation transfer function:

$$G_{ZC}(z) = \frac{\frac{T_s K_i}{K_p}}{z + \left( \frac{T_s - \frac{K_p}{K_i}}{\frac{K_p}{K_i}} \right)}.$$

To avoid saturation of the integrator output, the block uses an anti-windup mechanism. The integrator gain is then equal to

$$K_i + K_{aw}(\text{control}_{sat} - \text{control}_{unsat}),$$

where:

- $K_{aw}$  is the anti-windup gain.
- $\text{control}_{sat}$  is the saturated control signal, which the block calculates as  $\text{control}_{sat} = \min(\max(\text{control}_{unsat}, \text{control}_{min}), \text{control}_{max})$ ,

where:

- $\text{control}_{unsat}$  is the unsaturated control signal.
- $\text{control}_{min}$  is the lower limit for the control signal.
- $v_{max}$  is the upper limit for the control signal.

## Ports

### Input

#### **vRef — Reference DC voltage**

scalar

Desired DC output voltage for the plant.

Data Types: `single` | `double`

#### **v — Measured DC voltage**

scalar

Measured DC output voltage for the plant.

Data Types: `single` | `double`

#### **Reset — External reset**

scalar

External reset signal (rising edge) for the integrator.

Data Types: `single` | `double`

### Output

#### **Control — Control signal**

scalar

Control signal, *control*, expressed as a duty cycle or a current.

Data Types: single | double

## Parameters

### Proportional gain — Proportional gain, $K_p$

0.1 (default) | positive scalar

Proportional gain,  $K_p$ , of the controller.

### Integral gain — Integral gain, $K_i$

50 (default) | positive scalar

Integral gain,  $K_i$ , of the controller.

### Anti-windup gain — Anti-windup gain, $K_{aw}$

1 (default) | positive scalar

Anti-windup gain,  $K_{aw}$ , of the controller.

### Control action upper limit — Upper limit for the control signal, $control_{max}$

1 (default) | positive scalar

Upper limit for the **Control** output signal. The value must be greater than the value of the **Control action lower limit** parameter.

### Control action lower limit — Lower limit for the control signal, $control_{min}$

0 (default) | non-negative scalar

Lower limit for the **Control** output signal.

### Sample time (-1 for inherited) — Block sample time

-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

### Discretization sample time — Sample time for discretization

0.001 (default) | positive scalar

Time, in s, between consecutive discretizations.

### Time constant voltage filter — DC voltage filter time constant, $\tau$

0.001 (default) | positive scalar

Time constant,  $\tau$ , for the DC voltage filter.

## Dependencies

The **Time constant voltage filter** parameter is only visible when the **Filter DC voltage** checkbox is selected.

**Enable zero cancellation — Feedforward zero cancellation**

off (default) | on

Option to use zero cancellation on the feedforward path.

**Dependencies**

If you select the **Enable zero cancellation** option and set **Sample time (-1 for inherited)** to -1, the **Discretization sample time** parameter becomes visible.

**Filter DC voltage — DC voltage filter option**

on (default) | off

To enable the filter on voltage measurement path, select the checkbox. To disable the filter, clear the check box.

**Dependencies**

The **Time constant voltage filter** parameter is only visible when the **Filter DC voltage** check box is selected.

# DC-DC Converter

Behavioral model of power converter

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The DC-DC Converter block represents a behavioral model of a power converter. This power converter regulates voltage on the load side. To balance input power, output power, and losses, the required amount of power is drawn from the supply side. Alternatively, the converter can support regenerative power flow from load to supply.

This circuit illustrates the converter's behavior.

The  $P_{fixed}$  component draws a constant power and corresponds to converter losses that are independent of load current. The power drawn is set by the **Converter losses at zero output power** parameter value. The resistor  $R_{out}$  corresponds to losses that increase with load current, and is determined from the value you specify for the **Percentage efficiency at rated output power** parameter.

The voltage source is defined by the following equation:

$$v = v_{ref} - i_{load} D + i_{load} R_{out}$$

Where:

- $v_{ref}$  is the load side voltage set point, as defined by the value you specify for the **Output voltage reference demand** parameter. Alternatively, you can provide this value as input to the **Vref** port when the **Voltage reference** parameter is set to External.
- $D$  is the value you specify for the **Output voltage droop with output current** parameter. For more information, see "Voltage Droop" on page 1-406.

The current source value  $i$  is calculated so that the power flowing in to the converter equals the sum of the power flowing out plus the converter losses.

To specify the converter behavior when the voltage presented by the load is higher than the converter output voltage reference demand, use the **Power direction** parameter:

- Unidirectional power flow from supply to regulated side — Current is blocked by the off-state diode, and the current source current  $i$  is zero. Set the conductance of this diode using the **Diode off-state conductance** parameter.
- Bidirectional power flow — Power is transmitted to the supply side, and  $i$  becomes negative.

Optionally, the block can include voltage regulation dynamics. If you select **Specify voltage regulation time constant** for the **Dynamics** parameter, then a first-order lag is added to the equation defining the voltage source value. With the dynamics enabled, a load step change results in a transient change in output voltage, the time constant being defined by the **Voltage regulation time constant** parameter.

### Voltage Droop

Voltage droop is the loss in output voltage for a device that drives a load. Droop is important in voltage regulation circuits as it increases the tolerance of the systems towards load transients.

A separate value for the droop allows you to control how the output voltage varies with the load regardless of load-dependent losses. To enable droop, select the **Enable droop** parameter. To specify the droop, set the **Droop parameterization** parameter to:

- By voltage droop with output current — Set the voltage droop directly by specifying the value of the **Output voltage droop with output current** parameter.
- By percent voltage droop at rated load — This equation calculates the voltage droop as a percent of the **Output voltage reference demand** parameter, based on the value of the **Voltage droop percent at rated load** parameter:

$$\Delta V = \frac{D_{\text{percent}}}{100} V_{\text{ref\_droop}}$$

$$D = \frac{\Delta V (V_{\text{ref\_droop}} - \Delta V)}{P_{\text{rated}}}$$

where  $V_{\text{ref\_droop}}$  is the value of the **Output voltage reference demand** parameter. If you set the **Voltage reference** parameter to **External**, the block uses the constant value of the **Voltage reference used to calculate droop percent** parameter to calculate the droop instead.

This plot shows how the block calculates the voltage droop:

The voltage droop,  $D$ , is the slope of the line, where  $I_{rated} = \frac{P_{rated}}{V_{rated}}$  and  $V_{rated} = V_{ref\_droop} - \Delta V$ .

### Tabulated efficiency

You can tabulate the DC-DC Converter block efficiency depending on the output current, input voltage, and temperature.

This equation defines the relationship between losses and efficiency:

$$loss(i_2, v_1, T) = \left[ 1 - \frac{eff(i_2, v_1, T)}{100} \right] abs(v_1 i_1) \text{ if } i_2 < 0 \text{ (power flow } 1 \rightarrow 2)$$

$$loss(i_2, v_1, T) = \left[ 1 - \frac{eff(i_2, v_1, T)}{100} \right] abs(v_2 i_2) \text{ if } i_2 > 0 \text{ (power flow } 2 \rightarrow 1)$$

where

- $loss(i_2, v_1, T)$  are the DC-DC converter losses.
- $v_1$  is the input voltage.
- $i_1$  is the input current.

- $i_2$  is the output current.
- $T$  is the device temperature, if you expose the thermal port of this block.
- $eff(i_2, v_1, T)$  is the efficiency of the DC-DC converter as a function of the output current, input voltage, and temperature, as specified in **Percentage efficiency table,  $eff(I2, V1, T)$** .

If the output current is equal to 0, the converter losses are equal to **Converter losses at zero output power**.

These are the steps to compute the used power losses depending on the output current:

- 1 If the output current is less than the last negative current point or greater than the first positive current point in the **Vector of output currents for tabulated efficiencies, I2** parameter, the block uses the **Percentage efficiency table,  $eff(I2)$**  parameter to find the corresponding efficiency (with linear interpolation or nearest extrapolation) and then convert that efficiency to losses.
- 2 Else, the block blends the zero output current case to the last negative point or the first positive point in the table, as shown in this figure:

If you set the **Modeling option** parameter to Show thermal port, the block tabulates the efficiency depending on the temperature, in addition to the output current and input voltage. The losses calculation remains the same as the option with hidden thermal ports.

### Simulating When the Supply Cannot Match the Load

The DC-DC Converter block uses the **Minimum supply voltage to function** parameter to protect the network when the voltage supply cannot deliver the load requirements. This happens if you connect a switch in series with the supply and then turn it off, or if the supply connection has a series resistance which drops too much voltage. During the simulation, if the voltage falls below the value of the **Minimum supply voltage to function** parameter, the block relaxes the regulation of the output voltage. Once the voltage falls below 90% of the **Minimum supply voltage to function** parameter, the input of the converter behaves like a fixed resistance equal to the value of the **Input resistance if not functioning** parameter. Similarly, the output of the DC-DC Converter block behaves like a fixed resistance equal to the value of the **Output resistance if not functioning** parameter.

### Simulating Faults

You can use the physical signal input port **F** to simulate a converter failure.

To expose the fault port, **F**, in the **Faults** tab, set the **Enable output open-circuit fault** parameter to Yes.

You control the behavior in response to the physical signal fault input F by the parameters on the **Faults** tab of the block dialog box. With the default parameter settings:

- **Fault condition** is Output open circuit if  $F \geq \text{Fault threshold}$
- **Fault threshold** is 0.5

If a signal is connected to port F, then the block operates according to the parameter settings on the **Faults** tab. For example, if **Fault condition** is Output open circuit if  $F \geq \text{Fault threshold}$ , then when the signal at port F rises above the **Fault threshold** value, the converter stops operating. Zero current is taken from the supply side, and zero current is supplied to the load side.

### Model thermal effects

This block has one optional thermal port. To expose the thermal port, set the **Modeling option** parameter to either:

- No thermal port — The block does not contain a thermal port.
- Show thermal port — The block contains one thermal conserving port.

The block transfers heat generated from electrical losses through a Controlled Heat Flow Rate Source to a Thermal Mass block. The electrical properties of the block do not change with temperature. Specify the thermal properties for this block using the parameters **Thermal mass** and **Initial temperature**.

### Assumptions

- The two electrical networks connected to the supply-side and regulated-side terminals must each have their own Electrical Reference block.
- The supply-side equation defines a power constraint on the product of the voltage,  $v_s$ , and the current,  $i_s$ . For simulation, the solver must be able to uniquely determine  $v_s$ . To ensure that the solution is unique, the block implements two assertions:
  - $v_s > 0$  — This assertion ensures that the sign of  $v_s$  is uniquely defined
  - $i_s < i_{max}$  — This assertion deals with the case when the voltage supply to the block has a series resistance

When there is a series resistance, there are two possible steady-state solutions for  $i_s$  that satisfy the power constraint, the one with the smaller magnitude being the desired one.

### Ports

#### Conserving

##### 1+ — Input positive terminal

electrical

Electrical conserving port associated with the positive terminal of the input side.

##### 1- — Input negative terminal

electrical

Electrical conserving port associated with the negative terminal of the input side.

**2+ – Output positive terminal**

electrical

Electrical conserving port associated with the positive terminal of the output side.

**2- – Output negative terminal**

electrical

Electrical conserving port associated with the negative terminal of the output side.

**Vref – Voltage reference**

physical

Physical signal input port that provides the external voltage reference signal.

**Dependencies**

To enable this port, set the **Voltage Reference** parameter to External.

**F – Fault signal**

physical

Physical signal input port that provides the external fault trigger signal.

**Dependencies**

To expose this port, in the **Faults** tab, set **Enable output open-circuit fault** to Yes.

**H – Thermal mass**

thermal

Thermal conserving port that represents the thermal mass. When you expose this port, provide additional parameters to define battery behavior at a second temperature. For more information, see the “Thermal” on page 1-416 parameters.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters****Modeling option – Whether to enable thermal port**

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model thermal parameters.

**Main****Voltage reference – Voltage reference**

Internal (default) | External

Whether to model the voltage reference internally or externally.

**Output voltage reference demand – Voltage set point**

10 V (default)

Set point for the voltage regulator, and the output voltage value when there is no output current.

**Dependencies**

This port is visible only when the **Voltage Reference** parameter is set to `Internal`.

**Rated output power — Rated power**

10 W (default)

Output power for which the percentage efficiency value is given. This parameter is also used to calculate droop,  $D$ , if droop is specified as a percentage.

**Enable droop — Droop option**

On (default) | Off

Whether to enable voltage droop.

**Droop parameterization — Droop model**

By voltage droop with output current (default) | By percent voltage droop at rated load

Select one of the following methods for droop parameterization:

- By voltage droop with output current — Specify the absolute value of droop,  $D$ . This is the default option.
- By percent voltage droop at rated load — Specify droop,  $D$ , as a percentage at rated load.

**Dependencies**

To enable this parameter, select the **Enable droop** parameter.

**Output voltage droop with output current — Voltage droop at 1 A**

0.1 V/A (default)

Number of volts that the output voltage will drop from the set point for an output current of 1 A.

**Dependencies**

To enable this parameter, select the **Enable droop** parameter and set **Droop parameterization** to `By voltage droop with output current`.

**Voltage droop percent at rated load — Voltage droop percent at rated load**

2 (default)

Percentage by which the voltage drops compared to the nominal output voltage when supplying the rated load. If you set the **Voltage reference** parameter to `Internal`, the block uses the **Output voltage reference demand** parameter to calculate the droop percent. If you set the **Voltage reference** parameter to `External`, the block uses the **Voltage reference used to calculate droop percent** parameter instead.

**Dependencies**

To enable this parameter, select the **Enable droop** parameter and set **Droop parameterization** to `By percent voltage droop at rated load`.

**Voltage reference used to calculate droop percent — Voltage droop percent at rated load**

10 V (default)

Voltage reference that the **Voltage droop percent at rated load** parameter uses to calculate the voltage droop during the simulation.

**Dependencies**

To enable this parameter:

- Set **Voltage reference** to External.
- Select the **Enable droop** parameter.
- Set **Droop parameterization** to By percent voltage droop at rated load.

**Power direction – Power flow direction**

Unidirectional power flow from supply to regulated side (default) | Bidirectional power flow

Select one of the following methods for the direction of power conversion:

- **Unidirectional power flow from supply to regulated side** — Most small power regulators are unidirectional. This is the default option.
- **Bidirectional power flow** — Larger power converters can be bidirectional, for example, converters used in electric vehicles to allow regenerative braking.

**Diode off-state conductance – Unidirectional diode**

1e-8 1/Ohm (default)

Ideal diode incorporated on the output side to prevent current from being forced into the converter in the unidirectional configuration.

**Losses****Converter losses at zero output power – Constant losses**

1 W (default)

Power drawn by the  $P_{\text{fixed}}$  component in the equivalent circuit diagram, which corresponds to converter losses that are independent of load current.

**Converter losses – Converter losses**

Assume proportional to square of output current (default) | Tabulate efficiency

Converter losses parameterization.

**Percentage efficiency at rated output power – Rated efficiency**

80 (default)

Efficiency as defined by 100 times the output load power divided by the input supply power.

**Dependencies**

To enable this parameter, set **Converter losses** to Assume proportional to square of output current.

**Variables for tabulation – Tabulation variables**

Output current (default) | Output current and input voltage | Output current and temperature | Output current, input voltage, and temperature

Whether to tabulate efficiency on the output current, the input voltage, and the temperature. To enable the temperature options, you need to expose the thermal ports of the block.

**Vector of output currents for tabulated efficiencies, I2 – Output currents for tabulated efficiencies**

[-2, -1, 1, 2] A (default) | vector of positive ascending scalars

Vector of output currents for tabulated efficiencies. The size of this parameter must be equal to or greater than 3 and equal to the size of **Percentage efficiency table, eff(I)**.

**Dependencies**

To enable this parameter, set **Converter losses** to Tabulate efficiency.

**Percentage efficiency table, eff(I2) – Efficiency table in function of current**

[66, 76, 80, 74] (default) | vector of positive scalars

Efficiency table in function of the current, in percentage. The size of this parameter must be equal to the size of **Vector of output currents for tabulated efficiencies, I2**.

**Dependencies**

To enable this parameter, set **Converter losses** to Tabulate efficiency and **Variables for tabulation** to Output current.

**Vector of input voltages for tabulated efficiencies, V1 – Input voltages for tabulated efficiencies**

[15, 30, 45] V (default) | vector of positive ascending scalars

Vector of input voltages for tabulated efficiencies. The size of this parameter must be equal to or greater than 2.

**Dependencies**

To enable this parameter, set **Converter losses** to Tabulate efficiency and **Variables for tabulation** to Output current and input voltage or Output current, input voltage, and temperature.

**Percentage efficiency table, eff(I2,V1) – Efficiency table in function of current and voltage**

[66, 66, 66; 76, 76, 76; 80, 80, 80; 74, 74, 74] (default) | vector of positive scalars

Efficiency table in function of the current, in percentage.

**Dependencies**

To enable this parameter, set **Converter losses** to Tabulate efficiency and **Variables for tabulation** to Output current.

**Vector of temperatures for tabulated efficiencies, T – Temperatures for tabulated efficiencies**

[280, 300, 320] K (default) | vector of positive ascending scalars

Vector of temperatures for tabulated efficiencies. The size of this parameter must be equal to or greater than 2.

**Dependencies**

To enable this parameter, expose the thermal port of this block and set **Converter losses** to Tabulate efficiency.

**Percentage efficiency table,  $\text{eff}(I_2, T)$  — Efficiency table in function of current and temperature**

[66, 66, 66; 76, 76, 76; 80, 80, 80; 74, 74, 74] (default) | vector of scalars

Efficiency table in function of current and temperature, in percentage.

**Dependencies**

To enable this parameter, expose the thermal port of this block and set **Converter losses** to Tabulate efficiency and **Variables for tabulation** to Output current and temperature.

**Percentage efficiency table,  $\text{eff}(I_2, V_1, T)$  — Efficiency table in function of current, voltage, and temperature**

repmat([66; 76; 80; 74], 1, 3, 3) (default) | vector of scalars

Efficiency table in function of current, voltage, and temperature, in percentage.

**Dependencies**

To enable this parameter, expose the thermal port of this block and set **Converter losses** to Tabulate efficiency and **Variables for tabulation** to Output current, input voltage, and temperature.

**Dynamics****Dynamics — Dynamics model**

No dynamics (default) | Specify voltage regulation time constant

Specify whether to include voltage regulation dynamics:

- **No dynamics** — Do not consider the voltage regulation dynamics.
- **Specify voltage regulation time constant** — Add a first-order lag to the equation defining the voltage source value. With the dynamics enabled, a load step change results in a transient change in output voltage.

**Voltage regulation time constant — Dynamics time constant**

0.02 s (default)

Time constant associated with voltage transients when the load current is stepped.

**Dependencies**

To enable this parameter, set **Dynamics** to Specify voltage regulation time constant.

**Initial output voltage demand — Initial demand voltage**

10 V (default)

Value of  $v_{\text{ref}}$  at time zero. Normally,  $v_{\text{ref}}$  is defined by the **Output voltage reference demand** parameter. However, if you want to initialize the model with no transients when delivering a steady-state load current, you can set the initial  $v_{\text{ref}}$  value by using this parameter, and increase it accordingly to take account of output resistance and droop.

**Dependencies**

To enable this parameter, set **Dynamics** to Specify voltage regulation time constant.

**Off State****Minimum supply voltage to function – Minimum supply voltage to operate**

1 V (default)

Minimum supply voltage for the converter to operate and regulate the output voltage to the set point. When the supply voltage drops below 90% of the value of this parameter, the input to the DC-DC Converter block behaves like a fixed resistance equal to the value of the **Input resistance if not functioning** parameter. Similarly, the output of the DC-DC Converter block behaves like a fixed resistance equal to the value of the **Output resistance if not functioning** parameter.

**Input resistance if not functioning – Input resistance if not functioning**

1000 Ohm (default)

Input resistance when the supply voltage falls below 90% of the value of the **Minimum supply voltage to function** parameter.

**Output resistance if not functioning – Output resistance if not functioning**

1000 Ohm (default)

Output resistance when the supply voltage falls below 90% of the value of the **Minimum supply voltage to function** parameter.

**Faults****Enable output open-circuit fault – Option to enable faults**

No (default) | Yes

Whether to model output open-circuit faults in the block.

**Fault condition – Fault model**

Output open circuit if  $F \geq \text{Fault threshold}$  (default) | Output open circuit if  $F \leq \text{Fault threshold}$

Selects whether the converter is disabled by a signal that is high or low:

- Output open circuit if  $F \geq \text{Fault threshold}$  — Converter is disabled if the signal at port F rises above the threshold value. This is the default option.
- Output open circuit if  $F \leq \text{Fault threshold}$  — Converter is disabled if the signal at port F falls below the threshold value.

**Dependencies**

To enable this parameter, set **Enable output open-circuit fault** to Yes.

**Fault threshold – Fault limit**

0.5 (default)

Threshold value used to detect a fault.

### Dependencies

To enable this parameter, set **Enable output open-circuit fault** to Yes.

### Thermal

To enable these parameters, set **Modeling option** to Show thermal port.

#### **Thermal mass — Thermal mass associated with the thermal port**

100 J/K (default)

Thermal mass associated with thermal port **H**. It represents the energy required to raise the temperature of the thermal port by one degree.

#### **Initial temperature — Initial temperature at the thermal port**

298.15 K (default)

Initial temperature associated with thermal port **H**.

## Version History

### Introduced in R2012b

#### **Support series-connected supply switch**

*Behavior changed in R2022b*

You can now connect a switch in series between the voltage supply and the DC-DC Converter block and toggle this switch on and off during the simulation.

To reflect this change, the **Maximum expected supply-side current** parameter is now called **Minimum supply voltage to function**. If the supply voltage drops below this value, both the input and the output sides of the converter behave like constant impedances and the converter ceases to convert.

If your model saved in an earlier release contains a DC-DC Converter block with dynamics enabled, and you configure this block to stop the power flowing from the load to the supply, the simulation results might behave slightly different. The voltage regulation time constant no longer lags the blocking diode that prevents reverse power flow and it is now instantaneous.

# DC-DC Voltage Controller

Discrete-time DC-DC voltage PI control with feedforward and optional integral anti-windup

**Library:** Simscape / Electrical / Control / General Machine Control

## Description

The DC-DC Voltage Controller block implements discrete-time proportional-integral (PI) DC-DC voltage control with feedforward,  $FF$ . The feedforward input optimizes the transient response. The block can output a duty cycle or a current control signal. To avoid saturation of the integral gain, the block can implement anti-windup gain.

## Equations

The equation that the DC-DC Voltage Controller block uses to calculate the control signal is

$$control = \left( K_p + K_i \frac{T_s z}{z-1} \right) (v_{ref} - v) + FF,$$

where:

- $control$  is the control signal, expressed as a duty cycle or a current.
- $K_p$  is the proportional gain.
- $K_i$  is the integral gain.
- $T_s$  is the sample time.

- $v_{ref}$  is the reference voltage.
- $v$  is the measured voltage.
- $FF$  is the feedforward input.

To avoid saturation of the integrator output, the block uses an anti-windup mechanism. The integrator gain is then equal to

$$K_i + K_{aw}(control_{sat} - control_{unsat}),$$

where:

- $K_{aw}$  is the anti-windup gain.
- $control_{sat}$  is the saturated control signal, which the block calculates as  $control_{sat} = \min(\max(control_{unsat}, control_{min}), control_{max})$ ,

where:

- $control_{unsat}$  is the unsaturated control signal.
- $control_{min}$  is the lower limit for the control signal.
- $control_{max}$  is the upper limit for the control signal.

## Ports

### Input

#### **vRef — Reference DC voltage**

scalar

Desired DC output voltage for the plant.

Data Types: `single` | `double`

#### **v — Measured DC voltage**

scalar

Measured DC output voltage for the plant.

Data Types: `single` | `double`

#### **FF — Feedforward**

scalar

Feedforward term.

Data Types: `single` | `double`

#### **Reset — External reset**

scalar

External reset signal (rising edge) for the integrator.

Data Types: `single` | `double`

## Output

### Control — Control signal

scalar

Control signal, *control*, expressed as a duty cycle or a current.

Data Types: `single` | `double`

## Parameters

### Proportional gain — Proportional gain, $K_p$

0.1 (default) | positive scalar

Proportional gain,  $K_p$ , of the controller.

### Integral gain — Integral gain, $K_i$

50 (default) | positive scalar

Integral gain,  $K_i$ , of the controller.

### Anti-windup gain — Anti-windup gain, $K_{aw}$

1 (default) | positive scalar

Anti-windup gain,  $K_{aw}$ , of the controller.

### Control action upper limit — Upper limit for the control signal, $control_{max}$

1 (default) | positive scalar

Upper limit for the **Control** output signal. The value must be greater than the value of the **Control action lower limit** parameter.

### Control action lower limit — Lower limit for the control signal, $control_{min}$

0 (default) | non-negative scalar

Lower limit for the **Control** output signal.

### Sample time (-1 for inherited) — Block sample time

-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

### Time constant voltage filter — DC voltage filter time constant, $\tau$

0.001 (default) | positive scalar

Time constant,  $\tau$ , for the DC voltage filter.

**Dependencies**

The **Time constant voltage filter** parameter is only visible when the **Filter DC voltage** checkbox is selected.

**Filter DC voltage — DC voltage filter option**

on (default) | off

To enable the filter on voltage measurement path, select the checkbox. To disable the filter, clear the check box.

**Dependencies**

The **Time constant voltage filter** parameter is only visible when the **Filter DC voltage** check box is selected.

## Decoupled Transform (Six-Phase)

Implement  $abc$  and  $xyz$  to  $dqz_1z_2o_1o_2$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

### Description

The Decoupled Transform (Six-Phase) block converts the time-domain components of a six-phase system in  $abc$  and  $xyz$  reference frames to direct, quadrature,  $z_1$ ,  $z_2$ ,  $o_1$ , and  $o_2$  components in a rotating reference frame. The three-phase systems  $abc$  and  $xyz$  are spatially shifted by 30 electrical degrees.

You can configure the block to align the phase  $a$ -axis of the six-phase system to either the  $d$ -axis or  $q$ -axis of the rotating reference frame at time  $t = 0$ .

$\theta = \omega t + \text{Offset}$  is the angle between the  $a$  and  $q$  axes for the  $q$ -axis alignment or the angle between the  $a$  and  $d$  axes for the  $d$ -axis alignment, where:

- $\omega$  is the rotational speed of the rotational reference frame.
- $t$  is the time, in s, from the initial alignment.
- $\text{Offset} = 0$ ,  $d$  - axis alignment
- $\text{Offset} = -\frac{\pi}{2}$ ,  $q$  - axis alignment

### Equations

The Decoupled Transform (Six-Phase) block implements the transform as

$$\begin{bmatrix} d \\ q \\ z_1 \\ z_2 \\ o_1 \\ o_2 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} \cos\theta & \cos\left(\theta - \frac{2\pi}{3}\right) & \cos\left(\theta + \frac{2\pi}{3}\right) & \cos\left(\theta - \frac{\pi}{6}\right) & \cos\left(\theta - \frac{5\pi}{6}\right) & \cos\left(\theta + \frac{\pi}{2}\right) \\ -\sin\theta & -\sin\left(\theta - \frac{2\pi}{3}\right) & -\sin\left(\theta + \frac{2\pi}{3}\right) & -\sin\left(\theta - \frac{\pi}{6}\right) & -\sin\left(\theta - \frac{5\pi}{6}\right) & -\sin\left(\theta + \frac{\pi}{2}\right) \\ 1 & -\frac{1}{2} & -\frac{1}{2} & -\frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} & 0 \\ 0 & -\frac{\sqrt{3}}{2} & \frac{\sqrt{3}}{2} & \frac{1}{2} & \frac{1}{2} & -1 \\ 1 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \\ x \\ y \\ z \end{bmatrix}$$

### Ports

#### Input

**abc** —  $a$ -,  $b$ -, and  $c$ -phase components  
vector

Components of the three-phase system in an *abc* reference frame, specified as a vector.

Data Types: `single` | `double`

### **xyz — x-, y-, and z-phase components**

vector

Components of the three-phase system in an *xyz* reference frame, specified as a vector.

Data Types: `single` | `double`

### **$\theta_{elec}$ — Rotational angle**

scalar

Angular position of the rotating reference frame, specified as a scalar.

Data Types: `single` | `double`

### **Output**

#### **dqz1z2o1o2 — Direct, Quadrature, $z_1$ , $z_2$ , $o_1$ , and $o_2$ components**

vector

Direct, quadrature,  $z_1$ -,  $z_2$ -,  $o_1$ -, and  $o_2$ -axis components of the system in the rotating reference frame, returned as a vector.

Data Types: `single` | `double`

### **Parameters**

#### **Phase-a axis alignment — $dqz_1z_2o_1o_2$ reference frame alignment**

Q-axis (default) | D-axis

Whether to align the *a*-phase vector of the *abc* reference frame to the *d*-axis or *q*-axis of the rotating reference frame.

## Delta-Connected Variable Load

Three-phase variable load wired in delta configuration

**Library:** Simscape / Electrical / Passive / RLC Assemblies

### Description

The Delta-Connected Variable Load block models a three-phase variable load wired in a delta configuration. Each limb of the load contains a resistor. The block calculates the resistance required to draw the real power of the physical signal input **P** at the rated voltage that you specify. Therefore, the block can represent a real load.

To ensure that the resistance is always greater than zero, you specify the minimum real power that the load consumes. The minimum real power must be greater than zero.

### Equations

The resistance is defined by

$$R = 3 \frac{V_{Rated}^2}{P},$$

where:

- $R$  is the per-phase series resistance.
- $V_{Rated}$  is the RMS of rated line-line voltage.
- $P$  is the three-phase real power required. If the value of the **P** input port is less than the value of the **Minimum real power** parameter, the block uses the minimum real power to calculate the resistance.

### Ports

#### Input

##### **P** — Real power

physical signal

Physical signal input port associated with the real power.

#### Conserving

##### ~ — Three-phase port

electrical

Expandable three-phase electrical conserving port.

## Parameters

### **Modeling option — Whether to model composite or expanded three-phase ports**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

Expanded three-phase ports represent the individual phases of a three-phase system using three separate electrical conserving ports.

### **Rated voltage — Rated line-line voltage**

24e3 V (default) | positive scalar

RMS of rated line-line voltage for the resistance equation.

### **Minimum real power — Minimum real power**

1e3 W (default) | positive scalar

Minimum real power that the three-phase load dissipates when supplied at the rated voltage. The value must be greater than 0.

# Delta Reference (Three-Phase)

Internal reference point for delta-connected network

**Library:** Simscape / Electrical / Connectors & References

## Description

In a Simscape Electrical model, connect a Delta Reference (Three-Phase) block to any part of the three-phase system that is connected in a delta winding configuration. The block provides a reference point for the delta winding, representing the center of the line-line vector voltage triangle. The software calculates absolute node voltages relative to the voltage at this reference point.

For example, suppose you model a transmission system that consists of a generator connected in a wye configuration, a wye-delta transformer, a delta-wye transformer, and a load connected in wye. Connect a Delta Reference (Three-Phase) block to the part of the circuit between the two transformers.

## Delta-Connected Load

Three-phase load wired in delta configuration

**Library:** Simscape / Electrical / Passive / RLC Assemblies

### Description

The Delta-Connected Load block models a three-phase load wired in a delta configuration. Each limb of the load can include any combination of a resistor (R), capacitor (C), and inductor (L), connected in series or in parallel.

You can specify values for the R, L, and C components directly in terms of resistance, inductance, and capacitance, or by rated powers at a rated voltage and frequency.

- If you parameterize the block directly in terms of R, L, and C values, then for initialization provide a three-element row vector of initial voltages for a capacitor, and a three-element row vector of initial currents for an inductor.
- If you parameterize the block in terms of rated powers, then specify initial conditions in terms of an initial voltage, initial voltage phase, and initial frequency. For example, if the load is connected directly to a three-phase voltage source, then the initial conditions are identical to the source values for RMS line voltage, frequency, and phase shift. To specify zero initial voltage magnitude, set the initial voltage to 0.

For certain combinations of R, L, and C, for some circuit topologies, specify parasitic resistance or conductance values that help the simulation to converge numerically. These parasitic terms ensure that an inductor has a small parallel resistive path and that a capacitor has a small series resistance. When you parameterize the block in terms of rated powers, the rated power values do not account for these small parasitic terms. The rated powers represent only the R, L, and C values of the load itself.

### Block parameterization

The following two tables list the block parameters for each **Component structure**, based on the selected **Parameterization** option:

- Specify by rated power

## Parameters

### Modeling option — Whether to model composite or expanded three-phase ports

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

### Main

#### Parameterization — Parameterization

Specify by rated power (default) | Specify component values directly

Select one of these values:

- **Specify by rated power** — Specify values for the R, L, and C components by rated powers at a rated voltage and frequency. This is the default.
- **Specify component values directly** — Specify values for the R, L, and C components directly in terms of resistance, inductance, and capacitance.

Switching the **Parameterization** value resets the **Component structure** value. Select the component parameterization option first, and then the component structure. If you later switch the **Parameterization** value, check the **Component structure** value and reselect it, if necessary.

#### Component structure — Desired combination

R (default) | L | C | Series RL | Series RC | Series LC | Series RLC | Parallel RL | Parallel RC | Parallel LC | Parallel RLC

Select the desired combination of a resistor (R), capacitor (C), and inductor (L), connected in series or in parallel.

#### Rated voltage — Rated voltage

2.4e4 V (default)

Voltage for which load powers are specified. This parameter is visible only when you specify values by rated power.

**Dependencies**

This parameter is visible only when you select **Specify by rated power** for the **Parameterization** parameter.

**Real power — Total real dissipated power**

1000 W (default) | positive scalar

Total real power dissipated by three-phase load when supplied at the rated voltage. The value must be greater than 0.

**Dependencies**

This parameter is visible only when you select **Specify by rated power** for the **Parameterization** parameter and select a component structure that includes a resistor.

**Rated electrical frequency — Rated electrical frequency**

60 Hz (default)

Frequency for which reactive load powers are specified.

**Dependencies**

This parameter is visible only when you select **Specify by rated power** for the **Parameterization** parameter.

**Inductive reactive power — Inductive reactive power**

100 V\*A (default) | positive scalar

Total inductive reactive power taken by the three-phase load when supplied at the rated voltage. The value must be greater than 0.

**Dependencies**

This parameter is visible only when you select **Specify by rated power** for the **Parameterization** parameter and select a component structure that includes an inductor.

**Capacitive reactive power — Total capacitive reactive power**

-100 V\*A (default) | negative scalar

Total capacitive reactive power taken by the three-phase load when supplied at the rated voltage. The value must be less than 0.

**Dependencies**

This parameter is visible only when you select **Specify by rated power** for the **Parameterization** parameter and select a component structure that includes a capacitor.

**Resistance — Resistance**

1 Ohm (default)

The resistance of each of the load limbs.

**Dependencies**

This parameter is visible only when you select **Specify component values directly** for the **Parameterization** parameter and select a component structure that includes a resistor.

**Inductance — Inductance**

0.001 H (default)

Inductance of each of the load limbs.

**Dependencies**

This parameter is visible only when you select **Specify component values directly** for the **Parameterization** parameter and select a component structure that includes an inductor.

**Capacitance — Capacitance**

1e-6 F (default)

Capacitance in each of the load limbs.

**Dependencies**

This parameter is visible only when you select **Specify component values directly** for the **Parameterization** parameter and select a component structure that includes a capacitor.

**Parasitics****Parasitic series resistance — Parasitic series resistance**

0 Ohm (default)

Represents small parasitic effects. The parameter value corresponds to the series resistance value added to all instances of capacitors in the load.

**Parasitic parallel conductance — Parasitic parallel conductance**

0 1/Ohm (default)

Represents small parasitic effects. The parameter value corresponds to the parallel conductance value added across all instances of inductors in the load.

If you set **Component structure** to either **Series RL**, **Series LC**, or **Series RLC**, the parasitic parallel conductance is connected across the full branch of the block.

# Diffusion Resistor

Resistor model with velocity saturation and optional tolerance, operational limits, fault behavior, and noise

**Library:** Simscape / Electrical / Passive

## Description

The Diffusion Resistor block represents a resistor with velocity saturation, while letting you model the following effects:

- “Tolerances” on page 1-436
- “Operating Limits” on page 1-437
- “Faults” on page 1-437
- “Thermal Noise” on page 1-437
- “Model Thermal Effects” on page 1-438

You can turn these modeling options on and off independently of each other.

In its simplest form, the resistance of the Diffusion Resistor block is:

$$R = R_0 \left( 1 - p_2 - p_3 + p_2 \sqrt{1 + (\theta_2 v_{pn})^2} + p_3 \sqrt[3]{1 + |\theta_3 v_{pn}|^3} \right)$$

where:

- $R_0$  is zero-bias resistance.
- $p_2$  and  $p_3$  are the quadratic and linear voltage coefficients, respectively.
- $\theta_2$  and  $\theta_3$  are inverse voltages for quadratic and linear voltage activation, respectively.
- $v_{pn}$  is applied voltage across the resistor.

At low bias,

$$R \approx R_0 \left( 1 + \frac{p_2 \theta_2^2 v_{pn}^2}{2} \right)$$

and therefore  $p_2$  and  $\theta_2$  determine the low-bias quadratic behavior of the resistor.

At high bias,

$$R \approx R_0 (1 - p_2 - p_3 + |v_{pn}| (p_2 \theta_2 + p_3 \theta_3))$$

and therefore  $p_3$  and  $\theta_3$  impact only the high-bias linear behavior of the resistor.

You can use the voltage-dependence of the resistance to model velocity saturation in a diffused resistor. For sufficiently high voltage,

$$i_{sat} = \frac{1}{R_0(p_2\theta_2 + p_3\theta_3)}$$

where  $i_{sat}$  is saturation current.

### Simplified Parameterization

The simplified parameterization model assumes that the quadratic and linear coefficients are the same. This is one of the recommended assumptions for the r2\_cmc model provided by the Compact Model Coalition, as a reasonable initial guess when performing parameter extraction. With this assumption, it is possible to define two new parameters, **Critical voltage** and **Corner voltage**, which provide a simpler means for parameterizing models:

$$p_2 = p_3 = \frac{v_{co}}{2v_{crit}}$$

$$\theta_2 = \theta_3 = \frac{1}{2v_{co}}$$

where:

- $v_{crit}$  is critical voltage.
- $v_{co}$  is corner voltage.

At high voltage,

$$\frac{dR}{dv_{pn}} \approx \frac{R_0}{v_{crit}}$$

and therefore, critical voltage is the reciprocal of the slope of the increase of  $R/R_0$  with voltage.

With this parameterization, the saturation current is

$$i_{sat} = \frac{v_{crit}}{R_0}$$

### Tolerances

You can apply tolerances to the nominal value you provide for the **Resistance** parameter. Datasheets typically provide a tolerance percentage for a given resistor type. The table shows how the block applies tolerances and calculates resistance based on the selected **Tolerance application** option.

Option	Resistance Value
None – use nominal value	$R_0$
Random tolerance	Uniform distribution: $R_0 \cdot (1 - tol + 2 \cdot tol \cdot rand)$ Gaussian distribution: $R_0 \cdot (1 + tol \cdot randn / nSigma)$
Apply maximum tolerance value	$R_0 \cdot (1 + tol)$
Apply minimum tolerance value	$R_0 \cdot (1 - tol)$

In the table,

- $R_0$  is the **Resistance** parameter value, nominal zero-bias resistance.
- $tol$  is fractional tolerance, **Tolerance (%)** /100.
- $nSigma$  is the value you provide for the **Number of standard deviations for quoted tolerance** parameter.
- `rand` and `randn` are standard MATLAB functions for generating uniform and normal distribution random numbers.

---

**Note** If you choose the `Random tolerance` option and you are in "Fast Restart" mode, the random tolerance value is updated on every simulation if at least one between the fractional tolerance,  $tol$ , or the **Number of standard deviations for quoted tolerance**,  $nSigma$ , is set to Run-time and is defined with a variable (even if you do not modify that variable).

---

### Operating Limits

You can specify operating limits in terms of power and maximum working voltage. If you set the **Modeling option** parameter to `Show thermal port` (see "Model Thermal Effects" on page 1-438), you can also specify operating limits in terms of temperature.

When an operating limit is exceeded, the block can either generate a warning or stop the simulation with an error. For more information, see the "Operating Limits" on page 1-442 parameters section.

### Faults

The Diffusion Resistor block allows you to model an electrical fault as an instantaneous change in resistance. The block can trigger fault events:

- At a specific time
- When a current limit is exceeded for longer than a specific time interval

You can enable or disable these trigger mechanisms separately, or use them together if more than one trigger mechanism is required in a simulation. When more than one mechanism is enabled, the first mechanism to trigger the fault takes precedence. In other words, component fails no more than once per simulation.

When the resistor fails, its resistance is changed to the value you specify for the **Faulted zero-voltage resistance** parameter. You can also choose whether to issue an assertion when a fault occurs, by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

### Thermal Noise

The Diffusion Resistor block can generate thermal noise current. If you set the **Noise mode** parameter to `Enabled`, then the block includes a noise current source connected in parallel to the diffusion resistor.

If the sampling time is  $h$ , then the thermal noise is given by:

$$i_N = \sqrt{2kT/R} \frac{N(0, 1)}{\sqrt{h}}$$

where:

- $k$  is the Boltzmann constant,  $1.3806504e-23$  J/K.
- $T$  is temperature.
- $R$  is resistance.
- $N$  is a Gaussian random number with zero mean and standard deviation of one.
- $2kT/R$  is the double-sided thermal noise power distribution (the single-sided equivalent is  $4kT/R$ ).

The block generates Gaussian noise by using the PS Random Number source in the Simscape Foundation library. You can control the random number seed by setting the **Repeatability** parameter:

- **Not repeatable** — Every time you simulate your model, the block resets the random seed using the MATLAB random number generator:  

$$\text{seed} = \text{randi}(2^{32}-1);$$
- **Repeatable** — The block automatically generates a seed value and stores it inside the block, to always start the simulation with the same random number. This auto-generated seed value is set when you add a Diffusion Resistor block from the block library to the model. When you make a new copy of the Diffusion Resistor block from an existing one in a model, a new seed value is generated. The block sets the value using the MATLAB random number generator command shown above.
- **Specify seed** — If you select this option, the additional **Seed** parameter lets you directly specify the random number seed value.

### Model Thermal Effects

You can expose thermal ports to specify how the resistance value changes with temperature and to set the thermal mass. To expose the thermal ports, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain thermal ports.
- **Show thermal port** — The block contains one thermal conserving port.

Use the **Variables** settings to set the initial temperature target.

If you set the **Modeling option** parameter to **Show thermal port**, the defining equation for the resistance is augmented with additional temperature scaling:

$$R = R_0 \left( 1 + T_{C1}^{eff} \Delta T + T_{C2}^{eff} (\Delta T)^2 \right) \left( 1 - p_2 - p_3 + p_2 \sqrt{1 + (\theta_2 v_{pn})^2} + p_3 \sqrt[3]{1 + |\theta_3 v_{pn}|^3} \right)$$

where  $T_{C1}^{eff}$  and  $T_{C2}^{eff}$  are the linear and quadratic temperature scaling coefficients, respectively.

$$\Delta T = T_{sim} - T_{meas}$$

where:

- $T_{sim}$  is simulation temperature.
- $T_{meas}$  is measurement temperature.

With the thermal port exposed, the generated noise uses the temperature at the thermal port when determining the instantaneous noise value. Exposing the thermal port also extends the options on the **Operating Limits** tab as follows:

- The **Power rating** parameter becomes temperature dependent. You define a temperature up to which the full power rating is available, plus a higher temperature for which the power rating is

reduced to zero. It is assumed that the power rating decreases linearly with temperature between these two values.

- An additional parameter, **Operating temperature range, [Tmin Tmax]**, lets you define the valid temperature range for block operation.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

This section appears only for the blocks with exposed thermal port. The **Temperature** variable lets you specify a high-priority target for the temperature at the start of simulation.

## Basic Assumptions and Limitations

Simulating with noise enabled slows down simulation. Choose the sample time ( $h$ ) so that noise is generated only at frequencies of interest, and not higher.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the resistor positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the resistor negative terminal.

#### H – Resistor thermal mass

thermal

Thermal conserving port that represents the resistor thermal mass.

### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### Modeling option – Whether to enable thermal port

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and specify how the resistance value changes with temperature and to set the thermal mass.

**Main****Resistance — Nominal zero-bias resistance**

1 Ohm (default)

The zero-bias resistance, used as the nominal resistance value. Resistance value must be greater than zero. If you set **Modeling option** to Show thermal port, this is the zero-bias resistance at a temperature equal to the **Measurement temperature** parameter in the “Thermal” on page 1-446 section.

**Tolerance (%) — Resistor tolerance, in percent**

5 (default)

The resistor tolerance as defined on the manufacturer datasheet.

**Tolerance application — Select how to apply tolerance during simulation**

None — use nominal value (default) | Random tolerance | Apply maximum tolerance value | Apply minimum tolerance value

Select how to apply tolerance during simulation:

- **None — use nominal value** — The block does not apply tolerance, uses the nominal resistance value. This is the default.
- **Random tolerance** — The block applies random offset to the resistance value, within the tolerance value limit. You can choose Uniform or Gaussian distribution for calculating the random number by using the **Tolerance distribution** parameter.
- **Apply maximum tolerance value** — The resistance is increased by the specified tolerance percent value.
- **Apply minimum tolerance value** — The resistance is decreased by the specified tolerance percent value.

**Tolerance distribution — Select the distribution type**

Uniform (default) | Gaussian

Select the distribution type for random tolerance:

- **Uniform** — Uniform distribution
- **Gaussian** — Gaussian distribution

**Dependencies**

Enabled when the **Tolerance application** parameter is set to Random tolerance.

**Number of standard deviations for quoted tolerance — Used for calculating the Gaussian random number**

4 (default)

Number of standard deviations for calculating the Gaussian random number.

**Dependencies**

Enabled when the **Tolerance distribution** parameter is set to Gaussian.

**Parameterization — Select parameterization method**

Simplified (default) | Advanced

Select how to apply tolerance during simulation:

- **Simplified** — Assume that the quadratic and linear coefficients are the same, and define block behavior using the **Critical voltage** and **Corner voltage** parameters.
- **Advanced** — Explicitly specify values for the quadratic and linear voltage coefficients and for the inverse voltages for quadratic and linear voltage activation.

#### **Critical voltage — Critical voltage for saturation**

4 V (default)

Critical voltage for the saturation mechanism. You can determine this parameter value by taking the reciprocal of the slope of the increase of  $R/R_0$  with voltage.

##### **Dependencies**

Enabled when the **Parameterization** parameter is set to **Simplified**.

#### **Corner voltage — Voltage at which the resistance increase starts to occur**

2 V (default)

Corner voltage, at which the resistance increase starts to occur. The **Corner voltage** must be less than the **Critical voltage**.

##### **Dependencies**

Enabled when the **Parameterization** parameter is set to **Simplified**.

#### **Quadratic voltage coefficient — Coefficient $p_2$**

0.25 (default)

Coefficient  $p_2$  from the defining equation.

##### **Dependencies**

Enabled when the **Parameterization** parameter is set to **Advanced**.

#### **Inverse voltage for quadratic voltage activation — Coefficient $\theta_2$**

0.25 1/V (default)

Coefficient  $\theta_2$  from the defining equation.

##### **Dependencies**

Enabled when the **Parameterization** parameter is set to **Advanced**.

#### **Linear voltage coefficient — Coefficient $p_3$**

0.25 (default)

Coefficient  $p_3$  from the defining equation.

##### **Dependencies**

Enabled when the **Parameterization** parameter is set to **Advanced**.

#### **Inverse voltage for linear voltage activation — Coefficient $\theta_3$**

0.25 1/V (default)

Coefficient  $\theta_3$  from the defining equation.

**Dependencies**

Enabled when the **Parameterization** parameter is set to Advanced.

**Operating Limits****Enable operating limits — Select Yes to enable reporting when the operational limits are exceeded**

No (default) | Yes

Select Yes to enable reporting when the operational limits are exceeded. The associated parameters in the **Operating Limits** section become visible to let you select the reporting method and specify the operating limits in terms of power and maximum working voltage. Parameters that specify operating limits in terms of temperature are visible only for blocks with exposed thermal port (see “Model Thermal Effects” on page 1-438). The default value is No.

**Reporting when operating limits exceeded — Select the reporting method**

Warn (default) | Error

Select what happens when an operating limit is exceeded:

- Warn — The block issues a warning.
- Error — Simulation stops with an error.

**Dependencies**

Enabled when the **Enable operating limits** parameter is set to Yes.

**Maximum working voltage — Maximum voltage allowed for normal block operation**

100 V (default)

Maximum voltage magnitude allowed for normal block operation.

**Dependencies**

Enabled when the **Enable operating limits** parameter is set to Yes.

**Power rating — Maximum power allowed for normal block operation**

1 W (default)

Maximum power allowed for normal block operation.

If you expose the thermal port of the block, this parameter becomes temperature dependent. The value you specify for the **Power rating** parameter applies up to the temperature specified by the **Temperature below which full power rating is available** parameter value. Then the power rating decreases linearly with temperature, until it becomes 0 at temperature specified by the **Temperature above which power rating is reduced to zero** parameter value.

**Dependencies**

Enabled when the **Enable operating limits** parameter is set to Yes.

**Temperature below which full power rating is available — Maximum temperature where full power rating still applies**

70 °C (default)

Maximum temperature where full power rating, specified by the **Power rating** parameter value, still applies.

#### Dependencies

To enable this parameter, set **Modeling option** to Show thermal port.

#### Temperature above which power rating is reduced to zero — Temperature where power rating becomes 0

155 °C (default)

Temperature where power rating becomes 0. Above this temperature, the simulation always issues an assertion regardless of dissipated power. This parameter value must be higher than **Temperature below which full power rating is available**.

#### Dependencies

To enable this parameter, set **Modeling option** to Show thermal port.

#### Operating temperature range, [Tmin Tmax] — Minimum and maximum temperature values allowed for normal block operation

[-50 150] °C (default)

A row vector of length 2 specifying minimum and maximum temperature values allowed for normal block operation. The first element is the lowest allowable operating temperature, and the second element is the largest allowable operating temperature.

#### Dependencies

To enable this parameter, set **Modeling option** to Show thermal port.

#### Faults

##### Enable faults — Select Yes to enable faults modeling

No (default) | Yes

Select Yes to enable faults modeling. The associated parameters in the **Faults** section become visible to let you select the reporting method and specify the trigger mechanism (temporal or behavioral). You can enable these trigger mechanisms separately or use them together.

##### Reporting when a fault occurs — Choose whether to issue an assertion when a fault occurs

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- None — The block does not issue an assertion.
- Warn — The block issues a warning.
- Error — Simulation stops with an error.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

##### Faulted zero-voltage resistance — Resistance when block is in faulted state

inf Ohm (default)

Zero-voltage resistance between the + and - ports when the block is in the faulted state.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Enable temporal fault trigger – Select Yes to enable time-based fault triggering**

No (default) | Yes

Select Yes to enable time-based fault triggering. You can enable the temporal and behavioral trigger mechanisms separately or use them together.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Simulation time for fault event – Time before entering faulted state**

1 s (default)

Set the simulation time at which you want the block to enter the faulted state.

**Dependencies**

Enabled when the **Enable temporal fault trigger** parameter is set to Yes.

**Enable behavioral fault trigger – Select Yes to enable behavioral fault triggering**

No (default) | Yes

Select Yes to enable behavioral fault triggering. You can enable the temporal and behavioral trigger mechanisms separately or use them together.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Maximum permissible current – Current threshold to fault transition**

1 A (default)

Specify the maximum permissible current value. If the current exceeds this value for longer than the **Time to fail when exceeding maximum permissible current** parameter value, then the block enters the faulted state.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

**Time to fail when exceeding maximum permissible current – Maximum length of time the current exceeds the threshold**

1 s (default)

Set the maximum length of time that the current can exceed the maximum permissible value without triggering the fault.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

## Noise

### Noise mode — Select whether to model thermal noise current

Disabled (default) | Enabled

Select whether to model thermal noise current:

- **Disabled** — No noise is produced by the resistor.
- **Enabled** — Resistor generates thermal noise current, and the associated parameters become visible in the **Noise** section.

### Sample time — Rate at which the noise source is sampled

1e-3 s (default)

Defines the rate at which the noise source is sampled. Choose it to reflect the frequencies of interest in your model. Making the sample time too small will unnecessarily slow down your simulation.

#### Dependencies

Enabled when the **Noise mode** parameter is set to Enabled.

### Repeatability — Select the noise control option

Not repeatable (default) | Repeatable | Specify seed

Select the noise control option:

- **Not repeatable** — The random sequence used for noise generation is not repeatable.
- **Repeatable** — The random sequence used for noise generation is repeatable, with a system-generated seed.
- **Specify seed** — The random sequence used for noise generation is repeatable, and you control the seed by using the **Seed** parameter.

#### Dependencies

Enabled when the **Noise mode** parameter is set to Enabled.

### Auto-generated seed used for repeatable option — Auto-generated random number seed

random real number

Random number seed stored inside the block to make the random sequence repeatable. The parameter value is automatically generated using the MATLAB random number generator command. You can modify this parameter value, but it gets overwritten by a new random value if you copy the block to another block in the model. Therefore, if you want to control the seed of the random sequence, use the **Specify seed** option for the **Repeatability** parameter and specify the desired seed value using the **Seed** parameter.

#### Dependencies

Enabled when the **Repeatability** parameter is set to Repeatable.

### Seed — Random number seed

0 (default)

Seed used by the noise random number generator.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Specify seed.

**Device simulation temperature — Temperature of resistor at the start of the simulation**

25 °C (default)

The temperature of the resistor at the start of the simulation.

**Dependencies**

Enabled when the **Noise mode** parameter is set to Enabled.

For blocks with an exposed thermal port, this parameter is disabled. Instead, use the **Variables** tab to set the initial temperature target. For more information, see “Variables” on page 1-439.

**Thermal**

To enable these parameters, set **Modeling option** to Show thermal port.

**Resistance linear temperature coefficient — Specifies how the resistance value changes with temperature**

0 1/K (default)

The coefficient  $T_{C1}^{eff}$  in the equation that describes resistance as a function of temperature. See “Model Thermal Effects” on page 1-438 for details.

**Resistance quadratic temperature coefficient — Specifies how the resistance value changes with temperature**

0 1/K<sup>2</sup> (default)

The coefficient  $T_{C2}^{eff}$  in the equation that describes resistance as a function of temperature. See “Model Thermal Effects” on page 1-438 for details.

**Measurement temperature — Temperature corresponding to nominal resistance**

25 °C (default)

The temperature  $T_0$ , for which the nominal resistance  $R$  is specified.

**Thermal mass — Thermal mass associated with port H**

100 J/K (default)

Thermal mass associated with the thermal port H. It represents the energy required to raise the temperature of the thermal port by one degree.

# Diode

Piecewise or exponential diode

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The Diode block can represent either a piecewise linear diode, an exponential diode, or a diode with tabulated I-V curve. Use the **Fidelity level** parameter to select the level of detail in the dynamics model.

### Piecewise Linear Diode

The piecewise linear diode model is the same model as the **Simscape > Foundation Library > Electrical > Electrical Elements > Diode** block, with the addition of a fixed junction capacitance and optional charge dynamics. If the diode forward voltage exceeds the value specified in the **Forward voltage** parameter, the diode behaves as a linear resistor with the resistance specified in the **On resistance** parameter. Otherwise, the diode behaves as a linear resistor with the small conductance specified in the **Off conductance** parameter. Zero voltage across the diode results in zero current flowing.

For more information about the Diode block in the Simscape Foundation library, see Diode.

### Exponential Diode

The exponential diode model represents the following relationship between the diode current  $I$  and the diode voltage  $V$ :

$$I = IS \cdot \left( e^{\frac{qV}{NkT_{m1}}} - 1 \right) V > -BV$$

$$I = -IS \cdot \left( e^{\frac{-q(V+Vz)}{kT_{m1}}} - e^{\frac{qV}{NkT_{m1}}} \right) V \leq -BV$$

where:

- $q$  is the elementary charge on an electron (1.602176e-19 coulombs).
- $k$  is the Boltzmann constant (1.3806503e-23 J/K).
- $BV$  is the **Reverse breakdown voltage** parameter value.
- $N$  is the emission coefficient.
- $IS$  is the saturation current.
- $T_{m1}$  is the temperature at which the diode parameters are specified, as defined by the **Measurement temperature** parameter value.

When  $(qV / NkT_{m1}) > 80$ , the block replaces  $e^{\frac{qV}{NkT_{m1}}}$  with  $(qV / NkT_{m1} - 79)e^{80}$ , which matches the gradient of the diode current at  $(qV / NkT_{m1}) = 80$  and extrapolates linearly. When  $(qV / NkT_{m1}) < -79$ ,

the block replaces  $e^{\frac{qV}{NkT_{m1}}}$  with  $(qV / NkT_{m1} + 80)e^{-79}$ , which also matches the gradient and extrapolates linearly. Typical electrical circuits do not reach these extreme values. The block provides this linear extrapolation to help convergence when solving for the constraints during simulation.

When you select Use parameters **IS** and **N** for the **Parameterization** parameter, you specify the diode in terms of the **Saturation current IS** and **Emission coefficient N** parameters. When you select Use two I-V curve data points for the **Parameterization** parameter, you specify two voltage and current measurement points on the diode I-V curve and the block derives the **IS** and **N** values. The block then calculates **IS** and **N** as follows:

- $N = ((V_1 - V_2)/V_t)/(\log(I_1) - \log(I_2))$
- $IS = (I_1/(\exp(V_1/(NV_t)) - 1) + I_2/(\exp(V_2/(NV_t)) - 1))/2$

where:

- $V_t = kT_{m1} / q$ .
- $V_1$  and  $V_2$  are the values in the **Voltages [V1 V2]** vector.
- $I_1$  and  $I_2$  are the values in the **Currents [I1 I2]** vector.

When you select Use an I-V data point and **IS** for the **Parameterization** parameter, then the block calculates **N** as follows:

$$N = V_1 / \left( V_t \log \left( \frac{I_1}{IS} + 1 \right) \right)$$

When you select Use an I-V data point and **N** for the **Parameterization** parameter, then the block calculates **IS** as follows:

$$IS = I_1 / (\exp(V_1 / (NV_t)) - 1)$$

### Tabulated Diode

To model a tabulated diode, set the **Diode model** parameter to Tabulated I-V curve. This figure shows the implementation of the tabulated diode option:

When choosing this parameterization, you must provide the data for the forward bias only. If the diode is reverse biased, it is modeled as a constant off-state conductance specified in the **Off**

**conductance** parameter instead. The value of the **Off conductance** must be less than the gradient of the forward I-V curve for small positive voltages.

The block implements the diode using a smooth interpolation option. If the diode exceeds the provided tabulated data range, the block uses a linear extrapolation technique at the last voltage-current data point.

---

**Note** The tabulated diode does not model the reverse breakdown.

---

## Junction Capacitance

The Diode block models the junction capacitance only if you set the **Fidelity level** parameter to **Include capacitance and charge dynamics**. To include a junction capacitance:

- Select **Include fixed or zero junction capacitance** for the **Parameterization** parameter. The capacitance is fixed.
- Select **Use parameters CJO, VJ, M & FC** for the **Parameterization** parameter. The block uses the coefficients  $CJO$ ,  $VJ$ ,  $M$ , and  $FC$  to calculate a junction capacitance that depends on the junction voltage.
- Select **Use C-V curve data points** for the **Parameterization** parameter. The block uses three capacitance values on the C-V capacitance curve to estimate  $CJO$ ,  $VJ$ , and  $M$  and uses these values with the specified value of  $FC$  to calculate a junction capacitance that depends on the junction voltage. The block calculates  $CJO$ ,  $VJ$ , and  $M$  as follows:

- $$CJO = C_1((V_{R2} - V_{R1})/(V_{R2} - V_{R1}(C_2/C_1)^{-1/M}))^M$$
- $$VJ = -(-V_{R2}(C_1/C_2)^{-1/M} + V_{R1})/(1 - (C_1/C_2)^{-1/M})$$
- $$M = \log(C_3/C_2)/\log(V_{R2}/V_{R3})$$

where:

- $V_{R1}$ ,  $V_{R2}$ , and  $V_{R3}$  are the values in the **Reverse bias voltages [VR1 VR2 VR3]** vector.
- $C_1$ ,  $C_2$ , and  $C_3$  are the values in the **Corresponding capacitances [C1 C2 C3]** vector.

The reverse bias voltages (defined as positive values) should satisfy  $V_{R3} > V_{R2} > V_{R1}$ . This means that the capacitances should satisfy  $C_1 > C_2 > C_3$  as reverse bias widens the depletion region and hence reduces capacitance. Violating these inequalities results in an error. Voltages  $V_{R2}$  and  $V_{R3}$  should be well away from the Junction potential  $VJ$ . Voltage  $V_{R1}$  should be less than the Junction potential  $VJ$ , with a typical value for  $V_{R1}$  being 0.1 V.

The voltage-dependent junction capacitance is defined in terms of the capacitor charge storage  $Q_j$  as:

- For  $V < FC \cdot VJ$ :

$$Q_j = CJO \cdot (VJ/(M - 1)) \cdot ((1 - V/VJ)^{1-M} - 1)$$

- For  $V \geq FC \cdot VJ$ :

$$Q_j = CJO \cdot F_1 + (CJO/F_2) \cdot (F_3 \cdot (V - FC \cdot VJ) + 0.5(M/VJ) \cdot (V^2 - (FC \cdot VJ)^2))$$

where:

- $F_1 = (VJ/(1 - M)) \cdot (1 - (1 - FC)^{1 - M})$
- $F_2 = (1 - FC)^{1 + M}$
- $F_3 = 1 - FC \cdot (1 + M)$

These equations are the same as used in [2 on page 1-480], except that the temperature dependence of  $VJ$  and  $FC$  is not modeled.

### Charge Dynamics

The Diode block models the charge dynamics only if you set the **Fidelity level** parameter to **Include capacitance and charge dynamics**. For applications such as commutation diodes it can be important to model diode charge dynamics. When a forward-biased diode has a reverse voltage applied across it, it takes time for the charge to dissipate and hence for the diode to turn off. The time taken for the diode to turn off is captured primarily by the transit time parameter. Once the diode is off, any remaining charge then dissipates, the rate at which this happens being determined by the carrier lifetime.

The Diode block uses the model of Lauritzen and Ma [3 on page 1-480] to capture these effects. These are the defining equations.

$$i = \frac{q_E - q_M}{T_M} \quad (1-2)$$

$$\frac{dq_M}{dt} + \frac{q_M}{\tau} - \frac{q_E - q_M}{T_M} = 0 \quad (1-3)$$

$$q_E = (\tau + T_M)i \quad (1-4)$$

where:

- $i$  is the diode current.
- $q_E$  is the junction charge.
- $q_M$  is the total stored charge.
- $T_M$  is the transit time.
- $\tau$  is the carrier lifetime.
- $v_D$  is the voltage across the diode.
- $v_F$  is the diode forward voltage.
- $R$  is the diode on resistance.
- $G$  is the diode off conductance.

This graphic shows a typical reverse-mode current characteristic for a diode device.

where:

- $i_{RM}$  is the peak reverse current.
- $i_F$  is the starting forward current when measuring  $i_{RM}$ .
- $a$  is the rate of change of current when measuring  $i_{RM}$ .
- $t_{rr}$  is the reverse recovery time.

Data sheets for diodes quote values for peak reverse current for an initial forward current and a steady rate of change of current. The data sheet might also provide values for reverse recovery time and total recovery charge.

#### How the Block Calculates $T_M$ and Tau

The block calculates transit time  $T_M$  and carrier lifetime  $\tau$  based on the values you enter for the **Charge Dynamics** parameters. The block uses  $T_M$  and  $\tau$  to solve the charge dynamics equations 1, 2, and 3.

During initial current drop in reverse mode, the diode is still on, and the rate of change of current is determined by an external test circuit.

First, the block uses equation 1 to perform this calculation.

$$i_F + at = \frac{qE - q_M}{T_M} \quad (1-5)$$

Then, it substitutes equation 4 into equation 2.

$$\frac{dq_M}{dt} + \frac{q_M}{\tau} = i_F + at \quad (1-6)$$

Then, it solves equation 5 for  $q_M$ ,

$$q_M = i_F \tau - a \tau^2 + \frac{k}{\exp\left(\frac{t}{\tau}\right)} + a \tau t, \quad (1-7)$$

where  $k$  is a constant.

When  $t$  is zero,  $i = i_F$  and  $q_M = \tau i_F$  because the system is in steady state.

Substituting these relationships into equation 6 and solving the equation gives  $k = a\tau^2$ .

Therefore,

$$q_M = i_F \tau + a\tau^2 \left( \frac{1}{\exp\left(\frac{t}{\tau}\right)} - 1 \right) + a\tau t. \quad (1-8)$$

At time  $t = t_s$ , the current is  $i_{RM}$  and the junction charge  $q_E$  is zero.

The block substitutes these values into equation 1.

$$i_{RM} = \frac{-q_M}{T_M} \quad (1-9)$$

The block rearranges equation 8 to solve for  $q_M$  and substitutes the result into equation 7.

$$-T_M i_{RM} = i_F \tau + a\tau^2 \left( \frac{1}{\exp\left(\frac{t_s}{\tau}\right)} - 1 \right) + a\tau t_s \quad (1-10)$$

Then, the block expresses time  $t_s$  in terms of  $i_{RM}$ ,  $i_F$ , and  $a$ .

$$t_s = \frac{i_{RM} - i_F}{a} \quad (1-11)$$

Consider the diode recovery, that is, when  $t > t_s$ . The diode is reverse biased, and current and junction charge are effectively zero.

The current is defined by this equation.

$$i = i_{RM} \exp\left[-\frac{(t - t_s)}{\tau_{rr}}\right], \quad (1-12)$$

where:

$$\frac{1}{\tau_{rr}} = \frac{1}{\tau} + \frac{1}{T_M}. \quad (1-13)$$

The block now relates the expression in equation 12 to the reverse recovery time  $t_{rr}$ .

When  $t = \frac{i_{RM}}{a} + t_{rr}$ , the current is  $\frac{i_{RM}}{10}$ .

Therefore,

$$\exp\left(-\frac{t - t_s}{\tau_{rr}}\right) = 0.1 \quad (1-14)$$

and

$$t_{rr} = \tau_{rr} \log(10) + \frac{i_{RM}}{a}. \quad (1-15)$$

The block uses equations 9 and 14 to calculate values for  $T_M$  and  $\tau$ . The calculation uses an iterative scheme because of the exponential term in Equation 9.

#### Alternatives to Specifying $t_{rr}$ Directly

In addition to allowing you to specify reverse recovery time  $t_{rr}$  directly, the block supports three alternative parameterizations. The block can derive  $t_{rr}$  from either of these parameters:

- Reverse recovery time stretch factor  $\lambda$
- Reverse recovery charge  $Q_{rr}$ , when the data sheet specifies this value instead of the reverse recovery time.
- Reverse recovery energy  $E_{rec}$ , when the data sheet specifies this value instead of the reverse recovery time.

The relationship between reverse recovery time stretch factor  $\lambda$  and  $t_{rr}$  is expressed by the equation

$$\lambda = \frac{t_{rr} a}{i_{RM}}.$$

Reverse recovery time must be greater than  $\frac{i_{RM}}{a}$  and a typical value is  $3(\frac{i_{RM}}{a})$ .

Therefore, a typical value for  $\lambda$  is 3.  $\lambda$  must be greater than 1.

Reverse recovery charge  $Q_{rr}$  is the integral over time of the reverse current from the point where the current goes negative until it decays back to zero.

The initial charge, to time  $t_s$  (as shown in the figure), is expressed by this equation:

$$Q_s = \frac{1}{2}(-i_{RM})\frac{i_{RM}}{a}. \quad (1-16)$$

Integrating equation 11 gives the charge between times  $t_s$  and inf. This charge is equal to

$$\tau_{rr} i_{RM}.$$

Therefore, total reverse recovery charge is given by this equation:

$$Q_{rr} = -\frac{i_{RM}^2}{2a} + \tau_{rr} i_{RM}. \quad (1-17)$$

Rearranging equation 16 to solve for  $\tau_{rr}$  and substituting the result into equation 14 gives an equation that expresses  $t_{rr}$  in terms of  $Q_{rr}$ :

$$t_{rr} = \left( \frac{Q_{rr}}{i_{RM}} + \frac{i_{RM}}{2a} \right) \log(10) + \frac{i_{RM}}{a}.$$

Alternatively, the block calculates  $\tau_{rr}$  by using the reverse recovery energy,  $E_{rec}$ . This equation defines the diode voltage curve:

$$v_d = v_R - (v_R - v_{RM}) \exp(-(t - t_1)/\tau_{rr}), \quad (1-18)$$

where  $v_{RM} = v_R - i_{RM}\left(R - \frac{L}{\tau_{rr}}\right)$  is the maximum diode reverse voltage.

If  $\frac{L}{\tau_{rr}} \gg R$ , which is a common condition for the reverse recovery test circuit, the block calculates the maximum diode reverse voltage as:

$$v_{RM} = v_R + i_{RM}\frac{L}{\tau_{rr}}.$$

Since the drop time value is small, the block assumes that the diode current drop is linear:

$$i_F + didt \cdot t = \frac{q_E - q_M}{T_M}. \quad (1-19)$$

Then, it substitutes equation 18 into equation 5:

$$\frac{dq_M}{dt} + \frac{q_M}{\tau} = i_F + didt \cdot t. \quad (1-20)$$

To obtain the total stored charge, it solves equation 19 :

$$q_M = i_F\tau + didt \cdot \tau^2 \left( \frac{1}{\exp\left(\frac{t}{\tau}\right)} - 1 \right) + didt \cdot \tau t, \quad (1-21)$$

where  $didt$  is the gradient of the current.

When  $t = t_1 = \frac{i_{RM} - i_F}{didt}$ , the peak reverse current is:

$$i_{RM} = \frac{-q_M}{T_M}. \quad (1-22)$$

The block now substitutes equation 21 into equation 20:

$$\begin{aligned} -i_{RM}T_M &= i_F\tau + didt \cdot \tau^2 \left( \exp\left(-\frac{i_{RM} - i_F}{didt \cdot \tau}\right) - 1 \right) + \tau(i_{RM} - i_F) \\ -(T_M + \tau)i_{RM} &= didt \cdot \tau^2 \left( \exp\left(-\frac{i_{RM} - i_F}{didt \cdot \tau}\right) - 1 \right) \end{aligned} \quad (1-23)$$

$$i_{RM} = F(didt, i_F, T_M, \tau).$$

Finally, the block solves equation 22 to obtain the reverse recovery energy:

$$\begin{aligned} E_{rec} &= \int_1^{t_2} i_d v_d dt \\ E_{rec} &= \frac{\tau_{rr} i_{RM} (v_R + v_{RM})}{2} \\ E_{rec} &= \frac{i_{RM} (2v_R \tau_{rr} + i_{RM} L)}{2}. \end{aligned} \quad (1-24)$$

### Charge dynamics with faults

When the device is faulted, the Diode block calculates the junction charge as

$$q_E = (\tau + T_M)i_{diode},$$

where:

- $i_{diode}$  is the diode current without the charge model.
- $q_E$  is the junction charge.
- $T_M$  is the transit time.
- $\tau$  is the carrier lifetime.

This equation then defines the value of the diode current:

$$\frac{dq_M}{dt} + \frac{q_M}{\tau} - \frac{q_E - q_M}{T_M} = 0$$

$$i = \frac{q_E - q_M}{T_M} Q_{scale} - (Q_{scale} - 1)i_{diode}$$

where:

- $i$  is the diode current.
- $q_M$  is the total stored charge.
- $Q_{scale}$  is the current value of the charge ratio.

### Temperature Dependence

The default behavior for the Diode block is that dependence on temperature is not modeled, and the device is simulated at the temperature for which you provide block parameters. The exponential diode model contains several options for modeling the dependence of the diode current-voltage relationship on temperature during simulation. Temperature dependence of the junction capacitance is not modeled because it has a much smaller effect.

When including temperature dependence, the diode defining equation remains the same. The measurement temperature value,  $T_{m1}$ , is replaced with the simulation temperature,  $T_s$ . The saturation current,  $IS$ , becomes a function of temperature according to the following equation:

$$IS_{T_s} = IS_{T_{m1}} \cdot (T_s/T_{m1})^{XTI/N} \cdot \exp\left(-\frac{EG}{NkT_s}(1 - T_s/T_{m1})\right)$$

where:

- $T_{m1}$  is the temperature at which the diode parameters are specified, as defined by the **Measurement temperature** parameter value.
- $T_s$  is the simulation temperature.
- $IS_{T_{m1}}$  is the saturation current at measurement temperature.
- $IS_{T_s}$  is the saturation current at simulation temperature. This is the saturation current value used in the standard diode equation when temperature dependence is modeled.
- $EG$  is the energy gap for the semiconductor type measured in joules(J). The value for silicon is usually taken to be 1.11 eV, where 1 eV is 1.602e-19.
- $XTI$  is the saturation current temperature exponent. This is usually set to 3.0 for pn-junction diodes, and 2.0 for Schottky barrier diodes.
- $N$  is the emission coefficient.

- $k$  is the Boltzmann constant ( $1.3806503e-23$  J/K).

Appropriate values for  $XTI$  and  $EG$  depend on the type of diode and the semiconductor material used. Default values for particular material types and diode types capture approximate behavior with temperature. The block provides default values for common types of diode.

In practice, the values of  $XTI$  and  $EG$  need tuning to model the exact behavior of a particular diode. Some manufacturers quote these tuned values in a SPICE Netlist, and you can read off the appropriate values. Otherwise, you can determine improved estimates for  $EG$  by using a datasheet-defined current-voltage data point at a higher temperature. The block provides a parameterization option for this. It also gives the option of specifying the saturation current at a higher temperature  $IS_{Tm2}$  directly.

You can also tune the values of  $XTI$  and  $EG$  yourself, to match lab data for your particular device. You can use Simulink Design Optimization™ software to help tune the values for  $XTI$  and  $EG$ .

---

**Caution** Device temperature behavior is also dependent on the emission coefficient. An inappropriate value for the emission coefficient can give incorrect temperature dependence, because saturation current is a function of the ratio of  $EG$  to  $N$ .

---

If defining a finite reverse breakdown voltage ( $BV$ ), then the value of the reverse  $BV$  is modulated by the reverse breakdown temperature coefficient  $TCV$  (specified using the **Reverse breakdown voltage temperature coefficient, dBV/dT** parameter):

$$BV_{T_s} = BV_{T_{m1}} - TCV \cdot (T_s - T_{m1}) \quad (1-25)$$

### Thermal Losses

This figure shows the voltage and current of the diode in a switching regime inside a half-bridge.

Reverse recovery loss is one of the main sources of thermal loss in diodes. The diode dissipates energy every time it turns off, from its conducting state to the open-circuit state.

In this block, reverse recovery losses are applied by stepping up the junction temperature with a value equal to the reverse recovery loss divided by the total thermal mass at the junction.

If you set the **Reverse recovery loss model** parameter to **Tabulated loss**, the value of the **Reverse recovery loss table, Erec(T<sub>j</sub>, I<sub>f</sub>)** parameter specifies the dissipated energy in function of the junction temperature and the forward current just before the switching event. The off-state voltage linearly scales the losses prior to the latest device turn-off event. The table uses delayed values for current and voltage. To ensure the value used in the lookup table is close enough to the instantaneous value, set the **Delay for voltage and current tabulation** parameter to a value that is lower than the fastest switching period.

If you set the **Reverse recovery loss model** parameter to **Fixed loss**, the value of the **Reverse recovery loss** parameter specifies the dissipated energy in each turn-off event, regardless of the state of the diode before or after switching event.

---

**Note** The `lastReverseRecoveryLoss` variable in the simlog includes the reverse recovery losses as a pulse with amplitude equal to the energy loss. If you use a script to sum the total losses over a defined simulation period, you must sum the pulse values at each pulse rising edge. Alternatively, you can use the `ee_getPowerLossSummary` and `ee_getPowerLossTimeSeries` functions to extract conduction and switching losses from logged data.

Note that the `power_dissipated` variable in the simlog does not include switching losses as they are modeled as instantaneous events. The `power_dissipated` variable therefore just reports instantaneous on-state losses.

---

## Faults

The Diode block allows you to model three types of faults:

- `Open` — Failure due to metallization burnout.
- `Short` — Failure due to punch-through.
- `Parameter shift` — Failure due to aging.

The block can trigger fault events:

- At a specific time
- When a current limit, a voltage limit, or a temperature limit are exceeded for longer than a specific time interval

You can enable or disable these trigger mechanisms separately, or use them together if more than one trigger mechanism is required in a simulation. When more than one mechanism is enabled, the first mechanism to trigger the fault takes precedence. In other words, the component fails no more than once per simulation.

You can also choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Modeling Thermal Effects

You can expose the thermal port to model the effects of generated heat and device temperature. To expose the thermal port, set the **Modeling option** parameter to either:

- `No thermal port` — The block does not contain a thermal port and does not simulate heat generation in the device.
- `Show thermal port` — The block contains a thermal port that allows you to model the heat that conduction losses generate. For numerical efficiency, the thermal state does not affect the electrical behavior of the block.

For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Assumptions and Limitations

- When you select Use two I-V curve data points for the **Parameterization** parameter, choose a pair of voltages near the diode turn-on voltage. Typically, this is in the range from 0.05 to 1 V. Using values outside of this region may lead to numerical issues and poor estimates for  $I_S$  and  $N$ .
- The block does not account for temperature-dependent effects on the junction capacitance.
- You may need to use nonzero ohmic resistance and junction capacitance values to prevent numerical simulation issues, but the simulation may run faster with these values set to zero.
- You cannot use the Tabulated I-V curve parameterization to model the reverse breakdown.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the anode.

#### - – Negative terminal

electrical

Electrical conserving port associated with the cathode.

#### H – Thermal port

thermal

Thermal conserving port.

### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### Modeling option – Whether to enable thermal port

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of generated heat and device temperature.

### Main

#### Fidelity level – Level of fidelity

Include capacitance and charge dynamics (default) | Ideal switching

Level of detail of the dynamics model of the diode. If you select **Ideal** switching, the block only models the reverse recovery losses. If you select **Include capacitance and charge dynamics**, the block models both junction capacitance and charge dynamics.

### Diode model — Diode model

Piecewise Linear (default) | Exponential | Tabulated I-V curve

Select one of these diode models:

- **Piecewise Linear** — Use a piecewise linear model for the diode, as described in “Piecewise Linear Diode” on page 1-448. This is the default method.
- **Exponential** — Use a standard exponential model for the diode, as described in “Exponential Diode” on page 1-448.
- **Tabulated I-V curve** — Use tabulated forward bias I-V data plus fixed reverse bias off conductance, as described in “Tabulated Diode” on page 1-449.

### Table type — Tabulated function

Table in  $I_f(T_j, V_f)$  form (default) | Table in  $V_f(T_j, I_f)$  form

Whether to tabulate the current as a function of temperature and voltage or the voltage as a function of temperature and current.

#### Dependencies

To enable this parameter, set **Diode model** to Tabulated I-V curve.

### Forward voltage — Forward voltage

0.6 V (default)

Minimum voltage that needs to be applied for the diode to become forward-biased.

#### Dependencies

To enable this parameter, set **Diode model** to Piecewise linear.

### On resistance — On resistance

0.3 Ohm (default)

Resistance of the diode when it is forward biased.

#### Dependencies

To enable this parameter, set **Diode model** to Piecewise linear.

### Off conductance — Off conductance

$1e-8$  1/Ohm (default)

Conductance of the diode when it is reverse biased.

#### Dependencies

To enable this parameter, set **Diode model** to Piecewise linear or Tabulated I-V curve.

### Parameterization — Model parameterization

Use two I-V curve data points (default) | Use parameters IS and N | Use an I-V data point and IS | Use an I-V data point and N

Select one of the following methods for model parameterization:

- Use two I-V curve data points — Specify measured data at two points on the diode I-V curve. This is the default method.
- Use parameters *IS* and *N* — Specify saturation current and emission coefficient.
- Use an I-V data point and *IS* — Specify measured data at a single point on the diode I-V curve in combination with the saturation current.
- Use an I-V data point and *N* — Specify measured data at a single point on the diode I-V curve in combination with the emission coefficient.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential.

**Currents [I1 I2] — Vector of current values at two points**

[.0137, .545] A (default)

Vector of the current values at the two points on the diode I-V curve that the block uses to calculate *IS* and *N*.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential and **Parameterization** to Use two I-V curve data points.

**Voltages [V1 V2] — Vector of voltage values at two points**

[.6, .7] V (default)

Vector of the voltage values at the two points on the diode I-V curve that the block uses to calculate *IS* and *N*.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential and **Parameterization** to Use two I-V curve data points.

**Saturation current, IS — Saturation current**

1e-12 A (default)

Magnitude of the current that the ideal diode equation approaches asymptotically for very large reverse bias levels.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential and **Parameterization** to Use parameters *IS* and *N* or Use an I-V data point and *IS*.

**Emission coefficient, N — Diode emission coefficient**

1 (default)

Diode emission coefficient or ideality factor.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential and **Parameterization** to Use parameters *IS* and *N* or Use an I-V data point and *IS*.

**Current I1 — Current value**

0.0137 A (default)

Current value at the point on the diode I-V curve that the block uses for calculations. Depending on the **Parameterization** value, the block uses this parameter to calculate either  $N$  or  $IS$ .

**Dependencies**

To enable this parameter, set **Diode model** to Exponential and **Parameterization** to Use an I-V data point and  $IS$  or Use an I-V data point and  $N$ .

**Voltage V1 — Voltage value**

0.6 V (default)

Voltage value at the point on the diode I-V curve that the block uses for calculations.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential and **Parameterization** to Use an I-V data point and  $IS$  or Use an I-V data point and  $N$ .

**Ohmic resistance, RS — Ohmic resistance**

0 Ohm (default)

Series diode connection resistance.

**Dependencies**

To enable this parameter, set **Diode model** to Exponential.

**Measurement temperature — Measurement temperature**

25 degC (default)

Temperature  $T_{m1}$  at which  $IS$  or the I-V curve was measured.

**Forward currents, If(Tj,Vf) — Vector of forward currents**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12] A (default) | nonnegative vector

Forward currents. This parameter must be a vector of at least three nonnegative elements.

**Dependencies**

To enable this parameter, set **Table type** to Table in  $If(Tj,Vf)$ .

**Forward voltages, Vf(Tj,If) — Vector of forward voltages**

[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85; .58, .68, .75, 1.1, 1.38, 1.77, 2.27, 2.7] V (default) | nonnegative vector

Forward voltages. This parameter must be a vector of at least three nonnegative elements.

**Dependencies**

To enable this parameter, set **Table type** to Table in  $Vf(Tj,If)$ .

**Junction temperatures, Tj — Vector of junction temperatures**

[25, 125] degC (default)

Vector of junction temperatures.

If the size of the vector is equal to 1, the diode characteristics does not depend on the temperature.

**Dependencies**

To enable this parameter, set **Diode model** to Tabulated I-V curve.

**Forward voltages, Vf — Vector of forward voltages**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Vector of forward voltages. This parameter must be a vector of at least three nonnegative values.

**Dependencies**

To enable this parameter, set **Table type** to Table in If(Tj,Vf).

**Forward currents, If — Vector of forward currents**

[.1, .2, .5, 1, 2, 4, 7, 10] A (default)

Vector of forward currents. This parameter must be a vector of at least three nonnegative values.

**Dependencies**

To enable this parameter, set **Table type** to Table in Vf(Tj,If).

**Number of series diodes — Number of diodes connected in series**

1 (default)

Number of diodes connected in series between the + and - block ports. Multiple diodes are not modeled. Rather, each diode has all voltage-related quantities scaled by the factor that you specify.

**Number of parallel diodes — Number of parallel diodes**

1 (default)

Number of parallel diodes, or number of parallel paths formed by series-connected diodes, between the + and - block ports. Multiple diodes are not modeled. Rather, each diode has all current-related quantities scaled by the factor that you specify.

**Breakdown****Zener resistance — Zener resistance**

0.3 Ohm (default)

Resistance of the diode when the voltage is less than the **Reverse breakdown voltage** value.

**Dependencies**

To enable this parameter, set **Diode model** to Piecewise linear.

**Reverse breakdown voltage — Reverse breakdown voltage**

inf V (default)

Reverse voltage below which to model the rapid increase in conductance that occurs at diode breakdown. The default value is Inf V, which effectively omits reverse breakdown from the model.

**Dependencies**

To enable this parameter, set **Diode model** to Piecewise linear or Exponential.

**Capacitance**

To enable these parameters, either set **Modeling option** to No thermal port or **Fidelity level** to Include capacitance and charge dynamics.

**Parameterization — Modeling junction capacitance**

Fixed or zero junction capacitance (default) | Use C-V curve data points | Use parameters CJ0, VJ, M & FC

Method for modeling the junction capacitance:

- Fixed or zero junction capacitance — Model the junction capacitance as a fixed value.
- Use C-V curve data points — Specify measured data at three points on the diode C-V curve.
- Use parameters CJ0, VJ, M & FC — Specify zero-bias junction capacitance, junction potential, grading coefficient, and forward-bias depletion capacitance coefficient.

**Junction capacitance — Junction capacitance**

0 pF (default)

Fixed junction capacitance value.

**Dependencies**

To enable this parameter, set **Parameterization** to Fixed or zero junction capacitance.

**Reverse bias voltages [VR1 VR2 VR3] — Vector of reverse bias voltage values**

[.1, 10, 100] V (default)

Vector of the reverse bias voltage values at the three points on the diode C-V curve that the block uses to calculate  $CJ0$ ,  $VJ$ , and  $M$ .

**Dependencies**

To enable this parameter, set **Parameterization** to Use C-V curve data points.

**Corresponding capacitances [C1 C2 C3] — Vector of capacitance values**

[3.5, 1, .4] pF (default)

Vector of the capacitance values at the three points on the diode C-V curve that the block uses to calculate  $CJ0$ ,  $VJ$ , and  $M$ .

**Dependencies**

To enable this parameter, set **Parameterization** to Use C-V curve data points.

**Zero-bias junction capacitance, CJ0 — Zero-bias junction capacitance**

5 pF (default)

Value of the capacitance placed in parallel with the conduction current term.

**Dependencies**

To enable this parameter, set **Parameterization** to Use parameters CJ0, VJ, M & FC.

**Junction potential, VJ — Junction potential**

1 V (default)

The junction potential.

**Dependencies**

To enable this parameter, set **Parameterization** to Use parameters CJ0, VJ, M & FC.

**Grading coefficient, M — Grading coefficient**

0.5 (default)

Grading coefficient.

**Dependencies**

To enable this parameter, set **Parameterization** to Use parameters CJ0, VJ, M & FC.

**Capacitance coefficient, FC — Capacitance coefficient**

0.5 (default)

Fitting coefficient that quantifies the decrease of the depletion capacitance with applied voltage.

**Dependencies**

To enable this parameter, set **Parameterization** to Use parameters CJ0, VJ, M & FC.

**Charge dynamics — Charge dynamics parameterization**

Do not model charge dynamics (default) | Use peak reverse current and stretch factor | Use peak reverse current and reverse recovery time | Use peak reverse current and reverse recovery charge | Use peak reverse current and reverse recovery energy | Use transit time and carrier lifetime

Select one of the following methods for charge dynamics parameterization:

- Do not model charge dynamics — Do not include charge dynamics modeling. This is the default method.
- Use peak reverse current and stretch factor — Model charge dynamics by providing values for peak reverse current  $i_{RM}$  and stretch factor  $\lambda$  plus information on the initial forward current and rate of change of current used in the test circuit when measuring  $i_{RM}$  and  $t_{rr}$ .
- Use peak reverse current and reverse recovery time — Model charge dynamics by providing values for peak reverse current  $i_{RM}$  and reverse recovery time  $t_{rr}$  plus information on the initial forward current and rate of change of current used in the test circuit when measuring  $i_{RM}$  and  $t_{rr}$ . Use this option if the manufacturer datasheet does not provide values for transit time  $TT$  and carrier lifetime  $\tau$ .
- Use peak reverse current and reverse recovery charge — Model charge dynamics by providing values for peak reverse current  $i_{RM}$  and reverse recovery charge  $Q_{rr}$  plus information on the initial forward current and rate of change of current used in the test circuit when measuring  $i_{RM}$  and  $t_{rr}$ .
- Use peak reverse current and reverse recovery energy — Model charge dynamics by providing values for peak reverse current  $i_{RM}$  and reverse recovery energy  $E_{rec}$  plus information on the initial forward current and rate of change of current used in the test circuit when measuring  $i_{RM}$ .

- Use transit time and carrier lifetime — Model charge dynamics by providing values for transit time  $TT$  and carrier lifetime  $\tau$ .

### Peak reverse current, $i_{RM}$ — Peak reverse current

-7.15 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Use peak reverse current and stretch factor, Use peak reverse current and reverse recovery time, Use peak reverse current and reverse recovery charge, or Use peak reverse current and reverse recovery energy.

### Initial forward current when measuring $i_{RM}$ — Initial forward current when measuring $i_{RM}$

4 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Use peak reverse current and stretch factor, Use peak reverse current and reverse recovery time, Use peak reverse current and reverse recovery charge, or Use peak reverse current and reverse recovery energy.

### Rate of change of current when measuring $i_{RM}$ — Rate of change of current when measuring $i_{RM}$

-750 A/ $\mu$ s (default) | negative scalar

Rate of change of current when measuring peak reverse current. This value must be less than zero.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Use peak reverse current and stretch factor, Use peak reverse current and reverse recovery time, Use peak reverse current and reverse recovery charge, or Use peak reverse current and reverse recovery energy.

### Reverse recovery time stretch factor — Reverse recovery time stretch factor

3 (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . This value must be greater than 1. The default value is 3.

Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

To enable this parameter, set **Charge dynamics** to Use peak reverse current and stretch factor.

**Reverse recovery time, trr – Reverse recovery time**

115 (default)

Time between the point where the current initially goes to zero when the diode turns off, and the point where the current falls to less than ten percent of the peak reverse current. The default value is 115 ns.

The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, iRM** parameter divided by the value of the **Rate of change of current when measuring iRM** parameter.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use peak reverse current and reverse recovery time.

**Reverse recovery charge, Qrr – Reverse recovery charge**

1500 s\*μA (default)

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use peak reverse current and reverse recovery charge.

**Diode turn-off voltage when measuring Erec – Diode turn-off voltage when measuring Erec**

-600 V (default)

Voltage between the diode in steady-state.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use peak reverse current and reverse recovery energy.

**Stray inductance when measuring Erec – Stray inductance when measuring Erec**

150 nH (default)

Total unintended inductance in the measurement circuit. The block uses this value to calculate **Reverse recovery energy, Erec**.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use peak reverse current and reverse recovery energy.

**Reverse recovery energy, Erec — Reverse recovery energy**

0.03 J (default)

Total switching losses due to the diode reverse recovery.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use peak reverse current and reverse recovery energy.

**Transit time, TT — Transit time**

50 ns (default)

Measure of how long it takes carriers to cross the diode junction.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use transit time and carrier lifetime.

**Carrier lifetime, tau — Carrier lifetime**

100 ns (default)

Measure of how long it takes for the carriers to dissipate once the diode is no longer conducting. The default value is 100 ns.

**Dependencies**

To enable this parameter, set **Charge dynamics** to Use transit time and carrier lifetime.

**Reverse Recovery Loss**

To enable these parameters, set **Modeling option** to Show thermal port and **Fidelity level** to Ideal switching.

**Reverse recovery loss model — Model for reverse recovery loss**

Fixed loss (default) | Tabulated loss

Whether to model fixed or tabulated reverse recovery losses.

**Reverse recovery loss — Reverse recovery loss**

0 J (default)

Dissipated energy in each turn-off event, regardless of the state of the diode before or after the switching event.

**Dependencies**

To enable this parameter, set **Reverse recovery loss model** to Fixed loss.

**Reverse recovery loss table, Erec(Tj, If) — Reverse recovery loss**

zeros(2, 3) J (default)

Dissipated energy in function of the forward current,  $I_f$ , just before the switching event, and the final off-state voltage once the diode is in off state.

**Dependencies**

To enable this parameter, set **Reverse recovery loss model** to Tabulated loss.

**Temperature vector for recovery loss table,  $T_j$  – Temperature vector for recovery loss table**

[298.15, 398.15] K (default)

Temperature vector used in the tabulation of the reverse recovery loss.

**Dependencies**

To enable this parameter, set **Reverse recovery loss model** to Tabulated loss.

**Forward current vector for recovery loss table,  $I_f$  – Forward current vector for recovery loss table**

[.1, 1, 10] A (default)

Forward current vector used in the tabulation of the reverse recovery loss.

**Dependencies**

To enable this parameter, set **Reverse recovery loss model** to Tabulated loss.

**Turn-off voltage when measuring recovery loss,  $V_{rec}$  – Turn-off voltage when measuring recovery loss**

10 V (default)

Voltage between the diode in steady-state when measuring recovery loss.

**Dependencies**

To enable this parameter, set **Reverse recovery loss model** to Tabulated loss.

**Filter time constant for voltage and current values in recovery loss table – Filter time constant for voltage and current values in recovery loss table**

1 / 1000 / 100 s (default)

Filter time constant for voltage and current values in the recovery loss table. To ensure the value used in the lookup table is close enough to the instantaneous value, specify a value that is lower than the fastest switching period.

**Dependencies**

To enable this parameter, set **Reverse recovery loss model** to Tabulated loss.

**Temperature Dependence**

This section is applicable to Exponential and Tabulated I-V curve diode models only.

This table shows how the visibility of **Temperature Dependence** setting depends on how you configure the **Diode model** parameter in the **Main** setting and whether you expose the thermal port. To learn how to read this table, see “Parameter Dependencies” on page A-2

### Parameterization — Temperature dependence parameterization

None - Use characteristics at parameter measurement temperature (default) | Use an I-V data point at second measurement temperature | Specify saturation current at second measurement temperature | Specify the energy gap EG

Select one of the following methods for temperature dependence parameterization:

- None - Use characteristics at parameter measurement temperature — Temperature dependence is not modeled, or the model is simulated at the measurement temperature  $T_{m1}$  (as specified by the **Measurement temperature** parameter on the **Main** tab). This is the default method.
- Use an I-V data point at second measurement temperature T2 — If you select this option, you specify a second measurement temperature  $T_{m2}$ , and the current and voltage values at this temperature. The model uses these values, along with the parameter values at the first measurement temperature  $T_{m1}$ , to calculate the energy gap value.
- Specify saturation current at second measurement temperature T2 — If you select this option, you specify a second measurement temperature  $T_{m2}$ , and saturation current value at this temperature. The model uses these values, along with the parameter values at the first measurement temperature  $T_{m1}$ , to calculate the energy gap value.
- Specify the energy gap EG — Specify the energy gap value directly.

### Current I1 at second measurement temperature — Current I1 at second measurement temperature

0.0245 A (default)

Specify the diode current  $I1$  value when the voltage is  $V1$  at the second measurement temperature.

#### Dependencies

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature.

### Voltage V1 at second measurement temperature — Voltage V1 at second measurement temperature

0.5 V (default)

Specify the diode voltage  $V1$  value when the current is  $I1$  at the second measurement temperature.

#### Dependencies

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature.

**Saturation current,  $I_S$ , at second measurement temperature — Saturation current,  $I_S$ , at second measurement temperature**

1.25e-7 A (default)

Specify the saturation current  $I_S$  value at the second measurement temperature.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify saturation current at second measurement temperature.

**Second measurement temperature — Second measurement temperature**

125 °C (default)

Specify the value for the second measurement temperature.

**Dependencies**

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature or Specify saturation current at second measurement temperature.

**Energy gap parameterization — Energy gap parameterization**

Use nominal value for silicon (EG=1.11eV) (default) | Use nominal value for 4H-SiC silicon carbide (EG=3.23eV) | Use nominal value for 6H-SiC silicon carbide (EG=3.00eV) | Use nominal value for germanium (EG=0.67eV) | Use nominal value for gallium arsenide (EG=1.43eV) | Use nominal value for selenium (EG=1.74eV) | Use nominal value for Schottky barrier diodes (EG=0.69eV) | Specify a custom value

Select a value for the energy gap from a list of predetermined options, or specify a custom value:

- Use nominal value for silicon (EG=1.11eV) — This is the default.
- Use nominal value for 4H-SiC silicon carbide (EG=3.23eV)
- Use nominal value for 6H-SiC silicon carbide (EG=3.00eV)
- Use nominal value for germanium (EG=0.67eV)
- Use nominal value for gallium arsenide (EG=1.43eV)
- Use nominal value for selenium (EG=1.74eV)
- Use nominal value for Schottky barrier diodes (EG=0.69eV)
- Specify a custom value — If you select this option, the **Energy gap, EG** parameter appears in the dialog box, to let you specify a custom value for  $EG$ .

**Dependencies**

To enable this parameter, set **Parameterization** to Specify the energy gap  $EG$ .

**Energy gap,  $EG$  — Energy gap**

1.11 eV (default)

Specify a custom value for the energy gap,  $EG$ .

**Dependencies**

To enable this parameter, set **Energy gap parameterization** to Specify a custom value.

### Saturation current temperature exponent parameterization — Saturation current temperature exponent parameterization

Use nominal value for pn-junction diode (XTI=3) (default) | Use nominal value for Schottky barrier diode (XTI=2) | Specify a custom value

Select one of the following options to specify the saturation current temperature exponent value:

- Use nominal value for pn-junction diode (XTI=3) — This is the default.
- Use nominal value for Schottky barrier diode (XTI=2)
- Specify a custom value — If you select this option, the **Saturation current temperature exponent, XTI** parameter appears in the dialog box, to let you specify a custom value for *XTI*.

#### Dependencies

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature, Specify saturation current at second measurement temperature, or Specify the energy gap, EG.

### Saturation current temperature exponent, XTI — Saturation current temperature exponent

3 (default)

Specify a custom value for the saturation current temperature exponent, *XTI*.

#### Dependencies

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature, Specify saturation current at second measurement temperature, or Specify the energy gap, EG and **Saturation current temperature exponent parameterization** to Specify a custom value.

### Reverse breakdown voltage temperature coefficient, dBV/dT — Reverse breakdown voltage temperature coefficient

0 V/K (default)

Modulate the reverse breakdown voltage *BV*. If you define the reverse breakdown voltage *BV* as a positive quantity, a positive value for *TCV* implies that the magnitude of the reverse breakdown voltage decreases with temperature.

#### Dependencies

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature, Specify saturation current at second measurement temperature, or Specify the energy gap, EG.

### Device simulation temperature — Device simulation temperature

25 °C (default)

Specify the value for the temperature  $T_s$ , at which the device is to be simulated.

#### Dependencies

To enable this parameter, set **Parameterization** to Use an I-V data point at second measurement temperature, Specify saturation current at second measurement temperature, or Specify the energy gap, EG.

## Faults

### Enable faults — Whether to enable faults

Off (default) | On

Select On to enable faults modeling and expose parameters that allow you to select the reporting method and specify the trigger mechanism.

### Reporting when a fault occurs — Reporting when a fault occurs

None (default) | Warn | Error

Simulation reporting when a fault occurs:

- None — Does not generate a warning or an error.
- Warn — Generates a warning.
- Error — The simulation stops and generates an error.

### Dependencies

To enable this parameter, set **Enable faults** to On.

### Fault mode — Failure category

Open (default) | Short | Parameter shift

Specify the failure mode of the Diode block:

- Open — Failure due to metallization burnout.
- Short — Failure due to punch-through.
- Parameter shift — Failure due to aging.

### Dependencies

To enable this parameter, set **Enable faults** to On.

### Fault transition time constant — Fault transition time constant

1e-3 s (default)

Time constant for transitioning to faulted state.

### Dependencies

To enable this parameter, set **Enable faults** to On.

### Faulted series resistance — Faulted series resistance

1000 Ohm (default)

Series resistance in faulted state.

### Dependencies

To enable this parameter, set **Enable faults** to On and **Fault mode** to Open.

### Faulted parallel conductance — Faulted series resistance

1000 1/Ohm (default)

Parallel conductance in faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Fault mode** to Short.

**Faulted forward voltage — Faulted forward voltage**

0.6 V (default)

Forward voltage in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Piecewise linear.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted on resistance — Faulted on resistance**

0.3 Ohm (default)

On resistance in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Piecewise linear.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted off conductance — Faulted off conductance**

1e-8 S (default)

Off conductance in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Piecewise linear or Tabulated I-V curve.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted zener resistance — Faulted zener resistance**

0.3 Ohm (default)

Off conductance in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Piecewise linear.
- **Enable faults** to On.

- **Fault mode** to Parameter shift.

**Faulted reverse breakdown voltage — Faulted reverse breakdown voltage**

$\infty$  V (default)

Reverse breakdown voltage in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Piecewise linear or Exponential.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted currents, [I1 I2] — Faulted currents**

[.0137, .545] A (default)

$I1$  and  $I2$  currents in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.
- **Parameterization** to Use two I-V curve data points.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted voltages, [V1 V2] — Faulted voltages**

[.6, .7] V (default)

$V1$  and  $V2$  voltages in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.
- **Parameterization** to Use two I-V curve data points.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted ohmic resistance,  $R_S$  — Faulted voltages**

0 Ohm (default)

Ohmic resistance in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.
- **Enable faults** to On.

- **Fault mode** to Parameter shift.

#### **Faulted saturation current, IS — Faulted saturation current**

1e-12 A (default)

Saturation current in faulted state.

##### **Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.
- **Parameterization** to Use parameters IS and N or Use an I-V data point and IS.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

#### **Faulted emission coefficient, N — Faulted emission coefficient**

1 (default)

Emission coefficient in faulted state.

##### **Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.
- **Parameterization** to Use parameters IS and N or Use an I-V data point and N.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

#### **Faulted current, I1 — Faulted current**

0.0137 A (default)

Current in faulted state.

##### **Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.
- **Parameterization** to Use an I-V data point and IS or Use an I-V data point and N.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

#### **Faulted voltage, V1 — Faulted voltage**

0.6 V (default)

Voltage in faulted state.

##### **Dependencies**

To enable this parameter, set:

- **Diode model** to Exponential.

- **Parameterization** to Use an I-V data point and IS or Use an I-V data point and N.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted forward currents,  $I_f(T_j, V_f)$  — Faulted forward currents**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12]  
A (default)

Forward currents,  $I_f(T_j, V_f)$ , in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Tabulated I-V curve.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted forward voltages,  $V_f$  — Faulted forward currents**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Forward currents,  $V_f$ , in faulted state.

**Dependencies**

To enable this parameter, set:

- **Diode model** to Tabulated I-V curve.
- **Enable faults** to On.
- **Fault mode** to Parameter shift.

**Faulted capacitance and charge as percentage of unfaulted — Faulted capacitance and charge as percentage of unfaulted**

100 (default)

Capacitance and charge in faulted state as percentage of unfaulted.

**Dependencies**

To enable this parameter, set **Enable faults** to On.

**Enable temporal fault trigger — Whether to enable a temporal fault trigger**

Off (default) | On

Whether to enable a temporal fault trigger.

**Dependencies**

To enable this parameter, set **Enable faults** to On.

**Simulation time for fault event — Time before entering faulted state**

inf s (default)

Simulation time at which you want the block to enter the faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Enable temporal fault trigger** to On.

**Enable behavioral fault trigger — Whether to enable a behavioral fault trigger**

Off (default) | On

Whether to enable a behavioral fault trigger.

**Dependencies**

To enable this parameter, set **Enable faults** to On.

**Maximum permissible reverse voltage — Maximum permissible reverse voltage**

inf V (default) | positive scalar

Maximum reverse voltage above which a fault may be triggered.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Enable behavioral fault trigger** to On.

**Number of events to fail when exceeding voltage — Number of events to fail when exceeding voltage**

1 (default) | positive scalar integer

Number of times the diode must exceed the reverse voltage threshold before a fault is triggered.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Enable behavioral fault trigger** to On.

**Maximum permissible current — Current threshold to fault transition**

inf A (default) | positive scalar

Maximum permissible current value. If the current exceeds this value for longer than the value of the **Time to fail when exceeding current** parameter, then the block enters the faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Enable behavioral fault trigger** to On.

**Time to fail when exceeding current — Time to fail when exceeding current**

1 s (default) | positive scalar

Amount of time that the current must continuously exceed the maximum permissible current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Enable behavioral fault trigger** to On.

**Maximum diode recovery, dV/dt — Diode recovery threshold**

inf V/s (default) | positive scalar

Maximum diode recovery.

### Dependencies

To enable this parameter, set **Enable faults** to On and **Enable behavioral fault trigger** to On.

### Maximum permissible temperature — Temperature threshold to fault transition

inf K (default) | positive scalar

Maximum permissible temperature value. If the temperature exceeds this value for longer than the value of the **Time to fail when exceeding temperature** parameter, then the block enters the faulted state.

### Dependencies

To enable this parameter, set:

- **Diode model** to Piecewise linear.
- **Enable faults** to On.
- **Enable behavioral fault trigger** to On.

### Time to fail when exceeding temperature — Time to fail when exceeding current

1 s (default) | positive scalar

Amount of time that the temperature must continuously exceed the maximum permissible temperature before a behavioral fault is triggered.

### Dependencies

To enable this parameter, set:

- **Diode model** to Piecewise linear.
- **Enable faults** to On.
- **Enable behavioral fault trigger** to On.

### Thermal Port

Use the thermal port to simulate the effects of generated heat and device temperature. For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

## Discrete PI Controller

Discrete-time PI controller with external anti-windup input

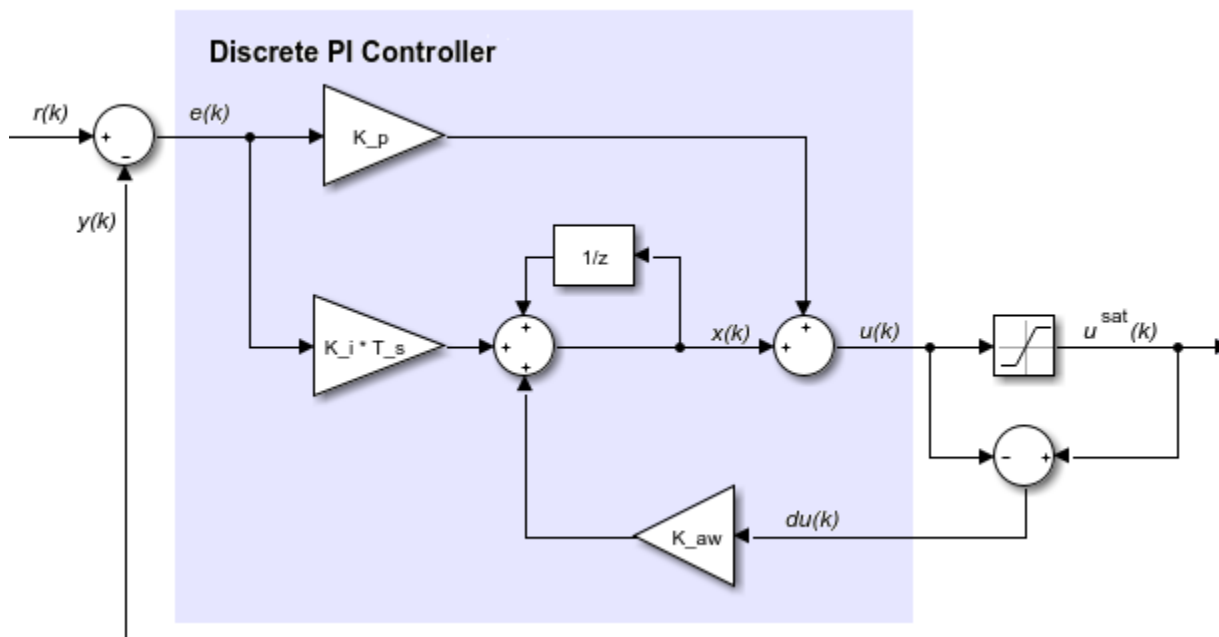

**Library:** Simscape / Electrical / Control / General Control

### Description

The Discrete PI Controller block implements discrete PI control with external anti-windup input.

This diagram is the equivalent circuit for the controller with external anti-windup input.

### Equations

The Discrete PI Controller block calculates the control signal using the backward Euler discretization method:

$$u(k) = \left[ K_p + (K_i + du(k)K_{aw}) \frac{T_s z}{z-1} \right] e(k),$$

where

- $u$  is the control signal.
- $K_p$  is the proportional gain coefficient.
- $K_i$  is the integral gain coefficient.

- $K_{aw}$  is the anti-windup gain coefficient.
- $T_s$  is the sampling period.
- $e$  is the error signal.

To prevent excessive overshoot, the block can use back calculation to implement an external anti-windup mechanism. It inputs  $du(k)$ , the difference between the saturated control signal,  $u^{sat}(k)$ , and the calculated unsaturated control signal,  $u(k)$ . It then multiplies the difference by the anti-windup coefficient and adds the amplified signal from the integral gain.

## Ports

### Input

#### **e — Error signal**

scalar

Error signal,  $e(k)$ , obtained as the difference between the reference,  $r(k)$ , and measurement,  $y(k)$ , signals.

Data Types: single | double

#### **du — Control signal saturation**

scalar

Difference,  $du(k)$ , between the saturated  $u^{sat}(k)$  and the unsaturated control signals,  $u(k)$ . If  $du(k)$  is zero, the anti-windup is disabled.

Description

Data Types: single | double

#### **Reset — Integrator gain reset**

scalar

External reset (rising edge) signal for the integrator.

Data Types: single | double

### Output

#### **u — Control signal**

scalar

Control signal,  $u(k)$ .

Data Types: single | double

## Parameters

#### **Proportional gain — $K_p$**

1 (default) | positive scalar

Proportional gain,  $K_p$ , of the PI controller.

**Integral gain –  $K_i$** 

1 (default) | positive scalar

Integral gain,  $K_i$ , of the PI controller.**Anti-windup gain –  $K_{aw}$** 

1 (default) | positive scalar

Anti-windup gain,  $K_{aw}$ , of the PI controller.**Integrator initial condition – Initial integrator value**

0 (default) | scalar

Value of the integrator at simulation start time.

**Sample time (-1 for inherited) – Sampling interval**

-1 (default) | default value or a positive number

Time interval between samples. If the block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

## Parameters

#### **Proportional gain – $K_p$**

1 (default) | positive scalar

Proportional gain,  $K_p$ , of the PI controller.

#### **Integral gain – $K_i$**

1 (default) | positive scalar

Integral gain,  $K_i$ , of the PI controller.

#### **Upper saturation limit – $B$**

5 (default) | scalar greater than the value of the **Lower saturation limit** parameter

Upper limit,  $B$ , of the output for the PI controller.

#### **Lower saturation limit – $A$**

-5 (default) | scalar

Lower limit,  $A$ , of the output for the PI controller.

#### **Integrator initial condition – Initial integrator value**

0 (default) | scalar

Value of the integrator at simulation start time.

### **Sample time (-1 for inherited) – Block sample time**

-1 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

## DPDT Switch

Double-pole double-throw switch

**Library:** Simscape / Electrical / Switches & Breakers

### Description

The DPDT Switch block models a double-pole double-throw switch:

- When the switch is closed, ports **p1** and **p2** are connected to ports **n12** and **n22**, respectively.
- When the switch is open, ports **p1** and **p2** are connected to ports **n11** and **n21**, respectively.

Closed connections are modeled by a resistor with value equal to the **Closed resistance** parameter value. Open connections are modeled by a resistor with value equal to the reciprocal of the **Open conductance** parameter value.

If the **Threshold width** parameter is set to zero, the switch is closed if the voltage presented at the **vT** control port exceeds the value of the **Threshold** parameter.

If the **Threshold width** parameter is greater than zero, then switch conductance  $G$  varies smoothly between off-state and on-state values:

$$G = \frac{x}{R_{closed}} + (1 - x)G_{open}$$

$$\lambda = \frac{vT - \text{Threshold}}{\text{Threshold width}}$$

$$x = \begin{cases} 0 & \text{for } \lambda \leq 0 \\ 3\lambda^2 - 2\lambda^3 & \text{for } 0 < \lambda < 1 \\ 1 & \text{for } \lambda \geq 1 \end{cases}$$

The block uses the function  $3\lambda^2 - 2\lambda^3$  because its derivative is zero for  $\lambda = 0$  and  $\lambda = 1$ .

Defining a small positive **Threshold width** can help solver convergence in some models, particularly if the control port signal  $vT$  varies continuously as a function of other network variables. However,

defining a nonzero threshold width precludes the solver making use of switched linear optimizations. Therefore, if the rest of your network is switched linear, set **Threshold width** to zero.

Optionally, you can add a delay between the point at which the voltage at **vT** passes the threshold and the switch opening or closing. To enable the delay, on the **Dynamics** tab, set the **Model dynamics** parameter to Model turn-on and turn-off times.

## d-q Voltage Limiter

Limit voltage in the rotor direct-quadrature reference frame

**Library:** Simscape / Electrical / Control / Protection

### Description

The d-q Voltage Limiter block implements a voltage limiter in the rotor direct-quadrature ( $d$ - $q$ ) reference frame.

### Equations

The figure shows the circle that limits the  $d$ - $q$  voltage vector.

That is,

$$\sqrt{v_d^2 + v_q^2} \leq V_{ph\_max}$$

where:

- $v_d$  is the  $d$ -axis voltage.
- $v_q$  is the  $q$ -axis voltage.
- $V_{ph\_max}$  is the maximum phase voltage.

Three cases of voltage limiting are possible:

- $d$ -axis prioritization
- $q$ -axis prioritization
- $d$ - $q$  equivalence

If one axis is prioritized over the other axis, the constrained or saturated voltages are defined as

$$v_1^{sat} = \min(\max(v_1^{unsat}, -V_{ph\_max}), V_{ph\_max})$$

and

$$v_2^{sat} = \min(\max(v_2^{unsat}, -V_{2\_max}), V_{2\_max}),$$

where:

- $v_{2\_max} = \sqrt{(V_{ph\_max})^2 - (v_1^{sat})^2}$
- $v_1$  is voltage of the prioritized axis.
- $v_2$  is voltage of the nonprioritized axis.

If neither axis is prioritized, the constrained voltages are defined as

$$v_d^{sat} = \min(\max(v_d^{unsat}, -V_{d\_max}), V_{d\_max})$$

and

$$v_q^{sat} = \min(\max(v_q^{unsat}, -V_{q\_max}), V_{q\_max}),$$

where:

- $V_{d\_max} = \frac{V_{ph\_max}|v_d^{unsat}|}{\sqrt{(v_d^{unsat})^2 + (v_q^{unsat})^2}}$
- $V_{q\_max} = \frac{V_{ph\_max}|v_q^{unsat}|}{\sqrt{(v_d^{unsat})^2 + (v_q^{unsat})^2}}$

## Dynamic Load

Dynamic load for DC or AC supply

**Library:** Simscape / Electrical / Passive

### Description

The Dynamic Load block implements a dynamic load for a DC or AC supply.

If you set the **Load type** parameter to DC:

- The consumed power of the block is equal to the **P** port as long as it is greater than the value of the **Minimum consumed power** parameter and the voltage from the DC supply is equal to or greater than the value specified for the **Minimum supply voltage** parameter.
- When the voltage from the DC supply drops below the **Minimum supply voltage**, the load behaviour changes and the block acts as a resistive load. If the supply voltage becomes negative, the block acts as an open circuit conductance.

To ensure smooth transitions between these behaviours, the block uses a third-order polynomial spline with continuous derivatives. You can specify the width of this transition using the **Transition voltage width** parameter.

If you set the **Load type** parameter to AC, this table shows the relationship between the voltage from the AC supply,  $V$ , the active power at the **P** port,  $P_{in}$ , and the consumed active power of the block,  $P_{actual}$ :

Applicable Range of $V$ Values	Applicable Range of $P_{in}$ Values	Corresponding Consumed Active Power
$V > V_{min}$	$P_{in} > P_{min}$	$P_{actual} = P_{in}$
	$P_{in} < P_{min}$	$P_{actual} = P_{min}$
$V < V_{min}$	$P_{in} > P_{min}$	The block models a load with an impedance equal to: $R = V_{min}^2 \frac{P_{actual}}{P_{actual}^2 + Q_{actual}^2}$ $X = V_{min}^2 \frac{Q_{actual}}{P_{actual}^2 + Q_{actual}^2}$ $Z = \sqrt{R^2 + X^2}$
	$P_{in} < P_{min}$	$P_{actual} = P_{min}$

Where:

- $V_{min}$  is the value of the “Minimum supply voltage (RMS)” on page 1-0 parameter.
- $P_{min}$  is the value of the “Minimum active power” on page 1-0 parameter.
- $P_{actual}$  is the consumed active power of the Dynamic Load block.
- $Q_{actual}$  is the consumed reactive power of the Dynamic Load block.

The consumed reactive power of the block is equal to the **Q** port as long as the voltage from the AC supply is equal to or greater than the value specified for the **Minimum supply voltage (RMS)** parameter. Otherwise, the block models a load with an impedance equal to:

$$R = V_{min}^2 \frac{P_{actual}}{P_{actual}^2 + Q_{actual}^2}$$

$$X = V_{min}^2 \frac{Q_{actual}}{P_{actual}^2 + Q_{actual}^2}$$

$$Z = \sqrt{R^2 + X^2}$$

.

## Faults

The Dynamic Load block allows you to model an electrical fault as an open circuit. The block can trigger fault events at a specific time.

You can also choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Load-Flow Analysis

If the block is in a network that is compatible with the frequency-time simulation mode, you can perform a load-flow analysis on the network. A load-flow analysis provides steady-state values that you can use to initialize a machine.

For more information, see “Perform a Load-Flow Analysis Using Simscape Electrical” and “Frequency and Time Simulation Mode”.

**Minimum supply voltage – Minimum DC supply voltage**

20 V (default) | scalar

Minimum voltage the DC supply needs to give the block to act as a constant power load.

**Dependencies**

To enable this parameter, set **Load Type** to DC.

**Minimum consumed power – Minimum consumed power**

1e-3 W (default) | scalar

Minimum amount of power consumed by the block.

**Dependencies**

To enable this parameter, set **Load Type** to DC.

**Reverse conductance – Reverse conductance**

1e-6 S (default) | scalar

Value of the reverse conductance when the supply voltage becomes negative.

**Dependencies**

To enable this parameter, set **Load Type** to DC.

**Transition voltage width – Transition voltage width**

1e-3 V (default) | scalar

Transition voltage width. This value is used to ensure smooth transitions between the block's behaviours when the supply voltage drops below the **Minimum supply voltage** or becomes negative.

**Dependencies**

To enable this parameter, set **Load Type** to DC.

**Rated frequency – Rated frequency**

60 Hz (default) | scalar

Rated frequency.

#### Dependencies

To enable this parameter, set **Load Type** to AC.

#### Minimum supply voltage (RMS) — Minimum AC supply voltage

200 V (default) | scalar

Minimum voltage, in RMS, that the AC supply needs to give the block to act as a dynamic load.

#### Dependencies

To enable this parameter, set **Load Type** to AC.

#### Minimum active power — Minimum active power

1e-3 W (default) | scalar

Minimum active power of the block.

#### Dependencies

To enable this parameter, set **Load Type** to AC.

#### Faults

#### Enable open circuit fault — Whether to enable fault modeling

Off (default) | On

Select **On** to enable fault modeling and expose the associated parameters in the **Faults** section, which enables you to select the reporting method and specify the time at which the fault triggers.

#### Reporting when a fault occurs — Whether to issue assertion when fault occurs

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- **None** — The block does not issue an assertion.
- **Warn** — The block issues a warning.
- **Error** — Simulation stops with an error.

#### Dependencies

To enable this parameter, set **Enable open circuit fault** to On.

#### Simulation time for fault event — Time before entering faulted state

1 s (default) | scalar

Simulation time when the block enters the faulted state.

#### Dependencies

To enable this parameter, set **Enable open circuit fault** to On.

#### Open-circuit conductance — Open-circuit conductance

1e-4 S (default) | scalar

Conductance during the open-circuit state.

### **Dependencies**

To enable this parameter, set **Enable open circuit fault** to On.

# Dynamic Load (Three-Phase)

Balanced three-phase dynamic load

**Library:** Simscape / Electrical / Passive

## Description

The Dynamic Load (Three-Phase) block models a balanced dynamic load for balanced three-phase supplies.

This table shows the relationship between the voltage from the supply,  $V$ , the active power at the **P** port,  $P_{in}$ , and the consumed active power of the block,  $P_{actual}$ .

Applicable Range of $V$ Values	Applicable Range of $P_{in}$ Values	Corresponding Consumed Active Power
$V > V_{min}$	$P_{in} > P_{min}$	$P_{actual} = P_{in}$
	$P_{in} < P_{min}$	$P_{actual} = P_{min}$
$V < V_{min}$	$P_{in} > P_{min}$	The block models a load with an impedance equal to: $R = V_{min}^2 \frac{P_{actual}}{P_{actual}^2 + Q_{actual}^2}$ $X = V_{min}^2 \frac{Q_{actual}}{P_{actual}^2 + Q_{actual}^2}$ $Z = \sqrt{R^2 + X^2}$
	$P_{in} < P_{min}$	$P_{actual} = P_{min}$

Where:

- $V_{min}$  is the value of the “Minimum supply voltage (phase-to-phase RMS)” on page 1-0 parameter.
- $P_{min}$  is the value of the “Minimum active power” on page 1-0 parameter.
- $P_{actual}$  is the consumed active power of the Dynamic Load (Three-Phase) block.
- $Q_{actual}$  is the consumed reactive power of the Dynamic Load (Three-Phase) block.

The consumed reactive power of the block is equal to the **Q** port as long as the voltage from the supply is equal to or greater than the value specified for the **Minimum supply voltage (phase-to-phase RMS)** parameter. Otherwise, the block models a load with an impedance equal to:

$$R = V_{\min}^2 \frac{P_{\text{actual}}}{P_{\text{actual}}^2 + Q_{\text{actual}}^2}$$

$$X = V_{\min}^2 \frac{Q_{\text{actual}}}{P_{\text{actual}}^2 + Q_{\text{actual}}^2}$$

$$Z = \sqrt{R^2 + X^2}$$

## Faults

The Dynamic Load (Three-Phase) block allows you to model an electrical fault as an open circuit. The block can trigger fault events at a specific time.

You can also choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

## Load-Flow Analysis

If the block is in a network that is compatible with the frequency-time simulation mode, you can perform a load-flow analysis on the network. A load-flow analysis provides steady-state values that you can use to initialize a machine.

For more information, see “Perform a Load-Flow Analysis Using Simscape Electrical” and “Frequency and Time Simulation Mode”.

## Limitations

If you connect this block to an inductive node or a current source, you must provide a large parasitic.

## Ports

# Earthing Transformer

Three-phase earthing transformer in zigzag configuration

**Library:** Simscape / Electrical / Passive / Transformers

## Description

The Earthing Transformer block models a three-phase zigzag-connection earthing or grounding transformer. The block allows you to provide an artificial neutral in an ungrounded three-phase power system. The artificial neutral creates a low-impedance path for the zero-sequence current and high-impedance path for the positive-sequence current. To accommodate a phase-to-neutral load, the return path allows a delta-connected supply.

For more information on using a three-phase zigzag-connection earthing or grounding transformer, see “Engineering Applications” on page 1-513

## Equations

This block is implemented in both electrical and magnetic domains, representing the physics of phase windings and magnetic core. The equivalent circuit for the block includes windings, reluctances, and eddy currents.

For a zigzag configuration in magnetic circuit, the  $a$ -,  $b$ -, and  $c$ -phases represent each leg of the magnetic core.

You can obtain the relationship between the electrical and the magnetic properties by applying several mathematical steps based on the magnetic flux conservation rule and on the Hopkinson's law.

For earthing transformers, the couplings between the phases and all the windings are identical. In the equations below:

- $n$  is the number of turns of the winding.
- $R$  is the magnetizing reluctance between phases.
- $R_L$  is the leakage reluctance.
- $L_{eddy}$  is the magnetic inductance due to eddy current losses between phases.

Then the relationship between the inductance matrix in electrical domain and the reluctance matrix in the magnetic domain can be written as:

$$L = \begin{bmatrix} L_{11} & L_{12} & L_{13} \\ L_{21} & L_{22} & L_{23} \\ L_{31} & L_{32} & L_{33} \end{bmatrix} = \begin{bmatrix} n^2\left(\frac{2}{Rl} + \frac{6}{R}\right) & -3\frac{n^2}{R} & -3\frac{n^2}{R} \\ -3\frac{n^2}{R} & n^2\left(\frac{2}{Rl} + \frac{6}{R}\right) & -3\frac{n^2}{R} \\ -3\frac{n^2}{R} & -3\frac{n^2}{R} & n^2\left(\frac{2}{Rl} + \frac{6}{R}\right) \end{bmatrix}$$

The diagonal elements represent the sum of a leakage and magnetizing inductance for each phase, such that:

$$L_l = \frac{2n^2}{Rl}$$

Therefore:

$$R_L = \frac{2n^2}{L_l}$$

$$R = \frac{9n^2}{L_m}$$

$$L_{eddy} = \frac{9n^2}{R_m}$$

**More About****Engineering Applications**

To facilitate grounding and detection of an earth fault, earthing transformers provide a ground path to either an ungrounded "Y" or a delta-connected system. They are typically used to:

- Provide a relatively low impedance path to ground, thereby maintaining the system neutral at or near ground potential.
- Limit the magnitude of transient overvoltages when re-striking ground faults occur.
- Provide a source of ground fault current during line-to-ground faults.
- Permit the connection of phase-to-neutral loads when desired.

# Eddy Current

Eddy current loss representation

**Library:** Simscape / Electrical / Passive

## Description

The Eddy Current block models the effect of eddy currents by generating a magnetomotive force (MMF) that opposes changes in the magnetic flux. In addition, the block models parasitic effects using a series reluctance and a parallel leakage permeance, and thermal effects using an optional thermal port, **H**.

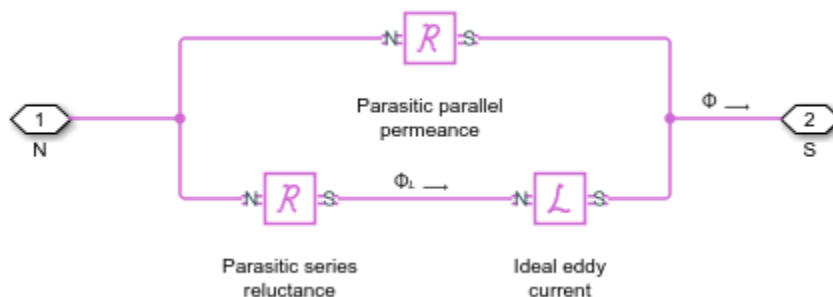

Eddy currents in magnetic core materials are caused by time-varying magnetic fields. These changing field densities induce voltage potentials within the material, causing current to flow in closed loops. Such currents are usually undesired and cause heating of the magnetic material.

Use this block to add eddy current losses in the magnetic domain to a custom transformer or other magnetic component.

The eddy current component is sometimes referred to as magnetic inductance because it is the magnetic-domain analog to an inductor in the electrical domain.

## Equations

This is the equivalent magnetic circuit for the block, including the eddy current path (bottom) and parallel leakage path (top).

In the diagram:

- $\Phi$  is the total flux at the terminals. This flux is the summation of the eddy current loop and the parallel leakage path.
- $\Phi_L$  is the flux through the eddy current loop.

The block calculates the terminal MMF,  $\mathcal{F}$ , and flux,  $\Phi$ , as:

$$\mathcal{F} = G_{\text{eddy}} \frac{d\Phi_L}{dt} + \mathcal{R}\Phi_L$$

$$\Phi = \mathcal{F}P + \Phi_L$$

where:

- $G_{\text{eddy}}$  is the conductance of the eddy current loop.
- $\mathcal{R}$  is the parasitic series reluctance of the eddy current path.
- $P$  is the parallel permeance.

Because the parasitic series reluctance and parallel permeance are lossless, the total dissipated power over the block is:

$$P_{\text{diss}} = G_{\text{eddy}} \left( \frac{d\Phi_L}{dt} \right)^2$$

### Relating Transformer Electrical and Magnetic Models

In the electrical domain, eddy current losses are modeled using a parallel resistance across the primary winding. This is the equivalent circuit for a nonideal two-winding transformer.

In the diagram:

- $L_p$  and  $L_s$  are the self-inductances of the primary and secondary windings, respectively.
- $L_m$  is the mutual inductance between the two windings.
- $R_m$  is the mutual resistance between the two windings, caused by the eddy current losses.

This two-winding transformer can similarly be represented in the magnetic domain. This is the equivalent circuit.

In the diagram:

- $\mathcal{R}_p$  and  $\mathcal{R}_s$  are the reluctances associated with the primary and secondary windings, respectively.
- $\mathcal{R}_g$  is the reluctance associated with the magnetic coupling of the two windings.
- $n$  is the turns ratio between the two windings.

The electrical- and magnetic-domain circuits are equivalent if:

$$\mathcal{R}_g = \frac{n^2}{L_m}$$

$$\mathcal{R}_p = \frac{n^2}{L_p}$$

$$\mathcal{R}_s = \frac{1}{L_s}$$

$$G_{\text{eddy}} = \frac{n^2}{R_m}$$

You can use these relationships to calculate the equivalent two-winding transformer properties for one domain from the other.

## Eight-Pulse Gate Multiplexer

Multiplex gate voltage signals to Bidirectional DC-DC Converter block

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

### Description

The Eight-Pulse Gate Multiplexer block routes gate voltage signals to the eight switching devices in a Bidirectional DC-DC Converter block. The block multiplexes the eight separate gate signals into a single vector.

When you set the **Gate-control port** parameter to `Electrical`, the block exposes conserving ports that represent electrical reference points. These ports are associated with the individual phase voltages that connect to the high-side switching devices and the negative DC voltage common to each low-side switching device in the Bidirectional DC-DC Converter block.

### Ports

#### Input

##### **G1 — Gate-control voltage signal 1, V**

physical signal

# Electrolyzer

Electric load for electrolyzer

**Library:** Simscape / Electrical / Sources

## Description

The Electrolyzer block represents the electric load associated with an electrolyzer. An electrolyzer consists of an anode and a cathode separated by an electrolyte. The block calculates the amount of produced hydrogen based on the electrical energy provided and the water temperature in the tank.

In polymer electrolyte membrane (PEM) electrolyzers, these chemical reactions define the anode and cathode conversions:

An electrolysis stack comprises several series-connected individual electrolyzer cells. Specify the **Assumption pH** parameter to model this block either in a pH-dependent state or in an ideal state with constant pH.

## Equations

The Electrolyzer block calculates the electrical power by using

$$P_E = \frac{v^2}{R_T},$$

where  $v$  is the voltage and  $R_T$  is the total resistance. The total resistance,  $R_T$ , is defined by

$$\frac{1}{R_T} = \frac{1}{R_{el}} + \frac{1}{R},$$

where:

- $R$  is the external resistance.
- $R_{el} = \frac{\rho(pH)x}{A}$ . This value is a resistive term obtained from the cross-sectional transport area,  $A$ , the distance anode-cathode,  $x$ , and the electrical resistivity of the solution,  $\rho(pH)$ .

The molar energy stored across the electrical load enables the process of water electrolysis and is calculated by this equation:

$$G_E = \frac{P_E}{1 \text{ mol/s}}.$$

To accomplish electrolysis, the electrolyzer requires a minimum amount of energy

$$G_{\min} = \Delta H - \frac{T}{T_0} T_{\Delta S},$$

where:

- $\Delta H$  is the water enthalpy.
- $T_{\Delta S}$  is the reaction entropy.
- $T$  is the water temperature.
- $T_0$  is the reference temperature.

If the electrical energy is not sufficient to dissociate the water, the electrolyzer does not produce hydrogen. Therefore, the Electrolyzer block calculates the mole rate of electron,  $mol_e$ , and the mole rate of hydrogen,  $mol_{H_2}$

$$mol_e = \begin{cases} \frac{\mu(G_E - G_{\min})}{e_V N_A} & G_E > G_{\min} \\ 0 & G_E \leq G_{\min} \end{cases}$$

$$mol_{H_2} = \begin{cases} \frac{N_c mol_e}{2}, & G_E > G_{\min} \\ 0, & G_E \leq G_{\min} \end{cases}$$

where:

- $N_A$  is the Avogadro constant.
- $e_V$  is the energy per electron.
- $N_c$  is the number of cells.
- $\mu$  is the temperature-dependent efficiency of the electrolysis.

The current that flows through the electrolyzer tank is then obtained as

$$i = mol_e F,$$

where  $F$  is the Faraday constant.

The Electrolyzer block calculates the mass rates of consumed water and generated hydrogen by using these equations:

$$\dot{m}_{H_2O} = mol_{H_2} M_{H_2O}$$

$$\dot{m}_{H_2} = mol_{H_2} M_{H_2}$$

where  $M_{H_2O}$  is the molar mass of water and  $M_{H_2}$  is the molar mass of hydrogen.

To compute the pH of the water in the tank, the block uses

$$pH = -\ln\left(\frac{x_{hp}}{mol_{H_2\_acc}}\right),$$

where:

- $$x_{hp} = \begin{cases} \int mol_e, & pH \text{ assumed constant} \\ \int (1 - purge)mol_e, & pH \text{ assumed dynamic} \end{cases}$$
 captures the floating hydrons (H+) in the solution.
- $mol_{H_2\_acc} = \frac{V\rho_{H_2O}(T)}{M_{H_2O}}$  is the number of moles of water.
- $V$  is the volume.
- $\rho_{H_2O}(T)$  is the density of the water in the tank.

The residual protons in the solution inside the electrolyzer naturally increases the pH and conductivity of the water in the tank over time. The increase in conductivity leads to a run-away phenomenon. To prevent the run-away, you must purge the water in the tank by taking out the volume of the tank and fill it with clean water.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the anode of the electrolyzer tank.

#### - – Negative terminal

electrical

Electrical conserving port associated with the cathode of the electrolyzer tank.

### Input

#### purge – Purge logic input, unitless

physical signal

Purge logic input, specified as a physical signal. This signal enables the substitution of the water in the tank.

#### vol – Water volume, m<sup>3</sup>

physical signal

Water volume in the electrolyzer tank, in m<sup>3</sup>, specified as a physical signal.

#### T – Water temperature, K

physical signal

Water temperature, in K, specified as a physical signal.

### Output

#### volPurging – Purged water volume, m<sup>3</sup>

physical signal

Volume of water consumed for purging, in m<sup>3</sup>, specified as a physical signal.

**pH — Water pH, unitless**

physical signal

Water pH in the electrolyzer tank, specified as a physical signal.

**mdotH2 — Mass flow rate of hydrogen, g/s**

physical signal

Mass flow rate of the hydrogen, in g/s, specified as a physical signal.

**mdotH2O — Mass flow rate of consumed water, g/s**

physical signal

Mass flow rate of the consumed water, in g/s, specified as a physical signal.

**Parameters****Assumption pH — Constant or dynamic pH**

Constant (default) | Dynamic

Whether to assume constant or dynamic pH in the electrolyzer tank.

**Resistance — External resistance**

10 Ohm (default) | nonnegative scalar

Amount of external resistance.

**Cross-sectional transport area — Cross-sectional transport area**0.04 m<sup>2</sup> (default) | positive scalar

Normal area to the vector that links the anode and the cathode. Positively charged ions travel across this area from anode to cathode, where they get reduced and the hydrogen is produced.

**Distance anode-cathode — Distance between anode and cathode**

0.01 m (default) | positive scalar

Distance between the anode and the cathode, submerged in the electrolytic solution.

**Number of electrode pairs — Electrode pairs**

4 (default) | positive scalar

Number of electrode pairs.

**Number of cells — Number of cells**

50 (default) | positive scalar

Number of cells in the electrolyzer.

**Initial pH — Initial pH**

0 (default) | scalar

Initial pH value of the water in the tank.

**Constant pH — Constant pH**

6 (default) | scalar

Constant pH value of the water in the tank.

#### Dependencies

To enable this parameter, set **Assumption pH** to Constant.

#### pH vector, pH\_vec – pH vector

[5, 5.5, 6, 6.5, 7] (default) | row vector of positive scalars

Vector of pH values. This parameter must have the same number of elements as the **Electrical resistivity vector, rho\_vec** parameter.

#### Dependencies

To enable this parameter, set **Assumption pH** to Dynamic

#### Electrical resistivity vector, rho\_vec – Electrical resistivity vector

[.2, .75, 2.5, 8, 18.2] MOhm\*cm (default) | vector of scalars

Vector of electrical resistivity values. This parameter must have the same number of elements as the **pH vector, pH\_vec** parameter.

#### Dependencies

To enable this parameter, set **Assumption pH** to Dynamic

#### Temperature vector for efficiency, T\_vec – Efficiency temperature vector

[273, 298, 323, 348, 373] K (default) | vector of scalars

Vector of temperatures for efficiency. This parameter must have the same number of elements as the **Electrolysis efficiency vector, efficiency(T)** parameter.

#### Electrolysis efficiency vector, efficiency(T) – Electrolysis efficiency vector

ones(5, 1) (default) | vector of scalars

Vector of electrolysis efficiency values. This parameter must have the same number of elements as the **Temperature vector for efficiency, T\_vec** parameter.

# Environment Parameters

Set parameters that apply to all connected SPICE-compatible blocks

**Library:** Simscape / Electrical / Utilities

## Description

The Environment Parameters block lets you set parameters that apply to all SPICE-compatible blocks in an electrical network:

- Circuit temperature
- Minimum conductance

If your model does not contain an Environment Parameters block, all blocks use the default values of these parameters. To override the default values, connect every network in the system to an Environment Parameters block.

---

**Note** The simple semiconductor models in the Semiconductors sublibrary are not temperature dependent, so the Environment Parameters block only changes the minimum conductance parameter used by the exponential diode and bipolar transistor models.

---

## Ports

### Conserving

#### OUT — Output port

electrical

Electrical conserving port associated with the environment parameters output

## Parameters

### Temperature — SPICE temperature

300.15 K (default)

The temperature of the connected SPICE-compatible blocks.

### GMIN — Minimum conductance

1e-12 1/Ohm (default)

The minimum conductance for applicable connected SPICE-compatible blocks.

# Exponential Current Source

Exponential pulse current source

**Library:** Simscape / Electrical / Additional Components / SPICE Sources

## Description

The Exponential Current Source block represents a current source whose output current value is an exponential pulse as a function of time and is independent of the voltage across the terminals of the source. The following equations describe the current through the source as a function of time:

$$I_{out}(0 \leq \text{Time} \leq \text{TDR}) = I1$$

$$I_{out}(\text{TDR} < \text{Time} \leq \text{TDF}) = I1 + (I2 - I1) * (1 - e^{-(\text{Time} - \text{TDR})/\text{TR}})$$

$$I_{out}(\text{TDF} < \text{Time}) = I1 + (I2 - I1) * (e^{-(\text{Time} - \text{TDF})/\text{TF}} - e^{-(\text{Time} - \text{TDR})/\text{TR}})$$

where:

- $I1$  is the **Initial value**, **I1** parameter value.
- $I2$  is the **Pulse value**, **I2** parameter value.
- $\text{TDR}$  is the **Rise delay time**, **TDR** parameter value.
- $\text{TR}$  is the **Rise time**, **TR** parameter value.
- $\text{TDF}$  is the **Fall delay time**, **TDF** parameter value.
- $\text{TF}$  is the **Fall time**, **TF** parameter value.

The block uses a small conductance internally to prevent numerical simulation issues. The conductance connects the + and - ports of the device and has a conductance  $GMIN$ :

- By default,  $GMIN$  matches the **GMIN** parameter of the Environment Parameters block, whose default value is  $1e-12$ .
- To change  $GMIN$ , add an Environment Parameters block to your model and set the **GMIN** parameter to the desired value.

## Ports

### Conserving

**Parameters****Initial value, I1 — Output current initial value**

0 A (default)

Value of the output current at time zero, in A.

**Pulse value, I2 — Output current asymptotic value**

0 A (default)

Asymptotic value of the output current when the output is high, in A.

**Rise delay time, TDR — Rise delay time**

0 s (default)

Rise time delay, in s.

**Rise time, TR — Rise time**

1e-9 s (default) | positive scalar

Time it takes the output current to rise from the **Initial Value, I1** value to the **Pulse Value, I2** value.

**Fall delay time, TDF — Fall delay time**

0 s (default)

Fall time delay. The default value is 0s, which differs from the SPICE default value.

**Fall time, TF — Fall time**

1e-9 s (default) | positive scalar

Time it takes the output current to fall from the **Pulse value, I2** value to the **Initial value, I1** value.

**Include parallel conductance, GMIN — Whether to include parallel conductance**

Yes (default) | No

Specify if the current source includes a parallel conductance. The value of the parallel conductance, *GMIN*, depends on whether your model contains an Environment Parameters block.

This table shows the possible values of the parallel conductance, *GMIN*:

**Values of parallel conductance, GMIN**

Include parallel conductance, GMIN		
Yes		No
<b>Model contains Environment Parameters block</b>	<b>Model does not contain Environment Parameters block</b>	Parallel conductance, <i>GMIN</i> , is not included and it does not affect the current source.
<i>GMIN</i> is equal to the value of the <b>GMIN</b> parameter in the Environment Parameters block.	<i>GMIN</i> = 1e-12 Ohm

# Fault

Electrical fault with temporal, behavioral, or external trigger

**Library:** Simscape / Electrical / Utilities

## Description

The Fault block allows you to represent an electrical fault as an instantaneous change in resistance. You can use it to replicate both open-circuit and short-circuit fault behaviors. The block can trigger fault events:

- At a specific time. The block can also stop imposing a temporal fault after a specified time duration.
- When a predefined voltage range or current range is exceeded
- When an external trigger signal goes high or low

Optionally, the external trigger option also permits the fault to reset when the trigger signal reverts. You can enable or disable all three trigger mechanisms separately. If more than one trigger mechanism is required in a simulation, you can use them together.

When no fault is triggered, the resistance between the two electrical ports is defined by the **Unfaulted resistance** parameter value. The default value for this parameter is `inf` ohms, that is the ports are open-circuit. When a fault is triggered, the block changes the resistance between the two electrical ports to the **Faulted resistance** value. The default value for this parameter is `1e-3` ohms, that is the ports are short-circuited.

You can choose whether to issue an assertion when a fault occurs, by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

The physical output  $X$  represents the fault state; if the block is faulted, the output is 1, otherwise, it is 0. The physical signal input  $F$  is the external fault trigger signal and is used only if **Enable external fault trigger** is set to Yes.

## Ports

### Input

**F — External fault trigger signal**

physical

Physical signal input port associated with the external fault trigger signal.

### Output

**X — Fault state**

physical

Physical signal output port associated with the fault state. It outputs 1 if the block is faulted, 0 otherwise.

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the fault positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the fault negative terminal.

## Parameters

### Main

#### Unfaulted resistance – Resistance with no fault

inf Ohm (default)

Resistance between the + and - ports when there is no fault.

#### Faulted resistance – Resistance with fault

1e-3 Ohm (default)

Resistance between the + and - ports when the block is in the faulted state.

#### Reporting when a fault occurs – Fault occurrence report

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- None – The block does not issue an assertion.
- Warn – The block issues a warning.
- Error – Simulation stops with an error.

### Temporal Trigger

#### Enable temporal fault trigger – Temporal fault trigger option

No (default) | Yes

Select Yes to enable time-based fault triggering.

#### Simulation time for fault event – Simulation time for fault event

1 s (default)

Set the simulation time that the block enters the fault state.

### Dependencies

This parameter is visible only when you set the **Enable temporal fault trigger** parameter to Yes.

**Fault duration — Duration time for the fault**

inf s (default)

Set the simulation duration time for the fault. The block exits the fault state when the duration time is over.

**Dependencies**

This parameter is visible only when you set the **Enable temporal fault trigger** parameter to Yes.

**Behavioral Trigger****Enable behavioral fault trigger — Behavioral fault trigger option**

No (default) | Yes

Select Yes to enable behavioral fault triggering.

**Permissible voltage range — Permissible voltage range**

[-100, 100] V (default)

Specify a vector of length 2 that defines the permissible voltage range. If the voltage is outside this range for longer than the **Time to fail when exceeding voltage range** parameter value, then the block enters the fault state.

**Dependencies**

This parameter is visible only when you set the **Enable behavioral fault trigger** parameter to Yes.

**Time to fail when exceeding voltage range — Time to fail when exceeding voltage range**

1 s (default)

Set the maximum length of time that the voltage can be outside the permissible voltage range without triggering the fault.

**Dependencies**

This parameter is visible only when you set the **Enable behavioral fault trigger** parameter to Yes.

**Permissible current range — Permissible current range**

[-1, 1] A (default)

Specify a vector of length 2 that defines the permissible current range. If the current is outside this range for longer than the **Time to fail when exceeding current range** parameter value, then the block enters the fault state.

**Dependencies**

This parameter is visible only when you set the **Enable behavioral fault trigger** parameter to Yes.

**Time to fail when exceeding current range — Time to fail when exceeding current range**

1 s (default)

Set the maximum length of time that the current can be outside the permissible current range without triggering the fault.

**Dependencies**

This parameter is visible only when you set the **Enable behavioral fault trigger** parameter to Yes.

**External Trigger****Enable external fault trigger – External fault trigger option**

No (default) | Yes

Select Yes to enable external fault triggering. The physical signal input F provides the external fault trigger signal.

**External fault trigger – External fault trigger condition**

Faulted if  $F \geq$  Fault threshold (default) | Faulted if  $F \leq$  Fault threshold

Choose the fault condition:

- Faulted if  $F \geq$  Fault threshold — The fault occurs when the external signal value becomes greater than, or equal to, the **Fault threshold** parameter value.
- Faulted if  $F \leq$  Fault threshold — The fault occurs when the external signal value becomes less than, or equal to, the **Fault threshold** parameter value.

**Dependencies**

This parameter is visible only when you set the **Enable external fault trigger** parameter to Yes.

**Fault threshold – Fault threshold**

0.5 (default)

The threshold value that triggers the fault when the external signal crosses it in the direction, specified by the fault condition.

**Dependencies**

This parameter is visible only when you set the **Enable external fault trigger** parameter to Yes.

**Fault resets when fault trigger reverts – Fault resets when fault trigger reverts**

No (default) | Yes

Select Yes to have the fault reset when the trigger signal reverts.

**Dependencies**

This parameter is visible only when you set the **Enable external fault trigger** parameter to Yes.

## Fault (Three-Phase)

Signal-enabled or time-based, single-phase, two-phase, or three-phase, grounded or ungrounded fault

**Library:** Simscape / Electrical / Utilities

### Description

The Fault (Three-Phase) models any permutation of a single-phase, two-phase, or three-phase grounded or ungrounded fault. The block can impose both time- and event-based faults. The block can impose one or both type of faults, consecutively, at the same time, or for an overlapping time period.

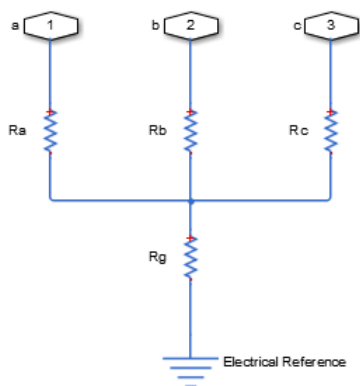

For a time-based or temporal fault, specify the fault activation time using the block **Fault start time** parameter. The fault becomes inactive when the fault duration that you specify elapses.

For an event-based fault, specify the fault activation threshold using the block **Threshold** parameter. An external control signal  $F$  enables the fault. The fault is active when  $F$  is greater than the threshold. The fault is inactive when  $F$  is less than or equal to the threshold.

The block can represent these permutations:

- Single-phase-to-ground fault ( $a-g$ ,  $b-g$ , or  $c-g$ )
- Two-phase fault ( $a-b$ ,  $b-c$ , or  $c-a$ )
- Two-phase-to-ground fault ( $a-b-g$ ,  $b-c-g$ , or  $c-a-g$ )
- Three-phase fault ( $a-b-c$ )
- Three-phase-to-ground fault ( $a-b-c-g$ )

The figure shows the equivalent circuit diagram for the block.

To determine the resistance in the equivalent circuit, apply the relevant equations from the table.

Failure mode		Value of $R_a$	Value of $R_b$	Value of $R_c$	Value of $R_g$
None / inactive		$\frac{1}{G_{pn}}$	$\frac{1}{G_{pn}}$	$\frac{1}{G_{pn}}$	Infinity / open circuit
Single phase to ground	$a-g$	$R_{pn}$	$\frac{1}{G_{pn}}$	$\frac{1}{G_{pn}}$	$R_{ng}$
	$b-g$	$\frac{1}{G_{pn}}$	$R_{pn}$	$\frac{1}{G_{pn}}$	$R_{ng}$
	$c-g$	$\frac{1}{G_{pn}}$	$\frac{1}{G_{pn}}$	$R_{pn}$	$R_{ng}$

Three phase to ground	$a-b-c-g$	$R_{pn}$	$R_{pn}$	$R_{pn}$	$R_{ng}$

where:

- $R_a$  is the resistance between the  $a$ -phase and the neutral point of a wye connection.
- $R_b$  is the resistance between the  $b$ -phase and the neutral point of a wye connection.
- $R_c$  is the resistance between the  $c$ -phase and the neutral point of a wye connection.
- $R_g$  is the resistance between the neutral point of a wye connection and electrical reference.
- $R_{pn}$  is the value of the **Faulted phase-neutral resistance** parameter.
- $R_{ng}$  is the value of the **Faulted neutral-ground resistance** parameter.
- $G_{pn}$  is the value of the **Unfaulted phase-neutral conductance** parameter.

## Ports

### Conserving

#### ~ – Three-phase port

electrical

Expandable electrical conserving three-phase port for connecting the fault to the system.

## Input

### F — Externally triggered fault control input

physical

Physical signal scalar control input port for enabling an externally triggered fault.

#### Dependencies

To enable this port, on the **External Trigger** settings, set the **Enable external fault trigger** parameter to Yes.

## Output

### X — Fault state

physical

Physical signal scalar output port for reporting the fault state:

- 1 — Faulted
- 0 — Unfaulted

#### Dependencies

To enable this port, on the **Main** settings, set the **State port** parameter to Visible.

## Parameters

### Modeling option — Whether to model composite or expanded three-phase ports

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

Expanded three-phase ports represent the individual phases of a three-phase system using three separate electrical conserving ports.

## Main

### Failure mode — Type of fault

None (default) | Single-phase to ground (a-g) | Single-phase to ground (b-g) | Single-phase to ground (c-g) | Two-phase (a-b) | Two-phase (b-c) | Two-phase (c-a) | Two-phase to ground (a-b-g) | Two-phase to ground (b-c-g) | Two-phase to ground (c-a-g) | Three-phase (a-b-c) | Three-phase to ground (a-b-c-g)

Type of fault to model. The visibility of related parameters depends on the fault model. Options are:

- None — Specifies that the fault is not active.
- Single-phase to ground (a-g)
- Single-phase to ground (b-g)

- Single-phase to ground (c-g)
- Two-phase (a-b)
- Two-phase (b-c)
- Two-phase (c-a)
- Two-phase to ground (a-b-g)
- Two-phase to ground (b-c-g)
- Two-phase to ground (c-a-g)
- Three-phase (a-b-c)
- Three-phase to ground (a-b-c-g)

**Faulted phase-neutral resistance – Faulted phase-neutral resistance**

1e-3 Ohm (default)

Resistance between the phase connection and the neutral point when the fault is active.

**Dependencies**

To enable this parameter set the **Failure mode** parameter to:

- Single-phase to ground (a-g)
- Single-phase to ground (b-g)
- Single-phase to ground (c-g)
- Two-phase (a-b)
- Two-phase (b-c)
- Two-phase (c-a)
- Two-phase to ground (a-b-g)
- Two-phase to ground (b-c-g)
- Two-phase to ground (c-a-g)
- Three-phase (a-b-c)
- Three-phase to ground (a-b-c-g)

**Faulted neutral-ground resistance – Faulted neutral-ground resistance**

1e-3 Ohm (default)

Resistance between the neutral point and the electrical reference when fault is active.

**Dependencies**

To enable this parameter set the **Failure mode** parameter to:

- Single-phase to ground (a-g)
- Single-phase to ground (b-g)
- Single-phase to ground (c-g)
- Two-phase to ground (a-b-g)
- Two-phase to ground (b-c-g)
- Two-phase to ground (c-a-g)

- Three-phase to ground (a-b-c-g)

### State port — State port visibility

Hidden (default) | Visible

Option to hide or expose port **x**, a physical signal output port that reports the fault state:

- Hidden — Port **x** is not visible if you select this option.
- Visible — Port **x** is visible only if you select this option.

### External Trigger

#### Enable external fault trigger — External fault model

No (default) | Yes

External fault model. Choose between

- No — Do not model an external fault. Physical signal input port **F** is not visible if you select this option.
- Yes — Model an external fault. Related parameters and physical signal input port **F** are visible only if you select this option.

#### Fault threshold — Threshold value that triggers the fault

0.5 (default)

The threshold value that triggers the fault when the external signal crosses it in the direction, specified by the fault condition. This parameter is visible only if the **Enable external fault trigger** parameter is set to Yes. The default value is 0.5.

#### Dependencies

To enable this parameter, set the **Enable external fault trigger** parameter to Yes.

#### External fault trigger — Fault condition

Faulted if  $F \geq \text{Fault threshold}$  (default) | Faulted if  $F \leq \text{Fault threshold}$

Choose the fault condition:

- Faulted if  $F \geq \text{Fault threshold}$  — The fault occurs when the external signal value becomes greater than, or equal to, the **Fault threshold** parameter value.
- Faulted if  $F \leq \text{Fault threshold}$  — The fault occurs when the external signal value becomes less than, or equal to, the **Fault threshold** parameter value.

#### Dependencies

To enable this parameter, set the **Enable external fault trigger** parameter to Yes.

#### Fault resets when fault trigger reverts — Fault resets when fault trigger reverts

No (default) | Yes

Select Yes to have the fault reset when the trigger signal reverts. The default value is No.

#### Dependencies

To enable this parameter, set the **Enable external fault trigger** parameter to Yes.

## Temporal Trigger

### Enable temporal fault trigger — Temporal fault model

No (default) | Yes

Temporal fault model. Choose between

- No — Do not model a temporal fault.
- Yes — Model a temporal fault. Related parameters are visible only if you select this option.

### Fault start time — Fault start time

1 s (default)

Simulation time that the block enters the fault state.

#### Dependencies

To enable this parameter, set the **Enable temporal fault trigger** parameter to Yes.

### Fault duration — Fault duration

0.1 s (default)

Simulation duration time for the fault. The block exits the fault state when the duration time is over.

#### Dependencies

To enable this parameter, set the **Enable temporal fault trigger** parameter to Yes.

#### Parasitics

### Unfaulted phase-neutral conductance — Unfaulted phase-neutral conductance

1e-6 1/Ohm (default)

Conductance between the phase connections and the neutral point when a phase is not involved in the fault.

# FEM-Parameterized Linear Actuator

Linear actuator defined in terms of magnetic flux

**Library:** Simscape / Electrical / Electromechanical / Mechatronics Actuators

## Description

The FEM-Parameterized Linear Actuator block implements a model of a linear actuator defined in terms of magnetic flux. Use this block to model custom solenoids and linear motors where magnetic flux depends on both distance and current. You parameterize the block using data from a third-party magnetic finite-element method (FEM) package.

---

**Note** To use this block to represent a solenoid with air gap  $x$  between case **C** and plunger **R**, then the tabulated force should be negative to represent the pulling force bringing **R** towards **C**.

---

The block has two options for the electrical equation. The first, **Define in terms of**  $d\Phi(i, x)/dx$  and  $d\Phi(i, x)/di$ , defines the current in terms of partial derivatives of the magnetic flux ( $\Phi$ ) with respect to distance ( $x$ ) and current ( $i$ ), the equations for which are:

$$\frac{di}{dt} = \left( v - iR - \frac{\partial \Phi}{\partial x} \frac{dx}{dt} \right) / \frac{\partial \Phi}{\partial i}$$

The second option, **Define in terms of**  $\Phi(i, x)$ , defines the voltage across the component directly in terms of the flux, the equation for which is:

$$v = iR + \frac{d}{dt} \Phi(x, i)$$

Numerically, defining the electrical equation in terms of flux partial derivatives is better because the back-emf is piecewise continuous. If using the flux directly, using a finer grid size for current and position will improve results, as will selecting cubic or spline interpolation.

In both cases, you have an option to either directly specify the force as a function of current and position, by using the **Force matrix,  $F(i, x)$**  parameter, or have the block automatically calculate the force matrix.

If entering the electromagnetic force data directly, you can either use data supplied by the finite element magnetic package (which you used to determine the flux) or calculate the force from the flux with following equation:

$$F = \int_0^i \frac{\partial \Phi(x, i)}{\partial x} di$$

For an example that shows how to implement this type of integration in MATLAB, see “Solenoid Parameterized with FEM Data”. The related file `ee_solenoid_fem_params.m` contains the code that calculates and plots the flux data.

Alternatively, the block can automatically calculate the force matrix from the flux information that you provide. To select this option, set the **Calculate force matrix?** parameter to **Yes**. The force matrix calculation occurs at model initialization based on current block flux linkage information. The force is calculated by numerically integrating the rate of change of flux linkage with respect to position over current, according to the preceding equation. If the **Electrical model** parameter is set to **Define in terms of  $\Phi(i,x)$** , then the block must first estimate the **Flux partial derivative wrt displacement,  $d\Phi(i,x)/dx$**  parameter value from the flux linkage data. When doing this, the block uses the interpolation method specified by the **Interpolation method** parameter. Typically, the **Smooth** option is most accurate, but the **Linear** option is most robust.

You can define  $\Phi$  and its partial derivatives for just positive, or positive and negative currents. If defining for just positive currents, then the block assumes that  $\Phi(-i,x) = -\Phi(i,x)$ . Therefore, if the current vector is positive only:

- The first current value must be zero.
- The flux corresponding to zero current must be zero.
- The partial derivative of flux with respect to displacement must be zero for zero current.

To model a linear motor with a repeated flux pattern, set the **Flux dependence on displacement** parameter to **Cyclic**. When selecting this option, the force and flux (or force and flux partial derivatives depending on the option chosen) must have identical first and last columns.

---

**Note** The actuated motion direction of this block can be swapped by flipping the block and swapping the R and C connections.

---

### Model Thermal Effects

You can expose the thermal port to model the effects of losses that convert power to heat. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port.
- **Show thermal port** — The block contains one thermal conserving port.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Assumptions and Limitations

- You must supply a consistent set of force and flux data. There is no check that ensures that the force matrix is consistent with the flux data.
- When driving the FEM-Parameterized Linear Actuator block via a series inductor, you may need to include a parallel conductance in the inductor component.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the actuator positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the actuator negative terminal.

#### C – Case

mechanical

Mechanical translational conserving port associated with the actuator case.

#### R – Plunger

mechanical

Mechanical translational conserving port associated with the plunger.

#### H – Thermal port

thermal

Thermal port.

### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### Modeling option – Whether to enable thermal port

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of losses that convert power to heat.

### Magnetic Force

#### Electrical model – Electrical model parameterization

Define in terms of  $d\Phi(i,x)/dx$  and  $d\Phi(i,x)/di$  (default) | Define in terms of  $\Phi(i,x)$

Select one of the following parameterization options, based on the underlying electrical model:

- Define in terms of  $d\Phi(i,x)/dx$  and  $d\Phi(i,x)/di$  – Define the current through the block in terms of partial derivatives of the magnetic flux with respect to distance and current.
- Define in terms of  $\Phi(i,x)$  – Define the voltage across the block terminals directly in terms of the flux.

**Current vector, i – Current vector**

[0, .1, .2, .3, .4, .5, .6, .7, .8, .9, 1] A (default)

Specify a vector of monotonically increasing current values corresponding to your force-flux data. If you specify positive currents only, the first element must be zero.

**Displacement vector, x – Displacement vector**

[0, .05, .1, .15, .2] mm (default)

Specify a vector of monotonically increasing displacement values corresponding to your force-flux data.

**Flux partial derivative wrt current,  $d\Phi(i,x)/di$  – Flux partial derivative with respect to current**

### Dependencies

This parameter is visible only when you set the **Calculate force matrix?** parameter to **No**.

### Flux dependence on displacement — Flux pattern

Unique (default) | Cyclic

Specify the flux pattern:

- **Unique** — No flux pattern present.
- **Cyclic** — Select this option to model a linear motor with a repeated flux pattern. The force and flux (or force and flux partial derivatives, depending on the **Electrical model** option chosen) must have identical first and last columns.

### Interpolation method — Interpolation method

Linear (default) | Smooth

Select one of the following interpolation methods for approximating the output value when the input value is between two consecutive grid points:

- **Linear** — Select this option to get the best performance.
- **Smooth** — Select this option to produce a continuous surface with continuous first-order derivatives.

For more information on interpolation algorithms, see the PS Lookup Table (2D) block reference page.

### Extrapolation method — Extrapolation method

Linear (default) | Nearest | Error

Select one of the following extrapolation methods for determining the output value when the input value is outside the range specified in the argument list:

- **Linear** — Select this option to produce a surface with continuous first-order derivatives in the extrapolation region and at the boundary with the interpolation region.
- **Nearest** — Select this option to produce an extrapolation that does not go above the highest point in the data or below the lowest point in the data.
- **Error** — Issues an error if the input signal is outside the range of the table. Select this option to avoid getting into the extrapolation mode when you want your data to be within the table range.

For more information on extrapolation algorithms, see the PS Lookup Table (2D) block reference page.

### **Winding resistance — Electrical winding total resistance**

14 Ohm (default)

Total resistance of the electrical winding.

### **Magnetizing resistance — Magnetizing resistance for iron losses**

inf Ohm (default)

Magnetizing resistance. The value must be greater than zero. The default value is inf, which implies that there are no iron losses.

## **Mechanical**

### **Damping — Damping**

1 N/(m/s) (default)

Linear damping. The value can be zero.

### **Plunger mass — Mass of the moving part**

0.05 kg (default)

Mass of the moving part, which corresponds to mechanical translational port **R**. The value can be zero.

### **Minimum stroke — Minimum stroke**

0 mm (default)

The stroke at which the lower mechanical end stop is applied. The value can be -Inf.

### **Maximum stroke — Maximum stroke**

0.2 mm (default)

The stroke at which the upper mechanical end stop is applied. The value can be Inf.

### **Contact stiffness — Contact stiffness**

1e8 N/m (default)

Contact stiffness between plunger and end stops.

### **Contact damping — Contact damping**

1e4 N/(m/s) (default)

Contact damping between plunger and end stops.

## FEM-Parameterized PMSM

Permanent magnet synchronous motor defined in terms of magnetic flux linkage

**Library:** Simscape / Electrical / Electromechanical / Permanent Magnet

### Description

The FEM-Parameterized PMSM block implements a model of a permanent magnet synchronous motor (PMSM) defined in terms of magnetic flux linkage. You parameterize the block by providing tabulated data of motor magnetic flux as a function of current and rotor angle. This is the way third-party magnetic finite-element method (FEM) packages usually export flux information. Because of the tabulated form, the flux can vary in a nonlinear way on both rotor angle and current. You can therefore use this block to model PMSM with trapezoidal back-emf profile, sometimes called brushless DC motor, as well as regular PMSM.

The figure shows the equivalent circuit for a wye-connected PMSM. The rotor angle is zero when the permanent magnet flux aligns with the A-phase magnetic axis.

In practice, the flux linking each of the three windings depends on all three currents and rotor angle. Tabulating flux as a function of four independent variables might lead to simulation inefficiency and significant memory requirements to manage the data. The block, therefore, lets you select between the following parameterization methods for flux and torque:

- **2-D partial derivative data** — 2-D table lookup, with options to tabulate in terms of current and rotor angle, or in terms of  $d$ -axis and  $q$ -axis currents. The first option assumes constant mutual inductance and supports nonsinusoidal back emf profiles. The second option assumes a sinusoidal back emf and captures saturation effects for interior PMSMs (IPMSMs).
- **3-D partial derivative data** — 3-D table lookup, based on direct current, quadrature current, and rotor angle. You provide the flux lookup data for the  $a$  phase. The block uses Park transform to map the three stator winding currents to direct and quadrature currents. This method reduces the data complexity, as compared to the 4-D table lookup, and therefore results in improved simulation performance.

- **4-D partial derivative data** — 4-D table lookup, based on the three stator winding currents and the rotor angle. You provide the flux lookup data for the *a* phase. This model has the best fidelity of the three, but also is the most costly in terms of simulation performance and memory requirements.
- **3-D flux linkage data** — 3-D table lookup, based on the flux linkage data. You can provide the flux linkage data in a variety of formats. The block uses Park transform to map the three stator winding currents to direct and quadrature currents. This method reduces the data complexity, as compared to the 4-D table lookup, and therefore results in improved simulation performance.

By default, the blocks implements a wye-wound configuration for the stator windings for all these parameterizations. However, it is possible to switch to a delta-wound configuration, selectable using the **Winding type** parameter. When in the delta-wound configuration, the *a* phase is connected between ports **a** and **b**, the *b* phase between ports **b** and **c** and the *c* phase between ports **c** and **a**.

To access these parameterization methods, double-click the block in your model and set the **Modeling option** parameter to the desired option, with or without thermal ports. By default, the thermal ports are not exposed. For more information, see “Model Thermal Effects” on page 1-567.

## 2-D Data Model with Constant Mutual Inductance

In this 2-D flux data model, the flux linking each winding is assumed to depend nonlinearly only on the current in that same winding, plus the rotor angle. In practice, this is a reasonable assumption for many permanent magnet synchronous motors; however, it is less accurate for switched reluctance motors. Given this assumption, the fluxes in the three windings are:

$$\begin{bmatrix} \phi_a \\ \phi_b \\ \phi_c \end{bmatrix} = \begin{bmatrix} 0 & -M_s & -M_s \\ -M_s & 0 & -M_s \\ -M_s & -M_s & 0 \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} \phi(i_a, \theta_r) \\ \phi(i_b, \theta_r - 2\pi/(3N)) \\ \phi(i_c, \theta_r - 4\pi/(3N)) \end{bmatrix}$$

where  $\phi(\theta_r, i_a)$  is the flux linkage for the A-phase winding as a function of rotor angle and A-phase current.  $\theta_r = 0$  corresponds to the rotor *d*-axis aligning with the A-phase positive magnetic flux direction.  $M_s$  is the stator-stator mutual inductance.

For improved numerical performance, the equations implemented in the block actually work with the partial derivatives of flux linkage with respect to current,  $\partial\phi(i, \theta_r)/\partial i$ , and rotor angle,  $\partial\phi(i, \theta_r)/\partial\theta_r$ , rather than the flux directly. If your FEM package does not export these partial derivatives, you can determine them using a MATLAB script. See the Solenoid Parameterized with FEM Data example model and its supporting MATLAB script for an example of how to do this.

The electrical equations for the block, defined in terms of flux partial derivatives, are:

$$\begin{aligned} v_a &= \frac{\partial\phi}{\partial i_a} \frac{di_a}{dt} + \frac{\partial\phi}{\partial\theta_r} \frac{d\theta_r}{dt} - M_s \left( \frac{di_b}{dt} + \frac{di_c}{dt} \right) + R_s i_a \\ v_b &= \frac{\partial\phi}{\partial i_b} \frac{di_b}{dt} + \frac{\partial\phi}{\partial\theta_r} \frac{d\theta_r}{dt} - M_s \left( \frac{di_a}{dt} + \frac{di_c}{dt} \right) + R_s i_b \\ v_c &= \frac{\partial\phi}{\partial i_c} \frac{di_c}{dt} + \frac{\partial\phi}{\partial\theta_r} \frac{d\theta_r}{dt} - M_s \left( \frac{di_a}{dt} + \frac{di_b}{dt} \right) + R_s i_c \end{aligned}$$

where

- $v_a, v_b, v_c$  are the voltages applied to the A, B, and C stator windings.

- $i_a, i_b, i_c$  are the stator currents in each of the three windings.
- $R_s$  is the resistance of each of the stator windings.
- $M_s$  is the stator-stator mutual inductance.
- $\partial\phi/\partial i_a, \partial\phi/\partial i_b, \partial\phi/\partial i_c$  are the partial derivatives of flux linkage with respect to stator current in each of the three windings.
- $\partial\phi/\partial\theta_r$  is the partial derivative of flux linkage with respect to rotor angle.

The block can automatically calculate the torque matrix from the flux information that you provide. Alternatively, you can set the **Calculate torque matrix?** parameter to **No** and directly specify the torque as a function of current and rotor angle. See the FEM-Parameterized Rotary Actuator block reference page for more information.

### 2-D Data Model with Sinusoidal Back EMF

In this 2-D flux data model, the flux linking each winding is assumed to depend nonlinearly on all stator winding currents, plus it is assumed that the permanent magnet flux linkage is sinusoidal. Interior magnet PMSMs (or IPMSMs) usually fit this assumption well. The equations are:

$$\begin{bmatrix} \phi_d \\ \phi_q \end{bmatrix} = \begin{bmatrix} L_d(i_d, i_q) & \\ & L_q(i_d, i_q) \end{bmatrix} \begin{bmatrix} i_d \\ i_q \end{bmatrix} + \begin{bmatrix} \phi_m(i_d, i_q) \\ 0 \end{bmatrix}$$

$$T = \frac{3}{2}N(i_q(i_d L_d(i_d, i_q) + \phi_m(i_d, i_q)) - i_d i_q L_q(i_d, i_q))$$

where

- $i_d$  and  $i_q$  are the  $d$ -axis and  $q$ -axis currents, respectively.
- $\phi_d$  and  $\phi_q$  are the  $d$ -axis and  $q$ -axis flux linkages, respectively.
- $\phi_m$  is the permanent magnet flux linkage.
- $L_d$  and  $L_q$  are the  $d$ -axis and  $q$ -axis inductances, respectively. They are assumed to depend on the  $d$ -axis and  $q$ -axis currents.
- $N$  is the number of pole pairs.
- $T$  is the electrical torque.

### 3-D Partial Derivative Data Model Using Park Transform

Working with four-dimensional data has both a simulation performance cost and a memory cost. To reduce the table dimension to three-dimensional, the 3-D data model uses Park transform to map the three currents to direct and quadrature currents:

$$\begin{bmatrix} i_d \\ i_q \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \cos(N\theta_r) & \cos\left(N\theta_r - \frac{2\pi}{3}\right) & \cos\left(N\theta_r + \frac{2\pi}{3}\right) \\ -\sin(N\theta_r) & -\sin\left(N\theta_r - \frac{2\pi}{3}\right) & -\sin\left(N\theta_r + \frac{2\pi}{3}\right) \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}$$

In the general case, Park transform maps to direct, quadrature, and zero-sequence currents. However, the zero-sequence current is typically small under normal operating conditions. Therefore, the model neglects the dependence of the flux linkage terms on zero-sequence current, and determines the flux linkage in terms of just direct and quadrature currents plus rotor angle. The flux equation for the 3-D data model is:

$$\begin{bmatrix} \phi_a \\ \phi_b \\ \phi_c \end{bmatrix} = \begin{bmatrix} \phi(i_d, i_q, \theta_r) \\ \phi(i_d, i_q, \theta_r - 2\pi/(3N)) \\ \phi(i_d, i_q, \theta_r - 4\pi/(3N)) \end{bmatrix}$$

The electrical equations for the block are also defined in terms of flux partial derivatives, similar to the 4-D data model. You can calculate 3-D flux linkage partial derivative data from 4-D flux linkage data using `ee_calculateFluxPartialDerivatives`.

#### 4-D Partial Derivative Data Model

The flux linking each of the windings is a function of the current in that winding, the currents in the other two windings, and the rotor angle. For full accuracy, the 4-D flux data model assumes that the flux linkage is a function of the three currents and the rotor angle, therefore performing four-dimensional table lookups. The flux equation is:

$$\begin{bmatrix} \phi_a \\ \phi_b \\ \phi_c \end{bmatrix} = \begin{bmatrix} \phi(i_a, i_b, i_c, \theta_r) \\ \phi(i_b, i_c, i_a, \theta_r - 2\pi/(3N)) \\ \phi(i_c, i_a, i_b, \theta_r - 4\pi/(3N)) \end{bmatrix}$$

where

- $\phi_a, \phi_b, \phi_c$  are the flux linkages for the A, B, and C stator windings.
- $i_a, i_b, i_c$  are the stator currents in each of the three windings.
- $\theta_r$  is the rotor angle.  $\theta_r = 0$  corresponds to the case where the permanent magnet flux is aligned with the A-phase stator winding flux.
- $N$  is the number of pole pairs.

Flux linkage data is assumed cyclic with  $\theta_r$ . If, for example, the motor has six pole pairs, then the range for the data is  $0 \leq \theta_r \leq 60^\circ$ . You must provide data both at 0 and 60 degrees, and because the data is cyclic, the flux linkage partial derivatives must be the same at these two end points.

The torque equation is:

$$\tau = T(i_a, i_b, i_c, \theta_r)$$

The 4-D data model does not have an option for the block to determine torque from flux linkage. Because of the increased numerical overhead in the 4-D case, it is better to precalculate the torque just once, rather than calculate it every time you run the simulation.

For improved numerical performance, the equations implemented in the block actually work with the partial derivatives of flux linkage with respect to the three currents and the rotor angle, rather than the flux directly. If your FEM package does not export these partial derivatives, you can determine them using `ee_calculateFluxPartialDerivatives`.

The electrical equations for the block, defined in terms of flux partial derivatives, are:

$$\begin{aligned} v_a &= \frac{\partial \phi_a}{\partial i_a} \frac{di_a}{dt} + \frac{\partial \phi_a}{\partial i_b} \frac{di_b}{dt} + \frac{\partial \phi_a}{\partial i_c} \frac{di_c}{dt} + \frac{\partial \phi_a}{\partial \theta_r} \frac{d\theta_r}{dt} + R_s i_a \\ v_b &= \frac{\partial \phi_b}{\partial i_a} \frac{di_a}{dt} + \frac{\partial \phi_b}{\partial i_b} \frac{di_b}{dt} + \frac{\partial \phi_b}{\partial i_c} \frac{di_c}{dt} + \frac{\partial \phi_b}{\partial \theta_r} \frac{d\theta_r}{dt} + R_s i_b \\ v_c &= \frac{\partial \phi_c}{\partial i_a} \frac{di_a}{dt} + \frac{\partial \phi_c}{\partial i_b} \frac{di_b}{dt} + \frac{\partial \phi_c}{\partial i_c} \frac{di_c}{dt} + \frac{\partial \phi_c}{\partial \theta_r} \frac{d\theta_r}{dt} + R_s i_c \end{aligned}$$

where

- $v_a, v_b, v_c$  are the voltages applied to the A, B, and C stator windings.
- $i_a, i_b, i_c$  are the stator currents in each of the three windings.
- $R_s$  is the resistance of each of the stator windings.

### 3-D Flux Linkage Data Models

The 3-D flux linkage data options let you work with raw flux linkage data exported from your finite-element (FE) motor design tool. This is in contrast to the 3-D partial derivative data options, for which you need to determine the partial derivatives. You can provide flux linkage data in a variety of formats, to support different FE tool conventions:

- Tabulate DQ-axes flux linkage data or A-phase flux linkage data — Some tools support working with flux linkage resolved into direct (D) and quadrature (Q) axes. An advantage of this approach is that data for rotor angles in the range 0 to  $360/N/3$  degrees is required (where  $N$  is the number of pole pairs). Other tools work directly with A-, B-, and C-phase flux linkages, and for this you can import just the A-phase flux linkage, for which the rotor angle range must be in the range 0 to  $360/N$  degrees. The implicit assumption of importing just the A-phase data is that the B and C phase data is the same except shifted in phase.
- Tabulate using cartesian or polar current coordinates — Cartesian tabulation implies the flux linkage is tabulated in terms of D-axis current and Q-axis current (plus rotor angle). Alternatively, polar tabulation involves tabulating flux linkages in terms of current magnitude, current advance angle relative to the Q-axis, and rotor angle. The advantage of polar coordinates is that it more naturally reflects the permitted operating currents, thereby avoiding unused table data points.

These conventions result in four **Flux linkage data format** parameterization options:

- D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ )
- D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ )
- A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ )
- A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ )

Besides selecting the flux linkage data format used by your FE tool, you have to select the version of Park transform used by the tool. The four conventions are described below and correspond to the four options for the **Park's convention for tabulated data** drop-down menu.

---

**Note** When looking at logged values for D- and Q-axis currents, keep in mind that for each of these options, the format is converted, as needed, so that internally the FEM-Parameterized PMSM block consistently uses Option 1.

---

---

**Note** To preserve higher-order harmonics due to the permanent magnet back EMF, provide the A-phase flux data rather than the D-axis and Q-axis flux data. Conversely, if you provide D-axis and Q-axis fluxes, the Park's transform removes the higher-order harmonics. Working with D and Q fluxes is sufficient for many applications, particularly if you set the **Winding type** parameter to Wye-wound and there aren't connections to the neutral port of this block. For this particular case, the constraint that the sum of the currents is zero at the neutral port removes all third-order harmonics.

---

**Option 1. Q leads D, rotor angle measured from A-phase to D-axis**

This is the Park's convention used internally by Simscape Electrical motor and machine blocks. All other options are converted into this format.

- $N$ : number of pole pairs
- $\theta_r$ : rotor angle
- $i_d, i_q$ : D-axis and Q-axis currents
- $i_p$ : Current magnitude =  $\sqrt{i_d^2 + i_q^2}$
- $\beta$ : Current advance angle =  $\tan^{-1}(-i_d/i_q)$

Corresponding Park transform is

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \cos(N\theta_r) & \cos\left(N\theta_r - \frac{2\pi}{3}\right) & \cos\left(N\theta_r + \frac{2\pi}{3}\right) \\ -\sin(N\theta_r) & -\sin\left(N\theta_r - \frac{2\pi}{3}\right) & -\sin\left(N\theta_r + \frac{2\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}$$

where  $i_a, i_b,$  and  $i_c$  are the A-phase, B-phase, and C-phase currents, respectively.

**Option 2. Q leads D, rotor angle measured from A-phase to Q-axis**

- $N$ : number of pole pairs
- $\theta_r$ : rotor angle
- $i_d, i_q$ : D-axis and Q-axis currents
- $i_p$ : Current magnitude =  $\sqrt{i_d^2 + i_q^2}$
- $\beta$ : Current advance angle =  $\tan^{-1}(-i_d/i_q)$

Corresponding Park transform is

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \sin(N\theta_r) & \sin\left(N\theta_r - \frac{2\pi}{3}\right) & \sin\left(N\theta_r + \frac{2\pi}{3}\right) \\ \cos(N\theta_r) & \cos\left(N\theta_r - \frac{2\pi}{3}\right) & \cos\left(N\theta_r + \frac{2\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}$$

where  $i_a$ ,  $i_b$ , and  $i_c$  are the A-phase, B-phase, and C-phase currents, respectively.

**Option 3. D leads Q, rotor angle measured from A-phase to D-axis**

- $N$ : number of pole pairs
- $\theta_r$ : rotor angle
- $i_d, i_q$ : D-axis and Q-axis currents
- $i_p$ : Current magnitude =  $\sqrt{i_d^2 + i_q^2}$
- $\beta$ : Current advance angle =  $\tan^{-1}(-i_d/i_q)$

Corresponding Park transform is

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \cos(N\theta_r) & \cos\left(N\theta_r - \frac{2\pi}{3}\right) & \cos\left(N\theta_r + \frac{2\pi}{3}\right) \\ \sin(N\theta_r) & \sin\left(N\theta_r - \frac{2\pi}{3}\right) & \sin\left(N\theta_r + \frac{2\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}$$

where  $i_a, i_b,$  and  $i_c$  are the A-phase, B-phase, and C-phase currents, respectively.

**Option 4. D leads Q, rotor angle measured from A-phase to Q-axis**

- $N$ : number of pole pairs
- $\theta_r$ : rotor angle
- $i_d, i_q$ : D-axis and Q-axis currents
- $i_p$ : Current magnitude =  $\sqrt{i_d^2 + i_q^2}$
- $\beta$ : Current advance angle =  $\tan^{-1}(-i_d/i_q)$

Corresponding Park transform is

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} -\sin(N\theta_r) & -\sin\left(N\theta_r - \frac{2\pi}{3}\right) & -\sin\left(N\theta_r + \frac{2\pi}{3}\right) \\ \cos(N\theta_r) & \cos\left(N\theta_r - \frac{2\pi}{3}\right) & \cos\left(N\theta_r + \frac{2\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}$$

where  $i_a$ ,  $i_b$ , and  $i_c$  are the A-phase, B-phase, and C-phase currents, respectively.

### Calculating Iron Losses

The FEM-Parameterized PMSM block models iron losses according to the parameterization methods you choose for flux and torque.

#### Specify open-circuit and short-circuit loss data (permanent magnet motors only)

For the **2-D partial derivative data**, **3-D partial derivative data**, and **4-D partial derivative data** options, with or without thermal ports, the iron loss model is based on the work of Mellor [1]. Iron losses are divided into two terms, one representing the main magnetizing path, and the other representing the cross-tooth tip path that becomes active during field weakened operation.

The term representing the main magnetizing path depends on the induced RMS stator voltage,  $V_{m_{rms}}$ :

$$P_{OC}(V_{m_{rms}}) = \frac{a_h}{k} V_{m_{rms}} + \frac{a_j}{k^2} V_{m_{rms}}^2 + \frac{a_{ex}}{k^{1.5}} V_{m_{rms}}^{1.5}$$

This is the dominant term during no-load operation.  $k$  is the back emf constant relating RMS volts per Hz. It is defined as  $k = V_{m_{rms}}/f$ , where  $f$  is the electrical frequency. The first term on the right-hand side is the magnetic hysteresis loss, the second is the eddy current loss and the third is the excess loss. The three coefficients appearing on the numerators are derived from the values that you provide for the open-circuit hysteresis, eddy, and excess losses.

The term representing the cross-tooth tip path becomes important when a demagnetizing field is set up and can be determined from a finite element analysis short-circuit test. It depends on the RMS emf associated with the cross-tooth tip flux,  $V_{d_{rms}}^*$ :

$$P_{SC}(V_{d_{rms}}^*) = \frac{b_h}{k} V_{d_{rms}}^* + \frac{b_j}{k^2} V_{d_{rms}}^{*2} + \frac{b_{ex}}{k^{1.5}} V_{d_{rms}}^{*1.5}$$

The three numerator terms are derived from the values you provide for the short-circuit hysteresis, eddy, and excess losses.

#### Steinmetz parameterization method

For the **3-D flux linkage data** with or without thermal ports, you can also model the iron losses based on the Steinmetz equation. The Steinmetz method scales for different motor speeds or electrical frequencies so that iron loss data is only required as function of motor currents.

If, in the **Iron Losses** setting, you set the **Model** parameter to **Specify open and short circuit loss data (permanent magnet motors only)**, the block uses the Steinmetz method, but assumes constant coefficients and no dependency on peak current and current phase advance. Select this option if you have dyno measurements or if you perform an FE analysis to get the iron losses from just open-circuit and short-circuit simulations.

Conversely, if you set the **Flux linkage data format** parameter to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ), then the block tabulated the coefficients with the **Peak current magnitude vector, I** and **Current advance angle vector, B** parameters, so that the iron losses are given by:

$$P_{rotor}(f) = k_{hr}(I_p, \beta)f + k_{Jr}(I_p, \beta)f^2 + k_{er}(I_p, \beta)f^{1.5}$$

$$P_{stator}(f) = k_{hs}(I_p, \beta)f + k_{Js}(I_p, \beta)f^2 + k_{es}(I_p, \beta)f^{1.5}$$

where:

- $f$  is the electrical frequency, in Hz.
- $k_{hr}(I_p, \beta)$  is the **Rotor hysteresis loss coefficient,  $k_{hr}(I, B)$ .**
- $k_{Jr}(I_p, \beta)$  is the **Rotor eddy current loss coefficient,  $k_{Jr}(I, B)$ .**
- $k_{er}(I_p, \beta)$  is the **Rotor excess current loss coefficient,  $k_{er}(I, B)$ .**
- $k_{hs}(I_p, \beta)$  is the **Stator hysteresis loss coefficient,  $k_{hs}(I, B)$ .**
- $k_{Js}(I_p, \beta)$  is the **Stator eddy current loss coefficient,  $k_{Js}(I, B)$ .**
- $k_{es}(I_p, \beta)$  is the **Stator excess current loss coefficient,  $k_{es}(I, B)$ .**

Similarly, if you set the **Flux linkage data format** parameter to either D and Q axes flux linkages as a function of D-axis current ( $i_d$ ), Q-axis current ( $i_q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_d$ ), Q-axis current ( $i_q$ ), and rotor angle ( $\theta$ ), then the iron losses are given by:

$$P_{loss, rotor}(f) = k_{hr}(i_d, i_q)f + k_{Jr}(i_d, i_q)f^2 + k_{er}(i_d, i_q)f^{1.5}$$

$$P_{loss, stator}(f) = k_{hs}(i_d, i_q)f + k_{Js}(i_d, i_q)f^2 + k_{es}(i_d, i_q)f^{1.5}$$

where:

- $k_{hr}(i_d, i_q)$  is the **Rotor hysteresis loss coefficient,  $k_{hr}(id, iq)$ .**
- $k_{Jr}(i_d, i_q)$  is the **Rotor eddy current loss coefficient,  $k_{Jr}(id, iq)$ .**
- $k_{er}(i_d, i_q)$  is the **Rotor excess current loss coefficient,  $k_{er}(id, iq)$ .**
- $k_{hs}(i_d, i_q)$  is the **Stator hysteresis loss coefficient,  $k_{hs}(id, iq)$ .**
- $k_{Js}(i_d, i_q)$  is the **Stator eddy current loss coefficient,  $k_{Js}(id, iq)$ .**
- $k_{es}(i_d, i_q)$  is the **Stator excess current loss coefficient,  $k_{es}(id, iq)$ .**

Select this option only in conjunction with a motor design tool that can calculate the coefficients. For more information, see the “Import IPMSM Flux Linkage Data from Motor-CAD” example.

#### **Tabulate with current and speed**

For the **3-D flux linkage data** with or without thermal ports, you can also model the iron losses by tabulating them independently for rotor and stator.

If you set the **Flux linkage data format** parameter to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ), the block tabulated the iron losses with the **Peak current magnitude vector,  $I$**  and **Current advance angle vector,  $B$**  parameters, so that the iron losses are given by:

$$P_{loss}(I_p, \beta, w) = \text{tablelookup}(P_{table}, I_p, \beta, w)$$

where  $w$  is the **Rotor speed vector,  $w$**  parameter.

Similarly, if you set the **Flux linkage data format** parameter to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ), then the iron losses are given by:

$$P_{\text{loss}}(i_d, i_q, w) = \text{tablelookup}(P_{\text{table}}, i_d, i_q, w).$$

### Model Thermal Effects

You can expose thermal ports to model the effects of losses that convert power to heat. To expose the thermal ports, set the **Modeling option** parameter to either:

- 2-D partial derivative data | No thermal port — 2-D table lookup parameterization, with options to tabulate in terms of current and rotor angle, but without thermal ports.
- 2-D partial derivative data | Show thermal port — 2-D table lookup parameterization, with options to tabulate in terms of current and rotor angle, and with thermal ports.
- 3-D partial derivative data | No thermal port — 3-D table lookup parameterization, based on direct current, quadrature current, and rotor angle, but without thermal ports.
- 3-D partial derivative data | Show thermal port — 3-D table lookup parameterization, based on direct current, quadrature current, and rotor angle, and with thermal ports.
- 4-D partial derivative data | No thermal port — 4-D table lookup parameterization, based on the three stator winding currents and the rotor angle, but without thermal ports.
- 4-D partial derivative data | Show thermal port — 4-D table lookup parameterization, based on the three stator winding currents and the rotor angle, and with thermal ports.
- 3-D flux linkage data | No thermal port — 3-D table lookup parameterization, based on the flux linkage data without thermal ports.
- 3-D flux linkage data | Show thermal port — 3-D table lookup parameterization, based on the flux linkage data with thermal ports.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Assumptions and Limitations

This block has the following limitations:

- For the 2-D data model, the stator-stator mutual inductance, defined by the **Stator mutual inductance,  $M_s$**  parameter value, is constant during simulation and does not vary with rotor angle. This means that the block is suitable for modeling most PMSM and brushless DC motors, but not switched reluctance motors.
- The 3-D and 4-D data models assume symmetry, so that the flux linkage dependency on currents and rotor angle for windings B and C can be determined from that for winding A.
- For the 4-D data model, consider memory requirements when fixing the independent parameter values (three currents and rotor angles). The linear interpolation option uses less memory, but the smooth interpolation option is more accurate for a given independent parameter spacing.
- The iron losses model assumes sinusoidal currents.

## Ports

### Conserving

#### **a – A-phase connection**

electrical

Electrical conserving port associated with the A-phase connection.

#### **b – B-phase connection**

## Parameters

#### Modeling option — Flux and torque parameterization methods

2-D partial derivative data | No thermal port (default) | 2-D partial derivative data | Show thermal port | 3-D partial derivative data | No thermal port | 3-D partial derivative data | Show thermal port | 4-D partial derivative data | No thermal port | 4-D partial derivative data | Show thermal port | 3-D flux linkage data | No thermal port | 3-D flux linkage data | Show thermal port

Parameterization method for the flux and torque. To model the effects of copper resistance and iron losses that convert electrical power to heat, choose the options with thermal ports.

#### Electrical (2-D Partial Derivative Data Parameterization)

This configuration of the **Electrical** parameters corresponds to the 2-D Partial Derivative Data block parameterizations, with or without thermal ports. If you are using the 3-D Partial Derivative Data, 4-D Partial Derivative Data, or 3-D Flux Linkage Data parameterization of the block, see “Electrical (3-D Partial Derivative Data Parameterization)” on page 1-573, “Electrical (4-D Partial Derivative Data Parameterization)” on page 1-575, or “Electrical (3-D Flux Linkage Data Parameterization)” on page 1-577 respectively.

#### Parameterization — Parameterization method

Assume constant mutual inductance - tabulate with phase current and rotor angle (default) | Assume sinusoidal back emf - tabulate with d- and q-axis currents

Select the parameterization method:

- Assume constant mutual inductance - tabulate with phase current and rotor angle — This method assumes that the flux linking each winding depends nonlinearly only on the current in that same winding, plus the rotor angle.

- Assume sinusoidal back emf - tabulate with d- and q-axis currents — This method assumes that the flux linking each winding depends nonlinearly on all stator winding currents. It also assumes that the permanent magnet flux linkage is sinusoidal. This option is usually a good fit for interior magnet PMSMs (or IPMSMs).

### Winding type — Stator windings configuration

Wye-wound (default) | Delta-wound

Select the configuration for the stator windings:

- Wye-wound — The stator windings are wye-wound.
- Delta-wound — The stator windings are delta-wound. The *a*-phase is connected between ports **a** and **b**, the *b*-phase between ports **b** and **c** and the *c*-phase between ports **c** and **a**.

### Current vector, **i** — Vector of currents

[-2, 0, 2] A (default)

Vector of currents corresponding to the provided flux linkage partial derivatives. The current vector must be two-sided (have positive and negative values).

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume constant mutual inductance - tabulate with phase current and rotor angle.

### Rotor angle vector, **theta** — Vector of rotor angles

[0, 20, 40, 60] deg (default)

Vector of rotor angles corresponding to the provided flux linkage partial derivatives. The vector must start at zero. This value corresponds to the angle where the A-phase magnetic flux aligns with the rotor permanent magnetic peak flux direction (the direct-axis, or *d*-axis). The last value,  $\theta_{\max}$ , must be the rotor angle where the flux linkage pattern peaks again. Therefore, the number of pole pairs is  $360/\theta_{\max}$  if  $\theta_{\max}$  is expressed in degrees. The default value corresponds to a 6 pole-pair motor.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume constant mutual inductance - tabulate with phase current and rotor angle.

### Flux linkage partial derivative wrt current, $d\Phi(i, \theta)/di$ — Flux linkage partial derivative with respect to current

0.0002\*ones(3,4) Wb/A (default)

Matrix of the flux linkage partial derivatives with respect to current, defined as a function of current vector and rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns. The default value corresponds to the special case where stator inductance does not depend on stator current or on rotor angle.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume constant mutual inductance - tabulate with phase current and rotor angle.

### Flux linkage partial derivative wrt angle, $d\Phi(i, \theta)/d\theta$ — Flux linkage partial derivative with respect to angle

[0, -0.16, 0.16, 0; 0, -0.16, 0.16, 0; 0, -0.16, 0.16, 0] Wb/rad (default)

Matrix of the flux linkage partial derivatives with respect to rotor angle, defined as a function of current vector and rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns. The default value is  $[0, -0.16, 0.16, 0; 0, -0.16, 0.16, 0; 0, -0.16, 0.16, 0]$  Wb/rad, which corresponds to the special case where stator inductance does not depend on stator current.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume constant mutual inductance - tabulate with phase current and rotor angle.

#### Direct axis current vector, $i_d$ — Direct axis current vector

$[-200, 0, 200]$  A (default)

Vector of  $d$ -axis currents corresponding to the provided inductances. The current vector must be two-sided (have positive and negative values).

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with  $d$ - and  $q$ -axis currents.

#### Quadrature axis current vector, $i_q$ — Quadrature axis current vector

$[-200, 0, 200]$  A (default)

Vector of  $q$ -axis currents corresponding to the provided inductances. The current vector must be two-sided (have positive and negative values).

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with  $d$ - and  $q$ -axis currents.

#### Ld matrix, $L_d(i_d, i_q)$ — Ld matrix

$0.0002 * \text{ones}(3, 3)$  H (default)

Matrix of the  $d$ -axis inductances with respect to current, defined as a function of  $d$ -axis and  $q$ -axis current vectors.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with  $d$ - and  $q$ -axis currents.

#### Lq matrix, $L_q(i_d, i_q)$ — Lq matrix

$0.0002 * \text{ones}(3, 3)$  H (default)

Matrix of the  $q$ -axis inductances with respect to current, defined as a function of  $d$ -axis and  $q$ -axis current vectors.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with  $d$ - and  $q$ -axis currents.

#### Permanent magnet flux linkage, $PM(i_d, i_q)$ — Permanent magnet flux linkage

$0.1 * \text{ones}(3, 3)$  Wb (default)

Matrix of the permanent magnet flux linkages with respect to current, defined as a function of  $d$ -axis and  $q$ -axis current vectors. Flux linkage is the flux multiplied by the number of winding turns.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with d- and q-axis currents.

#### Number of pole pairs — Number of pole pairs

6 (default)

Number of the permanent magnet motor pole pairs.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with d- and q-axis currents.

#### Calculate torque matrix? — Electromagnetic torque data specification

Yes (default) | No — specify directly

Specify the way of providing the electromagnetic torque data:

- Yes — The block calculates the torque from the flux linkage information, as a function of current and rotor angle.
- No — specify directly — Enter the electromagnetic torque data directly, by using the **Torque matrix,  $T(i, \theta)$**  parameter.

#### Dependencies

This parameter is visible only when you set the **Parameterization** parameter to Assume constant mutual inductance - tabulate with phase current and rotor angle. If you set the **Parameterization** parameter to Assume sinusoidal back emf - tabulate with d- and q-axis currents, the equation for torque is explicit in terms of the provided matrices.

#### Torque matrix, $T(i, \theta)$ — Torque matrix

zeros(3, 3, 3, 4) N\*m (default)

Specify a matrix of the electromagnetic torque applied to the rotor, as a function of current and rotor angle. This parameter is visible only if **Calculate torque matrix?** is set to No — specify directly.

#### Dependencies

This parameter is visible only when you set the **Calculate torque matrix?** parameter to No — specify directly.

#### Interpolation method — Interpolation method

Linear Smooth (default)

Select one of the following interpolation methods for approximating the output value when the input value is between two consecutive grid points:

- Linear — Uses an extension of linear algorithm for multidimensional interpolation. Select this option to get the best performance.

- **Smooth** — Uses a modified Akima interpolation algorithm. Select this option to produce a continuous surface with continuous first-order derivatives.

For more information on interpolation methods, see the PS Lookup Table (2D) block reference page.

### **Stator resistance per phase, $R_s$ — Stator resistance per phase**

0.013 Ohm (default)

Resistance of each of the stator windings.

### **Stator mutual inductance, $M_s$ — Stator mutual inductance**

0.00002 H (default)

Stator-stator mutual inductance, which is assumed to be independent of both current and rotor angle.

#### **Dependencies**

This parameter is visible only when you set the **Parameterization** parameter to Assume constant mutual inductance - tabulate with phase current and rotor angle.

### **Stator zero-sequence inductance, $L_0$ — Stator zero-sequence inductance**

0.00016 H (default)

Zero-sequence inductance.

#### **Dependencies**

To enable this parameter, set **Parameterization** to Assume sinusoidal back emf - tabulate with d- and q-axis currents.

### **Electrical (3-D Partial Derivative Data Parameterization)**

This configuration of the **Electrical** parameters corresponds to the 3-D Partial Derivative Data block variants, with or without thermal ports. If you are using the 2-D Partial Derivative Data, 4-D Partial Derivative Data, or 3-D Flux Linkage Data parameterization of the block, see “Electrical (2-D Partial Derivative Data Parameterization)” on page 1-569, “Electrical (4-D Partial Derivative Data Parameterization)” on page 1-575, or “Electrical (3-D Flux Linkage Data Parameterization)” on page 1-577 respectively.

### **Winding type — Stator windings configuration**

Wye-wound (default) | Delta-wound

Select the configuration for the stator windings:

- **Wye-wound** — The stator windings are wye-wound.
- **Delta-wound** — The stator windings are delta-wound. The *a*-phase is connected between ports **a** and **b**, the *b*-phase between ports **b** and **c** and the *c*-phase between ports **c** and **a**.

### **Direct-axis current vector, $i_D$ — Direct-axis current vector**

[-200, 0, 200] A (default)

Vector of direct-axis currents corresponding to the provided flux linkage partial derivatives. The current vector must be two-sided (have positive and negative values).

### **Quadrature-axis current vector, $i_Q$ — Quadrature-axis current vector**

[-200, 0, 200] A (default)

Vector of quadrature-axis currents corresponding to the provided flux linkage partial derivatives. The current vector must be two-sided (have positive and negative values).

**Rotor angle vector, theta — Rotor angle vector**

[0, 20, 40, 60] deg (default)

Vector of rotor angles corresponding to the provided flux linkage partial derivatives. The vector must start at zero. This value corresponds to the angle where the A-phase magnetic flux aligns with the rotor permanent magnetic peak flux direction (the direct-axis, or  $d$ -axis). The last value,  $\theta_{\max}$ , must be the rotor angle where the flux linkage pattern peaks again. Therefore, the number of pole pairs is  $360/\theta_{\max}$  if  $\theta_{\max}$  is expressed in degrees. The default value corresponds to a 6 pole-pair motor.

**A-phase flux linkage partial derivative wrt iA, dPhiA(id,iq,theta)/diA — A-phase flux linkage partial derivative with respect to iA**

zeros(3, 3, 4) Wb/A (default)

Matrix of the A-phase flux linkage partial derivatives with respect to current in winding A, defined as a function of the two current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**A-phase flux linkage partial derivative wrt iB, dPhiA(id,iq,theta)/diB — A-phase flux linkage partial derivative with respect to iB**

zeros(3, 3, 4) Wb/A (default)

Matrix of the A-phase flux linkage partial derivatives with respect to current in winding B, defined as a function of the two current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**A-phase flux linkage partial derivative wrt iC, dPhiA(id,iq,theta)/diC — A-phase flux linkage partial derivative with respect to iC**

zeros(3, 3, 4) Wb/A (default)

Matrix of the A-phase flux linkage partial derivatives with respect to current in winding C, defined as a function of the two current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**A-phase flux linkage partial derivative wrt angle, dPhiA(id,iq,theta)/dtheta — A-phase flux linkage partial derivative with respect to angle**

zeros(3, 3, 4) Wb/rad (default)

Matrix of the A-phase flux linkage partial derivatives with respect to rotor angle, defined as a function of the two current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**Torque matrix, T(id,iq,theta) — Torque matrix**

zeros(3, 3, 4) N\*m (default)

Specify a matrix of the electromagnetic torque applied to the rotor, as a function of the two currents and the rotor angle.

**Interpolation method — Interpolation method**

Linear (default) | Smooth

Select one of the following interpolation methods for approximating the output value when the input value is between two consecutive grid points:

- **Linear** — Uses an extension of linear algorithm for multidimensional interpolation. Select this option to get the best performance.
- **Smooth** — Uses a modified Akima interpolation algorithm. Select this option to produce a continuous surface with continuous first-order derivatives.

For more information on interpolation methods, see the PS Lookup Table (3D) block reference page.

### Stator resistance per phase, $R_s$ — Stator resistance per phase

0.013 Ohm (default)

Resistance of each of the stator windings.

### Electrical (4-D Partial Derivative Data Parameterization)

This configuration of the **Electrical** parameters corresponds to the 4-D Partial Derivative Data block variants, with or without thermal ports. If you are using the 2-D Partial Derivative Data, 3-D Partial Derivative Data, or 3-D Flux Linkage Data parameterization of the block, see “Electrical (2-D Partial Derivative Data Parameterization)” on page 1-569, “Electrical (3-D Partial Derivative Data Parameterization)” on page 1-573, or “Electrical (3-D Flux Linkage Data Parameterization)” on page 1-577 respectively.

### Winding type — Stator windings configuration

Wye-wound (default) | Delta-wound

Select the configuration for the stator windings:

- **Wye-wound** — The stator windings are wye-wound.
- **Delta-wound** — The stator windings are delta-wound. The *a*-phase is connected between ports **a** and **b**, the *b*-phase between ports **b** and **c** and the *c*-phase between ports **c** and **a**.

### A-phase current vector, $i_A$ — A-phase current vector

[-200, 0, 200] A (default)

Vector of A-phase currents corresponding to the provided flux linkage partial derivatives. The current vector must be two-sided (have positive and negative values).

### B-phase current vector, $i_B$ — B-phase current vector

[-200, 0, 200] A (default)

Vector of B-phase currents corresponding to the provided flux linkage partial derivatives. The current vector must be two-sided (have positive and negative values).

### C-phase current vector, $i_C$ — C-phase current vector

[-200, 0, 200] A (default)

Vector of C-phase currents corresponding to the provided flux linkage partial derivatives. The current vector must be two-sided (have positive and negative values).

### Rotor angle vector, $\theta$ — Rotor angle vector

[0, 20, 40, 60] deg (default)

Vector of rotor angles corresponding to the provided flux linkage partial derivatives. The vector must start at zero. This value corresponds to the angle where the A-phase magnetic flux aligns with the rotor permanent magnetic peak flux direction (the direct-axis, or *d*-axis). The last value,  $\theta_{\max}$ , must be

the rotor angle where the flux linkage pattern peaks again. Therefore, the number of pole pairs is  $360/\theta_{\max}$  if  $\theta_{\max}$  is expressed in degrees. The default value corresponds to a 6 pole-pair motor.

**A-phase flux linkage partial derivative wrt  $i_A$ ,  $d\Phi_A(i_A, i_B, i_C, \theta)/di_A$  – A-phase flux linkage partial derivative with respect to  $i_A$**

`zeros(3, 3, 3, 4) Wb/A (default)`

Matrix of the A-phase flux linkage partial derivatives with respect to current in winding A, defined as a function of the three current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**A-phase flux linkage partial derivative wrt  $i_B$ ,  $d\Phi_A(i_A, i_B, i_C, \theta)/di_B$  – A-phase flux linkage partial derivative with respect to  $i_B$**

`zeros(3, 3, 3, 4) Wb/A (default)`

Matrix of the A-phase flux linkage partial derivatives with respect to current in winding B, defined as a function of the three current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**A-phase flux linkage partial derivative wrt  $i_C$ ,  $d\Phi_A(i_A, i_B, i_C, \theta)/di_C$  – A-phase flux linkage partial derivative with respect to  $i_C$**

`zeros(3, 3, 3, 4) Wb/A (default)`

Matrix of the A-phase flux linkage partial derivatives with respect to current in winding C, defined as a function of the three current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**A-phase flux linkage partial derivative wrt angle,  $d\Phi_A(i_A, i_B, i_C, \theta)/d\theta$  – A-phase flux linkage partial derivative with respect to angle**

`zeros(3, 3, 3, 4) Wb/rad (default)`

Matrix of the A-phase flux linkage partial derivatives with respect to rotor angle, defined as a function of the three current vectors and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

**Torque matrix,  $T(i_A, i_B, i_C, \theta)$  – Torque matrix**

`zeros(3, 3, 3, 4) N*m (default)`

Specify a matrix of the electromagnetic torque applied to the rotor, as a function of the three currents and the rotor angle.

**Interpolation method – Interpolation method**

`Linear (default) | Smooth`

Select one of the following interpolation methods for approximating the output value when the input value is between two consecutive grid points:

- **Linear** — Uses an extension of linear algorithm for multidimensional interpolation. Select this option to get the best performance.
- **Smooth** — Uses a modified Akima interpolation algorithm. Select this option to produce a continuous surface with continuous first-order derivatives.

For more information on interpolation methods, see the PS Lookup Table (3D) block reference page.

**Stator resistance per phase,  $R_s$  — Stator resistance per phase**

0.013 Ohm (default)

Resistance of each of the stator windings.

**Electrical (3-D Flux Linkage Data Parameterization)**

This configuration of the **Electrical** parameters corresponds to the 3-D Flux Linkage Data block variants, with or without thermal ports. If you are using the 2-D Partial Derivative Data, 3-D Partial Derivative Data, or 4-D Partial Derivative Data parameterization of the block, see “Electrical (2-D Partial Derivative Data Parameterization)” on page 1-569, “Electrical (3-D Partial Derivative Data Parameterization)” on page 1-573, or “Electrical (4-D Partial Derivative Data Parameterization)” on page 1-575, respectively.

**Flux linkage data format — Flux linkage data format**

D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) (default) | D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) | A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) | A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ )

Select the flux linkage data format used by your FE tool:

- D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ )
- D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ )
- A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ )
- A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ )

**Winding type — Stator windings configuration**

Wye-wound (default) | Delta-wound

Select the configuration for the stator windings:

- Wye-wound — The stator windings are wye-wound.
- Delta-wound — The stator windings are delta-wound. The  $a$ -phase is connected between ports **a** and **b**, the  $b$ -phase between ports **b** and **c** and the  $c$ -phase between ports **c** and **a**.

**Expose neutral port — Neutral port visibility**

No (default) | Yes

Whether to expose the neutral port of the block.

If you expose the neutral port, the block also models the zero sequence currents. The zero sequence is parameterized by the **Stator zero-sequence inductance,  $L_0$**  parameter. When you tabulate in terms of  $i_D$  and  $i_Q$ , or in terms of current magnitude and phase advance, there is no information about non-linear dependence on the zero-sequence current, and the block introduces a degree of approximation. For more accurate results, particularly for large zero-sequence currents, use the **4-D partial derivative data** parameterization option.

**Dependencies**

To enable this parameter, set **Winding type** parameter to Wye-wound.

**Number of pole pairs — Number of pole pairs**

4 (default)

Number of the permanent magnet motor pole pairs. The default value is 4.

**Park's convention for tabulated data — Park's convention for tabulated data**

Q leads D, rotor angle measured from A-phase to D-axis (default) | Q leads D, rotor angle measured from A-phase to Q-axis | D leads Q, rotor angle measured from A-phase to D-axis | D leads Q, rotor angle measured from A-phase to Q-axis

Select the order and reference angle for the Park transform mapping the given  $dq$  data to the three windings.

- Q leads D, rotor angle measured from A-phase to D-axis — Quadrature-direct transformation with angle measured with respect to  $d$  axis.
- Q leads D, rotor angle measured from A-phase to Q-axis — Quadrature-direct transformation with angle measured with respect to  $q$  axis.
- D leads Q, rotor angle measured from A-phase to D-axis — Direct-quadrature transformation with angle measured with respect to  $d$  axis.
- D leads Q, rotor angle measured from A-phase to Q-axis — Direct-quadrature transformation with angle measured with respect to  $q$  axis.

**Direct-axis current vector,  $i_D$  — Direct-axis current vector**

[-200, 0, 200] A (default)

Vector of direct-axis currents at which the flux linkage is tabulated. The current vector must be two-sided (have positive and negative values).

**Dependencies**

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Quadrature-axis current vector,  $i_Q$  — Quadrature-axis current vector**

[-200, 0, 200] A (default)

Vector of quadrature-axis currents at which the flux linkage is tabulated. The current vector must be two-sided (have positive and negative values).

**Dependencies**

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Peak current magnitude vector,  $I$  — Peak current magnitude vector**

[0, 100, 200] A (default)

Row vector of current magnitudes at which the flux linkage is tabulated. The first element must be zero. The adjacent current value should be small relative to the current values at which magnetic saturation begins to occur. This is because derived flux partial derivatives are ill-defined at zero current, and so are calculated at this first nonzero current instead.

#### Dependencies

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta).

#### Current advance angle, B — Current advance angle

[-180, -90, 0, 90, 180] deg (default)

Row vector of current advance angle values at which the flux linkage is tabulated. Current advance angle is defined as the angle by which the current leads the quadrature (Q) axis.

#### Dependencies

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta).

#### Rotor angle vector, theta — Rotor angle vector

[[0, 5, 10, 15, 20, 25, 30] deg (default)

Vector of rotor angles at which the flux linkage is tabulated. The vector must start at zero. This value corresponds to the angle where the A-phase magnetic flux aligns with the rotor permanent magnetic peak flux direction (the direct-axis, or *d*-axis). The last value,  $\theta_{\max}$ , must be the rotor angle where the flux linkage pattern peaks again. Therefore, the number of pole pairs is  $360/\theta_{\max}$  if  $\theta_{\max}$  is expressed in degrees. The default value corresponds to a 4 pole-pair motor.

If **Flux linkage data format** is D and Q axes flux linkages as a function of D-axis current (*i*<sub>D</sub>), Q-axis current (*i*<sub>Q</sub>), and rotor angle (theta) or D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) (that is, if you tabulate D and Q flux linkage data), then the rotor angle vector must have four or more points and a range from 0 to  $120/N$  degrees, where *N* is the number of pole pairs. If **Flux linkage data format** is A-phase flux linkage as a function of D-axis current (*i*<sub>D</sub>), Q-axis current (*i*<sub>Q</sub>), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) (that is, if you tabulate A-phase flux linkage data), then the rotor angle vector must have  $3n+1$  points, where  $n \geq 2$ , and the range must be from 0 to  $360/3/N$  degrees.

#### D-axis flux linkage, Fd(*i*<sub>D</sub>,*i*<sub>Q</sub>,theta) — D-axis flux linkage

zeros(3, 3, 7) Wb (default)

Matrix of the *d*-axis flux linkage, defined as a function of the *dq* currents, and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

#### Dependencies

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of D-axis current (`iD`), Q-axis current (`iQ`), and rotor angle (`theta`).

#### Q-axis flux linkage, $F_q(iD, iQ, \theta)$ – Q-axis flux linkage

`zeros(3, 3, 7) Wb (default)`

Matrix of the  $q$ -axis flux linkage, defined as a function of the  $dq$  currents, and the rotor angle vector. Flux linkage is the flux multiplied by the number of winding turns.

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

#### Dependencies

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of D-axis current (`iD`), Q-axis current (`iQ`), and rotor angle (`theta`).

#### D-axis flux linkage, $F_d(I, B, \theta)$ – D-axis flux linkage

`zeros(3, 5, 7) Wb (default)`

3-D matrix of  $d$ -axis flux linkage values as a function of **Peak current magnitude vector, I**, **Current advance angle, B**, and **Rotor angle vector, theta**.

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

#### Dependencies

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of peak current magnitude (`I`), current advance angle (`B`), and rotor angle (`theta`).

#### Q-axis flux linkage, $F_q(I, B, \theta)$ – Q-axis flux linkage

`zeros(3, 5, 7) Wb (default)`

3-D matrix of  $q$ -axis flux linkage values as a function of **Peak current magnitude vector, I**, **Current advance angle, B**, and **Rotor angle vector, theta**.

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

#### Dependencies

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of peak current magnitude (`I`), current advance angle (`B`), and rotor angle (`theta`).

**A-phase flux linkage,  $F(i_D, i_Q, \theta)$  – A-phase flux linkage**

zeros(3, 3, 7) Wb (default)

3-D matrix of A-phase flux linkage values, as a function of the  $dq$  currents and the rotor angle.

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

**Dependencies**

This parameter is visible only when you set the **Flux linkage data format** parameter to A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**A-phase flux linkage,  $F(I, B, \theta)$  – A-phase flux linkage**

zeros(3, 5, 7) Wb (default)

3-D matrix of A-phase flux linkage values, as a function of **Peak current magnitude vector, I, Current advance angle, B,** and **Rotor angle vector, theta.**

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

**Dependencies**

This parameter is visible only when you set the **Flux linkage data format** parameter to A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Torque matrix,  $T(i_D, i_Q, \theta)$  – Torque matrix**

zeros(3, 3, 7) N\*m (default)

3-D matrix of the electromagnetic torque applied to the rotor, as a function of the  $dq$  currents and the rotor angle.

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

**Dependencies**

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Torque matrix,  $T(I, B, \theta)$  – Torque matrix**

zeros(3, 5, 7) N\*m (default)

3-D matrix of the electromagnetic torque applied to the rotor, as a function of **Peak current magnitude vector, I, Current advance angle, B,** and **Rotor angle vector, theta.**

If your flux data is given in a different order, you can use the `permute` function to reorder it. For an example of this reordering, see the associated MATLAB script in “Import IPMSM Flux Linkage Data from ANSYS Maxwell”.

**Dependencies**

This parameter is visible only when you set the **Flux linkage data format** parameter to D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta).

**Interpolation method — Interpolation method**

Linear (default) | Smooth

Select one of the following interpolation methods for approximating the output value when the input value is between two consecutive grid points:

- **Linear** — Uses an extension of linear algorithm for multidimensional interpolation. Select this option to get the best performance.
- **Smooth** — Uses a modified Akima interpolation algorithm. Select this option to produce a continuous surface with continuous first-order derivatives.

For more information on interpolation methods, see the PS Lookup Table (4D) block reference page.

**Stator resistance per phase, Rs — Stator resistance per phase**

0.013 Ohm (default)

Resistance of each of the stator windings.

**Stator zero-sequence inductance, L0 — Stator zero-sequence inductance**

0.00016 H (default)

Zero-sequence inductance.

**Dependencies**

To enable this parameter, set **Winding type** to Delta-Wound or **Expose neutral port** to Yes.

**Iron Losses**

For more information on calculating iron losses, see “Calculating Iron Losses” on page 1-565.

**Model — Iron losses modeling option**

None (default) | Specify open and short circuit loss data (permanent magnet motors only) | Specify tabulated Steinmetz coefficients | Tabulate with current and speed

Whether to enable iron losses modeling. The Specify tabulated Steinmetz coefficients and Tabulate with current and speed options are only available if you choose the **3-D flux linkage data** | **No thermal port** or **3-D flux linkage data** | **Show thermal port** variants.

**Open-circuit iron losses, [P\_hysteresis P\_eddy P\_excess] — Open-circuit iron losses**

[0.0, 0.0, 0.0] W (default)

Row vector, of length 3, of the open-circuit iron losses due to hysteresis, Eddy, and excess losses, respectively, at the frequency specified by **Electrical frequency at which losses determined**.

**Dependencies**

To enable this parameter, set **Model** to Specify open and short circuit loss data (permanent magnet motors only)

**Short-circuit iron losses, [P\_hysteresis P\_eddy P\_excess] — Short-circuit iron losses**

[0.0, 0.0, 0.0] W (default)

Row vector, of length 3, of the short-circuit iron losses due to hysteresis, Eddy, and excess losses, respectively, at the frequency specified by **Electrical frequency at which losses determined**.

**Dependencies**

To enable this parameter, set **Model** to Specify open and short circuit loss data (permanent magnet motors only)

**Electrical frequency at which losses determined — Electrical frequency at which losses determined**

60 Hz (default)

Electrical frequency at which the open-circuit and short-circuit iron losses were measured.

**Dependencies**

To enable this parameter, set **Model** to Specify open and short circuit loss data (permanent magnet motors only).

**Short-circuit RMS current for short-circuit iron losses — Short-circuit RMS current for short-circuit iron losses**

95 A (default)

The resulting short-circuit RMS phase current when measuring the short-circuit losses.

**Dependencies**

To enable this parameter, set **Model** to Specify open and short circuit loss data (permanent magnet motors only)

**Rotor hysteresis loss coefficient, k\_hr(id,iq) — Rotor hysteresis loss coefficient**

zeros(3, 3) W/Hz (default)

Hysteresis loss coefficient of the rotor depending on the *d*-axis and *q*-axis currents. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current (*i*<sub>D</sub>), Q-axis current (*i*<sub>Q</sub>), and rotor angle (*theta*) or A-phase flux linkage as a function of D-axis current (*i*<sub>D</sub>), Q-axis current (*i*<sub>Q</sub>), and rotor angle (*theta*).

**Rotor eddy current loss coefficient, k\_Jr(id,iq) — Rotor eddy current loss coefficient**

zeros(3, 3) W/Hz<sup>2</sup> (default)

Eddy current loss coefficient of the rotor depending on the  $d$ -axis and  $q$ -axis currents. It is used by the Steinmetz equation.

#### Dependencies

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

#### Rotor excess current loss coefficient, $k_{er}(i_D, i_Q)$ – Rotor excess current loss coefficient

`zeros(3, 3) W/Hz^1.50000` (default)

Excess current loss coefficient of the rotor depending on the  $d$ -axis and  $q$ -axis currents. It is used by the Steinmetz equation.

#### Dependencies

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

#### Stator hysteresis loss coefficient, $k_{hs}(i_D, i_Q)$ – Stator hysteresis loss coefficient

`zeros(3, 3) W/Hz` (default)

Hysteresis loss coefficient of the stator depending on the  $d$ -axis and  $q$ -axis currents. It is used by the Steinmetz equation.

#### Dependencies

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

#### Stator eddy current loss coefficient, $k_{Js}(i_D, i_Q)$ – Stator eddy current loss coefficient

`zeros(3, 3) W/Hz^2` (default)

Eddy current loss coefficient of the stator depending on the  $d$ -axis and  $q$ -axis currents. It is used by the Steinmetz equation.

#### Dependencies

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Stator excess current loss coefficient,  $k_{es}(i_d, i_q)$  – Stator excess current loss coefficient**

$\text{zeros}(3, 3)$  W/Hz<sup>1.50000</sup> (default)

Excess current loss coefficient of the stator depending on the  $d$ -axis and  $q$ -axis currents. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_d$ ), Q-axis current ( $i_q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_d$ ), Q-axis current ( $i_q$ ), and rotor angle ( $\theta$ ).

**Rotor hysteresis loss coefficient,  $k_{hr}(I, B)$  – Rotor hysteresis loss coefficient**

$\text{zeros}(3, 5)$  W/Hz (default)

Hysteresis loss coefficient of the rotor depending on the current magnitude and current phase advance. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ).

**Rotor eddy current loss coefficient,  $k_{Jr}(I, B)$  – Rotor eddy current loss coefficient**

$\text{zeros}(3, 5)$  W/Hz<sup>2</sup> (default)

Eddy current loss coefficient of the rotor depending on the current magnitude and current phase advance. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ).

**Rotor excess current loss coefficient,  $k_{er}(I, B)$  – Rotor excess current loss coefficient**

$\text{zeros}(3, 5)$  W/Hz<sup>1.50000</sup> (default)

Excess current loss coefficient of the rotor depending on the current magnitude and current phase advance. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ).

**Stator hysteresis loss coefficient,  $k_{hs}(I,B)$  – Stator hysteresis loss coefficient**  
zeros(3, 5) W/Hz (default)

Hysteresis loss coefficient of the stator depending on the current magnitude and current phase advance. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta).

**Stator eddy current loss coefficient,  $k_{Js}(I,B)$  – Stator eddy current loss coefficient**  
zeros(3, 5) W/Hz<sup>2</sup> (default)

Eddy current loss coefficient of the stator depending on the current magnitude and current phase advance. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta).

**Stator excess current loss coefficient,  $k_{es}(I,B)$  – Stator excess current loss coefficient**  
zeros(3, 5) W/Hz<sup>1.50000</sup> (default)

Excess current loss coefficient of the stator depending on the current magnitude and current phase advance. It is used by the Steinmetz equation.

**Dependencies**

To enable this parameter, set **Model** to Specify tabulated Steinmetz coefficients and, in the **Electrical** tab, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta) or A-phase flux linkage as a function of peak current magnitude (I), current advance angle (B), and rotor angle (theta).

**Rotor speed vector,  $w$  – Rotor speed**  
[1000, 2000] rpm (default)

Vector of rotor speed at which the iron loss is tabulated.

**Dependencies**

To enable this parameter, set **Model** to Tabulate with current and speed and, in the **Electrical** setting, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current (iD), Q-axis current (iQ), and rotor angle (theta) or A-phase flux linkage as a function of D-axis current (iD), Q-axis current (iQ), and rotor angle (theta).

**Rotor iron loss table,  $P_r(i_d, i_q, w)$  – Rotor iron loss table**

zeros(3, 3, 2) W (default)

Iron losses of the rotor tabulated on the  $d$ -axis and  $q$ -axis currents, and rotor speed.

**Dependencies**

To enable this parameter, set **Model** to Tabulate with current and speed and, in the **Electrical** setting, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Stator iron loss table,  $P_s(i_d, i_q, w)$  – Stator iron loss table**

zeros(3, 3, 2) W (default)

Iron losses of the stator tabulated on the  $d$ -axis and  $q$ -axis currents, and rotor speed.

**Dependencies**

To enable this parameter, set **Model** to Tabulate with current and speed and, in the **Electrical** setting, set **Flux linkage data format** to either D and Q axes flux linkages as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of D-axis current ( $i_D$ ), Q-axis current ( $i_Q$ ), and rotor angle ( $\theta$ ).

**Rotor iron loss table,  $P_r(I, B, w)$  – Rotor iron loss table**

zeros(3, 5, 2) W (default)

Iron losses of the rotor tabulated on the current magnitude, current phase advance, and rotor speed.

**Dependencies**

To enable this parameter, set **Model** to Tabulate with current and speed and, in the **Electrical** setting, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ).

**Stator iron loss table,  $P_s(I, B, w)$  – Stator iron loss table**

zeros(3, 5, 2) W (default)

Iron losses of the stator tabulated on the current magnitude, current phase advance, and rotor speed.

**Dependencies**

To enable this parameter, set **Model** to Tabulate with current and speed and, in the **Electrical** setting, set **Flux linkage data format** to either D and Q axes flux linkages as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ) or A-phase flux linkage as a function of peak current magnitude ( $I$ ), current advance angle ( $B$ ), and rotor angle ( $\theta$ ).

**Mechanical****Rotor inertia – Rotor inertia**0.01 kg\*m<sup>2</sup> (default)

Inertia of the rotor attached to mechanical translational port **R**. The value can be zero.

**Rotor damping — Rotor damping**

0 N\*m/(rad/s) (default)

Rotary damping.

**Temperature Dependence**

To enable these parameters, set **Modeling option** to Show thermal port.

**Measurement temperature — Measurement temperature**

298.15 K (default)

The temperature for which motor parameters are quoted.

**Resistance temperature coefficient — Resistance temperature coefficient**

3.93e-3 1/K (default)

Coefficient  $\alpha$  in the equation relating resistance to temperature, as described in “Thermal Model for Actuator Blocks”. The default value is for copper.

**Permanent magnet flux temperature coefficient — Permanent magnet flux temperature coefficient**

-0.001 (default)

The fractional rate of change of permanent magnet flux density with temperature. It is used to linearly reduce the torque and the induced back EMF as temperature rises.

**Thermal Port**

To enable these parameters, set **Modeling option** to Show thermal port.

**Thermal mass for each stator winding — Thermal mass for each stator winding**

100 J/K (default)

The thermal mass value for the A, B, and C windings. The thermal mass is the energy required to raise the temperature by one degree.

**Initial stator winding temperatures — Initial stator winding temperatures**

[298.15, 298.15, 298.15] K (default)

A 1-by-3 row vector defining the temperature of the A, B, and C thermal ports at the start of simulation.

**Rotor thermal mass — Rotor thermal mass**

200 J/K (default)

The thermal mass of the rotor, that is, the energy required to raise the temperature of the rotor by one degree.

**Rotor initial temperature — Rotor initial temperature**

298.15 K (default)

The temperature of the rotor at the start of simulation.

**Percentage of main flux path iron losses associated with the rotor –  
Percentage of main flux path iron losses associated with the rotor**

90 (default)

The percentage of the main flux path iron losses associated with the magnetic path through the rotor. It determines how much of the iron loss heating is attributed to the rotor thermal port **HR**, and how much is attributed to the three winding thermal ports **HA**, **HB**, and **HC**.

**Percentage of cross-tooth flux path iron losses associated with the rotor –  
Percentage of cross-tooth flux path iron losses associated with the rotor**

30 (default)

The percentage of the cross-tooth flux path iron losses associated with the magnetic path through the rotor. It determines how much of the iron loss heating is attributed to the rotor thermal port **HR**, and how much is attributed to the three winding thermal ports **HA**, **HB**, and **HC**.

# FEM-Parameterized Rotary Actuator

Rotary actuator defined in terms of magnetic flux

**Library:** Simscape / Electrical / Electromechanical / Mechatronic Actuators

## Description

The FEM-Parameterized Rotary Actuator block implements a model of a rotary actuator defined in terms of magnetic flux. Use this block to model custom rotary actuators and motors where magnetic flux depends on both rotor angle and current. You parameterize the block using data from a third-party Finite Element Magnetic (FEM) package.

The block has two options for the electrical equation. The first, **Define in terms of  $d\Phi(i, \theta)/d\theta$  and  $d\Phi(i, \theta)/di$** , defines the current in terms of partial derivatives of the magnetic flux ( $\Phi$ ) with respect to rotor angle ( $\theta$ ) and current ( $i$ ), the equations for which are:

$$\frac{di}{dt} = \left( v - iR - \frac{\partial \Phi}{\partial \theta} \frac{d\theta}{dt} \right) / \frac{\partial \Phi}{\partial i}$$

The second option, **Define in terms of  $\Phi(i, \theta)$** , defines the voltage across the component directly in terms of the flux, the equation for which is:

$$v = iR + \frac{d}{dt} \Phi(\theta, i)$$

Numerically, defining the electrical equation in terms of flux partial derivatives is better because the back-emf is piecewise continuous. If using the flux directly, using a finer grid size for current and position will improve results, as will selecting cubic or spline interpolation.

In both cases, you have an option to either directly specify the torque as a function of current and rotor angle, by using the **Torque matrix,  $T(i, \theta)$**  parameter, or have the block automatically calculate the torque matrix.

If entering the electromagnetic torque data directly, you can either use data supplied by the finite element magnetic package (which you used to determine the flux) or calculate the torque from the flux with following equation:

$$T = \int_0^i \frac{\partial \Phi(\theta, i)}{\partial \theta} di$$

See the “Solenoid Parameterized with FEM Data” example model for an example of how to implement this type of integration in MATLAB.

Alternatively, the block can automatically calculate the torque matrix from the flux information that you provide. To select this option, set the **Calculate torque matrix?** parameter to Yes. The torque

matrix calculation occurs at model initialization based on current block flux linkage information. The torque is calculated by numerically integrating the rate of change of flux linkage with respect to angle over current, according to the preceding equation. If the **Electrical model** parameter is set to **Define in terms of  $\Phi(i, \theta)$** , then the block must first estimate the **Flux partial derivative wrt angle,  $\Phi(i, \theta)/d\theta$**  parameter value from the flux linkage data. When doing this, the block uses the interpolation method specified by the **Interpolation method** parameter. Typically, the **Smooth** option is most accurate, but the **Linear** option is most robust.

You can define  $\Phi$  and its partial derivatives for just positive, or positive and negative currents. If defining for just positive currents, then the block assumes that  $\Phi(-i, x) = -\Phi(i, x)$ . Therefore, if the current vector is positive only:

- The first current value must be zero.
- The flux corresponding to zero current must be zero.
- The partial derivative of flux with respect to rotor angle must be zero for zero current.

To model a rotary motor with a repeated flux pattern, set the **Flux dependence on displacement** parameter to **Cyclic**. When selecting this option, the torque and flux (or torque and flux partial derivatives depending on the option chosen) must have identical first and last columns.

### Model Thermal Effects

You can expose the thermal port to model the effects of losses that convert power to heat. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port.
- **Show thermal port** — The block contains one thermal conserving port.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

## Assumptions and Limitations

- You must supply a consistent set of torque and flux data. There is no check to ensure that the torque matrix is consistent with the flux data.
- When driving the FEM-Parameterized Rotary Actuator block via a series inductor, you may need to include a parallel conductance in the inductor component.

## Ports

### Conserving

#### + — Positive terminal

electrical

Electrical conserving port associated with the actuator positive terminal.

#### - — Negative terminal

electrical

Electrical conserving port associated with the actuator negative terminal.

**C – Case**

mechanical

Mechanical rotational conserving port associated with the actuator case.

**R – Rotor**

mechanical

Mechanical rotational conserving port associated with the rotor.

**H – Thermal port**

thermal

Thermal port.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters****Modeling option – Whether to enable thermal port**

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of losses that convert power to heat.

**Magnetic Force****Electrical model – Electrical model parameterization**Define in terms of  $d\Phi(i,\theta)/d\theta$  and  $d\Phi(i,\theta)/di$  (default) | Define in terms of  $\Phi(i,\theta)$ 

Select one of the following parameterization options, based on the underlying electrical model:

- Define in terms of  $d\Phi(i,\theta)/d\theta$  and  $d\Phi(i,\theta)/di$  — Define the current through the block in terms of partial derivatives of the magnetic flux with respect to distance and current.
- Define in terms of  $\Phi(i,\theta)$  — Define the voltage across the block terminals directly in terms of the flux.

**Current vector,  $i$  – Current vector**

[0, .2, .4, .6, .8, 1] A (default)

Specify a vector of monotonically increasing current values corresponding to your torque-flux data. If you specify positive currents only, the first element must be zero.

**Angle vector,  $\theta$  – Angle vector**

[0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 160, 170, 180] deg (default)

Specify a vector of monotonically increasing rotor angle values corresponding to your torque-flux data.

### Dependencies

This parameter is visible only when you set the **Calculate torque matrix?** parameter to No.

### Flux dependence on displacement — Flux pattern

Unique (default) | Cyclic

Specify the flux pattern:

- **Unique** — No flux pattern present.
- **Cyclic** — Select this option to model a linear motor with a repeated flux pattern. The force and flux (or force and flux partial derivatives, depending on the **Electrical model** option chosen) must have identical first and last columns.

### Interpolation method — Interpolation method

Linear (default) | Smooth

Select one of the following interpolation methods for approximating the output value when the input value is between two consecutive grid points:

- **Linear** — Select this option to get the best performance.
- **Smooth** — Select this option to produce a continuous surface with continuous first-order derivatives.

For more information on interpolation algorithms, see the PS Lookup Table (2D) block reference page.

### Extrapolation method — Extrapolation method

Linear (default) | Nearest | Error

Select one of the following extrapolation methods for determining the output value when the input value is outside the range specified in the argument list:

- **Linear** — Select this option to produce a surface with continuous first-order derivatives in the extrapolation region and at the boundary with the interpolation region.
- **Nearest** — Select this option to produce an extrapolation that does not go above the highest point in the data or below the lowest point in the data.

- **Error** — Issues an error if the input signal is outside the range of the table. Select this option to avoid going into the extrapolation mode when you want your data to be within the table range.

For more information on extrapolation algorithms, see the PS Lookup Table (2D) block reference page.

### **Dependencies**

This parameter is visible only when you set the **Flux dependence on displacement** parameter to Unique.

### **Winding resistance — Electrical winding total resistance**

14 Ohm (default)

Total resistance of the electrical winding.

### **Magnetizing resistance — Magnetizing resistance for iron losses**

inf Ohm (default)

Magnetizing resistance. The value must be greater than zero. The default value is inf, which implies that there are no iron losses.

### **Mechanical**

#### **Damping — Rotary damping**

0.0001 N\*m/(rad/s) (default)

Rotary damping. The value can be zero.

#### **Rotor inertia — Rotor inertia**

0.00005 kg\*m<sup>2</sup> (default)

Inertia of the rotor attached to mechanical translational port **R**. The value can be zero.

#### **Minimum rotor angle — Minimum rotor angle**

-Inf deg (default)

The rotor angle at which the lower mechanical end stop is applied.

#### **Maximum rotor angle — Maximum rotor angle**

Inf deg (default)

The rotor angle at which the upper mechanical end stop is applied.

#### **Contact stiffness — Contact stiffness**

1e8 N\*m/rad (default)

Contact stiffness between rotor and end stops.

#### **Contact damping — Contact damping**

1e4 N\*m/(rad/s) (default)

Contact damping between rotor and end stops.

### **Temperature Dependence**

To enable these parameters, set **Modeling option** to Show thermal port.

**Resistance temperature coefficient – Resistance temperature coefficient**

3.93e-3 1/K (default)

Resistance temperature coefficient.

**Measurement temperature – Measurement temperature**

25 degC (default)

Temperature for which the actuator parameters are defined.

**Thermal Port**To enable this parameter, set **Modeling option** to Show thermal port.**Thermal mass – Thermal mass**

100 J/K (default)

Thermal mass is the energy required to raise the temperature by one degree.

## Filtered Derivative (Discrete or Continuous)

Discrete-time or continuous-time filtered derivative

**Library:** Simscape / Electrical / Control / General Control

### Description

The Filtered Derivative (Discrete or Continuous) block implements a filtered derivative in conformance with IEEE 421.5-2016<sup>[1]</sup>.

You can switch between continuous and discrete implementations of the derivative using the **Sample time** parameter.

### Equations

#### Continuous

To configure the filtered derivative for continuous time, set the **Sample time** property to 0. This representation is equivalent to the continuous transfer function:

$$G(s) = \frac{Ks}{Ts + 1},$$

where:

- $K$  is the gain.
- $T$  is the time constant.

From the preceding transfer function, the derivative defining equations are:

$$\begin{cases} \dot{x}(t) = \frac{1}{T}(Ku(t) - x(t)) \\ y(t) = \frac{1}{T}(Ku(t) - x(t)) \end{cases} \quad x(0) = u_0, \quad y(0) = 0,$$

where:

- $u$  is the block input.
- $x$  is the state.
- $y$  is the block output.
- $t$  is the simulation time.
- $u_0$  is the initial input to the block.

## Discrete

To configure the filtered derivative for discrete time, set the **Sample time** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block. The discrete representation is equivalent to the transfer function:

$$\left(\frac{K}{T}\right)\frac{z-1}{z+T_s/T-1},$$

where:

- $K$  is the gain.
- $T$  is the time constant.
- $T_s$  is the sample time.

From the discrete transfer function, the derivative equations are defined using the forward Euler method:

$$\begin{cases} x(n+1) = \left(1 - \frac{T_s}{T}\right)x(n) + \left(\frac{T_s}{T}\right)u(n) \\ y(n) = \frac{K}{T}(u(n) - x(n)) \end{cases} \quad x(0) = u_0, y(0) = 0,$$

where:

- $u$  is the block input.
- $x$  is the block state.
- $y$  is the block output.
- $n$  is the simulation time step.
- $u_0$  is the initial input to the block.

## Initial Conditions

To specify the initial conditions of this block, set **Initialization** to:

- **Inherited from block input** — The block sets the state initial condition to the initial input, making the initial output zero.
- **Specify as parameter** — The block sets the state initial condition to the value of **Initial state**.

## Limiting the Output

Limit the filtered derivative output by setting the **Upper saturation limit** and **Lower saturation limit** parameters to finite values.

Unlike other common blocks given in IEEE 421.5-2016, there is no difference between the windup and anti-windup saturation methods for the filtered derivative. The output can respond immediately to a reversal of the input sign when the output is saturated.

## Ports

### Input

#### **u — Derivative input**

vector

Filtered derivative input signal. The block uses the input initial value to determine the state initial value.

Data Types: `single` | `double`

### Output

#### **y — Derivative output**

vector

Filtered derivative output signal.

Data Types: `single` | `double`

## Parameters

#### **Gain — Derivative gain**

1 (default) | positive number

Filtered derivative gain.

#### **Time constant — Derivative time constant**

0.1 (default) | positive number

Filtered derivative time constant. For acceptable accuracy, set this value at least 10 times greater than the **Sample time**.

#### **Upper saturation limit — Output upper limit**

`inf` (default) | real number

Filtered derivative upper output limit. Set this to `inf` for an unsaturated upper limit.

#### **Lower saturation limit — Output lower limit**

`-inf` (default) | real number

Filtered derivative lower output limit. Set this to `-inf` for an unsaturated lower limit.

#### **Minimum sample time to time constant ratio — Discrete ratio**

10 (default) | real number

Minimum acceptable sample time to time constant ratio. As the sample time approaches the time constant, the accuracy of the block decreases. Use this parameter to set the tolerance of this ratio.

#### **Initialization — Initial state specification**

Inherited from block input (default) | Specify as parameter

Specify the initial state condition for this block. For more information, see “Initial Conditions” on page 1-599.

**Initial state – Initial state**

0 (default) | real number

Block initial state.

**Dependencies**To enable this parameter, set **Initialization to Specify** as parameter.**Sample time (-1 for inherited) – Block sample time**

-1 (default) | positive number

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

For acceptable accuracy, set this value at least 10 times smaller than the **Time constant** parameter.

If this block is in a masked subsystem, or other variant subsystem that allows either continuous and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

## Finite-Gain Op-Amp

Gain-limited operational amplifier model with optional noise

**Library:** Simscape / Electrical / Integrated Circuits

### Description

The Finite-Gain Op-Amp block models a gain-limited operational amplifier. If the voltages at the positive and negative ports are  $V_p$  and  $V_m$ , respectively, the output voltage is:

$$V_{out} = A(V_p - V_m) - I_{out} * R_{out}$$

where:

- $A$  is the gain.
- $R_{out}$  is the output resistance.
- $I_{out}$  is the output current.

The input current is:

$$\frac{V_p - V_m}{R_{in}}$$

where  $R_{in}$  is the input resistance.

The output voltage is limited by the minimum and maximum output values you specify in the block dialog box.

### Thermal Noise

The Finite-Gain Op-Amp block can generate thermal noise. If you set the **Noise mode** parameter to Enabled, then the equivalent circuit for the block includes a noise current source attached to each of the inputs, and a noise voltage source attached to the noninverting input. These three noise sources are independent and uncorrelated.

The block generates noise voltage and current according to:

$$v_{noise} = \frac{v_{density}}{\sqrt{2h}}N(0, 1)$$

$$i_{noise} = \frac{i_{density}}{\sqrt{2h}}N(0, 1)$$

where:

- $v_{noise}$  is the noise voltage.
- $v_{density}$  is the single-sided, spectral amplitude density of the voltage noise.
- $i_{noise}$  is the noise current at an input.
- $i_{density}$  is the single-sided, spectral amplitude density of the current noise applied to that input.
- $h$  is the sampling time.
- $N$  is a Gaussian random number with zero mean and standard deviation of one.

The block generates Gaussian noise by using the PS Random Number source in the Simscape Foundation library. You can control the random number seed by setting the **Repeatability** parameter:

- **Not repeatable** — Every time you simulate your model, the block resets the random seed using the MATLAB random number generator:

```
seed = randi(2^32-1);
```

- **Repeatable** — The block automatically generates a seed value and stores it inside the block, to always start the simulation with the same random number. This auto-generated seed value is set when you add a Finite-Gain Op-Amp block from the block library to the model. When you make a new copy of the Finite-Gain Op-Amp block from an existing one in a model, a new seed value is generated. The block sets the value using the MATLAB random number generator command shown above.
- **Specify seed** — If you select this option, additional parameters let you directly specify the random number seed values for input voltage, noninverting input current, and inverting input current.

## Ports

### Conserving

#### + — Positive electrical voltage

electrical

Electrical conserving port associated with the op-amp noninverting input.

#### - — Negative electrical voltage

electrical

Electrical conserving port associated with the op-amp inverting input.

#### out — Output voltage

electrical

Electrical conserving port associated with the op-amp output. The port name is hidden on the block icon, but you can see it in simulation data logs.

## Parameters

### Main

#### Gain, A — Open-loop gain

1000 (default)

The open-loop gain of the operational amplifier.

#### Input resistance, Rin — Resistance at block input

1e6 Ohm (default)

The resistance at the input of the operational amplifier that the block uses to calculate the input current.

#### Output resistance, Rout — Resistance at block output

100 Ohm (default)

The resistance at the output of the operational amplifier that the block uses to calculate the drop in output voltage due to output current.

#### Minimum output, Vmin — Output voltage lower limit

-15 V (default)

The lower limit on the operational amplifier output voltage.

#### Maximum output, Vmax — Output voltage upper limit

15 V (default)

The upper limit on the operational amplifier output voltage.

### Noise

#### Noise mode — Select whether op-amp generates thermal noise

Disabled (default) | Enabled

Select whether to model thermal noise effects:

- Disabled — Op-amp does not generate thermal noise.
- Enabled — Op-amp generates thermal noise voltage and current, and the associated parameters become visible in the **Noise** section.

#### Input noise voltage density — Density of voltage noise

30e-9 V/Hz<sup>0.5</sup> (default)

Single-sided, spectral amplitude density of the voltage noise applied to the noninverting input.

### Dependencies

Enabled when the **Noise mode** parameter is set to Enabled.

**Noise current parameterization — Select whether noise current density is different or the same for both inputs**

Apply same density function to both inputs (default) | Apply different density function to each input

Select whether current density values applied to block inputs are different or the same.

**Dependencies**

Enabled when the **Noise mode** parameter is set to Enabled.

**Input noise current density — Current noise at both inputs**

0.5e-12 A/Hz<sup>0.5</sup> (default)

Single-sided, spectral amplitude density of the current noise applied to both inputs. Note that even though the density function is the same for both inputs, the actual noise current also depends on the random number seed. If the seeds used for the random number generation are different, then the actual noise currents at the inputs are also different.

**Dependencies**

Enabled when the **Noise current parameterization** parameter is set to Apply same density function to both inputs.

**Noninverting input noise current density — Current noise at noninverting input**

0.5e-12 A/Hz<sup>0.5</sup> (default)

Single-sided, spectral amplitude density of the current noise applied to noninverting input.

**Dependencies**

Enabled when the **Noise current parameterization** parameter is set to Apply different density function to each input.

**Inverting input noise current density — Current noise at inverting input**

0.5e-12 A/Hz<sup>0.5</sup> (default)

Single-sided, spectral amplitude density of the current noise applied to inverting input.

**Dependencies**

Enabled when the **Noise current parameterization** parameter is set to Apply different density function to each input.

**Sample time — Rate at which the noise source is sampled**

1e-3 s (default)

Defines the rate at which the noise source is sampled. Choose it to reflect the frequencies of interest in your model. Making the sample time too small will unnecessarily slow down your simulation.

**Dependencies**

Enabled when the **Noise mode** parameter is set to Enabled.

**Repeatability — Select the noise control option**

Not repeatable (default) | Repeatable | Specify seed

Select the noise control option:

- **Not repeatable** — The random sequence used for noise generation is not repeatable.
- **Repeatable** — The random sequence used for noise generation is repeatable, with a system-generated seed.
- **Specify seed** — The random sequence used for noise generation is repeatable, and you control the seed by using the seed parameters. You specify seed values separately for input noise voltage, noninverting input noise current, and inverting input noise current.

**Dependencies**

Enabled when the **Noise mode** parameter is set to Enabled.

**Input noise voltage auto-generated seed used for repeatable option — Auto-generated random number seed for voltage noise**

random real number

Random number seed stored inside the block to make the random sequence repeatable. The parameter value is automatically generated using the MATLAB random number generator command. You can modify this parameter value, but it gets overwritten by a new random value if you copy the block to another block in the model. Therefore, if you want to control the seed of the random sequence, use the **Specify seed** option for the **Repeatability** parameter and specify the desired seed value using the **Input noise voltage seed** parameter.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Repeatable.

**Noninverting input noise current auto-generated seed used for repeatable option — Auto-generated random number seed for current noise at noninverting input**

random real number

Random number seed stored inside the block to make the random sequence repeatable. The parameter value is automatically generated using the MATLAB random number generator command. You can modify this parameter value, but it gets overwritten by a new random value if you copy the block to another block in the model. Therefore, if you want to control the seed of the random sequence, use the **Specify seed** option for the **Repeatability** parameter and specify the desired seed value using the **Noninverting input noise current seed** parameter.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Repeatable.

**Inverting input noise current auto-generated seed used for repeatable option — Auto-generated random number seed for current noise at inverting input**

random real number

Random number seed stored inside the block to make the random sequence repeatable. The parameter value is automatically generated using the MATLAB random number generator command. You can modify this parameter value, but it gets overwritten by a new random value if you copy the block to another block in the model. Therefore, if you want to control the seed of the random sequence, use the **Specify seed** option for the **Repeatability** parameter and specify the desired seed value using the **Inverting input noise current seed** parameter.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Repeatable.

**Input noise voltage seed — Random number seed for voltage noise**

0 (default)

Seed used by the noise random number generator.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Specify seed.

**Noninverting input noise current seed — Random number seed for current noise at noninverting input**

0 (default)

Seed used by the noise random number generator.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Specify seed.

**Inverting input noise current seed — Random number seed for current noise at inverting input**

0 (default)

Seed used by the noise random number generator.

**Dependencies**

Enabled when the **Repeatability** parameter is set to Specify seed.

## Foster Thermal Model

Heat transfer through a semiconductor module

**Library:** Simscape / Electrical / Passive / Thermal

### Description

**Note** The Foster Thermal Model block represents an end-to-end behavioral model for temperature drop across the  $T_j$  and  $T_c$  ports. This block does not predict the heatflow rate at port **B**. You cannot extend this model with additional blocks either. To predict the heatflow rate at port B and to extend the model with additional blocks, use the Causer Thermal Model block and select the **Parameterize from Foster coefficients** parameter.

The Foster Thermal Model block represents heat transfer through a semiconductor module. The figure shows an equivalent circuit for a fourth-order Foster Thermal Model block.  $T_j$  is the junction temperature and  $T_c$  is the base plate or ambient temperature.

A Foster thermal model contains one or more instances of Foster thermal model elements. The figure shows an equivalent circuit for a Foster thermal model element.

The number of thermal elements is equal to the order of representation. For a first order model, use scalar block parameters. For an  $n$ th order model, use row vectors of length  $n$ . Other terms that describe a Foster thermal model are:

- Partial fraction circuit
- Pi model

The defining equations for a first-order Foster thermal model element are:

$$C_{thermal} = \frac{\tau}{R_{thermal}}$$

and

$$Q_{AB} = \frac{T_{AB}}{R_{thermal}} + C_{thermal} \frac{dT_{AB}}{dt},$$

where:

- $C_{thermal}$  is the thermal capacity.
- $\tau$  is the thermal time constant.
- $R_{thermal}$  is the thermal resistance.
- $Q_{AB}$  is the heat flow through the material.
- $T_{AB}$  is the temperature difference between the material layers.

### Initial Conditions

You can initialize the model in steady state or specify the initial node temperatures. To initialize the block in steady state, set the **Start from steady state** parameter to On. To specify the initial node temperatures and enable the **Initial Targets** section, set **Start from steady state** to Off. The first node temperature corresponds to the temperature in port A.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

# Four-Pulse Gate Multiplexer

Multiplex gate input signals to four quadrant

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Four-Pulse Gate Multiplexer block multiplexes four separate voltage signals into a single vector. The vectorized signal can control the gates of four switching devices in a converter, such as a Four-Quadrant Chopper block.

## Model

This block can model a four-pulse gate multiplexer through either physical signal ports or electrical ports:

- PS ports — Four-pulse gate multiplexer with physical signal ports. Set the **Gate-control port** parameter to PS to control switching device gates in a converter block using Simulink gate-control voltage signals. To multiplex and connect Simulink signals to the gate-control inport of a converter block:
  - 1 Convert each voltage signal using a Simulink-PS Converter block.
  - 2 Multiplex the converted gate signals into a single vector using the multiplexer block.
  - 3 Connect the vector signal to the **G** port of the converter.
- Electrical ports — Four-pulse gate multiplexer with electrical conserving ports. To control switching device gates in a converter block using Simscape Electrical Electronics and Mechatronics blocks, set the **Gate-control port** parameter to **Electrical**. The electrical ports include pairs of electrical connections. Each pair corresponds to the gate and cathode of a switching device in the connected converter block.

Switch Between Physical Signal and Electrical Ports

# Four-Quadrant Chopper

Controller-driven four quadrant DC-DC chopper

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Four-Quadrant Chopper block represents a four-quadrant controlled chopper for converting a fixed DC input to a variable DC output. The block contains two bridge arms. Each bridge arm each has two switching devices. Options for the type of switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

The figures show the equivalent circuit and the operation for the block.

**Protection**

The block contains an integral protection diode for each switching device. The integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

To configure the internal protection diode block, use the **Diode** parameters. This table shows how to set the **Model dynamics** parameter based on your goals.

Goals	Value to Select	Integral Protection Diode
Prioritize simulation speed.	Diode with no dynamics	The Diode block
Prioritize model fidelity by precisely specifying reverse-mode charge dynamics.	Diode with charge dynamics	The dynamic model of the Diode block

You can also include a snubber circuit for each switching device. Snubber circuits contain a series-connected resistor and capacitor. They protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of current change when a switching device turns on.

To include and configure a snubber circuit for each switching device, use the **Snubbers** parameters.

### Gate Control

To connect Simulink gate-control voltage signals to the gate ports of the internal switching devices:

- 1 Convert each voltage signal using a Simulink-PS Converter block.
- 2 Multiplex the converted gate signals into a single vector using a Four-Pulse Gate Multiplexer block.
- 3 Connect the vector signal to the **G** port.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to *Averaged switch* and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

### Assumptions and Limitations

If, in the Solver Configuration block inside your model, you set the **Solver type** parameter to *Partitioning*, the averaged switches introduce instability during dead time, when all gate inputs are set to 0. Where possible, use the open-zero state by setting all high-side switches to 0 and all low-side switches to 1.

For the different switching device types, the **Forward voltage** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

### Dependencies

See the Switching Devices Parameter Dependencies table.

### On-state resistance – Resistance

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on

- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 0hm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance**

1e-5 1/0hm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate trigger voltage, Vgt — Voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate turn-off voltage, Vgt\_off – Voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Holding current – Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Integer for piecewise constant approximation of gate input (0 for disabled) – Integer mode for FPGA deployment**

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

**Dependencies**

To enable this parameter, set **Switching device** to Averaged Switch.

**Protection Diode**

The visibility of **Diode** parameters depends on how you configure the protection diode **Model dynamics** and **Reverse recovery time parameterization** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

## Protection Diode Parameter Dependencies

	Reverse recovery time stretch factor	Reverse recovery time, trr	Reverse recovery charge, Qrr

### Model dynamics – Diode model

Diode with no dynamics (default) | None | Diode with charge dynamics

Diode type. The options are:

- None.
- Diode with no dynamics — Select this option to prioritize simulation speed using the Diode block.
- Diode with charge dynamics — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation model of the Diode block.

**Note** If you select Averaged Switch for the **Switching Device** parameter in the **Switching Devices** setting, this parameter is not visible and Diode with no dynamics is automatically selected.

### Dependencies

See the Protection Diode Parameter Dependencies table.

### Forward voltage – Voltage

0.8 V (default) | scalar

Minimum voltage required across the positive and negative block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

### On resistance – Resistance

0.001 Ohm (default) | scalar

Rate of change of voltage versus current above the **Forward voltage**.

**Off conductance – Conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

**Junction capacitance – Capacitance**

50 nF (default) | scalar

Diode junction capacitance.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Peak reverse current,  $i_{RM}$  – Current**

-235 A (default) | scalar less than 0

Peak reverse current measured by an external test circuit.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Initial forward current when measuring  $i_{RM}$  – Current**

300 A (default) | scalar greater than 0

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Rate of change of current when measuring  $i_{RM}$  – Current change rate**

-50 A/us (default) | scalar

Rate of change of current when measuring peak reverse current.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Reverse recovery time parameterization – Recovery-time model**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Model for parameterizing the recovery time. When you select **Specify stretch factor** or **Specify reverse recovery charge**, you can specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates  $T_M$  and  $\tau$ ” on page 1-452.

**Dependencies**

See the Protection Diode Parameter Dependencies table.

**Reverse recovery time stretch factor – Stretch factor**

3 (default) | scalar greater than 1

Value that the block uses to calculate **Reverse recovery time, trr**. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Reverse recovery time, trr – Time

15 us (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10 percent of the peak reverse current.

The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, iRM** parameter divided by the value of the **Rate of change of current when measuring iRM** parameter.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Reverse recovery charge, Qrr – Charge

1500 s\*uA (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

#### Dependencies

See the Protection Diode Parameter Dependencies table.

#### Snubbers

The **Snubbers** parameters tab is not visible if you set **Switching device** to Averaged Switch.

The table summarizes the **Snubbers** parameter dependencies. To learn how to read the table, see “Parameter Dependencies” on page A-2.

## Snubbers Parameter Dependencies

Snubbers Parameter Dependencies	
<b>Snubber</b>	
None	<i>RC Snubber</i>
	Snubber resistance
	Snubber capacitance

### Snubber – Snubber model

None (default) | RC snubber

Switching device snubber.

#### Dependencies

See the Snubbers Parameter Dependencies table.

### Snubber resistance – Resistance

0.1 Ohm (default) | scalar

Resistance of the switching device snubber.

#### Dependencies

See the Snubbers Parameter Dependencies table.

### Snubber capacitance – Capacitance

1e-7 (default) | F | scalar

Capacitance of the switching device snubber.

#### Dependencies

See the Snubbers Parameter Dependencies table.

# Fourier Analysis

Discrete or continuous time Fourier analysis

**Library:** Simscape / Electrical / Control / General Control

## Description

The Fourier Analysis block performs a Fourier analysis on the input signal in either discrete or continuous time.

## Equations

A periodic function  $x(t)$  can be decomposed to an infinite sum of sine and cosine functions as

$$x(t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} [a_n \cos(nt) + b_n \sin(nt)]$$

where:

- $a_0$  is the DC component.
- $a_n$  and  $b_n$  are constant Fourier coefficients.
- $n$  is the harmonic number.

The coefficients  $a_n$  and  $b_n$  are defined as

$$a_n = \frac{2}{T_0} \int_{t_0}^{t_0 + T_0} x(t) \cos(n\Omega_0 t) dt, \quad n = 0, 1, \dots$$

$$b_n = \frac{2}{T_0} \int_{t_0}^{t_0 + T_0} x(t) \sin(n\Omega_0 t) dt, \quad n = 1, 2, \dots$$

$$\Omega_0 = \frac{2\pi}{T_0}$$

$$T_0 = \frac{1}{f}$$

where  $f$  is the fundamental frequency.

The magnitude and angle corresponding to the harmonic number are defined as:

$$|X_n| = \sqrt{a_n^2 + b_n^2}$$

$$\theta_n = -\tan^{-1} \left[ \frac{b_n}{a_n} \right]$$

---

**Note** If you use this block for continuous-time operations and set the **Sample time (-1 for inherited)** parameter to 0, you should also specify the value of the **Buffer size** parameter to ensure it covers the moving time window.

## Ports

### Input

#### **u — Fourier analysis input**

scalar | vector

Input signal to be analyzed. The input can be a single signal or multiple multiplexed signals. Input signals can be AC currents or voltages in an electrical system.

Data Types: single | double

### Output

#### **Magnitude — Signal magnitude**

scalar | vector

Signal magnitude corresponding to the harmonic number.

Data Types: single | double

#### **Angle — Signal angle**

scalar | vector

Signal angle corresponding to the harmonic number.

Data Types: single | double

## Parameters

#### **Fundamental frequency (Hz) — Signal fundamental frequency**

60 (default) | positive scalar | vector with positive values

Fundamental frequency of the signal, in Hz. If you specify the fundamental frequency using a vector, it must match the input vector dimensions.

#### **Harmonic numbers — Signal harmonic numbers**

[1 2] (default) | vector with elements  $\geq 0$

Specify signal harmonic numbers. Vector elements must be greater than or equal to 0.

#### **Initial magnitude — Initial signal magnitude**

1 (default) | vector with elements  $\geq 0$

Specify the initial magnitude of the signal. Vector elements must be greater than or equal to 0.

#### **Initial phase (rad) — Initial signal phase**

0 (default) | vector

Initial phase angle of the signal, in rad.

**Buffer size – Buffer size**

8192 (default) | scalar

Size of the buffer.

**Dependencies**To enable this parameter, set **Sample time (-1 for inherited)** to 0.**Sample time (-1 for inherited) – Block sample time**

-1 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

## Frequency-Dependent Overhead Line (Three-Phase)

Three-phase overhead line which includes effects that vary as a function of frequency

**Library:** Simscape / Electrical / Passive / Lines

### Description

The Frequency-Dependent Overhead Line (Three-Phase) block represents a high-fidelity frequency-dependent overhead line that offers accurate transient response simulation from 0.01 Hz to 100 kHz.

The block computes frequency-dependent impedance and admittance matrices. The calculations also depend on the loss, inductance, and capacitance of the return path.

For more information on using a frequency-dependent overhead line (three-phase), see “Engineering Applications” on page 1-636.

## Equations

### Line Model

The electromagnetic behavior of a multiconductor transmission line is described by the telegrapher's equation.

$$-\frac{dV}{dx} = ZI$$

$$-\frac{dI}{dx} = YV$$

Where:

- $V$  is the vector of line phase voltages.
- $I$  is the vector of phase currents.
- $Z$  is the series impedance matrix in per unit length.
- $Y$  is the shunt admittance matrix in per unit length.

These are general solutions for the vector of currents and voltages.

$$I(x) = e^{-\Psi x}C_1 + e^{\Psi x}C_2 \quad (1-26)$$

$$Y_c V(x) = e^{-\Psi x}C_1 - e^{\Psi x}C_2 \quad (1-27)$$

Where  $\Psi = \sqrt{YZ}$  is the propagation matrix and  $Y_c = (\sqrt{YZ})^{-1}Y$  is the characteristic admittance.

Consider now a transmission line segment of length  $x = l$ . At the beginning of one of its ends, when  $x = 0$ , the equations 1 and 2 are evaluated as follows.

$$I_1 = C_1 + C_2 \quad (1-28)$$

$$Y_c V_1 = C_1 - C_2 \quad (1-29)$$

The integration constant vectors  $C_1$  and  $C_2$  can be expressed in terms of  $I_0$  and  $V_0$ .

$$C_1 = \frac{(I_1 + Y_c V_1)}{2} \quad (1-30)$$

$$C_2 = \frac{(I_1 - Y_c V_1)}{2} \quad (1-31)$$

Similarly, at  $x = l$ , equations 1 and 2 are evaluated as follows.

$$I_2 = e^{-\Psi l} C_1 + e^{\Psi l} C_2 \quad (1-32)$$

$$Y_c V_2 = e^{-\Psi l} C_1 - e^{\Psi l} C_2 \quad (1-33)$$

To obtain the two fundamental equations for the transmission line model, first you use equations 7 and 8 to perform this calculation.

$$I_2 - Y_c V_2 = -2e^{-\Psi l} C_1 \quad (1-34)$$

Then you substitute equation 5 into equation 9.

$$I_2 - Y_c V_2 = -H(I_1 + Y_c V_1) \quad (1-35)$$

Where  $H = e^{-\Psi l}$  is the propagation factor matrix. Equation 10 establishes the relation between voltages and currents at the terminals of a multi-conductor line section.

You can obtain a companion expression providing the model for the terminal 1 at  $x = 0$ .

$$I_1 - Y_c V_1 = -H(I_2 + Y_c V_2) \quad (1-36)$$

Define:

- $I_{sh,1} = Y_c V_1$  — Shunt current vector produced at terminal 1 by injected voltages  $V_1$
- $I_{sh,2} = Y_c V_2$  — Shunt current vector produced at terminal 2 by injected voltages  $V_2$
- $I_{rfl,1} = \frac{1}{2}(I_1 + Y_c V_1)$  — Reflected currents of terminal 1
- $I_{rfl,2} = \frac{1}{2}(I_2 + Y_c V_2)$  — Reflected currents of terminal 2

And finally rewrite equations 10 and 11 as follows:

$$I_1 = I_{sh,1} - 2H I_{rfl,2}$$

$$I_2 = I_{sh,2} - 2H I_{rfl,1}$$

These equations constitute a traveling wave line model for the segment of length  $L$ .

Particularly for transmission lines with ground return, the parameters are highly dependent on frequency. Model solutions are then carried out directly in the phase domain. The block computes automatically the impedance and the characteristic admittance matrices on the full frequency range, performing an approximation through rational fitting.

Rational fitting for this model is performed by using the vector fitting (VF) procedure. For more information on the phase domain line model and the state-space analysis, see *Wide-Band Line Model Implementation in Matlab for EMT Analysis* [1].

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

### Parameters

#### Modeling option — Whether to model composite or expanded three-phase ports

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

Expanded three-phase ports represent the individual phases of a three-phase system using three separate electrical conserving ports.

**X position of the line – Horizontal line position**

`[-6, 0, 6] m (default) | vector of three elements`

Position of the line in terms of the x-axis of the reference frame.

**Y position of the line – Vertical line position**

`[16, 26, 16] m (default) | vector of three positive elements`

Position of the line in terms of the y-axis of the reference frame. The elements of the vector need to be greater than 0.

**Resistivity of the conductor – Conductor resistivity**

`2.7e-8 m*Ohm (default) | positive scalar`

Conductor resistivity. The value must be greater than 0.

**Resistivity of the earth – Earth return resistivity**

`100 m*Ohm (default) | positive scalar`

Earth return resistivity. The value must be greater than 0.

**Radius of the conductor – Conductor radius**

`0.017 m (default) | positive scalar`

Conductor radius. The value must be greater than 0.

**Length of the line – Line length**

`150e3 m (default) | positive scalar`

Line length. The value must be greater or equal than 1 and less or equal than 3e5.

**Ground configuration – Ground node accessibility**

`Internally grounded (default) | Accessible ground nodes`

Configuration of the ground nodes.

**More About****Engineering Applications**

Three-phase frequency-dependent overhead lines are typically used in:

- Simulations of transient phenomena in electrical power systems
- Design and operation of power systems and power apparatuses

# Fuel Cell

Fuel cell electrical system

**Library:** Simscape / Electrical / Sources

## Description

The Fuel Cell block models a fuel cell that converts the chemical energy of hydrogen into electrical energy.

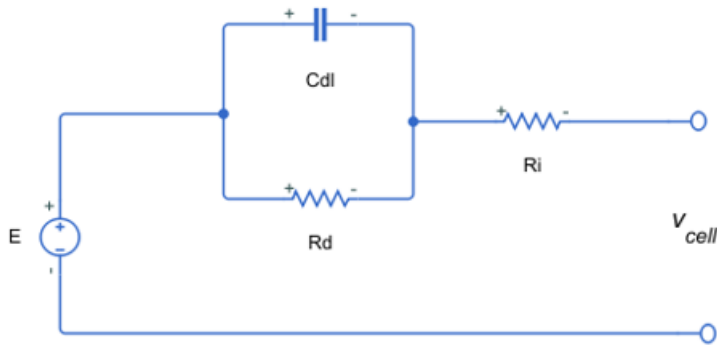

This chemical reaction defines the electrical conversion:

which occurs due to these anode and cathode half-reactions:

A fuel cell stack comprises several series-connected fuel cells. This figure shows the equivalent circuit of a single fuel cell that this block uses

where:

- $V_{cell}$  is the cell voltage.
- $R_i$  is the **Internal resistance**.
- $R_d$  is the **Sum of activation and concentration resistances**.
- $C_{dl}$  is the parallel RC capacitance that accounts for time dynamics in the cell.

### Equations

You can use the **Model fidelity** parameter to set the Fuel Cell block to two different levels of fidelity:

- **Simplified - nominal conditions** — The block calculates the Nernst voltage at the nominal condition of temperature and pressure.
- **Detailed with physical inputs** — The block calculates the Nernst voltage by considering the pressures and flow rates of fuel and air.

### Simplified Electrical Model

When **Model fidelity** is set to **Simplified - nominal conditions**, the Fuel Cell block calculates the Nernst voltage,  $E$ , at the nominal condition of temperature and pressure, as defined by these equations:

$$E = E_{oc} - NA \ln \left( \frac{i_{FC}}{i_0} \right)$$

$$v_{FC} = N_{unit} E - R_i i_{FC} - v_d$$

$$\frac{1}{R_d} \left( \tau \frac{dv_d}{dt} + v_d \right) = i_{FC}$$

where:

- $E_{oc}$  is the **Open-circuit voltage**.
- $N$  is the **Number of cells per module**.
- $i_{FC}$  is the current that the fuel cell generates.
- $v_{FC}$  is the voltage across the fuel cell terminals.
- $N_{unit}$  is the **Module units (Series)**.
- $v_d$  is the voltage drop that accounts for fuel cell dynamics.

- $A$  is the **Tafel slope**, in volts.
- $i_0$  is the **Nominal exchange current**.
- $\tau = \frac{C_{dl}}{R_d}$ .

**Detailed Electrical Model**

When **Model fidelity** is set to Detailed with physical inputs, the Fuel Cell block calculates the Nernst voltage,  $E$ , by considering the pressures and flow rates of fuel and air.

These equations determine the rates of utilization of hydrogen,  $U_{H_2}$ , and oxygen,  $U_{O_2}$

$$U_{H_2} = \frac{60000Ni_{FC}V_e}{p_{fuel}q_{fuel}x_{H_2}}$$

$$U_{O_2} = \frac{60000Ni_{FC}V_e}{2p_{air}q_{air}x_{O_2}}$$

where:

- $V_e$  is the thermal voltage at room temperature.
- $p_{fuel}$  is the supply pressure of the fuel, in bar.
- $q_{fuel}$  is the fuel flow rate.
- $x_{H_2}$  is the concentration of hydrogen in the fuel, in percent.
- $p_{air}$  is the supply pressure of air, in bar.
- $q_{air}$  is the air flow rate.
- $x_{O_2}$  is the concentration of oxygen in the air, in percent.

These equations define the partial pressures:

$$p_{H_2} = p_{fuel}x_{H_2} - U_{H_2}$$

$$p_{O_2} = p_{air}x_{O_2} - U_{O_2}$$

$$p_{H_2O} = p_{air}x_{H_2O} - 2U_{O_2}$$

where  $x_{H_2O}$  is the concentration of vapor in air, in percent.

Then, the block computes the Nernst voltage as

$$E = \begin{cases} \left[ \begin{array}{c} \text{Reactant} \\ K_c N \left( 1.229 + K_z \frac{RT}{ZF} \ln \left( \frac{p_{H_2} p_{O_2}^{\frac{1}{2}}}{p_{H_2O}} \right) \right) \end{array} \right] - E_{Tafel} - E_{conc}, T < 373.15 K \\ \left[ \begin{array}{c} \text{Activation} \\ K_c N \left( 1.229 + K_z \frac{RT}{ZF} \ln \left( \frac{p_{H_2} p_{O_2}^{\frac{1}{2}}}{p_{H_2O}} \right) \right) \end{array} \right] - E_{Tafel} - E_{conc}, T \geq 373.15 K \end{cases}$$

where:

- $$K_z = \frac{\frac{E_{oc\_adm}}{K_c N} - 1.229}{(T_{nom} - 298) \frac{-44.43}{z_0 F} + \frac{RT_{nom}}{z_0 F} \ln \left( p_{nH_2} p_{nO_2}^{\frac{1}{2}} \right)}$$
- $E_{Tafel} = N A_T \ln \left( \frac{i_{FC}}{i_0} \right)$  is the electrokinetic term for the activation.
- $E_{conc} = V_e \frac{T}{298} \ln \left( \frac{i_{lim}}{i_{lim} - i_{FC}} \right)$  is the electrokinetic term for the concentration.
- $$E_{oc\_adm} = \max \left( E_{oc}, N \left( 1.229 + \frac{RT_{nom}}{2F} \ln \left( p_{nH_2} p_{nO_2}^{\frac{1}{2}} \right) \right) \right)$$
- $K_c$  is the voltage constant at nominal condition of operation.
- $T$  is the operating temperature of the fuel cell.
- $T_{nom}$  is the value of the **Nominal temperature** parameter.
- $z$  is the number of moving electrons per second.
- $z_0$  is the number of moving electrons per second at the value of the **Nominal exchange current** parameter.
- $F$  is the Faraday constant.
- $R$  is the universal gas constant.
- $p_{nH_2}$  is the nominal hydrogen pressure, in bar.
- $p_{nO_2}$  is the nominal oxygen pressure, in bar.
- $A_T = \frac{AT}{\ln(10) * 298}$  is the Tafel slope as a function of the temperature.
- $i_{lim}$  is the value of the **Collapse current** parameter.
- The voltage 1.229 represents the standard cell potential for the Nernst equation.

The block computes the power dissipated, or the heat released in the fuel cell, by using this equation

$$P_{dissipated} = Z_{e\_agg}(T\Delta S) + R_i i_{FC} + v_d^2 \frac{1}{R_d}$$

where:

- $Z_{e\_agg} = \frac{(N_{unit}E - R_i i_{FC} - v_d) i_{FC}}{2\Delta G}$  is the total electron circulation rate, in mol/s.
- $T\Delta S$  is the change in entropy of the fuel cell reaction, in kJ/(mol\*K), at the operating temperature of the fuel cell.
- $\Delta G$  is the change in Gibbs free energy of the full fuel cell reaction, in kJ/mol, at the operating temperature of the fuel cell.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can

come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

To enable this port, set **Model fidelity** to Detailed with physical inputs.

#### **qfuel** — Fuel flow rate, l/min

physical signal

Physical signal port associated with the fuel flow rate, specified as a physical signal.

#### Dependencies

To enable this port, set **Model fidelity** to Detailed with physical inputs.

#### **qair** — Air flow rate, l/min

physical signal

Physical signal port associated with the air flow rate, specified as a physical signal.

#### Dependencies

To enable this port, set **Model fidelity** to Detailed with physical inputs.

## Conserving

#### **+ — Positive terminal**

electrical

Electrical conserving port associated with the fuel cell positive terminal.

**- — Negative terminal**

electrical

Electrical conserving port associated with the fuel cell negative terminal.

**H — Thermal port**

thermal

Thermal conserving port.

**Dependencies**

To enable this port, set **Model fidelity** to Detailed with physical inputs.

**Parameters****Main****Model fidelity — Fuel cell fidelity**

Detailed with physical inputs (default) | Simplified - nominal conditions

Level of fidelity of the fuel cell model.

**Open-circuit voltage — Open-circuit voltage**

65 V (default) | positive scalar

Open-circuit voltage.

When the amount of flow is very low or close to zero and the values of the fuel and air pressures are equal to their nominal values, the output voltage of the fuel cell is equal to the open-circuit voltage multiplied by the number of module units. The current that flows out of the fuel cell is negligible. This figure shows how to set the open-circuit test:

**Tafel slope — Tafel slope**

0.23 V (default) | positive scalar

Amount of overpotential required to increase the reaction rate by a factor ten.

**Internal resistance — Internal resistance**

0.05 Ohm (default) | positive scalar

Internal resistance.

**Nominal exchange current — Nominal exchange current**

80 A (default) | positive scalar

Exchange current at the nominal temperature.

At the nominal exchange current, the fuel cell leaves the region of activation polarization and enters the region of ohmic polarization.

**Collapse current — Collapse current**

200 A (default) | positive scalar

Value of current at which the fuel cell voltage becomes zero. As the fuel cell enters the region of concentration polarization and the current continues to increase, the voltage starts decreasing at a faster rate.

**Dependencies**

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

**Number of cells per module — Number of cells per module**

65 (default) | positive scalar

Number of cells per module.

The cell count value in this block is consistent with the fuel cell delivering its maximum output power for specified set points of flow and H<sub>2</sub> pressure.

**Module units (Series) — Stack of module units in series**

10 (default) | positive scalar

Stack of module units in series.

Stack module in series to scale up voltage. For example, 10 module units in series with an open-circuit voltage of 65 V deliver a voltage of 650V.

**Supply**

To enable these parameters, in the **Main** tab, set **Model fidelity** to Detailed with physical inputs.

**Nominal H<sub>2</sub> pressure — Nominal hydrogen pressure**

1.5e5 Pa (default) | positive scalar

Hydrogen gauge pressure at nominal temperature.

**Dependencies**

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

**Nominal O<sub>2</sub> pressure — Nominal oxygen pressure**

1.0e5 Pa (default) | positive scalar

Oxygen gauge pressure at nominal temperature.

**Dependencies**

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

**Concentration H<sub>2</sub> in fuel (%) — Hydrogen concentration in fuel**

99 (default) | integer between 0 and 100

Molar fraction concentration of hydrogen in fuel, in percent.

**Dependencies**

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

**Concentration O<sub>2</sub> in air (%) – Oxygen concentration in fuel**

21 (default) | integer between 0 and 100

Molar fraction concentration of oxygen in fuel, in percent.

**Dependencies**

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

**Concentration vapor in air (%) – Vapor concentration in air**

1 (default) | integer between 0 and 100

Molar fraction concentration of vapor in air, in percent.

**Dependencies**

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

**Dynamics****Model activation delay – Activation delay modeling option**

No (default) | Yes

Whether to model the activation delay of the fuel cell.

**Sum of activation and concentration resistance – Sum of activation and concentration resistance**

0.005 Ohm (default) | positive scalar

Sum of the activation resistance and concentration resistance.

**Dependencies**

To enable this parameter, set **Model activation delay** to Yes.

**Time constant – Time constant**

10 s (default) | positive scalar

Time constant.

**Dependencies**

To enable this parameter, set **Model activation delay** to Yes.

**Thermal**

To enable these parameters, in the **Main** tab, set **Model fidelity** to Detailed with physical inputs.

**Nominal temperature – Nominal temperature**

293.15 K (default) | scalar

Temperature at which the nominal parameters are measured.

### Dependencies

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

### Thermal mass — Thermal mass associated with thermal port H

30000 J/K (default) | positive scalar

Thermal mass associated with the thermal port, **H**. This value represents the energy required to raise the temperature of the thermal port by one degree.

### Dependencies

To enable this parameter, set **Model fidelity** to Detailed with physical inputs.

# Fully Differential Op-Amp

Operational amplifier with fully differential output, that is, not referenced to ground

**Library:** Simscape / Electrical / Integrated Circuits

## Description

The Fully Differential Op-Amp block models a fully differential operational amplifier. Differential signal transmission is better than single-ended transmission due to reduced susceptibility to external noise sources. Applications include data acquisition where inputs are differential, for example, sigma-delta converters.

The following diagram shows the internal representation of the amplifier.

Parameters for the circuit components are derived from the block parameters that you provide. The gain of the two voltage-controlled voltage sources (VCVS1 and VCVS2) is set to half of the differential gain value. Similarly the slew rate of each of the voltage sources is set to half of the differential maximum slew rate value. The voltages of the two output ports  $V_{out+}$  and  $V_{out-}$  are both limited to be within the minimum and maximum output voltages that you specify.

The output voltage for zero differential input voltage is controlled by the common-mode port,  $cm$ . If no current is drawn from the  $cm$  port by the external circuit, then the output voltage is set to be the average of the positive and negative supply voltages by the resistor ladder of  $R_{3a}$  and  $R_{3b}$ . Note that the negative supply voltage can be zero, which corresponds to operation when a split supply is not available. The values for the minimum and maximum output voltages that you provide must be consistent with the values for the supply voltages that you provide. So, for example, the maximum output high voltage will be less than the positive supply voltage, the difference corresponding to the number of p-n junction voltage drops in the circuit.

## Assumptions and Limitations

- This block provides a behavioral model of a fully differential operational amplifier. It does not represent nonlinear effects, such as variation in gain with output voltage amplitude, and the nonlinear nature of the output voltage-current relationship for large load currents.

## Ports

### Conserving

#### + – Non-inverting input

electrical

Electrical conserving port associated with the op-amp non-inverting input.

#### - – Inverting input

electrical

Electrical conserving port associated with the op-amp inverting input.

#### cm – Common-mode port

electrical

Electrical conserving port associated with the op-amp common-mode port. If you want to leave this pin open-circuit, connect a voltage sensor between the cm port and a reference port.

#### Vout+ – Non-inverting output

electrical

Electrical conserving port associated with the op-amp non-inverting output.

#### Vout- – Inverting output

electrical

Electrical conserving port associated with the op-amp inverting output.

## Parameters

### Gain

#### Differential gain – Differential gain

1e3 (default)

The gain applied to a voltage difference between the + and - inputs.

#### Bandwidth – Bandwidth

1.5 GHz (default)

The frequency at which the differential voltage gain drops by 3 dB from its dc value.

## Input Impedance

### Differential input resistance – Differential input resistance

1.3 M $\Omega$  (default)

The input resistance seen by a voltage source applied across the + and - inputs. The default value is 1.3 M $\Omega$ .

### Differential input capacitance – Differential input capacitance

1.8 pF (default)

The input capacitance seen by a current source applied across the + and - inputs.

### Common-mode input resistance – Common-mode input resistance

1.0 M $\Omega$  (default)

The input resistance seen by a voltage source applied between ground and the + input, or between ground and the - input.

### Common-mode input capacitance – Common-mode input capacitance

2.3 pF (default)

The input capacitance seen by a current source applied between ground and the + input, or between ground and the - input.

## Output Limits

### Output resistance – Output resistance

1  $\Omega$  (default)

The output resistance of either of the outputs with respect to the common-mode voltage reference. Differential output resistance is therefore twice the value of the output resistance  $R_{out}$ .

### Minimum output voltage low – Minimum output voltage low

-1.4 V (default)

The minimum output voltage for either of the two output pins with respect to ground.

### Maximum output voltage low – Maximum output voltage low

1.4 V (default)

The maximum output voltage for either of the two output pins with respect to ground.

### Differential maximum slew rate – Differential maximum slew rate

5000 V/ $\mu$ s (default)

The maximum slew rate of the differential output voltage.

## Output Bias

### Common-mode port input resistance – Common-mode port input resistance

23.0 k $\Omega$  (default)

The input resistance seen by a voltage source applied between ground and the common mode port.

**Negative supply voltage — Negative supply voltage**

-5 V (default)

The value of the negative supply voltage connected to common-mode bias resistor R3b (see diagram).

**Positive supply voltage — Positive supply voltage**

5 V (default)

The value of the positive supply voltage connected to common-mode bias resistor R3a (see diagram).

**Initial Conditions****Initial differential output voltage — Initial differential output voltage**

0 V (default)

The initial differential voltage across the two outputs if the output current is zero.

# Fuse

Fuse that protects against excessive current

**Library:** Simscape / Electrical / Switches & Breakers

## Description

The Fuse block breaks the circuit, to protect it against excessive current. The block provides the following modeling options:

- **Opening time is independent of current** — The fuse opens when the current through the fuse exceeds the threshold current continuously for longer than the specified amount of time. This option assumes that the time to open is independent of the current. It also implicitly assumes that heat in the fuse is instantaneously dissipated once the current drops below a certain threshold.
- **Opening time depends on  $I^2 \cdot t$**  — Makes fuse opening dependent on the energy dissipated in the fuse. The nominal melting value ( $I^2 \cdot t$ ) is usually available on manufacturer datasheets. If you select this option, the fuse blows when:

$$\int_{t_{\text{over}}}^t i^2 dt \geq I^2 t$$

where  $t_{\text{over}}$  is the time when the current crosses over the threshold current,  $i$  is instantaneous current through the fuse, and  $I^2 t$  is the nominal melting value from the datasheet. Use this option for high-current range of operation.

- **Opening time is tabulated** — Makes fuse opening dependent on the average time-current tabulated data. This data indicates the time that it takes for the fuse to open given a certain current, and is available on manufacturer datasheets as time-current curves.

For example, these are the time-current curves from a Littelfuse® 218 Series fuse datasheet.

Select the appropriate curve and enter the corresponding current and time values into the **Tabulated currents** and **Tabulated opening time** parameter vectors, respectively. Use this option for small currents.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the fuse positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the fuse negative terminal.

### Output

#### x – Fuse state

physical signal

Outputs the fuse state as a unitless physical signal. The port outputs 0 if the fuse is intact, and 1 if the fuse is blown.

### Dependencies

Exposed when the **PS output for fuse state** parameter is set to Visible.

## Parameters

### Parameterization — Model dependence of opening time on current

Opening time is independent of current (default) | Opening time depends on  $I^2 \cdot t$  | Opening time is tabulated

Select whether opening time depends on current:

- **Opening time is independent of current** — The fuse opens when the current through the fuse exceeds the threshold current continuously for longer than the specified amount of time.
- **Opening time depends on  $I^2 \cdot t$**  — Makes fuse opening dependent on the energy dissipated in the fuse. Use this option for high-current range of operation.
- **Opening time is tabulated** — Makes fuse opening dependent on the average time-current tabulated data. Use this option for small currents.

### Rated current, $I_{\text{rated}}$ — Nominal operating current

1 A (default)

The fuse rating from the datasheet, or nominal operating current.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Opening time is independent of current or Opening time depends on  $I^2 \cdot t$ .

### Ratio of minimum melting current to rated current, $I_{\text{melt}}/I_{\text{rated}}$ — Defined threshold current for melting

1 (default)

Minimum melting current defines the fuse operating threshold. If the current through the fuse does not exceed this threshold, the fuse stays in low-ohmic state. With the default parameter value, 1, the threshold current is the same as the rated current. In most cases, this parameter value should be greater than 1. You can also set it to a value less than 1, for situations where the fuse may blow at a current level below the rated current (for example, due to high temperature, or due to repetitive pulses). The parameter value must be greater than 0.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Opening time is independent of current or Opening time depends on  $I^2 \cdot t$ .

### Time to fuse — Time needed for the fuse to blow

0 s (default)

The amount of time needed for the fuse to blow. If the current through the fuse exceeds the threshold current continuously for longer than this amount of time, the fuse enters the high-ohmic state and breaks the circuit. If the current falls below the threshold before the time elapsed, the fuse stays in the low-ohmic state. If the current exceeds the threshold again, the time counter restarts. With the default parameter value, 0, the fuse blows immediately as soon as the current exceeds the minimum melting current. The parameter value must be greater than or equal to 0.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Opening time is independent of current.

**Nominal melting,  $I^2t$  — Dissipated energy needed for the fuse to blow**

1 s\*A<sup>2</sup> (default)

The amount of energy dissipated in the fuse that is needed for the fuse to blow. This is the nominal melting, or  $I^2t$ , parameter from the datasheet. The value must be greater than or equal to 0.

**Dependencies**

Enabled when the **Parameterization** parameter is set to Opening time depends on  $I^2t$ .

**Tabulated currents — Currents data from the time-current curves**

[1.9, 2, 2.5, 30] A (default)

The tabulated current values from a time-current curve on the manufacturer datasheet. Every element in this vector must be greater than 0, and the vector must be strictly ascending.

**Dependencies**

Enabled when the **Parameterization** parameter is set to Opening time is tabulated.

**Tabulated opening times — Times data from the time-current curves**

[10000, 1, 0.3, 0.001] s (default)

The tabulated time values from a time-current curve on the manufacturer datasheet. Every element in this vector must be greater than or equal to 0, and the vector must be strictly descending. The vector must be of the same size as the **Tabulated currents** vector.

**Dependencies**

Enabled when the **Parameterization** parameter is set to Opening time is tabulated.

**Fuse resistance R — Resistance of the fuse**

0.01  $\Omega$  (default)

The fuse resistance in low-ohmic state. The parameter value must be greater than 0.

**Open-circuit conductance G — Open-circuit fuse conductance**

1e-8 1/ $\Omega$  (default)

The open-circuit fuse conductance in high-ohmic state, when the fuse has blown. The parameter value must be greater than 0.

**PS output for fuse state — Controls the visibility of the output port for fuse state**

Hidden (default) | Visible

When set to Visible, a PS output port **x** appears on the block icon. The port outputs 0 if the fuse is intact, and 1 if the fuse is blown.

# Gate Driver

Behavioral model of gate driver integrated circuit

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The Gate Driver block provides an abstracted representation of a gate driver integrated circuit. The block models input hysteresis, propagation delay, and turn-on/turn-off dynamics. Unless modeling a gate driver circuit explicitly, always use this block or the Half-Bridge Driver block to set gate-source voltage on a MOSFET block or gate-emitter voltage on an IGBT block. Do not connect a controlled voltage source directly to a semiconductor gate, because this omits the gate driver output impedance that determines switching dynamics.

You can model electrical or physical signal input ports by setting the **Modeling option** parameter to either:

- **PS input** — The driver output state is controlled by a physical signal input  $u$ . Use this modeling option if all of your controller, including PWM waveform generation, is determined by Simulink blocks. This modeling option is the default.
- **Electrical input ports** — The driver output state is controlled by two electrical input connections, PWM and REF. Use this option if your model has upstream analog components, such as the Controlled PWM Voltage source.

When the input rises above the logic 1 input level, the transition of the output state from off to on is initiated after a delay equal to the turn-on propagation delay. The demanded output voltage across the **G** and **S** ports steps in value from the off-state output voltage to the on-state output voltage, but the actual output voltage is set by the RC time constant associated with the **On-state gate drive resistance** value and the total load capacitance. Similarly, when the input falls below the logic 0 input value, the transition of the output state from on to off is initiated after a delay equal to the turn-off propagation delay and with dynamics now set by the **Off-state gate drive resistance** value.

## Faults

You can insert a fault into the output of the gate driver at a specified simulation time, to make the connected semiconductor device either permanently off or permanently on. Use this feature to represent a failed semiconductor device as failed at open-circuit or at normal on-state conditions.

## Ports

### Input

**u — Control signal, unitless**

physical signal

Input physical signal that specifies the input control value.

**Dependencies**

To enable this port, set **Modeling option** to PS input.

**Conserving****PWM — Pulse-width modulated signal**

electrical

Electrical conserving port associated with the pulse-width modulated signal.

**Dependencies**

To enable this port, set **Modeling option** to Electrical input ports.

**REF — Floating zero volt reference**

electrical

Electrical conserving port associated with the floating zero volt reference.

**Dependencies**

To enable this port, set **Modeling option** to Electrical input ports.

**G — Gate connection**

electrical

Electrical conserving port associated with the gate. Connect this port to the gate of a MOSFET or IGBT block.

**S — Source or emitter connection**

electrical

Electrical conserving port associated with the source or emitter. Connect this port to the source of a MOSFET block or the emitter of an IGBT block.

**Parameters****Modeling option — Whether to model electrical or physical signal input ports**

PS input (default) | Electrical input ports

Whether to model physical signal or electrical input ports.

**Input Logic****Logic 1 input value — Signal value for logic 1**

0.7 (default)

Value of the input signal corresponding to the logic 1 level.

**Dependencies**

To enable this port, set **Modeling option** to PS input.

**Logic 0 input value — Signal value for logic 0**

0.3 (default)

Value of the input signal corresponding to the logic 0 level.

**Dependencies**

To enable this port, set **Modeling option** to PS input.

**Logic 1 input voltage – Voltage value for logic 1**

2.0 V (default)

Value of the input voltage corresponding to the logic 1 level.

**Dependencies**

To enable this port, set **Modeling option** to Electrical input ports.

**Logic 0 input voltage – Voltage value for logic 0**

0.8 V (default)

Value of the input voltage corresponding to the logic 0 level.

**Dependencies**

To enable this port, set **Modeling option** to Electrical input ports.

**Outputs****On-state gate-source voltage – Demanded output voltage for on state**

15 V (default)

Demanded output voltage when the driver is in on state.

**Off-state gate-source voltage – Demanded output voltage for off state**

0 V (default)

Demanded output voltage when the driver is in off state.

**Timing****Propagation delay (logic 0->logic 1) – Turn-on propagation delay**

50 ns (default)

When the input rises above the logic 1 input level, the transition of the output state from off to on is initiated after a delay equal to the turn-on propagation delay.

**Propagation delay (logic 1->logic 0) – Turn-off propagation delay**

50 ns (default)

When the input falls below the logic 0 input value, the transition of the output state from on to off is initiated after a delay equal to the turn-off propagation delay.

**Dynamics****Parameterization – Select driver parameterization**

Output impedance (default) | Rise and fall times

Select the type of driver parameterization:

- **Output impedance** — Specify on-state and off-state gate drive resistances.
- **Rise and fall times** — Specify rise time, fall time, and load capacitance.

**On-state gate drive resistance — Gate drive resistance for on state**  
2  $\Omega$  (default)

Gate drive resistance when the driver is in on state.

**Dependencies**

Enabled when the **Parameterization** parameter is set to **Output impedance**.

**Off-state gate drive resistance — Gate drive resistance for off state**  
2  $\Omega$  (default)

Gate drive resistance when the driver is in off state.

**Dependencies**

Enabled when the **Parameterization** parameter is set to **Output impedance**.

**Rise time — Driver rise time**  
20 ns (default)

Driver rise time from 10% to 90%.

**Dependencies**

Enabled when the **Parameterization** parameter is set to **Rise and fall times**.

**Fall time — Driver fall time**  
20 ns (default)

Driver fall time from 90% to 10%.

**Dependencies**

Enabled when the **Parameterization** parameter is set to **Rise and fall times**.

**Load capacitance for rise and fall times — Driver load capacitance**  
10 nF (default)

Driver load capacitance.

**Dependencies**

Enabled when the **Parameterization** parameter is set to **Rise and fall times**.

**Faults**

**Enable faults — Select Yes to enable faults modeling**  
No (default) | Yes

Select **Yes** to enable faults modeling. The associated parameters in the **Faults** section become visible to let you specify time to fail and the failure mode.

**Simulation time for fault event — Time before entering faulted state**  
1 s (default)

Set the simulation time at which you want the block to enter the faulted state.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Failure mode — State of driver after failure**

Fail off (default) | Fail on

Select whether driver fails by making the connected semiconductor device permanently turned off or on.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

# Generic Linear Actuator

Generic linear actuator driven from DC voltage source or PWM driver

**Library:** Simscape / Electrical / Electromechanical / Mechatronic Actuators

## Description

The Generic Linear Actuator block implements a model of a generic linear actuator designed to be driven from a DC voltage source or a PWM driver. Define force-speed characteristics in terms of tabulated values for powering the motor at the rated voltage. This functionality enables you to model a motor without referencing an equivalent circuit.

The motor or actuator architecture determines the way in which electrical losses depend on force. For example, a DC motor has losses that are proportional to the square of the current. As force is proportional to current, losses are also proportional to mechanical force. Most motors have an electrical loss term that is proportional to the square of mechanical force. The Generic Linear Actuator block calculates this loss term using the **Motor efficiency (percent)** and **Speed at which efficiency is measured** parameters that you provide.

Some motors also have a loss term that is independent of force. An example is a shunt motor where the field winding draws a constant current regardless of load. The **Force-independent electrical losses** parameter accounts for this effect.

The motor efficiency is the mechanical power divided by the sum of the mechanical power and both electrical loss terms. The block assumes that the speed at which the motor efficiency is defined is in the motoring quadrant and, therefore, positive.

You can operate the block in the reverse direction by changing the sign of the voltage applied. The H-Bridge block, for example, reverses motor direction if the voltage at the REV port is greater than the **Reverse threshold voltage** parameter. However, if you are using the block in reverse, specify the force-speed data for forward operation:

- Positive forces and positive speeds in the motoring quadrant.
- Positive force and negative speeds in the generating counterclockwise quadrant.
- Negative force and positive speed in the generating clockwise quadrant.

### Model Thermal Effects

You can expose the thermal port to model the effects of losses that convert power to heat. To expose the thermal port, set the **Modeling option** parameter to either:

- No thermal port — The block does not contain a thermal port.
- Show thermal port — The block contains one thermal conserving port.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

## Assumptions and Limitations

- The force-speed curve data corresponds only to the rated voltage, so the block produces accurate results only when driven by plus or minus the rated voltage.
- The block requires you to provide force-speed data for the full range over which you use the actuator. To use the actuator in the generating and braking regions, provide additional data outside of the normal motoring region.
- Model behavior is sensitive to force-speed data. For example, no-load speed is correctly defined and finite only when the data crosses the speed axis.
- To drive the block from the H-Bridge block:
  - Do not place any other blocks between the H-Bridge and the Generic Linear Actuator blocks.
  - In the H-Bridge block dialog box, set the **Freewheeling mode** to **Via one semiconductor switch and one freewheeling diode**. Selecting **Via two freewheeling diodes** does not set the bridge output voltage to zero when the PWM input signal is low.
  - In the H-Bridge, Generic Linear Actuator, and Controlled PWM Voltage block dialog boxes, ensure that the **Simulation mode** is the same for all three blocks.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the actuator positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the actuator negative terminal.

#### C – Case

mechanical

Mechanical translational conserving port associated with the actuator case.

#### R – Plunger

mechanical

Mechanical translational conserving port associated with the plunger.

#### H – Thermal port

thermal

Thermal port.

### Dependencies

To enable this port, set **Modeling option** to **Show thermal port**.

## Parameters

### Modeling option — Whether to enable thermal port

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of losses that convert power to heat.

### Electrical Force

#### Speed values — Speed values

[-15, -10, -5, 0, 5, 10, 15, 20, 25, 30] m/s (default)

Specify a vector of speeds, including their units, for your force-speed data.

#### Force values — Force values

[4, 3.5, 3, 2.5, 2, 1.5, 1, .5, 0, -.5] N (default)

Specify a vector of forces, including their units, for your force-speed data.

#### Rated voltage — Rated voltage

12 V (default)

Indicate the voltage for which the device you are modeling is rated.

#### Motor efficiency (percent) — Motor efficiency

70 (default)

Efficiency that the block uses to calculate force-dependent electrical losses.

#### Speed at which efficiency is measured — Speed at which efficiency is measured

20 m/s (default)

Speed that the block uses to calculate force-dependent electrical losses.

#### Force-independent electrical losses — Force-independent electrical losses

2 W (default)

Fixed electrical loss associated with the actuator when the force is zero.

#### Simulation mode — Simulation mode

PWM (default) | Averaged

If you set the **Simulation mode** parameter to **PWM**, apply a PWM waveform switching between zero and rated volts to the block electrical terminals. The current drawn from the electrical supply is equal to the amount required to deliver the mechanical power and to compensate for electrical losses. If the applied voltage exceeds the rated voltage, the resultant force scales proportionately. However, applying anything other than the rated voltage can provide unrepresentative results.

If you set the **Simulation mode** parameter to **Averaged**, the force generated in response to an applied voltage  $V_{av}$  is

$$\frac{V_{av}}{V_{rated}} \times F(v)$$

where  $F(v)$  is the force value at speed  $v$ . The current drawn from the supply is such that the product of the current and  $V_{av}$  is equal to the average power that is consumed.

### **Mechanical**

#### **Plunger mass — Plunger mass**

0.1 kg (default)

Mass of the moving part of the motor. The value can be zero.

# Generic Rotary Actuator

Generic rotary actuator driven from DC voltage source or PWM driver

**Library:** Simscape / Electrical / Electromechanical / Mechatronic Actuators

## Description

The Generic Rotary Actuator block implements a model of a generic rotary actuator designed to be driven from a DC voltage source or PWM driver. You define torque-speed characteristics in terms of tabulated values for powering the motor at the rated voltage. This functionality allows you to model a motor without referencing an equivalent circuit.

The motor or actuator architecture determines the way in which electrical losses depend on torque. For example, a DC motor has losses that are proportional to the square of the current. As torque is proportional to current, losses are also proportional to mechanical torque. Most motors have an electrical loss term that is proportional to the square of mechanical torque. The Generic Rotary Actuator block calculates this loss term using the **Motor efficiency (percent)** and **Speed at which efficiency is measured** parameters that you provide.

Some motors also have a loss term that is independent of torque. An example is a shunt motor where the field winding draws a constant current regardless of load. The **Torque-independent electrical losses** parameter accounts for this effect.

The motor efficiency is the mechanical power divided by the sum of the mechanical power and both electrical loss terms. The block assumes that the speed at which the motor efficiency is defined is in the motoring quadrant and, therefore, positive.

You can operate the block in the reverse direction by changing the sign of the voltage that you apply. The H-Bridge block, for example, reverses motor direction if the voltage at the REV port is greater than the **Reverse threshold voltage** parameter. However, if you are using the block in reverse, specify the torque-speed data for forward operation:

- Positive torques and positive speeds in the motoring quadrant.
- Positive torque and negative speeds in the generating counterclockwise quadrant.
- Negative torque and positive speed in the generating clockwise quadrant.

### Model Thermal Effects

You can expose the thermal port to model the effects of losses that convert power to heat. To expose the thermal port, set the **Modeling option** parameter to either:

- No thermal port — The block does not contain a thermal port.
- Show thermal port — The block contains one thermal conserving port.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

## Assumptions and Limitations

- The torque-speed curve data corresponds only to the rated voltage, so the block produces accurate results only when driven by plus or minus the rated voltage.
- In this block requires, you must provide torque-speed data for the full range over which you use the actuator. To use the actuator in the generating and braking regions, provide additional data outside of the normal motoring region.
- Model behavior is sensitive to torque-speed data. For example, no-load speed is correctly defined and finite only when the data crosses the speed axis.
- To drive the block from the H-Bridge block:
  - Do not place any other blocks between the H-Bridge and the Generic Rotary Actuator blocks.
  - In the H-Bridge block dialog box, set the **Freewheeling mode** to **Via one semiconductor switch and one freewheeling diode**. Selecting **Via two freewheeling diodes** does not set the bridge output voltage to zero when the PWM input signal is low.
  - In the H-Bridge, Generic Rotary Actuator, and Controlled PWM Voltage block dialog boxes, ensure that the **Simulation mode** is the same for all three blocks.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the actuator positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the actuator negative terminal.

#### C – Case

mechanical

Mechanical rotational conserving port associated with the actuator case.

#### R – Rotor

mechanical

Mechanical rotational conserving port associated with the rotor.

#### H – Thermal port

thermal

Thermal port.

### Dependencies

To enable this port, set **Modeling option** to **Show thermal port**.

## Parameters

### Modeling option — Whether to enable thermal port

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of losses that convert power to heat.

### Electrical Torque

#### Speed values — Vector of speeds

[-1500, -1000, -500, 0, 500, 1000, 1500, 2000, 2500, 3000] rpm (default)

Specify a vector of speeds, including their units, for your torque-speed data.

#### Torque values — Vector of torques

[.04, .035, .03, .025, .02, .015, .01, .005, 0, -.005] Nm (default)

Specify a vector of torques, including their units, for your torque-speed data.

#### Rated voltage — Rated voltage

12 V (default)

Indicate the voltage for which the device you are modeling is rated.

#### Motor efficiency (percent) — Motor efficiency

80 (default)

The efficiency that the block uses to calculate torque-dependent electrical losses.

#### Speed at which efficiency is measured — Speed at which efficiency is measured

2000 rpm (default)

The speed that the block uses to calculate torque-dependent electrical losses.

#### Torque-independent electrical losses — Fixed electrical loss

0.1 W (default)

Fixed electrical loss associated with the actuator when the torque is zero.

#### Simulation mode — Simulation mode

PWM (default) | Averaged

If you set the **Simulation mode** parameter to PWM, apply a PWM waveform switching between zero and rated volts to the block electrical terminals. The current drawn from the electrical supply is equal to the amount required to deliver the mechanical power and to compensate for electrical losses. If the applied voltage exceeds the rated voltage, the resultant torque scales proportionately. However, applying anything other than the rated voltage can provide unrepresentative results.

If you set the **Simulation mode** parameter to Averaged, the torque generated in response to an applied voltage  $V_{av}$  is

$$\frac{V_{av}}{V_{rated}} \times T(\omega)$$

where  $T(\omega)$  is the torque value at speed  $\omega$ . The current drawn from the supply is such that the product of the current and  $V_{av}$  is equal to the average power that is consumed.

## **Mechanical**

### **Rotor inertia — Rotor inertia**

0.0001 kg\*m<sup>2</sup> (default)

Rotor resistance to change in motor motion. The value can be zero.

### **Rotor damping — Rotor damping**

1e-8 N\*m/(rad/s) (default)

Rotor damping. The value can be zero.

## **Temperature Dependence**

To enable these parameters, set **Modeling option** to Show thermal port.

### **Resistance temperature coefficient — Resistance temperature coefficient**

3.93e-3 1/K (default)

# Governor Type 1

IEEE type 1 linearized speed-governing steam turbine model

**Library:** Simscape / Electrical / Control / Turbine-Governors

## Description

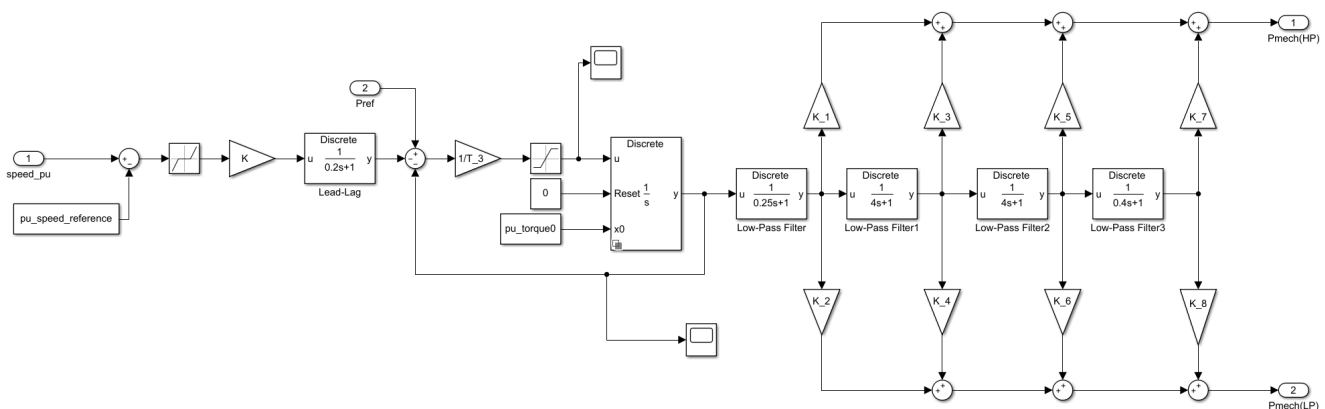

The Governor Type 1 block models a model IEEEG1 steam turbine-governor model IEEEG1.

This block allows the modeling of cross-compound units and it has two sets of turbine fractions:

- **LP Fraction, K\_2, LP Fraction, K\_4, LP Fraction, K\_6, LP Fraction, K\_8** for low-pressure (LP).
- **HP Fraction, K\_1, HP Fraction, K\_3, HP Fraction, K\_5, HP Fraction, K\_7** for high-pressure (HP).

You can switch between continuous and discrete implementations of the block by using the **Sample time (-1 for inherited)** parameter. To configure the governor for continuous time, set the **Sample time (-1 for inherited)** property to 0. To configure the governor for discrete time, set the **Sample time (-1 for inherited)** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block.

This diagram illustrates the overall structure of the block:

## Ports

### Input

#### **speed\_pu — Turbine speed**

scalar

Speed of the turbine, in per-unit representation, specified as a scalar.

Data Types: `single` | `double`

#### **Pref — Speed reference bias**

scalar

Bias to the speed load reference, specified as a scalar. Connect this port to the **Pref** output port of a turbine load controller block, such as the Controller LCFB1 block.

Data Types: `single` | `double`

### Output

#### **Pmech(HP) — High-pressure mechanical power**

scalar

High-pressure mechanical power, returned as a scalar.

Data Types: `single` | `double`

#### **Pmech(LP) — Low-pressure mechanical power**

scalar

Low-pressure mechanical power, returned as a scalar.

Data Types: `single` | `double`

## Parameters

### General

#### **Speed reference (pu) — Speed reference**

1 (default) | scalar

Per-unit speed reference.

#### **Initial torque (pu) — Initial torque**

0.45 (default) | scalar

Per-unit initial torque at the start of the simulation.

#### **Sample time (-1 for inherited) — Block sample time**

-1 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see "Promote Block Parameters on a Mask".

## **Governor**

### **Governor gain (1/droop), K (pu) – Gain of governor**

20 (default) | scalar

Per-unit gain of the governor.

### **Lag time constant, T\_1 (s) – Governor lag time constant**

0.2 (default) | scalar

Equivalent lag time constant. This parameter is associated with the block labeled "Lead-Lag" in the diagram. Set this parameter to 0 when the additional lag dynamics are negligible.

### **Lead time constant, T\_2 (s) – Governor lead time constant**

0 (default) | scalar

Equivalent lead time constant. This parameter is associated with the block labeled "Lead-Lag" in the diagram. Set this parameter to 0 when the additional lead dynamics are negligible.

### **Valve position time constant, T\_3 (s) – Time constant of valve position**

0.1 (default) | scalar

Time constant of the valve position, in seconds.

### **Maximum valve opening rate, U\_o (pu/s) – Maximum opening rate of the valve**

0.1 (default) | scalar

Per-unit maximum opening rate of the valve.

### **Maximum valve closing rate, U\_c (pu/s) – Maximum closing rate of the valve**

-0.1 (default) | scalar

Per-unit maximum closing rate of the valve.

### **Maximum valve opening, on MW capability, P\_max (pu) – Maximum opening of the valve on MW capability**

0.98 (default) | scalar

Per-unit maximum opening of the valve, on MW capability.

### **Minimum valve opening, on MW capability, P\_min (pu) – Minimum opening of the valve, on MW capability**

0 (default) | scalar

Per-unit minimum opening of the valve, on MW capability.

### **Time constant for steam inlet, T\_4 (s) – Time constant of the inlet steam**

0.25 (default) | scalar

Time constant of the inlet steam bowl, in seconds. This parameter is associated with the block labeled "Low-Pass Filter" in the diagram.

**HP fraction, K\_1 — Fraction of high-pressure shaft power**

0.22 (default) | scalar

Fraction of the high-pressure shaft power after the first boiler pass.

**LP fraction, K2 — Fraction of low-pressure shaft power**

0 (default) | scalar

Fraction of the low-pressure shaft power after the first boiler pass.

**Time constant for second boiler pass, T\_5 (s) — Time constant for second boiler pass**

4 (default) | scalar

Time constant of the second boiler pass, in seconds. This parameter is associated with the block labeled "Low-Pass Filter1" in the diagram.

**HP fraction, K\_3 — Fraction of high-pressure shaft power**

0.22 (default) | scalar

Fraction of the high-pressure shaft power after the second boiler pass.

**LP fraction, K\_4 — Fraction of low-pressure shaft power**

0 (default) | scalar

Fraction of the low-pressure shaft power after the second boiler pass.

**Time constant for third boiler pass, T\_6 (s) — Time constant for third boiler pass**

4 (default) | scalar

Time constant of the third boiler pass, in seconds. This parameter is associated with the block labeled "Low-Pass Filter2" in the diagram.

**HP fraction, K\_5 — Fraction of high-pressure shaft power**

0.3 (default) | scalar

Fraction of the high-pressure shaft power after the third boiler pass.

**LP fraction, K\_6 — Fraction of low-pressure shaft power**

0 (default) | scalar

Fraction of the low-pressure shaft power after the third boiler pass.

**Time constant for fourth boiler pass, T\_7 (s) — Time constant for fourth boiler pass**

0.4 (default) | scalar

Time constant of the fourth boiler pass, in seconds. This parameter is associated with the block labeled "Low-Pass Filter3" in the diagram.

**HP fraction, K\_7 — Fraction of high-pressure shaft power**

0.26 (default) | scalar

Fraction of the high-pressure shaft power after the fourth boiler pass.

**LP fraction, K\_8 – Fraction of low-pressure shaft power**

0 (default) | scalar

Fraction of the low-pressure shaft power after the fourth boiler pass.

**Deadband – Deadband width**

0.02 (default) | scalar

Intentional deadband width.

# GTO

Gate Turn-Off Thyristor

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The GTO block models a gate turn-off thyristor (GTO). The I-V characteristic of a GTO is such that if the gate-cathode voltage exceeds the specified gate trigger voltage, the GTO turns on. If the gate-cathode voltage falls below the specified gate turn-off voltage value, or if the load current falls below the specified holding-current value, the device turns off.

To define the I-V characteristic of the GTO, set the **On-state behaviour and switching losses** parameter to either **Specify constant values** or **Tabulate with temperature and current**. The **Tabulate with temperature and current** option is available only if you expose the thermal port of the block.

In the on state, the anode-cathode path behaves like a linear diode with forward-voltage drop,  $V_f$ , and on-resistance,  $R_{on}$ . However, if you expose the thermal port of the block and parameterize the device using tabulated I-V data, the tabulated resistance is a function of the temperature and current.

In the off state, the anode-cathode path behaves like a linear resistor with a low off-state conductance value,  $G_{off}$ .

The defining Simscape equations for the block are:

```

if ((v > Vf)&&((G>Vgt)|| (i>Ih)))&&(G>Vgt_off)
    i == (v - Vf*(1-Ron*Goff))/Ron;
else
    i == v*Goff;
end

```

where:

- $v$  is the anode-cathode voltage.
- $V_f$  is the forward voltage.
- $G$  is the gate voltage.
- $V_{gt}$  is the gate trigger voltage.
- $i$  is the anode-cathode current.
- $I_h$  is the holding current.
- $V_{gt\_off}$  is the gate turn-off voltage.
- $R_{on}$  is the on-state resistance.
- $G_{off}$  is the off-state conductance.

Using the **Integral Diode** parameters, you can include an integral cathode-anode diode. A GTO that includes an integral cathode-anode diode is known as an asymmetrical GTO (A-GTO) or reverse-conducting GTO (RCGTO). An integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

The table shows you how to set the **Integral protection diode** parameter based on your goals.

Goal	Value to Select	Block Behavior
Prioritize simulation speed.	Protection diode with no dynamics	The block includes an integral copy of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.
Precisely specify reverse-mode charge dynamics.	Protection diode with charge dynamics	The block includes an integral copy of the dynamic model of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.

### Model Gate Port and Thermal Effects

You can choose between physical or electrical ports to control the gate terminal and expose the thermal port to model the heat that switching events and conduction losses generate. To choose the gate control port, set the **Gate control port** parameter to PS or Electrical. To expose the thermal port, set the **Modeling option** parameter to either No thermal port or Show thermal port.

For more information about using thermal ports, see “Simulating Thermal Effects in Semiconductors”.

### Thermal Losses

The figure shows an idealized representation of the output voltage,  $V_{out}$ , and the output current,  $I_{out}$ , of the semiconductor device. The interval shown includes the entire  $n^{\text{th}}$  switching cycle, during which the block turns off and then on.

Switching losses are one of the main sources of thermal loss in semiconductors. During each on-off switching transition, the GTO parasitics store and then dissipate energy.

Switching losses depend on the off-state voltage and the on-state current. When the switching device is turned on, the power losses depend on the initial off-state voltage across the device and the final on-state current once the device is fully in its on state. Similarly, when the switching device is force commutated off, the power losses depend on the initial on-state current through the device and the final off-state voltage once the device is fully in its off state. The switch on and force commutated switch off losses are either fixed or dependent on junction temperature and drain-source current, depending on how you specify the **On-state behavior and switching losses** parameter. In both cases, the losses are scaled by the off-state voltage prior to the latest device turn-on event.

When the current falls below the holding current and the device is naturally commutated off, the losses are set by the **Natural commutation rectification loss** parameter. Because it's not possible to know when to measure the starting current or final voltage for the rectification loss, it is not possible to scale it by the off-state voltage or on-state current.

In this block, switching losses are applied by stepping up the junction temperature with a value equal to the switching loss divided by the total thermal mass at the junction.

**Note** As the final current after a switching event is not known during the simulation, if you use the GTO block as a fully-controlled device, the block records the on-state current at the point that the device is commanded off. If you use the GTO block as a partially-controlled device, the block records the on-state current once the current is greater than the holding current for a time longer than the value of the **Wait time before switch-on current measurement** parameter. Similarly, the block records the off-state voltage at the point that the device is commanded on. For this reason, the simlog does not report the switching losses to the thermal network until one switching cycle later

For all ideal switching devices, the switching losses are reported in the simlog as `lastTurnOffLoss` and `lastTurnOnLoss` and recorded as a pulse with amplitude equal to the energy loss. If you use a

script to sum the total losses over a defined simulation period, you must sum the pulse values at each pulse rising edge. Alternatively, you can use the `ee_getPowerLossSummary` and `ee_getPowerLossTimeSeries` functions to extract conduction and switching losses from logged data.

Note that the `power_dissipated` variable in the simlog does not include switching losses as they are modeled as instantaneous events. The `power_dissipated` variable therefore just reports instantaneous on-state losses.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

**Gate-control port – Whether to specify physical or electrical control port**

PS (default) | Electrical

Whether to specify physical or electrical control port for the switch gate.

**On-state behaviour and switching losses — On-state current for switching loss data**

Specify constant values (default) | Tabulate with temperature and current

Select a parameterization method. The option that you select determines which other parameters are enabled. Options are:

- **Specify constant values** — Use scalar values to specify the output current, switch-on loss, switch-off loss, and on-state voltage data. This is the default parameterization method.
- **Tabulate with temperature and current** — Use vectors to specify the output current, switch-on loss, switch-off loss, and temperature data.

**Dependencies**

See the Main Parameter Dependencies table.

**Gate trigger voltage, Vgt — Gate trigger voltage**

6 V (default)

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Main Parameter Dependencies table.

**Gate turn-off voltage, Vgt\_off — Gate turn-off voltage**

-1 V (default)

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Main Parameter Dependencies table.

**Holding current — Holding current**

1 A (default)

Current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Main Parameter Dependencies table.

**Forward voltage, Vf — Forward voltage**

0.8 V (default)

Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state resistance — On-state resistance**

0.001 Ohm (default)

Rate of change of voltage versus current above the forward voltage. The default value is 0.001.

**Dependencies**

See the Main Parameter Dependencies table.

**Off-state conductance — Off-state conductance**

1e-5 1/Ohm (default)

Anode-cathode conductance when the device is off. The value must be less than 1/R, where R is the value of **On-state resistance**. The default value is 1e-5.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state voltage,  $V_{ak}(T_j, I_{ak})$  — On-state voltage**

[0, .1, .6, .8, 1, 1.3, 1.6, 2, 2.4; 0, .1, .7, 1, 1.2, 1.5, 1.9, 2.4, 2.8] V (default)

Voltage drop across the device while it is in a triggered conductive state. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Temperature vector,  $T_j$  — Temperature vector**

[298.15, 398.15] K (default)

Temperature values at which the on-state voltage is specified. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Anode-cathode current vector,  $I_{ak}$  — Anode-cathode current vector**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default)

Anode-cathode currents for which the on-state voltage is defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Switching Losses**

To enable these parameters, set **Modeling option** to Show thermal port.

**Switch-on loss — Switch-on loss**

22.86e-3 J (default)

Energy dissipated during a single switch-on event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Forced commutation switch-off loss — Forced commutation switch-off loss**

17.14e-3 J (default)

Energy dissipated during a single switch-off event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Natural commutation rectification loss — Natural commutation rectification loss**

10e-3 J (default)

Rectification loss applied at the point that the block switches off when the current falls below the **Holding current**. Specify this parameter using a scalar quantity.

**Off-state voltage for switching loss data — Off-state voltage for losses data**

600 V (default) | 300 V

The output voltage of the device during the off state. This is the blocking voltage at which the switch-on loss and switch-off loss data are defined.

**On-state current for switching loss data — Output current**

600 A (default)

Output currents for which the switch-on loss, switch-off loss, and on-state voltage are defined. The first element must be zero. Specify this parameter using a scalar quantity.

---

**Note** This parameter is measured at the point that the gate voltage falls below the **Gate trigger voltage, Vgt**. The turn-on pulse is longer than the time it takes the current to reach its maximum value.

---

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Switch-on loss,  $E_{on}(T_j, I_{ak})$  — Switch-on loss**

[0, .0024, .024, .12, .2, .48, 1.04, 2.16, 3.24; 0, .003, .03, .15, .25, .6, 1.3, 2.7, 4.05] \* 1e-3 J (default)

Energy dissipated during a single switch on event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Switch-off loss,  $E_{\text{off}}(T_j, I_{\text{ak}})$  — Switch-off loss**

[0, .0007, .0066, .033, .066, .17, .33, .83, 1.5;  
0, .001, .01, .05, .1, .25, .5, 1.2, 2.2] \* 1e-3 J (default)

Energy dissipated during a single switch-off event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Temperature vector for switching losses,  $T_j$  — Temperature vector for switching losses**

[298.15, 398.15] K (default)

Temperature values at which the switch-on loss and switch-off loss are specified. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Anode-cathode current vector for switching losses,  $I_{\text{ak}}$  — Anode-cathode current vector for switching losses**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default)

Anode-cathode currents for which the switch-on loss and switch-off loss are defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Wait time before switch-on current measurement — Wait time before switch-on current measurement**

0 s (default)

Time to wait before recording the on-state current if you use the GTO block as a partially-controlled device. If you use the GTO block as a fully-controlled device, set this parameter to 0.

**Integral Diode****Integral protection diode — Integral protection diode**

None (default) | Protection diode with no dynamics | Protection diode with charge dynamics

Block integral protection diode. The default value is None.

The diodes you can select are:

- Protection diode with no dynamics
- Protection diode with charge dynamics

**Diode model — Diode model**

Piecewise Linear (default) | Tabulated I-V curve

Select one of these diode models:

- **Piecewise Linear** — Use a piecewise linear model for the diode, as described in “Piecewise Linear Diode” on page 1-448. This is the default method.
- **Tabulated I-V curve** — Use tabulated forward bias I-V data plus fixed reverse bias off conductance.

**Dependencies**

This parameter is visible only when the thermal port is exposed and the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

**Table type — Tabulated function**

Table in  $I_f(T_j, V_f)$  form (default) | Table in  $V_f(T_j, I_f)$  form

Whether to tabulate the current as a function of temperature and voltage or the voltage as a function of temperature and current.

**Dependencies**

This parameter is visible only when the thermal port is exposed and the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** is set to Tabulated I-V curve.

**Forward voltage — Forward voltage**

0.8 V (default)

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

**Dependencies**

To enable this parameter:

- If the thermal port is hidden, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.
- If the thermal port is exposed, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** to Piecewise linear.

**On resistance — On resistance**

0.001 Ohm (default)

Rate of change of voltage versus current above the **Forward voltage**.

**Dependencies**

To enable this parameter:

- If the thermal port is hidden, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.

- If the thermal port is exposed, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** to Piecewise linear.

#### **Forward currents, $I_f(T_j, V_f)$ — Vector of forward currents**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12]  
A (default) | nonnegative vector

Forward currents. This parameter must be a vector of at least three nonnegative elements.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $I_f(T_j, V_f)$  form.

#### **Junction temperatures, $T_j$ — Vector of junction temperatures**

[25, 125] degC (default)

Vector of junction temperatures. This parameter must be a vector of at least two elements.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve.

#### **Forward voltages, $V_f$ — Vector of forward voltages**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Vector of forward voltages. This parameter must be a vector of at least three nonnegative values.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $I_f(T_j, V_f)$  form.

#### **Forward voltages, $V_f(T_j, I_f)$ — Vector of forward voltages**

[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85; .58, .68, .75, 1.1, 1.38, 1.77, 2.27, 2.7] V (default) | nonnegative vector

Forward voltages. This parameter must be a vector of at least three nonnegative elements.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $V_f(T_j, I_f)$  form.

#### **Forward currents, $I_f$ — Vector of forward currents**

[.1, .2, .5, 1, 2, 4, 7, 10] A (default)

Vector of forward currents. This parameter must be a vector of at least three nonnegative values.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $V_f(T_j, I_f)$  form.

#### **Off conductance — Off conductance**

1e-5 1/Ohm (default)

Conductance of the reverse-biased diode.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

**Junction capacitance – Junction capacitance**

50e-9 F (default)

Diode junction capacitance.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Peak reverse current,  $i_{RM}$  – Peak reverse current**

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero. The default value is -235 A.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Initial forward current when measuring  $i_{RM}$  – Initial forward current when measuring  $i_{RM}$**

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Rate of change of current when measuring  $i_{RM}$  – Rate of change of current when measuring  $i_{RM}$**

-50A/ $\mu$ s (default) | negative scalar

Rate of change of current when measuring peak reverse current. This value must be less than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Reverse recovery time parameterization – Reverse recovery time parameterization**

Specify reverse recovery time directly (default) | Specify stretch factor | Specify reverse recovery charge

Determines how you specify reverse recovery time in the block. The default value is Specify reverse recovery time directly.

If you select **Specify stretch factor** or **Specify reverse recovery charge**, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates TM and Tau” on page 1-452.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics**.

#### Reverse recovery time, $t_{rr}$ — Reverse recovery time

15  $\mu$ s (default)

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics** and the **Reverse recovery time parameterization** parameter is set to **Specify reverse recovery time directly**.

#### Reverse recovery time stretch factor — Reverse recovery time stretch factor

3 (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics** and the **Reverse recovery time parameterization** parameter is set to **Specify stretch factor**.

#### Reverse recovery charge, $Q_{rr}$ — Reverse recovery charge

1500  $\mu$ As (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current,  $i_{RM}$** .
- $a$  is the value specified for **Rate of change of current when measuring  $i_{RM}$** .

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery charge.

**Diode turn-off voltage when measuring Erec — Diode turn-off voltage when measuring Erec**

-600 V (default)

Voltage between the diode in steady-state.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Stray inductance when measuring Erec — Stray inductance when measuring Erec**

150 nH (default)

Total unintended inductance in the measurement circuit. The block uses this value to calculate **Reverse recovery energy, Erec**.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Reverse recovery energy, Erec — Reverse recovery energy**

0.03 J (default)

Total switching losses due to the diode reverse recovery.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

For more information on these parameters, see Diode.

**Thermal Port**

Use the thermal port to simulate the effects of generated heat and device temperature. For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

**Version History****Introduced in R2013b****Update on switching losses and thermal modelling options**

*Behavior changed in R2020b*

From R2020b forward, the GTO (Ideal, Switching) block has improved losses and thermal modelling options.

As a result from these changes:

- Electrical and thermal on-state losses are now always identical. The **Thermal loss dependent on** parameter and its options, **Voltage** and **current** and **Voltage, current, and temperature**, have been renamed to **On-state behavior and switching losses**, **Specify constant values**, and **Tabulate with temperature and current**:
  - If you selected **Voltage** and **current** for **Thermal loss dependent on**, then the electrical on-state losses are unchanged and their values are determined using the on-state resistance. However, the thermal on-state losses are now also determined by the on-state resistance. Prior to R2020b, the thermal on-state losses were defined by the product of the **On-state voltage** and **Output current, Iout** parameters.
  - If you selected **Voltage, current, and temperature** for **Thermal loss dependent on**, then the thermal on-state losses are unchanged and the **On-state voltage, Vak(Tj,Iak)** parameter sets their values. However, the electrical on-state losses are now equal to the thermal on-state losses. Prior to R2020b, the electrical on-state losses were defined by the value of the on-state resistance.
- The **On-state voltage** parameter is no longer used.

### **Removal of energy dissipation time constant parameter**

*Behavior changed in R2021a*

From R2021a forward, the **Energy dissipation time constant** parameter of the GTO (Ideal, Switching) block is no longer used. A step in junction temperature now reflects the switching losses. If your model contains a thermal mass directly connected to this block thermal port, remove it and model the thermal mass inside the component itself.

# Gyro

Behavioral model of MEMS gyro

**Library:** Simscape / Electrical / Sensors & Transducers

## Description

The Gyro block implements a behavioral model of a MicroElectroMechanical Systems (MEMS) gyro. The gyro provides an output voltage that is proportional to the angular rotation rate presented at the mechanical rotational physical port R. The output voltage is limited according to the values that you provide for maximum and minimum output voltage.

Optionally, you can model sensor dynamics by setting the **Dynamics** parameter to `Model sensor bandwidth`. Including dynamics adds a first-order lag between the angular rate presented at port R and the corresponding voltage applied to the electrical + and - ports.

If running your simulation with a fixed-step solver, or generating code for hardware-in-the-loop testing, MathWorks recommends that you set the **Dynamics** parameter to `No dynamics – Suitable for HIL`, because this avoids the need for a small simulation time step if the sensor bandwidth is high.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

The **Measured angular rate** variable target specifies the initial output for the sensor.

## Ports

### Conserving

#### R – Translational port

mechanical

Mechanical conserving port associated with the gyro translational port.

#### + – Positive port

electrical

Electrical conserving port associated with the gyro positive terminal.

**- – Negative port**

electrical

Electrical conserving port associated with the gyro negative terminal.

## Parameters

**Sensitivity – Sensitivity**

12.5 s\*mV/deg (default)

The change in output voltage level per unit change in rotation rate when the output is not being limited.

**Output voltage for zero rotation – Output voltage for zero rotation**

2.5 V (default)

The output voltage from the sensor when the rotation rate is zero.

**Maximum output voltage – Maximum output voltage**

4 V (default)

The maximum output voltage from the sensor, which determines the sensor maximum measured rotational rate.

**Minimum output voltage – Minimum output voltage**

1 V (default)

The minimum output voltage from the sensor, which determines the sensor minimum measured rotational rate.

**Dynamics – Dynamics modeling option**

No dynamics – Suitable for HIL (default) | Model sensor bandwidth

Select one of the following options for modeling sensor dynamics:

- **No dynamics – Suitable for HIL** – Do not model sensor dynamics. Use this option when running your simulation fixed step or generating code for hardware-in-the-loop testing, because this avoids the need for a small simulation time step if the sensor bandwidth is high. This is the default option.
- **Model sensor bandwidth** – Model sensor dynamics with a first-order lag approximation, based on the **Bandwidth** parameter value. You can control the initial condition for the lag by specifying the **Measured angular rate** variable target.

**Bandwidth – Bandwidth**

3 kHz (default)

Specifies the 3dB bandwidth for the measured rotational rate assuming a first-order time constant.

**Dependencies**

This parameter is visible only when you select Model sensor bandwidth for the **Dynamics** parameter.

# Hall-Effect Rotary Encoder

Four-element Hall-effect rotary encoder

**Library:** Simscape / Electrical / Sensors & Transducers

## Description

The Hall-Effect Rotary Encoder block models a 360° rotary position sensor using four Hall elements equally spaced under a magnetized, rotating magnet. The elements generate four sinusoidal waveforms.

## Equations

The voltages between the elements of the rotary encoder are described by the equations:

$$v_x = V_{x0} + A_x \cos(\theta)$$

$$v_y = V_{y0} + A_y \cos\left(\theta - \frac{\pi}{2} + \beta\right),$$

where:

- $v_x$  is the voltage between elements  $x_p$  and  $x_n$ ;
- $v_y$  is the voltage between elements  $y_p$  and  $y_n$ ;
- $A_x$  and  $A_y$  are the voltage amplitudes for the  $x$  and  $y$  axes that reflect the sensitivity mismatch;
- $V_{x0}$  and  $V_{y0}$  are the voltage offsets for the  $x$  and  $y$  axes;
- $\beta$  is the quadrature error.

The block uses this equation to decode the angle:

$$\theta_{out} = \arctan\left(\frac{v_y}{v_x}\right).$$

# H-Bridge

H-bridge motor driver

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The H-Bridge block represents an H-bridge motor driver. The block has the following two **Simulation mode** options:

- **PWM** — The H-Bridge block output is a controlled voltage that depends on the input signal at the **PWM** port. If the input signal has a value greater than the **Enable threshold voltage** parameter value, the H-Bridge block output is on and has a value equal to the value of the **Output voltage amplitude** parameter. If it has a value less than the **Enable threshold voltage** parameter value, the block maintains the load circuit using one of the following three **Freewheeling mode** options:
  - Via one semiconductor switch and one freewheeling diode
  - Via two freewheeling diodes
  - Via two semiconductor switches and one freewheeling diode

The first and third options are sometimes referred to as synchronous operation.

The signal at the **REV** port determines the polarity of the output. If the value of the signal at the **REV** port is less than the value of the **Reverse threshold voltage** parameter, the output has positive polarity; otherwise, it has negative polarity.

- **Averaged** — This mode has two **Load current characteristics** options:
  - Smoothed
  - Unsmoothed or discontinuous

The Smoothed option assumes that the current is practically continuous due to load inductance. In this case, the H-Bridge block output is:

$$\frac{V_O V_{PWM}}{A_{PWM}} - I_{OUT} R_{ON}$$

where:

- $V_O$  is the value of the **Output voltage amplitude** parameter.
- $V_{PWM}$  is the value of the voltage at the **PWM** port.
- $A_{PWM}$  is the value of the **PWM signal amplitude** parameter.
- $I_{OUT}$  is the value of the output current.

- $R_{ON}$  is the **Bridge on resistance** parameter.

The current will be smooth if the PWM frequency is large enough. Synchronous operation where freewheeling is via a bridge arm back to the supply also helps smooth the current. For cases where the current is not smooth, or possibly discontinuous (that is, it goes to zero between PWM cycles), use the **Unsmoothed** or **discontinuous** option. For this option, you must also provide values for the **Total load series resistance**, **Total load series inductance**, and **PWM frequency**. During simulation, the block uses these values to calculate a more accurate value for H-bridge output voltage that achieves the same average current as would be present if simulating in PWM mode.

Set the **Simulation mode** parameter to **Averaged** to speed up simulations when driving the H-Bridge block with a Controlled PWM Voltage block. You must also set the **Simulation mode** parameter of the Controlled PWM Voltage block to **Averaged** mode. This applies the average of the demanded PWM voltage to the motor. The accuracy of the **Averaged** mode simulation results relies on the validity of your assumption about the load current. If you specify that the current is **Unsmoothed** or **discontinuous**, then the accuracy also depends on the values you provide for load resistance and inductance being representative. This mode also makes some simplifying assumptions about the underlying equations for the case when current is discontinuous. For typical motor and bridge parameters, accuracy should be within a few percent. To verify **Averaged** mode accuracy, run the simulation using the **PWM** mode and compare the results to those obtained from using the **Averaged** mode.

Braking mode is invoked when the voltage presented at the **BRK** port is larger than the **Braking threshold voltage**. Regardless of whether in PWM or **Averaged** mode, when in braking mode the H-bridge is modeled by a series combination of two resistances  $R1$  and  $R2$  where:

- $R1$  is the resistance of a single bridge arm, that is, half the value of the **Total bridge on resistance** parameter.
- $R2$  is the resistance of a single bridge arm in parallel with a diode resistance, that is,  $R1 \cdot Rd / (R1 + Rd)$ , where  $Rd$  is the diode resistance.

### External Power Supply

To model the demands placed on the DC supply, you can choose to expose the power supply ports of the H-Bridge block by setting the **Power supply** parameter to **External**. If the power supply ports are exposed, then only PWM simulation mode is supported.

**Note** If the **Power supply** parameter is set to **External**, the block is able to figure out the load-side voltage offset by referencing to the supply rail voltages. However, if the supply rail connections are not exposed, you must add an Electrical Reference block on the load side.

## Model Thermal Effects

This block has one optional thermal port. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port.
- **Show thermal port** — The block contains one thermal conserving port.

When you expose the thermal port:

- The heat generated by the bridge on-resistance and freewheeling diodes is added to the thermal port. The thermal port has an associated thermal mass and initial temperature that you can set from the **Thermal Port** parameters.
- The bridge on-resistance and freewheeling diode resistance become functions of temperature. You can define the values for these resistances and the second measurement temperature from the **Temperature Dependence** parameters. Resistance is assumed to vary linearly between the two measurement temperatures. Extrapolation is used for temperatures outside of this range, except for when simulating in averaged mode with discontinuous load current characteristics.

## Assumptions and Limitations

- If you are linearizing your model, set the **Simulation mode** parameter to **Averaged** and ensure that you have specified the operating point correctly. You can only linearize the H-Bridge block for duty cycles that are greater than zero and less than the PWM signal amplitude. If you need to linearize around zero duty cycle, and if your controller always uses regenerative braking mode, set the **Regenerative braking** parameter to **Always enabled** (suitable for linearization).
- In **Averaged** mode, and with the **Unsmoothed** or **discontinuous** choice for **Load current characteristics**, you must provide representative values for load inductance and resistance. If driving a DC Motor, then the resistance is the armature resistance, and the inductance is the sum of the armature inductance plus series smoothing inductor (if present). For a Universal Motor, total resistance is the sum of the armature and field windings, and total inductance is the sum of armature and field inductances plus any series smoothing inductance. For a Shunt Motor, MathWorks recommends that you draw a Thévenin equivalent circuit to determine appropriate values.
- No forward voltage is modeled for the freewheeling diodes. They are approximated as ideal resistances when forward biased, with resistance equal to the **Freewheeling diode on resistance** parameter value.
- If the supply rail connections are exposed, only the PWM simulation mode is supported.

## Ports

### Conserving

+ — **Positive load connection port**  
electrical

Electrical conserving port associated with the positive load connection.

- — **Negative load connection port**  
electrical

Electrical conserving port associated with the negative load connection.

#### **V+ — Positive supply connection**

electrical

Electrical conserving port associated with the positive electrical supply connection.

#### **Dependencies**

This port is visible only when you select External for the **Power supply** parameter.

#### **V- — Negative supply connection**

electrical

Electrical conserving port associated with the negative electrical supply connection.

#### **Dependencies**

This port is visible only when you select External for the **Power supply** parameter.

#### **PWM — Pulse-width modulated signal**

electrical

Electrical conserving port associated with the pulse-width modulated signal. The voltage is defined relative to the **REF** port.

#### **REF — Reference**

electrical

Electrical conserving port associated with the floating zero volt reference.

#### **REV — REV**

electrical

Electrical conserving port associated with the voltage that controls when to reverse the polarity of the H-Bridge block output. The voltage is defined relative to the **REF** port.

#### **BRK — BRK**

electrical

Electrical conserving port associated with the voltage that controls when to short circuit the H-Bridge block output. The voltage is defined relative to the **REF** port.

#### **H — Thermal port**

thermal

Thermal conserving port.

#### **Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

### **Parameters**

#### **Modeling option — Whether to enable thermal port**

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model thermal parameters.

### **Simulation Mode & Load Assumptions**

#### **Power supply — Visibility of power supply ports**

Internal (default) | External

Select one of the following options for the type of power supply:

- **Internal** — The power supply ports are internal and not visible. This is the default option.
- **External** — The power supply ports are exposed.

#### **Simulation mode — Simulation mode**

PWM (default) | Averaged

Select one of the following options for the type of output voltage:

- **PWM** — The output voltage is a pulse-width modulated signal. This is the default option.
- **Averaged** — The output voltage is a constant whose value is equal to the average value of the PWM signal.

#### **Freewheeling mode — Freewheeling mode**

Via one semiconductor switch and one freewheeling diode (default) | Via two freewheeling diodes | Via two semiconductor switches and one freewheeling diode

Select one of the following options for the type of H-bridge dissipation circuit:

- **Via one semiconductor switch and one freewheeling diode** — In this mode, the block controls the load by maintaining one high-side bridge arm permanently on and using the PWM signal to modulate the corresponding low-side bridge arm. This means that the block uses only one of the freewheeling diodes in completing the dissipation circuit when the bridge turns off. This option is the default.
- **Via two freewheeling diodes** — In this mode, all bridge arms are off during the bridge off-state. This means that the block dissipates the load current across the power supply by two freewheeling diodes.
- **Via two semiconductor switches and one freewheeling diode** — In this mode, the block controls the load by maintaining one high-side bridge arm permanently on and using the PWM signal to toggle between enabling the corresponding low-side bridge arm and the opposite high-side bridge arm. This means that the block uses a freewheeling diode in parallel with a bridge arm, plus another series bridge arm, to complete the dissipation circuit when the bridge turns off.

### **Dependencies**

This parameter is visible only when you select PWM for the **Simulation mode** parameter, or when you select Averaged for the **Simulation mode** parameter and Unsmoothed or discontinuous for the **Load current characteristics** parameter.

#### **Regenerative braking — Regenerative braking**

Depends on REV flag and current sign (default) | Always enabled (suitable for linearization)

Select one of the following options for the type of H-bridge dissipation circuit:

- Depends on REV flag and current sign — This option is the default.
- Always enabled (suitable for linearization) — This option can be used when the controller always sets the **REV** flag to ensure regenerative braking. It is useful if you need to linearize the model for control purposes, to ensure that the H-Bridge is linearizable around zero duty cycle demand.

#### Dependencies

This parameter is visible only when you select Averaged for the **Simulation mode** parameter.

#### Load current characteristics — Load current characteristics

Smoothed (default) | Unsmoothed or discontinuous

Select one of the following options for the type of load current:

- Smoothed — Assumes that the current is practically continuous due to load inductance. This option is the default.
- Unsmoothed or discontinuous — Use this option for cases where the current is not smooth, or possibly discontinuous (that is, it goes to zero between PWM cycles). For this option, you must also provide values for the **Total load series resistance**, **Total load series inductance**, and **PWM frequency** parameters. During simulation, the block uses these values to calculate a more accurate value for H-bridge output voltage that achieves the same average current as would be present if simulating in PWM mode.

#### Dependencies

This parameter is only visible when you select Averaged for the **Simulation mode** parameter.

#### Load total series resistance — Load total series resistance

100hm (default)

The total load series resistance seen by the H-bridge.

#### Dependencies

This parameter is only visible when you select Averaged for the **Simulation mode** parameter and Unsmoothed or discontinuous for the **Load current characteristics** parameter.

#### Load total series inductance — Load total series inductance

1e-5H (default)

The total load series inductance seen by the H-bridge. As well as motor inductance, you should include any series inductance added external to the motor to smooth current.

#### Dependencies

This parameter is only visible when you select Averaged for the **Simulation mode** parameter and Unsmoothed or discontinuous for the **Load current characteristics** parameter.

#### PWM frequency — PWM Frequency

10kHz (default)

The PWM frequency at which the H-bridge is driven. For consistency, this should be the same value as the PWM frequency specified by the Controlled PWM Voltage block driving the H-Bridge block.

**Dependencies**

This parameter is only visible when you select Averaged for the **Simulation mode** parameter and Unsmoothed or discontinuous for the **Load current characteristics** parameter.

**Freewheeling diode off-state conductance — Freewheeling diode off-state conductance**

1e-6S (default)

The conductance of the reverse-biased freewheeling diode.

**Dependencies**

This parameter is visible only when you select External for the **Power supply** parameter or Averaged for the **Simulation mode** parameter and Depends on REV flag and current sign for the **Regenerative braking** parameter.

**Input Thresholds****Enable threshold voltage — Enable threshold voltage**

2.5V (default)

Threshold above which the voltage at the **PWM** port must rise to enable the H-Bridge block output.

**Dependencies**

This parameter is used only when **Simulation mode**, a **Simulation Mode & Load Assumptions** parameter, is set to PWM.

**PWM signal amplitude — PWM signal amplitude**

5.0V (default)

The amplitude of the signal at the PWM input.

**Dependencies**

The H-Bridge block uses this parameter only when the **Simulation mode** parameter on the **Simulation Mode & Load Assumptions** tab is set to Averaged.

**Reverse threshold voltage — Reverse threshold voltage**

2.5V (default)

When the voltage at the **REV** port is greater than this threshold, the output polarity becomes negative.

**Braking threshold voltage — Braking threshold voltage**

2.5V (default)

When the voltage at the **BRK** port is greater than this threshold, the H-Bridge block output terminals are short-circuited via the following series of devices:

- One bridge arm
- One bridge arm in parallel with a conducting freewheeling diode

## Bridge Parameters

### Output voltage amplitude — Output voltage amplitude

12V (default)

The amplitude of the voltage across the H-Bridge block output ports when the output is on.

#### Dependencies

This parameter is visible only when you select Internal for the **Power supply** parameter.

### Total bridge on resistance — Total bridge on resistance

0.10hm (default)

The total effective resistance of the two semiconductor switches that connect the load to the two power rails when the voltage at the **PWM** port is greater than the value of the **Enable threshold voltage** parameter on the **Input Thresholds** tab.

### Freewheeling diode on resistance — Freewheeling diode on resistance

0.050hm (default)

The total resistance in the freewheeling diodes that dissipate the current that flows through the motor when the voltage at the **PWM** port is less than the value of the **Enable threshold voltage** parameter on the **Input Thresholds** tab.

### Measurement temperature — Measurement temperature

298.15K (default)

The temperature for which the resistance values on the **Bridge Parameters** tab are specified.

#### Dependencies

To enable this parameter, set **Modeling option** to Show thermal port.

#### Temperature Dependence

To enable these parameters, set **Modeling option** to Show thermal port.

### Total bridge on resistance at second measurement temperature — Total bridge on resistance at second measurement temperature

0.10hm (default)

The total effective resistance of the two semiconductor switches that connect the load to the two power rails (as described in the **Total bridge on resistance** parameter definition), quoted at the **Second measurement temperature**.

### Freewheeling diode on resistance at second measurement temperature — Freewheeling diode on resistance at second measurement temperature

0.050hm (default)

The total resistance in the freewheeling diodes that dissipate the current that flows through the motor (as described in the **Total bridge on resistance** parameter definition), quoted at the **Second measurement temperature**.

### Second measurement temperature — Second measurement temperature

398.15K (default)

The temperature for which for which the resistance values on the **Temperature Dependence** tab are specified.

### **Thermal Port**

To enable these parameters, set **Modeling option** to Show thermal port.

#### **Thermal mass – Thermal mass**

100J/K (default)

Thermal mass associated with the thermal port **H**. It represents the energy required to raise the temperature of the thermal port by one degree. The default value is 100 J/K.

#### **Initial temperature – Initial temperature**

298.15K (default)

The temperature of the thermal port at the start of simulation.

## **Version History**

### **Introduced in R2008a**

#### **Freewheeling mode**

*Behavior changed in R2019b*

From R2019b forward, the H-Bridge block has the option to expose the internal supply rail connections.

As a result from this change, inside a model saved in an earlier release, check if the Freewheeling mode parameter of a H-Bridge block in Averaged mode with the assumption of Unsmoothed or discontinuous current is still set to the option you require.

#### **Regenerative braking**

*Behavior changed in R2019b*

Prior to R2019b, in Averaged simulation mode, regardless of the voltage applied at the **REV** port for controlling block output polarity reversal, the H-Bridge block assumed regenerative braking. A model saved from an earlier release that contains an H-Bridge block in Averaged simulation mode will open in later releases with the **Regenerative braking** parameter set to Always enabled (suitable for parameterization) and results will be unchanged. It is recommended that you change this parameter to Depends on REV flag and current sign so that the **REV** flag is correctly interpreted if not set by the controller for regenerative braking.

# Half-Bridge (Ideal, Switching)

Half-bridge with ideal switches and thermal port

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The Half-Bridge (Ideal, Switching) block models a half-bridge with ideal switches and a thermal port. To choose the ideal switching device, set the **Switching device** parameter to either MOSFET, IGBT, or GTO.

You can specify an integral protection diode for each switching device. An integral diode protects the semiconductor device by providing a conduction path for a reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

---

**Note** The `lastReverseRecoveryLoss` variable in the simlog includes the reverse recovery losses as a pulse with amplitude equal to the energy loss. If you use a script to sum the total losses over a defined simulation period, you must sum the pulse values at each pulse rising edge. Alternatively, you can use the `ee_getPowerLossSummary` and `ee_getPowerLossTimeSeries` functions to extract conduction and switching losses from logged data.

Note that the `power_dissipated` variable in the simlog does not include switching losses as they are modeled as instantaneous events. The `power_dissipated` variable therefore just reports instantaneous on-state losses.

---

## Equations

The protection diodes inside the half-bridge use the Lauritzen and Ma model to capture the charge dynamics effects. The defining equations are:

$$i_{RM} = \frac{q_E - q_M}{T_M} \quad (1-37)$$

$$\frac{dq_M}{dt} + \frac{q_M}{\tau} - \frac{q_E - q_M}{T_M} = 0 \quad (1-38)$$

where:

- $i_{RM}$  is the diode peak reverse current.
- $q_E$  is the junction charge.
- $q_M$  is the total stored charge.

- $T_M$  is the transit time.
- $\tau$  is the carrier lifetime.

The block solves equation 2 at  $t = \theta$  and  $q_M$  in steady-state:

$$q_M = i_{RM}\tau - \tau(i_{RM} - i_F)\exp\left(-\frac{t}{\tau}\right) = \tau i_F. \quad (1-39)$$

At  $t = \theta$  and  $q_E = \theta$ , equation 1 is equal to:

$$i_{RM} = \frac{-q_M}{T_M}. \quad (1-40)$$

The block then substitutes equation 3 into equation 4:

$$i_{RM} = \frac{-\tau}{T_M} i_F, \quad (1-41)$$

where  $i_F$  is the starting forward current when measuring  $i_{RM}$ .

Finally, the block calculates the reverse recovery energy,  $E_{rec}$ , as:

$$E_{rec} = \int_{t_1}^{t_2} i_d v_d dt = \int_{t_1}^{t_2} i_{RM} \exp\left(-\frac{t - t_1}{\tau_{rr}}\right) v_R dt, \quad (1-42)$$

where:

- $i_d$  is the current through the diode.
- $v_d$  is the voltage across the diode.
- $\tau_{rr}$  is the reverse recovery time.

Given  $t_2 = \tau_{rr} \ln(10)$ , the total reverse recovery energy is:

$$E_{rec} = -0.9 \tau_{rr} \frac{\tau}{T_M} i_F v_R = -0.9 \frac{\tau^2}{\tau + T_M} i_F v_R. \quad (1-43)$$

## Assumptions and Limitations

- The current change in the load is negligible. The inductance or the switching frequency are large enough so that the load current is constant between the switches.
- The stray inductance of the circuit is negligible.

## Ports

### Input

#### G – Gate terminals vector

physical signal

Physical signal conserving port associated with the gate terminals of the two switching devices, specified as a vector of two physical signals.

The first element of the vector controls the upper side switch. The second element of the vector controls the lower side switch. If, in the **Diode** settings, you set the **Integral protection diode** parameter to **Yes**, the first and second element of the vector also controls the lower and upper diode, respectively.

### Dependencies

To enable this port, set **Gate-control port** to **PS**.

### Conserving

#### + — Positive terminal

electrical

Electrical conserving port associated with the positive terminal.

#### - — Negative terminal

electrical

Electrical conserving port associated with the negative terminal.

#### 0 — Output node

electrical

Electrical conserving port associated with the output node.

#### G1 — Gate terminal 1

electrical

Electrical conserving port associated with the gate terminal for the first switching device.

### Dependencies

To enable this port, set **Gate-control port** to **Electrical**.

#### G2 — Gate terminal 2

electrical

Electrical conserving port associated with the gate terminal for the second switching device.

### Dependencies

To enable this port, set **Gate-control port** to **Electrical**.

#### H — Thermal port

thermal

Thermal conserving port.

## Parameters

### Main

The visibility of the **Main** parameters depends on the **Switching device** and **On-state behavior and losses** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

**Gate control port – Gate control port**

PS (default) | Electrical

Whether to use the physical signal input port, **G**, or the electrical conserving ports **G1** and **G2**, as the gate control ports.

**Switching device – Switching device option**

MOSFET (default) | IGBT | GTO

Switching device to use for the half-bridge.

**Threshold voltage, Vth – Threshold voltage**

2 V | 6 V | positive scalar

Threshold voltage at which the device turns on. The default value depends on the **Switching device** setting.

**Dependencies**

See the Main Parameter Dependencies table.

**Gate trigger voltage, Vgt – Gate trigger voltage**

6 V (default) | positive scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Main Parameter Dependencies table.

**Gate turn-off voltage, Vgt\_off — Gate turn-off voltage**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Main Parameter Dependencies table.

**Holding current — Current threshold**

1 A (default) | positive scalar

Current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state behaviour and losses — On-state current for loss data**

Specify constant values (default) | Tabulate with temperature and current

Parameterization method, specified as either:

- **Specify constant values** — Use scalar values to specify the output current, switch-on loss, and switch-off loss data.
- **Tabulate with temperature and current** — Use vectors to specify the output current, switch-on loss, switch-off loss, and temperature data.

**Dependencies**

See the Main Parameter Dependencies table.

**Drain-source on resistance, R\_DS(on) — Drain-source on resistance**

0.01 Ohm (default)

Drain-source resistance when the device is on.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state voltage, Vds(Tj,Ids) — On-state voltage**

[0, 1.1, 1.3, 1.45, 1.75, 2.25, 2.7; 0, 1, 1.15, 1.35, 1.7, 2.35, 3] V (default) | vector of positive scalars

Voltage drop across the device when the device is in a triggered conductive state. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Main Parameter Dependencies table.

**Drain-source current vector,  $I_{ds}$  — Drain-source current vector**

[ 0 10 50 100 200 400 600 ] A (default) | vector of positive scalars

Drain-source currents for which the on-state voltage is defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Forward voltage,  $V_f$  — Forward voltage**

0.8 V (default) | positive scalar

Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of the **On-state resistance** parameter.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state resistance — On-state collector-emitter resistance**

0.001 Ohm (default) | positive scalar

Collector-emitter resistance when the device is on.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state voltage,  $V_{ds}(T_j, I_{ce})$  — On-state voltage**

[0, .1, .6, .8, 1, 1.3, 1.6, 2, 2.4; 0, .1, .7, 1, 1.2, 1.5, 1.9, 2.4, 2.8] V (default) | vector of positive scalars

Voltage drop across the device when the device is in a triggered conductive state. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Main Parameter Dependencies table.

**Collector-emitter current vector,  $I_{ce}$  — Collector-emitter current vector**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default) | vector of positive scalars

Collector-emitter currents for the on-state voltage. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state voltage,  $V_{ak}(T_j, I_{ak})$  — On-state voltage**

[0, .1, .6, .8, 1, 1.3, 1.6, 2, 2.4; 0, .1, .7, 1, 1.2, 1.5, 1.9, 2.4, 2.8] V (default) | vector of positive scalars

Voltage drop across the device when the device is in a triggered conductive state. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Main Parameter Dependencies table.

**Anode-cathode current vector,  $I_{ak}$  — Anode-cathode current vector**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default) | vector of positive scalars

Anode-cathode currents for which the on-state voltage is defined. The first element must be zero.

**Dependencies**

See the Main Parameter Dependencies table.

**Temperature vector,  $T_j$  — Temperature vector**

[298.15, 398.15] K (default) | vector of positive scalars

Temperature values at which the on-state voltage is specified.

**Dependencies**

See the Main Parameter Dependencies table.

**Off-state conductance — Off-state collector-emitter conductance**

1e-6 1/Ohm (default) | positive scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of the **On-state resistance** parameter.

**Dependencies**

See the Main Parameter Dependencies table.

**Losses**

The visibility of the **Losses** parameters depends on the **Switching device** and **On-state behavior and losses** parameters in the **Main** tab. To learn how to read this table, see “Parameter Dependencies” on page A-2.

Off-state voltage for loss data					

**Switch-on loss — Switch-on loss**

0.02286 J (default) | positive scalar

Energy dissipated during a single switch-on event. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Switch-off loss — Switch-off loss**

0.01714 J (default) | positive scalar

Energy dissipated during a single switch-off event. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Diode reverse recovery loss — Loss from diode-reverse recovery**

5.70e-3 J (default) | positive scalar

Energy dissipated during a diode-reverse recovery event.

**Dependencies**

See the Losses Parameter Dependencies table.

**Off-state voltage for loss data — Off-state voltage**

300 V (default) | positive scalar

Output voltage when the device is off. The loss data define the blocking voltage at this value.

**Dependencies**

See the Losses Parameter Dependencies table.

**On-state current for loss data — Output current**

600 A (default) | positive scalar

Output current for which the switch-on loss, switch-off loss, and on-state voltage are defined.

**Dependencies**

See the Losses Parameter Dependencies table.

**Switch-on loss,  $E_{on}(T_j, I_{ds})$  — Switch-on loss**

Energy dissipated during a diode-reverse recovery event. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Collector-emitter current vector for losses,  $I_{ce}$  — Collector-emitter current for losses**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default) | vector of positive scalars

Collector-emitter currents for which the losses are defined. The first element must be zero.

**Dependencies**

See the Losses Parameter Dependencies table.

**Forced commutation switch-off loss — Forced commutation switch-off loss**

17.14e-3 J (default) | positive scalar

Energy dissipated during a forced commutation switch-off event. This parameter is a function of temperature and final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Natural commutation rectification loss — Natural commutation rectification loss**

10e-3 J (default) | positive scalar

Rectification loss applied when the block switches off because the current falls below the value of the **Holding current** parameter.

**Dependencies**

See the Losses Parameter Dependencies table.

**Switch-on loss,  $E_{on}(T_j, I_{ak})$  — Switch-on loss**

[0, .0024, .024, .12, .2, .48, 1.04, 2.16, 3.24; 0, .003, .03, .15, .25, .6, 1.3, 2.7, 4.05] \* 1e-3 J (default) | vector of positive scalars

Energy dissipated during a single switch-on event. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Switch-off loss,  $E_{off}(T_j, I_{ak})$  — Switch-off loss**

[0, .0007, .0066, .033, .066, .17, .33, .83, 1.5; 0, .001, .01, .05, .1, .25, .5, 1.2, 2.2] \* 1e-3 J (default) | vector of positive scalars

Energy dissipated during a single switch-off event. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Diode reverse recovery loss,  $E_{rec}(T_j, I_{ak})$  — Loss from diode-reverse recovery loss**

[0, .0031, .021, .11, .21, .43, .99, 1.71, 3.078; 0, .0041, .043, .2, .39, .77, 1.54, 2.27, 4.08] \* 1e-3 J (default) | vector of positive scalars

Energy dissipated during a diode-reverse recovery event. This parameter is a function of temperature and the final on-state output current.

**Dependencies**

See the Losses Parameter Dependencies table.

**Anode-cathode current vector for losses,  $I_{ak}$  — Anode-cathode current for losses**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default) | vector of positive scalars

Anode-cathode currents for which the losses are defined. The first element must be zero.

**Dependencies**

See the Losses Parameter Dependencies table.

**Temperature vector for losses, Tj — Temperature for losses**

[298.15, 398.15] K (default) | vector of positive scalars

Temperature values at which the losses are specified. Specify this parameter using a vector quantity.

**Dependencies**

See the Losses Parameter Dependencies table.

**Temperature vector for losses, Tj — Temperature for losses**

[298.15, 398.15] K (default) | vector of positive scalars

Temperature values at which the losses are specified. Specify this parameter using a vector quantity.

**Dependencies**

See the Losses Parameter Dependencies table.

**Off-state voltage for loss data — Off-state voltage for losses data**

300 V (default) | positive scalar

Output voltage when the device is off. The loss data define the blocking voltage at this value.

**Dependencies**

See the Losses Parameter Dependencies table.

**Integral Diode****Integral protection diode — Protection diode**

No (default) | Yes

Whether to model the block integral protection diode.

**Diode model — Diode model**

Piecewise Linear (default) | Tabulated I-V curve

Diode model, specified as either:

- **Piecewise Linear** — Use a piecewise linear model for the diode, as described in “Piecewise Linear Diode” on page 1-448.
- **Tabulated I-V curve** — Use tabulated forward bias I-V data and fixed reverse bias off conductance.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes.

**Forward voltage — Forward voltage**

0.8 V (default) | positive scalar

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of the **On resistance** parameter.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes and **Diode model** to Piecewise linear.

**On resistance — On resistance**

0.001 Ohm (default) | positive scalar

Rate of change of the voltage versus the current above the value of the **Forward voltage** parameter.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes and **Diode model** to Piecewise linear.

**Off conductance — Off conductance**

1e-5 1/Ohm (default)

Conductance of the reverse-biased diode.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes and **Diode model** to Piecewise linear.

**Table type — Tabulated function**

Table in  $I_f(T_j, V_f)$  form (default) | Table in  $V_f(T_j, I_f)$  form

Whether to tabulate the current as a function of temperature and voltage or the voltage as a function of temperature and current.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes and **Diode model** to Tabulated I-V curve.

**Forward currents,  $I_f(T_j, V_f)$  — Forward currents**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12]

A (default) | nonnegative vector

Forward currents. This parameter must be a vector of at least three nonnegative elements.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes, **Diode model** to Tabulated I-V curve, and **Table type** to Table in  $I_f(T_j, V_f)$  form.

**Junction temperatures,  $T_j$  — Junction temperatures**

[25, 125] degC (default) | vector of positive scalars

Vector of junction temperatures. This parameter must be a vector of at least two elements.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes, and **Diode model** to Tabulated I-V curve.

**Forward voltages, Vf — Forward voltages**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default) | nonnegative vector

Vector of forward voltages. This parameter must be a vector of at least three nonnegative values.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes, **Diode model** to Tabulated I-V curve, and **Table type** to Table in If(Tj,Vf) form.

**Forward voltages, Vf(Tj,If) — Forward voltages**

[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85; .58, .68, .75, 1.1, 1.38, 1.77, 2.27, 2.7] V (default) | nonnegative vector

Forward voltages. This parameter must be a vector of at least three nonnegative elements.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes, **Diode model** to Tabulated I-V curve, and **Table type** to Table in Vf(Tj,If) form.

**Forward currents, If — Forward currents**

[.1, .2, .5, 1, 2, 4, 7, 10] A (default) | nonnegative vector

Vector of forward currents. This parameter must be a vector of at least three nonnegative values.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Yes, **Diode model** to Tabulated I-V curve, and **Table type** to Table in Vf(Tj,If) form.

# Half-Bridge Driver

Behavioral model of half-bridge driver integrated circuit

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The Half-Bridge Driver block provides an abstracted representation of an integrated circuit for driving MOSFET and IGBT half-bridges. The block models input hysteresis, propagation delay, and turn-on/turn-off dynamics. Unless modeling a gate driver circuit explicitly, always use this block or the Gate Driver block to set gate-source voltage on a MOSFET block or gate-emitter voltage on an IGBT block. Do not connect a controlled voltage source directly to a semiconductor gate, because this omits the gate driver output impedance that determines switching dynamics.

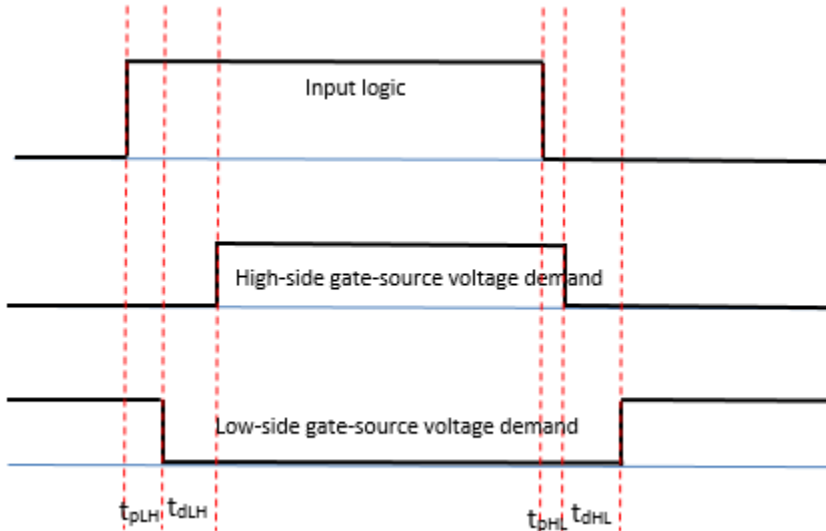

You can model electrical or physical signal input ports by setting the **Modeling option** parameter to either:

- **PS input** — The driver output state is controlled by a physical signal input  $u$ . Use this modeling option if all of your controller, including PWM waveform generation, is determined by Simulink blocks. This modeling option is the default.
- **Electrical input ports** — The driver output state is controlled by two electrical input connections, PWM and REF. Use this option if your model has upstream analog components, such as the Controlled PWM Voltage source.

The first pair of output electrical ports, HO and HS, behave in the same way as the G and S ports of the Gate Driver block. Connect these ports to the high-side MOSFET or IGBT of the half-bridge. The second pair of ports, LO and LS, connect to the low-side MOSFET or IGBT of the half-bridge. They behave in a similar way, except that their logic is inverted with respect to that of the high side.

The diagram shows the timing properties for the half-bridge driver, where:

- $t_{pLH}$  is low-side propagation delay when the input logic goes from 0 to 1.
- $t_{dLH}$  is high-side dead time when the input logic goes from 0 to 1.
- $t_{pHL}$  is high-side propagation delay when the input logic goes from 1 to 0.
- $t_{dHL}$  is low-side dead time when the input logic goes from 1 to 0.

## Faults

You can insert a fault into one or both of the outputs at a specified simulation time. The fault options are:

- Fail input fixed at logic 0
- Fail input fixed at logic 1
- Fail high side off
- Fail high side on
- Fail low side off
- Fail low side on
- Fail high and low sides off
- Fail high and low sides on

## Ports

### Input

**u** — Control signal, unitless

physical signal

Input physical signal that specifies the input control value.

### Dependencies

To enable this port, set **Modeling option** to PS input.

### Conserving

**PWM** — Pulse-width modulated signal

electrical

Electrical conserving port associated with the pulse-width modulated signal.

**Dependencies**

To enable this port, set **Modeling option** to `Electrical input ports`.

**REF — Floating zero volt reference**

`electrical`

Electrical conserving port associated with the floating zero volt reference.

**Dependencies**

To enable this port, set **Modeling option** to `Electrical input ports`.

**H0 — High-side gate connection**

`electrical`

Electrical conserving port associated with the gate on the high side of the half bridge. Connect this port to the gate of a MOSFET or IGBT block.

**HS — High-side source or emitter connection**

`electrical`

Electrical conserving port associated with the source or emitter on the high side of the half bridge. Connect this port to the source of a MOSFET block or the emitter of an IGBT block.

**L0 — Low-side gate connection**

`electrical`

Electrical conserving port associated with the gate on the low side of the half bridge. Connect this port to the gate of a MOSFET or IGBT block.

**LS — Low-side source or emitter connection**

`electrical`

Electrical conserving port associated with the source or emitter on the low side of the half bridge. Connect this port to the source of a MOSFET block or the emitter of an IGBT block.

**Parameters****Modeling option — Whether to model electrical or physical signal input ports**

`PS input (default) | Electrical input ports`

Whether to model physical signal or electrical input ports.

**Input Logic****Logic 1 input value — Signal value for logic 1**

`0.7 (default)`

Value of the input signal corresponding to the logic 1 level.

**Dependencies**

To enable this port, set **Modeling option** to `PS input`.

**Logic 0 input value — Signal value for logic 0**

0.3 (default)

Value of the input signal corresponding to the logic 0 level.

**Dependencies**To enable this port, set **Modeling option** to PS input.**Logic 1 input voltage — Voltage value for logic 1**

2.0 V (default)

Value of the input voltage corresponding to the logic 1 level.

**Dependencies**To enable this port, set **Modeling option** to Electrical input ports.**Logic 0 input voltage — Voltage value for logic 0**

0.8 V (default)

Value of the input voltage corresponding to the logic 0 level.

**Dependencies**To enable this port, set **Modeling option** to Electrical input ports.**Outputs****On-state gate-source voltage — Demanded output voltage for on state**

15 V (default)

Demanded output voltage when the driver is in on state.

**Off-state gate-source voltage — Demanded output voltage for off state**

0 V (default)

Demanded output voltage when the driver is in off state.

**Timing****Low-side propagation delay (logic 0->logic 1) —  $t_{pLH}$  in timing diagram**

50 ns (default)

Low-side propagation delay when the input logic goes from 0 to 1.

**High-side dead time (logic 0->logic 1) —  $t_{dLH}$  in timing diagram**

100 ns (default)

High-side dead time when the input logic goes from 0 to 1.

**High-side propagation delay (logic 1->logic 0) —  $t_{pHL}$  in timing diagram**

50 ns (default)

High-side propagation delay when the input logic goes from 1 to 0.

**Low-side dead time (logic 1->logic 0) —  $t_{dHL}$  in timing diagram**

100 ns (default)

Low-side dead time when the input logic goes from 1 to 0.

## Dynamics

### Parameterization — Select driver parameterization

Output impedance (default) | Rise and fall times

Select the type of driver parameterization:

- Output impedance — Specify on-state and off-state gate drive resistances.
- Rise and fall times — Specify rise time, fall time, and load capacitance.

### On-state gate drive resistance — Demanded output voltage for on state

2  $\Omega$  (default)

Demanded output voltage when the driver is in on state.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Output impedance.

### Off-state gate drive resistance — Demanded output voltage for off state

2  $\Omega$  (default)

Demanded output voltage when the driver is in off state.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Output impedance.

### Rise time — Driver rise time

20 ns (default)

Driver rise time from 10% to 90%.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Rise and fall times.

### Fall time — Driver fall time

20 ns (default)

Driver fall time from 90% to 10%.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Rise and fall times.

### Load capacitance for rise and fall times — Driver load capacitance

10 nF (default)

Driver load capacitance.

#### Dependencies

Enabled when the **Parameterization** parameter is set to Rise and fall times.

## Faults

### Enable faults — Select Yes to enable faults modeling

No (default) | Yes

Select Yes to enable faults modeling. The associated parameters in the **Faults** section become visible to let you specify time to fail and the failure mode.

### Simulation time for fault event — Time before entering faulted state

1 s (default)

Set the simulation time at which you want the block to enter the faulted state.

### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

### Failure mode — State of driver after failure

Fail input fixed at logic 0 (default) | Fail input fixed at logic 1 | Fail high side off | Fail high side on | Fail low side off | Fail low side on | Fail high and low sides off | Fail high and low sides on

Select the driver state after the failure.

### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

# Heatsink

Dissipate heat from power semiconductors to ambient temperature

**Library:** Simscape / Electrical / Passive / Thermal

## Description

The Heatsink block models a heatsink that dissipates heat from power semiconductors. The heat from the case conducts through the fins and dissipates to the ambient temperature through convection. The environment and the working fluid are the same.

You can parameterize this block from a datasheet, from tabulated heat transfer properties, or from geometry that assumes an empirical convection correlation. If you set the **Convection** parameter to Forced - specify flow speed, the **v** input port specifies the flow speed.

### Parameterization: Datasheet

To parameterize the Heatsink block from a datasheet, set the **Parameterization** parameter to Datasheet and specify both the **Vector of temperature rises above ambient, T** and **Corresponding heat dissipated to ambient, Q\_TLU1(T)** parameters.

If you enable forced convection in the system by setting **Convection** to Forced - specify flow speed, specify both the **Vector of temperature rises above ambient, T** and **Corresponding heat dissipated to ambient, Q\_TLU2(T,v)** parameters.

### Parameterization: Tabulated Convection and Fin Efficiency

To parameterize the Heatsink block based on the convection coefficient as a function of the coolant flow speed and temperature difference with the ambient temperature and the fin efficiency as a function of the convective coefficient, set the **Parameterization** parameter to Tabulated convection and fin efficiency.

The block uses this equation to calculate the dissipated heat:

$$Q_{dissipated} = h(v_{fluid}, \Delta T) \cdot A_{total} \cdot \frac{Eff(h)}{100} \cdot (T_{heatsink} - T_{ambient}),$$

where:

- $h(v_{fluid}, \Delta T)$  is the convective heat transfer coefficient tabulated against the fluid flow speed (for forced convection) and the temperature rise above the ambient temperature.
- $A_{total}$  is the total heat exchange surface area.
- $Eff(h)$  is the fin efficiency, in percent values, tabulated against different convective heat transfer coefficients. The fin efficiency is the actual heat dissipated by the fin divided by the heat it would

dissipate if all its volume was at the case temperature. This value depends on fin geometry and fin thermal conductivity.

### Parameterization: Assume Rectangular Parallel Fins

If you set the **Parameterization** parameter to Assume rectangular parallel fins, the block uses this equation to calculate the dissipated heat:

$$Q_{dissipated} = h(v_{fluid}, \Delta T) \cdot A_{total} \cdot \frac{Eff(h)}{100} \cdot (T_{heatsink} - T_{ambient}),$$

where:

- $h(v_{fluid}, \Delta T) = h_{natural}(\Delta T) + h_{forced}(v_{fluid})$
- $$h_{natural}(\Delta T) = \frac{k_{fluid}}{H} \left( 0.825 + \frac{0.387 Ra_H^{1/6}}{\left( 1 + \left( \frac{0.492}{Pr} \right)^{9/16} \right)^{8/27}} \right)^2$$
- $$h_{forced}(v_{fluid}) = \frac{k_{fluid}}{b} \left( \frac{1}{\left( \frac{RePr}{2} \right)^3} + \frac{1}{\left( 0.664 \sqrt{RePr}^{0.33} \sqrt{1 + \frac{3.65}{\sqrt{Re}}} \right)^3} \right)^{-0.33}$$
- $Ra_H = \frac{g\beta}{\nu\alpha} H^3 abs(\Delta T)$  is the Rayleigh number.
- $Re = \frac{b^2}{\nu d} abs(v_{fluid})$  is the Reynolds number.
- $g = 9.81 \text{ m/s}^2$  is the acceleration of gravity.
- $\beta$  is the coefficient of volume thermal expansion of the fluid.
- $\nu$  is the fluid kinematic viscosity.
- $\alpha$  is the fluid thermal diffusivity.
- $k_{fluid}$  is the fluid thermal conductivity.
- $H$  is the fin height.
- $d$  is the fin depth.
- $t$  is the fin thickness.
- $b$  is the gap between fins.

If one side of size  $t \times d$  is welded in the base, this equation calculates the total heat exchange area:

$$A_{total} = (2H(d + t) + dt)N.$$

Then this equation computes the efficiency of a rectangular fin:

$$Eff(h) = 100 \frac{\tanh\left(\sqrt{\frac{2h}{kt}} H\right)}{\sqrt{\frac{2h}{kt}} H}$$

where  $k$  is the fin thermal conductivity.

## Ports

### Input

#### **v – Flow speed**

physical

Physical input port associated with the flow speed.

#### **Dependencies**

To enable this port, set **Convection** to Forced - specify flow speed.

### Conserving

#### **A – Ambient temperature**

thermal

Thermal conserving port associated with the ambient temperature.

#### **C – Case**

thermal

Thermal conserving port associated with the case.

## Parameters

### Steady State

#### **Parameterization – Parameterization type**

Assume rectangular parallel fins (default) | Datasheet | Tabulated convection and fin efficiency

Whether to parameterize the block as a function of rectangular parallel fins, datasheet, or tabulated convection and fin efficiency.

#### **Convection – Convection type**

Natural (default) | Forced - specify flow speed

Whether the block models natural convection or uses convection values provided by an input port.

#### **Fin height – Fin height**

38.1e-3 m (default) | positive scalar

Height of the fin.

#### **Dependencies**

To enable this parameter, set **Parameterization** to Assume rectangular parallel fins.

#### **Fin thickness – Fin thickness**

6.5e-4 m (default) | positive scalar

Thickness of the fin.

**Dependencies**

To enable this parameter, set **Parameterization** to Assume rectangular parallel fins.

**Fin depth — Fin depth**

139.7e-3 m (default) | positive scalar

Depth of the fin.

**Dependencies**

To enable this parameter, set **Parameterization** to Assume rectangular parallel fins.

**Gap between fins — Gap between fins**

9.4e-3 m (default) | positive scalar

Gap between fins.

**Dependencies**

To enable this parameter, set **Parameterization** to Assume rectangular parallel fins and **Convection** to Forced - specify flow speed.

**Number of fins — Number of fins**

11 (default) | positive scalar

Number of fins. The value of this parameter must be equal to or greater than 1.

**Dependencies**

To enable this parameter, set **Parameterization** to Assume rectangular parallel fins.

**Fin thermal conductivity — Fin thermal conductivity**

237 W/(m\*K) (default) | positive scalar

Thermal conductivity of the fins.

**Dependencies**

To enable this parameter, set **Parameterization** to Assume rectangular parallel fins.

**Vector of temperature rises above ambient, T — Vector of temperature rises above ambient temperature**

[10, 30, 50, 70, 90] K (default) | vector of positive scalars

Vector of temperature rises above the ambient temperature. The values in this parameter must be positive and strictly ascending.

**Dependencies**

To enable this parameter, set **Parameterization** to Datasheet or Tabulated convection and fin efficiency.

**Vector of fluid flow speed, v — Vector of fluid flow speed**

[0, 1, 2, 3] m/s (default) | vector of positive scalars

Vector of fluid flow speed. The values in this parameter must be positive and strictly ascending.

**Dependencies**

To enable this parameter, set **Parameterization** to Datasheet or Tabulated convection and fin efficiency, and **Convection** to Forced - specify flow speed.

**Corresponding heat dissipated to ambient,  $Q_{TLU1}(T)$  — Corresponding heat dissipated to ambient against temperature**

[6.1, 23.6, 44.5, 67.5, 92.3] W (default) | vector of positive scalars

Vector of heat values dissipated to the ambient temperature tabulated against the temperature rise above the ambient temperature. The values in this parameter correspond to the values in the **Vector of temperature rises above ambient, T** parameter. The values in this parameter must be positive and ascending.

**Dependencies**

To enable this parameter, set **Parameterization** to Datasheet and **Convection** to Natural.

**Corresponding heat dissipated to ambient,  $Q_{TLU2}(T, v)$  — Corresponding heat dissipated to ambient against temperature and flow speed**

[6.1, 18.8, 22.8, 25.7; 23.6, 61.1, 73, 81.5; 44.5, 106.4, 125.9, 140.1; 67.5, 153.5, 180.7, 200.3; 92.3, 202.1, 236.9, 262] W (default) | vector of positive scalars

Vector of heat values dissipated to the ambient temperature tabulated against the flow speed and temperature rise above the ambient temperature. The values in this parameter correspond to the values in the **Vector of temperature rises above ambient, T** parameter.

**Dependencies**

To enable this parameter, set **Parameterization** to Datasheet and **Convection** to Forced - specify flow speed.

**Corresponding convective heat transfer coefficient,  $h_{TLU1}(T)$  — Corresponding convective heat transfer coefficient against temperature**

[5.4, 7.02, 7.98, 8.68, 9.26] W/(m<sup>2</sup>\*K) (default) | vector of positive scalars

Convective heat transfer coefficient tabulated against the temperature rise above the ambient temperature.

**Dependencies**

To enable this parameter, set **Parameterization** to Tabulated convection and fin efficiency and **Convection** to Natural.

**Corresponding convective heat transfer coefficient,  $h_{TLU2}(T, v)$  — Corresponding convective heat transfer coefficient against temperature and flow speed**

[5.4, 17.86, 22.17, 25.41; 7.02, 19.49, 23.8, 27.03; 7.97, 20.44, 24.75, 27.99; 8.68, 21.15, 25.46, 28.69; 9.26, 21.73, 26.04, 29.27] (default) | W/(m<sup>2</sup>\*K) | vector of positive scalars

Convective heat transfer coefficient tabulated against fluid flow speed caused by forced convection, and temperature rise above the ambient temperature caused by natural convection.

**Dependencies**

To enable this parameter, set **Parameterization** to Tabulated convection and fin efficiency and **Convection** to Forced - specify flow speed.

**Vector of convective heat transfer coefficients, h – Vector of convective heat transfer coefficients**

[5, 10, 15, 20, 25, 30] W/(m<sup>2</sup>\*K) (default) | vector of positive scalars

Convective heat transfer coefficients. This parameter depends on the temperature difference caused by natural convection, and the fluid flow speed caused by forced convection. The values of this parameter must be positive and strictly ascending.

**Dependencies**

To enable this parameter, set **Parameterization** to Tabulated convection and fin efficiency.

**Corresponding fin efficiency (percent), eff\_TLU(h) – Fin efficiency that corresponds to heat transfer coefficients**

[96.97, 94.16, 91.53, 89.08, 86.78, 84.62] (default) | vector of positive scalars

Fin efficiency tabulated against different convective heat transfer coefficients. Fin efficiency is the actual heat dissipated by the fin divided by the heat it would dissipate if all its volume was at case temperature. This parameter depends on fin geometry and fin thermal conductivity.

**Dependencies**

To enable this parameter, set **Parameterization** to Tabulated convection and fin efficiency.

**Total heat exchange surface area – Total heat exchange surface area**

0.1171 m<sup>2</sup> (default) | positive scalar

Total area of the surface of the heat exchange.

**Dependencies**

To enable this parameter, set **Parameterization** to Tabulated convection and fin efficiency.

**Fluid Properties**

To enable these settings, set **Parameterization** to Assume rectangular parallel fins.

**Fluid kinematic viscosity – Fluid kinematic viscosity**

1.51e-5 m<sup>2</sup>/s (default) | positive scalar

Kinematic viscosity of the fluid.

**Fluid thermal diffusivity – Fluid thermal diffusivity**

2.07e-5 m<sup>2</sup>/s (default) | positive scalar

Thermal diffusivity of the fluid.

**Fluid thermal conductivity – Fluid thermal conductivity**

25e-3 W/(m\*K) (default) | positive scalar

Thermal conductivity of the fluid.

**Fluid coefficient of volume thermal expansion — Fluid coefficient of volume thermal expansion**

3.3e-3 1/K (default) | positive scalar

Fluid coefficient of the volume thermal expansion.

**Dynamics**

**Heatsink mass — Heatsink mass**

0.35 kg (default) | positive scalar

Mass of the heatsink.

**Heatsink specific heat — Heatsink specific heat**

437 J/(K\*kg) (default) | positive scalar

Specific heat of the heatsink.

Hybrid excitation synchronous machine with three-phase wye-wound stator

**Library:** Simscape / Electrical / Electromechanical / Permanent Magnet

## Description

The Hybrid Excitation PMSM block represents a hybrid excitation synchronous machine with a three-phase wye-wound stator. Permanent magnets and excitation windings provide the machine excitation. The figure shows the equivalent electrical circuit for the stator and rotor windings.

## Motor Construction

The diagram shows the motor construction with a single pole-pair on the rotor. For the axes convention, when rotor mechanical angle  $\theta_r$  is zero, the  $a$ -phase and permanent magnet fluxes are aligned. The block supports a second rotor axis definition for which rotor mechanical angle is defined as the angle between the  $a$ -phase magnetic axis and the rotor  $q$ -axis.

### Equations

Voltages across the stator windings are defined by

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} R_s & 0 & 0 \\ 0 & R_s & 0 \\ 0 & 0 & R_s \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} \frac{d\psi_a}{dt} \\ \frac{d\psi_b}{dt} \\ \frac{d\psi_c}{dt} \end{bmatrix},$$

where:

- $v_a$ ,  $v_b$ , and  $v_c$  are the individual phase voltages across the stator windings.
- $R_s$  is the equivalent resistance of each stator winding.
- $i_a$ ,  $i_b$ , and  $i_c$  are the currents flowing in the stator windings.
- $\frac{d\psi_a}{dt}$ ,  $\frac{d\psi_b}{dt}$ , and  $\frac{d\psi_c}{dt}$  are the rates of change of magnetic flux in each stator winding.

The voltage across the field winding is expressed as

$$v_f = R_f i_f + \frac{d\psi_f}{dt},$$

where:

- $v_f$  is the individual phase voltage across the field winding.
- $R_f$  is the equivalent resistance of the field winding.
- $i_f$  is the current flowing in the field winding.
- $\frac{d\psi_f}{dt}$  is the rate of change of magnetic flux in the field winding.

The permanent magnet, excitation winding, and the three star-wound stator windings contribute to the flux linking each winding. The total flux is defined by

$$\begin{bmatrix} \psi_a \\ \psi_b \\ \psi_c \end{bmatrix} = \begin{bmatrix} L_{aa} & L_{ab} & L_{ac} \\ L_{ba} & L_{bb} & L_{bc} \\ L_{ca} & L_{cb} & L_{cc} \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} \psi_{am} \\ \psi_{bm} \\ \psi_{cm} \end{bmatrix} + \begin{bmatrix} L_{amf} \\ L_{bmf} \\ L_{cmf} \end{bmatrix} i_f,$$

where:

- $\psi_a$ ,  $\psi_b$ , and  $\psi_c$  are the total fluxes linking each stator winding.
- $L_{aa}$ ,  $L_{bb}$ , and  $L_{cc}$  are the self-inductances of the stator windings.
- $L_{ab}$ ,  $L_{ac}$ ,  $L_{ba}$ ,  $L_{bc}$ ,  $L_{ca}$ , and  $L_{cb}$  are the mutual inductances of the stator windings.
- $\psi_{am}$ ,  $\psi_{bm}$ , and  $\psi_{cm}$  are the magnetization fluxes linking the stator windings.
- $L_{amf}$ ,  $L_{bmf}$ , and  $L_{cmf}$  are the mutual inductances of the field winding.

The inductances in the stator windings are functions of rotor electrical angle and are defined by

$$\theta_e = N\theta_r + \text{rotor offset}$$

$$L_{aa} = L_s + L_m \cos(2\theta_e),$$

$$L_{bb} = L_s + L_m \cos(2(\theta_e - 2\pi/3)),$$

$$L_{cc} = L_s + L_m \cos(2(\theta_e + 2\pi/3)),$$

$$L_{ab} = L_{ba} = -M_s - L_m \cos(2(\theta_e + \pi/6)),$$

$$L_{bc} = L_{cb} = -M_s - L_m \cos(2(\theta_e + \pi/6 - 2\pi/3)),$$

$$L_{ca} = L_{ac} = -M_s - L_m \cos(2(\theta_e + \pi/6 + 2\pi/3)),$$

where:

- $N$  is the number of rotor pole pairs.
- $\theta_r$  is the rotor mechanical angle.
- $\theta_e$  is the rotor electrical angle.
- *rotor offset* is  $\theta$  if you define the rotor electrical angle with respect to the d-axis, or  $-\pi/2$  if you define the rotor electrical angle with respect to the q-axis.
- $L_s$  is the stator self-inductance per phase. This value is the average self-inductance of each of the stator windings.
- $L_m$  is the stator inductance fluctuation. This value is fluctuation in self-inductance and mutual inductance with changing rotor angle.
- $M_s$  is the stator mutual inductance. This value is the average mutual inductance between the stator windings.

The magnetization flux linking winding,  $a-a'$  is a maximum when  $\theta_e = 0^\circ$  and zero when  $\theta_e = 90^\circ$ . Therefore:

$$\psi_m = \begin{bmatrix} \psi_{am} \\ \psi_{bm} \\ \psi_{cm} \end{bmatrix} = \begin{bmatrix} \psi_m \cos \theta_e \\ \psi_m \cos(\theta_e - 2\pi/3) \\ \psi_m \cos(\theta_e + 2\pi/3) \end{bmatrix},$$

$$L_{mf} = \begin{bmatrix} L_{amf} \\ L_{bmf} \\ L_{cmf} \end{bmatrix} = \begin{bmatrix} L_{mf} \cos \theta_e \\ L_{mf} \cos(\theta_e - 2\pi/3) \\ L_{mf} \cos(\theta_e + 2\pi/3) \end{bmatrix},$$

and

$$\Psi_f = L_f i_f + L_{mf}^T \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix},$$

where:

- $\psi_m$  is the linked motor flux.
- $L_{mf}$  is the mutual field armature inductance.
- $\psi_f$  is the flux linking the field winding.
- $L_f$  is the field winding inductance.
- $[L_{mf}]^T$  is the transform of the  $L_{mf}$  vector, that is,

$$[L_{mf}]^T = \begin{bmatrix} L_{amf} \\ L_{bmf} \\ L_{cmf} \end{bmatrix}^T = [L_{amf} \ L_{bmf} \ L_{cmf}].$$

### Simplified Equations

Applying the Park transformation to the block electrical defining equations produces an expression for torque that is independent of rotor angle.

The Park transformation is defined by

$$P = 2/3 \begin{bmatrix} \cos \theta_e & \cos(\theta_e - 2\pi/3) & \cos(\theta_e + 2\pi/3) \\ -\sin \theta_e & -\sin(\theta_e - 2\pi/3) & -\sin(\theta_e + 2\pi/3) \\ 0.5 & 0.5 & 0.5 \end{bmatrix}$$

Applying the Park transformation to the first two electrical defining equations produces equations that define the block behavior:

$$v_d = R_s i_d + L_d \frac{di_d}{dt} + L_{mf} \frac{di_f}{dt} - N \omega i_q L_q,$$

$$v_q = R_s i_q + L_q \frac{di_q}{dt} + N \omega (i_d L_d + \psi_m + i_f L_{mf}),$$

$$v_0 = R_s i_0 + L_0 \frac{di_0}{dt}$$

$$v_f = R_f i_f + L_f \frac{di_f}{dt} + \frac{3}{2} L_{mf} \frac{di_d}{dt},$$

$$T = \frac{3}{2} N (i_q (i_d L_d + \psi_m + i_f L_{mf}) - i_d i_q L_q),$$

and

$$J \frac{d\omega}{dt} = T = T_L - B_m \omega.$$

where:

- $v_d$ ,  $v_q$ , and  $v_0$  are the  $d$ -axis,  $q$ -axis, and zero-sequence voltages. These voltages are defined by

$$\begin{bmatrix} v_d \\ v_q \\ v_0 \end{bmatrix} = P \begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix}.$$

- $i_d$ ,  $i_q$ , and  $i_0$  are the  $d$ -axis,  $q$ -axis, and zero-sequence currents, defined by

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = P \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}.$$

- $L_d$  is the stator  $d$ -axis inductance.  $L_d = L_s + M_s + 3/2 L_m$ .
- $\omega$  is the mechanical rotational speed.
- $L_q$  is the stator  $q$ -axis inductance.  $L_q = L_s + M_s - 3/2 L_m$ .
- $L_0$  is the stator zero-sequence inductance.  $L_0 = L_s - 2M_s$ .
- $T$  is the rotor torque. For the Hybrid Excitation PMSM block, torque flows from the machine case (block conserving port **C**) to the machine rotor (block conserving port **R**).
- $J$  is the rotor inertia.
- $T_L$  is the load torque.
- $B_m$  is the rotor damping.

### Model Thermal Effects

You can expose thermal ports to model the effects of generated heat and motor temperature. To expose the thermal ports, set the **Modeling option** parameter to either:

- **No thermal port** — The block contains expanded electrical conserving ports associated with the stator windings, but does not contain thermal ports.
- **Show thermal port** — The block contains expanded electrical conserving ports associated with the stator windings and thermal conserving ports for each of the windings and for the rotor.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

**Parameters****Modeling option – Whether to enable thermal ports**

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of generated heat and motor temperature.

### Main

#### Electrical connection — Electrical connection

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

#### Modeling fidelity — Modeling fidelity

Constant  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and  $PM$  (default) | Tabulated  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and  $PM$

Select the modeling fidelity:

- Constant  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and  $PM$  —  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$ , and  $PM$  values are constant and defined by their respective parameters.
- Tabulated  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and  $PM$  —  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$ , and  $PM$  values are computed online from DQ and field currents look-up tables as follows:

$$L_d = f_1(i_d, i_q, i_f)$$

$$L_q = f_2(i_d, i_q, i_f)$$

$$L_{mf} = f_3(i_d, i_q, i_f)$$

$$\lambda_{PM} = f_4(i_d, i_q, i_f)$$

$$L_f = f_5(i_f)$$

#### Dependencies

This parameter is visible only when you set the **Stator parameterization** parameter to Specify  $L_d$ ,  $L_q$ , and  $L_0$ .

#### Number of pole pairs — Rotor pole pairs

6 (default) | integer

Number of permanent magnet pole pairs on the rotor.

#### Permanent magnet flux linkage — Flux linkage

0.09 Wb (default) | positive integer

Peak permanent magnet flux linkage for any of the stator windings.

#### Dependencies

This parameter is visible only when you set the **Modeling fidelity** parameter to Constant  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and  $PM$ .

#### Stator parameterization — Parameterization model

Specify  $L_d$ ,  $L_q$  and  $L_0$  (default) | Specify  $L_s$ ,  $L_m$ , and  $M_s$

Stator parameterization model.

**Dependencies**

The **Stator parameterization** setting affects the visibility of other parameters.

**Stator d-axis inductance, Ld – Inductance**

0.0031 H (default)

Direct-axis inductance of the machine stator.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L $\theta$  and the **Modeling fidelity** parameter to Constant Ld, Lq, Lmf, Lf and PM.

**Stator q-axis inductance, Lq – Inductance**

0.0045 H (default)

Quadrature-axis inductance of the machine stator.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L $\theta$  and the **Modeling fidelity** parameter to Constant Ld, Lq, Lmf, Lf and PM.

**Direct-axis current vector, iD – Direct-axis current vector**

[-200, 0, 200] A (default)

Direct-axis current vector, iD.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L $\theta$  and the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Quadrature-axis current vector, iQ – Quadrature-axis current vector**

[-200, 0, 200] A (default)

Quadrature-axis current vector, iQ.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L $\theta$  and the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Excitation current vector, iF – Excitation current vector**

[-20, 0, 20] A (default)

Excitation current vector, iF.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L $\theta$  and the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Ld matrix,  $Ld(id,iq,if)$  – Ld matrix**

0.0031 \* ones(3, 3, 3) H (default)

Ld matrix.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L0 and the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Lq matrix,  $Lq(id,iq,if)$  – Lq matrix**

0.0045 \* ones(3, 3, 3) H (default)

Lq matrix.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L0 and the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Mutual field armature inductance,  $Lmf(id,iq,if)$  – Mutual field armature inductance**

0.0067 \* ones(3, 3, 3) H (default)

Mutual field armature inductance.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L0 and the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Permanent magnet flux linkage,  $PM(id,iq,if)$  – Permanent magnet flux linkage**

0.1 \* ones(3, 3, 3) Wb (default)

Permanent magnet flux linkage.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L0, the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Lf vector,  $Lf(if)$  – Lf vector**

0.06 \* ones(1, 3) H (default)

Lf vector.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify Ld, Lq, and L0, the **Modeling fidelity** parameter to Tabulated Ld, Lq, Lmf, Lf and PM.

**Stator zero-sequence inductance,  $L0$  – Inductance**

0.0006 H (default)

Zero-axis inductance for the machine stator.

**Dependencies**

This parameter is visible only if **Stator parameterization** is set to Specify  $L_d$ ,  $L_q$  and  $L_0$  and **Zero sequence** is set to Include.

**Stator self-inductance per phase,  $L_s$  – Inductance**

0.0027 H (default)

Average self-inductance of the three stator windings.

**Dependencies**

This parameter is visible only if **Stator parameterization** is set to Specify  $L_s$ ,  $L_m$ , and  $M_s$ .

**Stator inductance fluctuation,  $L_m$  – Inductance**

-0.0005 H (default)

Fluctuation in self-inductance and mutual inductance with the rotor angle.

**Dependencies**

This parameter is visible only if **Stator parameterization** is set to Specify  $L_s$ ,  $L_m$ , and  $M_s$ .

**Stator mutual inductance,  $M_s$  – Inductance**

0.0011 H (default)

Average mutual inductance between the stator windings.

**Dependencies**

This parameter is visible only if **Stator parameterization** is set to Specify  $L_s$ ,  $L_m$ , and  $M_s$ .

**Field winding inductance,  $L_f$  – Inductance**

0.06 H (default)

Inductance of the field winding.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify  $L_d$ ,  $L_q$ , and  $L_0$  and the **Modeling fidelity** parameter to Constant  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and PM or **Stator parameterization** parameter to Specify  $L_s$ ,  $L_m$ , and  $M_s$

**Mutual field armature inductance,  $L_{mf}$  – Inductance**

0.0067 H (default)

Armature-field mutual inductance.

**Dependencies**

This parameter is visible only when you set the **Stator parameterization** parameter to Specify  $L_d$ ,  $L_q$ , and  $L_0$  and the **Modeling fidelity** parameter to Constant  $L_d$ ,  $L_q$ ,  $L_{mf}$ ,  $L_f$  and PM or **Stator parameterization** parameter to Specify  $L_s$ ,  $L_m$ , and  $M_s$

**Stator resistance per phase,  $R_s$  – Resistance**

0.7 Ohm (default)

Resistance of each of the stator windings.

**Field winding resistance,  $R_f$  — Resistance**

2.85 Ohm (default)

Resistance of the field winding.

**Zero sequence — Zero-sequence model**

Include (default) | Exclude

Zero-sequence model:

- **Include** — Prioritize model fidelity. An error occurs if you Include zero-sequence terms for simulations that use the Partitioning solver. For more information, see “Increase Simulation Speed Using the Partitioning Solver”.
- **Exclude** — Prioritize simulation speed for desktop simulation or real-time deployment.

**Dependencies**

If this parameter is set to:

- **Include** and **Stator parameterization** is set to **Specify  $L_d$ ,  $L_q$ , and  $L_0$**  — The **Stator zero-sequence inductance,  $L_0$**  parameter is visible.
- **Exclude** — The **Stator zero-sequence inductance,  $L_0$**  parameter is not visible.

**Rotor angle definition — Angle**

Angle between the a-phase magnetic axis and the d-axis (default) | Angle between the a-phase magnetic axis and the q-axis

Reference point for the rotor angle measurement. If you select the default value, the rotor and  $a$ -phase fluxes are aligned for a zero-rotor angle. Otherwise, an  $a$ -phase current generates the maximum torque value for a zero-rotor angle.

**Mechanical****Rotor inertia — Inertia**0.01 kg\*m<sup>2</sup> (default)Inertia of the rotor attached to mechanical translational port **R**.**Rotor Damping — Damping**

0 N\*m/(rad/s) (default)

Rotary damping.

**Thermal**To enable these parameters, set **Modeling option** to Show thermal port.**Measurement temperature — Measurement temperature**

298.15 K (default)

The temperature for which motor parameters are quoted.

**Resistance temperature coefficient — Resistance temperature coefficient**

3.93e-3 1/K (default)

Coefficient  $\alpha$  in the equation relating resistance to temperature, as described in “Thermal Model for Actuator Blocks”. The default value is for copper.

**Permanent magnet flux temperature coefficient – Permanent magnet flux temperature coefficient**

-0.001 (default)

The fractional rate of change of permanent magnet flux density with temperature. It is used to linearly reduce the torque and the induced back EMF as temperature rises.

**Thermal mass for each stator winding – Thermal mass for each stator winding**

100 J/K (default)

The thermal mass value for the A, B, and C windings. The thermal mass is the energy required to raise the temperature by one degree.

**Rotor thermal mass – Rotor thermal mass**

200 J/K (default)

The thermal mass of the rotor, that is, the energy required to raise the temperature of the rotor by one degree.

## Hysteresis Current Controller (Three-Phase)

Three-phase hysteresis current control

**Library:** Simscape / Electrical / Control / General Machine Control

### Description

The Hysteresis Current Controller (Three-Phase) block implements three-phase hysteresis current control for power converters.

### Ports

#### Input

##### **$i_{abc}^*$ – Current**

vector

Three-phase reference currents.

Data Types: single | double

##### **$i_{abc}$ – Current**

vector

Measured three-phase currents.

Data Types: single | double

#### Output

##### **S – Controller output**

vector

Six-pulse vector for power converter control.

Data Types: single | double

## Parameters

### Current hysteresis band (A) — Hysteresis band

1 (default) | positive number

Hysteresis band,  $h$ , for the current controller. The switch-on point is  $h/2$  and the switch-off point is  $-h/2$ .

### Sample time (-1 for inherited) — Block sample time

-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

# Ideal Semiconductor Switch

Ideal Semiconductor Switch

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The Ideal Semiconductor Switch block models an ideal semiconductor switching device.

The figure shows a typical i-v characteristic for an ideal semiconductor switch.

If the gate-cathode voltage exceeds the specified threshold voltage, the ideal semiconductor switch is in the on state. Otherwise the device is in the off state.

In the on state, the anode-cathode path behaves like a linear resistor with on-resistance  $R_{on}$ .

In the off state, the anode-cathode path behaves like a linear resistor with a low off-state conductance  $G_{off}$ .

Using the **Integral Diode** parameters, you can include an integral cathode-anode diode. An integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

The table shows you how to set the **Integral protection diode** parameter based on your goals.

Goal	Value to Select	Block Behavior
Prioritize simulation speed.	Protection diode with no dynamics	The block includes an integral copy of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.

Goal	Value to Select	Block Behavior
Precisely specify reverse-mode charge dynamics.	Protection diode with charge dynamics	The block includes an integral copy of the dynamic model of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.

## Ports

This figure shows the block port names.

## Input

### G – Gate terminal

physical signal

Physical signal port associated with the gate terminal.

### Dependencies

To enable this port, set **Gate-control port** to PS control port.

### Conserving

### G – Gate terminal

electrical

Electrical conserving port associated with the gate terminal.

### Dependencies

To enable this port, set **Gate-control port** to Electrical control port.

### A – Anode terminal

electrical

Electrical conserving port associated with the anode terminal.

**K – Cathode terminal**

electrical

Electrical conserving port associated with the cathode terminal.

**Parameters****Main****Gate-control port – Whether to specify physical or electrical control port**

PS (default) | Electrical

Whether to specify physical or electrical control port for the switch gate.

**On-state resistance – On-state resistance**

0.001 Ohm (default)

Anode-cathode resistance when the device is on.

**Off-state conductance – Off-state conductance**

1e-6 1/Ohm (default)

Anode-cathode conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

**Threshold voltage,  $V_{th}$  – Threshold voltage**

0.5 V (default)

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Integral Diode****Integral protection diode – Integral protection diode**

None (default) | Protection diode with no dynamics | Protection diode with charge dynamics

Specify whether the block includes an integral protection diode. The default value is None.

If you want to include an integral protection diode, there are two options:

- Protection diode with no dynamics
- Protection diode with charge dynamics

**Forward voltage – Forward voltage**

0.8 V (default)

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.

**On resistance — On resistance**

0.001 Ohm (default)

Rate of change of voltage versus current above the **Forward voltage**.

**Dependencies**

To enable this parameter, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.

**Off conductance — Off conductance**

1e-5 1/Ohm (default)

Conductance of the reverse-biased diode.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

**Junction capacitance — Junction capacitance**

50e-9 F (default)

Diode junction capacitance.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Initial forward current when measuring iRM — Initial forward current when measuring iRM**

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Rate of change of current when measuring iRM — Rate of change of current when measuring iRM**

-50A/μs (default) | negative scalar

Rate of change of current when measuring peak reverse current. This value must be less than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Reverse recovery time parameterization — Reverse recovery time parameterization**

Specify reverse recovery time directly (default) | Specify stretch factor | Specify reverse recovery charge

Determines how you specify reverse recovery time in the block. The default value is Specify reverse recovery time directly.

If you select **Specify stretch factor** or **Specify reverse recovery charge**, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates TM and Tau” on page 1-452.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics**.

#### Reverse recovery time, $t_{rr}$ – Reverse recovery time

15  $\mu$ s (default)

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics** and the **Reverse recovery time parameterization** parameter is set to **Specify reverse recovery time directly**.

#### Reverse recovery time stretch factor – Reverse recovery time stretch factor

3 (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics** and the **Reverse recovery time parameterization** parameter is set to **Specify stretch factor**.

#### Reverse recovery charge, $Q_{rr}$ – Reverse recovery charge

1500  $\mu$ As (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current,  $i_{RM}$** .
- $a$  is the value specified for **Rate of change of current when measuring  $i_{RM}$** .

### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to **Protection diode with charge dynamics** and the **Reverse recovery time parameterization** parameter is set to **Specify reverse recovery charge**.

For more information on these parameters, see Diode.

## IGBT (Ideal, Switching)

Ideal insulated-gate bipolar transistor for switching applications

**Library:** Simscape / Electrical / Semiconductors & Converters

### Description

The IGBT (Ideal, Switching) block models an ideal insulated-gate bipolar transistor (IGBT) for switching applications. The switching characteristic of an IGBT is such that if the gate-emitter voltage exceeds the specified threshold voltage,  $V_{th}$ , the IGBT is in the on state. Otherwise, the device is in the off state. This figure shows a typical i-v characteristic:

To define the I-V characteristic of the IGBT, set the **On-state behaviour and switching losses** parameter to either **Specify constant values** or **Tabulate with temperature and current**. The **Tabulate with temperature and current** option is available only if you expose the thermal port of the block.

In the on state, the collector-emitter path behaves like a linear diode with forward-voltage drop,  $V_f$ , and on-resistance,  $R_{on}$ . However, if you expose the thermal port of the block and parameterize the device using tabulated I-V data, the tabulated resistance is a function of the temperature and current.

In the off state, the collector-emitter path behaves like a linear resistor with a low off-state conductance value,  $G_{off}$ .

The defining Simscape equations for the block are:

```

if (v>Vf)&&(G>Vth)
    i == (v - Vf*(1-Ron*Goff))/Ron;
else
    i == v*Goff;
end

```

where:

- $v$  is the collector-emitter voltage.
- $V_f$  is the forward voltage.
- $G$  is the gate-emitter voltage.
- $V_{th}$  is the threshold voltage.
- $i$  is the collector-emitter current.
- $R_{on}$  is the on-state resistance.
- $G_{off}$  is the off-state conductance.

### Integral Protection Diode Option

Using the **Integral Diode** parameters, you can include an integral emitter-collector diode. An integral diode protects the semiconductor device by providing a conduction path for reverse current. An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load.

Set the **Integral protection diode** parameter based on your goal.

Goal	Value to Select	Block Behavior
Prioritize simulation speed.	Protection diode with no dynamics	The block includes an integral copy of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.
Precisely specify reverse-mode charge dynamics.	Protection diode with charge dynamics	The block includes an integral copy of the dynamic model of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.

### Model Gate Port and Thermal Effects

You can choose between physical or electrical ports to control the gate terminal and expose the thermal port to model the heat that switching events and conduction losses generate. To choose the gate control port, set the **Gate control port** parameter to PS or Electrical. To expose the thermal port, set the **Modeling option** parameter to either No thermal port or Show thermal port.

For more information about using thermal ports, see “Simulating Thermal Effects in Semiconductors”.

### Thermal Losses

The figure shows an idealized representation of the output voltage,  $V_{out}$ , and the output current,  $I_{out}$ , of the semiconductor device. The interval shown includes the entire  $n^{\text{th}}$  switching cycle, during which the block turns off and then on.

Switching losses are one of the main sources of thermal loss in semiconductors. During each on-off switching transition, the IGBT parasitics store and then dissipate energy.

Switching losses depend on the off-state voltage and the on-state current. When a switching device is turned on, the power losses depend on the initial off-state voltage across the device and the final on-state current once the device is fully in its on state. Similarly, when a switching device is turned off, the power losses depend on the initial on-state current through the device and the final off-state voltage once the device is fully in its off state.

In this block, switching losses are applied by stepping up the junction temperature with a value equal to the switching loss divided by the total thermal mass at the junction. The **Switch-on loss,  $E_{on}(T_j, I_{ce})$**  and **Switch-off loss,  $E_{off}(T_j, I_{ce})$**  parameter values set the sizes of the switching losses and they are either fixed or dependent on junction temperature and drain-source current. In both cases, losses are scaled by the off-state voltage prior to the latest device turn-on event.

---

**Note** As the final current after a switching event is not known during the simulation, the block records the on-state current at the point that the device is commanded off. Similarly, the block records the off-state voltage at the point that the device is commanded on. For this reason, the simlog does not report the switching losses to the thermal network until one switching cycle later.

For all ideal switching devices, the switching losses are reported in the simlog as `lastTurnOffLoss` and `lastTurnOnLoss` and recorded as a pulse with amplitude equal to the energy loss. If you use a script to sum the total losses over a defined simulation period, you must sum the pulse values at each pulse rising edge. Alternatively, you can use the `ee_getPowerLossSummary` and `ee_getPowerLossTimeSeries` functions to extract conduction and switching losses from logged data.

Note that the `power_dissipated` variable in the simlog does not include switching losses as they are modeled as instantaneous events. The `power_dissipated` variable therefore just reports instantaneous on-state losses.

---

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Ports

The figure shows the block port names.

## Conserving

### G – Gate terminal

electrical

Port associated with the gate terminal. You can set the port to either a physical signal or electrical port

### C – Collector terminal

electrical

Electrical conserving port associated with the collector terminal

### E – Emitter terminal

electrical

Electrical conserving port associated with the emitter terminal

### H – Thermal port

thermal

Thermal conserving port.

## Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### Modeling option — Thermal port visibility

No thermal port (default) | Show thermal port

Whether to enable the thermal port.

### Main

This table shows how the visibility of **Main** parameters depends on how you configure the **Modeling option** and **On-state behavior and switching losses** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

### Main Parameter Dependencies

Parameters and Options		
<b>Modeling option</b>		
<i>No thermal port</i>	<i>Show thermal port</i>	
Gate-control port	Gate-control port	
Forward voltage, Vf	Threshold voltage, Vth	
On-state resistance	<b>On-state behaviour and switching losses</b>	
	<i>Specify constant values</i>	<i>Tabulate with temperature and current</i>
Off-state conductance	Forward voltage, Vf	On-state voltage, Vds(Tj,Ice)
Threshold voltage, Vth	On-state resistance	Temperature vector, Tj
	Off-state conductance	Collector-emitter current vector, Ice
		Off-state conductance

### Gate-control port — Whether to specify physical or electrical control port

PS (default) | Electrical

Whether to specify physical or electrical control port for the switch gate.

### On-state behaviour and switching losses — On-state current for switching loss data

*Specify constant values* (default) | *Tabulate with temperature and current*

Select a parameterization method. The option that you select determines which other parameters are enabled. Options are:

- *Specify constant values* — Use scalar values to specify the output current, switch-on loss, and switch-off loss data. This is the default parameterization method.
- *Tabulate with temperature and current* — Use vectors to specify the output current, switch-on loss, switch-off loss, and temperature data.

### Dependencies

See the Main Parameter Dependencies table.

**Forward voltage, Vf — Forward voltage**

0.8 V (default)

Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state resistance — On-state collector-emitter resistance**

0.001 Ohm (default)

Collector-emitter resistance when the device is on.

**Dependencies**

See the Main Parameter Dependencies table.

**Off-state conductance — Off-state collector-emitter conductance**

1e-5 1/Ohm (default)

Collector-emitter conductance when the device is off. The value must be less than  $1/R$ , where R is the value of **On-state resistance**.

**Dependencies**

See the Main Parameter Dependencies table.

**Threshold voltage, Vth — Threshold voltage**

6 V (default)

Gate-emitter voltage at which the device turns on.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state voltage, Vds(Tj,Ice) — On-state voltage**

[0, .1, .6, .8, 1, 1.3, 1.6, 2, 2.4; 0, .1, .7, 1, 1.2, 1.5, 1.9, 2.4, 2.8] V (default)

Voltage drop across the device while it is in a triggered conductive state. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Temperature vector, Tj — Temperature vector**

[298.15, 398.15] K (default)

Temperature values at which the on-state voltage is specified. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Collector-emitter current vector, Ice — Collector-emitter current vector**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default)

Collector-emitter currents for the on-state voltage is defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Switching Losses**

To enable these parameters, set **Modeling option** to Show thermal port.

**Temperature vector for switching losses, Tj — Temperature vector for switching losses**

[298.15, 398.15] K (default)

Temperature values at which the switch-on loss and switch-off loss are specified. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Collector-emitter current vector for switching losses, Ice — Collector-emitter current vector for switching losses**

[0, .1, 1, 5, 10, 20, 40, 70, 100] A (default)

Collector-emitter currents for which the switch-on loss and switch-off-loss are defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Switch-on loss — Switch-on loss**

22.86e-3 J (default)

Energy dissipated during a single switch-on event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Switch-off loss — Switch-off loss**

17.14e-3 J (default)

Energy dissipated during a single switch-off event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Off-state voltage for switching loss data — Off-state voltage for losses data**

600 V (default) | 300 V

The output voltage of the device during the off state. This is the blocking voltage at which the switch-on loss and switch-off loss data are defined.

**On-state current for switching loss data — Output current**

600 A (default)

Output currents for which the switch-on loss, switch-off loss, and on-state voltage are defined. The first element must be zero. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Switch-on loss,  $E_{on}(T_j, I_{ce})$  — Switch-on loss**

[0, .0024, .024, .12, .2, .48, 1.04, 2.16, 3.24; 0, .003, .03, .15, .25, .6, 1.3, 2.7, 4.05] \* 1e-3 J (default)

Energy dissipated during a single switch on event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Switch-off loss,  $E_{off}(T_j, I_{ce})$  — Switch-off loss**

[0, .0007, .0066, .033, .066, .17, .33, .83, 1.5; 0, .001, .01, .05, .1, .25, .5, 1.2, 2.2] \* 1e-3 J (default)

Energy dissipated during a single switch-off event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Integral Diode****Integral protection diode — Integral protection diode**

None (default) | Protection diode with no dynamics | Protection diode with charge dynamics

Block integral protection diode.

The diodes you can select are:

- None
- Protection diode with no dynamics
- Protection diode with charge dynamics

**Diode model — Diode model**

Piecewise Linear (default) | Tabulated I-V curve

Select one of these diode models:

- **Piecewise Linear** — Use a piecewise linear model for the diode, as described in “Piecewise Linear Diode” on page 1-448. This is the default method.
- **Tabulated I-V curve** — Use tabulated forward bias I-V data plus fixed reverse bias off conductance.

**Dependencies**

This parameter is visible only when the thermal port is exposed and the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

**Table type — Tabulated function**Table in  $I_f(T_j, V_f)$  form (default) | Table in  $V_f(T_j, I_f)$  form

Whether to tabulate the current as a function of temperature and voltage or the voltage as a function of temperature and current.

**Dependencies**

This parameter is visible only when the thermal port is exposed and the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** is set to Tabulated I-V curve.

**Forward voltage — Forward voltage**

0.8 V (default)

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

**Dependencies**

To enable this parameter:

- If the thermal port is hidden, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.
- If the thermal port is exposed, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** to Piecewise linear.

**On resistance — On resistance**

0.001 Ohm (default)

Rate of change of voltage versus current above the **Forward voltage**.

**Dependencies**

To enable this parameter:

- If the thermal port is hidden, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.
- If the thermal port is exposed, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** to Piecewise linear.

#### **Forward currents, $I_f(T_j, V_f)$ – Vector of forward currents**

A (default) | nonnegative vector

Forward currents. This parameter must be a vector of at least three nonnegative elements.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $I_f(T_j, V_f)$  form.

#### **Junction temperatures, $T_j$ – Vector of junction temperatures**

[25, 125] degC (default)

Vector of junction temperatures. This parameter must be a vector of at least two elements.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve.

#### **Forward voltages, $V_f$ – Vector of forward voltages**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Vector of forward voltages. This parameter must be a vector of at least three nonnegative values.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $I_f(T_j, V_f)$  form.

Forward voltages. This parameter must be a vector of at least three nonnegative elements.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $V_f(T_j, I_f)$  form.

#### **Forward currents, $I_f$ – Vector of forward currents**

[.1, .2, .5, 1, 2, 4, 7, 10] A (default)

Vector of forward currents. This parameter must be a vector of at least three nonnegative values.

#### **Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $V_f(T_j, I_f)$  form.

**Off conductance — Off conductance**

1e-5 1/Ohm (default)

Conductance of the reverse-biased diode.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

**Junction capacitance — Junction capacitance**

50e-9 F (default)

Diode junction capacitance.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Peak reverse current,  $i_{RM}$  — Peak reverse current**

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero. The default value is -235 A.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Initial forward current when measuring  $i_{RM}$  — Initial forward current when measuring  $i_{RM}$** 

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Rate of change of current when measuring  $i_{RM}$  — Rate of change of current when measuring  $i_{RM}$** 

-50A/ $\mu$ s (default) | negative scalar

Rate of change of current when measuring peak reverse current. This value must be less than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Reverse recovery time parameterization — Reverse recovery time parameterization**

Specify reverse recovery time directly (default) | Specify stretch factor | Specify reverse recovery charge

Determines how you specify reverse recovery time in the block. The default value is Specify reverse recovery time directly.

If you select Specify stretch factor or Specify reverse recovery charge, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates TM and Tau” on page 1-452.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

#### Reverse recovery time, trr – Reverse recovery time

15  $\mu$ s (default)

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, iRM** parameter divided by the value of the **Rate of change of current when measuring iRM** parameter.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery time directly.

#### Reverse recovery time stretch factor – Reverse recovery time stretch factor

3 (default)

Value that the block uses to calculate **Reverse recovery time, trr**. This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify stretch factor.

#### Reverse recovery charge, Qrr – Reverse recovery charge

1500  $\mu$ As (default)

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery charge.

**Diode turn-off voltage when measuring Erec — Diode turn-off voltage when measuring Erec**

-600 V (default)

Voltage between the diode in steady-state.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Stray inductance when measuring Erec — Stray inductance when measuring Erec**

150 nH (default)

Total unintended inductance in the measurement circuit. The block uses this value to calculate **Reverse recovery energy, Erec**.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Reverse recovery energy, Erec — Reverse recovery energy**

0.03 J (default)

Total switching losses due to the diode reverse recovery.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Thermal Port**

Use the thermal port to simulate the effects of generated heat and device temperature. For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

## Version History

**Introduced in R2013b****Update on switching losses and thermal modelling options**

*Behavior changed in R2020b*

From R2020b forward, the IGBT (Ideal, Switching) block has improved losses and thermal modelling options.

As a result from these changes:

- Electrical and thermal on-state losses are now always identical. The **Thermal loss dependent on** parameter and its options, **Voltage and current** and **Voltage, current, and temperature**, have been renamed to **On-state behavior and switching losses**, **Specify constant values**, and **Tabulate with temperature and current**:
  - If you selected **Voltage and current** for **Thermal loss dependent on**, then the electrical on-state losses are unchanged and their values are determined using the on-state resistance. However, the thermal on-state losses are now also determined by the on-state resistance. Prior to R2020b, the thermal on-state losses were defined by the product of the **On-state voltage** and **Output current, Iout** parameters.
  - If you selected **Voltage, current, and temperature** for **Thermal loss dependent on**, then the thermal on-state losses are unchanged and the **On-state voltage, Vds(Tj,Ice)** parameter sets their values. However, the electrical on-state losses are now equal to the thermal on-state losses. Prior to R2020b, the electrical on-state losses were defined by the value of the on-state resistance.
- The **On-state voltage** parameter is no longer used.

### Removal of energy dissipation time constant parameter

*Behavior changed in R2021a*

From R2021a forward, the **Energy dissipation time constant** parameter of the IGBT (Ideal, Switching) block is no longer used. A step in junction temperature now reflects the switching losses. If your model contains a thermal mass directly connected to this block thermal port, remove it and model the thermal mass inside the component itself.

# Incandescent Lamp

Incandescent lamp with temperature dependent resistance

**Library:** Simscape / Electrical / Passive

## Description

The Incandescent Lamp block models an incandescent lamp, the key characteristic of which is that the resistance increases as the filament warms up.

Under the simplifying assumption that the rate of heat loss from the filament is proportional to temperature difference to ambient, the temperature of the filament is governed by

$$kt_c \frac{dT}{dt} = i^2 R - kT$$

and the filament resistance is governed by the following equation

$$R = R_0(1 + \alpha T)$$

where:

- $R_0$  is the initial resistance at turn-on (when filament is at ambient temperature).
- $T$  is the filament temperature relative to ambient temperature.
- $\alpha$  is the resistance temperature coefficient.
- $t_c$  is the thermal time constant.
- $k$  is the heat transfer coefficient.
- $R$  is the filament resistance.
- $i$  is the filament current.

There are two parameterization options:

- If you select **Specify resistance values directly**, the block uses values that you provide for filament resistance when on and at turn-on to determine the value for the heat transfer coefficient.
- If you select **Specify currents**, the block uses values that you provide for filament current when on and at turn-on to determine the value for the heat transfer coefficient.

Optionally you can specify a simulation time at which the lamp fails by providing a finite value for the **Simulation time for open circuit fault event** parameter on the **Faults** tab. When in the open-circuit state, the lamp resistance is set to be the value of the **Open-circuit resistance** parameter.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the lamp positive voltage.

#### - – Negative terminal

electrical

Electrical conserving port associated with the lamp negative voltage.

## Parameters

### Resistance

#### Parameterization – Block parameterization

Specify resistance values directly (default) | Specify currents

Select one of the following methods for block parameterization:

- Specify resistance values directly — Provide the values for filament resistance at turn-on and when on in steady state. The block determines the value for the heat transfer coefficient based on these values. This is the default option.
- Specify currents — Provide the values for filament current at turn-on and when on in steady state. The block determines the value for the heat transfer coefficient based on these values.

#### Initial resistance at turn-on – Initial resistance at turn-on

0.15 Ohm (default)

The resistance seen by the external circuit when the lamp is initially turned on.

#### Dependencies

This parameter is visible only when you select Specify resistance values directly for the **Parameterization** parameter.

#### Steady-state resistance when on – Steady-state resistance when on

1 Ohm (default)

The resistance seen by the external circuit when the lamp is on and in steady state. This resistance should be greater than the **Initial resistance at turn-on**.

#### Dependencies

This parameter is visible only when you select Specify resistance values directly for the **Parameterization** parameter.

#### Inrush current at turn-on – Inrush current at turn-on

70 A (default)

The current through the lamp when it is initially turned on.

**Dependencies**

This parameter is visible only when you select **Specify currents** for the **Parameterization** parameter.

**Steady-state current when on — Steady-state current when on**

10 A (default)

The current through the lamp when it is on and in steady state. This current should be less than the **Inrush current at turn-on**.

**Dependencies**

This parameter is visible only when you select **Specify currents** for the **Parameterization** parameter.

**Rated voltage — Lamp rated voltage**

12 V (default)

The rated voltage for the lamp, and the voltage value for which the resistance or current values are provided in the on and turn-on states.

**Resistance temperature coefficient — Resistance temperature coefficient**

0.004 1/K (default)

The fractional increase in resistance per unit increase in temperature.

**Dynamics****Thermal time constant — Thermal time constant**

25 ms (default)

The first-order thermal time constant for filament temperature when the lamp is turned on or off.

**Initial lamp state — Initial lamp state**

Off (default) | On

Select between On and Off.

**Faults****Enable open circuit fault — Open circuit fault option**

Off (default) | On

Whether to enable open circuit fault.

**Simulation time for open circuit fault event — Simulation time for open circuit fault event**

inf s (default)

For simulation times greater than this parameter value the filament resistance becomes equal to the **Open-circuit resistance**. Specifying a finite value for this parameter lets you simulate the fault dynamics when the bulb burns out.

**Dependencies**

To enable this parameter, set **Enable open circuit fault** to On.

**Open-circuit resistance — Open-circuit resistance**

1e6 Ohm (default)

The value of the filament resistance used when the lamp goes open-circuit.

**Dependencies**

To enable this parameter, set **Enable open circuit fault** to On.

# Incremental Shaft Encoder

Behavioral model that converts angular position to electrical pulses

**Library:** Simscape / Electrical / Sensors & Transducers

## Description

The Incremental Shaft Encoder block represents a device that converts information about the angular position of a shaft into electrical pulses. The block produces  $N$  pulses on ports **A** and **B** per shaft revolution, where  $N$  is the value you specify for the **Pulses per revolution** parameter. Pulses **A** and **B** are 90 degrees out of phase. If the shaft rotates in a positive direction, then **A** leads **B**. The block produces a single index pulse on port **Z** once per revolution. The **Z**-pulse positive transition always coincides with an **A**- pulse positive transition, and **Z**- pulse length is equal to the length for the **A** and **B** pulses. The voltages at ports **A**, **B**, and **Z** are defined relative to the **Ref** reference port voltage.

Use this block if you need to model the shaft encoder signals, either to support development of a decoding algorithm or to include the quantization effects. Otherwise, use the Ideal Rotational Motion Sensor block from the Simscape Foundation library.

## Assumptions and Limitations

- The Incremental Shaft Encoder block is not linearizable. For control design studies that require model linearization, use the Ideal Rotational Motion Sensor block from the Simscape Foundation library.

# Induction Machine (Single-Phase)

Single-phase induction machine with SI or pu fundamental parameterization

**Library:** Simscape / Electrical / Electromechanical / Asynchronous

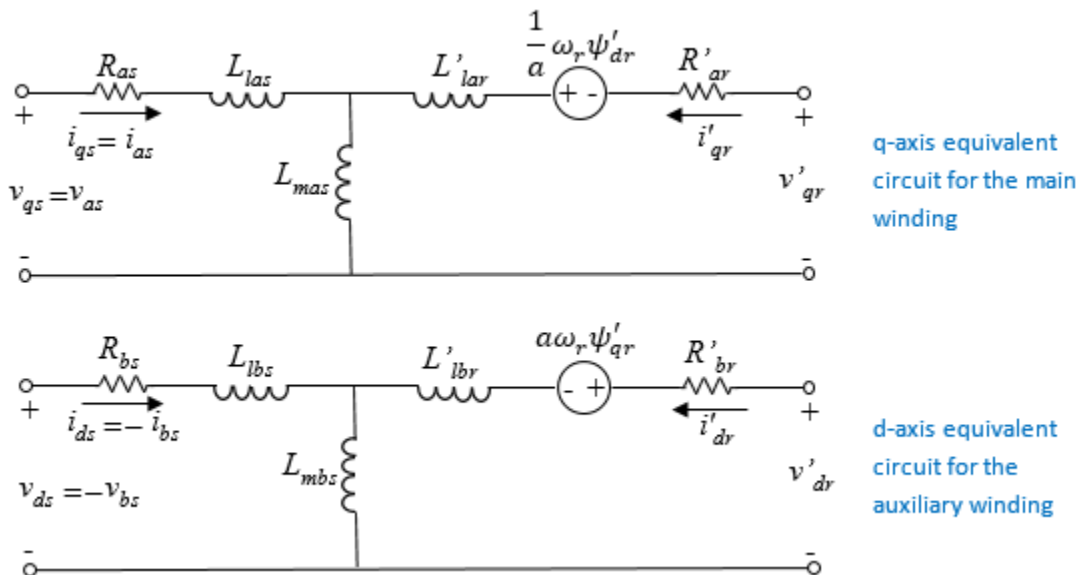

## Description

The Induction Machine (Single-Phase) block represents a single-phase induction machine with a squirrel cage rotor with fundamental parameters expressed in per-unit or in the International System of Units (SI).

This block models four types of single-phase induction machines:

- Split-phase
- Capacitor-start
- Capacitor-start-capacitor-run
- Main and auxiliary windings

The single phase induction machine consists of a squirrel cage rotor and two stator windings, the main and the auxiliary windings. The auxiliary winding is typically only active during startup. However, to improve performance, the auxiliary winding can be active during running for low-power applications. The figure shows the equivalent  $d$ - and  $q$ -axis circuits for the main and auxiliary windings.

The table defines the variables.

Variable	Definition
$v_{qs}v_{ds}$	Stator voltages in the $d$ - $q$ representation
$i_{qs}i_{ds}$	Stator currents in the $d$ - $q$ representation
$\Psi_{qr}\Psi_{dr}$	Rotor fluxes in the $d$ - $q$ representation
$\omega$	Rotor electrical speed
$a$	Auxiliary/main windings turn ratio
$R_{as}$	Main winding stator resistance
$L_{as}$	Main winding stator leakage inductance
$R'_{ar}$	Main winding rotor resistance
$L'_{lar}$	Main winding rotor leakage inductance
$L_{mas}$	Main winding mutual inductance
$R_{bs}$	Auxiliary winding stator resistance
$R_{lbs}$	Auxiliary winding stator leakage inductance
$R'_{br}$	Auxiliary winding rotor resistance
$L'_{lbr}$	Auxiliary winding rotor leakage inductance
$L_{mbs}$	Auxiliary winding mutual inductance

### Equations

The SI model converts the SI values that you enter in the dialog box to per-unit values for simulation. For information on the relationship between SI and per-unit machine parameters, see “Per-Unit Conversion for Machine Parameters”. For information on per-unit parameterization, see “Per-Unit System of Units”.

These transformations reduce the rotor resistance, rotor leakage inductance, and stator mutual inductance to a single set of values by defining the equivalent circuits with respect to the main winding:

$$L_{ms} = L_{mas} = \frac{1}{a^2}L_{mbs}$$

$$R'_{ar} = \frac{1}{a^2}R'_{br}$$

$$L'_{lar} = \frac{1}{a^2}L'_{lbr}$$

The voltage equations for the stator and rotor are:

$$v_{qs} = R_{as}i_{qs} + \frac{d\psi_{qs}}{dt}$$

$$v_{ds} = R_{bs}i_{ds} + \frac{d\psi_{ds}}{dt}$$

$$0 = R'_{ar}i'_{qr} + \frac{d\psi'_{qr}}{dt} - \frac{1}{a}\omega_r\psi'_{dr}$$

$$0 = a^2 R'_{ar} i'_{dr} + \frac{d\psi'_{dr}}{dt} + a\omega_r \psi'_{qr}$$

$$\psi_{qs} = (L_{las} + L_{ms}) i_{qs} + L_{ms} i'_{qr}$$

$$\psi_{ds} = (L_{lbs} + a^2 L_{ms}) i_{ds} + a^2 L_{ms} i'_{dr}$$

$$\psi'_{qr} = (L'_{iar} + L_{ms}) i'_{qr} + L_{ms} i_{qs}$$

$$\psi'_{dr} = a^2 (L'_{iar} + L_{ms}) i'_{dr} + a^2 L_{ms} i_{ds}$$

The expression for the electromagnetic torque,  $T$ , is obtained by applying the principle of virtual displacement [1].

$$T = p \left( a \psi'_{qr} i'_{dr} - \frac{1}{a} \psi'_{dr} i_{qr} \right)$$

The mechanical equation is

$$J \frac{d\omega_m}{dt} = T - T_L - B_m \omega_m,$$

where  $\omega_m$  is the rotor angular velocity.

In split-phase machines, the auxiliary winding is displaced at 90 electrical degrees from the main winding and operates only until the speed reaches the disconnection speed, which is typically 70 to 80 percent of rated speed. In this configuration, the auxiliary winding has high resistance and small reactance compared to the main winding. The resulting phase difference makes the machine behave like a two-phase machine.

The capacitor-start machine is a type of split-phase machine that uses a capacitor in series with the auxiliary winding to start the machine. In this configuration, auxiliary and main windings have the same number of turns. The value of the capacitor ensures that the current in the auxiliary coil leads the current in the main winding by approximately 80 electrical degrees.

The capacitor-start voltage is:

$$v_c = R_s i_{ds} + \int \frac{1}{C_s} \omega_r i_{ds}.$$

When a capacitor is connected in series with the auxiliary winding, the voltage equation for the  $d$ -axis is

$$v_{ds} = R_{bs} i_{ds} + \frac{d\psi_{ds}}{dt} - R_s i_{ds} - \int \frac{1}{C_s} \omega_r i_{ds}.$$

The extension is obtained immediately for capacitor-start-capacitor-run machines. In this configuration, two capacitors are connected in parallel.

The  $d$ -axis voltage after disconnecting the capacitor-start is

$$v_{ds} = R_{bs}i_{ds} + \frac{d\psi_{ds}}{dt} - R_r i_{ds} - \int \frac{1}{C_r} \omega_r i_{ds}.$$

### Display Option

To display the machine per-unit base values in the MATLAB Command Window, right-click the block and, from the **Electrical** menu, select **Display Base Values**.

### Model Thermal Effects

You can expose thermal ports to simulate the effects of generated heat and motor temperature. To expose the thermal ports and the **Thermal** parameters, set the **Modeling option** parameter to either:

- **No thermal port** — The block contains electrical conserving ports associated with the stator windings, but does not contain thermal ports.
- **Show thermal port** — The block contains expanded electrical conserving ports associated with the stator windings and thermal conserving ports for each of the windings and for the rotor.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

**Parameters**

**Modeling option – Whether to enable thermal ports**

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of generated heat and motor temperature.

**Main**

**Type – Induction machine type**

Split-phase (default) | Capacitor-start | Capacitor-start-capacitor-run | Main and auxiliary windings

Type of induction machine.

**Rated apparent power – Rated apparent power**

180 V\*A (default) | positive scalar

Rated apparent power of the induction machine.

**Rated voltage – Rated voltage**

220 V (default) | positive scalar

RMS voltage.

**Rated electrical frequency – Rated electrical frequency**

60 Hz (default) | positive scalar

Nominal electrical frequency corresponding to the rated apparent power.

**Number of pole pairs – Number of pole pairs**

2 (default) | positive integer

Number of machine pole pairs. The value is used as a back-electromotive force constant.

**Parameterization unit — SI or per-unit parameterization option**

SI (default) | Per unit

Unit system for block parameterization.

**Dependencies**

Selecting:

- SI exposes SI **Electrical** parameters.
- Per unit exposes per-unit **Electrical** parameters.

**Electrical**

For the **Parameterization unit** parameter in the **Main** settings, select SI to expose the SI **Electrical** parameters, or Per unit to expose the per-unit **Electrical** parameters.

**Main winding stator resistance, Ras — Main winding stator resistance**

1.8180 Ohm (default) | positive scalar

SI stator resistance for the main winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Main winding stator leakage inductance, Llas — Main winding stator leakage inductance**

0.0067 H (default) | positive scalar

SI leakage inductance for the main winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Main winding rotor resistance, Rar' — Main winding rotor resistance**

3.7080 Ohm (default) | positive scalar

SI rotor resistance for the main winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Main winding rotor leakage inductance, Llar' — Main winding rotor leakage inductance**

0.0050 H (default) | positive scalar

SI rotor leakage inductance for the main winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Main winding mutual inductance, Lms — Main winding mutual inductance**

0.1595 H (default) | positive scalar

SI mutual inductance for the main winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Auxiliary winding stator resistance, Rbs — Auxiliary winding stator resistance**

6.4260 Ohm (default) | positive scalar

SI stator resistance for the auxiliary winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Auxiliary winding stator leakage inductance, Llbs — Auxiliary winding stator leakage inductance**

0.0077 H (default) | positive scalar

SI stator leakage inductance for the auxiliary winding.

**Dependencies**

Selecting SI for the **Parameterization unit** parameter in the **Main** settings exposes SI **Electrical** parameters.

**Auxiliary/main windings turn ratio — Turn ratio**

1.1 (default) | positive scalar

Winding ratio between the main and auxiliary winding.

**Main winding stator resistance, Ras (pu) — Main winding stator resistance**

0.0135 (default) | positive scalar

Per-unit stator resistance for the main winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Main winding stator leakage inductance, Llas (pu) — Main winding stator leakage inductance**

0.0188 (default) | positive scalar

Per-unit leakage inductance for the main winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Main winding rotor resistance,  $R_{ar}'$  (pu) — Main winding rotor resistance**

0.0276 (default) | positive scalar

Per-unit rotor resistance for the main winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Main winding rotor leakage inductance,  $L_{lar}'$  (pu) — Main winding rotor leakage inductance**

0.0140 (default) | positive scalar

Per-unit rotor leakage inductance for the main winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Main winding mutual inductance,  $L_{ms}$  (pu) — Main winding mutual inductance**

0.4472 (default) | positive scalar

Per-unit mutual inductance for the main winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Auxiliary winding stator resistance,  $R_{bs}$  (pu) — Auxiliary winding stator resistance**

0.0478 (default) | positive scalar

Per-unit stator resistance for the auxiliary winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Auxiliary winding stator leakage inductance,  $L_{lbs}$  (pu) — Auxiliary winding stator leakage inductance**

0.0216 (default) | positive scalar

Per-unit stator leakage inductance for the auxiliary winding.

**Dependencies**

Selecting Per unit for the **Parameterization unit** parameter in the **Main** settings exposes per-unit **Electrical** parameters.

**Auxiliary/main windings turn ratio – Turn ratio**

1.1 (default) | positive scalar

Winding ratio between the main and auxiliary winding.

**Capacitor-start resistance,  $R_s$  – Capacitor-start resistance**

3 Ohm (default) | positive scalar

SI capacitor-start resistance.

9.1232 (default) | positive scalar

Per-unit capacitor-start capacitance.

**Dependencies**

To enable this parameter, set **Type** to Capacitor-start-capacitor-run and **Parameterization unit** to Per unit.

**Capacitor-run resistance,  $R_r$  (pu) — Capacitor-run resistance**

0.0669 (default) | positive scalar

Per-unit capacitor-run resistance.

**Dependencies**

To enable this parameter, set **Type** to Capacitor-start-capacitor-run and **Parameterization unit** to Per unit.

**Capacitor-run resistance,  $C_r$  (pu) — Capacitor-run capacitance**

0.000015 (default) | positive scalar

Per-unit capacitor-run capacitance.

**Dependencies**

To enable this parameter, set **Type** to Capacitor-start-capacitor-run and **Parameterization unit** to Per unit.

**Disconnection speed (% of rated speed) — Disconnection speed**

80 (default) | scalar in range [0,100]

Speed when capacitor is disconnected, expressed as a percentage of rated speed. The value must be between 0 and 100, inclusive.

**Dependencies**

To enable this parameter, set **Type** to either Split-phase, Capacitor-start, or Capacitor-start-capacitor-run.

**Mechanical****Rotor inertia — Rotor inertia**

0.01 kg\*m<sup>2</sup> (default) | positive scalar

Inertia of the rotor.

**Rotor damping — Rotor damping**

0 N\*m/(rad/s) (default) | scalar

Damping of the rotor.

**Thermal**

These parameters appear only for blocks with exposed thermal ports.

**Measurement temperature — Rated temperature**

298.15 K (default) | real scalar

Temperature for which motor parameters are quoted.

**Resistance temperature coefficient – Temperature coefficient**

3.93e-3 1/K (default) | positive scalar

Coefficient  $\alpha$  in the equation relating resistance to temperature for all three windings, as described in “Thermal Model for Actuator Blocks”. The default value, 3.93e-3 1/K, is for copper.

**Cage resistance temperature coefficient – Rotor temperature coefficient**

4.4e-3 (default) | 1/K | scalar

Coefficient relating cage resistance to temperature for the rotor. The default value, 4.4e-3 1/K, is for aluminium.

**Thermal mass for each stator winding – Winding thermal mass**

100 J/K (default) | positive scalar

# Induction Machine Current Controller

Discrete-time induction machine current PI controller

**Library:** Simscape / Electrical / Control / Induction Machine Control

## Description

The Induction Machine Current Controller implements discrete-time proportional-integral (PI) based induction machine current control in the rotor  $d$ - $q$  reference frame. You typically use the Induction Machine Current Controller in a series of blocks that make up a control structure. For example, to convert the  $dq0$  reference frame output voltage to voltage in an  $abc$  reference frame, connect the Induction Machine Current Controller to an Inverse Clarke Transform in the control structure.

## Equations

The block uses the backward Euler discretization method.

Two PI current controllers that are implemented in the rotor reference frame produce the reference voltage vector:

$$v_d^{ref} = \left( K_{p\_id} + K_{i\_id} \frac{T_s z}{z-1} \right) (i_d^{ref} - i_d) + v_{d\_FF},$$

and

$$v_q^{ref} = \left( K_{p\_iq} + K_{i\_iq} \frac{T_s z}{z-1} \right) (i_q^{ref} - i_q) + v_{q\_FF},$$

where

- $v_d^{ref}$ , and  $v_q^{ref}$  are the  $d$ -axis and  $q$ -axis reference voltages, respectively.
- $i_d^{ref}$ , and  $i_q^{ref}$  are the  $d$ -axis and  $q$ -axis reference currents, respectively.
- $i_d$  and  $i_q$  are the  $d$ -axis and  $q$ -axis currents, respectively.
- $K_{p\_id}$ , and  $K_{p\_iq}$  are the proportional gains for the  $d$ -axis and  $q$ -axis controllers, respectively.
- $K_{i\_id}$  and  $K_{i\_iq}$  are the integral gains for the  $d$ -axis and  $q$ -axis controllers, respectively.
- $v_{d\_FF}$ , and  $v_{q\_FF}$  are the feedforward voltages for the  $d$ -axis and  $q$ -axis, respectively. The feedforward voltages are obtained from the machine mathematical equations and provided as inputs.
- $T_s$ , is the sample time of the discrete controller.

### Voltage Saturation

Saturation is imposed when the stator voltage vector exceeds the voltage phase limit  $V_{ph\_max}$ :

$$\sqrt{v_d^2 + v_q^2} \leq V_{ph\_max},$$

where  $v_d$ , and  $v_q$  are the  $d$ -axis and  $q$ -axis voltages, respectively.

In the case of axis prioritization, the voltages  $v_1$  and  $v_2$  are introduced, where:

- For  $d$ -axis prioritization —  $v_1 = v_d$  and  $v_2 = v_q$ .
- For  $q$ -axis prioritization —  $v_1 = v_q$  and  $v_2 = v_d$ .

The constrained (saturated) voltages  $v_1^{sat}$  and  $v_2^{sat}$  are obtained as:

$$v_1^{sat} = \min(\max(v_1^{unsat}, -V_{ph\_max}), V_{ph\_max})$$

and

$$v_2^{sat} = \min(\max(v_2^{unsat}, -V_{2\_max}), V_{2\_max}),$$

where:

- $v_1^{unsat}$  and  $v_2^{unsat}$  are the unconstrained (unsaturated) voltages.
- $v_{2\_max}$  is the maximum value of  $v_2$  that does not exceed the voltage phase limit. The equation that define  $v_{2\_max}$  is  $v_{2\_max} = \sqrt{(V_{ph\_max})^2 - (v_1^{sat})^2}$ .

In the case of  $d$ - $q$  equivalence, the direct and quadrature axes have the same priority, and the constrained voltages are:

$$v_d^{sat} = \min(\max(v_d^{unsat}, -V_{d\_max}), V_{d\_max})$$

and

$$v_q^{sat} = \min(\max(v_q^{unsat}, -V_{q\_max}), V_{q\_max}),$$

where:

$$V_{d\_max} = \frac{V_{ph\_max}|v_d^{unsat}|}{\sqrt{(v_d^{unsat})^2 + (v_q^{unsat})^2}}$$

and

$$V_{q\_max} = \frac{V_{ph\_max}|v_q^{unsat}|}{\sqrt{(v_d^{unsat})^2 + (v_q^{unsat})^2}}.$$

### Integral Anti-Windup

An anti-windup mechanism is employed to avoid the saturation of the integrator output. In such a situation, the integrator gains become:

$$K_{i\_id} + K_{aw\_id}(v_d^{sat} - v_d^{unsat})$$

and

$$K_{i\_iq} + K_{aw\_iq}(v_q^{sat} - v_q^{unsat}),$$

where  $K_{aw\_id}$ ,  $K_{aw\_iq}$ , and  $K_{aw\_if}$  are the anti-windup gains for the  $d$ -axis,  $q$ -axis, and field controllers, respectively.

### Assumptions and Limitations

- The plant model for the direct and quadrature axes can be approximated with a first-order system.

## Description

The Induction Machine Direct Torque Control block implements an induction machine direct torque control (DTC) structure. The figure shows the equivalent circuit for the block.

## Equations

To estimate the torque and flux, the Induction Machine Direct Torque Control block discretizes the machine voltage equations in the stationary  $\alpha\beta$  reference frame using the backward Euler method. The discrete-time equations for stator fluxes in the  $\alpha\beta$  frame are:

$$\psi_{\alpha} = (v_{\alpha} - i_{\alpha}R_s) \frac{T_s z}{z-1}$$

and

$$\psi_{\beta} = (v_{\beta} - i_{\beta}R_s) \frac{T_s z}{z-1}$$

where:

- $v_\alpha$  is  $\alpha$ -axis voltage.
- $i_\alpha$  is  $\alpha$ -axis current.
- $R_s$  is the stator resistance.
- $\Psi_\alpha$  is the  $\alpha$ -axis stator flux.
- $v_\beta$  is  $\beta$ -axis voltage.
- $i_\beta$  is  $\beta$ -axis current.
- $\Psi_\beta$  is the  $\beta$ -axis stator flux.

The block calculates the torque and flux as:

$$T = \frac{3p}{2}(\psi_\alpha i_\beta - \psi_\beta i_\alpha)$$

and

$$\psi_s = \sqrt{\psi_\alpha^2 + \psi_\beta^2}$$

where:

- $p$  is the number of pole pairs.
- $\Psi_s$  is the stator flux.

To detect flux and torque estimation errors, the block uses hysteresis comparators. The figure shows hysteresis comparators and the associated switching sectors.

# Induction Machine Direct Torque Control (Single-Phase)

Single-phase induction machine direct torque control

**Library:** Simscape / Electrical / Control / Induction Machine Control

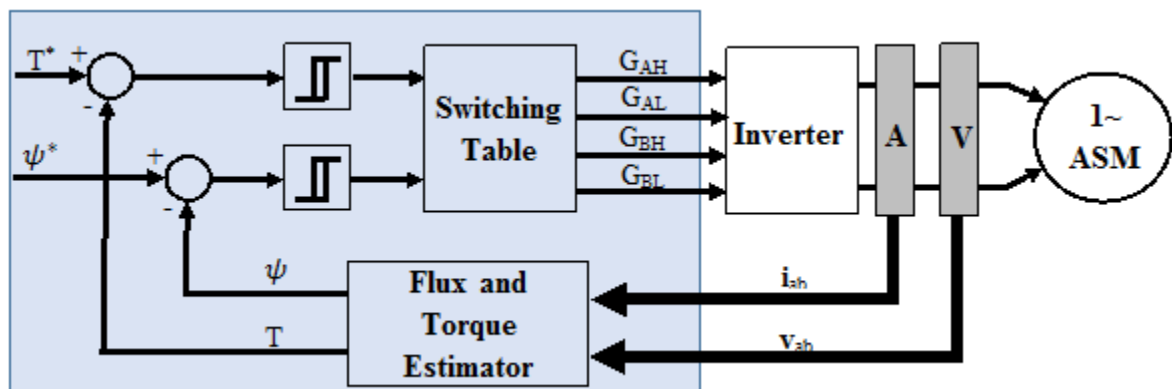

## Description

The Induction Machine Direct Torque Control (Single-Phase) block implements a single-phase induction machine direct torque control structure.

## Equations

This diagram shows the direct torque control architecture for single-phase machines

The torque and flux estimation is based on machine voltage equations. The discrete-time voltage equations using the backward Euler discretization method, are:

$$\psi_a = (v_a - i_a R_{as}) \frac{T_s z}{z - 1}$$

$$\psi_b = (v_b - i_b R_{bs}) \frac{T_s z}{z - 1}$$

where:

- $R_{as}$  and  $R_{bs}$  are the main winding resistance and the auxiliary winding resistance, respectively.

- $i_a$  and  $i_b$  are the main winding current and the auxiliary winding current, respectively.
- $v_a$  and  $v_b$  are the main and auxiliary winding voltage, respectively.
- $\psi_a$  and  $\psi_b$  are the main and auxiliary winding flux, respectively.

The torque and flux are obtained from:

$$T = -p(a\psi_a i_b - \frac{1}{a}\psi_b i_a)$$

$$\psi_s = \sqrt{\psi_a^2 + \psi_b^2}$$

where:

- $p$  is the number of pole pairs.
- $a$  is the auxiliary to main windings turn ratio.

Employing simple hysteresis comparators detects the status of flux and torque errors. The following figures illustrate the hysteresis comparators and the switching sectors.

The table shows the optimum switching table (inverter high side).

$c_\psi, c_T, S(\theta)$		$S_0$	$S_1$	$S_2$	$S_3$
$c_\psi = 1$	$c_T = 1$	1, 0	1, 1	0, 1	0, 0
	$c_T = 0$	1, 1	0, 1	0, 0	1, 0
$c_\psi = 0$	$c_T = 1$	0, 0	1, 0	1, 1	0, 1

$c_\psi, c_T, S(\theta)$	$S_0$	$S_1$	$S_2$	$S_3$
$c_T = 0$	0, 1	0, 0	1, 0	1, 1

The torque reference can be provided as an input, or, in the case of speed control, be generated internally using a PI speed controller.

The flux reference is generated internally using:

$$\psi_s^* = \frac{2\pi f_n \psi_n}{p \min\left(\omega_r, \frac{2\pi f_n}{p}\right)}$$

where,

- $\omega_r$  is the rotor angular mechanical speed in rad/s.
- $f_n$  is the rated frequency.
- $\psi_n$  is the rated flux.

### Limitations

- The power inverter dead-times are not considered in this block. For hardware implementation, add the dead-time externally.

# Induction Machine Direct Torque Control with Space Vector Modulator

Induction machine DTC structure with SVM

**Library:** Simscape / Electrical / Control / Induction Machine Control

## Description

The Induction Machine Direct Torque Control with Space Vector Modulator implements an induction machine direct torque control structure (DTC) with space vector modulator (SVM). Use this block to generate the gate pulses for an inverter controlling an induction machine. This diagram shows the architecture of the block.

In the diagram:

- You provide the reference torque,  $T^*$ , and flux,  $\psi^*$ .
- The Flux and Torque Estimator estimates the actual torque,  $T$ , and flux,  $\psi$  from the measured phase currents,  $i_{abc}$ , and voltages,  $v_{abc}$ .
- Two PI controllers determine the reference  $d$  and  $q$  voltages,  $v_d$  and  $v_q$ , from the flux and torque errors, respectively.
- The SVM generates the gates pulses,  $G_{ij}$ , required to control an inverter driving the induction machine. Subscript  $i$  corresponds to the phase ( $a$ ,  $b$ , or  $c$ ). Subscript  $j$  corresponds to the high,  $H$ , or low,  $L$ , signal.

### Flux and Torque Estimator

To estimate the torque and flux, the block discretizes the machine voltage equations in the stationary  $\alpha\beta$  reference frame using the backward Euler method. The discrete-time equations for stator fluxes in the  $\alpha\beta$  frame are:

$$\psi_\alpha = (v_\alpha - i_\alpha R_s) \frac{T_s z}{z-1}$$

$$\psi_\beta = (v_\beta - i_\beta R_s) \frac{T_s z}{z-1}$$

Where:

- $v_\alpha$  and  $v_\beta$  are the  $\alpha$ - and  $\beta$ -axis voltages, respectively.
- $i_\alpha$  and  $i_\beta$  are the  $\alpha$ - and  $\beta$ -axis currents, respectively.
- $\Psi_\alpha$  and  $\Psi_\beta$  are the  $\alpha$ - and  $\beta$ -axis stator fluxes, respectively.
- $R_s$  is the stator resistance.

The block calculates the torque and total stator flux as:

$$T = \frac{3p}{2} (\psi_\alpha i_\beta - \psi_\beta i_\alpha)$$

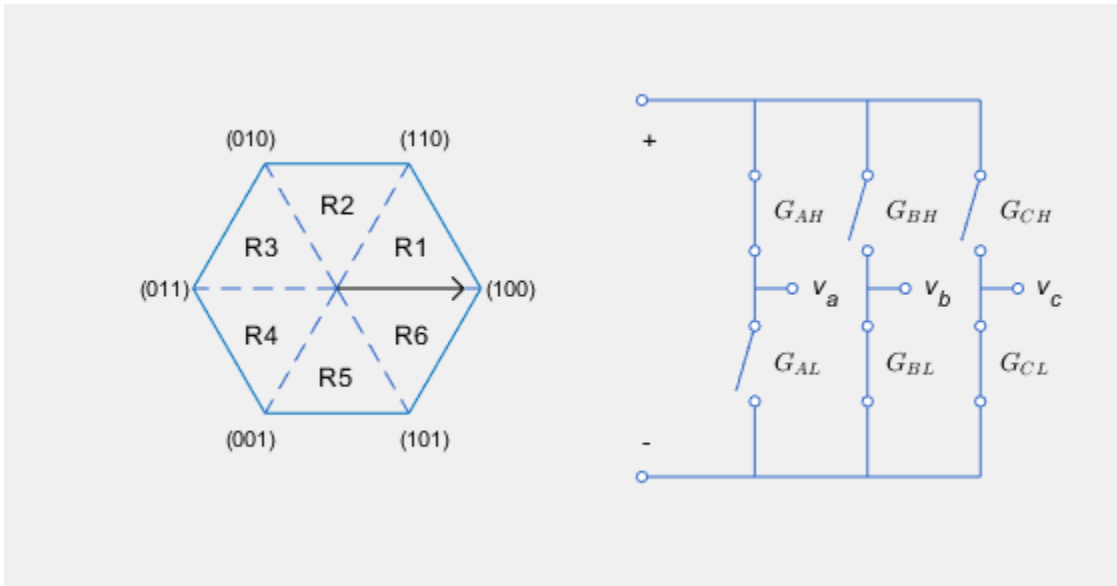

$$\psi_s = \sqrt{\psi_\alpha^2 + \psi_\beta^2}$$

Where:

- $p$  is the number of pole pairs.
- $\Psi_s$  is the total stator flux.

### Space Vector Modulator

The SVM converts the desired voltages into gate pulses, which you use to control an inverter. This figure shows possible switching states of a three-phase inverter.

The hexagon represents the space vector diagram. Each of the six vertices represents a possible switching state ( $G_{AH}, G_{BH}, G_{CH}$ ) of the three-phase inverter. Each low gate takes the opposite state as its corresponding high gate. The inverter diagram illustrates the current state.

The rotating vector in the space vector diagram corresponds to the complex reference voltage vector, which rotates at the desired electrical frequency of the machine. In reality, the switching frequency is much faster than this electrical frequency. As a result, the inverter switches continually between the two states enclosing its current region  $R_i$ , and the zero state corresponding to  $(0,0,0)$ , to generate the desired voltages.

To learn about the implementation of this method, see the PWM Generator (Three-phase, Two-level) block.

## Description

The Induction Machine Field-Oriented Controller block implements an induction machine field-oriented control (FOC) structure using the per-unit system. To decouple the torque and flux, FOC uses the rotor  $d$ - $q$  reference frame. The figure shows the control structure.

In the diagram:

- $\omega_r$  is the measured angular velocity.
- $\omega_{ref}$  is the reference angular velocity.
- $i_d$  and  $i_q$  are the  $d$ - and  $q$ -axis stator currents.
- $i_a$ ,  $i_b$ , and  $i_c$  are the  $a$ -,  $b$ - and  $c$ -phase stator winding currents.
- $i_{mr\_ref}$  is the reference magnetizing current.
- $i_{mr}$  is the magnetizing current.
- $v_d$  and  $v_q$  are the  $d$ - and  $q$ -axis stator voltages.

- $v_a$ ,  $v_b$ , and  $v_c$  are the  $a$ -,  $b$ - and  $c$ -phase stator winding voltages.
- $\theta_e$  is the rotor electrical angle.
- $G_{AH}$ ,  $G_{AL}$ ,  $G_{BH}$ ,  $G_{BL}$ ,  $G_{CH}$ , and  $G_{CL}$  are the  $a$ -,  $b$ - and  $c$ -phase high (H) and low(L) gate pulses.

### Assumptions and Limitations

- The machine parameters are known.
- The implementation uses the per-unit system.
- The control structure implementation uses a single sample rate.

## Ports

### Input

#### **imRef — Current**

scalar

Magnetizing reference current in the per-unit system.

Data Types: `single` | `double`

#### **wrRef — Velocity**

scalar

Rotor reference velocity in per-unit system.

Data Types: `single` | `double`

#### **iabc — Current**

vector

Measured phase currents in the per-unit system.

Data Types: `single` | `double`

#### **wr — Velocity**

scalar

Measured angular velocity in per-unit system.

Data Types: `single` | `double`

#### **Vdc — Voltage**

scalar

Measured dc-link voltage, in V.

Data Types: `single` | `double`

### Output

#### **G — Gate pulses**

vector | 0 or 1

Inverter gate pulses. The block does not consider any dead time.

Data Types: single | double

### **Visualization — Visualization signals**

vector

Bus containing signals for visualization.

Data Types: single | double | bus

## **Parameters**

### **General**

#### **Rated voltage, rms line-to-line (V) — Voltage**

550 (default)

Nominal voltage.

#### **Rated electrical frequency (Hz) — Frequency**

60 (default)

Nominal electrical frequency.

#### **Rotor resistance, referred to the stator side (pu) — Resistance**

0.01 (default)

Rotor, stator-side resistance in the per-unit system.

#### **Rotor leakage inductance, referred to the stator side (pu) — Inductance**

0.06 (default)

Rotor stator-side leakage inductance, in the pu-unit system.

#### **Magnetizing inductance (pu) — Inductance**

2.7 (default)

Magnetizing inductance in the per-unit system.

#### **Time constant for dq currents filters (s) — Time constant**

1e-4 (default)

Time constant for filtering the  $d$  and  $q$  currents.

#### **Inverter dc-link voltage threshold (V) — Voltage**

500 (default)

Voltage threshold to activate the power inverter.

#### **Fundamental sample time (s) — Time**

5e-6 (default) | positive scalar less than the control sample time

Fundamental sample time must be less than the control sample time.

#### **Control sample time (s) — Time**

5e-5 (default) | positive scalar greater than the fundamental sample time

Control sample time must be greater than the fundamental sample time.

### **Outer Loop**

#### **Magnetizing current controller proportional gain – Gain**

10 (default)

Proportional gain for the magnetizing current controller.

#### **Magnetizing current controller integral gain – Gain**

1000 (default)

Integral gain for the magnetizing current controller.

#### **Magnetizing current controller integral anti-windup gain – Gain**

1000 (default)

Integral anti-windup gain for the magnetizing current controller.

#### **Speed controller proportional gain – Gain**

10 (default)

Proportional gain for the speed controller.

#### **Speed controller integral gain – Gain**

1000 (default)

Integral gain for the speed controller.

#### **Speed controller integral anti-windup gain – Gain**

1000 (default)

Integral anti-windup gain for the speed controller.

#### **Maximum d-axis current [pu] – Current**

2 (default)

Maximum current for the  $d$ -axis.

#### **Maximum q-axis current [pu] – Current**

2 (default)

Maximum current for the  $q$ -axis.

### **Inner Loop**

#### **Phase-a axis alignment – $dq0$ reference frame alignment**

Q-axis (default) | D-axis

Align the  $a$ -phase vector of the  $abc$  reference frame to the  $d$ - or  $q$ -axis of the rotating reference frame.

#### **D-axis current proportional gain – D-axis proportional gain**

1 (default) | positive number

Proportional gain of the PI controller used for direct-axis current control.

**D-axis current integral gain — D-axis integral gain**

100 (default) | positive number

Integrator gain of the PI controller used for direct-axis current control.

**D-axis current anti-windup gain — D-axis anti-windup gain**

1 (default) | positive number

Anti-windup gain of the PI controller used for direct-axis current control.

**Q-axis current proportional gain — Q-axis proportional gain**

1 (default) | positive number

Proportional gain of the PI controller used for quadrature-axis current control.

**Q-axis current integral gain — Q-axis integral gain**

100 (default) | positive number

Integrator gain of the PI controller used for quadrature-axis current control.

**Q-axis current anti-windup gain — Q-axis anti-windup gain**

1 (default) | positive number

Anti-windup gain of the PI controller used for quadrature-axis current control.

**Axis prioritization — Axis prioritization for voltage limiter**

Q-axis (default) | D-axis | D-Q equivalence

Prioritize or maintain ratio between  $d$ - and  $q$ -axes when block limits voltage.

**PWM****PWM method — Pulse width modulation method**

SVM: space vector modulation (default) | SPWM: sinusoidal PWM

Specify the waveform technique.

**Sampling mode — Wave-sampling method**

Natural (default) | Asymmetric | Symmetric

The sampling mode determines whether the block samples the modulation waveform when the waves intersect or when the carrier wave is at one or both of its boundary conditions.

**Switching frequency (Hz) — Switching rate**

1000 (default) | positive integer

Specify the rate at which you want the switches in the power converter to switch.

# Induction Machine Flux Observer

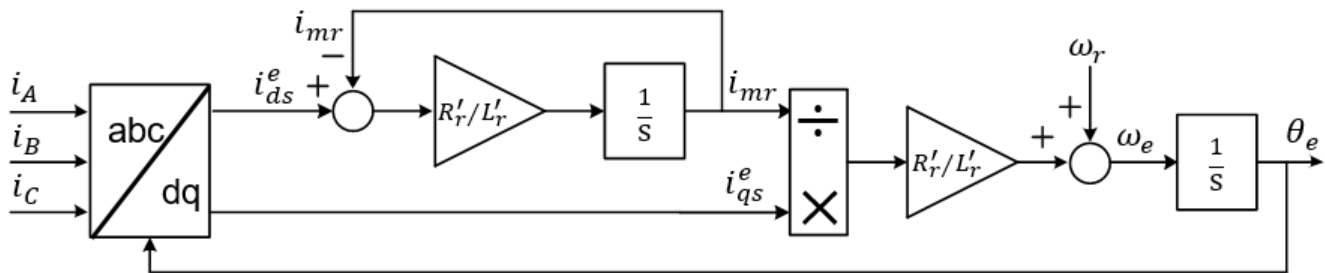

Induction machine flux observer for field-oriented control

**Library:** Simscape / Electrical / Control / Observers

## Description

The Induction Machine Flux Observer block obtains the synchronous speed,  $\omega_e$ , and electrical angle,  $\theta_e$ , that are required for performing rotor field-oriented control (FOC). The figure shows the equivalent circuit for the observer.

## Equations

To determine the synchronous speed and electrical angle, the Induction Machine Flux Observer block uses these relationships:

$$\lambda_{dr}^e = L_r' i_{dr}^e + L_M i_{ds}^e \triangleq L_M i_{mr}^e,$$

$$0 = R_r' i_{dr}^e - (\omega_e - \omega_r) \lambda_{qr}^e + \frac{d\lambda_{dr}^e}{dt},$$

and

$$i_{qr}^e = -\frac{L_M}{L_r'} i_{qs}^e,$$

in these combined forms:

$$i_{dr}^e = \frac{L_M}{L_r'} (i_{mr} - i_{ds}^e)$$

$$\frac{di_{mr}}{dt} = \frac{R_r'}{L_r'} (i_{ds}^e - i_{mr})$$

and

$$\omega_e = \omega_r + \frac{R_r i_{qs}^e}{L_r i_{mr}}$$

where:

- $\lambda_{dr}^e$  is the  $d$ -axis rotor flux.
- $i_{mr}$  is the magnetizing current.
- $i_{ds}^e$  and  $i_{qs}^e$  are the  $d$ -axis and  $q$ -axis stator currents.
- $i_{dr}^e$  and  $i_{qr}^e$  are the  $d$ -axis and  $q$ -axis rotor currents.
- $\omega_e$  is the synchronous speed.
- $\omega_r$  is the mechanical rotational speed.
- $R_r$  is the rotor resistance, referred to the stator side.
- $L_r$  is the rotor leakage inductance, referred to the stator side.
- $L_M$  the magnetizing inductance.

# Induction Machine Measurement

Per-unit measurement from induction machine

**Library:** Simscape / Electrical / Electromechanical / Asynchronous

## Description

The Induction Machine Measurement block outputs a per-unit measurement associated with a connected Induction Machine Squirrel Cage or Induction Machine Wound Rotor block. The input of the Induction Machine Measurement block connects to the pu output port of the induction machine block.

You set the **Output** parameter to a per-unit measurement associated with the induction machine. Based on the value you select, the Induction Machine Measurement block:

- Directly outputs the value of an element in the input signal vector
- Calculates the per-unit measurement by using values of elements in the input signal vector in mathematical expressions

The Induction Machine Measurement block outputs a per-unit measurement from the induction machine according to the output value expressions in the table. For example, when you set **Output** to *Stator d-axis voltage*, the block directly outputs the value of the *pu\_vds* element in the input signal vector. However, when you set **Output** to *Slip*, the block calculates the slip value by subtracting the value of the *pu\_velocity* element from 1.

Output Parameter Setting	Output Value Expression
Electrical torque	pu_torque
Rotor velocity	pu_velocity
Stator d-axis voltage	pu_vds
Stator q-axis voltage	pu_vqs
Stator zero-sequence voltage	pu_v0s
Stator d-axis current	pu_ids
Stator q-axis current	pu_iqs
Stator zero-sequence current	pu_i0s
Slip	1-pu_velocity
Apparent power	$\sqrt{pu_{Pt}^2 + pu_{Qt}^2}$
Real power	$pu_{Pt} = (pu_{vds} * pu_{ids}) + (pu_{vqs} * pu_{iqs}) + 2(pu_{v0s} * pu_{i0s})$
Reactive power	$pu_{Qt} = (pu_{vqs} * pu_{ids}) - (pu_{vds} * pu_{iqs})$
Terminal voltage	$\sqrt{pu_{vds}^2 + pu_{vqs}^2}$

Output Parameter Setting	Output Value Expression
Terminal current	$\sqrt{pu\_ids^2 + pu\_iqs^2}$
Power factor angle (rad)	<code>power_factor_angle = atan2(pu_Qt, pu_Pt)</code>
Power factor	<code>cos(power_factor_angle)</code>

# Induction Machine Scalar Control

Induction machine V/f control

**Library:** Simscape / Electrical / Control / Induction Machine Control

## Description

The Induction Machine Scalar Control block implements an induction machine scalar, that is V/f or V/Hz, control structure. The diagram shows the open-loop V/f control structure that the block implements.

## Equations

The Induction Machine Scalar Control block computes the magnitude of the stator voltage based on the reference frequency,  $f_s^*$ , as:

$$V_s^* = \left( \frac{V_n - V_{min}}{f_n - f_{min}} \right) f_s^*,$$

where:

- $V_n$  is the rated voltage.
- $V_{min}$  is the minimum voltage.
- $f_n$  is the rated electrical frequency.
- $f_{min}$  is the minimum frequency.

The voltage components in the stationary reference frame are:

$$V_\alpha = V_s^* \cos(2\pi f_s^* t)$$

and

$$V_{\beta} = V_s^* \sin(2\pi f_s^* t).$$

The block obtains  $V_{abc}$  from  $V_{\alpha}$  and  $V_{\beta}$  by using an inverse Clarke transformation.

# Induction Machine Squirrel Cage

Squirrel-cage-rotor induction machine with per-unit or SI parameterization

**Library:** Simscape / Electrical / Electromechanical / Asynchronous

## Description

The Induction Machine Squirrel Cage block models a squirrel-cage-rotor induction machine with fundamental parameters expressed in per-unit or in the International System of Units (SI). A squirrel-cage-rotor induction machine is a type of induction machine. All stator connections are accessible on the block. Therefore, you can model soft-start regimes using a switch between wye and delta configurations. If you need access to the rotor windings, use the Induction Machine Wound Rotor block instead.

Connect port ~1 to a three-phase circuit. To connect the stator in delta configuration, connect a Phase Permute block between ports ~1 and ~2. To connect the stator in wye configuration, connect port ~2 to a Grounded Neutral (Three-Phase) or a Floating Neutral (Three-Phase) block.

## Induction Machine Initialization Using Load-Flow Target Values

If the block is in a network that is compatible with the frequency-time simulation mode, you can perform a load-flow analysis on the network. A load-flow analysis provides steady-state values that you can use to initialize the machine.

For more information, see “Perform a Load-Flow Analysis Using Simscape Electrical” and “Frequency and Time Simulation Mode”. For an example that shows how initialize an induction machine using data from a load flow analysis, see “Induction Motor Initialization with Loadflow”.

## Equations

For the SI implementation, the block converts the SI values that you enter to per-unit values for simulation. The converted values are based on the machine being connected in a delta-winding configuration.

For the per-unit implementation, you must specify the resistances and inductances in the impedances tab based on the machine being connected in a delta-winding configuration.

For information on the relationship between SI and per-unit machine parameters, see “Per-Unit Conversion for Machine Parameters”. For information on per-unit parameterization, see “Per-Unit System of Units”.

The induction machine equations are expressed with respect to a synchronous reference frame, defined by

$$\theta_e(t) = \int_0^t 2\pi f_{rated} dt,$$

where  $f_{rated}$  is the value of the **Rated electrical frequency** parameter.

The Park transformation maps stator equations to a reference frame that is stationary with respect to the rated electrical frequency. The Park transformation is defined by

$$P_s = \frac{2}{3} \begin{bmatrix} \cos\theta_e & \cos(\theta_e - \frac{2\pi}{3}) & \cos(\theta_e + \frac{2\pi}{3}) \\ -\sin\theta_e & -\sin(\theta_e - \frac{2\pi}{3}) & -\sin(\theta_e + \frac{2\pi}{3}) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix},$$

where  $\theta_e$  is the electrical angle.

The Park transformation is used to define the per-unit induction machine equations. The stator voltage equations are defined by

$$v_{ds} = \frac{1}{\omega_{base}} \frac{d\psi_{ds}}{dt} - \omega\psi_{qs} + R_s i_{ds},$$

$$v_{qs} = \frac{1}{\omega_{base}} \frac{d\psi_{qs}}{dt} + \omega\psi_{ds} + R_s i_{qs},$$

and

$$v_{0s} = \frac{1}{\omega_{base}} \frac{d\psi_{0s}}{dt} + R_s i_{0s},$$

where:

- $v_{ds}$ ,  $v_{qs}$ , and  $v_{0s}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence stator voltages, defined by

$$\begin{bmatrix} v_{ds} \\ v_{qs} \\ v_{0s} \end{bmatrix} = P_s \begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix}.$$

$v_a$ ,  $v_b$ , and  $v_c$  are the stator voltages across ports ~1 and ~2.

- $\omega_{base}$  is the per-unit base electrical speed.
- $\psi_{ds}$ ,  $\psi_{qs}$ , and  $\psi_{0s}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence stator flux linkages.
- $R_s$  is the stator resistance.
- $i_{ds}$ ,  $i_{qs}$ , and  $i_{0s}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence stator currents defined by

$$\begin{bmatrix} i_{ds} \\ i_{qs} \\ i_{0s} \end{bmatrix} = P_s \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}.$$

$i_a$ ,  $i_b$ , and  $i_c$  are the stator currents flowing from port ~1 to port ~2.

The rotor voltage equations are defined by

$$v_{dr} = \frac{1}{\omega_{base}} \frac{d\psi_{dr}}{dt} - (\omega - \omega_r)\psi_{qr} + R_{rd}i_{dr} = 0$$

and

$$v_{qr} = \frac{1}{\omega_{base}} \frac{d\psi_{qr}}{dt} + (\omega - \omega_r)\psi_{dr} + R_{rd}i_{qr} = 0,$$

where:

- $v_{dr}$  and  $v_{qr}$  are the  $d$ -axis and  $q$ -axis rotor voltages.
- $\psi_{dr}$  and  $\psi_{qr}$  are the  $d$ -axis and  $q$ -axis rotor flux linkages.
- $\omega$  is the per-unit synchronous speed. For a synchronous reference frame, the value is 1.
- $\omega_r$  is the per-unit mechanical rotational speed.
- $R_{rd}$  is the rotor resistance referred to the stator.
- $i_{dr}$  and  $i_{qr}$  are the  $d$ -axis and  $q$ -axis rotor currents.

The stator flux linkage equations are defined by

$$\psi_{ds} = L_{ss}i_{ds} + L_m i_{dr},$$

$$\psi_{qs} = L_{ss}i_{qs} + L_m i_{qr},$$

and

$$\psi_{0s} = L_{ss}i_{0s},$$

where  $L_{ss}$  is the stator self-inductance and  $L_m$  is the magnetizing inductance.

The rotor flux linkage equations are defined by

$$\psi_{dr} = L_{rrd}i_{dr} + L_m i_{ds}$$

and

$$\psi_{qr} = L_{rrd}i_{qr} + L_m i_{qs},$$

where  $L_{rrd}$  is the rotor self-inductance referred to the stator.

The rotor torque is defined by

$$T = \psi_{ds}i_{qs} - \psi_{qs}i_{ds}.$$

The stator self-inductance  $L_{ss}$ , stator leakage inductance  $L_{ls}$ , and magnetizing inductance  $L_m$  are related by

$$L_{ss} = L_{ls} + L_m.$$

The rotor self-inductance  $L_{rrd}$ , rotor leakage inductance  $L_{lrd}$ , and magnetizing inductance  $L_m$  are related by

$$L_{rrd} = L_{lrd} + L_m.$$

When a saturation curve is provided, the equations to determine the saturated magnetizing inductance as a function of magnetizing flux are:

$$L_{m\_sat} = f(\psi_m)$$

$$\psi_m = \sqrt{\psi_{dm}^2 + \psi_{qm}^2}$$

For no saturation, the equation reduces to

$$L_{m\_sat} = L_m$$

### Plotting and Display Options

You can perform plotting and display actions using the **Electrical** menu on the block context menu.

Right-click the block and, from the **Electrical** menu, select an option:

- **Display Base Values** — Displays the machine per-unit base values in the MATLAB Command Window.
- **Plot Torque Speed (SI)** — Plots torque versus speed, both measured in SI units, in a MATLAB figure window using the current machine parameters.
- **Plot Torque Speed (pu)** — Plots torque versus speed, both measured in per-unit, in a MATLAB figure window using the current machine parameters.
- **Plot Open-Circuit Saturation** — Plots terminal voltage versus no-load line current, both in per-unit, in a MATLAB figure window. The plot contains three traces:
  - Unsaturated — Stator magnetizing inductance (unsaturated).
  - Saturated — Open-circuit lookup table ( $v$  versus  $i$ ) you specify.
  - Derived — Open-circuit lookup table derived from the per-unit open-circuit lookup table ( $v$  versus  $i$ ) you specify. This data is used to calculate the saturated magnetizing inductance,  $L_{m\_sat}$ , and the saturation factor,  $K_s$ , versus magnetic flux linkage,  $\psi_m$ , characteristics.
- **Plot Saturation Factor** — Plots saturation factor,  $K_s$ , versus magnetic flux linkage,  $\psi_m$ , in a MATLAB figure window using the machine parameters. This parameter is derived from other parameters that you specify:
  - No-load line current saturation data,  $i$
  - Terminal voltage saturation data,  $v$
  - Leakage inductance,  $L_{ls}$
- **Plot Saturated Inductance** — Plots magnetizing inductance,  $L_{m\_sat}$ , versus magnetic flux linkage,  $\psi_m$ , in a MATLAB figure window using the machine parameters. This parameter is derived from other parameters that you specify:
  - No-load line current saturation data,  $i$
  - Terminal voltage saturation data,  $v$
  - Leakage inductance,  $L_{ls}$

For the SI implementation,  $v$  is in V (phase-phase RMS) and  $i$  is in A (rms).

## Model Thermal Effects

You can expose thermal ports to simulate the effects of generated heat and motor temperature. To expose the thermal ports and the **Thermal** parameters, set the **Modeling option** parameter to either:

- **No thermal port** — The block contains electrical conserving ports associated with the stator windings, but does not contain thermal ports.
- **Show thermal port** — The block contains expanded electrical conserving ports associated with the stator windings and thermal conserving ports for each of the windings and for the rotor.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

The type of variables that are visible in the **Initial Targets** section depends on the initialization method that you select, in the **Main** section, for the **Initialization option** parameter. To specify target values using:

- **Flux variables** — Set the **Initialization option** parameter to **Set targets for flux variables**.
- **Data from a load-flow analysis** — Set the **Initialization option** parameter to **Set targets for load flow variables**.

If you select **Set targets for load flow variables**, to fully specify the initial condition, you must include an initialization constraint in the form of a high-priority target value. For example, if your induction machine is connected to an Inertia block, the initial condition for the induction machine is completely specified if, in the **Initial Targets** section of the Inertia block, the **Priority** for **Rotational velocity** is set to High. Alternatively, you could set the **Priority** to None for the Inertia block **Rotational velocity**, and instead set the **Priority** for the induction machine block **Slip**, **Real power generated**, or **Mechanical power consumed** to High.

### **~1 — Stator positive-end connections**

electrical

Expandable three-phase port associated with the stator positive-end connections.

#### **Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

### **~2 — Stator negative-end connections**

electrical

Expandable three-phase port associated with the stator negative-end connections.

#### **Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

### **a1 — a positive-end connection**

electrical

Electrical conserving port associated with *a* positive-end connection.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

### **b1 — b positive-end connection**

electrical

Electrical conserving port associated with *b* positive-end connection.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c1 – c positive-end connection**

electrical

Electrical conserving port associated with *c* positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**a2 – a negative-end connection**

electrical

Electrical conserving port associated with *a* negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**b2 – b negative-end connection**

electrical

Electrical conserving port associated with *b* negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c2 – c negative-end connection**

electrical

Electrical conserving port associated with *c* negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**HA – a-phase terminal thermal port**

thermal

Thermal conserving port associated with stator winding *a*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HB – b-phase terminal thermal port**

thermal

Thermal conserving port associated with stator winding *b*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HC – c-phase terminal thermal port**

thermal

Thermal conserving port associated with stator winding *c*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HR — Rotor thermal port**

thermal

Thermal conserving port associated with the rotor.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters**

All default parameter values are based on a machine delta-winding configuration.

**Modeling option — Whether to enable thermal ports**

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of generated heat and motor temperature.

**Main****Electrical connection — Electrical connection**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

**Rated apparent power — Rated apparent power**

15e3 V\*A (default)

Rated apparent power of the induction machine at the electrical side.

**Rated voltage — RMS voltage**

220 V (default)

RMS line-line voltage.

**Rated electrical frequency — Nominal electrical frequency**

60 Hz (default)

Nominal electrical frequency corresponding to the rated apparent power.

**Number of pole pairs — Machine pole pairs**

1 (default)

Number of machine pole pairs.

**Parameterization unit — Unit system for block parameterization**

SI (default) | Per unit

Unit system for block parameterization. Choose between SI, the international system of units, and Per unit, the per-unit system.

**Dependencies**

Selecting:

- SI exposes SI parameters in the **Impedances** and **Saturation** settings.
- Per unit exposes per-unit parameters in the **Impedances** and **Saturation** settings.

**Squirrel cage — Squirrel cage specification option**

Single squirrel cage (default) | Double squirrel cage

Option to specify a single or double squirrel cage for the machine.

Setting this parameter to Double squirrel cage exposes **Impedances** parameters for the second cage.

**Zero sequence — Zero sequence**

Include (default) | Exclude

Zero-sequence model:

- Include — Prioritize model fidelity. An error occurs if you Include zero-sequence terms for simulations that use the Partitioning solver. For more information, see “Increase Simulation Speed Using the Partitioning Solver”.
- Exclude — Prioritize simulation speed for desktop simulation or real-time deployment.

**Dependencies**

If this parameter is set to:

- Include and **Parameterization unit** is set to SI — The **Stator zero-sequence reactance, X0** parameter in the **Impedances** settings is visible.
- Include and **Parameterization unit** is set to Per unit — The **Stator zero-sequence inductance, pu\_L0 (pu)** parameter in the **Impedances** settings is visible.
- Exclude — The stator zero-sequence parameter in the **Impedances** settings is not visible.

**Initialization option — Initialization method**

Set targets for flux variables (default) | Set targets for load flow variables

Initialization method. You can initialize a machine for steady-state simulation using either flux data or data from a load-flow analysis.

If you select Set targets for load flow variables, to fully specify the initial condition, you must include an initialization constraint in the form of a high-priority target value. For example, if your induction machine is connected to an Inertia block, the initial condition for the induction machine is completely specified if, in the **Initial Targets** section of the Inertia block, the **Priority** for **Rotational velocity** is set to High. Alternatively, you could set the **Priority** to None for the Inertia block **Rotational velocity**, and instead set the **Priority** for the induction machine block **Slip, Real power generated**, or **Mechanical power consumed** to High.

**Dependencies**

The type of variables that are visible in the **Initial Targets** section depends on the initialization method that you select, in the **Main** section, for the **Initialization option** parameter. To specify target values using:

- Flux variables — Set the **Initialization option** parameter to `Set targets for flux variables`.
- Data from a load-flow analysis — Set the **Initialization option** parameter to `Set targets for load flow variables`.

### **Impedances**

For the **Parameterization unit** parameter in the **Main** settings, select `SI` to expose SI parameters or `Per unit` to expose per-unit parameters.

#### **Stator resistance, $R_s$ — Stator resistance**

0.25 Ohm (default)

Stator resistance.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to `SI`.

#### **Stator leakage reactance, $X_{ls}$ — Stator leakage reactance**

0.4 Ohm (default)

Stator leakage reactance.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to `SI`.

#### **Referred rotor resistance, $R_r'$ — Referred rotor resistance**

0.14 Ohm (default)

Rotor resistance referred to the stator.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to `SI` and the **Squirrel cage** parameter in the **Main** setting to `Single squirrel cage`.

#### **Referred rotor leakage reactance, $X_{lr}'$ — Referred rotor leakage reactance**

0.41 Ohm (default)

Rotor leakage reactance referred to the stator.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to `SI` and the **Squirrel cage** parameter in the **Main** setting to `Single squirrel cage`.

#### **Referred rotor resistance in cage 1, $R_{r1}'$ — Referred rotor resistance in the first cage**

0.28 Ohm (default)

Rotor resistance in cage 1.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to SI and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Referred rotor leakage reactance in cage 1,  $X_{lr1}'$  — Referred rotor leakage reactance in the first cage**

0.82 Ohm (default)

Rotor leakage reactance in cage 1.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to SI and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Referred rotor resistance in cage 2,  $R_{r2}'$  — Referred rotor resistance in the second cage**

0.28 Ohm (default)

Rotor resistance in cage 2.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to SI and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Referred rotor leakage reactance in cage 2,  $X_{lr2}'$  — Referred rotor leakage reactance in the first cage**

0.82 Ohm (default)

Rotor leakage reactance in cage 2.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to SI and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Magnetizing reactance,  $X_m$  — Magnetizing reactance**

17 Ohm (default)

Magnetizing reactance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to SI.

**Stator zero-sequence reactance,  $X_0$  — Stator zero-sequence reactance**

0.4 Ohm (default)

Stator zero-sequence reactance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to SI and the **Zero sequence** parameter in the **Main** setting to Include.

**Stator resistance,  $R_s$  (pu) — Per-unit stator resistance**

0.0258 (default)

Per-unit stator resistance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit.

**Stator leakage inductance,  $L_{ls}$  (pu) — Per-unit stator leakage inductance**

0.0413 (default)

Per-unit stator leakage inductance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit.

**Referred rotor resistance,  $R_r'$  (pu) — Per-unit referred rotor resistance**

0.0145 (default)

Per-unit rotor resistance referred to the stator.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Squirrel cage** parameter in the **Main** setting to Single squirrel cage.

**Referred rotor leakage inductance,  $L_{lr}'$  (pu) — Per-unit referred rotor leakage inductance**

0.0424 (default)

Per-unit rotor leakage inductance referred to the stator.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Squirrel cage** parameter in the **Main** setting to Single squirrel cage.

**Referred rotor resistance in cage 1,  $R_{r1}'$  (pu) — Per-unit referred rotor resistance in cage 1**

0.0290 (default)

Per-unit rotor resistance in cage 1.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Referred rotor leakage inductance in cage 1,  $L_{lr1}'$  (pu) — Per-unit referred rotor leakage inductance**

0.0848 (default)

Per-unit rotor leakage inductance in cage 1.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Referred rotor resistance in cage 2,  $R_{r2'}$  (pu) — Per-unit referred rotor resistance in cage 2**

0.0290 (default)

Per-unit rotor resistance in cage 2.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Referred rotor leakage inductance in cage 2,  $L_{lr2'}$  (pu) — Per-unit referred rotor leakage inductance**

0.0848 (default)

Per-unit rotor leakage inductance in cage 2.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Squirrel cage** parameter in the **Main** setting to Double squirrel cage.

**Magnetizing inductance,  $L_m$  (pu) — Per-unit magnetizing inductance**

1.7562 (default)

Per-unit magnetizing inductance, that is, the peak value of stator-rotor mutual inductance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit.

**Stator zero-sequence inductance,  $L_0$  (pu) — Per-unit stator zero-sequence inductance**

0.0413 (default)

Per-unit stator zero-sequence inductance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit and the **Zero sequence** parameter in the **Main** setting to Include.

**Saturation**

For the **Parameterization unit** parameter in the **Main** settings, select SI to expose SI parameters or Per unit to expose per-unit parameters.

The saturation characteristic is based on the machine being connected in a delta-winding configuration.

**Magnetic saturation representation — Magnetic saturation representation**

None (default) | Open-circuit lookup table (v versus i)

Block magnetic saturation representation.

**Dependencies**

If this parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ), related parameters are visible.

**No-load line current saturation data,  $i$  (rms) — No-load line RMS current saturation data**

[0, 4, 9, 18, 25, 34, 50, 68, 95, 120] A (default)

Current  $i$  data populates the voltage  $v$  versus field current  $i$  lookup table. This parameter must contain a vector with at least 10 elements.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ) and, in the **Main** settings, the **Parameterization unit** parameter is set to SI.

**Terminal voltage saturation data,  $v$  (phase-phase, rms) — Terminal RMS voltage saturation data**

[0, 88, 154, 198, 220, 242, 264, 286, 308, 327] V (default)

Terminal voltage  $v$  data populates the voltage  $v$  versus current  $i$  lookup table. This parameter must contain a vector with at least 10 elements. The number of elements must match the number of elements in the vector for the **No-load line current saturation data,  $i$  (rms)** parameter.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ) and, in the **Main** settings, the **Parameterization unit** parameter is set to SI.

**Per-unit no-load line current saturation data,  $i$  — Per-unit no-load line current saturation data**

[0, .176, .396, .792, 1.1, 1.496, 2.2, 2.992, 4.18, 5.28] (default)

Current  $i$  data populates the voltage  $v$  versus field current  $i$  lookup table. This parameter must contain a vector with at least 10 elements.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ) and, in the **Main** settings, the **Parameterization unit** parameter is set to Per unit.

**Per-unit terminal voltage saturation data,  $v$  — Per-unit terminal voltage saturation data**

[0, .4, .7, .9, 1, 1.1, 1.2, 1.3, 1.4, 1.4864] (default)

Terminal voltage  $v$  data populates the voltage  $v$  versus current  $i$  lookup table. This parameter must contain a vector with at least 10 elements. The number of elements must match the number of elements in the vector for the **Per-unit no-load line current saturation data,  $i$**  parameter.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table (v versus i) and, in the **Main** settings, the **Parameterization unit** parameter is set to Per unit.

**Thermal**

These parameters appear only for blocks with exposed thermal ports.

**Measurement temperature — Rated temperature**

298.15 k (default) | real scalar

Temperature for which motor parameters are quoted.

**Resistance temperature coefficient — Temperature coefficient**

$3.93e-3$  1/K (default) | positive scalar

Coefficient  $\alpha$  in the equation relating resistance to temperature for all three windings, as described in “Thermal Model for Actuator Blocks”. The default value,  $3.93e-3$  1/K, is for copper.

**Cage resistance temperature coefficient — Rotor temperature coefficient**

$4.4e-3$  (default) | 1/K | scalar

Coefficient relating cage resistance to temperature for the rotor. The default value,  $4.4e-3$  1/K, is for aluminium.

**Thermal mass for each stator winding — Winding thermal mass**

100 J/K (default) | positive scalar

Thermal mass value for each stator winding. The thermal mass is the energy required to raise the temperature by one degree.

**Rotor thermal mass — Rotor thermal mass**

200 J/K (default) | positive scalar

Thermal mass of the rotor. The thermal mass is the energy required to raise the temperature of the rotor by one degree.

**Version History****Introduced in R2013b****Electrical connection ports update**

*Behavior changed in R2021b*

From R2021b forward, to switch between composite and expanded ports, set the **Electrical connection** parameter to either Composite three-phase ports or Expanded three-phase ports. Also, the simlog format is identical for Composite three-phase ports and Expanded three-phase ports.

As a result of these changes, inside a model saved in an earlier release, review the **Electrical connection** parameter of this block.

## Saturation characteristic update

*Behavior changed in R2020a*

From R2020a forward, for the saturation characteristic, the Induction Machine Squirrel Cage block takes into account the magnetic flux due to the leakage inductance.

The default values for these parameters have changed:

- **Stator leakage reactance,  $X_{ls}$**
- **Stator zero-sequence reactance,  $X_0$**
- **Stator leakage inductance,  $L_{ls}$  (pu)**
- **Stator zero-sequence inductance,  $L_0$  (pu)**
- **Terminal voltage saturation data,  $v$  (phase-phase, rms)**
- **Per-unit terminal voltage saturation data,  $v$**

As a result of these changes, inside a model saved in an earlier release, if you have used the Induction Machine Squirrel Cage block with saturation enabled, review the saturation data.

# Induction Machine Wound Rotor

Wound-rotor induction machine with per-unit or SI parameterization

**Library:** Simscape / Electrical / Electromechanical / Asynchronous

## Description

The Induction Machine Wound Rotor block models a wound-rotor asynchronous machine with fundamental parameters expressed in per-unit or in the International System of Units (SI). A wound-rotor asynchronous machine is a type of induction machine. All stator and rotor connections are accessible on the block. Therefore, you can model soft-start regimes using a switch between wye and delta configurations or by increasing rotor resistance. If you do not need access to the rotor windings, use the Induction Machine Squirrel Cage block instead.

Connect port **~1** to a three-phase circuit. To connect the stator in delta configuration, connect a Phase Permute block between ports **~1** and **~2**. To connect the stator in wye configuration, connect port **~2** to a Grounded Neutral or a Floating Neutral block. If you do not need to vary rotor resistance, connect rotor port **~1r'** to a Floating Neutral block and rotor port **~2r'** to a Grounded Neutral block.

The rotor circuit is referred to the stator. Therefore, when you use the block in a circuit, refer any additional circuit parameters to the stator.

## Induction Machine Initialization Using Load-Flow Target Values

If the block is in a network that is compatible with the frequency-time simulation mode, you can perform a load-flow analysis on the network. A load-flow analysis provides steady-state values that you can use to initialize the machine.

For more information, see “Perform a Load-Flow Analysis Using Simscape Electrical” and “Frequency and Time Simulation Mode”. For an example that shows how initialize an induction machine using data from a load flow analysis, see “Induction Motor Initialization with Loadflow”.

## Equations

For the SI implementation, the block converts the SI values that you enter to per-unit values for simulation. The converted values are based on the machine being connected in a delta-winding configuration.

For the per-unit implementation, you must specify the resistances and inductances in the impedances tab based on the machine being connected in a delta-winding configuration.

For information on the relationship between SI and per-unit machine parameters, see “Per-Unit Conversion for Machine Parameters”. For information on per-unit parameterization, see “Per-Unit System of Units”.

The asynchronous machine equations are expressed with respect to a synchronous reference frame, defined by

$$\theta_e(t) = \int_0^t 2\pi f_{rated} dt,$$

where  $f_{rated}$  is the value of the **Rated electrical frequency** parameter.

The Park transformation maps stator equations to a reference frame that is stationary with respect to the rated electrical frequency. The Park transformation is defined by

$$P_s = \frac{2}{3} \begin{bmatrix} \cos\theta_e & \cos(\theta_e - \frac{2\pi}{3}) & \cos(\theta_e + \frac{2\pi}{3}) \\ -\sin\theta_e & -\sin(\theta_e - \frac{2\pi}{3}) & -\sin(\theta_e + \frac{2\pi}{3}) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix},$$

where  $\theta_e$  is the electrical angle.

The rotor equations are mapped to another reference frame, defined by the difference between the electrical angle and the product of rotor angle  $\theta_r$  and number of pole pairs  $N$ :

$$P_r = \frac{2}{3} \begin{bmatrix} \cos(\theta_e - N\theta_r) & \cos(\theta_e - N\theta_r - \frac{2\pi}{3}) & \cos(\theta_e - N\theta_r + \frac{2\pi}{3}) \\ -\sin(\theta_e - N\theta_r) & -\sin(\theta_e - N\theta_r - \frac{2\pi}{3}) & -\sin(\theta_e - N\theta_r + \frac{2\pi}{3}) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix}.$$

The Park transformation is used to define the per-unit asynchronous machine equations. The stator voltage equations are defined by

$$v_{ds} = \frac{1}{\omega_{base}} \frac{d\psi_{ds}}{dt} - \omega\psi_{qs} + R_s i_{ds},$$

$$v_{qs} = \frac{1}{\omega_{base}} \frac{d\psi_{qs}}{dt} + \omega\psi_{ds} + R_s i_{qs},$$

and

$$v_{0s} = \frac{1}{\omega_{base}} \frac{d\psi_{0s}}{dt} + R_s i_{0s},$$

where:

- $v_{ds}$ ,  $v_{qs}$ , and  $v_{0s}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence stator voltages, defined by

$$\begin{bmatrix} v_{ds} \\ v_{qs} \\ v_{0s} \end{bmatrix} = P_s \begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix}.$$

$v_a$ ,  $v_b$ , and  $v_c$  are the stator voltages across ports ~1 and ~2.

- $\omega_{base}$  is the per-unit base electrical speed.
- $\psi_{ds}$ ,  $\psi_{qs}$ , and  $\psi_{0s}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence stator flux linkages.
- $R_s$  is the stator resistance.
- $i_{ds}$ ,  $i_{qs}$ , and  $i_{0s}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence stator currents, defined by

$$\begin{bmatrix} i_{ds} \\ i_{qs} \\ i_{0s} \end{bmatrix} = P_s \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix}.$$

$i_a$ ,  $i_b$ , and  $i_c$  are the stator currents flowing from port  $\sim 1$  to port  $\sim 2$ .

The rotor voltage equations are defined by

$$v_{dr} = \frac{1}{\omega_{base}} \frac{d\psi_{dr}}{dt} - (\omega - \omega_r)\psi_{qr} + R_{rd}i_{dr},$$

$$v_{qr} = \frac{1}{\omega_{base}} \frac{d\psi_{qr}}{dt} + (\omega - \omega_r)\psi_{dr} + R_{rd}i_{qr},$$

and

$$v_{0r} = \frac{1}{\omega_{base}} \frac{d\psi_{0r}}{dt} + R_{rd}i_{0s},$$

where:

- $v_{dr}$ ,  $v_{qr}$ , and  $v_{0r}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence rotor voltages, defined by

$$\begin{bmatrix} v_{dr} \\ v_{qr} \\ v_{0r} \end{bmatrix} = P_r \begin{bmatrix} v_{ar} \\ v_{br} \\ v_{cr} \end{bmatrix}.$$

$v_{ar}$ ,  $v_{br}$ , and  $v_{cr}$  are the rotor voltages across ports  $\sim 1r'$  and  $\sim 2r'$ .

- $\psi_{dr}$ ,  $\psi_{qr}$ , and  $\psi_{0r}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence rotor flux linkages.
- $\omega$  is the per-unit synchronous speed. For a synchronous reference frame, the value is 1.
- $\omega_r$  is the per-unit mechanical rotational speed.
- $R_{rd}$  is the rotor resistance referred to the stator.
- $i_{dr}$ ,  $i_{qr}$ , and  $i_{0r}$  are the  $d$ -axis,  $q$ -axis, and zero-sequence rotor currents, defined by

$$\begin{bmatrix} i_{dr} \\ i_{qr} \\ i_{0r} \end{bmatrix} = P_r \begin{bmatrix} i_{ar} \\ i_{br} \\ i_{cr} \end{bmatrix}.$$

$i_{ar}$ ,  $i_{br}$ , and  $i_{cr}$  are the rotor currents flowing from port  $\sim 1r'$  to port  $\sim 2r'$ .

The stator flux linkage equations are defined by

$$\psi_{ds} = L_{ss}i_{ds} + L_m i_{dr},$$

$$\psi_{qs} = L_{ss}i_{qs} + L_m i_{qr},$$

and

$$\psi_{0s} = L_{ss}i_{0s},$$

where  $L_{ss}$  is the stator self-inductance and  $L_m$  is the magnetizing inductance.

The rotor flux linkage equations are defined by

$$\psi_{dr} = L_{rrd}i_{dr} + L_m i_{ds}$$

$$\psi_{qr} = L_{rrd}i_{qr} + L_m i_{qs},$$

and

$$\psi_{0r} = L_{rrd}i_{0r},$$

where  $L_{rrd}$  is the rotor self-inductance referred to the stator.

The rotor torque is defined by

$$T = \psi_{ds}i_{qs} - \psi_{qs}i_{ds}.$$

The stator self-inductance  $L_{ss}$ , stator leakage inductance  $L_{ls}$ , and magnetizing inductance  $L_m$  are related by

$$L_{ss} = L_{ls} + L_m.$$

The rotor self-inductance  $L_{rrd}$ , rotor leakage inductance  $L_{lr}$ , and magnetizing inductance  $L_m$  are related by

$$L_{rrd} = L_{lr} + L_m.$$

When a saturation curve is provided, the equations to determine the saturated magnetizing inductance as a function of magnetizing flux are:

$$L_{m\_sat} = f(\psi_m)$$

$$\psi_m = \sqrt{\psi_{dm}^2 + \psi_{qm}^2}$$

For no saturation, the equation reduces to

$$L_{m\_sat} = L_m$$

### Plotting and Display Options

You can perform plotting and display actions using the **Electrical** menu on the block context menu.

Right-click the block and, from the **Electrical** menu, select an option:

- **Display Base Values** — Displays the machine per-unit base values in the MATLAB Command Window.
- **Plot Torque Speed (SI)** — Plots torque versus speed, both measured in SI units, in a MATLAB figure window using the current machine parameters.
- **Plot Torque Speed (pu)** — Plots torque versus speed, both measured in per-unit, in a MATLAB figure window using the current machine parameters.

- **Plot Open-Circuit Saturation** — Plots terminal voltage versus no-load line current, both in per-unit, in a MATLAB figure window. The plot contains three traces:
  - Unsaturated — Stator magnetizing inductance (unsaturated).
  - Saturated — Open-circuit lookup table ( $v$  versus  $i$ ) you specify.
  - Derived — Open-circuit lookup table derived from the per-unit open-circuit lookup table ( $v$  versus  $i$ ) you specify. This data is used to calculate the saturated magnetizing inductance,  $L_{m\ sat}$ , and the saturation factor,  $K_s$ , versus magnetic flux linkage,  $\psi_m$ , characteristics.
- **Plot Saturation Factor** — Plots saturation factor,  $K_s$ , versus magnetic flux linkage,  $\psi_m$ , in a MATLAB figure window using the machine parameters. This parameter is derived from other parameters that you specify:
  - No-load line current saturation data,  $i$
  - Terminal voltage saturation data,  $v$
  - Leakage inductance,  $L_{ls}$
- **Plot Saturated Inductance** — Plots magnetizing inductance,  $L_{m\ sat}$ , versus magnetic flux linkage,  $\psi_m$ , in a MATLAB figure window using the machine parameters. This parameter is derived from other parameters that you specify:
  - No-load line current saturation data,  $i$
  - Terminal voltage saturation data,  $v$
  - Leakage inductance,  $L_{ls}$

For the SI implementation,  $v$  is in V (phase-phase RMS) and  $i$  is in A (rms).

### Model Thermal Effects

You can expose thermal ports to simulate the effects of generated heat and motor temperature. To expose the thermal ports and the **Thermal** parameters, set the **Modeling option** parameter to either:

- **No thermal port** — The block contains electrical conserving ports associated with the stator windings, but does not contain thermal ports.
- **Show thermal port** — The block contains expanded electrical conserving ports associated with the stator windings and thermal conserving ports for each of the windings and for the rotor.

For more information about using thermal ports in actuator blocks, see “Simulating Thermal Effects in Rotational and Translational Actuators”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

The type of variables that are visible in the **Initial Targets** section depends on the initialization method that you select, in the **Main** section, for the **Initialization option** parameter. To specify target values using:

- Flux variables — Set the **Initialization option** parameter to `Set targets for flux variables`.
- Data from a load-flow analysis — Set the **Initialization option** parameter to `Set targets for load flow variables`.

If you select `Set targets for load flow variables`, to fully specify the initial condition, you must include an initialization constraint in the form of a high-priority target value. For example, if your induction machine is connected to an Inertia block, the initial condition for the induction machine is completely specified if, in the **Initial Targets** section of the Inertia block, the **Priority** for **Rotational velocity** is set to `High`. Alternatively, you could set the **Priority** to `None` for the Inertia block **Rotational velocity**, and instead set the **Priority** for the induction machine block **Slip, Real power generated**, or **Mechanical power consumed** to `High`.

## Ports

### Output

#### **pu — Per-unit measurements output port**

physical

Physical signal vector port associated with the machine per-unit measurements. The vector elements are:

- *pu\_torque*
- *pu\_velocity*
- *pu\_vds*
- *pu\_vqs*
- *pu\_v0s*
- *pu\_ids*
- *pu\_iqs*
- *pu\_i0s*

### Conserving

#### **R — Machine rotor**

mechanical

Mechanical rotational conserving port associated with the machine rotor.

#### **C — Machine case**

mechanical

Mechanical rotational conserving port associated with the machine case.

#### **~1 — Stator positive-end connections**

electrical

Expandable three-phase port associated with the stator positive-end connections.

**Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

**~2 — Stator negative-end connections**

electrical

Expandable three-phase port associated with the stator negative-end connections.

**Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

**~1r' — Rotor positive-end connections**

electrical

Expandable three-phase port associated with the rotor positive-end connections.

**Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

**~2r' — Rotor negative-end connections**

electrical

Expandable three-phase port associated with the rotor negative-end connections.

**Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

**a1 — a stator positive-end connection**

electrical

Electrical conserving port associated with *a* stator positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**b1 — b stator positive-end connection**

electrical

Electrical conserving port associated with *b* stator positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c1 — c stator positive-end connection**

electrical

Electrical conserving port associated with *c* stator positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**a2 — a stator negative-end connection**

electrical

Electrical conserving port associated with *a* stator negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**b2 — b stator negative-end connection**

electrical

Electrical conserving port associated with *b* stator negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c2 — c negative-end connection**

electrical

Electrical conserving port associated with *c* stator negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**a1r' — a rotor positive-end connection**

electrical

Electrical conserving port associated with *a* rotor positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**b1r' — b rotor positive-end connection**

electrical

Electrical conserving port associated with *b* rotor positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c1r' — c rotor positive-end connection**

electrical

Electrical conserving port associated with *c* rotor positive-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**a2r' — a rotor negative-end connection**

electrical

Electrical conserving port associated with *a* rotor negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**b2r' — b rotor negative-end connection**

electrical

Electrical conserving port associated with *b* rotor negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**c2r' — c rotor-end connection**

electrical

Electrical conserving port associated with *c* rotor negative-end connection.

**Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

**HA — a-phase terminal thermal port**

thermal

Thermal conserving port associated with stator winding *a*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HB — b-phase terminal thermal port**

thermal

Thermal conserving port associated with stator winding *b*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HC — c-phase terminal thermal port**

thermal

Thermal conserving port associated with stator winding *c*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HAr — a-phase terminal thermal port**

thermal

Thermal conserving port associated with rotor winding *a*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HBr – b-phase terminal thermal port**

thermal

Thermal conserving port associated with rotor winding *b*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**HCr – c-phase terminal thermal port**

thermal

Thermal conserving port associated with rotor winding *c*.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters**

All default parameter values are based on a machine delta-winding configuration.

**Modeling option – Whether to enable thermal ports**

No thermal port (default) | Show thermal port

Whether to enable the thermal ports of the block and model the effects of generated heat and motor temperature.

**Main****Electrical connection – Electrical connection**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

**Rated apparent power – Rated apparent power**

15e3 V\*A (default)

Rated apparent power of the induction machine.

**Rated voltage – RMS voltage**

220 V (default)

RMS line-line voltage.

**Rated electrical frequency – Nominal electrical frequency**

60 Hz (default)

Nominal electrical frequency corresponding to the rated apparent power.

**Number of pole pairs – Machine pole pairs**

1 (default)

Number of machine pole pairs.

**Parameterization unit — Unit system for block parameterization**

SI (default) | Per unit

Unit system for block parameterization. Choose between SI, the international system of units, and Per unit, the per-unit system.

**Dependencies**

Selecting:

- SI exposes SI parameters in the **Impedances** and **Saturation** settings.
- Per unit exposes per-unit parameters in the **Impedances** and **Saturation** settings.

**Zero sequence — Zero sequence**

Include (default) | Exclude

Zero-sequence model:

- Include — Prioritize model fidelity. An error occurs if you Include zero-sequence terms for simulations that use the Partitioning solver. For more information, see “Increase Simulation Speed Using the Partitioning Solver”.
- Exclude — Prioritize simulation speed for desktop simulation or real-time deployment.

**Dependencies**

If this parameter is set to:

- Include and **Parameterization unit** is set to SI — The **Stator zero-sequence reactance, X0** parameter in the **Impedances** settings is visible.
- Include and **Parameterization unit** is set to Per unit — The **Stator zero-sequence inductance, L0 (pu)** parameter in the **Impedances** settings is visible.
- Exclude — The stator zero-sequence parameter in the **Impedances** settings is not visible.

**Initialization option — Initialization method**

Set targets for flux variables (default) | Set targets for load flow variables

Initialization method. You can initialize a machine for steady-state simulation using either flux data or data from a load-flow analysis.

If you select Set targets for load flow variables, to fully specify the initial condition, you must include an initialization constraint in the form of a high-priority target value. For example, if your induction machine is connected to an Inertia block, the initial condition for the induction machine is completely specified if, in the **Initial Targets** section of the Inertia block, the **Priority** for **Rotational velocity** is set to High. Alternatively, you could set the **Priority** to None for the Inertia block **Rotational velocity**, and instead set the **Priority** for the induction machine block **Slip, Real power generated**, or **Mechanical power consumed** to High.

**Dependencies**

The type of variables that are visible in the **Initial Targets** section depends on the initialization method that you select, in the **Main** section, for the **Initialization option** parameter. To specify target values using:

- Flux variables — Set the **Initialization option** parameter to Set targets for flux variables.

- Data from a load-flow analysis — Set the **Initialization option** parameter to **Set targets** for load flow variables.

### **Impedances**

For the **Parameterization unit** parameter in the **Main** settings, select **SI** to expose SI parameters or **Per unit** to expose per-unit parameters.

#### **Stator resistance, $R_s$ — Stator resistance**

0.25 Ohm (default)

Stator resistance.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **SI**.

#### **Stator leakage reactance, $X_l$ — Stator leakage reactance**

0.4 Ohm (default)

Stator leakage reactance.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **SI**.

#### **Referred rotor resistance, $R_r'$ — Referred rotor resistance**

0.14 Ohm (default)

Rotor resistance referred to the stator.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **SI**.

#### **Referred rotor leakage reactance, $X_{lr}'$ — Referred rotor leakage reactance**

0.41 Ohm (default)

Rotor leakage reactance referred to the stator.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **SI**.

#### **Magnetizing reactance, $X_m$ — Magnetizing reactance**

17 Ohm (default)

Magnetizing reactance.

#### **Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **SI**.

**Stator zero-sequence reactance,  $X_0$  — Stator zero-sequence reactance**

0.4 Ohm (default)

Stator zero-sequence reactance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **SI**.

**Stator resistance,  $R_s$  (pu) — Per-unit stator resistance**

0.0258 (default)

Per-unit stator resistance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **Per unit**.

**Stator leakage inductance,  $L_{ls}$  (pu) — Per-unit stator leakage inductance**

0.0413 (default)

Per-unit stator leakage inductance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **Per unit**.

**Referred rotor resistance,  $R_r'$  (pu) — Per-unit referred rotor resistance**

0.0145 (default)

Per-unit rotor resistance referred to the stator.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **Per unit**.

**Referred rotor leakage inductance,  $L_{lr}'$  (pu) — Per-unit referred rotor leakage inductance**

0.0424 (default)

Per-unit rotor leakage inductance referred to the stator.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to **Per unit**.

**Magnetizing inductance,  $L_m$  (pu) — Per-unit magnetizing inductance**

1.7562 (default)

Per-unit magnetizing inductance, that is, the peak value of stator-rotor mutual inductance.

**Dependencies**

This parameter is visible only if you set the **Parameterization unit** parameter in the **Main** setting to Per unit.

**Stator zero-sequence inductance,  $L_0$  (pu) — Per-unit stator zero-sequence inductance**  
0.0413 (default)

Per-unit stator zero-sequence inductance.

**Dependencies**

This parameter is visible only if, in the **Main** settings, the **Parameterization unit** parameter is set to Per unit and the **Zero sequence** parameter is set to Include.

**Saturation**

For the **Parameterization unit** parameter in the **Main** settings, select SI to expose SI parameters or Per unit to expose per-unit parameters.

The saturation characteristic is based on the machine being connected in a delta-winding configuration.

**Magnetic saturation representation — Magnetic saturation representation**  
None (default) | Open-circuit lookup table (v versus i)

Block magnetic saturation representation.

**Dependencies**

If this parameter is set to Open-circuit lookup table (v versus i), related parameters are visible.

**No-load line current saturation data,  $i$  (rms) — No-load line RMS current saturation data**  
[0, 4, 9, 18, 25, 34, 50, 68, 95, 120] A (default)

Current  $i$  data populates the voltage  $v$  versus field current  $i$  lookup table. This parameter must contain a vector with at least 10 elements.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table (v versus i) and, in the **Main** settings, the **Parameterization unit** parameter is set to SI.

**Terminal voltage saturation data,  $v$  (phase-phase, rms) — Terminal RMS voltage saturation data**  
[0, 88, 154, 198, 220, 242, 264, 286, 308, 327] V (default)

Terminal voltage  $v$  data populates the voltage  $v$  versus current  $i$  lookup table. This parameter must contain a vector with at least 10 elements. The number of elements must match the number of elements in the vector for the **No-load line current saturation data,  $i$  (rms)** parameter.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ) and, in the **Main** settings, the **Parameterization unit** parameter is set to SI.

**Per-unit no-load line current saturation data,  $i$  — Per-unit no-load line current saturation data**

[0, .176, .396, .792, 1.1, 1.496, 2.2, 2.992, 4.18, 5.28] (default)

Current  $i$  data populates the voltage  $v$  versus field current  $i$  lookup table. This parameter must contain a vector with at least 10 elements.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ) and, in the **Main** settings, the **Parameterization unit** parameter is set to Per unit.

**Per-unit terminal voltage saturation data,  $v$  — Per-unit terminal voltage saturation data**

[0, .4, .7, .9, 1, 1.1, 1.2, 1.3, 1.4, 1.4864] (default)

Terminal voltage  $v$  data populates the voltage  $v$  versus current  $i$  lookup table. This parameter must contain a vector with at least 10 elements. The number of elements must match the number of elements in the vector for the **Per-unit no-load line current saturation data,  $i$**  parameter.

**Dependencies**

This parameter is visible only if the **Magnetic saturation representation** parameter is set to Open-circuit lookup table ( $v$  versus  $i$ ) and, in the **Main** settings, the **Parameterization unit** parameter is set to Per unit.

**Thermal**

These parameters appear only for blocks with exposed thermal ports.

**Measurement temperature — Rated temperature**

298.15 k (default) | real scalar

Temperature for which motor parameters are quoted.

**Resistance temperature coefficient — Temperature coefficient**

$3.93e-3$  1/K (default) | positive scalar

Coefficient  $\alpha$  in the equation relating resistance to temperature for all three windings, as described in “Thermal Model for Actuator Blocks”. The default value,  $3.93e-3$  1/K, is for copper.

**Thermal mass for each stator winding — Winding thermal mass**

100 J/K (default) | positive scalar

Thermal mass value for each stator winding. The thermal mass is the energy required to raise the temperature by one degree.

**Rotor thermal mass — Rotor thermal mass**

200 J/K (default) | positive scalar

Thermal mass of the rotor. The thermal mass is the energy required to raise the temperature of the rotor by one degree.

## Version History

### Introduced in R2013b

#### Electrical connection ports update

*Behavior changed in R2021b*

From R2021b forward, to switch between composite and expanded ports, set the **Electrical connection** parameter to either Composite three-phase ports or Expanded three-phase ports. Also, the simlog format is identical for Composite three-phase ports and Expanded three-phase ports.

As a result of these changes, inside a model saved in an earlier release, review the **Electrical connection** parameter of this block.

#### Saturation characteristic update

*Behavior changed in R2020a*

From R2020a forward, for the saturation characteristic, the Induction Machine Wound Rotor block takes into account the magnetic flux due to the leakage inductance.

The default values for these parameters have changed:

- **Stator leakage reactance,  $X_{ls}$**
- **Stator zero-sequence reactance,  $X_0$**
- **Stator leakage inductance,  $L_{ls}$  (pu)**
- **Stator zero-sequence inductance,  $L_0$  (pu)**
- **Terminal voltage saturation data,  $v$  (phase-phase, rms)**
- **Per-unit terminal voltage saturation data,  $v$**

As a result of these changes, inside a model saved in an earlier release, if you have used the Induction Machine Wound Rotor block with saturation enabled, review the saturation data.

# Induction Machine Field-Oriented Control (Single-Phase)

Per-unit discrete-time single-phase induction machine field-oriented control

**Library:** Simscape / Electrical / Control / Induction Machine Control

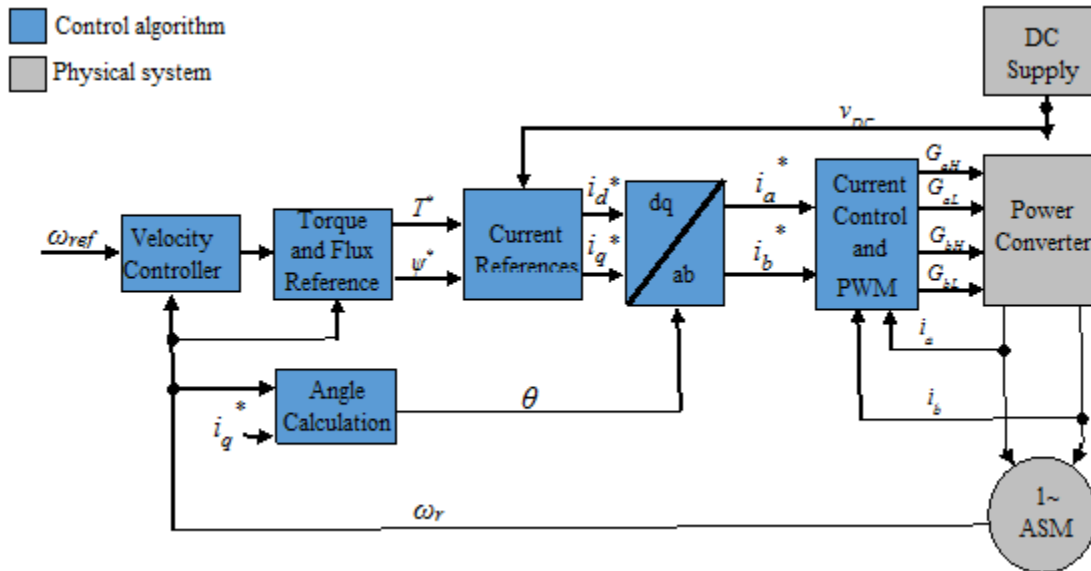

## Description

The Induction Machine Field-Oriented Control (Single-Phase) block implements a single-phase induction machine field-oriented control structure.

## Equations

The field-oriented control architecture for a single-phase induction machine is:

You can provide the torque reference as an input, or, in the case of speed control, generate the reference internally using a PI speed controller. The torque reference as derived from a PI speed controller is:

$$T^* = (K_{p_\omega} + K_{i_\omega} \frac{T_s z}{z-1})(\omega_{ref} - \omega_r)$$

where  $\omega_r$  is the rotor angular mechanical speed in rad/s.

The block generates the flux reference as

$$\psi^* = \frac{2\pi f_n \psi_n}{p \min\left(\left|\omega_r\right|, \frac{2\pi f_n}{p}\right)}$$

where:

- $p$  is the number of pole pairs.
- $f_n$  is the rated frequency.
- $\psi_n$  is the rated flux.

Current references are obtained from machine parameters:

$$i_q^* = \frac{(L_{ms} + L_{lar})T^*}{paL_{ms}\psi^*}$$

$$i_d^* = \frac{\psi^*}{a^2L_{ms}}$$

where:

- $L_{ms}$  is the main winding mutual inductance.
- $L_{lar}$  is the main winding rotor leakage inductance.
- $a$  is the auxiliary-to-main windings turn ratio.

The angle is calculated by solving:

$$\frac{d\theta}{dt} = p\omega_r + \frac{a^3L_{ms}R_{ar}}{\psi^*(L_{ms} + L_{lar})}$$

The transformation to the stationary reference frame is done by using:

$$\begin{pmatrix} i_a \\ i_b \end{pmatrix} = \begin{pmatrix} a^2 \sin(\theta) & a^2 \cos(\theta) \\ \cos(\theta) & -\sin(\theta) \end{pmatrix} \begin{pmatrix} i_d \\ i_q \end{pmatrix}$$

### Limitations

- The control structure is implemented in a single sample rate.

## Ports

### Input

#### Reference — Torque or angular velocity reference

scalar

Specify the angular velocity reference, in rad/s, or the torque reference, in Nm.

Data Types: `single` | `double`

#### **iab** — Stator currents

scalar

Stator currents for main and auxiliary windings.

Data Types: `single` | `double`

### **wr — Rotor angular speed**

scalar

Measured rotor angular speed, in rad/s.

Data Types: `single` | `double`

## **Output**

### **G — Inverter gate pulses**

`0` | `1`

Inverter gate pulses, specified as a Boolean. The dead-time is not considered.

Data Types: `single` | `double`

### **Visualization — Internal signals for visualization**

`Reference` | `Rotor velocity` |  `$\theta$`  | `iab` | `iabRef` | `TqRef` | `FluxRef`

Bus containing internal signals for visualization. The signals are:

- Reference torque or speed
- Rotor velocity, in rad/s
- $\theta$ , in radians
- Stator currents (*iab*), in A
- Stator current reference (*iabRef*), in A
- Torque Reference (*TqRef*), in Nm
- Flux Reference (*FluxRef*), in Wb

Data Types: `single` | `double` | `bus`

## **Parameters**

### **General**

#### **Control mode — Specify control mode**

`Speed control` (default) | `Torque control`

Specify the control mode. The reference input is taken as angular speed, in rad/s, for `Speed control` and torque, in Nm for `Torque control`.

#### **Rated electrical frequency (Hz) — Specify rated electrical frequency**

`60` (default) | positive scalar

Rated electrical frequency, in Hz.

#### **Number of pole pairs — Specify pole pairs**

`2` (default) | positive scalar

Number of pole pairs.

**Main winding rotor resistance,  $R_{ar}'$  (Ohm) – Specify main winding rotor resistance**

3.7080 (default) | positive scalar

Main winding rotor resistance, in Ohms.

**Main winding rotor leakage inductance,  $L_{lar}'$  (H) – Specify main winding rotor leakage inductance**

0.0050 (default) | positive scalar

Main winding rotor leakage inductance, in H.

**Main winding mutual inductance,  $L_{ms}$  (H) – Specify main winding mutual inductance**

0.1595 (default) | positive scalar

Main winding mutual inductance, in H.

**Auxiliary/main windings turn ratio – Specify the auxiliary-to-main windings turn ratio**

1.1 (default) | positive scalar

Auxiliary-to-main windings turns ratio.

**Fundamental sample time (s) – Specify the block sample time**

5e-6 (default) | positive scalar

Sample time for the block, in s.

**Control sample time (s) – Specify the control sample time**

5e-5 (default) | positive scalar

Control sample time, in s.

**Outer Loop**

This table shows how the visibility of some parameters in the **Outer Loop** tab depend on the option that you choose for the **Control mode** parameter in the **General** tab.

Control mode	Available Parameters
Speed control	Speed controller proportional gain
	Speed controller integral gain
	Speed controller integral anti-windup gain
	Maximum torque (Nm)
	Minimum torque (Nm)
Torque control	Rated flux (Wb)
	Rated flux (Wb)

**Speed controller proportional gain – Specify the speed controller proportional gain**

1 (default) | positive scalar

Proportional gain for the PI speed controller.

**Speed controller integral gain – Specify the speed controller integral gain**

10 (default) | positive scalar

Integral gain for the PI speed controller.

**Speed controller integral anti-windup gain — Specify the speed controller integral anti-windup gain**

1000 (default) | positive scalar

Integral anti-windup gain.

**Maximum torque (Nm) — Specify the maximum torque**

5 (default) | positive scalar

Maximum torque used in speed controller saturation, in Nm.

**Minimum torque (Nm) — Specify the minimum torque**

-5 (default) | scalar

Minimum torque used in speed controller saturation, in Nm.

**Rated flux (Wb) — Specify the rated flux**

0.5 (default) | positive scalar

Rated flux, in Wb. The rated flux is used to compute the flux reference.

**Inner Loop**

This table shows how the visibility of some parameters in the **Inner Loop** tab depend on the option that you choose for the **Control type** parameter.

Control type	Available Parameters
Hysteresis control	Current hysteresis band (A)
PI control	A-phase current proportional gain
	A-phase current integral gain
	A-phase current anti-windup gain
	B-phase current proportional gain
	B-phase current integral gain
	B-phase current anti-windup gain

**Control type — Specify the control type**

Hysteresis control (default) | PI control

Control type for current control loop.

**Current hysteresis band (A) — Specify the current hysteresis band**

0.5 (default) | positive scalar

Current hysteresis band for the controller, in A.

**A-phase current proportional gain — Main winding current proportional gain**

1 (default) | positive scalar

Proportional gain for the A-phase (main winding) controller current.

**A-phase current integral gain – Main winding current integral gain**

500 (default)

Integral gain for the A-phase (main winding) controller current.

**A-phase current anti-windup gain – Main winding current anti-windup gain**

1000 (default)

Anti-windup gain for the A-phase (main winding) controller current.

**B-phase current proportional gain – Auxiliary winding current proportional gain**

1 (default)

Proportional gain for the B-phase (auxiliary winding) controller current.

**B-phase current integral gain – Auxiliary winding current integral gain**

500 (default)

Integral gain for the B-phase (auxiliary winding) controller current.

**B-phase current anti-windup gain – Auxiliary winding current anti-windup gain**

1000 (default)

Anti-windup gain for the B-phase (auxiliary winding) controller current.

# Inductor

Inductor including optional tolerance, operational limits and fault behavior

**Library:** Simscape / Electrical / Passive

## Description

The Inductor block lets you model linear inductors, including the following effects:

- “Tolerances” on page 1-868
- “Operating Limits” on page 1-869
- “Faults” on page 1-869

You can turn these modeling options on and off independently of each other. When all the additional options are turned off, the component behavior is identical to the Simscape Foundation library Inductor block.

In its simplest form, the Inductor block models a linear inductor, described with the following equation:

$$V = L \frac{dI}{dt}$$

where:

- $V$  is voltage.
- $L$  is inductance.
- $I$  is current.
- $t$  is time.

To model a nonlinear inductor, use the Nonlinear Inductor block.

## Tolerances

You can apply tolerances to the nominal value you provide for the **Inductance** parameter. Datasheets typically provide a tolerance percentage for a given inductor type. The table shows how the block applies tolerances and calculates inductance based on the selected **Tolerance application** option.

Option	Inductance Value
None – use nominal value	$L$
Random tolerance	Uniform distribution: $L \cdot (1 - tol + 2 \cdot tol \cdot rand)$ Gaussian distribution: $L \cdot (1 + tol \cdot randn / nSigma)$
Apply maximum tolerance value	$L \cdot (1 + tol)$

Option	Inductance Value
Apply minimum tolerance value	$L \cdot (1 - tol)$

In the table,

- $L$  is the **Inductance** parameter value, nominal inductance.
- $tol$  is fractional tolerance, **Inductance tolerance (%)** /100.
- $nSigma$  is the value you provide for the **Number of standard deviations for quoted tolerance** parameter.
- `rand` and `randn` are standard MATLAB functions for generating uniform and normal distribution random numbers.

---

**Note** If you choose the `Random tolerance` option and you are in "Fast Restart" mode, the random tolerance value is updated on every simulation if at least one between the fractional tolerance,  $tol$ , or the **Number of standard deviations for quoted tolerance**,  $nSigma$ , is set to Run-time and is defined with a variable (even if you do not modify that variable).

---

### Operating Limits

Inductors are typically rated with a particular saturation current, and possibly with a maximum allowable power dissipation. You can specify operating limits in terms of these values, to generate warnings or errors if the inductor is driven outside its specification.

When an operating limit is exceeded, the block can either generate a warning or stop the simulation with an error. For more information, see the "Operating Limits" on page 1-872 parameters section.

### Faults

Instantaneous changes in inductor parameters are unphysical. Therefore, when the Inductor block enters the faulted state, short-circuit and open-circuit voltages transition to their faulted values over a period of time based on this formula:

$$CurrentValue = FaultedValue - (FaultedValue - UnfaultedValue) \cdot \operatorname{sech}(\Delta t / \tau)$$

where:

- $\Delta t$  is time since the onset of the fault condition.
- $\tau$  is user-defined time constant associated with the fault transition.

For short-circuit faults, the conductance of the short-circuit path also changes according to the  $\operatorname{sech}(\Delta t / \tau)$  function from a small value (representing an open-circuit path) to a large value.

The block can trigger the start of fault transition:

- At a specific time
- After voltage exceeds the maximum permissible value a certain number of times
- When current exceeds the maximum permissible value for longer than a specific time interval

You can enable or disable these trigger mechanisms separately, or use them together if more than one trigger mechanism is required in a simulation. When more than one mechanism is enabled, the first

mechanism to trigger the fault transition takes precedence. In other words, a component fails no more than once per simulation.

You can also choose whether to issue an assertion when a fault occurs, by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

Faultable inductors often require that you use the fixed-step local solver rather than the variable-step solver. In particular, if you model transitions to a faulted state that include short circuits, MathWorks recommends that you use the fixed-step local solver. For more information, see “Making Optimal Solver Choices for Physical Simulation”.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

The **Inductor current** variable lets you specify a high-priority target for the initial inductor current at the start of simulation.

## Ports

### Conserving

#### + – Positive terminal

electrical

Electrical conserving port associated with the inductor positive terminal.

#### - – Negative terminal

electrical

Electrical conserving port associated with the inductor negative terminal.

## Parameters

### Main

#### Inductance – Nominal inductance value

1e-6 H (default)

The nominal inductance value. Inductance value must be greater than zero.

#### Tolerance (%) – Inductor tolerance, in percent

20 (default)

The inductor tolerance as defined on the manufacturer datasheet.

**Tolerance application — Select how to apply tolerance during simulation**

None — use nominal value (default) | Random tolerance | Apply maximum tolerance value | Apply minimum tolerance value

Select how to apply tolerance during simulation:

- **None — use nominal value** — The block does not apply tolerance, it uses the nominal inductance value.
- **Random tolerance** — The block applies random offset to the inductance value, within the tolerance value limit. You can choose Uniform or Gaussian distribution for calculating the random number by using the **Tolerance distribution** parameter.
- **Apply maximum tolerance value** — The inductance is increased by the specified tolerance percent value.
- **Apply minimum tolerance value** — The inductance is decreased by the specified tolerance percent value.

**Tolerance distribution — Select the distribution type**

Uniform (default) | Gaussian

Select the distribution type for random tolerance:

- **Uniform** — Uniform distribution
- **Gaussian** — Gaussian distribution

**Dependencies**

Enabled when the **Tolerance application** parameter is set to Random tolerance.

**Number of standard deviations for quoted tolerance — Used for calculating the Gaussian random number**

4 (default)

Number of standard deviations for calculating the Gaussian random number.

**Dependencies**

Enabled when the **Tolerance distribution** parameter is set to Gaussian.

**Series resistance — Equivalent series resistance of the inductor**

0 Ohm (default)

Equivalent series resistance (ESR) of the inductor, as sometimes specified on manufacturer datasheets. The default value is consistent with the Simscape Foundation library Inductor block. If you model faults, specify a positive value for this parameter.

**Parallel conductance — Parallel leakage path associated with the inductor**

1e-9 1/Ohm (default)

Parallel leakage path associated with the inductor. Simulation of some circuits may require the presence of a small parallel conductance. You can also use this parameter to model the inductor core losses.

## Operating Limits

### Enable operating limits — Select Yes to enable reporting when the operational limits are exceeded

No (default) | Yes

Select Yes to enable reporting when the operational limits are exceeded. The associated parameters in the **Operating Limits** section become visible to let you select the reporting method and specify the operating limits in terms of power and current.

### Reporting when operating limits exceeded — Select the reporting method

Warn (default) | Error

Select what happens when an operating limit is exceeded:

- Warn — The block issues a warning.
- Error — Simulation stops with an error.

## Dependencies

Enabled when the **Enable operating limits** parameter is set to Yes.

### Saturation current — Inductor saturation current

1 A (default)

Inductor saturation current, as defined in the manufacturer datasheets. If the current exceeds this value, the core material enters saturation.

## Dependencies

Enabled when the **Enable operating limits** parameter is set to Yes.

### Power rating — Maximum power dissipation in the inductor

1 W (default)

Maximum instantaneous power dissipation in the resistance and conductance elements associated with the inductor.

## Dependencies

Enabled when the **Enable operating limits** parameter is set to Yes.

## Faults

### Enable faults — Select Yes to enable faults modeling

No (default) | Yes

Select Yes to enable faults modeling. The associated parameters in the **Faults** section become visible to let you select the reporting method and specify the trigger mechanism (temporal or behavioral). You can enable these trigger mechanisms separately or use them together.

### Reporting when a fault occurs — Choose whether to issue an assertion when a fault occurs

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- None — The block does not issue an assertion.
- Warn — The block issues a warning.
- Error — Simulation stops with an error.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

#### Location of fault node (% of total turns from - terminal) — Percentage of turns in the subinductor that is in contact with the - port of the block

50 (default)

In practice, faults are enabled by segmenting the inductor into two coupled subinductors, connected in a series. The inductance is proportional to the square of the number of turns in the respective segment, and the series resistance of each subinductor is proportional to the number of turns in each segment. The parallel conductance spans both segments.

This parameter indicates the percentage of turns that are assigned to the subinductor that is in contact with the - port of the block. The remaining turns are assigned to the other subinductor. The default value is 50, which means that the overall inductance is divided into two equal, coupled subinductors.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

#### Faulted coupling factor — Mutual coupling between the two subinductors

0.9999 (default)

The faulted value for the mutual coupling between the two subinductors. The differential equations governing such a construction break down in the limit of perfect coupling, so the coupling should be less than unity. A value of 0 corresponds to no coupling at all between the subinductors. Physically, this corresponds to a fault that affects the flux within the inductor core. This could be a crack in the core material, or windings coming away from the core.

The default value of this parameter is also the internal value the block uses when computing a faultable inductor in the unfaulted state. For an unfaultable inductor, there is only a single equation being solved, and this corresponds to the ideal case of perfect mutual coupling.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

#### Short-circuit turns — Select whether fault results in one of the segments being short-circuited

No (default) | To negative terminal | To positive terminal

Select whether the fault results in one of the subinductor segments being short-circuited:

- No — The fault does not produce a short circuit.
- To negative terminal — The fault short-circuits the subinductor that is in contact with the - port of the block.
- To positive terminal — The fault short-circuits the subinductor that is in contact with the + port of the block.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Open-circuit at fault node — Select whether to apply an open-circuit fault between the segments**

No (default) | Yes

Select whether to apply an open-circuit fault between the two subinductor segments. The default is No. Even with an open-circuit fault, the characteristics of the subinductors may still be related, depending on the value of the **Faulted coupling factor** parameter:

- If the coupling factor is not zero, the subinductors are galvanically isolated from each other, but they are still magnetically coupled. Physically, this corresponds to a break in the winding.
- With zero coupling factor, the subinductors are galvanically and magnetically isolated.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Ground fault — Select whether fault results in one of the segments being short-circuited**

No (default) | Negative terminal side of fault node | Positive terminal side of fault node

Select whether, in case of fault, there is a path for current to flow towards the ground node:

- No — The fault does not result in a connection to ground.
- Negative terminal side of fault node — The side that is in contact with the - port of the block is connected to ground.
- Positive terminal side of fault node — The side that is in contact with the + port of the block is connected to ground.

If the **Open-circuit at fault node** parameter is set to Yes, you need to specify which side (negative or positive) is connected to ground. If there is no open circuit, the two options behave similarly. Physically, this corresponds to a breakdown in the insulation between the windings and the grounded core or chassis.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Conductance of faulted ground path — Mutual coupling between the two subinductors**

1 1/0hm (default)

If there is a ground fault, this parameter represents the conductance of the current path to ground. For example, if the path to ground is through the core material, then specify a small conductance value depending on the core material being used. For highly conductive core material or for chassis-shorts, specify a higher conductance value.

**Dependencies**

Enabled when the **Ground fault** parameter is set to Negative terminal side of fault node or Positive terminal side of fault node.

**Fault transition time constant — Time constant for the transition to faulted state**

1e-3 s (default)

Time constant associated with the transition to the faulted state, as described in “Faults” on page 1-872.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

#### Enable temporal fault trigger – Select Yes to enable time-based fault triggering

No (default) | Yes

Select Yes to enable time-based fault triggering. You can enable the temporal and behavioral trigger mechanisms separately or use them together.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

#### Simulation time for a fault event – Time before entering faulted state

1 s (default)

Set the simulation time at which you want the block to start entering the fault state.

#### Dependencies

Enabled when the **Enable temporal fault trigger** parameter is set to Yes.

#### Enable behavioral fault trigger – Select Yes to enable behavioral fault triggering

No (default) | Yes

Select Yes to enable behavioral fault triggering. You can enable the temporal and behavioral trigger mechanisms separately or use them together.

#### Dependencies

Enabled when the **Enable faults** parameter is set to Yes.

#### Maximum permissible voltage – Voltage threshold to fault transition

100 V (default)

Define the voltage threshold to a fault transition. If the voltage value exceeds this threshold a certain number of times, specified by the **Number of events to fail when exceeding voltage** parameter value, then the block starts entering the fault state.

#### Dependencies

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

#### Number of events to fail when exceeding voltage – Maximum number of times the voltage exceeds the threshold

1 (default)

Since the physical mechanism underlying voltage-based failures depends on one or more partial discharge events occurring, this parameter allows you to set the number of voltage overshoots that the inductor can withstand before the fault transition begins. Note that the block does not check the time spent in the overvoltage condition, only the number of transitions.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

**Maximum permissible current – Current threshold to fault transition**

1 A (default)

Define the current threshold to a fault transition. If the current value exceeds this threshold for longer than the **Time to fail when exceeding current** parameter value, then the block starts entering the fault state.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

**Time to fail when exceeding current – Maximum length of time the current exceeds the threshold**

1 s (default)

Set the maximum length of time that the current can exceed the maximum permissible value without triggering the fault.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

# Inductive Rotor Position Sensor

Inductive rotor position sensor with four inductive coils

**Library:** Simscape / Electrical / Sensors & Transducers

## Description

The Inductive Rotor Position Sensor block uses the theory of eddy current losses to obtain the rotor position. It consists of four planar coils and a target trace that detect the rotor position. The target trace is shaped in a sinusoidal way and made from conductive material. The distance between the four planar coils is equivalent to 90 degrees of one cycle.

## Equations

The voltages between the elements of the sensor are described by the equations:

$$v_x = V_{x0} + A_x \cos(N\theta) + K \sin(\theta)$$

$$v_y = V_{y0} + A_y \cos(N\theta - \frac{\pi}{2} + \beta) + K \sin(\theta)$$

where:

- $v_x$  is the cosine voltage.
- $v_y$  is the sine voltage.
- $A_x$  and  $A_y$  are the voltage amplitudes for the x and y axes that reflect the sensitivity mismatch.
- $V_{x0}$  and  $V_{y0}$  are the voltage offsets for the x and y axes.

- $N$  is the number of pole pairs.
- $\theta$  is the mechanical position.
- $\beta$  is the quadrature error.
- $K$  is the tumbling factor.

The block uses this equation to decode the angle:

$$\theta_{out} = \arctan\left(\frac{v_y}{v_x}\right).$$

This figure shows the effects of the tumbling factor:

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

# Integrator (Discrete or Continuous)

Discrete-time or continuous-time integrator

**Library:** Simscape / Electrical / Control / General Control

## Description

The Integrator (Discrete or Continuous) block implements a simple integrator in conformance with IEEE 421.5-2016<sup>[1]</sup>.

You can switch between continuous and discrete implementations of the integrator using the **Sample time** parameter.

## Equations

### Continuous

To configure the integrator for continuous time, set the **Sample time** property to 0. This representation is equivalent to the continuous transfer function:

$$G(s) = \frac{1}{s}.$$

From the preceding transfer function, the integrator defining equations are:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(0) = x_0,$$

where:

- $u$  is the integrator input.
- $x$  is the integrator state.
- $y$  is the integrator output.
- $t$  is the simulation time.
- $x_0$  is the initial state of the integrator.

### Discrete

To configure the integrator for discrete time, set the **Sample time** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block. The discrete representation is equivalent to the transfer function:

$$G(z) = \frac{T_s}{z - 1},$$

where  $T_s$  is the sample time. From the discrete transfer function, the integrator equations are defined using the forward Euler method:

$$\begin{cases} x(n+1) = x(n) + T_s u(n) \\ y(n) = x(n) \end{cases} \quad x(0) = x_0,$$

where:

- $u$  is the integrator input.
- $x$  is the integrator state.
- $y$  is the integrator output.
- $n$  is the simulation time step.
- $x_0$  is the initial state of the integrator.

### Defining Initial Conditions

You can define the state initial conditions using the input port **x0**. The integrator state reverts to the initial condition any time it is reset.

### Limiting the Integral

You can limit the integral output using one of two methods:

- Set **Limit type** to **Anti-windup** to use the anti-windup saturation method.

The anti-windup method limits the integrator state  $x$  between the lower saturation limit  $A$  and upper saturation limit  $B$ :

$$A \leq x \leq B.$$

Because the state is limited, the output can respond immediately to a reversal of the input sign when the integral is saturated.

- Set **Limit type** to **Windup** to use the windup saturation method.

The windup method limits the integrator output  $y$  between the lower saturation limit  $A$  and upper saturation limit  $B$ :

$$A \leq y \leq B.$$

Because the output is limited, the state can continue to grow when the integrator is saturated. As a result, the output cannot respond to a reversal of the input sign until the state has reached the limiting saturation point.

### Resetting the State

You can reset the state of the integrator by passing a nonzero signal to the **Reset** port of the block.

## Ports

### Input

#### **u — Integrator input**

vector

Integrator input.

Data Types: `single` | `double`

#### **Reset — Revert to initial state**

scalar

Integrator reset. To reset the integrator state to the value of the **x0** port, pass a nonzero value to this port. Alternatively, attach a zero-valued Constant block to this port to override the external reset.

Data Types: `single` | `double`

#### **x0 — Initial state**

vector

Integrator initial state. To specify the value of the state after a reset, pass a signal to this port.

Data Types: `single` | `double`

### Output

#### **y — Integrator output**

vector

Integrator output.

Data Types: `single` | `double`

## Parameters

#### **External reset — Reset strategy**

`level` (default) | `rising` | `falling` | `either`

Select the external reset strategy for the integrator:

- Select `rising` to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select `falling` to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select `either` to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select `level` to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

#### **Limit type — Saturation strategy**

`Anti-windup` (default) | `Windup`

Select the limit type of the integrator:

- Select Anti-windup to limit the state of the integrator, preventing windup.
- Select windup to limit the output of the integrator, allowing windup of the integrator state.

**Upper saturation limit – State upper limit**

`inf` (default) | real number

Integrator upper saturation limit. Set this to `inf` for an unsaturated upper limit, or to a finite value to saturate the integrator using the strategy set by **Limit type**.

**Lower saturation limit – State lower limit**

`-inf` (default) | real number

Integrator lower saturation limit. Set this to `-inf` for an unsaturated lower limit, or to a finite value to saturate the integrator using the strategy set by **Limit type**.

**Sample time (-1 for inherited) – Block sample time**

`-1` (default) | `0` | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify `-1`. For discrete-time operation, specify a positive integer. For continuous-time operation, specify `0`.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

# Integrator with Wrapped State (Discrete or Continuous)

Discrete-time or continuous-time integrator with wrapped state

**Library:** Simscape / Electrical / Control / General Control

## Description

The Integrator with Wrapped State (Discrete or Continuous) block implements a wrapped state integrator in conformance with IEEE 421.5-2016<sup>[1]</sup>.

Use this block to generate periodic signals such as angles or to represent a voltage-controlled oscillator. You can switch between continuous and discrete implementations of the integrator using the **Sample time** parameter.

## Equations

### Continuous

To configure the integrator for continuous time, set the **Sample time** property to 0. This representation is equivalent to the continuous transfer function:

$$G(s) = \frac{1}{s}.$$

From the preceding transfer function, the integrator defining equations are:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(0) = x_0,$$

where:

- $u$  is the integrator input.
- $x$  is the integrator state.
- $y$  is the integrator output.
- $t$  is the simulation time.
- $x_0$  is the initial state of the integrator.

### Discrete

To configure the integrator for discrete time, set the **Sample time** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block. The discrete representation is equivalent to the transfer function:

$$G(z) = \frac{T_s}{z-1},$$

where  $T_s$  is the sample time. From the discrete transfer function, the integrator equations are defined using the forward Euler method:

$$\begin{cases} x(n+1) = x(n) + T_s u(n) \\ y(n) = x(n) \end{cases} \quad x(0) = x_0,$$

where:

- $u$  is the integrator input.
- $x$  is the integrator state.
- $y$  is the integrator output.
- $n$  is the simulation time step.
- $x_0$  is the initial state of the integrator.

### Defining Initial Conditions

You can define the state initial conditions using **Initial condition** parameter.

### Wrapping Cyclic States

The integrator wraps its state between the specified lower and upper values. This diagram shows the outputs of a wrapped and nonwrapped state integrator for a constant input.

In the diagram, the lower and upper limits are  $0$  and  $2\pi$ , respectively.

# Inverse Clarke Transform

Implement  $\alpha\beta 0$  to  $abc$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

## Description

The Inverse Clarke Transform block converts the time-domain alpha, beta, and zero components in a stationary reference frame to three-phase components in an  $abc$  reference frame. The block can preserve the active and reactive powers with the powers of the system in the stationary reference frame by implementing an invariant power version of the inverse Clarke transform. If the zero component is zero, the components in the three-phase system are balanced.

The figures show:

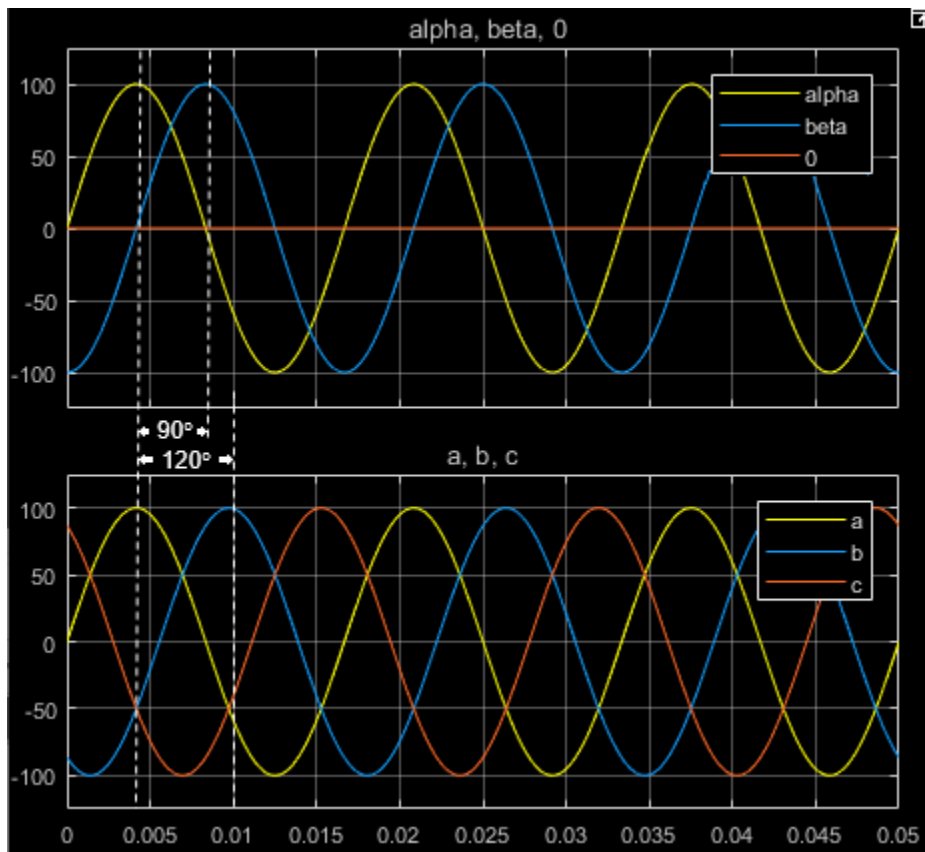

- Balanced  $\alpha$ ,  $\beta$ , and zero components in a stationary reference frame

- The direction of the magnetic axes of the stator windings in the stationary  $\alpha\beta 0$  reference frame and the  $abc$  reference frame

- The time-response of the individual components of equivalent balanced  $\alpha\beta 0$  and  $abc$  systems

### Equations

The block implements the inverse Clarke transform as

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1 \\ -\frac{1}{2} & \frac{\sqrt{3}}{2} & 1 \\ -\frac{1}{2} & -\frac{\sqrt{3}}{2} & 1 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \\ 0 \end{bmatrix}$$

where:

- $\alpha$  and  $\beta$  are the components in the stationary reference frame.
- $0$  is the zero component in the stationary reference frame.
- $a$ ,  $b$ , and  $c$  are the components of the three-phase system in the  $abc$  reference frame.

The block implements this power invariant version of the inverse Clarke transform as

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} 1 & 0 & \frac{1}{\sqrt{2}} \\ -\frac{1}{2} & \frac{\sqrt{3}}{2} & \frac{1}{\sqrt{2}} \\ -\frac{1}{2} & -\frac{\sqrt{3}}{2} & \frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \\ 0 \end{bmatrix}$$

## Ports

### Input

#### $\alpha\beta 0$ — $\alpha$ - $\beta$ axis and zero components

vector

Alpha-axis component  $\alpha$ , beta-axis component  $\beta$ , and zero component in the stationary reference frame.

Data Types: single | double

### Output

#### $abc$ — $a$ -, $b$ -, and $c$ -phase components

vector

Components of the three-phase system in the  $abc$  reference frame.

Data Types: single | double

## Parameters

#### Power Invariant — Power invariant transform

off (default) | on

Preserve the active and reactive power of the system in the rotating reference frame.

# Inverse Coordinate Transform (Five-Phase)

Implement  $dqxy0$  to  $abcde$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

## Description

The Inverse Coordinate Transform (Five-Phase) block converts the time-domain direct, quadrature,  $x$ ,  $y$ , and zero components in a rotating reference frame to the components of a five-phase system in an  $abcde$  reference frame.

You can configure the block to align the phase  $a$ -axis of the five-phase system to either the  $d$ -axis or  $q$ -axis of the rotating reference frame at time  $t = 0$ .

$\theta = \omega t + \text{Offset}$  is the angle between the  $a$  and  $q$  axes for the  $q$ -axis alignment or the angle between the  $a$  and  $d$  axes for the  $d$ -axis alignment, where:

- $\omega$  is the rotational speed of the rotational reference frame.
- $t$  is the time, in s, from the initial alignment.
- $\text{Offset} = \frac{\pi}{2}$ ,  $d$  - axis alignment
- $0$ ,  $q$  - axis alignment

## Equations

The Inverse Coordinate Transform (Five-Phase) block implements the transform as

$$\begin{bmatrix} a \\ b \\ c \\ d \\ e \end{bmatrix} = \begin{bmatrix} \sin\theta & \cos\theta & \sin\theta & \cos\theta & \frac{1}{\sqrt{2}} \\ \sin\left(\theta - \frac{2\pi}{5}\right) & \cos\left(\theta - \frac{2\pi}{5}\right) & \sin\left(\theta + \frac{4\pi}{5}\right) & \cos\left(\theta + \frac{4\pi}{5}\right) & \frac{1}{\sqrt{2}} \\ \sin\left(\theta - \frac{4\pi}{5}\right) & \cos\left(\theta - \frac{4\pi}{5}\right) & \sin\left(\theta - \frac{2\pi}{5}\right) & \cos\left(\theta - \frac{2\pi}{5}\right) & \frac{1}{\sqrt{2}} \\ \sin\left(\theta + \frac{4\pi}{5}\right) & \cos\left(\theta + \frac{4\pi}{5}\right) & \sin\left(\theta + \frac{2\pi}{5}\right) & \cos\left(\theta + \frac{2\pi}{5}\right) & \frac{1}{\sqrt{2}} \\ \sin\left(\theta + \frac{2\pi}{5}\right) & \cos\left(\theta + \frac{2\pi}{5}\right) & \sin\left(\theta - \frac{4\pi}{5}\right) & \cos\left(\theta - \frac{4\pi}{5}\right) & \frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} d \\ q \\ x \\ y \\ 0 \end{bmatrix}$$

## Ports

### Input

**dqxy0** — Direct, quadrature,  $x$ ,  $y$ , and zero components  
vector

Direct, quadrature, x-axis, y-axis, and zero components of the system in the rotating reference frame, specified as a vector.

Data Types: `single` | `double`

### **$\theta_{elec}$ — Rotational angle**

scalar

Angular position of the rotating reference frame, specified as a scalar.

Data Types: `single` | `double`

### **Output**

#### **$abcde$ — $a$ -, $b$ -, $c$ -, $d$ -, and $e$ -phase components**

vector

Components of the five-phase system in the  $abcde$  reference frame, returned as a vector.

Data Types: `single` | `double`

### **Parameters**

#### **Phase-a axis alignment — $dqxy0$ reference frame alignment**

## Inverse Decoupled Transform (Six-Phase)

Implement  $dqz_1z_2o_1o_2$  to  $abc$  and  $xyz$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

### Description

The Inverse Decoupled Transform (Six-Phase) block converts the direct, quadrature,  $z_1$ ,  $z_2$ ,  $o_1$ , and  $o_2$  components in a rotating reference frame to the components of a six-phase system in the  $abc$  and  $xyz$  reference frame. The three-phase systems  $abc$  and  $xyz$  are spatially shifted by 30 electrical degrees.

You can configure the block to align the phase  $a$ -axis of the five-phase system to either the  $d$ -axis or  $q$ -axis of the rotating reference frame at time  $t = 0$ .

$\theta = \omega t + \text{Offset}$  is the angle between the  $a$  and  $q$  axes for the  $q$ -axis alignment or the angle between the  $a$  and  $d$  axes for the  $d$ -axis alignment, where:

- $\omega$  is the rotational speed of the rotational reference frame.
- $t$  is the time, in s, from the initial alignment.
- $\text{Offset} = 0$ ,  $d$  - axis alignment
- $\text{Offset} = -\frac{\pi}{2}$ ,  $q$  - axis alignment

### Equations

The Inverse Decoupled Transform (Six-Phase) block implements the transform as

$$\begin{bmatrix} a \\ b \\ c \\ x \\ y \\ z \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta & 1 & 0 & 1 & 0 \\ \cos\left(\theta - \frac{2\pi}{3}\right) & -\sin\left(\theta - \frac{2\pi}{3}\right) & -\frac{1}{2} & -\frac{\sqrt{3}}{2} & 1 & 0 \\ \cos\left(\theta + \frac{2\pi}{3}\right) & -\sin\left(\theta + \frac{2\pi}{3}\right) & -\frac{1}{2} & \frac{\sqrt{3}}{2} & 1 & 0 \\ \cos\left(\theta - \frac{\pi}{6}\right) & -\sin\left(\theta - \frac{\pi}{6}\right) & -\frac{\sqrt{3}}{2} & \frac{1}{2} & 0 & 1 \\ \cos\left(\theta - \frac{5\pi}{6}\right) & -\sin\left(\theta - \frac{5\pi}{6}\right) & \frac{\sqrt{3}}{2} & \frac{1}{2} & 0 & 1 \\ \cos\left(\theta + \frac{\pi}{2}\right) & -\sin\left(\theta + \frac{\pi}{2}\right) & 0 & -1 & 0 & 1 \end{bmatrix} \begin{bmatrix} d \\ q \\ z_1 \\ z_2 \\ o_1 \\ o_2 \end{bmatrix}$$

The  $z_1$ - $z_2$  and  $o_1$ - $o_2$  pairs do not form a rotating magnetic potential. They are generalized zero-sequence components.

## Inverse Park Transform

Implement  $dq0$  to  $abc$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

### Description

The Inverse Park Transform block converts the time-domain direct, quadrature, and zero components in a rotating reference frame to the components of a three-phase system in an  $abc$  reference frame. The block can preserve the active and reactive powers with the powers of the system in the rotating reference frame by implementing an invariant version of the Park transform. For a balanced system, the zero component is equal to zero.

You can configure the block to align the  $a$ -axis of the three-phase system to either the  $d$ - or  $q$ -axis of the rotating reference frame at time,  $t = 0$ . The figures show the direction of the magnetic axes of the stator windings in an  $abc$  reference frame and a rotating  $d$ - $q$  reference frame where:

- The  $a$ -axis and the  $q$ -axis are initially aligned.

- The  $a$ -axis and the  $d$ -axis are initially aligned.

In both cases, the angle  $\theta = \omega t$ , where

- $\theta$  is the angle between the  $a$  and  $q$  axes for the  $q$ -axis alignment or the angle between the  $a$  and  $d$  axes for the  $d$ -axis alignment.
- $\omega$  is the rotational speed of the  $d$ - $q$  reference frame.
- $t$  is the time, in s, from the initial alignment.

The figures show the time-response of the individual components of equivalent balanced  $dq0$  and  $abc$  for an:

- Alignment of the  $a$ -phase vector to the  $q$ -axis

- Alignment of the  $a$ -phase vector to the  $d$ -axis

## Defining Equations

The Inverse Park Transform block implements the transform for an  $a$ -phase to  $q$ -axis alignment as

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} \sin(\theta) & \cos(\theta) & 1 \\ \sin(\theta - \frac{2\pi}{3}) & \cos(\theta - \frac{2\pi}{3}) & 1 \\ \sin(\theta + \frac{2\pi}{3}) & \cos(\theta + \frac{2\pi}{3}) & 1 \end{bmatrix} \begin{bmatrix} d \\ q \\ 0 \end{bmatrix},$$

where:

- $d$  and  $q$  are the components of the two-axis system in the rotating reference frame.
- $a$ ,  $b$ , and  $c$  are the components of the three-phase system in the  $abc$  reference frame.
- $0$  is the zero component of the two-axis system in the stationary reference frame.

For a power invariant  $a$ -phase to  $q$ -axis alignment, the block implements the transform using this equation:

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} \sin(\theta) & \cos(\theta) & \sqrt{\frac{1}{2}} \\ \sin(\theta - \frac{2\pi}{3}) & \cos(\theta - \frac{2\pi}{3}) & \sqrt{\frac{1}{2}} \\ \sin(\theta + \frac{2\pi}{3}) & \cos(\theta + \frac{2\pi}{3}) & \sqrt{\frac{1}{2}} \end{bmatrix} \begin{bmatrix} d \\ q \\ 0 \end{bmatrix}.$$

For an  $a$ -phase to  $d$ -axis alignment, the block implements the transform using this equation:

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} \cos(\theta) & -\sin(\theta) & 1 \\ \cos(\theta - \frac{2\pi}{3}) & -\sin(\theta - \frac{2\pi}{3}) & 1 \\ \cos(\theta + \frac{2\pi}{3}) & -\sin(\theta + \frac{2\pi}{3}) & 1 \end{bmatrix} \begin{bmatrix} d \\ q \\ 0 \end{bmatrix}.$$

The block implements a power invariant  $a$ -phase to  $d$ -axis alignment as

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} \cos(\theta) & -\sin(\theta) & \sqrt{\frac{1}{2}} \\ \cos(\theta - \frac{2\pi}{3}) & -\sin(\theta - \frac{2\pi}{3}) & \sqrt{\frac{1}{2}} \\ \cos(\theta + \frac{2\pi}{3}) & -\sin(\theta + \frac{2\pi}{3}) & \sqrt{\frac{1}{2}} \end{bmatrix} \begin{bmatrix} d \\ q \\ 0 \end{bmatrix}.$$

# Inverse Symmetrical-Components Transform

Implement  $+0$  to  $abc$  transform

**Library:** Simscape / Electrical / Control / Mathematical Transforms

## Description

The Inverse Symmetrical-Components Transform block implements an inverse symmetrical transform of a positive, negative, and zero phasor. The transform splits a symmetrical set of three phasors into the equivalent unbalanced set of  $a$ ,  $b$ , and  $c$  phasors.

Use this transform to regenerate a three-phase signal from a system that was decoupled using the Symmetrical-Components Transform block.

Use the **Power invariant** property to choose between the Fortescue transform, and the alternative, power-invariant version.

## Equations

The inverse symmetrical-components transform regenerates an unbalanced three-phase signal  $[V_a, V_b, V_c]$  from the  $a$  components of a balanced set of phasors  $[V_{a+}, V_{a-}, V_{a0}]$ , given in the  $+0$  domain:

$$\begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} = \frac{1}{K} \begin{bmatrix} 1 & 1 & 1 \\ a^2 & a & 1 \\ a & a^2 & 1 \end{bmatrix} \begin{bmatrix} V_{a+} \\ V_{a-} \\ V_{a0} \end{bmatrix}$$

where,  $a$  is the complex rotation operator

$$a = e^{2\pi i/3},$$

and  $K$  is the constant that determines the type of transform:

$$\begin{cases} K = 1 & \text{Fortescue transform} \\ K = \sqrt{3} & \text{Power-invariant transform} \end{cases}$$

If the transform was performed using the power-invariant option, enable the **Power invariant** property to select the power-invariant inverse transform and regenerate the correct  $abc$  signal.

## Symmetrical-Components Transform

The symmetrical-components transform separates an unbalanced three-phase signal given in phasor quantities into three balanced sets of phasors:

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} v_{a+} \\ v_{b+} \\ v_{c+} \end{bmatrix} + \begin{bmatrix} v_{a-} \\ v_{b-} \\ v_{c-} \end{bmatrix} + \begin{bmatrix} v_{a0} \\ v_{b0} \\ v_{c0} \end{bmatrix},$$

where:

- $v_a$ ,  $v_b$ , and  $v_c$  make up the original, unbalanced set of phasors.
- $v_{a+}$ ,  $v_{b+}$ , and  $v_{c+}$  make up the balanced, positive set of phasors.
- $v_{a-}$ ,  $v_{b-}$ , and  $v_{c-}$  make up the balanced, negative set of phasors.
- $v_{a0}$ ,  $v_{b0}$ , and  $v_{c0}$  make up the balanced, zero set of phasors.

The symmetrical-components transform calculates the symmetric  $a$ -phase as:

$$\begin{bmatrix} V_{a+} \\ V_{a-} \\ V_{a0} \end{bmatrix} = \frac{K}{3} \begin{bmatrix} 1 & a & a^2 \\ 1 & a^2 & a \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix}.$$

Because the remaining two sets of symmetrical phasors are not often used in calculation, the transformation only generates the first set. However, you can calculate the  $b$ - and  $c$ -sets in terms of simple rotations of the first:

$$\begin{bmatrix} V_{b+} \\ V_{b-} \\ V_{b0} \end{bmatrix} = \begin{bmatrix} a^2 & 0 & 0 \\ 0 & a & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} V_{a+} \\ V_{a-} \\ V_{a0} \end{bmatrix},$$

and

$$\begin{bmatrix} V_{c+} \\ V_{c-} \\ V_{c0} \end{bmatrix} = \begin{bmatrix} a & 0 & 0 \\ 0 & a^2 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} V_{a+} \\ V_{a-} \\ V_{a0} \end{bmatrix}.$$

### Operating Principle

The three sets of balanced phasors generated by the symmetrical-components transform have the following properties:

- The positive set has the same order as the unbalanced set of phasors  $a$ - $b$ - $c$ .
- The negative set has the opposite order as the unbalanced set of phasors  $a$ - $c$ - $b$ .
- The zero set has no order because all three phasor angles are equal.

This diagram visualizes the separation performed by the transform.

In the diagram, the top axis shows an unbalanced three-phase signal with components  $a$ ,  $b$ , and  $c$ . The bottom set of axes separates the three-phase signal into symmetrical positive, negative, and zero phasors.

Observe that in each case, the  $a$ ,  $b$ , and  $c$  components are symmetrical and are separated by:

- +120 degrees for the positive set.
- -120 degrees for the negative set.
- 0 degrees for the zero set.

## Ports

### Input

#### + - 0 — Balanced $a$ phasor components

vector

Positive, negative, and zero  $a$  phasors given as a complex signal. Use the rotations given in the Symmetrical-Components Transform section to compute the  $b$  and  $c$  phasor sets.

Data Types: single | double

### Output

#### abc — $a$ , $b$ , and $c$ phasors

vector

Regenerated three-phase set of unbalanced phasors, output as a complex signal.

Data Types: single | double

## Parameters

### Power invariant – Transform type

off (default) | on

Power invariant toggle. Select this parameter to use the power-invariant alternative of the original Fortescue transform.

## Lead-Lag (Discrete or Continuous)

Discrete-time or continuous-time lead-lag compensator

**Library:** Simscape / Electrical / Control / General Control

### Description

The Lead-Lag (Discrete or Continuous) block implements a lead-lag compensator in conformance with IEEE 421.5-2016<sup>[1]</sup>.

You can switch between continuous and discrete implementations of the block using the **Sample time** parameter.

### Equations

#### Continuous

To configure the compensator for continuous time, set the **Sample time** property to 0. This representation is equivalent to the continuous transfer function:

$$G(s) = \frac{T_1s + 1}{T_2s + 1},$$

where:

- $T_1$  is the lead time constant.
- $T_2$  is the lag time constant.

From the preceding transfer function, the compensator defining equations are:

$$\begin{cases} \dot{x}(t) = \frac{1}{T_2}(u(t) - x(t)) \\ y(t) = \frac{T_1}{T_2}u(t) + \left(1 - \frac{T_1}{T_2}\right)x(t) \end{cases} \quad y(0) = x(0) = u_0,$$

where:

- $u$  is the block input.
- $x$  is the block state.
- $y$  is the block output.
- $t$  is the simulation time.
- $u_0$  is the initial input to the block.

### Discrete

To configure the compensator for discrete time, set the **Sample time** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block. The discrete representation is equivalent to the transfer function:

$$\frac{T_1 z + (T_s - T_1)}{T_2 z + (T_s - T_2)},$$

where:

- $T_1$  is the lead time constant.
- $T_2$  is the lag time constant.
- $T_s$  is the compensator sample time.

From the discrete transfer function, the compensator equations are defined using the forward Euler method:

$$\begin{cases} x(n+1) = \left(1 - \frac{T_s}{T_2}\right)x(n) + \left(\frac{T_s}{T_2}\right)u(n) \\ y(n) = \left(1 - \frac{T_1}{T_2}\right)x(n) + \left(\frac{T_1}{T_2}\right)u(n) \end{cases} \quad y(0) = x(0) = u_0,$$

where:

- $u$  is the block input.
- $x$  is the state.
- $y$  is the block output.
- $n$  is the simulation time step.
- $u_0$  is the initial input to the block.

### Initial Conditions

To specify the initial conditions of this block, set **Initialization** to:

- **Inherited from block input** — The block sets the state and output initial conditions to the initial input.
- **Specify as parameter** — The block sets the state initial condition to the value of **Initial state**.

### Limiting the Integral

Set the **Upper saturation limit** and **Lower saturation limit** parameters to use the anti-windup saturation method.

The anti-windup method limits the compensator state between the lower saturation limit  $A$  and upper saturation limit  $B$ :

$$A < = x < = B .$$

Because the state is limited, the output can respond immediately to a reversal of the input sign when the integral is saturated.

This block does not provide a windup saturation method. To use the windup saturation method, set the **Upper saturation limit** parameter to `inf`, the **Lower saturation limit** parameter to `-inf`, and attach a Saturation block to the output.

### Bypass Compensator Dynamics

Set the lag time constant to zero or to a value equal to that of the lead time constant to ignore the dynamics of the compensator. When bypassed, the block feeds the input directly to the output:

$$\left. \begin{array}{l} T_1 = 0 \\ T_2 = 0 \\ T_1 = T_2 \end{array} \right\} y = u .$$

In the continuous case, both the sample time and at least one time constant must be zero.

## Ports

### Input

#### **u — Compensator input**

vector

Lead-lag compensator input signal. The block uses the input initial value to determine the state initial value.

Data Types: `single` | `double`

### Output

#### **y — Compensator output**

vector

Lead-lag compensator output.

Data Types: `single` | `double`

## Parameters

#### **Lead time constant, T1 — Lead time constant**

0.2 (default) | positive number

Compensator lead time constant. To bypass the dynamics of the compensator, set this value to 0 or to the value of the **Lag time constant, T2** parameter.

#### **Lag time constant, T2 — Lag time constant**

0.1 (default) | positive number

Compensator lag time constant. To bypass the dynamics of the compensator, set this value to 0 or to the value of the **Lead time constant, T1** parameter.

#### **Upper saturation limit — State upper limit**

`inf` (default) | real number

Compensator upper state limit. Set this to `inf` for an unsaturated upper limit, or to a finite value to prevent upper windup of the system's integrator.

**Lower saturation limit — State lower limit**

`-inf` (default) | real number

Compensator lower state limit. Set this to `-inf` for an unsaturated lower limit, or to a finite value to prevent lower windup of the system's integrator.

**Initialization — Initial state specification**

Inherited from block input (default) | Specify as parameter

Specify the initial state condition for this block. For more information, see “Initial Conditions” on page 1-908.

**Initial state — Initial state**

`0` (default) | real number

Block initial state.

**Dependencies**

To enable this parameter, set **Initialization** to `Specify as parameter`.

**Sample time (-1 for inherited) — Block sample time**

`-1` (default) | `0` | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify `-1`. For discrete-time operation, specify a positive integer. For continuous-time operation, specify `0`.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

# Light-Emitting Diode

Exponential light-emitting diode with optical power output port

**Library:** Simscape / Electrical / Sensors & Transducers

## Description

The Light-Emitting Diode block represents a light-emitting diode as an exponential diode in series with a current sensor. The optical power presented at the signal port W is equal to the product of the current flowing through the diode and the **Optical power per unit current** parameter value.

The exponential diode model provides the following relationship between the diode current  $I$  and the diode voltage  $V$ :

$$I = IS \cdot \left( e^{\frac{qV}{NkT_{m1}}} - 1 \right)$$

where:

- $q$  is the elementary charge on an electron (1.602176e-19 Coulombs).
- $k$  is the Boltzmann constant (1.3806503e-23 J/K).
- $N$  is the emission coefficient.
- $IS$  is the saturation current.
- $T_{m1}$  is the temperature at which the diode parameters are specified, as defined by the **Measurement temperature** parameter value.

When  $(qV / NkT_{m1}) > 80$ , the block replaces  $e^{\frac{qV}{NkT_{m1}}}$  with  $(qV / NkT_{m1} - 79)e^{80}$ , which matches the gradient of the diode current at  $(qV / NkT_{m1}) = 80$  and extrapolates linearly. When  $(qV / NkT_{m1}) < -79$ ,

the block replaces  $e^{\frac{qV}{NkT_{m1}}}$  with  $(qV / NkT_{m1} + 80)e^{-79}$ , which also matches the gradient and extrapolates linearly. Typical electrical circuits do not reach these extreme values. The block provides this linear extrapolation to help convergence when solving for the constraints during simulation.

When you select **Use parameters IS and N** for the **Parameterization** parameter, you specify the diode in terms of the **Saturation current IS** and **Emission coefficient N** parameters. When you select **Use I-V curve data points** for the **Parameterization** parameter, you specify two voltage and current measurement points on the diode I-V curve and the block derives the  $IS$  and  $N$  values. When you specify current and voltage measurements, the block calculates  $IS$  and  $N$  as follows:

- $N = ((V_1 - V_2)/V_t) / (\log(I_1) - \log(I_2))$
- $IS = (I_1 / (\exp(V_1 / (NV_t)) - 1) + I_2 / (\exp(V_2 / (NV_t)) - 1)) / 2$

where:

- $V_t = kT_{m1} / q$ .

- $V_1$  and  $V_2$  are the values in the **Voltages [V1 V2]** vector.
- $I_1$  and  $I_2$  are the values in the **Currents [I1 I2]** vector.

The exponential diode model provides the option to include a junction capacitance:

- When you select **Fixed** or **zero junction capacitance** for the **Parameterization** parameter, the capacitance is fixed.
- When you select **Use parameters CJO, VJ, M & FC** for the **Parameterization** parameter, the block uses the coefficients  $CJO$ ,  $VJ$ ,  $M$ , and  $FC$  to calculate a junction capacitance that depends on the junction voltage.
- When you select **Use C-V curve data points** for the **Parameterization** parameter, the block uses three capacitance values on the C-V capacitance curve to estimate  $CJO$ ,  $VJ$ , and  $M$  and uses these values with the specified value of  $FC$  to calculate a junction capacitance that depends on the junction voltage. The block calculates  $CJO$ ,  $VJ$ , and  $M$  as follows:
  - $CJO = C_1((V_{R2} - V_{R1})/(V_{R2} - V_{R1}(C_2/C_1)^{-1/M}))^M$
  - $VJ = -(-V_{R2}(C_1/C_2)^{-1/M} + V_{R1})/(1 - (C_1/C_2)^{-1/M})$
  - $M = \log(C_3/C_2)/\log(V_{R2}/V_{R3})$

where:

- $V_{R1}$ ,  $V_{R2}$ , and  $V_{R3}$  are the values in the **Reverse bias voltages [VR1 VR2 VR3]** vector.
- $C_1$ ,  $C_2$ , and  $C_3$  are the values in the **Corresponding capacitances [C1 C2 C3]** vector.

It is not possible to estimate  $FC$  reliably from tabulated data, so you must specify its value using the **Capacitance coefficient FC** parameter. In the absence of suitable data for this parameter, use a typical value of 0.5.

The reverse bias voltages (defined as positive values) should satisfy  $V_{R3} > V_{R2} > V_{R1}$ . This means that the capacitances should satisfy  $C_1 > C_2 > C_3$  as reverse bias widens the depletion region and hence reduces capacitance. Violating these inequalities results in an error. Voltages  $V_{R2}$  and  $V_{R3}$  should be well away from the Junction potential  $VJ$ . Voltage  $V_{R1}$  should be less than the Junction potential  $VJ$ , with a typical value for  $V_{R1}$  being 0.1 V.

The voltage-dependent junction is defined in terms of the capacitor charge storage  $Q_j$  as:

- For  $V < FC \cdot VJ$ :

$$Q_j = CJO \cdot (VJ/(M - 1)) \cdot ((1 - V/VJ)^{1-M} - 1)$$

- For  $V \geq FC \cdot VJ$ :

$$Q_j = CJO \cdot F_1 + (CJO/F_2) \cdot (F_3 \cdot (V - FC \cdot VJ) + 0.5(M/VJ) \cdot (V^2 - (FC \cdot VJ)^2))$$

where:

- $F_1 = (VJ/(1 - M)) \cdot (1 - (1 - FC)^{1-M})$
- $F_2 = (1 - FC)^{1+M}$
- $F_3 = 1 - FC \cdot (1 + M)$

These equations are the same as used in [2], except that the temperature dependence of  $VJ$  and  $FC$  is not modeled. This model does not include the diffusion capacitance term that affects performance for high frequency switching applications.

The Light-Emitting Diode block contains several options for modeling the dependence of the diode current-voltage relationship on the temperature during simulation. Temperature dependence of the junction capacitance is not modeled, this being a much smaller effect. For details, see the Diode reference page.

### **Thermal Port**

You can expose the thermal port to model the effects of generated heat and device temperature. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port and does not simulate heat generation in the device.
- **Show thermal port** — The block contains a thermal port that allows you to model the heat that conduction losses generate. For numerical efficiency, the thermal state does not affect the electrical behavior of the block.

For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

### **Variables**

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## **Assumptions and Limitations**

- When you select **Use I-V curve data points** for the **Parameterization** parameter, choose a pair of voltages near the diode turn-on voltage. Typically this is in the range from 0.05 to 1 Volt. Using values outside of this region may lead to numerical issues and poor estimates for  $IS$  and  $N$ .
- You may need to use nonzero ohmic resistance and junction capacitance values to prevent numerical simulation issues, but the simulation may run faster with these values set to zero.

## **Ports**

### **Output**

#### **W — Optical output power**

physical signal

Physical signal port associated with the optical output power.

**Conserving****+ — Positive terminal**

electrical

Electrical conserving port associated with the anode.

**- — Negative terminal**

electrical

Electrical conserving port associated with the cathode.

**H — Thermal port**

thermal

Thermal conserving port.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters****Modeling option — Whether to enable thermal port**

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of generated heat and device temperature.

**Main****Optical power per unit current — Optical power per unit current**

0.005 W/A (default)

Amount of optical power the light-emitting diode generates per unit of current flowing through the diode.

**Parameterization — Model parameterization**

Use I-V curve data points (default) | Use parameters IS and N

Select one of the following methods for model parameterization:

- **Use I-V curve data points** — Specify measured data at two points on the diode I-V curve. This is the default method.
- **Use parameters IS and N** — Specify saturation current and emission coefficient.

**Currents [I1 I2] — Vector of current values at two points**

[ 0.0017 0.003 ] A (default)

A vector of the current values at the two points on the diode I-V curve that the block uses to calculate IS and N.

**Dependencies**

This parameter is visible only when you select Use I-V curve data points for the **Parameterization** parameter.

**Voltages [V1 V2] — Vector of voltage values at two points**

[ 0.9 1.05 ] V (default)

A vector of the voltage values at the two points on the diode I-V curve that the block uses to calculate  $I_S$  and  $N$ .

**Dependencies**

This parameter is visible only when you select Use I-V curve data points for the **Parameterization** parameter.

**Saturation current,  $I_S$  — Saturation current**

5e-5 A (default)

The magnitude of the current that the ideal diode equation approaches asymptotically for very large reverse bias levels.

**Dependencies**

This parameter is visible only when you select Use parameters  $I_S$  and  $N$  for the **Parameterization** parameter.

**Emission coefficient,  $N$  — Emission coefficient**

10 (default)

The diode emission coefficient or ideality factor.

**Dependencies**

This parameter is visible only when you select Use parameters  $I_S$  and  $N$  for the **Parameterization** parameter.

**Ohmic resistance,  $R_S$  — Series diode connection resistance**

0.1 Ohm (default)

The series diode connection resistance.

**Measurement temperature — Measurement temperature**

25 degC (default)

The temperature at which  $I_S$  or the I-V curve was measured.

**Junction Capacitance****Parameterization — Junction capacitance parameterization**

Fixed or zero junction capacitance (default) | Use C-V curve data points | Use parameters  $C_{J0}$ ,  $V_J$ ,  $M$  &  $FC$

Select one of the following options for modeling the junction capacitance:

- Fixed or zero junction capacitance — Model the junction capacitance as a fixed value.
- Use C-V curve data points — Specify measured data at three points on the diode C-V curve.
- Use parameters  $C_{J0}$ ,  $V_J$ ,  $M$  &  $FC$  — Specify zero-bias junction capacitance, junction potential, grading coefficient, and forward-bias depletion capacitance coefficient.

**Junction capacitance — Junction capacitance**

20 pF (default)

Fixed value of the junction capacitance.

**Dependencies**

This parameter is visible only when you select Fixed or zero junction capacitance for the **Parameterization** parameter.

**Zero-bias junction capacitance, CJ0 — Zero-bias junction capacitance**

20 pF (default)

Value of the capacitance placed in parallel with the exponential diode term.

**Dependencies**

This parameter is visible only when you select Use parameters CJ0, VJ, M & FC for the **Parameterization** parameter.

**Reverse bias voltages [VR1 VR2 VR3] — Reverse bias voltages**

[ 0.1 10 100 ] V (default)

A vector of the reverse bias voltage values at the three points on the diode C-V curve that the block uses to calculate  $CJ0$ ,  $VJ$ , and  $M$ .

**Dependencies**

This parameter is visible only when you select Use C-V curve data points for the **Parameterization** parameter.

**Corresponding capacitances [C1 C2 C3] — Corresponding capacitances**

[ 15 10 2 ] pF (default)

A vector of the capacitance values at the three points on the diode C-V curve that the block uses to calculate  $CJ0$ ,  $VJ$ , and  $M$ .

**Dependencies**

This parameter is visible only when you select Use C-V curve data points for the **Parameterization** parameter.

**Junction potential, VJ — Junction potential**

1 V (default)

Junction potential.

**Dependencies**

This parameter is visible only when you select Use parameters CJ0, VJ, M & FC for the **Parameterization** parameter.

**Grading coefficient, M — Grading coefficient**

0.5 (default)

The grading coefficient.

**Dependencies**

This parameter is visible only when you select Use parameters  $CJ0$ ,  $VJ$ ,  $M$  &  $FC$  for the **Parameterization** parameter.

**Capacitance coefficient, FC — Capacitance coefficient**

0.5 (default)

Fitting coefficient that quantifies the decrease of the depletion capacitance with applied voltage.

**Dependencies**

This parameter is visible only when you select Use C-V curve data points or Use parameters  $CJ0$ ,  $VJ$ ,  $M$  &  $FC$  for the **Parameterization** parameter.

**Temperature Dependence****Parameterization — Temperature dependence parameterization**

None — Simulate at parameter measurement temperature (default) | Use an I-V data point at second measurement temperature  $T2$  | Specify saturation current at second measurement temperature  $T2$  | Specify the energy gap  $EG$

Select one of the following methods for temperature dependence parameterization:

- None — Simulate at parameter measurement temperature — Temperature dependence is not modeled, or the model is simulated at the measurement temperature  $T_{m1}$  (as specified by the **Measurement temperature** parameter on the **Main** tab). This is the default method.
- Use an I-V data point at second measurement temperature  $T2$  — If you select this option, you specify a second measurement temperature  $T_{m2}$ , and the current and voltage values at this temperature. The model uses these values, along with the parameter values at the first measurement temperature  $T_{m1}$ , to calculate the energy gap value.
- Specify saturation current at second measurement temperature  $T2$  — If you select this option, you specify a second measurement temperature  $T_{m2}$ , and saturation current value at this temperature. The model uses these values, along with the parameter values at the first measurement temperature  $T_{m1}$ , to calculate the energy gap value.
- Specify the energy gap  $EG$  — Specify the energy gap value directly.

**Current  $I1$  at second measurement temperature — Current  $I1$  at second measurement temperature**

0.0034 A (default)

Specify the diode current  $I1$  value when the voltage is  $V1$  at the second measurement temperature.

**Dependencies**

This parameter is visible only when you select Use an I-V data point at second measurement temperature  $T2$  for the **Parameterization** parameter.

**Voltage  $V1$  at second measurement temperature — Voltage  $V1$  at second measurement temperature**

1.05 V (default)

Specify the diode voltage  $V1$  value when the current is  $I1$  at the second measurement temperature.

**Dependencies**

This parameter is visible only when you select Use an I-V data point at second measurement temperature T2 for the **Parameterization** parameter.

**Saturation current, IS, at second measurement temperature – Saturation current, IS, at second measurement temperature**

1.8e-4 A (default)

Specify the saturation current *IS* value at the second measurement temperature.

**Dependencies**

This parameter is visible only when you select Specify saturation current at second measurement temperature T2 for the **Parameterization** parameter.

**Second measurement temperature – Second measurement temperature**

125 degC (default)

Specify the value for the second measurement temperature.

**Dependencies**

This parameter is visible only when you select Use an I-V data point at second measurement temperature T2 or Specify saturation current at second measurement temperature T2 for the **Parameterization** parameter.

**Energy gap parameterization – Energy gap parameterization**

Use nominal value for silicon (EG=1.11eV) (default) | Use nominal value for 4H-SiC silicon carbide (EG=3.23eV) | Use nominal value for 6H-SiC silicon carbide (EG=3.00eV) | Use nominal value for germanium (EG=0.67eV) | Use nominal value for gallium arsenide (EG=1.43eV) | Use nominal value for selenium (EG=1.74eV) | Use nominal value for Schottky barrier diodes (EG=0.69eV) | Specify a custom value

Select a value for the energy gap from a list of predetermined options, or specify a custom value:

- Use nominal value for silicon (EG=1.11eV) – This is the default.
- Use nominal value for 4H-SiC silicon carbide (EG=3.23eV)
- Use nominal value for 6H-SiC silicon carbide (EG=3.00eV)
- Use nominal value for germanium (EG=0.67eV)
- Use nominal value for gallium arsenide (EG=1.43eV)
- Use nominal value for selenium (EG=1.74eV)
- Use nominal value for Schottky barrier diodes (EG=0.69eV)
- Specify a custom value – If you select this option, the **Energy gap, EG** parameter appears in the dialog box, to let you specify a custom value for *EG*.

**Dependencies**

This parameter is visible only when you select Specify the energy gap EG for the **Parameterization** parameter.

**Energy gap, EG – Energy gap**

1.11 eV (default)

Specify a custom value for the energy gap, *EG*.

**Dependencies**

This parameter is visible only when you select Specify a custom value for the **Energy gap parameterization** parameter.

**Saturation current temperature exponent parameterization – Saturation current temperature exponent parameterization**

Use nominal value for pn-junction diode (XTI=3) (default) | Use nominal value for Schottky barrier diode (XTI=2) | Specify a custom value

Select one of the following options to specify the saturation current temperature exponent value:

- Use nominal value for pn-junction diode (XTI=3) — This is the default.
- Use nominal value for Schottky barrier diode (XTI=2)
- Specify a custom value — If you select this option, the **Saturation current temperature exponent, XTI** parameter appears in the dialog box, to let you specify a custom value for *XTI*.

**Saturation current temperature exponent, XTI – Saturation current temperature exponent**

3 (default)

Specify a custom value for the saturation current temperature exponent, *XTI*.

**Dependencies**

This parameter is visible only when you select Specify a custom value for the **Saturation current temperature exponent parameterization** parameter.

**Device simulation temperature – Device simulation temperature**

25 degC (default)

Specify the value for the temperature  $T_s$ , at which the device is to be simulated.

## Line Voltage Sensor (Three-Phase)

Ideal three-phase line voltage measurement

**Library:** Simscape / Electrical / Sensors & Transducers

### Description

The Line Voltage Sensor (Three-Phase) block represents an ideal three-phase line voltage sensor. The block measures the line-line voltages of a three-phase system and outputs a three-element physical signal vector. Each element of the physical signal output vector is proportional to the voltage between the phases as follows:

- Element 1:  $V_{ab} = V_a - V_b$
- Element 2:  $V_{bc} = V_b - V_c$
- Element 3:  $V_{ca} = V_c - V_a$

where  $V_a$ ,  $V_b$ , and  $V_c$  are the absolute  $a$ -,  $b$ -, and  $c$ -phase voltages.

---

**Note** You must connect the Line Voltage Sensor (Three-Phase) block in shunt with the three-phase element. For more information on how to use this block, see “Build and Simulate Composite and Expanded Three-Phase Models”.

## Load Flow Source

Three-phase voltage source for performing load flow analysis

**Library:** Simscape / Electrical / Sources

### Description

The Load Flow Source block is a three-phase voltage source that you use for a load-flow analysis. This block is only for three-phase Simscape networks that are compatible with frequency-time simulation mode.

The block can be used with the Busbar block to implement a swing bus, PV bus, or PQ bus. The type of bus is selected from the **Source type** drop-down menu parameter. See “Perform a Load-Flow Analysis Using Simscape Electrical” for more information about load flow in Simscape Electrical.

When you select **None** for the **Source impedance** parameter, the Load Flow Source block models an ideal three-phase voltage source that maintains sinusoidal voltage of the specified magnitude across its terminals, independently of the current flowing through the source.

The source has a wye configuration, and port **n** provides a connection to the center of the wye. Port **~** is a three-phase port that represents the phases *a*, *b*, and *c*. The current is positive if it flows from positive to the center of the wye, and the voltage across each phase is equal to the difference between the voltage at the positive terminal and the center of the wye,  $V(+)$  -  $V_n$ .

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

### Limitations

- If you do not initialize or simulate by using frequency-time equations, the **Source type** parameter must be set to Voltage source with series impedance.
- When initializing the block when **Source type** is set to swing bus, PV bus or PQ bus, including the internal impedance can result in initialization convergence issues. Resolve the convergence issues by using the **Internal source phase search range** parameter, omitting the impedance, or modelling the impedance external to the Load Flow Source block.

## Ports

### Conserving

electrical

Three-phase port associated with the voltage phases *a*, *b*, and *c*.

#### n — Wye center

electrical

Electrical conserving port associated with the center of the wye.

## Parameters

### Main

#### Source type — Voltage source model

Swing bus (default) | Voltage source with series impedance | PV bus | PQ bus

Type of voltage source that the block models.

#### Dependencies

The visibility of **Source voltage (pu)**, **Terminal voltage (pu)**, **Active power generated**, **Active power consumed**, **Reactive power consumed**, **Source phase**, **Minimum voltage (pu)** and **Internal source phase search range** depend on the value that you choose for this parameter.

#### Source voltage (pu) — Source voltage

1 (default) | scalar

Per-unit voltage that the source generates.

#### Dependencies

This parameter is visible only when you set the **Source type** parameter to **Voltage source with series impedance**.

#### Terminal voltage (pu) — Terminal voltage

1 (default) | scalar

Per-unit terminal voltage that the source generates.

#### Dependencies

This parameter is visible only if you set the **Source type** parameter to **Swing bus** or **PV bus**.

#### Active power generated — Active power generated

0 W (default) | scalar

Active power that the source generates.

#### Dependencies

This parameter is visible only if you set the **Source type** parameter to **PV bus**.

**Active power consumed — Active power consumed**

0 W (default)

Active power that the source consumes.

**Dependencies**

This parameter is visible only if you set the **Source type** parameter to PQ bus.

**Reactive power consumed — Reactive power consumed**

0 V\*A (default)

Reactive power that the source consumes.

**Dependencies**

This parameter is visible only if you set the **Source type** parameter to PQ bus.

**Rated voltage (phase-to-phase RMS) — Rated phase-to-phase RMS voltage**

$\sqrt{3} * 100 / \sqrt{2}$  V (default) | scalar

Rated phase-to-phase root mean square (RMS) voltage.

**Rated frequency — Rated frequency**

60 Hz (default) | scalar

Rated frequency, in Hz.

**Source phase — Source phase**

0 deg (default) | scalar

Phase shift of the source.

**Dependencies**

This parameter is visible only if you set the **Source type** parameter to Voltage source with series impedance.

**Impedance****Source impedance — Source impedance method**

None (default) | X/R Ratio | Series R | Series L | Series RL

Type of source impedance. Selecting any other options enables other parameters. The options are:

- None
- X/R Ratio
- Series R
- Series L
- Series RL

**Dependencies**

The visibility of **Short-circuit power level**, **Source X/R ratio**, **Source impedance parasitic parallel conductance**, **Source resistance**, and **Source inductance** depend on the value that you choose for this parameter.

**Short-circuit power level – Short-circuit power level**

1e6 V\*A (default) | scalar

Short-circuit power level.

**Dependencies**This parameter is visible only if you set the **Source impedance** parameter to X/R ratio.**Source X/R ratio – Reactance-to-resistance ratio**

15 (default) | scalar

Reactance-to-resistance ratio.

**Dependencies**This parameter is visible only if you set the **Source impedance** parameter to X/R ratio.**Source impedance parasitic parallel conductance – Source impedance parasitic parallel conductance**

0 1/0hm (default) | scalar

Source impedance parasitic parallel conductance.

**Dependencies**This parameter is visible only if you set the **Source impedance** parameter to X/R ratio or Series L or Series RL.**Source resistance – Source resistance**

0.01 Ohm (default) | scalar

Source resistance.

**Dependencies**This parameter is visible only if you set the **Source impedance** parameter to Series R or Series RL.**Source inductance – Source inductance**

3.97e-4 H (default) | scalar

Source inductance.

**Dependencies**This parameter is visible only if you set the **Source impedance** parameter to Series L or Series RL.**Expected Ranges****Minimum voltage (pu) – Minimum voltage**

0.95 (default) | scalar

Per-unit minimum voltage. This parameter assists with the initial solve in models with non-physical, very low voltages.

**Dependencies**

This parameter is visible only if you set the **Source type** parameter in the **Main** setting to **Swing bus**, **PV bus** or **PQ bus**.

**Internal source phase search range — Phase search range**

`[-inf, inf] deg (default) | vector`

Vector of the lower and upper boundaries for the internal source phase search. Use this range to help the initial solve converge to the desired load flow solution.

**Dependencies**

This parameter is visible only if, in the **Main** setting, you set the **Source type** parameter to **PV bus** or **PQ bus**.

## Low-Pass Filter (Discrete or Continuous)

Discrete-time or continuous-time low-pass filter

**Library:** Simscape / Electrical / Control / General Control

### Description

The Low-Pass Filter (Discrete or Continuous) block implements a low-pass filter in conformance with IEEE 421.5-2016<sup>[1]</sup>. In the standard, the filter is referred to as a Simple Time Constant.

You can switch between continuous and discrete implementations of the integrator using the **Sample time** parameter.

### Equations

#### Continuous

To configure the filter for continuous time, set the **Sample time** property to 0. This representation is equivalent to the continuous transfer function:

$$G(s) = \frac{K}{Ts + 1},$$

where:

- $K$  is the filter gain.
- $T$  is the filter time constant.

From the preceding transfer function, the filter defining equations are:

$$\begin{cases} \dot{x}(t) = \frac{1}{T}(Ku(t) - x(t)) \\ y(t) = x(t) \end{cases} \quad y(0) = x(0) = Ku_0,$$

where:

- $u$  is filter input.
- $x$  is filter state.
- $y$  is filter output.
- $t$  is simulation time.
- $u_0$  is the initial input to the block.

### Discrete

To configure the filter for discrete time, set the **Sample time** property to a positive, nonzero value, or to -1 to inherit the sample time from an upstream block. The discrete representation is equivalent to the transfer function:

$$G(z) = K \frac{(T_s/T)z^{-1}}{1 + (T_s/T - 1)z^{-1}},$$

where:

- $K$  is the filter gain.
- $T$  is the filter time constant.
- $T_s$  is the filter sample time.

From the discrete transfer function, the filter equations are defined using the forward Euler method:

$$\begin{cases} x(n+1) = \left(1 - \frac{T_s}{T}\right)x(n) + K\left(\frac{T_s}{T}\right)u(n) \\ y(n) = x(n) \end{cases} \quad y(0) = x(0) = Ku_0,$$

where:

- $u$  is the filter input.
- $x$  is the filter state.
- $y$  is the filter output.
- $n$  is the simulation time step.
- $u_0$  is the initial input to the block.

### Initial Conditions

To specify the initial conditions of this block, set **Initialization** to:

- **Inherited from block input** — The block sets the state and output initial conditions to the initial input.
- **Specify as parameter** — The block sets the state initial condition to the value of **Initial state**.

### Limiting the Integral

Set the **Upper saturation limit** and **Lower saturation limit** parameters to use the anti-windup saturation method.

The anti-windup method limits the integrator state between the lower saturation limit  $A$  and upper saturation limit  $B$ :

$$A < = x < = B .$$

Because the state is limited, the output can respond immediately to a reversal of the input sign when the integral is saturated. This block diagram depicts the implementation of the anti-windup saturation method in the filter.

This block does not provide a windup saturation method. To use the windup saturation method, set the **Upper saturation limit** parameter to `inf`, the **Lower saturation limit** parameter to `-inf`, and attach a saturation block to the output.

### Bypass Filter Dynamics

Set the time constant to a value smaller than or equal to the sample time to ignore the dynamics of the filter. When bypassed, the block feeds the gain-scaled input directly to the output:

$$T \leq T_s \rightarrow y = Ku$$

In the continuous case, the sample time and time constant must both be zero.

## Ports

### Input

#### **u** – Filter input

vector

Low-pass filter input signal. The block uses the input initial value to determine the state initial value.

Data Types: `single` | `double`

### Output

#### **y** – Filter output

vector

Low-pass filter output.

Data Types: `single` | `double`

## Parameters

#### **Gain** – Filter gain

1 (default) | positive number

Low-pass filter gain.

#### **Time constant** – Filter time constant

1 (default) | positive number

Low-pass filter time constant. In the discrete implementation, set this value to less than the **Sample time** to bypass the dynamics of the filter.

#### **Upper saturation limit** – State upper limit

`inf` (default) | real number

Low-pass filter upper state limit. Set this to `inf` for an unsaturated upper limit, or to a finite value to prevent upper windup of the filter's integrator.

**Lower saturation limit — State lower limit**

`-inf` (default) | real number

Low-pass filter lower state limit. Set this to `-inf` for an unsaturated lower limit, or to a finite value to prevent lower windup of the filter's integrator.

**Initialization — Initial state specification**

Inherited from block input (default) | Specify as parameter

Specify the initial state condition for this block. For more information, see “Initial Conditions” on page 1-930.

**Initial state — Initial state**

`0` (default) | real number

Block initial state.

**Dependencies**

To enable this parameter, set **Initialization** to `Specify as parameter`.

**Sample time (-1 for inherited) — Block sample time**

`-1` (default) | `0` | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify `-1`. For discrete-time operation, specify a positive integer. For continuous-time operation, specify `0`.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

# Luenberger Observer

Discrete-time Luenberger observer

**Library:** Simscape / Electrical / Control / Observers

## Description

The Luenberger Observer block implements a discrete time Luenberger observer. Use this block to estimate the states of an observable system using:

- The discrete inputs and outputs of the system.
- A discrete state-space representation of the system.

The Luenberger Observer is also sometimes referred to as a state observer or simply an observer.

You can control multi-input, multi-output systems by passing the output state vector of this block to a State Feedback Controller block.

## Defining Equations

The block implements a discrete time Luenberger Observer using the backward Euler method due to its simplicity and stability.

The estimator is given by this difference equation:

$$\hat{x}(k+1) = A_d \hat{x}(k) + B_d u(k) + L_d (y(k) - \hat{y}(k)),$$

where:

- $\hat{x}(k)$  is the  $k^{\text{th}}$  estimated state vector.
- $\hat{y}(k)$  is the  $k^{\text{th}}$  estimated output vector.
- $u(k)$  is the  $k^{\text{th}}$  input vector.
- $y(k)$  is the  $k^{\text{th}}$  measured output vector.
- $A_d$  is the discretized state matrix.
- $B_d$  is the discretized input matrix.
- $L_d$  is the discretized observer gain matrix.

The dynamics of the estimation error are described by:

$$e(k+1) = (A_d - L_d C_d) e(k),$$

where:

- $e(k)$  is the  $k^{\text{th}}$  error vector.

- $C_d$  is the output matrix.

The estimation error converges to zero when  $A_d - L_d C_d$  has its eigenvalues inside the unit circle. Therefore, the value of  $L_d$  should be such that this goal is achieved. The block computes the observer gain by solving

$$L_d^T = GX^{-1},$$

where  $G$  is an arbitrary matrix and  $X$  is obtained by solving the Sylvester equation:

$$A_d^T X - X \Lambda = C_d^T G.$$

Here,  $\Lambda$  is a matrix with the desired eigenvalues, which are not the same as the eigenvalues of  $A_d$ . This diagram shows the basic structure of a discrete time Luenberger Observer.

### Assumptions

The system is observable, which is true if the state of the system can be determined from the input and output in a finite time. Mathematically, this means that the system observability matrix has full rank.

### Limitations

The desired eigenvalues are not the same as the eigenvalues of the open-loop model.

### Ports

#### Input

##### **u** – Control input

vector

Input signal to the system whose state we want to estimate, specified as a vector.

Data Types: `single` | `double`

### **y — System output**

vector

Measured output of the system whose state we want to estimate, specified as a vector.

Data Types: `single` | `double`

### **Output**

#### **xhat — State estimate**

vector

Estimate of the state of the system, specified as a vector.

Data Types: `single` | `double`

## **Parameters**

### **State-space parameterization — State-space parameterization**

`Discrete-time` (default) | `Continuous-time`

Select the strategy for parameterizing the state-space matrices and desired poles for the observer. The block implementation is discrete regardless of this parameterization.

#### **Discrete A matrix — A matrix in discrete time**

1 (default) | real scalar or matrix

State matrix of the discrete-time state-space model. The A matrix must be square, with the number of rows and columns equal to the order of the system.

#### **Dependencies**

To enable this parameter, set **State-space parameterization** to `Discrete-time`.

#### **Discrete B matrix — B matrix in discrete time**

1 (default) | real scalar or matrix

Input matrix of the discrete-time state-space model. The B matrix must have the number of rows equal to the order of the system, and the number of columns equal to the number of system inputs.

#### **Dependencies**

To enable this parameter, set **State-space parameterization** to `Discrete-time`.

#### **Discrete C matrix — C matrix in discrete time**

1 (default) | real scalar or matrix

Output matrix of the discrete-time state-space model. The C matrix must have the number of rows equal to the number of outputs of the system, and the number of columns equal to the order of the system.

#### **Dependencies**

To enable this parameter, set **State-space parameterization** to `Discrete-time`.

**Discrete D matrix — D matrix in discrete time**

1 (default) | real scalar or matrix

Feedthrough matrix of the discrete-time state-space model. The D matrix must have the number of rows equal to the number of system outputs, and the number of columns equal to the number of system inputs.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Discrete-time.

**Continuous A matrix — A matrix in continuous time**

1 (default) | real scalar or matrix

State matrix of the continuous-time state-space model. The A matrix must be square, with the number of rows and columns equal to the order of the system.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Continuous-time.

**Continuous B matrix — B matrix in continuous time**

1 (default) | real scalar or matrix

Input matrix of the continuous-time state-space model. The B matrix must have the number of rows equal to the order of the system, and the number of columns equal to the number of system inputs.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Continuous-time.

**Continuous C matrix — C matrix in continuous time**

1 (default) | real scalar or matrix

Output matrix of the continuous-time state-space model. The C matrix must have the number of rows equal the number of outputs of the system, and the number of columns equal to the order of the system.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Continuous-time.

**Continuous D matrix — D matrix in continuous time**

1 (default) | real scalar or matrix

Feedthrough matrix of the continuous-time state-space model. The D matrix must have the number of rows equal to the number of system outputs, and the number of columns equal to the number of system inputs.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Continuous-time.

**Observer design — State-space parameterization**

Desired eigenvalues (default) | Observer gain

Select the strategy for parameterizing observer gain.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Discrete-time.

**Observer gain — Observer gain**

1 (default) | real scalar or matrix

Specify the observer gain that puts all eigenvalues of the matrix  $A_d - L_d C_d$  inside the unit circle. The gain matrix must have the number of rows equal to number of system inputs and the number of columns equal to the order of the system.

**Dependencies**

To enable this parameter, set:

- **State-space parameterization** to Discrete-time.
- **Observer design** to Observer gain.

**Desired eigenvalues — Observer eigenvalues**

0 (default) | real vector

Specify the location of the eigenvalues:

- To have negative real part if **State-space parameterization** is set to Continuous-time. In this case, the eigenvalues of the continuous-time system are approximated to the discrete ones based on the **Discretization sample time**.
- To lie within the unit circle if **State-space parameterization** is set to Discrete-time.

The Observer gain is then calculated based on these eigenvalues. The size of the vector should be the same as the system order.

**Initial conditions — Initial conditions**

0 (default) | real vector with length equal to system order

Select the initial condition of each state.

**Discretization sample time — Discretization sample time**

0.1 (default) | positive real number

Value used to discretize the state space matrices and also approximate the discrete-time eigenvalues.

**Dependencies**

To enable this parameter, set **State-space parameterization** to Continuous-time.

**Sample time — Sample time**

0.1 (default) | -1 or positive real number

Value used to simulate the dynamics of the model. Choose the same value as **Discretization sample time**, unless the block is placed within a triggered subsystem, in which case you must set it to -1.

# Machine Inertia

Machine inertia parameterized using machine inertia constant or anchor inertia

**Library:** Simscape / Electrical / Electromechanical / Mechanical

## Description

The Machine Inertia block models inertia and damping that you connect to the mechanical rotational R port of a three-phase machine. The block has an internal connection to a mechanical rotational reference. The figure shows an equivalent configuration to the Machine Inertia block using Simscape mechanical rotational components.

Based on the value you select for the **Specify inertia parameterization** by parameter, you specify inertia  $J$  directly or using the machine inertia constant  $H$ .

If you specify the inertia constant, the block calculates inertia by

$$J = \frac{2HS_{rated}}{(2\pi F_{rated}/N)^2},$$

where:

- $J$  is inertia in  $\text{kg}\cdot\text{m}^2$ .
- $H$  is the inertia constant in  $\text{sW}/\text{VA}$ .
- $S_{rated}$  is the machine rated apparent power in VA.
- $F_{rated}$  is the machine rated electrical frequency in Hz.
- $N$  is the number of machine pole pairs.

You specify damping that represents viscous friction between the machine rotor and mechanical rotational reference. Based on the value you select for the **Specify damper parameterization** by parameter, you specify a damping coefficient in SI units or in per-unit. If you specify the damping coefficient in per-unit, the block calculates the damping coefficient in SI units by

$$\omega_{base} = \frac{2\pi F_{rated}}{N},$$

$$T_{base} = \frac{S_{rated}}{\omega_{base}},$$

$$D_{base} = \frac{T_{base}}{\omega_{base}},$$

and

$$D = D_{pu}D_{base},$$

where:

- $\omega_{base}$  is the base mechanical angular speed in rad/s.
- $T_{base}$  is the base damping torque in Nm.
- $D_{base}$  is the base damping coefficient in Nm/(rad/s).
- $D_{pu}$  is the damping coefficient in per-unit.
- $D$  is the damping coefficient in SI units of Nm/(rad/s).

### Display Option

You can display machine parameters using the **Electrical** menu on the block context menu.

Machine Mechanical Power

## Machine Mechanical Power

Machine mechanical power defined in the SI or per-unit system

**Library:** Simscape / Electrical / Electromechanical / Mechanical

### Description

The Machine Mechanical Power block supplies specified power to, or draws specified power from, the machine that it connects to. It includes a representation of machine inertia and a mechanical rotational reference. In generator mode, the physical signal input defines the mechanical power that is input to the machine. In motor mode, it defines the mechanical power output from the machine.

The figure shows an equivalent configuration to the per-unit variant model of the Machine Mechanical Power block using Simscape mechanical rotational components.

### Electrical Defining Equations

The SI model converts the SI values that you enter in the dialog box to per-unit values for simulation. For information on the relationship between SI and per-unit machine parameters, see “Per-Unit Conversion for Machine Parameters”. For information on per-unit parameterization, see “Per-Unit System of Units”.

To calculate the torque that it applies to the inertia, the block divides the power demand by the present speed. To set the peak torque limit, specify a value for the **Peak torque to rated torque ratio** parameter. Use the **Specify inertia parameterization by** parameter to specify inertia,  $J$ , directly or indirectly, with the inertia constant for the machine,  $H$ .

If you specify the inertia constant for the machine, the block calculates inertia as

$$J = \frac{2HS_{rated}}{(2\pi F_{rated}/N)^2},$$

where:

- $J$  is inertia in kg·m<sup>2</sup>.
- $H$  is the inertia constant in sW/VA.
- $S_{rated}$  is the rated apparent power of the connected machine in VA.
- $F_{rated}$  is the rated electrical frequency of the connected machine in Hz.
- $N$  is the number of machine pole pairs.

Damping represents viscous friction between the machine rotor and mechanical rotational reference. Based on the value you select for the **Specify damper parameterization by** parameter, you specify a damping coefficient in per-unit or in SI units. If you specify the damping coefficient in per-unit, the block calculates the damping coefficient in SI units using these equations:

$$\omega_{base} = \frac{2\pi F_{rated}}{N},$$

$$T_{base} = \frac{S_{rated}}{\omega_{base}},$$

$$D_{base} = \frac{T_{base}}{\omega_{base}},$$

and

$$D = D_{pu}D_{base},$$

where:

- $\omega_{base}$  is the base mechanical speed in rad/s.
- $T_{base}$  is the base damping torque in Nm.
- $D_{base}$  is the base damping coefficient in Nm/(rad/s).
- $D_{pu}$  is the damping coefficient in per-unit.
- $D$  is the damping coefficient in SI units of Nm/(rad/s).

# Model Reference Adaptive Controller

Discrete-time PID-based model reference adaptive control

**Library:** Simscape / Electrical / Control / General Control

## Description

The Model Reference Adaptive Controller block implements discrete-time proportional-integral-derivative (PID) model reference adaptive control (MRAC). The three main components of an MRAC system are the reference model, the adjustment mechanism, and the controller.

## Equations

The control equation is

$$u_{pid}(k) = \left[ K_p + K_i \frac{T_s z}{z-1} + K_d \frac{z-1}{T_s z} \right] e(k),$$

where:

- $u_{pid}$  is the controller output.
- $K_p$  is the proportional gain.
- $K_i$  is the integral gain.
- $K_d$  is the differential gain.

- $T_s$  is the sample time.
- $e$  is the error.

The reference model is the transfer function for the closed-loop system. This model captures the desired behavior of the closed-loop system. It is implemented as the discrete-time transfer function

$$G_m(z) = \frac{B(z)}{A(z)}.$$

The adaptation mechanism adjusts the control action based on the error between the plant output and the reference model output as

$$\theta = (y - y_m)y_m \frac{-\gamma T_s z}{z-1},$$

where:

- $\theta$  is the adaptation parameter.
- $y$  is the plant output.
- $y_m$  is the reference model output.
- $\gamma$  is the learning rate.

Increasing the value of  $\gamma$  results in faster adaptation to plant changes.

The adjusted control signal,  $u$ , is

$$u(k) = u_{pid}(k)\theta(k).$$

## Ports

### Input

#### **r — Plant reference, r**

scalar

Plant system reference signal.

Data Types: `single` | `double`

#### **y — Plant output, y**

scalar

Plant system output signal.

Data Types: `single` | `double`

#### **Reset — Integrator reset**

scalar

External reset signal (rising edge) for the integrator.

Data Types: `Boolean`

**Output****u — Controller adjusted output,  $u$** 

scalar

Adjusted control signal.

Data Types: single | double

**Parameters****Controller Parameters****Proportional gain — Controller proportional gain,  $K_p$** 

1 (default) | positive scalar

Proportional gain,  $K_p$ , of the controller.**Integral gain — Controller integral gain,  $K_i$** 

1 (default) | positive scalar

Integral gain,  $K_i$ , of the controller.**Derivative gain — Controller derivative gain,  $K_d$** 

0 (default)

Derivative gain,  $K_d$ , of the controller.**Anti-windup gain — Controller anti-windup gain**

1 (default) | positive scalar

Anti-windup gain of the controller.

**Use filtered derivative — Filter option**

on (default) | off

Choose whether to use a filter coefficient for the reference signal.

**Dependencies**The **Filter coefficient** parameter is only visible when the **Use filtered derivative** check box is selected.**Filter coefficient — Reference signal filter coefficient**

100 (default)

Filter coefficient for the reference signal.

**Dependencies**This parameter is only visible when the **Use filtered derivative** check box is selected.**Control action upper limit — Control signal upper limit,  $u_{pid\_max}$** 

5 (default)

Upper bound for the control signal.

**Control action lower limit – Control signal lower limit,  $u_{pid\_min}$**   
-5 (default)

Lower bound for the control signal.

**Sample time (-1 for inherited) – Block sample time**  
-1 (default) | positive scalar

Time, in s, between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

If this block is inside a triggered subsystem, inherit the sample time by setting this parameter to -1. If this block is in a continuous variable-step model, specify the sample time explicitly using a positive scalar.

#### Dependencies

If you set **Sample time (-1 for inherited)** to -1 and, in the **Reference Model** settings, set **Model parameterization** to Continuous-time, the **Discretization sample time** parameter becomes visible in the **Reference Model** settings.

#### Reference Model

**Model parameterization – Discrete or continuous model option**  
Discrete-time (default) | Continuous-time

Mathematical model for the controller.

#### Dependencies

Choosing:

- Discrete-time makes the discrete-time parameters visible.
- Continuous-time makes the continuous-time parameters visible. Also, in the **Controller Parameter** settings, if **Sample time (-1 for inherited)** is set to -1, choosing this option makes the **Discretization sample time** parameter visible in the **Reference Model** settings.

**Discrete-time numerator – Discrete-time transfer function numerator**  
[0.01 -0.0099] (default)

Numerator for the discrete-time transfer function.

#### Dependencies

Choosing Discrete-time for **Model parameterization** makes this parameter visible.

**Discrete-time denominator – Discrete-time transfer function denominator**  
[1 -1.9801 0.9802] (default) | vector

Denominator for the discrete-time transfer function.

#### Dependencies

Choosing Discrete-time for **Model parameterization** makes this parameter visible.

**Discretization sample time — Sample time for discretization**

0.01 (default) | -1 or positive number

Time, in seconds, between consecutive discretizations. If block sample time is inherited, specify the discretization sample time explicitly.

**Dependencies**

This parameter is only visible when both of these conditions are met:

- In the **Control Parameters** settings, **Sample time (-1 for inherited)** is set to -1.
- In the **Reference Model** settings, **Model parameterization** is set to Continuous-time.

**Continuous-time numerator — Continuous-time transfer function numerator**

[1 1] (default) | vector

Numerator for the continuous-time transfer function.

**Dependencies**

Choosing Continuous-time for **Model parameterization** makes this parameter visible.

**Continuous-time denominator — Continuous-time transfer function denominator**

[1 2 1] (default) | vector

Denominator for the continuous-time transfer function.

**Dependencies**

Choosing Continuous-time for **Model parameterization** makes this parameter visible.

**Adjustment Mechanism****Learning rate —  $\gamma$** 

0.5 (default)

Rate of adjustment to plant changes.

# Modular Multilevel Converter Arm

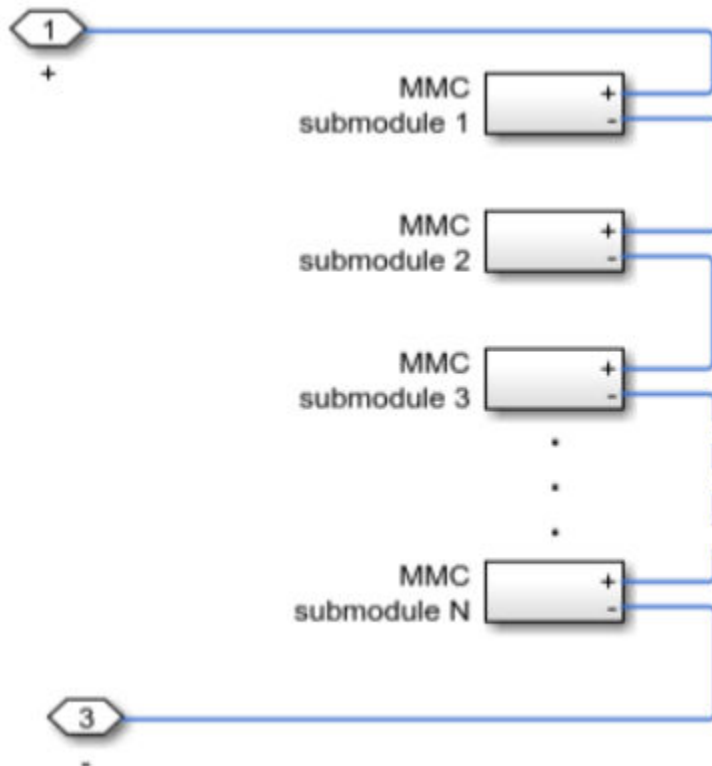

Modular multilevel converter arm with series-connected power submodules

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Modular Multilevel Converter Arm block models a modular multilevel converter arm as a number of series-connected power submodules.

**Half-Bridge Topology**

**Full-Bridge Topology**

This blocks allows you to select the level of model fidelity by choosing between a detailed model with switching devices or an equivalent model. You can choose from these switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to *Averaged switch* and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

## Ports

### Input

#### **G — Submodule gate control**

vector of physical signals

Physical signal port associated with the gate signal for all submodules of the modular multilevel converter arm, specified as a vector of physical signals.

If you set the **Converter topology** parameter to *Half-bridge*, the output is a vector of length  $2 * Nsm$ , where  $Nsm$  is the **Number of power submodules**.

If you set the **Converter topology** parameter to Full-bridge, the output is a vector of length  $4 \cdot N_{sm}$ .

#### **Dependencies**

To enable this port, set **Fidelity level** to Detailed model - switching devices or Equivalent model - PWM-controlled.

#### **ref — Submodules reference waveform**

physical signal

Physical signal port associated with the reference waveforms, specified as a physical signal.

#### **Dependencies**

To enable this port, set **Fidelity level** to Equivalent model - waveform-controlled.

#### **Output**

#### **vc — Capacitor voltages**

vector of physical signals

Physical signal port associated with the capacitor voltages for each submodule in the modular multilevel converter arm, specified as a vector of physical signals.

#### **Dependencies**

To enable this port, set **Capacitor voltages** to Instrumented.

#### **Conserving**

#### **+ — Positive terminal**

electrical

Electrical conserving port associated with the positive terminal of the modular multilevel converter arm.

#### **- — Negative terminal**

electrical

Electrical conserving port associated with the negative terminal of the modular multilevel converter arm.

## **Parameters**

### **Main**

#### **Converter topology — Converter topology**

Half-bridge (default) | Full-bridge

Topology of the modular multilevel converter.

#### **Fidelity level — Model fidelity**

Detailed model - switching devices (default) | Equivalent model - PWM-controlled |  
Equivalent model - waveform-controlled

Level of fidelity of the model.

**Capacitor voltages — Capacitor voltage instrumentation**

Instrumented (default) | Uninstrumented

Whether to instrument the capacitor voltages.

**Number of power submodules — Number of submodules**

1 (default) | positive scalar

Number of power submodules of the modular multilevel converter.

**Capacitance — Submodule capacitance**

1e-7 F (default) | scalar | vector

Capacitance of a submodule. If you enter a vector, the vector must be of length  $N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.**Capacitor effective series resistance — Capacitor effective series resistance**

1e-6 Ohm (default) | scalar | vector

Capacitor effective series resistance. If you enter a vector, the vector must be of length  $N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.**Dependencies**To enable this parameter, set **Fidelity level** to Detailed model - switching devices.**Capacitor initial voltage — Capacitor initial voltage**

500 V (default) | scalar | vector

Initial voltage of the capacitor. If you enter a vector, the vector must be of length  $N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.**Switching Devices**

This table shows how enabled parameters in the **Switching Devices** settings depend on the **Switching device** that you select. To learn how to read the table, see “Parameter Dependencies” on page A-2. To enable these settings, set **Fidelity level** to Detailed model - switching devices.

### Switching device – Switch type

*Ideal Semiconductor Switch* (default) | *GTO* | *IGBT* | *MOSFET* | *Thyristor* | *Averaged Switch*

Switching device type for the converter.

### Dependencies

See the Switching Devices Parameter Dependencies table.

### Forward voltage – Voltage

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is the:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

### Dependencies

See the Switching Devices Parameter Dependencies table.

### On-state resistance – Resistance

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is the:

- GTO — Rate of change of the voltage versus the current above the forward voltage

- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Drain-source on resistance — Resistance

0.001 Ohm (default) | scalar

Resistance between the drain and the source. The gate-to-source voltage also affects the **Drain-source on resistance** parameter.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Off-state conductance — Conductance when device is off

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is the:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Threshold voltage — Voltage threshold

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. The voltage threshold applies to different devices depending on the switching device used:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate trigger voltage, Vgt — Gate-cathode activation voltage threshold

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate turn-off voltage, Vgt\_off – Gate-cathode deactivation voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Holding current – Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Integer for piecewise constant approximation of gate input (0 for disabled) – Integer mode for FPGA deployment**

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

**Dependencies**

To enable this parameter, set **Switching device** to Averaged Switch.

**Protection Diodes**

For more information on these parameters, see Diode.

**Model dynamics – Diode model**

Diode with no dynamics (default) | Diode with charge dynamics | None

Diode type. The options are:

- **None** — The block does not model diode dynamics.
- **Diode with no dynamics** — Select this option to prioritize simulation speed using the Diode block.
- **Diode with charge dynamics** — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

---

**Note** If you set **Switching device** to Averaged Switch in the **Switching Device** settings, the **Diode with no dynamics** setting is automatically selected.

---

**Dependencies**

To enable this parameter, set **Switching device** to GTO, Ideal Semiconductor Switch, IGBT, MOFSET, or Thyristor.

**Forward voltage — Forward voltage**

0.8 V (default) | scalar

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

**On resistance — On resistance**

0.001 Ohm (default) | scalar

Rate of change of voltage versus the current above the **Forward voltage**.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

**Off conductance — Off conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

**Junction capacitance — Junction capacitance**

50 nF (default) | scalar

Diode junction capacitance.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Peak reverse current,  $i_{RM}$  — Peak reverse current**

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Initial forward current when measuring  $i_{RM}$  — Initial forward current when measuring  $i_{RM}$** 

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Rate of change of current when measuring iRM – Rate of change of current when measuring iRM**

-50 A/ $\mu$ s (default) | negative scalar

Rate of change of the current when measuring the peak reverse current. This value must be less than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Reverse recovery time parameterization – Reverse recovery time option**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Determines how you specify reverse recovery time.

If you select Specify stretch factor or Specify reverse recovery charge, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates TM and Tau” on page 1-452.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Reverse recovery time, trr – Reverse recovery time**

15  $\mu$ s (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, iRM** parameter divided by the value of the **Rate of change of current when measuring iRM** parameter.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery time directly.

**Reverse recovery time stretch factor – Reverse recovery time stretch factor**

3 (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify stretch factor.

**Reverse recovery charge,  $Q_{rr}$  — Reverse recovery charge**1500 s\* $\mu$ A (default) | scalar

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Use this parameter if the data sheet for your diode specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ , where:

- $i_{RM}$  is the value specified for **Peak reverse current,  $i_{RM}$** .
- $a$  is the value specified for **Rate of change of current when measuring  $i_{RM}$** .

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery charge.

**Snubbers**

To enable the **Snubbers** settings, set **Fidelity level** to Detailed model - switching devices and **Switching device** to GTO, Ideal Semiconductor Switch, IGBT, MOFSET, or Thyristor.

**Snubber — Snubber**

None (default) | RC snubber

Snubber for each switching device:

- None
- RC snubber

**Snubber resistance — Snubber resistance**

0.1 Ohm (default) | scalar

Snubber resistance.

**Dependencies**

To enable this parameter, set **Snubber** to RC snubber.

**Snubber capacitance — Snubber capacitance**

1e-7 F (default) | scalar

Snubber capacitance.

**Dependencies**

To enable this parameter, set **Snubber** to RC snubber.

# Modular Multilevel Converter Leg

Modular multilevel converter leg with series-connected power submodules

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The Modular Multilevel Converter Leg block models a modular multilevel converter leg as a two arms that are implemented with a number of series-connected power submodules.

**Half-Bridge Topology**

**Full-Bridge Topology**

This blocks allows you to select the level of model fidelity by choosing between a detailed model with switching devices or an equivalent model. You can choose from these switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to **Averaged switch** and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Ports

### Input

#### **G — Submodule gate control**

vector of physical signals

Physical signal port associated with the gate signal for all submodules of the modular multilevel converter leg, specified as a vector of physical signals.

If you set the **Converter topology** parameter to `Half-bridge`, the output is a vector of length  $4 * N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.

If you set the **Converter topology** parameter to `Full-bridge`, the output is a vector of length  $8 * N_{sm}$ .

#### **Dependencies**

To enable this port, set **Fidelity level** to `Detailed model - switching devices` or `Equivalent model - PWM-controlled`.

#### **ref — Submodules reference waveform**

vector of physical signals

Physical signal port associated with the reference waveforms, specified as a vector of physical signals of length 2.

#### **Dependencies**

To enable this port, set **Fidelity level** to `Equivalent model - waveform-controlled`.

### Output

#### **vc — Capacitor voltages**

vector of physical signals

Physical signal port associated with the capacitor voltages for each submodule in the modular multilevel converter leg, specified as a vector of physical signals.

#### **Dependencies**

To enable this port, set **Capacitor voltages** to `Instrumented`.

### Conserving

#### **+ — Positive terminal**

electrical

Electrical conserving port associated with the positive terminal of the modular multilevel converter leg.

#### **- — Negative terminal**

electrical

Electrical conserving port associated with the negative terminal of the modular multilevel converter leg.

**a – Phase a terminal**

electrical

Electrical conserving port associated with the single-phase terminal of the modular multilevel converter leg.

**Parameters****Main****Converter topology – Converter topology**

Half-bridge (default) | Full-bridge

Topology of the modular multilevel converter.

**Fidelity level – Model fidelity**

Detailed model - switching devices (default) | Equivalent model - PWM-controlled | Equivalent model - waveform-controlled

Level of fidelity of the model.

**Capacitor voltages – Capacitor voltage instrumentation**

Instrumented (default) | Uninstrumented

Whether to instrument the capacitor voltages.

**Number of power submodules – Number of submodules**

1 (default) | positive scalar

Number of power submodules of the modular multilevel converter.

**Capacitance – Submodule capacitance**

1e-7 F (default) | scalar | vector

Capacitance of a submodule. If you enter a vector, the vector must be of length  $2 * N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.

**Capacitor effective series resistance – Capacitor effective series resistance**

1e-6 Ohm (default) | scalar | vector

Capacitor effective series resistance. If you enter a vector, the vector must be of length  $2 * N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.

**Dependencies**

To enable this parameter, set **Fidelity level** to Detailed model - switching devices.

**Arm inductance – Arm inductance**

1e-6 H (default) | scalar

Inductance of the arm.

**Arm inductance series resistance – Arm inductance series resistance**

0 Ohm (default) | scalar

Arm inductance series resistance.

**Capacitor initial voltage – Capacitor initial voltage**

500 V (default) | scalar | vector

Initial voltage of the capacitor. If you enter a vector, the vector must be of length  $2 * N_{sm}$ , where  $N_{sm}$  is the **Number of power submodules**.

**Switching Devices**

This table shows how enabled parameters in the **Switching Devices** settings depend on the **Switching device** that you select. To learn how to read the table, see “Parameter Dependencies” on page A-2. To enable these settings, set **Fidelity level** to Detailed model - switching devices.

**Switching device – Switch type**

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Switching device type for the converter.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Forward voltage – Voltage**

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is the:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**

- Thyristor — Minimum voltage required for the device to turn on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**On-state resistance — Resistance**

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is the:

- GTO — Rate of change of the voltage versus the current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source. The gate-to-source voltage also affects the **Drain-source on resistance** parameter.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance when device is off**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is the:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. The voltage threshold applies to different devices depending on the switching device used:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate trigger voltage, $V_{gt}$ — Gate-cathode activation voltage threshold

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate turn-off voltage, $V_{gt\_off}$ — Gate-cathode deactivation voltage threshold

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Holding current — Current threshold

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Integer for piecewise constant approximation of gate input (0 for disabled) — Integer mode for FPGA deployment

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

#### Dependencies

To enable this parameter, set **Switching device** to Averaged Switch.

#### Protection Diodes

For more information on these parameters, see Diode.

#### Model dynamics — Diode model

Diode with no dynamics (default) | Diode with charge dynamics | None

Diode type. The options are:

- **None** — The block does not model diode dynamics.
- **Diode with no dynamics** — Select this option to prioritize simulation speed using the Diode block.
- **Diode with charge dynamics** — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

---

**Note** If you set **Switching device** to Averaged Switch in the **Switching Device** settings, the Diode with no dynamics setting is automatically selected.

---

### **Dependencies**

To enable this parameter, set **Switching device** to GTO, Ideal Semiconductor Switch, IGBT, MOFSET, or Thyristor.

### **Forward voltage — Forward voltage**

0.8 V (default) | scalar

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

### **Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

### **On resistance — On resistance**

0.001 Ohm (default) | scalar

Rate of change of voltage versus the current above the **Forward voltage**.

### **Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

### **Off conductance — Off conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

### **Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

### **Junction capacitance — Junction capacitance**

50 nF (default) | scalar

Diode junction capacitance.

### **Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Peak reverse current,  $i_{RM}$  — Peak reverse current**

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Initial forward current when measuring  $i_{RM}$  — Initial forward current when measuring  $i_{RM}$** 

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Rate of change of current when measuring  $i_{RM}$  — Rate of change of current when measuring  $i_{RM}$** -50 A/ $\mu$ s (default) | negative scalar

Rate of change of the current when measuring the peak reverse current. This value must be less than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Reverse recovery time parameterization — Reverse recovery time option**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Determines how you specify reverse recovery time.

If you select Specify stretch factor or Specify reverse recovery charge, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates  $T_M$  and  $\tau$ ” on page 1-452.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Reverse recovery time,  $t_{rr}$  — Reverse recovery time**15  $\mu$ s (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery time directly.

**Reverse recovery time stretch factor – Reverse recovery time stretch factor**

3 (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify stretch factor.

**Reverse recovery charge, Qrr – Reverse recovery charge**

1500 s\*μA (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ , where:

- $i_{RM}$  is the value specified for **Peak reverse current, iRM**.
- $a$  is the value specified for **Rate of change of current when measuring iRM**.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery charge.

**Snubbers**

To enable the **Snubbers** settings, set **Fidelity level** to Detailed model - switching devices and **Switching device** to GTO, Ideal Semiconductor Switch, IGBT, MOFSET, or Thyristor.

**Snubber – Snubber**

None (default) | RC snubber

Snubber for each switching device:

- None
- RC snubber

**Snubber resistance – Snubber resistance**

0.1 Ohm (default) | scalar

Snubber resistance.

**Dependencies**

To enable this parameter, set **Snubber** to RC snubber.

**Snubber capacitance – Snubber capacitance**

1e-7 F (default) | scalar

Snubber capacitance.

### Dependencies

To enable this parameter, set **Snubber** to RC snubber.

## Modular Multilevel Converter (Three-Phase)

Three-phase modular multilevel converter with series-connected power submodules

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

### Description

The Modular Multilevel Converter (Three-Phase) block models a three-phase modular multilevel converter. Each phase consists of two arms that are implemented with a number of series-connected power submodules.

Each submodule consists of a half-bridge or full-bridge converter and a capacitor.

### Half-Bridge Topology

**Full-Bridge Topology**

This blocks allows you to select the level of model fidelity by choosing between a detailed model with switching devices or an equivalent model. You can choose from these switching devices are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).
- Averaged Switch — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

### Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to **Averaged switch** and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input **G**. To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Ports

### Input

#### **G — Submodule gate control**

matrix of physical signals

Physical signal port associated with the gate signal for all submodules of the modular multilevel converter, specified as a matrix.

If you set the **Converter topology** parameter to `Half-bridge`, the signal is a vector of length  $12 * Nsm$ , where  $Nsm$  is the **Number of power submodules**.

If you set the **Converter topology** parameter to `Full-bridge`, the signal is a vector of length  $24 * Nsm$ .

#### **Dependencies**

To enable this port, set **Fidelity level** to `Detailed model - switching devices` or `Equivalent model - PWM-controlled`.

#### **ref — Submodule reference waveform**

vector of physical signals

Physical signal port associated with the reference waveforms of the submodules, specified as a vector of length 6.

#### **Dependencies**

To enable this port, set **Fidelity level** to `Equivalent model - waveform-controlled`.

### Output

#### **vc — Capacitor voltages**

vector of physical signals

Physical signal port associated with the capacitor voltages for each submodule in the modular multilevel converter, returned as a vector.

#### **Dependencies**

To enable this port, set **Capacitor voltages** to `Instrumented`.

### Conserving

#### **+ — Positive terminal**

electrical

Electrical conserving port associated with the positive terminal of the modular multilevel converter.

#### **- — Negative terminal**

electrical

Electrical conserving port associated with the negative terminal of the modular multilevel converter.

#### **~ — Three-phase port**

electrical

Expandable three-phase electrical port associated with the three-phase terminal of the modular multilevel converter.

#### **Dependencies**

To enable this port, set **Electrical connection** to Composite three-phase ports.

#### **a – a-phase**

electrical

Electrical conserving port associated with *a*-phase.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

#### **b – b-phase**

electrical

Electrical conserving port associated with *b*-phase.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

#### **c – c-phase**

electrical

Electrical conserving port associated with *c*-phase.

#### **Dependencies**

To enable this port, set **Electrical connection** to Expanded three-phase ports.

## **Parameters**

### **Main**

#### **Electrical connection – Electrical connection**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to have composite or expanded three-phase ports.

#### **Converter topology – Converter topology**

Half-bridge (default) | Full-bridge

Topology of the modular multilevel converter.

#### **Fidelity level – Model fidelity**

Detailed model - switching devices (default) | Equivalent model - PWM-controlled |  
Equivalent model - waveform-controlled

Level of fidelity of the model.

#### **Capacitor voltages – Capacitor voltage instrumentation**

Instrumented (default) | Uninstrumented

Whether to instrument the capacitor voltages.

**Number of power submodules – Number of submodules**

1 (default) | positive scalar

Number of power submodules of the modular multilevel converter.

**Capacitance – Submodule capacitance**

1e-7 F (default) | scalar | vector

Capacitance of a submodule. If you enter a vector, the vector must be of length  $6 * Nsm$ , where  $Nsm$  is the **Number of power submodules**.

**Capacitor effective series resistance – Capacitor effective series resistance**

1e-6 Ohm (default) | scalar | vector

Capacitor effective series resistance. If you enter a vector, the vector must be of length  $6 * Nsm$ , where  $Nsm$  is the **Number of power submodules**.

**Dependencies**

To enable this parameter, set **Fidelity level** to Detailed model - switching devices.

**Arm inductance – Arm inductance**

1e-6 H (default) | scalar

Inductance of the arm.

**Arm inductance series resistance – Arm inductance series resistance**

0 Ohm (default) | scalar

Arm inductance series resistance.

**Capacitor initial voltage – Capacitor initial voltage**

500 V (default) | scalar | vector

Initial voltage of the capacitor. If you enter a vector, the vector must be of length  $6 * Nsm$ , where  $Nsm$  is the **Number of power submodules**.

**Switching Devices**

This table shows how enabled parameters in the **Switching Devices** settings depend on the **Switching device** that you select. To learn how to read the table, see “Parameter Dependencies” on page A-2. To enable these settings, set **Fidelity level** to Detailed model - switching devices.

### Switching device – Switch type

*Ideal Semiconductor Switch* (default) | *GTO* | *IGBT* | *MOSFET* | *Thyristor* | *Averaged Switch*

Switching device type for the converter.

### Dependencies

See the Switching Devices Parameter Dependencies table.

### Forward voltage – Voltage

0.8 V (default) | scalar

For the different switching device types, the **Forward voltage** is the:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

### Dependencies

See the Switching Devices Parameter Dependencies table.

### On-state resistance – Resistance

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is the:

- GTO — Rate of change of the voltage versus the current above the forward voltage

- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Drain-source on resistance — Resistance**

0.001 Ohm (default) | scalar

Resistance between the drain and the source. The gate-to-source voltage also affects the **Drain-source on resistance** parameter.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Off-state conductance — Conductance when device is off**

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is the:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. The voltage threshold applies to different devices depending on the switching device used:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate trigger voltage, Vgt — Gate-cathode activation voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Gate turn-off voltage, `Vgt_off` – Gate-cathode deactivation voltage threshold

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Holding current – Current threshold

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Integer for piecewise constant approximation of gate input (0 for disabled) – Integer mode for FPGA deployment

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

#### Dependencies

To enable this parameter, set **Switching device** to Averaged Switch.

#### Protection Diodes

For more information on these parameters, see Diode.

#### Model dynamics – Diode model

Diode with no dynamics (default) | Diode with charge dynamics | None

Diode type. The options are:

- **None** — The block does not model diode dynamics.
- **Diode with no dynamics** — Select this option to prioritize simulation speed using the Diode block.
- **Diode with charge dynamics** — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation diode model of the Diode block.

---

**Note** If you set **Switching device** to Averaged Switch in the **Switching Device** settings, the **Diode with no dynamics** setting is automatically selected.

---

**Dependencies**

To enable this parameter, set **Switching device** to GTO, Ideal Semiconductor Switch, IGBT, MOFSET, or Thyristor.

**Forward voltage — Forward voltage**

0.8 V (default) | scalar

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

**On resistance — On resistance**

0.001 Ohm (default) | scalar

Rate of change of voltage versus the current above the **Forward voltage**.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

**Off conductance — Off conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with no dynamics or Diode with charge dynamics.

**Junction capacitance — Junction capacitance**

50 nF (default) | scalar

Diode junction capacitance.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Peak reverse current,  $i_{RM}$  — Peak reverse current**

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

**Initial forward current when measuring  $i_{RM}$  — Initial forward current when measuring  $i_{RM}$** 

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

#### Dependencies

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

#### Rate of change of current when measuring **i<sub>RM</sub>** — Rate of change of current when measuring **i<sub>RM</sub>**

-50 A/μs (default) | negative scalar

Rate of change of the current when measuring the peak reverse current. This value must be less than zero.

#### Dependencies

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

#### Reverse recovery time parameterization — Reverse recovery time option

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge

Determines how you specify reverse recovery time.

If you select Specify stretch factor or Specify reverse recovery charge, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates  $T_M$  and  $\tau$ ” on page 1-452.

#### Dependencies

To enable this parameter, set **Model dynamics** to Diode with charge dynamics.

#### Reverse recovery time, **trr** — Reverse recovery time

15 μs (default) | scalar

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time, trr** parameter must be greater than the value of the **Peak reverse current, i<sub>RM</sub>** parameter divided by the value of the **Rate of change of current when measuring i<sub>RM</sub>** parameter.

#### Dependencies

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery time directly.

#### Reverse recovery time stretch factor — Reverse recovery time stretch factor

3 (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify stretch factor.

**Reverse recovery charge, Q<sub>rr</sub> — Reverse recovery charge**

1500 s\*μA (default) | scalar

Value that the block uses to calculate **Reverse recovery time, trr**. Use this parameter if the data sheet for your diode specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ , where:

- $i_{RM}$  is the value specified for **Peak reverse current, i<sub>RM</sub>**.
- $a$  is the value specified for **Rate of change of current when measuring i<sub>RM</sub>**.

**Dependencies**

To enable this parameter, set **Model dynamics** to Diode with charge dynamics and **Reverse recovery time parameterization** to Specify reverse recovery charge.

**Snubbers**

To enable the **Snubbers** settings, set **Fidelity level** to Detailed model - switching devices and **Switching device** to GTO, Ideal Semiconductor Switch, IGBT, MOFSET, or Thyristor.

**Snubber — Snubber**

None (default) | RC snubber

Snubber for each switching device:

- None
- RC snubber

**Snubber resistance — Snubber resistance**

0.1 Ohm (default) | scalar

Snubber resistance.

**Dependencies**

To enable this parameter, set **Snubber** to RC snubber.

**Snubber capacitance — Snubber capacitance**

1e-7 F (default) | scalar

Snubber capacitance.

**Dependencies**

To enable this parameter, set **Snubber** to RC snubber.

**Version History****Introduced in R2020b**

## Electrical connection ports update

*Behavior changed in R2021b*

From R2021b forward, to switch between composite and expanded ports, set the **Electrical connection** parameter to either Composite three-phase ports or Expanded three-phase ports.

As a result of these changes, inside a model saved in an earlier release, review the **Electrical connection** parameter of this block.

## Monostable Flip-Flop

Rising edge, falling edge, either edge monostable flip-flop

**Library:** Simscape / Electrical / Control / General Control

### Description

The Monostable Flip-Flop (or monostable multivibrator) block generates a single output pulse of a specified duration when it is triggered externally. The external trigger is a Boolean signal. Pulse generation is triggered when a change is detected in the external trigger signal. The change detection can be:

- Rising edge
- Falling edge
- Either edge

When the output is true, a change in the external trigger signal has no effect.

The operation of a monostable flip-flop is represented in the following figure:

### Ports

#### Input

**Trigger – Flip-flop trigger**

0 | 1

Input trigger signal to the flip-flop.

Data Types: Boolean

## Output

### Q — Flip-flop output

0 | 1

Flip-flop output signal.

Data Types: Boolean

## Parameters

### Change detection — Change in trigger signal

Rising edge (default) | Falling edge | Either edge

Change detection strategy for output pulse generation.

### Initial output — Flip-flop initial output

0 (default) | scalar

The initial output of the flip-flop.

### Pulse duration (s) — Output pulse duration

0.01 (default) | positive scalar

Duration of the output pulse, in s.

### Sample time — Block sample time

0.001 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For discrete-time operation, set the sample time to a positive value. For continuous-time operation, set the sample time to 0.

If this block is in a masked subsystem, or other variant subsystem that allows either continuous and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

# MOSFET (Ideal, Switching)

Ideal N-channel MOSFET for switching applications

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The MOSFET (Ideal, Switching) block models the ideal switching behavior of an n-channel metal-oxide-semiconductor field-effect transistor (MOSFET).

The switching characteristic of an n-channel MOSFET is such that if the gate-source voltage exceeds the specified threshold voltage, the MOSFET is in the on state. Otherwise, the device is in the off state. This figure shows a typical i-v characteristic:

To define the I-V characteristic of the MOSFET, set the **On-state behaviour and switching losses** parameter to either **Specify constant values** or **Tabulate with temperature and current**. The **Tabulate with temperature and current** option is available only if you expose the thermal port of the block.

In the on state, the drain-source path behaves like a linear resistor with resistance,  $R_{ds\ on}$ . However, if you expose the thermal port of the block and parameterize the device using tabulated  $\bar{I}$ - $\bar{V}$  data, the tabulated resistance is a function of the temperature and current.

In the off state, the drain-source path behaves like a linear resistor with low off-state conductance,  $G_{off}$ .

Then, the defining Simscape equations for the block are:

```
if G > Vth      v == i*Rds_on;      else      v == i/Goff;      end
```

where:

- $G$  depends on the value of the **Gate control port** parameter.
- If you set the **Gate control port** parameter to PS, you control the gate terminal through a physical signal.  $G$  is the value at the input port **G**.

- If you set the **Gate control port** parameter to `Electrical`, you control the gate terminal through an electrical signal.  $G$  is equal to:

```
if v >= 0      G = G.v - S.v;      else      G = G.v - D.v;      end
```

where  $G.v$  is the gate voltage,  $S.v$  is the source voltage, and  $D.v$  is the drain voltage.

- $V_{th}$  is the threshold voltage.
- $v$  is the drain-source voltage.
- $i$  is the drain-source current.
- $R_{ds\_on}$  is the on-state resistance.
- $G_{off}$  is the off-state conductance.

Using the **Integral Diode** settings, you can include the body diode or an integral protection diode. The integral diode provides a conduction path for reverse current. For example, to provide a path for a high reverse-voltage spike that is generated when a semiconductor device suddenly switches off the voltage supply to an inductive load.

Set the **Integral protection diode** parameter based on your goal.

Goal	Value to Select	Block Behavior
Prioritize simulation speed.	Protection diode with no dynamics	The block includes an integral copy of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.
Precisely specify reverse-mode charge dynamics.	Protection diode with charge dynamics	The block includes an integral copy of the dynamic model of the Diode block. To parameterize the internal Diode block, use the <b>Protection</b> parameters.

### Model Gate Port and Thermal Effects

You can choose between physical or electrical ports to control the gate terminal and expose the thermal port to model the heat that switching events and conduction losses generate. To choose the gate control port, set the **Gate control port** parameter to `PS` or `Electrical`. To expose the thermal port, set the **Modeling option** parameter to either `No thermal port` or `Show thermal port`.

For more information about using thermal ports, see “Simulating Thermal Effects in Semiconductors”.

### Thermal Losses

The figure shows an idealized representation of the output voltage,  $V_{out}$ , and the output current,  $I_{out}$ , of the semiconductor device. The interval shown includes the entire  $n^{th}$  switching cycle, during which the block turns off and then on.

Switching losses are one of the main sources of thermal loss in semiconductors. During each on-off switching transition, the MOSFET parasitics store and then dissipate energy.

Switching losses depend on the off-state voltage and the on-state current. When a switching device is turned on, the power losses depend on the initial off-state voltage across the device and the final on-state current once the device is fully in its on state. Similarly, when a switching device is turned off, the power losses depend on the initial on-state current through the device and the final off-state voltage across the device when in the fully off state.

In this block, switching losses are applied by stepping up the junction temperature with a value equal to the switching loss divided by the total thermal mass at the junction. The **Switch-on loss,  $E_{on}(T_j, I_{ds})$**  and **Switch-off loss,  $E_{off}(T_j, I_{ds})$**  parameter values set the sizes of the switching losses and they are either fixed or dependent on junction temperature and drain-source current. In both cases, losses are scaled by the off-state voltage prior to the latest device turn-on event.

**Note** As the final current after a switching event is not known during the simulation, the block records the on-state current at the point that the device is commanded off. Similarly, the block records the off-state voltage at the point that the device is commanded on. For this reason, the simlog does not report the switching losses to the thermal network until one switching cycle later.

For all ideal switching devices, the switching losses are reported in the simlog as `lastTurnOffLoss` and `lastTurnOnLoss` and recorded as a pulse with amplitude equal to the energy loss. If you use a script to sum the total losses over a defined simulation period, you must sum the pulse values at each pulse rising edge. Alternatively, you can use the `ee_getPowerLossSummary` and `ee_getPowerLossTimeSeries` functions to extract conduction and switching losses from logged data.

Note that the `power_dissipated` variable in the simlog does not include switching losses as they are modeled as instantaneous events. The `power_dissipated` variable therefore just reports instantaneous on-state losses.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Ports

The figure shows the block port names.

## Conserving

### G – Gate terminal

electrical

Port associated with the gate terminal. You can set the port to either a physical signal or electrical port.

### S – Source terminal

electrical

Electrical conserving port associated with the source terminal.

### D – Drain terminal

electrical

Electrical conserving port associated with the drain terminal.

### H – Thermal port

thermal

Thermal conserving port.

## Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### Modeling option – Thermal port visibility

No thermal port (default) | Show thermal port

Whether to enable the thermal port.

### Main

This table shows how the visibility of **Main** parameters depends on how you configure the **Modeling option** and **On-state behaviour and switching losses** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

### Main Parameter Dependencies

Parameters and Options		
<b>Modeling option</b>		
<i>No thermal port</i>	<i>Show thermal port</i>	
Gate-control port	Gate-control port	
Drain-source on resistance, R_DS(on)	Threshold voltage, Vth	
Off-state conductance	<b>On-state behaviour and switching losses</b>	
	<i>Specify constant values</i>	<i>Tabulate with temperature and current</i>
Threshold voltage, Vth	Drain-source on resistance, R_DS(on)	On-state voltage, Vds(Tj,Ids)
	Off-state conductance	Temperature vector, Tj
		Drain-source current vector, Ids
		Off-state conductance

### Gate-control port – Whether to specify physical or electrical control port

PS (default) | Electrical

Whether to specify physical or electrical control port for the switch gate.

**Note** If you set this parameter to `Electrical`, use an internal or external reverse diode along with this block. For numerical considerations, the forward voltage of the diode must be smaller than the value of the **Threshold voltage, Vth** parameter of this block.

### On-state behaviour and switching losses – On-state current for switching loss data

Specify constant values (default) | Tabulate with temperature and current

Select a parameterization method. The option that you select determines which other parameters are enabled. Options are:

- **Specify constant values** — Use scalar values to specify the output current, switch-on loss, and switch-off loss data. This is the default parameterization method.
- **Tabulate with temperature and current** — Use vectors to specify the output current, switch-on loss, switch-off loss, and temperature data.

**Dependencies**

See the Main Parameter Dependencies table.

**Drain-source on resistance,  $R_{DS(on)}$  — Drain-source on resistance**

0.01 Ohm (default)

Drain-source resistance when the device is on.

**Dependencies**

See the Main Parameter Dependencies table.

**Off-state conductance — Off-state conductance**

1e-6 1/Ohm (default)

Drain-source conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

**Dependencies**

See the Main Parameter Dependencies table.

**Threshold voltage,  $V_{th}$  — Threshold voltage**

2 V (default)

Gate-source voltage threshold. The device turns on when the gate-source voltage is above this value.

**Dependencies**

See the Main Parameter Dependencies table.

**On-state voltage,  $V_{ds}(T_j, I_{ds})$  — On-state voltage**

[0, 1.1, 1.3, 1.45, 1.75, 2.25, 2.7; 0, 1, 1.15, 1.35, 1.7, 2.35, 3] V (default)

Voltage drop across the device while it is in a triggered conductive state. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Temperature vector,  $T_j$  — Temperature vector**

[298.15, 398.15] K (default)

Temperature values at which the on-state voltage is specified. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Drain-source current vector, Ids — Drain-source current vector**

[ 0 10 50 100 200 400 600 ] A (default)

Drain-source currents for which the on-state voltage is defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

See the Main Parameter Dependencies table.

**Switching Losses**

To enable these parameters, set **Modeling option** to Show thermal port.

**Switch-on loss — Switch-on loss**

0.02286 J (default)

Energy dissipated during a single switch-on event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Switch-off loss — Switch-off loss**

0.01714 J (default)

Energy dissipated during a single switch-off event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Off-state voltage for switching loss data — Off-state voltage for losses data**

300 V (default)

The output voltage of the device during the off state. This is the blocking voltage at which the switch-on loss and switch-off loss data are defined.

**On-state current for switching loss data — Output current**

600 A (default)

Output currents for which the switch-on loss, switch-off loss, and on-state voltage are defined. The first element must be zero. Specify this parameter using a scalar quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Specify constant values.

**Switch-on loss,  $E_{on}(T_j, I_{ds})$  — Switch-on loss**

[ 0 2.9e-4 0.00143 0.00286 0.00571 0.01314 0.02286; 0 5.7e-4 0.00263 0.00514 0.01029 0.02057 0.03029 ] J (default)

Energy dissipated during a single switch on event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Switch-off loss,  $E_{off}(T_j, I_{ds})$  — Switch-off loss**

[0, .21, 1.07, 2.14, 4.29, 9.86, 17.14; 0, .43, 1.97, 3.86, 7.71, 15.43, 22.71] \* 1e-3 J (default)

Energy dissipated during a single switch-off event. This parameter is defined as a function of temperature and final on-state output current. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Temperature vector for switching losses,  $T_j$  — Temperature vector for switching losses**

[298.15, 398.15] K (default)

Temperature values at which the switch-on loss and switch-off loss are specified. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Drain-source current vector for switching losses,  $I_{ds}$  — Drain-source current vector for switching losses**

[ 0 10 50 100 200 400 600 ] A (default)

Drain-source currents for which the switch-on loss and switch-off-loss are defined. The first element must be zero. Specify this parameter using a vector quantity.

**Dependencies**

To enable this parameter, set **On-state behavior and switching losses** to Tabulate with temperature and current.

**Integral Diode****Integral protection diode — Protection diode**

Protection diode with no dynamics (default) | None | Protection diode with charge dynamics

Block integral protection diode. The default value is Protection diode with no dynamics.

The diodes you can select are:

- Protection diode with no dynamics
- Protection diode with charge dynamics

### Diode model — Diode model

Piecewise Linear (default) | Tabulated I-V curve

Select one of these diode models:

- **Piecewise Linear** — Use a piecewise linear model for the diode, as described in “Piecewise Linear Diode” on page 1-448. This is the default method.
- **Tabulated I-V curve** — Use tabulated forward bias I-V data plus fixed reverse bias off conductance.

### Dependencies

This parameter is visible only when the thermal port is exposed and the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

### Table type — Tabulated function

Table in  $I_f(T_j, V_f)$  form (default) | Table in  $V_f(T_j, I_f)$  form

Whether to tabulate the current as a function of temperature and voltage or the voltage as a function of temperature and current.

### Dependencies

This parameter is visible only when the thermal port is exposed and the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** is set to Tabulated I-V curve.

### Forward voltage — Forward voltage

0.8 V (default)

Minimum voltage required across the + and - block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

### Dependencies

To enable this parameter:

- If the thermal port is hidden, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.
- If the thermal port is exposed, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** to Piecewise linear.

### On resistance — On resistance

0.001 Ohm (default)

Rate of change of voltage versus current above the **Forward voltage**.

### Dependencies

To enable this parameter:

- If the thermal port is hidden, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics.
- If the thermal port is exposed, set **Integral protection diode** to Protection diode with no dynamics or Protection diode with charge dynamics and **Diode model** to Piecewise linear.

**Forward currents,  $I_f(T_j, V_f)$  – Vector of forward currents**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12]  
A (default) | nonnegative vector

Forward currents. This parameter must be a vector of at least three nonnegative elements.

**Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $I_f(T_j, V_f)$  form.

**Junction temperatures,  $T_j$  – Vector of junction temperatures**

[25, 125] degC (default)

Vector of junction temperatures. This parameter must be a vector of at least two elements.

**Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve.

**Forward voltages,  $V_f$  – Vector of forward voltages**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Vector of forward voltages. This parameter must be a vector of at least three nonnegative values.

**Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $I_f(T_j, V_f)$  form.

**Forward voltages,  $V_f(T_j, I_f)$  – Vector of forward voltages**

[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85; .58, .68, .75, 1.1, 1.38, 1.77, 2.27, 2.7] V (default) | nonnegative vector

Forward voltages. This parameter must be a vector of at least three nonnegative elements.

**Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $V_f(T_j, I_f)$  form.

**Forward currents,  $I_f$  – Vector of forward currents**

[.1, .2, .5, 1, 2, 4, 7, 10] A (default)

Vector of forward currents. This parameter must be a vector of at least three nonnegative values.

**Dependencies**

To enable this parameter, expose the thermal port and set **Diode model** to Tabulated I-V curve and **Table type** to Table in  $V_f(T_j, I_f)$  form.

**Off conductance — Off conductance**

1e-5 1/Ohm (default)

Conductance of the reverse-biased diode.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with no dynamics or Protection diode with charge dynamics.

**Junction capacitance — Junction capacitance**

50e-9 F (default)

Diode junction capacitance.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Peak reverse current,  $i_{RM}$  — Peak reverse current**

-235 A (default) | negative scalar

Peak reverse current measured by an external test circuit. This value must be less than zero. The default value is -235 A.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Initial forward current when measuring  $i_{RM}$  — Initial forward current when measuring  $i_{RM}$** 

300 A (default) | positive scalar

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Rate of change of current when measuring  $i_{RM}$  — Rate of change of current when measuring  $i_{RM}$** -50A/ $\mu$ s (default) | negative scalar

Rate of change of current when measuring peak reverse current. This value must be less than zero.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

**Reverse recovery time parameterization — Reverse recovery time parameterization**

Specify reverse recovery time directly (default) | Specify stretch factor | Specify reverse recovery charge

Determines how you specify reverse recovery time in the block. The default value is Specify reverse recovery time directly.

If you select Specify stretch factor or Specify reverse recovery charge, you specify a value that the block uses to derive the reverse recovery time. For more information on these options, see “How the Block Calculates TM and Tau” on page 1-452.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics.

#### Reverse recovery time, $t_{rr}$ – Reverse recovery time

15  $\mu$ s (default)

Interval between the time when the current initially goes to zero (when the diode turns off) and the time when the current falls to less than 10% of the peak reverse current. The value of the **Reverse recovery time,  $t_{rr}$**  parameter must be greater than the value of the **Peak reverse current,  $i_{RM}$**  parameter divided by the value of the **Rate of change of current when measuring  $i_{RM}$**  parameter.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery time directly.

#### Reverse recovery time stretch factor – Reverse recovery time stretch factor

3 (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . This value must be greater than 1. Specifying the stretch factor is an easier way to parameterize the reverse recovery time than specifying the reverse recovery charge. The larger the value of the stretch factor, the longer it takes for the reverse recovery current to dissipate.

#### Dependencies

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify stretch factor.

#### Reverse recovery charge, $Q_{rr}$ – Reverse recovery charge

1500  $\mu$ As (default)

Value that the block uses to calculate **Reverse recovery time,  $t_{rr}$** . Use this parameter if the data sheet for your diode device specifies a value for the reverse recovery charge instead of a value for the reverse recovery time.

The reverse recovery charge is the total charge that continues to dissipate when the diode turns off.

The value must be less than  $-\frac{i_{RM}^2}{2a}$ ,

where:

- $i_{RM}$  is the value specified for **Peak reverse current,  $i_{RM}$** .
- $a$  is the value specified for **Rate of change of current when measuring  $i_{RM}$** .

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery charge.

**Diode turn-off voltage when measuring Erec — Diode turn-off voltage when measuring Erec**

-600 V (default)

Voltage between the diode in steady-state.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Stray inductance when measuring Erec — Stray inductance when measuring Erec**

150 nH (default)

Total unintended inductance in the measurement circuit. The block uses this value to calculate **Reverse recovery energy, Erec**.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

**Reverse recovery energy, Erec — Reverse recovery energy**

0.03 J (default)

Total switching losses due to the diode reverse recovery.

**Dependencies**

This parameter is visible only when the **Integral protection diode** parameter is set to Protection diode with charge dynamics and the **Reverse recovery time parameterization** parameter is set to Specify reverse recovery energy.

For more information on these parameters, see Diode.

**Thermal Port**

Use the thermal port to simulate the effects of generated heat and device temperature. For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

**Version History****Introduced in R2013b****Update on switching losses and thermal modelling options**

*Behavior changed in R2020b*

From R2020b forward, the MOSFET (Ideal, Switching) block has improved losses and thermal modelling options.

As a result of these changes:

- Electrical and thermal on-state losses are now always identical. The **Thermal loss dependent on** parameter and its options, **Voltage** and **current** and **Voltage, current, and temperature**, have been renamed to **On-state behavior and switching losses**, **Specify constant values**, and **Tabulate with temperature and current**:
  - If you selected **Voltage** and **current** for **Thermal loss dependent on**, then the electrical on-state losses are unchanged and their values are determined using the on-state resistance. However, the thermal on-state losses are now also determined by the on-state resistance. Prior to R2020b, the thermal on-state losses were defined by the product of the **On-state voltage** and **Output current, Iout** parameters.
  - If you selected **Voltage, current, and temperature** for **Thermal loss dependent on**, then the thermal on-state losses are unchanged and the **On-state voltage, Vds(Tj,Ids)** parameter sets their values. However, the electrical on-state losses are now equal to the thermal on-state losses. Prior to R2020b, the electrical on-state losses were defined by the value of the on-state resistance.
- The **On-state voltage** parameter is no longer used.

### **Removal of energy dissipation time constant parameter**

*Behavior changed in R2021a*

From R2021a forward, the **Energy dissipation time constant** parameter of the MOSFET (Ideal, Switching) block is no longer used. A step in junction temperature now reflects the switching losses. If your model contains a thermal mass directly connected to this block thermal port, remove it and model the thermal mass inside the component itself.

# Moving Average

Moving average-value computation

**Library:** Simscape / Electrical / Control / General Control

## Description

The Moving Average block computes the moving average value of the input signal. Use this block to filter higher frequency signal components and to smooth noisy signals.

## Equations

The moving average is computed based on a moving time window. The moving average for continuous-time is calculated as

$$\bar{u} = \frac{1}{T_0} \int_{t_0}^{t_0 + T_0} u(t) dt,$$

where:

- $u(t)$  is the input signal,
- $\frac{1}{f}$
- $f$  is the fundamental frequency of the signal.

The moving average for discrete-time is calculated as:

$$\bar{u}(k) = \frac{1}{T_0} \sum_{i=0}^{n-1} u(k-i).$$

---

**Note** If you use this block for continuous-time operations and set the **Sample time (-1 for inherited)** parameter to  $\emptyset$ , you should also specify the value of the **Buffer size** parameter to ensure it covers the moving time window.

---

## Assumptions

- The output is initialized with the initial condition in the time interval  $[\emptyset, T_\emptyset]$

## Ports

### Input

#### **u — Moving average input**

scalar | vector

Input signal.

Data Types: single | double

### Output

#### **Mean — Moving average output**

scalar | vector

Moving average of the input signal.

Data Types: single | double

## Parameters

#### **Fundamental frequency (Hz) — Signal fundamental frequency**

60 (default) | positive scalar | vector with positive values

Fundamental frequency of the signal, in Hz. If you specify the fundamental frequency using a vector, it must match the input vector dimension.

#### **Initial value — Initial input signal value**

0 (default) | scalar

The initial value of the input signal.

#### **Buffer size — Buffer size**

8192 (default) | scalar

Size of the buffer.

### Dependencies

To enable this parameter, set **Sample time (-1 for inherited)** to 0.

#### **Sample time (-1 for inherited) — Block sample time**

-1 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For inherited discrete-time operation, specify -1. For discrete-time operation, specify a positive integer. For continuous-time operation, specify 0.

If this block is in a masked subsystem, or other variant subsystem that allows you to switch between continuous operation and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

## Moving Average (Variable Frequency)

Variable frequency moving average-value computation

**Library:** Simscape / Electrical / Control / General Control

### Description

The Moving Average (Variable Frequency) block computes the moving average value of an input signal of variable frequency. Use this block to filter higher frequency signal components and to smooth noisy signals.

### Equations

The moving average is computed based on a moving time window. The moving average for continuous-time is calculated as

$$\bar{u} = \frac{1}{T_0} \int_{t_0}^{t_0 + T_0} u(t) dt,$$

where:

- $u(t)$  is the input signal.
- $T_0$  is equal to  $\frac{1}{f}$
- $f$  is the fundamental frequency of the signal.

The moving average for discrete-time is calculated as:

$$\bar{u}(k) = \frac{1}{T_0} \sum_{i=0}^{n-1} u(k-i).$$

---

**Note** If you use this block for continuous-time operations and set the **Sample time (-1 for inherited)** parameter to  $\emptyset$ , you should also specify the value of the **Buffer size** parameter to ensure it covers the moving time window.

### Assumptions and Limitations

The output is initialized with an initial condition in the time interval  $[\emptyset, T_\emptyset]$ .

## Ports

### Input

#### **u — Moving average input**

scalar | vector

Moving average input, specified as a scalar or vector.

Data Types: single | double

#### **f — Frequency, Hz**

scalar | vector

Frequency, specified as a scalar or vector in Hz.

Data Types: single | double

### Output

#### **Mean — Moving average output**

scalar | vector

Moving average of the input signal, returned as a scalar or vector.

Data Types: single | double

## Parameters

#### **Initial frequency (Hz) — Initial signal frequency**

60 (default) | positive scalar | vector with positive values

Initial frequency of the signal, in Hz. If you specify the initial frequency using a vector, it must match the dimensions of the input vector.

#### **Minimum frequency (Hz) — Minimum signal frequency**

30 (default) | positive scalar | vector with positive values

Minimum frequency of the signal, in Hz. If you specify the minimum frequency using a vector, it must match the dimensions of the input vector.

#### **Initial value — Initial input signal value**

0 (default) | scalar

Initial value of the input signal.

#### **Buffer size — Buffer size**

8192 (default) | scalar

Size of the buffer.

# Multiplier

Integrated circuit multiplier

**Library:** Simscape / Electrical / Integrated Circuits

## Description

The Multiplier block models an integrated circuit multiplier. The block implements the following equation, which defines the voltage applied to the output port:

$$V_{out} = A \left( \frac{(X_1 - X_2)(Y_1 - Y_2)}{K} - (Z_1 - Z_2) \right)$$

where  $X_1$ ,  $X_2$ ,  $Y_1$ ,  $Y_2$ ,  $Z_1$ ,  $Z_2$  are the voltages presented at the input ports,  $A$  is the gain, and  $K$  is the scale factor.

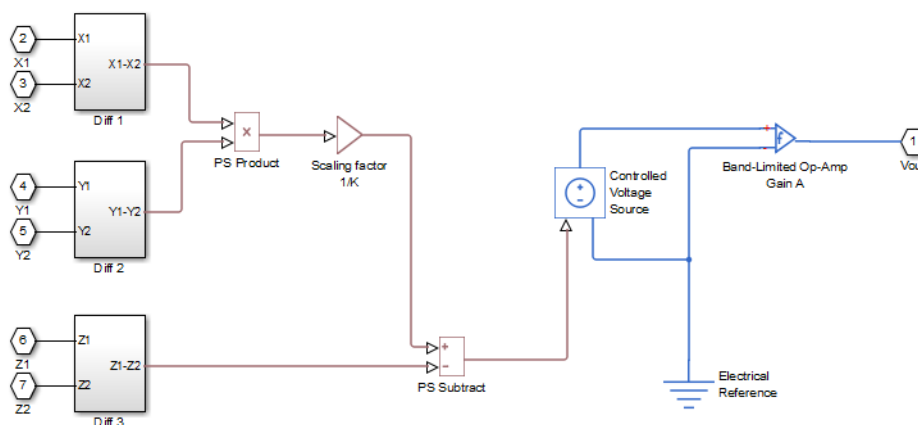

In a typical multiplication circuit, the output is fed back into input  $Z_1$ , which results in the following gain (assuming that  $A$  is large):

$$V_{out} = \left( \frac{(X_1 - X_2)(Y_1 - Y_2)}{K} + Z_2 \right)$$

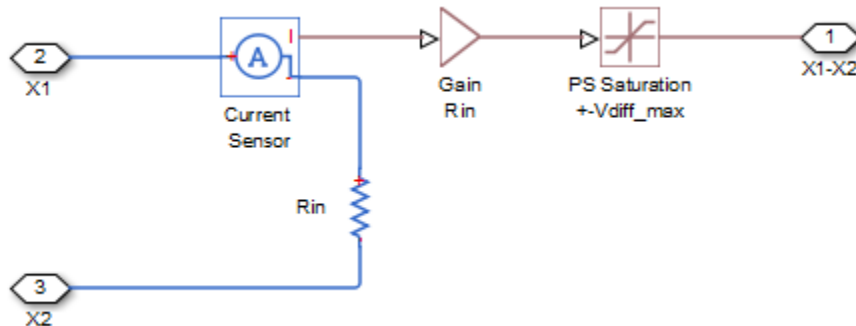

The value of the scale factor  $K$  is usually altered by an external resistor bias network. The Multiplier block implements  $K$  as an internal gain, and the external bias network is not necessary for system simulation. A typical value for  $K$  is 10, with a typical adjustment down to 3.

You can use the Multiplier block to implement a number of other functions, as well as multiplication. Examples include division, squares, and square roots. For example circuits, consult manufacturer datasheets.

The following figure shows the internal model structure of the Multiplier block. It includes the Band-Limited Op-Amp block to model finite bandwidth and slew-rate limiting.

The next figure shows one of the differential subsystem blocks. All three differential subsystem blocks are identical in structure.

## Assumptions and Limitations

- Only differential limiting of the inputs is implemented. You must ensure that the absolute values of the inputs you use keep the actual device operating in its linear region.
- Output current is such that the integrated circuit is operating in the linear I-V region, which can be approximated by a voltage source plus a series output resistance.
- Input offset voltage is not modeled, and the input voltage-current relationship is treated as linear within the differential signal voltage range.

### Conserving

#### X1 – X-input non-inverting input

electrical

Electrical conserving port associated with the multiplier X1 non-inverting input.

#### X2 – X-input inverting input

electrical

Electrical conserving port associated with the multiplier X2 inverting input.

#### Y1 – Y-input non-inverting input

electrical

Electrical conserving port associated with the multiplier Y1 non-inverting input.

#### Y2 – Y-input inverting input

electrical

Electrical conserving port associated with the multiplier Y2 inverting input.

#### Z1 – Z-input non-inverting input

electrical

Electrical conserving port associated with the multiplier Z1 non-inverting input.

**Z2 – Z-input inverting input**

electrical

Electrical conserving port associated with the multiplier Z2 inverting input.

**~ – Multiplied output signal**

electrical

Electrical conserving port associated with the multiplier output port.

**Parameters****Main****Scaling factor, K – Scaling factor**

10 V (default)

The scaling factor  $K$  in the equation that defines output voltage. Datasheets sometimes refer to it as the scale factor, or SF.

**Gain, A – Gain**

3000 (default)

The gain of the internal operational amplifier, corresponding to the gain  $A$  in the equation that defines output voltage.

**Inputs****Differential resistance, Rin – Differential resistance**

10e6 Ohm (default)

Each of the differential inputs is approximated as a linear resistor with value  $R_{in}$ . Set this value to the datasheet value for differential resistance.

**Differential signal voltage range – Differential signal voltage range**

10 V (default)

This value,  $V_{diff\_max}$ , is used to limit the magnitude of each of the three differential input voltages. Set this value to the datasheet value for differential signal voltage range.

**Outputs****Output resistance, Rout – Output resistance**

0.1 Ohm (default)

The multiplier output stage is modeled as a voltage source plus series resistor inside the Band-Limited Op-Amp block. This parameter specifies the value of this series resistor.

**Minimum output, Vmin – Minimum output**

-11 V (default)

The lower limit of the output voltage.

**Maximum output, Vmax – Maximum output**

11 V (default)

The upper limit of the output voltage.

**Maximum slew rate, Vdot – Maximum slew rate**

20 V/us (default)

The maximum positive or negative rate of change of output voltage magnitude.

**Bandwidth, f – Bandwidth**

1 MHz (default)

The bandwidth of the Band-Limited Op-Amp block.

**Initial output voltage, V0 – Initial output voltage**

0 V (default)

The value of the initial Multiplier block output if the **Start simulation from steady-state** option is not selected in the Solver block.

# Mutual Inductor

Mutual inductor model with nominal inductance optional tolerances for each winding, operating limits and faults

**Library:** Simscape / Electrical / Passive / Transformers

## Description

The Mutual Inductor block lets you model a mutual inductor (two-winding transformer) with nominal inductance tolerances for each winding. The model includes the following effects:

- “Tolerances” on page 1-1021
- “Operating Limits” on page 1-1022
- “Faults” on page 1-1022

You can turn these modeling options on and off independently of each other.

In the unfaulted state, the following equations describe the Mutual Inductor block behavior:

$$v_1 = L_1 \frac{di_{L1}}{dt} + M \frac{di_{L2}}{dt} + i_{L1} R_1$$

$$v_2 = L_2 \frac{di_{L2}}{dt} + M \frac{di_{L1}}{dt} + i_{L2} R_2$$

$$M = k \sqrt{L_1 L_2}$$

where:

- $v_1$  and  $v_2$  are voltages across the primary and secondary winding, respectively.
- $L_1$  and  $L_2$  are inductances of the primary and secondary winding.
- $R_1$  and  $R_2$  are series resistances of the primary and secondary winding.
- $M$  is mutual inductance.
- $k$  is coefficient of coupling. To reverse one of the winding directions, use a negative value.
- $t$  is time.

A parallel conductance is placed across the + and - terminals of the primary and secondary windings, so that  $i_{L1} = i_1 - G_1 v_1$ , where  $G_1$  is the parallel conductance of the primary winding, and  $i_1$  is the terminal current into the primary. Similar definitions and equation apply to  $i_{L2}$ .

## Tolerances

You can apply tolerances separately for each winding. Datasheets typically provide a tolerance percentage for a given inductor type. Therefore, this value is the same for both windings. The table

shows how the block applies tolerances to the nominal inductance value and calculates inductance based on the selected tolerance application option for the winding, **L1 tolerance application** or **L2 tolerance application**.

Option	Inductance Value
None – use nominal value	$L$
Random tolerance	Uniform distribution: $L \cdot (1 - tol + 2 \cdot tol \cdot rand)$ Gaussian distribution: $L \cdot (1 + tol \cdot randn / nSigma)$
Apply maximum tolerance value	$L \cdot (1 + tol)$
Apply minimum tolerance value	$L \cdot (1 - tol)$

In the table:

- $L$  is nominal inductance for the primary or secondary winding, **Inductance L1** or **Inductance L2** parameter value.
- $tol$  is fractional tolerance, **Tolerance (%)** /100.
- $nSigma$  is the value you provide for the **Number of standard deviations for quoted tolerance** parameter.
- $rand$  and  $randn$  are standard MATLAB functions for generating uniform and normal distribution random numbers.

**Note** If you choose the Random tolerance option and you are in "Fast Restart" mode, the random tolerance value is updated on every simulation if at least one between the fractional tolerance,  $tol$ , or the **Number of standard deviations for quoted tolerance**,  $nSigma$ , is set to Run-time and is defined with a variable (even if you do not modify that variable).

### Operating Limits

Inductors are typically rated with a particular saturation current, and possibly with a maximum allowable power dissipation. You can specify operating limits in terms of these values, to generate warnings or errors if the inductor is driven outside its specification.

When an operating limit is exceeded, the block can either generate a warning or stop the simulation with an error. For more information, see the "Operating Limits" on page 1-1026 parameters section.

### Faults

Instantaneous changes in inductor parameters are unphysical. Therefore, when the Mutual Inductor block enters the faulted state, short-circuit and open-circuit voltages transition to their faulted values over a period of time based on this formula:

$$CurrentValue = FaultedValue - (FaultedValue - UnfaultedValue) \cdot \operatorname{sech}(\Delta t / \tau)$$

where:

- $\Delta t$  is time since the onset of the fault condition.
- $\tau$  is user-defined time constant associated with the fault transition.

For short-circuit faults, the conductance of the short-circuit path also changes according to the  $\text{sech}(\Delta t / \tau)$  function from a small value (representing an open-circuit path) to a large value.

The Mutual Inductor block lets you select whether the faults occur in the primary or secondary winding. The block models the faulted winding as a faulted inductor. The unfaulted winding is coupled to the faulted winding. As a result, the actual equations involve a total of three coupled windings: two for the faulted winding and one for the unfaulted winding. The coupling between the primary and secondary windings is defined by the **Coefficient of coupling** parameter.

The block can trigger the start of fault transition:

- At a specific time
- After voltage exceeds the maximum permissible value a certain number of times
- When current exceeds the maximum permissible value for longer than a specific time interval

You can enable or disable these trigger mechanisms separately, or use them together if more than one trigger mechanism is required in a simulation. When more than one mechanism is enabled, the first mechanism to trigger the fault transition takes precedence. In other words, a component fails no more than once per simulation.

You can also choose whether to issue an assertion when a fault occurs by using the **Reporting when a fault occurs** parameter. The assertion can take the form of a warning or an error. By default, the block does not issue an assertion.

Faultable inductors often require that you use the fixed-step local solver, rather than the variable-step solver. In particular, if you model transitions to a faulted state that include short circuits, MathWorks recommends that you use the fixed-step local solver. For more information, see “Making Optimal Solver Choices for Physical Simulation”.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

The **Primary current** and **Secondary current** variables let you specify a high-priority target for the initial inductor current in the respective winding at the start of simulation.

### Conserving

#### 1+ — Positive terminal of the primary winding

electrical

Electrical conserving port associated with the primary winding positive terminal.

#### 1- — Negative terminal of the primary winding

electrical

Electrical conserving port associated with the primary winding negative terminal.

**2+ — Positive terminal of the secondary winding**

electrical

Electrical conserving port associated with the secondary winding positive terminal.

**2- — Negative terminal of the secondary winding**

electrical

Electrical conserving port associated with the secondary winding negative terminal.

## Parameters

### Main

**Inductance L1 — Nominal inductance value in the primary winding**

10 H (default)

The nominal inductance value in the primary winding. Inductance value must be greater than zero.

**Inductance L2 — Nominal inductance value in the secondary winding**

0.1 H (default)

The nominal inductance value in the secondary winding. Inductance value must be greater than zero.

**Coefficient of coupling — Mutual inductance coupling between windings**

0.9 (default)

The coupling between the primary and secondary windings. This coefficient defines the mutual inductance. To reverse one of the winding directions, use a negative value.

**Tolerance (%) — Inductor tolerance, in percent**

20 (default)

The inductor tolerance as defined on the manufacturer datasheet. Datasheets typically provide a tolerance percentage for a given inductor type. Therefore, this value is the same for both windings.

**L1 tolerance application — Select how to apply tolerance to primary winding**

None — use nominal value (default) | Random tolerance | Apply maximum tolerance value | Apply minimum tolerance value

Select how to apply tolerance during simulation to the primary winding:

- **None — use nominal value** — The block does not apply tolerance, it uses the nominal inductance value.
- **Random tolerance** — The block applies random offset to the inductance value, within the tolerance value limit. You can choose Uniform or Gaussian distribution for calculating the random number by using the **Tolerance distribution** parameter.
- **Apply maximum tolerance value** — The inductance is increased by the specified tolerance percent value.
- **Apply minimum tolerance value** — The inductance is decreased by the specified tolerance percent value.

**L1 tolerance distribution — Select the distribution type for primary winding**

Uniform (default) | Gaussian

Select the distribution type for random tolerance:

- Uniform — Uniform distribution
- Gaussian — Gaussian distribution

**Dependencies**

Enabled when the **L1 tolerance application** parameter is set to Random tolerance.

**L1 number of standard deviations for quoted tolerance — Used for calculating the Gaussian random number for primary winding**

4 (default)

Number of standard deviations for calculating the Gaussian random number.

**Dependencies**

Enabled when the **L1 tolerance distribution** parameter is set to Gaussian.

**L2 tolerance application — Select how to apply tolerance to secondary winding**

None — use nominal value (default) | Random tolerance | Apply maximum tolerance value | Apply minimum tolerance value

Select how to apply tolerance during simulation to the secondary winding:

- None — use nominal value — The block does not apply tolerance, it uses the nominal inductance value.
- Random tolerance — The block applies random offset to the inductance value, within the tolerance value limit. You can choose Uniform or Gaussian distribution for calculating the random number by using the **Tolerance distribution** parameter.
- Apply maximum tolerance value — The inductance is increased by the specified tolerance percent value.
- Apply minimum tolerance value — The inductance is decreased by the specified tolerance percent value.

**L2 tolerance distribution — Select the distribution type for secondary winding**

Uniform (default) | Gaussian

Select the distribution type for random tolerance:

- Uniform — Uniform distribution
- Gaussian — Gaussian distribution

**Dependencies**

Enabled when the **L2 tolerance application** parameter is set to Random tolerance.

**L2 number of standard deviations for quoted tolerance — Used for calculating the Gaussian random number for secondary winding**

4 (default)

Number of standard deviations for calculating the Gaussian random number.

**Dependencies**

Enabled when the **L2 tolerance distribution** parameter is set to Gaussian.

**Resistance****Series resistance, [R\_primary R\_secondary] – Equivalent series resistance of the primary and secondary winding**

[0.001, 0.001] Ohm (default)

Equivalent series resistance of the primary and secondary winding, specified as a two-element vector. The first number corresponds to the primary winding, the second number to the secondary winding. For a faulted winding, the block allocates the resistance to each segment in proportion to the number of turns in that segment.

**Parallel conductance, [G\_primary G\_secondary] – Parallel leakage path associated with the primary and secondary winding**

[1e-9, 1e-9] 1/Ohm (default)

Parallel leakage path associated with the primary and secondary winding, specified as a two-element vector. The first number corresponds to the primary winding, the second number to the secondary winding. The parallel conductances are placed directly across the + and - terminals of the primary and secondary winding, respectively.

**Operating Limits****Enable operating limits – Select Yes to enable reporting when the operational limits are exceeded**

No (default) | Yes

Select Yes to enable reporting when the operational limits are exceeded. The associated parameters in the **Operating Limits** section become visible to let you select the reporting method and specify the operating limits in terms of power and current.

**Reporting when operating limits exceeded – Select the reporting method**

Warn (default) | Error

Select what happens when an operating limit is exceeded:

- Warn – The block issues a warning.
- Error – Simulation stops with an error.

**Dependencies**

Enabled when the **Enable operating limits** parameter is set to Yes.

**Saturation current – Inductor saturation current**

1 A (default)

Inductor saturation current, as defined in the manufacturer datasheets. If the net current into the primary and secondary windings exceeds this value, the core material enters saturation, and the block reports an operating limits violation. That is, the block compares the limit against  $|i_1 + i_2|$ , where currents are defined as being positive when they are into the + nodes.

**Dependencies**

Enabled when the **Enable operating limits** parameter is set to Yes.

**Power rating — Maximum power dissipation in the inductor**

1 A (default)

Maximum instantaneous (total) power dissipation in the resistance and conductance elements associated with the mutual inductor. If the total power (including both primary and secondary winding) exceeds this number, the block reports an operating limits violation.

**Dependencies**

Enabled when the **Enable operating limits** parameter is set to Yes.

**Faults****Enable faults — Select On to enable faults modeling**

Off (default) | On

Select On to enable faults modeling. The associated parameters in the **Faults** section become visible to let you select the reporting method and specify the trigger mechanism (temporal or behavioral). You can enable these trigger mechanisms separately or use them together.

**Reporting when a fault occurs — Choose whether to issue an assertion when a fault occurs**

None (default) | Warn | Error

Choose whether to issue an assertion when a fault occurs:

- None — The block does not issue an assertion.
- Warn — The block issues a warning.
- Error — Simulation stops with an error.

**Dependencies**

Enabled when the **Enable faults** parameter is set to On.

**Faulted winding — Select winding to use for fault modeling**

Primary (default) | Secondary

Select whether the faults occur in the primary or secondary winding.

**Dependencies**

Enabled when the **Enable faults** parameter is set to On.

**Location of fault node (% of total turns from - terminal) — Percentage of turns in the subinductor that is in contact with the - port of the faulted winding**

50 (default)

In practice, faults are enabled by segmenting the faulted winding into two coupled subinductors, connected in a series. The inductance is proportional to the square of the number of turns in the respective segment, and the series resistance of each subinductor is proportional to the number of turns in each segment. The parallel conductance spans both segments.

This parameter indicates the percentage of turns that are assigned to the subinductor that is in contact with the - port of the faulted winding. The remaining turns are assigned to the other subinductor. The default value is 50, which means that the overall inductance of the faulted winding is divided into two equal, coupled subinductors.

**Dependencies**

Enabled when the **Enable faults** parameter is set to On.

**Short-circuit turns — Select whether fault results in one of the segments being short-circuited**

No (default) | To negative terminal | To positive terminal

Select whether the fault results in one of the subinductor segments being short-circuited:

- No — The fault does not produce a short circuit.
- To negative terminal — The fault short-circuits the subinductor that is in contact with the - port of the block.
- To positive terminal — The fault short-circuits the subinductor that is in contact with the + port of the block.

**Dependencies**

Enabled when the **Enable faults** parameter is set to On.

**Open-circuit at fault node — Select whether to apply an open-circuit fault between the segments**

No (default) | Yes

Select whether to apply an open-circuit fault between the two subinductor segments. The default is No. Even with an open-circuit fault, the characteristics of the subinductors are still related because they are magnetically coupled even in the faulted state.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Ground fault — Select whether fault results in one of the segments being short-circuited**

No (default) | Negative terminal side of fault node | Positive terminal side of fault node

Select whether, in case of fault, there is a path for current to flow towards the ground node:

- No — The fault does not result in a connection to ground.
- Negative terminal side of fault node — The side that is in contact with the - port of the block is connected to ground.
- Positive terminal side of fault node — The side that is in contact with the + port of the block is connected to ground.

If the **Open-circuit at fault node** parameter is set to Yes, you need to specify which side (negative or positive) is connected to ground. If there is no open circuit, the two options behave similarly. Physically, this corresponds to a breakdown in the insulation between the windings and the grounded core or chassis.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Conductance of faulted ground path — Mutual coupling between the two subinductors**

0 1/0hm (default)

If there is a ground fault, this parameter represents conductance of the current path to ground. For example, if the path to ground is through the core material, then specify a small conductance value depending on the core material being used. For highly conductive core material or for chassis-shorts, specify a higher conductance value.

**Dependencies**

Enabled when the **Ground fault** parameter is set to Negative terminal side of fault node or Positive terminal side of fault node.

**Fault transition time constant — Time constant for the transition to faulted state**

1e-3 s (default)

Time constant associated with the transition to the faulted state, as described in “Faults” on page 1-1022.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Enable temporal fault trigger — Select Yes to enable time-based fault triggering**

No (default) | Yes

Select Yes to enable time-based fault triggering. You can enable the temporal and behavioral trigger mechanisms separately or use them together.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Simulation time for fault event — Time before entering faulted state**

1 s (default)

Set the simulation time at which you want the block to start entering the fault state.

**Dependencies**

Enabled when the **Enable temporal fault trigger** parameter is set to Yes.

**Enable behavioral fault trigger — Select Yes to enable behavioral fault triggering**

No (default) | Yes

Select Yes to enable behavioral fault triggering. You can enable the temporal and behavioral trigger mechanisms separately or use them together.

**Dependencies**

Enabled when the **Enable faults** parameter is set to Yes.

**Maximum permissible voltage — Voltage threshold to fault transition**

100 V (default)

Define the voltage threshold to a fault transition. If the voltage value exceeds this threshold a certain number of times, specified by the **Number of events to fail when exceeding voltage** parameter value, then the block starts entering the fault state.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

**Number of events to fail when exceeding voltage — Maximum number of times the voltage exceeds the threshold**

1 (default)

Because the physical mechanism underlying voltage-based failures depends on one or more partial discharge events occurring, this parameter allows you to set the number of voltage overshoots that the inductor can withstand before the fault transition begins. Note that the block does not check the time spent in the overvoltage condition, only the number of transitions.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

**Maximum permissible current — Current threshold to fault transition**

1 A (default)

Define the current threshold to a fault transition. If the current value exceeds this threshold for longer than the **Time to fail when exceeding current** parameter value, then the block starts entering the fault state.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

**Time to fail when exceeding current — Maximum length of time the current exceeds the threshold**

1 s (default)

Set the maximum length of time that the current can exceed the maximum permissible value without triggering the fault.

**Dependencies**

Enabled when the **Enable behavioral fault trigger** parameter is set to Yes.

# N-Channel IGBT

N-Channel insulated gate bipolar transistor

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The N-Channel IGBT block models an Insulated Gate Bipolar Transistor (IGBT). The block provides two main modeling options, by setting the **Modeling option** parameter to either:

- **Full I-V and capacitance characteristics** — This modeling option is a detailed component model suitable for simulating detailed switching characteristics and predicting component losses. This modeling option, in turn, provides two ways of modeling an IGBT:
  - As an equivalent circuit based on a PNP bipolar transistor and N-channel MOSFET. For more information on using this model, see “Representation by Equivalent Circuit” on page 1-1032, “Fine-Tuning the Current-Voltage Characteristics” on page 1-1037, and “Modeling Temperature Dependence” on page 1-1037.
  - By a 2D lookup table approximation to the I-V (current-voltage) curve. For details, see “Representation by 2D Lookup Table” on page 1-1033.
  - By a 3D lookup table approximation to the I-V (current-voltage) curve that includes temperature data. For details, see “Representation by 3D Lookup Table” on page 1-1034.

The gate capacitance in the detailed model is represented as a fixed gate-emitter capacitance  $C_{GE}$  and either a fixed or a nonlinear gate-collector capacitance  $C_{GC}$ . For details, see “Charge Model” on page 1-1034.

- **Simplified I-V characteristics and event-based timing** — This modeling option models the IGBT more simply by using just the on-state I-V data as a function of the collector-emitter voltage. In the off state (gate-emitter voltage less than **Threshold voltage,  $V_{th}$** ), the IGBT is modeled by a constant **Off-state conductance**. This simplified model is suitable when approximate dynamic characteristics are sufficient, and simulation speed is of paramount importance. For details, see “Event-Based IGBT Modeling Option” on page 1-1038.

Together with the thermal port modeling options (see “Thermal Port” on page 1-1039), the block therefore provides you with four choices. To select the desired modeling option, set the **Modeling option** parameter to either:

- Full I-V and capacitance characteristics | No thermal port — Detailed model that does not simulate the effects of generated heat and device temperature. This is the default.
- Full I-V and capacitance characteristics | Show thermal port — Detailed model with exposed thermal port.
- Simplified I-V characteristics and event-based timing | No thermal port — Simplified event-based model, which also does not simulate the effects of generated heat and device temperature.

- Simplified I-V characteristics and event-based timing | Show thermal port — Simplified event-based model with exposed thermal port.

### Representation by Equivalent Circuit

The equivalent circuit of the detailed block modeling option consists of a PNP Bipolar Transistor block driven by an N-Channel MOSFET block, as shown in the following figure:

The MOSFET source is connected to the bipolar transistor collector, and the MOSFET drain is connected to the bipolar transistor base. The MOSFET uses the threshold-based equations shown in the N-Channel MOSFET block reference page. The bipolar transistor uses the equations shown in the PNP Bipolar Transistor block reference page, but with the addition of an emission coefficient parameter  $N$  that scales  $kT/q$ .

The N-Channel IGBT block uses the on and off characteristics you specify in the block dialog box to estimate the parameter values for the underlying N-Channel MOSFET and PNP bipolar transistor.

The block uses the off characteristics to calculate the base-emitter voltage,  $V_{be}$ , and the saturation current,  $I_S$ .

When the transistor is off, the gate-emitter voltage is zero and the IGBT base-collector voltage is large, so the PNP base and collector current equations simplify to:

$$I_b = 0 = -I_S \left[ \frac{1}{\beta_F} (e^{-qV_{be}/(NkT)} - 1) - \frac{1}{\beta_R} \right]$$

$$I_c = -I_S \left[ e^{-qV_{be}/(NkT)} \left( 1 + \frac{V_{bc}}{V_{AF}} \right) + \frac{1}{\beta_R} \right]$$

where  $N$  is the **Emission coefficient**,  $N$  parameter value,  $V_{AF}$  is the forward Early voltage, and  $I_c$  and  $I_b$  are defined as positive flowing into the collector and base, respectively. See the PNP Bipolar Transistor reference page for definitions of the remaining variables. The first equation can be solved for  $V_{be}$ .

The base current is zero in the off-condition, and hence  $I_c = -I_{ces}$ , where  $I_{ces}$  is the Zero gate voltage collector current. The base-collector voltage,  $V_{bc}$ , is given by  $V_{bc} = V_{ces} + V_{ces}$ , where  $V_{ces}$  is the voltage at which  $I_{ces}$  is measured. Hence we can rewrite the second equation as follows:

$$I_{ces} = I_S \left[ e^{-qV_{be}/(NkT)} \left( 1 + \frac{V_{ces} + V_{be}}{V_{AF}} \right) + \frac{1}{\beta_R} \right]$$

The block sets  $\beta_R$  and  $\beta_F$  to typical values of 1 and 50, so these two equations can be used to solve for  $V_{be}$  and  $I_S$ :

$$V_{be} = \frac{-NkT}{q} \log\left(1 + \frac{\beta_F}{\beta_R}\right)$$

$$I_S = \frac{I_C}{e^{-qV_{be}/(NkT)} + \frac{1}{\beta_R}}$$

---

**Note** The block does not require an exact value for  $\beta_F$  because it can adjust the MOSFET gain  $K$  to ensure the overall device gain is correct.

---

The block parameters **Collector-emitter saturation voltage, Vce(sat)** and **Collector current at which Vce(sat) is defined** are used to determine  $V_{be(sat)}$  by solving the following equation:

$$I_{ce(sat)} = I_S \left[ e^{-qV_{be(sat)}/(NkT)} \left( 1 + \frac{V_{ce(sat)} + V_{be(sat)}}{V_{AF}} \right) + \frac{1}{\beta_R} \right]$$

Given this value, the block calculates the MOSFET gain,  $K$ , using the following equation:

$$I_{tf} = TF \frac{dI_C}{dt}$$

$$I_{ds} = I_b - I_{tf} = K \left[ (V_{GE(sat)} - V_{th})V_{ds} - \frac{V_{ds}^2}{2} \right]$$

where  $V_{th}$  is the **Gate-emitter threshold voltage, Vge(th)** parameter value,  $V_{GE(sat)}$  is the **Gate-emitter voltage at which Vce(sat) is defined** parameter value, and  $TF$  is the **Total forward transit time** parameter value.

$V_{ds}$  is related to the transistor voltages as  $V_{ds} = V_{ce} - V_{be}$ . The block substitutes this relationship for  $V_{ds}$ , sets the base-emitter voltage and base current to their saturated values, and rearranges the MOSFET equation to give

$$K = \frac{I_{b(sat)}}{\left[ (V_{GE(sat)} - V_{th})(V_{be(sat)} + V_{ce(sat)}) - \frac{(V_{be(sat)} + V_{ce(sat)})^2}{2} \right]}$$

where  $V_{ce(sat)}$  is the **Collector-emitter saturation voltage, Vce(sat)** parameter value.

These calculations ensure the zero gate voltage collector current and collector-emitter saturation voltage are exactly met at these two specified conditions. However, the current-voltage plots are very sensitive to the emission coefficient  $N$  and the precise value of  $V_{th}$ . If the manufacturer datasheet gives current-voltage plots for different  $V_{GE}$  values, then the  $N$  and  $V_{th}$  can be tuned by hand to improve the match.

### Representation by 2D Lookup Table

For the lookup table representation of the detailed block modeling option, you provide tabulated values for collector current as a function of gate-emitter voltage and collector-emitter voltage. The main advantage of using this option is simulation speed. It also lets you parameterize the device from either measured data or from data obtained from another simulation environment. To generate your

own data from the equivalent circuit representation, you can use a test harness, such as shown in the “IGBT Characteristics” example.

The lookup table representation combines all of the equivalent circuit components (PNP transistor, N-channel MOSFET, collector resistor and emitter resistor) into one equivalent lookup table.

### Representation by 3D Lookup Table

For the temperature-dependent lookup table representation of the detailed block modeling option, you provide tabulated values for collector current as a function of gate-emitter voltage, collector-emitter voltage, and temperature.

The lookup table representation combines all of the equivalent circuit components (PNP transistor, N-channel MOSFET, collector resistor and emitter resistor) into one equivalent lookup table.

If the block thermal port is not exposed, then the **Device simulation temperature** parameter on the **Temperature Dependence** setting lets you specify the simulation temperature.

### Charge Model

The detailed modeling option of the block models capacitances either by fixed capacitance values, or by tabulated values as a function of the collector-emitter voltage. In either case, you can either directly specify the gate-emitter and gate-collector capacitance values, or let the block derive them from the input and reverse transfer capacitance values. Therefore, the **Parameterization** options for charge model on the **Junction Capacitance** setting are:

- Specify fixed input, reverse transfer and output capacitance — Provide fixed parameter values from datasheet and let the block convert the input and reverse transfer capacitance values to capacitance values, as described below. This is the default method.
- Specify fixed gate-emitter, gate-collector and collector-emitter capacitance — Provide fixed values for capacitance parameters directly.
- Specify tabulated input, reverse transfer and output capacitance — Provide tabulated capacitance and collector-emitter voltage values based on datasheet plots. The block converts the input and reverse transfer capacitance values to capacitance values, as described below.
- Specify tabulated gate-emitter, gate-collector and collector-emitter capacitance — Provide tabulated values for capacitances and collector-emitter voltage.

Use one of the tabulated capacitance options (Specify tabulated input, reverse transfer and output capacitance or Specify tabulated gate-emitter, gate-collector and collector-emitter capacitance) when the datasheet provides a plot of capacitances as a function of collector-emitter voltage. Using tabulated capacitance values will give more accurate dynamic characteristics, and avoids the need to iteratively tune parameters to fit the dynamics.

If you use the Specify fixed gate-emitter, gate-collector and collector-emitter capacitance or Specify tabulated gate-emitter, gate-collector and collector-emitter capacitance option, the **Junction Capacitance** setting lets you specify the **Gate-emitter capacitance**, **Gate-collector capacitance**, and **Collector-emitter capacitance** parameter values (fixed or tabulated) directly. Otherwise, the block derives them from the **Input capacitance**, **Cies**, **Reverse transfer capacitance**, **Cres**, and **Output capacitance**, **Coes** parameter values. These two parameterization methods are related as follows:

- $C_{GC} = C_{res}$

- $C_{GE} = C_{ies} - C_{res}$
- $C_{CE} = C_{oes} - C_{res}$

The two fixed capacitance options (Specify fixed input, reverse transfer and output capacitance or Specify fixed gate-emitter, gate-collector and collector-emitter capacitance) let you model gate capacitance as a fixed gate-emitter capacitance  $C_{GE}$  and either a fixed or a nonlinear gate-collector capacitance  $C_{GC}$ . If you select the Gate-collector charge function is nonlinear option for the **Charge-voltage linearity** parameter, then the gate-collector charge relationship is defined by the piecewise-linear function shown in the following figure.

With this nonlinear capacitance, the gate-emitter and collector-emitter voltage profiles take the form shown in the next figure, where the collector-emitter voltage fall has two regions (labeled 2 and 3) and the gate-emitter voltage has two time-constants (before and after the threshold voltage  $V_{th}$ ):

You can determine the capacitor values for  $C_{ies}$ ,  $C_{res}$ , and  $C_{ox}$  as follows, assuming that the IGBT gate is driven through an external resistance  $R_G$ :

- 1 Set  $C_{ies}$  to get correct time-constant for  $V_{GE}$  in Region 1. The time constant is defined by the product of  $C_{ies}$  and  $R_G$ . Alternatively, you can use a datasheet value for  $C_{ies}$ .
- 2 Set  $C_{res}$  so as to achieve the correct  $V_{CE}$  gradient in Region 2. The gradient is given by  $(V_{GE} - V_{th}) / (C_{res} \cdot R_G)$ .
- 3 Set  $V_{Cox}$  to the voltage at which the  $V_{CE}$  gradient changes minus the threshold voltage  $V_{th}$ .
- 4 Set  $C_{ox}$  to get correct Miller length and time constant in Region 4.

Because the underlying model is a simplification of an actual charge distribution, some iteration of these four steps may be required to get a best overall fit to measured data.

The collector current tail when the IGBT is turned off is determined by the **Total forward transit time** parameter if you set the **I-V characteristics defined by** parameter to Fundamental nonlinear equation.

If you set the **I-V characteristics defined by** parameter to Lookup table (2D, temperature independent) or Lookup table (3D, temperature dependent), then the collector current tail when the IGBT is turned off is determined by the **Turn-off tail current transit time** parameter:

$$i_c = i_{off} + (i_{on} - i_{off}) \exp\left(-\frac{t - t_{off}}{TT}\right)$$

Where  $i_{off}$  is the IGBT turn-off current,  $i_{on}$  is the IGBT turn-on current,  $t_{off}$  is the turn-off time, and  $TT$  is the value of the **Turn-off tail current transit time** parameter.

**Note** Because this block implementation includes a charge model, you must model the impedance of the circuit driving the gate to obtain representative turn-on and turn-off dynamics. Therefore, if you are simplifying the gate drive circuit by representing it as a controlled voltage source, you must include a suitable series resistor between the voltage source and the gate.

### Fine-Tuning the Current-Voltage Characteristics

For the equivalent circuit representation of the detailed model, use the parameters on the **Advanced** setting to fine-tune the current-voltage characteristics of the modeled device. To use these additional parameters effectively, you will need a manufacturer datasheet that provides plots of the collector current versus collector-emitter voltage for different values of gate-emitter voltage. The parameters on the **Advanced** setting have the following effects:

- The **Emission coefficient, N** parameter controls the shape of the current-voltage curves around the origin.
- The **Collector resistance, RC** and **Emitter resistance, RE** parameters affect the slope of the current-voltage curve at higher currents, and when fully turned on by a high gate-emitter voltage.
- The **Forward Early voltage, VAF** parameter affects the shape of the current-voltage curves for gate-emitter voltages around the **Gate-emitter threshold voltage, Vge(th)**.

### Modeling Temperature Dependence

For the 2D lookup table representation, the electrical equations do not depend on temperature. However, you can model temperature dependence by either using the 3D lookup table representation, or by using the equivalent circuit representation of the detailed model.

For the equivalent circuit representation, temperature dependence is modeled by the temperature dependence of the constituent components. See the N-Channel MOSFET and PNP Bipolar Transistor block reference pages for further information on the defining equations.

Some datasheets do not provide information on the zero gate voltage collector current,  $I_{ces}$ , at a higher measurement temperature. In this case, you can alternatively specify the energy gap,  $EG$ , for the device, using a typical value for the semiconductor type. For silicon, the energy gap is usually 1.11 eV.

### **Event-Based IGBT Modeling Option**

This implementation has much simpler equations than that with full I-V and capacitance characteristics. Use the event-based modeling option when the focus of the analysis is to understand overall circuit behavior rather than to verify the precise IGBT timing or losses characteristics.

The device is always in one of the following four states:

- Off
- Turning on
- On
- Turning off

In the off state, the relationship between collector current ( $i_c$ ) and collector-emitter voltage ( $v_{ce}$ ) is

$$i_c = G_{off}v_{ce} \quad (1-44)$$

In the on state, the relationship between collector current ( $i_c$ ) and collector-emitter voltage ( $v_{ce}$ ) is

$$v_{ce} = \text{tablelookup}(i_c) \quad (1-45)$$

When turning on, the collector-emitter voltage is ramped down to zero over the rise time, the device moving into the on state when the voltage falls below the tabulated on-state value. Similarly when turning off, the collector-emitter voltage is ramped up over the (current) fall time to the specified blocking voltage value.

The following figure shows the resulting voltage and current profiles when driving a resistive load.

### Thermal Port

The block has an optional thermal port, hidden by default. To expose the thermal port, set the **Modeling option** parameter to:

- Full I-V and capacitance characteristics | Show thermal port — Detailed model. This action displays the thermal port **H** on the block icon, and exposes the **Thermal Port** parameters.
- Simplified I-V characteristics and event-based timing | Show thermal port — Simplified event-based model. This action displays the thermal port **H** on the block icon, exposes **Thermal Port** parameters and additional **Main** parameters. To simulate thermal effects, you must provide additional tabulated data for turn-on and turn-off losses and define the collector-emitter on-state voltage as a function of both current and temperature.

Use the thermal port to simulate the effects of generated heat and device temperature. For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

This table shows the relationship between the capacitances of the block and the initial targets:

Defined Capacitance	Initial Targets
Gate-emitter capacitance, $C_{ge}$	Set the initial target for the gate-emitter capacitance voltage only. Set the initial target of the collector-emitter capacitance voltage to 0 or set its priority to None.
Collector-emitter capacitance, $C_{ce}$	Set the initial target for the collector-emitter capacitance voltage only. Set the initial target of the gate-emitter capacitance voltage to 0 or set its priority to None.
Gate-collector capacitance, $C_{gc}$	Set the initial targets for the gate-collector voltages by applying constraints on the gate-emitter and collector-emitter voltages. The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and collector-emitter.
Gate-emitter capacitance, $C_{ge}$ , and gate-collector capacitance, $C_{gc}$	Set the initial targets for the gate-emitter and gate-collector voltages by applying constraints on the gate-emitter and collector-emitter voltages. The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and the collector-emitter.
Gate-emitter capacitance, $C_{ge}$ , and collector-emitter capacitance, $C_{ce}$	Set the initial target for the gate-emitter and the collector-emitter capacitance.
Gate-collector capacitance, $C_{gc}$ , and collector-emitter capacitance, $C_{ce}$	Set the initial targets for the gate-collector and collector-emitter voltages by applying constraints on the gate-emitter and collector-emitter voltages. The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and the collector-emitter.
Gate-emitter capacitance, $C_{ge}$ , gate-collector capacitance, $C_{gc}$ , and collector-emitter capacitance, $C_{ce}$	Set the initial targets for the gate-emitter, gate collector and collector-emitter capacitances by applying constraints on the gate-emitter and collector-emitter voltages. The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and the collector-emitter.

**Note** Inside your model, the number of initial targets with **Priority** equal to Low or High must match the number of differential variables. The differential variables come from the inductors and the capacitances in the model.

## Assumptions and Limitations

The detailed model is based on the following assumptions:

- This block does not allow you to specify initial conditions on the capacitances. If you select the **Start simulation from steady state** option in the Solver Configuration block, the block solves the initial voltages to be consistent with the calculated steady state. Otherwise, voltages are zero at the start of the simulation.
- You may need to use nonzero capacitance values to prevent numerical simulation issues, but the simulation may run faster with these values set to zero.
- The block does not account for temperature-dependent effects on the capacitances.

The simplified, event-based model is based on the following assumptions:

- When you use a pair of IGBTs in a bridge arm, normally the gate drive circuitry will prevent a device turning on until the corresponding device has turned off, thereby implementing a minimum dead band. If you need to simulate the case where there is no minimum dead band and both devices are momentarily partially on, use the detailed IGBT model modeling option (**Full I-V and capacitance characteristics**). The assumption used by the event-based modeling option that the collector-emitter voltages can be ramped between on and off states is not valid for such cases.
- A minimum pulse width is applied when turning on or off; at the point where the gate-collector voltage rises above the threshold, any subsequent gate voltage changes are ignored for a time equal to the sum of the turn-on delay and current rise time. Similarly at the point where the gate collector voltage falls below the threshold, any subsequent gate voltage changes are ignored for a time equal to the sum of the turn-off delay and current fall time. This feature is normally implemented in the gate drive circuitry.
- This model does not account for charge. Hence there is no current tail when turning off an inductive load.
- Representative modeling of the current spike during turn-on of an inductive load with preexisting freewheeling current requires tuning of the **Miller resistance** parameter.
- The tabulated turn-on switching loss uses the previous on-state current, not the current value (which is not known until the device reaches the final on state).
- Due to high model stiffness that can arise from the simplified equations, you may get minimum step size violation warnings when using this block. Open the Solver pane of the Configuration Parameters dialog box and increase the **Number of consecutive min steps** parameter value as necessary to remove these warnings.

## Parameters

### Modeling Option — IGBT representation

Full I-V and capacitance characteristics | No thermal port (default) | Full I-V and capacitance characteristics | Show thermal port | Simplified I-V characteristics and event-based timing | No thermal port | Simplified I-V characteristics and event-based timing | Show thermal port

Select the IGBT representation:

- Full I-V and capacitance characteristics | No thermal port — Detailed model that does not simulate the effects of generated heat and device temperature. This is the default.
- Full I-V and capacitance characteristics | Show thermal port — Detailed model with exposed thermal port.
- Simplified I-V characteristics and event-based timing | No thermal port — Simplified event-based model, which also does not simulate the effects of generated heat and device temperature.
- Simplified I-V characteristics and event-based timing | Show thermal port — Simplified event-based model with exposed thermal port.

### Main (Full I-V and Capacitance Characteristics)

This configuration of the **Main** setting corresponds to the detailed block modeling option, which is the default. If you are using the simplified, event-based modeling option of the block, see “Main (Simplified I-V Characteristics and Event-Based Timing)” on page 1-1052.

### I-V characteristics defined by — IGBT representation

Fundamental nonlinear equations (default) | Lookup table (2D, temperature independent) | Lookup table (3D, temperature dependent)

Select the IGBT representation:

- Fundamental nonlinear equations — Use an equivalent circuit based on a PNP bipolar transistor and N-channel MOSFET. This is the default.
- Lookup table (2D, temperature independent) — Use 2D table lookup for collector current as a function of gate-emitter voltage and collector-emitter voltage.
- Lookup table (3D, temperature dependent) — Use 3D table lookup for collector current as a function of gate-emitter voltage, collector-emitter voltage, and temperature.

### Zero gate voltage collector current, $I_{ces}$ — Zero gate voltage collector current

2 mA (default)

Collector current that flows when the gate-emitter voltage is set to zero, and a large collector-emitter voltage is applied, that is, the device is in the off-state. The value of the large collector-emitter voltage is defined by the parameter **Voltage at which  $I_{ces}$  is defined**.

### Dependencies

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

### Voltage at which $I_{ces}$ is defined — Voltage at which $I_{ces}$ is defined

600 V (default)

Voltage used when measuring the **Zero gate voltage collector current,  $I_{ces}$** .

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Gate-emitter threshold voltage,  $V_{ge(th)}$  – Gate-emitter threshold voltage**  
6 V (default)

Threshold voltage used in the MOSFET equations.

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Collector-emitter saturation voltage,  $V_{ce(sat)}$  – Collector-emitter saturation voltage**  
2.6 V (default)

Collector-emitter voltage for a typical on-state as specified by the manufacturer.

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Collector current at which  $V_{ce(sat)}$  is defined – Collector current at which  $V_{ce(sat)}$  is defined**  
400 A (default)

Collector-emitter current when the gate-emitter voltage is  $V_{ge(sat)}$  and collector-emitter voltage is  $V_{ce(sat)}$ .

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Gate-emitter voltage at which  $V_{ce(sat)}$  is defined – Gate-emitter voltage at which  $V_{ce(sat)}$  is defined**  
10 V (default)

Gate voltage used when measuring  $V_{ce(sat)}$  and  $I_{ce(sat)}$ .

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Measurement temperature – Measurement temperature**  
25 degC (default)

Temperature for which the parameters are quoted ( $T_{m1}$ ).

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Vector of gate-emitter voltages, Vge — Vector of gate-emitter voltages**

[-1 0 0.5 1 1.5 2 2.5 3 3.5 4] V (default)

Vector of gate-emitter voltages, to be used for table lookup. The vector values must be strictly increasing. The values can be nonuniformly spaced.

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to either Lookup table (2D, temperature independent) or Lookup table (3D, temperature dependent).

**Vector of collector-emitter voltages, Vce — Vector of collector-emitter voltages**

[-2 6 7 8 10 12 15 20] V (default)

Vector of collector-emitter voltages, to be used for table lookup. The vector values must be strictly increasing. The values can be nonuniformly spaced.

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to either Lookup table (2D, temperature independent) or Lookup table (3D, temperature dependent).

**Tabulated collector currents, Ic(Vge,Vce) — Tabulated collector currents temperature independent**

**Vector of temperatures, T — Vector of temperatures**

[25 125] degC (default)

Vector of temperatures, to be used for table lookup. The vector values must be strictly increasing. The values can be nonuniformly spaced.

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Lookup table (3D, temperature dependent).

**Tabulated collector currents,  $I_c(V_{ge}, V_{ce}, T)$  — Tabulated collector currents temperature dependent**

zeros(8, 10, 2) A (default)

Tabulated values for collector current as a function of gate-emitter voltage, collector-emitter voltage, and temperature, to be used for 3D table lookup. Each value in the matrix specifies the collector current for a specific combination of gate-emitter voltage and collector-emitter voltage at a specific temperature. The matrix size must match the dimensions defined by the gate-emitter voltage, collector-emitter voltage, and temperature vectors.

**Dependencies**

To enable this parameter, set **I-V characteristics defined by** to Lookup table (3D, temperature dependent).

**Junction Capacitance (Full I-V and Capacitance Characteristics)****Parameterization — Junction capacitance parameterization**

Specify fixed input, reverse transfer, and output capacitance (default) | Specify fixed gate-emitter, gate-collector, and collector-emitter capacitance | Specify tabulated input, reverse transfer, and output capacitance | Specify tabulated gate-emitter, gate-collector, and collector-emitter capacitance

Select one of the following methods for block parameterization:

- Specify fixed input, reverse transfer, and output capacitance — Provide fixed parameter values from datasheet and let the block convert the input, output, and reverse transfer capacitance values to junction capacitance values, as described in “Charge Model” on page 1-1034. This is the default method.
- Specify fixed gate-emitter, gate-collector, and collector-emitter capacitance — Provide fixed values for junction capacitance parameters directly.
- Specify tabulated input, reverse transfer, and output capacitance — Provide tabulated capacitance and collector-emitter voltage values based on datasheet plots. The block converts the input, output, and reverse transfer capacitance values to junction capacitance values, as described in “Charge Model” on page 1-1034.
- Specify tabulated gate-emitter, gate-collector, and collector-emitter capacitance — Provide tabulated values for junction capacitances and collector-emitter voltage.

**Input capacitance, Cies – Input capacitance**

26.4 nF (default)

Gate-emitter capacitance with the collector shorted to the emitter.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance.

**Input capacitance, Cies (Vce) – Input capacitance with tabulated input**

[80 40 32 28 27.5 27 26.5 26.5 26.5] nF (default)

Gate-emitter capacitance with the collector shorted to the emitter, tabulated with the collector-emitter voltage.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

**Reverse transfer capacitance, Cres – Reverse transfer capacitance**

2.7 nF (default)

Collector-gate capacitance with the emitter connected to ground.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance.

**Reverse transfer capacitance, Cres (Vce) – Reverse transfer capacitance with tabulated input**

[55 9 5.5 3.1 2.5 2.1 1.9 1.8 1.7] nF (default)

Collector-gate capacitance with the emitter connected to ground, tabulated with the collector-emitter voltage.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

**Output capacitance, Coes – Output capacitance**

0 nF (default)

Collector-emitter capacitance with the gate and emitter shorted.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance.

**Output capacitance, Coes (Vce) – Output capacitance with tabulated input**

[60 20 12 8 6 4.8 4 3.5 3.1] nF (default)

Collector-emitter capacitance with the gate and emitter shorted, tabulated with collector-emitter voltage.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

**Gate-emitter capacitance — Gate-emitter capacitance**

23.7 nF (default)

Capacitance placed between the gate and the emitter.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify fixed gate-emitter, gate-collector, and collector-emitter capacitance.

**Gate-emitter capacitance,  $C_{ge}(V_{ge}, V_{ce})$  — Gate-emitter capacitance with tabulated values**

[25 31 26.5 24.9 25 24.9 24.6 24.7 24.8] nF (default)

**Gate-collector capacitance,  $C_{gc}(V_{ge}, V_{ce})$  — Gate-collector capacitance with tabulated values**

[55 9 5.5 3.1 2.5 2.1 1.9 1.8 1.7] nF (default)

Capacitance placed between the gate and the collector, tabulated with the gate-emitter voltage and the collector-emitter voltage.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated gate-emitter, gate-collector, and collector-emitter capacitance.

**Corresponding gate-emitter voltages for tabulated gate capacitance,  $V_{ge}$  — Corresponding collector-emitter voltages**

0 V (default)

Gate-emitter voltages corresponding to the tabulated gate capacitance values.

If this value is a scalar, then **Gate-emitter capacitance,  $C_{ge}(V_{ge}, V_{ce})$**  and **Gate-collector capacitance,  $C_{gc}(V_{ge}, V_{ce})$**  are vectors of scalars. If this value is a vector, then **Gate-emitter**

**capacitance,  $C_{ge}(V_{ge}, V_{ce})$  and Gate-collector capacitance,  $C_{gc}(V_{ge}, V_{ce})$**  are matrices of scalars.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated gate-emitter, gate-collector, and collector-emitter capacitance.

**Collector-emitter capacitance — Collector-emitter capacitance**

0 nF (default)

Capacitance placed between the collector and the emitter.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify fixed gate-emitter, gate-collector, and collector-emitter capacitance.

**Collector-emitter capacitance,  $C_{ce}(V_{ce})$  — Collector-emitter capacitance with tabulated values**

[5 11 6.5 4.9 3.5 2.7 2.1 1.7 1.4] nF (default) | nF

Capacitance placed between the collector and the emitter, tabulated with the collector-emitter voltage.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated gate-emitter, gate-collector, and collector-emitter capacitance.

**Corresponding collector-emitter voltages — Corresponding collector-emitter voltages**

[0 1 2 5 10 15 20 25 30] V (default)

Collector-emitter voltages corresponding to the tabulated capacitance values.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance or Specify tabulated gate-emitter, gate-collector, and collector-emitter capacitance.

**Charge-voltage linearity — Charge-voltage linearity**

Gate-collector capacitance is constant (default) | Gate-collector charge function is nonlinear

Whether the gate-drain capacitance is fixed or nonlinear:

- **Gate-collector capacitance is constant** — The capacitance value is constant and defined according to the selected parameterization option, either directly or derived from a datasheet. This is the default method.
- **Gate-collector charge function is nonlinear** — The gate-collector charge relationship is defined according to the piecewise-nonlinear function described in “Charge Model” on page 1-1034. Two additional parameters appear to let you define the gate-collector charge function.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify fixed input, reverse transfer and output capacitance or Specify fixed gate-emitter, gate-collector and output capacitance.

**Gate-collector oxide capacitance — Gate-collector oxide capacitance**

20 nF (default)

Gate-collector capacitance when the device is on and the collector-gate voltage is small.

**Dependencies**

To enable this parameter, set **Charge-voltage linearity** to Gate-collector charge function is nonlinear.

**Collector-gate voltage below which oxide capacitance becomes active — Collector-gate voltage below which oxide capacitance becomes active**

-5 V (default)

Collector-gate voltage at which the collector-gate capacitance switches between off-state ( $C_{GC}$ ) and on-state ( $C_{ox}$ ) capacitance values.

**Dependencies**

To enable this parameter, set **Charge-voltage linearity** to Gate-collector charge function is nonlinear.

**Total forward transit time — Total forward transit time**

0 us (default)

Forward transit time for the PNP transistor used as part of the underlying IGBT model. It affects how quickly charge is removed from the channel when the IGBT is turned off.

**Dependencies**

To enable this parameter, in the **Main** settings, set **I-V characteristics defined by** to Fundamental nonlinear equations.

**Turn-off tail current transit time — Total forward transit time**

0 us (default)

Turn-off transit time for the tail current.

**Dependencies**

To enable this parameter, in the **Main** settings, set **I-V characteristics defined by** to Lookup table (2D, temperature independent) or Lookup table (3D, temperature dependent).

**Advanced (Full I-V and Capacitance Characteristics)**

The lookup table representation combines all the equivalent circuit components into one lookup table, and therefore this setting is empty. If you use the equivalent circuit representation, this setting has the following parameters.

**Emission coefficient, N – Emission coefficient**

1 (default)

Emission coefficient or ideality factor of the bipolar transistor.

**Forward Early voltage, VAF – Forward Early voltage**

200 V (default)

Forward Early voltage for the PNP transistor used in the IGBT model. For more information, see the PNP Bipolar Transistor block reference page.

**Collector resistance, RC – Collector resistance**

0.001 Ohm (default)

Resistance at the collector.

**Emitter resistance, RE – Emitter resistance**

0.0010hm (default)

Resistance at the emitter.

**Internal gate resistance, RG – Internal gate resistance**

0.0010hm (default)

Resistance of the internal gate resistor at the measurement temperature. This is not the value of the external circuit series gate resistance, which you should model externally to the IGBT.

**Forward current transfer ratio, BF – Forward current transfer ratio**

50 (default)

Ideal maximum forward current gain for the PNP transistor used in the IGBT model. See the PNP Bipolar Transistor block reference page for more information.

**Temperature Dependence (Full I-V and Capacitance Characteristics)**

For the 2D lookup table representation, the electrical equations do not depend on temperature and therefore this setting is empty. For the 3D lookup table representation with exposed thermal port, this setting is also empty because the 3D matrix on the **Main** setting captures the temperature dependence. If the block thermal port is not exposed for the 3D lookup table representation, then this setting contains only the **Device simulation temperature** parameter. If you use the equivalent circuit representation, this setting has the following parameters.

**Parameterization – Temperature dependence parameterization**

None – Simulate at parameter measurement temperature (default) | Specify  $I_{ces}$  and  $V_{ce(sat)}$  at second measurement temperature | Specify  $V_{ce(sat)}$  at second measurement temperature plus the energy gap, EG

Select one of the following methods for temperature dependence parameterization:

- None – Simulate at parameter measurement temperature — Temperature dependence is not modeled, and none of the other parameters on this setting are visible. This is the default method.
- Specify  $I_{ces}$  and  $V_{ce(sat)}$  at second measurement temperature — Model temperature-dependent effects by providing values for the zero gate voltage collector current,  $I_{ces}$ , and collector-emitter voltage,  $V_{ce(sat)}$ , at the second measurement temperature.

- Specify  $V_{ce(sat)}$  at second measurement temperature plus the energy gap, EG
  - Use this option when the datasheet does not provide information on the zero gate voltage collector current,  $I_{ces}$ , at a higher measurement temperature.

### Energy gap, EG – Energy gap

1.11 eV (default)

Energy gap value.

#### Dependencies

To enable this parameter, in the **Temperature Dependence** setting, set **Parameterization** to Specify  $V_{ce(sat)}$  at second measurement temperature plus the energy gap, EG.

### Zero gate voltage collector current, $I_{ces}$ , at second measurement temperature – Zero gate voltage collector current, $I_{ces}$ , at second measurement temperature

100 mA (default)

Zero gate collector current value at the second measurement temperature.

#### Dependencies

To enable this parameter, in the **Temperature Dependence** setting, set **Parameterization** to Specify  $I_{ces}$  and  $V_{ce(sat)}$  at second measurement temperature.

### Collector-emitter saturation voltage, $V_{ce(sat)}$ , at second measurement temperature – Collector-emitter saturation voltage, $V_{ce(sat)}$ , at second measurement temperature

3 V (default)

Collector-emitter saturation voltage value at the second measurement temperature, and when the collector current and gate-emitter voltage are as defined by the corresponding parameters on the **Main** setting.

### Second measurement temperature – Second measurement temperature

125 degC (default)

Second temperature  $T_{m2}$  at which **Zero gate voltage collector current,  $I_{ces}$ , at second measurement temperature** and **Collector-emitter saturation voltage,  $V_{ce(sat)}$ , at second measurement temperature** are measured.

### Saturation current temperature exponent, $X_{TI}$ – Saturation current temperature exponent

3 (default)

Saturation current exponent value for your device type. If you have graphical data for the value of  $I_{ces}$  as a function of temperature, you can use it to fine-tune the value of  $X_{TI}$ .

### Mobility temperature exponent, $BEX$ – Mobility temperature exponent

-1.5 (default)

Mobility temperature coefficient value. You can use the default value for most devices. If you have graphical data for  $V_{ce(sat)}$  at different temperatures, you can use it to fine-tune the value of  $BEX$ .

**Internal gate resistance temperature coefficient – Internal gate resistance temperature coefficient**

0 1/K (default)

Represents the fractional rate of change ( $\alpha$ ) of internal gate resistance (RG) with temperature. Thus the gate resistance is  $R = R_{\text{meas}}(1 + \alpha (T_s - T_{m1}))$ , where  $R_{\text{meas}}$  is the **Internal gate resistance, RG** parameter value.

**Device simulation temperature – Device simulation temperature**

25 degC (default)

Temperature  $T_s$  at which the device is simulated.

**Main (Simplified I-V Characteristics and Event-Based Timing)**

This configuration of the **Main** setting corresponds to the simplified, event-based block modeling option. If you are using the detailed modeling option of the block, see “Main (Full I-V and Capacitance Characteristics)” on page 1-1042.

**Vector of collector currents, Ic – Vector of collector currents**

[0, 10, 50, 100, 200, 400, 600] A (default)

Collector currents for which the on-state collector-emitter voltages are defined. The first element must be zero.

**Vector of temperatures, Tj – Vector of temperatures**

[298.15, 398.15] K (default)

Temperature values at which the collector-emitter and turn-on/turn-off losses are quoted.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

**Corresponding on-state collector-emitter voltages – Corresponding on-state collector-emitter voltages**

[0, 1.1, 1.3, 1.45, 1.75, 2.25, 2.7] V (default)

Collector-emitter voltages corresponding to the vector of collector currents. The first element must be zero.

**Dependencies**

To enable this parameter, set **Modeling option** to Simplified I-V characteristics and event-based timing | No thermal port.

**Collector-emitter on-state voltages, Vce=fcn(Tj,Ic) – Collector-emitter on-state voltages**

[0, 1.1, 1.3, 1.45, 1.75, 2.25, 2.7; 0, 1.0, 1.15, 1.35, 1.7, 2.35, 3.0] V (default)

Collector-emitter voltages when in the on state, defined as a function of both temperature and current.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

**Miller resistance – Miller resistance**

0.1 Ohm (default)

When the device turns on, it has a constant-value Miller resistance in series with the demanded voltage ramp. This resistance represents the partial conductance path through the device during turn on, and can be used to match the voltage spike observed when reconnecting a current-carrying inductor and corresponding freewheeling diode. A typical value is 10 to 50 times the effective on-state resistance.

**Off-state conductance – Off-state conductance**

1e-5 Ohm (default)

Conductance when the device is in the off state.

**Gate-emitter threshold voltage,  $V_{ge(th)}$  – Threshold voltage**

6 V (default)

Gate-emitter voltage must be greater than this value for the device to turn on.

**Switching Losses (Simplified I-V Characteristics and Event-Based Timing)****Vector of temperatures for switching losses,  $T_j$  – Switching losses temperatures**

[298.15, 398.15] K (default)

Temperatures at which switching losses are tabulated.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

**Vector of collector currents for switching losses,  $I_c$  – Switching losses collector currents**

[0, 10, 50, 100, 200, 400, 600] A (default)

Collector currents at which switching losses are tabulated.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

**Turn-on switching losses,  $E_{on}=f_{cn}(T_j, I_c)$  – Turn-on switching losses**

[0, 0.2, 1, 2, 4, 8, 15; 0, 0.3, 1.3, 2.5, 5, 11, 18]\*1e-3 J (default)

Energy loss when turning the device on, defined as a function of temperature and final on-state current.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

**Turn-off switching losses,  $E_{off}=f_{cn}(T_j, I_c)$  — Turn-off switching losses**

[0, 0.3, 1.5, 3, 6, 15, 25; 0, 0.7, 3.3, 6.5, 13, 25, 35]\*1e-3 J (default)

Energy loss when turning the device off, defined as a function of temperature and final on-state current.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

**Dynamics (Simplified I-V Characteristics and Event-Based Timing)****Turn-on delay — Turn-on delay**

0.07 us (default)

Time before which the device starts to ramp on.

**Current rise time — Current rise time**

0.7 us (default)

Time taken for the current to ramp up when driving a resistive load.

**Turn-off delay — Turn-off delay**

0.2 us (default)

Time before which the device starts to ramp off.

**Current fall time — Current fall time**

0.5 us (default)

Time taken for the current to ramp down when driving a resistive load.

**Off-state voltage for rise and fall times — Off-state voltage for rise and fall times**

300 V (default)

Off-state collector-emitter voltage used when specifying the rise and fall times. The default value is 300 V.

**Dependencies**

To enable this parameter, set **Modeling option** to Simplified I-V characteristics and event-based timing | No thermal port.

**Off-state voltage for rise and fall times — Off-state voltage for rise and fall times**

300 V (default)

Off-state collector-emitter voltage used when specifying the rise times, fall times, and the losses data.

**Dependencies**

To enable this parameter, expose the thermal port by setting **Modeling option** to Simplified I-V characteristics and event-based timing | Show thermal port.

### Description

The N-Channel JFET block uses the Shichman and Hodges equations to represent an N-Channel JFET using a model with the following structure:

G is the transistor gate, D is the transistor drain, and S is the transistor source. The drain current,  $I_D$ , depends on the region of operation and whether the transistor is operating in normal or inverse mode.

- In normal mode ( $V_{DS} \geq 0$ ), the block provides the following relationship between the drain current  $I_D$  and the drain-source voltage  $V_{DS}$ .

Region	Applicable Range of $V_{GS}$ and $V_{DS}$ Values	Corresponding $I_D$ Equation
Off	$V_{GS} - V_{t0} \leq 0$	$I_D = 0$
Linear	$0 < V_{DS} < V_{GS} - V_{t0}$	$I_D = \beta V_{DS}(2(V_{GS} - V_{t0}) - V_{DS})(1 + \lambda V_{DS})$
Saturated	$0 < V_{GS} - V_{t0} \leq V_{DS}$	$I_D = \beta (V_{GS} - V_{t0})^2 (1 + \lambda V_{DS})$

- In inverse mode ( $V_{DS} < 0$ ), the block provides the following relationship between the drain current  $I_D$  and the drain-source voltage  $V_{DS}$ .

Region	Applicable Range of $V_{GS}$ and $V_{DS}$ Values	Corresponding $I_D$ Equation
Off	$V_{GD} - V_{t0} \leq 0$	$I_D = 0$
Linear	$0 < -V_{DS} < V_{GD} - V_{t0}$	$I_D = \beta V_{DS}(2(V_{GD} - V_{t0}) + V_{DS})(1 - \lambda V_{DS})$

Region	Applicable Range of $V_{GS}$ and $V_{DS}$ Values	Corresponding $I_D$ Equation
Saturated	$0 < V_{GD} - V_{t0} \leq -V_{DS}$	$I_D = \beta (V_{GD} - V_{t0})^2 (1 - \lambda V_{DS})$

In the preceding equations:

- $V_{GS}$  is the gate-source voltage.
- $V_{GD}$  is the gate-drain voltage.
- $V_{t0}$  is the threshold voltage. If you select **Specify using equation parameters directly** for the **Parameterization** parameter,  $V_{t0}$  is the **Threshold voltage** parameter value. Otherwise, the block calculates  $V_{t0}$  from the datasheet parameters you specify.
- $\beta$  is the transconductance parameter. If you select **Specify using equation parameters directly** for the **Parameterization** parameter,  $\beta$  is the **Transconductance parameter** parameter value. Otherwise, the block calculates  $\beta$  from the datasheet parameters you specify.
- $\lambda$  is the channel-length modulation parameter. If you select **Specify using equation parameters directly** for the **Parameterization** parameter,  $\lambda$  is the **Channel-length modulation** parameter value. Otherwise, the block calculates  $\lambda$  from the datasheet parameters you specify.

The currents in each of the diodes satisfy the exponential diode equation

$$I_{GD} = IS \cdot \left( e^{\frac{qV_{GD}}{kT_{m1}}} - 1 \right)$$

$$I_{GS} = IS \cdot \left( e^{\frac{qV_{GS}}{kT_{m1}}} - 1 \right)$$

where:

- $IS$  is the saturation current. If you select **Specify using equation parameters directly** for the **Parameterization** parameter,  $IS$  is the **Saturation current** parameter value. Otherwise, the block calculates  $IS$  from the datasheet parameters you specify.
- $q$  is the elementary charge on an electron (1.602176e-19 Coulombs).
- $k$  is the Boltzmann constant (1.3806503e-23 J/K).
- $T_{m1}$  is the measurement temperature. The value comes from the **Measurement temperature** parameter.

The block models gate junction capacitance as a fixed gate-drain capacitance  $C_{GD}$  and a fixed gate-source capacitance  $C_{GS}$ . If you select **Specify using equation parameters directly** for the **Parameterization** parameter, you specify these values directly using the **Gate-drain junction capacitance** and **Gate-source junction capacitance** parameters. Otherwise, the block derives them from the **Input capacitance Ciss** and **Reverse transfer capacitance Crss** parameter values. The two parameterizations are related as follows:

- $C_{GD} = Crss$
- $C_{GS} = Ciss - Crss$

### Modeling Temperature Dependence

The default behavior is that dependence on temperature is not modeled, and the device is simulated at the temperature for which you provide block parameters. You can optionally include modeling the

dependence of the transistor static behavior on temperature during simulation. Temperature dependence of the junction capacitances is not modeled, this being a much smaller effect.

When including temperature dependence, the transistor defining equations remain the same. The measurement temperature value,  $T_{m1}$ , is replaced with the simulation temperature,  $T_s$ . The transconductance,  $\beta$ , and the threshold voltage,  $V_{t0}$ , become a function of temperature according to the following equations:

$$\beta_{T_s} = \beta_{T_{m1}} \left( \frac{T_s}{T_{m1}} \right)^{BEX}$$

$$V_{t0s} = V_{t01} + \alpha (T_s - T_{m1})$$

where:

- $T_{m1}$  is the temperature at which the transistor parameters are specified, as defined by the **Measurement temperature** parameter value.
- $T_s$  is the simulation temperature.
- $\beta_{T_{m1}}$  is JFET transconductance at the measurement temperature.
- $\beta_{T_s}$  is JFET transconductance at the simulation temperature. This is the transconductance value used in the JFET equations when temperature dependence is modeled.
- $V_{t01}$  is the threshold voltage at measurement temperature.
- $V_{t0s}$  is the threshold voltage at simulation temperature. This is the threshold voltage value used in the JFET equations when temperature dependence is modeled.
- $BEX$  is the mobility temperature exponent. A typical value of  $BEX$  is -1.5.
- $\alpha$  is the gate threshold voltage temperature coefficient,  $dV_{th}/dT$ .

For most JFETS, you can use the default value of -1.5 for  $BEX$ . Some datasheets quote the value for  $\alpha$ , but most typically they provide the temperature dependence for the saturated drain current,  $I_{dss}$ . Depending on the block parameterization method, you have two ways of specifying  $\alpha$ :

- If you parameterize the block from a datasheet, you have to provide  $I_{dss}$  at a second measurement temperature. The block then calculates the value for  $\alpha$  based on this data.
- If you parameterize by specifying equation parameters, you have to provide the value for  $\alpha$  directly.

If you have more data comprising drain current as a function of gate-source voltage for fixed drain-source voltage plotted at more than one temperature, then you can also use Simulink Design Optimization software to help tune the values for  $\alpha$  and  $BEX$ .

In addition, the saturation current term,  $IS$ , in the gate-drain and gate-source current equations depends on temperature

$$IS_{T_s} = IS_{T_{m1}} \cdot (T_s/T_{m1})^{XTI} \cdot \exp\left(-\frac{EG}{kT_s}(1 - T_s/T_{m1})\right)$$

where:

- $IS_{T_{m1}}$  is the saturation current at the measurement temperature.
- $IS_{T_s}$  is the saturation current at the simulation temperature. This is the saturation current value used in the gate diode equations when temperature dependence is modeled.

- $EG$  is the energy gap.
- $k$  is the Boltzmann constant ( $1.3806503e-23$  J/K).
- $XTI$  is the saturation current temperature exponent.

Similar to  $\alpha$ , you have two ways of specifying  $EG$  and  $XTI$ :

- If you parameterize the block from a datasheet, you have to specify the gate reverse current,  $I_{gss}$ , at a second measurement temperature. The block then calculates the value for  $EG$  based on this data and assuming a p-n junction nominal value of 3 for  $XTI$ .
- If you parameterize by specifying equation parameters, you have to provide the values for  $EG$  and  $XTI$  directly. This option gives you most flexibility to match device behavior, for example, if you have a graph of  $I_{gss}$  as a function of temperature. With this data you can use Simulink Design Optimization software to help tune the values for  $EG$  and  $XTI$ .

### Thermal Port

You can expose the thermal port to model the effects of generated heat and device temperature. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port and does not simulate heat generation in the device.
- **Show thermal port** — The block contains a thermal port that allows you to model the heat that conduction losses generate. For numerical efficiency, the thermal state does not affect the electrical behavior of the block.

For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

### Assumptions and Limitations

- This block does not allow you to specify initial conditions on the junction capacitances. If you select the **Start simulation from steady state** option in the Solver Configuration block, the block solves the initial voltages to be consistent with the calculated steady state. Otherwise, voltages are zero at the start of the simulation.
- You may need to use nonzero ohmic resistance and junction capacitance values to prevent numerical simulation issues, but the simulation may run faster with these values set to zero.
- The block does not account for temperature-dependent effects on the junction capacitances.
- When you specify  $I_{dss}$  at a second measurement temperature, it must be quoted for the same working point (that is, the same drain current and gate-source voltage) as for the  $I_{dss}$  value on the **Main** tab. Inconsistent values for  $I_{dss}$  at the higher temperature will result in unphysical values for  $\alpha$  and unrepresentative simulation results.

- You may need to tune the value of *BEX* to replicate the  $I_D$ - $V_{GS}$  relationship (if available) for a given device. The value of *BEX* affects whether the  $I_D$ - $V_{GS}$  curves for different temperatures cross each other, or not, for the ranges of  $I_D$  and  $V_{GS}$  considered.

Electrical conserving port associated with the transistor gate terminal

#### **D – Drain terminal**

electrical

Electrical conserving port associated with the transistor drain terminal

#### **S – Source terminal**

electrical

Electrical conserving port associated with the transistor source terminal

#### **H – Thermal port**

thermal

Thermal conserving port.

### Dependencies

To enable this port, set **Modeling option** to Show thermal port.

## Parameters

### **Modeling option – Whether to enable thermal port**

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of generated heat and device temperature.

### Main

#### **Parameterization – Block parameterization**

Specify from a datasheet (default) | Specify using equation parameters directly

Select one of the following methods for block parameterization:

- **Specify from a datasheet** – Provide parameters that the block converts to equations that describe the transistor. This is the default method.
- **Specify using equation parameters directly** – Provide equation parameters  $\beta$ ,  $I_S$ ,  $V_{t0}$ , and  $\lambda$ .

#### **Gate reverse current, I\_gss – Gate reverse current**

-1 nA (default)

The reverse current that flows in the diode when the drain and source are short-circuited and a large negative gate-source voltage is applied.

#### Dependencies

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter.

#### Saturated drain current, $I_{dss}$ — Saturated drain current

3 .mA (default)

The current that flows when a large positive drain-source voltage is applied for a specified gate-source voltage. For a depletion-mode device, this gate-source voltage may be zero, in which case  $I_{dss}$  may be referred to as the zero-gate voltage drain current.

#### Dependencies

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter.

#### $I_{dss}$ measurement point, $[V_{gs} V_{ds}]$ — $I_{dss}$ measurement point

[0, 15] V (default)

A vector of the values of  $V_{GS}$  and  $V_{DS}$  at which  $I_{dss}$  is measured. Normally  $V_{GS}$  is zero.  $V_{DS}$  should be greater than zero.

#### Dependencies

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter.

#### Small-signal parameters, $[g_{fs} g_{os}]$ — Small-signal parameters

[3000, 10] uSuS (default)

A vector of the values of  $g_{fs}$  and  $g_{os}$ .  $g_{fs}$  is the forward transfer conductance, that is, the conductance for a fixed drain-source voltage.  $g_{os}$  is the output conductance, that is, the conductance for a fixed gate-source voltage.

#### Dependencies

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter.

#### Small-signal measurement point, $[V_{gs} V_{ds}]$ — Small-signal measurement point

[0, 15] V (default)

A vector of the values of  $V_{GS}$  and  $V_{DS}$  at which  $g_{fs}$  and  $g_{os}$  are measured.  $V_{DS}$  should be greater than zero. For depletion-mode devices,  $V_{GS}$  is typically zero.

#### Dependencies

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter.

#### Transconductance parameter — Transconductance parameter

6.2e-4 AV<sup>2</sup> (default)

The derivative of drain current with respect to gate voltage.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Saturation current — Saturation current**

5e-10 A (default)

The magnitude of the current that the ideal diode equation approaches asymptotically for very large reverse bias levels.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Threshold voltage — Threshold voltage**

-2.3 V (default)

The gate-source voltage above which the transistor produces a nonzero drain current. For an enhancement device,  $V_{t0}$  should be positive. For a depletion mode device,  $V_{t0}$  should be negative.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Channel-length modulation — Channel-length modulation**

0.003 1/V (default)

The channel-length modulation.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Measurement temperature — Measurement temperature**

25 degC (default)

The temperature for which the datasheet parameters are quoted.

**Ohmic Resistance****Source ohmic resistance — Source ohmic resistance**

0.0001 Ohm (default) | nonnegative scalar

The transistor source resistance.

**Drain ohmic resistance — Drain ohmic resistance**

0.01 Ohm (default) | nonnegative scalar

The transistor drain resistance.

## Junction Capacitance

### Parameterization — Junction capacitance parameterization

Specify from a datasheet (default) | Specify using equation parameters directly

Select one of the following methods for block parameterization:

- Specify from a datasheet — Provide parameters that the block converts to junction capacitance values. This is the default method.
- Specify using equation parameters directly — Provide junction capacitance parameters directly.

### Input capacitance, Ciss — Input capacitance

4.5 pF (default)

The gate-source capacitance with the drain shorted to the source.

#### Dependencies

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter in the **Junction Capacitance** tab.

### Reverse transfer capacitance, Crss — Reverse transfer capacitance

1.5 pF (default)

The drain-gate capacitance with the source connected to ground.

#### Dependencies

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter in the **Junction Capacitance** tab.

### Gate-source junction capacitance — Gate-source junction capacitance

3 pF (default)

The value of the capacitance placed between the gate and the source.

#### Dependencies

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter in the **Junction Capacitance** tab.

### Gate-drain junction capacitance — Gate-drain junction capacitance

1.5 pF (default)

The value of the capacitance placed between the gate and the drain.

#### Dependencies

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter in the **Junction Capacitance** tab.

## Temperature Dependence

### Parameterization — Temperature dependence parameterization

None — Simulate at parameter measurement temperature (default) | Model temperature dependence

Select one of the following methods for temperature dependence parameterization:

- **None** – Simulate at parameter measurement temperature – Temperature dependence is not modeled. This is the default method.
- **Model temperature dependence** – Model temperature-dependent effects. You also have to provide a set of additional parameters depending on the block parameterization method. If you parameterize the block from a datasheet, you have to provide values for  $I_{gss}$  and  $I_{dss}$  at second measurement temperature. If you parameterize by directly specifying equation parameters, you have to provide the values for  $EG$ ,  $XTI$ , and the gate threshold voltage temperature coefficient,  $dV_{t0}/dT$ . Regardless of the block parameterization method, you also have to provide values for  $BEX$  and for the simulation temperature,  $T_s$ .

**Gate reverse current,  $I_{gss}$ , at second measurement temperature – Gate reverse current at second measurement temperature**

-200 nA (default)

The value of the gate reverse current,  $I_{gss}$ , at the second measurement temperature.

**Dependencies**

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Saturated drain current,  $I_{dss}$ , at second measurement temperature – Saturated drain current at second measurement temperature**

2.5 mA (default)

The value of the saturated drain current,  $I_{dss}$ , at the second measurement temperature, and when the  $I_{dss}$  measurement point is the same as defined by the  **$I_{dss}$  measurement point, [V<sub>gs</sub> V<sub>ds</sub>]** parameter on the **Main** tab.

**Dependencies**

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Second measurement temperature – Second measurement temperature**

125 degC (default)

Second temperature  $T_{m2}$  at which **Gate reverse current,  $I_{gss}$ , at second measurement temperature** and **Saturated drain current,  $I_{dss}$ , at second measurement temperature** are measured.

**Dependencies**

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Energy gap,  $EG$  – Energy gap**

1.11 eV (default)

Energy gap value.

**Dependencies**

This parameter is visible only when you select **Specify** using equation parameters directly for the **Parameterization** parameter on the **Main** tab.

**Saturation current temperature exponent, XTI – Saturation current temperature exponent**

3 (default)

Saturation current temperature coefficient value.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter on the **Main** tab.

**Gate threshold voltage temperature coefficient,  $dV_{t0}/dT$  – Gate threshold voltage temperature coefficient**

-2 mV/K (default)

The rate of change of gate threshold voltage with temperature.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter on the **Main** tab.

**Mobility temperature exponent, BEX – Mobility temperature exponent**

-1.5 (default)

Mobility temperature coefficient value. You can use the default value for most JFETs. See the “Assumptions and Limitations” on page 1-1059 section for additional considerations.

**Device simulation temperature – Device simulation temperature**

25 degC (default)

Temperature  $T_s$  at which the device is simulated.

## N-Channel LDMOS FET

N-Channel laterally diffused metal oxide semiconductor or vertically diffused metal oxide semiconductor transistors suitable for high voltage

**Library:** Simscape / Electrical / Semiconductors & Converters

### Description

The N-Channel LDMOS FET block lets you model LDMOS (or VDMOS) transistors suitable for high voltage. The model is based on surface potential and includes effects due to an extended drain (drift) region:

- Nonlinear capacitive effects associated with the drift region
- Surface scattering and velocity saturation in the drift region
- Velocity saturation and channel-length modulation in the channel region
- Charge conservation inside the model, so you can use the model for charge sensitive simulations
- The intrinsic body diode
- Reverse recovery in the body diode model
- Temperature scaling of physical parameters
- For the option with exposed thermal ports (see “Thermal Port” on page 1-1071), dynamic self-heating

The physical structure of the model is shown in the following figure.

The channel region is in the p+ region, from the heavily n-doped source well to the end of the p+ region. The drift region is a lightly doped drain extension. Further down, there is a p-type epi-layer,

and then the entire structure is on a heavily p-doped substrate. The gate oxide is thin over the entire channel region and over part of the drift region. Further into the drift region, the gate oxide has a greater thickness in the local-oxidation-of-silicon (LOCOS) region.

The next figure shows the equivalent circuit of the model.

The modeling approach is similar to [1]. The overlaps of the gate contact with the source and drain n-wells are modeled as lumped linear capacitances. The channel (p+) region is modeled using the surface-potential-based MOSFET model. The pn-junction between the source/bulk and drain is modeled using an ideal diode, including both junction and diffusion capacitances. The drift region underneath the thin gate oxide is modeled according to a surface-potential formulation, which includes:

- The current due to the accumulation layer at the semiconductor-oxide interface
- The current due to the electrons flowing towards the drain deeper inside the drift region

The space-charge region between the epi-layer and the drift region is represented using a pinching effect on the current flowing through the bulk of the drift region. The LOCOS part of the drift region is modeled as a lumped, series resistor, and there are also series resistances added to the source and gate contacts.

For detailed description of the channel model, see the surface-potential-based model of the N-Channel MOSFET block. The drift region model is similarly derived from the surface potential using the Poisson equation. For an n-type semiconductor under the gradual-channel approximation, the defining equations are:

$$\frac{\partial^2 \psi}{\partial y^2} \approx \frac{qN_D}{\epsilon_{Si}} \left[ -1 - \exp\left(\frac{-\psi - 2\phi_B}{\phi_T}\right) + \exp\left(\frac{\psi - V_{CB}}{\phi_T}\right) \right]$$

$$\phi_T = \frac{k_B T}{q}$$

where:

- $\psi$  is the electrostatic potential.
- $q$  is the magnitude of the electronic charge.

- $N_D$  is the doping density of the drift region.
- $\epsilon_{Si}$  is the dielectric permittivity of the semiconductor material (for example, silicon).
- $\phi_B$  is the difference between the intrinsic Fermi level and the Fermi level deep in the drift region.
- $V_{CB}$  is the quasi-Fermi potential of the drift region referenced to the bulk.
- $\phi_T$  is the thermal voltage.
- $k_B$  is Boltzmann's constant.
- $T$  is temperature.

If we neglect inversion for the DC current model, we obtain the following current expression:

$$I_D = \frac{1}{1 + \theta_{sat} V_{DK}} \left[ \frac{f_{lin}}{R_D} V_{DK} + \frac{\beta}{2} \cdot \frac{V_{GK}^2 - V_{GD}^2}{1 + \frac{\theta_{surf}}{2} (V_{GK} + V_{GD})} \right]$$

where:

- $I_D$  is the drain current.
- $\theta_{sat}$  is the velocity saturation.
- $V_{ij}$  is the voltage difference between nodes  $i$  and  $j$ , where subscripts D and K refer to the drain and to the junction of the channel and drift regions, respectively, and subscript G refers to the gate with a correction due to the flatband voltage being applied.
- $f_{lin}/R_D$  represents the conductance of the bulk of the drift region, including the effect of pinching due to depletion from the epi-drift interface.
- $\beta$  is the gain of the accumulation layer at the interface between the drift region and the thin gate oxide.
- $\theta_{surf}$  is the parameter that accounts for scattering in the accumulation layer due to the vertical electric field.

The pinching off of the bulk part of the drift region is described by

$$f_{lin} = 1 - \lambda_D \frac{\sqrt{V_{bi} + V_{SB}} - \sqrt{V_{bi}}}{\sqrt{V_{bi}}}$$

where:

- $\lambda_D$  is the parameter representing the n-side vertical depth of the space-charge region along the epi-drift interface at zero bias divided by the vertical depth of the undepleted part of the drift region at zero bias.

In the figure, the top solid line is the semiconductor surface. The lower solid line is the junction between the drift region and the epi layer. The dashed lines show the extent of the space-charge region around the drift-epi interface.  $\lambda_D$  is  $y_1/y_2$  at zero bias.

- $V_{bi}$  is the built-in voltage for the epi-drift diode.
- $V_{SB}$  is the source-body voltage, used as an approximation to the bias applied across the epi-drift diode. Using this voltage instead of  $V_{KB}$  is more numerically stable, and is justified because most of the drain-source voltage drops across the drift region in the transistor on-state.

The charge model is similar to that of the surface-potential-based MOSFET model, with additional expressions to account for the charge in the drift region. The block uses the derived equations as described in [1], which include both inversion and accumulation in the drift region.

### Modeling Body Diode

The block models the body diode as an ideal, exponential diode with both junction and diffusion capacitances:

$$I_{dio} = I_s \left[ \exp\left(-\frac{V_{DB}}{n\phi_T}\right) - 1 \right]$$

$$C_j = \frac{C_{j0}}{\sqrt{1 + \frac{V_{DB}}{V_{bi}}}}$$

$$C_{diff} = \frac{\tau I_s}{n\phi_T} \exp\left(-\frac{V_{DB}}{n\phi_T}\right)$$

where:

- $I_{dio}$  is the current through the diode.
- $I_s$  is the reverse saturation current.
- $V_{DB}$  is the drain-body voltage.
- $n$  is the ideality factor.
- $\phi_T$  is the thermal voltage.
- $C_j$  is the junction capacitance of the diode.
- $C_{j0}$  is the zero-bias junction capacitance.
- $V_{bi}$  is the built-in voltage.
- $C_{diff}$  is the diffusion capacitance of the diode.
- $\tau$  is the transit time.

The capacitances are defined through an explicit calculation of charges, which are then differentiated to give the capacitive expressions above. The block computes the capacitive diode currents as time derivatives of the relevant charges, similar to the computation in the surface-potential-based MOSFET model.

### Modeling Temperature Dependence

The default behavior is that dependence on temperature is not modeled, and the device is simulated at the temperature for which you provide block parameters. To model the dependence on

temperature during simulation, select **Model temperature dependence** for the **Parameterization** parameter on the **Temperature Dependence** tab.

The model includes temperature effects on the capacitance characteristics, as well as modeling the dependence of the transistor static behavior on temperature during simulation.

The **Measurement temperature** parameter on the **Main** tab specifies temperature  $T_{m1}$  at which the other device parameters have been extracted. The **Temperature Dependence** parameters provides the simulation temperature,  $T_s$ , and the temperature-scaling coefficients for the other device parameters. For more information, see “Temperature Dependence” on page 1-1075.

## Thermal Port

You can expose the thermal port to model the effects of generated heat and device temperature. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port and does not simulate heat generation in the device.
- **Show thermal port** — The block contains a thermal port that allows you to model the heat that conduction losses generate. For numerical efficiency, the thermal state does not affect the electrical behavior of the block.

For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

The thermal option of this block includes dynamic self-heating. This lets you simulate the effect of self-heating on the electrical characteristics of the device.

## Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Parameters

### Modeling option — Whether to enable thermal port

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of generated heat and device temperature.

### Main

### Gain, [channel drift\_region] — Gain

[11.6, .01] A/V (default) | positive vector

The gain,  $\beta$ , of the MOSFET regions. The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region. This parameter primarily defines the linear region of operation on an  $I_D$ - $V_{DS}$  characteristic.

### Flatband voltage, [channel drift\_region] — Flatband voltage

[-1.05, -.1] V (default)

The flatband voltage,  $V_{FB}$ , defines the gate bias that must be applied in order to achieve the flatband condition at the surface of the silicon. The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region. The default value is [-1.05, -0.1] V. You can also use this parameter to arbitrarily shift the threshold voltage due to material work function differences, and to trapped interface or oxide charges. In practice, however, it is usually recommended to modify the threshold voltage by using the **Body factor** and **Surface potential at strong inversion** parameters first, and only use this parameter for fine-tuning.

The threshold voltage for the channel region, for a short-circuited source-bulk connection, is approximately

$$V_T = V_{FB} + 2\phi_B + 2\phi_T + \gamma\sqrt{2\phi_B + 2\phi_T}$$

where  $2\phi_B$  is the surface potential at strong inversion and  $\gamma$  is the body factor, both at the channel region.

### Body factor, [channel drift\_region] — Body factor

[3.4, 2.5]  $V^{1/2}$  (default)

Body factor,  $\gamma$ , in the surface-potential equation. The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region.

For the channel region, the body factor is

$$\gamma = \frac{\sqrt{2q\epsilon_{Si}N_A}}{C_{ox}}$$

See the N-Channel MOSFET block reference page for details on this equation. The drift region equation is similar, except that  $N_A$  is replaced by the doping density,  $N_D$ . The channel-region parameter value primarily impacts the threshold voltage. For the drift region, this parameter primarily affects the charge model, and also has a minor effect on the pinch-off behavior of the bulk current through the drift region.

**Surface potential at strong inversion, [channel drift\_region] – Surface potential at strong inversion**

[.95, .95] V (default)

The  $2\phi_B$  term in the surface-potential equation. The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region.

The channel-region parameter value also primarily impacts the threshold voltage. For the drift region, this parameter affects the charge model only.

**Velocity saturation factor, [channel drift\_region] – Velocity saturation factor**

[0, .1] 1/V (default)

Velocity saturation,  $\theta_{sat}$ , in the drain-current equation. Use this parameter in cases where a good fit to linear operation leads to a saturation current that is too high. By increasing this parameter value, you reduce the saturation current. The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region. The default value is [0.0, 0.1] 1/V, which means that velocity saturation in the channel region is off by default.

**Drift region surface scattering factor – Drift region surface scattering factor**

0 V (default)

Surface scattering factor,  $\theta_{surf}$ , in the drain-current equation. This parameter applies to the drift region only and accounts for scattering in the accumulation layer due to the vertical electric field.

**Channel-length modulation factor – Channel-length modulation factor**

0 (default)

The factor,  $\alpha$ , multiplying the logarithmic term in the  $G_{AL}$  equation. See the N-Channel MOSFET block reference page for details on this equation. This parameter describes the onset of channel-length modulation. For device characteristics that exhibit a positive conductance in saturation, increase the parameter value to fit this behavior. This parameter applies to the channel region only. The default value is 0, which means that channel-length modulation is off by default.

**Channel-length modulation voltage – Channel-length modulation voltage**

5e-2 V (default)

The voltage  $V_p$  in the  $G_{AL}$  equation. See the N-Channel MOSFET block reference page for details on this equation. This parameter controls the drain-voltage at which channel-length modulation starts to become active. This parameter applies to the channel region only.

**Linear-to-saturation transition coefficient – Linear-to-saturation transition coefficient**

8 (default)

This parameter controls how smoothly the MOSFET transitions from linear into saturation, particularly when velocity saturation is enabled. This parameter can usually be left at its default value, but you can use it to fine-tune the knee of the  $I_D$ - $V_{DS}$  characteristic. This parameter applies both to the channel and drift regions. The expected range for this parameter value is between 2 and 8.

### Measurement temperature — Measurement temperature

25 degC (default)

Temperature  $T_{m1}$  at which the block parameters are measured. If the **Device simulation temperature** parameter on the **Temperature Dependence** tab differs from this value, then device parameters will be scaled from their defined values according to the simulation and reference temperatures. For more information, see “Temperature Dependence” on page 1-1075.

### Ohmic Resistance

#### Source ohmic resistance — Source ohmic resistance

1e-4 Ohm (default) | nonnegative scalar

The transistor source resistance, that is, the series resistance associated with the source contact.

#### Drain ohmic resistance — Drain ohmic resistance

0.07 Ohm (default) | nonnegative scalar

The transistor drain resistance, that is, the series resistance associated with the drain contact and with the LOCOS part of the drift region, which is not heavily impacted by the applied gate voltage.

#### Gate ohmic resistance — Gate ohmic resistance

8.4 Ohm (default) | nonnegative scalar

The transistor gate resistance, that is, the series resistance associated with the gate contact.

#### Drift region low-bias resistance for gated region — Drift region low-bias resistance for gated region

0.1 Ohm (default) | nonnegative scalar

Resistance  $R_D$  in the drain-current equation. It represents the resistance of the bulk part of the drift region in the absence of depletion from the top and bottom interfaces.

#### Drift region depletion layer thickness factor — Drift region depletion layer thickness factor

0.2 (default)

Parameter  $\lambda_D$  in the drain-current equation. It is the ratio of vertical depths  $y_1$  and  $y_2$  at zero bias, where  $y_1$  represents the space-charge region and  $y_2$  represents the undepleted part of the drift region.

### Capacitances

#### Oxide capacitance, [channel drift\_region] — Oxide capacitance

[1600, 1000] pF (default)

The parallel plate gate-channel and gate-drift-region capacitance. The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region.

**Gate-source overlap capacitance — Gate-source overlap capacitance**

15 pF (default)

The fixed, linear capacitance associated with the overlap of the gate electrode with the source well.

**Gate-drain overlap capacitance — Gate-drain overlap capacitance**

15 pF (default)

The fixed, linear capacitance associated with the overlap of the gate electrode with the drain well.

**Body Diode****Reverse saturation current — Reverse saturation current**

1e-13 A (default)

The current designated by the  $I_s$  symbol in the body-diode equations.

**Built-in voltage — Built-in voltage**

0.6 V (default)

The built-in voltage of the diode, designated by the  $V_{bi}$  symbol in the body-diode equations.

**Ideality factor — Ideality factor**

1 (default)

The factor designated by the  $n$  symbol in the body-diode equations.

**Zero-bias junction capacitance — Zero-bias junction capacitance**

1800 pF (default)

The capacitance between the drain and bulk contacts at zero-bias due to the body diode alone. It is designated by the  $C_{j0}$  symbol in the body-diode equations.

**Transit time — Transit time**

50e-9 s (default)

The time designated by the  $\tau$  symbol in the body-diode equations.

**Temperature Dependence****Parameterization — Temperature dependence parameterization**

None — Simulate at parameter measurement temperature (default) | Model temperature dependence

Select one of the following methods for temperature dependence parameterization:

- None — Simulate at parameter measurement temperature — Temperature dependence is not modeled. This is the default method.
- Model temperature dependence — Model temperature-dependent effects. Provide a value for the device simulation temperature,  $T_s$ , and the temperature-scaling coefficients for other block parameters.

**Device simulation temperature — Device simulation temperature**

25 degC (default)

Temperature  $T_s$  at which the device is simulated

### Gain temperature exponent, [channel drift\_region] – Gain temperature exponent [1.3, 1.3] (default)

The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region. Both in the channel and the drift region, the MOSFET gain,  $\beta$ , is assumed to scale exponentially with temperature,  $\beta = \beta_{m1} (T_{m1}/T_s)^{\eta_\beta}$ .  $\beta_{m1}$  is the value of the channel or drift region gain, as specified by the **Gain, [channel drift\_region]** parameter from the **Main** tab.  $\eta_\beta$  is the corresponding element of the **Gain temperature exponent, [channel drift\_region]** parameter.

### Flatband voltage temperature coefficient, [channel drift\_region] – Flatband voltage temperature coefficient [.0005, .0005] V/K (default)

The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region. The flatband voltage,  $V_{FB}$ , is assumed to scale linearly with temperature,  $V_{FB} = V_{FBm1} + (T_s - T_{m1})S_{TV_{FB}}$ .  $V_{FBm1}$  is the value of the channel or drift region flatband voltage, as specified by the **Flatband voltage, [channel drift\_region]** parameter from the **Main** tab.  $S_{TV_{FB}}$  is the corresponding element of the **Flatband voltage temperature coefficient, [channel drift\_region]** parameter.

### Surface potential at strong inversion temperature coefficient – Surface potential -8.5e-4 V/K (default)

The surface potential at strong inversion,  $2\phi_B$ , is assumed to scale linearly with temperature,  $2\phi_B = 2\phi_{Bm1} + (T_s - T_{m1})S_{T\phi_B}$ .  $2\phi_{Bm1}$  is the value of the **Surface potential at strong inversion** parameter from the **Main** tab and  $S_{T\phi_B}$  is the **Surface potential at strong inversion temperature coefficient**.

### Velocity saturation temperature exponent, [channel drift\_region] – Velocity saturation temperature exponent [1.04, 1.04] (default)

The parameter value is a two-element vector, with the first element corresponding to the channel, and the second — to the drift region. The velocity saturation,  $\theta_{sat}$ , is assumed to scale exponentially with temperature,  $\theta_{sat} = \theta_{sat,m1} (T_{m1}/T_s)^{\eta_\theta}$ .  $\theta_{sat,m1}$  is the value of the channel or drift region velocity saturation factor, as specified by the **Velocity saturation factor, [channel drift\_region]** parameter from the **Main** tab.  $\eta_\theta$  is the corresponding element of the **Velocity saturation temperature exponent, [channel drift\_region]** parameter.

### Ohmic resistance temperature exponent – Ohmic resistance temperature exponent 0.95 (default)

The series resistances are assumed to correspond to semiconductor resistances. Therefore, they decrease exponentially with increasing temperature.  $R_i = R_{i,m1} (T/T_s)^{\eta_R}$ , where  $i$  is  $S_{m1}$ ,  $D$ , or  $G$ , for the source, drain, or gate series resistance, respectively.  $R_{i,m1}$  is the value of the corresponding series resistance parameter from the **Ohmic Resistance** tab and  $\eta_R$  is the **Ohmic resistance temperature exponent**.

### Drift region low-bias resistance temperature exponent for gated portion – Drift region low-bias resistance temperature exponent for gated portion 0.95 (default)

Resistance  $R_D$ , the low-bias resistance of the bulk part of the drift region, scales similarly to the other series resistances. A separate value of the temperature exponent for this resistance provides an extra degree of freedom.

### Body diode reverse saturation current temperature exponent – Body diode reverse saturation current temperature exponent

3 (default)

The reverse saturation current for the body diode is assumed to be proportional to the square of the intrinsic carrier concentration,  $n_i = N_C \exp(-E_G/2k_B T)$ .  $N_C$  is the temperature-dependent effective density of states and  $E_G$  is the temperature-dependent bandgap for the semiconductor material. To avoid introducing another temperature-scaling parameter, the block neglects the temperature dependence of the bandgap and uses the bandgap of silicon at 300K (1.12eV) for all device types. Therefore, the temperature-scaled reverse saturation current is given by

$$I_s = I_{s,m1} \left( \frac{T_s}{T_{m1}} \right)^{\eta_{Is}} \cdot \exp \left( \frac{E_G}{k_B} \cdot \left( \frac{1}{T_{m1}} - \frac{1}{T_s} \right) \right).$$

$I_{s,m1}$  is the value of the **Reverse saturation current** parameter from the **Body Diode** tab,  $k_B$  is Boltzmann's constant (8.617x10<sup>-5</sup>eV/K), and  $\eta_{Is}$  is the **Body diode reverse saturation current temperature exponent**. The default value is 3, because  $N_C$  for silicon is roughly proportional to  $T^{3/2}$ . You can remedy the effect of neglecting the temperature-dependence of the bandgap by a pragmatic choice of  $\eta_{Is}$ .

## Description

The N-Channel MOSFET block provides two main modeling options:

- Based on threshold voltage — Uses the Shichman-Hodges equation to represent the device. This modeling approach, based on threshold voltage, has the benefits of simple parameterization and simple current-voltage expressions. However, these models have difficulty in accurately capturing transitions across the threshold voltage and lack some important effects, such as velocity saturation. For details, see “Threshold-Based Model” on page 1-1080.

This modeling option provides four ways of parameterizing an N-Channel MOSFET:

- By specifying parameters from a datasheet.
- By specifying equation parameters directly.
- By a 2-D lookup table approximation to the I-V (current-voltage) curve. For details, see “Representation by 2-D Lookup Table” on page 1-1084.
- By a 3-D lookup table approximation to the I-V (current-voltage) curve that includes temperature data. For details, see “Representation by 3-D Lookup Table” on page 1-1086.
- Based on surface potential — Uses the surface-potential equation to represent the device. This modeling approach provides a greater level of model fidelity than the simple square-law (threshold-voltage-based) models can provide. The trade-off is that there are more parameters that require extraction. For details, see “Surface-Potential-Based Model” on page 1-1086.

Together with the thermal port options (see “Thermal Port” on page 1-1093), the block therefore provides you with four choices. To select the desired option, set the **Modeling option** parameter to either:

- **Threshold-based** — Basic model, which represents the device using the Shichman-Hodges equation (based on threshold voltage) and does not simulate thermal effects. This is the default.
- **Threshold-based with thermal** — Model based on threshold voltage and with exposed thermal port.
- **Surface-potential-based** — Model based on surface potential. This model does not simulate thermal effects.
- **Surface-potential-based with thermal** — Thermal modeling option of the model based on surface potential.

### Threshold-Based Model

The threshold-based option of the block uses the Shichman and Hodges equations [1] for an insulated-gate field-effect transistor to represent an N-Channel MOSFET.

The drain-source current,  $I_{DS}$ , depends on the region of operation:

- In the off region ( $V_{GS} < V_{th}$ ), the drain-source current is:

$$I_{DS} = 0$$

- In the linear region ( $0 < V_{DS} < V_{GS} - V_{th}$ ), the drain-source current is:

$$I_{DS} = K((V_{GS} - V_{th})V_{DS} - V_{DS}^2/2)(1 + \lambda |V_{DS}|)$$

- In the saturated region ( $0 < V_{GS} - V_{th} < V_{DS}$ ), the drain-source current is:

$$I_{DS} = (K/2)(V_{GS} - V_{th})^2(1 + \lambda |V_{DS}|)$$

In the preceding equations:

- $K$  is the transistor gain.
- $V_{DS}$  is the positive drain-source voltage.
- $V_{GS}$  is the gate-source voltage.
- $V_{th}$  is the threshold voltage. For the four terminal parameterization,  $V_{th}$  is obtained using these equations:

$V_{BS}$ Range	$V_{th}$ Equation
$V_{BS} \leq 0$	$V_{th} = V_{T0} + \gamma(-\sqrt{2\phi_B}) + \gamma(\sqrt{2\phi_B - V_{BS}})$
$0 < V_{BS} \leq 4\phi_B$	$V_{th} = V_{T0} - \frac{\gamma V_{BS}}{\sqrt{2\phi_B}}$
$V_{BS} > 4\phi_B$	$V_{th} = V_{T0} + \gamma(-\sqrt{2\phi_B})$

- $\lambda$  is the channel modulation.

### Charge Model for Threshold-Based Modeling Option

The block models capacitances either by fixed capacitance values, or by tabulated values as a function of the drain-source voltage. In either case, you can either directly specify the gate-source and gate-drain capacitance values, or let the block derive them from the input and reverse transfer capacitance values. Therefore, the **Parameterization** options for charge model on the **Capacitance** setting are:

- Specify fixed input, reverse transfer and output capacitance — Provide fixed parameter values from datasheet and let the block convert the input and reverse transfer capacitance values to capacitance values, as described below. This is the default method.
- Specify fixed gate-source, gate-drain and drain-source capacitance — Provide fixed values for capacitance parameters directly.
- Specify tabulated input, reverse transfer and output capacitance — Provide tabulated capacitance and drain-source voltage values based on datasheet plots. The block converts the input and reverse transfer capacitance values to capacitance values, as described below.

- **Specify tabulated gate-source, gate-drain and drain-source capacitance** — Provide tabulated values for capacitances and drain-source voltage.

Use one of the tabulated capacitance options (**Specify tabulated input, reverse transfer and output capacitance** or **Specify tabulated gate-source, gate-drain and drain-source capacitance**) when the datasheet provides a plot of capacitances as a function of drain-source voltage. Using tabulated capacitance values gives more accurate dynamic characteristics and avoids the need for interactive tuning of parameters to fit the dynamics.

If you use the **Specify fixed gate-source, gate-drain and drain-source capacitance** or **Specify tabulated gate-source, gate-drain and drain-source capacitance** option, the **Capacitance** setting lets you specify the **Gate-drain capacitance, Cgd**, **Gate-source capacitance, Cgs**, and **Drain-source capacitance, Cds** parameter values (fixed or tabulated) directly. Otherwise, the block derives them from the **Input capacitance, Ciss**, **Reverse transfer capacitance, Crss**, and **Output capacitance, Coss** parameter values. These two parameterization methods are related as follows:

- $C_{GD} = Crss$
- $C_{GS} = Ciss - Crss$
- $C_{DS} = Coss - Crss$

For the four terminals parameterization, the **Input capacitance, Ciss**, **Reverse transfer capacitance, Crss**, and **Output capacitance, Coss** are obtained using these equations:

- $C_{GD} = Crss$
- $C_{GS} + C_{GB} = Ciss - Crss$
- $C_{DB} = Coss - Crss$

A simplified Meyer's capacitance model is used to describe the gate-source capacitance,  $C_{GS}$ , the gate-bulk capacitance,  $C_{GB}$ , and the gate-drain capacitance,  $C_{GD}$ . These figures show how the gate-bulk and gate-source capacitances change instantaneously, while the

Gate-bulk and gate-source capacitance change instantaneously.

The two fixed capacitance options (Specify fixed input, reverse transfer and output capacitance or Specify fixed gate-source, gate-drain and drain-source capacitance) let you model gate capacitance as a fixed gate-source capacitance  $C_{GS}$  and either a fixed or a nonlinear gate-drain capacitance  $C_{GD}$ . If you select the Gate-drain charge function is nonlinear option for the **Gate-drain charge-voltage linearity** parameter, then the gate-drain charge relationship is defined by the piecewise-linear function shown in the following figure.

**Nonlinear gate-drain charge function**

For instructions on how to map a time response to device capacitance values, see the N-Channel IGBT block reference page. However, this mapping is only approximate because the Miller voltage typically varies more from the threshold voltage than in the case for the IGBT.

**Note** Because this block implementation includes a charge model, you must model the impedance of the circuit driving the gate to obtain representative turn-on and turn-off dynamics. Therefore, if you are simplifying the gate drive circuit by representing it as a controlled voltage source, you must include a suitable series resistor between the voltage source and the gate.

### Representation by 2-D Lookup Table

For the lookup table representation of the detailed block modeling option, you provide tabulated values for drain-source currents as a function of gate-source voltage and drain-source voltage. The main advantage of using this option is simulation speed. It also lets you parameterize the device from either measured data or from data obtained from another simulation environment.

This figure shows the implementation of the 2-D lookup table option when you set **Ids-Vds parameterization** to Provide negative and positive Vds data:

This figure shows the implementation of the 2-D lookup table option when you set **Ids-Vds parameterization** to Provide positive Vds data only:

For the four terminal MOSFET, the surface potential and body factor values are calculated based on the nearest threshold voltage as shown in this picture:

### Representation by 3-D Lookup Table

For the temperature-dependent lookup table representation of the detailed block modeling option, you provide tabulated values for drain-source currents as a function of gate-source voltage, drain-source voltage, and temperature.

### Surface-Potential-Based Model

The surface-potential-based modeling option of the block provides a greater level of model fidelity than the simple square-law (threshold-voltage-based) model. The surface-potential-based block modeling option includes the following effects:

- Fully nonlinear capacitance model (including the nonlinear Miller capacitance)
- Charge conservation inside the model, so you can use the model for charge sensitive simulations
- Velocity saturation and channel-length modulation
- The intrinsic body diode
- Reverse recovery in the body diode model
- Temperature scaling of physical parameters
- For the thermal modeling option, dynamic self-heating (that is, you can simulate the effect of self-heating on the electrical characteristics of the device)

This model is a minimal version of the world-standard PSP model (see <https://briefs.techconnect.org/papers/introduction-to-psp-mosfet-model/>), including only certain effects from the PSP model in order

to strike a balance between model fidelity and complexity. For details of the physical background to the phenomena included in this model, see [2].

The basis of the model is Poisson equation:

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2} = \frac{qN_A}{\epsilon_{Si}} \left[ 1 - \exp\left(\frac{-\psi}{\phi_T}\right) + \exp\left(\frac{\psi - 2\phi_B - V_{CB}}{\phi_T}\right) \right]$$

$$\phi_T = \frac{k_B T}{q}$$

where:

- $\psi$  is the electrostatic potential.
- $q$  is the magnitude of the electronic charge.
- $N_A$  is the density of acceptors in the substrate.
- $\epsilon_{Si}$  is the dielectric permittivity of the semiconductor material (for example, silicon).
- $\phi_B$  is the difference between the intrinsic Fermi level and the Fermi level in the bulk silicon.
- $V_{CB}$  is the quasi-Fermi potential of the surface layer referenced to the bulk.
- $\phi_T$  is the thermal voltage.
- $k_B$  is Boltzmann's constant.
- $T$  is temperature.

Poisson equation is used to derive the surface-potential equation:

$$(V_{GB} - V_{FB} - \psi_s)^2 = \gamma^2 \left[ \psi_s + \phi_T \left( \exp\left(\frac{-\psi_s}{\phi_T}\right) - 1 \right) + \phi_T \exp\left(-\frac{2\phi_B + V_{CB}}{\phi_T}\right) \left( \exp\left(\frac{\psi_s}{\phi_T}\right) - 1 \right) \right]$$

where:

- $V_{GB}$  is the applied gate-body voltage.
- $V_{FB}$  is the flatband voltage.
- $\psi_s$  is the surface potential.
- $\gamma$  is the body factor,

$$\gamma = \frac{\sqrt{2q\epsilon_{Si}N_A}}{C_{ox}}$$

- $C_{ox}$  is the capacitance per unit area.

The block uses an explicit approximation to the surface-potential equation, to avoid the need for numerical solution to this implicit equation.

Once the surface potential is known, the drain current  $I_D$  is given by

$$I_D = \frac{W\mu_0}{LG_{\Delta L}G_{mob}} \sqrt{1 + (\theta_{sat}\Delta\psi)^2} \left[ -\bar{Q}_{inv}\Delta\psi + \phi_T(Q_{invL} - Q_{inv0}) \right]$$

where:

- $W$  is the device width.
- $L$  is the channel length.
- $\mu_0$  is the low-field mobility.
- $\theta_{sat}$  is the velocity saturation.
- $\Delta\psi$  is the difference in the surface potential between the drain and the source.
- $Q_{inv0}$  and  $Q_{invL}$  are the inversion charge densities at the source and drain, respectively.
- $\bar{Q}_{inv}$  is the average inversion charge density across the channel.
- $G_{mob}$  is the mobility reduction factor. For more information, see the **Surface roughness scattering factor** parameter description in the “Main (Surface-Potential-Based Modeling Option)” on page 1-1102 section.
- $G_{\Delta L}$  is the channel-length modulation.

$$G_{\Delta L} = 1 - \frac{\Delta L}{L} = 1 - \alpha \ln \left[ \frac{V_{DB} - V_{DB,eff} + \sqrt{(V_{DB} - V_{DB,eff})^2 + V_p^2}}{V_p} \right]$$

where:

- $\alpha$  is the channel-length modulation factor.
- $V_{DB}$  is the drain-body voltage.
- $V_{DB,eff}$  is the drain-body voltage clipped to a maximum value corresponding to velocity saturation or pinch-off (whichever occurs first).
- $V_p$  is the channel-length modulation voltage.

The block computes the inversion charge densities directly from the surface potential.

The block also computes the nonlinear capacitances from the surface potential. Source and drain charge contributions are assigned via a bias-dependent Ward-Dutton charge-partitioning scheme, as described in [3]. These charges are computed explicitly, so this model is charge-conserving. The capacitive currents are computed by taking the time derivatives of the relevant charges. In practice, the charges within the simulation are normalized to the oxide capacitance and computed in units of volts.

The MOSFET gain,  $\beta$ , is given by

$$\beta = \frac{W\mu_0 C_{ox}}{L}$$

The threshold voltage for a short-circuited source-bulk connection is approximately given by

$$V_T = V_{FB} + 2\phi_B + 2\phi_T + \gamma\sqrt{2\phi_B + 2\phi_T}$$

where:

- $2\phi_B$  is the surface potential at strong inversion.

The overall three and four terminal models consist of an intrinsic MOSFET defined by the surface-potential formulation, a body diode, series resistances, and fixed overlap capacitances, as shown in the schematics.

### Modeling Body Diode

The block models the body diode either as an ideal, exponential diode or as a tabulated diode.

#### Exponential Diode

When you set **Model body diode** to **Exponential**, the junction and diffusion capacitances are:

$$I_{dio} = I_s \left[ \exp\left(-\frac{V_{DB}}{n\phi_T}\right) - 1 \right]$$

$$C_j = \frac{C_{j0}}{\sqrt{1 + \frac{V_{DB}}{V_{bi}}}}$$

$$C_{diff} = \frac{\tau I_s}{n\phi_T} \exp\left(-\frac{V_{DB}}{n\phi_T}\right)$$

where:

- $I_{dio}$  is the current through the diode.
- $I_s$  is the reverse saturation current.
- $V_{DB}$  is the drain-body voltage.
- $n$  is the ideality factor.
- $\phi_T$  is the thermal voltage.
- $C_j$  is the junction capacitance of the diode.
- $C_{j0}$  is the zero-bias junction capacitance.
- $V_{bi}$  is the built-in voltage.
- $C_{diff}$  is the diffusion capacitance of the diode.
- $\tau$  is the transit time.

The capacitances are defined through an explicit calculation of charges, which are then differentiated to give the capacitive expressions above. The block computes the capacitive diode currents as time derivatives of the relevant charges, similar to the computation in the surface-potential-based MOSFET model.

### Tabulated Diode

To model a tabulated diode, set the **Model body diode** parameter to Tabulated I-V curve. This figure shows the implementation of the tabulated diode option:

When choosing this parameterization, you must provide the data for the forward bias only.

The block implements the diode using a smooth interpolation option. If the diode exceeds the provided tabulated data range, the block uses a linear extrapolation technique at the last voltage-current data point.

---

**Note** The tabulated diode does not model the reverse breakdown.

---

### Modeling Temperature Dependence

The default behavior is that dependence on temperature is not modeled, and the device is simulated at the temperature for which you provide block parameters. To model the dependence on temperature during simulation, select **Model temperature dependence** for the **Parameterization** parameter in the **Temperature Dependence** setting.

### Threshold-Based Model

For threshold-based modeling option, you can include modeling the dependence of the transistor static behavior on temperature during simulation. Temperature dependence of the capacitances is not modeled, this being a much smaller effect.

When including temperature dependence, the transistor defining equations remain the same. The gain,  $K$ , and the threshold voltage,  $V_{th}$ , become a function of temperature according to the following equations:

$$K_{T_s} = K_{T_{m1}} \left( \frac{T_s}{T_{m1}} \right)^{BEX}$$

$$V_{th_s} = V_{th1} + \alpha (T_s - T_{m1})$$

where:

- $T_{m1}$  is the temperature at which the transistor parameters are specified, as defined by the **Measurement temperature** parameter value.
- $T_s$  is the simulation temperature.
- $K_{T_{m1}}$  is the transistor gain at the measurement temperature.
- $K_{T_s}$  is the transistor gain at the simulation temperature. This is the transistor gain value used in the MOSFET equations when temperature dependence is modeled.
- $V_{th1}$  is the threshold voltage at the measurement temperature.
- $V_{th_s}$  is the threshold voltage at the simulation temperature. This is the threshold voltage value used in the MOSFET equations when temperature dependence is modeled.
- $BEX$  is the mobility temperature exponent. A typical value of  $BEX$  is -1.5.
- $\alpha$  is the gate threshold voltage temperature coefficient,  $dV_{th}/dT$ .

For the four terminals parameterization,  $V_{th}$  is obtained using these equations:

$V_{BS}$ Range	$V_{th}$ Equation
$V_{BS} \leq 0$	$\frac{dV_{th}}{dT} = \frac{dV_{T0}}{dT} - \frac{\gamma}{2\sqrt{2\phi_B}} \frac{d2\phi_B}{dT} + \frac{\gamma}{2\sqrt{2\phi_B - V_{BS}}} \frac{d2\phi_B}{dT}$
$0 < V_{BS} \leq 4\phi_B$	$\frac{dV_{th}}{dT} = \frac{dV_{T0}}{dT} - \frac{\gamma V_{BS}}{4} (2\phi_B)^{-\frac{3}{2}} \frac{d2\phi_B}{dT}$
$V_{BS} > 4\phi_B$	$\frac{dV_{th}}{dT} = \frac{dV_{T0}}{dT} - \frac{\gamma}{2\sqrt{2\phi_B}} \frac{d2\phi_B}{dT}$

Where:

- $\phi_B = \frac{kT}{q} \ln\left(\frac{N_B}{n_i}\right)$  is the surface potential and  $\frac{d^2\phi_B}{dT} = \frac{1}{T} \left[ 2\phi_B - \left( \frac{E_g(0)}{q} + \frac{3kT}{q} \right) \right]$ .
- $E_g(0)$  is the extrapolated zero degree band-gap, which is equal to 1.16 eV for silicon.
- $V_{BS}$  is the bulk-source voltage.

For most MOSFETS, you can use the default value of -1.5 for  $BEX$ . Some datasheets quote the value for  $\alpha$ , but most typically they provide the temperature dependence for drain-source on resistance,  $R_{DS(on)}$ . Depending on the block parameterization method, you have two ways of specifying  $\alpha$ :

- If you parameterize the block from a datasheet, you have to provide  $R_{DS(on)}$  at a second measurement temperature. The block then calculates the value for  $\alpha$  based on this data.
- If you parameterize by specifying equation parameters, you have to provide the value for  $\alpha$  directly.

If you have more data comprising drain current as a function of gate-source voltage for more than one temperature, then you can also use Simulink Design Optimization software to help tune the values for  $\alpha$  and  $BEX$ .

### Surface-Potential-Based Model

The surface-potential-based model includes temperature effects on the capacitance characteristics, as well as modeling the dependence of the transistor static behavior on temperature during simulation.

The **Measurement temperature** parameter on the **Main** setting specifies temperature  $T_{m1}$  at which the other device parameters have been extracted. The **Temperature Dependence** setting provides the simulation temperature,  $T_s$ , and the temperature-scaling coefficients for the other device parameters. For more information, see “Temperature Dependence (Surface-Potential-Based Modeling Option)” on page 1-1115.

### Faults

The N-Channel MOSFET block models five types of fault:

- `Open circuit` — Failure due to metallization burnout
- `Drain-source short` — Failure due to avalanche breakdown on drain-source channel
- `Drain-bulk short or source-bulk short` — Failure due to avalanche breakdown on drain-bulk or source-bulk channels
- `Gate oxide short` — Failure of the gate oxide dielectric layer
- `Parameter shift` — Failure due to aging

The block can trigger fault events at a specific time or when the current or voltage exceed the limit for longer than a specific time interval.

To enable these trigger mechanisms, set the **Fault trigger** parameter to either `Temporal` or `Behavioral`.

#### Parameter Shift Fault

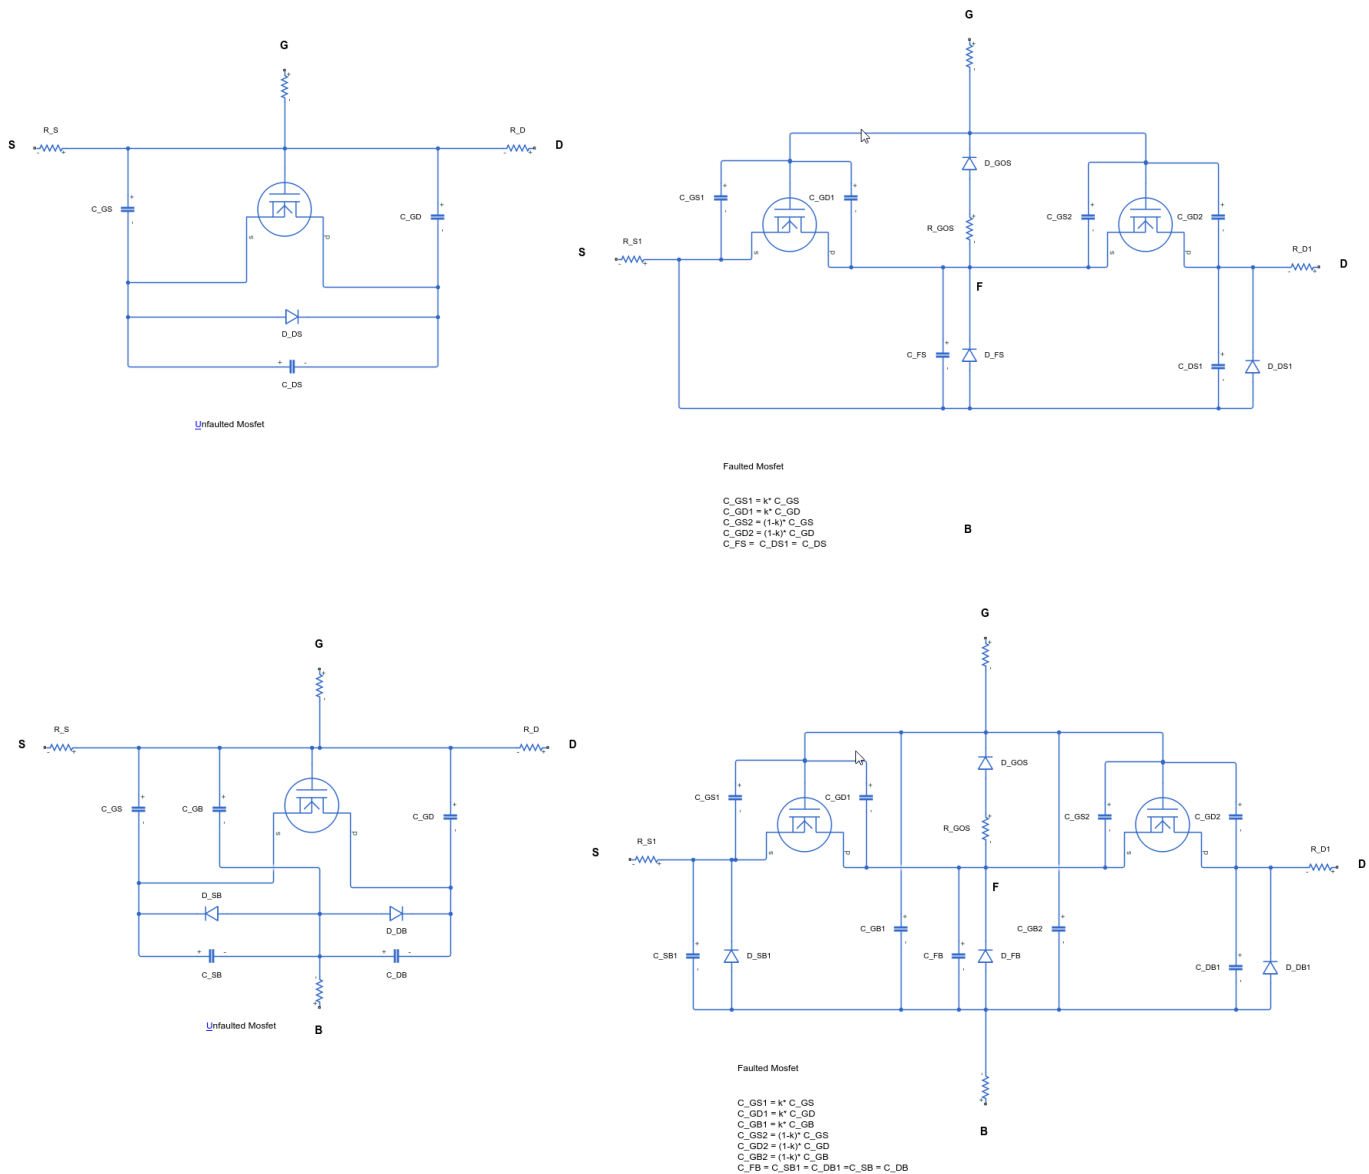

If, in the **Faults** settings, you set the **Failure mode** parameter to `Parameter shift`, the MOSFET fails due to the aging of its components. This equation defines the value of the shifted parameters:

$$Parameter(t) = Parameter_{faulted} - (Parameter_{faulted} - Parameter_{unfaulted}) \operatorname{sech}\left(\frac{t - t_{th}}{\tau}\right),$$

where  $t_{th}$  is the time threshold when the fault is triggered and  $\tau$  is the value of the **Fault transition time constant, tau** parameter.

### Gate Oxide Short Fault

If, in the **Faults** settings, you set the **Failure mode** parameter to Gate oxide short, the gate oxide dielectric layer fails. These figures show the equivalent circuits for the three terminal or four terminal MOSFET in the unfaulted and faulted state:

### Thermal Port

The block has an optional thermal port, hidden by default. To expose the thermal port, set the **Modeling option** parameter to:

- **Threshold-based with thermal** — Model based on threshold voltage and with exposed thermal port
- **Surface-potential-based with thermal** — Model based on surface potential and with exposed thermal port

This action displays the thermal port **H** on the block icon, and exposes the **Thermal Port** parameters.

Use the thermal port to simulate the effects of generated heat and device temperature. For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

This table shows the relationship between the capacitances of the block and the initial targets:

Defined Capacitance	Initial Targets
Gate-emitter capacitance, $C_{ge}$	Set the initial target for the gate-emitter capacitance voltage only. Set the initial target of the collector-emitter capacitance voltage to 0 or set its priority to None.
Collector-emitter capacitance, $C_{ce}$	Set the initial target for the collector-emitter capacitance voltage only. Set the initial target of the gate-emitter capacitance voltage to 0 or set its priority to None.
Gate-collector capacitance, $C_{gc}$	Set the initial targets for the gate-collector voltages by applying constraints on the gate-emitter and collector-emitter voltages. The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and collector-emitter.
Gate-emitter capacitance, $C_{ge}$ , and gate-collector capacitance, $C_{gc}$	Set the initial targets for the gate-emitter and gate-collector voltages by applying constraints on the gate-emitter and collector-emitter voltages. The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and the collector-emitter.
Gate-emitter capacitance, $C_{ge}$ , and collector-emitter capacitance, $C_{ce}$	Set the initial target for the gate-emitter and the collector-emitter capacitance.

Defined Capacitance	Initial Targets

The initial condition of the gate-collector capacitance voltage is equal to the voltage between the gate-emitter and the collector-emitter.

**Note** Inside your model, the number of initial targets with **Priority** equal to Low or High must match the number of differential variables. The differential variables come from the inductors and the capacitances in the model.

## Assumptions and Limitations

When modeling temperature dependence for the threshold-based block modeling option, consider the following:

- The block does not account for temperature-dependent effects on the capacitances.
- When you specify  $R_{DS(on)}$  at a second measurement temperature, it must be quoted for the same working point (that is, the same drain current and gate-source voltage) as for the other  $R_{DS(on)}$  value. Inconsistent values for  $R_{DS(on)}$  at the higher temperature will result in unphysical values for  $\alpha$  and unrepresentative simulation results. Typically  $R_{DS(on)}$  increases by a factor of about 1.5 for a hundred degree increase in temperature.
- You may need to tune the values of  $BEX$  and threshold voltage,  $V_{th}$ , to replicate the  $I_{DS}-V_{GS}$  relationship (if available) for a given device. Increasing  $V_{th}$  moves the  $I_{DS}-V_{GS}$  plots to the right. The value of  $BEX$  affects whether the  $I_{DS}-V_{GS}$  curves for different temperatures cross each other, or not, for the ranges of  $V_{DS}$  and  $V_{GS}$  considered. Therefore, an inappropriate value can result in the different temperature curves appearing to be reordered. Quoting  $R_{DS(on)}$  values for higher currents, preferably close to the current at which it will operate in your circuit, will reduce sensitivity to the precise value of  $BEX$ .

### Conserving

#### G – Gate terminal

electrical

Electrical conserving port associated with the transistor gate terminal

#### D – Drain terminal

electrical

Electrical conserving port associated with the transistor drain terminal

**S – Source terminal**

electrical

Electrical conserving port associated with the transistor source terminal

**B – Body terminal**

electrical

Electrical conserving port associated with the transistor body terminal

**Dependencies**

To enable this port, set **Parameterization** to Four.

**Parameters****Modeling Option – MOSFET representation**

Threshold-based (default) | Threshold-based with thermal | Surface-potential-based | Surface-potential-based with thermal

Select the MOSFET representation:

- **Threshold-based** — Basic model, which represents the device using the Shichman-Hodges equation (based on threshold voltage) and does not simulate thermal effects. This is the default.
- **Threshold-based with thermal** — Model based on threshold voltage and with exposed thermal port.
- **Surface-potential-based** — Model based on surface potential. This model does not simulate thermal effects.
- **Surface-potential-based with thermal** — Thermal modeling option of the model based on surface potential.

**Main (Threshold-Based Modeling Option)**

This configuration of the **Main** parameters corresponds to the threshold-based block modeling option, which is the default. If you are using the surface-potential-based modeling option of the block, see “Main (Surface-Potential-Based Modeling Option)” on page 1-1102.

**Number of terminals – Terminal parameterization**

Three (default) | Four

Number of terminals of the block.

**Parameterization – Block parameterization**

Specify from a datasheet (default) | Specify using equation parameters directly | Lookup table (2-D, temperature independent) | Lookup table (3-D, temperature dependent)

Select one of the following methods for block parameterization:

- **Specify from a datasheet** — Provide the drain-source on resistance and the corresponding drain current and gate-source voltage. The block calculates the transistor gain for the Shichman and Hodges equations from this information.

- Specify using equation parameters directly — Provide the transistor gain.
- Lookup table (2-D, temperature independent) — Use 2-D table lookup for drain-source current as a function of gate-source voltage and drain-source voltage.
- Lookup table (3-D, temperature dependent) — Use 3-D table lookup for drain-source current as a function of gate-source voltage, drain-source voltage, and temperature.

#### **Drain-source on resistance, $R_{DS(on)}$ — Drain-source on resistance**

0.025 Ohm (default)

Ratio of the drain-source voltage to the drain current for specified values of drain current and gate-source voltage.  $R_{DS(on)}$  should have a positive value.

#### **Dependencies**

To enable this parameter, set **Parameterization** to Specify from a datasheet.

#### **Drain current, $I_{DS}$ , for $R_{DS(on)}$ — Drain current**

6A (default)

Drain current the block uses to calculate the value of the drain-source resistance.  $I_{DS}$  should have a positive value.

#### **Dependencies**

To enable this parameter, set **Parameterization** to Specify from a datasheet.

#### **Gate-source voltage, $V_{GS}$ , for $R_{DS(on)}$ — Gate-source voltage, $V_{GS}$**

10 V (default)

Gate-source voltage the block uses to calculate the value of the drain-source resistance.  $V_{GS}$  should have a positive value.

#### **Dependencies**

To enable this parameter, set **Parameterization** to Specify from a datasheet.

#### **Gain, $K$ — Positive constant gain coefficient**

5.0 A/V<sup>2</sup> (default)

Positive constant gain coefficient for the Shichman and Hodges equations.

#### **Dependencies**

To enable this parameter, set **Parameterization** to Specify using equation parameters directly.

#### **Gate-source threshold voltage, $V_{th}$ — Gate-source threshold voltage**

1.7 V (default)

Gate-source threshold voltage  $V_{th}$  in the Shichman and Hodges equations. For an enhancement device,  $V_{th}$  should be positive. For a depletion mode device,  $V_{th}$  should be negative.

#### **Dependencies**

To enable this parameter, set **Number of terminals** to Three and **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.

**Gate-source threshold voltage at zero bulk-source voltage, Vth0 — Gate-source threshold voltage at zero bulk-source voltage**

1.7 V (default)

Gate-source threshold voltage at zero bulk-source voltage  $V_{th0}$  in the Shichman and Hodges equations.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.

**Channel modulation, L — Channel modulation**

0 1/V (default)

The channel-length modulation, usually denoted by the mathematical symbol  $\lambda$ . When in the saturated region, it is the rate of change of drain current with drain-source voltage. The effect on drain current is typically small, and the effect is neglected if calculating transistor gain  $K$  from drain-source on-resistance,  $R_{DS(on)}$ . A typical value is 0.02, but the effect can be ignored in most circuit simulations. However, in some circuits a small nonzero value may help numerical convergence.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.

**Gate-source threshold voltage at first non-zero bulk-source voltage, Vth1 — Gate-source threshold voltage at first non-zero bulk-source voltage**

1.9071 V (default)

Gate-source threshold voltage at first non-zero bulk-source voltage  $V_{th1}$  in the Shichman and Hodges equations.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify from a datasheet.

**First bulk-source voltage, Vbs1 — First bulk-source voltage**

-1 V (default)

First bulk-source voltage,  $V_{bs1}$

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify from a datasheet.

**Gate-source threshold voltage at second non-zero bulk-source voltage, Vth2 — Gate-source threshold voltage at second non-zero bulk-source voltage**

2.066 V (default)

Gate-source threshold voltage at second non-zero bulk-source voltage  $V_{th2}$  in the Shichman and Hodges equations.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify from a datasheet.

**Second bulk-source voltage, V<sub>bs2</sub> — Second bulk-source voltage**

-2 V (default)

Second bulk-source voltage,  $V_{bs2}$

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify from a datasheet.

**Body factor — Body factor**

$0.5 \text{ V}^{0.50000}$  (default)

Body factor,  $\gamma$ .

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify using equation parameters directly.

**Surface potential — Surface potential**

0.5 V (default)

Surface potential.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Specify using equation parameters directly.

**Measurement temperature — Measurement temperature**

25 °C (default)

Temperature  $T_{m1}$  at which **Drain-source on resistance, R<sub>DS(on)</sub>** is measured.

**Dependencies**

To enable this parameter, set **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.

**Vector of gate-source voltages, V<sub>gs</sub> — Vector of gate-source voltages**

[-.5, 2, 3, 4, 5] V (default)

Vector of gate-source voltages.

**Dependencies**

To enable this parameter, set **Parameterization** to either Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).

**Vector of drain-source voltages, V<sub>ds</sub> — Vector of drain-source voltages**

[0, 2, 4, 8, 12, 16, 20] V (default)

Vector of drain-source voltages, to be used for table lookup. The vector values must be strictly increasing.

#### Dependencies

To enable this parameter, set **Parameterization** to either Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).

#### Vector of bulk-source voltages, $V_{bs}$ — Vector of drain-source voltages

[0, -4, -6, -12] V (default)

Vector of bulk-source voltages, to be used for table lookup.

#### Dependencies

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to either Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).

#### Tabulated drain-source currents, $I_{ds}(V_{gs}, V_{ds})$ — Tabulated drain-source currents temperature independent

```
[0, 0, 0, 0, 0, 0, 0; 0, .003, .0038, .0043, .0046, .0048, .0049;

0, .0115, .016, .018, .019, .0195, .02;
0, .0152, .0225, .0265, .028, .0295, .03] A (default)
```

Tabulated values for drain-source currents as a function of gate-source voltage and drain-source voltage, to be used for 2-D table lookup. Each value in the matrix specifies the drain-source current for a specific combination of gate-source voltage and drain-source voltage. The matrix size must match the dimensions defined by the gate-source voltage and drain-source voltage vectors.

#### Dependencies

To enable this parameter, set **Number of terminals** to Three and **Parameterization** to Lookup table (2-D, temperature independent).

#### Vector of temperatures, $T$ — Vector of temperatures

[25 125] degC (default)

Vector of temperatures, to be used for table lookup. The vector values must be strictly increasing. The values can be nonuniformly spaced.

#### Dependencies

To enable this parameter, set **Parameterization** to Lookup table (3-D, temperature dependent).

#### Tabulated drain-source currents, $I_{ds}(V_{gs}, V_{ds}, T)$ — Tabulated drain-source currents temperature dependent

zeros(5, 7, 2) A (default)

Tabulated values for drain-source currents as a function of gate-source voltage, drain-source voltage, and temperature, to be used for 2-D table lookup. Each value in the matrix specifies the drain-source current for a specific combination of gate-source voltage and drain-source voltage. The matrix size must match the dimensions defined by the gate-source voltage, drain-source voltage, and temperature vectors.

**Dependencies**

To enable this parameter, set **Number of terminals** to Three and **Parameterization** to Lookup table (3-D, temperature dependent).

**Tabulated gate-source threshold voltage,  $V_{th}(V_{bs})$  — Vector of gate-source threshold voltage temperature independent**

[.4, 1.2, 1.4, 1.45] V (default)

Tabulated values for gate-source threshold voltage as a function of bulk-source voltage, to be used for 2-D table lookup. The vector values must be strictly increasing.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Lookup table (2-D, temperature independent).

**Tabulated drain-source currents at zero bulk-source voltage,  $I_{ds}(V_{gs}, V_{ds})$  — Tabulated drain-source currents at zero bulk-source voltage, temperature independent**

[0, 0, 0, 0, 0, 0, 0; 0, .003, .0038, .0043, .0046, .0048, .0049;  
0, .0055, .008, .009, .0095, .01, .0101;  
0, .0115, .016, .018, .019, .0195, .02;  
0, .0152, .0225, .0265, .028, .0295, .03] A (default)

Tabulated values for drain-source currents at zero bulk-source voltage, as a function of gate-source voltage and drain-source voltage, to be used for 2-D table lookup. Each value in the matrix specifies the drain-source current for a specific combination of gate-source voltage and drain-source voltage. The matrix size must match the dimensions defined by the gate-source voltage and drain-source voltage vectors.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Lookup table (2-D, temperature independent).

**Tabulated gate-source threshold voltage,  $V_{th}(V_{bs}, T)$  — Vector of gate-source threshold voltage temperature dependent**

[.4, .35; 1.2, 1.15; 1.4, 1.35; 1.45, 1.4] V (default)

Tabulated values for gate-source threshold voltage as a function of bulk-source voltage and temperature, to be used for 3-D table lookup. The vector values must be strictly increasing.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Lookup table (3-D, temperature dependent).

**Tabulated drain-source currents at zero bulk-source voltage,  $I_{ds}(V_{gs}, V_{ds}, T)$  — Tabulated drain-source currents at zero bulk-source voltage, temperature dependent**

zeros(5, 7, 2) A (default)

Tabulated values for drain-source currents at zero bulk-source voltage, as a function of gate-source voltage, drain-source voltage, and temperature, to be used for 3-D table lookup. Each value in the matrix specifies the drain-source current for a specific combination of gate-source voltage, drain-source voltage, and temperature. The matrix size must match the dimensions defined by the gate-source voltage, drain-source voltage, and temperature vectors.

**Dependencies**

To enable this parameter, set **Number of terminals** to Four and **Parameterization** to Lookup table (3-D, temperature dependent).

**Ids-Vds parameterization — Ids-Vds table data as symmetric data**

Provide negative and positive Vds data (default) | Provide positive Vds data only

Whether to provide Ids-Vds table data as symmetric data. If you choose Provide negative and positive Vds data, the data is not symmetric. If you choose Provide positive Vds data only, the block rotates and flips the positive data to obtain the negative data.

**Dependencies**

To enable this parameter, set **Parameterization** to either Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).

**Main (Surface-Potential-Based Modeling Option)**

This configuration of the **Main** setting corresponds to the surface-potential-based block modeling option. If you are using the threshold-based modeling option of the block, based on the Shichman and Hodges equations, see “Main (Threshold-Based Modeling Option)” on page 1-1096.

**Number of terminals — Terminal parameterization**

Three (default) | Four

Number of terminals of the block.

**Gain — MOSFET gain**

18 A/V<sup>2</sup> (default) | positive scalar

MOSFET gain,  $\beta$ . This parameter primarily defines the linear region of operation on an  $I_D$ - $V_{DS}$  characteristic.

**Flatband voltage — Flatband voltage**

-1.1 V (default)

Flatband voltage,  $V_{FB}$ , defines the gate bias that must be applied in order to achieve the flatband condition at the surface of the silicon. The default value is -1.1 V. You can also use this parameter to arbitrarily shift the threshold voltage due to material work function differences, and to trapped interface or oxide charges. In practice, however, it is usually recommended to modify the threshold voltage by using the **Body factor** and **Surface potential at strong inversion** parameters first, and only use this parameter for fine-tuning.

**Body factor — Body factor**

3.5 V<sup>1/2</sup> (default)

Body factor,  $\gamma$ , in the surface-potential equation. This parameter primarily impacts the threshold voltage.

**Surface potential at strong inversion — Surface potential at strong inversion**

1 V (default)

$2\phi_B$  term in the surface-potential equation. This parameter also primarily impacts the threshold voltage.

**Velocity saturation factor – Velocity saturation factor**

0.4 1/V (default)

Velocity saturation,  $\theta_{sat}$ , in the drain-current equation. Use this parameter in cases where a good fit to linear operation leads to a saturation current that is too high. By increasing this parameter value, you reduce the saturation current. For high-voltage devices, it is often the case that a good fit to linear operation leads to a saturation current that is too low. In such a case, either increase both the gain and the drain ohmic resistance or use an N-Channel LDMOS FET block instead.

**Channel-length modulation factor – Channel-length modulation factor**

0 (default)

Factor,  $\alpha$ , multiplying the logarithmic term in the  $G_{\Delta L}$  equation. This parameter describes the onset of channel-length modulation. For device characteristics that exhibit a positive conductance in saturation, increase the parameter value to fit this behavior. The default value is 0, which means that channel-length modulation is off by default.

**Channel-length modulation voltage – Channel-length modulation voltage**

5e-2 V (default)

Voltage  $V_p$  in the  $G_{\Delta L}$  equation. This parameter controls the drain-voltage at which channel-length modulation starts to become active

**Surface roughness scattering factor – Surface roughness scattering factor**

0 1/V (default)

Strength of the mobility reduction. The mobility is  $\mu = \mu_0/G_{mob}$ , where  $\mu_0$  is the low-field mobility without the effect of surface scattering. The mobility reduction factor,  $G_{mob}$ , is given by

$G_{mob} = \sqrt{1 + (\theta_{sr}V_{eff})^4}$ , where  $\theta_{sr}$  is the surface roughness scattering factor and  $V_{eff}$  is a voltage that is indicative of the effective vertical electric field strength in the channel,  $E_{eff}$ . For high vertical electric fields, the mobility is roughly proportional to  $E_{eff}^2$  for electrons.

**Linear-to-saturation transition coefficient – Linear-to-saturation transition coefficient**

8 (default)

Smoothness of the MOSFET transitions from linear into saturation, particularly when velocity saturation is enabled. This parameter can usually be left at its default value, but you can use it to fine-tune the knee of the  $I_D$ - $V_{DS}$  characteristic. The expected range for this parameter value is between 2 and 8.

**Measurement temperature – Measurement temperature**

25 °C (default)

Temperature  $T_{m1}$  at which the block parameters are measured. If the **Device simulation temperature** parameter on the **Temperature Dependence** setting differs from this value, then device parameters will be scaled from their defined values according to the simulation and reference temperatures. For more information, see “Temperature Dependence (Surface-Potential-Based Modeling Option)” on page 1-1115.

## Ohmic Resistance

If you set **Modeling option** to Threshold-based or Threshold-based with thermal, to enable this setting set **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.

### Source ohmic resistance, $R_s$ — Transistor source resistance

0.0001 Ohm (default) | nonnegative scalar

Transistor source resistance, that is, the series resistance associated with the source contact. The default value for threshold-based variants is  $1e-4$  Ohm. The default value for surface-potential-based variants is  $2e-3$  Ohm.

### Drain ohmic resistance, $R_d$ — Transistor drain resistance

0.01 Ohm (default) | nonnegative scalar

Transistor drain resistance, that is, the series resistance associated with the drain contact. The value must be greater than or equal to 0. The default value for threshold-based variants is 0.01 Ohm. The default value for surface-potential-based variants is 0.17 Ohm.

### Gate ohmic resistance, $R_g$ — Transistor gate resistance

8.4 Ohm (default) | nonnegative scalar

Transistor gate resistance, that is, the series resistance associated with the gate contact.

#### Dependencies

To enable this parameter, set **Modeling option** to Surface-potential-based or Surface-potential-based with thermal.

### Body ohmic resistance, $R_b$ — Transistor body resistance

0.001 Ohm (default) | nonnegative scalar

Transistor body resistance, that is, the series resistance associated with the body contact.

#### Dependencies

To enable this parameter, set:

- **Number of terminals** to Four.
- **Modeling option** to Threshold-based or Threshold-based with thermal.

### Bulk ohmic resistance — Transistor bulk resistance

$2e-3$  Ohm (default) | nonnegative scalar

Transistor body resistance, that is, the series resistance associated with the bulk contact.

#### Dependencies

To enable this parameter, set:

- **Number of terminals** to Four.
- **Modeling option** to Surface-potential-based or Surface-potential-based with thermal.

## Capacitance

To enable this setting, set **Modeling option** to Threshold-based or Threshold-based with thermal.

### Parameterization — Capacitance parameterization

Specify fixed input, reverse transfer, and output capacitance (default) | Specify fixed gate-source, gate-drain, and drain-source capacitance | Specify tabulated input, reverse transfer, and output capacitance | Specify tabulated gate-source, gate-drain, and drain-source capacitance

Select one of the following methods for capacitance parameterization:

- **Specify fixed input, reverse transfer, and output capacitance** — Provide fixed parameter values from datasheet and let the block convert the input, output, and reverse transfer capacitance values to capacitance values, as described in “Charge Model for Threshold-Based Modeling Option” on page 1-1080.
- **Specify fixed gate-source, gate-drain, and drain-source capacitance** — Provide fixed values for capacitance parameters directly.
- **Specify tabulated input, reverse transfer, and output capacitance** — Provide tabulated capacitance and drain-source voltage values based on datasheet plots. The block converts the input, output, and reverse transfer capacitance values to capacitance values, as described in “Charge Model for Threshold-Based Modeling Option” on page 1-1080.
- **Specify tabulated gate-source, gate-drain, and drain-source capacitance** — Provide tabulated values for capacitances and drain-source voltage.

### Input capacitance, $C_{iss}$ — Input gate-source capacitance

350 pF (default)

Gate-source capacitance with the drain shorted to the source.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance.

### Input capacitance, $C_{iss}(V_{ds})$ — Input gate-source capacitance with tabulated input

[720 700 590 470 390 310] pF (default)

Gate-source capacitance with the drain shorted to the source, tabulated with drain-source voltage.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

### Reverse transfer capacitance, $C_{rss}$ — Reverse transfer capacitance

80 pF (default)

Drain-gate capacitance with the source connected to ground, also known as the Miller capacitance.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance.

**Reverse transfer capacitance, Crss(Vds) – Reverse transfer capacitance with tabulated inputs**

[450 400 300 190 95 55] pF (default)

Drain-gate capacitance with the source connected to ground, also known as the Miller capacitance, tabulated with drain-source voltage.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

**Output capacitance, Coss – Output capacitance**

0 pF (default)

Drain-source capacitance with the gate and source shorted.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance.

**Output capacitance, Coss(Vds) – Output capacitance with tabulated inputs**

[900 810 690 420 270 170] pF (default)

Drain-source capacitance with the gate and source shorted, tabulated with drain-source voltage.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

**Gate-source capacitance, Cgs – Gate-source capacitance**

270 pF (default)

Capacitance placed between the gate and the source.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed gate-source, gate-drain, and drain-source capacitance.

**Gate-source capacitance, Cgs(Vgs, Vds) – Gate-source capacitance with tabulated values**

[270 300 290 280 295 255] pF (default)

Capacitance placed between the gate and the source, tabulated with gate-source voltage and drain-source voltage.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.

**Gate-drain capacitance, Cgd – Gate-drain capacitance**

80 pF (default)

Capacitance placed between the gate and the drain.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed gate-source, gate-drain, and drain-source capacitance.

**Gate-drain capacitance,  $C_{gd}(V_{gs}, V_{ds})$  — Gate-drain capacitance with tabulated values**  
[450 400 300 190 95 55] pF (default)

Capacitance placed between the gate and the drain, tabulated with gate-source voltage and drain-source voltage.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.

**Gate-bulk capacitance,  $C_{gb}$  — Gate-bulk capacitance**  
0 pF (default)

Capacitance placed between the gate and the bulk.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed gate-source, gate-drain, and drain-source capacitance and **Gate-bulk and gate-source charge-voltage linearity** to Separate gate-bulk and gate-source capacitance.

**Gate-bulk capacitance,  $C_{gb}(V_{gs}, V_{ds})$  — Gate-bulk capacitance with tabulated values**  
[450 400 300 190 95 55] pF (default)

Capacitance placed between the gate and the bulk, tabulated with gate-source voltage and drain-source voltage.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance and **Gate-bulk and gate-source charge-voltage linearity** to Separate gate-bulk and gate-source capacitance.

**Corresponding gate-source voltages,  $V_{gs}$  — Corresponding gate-source voltages**  
0 V (default)

Gate-source voltages corresponding to the tabulated capacitance values.

If this value is a scalar, then **Gate-source capacitance,  $C_{gs}(V_{gs}, V_{ds})$**  and **Gate-drain capacitance,  $C_{gd}(V_{gs}, V_{ds})$**  are vectors of scalars. If this value is a vector, then **Gate-source capacitance,  $C_{gs}(V_{gs}, V_{ds})$**  and **Gate-drain capacitance,  $C_{gd}(V_{gs}, V_{ds})$**  are matrices of scalars.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.

**Drain-source capacitance,  $C_{ds}$  — Drain-source capacitance**  
0 pF (default)

Capacitance placed between the drain and the source.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed gate-source, gate-drain, and drain-source capacitance.

#### Drain-source capacitance, $C_{ds}(v_{ds})$ — Drain-source capacitance with tabulated values [450 410 390 230 175 115] pF (default)

Capacitance placed between the drain and the source, tabulated with the drain-source voltage.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.

#### Corresponding drain-source voltages, $V_{ds}$ — Corresponding drain-source voltages [.1, .3, 1, 3, 10, 30] V (default)

Drain-source voltages corresponding to the tabulated capacitance values.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance or to Specify tabulated gate-source, gate-drain, and drain-source capacitance.

#### Gate-source voltage, $V_{gs}$ , for tabulated capacitances — Gate-source voltage for tabulated capacitances 0 V (default)

For tabulated capacitance models, this parameter controls the voltage dependence of the **Reverse transfer capacitance,  $C_{rss}$**  or the **Gate-drain capacitance,  $C_{gd}$**  parameter (depending on the selected parameterization option). These capacitances are a function of the drain-gate voltage. The block calculates drain-gate voltages by subtracting this gate-source voltage value from the values specified for the **Corresponding drain-source voltages** parameter.

#### Dependencies

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.

#### Gate-drain charge-voltage linearity — Charge-voltage linearity Gate-drain capacitance is constant (default) | Gate-drain charge function is nonlinear

The two fixed capacitance options let you model gate capacitance as a fixed gate-source capacitance  $C_{GS}$  and either a fixed or a nonlinear gate-drain capacitance  $C_{GD}$ . Select whether the gate-drain capacitance is fixed or nonlinear:

- **Gate-drain capacitance is constant** — The capacitance value is constant and defined according to the selected parameterization option, either directly or derived from a datasheet.
- **Gate-drain charge function is nonlinear** — The gate-drain charge relationship is defined according to the piecewise-nonlinear function described in “Charge Model for Threshold-Based Modeling Option” on page 1-1080. Two additional parameters appear to let you define the gate-drain charge function.

**Dependencies**

To enable this parameter, in the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer and output capacitance or to Specify fixed gate-source, gate-drain and drain-source capacitance.

**Gate-drain oxide capacitance — Gate-drain oxide capacitance**

200 pF (default)

Gate-drain capacitance when the drain-gate voltage is less than the **Drain-gate voltage at which oxide capacitance becomes active** parameter value.

**Dependencies**

To enable this parameter, set **Gate-drain charge-voltage linearity** to Gate-drain charge function is nonlinear.

**Drain-gate voltage at which oxide capacitance becomes active — Drain-gate voltage at which oxide capacitance becomes active**

-0.5 V (default)

Drain-gate voltage at which the drain-gate capacitance switches between off-state ( $C_{GD}$ ) and on-state ( $C_{ox}$ ) capacitance values.

**Dependencies**

To enable this parameter, set **Gate-drain charge-voltage linearity** to Gate-drain charge function is nonlinear.

**Gate-bulk and gate-source charge-voltage linearity — Gate-bulk and gate-source charge-voltage linearity**

Gate-bulk and gate-source capacitance change instantly (default) | Gate-bulk and gate-source capacitance change gradually | Separate gate-bulk and gate-source capacitance

Gate-bulk and gate-source charge-voltage linearity.

**Dependencies**

To enable this parameter, in the **Main** setting, set **Number of terminals** to Four.

To enable the Separate gate-bulk and gate-source capacitance option, in the **Capacitance** setting, set **Parameterization** to Specify fixed gate-source, gate-drain, and drain-source capacitance or Specify tabulated gate-source, gate-drain, and drain-source capacitance

**Channel Capacitances**

To enable this setting, set **Modeling option** to Surface-potential-based or Surface-potential-based with thermal.

**Oxide capacitance — Oxide capacitance**

1500 pF (default)

The parallel plate gate-channel capacitance.

**Gate-source overlap capacitance – Gate-source overlap capacitance**

100 pF (default)

The fixed, linear capacitance associated with the overlap of the gate electrode with the source well.

**Gate-drain overlap capacitance – Gate-drain overlap capacitance**

14 pF (default)

The fixed, linear capacitance associated with the overlap of the gate electrode with the drain well.

**Body Diode****Model body diode – Body diode modeling option**

No (default) | Exponential | Tabulated I-V curve

Whether to model the body diode.

**Table type – Tabulated function**Table in  $I_f(T_j, V_f)$  form (default) | Table in  $V_f(T_j, I_f)$  form

Whether to tabulate the current as a function of temperature and voltage or the voltage as a function of temperature and current.

**Dependencies**

To enable this parameter, set **Model body diode** to Tabulated I-V curve.

**Reverse saturation current,  $I_s$  – Reverse saturation current**

0 A (default)

The current designated by the  $I_s$  symbol in the body-diode equations. The default value for threshold-based modeling option is 0 A. The default value for surface-potential-based modeling option is  $5.2e-13$  A.

To enable conduction through the body diode, for applications where the MOSFET current changes sign during the simulation, such as when the MOSFET is driving an inductive load, set this parameter to a non-zero value.

For applications where the MOSFET current never changes sign, such as in a small-signal amplifier, set this parameter to 0 to improve simulation speed.

**Dependencies**

To enable this parameter, set **Model body diode** to Exponential.

**Built-in voltage,  $V_{bi}$  – Built-in voltage**

0.6 V (default)

The built-in voltage of the diode, designated by the  $V_{bi}$  symbol in the body-diode equations. Built-in voltage has an impact only on the junction capacitance equation. It does not affect the conduction current.

**Dependencies**

To enable this parameter, set **Model body diode** to Exponential.

**Ideality factor, n – Ideality factor**

1 (default)

The factor designated by the  $n$  symbol in the body-diode equations.

**Dependencies**

To enable this parameter, set **Model body diode** to Exponential.

**Zero-bias junction capacitance, Cj0 – Zero-bias junction capacitance**

0 pF (default)

The capacitance between the drain and bulk contacts at zero-bias due to the body diode alone. It is designated by the  $C_{j0}$  symbol in the body-diode equations. The default value for threshold-based modeling option is 0 pF. The default value for surface-potential-based modeling option is 480 pF.

**Dependencies**

To enable this parameter, set **Model body diode** to Exponential.

**Transit time, TT – Transit time**

50e-9 s (default)

The time designated by the  $\tau$  symbol in the body-diode equations.

When the **Reverse saturation current** and **Transit time** parameters are both non-zero, this block includes the reverse recovery inside the body diode model.

**Dependencies**

To enable this parameter, set **Model body diode** to Exponential.

**Measurement temperature – Measurement temperature**

25 °C (default)

Temperature at which the block parameters are measured.

**Dependencies**

To enable this parameter, set **Model body diode** to Exponential and, in the **Main** setting, set **Parameterization** to either Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent)

**Diode forward voltages, Vf(If) – Diode forward voltages**

[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85] V (default)

Tabulated values of the minimum voltage that needs to be applied for the diode to become forward-biased.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Specify from a datasheet, Specify from equation parameters directly, or Lookup table (2-D, temperature independent).
- In the **Body diode** setting, set:

- **Model body diode** to Tabulated I-V curve.

**Table type** to Table in Vf(If) form.

#### **Diode forward currents, If — Diode forward currents temperature independent**

[.1, .2, .5, 1, 2, 4, 7, 10] A (default)

Tabulated values of the forward currents.

#### **Dependencies**

To enable this parameter, in the **Body diode** setting, set **Model body diode** to Tabulated I-V curve and **Table type** to Table in Vf(If) form or Table in Vf(Tj,If) form.

#### **Diode forward currents, If(Vf) — Diode forward currents tabulated with forward voltages**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2] A (default)

Tabulated values of the forward current, as a function of the forward voltages.

#### **Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Specify from a datasheet, Specify from equation parameters directly, or Lookup table (2-D, temperature independent).
- In the **Body diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.

**Table type** to Table in If(Vf) form.

#### **Diode forward voltages, Vf — Diode forward voltages temperature independent**

[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Tabulated values of the forward voltages.

#### **Dependencies**

To enable this parameter, in the **Body diode** setting, set **Model body diode** to Tabulated I-V curve and **Table type** to Table in If(Vf) form or Table in If(Tj,Vf) form.

#### **Diode junction temperatures, Tj — Diode junction temperatures**

[25, 125] degC (default)

Vector of junction temperatures.

#### **Dependencies**

To enable this parameter, set **Model body diode** to Tabulated I-V curve and, in the **Main** setting, set **Parameterization** to Lookup table (3-D, temperature dependent).

#### **Diode forward currents, If(Tj,Vf) — Diode forward currents temperature dependent**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12] A (default)

Tabulated values of the forward current, as a function of the forward voltages and junction temperatures.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Lookup table (3-D, temperature dependent).
- In the **Body diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.

**Table type** to Table in  $I_f(T_j, V_f)$  form.

**Diode forward voltages,  $I_f(T_j, V_f)$  – Diode forward voltages temperature dependent**  
 [.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85; .58, .68, .75, 1.1, 1.38, 1.77, 2.27, 2.7] V (default)

Tabulated values of the forward voltage, as a function of the forward currents and junction temperatures.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Lookup table (3-D, temperature dependent).
- In the **Body diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.

**Table type** to Table in  $V_f(T_j, I_f)$  form.

**Temperature Dependence (Threshold-Based Modeling Option)**

This configuration of the **Temperature Dependence** setting corresponds to the threshold-based block modeling option, which is the default. If you are using the surface-potential-based modeling option of the block, see “Temperature Dependence (Surface-Potential-Based Modeling Option)” on page 1-1115

**Parameterization – Temperature dependence parameterization**

None – Simulate at parameter measurement temperature (default) | Model temperature dependence

Select one of the following methods for temperature dependence parameterization:

- None – Simulate at parameter measurement temperature – Temperature dependence is not modeled. This is the default method.
- Model temperature dependence – Model temperature-dependent effects. Provide a value for simulation temperature,  $T_s$ , a value for  $BEX$ , and a value for the measurement temperature  $T_{m1}$  (using the **Measurement temperature** parameter on the **Main** setting). You also have to provide a value for  $\alpha$  using one of two methods, depending on the value of the **Parameterization** parameter on the **Main** setting. If you parameterize the block from a datasheet, you have to provide  $R_{DS(on)}$  at a second measurement temperature, and the block will calculate  $\alpha$  based on that. If you parameterize by specifying equation parameters, you have to provide the value for  $\alpha$  directly.

**Drain-source on resistance, R\_DS(on), at second measurement temperature – Drain-source on resistance at second measurement temperature**

0.037 Ohm (default)

The ratio of the drain-source voltage to the drain current for specified values of drain current and gate-source voltage at second measurement temperature. It must be quoted for the same working point (drain current and gate-source voltage) as the **Drain-source on resistance, R\_DS(on)** parameter on the **Main** setting.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter on the **Main** setting.

**Second measurement temperature – Second temperature**

125 °C (default)

Second temperature  $T_{m2}$  at which **Drain-source on resistance, R\_DS(on), at second measurement temperature** is measured.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter on the **Main** setting.

**Gate threshold voltage temperature coefficient, dVth/dT – Gate-source voltage, Vgs**

-6 mV/K (default)

The rate of change of gate threshold voltage with temperature.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter on the **Main** setting.

**Mobility temperature exponent, BEX – Mobility temperature exponent**

-1.5 (default)

Mobility temperature coefficient value. You can use the default value for most MOSFETs. See the "Assumptions and Limitations" on page 1-1095 section for additional considerations.

**Body diode reverse saturation current temperature exponent – Body diode reverse saturation current temperature exponent**

3 (default)

The reverse saturation current for the body diode is assumed to be proportional to the square of the intrinsic carrier concentration,  $n_i = N_C \exp(-E_G/2k_B T)$ .  $N_C$  is the temperature-dependent effective density of states and  $E_G$  is the temperature-dependent bandgap for the semiconductor material. To avoid introducing another temperature-scaling parameter, the block neglects the temperature dependence of the bandgap and uses the bandgap of silicon at 300K (1.12eV) for all device types. Therefore, the temperature-scaled reverse saturation current is given by

$$I_s = I_{s,m1} \left( \frac{T_s}{T_{m1}} \right)^{\eta_{Is}} \cdot \exp \left( \frac{E_G}{k_B} \cdot \left( \frac{1}{T_{m1}} - \frac{1}{T_s} \right) \right).$$

$I_{s,m1}$  is the value of the **Reverse saturation current** parameter from the **Body Diode** setting,  $k_B$  is Boltzmann's constant ( $8.617 \times 10^{-5} \text{ eV/K}$ ), and  $\eta_{Is}$  is the **Body diode reverse saturation current temperature exponent**. The default value is 3, because  $N_C$  for silicon is roughly proportional to  $T^{3/2}$ . You can remedy the effect of neglecting the temperature-dependence of the bandgap by a pragmatic choice of  $\eta_{Is}$ .

### Device simulation temperature – Device simulation temperature

25 °C (default)

Temperature  $T_s$  at which the device is simulated.

### Temperature Dependence (Surface-Potential-Based Modeling Option)

This configuration of the **Temperature Dependence** setting corresponds to the surface-potential-based block modeling option. If you are using the threshold-based modeling option of the block, see “Temperature Dependence (Threshold-Based Modeling Option)” on page 1-1113

### Parameterization – Temperature dependence parameterization

None – Simulate at parameter measurement temperature (default) | Model temperature dependence

Select one of the following methods for temperature dependence parameterization:

- None – Simulate at parameter measurement temperature – Temperature dependence is not modeled.
- Model temperature dependence – Model temperature-dependent effects. Provide a value for the device simulation temperature,  $T_s$ , and the temperature-scaling coefficients for other block parameters.

### Gain temperature exponent – Gain temperature exponent

1.3 (default)

The MOSFET gain,  $\beta$ , is assumed to scale exponentially with temperature,  $\beta = \beta_{m1} (T_{m1}/T_s)^{\eta_\beta}$ .  $\beta_{m1}$  is the value of the **Gain** parameter from the **Main** setting and  $\eta_\beta$  is the **Gain temperature exponent**.

### Flatband voltage temperature coefficient – Flatband voltage temperature coefficient

$5 \times 10^{-4} \text{ V/K}$  (default)

The flatband voltage,  $V_{FB}$ , is assumed to scale linearly with temperature,  $V_{FB} = V_{FBm1} + (T_s - T_{m1})S_{TV_{FB}}$ .  $V_{FBm1}$  is the value of the **Flatband voltage** parameter from the **Main** setting and  $S_{TV_{FB}}$  is the **Flatband voltage temperature coefficient**.

### Surface potential at strong inversion temperature coefficient – Surface potential at strong inversion temperature coefficient

$-8.5 \times 10^{-4} \text{ V/K}$  (default)

The surface potential at strong inversion,  $2\phi_B$ , is assumed to scale linearly with temperature,  $2\phi_B = 2\phi_{Bm1} + (T_s - T_{m1})S_{T\phi_B}$ .  $2\phi_{Bm1}$  is the value of the **Surface potential at strong inversion** parameter from the **Main** setting and  $S_{T\phi_B}$  is the **Surface potential at strong inversion temperature coefficient**.

### Velocity saturation temperature exponent – Velocity saturation temperature exponent

1.04 (default)

The velocity saturation,  $\theta_{sat}$ , is assumed to scale exponentially with temperature,  $\theta_{sat} = \theta_{sat,m1} (T_{m1}/T_s)^{\eta_\theta}$ .  $\theta_{sat,m1}$  is the value of the **Velocity saturation factor** parameter from the **Main** setting and  $\eta_\theta$  is the **Velocity saturation temperature exponent**.

### Surface roughness scattering temperature exponent – Surface roughness scattering temperature exponent

0.65 (default)

This parameter leads to a temperature-dependent reduction in the MOSFET transconductance at high gate voltage. The surface roughness scattering,  $\theta_{sr}$ , is assumed to scale exponentially with temperature,  $\theta_{sr} = \theta_{sr,m1} (T_{m1}/T_s)^{\eta_{sr}}$ .  $\theta_{sr,m1}$  is the value of the **Surface roughness scattering factor** parameter from the **Main** setting and  $\eta_{sr}$  is the **Surface roughness scattering temperature exponent**.

### Resistance temperature exponent – Resistance temperature exponent

0.95 (default)

The series resistances are assumed to correspond to semiconductor resistances. Therefore, they decrease exponentially with increasing temperature.  $R_i = R_{i,m1} (T_{m1}/T_s)^{\eta_R}$ , where  $i$  is S, D, or G, for the source, drain, or gate series resistance, respectively.  $R_{i,m1}$  is the value of the corresponding series resistance parameter from the **Ohmic Resistance** setting and  $\eta_R$  is the **Resistance temperature exponent**.

### Body diode reverse saturation current temperature exponent – Body diode reverse saturation current temperature exponent

3 (default)

The reverse saturation current for the body diode is assumed to be proportional to the square of the intrinsic carrier concentration,  $n_i = N_C \exp(-E_G/2k_B T)$ .  $N_C$  is the temperature-dependent effective density of states and  $E_G$  is the temperature-dependent bandgap for the semiconductor material. To avoid introducing another temperature-scaling parameter, the block neglects the temperature dependence of the bandgap and uses the bandgap of silicon at 300K (1.12eV) for all device types. Therefore, the temperature-scaled reverse saturation current is given by

$$I_s = I_{s,m1} \left( \frac{T_s}{T_{m1}} \right)^{\eta_{Is}} \cdot \exp \left( \frac{E_G}{k_B} \cdot \left( \frac{1}{T_{m1}} - \frac{1}{T_s} \right) \right).$$

$I_{s,m1}$  is the value of the **Reverse saturation current** parameter from the **Body Diode** setting,  $k_B$  is Boltzmann's constant (8.617x10<sup>-5</sup>eV/K), and  $\eta_{Is}$  is the **Body diode reverse saturation current temperature exponent**. The default value is 3, because  $N_C$  for silicon is roughly proportional to  $T^{3/2}$ . You can remedy the effect of neglecting the temperature-dependence of the bandgap by a pragmatic choice of  $\eta_{Is}$ .

### Device simulation temperature – Device simulation temperature

25 °C (default)

Temperature  $T_s$  at which the device is simulate.

### Faults

#### Enable faults – Faults modeling option

Off (default) | On

Whether to enable faults in MOSFET.

**Fault trigger – Fault trigger option**

Temporal (default) | Behavioral

Whether to trigger faults on temporal or behavioral conditions. Set this parameter to:

- **Temporal** — Trigger fault at a specific time.
- **Behavioral** — Trigger fault when a current limit or a voltage limit are exceeded for longer than a specific time interval.

**Simulation time for fault event – Time before entering faulted state**

inf s (default)

Simulation time at which you want the block to enter the faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Fault trigger** to Temporal.

**Maximum permissible gate-source voltage – Gate-source voltage threshold to fault transition**

inf V (default) | positive scalar

Maximum permissible gate-source voltage value, above which a fault might be triggered.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Fault trigger** to Behavioral.

**Maximum permissible drain-source voltage – Drain-source voltage threshold to fault transition**

inf V (default) | positive scalar

Maximum permissible drain-source voltage value, above which a fault might be triggered.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Fault trigger** to Behavioral.

**Maximum permissible drain-bulk voltage – Drain-bulk voltage threshold to fault transition**

inf V (default) | positive scalar

Maximum permissible drain-bulk voltage value, above which a fault might be triggered.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- **Enable faults** to On.
- **Fault trigger** to Behavioral.

**Maximum permissible drain-source current – Current threshold to fault transition**

inf A (default) | positive scalar

Maximum permissible drain-source current value. If the current exceeds this value for longer than the value of the **Time to fail when exceeding drain-source current** parameter, then the block enters the faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Fault trigger** to Behavioral.

**Time to fail when exceeding drain-source current — Time to fail when exceeding drain-source current**

1 s (default) | positive scalar

Amount of time that the drain-source current must continuously exceed the maximum permissible drain-source current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Fault trigger** to Behavioral.

**Maximum permissible body diode current — Body diode current threshold to fault transition**

inf A (default) | positive scalar

Maximum permissible body diode current value. If the current exceeds this value for longer than the value of the **Time to fail when exceeding body diode current** parameter, then the block enters the faulted state.

**Dependencies**

To enable this parameter, set **Model body diode** to either Exponential or Tabulated I-V curve, **Enable faults** to On, and **Fault trigger** to Behavioral.

**Time to fail when exceeding body diode current — Time to fail when exceeding body diode current**

1 s (default) | positive scalar

Amount of time that the body diode current must continuously exceed the maximum permissible body diode current before a behavioral fault is triggered.

**Dependencies**

To enable this parameter, set **Model body diode** to either Exponential or Tabulated I-V curve, **Enable faults** to On, and **Fault trigger** to Behavioral.

**Maximum diode recovery, dV/dt — Maximum diode recovery**

inf V/s (default) | positive scalar

Maximum amount of diode recovery per second.

**Dependencies**

To enable this parameter, set **Model body diode** to either Exponential or Tabulated I-V curve, **Enable faults** to On, and **Fault trigger** to Behavioral.

**Maximum permissible temperature — Temperature threshold to fault transition**

inf K (default) | positive scalar

Maximum permissible temperature value. If the temperature exceeds this value for longer than the value of the **Time to fail when exceeding temperature** parameter, then the block enters the faulted state.

#### Dependencies

To enable this parameter, set **Modeling option** to Threshold-based with thermal, **Enable faults** to On, and **Fault trigger** to Behavioral.

#### Time to fail when exceeding temperature — Time to fail when exceeding temperature

1 s (default) | positive scalar

Amount of time that the temperature must continuously exceed the maximum permissible temperature before a behavioral fault is triggered.

#### Dependencies

To enable this parameter, set **Modeling option** to Threshold-based with thermal, **Enable faults** to On, and **Fault trigger** to Behavioral.

#### Fault transition time constant, tau — Fault transition time constant

1e-3 s (default)

Time constant for transitioning to faulted state.

#### Dependencies

To enable this parameter, set **Enable faults** to On.

#### Failure mode — Failure category

Open circuit (default) | Drain-source short | Drain-bulk short or source-bulk short | Gate oxide short | Parameter shift

Type of failure. You can set this parameter to:

- Open circuit — Failure due to metallization burnout.
- Drain-source short — Failure due to avalanche breakout on drain-source channel.
- Drain-bulk short or source-bulk short — Failure due to avalanche breakout on drain-bulk or source-bulk channels.
- Gate oxide short — Failure of the gate oxide dielectric layer.
- Parameter shift — Failure due to aging.

#### Dependencies

To enable this parameter, set **Enable faults** to On.

To enable the Drain-source short option, in the **Main** setting, set **Number of terminals** to Three.

To enable the Drain-bulk short or source-bulk short option, in the **Main** setting, set **Number of terminals** to Four.

#### Faulted series gate resistance, Rg — Faulted series gate resistance

1e6 Ohm (default)

Series gate resistance in faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Failure mode** to Open circuit.

**Faulted series drain resistance, Rd — Faulted series drain resistance**

1000 Ohm (default)

Series drain resistance in faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Failure mode** to Open circuit.

**Faulted series source resistance, Rs — Faulted series source resistance**

1000 Ohm (default)

Series source resistance in faulted state.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Failure mode** to Open circuit.

**Faulted series bulk resistance, Rb — Faulted series source resistance**

1000 Ohm (default)

Series source resistance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- **Enable faults** to On.
- **Failure mode** to Open circuit.

**Faulted parallel drain-source conductance, Gds — Faulted parallel drain-source conductance**

1000 1/Ohm (default)

Parallel drain-source conductance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Three.
- **Enable faults** to On.
- **Failure mode** to Drain-source short.

**Faulted parallel drain-bulk conductance, Gdb — Faulted parallel drain-bulk conductance**

1000 1/Ohm (default)

Parallel drain-bulk conductance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- **Enable faults** to On.
- **Failure mode** to Drain-bulk short or source-bulk short.

**Faulted parallel source-bulk conductance, Gsb — Faulted parallel source-bulk conductance**

1000 1/Ohm (default)

Parallel source-bulk conductance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- **Enable faults** to On.
- **Failure mode** to Drain-bulk short or source-bulk short.

**Location of fault node (percentage of total channel length from source) — Fault node location**

0 (default)

Location of the fault node, as a percentage of the total channel length from the source.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Failure mode** to Gate oxide short.

**Gate oxide short conductance, G — Gate oxide short conductance**

1000 1/Ohm (default)

Gate oxide short conductance.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Failure mode** to Gate oxide short.

**Model gate oxide short diode — Model option for gate oxide short diode**

No (default) | Yes

Whether to model the gate oxide short diode.

**Dependencies**

To enable this parameter, set **Enable faults** to On and **Failure mode** to Gate oxide short.

**Gate oxide short diode reverse saturation current, Is — Reverse saturation current of gate oxide short diode**

0 A (default)

Reverse saturation current of the gate oxide short diode.

**Dependencies**

To enable this parameter, set:

- **Enable faults** to On.
- **Failure mode** to Gate oxide short.
- **Model gate oxide short diode** to Yes.

**Gate oxide short diode built-in voltage,  $V_{bi}$  — Built-in voltage of gate oxide short diode**

0.6 V (default)

Built-in voltage of the gate oxide short diode.

**Dependencies**

To enable this parameter, set:

- **Enable faults** to On.
- **Failure mode** to Gate oxide short.
- **Model gate oxide short diode** to Yes.

**Gate oxide short diode ideality factor,  $n$  — Ideality factor of gate oxide short diode**

1 (default)

Ideality factor of the gate oxide short diode.

**Dependencies**

To enable this parameter, set:

- **Enable faults** to On.
- **Failure mode** to Gate oxide short.
- **Model gate oxide short diode** to Yes.

**Gate oxide short diode zero-bias junction capacitance,  $C_{j0}$  — Zero-bias junction capacitance of gate oxide short diode**

0 pF (default)

Zero-bias junction capacitance of the gate oxide short diode.

**Dependencies**

To enable this parameter, set:

- **Enable faults** to On.
- **Failure mode** to Gate oxide short.
- **Model gate oxide short diode** to Yes.

**Gate oxide short diode transit time,  $T_T$  — Transit time of gate oxide short diode**

50e-9 s (default)

Transit time of the gate oxide short diode.

**Dependencies**

To enable this parameter, set:

- **Enable faults** to On.
- **Failure mode** to Gate oxide short.
- **Model gate oxide short diode** to Yes.

**Shifted gain as percentage of unshifted — Shifted gain as percentage of unshifted**  
100 (default)

Shifted gain as percentage of unshifted.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Threshold voltage shift value,  $dV_{th}$  — Threshold voltage shift value**  
0 V (default)

Shift value of Threshold voltage.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted channel modulation,  $L$  — Faulted channel modulation**  
0 1/V (default)

Channel modulation in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Shifted body factor as percentage of unshifted — Shifted body factor as percentage of unshifted**  
100 (default)

Shifted body factor as percentage of unshifted.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Surface potential shift value, dPhib — Surface potential shift value**

0 V (default)

Shift value of surface potential.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted source ohmic resistance, Rs — Faulted source ohmic resistance**

0.0001 Ohm (default)

Transistor source resistance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted drain ohmic resistance, Rd — Faulted drain ohmic resistance**

0.01 Ohm (default)

Transistor drain resistance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted body ohmic resistance, Rb — Faulted body ohmic resistance**

0.001 Ohm (default)

Transistor body resistance in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Specify from a datasheet or Specify using equation parameters directly.
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted vector of gate-source voltages, Vgs — Faulted vector of gate-source voltages**

[-.5, 2, 3, 4, 5] V (default)

Gate-source voltages in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted vector of drain-source voltages, Vds — Faulted vector of drain-source voltages**

[0, 2, 4, 8, 12, 16, 20] V (default)

Drain-source voltages in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Parameterization** to Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted vector of bulk-source voltages, Vbs — Faulted vector of bulk-source voltages**

[0, -4, -6, -12] V (default)

Bulk-source voltages in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Lookup table (2-D, temperature independent) or Lookup table (3-D, temperature dependent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted tabulated gate-source threshold voltage,  $V_{th}(V_{bs})$  – Faulted tabulated gate-source threshold voltage**

[.4, 1.2, 1.4, 1.45] V (default)

Tabulated gate-source threshold voltage in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Lookup table (2-D, temperature independent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted tabulated gate-source threshold voltage,  $V_{th}(V_{bs}, T)$  – Faulted tabulated gate-source threshold voltage dependent on temperature**

[.4, .35; 1.2, 1.15; 1.4, 1.35; 1.45, 1.4] V (default)

Gate-source threshold voltage in faulted state, tabulated on bulk-source voltage and temperature.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Lookup table (3-D, temperature independent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted tabulated drain-source currents,  $I_{ds}(V_{gs}, V_{ds})$  – Faulted tabulated drain-source currents**

[0, 0, 0, 0, 0, 0, 0; 0, .003, .0038, .0043, .0046, .0048, .0049;  
0, .0055, .008, .009, .0095, .01, .0101;  
0, .0115, .016, .018, .019, .0195, .02;  
0, .0152, .0225, .0265, .028, .0295, .03] A (default)

Tabulated drain-source currents in faulted state.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Three.

- In the **Main** setting, **Parameterization** to Lookup table (2-D, temperature independent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted tabulated drain-source currents,  $I_{ds}(V_{gs}, V_{ds}, T)$  — Faulted tabulated drain-source currents, dependent on temperature**

zeros(5, 7, 2) A (default)

Drain-source currents in faulted state, tabulated on gate-source voltage, drain-source voltage, and temperature.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Three.
- In the **Main** setting, **Parameterization** to Lookup table (3-D, temperature independent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted tabulated drain-source currents at zero bulk-source voltage,  $I_{ds}(V_{gs}, V_{ds})$  — Faulted tabulated drain-source currents at zero bulk-source voltage**

[0, 0, 0, 0, 0, 0, 0; 0, .003, .0038, .0043, .0046, .0048, .0049;

0, .0152, .0225, .0265, .028, .0295, .03] A (default)

Tabulated drain-source currents in faulted state, when the bulk-source voltage is zero.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Lookup table (2-D, temperature independent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted tabulated drain-source currents at zero bulk-source voltage,  $I_{ds}(V_{gs}, V_{ds}, T)$  — Faulted tabulated drain-source currents at zero bulk-source voltage, dependent on temperature**

zeros(5, 7, 2) A (default)

Tabulated drain-source currents in faulted state, when the bulk-source voltage is zero, tabulated on gate-source voltage, drain-source voltage, and temperature.

**Dependencies**

To enable this parameter, set:

- In the **Main** setting, **Number of terminals** to Four.
- In the **Main** setting, **Parameterization** to Lookup table (3-D, temperature independent).
- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted gate-source capacitance as percentage of unfaulted — Faulted gate-source capacitance as percentage of unfaulted**

100 (default)

Gate-source capacitance in faulted state as percentage of unfaulted.

**Dependencies**

To enable this parameter, meet one of these sets of conditions:

**Condition Set One**

- In the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance or Specify fixed gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set **Enable faults** to On.

**Condition Set Two**

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance or Specify tabulated gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Open circuit, Drain-source short, Drain-bulk short or source-bulk short, or Gate oxide short.

**Faulted gate-drain capacitance as percentage of unfaulted — Faulted gate-drain capacitance as percentage of unfaulted**

100 (default)

Gate-drain capacitance in faulted state as percentage of unfaulted.

**Dependencies**

To enable this parameter, meet one of these sets of conditions:

**Condition Set One**

- In the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance or Specify fixed gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set **Enable faults** to On.

**Condition Set Two**

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance or Specify tabulated gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to 0n.
  - **Failure mode** to Open circuit, Drain-source short, Drain-bulk short or source-bulk short, or Gate oxide short.

**Faulted gate-bulk capacitance as percentage of unfaulted — Faulted gate-bulk capacitance as percentage of unfaulted**

100 (default)

Gate-bulk capacitance in faulted state as percentage of unfaulted.

**Dependencies**

To enable this parameter, meet one of these sets of conditions:

**Condition Set One**

- In the **Main** setting, **Number of terminals** to Four.
- In the **Capacitance** setting, set:
  - **Parameterization** to Specify fixed gate-source, gate-drain, and drain-source capacitance.
  - **Gate-bulk and gate-source charge-voltage linearity** to Separate gate-bulk and gate-source capacitance.
- In the **Faults** setting, set **Enable faults** to 0n.

**Condition Set Two**

- In the **Main** setting, **Number of terminals** to Four.
- In the **Capacitance** setting, set:
  - **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.
  - **Gate-bulk and gate-source charge-voltage linearity** to Separate gate-bulk and gate-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to 0n.
  - **Failure mode** to Open circuit, Drain-bulk short or source-bulk short, or Gate oxide short.

**Faulted drain-source capacitance as percentage of unfaulted — Faulted drain-source capacitance as percentage of unfaulted**

100 (default)

Drain-source capacitance in faulted state as percentage of unfaulted.

**Dependencies**

To enable this parameter, meet one of these sets of conditions:

**Condition Set One**

- In the **Capacitance** setting, set **Parameterization** to Specify fixed input, reverse transfer, and output capacitance or Specify fixed gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set **Enable faults** to On.

**Condition Set Two**

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance or Specify tabulated gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Open circuit, Drain-source short, Drain-bulk short or source-bulk short, or Gate oxide short.

**Faulted gate-drain oxide capacitance as percentage of unfaulted — Faulted gate-drain oxide capacitance as percentage of unfaulted**

100 (default)

Gate-drain oxide capacitance in faulted state as percentage of unfaulted.

**Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set:
  - **Parameterization** to Specify fixed input, reverse transfer, and output capacitance or Specify fixed gate-source, gate-drain, and drain-source capacitance.
  - **Gate-drain charge-voltage linearity** to Gate-drain charge function is non linear.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted drain-gate voltage at which oxide capacitance becomes active — Faulted drain-gate voltage at which oxide capacitance becomes active**

-0.5 V (default)

Drain-gate voltage in faulted state at which oxide capacitance becomes active.

**Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set:

- **Parameterization** to Specify fixed input, reverse transfer, and output capacitance or Specify fixed gate-source, gate-drain, and drain-source capacitance.
- **Gate-drain charge-voltage linearity** to Gate-drain charge function is non linear.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

#### **Faulted input capacitance, $C_{iss}(V_{ds})$ – Faulted input capacitance**

[720, 700, 590, 470, 390, 310] pF (default)

Input capacitance in faulted state.

##### **Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

#### **Faulted reverse transfer capacitance, $C_{rss}(V_{ds})$ – Faulted reverse transfer capacitance**

[450, 400, 300, 190, 95, 55] pF (default)

Reverse transfer capacitance in faulted state.

##### **Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

#### **Faulted output capacitance, $C_{oss}(V_{ds})$ – Faulted output capacitance**

[900, 810, 690, 420, 270, 170] pF (default)

Output capacitance in faulted state.

##### **Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.
- In the **Faults** setting, set:

- **Enable faults** to On.
- **Failure mode** to Parameter shift.

**Faulted corresponding drain-source voltages, Vds — Faulted corresponding drain-source voltages**

[.1, .3, 1, 3, 10, 30] V (default)

Corresponding drain-source voltages in faulted state.

**Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance or Specify tabulated gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted gate-source voltages, Vgs, for tabulated capacitances — Faulted gate-source voltages for tabulated capacitances**

0 V (default)

Gate-source voltages for tabulated capacitances, in faulted state.

**Dependencies**

To enable this parameter, meet one of these sets of conditions:

**Condition Set One**

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated input, reverse transfer, and output capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Condition Set Two**

- In the **Main** setting, **Number of terminals** to Four.
- In the **Capacitance** setting, set:
  - **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.
  - **Gate-bulk and gate-source charge-voltage linearity** to Gate-bulk and gate-source capacitance change instantly or Gate-bulk and gate-source capacitance change gradually.
- In the **Faults** setting, set:
  - **Enable faults** to On.

- **Failure mode** to Parameter shift.

**Faulted gate-source capacitance,  $C_{gs}(V_{gs}, V_{ds})$  — Faulted gate-source capacitance**  
[270, 300, 290, 280, 295, 255] pF (default)

Gate-source capacitance in faulted state, tabulated with gate-source voltage and drain-source voltage.

**Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted gate-drain capacitance,  $C_{gd}(V_{gs}, V_{ds})$  — Faulted gate-source capacitance**  
[450, 400, 300, 190, 95, 55] pF (default)

Gate-drain capacitance in faulted state, tabulated with gate-source voltage and drain-source voltage.

**Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted gate-bulk capacitance,  $C_{gb}(V_{gs}, V_{ds})$  — Faulted gate-source capacitance**  
[270, 300, 290, 280, 295, 255] pF (default)

Gate-bulk capacitance in faulted state, tabulated with gate-source voltage and drain-source voltage.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Number of terminals** to Four.
- In the **Capacitance** setting, set:
  - **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.
  - **Gate-bulk and gate-source charge-voltage linearity** to Separate gate-bulk and gate-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.

- **Failure mode** to Parameter shift.

**Faulted corresponding gate-source voltages,  $V_{gs}$  — Faulted corresponding gate-source voltages**

0 V (default)

Corresponding gate-source voltages in faulted state.

**Dependencies**

To enable this parameter,

- In the **Capacitance** setting, set:
  - **Parameterization** to Specify tabulated gate-source, gate-drain, and drain-source capacitance.
  - **Gate-bulk and gate-source charge-voltage linearity** to Separate gate-bulk and gate-source capacitance.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode reverse saturation current,  $I_s$  — Faulted diode reverse saturation current**

0 A (default)

Reverse saturation current of the diode in faulted state.

**Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set **Model body diode** to Exponential.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode built-in voltage,  $V_{bi}$  — Faulted diode built-in voltage**

0.6 V (default)

Built-in voltage of the diode in faulted state.

**Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set **Model body diode** to Exponential.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode ideality factor, n – Faulted diode ideality factor**

1 (default)

Ideality factor of the diode in faulted state.

**Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set **Model body diode** to Exponential.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode zero-bias junction capacitance as percentage of unfaulted – Faulted diode zero-bias junction capacitance as percentage of unfaulted**

100 (default)

Faulted diode zero-bias junction capacitance as percentage of unfaulted.

**Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set **Model body diode** to Exponential.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode transit time, TT – Faulted diode transit time**

50e-9 s (default)

Transit time of the diode in faulted state.

**Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set **Model body diode** to Exponential.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode forward currents, If(Vf) – Faulted diode forward currents**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2] A (default)

Forward currents of the diode in faulted state, tabulated with the forward voltages.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Specify from a datasheet, Specify using equation parameters directly, or Lookup table (2-D, temperature independent).
- In the **Body Diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.
  - **Table type** to Table in  $I_f(V_f)$  form.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode forward voltages,  $V_f$  — Faulted diode forward voltages**  
[.5, .7, .9, 1.3, 1.7, 2.1, 2.5] V (default)

Forward voltages of the diode in faulted state.

#### **Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.
  - **Table type** to Table in  $I_f(V_f)$  form or Table in  $I_f(T_j, V_f)$  form
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode forward voltages,  $V_f(I_f)$  — Faulted diode forward voltages**  
[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85] V (default)

Forward voltages of the diode in faulted state, tabulated with the forward currents.

#### **Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Specify from a datasheet, Specify using equation parameters directly, or Lookup table (2-D, temperature independent).
- In the **Body Diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.
  - **Table type** to Table in  $V_f(I_f)$  form.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode forward currents,  $I_f$  — Faulted diode forward currents**  
[.1, .2, .5, 1, 2, 4, 7, 10] A (default)

Forward currents of the diode in faulted state.

**Dependencies**

To enable this parameter,

- In the **Body Diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.
  - **Table type** to Table in  $V_f(I_f)$  form and Table in  $V_f(T_j, I_f)$  form.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode forward currents,  $I_f(T_j, V_f)$  – Faulted diode forward currents with tabulated inputs**

[.07, .12, .19, 1.75, 4.24, 7.32, 11.2; .16, .3, .72, 2.14, 4.02, 6.35, 9.12] A (default)

Forward currents of the diode in faulted state, tabulated with the forward voltages and junction temperatures.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Lookup table (3-D, temperature dependent).
- In the **Body Diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.
  - **Table type** to Table in  $I_f(T_j, V_f)$  form.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

**Faulted diode forward voltages,  $V_f(T_j, I_f)$  – Faulted diode forward voltages with tabulated inputs**

[.9, 1.15, 1.25, 1.5, 1.75, 2.17, 2.6, 2.85; .58, .68, .75, 1.1, 1.38, 1.77, 2.27, 2.7] V (default)

Forward voltages of the diode in faulted state, tabulated with the forward currents and junction temperatures.

**Dependencies**

To enable this parameter,

- In the **Main** setting, set **Parameterization** to Lookup table (3-D, temperature dependent).
- In the **Body Diode** setting, set:
  - **Model body diode** to Tabulated I-V curve.

- **Table type** to Table in Vf(Tj,If) form.
- In the **Faults** setting, set:
  - **Enable faults** to On.
  - **Failure mode** to Parameter shift.

# Negative Supply Rail

Ideal negative supply rail

**Library:** Simscape / Electrical / Sources

## Description

The Negative Supply Rail block represents an ideal negative supply rail. Use this block instead of the SimscapeDC Voltage Source block to define the output voltage relative to the SimscapeElectrical Reference block that must appear in each model.

---

**Note** Do not attach more than one Negative Supply Rail block to any connected line.

---

## Ports

### Conserving

- — **Negative voltage**

electrical

Electrical conserving port associated to the negative supply rail negative voltage.

## Parameters

**Constant voltage — Constant output voltage**

-1 V (default)

The voltage at the output port relative to the Electrical Reference block ground port.

## Neutral Port (Three-Phase)

Connect phases of three-phase system to electrical conserving port

**Library:** Simscape / Electrical / Connectors & References

### Description

The Neutral Port (Three-Phase) block connects the phases of a three-phase system to an electrical conserving port.

---

**Note** If you do not need to connect the neutral port to other blocks, use a Floating Neutral (Three-Phase) block instead. If you want to ground the neutral port, use a Grounded Neutral (Three-Phase) block.

### Ports

#### Conserving

**~ — Three-phase port**

electrical

Expandable composite (**a,b, c**) three-phase port.

**n — Neutral point**

electrical

Electrical conserving port associated with the neutral point

### Parameters

**Modeling option — Whether to model composite or expanded three-phase ports**

Composite three-phase ports (default) | Expanded three-phase ports

Whether to model composite or expanded three-phase ports.

Composite three-phase ports represent three individual electrical conserving ports with a single block port. You can use composite three-phase ports to build models that correspond to single-line diagrams of three-phase electrical systems.

Expanded three-phase ports represent the individual phases of a three-phase system using three separate electrical conserving ports.

**Parasitic ground conductance — Parasitic ground conductance**

1e-12 1/0hm (default)

Parasitic conductance to ground. A nonzero value is required for the simulation of some circuit topologies.

# Nonlinear Inductor

Inductor with nonideal core

**Library:** Simscape / Electrical / Passive

## Description

The Nonlinear Inductor block represents an inductor with a nonideal core. A core may be nonideal due to its magnetic properties and dimensions. The block provides the following parameterization options:

- Single inductance (linear) on page 1-1142
- Single saturation point on page 1-1142
- Magnetic flux versus current characteristic on page 1-1143
- Magnetic flux density versus magnetic field strength characteristic on page 1-1143
- Magnetic flux density versus magnetic field strength characteristic with hysteresis on page 1-1144

### Single Inductance (Linear)

The relationships between voltage, current and flux are defined by the following equations:

$$i = i_L + vG_p$$

$$v = N_w \frac{d\Phi}{dt}$$

$$\Phi = \frac{L}{N_w} i_L$$

where:

- $v$  is the terminal voltage.
- $i$  is the terminal current.
- $i_L$  is the current through inductor.
- $G_p$  is the parasitic parallel conductance.
- $N_w$  is the number of winding turns.
- $\Phi$  is the magnetic flux.
- $L$  is the unsaturated inductance.

### Single Saturation Point

The relationships between voltage, current and flux are defined by the following equations:

$$i = i_L + vG_p$$

$$v = N_w \frac{d\Phi}{dt}$$

$$\Phi = \frac{L}{N_w} i_L \text{ (for unsaturated)}$$

$$\Phi = \frac{L_{sat}}{N_w} i_L \pm \Phi_{offset} \text{ (for saturated)}$$

where:

- $v$  is the terminal voltage.
- $i$  is the terminal current.
- $i_L$  is the current through inductor.
- $G_p$  is the parasitic parallel conductance.
- $N_w$  is the number of winding turns.
- $\Phi$  is the magnetic flux.
- $\Phi_{offset}$  is the magnetic flux saturation offset.
- $L$  is the unsaturated inductance.
- $L_{sat}$  is the saturated inductance.

### Magnetic Flux Versus Current Characteristic

The relationships between voltage, current and flux are defined by the following equations:

$$i = i_L + vG_p$$

$$v = N_w \frac{d\Phi}{dt}$$

$$\Phi = f(i_L)$$

where:

- $v$  is the terminal voltage.
- $i$  is the terminal current.
- $i_L$  is the current through inductor.
- $G_p$  is the parasitic parallel conductance.
- $N_w$  is the number of winding turns.
- $\Phi$  is the magnetic flux.

Magnetic flux is determined by one-dimensional table lookup, based on the vector of current values and the vector of corresponding magnetic flux values that you provide. You can construct these vectors using either negative and positive data, or positive data only. If using positive data only, the vector must start at 0, and the negative data will be automatically calculated by rotation about (0,0).

### Magnetic Flux Density Versus Magnetic Field Strength Characteristic

The relationships between voltage, current and flux are defined by the following equations:

$$i = i_L + vG_p$$

$$v = N_w \frac{d\Phi}{dt}$$

$$\Phi = B \cdot A_e$$

$$B = f(H)$$

$$H = \frac{N_w}{l_e} i_L$$

where:

- $v$  is the terminal voltage.
- $i$  is the terminal current.
- $i_L$  is the current through inductor.
- $G_p$  is the parasitic parallel conductance.
- $N_w$  is the number of winding turns.
- $\Phi$  is the magnetic flux.
- $B$  is the magnetic flux density.
- $H$  is the magnetic field strength.
- $l_e$  is the effective core length.
- $A_e$  is the effective core cross-sectional area.

Magnetic flux density is determined by one-dimensional table lookup, based on the vector of magnetic field strength values and the vector of corresponding magnetic flux density values that you provide. You can construct these vectors using either negative and positive data, or positive data only. If using positive data only, the vector must start at 0, and the negative data will be automatically calculated by rotation about (0,0).

### **Magnetic Flux Density Versus Magnetic Field Strength Characteristic with Hysteresis**

The relationships between voltage, current and flux are defined by the following equations:

$$i = i_L + vG_p$$

$$v = N_w \frac{d\Phi}{dt}$$

$$\Phi = B \cdot A_e$$

$$B = \mu_0(H + M)$$

$$H = \frac{N_w}{l_e} i_L$$

where:

- $v$  is the terminal voltage.
- $i$  is the terminal current.
- $i_L$  is the current through inductor.

- $G_p$  is the parasitic parallel conductance.
- $N_w$  is the number of winding turns.
- $\Phi$  is the magnetic flux.
- $B$  is the magnetic flux density.
- $\mu_0$  is the magnetic constant, permeability of free space.
- $H$  is the magnetic field strength.
- $M$  is the magnetization of the inductor core.
- $l_e$  is the effective core length.
- $A_e$  is the effective core cross-sectional area.

The magnetization acts to increase the magnetic flux density, and its value depends on both the current value and the history of the field strength  $H$ . The Jiles-Atherton [1 on page 1-1152, 2 on page 1-1152] equations are used to determine  $M$  at any given time. The figure below shows a typical plot of the resulting relationship between  $B$  and  $H$ .

In this case the magnetization starts as zero, and hence the plot starts at  $B = H = 0$ . As the field strength increases, the plot tends to the positive-going hysteresis curve; then on reversal the rate of change of  $H$ , it follows the negative-going hysteresis curve. The difference between positive-going and negative-going curves is due to the dependence of  $M$  on the trajectory history. Physically the behavior corresponds to magnetic dipoles in the core aligning as the field strength increases, but not then fully recovering to their original position as field strength decreases.

The starting point for the Jiles-Atherton equation is to split the magnetization effect into two parts, one that is purely a function of effective field strength ( $H_{eff}$ ) and the other an irreversible part that depends on past history:

$$M = cM_{an} + (1 - c)M_{irr}$$

The  $M_{an}$  term is called the anhysteretic magnetization because it exhibits no hysteresis. It is described by the following function of the current value of the effective field strength,  $H_{eff}$ :

$$M_{an} = M_s \left( \coth\left(\frac{H_{eff}}{a}\right) - \frac{a}{H_{eff}} \right)$$

This function defines a saturation curve with limiting values  $\pm M_s$  and point of saturation determined by the value of  $a$ , the anhysteretic shape factor. It can be approximately thought of as describing the average of the two hysteretic curves. In the Nonlinear Inductor block, you provide values for  $dM_{an}/dH_{eff}$  when  $H_{eff} = 0$  and a point  $[H_1, B_1]$  on the anhysteretic B-H curve, and these are used to determine values for  $a$  and  $M_s$ .

The parameter  $c$  is the coefficient for reversible magnetization, and dictates how much of the behavior is defined by  $M_{an}$  and how much by the irreversible term  $M_{irr}$ . The Jiles-Atherton model defines the irreversible term by a partial derivative with respect to field strength:

$$\frac{dM_{irr}}{dH} = \frac{M_{an} - M_{irr}}{K\delta - \alpha(M_{an} - M_{irr})}$$

$$\delta = \begin{cases} 1 & \text{if } H \geq 0 \\ -1 & \text{if } H < 0 \end{cases}$$

Comparison of this equation with a standard first order differential equation reveals that as increments in field strength,  $H$ , are made, the irreversible term  $M_{irr}$  attempts to track the reversible term  $M_{an}$ , but with a variable tracking gain of  $1/(K\delta - \alpha(M_{an} - M_{irr}))$ . The tracking error acts to create the hysteresis at the points where  $\delta$  changes sign. The main parameter that shapes the irreversible characteristic is  $K$ , which is called the bulk coupling coefficient. The parameter  $\alpha$  is called the inter-domain coupling factor, and is also used to define the effective field strength used when defining the anhysteretic curve:

$$H_{eff} = H + \alpha M$$

The value of  $\alpha$  affects the shape of the hysteresis curve, larger values acting to increase the B-axis intercepts. However, notice that for stability the term  $K\delta - \alpha(M_{an} - M_{irr})$  must be positive for  $\delta > 0$  and negative for  $\delta < 0$ . Therefore not all values of  $\alpha$  are permissible, a typical maximum value being of the order  $1e-3$ .

### Procedure for Finding Approximate Values for Jiles-Atherton Equation Coefficients

You can determine representative parameters for the equation coefficients by using the following procedure:

- 1 Provide a value for the **Anhysteretic B-H gradient when H is zero** parameter ( $dM_{an}/dH_{eff}$  when  $H_{eff} = 0$ ) plus a data point  $[H_1, B_1]$  on the anhysteretic B-H curve. From these values, the block initialization determines values for  $a$  and  $M_s$ .
- 2 Set the **Coefficient for reversible magnetization, c** parameter to achieve correct initial B-H gradient when starting a simulation from  $[H \ B] = [0 \ 0]$ . The value of  $c$  is approximately the ratio of this initial gradient to the **Anhysteretic B-H gradient when H is zero**. The value of  $c$  must be greater than 0 and less than 1.
- 3 Set the **Bulk coupling coefficient, K** parameter to the approximate magnitude of  $H$  when  $B = 0$  on the positive-going hysteresis curve.
- 4 Start with  $\alpha$  very small, and gradually increase to tune the value of  $B$  when crossing  $H = 0$  line. A typical value is in the range of  $1e-4$  to  $1e-3$ . Values that are too large will cause the gradient of the B-H curve to tend to infinity, which is nonphysical and generates a run-time assertion error.

Sometimes you need to iterate on these four steps to get a good match against a predefined B-H curve.

Electrical conserving port associated with the inductor negative voltage.

## Parameters

### Main

#### Parameterized by – Block parameterization

Single saturation point (default) | Single inductance (linear) | Magnetic flux versus current characteristic | Magnetic flux density versus magnetic field strength characteristic | Magnetic flux density versus magnetic field strength characteristic with hysteresis

Select one of the following methods for block parameterization:

- **Single inductance (linear)** — Provide the values for number of turns, unsaturated inductance, and parasitic parallel conductance.
- **Single saturation point** — Provide the values for number of turns, unsaturated and saturated inductances, saturation magnetic flux, and parasitic parallel conductance. This is the default option.
- **Magnetic flux versus current characteristic** — In addition to the number of turns and the parasitic parallel conductance value, provide the current vector and the magnetic flux vector, to populate the magnetic flux versus current lookup table.
- **Magnetic flux density versus magnetic field strength characteristic** — In addition to the number of turns and the parasitic parallel conductance value, provide the values for effective core length and cross-sectional area, as well as the magnetic field strength vector and the magnetic flux density vector, to populate the magnetic flux density versus magnetic field strength lookup table.
- **Magnetic flux density versus magnetic field strength characteristic with hysteresis** — In addition to the number of turns and the effective core length and cross-sectional area, provide the values for the initial anhysteretic B-H curve gradient, the magnetic flux density and field strength at a certain point on the B-H curve, as well as the coefficient for the reversible magnetization, bulk coupling coefficient, and inter-domain coupling factor, to define magnetic flux density as a function of both the current value and the history of the field strength.

#### Number of turns – Total number of turns

10 (default)

The total number of turns of wire wound around the inductor core.

#### Unsaturated inductance – Unsaturated inductance

2e-4 H (default)

The value of inductance used when the inductor is operating in its linear region.

**Dependencies**

This parameter is visible only when you select `Single inductance (linear)` or `Single saturation point` for the **Parameterized by** parameter.

**Saturated inductance – Saturated inductance**

1e-4 H (default)

The value of inductance used when the inductor is operating beyond its saturation point.

**Dependencies**

This parameter is visible only when you select `Single saturation point` for the **Parameterized by** parameter.

**Saturation magnetic flux – Saturation magnetic flux**

1.3e-05 Wb (default)

The value of magnetic flux at which the inductor saturates.

**Dependencies**

This parameter is visible only when you select `Single saturation point` for the **Parameterized by** parameter.

**Current vector, i – Current data vector**

[0, .64, 1.28, 1.92, 2.56, 3.2] A (default)

The current data used to populate the magnetic flux versus current lookup table.

**Dependencies**

This parameter is visible only when you select `Magnetic flux versus current characteristic` for the **Parameterized by** parameter.

**Magnetic flux vector, phi – Magnetic flux data**

[0, 1.29, 2, 2.27, 2.36, 2.39] .\* 1e-5 Wb (default)

The magnetic flux data used to populate the magnetic flux versus current lookup table.

**Dependencies**

This parameter is visible only when you select `Magnetic flux versus current characteristic` for the **Parameterized by** parameter.

**Magnetic field strength vector, H – Magnetic field strength vector**

[0, 200, 400, 600, 800, 1000] A/m (default)

The magnetic field strength data used to populate the magnetic flux density versus magnetic field strength lookup table.

**Dependencies**

This parameter is visible only when you select `Magnetic flux density versus magnetic field strength characteristic` for the **Parameterized by** parameter.

**Magnetic flux density vector, B – Magnetic flux density data**

[0, .81, 1.25, 1.42, 1.48, 1.49] T (default)

The magnetic flux density data used to populate the magnetic flux density versus magnetic field strength lookup table.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic for the **Parameterized by** parameter.

**Effective length – Effective core length**

0.032 m (default)

The effective core length, that is, the average distance of the magnetic path.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic or Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Effective cross-sectional area – Effective cross-sectional area**1.6e-5 m<sup>2</sup> (default)

The effective core cross-sectional area, that is, the average area of the magnetic path.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic or Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Anhyseretic B-H gradient when H is zero – Anhyseretic B-H gradient around zero field strength**

0.005 m\*T/A (default)

The gradient of the anhyseretic (no hysteresis) B-H curve around zero field strength. Set it to the average gradient of the positive-going and negative-going hysteresis curves.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Flux density point on anhyseretic B-H curve – Flux density point on anhyseretic B-H curve**

1.49 T (default)

Specify a point on the anhyseretic curve by providing its flux density value. Picking a point at high field strength where the positive-going and negative-going hysteresis curves align is the most accurate option.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Corresponding field strength — Corresponding field strength**

1000 A/m (default)

The corresponding field strength for the point that you define by the **Flux density point on anhysteretic B-H curve** parameter.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Coefficient for reversible magnetization, c — Coefficient for reversible magnetization**

0.1 (default)

The proportion of the magnetization that is reversible. The value should be greater than zero and less than one.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Bulk coupling coefficient, K — Bulk coupling coefficient**

200 A/m (default)

The Jiles-Atherton parameter that primarily controls the field strength magnitude at which the B-H curve crosses the zero flux density line.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Inter-domain coupling factor, alpha — Inter-domain coupling factor**

1e-4 (default)

The Jiles-Atherton parameter that primarily affects the points at which the B-H curves intersect the zero field strength line. Typical values are in the range of 1e-4 to 1e-3.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Averaging period for power logging — Averaging period for power logging**

0 s (default)

Averaging period for the hysteresis losses calculation. These losses are proportional to the area enclosed by the B-H trajectory. If the block is excited at a known, fixed frequency, you can set this value to the corresponding excitation period to calculate the hysteresis loss. In this case, the block logs the hysteresis loss once per AC cycle to the variable `power_dissipated`. If you are using a fixed-step solver, this value must be an integer multiple of the simulation step size.

If the block is not excited at a known, fixed frequency, set this parameter to 0. In this case, the block sets `power_dissipated` to zero, and you can calculate the actual hysteresis loss by post-processing the logged variable `power_instantaneous`.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter on the **Main** tab.

**Parasitic parallel conductance — Parasitic parallel conductance**

1e-9 1/Ohm (default)

Use this parameter to represent small parasitic effects. A small parallel conductance may be required for the simulation of some circuit topologies.

**Interpolation option — Interpolation option**

Linear (default) | Smooth

The lookup table interpolation option. Select one of the following interpolation methods:

- **Linear** — Select this option to get the best performance.
- **Smooth** — Select this option to produce a continuous curve with continuous first-order derivatives.

For more information on interpolation algorithms, see the PS Lookup Table (1D) block reference page.

**Dependencies**

This parameter is visible only when you select Magnetic flux versus current characteristic or Magnetic flux density versus magnetic field strength characteristic for the **Parameterized by** parameter on the **Main** tab.

**Initial Conditions****Specify initial state by — Initial state specification option**

Current (default) | Magnetic flux

Select the appropriate initial state specification option:

- **Current** — Specify the initial state of the inductor by the initial current through the inductor ( $i_L$ ). This is the default option.
- **Magnetic flux** — Specify the initial state of the inductor by the magnetic flux.

**Dependencies**

This parameter is not visible when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter.

**Initial current — Initial current**

0 A (default)

The initial current value used to calculate the value of magnetic flux at time zero. This is the current passing through the inductor. Component current consists of current passing through the inductor and current passing through the parasitic parallel conductance.

**Dependencies**

This parameter is visible only when you select Current for the **Specify initial state by** parameter.

**Initial magnetic flux — Initial magnetic flux**

0 Wb (default)

The value of magnetic flux at time zero.

**Dependencies**

This parameter is visible only when you select Magnetic flux for the **Specify initial state by** parameter.

**Initial magnetic flux density — Initial magnetic flux density**

0 T (default)

The value of magnetic flux density at time zero.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter on the **Main** tab.

**Initial field strength — Initial field strength**

0 A/m (default)

The value of magnetic field strength at time zero.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Parameterized by** parameter on the **Main** tab.

## Description

The Nonlinear Reluctance block models linear or nonlinear reluctance with magnetic hysteresis. Use this block to build custom inductances and transformers that exhibit magnetic hysteresis.

The length and area parameters in the **Geometry** settings let you define the geometry for the part of the magnetic circuit that you are modeling. The block uses the geometry information to map the magnetic domain Through and Across variables to flux density and field strength.

## Equations for Linear Reluctance Parameterization

The equations for the linear reluctance parameterization are:

$$B = \mu_0 \mu_r H$$

$$mmf = l_{eff} H$$

$$\varphi = s_{eff} B$$

where:

- $B$  is the flux density.
- $\mu_0$  is the permeability in a vacuum.
- $\mu_r$  is the relative magnetic permeability.
- $H$  is the field strength.
- $mmf$  is the magnetomotive force (mmf) across the component.
- $l_{eff}$  is the effective length of the section being modeled.
- $\varphi$  is magnetic flux.
- $s_{eff}$  is the effective cross-sectional area of the section being modeled.

## Equations for Reluctance with Single Saturation Point Parameterization

This parameterization models a switch-linear reluctance. In the unsaturated state, the material has a specified relative magnetic permeability. In the saturated state, the relative permeability is  $\infty$ .

The equations for reluctance with single saturation point are

$$mmf = l_{eff} H$$

$$\varphi = s_{eff} B$$

$$mmf = R\phi$$

If  $B < B_{sat}$ .

$$B = \mu_0\mu_{r\_unsat}H$$

Otherwise,

$$B = B_{sat} + \mu_0\left(H - \frac{B_{sat}}{\mu_0\mu_{r\_unsat}}\right)$$

where:

- $mmf$  is the magnetomotive force (mmf) across the component.
- $l_{eff}$  is the effective length of the section being modeled.
- $H$  is the field strength.
- $\phi$  is magnetic flux.
- $s_{eff}$  is the effective cross-sectional area of the section being modeled.
- $B$  is the flux density.
- $B_{sat}$  is the flux density at saturation.
- $R_{sat}$  is the magnetic reluctance at saturation.
- $\mu_0$  is the permeability in a vacuum.
- $\mu_r$  is the relative magnetic permeability.
- $\mu_{r\_unsat}$  is the unstaured relative magnetic permeability.

### Reluctance (B-H Curve)

For the reluctance (B-H Curve) parameterization, specify the material property by B-H curve.

### Equations for Reluctance with Hysteresis Parameterization

The flux density and magnetomotive force equations are:

$$B = \phi/s_{eff}$$

$$mmf = l_{eff} \cdot H$$

where:

- $B$  is flux density.
- $\phi$  is magnetic flux.
- $s_{eff}$  is the effective cross-sectional area of the section being modeled.
- $mmf$  is magnetomotive force (mmf) across the component.
- $l_{eff}$  is the effective length of the section being modeled.
- $H$  is field strength.

The block then implements the relationship between  $B$  and  $H$  according to the Jiles-Atherton [1 on page 1-1160, 2 on page 1-1160] equations. The equation that relates  $B$  and  $H$  to the magnetization of the core is:

$$B = \mu_0(H + M)$$

where:

- $\mu_0$  is the magnetic permeability constant.
- $M$  is magnetization of the core.

The magnetization acts to increase the magnetic flux density, and its value depends on both the current value and the history of the field strength  $H$ . The block uses the Jiles-Atherton equations to determine  $M$  at any given time.

The figure below shows a typical plot of the resulting relationship between  $B$  and  $H$ .

In this case, the magnetization starts as zero, and hence the plot starts at  $B = H = 0$ . As the field strength increases, the plot tends to the positive-going hysteresis curve; then on reversal the rate of change of  $H$ , it follows the negative-going hysteresis curve. The difference between positive-going and negative-going curves is due to the dependence of  $M$  on the trajectory history. Physically the behavior corresponds to magnetic dipoles in the core aligning as the field strength increases, but not then fully recovering to their original position as field strength decreases.

The starting point for the Jiles-Atherton equation is to split the magnetization effect into two parts, one that is purely a function of effective field strength ( $H_{eff}$ ) and the other an irreversible part that depends on history:

$$M = cM_{an} + (1 - c)M_{irr}$$

The  $M_{an}$  term is called the anhysteretic magnetization because it exhibits no hysteresis. It is described by the following function of the current value of the effective field strength,  $H_{eff}$ :

$$M_{an} = M_s \left( \coth\left(\frac{H_{eff}}{a}\right) - \frac{a}{H_{eff}} \right)$$

This function defines a saturation curve with limiting values  $\pm M_s$  and point of saturation determined by the value of  $a$ , the anhysteretic shape factor. It can be approximately thought of as describing the average of the two hysteretic curves. In the block interface, you provide values for  $dM_{an}/dH_{eff}$  when

$H_{eff} = 0$  and a point  $[H_1, B_1]$  on the anhysteretic B-H curve, and these are used to determine values for  $\alpha$  and  $M_s$ .

The parameter  $c$  is the coefficient for reversible magnetization, and dictates how much of the behavior is defined by  $M_{an}$  and how much by the irreversible term  $M_{irr}$ . The Jiles-Atherton model defines the irreversible term by a partial derivative with respect to field strength:

$$\frac{dM_{irr}}{dH} = \frac{M_{an} - M_{irr}}{K\delta - \alpha(M_{an} - M_{irr})}$$

For  $H \geq 0$ ,  $\delta = 1$ .

For  $H < 0$ ,  $\delta = -1$ .

Comparison of this equation with a standard first order differential equation reveals that as increments in field strength,  $H$ , are made, the irreversible term  $M_{irr}$  attempts to track the reversible term  $M_{an}$ , but with a variable tracking gain of  $1/(K\delta - \alpha(M_{an} - M_{irr}))$ . The tracking error acts to create the hysteresis at the points where  $\delta$  changes sign. The main parameter that shapes the irreversible characteristic is  $K$ , which is called the bulk coupling coefficient. The parameter  $\alpha$  is called the inter-domain coupling factor, and is also used to define the effective field strength used when defining the anhysteretic curve:

$$H_{eff} = H + \alpha M$$

The value of  $\alpha$  affects the shape of the hysteresis curve, larger values acting to increase the B-axis intercepts. However, notice that for stability the term  $K\delta - \alpha(M_{an} - M_{irr})$  must be positive for  $\delta > 0$  and negative for  $\delta < 0$ . Therefore not all values of  $\alpha$  are permissible, a typical maximum value being of the order  $1e-3$ .

#### Procedure for Finding Approximate Values for Jiles-Atherton (JA) Equation Coefficients

You can determine representative parameters for the equation coefficients by using the following procedure:

- 1 Provide a value for the **Anhysteretic B-H gradient when H is zero** parameter ( $dM_{an}/dH_{eff}$  when  $H_{eff} = 0$ ) plus a data point  $[H_1, B_1]$  on the anhysteretic B-H curve. From these values, the block initialization determines values for  $\alpha$  and  $M_s$ .
- 2 Set the **Coefficient for reversible magnetization, c** parameter to achieve correct initial B-H gradient when starting a simulation from  $[H \ B] = [0 \ 0]$ . The value of  $c$  is approximately the ratio of this initial gradient to the **Anhysteretic B-H gradient when H is zero**. The value of  $c$  must be greater than 0 and less than 1.
- 3 Set the **Bulk coupling coefficient, K** parameter to the approximate magnitude of  $H$  when  $B = 0$  on the positive-going hysteresis curve.
- 4 Start with  $\alpha$  very small, and gradually increase to tune the value of  $B$  when crossing  $H = 0$  line. A typical value is in the range of  $1e-4$  to  $1e-3$ . Values that are too large cause the gradient of the B-H curve to tend to infinity, which is nonphysical and generates a run-time assertion error.

To get a good match against a predefined B-H curve, you may have to iterate on these four steps

#### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see "Set Priority and Initial Target for Block Variables".

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

## Parameters

### Main

#### **Effective length — Effective length of the section being modeled**

0.032 m (default) | positive noninfinite scalar

Effective length of the section being modeled, that is, the average distance of the magnetic path.

The value must be positive and noninfinite.

#### **Effective cross-sectional area — Effective cross-sectional area of the section being modeled**

1.6e-5 m<sup>2</sup> (default) | positive noninfinite scalar

Effective cross-sectional area of the section being modeled, that is, the average area of the magnetic path.

The value must be positive and noninfinite.

#### **Averaging period for power logging — Excitation period used for averaging**

0 s (default) | scalar

Averaging period for the hysteresis losses calculation. These losses are proportional to the area enclosed by the B-H trajectory. If the block is excited at a known, fixed frequency, you can set this value to the corresponding excitation period to calculate the hysteresis loss. In this case, the block logs the hysteresis loss once per AC cycle to the variable `power_dissipated`. If you are using a fixed-step solver, this value must be an integer multiple of the simulation step size.

If the block is not excited at a known, fixed frequency, set this parameter to 0. In this case, the block sets `power_dissipated` to zero, and you can calculate the actual hysteresis loss by post-processing the logged variable `power_instantaneous`.

**Dependencies**

This parameter is visible only when, in the **B-H Curve** settings, the **Parameterized by** parameter is set to Nonlinear reluctance with hysteresis (JA model).

**B-H Curve****Parameterized by — B-H Curve parameterization method**

Reluctance (B-H curve) (default) | Linear reluctance | Reluctance with single saturation point | Nonlinear reluctance with hysteresis (JA model)

B-H Curve parameterization method.

**Dependencies**

Selecting a parameterization method makes related parameters in the **B-H Curve** settings. If the Nonlinear reluctance with hysteresis (JA model) is the selected parameterization method, in the **Main** settings, the **Averaging period for power logging** is visible.

**Relative magnetic permeability — Relative magnetic permeability**

5000 (default) | scalar

Relative magnetic permeability.

The value must be positive and noninfinite.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Linear reluctance.

**Unsaturated relative magnetic permeability — Relative magnetic permeability**

5000 (default) | scalar

Relative magnetic permeability for an unsaturated inductor.

**Dependencies**

This parameter is visible only when the **Parameterization method** parameter is set to Reluctance with single saturation point.

**Magnetic flux density at saturation — Magnetic flux density at saturation**

1.5 T (default) | positive noninfinite scalar

Magnetic flux density for a saturated inductor.

The value must be positive and noninfinite.

**Dependencies**

This parameter is visible only when the **Parameterization method** parameter is set to Reluctance with single saturation point.

**Magnetic field strength vector, H — Magnetic field strength vector**

[0, 200, 400, 600, 800, 1000] A/m (default) | noninfinite vector

Magnetic field strength,  $H$ , specified as a vector with the same number of elements as the magnetic flux density,  $B$ . The vector must start with zero and increase monotonically.

**Dependencies**

This parameter is visible only when the **Parameterization method** parameter is set to Reluctance (B-H curve).

**Magnetic flux density vector, B — Magnetic flux density vector**

[0, 1.25, 1.35, 1.44, 1.48, 1.49] T (default) | vector

Magnetic flux density,  $B$ , specified as a vector with the same number of elements as the magnetic field strength vector,  $H$ . The vector must start with zero and increase monotonically.

**Dependencies**

This parameter is visible only when the **Parameterization method** parameter is set to Reluctance (B-H curve).

**Anhyseretic B-H gradient when H is zero — Gradient of the anhyseretic B-H curve around zero field strength**

0.0063 m\*T/A (default) | scalar

The gradient of the anhyseretic (no hysteresis) B-H curve around zero field strength. Set it to the average gradient of the positive-going and negative-going hysteresis curves.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Nonlinear reluctance with hysteresis (JA model).

**Flux density point on anhyseretic B-H curve — Flux density of the point for field strength measurement**

1.49 T (default) | scalar

Specify a point on the anhyseretic curve by providing its flux density value. Picking a point at high field strength where the positive-going and negative-going hysteresis curves align is the most accurate option.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Nonlinear reluctance with hysteresis (JA model).

**Corresponding field strength — Field strength at measurement point**

1000 A/m (default) | scalar

The corresponding field strength for the point that you define by the **Flux density point on anhyseretic B-H curve** parameter.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Nonlinear reluctance with hysteresis (JA model).

**Coefficient for reversible magnetization, c — Proportion of magnetization that is reversible**

0.1 (default) | scalar

The proportion of the magnetization that is reversible. The value must be greater than zero and less than one.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Nonlinear reluctance with hysteresis (JA model).

**Bulk coupling coefficient, K — Jiles-Atherton equations parameter**

200 A/m (default) | scalar

The Jiles-Atherton parameter that primarily controls the field strength magnitude at which the B-H curve crosses the zero flux density line.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Nonlinear reluctance with hysteresis (JA model).

**Inter-domain coupling factor, alpha — Jiles-Atherton equations parameter**

0.0001 (default) | scalar

The Jiles-Atherton parameter that primarily affects the points at which the B-H curves intersect the zero field strength line. Typical values are in the range of 1e-4 to 1e-3.

**Dependencies**

This parameter is visible only when the Parameterization method parameter is set to Nonlinear reluctance with hysteresis (JA model).

**Interpolation method — Interpolation method**

Linear (default) | Smooth

Select the method that the block uses to determine the output current values at intermediate time points that are not specified in the preceding vectors:

- **Linear** — Prioritize performance by using a linear function.
- **Smooth** — Prioritize accuracy by producing a continuous curve with continuous first-order derivatives.

# Nonlinear Transformer

Transformer with nonideal core

**Library:** Simscape / Electrical / Passive / Transformers

## Description

The Nonlinear Transformer block represents a transformer with a nonideal core. A core may be nonideal due to its magnetic properties and dimensions. The equivalent circuit topology depends upon which of the two winding leakage parameterization options you select:

- Combined primary and secondary values

- Separate primary and secondary values

where:

- $R_{eq}$  is the combined winding resistance.
- $L_{eq}$  is the combined leakage inductance.
- $R_1$  is the primary winding resistance.
- $L_1$  is the primary winding inductance.
- $R_2$  is the secondary winding resistance.
- $L_2$  is the secondary winding inductance.
- $R_m$  is the magnetization resistance.
- $L_m$  is the magnetization inductance.

The block provides the following parameterization options for the nonlinear magnetization inductance:

- Single inductance (linear)
- Single saturation point
- Magnetic flux versus current characteristic
- Magnetic flux density versus magnetic field strength characteristic
- Magnetic flux density versus magnetic field strength characteristic with hysteresis

For more information, see the Nonlinear Inductor block reference page.

## Parameters

### Main

#### **Primary number of turns — Primary number of turns**

100 (default)

The number of turns of wire on the primary winding of the transformer.

#### **Secondary number of turns — Secondary number of turns**

200 (default)

The number of turns of wire on the secondary winding of the transformer.

#### **Winding parameterized by — Winding leakage parameterization**

Combined primary and secondary values (default) | Separate primary and secondary values

Select one of the following methods for the winding leakage parameterization:

- **Combined primary and secondary values** — Use the lumped resistance and inductance values representing the combined leakage in the primary and secondary windings. This is the default option.
- **Separate primary and secondary values** — Use separate resistances and inductances to represent leakages in the primary and secondary windings.

#### **Combined winding resistance — Combined winding resistance**

0.01 Ohm (default)

The lumped equivalent resistance  $R_{eq}$ , which represents the combined power loss of the primary and secondary windings.

#### **Dependencies**

This parameter is visible only when you select Combined primary and secondary values for the **Winding parameterized by** parameter.

#### **Combined leakage inductance — Combined leakage inductance**

0.0001 H (default)

The lumped equivalent inductance  $L_{eq}$ , which represents the combined magnetic flux loss of the primary and secondary windings.

#### **Dependencies**

This parameter is visible only when you select Combined primary and secondary values for the **Winding parameterized by** parameter.

#### **Primary winding resistance — Primary winding resistance**

0.01 Ohm (default)

The resistance  $R_1$ , which represents the power loss of the primary winding.

**Dependencies**

This parameter is visible only when you select Separate primary and secondary values for the **Winding parameterized by** parameter.

**Primary leakage inductance — Primary leakage inductance**

0.0001 H (default)

The inductance  $L1$ , which represents the magnetic flux loss of the primary winding.

**Dependencies**

This parameter is visible only when you select Separate primary and secondary values for the **Winding parameterized by** parameter.

**Secondary winding resistance — Secondary winding resistance**

0.01 Ohm (default)

The resistance  $R2$ , which represents the power loss of the secondary winding.

**Dependencies**

This parameter is visible only when you select Separate primary and secondary values for the **Winding parameterized by** parameter.

**Secondary leakage inductance — Secondary leakage inductance**

0.0001 H (default)

The inductance  $L2$ , which represents the magnetic flux loss of the secondary winding.

**Dependencies**

This parameter is visible only when you select Separate primary and secondary values for the **Winding parameterized by** parameter.

**Averaging period for power logging — Averaging period for power logging**

0 s (default)

Averaging period for power logging

**Magnetization****Magnetization resistance — Magnetization resistance**

100 Ohm (default)

The resistance  $Rm$ , which represents the magnetic losses in the transformer core.

**Magnetization inductance parameterized by — Nonlinear magnetization inductance parameterization**

Single saturation point (default) | Single inductance (linear) | Magnetic flux versus current characteristic | Magnetic flux density versus field strength characteristic | Magnetic flux density versus field strength characteristic with hysteresis

Select one of the following methods for the nonlinear magnetization inductance parameterization:

- **Single inductance (linear)** — Provide the unsaturated inductance value.
- **Single saturation point** — Provide the values for the unsaturated and saturated inductances, as well as saturation magnetic flux. This is the default option.
- **Magnetic flux versus current characteristic** — Provide the current vector and the magnetic flux vector, to populate the magnetic flux versus current lookup table.
- **Magnetic flux density versus field strength characteristic** — Provide the values for effective core length and cross-sectional area, as well as the magnetic field strength vector and the magnetic flux density vector, to populate the magnetic flux density versus magnetic field strength lookup table.
- **Magnetic flux density versus field strength characteristic with hysteresis** — In addition to the number of turns and the effective core length and cross-sectional area, provide the values for the initial anhysteretic B-H curve gradient, the magnetic flux density and field strength at a certain point on the B-H curve, as well as the coefficient for the reversible magnetization, bulk coupling coefficient, and inter-domain coupling factor, to define magnetic flux density as a function of both the current value and the history of the field strength.

**Unsaturated inductance — Unsaturated inductance**

4e-2 H (default)

The value of inductance used when the magnetization inductance  $L_m$  is operating in its linear region.

**Dependencies**

This parameter is visible only when you select **Single inductance (linear)** or **Single saturation point** for the **Magnetization inductance parameterized by** parameter.

**Saturated inductance — Saturated inductance**

1e-2 H (default)

The value of inductance used when the magnetization inductance  $L_m$  is operating beyond its saturation point.

**Dependencies**

This parameter is visible only when you select **Single saturation point** for the **Magnetization inductance parameterized by** parameter.

**Saturation magnetic flux — Saturation magnetic flux**

1.6e-04 Wb (default)

The value of magnetic flux at which the magnetization inductance  $L_m$  saturates.

**Dependencies**

This parameter is visible only when you select **Single saturation point** for the **Magnetization inductance parameterized by** parameter.

**Current vector,  $i$  — Current data**

[0, .4, .8, 1.2, 1.6, 2] A (default)

The current data used to populate the magnetic flux versus current lookup table.

**Dependencies**

This parameter is visible only when you select Magnetic flux versus current characteristic for the **Magnetization inductance parameterized by** parameter.

**Magnetic flux vector, phi – Magnetic flux vector**

[0, .161, .25, .284, .295, .299] .\* 1e-3 Wb (default)

The magnetic flux data used to populate the magnetic flux versus current lookup table.

**Dependencies**

This parameter is visible only when you select Magnetic flux versus current characteristic for the **Magnetization inductance parameterized by** parameter.

**Magnetic field strength vector, H – Magnetic field strength vector**

[0, 200, 400, 600, 800, 1000] A/m (default)

The magnetic field strength data used to populate the magnetic flux density versus magnetic field strength lookup table.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic for the **Magnetization inductance parameterized by** parameter.

**Magnetic flux density vector, B – Magnetic flux density vector**

[0, .81, 1.25, 1.42, 1.48, 1.49] T (default)

The magnetic flux density data used to populate the magnetic flux density versus magnetic field strength lookup table.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic for the **Magnetization inductance parameterized by** parameter.

**Effective length – Effective length**

0.2 m (default)

The effective core length, that is, the average distance of the magnetic path around the transformer core.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic for the **Magnetization inductance parameterized by** parameter.

**Effective cross-sectional area – Effective cross-sectional area**

2e-4 m<sup>2</sup> (default)

The effective core cross-sectional area, that is, the average area of the magnetic path around the transformer core.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic for the **Magnetization inductance parameterized by** parameter.

**Anhyseretic B-H gradient when H is zero – Anhyseretic B-H gradient around zero field strength**

0.005 m\*T/A (default)

The gradient of the anhyseretic (no hysteresis) B-H curve around zero field strength. Set it to the average gradient of the positive-going and negative-going hysteresis curves.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Flux density point on anhyseretic B-H curve – Flux density point on anhyseretic B-H curve**

1.49 T (default)

Specify a point on the anhyseretic curve by providing its flux density value. Picking a point at high field strength where the positive-going and negative-going hysteresis curves align is the most accurate option.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Corresponding field strength – Corresponding field strength**

1000 A/m (default)

The corresponding field strength for the point that you define by the **Flux density point on anhyseretic B-H curve** parameter.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Coefficient for reversible magnetization, c – Coefficient for reversible magnetization**

0.1 (default)

The proportion of the magnetization that is reversible. The value should be greater than zero and less than one.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Bulk coupling coefficient, K – Bulk coupling coefficient**

200 A/m (default)

The Jiles-Atherton parameter that primarily controls the field strength magnitude at which the B-H curve crosses the zero flux density line.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Inter-domain coupling factor, alpha – Inter-domain coupling factor**

1e-4 (default)

The Jiles-Atherton parameter that primarily affects the points at which the B-H curves intersect the zero field strength line. Typical values are in the range of 1e-4 to 1e-3.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Interpolation option – Interpolation option**

Linear (default) | Smooth

The lookup table interpolation option. Select one of the following interpolation methods:

- **Linear** — Select this option to get the best performance.
- **Smooth** — Select this option to produce a continuous curve with continuous first-order derivatives.

For more information on interpolation algorithms, see the PS Lookup Table (1D) block reference page.

**Dependencies**

This parameter is visible only when you select Magnetic flux versus current characteristic or Magnetic flux density versus field strength characteristic for the **Magnetization inductance parameterized by** parameter.

**Initial Conditions****Combined leakage inductance initial current – Combined leakage inductance initial current**

0 A (default)

The value of current through the combined leakage inductance  $L_{eq}$  at time zero.

**Dependencies**

This parameter is visible only when you select Combined primary and secondary values for the **Winding parameterized by** parameter on the **Main** tab.

**Primary leakage inductance initial current – Primary leakage inductance initial current**

0 A (default)

The value of current through the primary leakage inductance  $L1$  at time zero.

**Dependencies**

This parameter is visible only when you select `Separate primary and secondary values` for the **Winding parameterized by** parameter on the **Main** tab.

**Secondary leakage inductance initial current — Secondary leakage inductance initial current**

0 A (default)

The value of current through the secondary leakage inductance  $L2$  at time zero.

**Dependencies**

This parameter is visible only when you select `Separate primary and secondary values` for the **Winding parameterized by** parameter on the **Main** tab.

**Specify magnetization inductance initial state by — Initial state specification option**

Current (default) | Magnetic flux

Select the appropriate initial state specification option:

- **Current** — Specify the initial state of the magnetization inductance  $Lm$  by the initial current. This is the default option.
- **Magnetic flux** — Specify the initial state of the magnetization inductance  $Lm$  by the magnetic flux.

**Dependencies**

This parameter is not visible only when you select `Magnetic flux density versus magnetic field strength characteristic with hysteresis` for the **Magnetization inductance parameterized by** parameter on the **Magnetization** tab.

**Magnetization inductance initial current — Magnetization inductance initial current**

0 A (default)

The initial current value used to calculate the value of magnetic flux within the magnetization inductance  $Lm$  at time zero. This is the current passing through the magnetization inductance  $Lm$ . Total magnetization current consists of current passing through the magnetization resistance  $Rm$  and current passing through the magnetization inductance  $Lm$ .

**Dependencies**

This parameter is visible only when you select `Current` for the **Specify magnetization inductance initial state by** parameter.

**Magnetization inductance initial magnetic flux — Magnetization inductance initial magnetic flux**

0 Wb (default)

The value of the magnetic flux in the magnetization inductance  $Lm$  at time zero.

**Dependencies**

This parameter is visible only when you select `Magnetic flux` for the **Specify magnetization inductance initial state by** parameter.

**Magnetization inductance initial magnetic flux density – Magnetization inductance initial magnetic flux density**

0 T (default)

The value of magnetic flux density at time zero. This parameter is visible only when you select Magnetic flux density versus magnetic field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter on the **Magnetization** tab.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Magnetization inductance initial field strength – Magnetization inductance initial field strength**

0 A/m (default)

The value of magnetic field strength at time zero.

**Dependencies**

This parameter is visible only when you select Magnetic flux density versus field strength characteristic with hysteresis for the **Magnetization inductance parameterized by** parameter.

**Parasitics****Combined leakage inductance parasitic parallel conductance – Combined leakage inductance parasitic parallel conductance**

1e-9 1/0hm (default)

Use this parameter to represent small parasitic effects in parallel to the combined leakage inductance  $L_{eq}$ . A small parallel conductance may be required for the simulation of some circuit topologies.

**Dependencies**

This parameter is visible only when you select Combined primary and secondary values for the **Winding parameterized by** parameter on the **Main** tab.

**Primary leakage inductance parasitic parallel conductance – Primary leakage inductance parasitic parallel conductance**

1e-9 1/0hm (default)

Use this parameter to represent small parasitic effects in parallel to the primary leakage inductance  $L_1$ . A small parallel conductance may be required for the simulation of some circuit topologies.

**Dependencies**

This parameter is visible only when you select Separate primary and secondary values for the **Winding parameterized by** parameter on the **Main** tab.

**Secondary leakage inductance parasitic parallel conductance – Secondary leakage inductance parasitic parallel conductance**

1e-9 (default)

Use this parameter to represent small parasitic effects in parallel to the secondary leakage inductance  $L2$ . A small parallel conductance may be required for the simulation of some circuit topologies.

**Dependencies**

This parameter is visible only when you select **Separate primary and secondary values** for the **Winding parameterized by** parameter on the **Main** tab.

# NPN Bipolar Transistor

NPN bipolar transistor using enhanced Ebers-Moll equations

**Library:** Simscape / Electrical / Semiconductors & Converters

## Description

The NPN Bipolar Transistor block uses a variant of the Ebers-Moll equations to represent an NPN bipolar transistor. The Ebers-Moll equations are based on two exponential diodes plus two current-controlled current sources. The NPN Bipolar Transistor block provides the following enhancements to that model:

- Early voltage effect
- Optional base, collector, and emitter resistances.
- Optional fixed base-emitter and base-collector capacitances.

The collector and base currents are:

$$I_C = IS \left[ \left( e^{qV_{BE}/(kT_{m1})} - e^{qV_{BC}/(kT_{m1})} \right) \left( 1 - \frac{V_{BC}}{V_A} \right) - \frac{1}{\beta_R} \left( e^{qV_{BC}/(kT_{m1})} - 1 \right) \right]$$

$$I_B = IS \left[ \frac{1}{\beta_F} \left( e^{qV_{BE}/(kT_{m1})} - 1 \right) + \frac{1}{\beta_R} \left( e^{qV_{BC}/(kT_{m1})} - 1 \right) \right]$$

Where:

- $I_B$  and  $I_C$  are base and collector currents, defined as positive into the device.
- $IS$  is the saturation current.
- $V_{BE}$  is the base-emitter voltage and  $V_{BC}$  is the base-collector voltage.
- $\beta_F$  is the ideal maximum forward current gain BF
- $\beta_R$  is the ideal maximum reverse current gain BR
- $V_A$  is the forward Early voltage VAF
- $q$  is the elementary charge on an electron (1.602176e-19 Coulombs).
- $k$  is the Boltzmann constant (1.3806503e-23 J/K).
- $T_{m1}$  is the transistor temperature, as defined by the **Measurement temperature** parameter value.

You can specify the transistor behavior using datasheet parameters that the block uses to calculate the parameters for these equations, or you can specify the equation parameters directly.

If  $qV_{BC} / (kT_{m1}) > 40$  or  $qV_{BE} / (kT_{m1}) > 40$ , the corresponding exponential terms in the equations are replaced with  $(qV_{BC} / (kT_{m1}) - 39)e^{40}$  and  $(qV_{BE} / (kT_{m1}) - 39)e^{40}$ , respectively. This helps prevent numerical issues associated with the steep gradient of the exponential function  $e^x$  at large values of  $x$ .

Similarly, if  $qV_{BC} / (kT_{m1}) < -39$  or  $qV_{BE} / (kT_{m1}) < -39$  then the corresponding exponential terms in the equations are replaced with  $(qV_{BC} / (kT_{m1}) + 40)e^{-39}$  and  $(qV_{BE} / (kT_{m1}) + 40)e^{-39}$ , respectively.

Optionally, you can specify fixed capacitances across the base-emitter and base-collector junctions. You also have the option to specify base, collector, and emitter connection resistances.

### Modeling Temperature Dependence

The default behavior is that dependence on temperature is not modeled, and the device is simulated at the temperature for which you provide block parameters. You can optionally include modeling the dependence of the transistor static behavior on temperature during simulation. Temperature dependence of the junction capacitances is not modeled, this being a much smaller effect.

When including temperature dependence, the transistor defining equations remain the same. The measurement temperature value,  $T_{m1}$ , is replaced with the simulation temperature,  $T_s$ . The saturation current,  $IS$ , and the forward and reverse gains ( $\beta_F$  and  $\beta_R$ ) become a function of temperature according to the following equations:

$$IS_{T_s} = IS_{T_{m1}} \cdot (T_s/T_{m1})^{XTI} \cdot \exp\left(-\frac{EG}{kT_s}(1 - T_s/T_{m1})\right)$$

$$\beta_{F_s} = \beta_{F_{m1}} \left(\frac{T_s}{T_{m1}}\right)^{XTB}$$

$$\beta_{R_s} = \beta_{R_{m1}} \left(\frac{T_s}{T_{m1}}\right)^{XTB}$$

where:

- $T_{m1}$  is the temperature at which the transistor parameters are specified, as defined by the **Measurement temperature** parameter value.
- $T_s$  is the simulation temperature.
- $IS_{T_{m1}}$  is the saturation current at the measurement temperature.
- $IS_{T_s}$  is the saturation current at the simulation temperature. This is the saturation current value used in the bipolar transistor equations when temperature dependence is modeled.
- $\beta_{F_{m1}}$  and  $\beta_{R_{m1}}$  are the forward and reverse gains at the measurement temperature.
- $\beta_{F_s}$  and  $\beta_{R_s}$  are the forward and reverse gains at the simulation temperature. These are the values used in the bipolar transistor equations when temperature dependence is modeled.
- $EG$  is the energy gap for the semiconductor type measured in Joules. The value for silicon is usually taken to be 1.11 eV, where 1 eV is 1.602e-19 Joules.
- $XTI$  is the saturation current temperature exponent.
- $XTB$  is the forward and reverse gain temperature coefficient.
- $k$  is the Boltzmann constant (1.3806503e-23 J/K).

Appropriate values for  $XTI$  and  $EG$  depend on the type of transistor and the semiconductor material used. In practice, the values of  $XTI$ ,  $EG$ , and  $XTB$  need tuning to model the exact behavior of a particular transistor. Some manufacturers quote these tuned values in a SPICE Netlist, and you can read off the appropriate values. Otherwise you can determine values for  $XTI$ ,  $EG$ , and  $XTB$  by using a datasheet-defined data at a higher temperature  $T_{m2}$ . The block provides a datasheet parameterization option for this.

You can also tune the values of  $X_{TI}$ ,  $EG$ , and  $X_{TB}$  yourself, to match lab data for your particular device. You can use Simulink Design Optimization software to help tune the values.

### Thermal Port

You can expose the thermal port to model the effects of generated heat and device temperature. To expose the thermal port, set the **Modeling option** parameter to either:

- **No thermal port** — The block does not contain a thermal port and does not simulate heat generation in the device.
- **Show thermal port** — The block contains a thermal port that allows you to model the heat that conduction losses generate. For numerical efficiency, the thermal state does not affect the electrical behavior of the block.

For more information on using thermal ports and on the **Thermal Port** parameters, see “Simulating Thermal Effects in Semiconductors”.

### Variables

To set the priority and initial target values for the block variables prior to simulation, use the **Initial Targets** section in the block dialog box or Property Inspector. For more information, see “Set Priority and Initial Target for Block Variables”.

Nominal values provide a way to specify the expected magnitude of a variable in a model. Using system scaling based on nominal values increases the simulation robustness. Nominal values can come from different sources, one of which is the **Nominal Values** section in the block dialog box or Property Inspector. For more information, see “System Scaling by Nominal Values”.

### Assumptions and Limitations

- The block does not account for temperature-dependent effects on the junction capacitances.
- You may need to use nonzero ohmic resistance and junction capacitance values to prevent numerical simulation issues, but the simulation may run faster with these values set to zero.

### Ports

#### Conserving

##### **B — Base terminal**

electrical

Electrical conserving port associated with the transistor base terminal

##### **C — Collector terminal**

electrical

Electrical conserving port associated with the transistor collector terminal

##### **E — Emitter terminal**

electrical

Electrical conserving port associated with the transistor emitter terminal

**H — Thermal port**

thermal

Thermal conserving port.

**Dependencies**

To enable this port, set **Modeling option** to Show thermal port.

**Parameters****Modeling option — Whether to enable thermal port**

No thermal port (default) | Show thermal port

Whether to enable the thermal port of the block and model the effects of generated heat and device temperature.

**Main****Parameterization — Block parameterization**

Specify from a datasheet (default) | Specify using equation parameters directly

Select one of the following methods for block parameterization:

- **Specify from a datasheet** — Provide parameters that the block converts to equations that describe the transistor. The block calculates the forward Early voltage  $VAF$  as  $I_c/h_{oe}$ , where  $I_c$  is the **Collector current at which h-parameters are defined** parameter value, and  $h_{oe}$  is the **Output admittance  $h_{oe}$**  parameter value [1]. The block sets  $BF$  to the small-signal **Forward current transfer ratio  $h_{fe}$**  value. The block calculates the saturation current  $IS$  from the specified **Voltage  $V_{be}$**  value and the corresponding **Current  $I_b$  for voltage  $V_{be}$**  value when  $I_c$  is zero. This is the default method.
- **Specify using equation parameters directly** — Provide equation parameters  $IS$ ,  $BF$ , and  $VAF$ .

**Forward current transfer ratio  $h_{fe}$  — Forward current transfer ratio**

100 (default)

Small-signal current gain.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter.

**Output admittance  $h_{oe}$  — Output admittance**

50e-6 1/0hm (default)

Derivative of the collector current with respect to the collector-emitter voltage for a fixed base current.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter.

**Collector current at which h-parameters are defined – Collector current at which h-parameters are defined**

1 mA (default)

The h-parameters vary with operating point, and are defined for this value of the collector current.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter.

**Collector-emitter voltage at which h-parameters are defined – Collector-emitter voltage at which h-parameters are defined**

5 V (default)

The h-parameters vary with operating point, and are defined for this value of the collector-emitter voltage.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter.

**Voltage Vbe – Base-emitter voltage**

0.55 V (default)

Base-emitter voltage when the base current is  $I_b$ . The [  $V_{be}$   $I_b$  ] data pair must be quoted for when the transistor is in the normal active region, that is, not in the saturated region.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter.

**Current  $I_b$  for voltage Vbe – Current  $I_b$  for voltage Vbe**

0.5 mA (default)

Base current when the base-emitter voltage is  $V_{be}$ . The [  $V_{be}$   $I_b$  ] data pair must be quoted for when the transistor is in the normal active region, that is, not in the saturated region.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter.

**Forward current transfer ratio BF – Forward current transfer ratio**

100 (default)

Ideal maximum forward current gain.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Saturation current  $I_S$  – Saturation current**

1e-14 A (default)

Transistor saturation current.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Forward Early voltage VAF — Forward Early voltage**

200 V (default)

In the standard Ebers-Moll equations, the gradient of the  $I_c$  versus  $V_{ce}$  curve is zero in the normal active region. The additional forward Early voltage term increases this gradient. The intercept on the  $V_{ce}$ -axis is equal to  $-VAF$  when the linear region is extrapolated.

**Dependencies**

This parameter is visible only when you select Specify using equation parameters directly for the **Parameterization** parameter.

**Reverse current transfer ratio BR — Reverse current transfer ratio**

1 (default)

Ideal maximum reverse current gain. This value is often not quoted in manufacturer datasheets, because it is not significant when the transistor is biased to operate in the normal active region. When the value is not known and the transistor is not to be operated on the inverse region, use the default value of 1.

**Measurement temperature — Measurement temperature**

25 degC (default)

Temperature  $T_{m1}$  at which  $V_{be}$  and  $I_b$ , or  $I_S$ , are measured. The default value is 25 °C.

**Ohmic Resistance****Collector resistance RC — Collector resistance**

0.01 Ohm (default)

Resistance at the collector.

**Emitter resistance RE — Emitter resistance**

1e-4 Ohm (default)

Resistance at the emitter.

**Zero bias base resistance RB — Zero bias base resistance RB**

1 Ohm (default)

Resistance at the base at zero bias.

**Capacitance****Base-collector junction capacitance — Base-collector junction capacitance**

5 pF (default)

Parasitic capacitance across the base-collector junction.

**Base-emitter junction capacitance — Base-emitter junction capacitance**

5 pF (default)

Parasitic capacitance across the base-emitter junction.

**Total forward transit time — Total forward transit time**

0 us (default)

Represents the mean time for the minority carriers to cross the base region from the emitter to the collector, and is often denoted by the parameter TF [1].

**Total reverse transit time — Total reverse transit time**

0 us (default)

Represents the mean time for the minority carriers to cross the base region from the collector to the emitter, and is often denoted by the parameter TR [1].

**Temperature Dependence****Parameterization — Temperature dependence parameterization**

None — Simulate at parameter measurement temperature (default) | Model temperature dependence

Select one of the following methods for temperature dependence parameterization:

- None — Simulate at parameter measurement temperature — Temperature dependence is not modeled, or the model is simulated at the measurement temperature  $T_{m1}$  (as specified by the **Measurement temperature** parameter on the **Main** tab). This is the default method.
- Model temperature dependence — Provide a value for simulation temperature, to model temperature-dependent effects. You also have to provide a set of additional parameters depending on the block parameterization method. If you parameterize the block from a datasheet, you have to provide values for a second [ *Vbe Ib* ] data pair and  $h_{fe}$  at second measurement temperature. If you parameterize by directly specifying equation parameters, you have to provide the values for *XTI*, *EG*, and *XTB*.

**Forward current transfer ratio,  $h_{fe}$ , at second measurement temperature — Forward current transfer ratio,  $h_{fe}$ , at second measurement temperature**

125 (default)

Small-signal current gain at the second measurement temperature. It must be quoted at the same collector-emitter voltage and collector current as for the **Forward current transfer ratio  $h_{fe}$**  parameter on the **Main** tab.

**Dependencies**

This parameter is visible only when you select Specify from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Voltage  $V_{be}$  at second measurement temperature — Voltage  $V_{be}$  at second measurement temperature**

0.45 V (default)

Base-emitter voltage when the base current is  $I_b$  and the temperature is set to the second measurement temperature. The [ *Vbe Ib* ] data pair must be quoted for when the transistor is in the normal active region, that is, not in the saturated region.

**Dependencies**

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Current  $I_b$  for voltage  $V_{be}$  at second measurement temperature – Current  $I_b$  for voltage  $V_{be}$  at second measurement temperature**

0.5 mA (default)

Base current when the base-emitter voltage is  $V_{be}$  and the temperature is set to the second measurement temperature. The [  $V_{be}$   $I_b$  ] data pair must be quoted for when the transistor is in the normal active region, that is, not in the saturated region.

**Dependencies**

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Second measurement temperature – Second measurement temperature**

125 degC (default)

Second temperature  $T_{m2}$  at which  $h_{fe}$ ,  $V_{be}$ , and  $I_b$  are measured.

**Dependencies**

This parameter is visible only when you select **Specify** from a datasheet for the **Parameterization** parameter on the **Main** tab.

**Current gain temperature coefficient, XTB – Current gain temperature coefficient**

0 (default)

Current gain temperature coefficient value.

**Dependencies**

This parameter is visible only when you select **Specify** using equation parameters directly for the **Parameterization** parameter on the **Main** tab.

**Energy gap, EG – Energy gap**

1.11 eV (default)

Energy gap value.

**Dependencies**

This parameter is visible only when you select **Specify** using equation parameters directly for the **Parameterization** parameter on the **Main** tab.

**Saturation current temperature exponent, XTI – Saturation current temperature exponent**

3 (default)

Saturation current temperature coefficient value.

**Dependencies**

This parameter is visible only when you select **Specify** using equation parameters directly for the **Parameterization** parameter on the **Main** tab.

**Device simulation temperature – Device simulation temperature**

25 degC (default)

Temperature  $T_s$  at which the device is simulated.

**Version History****Introduced in R2008a****Thermal network simlog paths***Behavior changed in R2019b*

From R2019b forward, it is possible to model the thermal network of this block either internally or externally.

As a result, the simlog paths corresponding to the thermal network have changed. If you have a script that programmatically access the simlog, you have to manually update it to reflect these changes.

## On-Off Delay

Boolean-signal delay

**Library:** Simscape / Electrical / Control / General Control

### Description

The On-Off Delay block applies a delay on the Boolean input signal.

A time delay is added when a transition is detected in the input signal. This block allows you to add a time delay to the input signal when:

- An ON transition (input change from 0 to 1) is detected,
- An OFF transition (input signal change from 1 to 0) is detected, or
- Either transition is detected.

The operation of the on-off delay is represented in the following figure:

### Ports

#### Input

**u** – Input signal

0 | 1

Input Boolean signal.

Data Types: Boolean

## Output

**y — Output signal**

0 | 1

Output signal with delays.

Data Types: Boolean

## Parameters

**ON delay time (s) — Input ON delay time**

0.01 (default) | 0 | positive scalar

Specify delay time when input is ON.

**OFF delay time (s) — Input OFF delay time**

0 (default) | positive scalar

Specify delay time when input is OFF.

**Initial state — Signal initial state**

0 (default) | 1

Specify initial state.

**Sample time — Block sample time**

0.001 (default) | 0 | positive scalar

Time between consecutive block executions. During execution, the block produces outputs and, if appropriate, updates its internal state. For more information, see “What Is Sample Time?” and “Specify Sample Time”.

For discrete-time operation, set the sample time to a positive value. For continuous-time operation, set the sample time to 0.

If this block is in a masked subsystem, or other variant subsystem that allows either continuous and discrete operation, promote the sample time parameter. Promoting the sample time parameter ensures correct switching between the continuous and discrete implementations of the block. For more information, see “Promote Block Parameters on a Mask”.

# One-Quadrant Chopper

Controller-driven one-quadrant chopper

**Library:** Simscape / Electrical / Semiconductors & Converters / Converters

## Description

The One-Quadrant Chopper block represents a one-quadrant controlled chopper for converting a fixed DC input to a variable DC output.

The circuit topology and quadrant depend on the class of chopper that you specify.

A first-quadrant or class A chopper contains a power switch and a diode.

A second-quadrant or class B chopper also contains a power switch and a diode.

For either topology, the switch S can be a fully controlled switching device (for example, an IGBT or GTO) or a partially controlled switching device (for example, a thyristor).

Options for the switching device type are:

- GTO — Gate turn-off thyristor. For information about the I-V characteristic of the device, see GTO.
- Ideal semiconductor switch — For information about the I-V characteristic of the device, see Ideal Semiconductor Switch.
- IGBT — Insulated-gate bipolar transistor. For information about the I-V characteristic of the device, see IGBT (Ideal, Switching).
- MOSFET — N-channel metal-oxide-semiconductor field-effect transistor. For information about the I-V characteristic of the device, see MOSFET (Ideal, Switching).
- Thyristor — For information about the I-V characteristic of the device, see Thyristor (Piecewise Linear).

- **Averaged Switch** — Semiconductor switch with an anti-parallel diode. The control signal port, **G**, accepts values in the  $[0, 1]$  interval. When the value at port **G** is equal to 0 or 1, the averaged switch is either fully opened or fully closed, and it behaves similarly to the Ideal Semiconductor Switch block with an anti-parallel diode. When the value at port **G** is between 0 and 1, the averaged switch is partly opened. You can then average the PWM signal over a specified period. This allows for undersampling of the model or using modulation waveforms instead of PWM signals.

## Protection

An inductive load can produce a high reverse-voltage spike when the semiconductor device suddenly switches off the voltage supply to the load. To protect the semiconductor device, an integral protection diode provides a conduction path for reverse current.

To include and configure the internal protection diode block for the *S* switching device, use the **Diode** parameters. This table shows how to set the **Model dynamics** parameter based on your goals.

Goals		Value to Select	Integral Protection Diode
Do not include protection.		None	None
Include protection.	Prioritize simulation speed.	Diode with no dynamics	The Diode block
	Prioritize model fidelity by precisely specifying reverse-mode charge dynamics.	Diode with charge dynamics	The dynamic model of the Diode block

You can also include a snubber circuit for each switching device. Snubber circuits contain a series-connected resistor and capacitor. They protect switching devices against high voltages that inductive loads produce when the device turns off the voltage supply to the load. Snubber circuits also prevent excessive rates of current change when a switching device turns on.

To include and configure a snubber circuit for each switching device, use the **Snubbers** parameters.

## Gate Control

You can connect gate-control voltage signals to the gate ports of the switching devices.

- For the PS control port model:
  - 1 Convert a Simulink gate-control voltage signal to a physical signal using a Simulink-PS Converter block.
  - 2 Connect the Simulink-PS Converter block to the **G** port.
- For the electrical control ports model:
  - 1 Connect a Simscape electrical-domain positive DC voltage signal to the **G+** port.
  - 2 Connect the Simscape electrical-domain negative DC voltage signal to the **G-** port.

## Piecewise Constant Approximation in Averaged Switch for FPGA Deployment

If you set the **Switching device** parameter to `Averaged switch` and your model uses a partitioning solver, this block produces nonlinear partitions because the average mode equations include modes,  $G_{sat}$  that are functions of the input  $\mathbf{G}$ . To make these equations compatible with hardware description language (HDL) code generation, and therefore FPGA deployment, set the **Integer for piecewise constant approximation of gate input (0 for disabled)** parameter to a value greater than 0. This block then treats the  $G_{sat}$  mode as a piecewise constant integer with a fixed range. This turns the previously nonlinear partitions to linear time varying partitions.

An integer value in the range  $[0, K]$ , where  $K$  is the value of the **Integer for piecewise constant approximation of gate input (0 for disabled)**, is now associated with each real value mode in the range  $[0, 1]$ . The block computes the piecewise constant mode by dividing the original mode by  $K$  to normalize it back to the range  $[0, 1]$ :

$$u_I = (\text{floor}(u \cdot K))$$

$$\hat{u} = \frac{u_I}{K}$$

## **Parameters**

### **Switching Devices**

This table shows how the visibility of **Switching Devices** parameters depends on the **Switching device** that you select. To learn how to read the table, see “Parameter Dependencies” on page A-2.

**Switching Devices Parameter Dependencies**

<b>Switching Device</b>					
<b>Chopper type</b> — Choose Class A - first quadrant or Class B - second quadrant.					
<b>Switching device</b> — Choose Ideal Semiconductor Switch, GTO, IGBT, MOSFET, Thyristor, or Averaged Switch.					
<b>Ideal Semiconductor Switch</b>	<b>GTO</b>	<b>IGBT</b>	<b>MOSFET</b>	<b>Thyristor</b>	<b>Averaged Switch</b>
On-state resistance	Forward voltage	Forward voltage	Drain-source on resistance	Forward voltage	On-state resistance
Off-state conductance	On-state resistance	On-state resistance	Off-state conductance	On-state resistance	
Threshold voltage	Off-state conductance	Off-state conductance	Threshold voltage	Off-state conductance	
	Gate trigger voltage, Vgt	Threshold voltage		Gate trigger voltage, Vgt	Integer for piecewise constant approximation of gate input (0 for disabled)
	Gate turn-off voltage, Vgt_off			Gate turn-off voltage, Vgt_off	
	Holding current			Holding current	

**Gate-control port — Whether to specify physical or electrical control ports**

PS (default) | Electrical

Whether to specify physical or electrical control ports for the switching device gate.

**Chopper type — Chopper class**

Class A - first quadrant (default) | Class B - second quadrant

Chopper class.

**Switching device — Switch type**

Ideal Semiconductor Switch (default) | GTO | IGBT | MOSFET | Thyristor | Averaged Switch

Switching device type for the converter.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Forward voltage — Voltage**

0.8 Ohm (default) | scalar

For the different switching device types, the **Forward voltage** is taken as:

- GTO — Minimum voltage required across the anode and cathode block ports for the gradient of the device I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- IGBT — Minimum voltage required across the collector and emitter block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On-state resistance**
- Thyristor — Minimum voltage required for the device to turn on

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### On-state resistance — Resistance

0.001 Ohm (default) | scalar

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Rate of change of voltage versus current above the forward voltage
- Ideal semiconductor switch — Anode-cathode resistance when the device is on
- IGBT — Collector-emitter resistance when the device is on
- Thyristor — Anode-cathode resistance when the device is on
- Averaged switch — Anode-cathode resistance when the device is on

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Drain-source on resistance — Resistance

0.001 Ohm (default) | scalar

Resistance between the drain and the source, which also depends on the gate-to-source voltage.

#### Dependencies

See the Switching Devices Parameter Dependencies table.

#### Off-state conductance — Conductance

1e-5 1/Ohm (default) | scalar

Conductance when the device is off. The value must be less than  $1/R$ , where  $R$  is the value of **On-state resistance**.

For the different switching device types, the **On-state resistance** is taken as:

- GTO — Anode-cathode conductance
- Ideal semiconductor switch — Anode-cathode conductance
- IGBT — Collector-emitter conductance
- MOSFET — Drain-source conductance
- Thyristor — Anode-cathode conductance

#### Dependencies

See the Switching Devices Parameter Dependencies table.

**Threshold voltage — Voltage threshold**

6 V (default) | scalar

Gate voltage threshold. The device turns on when the gate voltage is above this value. For the different switching device types, the device voltage of interest is:

- Ideal semiconductor switch — Gate-emitter voltage
- IGBT — Gate-cathode voltage
- MOSFET — Gate-source voltage

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate trigger voltage,  $V_{gt}$  — Voltage threshold**

1 V (default) | scalar

Gate-cathode voltage threshold. The device turns on when the gate-cathode voltage is above this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Gate turn-off voltage,  $V_{gt\_off}$  — Voltage threshold**

-1 V (default) | scalar

Gate-cathode voltage threshold. The device turns off when the gate-cathode voltage is below this value.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Holding current — Current threshold**

1 A (default) | scalar

Gate current threshold. The device stays on when the current is above this value, even when the gate-cathode voltage falls below the gate trigger voltage.

**Dependencies**

See the Switching Devices Parameter Dependencies table.

**Integer for piecewise constant approximation of gate input (0 for disabled) — Integer mode for FPGA deployment**

0 (default) | nonnegative scalar

Integer used to perform piecewise constant approximation of the gate input for FPGA deployment.

**Dependencies**

To enable this parameter, set **Switching device** to Averaged Switch.

## Diode

The visibility of **Diode** parameters depends on how you configure the protection diode **Model dynamics** and **Reverse recovery time parameterization** parameters. To learn how to read this table, see “Parameter Dependencies” on page A-2.

### Model dynamics — Diode model

Diode with no dynamics (default) | Diode with charge dynamics

Diode type. The options are:

- Diode with no dynamics — Select this option to prioritize simulation speed using the Diode block.
- Diode with charge dynamics — Select this option to prioritize model fidelity in terms of reverse mode charge dynamics using the commutation model of the Diode block.

**Note** If you select Averaged Switch for the **Switching Device** parameter in the **Switching Device** setting, this parameter is not visible and Diode with no dynamics is automatically selected.

### Dependencies

See the Diode Parameter Dependencies table.

### Forward voltage — Voltage

0.8 V (default) | scalar

Minimum voltage required across the positive and negative block ports for the gradient of the diode I-V characteristic to be  $1/R_{on}$ , where  $R_{on}$  is the value of **On resistance**.

**On resistance — Resistance**

0.001 Ohm (default) | scalar

Rate of change of voltage versus current above the **Forward voltage**.

**Off conductance — Conductance**

1e-5 1/Ohm (default) | scalar

Conductance of the reverse-biased diode.

**Junction capacitance — Capacitance**

50 nF (default) | scalar

Diode junction capacitance.

**Dependencies**

See the Diode Parameter Dependencies table.

**Peak reverse current,  $i_{RM}$  — Current**

-235 A (default) | scalar less than 0

Peak reverse current measured by an external test circuit.

**Dependencies**

See the Diode Parameter Dependencies table.

**Initial forward current when measuring  $i_{RM}$  — Current**

300 A (default) | scalar greater than 0

Initial forward current when measuring peak reverse current. This value must be greater than zero.

**Dependencies**

See the Diode Parameter Dependencies table.

**Rate of change of current when measuring  $i_{RM}$  — Current change rate**

-50 A/us (default) | scalar

Rate of change of current when measuring peak reverse current.

**Dependencies**

See the Diode Parameter Dependencies table.

**Reverse recovery time parameterization — Recovery-time model**

Specify stretch factor (default) | Specify reverse recovery time directly | Specify reverse recovery charge
