Simplified initialization mode was introduced in R2008b to improve the consistency of simulation results. For more information, see “Simplified Initialization Mode” and “Classic Initialization Mode”.

This Model Advisor check identifies settings in Discrete-Time Integrator blocks in your model that can cause problems if you use the simplified initialization mode. It also recommends settings for consistent behavior of Discrete-Time Integrator blocks. The results of the subchecks contain two types of statements: Failed and Warning. Failed statements identify issues that you must address manually before you can migrate the model to the simplified initialization mode. Warning statements identify issues or changes in behavior that can occur after migration.

## Results and Recommended Actions

Condition	Recommended Action
Check for Discrete-Time Integrator blocks whose parameter <b>Initial condition setting</b> is set to Output.	Determine if the new behavior of the Discrete-Time Integrator blocks is acceptable. If it is not acceptable, modify the model to account for the new behavior before migrating to the simplified initialization mode.
Check for Discrete-Time Integrator blocks whose <b>Initial condition setting</b> parameter is set to State (most efficient) and are in a subsystem that uses triggered sample time.	Use periodic sample time for the block, or set <b>Initial Condition setting</b> to Output.
Check for blocks inside of the Iterator Subsystem that require elapsed time.	<p>Within an Iterator Subsystem hierarchy, do not use blocks that require a service that maintains the time that has elapsed between two consecutive executions.</p> <p>Since an Iterator Subsystem can execute multiple times at a given time step, the concept of elapsed time is not well-defined between two such executions. Using these blocks inside of an Iterator Subsystem can cause unexpected behavior.</p>

## Check model settings for migration to simplified initialization mode

---

**Note** Do not run this check in isolation. Run this check along with the other checks in the “Migrating to Simplified Initialization Mode Overview” on page 9-4.

---

**Check ID:** mathworks.design.ModelLevelMessages

Identify settings in Model blocks and model configuration parameters that can lead to unexpected behavior, and help migrate your model to simplified initialization mode.

### Description

Simplified initialization mode was introduced in R2008b to improve consistency of simulation results. For more information, see “Simplified Initialization Mode” and “Classic Initialization Mode”.

This Model Advisor check identifies issues in the model configuration parameters and Model blocks in your model that can cause problems when you migrate to simplified initialization mode. The results of the subchecks contain two types of statements: Failed and Warning. Failed statements identify issues that you must address manually before you can migrate the model to simplified initialization mode. Warning statements identify issues or changes in behavior that can occur after migration.

After running this Model Advisor consistency check, if you click **Explore Result** button, the messages pertain only to blocks that are not library-links.

---

**Note** Because it is difficult to undo these changes, select **File > Save Restore Point As** to back up your model before migrating to the simplified initialization mode.

---

For more information, see “Model Configuration Parameters: Connectivity Diagnostics”.

### Results and Recommended Actions

Condition	Recommended Action
Verify that all Model blocks are using the simplified initialization mode.	Migrate the model referenced by the Model block to the simplified initialization mode, then migrate the top model.
Verify simplified initialization mode setting	Set <b>Configuration Parameters &gt; Underspecified initialization detection</b> to Simplified.

### Action Results

Clicking **Modify Settings** causes the following:

- The Model parameter is set to **simplified**
- If an Outport block has the **Initial output** parameter set to the empty character vector, [], then the **SourceOfInitialOutputValue** parameter is set to **Input signal**.
- If an Outport has an empty **Initial output** and a variable-size signal, then the **Initial output** is set to zero.

### See Also

- “Migrating to Simplified Initialization Mode Overview” on page 9-4

## Check S-functions in the model

**Check ID:** `mathworks.design.SFuncAnalyzer`

Perform quality checks on S-functions in Simulink models or subsystems.

**Description**

The S-function analyzer performs quality checks on S-functions to identify improvements and potential problems in the specified model. The checks displays an error when the build dependency cannot be automatically derived, for example, when the source code is not in the current folder.

**Results and Recommended Actions**

Condition	Recommended Action
Continuous states are modified in <code>mdlOutputs</code> method.	Modify Continuous States at a major time step and use <code>ssSetSolverNeedsReset</code> function in S-function code.
Continuous states are modified in the <code>mdlUpdate</code> method.	Modify Continuous States only at a major time step and use <code>ssSetSolverNeedsReset</code> function in S-function code.
S-function discrete states are modified in the <code>mdlOutputs</code> at a minor step.	Modify the discrete states only at a major step guarded by <code>ssIsMajorTimeStep</code> function.
S-function mode vector is modified in the <code>mdlOutputs</code> method at a minor step.	Modify the mode vector only at a major step guarded by <code>ssIsMajorTimeStep</code> function.
S-function is using static or global variables to declare internal states.	Declare the states explicitly using <code>ssSetNumDiscStates</code> function or "Model Global Data by Creating Data Stores".
S-function has continuous states but sample time is not declared continuous.	Specify continuous sample time using <code>ssSetSampleTime</code> function.
S-function has discrete states but the <code>mdlOutputs</code> and <code>mdlUpdate</code> methods are combined.	Define the <code>mdlOutputs</code> and <code>mdlUpdate</code> methods separately and modify discrete states only in <code>mdlUpdate</code> method.
S-function sets the <code>SS_OPTION_CAN_BE_CALLED_CONDITIONALLY</code> option when having state-like data or multiple sample times.	Remove the options when the S-function has state-like data or multiple sample times.
MEX compilers do not exist on the machine.	Check for the presence or install MEX compilers on the machine.
S-function encounters errors while compiling the model.	Check the <b>Diagnostic Viewer</b> output and recompile the model.

**Check for non-continuous signals driving derivative ports****Check ID:** `mathworks.design.NonContSigDerivPort`

Identify noncontinuous signals that drive derivative ports.

**Description**

Noncontinuous signals that drive derivative ports cause the solver to reset every time the signal changes value, which slows down simulation.

**Results and Recommended Actions**

Condition	Recommended Action
There are noncontinuous signals in the model driving derivative ports.	<ul style="list-style-type: none"> <li>• Make the specified signals continuous.</li> <li>• Replace the continuous blocks receiving these signals with discrete state versions of the blocks.</li> </ul>

**Capabilities and Limitations**

If you have a Simulink Check license, you can exclude blocks and charts from this check.

**See Also**

- “Simulink Models” on page 11-6
- “Simulation Phases in Dynamic Systems”
- “Model Advisor Exclusion Overview” (Simulink Check)

**Runtime diagnostics for S-functions**

**Check ID:** `mathworks.design.DiagnosticSFcn`

Check array bounds and solver consistency if S-Function blocks are in the model.

**Description**

Validates whether S-Function blocks adhere to the ODE solver consistency rules that Simulink applies to its built-in blocks.

**Results and Recommended Actions**

Condition	Recommended Action
<b>Solver data inconsistency</b> is set to none.	In the Configuration Parameters dialog box, set <b>Solver data inconsistency</b> to warning or error.
<b>Array bounds exceeded</b> is set to none.	In the Configuration Parameters dialog box, set <b>Array bounds exceeded</b> to warning or error

**Capabilities and Limitations**

If you have a Simulink Check license, you can exclude blocks and charts from this check.

**See Also**

- “What Is an S-Function?”

- “How S-Functions Work”

## Identify unit mismatches in the model

**Check ID:** `mathworks.design.UnitMismatches`

Identify instances of unit mismatches between ports in the model.

### Description

Check for instances of unit mismatches between ports in the model.

### Results and Recommended Actions

Condition	Recommended Action
Unit mismatches found	Change one of the mismatched unit settings to match the unit settings for the other port.

### See Also

- “Unit Specification in Simulink Models”.

## Identify automatic unit conversions in the model

**Check ID:** `mathworks.design.AutoUnitConversions`

Identify instances of automatic unit conversions in the model.

### Description

Identify instances of automatic unit conversions in the model.

### Results and Recommended Actions

Condition	Recommended Action
Automatic unit conversions found	Check that the converted units are expected for the model.

### See Also

- “Unit Specification in Simulink Models”.

## Identify disallowed unit systems in the model

**Check ID:** `mathworks.design.DisallowedUnitSystems`

Identify instances of disallowed unit systems in the model.

**Description**

Identify instances of disallowed unit systems in the model.

**Results and Recommended Actions**

Condition	Recommended Action
Disallowed unit systems found	Either choose a unit that conforms to the configured unit system, or select another unit system. For more information, see “Restricting Unit Systems”.

**See Also**

- “Unit Specification in Simulink Models”.

**Identify undefined units in the model**

**Check ID:** `mathworks.design.UndefinedUnits`

Identify instances of unit specifications, not defined in the unit database, in the model.

**Description**

Identify instances of unit specifications, not defined in the unit database, in the model.

**Results and Recommended Actions**

Condition	Recommended Action
Undefined units found	Change the unit to one that Simulink supports.

**See Also**

- “Unit Specification in Simulink Models”.
- Allowed Units

**Identify ambiguous units in the model**

**Check ID:** `mathworks.design.AmbiguousUnits`

Identify instances of ambiguous unit specifications, such as duplicate unit names in the unit database, in the model.

**Description**

Identify instances of ambiguous unit specifications, such as duplicate unit names in the unit database, in the model.

## Results and Recommended Actions

Condition	Recommended Action
Ambiguous units found	You can ignore the warning or specify the unit with corresponding unit system using the format <code>unit_system::unit_name</code> .

### See Also

- “Unit Specification in Simulink Models”.
- Allowed Units

## Check model for block upgrade issues

**Check ID:** `mathworks.design.Update`

Check for common block upgrade issues.

### Description

Check blocks in the model for compatibility issues resulting from using a new version of Simulink software.

## Results and Recommended Actions

Condition	Recommended Action
Blocks with compatibility issues found.	Click <b>Modify</b> to fix the detected block issues.
Check update status for the Level 2 API S-functions.	Consider replacing Level 1 S-functions with Level 2.

### Action Results

Clicking **Modify** replaces blocks from a previous release of Simulink software with the latest versions.

### See Also

- “Write Level-2 MATLAB S-Functions”.
- “Consult the Upgrade Advisor”.
- “Model Upgrades”

## Check model for block upgrade issues requiring compile time information

**Check ID:** `mathworks.design.UpdateRequireCompile`

Check for common block upgrade issues.

## Description

Check blocks for compatibility issues resulting from upgrading to a new version of Simulink software. Some block upgrades require the collection of information or data when the model is in the compile mode. For this check, the model is set to compiled mode and then checked for upgrades.

## Results and Recommended Actions

Condition	Recommended Action
Model contains Lookup Table or Lookup Table (2-D) blocks and some of the blocks specify <b>Use Input Nearest</b> or <b>Use Input Above</b> for a lookup method.	Replace Lookup Table blocks and Lookup Table (2-D) blocks with n-D Lookup Table blocks. Do not apply <b>Use Input Nearest</b> or <b>Use Input Above</b> for lookup methods; select another option.
Model contains Lookup Table or Lookup Table (2-D) blocks and some blocks perform multiplication first during interpolation.	Replace Lookup Table blocks and Lookup Table (2-D) blocks with n-D Lookup Table blocks. However, because the n-D Lookup Table block performs division first, this replacement might cause a numerical difference in the result.
Model contains Lookup Table or Lookup Table (2-D) blocks. Some of these blocks specify <b>Interpolation-Extrapolation</b> as the <b>Lookup method</b> but their input and output are not the same floating-point type.	Replace Lookup Table blocks and Lookup Table (2-D) blocks with n-D Lookup Table blocks. Then change the extrapolation method or the port data types for block replacement.
Model contains Unit Delay blocks with <b>Sample time</b> set to -1 that inherit a continuous sample time.	Replace Unit Delay blocks with Memory blocks.

## Check Data Store Memory blocks for multitasking

### Action Results

Clicking **Modify** replaces blocks from a previous release of Simulink software with the latest versions.

### See Also

- n-D Lookup Table
- Unit Delay

## Check if SLX file compression is off

**Check ID:** `mathworks.design.CheckSLXFileCompressionLevel`

Check if SLX file compression is turned off to reduce Git™ repository size.

**Description**

Check whether compression for the SLX model is turned off.

**Results and Recommended Actions**

Condition	Recommended Action
Model, library, or subsystem is saved in SLX format. File compression is turned on.	Consider turning off file compression to optimize storage under source control.

**Capabilities and Limitations**

You can run this check on models, libraries, and subsystems checked in to Git source control.

**See Also**

- “Consult the Upgrade Advisor”.
- “Model Upgrades”

**Check that the model or library is saved in current version**

**Check ID:** `mathworks.design.CheckSavedInCurrentVersion`

Check that the model, library, or subsystem is saved in the current version of Simulink.

**Description**

Check whether the model file is saved in the current Simulink release.

**Results and Recommended Actions**

Condition	Recommended Action
Model, library, or subsystem not saved in the current version of Simulink.	Consider resaving the model file in the current version of Simulink.

**Capabilities and Limitations**

You can run this check on your models, libraries, and subsystems.

**Tips**

Projects can help you save all the models and libraries in your project to the current Simulink release. See “Upgrade All Project Models, Libraries, and MATLAB Code Files”.

**See Also**

- “Consult the Upgrade Advisor”.
- “Model Upgrades”
- “Upgrade All Project Models, Libraries, and MATLAB Code Files”

**Check model for SB2SL blocks**

**Check ID:** `mathworks.simulink.SB2SL.Check`

Check that the model does not have outdated SB2SL blocks.

### Description

Check if the model contains outdated SB2SL blocks.

### Results and Recommended Actions

Condition	Recommended Action
Model contains outdated SB2SL blocks	Consider upgrading the model to current SB2SL blocks.

### Action Results

Clicking **Update SB2SL Blocks** replaces blocks with the latest versions.

### See Also

- “Consult the Upgrade Advisor”.

## Check Model History properties

**Check ID:** `mathworks.design.SLXModelProperties`

Check for edited model history properties

### Description

Check models for edited Model History property values that could be used with source control tool keyword substitution. This keyword substitution is incompatible with SLX file format.

In the MDL file format you can configure some model properties to make use of source control tool keyword substitution. If you save your model in SLX format, source control tools cannot perform keyword substitution. Information in the model file from such keyword substitution is cached when you first save the MDL file as SLX, and is not updated again. The Model Properties History pane and Model Info blocks in your model show stale information from then on.

### Results and Recommended Actions

Condition	Recommended Action
Edited model history properties	Manually or automatically reset the properties to the default values. Click the button to reset, or to inspect and change these properties manually, open the Model Properties dialog and look in the History pane.

### Capabilities and Limitations

You can run this check on your library models.

**See Also**

- “Consult the Upgrade Advisor”.
- “Model Upgrades”

**Identify Model Info blocks that can interact with external source control tools**

**Check ID:** `mathworks.design.ModelInfoKeywordSubstitution`

Use this check to find Model Info blocks that can be altered by external source control tools through keyword substitution.

**Description**

This check searches for character vectors in the Model Info block enclosed within dollar signs that can be overwritten by an external source control tool. Using third-party source control tool keyword expansion might corrupt your model files when you submit them. Keyword substitution is not available in SLX model file format.

For a more flexible interface to source control tools, use a Simulink project instead of the Model Info block. See “About Source Control with Projects”.

**Results and Recommended Actions**

Condition	Recommended Action
The Model Info block contains fields like this: <code>\$keyword\$</code>	Review the list of fields in the report, then remove the keyword character vectors from the Model Info block.

**See Also**

- “Consult the Upgrade Advisor”.
- “About Source Control with Projects”

**Identify Model Info blocks that use the Configuration Manager**

**Check ID:** `mathworks.design.ModelInfoConfigurationManager`

Use this check to find Model Info blocks that use the Configuration Manager.

**Description**

Model Info blocks using the Configuration Manager allow risky keyword substitution using external source control tools. Using third-party source control tool keyword expansion might corrupt your model files when you submit them. Keyword substitution is not available in SLX model file format. The Configuration Manager for the Model Info block will be removed in a future release.

For a more flexible interface to source control tools, use a Simulink project instead of the Model Info block. See “About Source Control with Projects”.

**Results and Recommended Actions**

Condition	Recommended Action
A Model Info block is using the Configuration Manager.	Click <b>Remove the Configuration Manager</b> .

**See Also**

- “Consult the Upgrade Advisor”.
- “About Source Control with Projects”

**Check model for upgradable SerDes Toolbox blocks**

**Check ID:** `mathworks.design.serdesUpgrades`

Lists blocks saved in a previous version of SerDes Toolbox™ that are outdated.

**Description**

This check searches for and lists SerDes Toolbox blocks that can be upgraded for compatibility with the current release.

**Results and Recommended Actions**

Condition	Recommended Action
Blocks saved in older versions of SerDes Toolbox are found.	Click <b>Upgrade SerDes Toolbox Blocks</b> to upgrade the SerDes Toolbox blocks to be compatible with the current release.

**Action Results**

Clicking **Upgrade SerDes Toolbox Blocks** upgrades the outdated SerDes Toolbox blocks to be compatible with the current release.

**See Also**

- “Design and Simulate SerDes Systems” (SerDes Toolbox)

**Check model for legacy 3DoF or 6DoF blocks**

**Check ID:** `mathworks.design.Aeroblks.CheckDOF`

Lists 3DoF and 6DoF blocks are outdated.

**Description**

This check searches for 3DoF and 6DoF blocks from library versions prior to 3.13 (R2014a).

## Results and Recommended Actions

Condition	Recommended Action
Blocks configured with old versions of 3DoF or 6DoF blocks found.	Click <b>Replace 3DoF and 6DoF Blocks</b> to replace the blocks with latest versions.

### Action Results

Clicking **Replace 3DoF and 6DoF Blocks** replaces blocks with the latest versions.

### See Also

- “Equations of Motion” (Aerospace Blockset)

## Check model for Aerospace Blockset navigation blocks

**Check ID:** `mathworks.design.Aeroblks.CheckNAV`

Searches for Three-Axis Inertial Measurement Unit, Three-Axis Gyroscope, and Three-Axis Accelerometer blocks prior to 3.21 (R2018a).

### Description

This check searches for Three-Axis Inertial Measurement Unit, Three-Axis Gyroscope, and Three-Axis Accelerometer blocks that have been updated in R2018a.

## Results and Recommended Actions

Condition	Recommended Action
Three-Axis Inertial Measurement Unit, Three-Axis Gyroscope, and Three-Axis Accelerometer blocks prior to R2018a.	In R2018a or later, if you did not previously solve for steady state conditions, save the model now. If you previously solved for steady state conditions for the model, solve for these steady state conditions again, and then save the model.

### See Also

- Three-axis Accelerometer
- Three-axis Gyroscope
- Three-axis Inertial Measurement Unit

## Check and update masked blocks in library to use promoted parameters

**Check ID:** `mathworks.design.CheckAndUpdateOldMaskedBuiltinBlocks`

Check for libraries that should be updated to use promoted parameters.

**Description**

This check searches libraries created before R2011b for masked blocks that should be updated to use promoted parameters. Since R2011b, if a block parameter is not promoted, its value in the linked block is locked to its value in the library block. This check excludes blocks of type Subsystem, Model reference, S-Function and M-S-Function.

**Results and Recommended Actions**

Condition	Recommended Action
Libraries that need to be updated are found	Click <b>Update</b> . Once the libraries have been updated, run the check again

**Capabilities and Limitations**

You can:

- Run this check on your library models.
- Exclude blocks and charts from this check if you have a Simulink Check license.

**See Also**

- “Consult the Upgrade Advisor”.
- “Model Upgrades”
- “Model Advisor Exclusion Overview” (Simulink Check)

**Check and update mask image display commands with unnecessary imread() function calls**

**Check ID:** `mathworks.design.CheckMaskDisplayImageFormat`

Check identifies masks using image display commands with unnecessary calls to the `imread()` function.

**Description**

This check searches for the mask display commands that make unnecessary calls to the `imread()` function, and updates them with mask display commands that do not call the `imread()` function. Since 2013a, a performance and memory optimization is available for mask images specified using the image path instead of the RGB triple matrix.

**Results and Recommended Actions**

Condition	Recommended Action
Mask display commands that make unnecessary calls to the <code>imread()</code> function are found.	Click <b>Update</b> . Once the blocks have been updated, run the check again.

**Capabilities and Limitations**

You can:

- Run this check on your library models.
- Exclude blocks and charts from this check if you have a Simulink Check license.

### See Also

- “Consult the Upgrade Advisor”.
- “Model Upgrades”
- “Model Advisor Exclusion Overview” (Simulink Check)

## Check and update mask to affirm icon drawing commands dependency on mask workspace

**Check ID:** `mathworks.design.CheckMaskRunInitFlag`

Check identifies if the mask icon drawing commands have dependency on the mask workspace.

### Description

This check identifies if the mask icon drawing commands have dependency on the mask workspace and updates the `RunInitForIconRedraw` property accordingly. If there is no mask workspace dependency, the value of `RunInitForIconRedraw` is set to `off`, whereas, if there is mask workspace dependency the values is set to `on`.

Setting the values of `RunInitForIconRedraw` to `off` when there is no mask workspace dependency optimizes the performance by not executing the mask initialization code before drawing the block icon.

### Results and Recommended Actions

Condition	Recommended Action
Mask drawing commands that are dependent or independent of the mask workspace are found.	Click <b>Update</b> . Once the blocks have been updated, run the check again.

### Capabilities and Limitations

You can:

- Run this check on your library models.
- Exclude blocks and charts from this check if you have a Simulink Check license.

### See Also

- “Consult the Upgrade Advisor”.
- “Model Upgrades”
- “Model Advisor Exclusion Overview” (Simulink Check)

## Identify masked blocks that specify tabs in mask dialog using `MaskTabNames` parameter

**Check ID:** `mathworks.design.CheckAndUpdateOldMaskTabnames`

This check identifies masked blocks that specify tabs in mask dialog using the `MaskTabNames` parameter.

### Description

This check identifies masked blocks that use the `MaskTabNames` parameter to programmatically create tabs in the mask dialog. Since R2013b, dialog controls are used to group parameters in a tab on the mask dialog.

### Results and Recommended Actions

Condition	Recommended Action
Masked blocks that use the <code>MaskTabNames</code> parameter to create tabs programmatically in the mask dialog are found.	Click <b>Upgrade</b> available in the <b>Action</b> section. Once the blocks have been updated, run the check again.

### Capabilities and Limitations

You can run this check on your library models.

### See Also

- “Consult the Upgrade Advisor”.
- “Model Upgrades”

## Identify questionable operations for strict single-precision design

**Check ID:** `mathworks.design.StowawayDoubles`

For a strict single-precision design, this check identifies the blocks that introduce double-precision operations, and non-optimal model settings.

### Description

For a strict single-precision design, this check identifies the blocks that introduce double-precision operations, and non-optimal model settings.

### Results and Recommended Actions

Condition	Recommended Action
Double-precision floating-point operations found in model.	Verify that: <ul style="list-style-type: none"> <li>• Block input and output data types are set correctly.</li> <li>• In the Configuration Parameters dialog box, <b>Default for underspecified data type</b> is set to single.</li> </ul>

Condition	Recommended Action
Model uses a library standard that is not optimal for strict-single designs.	Verify that: <ul style="list-style-type: none"> <li>All target-specific math libraries used by the model support single-precision implementations.</li> </ul> Set <b>Configuration Parameters &gt; Language standard</b> to C99 (ISO).
Logic signals are not implemented as Boolean data.	Verify that: <ul style="list-style-type: none"> <li>In the Configuration Parameters dialog box, <b>Implement logic signals as Boolean data</b> is selected.</li> </ul>

### Capabilities and Limitations

If you have a Simulink Check license, you can exclude blocks and charts from this check.

### See Also

- “Validate a Floating-Point Embedded Model”
- “Consult the Upgrade Advisor”.

- “Model Advisor Exclusion Overview” (Simulink Check)

## Check `get_param` calls for block `CompiledSampleTime`

**Check ID:** `mathworks.design.CallsGetParamCompiledSampleTime`

Use this check to identify MATLAB files in your working environment that contain `get_param` function calls to return the block `CompiledSampleTime` parameter.

### Description

For multi-rate blocks (including subsystems), Simulink returns the block compiled sample time as a cell array of the sample rates in the block. The return value is a cell array of pairs of doubles. MATLAB code that accepts this return value only as pairs of doubles can return an error when called with a multi-rate block. Use this check to identify such code in your environment. Modify these instances of code to accept a cell array of pairs of doubles instead.

For example, consider a variable `blkTs`, which has been assigned the compiled sample time of a multi-rate block.

```
blkTs = get_param(block, 'CompiledSampleTime');
```

Here are some examples in which the original code works only if `blkTs` is a pair of doubles and the block is a single-rate block:

- Example 1

```
if isinf(blkTs(1))
 disp('found constant sample time')
end
```

Since blkTs is now a cell array, Simulink gives this error message:

Undefined function 'isinf' for input arguments of type 'cell'

Instead, use this code, for which blkTs can be a cell array or a pair of doubles.

```
if isequal(blkTs, [inf,0])
 disp('found constant sample time')
end
```

- Example 2

```
if all(blkTs == [-1,-1])
 disp('found triggered sample time')
end
```

For the above example, since blkTs is now a cell array, Simulink gives this error:

Undefined function 'eq' for input arguments of type 'cell'

Instead, use this code, for which blkTs can be a cell array or a pair of doubles.

```
if isequal(blkTs, [-1,-1])
 disp('found triggered sample time')
end
```

- Example 3

```
if (blkTs(1) == -1)
 disp('found a triggered context')
end
```

Again, since blkTs is now a cell array, Simulink gives this error:

Undefined function 'eq' for input arguments of type 'cell'

Instead, use this code.

```
if ~iscell(blkTs)
 blkTs = {blkTs};
end
for idx = 1:length(blkTs)
 thisTs = blkTs{idx};
 if (thisTs(1) == -1)
 disp('found a triggered context')
 end
end
```

The above code checks for a triggered type sample time (triggered or async). In cases in which a block has constant sample time ([inf,0]) in addition to triggered or async or when a block has multiple async rates, this alternative property detects the triggered type sample time.

This check scans MATLAB files in your environment. If the check finds instances of MATLAB code that contain `get_param` calls to output the block compiled sample time, Upgrade Advisor displays these results. It suggests that you modify code that accepts the block compiled sample time from multi-rate blocks.

### Results and Recommended Actions

Condition	Recommended Action
No MATLAB files call <code>get_param(block,CompiledSampleTime)</code>	None
Some MATLAB files call <code>get_param(block,CompiledSampleTime)</code>	If files use the block <code>CompiledSampleTime</code> parameter from multi-rate blocks, modify these files to accept the parameter as a cell array of pairs of doubles

#### See Also

- “Sample Times in Subsystems”
- “Block Compiled Sample Time”

## Check if all simulation outputs are returned as a single `Simulink.SimulationOutput` object

**Check ID:** `mathworks.design.CheckSingleSimulationOutput`

Use this check to identify if the simulation result is returned as a single `Simulink.SimulationOutput` object.

#### Description

This check scans your model to verify if the parameter `ReturnWorkspaceOutputs` is enabled. Enabling this parameter, returns simulation outputs in a `Simulink.SimulationOutput` when simulating interactively. Simulation outputs include signal, state, output, DSM logging, and scope and To Workspace block logging.

When `ReturnWorkspaceOutputs` is enabled, it provides:

- Easier management of simulation data.
- Automatic access to `SimulationMetadata`.
- Compatibility with multiple parallel simulations and batch simulations.

### Results and Recommended Actions

Condition	Recommended Action
Simulation outputs are not returned as a single <code>Simulink.SimulationOutput</code> object	Return all simulation outputs as a single <code>Simulink.SimulationOutput</code> object

#### See Also

- “Single simulation output”
- `Simulink.SimulationOutput`

## Check model for parameter initialization and tuning issues

**Check ID:** `mathworks.design.ParameterTuning`

Use this check to identify issues in the model that occur when you initialize parameters or tune them.

**Description**

This check scans your model for parameter initialization and tuning issues like:

- Rate mismatch between blocks
- Divide by zero issue in conditionally executed subsystems
- Invalid control port value in Index Vector blocks

**Results and Recommended Actions**

Condition	Recommended Action
The model has rate transition issues.	Select <b>Automatically handle rate transition for data transfer</b> in the <b>Solver</b> pane of the model configuration parameters.
The model has a divide by zero issue in a conditionally executed subsystem with a control port.	At the command prompt, run <code>set_param(control_port, 'DisallowConstTsAndPrmTs', 'on')</code>
The model has an invalid control port value in a conditionally executed subsystem.	At the command prompt, run <code>set_param(control_port, 'DisallowConstTsAndPrmTs', 'on')</code>

**Action Results**

Select **Upgrade model** to resolve issues in the model related to parameter initialization and tuning.

**See Also**

- “Automatic Rate Transition”

**Check for virtual bus across model reference boundaries****Check ID:** `mathworks.design.CheckVirtualBusAcrossModelReference`

Check virtual bus signals that cross model reference boundaries.

**Description**

This check identifies root-level Inport and Outport blocks in referenced models and Model blocks with virtual bus outputs that require updates to change to nonvirtual bus signals.

If the check identifies issues, click **Update Model** to convert root-level Inport and Outport blocks configured for virtual buses to use nonvirtual buses in these situations:

- For root-level Inport blocks — Enable the **Output as nonvirtual bus** parameter and insert a Signal Conversion block after the Inport block. The Signal Conversion block is configured to output a virtual bus.
- For root-level Outport blocks — Enable the **Output as nonvirtual bus in parent model** parameter.

- For Model blocks — For ports whose Outport blocks were updated to address issues, insert a Signal Conversion block after the corresponding ports of the Model block. The Signal Conversion block is configured to output a virtual bus.

### Recommended Action and Results

To resolve issues, click **Upgrade Model**.

---

**Note** Run the **Analyze model hierarchy and continue upgrade sequence** check on the top-level model and then down through the model reference hierarchy.

---

Clicking **Upgrade Model** converts affected root-level Inport and Outport blocks configured for virtual buses to use nonvirtual buses in models where you:

- Use function prototype control
- Perform C++ code generation with the I/O arguments step method option.

Alternatively, you can change the C++ code generation function specification setting to Default step method:

- 1 In the **Configuration Parameters > Code Generation > Interface** pane, click **Configure C++ Class Interface**.
  - 2 In the dialog box, set the **Function specification** parameter to Default step method.
- Use buses that have variable-dimension signals
  - Use an associated non-auto storage class for Outport block signals
    - The conversion for non-auto storage class occurs only if you have the target generation license that the model requires. For example, an ERT target requires an Embedded Coder license.
  - Use Export-function models where an Outport block is driven by a nonvirtual bus
  - Have Model blocks that reference models containing Outport blocks that have been fixed — Clicking **Upgrade Model** updates Model blocks referencing the models that had Outport blocks fixed by the **Analyze model hierarchy and continue upgrade sequence** check.

## Check model for custom library blocks that rely on frame status of the signal

**Check ID:** `mathworks.design.DSPFrameUpgrade`

This check identifies custom library blocks in the model that depend on the frame status of the signal.

### Description

This check searches for the custom library blocks in a model that depend on the frame status of the signal. The check analyzes the blocks, recommends fixes, and gives reasons for the fixes. You must make the fixes manually.

### Results and Recommended Actions

Condition	Recommended Action
The check finds custom library blocks that depend on the frame status of the signal.	Follow the recommendation given by the Upgrade Advisor.

### Capabilities and Limitations

You can run this check only on custom library blocks in your model.

You must make the fixes manually.

This check appears only if you have the DSP System Toolbox installed.

### See Also

“Frame-based processing” (DSP System Toolbox)

## Check model for S-function upgrade issues

**Check ID:** 'mathworks.design.CheckForSFcnUpgradeIssues'

Use this check on your model to identify your S-function's upgrade compatibility issues. These issues may include the use of 32-bit APIs, compilation with incompatible options, or use of deprecated separate complex APIs. Some common issues and information related to the fixes are described in results and recommendations section below.

### Description

When upgrading your S-functions to use the features in the latest release, this check scans your model to warn against S-function upgrade incompatibility issues. If the result of this check gives a warning or error, fix your C MEX S-functions according to the description.

### Results and Recommended Actions

Condition	Recommended Action
Custom-built S-functions are not supported.	Recompile your S-function with available compatible options. See “Custom-built MEX File Not Supported In Current Release” for more information.
S-function is not compiled with the latest API (mex -R2018a).	Recompile using the latest flag (mex -R2018a). See “MEX File Is Compiled With Outdated Option” for more information.
S-function uses 32-bit functions.	Modify your code according to the instructions in “MEX File Calls A 32-bit Function”.
S-function is using deprecated separate complex APIs (mxGetPi, mxSetPi, mxGetImagData, mxSetImagData).	Use interleaved complex APIs and recompile your code with the latest flag (mex -R2018a). See “Upgrade MEX Files to Use Interleaved Complex API” for more information.

Condition	Recommended Action
S-function is using deprecated type-unsafe data API (mxGetData, mxSetData).	Use type-safe data APIs and recompile your code. See “MEX File Calls An Untyped Data Access Function” for more information.
S-function is compiled with a future release and not supported in current release.	See “MEX File Built In MATLAB Release Not Supported In Current Release” to recompile your files.

**See Also**

- “MATLAB Data in C S-Functions”

**Update System object syntax**

**Check ID:** 'mathworks.design.CheckSystemObjectUpdate'

Use this check to identify and update any custom MATLAB System object in your model that have outdated syntax.

**Description**

This check scans your model to identify outdated System object syntax. If the check passes, all the syntax is up to date. If the check fails, you can update the syntax.

**Results and Recommended Actions**

Condition	Recommended Action
System object syntax is up to date.	None.
System object syntax requires update.	A report is generated for each unique System object associated with a MATLAB System block. Use <b>Update</b> to update the syntax.

**See Also**

- “Consult the Upgrade Advisor”

**Check Rapid accelerator signal logging**

**Check ID:** mathworks.design.CheckRapidAcceleratorSignalLogging

When simulating your model in rapid accelerator mode, use this check to find signals logged in your model that are globally disabled. Rapid accelerator mode supports signal logging. Use this check to enable signal logging globally.

**Description**

This check scans your model to see if a simulation is in rapid accelerator mode and whether the model contains signals with signal logging. If the check finds an instance and signal logging is globally disabled, an option to turn on signal logging globally appears.

## Results and Recommended Actions

Condition	Recommended Action
Simulation mode is not rapid accelerator.	None. You can enable signal logging in rapid accelerator mode.
Simulation mode is rapid accelerator. Upgrade Advisor did not find signals with signal logging enabled.	None. The model does not use signal logging. Enable signal logging for signals and globally if you want to log signals.
Simulation mode is rapid accelerator. Upgrade Advisor found signals with signal logging enabled. However, global setting for signal logging was disabled.	Enable signal logging globally if you want to log signals with signal logging enabled.
Signal logging was already globally enabled.	None.

### Action Results

Selecting **Modify** enables signal logging globally in your model.

### See Also

- “Consult the Upgrade Advisor”.

## Check virtual bus inputs to blocks

**Check ID:** `mathworks.design.VirtualBusUsage`

Check bus input signals for a set of blocks.

### Description

Check bus input signals for a set of blocks.

Starting in R2015b, virtual bus signal inputs to blocks that require nonbus or nonvirtual bus input can cause an error. Examples of blocks that can specify a bus object as their output data type include a Bus Creator block and a root Inport block. The blocks that cause an error when they have a virtual bus input in this situation are:

- Assignment
- Delay

The Delay block causes an error only if you use the Block Parameters dialog box to:

- Set an initial condition that is a MATLAB structure or zero.
- Specify a value for **State name**.

- Permute Dimension
- Reshape
- Selector
- Unit Delay

The Unit Delay block causes an error only if you use the Block Parameters dialog box to:

- Set an initial condition that is a MATLAB structure or zero.
- Specify a value for **State name**.
- Vector Concatenate

**Results and Recommended Actions**

Condition	Recommended Action
Virtual bus signal input to these blocks: <ul style="list-style-type: none"> <li>• Assignment</li> <li>• Delay (if you specify an initial condition from the dialog box that is a MATLAB structure or zero and the value for <b>State name</b> is not empty)</li> <li>• Permute Dimension</li> <li>• Reshape</li> <li>• Selector</li> <li>• Unit Delay (if you specify an initial condition that is a MATLAB structure or zero and the value for <b>State name</b> is not empty)</li> <li>• Vector Concatenate</li> </ul>	In the Upgrade Advisor, click <b>Modify</b> .  The check inserts a Bus to Vector block to attempt to convert virtual bus input signals to vector signals. For issues that the Upgrade Advisor identifies but cannot fix, modify the model manually. For details, see “Identify Automatic Bus Conversions”.

**Action Results**

Clicking **Modify** inserts a Bus to Vector block at the input ports of blocks.

For many models, running the Upgrade Advisor modifies your model so that bus signals are not treated as vectors. However, for some models you can encounter compatibility issues even after running the check. Modify your model manually to address those issues.

After you compile the model using Upgrade Advisor, the Simulink Editor sometimes indicates that you need to save the model (the model is dirty), even though you did not make changes. To prevent this issue from reoccurring for this model, save the model.

Modeling Pattern	Issue	Solution
Data Store Memory block with <b>Data Type</b> set to <b>Inherit: auto</b>	A Data Store Memory block whose associated Data Store Read or Data Store Write blocks read or write bus signal data must use a bus object.	In the Data Store Memory block, set the <b>Data Type</b> signal attribute to <b>Bus: &lt;BusObject&gt;</b> .
Signal Conversion block <b>Output</b> parameter matches input bus type	A Signal Conversion block whose <b>Output</b> parameter is set to <b>Nonvirtual</b> bus requires a virtual bus input.  A Signal Conversion block whose <b>Output</b> parameter is set to <b>Virtual</b> bus requires a nonvirtual bus input.	To create a copy of the input signal, set <b>Output</b> to <b>Signal copy</b> .

Modeling Pattern	Issue	Solution
Merge, Switch, or Multiport Switch block with multiple bus inputs	Merge, Switch, or Multiport Switch blocks with multiple bus inputs require those inputs to have the same names and hierarchy.	Reconfigure the model so that the bus inputs have the same names and hierarchy.
Root Inport block outputting a virtual bus and specifying a value for <b>Port dimensions</b>	A root Inport block that outputs to a virtual bus must inherit the dimensions.	Set the Inport block <b>Port dimensions</b> signal attribute to 1 or -1 ( <i>inherit</i> ).
Mux block with nonvirtual bus inputs	A Mux block cannot accept nonvirtual bus signals.	To treat the output as an array, replace the Mux block with a Vector Concatenate block.  If you want a virtual bus output, use a Bus Creator block to combine the signals.
Bus to Vector block without a virtual bus signal input	A nonbus signal does not need a Bus to Vector block.	Remove the Bus to Vector block.
Assignment block with virtual bus inputs	The Upgrade Advisor converts the Assignment block Y0 port bus input to a vector.	Add a Bus to Vector block before the Assignment block.
S-function using a nonvirtual bus	An S-function that is not a Level-2 C S-function does not support nonvirtual bus signals.	Change the S-function to be a Level-2 C S-function.  Consider using an S-Function Builder block to create a Level-2 C S-function.
Stateflow chart with parameterized data type	In a Stateflow chart, you cannot parameterize the data type of an input or output in terms of another input or output if the data type is a bus object.	For the parameterized port, set <b>Data Type</b> to Bus: <object name>.
Subsystem with bus operations in a Stateflow chart	An Inport block inside a subsystem in a Stateflow chart requires a bus object data type if its signal is a bus.	In the Inport block, set <b>Data type</b> to Bus: <object name>.
Ground block used as a bus source	The output signal of a Ground block cannot be a source for a bus.	Use a Constant block with <b>Constant value</b> set to 0 and the <b>Output data type</b> signal attribute set to Bus: <object name>.
Root Outport block with a single-element bus object data type	The input to the Outport block must be a bus if it specifies a bus object as its data type.	In the Outport block, set <b>Data type</b> to <i>Inherit: auto</i> .

## Check for root outports with constant sample time

**Check ID:** `mathworks.design.CheckConstRootOutportWithInterfaceUpgrade`

Use this check to identify root outports with a constant sample time used with an AUTOSAR target, Function Prototype Control, or the model C++ class interface.

### Description

Root outports with constant sample time are not supported when using an AUTOSAR target, Function Prototype Control, or the model C++ class interface. Use this check to identify root Output blocks with this condition and modify the blocks as recommended.

### Results and Recommended Actions

Condition	Recommended Action
Root output with constant sample time used with an AUTOSAR target, Function Prototype Control or the model C++ class interface.	Consider one of the following: <ul style="list-style-type: none"> <li>• Set the sample time of the block to the fundamental sample time.</li> <li>• Identify the source of the constant sample time and set its sample time to the fundamental sample time.</li> <li>• Place a Rate Transition block with inherited sample time (-1) before the block.</li> </ul>

### See Also

- “Consult the Upgrade Advisor”.

## Analyze model hierarchy and continue upgrade sequence

**Check ID:** `com.mathworks.Simulink.UpgradeAdvisor.UpgradeModelHierarchy`

Check for child models and guide you through upgrade checks.

### Description

This check identifies child models of this model, and guides you through upgrade checks to run both non-compile and compile checks. The Advisor provides tools to help with these tasks:

- If the check finds child models, it offers to run the Upgrade Advisor upon each child model in turn and continue the upgrade sequence. If you have a model hierarchy you need to check and update each child model in turn.
- If there are no child models, you still need to continue the check sequence until you have run both non-compile and compile checks.

You must run upgrade checks in this order: first the checks that do not require compile time information and do not trigger an Update Diagram, then the compile checks.

Click **Continue Upgrade Sequence** to run the next checks. If there are child models, this will open the next model. Keep clicking **Continue Upgrade Sequence** until the check passes.

### Results and Recommended Actions

Condition	Recommended Action
Child models found	Click <b>Continue Upgrade Sequence</b> to run the next checks. If there are child models, this will close the current Upgrade Advisor session, and open Upgrade Advisor for the next model in the hierarchy.
No child models, but more checks to run	If there are no child models, click <b>Continue Upgrade Sequence</b> to refresh the Upgrade Advisor with compilation checks selected. The compile checks trigger an Update Diagram (marked with ^). Run the next checks and take advised actions. When you return to this check, click <b>Continue Upgrade Sequence</b> until this check passes.

### Tips

Best practice for upgrading a model hierarchy is to check and upgrade each model starting at the leaf end and working up to the root model.

When you click **Continue Upgrade Sequence**, the Upgrade Advisor opens the leaf model as far inside the hierarchy as it can find. Subsequent steps guide you through upgrading your hierarchy from leaf to root model.

When you open the Upgrade Advisor, the checks that are selected do not require compile time information and do not trigger an Update Diagram. Checks that trigger an Update Diagram are not selected to run by default, and are marked with ^. When you use the Upgrade Advisor on a hierarchy, keep clicking **Continue Upgrade Sequence** to move through this sequence of analysis:

- 1 The Upgrade Advisor opens each model and library in turn, from leaf to root, and selects the non-compile checks. Run the checks, take any advised actions, then click **Continue Upgrade Sequence** to open the next model and continue.
- 2 When you reach the root end of the hierarchy, the Upgrade Advisor then opens each model again in the same order (but not libraries) and selects only the checks that require a model compile. Run the checks, take any advised actions, then click **Continue Upgrade Sequence** to open the next model. Continue until you reach the end of the hierarchy and this check passes.

### See Also

- “Consult the Upgrade Advisor”.

## Check Access to Data Stores

**Check ID:** mathworks.design.ConflictsForDataStoreReadWriters

Identify potential execution order sensitivity when reading and writing to data stores.

### Description

The execution order of blocks that read and write to the same data store can change the simulation result. When blocks in the same hierarchy access the same data store, the execution order is not deterministic.

### Results and Recommended Actions

Condition	Recommended Action
Data Store Memory block accessed by multiple blocks in the same hierarchy.	To enforce execution order for the blocks, consider the following: <ul style="list-style-type: none"> <li>• Add a data dependency between the blocks.</li> <li>• Set block priority.</li> <li>• Move blocks into separate Function-Call Subsystem blocks and schedule them.</li> </ul>

### See Also

- “Local and Global Data Stores”
- Data Store Memory
- Data Store Read
- Data Store Write

## Check relative execution orders for Data Store Read and Data Store Write blocks

**Check ID:** mathworks.design.TaskBasedSorting

Check relative execution order changes between legacy and task-based sorting for Data Store Read and Data Store Write blocks.

### Description

Legacy models used block sorting to determine block execution order. With task-based sorting, the relative execution order involving Data Store Memory blocks can change. This check detects the changes and provides an option to update your model with the original execution order.

### Results and Recommended Actions

Condition	Recommended Action
Execution order with a Data Store Memory block changes. You want the original execution order.	Click the <b>Modify</b> button.

**See Also**

- “Control and Display Execution Order”

**Check for case mismatches in references to models and libraries**

**Check ID:** `mathworks.design.CaseSensitiveBlockDiagramNames`

Identify and fix case-insensitive references to models and libraries.

**Description**

Starting R2020a, Simulink model and library names are case-sensitive. This check detects and provides an option to fix case-insensitive references to models and libraries.

**Results and Recommended Actions**

Condition	Recommended Action
The check finds case mismatches in references to models and libraries.	Follow the recommendation given by the Upgrade Advisor.

**See Also**

- “Consult the Upgrade Advisor”

**Check model for Signal Builder blocks**

**Check ID:** `mathworks.design.SigblDR.upgradeCheck`

Searches for Signal Builder blocks in models.

**Description**

Find Signal Builder blocks in models and replace them with equivalently configured Signal Editor blocks.

**Results and Recommended Actions**

Condition	Recommended Action
Model contains one or more Signal Builder blocks.	To replace all Signal Builder blocks with equivalent Signal Editor blocks, click the associated link.

**See Also**

- Signal Editor
- “Consult the Upgrade Advisor”

**Check output dimensions of MATLAB Function blocks**

**Check ID:** `mathworks.simulink.MLFBOutputDimensions`

Check lists all the MATLAB Function blocks that have the **Interpret output column vectors as one-dimensional data** property enabled. If the property is enabled, the block converts output column vectors of size N-by-1 to one-dimensional signals with a signal size equal to N.

### Results and Recommended Actions

Condition	Recommended Action
MATLAB Function block produces one-dimensional output data and has property enabled	<p>Clicking the <b>Fix It</b> button does not disable the property for the MATLAB function block. To disable the property:</p> <ol style="list-style-type: none"> <li>1 Select the MATLAB Function block.</li> <li>2 Open the Property Inspector. In the <b>Modeling</b> tab, in the <b>Design</b> section, click <b>Property Inspector</b>.</li> <li>3 In the <b>General</b> tab, clear the <b>Interpret output column vectors as one-dimensional data</b> property.</li> </ol> <p>Check the simulation behavior of the model, as disabling the property changes the size propagation of the MATLAB function block.</p>
MATLAB Function block does not produce one-dimensional data and has property enabled	Click the <b>Fix It</b> button to disable the property for the MATLAB function block.

### See Also

- “Consult the Upgrade Advisor”
- “Interpret output column vectors as one-dimensional data”

## Check model for RF Blockset Divider blocks using Wilkinson power divider component with broken connections

**Check ID:** `mathworks.design.rfblockset.ce.checkDisconnectedDividerBlocks`

Search the model and list the RF Blockset™ Divider blocks using the Wilkinson power divider component with broken port connections on port **3**.

### Description

Starting R2021a, port positions of the RF Blockset Divider blocks using the Wilkinson power divider component are changed. This check searches and lists the Divider blocks using the Wilkinson power divider component model with broken port connections on port 3 prior to R2021a. You can then rewire the connections using the Modify button.

### Results and Recommended Actions

Condition	Recommended Action
Models have RF Blockset Divider blocks using the Wilkinson power divider component with broken port connections on port 3.	Click the <b>Modify</b> button to rewire the broken connections on port 3 of the RF Blockset Divider blocks.

### Action Results

Clicking **Modify** rewires the broken port connections on port 3 of the RF Blockset Divider blocks.

**Note** The **Modify** button will attempt to automatically rewire all the broken connections at port 3 of the Divider blocks using the Wilkinson power divider component in your model. To ensure accuracy, you must subsequently:

- Examine the details listed under the **Result** pane of the Upgrade Advisor.
- The first list enumerates the RF Blockset Divider blocks using the Wilkinson power divider component that require manual rewiring due to model complexity.
- The second list enumerates the automatically rewired blocks.
- Fixed and unfixed Divider blocks are temporarily highlighted in colors green and red, respectively. Click the **Remove all temporary block highlighting** link at the bottom of the **Result** pane to remove the highlights.

### See Also

- “Consult the Upgrade Advisor”

## Identify Environment Controller Blocks and Replace Them with Variant Source Blocks

**Check ID:**mathworks.design.ReplaceEnvironmentControllerBlk

Search for Environment Controller blocks in the model.

### Description

Find Environment Controller blocks in the model and replace them with Variant Source blocks with the **Variant control mode** parameter set to 'sim codegen switching'.

### Results and Recommended Actions

Condition	Recommended Action
Model contains one or more Environment Controller blocks.	Replace Environment Controller blocks with Variant Source blocks with the <b>Variant control mode</b> parameter set to 'sim codegen switching'.

**Capabilities and Limitations**

- You can run this check on your library models.
- You cannot use this check to identify Environment Controller blocks in referenced models and linked blocks.

**See Also**

- “Environment Controller block has been removed” on page 1-624
- Variant Source

**Identify variant blocks with VariantActivation set to "Inherit From Simulink.VariantControl" but does not use Simulink.VariantControl**

**Check ID:** `mathworks.simulink.InheritVATFromSlVarCtrlCheck`

Identify variant blocks in the model that have no variant control variables of type `Simulink.VariantControl` to inherit activation time.

**Description**

Identify variant blocks with **Variant activation time** set to inherit from `Simulink.VariantControl` but no variant control variables of type `Simulink.VariantControl`.

**Results and Recommended Actions**

Condition	Recommended Action
Variant block with inherit from <code>Simulink.VariantControl</code> activation time has no variant control variables of type <code>Simulink.VariantControl</code> .	Change the type of at least one variant control variable to <code>Simulink.VariantControl</code> .

**Capabilities and Limitations**

- You can run this check on your library models.

**See Also**

- `Simulink.VariantControl`
- “Types of Variant Activation Time in Variants Blocks and Variant Parameters”

**Check for machine-parented data**

**Check ID:** `mathworks.stateflow.MachineParentedData.check`

Check the model for instances of machine-parented data.

**Description**

Machine-parented data prevents models from reusing generated code and other code optimizations. Machine-parented data is also incompatible with many Simulink and Stateflow features. To make

Stateflow data accessible to other charts and blocks in a model, use chart-parented data of scope `Data Store Memory`. For more information, see “Best Practices for Using Data in Charts” (Stateflow) and “Access Data Store Memory from a Chart” (Stateflow).

---

**Note** Machine-parented data will no longer be supported in a future release.

---

### Results and Recommended Actions

Condition	Recommended Action
A Simulink model contains Stateflow machine-parented data.	Upgrade the model by converting machine-parented data to chart-parented data with values in the model workspace.

### Action Results

Clicking **Upgrade model** creates chart-parented data in the charts that use machine-parented data.

- If a machine-parented data object has a scope of `Parameter`, the new chart-parented data object has a scope of `Parameter`. The value is stored as a `Simulink.Parameter` object in the model workspace.
- If a machine-parented data object has any other scope, the new chart-parented data object has a scope of `Data Store Memory`. The value is stored as a `Simulink.Signal` object in the model workspace.

### Capabilities and Limitations

Automatic conversion fails when:

- The model workspace contains a `Simulink.Parameter` or `Simulink.Signal` object with the same name as the machine-parented data.
- The model contains chart-parented data, events, or messages with the same name as the machine-parented data.
- The machine-parented data uses Stateflow semantics that do not have an equivalent for `Simulink.Parameter` or `Simulink.Signal` objects.

### Tips

If your model contains a library chart or an atomic subchart linked from a library, you must upgrade every model that uses the library before you upgrade the library.

- 1 Open and upgrade each top model that uses the library.

Upgrading the top model creates a `Simulink.Parameter` or `Simulink.Signal` object in the model workspace for each machine-parented data in the library.

- 2 Save and close the top models.
- 3 Open and upgrade the library model.

Upgrading the library model creates chart-parented data that replaces the machine-parented data in the library.

- 4 Save and close the library model.

**See Also**

- “Share Parameters with Simulink and the MATLAB Workspace” (Stateflow)
- “Access Data Store Memory from a Chart” (Stateflow)
- “Best Practices for Using Data in Charts” (Stateflow)
- “Consult the Upgrade Advisor”

**Identify clones from the linked library**

**Check ID:** `mathworks.cloneDetection.libraryEdittime`

Identify clones in the model from linked library file.

**Description**

Clones are modeling patterns that have identical block types and connections. The Clone Detector (Simulink Check) identifies clones across the model. You can reuse components in your model by identifying clone patterns and replacing clones with links to the library blocks.

This check highlights the clones present in the model from linked library.

**Results and Recommended Actions**

Condition	Recommended Action
Model contains a clone pattern from the linked library.	Replace the clones with links to the library file from Clone Detector app.

**Capabilities**

You can run this check to:

- Highlight both Exact and Similar clones from the linked library. For more information, see “Exact Clones and Similar Clones” (Simulink Check).
- Highlight both subsystem clones and clones across the model from the linked library. For more information, see “Specify Where to Detect Clones” (Simulink Check).

**Limitations**

- The check cannot identify clones in variants and Stateflow chart in the model.
- The check does not highlight clones if a subsystem contains nested subsystem which is more than two-level deep.
- You cannot undo the change if you replace clones in the model.

**Action Results**

**Fix** button opens the Clone Detector app. Click **Replace Clones** and this replaces clones with links to the linked library file.

**See Also**

- “Enable Component Reuse by Using Clone Detection” (Simulink Check)

- “Replace Exact Clones with Subsystem Reference” (Simulink Check)

## Refactor Bus Selector and Bus Creator blocks to In Bus Element and Out Bus Element blocks

**Check ID:**mathworks.m2m\_edittime.BusPortsXform

Refactor Bus Selector and Bus Creator blocks to In Bus Element and Out Bus Element blocks.

### Description

To simplify your model, it is recommended to use In Bus Element and Out Bus Element blocks instead of Bus Selector blocks for inputs and Bus Creator blocks for outputs. For more information, see “Simplify Subsystem and Model Interfaces with Bus Element Ports”.

This check highlights the Bus Selector and Bus Creator blocks in the model and you can transform those blocks to In Bus Element and Out Bus Element blocks.

### Results and Recommended Actions

Condition	Recommended Action
Model contains Bus Selector and Bus Creator blocks.	Replace the Bus Selector and Bus Creator blocks to In Bus Element and Out Bus Element blocks.

### Capabilities and Limitations

- You can refactor the model by clicking **Fix** button in Model Advisor.
- You cannot undo the changes once you transform the model.

### Action Results

**Fix** button transforms the model by replacing the suitable Bus Selector and Bus Creator blocks to In Bus Element and Out Bus Element blocks.

### Simulink Performance Advisor Check Overview

Use Performance Advisor checks to improve model simulation time.

#### See Also

“Improve Simulation Performance Using Performance Advisor”

## Baseline

Establish a measurement to compare the performance of a simulation after Performance Advisor implements improvements.

### See Also

“Create a Performance Advisor Baseline Measurement”

## Checks that Require Update Diagram

These checks require that **Update Diagram** occurs in order to run.

### See Also

“Improve Simulation Performance Using Performance Advisor”

## Checks that Require Simulation to Run

These checks require simulation to run in order to collect sufficient performance data. Performance Advisor reports the results after simulation completes.

### See Also

“Improve Simulation Performance Using Performance Advisor”

## Check Simulation Modes Settings

These checks evaluate simulation modes (Normal, Accelerator, Rapid Accelerator, Rapid Accelerator with up-to-date check off) and identify the optimal mode to achieve fastest simulation.

### See Also

“What Is Acceleration?”

## Check Compiler Optimization Settings

Use these checks to select compiler optimization settings for improved performance.

### See Also

“Compiler optimization level”

## Check Hardware Acceleration Settings

Use the check to compare three hardware acceleration options based on their simulation times.

**See Also**

“Hardware acceleration”

**Create baseline**

Select this check to create a baseline when Performance Advisor runs. You can also create a baseline manually. A baseline is the measurement of simulation performance before you run checks in Performance Advisor. The baseline includes the time to run the simulation and the simulation results (signals logged). Before you create a baseline for a model, in the **Data Import/Export** pane of the Configuration Parameters dialog box:

- Select the **States** check box.
- Set the **Format** parameter to Structure with time.

**See Also**

“Create a Performance Advisor Baseline Measurement”

**Identify resource-intensive diagnostic settings**

To improve simulation speed, disable diagnostics where possible. For example, some diagnostics, such as **Solver data inconsistency** or **Array bounds exceeded**, incur run-time overheads during simulations.

**See Also**

- “Diagnostics”
- “Improve Simulation Performance Using Performance Advisor”

**Check optimization settings**

To improve simulation speed, enable optimizations where possible. For example, if some optimizations, such as Block Reduction, are disabled, enable these optimizations to improve simulation speed.

You can also trade off compile-time speed for simulation speed by setting the compiler optimization level. Compiler optimizations for accelerations are disabled by default. Enabling them accelerates simulation runs but results in longer build times. The speed and efficiency of the C compiler used for Accelerator and Rapid Accelerator modes also affects the time required in the compile step.

**See Also**

- “Model Configuration Parameters: Code Generation Optimization” (Simulink Coder)
- “Improve Simulation Performance Using Performance Advisor”

**Identify inefficient lookup table blocks**

To improve simulation speed, use properly configured lookup table blocks.

**See Also**

- “Lookup Tables”
- “Optimize Generated Code for Lookup Table Blocks”
- “Optimize Breakpoint Spacing in Lookup Tables”
- “Improve Simulation Performance Using Performance Advisor”

**Check MATLAB System block simulation mode**

In general, to improve simulation speed, choose `Code generation` for the **Simulate using** parameter of the MATLAB System block. Because data exchange between MATLAB and Simulink passes through several software layers, `Interpreted execution` usually slows simulations, particularly if the model needs many data exchanges.

This check identifies which MATLAB System blocks can generate code and changes the **Simulate using** parameter value to `Code generation` where possible.

While `Code generation` does not support all MATLAB functions, the subset of the MATLAB language that it does support is extensive. By using this `Code generation`, you can improve performance.

**See Also**

- MATLAB System
- “Simulation Modes”
- “Improve Simulation Performance Using Performance Advisor”

**Identify Interpreted MATLAB Function blocks**

To improve simulation speed, replace Interpreted MATLAB Function blocks with MATLAB Function blocks where possible. Because data exchange between MATLAB and Simulink passes through several software layers, Interpreted MATLAB Function blocks usually slow simulations, particularly if the model needs many data exchanges.

Additionally, because you cannot compile an Interpreted MATLAB Function, an Interpreted MATLAB Function block impedes attempts to use an acceleration mode to speed up simulations.

While MATLAB Function blocks do not support all MATLAB functions, the subset of the MATLAB language that it does support is extensive. By replacing your interpreted MATLAB code with code that uses only this embeddable MATLAB subset, you can improve performance.

**See Also**

- “Improve Simulation Performance Using Performance Advisor”

**Identify simulation target settings**

To improve simulation speed, disable simulation target settings where possible. For example, in the Configuration Parameters dialog box, clear the **Simulation Target > Echo expression without semicolons** check box to improve simulation speed.

**See Also**

- “Model Configuration Parameters: Simulation Target”
- “Improve Simulation Performance Using Performance Advisor”

**Check model reference rebuild setting**

To improve simulation speed, in the Configuration Parameters dialog box, verify that the **Model Referencing > Rebuild** parameter is set to **If any changes in known dependencies detected**.

**See Also**

- “Rebuild”
- “Improve Simulation Performance Using Performance Advisor”

**Identify Scope blocks**

Opened and uncommented Scope blocks can impact simulation performance. To improve simulation performance, close and comment out Scope blocks. Right-click a scope block, and then select **Comment Out**.

For opened Scopes, you can improve simulation speed by reducing updates. From the Scope **Simulation** menu, select **Reduce Updates to Improve Performance**.

**See Also**

- “Improve Simulation Performance Using Performance Advisor”

**Identify active instrumentation settings on the model**

Identify active instrumentation settings on the model. The fixed-point instrumentation mode controls which objects log minimum, maximum, and overflow data during simulation. Instrumentation is required to collect simulation ranges using the Fixed-Point Tool. These ranges are used to propose data types for the model (requires Fixed-Point Designer). When you are not actively converting your model to fixed point, disable the fixed-point instrumentation to restore the maximum simulation speed to your model.

In the **Apps** tab, select **Fixed-Point Tool**. Under **System under design**, click **Continue**.

In the Model Hierarchy pane, the Fixed-Point Tool denotes systems that currently have instrumentation turned on with (mmo), or (o). Right-click the system in the model hierarchy and, under **Fixed-point instrumentation mode**, select **Use local settings** or **Force off**.

## See Also

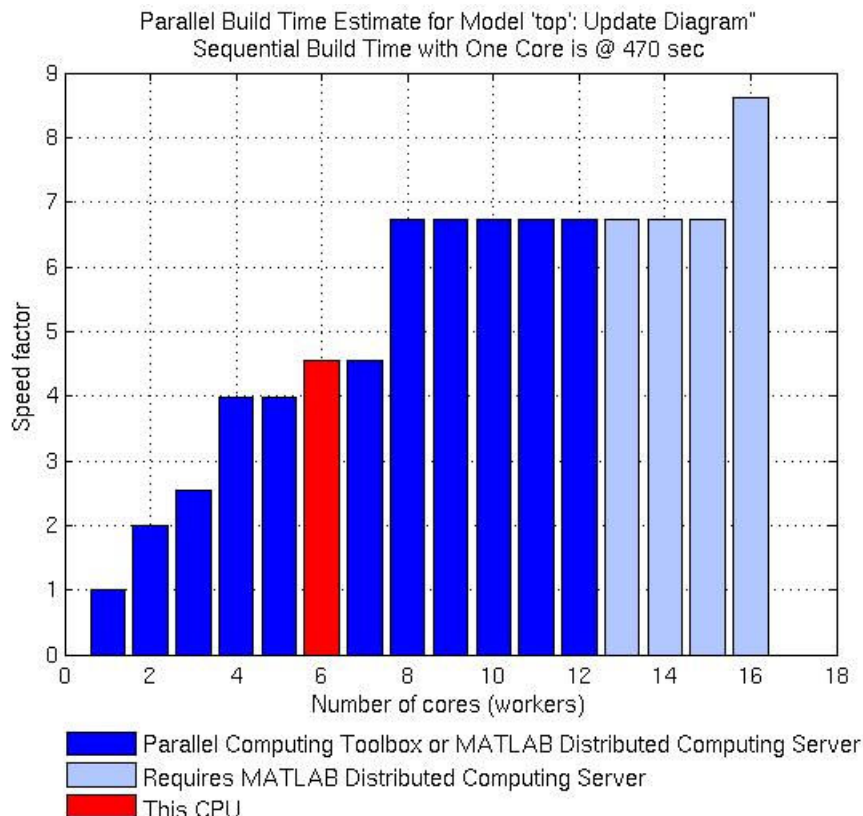

- Fixed-Point Instrumentation and Data Type Override (Fixed-Point Designer)

## Check model reference parallel build

To improve simulation, verify the number of referenced models in the model. If there are two or more referenced models, build the model in parallel if possible.

Performance Advisor analyzes the model and estimates the build time on the current computer as if it were using several cores. It also estimates the parallel build time for the model in the same way an estimation would be performed if Parallel Computing Toolbox or MATLAB Parallel Server software were installed on the computer. Performance Advisor performs this estimate as follows:

- 1 Search the model for referenced models that do not refer to other referenced models.
- 2 Calculate the average number of blocks in each of the referenced models that do not refer to other referenced models.
- 3 Of the list of referenced models that do not refer to others, select a referenced model whose number of blocks is closest to the calculated average.
- 4 Build this model to obtain the build time.
- 5 Based on the number of blocks and the build time for this referenced model, estimate the build time for all other referenced models.
- 6 Based on these build times, estimate the parallel build time for the top model.

To calculate the overhead time introduced by the parallel build mechanism, set the Parallel Build Overhead Time Estimation Factor. Performance Advisor calculates the estimated build time with overhead as:

$(1 + \text{Parallel Build Overhead Time Estimation Factor}) * (\text{Build time on a single machine})$

**See Also**

- “Enable parallel model reference builds”
- “Improve Simulation Performance Using Performance Advisor”

## Check Delay block circular buffer setting

To improve simulation, check that each Delay block in the model uses the appropriate buffer type. By default, the block uses an array buffer (the **Use circular buffer for state** option is not selected). However, when the delay length is large, a circular buffer can improve execution speed by keeping the number of copy operations constant.

If the Delay block is currently using an array buffer, and all of the following conditions are true, Performance Advisor selects a circular buffer:

- The Delay block is in sample-based mode, i.e., either the **Input processing** parameter is set to `Elements as channels (sample based)`, or the input signal type is set to `Sample based`.
- The value or upper limit of the delay length is 10 or greater.
- The size of the state—equal to the delay length multiplied by the total of all output signal widths—is 1000 or greater.

**See Also**

- Delay
- “Improve Simulation Performance Using Performance Advisor”

## Check continuous and discrete rate coupling

If your model contains both discrete and continuous rates, the coupling between these rates can slow down simulation. Performance Advisor checks for these conditions in your model.

- The model is using a variable step solver.
- The model contains both continuous and discrete rates.
- The fastest discrete rate is relatively smaller than **Max step size** determined by the solver.

Setting the `DecoupledContinuousIntegration` parameter to `on` might speed up simulation.

**See Also**

- “Solver Selection Criteria”
- “Speed Up Simulation”
- “Improve Simulation Performance Using Performance Advisor”

## Check zero-crossing impact on continuous integration

If your model contains zero-crossings which do not impact the continuous integration, the simulation might slow down when all the following conditions are satisfied:

- The model uses a variable-step solver.
- The model contains blocks that have continuous states and zero-crossings.
- Some of the zero-crossings do not affect the integration of the continuous states.

Setting the `MinimalZcImpactIntegration` parameter to `On` might speed up simulation.

### See Also

- “Speed Up Simulation”
- “Solver Selection Criteria”
- “Improve Simulation Performance Using Performance Advisor”

## Check discrete signals driving derivative port

Run this check if your simulation has many unnecessary resets. A discrete signal driving a block with continuous states triggers a reset at every sample time hit of the block. These resets are computationally expensive. Performance Advisor checks for these signals and blocks and provides a list of the same.

You can edit the model around the discovered discrete signals that drive these blocks to remove such cases. For example, inserting a Zero Order Hold block between the discrete signal and the corresponding block with continuous states might help resolve the issue.

- “Speed Up Simulation”
- “Modeling Techniques That Improve Performance”

## Check solver type selection

To improve simulation, check that the model uses the appropriate solver type.

### Explicit vs. Implicit Solvers

Selecting a solver depends on the approximation of the model stiffness at the beginning of the simulation. A stiff system has both slowly and quickly varying continuous dynamics. Implicit solvers are specifically designed for stiff problems, whereas explicit solvers are designed for non-stiff problems. Using non-stiff solvers to solve stiff systems is inefficient and can lead to incorrect results. If a non-stiff solver uses a very small step size to solve your model, check to see if you have a stiff system.

Model	Recommended Solver
Represents a stiff system	ode15s
Does not represent a stiff system	ode45

Performance Advisor uses the heuristic shown in the table to choose between explicit and implicit solvers.

Original Solver	Performance Advisor Action
Variable step solver	<p>Calculates the system stiffness at 0 first. Then:</p> <ul style="list-style-type: none"> <li>• If the stiffness is greater than 1000, Performance Advisor chooses ode15s.</li> <li>• If the stiffness is less than 1000, Performance Advisor chooses ode45.</li> </ul>
Fixed-step continuous solver	<ul style="list-style-type: none"> <li>• If the stiffness is greater than 1000, Performance Advisor chooses ode14x.</li> <li>• If the stiffness is less than 1000, Performance Advisor chooses ode3.</li> </ul>

This heuristic works best if the system stiffness does not vary during simulation. If the system stiffness varies with time, choose the most appropriate solver for that system rather than the one Performance Advisor suggests.

**Select multi-thread co-simulation setting on or off**

Adjust co-simulation settings for better performance and accuracy.

- Validate and revert changes if simulation time increases — Performance Advisor reverts previous co-simulation settings when the simulation time increases.
- Validate and revert changes if degree of accuracy is greater than tolerance — Performance Advisor reverts previous co-simulation settings if the degree of accuracy is greater than tolerance.

---

**Tip** You can use the `tic` and `toc` functions to measure the simulation time.

---

**See Also**

- `tic`
- `toc`
- `sim`

## Identify co-simulation signals for numerical compensation

Identify co-simulation signals that may need explicit numerical compensation.

- Validate and revert changes if time of simulation increases — Performance Advisor reverts previous co-simulation settings the simulation time increases.
- Validate and revert changes if degree of accuracy is greater than tolerance — Performance Advisor reverts co-simulations if the degree of accuracy is greater than tolerance.

---

**Tip** You can use the `tic` and `toc` functions to measure the simulation time.

---

- `toc`
- `sim`

## Check Dataflow Domain Settings

To increase the throughput of a dataflow domain, it can be advantageous to increase the latency of the system. The Performance Advisor analyzes the dataflow domains in your model and finds the optimal latency settings. The analysis also identifies any other multithreading limitations in the dataflow domains.

The dataflow analysis is a multistep process where the analysis may simulate the model with run-time profiling enabled for each block inside the dataflow domains before running partitioning analysis.

After the analysis completes, the Performance Advisor suggests a latency value that optimizes the throughput of the system for the multicore CPU architecture of the host computer and identifies any other multithreading limitations in the dataflow domains

### See Also

- “Dataflow Domain” (DSP System Toolbox)

## Select simulation mode

To achieve fastest simulation time, use this check to evaluate the following modes and identify the optimal selection:

- Normal
- Accelerator
- Rapid Accelerator
- Rapid Accelerator with up-to-date check off

In Normal mode, Simulink interprets your model during each simulation run. If you change the model frequently, this is generally the preferred mode to use because it requires no separate compilation step. It also offers the most flexibility to make changes to your model.

In Accelerator mode, Simulink compiles a model into a binary shared library or DLL where possible, eliminating the block-to-block overhead of an interpreted simulation in Normal mode. Accelerator mode supports the debugger and profiler, but not runtime diagnostics.

In Rapid Accelerator mode, simulation speeds are fastest but this mode only works with models where C-code is available for all blocks in the model. Also, this mode does not support the debugger or profiler.

When choosing Rapid Accelerator with up-to-date check off, Performance Advisor does not perform an up-to-date check during simulation. You can run the Rapid Accelerator executable repeatedly while tuning parameters without incurring the overhead of up-to-date checks. For instance, if you have a large model or a model that makes extensive use of model reference, this method of execution can increase efficiency.

For models with 3-D signals, Normal or Accelerator modes work best.

#### **See Also**

- “How Acceleration Modes Work”
- “Choosing a Simulation Mode”
- “Comparing Performance”
- “Run Simulations Programmatically”

### **Select compiler optimizations on or off**

Use this check to determine whether performing compiler optimization can help improve simulation speed. The optimization can only be performed in Accelerator or Rapid Accelerator modes.

---

**Note** This check will be skipped if MATLAB is not configured to use an optimizing compiler.

---

#### **See Also**

- “How Acceleration Modes Work”
- “Choosing a Simulation Mode”
- “Comparing Performance”
- “Improve Simulation Performance Using Performance Advisor”

### **Select hardware acceleration setting**

This check will compare three hardware acceleration options based on their simulation times.

- **Off** — Hardware acceleration is disabled and no SIMD is used.

- **Leverage generic hardware (Faster, no rebuild)** — Leverage SIMD instructions for hardware generic to Simulink system requirements. This option does not require rebuilding the model for simulation when the host computer changes.
- **Leverage native hardware (Fastest, rebuild allowed)** — Leverage SIMD instructions for hardware native to the host computer. This option may require rebuilding the model for simulation when the host computer changes.

You can select the hardware acceleration based on the comparison.

**See Also**

- “Hardware acceleration”

**Final Validation**

This check validates the overall performance improvement of simulation time and accuracy in a model. If the performance is worse than the original model, Performance Advisor discards all changes to the model and loads the original model.

Global settings for validation do not apply to this check. If you have not validated the performance improvement from changes resulting from other checks, use this check to perform a final validation of all changes to a model.

# Simulink Limits

---

- “Maximum Size Limits of Simulink Models” on page 11-2
- “Systems and Models” on page 11-3
- “Simulink Models” on page 11-6
- “Simulink Simulation” on page 11-28
- “Simulink Tools” on page 11-33
- “Programming Constructs in Simulink” on page 11-44
- “Model Development Processes” on page 11-46
- “What is Simulink Online?” on page 11-49

## Maximum Size Limits of Simulink Models

The following table documents some limits on the size and complexity of Simulink models.

Model Feature	Limit
Maximum number of levels in a block diagram	1024
Maximum number of branches in a line	1024
Maximum length of a parameter name	63
Maximum length of a parameter character vector value	32768
Maximum size of a model window, as determined by supported coordinates	-1073740824 to 1073740823, inclusive
Maximum number of bytes for a single logged data point	90 MB
Maximum number of bytes of logged simulation data	Limited by available hard drive space
Maximum number of bytes for an individual block I/O buffer length	$2^{31}-1$ bytes
Maximum number of bytes for an individual DWork buffer length	$2^{31}-1$ bytes
Maximum length of integer and fixed-point data types	128 bits
Maximum length of string data type	32,766 characters

## Systems and Models

The concepts in this topic provide a consistent and common language for using Simulink software tools.

### System

A system is a group of interdependent physical and functional parts with measurable characteristics that change over time.

For example, a vehicle is a *system* with multiple parts. Measurable characteristics include the linear speed of the vehicle and the rotational speed of the wheels.

### System Component

A system component is part of a *system* that interacts with the other parts of the *system*. The interactions between components define the structure and behavior of the *system*.

For example, a cruise control module is a *system component* in a vehicle *system*. A microcontroller and the hardware associated with it define the structure while a software algorithm to control speed defines the behavior.

### Model

A model is a mathematical description of a *system* derived either from physical laws or experimental data. The description typically uses a set of variables with a set of differential and difference equations that define the relationships between the variables.

In the following example for a vehicle,  $u(t)$  is the force (N) moving a vehicle forward,  $v(t)$  is the velocity (m/s),  $b$  is a drag coefficient (N·s/m), and  $m$  is the mass of the vehicle (kg).

The vehicle is a continuous system. For continuous systems, differential equations describe the rate of change for variables with the equations defined for all values of time. The velocity of the vehicle  $v(t)$  and its acceleration  $v'(t)$  are defined with the following first order differential equation.

$$mv'(t) + bv(t) = u(t)$$

You can create a Simulink model for this equation by adding blocks, specifying block behavior, and using signal lines to connect the blocks to each other. The following Simulink block diagram implements the differential equation.

## Model Component

A model component is part of a *model* that interacts with the other parts through an interface of inputs and outputs. Simulink implements *model components* using Subsystem and Model blocks. A Model block references another Simulink model saved in a separate file.

In the following example, the control model was saved in the Simulink model file `control_model.slx`, and then referenced from a Model block in a second Simulink model. A Subsystem block was added for modeling the vehicle mechanics.

Typically, controllers are built with discrete systems using a computer to implement the control algorithm. For discrete systems, difference equations describe the rate of change for variables defined only at specific times. For example, the control signal for a simple discrete PI (proportional-integral) controller can be defined with the following difference equation.

$$PI[n] = e[n]K_p + (e[n] + \text{integral}[n-1])K_i$$

Where  $e[n]$  is the error between a signal whose value is controlled (velocity) and the specified value (set velocity),  $K_p$  is the proportion constant,  $K_i$  is the integration constant, and  $n$  is the time step.

The following Simulink *block diagram* implements the difference equation.

See also: “Model a Continuous System”, “Component-Based Modeling Guidelines”, “Create Custom Library”, “Model Reference Basics”.

## Differential Algebraic Equations

Some systems of equations contain additional constraints that involve the independent variable and the state vector in addition to differential equations. Such systems are called differential algebraic equations (DAEs),

The term algebraic refers to equations that do not involve any derivatives.

In Simulink models, algebraic loops are algebraic constraints. Models with algebraic loops define a system of differential algebraic equations.

For example,

$$\begin{aligned}x' &= x \\ 0 &= -x + u - 2x\end{aligned}$$

is a system of differential algebraic equations implemented in the following Simulink model

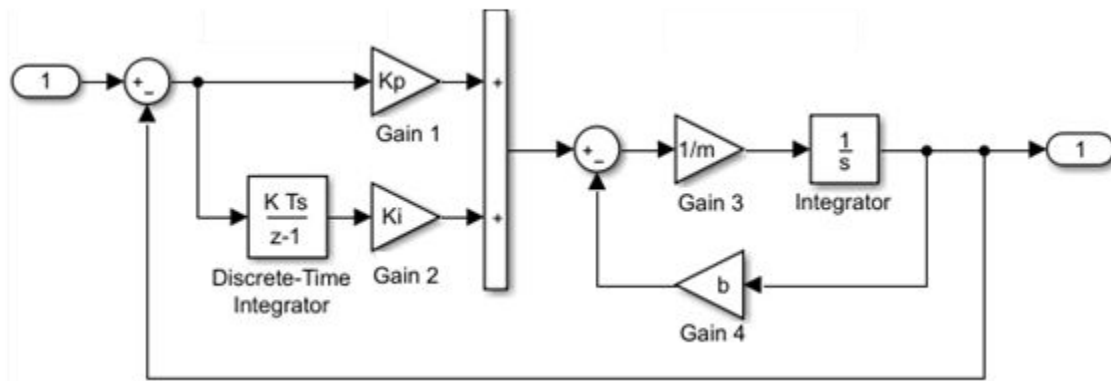

## Simulink Models

A model is an abstract and simplified description of a system using mathematical equations and diagrams. The modeling concepts in this topic provide context for understanding the process of mathematically describing a system with Simulink software tools.

### Block Diagram

A block diagram is a visual representation of a model in the Simulink Editor. The editor allows you to add blocks selected from block libraries representing elementary model components. Elementary components include integrator, gain, and sum blocks. Blocks are connected to each other with signal and event lines to visually construct the model equations.

### Block Diagram Semantics

A classic block diagram of a system is drawn graphically with blocks and lines. The history of these block diagrams is derived from engineering areas such as Feedback Control Theory and Signal Processing. A block within a block diagram defines a model in itself. The relationships between elementary models are represented by signal lines connecting the blocks. The blocks and lines in a block diagram collectively describe the overall model of a system.

Simulink extends classic block diagrams by:

- Adding a set of equations (block methods) to each block that defines the time-based relationships between the input signals, output signals, and block state variables.
- Adding parameters to each block that specify the coefficients from the model equations.
- Providing an engine for numerical solution of the block diagram by evaluating the relationships over time, where time starts at a user-specified “start time” and ends at a user-specified “stop time.”

See also: “Simulink Block Diagrams”, “Build and Edit a Model Interactively”, “Simulation”.

## Blocks

A block is a basic modeling construct of the Simulink Editor. Add blocks from the built-in Simulink libraries to perform specific operations. You can also create custom blocks. Some blocks have input signals, output signals, and states. Most blocks have parameters that you use to specify block behavior. Whether a block has parameters and the nature of those parameters is specific to each block.

Each block represents a set of equations for the Simulink engine. The equations are represented as block methods. The blocks shown above have the following block methods.

$$\begin{cases} x[n + 1] = u[n] \\ y[n] = x[n] \end{cases} \quad \begin{cases} \frac{dx}{dt} = u(t) \\ y(t) = x(t) \end{cases} \quad y(t) = 2 * x(t) \quad y(t) = 5$$

Block methods are evaluated during the simulation of a block diagram. The evaluation of the block methods is performed within a simulation loop, where each cycle through the simulation loop represents the evaluation of the block diagram at a given point in time.

## Virtual Blocks

Virtual blocks organize and provide graphical hierarchy in a model. During model simulation, Simulink expands the blocks in place before execution, a process known as flattening. This expansion is similar to the way macros work in a programming language such as C or C++.

Simulink defines the following virtual blocks:

- Virtual Subsystem - Use a virtual subsystem to encapsulate related and functional parts within a larger model. A Virtual Subsystem block has the check box for the parameter **Treat as atomic unit** cleared.

- Inport and Outport - Use port blocks to move data (signals) and events (function calls) from outside a Subsystem block or Model block to within the block, and vice versa.

- Bus Creator, Bus Assignment, Bus Selector - Bus blocks combine signals into a virtual bus and manage the routing of signals around a complex block diagram. Virtual buses are a graphical convenience and do not change the behavior of the model.

See “Nonvirtual and Virtual Blocks”, “Signal Types”, “Composite Interface Guidelines”.

### Nonvirtual Blocks

Nonvirtual blocks provide execution control and graphical hierarchy in a model. Simulink defines the following nonvirtual Subsystem and Model blocks:

- Atomic Subsystem and Model - Blocks within an Atomic Subsystem block or a Model block that references a model execute as a single unit (atomic execution) at each time step. For an Atomic Subsystem block, the check box for the parameter **Treat as atomic unit** is selected.

You can place any Simulink block in an Atomic Subsystem or referenced model, including blocks with different execution rates. This flexibility provides the advantage of grouping functional aspects of a model at the execution level.

In the following example, the vehicle model is an Atomic Subsystem block containing blocks that model the mechanics of a car. The control model is referenced from a Model block.

- Enabled and/or Triggered - Atomic Subsystem or Model block whose execution is controlled by external data from a signal. Contains an Enable or Trigger block, or both. For the Trigger block, the parameter **Trigger type** is set to rising, falling, or either.

- Function-Call - Atomic Subsystem or Model block whose execution is controlled by an event from a function-call initiator (such as a Stateflow chart or a Function-Call Generator, S-Function, or Hit Crossing block). Contains a Trigger block with **Trigger type** set to function-call.

Simulink defines the following nonvirtual components only for Subsystem blocks.

- Action Subsystem - Atomic Subsystem block whose execution is controlled by an event from an action initiator (e.g., If or Switch Case block). Contains an Action Port block within the Subsystem block.

- While Iterator Subsystem - Atomic Subsystem block that runs multiple iterations during each model time step. Contains a While Iterator block that controls the number of iterations by evaluating a logical condition.

A while iterator subsystem is similar to a function-call subsystem in that it can run for any number of iterations at a given time step. The while iterator subsystem differs from a function-call subsystem in that there is no separate initiator.

- For Iterator Subsystem - Atomic Subsystem block that runs a fixed number of iterations during each model time step. Contains a For Iterator block that controls the number of iterations.

See “Nonvirtual and Virtual Blocks”.

### **Block Mask**

A block mask is a custom block parameter interface that displays only selected block parameters. A mask for a Subsystem block allows you to provide an interface for setting parameters on blocks inside the Subsystem block without having to navigate the model hierarchy.

See “Masking Fundamentals”.

### **Custom Blocks**

Custom blocks are new blocks that extend the built-in functionality of Simulink. You can create libraries of custom blocks to use in your model.

The following blocks define the algorithm of a custom block either graphically with a block diagram or programmatically:

- MATLAB Function - Code a MATLAB function using the MATLAB language that runs in a Simulink model. See “Implement MATLAB Functions in Simulink with MATLAB Function Blocks”.
- MATLAB System - Bring existing System objects based on `matlab.System` into Simulink. See “MATLAB System Block”.
- Subsystem - Draw a block diagram representing an algorithm, wrap this diagram in an instance of the Simulink Subsystem block, then provide the block with a parameter dialog using a Simulink block mask. See Subsystem.
- C Caller - Integrate your external C code into a Simulink model. See “Integrate C Code Using C Caller Blocks”.
- S-Function - Create a custom block programmatically by creating a MATLAB file or a MEX file that contains the block's system functions. The resulting file is called an S-function. You then associate the S-function with instances of the Simulink S-Function block in your model. See S-Function.

See “Types of Custom Blocks”, “Block Authoring and Simulation Integration”.

## **Lines**

A line is a basic modeling construct of the Simulink Editor. Lines connect the output ports of blocks with the input ports of other blocks.

### **Signal Lines**

Signal lines transfer data during a simulation from one block to another block. Signals are time-varying quantities that have values at all points in time (continuous) or at specified time points

(discrete). The source of a signal corresponds to the block that writes to the signal during evaluation of its block output method. The destination of a signal is the block that reads the signal during the evaluation of its block input method.

You can specify signal attributes, including signal name, data type (e.g., double, 32-bit integer), numeric type (e.g., real, complex) and dimension (e.g., one-dimensional, two-dimensional, multi-dimension array). Many blocks can accept or output a signal of any data type or dimensionality. Other blocks impose restrictions on the attributes of the signals they can handle.

During a simulation, save data from a signal by logging the signals.

**Event Lines**

In response to a function-call or action initiator, event lines send an event to a Subsystem or Model block. The block that receives the event executes the blocks within it one or more times during a time step. Function-call initiators include Stateflow charts, Function-Call Generator blocks, S-Function blocks, and Hit Crossing blocks. Action initiators include If and Switch Case blocks.

See “Signals” and “Signal Basics”.

**Data**

Data includes the parameter and input signal values that Simulink uses to produce the output values resulting from simulating the behavior of a model.

Types of data:

- Model parameters - Variables to specify block and signal parameters in a model. Includes MATLAB variables, parameter and signal data objects, data type objects, and bus objects.
- Model configuration parameters - Parameters that determine how your model runs by specifying the settings that control model behavior.

- Simulation data - Input data to drive a simulation and output data generated by a simulation.
- Data Objects - Instances of data classes that allow you to specify characteristics of signals, states, and block parameters. Use the `Simulink.Signal` and `Simulink.Parameter` classes to create data objects. See "Data Objects".

Location of data:

- **Block parameters** - Use block parameters to directly specify numerical values. You can also enter a variable name and define its value in the Simulink model workspace, a Simulink data dictionary, or the MATLAB base workspace.

- **MATLAB base workspace** - Use the MATLAB base workspace to save variables that are separate from the model in a MAT-file or MATLAB script.

Simulink treats the base workspace and the data dictionary as a single global name space. If the base workspace and a referenced data dictionary have identical variable names, Simulink uses the variable value in the data dictionary.

The MATLAB base workspace contains variables that are global and visible to all Simulink models.

See “Comparison of Signal Loading Techniques”, “Export Simulation Data”.

- **Simulink model workspace** - Use the model workspace to define and store local data variables. Variables defined in a model workspace are visible only within the scope of the model with a unique name space. Therefore, you can use the same variable name in multiple model workspaces and you can assign a unique variable value to the name in each model.

Define variables in the data dictionary using Model Explorer. In the **Modeling** tab, click **Model Explorer** . In the left pane, select Model Workspace.

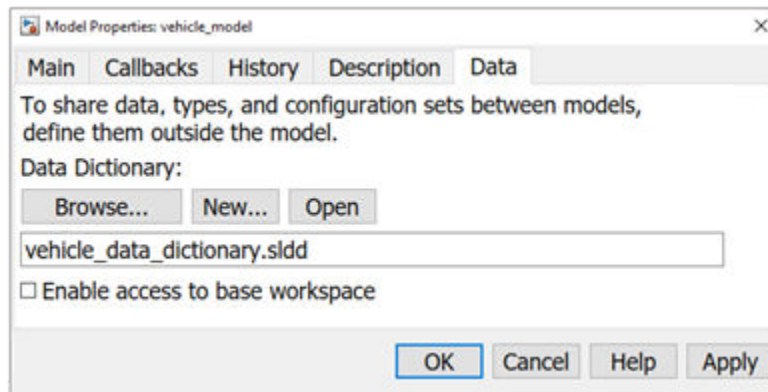

Values for the model workspace variables are initialized from values saved with the model, from a separate MAT-file or MATLAB file, or using MATLAB code saved with the model.

See “Model Workspaces”, “Specify Source for Data in Model Workspace”.

- **Simulink data dictionary** - Use a data dictionary to define and store global data, share data between models, and track changes made to the data. Data is saved in a file separate from the model.

Create a data dictionary file. In the **Modeling** tab, under **Design**, click **Data Dictionary** . Click **New** and enter a file name with an extension `.sldd`.

Define variables in the data dictionary using Model Explorer. In the **Modeling** tab, click **Model Explorer** . In the left pane, select **Design Data**.

See “What Is a Data Dictionary?”.

- **Imported and exported data** - Import signals for a simulation from the MATLAB base workspace, a MAT-file, or a spreadsheet. Create input signals using a source block or the Signal Editor block. Use signal logging to export simulation results. Signals are saved as vectors [t, X, Y] for time, state and output at each major time step.

See also: “Determine Where to Store Variables and Objects for Simulink Models”, “Symbol Resolution”.

## Parameters

Parameters are Simulink model characteristics that affect the simulation and code generation result.

### Model Configuration Parameters

Model configuration parameters specify model behavior during compilation, simulation, and code generation, such as the solver to use and the types of errors and warnings to display.

To specify model configuration parameters, in the **Modeling** tab, click **Model Settings**. The Configuration Parameters dialog box opens.

See “Set Model Configuration Parameters for a Model”.

### Block Parameters

Block parameters define model dynamics and mathematics. Whether a block has parameters that you can set and the nature of those parameters is specific to each block. To specify block parameters, open the block parameter dialog box, or in the **Modeling** tab, under **Design**, click one of the following:

- **Property Inspector** – Specify block parameters directly or enter a variable name for a parameter value.
- **Model Data Editor** – Specify block parameters with variables.
- **Model Explorer** – Specify block parameters with variables.

See “Set Block Parameter Values”.

### Block Parameter Variables

If you have a single parameter used in many locations across a large model, updating every instance of that parameter can be a difficult task. Instead, enter a variable name as the value of a parameter, then define the variable once using one of the following methods:

- **Simulink Model Workspace** – Create model workspace variables and assign values to the variables. The parameters you define are specific to the model and saved with the model. Use a MATLAB variable for ease of maintenance. Use a `Simulink.Parameter` object to control additional properties including data type, dimensions, and units. See “Edit and Manage Workspace Variables by Using Model Explorer”.
- **Simulink Data Dictionary** – Create design data variables in a data dictionary and link the dictionary to a model. During model simulation, Simulink retrieves data from the data dictionary.
- **MATLAB Base Workspace** – In the MATLAB base workspace, define parameters using any MATLAB mechanism for defining a variable. For example, you can use a MAT-file and load the variables when you open the model. Use MATLAB expressions to specify parameter variable values. Simulink evaluates the expressions before running a simulation. See “Save and Load Workspace Variables”.

Using the MATLAB base workspace or a Simulink data dictionary to define variables is useful when you are using the same set of parameters for more than one model. This mechanism also allows you to use different sets of parameter values for the same model.

See also: “Share and Reuse Block Parameter Values by Creating Variables”, “Create, Edit, and Manage Workspace Variables”.

### Model Argument and Instance Parameters

When you reference the same model from multiple Model blocks, you create instances of the model. You can set block parameters to use the same value or a different value for each instance of the model.

To use different values,

- 1 In the model workspace for the referenced model, create a MATLAB variable or `Simulink.Parameter` object.
- 2 Enter a parameter name and a default parameter **Value**. Select the **Argument** check box to create a model argument.
- 3 For a block in the referenced model, enter the name of the model argument for the value of a block parameter.
- 4 For each Model block, open the block parameters dialog box, select the **Instance parameters** tab, and enter a value for the instance parameter with the model argument name.

See also: “Parameterize Instances of a Reusable Referenced Model”.

## Tunable Block Parameters

You can change the value of a tunable block parameter during a simulation. This allows you to determine interactively the most suitable value for a parameter. When you change the value of a tunable parameter, the change takes effect at the start of the next time step. For example, the gain parameter of the Gain block is tunable. You can change the block gain while a simulation is running. See “Tune and Experiment with Block Parameter Values”.

## Setting Block Parameters with the Property Inspector

To specify parameters, in the **Modeling** tab, under **Design**, click **Property Inspector**. Click a block to display the block parameters and properties.

See also: “Specify Block Properties”.

## Properties

Properties are Simulink model characteristics that generally do not affect the simulation result. To specify properties, in the **Modeling** tab, under **Design**, click **Property Inspector**.

### Model Properties

With the Property Inspector opened, click a blank space within a block diagram, or in the **Modeling** tab, select **Model Settings > Model Properties**. Model properties include:

- General - Name and location of model file.
- Design Data - Variables defined outside the model that parameterize the model and its blocks and signals.
- Callbacks - Commands that execute when a specific model event occurs.

See “Manage Model Versions and Specify Model Properties”.

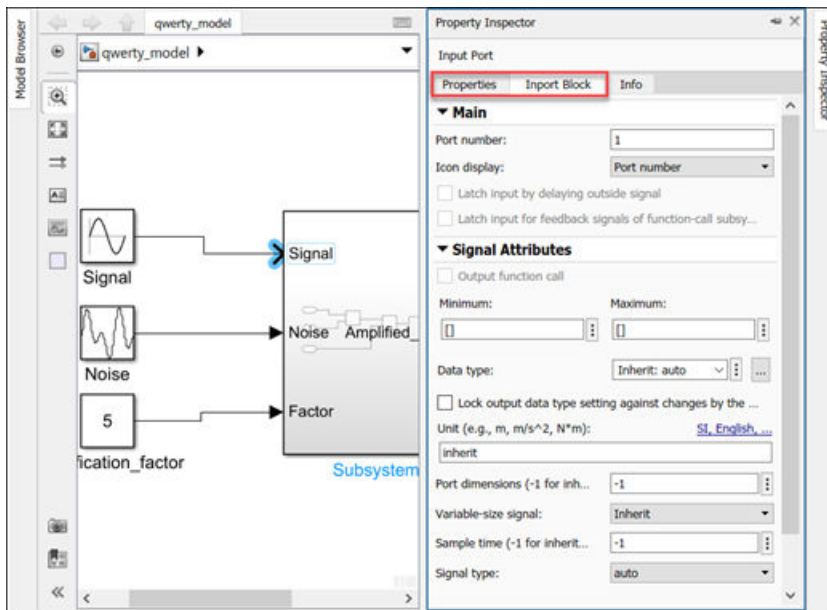

## Block Properties

With the Property Inspector opened, select a block, then select the **Properties** tab. Block properties include:

- Block Annotation - Values of selected block parameters displayed below the block.
- Callbacks - Commands that execute when a specific block event occurs. For example, you can set up a MATLAB script to load and define block parameter variables using expressions.
- Priority - Set the relative execution order of blocks. A lower value executes the block before a larger priority value.
- Tags - Block identifiers that are programmatically searchable.

## Port Properties

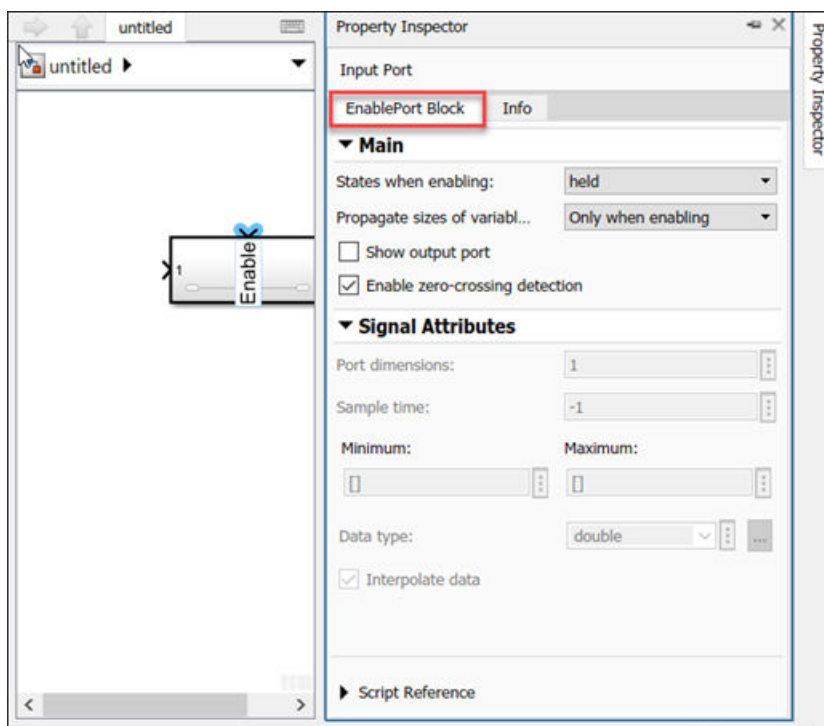

With the Property Inspector opened, select a port, then select the **Properties** tab. You can modify properties of port objects, signals, and port blocks with the Property Inspector. The ports on a subsystem block also have a port block tab, which contains properties of the associated port block.

- The port block properties are displayed for these subsystem blocks:
  - Subsystem, Atomic Subsystem, CodeReuse Subsystem
  - Variant Subsystem, Variant Model
  - For Each
  - For Iterator Subsystem
  - Function-Call Feedback Latch
  - Function-Call Subsystem
  - Function-Call Generator
  - Function-Call Split
  - If

- While Iterator Subsystem
- The ports on these blocks show a tab with the same name as the type of port block and list the properties that are shown in the Model Explorer window. For example, an **EnablePort Block** tab is shown for ports on an Enable block, and **Data**, **Message**, or **Event** tabs are shown for ports on Stateflow blocks.
- Enable block
- Trigger block
- Function Call block
- Reset block
- Action Port block
- Chart
- Truth Table
- State Transition Table
- Test Sequence
- matlabFunctionBlock

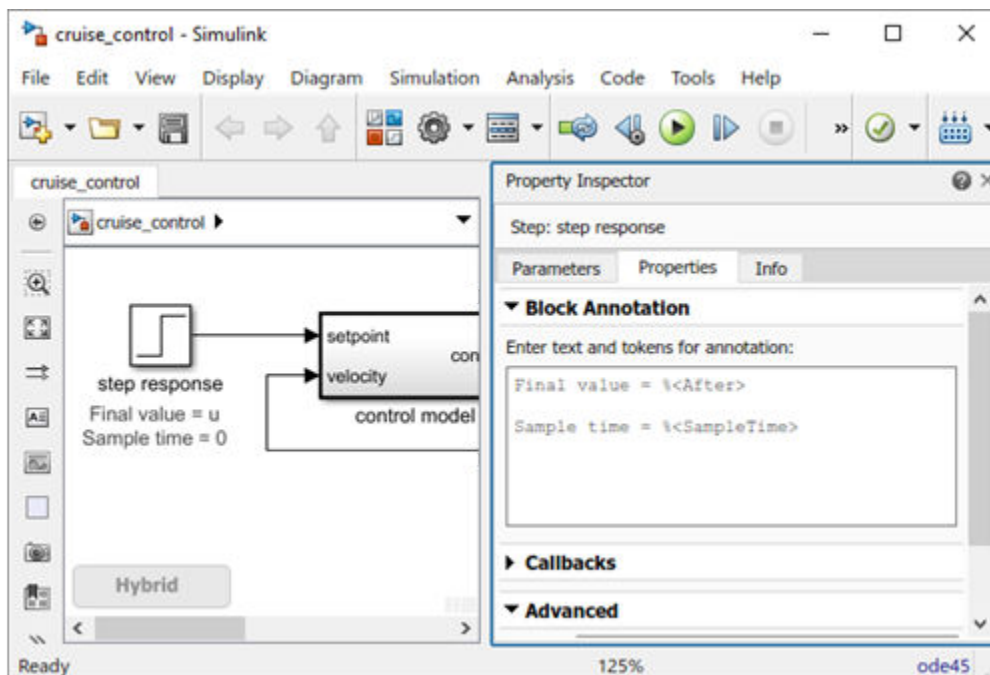

- The port properties of read-only blocks are not editable. For example, the port properties of locked linked library blocks, masked blocks, and protected referenced models are read-only.
- The port block properties on Model blocks are shown only if the model is loaded.

### Setting Model and Block Properties with Property Inspector

To set properties, in the **Simulation** tab, under **Prepare**, click **Property Inspector**. Click an empty space to display the model properties. Click a block to display the block properties.

See also: “Specify Block Properties”, “Customize Model Behavior with Callbacks”.

## State variables

The state of a model is defined by the values of its state variables. State variables are the set of variables whose values at time zero, along with the values of model inputs and the model equations, can determine the behavior of a model during a simulation. Examples of state variables include motor position and velocity, inductor current, capacitor voltage, solution temperature, and gas pressure.

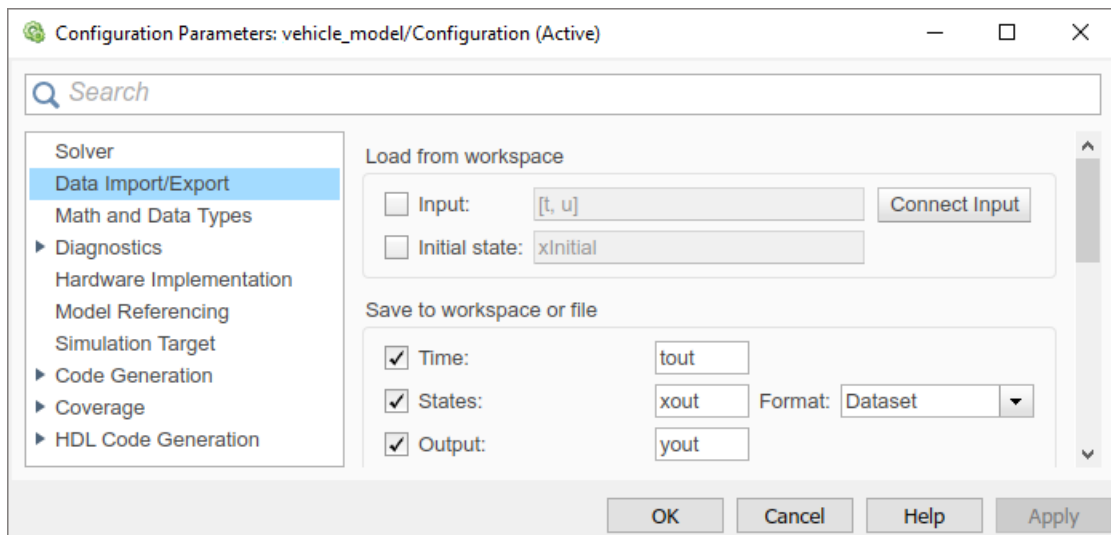

If the current output value of a block is a function of the previous output value, the block defines a state variable that needs to be saved between time steps. Computing a block output hence entails saving the value of the state variable at the current time step for use in computing the output at a subsequent time step.

## Working with States

The following facilities are provided for determining, initializing, and logging model states during simulation:

- The **Data Import/Export** pane of a model's Configuration Parameters dialog box (see “Save Block States and Simulation Operating Points”) allows you to specify initial values for model states, and to record the values of the states at each time step during simulation as an array or structure variable in the MATLAB workspace.

Open the Configuration Parameters dialog box. Select the **States** check block for logging to the MATLAB variable `xout`.

In the MATLAB Command Window, list the logged values for state of the Integrator block at each time step.

```
>> xout{1}.Values.Data
ans =
 0.0000
 1.8127
```

```
3.2968
4.5119 . . .
```

- You can use the name of a model as a programmatic interface to display information about the states defined by a model, including the total number of states and the block that defines each state with its initial value.

List blocks in the model `vehicle_model` with states. In the MATLAB Command Window, enter the model function, then list blocks with states.

```
[sys,x0,blks,ts] = vehicle_model([],[],[],'sizes');
blks
```

```
blks =
 {'vehicle_model/Integrator'}
```

- The Simulink debugger displays the value of a state at each time step during a simulation, and the `states` function for the Simulink debugger displays information about the current states (see “Simulink Debugger”).

In the MATLAB Command Window, start the Simulink debugger, then enter the command `states`.

```
sldebug 'vehicle_model'
(sldebug @0): >> states

Continuous States for 'vehicle_model':
Idx Value (system:block:element Name 'BlockName')
 0. 0 (0:0:0 CSTATE 'vehicle_model/Integrator')
```

- Using the Block Parameters dialog box or the `get_param` function with the `ContinuousStateAttributes` parameter, you can name states for blocks that have continuous states, such as the Integrator block. Naming states can simplify analyzing logged states data, especially when a block has multiple states.

## Continuous States

A continuous state is defined for all values of time. An example of a continuous state would be the speed of a car shown on an analog speedometer with a needle position that changes continuously with the rotation of a tire.

Blocks with continuous states and the block parameter **Initial condition** include:

- Integrator
- State-Space
- Transfer Fcn

In general, excluding simple models, analytical methods do not exist for integrating states represented by ordinary differential equations. Integrating the states requires the use of numerical methods.

### **Discrete States**

A discrete state is defined only at specific times. It is an approximation of a continuous state where the state is updated at periodic or aperiodic time intervals. An example of a discrete state would be the speed of a car shown on a digital speedometer that is updated every second as opposed to continuously.

Blocks with discrete states include:

- Discrete-Time Integrator
- Discrete State-Space
- Discrete Transfer Fcn
- Delay

Computing the discrete state for a block requires knowing its value at the previous time step and also the current input value to the block. Simulink provides two types of discrete solvers:

- Fixed-step discrete solver - determines a fixed step size that hits all the sample times for all the model's discrete states, regardless of whether the states actually change value at the sample time hits.
- Variable-step discrete solver - varies the step size to ensure that sample time hits occur only at times when the states change value.

### **Modeling Hybrid Systems**

A hybrid model has both continuous and discrete states. Solving such a model entails choosing a step size that satisfies both the precision constraint on the continuous state integration and the sample time interval constraint on the discrete states. Simulink meets this requirement by passing the next sample time interval for the discrete solver as an additional constraint on the continuous solver. The continuous solver chooses a step size that advances the simulation up to but not beyond the time of the next discrete sample time. The continuous solver can take a time step short of the next sample time hit to meet its accuracy constraint but it cannot take a step beyond the next sample time hit even if its accuracy constraint allows it to.

You can simulate hybrid systems using any of the integration methods, but certain methods are more effective than others. For most hybrid systems, `ode23` and `ode45` are superior to the other solvers in terms of efficiency. Because of discontinuities associated with the sample and hold of the discrete blocks, do not use the `ode15s` and `ode113` solvers for hybrid systems.

## Sample Time

Sample time is the time interval that specifies the rate (1 / sample time) for executing block methods to produce outputs and update the internal states of blocks. Time is an inherent component of a block diagram in that the simulation results of a block diagram change with time.

Sample time is specified as:

- Continuous - Blocks run at variable times based on solver settings.
- Discrete - Blocks run at specific times that are explicitly specified.

In the following example, the controller runs at a discrete rate specified with a sample time of 0.01 seconds while Simulink determines the vehicle model to have a continuous sample time.

Determining a system's behavior over time thus entails repeatedly solving the model at intervals, called time steps or time intervals, from the start of the time span to the end of the time span. The process of solving a model at successive time steps is referred to as simulating the system that the model represents.

See also "What Is Sample Time?", "Types of Sample Time", "Specify Sample Time", "View Sample Time Information".

### Block Sample Times

Every Simulink block has a sample time which defines when the block will execute. Most blocks allow you to specify the sample time via a `SampleTime` parameter. Common choices include discrete, continuous, and inherited sample times.

Common Sample Time Types	Sample Time	Examples
Discrete	$[T_s, T_o]$	Unit Delay, Digital Filter
Continuous	$[0, 0]$	Integrator, Derivative
Inherited	$[-1, 0]$	Gain, Sum

For discrete blocks, the sample time is a vector  $[T_s, T_o]$  where  $T_s$  is the time interval or period between consecutive sample times and  $T_o$  is an initial offset to the sample time. In contrast, the sample times for nondiscrete blocks are represented by ordered pairs that use zero, a negative integer, or infinity to represent a specific type of sample time. For example, continuous blocks have a nominal sample time of  $[0, 0]$  and are used to model systems in which the states change continuously (e.g., a car accelerating), whereas you indicate the sample time type of an inherited block symbolically as  $[-1, 0]$ , and Simulink then determines the actual value based upon the context of the inherited block within the model.

Note that not all blocks accept all types of sample times. For example, a discrete block cannot accept a continuous sample time.

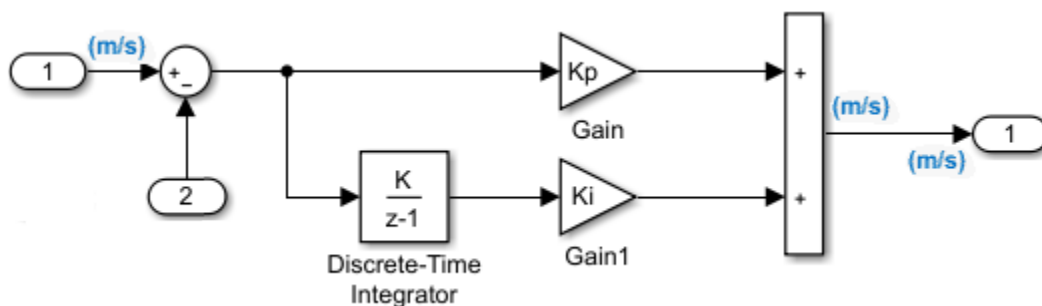

For a visual aid, Simulink allows the optional color-coding and annotation of any block diagram to indicate the type and speed of the block sample times. You can capture all of the colors and the annotations within a legend (see “View Sample Time Information”).

For a more detailed discussion of sample times, see “Sample Time”.

## Units

Units are used to measure the total amount of a quantity.

Simulink units are specified as an Inport block or Outport block parameter at the boundaries of a Simulink model component. Simulink model components include Subsystem blocks, Model blocks, Stateflow charts, and Simulink to Simscape converter blocks. To display units on a model, in the **Debug** tab, select **Information Overlays > Units**.

See also: “Unit Specification in Simulink Models”, “Converting Units”.

## Direct Feedthrough

Direct feedthrough is where the output port signal of a block is computed from the values of its input port signals. The output signal value is a function of the input signal values.

Blocks with direct feedthrough include the Gain, Product, Sum, and Math Function blocks.

## Algebraic Loop

A signal loop between blocks with direct feedthrough is called an algebraic loop. An algebraic loop generally occurs when an input port of a block with direct feedthrough is driven directly by the output port of the same block or indirectly through other blocks with direct feedthrough.

In the following model, the two Gain blocks with direct feedthrough create an algebraic loop:

See also: “Algebraic Loop Concepts”.

## Artificial Algebraic Loops

An *artificial algebraic loop* occurs when an atomic subsystem or Model block causes Simulink to detect an algebraic loop, even though the contents of the subsystem do not contain a direct feedthrough from the input to the output. When you create an atomic subsystem, all input blocks are direct feedthrough, resulting in an algebraic loop.

Start with the included model, which represents a simple proportional control of the plant described by

$$G(s) = \frac{1}{s^2 + 2s + 1}$$

which can be rewritten in state-space form as

$$\dot{x} = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u$$

$$y = [ 0 \quad 1 ] x$$

The system has neither algebraic variables nor direct feedthrough and does not contain an algebraic loop.

Modify the model as described in the following steps:

- 1 Enclose the Controller and Plant blocks in a subsystem.
- 2 In the subsystem dialog box, select **Treat as atomic unit** to make the subsystem atomic.
- 3 In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic Loop** parameter to error.

When simulating this model, an algebraic loop occurs because the subsystem is direct feedthrough, even though the path within the atomic subsystem is not direct feedthrough. Simulation stops with an algebraic loop error.

## Zero-Crossing Detection

Simulink uses a technique known as zero-crossing detection to accurately locate a discontinuity without resorting to excessively small time steps during a simulation. Usually this technique improves simulation run times.

### Related Examples

- Use Block Diagrams To Graphically Represent Dynamic Systems

## Simulink Simulation

Simulating the model of a dynamic system allows you to gain insight about the behavior of a proposed system design without the time consuming process of actually building the system. The concepts in this topic provide a context for understanding how to control a model simulation with Simulink software tools.

### Compilation

Compilation is the Simulink process where the block diagram is translated to an internal representation that interacts with the Simulink engine.

There are no model-level sets of differential equations that are solved numerically as a whole. Instead, the model-level equations correspond to the individual block equations that are solved numerically in a specific order.

### Block Methods

The functionality of a single block is defined by multiple equations. These equations are represented as block methods. These block methods are evaluated (executed) during the execution of a block diagram. The evaluation of these block methods is performed within a simulation loop, where each cycle through the simulation loop represent the evaluation of the block diagram at a given point in time. Common block methods include:

- Derivative - Computes the derivatives of the block's continuous states at the current time step, given the block inputs and the values of the states at the previous time step.
- Update - Computes the value of the block's discrete states at the current time step, given its inputs at the current time step and its discrete states at the previous time step.
- Output - Computes the outputs of a block given its inputs at the current time step and its states at the previous time step.

$$\left\{ \begin{array}{ll} X = [x_c, x_d] & \text{Model states} \\ \dot{x}_c = f_c(X, U, t) & \text{Derivative method} \\ x_d[n + 1] = f_d(X, U, t) & \text{Update method} \\ Y = [y_1, y_2] & \\ Y = g(X, U, t) & \text{Output method} \end{array} \right.$$

$$X(t_0) = X_0 \quad \text{Initial model states}$$

### Model Method

In addition to block methods, a set of methods is provided that compute the model properties and its outputs. The Simulink software similarly invokes these methods during simulation to determine a model's properties and its outputs. The model methods generally perform their tasks by invoking block methods of the same type. For example, the model Outputs method invokes the Outputs methods of the blocks that it contains in the order specified by the model to compute its outputs. The model Derivatives method similarly invokes the Derivatives methods of the blocks that it contains to determine the derivatives of its states.

See also: "Simulation Phases in Dynamic Systems".

## Callback

Callbacks are MATLAB expressions that execute in response to a specific modeling action. Simulink provides model, block, and port callback parameters that identify specific kinds of modeling actions. You provide the code for callback parameters. Simulink executes the callback code when the associated modeling action occurs.

### Model Callback

Model callback parameters include:

- `PreloadFcn` - Executes before a model loads. For example, you can provide code that loads the variable values a model uses into the MATLAB workspace.

See “Model Callbacks”.

### Block Callback

Block callback parameters include:

- `OpenFcn` - Execute when you open a Subsystem block.
- `LoadFcn` - Execute after a diagram is loaded. For a Subsystem blocks, also execute block callback parameters for the blocks within Subsystem block.

### Port Callback

Port callback parameter:

- `ConnectionCallback` - Execute code every time the connectivity of a port changes.

See “Port Callbacks”.

## Execution Order

The Execution order is the sequence in which block output methods are called after evaluating direct feedthrough of each input port. To display execution order, in the **Debug** tab, select **Information Overlays > Execution Order**.

In the following model, the Integrator block output runs first, and then the loop of blocks connected to the Integrator block input. Missing execution numbers in a sequence are usually due to so-called “hidden buffer” blocks; see “Ensure Outputport is Virtual”.

See also: “Control and Display Execution Order”, “Simulation Phases in Dynamic Systems”.

## Simulation

Simulation is the process after model *compilation* where block method outputs and states are computed at successive time steps over a specified time range using a numerical solver.

During each simulation loop, Simulink calculates a  $\Delta t$  to determine the time step  $t(k+1) = t(k) + \Delta t$ . The size of  $\Delta t$  is based on an estimated error between the simulated solution and the actual solution. At the end of a simulation, data results are given as vectors  $[t, X, Y]$  for time, state and output at each time step.

See also: “Simulation Phases in Dynamic Systems”, “Simulate a Model Interactively”, “Speed Up Simulation”.

## Solver

A Solver finds an approximate solution for a set of model equations. Simulink uses established numerical solvers for this task.

Solver step size can be fixed or variable:

- Fixed step - Time step  $T(k+1) = T(k) + \Delta t$  where  $\Delta t$  is constant. If step size is too large, simulation results can have a large error. In the following example, a step size of 2 distorts the shape of a sine wave signal. You can specify the size of the time step in the case of fixed-step solvers, or the solver can automatically determine the step size in the case of variable-step solvers.

- Variable step - Variable step solvers iterate to reach a solution based on an error tolerance. Time step  $T(k+1) = T(k) + \Delta t_k$  where  $\Delta t_k$  changes from one simulation step to the next depending on the estimated error. Smaller time steps increase the accuracy of the simulation results. To minimize the computation workload, a variable-step solver chooses the largest step size consistent with achieving an overall level of precision specified by the error tolerance and observing zero-crossings. This ensures that all model states are computed to the accuracy specified by the user.

Choosing a solver method depends on the nature of the model equations. Euler's method is a simple numerical solver that calculates the next value of  $y$  by using the slope ( $y'$ ) of a tangent line to  $y$ . If  $y$  is a function that integrates a ramp function  $x$  with a slope of 1,  $y' = x$ , and a numerical solver would use the following equations.

$$x[n+1] = x[n] + \Delta t * 1$$

$$y[n+1] = y[n] + \Delta t * x[n+1]$$

Decreasing the step size increases the accuracy of the results. but it increases the time to complete a simulation. In the following example, a step size of 2 shows an error of about 20 percent after 10 seconds while a step size of 0.5 produces a result that is closer to the actual solution.

.

## Simulink Tools

**Code Generation Advisor** - Simulink tool that checks a model for how objectives such as efficiency, traceability, and safety, map to code generation options in a model configuration set. To open and run the advisor, in the **Modeling** tab, click **Model Advisor**, and then click **Code Generation Advisor**.

**Configuration Parameter dialog** - Simulink tool to select and specify *model parameters*. To open the dialog box, in the **Simulation** tab, under **Configuration & Simulation**, click **Model Settings**.

**Performance Advisor** - Simulink tool that checks for conditions that might slow down a simulation. The advisor can automatically make changes to a model to address these conditions or you can review and apply suggested changes manually. To open the advisor, in the **Debug** tab, click **Performance Advisor**.

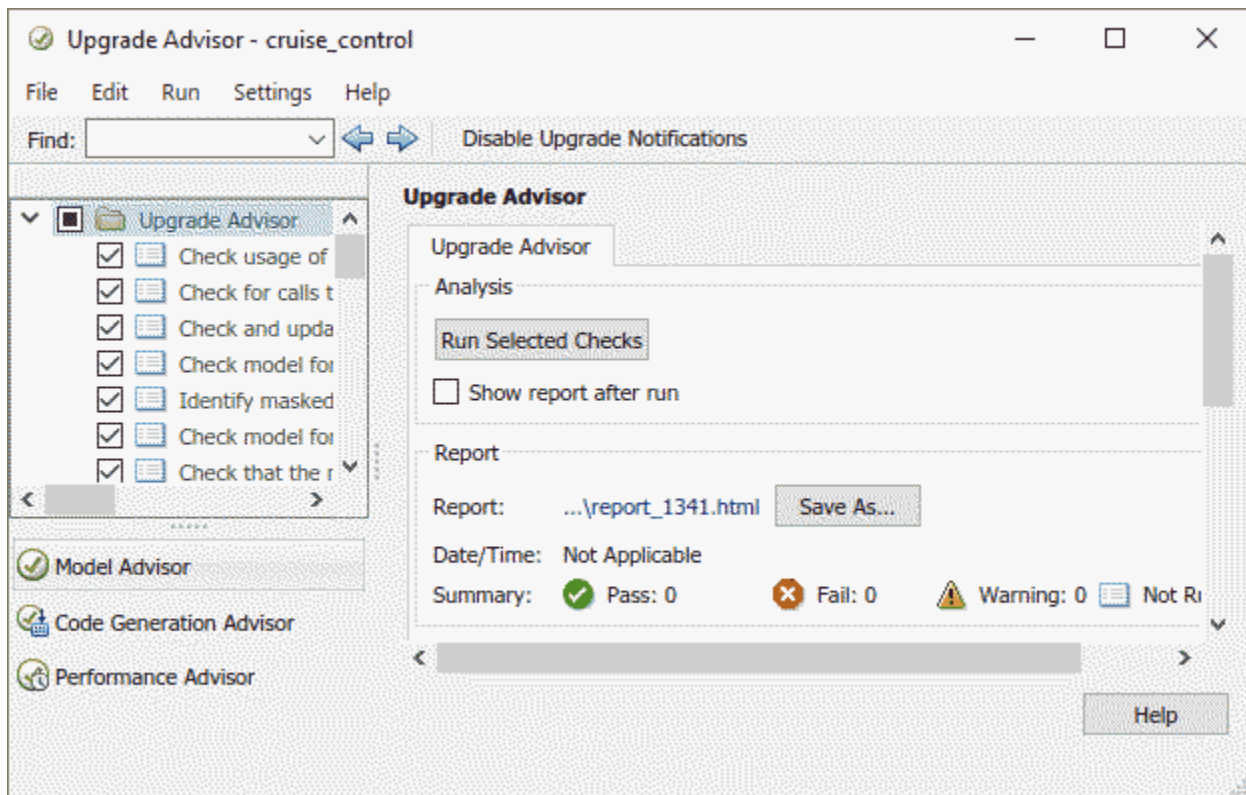

**Property Inspector** - Simulink tool to define and edit parameters and properties for models and blocks. To open the inspector in a Simulink Editor pane, in the **Modeling** tab, under **Design**, click **Property Inspector**.

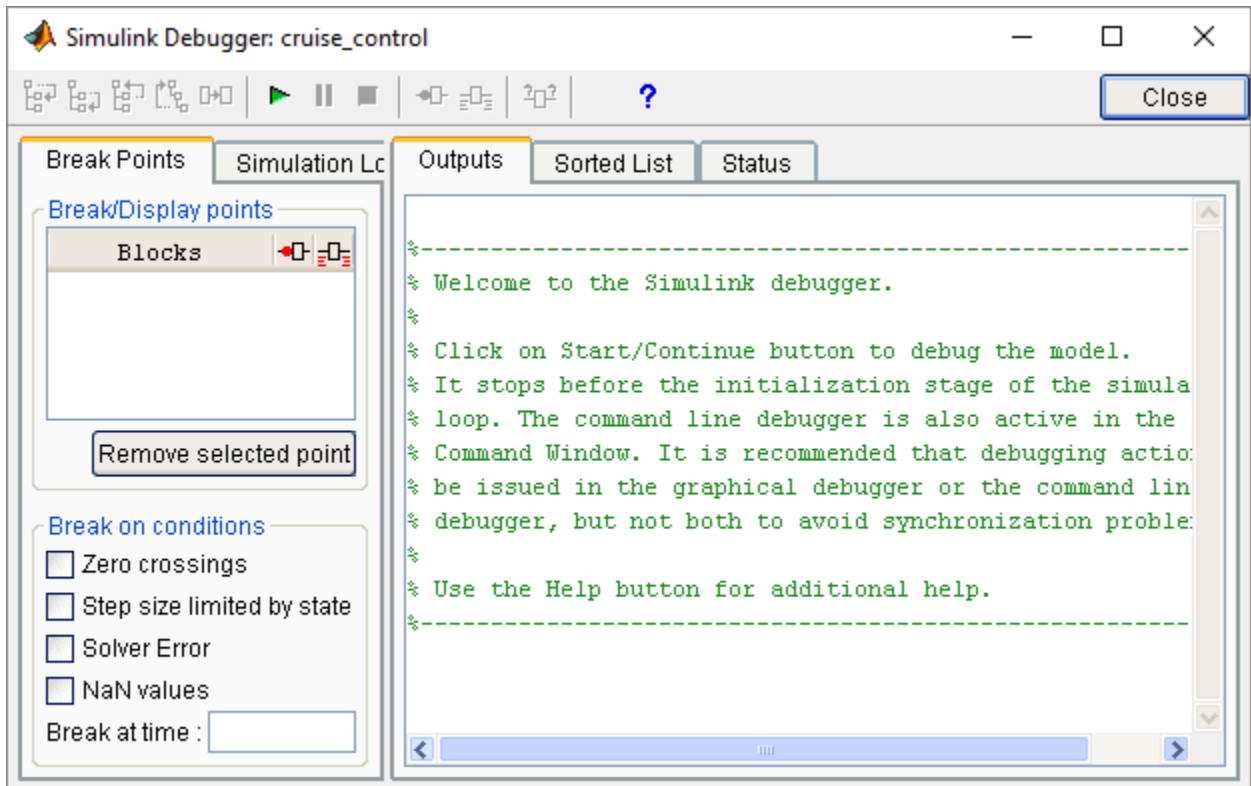

**Simulation Data Inspector** - Simulink tool to visualize simulation results and compare results from multiple simulations. Select signals to log by right-clicking a signal and then selecting **Log Selected Signals**. After running a simulation, open the inspector by clicking the toolbar icon .

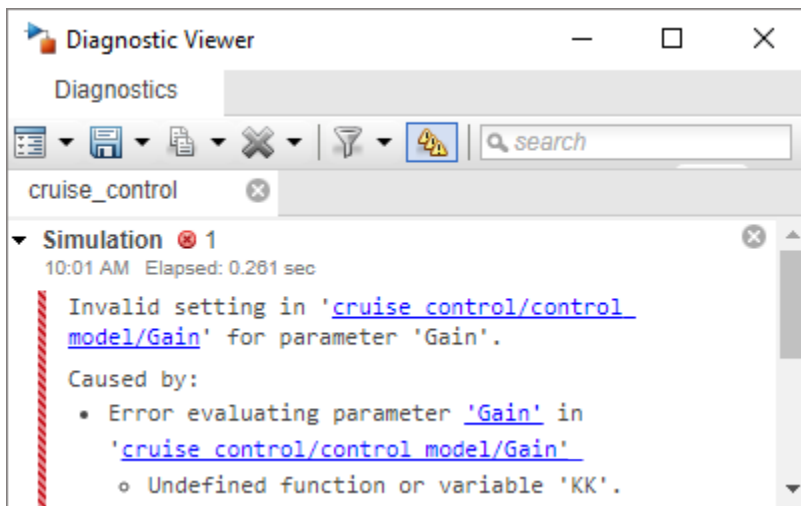

**Upgrade Advisor** - Simulink tool to identify new feature benefits and needed changes to your model when upgrading to a new release. To open the advisor, in the **Modeling** tab, select **Model Advisor** > **Upgrade Advisor**.

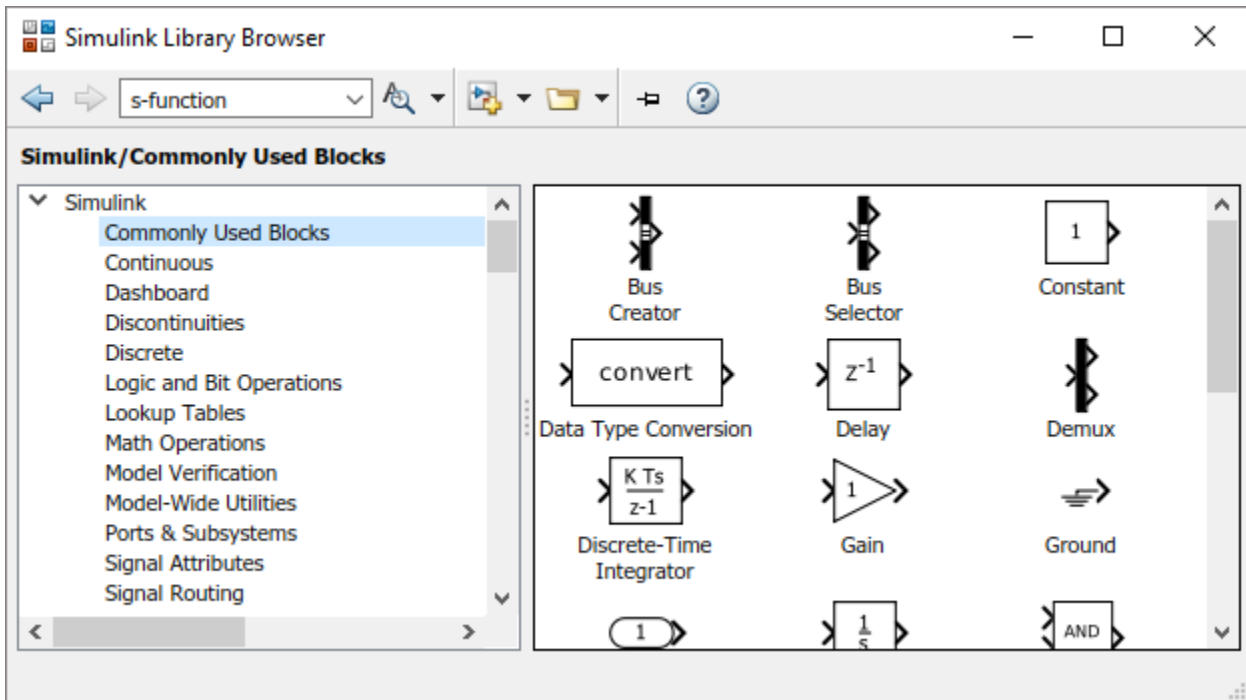

**debugger, Simulink debugger** - Simulink tool to troubleshoot model simulations by stepping through calls to the block-level methods. To open the debugger, in the **Debug** tab, select **Breakpoints List > Debug Model**.

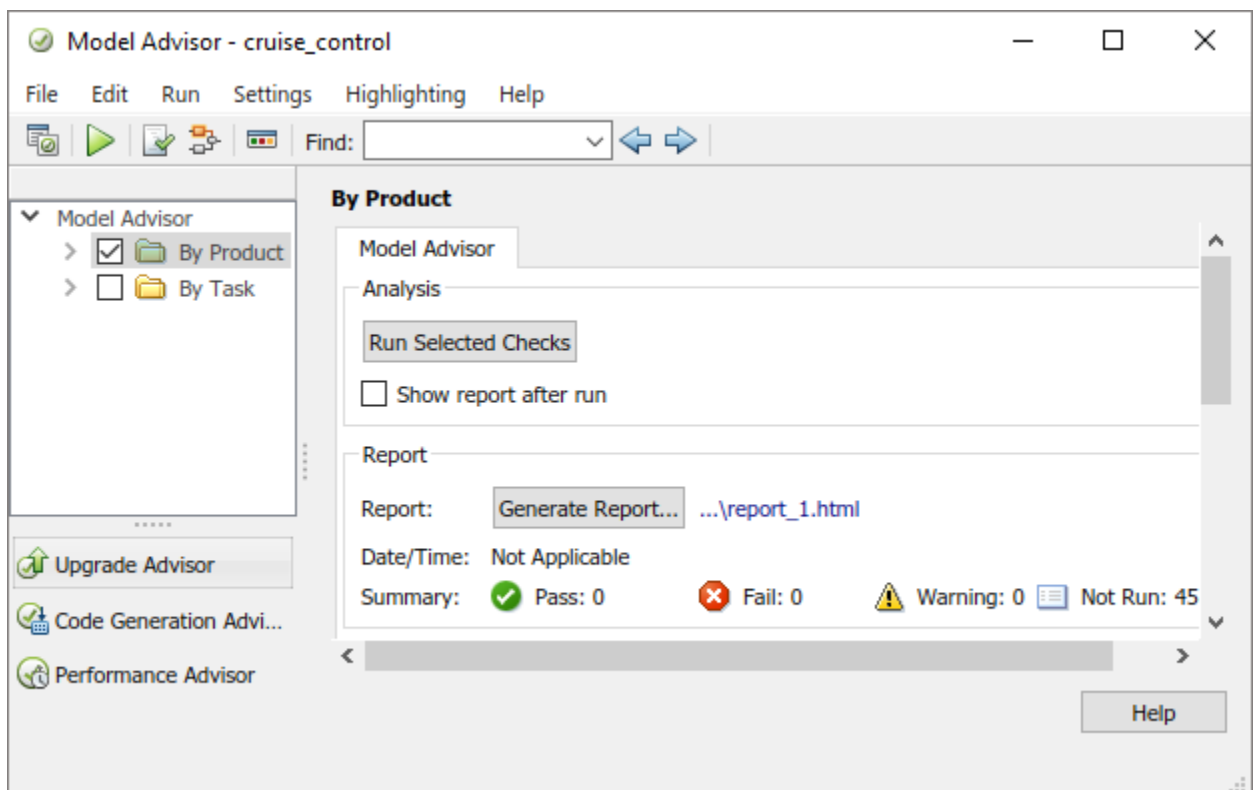

**Diagnostic Viewer** - Simulink tool that displays error, warning, and information messages for conditions detected during a Simulink operation. To open the viewer, in the **Debug** tab, click **Diagnostics**.

**Library Browser, Simulink Library Browser** - Simulink tool for searching and selecting model blocks. To open the browser, click the Simulink Editor toolbar icon .

**Model Advisor** - Simulink tool that checks a Simulink model for conditions and configuration settings that cause inaccurate or inefficient simulation of a *model*. To open and run the advisor, in the **Modeling** tab, click **Model Advisor**.

**Model Browser** - Simulink tool to view and navigate the structure of a *model*. To open the Model Browser in a Simulink Editor pane, in the **Modeling** tab, select **Environment** > **Model Browser**.

**Model Data Editor** - Simulink tool to define and edit data items in a list that you can sort, group, and filter. For example, enter property and parameter values, such as data types and dimensions without having to locate the items in the block diagram. To open the Model Data Editor, in the Simulink Editor, in the **Modeling** tab, under **Design**, click **Model Data Editor**.

The screenshot shows the Simulink Model Data Editor for a model named 'cruise\_control'. The top part displays a block diagram with three main components: 'step response', 'control model', and 'plant model'. The 'control model' block is highlighted with a blue border. It has two inputs: 'setpoint' and 'velocity', and one output: 'control'. The 'plant model' block has two inputs: 'control' and 'velocity', and one output: 'velocity'. The 'step response' block has one output: 'setpoint'. The 'velocity' output of the 'plant model' is connected to the 'velocity' input of the 'control model'.

The bottom part of the screenshot shows the 'Model Data Editor' window with the 'Signals' tab selected. The table below lists the signals and their properties:

	Source	Name	Data Type	Min	Max	Dimensions	Complexity	Sample Time	Unit	Resolve	
	control m...		double	-Inf	Inf	1	real	[0 0]	m/s	<input type="checkbox"/>	
	plant mo...		double	-Inf	Inf	1	real	[0 0]	inherit	<input type="checkbox"/>	
	step resp...		double	-Inf	Inf	1	real	0	[0 0]	m/s	<input type="checkbox"/>

The status bar at the bottom indicates 'Ready', '125%' zoom, and 'auto(ode3)' solver.

**Model Dependency Viewer** - Simulink tool to graph the models and libraries referenced directly or indirectly by the parent model. To open the viewer, in the **Modeling** tab, select **Compare > Dependencies > Models & Libraries**. In the following example, the `plant_model` is referenced from the parent `cruise_control` model.

**Model Explorer** - Simulink tool to view and modify elements of a Simulink model, Stateflow chart, or model workspace variables. To open the explorer window, in the **Modeling** tab, click **Model Explorer**.

## Programming Constructs in Simulink

**Simulink command** - MATLAB command that is specific to Simulink modeling or simulation. Enter Simulink commands in the MATLAB Command Window or use in MATLAB scripts for testing a model programmatically. The following commands set simulation parameters, run a simulation, and saves the simulation results. In the first statement, `sim` is a *Simulink command* for running a simulation.

```
simOut = sim('cruise_control','SimulationMode','normal',...
 'AbsTol','1e-5','SaveState','on',...
 'StateSaveName','xout','SaveOutput','on',...
 'OutputSaveName','yout','SaveFormat','Dataset');
outputs = simOut.get('yout')
```

**callback, model callback** - MATLAB code that executes in response to a specific *model* or *block* action. To add a model callback, in the **Modeling** tab, under **Design**, click **Property Inspector**, then in the **Properties** tab, select a function from the **Callbacks** list, and then enter MATLAB code or the name of a MATLAB script.

In the following example, when Simulink loads a model it also loads a file into the MATLAB workspace with parameters values for the model.

**Simulink function** - Computational unit that calculates a set of outputs when provided with a set of inputs. A common text interface between function caller and function definition allows various definition formats using a Simulink Function block, exported Stateflow graphical function, or exported Stateflow MATLAB function.

**MATLAB Function** -

**S-function, system-function** - Computer language description of a Simulink S-Function block written in MATLAB code, C, C++, or Fortran. C, C++, and Fortran S-functions are compiled as MEX files using the MATLAB mex utility.

```
Editor - E:\matlab\toolbox\simulink\simdemos\simfeatures\src\sfunmem.c
sfunmem.c* x +
1 /* File : sfunmem.c
2 * Abstract:
3 * A one integration-step delay and hold "memory" function.
4 * Syntax: [sys, x0] = sfunmem(t,x,u,flag)
5
6 #define S_FUNCTION_NAME sfunme
7 #include "simstruc.h"
8
9 /*=====
10 * S-function methods *
11 *=====*/
12 /* Function: mdlInitializeSizes =====
13 * Abstract:
14 * Call mdlCheckParameters to verify that the parameters are okay,
15 * then setup sizes of the various vectors.
16 */
17 static void mdlInitializeSizes(SimStruct *S)
18 {
19 ssSetNumSFcnParams(S, 0); /* Number of expected parameters */
20 if (ssGetNumSFcnParams(S) != ssGetSFcnParamsCount(S)) {
21 return; /* Parameter mismatch will be reported by Simulink */
22 }
```

## Model Development Processes

**model-based design** - Development process that uses a system model as an executable specification throughout development. The process supports model and model component design, model simulation of dynamic behavior, code generation from the model, and continuous test and verification.

**software-in-the-loop (SIL) simulation** - Development process where compiled source code on a development computer executes as a separate process from the rest of the Simulink model. Typical goals include initial source code testing and verification by comparing *software-in-the-loop* results with model simulation results and system requirements.

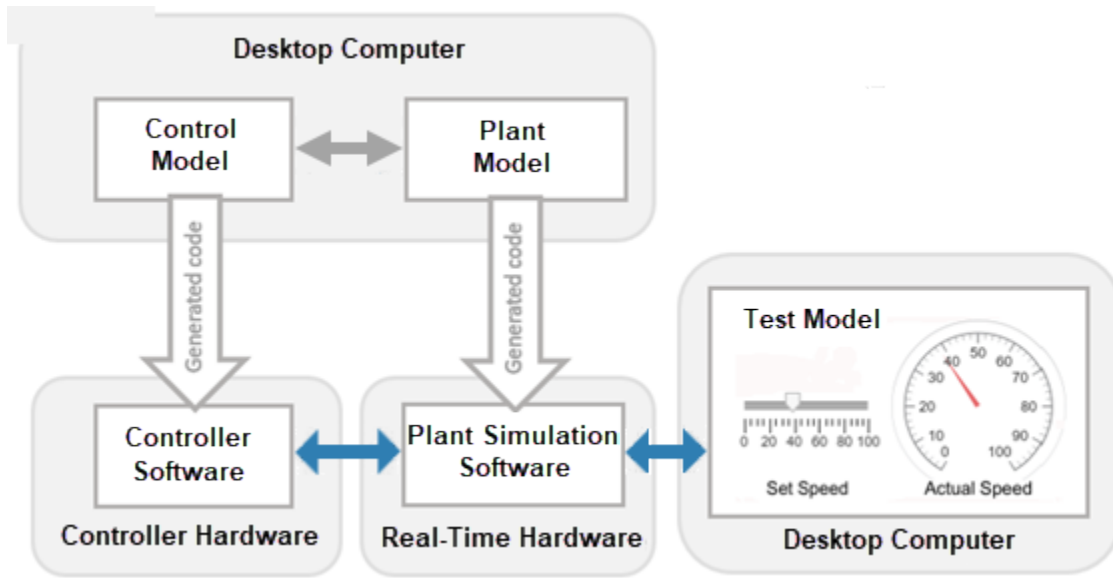

In the following example, to run a software-in-the-loop simulation for the controller, right-click the Model block labeled `control_model` and then select **Block parameters**. From the **Simulation mode** list, select Software-in-the-loop (SIL).

**processor-in-the-loop (PIL) simulation** - Development process that cross-compiler source code and runs the resulting object code on a target processor using hardware-specific data attributes and sample time attributes. Typical goals include object code verification by comparing *processor-in-the-loop* results with model simulation and *software-in-the-loop (SIL)* results.

**hardware-in-the-loop (HIL) simulation** - Development process that pairs physical components, such as the hardware and software for a controller, with a virtual real-time implementation of a physical component, such as a plant.

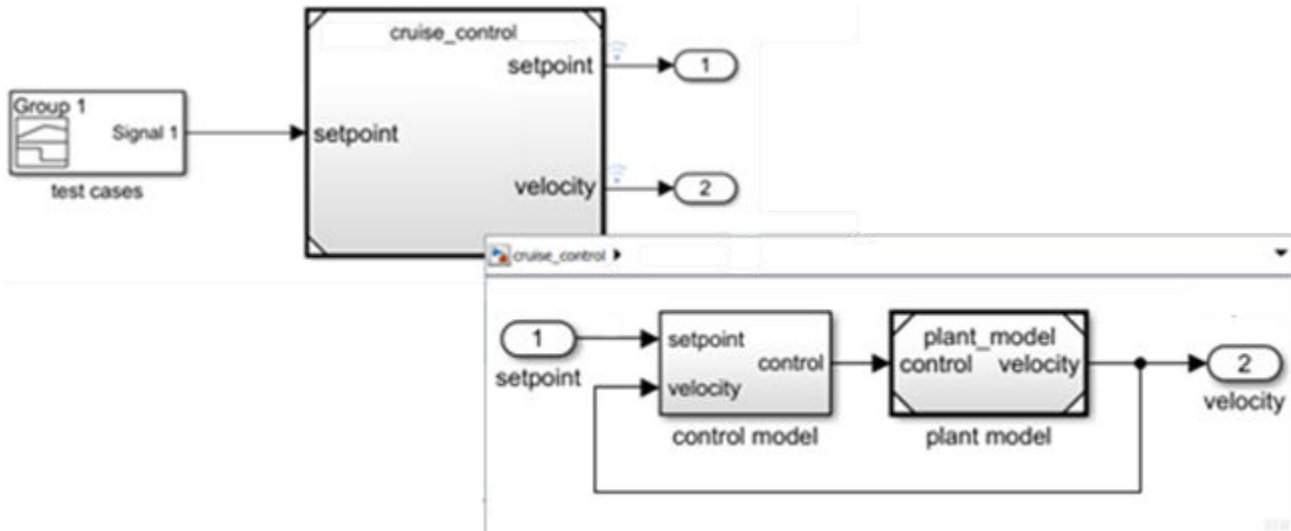

In the following example, code for the controller model is generated and downloaded to the production controller hardware. Code is generated for the plant model and downloaded to a real-time hardware computer (e.g. Simulink Realtime).

## Test Harness

Simulink model that provides a framework for testing the simulation behavior and outputs of another *model* or *model component*. Objectives of the *test harness* are to automate the testing process, execute a test suite with multiple test cases, and analyze results.

In the following model, a Signal Builder block provides test signals while outputs are logged for analysis in the *Simulation Data Inspector* or MATLAB.

## What is Simulink Online?

Simulink Online™ provides access to the latest version of Simulink from a standard web browser using MathWorks hosted computing resources and storage.

With Simulink Online, you can:

- Access the latest version of Simulink with all the latest features available to you through your current license.
- Use Simulink in your web browser without any downloads, installation, or maintenance.
- Store up to 5 GB of MATLAB and Simulink files in your MATLAB Drive™.
- Collaborate with other Simulink users by giving them view-only or can-edit access to your files.
- Create a link to your work and share it globally.
- Synchronize your desktop files with Simulink Online and MATLAB Drive using the MATLAB Drive Connector.

To start using Simulink Online, go to <https://matlab.mathworks.com/>.

For more information about Simulink Online, including supported license types, specifications, limitations, and system requirements, see [Simulink Online](#).

## Function-Call Subsystems with Multiple Initiators

This example shows a function-call subsystem that is called by multiple different function-call initiators that are grouped by a Mux block.

Open the example model `FunctionCallSubsystemMultipleInitiators`.

Copyright 1990-2022 The MathWorks, Inc.

The model contains a function-call subsystem, `f`, that receives a mux signal at its function-call input port. The Mux block groups function-call signals from the Stateflow charts `Chart1` and `Chart2` into the mux signal.

The data connection between port `out1` of `Chart1` and port `d1` of `Chart2` guarantees that `Chart1` executes before `Chart2`.

When you create function-call subsystems with multiple callers, clearly define the relative execution order of each chart that calls `f()`. For example, if you remove the data connection between `Chart1` and `Chart2`, add priorities to `Chart1` and `Chart2` to specify the relative execution order of these charts.

Ambiguity does not cause an error because it may be valid for specific cases. For example, if you remove all states from subsystem `f` and delete the line from `out1` of `Chart1` to `d1` of `Chart2`, then the order in which `Chart1` and `Chart2` execute does not matter.

## Feedback System

This example demonstrates a state-space system that has matrix signals:

$$\dot{x} = Ax - BKx + Bu$$

$$y = Cx$$

Open the example model.

Copyright 2000-2022 The MathWorks, Inc.

To ensure that the system is stable, the state feedback matrix,  $K$ , is chosen such that the eigenvalues of  $A - BK$  equal  $-1 + i$ ,  $-1 - i$ ,  $-2$ ,  $-3$ .

## Programmatically Create Bus Element Ports

This example shows how to create bus element ports by adding In Bus Element and Out Bus Element blocks with the `add_block` function. To get and set the attribute values for an element of a bus element port, this example uses the `get_param` and `set_param` functions.

Open a new model.

```
open_system(new_system);
```

### Programmatically Create Input Bus Element Ports

Add an In Bus Element block to the model.

```
add_block('simulink/Ports & Subsystems/In Bus Element',...
 [gcs '/In Bus Element']);
```

InBus . signal1 

When you do not specify the port or element name, the new block uses the default names. By default, the input bus element port is named `InBus`, and the bus element is named `signal1`.

Add another In Bus Element block to the model. Instead of specifying a new block name, have the function make the block name unique with the `MakeNameUnique` argument. To avoid overlapping blocks, use the `Position` argument.

```
add_block('simulink/Ports & Subsystems/In Bus Element',...
 [gcs '/In Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[230 35 240 45]');
```

InBus . signal1 

InBus . signal1 

The new block duplicates the previous block. Both blocks use the same default names.

Add a block for an element of the port named `chirp`, and replace the default port name with a custom name, such as `Input1`. Optionally, specify additional block parameters, such as background color, and element attributes, such as data type.

```
add_block('simulink/Ports & Subsystems/In Bus Element',...
 [gcs '/In Bus Element'], ...
 'MakeNameUnique','on',...
 'Position','[230 65 240 75]', ...
 'PortName','Input1', ...
 'Element','chirp',...
 'BackgroundColor','cyan',...
 'OutDataTypeStr','int32');
```

Input1 . signal1 

Input1 . signal1 

Input1 . chirp 

When you programmatically add an In Bus Element block with a nondefault port name, In Bus Element blocks that use the default port name update to use the nondefault port name.

To add an In Bus Element block for an existing port, copy the corresponding In Bus Element block from your model. For example, create a block that selects an element named `sine` from the port you previously created.

```
add_block(['simulink/Ports & Subsystems/In Bus Element'],...
 [gcs '/In Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[230 95 240 105]', ...
 'Element','sine',...
 'BackgroundColor','magenta');
```

To add an In Bus Element block for a new port, add the In Bus Element block from the Simulink® library and specify the new port name. For example, create a block that selects an element named `pulse` from a port named `Input2`.

```
add_block('simulink/Ports & Subsystems/In Bus Element',...
 [gcs '/In Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[230 125 240 135]', ...
 'PortName','Input2',...
 'Element','pulse')
```

### Programmatically Create Output Bus Element Ports

Add an Out Bus Element block to the model.

```
add_block('simulink/Ports & Subsystems/Out Bus Element',...
 [gcs '/Out Bus Element'],...
 'Position','[290 5 300 15]');
```

When you do not specify the port or element name, the new block uses the default names. By default, the output bus element port is named `OutBus`, and the bus element is named `signal1`.

Add another Out Bus Element block to the model.

```
add_block('simulink/Ports & Subsystems/Out Bus Element',...
 [gcs '/Out Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[290 35 300 45]');
```

The new block adds an element to the output port. Both blocks use the same default port name, but the new block increments the element name to avoid a conflict.

Add a block for an element of the port named `chirp`, and replace the default port name with a custom name, such as `Output1`. Optionally, specify additional block parameters, such as background color, and element attributes, such as data type.

```
add_block('simulink/Ports & Subsystems/Out Bus Element',...
 [gcs '/Out Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[290 65 300 75]', ...
 'PortName','Output1', ...
 'Element','chirp',...
 'BackgroundColor','green',...
 'OutDataTypeStr','int32');
```

When you programmatically add an Out Bus Element block with a nondefault port name, Out Bus Element blocks that use the default port name update to use the nondefault port name.

To add an Out Bus Element block for an existing port, copy the corresponding Out Bus Element block from your model. For example, create a block that outputs an element named `sine` to the port you previously created.

```
add_block(['gcs '/Out Bus Element'],...
 [gcs '/Out Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[290 95 300 105]', ...
 'Element','sine',...
 'BackgroundColor','yellow');
```

To add an Out Bus Element block for a new port, add the Out Bus Element block from the Simulink library and specify the new port name. For example, create a block that outputs an element named `pulse` to a port named `Output2`.

```
add_block('simulink/Ports & Subsystems/Out Bus Element',...
 [gcs '/Out Bus Element'],...
 'MakeNameUnique','on',...
 'Position','[290 125 300 135]', ...
 'PortName','Output2',...
 'Element','pulse')
```

### Programmatically Change Port Parameters

When you change a port parameter, the change applies to all blocks that correspond to the port.

For example, rename the first output port from `Output1` to `Out1` with the `set_param` function.

```
set_param([gcs '/Out Bus Element'], 'PortName', 'Out1')
```

The labels of the Out Bus Element blocks that correspond with the port update to say Out1 instead of Output1.

The new port name must be unique within the model component.

### Programmatically Change Block Parameters

When you change a block parameter, the change applies to only the specified block.

For example, change the background color from black to orange for the first In Bus Element block you added by using the `set_param` function.

```
set_param([gcs '/In Bus Element'], 'BackgroundColor', 'orange')
```

### Programmatically Change Element Attributes

By specifying a combination of the model component and the element label, you can change the value of an attribute of an existing top-level bus, nested bus, signal, or message at a bus element port.

For example, set the minimum and maximum values of the element `Input1.sine` to -1 and 1, respectively, with the `get_param` function.

```
set_param([gcs '/Out1.sine'], 'OutMin', '-1', 'OutMax', '1')
```

To check the value of each attribute, use the `get_param` function.

```
get_param([gcs '/Out1.sine'], 'OutMin')
```

```
ans =
'-1'
```

```
get_param([gcs '/Out1.sine'], 'OutMax')
```

```
ans =
'1'
```

## Manage Bus-to-Vector Conversions

This example shows how to find and manage implicit bus-to-vector conversions.

Blocks that do not accept buses may implicitly convert buses to vectors. When a bus is treated as a vector, bus elements become inaccessible.

Some buses cannot convert to vectors. For more information, see [Bus to Vector](#).

### Identify Implicit Bus-to-Vector Conversions

Open and simulate model `ex_bus_to_vector`.

To accept the bus, the Gain blocks implicitly convert the bus to a vector.

To identify buses treated as vectors before simulation, use function `Simulink.BlockDiagram.addBusToVector`.

```
[blocks] = Simulink.BlockDiagram.addBusToVector('ex_bus_to_vector')

Processing block diagram 'ex_bus_to_vector'
Number of blocks left that are connected to a bus being used as a vector: 2
Done processing block diagram 'ex_bus_to_vector'

blocks =

 1x2 struct array with fields:

 BlockPath
 InputPort
 LibPath
```

To identify buses treated as vectors during simulation, set the **Bus signal treated as vector** configuration parameter to `warning` or `error`. The default setting for **Bus signal treated as vector** is `none`, which generates no warning or error message when a block implicitly converts a bus to a vector.

### Explicitly Define Bus-to-Vector Conversions

To insert Bus to Vector blocks where blocks implicitly convert buses to vectors, use function `Simulink.BlockDiagram.addBusToVector` with `reportOnly` set to `false`. When you use function `Simulink.BlockDiagram.addBusToVector` with `reportOnly` set to `false`, the function saves the model. To create a writable copy of model `ex_bus_to_vector`, this example uses the `save_system` function.

```
save_system('ex_bus_to_vector','ex_bus_to_vector_blocks');
[blocks,busToVectors] =
Simulink.BlockDiagram.addBusToVector('ex_bus_to_vector_blocks',true,false);
```

The Gain blocks no longer implicitly convert the bus to a vector. The inserted Bus to Vector blocks perform the conversion explicitly.

Bus to Vector blocks are virtual and do not affect simulation results, code generation, or performance.

Function `Simulink.BlockDiagram.addBusToVector` returns no remaining implicit bus-to-vector conversions.

```
[blocks] = Simulink.BlockDiagram.addBusToVector('ex_bus_to_vector_blocks')
###No buses used as vectors left to process
blocks =
 1x0 empty struct array with fields:
 BlockPath
 InputPort
 MixedAttributes
```

By specifying acceptable bus-to-vector conversions with Bus to Vector blocks, you can more easily identify unexpected conversions. Having configuration parameter **Bus signal treated as vector** set to warning or error alerts you when an unexpected bus-to-vector conversion occurs.

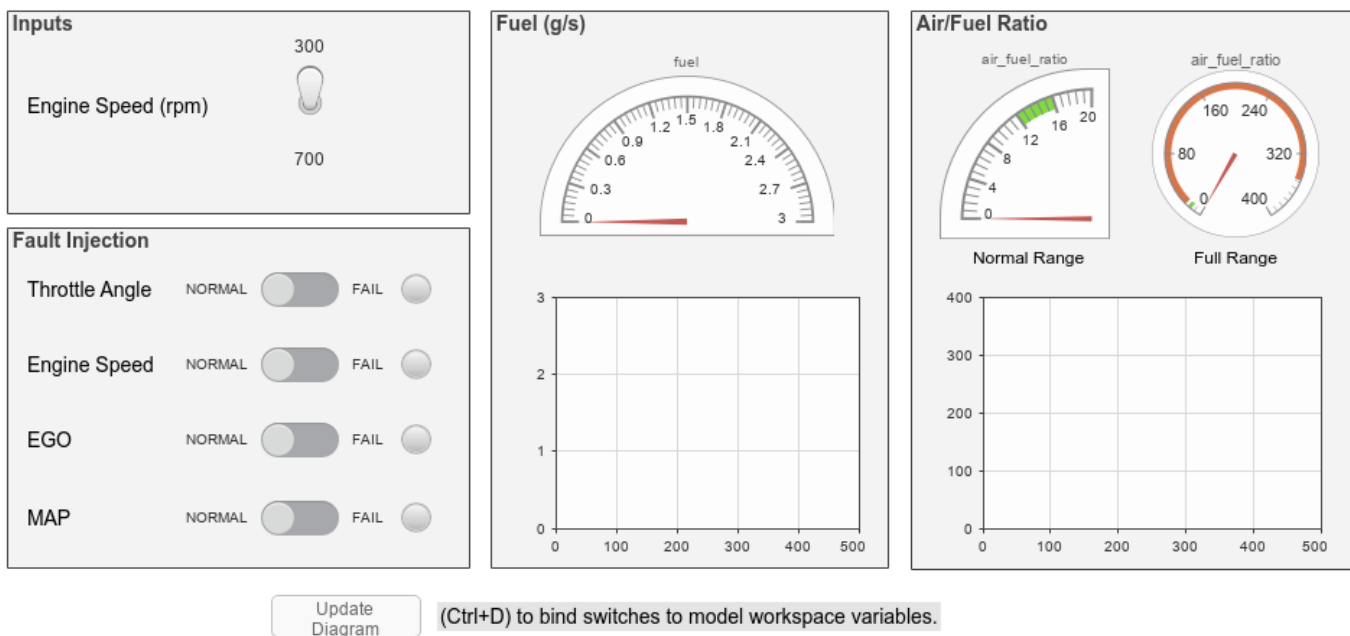

## Initialize Your Model Using the Callback Button Block

This example shows how to use the Callback Button block to perform initialization routines on your model.

### Explore the Model

The example model builds on the `sldemo_fuelsys` featured model. When you open the model, to bind the workspace variables to their Dashboard blocks, you have to update the model diagram. Here, the Callback Button block at the bottom of the Dashboard subsystem in the model has been configured to update the diagram on the release of the mouse button when you click the block.

### Fault-Tolerant Fuel Control System Dashboard

You do not need to start a simulation for the Callback Button to react to your input. Just select and then click the Callback Button to run the initialization code. Double-click the Callback Button block to view and edit its parameters, including the press and click scripts.

### See Also

### More About

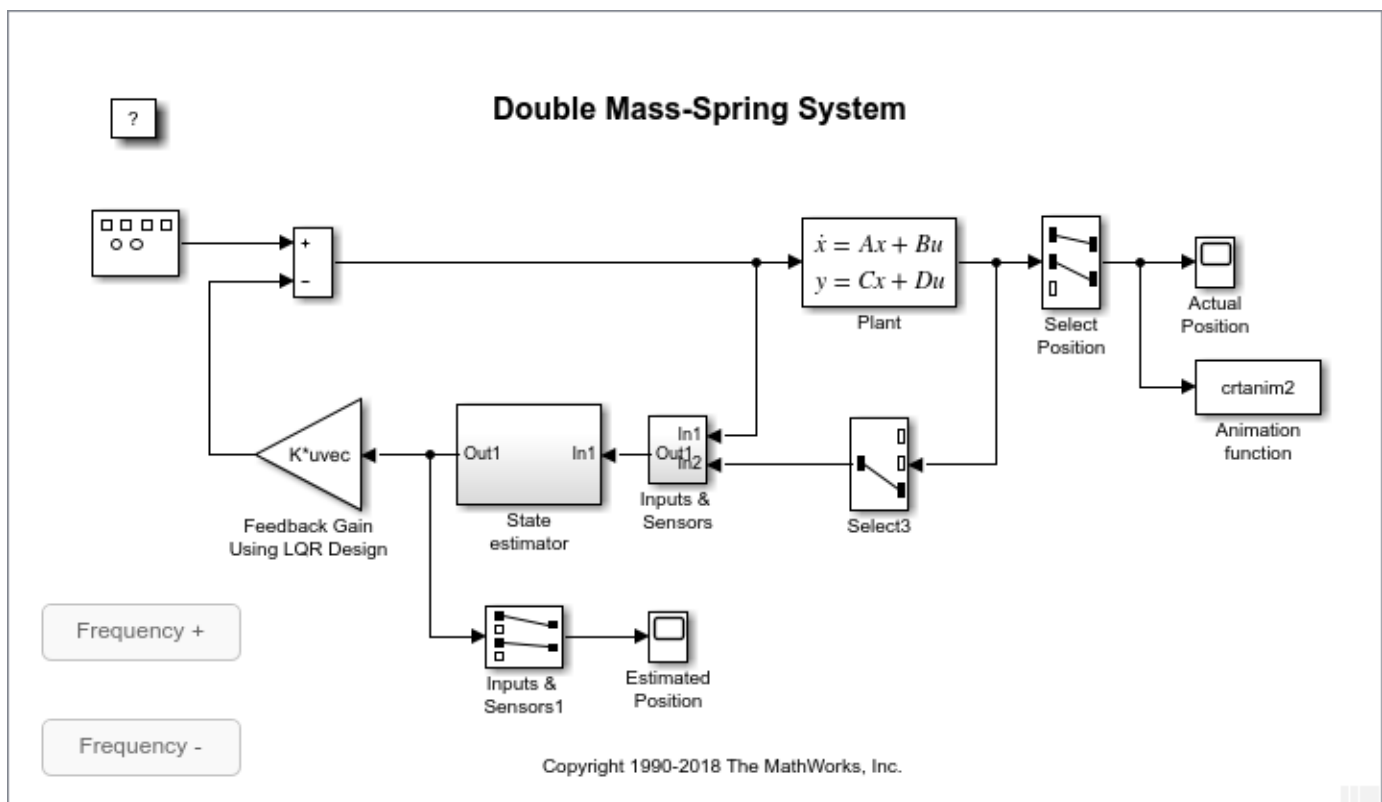

- “Modeling a Fault-Tolerant Fuel Control System” on page 13-121

## Control a Parameter Value with Callback Button Blocks

This example models control of a system that consists of two masses attached on either side of a spring. A control loop damps the oscillation of the spring that results when an external force acts on the system. The model uses Callback Button blocks to provide an interface for you to adjust the frequency of the external force before and during simulation.

### Explore the Model

The model for this example adds two Callback Button blocks, labeled Frequency + and Frequency - to the Double Mass-Spring System model. When you simulate the model, an animation visualizes the system.

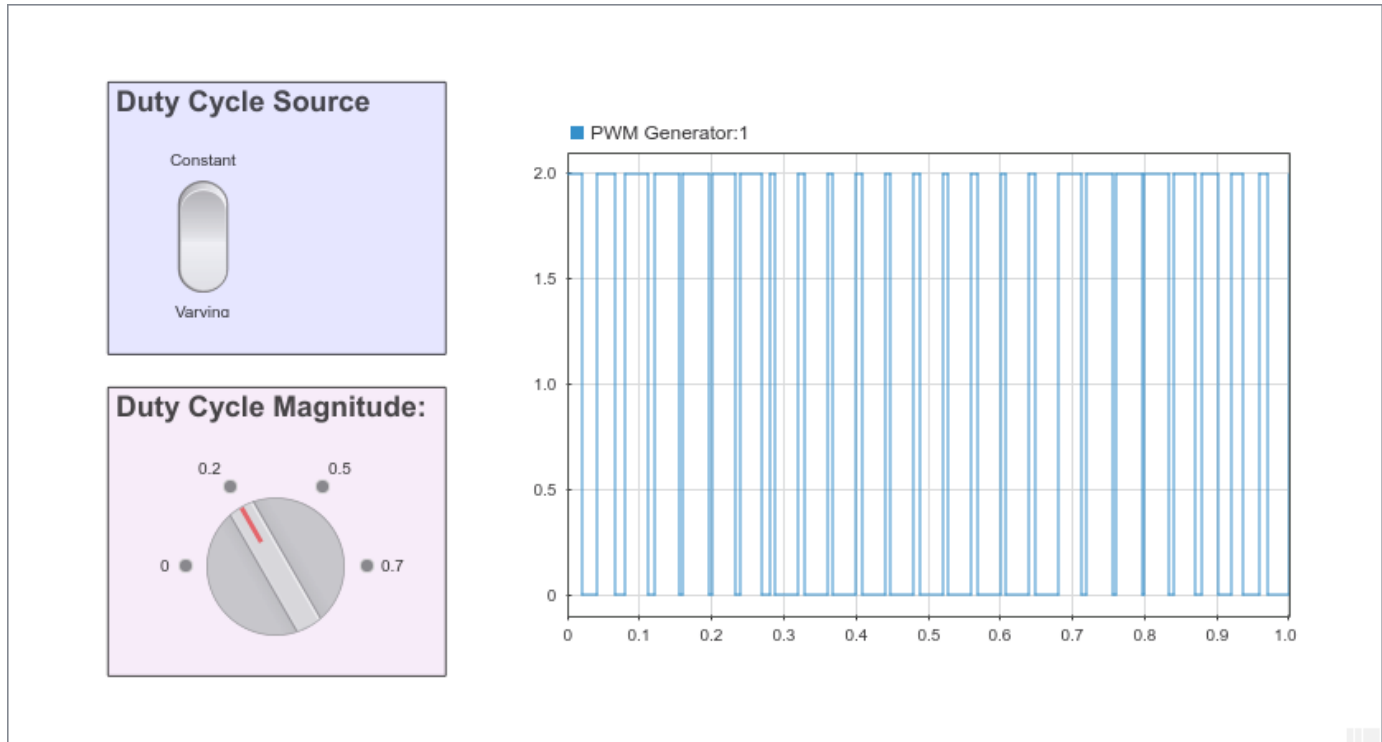

Click the button labeled Frequency + to increase the oscillation frequency. When you adjust the frequency of the external force, the Callback Button block displays a message in the command window indicating the new frequency value. You can adjust the parameter during a simulation and while the model is idle.

Both Callback Button blocks in this model are configured with a ClickFcn that responds to your clicks and a PressFcn that executes when you press the Callback Button block. Double-click the Frequency + Callback Button block to view its parameters.

When you click the Frequency + Callback Button block, the ClickFcn increases the frequency of the external force by 0.1. If you press the Callback Button block for more than the 500 ms Press Delay, the PressFcn increases the frequency of the external force by 0.1 every second.

## Control the Duty Cycle of a PWM Signal Using Dashboard Blocks

This example shows how a simulation dashboard built using Dashboard blocks controls the duty cycle of a PWM signal generated by the model. The example is a modified version of the `sfcdemo_pwm` example. The PWM Generator block takes a duty cycle and period as inputs to generate a PWM output. You can control the source for the duty cycle using a switch.

### Build the Dashboard Subsystem

To create the Dashboard subsystem in this example:

1. Add a Subsystem block to the model.
2. Delete the pre-populated contents of the subsystem.
3. Add the contents of the dashboard. The dashboard in this example includes a Rocker Switch block and a Knob block, which allow you to modify variables during simulation. The Dashboard Scope block displays the generated PWM signal.

Use areas in the Dashboard subsystem to group and label Dashboard blocks. For more information about creating areas, see "Box and Label Areas of a Model".

### Connect Blocks in the Model

In this model, the Rocker Switch block in the Dashboard subsystem provides the interface for selecting the duty cycle source. A Switch block with a Constant block as its control input replaces the

Manual Switch in the `sfcndemo_pwm` model. Replacing the Manual Switch block requires three blocks but allows you to gather model controls and visualizations in a single view. The Rocker Switch block connects to the value of the Constant block. In this model, the Constant block value is set by the variable `duty_cycle_source`.

This model also uses the variable `duty_cycle` to set the magnitude of the duty cycle for both the duty cycle (constant) and duty cycle (varying) sources. The Knob block in the Dashboard subsystem connects to the `duty_cycle` variable, allowing you to modify its value during simulation.

The Dashboard Scope block displays the output of the PWM Generator block, allowing you to observe the generated PWM signal during simulation.

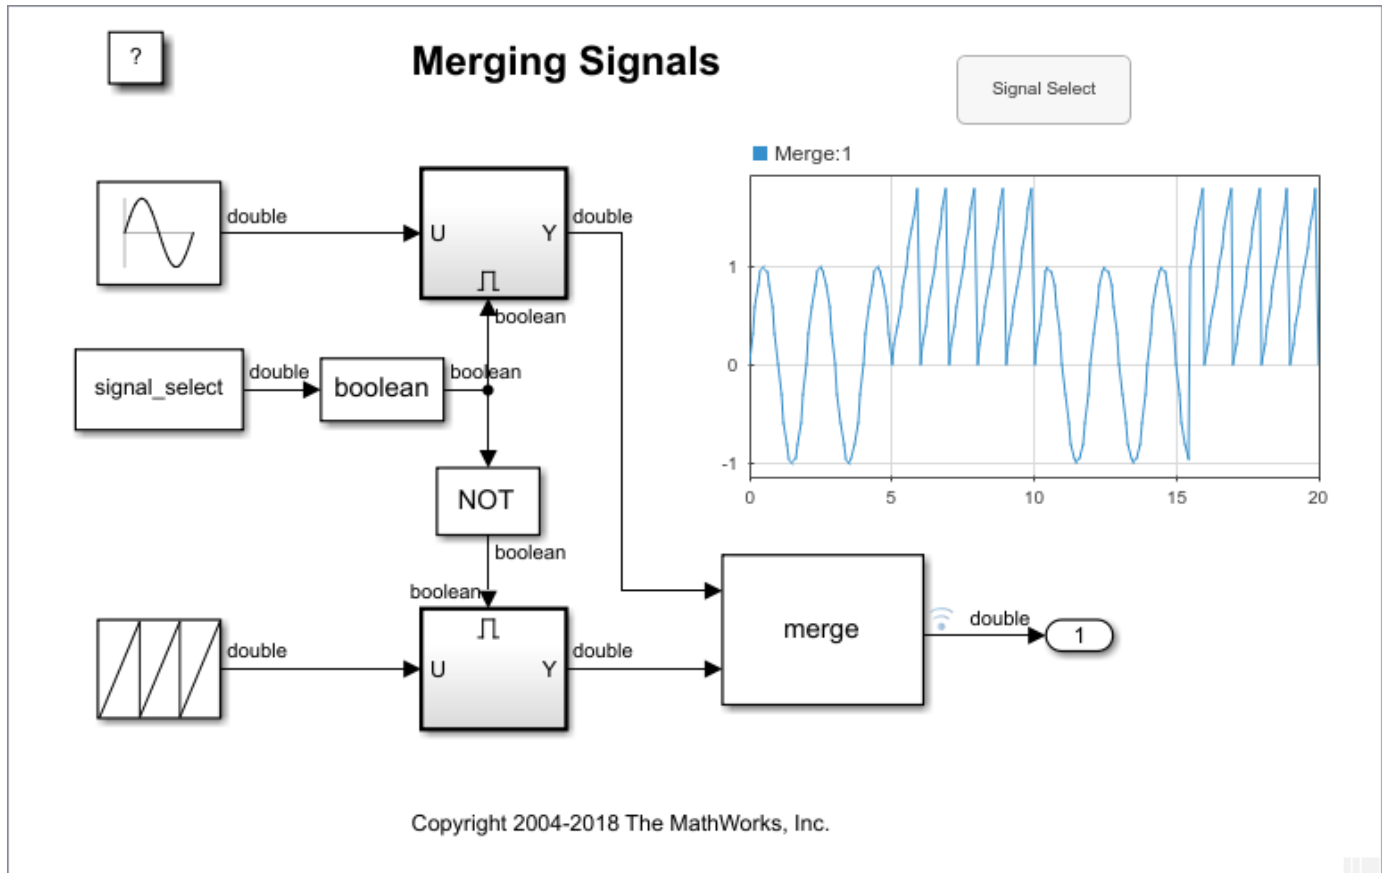

### **Interactively Simulate**

This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information, see “Simulation Pacing”.

Run the simulation. Use the Rocker Switch block to select the varying duty cycle input and observe the resulting PWM waveform on the Dashboard Scope block. Change the magnitude of the duty cycle using the Knob block and observe the effect on the generated PWM signal.

## Control Merging Signals with the Push Button Block

This example model is a modified version of the “Merging Signals” on page 13-330 example. The `mergedemo` model illustrates how to use Simulink® to merge two different signals using source blocks and triggered subsystems. In the `mergedemo` model, a square wave enables and disables the triggered subsystems that provide input to the Merge block. In this model, you can control the enable signal for the triggered subsystems using the Signal Select Push Button block.

### Model Modifications

To create this model from the `mergedemo` example:

1. Delete the Discrete Pulse Generator block controlling the triggered subsystem and the Scope block.
2. Add a Push Button block, an Output block, a Constant block, and a Dashboard Scope block.
3. Connect the Output block to the output of the Merge block.
4. Display the output signal of the Merge block on the Dashboard Scope.
5. Connect the Constant block to the input of the Data Type Conversion block and specify a variable name as its value. This model uses the variable name `signal_select`. Click the `Unrecognized functions or variables` error, and create the variable in the Model Workspace.

Now, the variable `signal_select` controls the triggered subsystems.

6. Press Ctrl+D to update the diagram so the variable you just created is available for connection.
7. Connect the Push Button block to the `signal_select` variable.

In this example, the On Value for the Push Button block is set to 0. When you press the Push Button block, the value of `signal_select` changes to 0, enabling the triggered subsystem connected to the sawtooth wave. If you want pressing the Push Button block to enable the triggered subsystem connected to the sine wave, set the On Value for the Push Button block to 1.

### Interactive Simulation

This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see "Simulation Pacing".

Run the simulation. As the model simulates, press and hold the Signal Selection Push Button block. You can observe the effect of pressing the Push Button block on the Dashboard Scope block.

## Tune the Relative Slip for an Anti-Lock Braking System

This example shows how to use a subsystem made of Dashboard blocks to tune the value of the `Desired relative slip` for the “Modeling an Anti-Lock Braking System” on page 13-169 example. You can use the Slider block or the Edit block to change the value of the `Desired relative slip` and observe the results during simulation on the Dashboard Scope block.

### Build the Dashboard Subsystem

This model uses a Subsystem block to gather the controls and displays for the model in a single interface. To create the subsystem for this model:

1. Add a Subsystem block to the `sldemo_absbrake` model.
2. Delete the pre-populated contents of the subsystem. A subsystem of Dashboard blocks does not need Inport or Outport blocks because Dashboard blocks do not use ports to make connections.
3. Add the components of the dashboard.

The dashboard for this model includes an Edit block and a Slider block that both control the value of the `Desired relative slip` input. The Dashboard Scope block displays the resulting slip value, `slp` throughout the simulation.

You can use areas in the subsystem to group and label related controls and displays. For more information about creating areas, see “Box and Label Areas of a Model”.

### Interactively Simulate

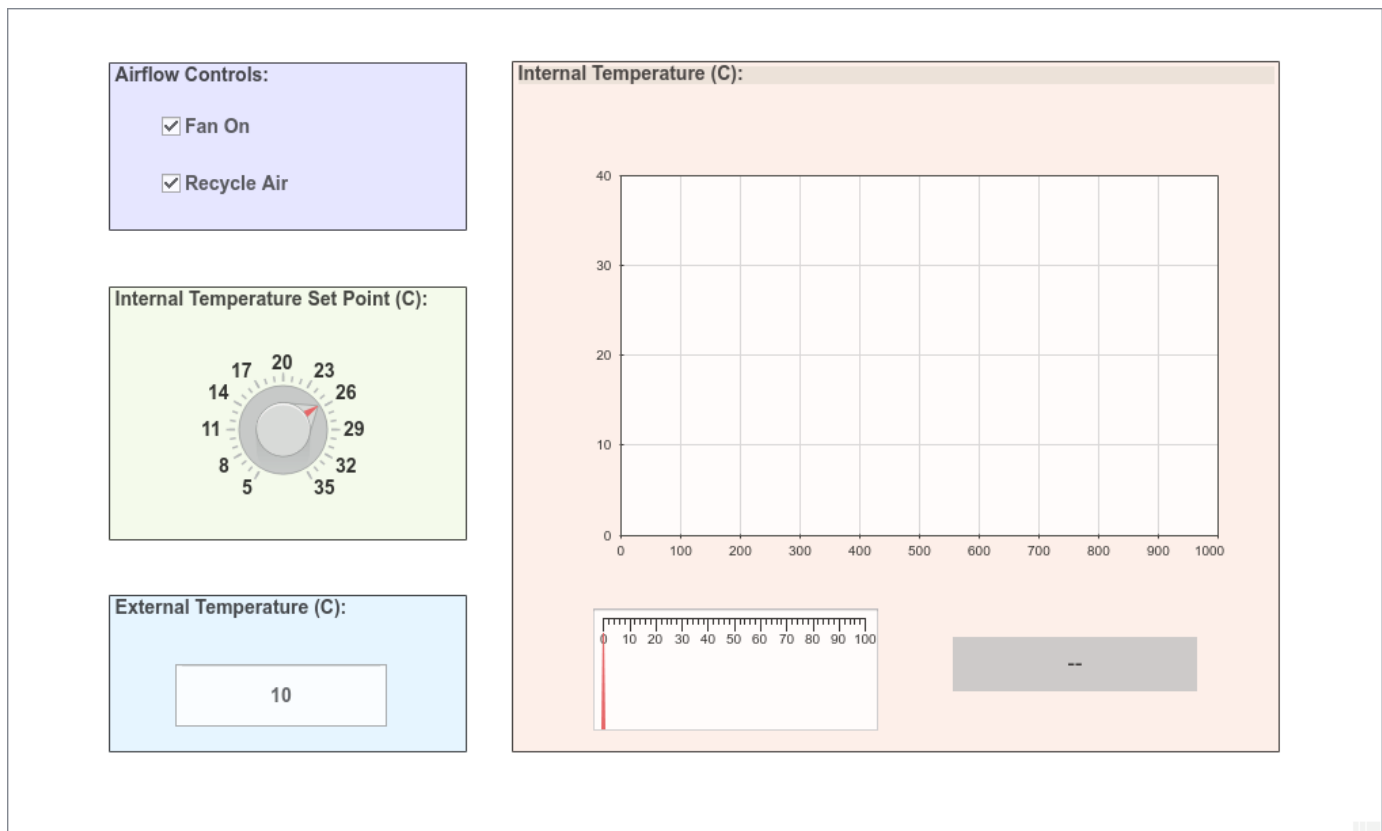

You can use the Dashboard subsystem as a convenient interface to configure separate simulations that use different values for the `Desired relative slip`.

The Slider block and the Edit block both change the value of the `Desired relative slip` input. Use the Slider block to fine tune the value of the relative slip input, and use the Edit block to enter an exact value.

## Interactively Simulate a Vehicle Climate Control System

In this example, you use a Dashboard of controls and displays to interactively simulate a climate control system of a car. You can adjust the fan and air recycling controls as well as set the internal temperature and modify the external temperature. A Linear Gauge block, a Dashboard Scope block, and a Display block show the internal temperature of the car. The model in this example adds the Dashboard to the `sldemo_auto_climatecontrol` model. For more information about the underlying model, see “Simulating Automatic Climate Control Systems” on page 13-194.

### Build the Dashboard Subsystem

This model uses a Subsystem block to gather the controls and displays in a single interface for the model. To create the subsystem in this example:

1. Add a Subsystem block to the `sldemo_auto_climatecontrol` model.
2. Delete the prepopulated contents of the subsystem. The subsystem does not need inports or outports because the Dashboard blocks do not use ports to make connections.
3. Add the contents of the dashboard.

In the dashboard for this model:

- Two Check Box blocks turn the fans and air recycling on and off.

- A Knob block sets the internal temperature.
- An Edit block allows you to specify the external temperature.
- A Dashboard Scope block displays the value of the internal temperature over time.
- A Linear Gauge block displays the instantaneous internal temperature value.
- A Display block shows the instantaneous internal temperature value.

You can use areas in the subsystem to group and label related controls and displays. For more information about creating areas, see “Box and Label Areas of a Model”.

### Connect Blocks in the Model

To explore connections between each block in the Dashboard subsystem and the model, you can select a block in the dashboard, pause on the ellipsis that appears above it, and click Jump to Connected Element. The Simulink® editor navigates to and highlights the block or signal connected to that block in the dashboard.

The Check Box blocks connect to the `dist_req` and `recycle_air` constant blocks. In the `sldemo_auto_climatecontrol` model, the fan and air recycling signals are controlled by Manual Switch blocks with two Constant blocks as inputs.

To replace a Manual Switch block in the `sldemo_auto_climatecontrol` model with a Check Box block:

1. Delete the Manual Switch block and one of the Constant blocks.
2. Connect the other Constant block directly to the Mux block.
3. Specify a variable as the Constant block value.

This model uses the variable `dist_req` to control the fans and the variable `recycle_air` to control air recycling.

4. Click the Unrecognized functions or variables error, and create the variable in the Model Workspace.

Now, the variable `dist_req` holds the state of the fans.

5. Press Ctrl+D to update the diagram so the variable you just created is available for connection.
6. Connect the Check Box block to the `dist_req` variable.

Follow a similar process to replace the air recycling manual switch.

The Knob block connects to the `USet` parameter of the User Setpoint in Celsius masked subsystem. Similarly, the Edit block connects to the `x` parameter of the External Temperature in Celsius masked

subsystem. The Dashboard Scope, Linear Gauge, and Display blocks all connect to the output signal of the Kelvin to Celsius subsystem.

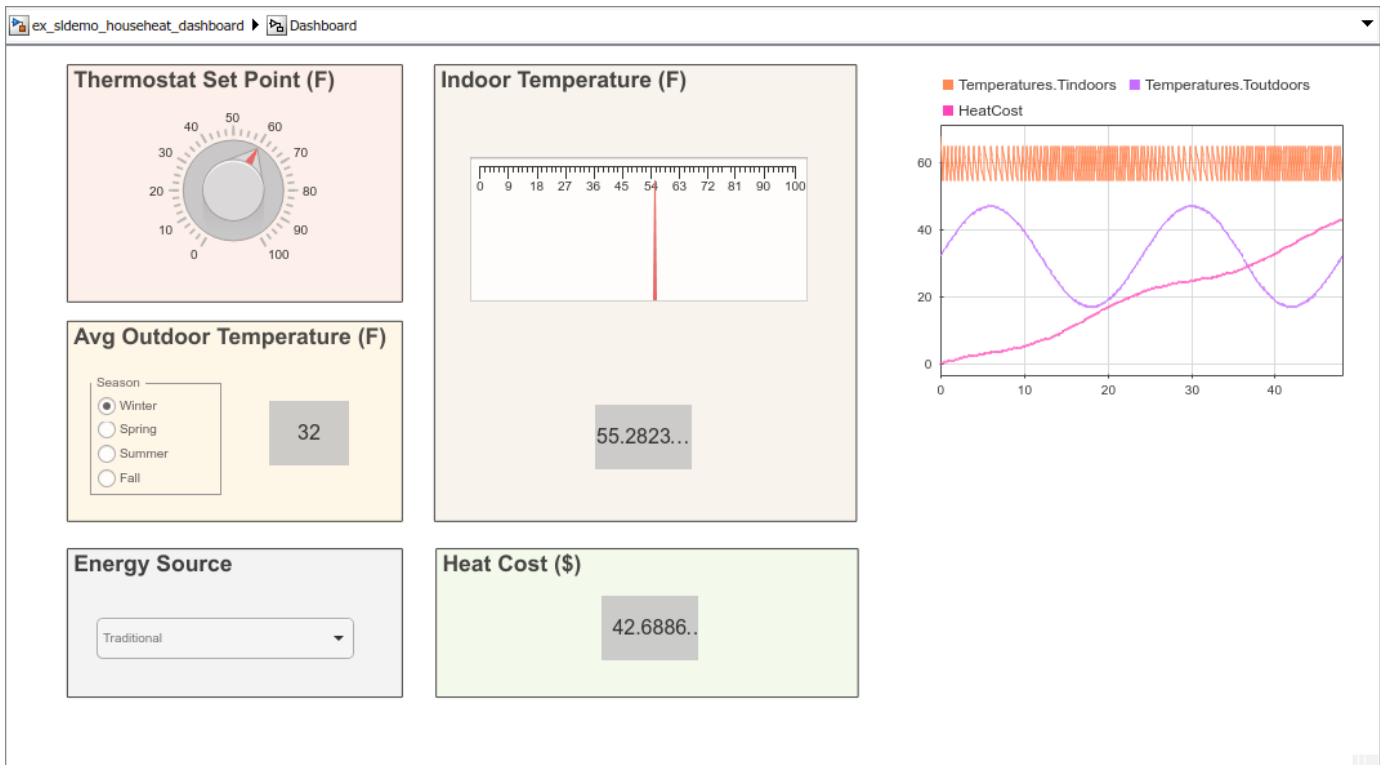

**Interactive Simulation**

This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information, see “Simulation Pacing”.

Run the simulation. Use the Check Box blocks to control the fans and air recycling. Use the Knob block to adjust the internal temperature set point, and specify the external temperature with the Edit block. You can observe the resulting internal temperature on the Dashboard Scope block, the Linear Gauge block, and the Display block.

## Interactively Simulate a Thermal Model of a House

This example uses a dashboard of controls and indicators to configure and then interactively simulate a thermal model of a house. You can configure the simulation to use either traditional or renewable energy sources and to use an outdoor temperature setpoint based on the season. During the simulation, you can adjust the thermostat and monitor the indoor temperature and heat cost. The model in this example adds a subsystem named Dashboard to the `sldemo_househeat` model. For more information about the underlying model, see “Thermal Model of a House” on page 13-21.

### Build the Dashboard Subsystem

This model uses a Subsystem block to organize the controls and displays for the model in a single interface. To create the subsystem in this example:

1. Add a Subsystem block to the model.
2. Delete the prepopulated contents of the subsystem. A subsystem of Dashboard blocks does not require Inport or Outport blocks because Dashboard blocks do not use ports to make connections.
3. Add the components of the dashboard.

The dashboard for this model includes a Knob block, a Radio Button block, and a Combo Box block to modify simulation parameters. A Linear Gauge block, three Display blocks, and a Dashboard Scope block display key signals during simulation.

You can use areas in the subsystem to group and label related controls and displays. For more information about creating areas, see “Box and Label Areas of a Model”.

### **Connect Dashboard Blocks to the Model**

To explore connections between each block in the Dashboard subsystem and the model, you can select a block in the dashboard, pause on the ellipsis that appears above it, and click Jump to Connected Element. The Simulink® editor navigates to and highlights the block or signal connected to that block in the dashboard.

- The Knob block connects to the Set Point block and allows you to adjust the thermostat set point in the model during simulation.
- The Radio Button Block connects to the Avg Outdoor Temp block and maps seasonal average temperatures for Boston, MA, to season labels. Right-click the Radio Button block and select Block Parameters from the context menu to modify the average temperature value used for each season.
- The Display block in the Avg Outdoor Temperature area shows the outdoor temperature value used in the simulation based on the selected season.
- The Combo Box block connects to the Gain block used to calculate the cost during simulation. Right-click the Combo Box block and select Block Parameters from the context menu to view or modify the cost, specified in units of cents per Joule.
- The Linear Scale and Display blocks in the Indoor Temperature area provide analog and digital indications of the instantaneous value of the house temperature during simulation.
- The Display block in the Heat Cost area shows the cumulative cost of heating the house over the course of the simulation is shown on a Display block.
- The Dashboard Scope block displays the heat cost, indoor temperature, and outdoor temperature in the same plot.

### **Interactively Simulate**

This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information, see “Simulation Pacing”.

The simulation is set up to run for 48 hours. Within that time period, it makes sense to use the Radio Button block and Combo Box block to configure a simulation for a particular season and energy source. If you want to run another type of simulation where you interactively modify the season or energy source, consider lengthening the simulation time to something more realistic for those types of changes.

Choose the season and energy source for a 48-hour simulation, and then run the simulation. During the simulation, use the Knob block to adjust the set point for the house thermostat, and observe the effect of the change on the indoor temperature and heat cost.

## Create a Realistic Dashboard Using the Circular Gauge Block

You can use the Circular Gauge block to create a dashboard of controls and indicators for your model that looks how it would in a real system. This example model uses four Circular Gauge blocks and a MultiStateImage block to create a dashboard for the `sf_car` model like one you might see in a real car.

### Explore the Model

To understand the connections between the Dashboard subsystem and the model, you can select each block and jump to the signal it displays in the model. To jump to the connected signal, first select a block. For example, select the speedometer gauge on the left. Select the **Gauge** tab that appears in the toolstrip and then select **Show Connection**. The model navigates to where the connected signal exists and briefly highlights the signal.

The Circular Gauge block on the left displays the `vehicle speed` signal, acting as a speedometer on the dashboard. The block uses the default Circular Gauge appearance and a value arc you can see when you simulate the model.

The Circular Gauge blocks at the top of the model display the throttle and brake signals. You can create this type of gauge by deleting the background image and needle image from the default Circular Gauge. Then, adjust the scale arc and select colors for the tick marks, scale, and value arc.

The Circular Gauge block on the right displays the engine RPM signal on a custom gauge face. You can create a gauge like this by deleting the background image in the default Circular Gauge and uploading your own.

The MultiStateImage block on the bottom displays the gear signal using seven segment display style number images that correspond to the value of the gear signal.

### Monitor System During Simulation

You can use the dashboard to monitor the system response during simulation. The User Inputs block includes several simulation inputs to model different vehicle maneuvers. To change the simulation input, navigate to the top level of the model and open User Inputs. You can use the drop-down menu to choose the vehicle action for the model to simulate. Choose between a passing maneuver, gradual acceleration, hard braking, and coasting. To monitor the system response during simulation, navigate back to the Dashboard subsystem and press the play button to simulate the model.

## Solve a Linear System of Algebraic Equations

Use the Algebraic Constraint block to solve the system

$$\begin{aligned} z_1 + z_2 &= 1 \\ z_2 - z_1 &= 1 \end{aligned}$$

The model represents the problem in a vectorized form as

$$\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The signal fed to the Algebraic Constraint block  $f(z)$  is a  $2 \times 1$  vector of the form

$$\begin{bmatrix} z_1 + z_2 - 1 \\ -z_1 - 1 + z_2 - 1 \end{bmatrix}$$

The block is configured to constrain  $f(z)$  to 0. Thus solving for  $f(z) = 0$  yields the solution  $z_1 = 0, z_2 = 1$

## Model a Planar Pendulum

Consider a point mass  $m$  suspended by a massless rod of length  $l$  under the influence of gravity. The position of the mass can be expressed in Cartesian coordinates by  $(x,y)$ .

### Modeling the System

A force balance of the mass gives the equations of motion in the  $x$  and  $y$  directions.

$$m\ddot{x} = F \sin \theta \quad (1)$$

$$m\ddot{y} + F \cos \theta = -mg \quad (2)$$

Let  $(u, v)$  be the velocities in  $(x, y)$  respectively. The system can be rewritten as a system of first order ODEs

$$\dot{x} = u \quad (3)$$

$$\dot{u} = -F \frac{x}{ml} \quad (4)$$

$$\dot{y} = v \quad (5)$$

$$\dot{v} = -F \frac{y}{ml} - g \quad (6)$$

where  $F$  is the tension in the rod. The system also possesses the geometric constraint

$$x^2 + y^2 = l^2 \quad (7)$$

Differentiate (7) twice with respect to time  $t$  to arrive at

$$m(u^2 + v^2) - Fl - mgy = 0 \quad (8)$$

This relationship is useful since it allows  $F$  to be determined at every step for use in modeling the kinematics of the system.

### Simulating the System

The system is simulated as shown in the figure below

Equation (8) contains one unknown  $F$  and is of the form  $f(z) = 0$  where  $f(z) = m(u^2 + v^2) - Fl - mgy$ . The Algebraic Constraint block constrains  $f(z)$  to 0 and solves for  $F$  in accordance with (8).

## Improved Linearization with Transfer Fcn Blocks

The Laplace domain transfer function for the operation of differentiation is:

$$\frac{Y(s)}{X(s)} = s$$

This equation is not a proper transfer function, nor does it have a state-space representation. As such, the Simulink software linearizes this block as an effective gain of 0 unless you explicitly specify that a proper first-order transfer function should be used to approximate the linear behavior of this block.

To improve linearization, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, try using a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

For example, you can replace the first set of blocks in this figure with the blocks below them:

## View Dead Zone Output on Sine Wave

This example shows the effect of the Dead Zone block on a sine wave. The model uses a dead zone lower limit of  $-0.5$  and an upper limit as  $0.5$ . Set these values through the parameters **Start of Dead Zone** and **End of Dead Zone**.

## View Backlash Output on Sine Wave

This example shows the effect of the Backlash block on a sine wave using default parameters. The initial **Deadband width** is 1 and the **Initial output** is 0.

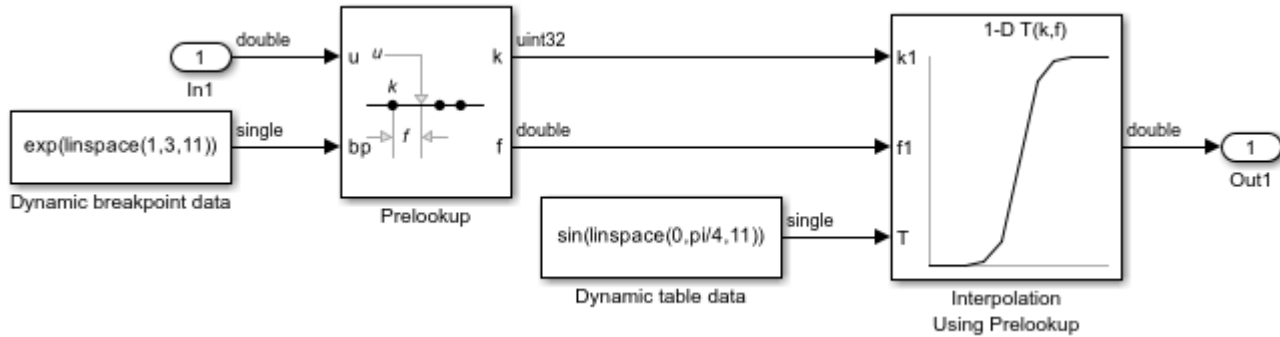

The initial deadband is centered around 0 and has a width of 1, which extends .5 in each direction. The output from the Backlash block begins at 0 and does not change until the input reaches the edge of the deadzone at .5. Then the output engages in a positive direction and changes an equal amount as the input. After the input reaches a value of 1, it starts moving in a negative direction. At this point the output disengages and stays flat until the input passes through the deadband width of 1. Once the input reaches the end of the deadband zone at 0, then the output engages and starts moving in a negative direction with the input.

## Prelookup With External Breakpoint Specification

This example shows how to feed a breakpoint dataset from a Constant block to the bp input port of the Prelookup block.

The Prelookup block inherits the following breakpoint attributes from the bp input port:

- **Minimum:** Inf
- **Maximum:** Inf
- **Data type:** single

Similarly, a Constant block feeds the table data values to the T input port of the Interpolation Using Prelookup block, which inherits the following attributes:

- **Minimum:** Inf
- **Maximum:** Inf
- **Data type:** single

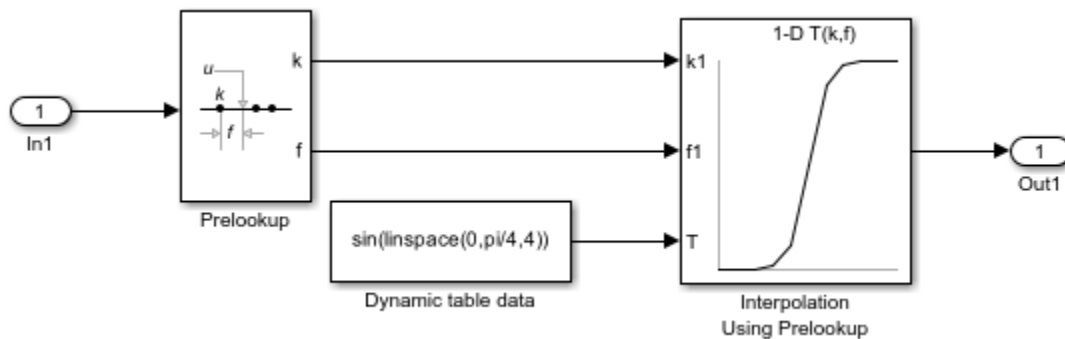

Simulink® uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoint and table data as single-precision, floating-point data. Using a lower-precision data type to store breakpoint and table data reduces the memory requirement.

## Prelookup with Evenly Spaced Breakpoints

This example shows how to specify evenly spaced breakpoint data in the Prelookup block.

In the **Breakpoints data** section, the **Specification** parameter is set to `Even spacing`. The parameters **First point**, **Spacing**, and **Number of points** are set to 25, 12, and 4 respectively. Specifying these parameters creates four evenly spaced breakpoints: [25, 37, 49, 61].

An alternative way to specify evenly spaced breakpoints is to set **Specification** to `Explicit values` and set **Value** to [25:12:61].

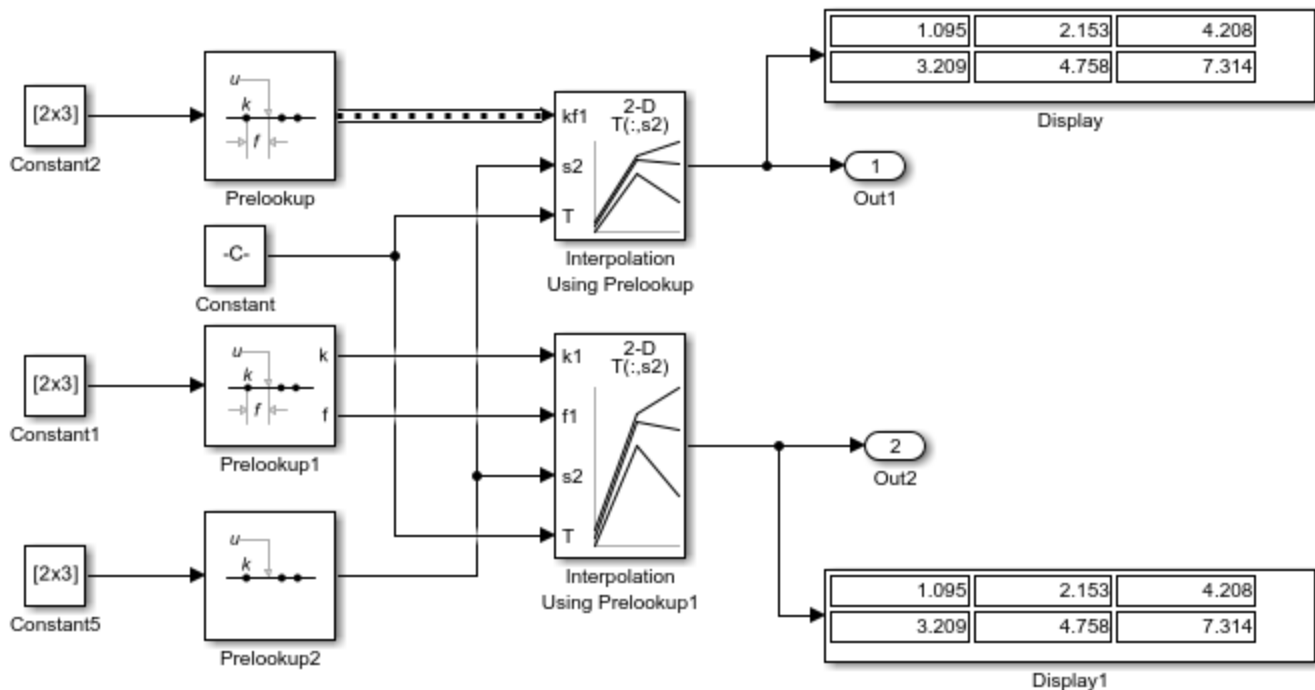

Simulink® uses double-precision, floating-point data to perform the computations in this model. However, the model stores the breakpoints and table data as double.

## Configure the Prelookup Block to Output Index and Fraction as a Bus

This example shows how to output a bus containing the index (k) and fraction (f) from the Prelookup block. The bus object can then be used as an input to the Interpolation Using Prelookup block. The example also shows how to get the same results without using a bus object.

Open and simulate the model.

At the top of the model, open the dialog box for the Prelookup block. In the **Main** tab, note that **Output selection** is set to Index and fraction as bus. In the **Data Types** tab, note that **Output** is set to Bus: myBus. In the Simulink® Editor, select **Modeling>Model Settings>Model Properties** and open the **Callbacks** tab. In the model's PreLoadFcn, the code defines the bus object myBus, which specifies the index as the first bus element and the fraction as the second element.

Open the dialog box for the Interpolation Using Prelookup block. In the **Main** tab, note that **Require index and fraction as bus** check box is selected. That option configures the block to use the bus output from the Prelookup block.

## Approximating the sinh Function Using the Lookup Table Dynamic Block

This example shows how to use the Lookup Table Dynamic block to approximate the `sinh` function. The breakpoint data is given by the vector `[-5:5]` and the table data is given by the vector `sinh([-5:5])`. The input `x` is provided by the Constant block as a 1-by-3 vector containing values that are below, within, and above the breakpoint data values.

To see how each lookup method handles input values that are below, within, and above the breakpoint data values, change the value of the **Lookup Method** parameter on the Lookup Table Dynamic block.

The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

Lookup Method	Input	Output	Comment
Interpolation-Extrapolation	1.4	2.156	N/A
	5.2	83.59	N/A
Interpolation-Use End Values	1.4	2.156	N/A
	5.2	74.2	The block uses the value for <code>sinh(5.0)</code> .
Use Input Above	1.4	3.627	The block uses the value for <code>sinh(2.0)</code> .
	5.2	74.2	The block uses the value for <code>sinh(5.0)</code> .
Use Input Below	1.4	1.175	The block uses the value for <code>sinh(1.0)</code> .
	-5.2	-74.2	The block uses the value for <code>sinh(-5.0)</code> .
Use Input Nearest	1.4	1.175	The block uses the value for <code>sinh(1.0)</code> .

## Create a Logarithm Lookup Table

This example shows how to use the n-D Lookup Table block to create a logarithm lookup table. The lookup table allows you to approximate the common logarithm (base 10) over the input range [1,10] without performing an expensive computation.

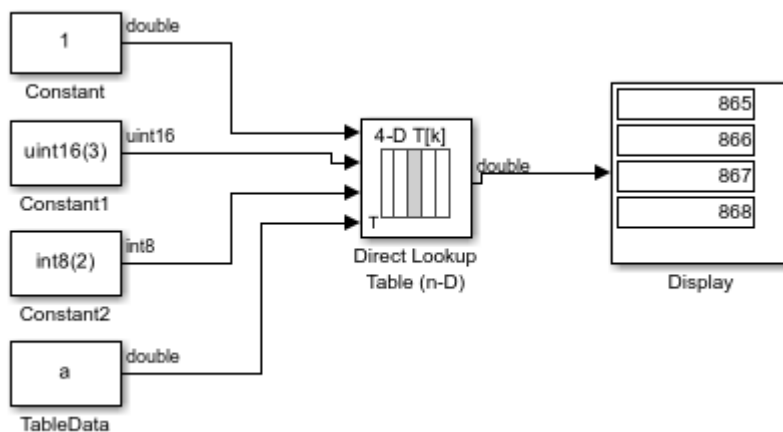

## Providing Table Data as an Input to the Direct Lookup Table Block

This example shows how to provide table data as an input to the Direct Lookup Table block. In the following model, `a` is a 4-D array of linearly increasing values that you define with the following model preload function:

```
a = reshape(1:2800, [4 5 20 7]);
```

When you run the model, you get the following results:

The block labeled TableData feeds a 4-D array to the Direct Lookup Table (n-D) block, with a data type of double. Because the Direct Lookup Table (n-D) block uses zero-based indexing, the output is:

```
a(:,2,4,3)
```

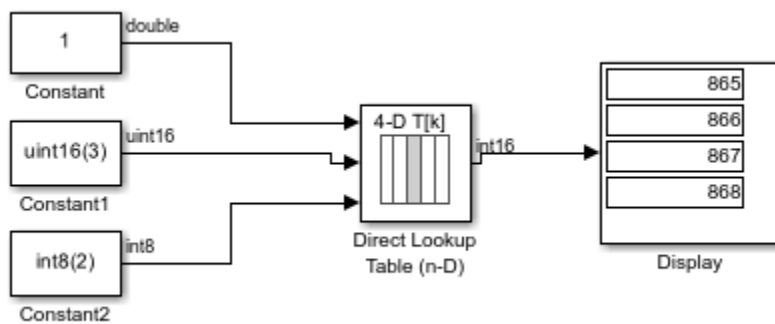

The output has the same data type as the table data input signal: double.

## Specifying Table Data in the Direct Lookup Table Block Dialog Box

This example shows how to specify table data on the dialog box of the Direct Lookup Table (n-D) block. In the following model, the table data is a 4-D array of linearly increasing values that you define with the following model preload function:

```
a = reshape(1:2800, [4 5 20 7]);
```

When you run the model, you get the following results:

Because the Direct Lookup Table (n-D) block uses zero-based indexing, the output is:

```
a(:,2,4,3)
```

The output data type matches the Direct Lookup Table block's **Table data type**, which is set to `int16`.

## Using the Quantizer and Saturation blocks in sldemo\_boiler

This example shows how the Quantizer and Saturation blocks are used in the model ex\_sldemo\_boiler. The ADC subsystem digitizes the input analog voltage by:

- Multiplying the analog voltage by 256/5 with the Gain block
- Rounding the value to integer floor with the Quantizer block
- Limiting the output to a maximum of 255 (the largest unsigned 8-bit integer value) with the Saturation block

This subsystem models a typical 8-bit analog-to-digital converter having an input range of 0-5 volts

## Scalar Expansion with the Coulomb and Viscous Friction Block

This example shows a model with a scalar input to a Coulomb & Viscous Friction block that uses scalar expansion to output a vector.

Double click the friction block to see the parameters. **Coefficient of viscous friction (Gain)** is a scalar value 2, but **Coulomb friction value (Offset)** is a vector value [1 3 2 0]. Therefore, the block uses element-wise scalar expansion to compute the output.

Each output is calculated using this formula.

$$y = \text{sign}(x) .* (\text{Gain} .* \text{abs}(x) + \text{Offset})$$

For example, the first offset 1 is calculated as follows.

$$y = - * ((2 * 5) + 1)$$

$$y = -11$$

If the dimensions for the input and **Offset** are the same, then no expansion is necessary.

## Sum Block Reorders Inputs

This example shows how the Sum block reorders inputs. If you use a - sign as the first operation, the block reorders the inputs, if possible, to use a + operation. For example, in the expression  $\text{output} = -a - b + c$ , the Sum block reorders the input so that  $\text{output} = c - a - b$ . To initialize the accumulator, the Sum block uses the first + input port.

The block avoids performing a unary minus operation on the first operand  $a$  because doing so can change the value of  $a$  for fixed-point data types. In that case, the output value differs from the result of accumulating the values for  $a$ ,  $b$ , and  $c$ .

Both the constant inputs use `int8` data types. The Sum block also uses `int8` for the accumulator and output data types and has **Saturate on integer overflow** turned on. The Sum block reorders the inputs to give the ideal result of 127.

- 1 Reorders inputs from  $(-Input1 + Input2)$  to  $(Input2 - Input1)$ .
- 2 Initializes the accumulator by using the first + input port.  $Accumulator = \text{int8}(-1) = -1$
- 3 Continues to accumulate values.  $Accumulator = Accumulator - \text{int8}(-128) = 127$
- 4 Calculates the block output.  $Output = \text{int8}(127) = 127$

If the Sum block does not reorder the inputs, then you get the nonideal result of 126.

- 1 Initializes the accumulator by using the first input port.  $Accumulator = \text{int8}(-(-128)) = 127$
- 2 Because saturation is on, the initial value of the accumulator saturates at 127 and does not wrap.
- 3 Continues to accumulate values.  $Accumulator = Accumulator + \text{int8}(-1) = 126$
- 4 Calculates the block output.  $Output = \text{int8}(126) = 126$

To explicitly specify a unary minus operation for  $\text{output} = -a - b + c$ , you can use the Unary Minus block in the Math Operations library.

## Iterated Assignment with the Assignment Block

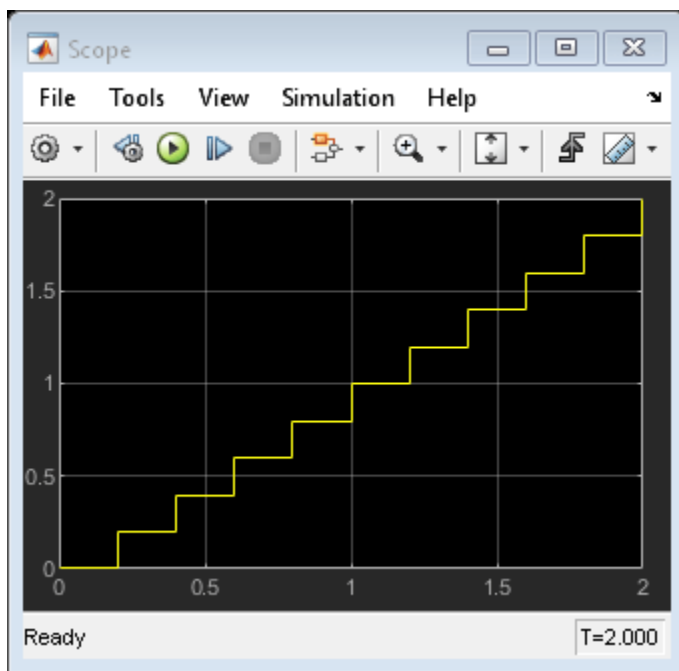

This example shows using the Assignment block to assign values computed in a For or While Iterator loop to successive elements. You can use vector, matrix or multidimensional signals and do the assignment in a single time step. In this model, the For Iterator block creates a vector signal each of whose elements equals  $3 * i$  where  $i$  is the index of the element.

The iterator generates indices for the Assignment block. On the first iteration, the Assignment block copies the first input (Y0) to the output (Y) and assigns the second input (U) to the output Y(E1). On successive iterations, the Assignment block assigns the current value of U to Y(Ei), that is, without first copying Y0 to Y. These actions occur in a single time step.

## View Sample Time Using the Digital Clock Block

This example shows how to view the simulation sample time at a specified sampling interval using the Digital Clock block. In this model, the Scope shows the output of a Digital Clock block with the **Sample time** set to 0.2.

In this configuration, the Digital Clock block outputs the simulation time every 0.2 seconds. Otherwise, the block holds the output at the previous value.

## Bit Specification Using a Positive Integer

This example shows how to specify the **Number of bits** in the Counter Free-Running block as a positive integer.

At  $t = 255$ , the counter reaches the maximum value of  $(2^8) - 1$ . If you increase the stop time of the simulation to 256, the counter wraps to zero.

## Bit Specification Using an Unsigned Integer Expression

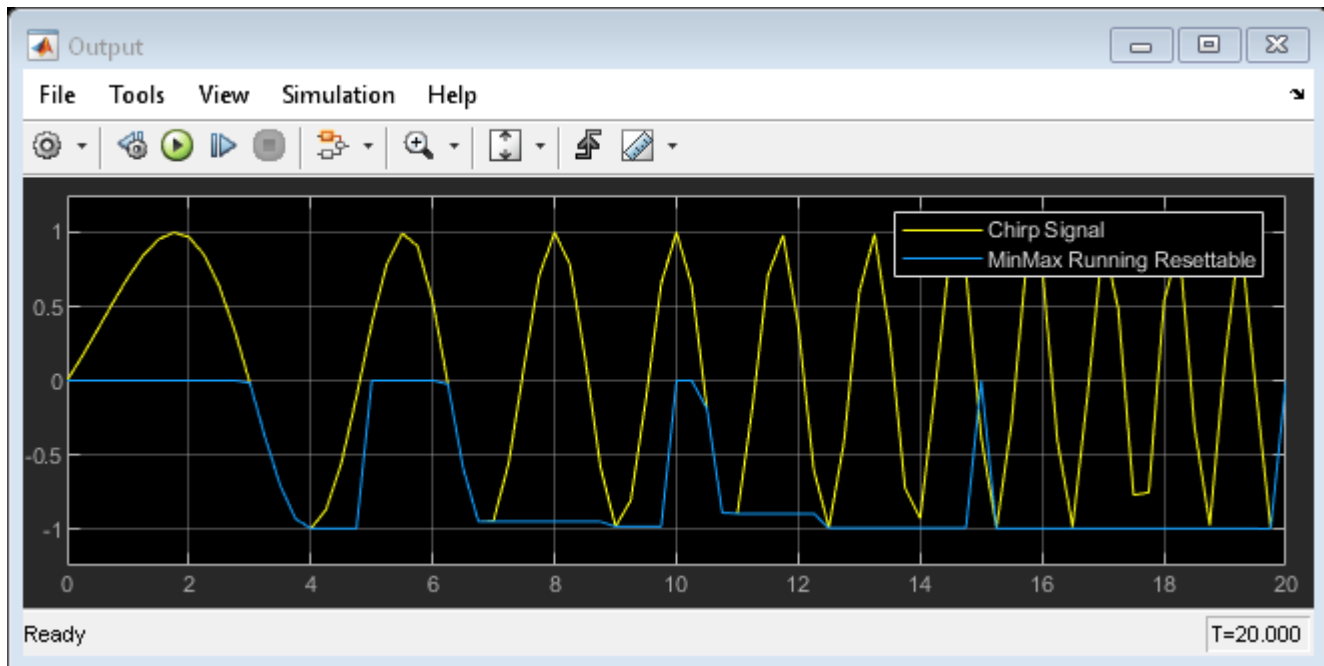

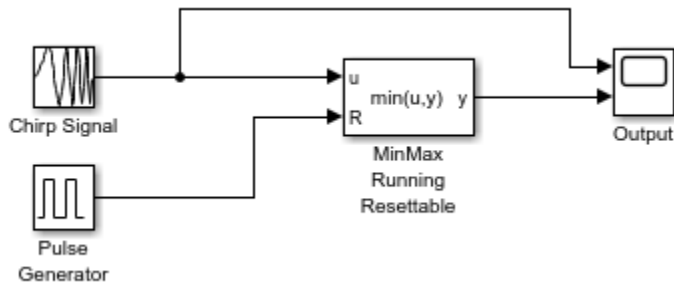

This example shows how to specify the **Number of bits** in the Counter Free-Running block as an unsigned integer expression.

At  $t = 254$ , the counter reaches the maximum value of  $\text{uint8}(2^{(\text{uint8}(8))} - 1)$ . If you increase the stop time of the simulation to 255, the counter wraps to zero.

## Track Running Minimum Value of Chirp Signal

This example shows how to track the running minimum value of a signal generated by the Chirp Signal block.

The Chirp Signal block generates a sine wave whose frequency increases at a linear rate with time. The MinMax Running Resettable block tracks the minimum value of that chirp signal over time. The running minimum value is reset every 5 seconds by the Pulse Generator block.

## Horizontal Matrix Concatenation

This example shows how to perform a horizontal matrix concatenation with the Matrix Concatenate block. When you set the **Concatenate dimension** parameter to 2 and the inputs are 2-D matrices, the block performs horizontal matrix concatenation and places the input matrices side-by-side to create the output matrix.

## Vertical Matrix Concatenation

This example shows how to perform a vertical matrix concatenation with the Matrix Concatenate block. When you set the **Concatenate dimension** parameter to 1 and the inputs are 2-D matrices, the block performs vertical matrix concatenation and places the input matrices on top of each other to create the output matrix.

## Multidimensional Matrix Concatenation

This example shows how to perform multidimensional matrix concatenation with the Matrix Concatenate block. When you set the **Concatenate dimension** parameter to 3 and the inputs are 2-D matrices, the block performs multidimensional matrix concatenation.

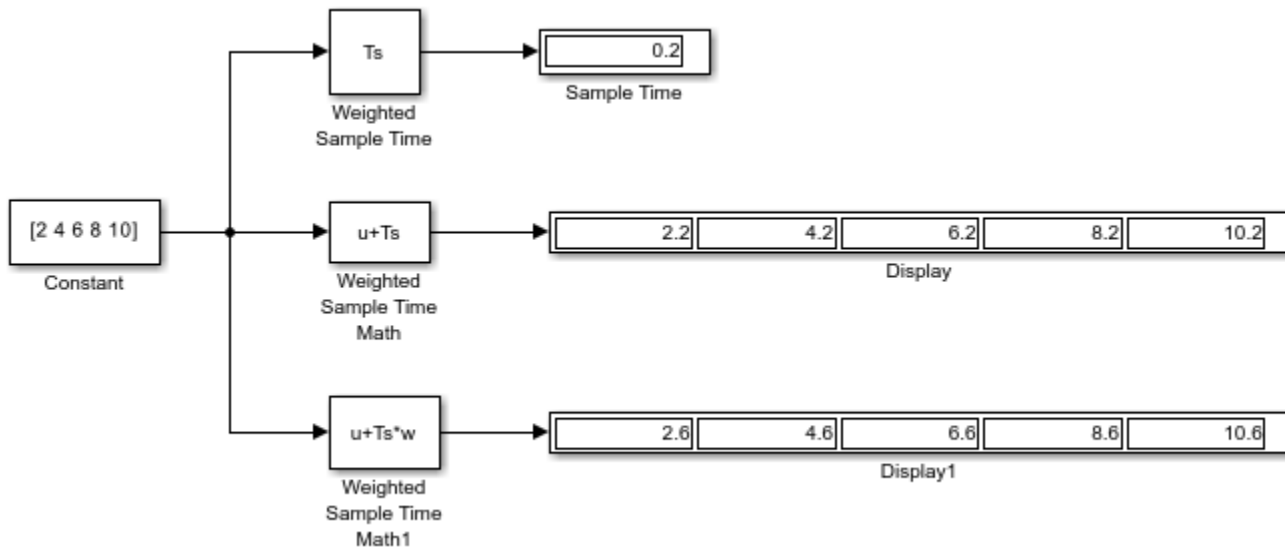

## Unary Minus of Matrix Input

This example shows how to compute the unary minus of a matrix input.

## Sample Time Math Operations Using the Weighted Sample Time Math Block

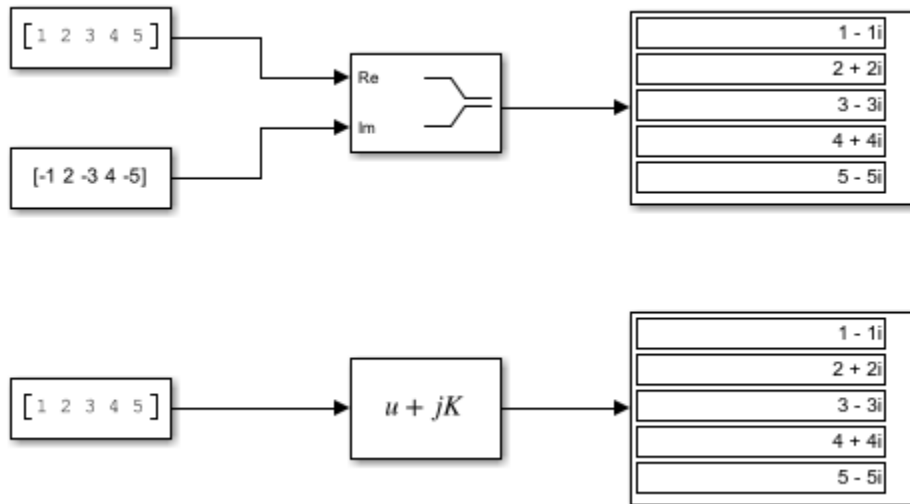

This example shows how to add the sample time value to a signal using the Weighted Sample Time Math block.

Using the Weighted Sample Time block, you can see the sample time of this model is `0.2`. When you set the **Operation** parameter to `+` and the **Weight value** to `1` on the Weighted Sample Time Math block, the block adds the sample time value of `0.2` to the input signal. When you set the **Weight value** to `3` in the Weighted Sample Time Math1 block, the block adds  $Ts \cdot 3$  to the input signal, thus increasing each value by `0.6`.

## Construct Complex Signal from Real and Imaginary Parts

This example shows how to use the Real-Imag to Complex block to construct a complex-valued signal from real and imaginary parts. You can provide both the real and imaginary parts as block inputs, or provide one value as an input, and the other on the block dialog box.

## Construct Complex Signal from Magnitude and Phase Angle

This example shows how to use the Magnitude-Angle to Complex block to construct a complex-valued signal. You can provide both the magnitude and phase angle as block inputs, or provide one value as an input, and the other on the block dialog box.

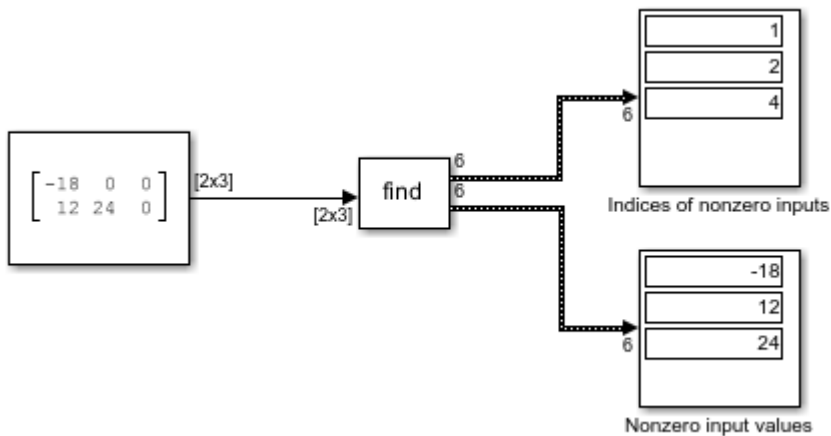

## Find Nonzero Elements in an Array

This example shows how to use the Find block to find nonzero elements in an array. In the following model, the block is configured to output both the one-based linear index and the value of each nonzero element.

ans =

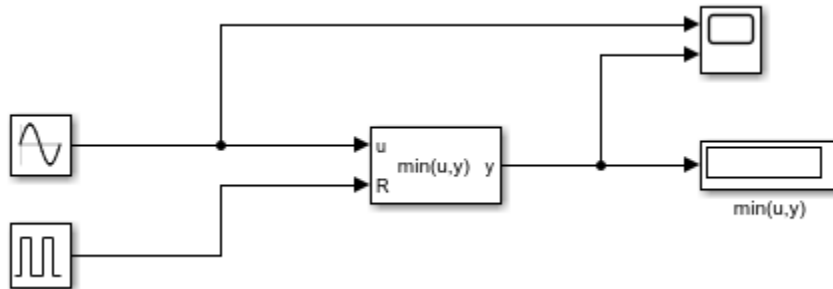

```
Simulink.SimulationOutput:
 tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

## Calculate the Running Minimum Value with the MinMax Running Resettable Block

This example shows how to use the MinMax Running Resettable block to calculate the running minimum value. To watch how the running minimum value changes at each time step, you can use the Step Forward button to advance the simulation one step at a time.

After running the full simulation, you can view the results in the Scope. The initial value of the running minimum is 0. It begins tracking the Sine Wave signal when the sine wave values turn negative. When the MinMax Running Resettable block receives a reset signal at  $T=8$ , the block resets the running minimum value to 0. The running minimum value tracks at 0 for a few time steps, until the sine wave values turn negative again.

ans =

```

Simulink.SimulationOutput:
 tout: [26x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]

```

## Find Maximum Value of Input

This example shows how to use the MinMax block to output the maximum value of two sine waves.

After running the full simulation, you can view the results in the Scope. Initially, the maximum value (orange line) tracks SineWave2. When the SineWave2 values turn negative, the maximum value begins tracking SineWave1. When the SineWave2 values become positive again, the maximum value resumes tracking SineWave2.

ans =

```
Simulink.SimulationOutput:
 tout: [57x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]
```

## Permute Array Dimensions

This example shows how to use the Permute Dimensions block to permute the first and third dimensions of a 3-by-4-by-5 input array.

When you set the **Order** parameter to `[3, 2, 1]`, the block permutes the first and third dimensions, and outputs a 5-by-4-by-3 array.

## Multiply Inputs of Different Dimensions with the Product Block

This example shows how to perform element-wise ( $\cdot$ ) multiplication of inputs using the Product block. In this example, the Product block multiplies two scalars, a scalar and a vector, and two 2x2 matrices.

## Multiply and Divide Inputs Using the Product Block

This example shows how to multiply and divide several input signals using the Product block.

## Divide Inputs of Different Dimensions Using the Divide Block

This example shows how to perform element-wise ( $\cdot$ \*) division of two inputs using the Divide block. In this example, the Divide block divides two scalars, a vector by a scalar, a scalar by a vector, and two matrices.

## Complex Division Using the Product of Elements Block

This example shows how to perform element-wise complex division using the Product of Elements block.

The top Product of Elements block collapses the matrix input to a scalar by taking successive inverses of the four elements:

- $y = (((1/2+i)/3)/4-i)/5$

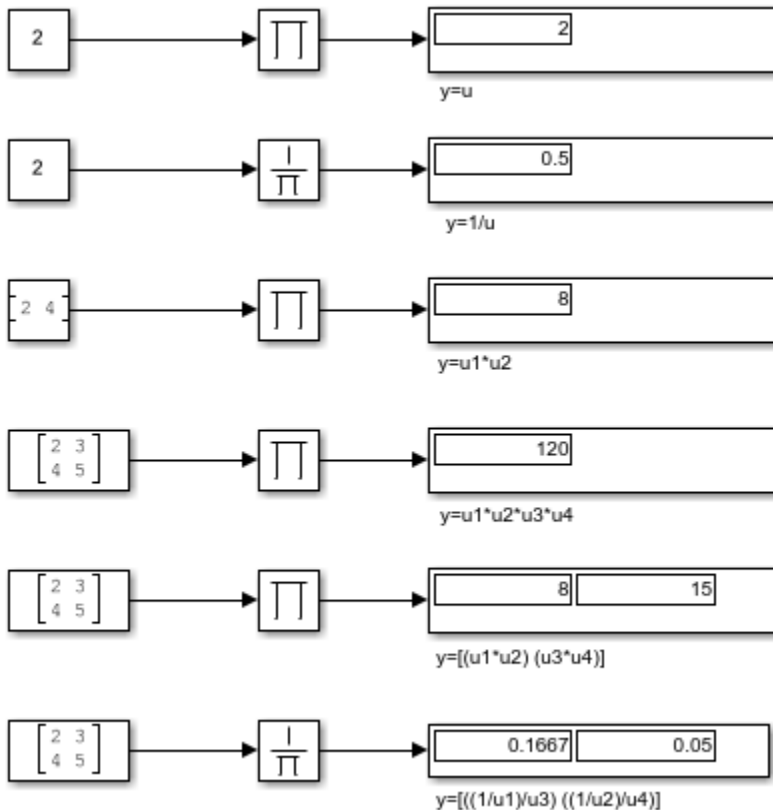

The bottom Product of Elements block collapses the matrix input to a vector by taking successive inverses along the second dimension:

- $y(1) = ((1/2+i)/3)$
- $y(2) = ((1/4-i)/5)$

## Element-Wise Multiplication and Division Using the Product of Elements Block

This example shows how to use the Product of Elements block to perform element-wise multiplication and division of inputs.

## sin Function with Floating-Point Input

This example shows how to use the Trigonometric Function block to compute the sine of a floating-point input. The output of the Trigonometric Function block has the same data type as the input because the input data type is floating-point and the **Approximation method** is none.

## sincos Function with Fixed-Point Input

This example shows how to use the Trigonometric Function block to compute the CORDIC approximation of `sincos` for a fixed-point input signal.

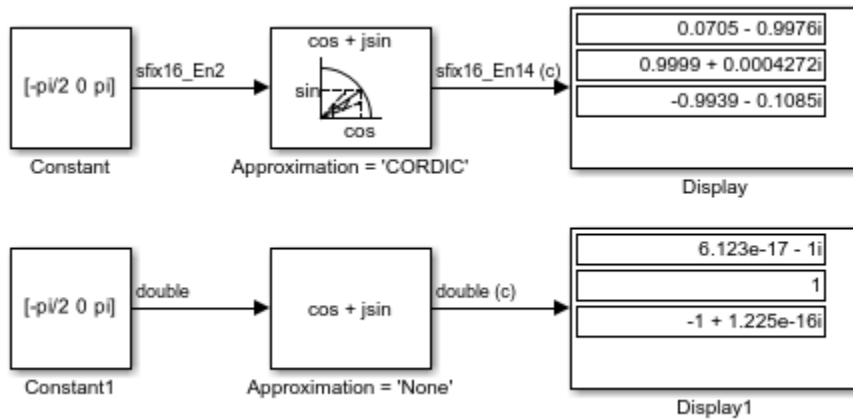

The Trigonometric Function block parameters are:

- **Function:** `sincos`
- **Approximation method:** CORDIC
- **Number of iterations:** 11

When using the CORDIC approximation method, the input to the Trigonometric Function block must be in the range  $[-2\pi, 2\pi)$ . The output type of the Trigonometric Function block is `fixdt(1, 13, 11)` because the input is a fixed-point signal and the **Approximation method** is set to CORDIC. The output fraction length equals the input word length minus two.

## Trigonometric Function Block Behavior for Complex Exponential Output

This example compares the complex exponential output for two different configurations of the Trigonometric Function block.

When the **Approximation method** is CORDIC, the input data type can be fixed point, in this case: `fixdt(1,16,2)`. The output data type is `fixdt(1,16,14)` because the output fraction length equals the input word length minus two.

When the **Approximation method** is None, the input data type must be floating point. The output data type is the same as the input data type.

## Control Algorithm Execution Using Enumerated Signal

This example shows how to use a signal of an enumerated data type to control the execution of a block algorithm. For basic information about using enumerated data types in models, see “Use Enumerated Data in Simulink Models”.

### Define Enumerated Type

Copy the enumerated type definition `ex_SwitchCase_MyColors` into a script file in your current folder.

```
classdef ex_SwitchCase_MyColors < Simulink.IntEnumType
 enumeration
 Red(0)
 Yellow(1)
 Blue(2)
 Mauve(3)
 end
end
```

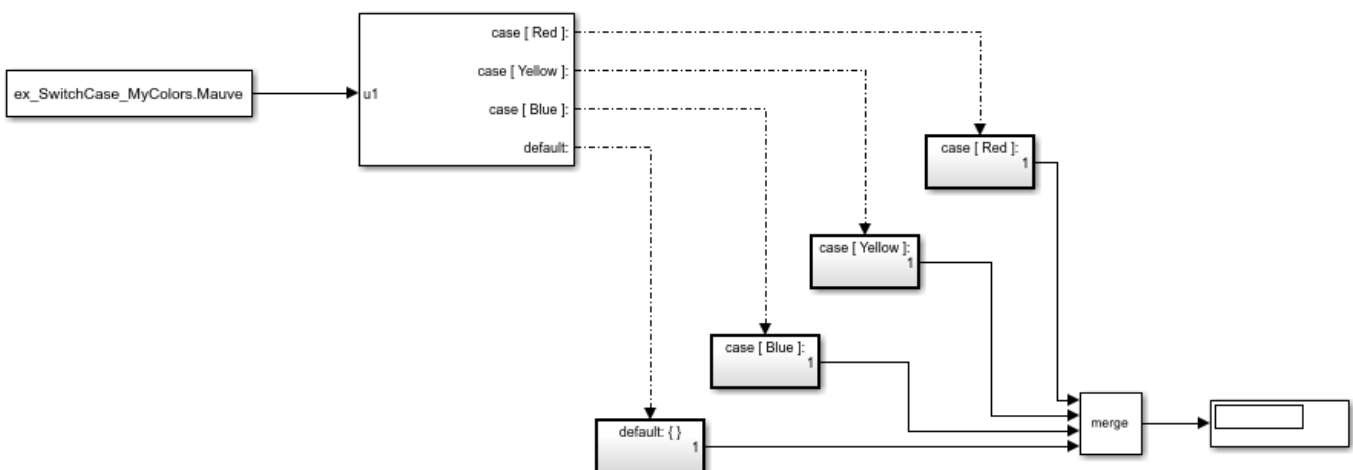

Alternatively, you can use the function `Simulink.defineIntEnumType` to define the type.

```
Simulink.defineIntEnumType('ex_SwitchCase_MyColors',...
 {'Red', 'Yellow', 'Blue', 'Mauve'}, [0;1;2;3])
```

### Explore Example Model

Open the example model `ex_enum_switch_case`.

```
open_system('ex_enum_switch_case')
```

Open the Enumerated Constant block dialog box. The constant output value is `ex_SwitchCase_MyColors.Blue`.

Open the Switch Case block dialog box. The **Case conditions** box is specified as a cell array containing three of the four possible enumeration members. The block has four outputs corresponding to the three specified enumeration members and a default case.

Open the Switch Case Action Subsystem blocks. The subsystems each contain a Constant block that uses a different constant value.

### **Control Execution During Simulation**

Simulate the model. The Display block shows the value 5, which corresponds to the case `ex_SwitchCase_MyColors.Blue`.

In the Enumerated Constant block dialog box, specify **Value** as `ex_SwitchCase_MyColors.Red` and click **Apply**. The Display block shows 19.

Specify **Value** as `ex_SwitchCase_MyColors.Mauve` and click **Apply**. The Display block shows 3, which corresponds to the default case.

## Integer and Enumerated Data Type Support in the Ground Block

This example shows how to use the Ground block to ground block input ports that have integer and enumerated data types. In top row of this example, the output of the Constant block determines the data type (`int8`) of the port to which the Ground block is connected. That port determines the output data type of the Ground block, and the Ground block outputs a signal with zero value, and data type `int8`.

In the bottom row of this example, the Ground block is connected to a port with an enumerated data type. For enumerated data types, the Ground block outputs the default value of the enumeration. This behavior applies whether or not:

- The enumeration can represent zero
- The default value of the enumeration is zero

If the enumerated type does not have a default value, the Ground block outputs the first enumeration value in the type definition.

## Fixed-Point Data Type Support in the Ground Block

This example shows how to use the Ground block to ground block input ports that have fixed-point data types. The top row of this example illustrates the Ground block behavior when the fixed-point data type can represent zero. In that case, the Ground block outputs a signal with zero value, and the same fixed-point data type as the port it is connected to.

In the bottom row of this example, the output of the Constant block determines the data type of the port to which the Ground block is connected (`fixdt(0,8,1,1)`). Because zero cannot be represented exactly by the data type `fixdt(0,8,1,1)`, the Ground block outputs a nonzero value that is the closest possible value to zero (in this case, 1).

## Read 2-D Signals in Structure Format From Workspace

This example shows how to read a 2-D structure from the MATLAB workspace. When you open the model, the following code is executed by a PreLoadFcn callback:

```
t1 = 0.2 * [0:49]';
m = magic(10);
M = repmat(m,[1 1 length(t1)]);
data.time=t1;
data.signals.values = M;
data.signals.dimensions=[10 10];
```

This code creates 10-by-10 matrix (2-D signal) by using the `magic` function, and then creates a 3-D matrix by adding a time vector. The time vector must be a column vector. The `signals.values` field is a 3-D matrix where the third dimension corresponds to time. The `signals.dimensions` field is a two-element vector. The first element is the number of rows and the second element is the number of columns in the `signals.values` field.

When you run the model, the From Workspace block reads the structure `data` from the workspace.

## Eliminate Singleton Dimension with the Squeeze Block

This example shows a model using the Squeeze block to eliminate a dimension of size 1.

The Squeeze block converts a multidimensional array from the Constant block of size 3-by-1-by-2 into a 3-by-2 signal.

## Difference Between Time- and Sample-Based Pulse Generation

This example shows the difference in behavior of the Pulse Generator block in time-based and sample-based modes.

Consider this model, with two Pulse Generator blocks. One block has the **Pulse type** parameter set to Time based, and the other to Sample based. Both blocks are configured to output a pulse with an amplitude of one that is on for five seconds, followed by off for five seconds. The simulation time runs from three seconds to a stop time of 18 seconds. Notice the time offset notice in the lower right corner.

```
ans =
```

```
Simulink.SimulationOutput:
 tout: [16x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

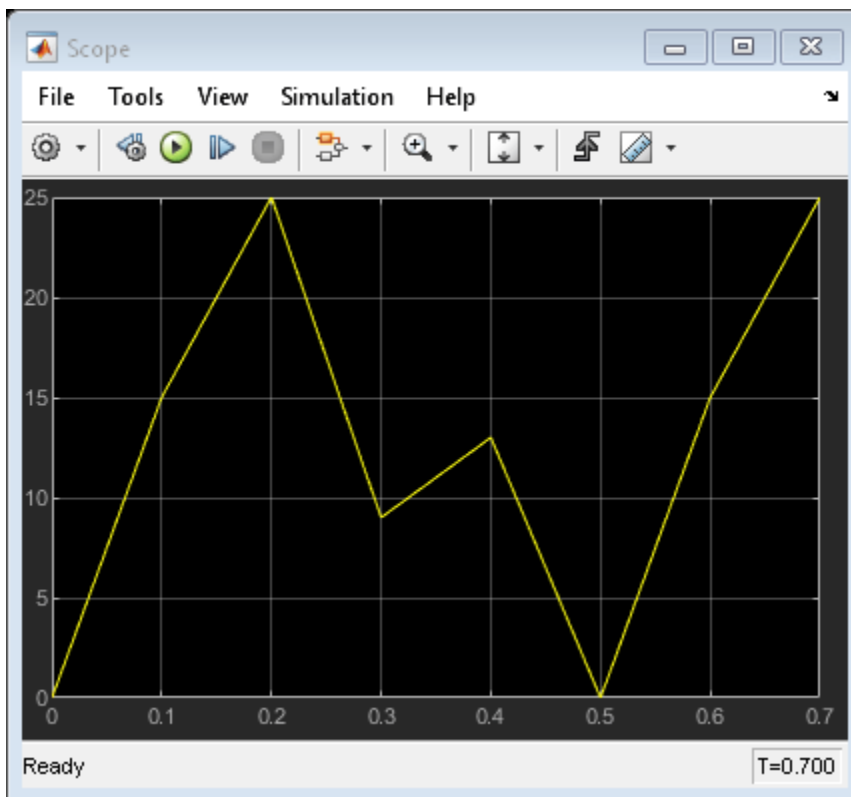

Notice that the time-based Pulse Generator produces an on signal for only two seconds and then switches to off. This is due to the block starting to compute the output from  $t=0$  even though it does not output the simulation until  $t=3$ . The sample-based block outputs a pulse of five seconds on followed by five seconds off. In this case, the block output does not depend on simulation time and starts only when the simulation starts.

## Specify a Waveform with the Repeating Sequence Block

This example shows how you specify a waveform with the Repeating Sequence block. In this model, the block defines the **Time values** parameter as  $[0:0.1:0.5]$  and the **Output values** parameter as  $[0\ 15\ 25\ 09\ 13\ 17]$ . The stop time of the simulation is  $0.7$  second.

- Input period is  $0.5$ .
- Output at any time  $t$  is the output at time  $t = t - 0.5n$ , where  $n = 0,1,2$ , and so on.
- Sequence repeats at  $t = 0.5n$ .

At  $t = 0.5$ , the expected output is equal to the output at  $t = 0$ , which is  $0$ . Therefore, the last value in the **Output values** parameter vector  $[0\ 15\ 25\ 09\ 13\ 17]$  does not appear.

## Tune Phase Delay on Pulse Generator During Simulation

This example shows how to modify a model so that you can change a phase delay for a Pulse Generation block during simulation. You cannot tune the value of the **Phase delay** parameter during simulation. As a workaround, add a Constant block and a Variable Time Delay block.

In the Pulse Generator block, set the value of the **Phase delay** parameter to zero. Use the Constant block to specify the delay time in seconds. To tune the delay time during simulation, change the value stored in the Constant block.

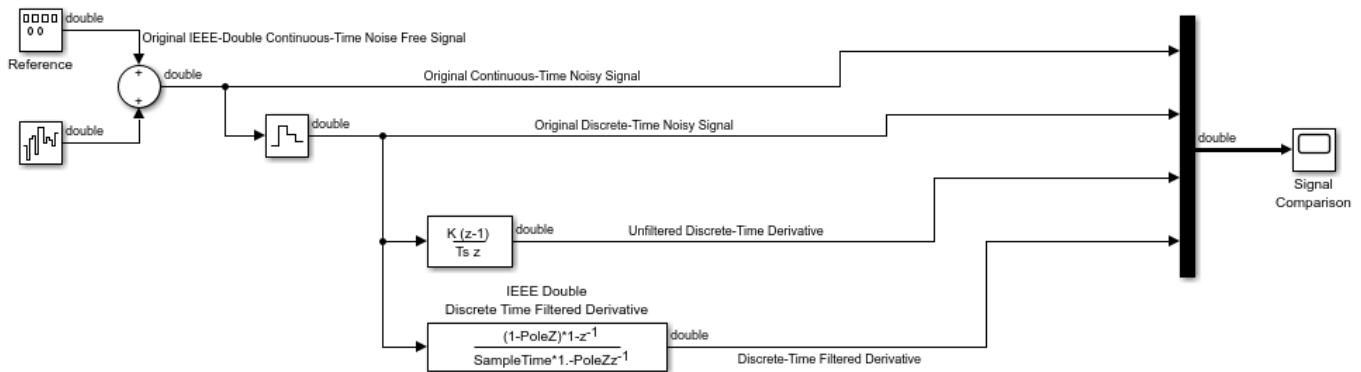

## Difference Sine Wave Signal

This example shows how to calculate the difference in a sine wave signal at each time step. The input is a 1-by-2 vector of sine waves, with amplitude 1 and 3. The difference block calculates the difference in each sine wave signal at every time step. The Scope block displays both the original sine waves and the output of the difference block.

## Discrete-Time Derivative of Floating-Point Input

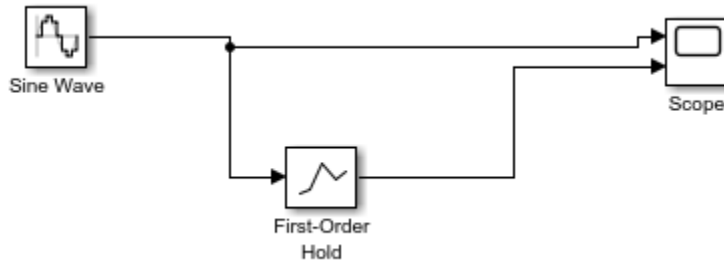

This example shows how to use the Discrete Derivative block to compute the discrete-time derivative of a floating-point input signal. The unfiltered discrete-time derivative is compared to a filtered discrete-time derivative that is computed by the Discrete Filter block.

## First-Order Sample-and-Hold of a Sine Wave

This example shows how to perform a first-order sample-and-hold of a sine wave signal using the First-Order Hold block.

## Calculate and Display Simulation Step Size using Memory and Clock Blocks

This example shows how to use the Memory and Clock blocks to calculate and display the step size in a simulation. The Sum block subtracts the time at the previous time step, which the Memory block generates, from the current time, which the Clock block generates.

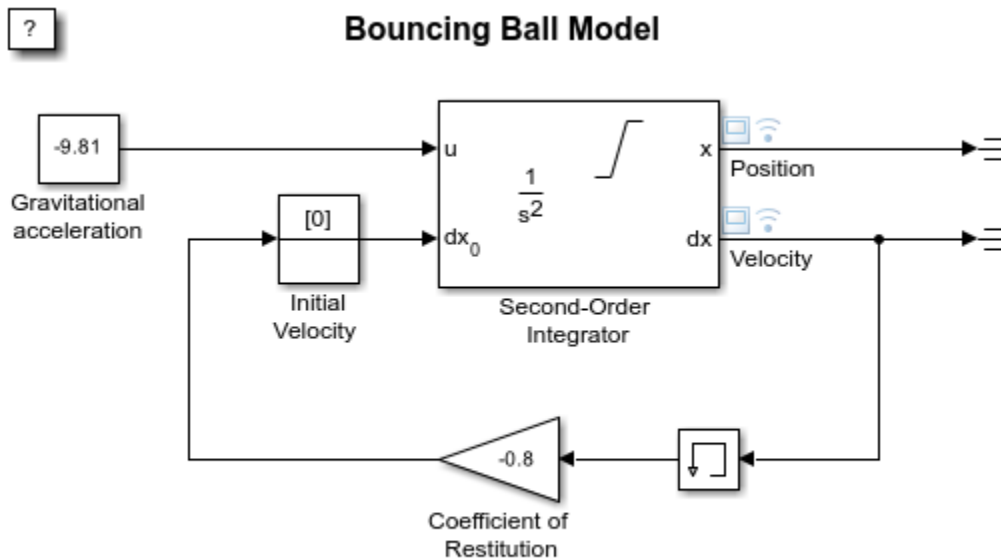

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a fixed-step solver. Therefore, the sample time of the Memory block is the solver step size, or 1.

If you replace the Memory block with a Unit Delay block, you get the same results. The Unit Delay block inherits a discrete sample time of 1.

## Capture the Velocity of a Bouncing Ball with the Memory Block

The `sldemo_bounce` example shows how to use the Second-Order Integrator and Memory blocks to capture the velocity of a bouncing ball just before it hits the ground.

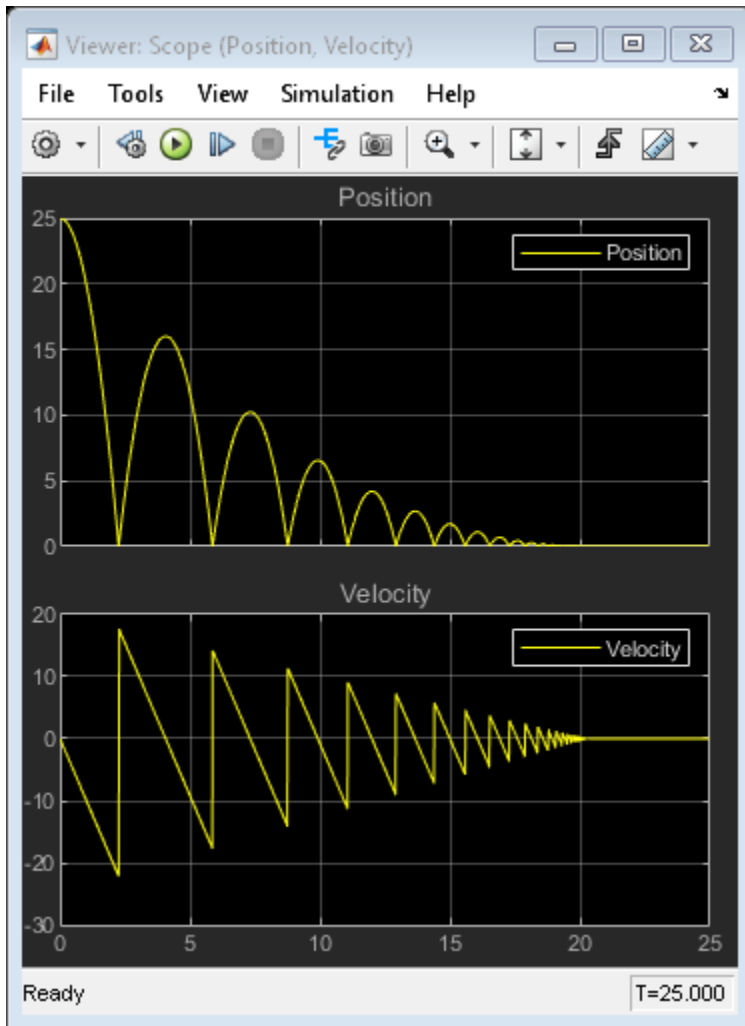

```
open_system('sldemo_bounce');
```

Copyright 2004-2022 The MathWorks, Inc.

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a variable-step (ode23) solver. Therefore, the sample time of the Memory block is continuous but fixed in minor time step:  $[0, 1]$ . When you run the model, you get these results.

```
sim('sldemo_bounce');
```

If you replace the Memory block with a Unit Delay block, you get the same results. However, a warning also appears due to the discrete Unit Delay block inheriting a continuous sample time.

For more information, see the model description.

## Implement a Finite-State Machine with the Combinatorial Logic and Memory Blocks

The `ex_sl_demo_clutch` example shows how you can use the Memory block with the Combinatorial Logic block to implement a finite-state machine. This construct appears in the Friction Mode Logic/Lockup FSM subsystem:

Because **Inherit sample time** is not selected for the Memory block, the block sample time depends on the type of solver for simulating the model. In this case, the model uses a variable-step (`ode23`) solver. Therefore, the sample time of the Memory block is continuous but fixed in minor time step: `[0, 1]`.

- “Building a Clutch Lock-Up Model” on page 13-153

## Discrete-Time Integration Using the Forward Euler Integration Method

The `sldemo_fuelsys` model uses a Discrete-Time Integrator block in the `fuel_rate_control/airflow_calc` subsystem. This block uses the Forward Euler integration method.

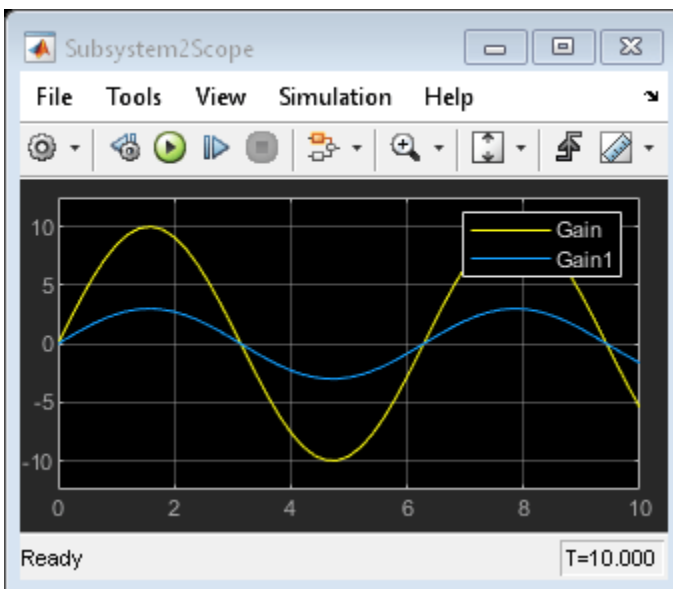

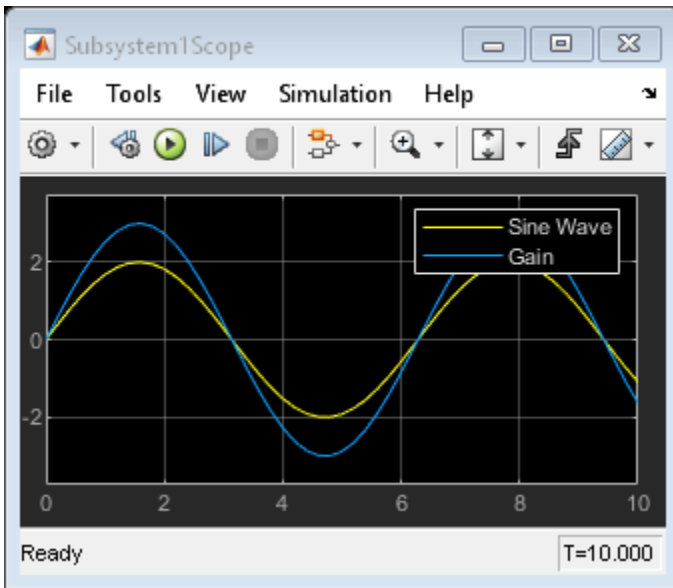

When the Switch block feeds a nonzero value into the Discrete-Time Integrator block, integration occurs. Otherwise, integration does not occur.

## Zero-Based and One-Based Indexing with the Index Vector Block

This example shows how the Index Vector block works with zero-based and one-based indexing.

The Index Vector block is from the Simulink Signal Routing library. It is a special configuration of the Multiport Switch block. To configure the Multiport Switch block as an Index Vector block, set the **Number of data ports** to 1 and **Data port order** to Zero-based contiguous.

## Noncontiguous Values for Data Port Indices of Multiport Switch Block

This example shows how to use a Multiport Switch block that specifies noncontiguous integer values for data ports. The values of the indices are visible on the data port labels. You do not have to open the block dialog box to determine which value maps to each data port.

When you set **Data port for default case** to Additional data port, an extra port with a \* label appears. This port corresponds to the default case, which applies when the control input does not match the data port indices 3, 5, 0, or 18. When that happens in this example, the Multiport Switch block outputs a value of 1.

## Using Variable-Size Signals on the Delay Block

This example shows how the Delay block supports variable-size signals for sample-based processing. The Switch block controls whether the input signal to the enabled subsystem is a 3-by-3 or 3-by-2 matrix.

The Delay block appears inside the enabled subsystem.

The model follows these rules for variable-size signals while using sample-based processing.

- Signal dimensions change only during state reset when the block is enabled.
- Initial condition must be scalar.

The rules are implemented by these blocks.

- Enable block sets **Propagate sizes of variable-size signals** to Only when enabling.
- Delay block sets the **Initial condition** to the scalar value 0.0.

## Buses with the Delay Block for Frame-Based Processing

This example shows how the Delay block supports buses for frame-based processing.

Each Constant block supplies an input signal to the Bus Creator block, which outputs a two-dimensional bus. After the Delay block delays the bus by three sample periods, the Bus Selector block separates the bus back into the two original signals.

The model follows these rules for buses:

- For the initial condition, set the value on the dialog box.
- For frame-based processing, signal dimensions of the data input port  $u$  cannot be larger than two.

The model implements the rules by:

- Setting **Initial condition** to a scalar value of 0.
- Setting bus input to the Delay block as two dimensions.

## Control Execution of Delay Block with Enable Port

This example shows how you can enable or disable the execution of the Delay block using an enable port. In this model, a ramp input signal feeds into a Delay block. The execution of the block is controlled by an enabling signal from the Pulse Generator block.

The blue line shows that the Delay block outputs the input signal value delayed by one time step while the enabling signal has a value of one. At  $t=5$  the enabling signal transitions to zero and the Delay block stops executing. The output is held at the last value until the block is enabled again.

## Zero-Based Indexing for Multiport Switch Data Ports

This example shows a Multiport Switch block that uses zero-based indexing for contiguous ordering of three data ports.

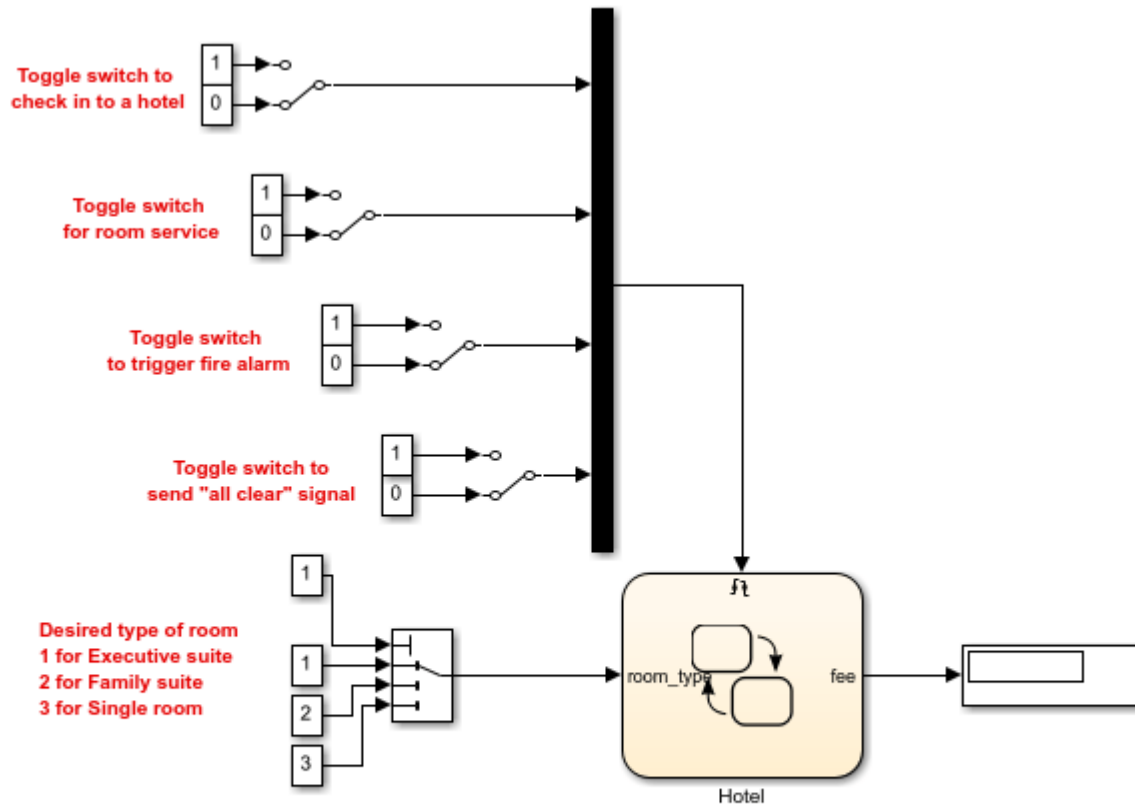

Copyright 2020 The MathWorks, Inc.

The indices are visible on the data port labels. You do not have to open the block dialog box to determine if the data ports use zero-based or one-based indexing.

When you set **Data port for default case** to Last data port, the last data port includes a \* on the label (in this case, the label is \*, 2). The comma after the \* indicates that the data port index has a value. This port corresponds to the default case, which applies when the control input does not match the data port indices. In this example, the Multiport Switch block outputs a value of -0.1 when the control input does not match the data port indices of 0, 1, or 2.

## One-Based Indexing for Multiport Switch Data Ports

The `sf_semantics_hotel_checkin` model uses a Multiport Switch block. This block uses one-based indexing for contiguous ordering of three data ports.

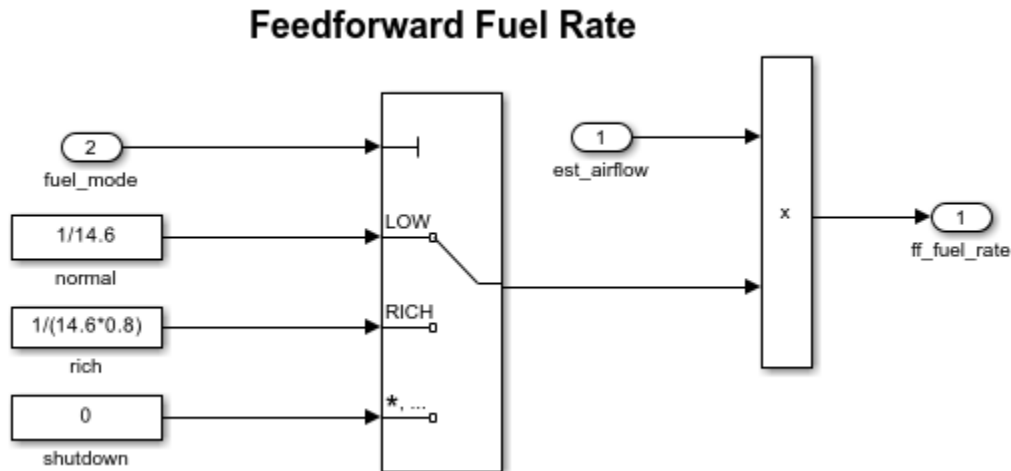

Copyright 2008-2022 The MathWorks, Inc.

When you increase the size of the block icon, the indices are visible on the data port labels. You do not have to open the block dialog box to determine whether the data ports use zero-based or one-based indexing.

## Enumerated Names for Data Port Indices of the Multiport Switch Block

The `sldemo_fuelsys` model uses a Multiport Switch block in the `fuel_rate_control/fuel_calc/feedforward_fuel_rate` subsystem. This block uses the enumerated type `sld_FuelModes` to specify three data port indices: LOW, RICH, and DISABLED.

When you set **Data port for default case** to Last data port, the last data port includes a \* on the label. The comma and ellipsis after the \* indicate that the data port index has a value. This port corresponds to the default case, which applies when the control input does not match the data port indices LOW, RICH, or DISABLED. In this case, the Multiport Switch block outputs a value of 0.

## Prevent Block Windup in Multiloop Control

This example shows how to use signal tracking to prevent block windup in a two-loop control system.

The Inner Loop subsystem contains a saturation limit:

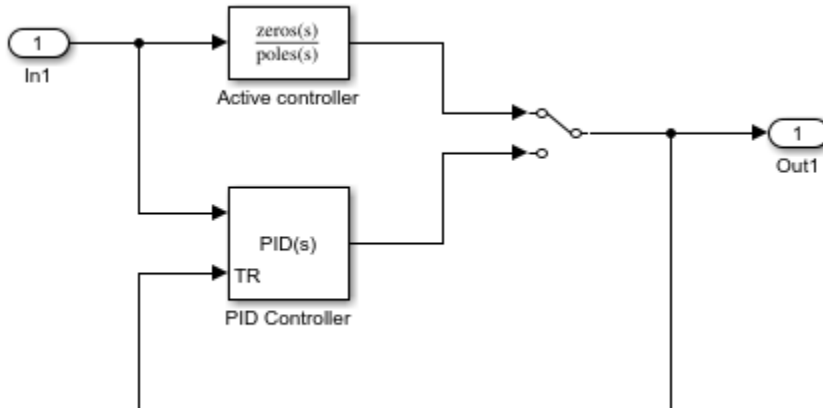

In this example, the inner loop has an effective gain of 1 when it does not saturate. When the inner loop does saturate, however, the integrator in the PID Controller can begin to wind up.

If the PID controller tracks the output of the inner loop, then its output never exceeds the saturated inner-loop output. To achieve this tracking, connect the Saturation block output to the tracking input of the PID Controller.

## Bumpless Control Transfer

This example shows how to use signal tracking to achieve bumpless control transfer in a system that switches between a PID Controller block and another controller. You can make the PID controller track the output of the other controller by connecting the signal you want to track to the TR port of the PID Controller block. For example:

The input **In1** takes a reference signal that feeds both controllers. The output **Out1** drives a controlled system (not shown). A switch transfers control between the Active controller block (a Zero-Pole block) and the PID Controller block. When the Active controller is in the loop, the PID Controller block tracks its output. Thus, the two controllers have the same output when you switch to PID control, ensuring smooth operation.

## Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller

This example shows how to use signal tracking to achieve bumpless control transfer in a system that switches between a PID Controller (2DOF) block and another controller. You can make the PID controller track the output of the other controller by connecting the signal you want to track to the TR port of the PID Controller block. For example:

The input Ref takes a reference signal, and the input y takes the measured feedback from the plant. These signals feed the 2DOF controller, and the difference between them feeds the Active controller block (a Zero-Pole block). The output u drives the plant. A switch transfers control between the active controller and the PID Controller (2DOF) block. When the Active controller is in the loop, the PID Controller (2DOF) block tracks its output. Thus, the two controllers have the same output when you switch to PID control, ensuring smooth operation.

## Using a Bit Set block

If the Bit Set block is turned on for bit 2 bit 2 is set to 1.

A vector of constants  $2.^{[0\ 1\ 2\ 3\ 4]}$  is represented in binary as [00001 00010 00100 01000 10000].

With bit 2 set to 1, the result is [00101 00110 00100 01100 10100], which is represented in decimal as [5 6 4 12 20].

## Using a Bit Clear block

If the Bit Clear block is turned on for bit 2, bit 2 is set to 0.

A vector of constants  $2.^{[0\ 1\ 2\ 3\ 4]}$  is represented in binary as [00001 00010 00100 01000 10000].

With bit 2 set to 1, the result is [00101 00110 00100 01100 10100], which is represented in decimal as [5 6 4 12 20].

With bit 2 set to 0, the result is [00001 00010 00000 01000 10000], which is represented in decimal as [1 2 0 8 16].

## Two-Input AND Logic

This example builds a two-input AND function, which returns 1 when both input elements are 1, and 0 otherwise. To implement this function, specify the **Truth table** parameter value as [0; 0; 0; 1]. The portion of the model that provides the inputs to and the output from the Combinatorial Logic block might look like this:

The following table indicates the combination of inputs that generate each output. The input signal labeled **Input** corresponds to the column in the table labeled **Input 1**. Similarly, the input signal **Input 2** corresponds to the column with the same name. The combination of these values determines the row of the **Output** column of the table that is passed as block output. For example, if the input vector is [1 0], the input references the third row:

( $2^{1*1} + 1$ ) The output value is 0.

Row	Input 1	Input 2	Output
1	0	0	0
2	0	1	0
3	1	0	0
4	1	1	1

## Circuit Logic

This sample circuit has three inputs: the two bits (**a** and **b**) to be summed and a carry-in bit (**c**). It has two outputs: the carry-out bit (**c'**) and the sum bit (**s**).

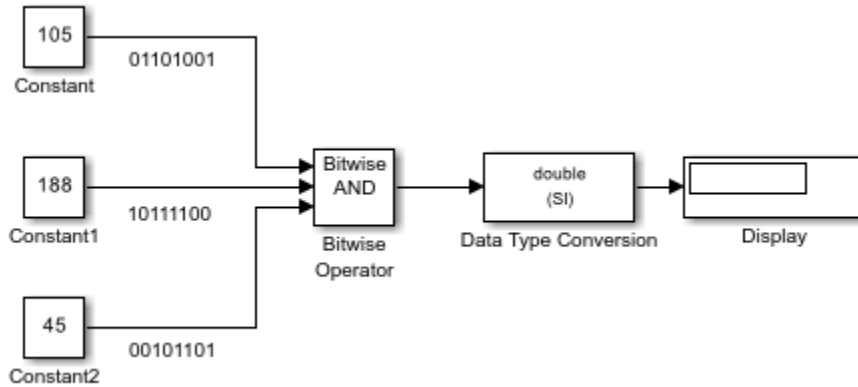

The truth table and corresponding outputs for each combination of input values for this circuit appear in the following table.

Inputs			Outputs	
a	b	c	c'	s
0	0	0	0	0
0	0	1	0	1
0	1	0	0	1
0	1	1	1	0
1	0	0	0	1
1	0	1	1	0
1	1	0	1	0
1	1	1	1	1

To implement this adder with the Combinatorial Logic block, you enter the 8-by-2 matrix formed by columns **c'** and **s** as the **Truth table** parameter. You can also implement sequential circuits (that is, circuits with states) with the Combinatorial Logic block by including an additional input for the state of the block and feeding the output of the block back into this state input.

## Unsigned Inputs for the Bitwise Operator Block

The following model shows how the Bitwise Operator block works for unsigned inputs.

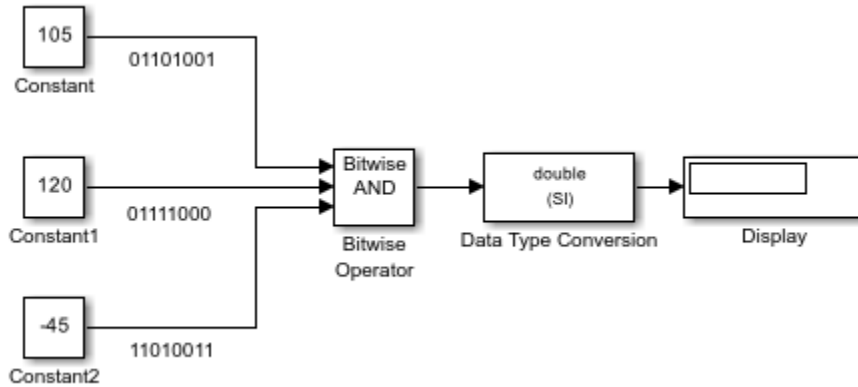

Each Constant block outputs an 8-bit unsigned integer (uint8). To determine the binary value of each Constant block output, use the dec2bin function. The results for all logic operations appear in the next table.

Operation	Binary Value	Decimal Value
AND	00101000	40
OR	11111101	253
NAND	11010111	215
NOR	00000010	2
XOR	11111000	248
NOT	N/A	N/A

## Signed Inputs for the Bitwise Operator Block

The following model shows how the Bitwise Operator block works for signed inputs.

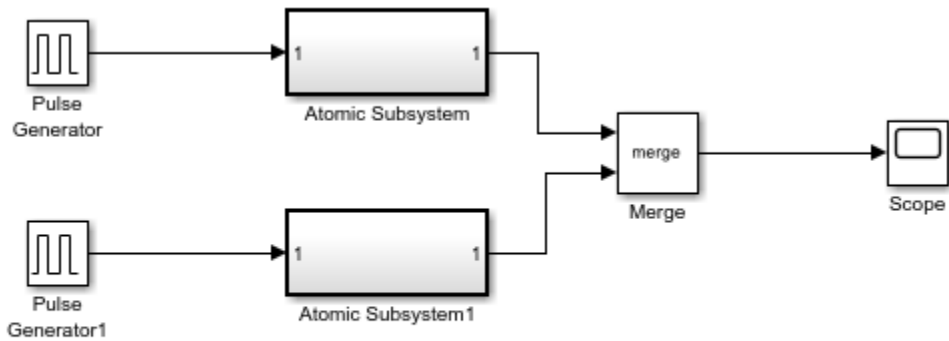

Each Constant block outputs an 8-bit signed integer (`int8`). To determine the binary value of each Constant block output, use the `dec2bin` function. The results for all logic operations appear in the next table.

Operation	Binary Value	Decimal Value
AND	01000000	64
OR	11111011	-5
NAND	10111111	-65
NOR	00000100	4
XOR	11000010	-62
NOT	N/A	N/A

## Merge Block with Input from Atomic Subsystems

This example shows a Merge block with inputs from two atomic subsystems.

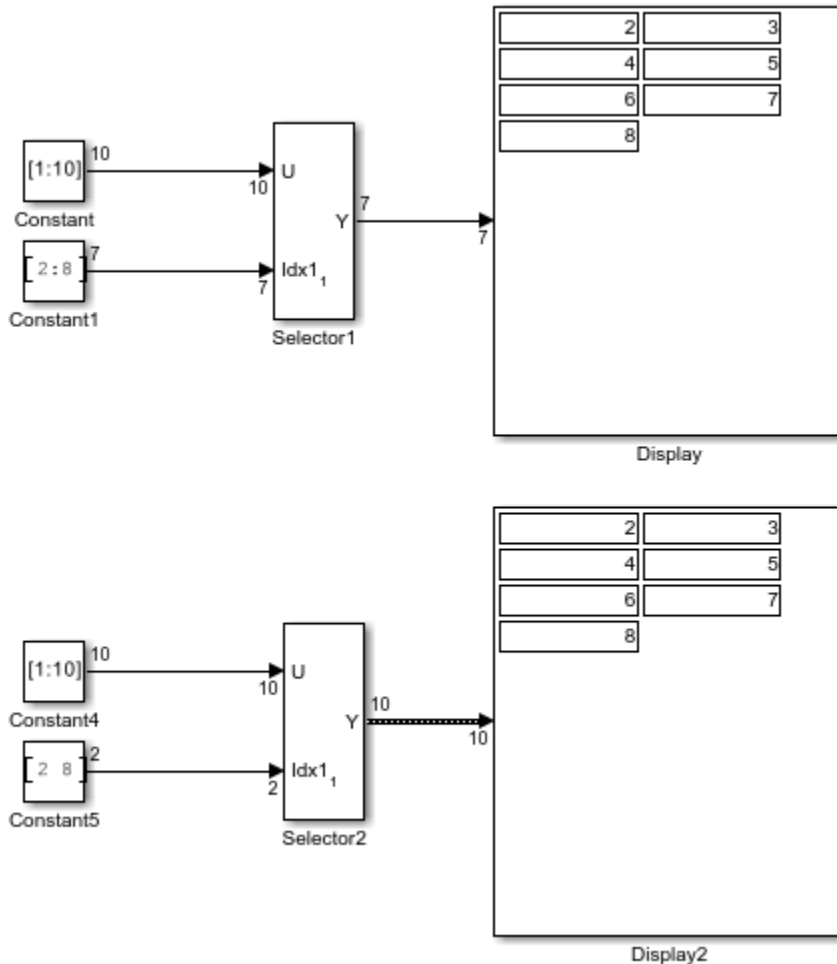

Copyright 2010-2022 The MathWorks, Inc.

Each Atomic Subsystem block contains an enabled subsystem. This satisfies the requirement that inputs to a Merge block are from a conditionally executed subsystem.

## Index Options with the Selector Block

This example shows two Selector blocks with the same kind of input signals, but two different **Index Option** settings.

Both Selector blocks select 7 values from the input signal that feeds the input port. The Selector1 block outputs a fixed-size signal, whereas the Selector2 block outputs a variable-size signal whose compiled signal dimension is 10 instead of 7.

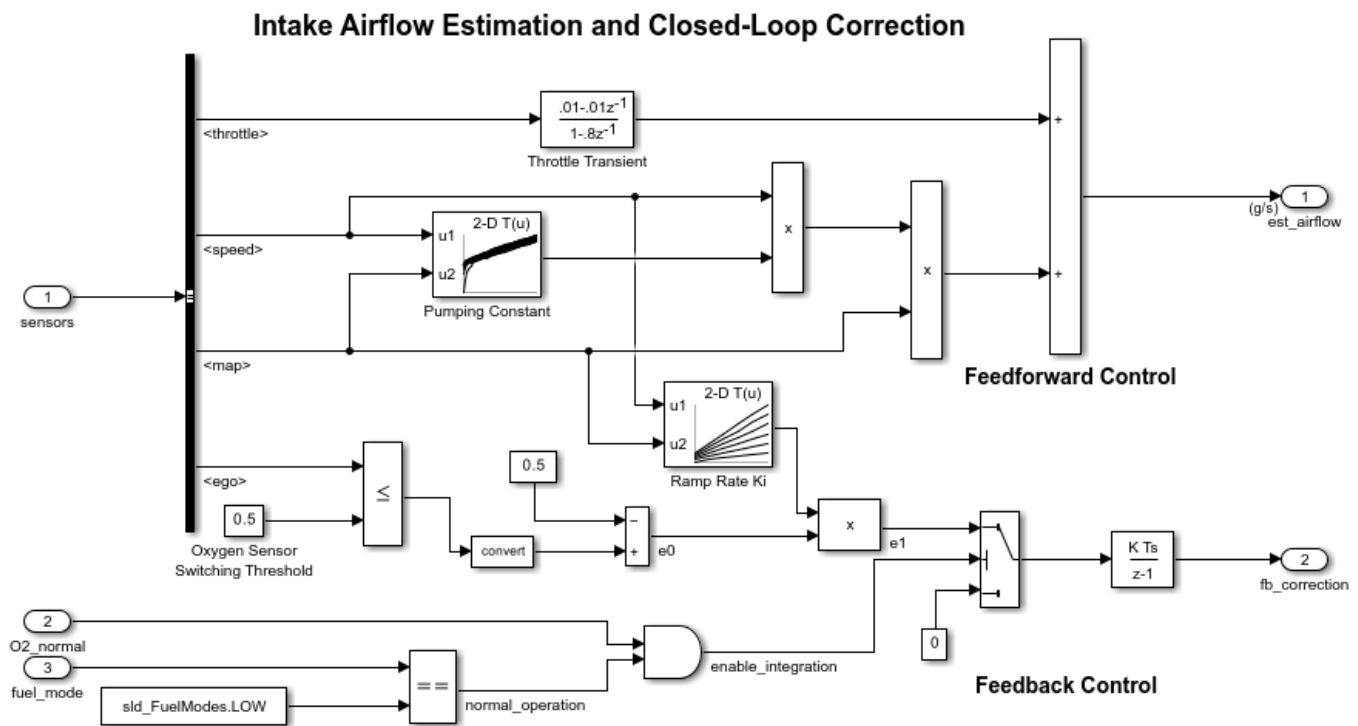

The Selector1 block sets **Index Option** to `Index vector (port)`, which uses the input signal from Constant1 as the index vector. The dimension of the input signal is 7, so the Display block shows the 7 values of the Constant1 block. The Selector2 block sets the **Input port size** parameter to 10, which is the size of the largest input signal to the Selector2 block.

The Selector2 block also sets the **Index Option** to `Starting and ending indices (port)`. The output is then set to the size of **Input port size** parameter (10), even though the size of the input signal is 7.

## Switch Block with a Boolean Control Port Example

This example shows a Switch block with a Boolean input for the control port.

```
open_system('sldemo_fuelsys');
open_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
```

The value of the control port on the Switch block determines whether or not the feedback correction occurs. The control port value depends on the output of the Logical Operator block. When the Logical Operator block output is `true`, then the Switch block control port is 1 and the feedback control occurs. If the Logical Operator block output is `false` then the feedback control does not occur.

## Merge Block with Unequal Input Widths Example

This example shows how to use the Merge block with inputs ports that have different widths. If you select `Allow unequal port widths`, the block accepts scalar and vector inputs having differing numbers of elements. You can specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is:

$$\max(w_1 + o_1, w_2 + o_2, \dots, w_n + o_n)$$

where  $w_n$  are the widths of the input signals, and  $o_n$  are the offsets.

The Merge block has the following output width.

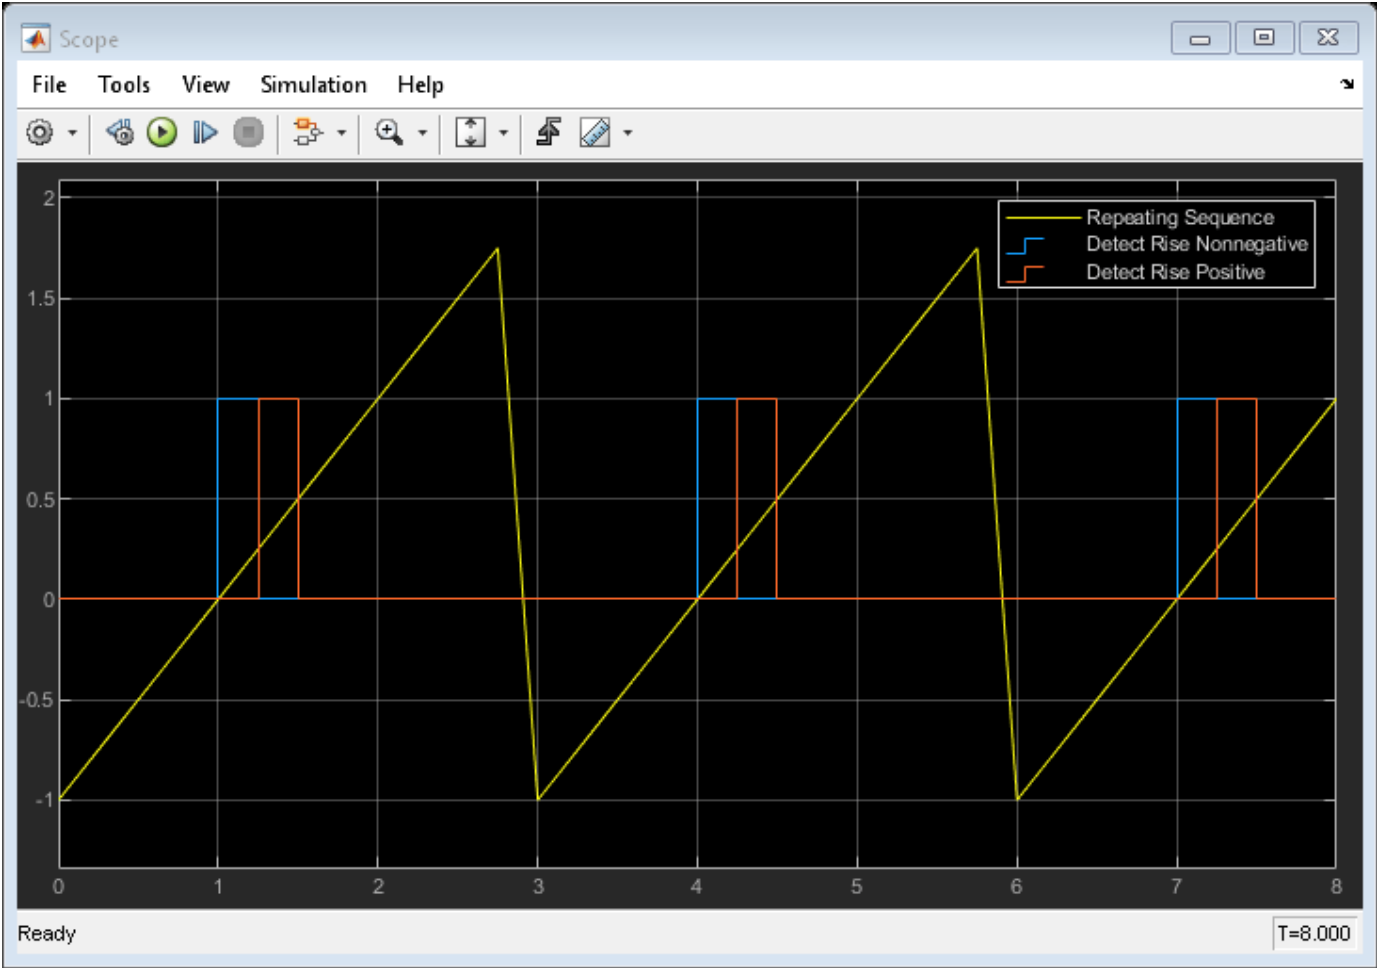

$$\max(2 + 0, 2 + 1) = 3$$

In this example, the offset of  $v1$  is 0 and the offset of  $v2$  is 1. The Merge block maps the elements of  $v1$  to the first two elements of  $v3$  and the elements of  $v2$  to the last two elements of  $v3$ . Only the second element of  $v3$  is effectively merged, as show in the scope output.

If you use Simplified Initialization Mode, you must clear the `Allow unequal port widths` check box. The input port offsets for all signals must be zero.

# Detect Rising Edge of Signals

This example shows how to detect the rising edge of a signal using the Detect Rise Nonnegative and Detect Rise Positive blocks.

With a fixed-step size of 0.25, this example illustrates the difference between the Detect Rise Nonnegative and Detect Rise Positive blocks. The Detect Rise Nonnegative block outputs true (1) at  $t=1$  because the input signal increased from a negative value to a nonnegative value (0). The Detect Rise Positive block outputs true (1) at  $t=1.25$  because the input signal increased from a nonpositive value (0) to a strictly positive value.

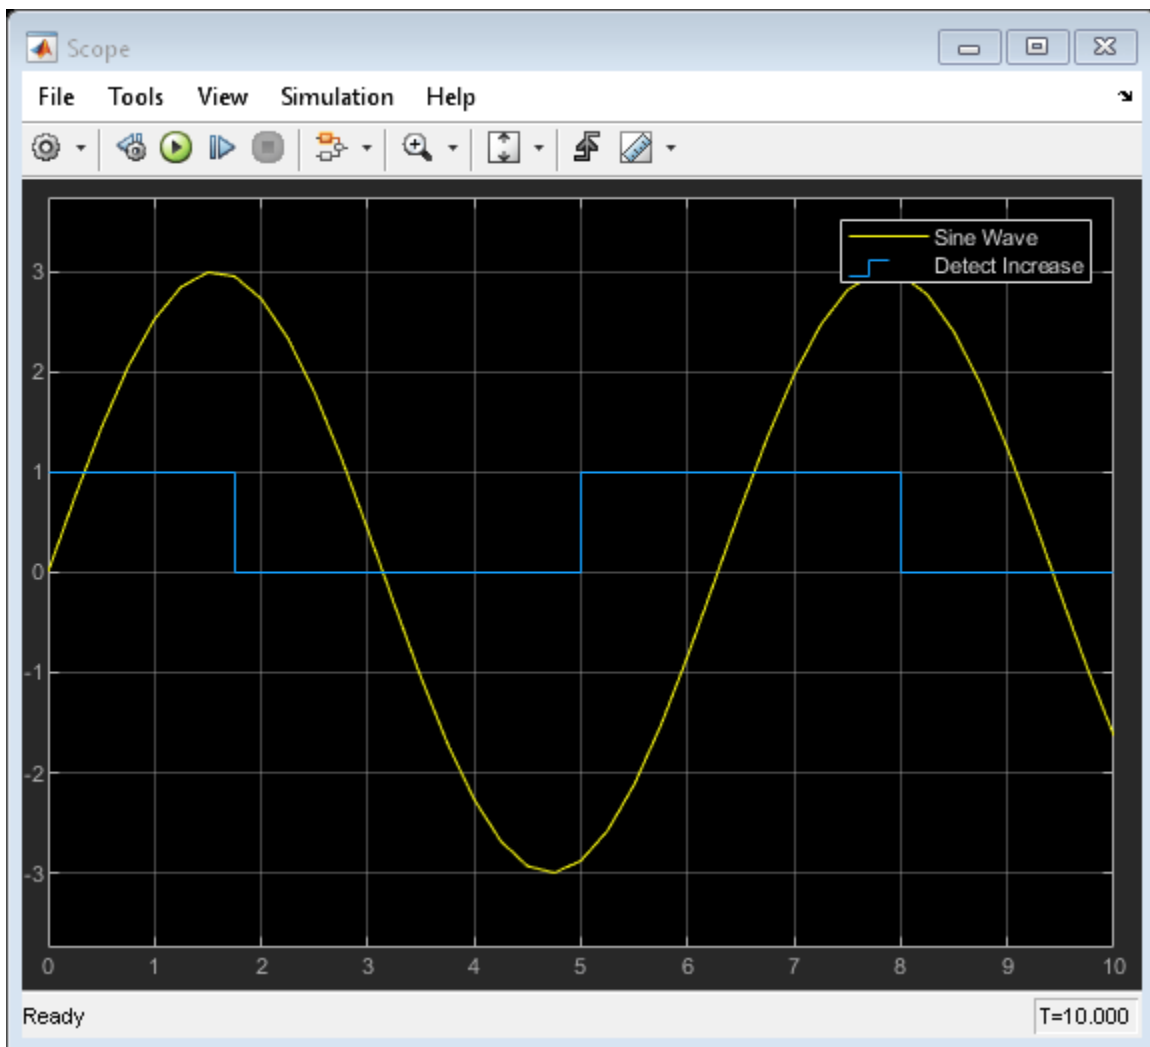

## Detect Falling Edge Using the Detect Fall Nonpositive Block

This example shows how to use the Detect Fall Nonpositive block to detect a falling edge in the input signal. The block detects a falling edge when the signal value decreases from a strictly positive value to a nonpositive value. In this example, the **Initial condition** of the Detect Fall Nonpositive block is set to 1. This means that the Boolean expression  $U/z \leq 0$  evaluates to true and the block assumes the initial value of the input signal is nonpositive.

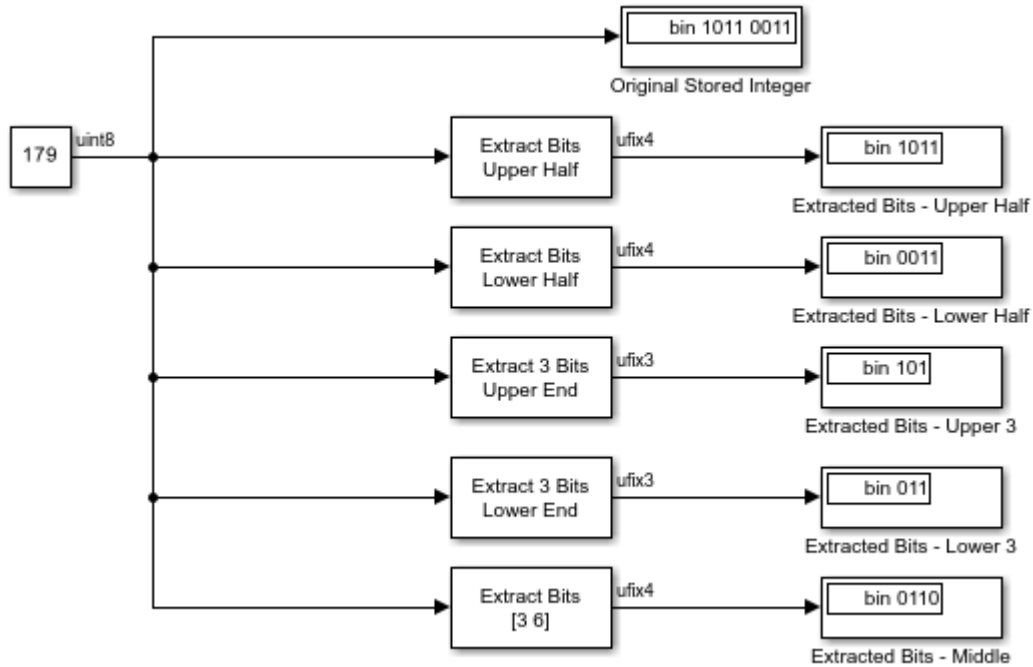

## Detect Increasing Signal Values with the Detect Increase Block

This example shows how to use the Detect Increase Block to detect increasing signal values. Because the **Initial condition** is set to -1, the block detects an increasing signal value starting at time  $t=0$ . If you change the **Initial condition** parameter to a nonnegative value, the block detects the first increasing signal value at  $t=0.25$ .

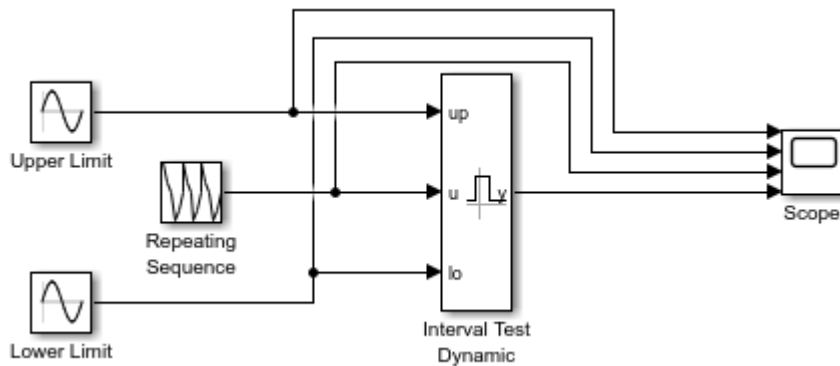

## Extract Bits from Stored Integer Value

This example shows how to extract specific bits from the stored integer value of an input signal.

## Detect Signal Values Within a Dynamically Specified Interval

This example shows how to detect when an input signal falls within a dynamically specified interval. The interval is defined by two Sine Wave blocks. When the input to the Interval Test Dynamic block falls between those sine waves, the Interval Test Dynamic block outputs true (1).

## Model a Digital Thermometer Using the Polynomial Block

This example shows how the `ex_sl_demo_boiler` model uses the Polynomial block.

In the Boiler Plant model/digital thermometer subsystem, the Polynomial Block models a first-order polynomial using the coefficients [0.05 0.75]

This subsystem models a digital thermometer composed of a simple temperature sensor and an ADC. The transfer function of the sensor is:

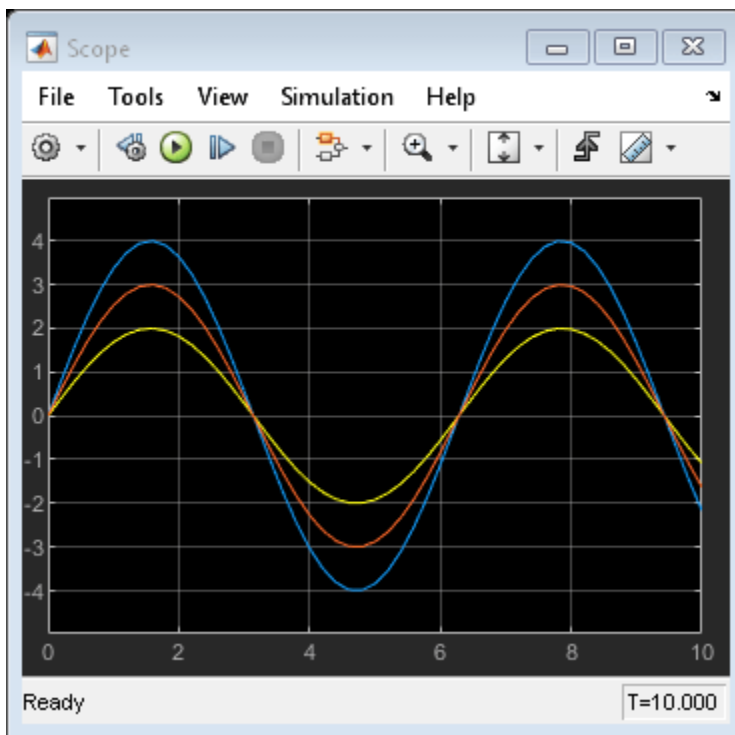

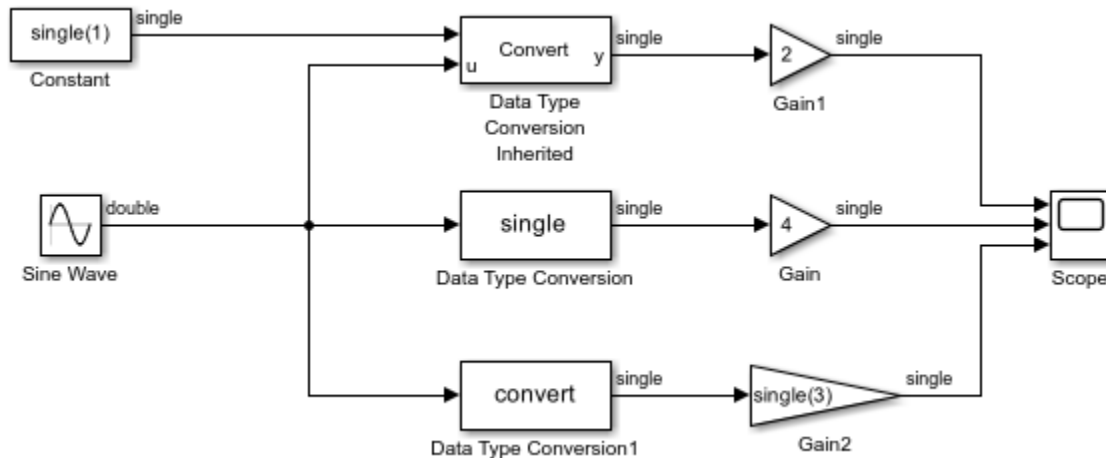

$$V = .05 * T + 0.75$$

for T in degrees C.

The conversion block inverts the combined transfer function of the sensor and ADC so that the output is an `sfix(8)` code representing T in degrees C.

## Convert Data Types in Simulink Models

This example shows three different methods of converting data types in your model using the Data Type Conversion and Data Type Conversion Inherited blocks. In this model, a Sine Wave block generates the input signal. The Sine Wave block only outputs double-precision data types, so to generate a sine wave with a data type of single, you must perform a data type conversion.

In the first row, the Data Type Conversion Inherited block uses the data type coming from the Constant block (single) as the reference data type, and converts the sine wave to single.

In the second row, the Data Type Conversion block has the **Output data type** set to `single`, and the sine wave is converted accordingly.

In the third row, the Data Type Conversion1 block has the **Output data type** set to `Inherit via back propagation`. Because the downstream Gain2 block has a data type of `single`, the Data Type Conversion1 block converts the sine wave to a data type of `single`.

## Control Data Types with the Data Type Duplicate Block

This example shows how to control data types in your model using the Data Type Duplicate block. In this model, the data type of the Constant block (currently `single`) drives the data types throughout the model.

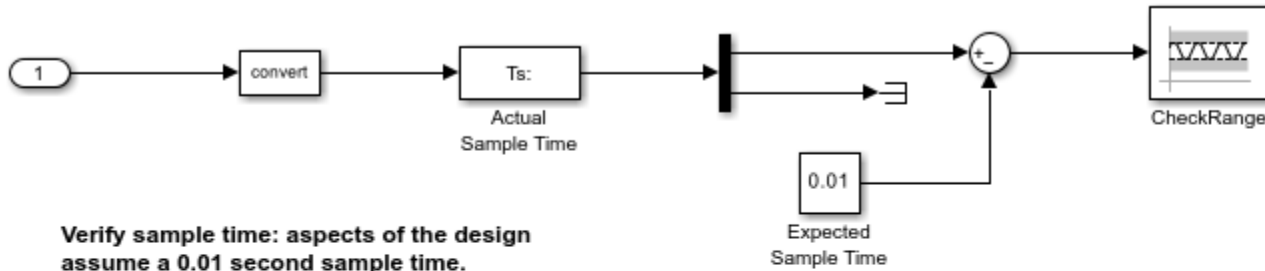

The Constant1 block has its **Output data type** parameter set to `Inherit: Inherit via back propagation`. Because the Constant1 and Constant blocks are both connected to the Data Type Duplicate block, the Constant1 block can inherit its data type from the Constant block. The Sum block has its **Output data type** set to `Inherit: Same as first input`, so it is also able to inherit its data type from the Constant block.

If you change the data type of the Constant block from `single` to `int32`, the `int32` data type propagates throughout the model.

## Probe Sample Time of a Signal

The `sldemo_fuelsys` model shows how to check the sample time of a signal using the Probe block. This enables you to verify that the sample time matches the assumed value of the design.

The contents of this subsystem are excluded from the code Simulink Coder generates.

To work correctly this system must continue to

- \* Contain no output ports
- \* Enable its 'Treat as Atomic Unit' parameter
- \* Specify its 'Mask type' parameter as "VerificationSubsystem"

## Convert Signals Between Continuous Time and Discrete Time

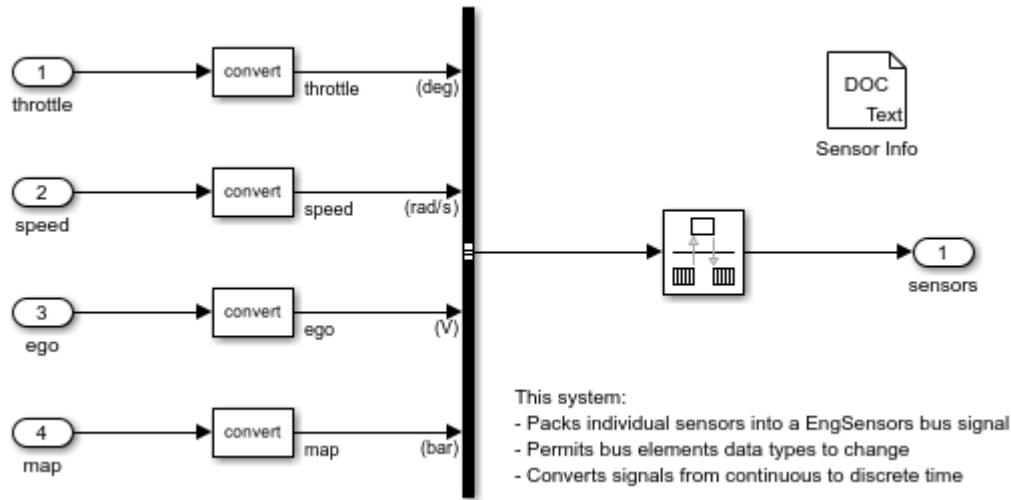

The `sldemo_fuelsys` model shows how to use the Rate Transition block to convert signals between continuous time and discrete time.

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

In the `To Controller` subsystem, the Rate Transition block converts the signal from continuous time to discrete time. This discrete-time signal can then be processed by the `fuel_rate_control` subsystem.

The To Plant subsystem uses the Rate Transition block to convert the discrete-time output of the fuel\_rate\_control subsystem back to continuous time.

## Convert Virtual Bus to Nonvirtual Bus

This example shows how to use the Signal Conversion block to convert a virtual bus to a nonvirtual bus.

Copyright 2011-2021 The MathWorks, Inc.

The Bus Creator block creates a virtual bus that is input to the Signal Conversion block. To convert the virtual bus to a nonvirtual bus, the Signal Conversion block has its **Output** parameter set to **Nonvirtual bus** and its **Data type** parameter set to a **Simulink.Bus** object. The specified **Bus** object matches the bus hierarchy of the bus from the Bus Creator block. The nonvirtual bus output from the Signal Conversion block is input to the Bus Selector block.

## Convert Nonvirtual Bus to Virtual Bus

This example shows how to use the Signal Conversion block to convert a nonvirtual bus to a virtual bus.

The Bus Creator block creates a nonvirtual bus that is input to the Signal Conversion block. To convert the nonvirtual bus to a virtual bus, the **Output** parameter of the Signal Conversion block is set to `Virtual bus`. The virtual bus output from the Signal Conversion block is input to the Bus Selector block.

## Remove Scaling from a Fixed-Point Signal

This example shows how to strip the scaling from a fixed-point input signal. To do so, the Data Type Scaling Strip block maps the input to the smallest built-in data type that has enough data bits to hold the input. The stored integer value of the input is the value of the output.

## Stop Simulation Block with Relational Operator Block

This example shows how to control when a simulation stops by using a Stop Simulation block with a Relational Operator block. When you simulate the model, the model stops simulation when the simulation time reaches 10.

## Output Simulation Data with Blocks

This example shows how To Workspace and To File blocks write data to the workspace and to a file respectively.

### Open Example Model

```
open_system('ex_ToWorkspace_ToFile');
```

### Output Simulation Data with Blocks

Copyright 1990-2018 The MathWorks, Inc.

### Simulate with Default Parameter Values

1. To name the output variables and file, modify the **Variable name** and **File name** block parameter values by using the Block Parameters dialog boxes or the command line.

```
set_param('ex_ToWorkspace_ToFile/To Workspace',...
 'VariableName','simoutToWorkspace')
```

```
set_param('ex_ToWorkspace_ToFile/To File',...
 'FileName','simoutToFile.mat',...
 'MatrixName','simoutToFileVariable')
```

2. Simulate the model.

```
out = sim('ex_ToWorkspace_ToFile');
```

3. To view the input signal for the To Workspace and To File blocks, open the scope viewer.

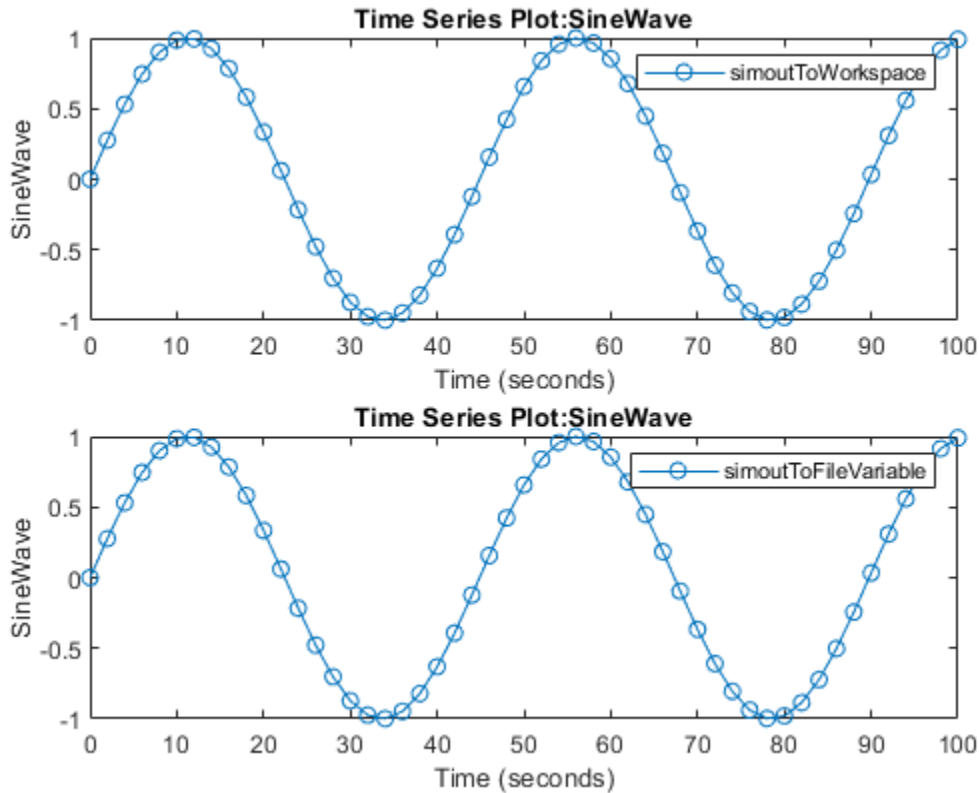

4. To access the data stored by the To File block, load the output file.

```
load('simoutToFile.mat')
```

5. Plot the data stored by the To Workspace and To File blocks.

```
subplot(2,1,1)
plot(out.simoutToWorkspace, '-o')
legend('simoutToWorkspace')
```

```
subplot(2,1,2)
plot(simoutToFileVariable, '-o')
legend('simoutToFileVariable')
```

As shown by the plots, the data stored by each block is the same given the default block parameter values.

### Simulate with Custom Parameter Values

1. To keep the data from the previous simulation, specify new names for the output variables and file.

```
set_param('ex_ToWorkspace_ToFile/To Workspace',...
 'VariableName', 'simoutToWorkspace2')
```

```
set_param('ex_ToWorkspace_ToFile/To File',...
 'FileName', 'simoutToFile2.mat',...
 'MatrixName', 'simoutToFileVariable2')
```

2. To change the amount of data collected, modify the **Limit data points to last**, **Decimation**, and **Sample time** block parameter values.

```
set_param('ex_ToWorkspace_ToFile/To Workspace',...
 'MaxDataPoints', '3',...
 'Decimation', '20',...
 'SampleTime', '0.5')
```

```
set_param('ex_ToWorkspace_ToFile/To File',...
 'Decimation', '20',...
 'SampleTime', '1')
```

The To File block does not provide the option to limit data points to the last data points collected.

3. Select **Single simulation output**, then modify the **Logging intervals** configuration parameter value.

```
set_param('ex_ToWorkspace_ToFile',...
 'ReturnWorkspaceOutputs','on',...
 'LoggingIntervals','[20,90]')
```

4. Simulate the model.

```
out = sim('ex_ToWorkspace_ToFile');
```

5. To access the data stored by the To File block, load the output file.

```
load('simoutToFile2.mat')
```

6. Plot the data stored by the To Workspace and To File blocks.

```
subplot(2,1,1)
hold on
plot(out.simoutToWorkspace2,'-*','DisplayName','simoutToWorkspace2')
hold off

subplot(2,1,2)
hold on
plot(simoutToFileVariable2,'-*','DisplayName','simoutToFileVariable2')
hold off
```

In this example, the To Workspace block collects data at 20, 30, 40, ..., 90 seconds. The data represents every 20th sample time within the logging intervals. When the simulation is completed or

paused, the To Workspace block writes only the last three collected sample points to the workspace: 70, 80, and 90 seconds.

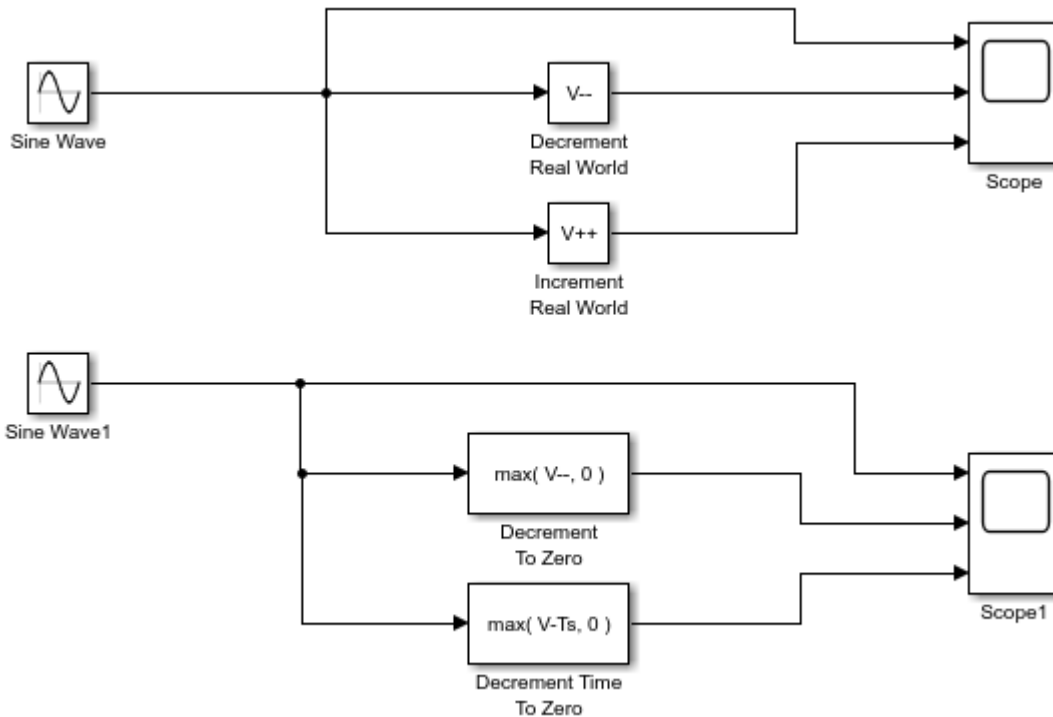

The To File block collects data at 20, 40, 60, and 80 seconds. The data similarly represents every 20th sample time within the logging intervals. However, the sample time for the To File block is double the sample time for the To Workspace block.

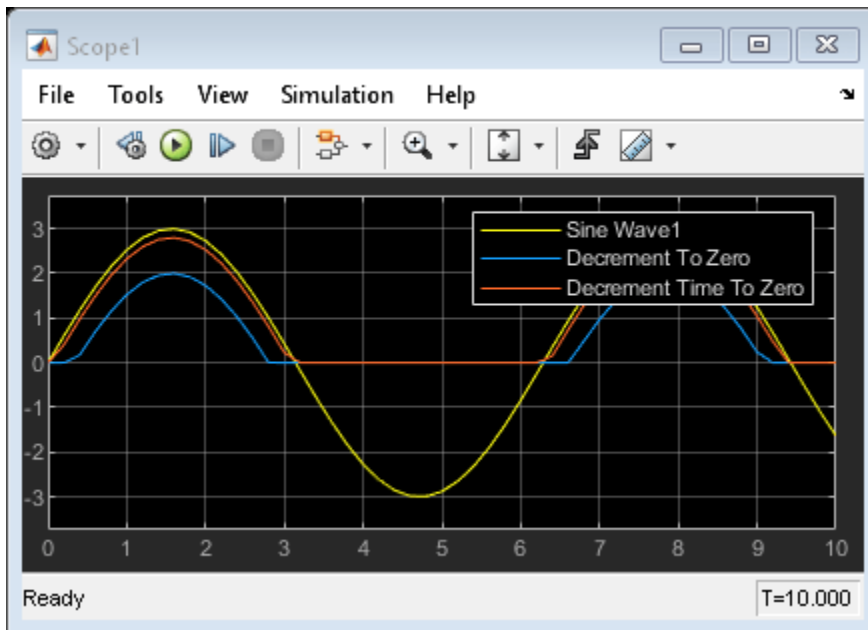

## Increment and Decrement Real-World Values

This example shows how to increase and decrease the real-world value of a signal using the following blocks:

- Increment Real World
- Decrement Real World
- Decrement Time To Zero
- Decrement To Zero

The Scope block shows the output of a Sine Wave block with amplitude 5, as well as the real-world value of that signal incremented and decremented by one.

The Scope1 block shows the output of a Sine Wave block with amplitude 3, as well as the output of the Decrement To Zero and Decrement Time To Zero blocks:

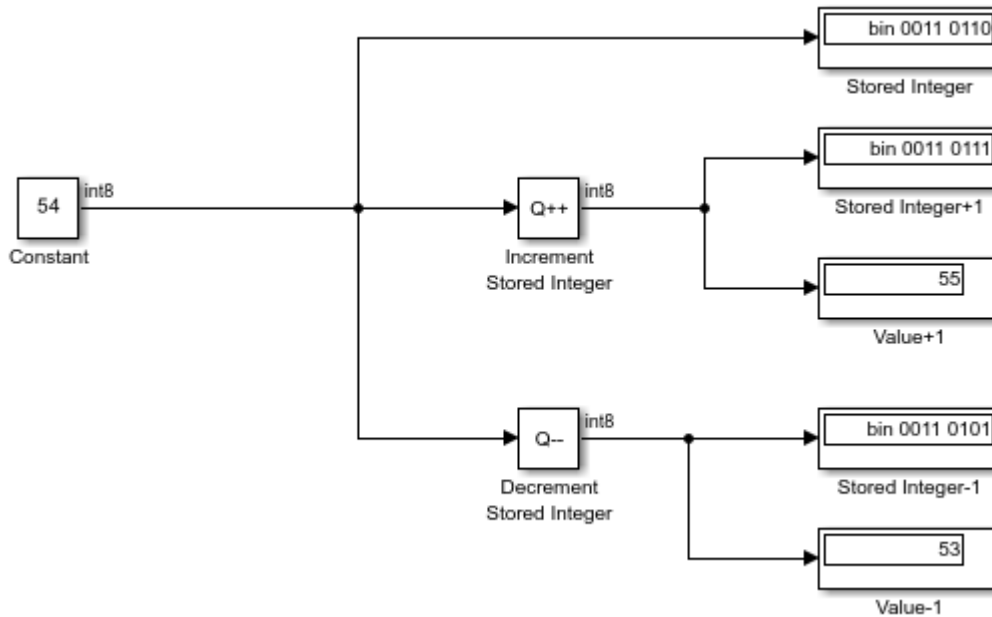

- The Decrement To Zero block decreases the input sine wave signal by one, and ensures the value never goes below zero.
- The Decrement Time To Zero block decreases the input sine wave signal by the sample time,  $T_s$ , and ensures that the value never goes below zero.

## Increment and Decrement Stored Integer Values

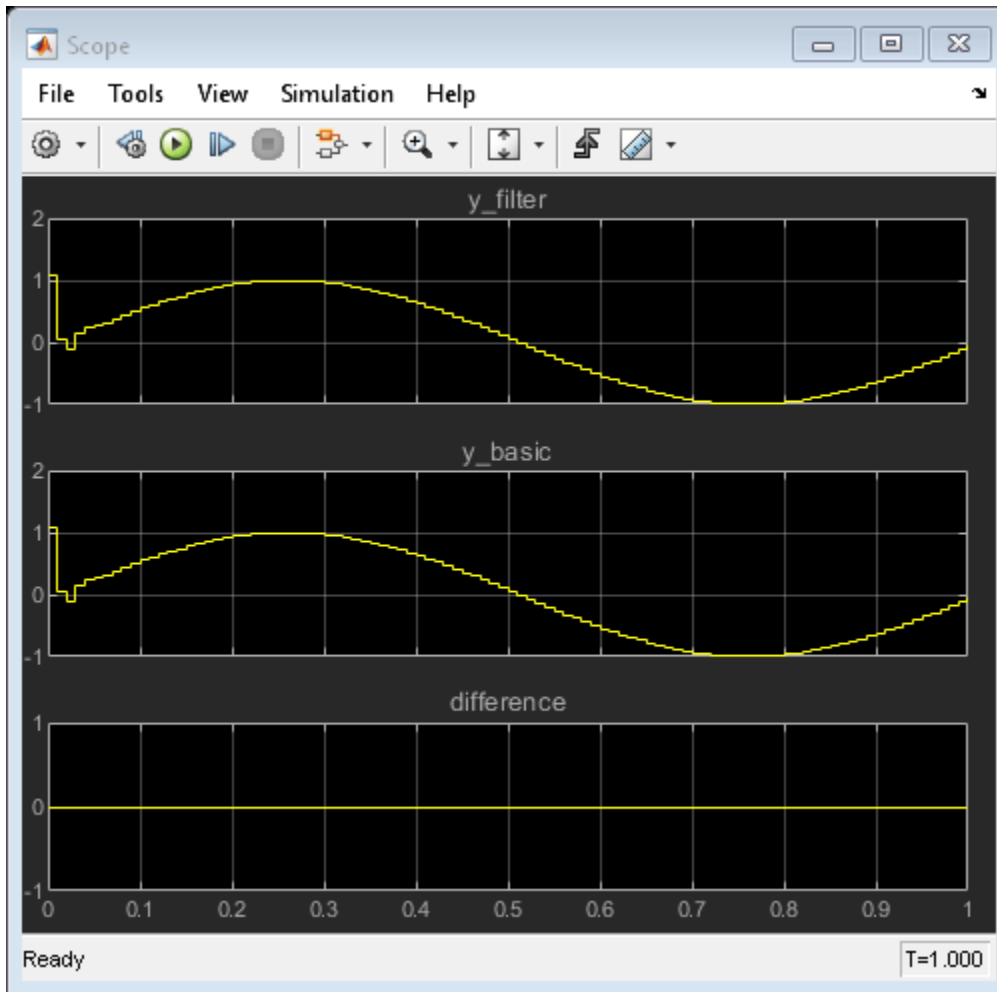

This example shows how to increase and decrease the stored integer value of a signal by one.

- The Increment Stored Integer block increases the stored integer value of the input signal by one.
- The Decrement Stored Integer block decreases the stored integer value of the input signal by one.

If you change the value of the input signal to 127 (the maximum value representable by an `int8` data type), incrementing the stored integer value by one causes an overflow. Because overflows in the Increment and Decrement Stored Integer blocks always wrap, the Increment Stored Integer block will output a value of -128.

The Scope shows that with the **Initial states** of the Discrete Filter block set to  $[1 \ 2]$ , the difference between the signal filtered by the Discrete Filter block and the signal from the filter's building blocks is zero. This demonstrates that you can enter the initial conditions of the Discrete Filter block as a vector of  $[1 \ 2]$ . As an alternative, to achieve the same result, you can set the initial condition of Unit Delay to 1 and Unit Delay1 to 2.

## Generate Linear Models for a Rising Edge Trigger Signal

You can use state and simulation time logging to extract the model states at operating points. In this example, the model is configured to get the states when the x1 signal triggers the Trigger-Based Linearization block on a rising edge.

In this model, the **Trigger type** of the Trigger-Based Linearization block is set to **rising**. On the Data Import/Export pane of the Model Configuration Parameters dialog box, the States and Time check boxes are selected.

After simulating the model, the following variables appear in the MATLAB workspace:

- `ex_vdp_triggered_linearization_Trigger_Based_Linearization`
- `tout`
- `xout`

To get the index to the first operating point time, execute the following command:

```
ind1 = find(ex_vdp_triggered_linearization_Trigger_Based_Linearization(1).OperPoint.t==tout);
```

To get the state vector at this operating point, execute the following command:

```
x1 = xout(ind1,:);
```

## Generate Linear Models at Predetermined Times

This example shows how to use the Timed-Based Linearization block to generate linear models at predetermined times.

In this model, the **Linearization time** of the Timed-Based Linearization block is set to [2 5]. On the Data Import/Export pane of the Model Configuration Parameters dialog box, the States and Time check boxes are selected. These settings enable you to get the states of the model at the simulation times of 2 and 5 seconds.

F-14 Flight Control

Copyright 1990-2014 The MathWorks, Inc.

After simulating the model, the following variables appear in the MATLAB workspace:

- ex\_f14\_linearization\_Timed\_Based\_Linearization
- tout
- xout

To get the indices to the operating point times, execute the following command:

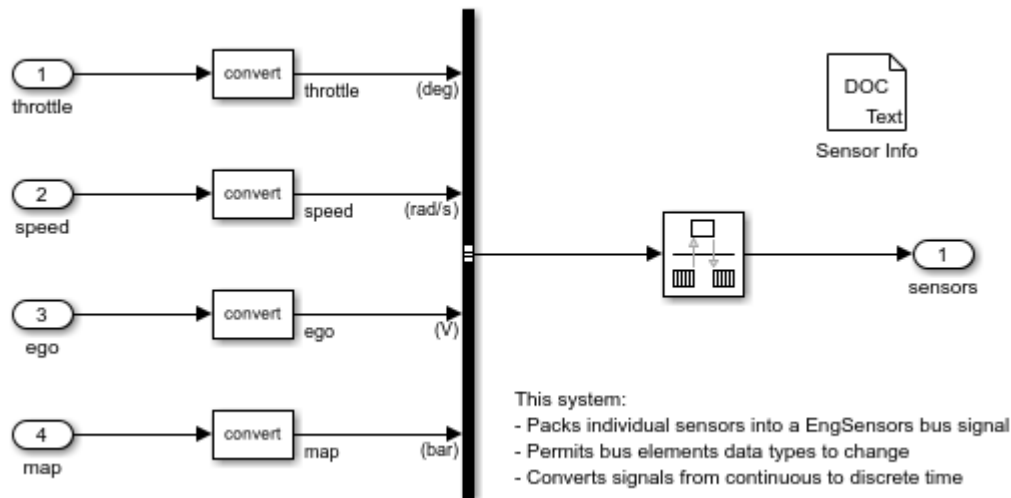

```
ind1 = find(ex_f14_linearization_Timed_Based_Linearization(1).OperPoint.t==tout);
```

To get the state vectors at the operating points, execute the following command:

```
ind2 = find(ex_f14_linearization_Timed_Based_Linearization(1).OperPoint.t==tout);
```

## Capture Measurement Descriptions in a DocBlock

This example shows how to use a DocBlock to capture information about a model. In the `sldemo_fuelsys` model, a DocBlock labeled `Sensor Info` is used to document measurement descriptions inside of the `To_Controller` subsystem.

## Square Root of Negative Values

This example shows how to compute the square root of a negative-valued input signal as complex-valued output.

ans =

```
Simulink.SimulationOutput:
 tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

By setting the **Function** to `sqrt` and **Output signal type** to `complex`, the block produces the correct result of `0 + 10i` for an input of `-100`. If you change the **Output signal type** to `auto` or `real`, the block outputs `NaN`.

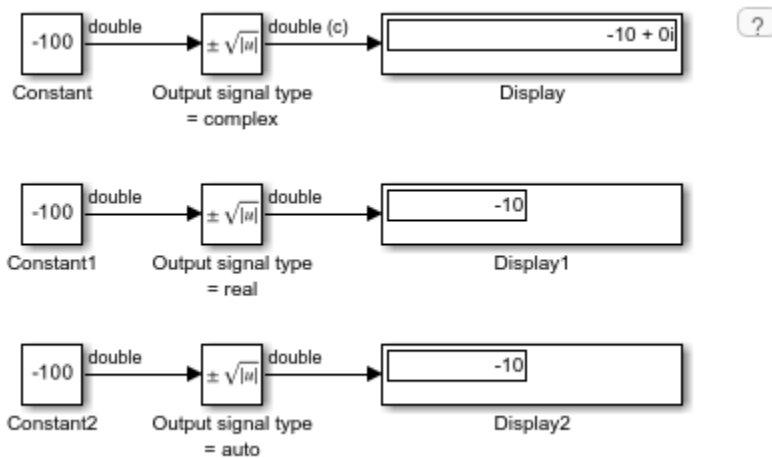

## Signed Square Root of Negative Values

This example shows how to compute the signed square root of a negative-valued input signal.

ans =

```
Simulink.SimulationOutput:
 tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

When the block input is negative and you set the **Function** to `signedSqrt`, the Sqrt block output is the same for any setting of the **Output signal type** parameter. By setting the **Numerica display format** of the first Display block to `decimal (Stored Integer)`, you can see the value of the imaginary part for the complex output.

## rSqrt of Floating-Point Inputs

This example shows how to compute the rSqrt of a floating-point input signal. The Sqrt block has the following settings:

- **Method** = Newton-Raphson
- **Number of iterations** = 1
- **Intermediate results data type** = Inherit: Inherit from input

After one iteration of the Newton-Raphson algorithm, the block output is within 0.0004 of the final value (0.4834).

ans =

```
Simulink.SimulationOutput:
 tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
ErrorMessage: [0x0 char]
```

## rSqrt of Fixed-Point Inputs

This example shows how to compute the rSqrt of a fixed-point input signal. The Sqrt block has the following settings:

- **Method** = Newton-Raphson
- **Number of iterations** = 1
- **Intermediate results data type** = Inherit: Inherit from input

After one iteration of the Newton-Raphson algorithm, the block output is within 0.0459 of the final value (0.4834).

ans =

```
Simulink.SimulationOutput:
 tout: [51x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]
```

## Model a Series RLC Circuit

Physical systems can be described as a series of differential equations in an implicit form,

$$F(t, x, \{\dot{x}\}) = 0, \text{ or in the implicit state-space form } E\dot{x} = Ax + Bu$$

If  $E$  is nonsingular, then the system can be easily converted to a system of ordinary differential equations (ODEs) and solved as such:

$$\dot{x} = (E^{-1}A)x + (E^{-1}B)u$$

Many times, states of a system appear without a direct relation to their derivatives, usually representing physical conservation laws. For example:

$$\begin{aligned} \dot{x}_1 &= x_2 \\ 0 &= x_1 + x_2 \end{aligned}$$

In this case,  $E$  is singular and cannot be inverted. This class of systems are commonly called *descriptor* systems and the equations are called differential-algebraic equations (DAEs).

### Series RLC Circuit

Consider the simple series RLC circuit.

From Kirchoff's Voltage Law, the voltage drop across the circuit is equal to the sum of the voltage drop across each of its elements:

$$V_{AC} = V_R + V_L + V_C$$

From Kirchoff's Current Law:

$$I_{AC} = I_R = I_L = I_C$$

where the subscripts  $R$ ,  $L$ , and  $C$  denote the resistance, inductance, and capacitance respectively.

$$V_R = I(t)R$$

$$V_L = L\dot{I}_L \text{ or } \dot{I}_L = \frac{1}{L}V_L$$

$$V_C = V_{AC}(0) + \int_0^t I_C(\tau) d\tau \text{ or } \dot{V}_c = \frac{1}{C}I_c$$

**In Implicit State-Space Form**

Model the system in Simulink with  $R = 10 \Omega$ ,  $L = 1 \times 10^{-6} H$ ,  $C = 1 \times 10^{-4} F$  to find the voltage across the resistor  $V_R$ . To use the Descriptor State-Space block, the system can be written in the implicit, or *descriptor*, state-space form  $E\dot{x} = Ax + Bu$  as shown below.

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{V}_C \\ \dot{V}_L \\ \dot{V}_R \\ \dot{I}_L \\ \dot{I}_{AC} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & \frac{1}{C} & 0 \\ 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & -1 & R & 0 \\ 0 & \frac{1}{L} & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 \end{bmatrix} \begin{bmatrix} V_C \\ V_L \\ V_R \\ I_L \\ I_{AC} \end{bmatrix} + \begin{bmatrix} 0 \\ -1 \\ 0 \\ 0 \\ 0 \end{bmatrix} V_{AC}$$

where  $x = [V_C \ V_L \ V_R \ I_L \ I_{AC}]^T$  is the state vector.

Set  $C = [0 \ 0 \ 1 \ 0 \ 0]$  since the voltage across the resistor is being measured.

Compare this to modeling the system with an algebraic loop in order to find  $V_R$ .

The simulation of both models produces identical results. However, the Descriptor State-Space block allows you to make a simpler block diagram and avoid algebraic loops.

## Extract Vector Elements and Distribute Evenly Across Outputs

This example shows how you can use the Demux block to distribute an input signal evenly over the desired number of outputs. For an input vector of length 6, when you set the **Number of outputs** parameter to 3, the Demux block creates three output signals, each of size 2.

Copyright 2018 The MathWorks, Inc.

### See Also

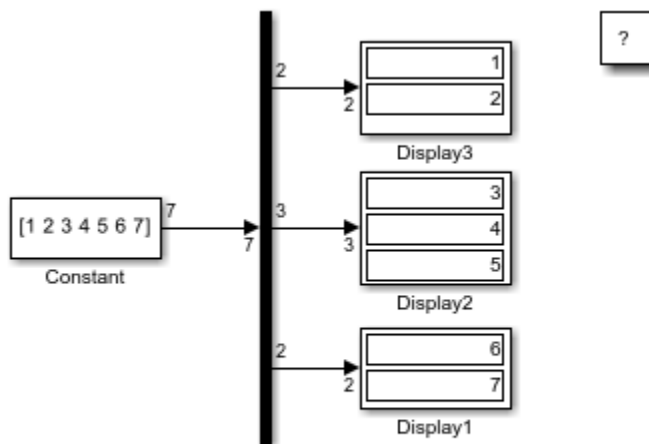

Demux

## Extract Vector Elements Using the Demux Block

When using the Demux block to extract and output elements from a vector input, you can use -1 in a vector expression to indicate that the block dynamically sizes the corresponding port. When a vector expression comprises both positive values and -1 values, the block assigns as many elements as needed to the ports with positive values. The block distributes the remaining elements as evenly as possible over the ports with -1 values.

In this example, the **Number of outputs** parameter of the Demux block is set to [-1, 3, -1]. Thus, the block outputs three signals where the second signal always has three elements. The sizes of the first and third signals depend on the size of the input signal. For an input vector with seven elements, the Demux block outputs two elements on the first port, three elements on the second port, and two elements on the third port.

## Detect Change in Signal Values

This example shows how to detect a change in signal values using the Detect Change block. When the input from the Pulse Generator block remains the same, the Detect Change block outputs zero (false), indicating that there was no change in signal values. When the value of the Pulse Generator block changes, the Detect Change block outputs one (true) indicating that the current signal value does not equal its previous value.

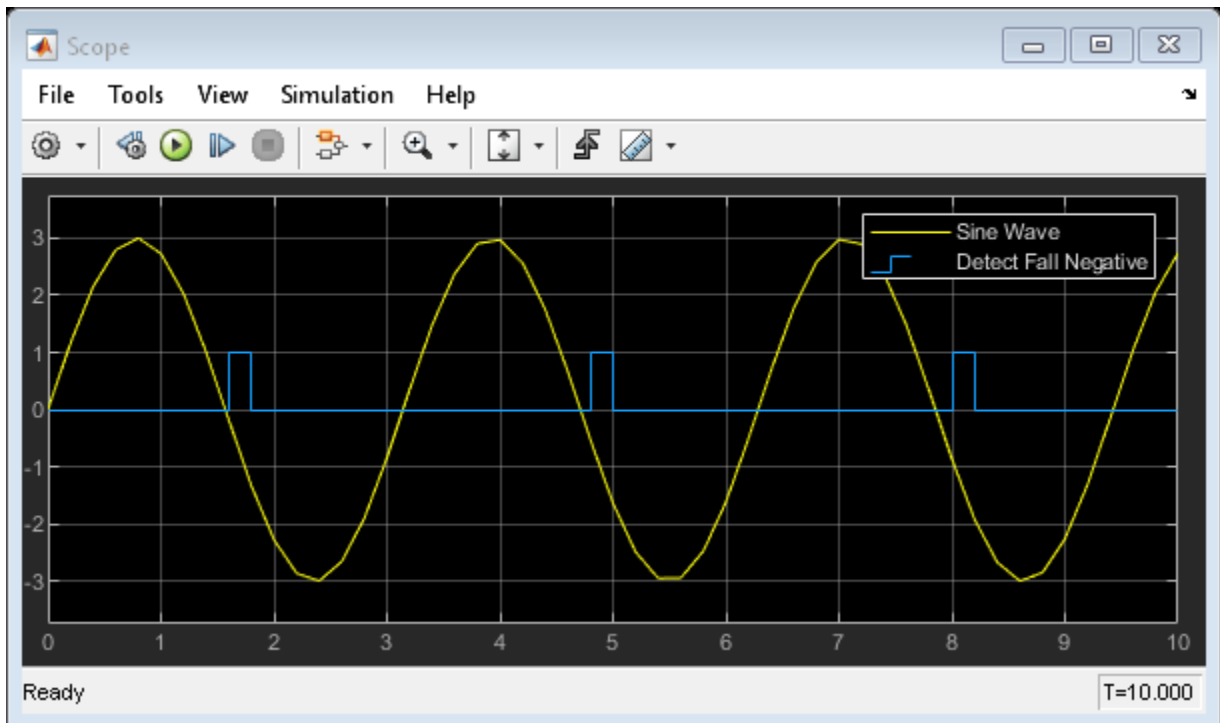

### See Also

Detect Change | Pulse Generator | Scope

## Detect Fall to Negative Signal Values

This example shows how to detect when a signal value decreases to a strictly negative value from a value that was greater than or equal to zero.

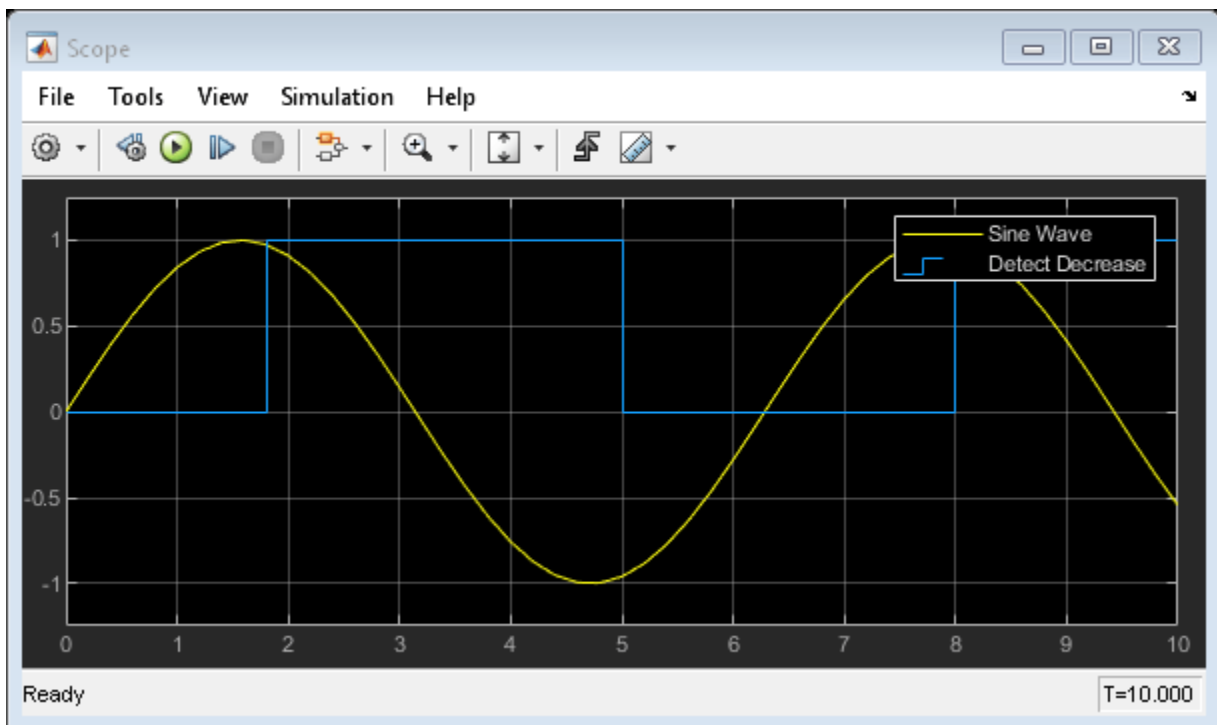

### See Also

Detect Fall Negative | Scope | Sine Wave

## Detect Decreasing Signal Values

This example shows how to determine if an input signal is strictly less than its previous value using the Detect Decrease block. When the current input to the Detect Decrease block is less than its previous value, the block outputs one (true). When the current input is greater than or equal to the previous signal value, the Detect Decrease block outputs zero (false).

Detect Decrease | Scope | Sine Wave

## Function-Call Blocks Connected to Branches of the Same Function-Call Signal

In this model, a Function-Call Feedback Latch block is on the feedback signal between the branched blocks. As a result, the latch block delays the signal at the input of the destination function-call block, and the destination function-call block executes prior to the source function-call block of the latch block.

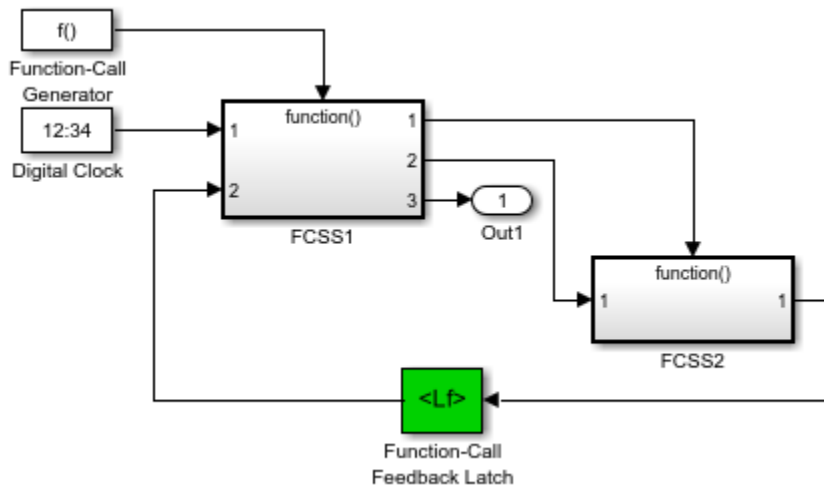

### See Also

Function-Call Feedback Latch | Function-Call Generator | Function-Call Subsystem | Function-Call Split

## Function-Call Feedback Latch on Feedback Signal Between Child and Parent

In this model, the Function-Call Feedback Latch block is on the feedback signal between the child and the parent. This arrangement prevents the signal value, read by the parent (FCSS1), from changing during execution of the child. In other words, the parent reads the value from the previous execution of the child (FCSS2).

### See Also

## Partitioning an Input Signal with the For Each Block

The following model demonstrates the partitioning of an input signal by a For Each block. Each row of this 2-by-3 input array contains three integers that represent the (x, y, z)-coordinates of a point. The goal is to translate each of these points based on a new origin at (-20, -10, -5) and to display the results.

By placing the process of summing an input signal and the new origin inside of a For Each Subsystem block, you can operate on each set of coordinates by partitioning the input signal into two row vectors. To accomplish such partitioning, use the default settings of 1 for both the partition dimension and the partition width. If you also use the default concatenation dimension of 1, each new set of coordinates stacks in the d1 direction, making your display a 2-by-3 array.

### See Also

For Each | For Each Subsystem

## Specifying the Concatenation Dimension in the For Each Block

This example shows how to specify a concatenation dimension in the For Each block. When you specify a **Concatenation Dimension** of 2 on the **Output Concatenation** tab, each set of results stacks in the d2 direction, and the result is a single row vector.

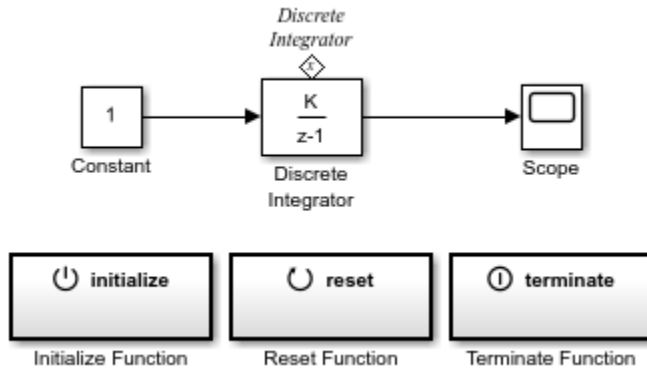

To learn how the For Each block and subsystem handle a model with states, see the For Each Subsystem block reference page.

## PWM Control of a Boost Converter

This example shows you how to control a boost converter using the PWM block in Simulink. The boost converter is implemented using the Boost Converter (Simscape Electrical) block in the Simscape™ Electrical™ library.

A PWM signal is used to control the switching device, or gate, of the boost converter. The command signal, or duty cycle, is generated from the PID controller to track the desired step-up voltage ( $V_{ref}$ ) of 18V

This is a relatively high frequency application; the switching gate operates at around 200kHz. Therefore, a pulse period of  $1/200,000$  or  $5e-6s$  is chosen for the PWM signal.

Given the small time steps, the `boostconverter_pwm` model provided with the example is loaded from a steady state at 0.069s.

A visualization of the boost converter operation around the 0.1s mark is shown below.

For alternate physical modeling implementations of PWM control, see “Pulse Width Modulation” (Simscape Electrical).

## Voltage Controlled Oscillator

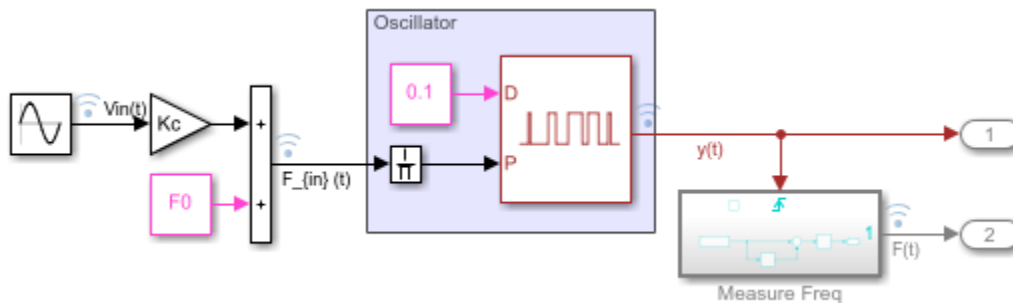

This example shows you how to model an ideal voltage controlled oscillator using the Variable Pulse Generator block to create the frequency oscillations.

A voltage controlled oscillator uses an input tuning voltage to produce waveforms of varying frequency. Over a small range of voltages, the relationship between the input voltage ( $V_{in}$ ) and the output oscillation frequency ( $F$ ) is proportional and can be expressed as

$$F(t) = K_c \cdot V_{in}(t) + F_0(1)$$

where

- $K_c$  is the oscillator sensitivity in Hz/V
- $f_0$  is the quiescent frequency, or nominal frequency of the oscillator at  $V_{in} = 0$

In the included `vco_using_vpg` model, the desired oscillation frequency signal  $F_{in}(t)$  is generated using the formula shown in equation (1). In this model, the tuning voltage  $V_{in}$  is a sinusoidal waveform.

Nominal Frequency  $f_0 = 42$  Hz

Oscillator Gain  $K_c = 3$

## Check Signal Lower Bound with Check Dynamic Lower Bound Block

Using the Check Dynamic Lower Bound block, you can check if an input signal falls below a changing lower bound during a simulation.

In this example, the Check Dynamic Lower Bound block compares the value of a tested input signal from a Step block at the **u** port to a Sine Wave block at the **min** port. The Check Dynamic Lower Bound block checks if the value of the signal at the **min** port is less than the value of the tested input signal. If it is, the block asserts `true (1)`. Because the **Output assertion signal** parameter of the Check Dynamic Lower Bound block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

At the start of the simulation, the Check Dynamic Lower Bound block outputs 0 because the value of the Sine Wave block is greater than the value of the Step block. At a time of 3.14, the sine wave dips below 0, causing the value of the Step block to exceed the sine wave. The Check Dynamic Lower Bound block recognizes this change and outputs 1.

At a time of 5, the Step block outputs a value of 0.5, which is still greater than the sine wave. The Step block value stays greater than the sine wave until the time reaches 6.81. The Check Dynamic Lower Bound block recognizes this change and the assertion fails. The assertion stays at 0 until the time reaches 8.90, where the sine wave goes below the value of the Step block.

## See Also

Assertion | Check Dynamic Lower Bound

## Check Signal Upper Bound with Check Dynamic Upper Bound Block

Using the Check Dynamic Upper Bound block, you can check if an input signal rises above a changing upper bound during a simulation.

Copyright 2018 The MathWorks, Inc.

In this example, the Check Dynamic Upper Bound block compares the value of a tested input signal from a Step block at the **u** port to a Sine Wave block at the **max** port. The Check Dynamic Upper Bound block checks if the value of the signal at the **max** port is greater than the value of the tested input signal. If it is, the block asserts `true` (1). Because the **Output assertion signal** parameter of the Check Dynamic Upper Bound block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

At the start of the simulation, the Check Dynamic Upper Bound block outputs 1 because the value of the Sine Wave block is greater than the value of the Step block. At a time of 3.14, the sine wave dips below 0, causing the value of the Step block to exceed the sine wave. The Check Dynamic Upper Bound block recognizes this change and outputs 0.

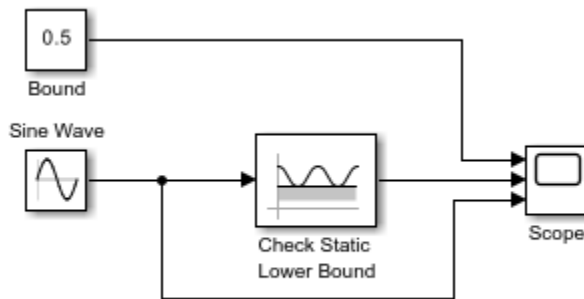

At a time of 5, the Step block outputs a value of 0.5, which is still greater than the sine wave. The Step block value stays greater than the sine wave until the time reaches 6.81. The Check Dynamic Upper Bound block recognizes this change and the assertion passes. The output stays at 1 until the time reaches 8.90, where the sine wave goes below the value of the Step block.

## See Also

Assertion | Check Dynamic Upper Bound

## Check Signal Lower Bound with Check Static Lower Bound Block

Using the Check Static Lower Bound block, you can check if an input signal falls below a defined value.

Copyright 2018 The MathWorks, Inc.

In this example, the Check Static Lower Bound block compares the value of a Sine Wave block to the value entered in the **Lower bound** parameter, which is 0.5. The Constant block, labeled Bound, illustrates this parameter in the Scope block but does not affect the parameter value. The Check Static Lower Bound block checks if the value of the input signal is greater than the **Lower bound**. If it is, the block asserts `true` (1). Because the **Output assertion signal** parameter of the block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

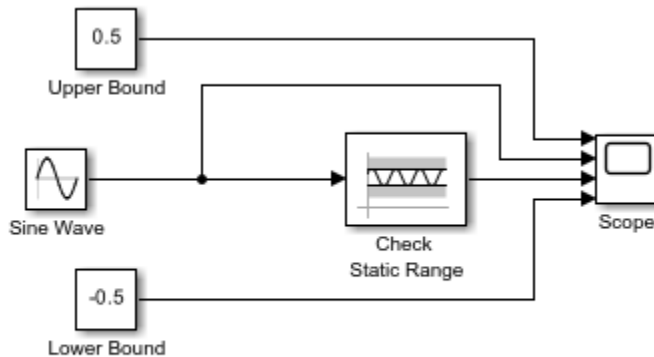

At the start of the simulation, the Check Static Lower Bound block outputs 0 because the value of the Sine Wave block is less than the bound. At a time of 0.52, the sine wave exceeds 0.5. The Check Static Lower Bound block recognizes this change and outputs 1. When the time reaches 2.62, the sine wave falls below the bound and the assertion is false. This pattern repeats until the simulation end time.

## See Also

Assertion | Check Static Lower Bound

## Check Signal Range with Check Static Range Block

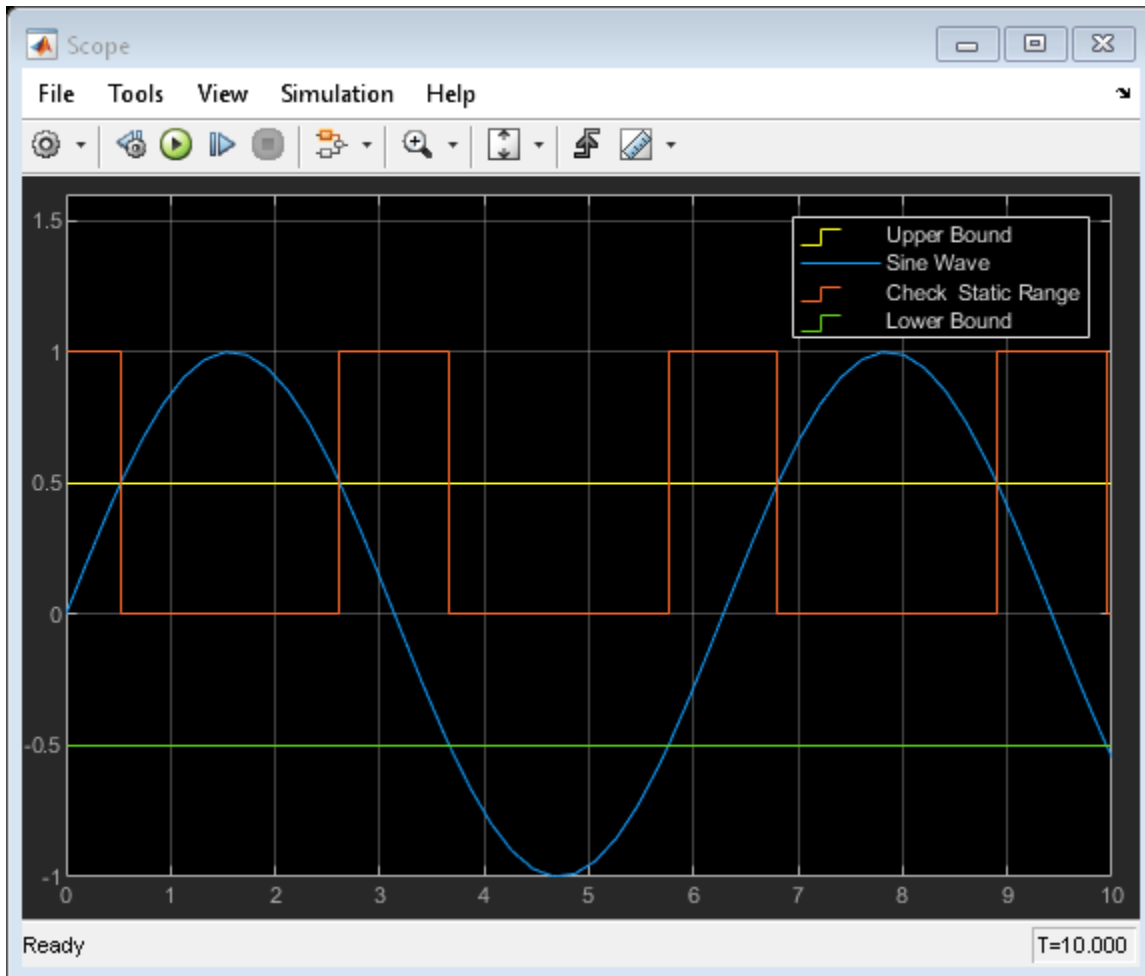

Using the Check Static Range block, you can check if an input signal falls outside of an unchanging range of values.

Copyright 2018 The MathWorks, Inc.

In this example, the Check Static Range block compares the value of a Sine Wave block to the values entered in the **Upper bound** and **Lower bound** parameters, which are 0.5 and -0.5. The Constant blocks, labeled Upper Bound and Lower Bound, illustrate these parameters in the Scope block but do not affect the parameter values. The Check Static Range block checks if the value of the input signal is greater than the **Lower bound** value or less than the **Upper bound** value. If it is, the block asserts `true` (1). Because the **Output assertion signal** parameter of the block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

At the start of the simulation, the Check Static Range block outputs 1 because the value of the Sine Wave block is less than the **Upper bound** value. At a time of 0.52, the sine wave exceeds 0.5. The Check Static Range block recognizes this change and outputs 0. When the time reaches 2.62, the sine wave falls below the **Upper bound** value and the assertion is true. When the time reaches 3.67, the sine wave falls below the **Lower bound** value. The Check Static Range block recognizes this change and outputs 0. The output stays at 0 until the time is 5.76, when the sine wave then exceeds the **Lower bound** value. This pattern repeats until the simulation end time.

## See Also

Assertion | Check Static Range

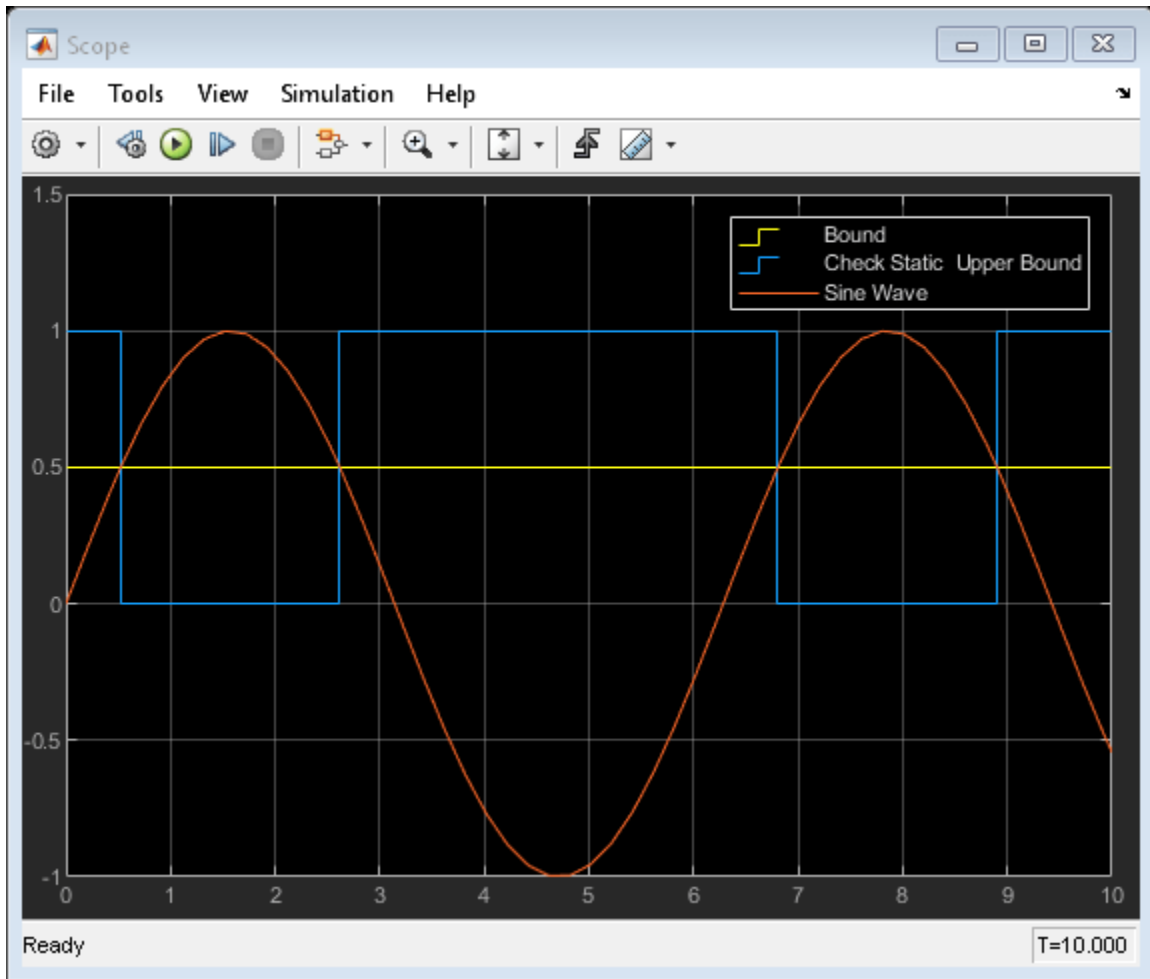

## Check Signal Upper Bound with Check Static Upper Bound Block

Using the Check Static Upper Bound block, you can check if an input signal exceeds a defined value.

Copyright 2018 The MathWorks, Inc.

In this example, the Check Static Upper Bound block compares the value of a Sine Wave block to the value entered in the **Upper bound** parameter, which is 0.5. The Constant block, labeled Bound, illustrates this parameter in the Scope block but does not affect the parameter value. The Check Static Upper Bound block checks if the value of the input signal is less than the **Upper bound**. If it is, the block asserts `true (1)`. Because the **Output assertion signal** parameter of the block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

At the start of the simulation, the Check Static Upper Bound block outputs 1 because the value of the Sine Wave block is less than the bound. At a time of 0.52, the sine wave exceeds 0.5. The Check Static Upper Bound block recognizes this change and outputs 0. When the time reaches 2.62, the sine wave falls below the bound and the assertion is true. This pattern repeats until the simulation end time.

Assertion | Check Static Upper Bound

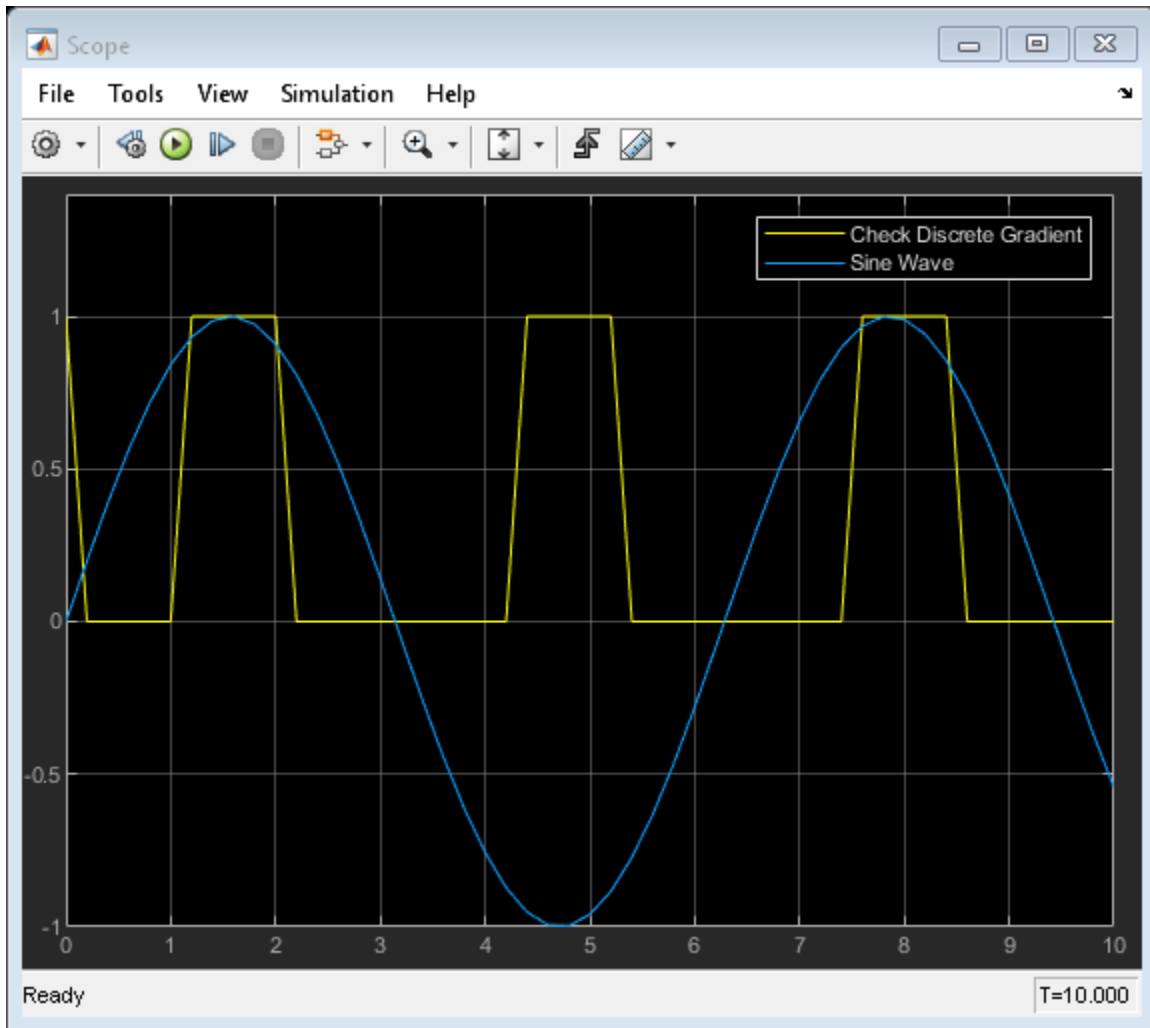

## Check Signal Slope with Check Discrete Gradient Block

Using the Check Discrete Gradient block, you can check if the absolute value of the difference between successive samples of a signal is less than a defined value.

Copyright 2018, The MathWorks, Inc.

In this example, the Check Discrete Gradient block compares the value of an input signal from a Sine Wave block to the **Maximum gradient** parameter value, which is  $0.1$ . If the absolute value of the difference between successive samples of the signal is less than  $0.1$ , the block asserts `true (1)`. Because the **Output assertion signal** parameter of the block is selected, the block outputs the assertion value. The block requires a fixed-step discrete solver, which has been selected in the model. Run the simulation to observe the model output.

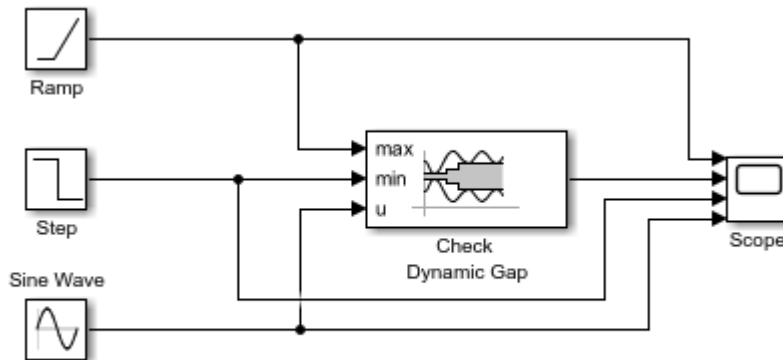

The block asserts `true` when the sine wave is near a maximum or minimum. In these sections of the signal, the absolute value of the gradient is less than the **Maximum gradient** value `0.1`. This pattern repeats until the simulation end time.

Assertion | Check Discrete Gradient

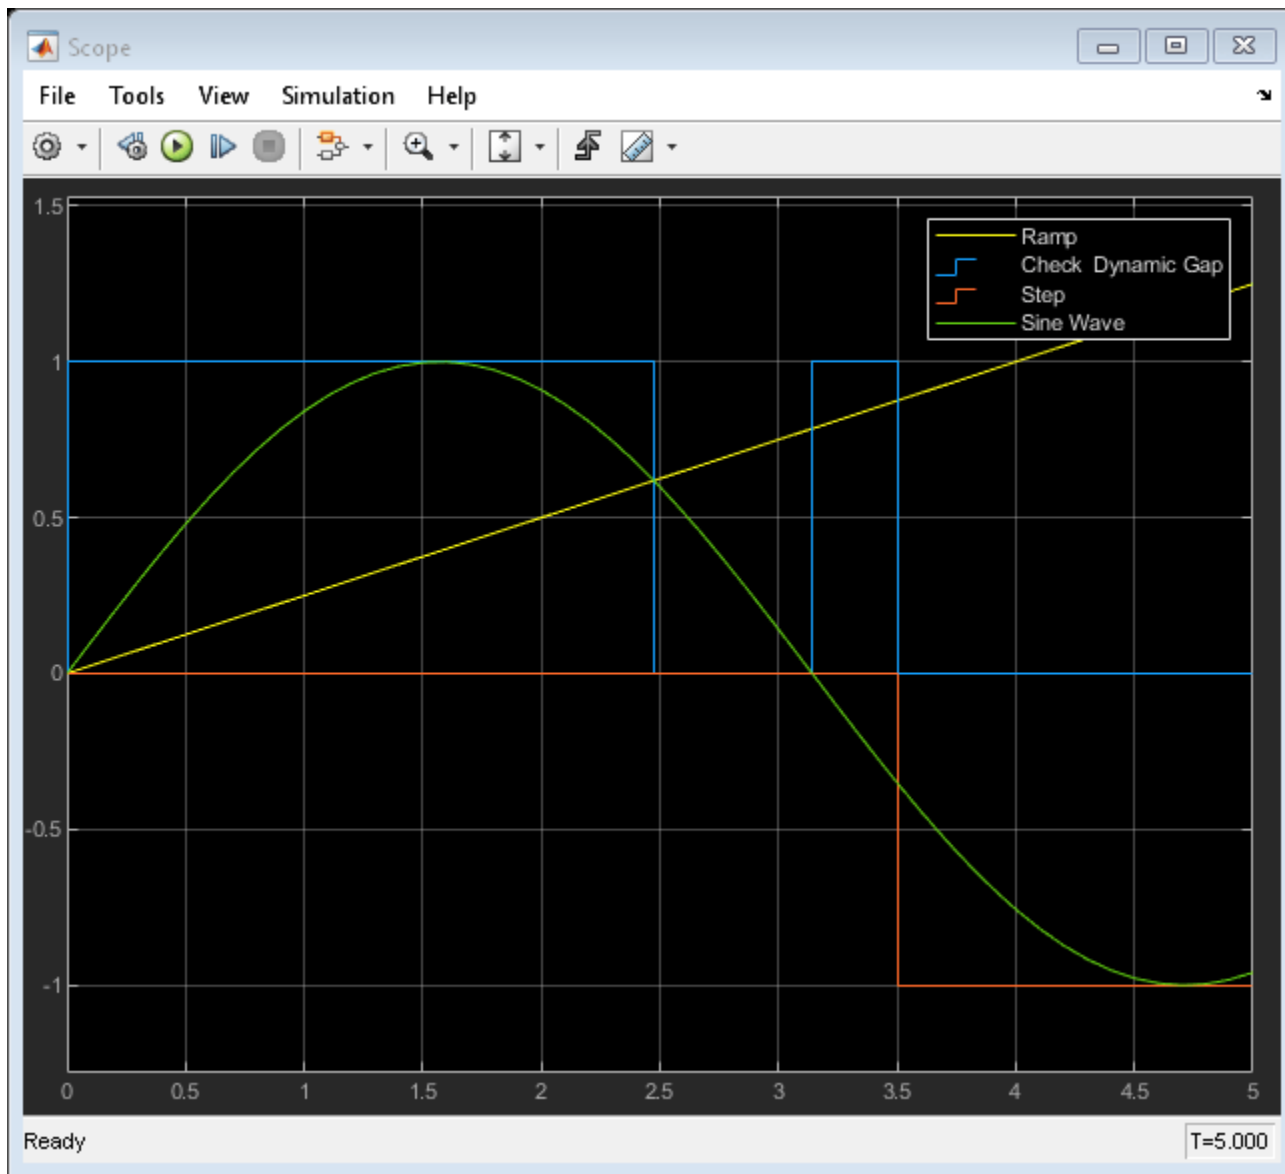

## Check Signal Value with Check Dynamic Gap Block

This example shows how to check if an input signal falls inside a dynamic upper and lower bound using the Check Dynamic Gap block. In this example, the Check Dynamic Gap block compares the value of a tested input signal from a Sine Wave block at the **u** port to a Ramp block at the **max** port and a Step block at the **min** port.

Copyright 2018, The MathWorks, Inc.

The Check Dynamic Gap block checks if the value of the signal at the **max** port is less than the value of the test signal, and if the value of the signal at the **min** port is greater than the value of the test signal. If it is, the block asserts `true (1)`. Because the **Output assertion signal** parameter of the Check Dynamic Gap block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

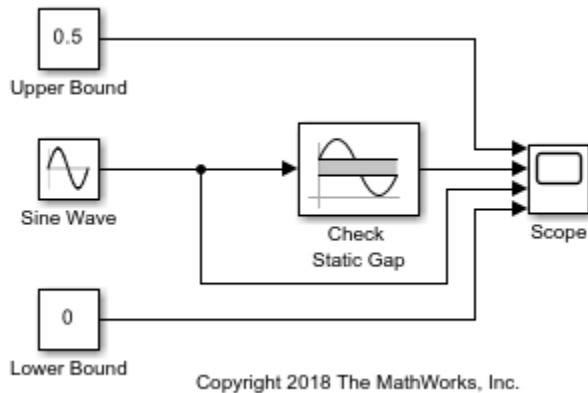

At the start of the simulation, the Check Dynamic Gap block output is 1. The output stays at 1 until the simulation time is 2.47, when the sine wave falls below the value of the Ramp block. The block output stays at 0 until the simulation time reaches 3.14, when the sine wave falls below the value of the Step block. The Step block activates when the simulation time reaches 3.5, placing the sine wave between the bounds. The Check Dynamic Gap block recognizes this change and sets the output to 0.

## See Also

Assertion | Check Dynamic Gap

## Check Signal Value with Check Static Gap Block

Using the Check Static Gap block, you can check if an input signal enters an unchanging gap of values.

In this example, the Check Static Gap block compares the value of a Sine Wave block to the values entered in the **Upper bound** and **Lower bound** parameters, which are 0.5 and 0. The Constant blocks, labeled Upper Bound and Lower Bound, illustrate these parameters in the Scope block but do not affect the parameter values. The Check Static Gap block checks if the value of the input signal is less than the **Lower bound** value or greater than the **Upper bound** value. If it is, the block asserts `true (1)`. Because the **Output assertion signal** parameter of the block is selected, the block outputs the assertion value. Run the simulation to observe the model output.

At the start of the simulation, the Check Static Gap block outputs 0 because the value of the Sine Wave block is less than the **Upper bound** value. At a time of 0.52, the sine wave exceeds 0.5. The Check Static Gap block recognizes this change and outputs 1. When the time reaches 2.62, the sine wave falls below the **Upper bound** value and the assertion is false. When the time reaches 3.14, the sine wave falls below the **Lower bound** value. The Check Static Gap block recognizes this change and outputs 1. The output stays at 1 until the time is 6.28, when the sine wave then exceeds the **Lower bound** value. This pattern repeats until the simulation end time.

Assertion | Check Static Gap

## Check Signal Range with Check Dynamic Range Block

You can check if an input signal falls outside of a dynamic upper and lower bound by using the Check Dynamic Range block.

Copyright 2020 The MathWorks, Inc.

This model uses a Sine Wave block as a dynamic test signal. The Check Dynamic Range block determines if the value of the sine wave exceeds the signal from the Ramp block or falls below the signal from the Step block at each time step. In the Check Dynamic Range block, the **Output assertion signal** parameter is selected, so the output signal indicates if the assertion condition is true (1) or false (0). Press **Run** to observe the model output.

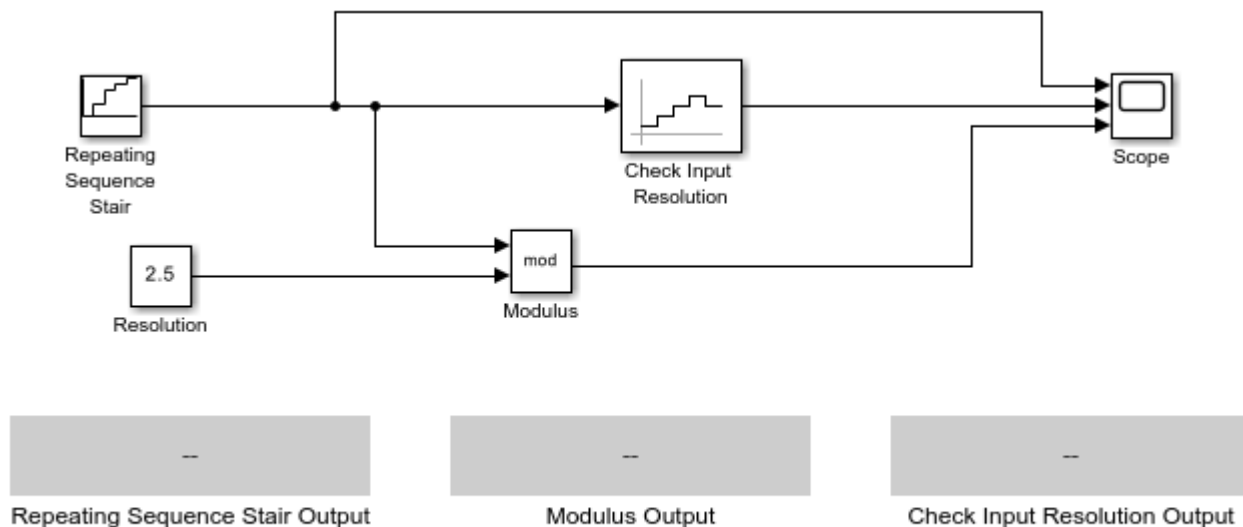

In the Scope block, you can see that the Check Dynamic Range block outputs 0 until the sine wave falls below the value of the Ramp block when the simulation time is 2.47. The block output stays at 1 until the simulation time reaches 3.14, when the sine wave falls below the value of the Step block. The Step block activates when the simulation time reaches 3.5, placing the sine wave between the bounds. The Check Dynamic Range block recognizes this change and outputs 1.

## See Also

Assertion | Check Dynamic Range

## Check Signal Resolution with Check Input Resolution Block

You can use a Check Input Resolution block to check when a signal has a specified resolution. The block can help verify if a signal is quantized within specification, such as when checking the output of an analog-to-digital converter.

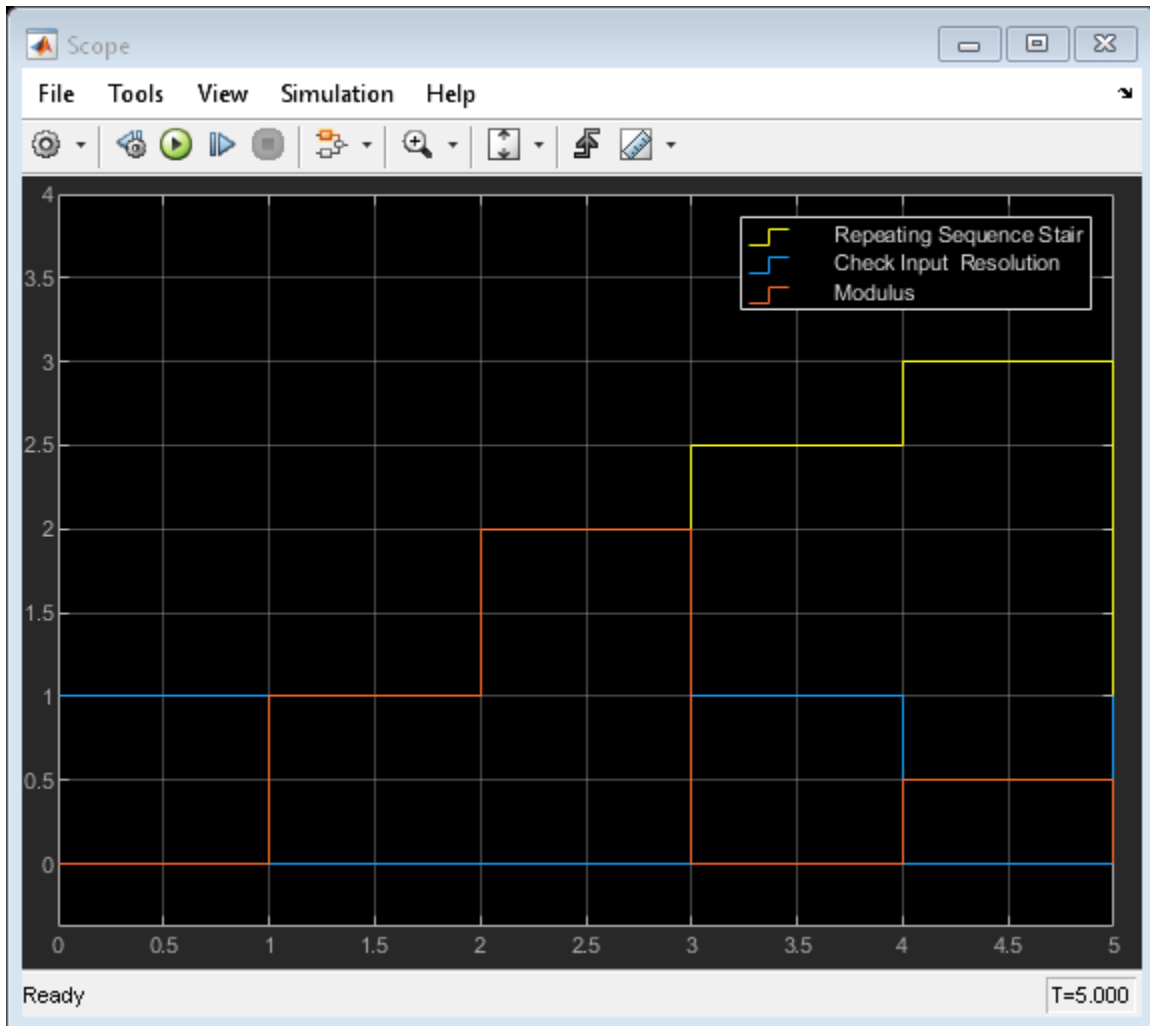

Copyright 2020 The MathWorks, Inc.

In this example, a Repeating Sequence Stair block outputs the values [0 1 2 2.5 3] in sequence starting at 0. During simulation, the block outputs each value in the vector for a time of 1.

First, the Check Input Resolution block calculates a modulus by calculating the remainder of the input value over the value of the **Resolution** parameter, which is set to 2.5. To illustrate this calculation, this example also uses a Math Function block, labeled Modulus, with the **Function** parameter set to `mod`. The Modulus block takes the value of the Repeating Sequence Stair block over the value of a Constant block, labeled Resolution, which has the same value as the **Resolution** parameter.

Then the Check Input Resolution block checks if the modulus is smaller than a tolerance of 0.01. If it is, the block asserts `true` (1). Because the **Output assertion signal** parameter of the Check Input Resolution Block is selected, the block outputs the assertion value. Run the simulation to observe the model output, or use the **Step Forward** button to step through each step.

When you run the model, the Scope block plots the Repeating Sequence Stair block output, the Modulus block output, and the Check Input Resolution block output. If you use the **Step Forward** button, the data populates the three Display blocks at each time step.

- 1 Initially, the modulus of the Repeating Sequence Stair block over the resolution is 0, so the Check Input Resolution block outputs 1.
- 2 When the simulation time reaches 1, the Repeating Sequence Stair block outputs 1. The modulus rises to 1, which is larger than the tolerance, causing the Check Input Resolution block to output 0.
- 3 The assertion stays at 0 until the time is 3, when the Repeating Sequence Stair block outputs 2.5. The modulus drops to 0, and the assertion returns to 1.
- 4 Finally, the Repeating Sequence Stair block outputs 3 when the time is 4, which causes the assertion to be 1.

The model repeats this pattern until the simulation end time.

## Generate Unit-Diagonal and Identity Matrices

This example shows how to generate a 3-by-6 unit-diagonal matrix and a 5-by-5 identity matrix using the Identity Matrix block.

Copyright 2018-2021 The MathWorks, Inc.

**See Also**  
Identity Matrix

## Extract 3-by-2 Submatrix from Input Signal

This example shows how to use the Submatrix block to extract a 3-by-2 submatrix from the lower-right corner of a 5-by-7 input matrix. The following figure illustrates the operation of the Submatrix block with a 5-by-7 input matrix of random integer elements, `randi([0 9],5,7)`.

Here are the settings used for the Submatrix block in this example.

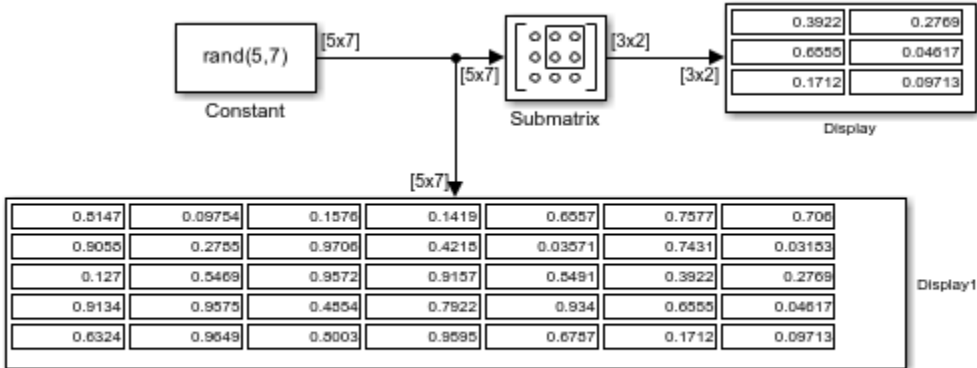

There are often several possible parameter combinations that you can use to select the same submatrix from the input. For example, in the case of a 5-by-7 input matrix, instead of specifying Last for **Ending column**, you could select the same submatrix by specifying:

- **Ending column** = Index
- **Ending column index** = 7

Open and simulate the model. You can see that the 3-by-2 submatrix from the lower-right corner of a 5-by-7 input matrix has been extracted.

Copyright 2018-2021 The MathWorks, Inc.

## Generate Diagonal Matrix from Vector Input

This example shows how to use the Create Diagonal Matrix block.

Open the Simulink model.

Copyright 2019-2021 The MathWorks, Inc.

The **Create Diagonal Matrix** block creates a diagonal matrix from the input values. The output matrix in the model has the input vector as its diagonal.

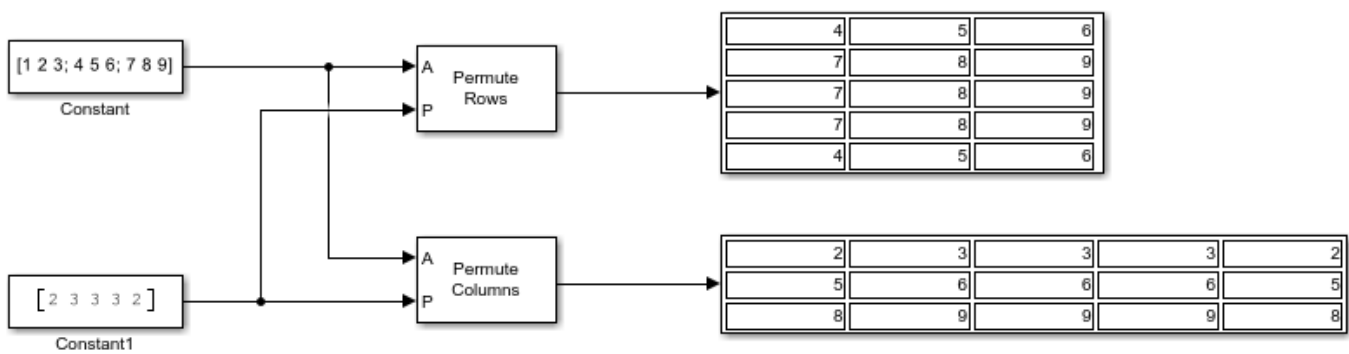

Run the model to verify the output.

## Permute Matrix by Row or Column

This example shows how to use the Permute Block to permute blocks by row or column.

In the model, the top Permute Matrix block places the second row of the input matrix in the first and fifth rows of the output matrix. The block places the third row of the input matrix in the three middle rows of the output matrix. The bottom Permute Matrix block places the second column of the input matrix in the first and fifth columns of the output matrix. It places the third column of the input matrix in the three middle columns of the output matrix.

Rows and columns of A can appear any number of times in the output, or not at all depending on the index vector.

Copyright 2019-2021 The MathWorks, Inc.

## Extract Diagonal of Matrix

This example shows how to use the Extract Diagonal block.

Open the Simulink model.

Copyright 2019-2021 The MathWorks, Inc.

The **Extract Diagonal** block returns the main diagonal of the input matrix. The main diagonal of the input matrix is [1,5,9].

Run the model to verify.

## Calculate Optical Flow by Using Neighborhood Processing Subsystem Blocks

This example shows how to calculate optical flow in a video by using Neighborhood Processing Subsystem blocks. Optical flow is the distribution of the apparent velocities of objects in an image. Use optical flow to identify and track objects in a video.

### Inspect Model

Open the model.

```
model = 'OpticalFlowNeighborhoodExample';
open_system(model);
```

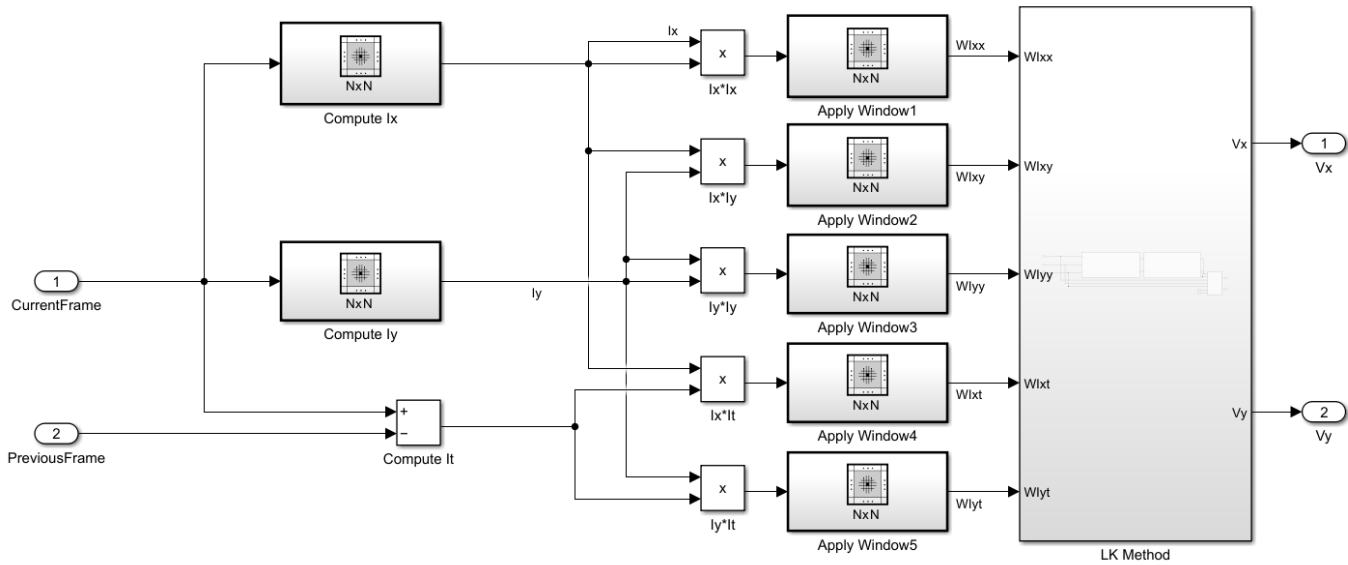

### Optical Flow using the Neighborhood Processing Subsystem

Copyright 2022 The MathWorks, Inc.

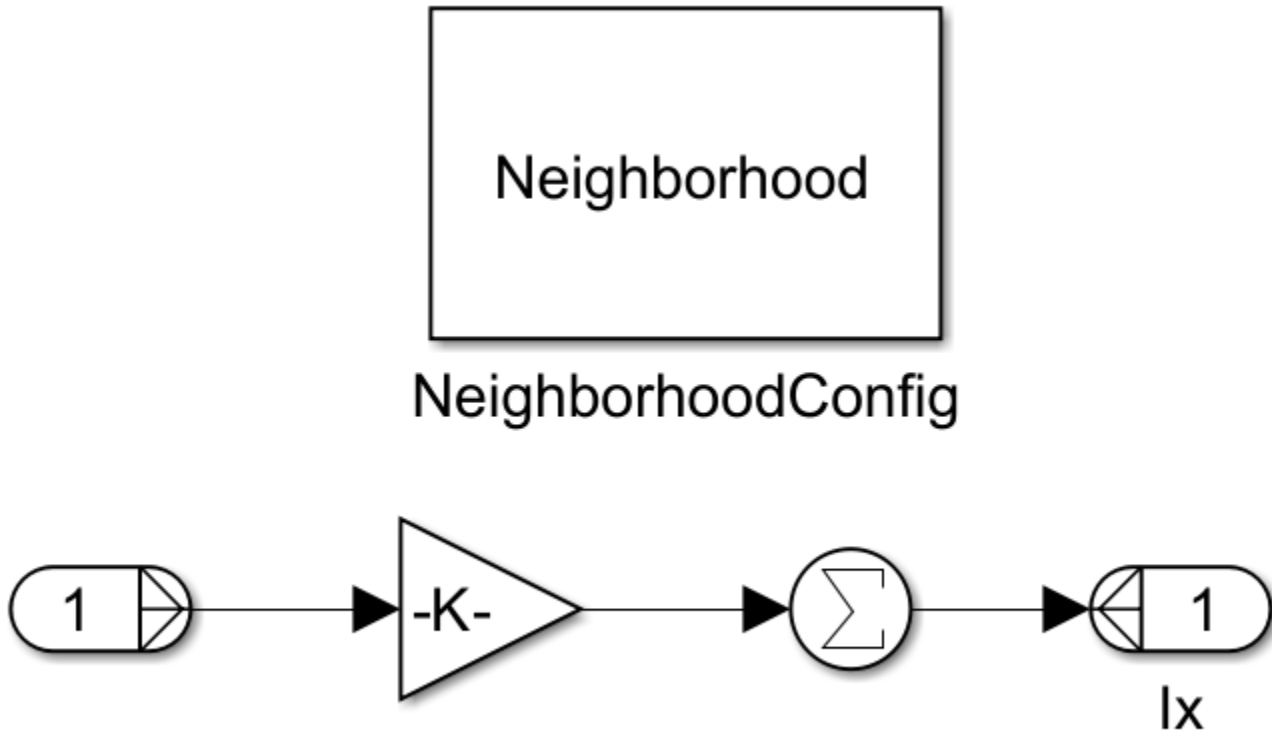

The model references a video input, `rhinos.avi`, by using the From Multimedia File block from Computer Vision Toolbox. At each iteration, the model passes the current and previous frames of the video to the DUT subsystem, which performs the optical flow calculation. This calculation outputs an optical flow matrix which represents the apparent motion at each pixel of the video. The model overlays these calculated motion vectors over the input video.

Open the DUT subsystem.

This example calculates optical flow by using the Lucas-Kanade method. The Lucas-Kanade method requires the values  $I_x$ ,  $I_y$ , and  $I_t$ , which are the derivatives of pixel brightness along the horizontal direction, vertical direction, and time, respectively.

The Compute  $I_x$  Neighborhood Processing Subsystem calculates  $I_x$  by using a 1-by-5 neighborhood and these blocks. The Neighborhood control block NeighborhoodConfig specifies the neighborhood size using its **Neighborhood size** parameter.

The Compute  $I_y$  subsystem calculates  $I_y$  with the same blocks and a 5-by-1 neighborhood. The model calculates  $I_t$  as the difference between the current video frame and previous video frame by using a Sum block.

The horizontal optical flow  $u$  and vertical optical flow  $v$  represent the solution to this equation.

$$I_x u + I_y v + I_t = 0$$

To solve this equation, the Lucas-Kanade method divides the input image into smaller sections and assumes a constant velocity in each section. Then it performs a weighted, least-square fit of the optical flow constraint equation to a constant model for  $[u \ v]^T$  in each section  $\Omega$ . The method achieves this fit by minimizing this equation, where  $W$  is a window function that emphasizes the constraints at the center of each section:

$$\sum_{x \in \Omega} W^2 [I_x u + I_y v + I_t]^2$$

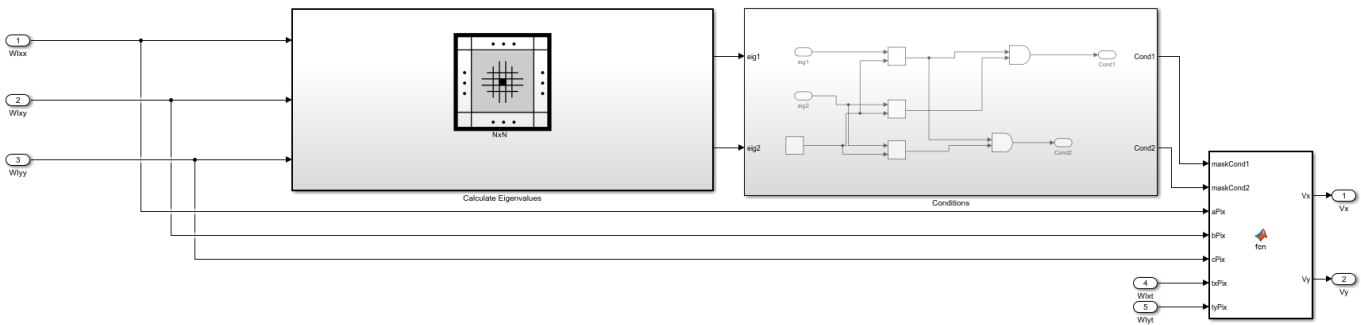

The solution to the minimization problem is:

$$\begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_x I_y & \sum W^2 I_y^2 \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} = - \begin{bmatrix} \sum W^2 I_x I_t \\ \sum W^2 I_y I_t \end{bmatrix}$$

The example calculates  $I_x^2$ ,  $I_x I_y$ ,  $I_y^2$ ,  $I_x I_t$ , and  $I_y I_t$  by using Product blocks. The example implements  $W$  by using Neighborhood Processing Subsystem blocks with 5-by-5 neighborhoods.

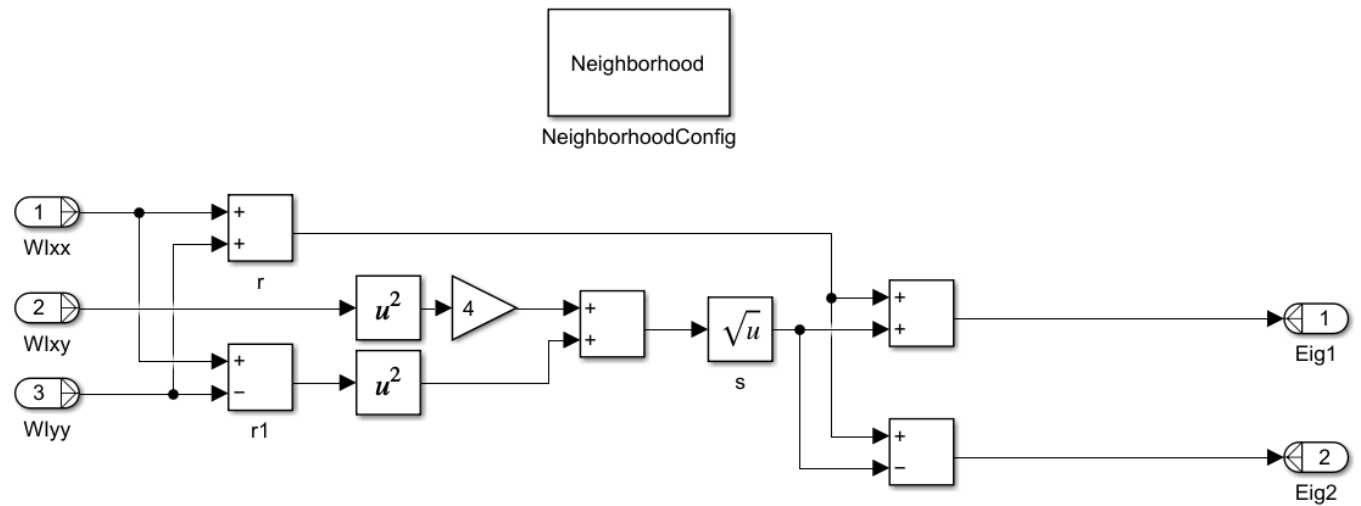

Open the LK Method subsystem.

The Calculate Eigenvalues Neighborhood Processing Subsystem calculates the eigenvalues of

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} \sum W^2 I_x^2 & \sum W^2 I_x I_y \\ \sum W^2 I_x I_y & \sum W^2 I_y^2 \end{bmatrix} \text{ by solving the equation } \lambda_i = \frac{a+c}{2} \pm \frac{\sqrt{4b^2 + (a+c)^2}}{2}; i = 1, 2.$$

The example implements the rest of the Lucas-Kanade method by using the Conditions subsystem and a MATLAB Function block. For information about these calculations, see opticalFlowLK (Computer Vision Toolbox).

## Simulation and Results

Simulate the model.

```
evalc(model);
```

The model displays the input video with vectors overlaid, representing the optical flow.

# Perform Fog Rectification by Using Neighborhood Processing Subsystem Blocks

This example shows how to remove fog from images captured under foggy conditions. Such images have low visibility and poor contrast, which leads to poor vision algorithm performance. Fog rectification is an important step for applications in autonomous driving and object recognition because it improves input image quality.

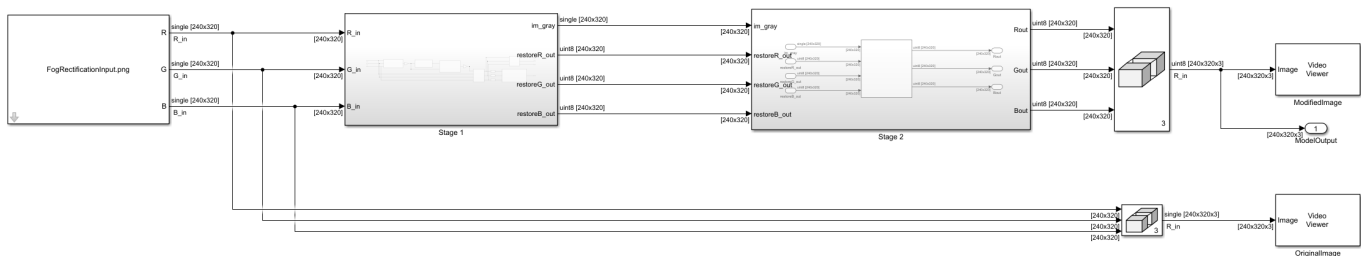

For more information about fog rectification algorithms, see “Fog Rectification” (Vision HDL Toolbox).

## Inspect Model

Open the model.

```
mdl = "FogRectificationNeighborhoodExample";
open_system(mdl);
```

Fog Rectification using the Neighborhood Processing Subsystem

Copyright 2022 The MathWorks, Inc.

The model references an input image and passes the red, blue, and green channels of that image to the Stage 1 subsystem, which performs fog removal. This process estimates the amount of fog in each pixel and creates an image with the fog removed. This image has a reduced range of intensity for each color channel, so the Stage 2 subsystem performs contrast enhancement to stretch the dynamic range of the image and improve the contrast between features of the image. The result is a defogged image with high contrast.

## Inspect Fog Removal

Open the Stage 1 subsystem, which performs fog removal in these steps.

**1. Dark Channel Estimation** — The pixels that represent the non-sky region of an image have low intensities in at least one color component. These low intensities form a *dark channel*. In a

normalized, fog-free image, the intensity of dark channel pixels is nearly zero. In a foggy image, the fog causes the intensity of dark channel pixels to be relatively high. The Dark Channel Estimation subsystem estimates the dark channel  $I_{\text{dark}}^c(x, y)$  by finding the pixel-wise minimum across all three components of the input image  $I^c(x, y)$  where  $c \in [r, g, b]$ .

The Dark Channel Estimation subsystem contains these blocks.

The Neighborhood Processing Subsystem uses a 1-by-1 neighborhood and calculates the minimum value across the color channels by using a Min block. This creates a two-dimensional dark channel output matrix consisting of the lowest channel intensity for each input image pixel.

**2. Airlight Map Calculation** — The white effect fog produces in an image is known as *airlight*. Airlight map calculation multiplies the dark channel by a value  $z$ , representing the amount of haze to remove.  $z$  is a value between 0 and 1; a higher value removes more fog in the final image.

$$I_{\text{air}}(x, y) = z \times \min_{c \in [r, g, b]} I_{\text{dark}}^c(x, y)$$

The model uses a Gain block with a  $z$  value of 0.9 for airlight map calculation.

**3. Airlight Map Refinement** — The Refine Dark Channel subsystem reduces visual noise in the image. The subsystem contains a sequence of three identical Neighborhood Processing Subsystem blocks.

### Anisotropic diffusion

Each Neighborhood Processing Subsystem implements anisotropic diffusion.

By repeating this process three times, the Refine Dark Channel subsystem reduces visual noise and strengthens the clarity of details in the image. This yields a refined image,  $I_{\text{refined}}(x, y)$ .

4. **Restoration** – This step counteracts over-smoothing from the previous step by implementing these equations.

$$I_{\text{reduced}}(x, y) = m \times \min(I_{\text{air}}(x, y), I_{\text{refined}}(x, y))$$

$$I_{\text{restored}}(x, y) = 255 \times \frac{I^c(x, y) - I_{\text{reduced}}(x, y)}{255 - I_{\text{reduced}}(x, y)}$$

The value  $m$  represents the mid-line of changing the dark regions of the airlight map from dark to bright values. This example uses an empirically derived value of  $m = 0.6$ .

The model uses a Min block inside a Neighborhood Processing Subsystem to derive the minimum between the airlight map and the refined image, then uses a Gain block to multiply that matrix by 0.6.

The MATLAB Function block subtracts the reduced airlight map from the original input image, then multiplies by the factor  $\frac{255}{255 - I_{\text{reduced}}(x, y)}$ . This yields  $I_{\text{restored}}(x, y)$ , which represents the defogged image.

**5. RGB to Grayscale Conversion** — The last Neighborhood Processing Subsystem in Stage 1, RGB to Grayscale, converts  $I_{\text{restored}}(x, y)$  to a grayscale image,  $I_{\text{gray}}(x, y)$ .

This grayscale image is necessary for the next stage of the model.

### Inspect Contrast Enhancement

The Stage 1 subsystem produces an image with the fog removed, but the output image has a limited dynamic range compared to the input image. The Stage 2 subsystem stretches the output image brightness values to span the dynamic range of the input image. This improves contrast between features of the output image.

Return to the root model and open the Stage 2 subsystem.

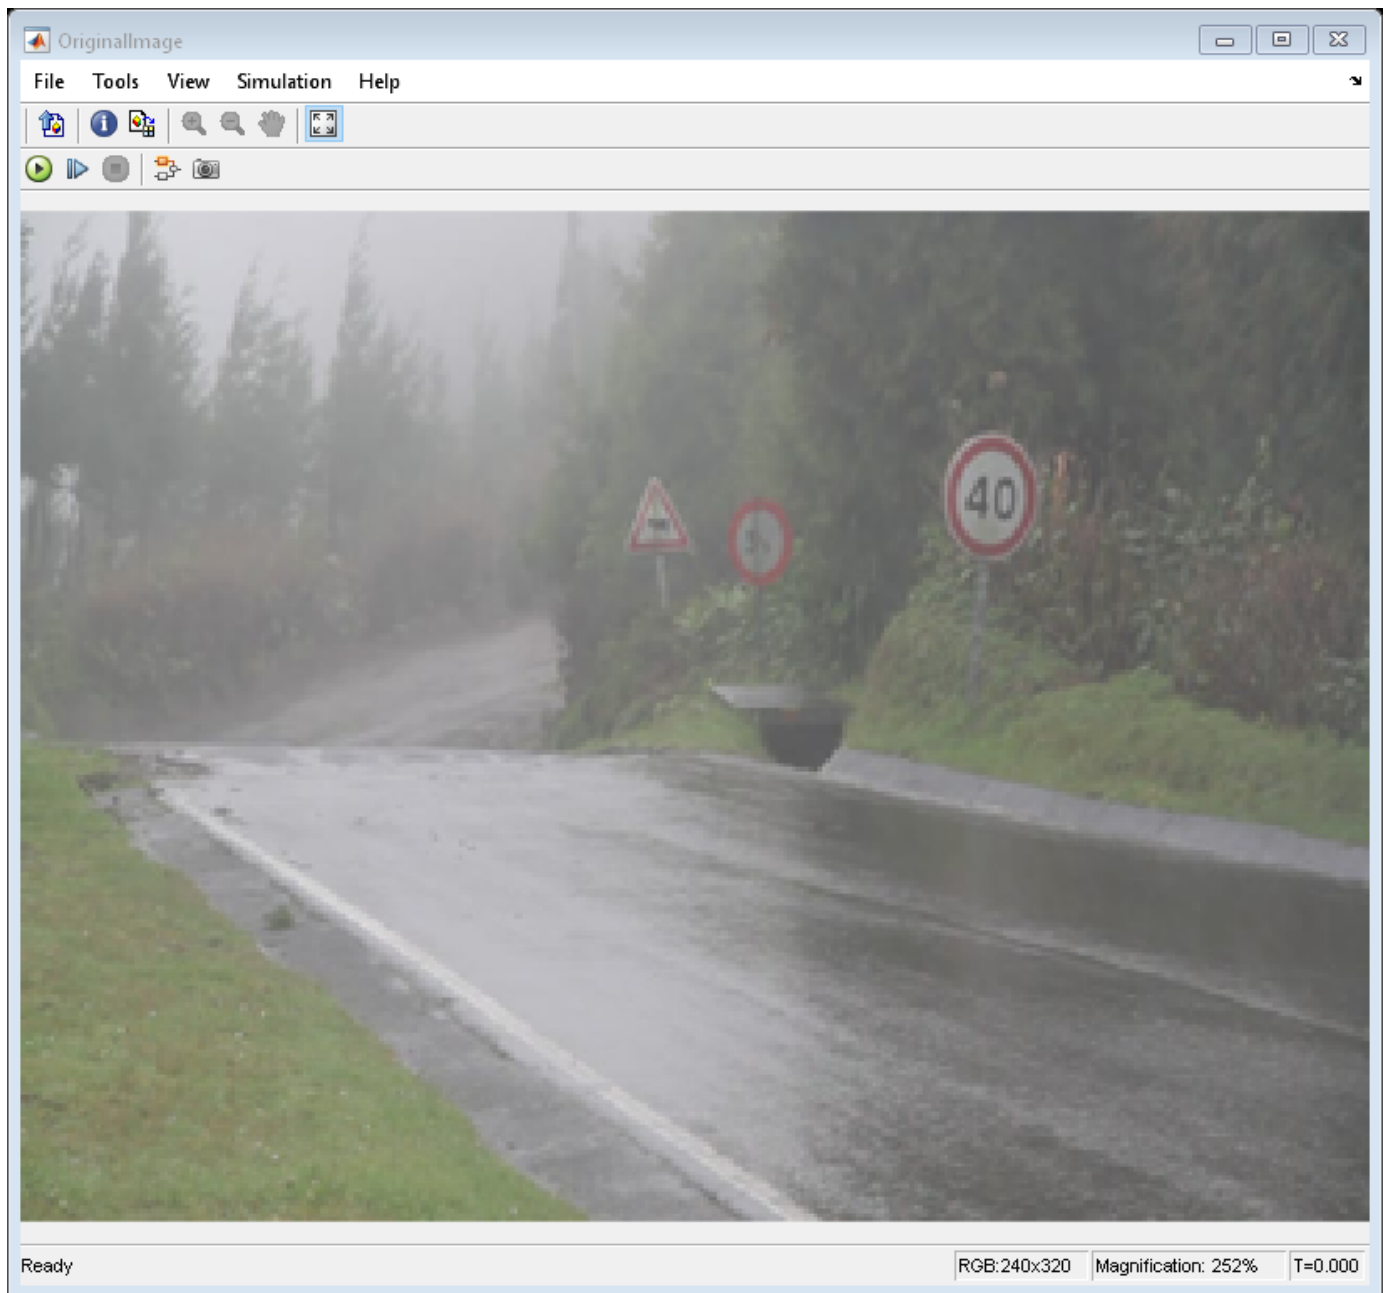

The subsystem uses a MATLAB Function block to perform contrast enhancement. For information about the calculations involved in this step, see “Fog Rectification” (Vision HDL Toolbox).

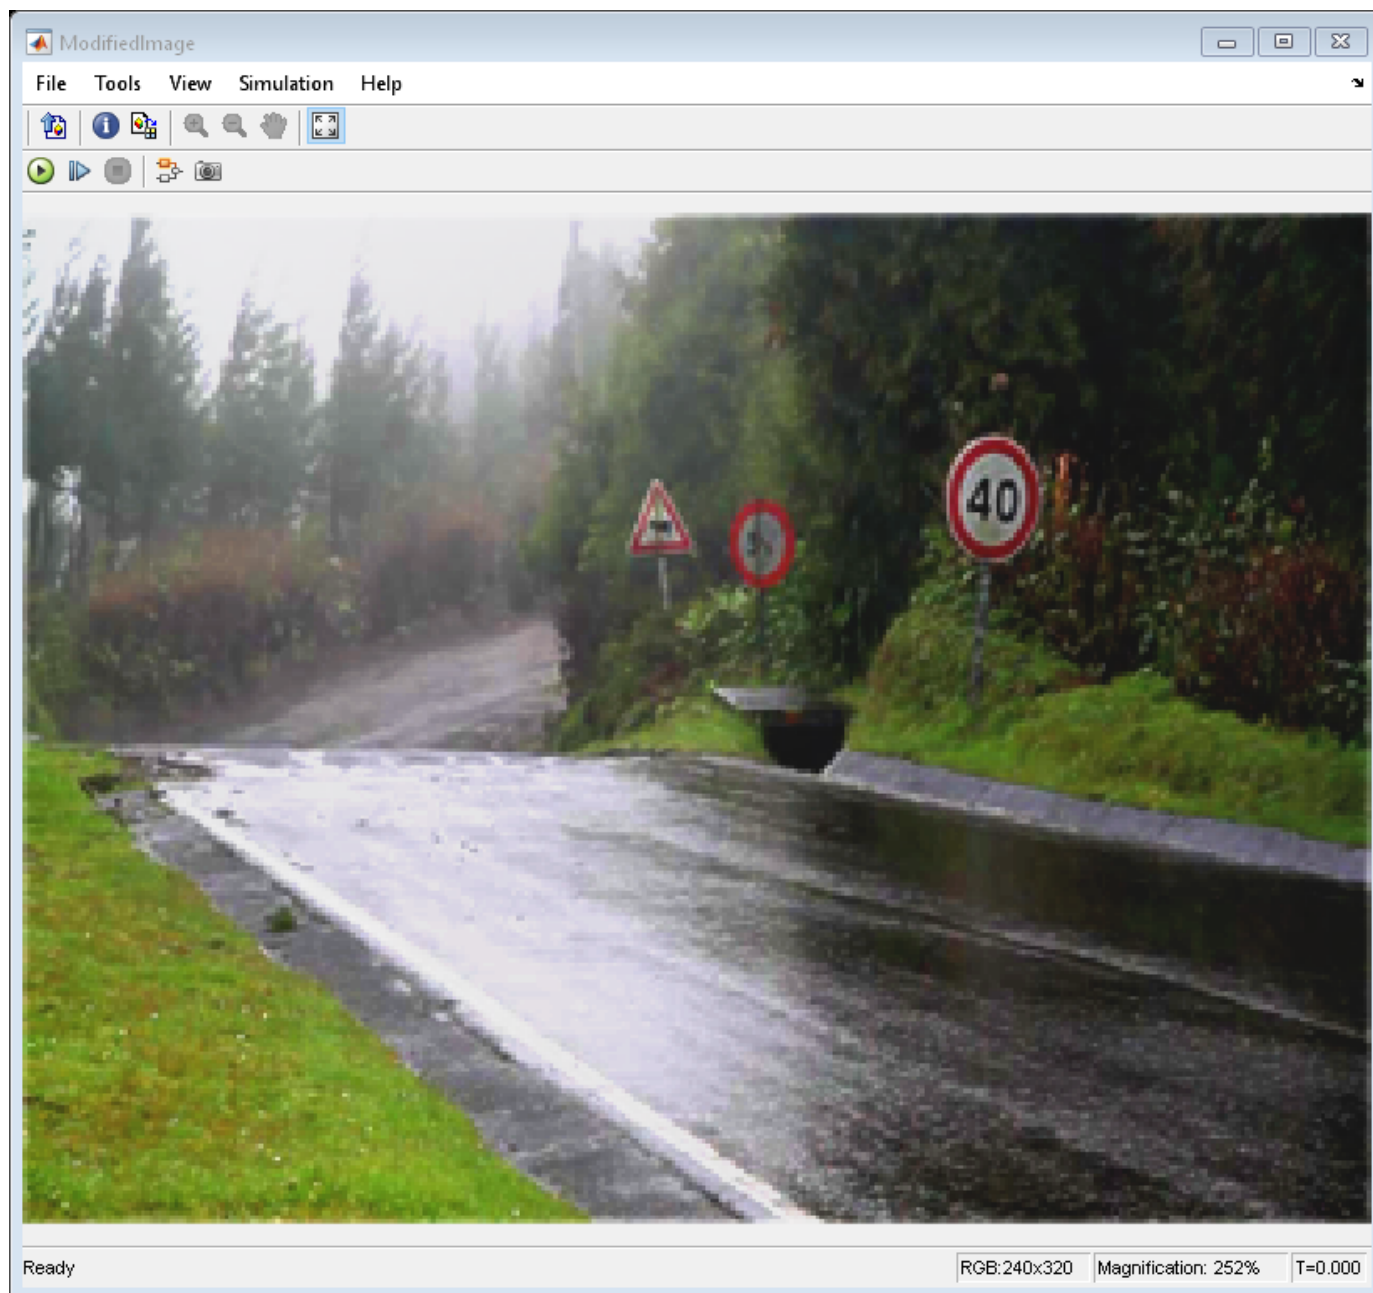

### Simulate Model

Simulate the model.

```
simout = sim mdl;
```

The model outputs the original image and the modified image. The modified image lacks the fog from the original image and has high contrast.

## Perform Corner Detection by Using Neighborhood Processing Subsystem Blocks

This example shows how to detect corners in an image by using Neighborhood Processing Subsystem blocks. Use corner detection to identify features and objects in an image.

### Inspect Model

1. Open the model.

```
mdl = 'CornerDetectionNeighborhoodExample';
open_system(mdl);
```

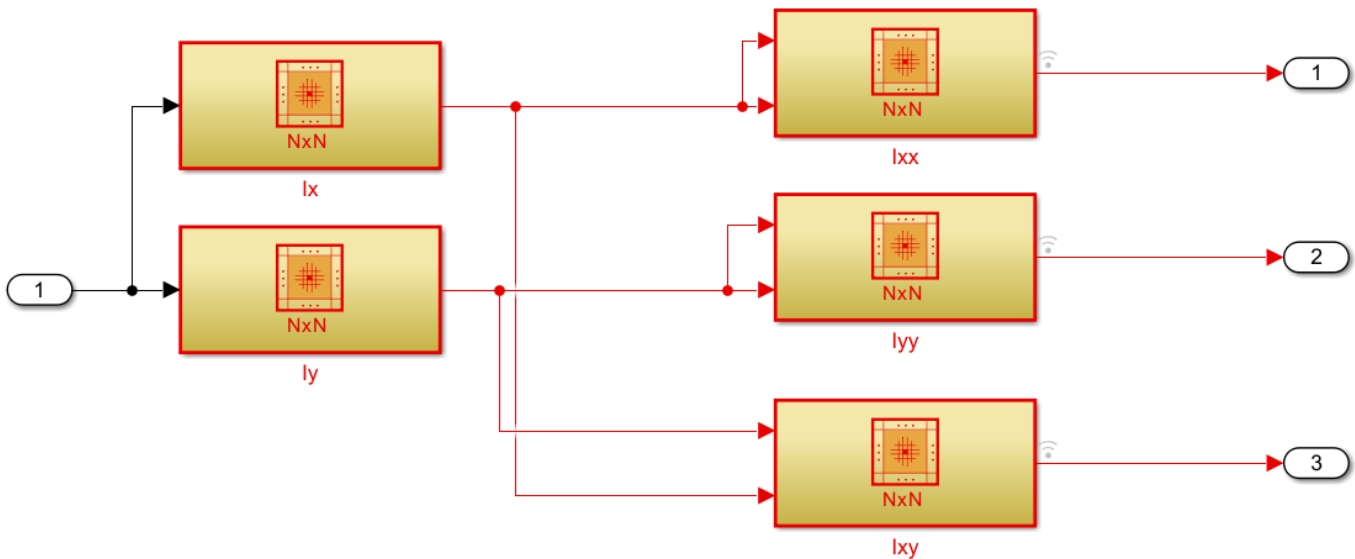

The model performs Harris corner detection. Harris corner detection calculates a value  $R$  for each pixel. The  $R$  value computes the rate of change of brightness in multiple directions around a pixel and reflects whether the pixel represents an edge, corner, or flat region in the image.

- A flat region has low rates of change in all directions and yields an  $R$  value near zero.
- An edge has a high rate of change in only one direction and yields a negative  $R$  value.
- A corner has high rates of change in all directions and yields a positive  $R$  value.

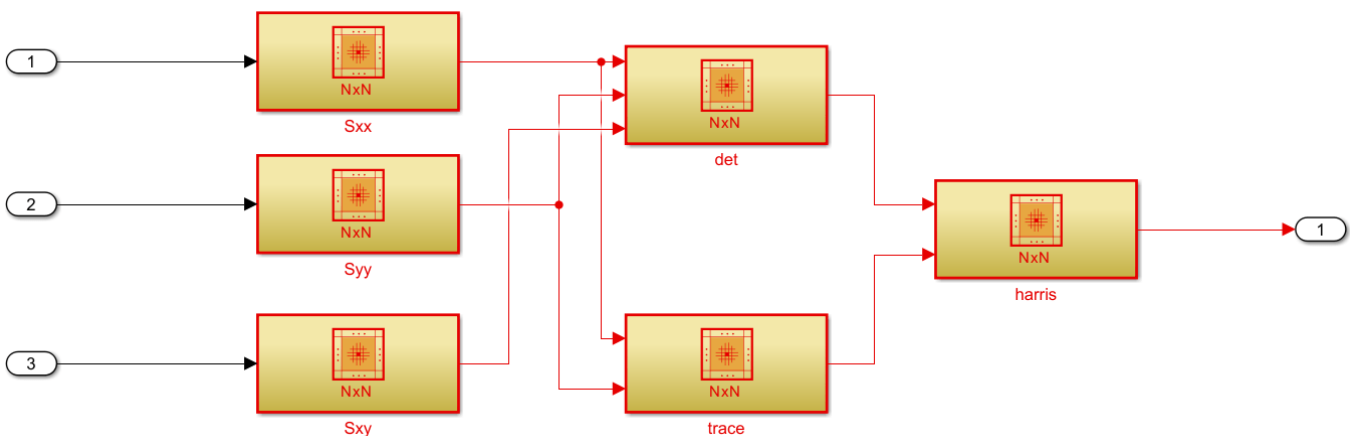

The model marks any pixel with a positive  $R$  values as a corner, and uses two Video Viewer blocks from Computer Vision Toolbox to display the image with and without the corner markings.

2. Return to the model root and open the Compute Gradients subsystem.

The  $I_x$  and  $I_y$  Neighborhood Processing Subsystem blocks compute the gradients of brightness with respect to the horizontal and vertical directions respectively,  $I_x$  and  $I_y$ . The  $I_{xx}$ ,  $I_{yy}$ , and  $I_{xy}$  Neighborhood Processing Subsystem blocks each contain a Product block and compute the products of the brightness gradients,  $I_x^2$ ,  $I_y^2$ , and  $I_x I_y$ .

3. Return to the model root and open the Corner Strength Function subsystem.

The subsystem computes  $R$  for each pixel. Consider the change function  $E(u, v)$ :

$$E(u, v) = \sum_{x, y} w(x, y) [I(x + u, y + v) - I(x, y)]^2.$$

For a neighborhood  $w(x, y)$ ,  $E(u, v)$  calculates the weighted sum of squared differences between the brightness in the neighborhood,  $I(x, y)$ , and the brightness in a neighborhood of the same size shifted by  $(u, v)$ ,  $I(x + u, y + v)$ . Applying Taylor expansion yields this approximation:

$$E(u, v) \approx [u \ v] \left( \sum \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} \right) \begin{bmatrix} u \\ v \end{bmatrix}.$$

The  $S_{xx}$ ,  $S_{yy}$ , and  $S_{xy}$  Neighborhood Processing Subsystem blocks each contain a Sum of Elements block and compute the sums of the brightness gradient products  $\sum I_x^2$ ,  $\sum I_y^2$ , and  $\sum I_x I_y$ .

Consider the matrix  $M$ :

$$M = \sum w(x, y) \begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix}.$$

Computing the eigenvalues of  $M$  yields the rates of change in brightness around the neighborhood  $w(x, y)$ . Computing eigenvalues directly is computationally expensive, so the subsystem calculates the determinant and trace of  $M$ , which relate to the eigenvalues  $\lambda_1$  and  $\lambda_2$  in these ways:

- $\det(M) = \lambda_1 \lambda_2$
- $\text{trace}(M) = \lambda_1 + \lambda_2$

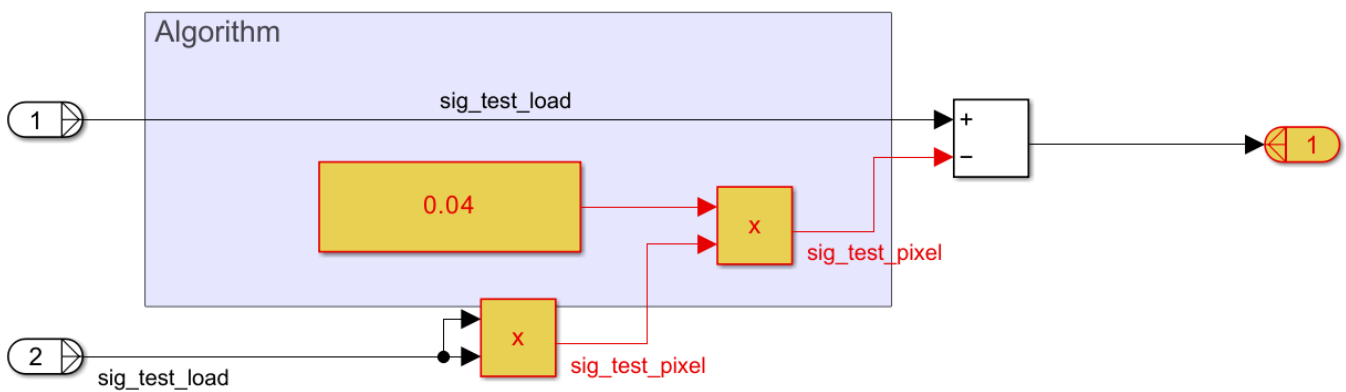

4. Open the **det** subsystem to see how the subsystem calculates the determinant of  $M$ ,  $\det(M)$ .

5. Return to the Corner Strength Function subsystem and open the **trace** subsystem to see how the subsystem calculates the trace of  $M$ ,  $\text{trace}(M)$ .

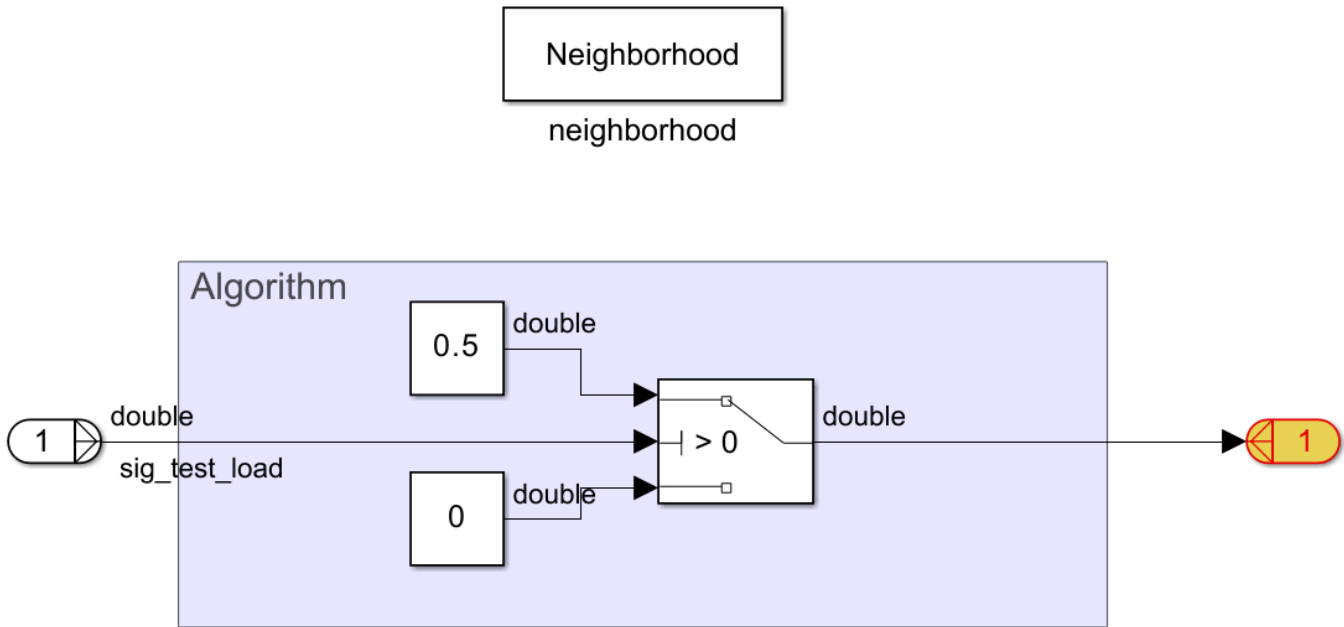

6. Return to the Corner Strength Function subsystem and open the harris subsystem to see how the subsystem calculates  $R$ .

The harris subsystem calculates  $R$  using this equation:

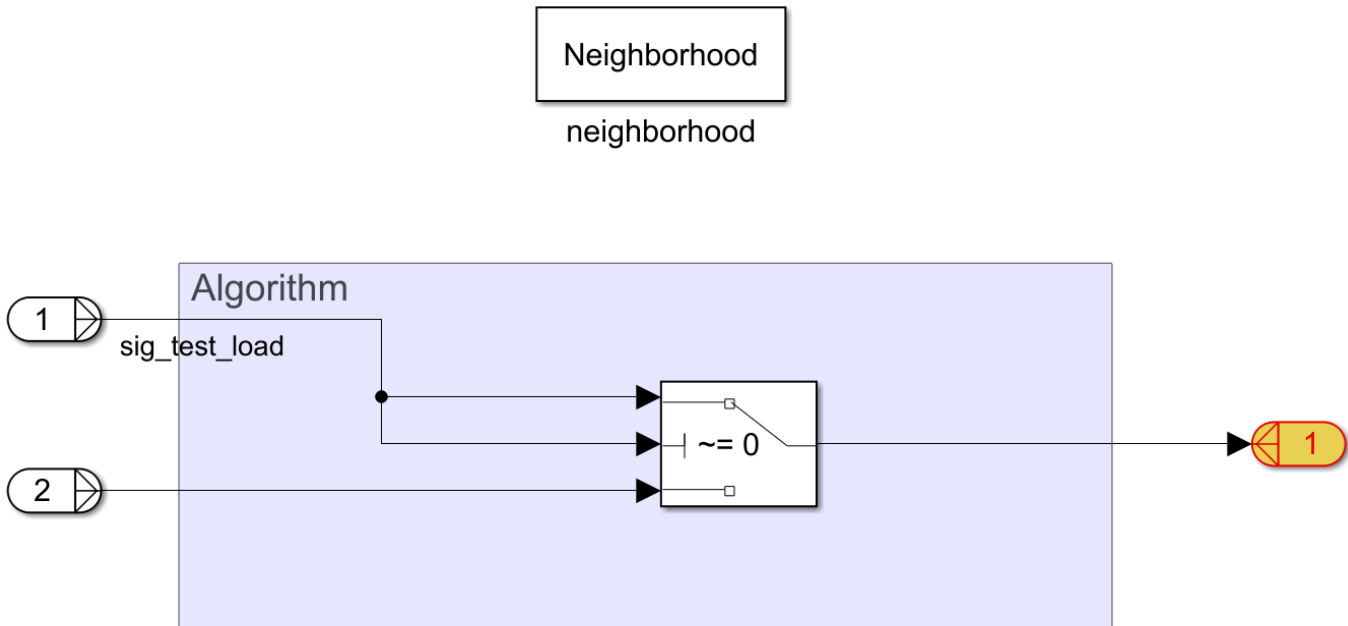

$$R = \det(M) - 0.04 \times \text{trace}(M)^2.$$

7. Return to the model root and open the Check Exceeds Threshold subsystem.

The subsystem uses a Switch block to identify pixels with positive  $R$  values, which represent corners. The neighborhood subsystem returns the value 0.5 for these pixels, which creates a moderate shade of gray in the output image.

8. Return to the model root and open the Overlay Original Image subsystem.

The subsystem uses a Switch block to overlay the corner markings and the original image.

## Simulate and View Results

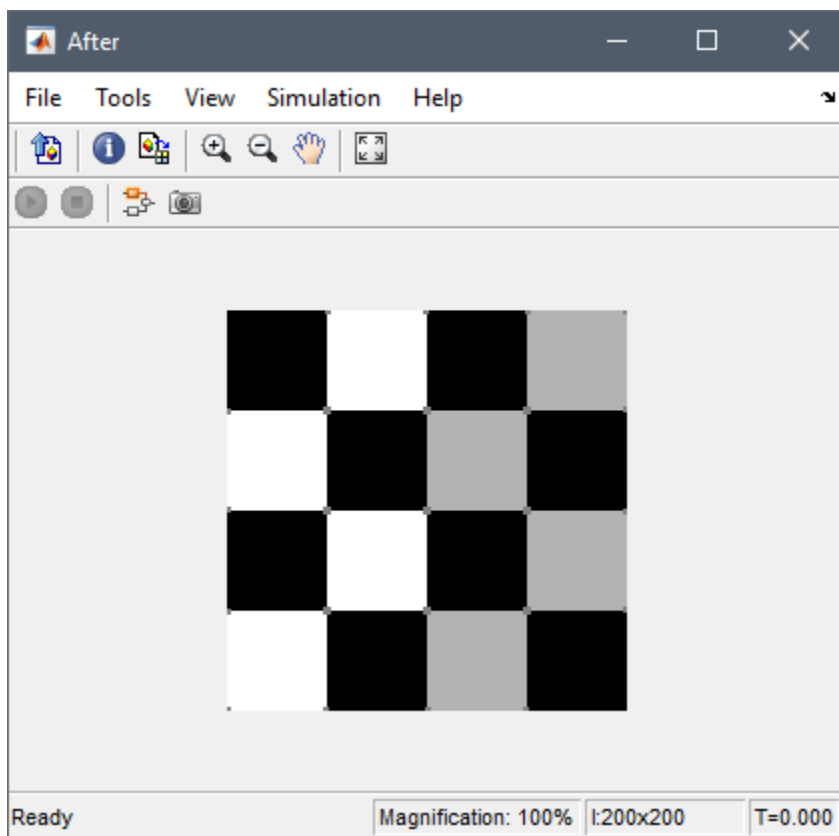

Simulate the model.

```
simout = evalc('sim mdl');
```

The Before Video Viewer block displays the original checkerboard image.

The After Video Viewer block displays the checkerboard image with gray dots marking the corners.

The upper left and lower right corners do not have markers because the Neighborhood Processing Subsystem blocks in the model use the Constant padding option with a padding value of 0. The **Padding option** block parameter controls how the Neighborhood Processing Subsystem block treats pixels in neighborhoods that extend beyond the input image. The parameters in the model configure the Neighborhood Processing Subsystem blocks to use the value 0 outside the input image, which treats the image as if it is surrounded by black pixels. Thus, the model recognizes only the white and gray corners of the image as corners.

For more information about the **Padding option** block parameter, see Neighborhood.

## Convert RGB Image to Grayscale by Using a Neighborhood Processing Subsystem Block

This example shows how to convert an RGB image to grayscale by using a Neighborhood Processing Subsystem block. Converting images to grayscale is an important step in image processing tasks such as corner detection. This example implements grayscale conversion using both the mean and luminosity methods, which weigh the red, green, and blue color channels differently. The luminosity method accounts for the different sensitivities that human eyes have for these colors, and the mean method does not.

### Inspect Model

1. Open the model.

```
mdl = 'RGBToGrayscaleNeighborhoodExample';
open_system(mdl);
```

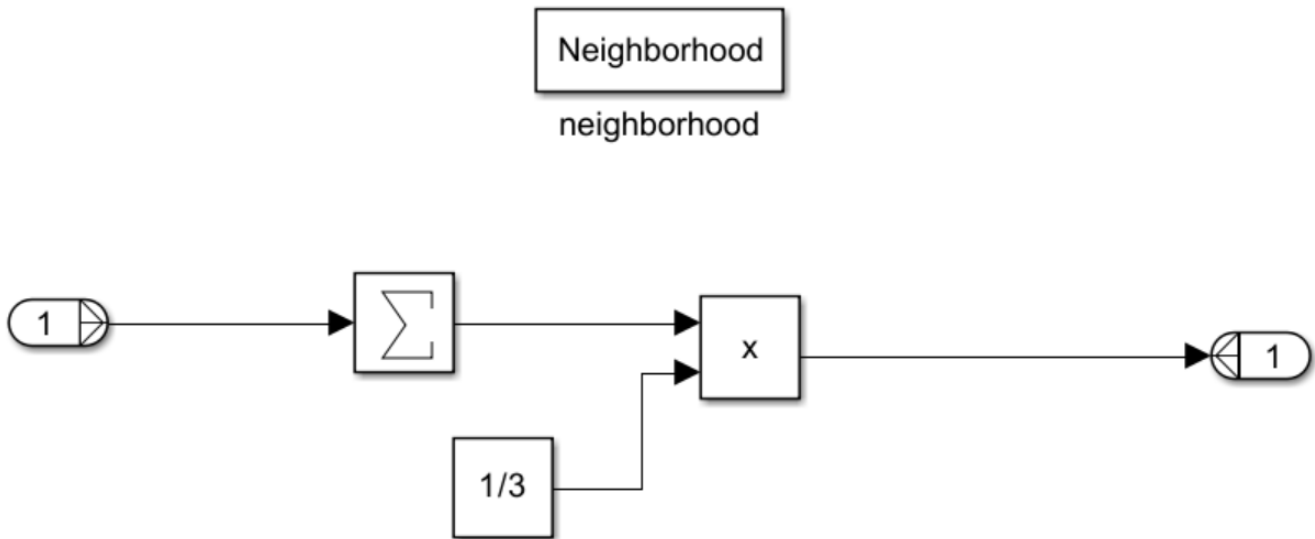

Copyright 2021 The MathWorks, Inc.

The model imports an image by using an Image From File block from Computer Vision Toolbox. The model uses two Neighborhood Processing Subsystem blocks to convert the image to grayscale in two different ways. Each Neighborhood Processing Subsystem block uses the **Valid** option for the **Padding option** parameter. The **Valid** option configures the Neighborhood Processing Subsystem block to output a matrix that is smaller than the input matrix by excluding elements whose neighborhoods extend beyond the input matrix. By using a **Neighborhood size** parameter of [1 1 3] and the **Valid** option, each Neighborhood Processing Subsystem block converts its RGB input to a single-channel output with the same horizontal and vertical dimensions as the input image.

The model displays the original image and each output image using Video Viewer blocks from Computer Vision Toolbox.

2. Open the MeanRGB2Gray subsystem.

The subsystem uses a Sum of Elements block to add the three channel values together, then multiplies the sum by 1/3 to calculate the mean brightness value of the pixel.

3. Open the LuminosityMethodRGB2Gray subsystem.

The subsystem calculates a weighted mean to account for the different sensitivities human eyes have for red, blue, and green light by:

- 1 Converting the 1-by-1-by-3 neighborhood to a 3-by-1 column vector by using a Reshape block
- 2 Multiplying the 3-by-1 column vector by the row vector  $[0.2126 \ 0.7152 \ 0.0722]$
- 3 Passing the product through a Sum of Elements block

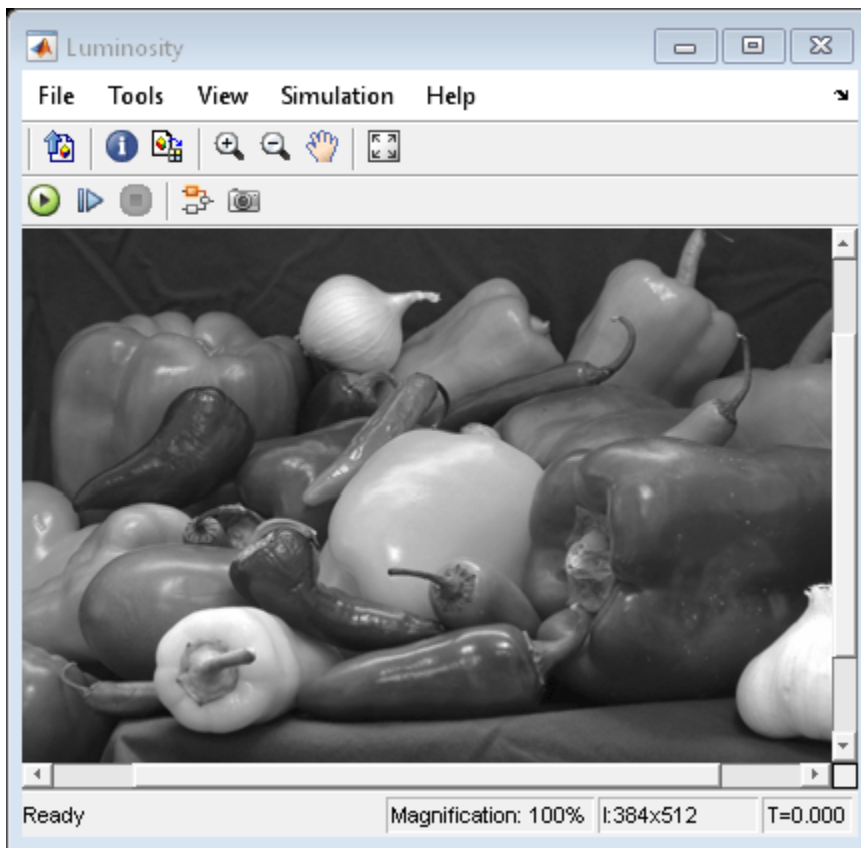

### Simulate Model and View Results

Simulate the model.

```
sim mdl;
```

Each Neighborhood Processing Subsystem block produces a single-channel grayscale version of the three-channel RGB input image.

## Perform Edge Detection by Using a Neighborhood Processing Subsystem Block

This example shows how to detect edges in an image by using a Neighborhood Processing Subsystem block to implement Laplacian edge detection. Use edge detection to identify objects and features in an image.

### Inspect Model

1. Open the model.

```
mdl = 'EdgeDetectionNeighborhoodExample';
open_system(mdl);
```

### Neighborhood Processing Subsystems: Image Edge Detection

Copyright 2022 The MathWorks, Inc.

The model uses an Image From File (Computer Vision Toolbox) block to import an image of the moon, a Neighborhood Processing Subsystem block to perform edge detection, and two Video Viewer (Computer Vision Toolbox) blocks to display the image before and after processing.

2. Open the Neighborhood Processing Subsystem block.

The Neighborhood Processing Subsystem operates over a 3-by-3 neighborhood. To implement Laplacian edge detection, it uses a Gain block to multiply each neighborhood by this kernel:

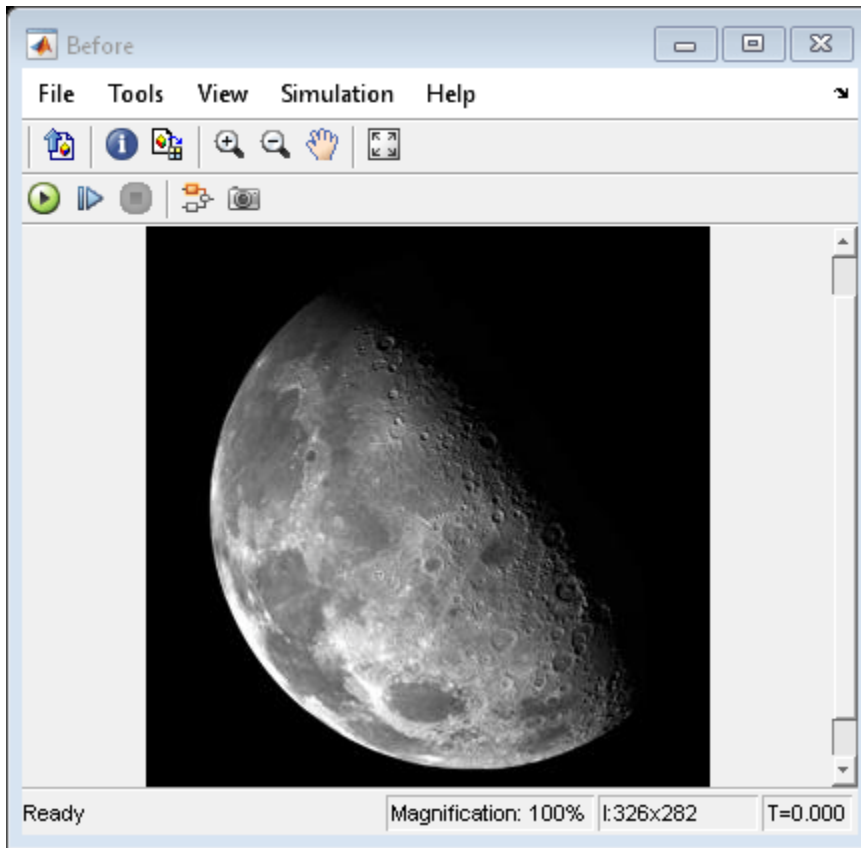

$$\begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix}$$

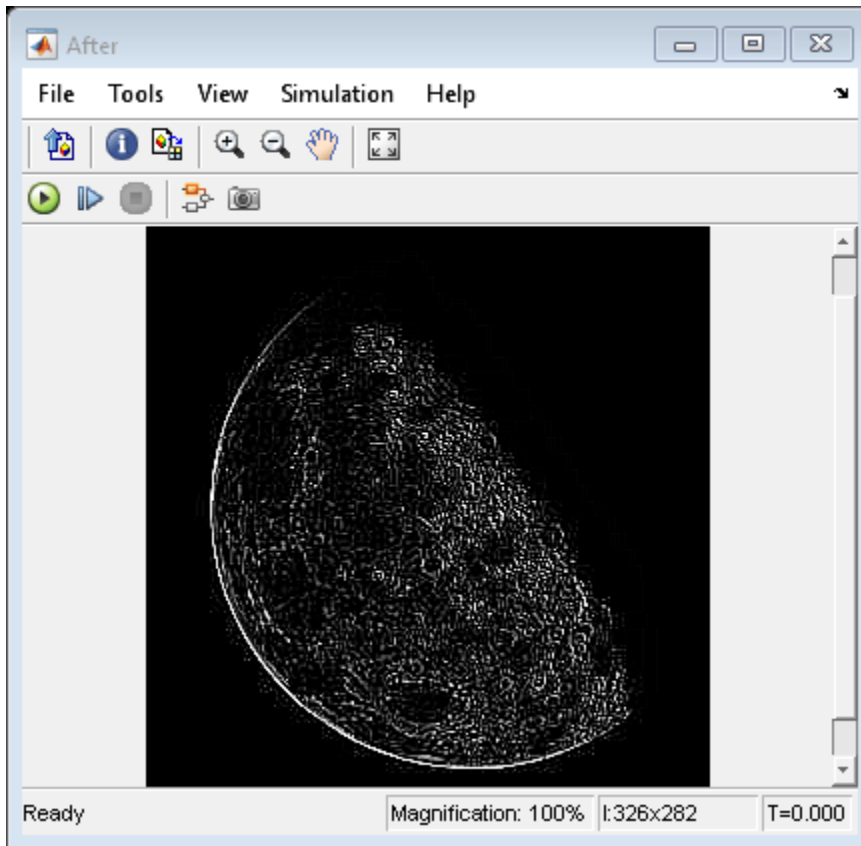

The Neighborhood Processing Subsystem block then uses a Sum of Elements block to sum the resulting matrix into a scalar value, then uses a Saturation block to saturate that scalar to the range  $[0, 255]$ . Pixels that represent edges in the image will have high values and saturate to 255 because they are different in brightness from the surrounding pixels.

### Simulate Model and View Results

Simulate the model.

```
sim mdl;
```

The modified image has bright pixels corresponding to areas in the original image that have high rates of change in brightness and dark pixels corresponding to areas that have low rates of change.

## Model Constant Propagation Delay

Open the model ConstantPropagationDelay. The model uses a Propagation Delay block to delay the output from a Sine Wave block by a constant value specified using a Constant block. The Sine Wave block is configured with a phase shift of  $\pi/2$ , so the output is a cosine wave.

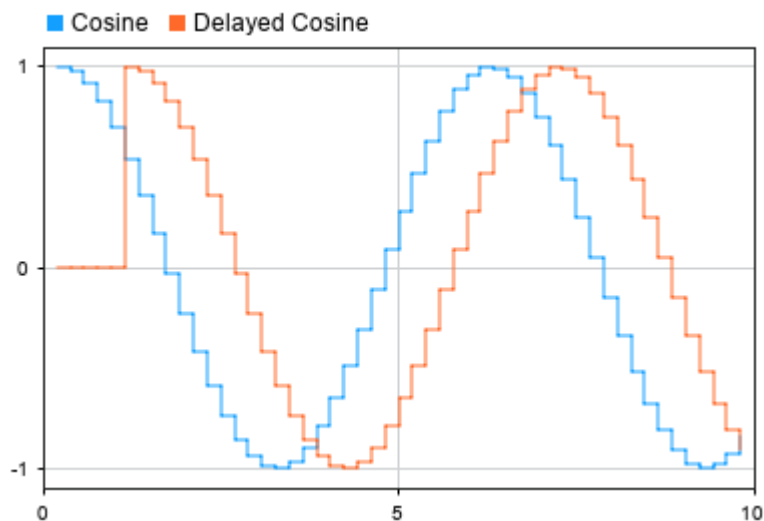

```
mdl = "ConstantPropagationDelay";
open_system(mdl)
```

Simulate the model.

```
out = sim(mdl);
```

The Cosine and Delayed Cosine signals are plotted on the Dashboard Scope block. The **Initial output** value for the block is 0, so the value for the Delayed Cosine signal is 0 until the simulation time reaches 1 second. Then, the output becomes the first delayed Cosine value.

To understand how the Propagation Delay block affects the output signal sample time, display the sample time colors on the model and the timing legend. Then, update the block diagram.

- 1 On the **Debug** tab, under **Diagnostics**, click **Information Overlays**.
- 2 From the menu that appears, under **Sample Time**, select **Colors** and **Timing Legend**.

- Press **Ctrl+D** to update the block diagram.

Alternatively, use the `set_param` function to enable the `SampleTimeColors` parameter for the model and to update the block diagram.

```
set_param mdl, "SampleTimeColors", "on"
set_param mdl, "SimulationCommand", "update")
```

The sample time colors show that:

- The Cosine signal has a discrete sample rate of 0.2, defined by the Sine Wave block **Sample time** parameter.
- The Delay signal has constant sample time, defined by the Constant block **Sample time** parameter.
- The Propagation Delay block has multirate sample time.
- The Delayed Sine Wave signal has fixed-in-minor-step sample time.

The Timing Legend shows that the Propagation Delay block introduces an additional sample time, which is one of the rates for the multirate block. The additional variable sample time for the block allows the Propagation Delay block to update the output value as soon as the delay for a particular sample elapses in a variable-step simulation.

Now, run a fixed-step simulation using a different constant delay value and initial output value.

Configure the model to use a fixed-step solver.

- On the **Modeling** tab, under **Setup**, click **Model Settings**.
- In the Configuration Parameters dialog box, on the **Solver** tab, for the solver **Type** select Fixed-step.
- In the Configuration Parameters dialog box, click **OK**.

Alternatively, use the `set_param` function to specify the `SolverType` parameter as Fixed-step.

```
set_param mdl, "SolverType", "Fixed-step")
```

When you use a fixed-step solver, you must configure the Propagation Delay block to run at a discrete rate.

- Double-click the block to open the Block Parameters dialog box, or select the block and press **Ctrl+Shift+I** to display the Property Inspector.

- 2 Select **Run at fixed time intervals**.
- 3 Specify the **Sample time** as 0.1.

Alternatively, use the `set_param` function to configure the `RunAtFixedTimeIntervals` parameter and the `SampleTime` parameter.

```
set_param("ConstantPropagationDelay/Propagation Delay", ...
 "RunAtFixedTimeIntervals", "on", "SampleTime", "0.1")
```

For this simulation, in addition to using a fixed-step solver, specify a different value for the constant delay and initial output.

Specify the **Initial output** value for the Propagation Delay block as 0.5 using the Block Parameters dialog box, the Property Inspector, or the `set_param` function.

```
set_param("ConstantPropagationDelay/Propagation Delay", ...
 "InitialOutput", "0.5")
```

Configure the constant delay value as 0.5.

Specify the **Value** parameter for the Constant block as 0.5 using the Block Parameters dialog box, the Property Inspector, or the `set_param` function.

```
set_param("ConstantPropagationDelay/Constant Delay", "Value", "0.5")
```

Simulate the model again.

```
out = sim mdl;
```

At the start of the simulation, the Delayed Sine signal value is 0.5. After the initial delay of 0.5 seconds, the output changes from the **Initial output** value to the delayed signal samples.

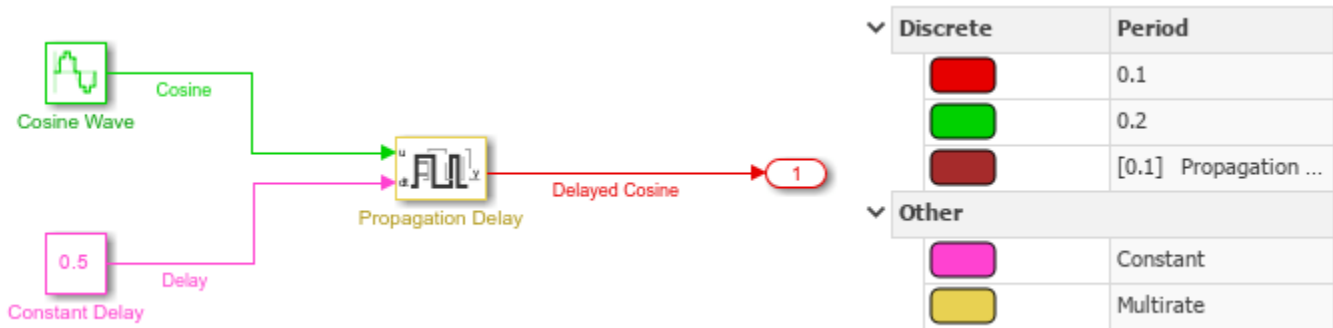

The sample time colors show that:

- The Cosine Wave signal has the discrete sample time of 0.2, defined by the Sine Wave **Sample time** parameter.

- The Delay signal has constant sample time, defined by the Constant block **Sample time** parameter.
- The Propagation Delay block has multirate sample time.
- The Delayed Sine Wave signal has discrete sample time.

The Timing Legend shows that the discrete sample time for the Delayed Sine Wave signal is 0.1, the same as the **Sample time** parameter value for the Propagation Delay block. The Propagation Delay block also introduces a controllable discrete rate with a minimum step size, or base rate, of 0.1.

## Model Variable Propagation Delay

Open the model `VariablePropagationDelay`. The model uses the Propagation Delay block to delay the output from a Sine Wave block. The delay signal is modeled using a Step block.

The Sine Wave and Delay signals are logged using signal logging. The Delayed Sine Wave signal is logged using output logging.

```
mdl = "VariablePropagationDelay";
open_system(mdl)
```

Simulate the model. Then, open the Simulation Data Inspector and use the `Simulink.sdi.loadView` function to load the view `VariablePropDelayView.mldatx`.

```
out = sim(mdl);
Simulink.sdi.view
Simulink.sdi.loadView("VariablePropDelayView.mldatx");
```

The delay signal value must be greater than zero throughout the simulation, so the Step block is configured to step from an initial value of 0.2 to a value of 1 at a simulation time of 2 seconds.

For the first simulation step, at 0 seconds, the Delayed Sine Wave signal value is the **Initial output** value defined for the Propagation Delay block, 0.1.

On the next time step, the delay of 0.2 seconds has elapsed, and the Propagation Delay block output is determined by the delayed sample values.

When the simulation reaches 2 seconds, the step occurs, and the delay becomes 1 second instead of 0.2 seconds. The Propagation Delay block holds the output value for the 1 second delay. Then, the output updates to the sample taken when the step occurred. For the rest of the simulation, the delay between the input and output is 1 second, and the Propagation Delay block output is determined by input signal samples.

## Schedule When Traffic Camera Takes Snapshot

You can use the Hit Scheduler block to schedule time hits for a variable-step solver during simulation based on the runtime behavior of a system. For example, some roads and highways have monitoring devices and systems to deter speeding and capture information about cars that speed.

At an intersection with a traffic light, such a monitoring system might consist of these components:

- Sensors that detect an approaching car and measure its speed
- A camera embedded in the traffic light that can capture an image of each speeding car

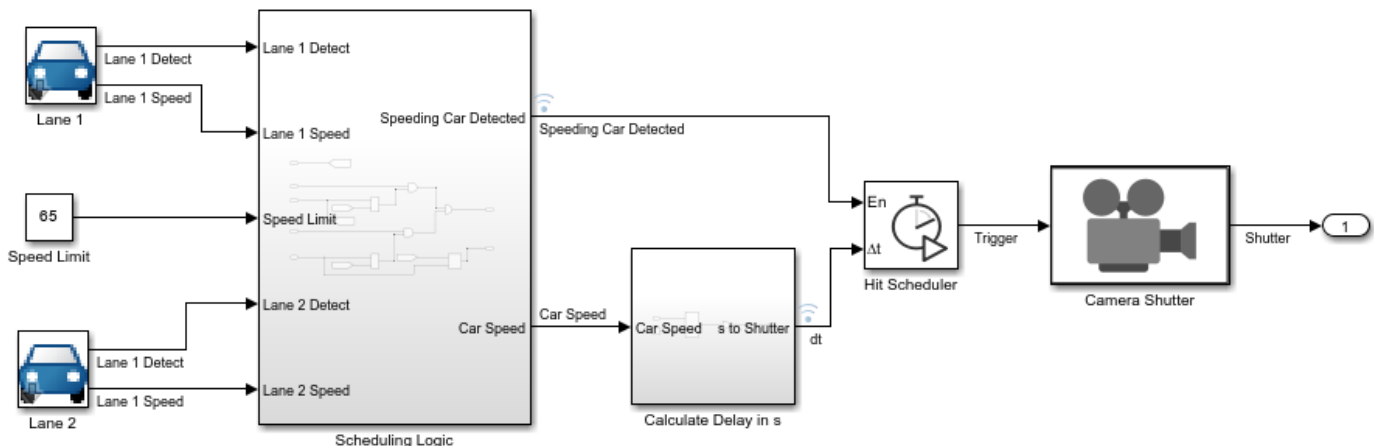

To ensure the camera captures a consistent image, the system needs to determine when the camera shutter activates based on the speed of each car.

This example shows how you can use the Hit Scheduler block to schedule when a traffic camera in this type of system captures an image.

### Open and Explore Model

Open the model `TrafficCam`. The model implements the scheduling for a traffic camera on a two-lane road with a speed limit of 65 miles per hour using the Hit Scheduler block on a triggered subsystem.

```
mdl = "TrafficCam";
open_system(mdl)
```

The blocks `Lane 1` and `Lane 2` are masked subsystems that contain logic to generate signals that represent car detection and the speed of the detected car. The car detection signals are random. The car speeds vary randomly around a nominal value of 64 miles per hour.

The car detection blocks and a Constant block that indicates the speed limit for the road feed a subsystem with scheduling logic that determines whether a speeding car has been detected. If a speeding car is detected in both lanes at the same time, the logic schedules the camera shutter to capture an image of the faster car.

The `Speeding Car Detected` output of the `Scheduling Logic` subsystem drives the enable port for the `Hit Scheduler` block so that the block schedules a time step each time a speeding car is detected.

The `Car Speed` output of the `Schedule Logic` subsystem connects to another subsystem that uses the speed of the car and the distance of the car from the camera to calculate the delay between the current time and when the camera should capture an image of the speeding car.

The `Hit Scheduler` block produces a function-call event on each scheduled time step that drives the trigger port for the `Camera Shutter` subsystem.

### Simulate Model and Analyze Results

Simulate the model. Then, open the Simulation Data Inspector and use the `Simulink.sdi.loadView` function to load the view file `TrafficCamView.mldatx`.

```
out = sim mdl;
Simulink.sdi.view
Simulink.sdi.loadView("TrafficCamView.mldatx");
```

On the first time step, a speeding car is detected. From the speed of the car, the delay time for the camera to capture a picture of the car is calculated as 0.1822 seconds.

```
logcout = out.logcout;
dt = getElement(logcout, "dt");
dt0 = dt.Values.Data(1)

dt0 = 0.1822
```

The Hit Scheduler block schedules a time step to occur at 0.1822 seconds. On the scheduled time step, the block produces a function-call event that triggers the Camera Shutter subsystem.

The shutter activates for the first time on the third time step in the simulation, which is the time step the Hit Scheduler block scheduled at the start of the simulation.

```
yout = out.yout;
shutter = getElement(yout, "Shutter");
t3 = shutter.Values.Time(3)

t3 = 0.1822
```

Use the cursors in the Simulation Data Inspector to continue analyzing the Speeding Car Detected, dt, and Shutter signals and analyze how the Hit Scheduler block controls the action of the camera.

## Related Examples

- “Model Effect of Temperature and Jitter on Crystal Oscillation Frequency” on page 12-246

## Model Effect of Temperature and Jitter on Crystal Oscillation Frequency

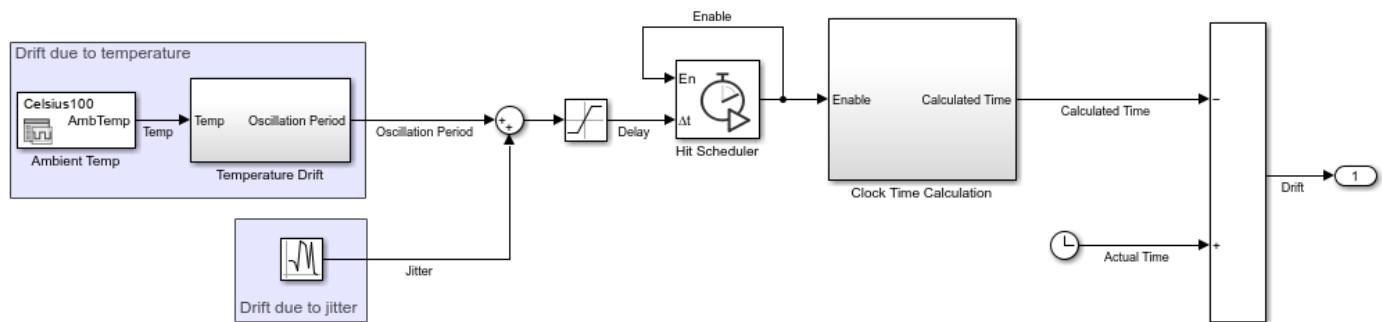

Many digital clocks use a crystal oscillator. The oscillator has a nominal frequency. Based on this frequency, the clock can calculate elapsed time by tracking the crystal oscillations.

The oscillator frequency can vary with environmental conditions such as electronic noise, or jitter, and the ambient temperature. You can use a Hit Scheduler block to model and simulate the effect of time-varying environmental conditions on the oscillation frequency.

### Open and Analyze Model

Open the model `ClockDrift`.

```
mdl = "ClockDrift";
open_system(mdl)
```

The model uses a Signal Editor block to load input data for different ambient temperature scenarios. Based on the current ambient temperature, the `Oscillation Period` subsystem calculates the oscillation period using the equation

$$\Delta f = f_0 \left( 1 - k(T_0 - T_{\text{amb}})^2 \right),$$

where:

- $\Delta f$  is the frequency shift due to temperature.
- $f_0$  is the nominal frequency for the crystal, 32 kHz in this example.
- $k$  is a physical constant that represents the peak temperature drift, 0.04 in this example.
- $T_0$  is the nominal temperature, 25 Celsius in this example.
- $T_{\text{amb}}$  is the ambient temperature.

Create a `Simulink.SimulationInput` object that sets the values of  $f_0$ ,  $k$ , and  $T_0$  for the simulation.

```
simIn = Simulink.SimulationInput(mdl);
simIn = setVariable(simIn, "f0", 32000);
simIn = setVariable(simIn, "k", 0.04);
simIn = setVariable(simIn, "T0", 25);
```

A Random Number block generates variation in the oscillation period due to noise. The sum of the oscillation period calculated based on the ambient temperature and the variation due to noise

represents the delay to the next oscillation. This sum also provides the delay input for the Hit Scheduler block.

The Hit Scheduler block is configured to generate a signal output. On a time step scheduled by the Hit Scheduler block, the output value is 1, and on other time steps, the value is 0. The signal output represents the oscillations and provides the enable input for scheduling each time hit.

The model calculates the time for the clock that uses the oscillator by counting the oscillations and multiplying by the nominal period for the oscillator. Due to the temperature variation and jitter, the nominal period is an estimation and the calculated time is not exact. A Clock block provides an indication of the true time for each time step.

### Simulate Drift for High Ambient Temperature

As saved, the Signal Editor block loads data for a constant ambient temperature of 100 C. Simulate the model using this scenario.

```
out = sim(simIn);
```

Two Display blocks show the calculated and actual time for each time step. The Dashboard Scope block shows the difference between the calculated time and actual time over the duration of the simulation. The drift error accumulates, resulting in a calculated time of 1.999562500000000 for the final simulation time of 2 seconds.

### Simulate Drift for Nominal Temperature

To simulate the clock drift when the ambient temperature is 25 C, change the scenario the Signal Editor block loads.

- 1 Double-click the Signal Editor block.
- 2 In the Block Parameters dialog box, from the **Active scenario** list, select Celsius25.
- 3 Click **OK**.

Alternatively, use the `setBlockParameter` function to modify the block parameter for the `Simulink.SimulationInput` object `simIn`.

```
simIn = setBlockParameter(simIn,"ClockDrift/Ambient Temp","ActiveScenario","Celsius25");
```

Simulate the model again.

```
out = sim(simIn);
```

At the nominal temperature, the oscillator frequency has no drift due to temperature. All the drift comes from the system noise, or jitter. For a simulation time of 2 seconds, the jitter in the system has no perceptible effect on the calculated time.

## Simulation of Bouncing Ball

This example uses two bouncing ball Simulink® models to show different approaches to modeling hybrid dynamic systems with Zeno behavior. The example also provides the benefits of each approach.

Bouncing ball models are hybrid dynamic systems with the Zeno phenomenon. Zeno behavior is informally characterized by an infinite number of events occurring in a finite time interval for certain hybrid systems. As the ball loses energy, a large number of collisions with the ground start occurring in successively smaller intervals of time.

### Hybrid Dynamic Systems

A bouncing ball model is an example of a hybrid dynamic system. A hybrid dynamic system is a system that involves both continuous dynamics and discrete transitions where the system dynamics can change and the state values can jump. The continuous dynamics of a bouncing ball is given by these equations:

$$\frac{dv}{dt} = -g,$$

$$\frac{dx}{dt} = v,$$

where  $g$  is the acceleration due to gravity,  $x(t)$  is the position of the ball, and  $v(t)$  is the velocity. Therefore, the system has two continuous states: position  $x$  and velocity  $v$ .

The hybrid system aspect of the model originates from the modeling of a collision of the ball with the ground. If one assumes a partially elastic collision with the ground, then the velocity before the collision,  $v^-$ , and velocity after the collision,  $v^+$ , can be related by the coefficient of restitution of the ball,  $\kappa$ , as follows:

$$v^+ = -\kappa v^-, \quad x = 0$$

The bouncing ball therefore displays a jump in a continuous state (velocity) at the transition condition,  $x = 0$ . This figure shows a ball thrown up with a velocity of 0 m/s from a height of 25 m.

## Use Two Integrator Blocks to Model Bouncing Ball

The `sldemo_bounce_two_integrators` model uses two Integrator blocks to model a bouncing ball. The Integrator block on the left is the velocity integrator modeling the first equation. The Integrator block on the right is the position integrator. Open the position integrator block dialog box and observe that the block has a lower limit of zero. This condition represents the constraint that the ball cannot go below the ground.

The state port of the position integrator and the corresponding comparison result is used to detect when the ball hits the ground and to reset both integrators. The state port of the velocity integrator is used for the calculation of  $v^+$ .

### Bouncing Ball Model

Two separate Integrators are less efficient than a single Second-Order Integrator for simulating a bouncing ball. [Click here to see `sldemo\_bounce` for the recommended modeling approach.](#)

Copyright 1990-2022 The MathWorks, Inc.

To observe the Zeno behavior of the system, go to the **Solver** pane of the Configuration Parameters dialog box. In Simulation time, set Stop time to 25.

- In **Simulation time**, set **Stop time** to 25.
- Expand **Sovler details**, In Zero-crossing options, set **Algorithm** to Nonadaptive.

Simulate the model.

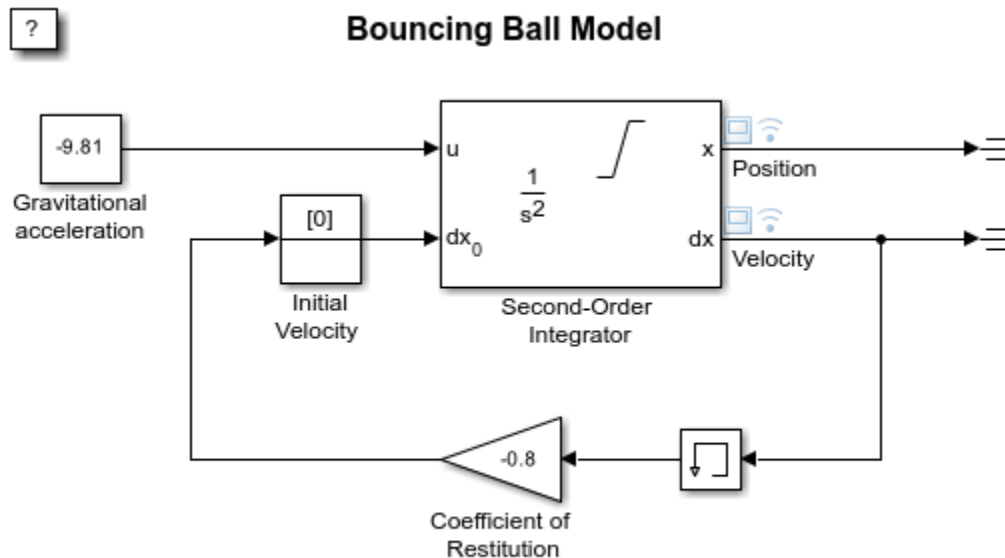

As the ball hits the ground more frequently and loses energy, the simulation exceeds the **Number of consecutive zero crossings** default limit of 1000.

On the Configuration Parameters dialog box and go to **Solver > Zero-crossing options**. Set **Algorithm** to Adaptive. This algorithm introduces a sophisticated treatment for chattering behavior. You can now simulate the system beyond 20 seconds. Note, however, the chatter of the

states between 21 seconds and 25 seconds and warning from Simulink about the strong chattering in the model around 20 seconds.

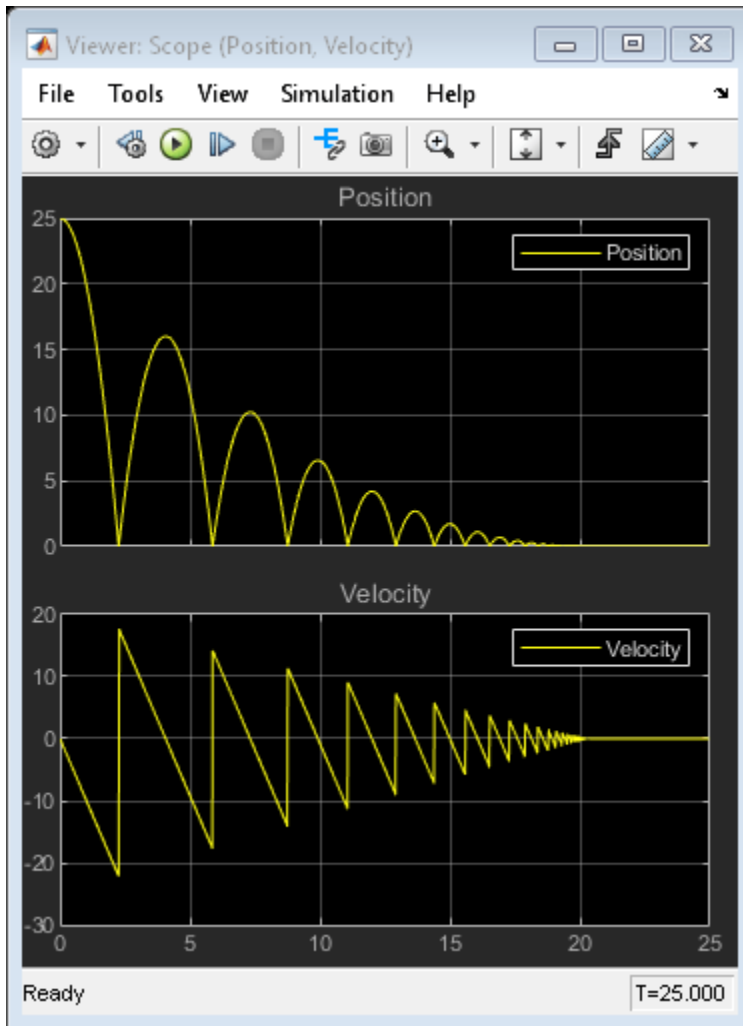

### Use Second-Order Integrator Block to Model Bouncing Ball

The `sldemo_bounce` model uses a single Second-Order Integrator block to model a bouncing ball. In this case, the second equation  $dx/dt = v$  is internal to the Second-Order Integrator block in this case. Open the Second-Order Integrator block dialog box and see that  $x$  has a lower limit of zero. On the **Attributes** tab, check **Reinitialize dx/dt when x reaches saturation**. This parameter allows you to reinitialize  $dx/dt$  ( $v$  in the bouncing ball model) to a new value when  $x$  reaches its saturation limit. So, in the bouncing ball model, when the ball hits the ground, its velocity can be set to a different value, such as to the velocity after the impact. Note the loop for calculating the velocity after a collision with the ground. To capture the velocity  $v^-$  of the ball just before the collision, the  $dx/dt$  output port of the Second-Order Integrator block and a Memory block are used.  $v^-$  is then used to calculate the rebound velocity  $v^+$ .

Copyright 2004-2022 The MathWorks, Inc.

In the Configuration Parameters dialog box, go to the **Solver** pane.

- In **Simulation time**, set **Stop time** to 25.
- Expand **Solver details**. In **Zero-crossing options**, set **Algorithm** to Nonadaptive .

Simulate the model.

Note that the simulation encounters no problems. You can simulate the model without experiencing excessive chatter after 20 seconds and without setting **Algorithm** to Adaptive.

### Compare Approaches to Modeling Bouncing Ball

You can analytically calculate the exact time  $t^*$  when the ball settles down to the ground with zero velocity by summing the time required for each bounce. This time is the sum of an infinite geometric series given by:

$$t^* = \frac{1}{g} \left( v_0 + v_1 \left( \frac{1 + \kappa}{1 - \kappa} \right) \right), \quad v_1 = \sqrt{v_0^2 + 2gx_0},$$

where  $x_0$  and  $v_0$  are initial conditions for position and velocity, respectively. The velocity and the position of the ball must be identically zero for  $t > t^*$ . The figure shows results from both simulations near  $t^*$ . The vertical red line in the plot is  $t^*$  for the given model parameters. For  $t < t^*$  and far away from  $t^*$ , both models produce accurate and identical results. Only a magenta line from the second model is visible in the plot. However, the simulation results from the first model are inexact after  $t^*$ . The plot continues to display excessive chattering behavior for  $t > t^*$ . In contrast, the model that uses the Second-Order Integrator block settles to exactly zero for  $t > t^*$ .

The model that uses the Second-Order Integrator block has superior numerical characteristics compared to the first model because the second differential equation  $dx/dt = v$  is internal to the Second-Order Integrator block. The block algorithms can leverage this relationship between the two states and use heuristics to clamp down chattering behavior for certain conditions. These heuristics become active when the two states are no longer mutually consistent due to integration errors and chattering behavior. You can thus use physical knowledge of the system to prevent simulations getting stuck in a Zeno state for certain classes of Zeno models.

## Single Hydraulic Cylinder Simulation

This example shows how to use Simulink® to model a hydraulic cylinder. You can apply these concepts to applications where you need to model hydraulic behavior. See two related examples that use the same basic components: four cylinder model and two cylinder model with load constraints.

- Note: This is a basic hydraulics example. You can more easily build hydraulic and automotive models using Simscape™ Driveline™ and Simscape Fluids™.
- **Simscape Fluids** provides component libraries for modeling and simulating fluid systems. It includes models of pumps, valves, actuators, pipelines, and heat exchangers. You can use these components to develop fluid power systems such as front-loader, power steering, and landing gear actuation systems. Engine cooling and fuel supply systems can also be developed with Simscape Fluids. You can integrate mechanical, electrical, thermal, and other systems using components available in the Simscape product family.
- **Simscape Driveline** provides component libraries for modeling and simulating one-dimensional mechanical systems. It includes models of rotational and translational components, such as worm gears, planetary gears, lead screws, and clutches. You can use these components to model the transmission of mechanical power in helicopter drivetrains, industrial machinery, vehicle powertrains, and other applications. Automotive components, such as engines, tires, transmissions, and torque converters, are also included.

### Analysis and Physics of the Model

Figure 1 shows a schematic diagram of the basic model. The model directs the pump flow,  $Q$ , to supply pressure,  $p_1$ , from which laminar flow,  $q_{1ex}$ , leaks to exhaust. The control valve for the piston/cylinder assembly is modeled as turbulent flow through a variable-area orifice. Its flow,  $q_{12}$ , leads to intermediate pressure,  $p_2$ , which undergoes a subsequent pressure drop in the line connecting it to the actuator cylinder. The cylinder pressure,  $p_3$ , moves the piston against a spring load, resulting in position  $x$ .

**Figure 1:** Schematic diagram of the basic hydraulic system

At the pump output, the flow is split between leakage and flow to the control valve. We model the leakage,  $q_{1ex}$ , as laminar flow (see Equation Block 1).

**Equation Block 1**

$$Q = q_{12} + q_{1ex}$$

$$q_{1ex} = C_2 \cdot p_1$$

$$p_1 = \frac{(Q - q_{12})}{C_2}$$

$$Q = \text{pump flow}$$

$$q_{12} = \text{control valve flow}$$

$$q_{1ex} = \text{leakage}$$

$$C_2 = \text{flow coefficient}$$

$$p_1 = \text{pump pressure}$$

We modeled turbulent flow through the control valve with the orifice equation. The sign and absolute value functions accommodate flow in either direction (see Equation Block 2).

**Equation Block 2**

$$q_{12} = C_d \cdot A \cdot \text{sgn}(p_1 - p_2) \cdot \sqrt{\frac{2}{\rho} |p_1 - p_2|}$$

$$C_d = \text{orifice discharge coefficient}$$

$$A = \text{orifice area}$$

$$p_2 = \text{pressure downstream of control valve}$$

$$\rho = \text{fluid density}$$

The fluid within the cylinder pressurizes due to this flow,  $q_{12} = q_{23}$ , minus the compliance of the piston motion. We also modeled fluid compressibility in this case (see Equation Block 3).

**Equation Block 3**

$$\frac{dp_3}{dt} = \frac{\beta}{V_3} \left( q_{12} - A_c \frac{dx}{dt} \right)$$

$$V_3 = V_{30} + A_c \cdot x$$

$$p_3 = \text{piston pressure}$$

$$\beta = \text{fluid bulk modulus}$$

$$V_3 = \text{fluid volume at } p_3$$

$$V_{30} = \text{fluid volume in the piston for } x = 0$$

$A_c =$  cylinder cross-sectional area

We neglected the piston and spring masses because of the large hydraulic forces. We completed the system of equations by differentiating this relationship and incorporating the pressure drop between  $p_2$  and  $p_3$ . Equation Block 3 models laminar flow in the line from the valve to the actuator. Equation block 4 gives the force balance at the piston.

#### Equation Block 4

$$x = p_3 \frac{A_c}{K}$$

$$\frac{dx}{dt} = \frac{dp_3}{dt} \frac{A_c}{K}$$

$$q_{23} = q_{12} = C_1 (p_2 - p_3)$$

$$p_2 = p_3 + \frac{q_{12}}{C_1}$$

$K =$  spring constant

$C_1 =$  laminar flow coefficient

#### Modeling

Figure 2 shows the top level diagram of the model. The pump flow and the control valve orifice area are simulation inputs. The model is organized as two subsystems: the 'Pump' and the 'Valve/Cylinder/Piston/Spring Assembly'.

#### Opening the Model and Running the Simulation

To open this model, type `sldemo_hydcyl` at MATLAB® terminal (click on the hyperlink if you are using MATLAB Help). Press the "Play" button on the model toolbar to run the simulation.

The model logs relevant data to MATLAB workspace, into the Simulink.SimulationOutput object `out`. The signal logging data is stored in the `out` object, in a structure called `sldemo_hydcyl_output`. Logged signals have a blue indicator (see the model). For more information, see "View and Access Signal Logging Data".

## Single Hydraulic Cylinder Simulation

Copyright 1990-2012 The MathWorks, Inc.

**Figure 2:** Single cylinder model and simulation results**'Pump' Subsystem**

Right-click the Pump masked subsystem and select **Mask > Look Under Mask**. The pump model computes the supply pressure as a function of the pump flow and the load (output) flow (Figure 3).  $Q_{\text{pump}}$  is the pump flow data (saved in the model workspace). A matrix with column vectors of time points and the corresponding flow rates  $[T, Q]$  specifies the flow data. The model calculates pressure  $p_1$  as indicated in Equation Block 1. Because  $Q_{\text{out}} = q_{12}$  is a direct function of  $p_1$  (via the control valve), an algebraic loop is formed. An estimate of the initial value,  $p_{10}$ , enables a more efficient solution.

**Figure 3:** The pump subsystem

We masked the 'Pump' subsystem in Simulink to allow the user to easily access the parameters (see Figure 4). The parameters to be specified are  $T$ ,  $Q$ ,  $p_{10}$ , and  $C_2$ . We then assigned the masked block the icon shown in Figure 2, and saved it in a Simulink library.

**Figure 4:** Entering pump parameters

### 'Valve/Cylinder/Piston/Spring Assembly' Subsystem

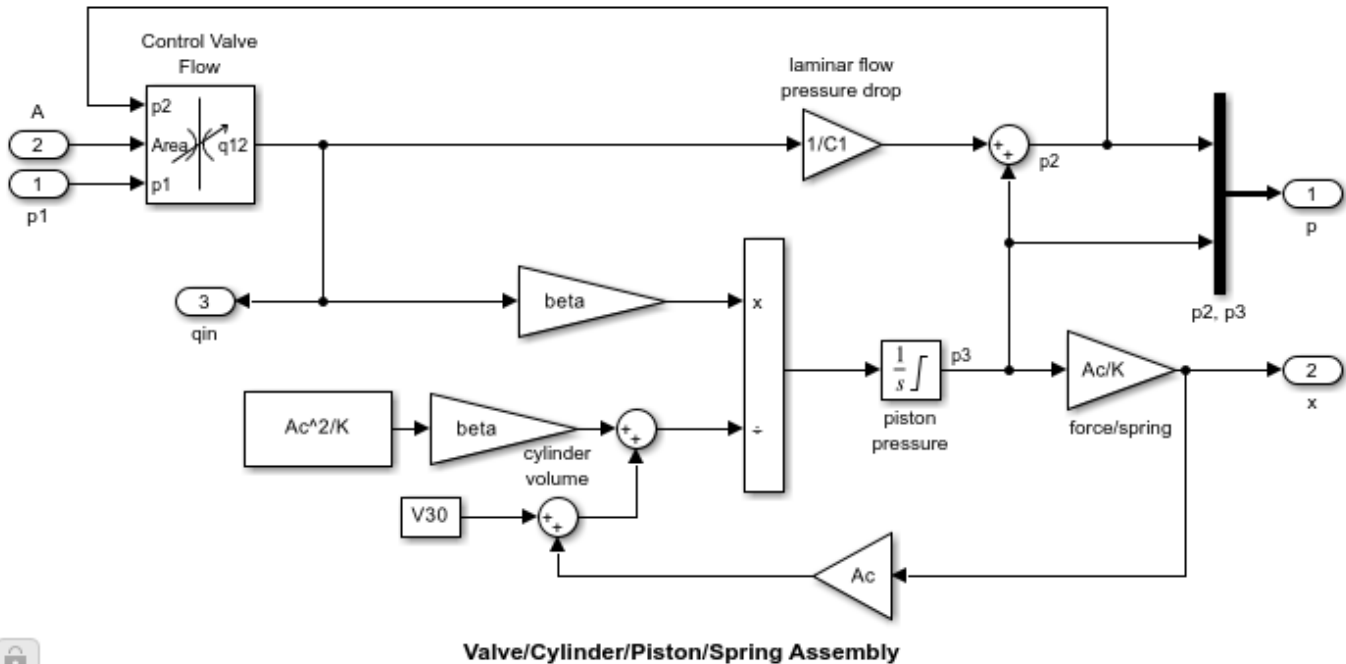

Right-click the 'Valve/Cylinder/Piston/Spring Assembly' subsystem and select **Mask > Look Under Mask** to see the Actuator subsystem (see Figure 5). A system of differential-algebraic equations models the cylinder pressurization with the pressure  $p_3$ , which appears as a derivative in Equation Block 3 and is used as the state (integrator). If we neglect piston mass, the spring force and piston position are direct multiples of  $p_3$  and the velocity is a direct multiple of  $p_3$ 's time derivative. This latter relationship forms an algebraic loop around the 'Beta' Gain block. The intermediate pressure  $p_2$  is the sum of  $p_3$  and the pressure drop due to the flow from the valve to the cylinder (Equation Block 4). This relationship also imposes an algebraic constraint through the control valve and the  $1/C_1$  gain.

The control valve subsystem computes the orifice (Equation Block2). It uses as inputs the upstream and downstream pressures and the variable orifice area. The 'Control Valve Flow' Subsystem computes the signed square root:

$$y = \text{sgn}(u)\sqrt{|u|}$$

Three nonlinear functions are used, two of which are discontinuous. In combination, however,  $y$  is a continuous function of  $u$ .

**Figure 5:** The valve/cylinder/piston/spring subsystem

## Results

### Simulation Parameters

We simulated the model using the following data. The information is loaded from a MAT-file - `sldemo_hydcyl_data.mat`, which is also used for the other two hydraulic cylinder models. The users can enter data via the Pump and Cylinder Masks shown in Figures 4 and 6.

$$C_d = 0.61$$

$$\rho = 800 \text{ kg/m}^3$$

$$C_1 = 2e - 8 \text{ m}^3/\text{sec}/\text{Pa}$$

$$C_2 = 3e - 9 \text{ m}^3/\text{sec}/\text{Pa}$$

$$\beta = 7e8 \text{ Pa}$$

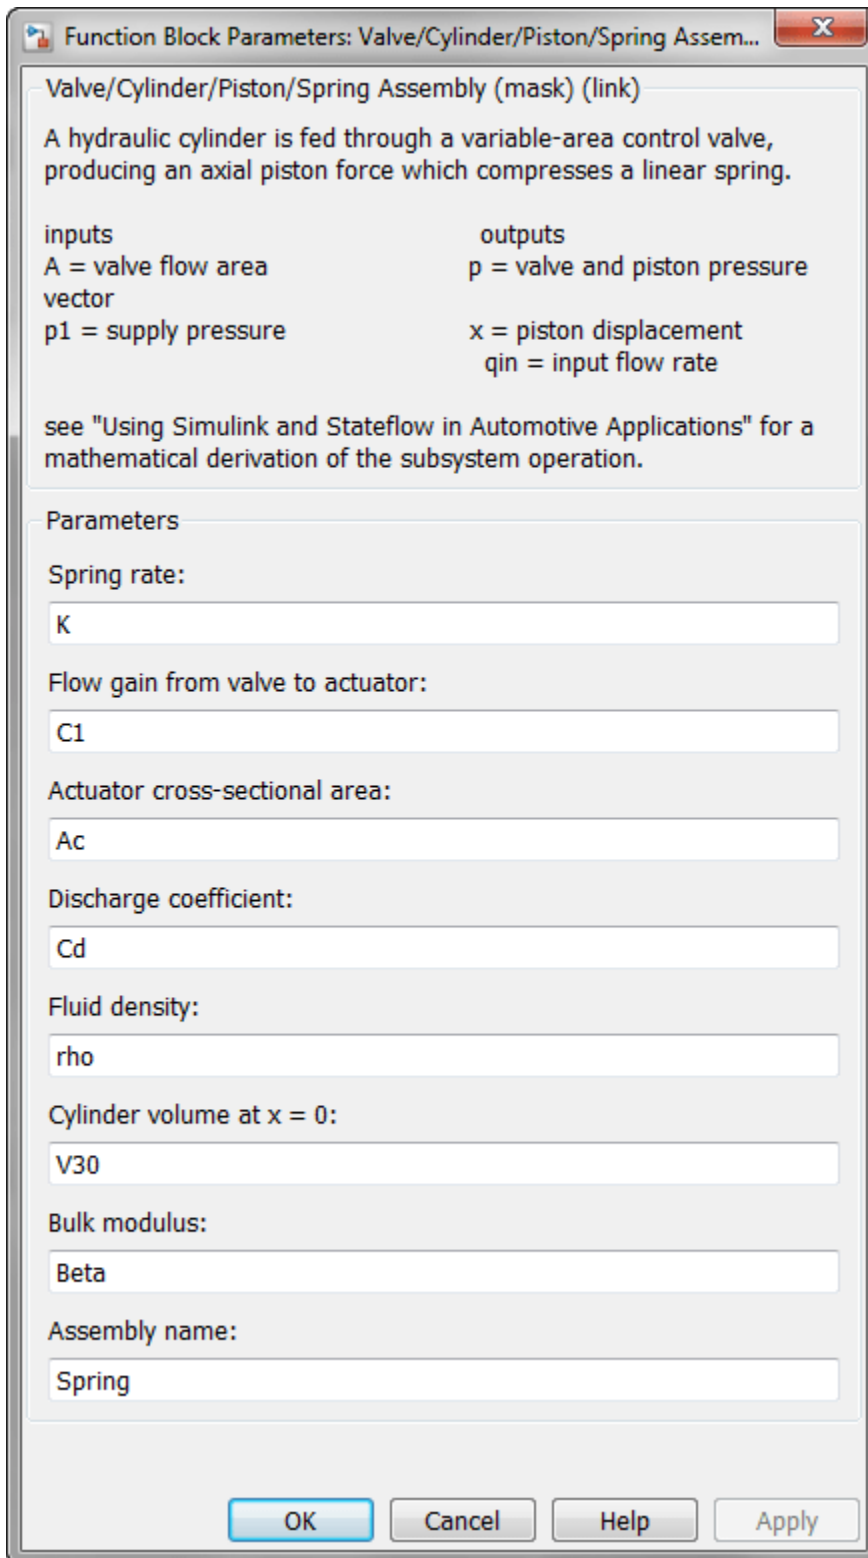

$$A_c = 1e - 3 \text{ m}^2$$

$$K = 5e4 \text{ N/m}$$

$$V_{30} = 2.5e - 5 \text{ m}^3$$

$$T = [0 \ 0.04 \ 0.04 \ 0.05 \ 0.05 \ 0.1] \text{ sec}$$

$$Q = [0.005 \ 0.005 \ 0 \ 0 \ 0.005 \ 0.005] \text{ m}^3/\text{sec}$$

### Plotting Simulation Results

The system initially steps to a pump flow of  $0.005 \text{ m}^3/\text{sec}=300 \text{ l/min}$ , abruptly steps to zero at  $t=0.04 \text{ sec}$ , then resumes its initial flow rate at  $t=0.05 \text{ sec}$ .

The control valve starts with zero orifice area and ramps to  $1e-4 \text{ sq.m.}$  during the  $0.1 \text{ sec}$  simulation time. With the valve closed, all of the pump flow goes to leakage so the initial pump pressure increases to  $p_{10} = Q/C2 = 1667 \text{ kPa}$ .

As the valve opens, pressures  $p_2$  and  $p_3$  build up while  $p_1$  decreases in response to the load increase as shown in Figure 7. When the pump flow cuts off, the spring and piston act like an accumulator and  $p_3$  decreases continuously. Then the flow reverses direction, so  $p_2$ , though relatively close to  $p_3$ , falls abruptly. At the pump itself, all of the back-flow leaks and  $p_1$  drops radically. The behavior reverses as the flow is restored.

The piston position is directly proportional to  $p_3$ , where the hydraulic and spring forces balance. Discontinuities in the velocity at  $0.04 \text{ sec}$  and  $0.05 \text{ sec}$  indicate negligible mass. The model reaches a steady state when all of the pump flow again goes to leakage, now due to zero pressure drop across the control valve (which means  $p_3 = p_2 = p_1 = p_{10}$ ).

## Thermal Model of a House

This example shows how to use Simulink® to create the thermal model of a house. This system models the outdoor environment, the thermal characteristics of the house, and the house heating system.

The `sldemo_househeat_data.m` file initializes data in the model workspace. To make changes, you can edit the model workspace directly or edit the file and re-load the model workspace. To view the model workspace, from the Simulink Editor **Modeling** tab, click **Model Explorer**.

### Open Model

First, open the `sldemo_househeat` model.

### Initialize Model

This model calculates heating costs for a generic house. Opening the model loads the information about the house from the `sldemo_househeat_data.m` file. The file does the following:

- Defines the house geometry (size, number of windows)
- Specifies the thermal properties of house materials
- Calculates the thermal resistance of the house
- Provides the heater characteristics (temperature of the hot air, flow-rate)
- Defines the cost of electricity (0.09\$/kWhr)
- Specifies the initial room temperature (20 °C = 68 °F)

- **Note:** Time is given in units of hours. Certain quantities, like air flow-rate, are expressed per hour (not per second).

### Model Components

#### Set Point

The Set Point is a constant block. It specifies the temperature that must be maintained indoors. By default, it is 70 °F. Temperatures are given in °F. The model converts the temperature to °C.

#### Thermostat

The Thermostat subsystem contains a Relay block. The thermostat allows fluctuations of 5 °F above or below the desired room temperature. If air temperature drops below 65 °F, the thermostat turns on the heater.

Open the Thermostat subsystem.

Thermostat Subsystem

#### Heater

The Heater subsystem models a constant air flow rate,  $Mdot$ , which is specified in the `sldemo_househeat_data.m` file. The thermostat signal turns the heater on or off. When the heater is on, it blows hot air at temperature  $T_{heater}$  (50 °C = 122 °F by default) at a constant flow rate of  $Mdot$  (1kg/sec = 3600kg/hr by default). Equation 1 expresses the heat flow into the room.

#### Equation 1

$$\frac{dQ}{dt} = (T_{heater} - T_{room}) \cdot Mdot \cdot c$$

$$\frac{dQ}{dt} = \text{heat flow from the heater into the room}$$

$c$  = heat capacity of air at constant pressure

$Mdot$  = air mass flow rate through heater (kg/hr)

$T_{heater}$  = temperature of hot air from heater

$T_{room}$  = current room air temperature

Open the Heater subsystem.

### Cost Calculator

The Cost Calculator is a Gain block. Cost Calculator integrates the heat flow over time and multiplies it by the energy cost. The model plots the heating cost in the PlotResults scope.

### House

The House is a subsystem that calculates room temperature variations. It takes into consideration the heat flow from the heater and heat losses to the environment. Heat losses and the temperature time derivative are expressed by Equation 2.

### Equation 2

$$\left(\frac{dQ}{dt}\right)_{\text{losses}} = \frac{T_{\text{room}} - T_{\text{out}}}{R_{\text{eq}}}$$

$$\frac{dT_{\text{room}}}{dt} = \frac{1}{M_{\text{air}} \cdot c} \cdot \left(\frac{dQ_{\text{heater}}}{dt} - \frac{dQ_{\text{losses}}}{dt}\right)$$

$M_{\text{air}}$  = mass of air inside the house

$R_{\text{eq}}$  = equivalent thermal resistance of the house

Open the House subsystem.

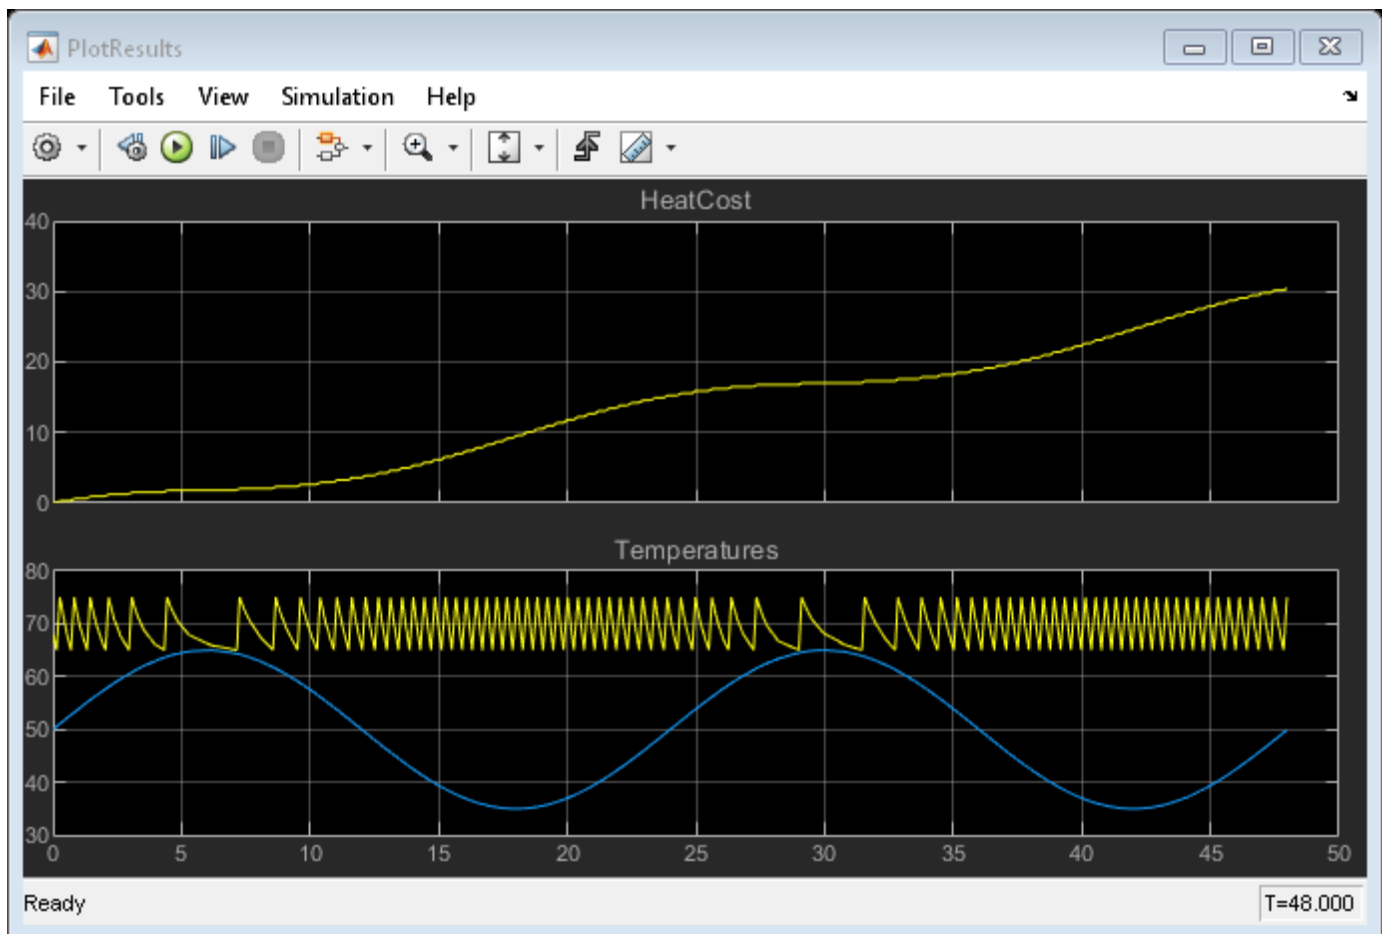

### Model the Environment

To simulate the environment, the model uses a heat sink with infinite heat capacity and time varying temperature,  $T_{out}$ . The constant block Avg Outdoor Temp specifies the average air temperature outdoors. The Daily Temp Variation Sine Wave block generates daily outdoor temperature fluctuations. You can vary these parameters and to see how they affect the heating costs.

### Run Simulation and Visualize Results

Run the simulation. Use the PlotResults scope to visualize the results. The scope plots the heat cost and indoor versus outdoor temperatures. The temperature outdoor varies sinusoidally. The indoors temperature remains within 5 °C of the Set Point. The Time axis is in hours.

According to this model, it would cost about \$30 to heat the house for two days. Try varying the parameters and observe the system response.

### Next Steps

This model calculates the heating costs only. If the temperature of the outside air is higher than the room temperature, the room temperature will exceed the desired Set Point.

You can modify this model to include an air conditioner. You can implement the air conditioner as a modified heater. To do this, add parameters like the following to `sldemo_househeat_data.m`.

- Cold air output
- Temperature of the stream from the air conditioner
- Air conditioner efficiency

To control both the air conditioner and the heater, modify the thermostat.

## Approximating Nonlinear Relationships: Type S Thermocouple

This example shows how to approximate nonlinear relationships of a type S thermocouple.

### Thermocouple Modeling and Signal Conversion

The thermocouple is one of the popular analog transducers today, along with other devices such as position sensors, strain gages, pressure transducers, and resistance temperature devices (RTDs). Operating under the principle of the Seebeck effect (a.k.a. thermoelectric effect), thermocouples have an empirically determined nonlinear behavior that is well known over each junction type's useful operating range. If you run the model, you will be able to see the cumulative effect of each component on dynamic measurement accuracy. This example will focus on models for each of these components in a dynamic temperature measurement system for a Type S (Platinum-10% Rhodium(+)) versus Platinum(-) : a thermocouple device and probe assembly, a signal conditioning method, an analog to digital converter (ADC), and a software specification for converting the ADC output into a temperature value. An additional section shows how to obtain and use standard NIST ITS-90 thermocouple data with Simulink® models. Look-up tables and a polynomial block are used in this design to capture the nonlinear behavior of the thermocouple. Note that the polynomial block is a viable alternative to look-up tables for some applications, minimizing ROM usage at the cost of some additional computation for the full polynomial representation.

```
open_system('sldemo_tc')
```

**Figure 1:** Temperature measurement system: a chain of components from physical phenomenon to software values

### Simulating the Thermocouple Signal

The two main features of the thermocouple model are the probe and bead dynamics and the thermocouple's conversion of temperature into a millivolt signal. The probe+bead dynamics are modeled as a 30 msec first order system, and the nonlinear thermocouple behavior is modeled using the segment 1 polynomial data from NIST Standard Database 60 for a Type S thermocouple from -50 to 1063 degC. For numerical stability, the coefficients were scaled to return microvolts from the polynomial block. The output of the 1 Type S Thermocouple model subsystem is then converted to volts with a Unit Conversion block. Note that units are specified on the subsystem input and output ports and displayed on the subsystem icons. To learn more about units, see "Unit Specification in Simulink Models".

An alternative implementation to using the polynomial is an interpolated look-up table. Table data could be used in a look-up table block in place of the polynomial block. Sample data was constructed from NIST Standard Database 60 for a Type S thermocouple in file `sldemo_create_tc_tabledata.m`. Access to this database is described below in the section titled "Thermocouple Reference Data Download and Import Procedure".

### **Anti-Aliasing Filter and Analog to Digital Converter (ADC) Models**

The ADC in this model expects a 0 to 5 volt signal, so the raw thermocouple sense voltage is biased and amplified corresponding to a range of -0.235 mV to 18.661 mV (-50 degC to 1765 degC). A third order Butterworth anti-aliasing filter was designed for  $W_n = 15$  Hz using the Signal Processing Toolbox™:

```
[num,den] = butter(3, 15*2*pi, 'low', 's')
```

The output of the anti-aliasing filter feeds a sample-and-hold device that drives the quantization model. Since the sample period is 20 msec in this example, the conversion time is ignored as it is typically 2 orders of magnitude smaller for devices currently available. (Note: if the conversion time were an appreciable fraction of the sample period, it could not be ignored as it would significantly affect the system's dynamics.)

The quantization algorithm in the model takes in a 0 to 5 volt signal and outputs a 12-bit digital word in a 16-bit signed integer. A value of 0 corresponds to 0 Volts and a value of 4096 would correspond to 5 Volts. A change in the least significant bit (LSB) is about 1.2 mV. As 12 bits can only reach the value of 4095, the highest voltage that can be read by this device is approximately 4.9988 Volts. In order to have no more than 1/2 LSB error within the operating range, the quantizer changes values midway between each voltage point, resulting in a 1/2-width interval at 0 Volts and a 3/2-width interval just below 5 Volts. The last interval has 1 full LSB due to its 3/2-width size.

### **Understanding Data Converters**

The `sldemo_adc_quantize` model allows you to explore the A/D converter component in more detail:

```
open_system('sldemo_adc_quantize')
```

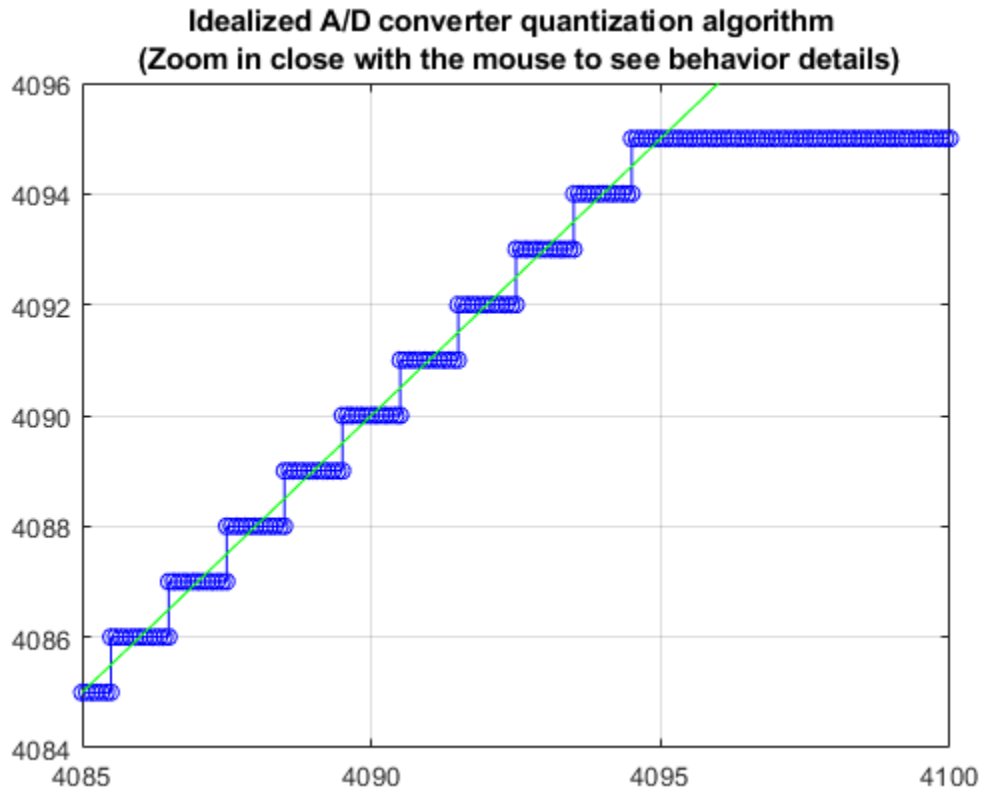

**Figure 2:** Details of ADC quantization modeling (zero conversion time)

```
sim('sldemo_adc_quantize')
set(gcf, 'Color', [1, 1, 1]);
```

**Figure 3:** Quantization characteristic of ADC

```
ax = get(gcf, 'Children');
set(ax(1), 'xlim', [4085, 4100]);
```

**Figure 4:** Quantization characteristic of ADC: zoomed in to top of range to reveal 1 LSB error behavior at high end (rest of range only has 1/2 LSB max error)

### Software Specification for Converting ADC Output to Temperature Values

The input conversion subsystem requires a 16 bit unsigned integer input from the ADC whose full scale range is 0 to 4095 counts, corresponding to -0.235 mV and 18.6564 mV thermocouple loop voltage. The best accuracy and fastest algorithm for input conversion is a direct look-up table. Since the input is an integer from 0 to 4095, a table can be constructed that gives the thermocouple temperature corresponding to each possible input value, so the conversion process can be reduced to indexing into a table. This however, requires one number per ADC output value and for a 12-bit ADC, this can be a burden in memory constrained environments. For double precision data, this is a 16 kB ROM requirement. See file `sldemo_create_tc_tabledata.m` for the method used to construct the direct look-up table from the Type S thermocouple reference data. The error associated with this approach is entirely isolated to the table construction process as there is an output value associated with every possible input value - the run-time look-up process introduces no additional error.

An interpolated table was also put into the model, using only 664 bytes. This is a big reduction in ROM required compared to the direct table look-up, but it takes a bit longer to compute than an indirect memory access and introduces error into the measurement, which goes down as the number of points in the table increases.

```
open_system(sprintf('sldemo_tc/3 Software specification\nfor converting\nADC values to temperatur
```

**Input: 0 to 4095 integer "counts" , where**  
**0 counts corresponds to 0 input volts and -0.236 thermocouple millivolts**  
**4096 counts corresponds to 5 input volts and 18.661 thermocouple millivolts**

**Tables derived from ITS-90 thermocouple reference data from NIST Standard Database 60 related to NIST Monograph 175 (ITS-90).**

### Thermocouple Reference Data Download and Import Procedure

Using the NIST ITS-90 Thermocouple Database (Standard Reference Database 60 from NIST Monograph 175), you can access the standard reference data describing the behavior for the eight standard thermocouple types. This database relates thermocouple output to the International Temperature Scale of 1990. Follow these steps to acquire and read in the data needed to fully exercise the support files included with this example:

1. Visit the NIST Standard database 60 site on the Internet and download the file all.tab to a local directory. This file is the one under the All Thermocouple Types hyperlink. After the download is complete, return to this page.
2. cd to the directory where you downloaded the all.tab thermocouple database
3. Parse the database and convert it to a MATLAB structure array using the conversion tool readstdtcdata.m:

```
tdata = readstdtcdata('all.tab');
save thermocouple_its90.mat tdata;
```

(tip: highlight the above MATLAB code and use right mouse menuitem "Evaluate Selection" to execute it)

You now have a complete set of temperature (T, degC) vs. voltage (E, mV) data, approximating polynomial coefficients, and inverse polynomial coefficients for the standard thermocouple types B, E, J, K, N, R, S, and T in the tdata variable of file thermocouple\_its90.mat. The MATLAB script in sldemo\_create\_tc\_tabledata.m uses this data to prepare lookup table block parameters used in the example model.

### Conditioning Reference Data for Use in a Look-Up Table

If you review the thermocouple data tables in the `tcdata` structure or in `all.tab`, you will probably notice a few things:

- Repeated 0 degC temperature points in the data
- Repeated voltage points in the data due to the 3-digit output format
- Non-monotonic behavior with two temperatures having the same output, e.g., for the Type B thermocouple,  $T(E)$  won't work but  $E(T)$  does work

The `readstdtcdata()` routine will remove the repeated 0 degC temperature points from the data, but the repeated voltages due to the data format and non-monotonic behavior of some of the curve ends must be dealt with on an individual basis. A reference model named `sldemo_tc_blocks` was constructed using `sldemo_tc_blocks_data.mat`. It contains look-up tables with data populated from the interpolating polynomials for the eight standard thermocouples in `all.tab`:

```
open_system('sldemo_tc_blocks')
```

### Full-Range 2 degrees Celsius Interpolated Thermocouple Tables created from ITS-90 Interpolating Polynomials

**Note: this model has data in its Model Workspace.**

**Browse/Edit the model workspace from the View / Model Explorer menu item.**

**To use these blocks, load data into the model workspace or base workspace:**

```
>> load sldemo_tc_blocks_data.mat
```

Copyright 1990-2013 The MathWorks, Inc.

## Digital Waveform Generation: Approximating a Sine Wave

This example shows some of the main steps needed to design and evaluate a sine wave data table for use in digital waveform synthesis applications in embedded systems and arbitrary waveform generation instruments.

Real-Time direct digital synthesis of analog waveforms using embedded processors and digital signal processors (DSPs) connected to digital-to-analog converters (DACs) is becoming pervasive even in the smallest systems. Developing waveforms for use in embedded systems or laboratory instruments can be streamlined using the tight integration of MATLAB® and Simulink®. You can develop and analyze the waveform generation algorithm and its associated data at your desktop before implementing it with Simulink® Coder™ on target hardware.

When feasible, the most accurate way to digitally synthesize a sine wave is to compute the full precision  $\sin()$  function directly for each time step, folding  $\omega t$  into the interval 0 to  $2\pi$ . In real-time systems, the computational burden is typically too large to permit this approach. One popular way around this obstacle is to use a table of values to approximate the behavior of the  $\sin()$  function, either from 0 to  $2\pi$ , or even half wave or quarter wave data to leverage symmetry.

Tradeoffs to consider include algorithm efficiency, data ROM size required, and accuracy/spectral purity of the implementation. Similar analysis is needed when performing your own waveform designs. The table data and look-up algorithm alone do not determine performance in the field. Additional considerations such as the accuracy and stability of the real-time clock, and digital to analog converter are also needed in order to assess overall performance. The Signal Processing Toolbox™ and the DSP System Toolbox™ complement the capabilities of MATLAB and Simulink for work in this area.

Another popular way to approximate the behavior of the sine wave is to use the CORDIC approximation method. CORDIC is an acronym for COordinate Rotation DIGital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms because it requires only shift-add iterative operations.

If you have a Fixed-Point Designer license, then you can see “Compute Sine and Cosine Using CORDIC Rotation Kernel” (Fixed-Point Designer) for an example on CORDIC approximation.

The distortion analysis in this example is based on principles presented in "Digital Sine-Wave Synthesis Using the DSP56001/DSP56002", by Andreas Chrysafis, Motorola® Inc. 1988

### Create a Table in Double Precision Floating Point

The following commands make a 256 point sine wave and measure its total harmonic distortion when sampled first on the points and then by jumping with a delta of 2.5 points per step using linear interpolation. Similar computations are done by replacing the sine values with CORDIC sine approximation. For frequency-based applications, spectral purity can be more important than absolute error in the table.

The file `ssinthd.m` is the core function in this example. It is used for calculating total harmonic distortion (THD) for digital sine wave generation with or without interpolation. This THD algorithm proceeds over an integral number of waves to achieve accurate results. The number of wave cycles used is  $A$ . Since the step size 'delta' is  $A/B$  and traversing  $A$  waves will hit all points in the table at least one time, which is needed to accurately find the average THD across a full cycle.

The relationship used to calculate THD is:

$$\text{THD} = (\text{ET} - \text{EF}) / \text{ET}$$

where ET = total energy, and EF = fundamental energy

The energy difference between ET and EF is spurious energy.

```
N = 256;
angle = 2*pi * (0:(N-1))/N;

s = sin(angle)';
thd_ref_1 = ssinthd(s, 1, N, 1, 'direct')
thd_ref_2p5 = ssinthd(s, 5/2, 2*N, 5, 'linear')

cs = cordicsin(angle, 50)';
thd_ref_1c = ssinthd(cs, 1, N, 1, 'direct')
thd_ref_2p5c = ssinthd(cs, 5/2, 2*N, 5, 'linear')
```

```
thd_ref_1 =
 4.8049e-32
```

```
thd_ref_2p5 =
 1.4176e-09
```

```
thd_ref_1c =
 1.2577e-30
```

```
thd_ref_2p5c =
 1.4176e-09
```

### Put the Sine Wave Approximations in a Model

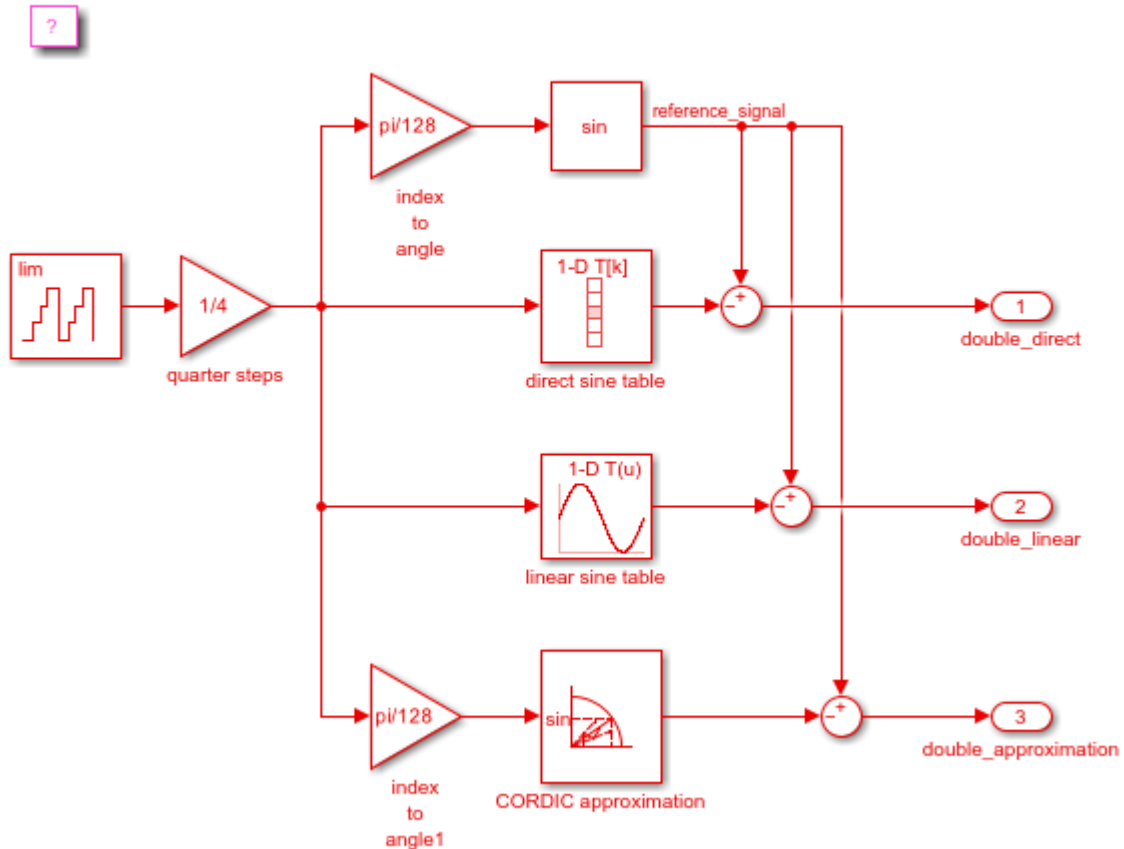

You can put the sine wave designed above into a Simulink model and see how it works as a direct lookup, with linear interpolation, and with CORDIC approximation. This model compares the output of the floating point tables to the `sin()` function. As expected from the THD calculations, the linear interpolation has a lower error than the direct table lookup in comparison to the `sin()` function. The CORDIC approximation shows a lower error margin when compared to the linear interpolation method. This margin depends on the number of iterations when computing the CORDIC sin approximation. You can typically achieve greater accuracy by increasing the number of iterations (corresponding to a longer computation time). The CORDIC approximation eliminates the need for explicit multipliers. It is used when multipliers are less efficient or non-existent in hardware.

Open the `sldemo_tonegen` model

```
open_system('sldemo_tonegen');
set_param('sldemo_tonegen', 'StopFcn', '');
out = sim('sldemo_tonegen');
currentFig = figure('Color',[1,1,1]);
subplot(3,1,1), plot(out.tonegenOut.time, out.tonegenOut.signals(1).values); grid
title({'Difference between direct look-up', 'and reference signal'});
```

```
subplot(3,1,2), plot(out.tonegenOut.time, out.tonegenOut.signals(2).values); grid
title({'Difference between interpolated look-up', 'and reference signal'});
subplot(3,1,3), plot(out.tonegenOut.time, out.tonegenOut.signals(3).values); grid
title({'Difference between CORDIC sine', 'and reference signal'});
```

### Comparison in approximate sine wave accuracy between direct look-up, linear interpolation and CORDIC approximation vs. reference signal

Copyright 1990-2013 The MathWorks, Inc.

### Taking a Closer Look at Waveform Accuracy

Zooming in on the signals between 4.8 and 5.2 seconds of simulation time (for example), you can see a different characteristic due to the different algorithms used:

```
ax = get(currentFig, 'Children');
set(ax(3), 'xlim', [4.8, 5.2])
set(ax(2), 'xlim', [4.8, 5.2])
set(ax(1), 'xlim', [4.8, 5.2])
```

### The Same Table, Implemented in Fixed Point

Now convert the floating point table into a 24 bit fractional number using 'nearest' rounding. The new table is tested for total harmonic distortion in direct lookup mode at 1, 2, and 3 points per step, then with fixed point linear interpolation.

```
bits = 24;
is = num2fixpt(s, sfrac(bits), [], 'Nearest', 'on');

thd_direct1 = ssinthd(is, 1, N, 1, 'direct')
thd_direct2 = ssinthd(is, 2, N, 2, 'direct')
thd_direct3 = ssinthd(is, 3, N, 3, 'direct')

thd_linterp_2p5 = ssinthd(is, 5/2, 2*N, 5, 'fixptlinear')

thd_direct1 =
 2.6423e-15

thd_direct2 =
 2.8660e-15

thd_direct3 =
```

```
2.6423e-15

thd_linterp_2p5 =
1.4175e-09
```

### Compare Results for Different Tables and Methods

Choosing a table step rate of 8.25 points per step (33/4), jump through the double precision and fixed point tables in both direct and linear modes and compare distortion results:

```
thd_double_direct = ssinthd(s, 33/4, 4*N, 33, 'direct')
thd_sfrac24_direct = ssinthd(is, 33/4, 4*N, 33, 'direct')

thd_double_linear = ssinthd(s, 33/4, 4*N, 33, 'linear')
thd_sfrac24_linear = ssinthd(is, 33/4, 4*N, 33, 'fixptlinear')
```

```
thd_double_direct =
4.7061e-05
```

```
thd_sfrac24_direct =
4.7061e-05
```

```
thd_double_linear =
7.9741e-10
```

```
thd_sfrac24_linear =
8.1751e-10
```

### Using Preconfigured Sine Wave Blocks

Simulink also includes a Sine Wave source block with continuous and discrete modes, plus fixed point Sin and Cosine function blocks that implement the function approximation with a linearly interpolated lookup table that exploits the quarter wave symmetry of sine and cosine. Example `sldemo_tonegen_fixpt` uses a sampled sine wave source as the reference signal and compares it with a lookup table with or without interpolation, and with CORDIC sine approximation in fixed point data types.

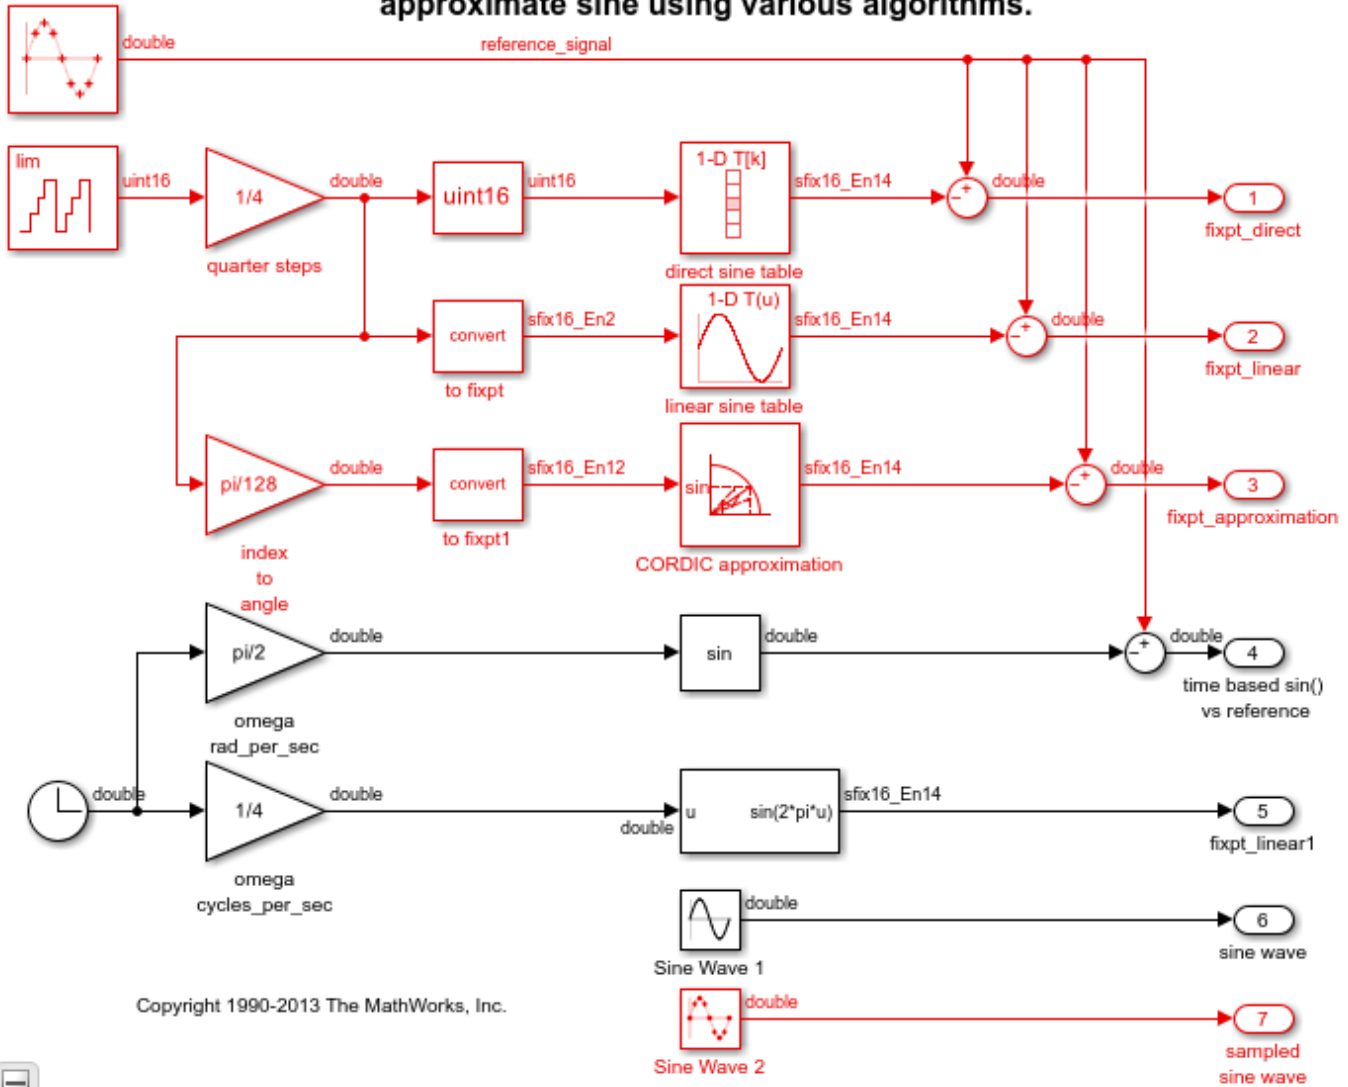

Open the `sldemo_tonegen_fixpt` model

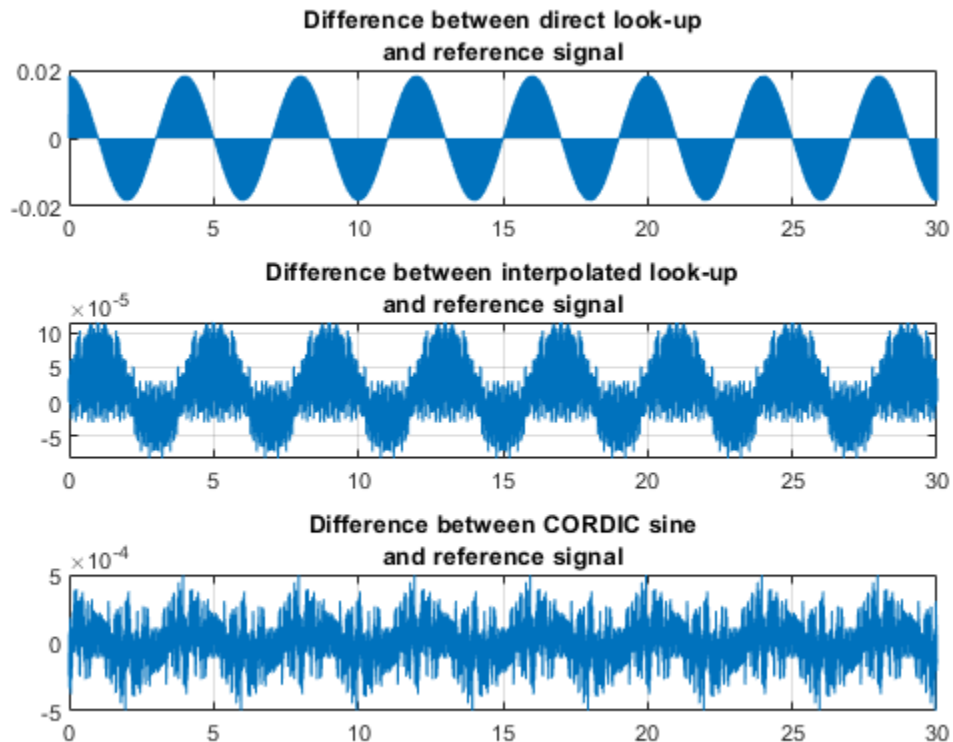

```
open_system('sldemo_tonegen_fixpt');
set_param('sldemo_tonegen_fixpt', 'StopFcn', '');
out = sim('sldemo_tonegen_fixpt');
figure('Color', [1,1,1]);
subplot(3,1,1), plot(out.tonegenOut.time, out.tonegenOut.signals(1).values); grid
title({'Difference between direct look-up', 'and reference signal'});
subplot(3,1,2), plot(out.tonegenOut.time, out.tonegenOut.signals(2).values); grid
```

```
title({'Difference between interpolated look-up', 'and reference signal'});
subplot(3,1,3), plot(out.tonegenOut.time, out.tonegenOut.signals(3).values); grid
title({'Difference between CORDIC sine', 'and reference signal'});
```

**Additional blocks to calculate sine and approximate sine using various algorithms.**

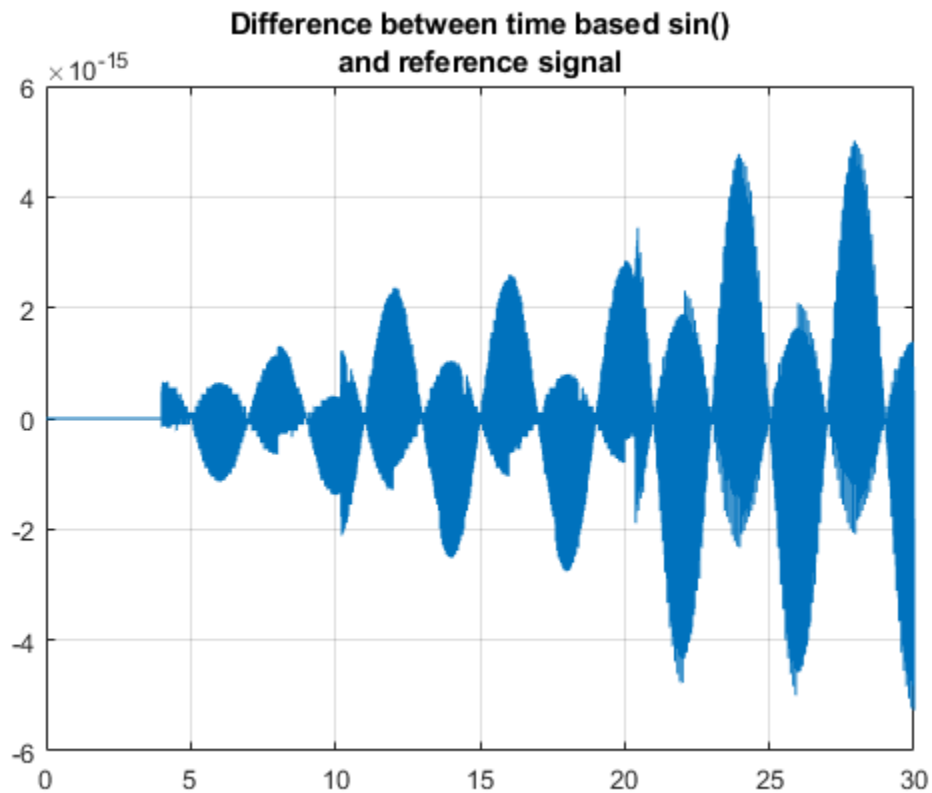

### Use of Sine Function with a Clock Input

The model also compares the sine wave source reference with the `sin()` function whose input angle in radians is time based (computed using a clock). This section tests the assumption that the clock input would return repeatable results from the `sin()` function for period  $2\pi$ . The following plot shows that the `sin()` function accumulates error when its input is time based. This also shows that a sampled sine wave source is more accurate to use as a waveform generator.

```
subplot(1,1,1), plot(out.tonegenOut.time, out.tonegenOut.signals(4).values); grid
title({'Difference between time based sin()', 'and reference signal'});
```

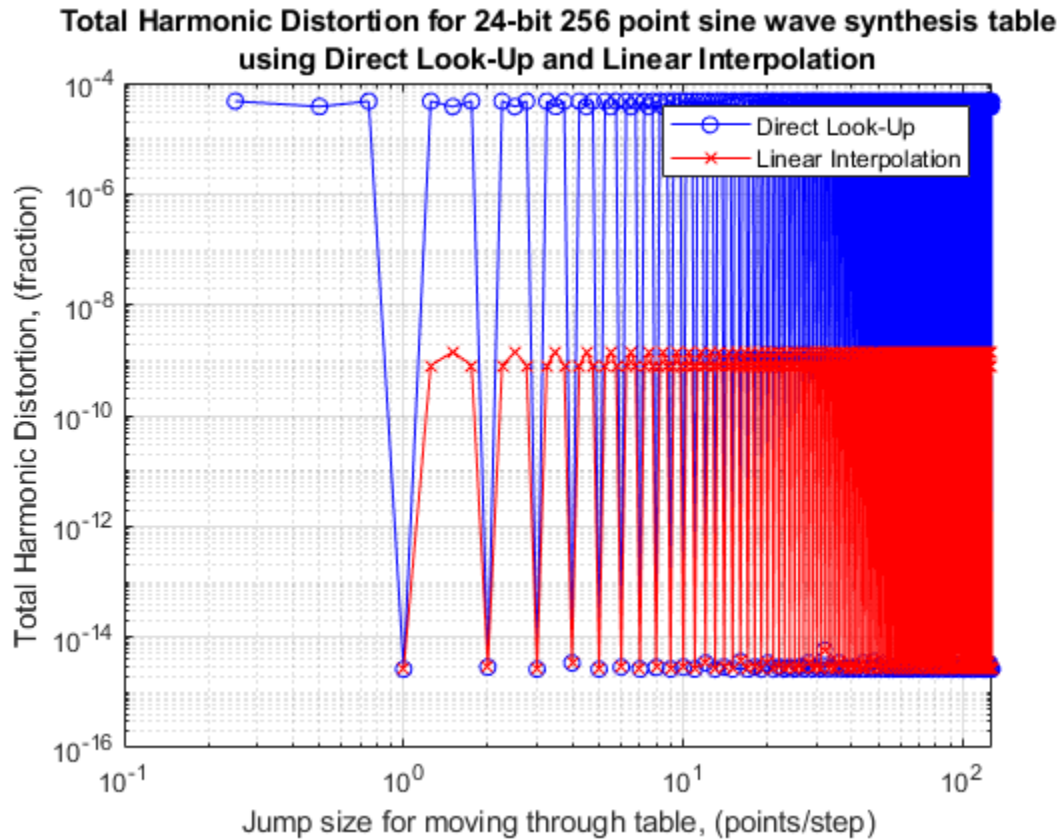

### Survey of Behavior for Direct Lookup and Linear Interpolation

The file `sldemo_sweeptable_thd.m` performs a full frequency sweep of the fixed point tables and will let us more thoroughly understand the behavior of this design. Total harmonic distortion of the 24-bit fractional fixed point table is measured at each step size, moving through it  $D$  points at a time, where  $D$  is a number from 1 to  $N/2$ , incrementing by 0.25 points.  $N$  is 256 points in this example; the 1, 2, 2.5, and 3 cases were done above. Frequency is discrete and therefore a function of the sample rate.

Notice the modes of the distortion behavior in the plot. They match with common sense: when retrieving from the table precisely at a point, the error is smallest; linear interpolation has a smaller error than direct lookup in between points. What is not intuitive is that the error is relatively constant for each of the modes up to the Nyquist frequency.

```
figure('Color',[1,1,1])
tic, sldemo_sweeptable_thd(24, 256), toc
```

Elapsed time is 1.121240 seconds.

### Next Steps

To take this example further, try different table precision and element counts to see the effect of each. Using CORDIC approximation, try different numbers of iterations to see the effects on accuracy and computation time. You can investigate different implementation options for waveform synthesis algorithms using automatic code generation available from the Simulink Coder and production code generation using Embedded Coder™. Embedded Target products offer direct connections to a variety of real-time processors and DSPs, including connection back to the Simulink diagram while the target is running in real-time. The Signal Processing Toolbox and DSP System Toolbox offer prepackaged capabilities for designing and implementing a wide variety of sample-based and frame-based signal processing systems with MATLAB and Simulink.

```
bdclose('sldemo_tonegen');
bdclose('sldemo_tonegen_fixpt')
```

## Use Model Reference with Local Solver in DC Motor

This example shows how to use local solvers to improve simulation performance in a DC motor with a mechanical load.

The subcomponents of a complex dynamic system often have different frequencies and time scales. For such systems, simulation speed can be accelerated by partitioning the model into different components and applying different solvers to components. Model reference with a local solver supports this approach by allowing the model reference with its own local solver to be referenced in a top model with a different solver.

### Analysis and Physics of the Model

In this DC motor model, torque is generated when an armature current flows through the armature coil. The torque is proportional to the armature current and the strength of the magnetic field of the motor. For a simple DC motor, you can assume that the magnetic field is constant and derive these equations [1] on page 13-50.

Torque  $T$  generated, where  $K_T$  is the motor torque constant and  $i$  is the armature current:

$$T = K_T i$$

Electro magnetic field  $e$  generated, where  $K_e$  is the motor voltage constant and  $\theta$  is the angle of the armature/load:

$$e = K_e \frac{d\theta}{dt}$$

The DC motor is composed of two subcomponents:

- The electrical part, where  $L$  is the inductance and  $R$  is the resistance of the armature coil:

$$v = Ri + L \frac{di}{dt} + e = Ri + L \frac{di}{dt} + K \frac{d\theta}{dt}$$

- The mechanical part, where  $J$  is the total moment of inertia of the motor armature plus load:

$$J \frac{d^2\theta}{dt^2} = T - b \frac{d\theta}{dt} = K i - b \frac{d\theta}{dt}$$

These two subcomponents are coupled through two states variables, current  $i$  and the angular speed  $\frac{d\theta}{dt}$ .

The mechanical time constant can be approximated by assuming  $b = 0$ .

$$t_m = \frac{RJ}{K_e K_T}$$

The electrical time constant is

$$t_e = \frac{L}{R}$$

### Model Parameters and Time Constant

Assume these values for the parameters used in this example.

Parameter	Value	Unit
$K_t$	0.025	Nm/A
$K_e$	0.025	V/rad/s
$R$	3	Ohm
$L$	$2.5e-6$	H
$J$	$3.2e-6$	Nms <sup>2</sup>
$b$	$3.5e-6$	Nm/rad

Thus,  $t_m = \frac{RJ}{K_e K_t} = 0.0154$  s; and  $t_e = \frac{L}{R} = 8.33e-07$ s.

If you use only one solver used to simulate this model, the step size required should be small enough to catch the electrical time constant. Assume a step size of  $t_s = 2e-7$ .

The time constant of two subcomponents of the model is quite different. Thus, local solver of model reference can be used to accelerate the model.

### DC Model Using Model Reference

Based on the time constant analysis, you can partition the DC model into two components. Group the electrical part into a virtual subsystem so that it can be solved with the top solver. Group the mechanical part into a model reference so it can be solved with top solver or with the local solver. The DC motor is shown in this Simulink model.

Partition the overall model into mechanical and electrical part and load the top model.

```
topModel = 'DCMotor_localsolver';
bottomModel = 'DCMotor_Mechanical';
```

```
open_system(topModel)
load_system(bottomModel)
```

### Simulation

Use a global solver with the small step size of  $2e-7$  to simulate the model, then use this result as the baseline. Compute the time constants of the two components and use them to select the solver step size.

Calculate the electrical and mechanical system time constants  $T_m$  and  $T_e$ , respectively. Calculate the time constant ratio that can be used to select the local solver step size. Also compute the global solver step based on time constant. Generally, you can calculate step size by dividing the time constant by 5.

```
Tm = R*J/Ke/Kt;
Te = L/R;
```

```
timeConstantRatio = Tm/Te;
```

```
topStep = 2E-7;
localStep = topStep*10000;
```

Simulate the entire model with the top solver.

```
set_param(topModel, 'Solver', 'ode3', 'fixedStep', num2str(topStep));
set_param(bottomModel, 'UseModelRefSolver', 'off');
```

```
sim(topModel);
y1 = yout.signals.values;
```

Now, enable the local solver of the model reference that models the mechanical part of the model. Since the mechanical part has a much larger time constant than the electrical part, the step size of the local solver can be much larger than the global solver. Set the value to 2e-3.

Simulate the model with two solvers. For the top, use an ode3 solver of step size 2e-7. For the local, use an ode3 solver of step size 2e-2. When using a local solver, use zero-order hold (ZOH) data handling at the input and output of the model reference. The local solver parameters can be accessed through the solver tab of the Property Inspector of the model reference.

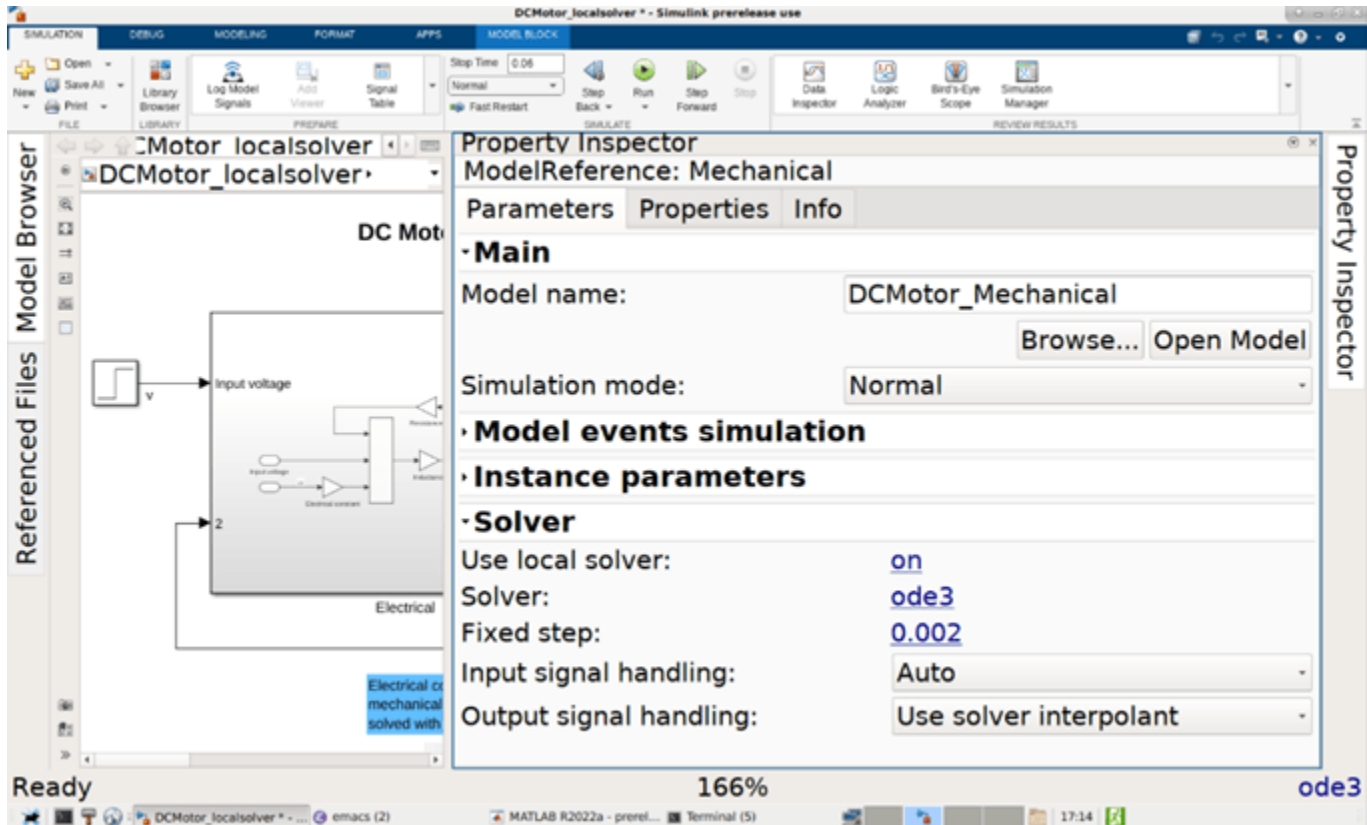

```
set_param(topModel, 'Solver', 'ode3', 'fixedStep', num2str(topStep));
set_param(bottomModel, 'UseModelRefSolver', 'on');
set_param(bottomModel, 'Solver', 'ode3', 'fixedstep', num2str(localStep));
```

Set the instance-based parameters.

```
mechanical = [topModel '/Mechanical'];
set_param(mechanical, 'InputSignalHandling', 'Zero-order hold');
set_param(mechanical, 'OutputSignalHandling', 'Zero-order hold');
```

```
sim(topModel);
y2 = yout.signals.values;
```

For **Input Signal Handling**, select 'auto' option. For **Output Signal Handling**, select 'use solver interpolant'. Finally, simulate the model with local fixed-step solver plus data exchange.

```
set_param(topModel, 'Solver', 'ode3', 'fixedStep', num2str(topStep));
set_param(bottomModel, 'UseModelRefSolver', 'on');
set_param(bottomModel, 'Solver', 'ode3', 'fixedstep', num2str(localStep));
```

```
mechanical = [topModel '/Mechanical'];
set_param(mechanical, 'InputSignalHandling', 'Auto');
set_param(mechanical, 'OutputSignalHandling', 'Use solver interpolant');
sim(topModel);
```

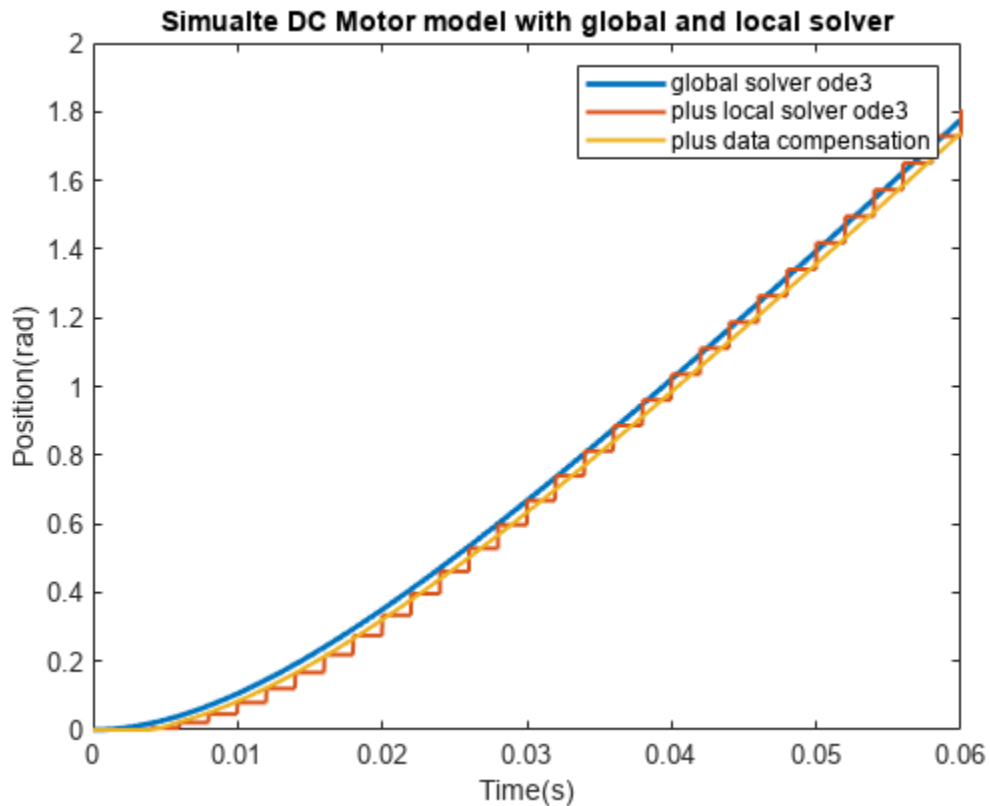

```
sim(topModel);
y3 = yout.signals.values;
```

## Results

This plot compares three simulation results. The figure shows the position step response of the DC motor when voltage is applied to the terminal and the motor starts to rotate. The smooth blue curve is the baseline. The orange step curve shows the result of using local solver and ZOH input output data handling. This strategy samples the input and output of the mechanical component with a sample rate of  $2e-3$ , and the local solver integrates its states with this step size. This strategy works well in this example as the result generated is fairly close to the baseline performance. The local solver using 'Auto' and 'Use solver interpolant' is the yellow curve. Compared to the ZOH strategy, this simulation result is even better. The orange line is smoother and closer to the baseline.

```
figure();
plot(tout, y1, 'LineWidth', 2); hold on;
```

```
plot(tout,y2,'LineWidth',1.5);hold on;
plot(tout,y3,'LineWidth',1.5);hold on;
legend('global solver ode3', 'plus local solver ode3', 'plus data compensation');
title('Simualte DC Motor model with global and local solver');
xlabel('Time(s)');
ylabel('Position(rad)');
```

## Accurate Zero-Crossing Detection

This example shows how zero crossings work in Simulink®. In this model, three shifted sine waves are fed into an absolute value block and saturation block. At exactly  $t = 5$ , the output of the switch block changes from the absolute value to the saturation block. Zero crossings in Simulink will automatically detect exactly when the switch block changes its output, and the solver will step to the exact time that the event happens. This can be seen by examining the output in the scope.

## Spiral Galaxy Formation Simulation Using MATLAB Function Blocks

This model was inspired by the classic paper "Galactic Bridges and Tails" (Toomre & Toomre 1972). The original paper explained how disc shaped galaxies could develop spiral arms. Two disc shape galaxies originally are far apart. They then fly by each other and almost collide. Once the galaxies are close enough, mutual gravitational forces cause spiral arms to form.

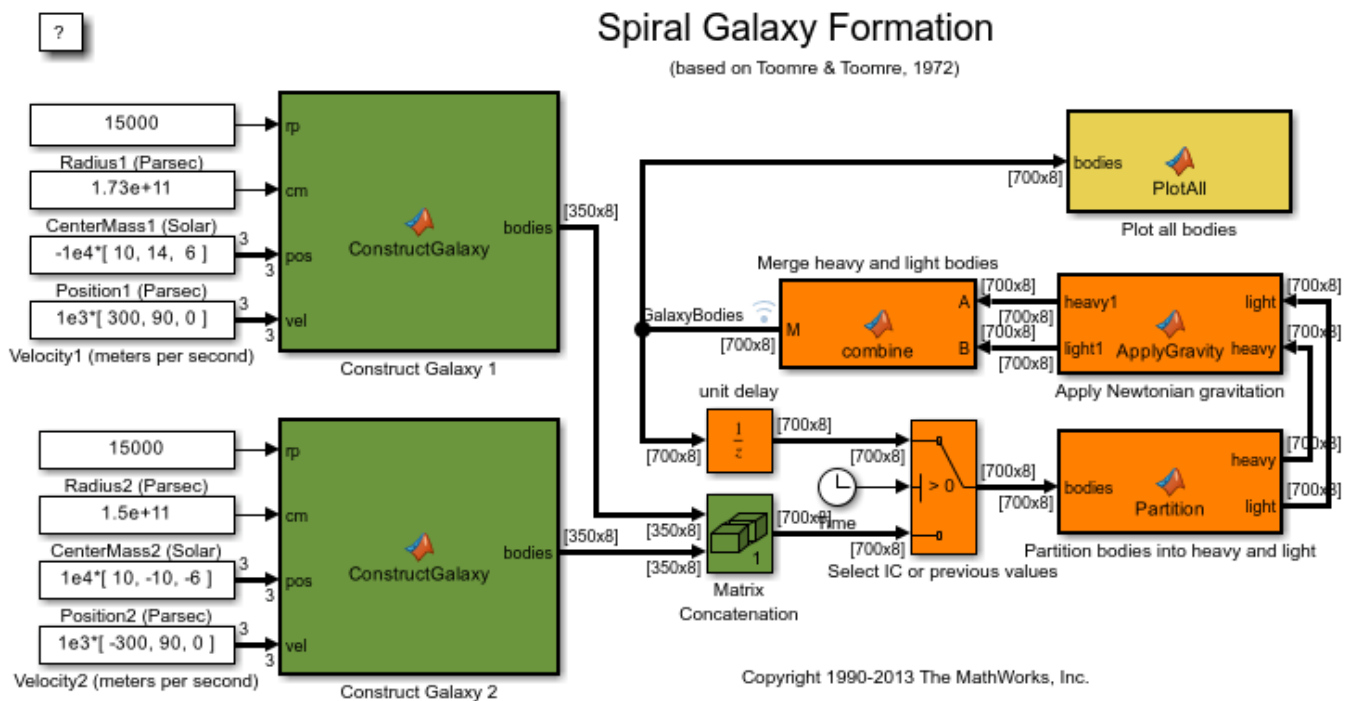

Except for the "PlotAll" visualization block's use of plotting routines, all MATLAB® function blocks in this model support code generation with Simulink® Coder™ and Embedded Coder™.

- Requirements:** For this example, Simulink® generates code for the simulation in a Simulink project directory created in the current working directory (pwd). If you do not want to affect the current directory (or if you cannot generate files in this directory), you should change your working directory.

### Opening the Model and Running the Simulation

Open the model and run the simulation by executing the code below. If you are using MATLAB® Help, select the code you want to execute and press F9 (or select code, right click on selection and select "Evaluate Selection"). The Simulink model will load, compile, and run.

```
model = 'sldemo_eml_galaxy';
open_system(model);
sim(model);
```

### **Model Description**

This section describes the model in detail and explains the role of each block in the model. The green blocks initialize the simulation, the orange blocks are the core of the simulation, and the yellow block makes the galaxy animation view.

### **Initial Conditions**

The model requires initial conditions for each galaxy. The initial conditions are: galaxy radius in parsecs (rp), galaxy mass in solar mass units (cm), galaxy position in parsecs (pos), and galaxy velocity in m/s (vel).

In the model, constant blocks specify the initial conditions. The initial conditions have been chosen such that the galaxies will nearly collide at some point in time.

### **"ConstructGalaxy" Blocks**

The initial conditions are passed to the MATLAB function blocks Construct Galaxy 1 and Construct Galaxy 2. These MATLAB function blocks contain MATLAB code that builds the galaxy models.

In a typical galaxy, most of the mass is concentrated in its center as a super-massive black hole and/or star agglomeration. We model the galaxy as a disc with radius  $r$  with most of its mass concentrated in the inner circle of radius  $r/3$ . In addition to this super-massive nucleus, the "ConstructGalaxy" MATLAB function block creates 349 random stars with masses ranging from 4 to 24 solar masses. These stars are randomly positioned within distance  $r/3$  and  $r$  from the center of the galaxy. The stars initially move in circular orbits around the galaxy core. Every object (star or galaxy core) has mass, position  $(x, y, z)$ , and velocity  $(V_x, V_y, V_z)$ .

### "Matrix Concatenation" Block

This block joins information about both galaxies. At this point the model has 700 objects: 1 core for each galaxy and 349 stars around each core. These 700 objects interact according to Newtonian mechanics.

### "Partition" Block

This MATLAB function block separates all 700 objects into two groups: heavy bodies and light bodies. The heavy bodies are the galaxy cores. The light bodies are the stars. Because the galaxy cores are much heavier than individual stars, the model will consider only the heavy-heavy and heavy-light interactions. We can ignore the light-light body interactions. This will save a lot of time since 698 out of 700 bodies in the model are light.

### "ApplyGravity" Block

This MATLAB function block uses Newtonian mechanics to compute the velocities and positions of the bodies at each step. The "combine" block is also a MATLAB function block. It merges the data about heavy and light objects together.

### "PlotAll" Block

This MATLAB function block plots the bodies in a figure and updates the position of each star at every step in the simulation.

### Closing the Model

Close the model without saving any changes. Clear data generated by simulation/example.

```
close_system(model,0);
clear model sldemo_eml_galaxy_output;
```

### Note:

- In this model, signal logging is turned on (observe that the 'GalaxyBodies' signal has a little blue signal logging antenna on it). The model saves output data in a `Dataset` object. Any other data is saved/modified in the model workspace to avoid cluttering the MATLAB workspace.
- To modify signal logging settings, right-click on the signal line and select "Signal Properties". In this example, the signal name is 'GalaxyBodies' and the "Log signal data" checkbox is checked.
- The logged data is saved to the MATLAB workspace as a `Dataset` object with the name 'sldemo\_eml\_galaxy\_output'. Information on the 'GalaxyBodies' signal can be retrieved from this object by typing `sldemo_eml_galaxy_output.get('GalaxyBodies')` which returns a `Simulink.SimulationData.Signal` object. See more about working with these objects in the "Simulink.SimulationData.Signal" documentation.

### Comments About the Model

Despite its simplicity, this model provides insight into how our own galaxy evolved. This example allows the user to maximally simplify the model and run a fast simulation. The user can easily modify this example by adding more galaxies.

## Counters Using Conditionally Executed Subsystems

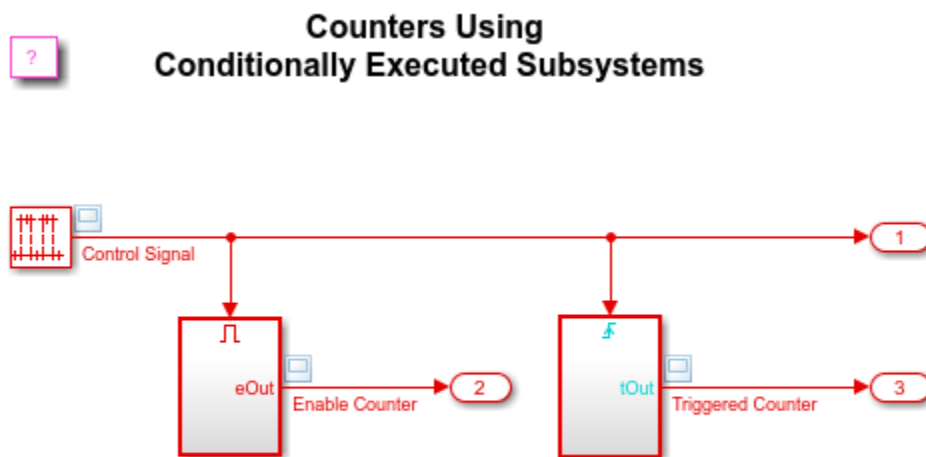

This model shows the contrast between enabled subsystems and triggered subsystems for the same control signal, through the use of counter circuits. After running the simulation, the scope shows three plots.

The first of these plots shows the control signal which is the output of the discrete pulse generator.

The second plot shows the output of the counter circuit in the enabled subsystem. The counter increments while the subsystem is enabled and then holds its output when the subsystem is disabled. The counter resets to zero when the subsystem is re-enabled because the enable port was configured to reset states when enabling.

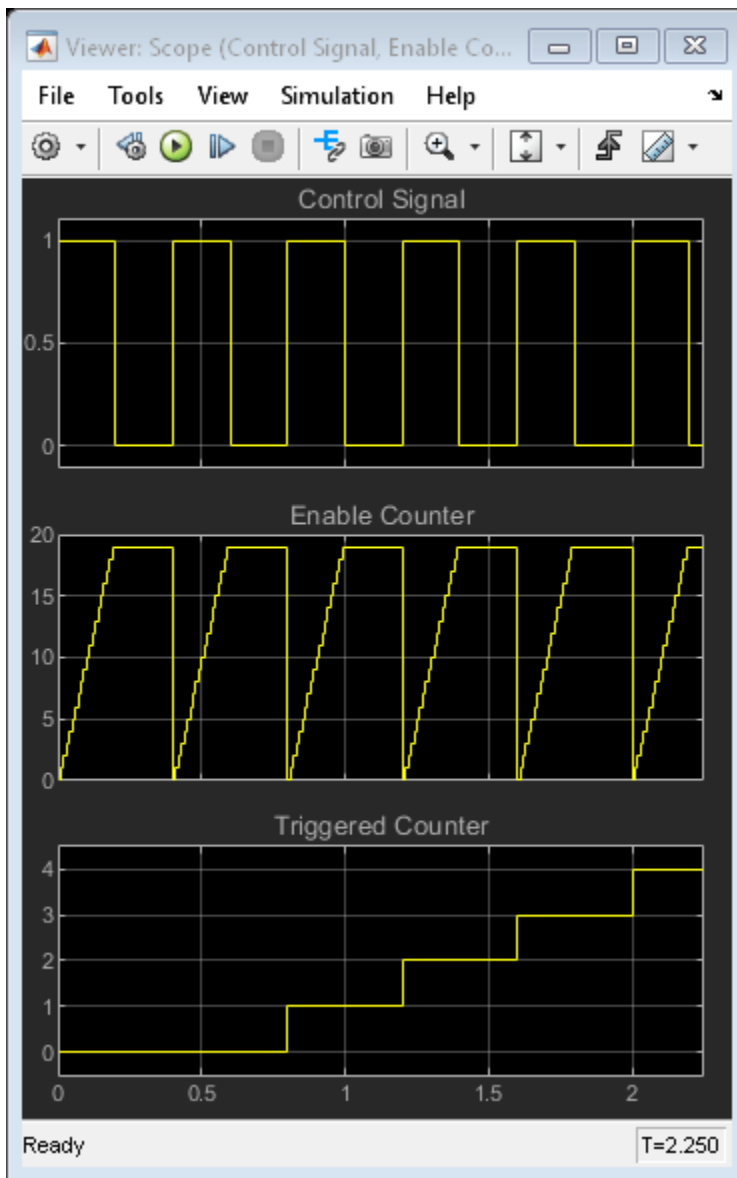

The third plot shows the output of the counter circuit in the triggered subsystem. The counter increments every rising edge of the control signal.

The signals are shown in a Signal Viewer scope that does not require a scope block to be put into the block diagram. Instead, the "scope" icon notation on the ports show that a Signal Viewer is attached. Double click on the scope icon to make the Signal Viewer appear if it is hidden.

## Simulating Systems with Variable Transport Delay Phenomena

This example shows two cases where you can use Simulink® to model variable transport delay phenomena.

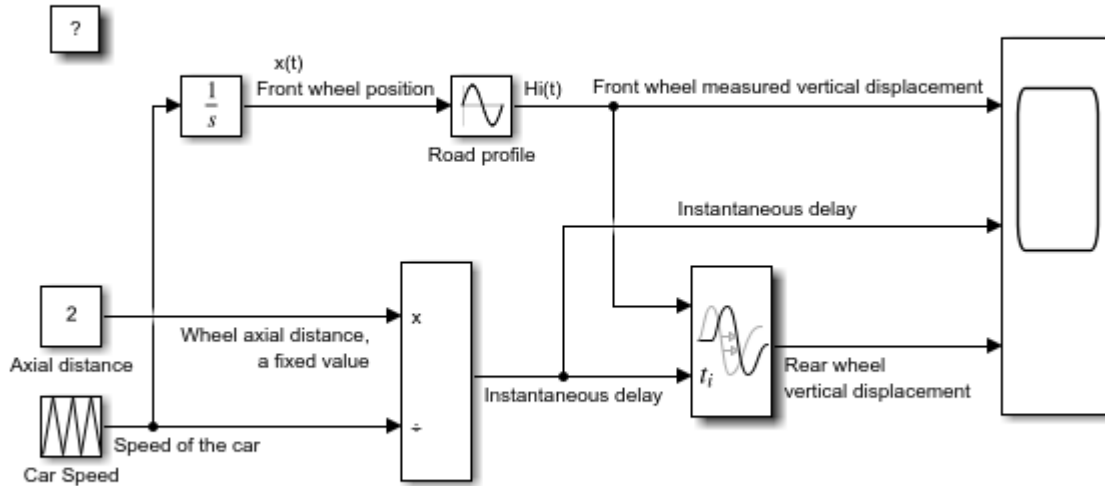

### Vertical Wheel Displacement on a One-Dimensional Car

**Figure 1:** Illustration of a car with speed  $v(t)$ .

A car is running along a road with speed  $v(t)$ . A sensor is installed at the front wheel to measure the vertical displacement  $H_i(t)$  of the front wheel caused by the road profile. If the wheels and road never lose contact, then the vertical displacement of the rear wheel,  $H_o(t)$ , can be seen as a variable transport delay of  $H_i(t)$ , which is determined by the length  $L$  between the two wheels and the speed  $v(t)$ .

### Vertical displacement of the wheels of a one dimensional car

Copyright 1990-2013 The MathWorks, Inc.

**Figure 2:** Vertical displacement of the wheels.

**Incompressible Flow Through a Fixed Length Pipe**

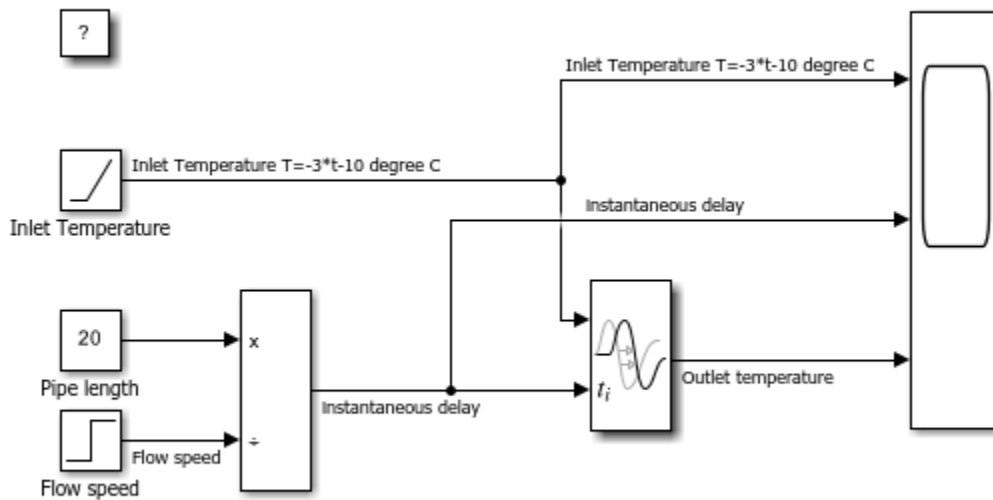

**Figure 3:** Illustration of a fixed-length pipe.

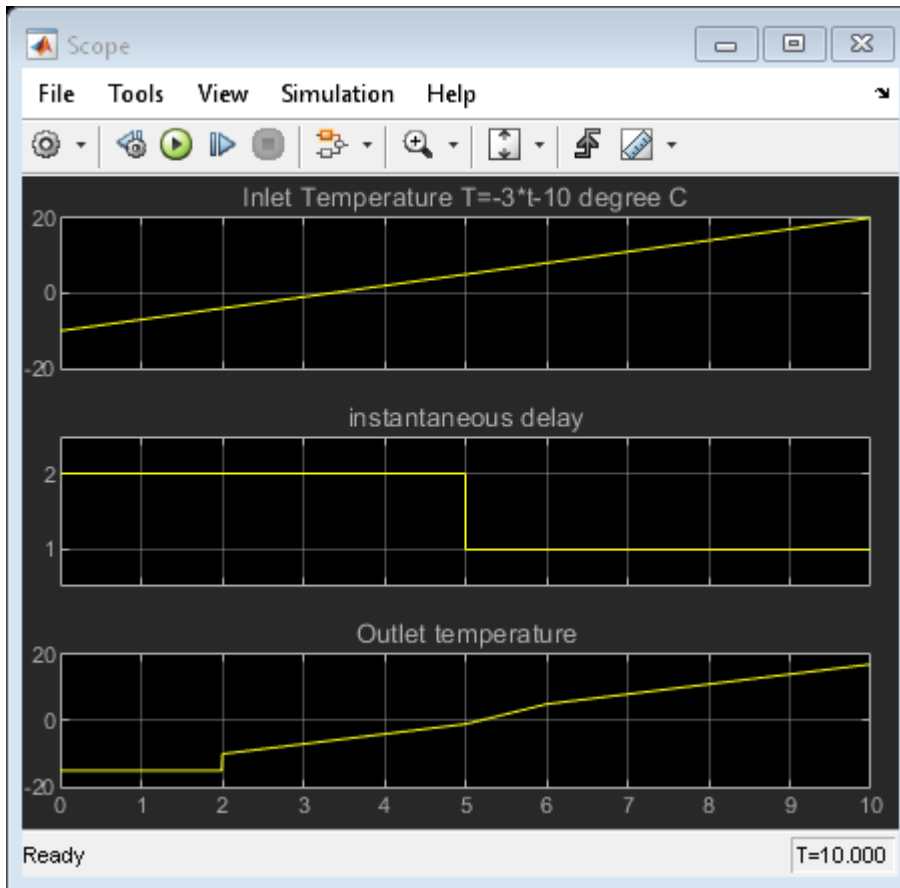

An incompressible flow goes through a pipe of length  $L$  with speed  $v(t)$ . At the inlet, the flow temperature is  $T_i$ . We can model the temperature at the outlet  $T_o$  as a variable transport delay of  $T_i$ . At time  $t=0$ , the pipe is empty and until  $t=2$ , there is no flow at the outlet. Thus, the output temperature before  $t=2$  is the initial output temperature.

## Modeling a Foucault Pendulum

This example shows how to model a Foucault pendulum. The Foucault pendulum was the brainchild of the French physicist Leon Foucault. It was intended to prove that Earth rotates around its axis. The oscillation plane of a Foucault pendulum rotates throughout the day as a result of axial rotation of the Earth. The plane of oscillation completes a whole circle in a time interval  $T$ , which depends on the geographical latitude.

Foucault's most famous pendulum was installed inside the Paris Pantheon. This was a 28kg metallic sphere attached to a 67 meter long wire. This example simulates a 67 meter long pendulum at the geographic latitude of Paris.

### Simulink® Model

The simplest way to solve the Foucault pendulum problem in Simulink® is to build a model that solves the coupled differential equations for the system. This model is shown in Figure 1. The equations that describe the Foucault pendulum are given below. For details on the physics of the model and the derivation of these equations, see Analysis and Physics.

$$\ddot{x} = 2\Omega \sin \lambda \dot{y} - \frac{g}{L}x$$

$$\ddot{y} = -2\Omega \sin \lambda \dot{x} - \frac{g}{L}y$$

$x, y$  = pendulum bob coordinates as seen by an observer on Earth

$\Omega$  = Earth's angular speed of revolution about its axis (*rad/sec*)

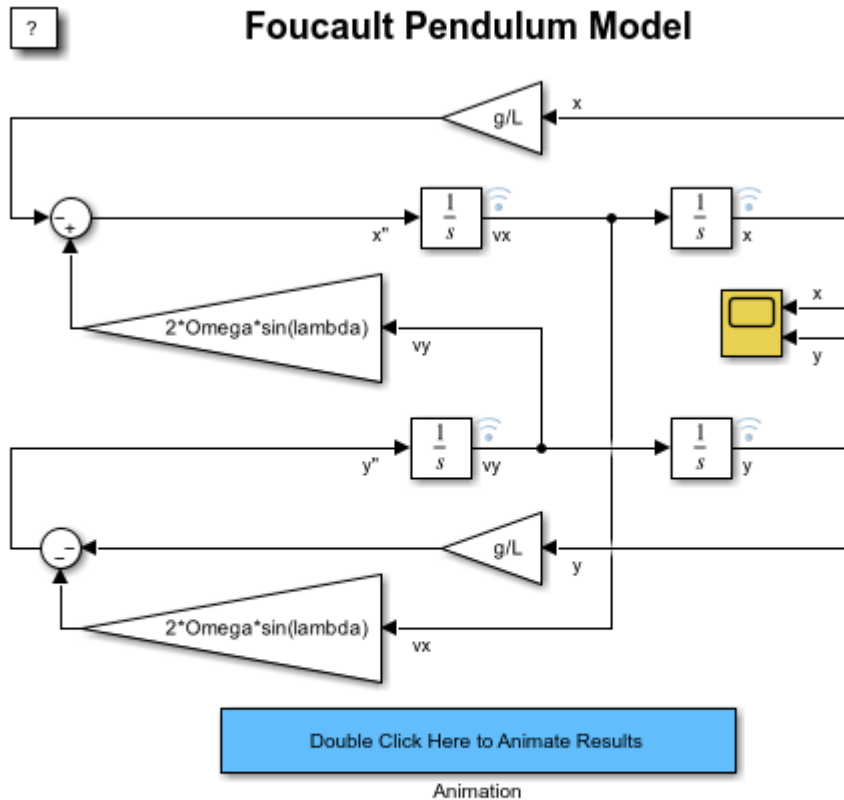

$g$  = acceleration of gravity (*m/sec<sup>2</sup>*)

$L$  = length of the pendulum string (*m*)

$\lambda$  = geographic latitude (*rad*)

### Opening the Model

Type `sldemo_foucault` in MATLAB® Command Window to open this model. This model logs simulation data to the variable `sldemo_foucault_output`. Logged signals have a blue indicator. For more information, see "Configure a Signal for Logging".

This model solves the differential equations for the Foucault Pendulum problem and plots the position of the pendulum bob in the XY plane. You can access or modify the parameters ( $g$ ,  $\Omega$ ,  $\lambda$ ,  $L$  and initial conditions) in MATLAB workspace.

Copyright 1990-2015 The MathWorks, Inc.

**Figure 1:** The Foucault pendulum model

### Initial Conditions

This model loads the constants and initial conditions from the `sldemo_foucault_data.m` file. The contents of this file are shown in Table 1 below. You can modify simulation parameters directly in MATLAB workspace. The initial amplitude of the pendulum must be small compared to pendulum length, because the differential equations are valid only for small oscillations.

**Table 1:** Initial conditions

```

g = 9.83; % acceleration of gravity (m/sec^2)
L = 67; % pendulum length (m)
initial_x = L/100; % initial x coordinate (m)
initial_y = 0; % initial y coordinate (m)
initial_xdot = 0; % initial x velocity (m/sec)
initial_ydot = 0; % initial y velocity (m/sec)
Omega=2*pi/86400; % Earth's angular velocity of rotation about its axis (rad/sec)
lambda=49/180*pi; % latitude in (rad)

```

## Running the Simulation

Press the "Play" button on the toolbar in the model window to run the simulation. The simulation will use a variable step stiff solver, ode23t. It will simulate a Foucault pendulum for 3600 seconds (you can change the simulation time). The model uses a default relative tolerance  $RelTol = 1e-6$ .

**Figure 2:** Foucault pendulum simulation results (simulation time of 3600 sec)

## Results

The simulation results are shown in Figure 2 above. The simulation calculates the pendulum x and y coordinates, and the x and y velocity components of the pendulum.

The pendulum oscillation plane completes a 360 degree sweep in more than 24 hours. The sweep period is a function of geographic latitude  $\lambda$  (see derivation in Analysis and Physics ).

**Figure 3:** The Animation block shows how much the pendulum oscillation plane rotates in an hour

After you run the simulation, double click the animation block to animate the results.

- Note: The "Animate Results" portion of the example requires Signal Processing Toolbox™. Double-clicking on the animation block will cause an error if it is not installed. All other parts of the example will function correctly without the Signal Processing Toolbox.

The `sldemo_foucault_animate.m` file plots the position of the pendulum bob at different points in time. You can clearly see how the pendulum oscillation plane rotates.

- Note: If you are running the simulation at a large relative tolerance, the result will be numerically unstable over a long period of time. Make sure that you are using a stiff variable-step solver. Read more about numerical instability of stiff problems and solver performance in the "Exploring Variable-Step Solvers Using a Stiff Model" example.

### Closing the Model

Close the model. Clear generated data.

### Analysis and Physics

This section analyzes the Foucault pendulum and describes the physics behind it. The pendulum can be modeled as a point mass suspended on a wire of length  $L$ . The pendulum is located at the geographical latitude  $\lambda$ . It is convenient to use the reference frames shown in Figure 4: the inertial frame  $I$  (relative to the center of the Earth), and the non-inertial frame  $N$  (relative to an observer on Earth's surface). The non-inertial frame accelerates as a result of rotation.

**Figure 4:** The Inertial and Non-Inertial Frames for the Problem

Point O is the origin of the non-inertial frame N. It is the point on the surface of the earth beneath the point of suspension of the pendulum. The non inertial frame is chosen such that the z-axis points away from the center of the Earth and is perpendicular to Earth's surface. The x-axis points south and the y-axis points west.

As mentioned in the introduction, the oscillation plane of a Foucault pendulum rotates. The oscillation plane completes a full rotation in time  $T_{rot}$  given by the following formula, where  $T_{day}$  is the duration of one day (i.e. the time it takes the Earth to revolve around its axis once).

$$T_{rot} = T_{day} \cdot \sin \lambda$$

The sine factor requires further discussion. It is often incorrectly assumed that the oscillation plane of the pendulum is fixed in the inertial frame relative to the center of the Earth. This is only true at the north and south poles. To eliminate this confusion, think about the point S (see Figure 4), where the pendulum is suspended. In the inertial frame I, point S moves on a circle. The pendulum bob is suspended on a wire of constant length. For simplicity ignore the air friction. In the inertial frame I, there are only two forces that act on the bob - the wire tension  $T$  and the gravitational force  $F_g$ .

The vector  $r$  gives the position of the pendulum bob, B (see Figure 4). Newton's second law states that the sum of all forces acting on a body equals the mass times the acceleration of the body.

$$m \vec{r} = \vec{T} + \vec{F}_g$$

Throughout this proof, the dots denote time derivatives, arrows denote vectors, caps denote unitary vectors (i, j, and k along x, y, and z axes). A dot above the vector arrow indicated the time derivative of the vector. An arrow above the dot indicated the vector of the time derivative. See the difference between total acceleration and radial acceleration below.

Total Acceleration:

$$\ddot{\vec{r}} = \frac{d^2 \vec{r}}{dt^2} = \frac{d^2}{dt^2} (x\hat{i} + y\hat{j} + z\hat{k})$$

Radial Acceleration:

$$\vec{r} = \left( \frac{d^2 r}{dt^2} \right) = \ddot{x}\hat{i} + \ddot{y}\hat{j} + \ddot{z}\hat{k}$$

The acceleration of gravity points towards the center of the earth (negative z-direction).

$$g = 9.83m/sec^2$$

$$\vec{g} = -g\hat{k}$$

$$m\ddot{\vec{r}} = \vec{T} - mg\hat{k}$$

Decompose the acceleration term:

$$\vec{r} = r_x\hat{i} + r_y\hat{j} + r_z\hat{k}$$

$$\dot{\vec{r}} = (\dot{r}_x\hat{i} + \dot{r}_y\hat{j} + \dot{r}_z\hat{k}) + r_x\dot{\hat{i}} + r_y\dot{\hat{j}} + r_z\dot{\hat{k}}$$

The time derivatives of unit vectors appear because the non-inertial reference frame N is rotating in space. This means that the unitary vectors i, j, and k rotate in space. Their time derivatives are given below. Omega is Earth's angular velocity of revolution around its axis. The scalar Omega is the value of the angular velocity. The vectorial Omega is the vector angular velocity. Its direction is determined by the right hand rule.

$$\dot{\hat{i}} = \vec{\Omega} \times \hat{i}$$

$$\dot{\hat{j}} = \vec{\Omega} \times \hat{j}$$

$$\dot{\hat{k}} = \vec{\Omega} \times \hat{k}$$

Rewrite the time derivative of the vector r relative to Omega.

$$\dot{\vec{r}} = (\dot{r}_x\hat{i} + \dot{r}_y\hat{j} + \dot{r}_z\hat{k}) + \vec{\Omega} \times \vec{r} = \vec{\dot{r}} + \vec{\Omega} \times \vec{r}$$

Similarly, express the second time derivative of the vector r.

$$\ddot{\vec{r}} = \vec{\ddot{r}} + 2\vec{\Omega} \times \vec{\dot{r}} + \vec{\Omega} \times (\vec{\Omega} \times \vec{r})$$

$\vec{r}$  = acceleration in the non-inertial frame N (x, y, z components)

$2\vec{\Omega} \times \vec{r}$  = Coriolis acceleration

$\vec{\Omega} \times (\vec{\Omega} \times \vec{r})$  = additional term due to rotation of non-inertial frame N

To simplify this equation, assume that Omega for Earth is very small. This allows us to ignore the third term in the equation above. In fact, the second term (which is already much smaller than the first term) is four orders of magnitude greater than the third term. This reduces the equation to the following form:

$$\ddot{\vec{r}} \simeq \vec{r} + 2\vec{\Omega} \times \dot{\vec{r}}$$

Newton's Second Law can be written and decomposed into x,y, and z components as follows:

$$m\ddot{\vec{r}} = \vec{T} - mg\hat{k} - 2m\vec{\Omega} \times \dot{\vec{r}}$$

$$m\ddot{x} = T_x + 2m\Omega\dot{y}\sin\lambda$$

$$m\ddot{y} = T_y - 2m\Omega(\dot{x}\sin\lambda + \dot{z}\cos\lambda)$$

$$m\ddot{z} = T_z - mg + 2m\Omega\dot{y}\cos\lambda$$

The angular amplitude of oscillations is small. Therefore, we can ignore the vertical velocity and vertical acceleration (z-dot and z-double-dot). The string tension components can be expressed using small angle approximations, which also considerably simplify the problem, making it two-dimensional (see below).

$$T_z = mg - 2m\Omega\dot{y}\cos\lambda \simeq mg$$

$$T_x = -T\frac{x}{L}$$

$$T_y = -T\frac{y}{L}$$

$$T_z = T\frac{L-z}{L} \simeq T$$

### Characteristic Differential Equations

Finally the physics of the problem can be described by the system of coupled equations given below. The x and y coordinates specify the position of the pendulum bob as seen by an observer on Earth.

$$\ddot{x} - 2\Omega\sin\lambda\dot{y} + \frac{g}{L}x = 0$$

$$\ddot{y} + 2\Omega\sin\lambda\dot{x} + \frac{g}{L}y = 0$$

### Analytic Solution (Approximate)

The following is an analytic solution to the Foucault pendulum problem. Unfortunately, it is not exact. If you try to substitute the analytic solution into the differential equations, uncanceled terms of the

order Omega squared will remain. However, because Omega is very small, we can ignore the uncanceled terms for practical purposes.

$$\eta = x + i \cdot y \text{ (complex number)}$$

$$\ddot{\eta} + (2i\Omega \sin \lambda)\dot{\eta} + \frac{g}{L}\eta = 0$$

$$\eta = \left( C_1 e^{i\sqrt{g/L}t} + C_2 e^{-i\sqrt{g/L}t} \right) e^{-i\Omega t \sin \lambda}$$

$C_1, C_2$  are complex integration constants

### Actual Differential Equation System Is Asymmetric

During the derivation, terms involving Omega squared were ignored. This resulted in xy symmetry in the differential equations. If the Omega squared terms are taken into consideration, the differential equation system becomes asymmetric (see below).

$$\ddot{x} - 2\Omega \sin \lambda \dot{y} + \left( \frac{g}{L} - \Omega^2 \sin^2 \lambda \right) x = 0$$

$$\ddot{y} + 2\Omega \sin \lambda \dot{x} + \left( \frac{g}{L} - \Omega^2 \right) y = 0$$

You can easily modify the current Foucault pendulum model to account for asymmetric differential equations. Simply edit the corresponding Gain blocks that contain g/L and add the necessary expression. This change will introduce a very small overall correction to the numerical result.

## Foucault Pendulum Model with VRML Visualization

This example shows how to solve the differential equations for the Foucault Pendulum problem and displays the pendulum bob movement in the VRML scene. You can modify the Pendulum location by changing the Latitude / Longitude constant values in the model and other parameters ( $g$ ,  $\Omega$ ,  $L$  and initial conditions) in MATLAB® workspace.

There are two VRML scenes associated with this model. The first scene shows the Foucault pendulum itself, the second shows geographical position of the pendulum on the Earth. During the simulation, two arrow markers indicate the current and the initial position of the pendulum in the Earth coordinate system.

This model solves the differential equations for the Foucault Pendulum problem and displays the pendulum bob movement in the VRML scene. You can modify the Pendulum location by changing the Latitude / Longitude constant values in the model and other parameters ( $g$ ,  $\Omega$ ,  $L$  and initial conditions) in MATLAB(R) workspace.

## Explore Variable-Step Solvers with Stiff Model

This example shows the behavior of variable-step solvers in a Foucault pendulum model. Simulink® solvers ode45, ode15s, ode23, and ode23t are used as test cases. Stiff differential equations are used to solve this problem. There is no exact definition of stiffness for equations. Some numerical methods are unstable when used to solve stiff equations and very small step sizes are required to obtain a numerically stable solution to a stiff problem. A stiff problem may have a fast changing component and a slow changing component.

Foucault pendulum is an example of a stiff problem. The pendulum completes an oscillation in a few seconds (fast changing component) whereas the Earth completes a rotation about its axis in a day (slow changing component). The oscillation plane of the pendulum slowly rotates because of Earth's axial rotation. You can read more about the physics of a Foucault pendulum in Modeling a Foucault Pendulum.

The simulation calculates the position of the pendulum bob in the x-y plane as viewed by an observer on the surface of Earth. The total energy of the pendulum is then calculated and used to assess the performance of various Simulink solvers.

### Foucault Pendulum Model

The Foucault pendulum is described by the system of coupled differential equations shown below. Friction and air drag are not taken into consideration (this greatly simplifies the equations). A full derivation of these equations is given in the Foucault Pendulum example.

$$\ddot{x} = 2\Omega \sin \lambda \dot{y} - \frac{g}{L}x$$

$$\ddot{y} = -2\Omega \sin \lambda \dot{x} - \frac{g}{L}y$$

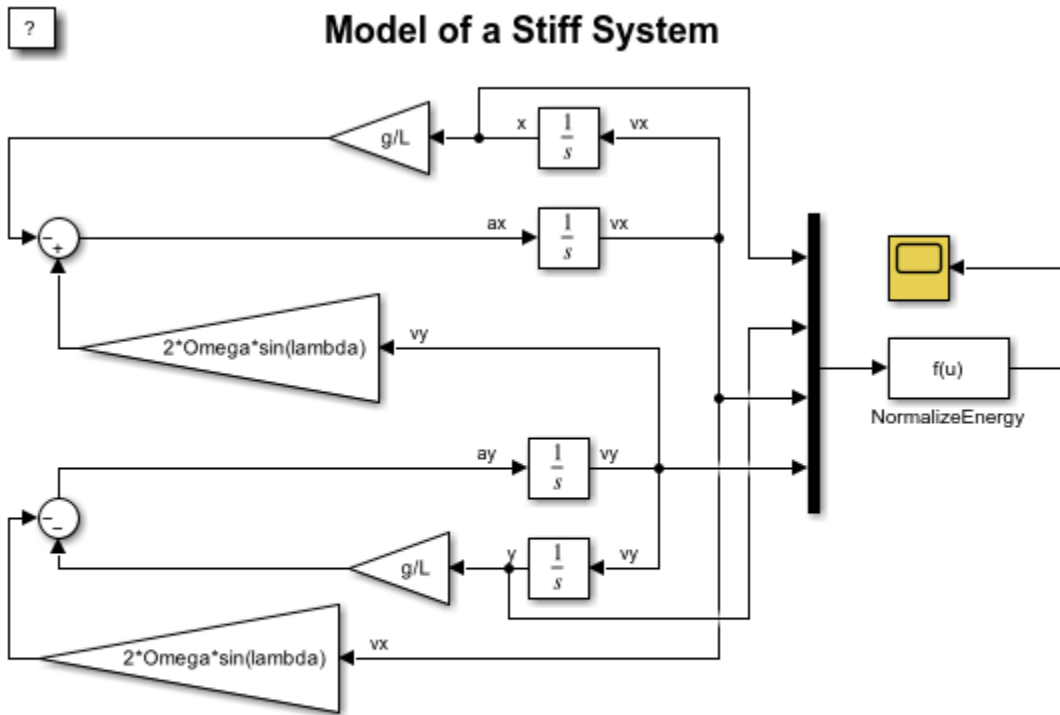

$\Omega$  = Earth's angular velocity of rotation around its axis

$\lambda$  = geographic latitude

$g$  = acceleration of gravity

$x$  and  $y$  = coordinates of the pendulum bob

The model `sldemo_solvers` is used to solve the differential equations that describe a Foucault pendulum. The example simulates a Foucault pendulum for 86,400 seconds. The constants and initial conditions are saved the model workspace.

This model simulates a Foucault pendulum (a stiff system). The model calculates the normalized pendulum energy, E.

Copyright 1990-2013 The MathWorks, Inc.

### Variable-Step Solvers

This example investigates the performance of the ode45, ode15s, ode23, and ode23t variable-step solvers.

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

### Assessing Solver Performance

There are different ways to assess the performance of a solver. If a problem has a closed form solution, you could compare the solver results with the expected theoretical result. You could also monitor the time it takes to simulate a model using a particular solver.

Unfortunately there is no exact theoretical solution for the Foucault Pendulum problem. There is an approximate closed form solution. However you cannot use the approximate closed form solution to assess solver performance (see the Foucault pendulum example).

### Total Energy Conservation

This example assesses solver performance by verifying the energy conservation law. In a frictionless environment, the total energy of the pendulum must remain constant. The calculated energy of the pendulum, however, does not remain constant as a result of limited numeric accuracy.

This example calculates the normalized total energy of the pendulum at every time step. The relative error in energy equals the change in total energy over the course of the simulation. Ideally, the relative error in energy must be zero because energy is conserved. Total energy is the sum of potential and kinetic energy. The `NormalizeEnergy` block calculates the normalized pendulum energy using these equations:

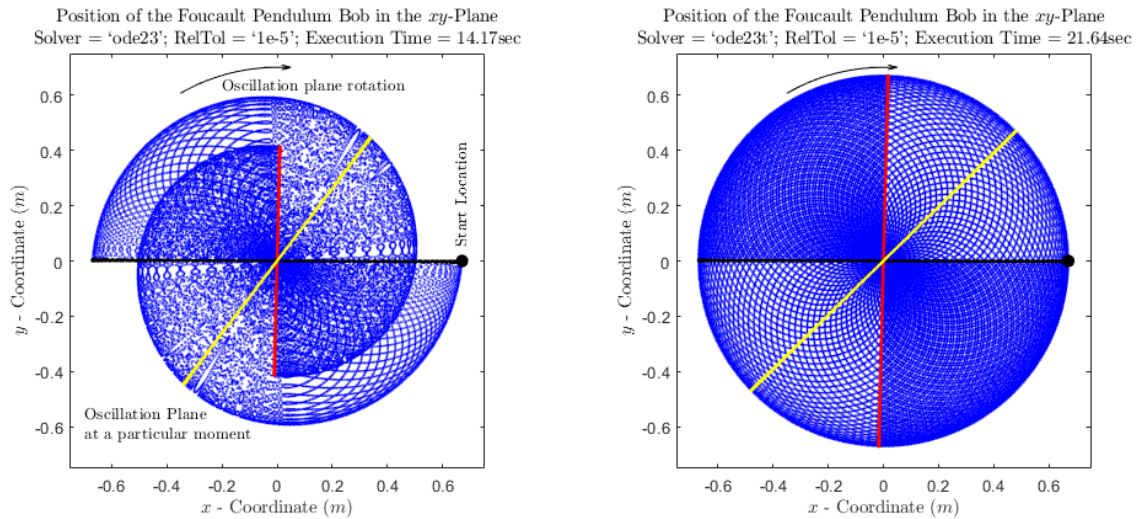

$$E = \frac{v_x^2 + v_y^2}{2} + g(L - \sqrt{L^2 - x^2 - y^2})$$

$$E_{normalized}(t) = \frac{E(t)}{E(0)}$$

$$E(0) = \text{initial total energy}$$

The plot shows the normalized energy versus time as calculated using `ode23` and `ode23t`. In this particular problem `ode23t` is much more accurate than `ode23`. In the simulation that used `ode23`, the normalized pendulum energy decreased by more than 60%. A pendulum with lower energy has a lower oscillation amplitude. You can see this effect in the next plot, where the amplitude of the pendulum calculated by `ode23` decreases as the oscillation plane rotates.

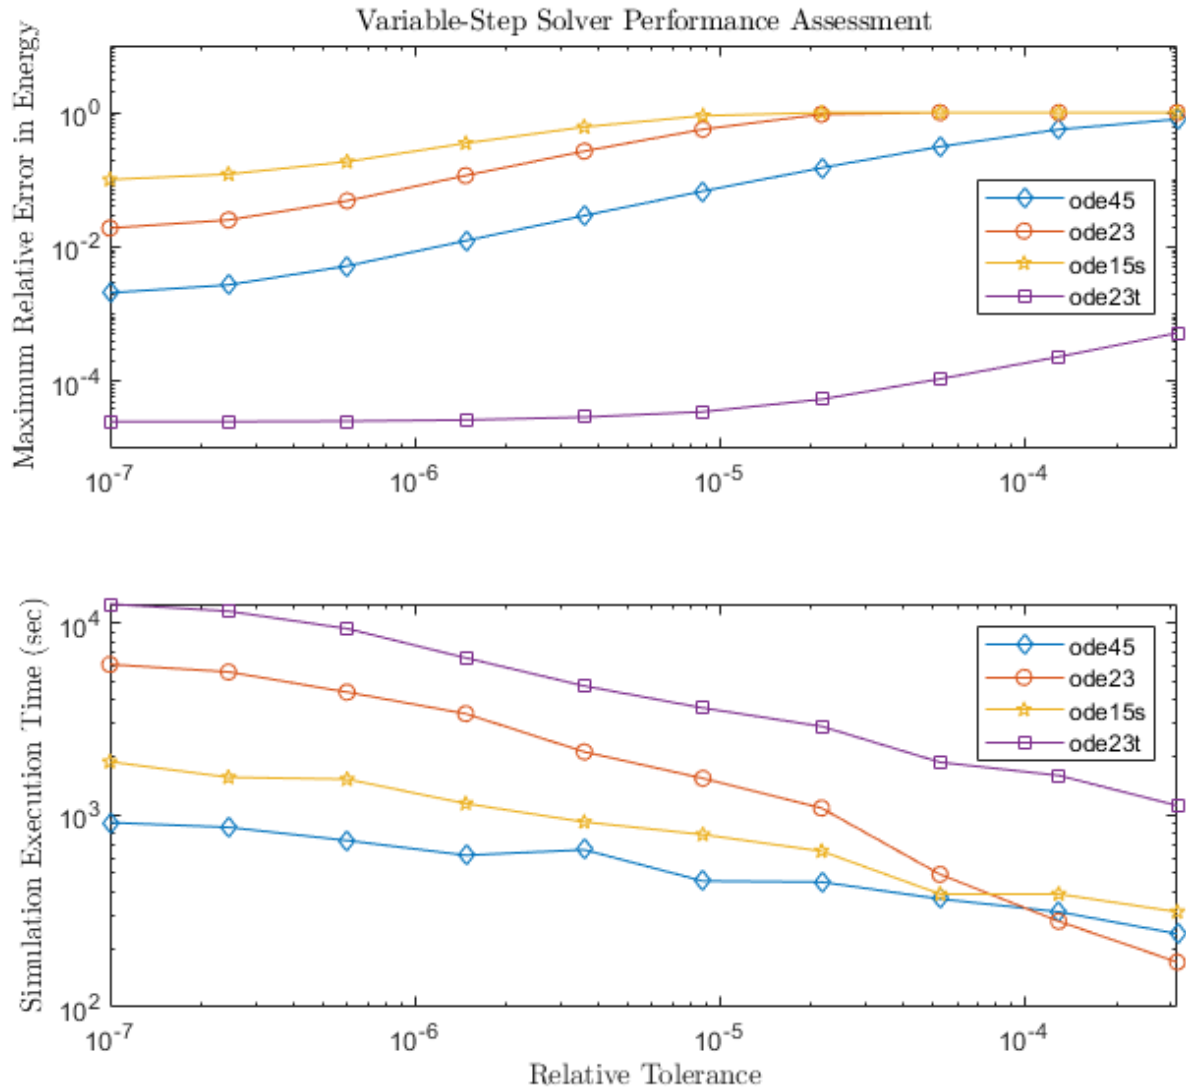

These plots illustrate the difference between a stiff and a non-stiff solver. Each plot shows the position of the pendulum bob throughout a day. Every 15th data point is plotted as a blue point. The black dot marks the initial position of the pendulum bob and the black line marks the initial pendulum oscillation plane. The red line indicates the oscillation plane after a day. The yellow line shows the oscillation plane at some intermediate point in time. The oscillation plane of the pendulum does not complete a full rotation within a day. How fast the oscillation plane rotates depends on the geographical latitude (see details in the Foucault pendulum example). The pendulum amplitude in the left plot decreases whereas the amplitude in the right plot remains constant. For the same relative tolerance of  $1e-5$ , the stiff solver gives a more accurate result but requires more execution time.

The next plots show a more detailed performance study of Simulink solvers. Four solvers were chosen to illustrate how relative error and execution time vary as a function of relative tolerance. You can use the script `sldemo_solvers_mcode.m` for more extensive solver tests. This script generates C code from the model to speed up the simulations and can take several minutes to run.

```
Building RSim executable for model..
Time taken: 40.900899 seconds.
```

```
Running generated RSim executable..
Time taken: 115.445625 seconds.
```

In this example, the relative error does not decrease significantly for relative tolerance values smaller than  $1e-6$ . This is a numeric solver limitation that depends on the particular model. Reducing the solver relative tolerance does not necessarily improve accuracy. You need to estimate the minimal accuracy that is required for your problem and choose the solver accordingly to balance simulation costs. For example, you might want to know the position of the Foucault pendulum bob within a few centimeters. Calculating the position of a pendulum within a few microns is not necessary because you cannot measure the position that accurately.

The numeric results and behavior of a simulation can differ depending on solver settings. This is crucial in the case of stiff problems. When working with stiff models, choose a solver that will give an accurate result with lower computational cost. The relative tolerance for a variable-step solver or the step size for a fixed-step solver has to be small enough that the result is numerically stable. Although

some solvers are more efficient than others, stiff solvers are better suited for solving stiff problems. Variable-step solvers are more robust than fixed-step solvers.

## Exploring the Solver Jacobian Structure of a Model

The example shows how to use Simulink® to explore the solver Jacobian sparsity pattern, and the connection between the solver Jacobian sparsity pattern and the dependency between components of a physical system. A Simulink model that models the synchronization of three metronomes placed on a free moving base are used.

### The Solver Jacobian Pattern

In general, the continuous part of a Simulink model can be written as:

$$\begin{cases} \dot{x} = f(x, u) \\ y = g(x, u) \end{cases}$$

where  $x$  are the continuous states and  $u$  are the inputs.  $y$  are the outputs.

The matrix:

$$J_x = \frac{\partial f}{\partial x}$$

is called the system solver Jacobian matrix. When an implicit ODE solver is used to solve the system equations,  $J_x$  needs to be computed when needed. For example, the Jacobian matrix of a set of first order ODEs

$$\begin{cases} \dot{x}_1 = x_1 x_2 \\ \dot{x}_2 = x_2 \end{cases}$$

is

$$J_x = \begin{bmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} \end{bmatrix} = \begin{bmatrix} x_2 & x_1 \\ 0 & 1 \end{bmatrix}$$

You can convert the solver Jacobian matrix to a Boolean sparse matrix by representing each non-zero element as 1, and each element that is always zero (hard zero) as 0. For example, the Boolean matrix corresponding to above Jacobian  $J_x$  is:

$$J_{xp} = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix},$$

where  $J_{xp}$  is called the solver Jacobian pattern matrix.

The solver Jacobian pattern matrix can be generated directly from the original system equations by using the following rule:

$$J_{xp}(i, j) = \begin{cases} 1 & \text{if } x_j \text{ is explicitly used to compute } \dot{x}_i \\ 0 & \text{otherwise} \end{cases}$$

As you can see, the solver Jacobian pattern matrix actually represents the dependency between the state variables and their derivatives. If computing of  $\dot{x}_i$  needs the value of  $x_j$ , then there exists a

dependency  $\dot{x}_i \leftarrow x_j$  and  $J_{xp}(i, j) = 1$ . These dependencies are determined by the physical nature of the system, and thus by studying the solver Jacobian matrix, you can explore the physical structure of the physical system represented by the model. Simulink provides APIs for the user to get the solver Jacobian pattern matrix. The following shows how to access the solver Jacobian pattern and to use it to study the model.

### The Pattern and Dependency: Synchronization of Metronomes

Synchronization is defined as an adjustment of rhythms of oscillating objects due to their weak interaction [1]. One of the first scientifically documented observations of synchronization was reported by the Dutch scientist Christiaan Huygens, the inventor of pendulum clock [2]. Huygens discovered that two pendulums attached to the same beam supported by chairs would swing in exact opposite direction after some time. A similar set up used in this example is shown in Figure 1.

**Moving base with mass  $M$**   
**Pendulum with mass  $m$ , rotational inertia  $J$ , length  $r$**

**Figure 1:** Set up used in this example: three metronomes on a moving base

### Modeling the System

The model of this physical system can be divided into two parts:

- The metronomes mechanism
- The moving base

### The metronomes mechanism

Referring to Figure 1, the dynamic equations of a single metronome on a moving base can be derived as[3]:

$$\underbrace{\ddot{\theta}}_{\text{Angular acceleration}} + \underbrace{\frac{mrg}{J} \sin \theta}_{\text{Gravitational term}} + \underbrace{\frac{b}{J} \left[ \left( \frac{\theta}{\theta_r} \right)^2 - 1 \right] \dot{\theta}}_{\text{Escapement and damping term}} + \underbrace{\left( \frac{rm \cos \theta}{J} \right) \ddot{x}}_{\text{Coupled inertial force term}} = 0 \quad (\text{eq.1})$$

The first two terms describe a simple pendulum without friction. The third term is used to approximate the escapement\* and any damping of the metronome. This term increases the angular velocity for  $\theta < \theta_0$  and decreases it for  $\theta > \theta_0$  [3]. The last term is the coupled effect from the moving base, in terms of an inertial force.

### The moving base

Assuming the motion of the base is frictionless, then the center of mass of the system will not change and you can derive the following:

$$x = -\frac{m}{M + 3m} r(\sin \theta_1 + \sin \theta_2 + \sin \theta_3),$$

where  $M$  is the mass of the base and  $m$  is the mass of the pendulum.

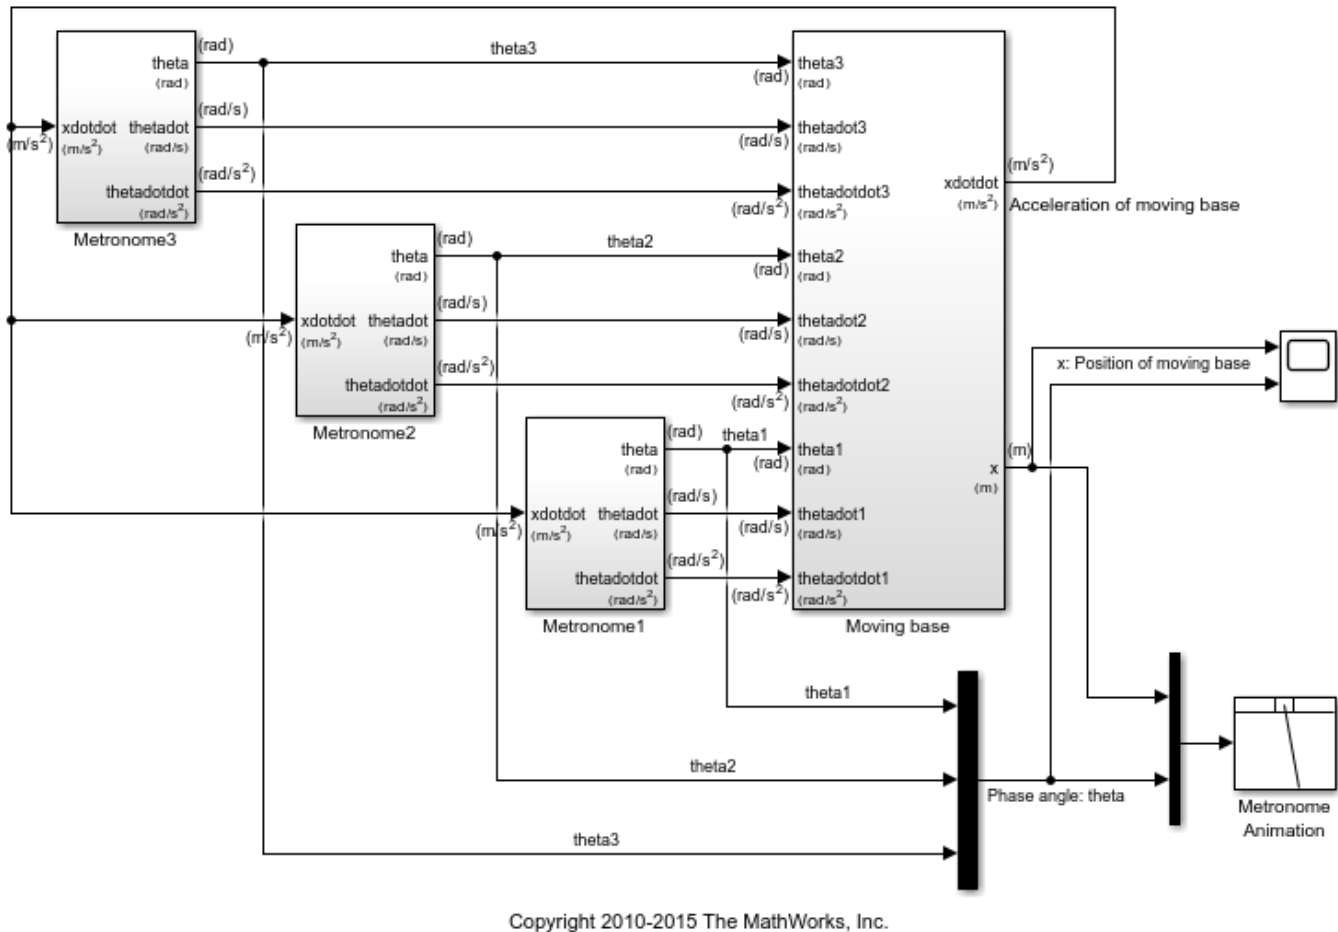

Then eq.1 can be changed to:

$$\ddot{x} = -\frac{m}{M + 3m} r \left[ \ddot{\theta}_1 \cos \theta_1 - \sin \theta_1 (\dot{\theta}_1)^2 + \ddot{\theta}_2 \cos \theta_2 - \sin \theta_2 (\dot{\theta}_2)^2 + \ddot{\theta}_3 \cos \theta_3 - \sin \theta_3 (\dot{\theta}_3)^2 \right] \quad (eq.2)$$

The following shows the above system implemented using Simulink. The model contains three metronome subsystems and the moving base.

?

## Exploring the Solver Jacobian Structure of a Model

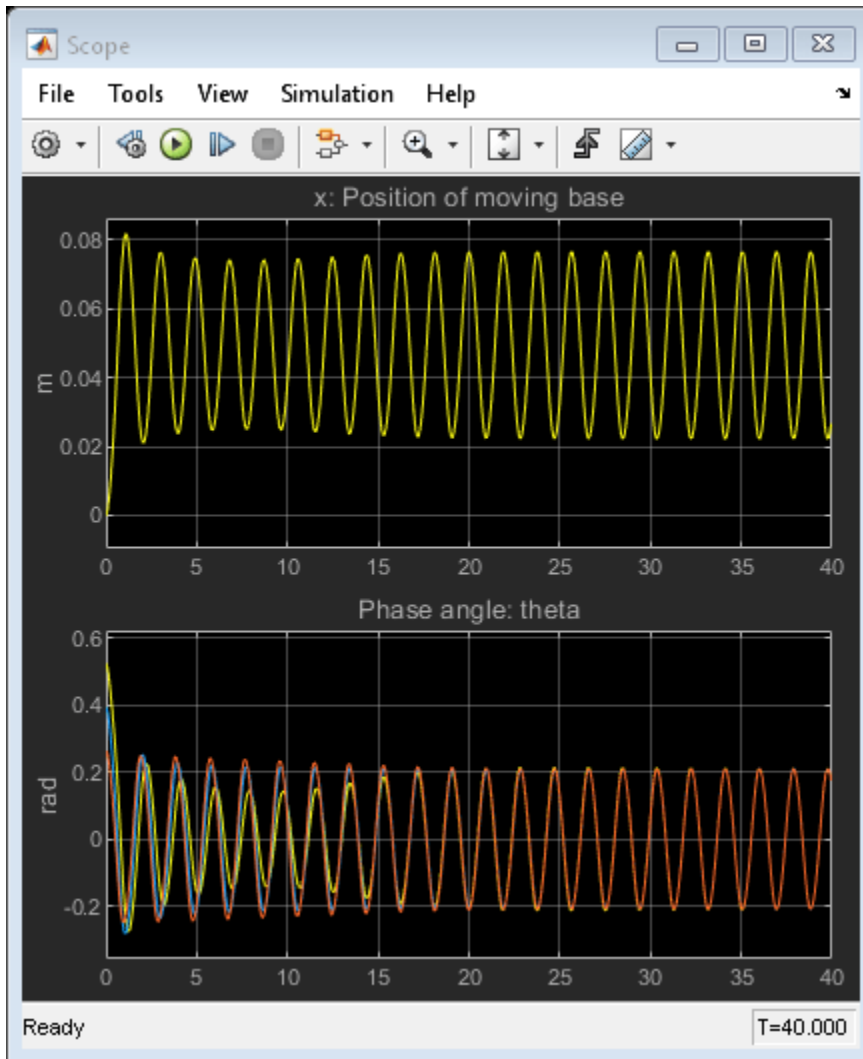

**Figure 2:** The Simulink model of the metronomes system

Simulation of this system shows an interesting phenomenon: Synchronization. It shows that all three metronomes with different initial phase angle eventually become synchronized with each other. Figure 3 shows the simulation results. The main cause for synchronization is the moving base that links all these metronomes together. This physical connection can be observed from the dynamic equation of each metronome.

Also, this physical connection can also be observed from the solver Jacobian pattern of this model. The following MATLAB® code shows how to get the solver Jacobian pattern.

Time: 40

**Figure 3:** The synchronized metronomes

### Steps to Get the Solver Jacobian Pattern

% 1. Set the solver to be any implicit solver

```
set_param mdl, 'Solver', 'ode15s');
```

% 2. Set the solver Jacobian method to be Sparse perturbation \*

```
set_param mdl, 'SolverJacobianMethodControl', 'SparsePerturbation');
```

% 3. Get the solver Jacobian object.

```
J = Simulink.Solver.getSlvrJacobianPattern(mdl);
disp('J = ');
disp(J);
```

% 4. Show the pattern in a figure. use the method J.show

```
J.show;
```

% 5. Explore the pattern with the given state name and other information

```
stateNames = J.stateNames;
disp('stateNames = ');
disp(stateNames);
```

The results you will see are:

```
J =
SlvrJacobianPattern with properties:

 Jpattern: [8x8 double]
 numColGroup: 6
 colGroup: [8x1 double]
 stateNames: {8x1 cell}
 blockHandles: [8x1 double]

stateNames =
{'sldemo_metro/Moving base/Integrator1' }
{'(sldemo_metro/Metronome1/Integrator2).(Theta1)' }
{'(sldemo_metro/Metronome2/Integrator2).(Theta2)' }
{'(sldemo_metro/Metronome3/Integrator2).(Theta3)' }
{'(sldemo_metro/Metronome3/Integrator1).(Thetadot_3)'}
{'(sldemo_metro/Metronome2/Integrator1).(Thetadot_2)'}
{'(sldemo_metro/Metronome1/Integrator1).(Thetadot_1)'}
{'sldemo_metro/Moving base/Integrator' }
```

**Figure 4:** The solver Jacobian pattern

### Properties of the Solver Jacobian Pattern Object

The solver Jacobian pattern J is an object. It contains the following properties:

`Jpattern`: A sparse mxArray which is the Jacobian pattern.

`numColGroup`: Number of column groups.

`colgroup`: A column partition of the sparse pattern matrix.

`stateNames`: A cell array containing the state name of each state.

`blockHandles`: Block handles of the owner of each state.

### Study of the Solver Jacobian Pattern

Referring to Figure 4. First, the solver Jacobian of this model is sparse and the number of non-zero element is 28. Secondly, the number of column groups is 6; is less than the number of states 8.

The row 1-4 indicates the following dependencies:

$$\begin{aligned}\dot{x}_1 &\leftarrow x_8(\text{baseposition} \leftarrow \text{baseseed}) \\ \dot{x}_2 &\leftarrow x_7(\dot{\text{Theta}}1 \leftarrow \text{Thetadot1}) \\ \dot{x}_3 &\leftarrow x_6(\dot{\text{Theta}}2 \leftarrow \text{Thetadot2}) \\ \dot{x}_4 &\leftarrow x_5(\dot{\text{Theta}}3 \leftarrow \text{Thetadot3})\end{aligned}$$

These relations are clear since speed is the derivative of position. Row 5-8 shows the following relations:

$$\begin{aligned}\dot{x}_5 &\leftarrow x_{2-7} \\ \dot{x}_6 &\leftarrow x_{2-7} \\ \dot{x}_7 &\leftarrow x_{2-7} \\ \dot{x}_8 &\leftarrow x_{2-7}\end{aligned}$$

These relations show that to compute the angular acceleration of the metronomes or acceleration of the moving base, the angular position and angular speed of the metronomes are needed, but not the position and speed of the base. These relations can be found by studying eq.(1) and eq.(2) directly.

### Conclusion

The Solver Jacobian pattern is a tool to study the data dependency relations between the derivatives of the state variables and the state variables. These relations usually reflect certain physical couplings in the physical system. By using the tools provided, you can discover these relations associated with a Simulink model, even without the original dynamic equations of the physical model.

## Double Bouncing Ball: Use of Adaptive Zero-Crossing Location

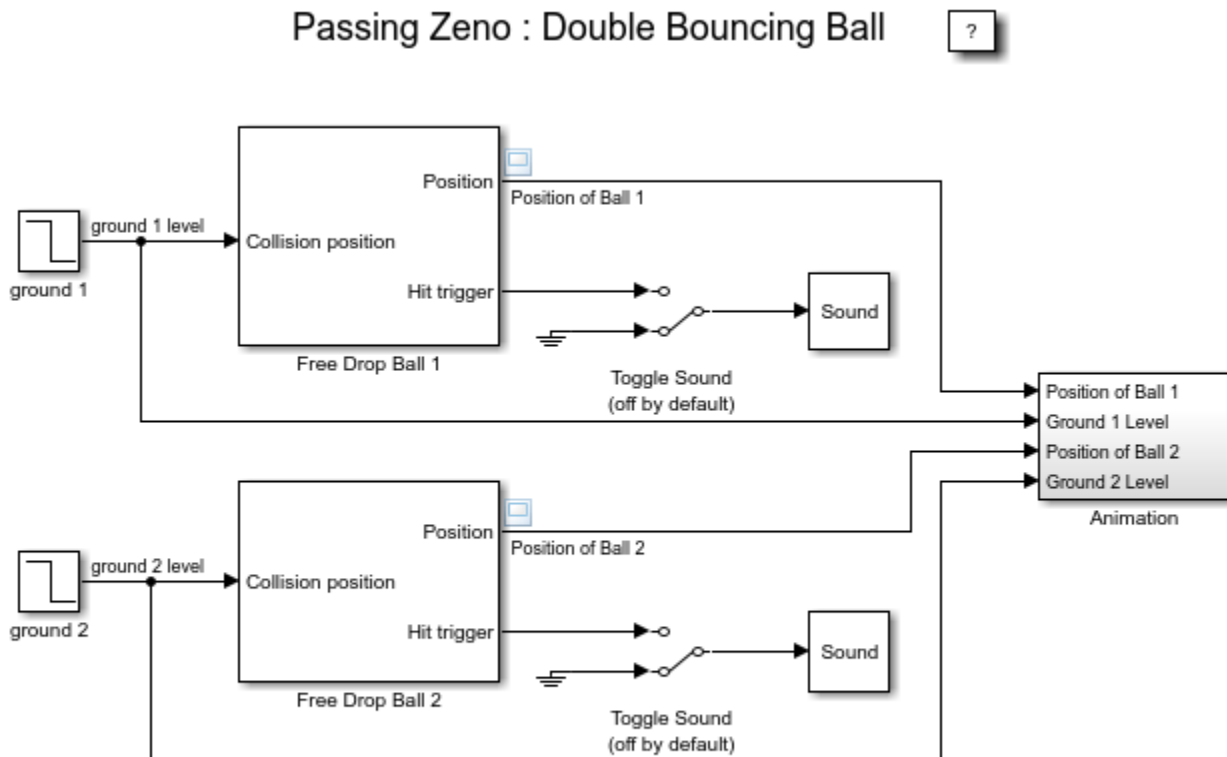

This example shows how to choose the correct zero-crossing location algorithm, based on the system dynamics. For Zeno dynamic systems, or systems with strong chattering, you can select the adaptive zero-crossing detection algorithm through the Configure pane:

```
--> Solver
 --> Zero-crossing options
 --> Algorithm: [Nonadaptive, Adaptive]
```

### The Double Bouncing Ball System

The Simulink® model in this example is used to simulate two bouncing balls. They start from the ground with different initial speeds, and their ground levels will change at different times.

Open the model

Copyright 1990-2013 The MathWorks, Inc.

**Figure 1:** The double bouncing ball model and animation

### **Double Bouncing Balls With Non-adaptive Zero-Crossing Location Algorithm**

If the Non-adaptive zero-crossing location algorithm is used, the consecutive zero-crossing error causes the simulation to stop. This system is actually a 'Zeno dynamic system'. When either ball is very close to the ground, Simulink will hang because too many zero crossings are detected in a very short period.

**Figure 2:** Vertical displacement of both balls with Non-adaptive zero-crossing location algorithm.

The simulation does not complete and an error message is shown. The ground level changing events cannot be observed.

### Double Bouncing Balls With Adaptive Zero-Crossing Location Algorithm

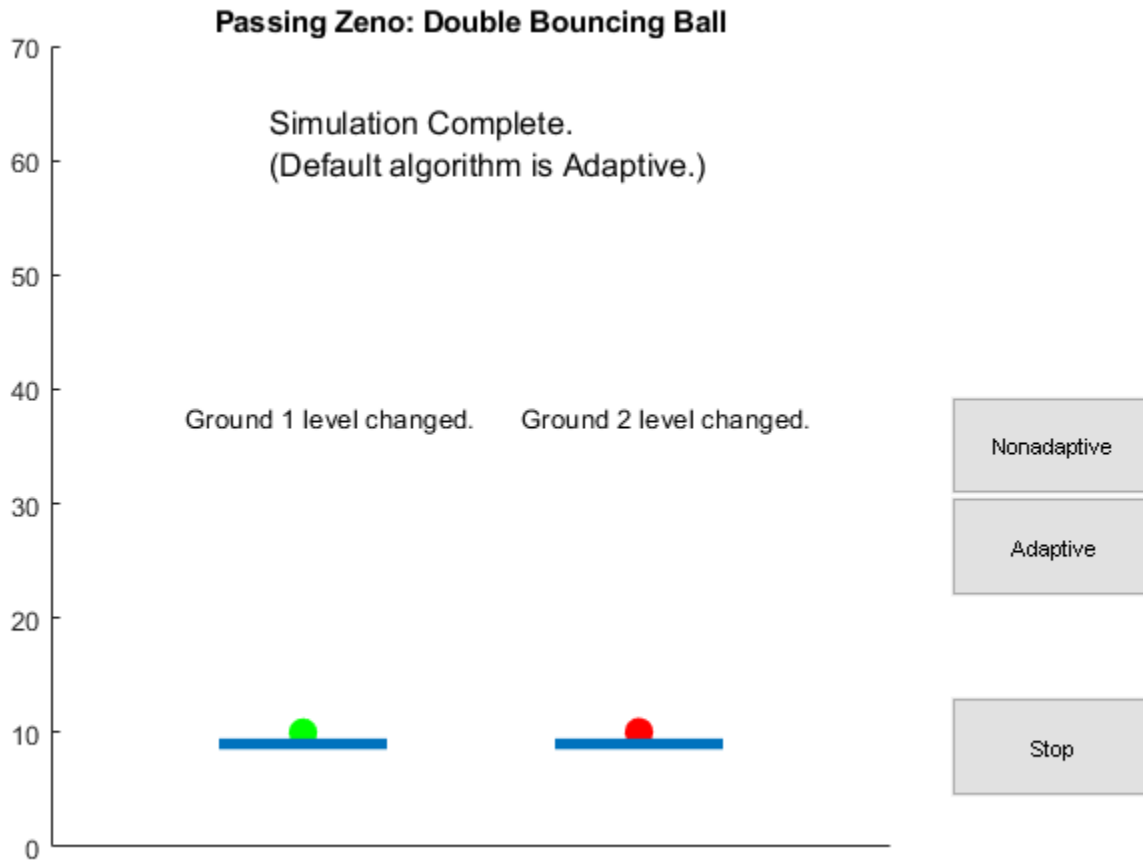

If the adaptive algorithm is selected, Simulink will adaptively turn on/off the process to precisely locate the zero-crossing time. The conditions to turn on/off the location are:

1) Zero-crossing signal value is below a threshold value. You can control the threshold value through the Configure pane:

```
--> Solver
 --> Zero-crossing options
 --> Algorithm: [Adaptive]
 --> Signal threshold
```

2) Consecutive zero-crossing diagnostic is hit. You can define consecutive zero crossing through the Configure pane:

```
--> Solver
--> Solver diagnostic controls
--> Time tolerance and
--> Number of consecutive zero crossings.
```

**Figure 3:** Vertical displacement of both balls with adaptive zero crossing location algorithm.

The simulation has completed. The ground level changing events can be observed. A warning is shown to inform you when searching for events is turned off.

## Four Hydraulic Cylinder Simulation

This example shows how to use Simulink® to create a model with four hydraulic cylinders. See two related examples that use the same basic components: single cylinder model and model with two cylinders and load constraints.

- Note: This is a basic hydraulics example. You can more easily build hydraulic and automotive models using Simscape™ Driveline™ and Simscape Fluids™.
- **Simscape Fluids** provides component libraries for modeling and simulating fluid systems. It includes models of pumps, valves, actuators, pipelines, and heat exchangers. You can use these components to develop fluid power systems such as front-loader, power steering, and landing gear actuation systems. Engine cooling and fuel supply systems can also be developed with Simscape Fluids. You can integrate mechanical, electrical, thermal, and other systems using components available within the Simscape product family.
- **Simscape Driveline** provides component libraries for modeling and simulating one-dimensional mechanical systems. It includes models of rotational and translational components, such as worm gears, planetary gears, lead screws, and clutches. You can use these components to model the transmission of mechanical power in helicopter drivetrains, industrial machinery, vehicle powertrains, and other applications. Automotive components, such as engines, tires, transmissions, and torque converters, are also included.

### Modeling

Figure 1 shows the top level diagram of the model. This model has a single pump and four actuators. The same pump pressure ( $p_1$ ) drives each cylinder assembly and the sum of their flows loads the pump. Although each of the four control valves could be controlled independently, as in an active suspension system, in this case all four receive the same commands, a linear ramp in orifice area from zero to  $0.002 \text{ sq.m.}$ .

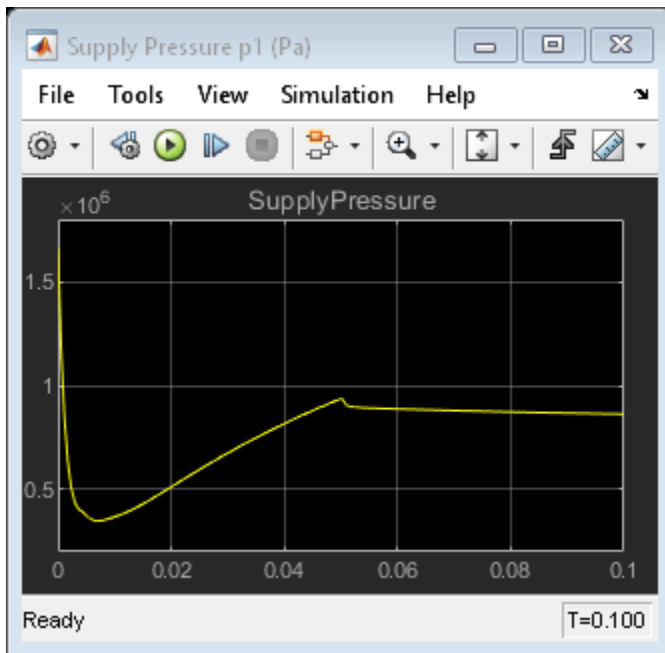

### Opening the Model and Running the Simulation

To open this model, type `sldemo_hydcyl4` at MATLAB® terminal (click on the hyperlink if you are using MATLAB Help). Press the "Play" button on the model toolbar to run the simulation.

The model logs relevant data to MATLAB workspace, into the Simulink.SimulationOutput object `out`. The signal logging data is stored within `out`, in a structure called `sldemo_hydcyl4_output`. Logged signals have a blue indicator (see the model). For more information, see "View and Access Signal Logging Data".

Copyright 1990-2012 The MathWorks, Inc.

**Figure 1:** Four cylinder model and simulation results

**Model Description**

The pump flow begins at  $0.005 \text{ m}^3/\text{sec}$  (just like in the single cylinder model), then it drops to  $0.0025 \text{ m}^3/\text{sec}$  at  $t=0.05 \text{ sec}$ . The parameters  $C1$ ,  $C2$ ,  $Cd$ ,  $\rho$ , and  $V30$  are identical to those in the single cylinder model. However, by assuming individual values for  $K$ ,  $A$ , and  $\beta$ , each one of the four cylinders exhibit distinctive transient responses. The table below gives the characteristics of the four actuators.

Parameter	Actuator1	Actuator2	Actuator3	Actuator4
Spring Constant	K	K/4	4K	K
Piston Area	Ac	Ac/4	4Ac	Ac
Bulk Modulus	Beta	Beta	Beta	Beta/1000

Beta = 7e8 Pa [fluid bulk modulus]  
 K = 5e4 N/m [spring constant]  
 Ac = 1e-3 m<sup>2</sup> [cylinder cross-sectional area]

The ratio of area and spring constant is the same for all pistons, so they should have the same steady state output. The dominant time constant for each actuator subsystem is proportional to

$$\frac{A_c^2}{K}$$

(result obtained from dimensional analysis), so we can expect the piston assembly 2 to be somewhat faster than assembly 1. The piston assembly 3 is expected to be slower than 1 or 2. The piston assembly 4 has a significantly lower bulk modulus beta (as would be the case with air), thus we expect piston 4 to respond more sluggishly than piston 1.

## Results

**Figure 2:** Piston positions in four cylinder example

**Figure 3:** Pump Supply Pressure,  $p_1$

The initial jolt of flow at  $t=0$  is seen by the four actuators as a pressure impulse. The pump pressure ( $p_1$ ), which is initially high, drops rapidly because there is a high flow demand from the four loads. During the initial transient (about 4 msec), distinct responses identify the individual dynamic characteristics of each assembly unit.

As predicted by the parameter values, actuator 2 responds much faster than actuator 1. The third and fourth pistons are much slower because they require more working fluid to move the same distance. In case 3, the piston displaces more volume due to its larger cross-sectional area. In case 4, although the displaced volume is the same as in case 1, the device requires more fluid because it is subsequently compressed.

As the pump pressure falls to the level within the cylinders, the distinctions in behavior are blurred. The individual responses blend into an overall system response which maintains the flow balance between the components. At  $t=0.05$  sec, the pump flow drops to a level that is close to the equilibrium and the actuator flows are nearly zero. The individual steady state piston positions are equal, as predicted by the design.

## Two Cylinder Model with Load Constraints

This example shows how to model a rigid rod supporting a large mass interconnecting two hydraulic actuators. The model eliminates the springs as it applies the piston forces directly to the load. These forces balance the gravitational force and result in both linear and rotational displacement.

See two related examples that use the same basic components: four cylinder model and single cylinder model.

- Note: This is a basic hydraulics example. You can more easily build hydraulic and automotive models using Simscape™ Driveline™ and Simscape Fluids™.
- **Simscape Fluids** provides component libraries for modeling and simulating fluid systems. It includes models of pumps, valves, actuators, pipelines, and heat exchangers. You can use these components to develop fluid power systems such as front-loader, power steering, and landing gear actuation systems. Engine cooling and fuel supply systems can also be developed with Simscape Fluids. You can integrate mechanical, electrical, thermal, and other systems using components available within the Simscape product family.
- **Simscape Driveline** provides component libraries for modeling and simulating one-dimensional mechanical systems. It includes models of rotational and translational components, such as worm gears, planetary gears, lead screws, and clutches. You can use these components to model the transmission of mechanical power in helicopter drivetrains, industrial machinery, vehicle powertrains, and other applications. Automotive components, such as engines, tires, transmissions, and torque converters, are also included.

### Analysis and Physics of the Model

We assume the rotation angle of the rod is small. The equations of motion for the rod are given below in Equation Block 1. The equations describing the cylinder and pump behavior are the same as in the single cylinder example.

#### Equation Block 1:

$$M \frac{d^2 z}{dt^2} = F_b + F_a + F_{ext}$$

$$I \frac{d^2 \theta}{dt^2} = \frac{L}{2} F_b - \frac{L}{2} F_a$$

$z$  – displacement at the center

$M$  – total mass

$F_a$  – piston A force

$F_b$  – piston B force

$F_{ext}$  – external force at center

$\theta$  – clockwise angular displacement

$I$  – moment of inertia of the rod

$L$  – rod length

The positions and velocities of the individual pistons follow directly from the geometry. See the corresponding equations below in Equation Block 2.

**Equation Block 2:**

$$z_a = z - \theta \frac{L}{2}$$

$$z_b = z + \theta \frac{L}{2}$$

$$\frac{dz_a}{dt} = \frac{dz}{dt} - \frac{d\theta}{dt} \frac{L}{2}$$

$$\frac{dz_b}{dt} = \frac{dz}{dt} + \frac{d\theta}{dt} \frac{L}{2}$$

$z_a$  – piston A displacement

$z_b$  – piston B displacement

**Opening the Model and Running the Simulation**

To open this model, type `sldemo_hydrod` into the MATLAB® Command Window (click the hyperlink if you are using MATLAB Help). To run the simulation, on the Simulation tab, press **Run**. The model:

- Logs signal data to the MATLAB workspace in the `Simulink.SimulationOutput` object `out`. The signal logging data is stored in `out`, in a `Simulink.SimulationData.Dataset` object called `sldemo_hydrod_output`.
- Logs continuous states data to MATLAB workspace. The states data is also contained in the `out` workspace variable, as a structure called `xout`. Each state is assigned a name in the model to facilitate working with logged data. The names of the states are available in the `stateName` field of `xout.signals`. For more information, see “Data Format for Logged Simulation Data”.
- Uses the customizable Circular Gauge and Vertical Gauge blocks to visualize the fluid flow, pressure, and linear displacement in the cylinders.

Figure 1: Two cylinder model and simulation results

**'Mechanical Load' Subsystem**

This subsystem is shown in Figure 2. It solves the equations of motion, which we compute directly using standard Simulink blocks. It is assumed that the rotation angle is small. Look under the mask of the 'Mechanical Load' subsystem to see its structure (right-click on the subsystem and select **Mask > Look Under Mask**).

Figure 2: 'Mechanical Load' subsystem

### Simulation Parameters

The parameters used in this simulation are identical to the parameters used in the single cylinder model, except for the following:

$L = 1.5 \text{ m}$   
 $M = 2500 \text{ kg}$   
 $I = 100 \text{ kg/m}^2$   
 $Q_{\max} = 0.005 \text{ m}^3/\text{sec}$  (constant)  
 $C_2 = 3e-9 \text{ m}^3/\text{sec}/\text{Pa}$   
 $F_{\text{ext}} = -9.81 * M \text{ Newtons}$

Although the pump flow is constant, the model controls the valves independently. Initially, at  $t = 0$ , the cross-section of valve B is zero. It grows linearly to  $1.2e-5 \text{ m}^2$  at  $t = 0.01 \text{ sec}$ , and then linearly decreases to zero at  $t = 0.02 \text{ sec}$ . The cross-section of valve A is  $1.2e-5 \text{ sq.m.}$  at  $t = 0$  and it linearly decreases to zero at  $t = 0.01 \text{ sec}$ , then it linearly increases to  $1.2e-5 \text{ sq.m.}$  at  $t = 0.02 \text{ sec}$ . Then the behavior of the valves A and B repeats periodically with the same pattern. In other words the valves A and B are 180 degrees out of phase.

### Results

Figures 3 and 4 show the linear and angular displacements of the rod. The linear displacement response is typical of a type-one integrating system. The relative positions and the angular movement of the rod illustrate the response of the two pistons to the out-of-phase control signals (the cross-section of the valves A and B).

**Figure 3:** Linear displacement of the pistons and the load (load is in the middle of the rod)

**Figure 4:** Angular displacement of the rod

#### Close Model

Close the model and clear all generated data.

#### Conclusions

Simulink provides a productive environment for simulating hydraulic systems, offering enhancements that provide enormous productivity in modeling and flexibility in numerical methods. The use of masked subsystems and model libraries facilitates structured modeling with automatic component updates. As users modify library elements, the models that use the elements automatically incorporate the new versions. Simulink can use differential-algebraic equations (DAEs) to model some fluid elements as incompressible and others as compliant, allowing efficient solutions for complex systems of interdependent circuits.

Models such as this one can ultimately be used as part of overall plant or vehicle systems. The hierarchical nature of Simulink allows independently developed hydraulic actuators to be placed, as appropriate, in larger system models (for example adding controls in the form of sensors or valves). In cases such as these, tools from the Control System Toolbox™ can analyze and tune the overall closed-loop system. The MATLAB/Simulink environment can thus support the entire design, analysis, and modeling cycle.

## Van der Pol Oscillator

This example shows how to model the second-order Van der Pol (VDP) differential equation in Simulink®. In dynamics, the VDP oscillator is non-conservative and has nonlinear damping. At high amplitudes, the oscillator dissipates energy. At low amplitudes, the oscillator generates energy. The oscillator is given by this second-order differential equation:

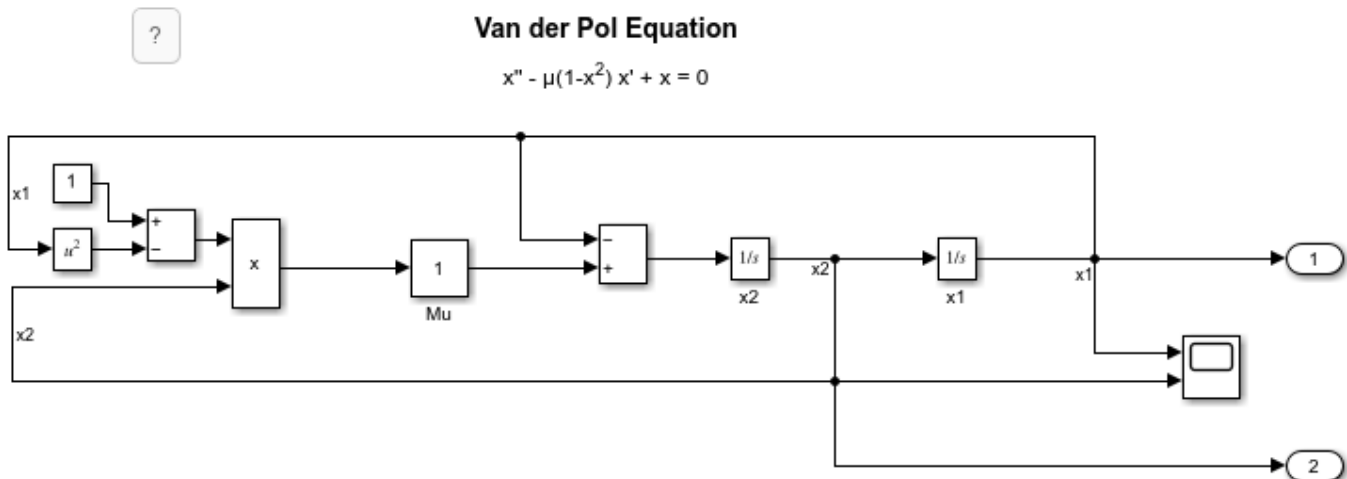

$$\frac{d^2x}{dt^2} - \mu(1 - x^2) \frac{dx}{dt} + x = 0$$

where:

- $x$  is position as a function of time.
- $\mu$  is damping.

The VDP oscillator is used in physical and biological sciences, including electric circuits.

```
open_system('vdp');
```

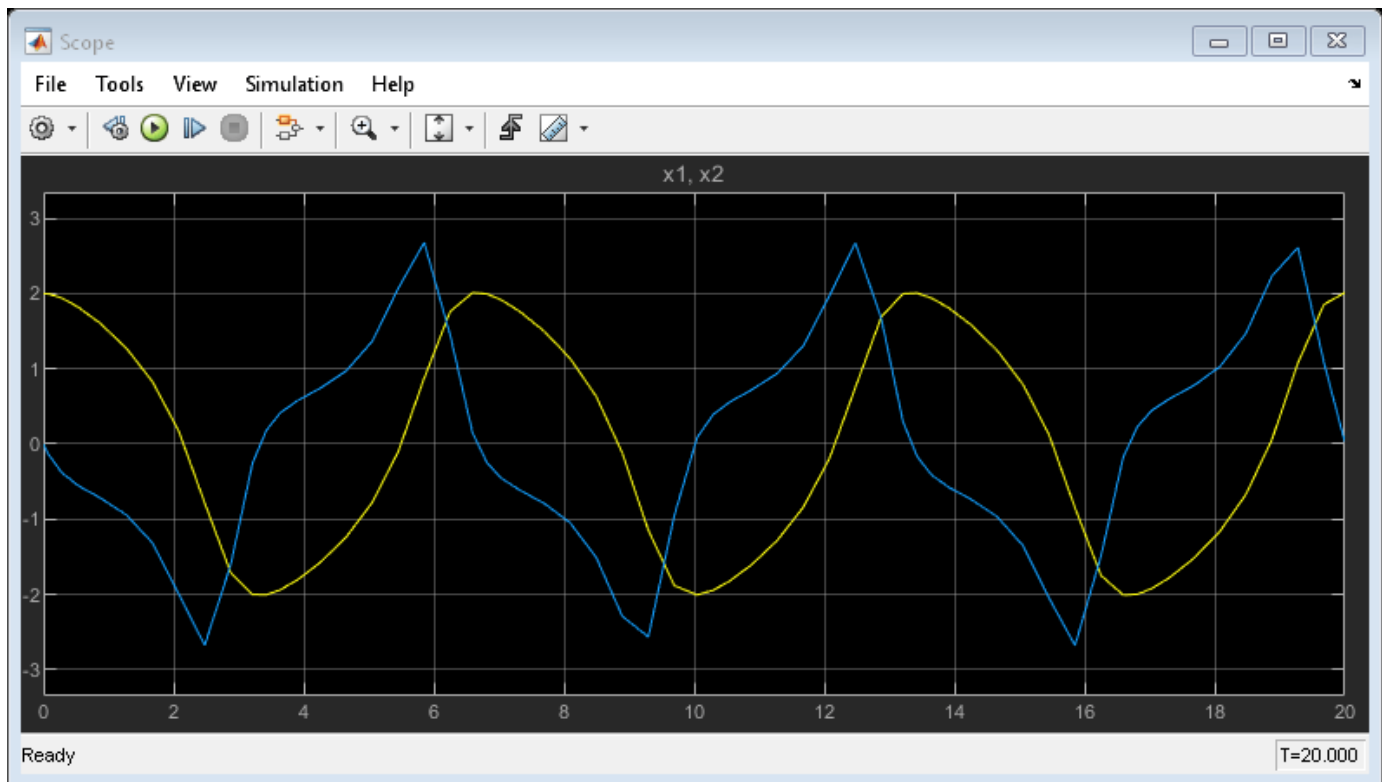

Copyright 2004-2022 The MathWorks, Inc.

### Simulate with $\mu = 1$

When  $\mu = 1$ , the VDP oscillator has nonlinear damping.

```
set_param('vdp/Mu', 'Gain', '1')
sim('vdp');
open_system('vdp/Scope');
```

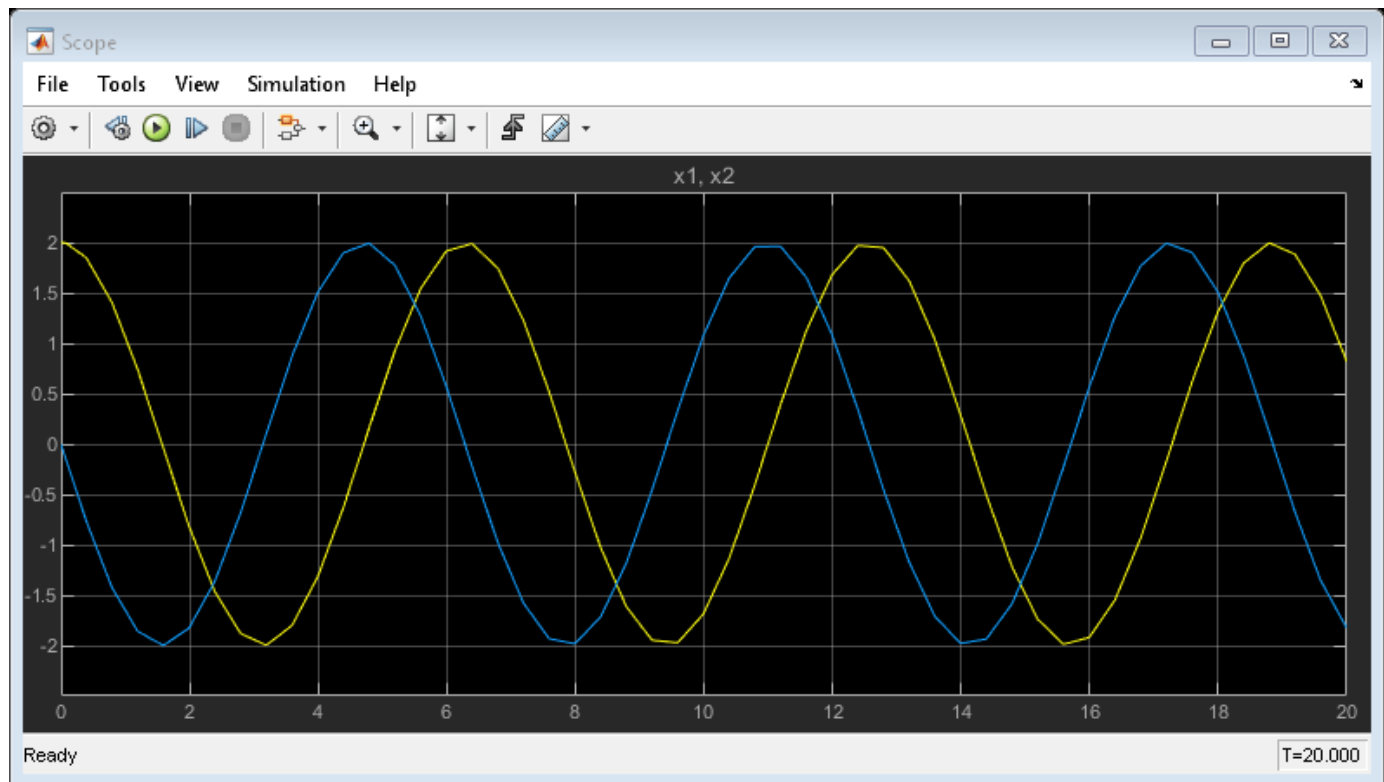

### Simulate with Mu = 0

When  $\mu = 0$ , the VDP oscillator has no damping. Energy is conserved in this simple harmonic oscillator. The equation becomes:

$$\frac{d^2 x}{dt^2} + x = 0$$

```
set_param('vdp/Mu','Gain','0')
sim('vdp');
open_system('vdp/Scope');
```

# Modeling a Fault-Tolerant Fuel Control System

This example shows how to combine Stateflow® with Simulink® to efficiently model hybrid systems. This type of modeling is particularly useful for systems that have numerous possible operational modes based on discrete events. Traditional signal flow is handled in Simulink while changes in control configuration are implemented in Stateflow. The model described below represents a fuel control system for a gasoline engine. The system is highly robust in that individual sensor failures are detected and the control system is dynamically reconfigured for uninterrupted operation.

## Analysis and Physics

Physical and empirical relationships form the basis for the throttle and intake manifold dynamics of this model. The air-fuel ratio is computed by dividing the air mass flow rate (pumped from the intake manifold) by the fuel mass flow rate (injected at the valves). The ideal (i.e. stoichiometric) mixture ratio provides a good compromise between power, fuel economy, and emissions. The target air-fuel ratio for this system is 14.6. Typically, a sensor determines the amount of residual oxygen present in the exhaust gas (EGO). This gives a good indication of the mixture ratio and provides a feedback measurement for closed-loop control. If the sensor indicates a high oxygen level, the control law increases the fuel rate. When the sensor detects a fuel-rich mixture, corresponding to a very low level of residual oxygen, the controller decreases the fuel rate.

## Modeling

Figure 1 shows the top level of the Simulink model. To open the model, click **Open Model**. Press the Play button in the model window toolbar to run the simulation. The model loads necessary data into the model workspace from `sldemo_fuelsys_data.m`. The model logs relevant data to MATLAB workspace in a data structure called `sldemo_fuelsys_output` and streams the data to the Simulation Data Inspector. Logged signals are marked with a blue indicator while streaming signals are marked with the light blue badge (see Figure 1).

Note that loading initial conditions into the model workspace keeps simulation data isolated from data in other open models that you may have open. This also helps avoid MATLAB workspace cluttering. To view the contents of the model workspace select Modeling > Model Explorer, and click on Model Workspace from the Model Hierarchy list.

Notice that units are visible on the model and subsystem icons and signal lines. Units are specified on the ports and on the bus object.

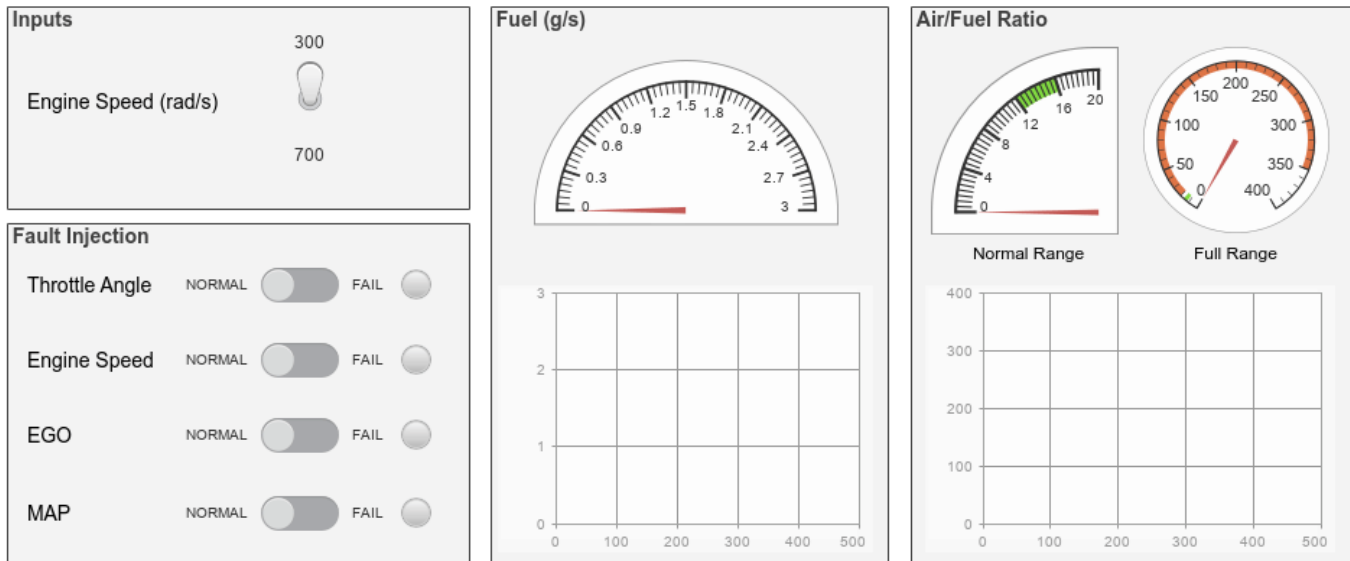

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2022 The MathWorks, Inc.

**Figure 1:** Top-level diagram for the fuel control system model

The Dashboard subsystem (shown in Figure 2) allows you to interact with the model during simulation. The Fault Injection switches can be moved from the Normal to Fail position to simulate sensor failures, while the Engine Speed selector switch can be toggled to change the engine speed. The fuel and air/fuel ratio signals are visualized using the dashboard gauges and scopes to provide visual feedback during a simulation run.

## Fault-Tolerant Fuel Control System Dashboard

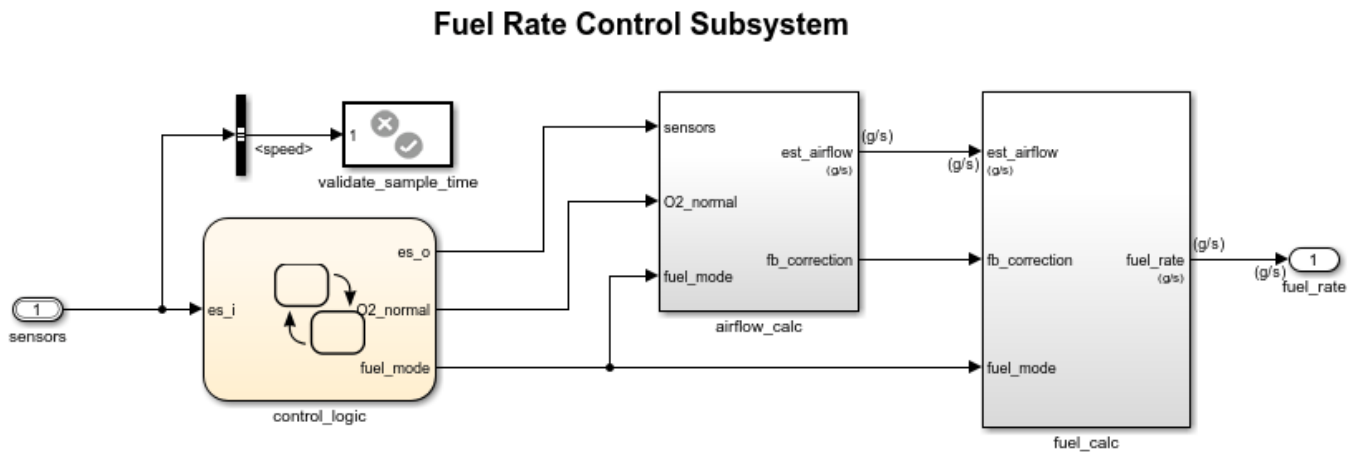

[Update Diagram](#) (Ctrl+D) to bind switches to model workspace variables.

**Figure 2:** Dashboard subsystem for the fuel control system model

The `fuel_rate_control` uses signals from the system's sensors to determine the fuel rate which gives a stoichiometric mixture. The fuel rate combines with the actual air flow in the engine gas dynamics model to determine the resulting mixture ratio as sensed at the exhaust.

You can selectively disable each of the four sensors (throttle angle, speed, EGO and manifold absolute pressure [MAP]) by using the slider switches in the dashboard subsystem, to simulate failures. Simulink accomplishes this by binding slider switches to the value parameter of the constant block. Double-click on the dashboard subsystem to open the control dashboard to change the position of the switch. Similarly, you can induce the failure condition of a high engine speed by toggling the engine speed switch on the dashboard subsystem. A Repeating Table block provides the throttle angle input and periodically repeats the sequence of data specified in the mask.

The `fuel_rate_control` block, shown in Figure 3, uses the sensor input and feedback signals to adjust the fuel rate to give a stoichiometric ratio. The model uses three subsystems to implement this strategy: control logic, airflow calculation, and fuel calculation. Under normal operation, the model estimates the airflow rate and multiplies the estimate by the reciprocal of the desired ratio to give the fuel rate. Feedback from the oxygen sensor provides a closed-loop adjustment of the rate estimation in order to maintain the ideal mixture ratio.

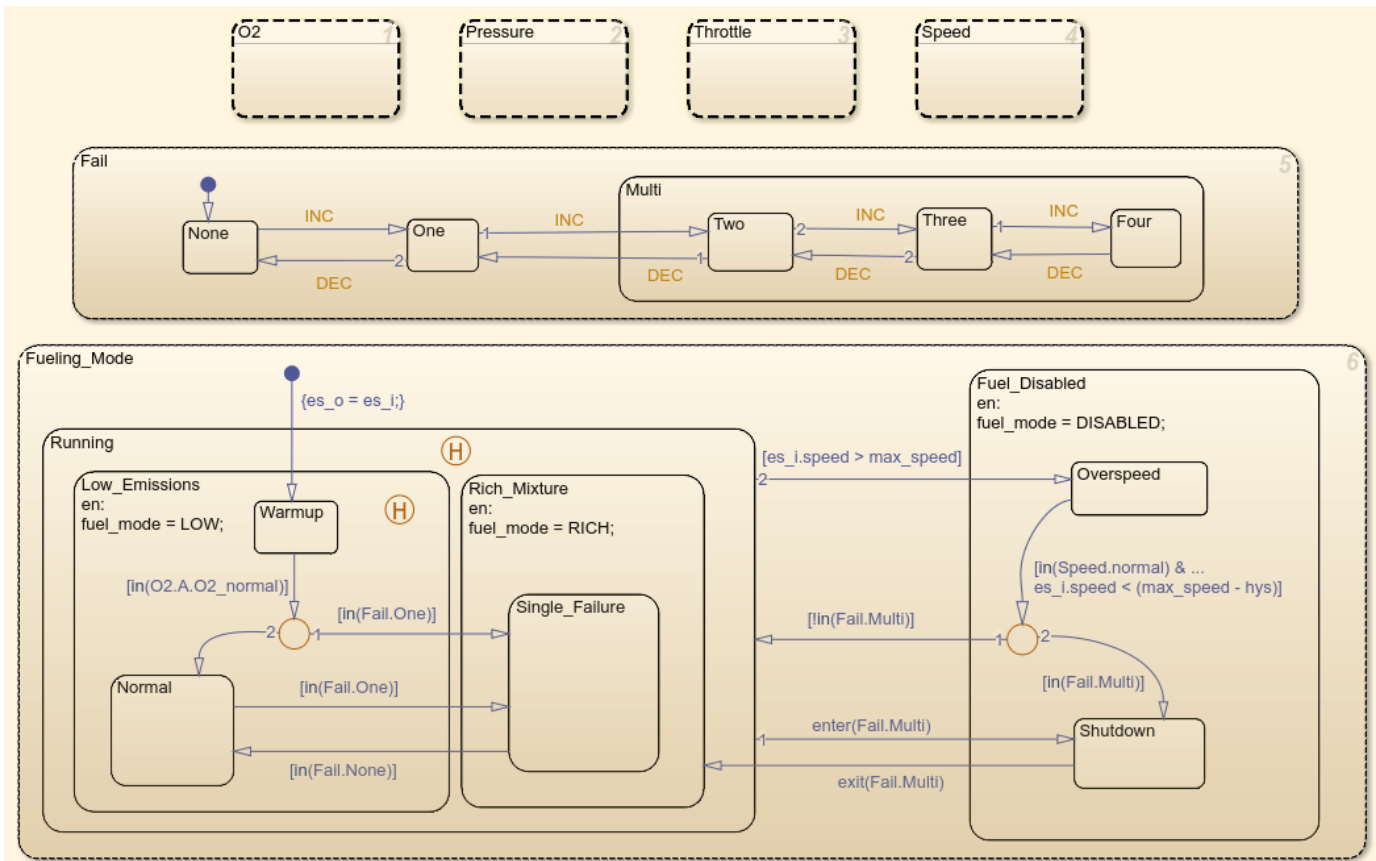

**Figure 3:** Fuel rate controller subsystem

### Control Logic

A single Stateflow chart, consisting of a set of six parallel states, implements the control logic in its entirety. The four parallel states shown at the top of Figure 4 correspond to the four individual sensors. The remaining two parallel states at the bottom consider the status of the four sensors simultaneously and determine the overall system operating mode. The model synchronously calls the entire Stateflow diagram at a regular sample time interval of 0.01 sec. This permits the conditions for transitions to the correct mode to be tested on a timely basis.

To open the control\_logic Stateflow chart, double-click on it in the fuel\_rate\_control subsystem.

**Figure 4:** The control logic chart

When execution begins, all of the states start in their **normal** mode with the exception of the oxygen sensor (EGO). The `O2_warmup` state is entered initially until the warmup period is complete. The system detects throttle and pressure sensor failures when their measured values fall outside their nominal ranges. A manifold vacuum in the absence of a speed signal indicates a speed sensor failure. The oxygen sensor also has a nominal range for failure conditions but, because zero is both the minimum signal level and the bottom of the range, failure can be detected only when it exceeds the upper limit.

Regardless of which sensor fails, the model always generates the directed event broadcast `Fail.INC`. In this way the triggering of the universal sensor failure logic is independent of the sensor. The model also uses a corresponding sensor recovery event, `Fail.DEC`. The `Fail` state keeps track of the number of failed sensors. The counter increments on each `Fail.INC` event and decrements on each `Fail.DEC` event. The model uses a superstate, `Multi`, to group all cases where more than one sensor has failed.

The bottom parallel state represents the fueling mode of the engine. If a single sensor fails, operation continues but the air/fuel mixture is richer to allow smoother running at the cost of higher emissions. If more than one sensor has failed, the engine shuts down as a safety measure, since the air/fuel ratio cannot be controlled reliably.

During the oxygen sensor warm-up, the model maintains the mixture at normal levels. If this is unsatisfactory, you can change the design by moving the warm-up state to within the `Rich_Mixture`

superstate. If a sensor failure occurs during the warm-up period, the `Single_Failure` state is entered after the warm-up time elapses. Otherwise, the `Normal` state is activated at this time.

A protective overspeed feature has been added to the model by creating a new state in the `Fuel_Disabled` superstate. Through the use of history junctions, we assured that the chart returns to the appropriate state when the model exits the overspeed state. As the safety requirements for the engine become better specified, we can add additional shutdown states to the `Fuel_Disabled` superstate.

### Sensor Correction

When a sensor fails, the model computes an estimate of the sensor. For example, open the pressure sensor calculation. Under normal sensor operation, the model uses the value of the pressure sensor. Otherwise, the model estimates the value.

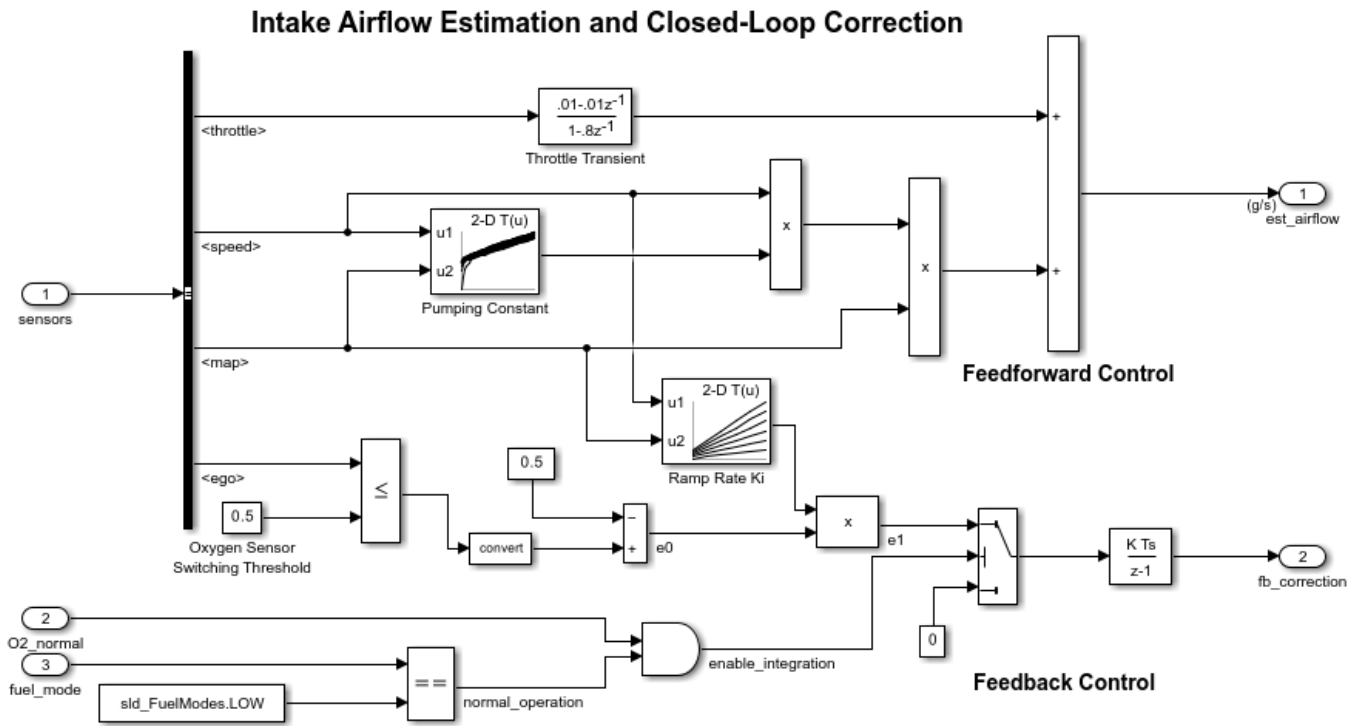

The model computes an estimate of manifold pressure as a function of the engine speed and throttle position. To compute the value, the model uses a Simulink function inside Stateflow.

## Airflow Calculation

The Airflow Calculation block (shown in Figure 6) is the location for the central control laws. This block is found inside the fuel\_rate\_control subsystem (open this block). The block estimates the intake air flow to determine the fuel rate which gives the appropriate air/fuel ratio. Closed-loop control adjusts the estimation according to the residual oxygen feedback in order to maintain the mixture ratio precisely. Even when a sensor failure mandates open-loop operation, the most recent closed-loop adjustment is retained to best meet the control objectives.

**Figure 6:** Airflow estimation and correction

### Equation 1

The engine's intake air flow can be formulated as the product of the engine speed, the manifold pressure and a time-varying scale factor.

$$q = \frac{N}{4\pi} V_{cd} \nu \frac{P_m}{RT} = C_{pump}(N, P_m) N P_m = \text{intake mass flow}$$

$N$  = engine angular speed (Rad/sec)

$V_{cd}$  = engine cylinder displacement volume

$\nu$  = volumetric efficiency

$P_m$  = manifold pressure

$R, T$  = specific gas constant, gas temperature

C<sub>pump</sub> is computed by a lookup table and multiplied by the speed and pressure to form the initial flow estimate. During transients, the throttle rate, with the derivative approximated by a high-pass filter, corrects the air flow for filling dynamics. The control algorithm provides additional correction according to Equation 2.

**Equation 2**

$$e_0 = 0.5 \text{ for } EGO \leq 0.5$$

$$e_0 = -0.5 \text{ for } EGO > 0.5$$

$$e_1 = K_i(N, P_m)e_0 \text{ for } EGO \leq 0.5$$

$$\dot{e}_2 = e_1 \text{ for LOW mode with valid EGO signal}$$

$$\dot{e}_2 = 0 \text{ for RICH, DISABLE or EGO warmup}$$

$e_0, e_1, e_2 =$  intermediate error signals

**Figure 7:** Engine Gas Dynamics subsystem

**Figure 8:** Mixing & Combustion block within the Engine Gas Dynamics subsystem

The nonlinear oxygen sensor (EGO Sensor block) is found inside the Mixing & Combustion block (see Figure 8) within the Engine Gas Dynamics subsystem (see Figure 7). EGO Sensor is modeled as a hyperbolic tangent function, and it provides a meaningful signal when in the vicinity of 0.5 volt. The raw error in the feedback loop is thus detected with a switching threshold, as indicated in Equation 2. If the air-fuel ratio is low (the mixture is lean), the original air estimate is too small and needs to be increased. Conversely, when the oxygen sensor output is high, the air estimate is too large and needs to be decreased. Integral control is utilized so that the correction term achieves a level that brings about zero steady-state error in the mixture ratio.

The normal closed-loop operation mode, LOW, adjusts the integrator dynamically to minimize the error. The integration is performed in discrete time, with updates every 10 milliseconds. When

operating open-loop however, in the RICH or O2 failure modes, the feedback error is ignored and the integrator is held. This gives the best correction based on the most recent valid feedback.

### Fuel Calculation

The fuel\_calc subsystem (within the fuel\_rate\_control subsystem, see Figure 9) sets the injector signal to match the given airflow calculation and fault status. The first input is the computed airflow estimation. This is multiplied with the target fuel/air ratio to get the commanded fuel rate. Normally the target is stoichiometric, i.e. equals the optimal air to fuel ratio of 14.6. When a sensor fault occurs, the Stateflow control logic sets the mode input to a value of 2 or 3 (RICH or DISABLED) so that the mixture is either slightly rich of stoichiometric or is shut down completely.

**Figure 9:** fuel\_calc subsystem

The fuel\_calc subsystem (Figure 9) employs adjustable compensation (Figure 10) in order to achieve different purposes in different modes. In normal operation, phase lead compensation of the feedback correction signal adds to the closed-loop stability margin. In RICH mode and during EGO sensor failure (open loop), however, the composite fuel signal is low-pass filtered to attenuate noise introduced in the estimation process. The end result is a signal representing the fuel flow rate which, in an actual system, would be translated to injector pulse times.

### Loop Compensation and Filtering

Figure 10: Switchable compensation subsystem

### Results and Conclusions

Simulation results are shown in Figure 11 and Figure 12. The simulation is run with a throttle input that ramps from 10 to 20 degrees over a period of two seconds, then goes back to 10 degrees over the next two seconds. This cycle repeats continuously while the engine is held at a constant speed so

that the user can experiment with different fault conditions and failure modes. Click on a sensor fault switch in the dashboard subsystem to simulate the failure of the associated sensor. Repeat this operation to slide the switch back for normal operation.

**Figure 11:** Comparing the fuel flow rate for different sensor failures

Figure 11 compares the fuel flow rate under fault-free conditions (baseline) with the rate applied in the presence of a single failure in each sensor individually. In each case note the nonlinear relationship between fuel flow and the triangular throttle command (shown in Figure 13). In the baseline case, the fuel rate is regulated tightly, exhibiting a small ripple due to the switching nature of the EGO sensor's input circuitry. In the other four cases the system operates open loop. The control strategy is proven effective in maintaining the correct fuel profile in the single-failure mode. In each of the fault conditions, the fuel rate is essentially 125% of the baseline flow, fulfilling the design objective of 80% rich.

**Figure 12:** Comparing the air-fuel ratio for different sensor failures

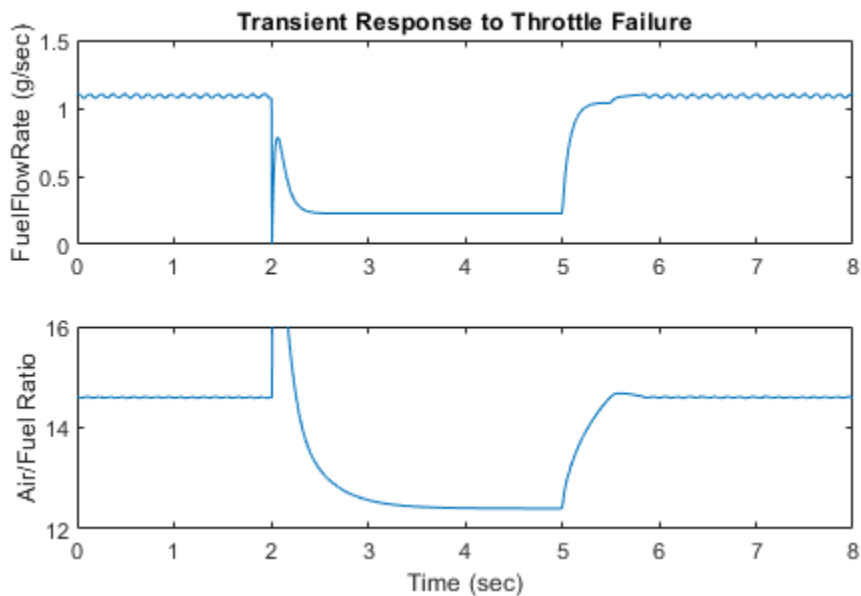

Figure 12 plots the corresponding air/fuel ratio for each case. The baseline plot shows the effects of closed-loop operation. The mixture ratio is regulated very tightly to the stoichiometric objective of

14.6. The rich mixture ratio is shown in the bottom four plots of Figure 12. Although they are not tightly regulated, as in the closed-loop case, they approximate the objective of air/fuel ( $0.8 \times 14.6 = 11.7$ ).

**Figure 13:** Throttle command

The transient behavior of the system is shown in Figure 14. With a constant 12 degree throttle angle and the system in steady-state, a throttle failure is introduced at  $t = 2$  and corrected at  $t = 5$ . At the onset of the failure, the fuel rate increases immediately. The effects are seen at the exhaust as the rich ratio propagates through the system. The steady-state condition is then quickly recovered when closed-loop operation is restored.

**Figure 14:** Transient response to fault detection

**Remarks**

If you enable animation in the Stateflow debugger, the state transitions are highlighted in the Stateflow diagram (see Figure 4) as the various states are activated. The sequence of activation is indicated by changing colors. This closely coupled synergy between Stateflow and Simulink fosters the modeling and development of complete control systems.

## Using a Data Dictionary to Manage the Data for a Fuel Control System

This example shows how to use data dictionaries to manage the data for a fuel rate control system designed using Simulink® and Stateflow®.

### Familiarize Yourself with the Model

The `sldemo_fuelsys_dd` model is a closed-loop system containing a "plant" and "controller". The plant is used to validate the design of the controller. In this example, the plant and controller are represented by separate models that are referenced from the test harness model. Let's take a look at these models.

### Open and Compile the Test Harness Model

The sensor switches simulate any combination of sensor failures. The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2022 The MathWorks, Inc.

### View the Engine Gas Dynamics System (Plant)

Double-click on the Engine Gas Dynamics block to open the plant model.

## Engine Gas Dynamics

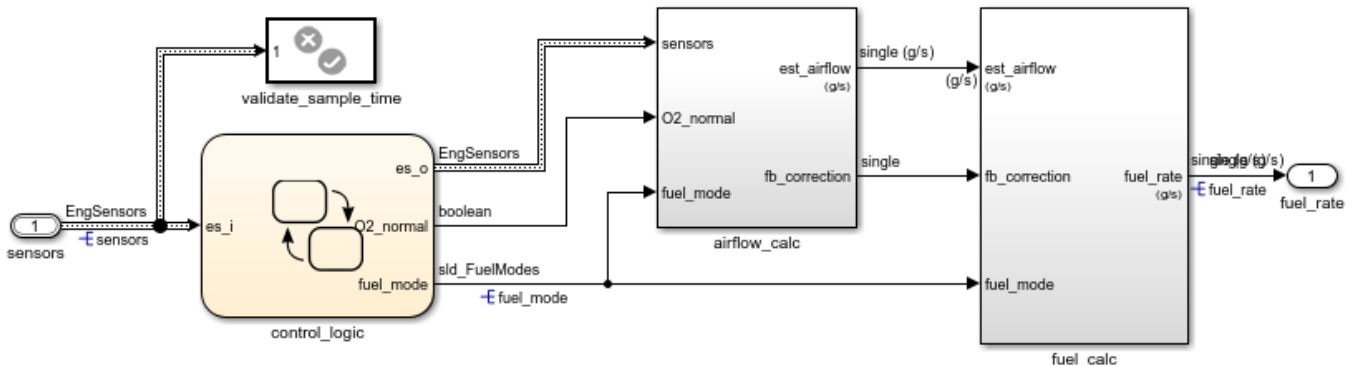

Copyright 1990-2022 The MathWorks, Inc.

### View the Fuel Rate Control System (Controller)

Double-click on the Fuel Rate Controller block to open the controller model.

## Fuel Rate Controller

Copyright 1990-2022 The MathWorks, Inc.

### Investigate the Data Used by the Controller

The global design data for the controller model is defined in a data dictionary. Using data dictionaries has many advantages over defining data in the base workspace.

The controller model is explicitly linked to a data dictionary. This link is set up on the **External Data** tab of the Model Properties dialog box. To open this dialog box, click the icon in the lower-left corner of the model window and select the gear icon on the right side.

To open the data dictionary in the Model Explorer, in the model window, click the same icon and select **External Data**. In Model Explorer, select `sldemo_fuelsys_dd_controller` under the **External Data** node.

In the **Contents** pane, you can see the parameter and signal objects that are used to configure the controller algorithm for simulation and code generation. In the **Dialog** pane on the right, you can see that the dictionary also contains a reference to another data dictionary, `sldemo_fuelsys_dd_types.sldd`, that defines the data type objects used by this model.

This data dictionary is configured for a float-point controller, as is seen by the data type display on the signal lines in the controller model. The data types dictionary, `sldemo_fuelsys_dd_types.sldd`, sources data type objects from the referenced dictionary `sldemo_fuelsys_dd_types_float.sldd`. To configure for a fixed-point controller, you could create a new dictionary that contains fixed-point data type objects and change the types dictionary (`sldemo_fuelsys_dd_types.sldd`) to reference that dictionary instead.

### **Investigate the Units Used by the Components**

Notice that units are visible on the model and subsystem icons and signal lines. Units are specified on the ports and on the bus, signal and parameter objects in the data dictionary.

### **Simulate the Test Harness Model**

The test harness model is also linked to a data dictionary (`sldemo_fuelsys_dd.sldd`). This data dictionary contains references to the data dictionaries for the plant and controller models but it does not contain any additional data.

Simulate the test harness model to validate the behavior of the controller in the floating-point configuration.

## Modeling Engine Timing Using Triggered Subsystems

This example shows how to model a four-cylinder spark ignition internal combustion engine from the throttle to the crankshaft output. We used well-defined physical principles supplemented, where appropriate, with empirical relationships that describe the system's dynamic behavior without introducing unnecessary complexity.

### Analysis and Physics

This example describes the concepts and details surrounding the creation of engine models with emphasis on important Simulink® modeling techniques. The basic model uses the enhanced capabilities of Simulink to capture time-based events with high fidelity. Within this simulation, a triggered subsystem models the transfer of the air-fuel mixture from the intake manifold to the cylinders via discrete valve events. This takes place concurrently with the continuous-time processes of intake flow, torque generation and acceleration. A second model adds an additional triggered subsystem that provides closed-loop engine speed control via a throttle actuator. These models can be used as standalone engine simulations. Or, they can be used within a larger system model, such as an integrated vehicle and powertrain simulation, in the development of a traction control system.

This model is based on published results by Crossley and Cook (1991). It describes the simulation of a four-cylinder spark ignition internal combustion engine. The Crossley and Cook work also shows how a simulation based on this model was validated against dynamometer test data. The ensuing sections (listed below) analyze the key elements of the engine model that were identified by Crossley and Cook:

- 1 Throttle
  - 2 Intake manifold
  - 3 Mass flow rate
  - 4 Compression stroke
  - 5 Torque generation and acceleration
- Note: Additional components can be added to the model to provide greater accuracy in simulation and to more closely replicate the behavior of the system.

### Throttle

The first element of the model is the throttle body. The control input is the angle of the throttle plate. The rate at which the model introduces air into the intake manifold can be expressed as the product of two functions:

- 1 an empirical function of the throttle plate angle only
- 2 a function of the atmospheric and manifold pressures

In cases of lower manifold pressure (greater vacuum), the flow rate through the throttle body is sonic and is only a function of the throttle angle. This model accounts for this low pressure behavior with a switching condition in the compressibility equations shown in Equation 1.

### Equation 1

$$\dot{m}_{ai} = f(\theta) \cdot g(P_m) = \text{mass flow rate into manifold (g/s)}$$

$$f(\theta) = 2.821 - 0.05231 \cdot \theta + 0.10299 \cdot \theta^2 - 0.00063 \cdot \theta^3$$

$$g(P_m) = 1; \text{ if } P_m \leq P_{amb}/2$$

$$g(P_m) = \frac{2}{P_{amb}} \sqrt{P_m P_{amb} - P_m^2}; \text{ if } P_{amb}/2 \leq P_m \leq P_{amb}$$

$$g(P_m) = -\frac{2}{P_m} \sqrt{P_m P_{amb} - P_{amb}^2}; \text{ if } P_{amb} \leq P_m \leq 2P_{amb}$$

$$g(P_m) = -1; \text{ if } P_m \geq 2P_{amb}$$

$\dot{m}_{ai}$  → mass flow rate into manifold (g/s);

$\theta$  → throttle angle (deg);

$P_m$  → manifold pressure (bar);

$P_{amb}$  → ambient (atmospheric) pressure (bar);

### Intake Manifold

The simulation models the intake manifold as a differential equation for the manifold pressure. The difference in the incoming and outgoing mass flow rates represents the net rate of change of air mass with respect to time. This quantity, according to the ideal gas law, is proportional to the time derivative of the manifold pressure (see Equation 2). Note that, unlike the model of Crossley and Cook (see also references 3 through 5), this model doesn't incorporate exhaust gas recirculation (EGR), although this can easily be added.

### Equation 2

$$\dot{P}_m = \frac{RT}{V_m} (\dot{m}_{ai} - \dot{m}_{ao})$$

$R$  → specific gas constant;

$T$  → temperature (K);

$V_m$  → manifold volume ( $m^3$ );

$\dot{m}_{ao}$  → mass flow rate of air out of the manifold (g/s);

$\dot{P}_m$  → rate of change of manifold pressure (bar/s);

### Intake Mass Flow Rate

The mass flow rate of air that the model pumps into the cylinders from the manifold is described in Equation 3 by an empirically derived equation. This mass rate is a function of the manifold pressure and the engine speed.

### Equation 3

$$\dot{m}_{ao} = -0.366 + 0.08979 \cdot N \cdot P_m - 0.0337 \cdot N \cdot P_m^2 + 0.0001 \cdot N^2 \cdot P_m$$

$N \rightarrow$  engine angular speed (rad/s);

$P_m \rightarrow$  manifold pressure (bar);

To determine the total air charge pumped into the cylinders, the simulation integrates the mass flow rate from the intake manifold and samples it at the end of each intake stroke event. This determines the total air mass that is present in each cylinder after the intake stroke and before compression.

### Compression Stroke

In an inline four-cylinder four-stroke engine, 180 degrees of crankshaft revolution separate the ignition of each successive cylinder. This results in each cylinder firing on every other crank revolution. In this model, the intake, compression, combustion, and exhaust strokes occur simultaneously (at any given time, one cylinder is in each phase). To account for compression, the combustion of each intake charge is delayed by 180 degrees of crank rotation from the end of the intake stroke.

### Torque Generation and Acceleration

The final element of the simulation describes the torque developed by the engine. An empirical relationship dependent upon the mass of the air charge, the air/fuel mixture ratio, the spark advance, and the engine speed is used for the torque computation (see Equation 4).

#### Equation 4

$$\begin{aligned} Torque_{eng} = & -181.3 + 379.36 \cdot m_a + 21.91 \cdot \left(\frac{A}{F}\right) - 0.85 \cdot \left(\frac{A}{F}\right)^2 + 0.26 \cdot \sigma - 0.0028 \cdot \sigma^2 + \\ & + 0.027 \cdot N - 0.000107 \cdot N^2 + 0.00048 \cdot N \cdot \sigma + 2.55 \cdot \sigma \cdot m_a - 0.05 \cdot \sigma^2 \cdot m_a \end{aligned}$$

$m_a \rightarrow$  mass of air in cylinder for combustion (g);

$\left(\frac{A}{F}\right) \rightarrow$  air to fuel ratio;

$\sigma \rightarrow$  spark advance (degrees before top - dead - center);

$Torque_{eng} \rightarrow$  torque produced by the engine (Nm);

Calculate the engine angular acceleration using Equation 5

#### Equation 5

$$J\dot{N} = Torque_{eng} - Torque_{load}$$

$J \rightarrow$  engine rotational moment of inertia ( $kg \cdot m^2$ );

$\dot{N} \rightarrow$  engine angular acceleration ( $rad/s^2$ );

### Open-Loop Model

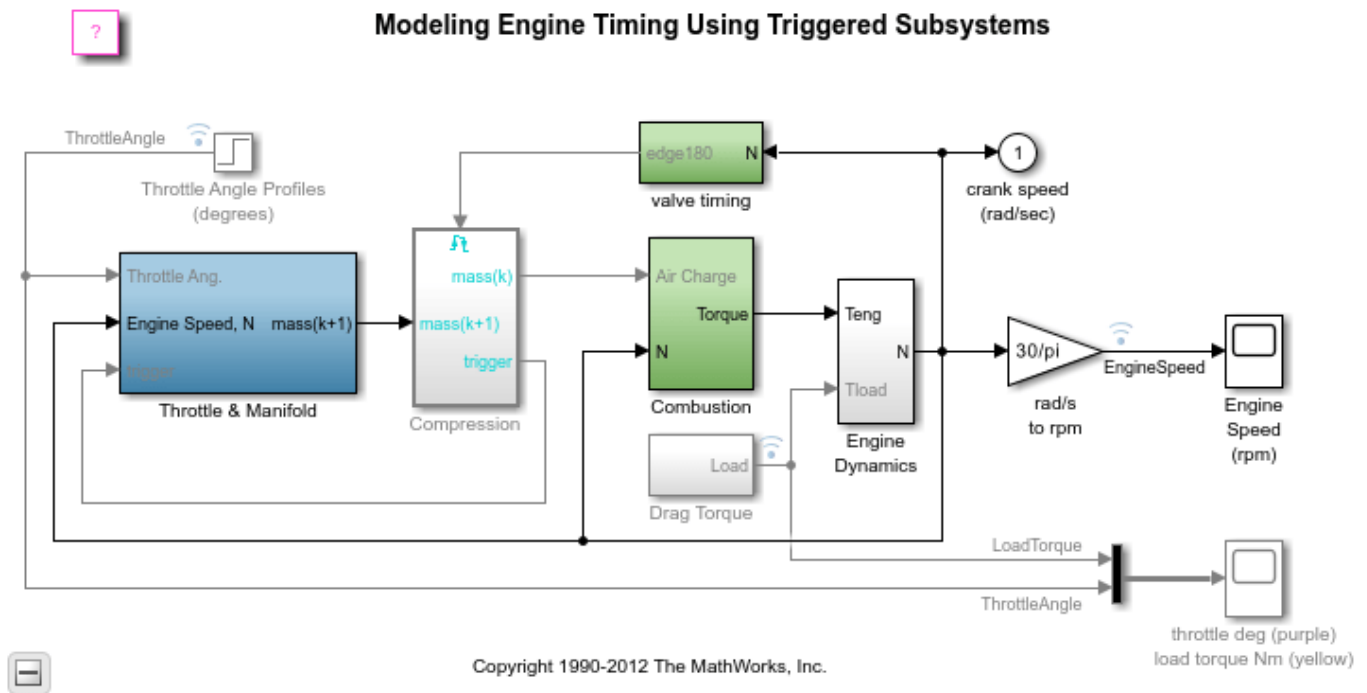

We incorporated the model elements described above into an engine model using Simulink. The following sections describe the decisions we made for this implementation and the key Simulink

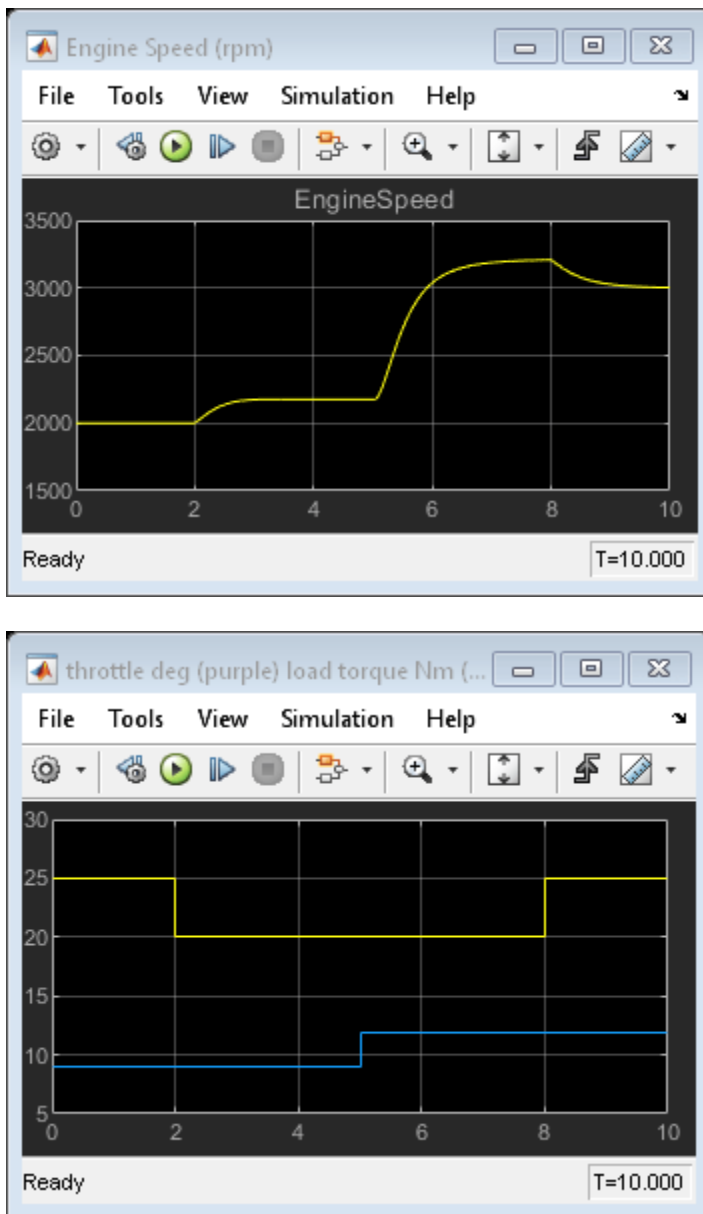

elements used. This section shows how to implement a complex nonlinear engine model easily and quickly in Simulink environment. We developed this model in conjunction with Ken Butts, Ford Motor Company® (2).

Figure 1 shows the top level of the model. Note that, in general, the major blocks correspond to the high-level list of functions given in the model description in the preceding summary. Taking advantage of Simulink's hierarchical modeling capabilities, most of the blocks in Figure 1 are made up of smaller blocks. The following paragraphs describe these smaller blocks.

### Running the Simulation

Press the "Play" button on the model toolbar to run the simulation.

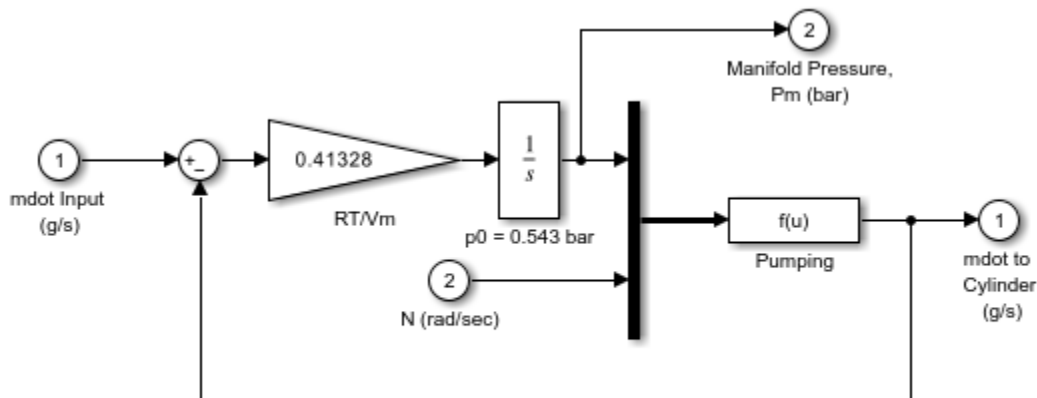

**Figure 1:** The top level of the engine model and simulation results

- Note: The model logs relevant data to MATLAB workspace in a structure called `sldemo_engine_output`. Logged signals have a blue indicator. Read more about Signal Logging in Simulink documentation.

### Throttle/Manifold

In the model, double click on the 'Throttle & Intake Manifold' subsystem to open it. It contains two other subsystems - the 'Throttle' and the 'Intake Manifold' subsystems. Open the 'Throttle' and 'Intake Manifold' to see their components.

### Intake Manifold Vacuum

**Figure 2:** The 'Throttle' and 'Intake Manifold' subsystems

Simulink models for the throttle and intake manifold subsystems are shown in Figure 2. The throttle valve behaves in a nonlinear manner and is modeled as a subsystem with three inputs. Simulink implements the individual equations, given in Equation 1, as function blocks. These provide a convenient way to describe a nonlinear equation of several variables. A 'Switch' block determines whether the flow is sonic by comparing the pressure ratio to its switch threshold, which is set at one half (Equation 1). In the sonic regime, the flow rate is a function of the throttle position only. The direction of flow is from the higher to lower pressure, as determined by the Sign block. With this in mind, the 'Min' block ensures that the pressure ratio is always unity or less.

The differential equation from Equation 2 models the intake manifold pressure. A Simulink function block computes the mass flow rate into the cylinder, a function of manifold pressure and engine speed (see Equation 3).

### Intake and Compression

An integrator accumulates the cylinder mass air flow in the 'Intake' block (located inside the 'Throttle & Manifold' subsystem). The 'Valve Timing' block issues pulses that correspond to specific rotational positions in order to manage the intake and compression timing. Valve events occur each cam rotation, or every 180 degrees of crankshaft rotation. Each event triggers a single execution of the 'Compression' subsystem. The output of the trigger block within the 'Compression' subsystem then feeds back to reset the Intake integrator. In this way, although both triggers conceptually occur at the same instant in time, the integrator output is processed by the 'Compression' block immediately prior to being reset. Functionally, the 'Compression' subsystem uses a 'Unit Delay' block to insert 180 degrees (one event period) of delay between the intake and combustion of each air charge.

Consider a complete four-stroke cycle for one cylinder. During the intake stroke, the 'Intake' block integrates the mass flow rate from the manifold. After 180 degrees of crank rotation, the intake valve closes and the 'Unit Delay' block in the 'Compression' subsystem samples the integrator state. This value, the accumulated mass charge, is available at the output of the 'Compression' subsystem 180 degrees later for use in combustion. During the combustion stroke, the crank accelerates due to the generated torque. The final 180 degrees, the exhaust stroke, ends with a reset of the Intake integrator, prepared for the next complete 720 degrees cycle of this particular cylinder.

For four cylinders, we could use four 'Intake' blocks, four 'Compression' subsystems, etc., but each would be idle 75% of the time. We've made the implementation more efficient by performing the tasks of all four cylinders with one set of blocks. This is possible because, at the level of detail we've modeled, each function applies to only one cylinder at a time.

### Combustion

Engine torque is a function of four variables. The model uses a 'Mux' block to combine these variables into a vector that provides input to the 'Torque Gen' block. A function block computes the engine torque (described empirically in Equation 4). The torque which loads the engine, computed by step functions in the Drag Torque block, is subtracted in the Engine Dynamics subsystem. The difference divided by the inertia yields the acceleration, which is integrated to arrive at the engine crankshaft speed.

### Plotting Simulation Results

We used the following default inputs for the simulation:

$$\textit{Throttle} = 8.97 \text{ (deg) if } t < 5$$

$$\textit{Throttle} = 11.93 \text{ (deg) if } t \geq 5$$

$$\textit{Load} = 25 \text{ (Nm) if } t \leq 2 \text{ or } t \geq 8$$

$$\textit{Load} = 20 \text{ (Nm) if } 2 < t \leq 8$$

Try adjusting the throttle to compensate for the load torque. Figure 3 shows the simulated engine speed, the throttle commands which drive the simulation, and the load torque which disturbs it.

**Figure 3a:** Open-loop simulation inputs

**Figure 3b:** Open-loops simulation results

### Closing Model

Close the model. Clear generated data.

### Conclusions

The ability to model nonlinear, complex systems, such as the engine model described here, is one of Simulink's key features. The power of the simulation is evident in the presentation of the models above. Simulink retains model fidelity, including precisely timed cylinder intake events, which is critical in creating a model of this type. The basic engine model shows the flexibility of Simulink.

## Engine Timing Model with Closed Loop Control

This example shows how to enhance a version of the open-loop engine model described in “Modeling Engine Timing Using Triggered Subsystems” on page 13-139. This model, `sldemo_enginewc`, contains a closed-loop and shows the flexibility and extensibility of Simulink® models. In this enhanced model, the objective of the controller is to regulate engine speed with a fast throttle actuator, such that changes in load torque have minimal effect. This is easily accomplished in Simulink by adding a discrete-time PI controller to the engine model.

### Closed-Loop Model

We chose a control law which uses proportional plus integral (PI) control. The integrator is needed to adjust the steady-state throttle as the operating point changes, and the proportional term compensates for phase lag introduced by the integrator.

### Equation 1

$$\theta = K_p(N_{set} - N) + K_I \int (N_{set} - N)dt$$

$N_{set}$  = speed set point (rpm)

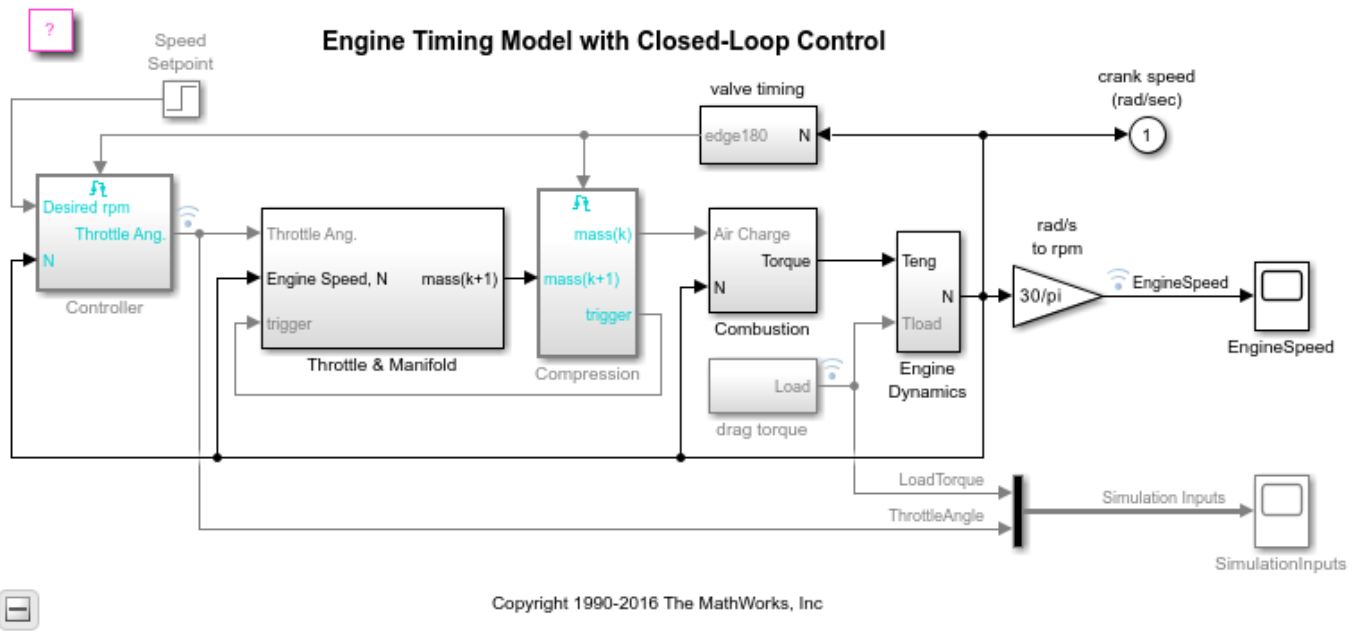

$K_p$  = proportional gain

$K_I$  = integral gain

### Running the Simulation

Press the "Play" button on the model toolbar to run the simulation.

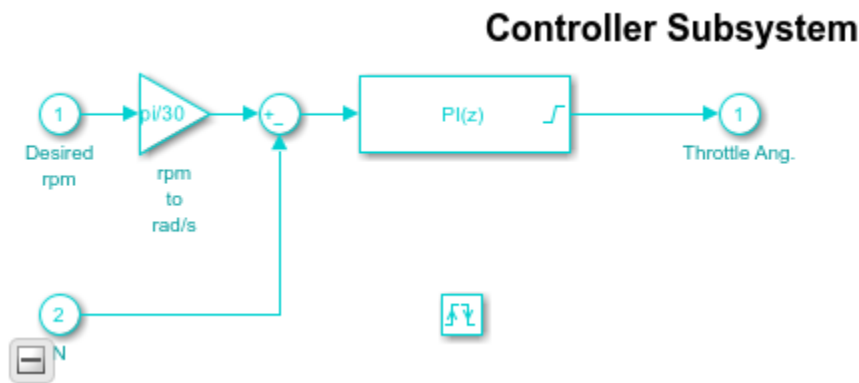

- Note: The model logs relevant data to MATLAB workspace in a structure called `sldemo_enginewc_output`. Logged signals have a blue indicator. Read more about Signal Logging in Simulink Help.

**Figure 1:** Closed-loop engine model and simulation results

In this model we employ a discrete-time controller, which is suitable for microprocessor implementation. The integral term in Equation 1 must thus be realized with a discrete-time approximation. As is typical in the industry, the controller execution is synchronized with the engine's crankshaft rotation. The controller is embedded in a triggered subsystem that is triggered by the valve timing signal described above.

The detailed construction of the 'Controller' subsystem is illustrated in Figure 2. Of note is the use of the 'PID Controller' block. This block implements a proportional-integral control system in discrete time. Note the setting for sample time set (internally) at -1. This indicates that the block inherits its sample time, in this case executing each time the subsystem is triggered. The key component that makes this a triggered subsystem is the 'Trigger' block shown at the bottom of Figure 2. Any subsystem can be converted to a triggered subsystem by dragging a copy of this block into the subsystem diagram from the Simulink Connections library.

**Figure 2:** Speed controller subsystem

## Results

Typical simulation results are shown in Figure 3. The speed set point steps from 2000 rpm to 3000 rpm at  $t = 5$  sec. The torque disturbances are identical to those used in `sldemo_engine`, the open-loop model. Note the quick transient response, with zero steady-state error. Several alternative controller tunings ( $K_i$  and  $K_p$ ) are shown. These can be adjusted by the user at MATLAB command line. This allows the engineer to understand the relative effects of parameter variations.

**Figure 3:** Typical simulation results

## Closing Model

Close the model. Clear logged data.

## Conclusions

The ability to model nonlinear, complex systems, such as the engine model described here, is one of Simulink's key features. The power of the simulation is evident in the presentation of the models above. Simulink retains model fidelity, including precisely timed cylinder intake events, which is critical in creating a model of this type. The complete speed control system shows the flexibility of Simulink. In particular, the Simulink modeling approaches allow rapid prototyping of an interrupt-driven engine speed controller.

## Building a Clutch Lock-Up Model

This example shows how to use Simulink® to model and simulate a rotating clutch system. Although modeling a clutch system is difficult because of topological changes in the system dynamics during lockup, this example shows how Simulink's enabled subsystems easily handle such problems. We illustrate how to employ important Simulink modeling concepts in the creation of the clutch simulation. Designers can apply these concepts to many models with strong discontinuities and constraints that may change dynamically.

In the example, you use enabled subsystems to build the clutch model. Two enabled subsystems model the clutch dynamics in either the locked or unlocked position. After running the simulation, a GUI opens. Checking any of the boxes on the GUI produces a plot of any of the selected variables (versus time).

### Analysis and Physics

The clutch system in this example consists of two plates that transmit torque between the engine and transmission (see Figure 1). There are two distinct modes of operation:

- 1) slipping - the two plates have differing angular velocities
- 2) lockup - the two plates rotate together.

Handling the transition between these two modes presents a modeling challenge. As the system loses a degree of freedom upon lockup, the transmitted torque goes through a step discontinuity. The magnitude of the torque drops from the maximum value supported by the friction capacity to a value that is necessary to keep the two halves of the system spinning at the same rate. The reverse transition, break-apart, is likewise challenging, as the torque transmitted by the clutch plates exceeds the friction capacity.

**Figure 1:** The clutch system, analyzed using a lumped-parameter model

### Variables Used

The following variables are used in the analysis and modeling.

$$T_{in} = \text{input (engine) torque;}$$

$F_n$  = normal force between friction plates;

$I_e, I_v$  = moments of inertia for the engine and for the transmission/vehicle;

$b_e, b_v$  = damping rates at the engine and transmission/vehicle sides of the clutch;

$\mu_k, \mu_s$  = kinetic and static coefficients of friction;

$\omega_e, \omega_v$  = angular speeds of the engine and transmission/vehicle input shafts;

$r_1, r_2$  = inner and outer radii of the clutch plate friction surfaces;

$R$  = equivalent net radius;

$T_{cl}$  = torque transmitted through the clutch;

$T_l$  = friction torque required of the clutch to maintain lockup;

### Equation 1

The state equations for the coupled system are derived as follows:

$$I_e \dot{\omega}_e = T_{in} - b_e \omega_e - T_{cl}$$

$$I_v \dot{\omega}_v = T_{cl} - b_v \omega_v$$

### Equation 2

The torque capacity of the clutch is a function of its size, friction characteristics, and the normal force that is applied.

$$(T_f)_{\max} = \int \int_A \frac{r \times F_f}{A} da = \frac{F_n \mu}{\pi(r_2^2 - r_1^2)} \int_{r_1}^{r_2} \int_0^{2\pi} r^2 dr d\theta = \frac{2}{3} R F_n \mu$$

$$R = \frac{r_2^3 - r_1^3}{r_2^2 - r_1^2}$$

### Equation 3

When the clutch is slipping, the model uses the kinetic coefficient of friction and the full capacity is available, in the direction that opposes slip.

$$T_{fmaxk} = \frac{2}{3} R F_n \mu_k$$

$$T_{cl} = \text{sgn}(\omega_e - \omega_v) T_{fmaxk}$$

where  $\text{sgn}$  denotes the sign function.

### Equation 4

When the clutch is locked, the angular velocities of the engine and transmission input shafts are the same, and the system torque acts on the combined inertia as a single unit. So, we combine the differential equations (Equation 1) into a single equation for the locked state.

$$\omega_e = \omega_v = \omega$$

$$(I_e + I_v)\dot{\omega} = T_{in} - (b_e + b_v)\omega$$

### Equation 5

Solving Equation 1 and Equation 4, the torque transmitted by the clutch while locked is:

$$T_{cl} = T_f = \frac{I_v T_{in} - (I_v b_e - I_e b_v)\omega}{I_v + I_e}$$

### Equation 6

The clutch thus remains locked unless the magnitude of  $T_f$  exceeds the static friction capacity,  $T_{fmaxs}$ .

$$T_{fmaxs} = \frac{2}{3}RF_n\mu_s$$

The state diagram in Figure 2 describes the overall behavior of the clutch.

**Figure 2:** A state diagram describing the friction mode transitions

### Modeling

There are two methods for solving this type of problem:

- 1) Compute the clutch torque transmitted at all times, and employ this value directly in the model.
- 2) Use two different dynamic models and switch between them at the appropriate times.

Because of its overall capabilities, Simulink can model either method. In this example, we describe a simulation for the second method. In the second method, switching between two dynamic models must be performed with care to ensure that the initialized states of the new model match the state values immediately prior to the switch. But, in either approach, Simulink facilitates accurate

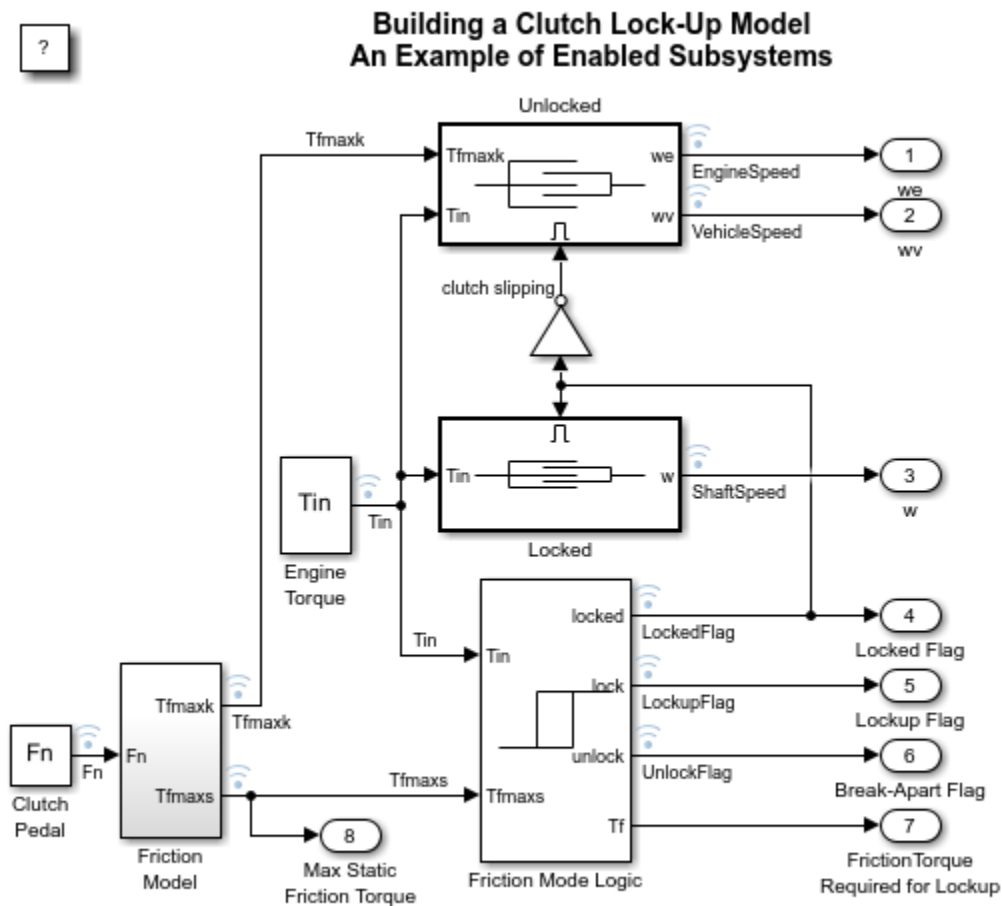

simulation due to its ability to recognize the precise moments at which transitions between lockup and slipping occur.

The simulation model for the clutch system uses enabled subsystems, a particularly useful feature in Simulink. The simulation can use one subsystem while the clutch is slipping and the other when it is locked. A diagram of the Simulink model appears in Figure 3.

**Opening the Model and Running the Simulation**

When the model is open, to run the simulation, click **Run**.

- Note: If you are using MATLAB Help, you can execute code from the example page by selecting the code and pressing F9. You can also Select Code > Right Click > Select "Evaluate Selection".

Copyright 1990-2022 The MathWorks, Inc.

**Figure 3:** Top level diagram for the clutch model

- Note: The model logs relevant data to MATLAB workspace in a structure called `sldemo_clutch_output`. For information about signal logging, see "Configure a Signal for Logging".

### The 'Unlocked' Subsystem

Double click on the 'Unlocked' subsystem in the model window to open it. This subsystem models both sides of the clutch, coupled by the friction torque. It is constructed around the integrator blocks which calculate engine and vehicle speeds (see Figure 4). The model uses gain, multiplication, and summation blocks to compute the speed derivatives (acceleration) from the states and the subsystem inputs of engine torque,  $T_{in}$ , and clutch capacity,  $T_{fmaxk}$ .

**Figure 4:** The 'Unlocked' subsystem

Enabled subsystems, such as 'Unlocked', feature several other noteworthy characteristics. The 'Enable' block at the top of the diagram in Figure 4, defines the model as an enabled subsystem. To create an enabled subsystem, we group the blocks together like any other subsystem. We then insert an 'Enable' block from the Simulink Connections library. This means that:

- An enable input appears on the subsystem block, identified by the pulse-shaped symbol used on the 'Enable' block itself.
- The subsystem executes only when the signal at the enable input is greater than zero.

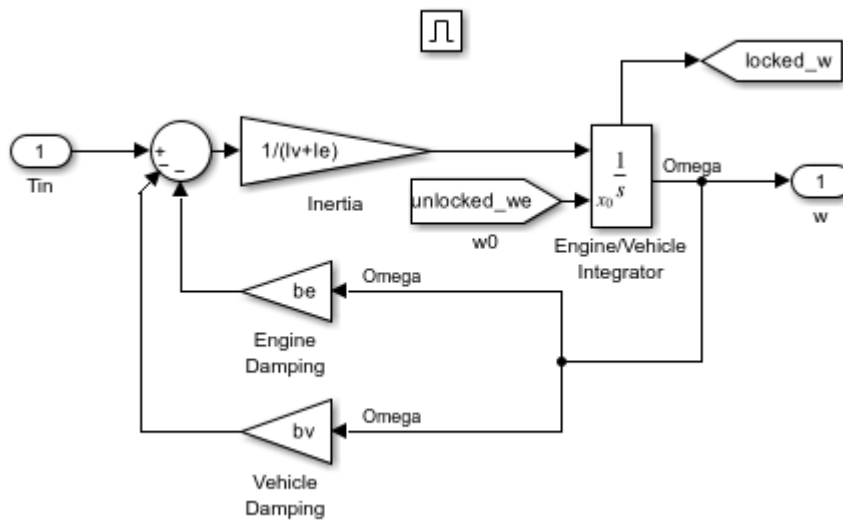

In this example, the 'Unlocked' subsystem executes only when the supervising system logic determines that it should be enabled.

There is another important consideration when using systems that can be enabled or disabled. When the system is enabled, the simulation must reinitialize the integrators to begin simulating from the correct point. In this case, both sides of the clutch are moving at the same velocity the moment it unlocks. The 'Unlocked' subsystem, which had been dormant, needs to initialize both integrators at that speed in order to keep the system speeds continuous.

The simulation uses 'From' blocks to communicate the state of the locked speed to the initial condition inputs of the two integrators. Each 'From' block represents an invisible connection between itself and a 'Goto' block somewhere else in the system. The 'Goto' blocks connect to the state ports of the integrators so that the model can use these states elsewhere in the system without explicitly drawing in the connecting lines.

### The 'Locked' Subsystem

Open the 'Locked' subsystem by double clicking on it in the model window. This is another enabled subsystem in the clutch model (see Figure 5). It uses a single state to represent the engine and vehicle speeds. It computes acceleration as a function of the speed and input torque. As in the 'Unlocked' case, a 'From' block provides the integrator initial conditions and a 'Goto' block broadcasts the state for use elsewhere in the model. While simulating, either the 'Locked' or the 'Unlocked' subsystem is active at all times. Whenever the control changes, the states are neatly handed off between the two.

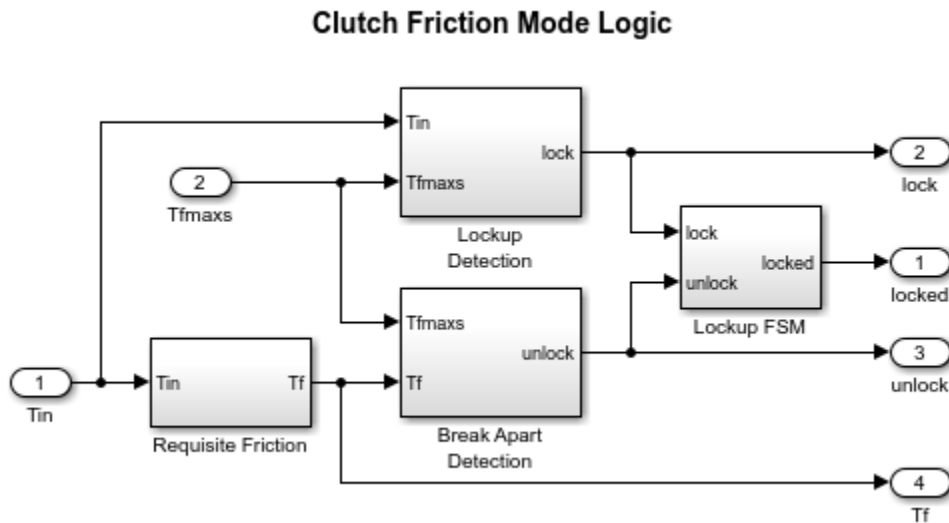

**Figure 5:** The 'Locked' Subsystem

### - The 'Friction Mode Logic' Subsystem

The 'Friction Mode Logic' subsystem (shown in Figure 6) computes the static and kinetic friction (with the appropriate friction coefficient) according to the following formula:

$$T_{fmax} = \frac{2}{3} R F_n \mu$$

Open the 'Friction Mode Logic' subsystem by double clicking on it in the model window.

**Figure 6:** The 'Friction Mode Logic' Subsystem

#### - Other Components

The remaining blocks calculate the torque required for lockup (Equation 5), and implement the logic described in Figure 2. One key element is located in the 'Lockup Detection' subsystem within the 'Friction Mode Logic' subsystem. This is the 'Simulink Hit Crossing' block which precisely locates the instant at which the clutch slip reaches zero. This places the mode transition at exactly the right moment.

#### - System Inputs

The system inputs are normal force,  $F_n$ , and engine torque,  $T_{in}$ . Each of these is represented by a matrix table in the model workspace. The inputs are plotted in Figure 7. You can visualize various signals by checking the corresponding boxes on the 'Clutch Demo Signals' GUI.

**Figure 7:** System inputs: normal force and engine torque

### Results

The following parameter values are used to show the simulation. These are not meant to represent the physical quantities corresponding to an actual system, but rather to facilitate a meaningful baseline example.

$$I_e = 1 \text{ kg} \cdot \text{m}^2$$

$$I_v = 5 \text{ kg} \cdot \text{m}^2$$

$$b_e = 2 \text{ Nm/rad/sec}$$

$$b_v = 1 \text{ Nm/rad/sec}$$

$$\mu_k = 1$$

$$\mu_s = 1.5$$

$$R = 1 \text{ m}$$

For the inputs shown above, the system velocities behave as shown in Figure 8 below. The simulation begins in the Unlocked mode, with an initial engine speed flare as the vehicle side accelerates its larger inertia. At about  $t = 4$  sec, the velocities come together and remain locked, indicating that

the clutch capacity is sufficient to transmit the torque. At  $t = 5$  sec, the engine torque begins to decrease, as does the normal force on the friction plates. Consequently, the onset of slip occurs at about  $t = 6.25$  sec as indicated by the separation of the engine and vehicle speeds.

**Figure 8:** Angular velocities of the engine, vehicle and shaft for default inputs

Notice that the various states remain constant while they are disabled. At the time instants at which transitions take place, the state hand-off is both continuous and smooth. This is a result of supplying each integrator with the appropriate initial conditions to use when the state is enabled.

### Closing Model

Close the model. Clear generated data.

### Conclusions

This example shows how to use Simulink and its standard block library to model, simulate, and analyze a system with topological discontinuities. This is a powerful example of the 'Hit Crossing' block and how it can be used to capture specific events during a simulation. The Simulink model of

this clutch system can serve as a guide when creating models with similar characteristics. You can apply the principles used in this example to any system with topological discontinuities.

## Modeling Clutch Lock-Up Using If Blocks

This example shows how to use If/Else subsystems to build a clutch model. An 'If' subsystem models the clutch dynamics in the locked position while an 'Else' subsystem models the unlocked position. One or the other is enabled using the 'If' block. The dot-dashed lines from the 'If' block denote control signals, which are used to enable If/Else (or other conditional) subsystems. Checking any of the boxes on the GUI produces a plot of any of the selected variables (versus time).

### Analysis and Physics

The clutch system in this example consists of two plates that transmit torque between the engine and transmission. There are two distinct modes of operation:

- 1) slipping - the two plates have differing angular velocities
- 2) lockup - the two plates rotate together.

Handling the transition between these two modes presents a modeling challenge. As the system loses a degree of freedom upon lockup, the transmitted torque goes through a step discontinuity. The magnitude of the torque drops from the maximum value supported by the friction capacity to a value that is necessary to keep the two halves of the system spinning at the same rate. The reverse transition, break-apart, is likewise challenging, as the torque transmitted by the clutch plates exceeds the friction capacity.

- Note: You can find a detailed analysis of this system, including equations and diagrams, in the example for the clutch model with enabled subsystems.

### Modeling

You can use the following two methods for solving this problem:

- 1) Compute the clutch torque transmitted at all times, and employ this value directly in the model.
- 2) Use two different dynamic models and switch between them at the appropriate times.

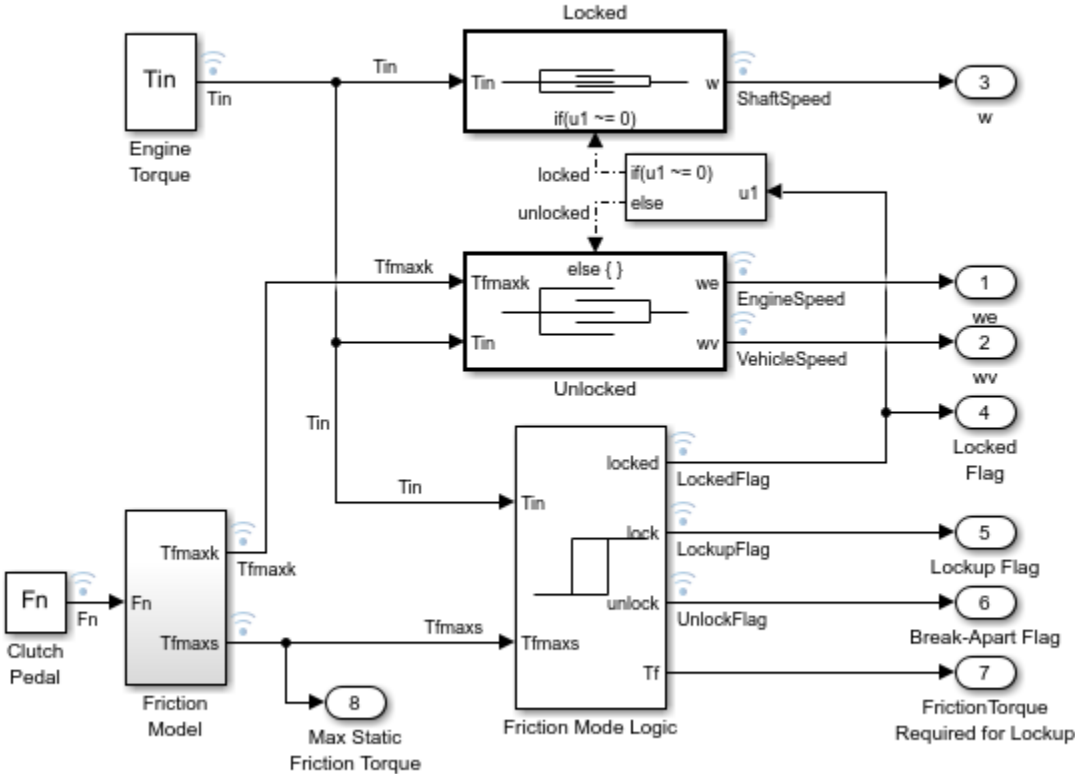

Simulink® can model either method. In this example, we describe a simulation for the second method. Switching between two dynamic models must be performed with care to ensure that the initialized states of the new model match the state values immediately prior to the switch. In either approach, Simulink facilitates accurate simulation due to its ability to recognize the precise moments at which transitions between lockup and slipping occur.

### Running the Simulation

When the model is open, to run the simulation, click **Run**.

?

### Clutch Simulation An Example of the If Block

Copyright 1990-2022 The MathWorks, Inc.

**Figure 1:** Top level diagram for the clutch model

- Note: The model logs relevant data to MATLAB workspace in a structure called `sldemo_clutch_if_output`. Logged signals have a blue indicator. For information about signal logging, see "Configure a Signal for Logging".

### The 'If' Block

The 'If' block uses the `LockedFlag` signal to switch between the 'Locked' and 'Unlocked' subsystems. Double click on the 'If' block in the model to set its parameters (see Figure 2). `LockedFlag` represents the status of the clutch. `LockedFlag = 1` if the clutch is locked and `LockedFlag = 0` if the clutch is unlocked.

**Figure 2:** Setting 'If' block parameters

## Results

The inputs for this model are the same as for the model that uses enabled subsystems (sldemo\_clutch). System velocities behave as shown in Figure 3 below. As expected, the results obtained from sldemo\_clutch and sldemo\_clutch\_if are identical.

**Figure 3:** Angular velocities of the engine, vehicle and shaft for default inputs

### Closing Model

Close the model. Clear generated data.

### Conclusions

This example shows how to use 'If' blocks in Simulink to model a system with topological discontinuities. This is an alternative to using enabled subsystems.

## Modeling an Anti-Lock Braking System

This example shows how to model a simple model for an Anti-Lock Braking System (ABS). It simulates the dynamic behavior of a vehicle under hard braking conditions. The model represents a single wheel, which may be replicated a number of times to create a model for a multi-wheel vehicle.

This model uses the signal logging feature in Simulink®. The model logs signals to the MATLAB® workspace where you can analyze and view them. You can view the code in `ModelingAnAntiLockBrakingSystemExample.m` to see how this is done.

In this model, the wheel speed is calculated in a separate model named `sldemo_wheel_speed_absbrake`. This component is then referenced using a 'Model' block. Note that both the top model and the referenced model use a variable step solver, so Simulink will track zero-crossings in the referenced model.

### Analysis and Physics

The wheel rotates with an initial angular speed that corresponds to the vehicle speed before the brakes are applied. We used separate integrators to compute wheel angular speed and vehicle speed. We use two speeds to calculate slip, which is determined by Equation 1. Note that we introduce vehicle speed expressed as an angular velocity (see below).

$$\omega_v = \frac{V}{R} \text{ (equals the wheel angular speed if there is no slip)}$$

### Equation 1

$$\omega_v = \frac{V_v}{R_r}$$

$$slip = 1 - \frac{\omega_w}{\omega_v}$$

$\omega_v$  = vehicle speed divided by wheel radius

$V_v$  = vehicle linear velocity

$R_r$  = wheel radius

$\omega_w$  = wheel angular velocity

From these expressions, we see that slip is zero when wheel speed and vehicle speed are equal, and slip equals one when the wheel is locked. A desirable slip value is 0.2, which means that the number of wheel revolutions equals 0.8 times the number of revolutions under non-braking conditions with the same vehicle velocity. This maximizes the adhesion between the tire and road and minimizes the stopping distance with the available friction.

### Modeling

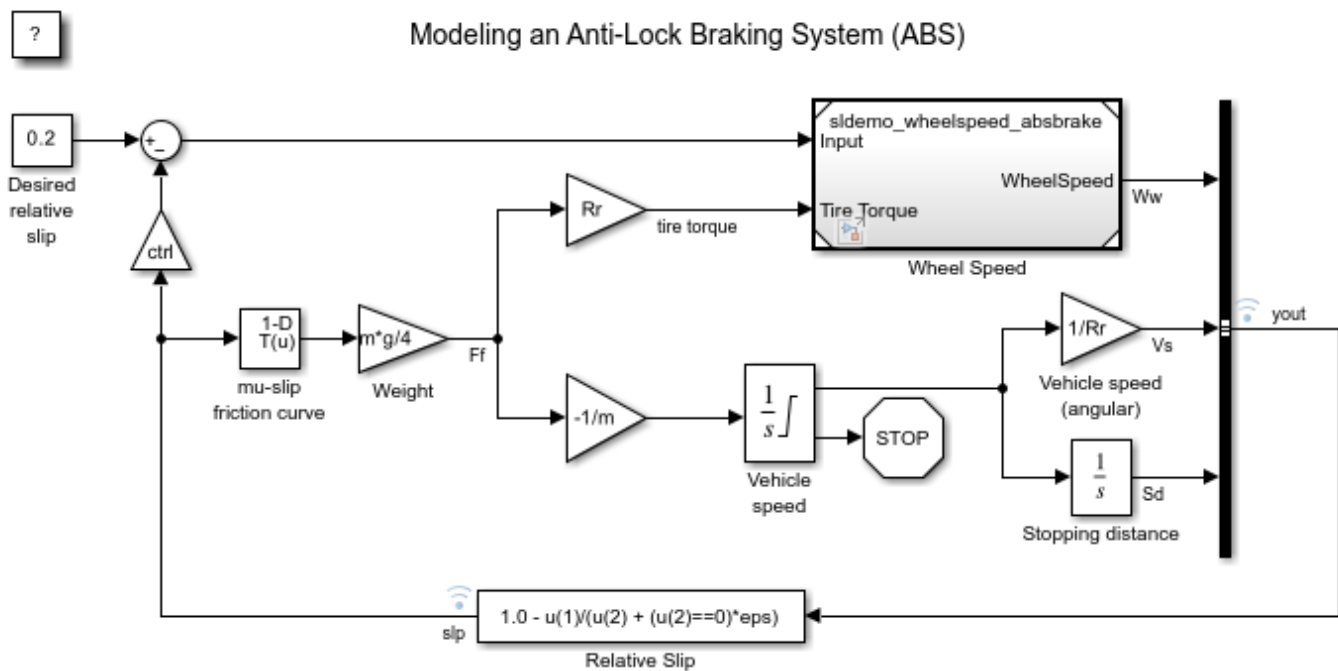

The friction coefficient between the tire and the road surface,  $\mu$ , is an empirical function of slip, known as the mu-slip curve. We created mu-slip curves by passing MATLAB variables into the block diagram using a Simulink lookup table. The model multiplies the friction coefficient,  $\mu$ , by the

weight on the wheel,  $W$ , to yield the frictional force,  $F_f$ , acting on the circumference of the tire.  $F_f$  is divided by the vehicle mass to produce the vehicle deceleration, which the model integrates to obtain vehicle velocity.

In this model, we used an ideal anti-lock braking controller, that uses 'bang-bang' control based upon the error between actual slip and desired slip. We set the desired slip to the value of slip at which the mu-slip curve reaches a peak value, this being the optimum value for minimum braking distance (see note below.).

- Note: In an actual vehicle, the slip cannot be measured directly, so this control algorithm is not practical. It is used in this example to illustrate the conceptual construction of such a simulation model. The real engineering value of a simulation like this is to show the potential of the control concept prior to addressing the specific issues of implementation.

### Opening the Model

Copyright 1990-2022 The MathWorks, Inc.

Double click on the Wheel Speed subsystem in the model window to open it. Given the wheel slip, the desired wheel slip, and the tire torque, this subsystem calculates the wheel angular speed.

?

### Calculate the Wheel Speed for the Anti-Lock Braking System (ABS) Simulation

Copyright 1990-2022 The MathWorks, Inc.

To control the rate of change of brake pressure, the model subtracts actual slip from the desired slip and feeds this signal into a bang-bang control (+1 or -1, depending on the sign of the error). This on/off rate passes through a first-order lag that represents the delay associated with the hydraulic lines of the brake system. The model then integrates the filtered rate to yield the actual brake pressure. The resulting signal, multiplied by the piston area and radius with respect to the wheel ( $K_f$ ), is the brake torque applied to the wheel.

The model multiplies the frictional force on the wheel by the wheel radius ( $R_r$ ) to give the accelerating torque of the road surface on the wheel. The brake torque is subtracted to give the net torque on the wheel. Dividing the net torque by the wheel rotational inertia,  $I$ , yields the wheel acceleration, which is then integrated to provide wheel velocity. In order to keep the wheel speed and vehicle speed positive, limited integrators are used in this model.

#### Running the Simulation in ABS Mode

On the Simulation tab, click **Run** to run the simulation. You can also run the simulation by executing the `sim('sldemo_absbrake')` command in MATLAB. ABS is turned on during this simulation.

- Note: The model logs relevant data to MATLAB workspace in a structure called `sldemo_absbrake_output`. Logged signals have a blue indicator. In this case `yout` and `slp` are logged. Read more about Signal Logging in Simulink Help.

The plots above show the ABS simulation results (for default parameters). The first plot shows the wheel angular velocity and corresponding vehicle angular velocity. This plot shows that the wheel speed stays below vehicle speed without locking up, with vehicle speed going to zero in less than 15 seconds.

### Running the Simulation Without ABS

For more meaningful results, consider the vehicle behavior without ABS. At the MATLAB command line, set the model variable `ctrl = 0`. This disconnects the slip feedback from the controller, resulting in maximum braking.

```
ctrl = 0;
```

Now run the simulation again. This will model braking without ABS.

### Braking With ABS Versus Braking Without ABS

In the plot showing vehicle speed and wheel speed, observe that the wheel locks up in about seven seconds. The braking, from that point on, is applied in a less-than-optimal part of the slip curve. That is, when  $\text{slip} = 1$ , as the slip plot shows, the tire is skidding so much on the pavement that the friction force has dropped off.

This is, perhaps, more meaningful in terms of the comparison shown below. The distance traveled by the vehicle is plotted for the two cases. Without ABS, the vehicle skids about an extra 100 feet, taking about three seconds longer to come to a stop.

### Closing the Model

Close the model. Close the 'Wheel Speed' subsystem. Clear logged data.

### Conclusions

This model shows how you can use Simulink to simulate a braking system under the action of an ABS controller. The controller in this example is idealized, but you can use any proposed control algorithm in its place to evaluate the system's performance. You can also use the Simulink® Coder™ with Simulink as a valuable tool for rapid prototyping of the proposed algorithm. C code is generated and compiled for the controller hardware to test the concept in a vehicle. This significantly reduces the time needed to prove new ideas by enabling actual testing early in the development cycle.

For a hardware-in-the-loop braking system simulation, you can remove the 'bang-bang' controller and run the equations of motion on real-time hardware to emulate the wheel and vehicle dynamics. You can do this by generating real-time C code for this model using the Simulink Coder. You can then test an actual ABS controller by interfacing it to the real-time hardware, which runs the generated code. In this scenario, the real-time model would send the wheel speed to the controller, and the controller would send brake action to the model.

## Automotive Suspension

This example shows how to model a simplified half-car model that includes an independent front and rear vertical suspension. The model also includes body pitch and bounce degrees of freedom. The example provides a description of the model to show how simulation can be used to investigate ride characteristics. You can use this model in conjunction with a powertrain simulation to investigate longitudinal shuffle resulting from changes in throttle setting.

### Analysis and Physics

Free-body diagram of the half-car model

The illustration shows the modeled characteristics of the half-car. The front and rear suspension are modeled as spring/damper systems. A more detailed model would include a tire model, and damper nonlinearities such as velocity-dependent damping (with greater damping during rebound than compression). The vehicle body has pitch and bounce degrees of freedom. They are represented in the model by four states: vertical displacement, vertical velocity, pitch angular displacement, and pitch angular velocity. A full model with six degrees of freedom can be implemented using vector algebra blocks to perform axis transformations and force/displacement/velocity calculations.

**Equation 1** describes the influence of the front suspension on the bounce (i.e. vertical degree of freedom):

$$F_f = 2K_f(L_f\theta - (z + h)) + 2C_f(L_f\dot{\theta} - \dot{z})$$

where:

$F_f, F_r$  = upward force on body from front/rear suspension

$K_f, K_r$  = front and rear suspension spring constant

$C_f, C_r$  = front and rear suspension damping rate

$L_f, L_r =$  horizontal distance from gravity center to front/rear suspension

$\theta, \dot{\theta} =$  pitch (rotational) angle and its rate of change

$z, \dot{z} =$  bounce (vertical) distance and its rate of change

$h =$  road height

**Equations 2** describe pitch moments due to the suspension.

$$M_f = -L_f F_f$$

$$F_r = -2K_r(L_r\theta + (z + h)) - 2C_r(L_r\dot{\theta} + \dot{z})$$

$$M_r = L_r F_r$$

where:

$M_f, M_r =$  Pitch moment due to front/rear suspension

**Equations 3** resolves the forces and moments result in body motion, according to Newton's Second Law:

$$m_b \ddot{z} = F_f + F_r - m_b g$$

$$I_{yy} \ddot{\theta} = M_f + M_r + M_y$$

where:

$m_b =$  body mass

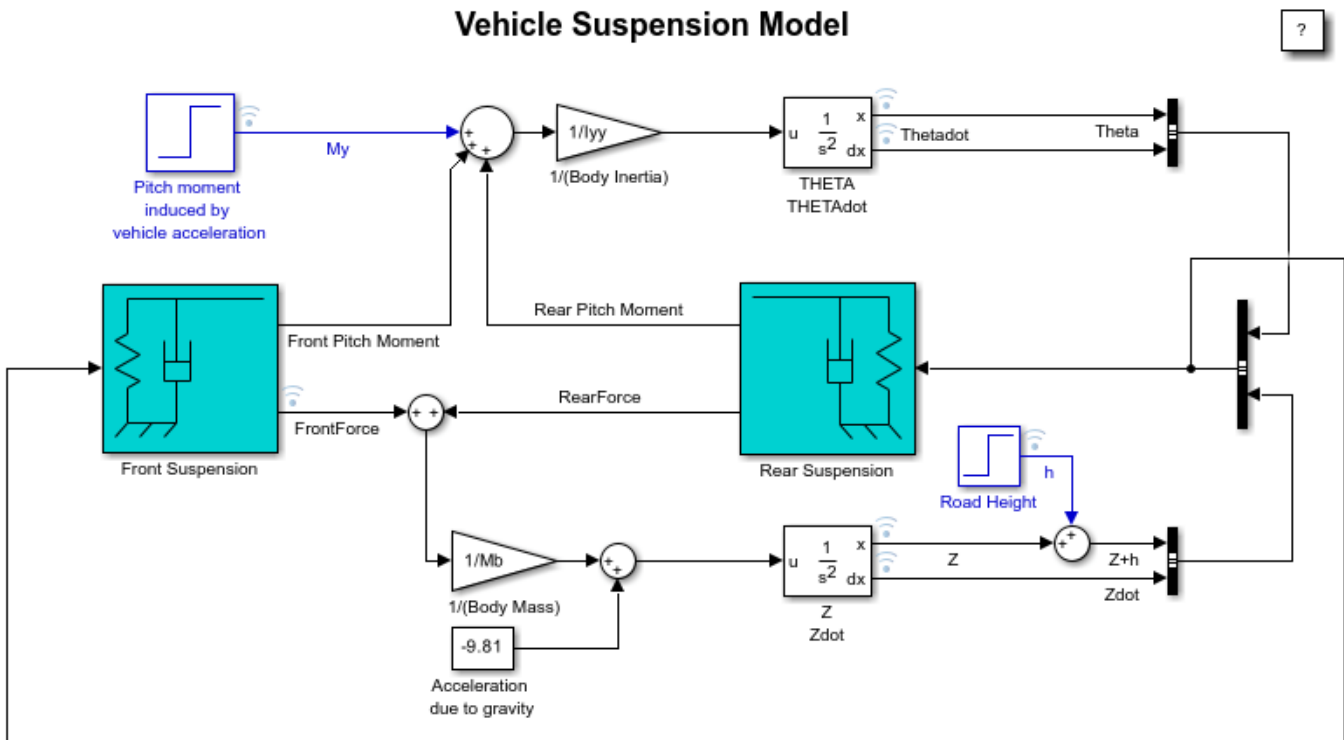

$M_y =$  pitch moment induced by vehicle acceleration

$I_{yy} =$  body moment of inertia about gravity center

### Model

To open the model, type `sldemo_suspn` in the MATLAB® command window.

### Top-level diagram of the suspension model

The suspension model has two inputs, and both input blocks are blue on the model diagram. The first input is the road height. A step input here corresponds to the vehicle driving over a road surface with a step change in height. The second input is a horizontal force acting through the center of the wheels that results from braking or acceleration maneuvers. This input appears only as a moment about the pitch axis because the longitudinal body motion is not modeled.

### Two DOF Spring/Damper Model

The Spring/Damper model used in FrontSuspension and RearSuspension subsystems

The spring/damper subsystem that models the front and rear suspensions is shown above. Right click on the Front/Rear Suspension block and select **Mask > Look Under Mask** to see the front/rear suspension subsystem. The suspension subsystems are used to model Equations 1-3. The equations are implemented directly in the Simulink® diagram through the straightforward use of Gain and Summation blocks.

The differences between front and rear are accounted for as follows. Because the subsystem is a masked block, a different data set (L, K and C) can be entered for each instance. Furthermore, L is thought of as the Cartesian coordinate  $x$ , being negative or positive with respect to the origin, or center of gravity. Thus,  $K_f$ ,  $C_f$ , and  $-L_f$  are used for the front suspension block whereas  $K_r$ ,  $C_r$ , and  $L_r$  are used for the rear suspension block.

#### Run the Simulation

To run this model, on the **Simulation** tab, click **Run**. Initial conditions are loaded into the model workspace from the `sldemo_suspdta.m` file. To see the contents of the model workspace, in the Simulink Editor, on the **Modeling** tab, under **Design**, select **Model Explorer**. In the Model Explorer, look under the contents of the `sldemo_suspn` model and select "Model Workspace". Loading initial conditions in the model workspace prevents any accidental modifications of parameters and keeps MATLAB workspace clean.

Note that the model logs relevant data to MATLAB workspace in a data structure called `sldemo_suspn_output`. Type the name of the structure to see what data it contains.

### Simulation results

Simulation results are displayed above. The results are plotted by the `sldemo_suspgraph.m` file. The default initial conditions are given in Table 1.

**Table 1:** Default initial conditions

```
Lf = 0.9; % front hub displacement from body gravity center (m)
Lr = 1.2; % rear hub displacement from body gravity center (m)
Mb = 1200; % body mass (kg)
Iyy = 2100; % body moment of inertia about y-axis in (kg m^2)
```

```
kf = 28000; % front suspension stiffness in (N/m)
kr = 21000; % rear suspension stiffness in (N/m)
cf = 2500; % front suspension damping in (N sec/m)
cr = 2000; % rear suspension damping in (N sec/m)
```

### Close the Model

Close the model and delete generated data from MATLAB workspace.

### Conclusions

This model allows you to simulate the effects of changing the suspension damping and stiffness, thereby investigating the tradeoff between comfort and performance. In general, racing cars have very stiff springs with a high damping factor, whereas passenger vehicles have softer springs and a more oscillatory response.

## Modeling an Automatic Transmission Controller

This example shows how to model an automotive drivetrain with Simulink®. Stateflow® enhances the Simulink model with its representation of the transmission control logic. Simulink provides a powerful environment for the modeling and simulation of dynamic systems and processes. In many systems, though, supervisory functions like changing modes or invoking new gain schedules must respond to events that may occur and conditions that develop over time. As a result, the environment requires a language capable of managing these multiple modes and developing conditions. In the following example, Stateflow shows its strength in this capacity by performing the function of gear selection in an automatic transmission. This function is combined with the drivetrain dynamics in a natural and intuitive manner by incorporating a Stateflow block in the Simulink block diagram.

### Analysis and Physics

The figure below shows the power flow in a typical automotive drivetrain. Nonlinear ordinary differential equations model the engine, four-speed automatic transmission, and vehicle. The model discussed in this example directly implements the blocks from this figure as modular Simulink subsystems. On the other hand, the logic and decisions made in the Transmission Control Unit (TCU) do not lend themselves to well-formulated equations. TCU is better suited for a Stateflow representation. Stateflow monitors the events which correspond to important relationships within the system and takes the appropriate action as they occur.

The throttle opening is one of the inputs to the engine. The engine is connected to the impeller of the torque converter which couples it to the transmission (see Equation 1).

### Equation 1

$$I_{ei}\dot{N}_e = T_e - T_i$$

$N_e$  = engine speed (RPM)

$I_{ei}$  = moment of inertia of the engine and the impeller

$T_e, T_i$  = engine and impeller torque

The input-output characteristics of the torque converter can be expressed as functions of the engine speed and the turbine speed. In this example, the direction of power flow is always assumed to be from the impeller to the turbine (see Equation 2).

**Equation 2**

$$T_i = \frac{N_e^2}{K^2}$$

$$K = f_2 \frac{N_{in}}{N_e} = \text{K-factor (capacity)}$$

$N_{in}$  = speed of turbine (torque converter output) = transmission input speed (RPM)

$$R_{TQ} = f_3 \frac{N_{in}}{N_e} = \text{torque ratio}$$

The transmission model is implemented via static gear ratios, assuming small shift times (see Equation 3).

**Equation 3**

$$R_{TR} = f_4(\text{gear}) = \text{transmission ratio}$$

$$T_{out} = R_{TR} T_{in}$$

$$N_{in} = R_{TR} N_{out}$$

$T_{in}, T_{out}$  = transmission input and output torques

$N_{in}, N_{out}$  = transmission input and output speed (RPM)

The final drive, inertia, and a dynamically varying load constitute the vehicle dynamics (see Equation 4).

**Equation 4**

$$I_v \dot{N}_w = R_{fd}(T_{out} - T_{load})$$

$I_v$  = vehicle inertia

$N_w$  = wheel speed (RPM)

$R_{fd}$  = final drive ratio

$T_{load} = f_5(N_w) = \text{load torque}$

The load torque includes both the road load and brake torque. The road load is the sum of frictional and aerodynamic losses (see Equation 5).

**Equation 5**

$$T_{load} = \text{sgn}(mph)(R_{load0} + R_{load2}mph^2 + T_{brake})$$

$R_{load0}, R_{load2}$  = friction and aerodynamic drag coefficients

$T_{load}, T_{brake}$  = load and brake torques

$mph$  = vehicle linear velocity

The model programs the shift points for the transmission according to the schedule shown in the figure below. For a given throttle in a given gear, there is a unique vehicle speed at which an upshift takes place. The simulation operates similarly for a downshift.

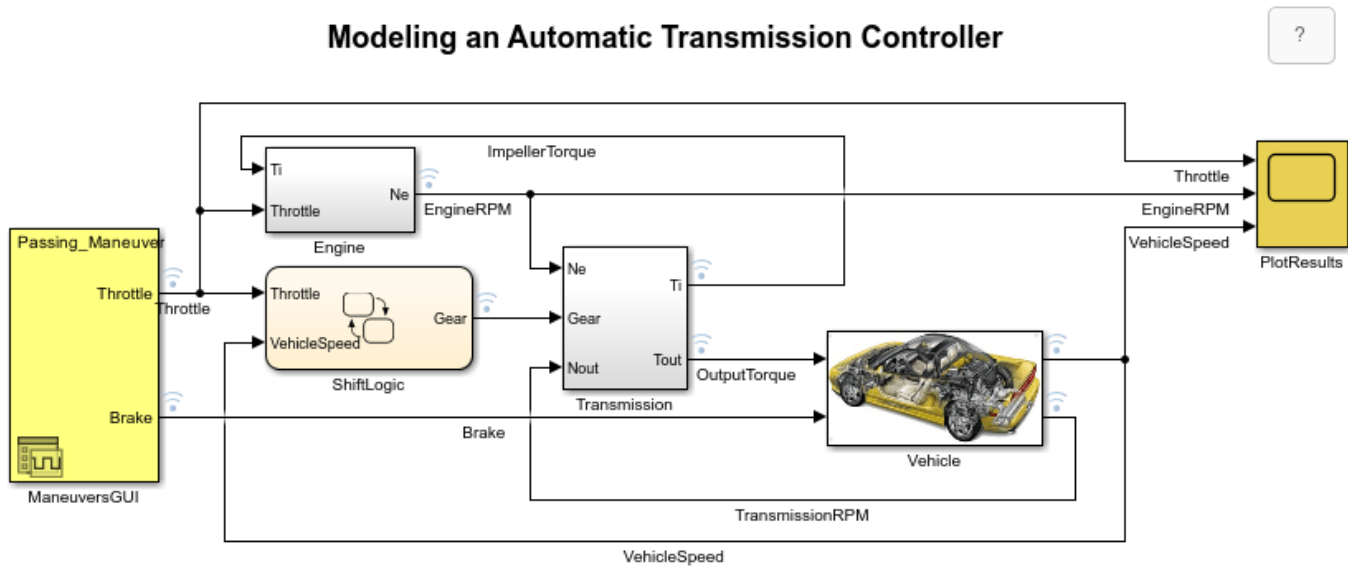

## Modeling

When you open the model, the Initial conditions are set in the Model Workspace.

The top-level diagram of the model is shown in the figure below. To run the simulation, on the Simulation tab, click **Run**. Note that the model logs relevant data to MATLAB Workspace in a data structure called `sldemo_autotrans_output`. Logged signals have a blue indicator. After you run the simulation, you can view the components of the data structure by typing `sldemo_autotrans_output` in MATLAB Command Window. Also note that the units appear on the subsystem icons and signal lines.

### Modeling an Automatic Transmission Controller

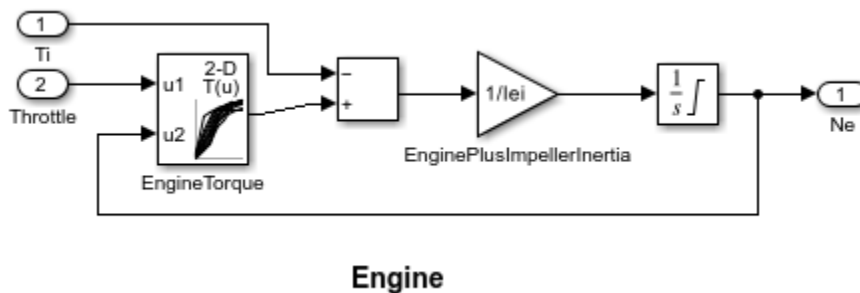

Copyright 1990-2022 The MathWorks, Inc.

#### Modeling

The Simulink model shown above is composed of modules which represent the engine, transmission, and the vehicle, with an additional shift logic block to control the transmission ratio. User inputs to the model are in the form of throttle (given in percent) and brake torque (given in ft-lb). The user inputs throttle and brake torques using the ManeuversGUI interface.

The Engine subsystem consists of a two-dimensional table that interpolates engine torque versus throttle and engine speed. The figure below shows the composite Engine subsystem. Double click on this subsystem in the model to view its structure.

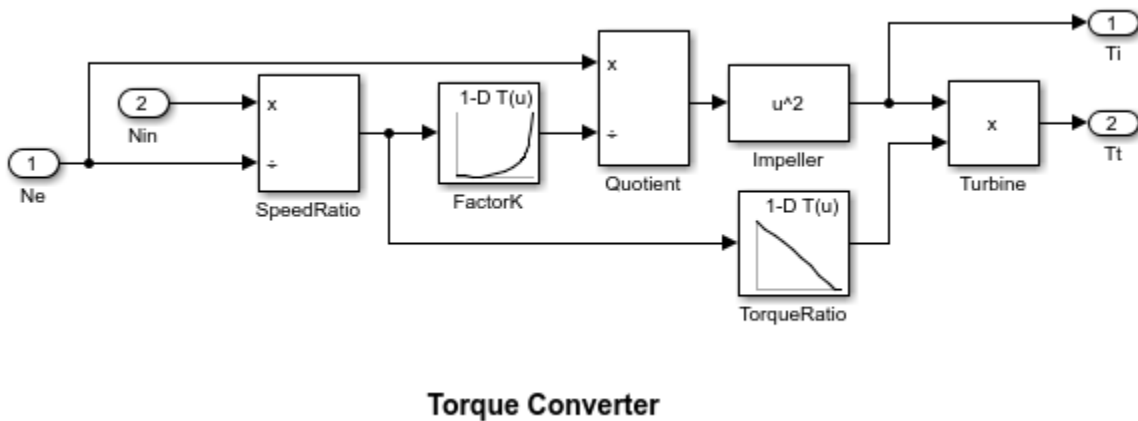

The TorqueConverter and the TransmissionRatio blocks make up the Transmission subsystem, as shown in the figure below. Double click on the Transmission subsystem in the model window to view its components.

The TorqueConverter is a masked subsystem, which implements Equation 2. To open this subsystem, right click on it and select **Mask > Look Under Mask** from the drop-down menu. The mask requires a vector of speed ratios (  $N_{in}/N_e$  ) and vectors of K-factor (f2) and torque ratio (f3). This figure shows the implementation of the TorqueConverter subsystem.

The transmission ratio block determines the ratio shown in Table 1 and computes the transmission output torque and input speed, as indicated in Equation 3. The figure that follows shows the block diagram for the subsystem that realizes this ratio in torque and speed.

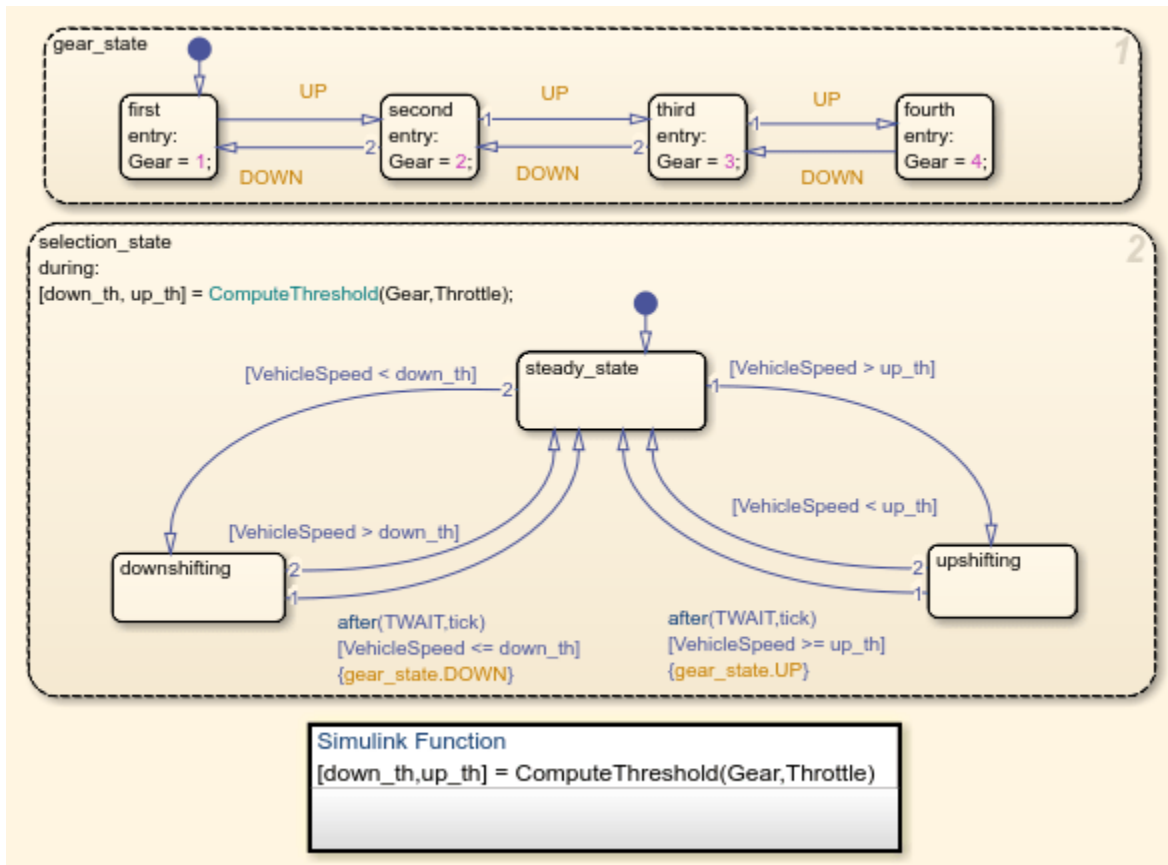

**Table 1:** Transmission gear ratios

gear	Rtr = $N_{in}/N_e$
1	2.393
2	1.450
3	1.000
4	0.677

**Transmission Gear Ratio**

The Stateflow diagram labeled ShiftLogic implements gear selection for the transmission. Double click on ShiftLogic in the model window to open the Stateflow diagram. The Model Explorer is utilized to define the inputs as throttle and vehicle speed and the output as the desired gear number. Two dashed AND states keep track of the gear state and the state of the gear selection process. The overall chart is executed as a discrete-time system, sampled every 40 milliseconds. The Stateflow diagram shown below illustrates the functionality of the block.

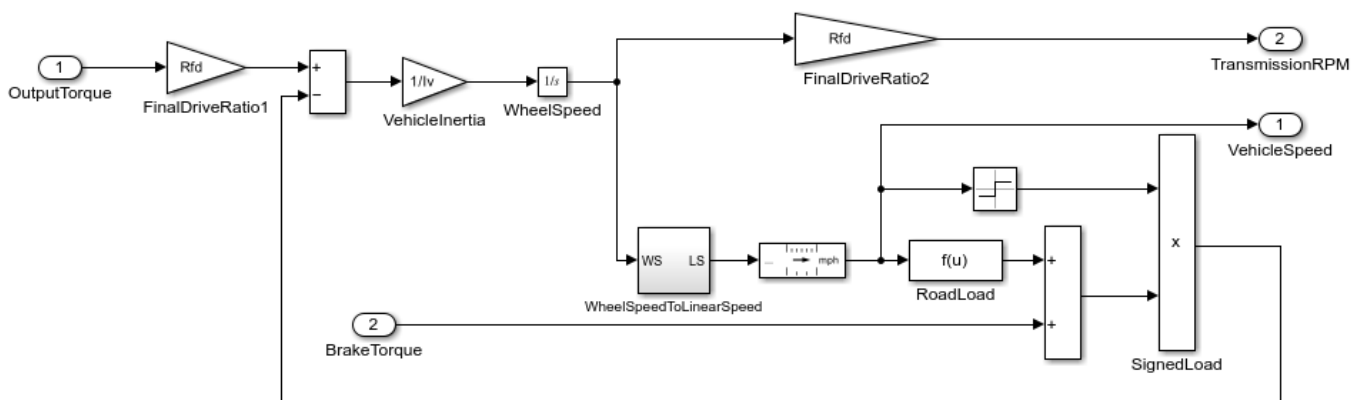

The shift logic behavior can be observed during simulation by enabling animation in the Stateflow debugger. The `selection_state` (always active) begins by performing the computations indicated in its `during` function. The model computes the upshift and downshift speed thresholds as a function of the instantaneous values of gear and throttle. While in `steady_state`, the model compares these values to the present vehicle speed to determine if a shift is required. If so, it enters one of the confirm states (`upshifting` or `downshifting`), which records the time of entry.

If the vehicle speed no longer satisfies the shift condition, while in the confirm state, the model ignores the shift and it transitions back to `steady_state`. This prevents extraneous shifts due to noise conditions. If the shift condition remains valid for a duration of `TWAIT` ticks, the model transitions through the lower junction and, depending on the current gear, it broadcasts one of the shift events. Subsequently, the model again activates `steady_state` after a transition through one of the central junctions. The shift event, which is broadcast to the `gear_selection` state, activates a transition to the appropriate new gear.

For example, if the vehicle is moving along in second gear with 25% throttle, the state `second` is active within `gear_state`, and `steady_state` is active in the `selection_state`. The `during` function of the latter, finds that an upshift should take place when the vehicle exceeds 30 mph. At the moment this becomes true, the model enters the `upshifting` state. While in this state, if the vehicle speed remains above 30 mph for `TWAIT` ticks, the model satisfies the transition condition leading down to the lower right junction. This also satisfies the condition `[[gear == 2]]` on the transition leading from here to `steady_state`, so the model now takes the overall transition from `upshifting` to `steady_state` and broadcasts the event `UP` as a transition action. Consequently, the transition from second to third is taken in `gear_state` which completes the shift logic.

The Vehicle subsystem uses the net torque to compute the acceleration and integrate it to compute the vehicle speed, per Equation 4 and Equation 5. The Vehicle subsystem is masked. To see the structure of the Vehicle block, right click on it and select **Mask > Look Under Mask** from the drop-down menu. The parameters entered in the mask menu are the final drive ratio, the polynomial coefficients for drag friction and aerodynamic drag, the wheel radius, vehicle inertia, and initial transmission output speed.

Vehicle

## Results

The engine torque map, and torque converter characteristics used in the simulations are shown below.

Get the FactorK (second row) and the TorqueRatio (third row) vs SpeedRatio(first row)

The first simulation (passing maneuver) uses the throttle schedule given in Table 2 (this data is interpolated linearly).

**Table 2:** Throttle schedule for first simulation (passing maneuver)

Time (sec)	Throttle (%)
0	60
14.9	40
15	100
100	0
200	0

The first column corresponds to time; the second column corresponds to throttle opening in percent. In this case no brake is applied (brake torque is zero). The vehicle speed starts at zero and the engine at 1000 RPM. The following figure shows the plot for the baseline results, using the default parameters. As the driver steps to 60% throttle at  $t=0$ , the engine immediately responds by more than doubling its speed. This brings about a low speed ratio across the torque converter and, hence, a large torque ratio. The vehicle accelerates quickly (no tire slip is modeled) and both the engine and the vehicle gain speed until about  $t = 2$  sec, at which time a 1-2 upshift occurs. The engine speed characteristically drops abruptly, then resumes its acceleration. The 2-3 and 3-4 upshifts take place at about four and eight seconds, respectively. Notice that the vehicle speed remains much smoother due to its large inertia.

At  $t=15\text{sec}$ , the driver steps the throttle to 100% as might be typical of a passing maneuver. The transmission downshifts to third gear and the engine jumps from about 2600 RPM to about 3700 RPM. The engine torque thus increases somewhat, as well as the mechanical advantage of the transmission. With continued heavy throttle, the vehicle accelerates to about 100 mph and then shifts into overdrive at about  $t = 21 \text{ sec}$ . The vehicle cruises along in fourth gear for the remainder of the simulation. Double click on the ManeuversGUI block and use the graphical interface to vary the throttle and brake history.

### Running Multiple Scenarios and Collecting Coverage

You can run the model for all scenarios while collecting coverage. To see a saved design study for running all of the scenarios of `sldemo_autotrans`, open `sldemo_autotrans_design_study.mldatx` in the Multiple Simulations panel of `sldemo_autotrans`.

After the design study has been opened, enable the model coverage and cumulative collection in the model settings.

```
set_param('sldemo_autotrans', 'CovEnable', 'on');
```

```
set_param('sldemo_autotrans', 'CovEnableCumulative', 'on');
```

Once this is set, click the Run All (Coverage) button on the Simulation tab on the Simulink toolstrip. Then check model coverage of the design cases.

### Closing the Model

Close the model, clear generated data.

## Conclusions

You can enhance this basic system in a modular manner, for example, by replacing the engine or transmission with a more complex model. You can build large systems within this structure via step-wise refinement. The seamless integration of Stateflow control logic with Simulink signal processing enables the construction of a model that is efficient and visually intuitive.

## Vehicle Electrical System

This example shows how to simulate the electrical system of a vehicle using Simulink® and Simscape Electrical™.

### System Components

The system simulated consists of a few components. The main power source is the internal combustion (IC) engine that drives the shaft of the alternator. The alternator produces the AC power. The diode trio rectifies the AC current generated from the alternator to DC current that is applied to the alternator field. The indicator lamp lights when the system is turned on and the alternator is not producing power. The rectifier bridge converts the AC power into DC power. The smoothing capacitor, voltage sensor, battery, and vehicle loads are connected to the DC bus.

The alternator is a three-phase synchronous machine with its field current regulated to give control over the DC bus voltage. This is simulated by using the Synchronous Machine Round Rotor block.

The three-phase AC output of the alternator is fed into the 6-pulse rectifier bridge to give the DC voltage required to charge the car battery and to supply the balance of the electrical system of the car.

### Operation of the System

When the IC engine is off, the battery supplies the current to the alternator field winding. The indicator lamp is turned on.

When the IC engine runs, the alternator will start to produce voltage and the diode trio will conduct and let the current flow to the alternator field winding. The indicator lamp is then turned off.

When the DC bus voltage reaches the upper voltage limit (which is 14.5 V in the model), the current flowing to the alternator field is bypassed. As a result, the DC bus voltage decreases. If it reaches the lower voltage limit (which is 13.5 V in the model), the diode trio is reconnected to the field winding.

in a reasonable amount of time, despite the temperature difference. When the air temperature in the car is within 0.5 deg C of the setpoint temperature, the system switches off.

Two switches trigger the Stateflow charts that control the Air Distribution(**AirDist**) and Recycling Air (**Recyc\_Air**) states. To facilitate effective window defrosting, the controller implements an internal transition within these two states. When the defrost state is active, the controller turns off the recycling air.

**Figure 2:** The supervisory control logic in Stateflow

**Heater and Air Conditioner Models**

The heater model implements this heat exchange equation:

$$T_{out} = T_s - (T_s - T_{in})e^{[(-\pi * D * L * hc) / (m_{dot} * C_p)]}$$

Where:

- $T_s$  = constant (radiator wall temperature)
- $D$  = 0.004m (channel diameter)
- $L$  = 0.05m (radiator thickness)

- $N = 30000$  (Number of channels)
- $k = 0.026 \text{ W/mK} = \text{constant}$  (thermal conductivity of air)
- $C_p = 1007 \text{ J/kgK} = \text{constant}$  (specific heat of air)
- Laminar flow ( $hc = 3.66(k/D) = 23.8 \text{ W/m}^2\text{K}$ )

The models account for the heater flap. Similar to the blower operation, the greater the temperature difference between the required setpoint temperature and the current interior temperature, the greater the heating effect.

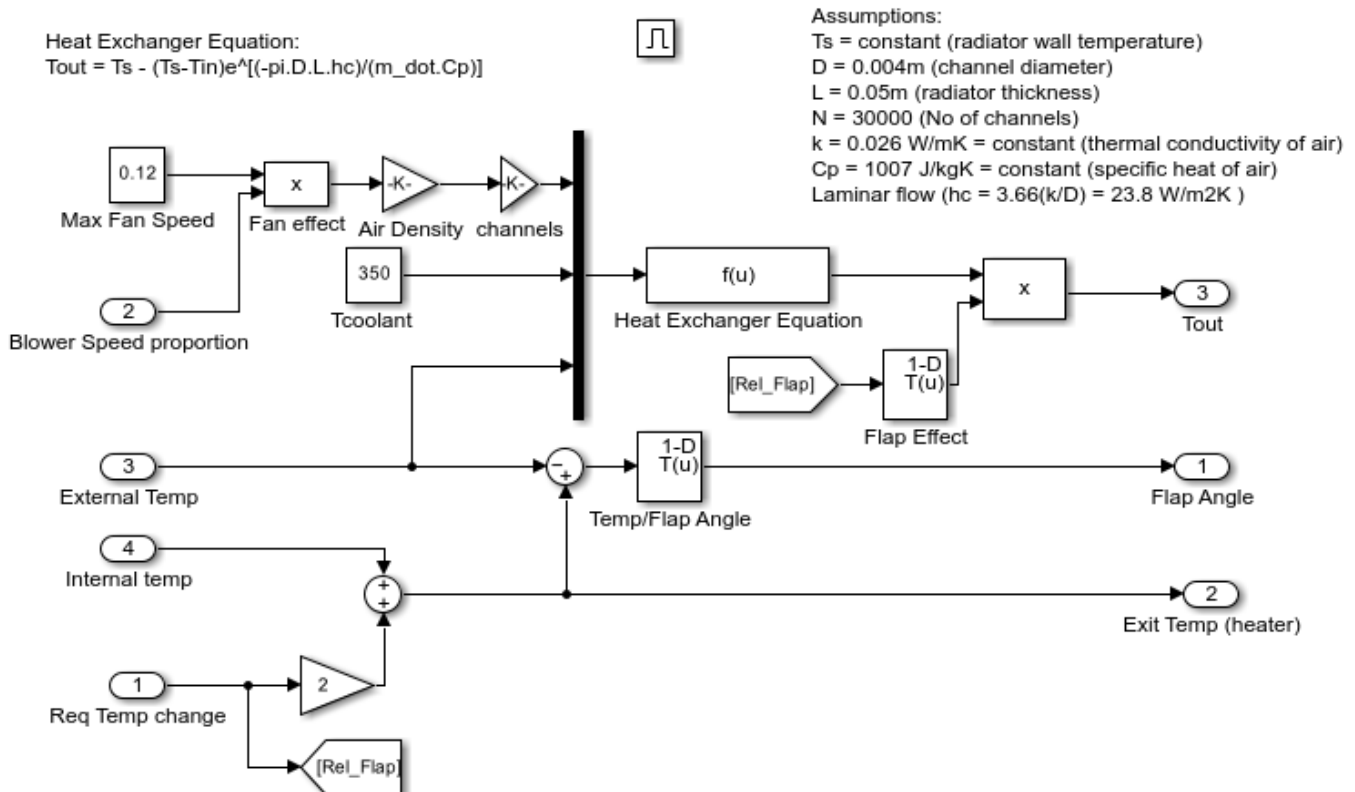

The air conditioner model implements this equation:

$$y \cdot (w \cdot T_{\text{comp}}) = \dot{m} \cdot (h_4 - h_1)$$

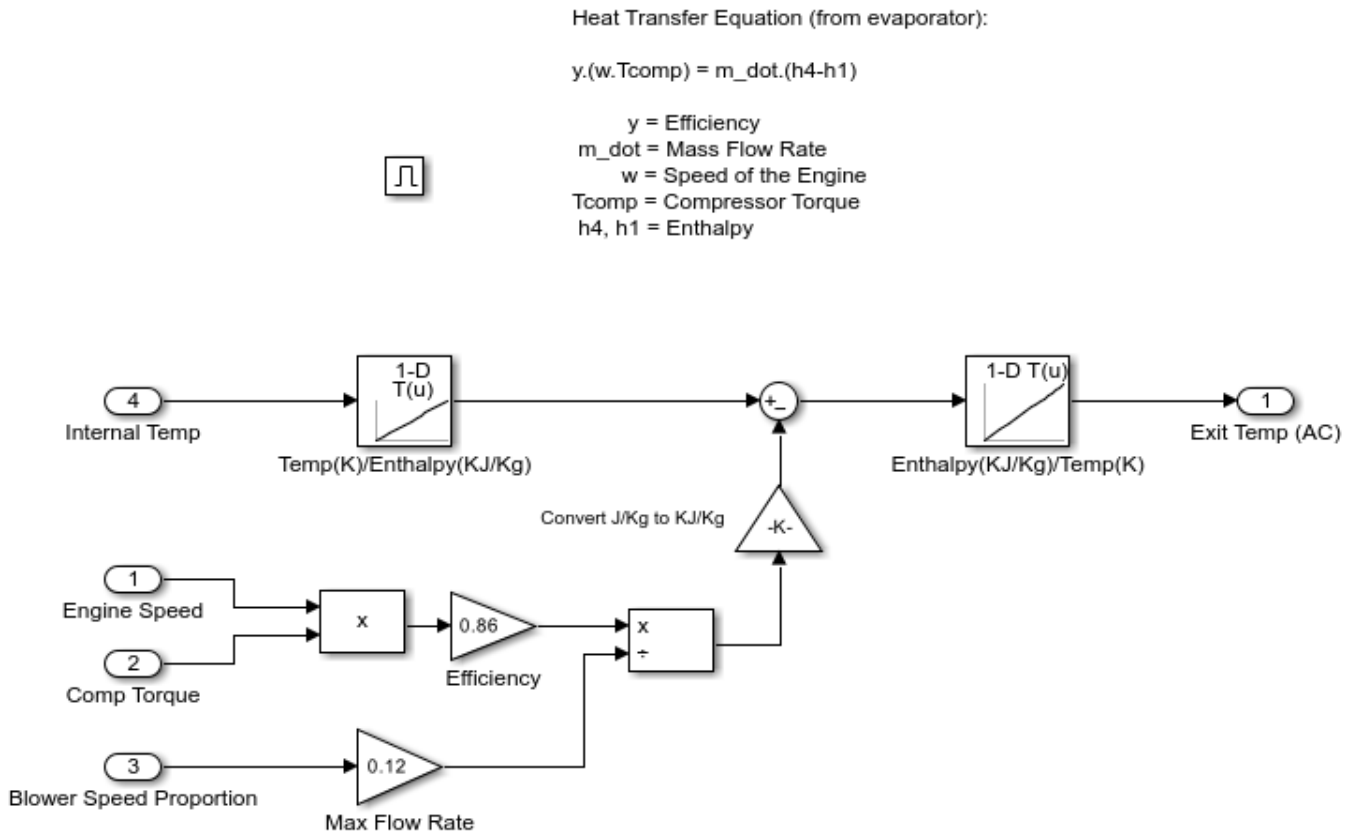

Where:

- $y = \text{efficiency}$
- $\dot{m} = \text{mass flow rate}$
- $w = \text{speed of the engine}$
- $T_{\text{comp}} = \text{compressor torque}$
- $h_4, h_1 = \text{enthalpy}$

The bang-bang control of the A/C system uses the engine speed and compressor torque to determine the temperature of the air that exits the A/C.

**Figure 3:** Heater control subsystem

**Figure 4:** A/C control subsystem

**Cabin Heat Transfer**

These factors affect the temperature of the air felt by the driver:

- Temperature of the air exiting the vents
- Temperature of the outside air
- Number of people in the car

The factors are inputs into the thermodynamic model of the cabin interior. To account for the temperature of the air exiting the vents, the model calculates the difference between the vent air and the current car temperature and multiplies it by the fan speed proportion (mass flow rate). The model adds 100 W of energy is per person in the car. To account for air radiating into the car from the outside, the model multiplies the difference between the outside and interior air temperature by a smaller mass flow rate.

The Thermometer Display block displays the Interior Dynamics model output. It is a reading of a temperature sensor placed behind the driver's head. If you run the simulation with the default settings, the temperature reading starts at the external temperature of 18 °C and then cools to the user setpoint of 9 °C.

**Figure 5:** Thermometer display versus time

## Vehicle Electrical and Climate Control Systems

This example shows how to interface the vehicle climate control system with a model of the electrical system to examine the loading effects of the climate control system on the entire electrical system of the car.

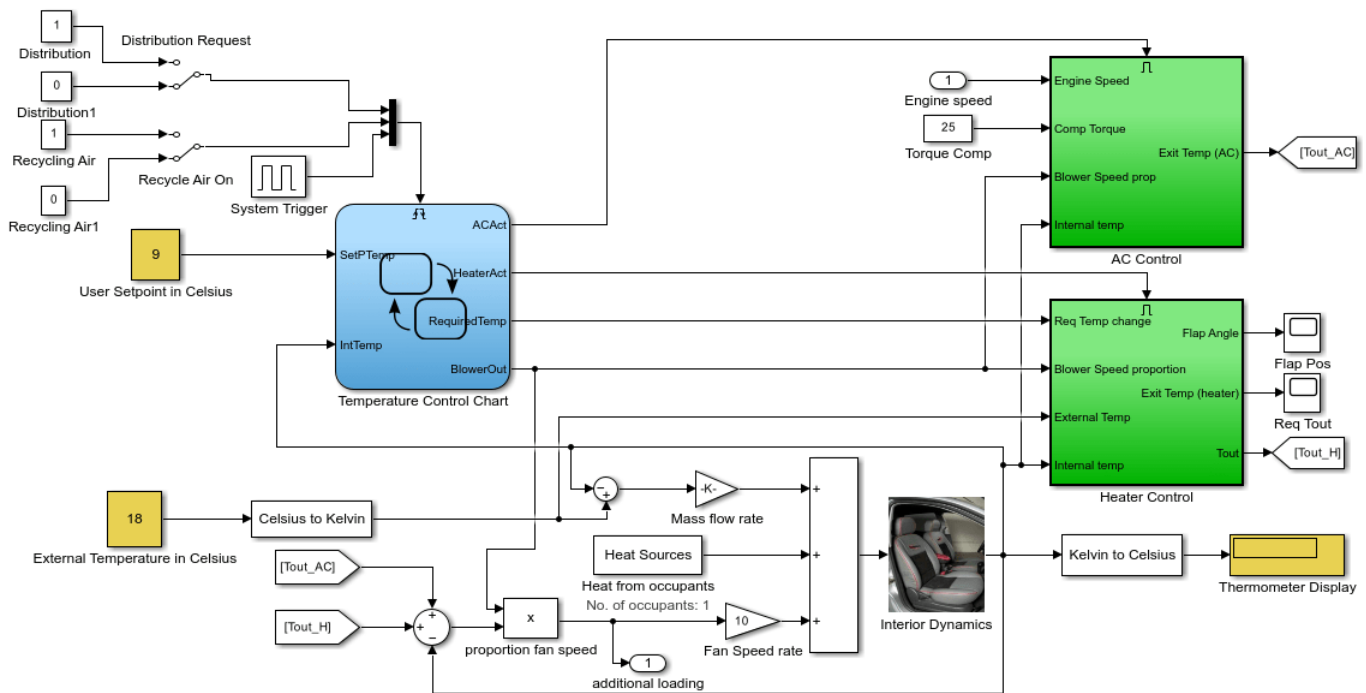

Copyright 2017-2019 The MathWorks, Inc.

**Figure 1:** Vehicle Electrical and Climate Control System

### The Climate Control System

Double clicking on the ClimateControlSystem subsystem will open the model of the climate control system. Here the user can enter the temperature value they would like the air in the car to reach by double clicking on the USER SETPOINT IN CELSIUS Block and entering the value into the dialog box. The EXTERNAL TEMPERATURE IN CELSIUS can also be set by the user in a similar way. The numerical display on the right hand side of the model shows the reading of a temperature sensor placed behind the driver's head. This is the temperature that the driver should be feeling. When the model is run and the climate control is active, it is this display box whose value changes showing the change of temperature in the car.

**Figure 2:** The automatic climate control system.

### The Stateflow® Controller

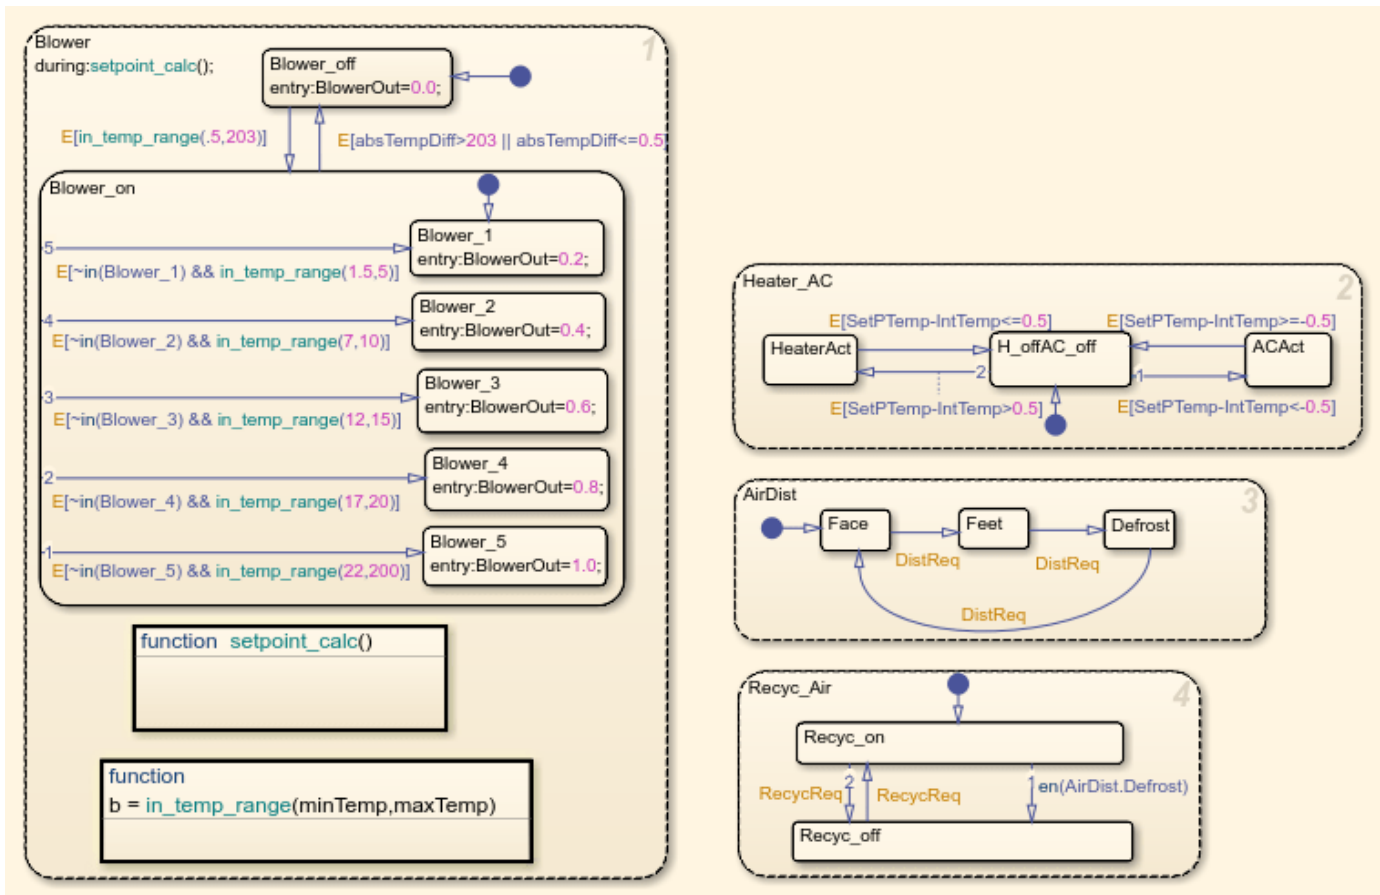

The control of the system is implemented in Stateflow®. Double clicking on the Stateflow chart will show how this supervisory control logic has been formulated.

The **Heater\_AC** state shows that when the user enters a setpoint temperature which is greater than the current temperature in the car by at least 0.5 deg C, the heater system will be switched on. The heater will remain active until the current temperature in the car reaches to within 0.5 deg of the setpoint temperature. Similarly, when the user enters a setpoint which is 0.5 deg C (or more) lower than the current car temperature, the Air Conditioner is turned on and stays active until the temperature of the air in the car reaches to within 0.5 deg C of the setpoint temperature. After which, the system will switch off. The dead band of 0.5 deg has been implemented to avoid the problem of continuous switching.

In the **Blower** State, the larger the difference between the setpoint temperature and the current temperature, the harder the fan blows. This ensures that the temperature will reach the required value in a reasonable amount of time, despite the temperature difference. Once again, when the temperature of the air in the car reaches to within 0.5 deg C of the setpoint temperature, the system will switch off.

The Air Distribution (**AirDist**) and Recycling Air States (**Recyc\_Air**) are controlled by the two switches that trigger the Stateflow chart. An internal transition has been implemented within these two states to facilitate effective defrosting of the windows when required. When the defrost state is activated, the recycling air is turned off.

**Figure 3:** The supervisory control logic in Stateflow.

### Heater and Air Conditioner Models

The heater model was built from the equation for a heat exchanger shown below:

$$T_{out} = T_s - (T_s - T_{in})e^{[-\pi \cdot D \cdot L \cdot hc / (m_{dot} \cdot C_p)]}$$

Where:

- $T_s$  = constant (radiator wall temperature)
- $D$  = 0.004m (channel diameter)
- $L$  = 0.05m (radiator thickness)
- $N$  = 30000 (Number of channels)
- $k$  = 0.026 W/mK = constant (thermal conductivity of air)
- $C_p$  = 1007 J/kgK = constant (specific heat of air)
- Laminar flow ( $hc = 3.66(k/D) = 23.8$  W/m<sup>2</sup>K)

In addition, the effect of the heater flap is taken into account. Similar to the operation of the blower, the greater the temperature difference between the required setpoint temperature and the current temperature in the car, the more the heater flap is opened and the greater the heating effect.

The Air Conditioner system is one of the two places where the climate control model interfaces with the car's electrical system model. The compressor loads the engine of the car when the A/C system is active. The final temperature to exit from the A/C is calculated as follows:

$$y \cdot (w \cdot T_{comp}) = \dot{m} \cdot (h_4 - h_1)$$

Where:

- $y$  = efficiency
- $\dot{m}$  = mass flow rate
- $w$  = speed of the engine
- $T_{comp}$  = compressor torque
- $h_4, h_1$  = enthalpy

Here we have bang-bang control of the A/C system where the temperature of the air that exits the A/C is determined by the engine speed and compressor torque.

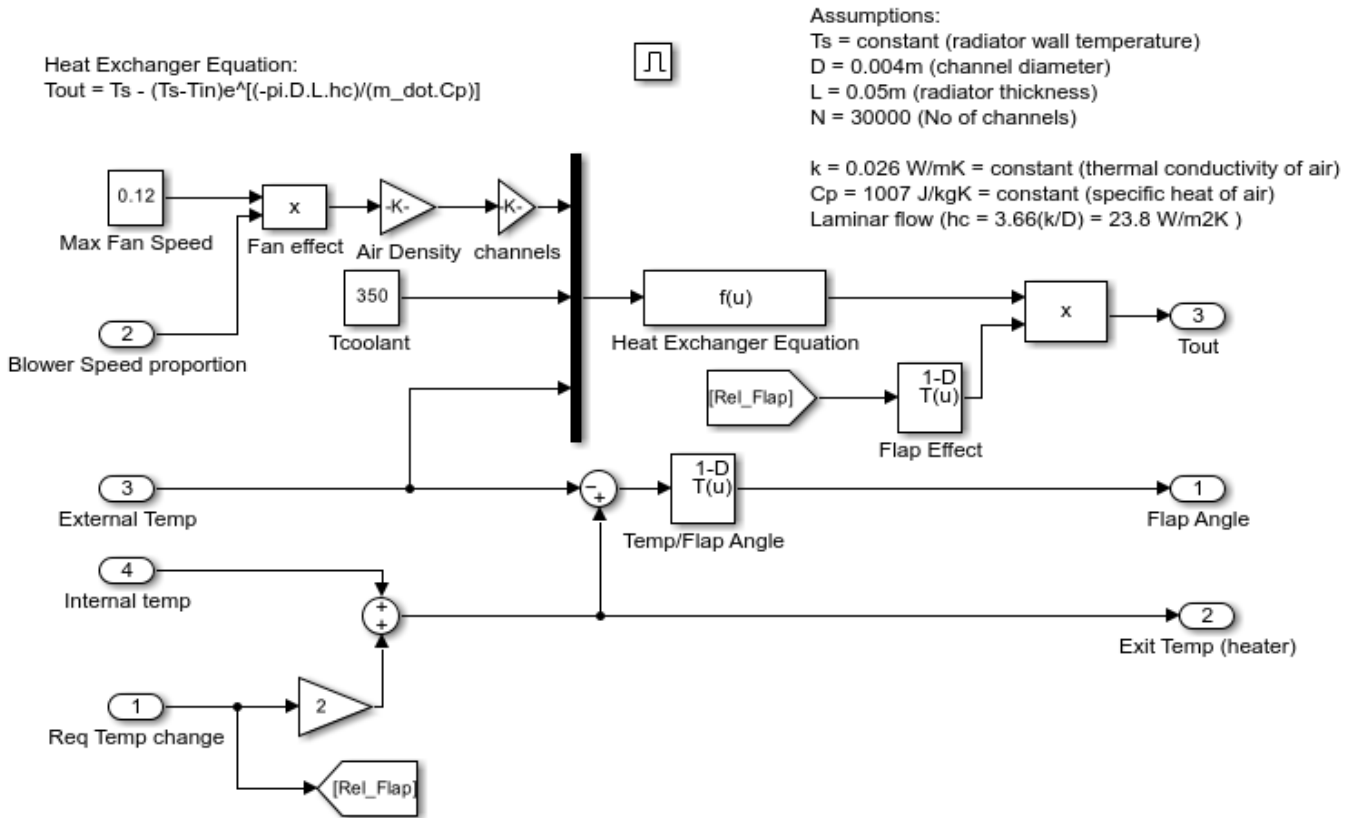

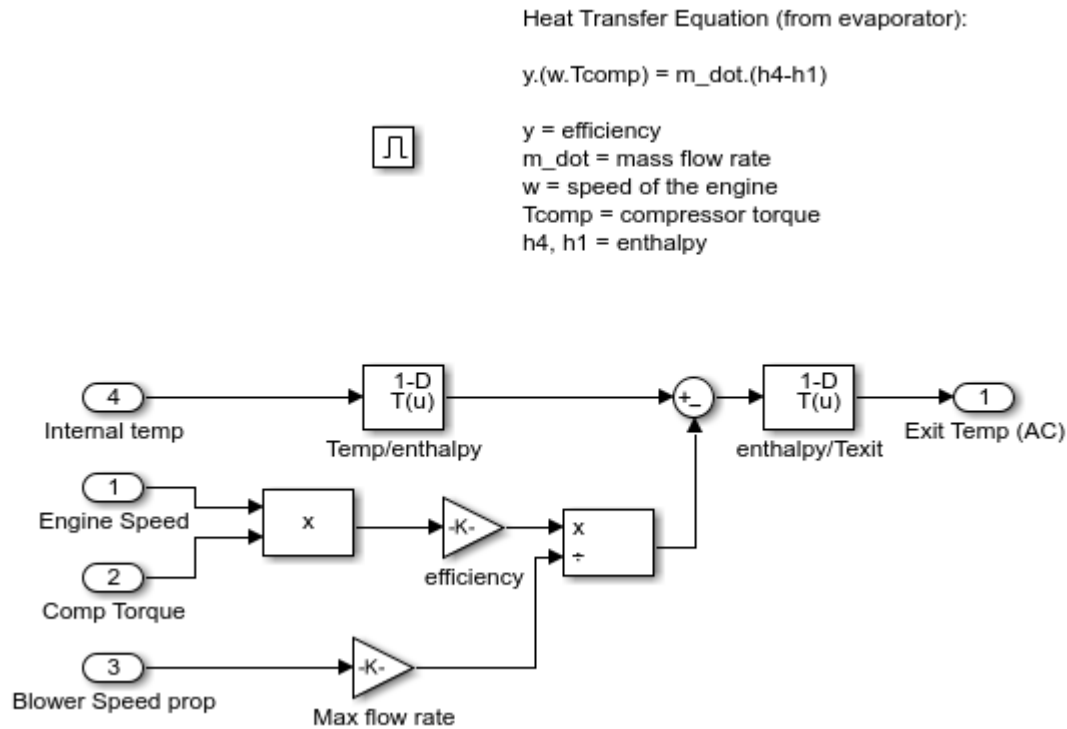

Figure 4: Heater control subsystem.

**Figure 5:** A/C control subsystem.

### Heat Transfer in the Cabin

The temperature of the air felt by the driver is affected by all of these factors:

- The temperature of the air exiting the vents
- The temperature of the outside air
- The number of people in the car

These factors are inputs into the thermodynamic model of the interior of the cabin. We take into account the temperature of the air exiting the vents by calculating the difference between the vent air temperature and the current temperature inside the car and multiplying it by the fan speed proportion (mass flow rate). Then 100W of energy is added per person in the car. Lastly, the difference between the temperature of the outside air and the interior air temperature is multiplied by a lesser mass flow rate to account for the air radiating into the car from the outside.

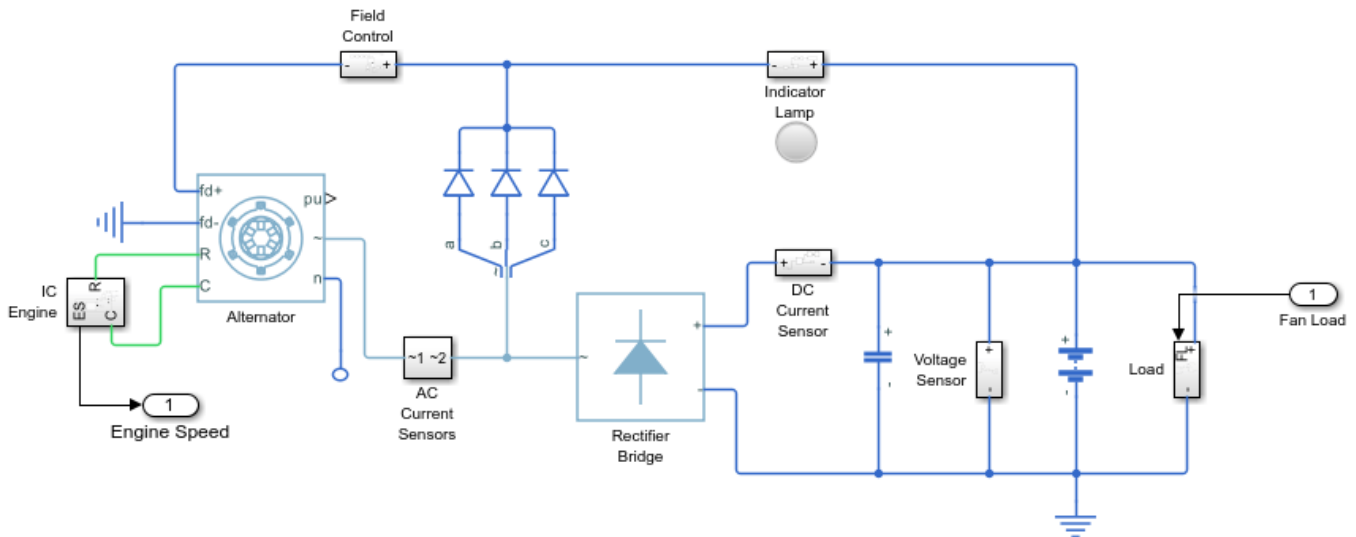

The output of the interior dynamics model is fed to the display block as a measure of the temperature read by a sensor placed behind the driver's head.

### The Electrical System

This electrical system models the car at idle speed. The PID controllers ensure that the car's alternator (modeled by a synchronous machine which has its field current regulated to control the output voltage) is also operating at the required speed. The alternator output is then fed through a 3-phase 6-pulse rectifier bridge to supply the voltage needed to charge the battery which supplies the voltage for the car's DC bus.

The fan used in the climate control system is fed off this DC bus as are the windscreen wipers, radio etc. As the difference between the setpoint temperature and the current temperature in the car drops, so does the fan speed and therefore so does the loading on the DC bus. The inclusion of feedback in the electrical system regulates the DC bus voltage.

The additional model of the car's electrical system allows for the changing of the engine speed. Changing the engine speed shows the effect on the DC bus voltage.

# Power Window Control Project

This example shows how you can use MathWorks® software and the Model-Based Development process to go from concept to implementation for a power window system for an automobile. This example uses Simulink®, Simulink® Coverage™, DSP System Toolbox™, Simscape™ Multibody™, Fixed-Point Designer™, Simscape™ Electrical™, Simscape™, and Simulink® Real-Time™.

## Overview of Design Requirements

In this example, consider the passenger-side power window system of an automobile. Note a critical aspect of this system is that it can never exert a force of more than 100 N on an object when closing the window, for example:

When the model detects such an object, it must lower the window by about 10 centimeters.

For more information on the design requirements, see “Power Window”.

## Using Model-Based Development and Large Scale Modeling

This example uses Model-Based Design and large scale modeling techniques such as,

- **Model Blocks** to separate the hierarchy into separate models.
- **Variant Subsystems Blocks** to model and switch between different design choices.
- **Libraries** to capture algorithms for reuse in variant subsystems.
- **Projects** to manage the files required for the system development.

## Opening Power Window Control Project

Run the following command to create and open a working copy of the project files for this example.

```
slxPowerWindowStart
```

## Exploring the Project

Upon visual inspection of the project, you can see features used to organize the example. These features are:

- Folders
- File Classification
- Shortcuts

### Folders

The project is organized into the following folders:

- **configureModel** - MATLAB® files controlling the main system model variant configuration
- **data** - Images required by the project
- **hmi** - Files that animate the power window response
- **model** - Main system model, controller model, models for testing the controller, and libraries which support these models
- **task** - MATLAB files that simulate the model for the different model configurations and generate coverage reports for the controller
- **utilities** - MATLAB files to initialize the model, to generate spreadsheet input, to add data to the generated spreadsheet and to manage the project environment at startup and shutdown

## File Classification

Files in Projects have different classifications visible in Labels pane. Each label describes the specific role a file contributes to the body of the project. In this project, new classifications were added, including:

- **Configuration** - Files that configure the project or model.
- **PrjConfig** - Files that configure the project by adding its files to the path at startup and removing them at shutdown
- **DesignConfig** - Files that determine which model configuration is active at a given time
- **Design** - Main system model and its referenced control model
- **DesignSupport** - Files such as libraries, data, and model simulation
- **Simulation** - Files that simulate the model for a specific configuration
- **Test** - Control coverage, the control interaction, and the test harness models
- **Visualization** - Files that animate the motion of the power window

## Shortcuts

Project shortcuts are used to obtain quick access to project files that are used most often. Some shortcuts contain general tasks such as adding the project to the path at startup and removing it at shutdown. In addition, project shortcut groups help organize the shortcuts. The new shortcut groups are

- **Interactive Testing** - Files used for interactive testing of the controller
- **Main Model** - File for top level Simulink model
- **Model Coverage** - Files used for model coverage of the controller
- **Simulation** - Files used for simulation of model variant configurations

## Exploring Simulink Models in Project

The Simulink models for this project are located in the model folder. The models of interest are:

- Main System Model
- Models for Testing

## Main System Model

In this example under the model folder, the main system model is `slexPowerWindowExample`. This model consists of the driver and passenger switch blocks, which generate the inputs to the system. The inputs then go through the control system model, which validates the states of the passenger and driver inputs. The control system block also determines if there is an obstacle blocking the window's path. The referenced controller produces the window motion command signals sent to the active variant of the window system. The window system output is the feedback to the control system block.

To visualize the results of simulation, Simulation Data Inspector (SDI) logs the output data and Simulink 3D Animation™ animates the window's motion.

## Model Variants

The main system model in this project uses the `Variant Subsystem` block to allow for multiple implementations of within a subsystem. The active implementation can be programmatically changed

prior to simulation. In the main model, there are four Variant Subsystem blocks each with variant choices that can be programmatically modified. Those four variant subsystems are:

- `slexPowerWindowExample/driver_switch`
- `slexPowerWindowExample/passenger_switch`
- `slexPowerWindowExample/window_system`
- `slexPowerWindowExample/power_window_control_system/detect_obstacle_endstop`

Each variant choice is associated with a variant control. The variant choice is active when its variant control evaluates to `true`.

Since there are four programmatically modifiable Variant Subsystem blocks in the main model, there are MATLAB files to control the combinations of variant choices to create model variant configurations which are found under the `DesignConfig` classification. Available model variant configurations are

- Power Window Controller Hybrid System Model
- Power Window Controller and Detailed Plant Model
- Power Window Controller With Data Acquisition Effects
- Power Window Controller With Controller Area Network (CAN) Communication

#### *Power Window Controller Hybrid System Model*

This model variant uses Stateflow® and Simulink to model both discrete event reactive behavior and continuous time behavior. It uses a low order plant model to validate the roll-up and roll-down behavior. You can simulate this variant configuration using the `SimHybridPlantLowOrder` shortcut. This shortcut activates only the variant subsystem corresponding to this model configuration. Since this model does not take into account power effects, the only output logged is position. Simulation Data Inspector (SDI) displays the logged position data.

#### *Power Window Controller and Detailed Plant Model*

This model variant shows a more detailed plant model that includes power effects in the electrical and mechanical domains is used to validate that the force exerted by the window on a trapped object never exceeds 100 N. This model variant requires Simscape™ Multibody™ and Simscape Power Systems™ products to be installed. You can simulate this variant configuration using the `SimHybridPlantPowerEffects` shortcut. Unlike the previous variant model, this variant configuration takes into account the power effects. SDI displays the logged data from armature current, position, and force exerted by the power window.

#### *Power Window Controller With Data Acquisition Effects*

This model variant shows additional effects due to implementation that affect the control. The phenomena included are signal conditioning to measure the armature current and quantization of the measurement. This model variant requires Simscape Multibody, Simscape Power Systems, DSP System Toolbox™, and Fixed-Point Designer™ products to be installed. You can simulate this variant configuration using the `SimHybridPlantPowerEffects+ControlDAQEffects` shortcut. Like the previous model, SDI displays the logged data from armature current, position, and force exerted by the power window.

#### *Power Window Controller With CAN Communication*

This model variant shows the use of a CAN to communicate the commands to control window movement. The switches that may be located in the center console of the vehicle and that produce the commands are included in this model variant. This model variant requires Simscape Multibody, Simscape Power Systems, DSP System Toolbox, and Fixed-Point Designer products to be installed. You can simulate this variant configuration on a machine running windows OS using the| SimCANCommunication| shortcut.

### **Models for Testing**

To test the state machine that controls the power window, you can run the project shortcuts for testing. Available model shortcuts for testing the controller are

- InteractiveExample
- CoverageExample
- IncreaseCoverageExample

### **InteractiveExample**

This model shortcut opens the model, slxPowerWindowCntlInteract. This model contains the power window controller which is a state machine. This model also contains inputs to the controller which are selected with manual switch blocks.

The power window controller has four external inputs:

- Passenger Input
- Driver Input
- Window Frame Endstops
- Obstacle Present

#### *Passenger Input*

This input consists of a vector with three elements:

- `neutral`: the passenger control switch is not depressed
- `up`: the passenger control switch generates the up signal
- `down`: the passenger control switch generates the down signal

#### *Driver Input*

This input consists of a vector with three elements:

- `neutral`: the driver control switch is not depressed
- `up`: the driver control switch generates the up signal
- `down`: the driver control switch generates the down signal

#### *Window Frame Endstops*

This input consists of a vector with two elements:

- `0`: window moves freely between top or bottom
- `1`: window is stuck at the top or bottom because of physical limitations

#### *Obstacle Present*

This input consists of a vector with two elements:

- 0: window moves freely between top or bottom
- 1: window has obstacle within its frame

You can interactively test the controller by simulating the model and selecting the desired combination of inputs via the manual switch blocks. After making the selection of inputs, you can verify the internal controller state and controller output against the desired result for this specific set of inputs.

### **CoverageExample**

This model shortcut opens the model, `slexPowerWindowCntlCoverage`. This model contains the power window controller which is a state machine. This model also contains inputs to the controller which are repeating sequence blocks.

You can use the Simulink Coverage (TM) Model Coverage tool to validate the discrete event control of the window. The Model Coverage tool helps determine the extent to which a model test case exercises the conditional branches of the controller. It also helps evaluate whether all transitions in the discrete event control are taken given the test case we run. It also evaluates whether all clauses in a condition that enables a particular transition have become true. One transition may be enabled by multiple clauses, e.g., the transition from emergency back to neutral occurs when either 100 ticks have occurred or when the endstop is reached.

### **IncreaseCoverageExample**

This model shortcut opens the model, `slexPowerWindowCntlCoverageIncrease`. This model contains the power window controller that is a state machine. This model also contains a From Spreadsheet block that provides multiple sets of inputs to the controller. These input sets combine with the one from the `CoverageExample` model to exercise more of the logic in the power window controller.

These input sets are:

- `Logged`: Logged from the `CoverageExample`.
- `LoggedObstacleOffEndStopOn`: Logged from the `CoverageExample` with ability to hit endstop.
- `LoggedObstacleOnEndStopOff`: Logged from the `CoverageExample` with obstacle in window.
- `LoggedObstacleOnEndStopOn`: Logged from the `CoverageExample` with obstacle in window and ability to hit endstop.
- `DriverLoggedPassengerNeutral`: Logged from the `CoverageExample` for only the driver. Passenger takes no action.
- `DriverDownPassengerNeutral`: Driver lowering window. Passenger takes no action.
- `DriverUpPassengerNeutral`: Driver raising window. Passenger takes no action.
- `DriverAutoDownPassengerNeutral`: Driver lowering window for 1 second (auto-down). Passenger takes no action.
- `DriverAutoUpPassengerNeutral`: Driver raising window for 1 second (auto-up). Passenger takes no action.
- `PassengerAutoDownDriverNeutral`: Passenger lowering window for 1 second (auto-down). Driver takes no action.
- `PassengerAutoUpDriverNeutral`: Passenger raising window for 1 second (auto-up). Driver takes no action.

The model coverage shortcut, `GenerateIncreasedCoverage`, uses the multiple input sets with the Simulink Coverage Model Coverage tool to validate the discrete event control of the window and generate a coverage report for the multiple input sets. The Model Coverage tool helps determine the extent to which a model test case exercises the conditional branches of the controller. It also helps evaluate if all transitions in the discrete event control have been taken into account given the input sets we run.

## Developing the Apollo Lunar Module Digital Autopilot

"Working on the design of the Lunar Module digital autopilot was the highlight of my career as an engineer. When Neil Armstrong stepped off the LM (Lunar Module) onto the moon's surface, every engineer who contributed to the Apollo program felt a sense of pride and accomplishment. We had succeeded in our goal. We had developed technology that never existed before, and through hard work and meticulous attention to detail, we had created a system that worked flawlessly." -Richard J. Gran, *The Apollo 11 Moon Landing: Spacecraft Design Then and Now*

This example shows how Richard and the other engineers who worked on the Apollo Lunar Module digital autopilot design team could have done it using Simulink® and Aerospace Blockset™ if they had been available in 1961.

### Model Description

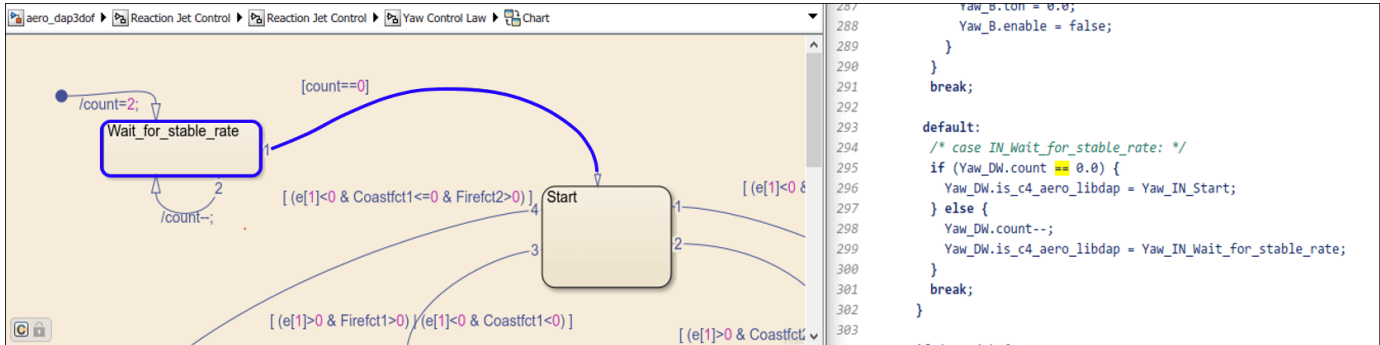

Developing the autopilot in Simulink takes a fraction of the time it took for the original design of the Apollo Lunar Module autopilot.

```
if ~bdIsLoaded("aero_dap3dof")
 open_system("aero_dap3dof");
end
```

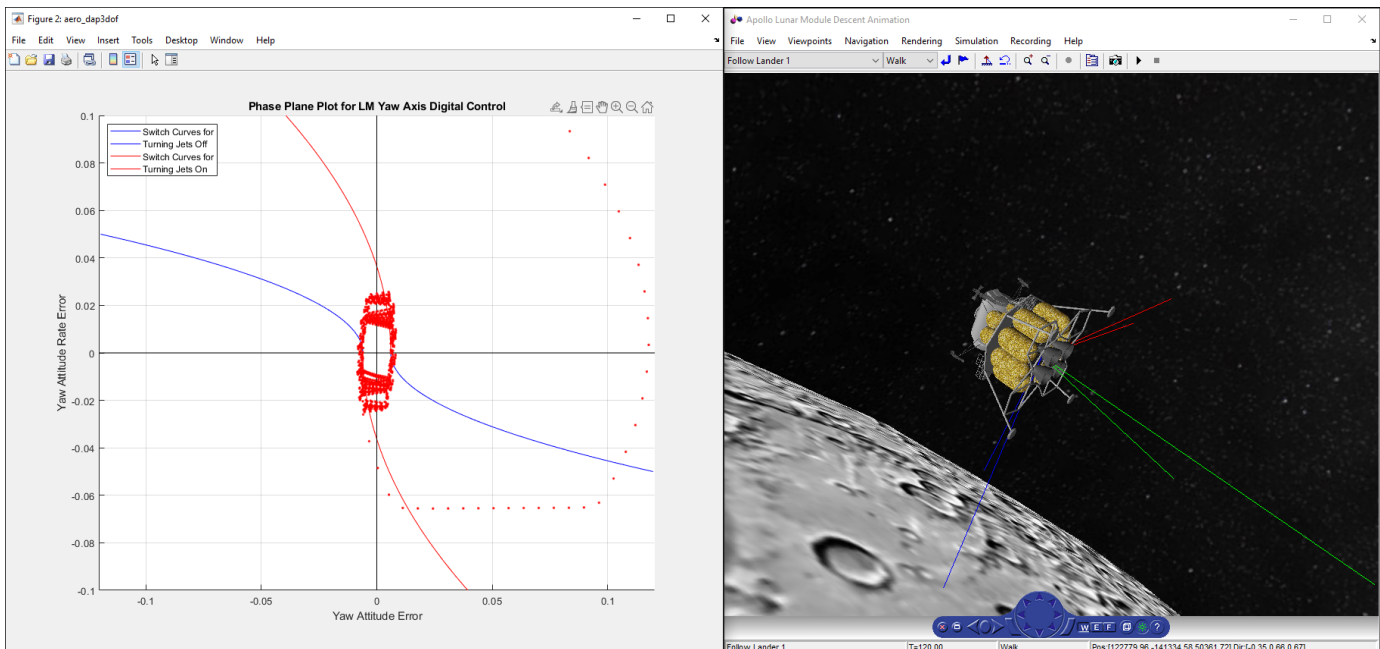

The Reaction Jet Control subsystem models the digital autopilot design proposed (and implemented) by MIT Instrumentation Laboratories (MIT IL), now called Draper Laboratory. A Stateflow® diagram in the model specifies the logic that implements the phase-plane control algorithm described in the technical article *The Apollo 11 Moon Landing: Spacecraft Design Then and Now*. Depending on which region of the diagram the Lunar Module is executing, the Stateflow diagram is in either a

Fire\_region or a Coast\_region. Note, the transitions between these different regions depend on certain parameters. The Stateflow diagram determines whether to transition to another state and then computes which reaction jets to fire.

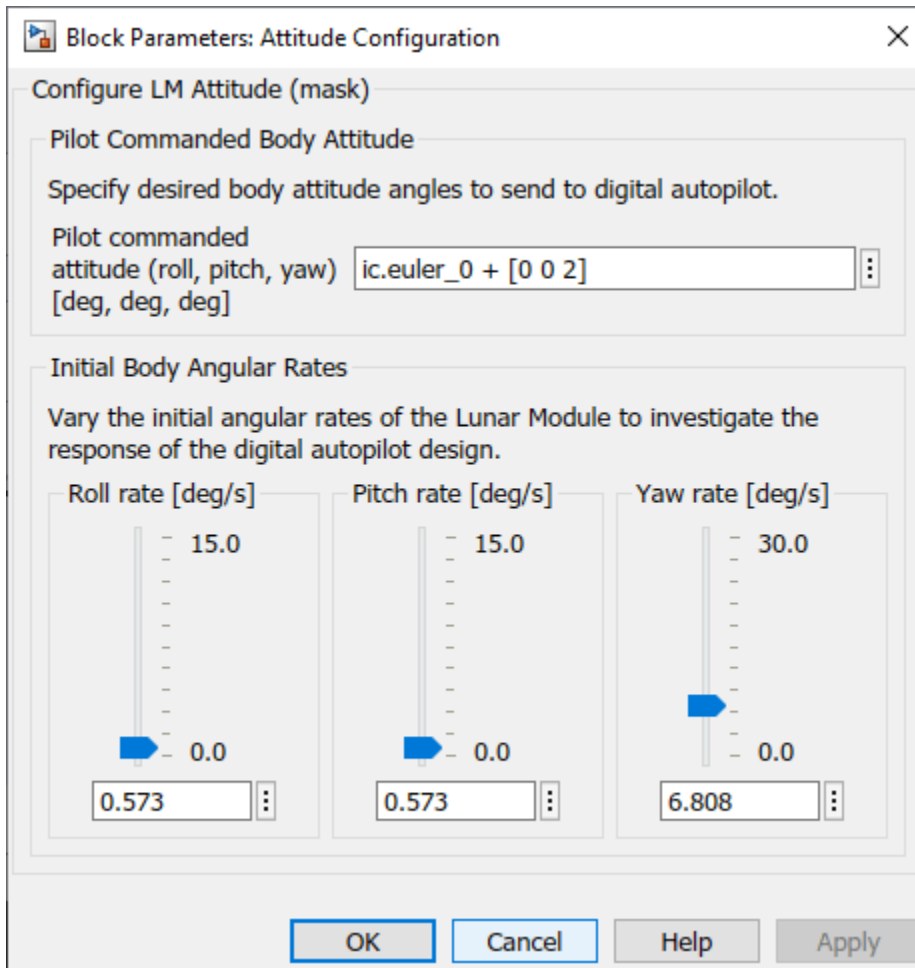

Translational and rotational dynamics of the Lunar Module are approximated in the Lunar Module Dynamics subsystem. Access various visualization methods of the Lunar Module states and autopilot performance in the Visualization area of the model, including Simulink scopes, animation with Simulink 3D Animation, and a phase plane plot.

### Interactive Controls

To interact with the Lunar Module model, vary autopilot settings and Lunar Module initial states in the Commands area. For example, to observe how the digital autopilot design handles increased initial body rates, use the slider components in Configure LM Attitude.

### Mission Description

The LM digital autopilot has three degrees of freedom. This means that by design, the reaction jet thrusters are configured and commanded to rotate the vehicle without impacting the vehicle's orbital trajectory. Therefore, the translational dynamics in his model are approximated via orbit propagation using the Spacecraft Dynamics block from Aerospace Blockset. The block is configured to use Moon spherical harmonic gravity model LP-100K.

To demonstrate the digital autopilot design behavior, the "Descent Orbit Insertion" mission segment, just prior to the initiation of the powered descent, was selected from the *Apollo 11 Mission Report*.

NASA-S-69-3709

Figure 5-1 . - Lunar descent orbital events .

6T-5

(Image Credit: NASA)

The "Descent Orbit Insertion" burn began 101 hours, 36 minutes, and 14 seconds after lift-off and lasted 30 seconds. The burn set the Lunar module on a trajectory to lower its orbit from approximately 60 nautical miles to 50,000 ft over about an hour. At 50,000 ft, the Module initiated its powered descent.

Initialize the model `aero_dap3dof` with the approximate trajectory of the Lunar Module immediately after the descent orbit insertion burn.

```
mission.t_rangeZero = datetime(1969,7,16,13,32,0); % lift-off
mission.t_descentInsertionStart = mission.t_rangeZero + hours(101) + minutes(36) + seconds(14);
mission.t_descentInsertion = mission.t_descentInsertionStart + seconds(30);
mission.t_poweredDescentStart = mission.t_rangeZero + hours(102) + minutes(33) + seconds(5.2);

disp(timetable([mission.t_rangeZero, mission.t_descentInsertionStart, ...
mission.t_descentInsertion, mission.t_poweredDescentStart]', ...
{'Range Zero (lift-off)', 'Descent Orbit Insertion (Engine ignition)', ...
'Descent Orbit Insertion (Engine cutoff)', 'Powered Descent (Engine ignition)'}', VariableName
```

Time	Mission Phase
16-Jul-1969 13:32:00	{'Range Zero (lift-off)'} }
20-Jul-1969 19:08:14	{'Descent Orbit Insertion (Engine ignition)'} }
20-Jul-1969 19:08:44	{'Descent Orbit Insertion (Engine cutoff)'} }
20-Jul-1969 20:05:05	{'Powered Descent (Engine ignition)'} }

The trajectory of the module at "Descent Orbit Insertion (Engine cutoff)" and "Powered Descent Initiation (Engine ignition)" is provided in the *Apollo 11 Mission Report* (Table 7-II.- Trajectory Parameters).

```
mission.Latitude_deg = [-1.16, 1.02]'; % [deg]
mission.Longitude_deg = [-141.88, 39.39]'; % [deg]
mission.Altitude_mi = [57.8, 6.4]'; % [nautical miles]
mission.Altitude_ft = convlength(mission.Altitude_mi, 'naut mi', 'ft');
mission.Velocity_fps = [5284.9, 5564.9]'; % [ft/s] (in Inertial frame)
mission.FlightPathAngle_deg = [-0.06, 0.03]'; % [deg] (measured upward from local horizontal plane)
mission.HeadingAngle_deg = [-75.19 -101.23]'; % [deg] (measured East of North)
disp(table({'Range Zero (lift-off)'; 'Descent Orbit Insertion (Engine ignition)'}, ...
 mission.Latitude_deg, mission.Longitude_deg, mission.Altitude_mi, ...
 mission.Velocity_fps, mission.FlightPathAngle_deg, mission.HeadingAngle_deg, ...
 VariableNames=["Mission Phase", ...
 "Latitude (deg)", "Longitude (deg)", "Altitude (mi)", ...
 "Velocity (ft/s)", "Flight path angle (deg)", "Heading (deg)"]));
```

Mission Phase	Latitude (deg)	Longitude (deg)	Altitude (mi)
{'Range Zero (lift-off)'} }	-1.16	-141.88	57.8
{'Descent Orbit Insertion (Engine ignition)'} }	1.02	39.39	6.4

### Model Initialization

Initialize model parameters for the mission phase "Descent Orbit Insertion (Engine cutoff)" using the data defined above.

The initialization function `aero_dap3dofdata` requires information about the orientation of the Moon, which can be calculated using the Aerospace Blockset function `moonLibration`. This function requires "Ephemeris Data for Aerospace Toolbox". Use `aeroDataPackage` to install this data if it is not already installed.

```
mission.LibrationAngles_deg = moonLibration(juliandate(mission.t_descentInsertion), "405");
```

This example uses saved libration angle data corresponding with `t_descentInsertion`. Use the above command after installing the required ephemeris data.

```
mission.LibrationAngles_deg = [0.006379917345247; 0.382328074214300; 6.535718297208969];
```

Run the initialization function:

```
[moon, ic, vehicle, rcs] = aero_dap3dofdata(...
 mission.Latitude_deg(1), mission.Longitude_deg(1), mission.Altitude_ft(1), ...
 mission.Velocity_fps(1), mission.FlightPathAngle_deg(1), ...
 mission.HeadingAngle_deg(1), mission.LibrationAngles_deg)
```

```
moon = struct with fields:
 r_moon_eq: 5702428
```

```
f_moon: 0.0012

ic = struct with fields:
 t_runtime: 120

```

## Closing Remarks

Building a digital autopilot was a daunting task in 1961 because there was very little industrial infrastructure for it - everything about it was in the process of being invented. Here is an excerpt from the technical article *The Apollo 11 Moon Landing: Spacecraft Design Then and Now*:

"One reason why the [autopilot's machine code] was so complex is that the number of jets that could be used to control the rotations about the pilot axes was large. A decision was made to change the axes that the autopilot was controlling to the "jet axes" shown in `aero_dap3dof`. This change dramatically reduced the number of lines of code and made it much easier to program the autopilot in the existing computer. Without this improvement, it would have been impossible to have the autopilot use only 2000 words of storage. The lesson of this change is that when engineers are given the opportunity to code the computer with the system they are designing, they can often modify the design to greatly improve the code."

## Designing a High Angle of Attack Pitch Mode Control

### Control Design Using Simulink®

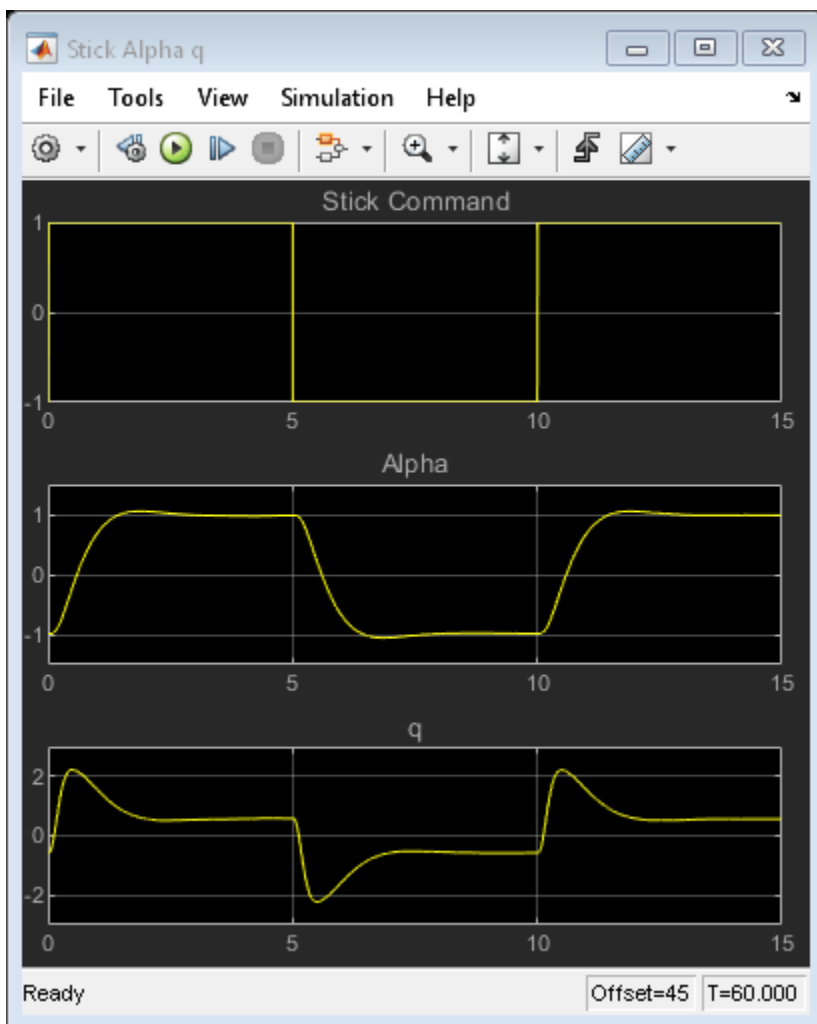

This example shows how to use the Control System Toolbox™ and Simulink® Control Design™ to interact with Simulink to design a digital pitch control for the aircraft. In this example, we will design the controller to permit the aircraft to operate at a high angle of attack with minimal pilot workload.

Our example takes you through the first pass at designing a digital autopilot for a high angle of attack controller. To run everything in this example you must have the Control System Toolbox, Simulink Control Design, Simulink, and Simulink® Coder™. If you don't have all of these products, you can still run portions of the example using cell execution mode of the MATLAB® editor.

Below is a Simulink model of the aircraft. The control systems in the Controllers block can be switched in the model to allow you to see the analog response and then to switch to a design created using the Control System Toolbox's Linear Time Invariant (LTI) objects. A controller is also included that is a discrete implementation of the analog design that is similar to the algorithm that would go into an on-board flight computer. Take a few moments to explore the model.

Copyright 2013-2022 The MathWorks, Inc.

**Figure 1:** Simulink model of the aircraft flight control system.

### Trimming and Linearization

You can linearize the model using Simulink Control Design software. To interactively linearize the model, use the **Model Linearizer** app. To open the app, in the Simulink Editor, on the **Apps** tab, under **Control Systems**, click **Model Linearizer**. You can also programmatically linearize the model using the `linearize` function.

Open the `slexAircraftPitchControlAutopilot` model.

To view the linearized model parameters:

```
apmdl = 'slexAircraftPitchControlAutopilot';
open_system(apmdl);
op = operpoint(apmdl);
io = getlinio(apmdl);
contap = linearize(apmdl,op,io)
```

contap =

```
A =
 Alpha-sensor Pitch Rate L Proportional Stick Prefil
Alpha-sensor -2.526 0 0 0
Pitch Rate L 0 -4.144 0 0
Proportional -1.71 0.9567 0 10
Stick Prefil 0 0 0 -10
```

```
B =
 Alpha Sensed Stick q Sensed
Alpha-sensor 1 0 0
Pitch Rate L 0 0 1
Proportional 0 0 -0.8156
Stick Prefil 0 1 0
```

```
C =
 Alpha-sensor Pitch Rate L Proportional Stick Prefil
Sum 2.986 -1.67 -3.864 -17.46
```

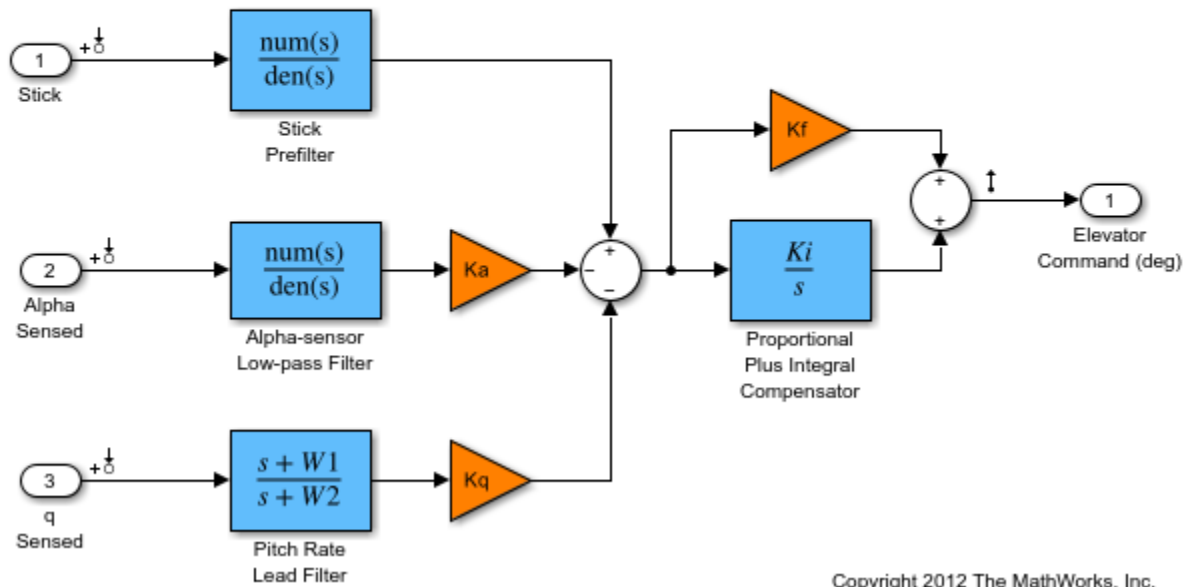

```
D =
 Alpha Sensed Stick q Sensed
Sum 0 0 1.424
```

Continuous-time state-space model.

## The Original Analog Autopilot for the High Angle of Attack Mode

?

This autopilot configuration uses a traditional design.  
The parameters  $T_s$ ,  $T_{al}$ ,  $W_1$ ,  $W_2$ ,  $K_a$ ,  $K_q$ ,  $K_f$ , and  $K_i$  need to be optimized.

**Figure 2:** Original analog autopilot.

### Linear Time-Invariant (LTI) Systems

There are three types of LTI objects you can use to develop a linear model:

State Space (SS), Transfer Function (TF), and Zero-Pole-Gain (ZPG) objects.

The variable `contap` is a State Space object. You can then get one of the other types with the other commands. When you create the object in MATLAB, you can manipulate it using operations such as `*`, `+`, `-`, etc. This is called "overloading" the MATLAB operators. Try creating an object of your own and see what happens when adding, multiplying, etc. with the `contap` object.

To see exactly what is stored in the LTI object, type `get(contap)` or `contap.InputName` for example.

To view Zero/Pole/Gain transfer functions:

```
contap = tf(contap);
contap = zpk(contap)
```

```
contap =
```

```
From input "Alpha Sensed" to output "Sum":
2.9857 (s+2.213)

s (s+2.526)
```

```

From input "Stick" to output "Sum":
-17.46 (s+2.213)

 s (s+10)

From input "q Sensed" to output "Sum":
 1.424 (s+2.971) (s+2.213)

 s (s+4.144)

```

Continuous-time zero/pole/gain model.

### Discretized Controller Using Zero-Order Hold

Now the LTI object will be used to design the digital autopilot that will replace the analog autopilot. The analog system is coded into the LTI object called `contap` (CONTinuous AutoPilot).

The first attempt at creating a digital autopilot will use a zero-order hold with a sample time of 0.1 seconds. Note that the discrete object maintains the type (`ss`, `tf`, or `zpk`).

It is clear from Bode plot below that the systems do not match in phase from 3 rad/sec to the half sample frequency (the vertical black line) for the pilot stick input and the angle of attack sensor. This design has poorer response than the analog system. Go to the Simulink model and start the simulation (make sure you can see the scope windows). While the simulation is running, double-click the manual switch labeled Analog or Digital.

Does the simulation verify the conclusion reached by interpreting the Bode diagram?

```

discap = c2d(contap, 0.1, 'zoh');
get(discap)
bode(contap,discap)

 Z: {[0.8016] [0.8039] [2x1 double]}
 P: {[2x1 double] [2x1 double] [2x1 double]}
 K: [0.2943 -1.2458 1.4240]
DisplayFormat: 'roots'
Variable: 'z'
IODElay: [0 0 0]
InputDelay: [3x1 double]
OutputDelay: 0
InputName: {3x1 cell}
InputUnit: {3x1 cell}
InputGroup: [1x1 struct]
OutputName: {'Sum'}
OutputUnit: {''}
OutputGroup: [1x1 struct]
Notes: [0x1 string]
UserData: []
Name: ''
Ts: 0.1000
TimeUnit: 'seconds'
SamplingGrid: [1x1 struct]

```

**Figure 3:** Bode diagram comparing analog and ZOH controllers.

### Tustin (Bilinear) Discretization

Now try different conversion techniques. You can use the Tustin transformation. In the command window type the commands above.

It should be clear that the systems still do not match in phase from 3 rad/sec to the half sample frequency, the Tustin transformation does better. The simulation uses the LTI object as it is designed. To see how the object is used look in the Controllers subsystem by using the browser or by double clicking the icon. The LTI block picks up an LTI object from the workspace. You can change the object name used in the block to any LTI object in the workspace.

Try using "discap1", the Tustin discretization of the analog design:

```
discap1 = c2d(contap,0.1,'tustin');
bode(contap,discap,discap1)
```

**Figure 4:** Bode diagram comparing analog and 0.1 sec Tustin controllers.

### Selecting a Sample Time

The Tustin transform performs better than the zero-order hold from the analysis so far. The sample time of 0.1 second appears to be too slow for the discrete system to track the performance of the analog system at half the sample frequency.

Now transform the analog design using the Tustin transform with a 0.05 second sample period:

```
discap = c2d(contap,0.05,'tustin')
bode(contap,discap)
```

```
discap =
```

```
From input "Alpha Sensed" to output "Sum":
0.074094 (z-0.8951) (z+1)

(z-1) (z-0.8812)
```

```
From input "Stick" to output "Sum":
-0.36852 (z-0.8951) (z+1)

(z-1) (z-0.6)
```

```
From input "q Sensed" to output "Sum":
```

$$\frac{1.4629 (z-0.8617) (z-0.8951)}{(z-1) (z-0.8123)}$$

Sample time: 0.05 seconds  
Discrete-time zero/pole/gain model.

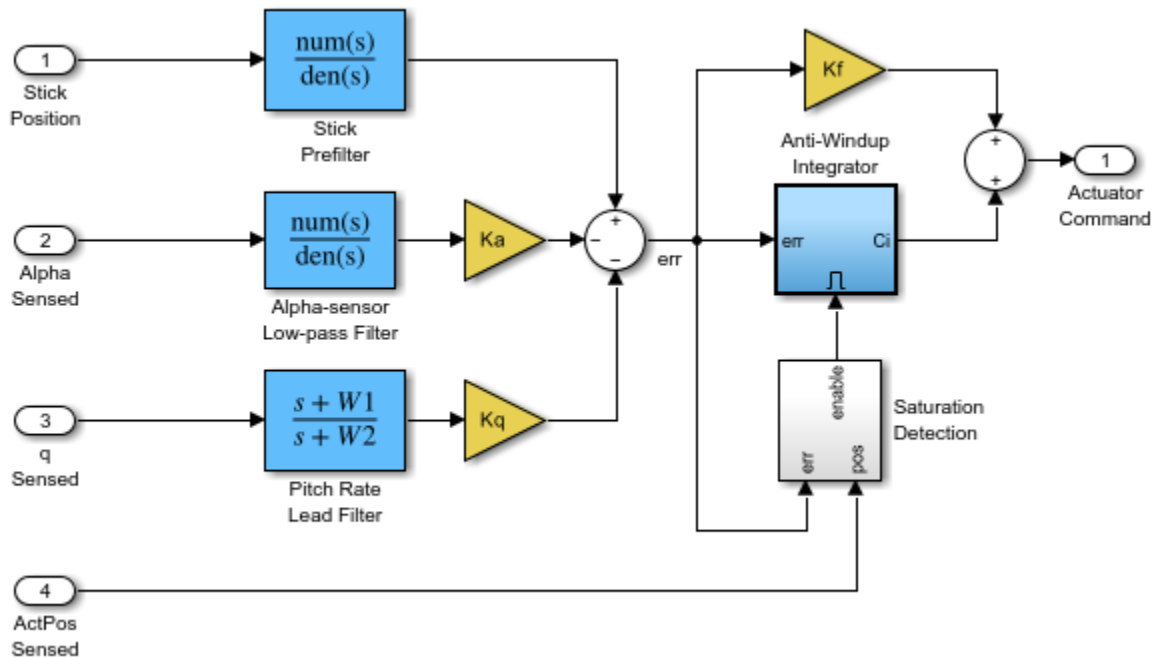

**Figure 5:** Bode diagram comparing analog and 0.05 sec Tustin controllers.

### Real-World Considerations

Now that we have what appears to be a workable design, we need to implement it in a form that will include some of the necessary elements that were ignored in the linear analysis. For example, if you look at the analog autopilot that is in the Controllers subsystem, you will see some logic that stops the integrator from winding up when the actuator saturates:

Open the AnalogControl subsystem.

**Figure 6:** AnalogControl subsystem.

### Implementation of the Full Design

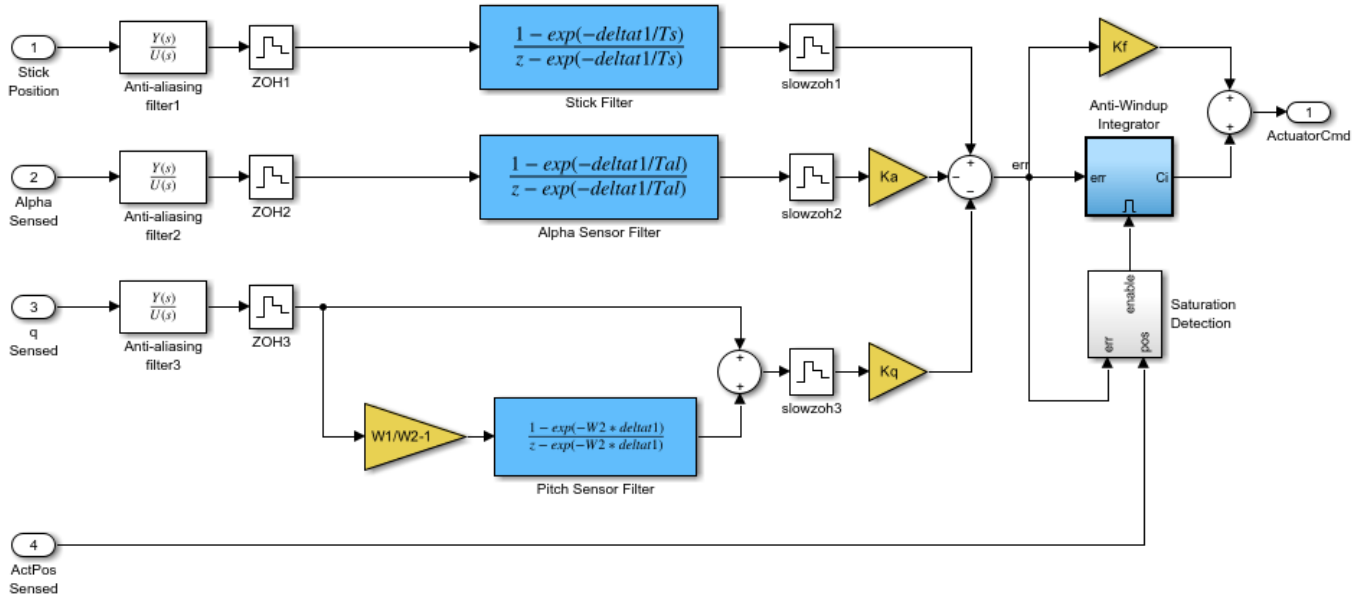

The integrator wind-up is only one of the practical issues that needs to be addressed. Another is the need to eliminate aliased high frequency signals that could enter at measurement points. These aliased signals can be prevented by specifying analog filters in front of the sample and hold (ZOH) blocks that model the analog-to-digital converter (ADC) devices typically used for measuring signals in an embedded application. Additionally, the filters in the digital section of the autopilot operate at a higher sampling rate than the compensator to provide a conditioned signal to the compensator. The analog filters are necessary because once a signal is aliased, there is no way to separate the valid in-band frequency content from aliased content.

This new controller is called Digital Control. The filters have a sample time of  $\text{deltat1}$  (set to be  $1/10$  of  $\text{deltat}$ ). The zero-order hold blocks specify these sample times for various downstream blocks through sample time inheritance.

The switches in the `slexAircraftPitchControlExample` model are set up so you can switch between the analog autopilot, the digital LTI object, and the digital autopilot that could be implemented using software.

Try simulating the system again and switch among the three autopilot designs. You should see that the designs are not significantly affected by which autopilot is active. You can also increase the amplitude of the wind gust and verify that the anti-aliasing filters are working satisfactorily. To increase the gust amplitude, open the Dryden Wind Gust subsystem and change (by double clicking the icon) the noise variance of the White Noise that drives the gust simulation.

Open the DigitalControl subsystem.

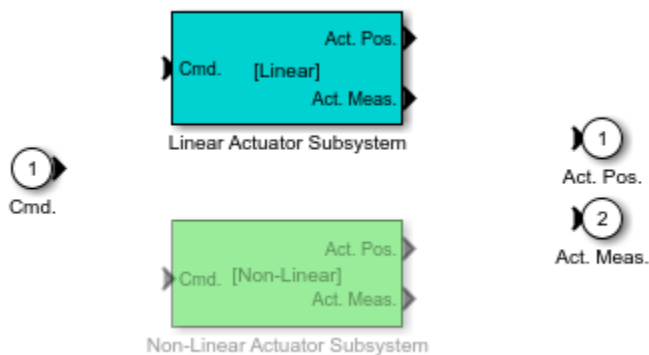

**Figure 7:** DigitalControl subsystem.

**Variant Systems for Design Variants**

The actuators in the Simulink model use the Variant Subsystems block to represent multiple actuator implementations, where only one implementation is active during simulation. You can double-click the Variant Actuator Subsystem block to view the different actuator implementations.

To make the simulation change, use the nonlinear actuator instead of the linear one. You can do this by using the Variant Subsystem block **Variant > Override using** context menu.

Note that Simulink must be stopped in order to reconfigure the actuator selection. You should also note that the nonlinear actuator has saturations on position and rate.

**Figure 8:** Variant Subsystem for Actuators

**Code Generation**

The autopilot design can be transformed into embeddable code using Simulink Coder. A separate model of the digital autopilot, slxAircraftPitchControlDAP, is open below; it was coded into a host-

based standalone program using Simulink Coder and the compiler specified using the mex -setup configuration. The simulation results can be used as a validation baseline for the functional correctness of the generated code.

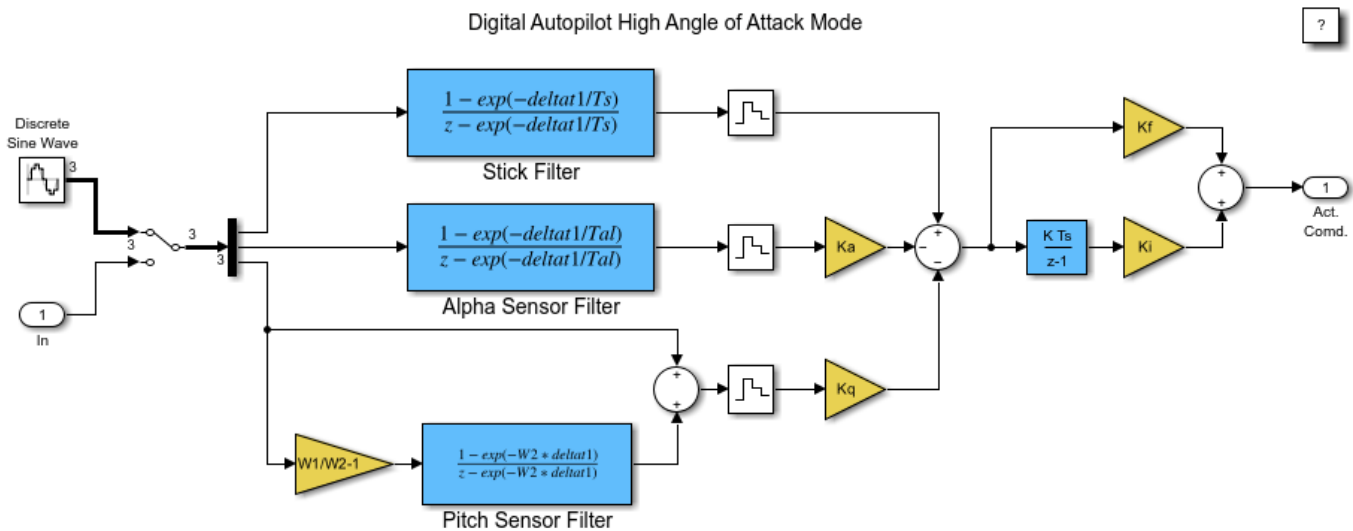

The executable file resulting from code generation and compilation is `slexAircraftPitchControlDAP.exe`. If you create it, it can be run from the OS shell (DOS) command line directly or from MATLAB by typing:

```
>> !slexAircraftPitchControlDAP.exe
```

The executable program creates a file called `slexAircraftPitchControlDAP.mat` that you can load by typing `load slexAircraftPitchControlDAP`.

Two variables called `rt_tout` and `rt_yout` will be in the workspace and their variance against the simulation baseline can be plotted. Note that the variance is effectively zero for this model on this host. Some small numeric variance is to be expected in more complex calculations due to differing compiler optimizations and use of intermediate register variables having higher precision than the 64-bit storage format of a double. Significant variances should be examined as they could indicate a numerical stability problem in your model's algorithms, a compiler or run-time library bug, or other problems.

Open the `slexAircraftPitchControlDAP` model.

**Figure 9:** Comparison of simulation and code generation results.

### **Behavior of the First Pass Design**

Here is the time response of the high angle of attack mode digital pitch controller design:

**Figure 10:** Response of the aircraft Digital Pitch Control Design.

### Summary

Further work on this design might include incorporating and analyzing more of the real-world effects on the compensator such as the effect of the anti-aliasing filter dynamics and computational delay of the embedded digital computer on the overall "plant" seen by the digital computations. The combination of the real plant, the computational delay, the anti-aliasing filters, and the sample-and-hold delay are just a few of the additional items that might affect the design of the digital compensator parameters.

## Aircraft Longitudinal Flight Control

This example shows how to model flight control for the longitudinal motion of an aircraft. First order linear approximations of the aircraft and actuator behavior are connected to an analog flight control design that uses the pilot's stick pitch command as the set point for the aircraft's pitch attitude and uses aircraft pitch angle and pitch rate to determine commands. A simplified Dryden wind gust model is incorporated to perturb the system.

The Viewers and Generators Manager was used in this model to create the model scope for viewing signals, Scope1. Found on **Simulation > Prepare > Viewers Manager**, the Viewers and Generators Manager allows you to instrument your model without having to add blocks to the model. If you close a model scope, such as for batch simulations, you can later reopen it by double-clicking the "scope" icon on the signal of interest.

Parameters for the model are stored in a file named slxAircraftData.m. This file is loaded by the model into the model workspace. You can view and edit data in the model workspace directly by using the Model Explorer, which is launched using the **Modeling > Design > Model Explorer** menu item.

## Simulink Model Discretizer

This interactive example discretizes the Actuator Model in the `slexAircraftExample` model. If you haven't already, click **Open Model** to open the model.

### Open the Model Discretizer

To open the Model Discretizer, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**. This opens the Model Discretizer.

The Simulink model window and the Model Discretizer GUI are laid out in the screen for easy navigation.

- The model tree is shown in the left panel of the Model Discretizer GUI.
- Discretization parameters are set through the right panel of the Model Discretizer GUI.
- Discretization status is shown in the lower part of the right panel.
- By default, only continuous blocks are shown in the Model Discretizer GUI.
- In the Simulink model window, blocks in red color are continuous blocks.

You can browse through the continuous blocks one by one using the model tree view. In the Simulink Model Discretizer, select the **View > Next continuous block**. This highlights the Actuator Model.

Before discretizing the Actuator Model block, set the discretization parameters: transform method, sample time, critical frequency. Critical frequency has to be specified if the transform method 'tustin with prewarping' is selected.

After setting the discretization parameters, select **Discretize > Discretize current block** in the Model Discretizer. Or you can just click the s->z button icon in the tool bar. The discretized Actuator Model is highlighted in blue color in the model.

By default, the Actuator Model was replaced by a discrete block beneath a continuous block dialog, allowing you to continue entering the Actuator Model parameters in the s-domain. In the model window, double-click the Actuator model. Two new fields 'Sample time' and 'Method' were added to the block dialog window. These parameters are used to automatically convert the continuous parameters to equivalent discrete parameters.

# Optical Sensor Image Generation

## Generating an Optical Sensor Image From Simulated Movement Data

This example shows how to generate a movie with 64 frames and a frame size of 64 by 64 pixels (at 10 frames per second). The movie contains a simulation of a moving target that is moving through a structured background that is itself moving. A jitter motion caused by random vibration is also generated (in a Simulink® model called "aero\_vibrati") and the jitter motion is added into the overall sensor motion. Finally, the image is blurred through a Gaussian optical point spread function.

Note: Changing `delt` here also requires a change in the parameters set-up dialog box in the Simulink model "vibration".

```
delt = 0.1; % Sample time of the generated sequence
num_frames= 64; % Number of frames to generate
framesize = 64; % Square frame size in pixels

out = zeros(framesize,framesize,num_frames); % Initialize movie storage as a 3D Array
```

## Generate a Target and Define Its Motion

The first stage is to define the shape and motion of the target object. The shape chosen is a large plus sign, and the image is defined by a matrix representing the image intensity at each pixel position. The Target is defined to be traveling from center to bottom right of the image.

```
target = [zeros(3,11)
 zeros(1,5) 6 zeros(1,5)
 zeros(1,5) 6 zeros(1,5)
 zeros(1,3) 6 6 6 6 6 zeros(1,3) % Target is a plus sign 5 by 5 pixels across
 zeros(1,5) 6 zeros(1,5) % with an intensity of 6 (S/N ratio is ~4).
 zeros(1,5) 6 zeros(1,5) % The total target image is made on an 11x11 grid to
 zeros(3,11)]; % allow the image to be interpolated without error.

target_velx = 1; % target velocity in x direction in pixels per second
target_vely = 1; % target velocity in y direction in pixels per second
target_x_initially = framesize/2; % the target is initially in the center of the frame in x
target_y_initially = framesize/2; % and in y

figure(1);
colormap('gray');
image(target*32);
title('Target Image')
```

### Build Background and Target Composite Image

Generate a sinusoidally correlated background and give it a drift motion. Then, overlay the target onto the background image.

```

backsize = framesize+36; % Make the background bigger than the frame so when it
 % drifts there are new pixels available to drift into.
xygrid = (1:backsize)/backsize;
B=2*sin(2*pi*xygrid).^2*cos(2*pi*xygrid).^2;

psd = fft2(B);
psd = real(psd.*conj(psd));

background = B + 0.5*randn(backsize); % Add a specular Gaussian white
 % sequence to the structure with
 % variance of 0.25 (sigma of 0.5).

xoff = 10;
yoff = 10; % Sensor location is offset from the 0,0 of the background
driftx = 1;
drifty = 1; % drift rate of the background in a and y directions pix/sec.

minout = min(min(min(background)));
maxout = max(max(max(background)));
colormap('gray');
image((background-minout)*64/(maxout-minout))
title('Background image with additive white specular noise')

```

### Simulate the Tracker's Rotational Vibration

Rotational vibration of the tracker is simulated using model `aero_vibrati`. The data required to simulate the vibration of the tracker is generated by running the Simulink model "aero\_vibrati".

Run Simulink vibration model using `sim` command (Note -- if the `delt` is changed from 0.1 seconds, the Simulink model must be changed also to ensure that the sample time for the vibration match the sample time in this tracker image model).

The resulting random rotations are shown in Figure 1.

```
omega = 2*pi*5; % The structural frequencies are 5, 10 and 15 Hz in the model.
zeta = 0.01; % Damping ratio for all modes

open_system('aero_vibrati')
simout = sim('aero_vibrati', 'SrcWorkspace', 'current');

vibdat = simout.get('vibdat'); % The Simulink model "aero_vibrati"
 % generates the vibration data at
 % a sample time of 0.01 sec.
vibx = vibdat(1:10:1000); % The output of simulation is
 % returned as the variable simout
viby = vibdat(1001:10:2000); % The variable simout contains
 % the in array vibdat that contains
 % the vibration data

levarmx = 10; % Rotational lever arm for vibration noise in x
```

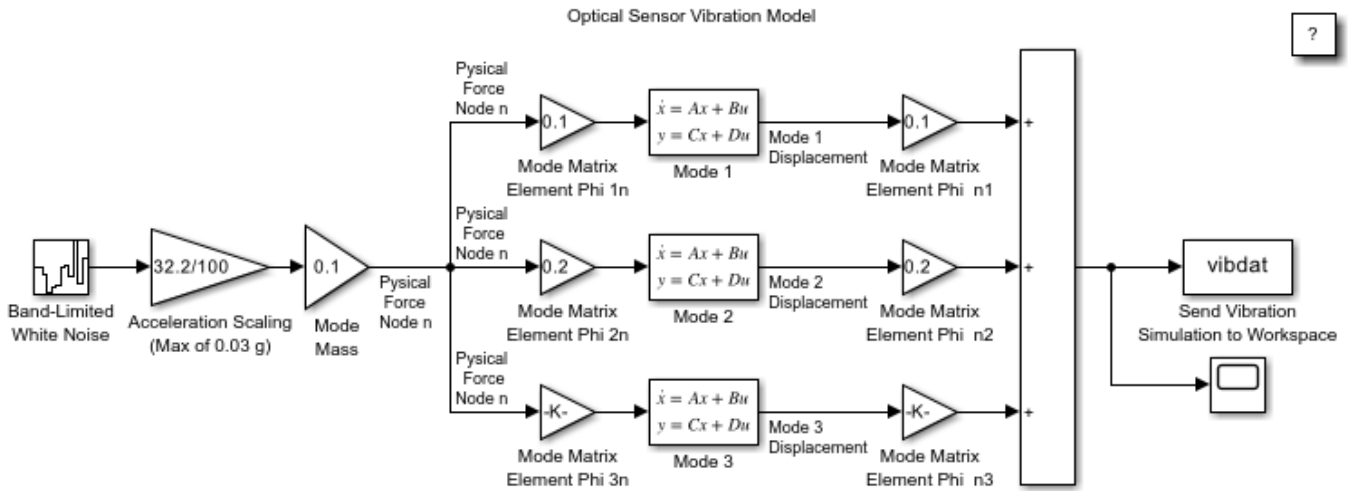

```

levarmy = 10; % and in y.

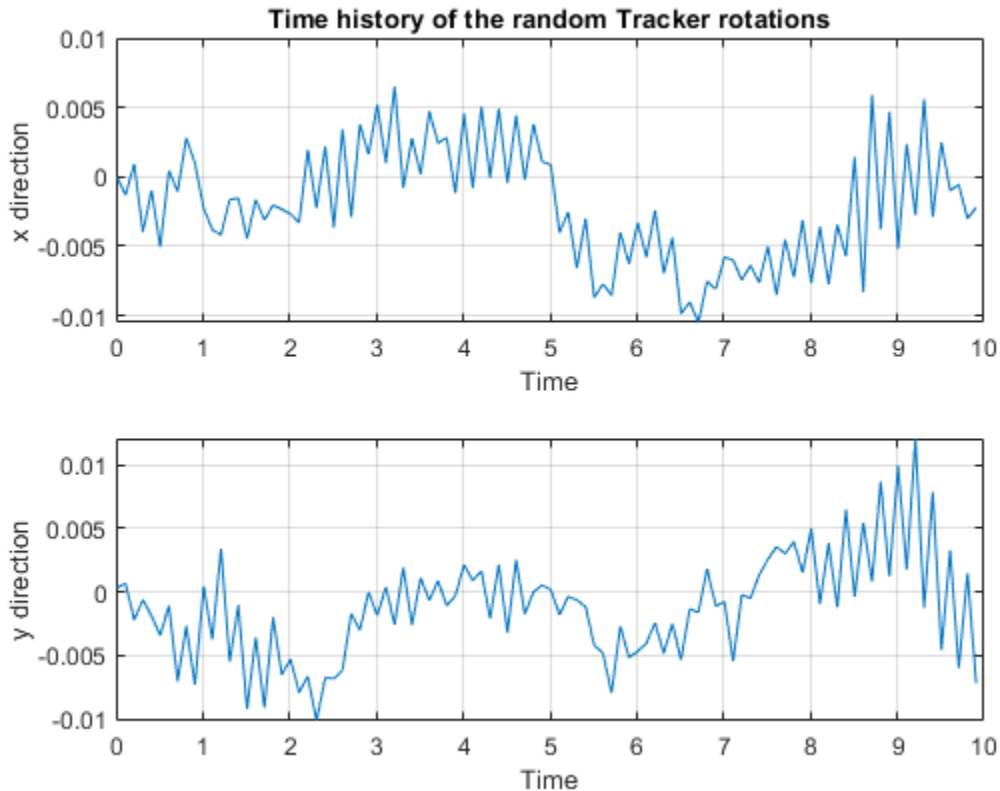

subplot(211);
plot(0.01*(1:10:1000),vibx);grid;
title('Time history of the random Tracker rotations')
xlabel('Time');ylabel('x direction')

subplot(212);
plot(0.01*(1:10:1000),viby);grid;
xlabel('Time');ylabel('y direction')

```

Copyright 1990-2013 The MathWorks, Inc.

### Simulate the Motion Effects From the Background, Target, and Jitter

The frames that will make up the movie are now created and stored in a multidimensional array (out). Each frame has the background and target at differing positions due to the target motion, background drift, and tracker vibration. The first frame of the movie will be shown in Figure 1.

```
clf; drawnow;
```

```
for t = 1:num_frames
```

```
 % Drift the Background at the rate driftx and drifty
 % (in pixels/second) and add in the vibration:
 xshift = driftx*delt*t+levarmx*vibx(t,1);
 yshift = drifty*delt*t+levarmy*viby(t,1);
```

```
 % Interpolate the 2D image using the MATLAB(R) function interp2:
 [xgrid, ygrid] = meshgrid(1:backsize);
 [xindex, yindex] = meshgrid(xshift:1:xshift+backsize,yshift:1:yshift+backsize);
 outtemp = interp2(xgrid,ygrid,background,xindex,yindex);
```

```
 % Truncate the drifted image down from backsize to framesize:
 out(:, :, t) = outtemp(xoff:xoff+framesize-1,xoff:xoff+framesize-1);
```

```
 % Now let the target move also:
 tpixinx = floor(target_velx*delt*t);
 tpixiny = floor(target_vely*delt*t); % Before interpolating extract the number of pixels moved
 txi = target_velx*delt*t - tpixinx;
```

```

tyi = target_vely*delt*t - tpixiny; % Interpolate on sub-pixels around the origin only
[txgrid tygrid] = meshgrid(1:11); % meshgrid here generates a matrix of grid elements
[txi tyi] = meshgrid(txi+1:txi+11,tyi+1:tyi+11); % meshgrid generates 2 matrices with the x and y coordinates

% Interpolate the intensity values first using interp2 -- a built in MATLAB command
temp = interp2(txgrid,tygrid,target,txi,tyi);

% Insert the target at the location determined by the initial offset, and the number of whole pixels
tx = tpixinx + target_x_initially-1;
ty = tpixiny + target_y_initially-1;
out(tx:tx+6,ty:ty+6,t) = temp(9:-1:3,9:-1:3) + out(tx:tx+6,ty:ty+6,t);

end

minout = min(min(min(out)));
maxout = max(max(max(out)));
colormap('gray');
image((out(:,:,1)-minout) * 64/(maxout-minout));
title('First frame of combined target and background image.')
```

### Pass the Images Through Optics -- Use a Gaussian "Aperture Function"

This code segment can use a measured aperture function just as easily - simply replace the next five lines by "load measured\_aperture" where measured\_aperture is the measured function stored in ASCII and the data stored in the file measured\_aperture.mat is a MATLAB® .mat file that contains the matrix apfunction. (in MATLAB type "help load" for how to use load and look at the c and fortran code that shows how to read and write MATLAB .mat files).

(Note: When the Point Spread Function is Gaussian, then so is the Aperture function)

To simulate the effect of the tracker optics, each of the movie frames is now blurred using a 2-D FFT (Fast Fourier Transform). The first frame of the resulting image is shown in Figure 1.

```
x = 1:framesize;
y = 1:framesize;
sigma = 120;
apfunction = exp(-(x-framesize/2).^2/(2*sigma))' * exp(-(y-framesize/2).^2/(2*sigma));
apfunction = fftshift(apfunction); % Rotate so it conforms with FFT convention

for j = 1:num_frames
 out(:,:,j) = real(ifft2(apfunction.*fft2(out(:,:,j))));
end

minout = min(min(min(out)));
maxout = max(max(max(out)));
colormap('gray');
image((out(:,:,1)-minout)*64/(maxout-minout));
title('First frame of blurred image.')
```

### Generate the MATLAB® Movie and Play It Back

Scale the movie frame so that it has 64 intensity values from the min to the max and then show the result as an image. See MATLAB help for how the `moviein` and `getframe` work.

```
minout = min(min(min(out)));
maxout = max(max(max(out)));
```

```
M = moviein(num_frames);
for j = 1:num_frames
 image((out(:,:,j)-minout)*64/(maxout-minout))
 drawnow
 M(:,j) = getframe;
end

% colormap('gray')
% movie(M);
```

#### **OPTIONAL: Save the Movie in a .mat File**

You can optionally save the generated tracker movie in a mat file and also save the psd of the background for later use with the movie.

```
save trackerimage out
save psdback psd
save moviedat M
```

```
bdclose('aero_vibrati');
```

## Air Traffic Control Radar Design

This example shows how to model a conceptual air traffic control (ATC) radar simulation based on the radar range equation.

### Model Description

To make parameters for *Radar System Design* easier to change and easier to determine their values, the model has a GUI. Radar and weather parameters may be changed from this GUI. While simulating, the effects of these parameters can be seen on the scope display which shows the actual aircraft range in yellow and the estimated aircraft range from the radar in magenta. Another output that can be viewed is the calculated signal to noise ratio (SNR) is compared to the ideal SNR. Ideal SNR is also specified from the GUI. The result is shown in the display block and will be either 1 (SNR  $\geq$  ideal SNR) or 0 (SNR  $<$  ideal SNR).

Simulink® and Stateflow® are used in the model, which is divided into three main subsystems, radar, aircraft, and weather.

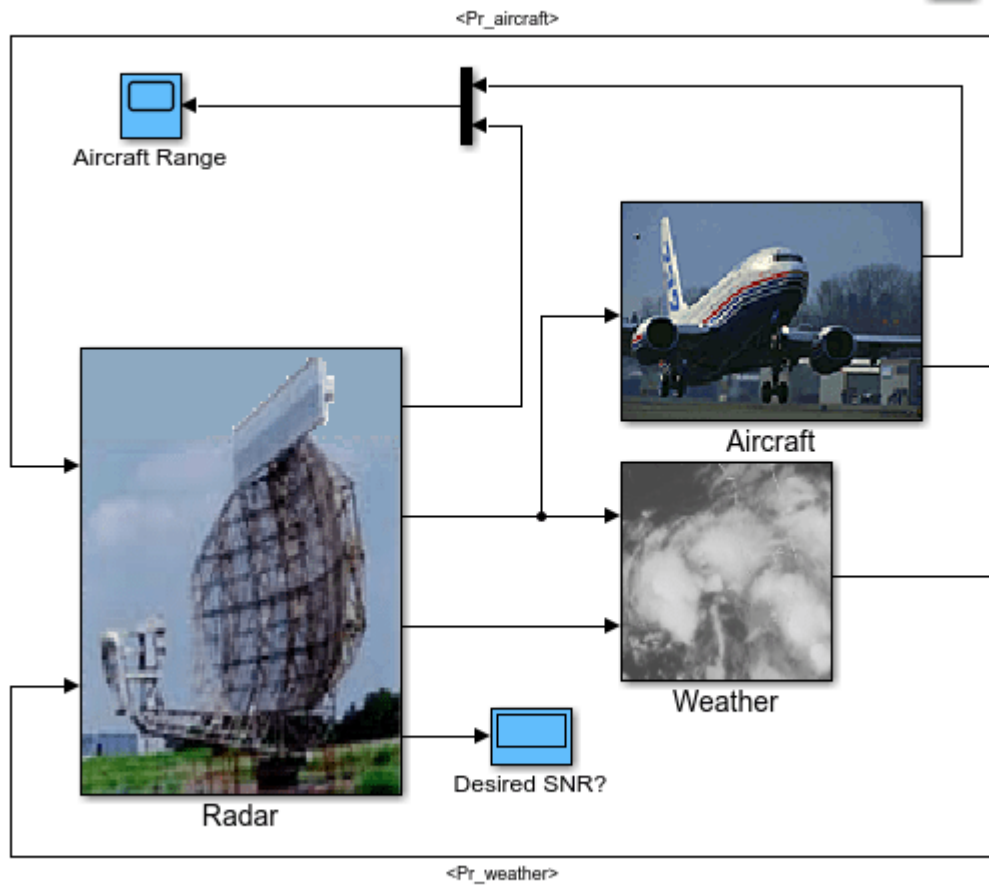

Using subsystems is helpful in two ways: the model is organized and easier to understand and the work can be split between multiple engineers by subsystems. The Stateflow machine labeled "check SNR" performs the logic comparing calculated SNR to the ideal SNR and output data based on this comparison.

You can run the simulation to determine if the radar can pick up the aircraft by the output on the scope. Using the GUI, the radar and the weather parameters can be altered and will change the range where the aircraft can be "seen".

Open and simulate the `aero_atc` model.

```
open_system('aero_atc');
```

### Design Issues

Radar systems are designed for a specific purpose and can very seldom be used for other applications effectively. Each new radar specification requires the computation of new parameter values. When designing a radar for an application, there are a number of parameters which shape the design. Some of these parameters are contained or derived logically from the customer specification. Others are selected arbitrarily using the design engineer's best judgment. This is the first approximate solution for the system design. From here, continual refinement of the design parameters takes place until an optimum design is reached. If any changes occur in the customer specification, it could cause a need to rework the design process over from the beginning. The parametric nature of this design strategy lends itself to automation.

### Design Specification

We're interested in performing conceptual design for a ground-based air traffic control (ATC) radar. Let's take a look at a potential customer specification.

- **Customer Requirements**

- Maximum Range = 50 Nautical Miles
- Lateral Resolution = 2 Nautical Miles
- Range Resolution = 150 meters

- **Logically Derived Parameters**

- Scan Time, Hits per Scan, Receiver Bandwidth, SNR, Antenna Gain,  $\text{Power}_{\text{ave}} * \text{Antenna Aperture}$

- **Best-Judgement Parameters**

- Target Cross-Section, Detection Performance, Coverage, Pulse Repetition Frequency, Integration Efficiency, Transmitted Waveform, Receiver Noise Figure, Attenuation, System Losses

- **Additional Concerns**

- Weather

© 1999 The MathWorks, Inc.

This is an example of a customer specification upon which a design process would be based. The customer, possibly the FAA, provides some basic requirements for the radar design leaving a number of parameter selections up to the design engineer.

It should be noted that some of the logically derived parameters depend on assumptions made by the engineer and would need to be recalculated each time the best-judgment parameters are optimized. This problem lends itself well to simulation. By using Simulink and Stateflow, the design engineer has the analysis capability to have time-varying design cases for Monte Carlo test runs, i.e.: aircraft cross-sections and locations, weather cross-sections, and locations.

#### **MathWorks® Products in the Design Process**

Here's how MathWorks® products fit the job of conceptual radar design:

Using the customer specification and the radar range equations along with equations describing the physics of the system, a model is built in MATLAB®, Simulink, and Stateflow. Using the model with the `sim` command for batch runs, those best-judgment parameters can be optimized for various conditions, weather, aircraft, using a Monte Carlo simulation run to prove robustness. The result is a set of optimized radar parameters that can be used to build a detailed block diagram model of the full radar system for further system analysis in Simulink with the DSP System Toolbox™.

## Designing a Guidance System in MATLAB and Simulink

This example shows how to use the model of the missile airframe presented in a number of published papers (References [1], [2] and [3]) on the use of advanced control methods applied to missile autopilot design. The model represents a tail controlled missile traveling between Mach 2 and Mach 4, at altitudes ranging between 10,000ft (3,050m) and 60,000ft (18,290m), and with typical angles of attack ranging between +/-20 degrees.

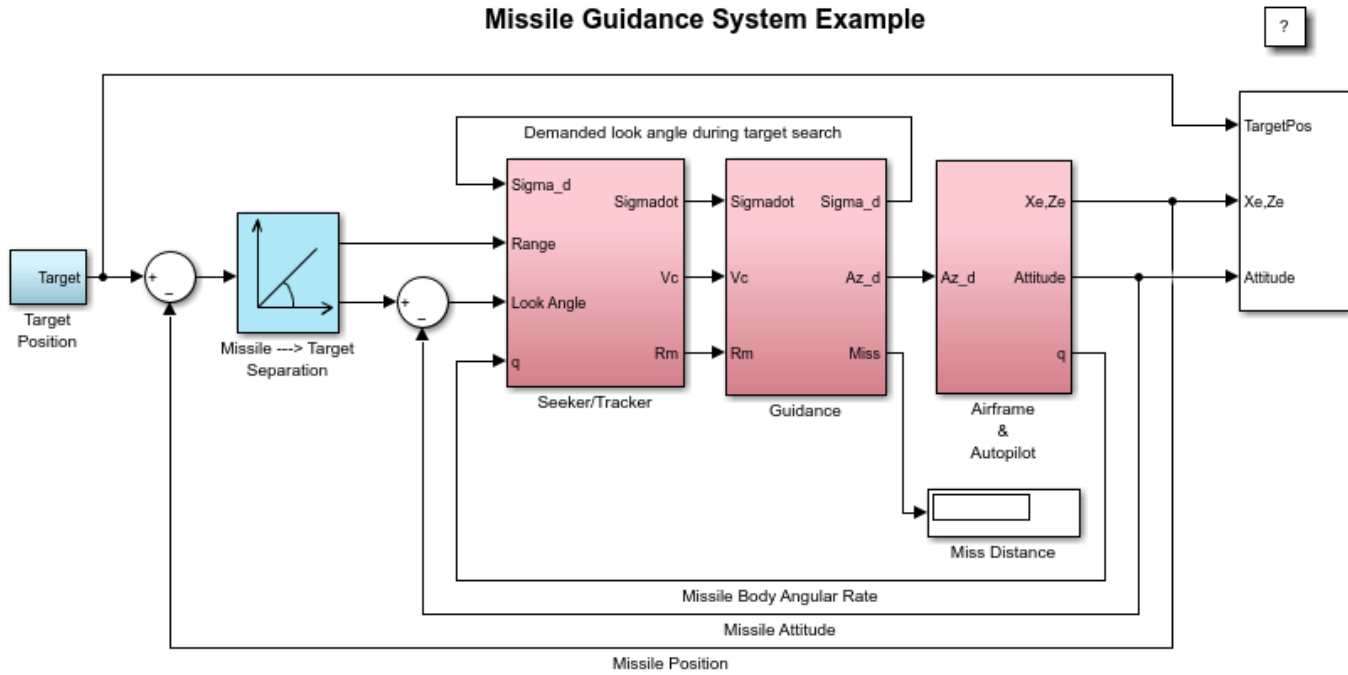

### Model of the Airframe Dynamics

The core element of the model is a nonlinear representation of the rigid body dynamics of the airframe. The aerodynamic forces and moments acting on the missile body are generated from coefficients that are non-linear functions of both incidence and Mach number. The model can be created with Simulink® and the Aerospace Blockset™. The aim of this blockset is to provide reference components, such as atmosphere models, which will be common to all models irrespective of the airframe configuration. Simplified versions of the components available in the Aerospace Blockset are included with these examples to give you a sense of the potential for reuse available from standard block libraries.

Open the model.

### Missile Guidance System Example

Copyright 1990-2014 The MathWorks, Inc.

### Representing the Airframe in Simulink

The airframe model consists of four principal subsystems, controlled through the acceleration-demand autopilot. The Atmosphere model calculates the change in atmospheric conditions with changing altitude, the Fin Actuator and Sensors models couple the autopilot to the airframe, and the Aerodynamics and Equations of Motion model calculates the magnitude of the forces and moments acting on the missile body, and integrates the equations of motion.

**International Standard Atmosphere Model**

$$\text{Troposphere Model} = \begin{cases} T = T_0 - Lh \\ \rho = \rho_0 \left( \frac{T}{T_0} \right)^{(g/LR)-1} \\ P = P_0 \left( \frac{T}{T_0} \right)^{(g/LR)} \\ a = \sqrt{\gamma RT} \end{cases}$$

- $T_0$  = Absolute temperature at mean sea level [K]
- $\rho_0$  = Air density at mean sea level [Kg/m<sup>3</sup>]
- $P_0$  = Static pressure at mean sea level [N/m<sup>2</sup>]
- $h$  = Altitude [m]
- $T$  = Temperature at altitude  $h$
- $\rho$  = Air density at altitude  $h$
- $P$  = Static pressure at altitude  $h$
- $a$  = Speed of sound at altitude  $h$
- $L$  = Lapse rate [K/m]
- $R$  = Characteristic gas constant [J/Kg/K]
- $g$  = Acceleration due to gravity [m/s<sup>2</sup>]

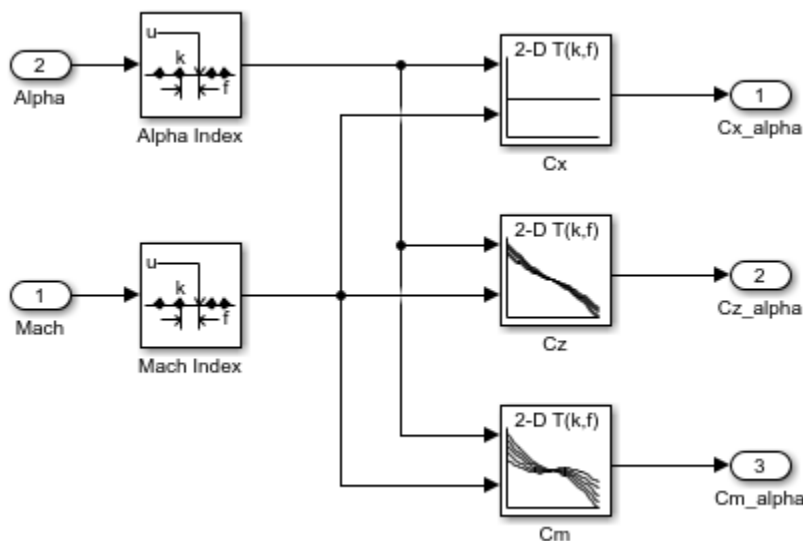

The Atmosphere Subsystem that is used is an approximation to the International Standard Atmosphere, and is split into two separate regions. The troposphere region lies between sea level and 11Km, and in this region there is assumed to be a linear temperature drop with changing altitude. Above the troposphere lies the lower stratosphere region ranging between 11Km and 20Km. In this region the temperature is assumed to remain constant.

**Aerodynamic Coefficients for Constructing Forces and Moments**

The Aerodynamics & Equations of Motion Subsystem generates the forces and moments applied to the missile in body axes, and integrates the equations of motion which define the linear and angular motion of the airframe.

The aerodynamic coefficients are stored in datasets, and during the simulation the value at the current operating condition is determined by interpolation using 2-D lookup table blocks.

### Classical Three Loop Autopilot Design

The aim of the missile autopilot is to control acceleration normal to the missile body. In this example the autopilot structure is a three loop design using measurements from an accelerometer placed

ahead of the center of gravity, and a rate gyro to provide additional damping. The controller gains are scheduled on incidence and Mach number, and are tuned for robust performance at an altitude of 10,000 ft.

To design the autopilot using classical design techniques requires that linear models of the airframe pitch dynamics be derived about a number of trimmed flight conditions. MATLAB® can determine the trim conditions, and derive linear state space models directly from the non-linear Simulink model, saving both time, and aiding in the validation of the model that has been created. The functions provided by the MATLAB Control System Toolbox™ and Simulink® Control Design™ allow the designer to visualize the behavior of the airframe open loop frequency (or time) responses. To see how to trim and linearize the airframe model you can run the companion example, "Airframe Trim and Linearize".

### Airframe Frequency Response

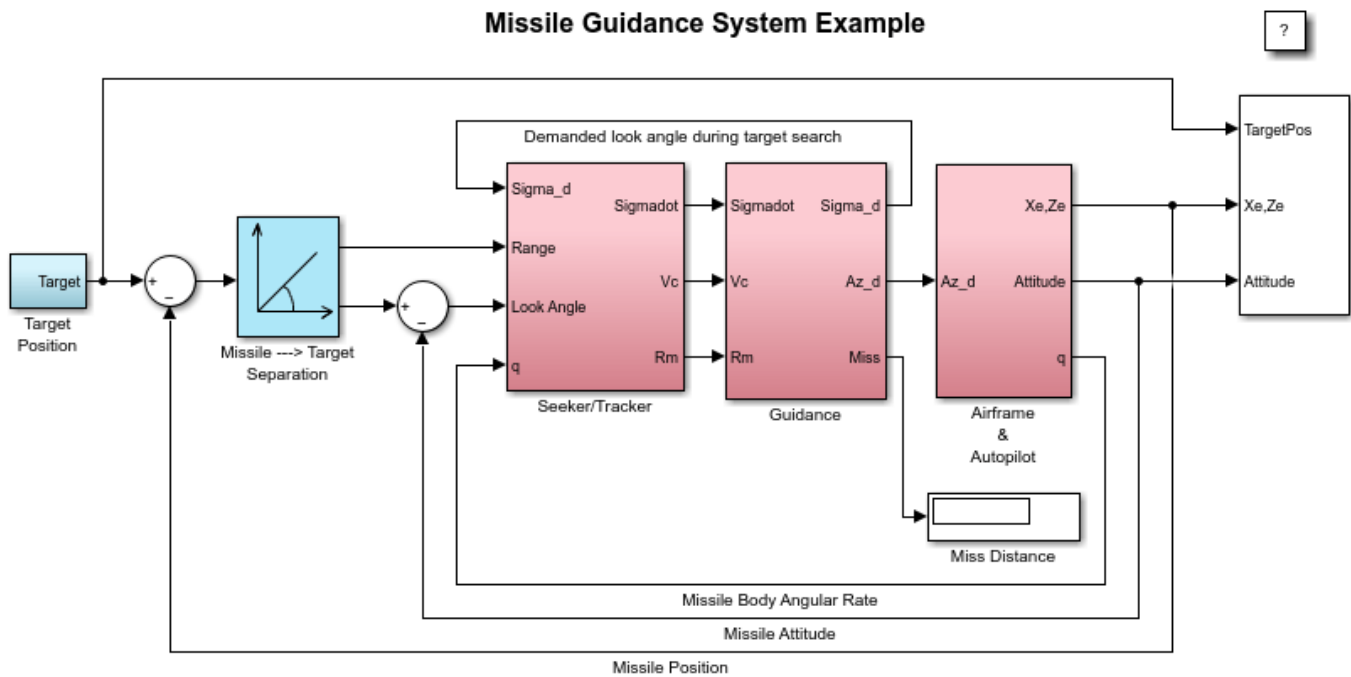

Autopilot designs are carried out on a number of linear airframe models derived at varying flight conditions across the expected flight envelope. To implement the autopilot in the non-linear model involves storing the autopilot gains in 2 dimensional lookup tables, and incorporating an anti-windup gain to prevent integrator windup when the fin demands exceed the maximum limits. Testing the autopilot in the nonlinear Simulink model is then the best way to show satisfactory performance in the presence of non-linearities such as actuator fin and rate limits, and with the gains now dynamically varying with changing flight condition.

**Figure:** Simulink implementation of gain scheduled autopilot

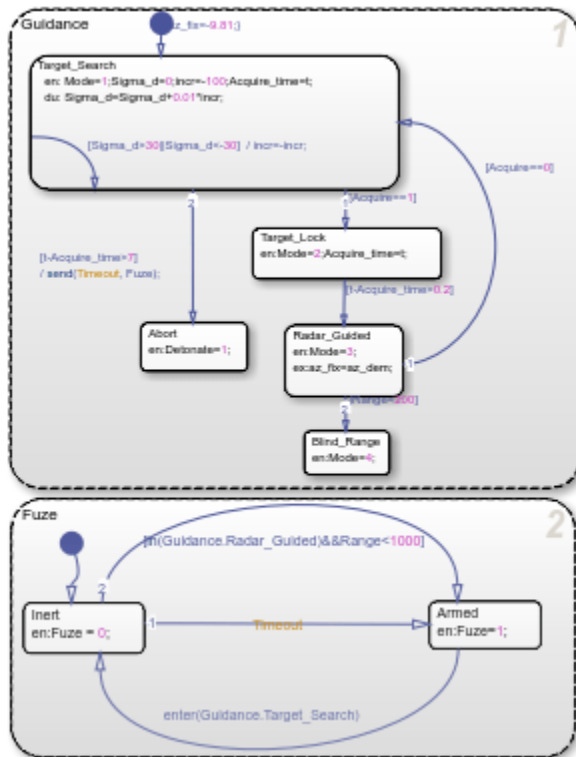

### Homing Guidance Loop

The complete Homing Guidance Loop consists of a Seeker/Tracker Subsystem which returns measurements of the relative motion between the missile and target, and the Guidance Subsystem which generates normal acceleration demands which are passed to the autopilot. The autopilot is now part of an inner loop within the overall homing guidance system. Reference [4] provides information on the differing forms of guidance that are currently in use, and provides background information on the analysis techniques that are used to quantify guidance loop performance.

### Guidance Subsystem

The function of the Guidance subsystem is to not only generate demands during closed loop tracking, but also perform an initial search to locate the target position. A Stateflow® model is used to control the transfer between these differing modes of operation. Switching between modes is triggered by events generated either in Simulink, or internal to the Stateflow model. Controlling the way the Simulink model then behaves is achieved by changing the value of the variable **Mode** that is passed out to Simulink. This variable is used to switch between the differing control demands that can be generated. During target search the Stateflow model controls the tracker directly by sending demands to the seeker gimbals (**Sigma**). Target acquisition is flagged by the tracker once the target lies within the beamwidth of the seeker (**Acquire**), and after a short delay closed loop guidance starts. Stateflow is an ideal tool for rapidly defining all the operational modes, whether they are for normal operation, or unusual situations. For example, the actions to be taken should there be loss of lock on the target, or should a target not be acquired during target search are catered for in this Stateflow diagram.

### Proportional Navigation Guidance

Once the seeker has acquired the target a Proportional Navigation Guidance (PNG) law is used to guide the missile until impact. This form of guidance law has been used in guided missiles since the 1950s, and can be applied to radar, infrared or television guided missiles. The navigation law requires measurements of the closing velocity between the missile and target, which for a radar guided missile could be obtained using a Doppler tracking device, and an estimate for the rate of change of the inertial sightline angle.

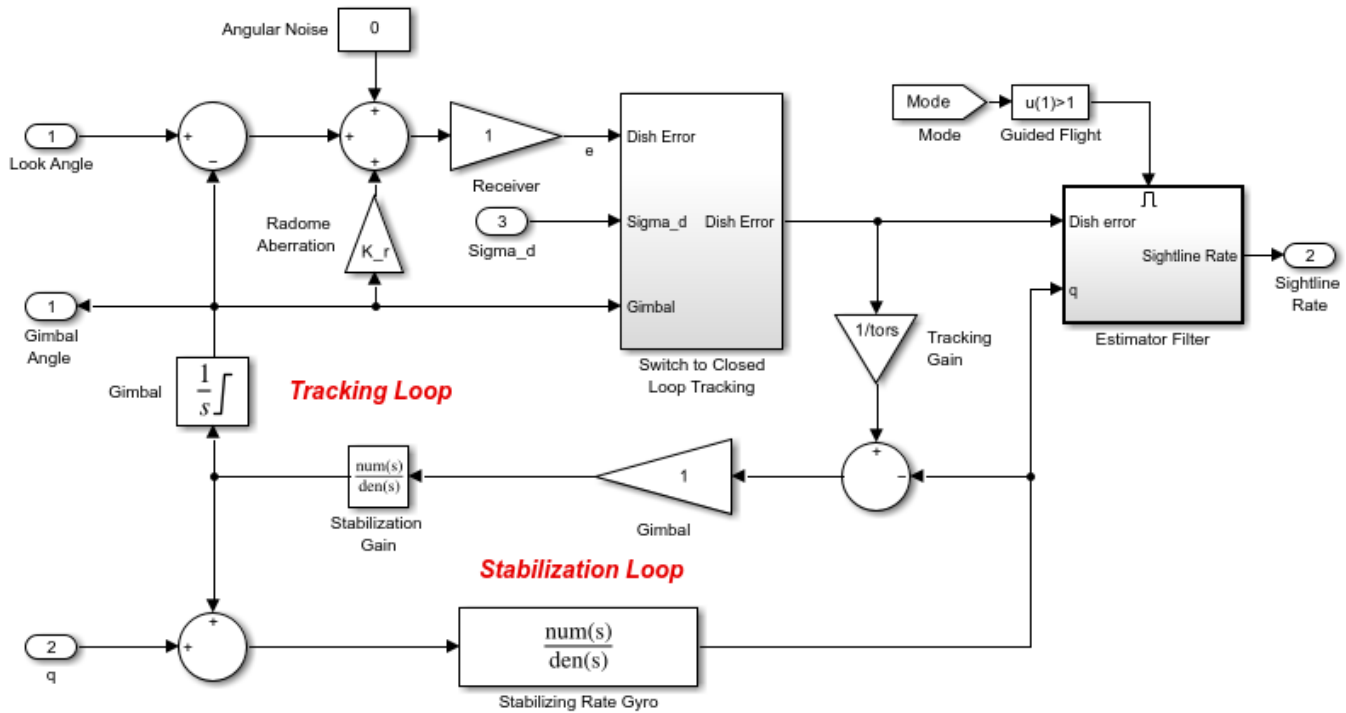

**Figure:** Proportional Navigation Guidance Law

### Seeker/Tracker Subsystem

The aim of the Seeker/Tracker Subsystem is both to drive the seeker gimbals to keep the seeker dish aligned with the target, and to provide the guidance law with an estimate of the sightline rate. The tracker loop time constant **tors** is set to 0.05 seconds, and is chosen as a compromise between maximizing speed of response, and keeping the noise transmission to within acceptable levels. The stabilization loop aims to compensate for body rotation rates, and the gain **Ks**, which is the loop cross-over frequency, is set as high as possible subject to the limitations of the bandwidth of the stabilizing rate gyro. The sightline rate estimate is a filtered value of the sum of the rate of change of the dish angle measured by the stabilizing rate gyro, and an estimated value for the rate of change of the angular tracking error (**e**) measured by the receiver. In this example the bandwidth of the estimator filter is set to half that of the bandwidth of the autopilot.

### Radome Aberration

For radar guided missiles a parasitic feedback effect that is commonly modelled is that of radome aberration. It occurs because the shape of the protective covering over the seeker distorts the returning signal, and then gives a false reading of the look angle to the target. Generally the amount of distortion is a nonlinear function of the current gimbal angle, but a commonly used approximation is to assume a linear relationship between the gimbal angle and the magnitude of the distortion. In the above system, the radome aberration is accounted for in the gain block labeled "Radome Aberration". Other parasitic effects, such as sensitivity in the rate gyros to normal acceleration, are also often modelled to test the robustness of the target tracker and estimator filters.

**Figure:** Radome aberration geometry

### Running the Guidance Simulation

Now to show the performance of the overall system. In this case the target is defined to be traveling at a constant speed of 328m/s, on a reciprocal course to the initial missile heading, and 500m above the initial missile position. From the simulation results it can be determined that acquisition occurred 0.69 seconds into the engagement, with closed loop guidance starting after 0.89 seconds. Impact with the target occurred at 3.46 seconds, and the range to go at the point of closest approach was calculated to be 0.265m.

The `aero_guid_plot.m` script creates a performance analysis

## Airframe Trim and Linearize

This example shows how to trim and linearize an airframe using Simulink® Control Design™.

Designing an autopilot using classical design techniques requires linear models of the airframe pitch dynamics for a number of trimmed flight conditions. MATLAB® can determine the trim conditions and derive linear state-space models directly from the nonlinear Simulink® and Aerospace Blockset™ model. This saves time and helps to validate the model. The functions provided by Simulink Control Design allow you to visualize the behavior of the airframe in terms of open-loop frequency (or time) responses.

### Initialize Guidance Model

The first problem is to find the elevator deflection, and the resulting trimmed body rate ( $q$ ), which will generate a given incidence value when the missile is traveling at a set speed. Once the trim condition is found, a linear model can be derived for the dynamics of the perturbations in the states around the trim condition.

```
open_system('aero_guidance_airframe');
```

### Define State Values

```

h_ini = 10000/m2ft; % Trim Height [m]
M_ini = 3; % Trim Mach Number
alpha_ini = -10*d2r; % Trim Incidence [rad]
theta_ini = 0*d2r; % Trim Flightpath Angle [rad]
v_ini = M_ini*(340+(295-340)*h_ini/11000); % Total Velocity [m/s]

q_ini = 0; % Initial pitch Body Rate [rad/sec]

```

### Set Operating Point and State Specifications

The first state specifications are Position states, the second state specification is Theta. Both are known, but not at steady state. The third state specifications are body axis angular rates of which the variable  $w$  is at steady state.

```

opspec = operspec('aero_guidance_airframe');
opspec.States(1).Known = [1;1];
opspec.States(1).SteadyState = [0;0];
opspec.States(2).Known = 1;

```

```

opspec.States(2).SteadyState = 0;
opspec.States(3).Known = [1 1];
opspec.States(3).SteadyState = [0 1];

```

### Search for Operating Point, Set I/O, then Linearize

```

op = findop('aero_guidance_airframe',opspec);

io(1) = linio('aero_guidance_airframe/Fin Deflection',1,'input');
io(2) = linio('aero_guidance_airframe/Selector',1,'output');
io(3) = linio(sprintf(['aero_guidance_airframe/Aerodynamics &\n', ...
 'Equations of Motion']),3,'output');

sys = linearize('aero_guidance_airframe',op,io);

```

## Anti-Windup Control Using PID Controller Block

This example shows how to use anti-windup schemes to prevent integration wind-up in PID controllers when the actuators are saturated. The PID Controller block in Simulink® features two built-in anti-windup methods, back-calculation and clamping, as well as a tracking mode to handle more complex industrial scenarios. The PID Controller block supports several features that allow it to handle controller windup issues under commonly encountered industrial scenarios.

The plant to be controlled is a saturated first-order process with dead-time.

Copyright 2009-2022 The MathWorks, Inc.

The PID Controller block has been tuned with saturation ignored using the Simulink® Control Design™ PID tuner.

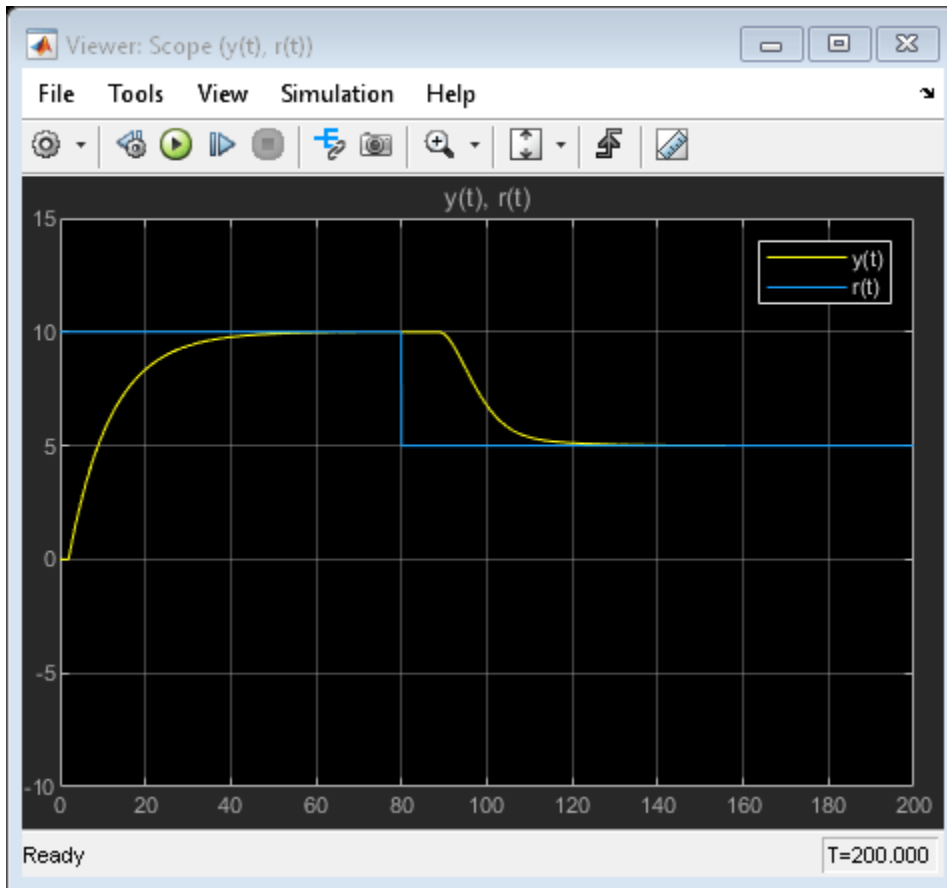

The controlled plant is a first-order process with dead-time described by

$$P(s) = \frac{1}{10s + 1} e^{-2s}$$

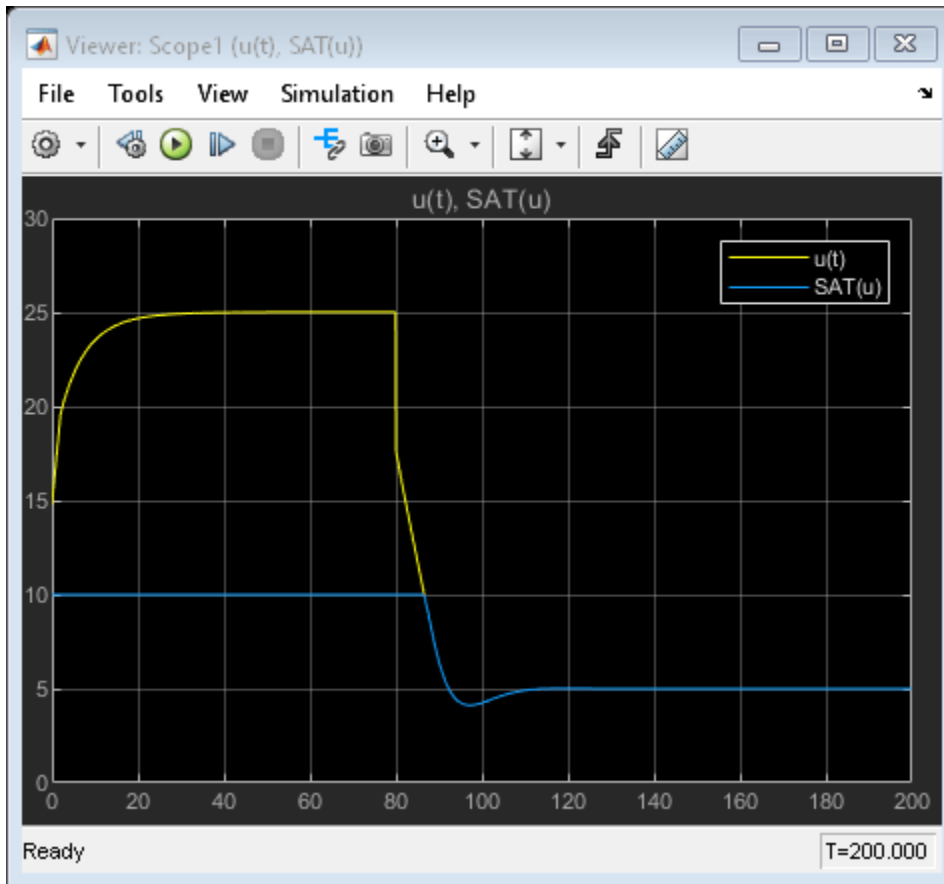

The plant has known input saturation limits of  $[-10, 10]$ , which are accounted for in the Saturation block labeled Plant Actuator. The PID Controller block in Simulink features two built-in anti-windup methods that allow it to account for the available information about the plant input saturation.

### Performance Without Using Anti-Windup

First, examine the effect of saturation on the closed-loop when the saturation model is not considered by the PID Controller block. Simulating the model generates these results. The figure shows the setpoint versus measured output with no anti-windup.

The figure shows the controller output and saturated input with no anti-windup.

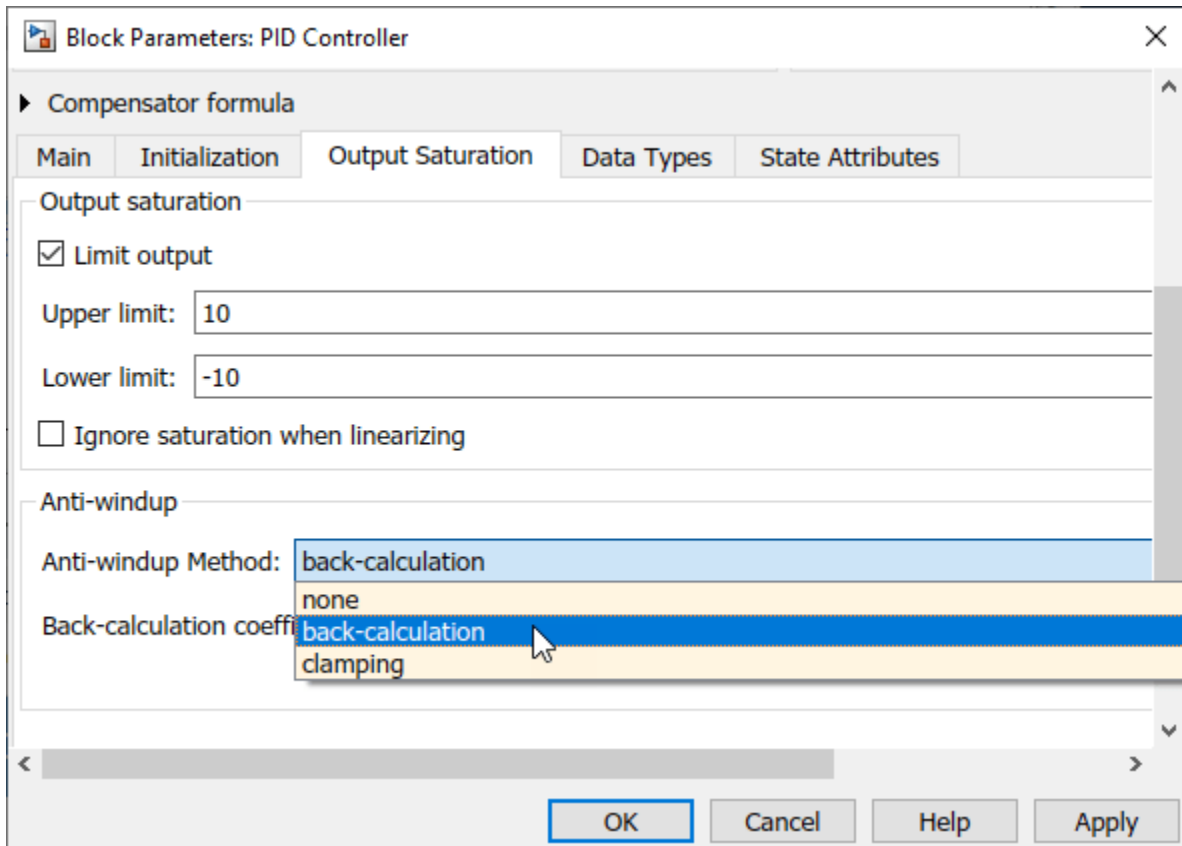

These figures highlight two problems with controlling a system with input saturation:

- 1 When the setpoint value is 10, the PID control signal reaches a steady-state at about 24, outside the range of the actuator. The controller is therefore operating in a nonlinear region where increasing the control signal has no effect on the system output, a condition known as *winding up*. Note that the DC-gain of the plant is unity. Therefore, the controller output does not need to have a steady-state value outside the range of the actuator.
- 2 When the setpoint value becomes 5, there is a considerable delay before the PID controller output returns to within the actuator range.

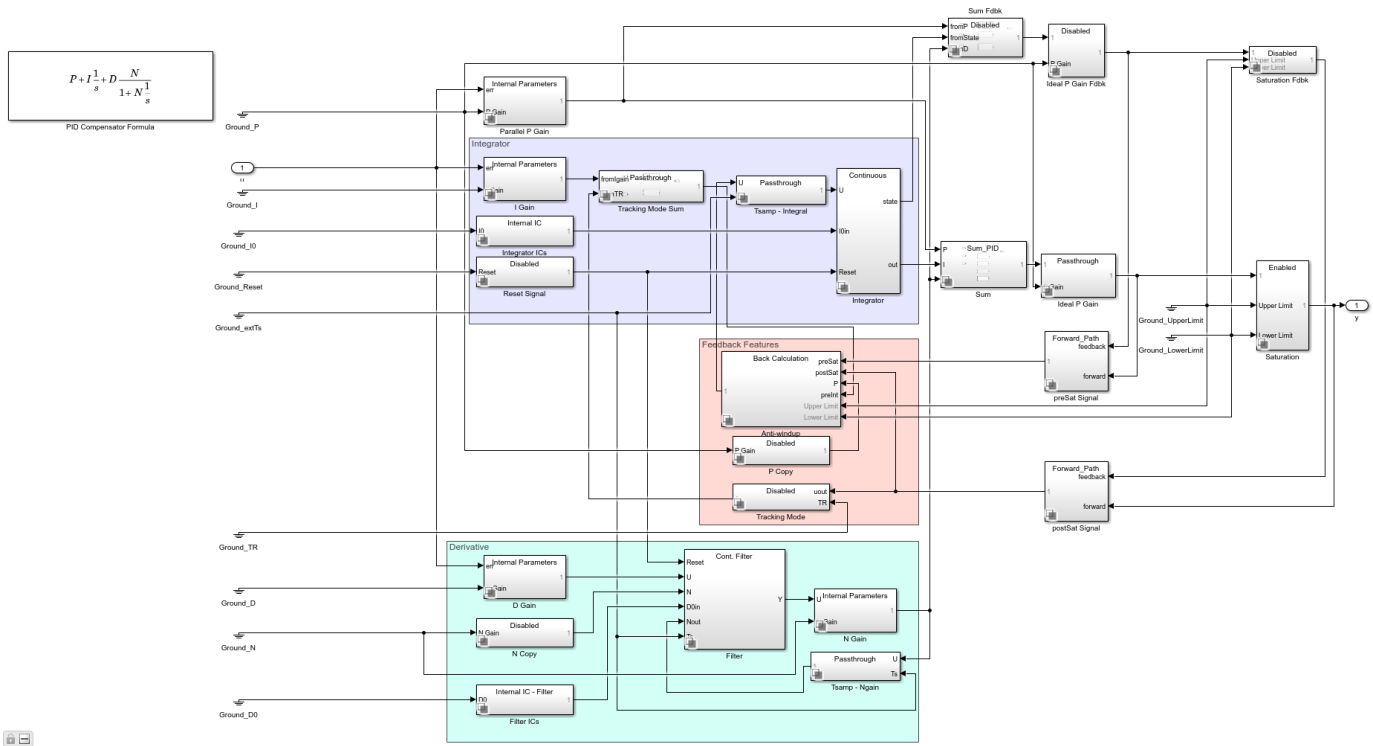

Designing the PID controller to account for the effect of saturation improves its performance by allowing it to operate in the linear region most of the time and recover quickly from nonlinearity. You can use anti-windup mechanism to achieve this.

### Configure Block for Anti-Windup Based on Back-Calculation

The back-calculation anti-windup method uses a feedback loop to unwind the PID Controller block internal integrator when the controller hits specified saturation limits and enters nonlinear operation. To enable anti-windup, go to the **Output Saturation** tab in the block dialog. Select **Limit output** and enter the saturation limits for the plant. Next, from the **Anti-windup method** list, select **back-calculation**. Then, specify the **Back-calculation coefficient (Kb)**. The inverse of this gain is the time constant of the anti-windup loop. In this example, the back-calculation gain is chosen to be 1. For more information on how to choose this value, see [1].

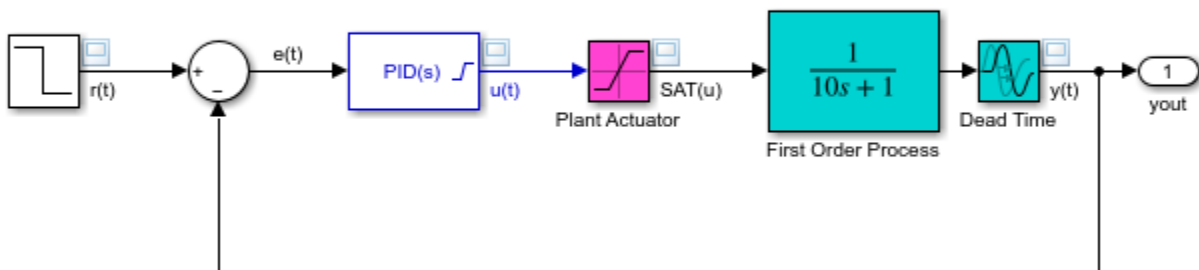

Once back-calculation is enabled, the block has an internal tracking loop that unwinds the Integrator output. This figure shows the under-mask view of the PID Controller block with back-calculation.

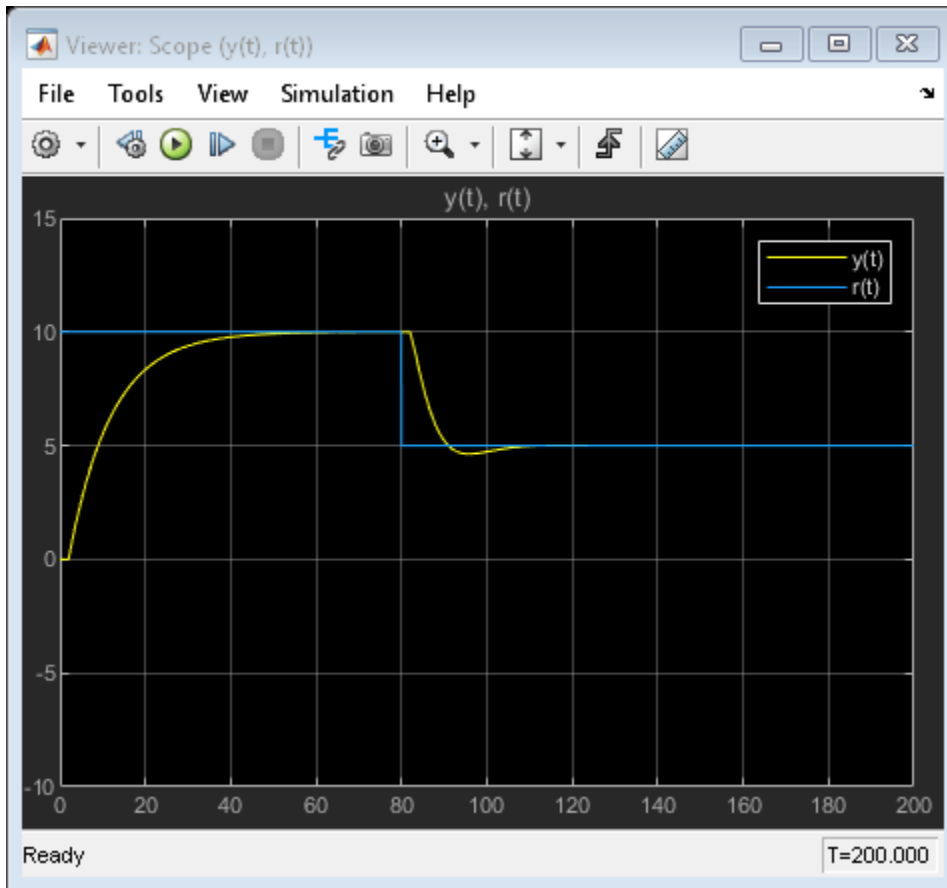

Note how quickly the PID control signal returns to the linear region and how fast the loop recovers from saturation.

### Anti-Windup PID Control Example

Copyright 2009-2022 The MathWorks, Inc.

The controller output  $u(t)$  and the saturated input  $SAT(u)$  coincide with each other because **Limit output** is enabled.

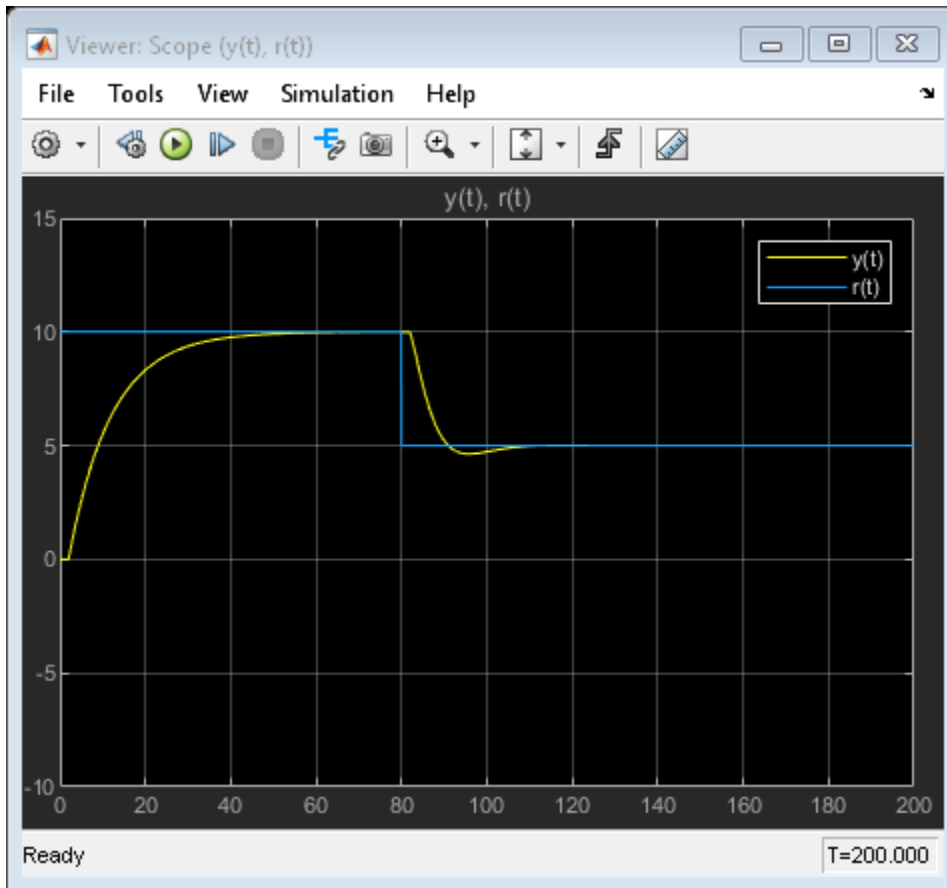

To better visualize the effect of anti-windup, this figure illustrates the plant measured output  $y(t)$  with and without anti-windup.

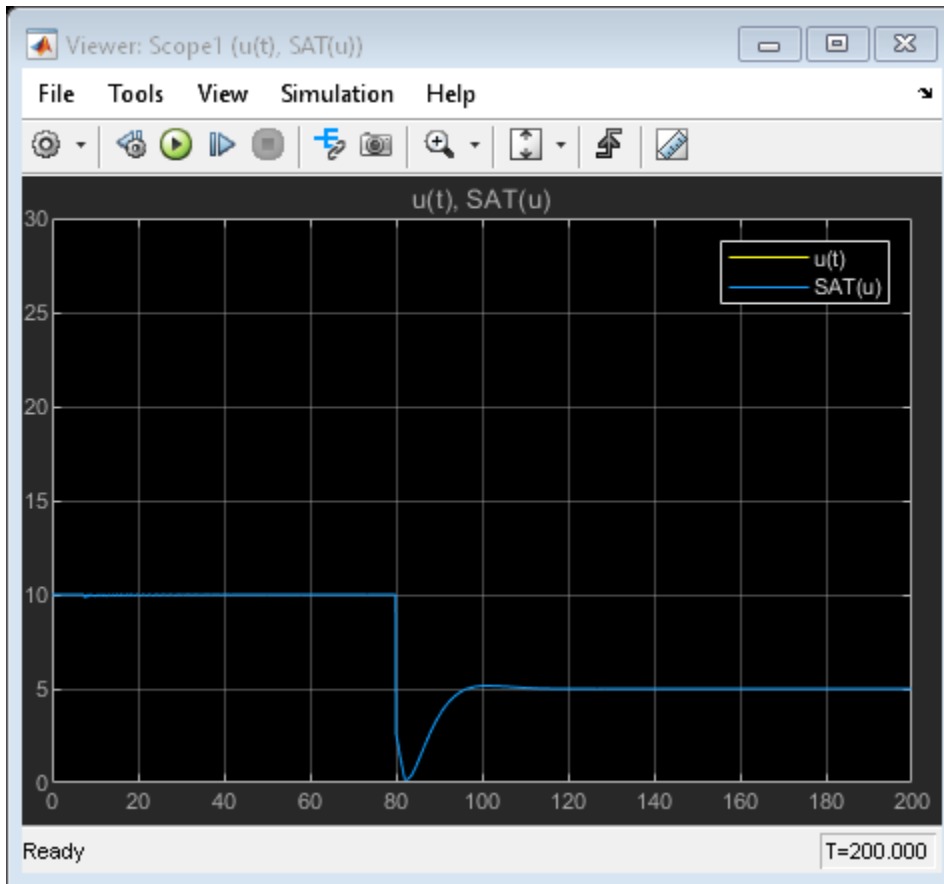

### Configure Block for Anti-Windup Based on Integrator Clamping

Another common anti-windup strategy is based on conditional integration. To enable anti-windup, in the Block Parameters dialog box, select the **PID Advanced** tab. Select **Limit output** and enter the saturation limits for the plant. Then, from the **Anti-windup method** list, select **clamping**.

This figure shows setpoint versus measured output with clamping.

This figure shows that the controller output  $u(t)$  and the saturated input  $SAT(u)$  coincide with each other because **Limit output** is enabled.

For more information on when to use clamping, see [1].

### Use Tracking Mode to Handle Complex Anti-Windup Scenarios

The anti-windup strategies discussed so far rely on built-in methods to process the saturation information provided to the block via its dialog. For those built-in techniques to work as intended, two conditions must be met:

- 1 The saturation limits of the plant are known and can be entered into the dialog of the block.
- 2 The PID Controller block output signal is the only signal feeding the actuator.

These conditions may be restrictive when handling general anti-windup scenarios. The PID Controller block features a tracking mode that allows you to set up a back-calculation anti-windup loop externally. The next two examples show the use of tracking mode for anti-windup purposes:

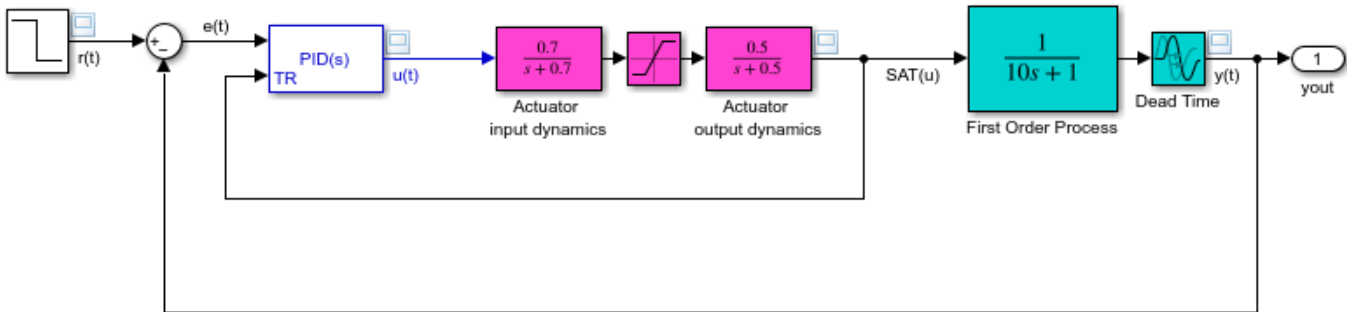

- 1 Anti-windup for saturated actuators with cascaded dynamics
- 2 Anti-windup for PID control with feedforward

### Construct Anti-Windup Scheme for Saturated Actuators with Cascaded Dynamics

The actuator in `sldemo_antiwindupactuator` has complex dynamics. Complex dynamics are common when an actuator has its own closed-loop dynamics. The PID controller is in an outer loop and sees the actuator dynamics as an inner loop, which is also called cascaded saturated dynamics.

### Anti-Windup PID Control Example with Actuator Dynamics

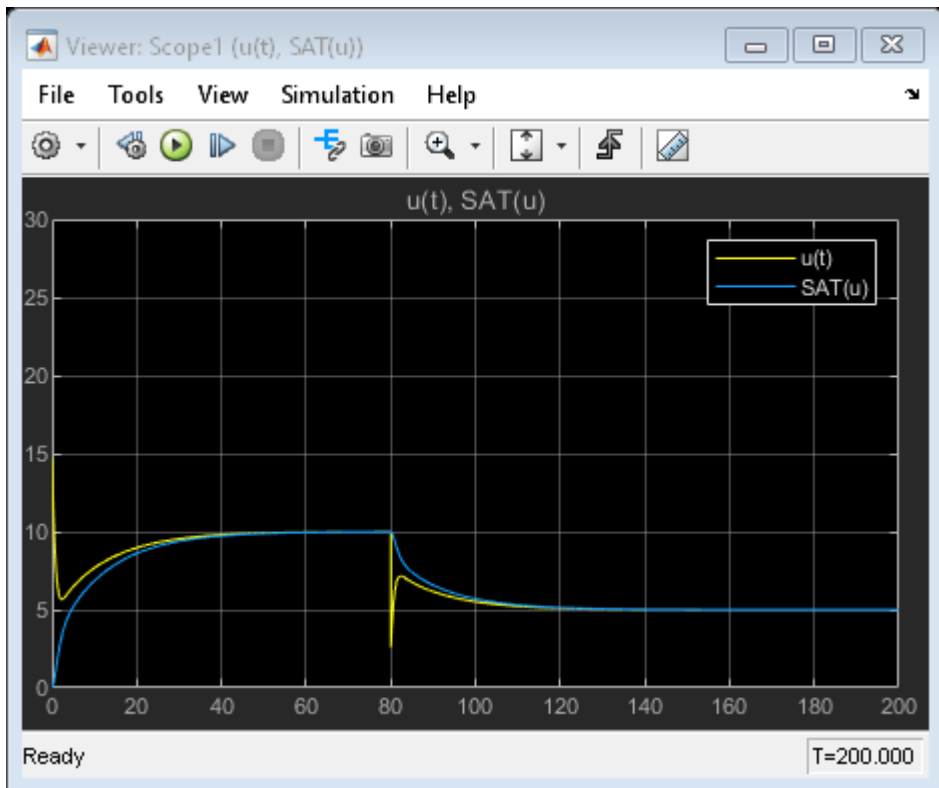

?

Copyright 2009-2022 The MathWorks, Inc.

A successful anti-windup strategy requires feeding back the actuator output to the tracking port of the PID Controller block. To configure the **tracking mode** of the PID Controller block, in the block Parameters dialog box, click the **PID Advanced** tab. Select **Enable tracking mode** and specify the gain  $Kt$ . The inverse of this gain is the time constant of the tracking loop. For more information on how to choose this gain, see [1].

The measured output of the plant  $y(t)$  and the controller output  $u(t)$  respond almost immediately to changes in the setpoint. Without the anti-windup mechanism, these responses have long delays.

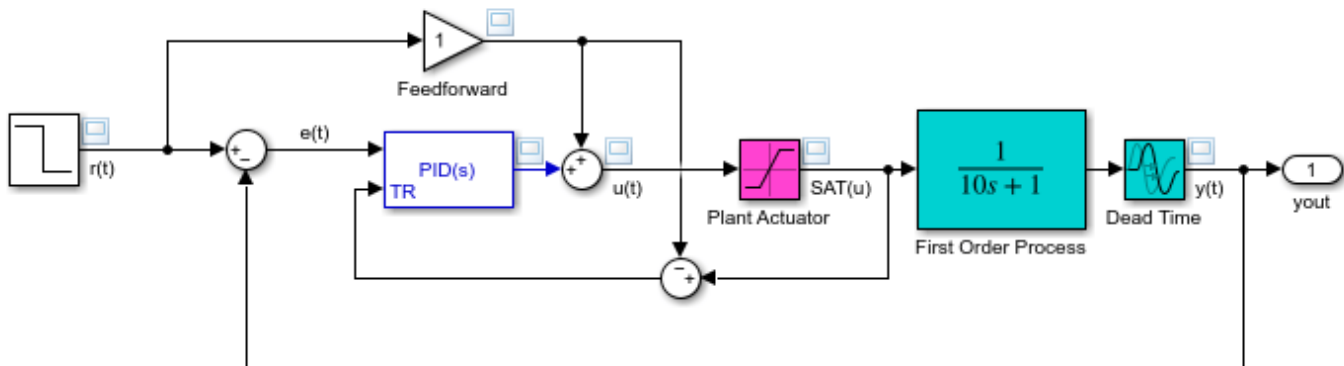

### Anti-Windup Scheme for PID Control with Feedforward

In another common control configuration, the actuator receives a control signal that is a combination of a PID control signal and a feedforward control signal. Open the model `sldemo_antiwindupfeedforward`.

To accurately build a back-calculation anti-windup loop, the tracking signal should subtract the contribution of the feedforward signal. This action allows the PID Controller block to know its share of the effective control signal applied to the actuator.

#### Anti-Windup PID Control Example with Feedforward Control

Copyright 2009-2022 The MathWorks, Inc.

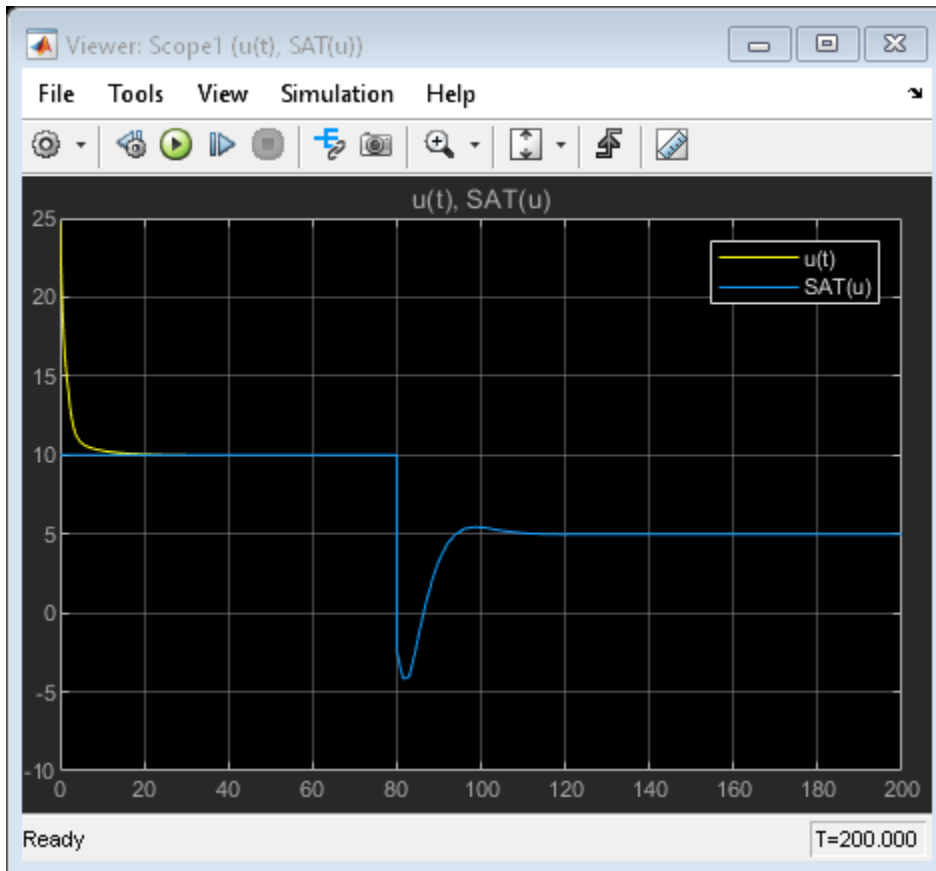

The feedforward gain is unity here because the plant has a DC-gain of 1.

The measured output of the plant  $y(t)$  and the controller output  $u(t)$  respond almost immediately to changes in the setpoint. When the setpoint value is 10, note how the controller output  $u(t)$  reduces to be within the range of the actuator.

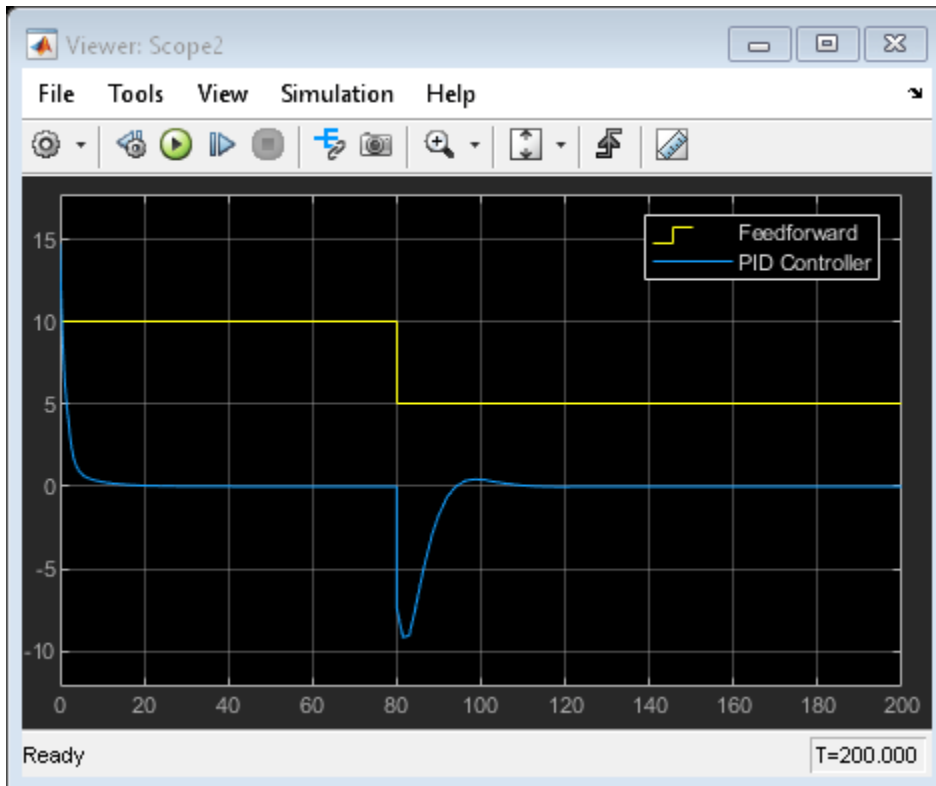

When the setpoint value is 10 , note how the controller output  $u(t)$  reduces to be within the range of the actuator.

This figure shows the PID Controller output and feed forward input with anti-windup.

## Bumpless Control Transfer Between Manual and PID Control

### Model Description

This example shows how to achieve bumpless control transfer when switching from manual control to PID control. We use the PID Controller block in Simulink® to control a first-order process with dead-time.

We start by opening the model.

Copyright 2009-2018 The MathWorks, Inc.

**Figure 1:** Simulink model of PID control with bumpless transfer.

To open this model, type `sldemo_bumpless` in a MATLAB® terminal.

The PID Controller has been tuned with saturation ignored using the PID tuner of Simulink® Control Design™.

The controlled plant is a first-order process with dead-time described by

$$P(s) = \frac{4}{2.5s + 1} e^{-s}$$

For several operational reasons, the engineers decided to start the control process in an open-loop manner by feeding the plant input with a saturating ramp signal to drive the output of the plant slowly to a desired steady-state value of 40. A control transfer is scheduled to happen at  $t = 150$ . This transition between open-loop control and closed-loop control therefore involves two control phases of operation:

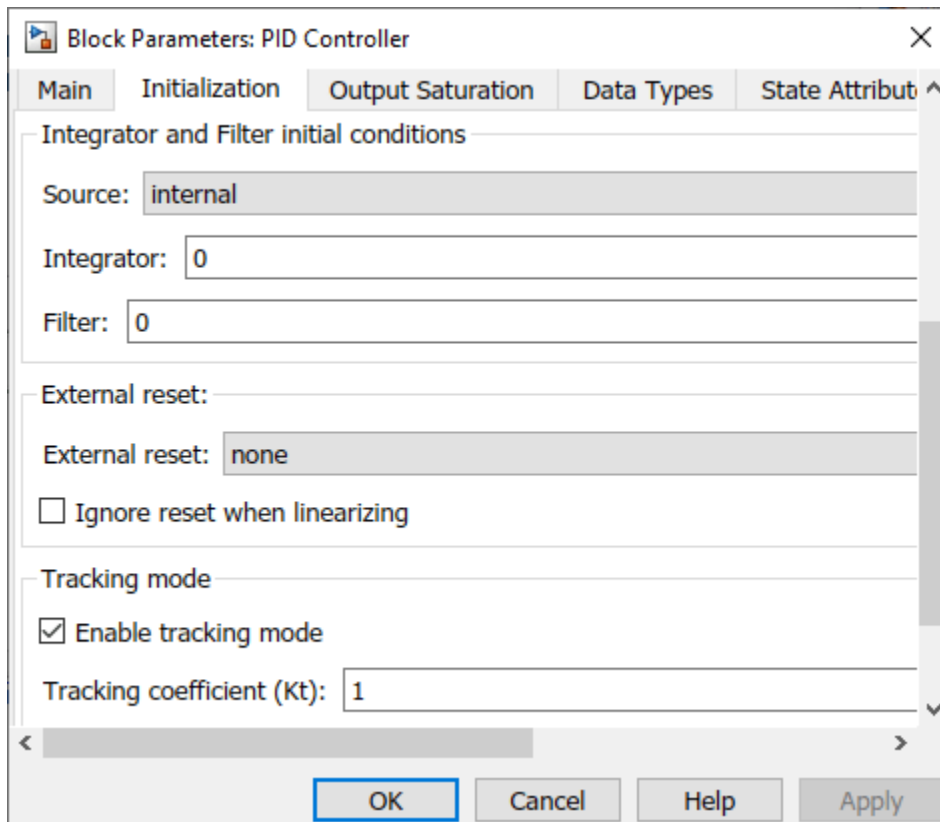

- 1 Manual: A saturated ramp signal feeds the plant input during start-up until  $t = 150$ .
- 2 Automatic: A PID controller will engage the plant at  $t = 150$ , and must take over the process without introducing bumps at the plant input.

To support smooth control transition, the PID Controller block supports two modes of operation: a **tracking mode** and a **control mode**. In control mode, the PID Controller block operates as an ordinary PID controller. In tracking mode, however, the block has an extra input that allows the PID block to adjust its internal state by changing its integrator output so that the block output tracks a prescribed signal feeding this extra input port.

To achieve bumpless control transfer, the PID Controller block must be in tracking mode when the plant is in the manual control phase (open-loop control), and in control mode when the plant is in the automatic control phase (closed-loop control).

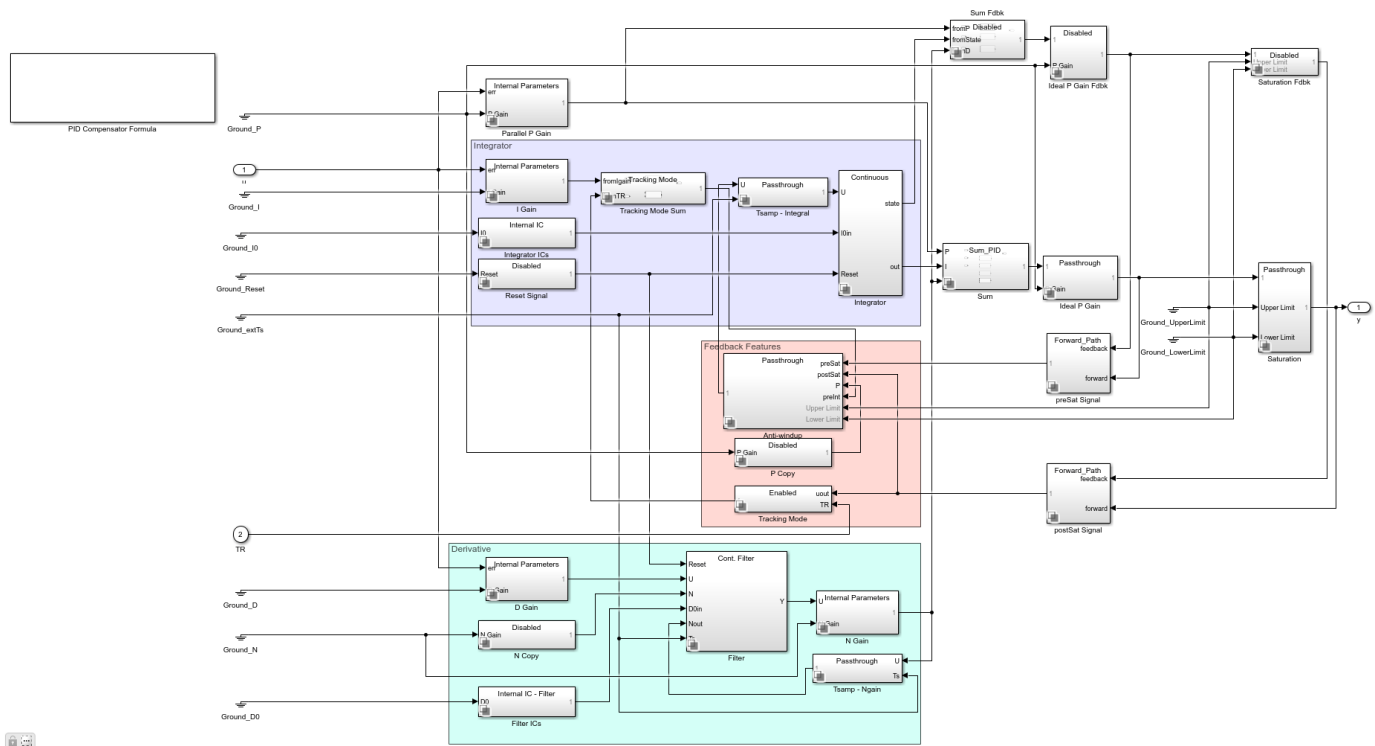

### Configuring the Block for Tracking Mode

To activate signal tracking, go to the **Initialization** tab in the block dialog; select **Enable tracking mode**, and specify the gain  $K_t$ . The inverse of this gain is the time constant of the tracking loop. For more information on how to choose this gain, see Reference [1].

**Figure 2:** Enabling the tracking mode of the PID Controller block.

As shown in Figure 1, once tracking mode is enabled, the block has a second input port denoted by TR. Internally this new port is wired as shown under mask:

**Figure 3:** Under-mask view of the PID Controller block with tracking mode.

### Setting Up the Switching Mechanism

In addition to enabling tracking mode for the PID Controller block, a switching mechanism is needed to achieve the control transfer. Switch 1 determines which signal feeds the plant input and feeds the tracking port of the PID Controller block.

At time  $t = 0$ , Switch 1 directs the manual control signal to the plant input and the tracking port of the PID Controller block. This allows the output of the PID Controller block to track the manual control signal during the manual phase by adjusting the PID Controller's internal integrator. When control transfer occurs, therefore, the PID Controller output will be approximately the same as the manual control signal.

At time  $t = 150$ , Switch 1 switches, directing the output of the PID Controller block to the plant input and the PID Controller block's tracking input. The PID Controller block now tracks its own output, which is equivalent to control mode.

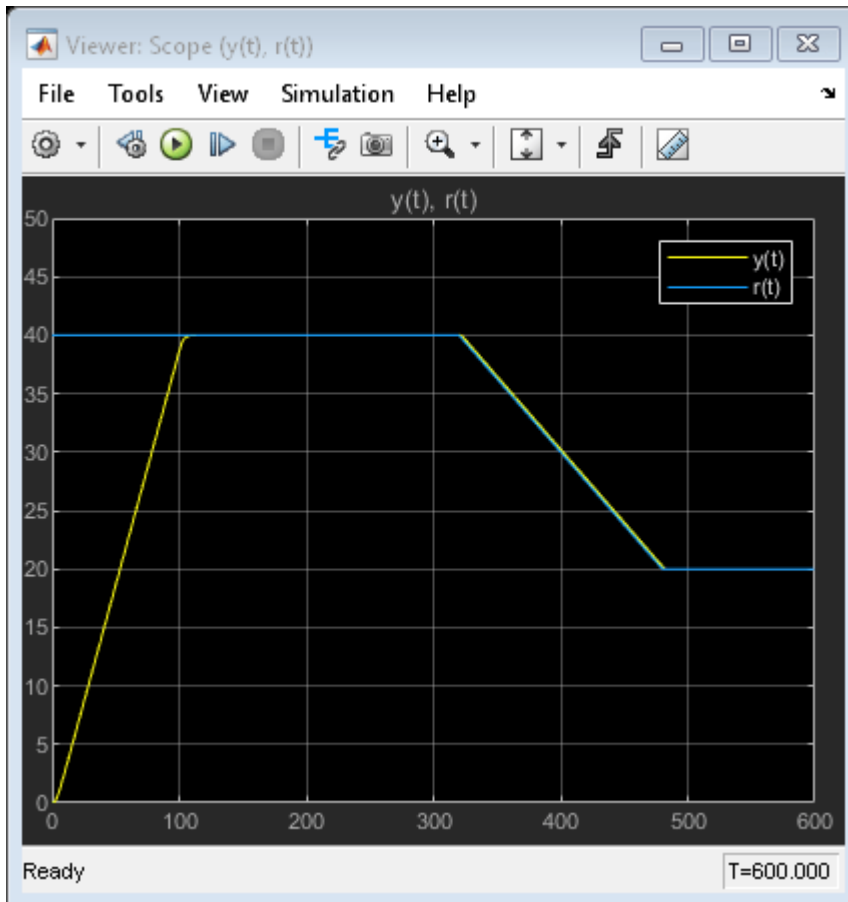

### Simulating the Bumpless Control Transfer

The setpoint signal and the closed-loop response of the model are shown in Figure 4.

### Bumpless Control Transfer Demonstration

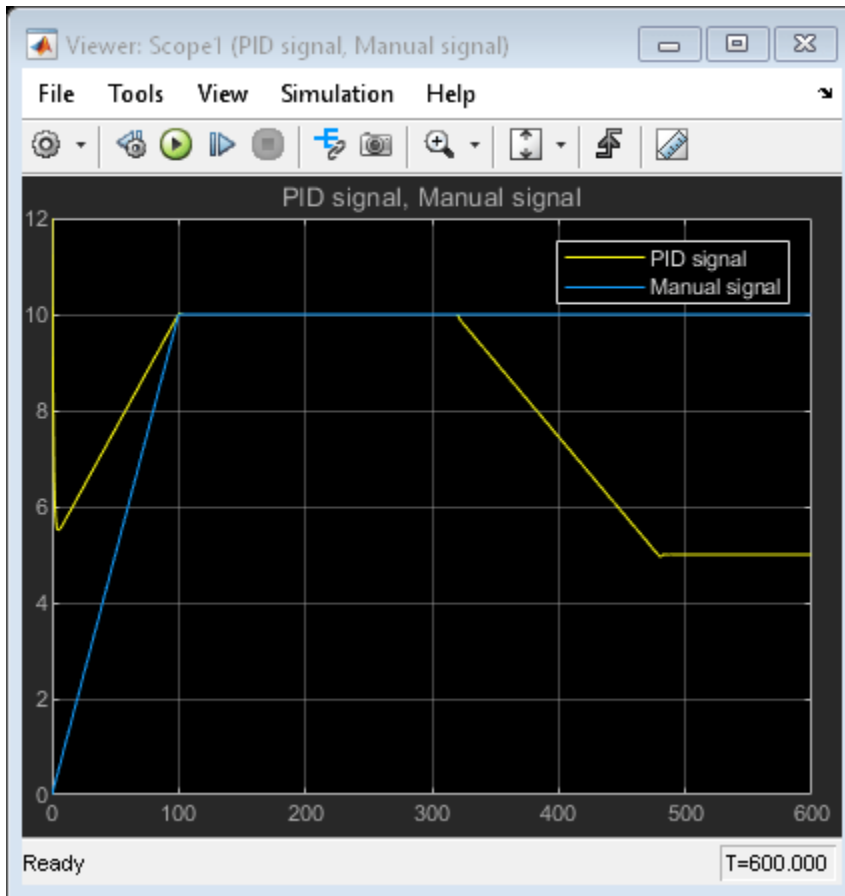

Copyright 2009-2018 The MathWorks, Inc.

**Figure 4:** Setpoint vs. measured output.

Figure 4 clearly shows that the measured output tracks the Setpoint profile without any output bumps at the time of switching ( $t = 150$ ). To investigate this further, the plant input, control signals are shown in Figure 5.

**Figure 5:** Control signal switching.

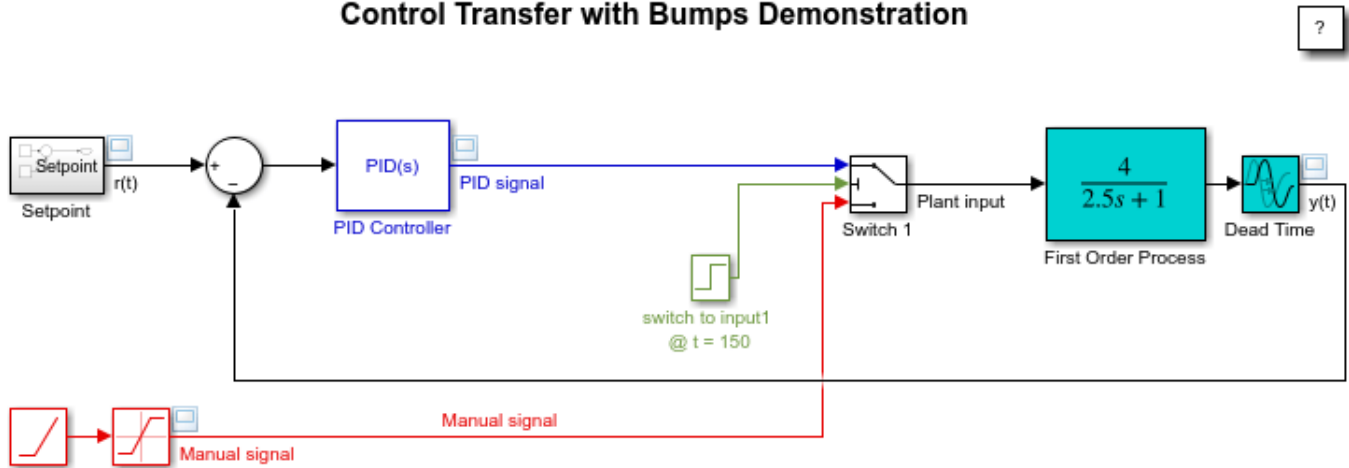

**Figure 6:** Plant input.

Figures 5 and 6 show that at the switching instance, the plant input has experienced no step changes (bumps), and therefore the control transfer happens in smooth bumpless fashion as intended.

To see the significance of the bumpless transfer setup, consider the case where tracking mode is not used. In this case, the following setup is obtained:

## Control Transfer with Bumps Demonstration

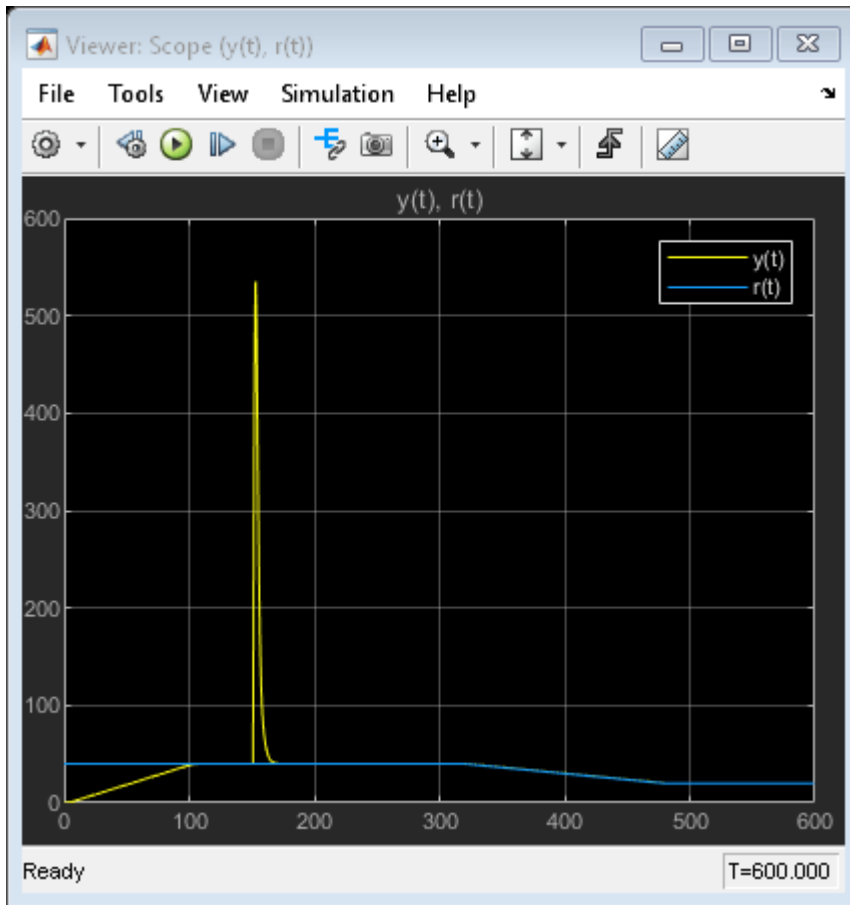

Copyright 2009-2018 The MathWorks, Inc.

**Figure 7:** Simulink model of PID control with no bumpless transfer.

To open this model, type `sldemo_bumplessno` in a MATLAB terminal.

Figures 8 and 9 show the performance in the absence of an appropriate bumpless control transfer strategy.

**Figure 8:** Setpoint vs. measured output.

**Figure 9:** Control signal switching.

It is evident from Figures 8 and 9 that allowing the PID controller to float while the plant is under manual control can result in undesirable large transients upon switching.

### Summary

As this example shows, the PID Controller block supports bumpless control transfer through the use of tracking mode.

## Two Degree-of-Freedom PID Control for Setpoint Tracking

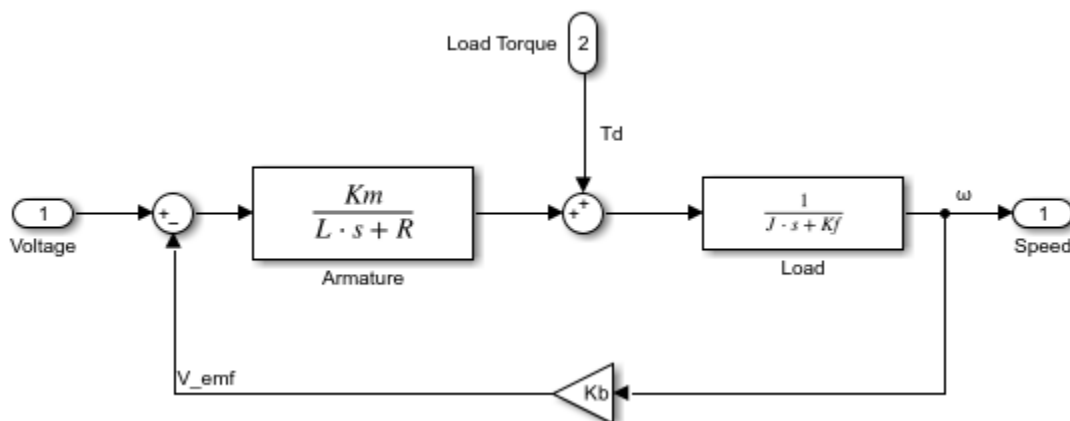

### Model Description

This example shows how to regulate the speed of an electric motor using two degrees-of-freedom PID control with set-point weighting. The model uses the PID Controller (2DOF) block. The model changes the setpoint values between 550 and 250 rpm. To convert the units to rad/s for use in the PID controller, the model uses a Signal Conversion block.

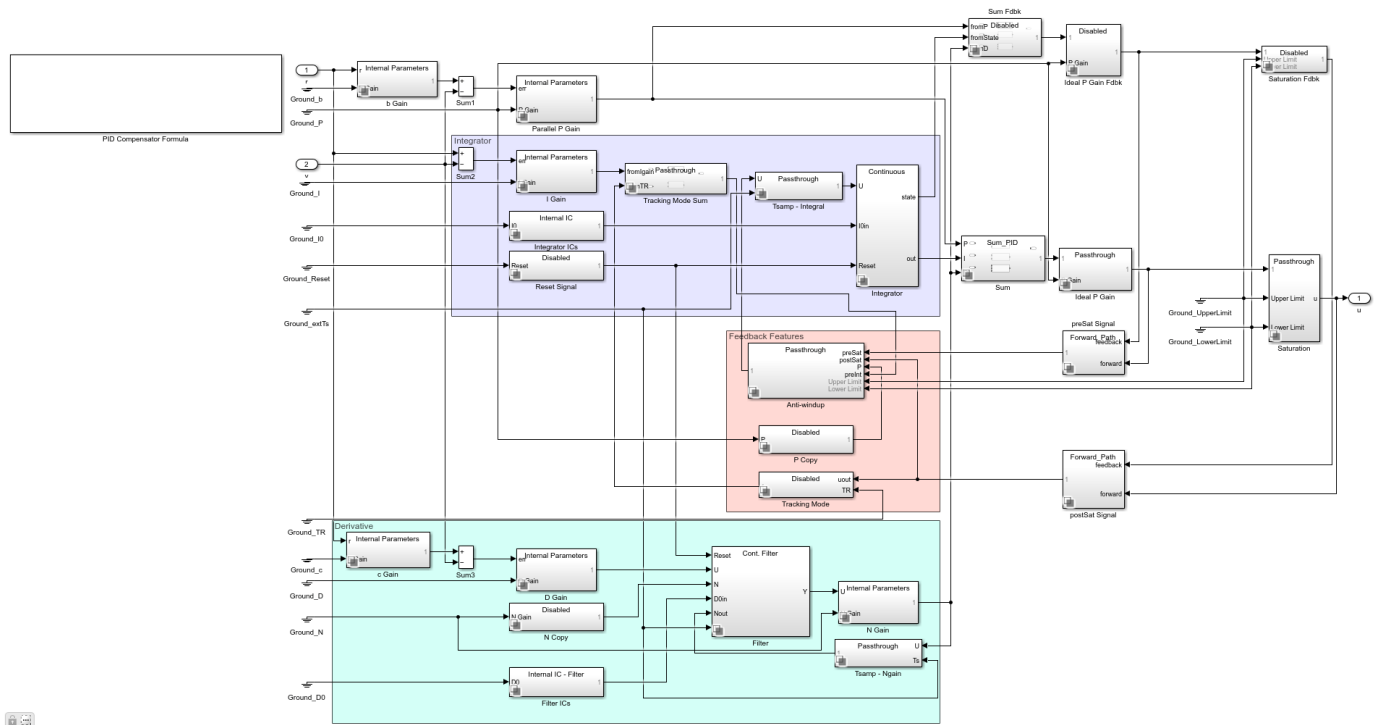

**Figure 1:** Simulink model with two degree-of-freedom PID control of a DC motor.

The electric motor is an armature-controlled DC motor. Voltage input controls the shaft speed of the motor. Figure 2 shows the block diagram of the motor. The motor experiences a load torque  $T_d$  (0-5 Nm).

**Figure 2:** Block diagram of the motor.**Two Degree-of-Freedom PID Control**

In contrast to the PID Controller block, the PID Controller (2DOF) block provides an extra degree of freedom, allowing you to weight the setpoint as it passes through the proportional action channel and the derivative action channel. Figure 3 shows the PID Controller (2DOF) block diagram.

**Figure 3:** Under-mask view of the PID Controller (2DOF).

As shown in Figure 3, the proportional action error signal is given by

$$b * r - y$$

The signal seen by the derivative action signal is given by

$$c * r - y$$

and the integral action signal is given by

$$r - y$$

In general, the setpoint weight  $c$  is set to 0. This prevents undesirable transients if the setpoint changes, an effect known as *derivative kick*. The setpoint  $b$  affects the overshoot performance of the controller. Generally, a small  $b$  value reduces overshoot. However, smaller  $b$  values can also result in slower response to setpoint changes. For more details on picking the right setpoint values, see Reference [1].

When  $b = 1$  and  $c = 1$ , the behavior of the two degree-of-freedom PID controller is identical to a classical PID controller.

### Simulating with $b = 1$ and $c = 1$

When  $b = 1$  and  $c = 1$ , the behavior of the two degree-of-freedom PID controller is identical to a classical PID controller. The control signal, setpoint signal, and closed-loop response of the model are shown in Figure 4.

Copyright 2009-2021 The MathWorks, Inc.

**Figure 4:** Control signal, setpoint vs. measured output.

Figure 4 clearly shows the spikes in the control signal, caused by aggressive proportional and derivative response to the setpoint change. Modifying the  $b$  and  $c$  weights can make this response less aggressive, as shown next.

#### Simulating with the $b = 0$ and $c = 0$

In this case, the two degree-of-freedom PID controller is known as I-PD where only the I action acts on the classical error signal, and the PD action acts only on the measured output.

**Figure 5:** Control signal, setpoint vs. measured output.

The simulation results show the absence of large transients in the control signal due to the sudden changes in the setpoint.

See Reference [1] for more information on how to choose  $b$  and  $c$ .

### Summary

The PID Controller (2DOF) block supports two degree-of-freedom PID control. Use this block for tracking complex setpoint profiles and moderating the impact of sudden setpoint changes on control signal transients. You can use the PID tuner in Simulink® Control Design™ to automatically tune all the gains ( $P$ ,  $I$ ,  $D$ ,  $N$ ,  $b$ ,  $c$ ) of the PID Controller (2DOF) block.

## Data Typing in Simulink

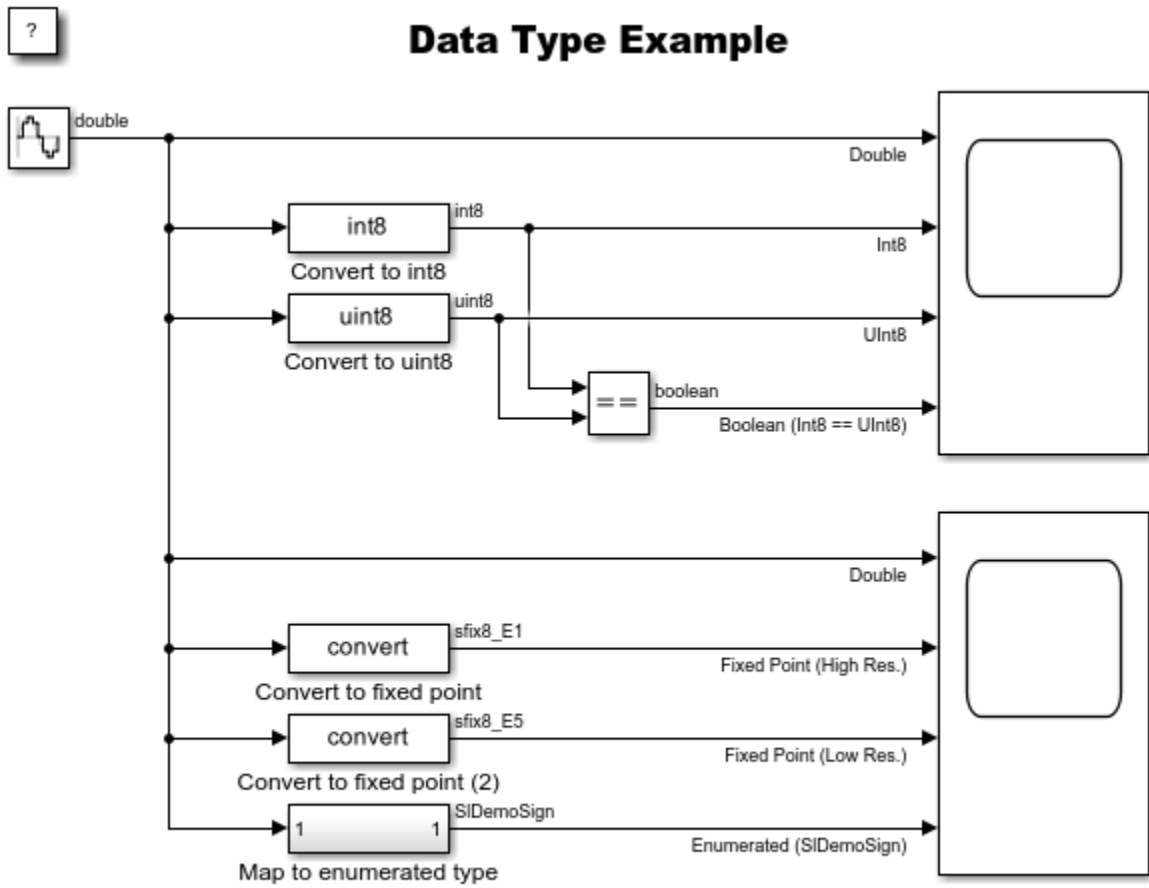

This example shows how to use data types in Simulink®. The model used in this example converts a double-precision sine wave having an amplitude of 150 to various data types and displays the converted signals on two scopes.

The first scope shows the original sine wave and the result of converting this signal to signed and unsigned 8-bit integer data types with saturation enabled. The bottom axes show the boolean results of comparing the signed and unsigned integer values.

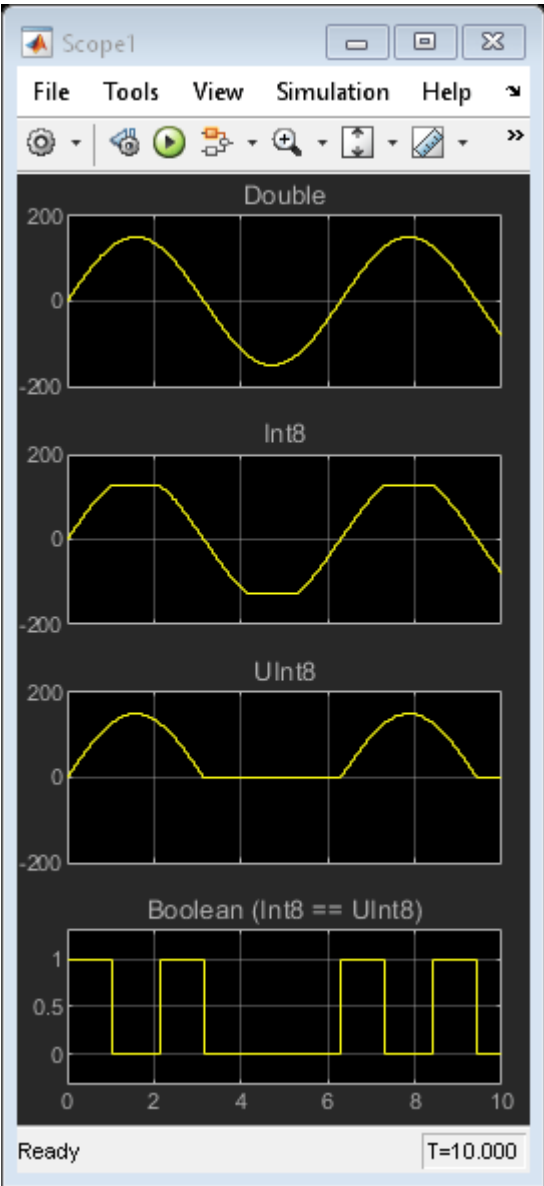

The second scope shows the original sine wave and the result of converting this signal to two fixed-point data types: one high-resolution, the other lower resolution. The bottom axes show the result of mapping the sine wave to an enumerated data type that indicates whether the signal is positive, negative, or zero.

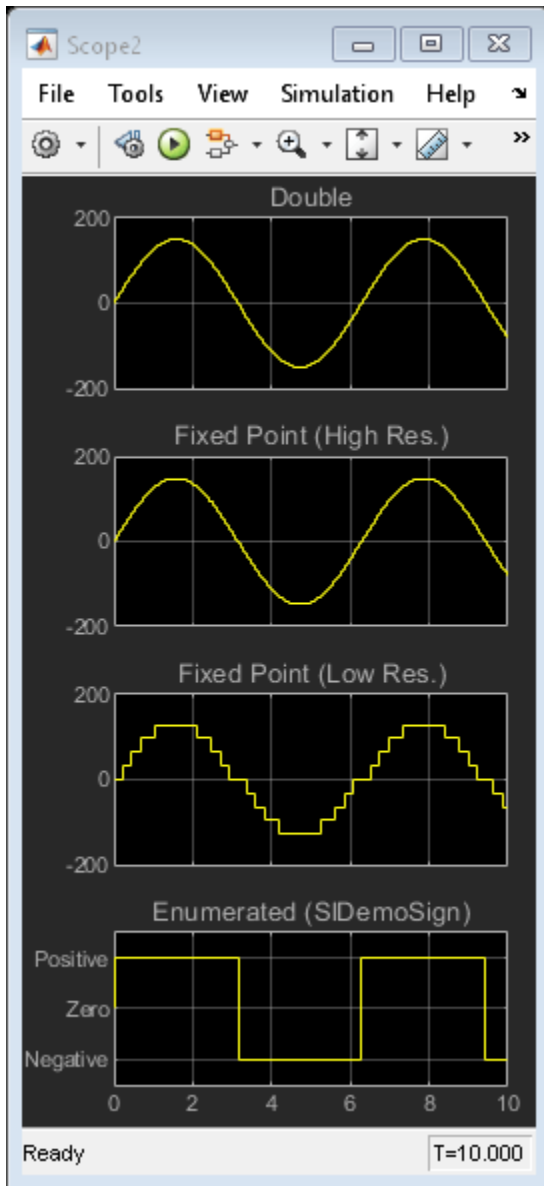

Similar data type support exists for parameters and states. Simulink also supports other integer and floating-point data types, such as, single, int16, and uint32, and fixed-point types with slope/bias and wordlengths from 1 to 128 bits. You can also define types for bus signals and aliases for existing types.

**NOTE:** If you do not have a license for Fixed-Point Designer™ then the fixed-point signals will be replaced by single-precision signals.

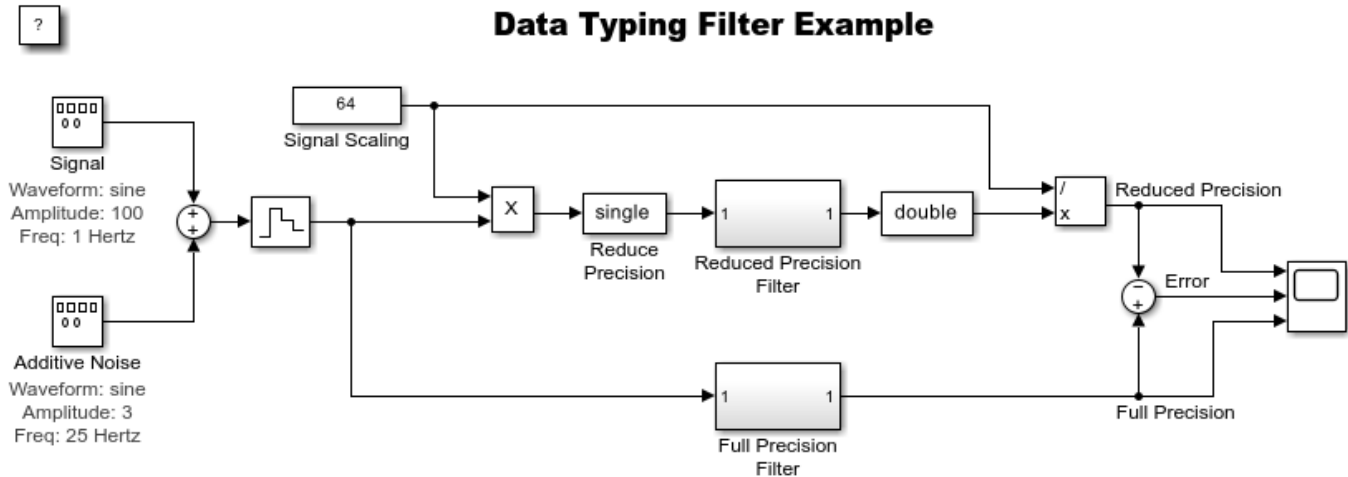

Copyright 2004-2015 The MathWorks, Inc.

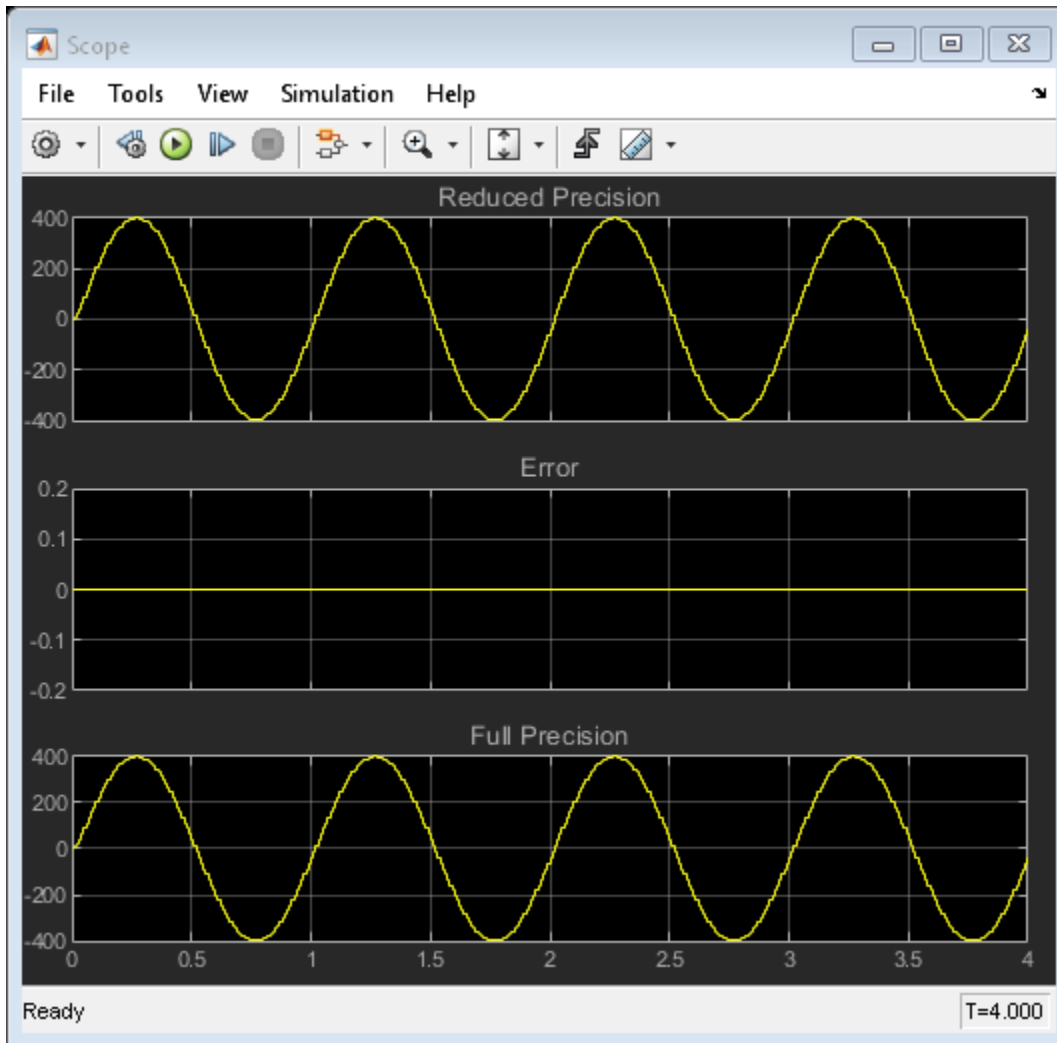

## Data Typing Filter

This example shows how to apply a filter to signals of different data types using standard Simulink® blocks. In this example, a signal with some noise is produced. This signal is then fed into a filter as a single precision data type and a standard double data type. The output from the filter for each signal is then compared and the error is displayed on the scope.

### Display Bus Line Styles

When you open a model that contains buses, the buses have the same line style as scalar signals. To update the line styles, on the **Modeling** tab, select **Update Model**.

After the model compiles, several lines appear with three lines. This line style indicates that the line represents a bus.

### Work with Buses in Components

The contents of the subsystem in the Working with Buses in Components area demonstrate how to:

- Create buses using Bus Creator blocks.
- Replace elements in a bus using a Bus Assignment block.
- Extract elements from a bus using a Bus Selector block.

Each Bus Creator block groups the elements connected to its input port into a bus. A bus represents a set of elements, analogous to a bundle of wires tied together. For example, the bus created by the Bus Creator block named Bus Creator 1 contains the signals `sine` and `chirp`, which are connected to its input ports.

To view the hierarchy of the bus, click the bus and, on the **Signal** tab, select **Signal Hierarchy**.

You can also create *nested* buses. For example, `sinusoidal` and `nonsinusoidal` are nested buses in the bus created by the Bus Creator block named Bus Creator 3.

A Bus Assignment block replaces one or more elements in the bus that connects to its **Bus** input port. For example, the Bus Assignment block replaces the signals `constant` and `nonsinusoidal` in the bus created by the Bus Creator block named Bus Creator 3 with new signals. You can use the Bus Assignment block to replace nested buses and nonbus elements.

A Bus Selector block extracts one or more elements from the bus connected to its input. For example, the Bus Selector block selects the `nonsinusoidal.pulse`, `sinusoidal.sine`, and `constant` signals. To display the values of `nonsinusoidal.pulse` and `sinusoidal.sine` in the Scope block and `constant` in the Display block, simulate the model.

### Use Bus Ports at Component Interfaces

The subsystems in the Using Bus Ports at Component Interfaces area demonstrate how to:

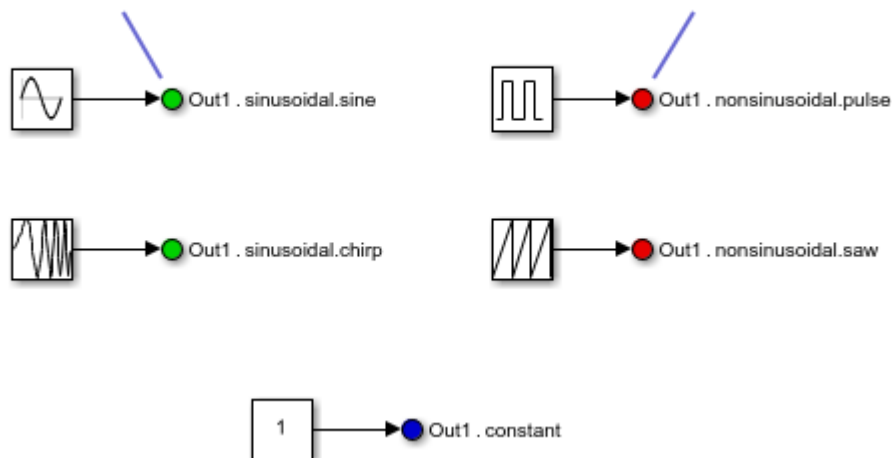

- Create buses at the output ports of components by using Out Bus Element blocks.
- Extract bus elements from the input ports of components by using In Bus Element blocks.

The first subsystem consists of five source blocks and five Out Bus Element blocks.

Click label text to edit name of output port and bus element.  
Double-click block to open dialog box for port.

Copy and paste block to create new element.

Right-click and drag, then select **Create New Port** to create new port.

Out Bus Element blocks are similar to a Bus Creator block connected to an Outport block. Each Out Bus Element block has a label that you can edit directly to change the names of the output port and bus elements.

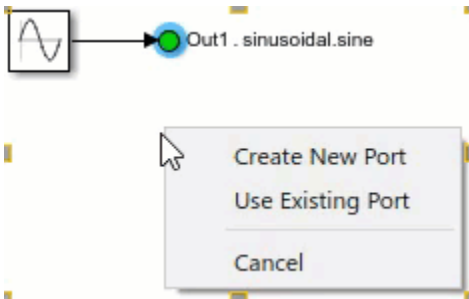

You can display the label in either expanded or compact notation.

- **Expanded Notation:** Label displays the corresponding port name and the element hierarchy. For example, the Out Bus Element block with the label `Out1.sinusoidal.sine` creates a bus element named `sine` in a nested bus named `sinusoidal` at the output port named **Out1**.
- **Compact Notation:** Label displays only the leaf bus element name. For example, the label `Out1.sinusoidal.sine` becomes `sine`.

In either mode, you can directly edit both parts of the label.

To create a new element in the bus, copy and paste an Out Bus Element block. To create a new output port at the interface, right-click and drag an Out Bus Element block, then select **Create New Port**.

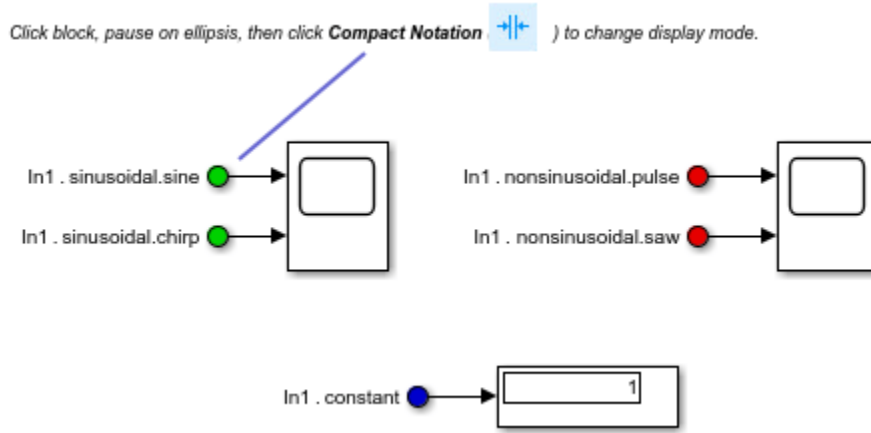

To see the bus created by a group of Out Bus Element blocks, double-click one of the blocks to open the dialog box for port properties. From the dialog box, you can:

- Change the name and number of the port.
- Highlight the lines that correspond to the elements you select.
- Change the colors of the blocks individually, by bus, or by selected elements.
- Reorder the elements in the bus.
- Add or delete bus elements and their corresponding blocks.
- Specify attributes.

The second subsystem consists of two Scope blocks, one Display block, and five In Bus Element blocks.

In Bus Element blocks are similar to an Inport block connected to a Bus Selector block. The labels of In Bus Element blocks work the same way as Out Bus Element block labels do. For example, the In Bus Element block with the label `In1 . sinusoidal . sine` selects a bus element named `sine` in a nested bus named `sinusoidal`.

To change the element selected from the input bus, edit the label text directly. When a bus is connected to the corresponding input port, you can select from the list of available signals.

`In1 . sinusoidal.sine` 

To select a new element from the bus, copy and paste an In Bus Element block. To create a new input port at the subsystem interface, right-click and drag an In Bus Element block, then select **Create New Port**.

To see the bus accessed by a group of In Bus Element blocks, double-click the icon of one of the blocks to open the dialog box for the port properties. From the dialog box, you can:

- Change the name and number of the port.
- Change the colors of the blocks individually, by bus, or by selected elements.
- Observe any missing or unused elements in the incoming bus.
- Add or delete blocks that correspond to selected elements.
- Specify attributes.

For more information about using In Bus Element and Out Bus Element blocks, see “Simplify Subsystem and Model Interfaces with Bus Element Ports”.

### Perform Common Bus Workflows Faster

The subsystems in the Smart Editing to Perform Common Bus Workflows Faster area show how to speed up common bus tasks:

- Convert Bus Selector and Bus Creator blocks to In Bus Element and Out Bus Element blocks.
- Create buses at subsystem interfaces and bundle outputs of individual blocks into a bus.
- Automatically create ports to add new elements to a Bus Creator block and select new elements from a Bus Selector block.

The **Bus Ports** smart editing cue converts Bus Selector and Bus Creator blocks at subsystem interfaces to In Bus Element and Out Bus Element blocks.

- 1 Click on a Bus Selector block that is connected to an Inport block or a Bus Creator block that is connected to an Outport block.
- 2 Select **Bus Ports** from the action bar.

The **Create Bus** smart editing cue bundles multiple elements into a bus.

- 1 Drag a selection box around elements.
- 2 Select **Create Bus** from the action bar.

When creating a bus at subsystem interfaces, this action bundles the selected elements in a bus, replaces the Inport and Outport blocks with In Bus Element and Out Bus Element blocks in the subsystem, and adds Bus Creator and Bus Selector blocks to maintain connectivity outside of the subsystem.

When creating a bus at the outputs of individual blocks, this action inserts a Bus Creator block, resizes it, and connects the elements.

To add an element to a bus, drag a line to a Bus Creator block. To select an element from a bus, drag a line to a Bus Selector block and choose the element you want from the list of available elements.

## Model Arrays of Buses

Arrays of buses represent structured data compactly, eliminating the need to include multiple copies of the same buses. They also support iterative processing with for-each subsystems.

The input buses for an array of buses must be nonvirtual and of the same data type (with the same names, hierarchies, and attributes for the bus elements).

The `sldemo_bus_arrays` model demonstrates multiple ways to use an array of buses.

In this model, a Vector Concatenate block creates an array of buses from nonvirtual buses. Bus Creator blocks create two of the nonvirtual buses, and a Constant block creates a nonvirtual bus from a struct.

The model uses the array of buses with:

- Selector blocks, to extract buses from the array of buses.
- An Assignment block, to assign new values to a bus in the array.
- A For Each Subsystem block, to iteratively process each bus in the array.

- A Memory block, to output the array of buses input from the previous time step.

## Variable-Size Signal Basic Operations

This example shows how variable-size signals can be generated. It also illustrates some of the operations that can be applied to them. The purpose of this example is to introduce the basic operations associated with variable-size signals.

### About This Example

The model contains several blocks that support variable-size signals.

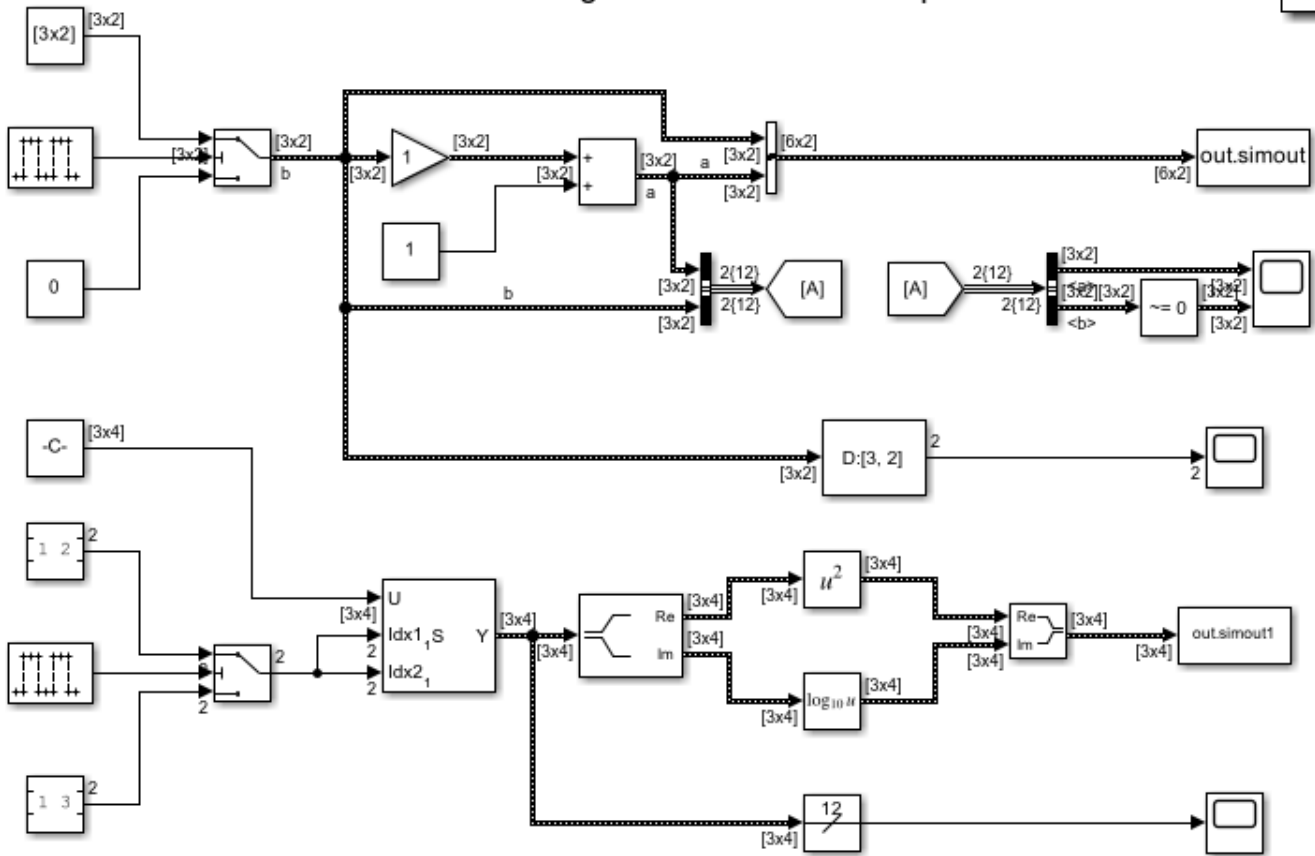

Common ways of generating variable-size signals are:

- Use a Switch block with a different size signal at each input port.
- Use a Selector block and allow the size selection index to change over time.

Eighty blocks can operate with variable-size signals including the Gain block, the Sum block, the Math Function block, the Matrix Concatenate block, and the Bus Creator block. In addition, you can probe variable-size signals using the Width or the Probe block, display variable-size signals on Scope blocks, and save variable-size signals to the workspace using the To Workspace block.

For a complete list of blocks that support variable-size signals, see “Simulink Block Support for Variable-Size Signals”.

### Variable-Size Signal Generation and Operations

Copyright 2009-2013 The MathWorks, Inc.

## Variable-Size Signal Length Adaptation

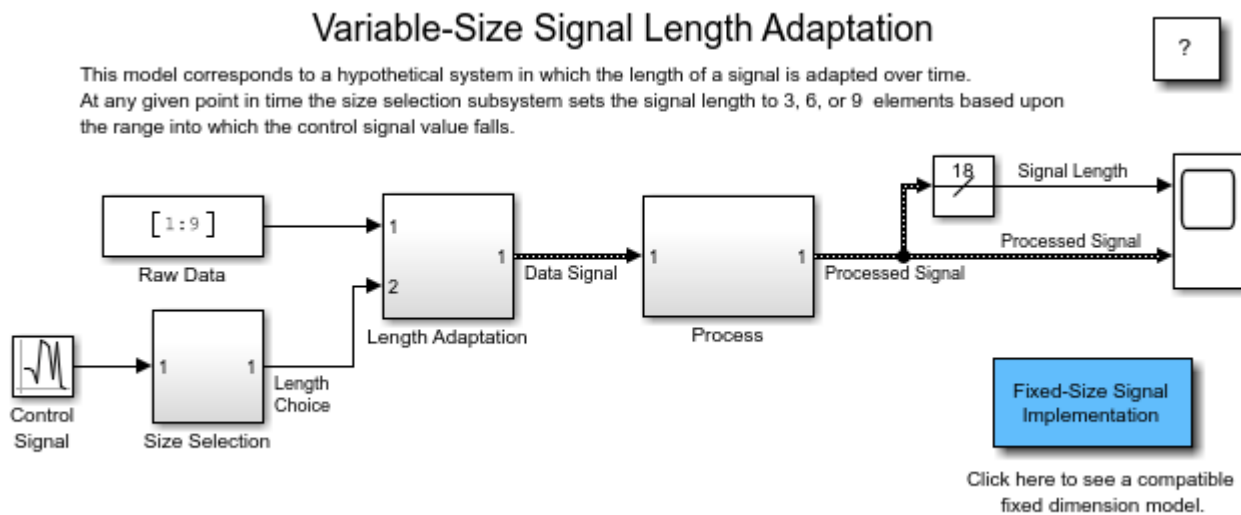

This example shows a hypothetical system where the length of a signal changes over time by adapting to the changes of a control signal.

### About This Example

Open the example model.

This model consists of two sections: the left section generates a signal and converts the signal to variable size; the right section processes the variable-size signal and outputs it to a scope. Length adaptation is based on the value of the control signal. When the control signal falls within one of the three predefined ranges, the size of the data signal changes accordingly.

This variable-size signal is then fed into a processing block, where blocks supportive of variable-size signals operate on it. Note the application of a MATLAB Function block with both the input and the output signals of variable-size. The resulting signal and the signal width are fed to a scope for visualization.

## Multimode Variable-Size Signal

This model shows how to use different operation modes to correspond to different signal sizes.

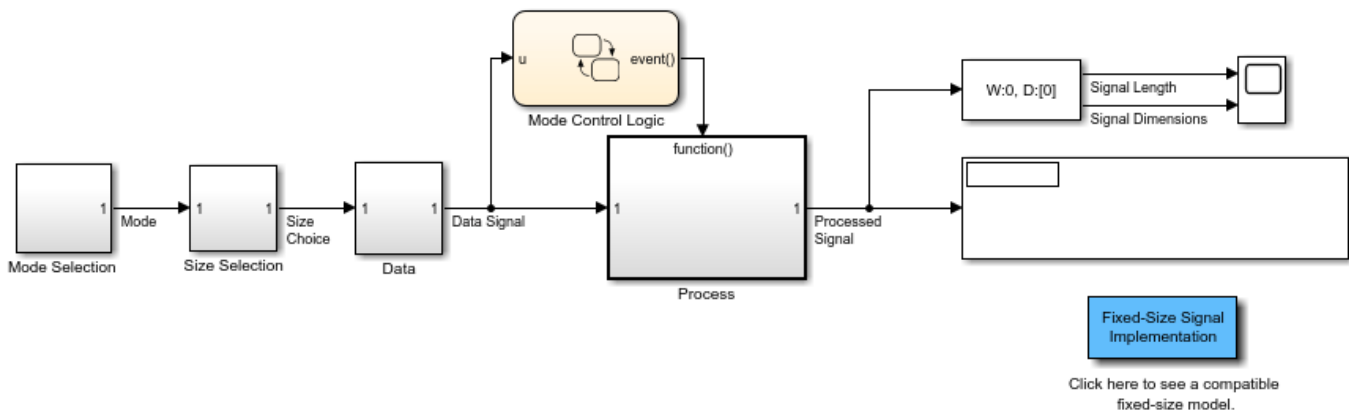

### About This Example

Open the example model:

#### Mode-Dependent Variable-Size Signals

This model represents a system that has three operation modes. For each mode, the signal has a different size. One Function-Call subsystem with variable-size signals handles the processing of the different signal sizes for each mode. The Mode Control Logic block detects the data signal length changes, and responds by issuing mode switching events. This event triggers the reset of the state and the repropagation of signal sizes within the subsystem.

Copyright 2009-2022 The MathWorks, Inc.

The processing subsystem in this model receives a variable-size signal, where the size of the signal depends on the operation mode of the system. For each mode change, the Mode Control Logic Stateflow® Chart generates a function-call to reset the blocks contained in the Process subsystem.

## Parallel Channel Power Allocation

This model shows a potential use of the Find Nonzero Elements block. This block outputs a variable-size signal containing the indices of the nonzero values of the input.

Open the example model `sldemo_varsize_channel_pow_alloc`. This model implements the waterfilling algorithm for obtaining the optimal power allocation for communication channels when a power budget exists. The communication channels involved are independent (i.e., parallel channels) and have different noise levels.

The algorithm iteratively increases the value of the waterline, so that the channels which have a noise level less than the waterline are broadcast. The power used by these transmitting channels is equal to the difference between the waterline and the noise level of the channel. The sum of the power used by all the channels transmitting should satisfy the power budget within the specified tolerance.

The Find Nonzero Elements block is used in the calculation of the total power used for a certain waterline value. The channels which are set to transmit at that waterline level are selected using logical indexing. The logical indices are obtained after thresholding the difference of the waterline and the channel noise levels. As a result, the channels with noise levels larger than the waterline are assigned a logical 0, and those with noise levels below the waterline are assigned a logical 1. The Find Nonzero Elements block is used for converting the logical indices into linear indices. Note that this signal is properly modeled by a variable-size signal, since the number of channels below the threshold is unknown at compile time. The linear indices are fed into a Selector block that picks the channel transmission powers. Subsequently, these powers are summed to get the current value of used power. If this value is smaller than the power budget, the waterline is increased and the process is repeated until the used power equals the power constraint.

### Optimal Power Allocation for Parallel Channels (Waterfilling)

The NL signal contains the channel noise levels.  
The Pcon signal is the total available power budget.  
Tol is the tolerance to use in the search for the waterline level.

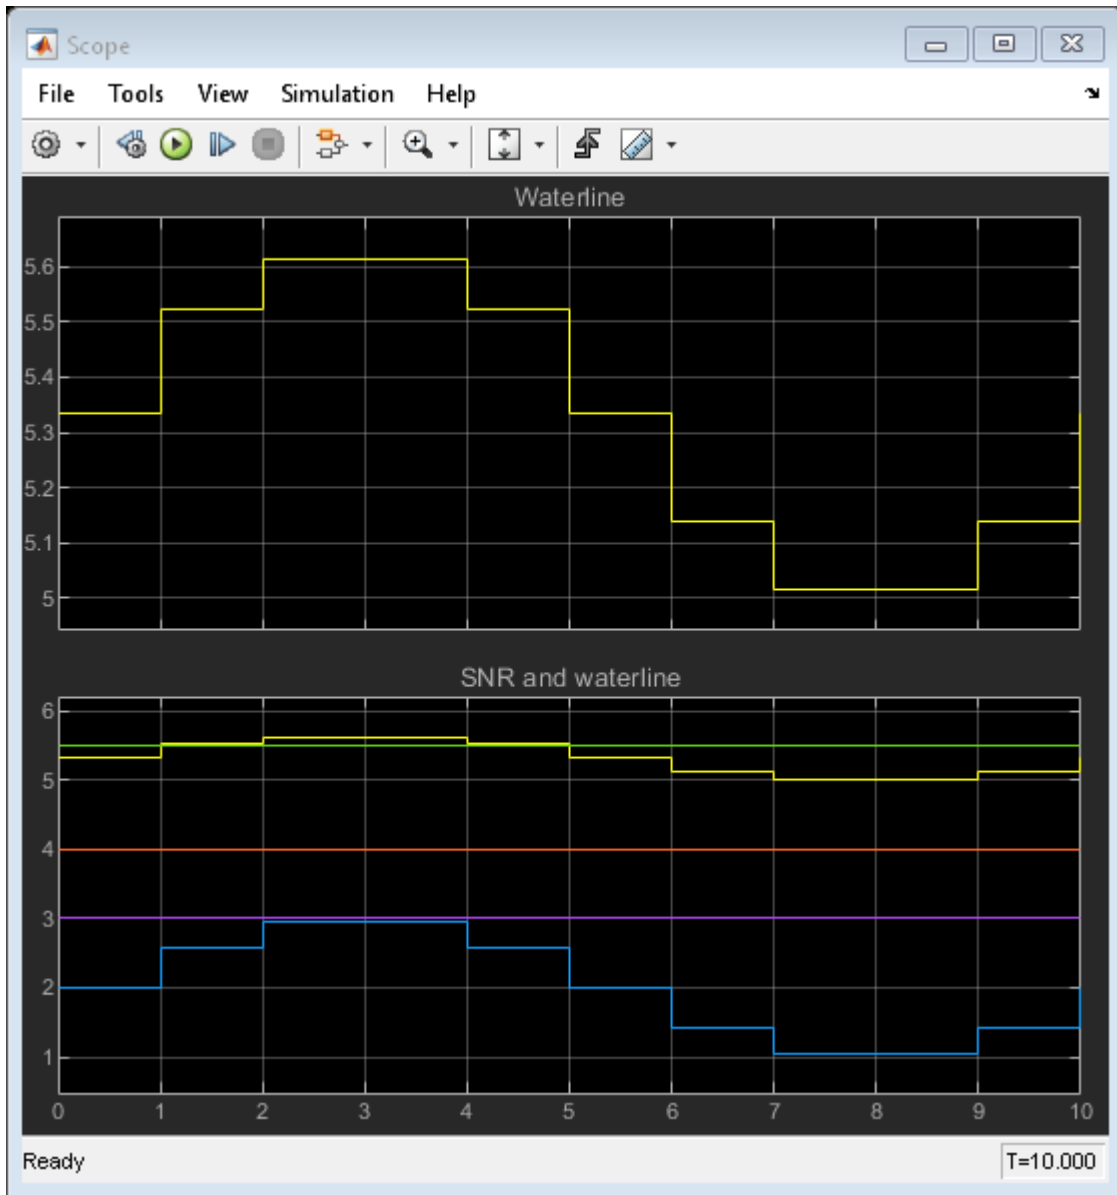

Copyright 2009-2013 The MathWorks, Inc.

### Simulate the Model and Review Results

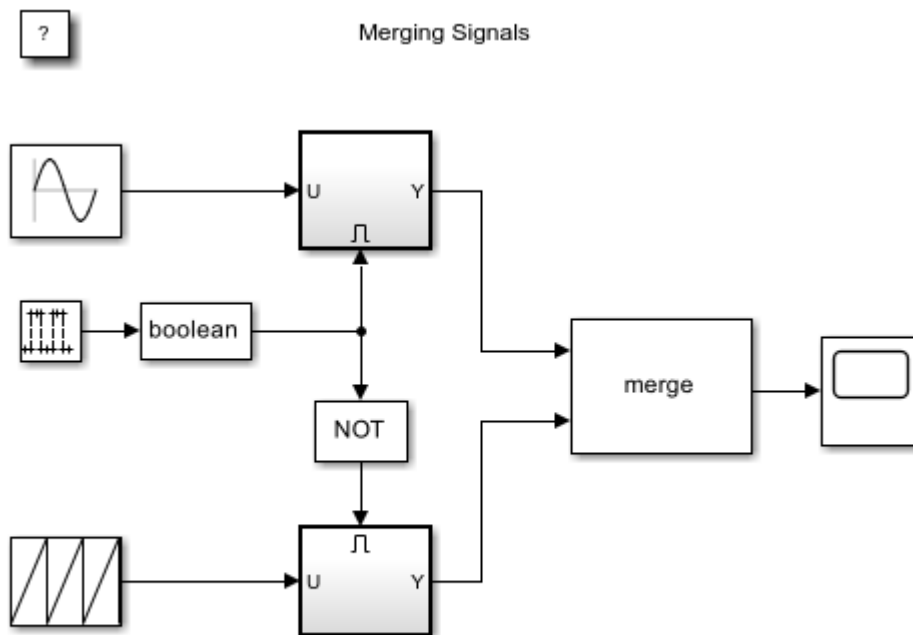

Simulate the model. Open the Scope block that displays the waterline and SNR together with waterline.

## Merging Signals

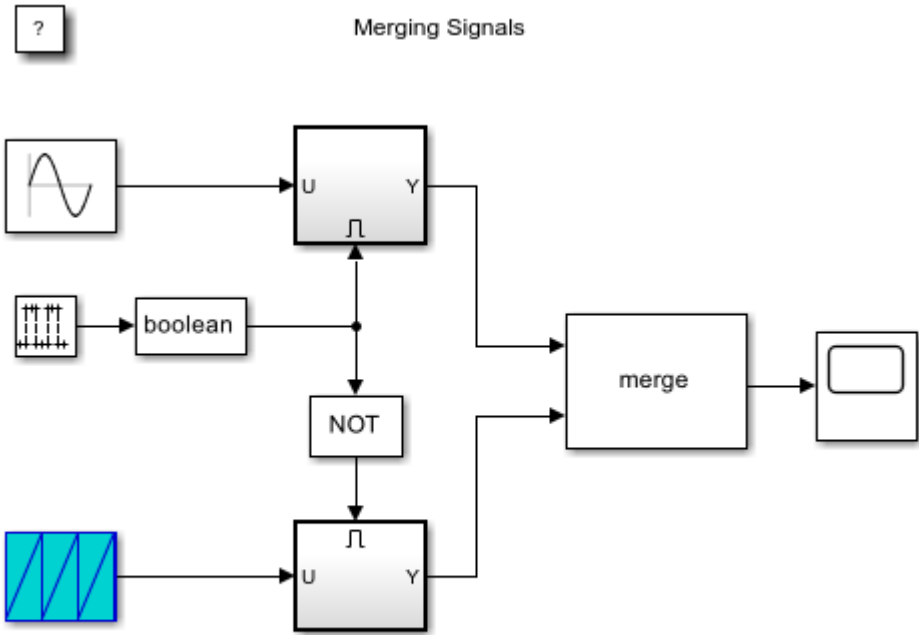

This example shows how to use conditionally executed subsystems and the Merge block to combine two inputs into a single output. The Merge block output value at any time is equal to the most recently computed output of its driving blocks.

Use Merge blocks to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Vector Concatenate, Matrix Concatenate block.

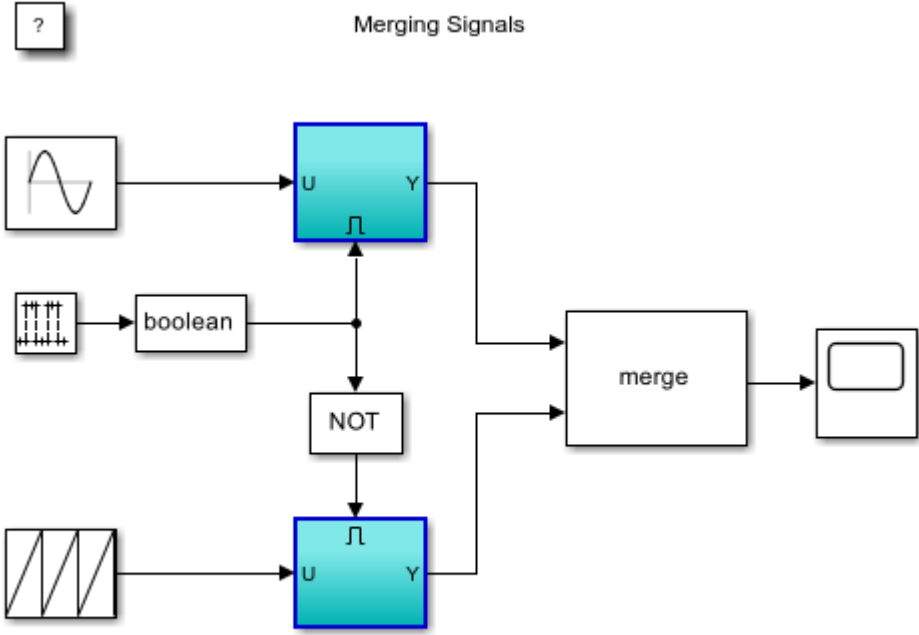

Copyright 2004-2015 The MathWorks, Inc.

The left side of the model contains two blocks Repeating Sequence blocks from the Simulink Sources library. Each block generates a scalar output signal of the form displayed on the block icon.

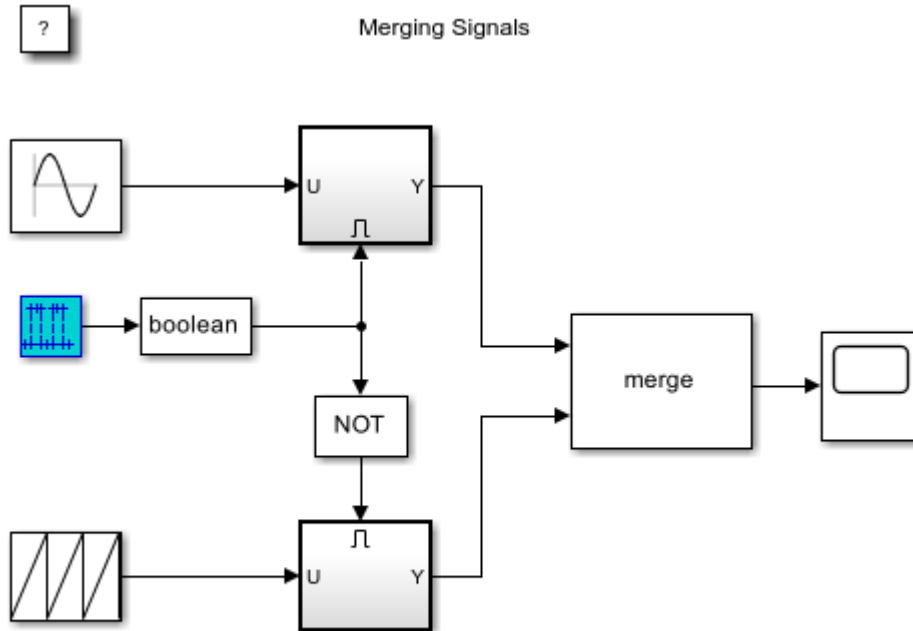

Copyright 2004-2015 The MathWorks, Inc.

These two signals are input into different Enabled Subsystem blocks, which are outlined with thick lines.

Copyright 2004-2015 The MathWorks, Inc.

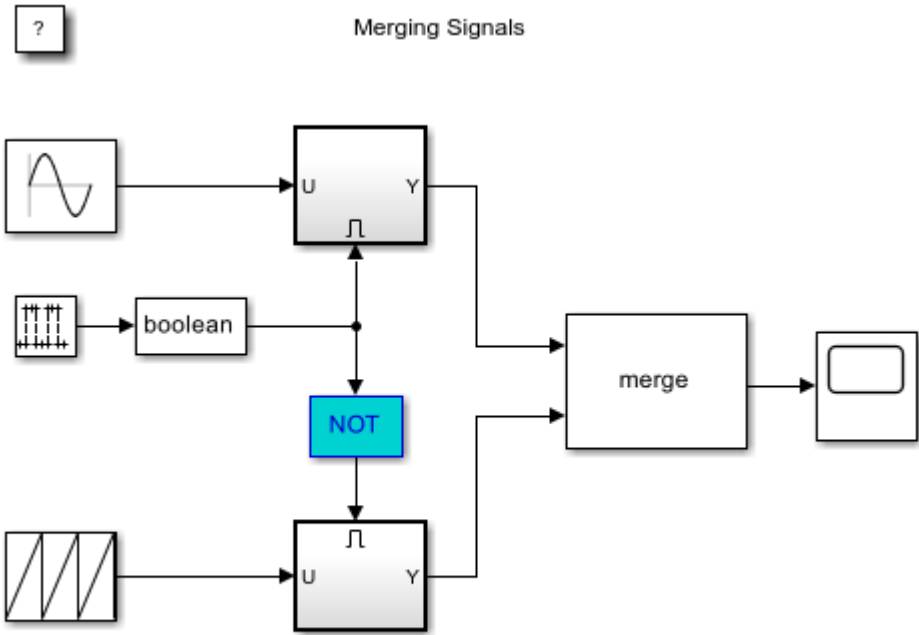

A signal generated by the Pulse Generator block controls the enabled (or conditionally executed) subsystems.

Copyright 2004-2015 The MathWorks, Inc.

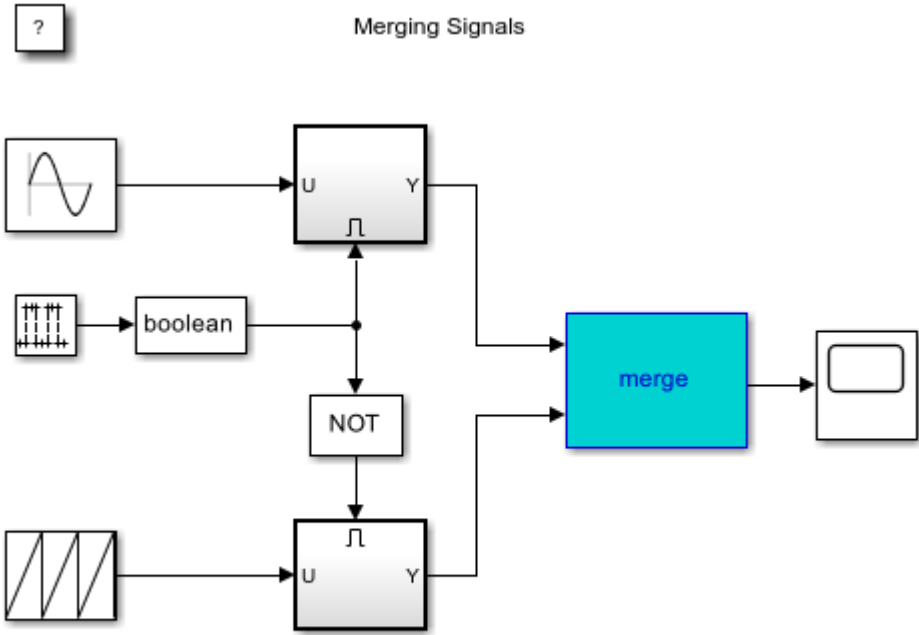

This block output toggles between the values of zero and one every five seconds. When the output of the Discrete Pulse Generator block is positive, the top enabled subsystem is simulating. When the output of the Discrete Pulse Generator block is zero, the bottom enabled subsystem is simulating.

To force the bottom enabled subsystem to simulate when the Discrete Pulse Generator block output is zero, the output is passed through a Logical Operator block set to the NOT operator. The NOT block outputs a value of one when its input is zero.

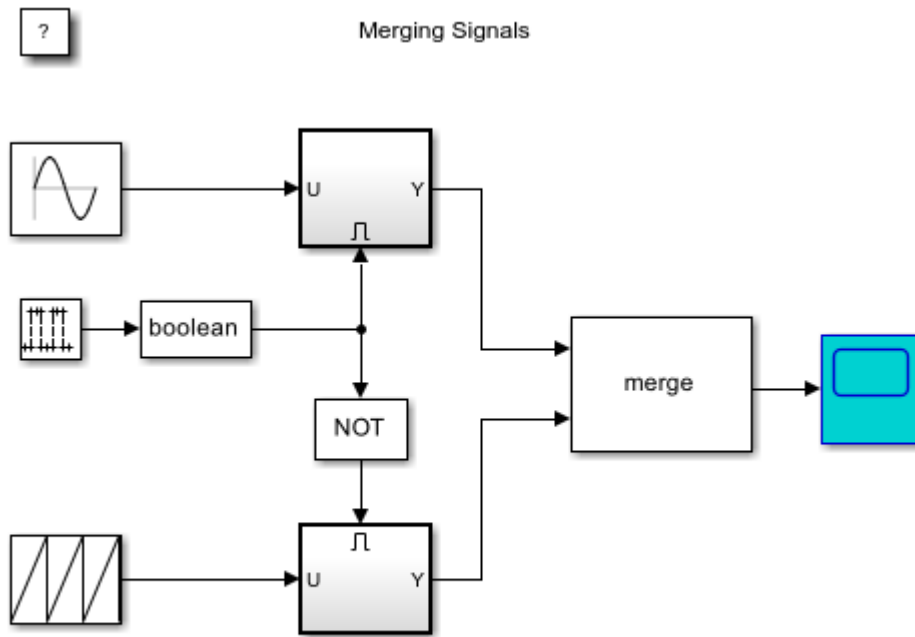

Copyright 2004-2015 The MathWorks, Inc.

The outputs of the two enabled subsystems are input into a Merge block.

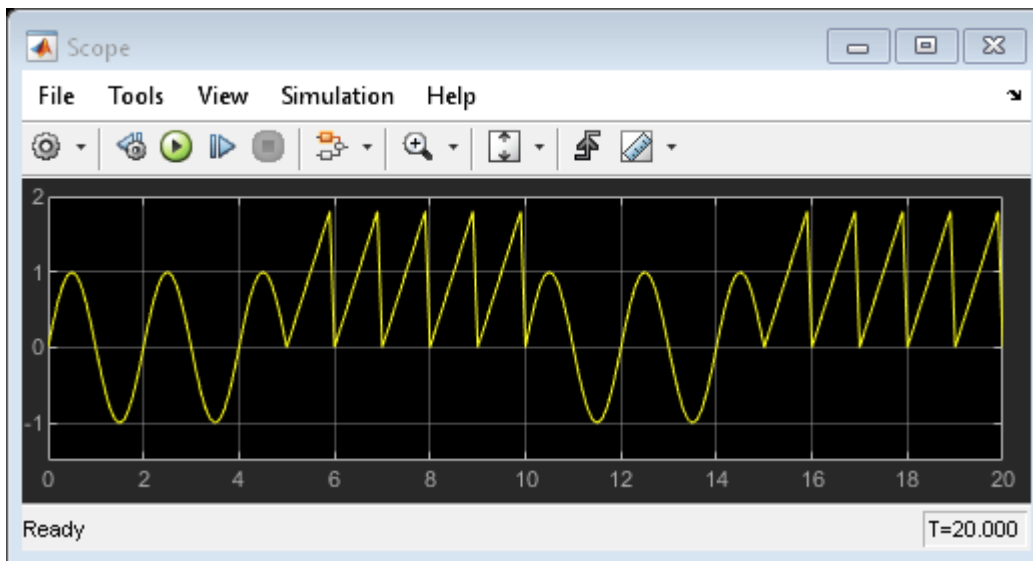

Copyright 2004-2015 The MathWorks, Inc.

A Scope block displays the Merge block output.

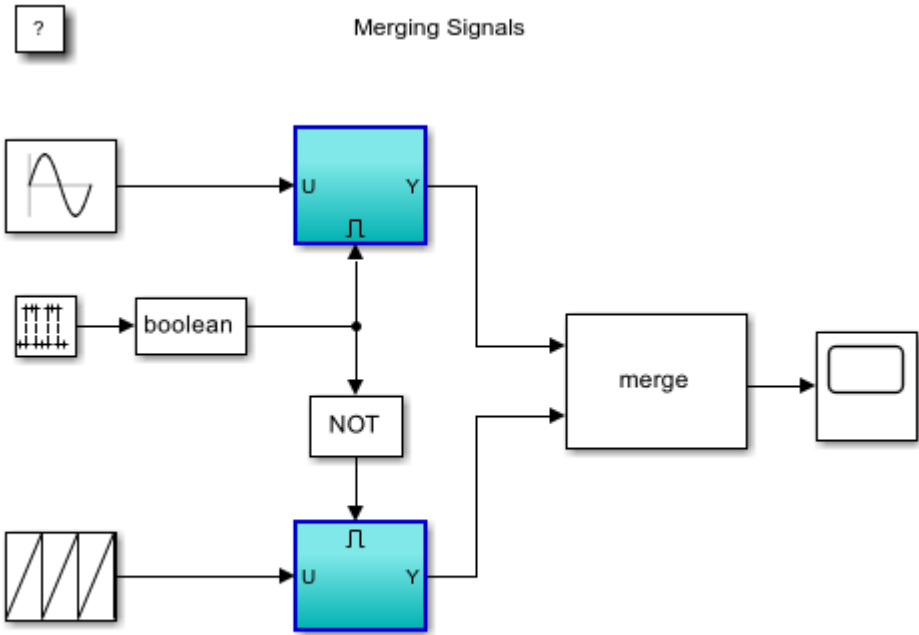

Copyright 2004-2015 The MathWorks, Inc.

Run the simulation to see the output of the Merge block on the Scope. Notice that the type of waveform shown on the Scope changes every five seconds. Due to the behavior of the Merge block, the type of waveform shown on the Scope changes every five seconds.

### Conditionally Executed Subsystems

This Merge block example contains two conditionally executed subsystems.

Copyright 2004-2015 The MathWorks, Inc.

A conditionally executed subsystem is a subsystem that is only executed at times during the simulation when certain conditions are met. In this case, the subsystems are enabled subsystems, distinguished by their icons and the additional input port on the top or bottom of the block.

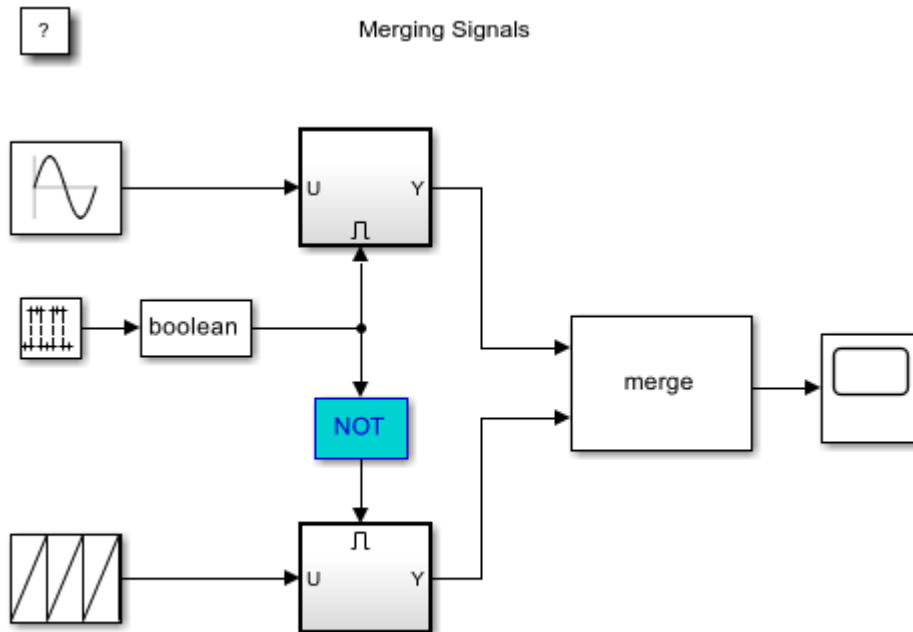

The signal feeding into the additional port is called the control signal. The value of this signal provides the condition that determines whether the subsystem is executed or not, at any given time step. Enabled subsystems are executed when the control signal is strictly positive.

In this example, you want to execute one of the enabled subsystems when the control signal is positive, and the other when the control signal is zero. You can do this by using the Logical Operator block.

## Logical Operator Block

The Logical Operator block provides a method for incorporating logical operators and boolean signals into your model.

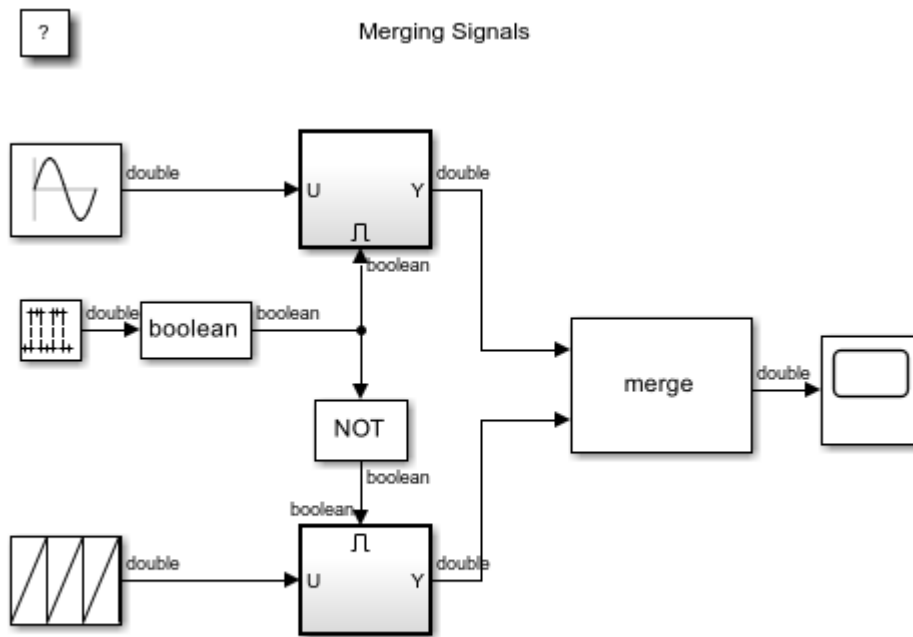

Copyright 2004-2015 The MathWorks, Inc.

Open the Logical Operator block to see the different types of operators. The current setting of NOT returns 1 (or TRUE) when the input signal is non-zero, or 0 (FALSE) when the input signal is strictly zero.

In this example, use this feature to generate a positive value when the control signal goes to zero by maintaining the current operator setting of NOT and closing the dialog.

**Note:** In the Simulink Editor, on the **Debug** tab, the **Information Overlays** menu offers options for displaying signal and port properties on the block diagram.

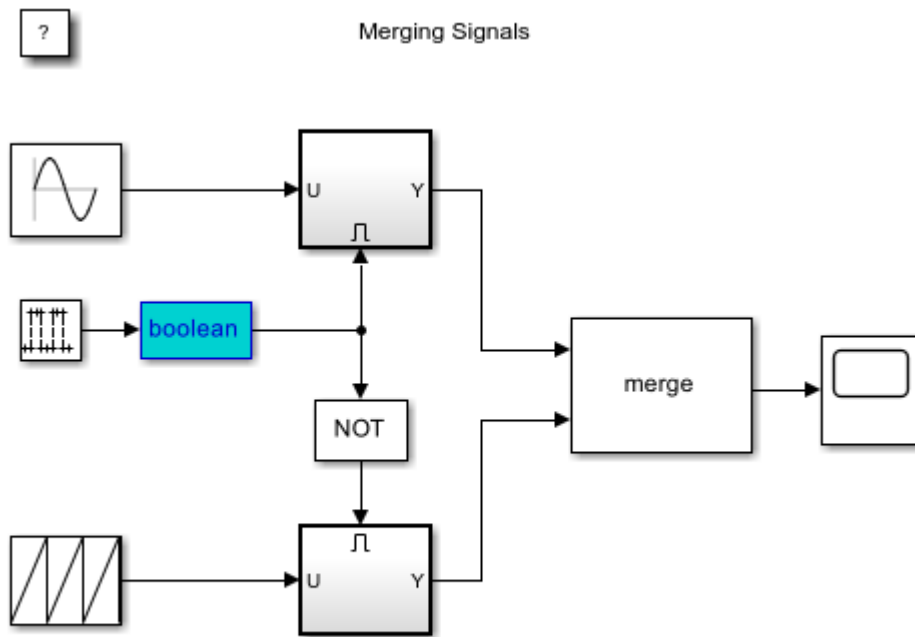

Copyright 2004-2015 The MathWorks, Inc.

## Boolean Signals

You can have Simulink use boolean or double values for the inputs and outputs of the Logical Operator block, using the following steps.

1. To open the Configuration Parameters dialog box, in the Simulink Editor, on the **Modeling** tab, select **Model Settings**.
2. Go to the Optimization page in the Configuration Parameters dialog.
3. Verify that the **Implement logic signals as boolean data (vs. double)** parameter is enabled. This optimization tells Simulink whether or not it should allow a signal whose data type is double to be passed into and out of blocks that support the boolean data type.
4. Click the **OK** button on the **Configuration Parameters dialog**.

Placing the Data Type Conversion block after the Discrete Pulse Generator block avoids an error indicating that the Logical Operator block expects a boolean input signal.

Copyright 2004-2015 The MathWorks, Inc.

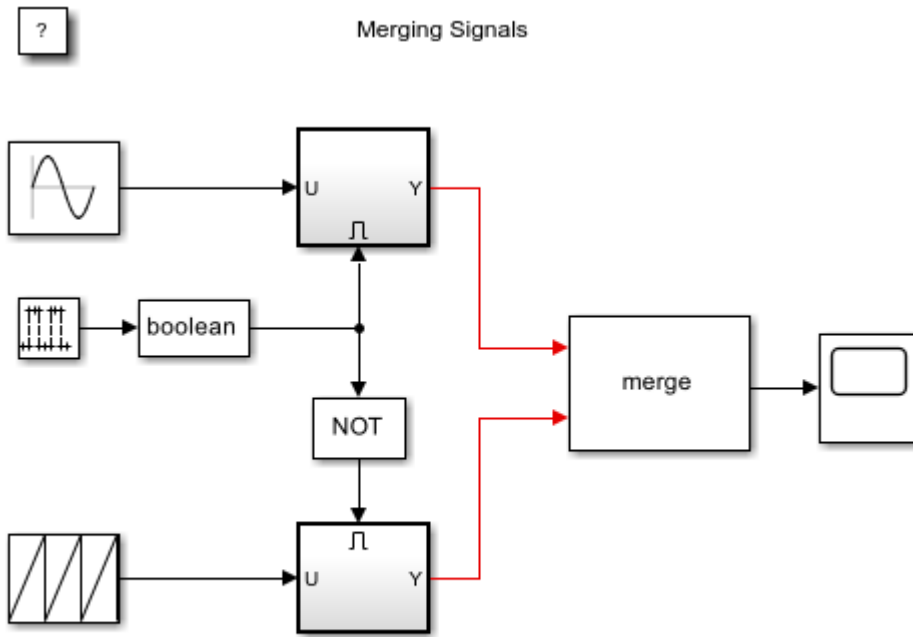

### Merge Block and Alternately Enabling Subsystems

Use the Merge block to create a single signal that is equal to the output of whichever enabled subsystem is currently executing.

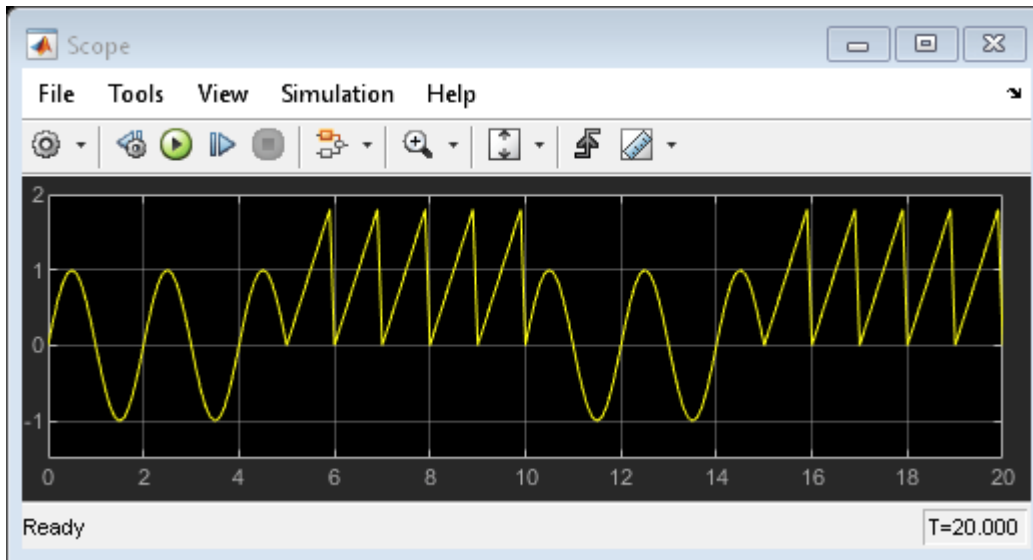

Copyright 2004-2015 The MathWorks, Inc.

1. Open the Merge block dialog box by double-clicking the block.
2. Specify the **Number of inputs** as the number of enabled subsystems whose outputs you want to merge. In this case you want to set the \*Number of inputs \*to 2.
3. Leave the **Initial output field** empty to specify that the Merge block sets its initial output to the initial value of one of its input signals. In this case, the output will be the initial value of the subsystem that is enabled when the simulation starts.
4. Close the Merge block dialog box.
5. Connect the output of the two conditionally executed subsystems to the inputs of the Merge block.

Copyright 2004-2015 The MathWorks, Inc.

As before, when you run the simulation, the output of the Merge block is the value of whatever conditionally executed subsystem is executing at any point in time.

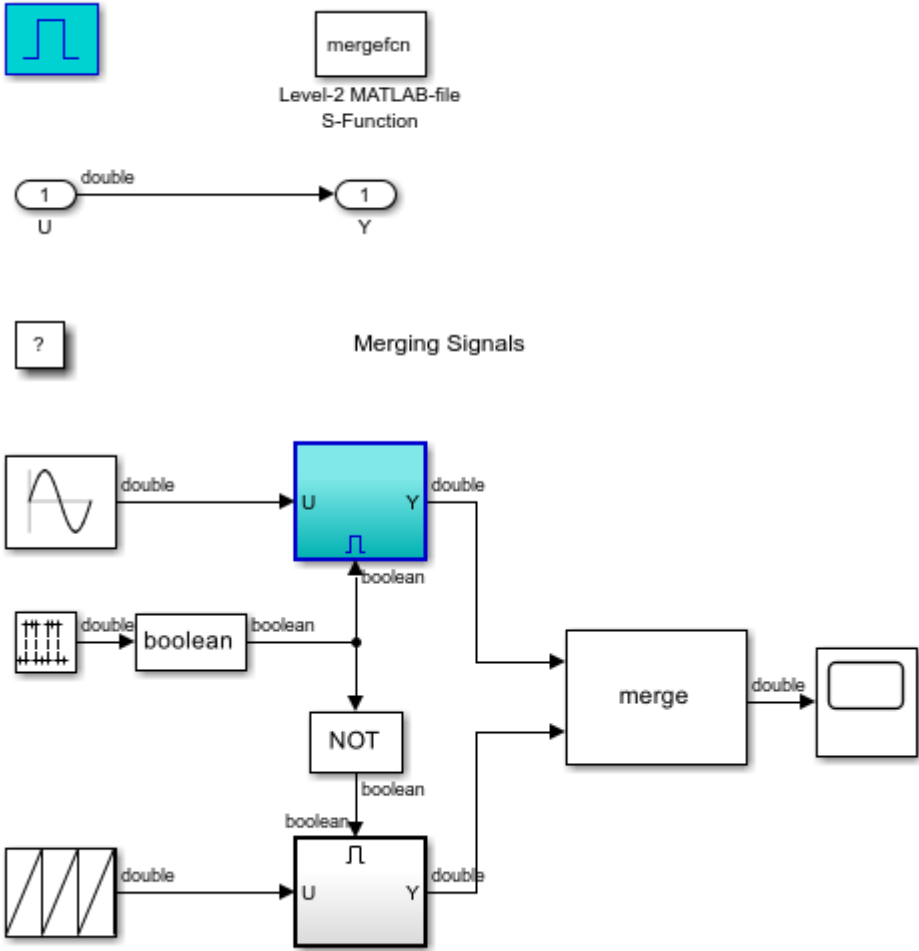

### Programmatically Change Block Background Color

When you run the simulation, the color of the currently executing conditionally executing subsystems change. This does **not** happen automatically for all conditionally executing subsystems. This example uses an S-function and MATLAB® code to change the block background color.

To see the code, double-click the one of the enabled subsystems to open it.

1. The Enable block makes this a conditionally executed subsystem and adds the input port for the control signal.

Copyright 2004-2015 The MathWorks, Inc.

2. The Level-2 MATLAB-file S-function block runs the MATLAB file S-function mergefcn.m.

At each time step, the S-function `mdlUpdate` subfunction executes. It sets the `BackgroundColor` property of the subsystems based on whether it is currently executing, or not, with the following command.

```
set_param('mergedemo/Subsystem','BackgroundColor','green')
```

### **See Also**

Merge | Level-2 MATLAB S-Function

## Share Data Store Between Instances of a Reusable Algorithm

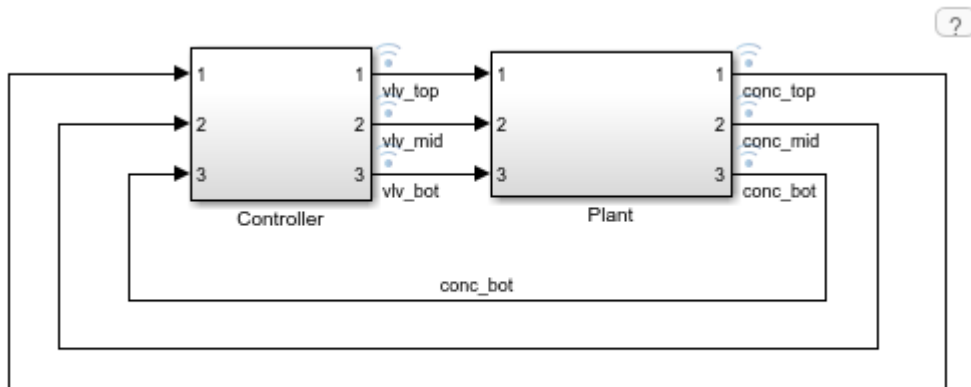

To reuse an algorithm, instead of copying and pasting the blocks, you can encapsulate them in a separate model file. Then, you can refer to the model repeatedly with Model blocks. Each Model block is a standalone instance of the algorithm.

By default, each instance calculates and stores its own copy of the signals that the model contains. Therefore, the instances do not interact. However, you can use a data store to share a piece of data between the instances.

This example shows how to share a fault indication between all instances of a reusable control algorithm. Any instance can set the fault, causing all instances to take action to clear it.

### Explore Example Models

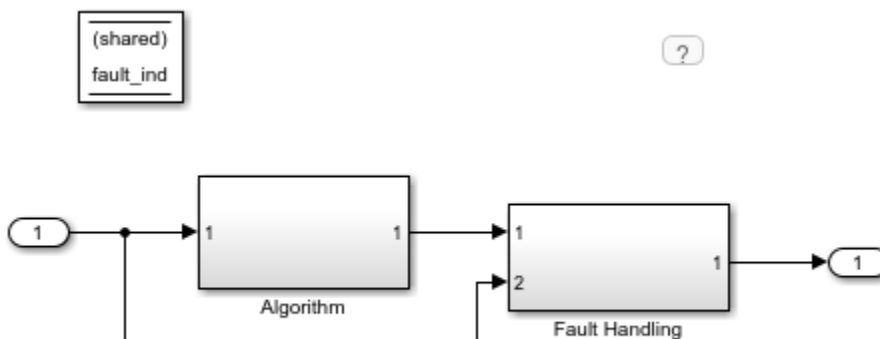

Open the example model `sldemo_shared_data`.

Copyright 2017 The MathWorks, Inc.

The Controller subsystem refers to the controller algorithm model, `sldemo_shared_data_alg`, multiple times through three Model blocks.

Open the algorithm model.

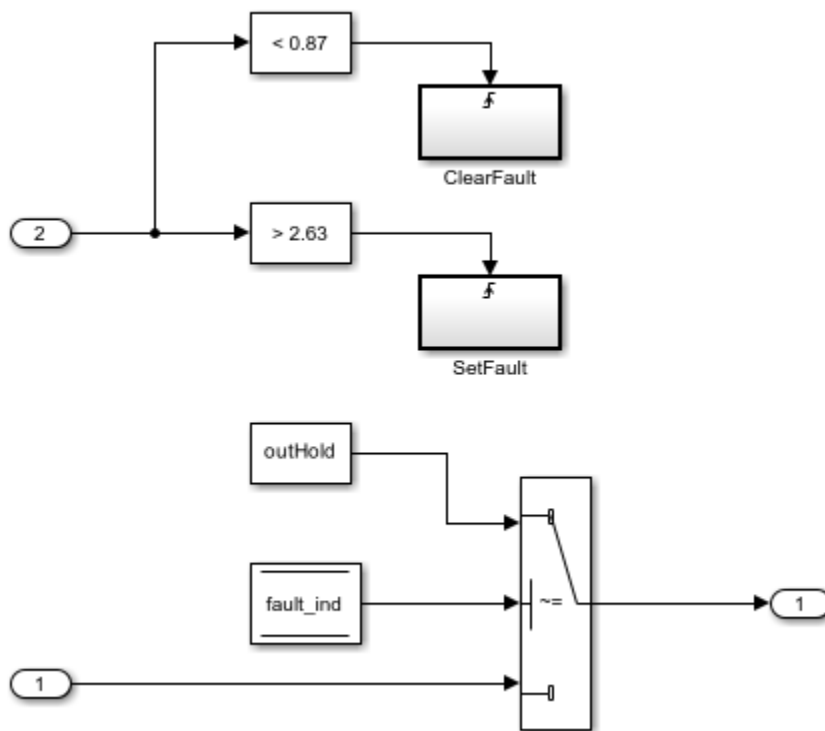

Copyright 2017-2020 The MathWorks, Inc.

The Data Store Memory block `fault_ind` represents a fault indication. The block parameter **Signal Attributes > Share across model instances** is selected, so all instances of `sldemo_shared_data_alg` share the indication. Because the block exists in `sldemo_shared_data_alg`, the indication is local to the model. Other models that refer to `sldemo_shared_data_alg` cannot read or write to the indication.

The Algorithm subsystem uses a PID controller to generate a position command for an actuator (represented by a block in `sldemo_shared_data`).

The Fault Handling subsystem sets and clears the fault indication. Each time an instance of the algorithm experiences a fault condition (the controlled input exceeds 2.63), the subsystem increments the value of the data store by 1. Each time an instance clears its fault condition, the subsystem decrements the value by 1.

### Simulate Example Models

Simulate the parent model, `sldemo_shared_data`.

Use the Simulation Data Inspector to observe the position commands and the controlled signals. In the Simulink Editor toolbar, click the highlighted button.

Partway through the simulation, the controlled signal `conc_mid` experiences a disturbance.

Current plot held

The disturbance triggers a fault in the corresponding instance of the control algorithm. Due to the fault, all three position commands (the vlv signals) lock at zero.

Later, when the fault condition clears, all of the position commands and controlled signals return to nominal values.

## Attaching Input Data to External Inputs via Custom Input Mappings

This example shows how to create a custom mapping function for the Root Inport Mapper tool. The Root Inport Mapper tool associates MAT-file data with a specific input port, based on one of these criteria.

- **Port Order** - Maps in the order it appears in the file to the corresponding port number.
- **Block Name** - Maps by variable name to the corresponding root inport with the matching block name.
- **Signal Name** - Maps by variable name to the corresponding root inport with the matching signal name.
- **Block Path** - Maps by the BlockPath parameter to the corresponding root inport with the matching block path.
- **Custom** - Maps using a MATLAB function.

Use a custom mapping criteria when the data you are trying to map does not match any of the other mapping criteria.

### Custom Mapping Scenario

If the combination of input data and the model input ports does not match Port Order, Block Name, Signal Name, or Block Path mapping criteria, you can do one of the following:

- Rename the input data in the MAT-file
- Rename the input ports on the model
- Use the custom mapping mode

This example shows how to write a custom mapping function.

The workflow described below includes

- Create a MATLAB File to contain the custom mapping function
- Declare the custom mapping function name, inputs, and outputs
- Initialize the output for assignment of the return value
- Define and implement your mapping algorithm
- Validate your mapping algorithm

### Create a New MATLAB Function File

Create a MATLAB function file. This file will contain your custom mapping function.

### Declare Custom Mapping Function

Declare a custom mapping function name, and specify the inputs and outputs. `slexCustomMappingMyCustomMap` is the custom mapping function in this example. It declares the function inputs and outputs as defined below.

### Inputs

- *modelName* - String that contains the model name.
- *signalNames* - Cell array of strings that contain variable names of signals to map
- *signals* - Cell array of signal data aligned with *signalNames* such that *signalNames*{1} is the variable name of the signal stored in *signals*{1}.

## Outputs

- *inputMap* - Array or scalar of objects that result from the `getRootInportMap` function.

## Initialize the Output

Initialize the value of the output variable `inputMap`. To do this use the `getRootInportMap` command with the empty property as shown in the example function `slexCustomMappingMyCustomMap` or in the code snippet below. This initializes the output variable to empty so that a value can be assigned to the output.

```
inputMap = getRootInportMap('empty');
```

## Define Your Custom Mapping Algorithm

Things to think about when defining your custom mapping algorithm.

- What is the criteria for mapping signals to a root-level inport, for example `BlockName` mapping matches the name of the input signal to the name of the root-level inport block name.
- What information is needed to create a mapping.
- What happens if the mapping criteria determines that there is no match between signal and root-level inport.

The example addresses these items by

- Using the root-level port number and signal name for mapping criteria.
- Using a utility function `slexCustomMappingGetPortNames` to get root-level inport block names to provide as input along with the variable `|signalName|` to the `getRootInportMap` function which creates the mapping.
- Including a logical condition to handle the case where there is no match between port number and signal name.

## Implement Your Mapping Algorithm

Next, implement your mapping algorithm.

In the `slexCustomMappingMyCustomMap` implementation, the root-level inport port number is the mapping criteria. The algorithm gets this port number from the root-level inport block. It then gets the numerical values appended to the names of the signals that are passed into the function, and compares the port number with the numerical values.

NOTE: In addition to implementing your mapping algorithm, you should also include a logical statement to handle situations where a mapping is not possible. The example function does this by using an `if` statement with the `isempty` function to determine if a mapping can be made.

## Create the Mapping

The final step is to use the `getRootInportMap` function to create a custom map. The `getRootInportMap` function uses Property-Value pairs to create a custom map. The properties are:

- *model* - String that represents the model name.
- *signalName* - String or cell of strings that contains the value of the variable name of the signal to map.
- *blockName* - String or cell of strings that contains the value of the block name of the port to be mapped.

The following code is an example of this function. This same code appears in the example function `slexCustomMappingMyCustomMap`.

```
inputMap = getRootInportMap(...
 'model',modelName,...
 'signalName',signalNames,...
 'blockName',portNames);
```

## Validate the Custom Mapping Function

To validate the custom mapping function at the command line:

- 1 Open the model against which you want to test your function.
- 2 Create some input signals to support the model.
- 3 Call your custom mapping function with the correct input parameters.
- 4 Validate the expected input string to send to the `sim` command, or to place in the model configuration parameters External Input String edit box.

Execute the lines of code in the following example. This code uses the custom mapping function provided with this example. If the custom map function succeeds, you should see a comma-separated list of variable names displayed in the order of the port number to which they are assigned ('port1,port2').

```
load_system('slexAutotransRootInportsExample'); port1 =
timeseries(ones(10,1)*10); port2 =
timeseries(zeros(10,1)); inputMap =
slexCustomMappingMyCustomMap('slexAutotransRootInportsExample',{'port1'
, 'port2'},{port1 , port2}); externalInputString =
getInputString(inputMap,'base');
close_system('slexAutotransRootInportsExample',0);
```

If your signals are in a `Simulink.SimulationData.Dataset`, you can execute the lines of code in the following example. This code uses the custom mapping function provided with this example. If the custom mapping function succeeds, you should see a comma-separated list of variable names displayed in the order of the port number to which they are assigned ('ds.getElement(1),port1,ds.getElement(2)').

```
load_system('slexAutotransRootInportsExample');
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(timeseries(ones(10,1)*10), 'port1');
ds = ds.addElement(timeseries(zeros(10,1)), 'port1');
inputMap = slexCustomMappingMyCustomMap('slexAutotransRootInportsExample',{'ds'},{ ds
```

```
externalInputString = getInputString(inputMap, 'base');
close_system('slexAutotransRootInportsExample',0);
```

- “Create Signal Data for Root Inport Mapping”

## Using Mapping Modes with Custom-Mapped External Inputs

This example shows how to implement a custom mapping algorithm similar to a Simulink mapping mode. It uses the `getSlRootInportMap` and `getRootInportMap` functions to implement the custom mapping.

Before running this example, make sure that you are familiar with the `getRootInportMap` command and the Root Inport Mapper Tool. For more information, see “Map Root Inport Signal Data”.

### Workflow

This example shows how you can use a built-in Simulink mapping mode to perform as many mappings as possible. It then flags the root inports that were not able to be assigned a signal. The algorithm then overrides the flagged mappings with custom mappings to map the remaining signals. To implement such a solution, create a custom mapping function using the `getSlRootInportMap`.

This example uses a list of inputs with two kinds of signals:

- Signals that can be mapped using the Simulink block name mapping mode.
- Signals that cannot be mapped using the Simulink block name mapping mode. You must map these signals with a custom mapping mode.

Assume the following scenario:

- You want to use a group of signals as inputs to your Simulink model.
- The signals are named such that the variable names match the block name of the root-level inport.
- Each signal that uses this naming convention is within tolerance.
- Each signal that has the 'x' character appended to its name is considered outside tolerance.

This example uses a mapping mode similar to the Simulink block name mapping method.

The root-level inport block names are:

- Throttle
- Brake

The signal variable names are:

- Throttlex
- Brake

To map inputs to root-level inport blocks in this scenario, you need a custom mapping function for the Root Inport Mapper tool. This example uses the `AlmostBlockName` custom mapping function.

For this example, you will use the `slexAutotransRootInportsExample` model to validate your custom mapping function.

### Declare the Custom Mapping Function

Declare the function name, inputs, and outputs. To do this, copy and paste the following code snippet into a MATLAB file and save the file as `AlmostBlockName.m`.

```
function inputMap = AlmostBlockName(modelName, signalNames, signals)
```

## Get the Simulink BlockName Mapping

Next, map all the signals. To do this, first map all the signals within tolerance using the Simulink block name mapping mode, then map the signals outside tolerance.

To map signals within tolerance to a model using one of the Simulink mapping modes, use the function `getSlRootInportMap`. This function returns the `inputMap` and a vector of logical values. Each logical value indicates a successful or unsuccessful mapping of `inputMap` to a signal. To map by block name, insert the following lines of code just after the function declaration.

```
inputMap = getRootInportMap('empty');
if ~bdIsLoaded(modelName)
 load_system(modelName);
end

[inputMap, hasASignal] = getSlRootInportMap('Model', modelName, ...
 'MappingMode','BlockName',...
 'signalName',signalNames, 'signalValue', signals);
```

## Find the Missing Input Signals

In the previous step, you created a mapping using a block name mapping mode. You must now account for an empty `inputMap` and for `inputMap(s)` that were not associated with a signal within tolerance. The function `getSlRootInportMap` has flagged these signals with the output variable `hasASignal`. To do this:

- 1 Check the `inputMap` variable.
- 2 If the `inputMap` variable is not empty, determine which elements of the `inputMap` vector were not assigned a signal. To do this, use the logical `~` on the `hasASignal` vector as shown below. The `emptyIndex` vector now contains a logical vector where true means the `inputMap` does not have a signal mapped to it.
- 3 Copy and paste the following code snippet under the call to the `getSlRootInportMap` and before the `end` to the `if bdIsLoaded(modelName)`.

```
if ~isempty(inputMap)
 emptyIndex = ~hasASignal;
end
```

The code snippet performs steps one and two for you.

## Complete the Mapping

In the previous step, you created a logical vector `emptyIndex` to see if any of the `inputMap` objects were not associated to a signal. If all the elements of the `emptyIndex` vector are false, you have a complete mapping and the code added in this section will not be executed.

If the `emptyIndex` vector contains at least one value that is true, you have `inputMap` objects that are not associated to a signal. Manually assign the variable `signal(s)` to that `inputMap`. Then, override the `inputMap` with the signal name that matches the expected signal name:

- 1 In the `emptyIndex` vector, find all the items that are true. These items point to the `inputMap(s)` that still need to be associated with a signal.
- 2 For each `inputMap`, use the 'BlockName' property to get the name of the inport block that the `inputMap` is assigned to.

- 3 Append an 'x' to the block name to get the name of the signal to be assigned to the `inputMap`.
- 4 Compare the result to each item in the `signalNames` variable cell array.
- 5 If a match is found, override the `inputMap` with the signal name that matches the expected signal name. To override the `inputMap` object, use the `getRootInportMap` function with the 'InputMap' and the 'SignalName' properties.

```

if isa(signals{1}, 'Simulink.SimulationData.Dataset')
 signalNames = signals{1}.getElementNames';
end

idxEmpty = find(emptyIndex==true);
for kEmpty =1:length(idxEmpty)
 idxOfEmpty = idxEmpty(kEmpty);
 destBlockName = get(inputMap(idxOfEmpty),'BlockName');
 outSideToleranceSig = [destBlockName 'x'];
 isAMatch = strcmp(signalNames, outSideToleranceSig);
 if any(isAMatch)
 inputMap(idxOfEmpty) = getRootInportMap('InputMap', ...
 inputMap(idxOfEmpty),'SignalName',outSideToleranceSig);
 end
end
end

```

### The Custom Map File

When you are done, the file `AlmostBlockName.m` should resemble the following code.

```

function inputMap = AlmostBlockName(modelName, signalNames, signals)
inputMap = getRootInportMap('empty');
if bdIsLoaded(modelName)

 [inputMap, hasASignal] = getSlRootInportMap('Model', modelName, ...
 'MappingMode','BlockName',...
 'signalName',signalNames, 'signalValue', signals);

 if ~isempty(inputMap)
 emptyIndex = ~hasASignal;
 idxEmpty = find(emptyIndex==1);

 if isa(signals{1}, 'Simulink.SimulationData.Dataset')
 signalNames = signals{1}.getElementNames';
 end

 for kEmpty =1:length(idxEmpty)
 idxOfEmpty = idxEmpty(kEmpty);
 destBlockName = get(inputMap(idxOfEmpty),'BlockName');
 nonNominalSig = [destBlockName 'x'];
 isAMatch = strcmp(signalNames, nonNominalSig);
 if any(isAMatch)
 inputMap(idxOfEmpty) = getRootInportMap('InputMap', ...
 inputMap(idxOfEmpty),'SignalName',nonNominalSig);
 end
 end
 end

end
end
end

```

### Validate the Custom Mapping

To validate your custom mapping:

- 1 Save the `AlmostBlockName` function in a file on the MATLAB path.
- 2 To see the results of your mapping function, copy and paste the following code snippet to the MATLAB Command Window.

```
modelName = 'slexAutotransRootInportsExample';
Throttlex = timeseries(zeros(10,1));
Brake = timeseries(ones(10,1));
signalNames= {'Throttlex' , 'Brake'};
signals = { Throttlex , Brake };
open_system(modelName);
inputMap = AlmostBlockName(modelName, signalNames, signals);
inputStr = getInputString(inputMap, 'base');
close_system(modelName);
```

After running the code snippet, the variable `inputStr` contains the string `'Throttlex,Brake'`.

If your signals are in a `Simulink.SimulationData.Dataset`, to see the results of your mapping function, use the following code snippet at the MATLAB Command Window.

```
modelName = 'slexAutotransRootInportsExample';
Throttlex = timeseries(zeros(10,1));
Brake = timeseries(ones(10,1));
ds = Simulink.SimulationData.Dataset;
ds = ds.addElement(Throttlex, 'Throttlex');
ds = ds.addElement(Brake, 'Brake');
signalNames= {'ds'};
signals = { ds };
open_system(modelName);
inputMap = AlmostBlockName(modelName, signalNames, signals);
inputStr = getInputString(inputMap, 'base');
close_system(modelName);
```

After running the code snippet for signals in a `Simulink.SimulationData.Dataset`, the variable `inputStr` contains the string `'ds.getElement('Throttlex'),ds.getElement('Brake)'`.

## Create Harness-Free Models With MAT-File Input Data

This example shows how to map MAT-file data to the root-level input ports, which creates a harness-free model. Using root-level input ports can speed up simulation time. In the example, you convert a model with a Signal Editor input block to a harness-free model with root-level input ports. The harness-free model uses the data from the Signal Editor block MAT-file.

### Open Example Model

Open the `sldemo_autotrans` model.

Copyright 1990-2022 The MathWorks, Inc.

### Remove Signal Editor Block

Replace the Signal Editor block named `ManeuversGUI` with two input ports.

- 1 Delete the Signal Editor block named `ManeuversGUI`.
- 2 From the **Simulink/Commonly Used Blocks** library, drag two Inport blocks into the model.
- 3 Connect the input ports to the lines previously connected to the Signal Editor block.
- 4 Rename the input ports. Name the input port connected to the `Throttle` signal **Throttle**. Name the input port connected to the `BrakeTorque` signal **Brake**.

Save the model as `slexAutotransRootInportsExample1` or `slexAutotransRootInportsExample`.

The remaining steps of this example use the model `slexAutotransRootInportsExample`. If you saved the model with a different name, use your model name.

?

## Modeling an Automatic Transmission Controller with Root Imports

Copyright 2012 - 2014 The MathWorks, Inc.

### Set Up Harness-Free Inputs

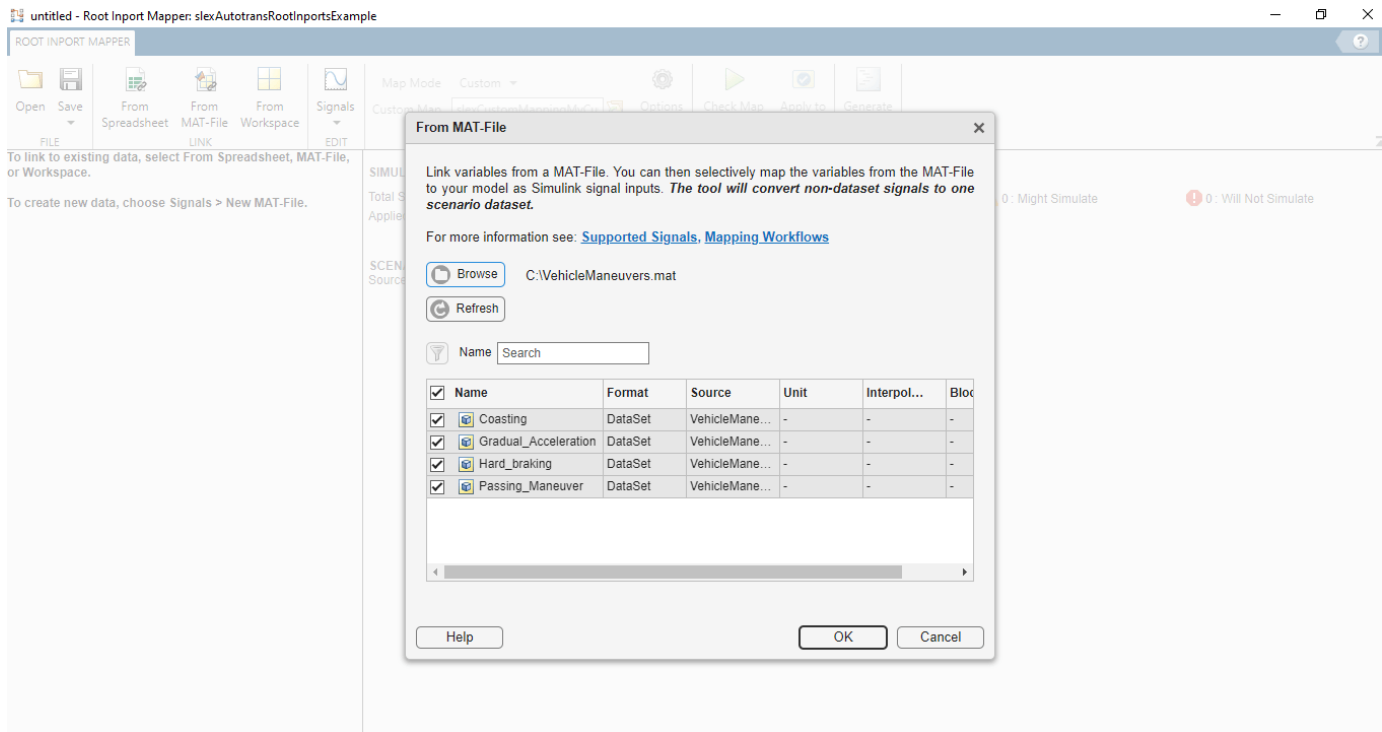

Now that the model is harness-free, set up the inputs from the MAT-file previously used by the Signal Editor block.

In the **Modeling** tab, click **Model Settings**. In the **Data Import/Export** pane, click **Connect Inputs**.

### Map Signals to Root Inport

The Root Inport Mapper tool opens.

The example uses this tool to set up the model inputs from the MAT-file and map those inputs to an input port, based on a mapping algorithm. To select the MAT-file that contains the input data, on the Root Inport Mapper toolbar, click **From MAT-File**. When the link dialog appears, click the Browse button. In the browser, select the MAT-file from the local working example folder. For this example, the file name is `VehicleManeuvers.mat`.

### Select Map Mode

When you select the MAT-file `VehicleManeuvers.mat`, determine the root input port to which to send input data. Simulink matches input data with input ports based on one of five **Map Mode** criteria:

- **Port Order** — Maps in the order it appears in the file to the corresponding port number.
- **Block Name** — Maps by variable name to the corresponding root input port with the matching block name.
- **Signal Name** — Maps by variable name to the corresponding root input port with the matching signal name.
- **Block Path** — Maps by the BlockPath parameter to the corresponding root input port with the matching block path.
- **Custom** — Maps using a MATLAB function.

The selected MAT-file has input data with variables of the same name as the harness signals `Throttle` and `Brake`, and input ports with names matching the variables. Given the set of conditions for the input data and the model input ports, the best choice for a mapping criterion is **Block Name**. Using this criterion, Simulink tries to match input data variable names to the names of the input ports. To select this option:

- 1 In the **Map Mode** list, click **Block Name**.
- 2 Click **Options** and select **Update Model Automatically**. This option verifies the mapping.
- 3 Click **Check Map Readiness**.

When compiling the data, Simulink evaluates input ports against the following criteria to determine compatibility issues. The status of this compatibility is reflected by the table colors green, orange, or

red. Warnings and errors are flagged with diagnostic messages. If the **Options > Update Model Automatically** option is not selected, the Root Inport Mapper tool determines the compatibility status by evaluating these block parameters and assigned signals:

- **Data Type** — Double, single, enum, ....
- **Complexity** — Real or complex
- **Dimensions** — Signal dimensions versus port dimensions

The screenshot shows the 'ROOT INPORT MAPPER' tool interface. The left pane contains a table with the following data:

Source	Scenario Dataset	Map Mode	Status
	Coasting	Block Name	✓
	Gradual_Acceleration	Block Name	✓
	Hard_braking	Block Name	✓
	Passing_Maneuver	Block Name	✓

The right pane displays 'SIMULATION READINESS' with a timestamp of 3:29:37pm 4/27/22. It shows 'Total Scenario Datasets: 4' and 'Applied to Model: Coasting'. The status is summarized as: 0 : Not Mapped, 4 : Will Simulate, 0 : Might Simulate, 0 : Will Not Simulate. Below this, 'SCENARIO DETAILS' are shown for 'Passing\_Maneuver - VehicleManeuvers.mat' in 'Block Name' mode. A table lists the mapped signals:

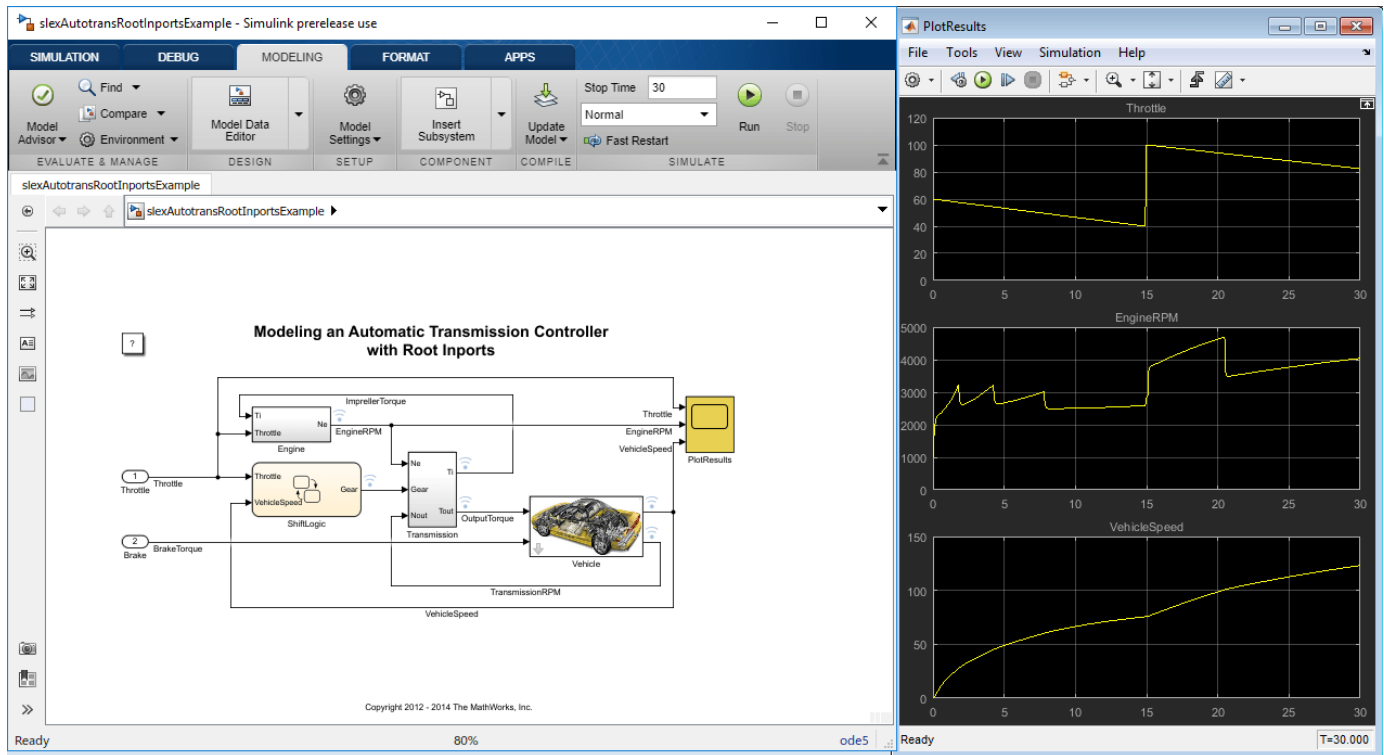

Status	Scenario Signal	Port	Block Name	Mapped Signal
✓	Throttle	1	Throttle	Passing_Maneuver.getElement('Throttle')
✓	Brake	2	Brake	Passing_Maneuver.getElement('Brake')

### Finalize Inputs to Model

Review the results of the mapping compatibility. In the **Scenario Dataset** list, select **Passing\_Maneuver**. To prepare for simulation, click **Apply to Model**. This action applies the mapping variables to the Configuration Parameter **Data Import/Export > External Input** text box. If this text box has content, the content is overwritten.

### Simulate Model

With the changes applied, you can now simulate the model. To view the results of the simulation, double-click the **PlotResults** scope block.

## Logging States in Structure Format

Logging states using the Structure format can provide advantages over the Array format. When you log states using the Array format, the ordering of the states along the columns in the logged array depends on the block sorted order. Various factors can affect the block sorted order, which can alter the ordering of the states from one simulation to the next. When you use the Structure format, the block names are stored along with the logged state data for that block, so you can process your data without considering the block sorted order.

### Logging States in Array Format

When you log states using the Array format, the logged data is stored in an array with  $N$  columns, where  $N$  is the number of states, and  $M$  rows, one for each simulation time step. This  $M$ -by- $N$  matrix form is easy to manipulate in MATLAB®. However, the ordering of the state variables along the columns of the logged matrix depends on the block sorted order. Therefore, any MATLAB code which expects a fixed mapping between the states of blocks in the model and the columns of the states matrix is prone to breaking when the block sorted order changes due to changes in the model.

For example, consider the models `sldemo_state_logging1` and `sldemo_state_logging2`.

```
mdl1 = 'sldemo_state_logging1';
mdl2 = 'sldemo_state_logging2';
open_system(mdl1);
open_system(mdl2);
```

sldemo\_state\_logging1

Copyright 2006-2013 The MathWorks, Inc.

sldemo\_state\_logging2

Copyright 2006-2013 The MathWorks, Inc.

The two models contain the same blocks, connected the same way. The only difference is the order of the output ports. Simulate the models and log the states using the Array format.

```
simOut1 = sim mdl1, 'SaveFormat', 'Array';
simOut2 = sim mdl2, 'SaveFormat', 'Array';
```

Extract the states vectors from the `Simulink.SimulationOutput` object, which contains all data logged in the simulation.

```
x1 = simOut1.get('xout');
x2 = simOut2.get('xout');
```

The logged states data for `x1` and `x2` are different because the blocks are ordered differently, so the mapping between the columns in the logged array and the blocks in the model is different.

```
isequal(x1, x2)
```

```
ans =
```

```
logical
```

```
0
```

### Log States Using the Structure Format

Simulate the models again, but this time log the states in structure format.

```
simOut1=sim mdl1, 'SaveFormat', 'Structure';
simOut2=sim mdl2, 'SaveFormat', 'Structure';
```

Extract the structures, which contain the logged states, from the `SimulationOutput` object.

```
x1s = simOut1.get('xout');
x2s = simOut2.get('xout');
```

Display these structures, which contain two fields: `time` and `signals`. The `time` field is empty because the data was logged using the `Structure` format and not the `StructureWithTime` format. You can use the `StructureWithTime` format when you need to save the time data along with the states data.

```
disp(x1s);
disp(x2s);
```

```
time: []
signals: [1x2 struct]
```

```
time: []
signals: [1x2 struct]
```

The structure `signals` field is an array of structures, with one structure for each block in the model that has state data. Each block data structure within the `signals` field contains a `values` field with the states data and a `blockName` field with the name of the block that produced that state data. You can extract the states data into a matrix that you can process similar to how you would had you logged the states using the Array format.

To fix the state ordering problem, first use the block names to sort the states data into a fixed order. For example, you could sort the states data so that the blocks are in alphabetical order, which will stay the same from one simulation to the next, regardless of the block sorted order.

```
[~, idx1] = sort({x1s.signals.blockName});
x1 = [x1s.signals(idx1).values];
```

```
[~, idx2] = sort({x2s.signals.blockName});
x2 = [x2s.signals(idx2).values];
```

```
isequal(x1, x2)
```

```
ans =
```

```
 logical
```

```
 1
```

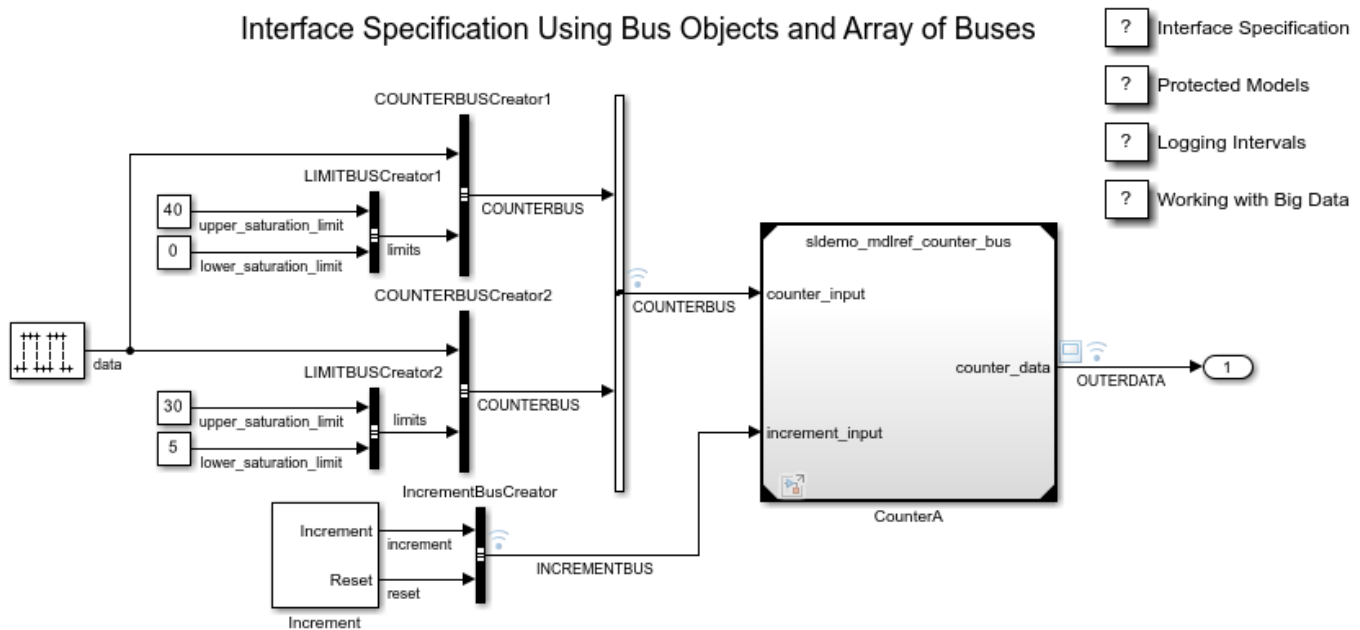

Once you reorder the signals fields alphabetically by block name, if you extract the values field data in the same order, you can then process the data similar to how you would when you use the Array format, but the order of the block states data does not change from one simulation to the next.

## Logging Intervals

This example shows how to specify logging intervals. Simulink® limits the data logging to the specified intervals.

### Open the Example Model

Open the example model, `sldemo_mdhref_bus`.

Copyright 1990-2019 The MathWorks, Inc.

### Set Logging Intervals

To reduce the amount of logged data, limit data logging to specific simulation time intervals. In this example, you specify two intervals to log the data of two system events triggered by the `increment` and `reset` signals. The first interval captures the first reset event. The second interval captures the behavior of the system after the increment event takes place and the signals reach the lower saturation limits. The intervals are based on the `increment` and `reset` signal values.

To set the **Logging Intervals** configuration parameter, in the Simulink Toolstrip, on the **Modeling** tab, click **Model Settings**. In the Configuration Parameters dialog box, on the **Data Import/Export** tab, enable the **Logging Intervals** parameter by selecting **Single simulation output**.

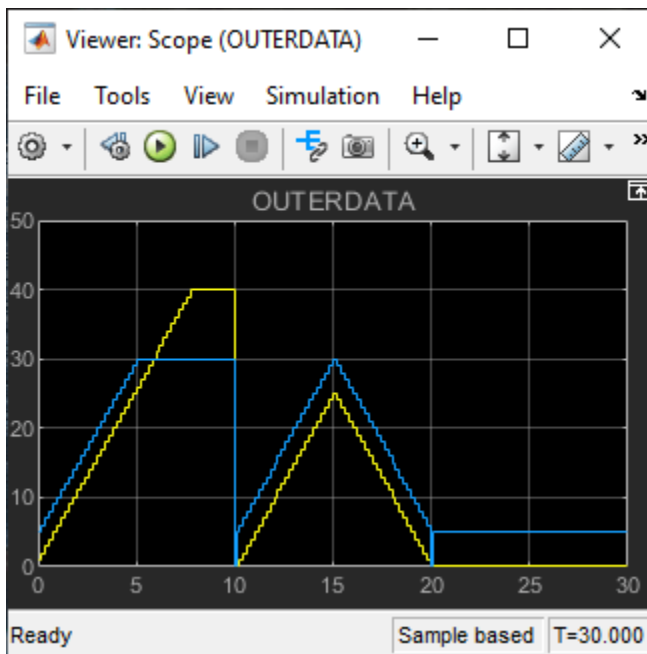

The **Logging Intervals** parameter value must be a real double matrix with two columns. The matrix elements must not be NaN. Each row defines the start and end times for an interval. Intervals must be disjoint and ordered.

For this example, set **Logging Intervals** to `[9, 10.5; 14.5, 30]`.

### Simulate the Model and View Results

Simulate the model.

OUTERDATA is a wide signal with two elements. The scope shows the values of the OUTERDATA signal during simulation. The scope does not honor the **Logging Intervals** setting.

The **Logging Intervals** setting is honored when logging time, root outputs, signals, data store memory, states, and other kinds of data. To display the logged values of OUTERDATA captured as part of signal logging, use the `stem` function, which ignores the interpolation settings of the data.

```
time = out.get('topOut').get('OUTERDATA').Values.Time;
data = out.get('topOut').get('OUTERDATA').Values.Data;
stem(time,data,':. ');
xlabel('Simulation Time');
xlim([0 35]);
ylabel('OUTERDATA');
ylim([0 45]);
```

## Working with Big Data

This example shows how Simulink models handle big data as input to and output from a simulation.

### Description of the Example

Big data refers to data that is too large to load into system memory all at once.

Simulink can produce big data as simulation output and consume big data as simulation input. To handle big data for both input and output, the entire data is stored in a MAT-file on the hard disk. Only small chunks of this data are loaded into system memory at any time during simulation. This approach is known as streaming. Simulink can stream data to and from a MAT-file. Streaming solves the memory issues because the capacity of the hard disk is typically much greater than the capacity of the random access memory.

This example shows how to handle big data in Simulink simulations. The logging to file capability is used to stream big data as the output of a simulation. Streaming from file then supplies big data as input to a simulation.

### Set up Logging to File

To stream output data to a MAT-file, enable logging to file.

Enable logging to file by selecting the "**Configuration Parameters > Data Import/Export > Log Dataset data to file**" option. You can also specify the name of the file that will contain the result.

The programmatic way to enable Logging to file is by setting the model parameter `LoggingToFile` to on.

When logging to file is enabled on a model, simulation of that model streams logged signals directly into the MAT-file. Additionally, if logging of States or Output is enabled and `SaveFormat` is specified as Dataset, those values are streamed into same the MAT-file.

### Simulate the Model

This example changes the directory to a temporary directory, which has write permissions. Then the example calls the `sim` command to simulate the model, logging to file.

Set the parameter `SignalLoggingName`, which specifies the name of the Dataset object to hold the result of signal logging, to `topOut`. Set the parameter `LoggingFileName`, which specifies the name of the resulting MAT-file, to `top.mat`. The `StopTime` parameter is set to 5000 seconds. For a more realistic big data example, the stop time would be a much larger value, which would result in many more data samples to log. `cd(tempdir);`

```

```

### Create a DatasetRef Object to Reference the Logged Dataset Within the MAT-file

Use a DatasetRef object to reference the resulting Dataset in the logged MAT-file. The benefit of using DatasetRef is that the referenced MAT-file is not loaded into memory. DatasetRef is a very light wrapper object for referencing a Dataset that is stored in a file. The alternative of calling the Load function on this file loads the entire file into memory, which might not be possible if this Dataset contains big data.

### Obtain a Reference to a Logged Signal

You can use { } indexing of DatasetRef object to reference individual signals within a Dataset, without loading these signals into memory. For example, to reference the seconds signal:

The Values field of sig2 is a SimulationDatastore object, which is a light-weight reference to the data of signal 2, stored on disk:

```
ans =
```

```
SimulationDatastore with properties:
```

```
 ReadSize: 100
 NumSamples: 50001
 FileName: 'C:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex3114572'
```

```
Data Preview:
```

Time	Data
0 sec	1 5
0.1 sec	1 5
0.2 sec	2 6
0.3 sec	2 6
0.4 sec	3 7
:	:

### Obtain More References to Other Logged Signals

This example uses some of these logged signals as inputs to the simulation of the referenced model. Create light-weight references for each of these. These are bus signals in the model and the resulting Values fields are structures of SimulationDatastore objects. Each structure reflects the hierarchy of the original bus signal.

### Create a New Dataset Object to Use as Simulation Input

Specify the input signals to a simulation through a Dataset object. Each element in this Dataset provides input data to the inport block corresponding to the same index. Create an empty Dataset ds and then place the references to the logged signals into it as elements number one and two.

Use { } indexing on the Dataset object to assign elements into appropriate positions.

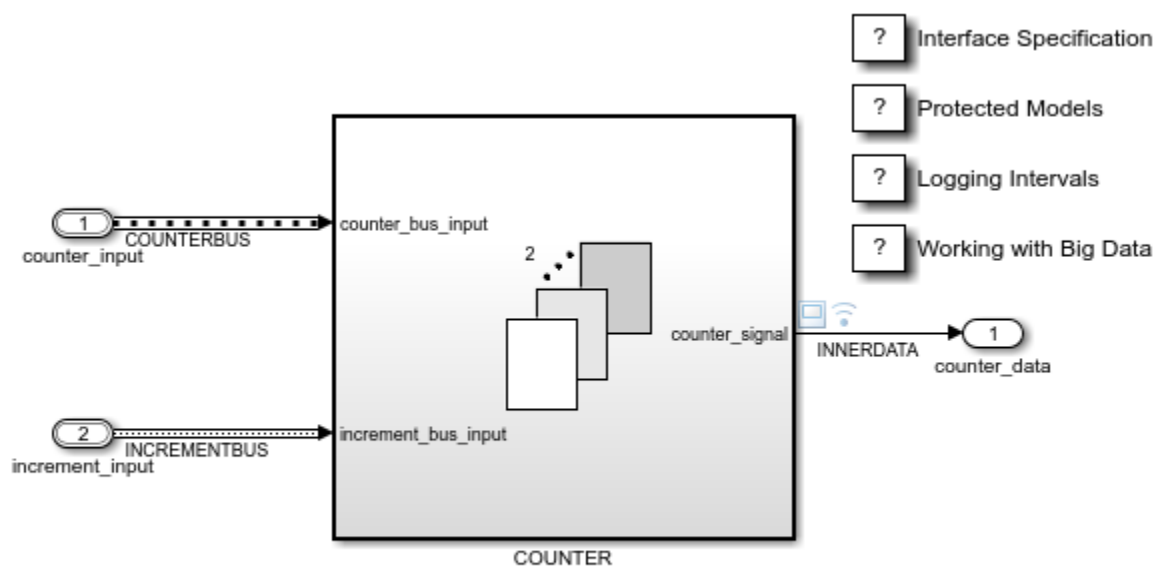

Within each element of the Dataset, you can mix references to signal data (e.g., SimulationDatastore object) with in-memory data (e.g., timeseries objects). To change one of the upper saturation limits from 30 to 37:

### Stream Input Data into Simulation

Now simulate the referenced model `sldemo_md\ref_counter_bus`, and use the Dataset `ds` as input. The data that is referenced by SimulationDatastore objects is streamed into the simulation without overwhelming the system.

The data for upper saturation limit is not streamed because that signal is specified as an in-memory timeseries. The change in saturation limit is reflected at around time 6 in the scope (the signal now saturates to a value of 37 instead of 30).

Copyright 1990-2019 The MathWorks, Inc.

### Summary

This example has demonstrated a round trip workflow of big data from and to simulation. Logging to persistent storage was used to stream data from the first simulation into a MAT-file. A second simulation was then set up to stream the data from that file as input. A more realistic example would have a larger value for the model `StopTime` parameter, resulting in a larger logged MAT-file. The second simulation could also be configured for a longer `StopTime`. However, even with the larger data files for output and input, the memory requirements for the longer simulations remain the same!

### MATLAB® Workflow

SimulationDatastore allows you to analyze the logged data incrementally in MATLAB. Going back to the reference to the second logged signal, assign the datastore to a new variable to simplify access to it.

### **Access the Data in Chunks**

SimulationDatastore allows incremental reading of the referenced data. The reading is done in chunks and is controlled by the ReadSize property. The default value for ReadSize is 100 samples (each sample for a signal is the data logged for a single time step of simulation). Change it to 1000 for this example. Each read of the datastore returns a timetable representation of the data.

### **Reset the SimulationDatastore Read Counter**

Each read on the datastore advances the read counter. You can reset this counter and start reading from the beginning:

### **Iterate Through All Data in the Datastore**

Use SimulationDatastore for incremental access to the logged simulation data for big data analysis in MATLAB. You can iterate over the entire data record and chunks:

## If-Then-Else Blocks

This example shows the effect of feeding a sine wave into If Action Subsystem blocks. It is designed to illustrate the similarity between the If Action Subsystem block and the Enabled Subsystem block.

A pulse generator is connected to an If block, which compares the input to zero. If the input is positive, as specified by the `if` condition, then the If Action Subsystem `Abs` is activated, which outputs the absolute value of the sine wave input signal. If the input to the If block is not positive, as specified by the `else` condition, then the If Action Subsystem `Saturation between -0.75 and 0.75` is activated, which outputs a clipped version of the sine wave signal using a Saturation block.

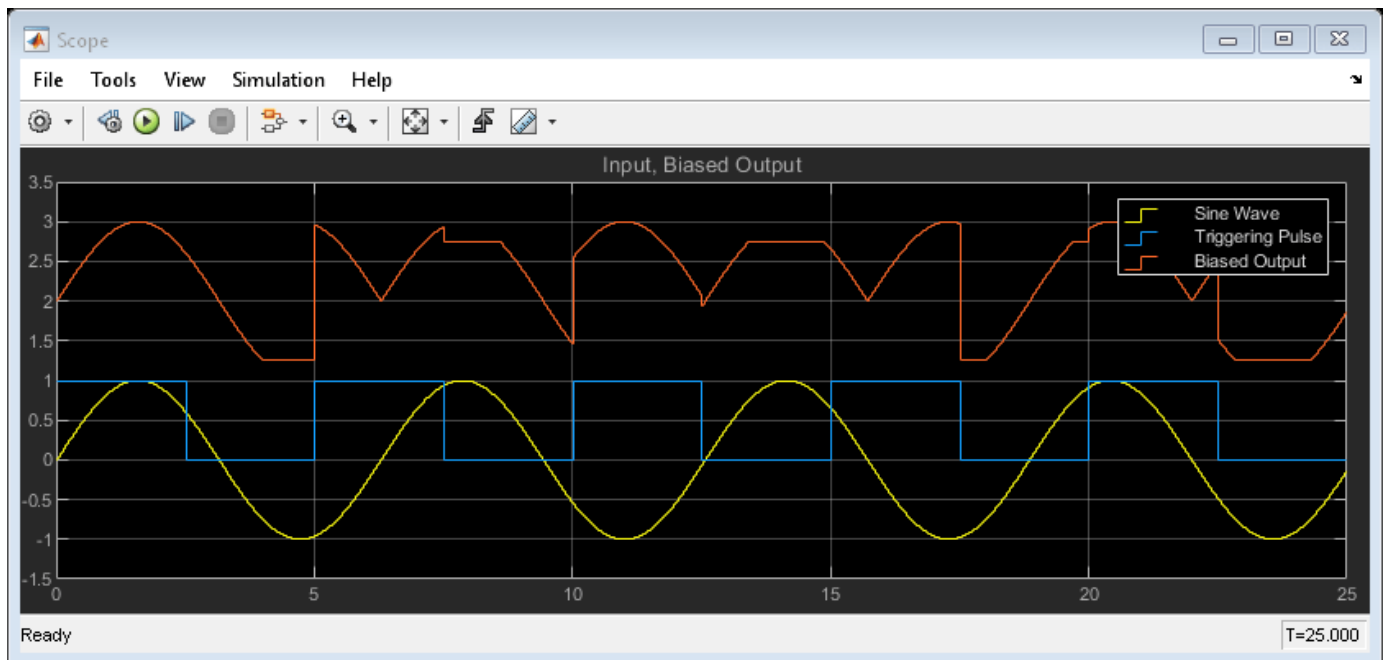

The outputs of the two subsystems are never active at the same time and are merged into one signal with a Merge block. The output signal is then biased by +2.

The scope shows the sine wave input, the triggering pulse input, and the merged and biased output. When the pulse is on, the output is the absolute value of the sine wave. When the pulse is off, the output is the clipped version of the sine wave. In each case, the output is biased by +2.

### If Block Example

- "Simulink Subsystem Semantics" on page 13-371

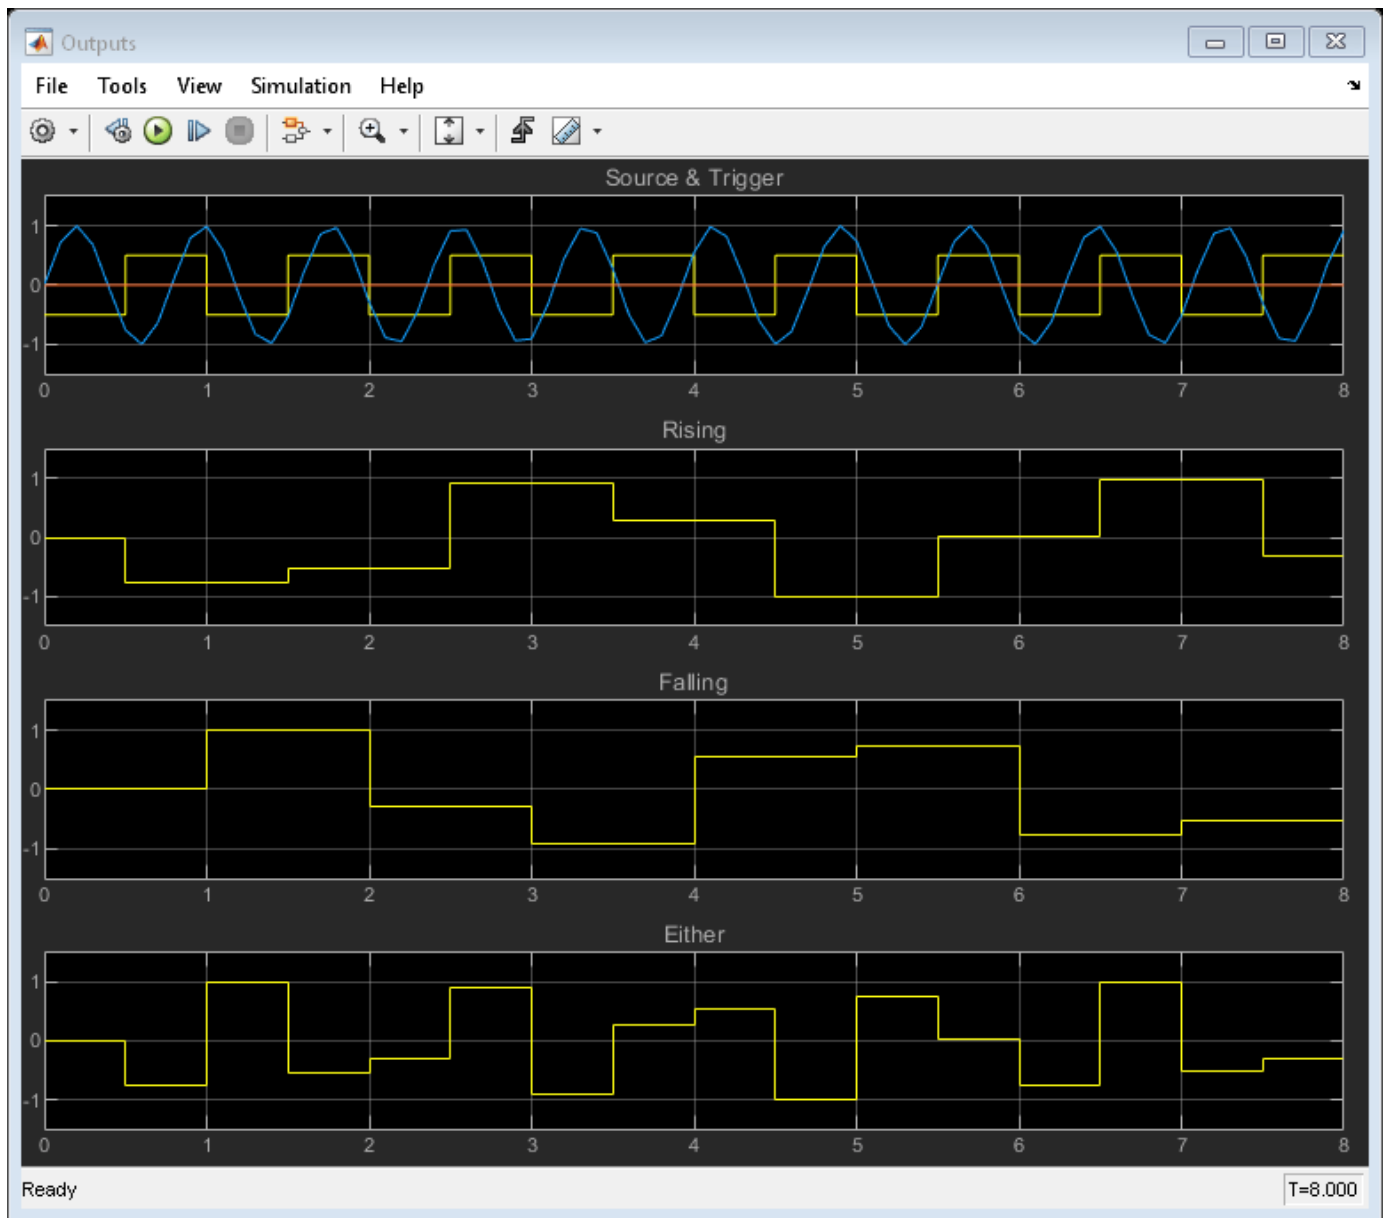

## Triggered Subsystems

This model shows triggered subsystems and describes the different trigger types. A triggered subsystem is executed for a single time step whenever the trigger port transitions in a specified direction. The transition of the trigger port may occur when the direction of the transition is rising, falling, or either rising or falling. A rising transition occurs when the trigger signal transitions from zero or below to a positive value. A falling transition occurs when the trigger signal transitions from zero or above to a negative value.

After running the simulation, look closely at the top plot in the scope. This shows a sine wave, a waveform, and the grounded value of zero. As the waveform transitions through zero, each of the subsystems is triggered appropriately. The output of each subsystem is equal to the current value of the sine wave at that time.

Copyright 1990-2015 The MathWorks, Inc.

## Enabled Subsystems

This example shows what happens when a sine wave is fed into an enabled subsystem. After running the simulation, the scope shows three plots.

The first of these plots shows the original sine wave and the absolute value of the original sine wave offset by two. The absolute value of the sine wave is shown only when the subsystem is enabled. This occurs between 0 and 2.5 seconds, and between 5 and 7.5 seconds. When the subsystem is not enabled, the output of the subsystem is reset to 0. The value of 0 is determined by the initial condition of the output. You can see when the subsystem is enabled by looking at the second plot. A value of 1 indicates that it is enabled.

The second plot shows the original value of the enable signal. When the signal is towards the top of the plot, the subsystem related to the first plot is enabled. When the signal is towards the bottom of the plot, the subsystem related to the third plot is enabled. The difference in when the subsystems are enabled is caused by the logical NOT block.

The third plot shows the original sine wave and the saturation limited sine wave offset by two. The saturated value of the sine wave is shown only when the subsystem is enabled. This occurs between 2.5 and 5 seconds, and between 7.5 and 10 seconds.

Copyright 2004-2015 The MathWorks, Inc.

## Advanced Enabled Subsystems

This model shows what happens when a sine wave is fed into an enabled subsystem. The four subsystems in the model contain integrators, either discrete or continuous as described by the subsystem name. After running the simulation, the two scopes show the results for the discrete enabled subsystems (top scope) and continuous enabled subsystems (bottom scope).

Each scope shows the output for all combinations of the states and outputs of the enabled subsystem being either held or reset when the subsystem is disabled. The colors on the scope correspond to the following state and output configurations:

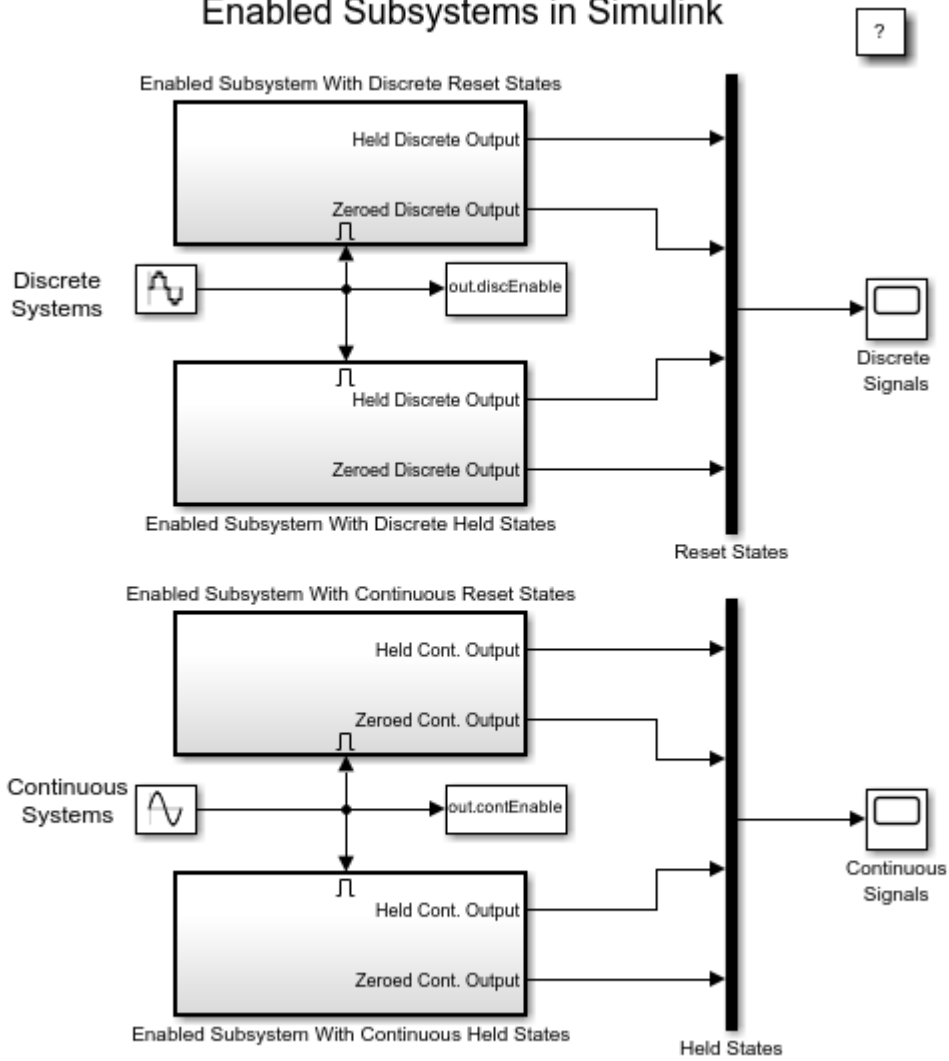

Yellow: Reset states; Held outputs

Purple: Reset states; Reset outputs

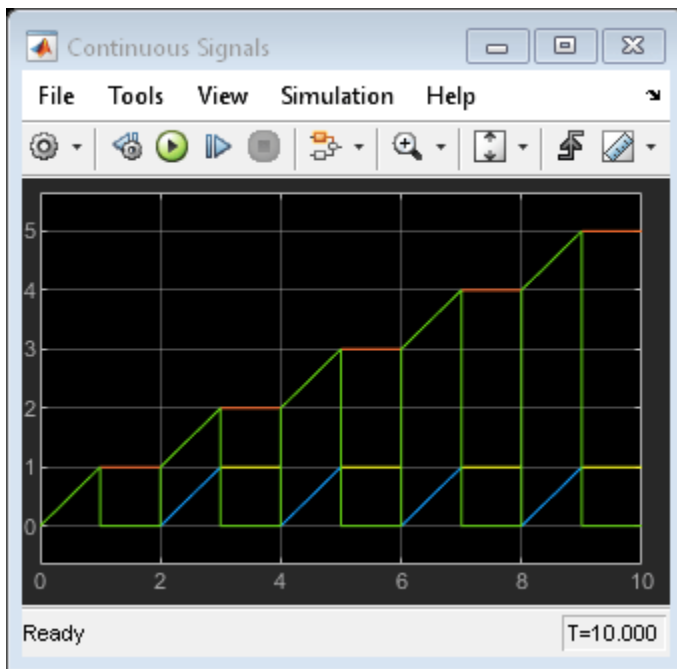

Cyan: Held states; Held outputs

Red: Held states; Reset outputs

## Enabled Subsystems in Simulink

Copyright 2004-2015 The MathWorks, Inc.

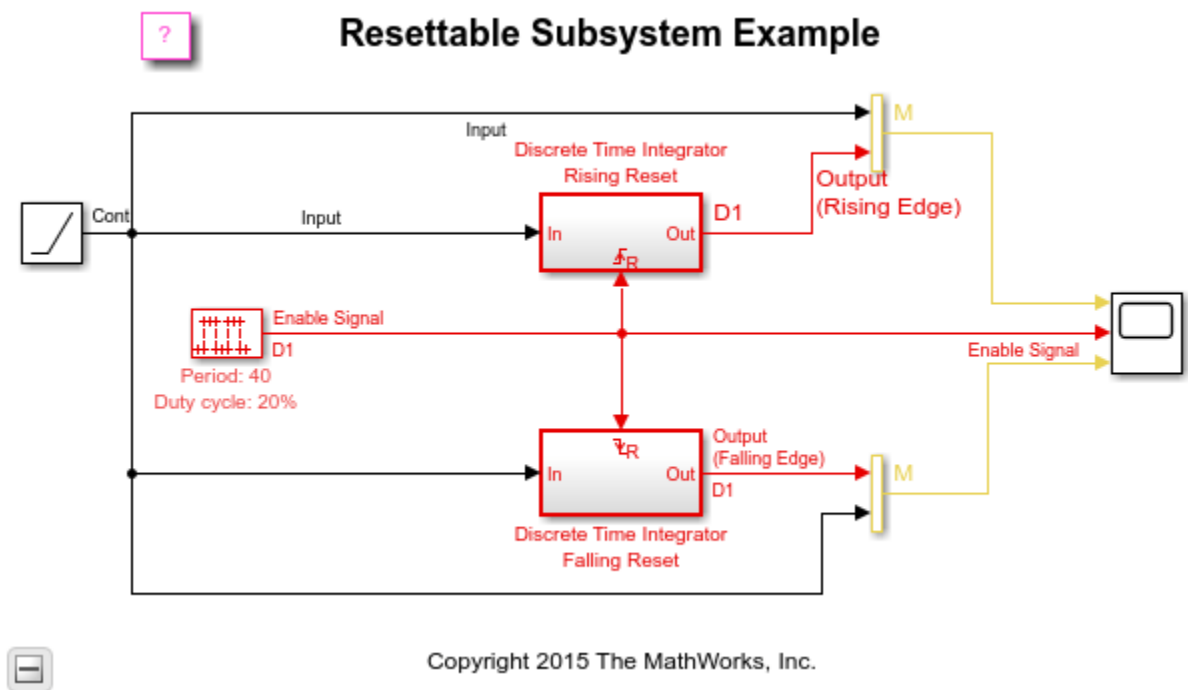

## Resettable Subsystems

This example shows how to use two resettable subsystems to implement a ramp signal. Consider using resettable subsystems when you want to conditionally reset the states of all blocks within a subsystem to their initial condition. A resettable subsystem executes at every time step but conditionally resets the states of blocks within it when a trigger signal occurs at the reset port. For more information, see “Using Resettable Subsystems”.

After running the simulation, the scope shows three plots. The top and bottom plots show the original ramp as a reference, along with its integration. The subsystems corresponding to the top and bottom plots reset on every rising and falling edge of the pulse, respectively. When each subsystem resets, the state of the Integrator block is set to its initial condition value, which is 0. Refer to the middle plot to determine when each subsystem resets.

The reset happens for blocks within the subsystem, without the need for each block to have its own reset port. This provides a more convenient way of handling resets at a subsystem level.

## Block Priority

This model shows what happens when blocks are assigned different priorities. The block priority affects the order in which the blocks are executed. You can set the block priority through the Block Properties dialog. A smaller number indicates a higher priority.

The block sorting order is calculated only at the beginning of a simulation. For this reason, changes to a block's Priority property are only updated when the simulation is started. Double click on the green block to change the priority levels for the blocks and see what happens.

Inside of each triggered subsystem is an S-Function which controls the coloring of the blocks and also slows down the simulation. The priority level of the block is displayed using the format attribute string that can be set in the Block Properties dialog.

## Monitoring Ink Status on a Shared Printer Using Simulink Functions

This example shows how clients, in this case three computers, can send jobs to a server, a printer, and receive status from that server. This example highlights how Simulink functions can be called from different subsystems and interact in both Simulink® and Stateflow®. (Note that when you simulate the example, Stateflow might generate code in the current working folder.)

The computers each generate randomly sized print jobs at regular intervals. The printer interacts with the computers through two Simulink functions on the Simulink canvas and one exported graphical function in Stateflow.

The clients use Function Caller blocks to invoke the `addPrintJob` interface of the printer. The client-server interaction modeled by this call may have a negative return value if the printer has run out of ink.

The example also shows how to interface Simulink and Stateflow using functions.

The implementation of `addPrintJob` uses a Function Caller block to invoke `queuePrintJob`, a Stateflow exported graphical function. The `queuePrintJob` function interacts with other content in the chart using a local chart variable `work`.

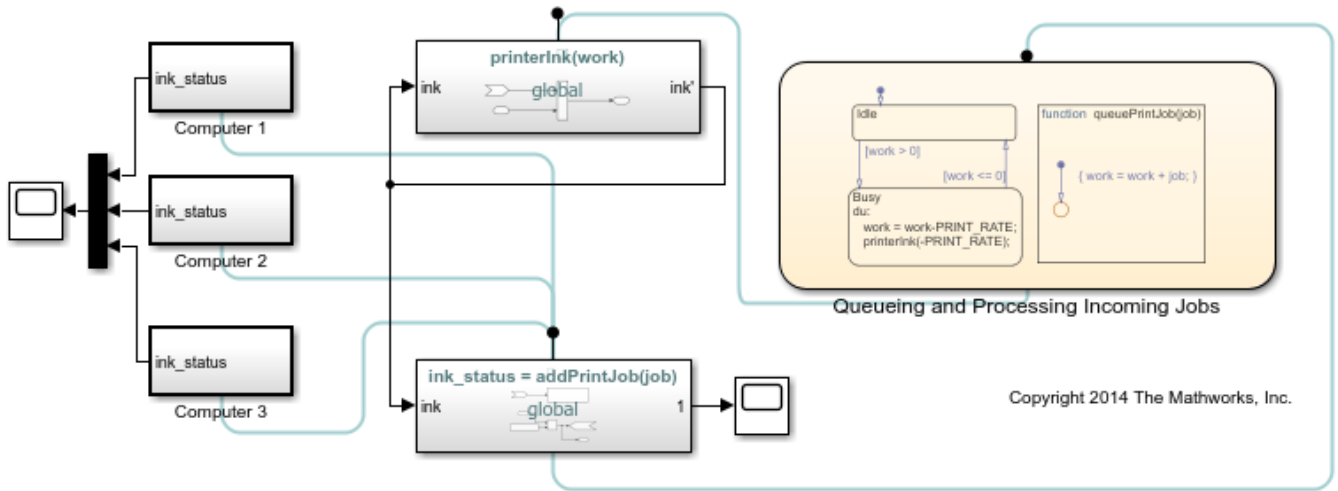

The implementation of the chart makes a call to `printerInk`, a Simulink function, which uses the graphical input and outputs to interact with the `addPrintJob` function.

You can also visualize and debug Simulink functions.

To enable the visualization lines connecting functions and their respective callers, in the Simulink Editor, on the **Debug** tab, under **Information Overlays**, click **Function Connectors**.

The Sequence Viewer block shows where calls to functions are generated and which functions are called at different times. This information allows you to understand the flow of calls with respect to time and analyze the arguments sent during these calls to functions.

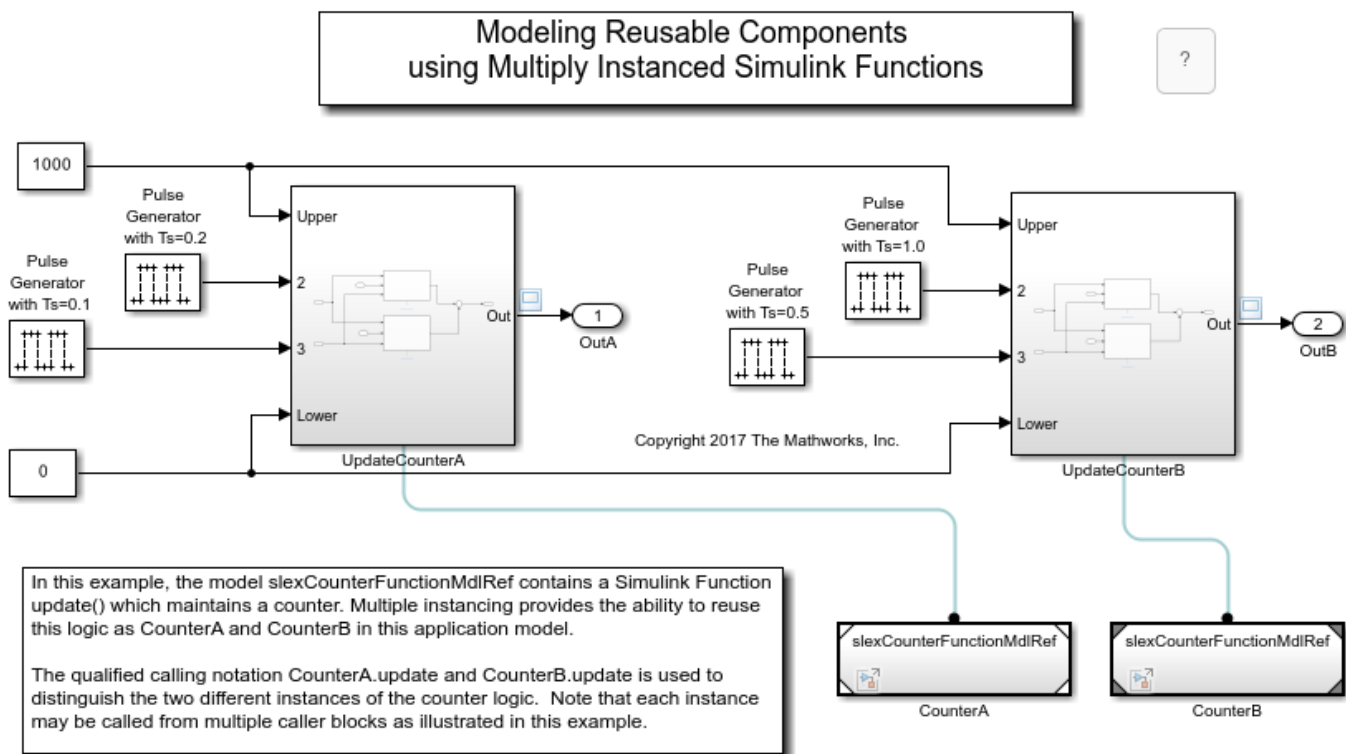

Monitoring Ink Status on a Shared Printer Using Simulink Functions

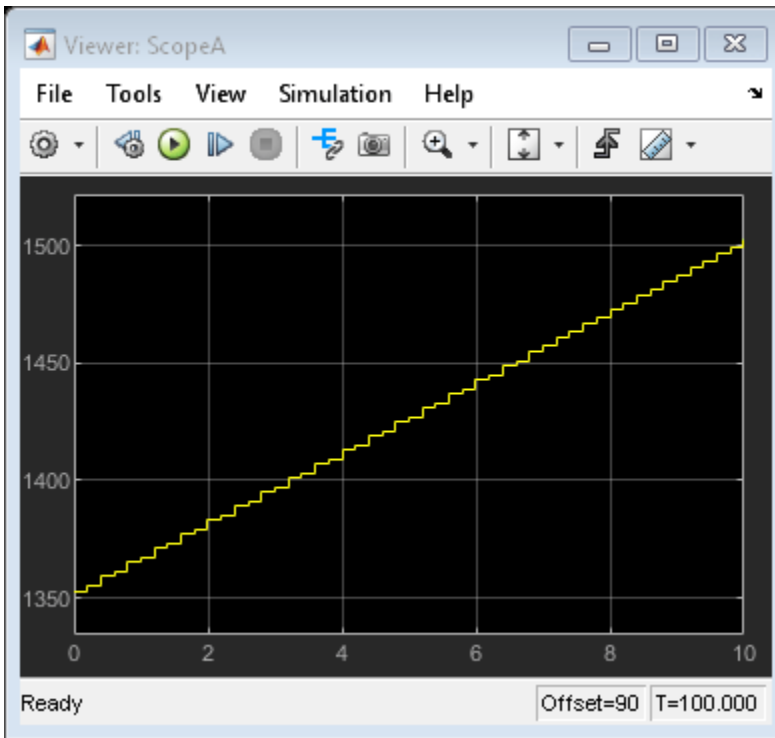

# Model Reusable Components Using Multiply Instanced Simulink Functions

In this example, the model `slexCounterFunctionMdlRef` contains the Simulink® function `update`, which maintains a counter. Multiple instancing provides the ability to reuse this logic as `CounterA` and `CounterB` in this example model.

The qualified calling notation `CounterA.update` and `CounterB.update` is used to distinguish the two different instances of the counter logic. As illustrated in this example, each instance can be called from multiple caller blocks.

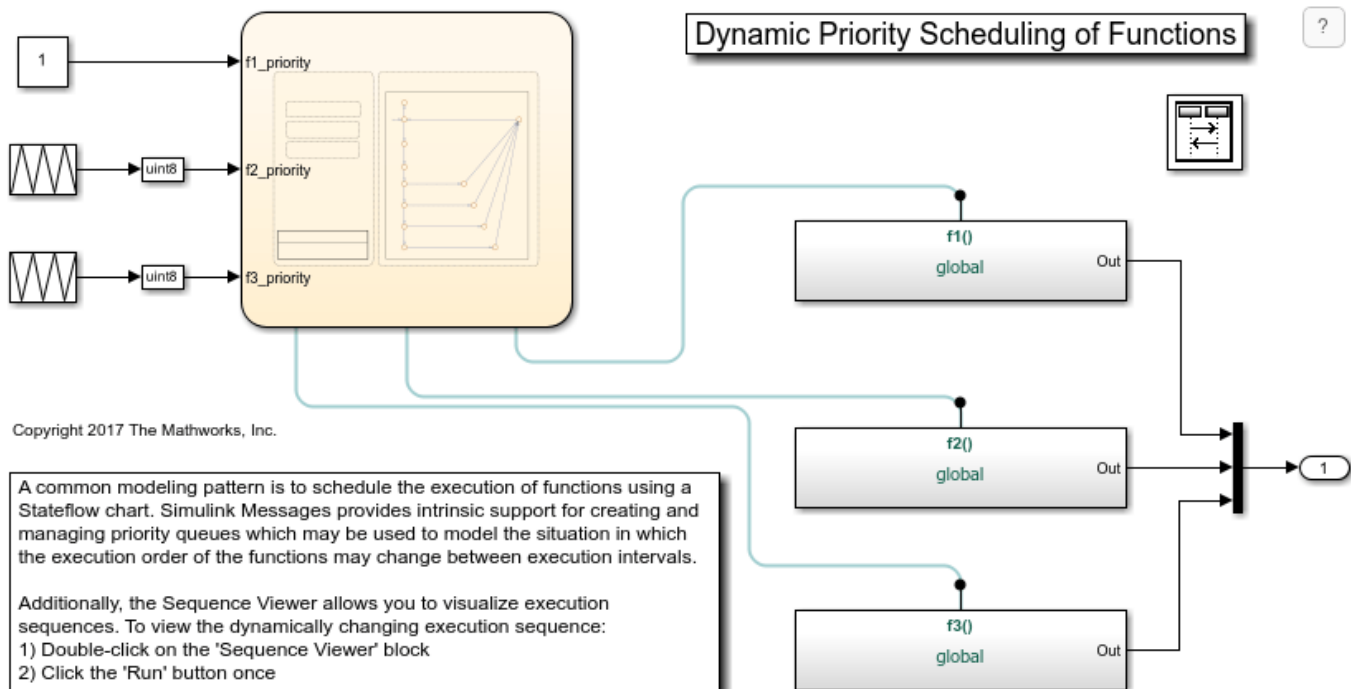

## Dynamic Priority Scheduling of Functions

This example shows a common modeling pattern to dynamically schedule the execution of functions using a Stateflow® chart.

### Overview

Simulink messages provide intrinsic support for creating and managing priority queues, which may be used to model a situation in which the execution order of the functions may change between execution intervals.

Additionally, the Sequence Viewer allows you to visualize execution sequences. To view the dynamically changing execution sequence: 1. Double-click on the 'Sequence Viewer' block 2. Click the 'Run' button once

## Component-Based Modeling with Model Reference

This example walks you through simulation and code generation of a model that references another model multiple times. In this example, Simulink® generates code for accelerated simulation, and Simulink® Coder™ generates code that can be deployed in standalone applications.

### Model Reference Behavior

Model Reference has several advantages over subsystems:

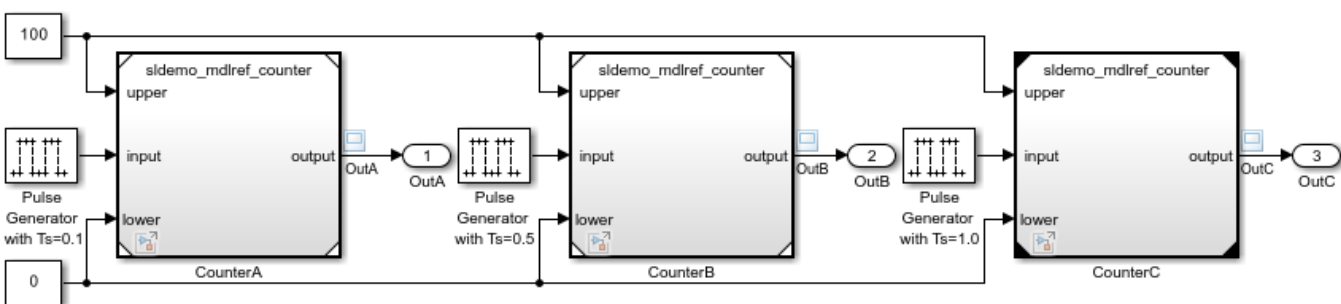

- You can develop the referenced model independently from the models in which it is used.
- You can reference a model multiple times in another model without having to make redundant copies.
- Multiple models can reference a single model.
- The referenced model is not loaded until it is needed. This incremental loading speeds up model load times.
- If a model is referenced in accelerator mode, Simulink creates special binaries to be used in simulations. If the referenced model has not changed since the binaries were created, and the binaries are therefore up to date, no code generation occurs when models that use these binaries are simulated or compiled. This process is called *incremental code generation*. The use of binaries makes updating and simulating the model faster and increases modularity in code generation.
- Generating code for a model with Model blocks also takes advantage of incremental code generation.

### Incremental Loading

Open the example model.

```
open_system('sldemo_mdhref_basic')
```

### Component-Based Modeling with Model Reference

Copyright 1990-2014 The MathWorks, Inc.

This model contains three Model blocks: CounterA, CounterB and CounterC. These blocks reference the same model, `sldemo_mdhref_counter`, which is a separate model and not a subsystem of `sldemo_mdhref_basic`.

To determine what models are loaded in memory after opening the top model in the model hierarchy, enter this command:

```
get_param(Simulink.allBlockDiagrams, 'Name')
```

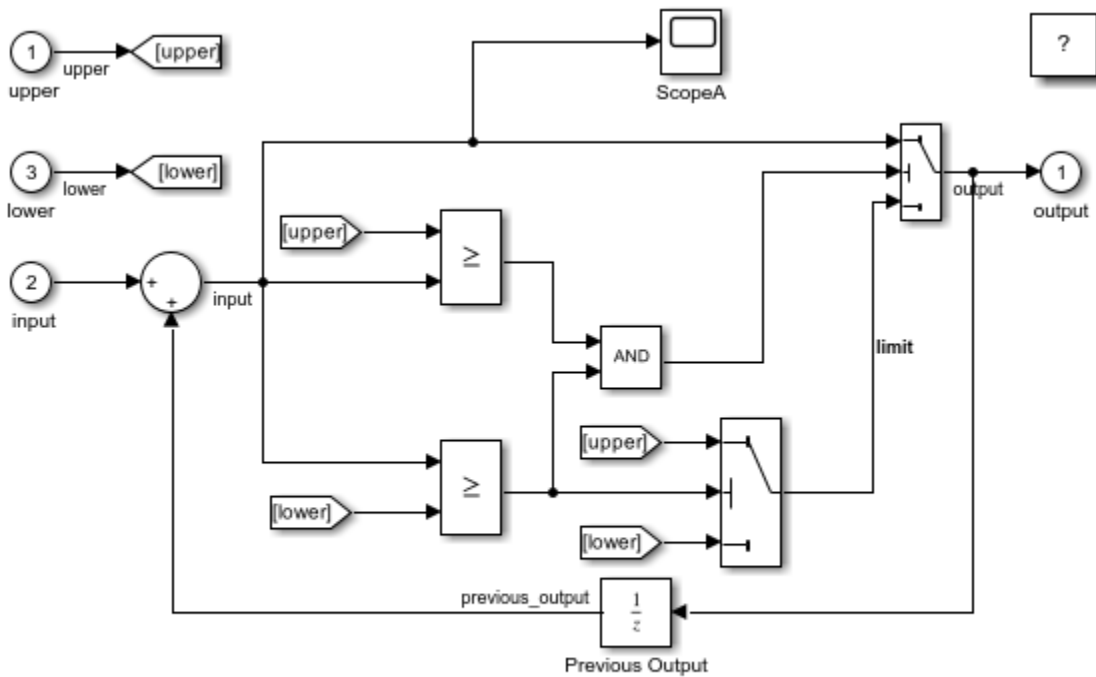

ans =

```
'sldemo_mdref_basic'
```

The referenced model is not listed because it is not loaded.

Open the referenced model by double-clicking on any Model block or by entering this command:

```
open_system('sldemo_mdref_counter')
```

Copyright 1990-2014 The MathWorks, Inc.

Query the models loaded in memory again.

```
get_param(Simulink.allBlockDiagrams, 'Name')
```

ans =

```
2x1 cell array
```

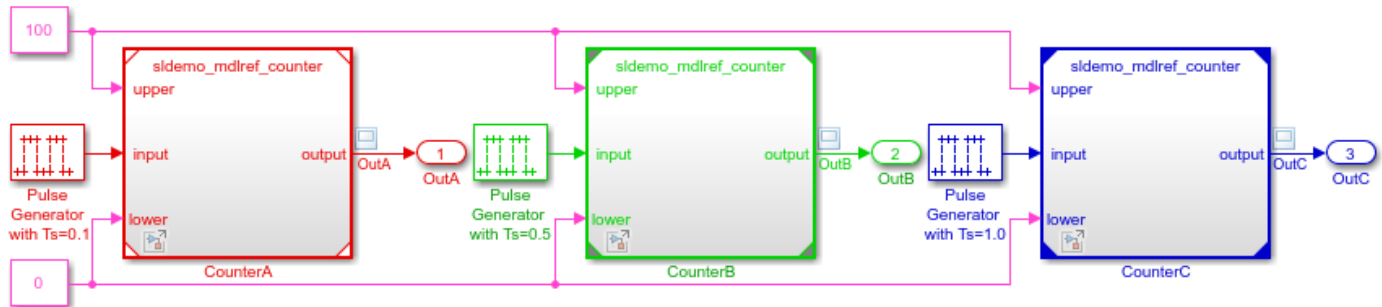

```
{'sldemo_mdref_counter'}
{'sldemo_mdref_basic' }
```

The referenced model is now listed, demonstrating that models are loaded incrementally as they are needed.

### Inherited Sample Times

Navigate back to the parent model `sldemo_mdhref_basic`.

`sldemo_mdhref_basic` is configured to display sample time colors when it is compiled. On the **Debug** tab, click **Update Model**.

The Model blocks inherit different sample times because the referenced model `sldemo_mdhref_counter` does not explicitly specify a sample time.

### Simulation Through Code Generation (Does Not Require Simulink Coder)

Model blocks have a **Simulation mode** parameter that controls how the referenced model is simulated. If the parameter is set to `Normal`, the referenced model is simulated in interpreted mode. If the parameter is set to `Accelerator`, the referenced model is simulated through code generation. This process uses a binary file called a *simulation target* for each unique model referenced in accelerator mode. Generating a simulation target does not require a Simulink Coder license.

In this model, CounterA and CounterB reference `sldemo_mdhref_counter` in normal mode, which is indicated by the hollow corners on the Model block icons. The other instance, CounterC, references `sldemo_mdhref_counter` in accelerator mode, which is indicated by the filled corners on the Model block icon.

You can create the simulation target for the `sldemo_mdhref_counter` model by performing any of these actions:

- Updating `sldemo_mdhref_basic`
- Simulating `sldemo_mdhref_basic`

To build the simulation target programmatically, use this command:

```
slbuild('sldemo_mdhref_counter', 'ModelReferenceSimTarget')
```

Once the simulation target is built, subsequently simulating or updating `sldemo_mdhref_basic` does not trigger a rebuild of the simulation target unless `sldemo_mdhref_counter` has changed.

If all three instances of the referenced model were set to simulate in normal mode, the simulation target would not be built.

### Code Generation for Standalone Applications (Requires Simulink Coder)

When creating a standalone executable for `sldemo_mdref_basic`, the build first generates the code and binaries for the *model reference coder target* of `sldemo_mdref_counter`. Generating a model reference coder target requires a Simulink Coder license.

You can build the model reference coder target for `sldemo_mdref_counter` and the standalone executable for `sldemo_mdref_basic` by performing any of these actions:

- Building the standalone executable for `sldemo_mdref_basic`.
- Building the model reference coder target of `sldemo_mdref_counter`, then building the standalone executable for `sldemo_mdref_basic`.

To build the standalone executable programmatically, use this command:

```
slbuild('sldemo_mdref_basic', 'StandaloneCoderTarget')
```

Once the model reference coder target is built, subsequently building `sldemo_mdref_basic` does not trigger a rebuild of the model reference coder target unless `sldemo_mdref_counter` has changed. The code generated for the referenced model `sldemo_mdref_counter` is reused.

The code generation report for `sldemo_mdref_basic` links to the report for `sldemo_mdref_counter` in the **Referenced Models** section.

## Viewing Signals in Model Reference Instances

This example shows how to use the Simulation Data Inspector to view and analyze signals in referenced models. The Simulation Data Inspector relies on signal logging so this example shows how to configure your model to log signals in referenced models.

```
origdir = pwd;
```

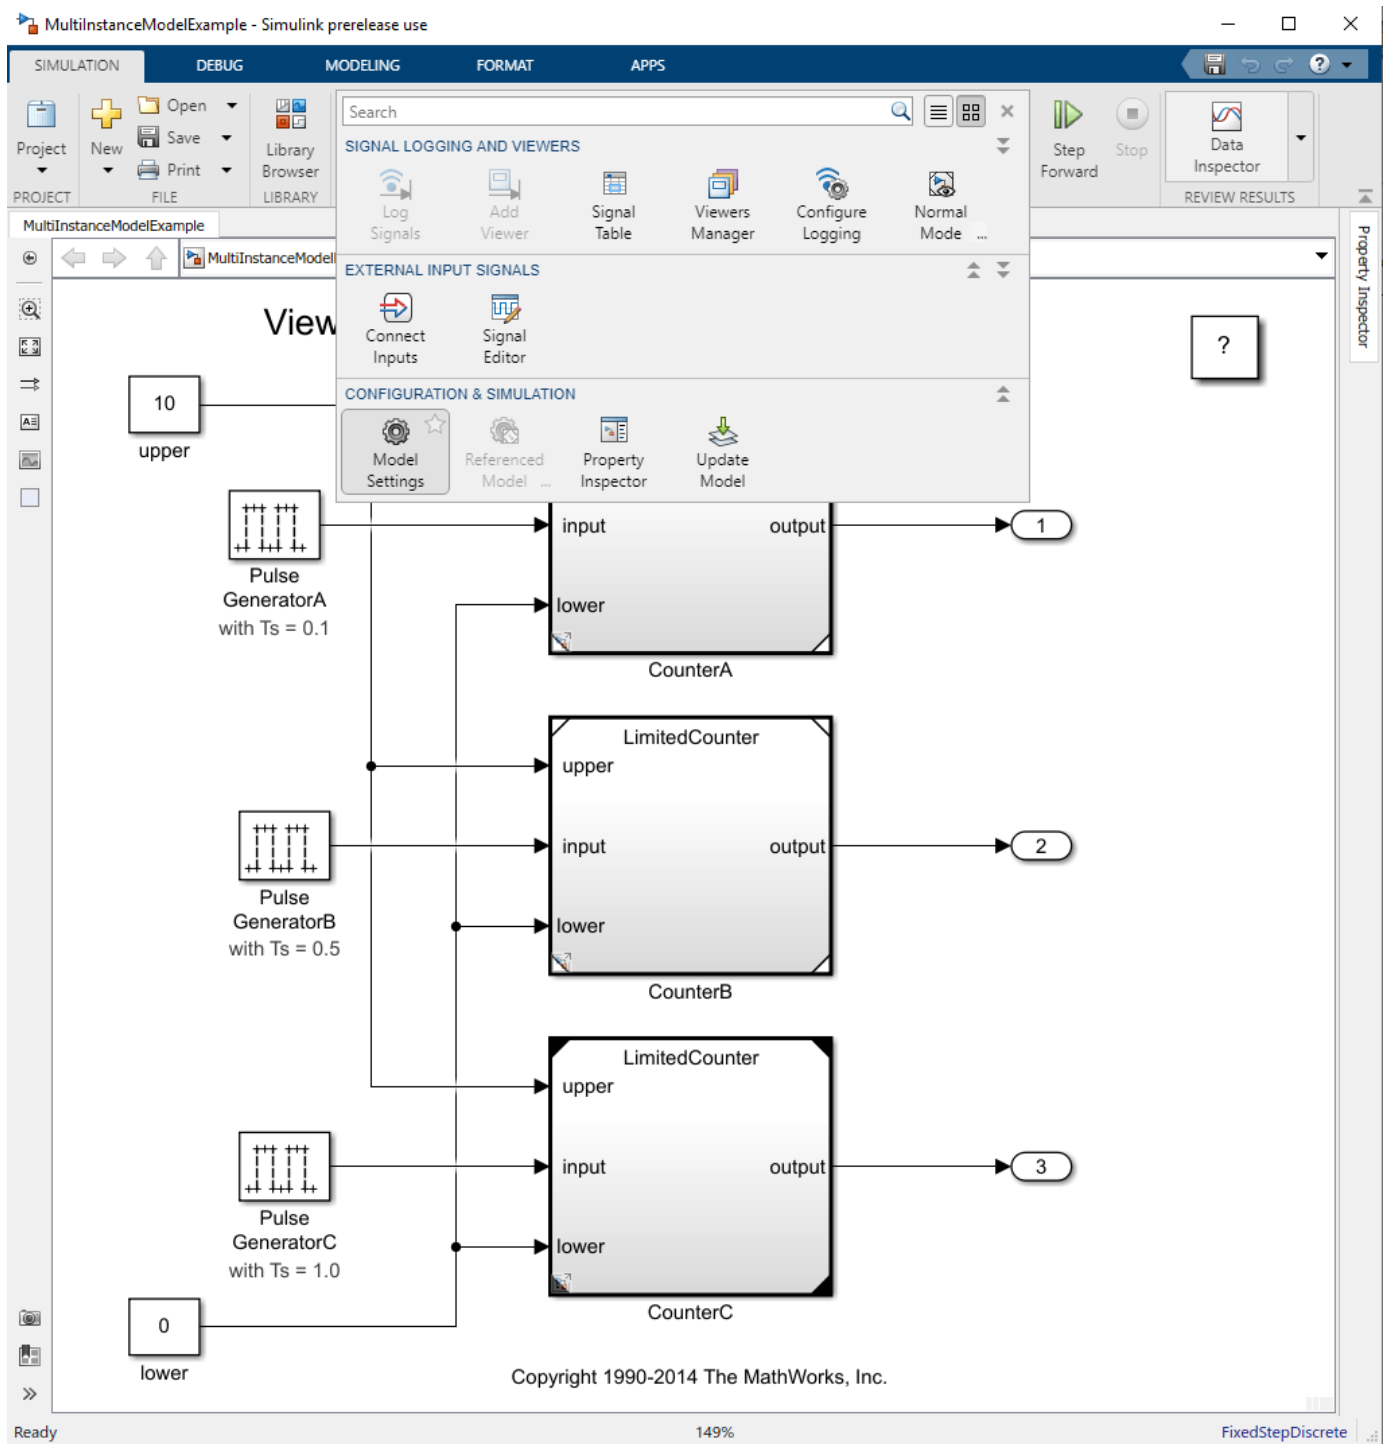

### Configure Signals to Log in Referenced Models

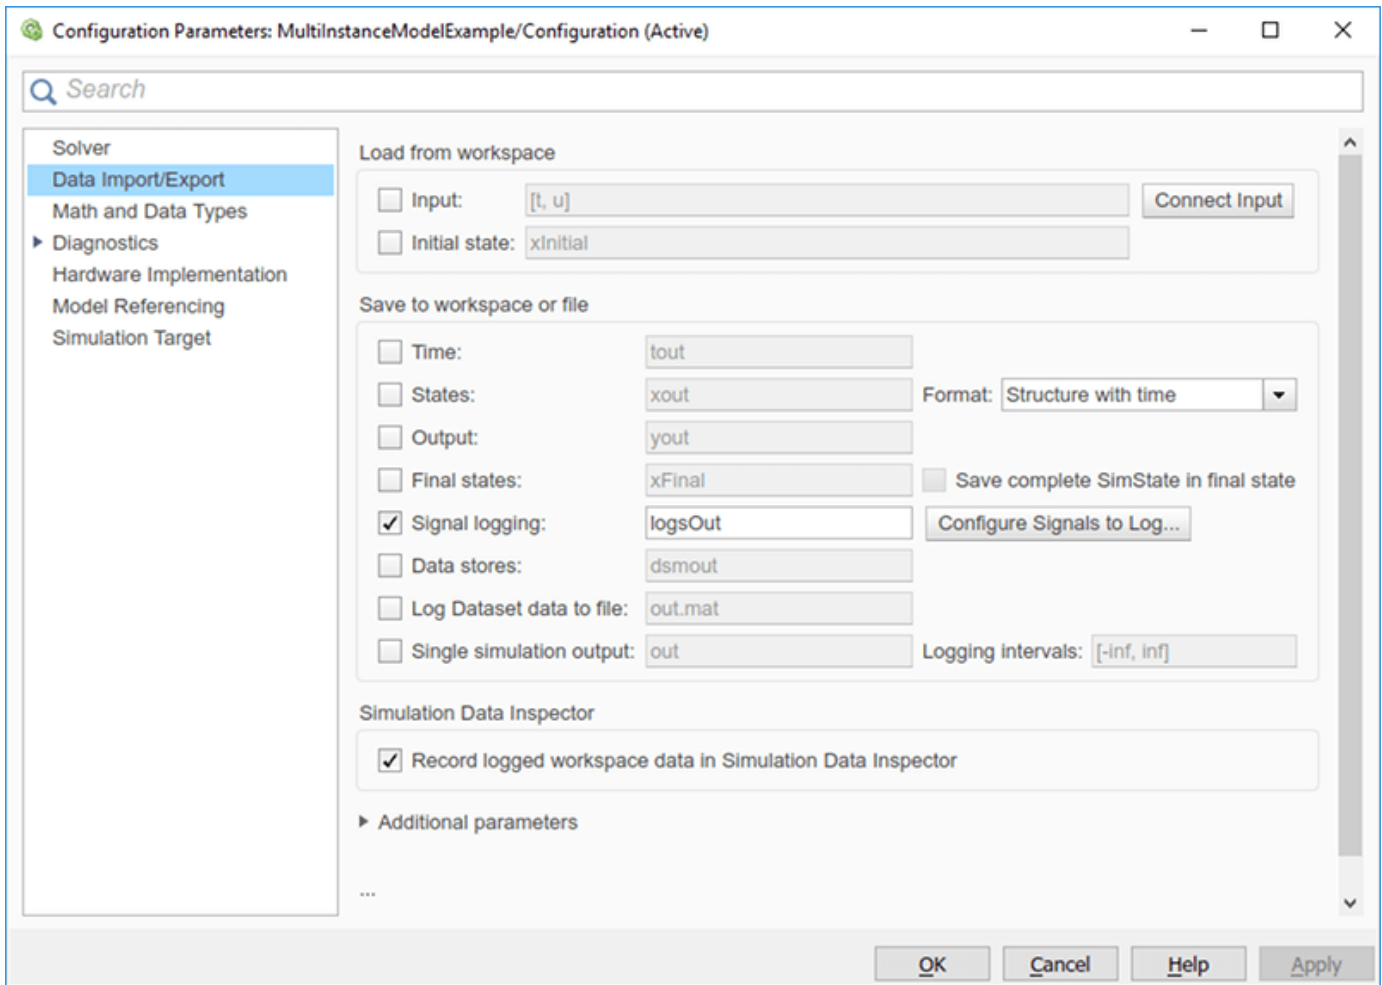

The first task in setting up a referenced model to view signals using the Simulation Data Inspector is to configure that model for logging. To do that, edit the referenced model and mark the signals for logging. Four signals are already marked for logging in the referenced model. To mark the `raw_output` signal for logging, select the signal. Then, on the **Simulation** tab, select **Log Signals**.

Once the signals to log have been selected in the referenced model, the next step is to select which signals to actually log from the topmost model in the hierarchy. In the top model, on the **Modeling** tab, click **Model Settings**.

On the **Data Import/Export** pane, click the **Configure Signals to Log...** button to activate the Simulink Signal Logging Selector dialog.

There are two Logging modes that can be used when logging signals in referenced models. The first is **Log all signals as specified in model**, which will honor any logging settings that were made in referenced models. If you need to override any of those settings, such as selecting only a subset of logged signals, then you should use the **Override signals** mode. In this mode, you are given the ability to select a subset of loggable signals and configure their properties, such as decimation and name.

### Viewing and Analyzing Logged Signals Using the Simulation Data Inspector

Once logging has been configured for a model hierarchy and all changes to the models have been saved, the model can be simulated. The simulation creates a Dataset object in the base workspace. You can analyze and view the logged data in this object using standard MATLAB® tools. In addition, Simulink® provides the Simulation Data Inspector for viewing and analyzing data created from simulations.

With the Simulation Data Inspector, you can:

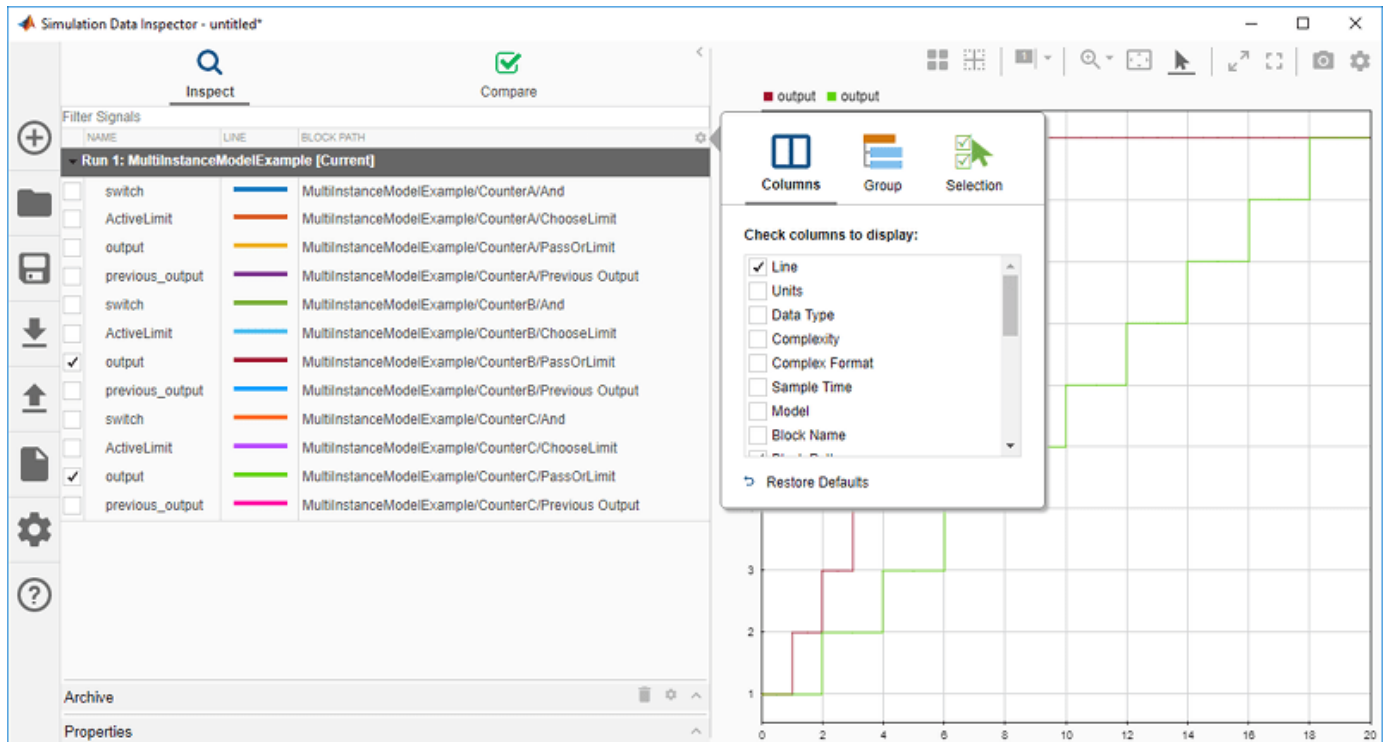

- View signal traces for any logged signals
- Visually compare signal values for any logged signals
- Compare signal values collected over multiple simulations

For example, you can use the Simulation Data Inspector to view the `output` signal of two of the instances of the model `LimitedCounter`. In the Simulation Data Inspector, you can see that `CounterA` increases more rapidly than `CounterB`. This behavior is expected because the Pulse Generator driving this model is running at a faster rate.

You can configure what to display in the inspect table by clicking the gear icon at the right top of the table.

Another useful tool that the Simulation Data Inspector provides is the ability to compare multiple simulation runs. This functionality can help you understand how changes to your model affect results. For example, you can change the value of the upper limit of the counter models to 8 and simulate the model again to see how that affects output values. To change the value, double click on the block `MultiInstanceModelExample/upper` and modify the Value parameter to 8.

Now if you compare the results from the first simulation for the output of the CounterA instance of `LimitedCounter`, you see that the upper limit of this signal has changed from 10 to 8, as expected. Because the tolerances are set to zero, the red octagon next to each signal indicates that the values have changed between runs.

## Visualize Model Reference Hierarchies

This example shows how to view, explore, and analyze model dependencies using the Dependency Analyzer. It shows how to find referenced models and interact with the dependency graph.

### Open Model

Open the example model `sldemo_mdref_depgraph`, which contains multiple referenced models in a model hierarchy.

Copyright 1990-2014 The MathWorks, Inc.

### Find Referenced Models

Use the `find_mdrefs` function to programmatically find referenced models and Model blocks. For example, enter this command in the MATLAB Command Window:

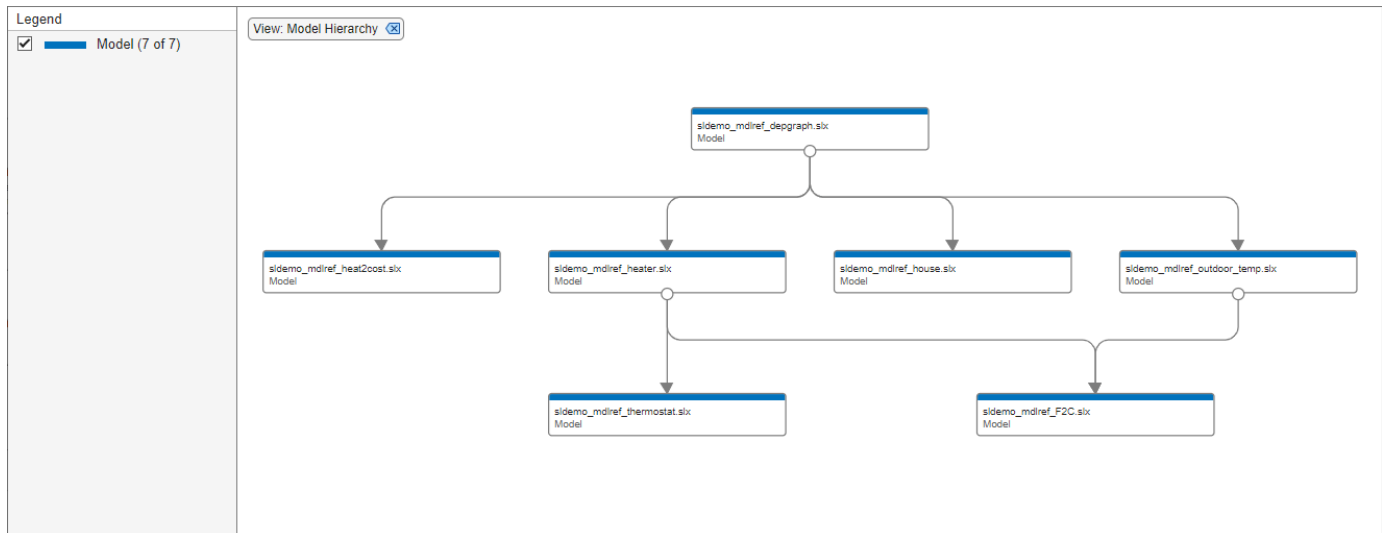

```
[refMdl, modelBlks] = find_mdrefs('sldemo_mdref_depgraph')
```

`find_mdrefs` returns two cell arrays, `refMdl` and `modelBlks`. `refMdl` contains the names of all models that are directly or indirectly referenced by `sldemo_mdref_depgraph`. By default, the last element in `refMdl` is the name of the input model. `modelBlks` contains block paths for all Model blocks in the top model and all referenced models.

## View Model Reference Dependency Graph

To view the dependency graph for the `sldemo_mdhref_depgraph` model, perform one of these actions to open the Dependency Analyzer for a model:

- Use the `depview` function.
- In the **Modeling** tab, in the **Design** section, click **Dependency Analyzer**.

In the dependency graph, the boxes represent Simulink models. The arrows indicate dependencies. For example, the link from `sldemo_mdhref_depgraph` to `sldemo_mdhref_house` indicates that `sldemo_mdhref_depgraph` references `sldemo_mdhref_house`. If the model references libraries, subsystems, or protected models, the dependency graph shows them in the hierarchy.

In this view, only one box exists for each model in the graph and at most one arrow exists from one box to another box. The dependency graph does not show if multiple references exist from one model to another model. This view does not show which models are referenced in normal mode and which models are referenced in accelerator mode.

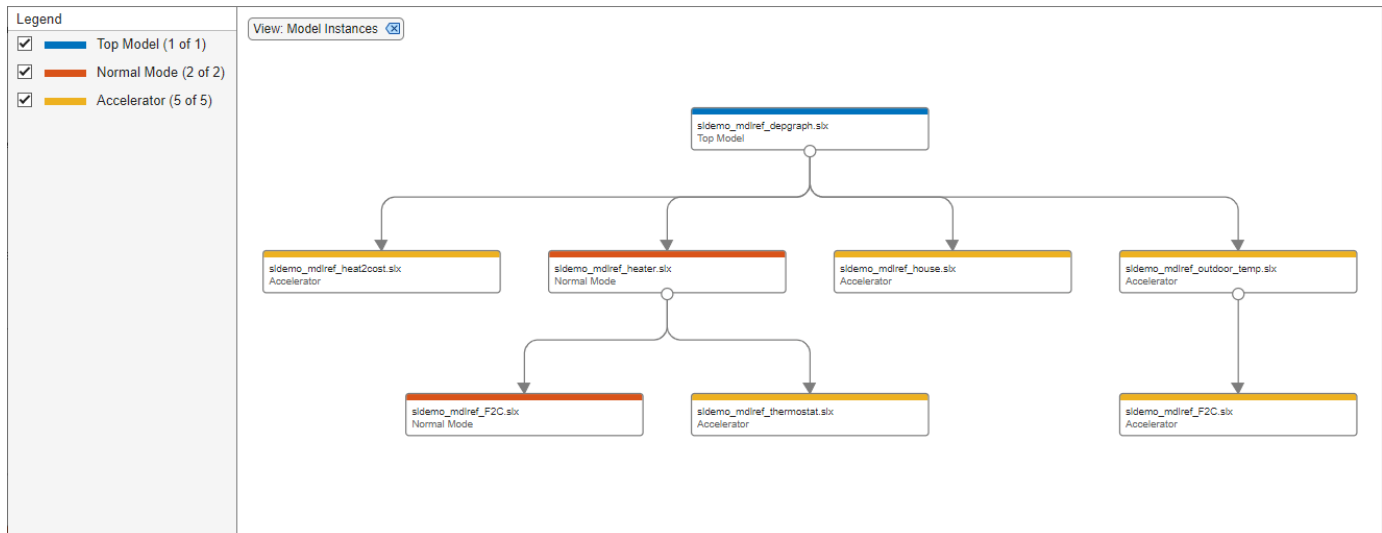

## Interact with Dependency Graph

- To select a box, click it.
- To open the model or library associated with a box, double-click it.
- To pan the dependency graph, click and hold the mouse wheel button then drag the mouse.
- To zoom in and out, use the mouse wheel.
- To center the dependency graph and adjust the zoom so that the dependency graph fills the available space, press the space bar.

## View Model Instances Dependency Graph

To view the referenced model instances in the dependency graph, perform one of these actions:

- Use `depview('sldemo_mdhref_depgraph', 'ModelReferenceInstance', true)`.
- From the Dependency Analyzer, in the **Views** section, select **Model Instances**.

In the instance view, the boxes represent Simulink models. The arrows indicate dependencies. The dependency graph shows when multiple references exist from one model to another model. In the instance view, libraries are never shown.

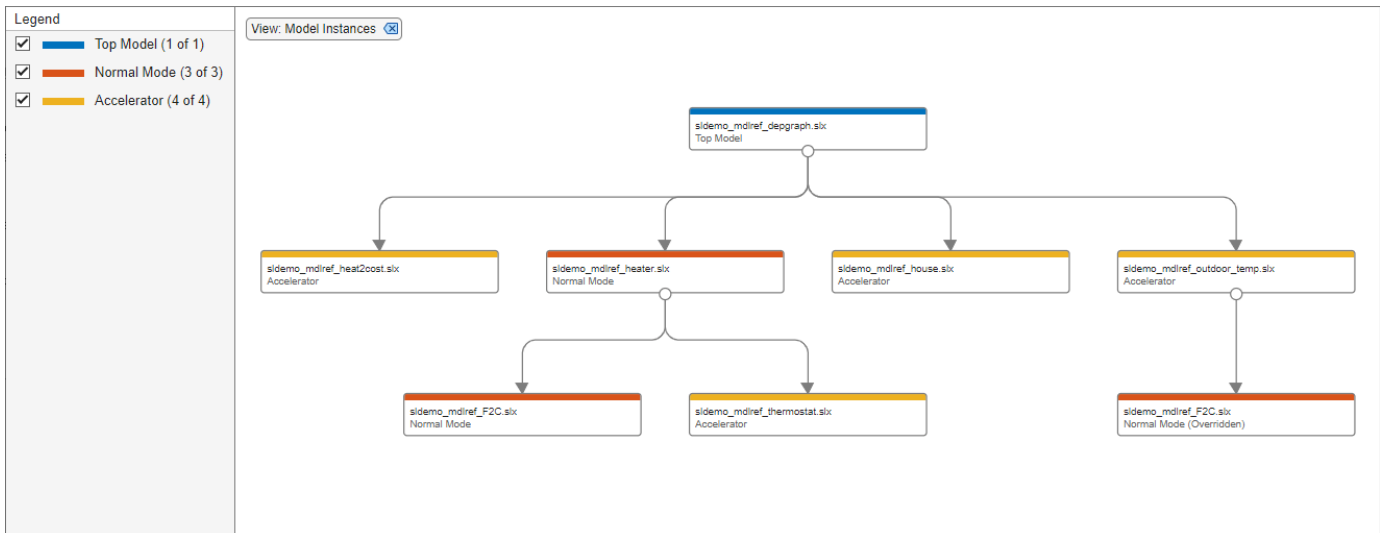

In this view two boxes are labeled `sldemo_mdref_F2C` because this model is referenced twice, once by `sldemo_mdref_outdoor_temp` and once by `sldemo_mdref_heater`. The top model is colored in blue. The red color denotes a normal mode reference, and the yellow color denotes an accelerator mode reference.

`sldemo_mdref_heater` makes a normal mode reference to `sldemo_mdref_F2C` and an accelerator mode reference to `sldemo_mdref_thermostat`.

### Explore Model Instance Views

Currently, the reference `sldemo_mdref_outdoor_temp` makes to `sldemo_mdref_F2C` is an accelerator mode reference. Suppose you want to change this reference to be a normal mode reference:

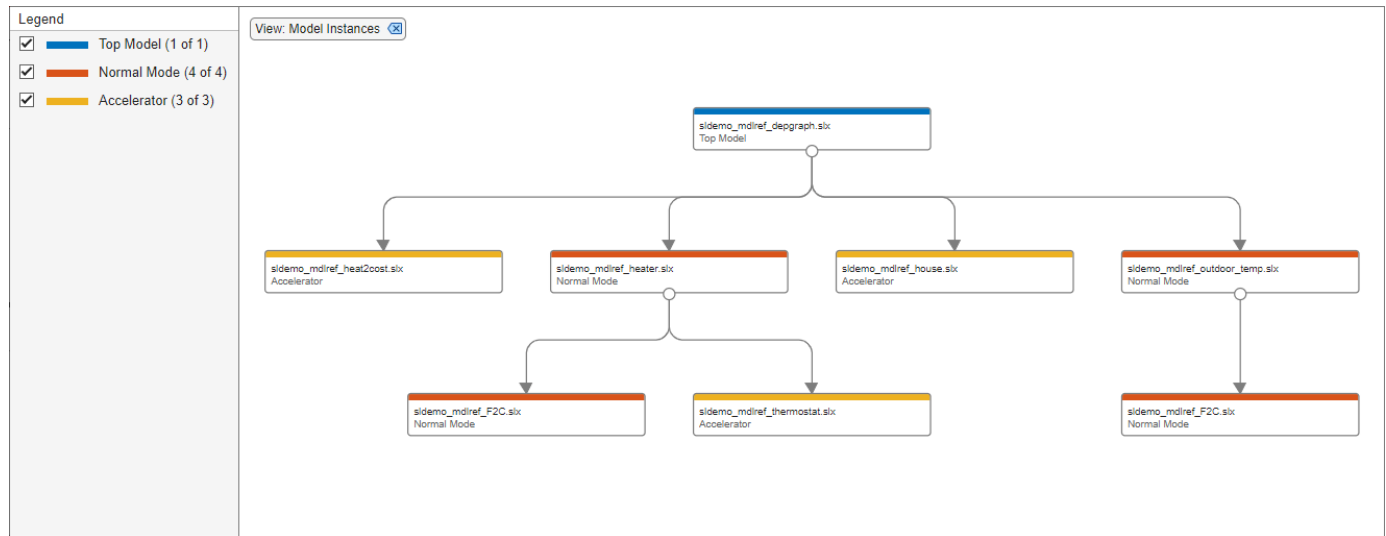

- 1 Select the arrow linking `sldemo_mdref_outdoor_temp` to `sldemo_mdref_F2C`.
- 2 In the **Properties** pane on the right, in the dependency table, click Fahrenheit to Celsius. Simulink opens the model `sldemo_mdref_outdoor_temp` and highlights the Model block named Fahrenheit to Celsius. This Model block references `sldemo_mdref_F2C`.
- 3 Select the Model block named Fahrenheit to Celsius.
- 4 In the **Model Block** tab, change the **Simulation Mode** to Normal.
- 5 To see this change, go to the dependency graph and click **Analyze**.

The dependency graph now shows the reference `sldemo_mdlnref_outdoor_temp` makes to `sldemo_mdlnref_F2C` as a Normal Mode (Overridden) reference. Note that `sldemo_mdlnref_F2C` is configured to run in normal mode but its parent, `sldemo_mdlnref_outdoor_temp`, is configured to run in accelerator mode. Normal mode references from models running in accelerator mode are not supported, so `sldemo_mdlnref_F2C` will run in accelerator mode during simulation.

To make this model run in normal mode, you must configure all of its ancestors to run in normal mode. To do this:

- 1 Select the arrow linking `sldemo_mdlnref_depgraph` to `sldemo_mdlnref_outdoor_temp`.
- 2 In the **Properties** pane on the right, in the dependency table, click `outdoor temp`. Simulink opens the model `sldemo_mdlnref_depgraph` and highlights the Model block named `outdoor temp`. This Model block references `sldemo_mdlnref_outdoor_temp`.
- 3 Select the Model block named `outdoor temp`.
- 4 In the **Model Block** tab, change the **Simulation Mode** to Normal. (If there were more accelerator mode ancestors of `sldemo_mdlnref_F2C`, these would also need to be changed to normal mode references.)
- 5 To see this change, go to the dependency graph and click **Analyze**.

## Introduction to Managing Data with Model Reference

This example shows the basic concepts related to managing data with model reference.

### Open the Example Model

Open the example model `sldemo_md1ref_datamngt`.

Copyright 1990-2022 The MathWorks, Inc.

### Example Content

This example uses a top model `sldemo_md1ref_datamngt` that contains three Model blocks: Counter1, Counter2, and Counter3. These blocks reference the same model `sldemo_md1ref_counter_datamngt`.

The referenced model implements a limited counter algorithm that:

- Resets the counter if the first trigger input changes
- Increments the counter by a specified amount if the second input changes
- Saturates the counter between the specified upper and lower limits

The referenced model outputs a bus signal that contains:

- **Count:** the value of the counter as an 8-bit integer
- **OverflowState:** an enumerated value that indicates whether the counter is at the upper limit, lower limit, or in range

### Related Examples

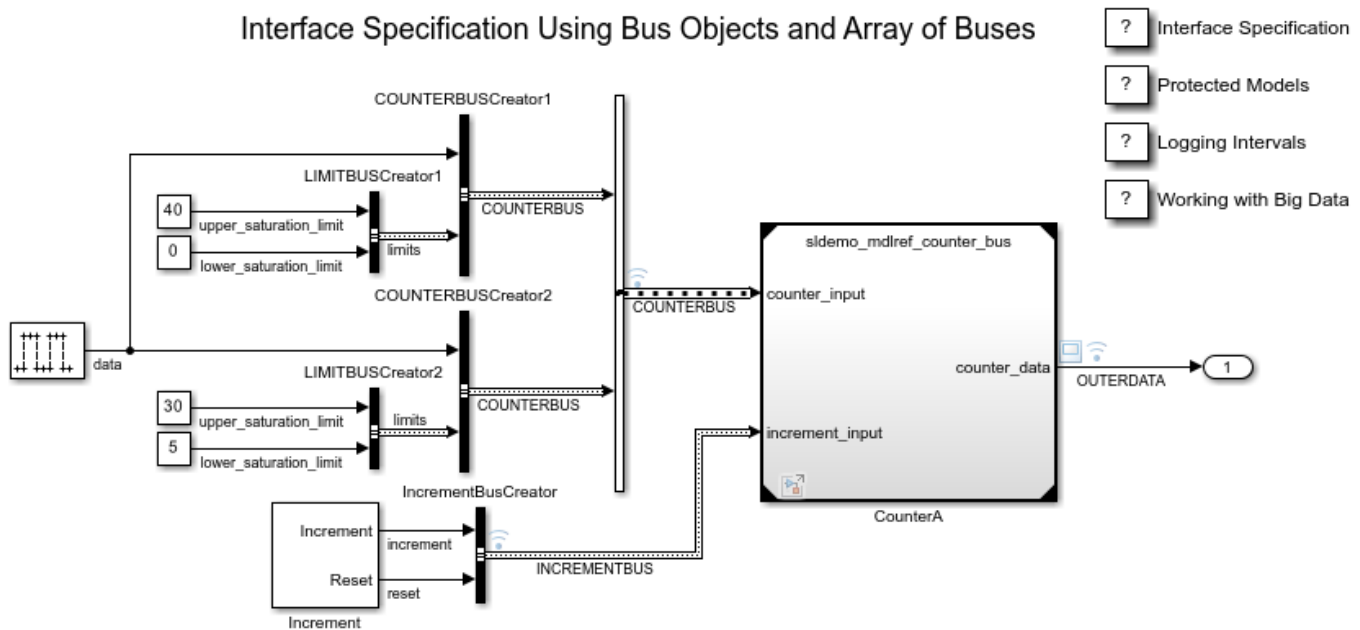

- “Model References”

## Interface Specification Using Bus Objects

This example shows how to propagate buses into referenced models. It also shows how you can simulate the referenced models independently using logged signal data from the parent model.

### Open the Example Model

Open and simulate the example model `sldemo_mdhref_bus`.

Copyright 1990-2019 The MathWorks, Inc.

### Examine the Model

The model contains a Model block named CounterA that references `sldemo_mdhref_counter_bus`, which is a model of a simple counter.

An array of buses named COUNTERBUS feeds the data and the saturation limits of the counter into the model. The buses named COUNTERBUS each contain two elements: a data signal and a nested bus named LIMITBUS. The data is used in counting, and LIMITBUS contains the upper and lower limit values of the counter.

The Model block has a second input port that connects to a bus named INCREMENTBUS. This bus contains elements that change the increment and reset the counter.

The model uses a data dictionary file named `sldemo_mdhref_bus.sldd` that contains Simulink.Bus objects that define the elements of COUNTERBUS, LIMITBUS, and INCREMENTBUS.

To view the Bus objects, open the Type Editor. In the Simulink® Toolstrip, on the **Modeling** tab, in the **Design** gallery, click **Type Editor**.

The model uses the Bus objects to specify the outputs of the following Bus Creator blocks:

- COUNTERBUSCreator1
- COUNTERBUSCreator2
- LIMITBUSCreator1
- LIMITBUSCreator2
- IncrementBusCreator

The Inport block named `counter_input` in `sldemo_mdref_counter_bus` specifies the Bus object named COUNTERBUS. Double-click the block. In the Block Parameters dialog box, on the **Signal Attributes** tab, **Data type** is set to Bus: COUNTERBUS.

The Inport block named `increment_input` is similarly configured to use the Bus object named INCREMENTBUS.

### Log Signal Data

These signals are marked for signal logging:

- COUNTERBUS
- INCREMENTBUS
- OUTERDATA
- INNERDATA

After you simulate the model, the logged signals are available in the base workspace in the `topOut` variable.

```
topOut =
```

```
Simulink.SimulationData.Dataset 'topOut' with 4 elements
```

	Name	BlockPath
1 [1x1 Signal]	COUNTERBUS	sldemo_mdref_bus/Concatenate
2 [1x1 Signal]	OUTERDATA	sldemo_mdref_bus/CounterA
3 [1x1 Signal]	INCREMENTBUS	sldemo_mdref_bus/IncrementBusCreator
4 [1x1 Signal]	INNERDATA	...erA sldemo_mdref_counter_bus/COUNTER

```
- Use braces { } to access, modify, or add elements using index.
```

The model uses Dataset format for signal logging. To access Dataset format logged data for a given signal, use the `getElement` method:

```
topOut.getElement('COUNTERBUS')
```

```
ans =
```

```
Simulink.SimulationData.Signal
Package: Simulink.SimulationData
```

```
Properties:
```

```

 Name: 'COUNTERBUS'
 PropagatedName: ''
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 PortType: 'outport'
 PortIndex: 1
 Values: [2x1 struct]

```

Bus data is logged as a MATLAB® structure in the `Values` field:

```
topOut.getElement('COUNTERBUS').Values
```

```
ans =
```

```
2x1 struct array with fields:
```

```

 data
 limits

```

This structure contains MATLAB timeseries objects for each bus:

```
topOut.getElement('COUNTERBUS').Values(1).data
```

```
timeseries
```

```
Common Properties:
```

```

 Name: 'data'
 Time: [301x1 double]
 TimeInfo: tsdata.timemetadata
 Data: [301x1 int32]
 DataInfo: tsdata.datametadata

```

```
topOut.getElement('COUNTERBUS').Values(2).data
```

```
timeseries
```

```
Common Properties:
```

```

 Name: 'data'
 Time: [301x1 double]
 TimeInfo: tsdata.timemetadata
 Data: [301x1 int32]
 DataInfo: tsdata.datametadata

```

You can also plot the logged data using the `plot` function:

```
topOut.getElement('OUTERDATA').Values.plot()
```

### Log Referenced Model Signals

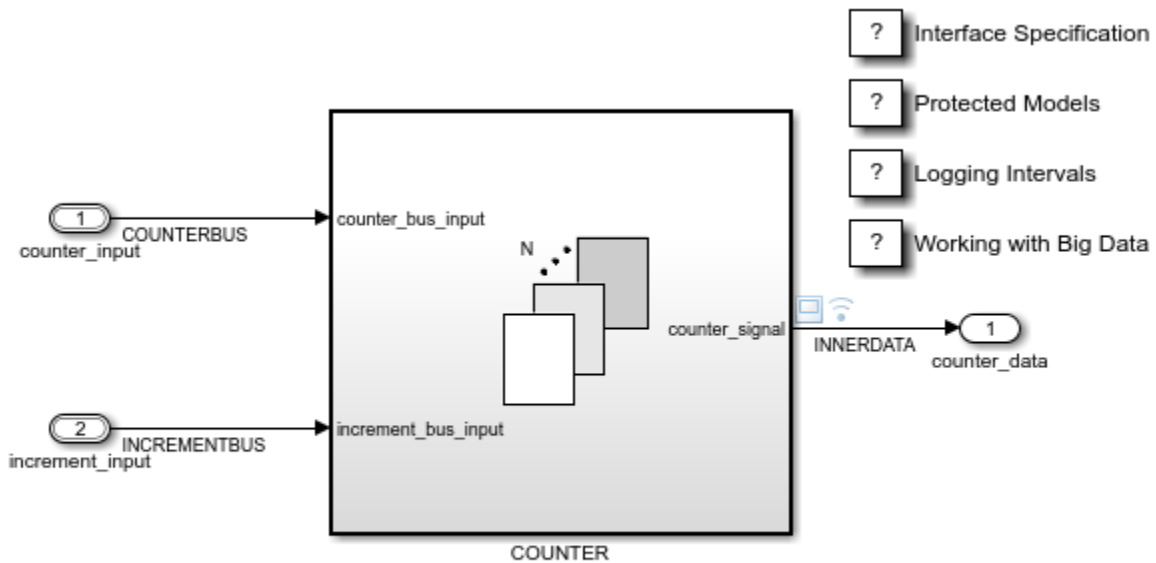

To log signals in the referenced model, select the Model block and click **Log Signals** on the **Model Block** tab.

For this model, **Logging Mode** is set to Log all signals as specified in model. All the signals that are logged when simulating `sldemo_mdref_counter_bus` as a top model are also logged when simulating it as a referenced model. To change logging for any of these signals or to log a subset of signals:

- 1 Set **Logging Mode** to Override signals.
- 2 In the **Model Hierarchy** pane, clear the **CounterA (sldemo\_mdref\_counter\_bus)** check box to indicate that this model should not use the Log all signals as specified in model setting.
- 3 In the table, select the signals to log when simulating the top model.
- 4 To save the changes, save the top model.

### Load Data

Open the referenced model `sldemo_mdref_counter_bus` as a top model by clicking the **Open As Top Model** badge at the lower left corner of the Model block.

Copyright 1990-2019 The MathWorks, Inc.

The referenced model is configured to read the logged signal data through the root Inport blocks. To see this configuration, open the Configuration Parameters dialog box. In the Simulink Toolstrip, on the **Modeling** tab, click **Model Settings**. On the **Data Import/Export** tab, **Input** uses a comma-separated list to specify logged data from **topOut** for the two input ports. The **counter\_input** port uses an array of structure of timeseries to load data for COUNTERBUS, and the **increment\_input** port uses a structure of timeseries to load data for INCREMENTBUS.

- `topOut.getElement('COUNTERBUS')`
- `topOut.getElement('INCREMENTBUS')`

You can configure the **Input** field by clicking the **Connect Inputs** button. The Root Inport Mapper tool opens. In this example, the tool uses a mapping algorithm to set up the **Input** field from logged data in the base workspace.

To select the data to import:

- 1 In the Root Inport Mapper, click **From Workspace**.
- 2 Select the logged data **topOut** and click **OK**.
- 3 In the dialog box that opens, specify a file name and click **Save**.

With the data loaded into the Root Inport Mapper tool, you can determine the root input port for which to assign input data. Simulink matches input data with input ports based on one of these criteria: block name, block path, signal name, port order, or a custom algorithm. Because **topOut** is logged using signal names from the model, the best choice for a mapping criterion is **Signal Name**. Using this criterion, Simulink tries to match input data variable names to the names of the input signals.

To select this option:

- 1 In the Root Inport Mapper hierarchy pane, select scenario dataset **topOut**.

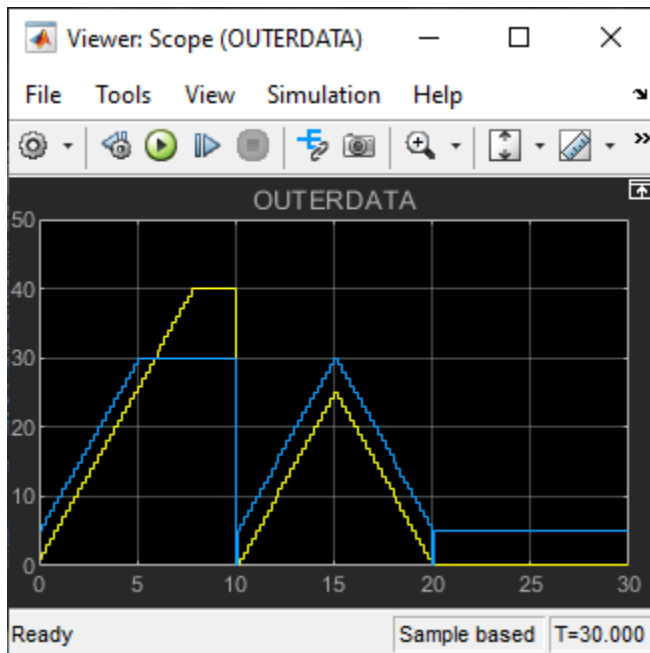

- 2 Click the **Signal Name** radio button from the dropdown.
- 3 Click the **Check Map Readiness** button arrow, then click **Map All**.

When mapping data, Simulink evaluates input ports against the input data to determine compatibility. The Root Inport Mapper table reflects the status of this compatibility with a green check mark, orange warning triangle, or red error exclamation mark. In this example, the table shows a green status indicating there is no compatibility issue. You can simulate the model with this mapping of input data to input ports. The mapping also sets **Input** in the **Data Import/Export** tab of the Configuration Parameters dialog to the proper comma-separated list of inputs. To apply the changes to the model, in the Configuration Parameters dialog, click **Apply**.

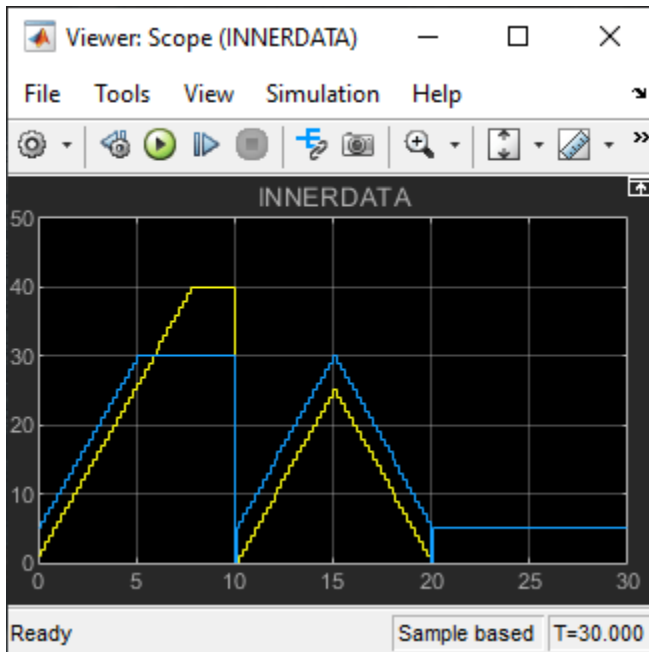

### Simulate Model with Imported Data

Simulate `sldemo_mdhref_counter_bus`.

After simulation, the scopes from `sldemo_mdhref_bus` (OUTERDATA) and `sldemo_mdhref_counter_bus` (INNERDATA) show the same trace.

The signal feeding the scope in the referenced model is also logged. The logged data is available in the MATLAB workspace under the variable `subOut`. You can verify that the data in `topOut.getElement('OUTERDATA')` and `subOut.getElement('INNERDATA')` is the same.

- “Explore Simulink Bus Capabilities” on page 13-313
- “Composite Interface Guidelines”
- “Convert Subsystem to Referenced Model” on page 13-418

## Convert Subsystem to Referenced Model

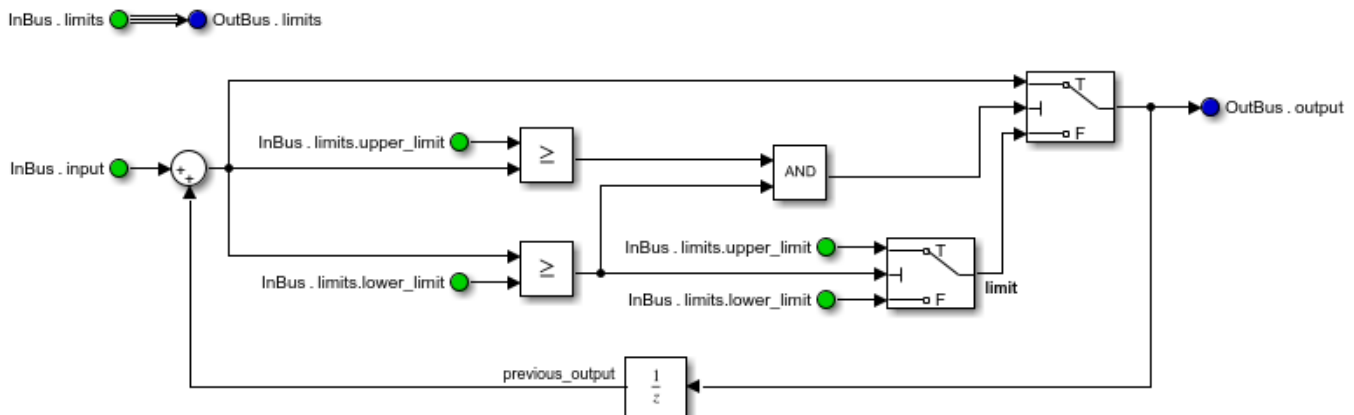

This example demonstrates how to convert a subsystem to a referenced model by using the **Model Reference Conversion Advisor** tool or the `Simulink.SubSystem.convertToModelReference` function.

### Examine Example Model

Open and simulate the example model.

The `sldemo_mdref_conversion` model contains an atomic subsystem named `Bus Counter` that models a counter algorithm.

The subsystem interface uses In Bus Element and Out Bus Element blocks to pass a virtual bus into and out of the subsystem. The virtual buses inherit their data types. To more strongly define the interface of the new model after conversion, create `Simulink.Bus` objects and use them as the data types of the buses.

### Interactively Convert Subsystem to Referenced Model

Use the Model Reference Conversion Advisor to interactively convert the subsystem. Select a Subsystem block, then on the **Subsystem Block** tab, select **Convert > Model Block**. In the Model Reference Conversion Advisor, set **New model name** to `sldemo_bus_counter`, then click **Convert**.

You can also open the Model Reference Conversion Advisor by setting `'UseConversionAdvisor'` to `'true'` when calling the `Simulink.SubSystem.convertToModelReference` function.

### Programmatically Convert Subsystem to Referenced Model

Use the `Simulink.SubSystem.convertToModelReference` function to programmatically convert the atomic subsystem to a referenced model. To convert the Bus Counter subsystem to a referenced model named `sldemo_bus_counter` and to replace the Subsystem block with a Model block that references the new model, enter this command in the MATLAB® Command Window:

```
Simulink.SubSystem.convertToModelReference(...
 'sldemo_mdref_conversion/Bus Counter', ...
 'sldemo_bus_counter', ...
 'ReplaceSubsystem', true);
```

Alternatively, double-click the blue block, which uses an `OpenFcn` block callback to execute this command.

## Use Data Stores Across Multiple Models

This example shows how to use and log local data stores. It also shows how to define, use, and log global data stores to share global data among referenced models.

### Inspect Example Models

Open the example models. The top model `sldemo_mdhref_dsm` references models `sldemo_mdhref_dsm_bot` and `sldemo_mdhref_dsm_bot2`. Logging of data stores is turned on for `sldemo_mdhref_dsm` on the **Data Import/Export** pane of the Configuration Parameters dialog box.

Copyright 1990-2013 The MathWorks, Inc.

Referenced model `sldemo_mdhref_dsm_bot` amplifies the incoming signal by 5 if the signal is positive or by 2 if the signal is negative and writes the value of this signal to local data store `RefSignalVal`. This local data store is configured to log all written values to the workspace after simulation. The logging parameters for this local data store are controlled by the **Logging** tab of the Block Parameters dialog box.

Copyright 1990-2013 The MathWorks, Inc.

The **PositiveSS** subsystem contains the blocks that amplify the incoming signal by 5 if the signal is positive and write the value of this signal to local data store **RefSignalVal**.

Copyright 1990-2013 The MathWorks, Inc.

The **NegativeSS** subsystem contains the blocks that amplify the incoming signal by 2 if the signal is negative and write the value of this signal to local data store **RefSignalVal**.

Copyright 1990-2013 The MathWorks, Inc.

Referenced model `sldemo_mdhref_dsm_bot2` sets the value of a global boolean data store named `ErrorCond` to true if the value of its incoming signal is outside of the range  $(-0.8, 0.8)$ . The top model also monitors the data store `ErrorCond` and switches between the outputs of the two referenced models, depending on the value of that data store.

Copyright 1990-2013 The MathWorks, Inc.

### Define Global Data Store Using Simulink® Signal Object

To specify to Simulink that the top model and both of the referenced models use the same memory for the data store named `ErrorCond` in each model, create an instance of a `Simulink.Signal` object named `ErrorCond` in a workspace or data dictionary that is visible to each model. Since this object is visible to each model, its scope encompasses the individual models and implies that there is one global data store of that name that is shared among the models. Note that none of the three models contains a Data Store Memory block with a data store name of `ErrorCond`. If any model contained such a block, that block would define a data store local to the model, which would shadow the global data store.

Since the object `ErrorCond` defines a global data store, it must explicitly define the `DataType`, `Complexity`, and `Dimensions` properties to non-inherited settings. `SampleTime` and `StorageClass` may be left as their inherited values, or explicitly set.

The example includes a MAT file named `sldemo_mdhref_dsm_data.mat` that contains the `Simulink.Signal` object `ErrorCond`. The preload function of the model `sldemo_mdhref_dsm` loads this MAT file, causing the object to be loaded in the base workspace. You can view this object by selecting the base workspace in the Model Explorer. You can also create this object in the MATLAB® Command Window. The following commands define the object used in this example.

```
ErrorCond = Simulink.Signal;
ErrorCond.Description = 'Use to signal that subsystem output is invalid';
ErrorCond.DataType = 'boolean';
ErrorCond.Complexity = 'real';
ErrorCond.Dimensions = 1;
ErrorCond.SampleTime = 0.1;
ErrorCond.LoggingInfo.DataLogging = true;
```

### Log Global Data Store

To log all the values written to the global data store, set the `DataLogging` property of the `LoggingInfo` property of the `Simulink.Signal` object. The `LoggingInfo` property also allows specification of other logging parameters such as decimation and maximum points.

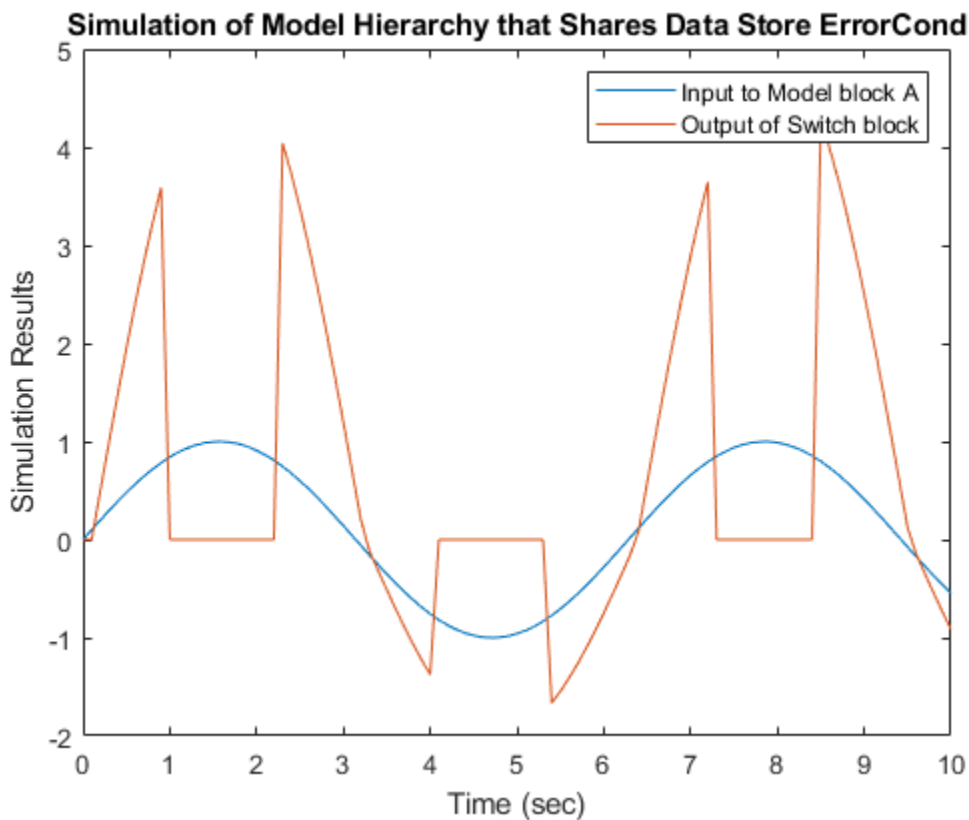

```

Simulink.LoggingInfo (handle)
 DataLogging: 1
 NameMode: 0
 LoggingName: ''
 DecimateData: 0
 Decimation: 2
 LimitDataPoints: 0
 MaxPoints: 5000

```

### Simulate Model Hierarchy

Simulate `sldemo_mdref_dsm` to see the output. The referenced model `sldemo_mdref_dsm_bot` writes to the data store `ErrorCond` while the top model `sldemo_mdref_dsm` reads from the data store. The blue line represents the input to Model block A, which references the model `sldemo_mdref_dsm_bot`. The orange line represents the output of the Switch block. The output switches when the magnitude of the input signal falls outside of the range.

### View Logged Results

Both the global data store `ErrorCond` and the local data store `RefSignalVal` are configured to log all written values after simulation. These logged results are stored in the base workspace in the `dsmout` variable.

```
dsmout =
```

```
Simulink.SimulationData.Dataset 'dsmout' with 2 elements
```

	Name	BlockPath	
1	[1x1 DataStoreMemory]	ErrorCond	''
2	[1x1 DataStoreMemory]	RefSignalVal	...dlref_dsm/A sldemo_mdref_dsm_bot/DSM

- Use braces { } to access, modify, or add elements using index.

To access the data stored for the local data store, use the `getElement` function to get the correct data store element based on the name `RefSignalVal`.

```
>> dsmout.getElement('RefSignalVal')

Simulink.SimulationData.DataStoreMemory
Package: Simulink.SimulationData

Properties:
 Name: 'RefSignalVal'
 BlockPath: [1x1 Simulink.SimulationData.BlockPath]
 Scope: 'local'
 DSMWriterBlockPaths: [1x2 Simulink.SimulationData.BlockPath]
 DSMWriters: [101x1 uint32]
 Values: [1x1 timeseries]
```

Data is stored in a `timeseries` within the `Values` field.

```
>> plot(dsmout.getElement('RefSignalVal').Values);
```

To determine which block wrote to the data store at a given time, use the `DSM Writers` property. This array contains a list of indices into the `DSM WriterBlockPaths` array. For example, the block path of the Data Store Write block that wrote the 5th value to the data store can be obtained as follows.

```
>> dsm = dsmout.getElement('RefSignalVal');
>> dsm.DSMWriterBlockPaths(dsm.DSMWriters(5))
```

```
Simulink.SimulationData.BlockPath
Package: Simulink.SimulationData
```

```
Block Path:
'sldemo_mdref_dsm/A'
'sldemo_mdref_dsm_bot/PositiveSS/DSW'
```

Use the `getBlock` method to access block path character vectors from this object.

## Model Reference Function-Call

This example shows how to use a Model block that is explicitly triggered by means of its function-call trigger port.

### Examine Example Model

Open the example model.

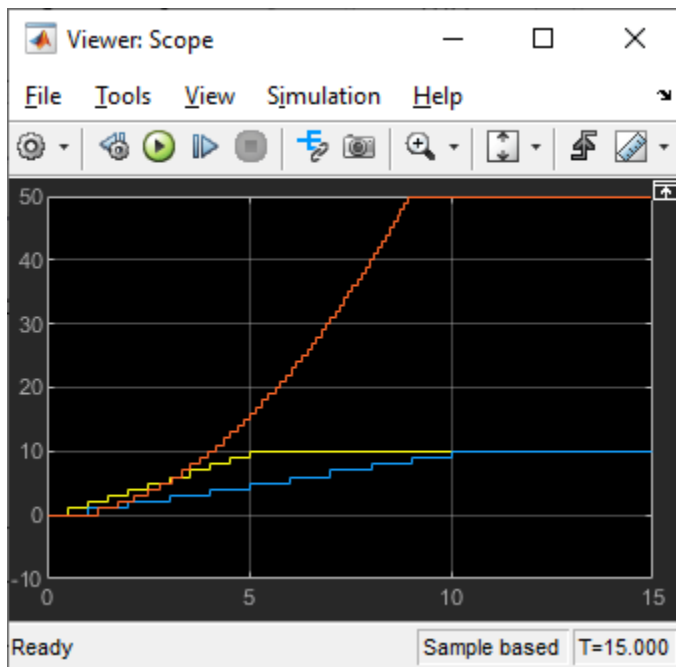

Copyright 1990-2014 The MathWorks, Inc.

This model contains three Model blocks: 500ms Counter, 1 sec Counter and Asynchronous Counter. These blocks reference the same model (sldemo\_mdref\_fcncall\_cntr). The Model blocks represent saturating counters that increment their output values by one each time they are explicitly triggered through their function-call trigger ports. The Stateflow® chart calls each Model block at its specified rate.

### Simulate Model and Examine Results

Simulate the model, and verify the behavior of the counters by examining the results displayed by the scope.

## Explore Protected Model Capabilities

This example shows how to create a protected model and use it in normal mode simulation, accelerator mode simulation, and code generation.

To create protected models, you must have Simulink® Coder™ installed. To generate the read-only view of protected models, you must have Simulink® Report Generator™ installed.

### Open the Example Model

Open and simulate the example model `sldemo_mdref_bus`.

### Protect the Referenced Model

The example model contains one Model block named CounterA. To protect the model referenced by this block, select the Model block and click **Protect** on the **Model Block** tab in the toolstrip. A dialog box opens where you can select options for creating a protected model.

The screenshot shows a dialog box titled "Create Protected Model: sldemo\_mdhref\_counter\_bus". It contains the following sections and controls:

- Description:** "Create a protected model (.slxp) that allows read-only view, simulation, and code generation of the model with optional password protection."
- Allow user of protected model to:**
  - Open read-only view of model: Includes "Enter password (optional)" and "Re-enter password (option..." fields.
  - Simulate: Includes "Enter password (optional)" and "Re-enter password (option..." fields.
  - Use generated code: Includes "Enter password (optional)" and "Re-enter password (option..." fields.
  - Content type:** A dropdown menu currently set to "Binaries".
  - Use generated HDL code: Includes "Enter password (optional)" and "Re-enter password (option..." fields.
- Tunable parameters for simulation:** A collapsed section.
- Options for saving protected model:**
  - Destination folder:** A text field containing "H:\MATLAB" and a "Browse..." button.
  - Contents:** A dropdown menu set to "Protected model (.slxp) and dependencies in a project".
  - Create harness model for protected model
  - Name of project archive (.mlproj):** A text field containing "sldemo\_mdhref\_counter\_bus\_protected".
- Buttons:** "Create", "Cancel", and "Help" at the bottom right.

Under **Allow user of protected model to**, select **Open read-only view of model**, **Simulate**, and **Use generated code**. To password-protect these actions, you can enter a unique password for each action. Then, click **Create**.

A project archive for the protected model, `sldemo_mdhref_counter_bus_protected.mlproj`, is generated in the specified destination folder.

Double-click the project archive in the **Current Folder** browser to open the corresponding project that contains the protected model (`sldemo_mdhref_counter_bus.slxp`). The project also contains a harness model that provides an isolated environment for the protected model and a data dictionary that defines the variables used by the protected model.

You can use the protected model in normal mode simulation, accelerator mode simulation, and code generation. You can also open a read-only view of the model. The original model file is not required.

The protected model is already compiled, which can accelerate simulation and code generation.

### Use the Protected Model

When a Model block references a protected model, the block displays a shield badge.

To enable password-protected functionality, right-click the shield badge and select **Authorize**. Enter the passwords you set while creating the protected model.

After entering the passwords, you can simulate the model in either normal or accelerator mode. You can also generate code for the top model.

To open a read-only view of the protected model, double-click the Model block or right-click the shield badge and select **Show Webview**.

## Model Reference Variants

This example shows how to use model reference variants. A Model block is used to reference one Simulink® model from another Simulink model. A Variant Subsystem block can contain Model blocks as variants. A *variant* describes one of  $N$  possible modes in which a Variant Subsystem block can operate. Each variant references a specific model with its associated model-specific arguments. For a given Variant Subsystem block, only one variant is active during simulation. You can switch the active variant by changing the values of variables in the base workspace or by manually overriding variant selection using the Variant Subsystem block dialog box.

### Switching Active Variants

The `sldemo_mdref_variants` model contains a Variant Subsystem block named Controller that references two models.

```
open_system('sldemo_mdref_variants')
```

Copyright 2009-2020 The MathWorks, Inc.

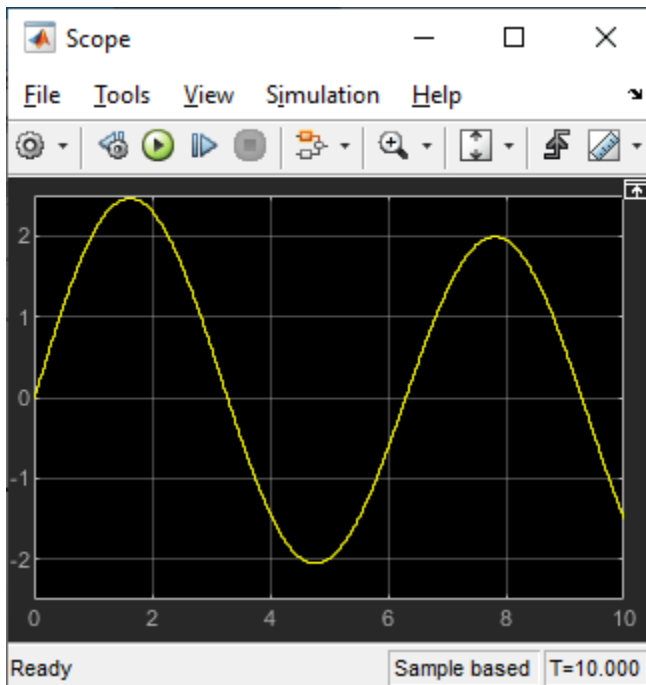

To see the variant choices, right-click the Variant Subsystem block named Controller and select **Block Parameters (Subsystem)**. The active variant is determined by the value of the CTRL variable in the MATLAB® base workspace. Defining CTRL=1 activates the Model block named Linear, and defining CTRL=2 activates the Model block named Nonlinear.

Opening the `sldemo_mdref_variants` model runs the **PreLoadFcn** model callback, which sets CTRL to 2.

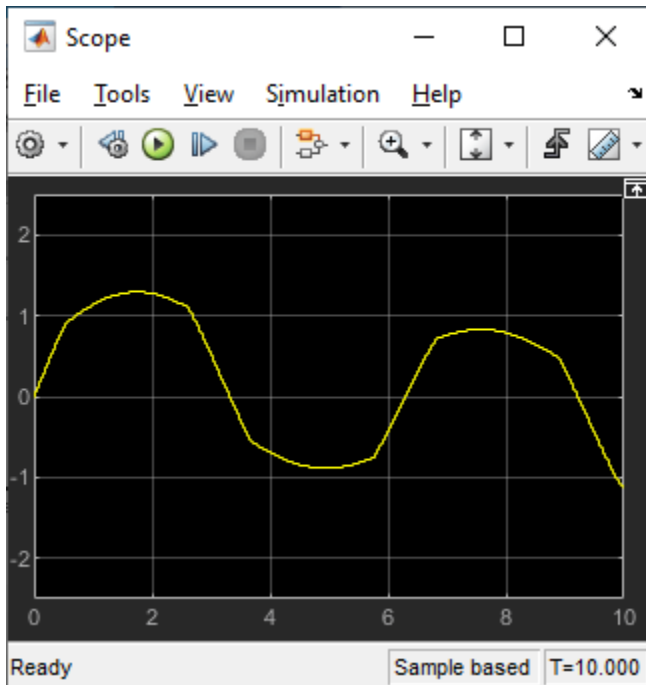

To simulate using the linear controller, define CTRL=1 in the base workspace, then simulate the model.

```
CTRL=1;
sim('sldemo_md1ref_variants');
```

To simulate using the nonlinear controller, define CTRL=2 in the base workspace, then simulate the model.

```
CTRL=2;
sim('sldemo_mdref_variants');
```

### Enumerations and Reuse

The `sldemo_mdref_variants_enum` model demonstrates `Simulink.Variant` object capabilities:

- **Enumerations:** MATLAB enumeration classes can be used to improve the readability of the conditions of the `Variant` object.
- **Reuse:** `Variant` objects can be reused in different `Variant Subsystem` blocks.

The `Variant Subsystem` blocks in this model require the following variables be defined in the MATLAB base workspace:

- `VE_LINEAR_CONTROLLER = Simulink.Variant('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.LINEAR')`
- `VE_NONLINEAR_CONTROLLER = Simulink.Variant('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')`
- `E_CTRL = sldemo_mrv_CONTROLLER_TYPE.LINEAR`
- `VE_PROTOTYPE = Simulink.Variant('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')`
- `VE_PRODUCTION = Simulink.Variant('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')`
- `E_CURRENT_BUILD = sldemo_mrv_BUILD_TYPE.PRODUCTION`

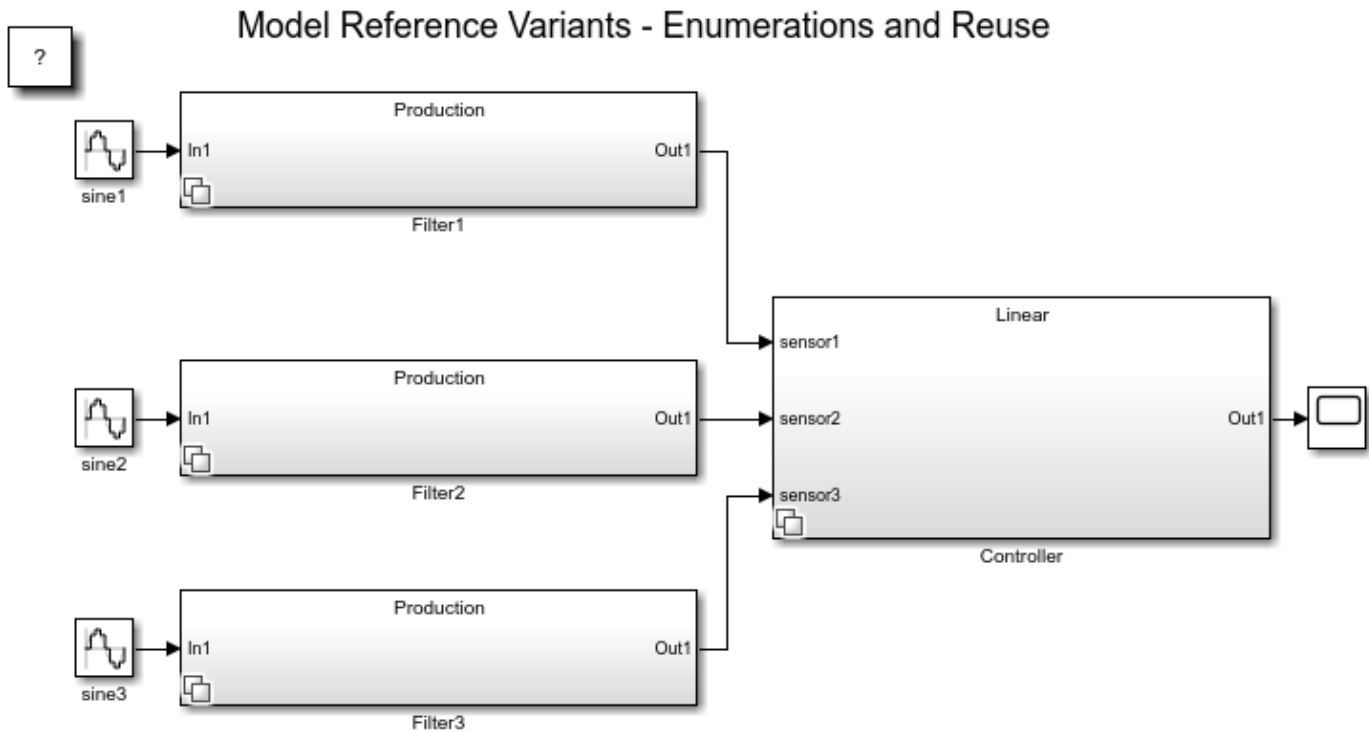

Each variant is associated with a `Simulink.Variant` object that uses either the `sldemo_mrv_BUILD_TYPE.m` or `sldemo_mrv_CONTROLLER_TYPE.m` enumeration class.

The `Variant` objects have a `Condition` property that is an expression. The expression evaluates to a Boolean and determines which variant is active. The expression can consist of scalar variables,

enumerations, equality, inequality, &&, ||, and ~. Parenthesis () can be used for precedence grouping. Variables may be standard MATLAB variables or Simulink.Parameter objects.

Opening the model `sldemo_mdhref_variants_enum` runs the **PreLoadFcn** model callback. This callback is set up to populate the base workspace with the variables required by the Variant Subsystem blocks.

```
open_system('sldemo_mdhref_variants_enum')
```

Copyright 2009-2017 The MathWorks, Inc.

The `VE_PROTOTYPE` and `VE_PRODUCTION` Variant objects are reused across the Variant Subsystem blocks named Filter1, Filter2, and Filter3.

The Block Parameters dialog box of the Variant Subsystem blocks show the **Condition** property of the related Variant objects.

# Assign Tasks to Cores for Multicore Programming

This example shows how to take advantage of executing code on a multicore processor by graphical partitioning. This example requires Simulink® Coder™ software to generate multithreaded code.

## Introduction

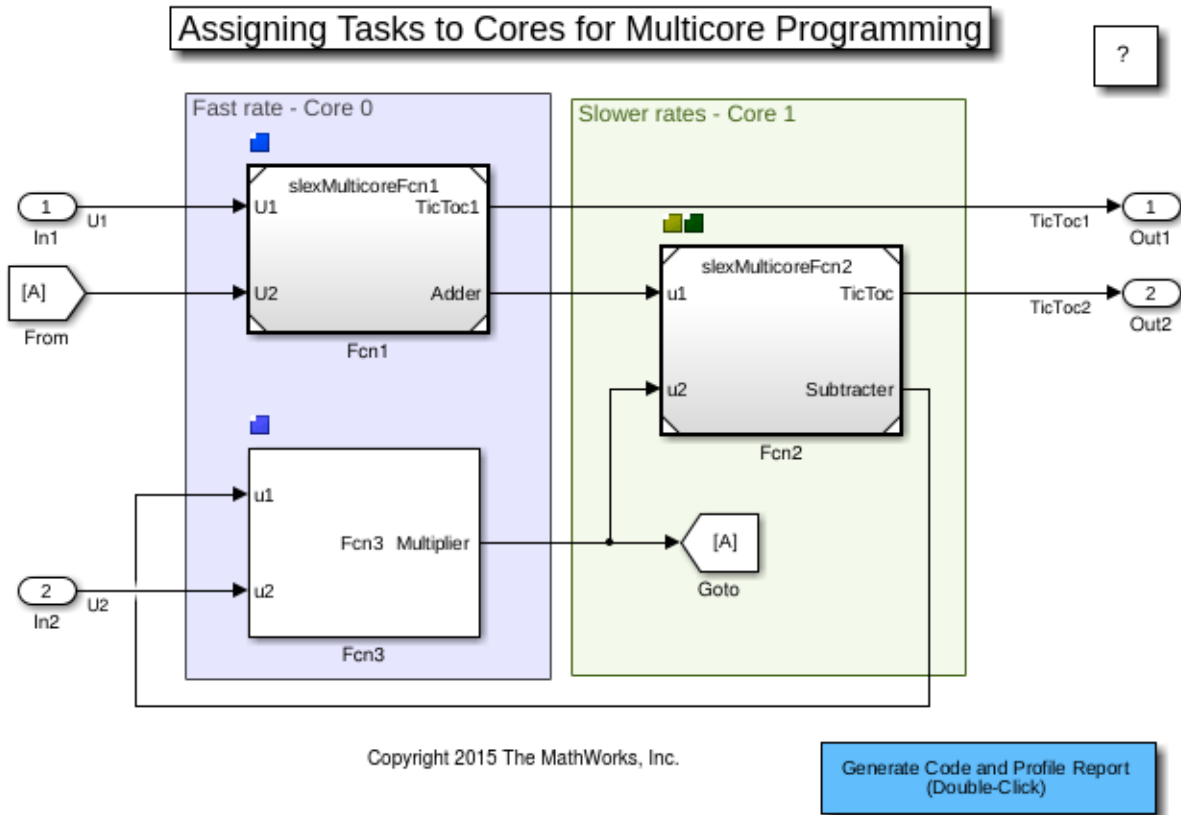

Multicore programming allows you to use the processing power of modern multicore processors to create high-performance applications. Simulink® software allows you to take advantage of multicore programming by allowing you to graphically partition your algorithms and to assign the code generated from those partitions to parallel threads on your multicore processor.

The parallel threads are typically scheduled by an operating system that assigns threads to cores dynamically. This allows the scheduler to make good use of the cores while providing a notion of fairness. However, in many applications, you may need additional control on how the cores are used or you may want to dedicate a set of cores to specific logic, for example to improve determinism. Graphical partitioning provides this level of control, as illustrated in this example.

## Open the Project

A typical multicore scenario involves a multi-rate model for which you want to assign code for the fast rates to one core and the code for the slower rates to other cores. This may allow you to add more logic to these faster rates or to achieve more determinism. More generally, you may want to dedicate cores to application logic with the greatest demand on resources. To begin, open the multicore project:

slexMulticoreExample

### Generate Multithreaded Code

This application model is already partitioned into four concurrent tasks through the Concurrent Execution dialog box you can access from the Solvers pane of the Configuration Parameters dialog box. Use this dialog box to specify logic, task, and core assignments. In this example, the application logic is partitioned as:

Name	TriggerType	Period
Block: Fcn1		
Core1:Task1	Periodic	.1
Block: Fcn2		
Core2:Task4	Periodic	.4
Core2:Task3	Periodic	.2
Block: Fcn3		
Core1:Task2	Periodic	.1

Double-click the **Generate Code and Profile Report** button to generate multi-threaded code and profile its execution. This action runs and instruments the generated executable and produces both profiling results and a core occupancy map. The core occupancy map shows how the cores were used at each time step of execution. In this example, the first core was used for the fast rates (Task1 and Task2) and the second core was used for the slower rates (Task3 and Task4).

You can return to the Concurrent Execution dialog box to try different core assignments. In particular, you can try to specify no core affinity by leaving the **Affinity** property as [ ]. This is the default setting which allows Simulink to generate multi-threaded code suitable for dynamic scheduling on your multicore processor.

Clock Tick / Task	0	10																		19		
<a href="#">Task1</a>	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
<a href="#">Task2</a>	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
<a href="#">Task3</a>	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR	1	NR
<a href="#">Task4</a>	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR	NR	NR	1	NR

## Implement an FFT on a Multicore Processor and an FPGA

This example shows you how to take advantage of a multicore processor target with FPGA acceleration by graphically partitioning a model. This example requires Simulink Coder™ to generate multi-threaded code and HDL Coder™ to generate HDL code. You cannot generate HDL code on Macintosh systems.

### Introduction

Several modern processors include multicore processors integrated with FPGA components to create high-performance applications. These require multicore and FPGA programming, including programming of parallel threads, HDL, and communication interfaces between the cores of the system. Simulink™ allows you to take advantage of these approaches by graphically partitioning your algorithms and by assigning the software generated from those partitions to threads on your processor and to modules on your FPGA. The example uses one application level model to generate one executable, consisting of multiple threads and HDL code, to take advantage of the hardware parallelism of the FPGA. This is illustrated in the figure below.

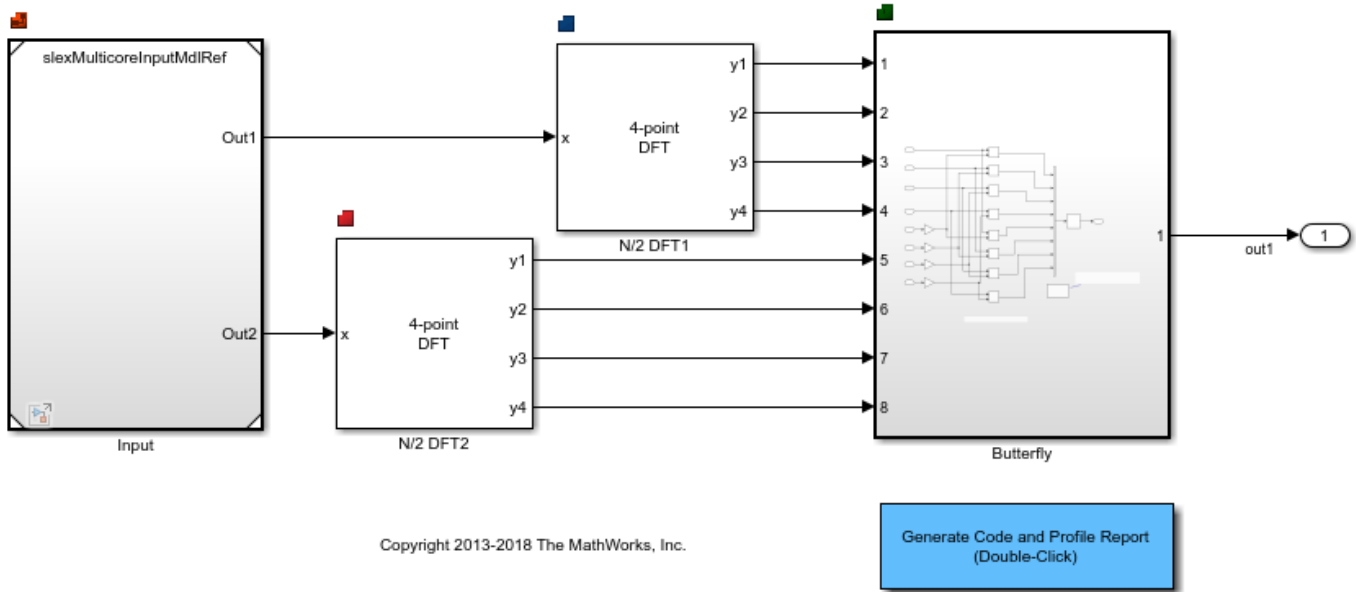

### Example Model

Load the example model:

```
slexMulticoreFPGAExample

Generate Code and Profile Report  
(Double-Click)

**Architecture Definition**

All concurrent execution settings for this model can be accessed in the Concurrent Execution dialog box (Configuration Parameters>Solvers>Configure Tasks).

The first step to implement our algorithm is to define structural elements of our target architecture. This includes structural elements of the hardware, such as the number and type of processing nodes (CPU, FPGA) and the communication channels (AXI, PCI).

This also includes software settings in the model's Configuration Parameters (e.g. System Target File, hardware Implementation, data transfer settings). In this example we have selected the pre-configured target architecture 'Sample architecture'. This architecture uses your desktop as a stand-in for the deployment process.

Software Node

Hardware Nodes

Simulation and Code Generation Options

Preconfigured Target Architectures including Simulink Real-Time and Zynq

## Partitioning and Mapping the Model

Partition the model to decide which functions run sequentially and which run concurrently.

The example model is partitioned explicitly, consisting of MATLAB System blocks, a Model block, an Atomic Subsystem and an Outport block. Explicit partitioning creates partitions based on these blocks at the root-level of the model. Implicit partitioning, on the other hand, creates partitions based on the block sample times and other scheduling constraints.

After partitioning the model, you can map partitions to CPU tasks and FPGA nodes. You can change the mapping for design space exploration, through the GUI or the API. During mapping, signals will be auto-mapped to channels.

You can change how the blocks are mapped to the threads and to the FPGA in the Concurrent Execution dialog box. For more information, see “Optimize and Deploy on a Multicore Target”.

**Map blocks to tasks**

Refresh mapping table (\*invokes update diagram) 

Name	TriggerType	Period	Autogenerated
Block: Butterfly			
 Butterfly	Periodic	0.2	No
Block: Input			
 FPGA2	FPGA		No
Block: N//2 DFT1			
 DFT:DFT1	Periodic	.2	No
Block: N//2 DFT2			
 DFT:DFT2	Periodic	.2	No

## Generate Multithreaded and HDL Code

Double-click on the 'Generate Code and Profile Report' button to generate multithreaded code. In this example, the host computer replaces the target environment. C code is generated for blocks mapped to processor tasks. This code is organized using threads native to the desktop machine. The code snippet shows how threads are created. In addition, HDL code is generated for blocks mapped to hardware nodes. The code snippet below illustrates how the module/entity is created in VHDL.

Host  
Computer  
Code

```
int main(int argc, char *argv[])
{
 /* Create periodic threads */
 for (i = 0; i < 2; i++) {
 periodicThread[i].index = (int_T) i;
 periodicThread[i].exitFlag = 0;

 /* Create the events that will be used by the thread */
 periodicThread[i].startEvent = CreateEvent(NULL, false, false, NULL);
 periodicThread[i].stopEvent = CreateEvent(NULL, false, true, NULL);

 /* Create the thread in suspended mode */
 periodicThread[i].threadHandle = (HANDLE) beginthreadex(NULL, 0,
 &periodicTask, &periodicThread[i], CREATE_SUSPENDED, &periodicThread[i].
 threadID);
 }
}
```

## Multicore Programming of a Field-Oriented Control on Zynq

This example demonstrates how to implement a control algorithm containing multiple rates on Zynq. To take advantage of both the cores and the FPGA hardware, the example uses graphical partitioning approach such that code from different partitions are distributed across the cores and the hardware.

### Introduction

In this example, we show a workflow for generating code for a motor control algorithm, and testing the generated code on a Xilinx® Zynq™-7000 SoC ZC702 evaluation board. The motor control algorithm in the example is a Field-Oriented Control algorithm composed of a speed controller (fast component) and a torque controller (slow component). One typical workflow is to generate code for these two components of the controller, upload the generated code to an evaluation board, and then connect the evaluation board to a real-world motor. This workflow is illustrated in the block diagram below.

In order for this example to be self-contained, and since there is redundant computer power on the target processor, we model the motor using one of the tasks of the CPU of the evaluation board.

The example assumes that a Xilinx® Zynq™-7000 SoC ZC702 evaluation board is connected to your computer. You can find the connection and installation steps in the “Install Support for Xilinx Zynq Platform” (Embedded Coder Support Package for Xilinx Zynq Platform) documentation.

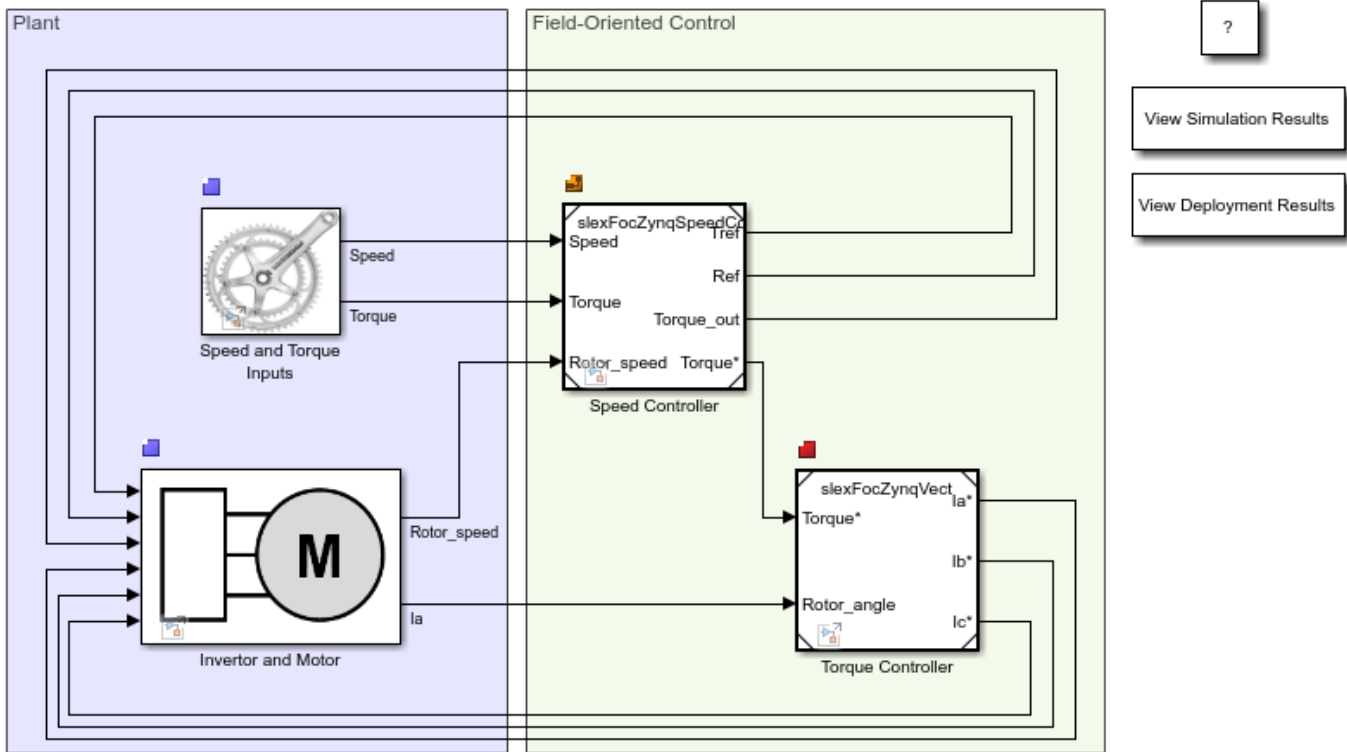

This example requires Embedded Coder™ to generate multi-threaded code, HDL Coder™ to generate HDL code, and Simscape Power Systems™ to model the permanent magnet synchronous machine in the example. You cannot generate HDL code on Macintosh systems.

### Example Model

The example model consists of two Simulink areas. In the Permanent Magnet Synchronous Machine area, there are two blocks: "Speed and Torque Inputs" block which provides the reference inputs to the feedback system, and "Invertor and Motor" block which is the plant we aim to control in this example. The "Invertor and Motor" block also contains peripherals: a scope that can be used for investigating the simulation results and a UDP sender. The generated code for the UDP sender is responsible for sending the simulation data from the Zynq ZC702 evaluation board to the host machine. The Field-Oriented Control contains the controller blocks "Speed controller" and "Torque controller". To load the model, enter

```
slexFocZynqExample
```

## Multicore Programming of a Field-Oriented Control on Zynq

Copyright 2015 - 2020 The MathWorks, Inc.

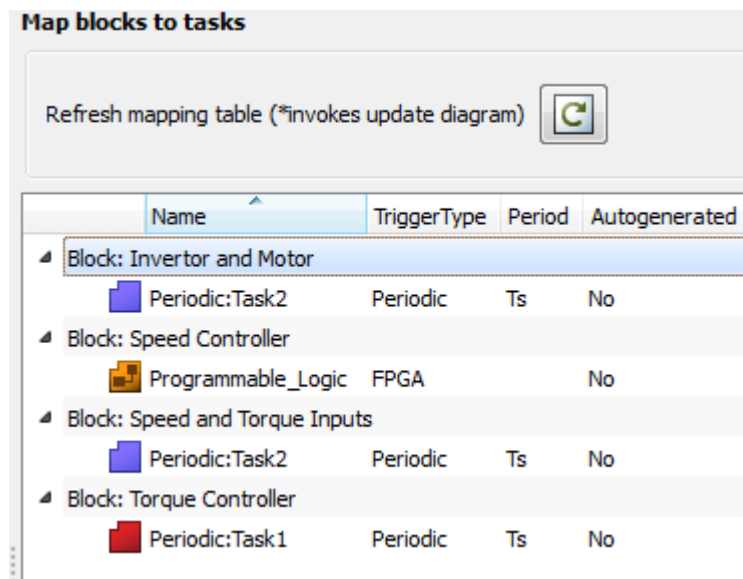

### Architecture Definition

The target architecture in the example is Xilinx Zynq ZC702 evaluation kit. This can be verified by accessing the **Concurrent Execution** dialog box.

In the **Modeling** tab, select **Model Settings**. In the **Model Configuration Parameters** dialog box, on the **Solver** tab, select **Allow tasks to execute concurrently on target**, then click **Configure Tasks**.

The evaluation board has an ARM Cortex-A9 CPU and a field-programmable gate array (FPGA). There are two tasks running on the ARM CPU. The "Torque controller" is mapped to the first task and the blocks that constitute the plant ("Speed and Torque Inputs" block and "Invertor and Motor") are mapped to the second task. The "Speed controller", which operates at high frequency in the control loop, is mapped to the FPGA. These settings can be changed in the "Tasks and Mapping" section of the "Concurrent Execution" dialog box.

### Generate Multi-threaded and HDL Code

Enter Ctrl-B or select **Deploy to Hardware** to generate the multi-threaded and HDL code. The generated executable and the FPGA bitstream will be uploaded to Zynq board automatically. This step requires that the Zynq board is connected to the computer and that the environment is set up

properly. For more information, see “Install Support for Xilinx Zynq Platform” (Embedded Coder Support Package for Xilinx Zynq Platform).

### Receive Data from the Zynq

Open the scope by selecting **View Simulation Results**, and run the simulation to obtain the following output:

Compare this simulation output with the output of the executable that runs on the Zynq ZC702 board. In order to make this comparison, access the UDP receiver model by selecting **View Deployment Results**. When the UDP receiver model is selected, run the simulation. The run command will send a signal to the Zynq ZC702 board to start running the executable on the board. The simulation data will be sent via UDP from the Zynq ZC702 board to the host machine. The captured UDP signal is displayed on the scope of the UDP Receiver model.

### Close the Model

```
close_system('slexFocZynqExample', 0);
```

## Multicore Deployment of a Plant Model

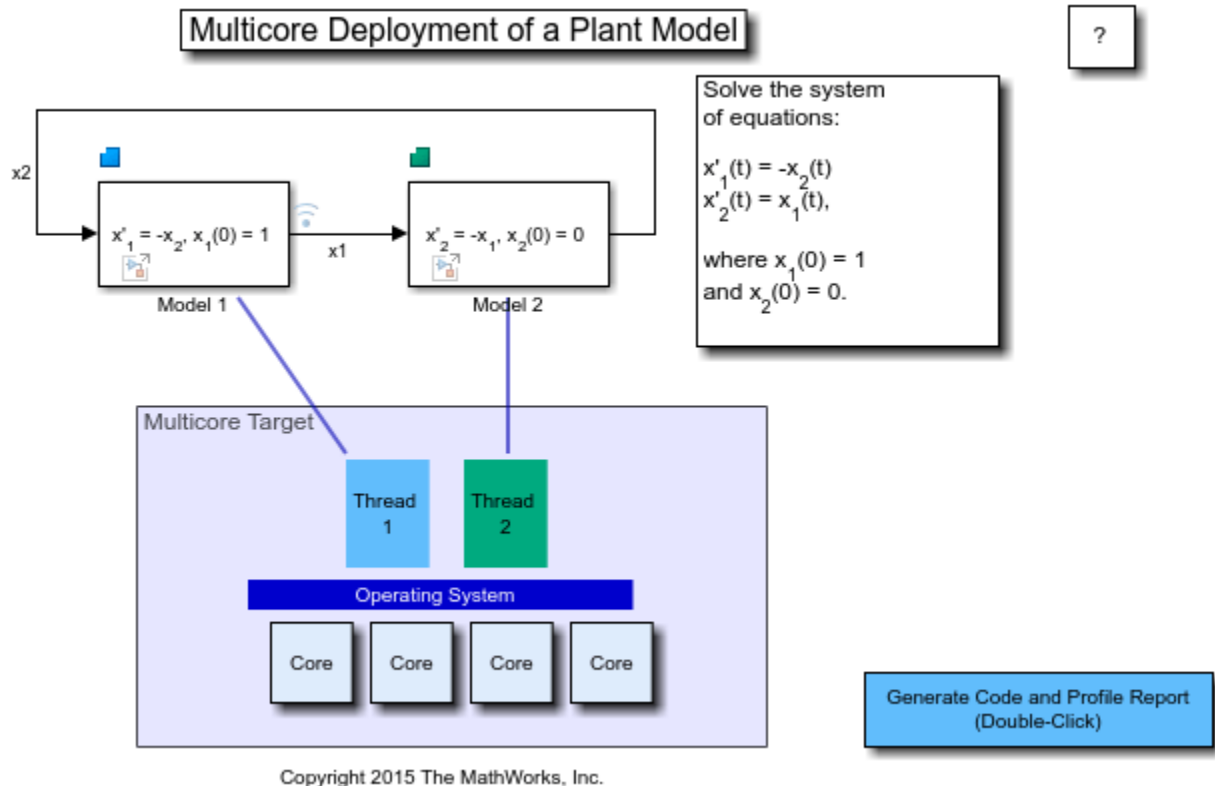

This example illustrates how to take advantage of executing multithreaded code on a multicore processor using graphical partitioning. This example requires Simulink® Coder™ to generate multithreaded code.

### Overview

One objective of model-based design is to create realistic models of physical systems and to simulate these models in real-time, for example, to verify controllers using hardware-in-the-loop (HIL). However, as more features are added to the plant model, the computational requirements may exceed the resources available by single-core processing systems.

Partitioning the plant and controller into separate pieces is one way to address the computational needs of complex models. With Simulink® you can partition a plant using Model blocks and then assign the code generated by each sub-model to threads for real-time execution on an HIL system such as Simulink Real-Time™. To see how this works, let us use our host computer as a stand-in for the real-time execution environment and generate real-time multi-threaded code for the following model.

slexMulticoreSolverExample

### Symmetric Multicore Processing

The illustration above shows that the code generated for the model is separated into two threads. In this example, the target is assumed to be a Symmetric Multicore Processor, so that the threads are

not associated with any particular core. The operating system is responsible for making the best use of the cores when scheduling thread execution. Ideally, to provide maximum flexibility, the number of threads (Nt) should be greater than the number of cores (Nc). Double-click on the 'Generate Code and Profile Report' button to generate multi-threaded code, profile its execution and visualize the results. The visualization shows a core occupancy map of how the cores were utilized at each time step of execution. It can be seen that the threads float across cores as deemed best by the operating system scheduler. This kind of scheduling is good when the operating system also needs to run other processes.

Clock Tick / Task	0	10	19
<a href="#">Thread1</a>	14 6 6 12 12 14 12 12 12 4 4 0 0 4 6 8 14 10 10 12		
<a href="#">Thread2</a>	10 2 0 0 0 0 14 14 14 2 2 14 14 2 2 0 0 0 14 4		

### Thread Synchronization

Simulink® Coder™ generates code such that the two threads may execute simultaneously and possibly on two different cores. This means that the signal values for  $x_1$  and  $x_2$  must be synchronized between the two threads. Simulink® provides several options to handle this requirement as illustrated here:

### Data Transfer Options

#### Defaults

- Periodic signals: Ensure deterministic transfer (maximum delay)
- Continuous signals: Ensure deterministic transfer (maximum delay)
- Extrapolation method: Ensure data integrity only
- Automatically handle: Ensure deterministic transfer (maximum delay)
- Automatically handle: Ensure deterministic transfer (minimum delay)

Using the script below, we will simulate and demonstrate the effect of the deterministic modes to understand how Simulink® handles synchronization.

- Reference solution (ode3) - Simulink® is configured to provide the reference solution by synchronizing data at each major and minor time step.
- Zero Order Hold - Each thread is solving a sub-system of equations using its own solver, while synchronizing data only on major time steps.
- Linear extrapolation - In addition to the Zero Order Hold mode, each solver extrapolates data using linear predictions to compensate for data latency errors.

For most systems where the synchronization points are smooth, the linear extrapolation mode provides a good tradeoff between communication bottlenecks and numerical accuracy.

```
h = figure;
hVal = ishold;
hold on;
mdl = 'slexMulticoreSolverExample';
dt = get_param(mdl, 'DataTransfer');

modes = { ...
 'Ensure deterministic transfer (minimum delay)', ...
 'None', 'k:', ...
 'Ensure deterministic transfer (maximum delay)', ...
 'Zero Order Hold', 'm', ...
 'Ensure deterministic transfer (maximum delay)', ...
 'Linear', 'b' ...
};

for i=1:3:length(modes)
dt.DefaultTransitionBetweenContTasks = modes{i};
dt.DefaultExtrapolationMethodBetweenContTasks = modes{i+1};
out = sim(mdl);
plot(out.logout.get('x1').Values.Time, ...
 out.logout.get('x1').Values.Data, ...
 modes{i+2});
end
```

```
legend('Reference solution (ode3)', ...
 'Zero Order Hold Extrapolation', ...
 'Linear Extrapolation');
```

### Closing the Models

```
close_system('slexMulticoreSolverExample',0);
close_system('slexMulticoreSolverMdlref',0);
if ~hVal, hold off; end
delete(h);
```

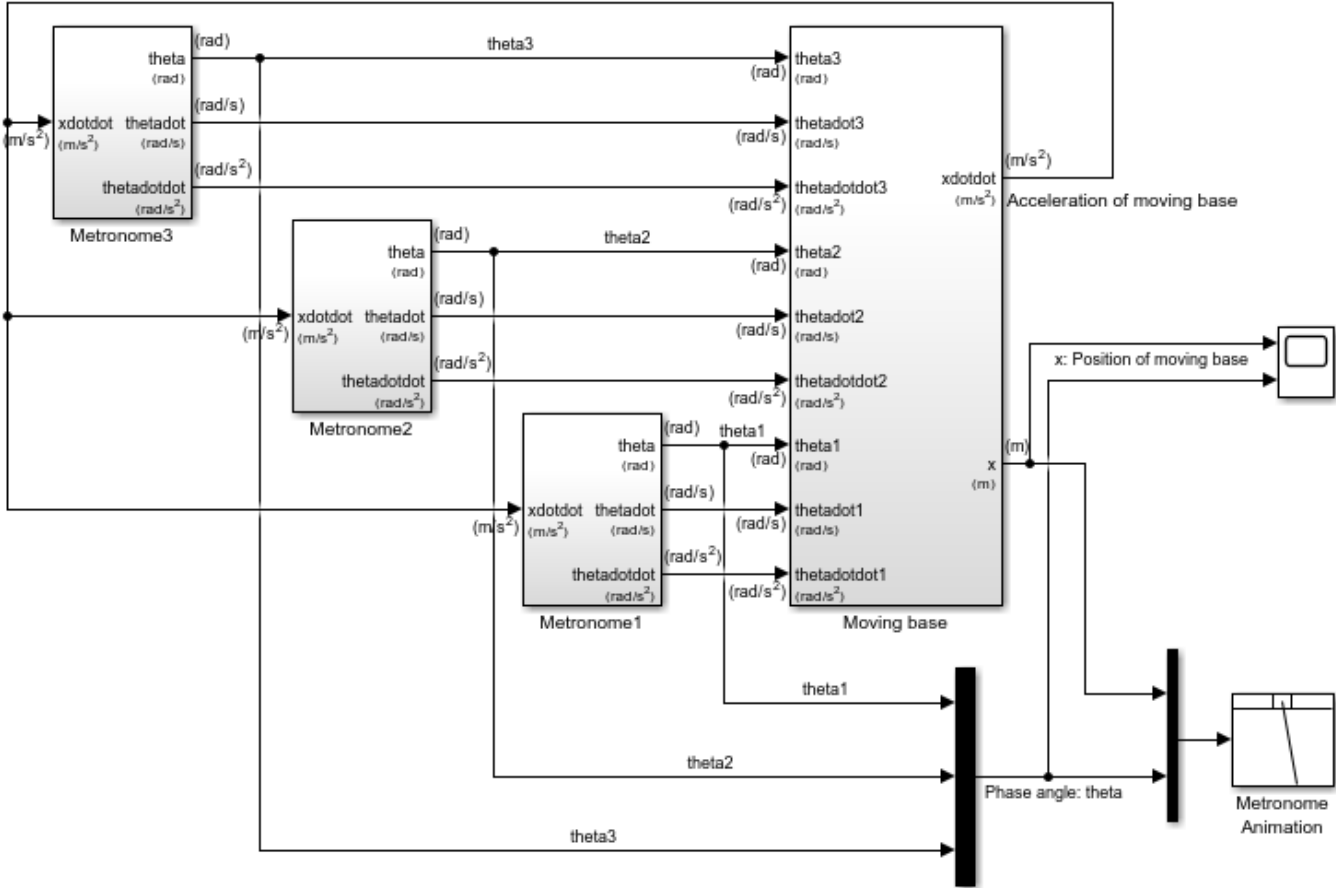

## Modeling Objects with Identical Dynamics Using For Each Subsystem

This example shows how to model multiple objects with identical dynamics using the For Each subsystem. The number of objects is parameterized by the length of the input signal.

This example illustrates how you can implement the model `sldemo_metro_basic`, using one For Each subsystem to model three identical metronomes and another to model the identical effect that the motion of each metronome has on the moving base.

The continuous dynamics of the three identical metronomes in `sldemo_metro_basic` are modeled in identical subsystems: `sldemo_metro_basic/Metronome1`, `sldemo_metro_basic/Metronome2`, and `sldemo_metro_basic/Metronome3`. You can represent these three subsystems as one For Each subsystem. The initial position of the metronomes is passed in as a mask parameter to the For Each subsystem, and is used as an initial condition for one of the integrators. The For Each subsystem is configured to partition this parameter along the first dimension. As a result, an input vector with three elements defines the initial positions for the three metronomes.

### Exploring the Solver Jacobian Structure of a Model Base model for `sldemo_metro_foreach`

Copyright 2018 The MathWorks, Inc.

**Figure 1:** Metronomes modeled using three subsystems with identical dynamics

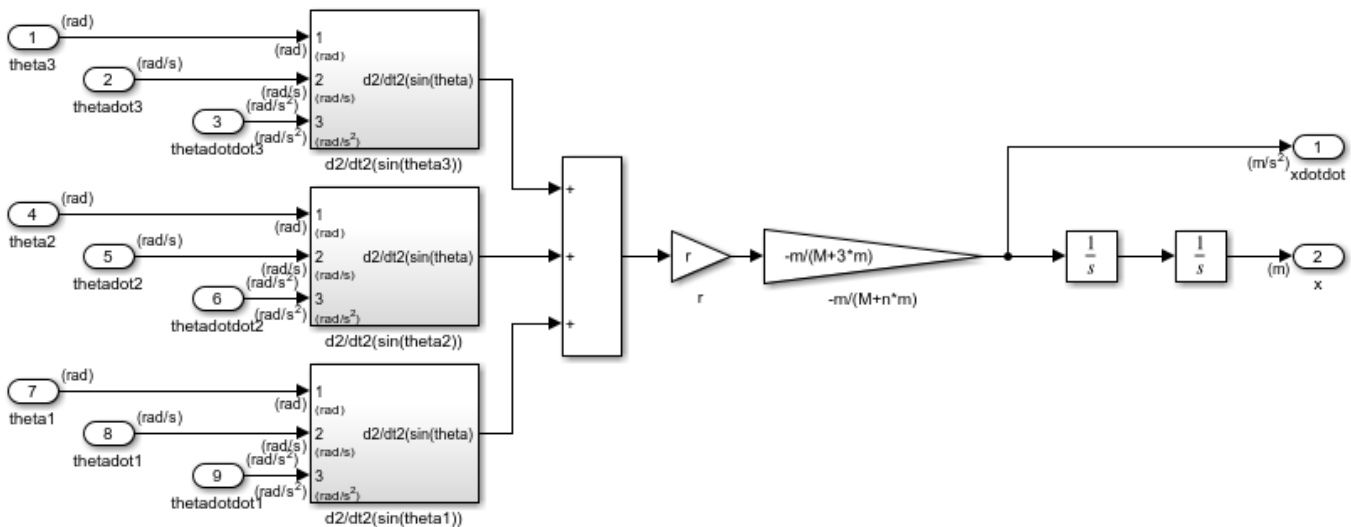

### Modeling Objects with Identical Dynamics using For Each Subsystem

Copyright 2011-2014 The MathWorks, Inc.

**Figure 2:** Metronomes modeled using one For Each subsystem

On examining the dynamics of the moving base, note that it involves three identical second-order differential terms corresponding to each metronome. You can replace the three copies with one For Each Subsystem. Instead of nine input signals, the For Each subsystem requires only three input signals: the angular displacements, the angular velocities, and the angular accelerations for all metronomes. The For Each subsystem is configured to partition the input signal along the first dimension and operates on one element from each signal for one iteration (i.e. one metronome).

**Figure 3:** Second-order differential terms modeled using copies of the same subsystem

**Figure 4:** Second-order differential terms modeled using one For Each subsystem

After implementing the original model with two For Each subsystems, the model is now parameterized for the number of metronomes. To increase the number of metronomes, introduce a new value to the mask parameter.

For example:

Theta4 = 0.7568;

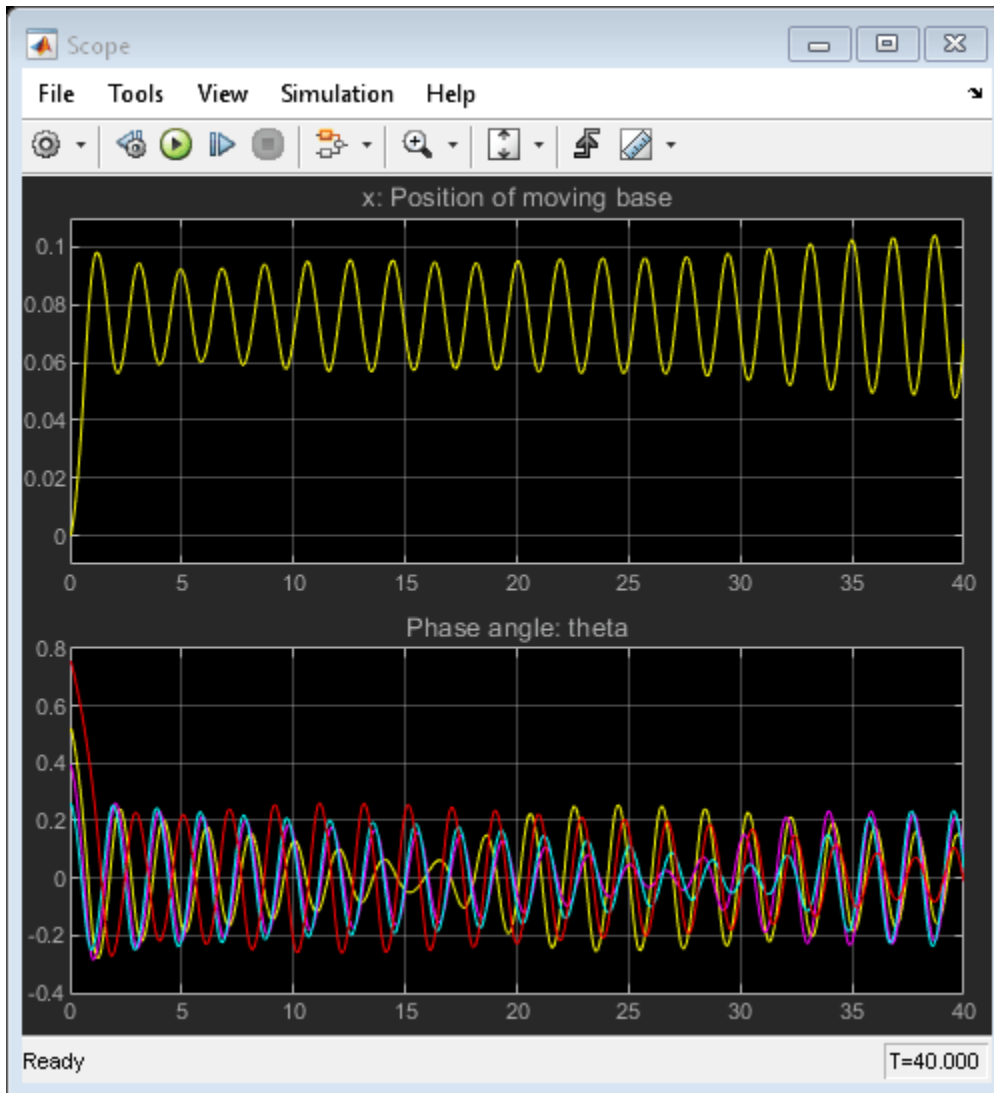

Double-click on the Metronome\_i block to open the mask dialog and change Input Positions (Partitioned) to: [Theta1 Theta2 Theta3 Theta4]

Execute the model to see the displacement angles of the four metronomes and the position of the moving base.

```
sim('sldemo_metro_foreach');
```

**Figure 5:** Simulation animation with For Each subsystem parameterized for four metronomes

**Figure 6:** Simulation result with For Each subsystem parameterized for four metronomes

## Vectorizing a Scalar Algorithm with a For Each Subsystem

This example shows how to use the For Each subsystem. In this example the operations are performed on a vector for simplicity.

Use the **Open Model** button to open the example model `sldemo_foreach_vectorized`. This model contains a For Each subsystem that processes the input signals one by one.

The inputs to the For Each subsystem are the signals to process, the coefficients of the FIR filter to use with each of these signals, and the common gain.

Each signal is scalar and needs to be processed individually. Consequently, the For Each block that controls the partition dimension is set to partition the input signal along dimension 1, by slicing through a partition width of 1. For each input signal, a corresponding set of coefficients must also be partitioned using the same criteria. The gain is common to all the signals, so this input is not partitioned.

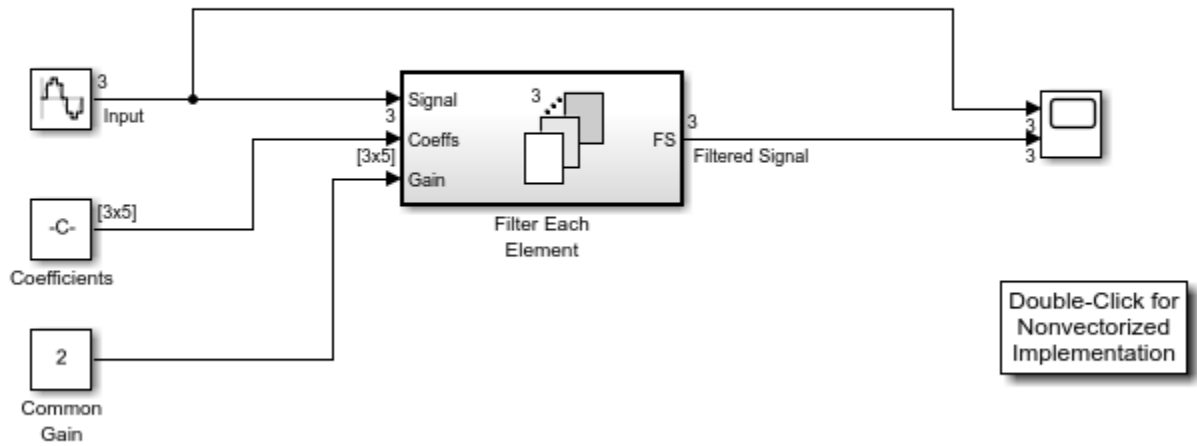

Since the output signal dimension is expected to match the input signal dimension, the concatenation dimension is set equal to the partition dimension. If you prefer to change the signal dimension (a transpose in this case), you can choose 2 as the concatenation dimension.

For the For Each subsystem, you must set the partition dimension and width, but not the input signal size. A check then ensures that this size is a multiple of the partition width. If no error is detected, the subsystem then calculates the number of independent executions that the enclosed subsystem will perform. These executions are independent, in that the state associated with a given block contained in the subsystem has a unique value in each of the respective executions.

To see a non-vectorized implementation for this model, double-click on the block in the lower-right corner of the model. This implementation does not use the For Each subsystem, but mimics its functionality by replicating the subsystem as many times as necessary and also by selecting and concatenating the signals appropriately. This replication process is prone to error and is not scalable -- changing the input signal size would require changing the model accordingly.

For Each Subsystem:  
Vectorizing a Scalar Algorithm

## Tiled Processing of 2D Signals with For Each Subsystem

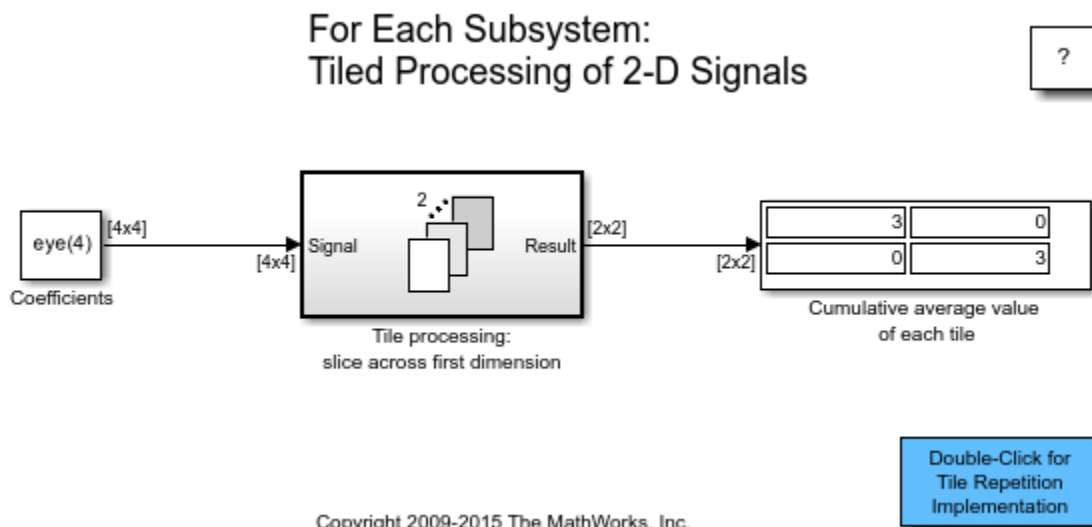

This example shows how to use the For Each Subsystem. In this example the operations are performed on matrices.

Open the example model `sldemo_foreach_tiled`. This model contains a For Each subsystem that processes submatrices of a matrix input signal.

To process submatrices of a matrix signal, you will need to use nested For Each subsystems. The outer subsystem can be used to partition the signal along the first dimension, while the inner one can be used to partition along the second dimension. This order is arbitrary, and can be changed without affecting the result.

In this example a 4-by-4 matrix is to be partitioned into 2-by-2 submatrices. The outer subsystem partitions the signal along the first dimension. The resulting subarrays are then partitioned by the inner subsystem along the second dimension. Concatenation of the outputs respects the partitioning order to preserve the shape of the input signal. Note, however, that the output dimensions change since the processing of the submatrices results in scalar outputs.

To see a tile repetition implementation for this model, double-click on the subsystem in the lower-right corner of the model window. This implementation does not use the For Each Subsystem. Instead, it mimics the functionality of the For Each Subsystem by replicating the subsystem as many times as necessary and by selecting and concatenating the signals appropriately. This replication process is prone to error and is not scalable -- changing the input signal size would require changing the model accordingly.

## Using a Project with SVN

This example shows how to use a project to manage the files within your design. Starting with an existing project that is already checked into source control, this example shows how to view modified files, compare file revisions, and analyze project dependencies.

### Set Up the Example Files and Open the Project

Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them. The example project is under Subversion (SVN) version control.

```
sldemo_slproject_airframe_svn
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

```
ans =
```

```
Project with properties:
```

```

 Name: "Airframe Example"
SourceControlIntegration: "SVN (1.9)"
 RepositoryLocation: "file:///C:/workSpace/examples/repositories/airframe2/trunk"
SourceControlMessages: [1x0 string]
 ReadOnly: 0
 TopLevel: 1
 Dependencies: [1x1 digraph]
 Categories: [1x1 matlab.project.Category]
 Files: [1x30 matlab.project.ProjectFile]
 Shortcuts: [1x7 matlab.project.Shortcut]
 ProjectPath: [1x7 matlab.project.PathFolder]
ProjectReferences: [1x0 matlab.project.ProjectReference]
 StartupFiles: [1x0 string]
 ShutdownFiles: [1x0 string]
DefinitionFileType: FixedPathMultiFile
 Description: "This is an example project. Use the "Project Shortcuts" toolstrip
 RootFolder: "C:\workSpace\examples\airframe2"
SimulinkCodeGenFolder: "C:\workSpace\examples\airframe2\work\codegen"
SimulinkCacheFolder: "C:\workSpace\examples\airframe2\work\cache"
ProjectStartupFolder: "C:\workSpace\examples\airframe2"
```

## Manage the Project Path

When you open your project, MATLAB adds the project path to the MATLAB search path before applying startup shortcuts.

When you close your project, MATLAB removes the project path from the MATLAB search path after applying shutdown shortcuts.

1. To add or remove folders to the project path, on the **Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

It is important to add project files to the project path to ensure the Dependency Analyzer detects all project files.

## Specify Project Details, Startup Folder, and Derived Files Folders

2. On the **Project** tab, in the **Environment** section, click **Details**. Use the Project Details dialog box to:

- Edit the project name or add a description.
- View the **Project root** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths.

- View or edit the **Start Up** folder. By default, this is set to the project root. When you open the project, the current working folder changes to the project root folder. You can specify a different startup folder or click **Clear**.
- View or edit the **Simulation cache folder** and **Code generation folder**.

To change the default project root for new projects, on the MATLAB **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project** and specify the **Default folder**.

### Automate Startup and Shutdown Tasks

You can set project files, such as MATLAB scripts and Simulink® models, to run, open, or close when the project opens or closes.

3. To configure an existing file to run on project startup and shutdown, or to specify environment options, click the **Startup Shutdown** button in the **Project** tab. In the Manage Project Startup and Shutdown dialog box

- Add or remove startup and shutdown files. If execution order is important, change the order using the arrow buttons.
- Use the check boxes to specify environment options. Select **Start Simulink before this project starts** to start Simulink when you open the project. Select **Refresh Simulink customizations** to run `sl_customization` files on project startup and shutdown.

### Project Shortcuts for Common Tasks

Create project shortcuts for common tasks to make it easy to find and access important files and operations. For example, find and open top models, run code, and simulate models.

4. On the **Project Shortcuts** tab, this example project has shortcuts for the top-level model, a utility function to rebuild s-functions, and a design description document.

- Click the shortcut *F14 Model* to open the root model for this project.
- Click the shortcut *Rebuild Project's S-functions* to generate the S-Function.
- Click the **New Shortcut** button to create new shortcuts for a project file.
- Right-click a shortcut and select **Edit Shortcut** to edit a shortcut.

### View Source Control Information

On the **Project** tab, in the **Source Control** section, click **SVN Details**.

5. Use the Source Control Information dialog box to:

- View the **Repository location** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths.
- View or change the used source control integration.

### Explore Files Views

6. In the **Files** view, select the **Project (number of files)** view to manage the files within your project. This view only shows files that are part of your project.

7. Use the **All** view to see all the files in your working copy. This shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to your project from your working copy.

8. Use the **Modified (number of files)** view to review the modified files before committing your changes to source control. The modified files view is visible only if you are using source control with your project.

9. In any **Files** view, at the top right, change the layout from **Tree** to **List** to view the files as a list. Click the Organize View button  to customize the views and to sort files.

The **SVN** column provides source control information on individual files such as Unmodified, Added, Modified, or Deleted.

### View Modified Files and Compare Revisions

10. Open and make a change to one of the models in the `models` folder or to one of the MATLAB files in the `utility` folder. For example, add a comment in `find_top_models.m` in the `utility` folder.

11. To review, analyze, and commit modified or added project files, use the **Modified (number of files)** view. You see:

- The file you made changes to, for example, `find_top_models.m`.
- The files stored in the `resources/project` folder. These are internal project definition files generated by your changes. The project definition files allow you to add metadata to files, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project. You can review changes in revisions of project definition files like any other project files.

12. To review changes in a modified file, right-click selected file, for example, `find_top_models.m`

- Select **Compare > Compare to Ancestor** to run a comparison against the local Git repository.
- Select **Compare > Compare to Revision** to compare the file to other revisions.

13. The Comparison Tool summarizes results in a report. Purple indicates modified items, blue indicates inserted items, and yellow indicates deleted items. To save a printable version of the report, select **Publish > HTML, Word, or PDF**.

14. If you are happy with your changes, on the **Project** tab, click the **Commit** button to commit your changes to source control.

### Analyze Project Dependencies

15. Use the Dependency Analyzer to investigate dependencies visually and explore the structure of your project. On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

The Dependency Analyzer summarizes the results in the pane on the right. It lists the names of the used **Products** and **Add-Ons**. It detects problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. In this example, the analyzer identifies a "File not in project" and tags it with a warning sign .

16. To highlight problem files, in the **Problems** section, point to the problem message and click the magnifying glass. In this example, the `timesthree.mexw64` file is required by the project but is

not currently part of it. Right-click `timesthree.mexw64` and select **Add to Project** or **Hide Warnings**. The next time you run the dependency analysis, the analyzer will not mark this file as a problem.

17. Perform an impact analysis on a selected file.

An impact analysis shows you how a change affects other files before you make the change. For example, to find required files for `timesthree.mexw64` to run properly, right-click `timesthree.mexw64` and select **Find Required**. To find how changes to `timesthree.mexw64` impact files, right-click `timesthree.mexw64` and select **Find Impacted**.

## Using a Project with Git

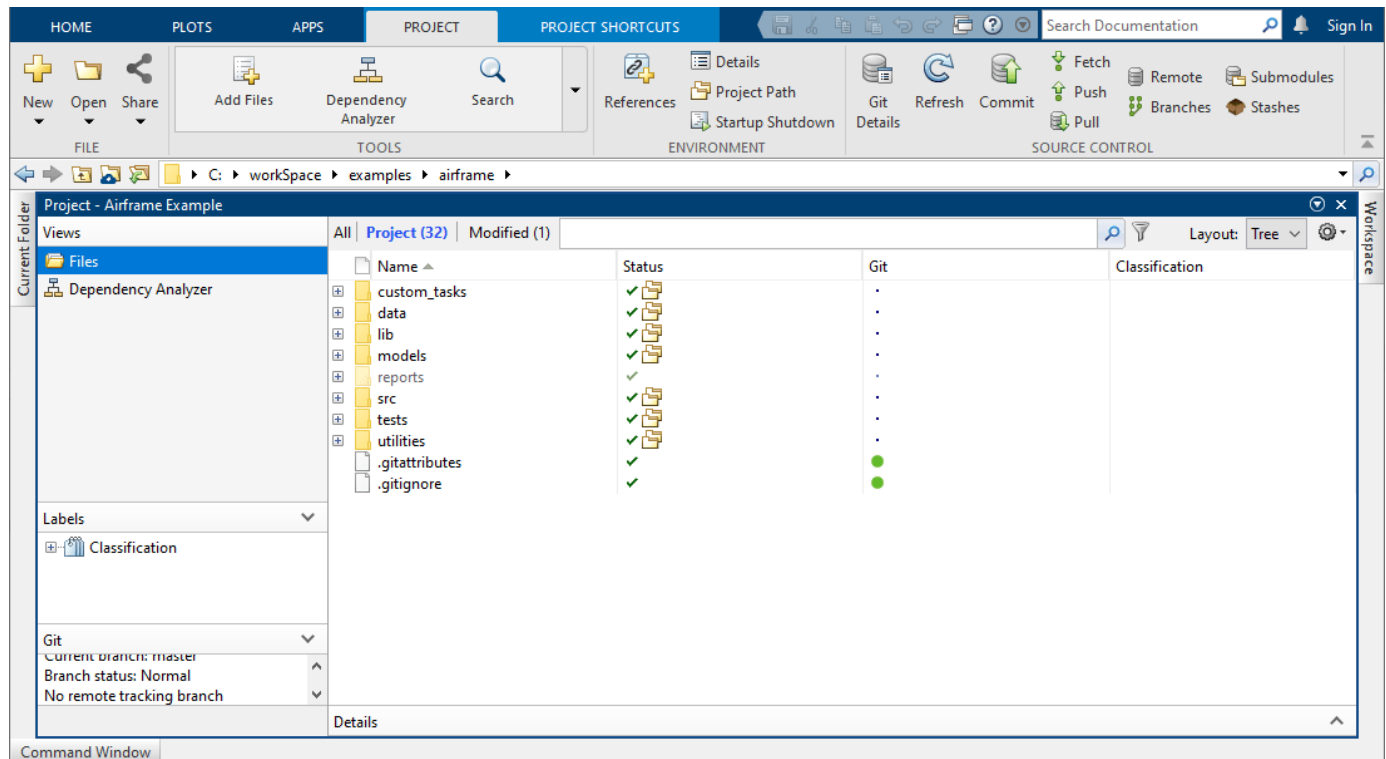

This example shows how to use a project to manage the files within your design. Starting with an existing project that is already checked into source control, this example shows how to view modified files, compare file revisions, and analyze project dependencies.

### Set up the Example Files and Open the Project

Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them. The example project is under Git™ source control.

```
sldemo_slproject_airframe;
```

```
Starting: Simulink
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

### Manage the Project Path

When you open your project, MATLAB adds the project path to the MATLAB search path before applying startup shortcuts.

When you close your project, MATLAB removes the project path from the MATLAB search path after applying shutdown shortcuts.

1. To add or remove folders to the project path, on the **Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

It is important to add project files to the project path to ensure the Dependency Analyzer detects all project files.

### Specify Project Details, Startup Folder, and Derived Files Folders

2. On the **Project** tab, in the **Environment** section, click **Details**. Use the Project Details dialog box to:

- Edit the project name or add a description.
- View the **Project root** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths.
- View or edit the **Start Up** folder. By default, this is set to the project root. When you open the project, the current working folder changes to the project root folder. You can specify a different startup folder or click **Clear**.
- View or edit the **Simulation cache folder** and **Code generation folder**.

To change the default project root for new projects, on the MATLAB **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project** and specify the **Default folder**.

### Automate Startup and Shutdown Tasks

You can set project files, such as MATLAB scripts and Simulink® models, to run, open, or close when the project opens or closes.

3. To configure an existing file to run on project startup and shutdown, or to specify environment options, click the **Startup Shutdown** button in the **Project** tab. In the Manage Project Startup and Shutdown dialog box

- Add or remove startup and shutdown files. If execution order is important, change the order using the arrow buttons.
- Use the check boxes to specify environment options. Select **Start Simulink before this project starts** to start Simulink when you open the project. Select **Refresh Simulink customizations** to run `sl_customization` files on project startup and shutdown.

### Project Shortcuts for Common Tasks

Create project shortcuts for common tasks to make it easy to find and access important files and operations. For example, find and open top models, run code, and simulate models.

4. On the **Project Shortcuts** tab, this example project has shortcuts for the top-level model, a utility function to rebuild s-functions, and a design description document.

- Click the shortcut *F14 Model* to open the root model for this project.
- Click the shortcut *Rebuild Project's S-functions* to generate the S-Function.
- Click the **New Shortcut** button to create new shortcuts for a project file.

- Right-click a shortcut and select **Edit Shortcut** to edit a shortcut.

### View Source Control Information

On the **Project** tab, in the **Source Control** section, click **Git Details**.

5. Use the Source Control Information dialog box to:

- View the **Repository location** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths.
- View or change the used source control integration.

### Explore Files Views

6. In the **Files** view, select the **Project (number of files)** view to manage the files within your project. This view only shows files that are part of your project.

7. Use the **All** view to see all the files in your working copy. This shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to your project from your working copy.

8. Use the **Modified (number of files)** view to review the modified files before committing your changes to source control. The modified files view is visible only if you are using source control with your project.

9. In any **Files** view, at the top right, change the layout from **Tree** to **List** to view the files as a list. Click the Organize View button  to customize the views and to sort files.

The **Git** column provides source control information on individual files such as Unmodified, Added, Modified, or Deleted.

### View Modified Files and Compare Revisions

10. Open and make a change to one of the models in the `models` folder or to one of the MATLAB files in the utility folder. For example, add a comment in `find_top_models.m` in the utility folder.

11. To review, analyze, and commit modified or added project files, use the **Modified (number of files)** view. You see:

- The file you made changes to, for example, `find_top_models.m`.
- The files stored in the `resources/project` folder. These are internal project definition files generated by your changes. The project definition files allow you to add metadata to files, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project. You can review changes in revisions of project definition files like any other project files.

12. To review changes in a modified file, right-click selected file, for example, `find_top_models.m`

- Select **Compare > Compare to Ancestor** to run a comparison against the local Git repository.
- Select **Compare > Compare to Revision** to compare the file to other revisions.

13. The Comparison Tool summarizes results in a report. Purple indicates modified items, blue indicates inserted items, and yellow indicates deleted items. To save a printable version of the report, select **Publish > HTML, Word, or PDF**.

14. If you are happy with your changes, on the **Project** tab, click the **Commit** button to commit your changes to source control.

### Analyze Project Dependencies

15. Use the Dependency Analyzer to investigate dependencies visually and explore the structure of your project. On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

The Dependency Analyzer summarizes the results in the pane on the right. It lists the names of the used **Products** and **Add-Ons**. It detects problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. In this example, the analyzer identifies a "File not in project" and tags it with a warning sign .

16. To highlight problem files, in the **Problems** section, point to the problem message and click the magnifying glass. In this example, the `timesthree.mexw64` file is required by the project but is not currently part of it. Right-click `timesthree.mexw64` and select **Add to Project** or **Hide Warnings**. The next time you run the dependency analysis, the analyzer will not mark this file as a problem.

17. Perform an impact analysis on a selected file.

An impact analysis shows you how a change affects other files before you make the change. For example, to find required files for `timesthree.mexw64` to run properly, right-click `timesthree.mexw64` and select **Find Required**. To find how changes to `timesthree.mexw64` impact files, right-click `timesthree.mexw64` and select **Find Impacted**.

"Project Management"

## Get Started with MATLAB Projects

This example shows how to use an existing project to manage the files within your design. It shows how to automate startup and shutdown tasks, add shortcuts for common tasks, run checks, upgrade project files, analyze project dependencies, and share your project.

As a design grows, managing referenced files and dependencies becomes more complicated. Projects help you organize large hierarchies by finding required files, managing and sharing files and settings, and interacting with source control.

This project example is not under source control. As a result, essential tools needed in a collaborative environment are not available for use, for example, comparing files to their ancestors, comparing revisions and resolving conflicts.

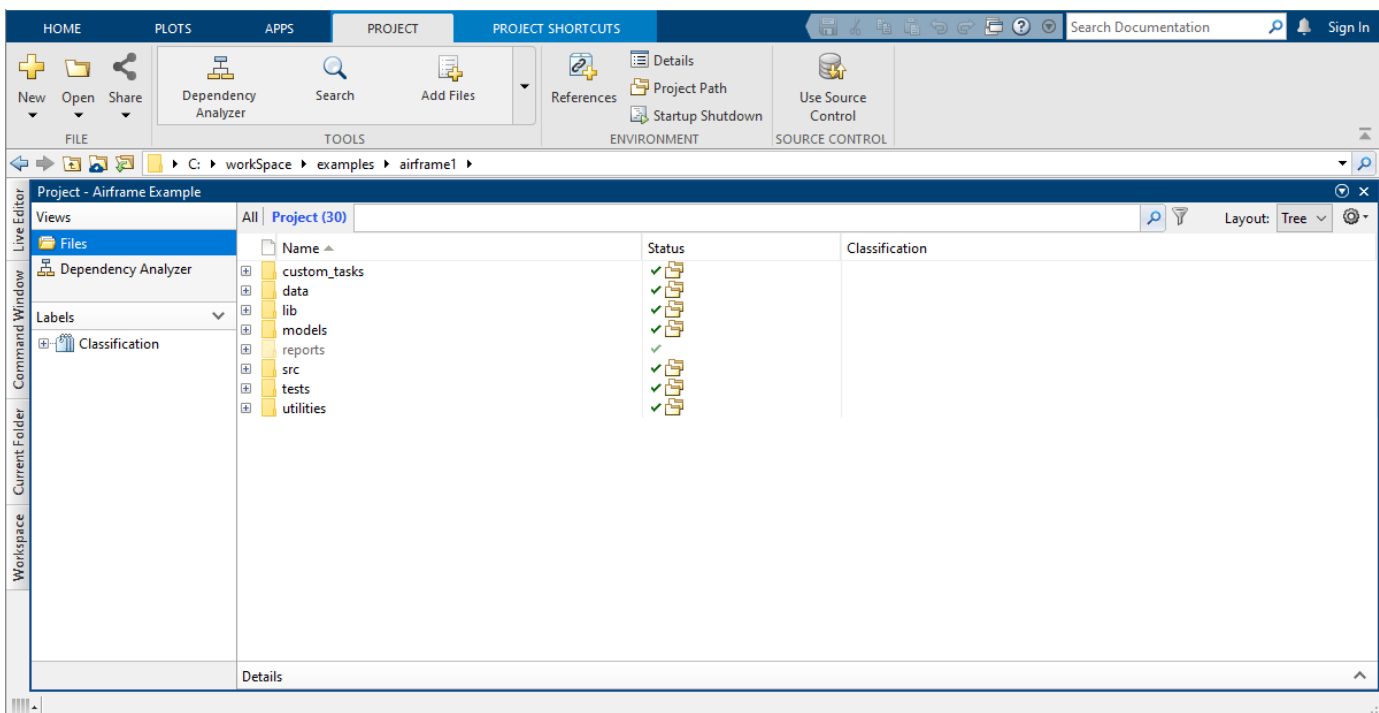

- To use available source control integration in MATLAB® such as Git™ and SVN, see “Using a Project with Git” on page 13-467 or “Using a Project with SVN” on page 13-462 example instead.
- To use an external source control with project, put the project folder under the source control of choice and customize it to use the MATLAB® Comparison Tool for diff and merge. For more information, see “Customize External Source Control to Use MATLAB for Diff and Merge”.

### Set up the Example Files and Open the Project

Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them.

```
sldemo_slproject_airframe_setup;
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

## Manage the Project Path

When you open your project, MATLAB adds the project path to the MATLAB search path before applying startup shortcuts.

When you close your project, MATLAB removes the project path from the MATLAB search path after applying shutdown shortcuts.

1. To add or remove folders to the project path, on the **Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

It is important to add project files to the project path to ensure the Dependency Analyzer detects all project files.

## Specify Project Details, Startup Folder, and Derived Files Folders

2. On the **Project** tab, in the **Environment** section, click **Details**. Use the Project Details dialog box to:

- Edit the project name or add a description.
- View the **Project root** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths.
- View or edit the **Start Up** folder. By default, this is set to the project root. When you open the project, the current working folder changes to the project root folder. You can specify a different startup folder or click **Clear**.
- View or edit the **Simulation cache folder** and **Code generation folder**.

To change the default project root for new projects, on the MATLAB **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project** and specify the **Default folder**.

## Automate Startup and Shutdown Tasks

You can set project files, such as MATLAB scripts and Simulink® models, to run, open, or close when the project opens or closes.

3. To configure an existing file to run on project startup and shutdown, or to specify environment options, click the **Startup Shutdown** button in the **Project** tab. In the Manage Project Startup and Shutdown dialog box

- Add or remove startup and shutdown files. If execution order is important, change the order using the arrow buttons.
- Use the check boxes to specify environment options. Select **Start Simulink before this project starts** to start Simulink when you open the project. Select **Refresh Simulink customizations** to run `sl_customization` files on project startup and shutdown.

## Project Shortcuts for Common Tasks

Create project shortcuts for common tasks to make it easy to find and access important files and operations. For example, find and open top models, run code, and simulate models.

4. On the **Project Shortcuts** tab, this example project has shortcuts for the top-level model, a utility function to rebuild s-functions, and a design description document.

- Click the shortcut *F14 Model* to open the root model for this project.
- Click the shortcut *Rebuild Project's S-functions* to generate the S-Function.
- Click the **New Shortcut** button to create new shortcuts for a project file.
- Right-click a shortcut and select **Edit Shortcut** to edit a shortcut.

## Explore Files Views

6. In the **Files** view, select the **Project (number of files)** view to manage the files within your project. This view only shows files that are part of your project.

7. Use the **All** view to see all the files in your working copy. This shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to your project from your working copy.

8. In any **Files** view, at the top right, change the layout from **Tree** to **List** to view the files as a list. Click the Organize View button  to customize the views and to sort files.

## Analyze Project Dependencies

9. Use the Dependency Analyzer to investigate dependencies visually and explore the structure of your project. On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

The Dependency Analyzer summarizes the results in the pane on the right. It lists the names of the used **Products** and **Add-Ons**. It detects problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. In this example, the analyzer identifies a "File not in project" and tags it with a warning sign .

10. To highlight problem files, in the **Problems** section, point to the problem message and click the magnifying glass. In this example, the `timesthree.mexw64` file is required by the project but is not part of it. Right-click `timesthree.mexw64` and select **Add to Project** or **Hide Warnings**. The next time you run the dependency analysis, the analyzer will not mark this file as a problem.

11. Perform an impact analysis on a selected file.

An impact analysis shows you how a change affects other files before you make the change. For example, to find required files for `timesthree.mexw64` to run properly, right-click `timesthree.mexw64` and select **Find Required**. To find how changes to `timesthree.mexw64` impact files, right-click `timesthree.mexw64` and select **Find Impacted**.

## Run Checks and Upgrade Project Files

12. Upgrade all models, libraries, and MATLAB code files in your project to the latest release using a simple workflow. On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Upgrade Project**.

To upgrade all files, run all checks, and apply fixes automatically where possible, click **Upgrade**. If you want to change the settings, use these options before clicking **Upgrade**:

- If you want to run upgrade checks but not apply fixes automatically where possible, clear the check box **Apply upgrades automatically**.
- If you want to change which files to upgrade and which checks to run, click **Change Options**. In the Upgrade Options dialog box, clear check boxes for models and checks you want to exclude from the upgrade.

The Upgrade Project tool apply all fixes automatically when possible, upgrade all model hierarchies in the project at once, and produce a report.

### **Share Project**

Before sharing projects with other users, it is helpful to find required files and products using the Dependency Analyzer.

13. On the **Project** tab, select **Share** and explore the different sharing options.

You can share your project as an archive and send it by email. On the **Project** tab, select **Share > Archive**. You can export the whole project or just a part of it using **Export profile**. If you decide to exclude files from your project, use the Dependency Analyzer to examine the impact of excluding a file on the project. If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.

You can also share your project and make it publicly available on GitHub®. This adds Git source control to the open project.

“Run Custom Tasks with a Project” on page 13-488

### **Further Information**

“Project Management”

## Perform Impact Analysis with a Project

This example shows how to perform file-level impact analysis using the Dependency Analyzer. It shows how to visualize project structure, analyze project dependencies, find required add-ons and products, identify and fix problems, and assess how a change will affect other project files.

You can run a dependency analysis at any point in your workflow. In a collaborative environment, you typically check dependencies

- when you first set up or explore a project
- when you run tests to validate changes to your design
- before you submit a version of your project to source control
- before you share or package your project

### Set Up the Example Files and Open the Project

Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them. The example project is under Git™ source control.

```
sldemo_slproject_airframe;
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

### Visualize Project Structure and Dependencies

Run a dependency analysis on all the files in your project.

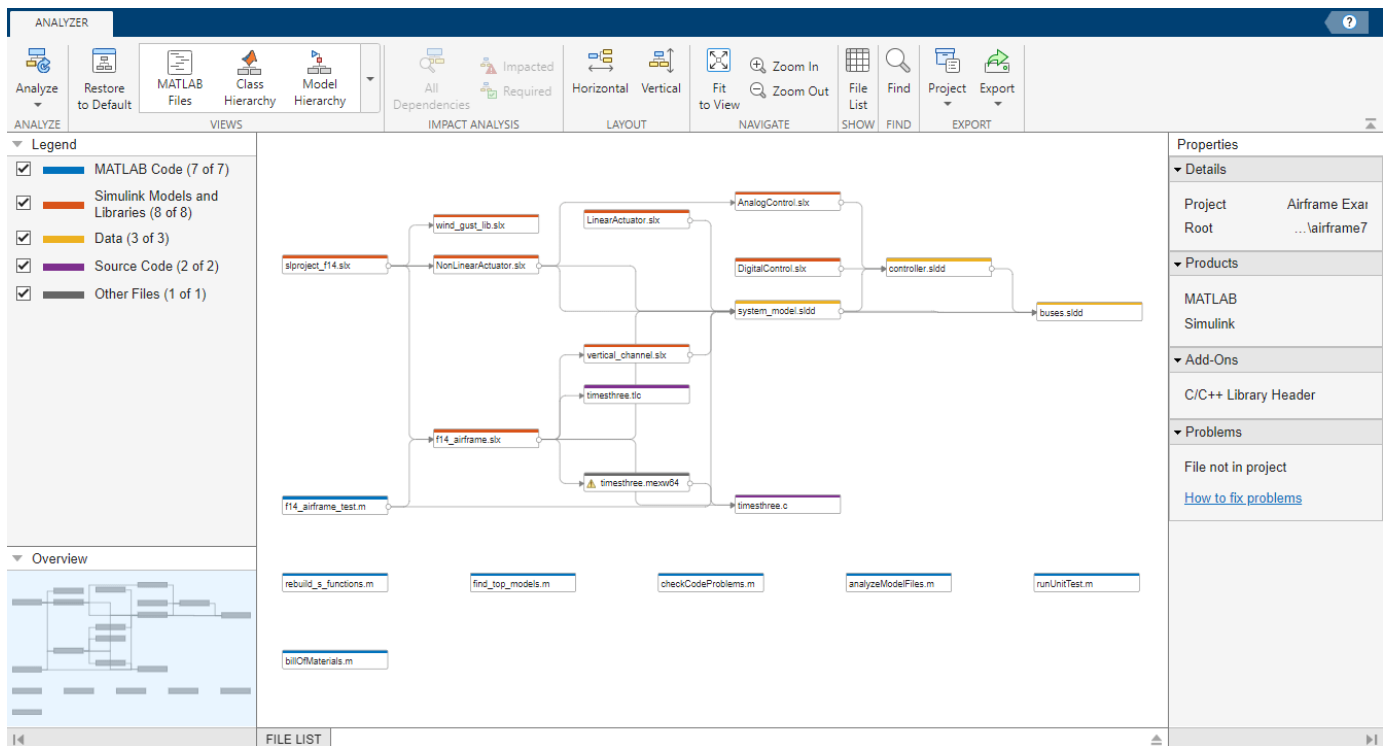

1. On the **Project** tab, click the down arrow to expand the **Tools** section. Under **Apps**, click **Dependency Analyzer**.

The dependency graph shows:

- Your project structure and its file dependencies, including how files such as models, libraries, functions, data files, source files, and derived files relate to each other. Each item in the graph represents a file and each arrow represents a dependency
- Relationships between source and derived files (such as .m and .p files, .slx and .slxp, and .c and .mex files), and between C/C++ source and header files

When no file is selected, the **Properties** pane shows:

- The project details
- The required products and add-ons for the entire project
- The list of problems for the entire project, such as missing files, files not in the project, files with unsaved changes, and out-of-date derived files

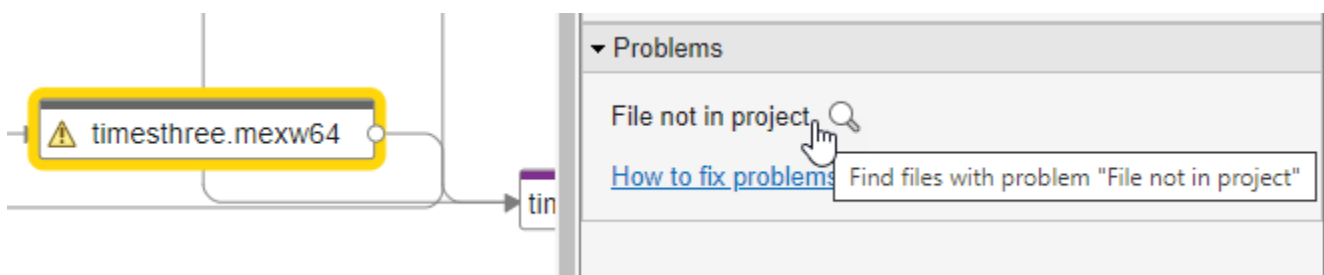

### Investigate and Resolve Problems

The Dependency Analyzer identifies problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. You can examine problem files using the dependency graph or the file list.

Use the graph to investigate problem files.

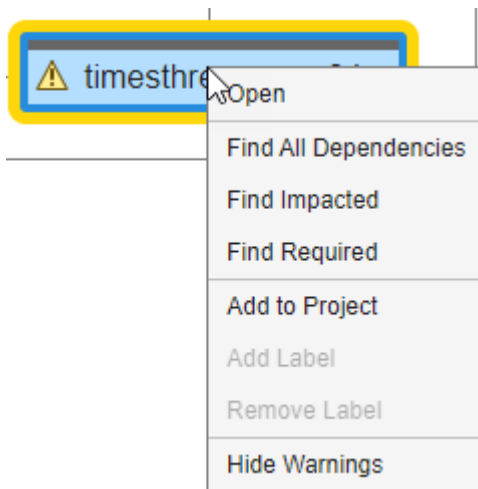

2. In the **Properties** pane, in the **Problems** section, point to **File not in project** and click the magnifying glass icon .

The graph highlights the files with this specific problem, in this example, `timesthree.mexw64`.

Take actions to resolve the problem file.

3. Right-click `timesthree.mexw64` and select **Add to Project**. To remove `timesthree.mexw64` from the problem list without adding it to the project, right-click and select **Hide Warnings**.

4. Click **Analyze** to update the graph and the **Problems** list.

Tip: For large projects, use the **File List** to investigate your project problem files. For more details, see “Investigate Problem Files in File List”.

#### **View Modified Files**

5. Open and make a change to one of the models, for example, `vertical_channel.slx`.

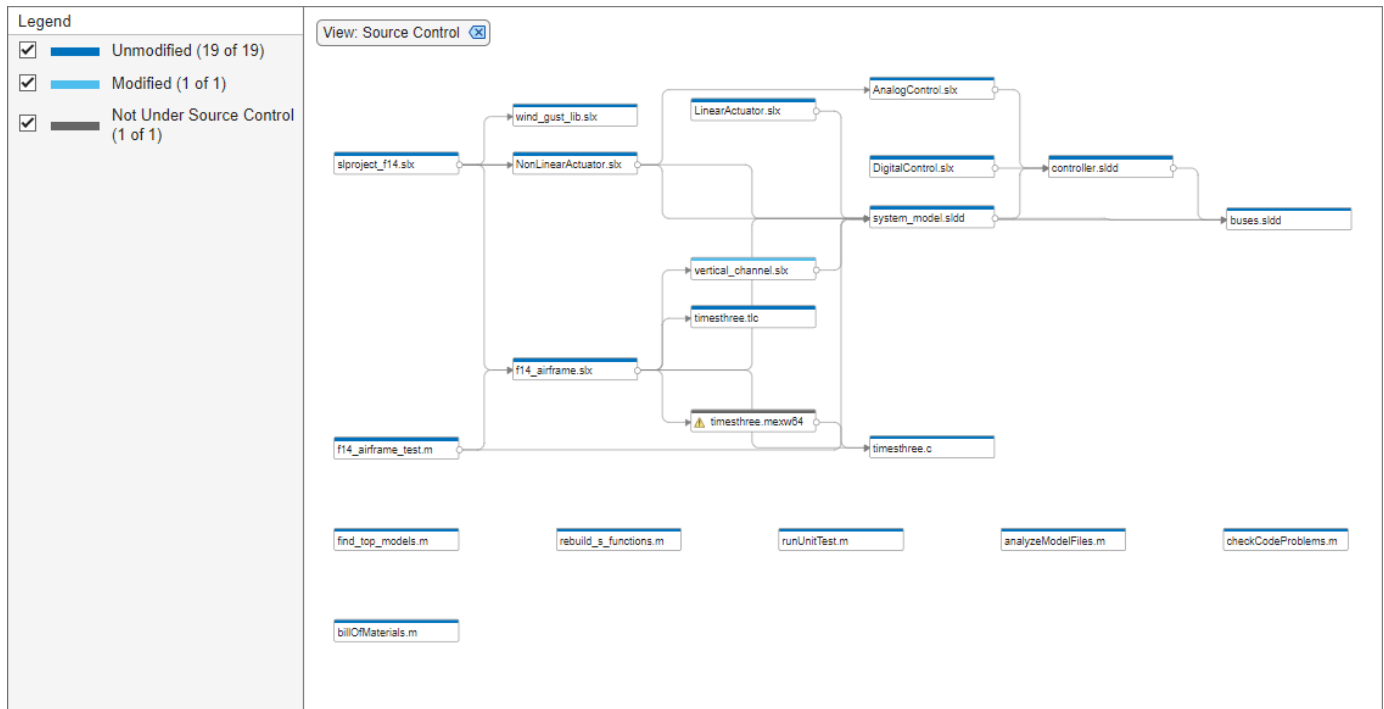

a. In the dependency graph, double-click `vertical_channel.slx` to open it.

b. Move a block in `vertical_channel.slx` and save the model.

Use the **Views** gallery to display the source control status of each file in the dependency graph.

6. In the Dependency Analyzer toolstrip, expand the **Views** gallery and click **Source Control**.

The color of each item in the graph now represents its source control status. Since you made a change to `vertical_channel.slx`, its source control status is **Modified**.

### Find the Impact of the Change

You can use the **Impact Analysis** tools to find:

- the files impacted by a change to a file
- the files required by a file to run successfully

7. Use the **Impact Analysis** tools to assess the impact your change has on other files.

a. In the dependency graph, select the file you modified, for example, `vertical_channel.slx`.

b. In the **Impact Analysis** section, click **Impacted**.

The dependency graph filters files and shows only those impacted by the changes you made to `vertical_channel.slx`.

The screenshot shows the Source Control tool interface. On the left is a Legend with three items: 'Unmodified (3 of 19)' (blue bar), 'Modified (1 of 1)' (light blue bar), and 'Not Under Source Control (0 of 1)' (grey bar). The main area shows a dependency graph with nodes: 'slproject\_f14.slx' (Unmodified), 'f14\_airframe.slx' (Unmodified), and 'vertical\_channel.slx' (Modified). A 'Model Reference' arrow points from 'f14\_airframe.slx' to 'vertical\_channel.slx'. On the right, the Properties pane shows details for the impacted model, including a table:

Model Reference	
Impacted	Required
<a href="#">Model</a>	vertical_channel

Below the table is a button labeled 'Open and highlight dependency Model'.

8. Find where the dependency to `vertical_channel.slx` is introduced in `f14_airframe.slx`.

a. Select the dependency arrow linking `f14_airframe.slx` to `vertical_channel.slx`.

b. In the **Properties** pane, click the link under **Impacted**. Simulink® opens the model `f14_airframe.slx` and highlights the model block `vertical_channel`.

Copyright 1990-2018 The MathWorks, Inc.

## Identify Tests to Run

Project automatically associates Classification labels to each project files. This includes **Design**, **Artifact**, **Convenience**, **Derived**, and **Test** labels. The **Test** label identifies which files are tests. You can create additional classification to label your files. See “Add Labels to Files”.

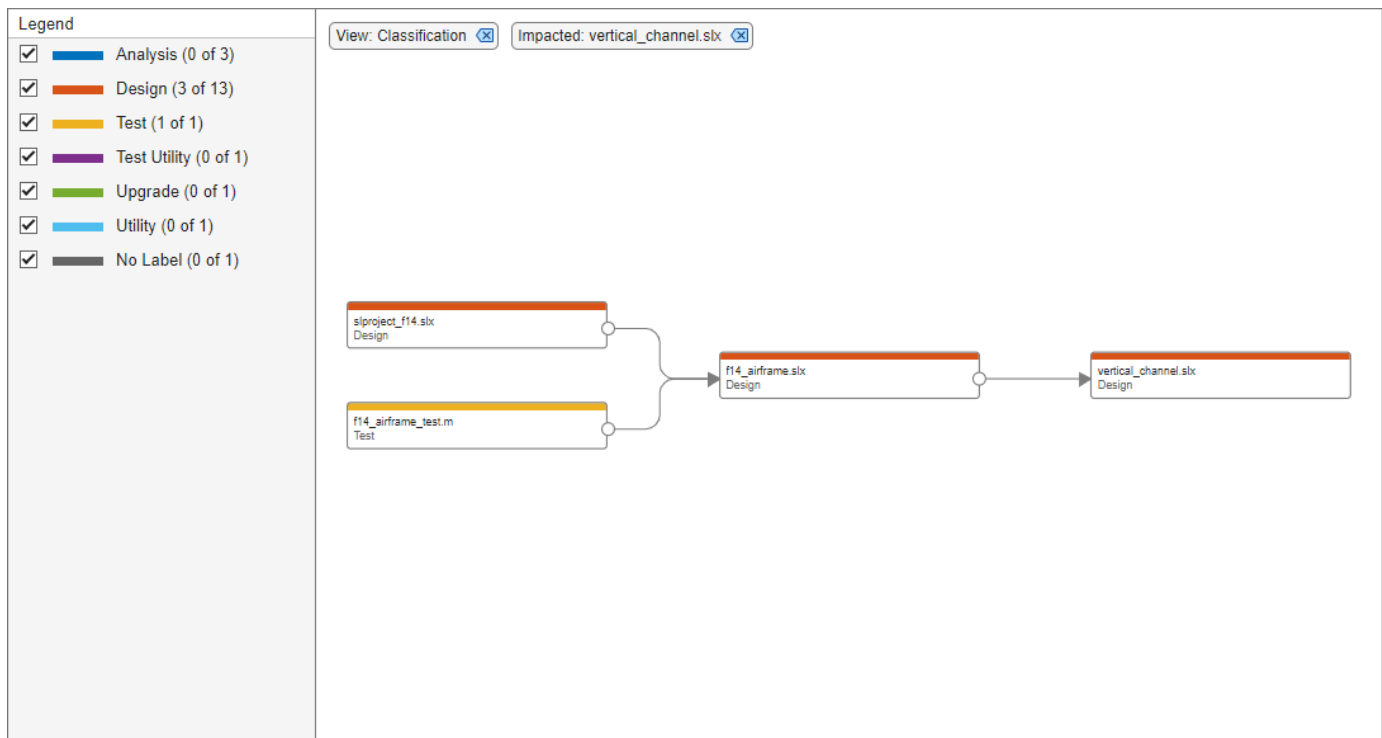

9. Determine which tests you need to run to validate the changes you made to `vertical_channel.slx`.

a. To display the Classification labels associated to each file in the dependency graph, expand the **Views** gallery and click **Classification**.

The dependency graph showing only files impacted by the changes you made to `vertical_channel.slx` is now colored by label Classifications.

b. Identify the tests affected by your change.

In the graph, there are two **Design** files and one **Test** file impacted by the changes you made to `vertical_channel.slx`. `f14_airframe_test.m` is the test you need to run to validate the design changes.

**Tip:** To clear all filters and restore the graph to show all analyzed dependencies in the project, click **Restore to Default**. Alternatively, manually remove all filters showing at the top of the graph.

## Export Results and Run Tests

You can send files to other Project tools using the **Project** menu. MATLAB exports only the selected files in the current filtered view.

10. Run the selected test to validate the design changes.

a. Select the test you want to run, in this example, `f14_airframe_test.m`.

b. In the Dependency Analyzer toolstrip, in the **Export** section, select **Project > Send to Custom Task**.

In the Custom Task dialog box, the test file `f14_airframe_test.m` exported from the impact analysis is already selected.

c. In the Custom Task dialog box, in the **Custom task** field, select **Run Unit Tests** and Click **Run Task**.

The **Run Unit Tests** custom task runs the MATLAB unit test you selected and creates a summary report. Examine the **Results** section after selecting the test you run, in this example `f14_airframe_test.m`.

- To save the selected file paths to a variable, select **Export > Save to Workspace**.
- To switch to the project **Files** view with the files selected, select **Project > Show in Project**.

## Work with Referenced Projects

This example shows how to use referenced projects as independent components within your project.

### Set up the Example Files

Create a working copy of the Airframe Example project and open the project. MATLAB® copies the files to an examples folder so that you can edit them.

```
sldemo_slproject_airframe_references;
```

The top-level Airframe Example project provides an airframe simulation. To use additional functionalities available in Signal Multiplier and Wind Gust library, the top-level project adds them as referenced projects.

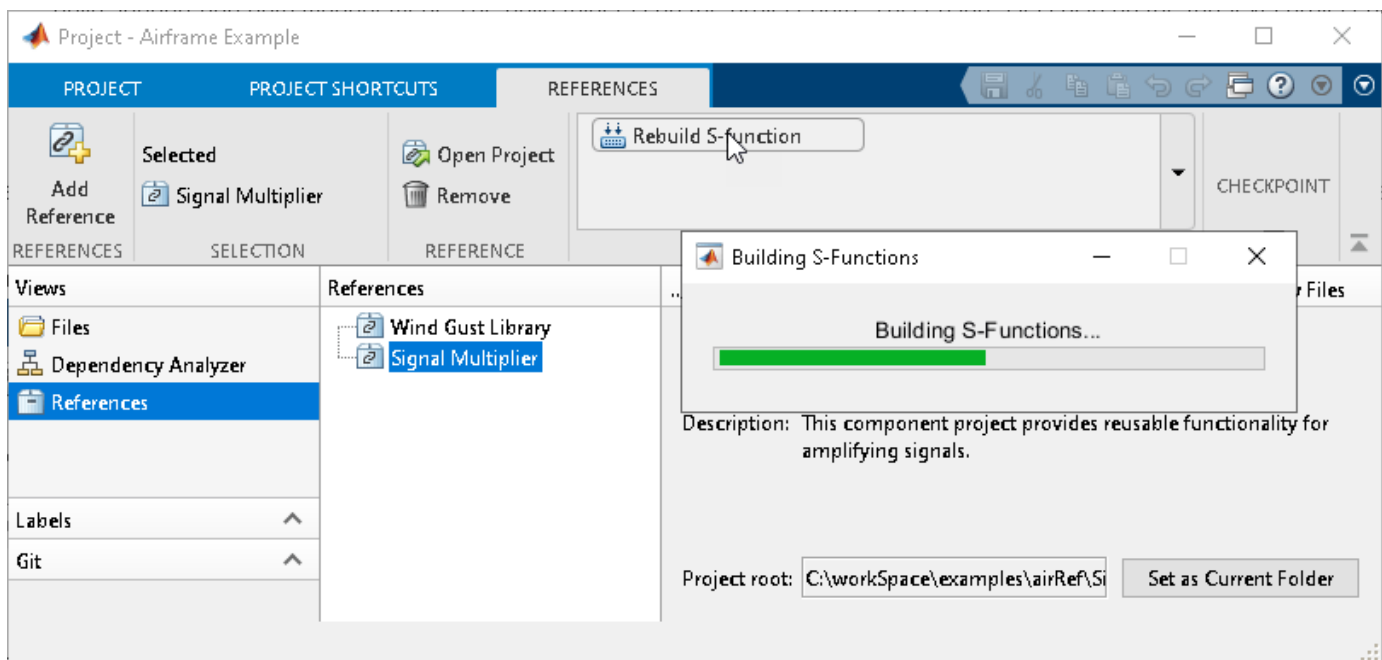

- The Signal Multiplier referenced project shows how to develop an S-function in a component independent from the top-level project. The referenced project provides source code, build support and path management. The build folder is on the project path. This ensures it is also on the top-level project path. The project has a Rebuild S-function shortcut.

- The **Wind Gust Library** referenced project provides a library and a data dictionary that contains the required bus objects for the library. This project path ensures that the library is set up for use in the top-level project.

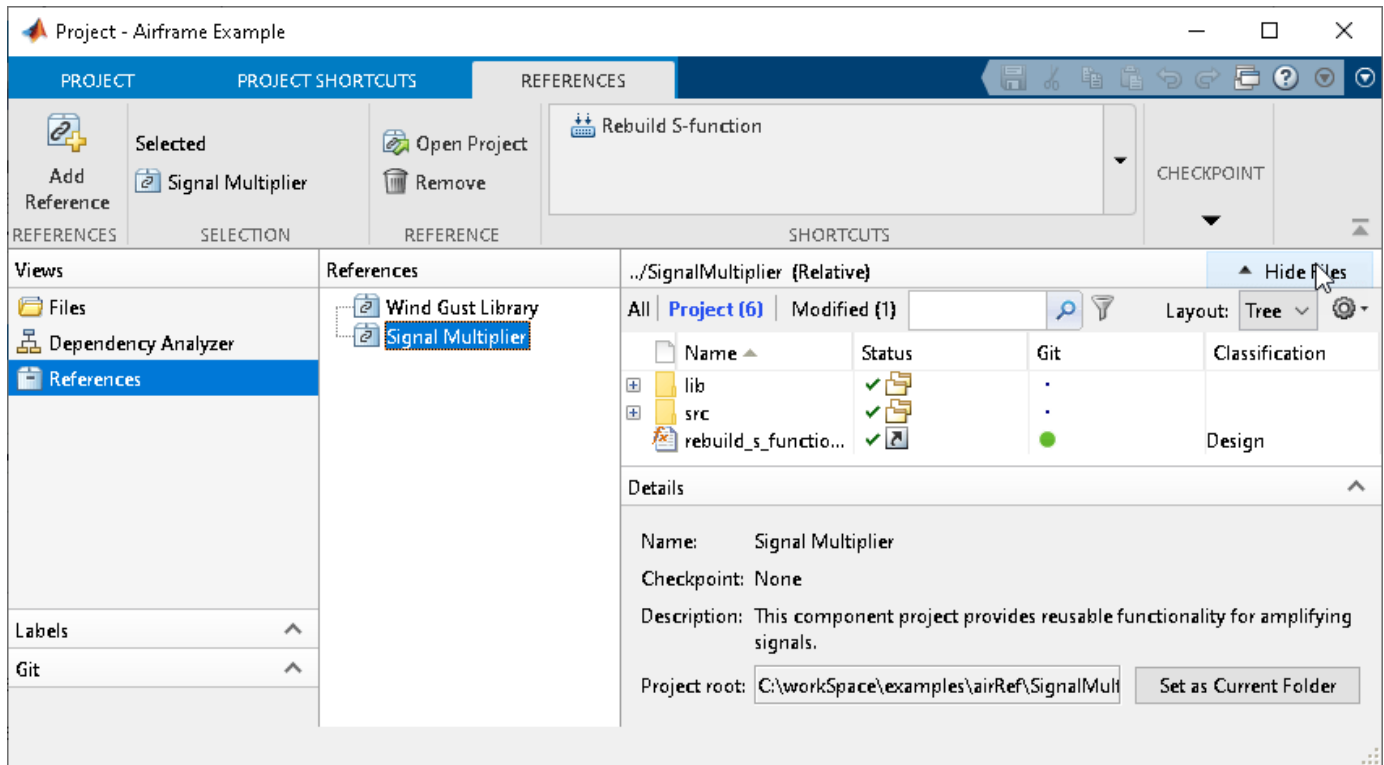

### How Referenced Projects Work

When you open the top-level project, referenced projects load first. This adds the referenced project paths to the MATLAB search path and runs any startup actions that you specified in the referenced projects.

To access content and run shortcuts in referenced projects from the top-level project, in the **References** view, select the reference project, for example, **Signal Multiplier**. In the **References** tab, in the **Shortcut** section, click on a shortcut, for example **Rebuild S-function**.

To examine files, labels, and source control status in the referenced projects, in the **References** view, select the referenced project, and click **Show Files**. For advanced manoeuvres, you can open the referenced project as a top-level project. In the **References** tab, click **Open Project**.

To learn how to create and reference projects programmatically, see “Create and Reference a Project Programmatically” on page 13-495. To learn how to use Git™ submodules to populate referenced projects, see “Organize Projects into Components Using References and Git Submodules” on page 13-499. For more information, watch How to Organize Large Projects into Components (3 min, 32 sec).

## Automate Label Management in a Project

This example shows how to use the project functions to manage labels.

### Open the Airframe Example Project

Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them.

```
sldemo_slproject_airframe;

Starting: Simulink
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

### Get a Project Object.

Create a project object to manipulate the currently open project at the command line.

```
project = currentProject;
```

### View the Labels of a File

Examine the files in the project.

```
files = project.Files;
disp(files);

1×31 ProjectFile array with properties:

 Path
 Labels
 Revision
 SourceControlStatus
```

Use indexing to access files in this list. For example, get file number 10. Each file has two properties describing its path and attached labels.

```
aFile = files(10);
disp(aFile);

ProjectFile with properties:

 Path: "C:\workspace\examples\airframe2\data\system_model.sldd"
 Labels: [1×1 matlab.project.Label]
 Revision: "57973f5e87ca65215ab688e3544287e07db794c4"
 SourceControlStatus: Unmodified
```

Find information about a file attached labels by indexing into the file object Labels property. The following command gets the first label attached to this particular file.

```
label = aFile.Labels(1);
disp(label);

Label with properties:

 File: "C:\workspace\examples\airframe2\data\system_model.sldd"
```

```
 DataType: 'none'
 Data: []
 Name: "Design"
 CategoryName: "Classification"
```

### Attach a Label to a Subset of Files.

The following code attaches the label **Design** in the **Classification** category to all files in the project with the .m file extension.

First get the list of files:

```
files = project.Files;
```

Then loop through each file and attach the label **Design** from the **Classification** category if the file has the extension .m.

```
for fileIdx = 1:numel(files)
 file = files(fileIdx);
 [~, ~, fileExtension] = fileparts(file.Path);
 if strcmp(fileExtension, '.m')
 addLabel(file, 'Classification', 'Design');
 end
end
```

### Find a Named Label

You can set and query data on a label that is attached to a file. To do this, you first need to find the file object. You can do this by looping through all files in the project, as shown in the previous step. Alternatively, you can use the `findFile` function on the project.

The following code finds the file object for the file 'utilities/rebuild\_s\_functions.m'.

```
pathToLocate = fullfile('utilities', 'rebuild_s_functions.m');
file = findFile(project, pathToLocate);
```

Examine the `Labels` property to get an array of Label objects, one for each label attached to the file.

```
labels = file.Labels;
disp(labels);
```

Label with properties:

```
 File: "C:\workspace\examples\airframe2\utilities\rebuild_s_functions.m"
 DataType: 'none'
 Data: []
 Name: "Design"
 CategoryName: "Classification"
```

To find a label by name, use `findLabel` on the file object.

```
label = findLabel(file, 'Classification', 'Design');
disp(label);
```

Label with properties:

```
 File: "C:\workspace\examples\airframe2\utilities\rebuild_s_functions.m"
 DataType: 'none'
 Data: []
```

```
Name: "Design"
CategoryName: "Classification"
```

### Create a New Category

You must create new labels before you can attach them to a file. You define labels in categories, giving each category a name and supported data type.

The following code creates a category of labels called Engineers which can be used to denote file ownership in a project. These labels have the char datatype for attaching String data.

```
createCategory(project, 'Engineers', 'char');
engineersCategory = findCategory(project, 'Engineers');
createLabel(engineersCategory, 'Sam');
createLabel(engineersCategory, 'Pat');
createLabel(engineersCategory, 'Alex');
```

You can now attach an Sam label from the 'Engineers' category to a file in the project.

```
addLabel(file, 'Engineers', 'Sam');
label = findLabel(file, 'Engineers', 'Sam');
```

### Set Label Data

The following command sets the data for the attached label.

```
label.Data = 'Maintenance responsibility';
disp(label)
```

Label with properties:

```
File: "C:\workSpace\examples\airframe2\utilities\rebuild_s_functions.m"
DataType: 'char'
Data: 'Maintenance responsibility'
Name: "Sam"
CategoryName: "Engineers"
```

### Further Information

“Project Management”

## Run Custom Tasks with a Project

This example shows how to apply a custom task to a set of files managed by project. The custom task in this example analyzes the Simulink® models in the project and reports the number of blocks in each model.

### Set Up the Example Files and Open the Project

1. Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them.

```
sldemo_slproject_airframe;
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

### Select a Custom Task

2. On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**.

You define a custom task with a MATLAB® function. The example Airframe project contains example custom tasks in the *custom\_tasks* folder.

3. The **Custom task** menu lists available custom tasks.

To view, edit, and create custom tasks, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**. In the Custom Task dialog box, click **Manage**.

4. Select the *Analyze Model Files* custom task.

The function name of your selected custom task appears in the **Custom task** field. The example *analyzeModelFiles* adds a label from the category *Metrics* to each model file in the project. Labels in this category have numerical data. The custom task counts the number of blocks in each model and attaches this number to the label.

### Select Files to Include in the Custom Task

5. In the Custom Task dialog box, in the **Include** column, verify that all the model files check boxes are selected.

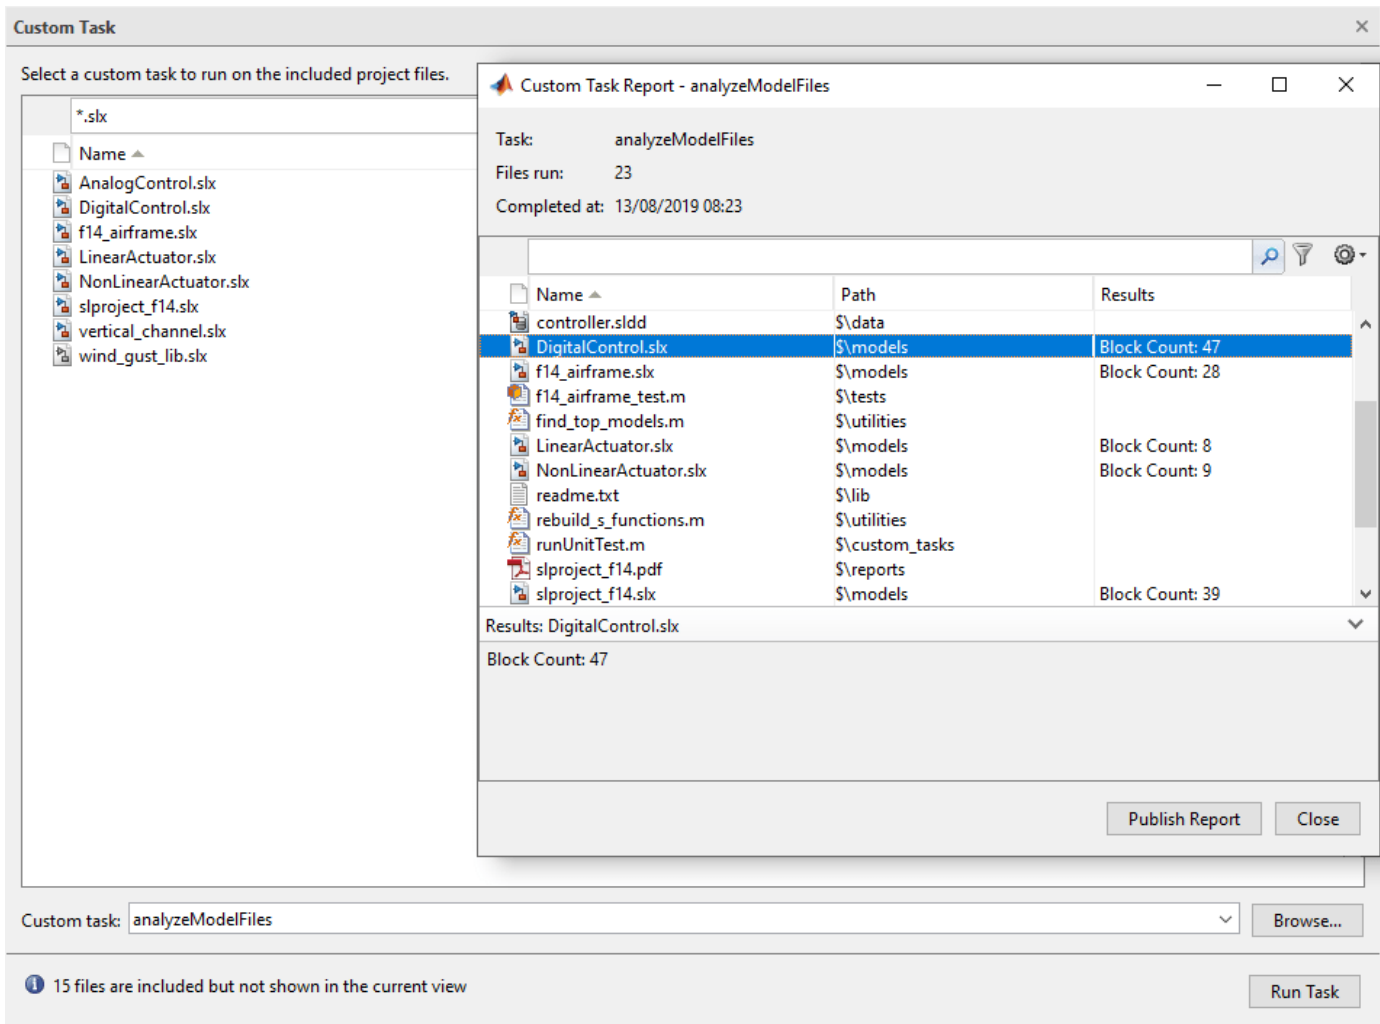

### Run a Custom Task

6. To run the custom task, click **Run Task**.

The results for a selected file are shown in the **Results** pane at the bottom of the dialog box. This can be useful when the returned results are long, or contain HTML markup.

The following example shows the dialog box after running the custom task on some models. You can customize the columns to show with the cog icon button .

## Edit an Existing Custom Task

Custom Tasks are MATLAB functions. Edit your custom task with the MATLAB Editor. For example, modify the custom task to programmatically add a label with data, as well as saving any dirty model files.

7. Run the following MATLAB code to create a Metrics category and a Block Count label in the project.

```
project = currentProject;
category = createCategory(project, 'Metrics', 'double');
```

8. Double-click *analyzeModelFiles.m* to edit it in the MATLAB Editor.

9. Add the following lines just after the `sprintf` command:

```
[~, compileStats] = sldiagnostics(name, 'CompileStats');
addLabel(projectFile, 'Metrics', 'CPU Compile Time', sum([compileStats.Statistics.CPUTime]));
```

You can use the MATLAB Editor to set breakpoints and debug a custom task function, just as with any other MATLAB function.

If you rerun the custom task, it adds the CPU Compile Time label to each model file that can be compiled, and attaches data to the label showing the total time for all compilation phases for the model. Models that cannot be compiled show **Failed to analyze file** in the Custom Task Report, and details display as a warning in the Command Window. Examine the custom task *analyzeModelFiles.m* to see how to handle errors.

To view the new metrics data, either show the **Metrics** column in the Custom Task Report, or look in the project **Files** view.

### **Create a New Custom Task**

Create a new custom task by creating a new MATLAB function. Your custom tasks must:

- Be saved on the MATLAB path.
- Accept a single input argument: a full path to a file.
- Return a single output argument.

To create custom tasks, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**. In the Custom Task dialog box, click **Manage**. In the Manage Custom Tasks dialog box, click **Add** to open a new file with instructions that guide you to create a custom task with the correct function signature.

#### **10. Select Add>Add Using New Function.**

A file dialog opens asking you to choose where to create the new custom task. The custom task must be saved on the MATLAB path to run.

#### **11. Provide a file name and save the file in the *custom\_tasks* folder within the project.**

The MATLAB editor opens the file pre-populated with a simple example custom task.

#### **12. To create your new custom task, edit the contents of the example custom task function and save.**

### **Further Information**

“Project Management”

## Upgrade Simulink Models Using a Project

Easily upgrade all the models in your project using the Upgrade Project tool in a project.

### Setting Up the Example Files and Opening the Project

Run the following commands to create and open a working copy of the project files.

```
sldemo_slproject_airframe;
```

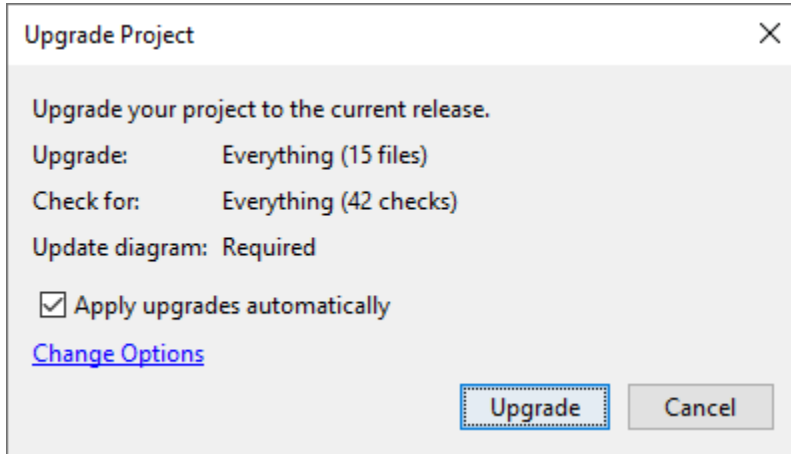

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

The project example copies files to a new folder so that you can edit them and use them under Git version control. Placing your files under version control lets you compare the upgraded model files with the original versions.

### Automatically Upgrade All Project Models and MATLAB Code at Once

Upgrade all models and MATLAB code in your project to the latest release using a simple workflow. The Upgrade Project tool can apply fixes automatically when possible, upgrade all model hierarchies in the project at once, and produce a report.

On the Project tab, click the down arrow to expand the Tools gallery. Under Project Checks, click Upgrade Project.

This loads the upgrade advisor checks and runs a dependency analysis on your project to ensure the project hierarchy is handled correctly.

Click Upgrade to run all upgrade checks on all models, libraries and MATLAB code in your project. If any check fails and there is a fix available, the project automatically applies the fix and runs the relevant checks again to ensure they now pass.

Inspect the results of the upgrade in the report.

The screenshot shows the 'Upgrade Project Report' window. At the top, a large green circle indicates '100% Passed'. Below this, a summary table shows the results for Models, Libraries, and MATLAB Code. The 'AnalogControl.slx' project is selected, and its details are shown in the main pane. A list of checks is displayed, all of which passed. The 'Turn off SLX file compression' check is highlighted, with a 'Learn more' link. The window also shows a file list on the left and a 'Close' button at the bottom right.

Category	Passed	Need attention
Models	7	-
Libraries	1	-
MATLAB Code	7	-

Check Name	Result
Turn off SLX file compression	✓
Return all simulation outputs as a single Simulink.SimulationOutput object	✓
Resave in current version of Simulink	✓
Identify variant blocks using variant objects with empty conditions	✓
Identify Model Variants blocks and convert those to Variant Subsystem blocks containing Model block choi...	✓
Identify Model Info blocks that can interact with external source control tools	✓
Identify masked blocks that specify tabs in mask dialog using MaskTabNames parameter	✓
Identify configurable subsystem template blocks having the instances in the model for converting to varia...	✓

**Further Information**

“Project Management”

“Model Upgrades”

“Upgrade All Project Models, Libraries, and MATLAB Code Files”

## Export a Subset of a Project Using an Export Profile

This example shows how to export a release version of a project using an export profile. The example export profile streamlines the exported project by removing files from the project which are only useful for the development of the project, but are not necessary for running the project's top-level models.

### Set Up the Example Files and Open the Project

1. Run the following commands to create and open a working copy of the airframe project.

```
sldemo_slproject_airframe;
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

The classification label set is used to define the purpose of each file in the project. This example project adds several new labels to the 'classification' label set: 'analysis', 'upgrade', and 'utility'. These labels are used to identify files which are used for custom analysis tasks, upgrading to the latest version and general purpose utility functions.

Some files in the project are useful for the development of the project, but do not need including in a release version of the project when it is exported. For this example, files labelled in the project with the labels 'analysis', 'test', 'upgrade' and 'artifact' do not need including in the release version of the project.

This example demonstrates how the export profile management feature can be used to exclude files from a project export based on the attached labels.

### Open the Export Profile Manager Tool

To view the available export profiles for a project:

2. Click the "Share" button in the Project toolstrip tab.
3. Select the menu item "Manage Export Profiles..."

The Manage Export Profiles dialog box will appear.

The left hand panel shows all of the defined export profiles. The airframe project defines one export profile called 'Release', which should be already be selected in the dialog box.

The export profile shows two panels. The first panels shows the labels which will cause a file to not be exported if attached to a file. The release profile has been defined such that any file which has the 'analysis', 'test', 'artifact', or 'upgrade' label attached will not be exported.

The second panel defines labels which will not be included in the exported project. Here the labels 'analysis' and 'upgrade' are removed because no files in the exported project will use them.

The export profile interface allows new profiles to be defined and existing profiles to be removed.

### Using an Export Profile When Exporting a Project

To use an export profile:

4. Click the "Share" button in the Project toolstrip tab.
5. Select the "Zip Archive".
6. In the project archive dialog, select the export profile to be applied. Select the 'Release' profile to use the profile that is defined by the airframe project.
7. Click the Archive button to export the project using the selected export profile.

**Further Information**

"Project Management"

## Create and Reference a Project Programmatically

This example shows how to programmatically create a new project and add it as a reference project in your main project. It covers how to create a project from the command line, add files and folders, set up the project path, define project shortcuts and create a reference to the new project in another project.

### Set up the Example Files

1. Create a working copy of the `Airframe Example` project and open the project. MATLAB® copies the files to an `examples` folder so that you can edit them. Use `currentProject` to create a project object from the currently loaded project.

```
sldemo_slproject_airframe_api;
mainProject = currentProject
```

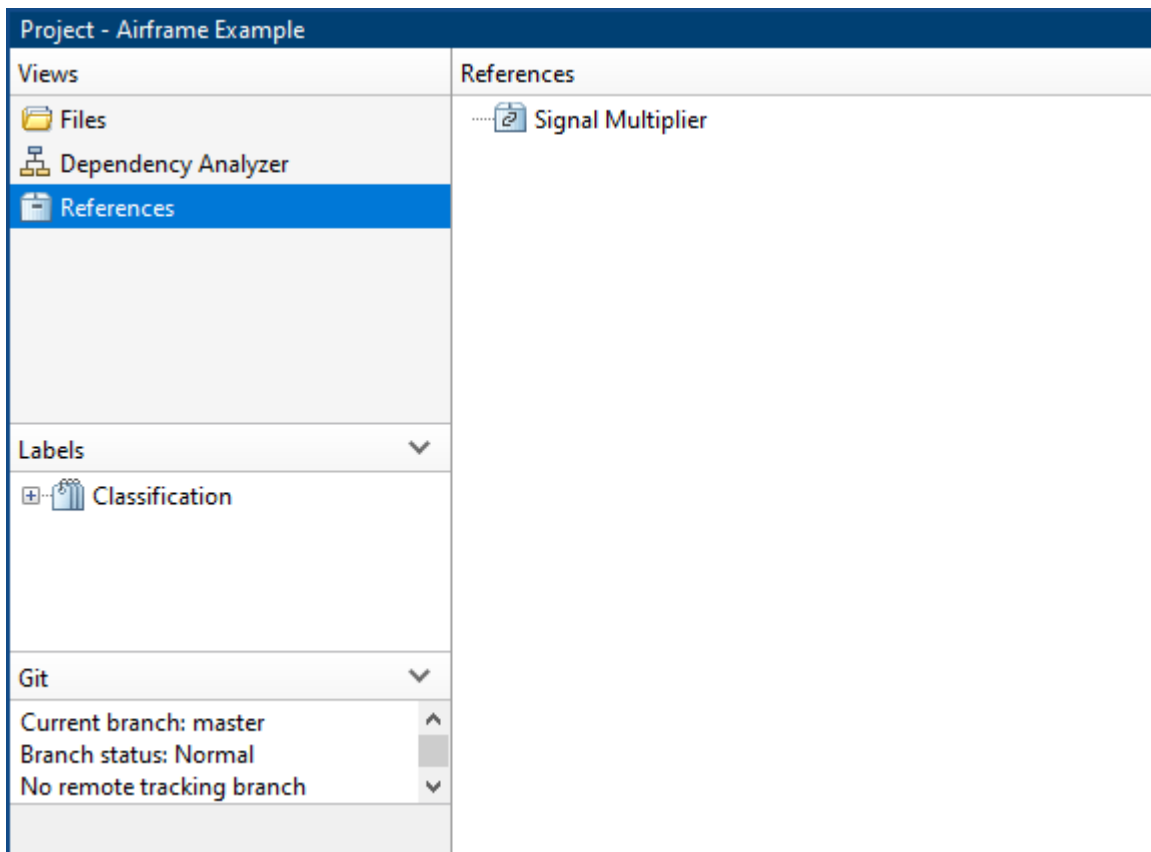

```
mainProject =
```

```
Project with properties:
```

```

 Name: "Airframe Example"
SourceControlIntegration: "Git"
 RepositoryLocation: "C:\workSpace\examples\repositories\airRef14"
SourceControlMessages: ["Current branch: main" "Branch status: Normal" "No remote t
 ReadOnly: 0
 TopLevel: 1
 Dependencies: [1x1 digraph]
 Categories: [1x1 matlab.project.Category]
 Files: [1x22 matlab.project.ProjectFile]
 Shortcuts: [1x5 matlab.project.Shortcut]
 ProjectPath: [1x4 matlab.project.PathFolder]
 ProjectReferences: [1x1 matlab.project.ProjectReference]
 StartupFiles: [1x0 string]
 ShutdownFiles: [1x0 string]
 DefinitionFileType: FixedPathMultiFile
 Description: "This example project demonstrates the Project referencing feature
 RootFolder: "C:\workSpace\examples\airRef14\airRef"
 SimulinkCodeGenFolder: "C:\workSpace\examples\airRef14\airRef\work\codegen"
 DependencyCacheFile: ""
 SimulinkCacheFolder: "C:\workSpace\examples\airRef14\airRef\work\cache"
 ProjectStartupFolder: "C:\workSpace\examples\airRef14\airRef"
```

The `Airframe Example` project is a top level project (`TopLevel: 1`) with one referenced project (`ProjectReferences: [1x1]`).

### Create New Project

2. Create a new project called Wind Gust Library. Airframe project will use Wind Gust Library through a project reference.

a. Create a blank project and set the project name.

```
windGustFolder = fullfile(mainProject.RootFolder, "..", "WindGustLibrary");
windGust = matlab.project.createProject(windGustFolder);
windGust.Name = "Wind Gust Library";
```

b. Add the data folder and the wind\_gust\_lib.slx file to the Wind Gust Library project.

```
addFolderIncludingChildFiles(windGust, "data");
addFile(windGust, "wind_gust_lib.slx");
```

c. Add the data folder and the Wind Gust Library project root folder to the Wind Gust Library project path. This makes the files available when the Airframe Example project or any project that references the Wind Gust Library project is loaded.

```
addPath(windGust, "data");
addPath(windGust, windGust.RootFolder);
```

d. Create a Wind Gust Library project shortcut.

```
shortcut = addShortcut(windGust, "wind_gust_lib.slx");
shortcut.Group = "Top Level Model";
```

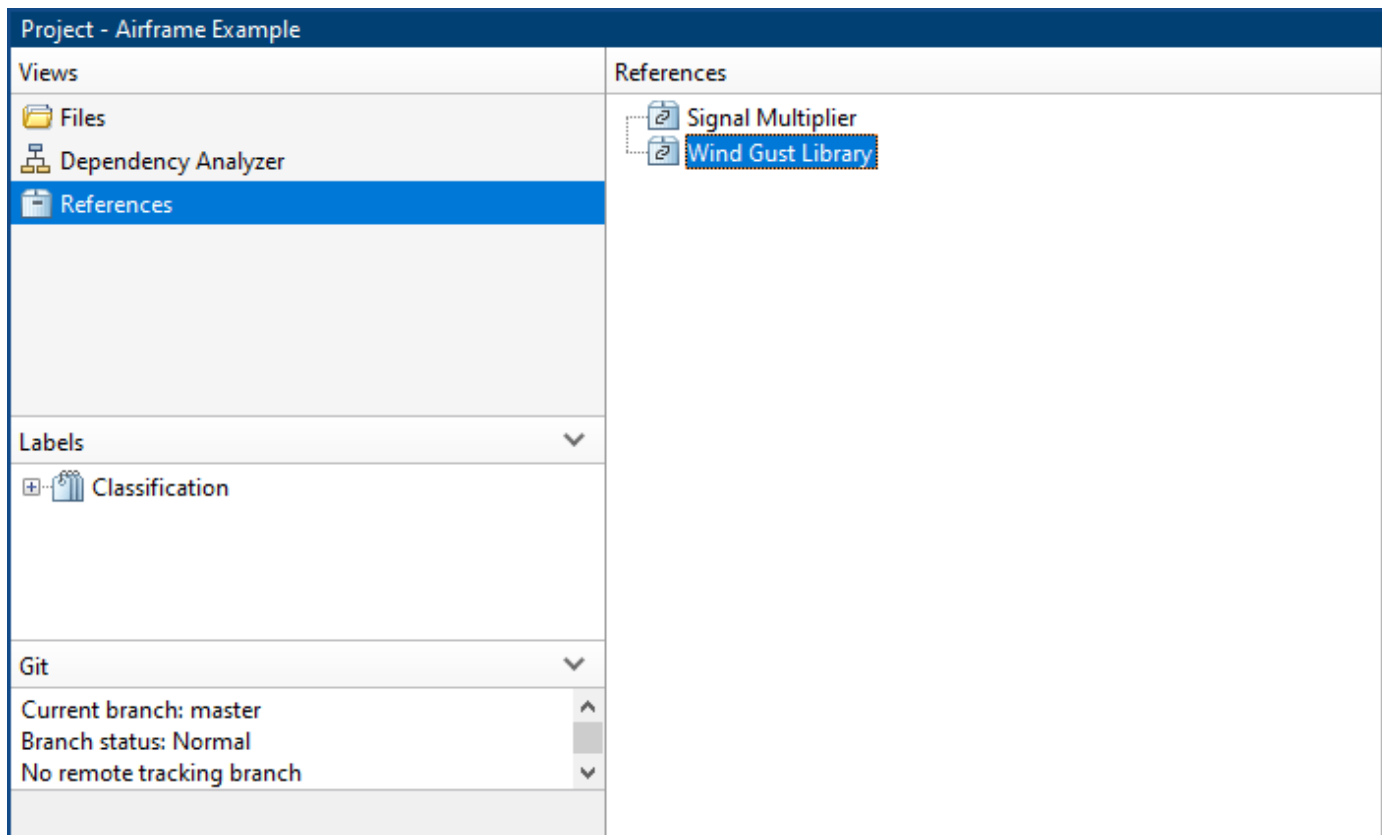

### Add a Project Reference

3. Add the new Wind Gust Library project to the Airframe Example project as a project reference. This allows the Airframe Example project to view, edit, and run files in the Wind Gust Library project.

```
reload(mainProject);
addReference(mainProject,windGust)

ans =
 ProjectReference with properties:
 Project: [1x1 matlab.project.Project]
 File: "C:\workSpace\examples\airRef14\WindGustLibrary"
 StoredLocation: "../WindGustLibrary"
 Type: "Relative"
```

The main project Airframe Example references the Wind Gust Library stored in "../refs/Wind Gust Library".

4. Use ProjectReferences method to query the Wind Gust Library project.

```
mainProject.ProjectReferences(2).Project

ans =
 Project with properties:
```

```
 Name: "Wind Gust Library"
SourceControlIntegration: ""
 RepositoryLocation: ""
 SourceControlMessages: [1x0 string]
 ReadOnly: 1
 TopLevel: 0
 Dependencies: [1x1 digraph]
 Categories: [1x1 matlab.project.Category]
 Files: [1x3 matlab.project.ProjectFile]
 Shortcuts: [1x1 matlab.project.Shortcut]
 ProjectPath: [1x2 matlab.project.PathFolder]
 ProjectReferences: [1x0 matlab.project.ProjectReference]
 StartupFiles: [1x0 string]
 ShutdownFiles: [1x0 string]
 DefinitionFileType: FixedPathMultiFile
 Description: ""
 RootFolder: "C:\workSpace\examples\airRef14\WindGustLibrary"
```

The Wind Gust Library project is not a top-level project (`TopLevel: 0`). It is referenced by the top level project Airframe Example (`TopLevel: 1`).

### **Close Project**

5. Close the project to run shutdown scripts and check for unsaved files.

```
close(mainProject)
```

### **See Also**

“Componentization of Large Projects”

# Organize Projects into Components Using References and Git Submodules

This example shows how to organize large projects into components using references and Git™ submodules.

By organizing your project into components, you can facilitate component reuse, team development, unit testing, and independent release of components.

In this example, you create a new component from an existing project folder. You also reuse other projects as referenced projects. For a project under Git source control, this example shows how to populate a reference project by using Git submodules. For more information, watch [How to Organize Large Projects into Components \(3 min, 32 sec\)](#).

## Create Referenced Project

Open the project you want to organize into components.

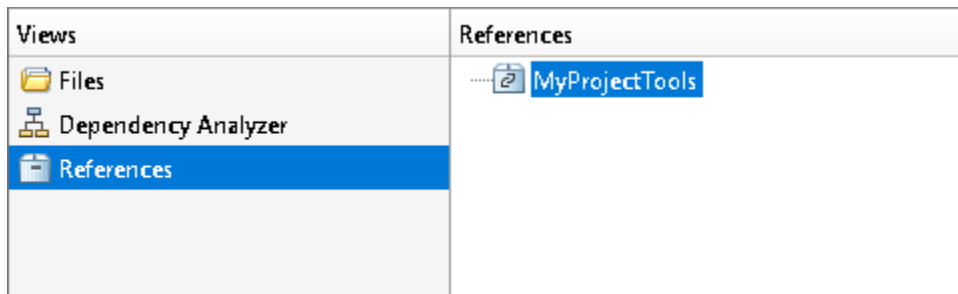

In a large project, you can create a new component from an existing folder in your project.

- 1 Right-click the folder you want to use to create a new project and select **Extract to Referenced Project**.
- 2 In the **Extract to Referenced Project** dialog box, specify the **New Project Name** and **New Project Location** fields, and then click **Extract**.

MATLAB® removes the folder from the parent project, creates a new component project, and adds it as a referenced project.

### Add Referenced Project

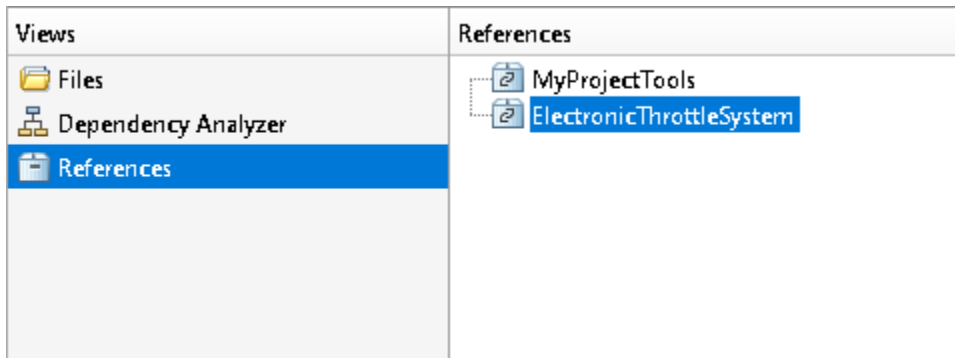

To reuse other components in the top-level project, you can add them as referenced projects.

- 1 On the **Project** tab, in the **Environment** section, click **References**.
- 2 Navigate to the **Referenced Project Location** and select the PRJ file.
- 3 Click **Add**.

MATLAB adds a new component project to the top-level project.

Creating or adding a referenced project modifies the parent project metadata. To make changes available to other project users, commit and push to the remote.

- 1 On the **Project** tab, in the **Source Control** section, click **Commit**.
- 2 Enter a comment and click **Submit**.
- 3 Click **Pull** and **Push**.

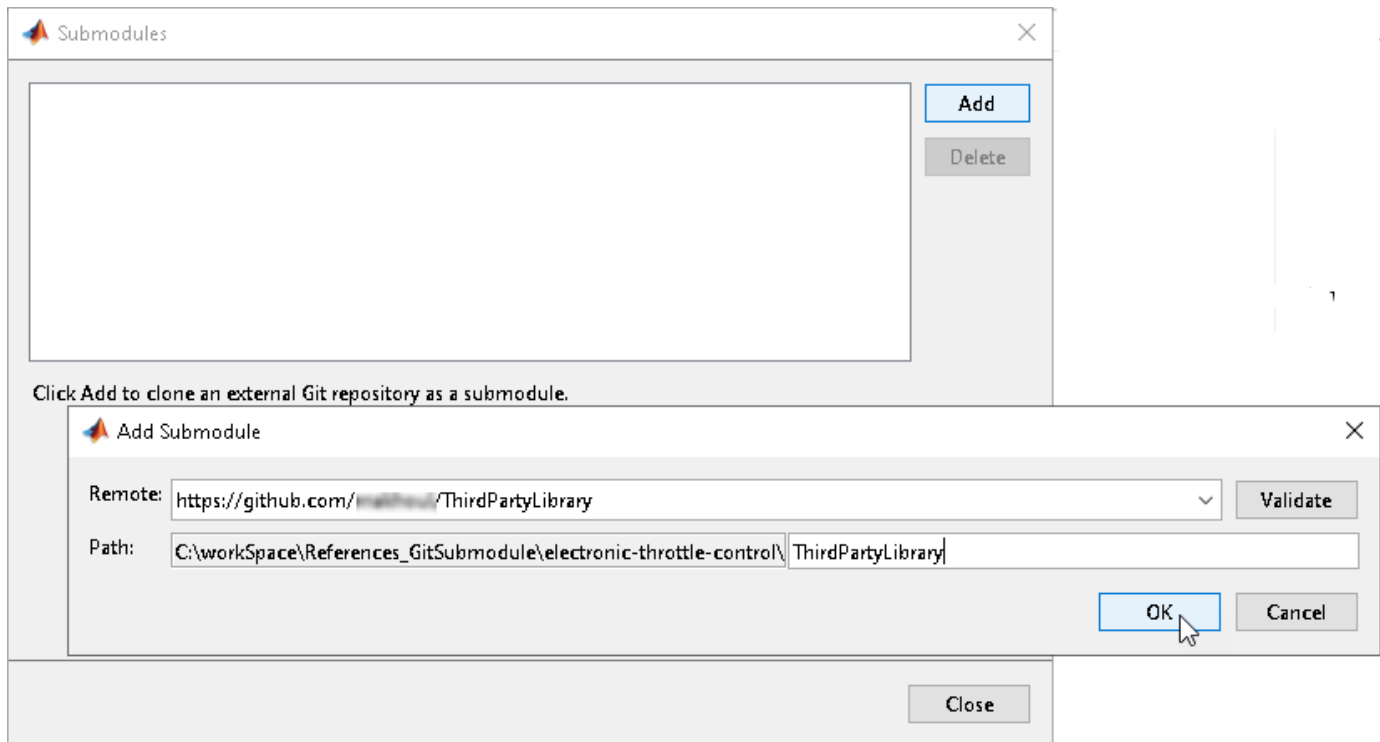

### Use Git Submodules with Referenced Projects

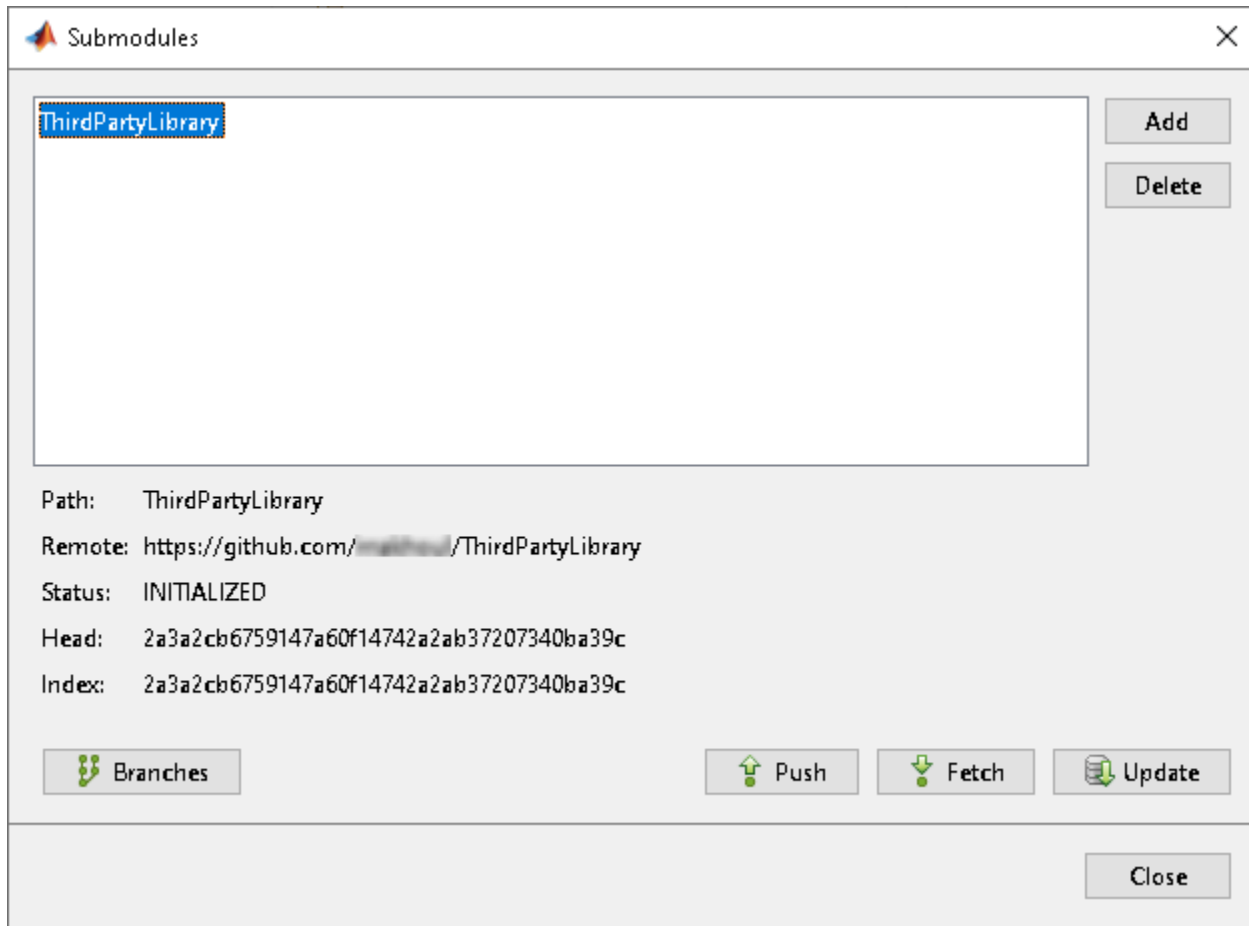

For a project under Git source control, a Git submodule helps you keep commits and changes in a repository separate from the parent repository. Use Git submodules when you want your parent repository to point to a specific commit in another external repository. Submodules are static and are typically used for utilities and shared libraries. When you update the parent repository, submodules do not update automatically.

To populate a new referenced project using Git submodule, clone an external repository.

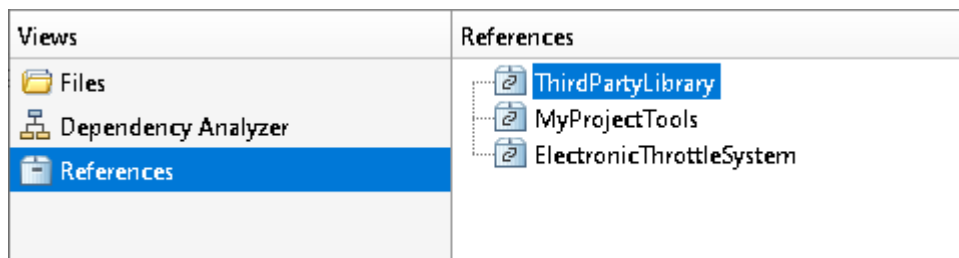

- 1 On the **Project** tab, in the **Source Control** section, click **Submodules**.
- 2 To clone an external Git repository as a submodule, click **Add**.
- 3 Specify the **Remote** URL and **Path**. Click **OK**.

The top-level project now points to the commit of the submodule specified by **Index**.

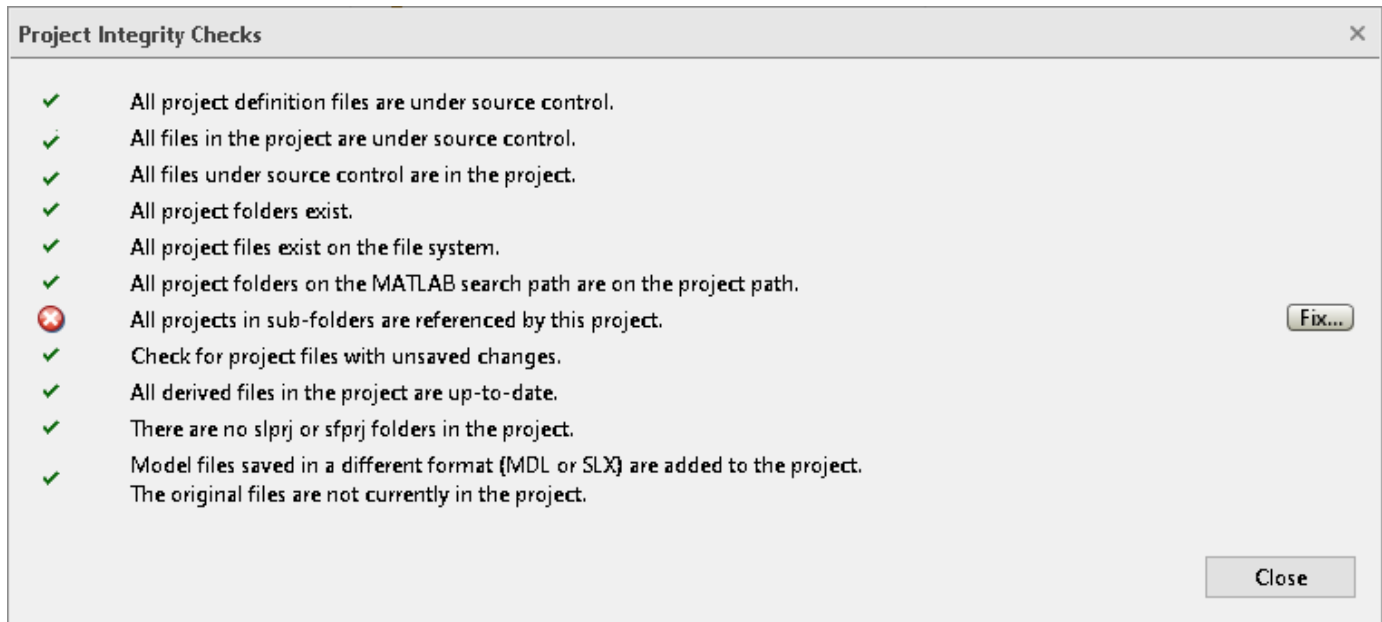

Add the submodule that you cloned as a referenced project using the steps described in Add Referenced Project on page 13-500.

If you cloned several submodules, use project integrity checks to ensure all submodules are referenced projects.

On the **Project** tab, expand the **Tools** gallery and click **Check Project**.

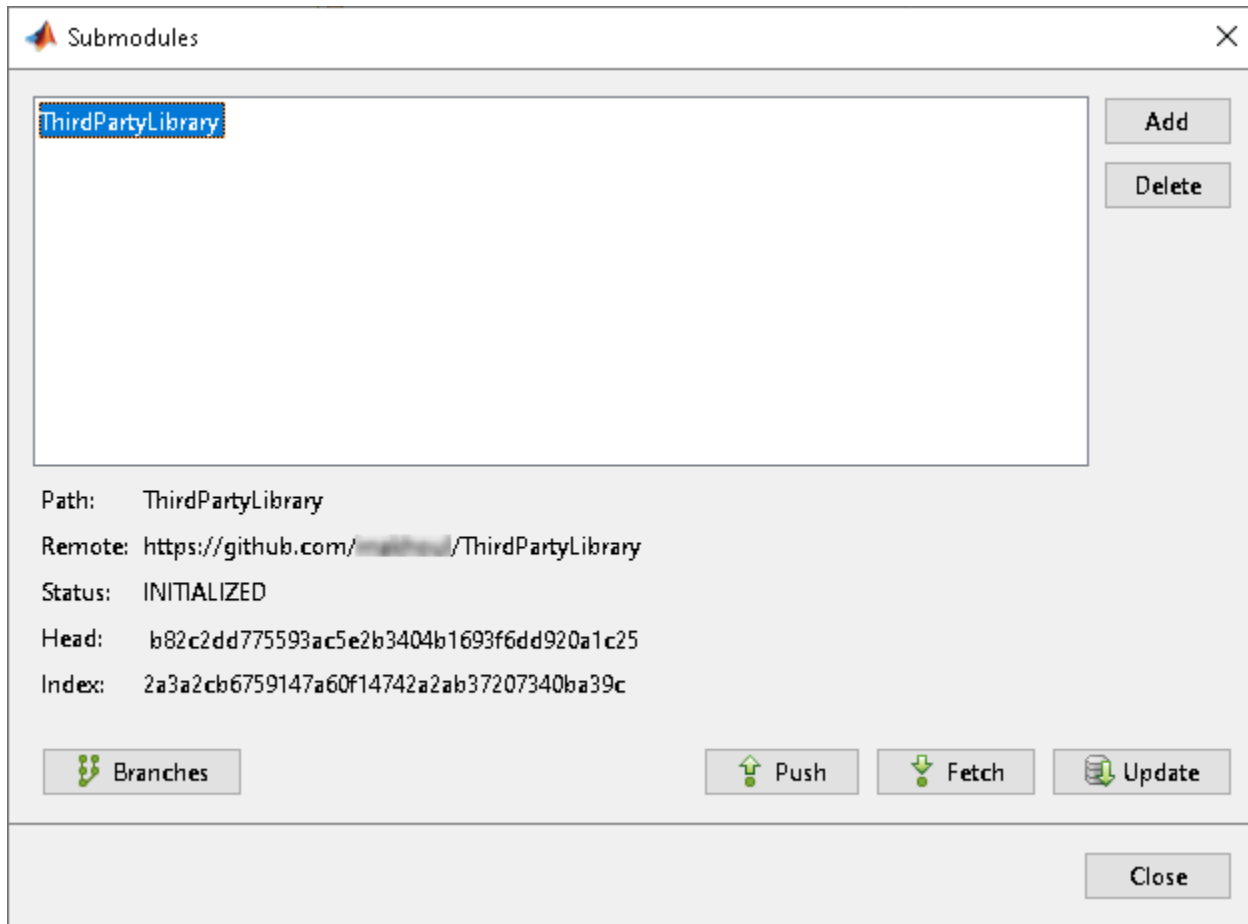

### Make Changes to Submodules

To make changes in a submodule:

- 1 Open the corresponding referenced project as a top-level project.
- 2 In the **References** view, select the referenced project. On the **References** tab, click **Open Project**.
- 3 Make changes.
- 4 On the **Project** tab, in the **Source Control** section, click **Commit**. Enter a comment and then click **Submit**.
- 5 To make changes available to other users, push to the submodule remote repository. In the **Source Control** section, click **Pull** and then **Push**.

### Update Submodule Index

The top-level project can now see all of the recent changes, but still points to the head commit from when you first cloned the submodule. The commit stored in **Index** remains the same.

To update the index to point to the latest commit:

- 1 On the **Project** tab, in the **Source Control** section, click **Submodules**.
- 2 In the **Submodules** dialog box, click **Branches**.
- 3 In the **Branches** dialog box, select the branch and the commit to which you want your top-level project to point. Click **Switch**. The submodule definition in the top-level repository changes.
- 4 Save the submodule definition and update the **Index** to the newly selected commit. On the **Project** tab, in the **Source Control** section, click **Commit**.
- 5 To send the new submodule definition to the top-level remote repository, click **Pull** and then **Push**.

The **Index** now matches the **Head**.

After you clone or update a Git submodule, it is in *detached head* state. Before committing any changes to a submodule, switch to the appropriate branch.

- 1 On the **Project** tab, in the **Source Control** section, click **Submodules**.
- 2 In the **Submodules** dialog box, click **Branches**.
- 3 In the **Branches** dialog box, select the branch and then click **Switch**.

For more information about branch merges and updating submodules, see “Add Git Submodules”.

## Compare and Merge Simulink Models

This example shows how to use the comparison report in MATLAB® to understand what has changed between two different designs. It shows how to view and merge the changes between two Simulink® models from the comparison report.

### Comparing Models

Create a working copy of the example files. MATLAB® copies the files to an example folder so that you can edit them.

```
slcomparisons.examples.simulinkMerge;
```

A user made some changes to the model `sl_aircraft1` and saved the resulting model as `sl_aircraft2`.

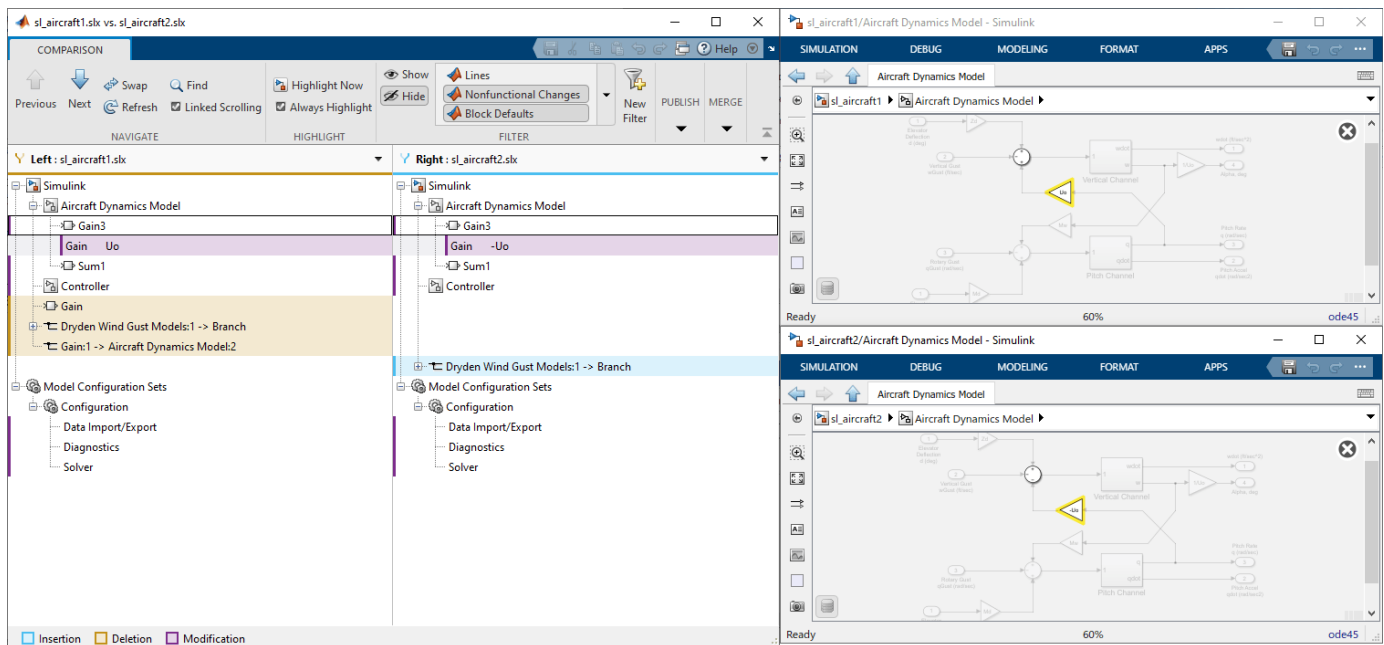

Use `visdiff` to compare the `sl_aircraft1` and `sl_aircraft2` models.

```
visdiff('sl_aircraft1','sl_aircraft2');
```

### Understanding Results

The Comparison Tool shows a report that only includes the differences between the two models, not the complete model hierarchies.

Colors indicate if items have been modified (purple), inserted (blue), or deleted (yellow).

### Stepping Through Differences

Use the **Next** and **Previous** navigation buttons on the **Comparison** tab to step through groups of changes in the report:

- The report goes through the changes one by one. If the selected item in the **Left** tree has a match, it will also be selected in the **Right** tree.
- MATLAB displays both models next to the report. The report highlights the selected items in both Simulink models if it is possible.

To control highlighting in models, on the **Comparison** tab, in the **Highlight** section, select or clear the check box **Always Highlight**. You can click the **Highlight Now** button to highlight the currently selected report node at any time.

### Filtering Results

You can control the type of changes displayed in the comparison report by applying filters. To see the available filters and whether or not they are applied to the current report, on the **Comparison** tab, in the **Filter** section, click the down arrow to expand the filter gallery. Click filter names to toggle whether they are applied. In the **Filter** section, click **Show** or **Hide** to control how the filters are applied.

For example, some information in the Simulink model file is defined as being nonfunctional. These are changes that are unlikely to change the behavior of the design. Nonfunctional items are hidden by default. You can show them by deselecting the **Nonfunctional Changes** button when the **Hide** filter button is selected.

### Publish Results

To save a printable version of a model comparison report, select **Publish > HTML, Word, or PDF**.

### Merge Changes in Simulink Models

You can merge the changes between the two Simulink models by clicking the **Merge Mode** button in the toolbar. This creates a third file, `targetFile`, which can contain the changes from either the left model (`sl_aircraft1`) or right model (`sl_aircraft2`). Use the buttons in the **Target** tree to select the differences to keep in the `targetFile`.

Click the **Save File** button to save the changes you selected over the right model (`sl_aircraft2`).

**Tip:** Merge blocks before lines, and merge states and junctions before merging transitions. See “Merging Tips”.

## Compare and Merge Simulink Models Containing Stateflow

This example shows how to use the comparison report in MATLAB® to understand what has changed between two different designs. It shows how to view and merge the changes between two Simulink® models containing Stateflow® using the comparison report. A Stateflow license is required to run this example.

### Compare Models

Create a working copy of the example files. MATLAB® copies the files to an example folder so that you can edit them.

```
slcomparisons.examples.stateflowMerge;
```

A user added a new kickdown mode to the `shift_logic`. You can use the Simulink Model Comparison to compare the two models and produce a report to explore and merge the differences.

Use `visdiff` to compare the `sl_sfcar_1` and `sl_sfcar_2` models.

```
visdiff('sl_sfcar_1', 'sl_sfcar_2');
```

### Understand Results

The Comparison Tool shows a report that only includes the differences between the two models, not the complete model hierarchies.

Colors indicate if items have been modified (purple), inserted (blue), or deleted (yellow).

The screenshot displays the Simulink Model Comparison tool interface. The top-left pane shows the comparison report for 'sl\_sfcar\_1.slx vs. sl\_sfcar\_2.slx'. The report is organized into two columns: 'Left: sl\_sfcar\_1.slx' and 'Right: sl\_sfcar\_2.slx'. Changes are color-coded: yellow for deletions, blue for insertions, and purple for modifications. The 'Left' column shows 'vehicle mph (yellow) & throttle %' and 'Vehicle2 -> transmission:3' as deletions. The 'Right' column shows 'Vehicle2 -> Branch' as an insertion. The 'Left' column also shows 'shift\_logic' and 'gear\_state' as modifications. The 'Right' column shows 'KICKDOWN' and 'fourth -> second' as insertions. The bottom-left pane shows the Simulink model hierarchy for 'sl\_sfcar\_1' and 'sl\_sfcar\_2', with the differences highlighted in the same colors. The bottom-right pane shows the Simulink model diagram for 'sl\_sfcar\_1' and 'sl\_sfcar\_2', with the differences highlighted in the same colors.

### Stepping Through Differences

Use the **Next** and **Previous** navigation buttons on the **Comparison** tab to step through groups of changes in the report:

- The report goes through the changes one by one. If the selected item in the **Left** tree has a match, it will also be selected in the **Right** tree.
- MATLAB displays both models next to the report. The report highlights the selected items in both Simulink models if it is possible.

### Highlight Differences in the Simulink Models

Select the tree node Out1 in the **Right** tree. Observe the report highlights Out1 in the report, and the corresponding block in the model sl\_sfcar\_2.

To control highlighting in models, on the **Comparison** tab, in the **Highlight** section, select or clear the check box **Always Highlight**. You can click the **Highlight Now** button to highlight the currently selected report node at any time.

### Highlight Differences in a Stateflow Chart

Browse down the tree to locate the Stateflow charts in the report. Observe the Stateflow chart icon next to the shift\_logic node. Click kickdown in the **Right** tree. The report displays both shift\_logic Stateflow charts. Observe where the new kickdown functionality has been added to one of the charts.

### Filtering Results

You can control the type of changes displayed in the comparison report by applying filters. To see the available filters and whether or not they are applied to the current report, on the **Comparison** tab, in the **Filter** section, click the down arrow to expand the filter gallery. Click filter names to toggle whether they are applied. In the **Filter** section, click **Show** or **Hide** to control how the filters are applied.

For example, some information in the Simulink model file is defined as being nonfunctional. These are changes that are unlikely to change the behavior of the design. Nonfunctional items are hidden by default. You can show them by deselecting the **Nonfunctional Changes** button when the **Hide** filter button is selected.

### Merge Changes in Models Containing Stateflow

You can merge the changes between the two Simulink and Stateflow models by clicking the **Merge Mode** button in the toolbar. This creates a third file, targetFile, which can contain the changes from either the left model or right model. Use the buttons in the **Target** tree to select the differences to keep in the targetFile.

Click the **Save File** button to save the changes you selected over the right model (sl\_sfcar\_2).

**Tip:** Merge blocks before lines, and merge states and junctions before merging transitions. See “Merging Tips”.

## Resolve Conflicts with Simulink Three-Way Merge

This example shows you how to use Simulink® Three-Way Merge to resolve conflicts in Simulink models. You can view and merge the Simulink model differences in the resulting report.

### Set up the Example Project

Create and open a working copy of the example project. MATLAB® copies the files to an example folder so that you can edit them.

```
slcomparisons.examples.simulinkThreeWayMerge;
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

### Simulink Model Changes and Conflicts

The example project is under Git™ source control. You attempt to merge the changes of another user on the main Git branch into your TaskBranch. This operation results in conflicts.

To resolve the conflicts using the Three-Way Model Merge tool, this example shows how to examine your local file (**Mine**), the conflicting revision (**Theirs**) and the common ancestor of these two files (**Base**).

**Theirs:** Another user updated the pilot model subsystem to use an explicit gain block for the amplitude of the pilot's input commands. He also updated the Simulation stop time.

**Mine:** You changed some configuration settings for the pilot model subsystem.

The Merge tool automatically merges nonconflicted differences. Follow the steps below to review the automerge choices, edit if desired, and decide how to resolve any remaining differences. After resolving the conflicts, commit the resolved model to source control.

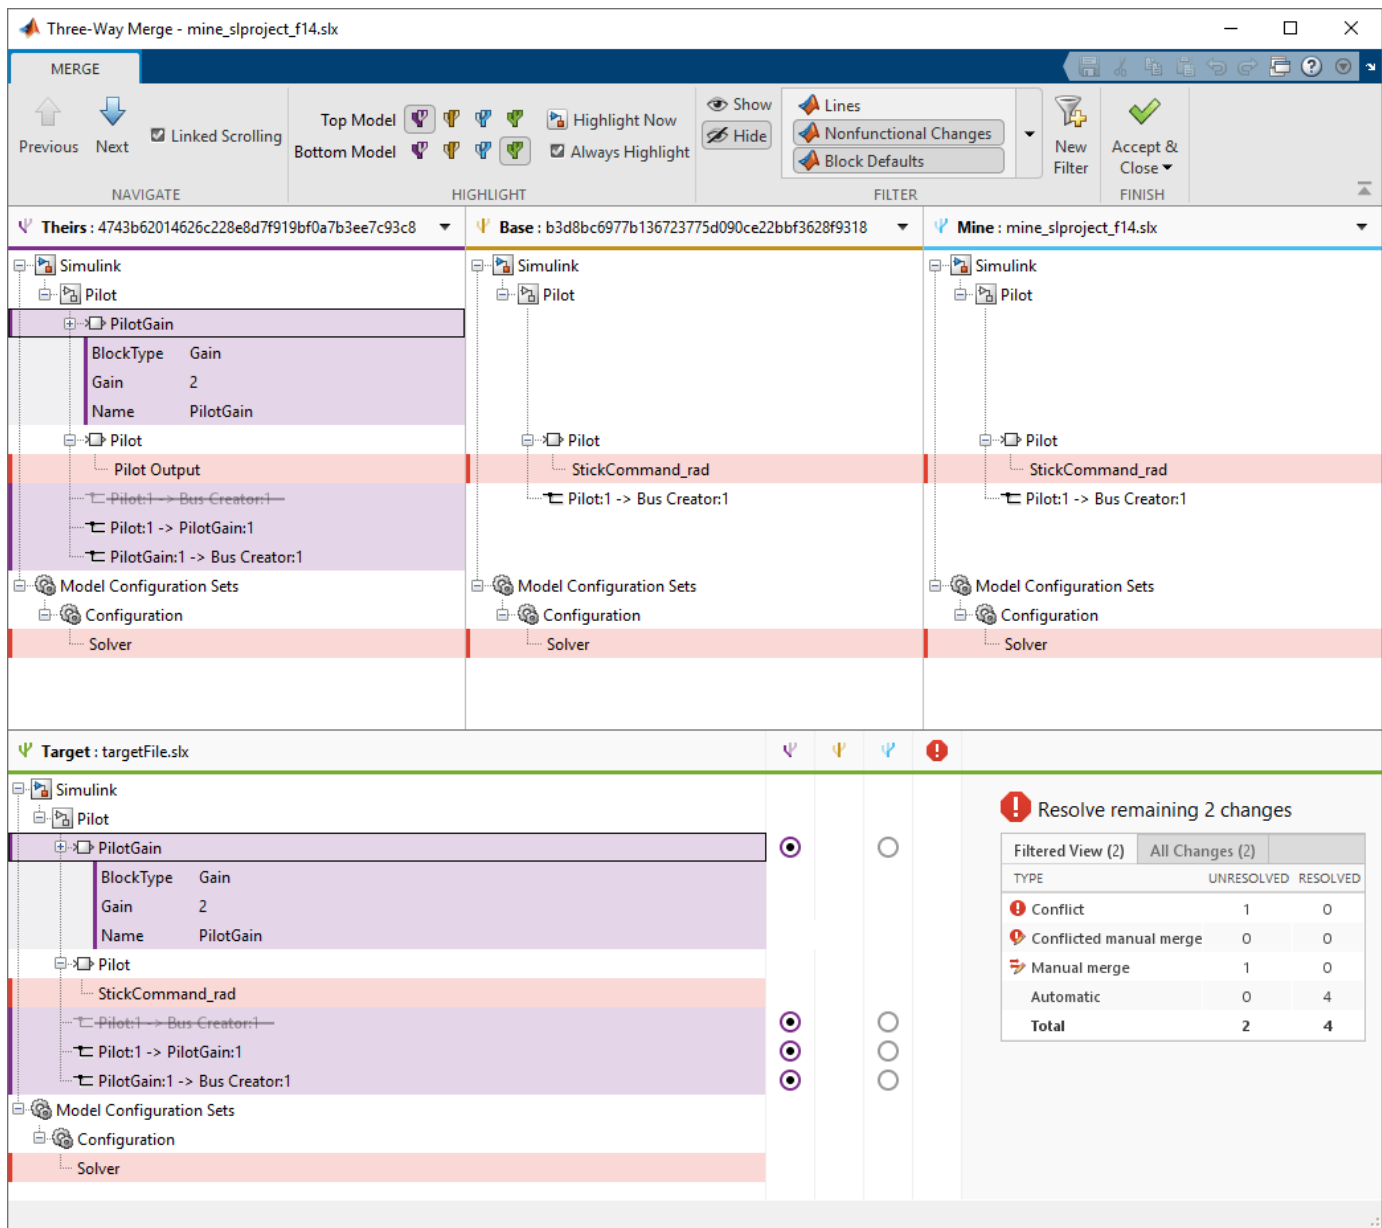

### Open Simulink Three-Way Merge

Look for conflicted files in the project files view. The `slproject_f14` file shows a red warning symbol in the Git column, which indicates a conflict.

1. To see a detailed report of the conflicts, right-click the `slproject_f14` file and select **View Conflicts**.

### View Changes

The Three-Way Merge tool shows the changes to the two Simulink designs that have caused this file conflict.

- The **Theirs**, **Base** and **Mine** trees show the differences between the conflicting revision, your revision, and the base ancestor of these files.
- The **Target** tree shows the file that you will merge changes into. This is a temporary file and will be copied into the project when you choose to accept the merge result.

2. Examine a difference by clicking a row in one of the trees. The merge tool displays the change for each model in an editor, for example the Simulink Editor or Configuration Parameters dialog box, to the right of the Three-Way Merge window.

3. On the **Merge** tab, in the **Highlight** section, choose the models to display with the **Top Model** or **Bottom Model** buttons.

## Review Automatic Merges

The merge tool automatically merges most nonconflicted differences.

4. Examine the first change at the top of the **Theirs** tree by clicking the row called `PilotGain`. This node has been merged automatically and you can adjust the automatic choices using the buttons in the **Target** tree. If you want, review the other automatic merge choices.

## Resolve Conflicts

There are two types of difference that require user action.

**Conflict:** The merge tool cannot automatically resolve these differences and you need to choose which design you want in the target file. In the **Target** pane, look for warnings in the conflict column

**Manual merge:** Some differences must be merged manually in Simulink or ignored. In the **Target**

pane, these items are indicated by a pencil icon in the conflict column .

5. Select the `StickCommand_rad` row. This difference requires a manual merge, indicated by a pencil icon in the conflict column .

Resolve the line change difference in the `targetFile` by renaming the line connected to the output of the block named `Pilot` in the Simulink Editor from `StickCommand_rad` to `Pilot Output`.

After resolving the difference save the changes in the Editor, and mark the change resolved using the manual merge control in the Conflicts column.

The merge report does not update to show any changes you make in the Editor.

6. Use the **Next** toolbar button to review and resolve the changes until you reach a conflict. This `StopTime` parameter has been changed by both users and is conflicted. Resolve the conflict using the **Mine** change. Select the button next to `StopTime` in the mine column in the **Target** pane.

## Change Filters

By default, the report hides all nonfunctional changes, such as the repositioning of items.

7. On the **Merge** tab, in the **Filter** section, turn on and off filters to explore the different changes between these designs.

## Accept Changes

8. After you resolve all filtered and unfiltered changes, click **Accept & Close**. The merge tool closes the report and the models, accepts the merge result in the `targetFile`, and marks the conflict as resolved in the source control tool. You can now commit changes to source control and continue your work.

## Call C Functions Using C Caller Block

This example shows how to use the C Caller block to call your handwritten C functions.

In this example, five custom C functions are defined in `my_func.h` and implemented in `my_func.c`.

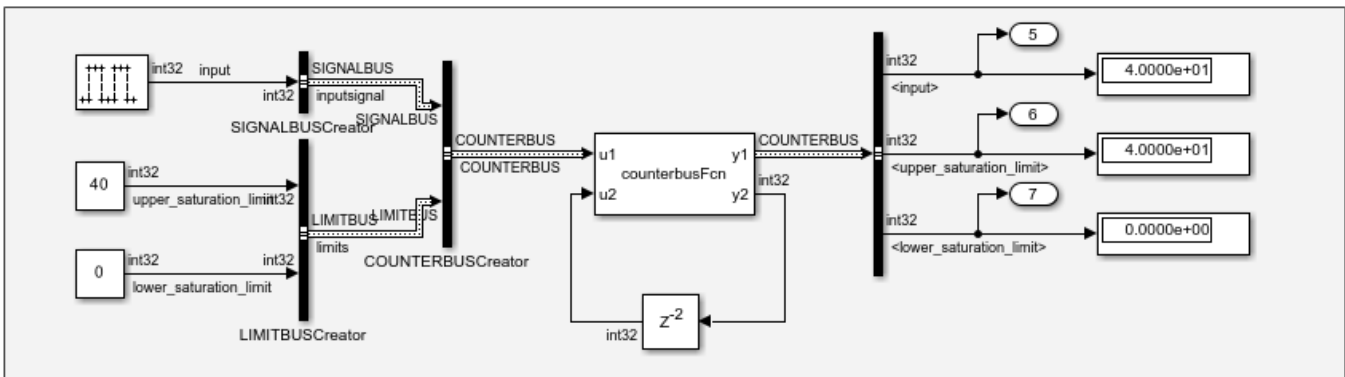

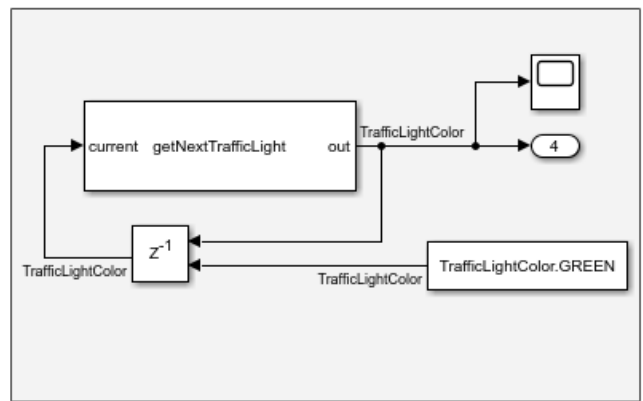

The header file and the source file are specified in the **Simulation Target** pane of the Model Configuration Parameters. Then C functions can be called via C Caller blocks. For example, the block `add` adds a signal and a constant together and the block `timesK` multiplies the signal by a parameter `K`. The C Caller block supports C structure and enumeration types. Use command `Simulink.importExternalCTypes` to import these types into Simulink as matching `Simulink.Bus` objects or `Simulink.IntEnumType` classes.

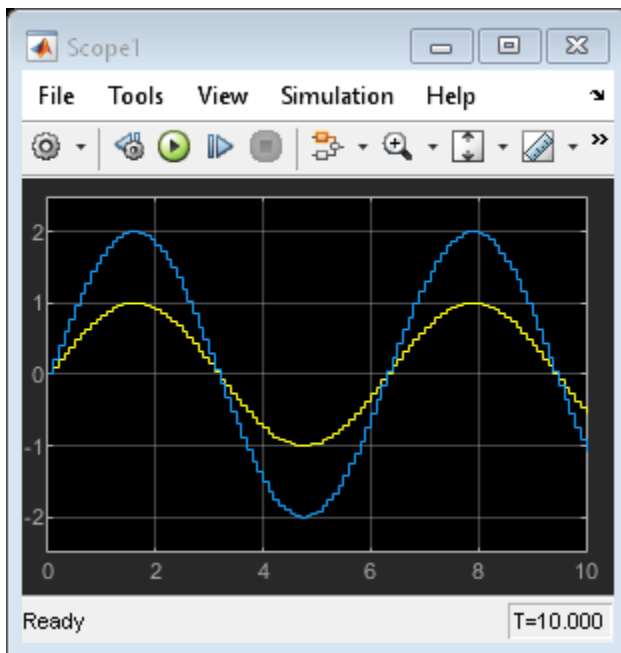

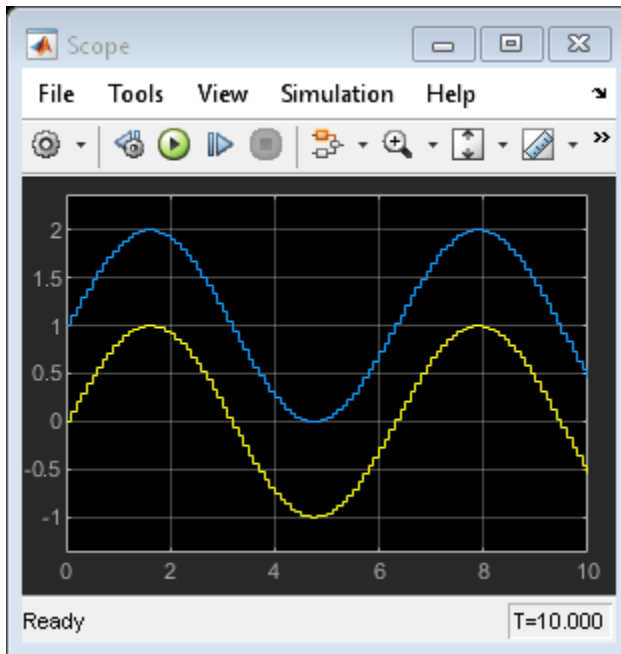

### Call C Functions Using C Caller Block

?

my\_func.h  
my\_func.c

Copyright 2019 The MathWorks, Inc.

### Set up custom C code in model configuration

Add '#include "my\_func.h"' to "Configuration Parameters > Simulation Target > Include headers" field.

Add 'include' to "Configuration Parameters > Simulation Target > Include directories" field.

Add 'src/my\_func.c' to "**Configuration Parameters > Simulation Target > Source files**" field.

## Use Custom Image Filter Algorithms as Reusable Blocks in Simulink

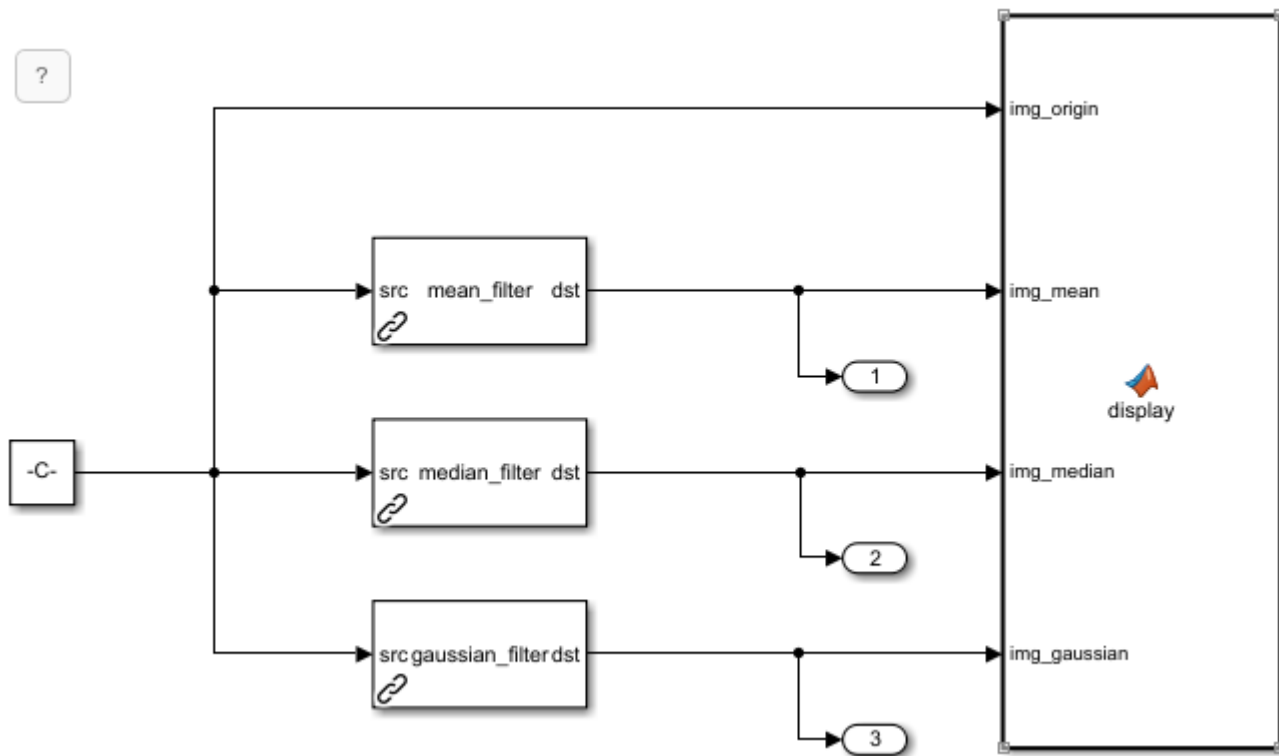

This example shows how to incorporate image filter algorithms written in C code into a model using C Caller blocks in a reusable Simulink® library.

In this example, three image filter blocks are C Caller blocks in a library model. Their dependent C code is specified in the library model custom code settings.

The image filter C functions are implemented using row-major array layout. The library custom code settings specify the default function array layout as row-major.

These library image filter blocks can be reused by adding them to models.

```
mdl = 'slexCCallerExampleImageFilter';
open_system(mdl);
```

As the simulation runs, the MATLAB Function block displays the filtered images.

```
evalc('sim(mdl)');
```

```
slcc('clearCustomCodeModules');
```

## Custom Code and Hand Coded Blocks using the S-function API

This library launches examples of different types of Simulink® S-functions. Simulink S-functions allow you to extend Simulink with new hand coded blocks, interface to custom external code, and create live interfaces to other programs. Use this example to access models containing S-functions in the C, C++, M, and Fortran.

Each example contains a model that exercises an S-function block and a link for editing the S-function code. You can also access the main S-function file by using the Edit button on the S-function block dialog. In some of the models, use **Look Under Mask** to access the S-function. Additionally, the S-function Builder block is a masked version of the S-function block. The block includes an editor that builds an S-function out of a core algorithm.

By default, the S-function Builder also creates a TLC file for use with Simulink® Coder™ and Embedded Coder™.

## Inputs Passed by Value or Address to Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- `FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)`
- `FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)`

where `FLT` is a typedef to `float`. The legacy source code is found in the files `your_types.h`, `myfilter.h`, `filterV1.c`, and `filterV2.c`.

Note the difference in the `OutputFcnSpec` defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```
defs = [];
```

```
% sldemo_sfun_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV1.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];

% sldemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles = {'myfilter.h'};
def.SourceFiles = {'filterV2.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by

the input argument 'defs'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the files `sldemo_sfuns_filterV1.c` and `sldemo_sfuns_filterV2.c`.

```
legacy_code('generate_for_sim', defs);
```

```
Start Compiling sldemo_sfuns_filterV1
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex08075368\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('sldemo_sfuns_filterV1.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfuns_filterV1
Exit
```

```
Start Compiling sldemo_sfuns_filterV2
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex08075368\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('sldemo_sfuns_filterV2.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfuns_filterV2
Exit
```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating Masked S-Function Blocks for Calling the Generated S-Functions

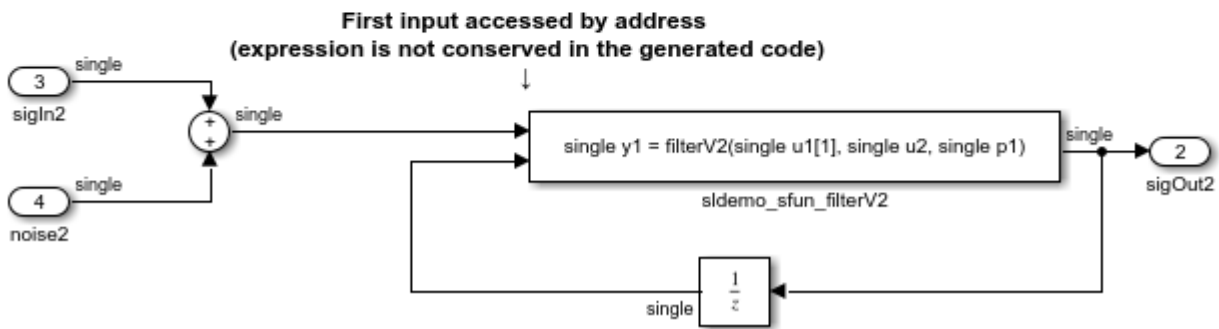

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate masked S-function blocks which are configured to call those S-functions. The blocks are placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', defs);
```

### Integrate the Legacy Code

The model `sldemo_lct_filter` shows integration with the legacy code. The subsystem `TestFilter` serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('sldemo_lct_filter')
open_system('sldemo_lct_filter/TestFilter')
sim('sldemo_lct_filter');
```

“Implement Algorithms Using Legacy Code Tool”

## Output Passed by Return Argument from Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
FLT gainScalar(const FLT in, const FLT gain)
```

where FLT is a typedef to float. The legacy source code is found in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
% sldemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_gain_scalar';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_gain_scalar.c`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_gain_scalar
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex60439838\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('sldemo_sfun_gain_scalar.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simu
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfun_gain_scalar
Exit
```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Integrate the Legacy Code

The model `sldemo_lct_gain` shows integration with the legacy code. The subsystem `TestGain` serves as a harness for the call to the legacy C function via the generate S-function.

```
if isempty(find_system('SearchDepth',0,'Name','sldemo_lct_gain'))
 open_system('sldemo_lct_gain')
 open_system('sldemo_lct_gain/TestGain')
 sim('sldemo_lct_gain');
end
```

## Fixed Point Signals in Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs using signals of fixed point data type.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

where `myFixpt` is logically a fixed point data type which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is found in the files `timesFixpt.h` and `timesS16.c`.

```
% sldemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_times_s16.c`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_times_s16
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex15473442\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
```

```
MEX completed successfully.
 mex('sldemo_sfun_times_s16.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simuli
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfun_times_s16
Exit
```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Integration with Legacy Code

The model `sldemo_lct_fixpt_signals` shows integration with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results are identical.

```
open_system('sldemo_lct_fixpt_signals')
open_system('sldemo_lct_fixpt_signals/TestFixpt')
sim('sldemo_lct_fixpt_signals')

ans =

 Simulink.SimulationOutput:
 yout: [101x2 double]

 SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]
```

## Fixed Point Parameters in Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs using parameters of fixed point data type.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)
```

where `myFixpt` is logically a fixed point data type which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is found in the files `timesFixpt.h`, and `timesS16.c`.

```
% sldemo_sfun_gain_fixpt
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_gain_fixpt';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt p1, uint8 p2)';
def.HeaderFiles = {'timesFixpt.h'};
def.SourceFiles = {'timesS16.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_gain_fixpt.c`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_gain_fixpt
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex52665162\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
```

```

MEX completed successfully.
 mex('sldemo_sfund_gain_fixpt.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simul.
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfund_gain_fixpt
Exit

```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Integration with Legacy Code

The model `sldemo_lct_fixpt_params` shows integration with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('sldemo_lct_fixpt_params')
open_system('sldemo_lct_fixpt_params/TestFixpt')
sim('sldemo_lct_fixpt_params')
```

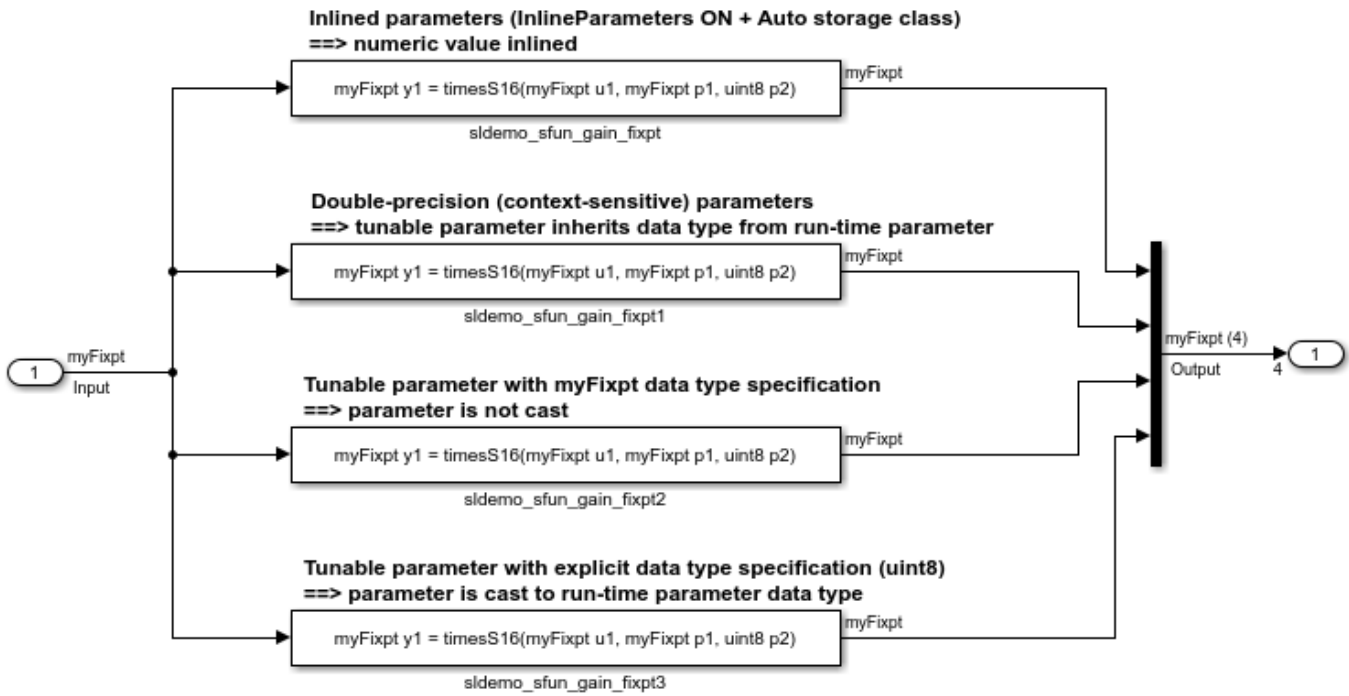

```
ans =
```

```

## Lookup Tables Implemented in Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that implement N-dimensional table lookups.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy function being called in this example is:

```
FLT directLookupTableND(const FLT *tableND, const UINT32 nbDims, const UINT32 *tableDims,
const UINT32 *tableIdx)
```

where FLT is a typedef to float, and UINT32 is a typedef to unsigned int32. The legacy source code is found in the files `your_types.h`, `lookupTable.h`, and `directLookupTableND.c`.

```
defs = [];
evalin('base','load sldemo_lct_data.mat')
```

```
% sldemo_sfun_dlut3D
```

```
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_dlut3D';
def.OutputFcnSpec = 'single y1 = DirectLookupTable3D(single p1[][][][], uint32 p2[3], uint32 u1[3]);
def.HeaderFiles = {'lookupTable.h'};
def.SourceFiles = {'directLookupTableND.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];
```

```
% sldemo_sfun_dlut4D
```

```
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_dlut4D';
def.OutputFcnSpec = 'single y1 = DirectLookupTable4D(single p1[][][][], uint32 p2[4], uint32 u1[4]);
def.HeaderFiles = {'lookupTable.h'};
def.SourceFiles = {'directLookupTableND.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'defs'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the files `sldemo_sfun_dlut3D.c` and `sldemo_sfun_dlut4D.c`.

LookUp Table are defined as:

```
>> LUT3D = single(reshape([1:4*5*6], [4 5 6]));
>> LUT4D = single(reshape([1:4*5*6*2], [4 5 6 2]))
```

## Start and Terminate Actions Within Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions that have start and terminate actions.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using the 'initialize' first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- `void initFaultCounter(unsigned int *counter)`
- `void openLogFile(void **fid)`
- `void incAndLogFaultCounter(void *fid, unsigned int *counter, double time)`
- `void closeLogFile(void **fid)`

To open the model and files, click **Open Model**. The legacy source code is found in the files `your_types.h`, `fault.h`, and `fault.c`.

```
% sldemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_fault';
def.InitializeConditionsFcnSpec = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec = 'openLogFile(void **work1)';
def.OutputFcnSpec = 'incAndLogFaultCounter(void *work1, uint32 work2[1], double u)';
def.TerminateFcnSpec = 'closeLogFile(void **work1)';
def.HeaderFiles = {'fault.h'};
def.SourceFiles = {'fault.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
def.Options.useTlcWithAccel = false;
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_fault.c`.

```
legacy_code('generate_for_sim', def);

Start Compiling sldemo_sfun_fault
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex33158503\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
```

```

MEX completed successfully.
 mex('sldemo_sfun_fault.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_f
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfun_fault
Exit

```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

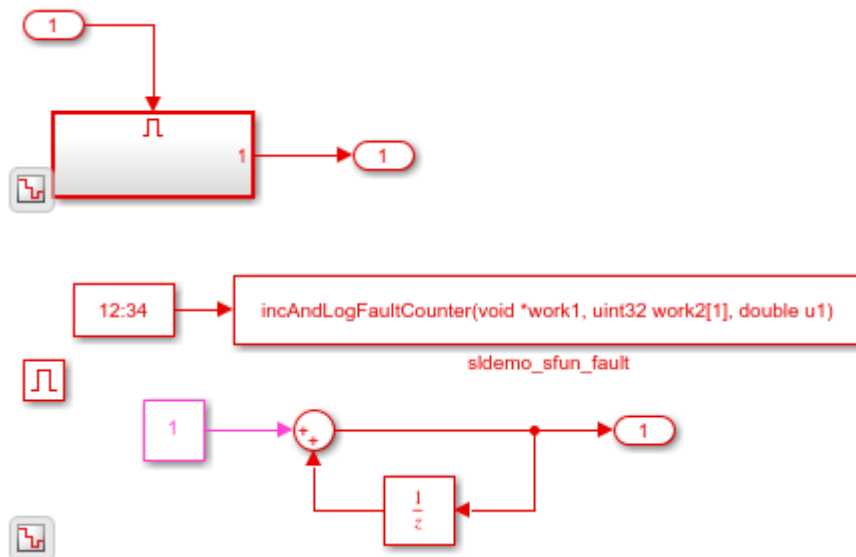

### Integrate the Legacy Code

The model `sldemo_lct_start_term` shows integration with the legacy code. The subsystem `TestFixpt` serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```

open_system('sldemo_lct_start_term')
open_system('sldemo_lct_start_term/TestFault')
sim('sldemo_lct_start_term');

```

Use the Legacy Code Tool to call legacy functions that have start and terminate actions

mdlInitializeConditions → call `initFaultCounter()` → reset the fault counter  
 mdlStart → call `openLogFile()` → open the file 'sldemo\_lct\_fault.log' for logging faults  
 mdlOutput → call `incAndLogFaultCounter()` → increment the fault counter and append one line in the log file  
 mdlTerminate → call `closeLogFile()` → close the logging file

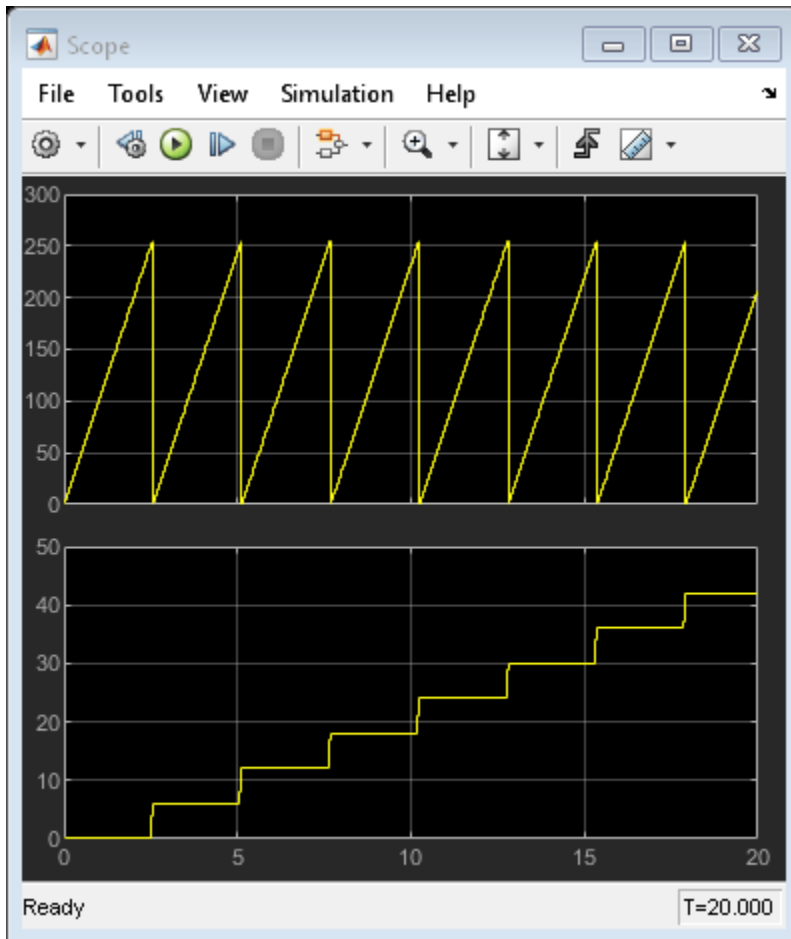

**- run the model and edit the generated logging file 'sldemo\_lct\_fault.log'**

To view the source files, click these links.

- open legacy files `fault.h` and `fault.c`
- open generated S-Function `sldemo_sfuns_fault.c`

## Using Buses with Legacy Functions Having Structure Arguments

This example shows you how to use the Legacy Code Tool to integrate legacy C functions with structure arguments using Simulink® buses.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
counterbusFcn(COUNTERBUS *u1, int32_T u2, COUNTERBUS *y1, int32_T *y2)
```

where COUNTERBUS is a struct typedef defined in `counterbus.h` and implemented with a Simulink.Bus object in the base workspace. The legacy source code is found in the files `counterbus.h` and `counterbus.c`. To open the model and files, click **Open Model**.

```
evalin('base','load sldemo_lct_data.mat')
```

```
% sldemo_sfun_counterbus
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_counterbus';
def.OutputFcnSpec = 'void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1]';
def.HeaderFiles = {'counterbus.h'};
def.SourceFiles = {'counterbus.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_counterbus.c`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_counterbus
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex39753963\slder

## Inherited Signal Dimensions for Legacy Function Arguments

This example shows you how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

- `void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)`
- `void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)`

where `real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is found in the files `mat_ops.h` and `mat_ops.c`.

```

defs = [];

% sldemo_sfun_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_mat_add';
def.OutputFcnSpec = ['void mat_add(double u1[][], double u2[][], ' ...
 'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)]]'];
def.HeaderFiles = {'mat_ops.h'};
def.SourceFiles = {'mat_ops.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];

% sldemo_sfun_mat_mult
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_mat_mult';
def.OutputFcnSpec = ['void mat_mult(double u1[p1][p2], double u2[p2][p3], ' ...
 'int32 p1, int32 p2, int32 p3, double y1[p1][p3]')'];
def.HeaderFiles = {'mat_ops.h'};
def.SourceFiles = {'mat_ops.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];

```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by

the input argument 'defs'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the files `sldemo_sfun_mat_add.c` and `sldemo_sfun_mat_mult.c`.

```
legacy_code('generate_for_sim', defs);
```

```
Start Compiling sldemo_sfun_mat_add
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex63241227\slder

```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you need to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating Masked S-Function Blocks for Calling the Generated S-Functions

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate masked S-function blocks which are configured to call those S-functions. The blocks are placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', defs);
```

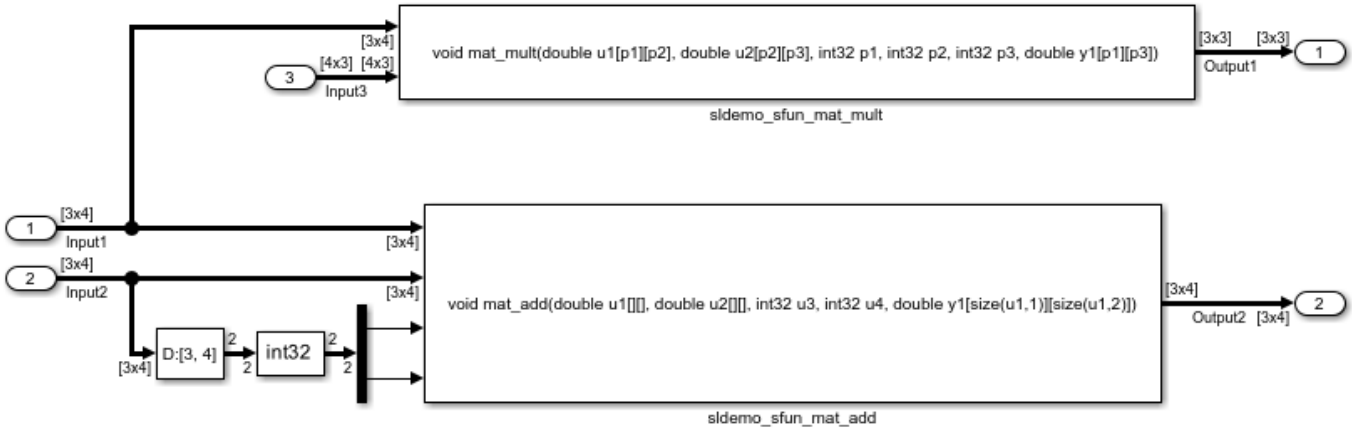

### Integrate the Legacy Code

The model `sldemo_lct_inherit_dims` shows integration with the legacy code. The subsystem `TestMatOps` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('sldemo_lct_inherit_dims')
open_system('sldemo_lct_inherit_dims/TestMatOps')
sim('sldemo_lct_inherit_dims');
```

Input/Output matrix dimensions are related to the parameter's values

Input matrices are dynamically sized  
the Output matrix dimensions are related to the Input matrices dimensions

## C++ Object Methods as Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C++ object methods.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- generate a C++ MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The definition of the legacy C++ class being used in this example is:

```
class adder {
private:
 int int_state;
public:
 adder();
 int add_one(int increment);
 int get_val();
};
```

The legacy source code is found in the files `adder_cpp.h` and `adder_cpp.cpp`.

```
% sldemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_adder_cpp';
def.StartFcnSpec = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles = {'adder_cpp.h'};
def.SourceFiles = {'adder_cpp.cpp'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_adder_cpp.cpp`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_adder_cpp
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex93865240\slder
Building with 'Microsoft Visual C++ 2019'.
```

```

MEX completed successfully.
 mex('sldemo_sfun_adder_cpp.cpp', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simu
Building with 'Microsoft Visual C++ 2019'.
MEX completed successfully.
Finish Compiling sldemo_sfun_adder_cpp
Exit

```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

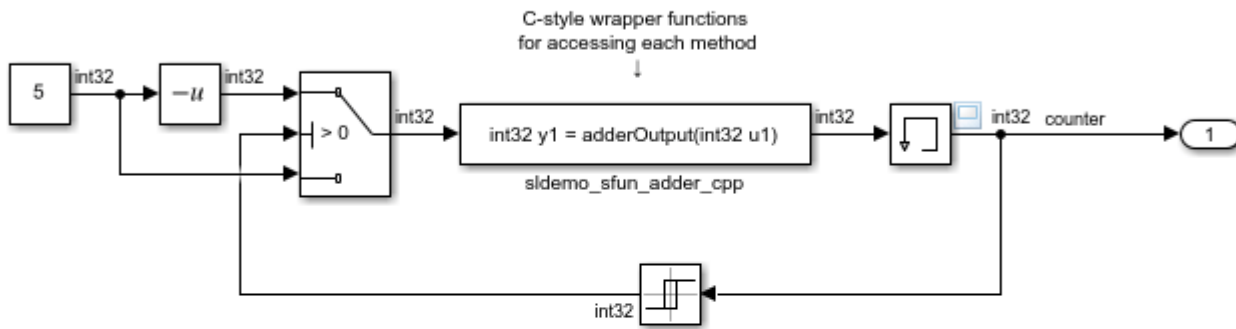

```
% legacy_code('slblock_generate', def);
```

### Integration with Legacy Code

The model `sldemo_lct_cpp` `sldemo_lct_cpp` shows integration with the legacy code.

```
open_system('sldemo_lct_cpp')
sim('sldemo_lct_cpp');
```

Use the Legacy Code Tool to  
call C++ object member functions

For this example to run, at the MATLAB command prompt enter: `>> mex -setup`  
and select a C++ compiler.

To view the source files, click these links.

- open legacy files [adder\\_cpp.h](#) and [adder\\_cpp.cpp](#)
- open generated S-Function [sldemo\\_sfund\\_adder\\_cpp.cpp](#)

## Persistent Memory Within Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions with instance-specific persistent memory.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example are:

```
void memory_bus_init(COUNTERBUS *mem, int32_T upper_sat, int32_T lower_sat);

void memory_bus_step(COUNTERBUS *input, COUNTERBUS *mem, COUNTERBUS *output);
```

where `mem` is an instance-specific persistent memory for applying a one integration step delay. `COUNTERBUS` is a struct typedef defined in `counterbus.h` and implemented with a `Simulink.Bus` object in the base workspace. The legacy source code is found in the files `memory_bus.h` and `memory_bus.c`.

```
evalin('base','load sldemo_lct_data.mat')
```

```
% sldemo_sfun_work
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_work';
def.InitializeConditionsFcnSpec = 'void memory_bus_init(COUNTERBUS work1[1], int32 p1, int32 p2)';
def.OutputFcnSpec = 'void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])';
def.HeaderFiles = {'memory_bus.h'};
def.SourceFiles = {'memory_bus.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_work.c`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_work
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex40483229\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

```
mex('sldemo_sfun_work.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_fe
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfun_work
Exit
```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Integrate the Legacy Code

The model `sldemo_lct_work` shows integration with the legacy code. The subsystem `memory_bus` serves as a harness for the call to the legacy C function.

```
open_system('sldemo_lct_work')
open_system('sldemo_lct_work/memory_bus')
sim('sldemo_lct_work')

ans =

Simulink.SimulationOutput:
 ScopeDataA: [11x3 double]
 tout: [11x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
 ErrorMessage: [0x0 char]
```

This legacy function apply a one integration step delay. The output is the previous input value. The parameters P1 and P2 set the initial values of the sub structure fields "upper\_saturation\_limit" and "lower\_saturation\_limit"

## Multi-Dimensional Signals in Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions with Multi-Dimensional Signals.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example are:

```
void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, int32_T nbPages);
```

where `real_T` is a typedef to `double`, and `int32_T` is a typedef to a 32-bit integer. The legacy source code is found in the files `ndarray_ops.h` and `ndarray_ops.c`.

```
% sldemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_ndarray_add';
def.OutputFcnSpec = ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)], ', ...
 'double u1[][][], double u2[][][], ' ...
 'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles = {'ndarray_ops.h'};
def.SourceFiles = {'ndarray_ops.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

where `y1` is a 3-D output signal of same dimensions as the 3-D input signal `u1`. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal `u1`.

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_ndarray_add.c`.

```
legacy_code('generate_for_sim', def);
```

```
Start Compiling sldemo_sfun_ndarray_add
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex68315702\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
```

```

 mex('sldemo_sfun_ndarray_add.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simu
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfun_ndarray_add
Exit

```

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

### Generating a Masked S-Function Block for Calling the Generated S-Function

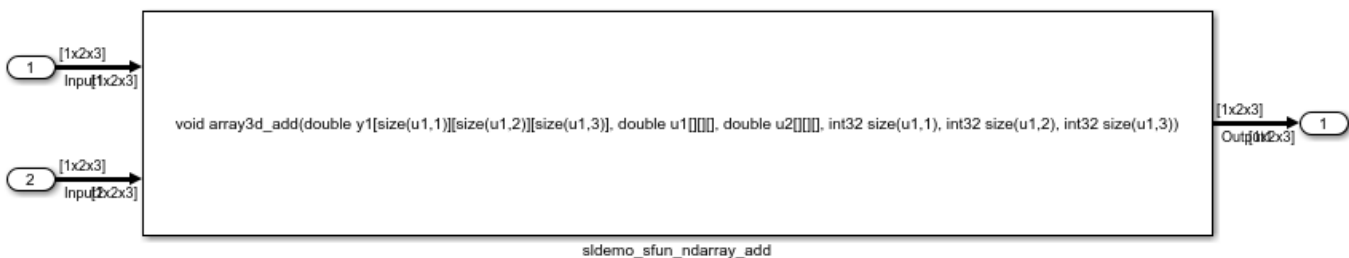

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

### Integrate the Legacy Code

The model `sldemo_lct_ndarray` shows integration with the legacy code. The subsystem `ndarray_add` serves as a harness for the call to the legacy C function.

```
open_system('sldemo_lct_ndarray')
open_system('sldemo_lct_ndarray/ndarray_add')
sim('sldemo_lct_ndarray');
```

```

This legacy function computes the addition of the 2 input signals:
- Input1 and Input2 are dynamically sized 3D arrays
- Output1 is a dynamically sized 3D array of same size as Input1
- the last 3 function's arguments allow to pass the Input1's dimensions to the legacy function

```

## Complex Signals in Legacy Function

This example shows you how to use the Legacy Code Tool to integrate legacy C functions using complex signals.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototype of the legacy functions being called in this example is:

```
void cplx_gain(creal_T *input, creal_T *gain, creal_T *output);
```

where `creal_T` is the complex representation of a double. The legacy source code is found in the files `cplxgain.h` and `cplxgain.c`.

```
% sldemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_cplx_gain';
def.OutputFcnSpec = 'void cplx_gain(complex<double> u1[1], complex<double> p1[1], complex<double>';
def.HeaderFiles = {'cplxgain.h'};
def.SourceFiles = {'cplxgain.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
```

### Generating and Compiling an S-Function for Use During Simulation

The function `legacy_code()` is called again with the first input set to 'generate\_for\_sim' in order to automatically generate and compile the C-MEX S-function according to the description provided by the input argument 'def'. This S-function is used to call the legacy functions in simulation. The source code for the S-function is found in the file `sldemo_sfun_cplx_gain.c`.

```
legacy_code('generate_for_sim', def);

Start Compiling sldemo_sfun_cplx_gain
mex('-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simulink_features-ex34942047\slder
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
mex('sldemo_sfun_cplx_gain.c', '-IC:\TEMP\Bdoc22b_2054784_11640\ib975175\0\tp2ecad9d5\simuli
Building with 'Microsoft Visual C++ 2019 (C)'.
MEX completed successfully.
Finish Compiling sldemo_sfun_cplx_gain
Exit
```

## Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

## Generating a Masked S-Function Block for Calling the Generated S-Function

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate a masked S-function block that is configured to call that S-function. The block is placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', def);
```

## Integration with Legacy Code

The model `sldemo_lct_cplxgain` shows integration with the legacy code. The subsystem `complex_gain` serves as a harness for the call to the legacy C function via the generate S-function.

```
if isempty(find_system('SearchDepth',0,'Name','sldemo_lct_cplxgain'))
 open_system('sldemo_lct_cplxgain')
 open_system('sldemo_lct_cplxgain/complex_gain')
 sim('sldemo_lct_cplxgain');
end
```

## Specified or Inherited Sample Time with Legacy Functions

This example shows you how to use the Legacy Code Tool to integrate legacy C functions with the sample time specified, inherited and parameterized.

The Legacy Code Tool allows you to:

- Provide the legacy function specification,
- Generate a C-MEX S-function that is used during simulation to call the legacy code, and
- Compile and build the generated S-function for simulation.

### Providing the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function `legacy_code()` using 'initialize' as the first input. After initializing the structure, you have to assign its properties to values corresponding to the legacy code being integrated. The prototypes of the legacy functions being called in this example are:

```
FLT gainScalar(const FLT in, const FLT gain)
```

where FLT is a typedef to float. The legacy source code is found in the files `your_types.h`, `gain.h`, and `gainScalar.c`.

```
defs = [];
```

```
% sldemo_sfun_st_inherited
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_st_inherited';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
defs = [defs; def];
```

```
% sldemo_sfun_st_fixed
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_st_fixed';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};
def.IncPaths = {'sldemo_lct_src'};
def.SrcPaths = {'sldemo_lct_src'};
def.SampleTime = [2 1];
defs = [defs; def];
```

```
% sldemo_sfun_st_parameterized
def = legacy_code('initialize');
def.SFunctionName = 'sldemo_sfun_st_parameterized';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles = {'gain.h'};
def.SourceFiles = {'gainScalar.c'};

### Generating an `rtwmakecfg.m` File for Code Generation

After the TLC block file is created, the function `legacy_code()` can be called again with the first input set to `'rtwmakecfg_generate'` in order to generate an `rtwmakecfg.m` file to support code generation through Simulink® Coder™. Generate the `rtwmakecfg.m` file if the required source and header files for the S-functions are not in the same directory as the S-functions, and you want to add these dependencies in the makefile produced during code generation.

Note: Complete this step only if you are going to simulate the model in accelerated mode.

```
legacy_code('rtwmakecfg_generate', def);
```

## Generating Masked S-Function Blocks for Calling the Generated S-Functions

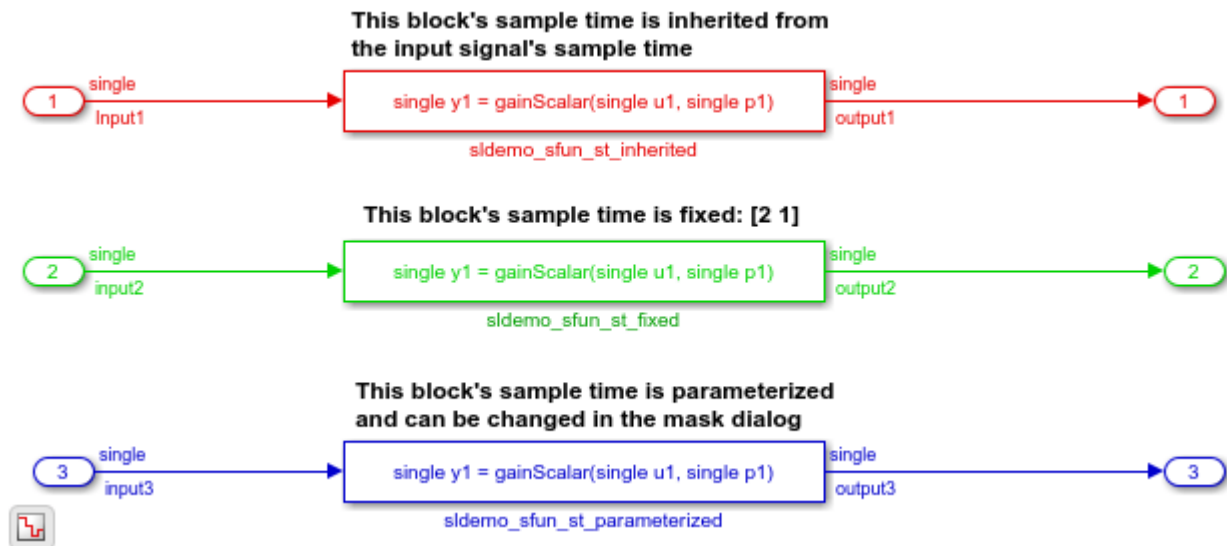

After the C-MEX S-function source is compiled, the function `legacy_code()` can be called again with the first input set to `'slblock_generate'` in order to generate masked S-function blocks which are configured to call those S-functions. The blocks are placed in a new model and can be copied to an existing model.

```
% legacy_code('slblock_generate', defs);
```

### Integration the Legacy Code

The model `sldemo_lct_sampletime` shows integration with the legacy code. The subsystem `sample_time` serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('sldemo_lct_sampletime')
open_system('sldemo_lct_sampletime/sample_time')
sim('sldemo_lct_sampletime');
```

## Illustration of Law of Large Numbers

This example shows how to use MATLAB System blocks to illustrate the law of large numbers.

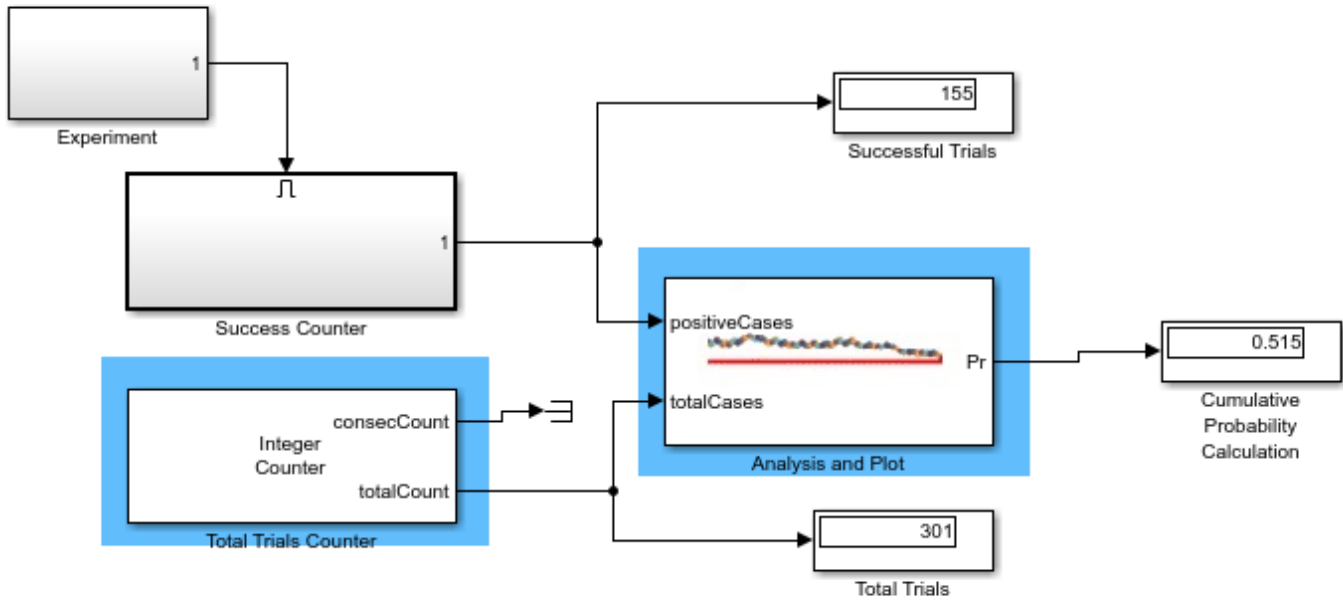

The law of large numbers states that the cumulative average probability of an event approaches the expected value as the number of trials approaches infinity. You can see this in the generated plot.

A Uniform Random Number block connected to Compare To Constant block acts as a Bernoulli trial. The example uses the high value as successful outcome of the experiment.

This example highlights the use of MATLAB System block as follows:

- The Success Counter counts the number of successful trials. The Total Trials Counter counts the total number of trials. Both blocks use the same System object™. This System object is a source block that uses the "resetImpl" method to count the number of times the block has run at consecutive time steps.
- The Analysis and Plot block calculates the average probability and plots it. It uses a System object that inherits from the interface classes matlab.System. The interface class matlab.System is required for all System objects. To use features not supported for code generation, such as unsupported functions, define propagator methods for the System object. As a result, this block cannot simulate in "Code generation" mode. It must simulate in "Interpreted execution" mode.
- The two MATLAB System blocks use custom icons. The Analysis and Plot block uses an image file icon. The Total Trials Counter block uses a multiline text icon. The "getIconImpl" methods of the corresponding System objects define these custom icons.

## MATLAB System Block Example: Illustration of Law of Large Numbers

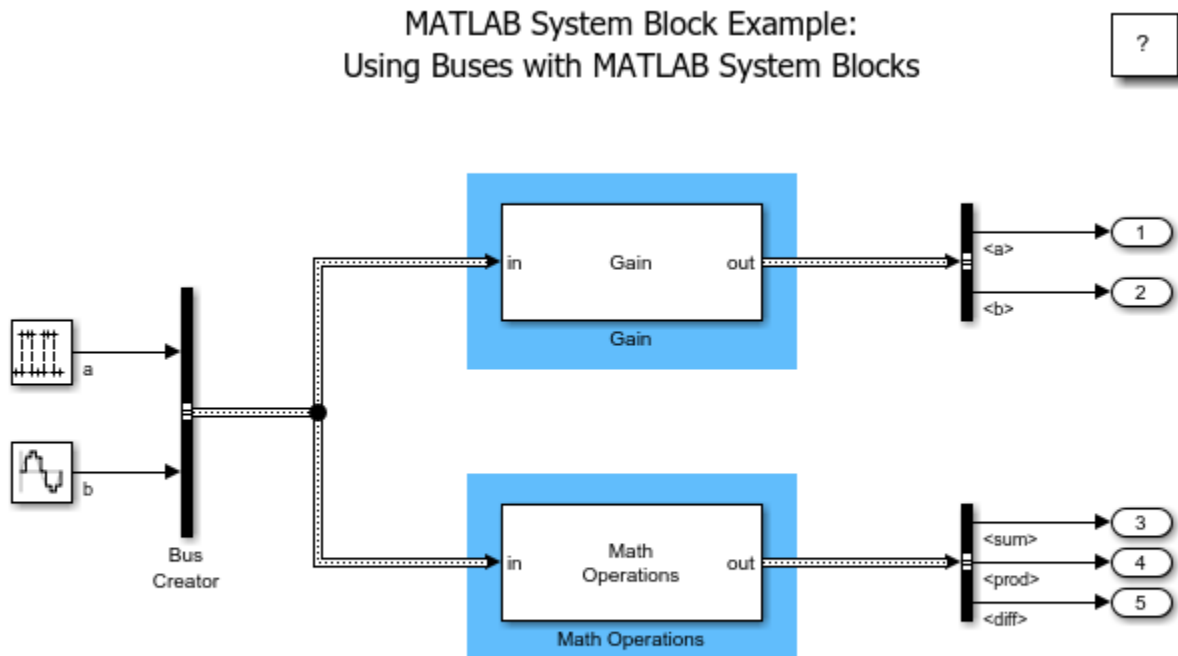

Copyright 2013 The Mathworks, Inc.

## Using Buses with MATLAB System Blocks

This example shows how to use buses as inputs and outputs to the MATLAB System block.

Copyright 2015 The MathWorks, Inc.

The Gain block uses a System object™ that applies the gain specified in the block to the bus elements 'a' and 'b' of the incoming bus. The output of the block is the same bus type as the input.

The Math Operations block uses a System object that computes the sum, product, and difference between the two bus elements 'a' and 'b' of the input bus. The output of the block is a bus with three elements: 'sum', 'prod', and 'diff'.

If a MATLAB System block output bus is the same type as the input bus, you must still specify the output bus name in the 'getOutputDataTypeImpl' method. This is because the 'propagatedInputDataType' method does not return the input bus object during bus propagation.

Before model initialization, all bus types used as either inputs or outputs to the MATLAB System block must be available in the MATLAB base workspace.

## Run Quality Checks on S-Functions

This example shows how to use S-Function analyzer programmatic interfaces to check S-functions for potential problems and improvements.

The S-Function analyzer programmatic interface consists of:

- **Simulink.sfunction.Analyzer** - Object used to launch S-function analyzer and get analysis results.
- **Simulink.sfunction.analyzer.BuildInfo** - Object used to create an object to specify the build information for an S-function.
- **Simulink.sfunction.analyzer.Options** - Object used to specify the running options for S-function analyzer.
- **Simulink.sfunction.analyzer.findSfunctions** - Function to return all feasible S-functions in a model or library for S-function analyzer.

### Specify Input Model or Library

The S-Function analyzer requires a model or a library on the MATLAB® path that contains the S-Function blocks to be analyzed.

```
model = 'slexSfunctionCheckExample';
```

### Specify Build Information for S-functions

S-function analyzer checks the source code of S-functions when they are available. Heuristics are applied to automatically locate the source code based on S-function names. For example, if S-function source code and the input model are in the same folder, the source code is included in the analysis automatically. Otherwise, the build information has to be specified using a `Simulink.sfunction.analyzer.BuildInfo` object. If no source code is available, you do not need to complete this step.

To specify the build information, first determine the eligible S-functions in the input model. Then, create a `Simulink.sfunction.analyzer.BuildInfo` object for each S-function. For the S-function `slexBadSFcn`, there are two associated source files: `slexBadSFcn.c` and `slexBadSFcn_wrapper.c`

```
sfunctions= Simulink.sfunction.analyzer.findSfunctions(model);
bdInfo= Simulink.sfunction.analyzer.BuildInfo(fullfile(matlabroot,'examples','simulink_features'
 'ExtraSrcFileList',{'slexBadSFcn_wrapper.c'},...
 'SrcPaths',{fullfile(matlabroot,'examples','simulink_features','slexBadSFcn_wrapper.c')});
```

### Specify Running Options for S-Function Analyzer

You can configure the execution options for S-function analyzer, such as whether to enable Polyspace checks and parameter robustness checks, the simulation timeout, and the output path for the result report, using a `Simulink.sfunction.analyzer.Options` object. If you do not need to modify options from their default values, you can skip this step.

```
opts = Simulink.sfunction.analyzer.Options;
opts.EnableRobustness = 1;
```

### Run S-Function Analyzer and View Results

Create a `Simulink.sfunction.Analyzer` object that captures the specified build information and options. Then, run the S-function analyzer with that configuration using the `run` function and generate a report of the analysis results using the `generateReport` function.

```
sfunAnalyzer = Simulink.sfunction.Analyzer(model, 'BuildInfo', {bdInfo}, 'Options', opts);
analysisResult=run(sfunAnalyzer);
generateReport(sfunAnalyzer);
```

## Using the Prelookup and Interpolation Blocks

This examples shows how to use the Prelookup and Interpolation Using Prelookup blocks.

### Introduction

This model uses Prelookup and Interpolation Using Prelookup blocks. The Prelookup block minimizes the number of index searches performed across a set of lookup tables. It also mixes clipping, extrapolation, and index search algorithms within one table calculation. Note how the Prelookup blocks perform the index search portion of the computation and the Interpolation Using Prelookup blocks perform the rest:

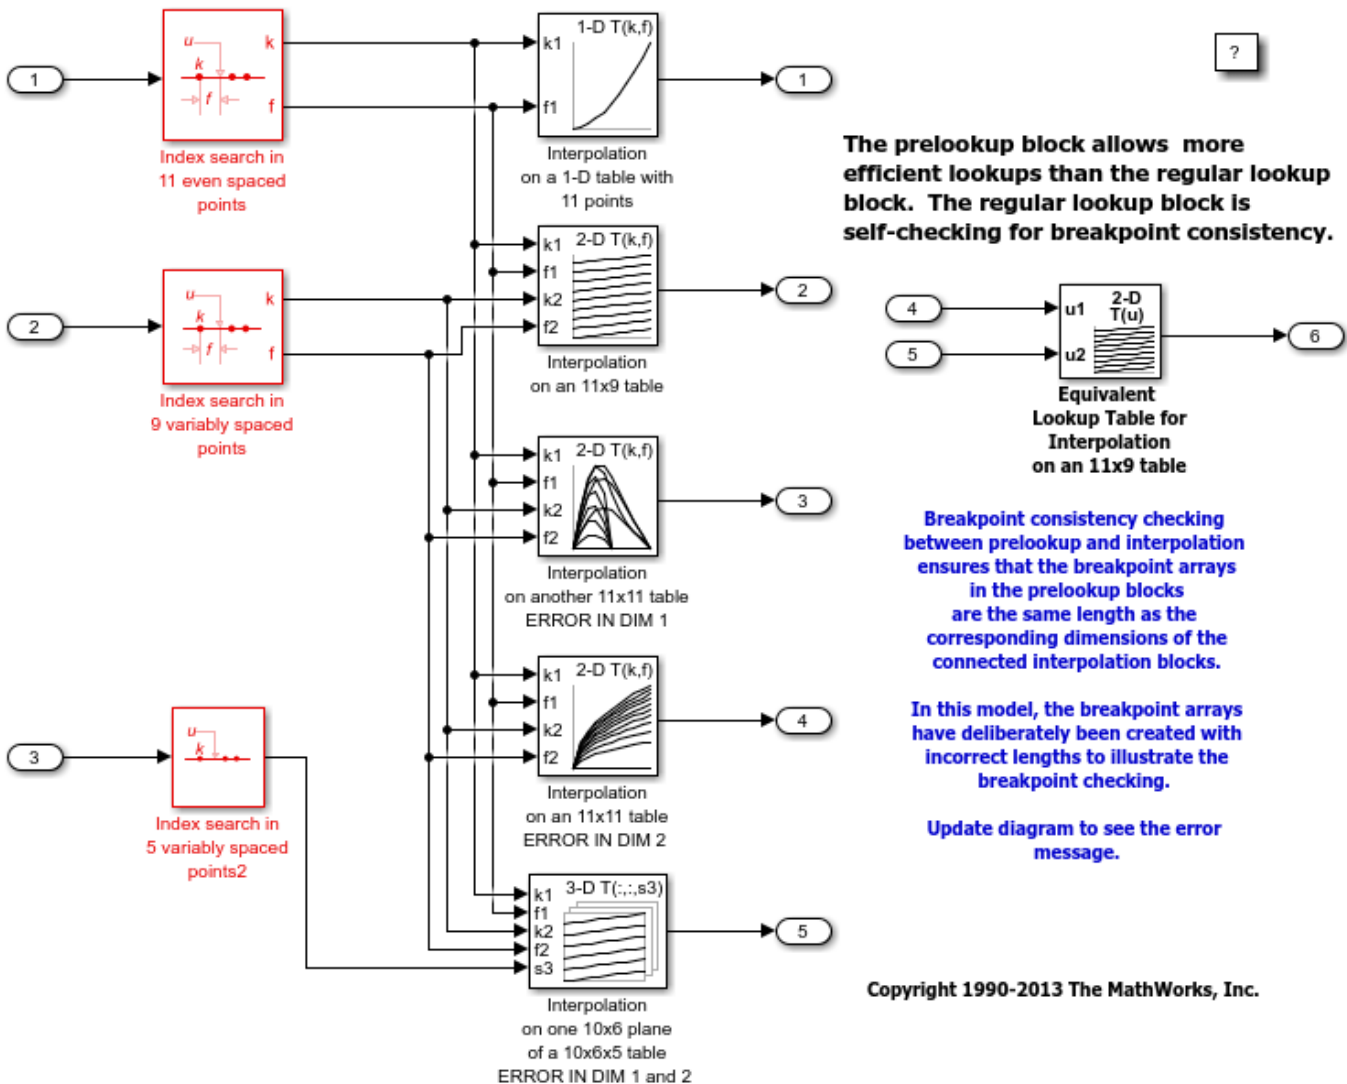

These blocks are in the Simulink® block library in the Lookup Tables sublibrary:

**Optimization: PreLookup and Interpolation Using Prelookup Blocks**

Consider using PreLookup block for tables with intensive index searches in breakpoint sets. The Prelookup blocks allow you to perform an index search once and reuse the result in many table lookups. In this model, three index search results are used in five blocks in a total of ten uses. Equivalent regular lookup tables such as the example to the right would have required ten index searches instead of three.

### Optimization: Subtable Selection Option in the Interpolation Using Prelookup Blocks

One of the interpolation blocks in this model is configured using a capability: trailing dimensions of an n-D table can be marked as "selection dimensions", meaning that the input for that dimension is an integer used only to make a subtable selection, such as picking a 2-D plane from a 3-D table. The subtable is then interpolated normally.

Interpolation of subtables can save tremendous amounts of computation. For every dimension eliminated from interpolation, the computation almost halves. Since an N-dimensional interpolation takes  $(2^N)-1$  individual interpolation operations ( $y = y_{low} + f^*(y_{high}-y_{low})$ ), just one dimension of selection can almost double the speed of the interpolation. Extreme example: a 5-D table with three dimensions of subtable selection and 2-D interpolation: 5-D interpolation would take  $2^5-1 = 31$  interpolations, but a 2-D interpolation takes only  $2^2 - 1 = 3$ .

The selection ports support vectorization to allow multiple subtable selection/interpolations in a single block.

The prelookup block allows more efficient lookups than the regular lookup block. The regular lookup block is self-checking for breakpoint consistency.

Breakpoint consistency checking between prelookup and interpolation ensures that the breakpoint arrays in the prelookup blocks are the same length as the corresponding dimensions of the connected interpolation blocks.

In this model, the breakpoint arrays have deliberately been created with incorrect lengths to illustrate the breakpoint checking.

Update diagram to see the error message.

Copyright 1990-2013 The MathWorks, Inc.

The subtable or multitable mode of operation is activated by setting a positive integer for the 'Number of sub-table selections dimensions' parameter in the block parameter dialog. The number you set is interpreted as the number of dimensions to select from the highest dimensions. For example, if you have a 3-D table and choose 2, that means the first dimension will be interpolated and dimensions 2 and 3 will be selected:

NOTE: You can remove highlighting from a model using the View/Remove highlighting menu item or this command:

```
set_param mdl, 'HiliteAncestors', 'none')
```

### Breakpoint and Table Data Consistency Checking

Using Prelookup and Interpolation Using Prelookup blocks introduces a need to ensure that the length of the 'Breakpoint data' parameter in the Prelookup blocks matches the corresponding dimension of the 'Table data' parameter in the connected Interpolation Using Prelookup blocks.

Simulink® always checks the consistency between the two blocks when updating the block diagram. Simulink reports errors if it encounters inconsistent breakpoint and table data. For example:

```
try
 evalc(['sim(', mdl, ')']);
catch E
 disp(['Error:', E.message]);
end
```

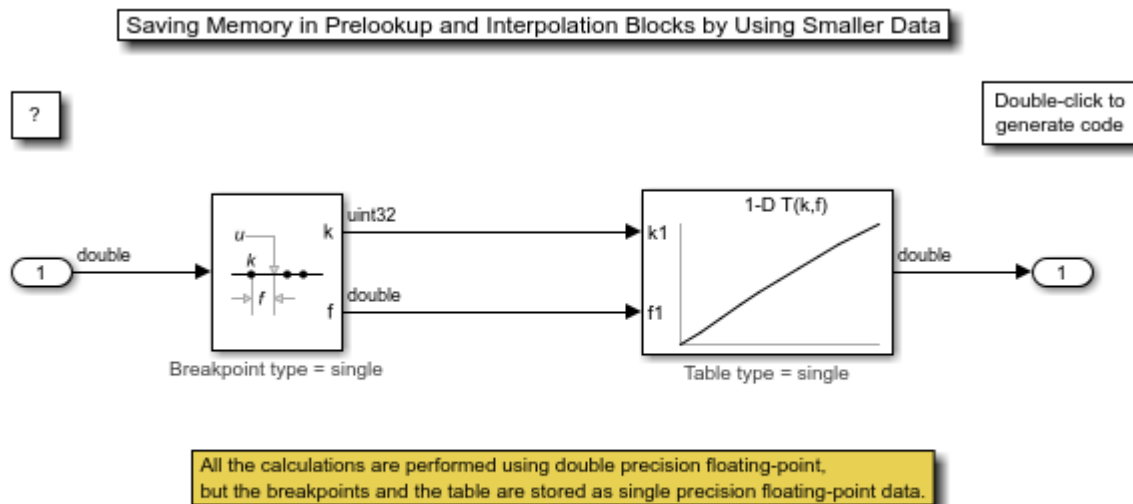

Error:The range of values for input port k2 of block '[k2](matlab:open_and_hilite_hyperlink)' is not consistent with the table data.

## Saving Memory in Prelookup and Interpolation Blocks by Using Smaller Data

This example shows how to save memory in Prelookup and Interpolation blocks. The Prelookup and Interpolation Using Prelookup blocks allow you to explicitly set data type storing breakpoints and table data. Note that the Prelookup block allows the breakpoint data to differ from the input data type, and the Interpolation Using Prelookup block allows the table data to differ from the output data type.

In this model, the breakpoints and table are stored using single precision floating-point data type, and the calculations are performed using double precision floating-point data type. This reduces the amount of breakpoint and table data memory by half.

To see this in the generated code, open the model and build it.

Copyright 2008-2013 The MathWorks, Inc.

## Model Advisor

This example shows the capabilities of the Model Advisor to check a model or subsystem for conditions and configuration settings that can result in inaccurate or inefficient simulation of the system represented by the model or generation of inefficient code from the model. The Model Advisor produces a report that lists all the suboptimal conditions or settings that it finds, suggesting better model configuration settings where appropriate.

The Model Advisor can be started through menus or the command line and can also be configured and used through a comprehensive API.

```
open_system('sldemo_mdladv')
evalc('sim(''sldemo_mdladv'')');
```

## Introduction to Profiling Models

This example shows how to use the **Simulink Profiler** to examine the `slAccelDemoF14` model and identify issues that can contribute to poor simulation performance. Consider using the **Simulink Profiler** to manually optimize model settings, identify simulation slowdowns, and resolve performance bottlenecks.

To automatically optimize your model and achieve faster simulation, see “Improve Simulation Performance Using Performance Advisor”.

To learn more about accelerator modes for faster simulation, see “What Is Acceleration?”.

### Activate the Profiler

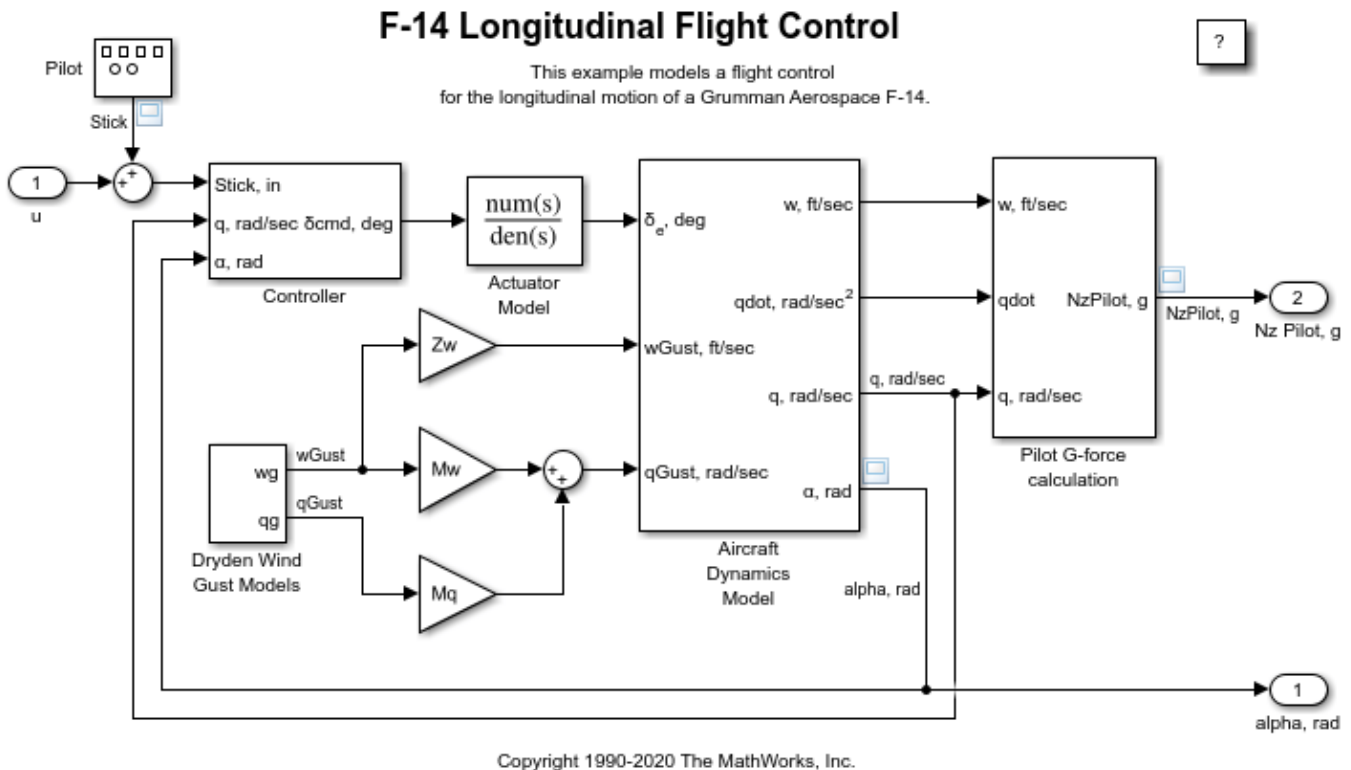

To activate the Simulink® Profiler, in the Simulink Editor, on the **Debug** tab, under **Performance Advisor**, click **Simulink Profiler**. You can also issue a `set_param` command at the command prompt.

```
modelName = 'slAccelDemoF14';
load_system(modelName)
set_param(modelName, 'Profile', 'on');
```

### Run Simulation

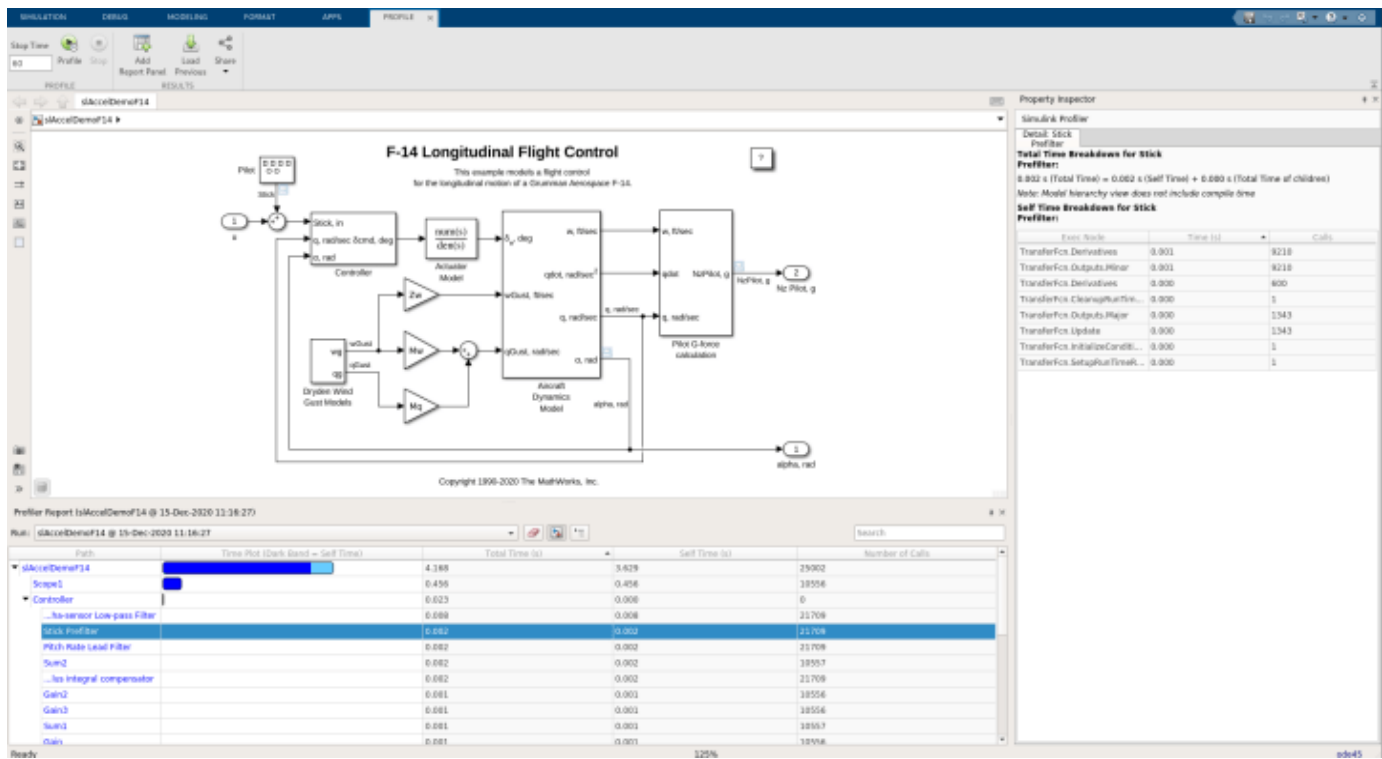

While the simulation runs, the profiler is collecting data for the report. Once the simulation is complete it creates an HTML report.

```
open_system(modelName)
sim(modelName);
```

### View Report

A detailed profiling report is shown in a docked panel on the Simulink Editor. Select a row to see the breakdown of the self-time of the specific model element in the Property Inspector.

## Share Report

You can share the profiling report with others as an HTML report or as a MAT file. To share your profiling run, select the desired run from the **Run** menu of the Profiling Report. Then select your desired export format from the **Share** menu on the Toolstrip.

## Introduction to Accelerating Models

Simulink® Accelerator™ speeds up the execution of your model, by creating and compiling C code. This C code takes the place of the interpretive code that Simulink uses when in Normal mode (that is, when Simulink® is not in Accelerator mode). Simulink Accelerator generates the C code from the Simulink model and invokes the MATLAB® mex function to compile and dynamically link the generated code to Simulink. This code generation and compilation process happens the first time you accelerate the model and any time the model changes are significant enough to require re-generation (for example, the addition of a block).

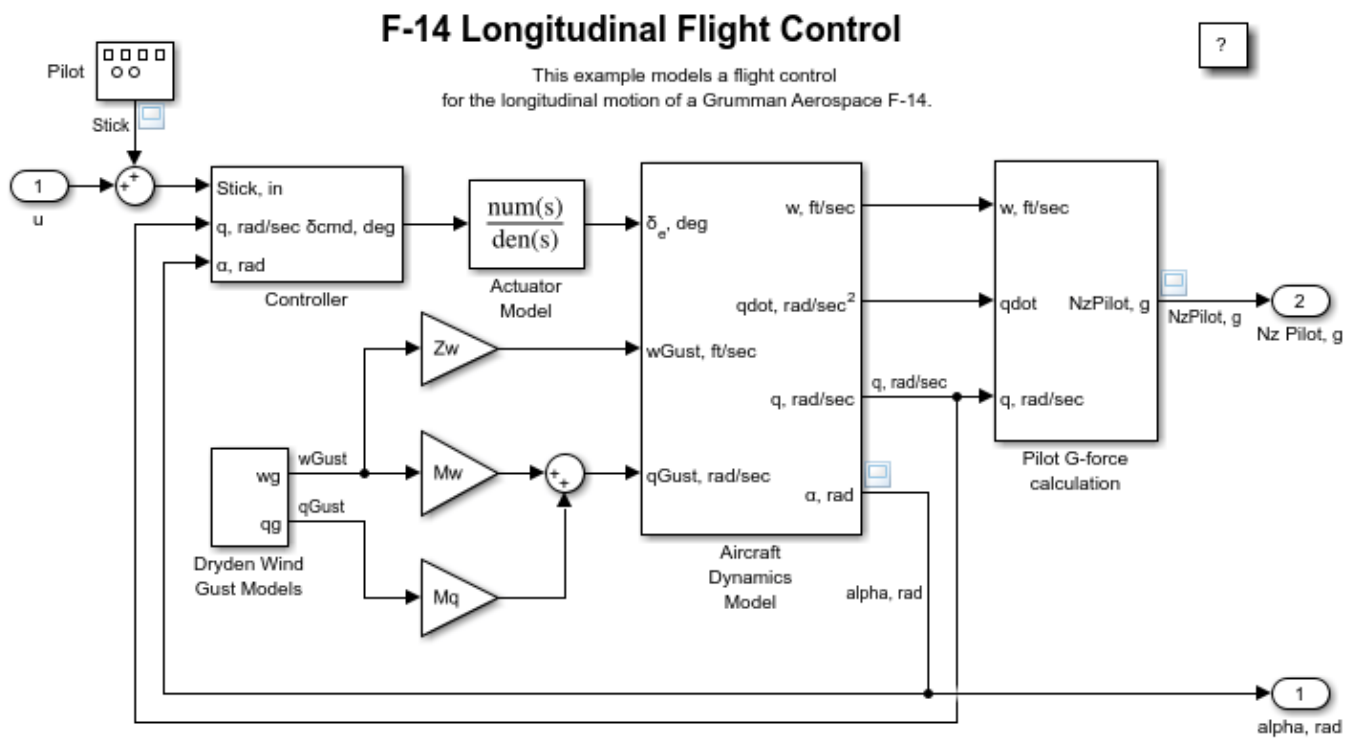

This example uses the slAccelDemoF14 model to illustrate the use of Simulink Accelerator.

### Measure Non-accelerated Time

Open the slAccelDemoF14 model and set the stop time to 3000 seconds. Simulate the model and time how long it takes using TIC/TOC.

```
modelName = 'slAccelDemoF14';
open_system(modelName)
set_param(modelName, 'stoptime', '3000')
tic
sim(modelName);
toc
```

Elapsed time is 22.318623 seconds.

Copyright 1990-2020 The MathWorks, Inc.

### Turn on the Accelerator

To activate the Simulink® Accelerator, in the Simulink Editor, on the **Simulation** tab, under **Simulate**, select **Accelerator**. You can also issue a `set_param` command at the MATLAB® command prompt.

```
set_param(modelName, 'SimulationMode', 'Accelerator')
```

### Build Accelerated Model

Build the accelerated model and simulate it. When running in Accelerator mode, you can start the model by selecting **Run** on the **Simulation** tab or by running the command:

```
sim(modelName)
```

at the MATLAB prompt. In either case, the progress of the code generation process will be displayed in the MATLAB command window. To suppress this display wrap the `sim` command inside an `evalc`.

```
evalc('sim(modelName);');
```

### Simulate the Accelerated Model

Simulate the model again. Notice the model simulation runs much faster on subsequent runs.

```
tic
sim(modelName);
toc
```

```
Elapsed time is 7.579780 seconds.
```

### Change Tunable Parameter and Simulate Accelerated Model

Change the value of one of the tunable parameters in the model and simulate the model again. Notice the accelerated version of the model does not have to be re-generated and so the simulation still runs more quickly in Accelerated mode than in Normal mode.

```
modelWorkspace = get_param(modelName, 'ModelWorkspace');
evalin(modelWorkspace, 'Mw=Mw*2;');
tic
sim(modelName);
toc
```

```
Elapsed time is 7.461747 seconds.
```

## Determine Why Simulink Accelerator Is Regenerating Code

Sometimes Simulink® regenerates the simulation target for a model at the beginning of a simulation in Accelerator Mode but it is not always clear why regeneration happens. This example shows how to use Simulink MATLAB® commands to determine why Simulink regenerates code for Accelerator Mode simulations.

Simulink's Accelerator Mode speeds up simulation of your model by creating an executable version of the model, called a simulation target, and running this target instead of interpreting the model, as is done during Normal Mode simulation.

The process of code generation happens during the first time that you simulate your model in Accelerator Mode. Additionally, code generation may happen on subsequent simulations, especially if the model changes between simulations (for example, after addition of a block). Code generation takes time and it is often desirable to avoid it, in order to maximize the number of simulations within a given time span.

Simulink uses the model's checksum to determine if the code needs to be regenerated. This checksum is an array of four integers computed by using an md5 checksum algorithm based on attributes of the model and the blocks that it contains. Any change in the model that changes the checksum causes Simulink to regenerate the simulation target for Accelerator Mode.

Sometimes, it is not clear which model change triggered a checksum change and hence code regeneration. This example shows how to investigate why Simulink needs to regenerate code for Accelerator Mode simulation for a given model and its configuration.

### Open an Example Model

We will use a simple model, `slAcceLDemoWhyRebuild`, throughout this example.

```
model = 'slAcceLDemoWhyRebuild';
open_system(model)
```

## Determine Why Simulink Accelerator Re-Builds

```
set_param(model, 'AccelVerboseBuild', 'on');
```

The first time the model runs in Accelerator mode, it generates and compiles code as expected.

```
simOutput = evalc(['sim('',model,'')']);
if ~isempty(strfind(simOutput,'Building the Accelerator target for model'))
 disp('Built Simulink Accelerator mex file')
else
```

```
 disp('Did not build Simulink Accelerator mex file')
end
```

```
Built Simulink Accelerator mex file
```

If the simulation is run again, without any changes to the model, we expect that Simulink can reuse the existing code and does not need to regenerate the code. Execute the same commands to verify.

```
simOutput = evalc(['sim('',model,'')']);
if ~isempty(strfind(simOutput,'Building the Accelerator target for model'))
 disp('Built Simulink Accelerator mex file')
else
 disp('Did not build Simulink Accelerator mex file')
end
```

```
Did not build Simulink Accelerator mex file
```

Now we change some parameters in the model. We will set the following settings for the block 'Integrator':

- Set 'Ignore limit and reset when linearizing' to 'on'
- Set 'Initial Condition' to '5'

```
set_param([model, '/Integrator'], 'IgnoreLimit', 'on');
set_param([model, '/Integrator'], 'InitialCondition', '5');
```

When we run the simulation again, we see that Simulink regenerates the code.

```
simOutput = evalc(['sim('',model,'')']);
if ~isempty(strfind(simOutput,'Building the Accelerator target for model'))
 disp('Built Simulink Accelerator mex file')
else
 disp('Did not build Simulink Accelerator mex file')
end
```

```
Built Simulink Accelerator mex file
```

We would like to know why.

To determine if the previously generated code is still valid for the current model configuration, Simulink compares the checksum of the model as used to generate the code to the current checksum. If they are equal, the previously generated code is still valid and Simulink Accelerator Mode reuses it for the current simulation. If the values differ, Simulink Accelerator Mode regenerates and rebuilds the code. Thus, examining the details of the checksum computation can reveal why Simulink regenerated the code.

### Get Checksum Details

The following command gets the model checksum computation details:

```
[cs1,csdet1]=Simulink.BlockDiagram.getChecksum(model);
```

The first output is the model checksum value itself. The second output gives details of what went into the checksum computation.

Let us set the modified block parameters to their original values and get the checksum and details for that configuration.

```
set_param([model, '/Integrator'], 'IgnoreLimit', 'off');
set_param([model, '/Integrator'], 'InitialCondition', '0');
[cs2, csdet2]=Simulink.BlockDiagram.getChecksum(model);
```

Comparing these two checksum values is equivalent to determining if the Simulink Accelerator will regenerate code. Note that the checksum values are different, as we expect based on the fact that Simulink Accelerator regenerates code every time it runs.

```
if (cs1 ~= cs2)
 disp('Checksums are different')
else
 disp('Checksums are the same')
end
```

Checksums are different

Now that we know that the checksums differ, the next question is why. Many things go into the checksum computation, including signal data types, some block parameter values, and block connectivity information. To understand why the checksums differ, we need to see what has changed about the items used in computing the checksum. The checksum details returned as the second argument give that information.

```
csdet1
```

```
csdet1 = struct with fields:
 ContentsChecksum: [1x1 struct]
 InterfaceChecksum: [1x1 struct]
 ContentsChecksumItems: [188x1 struct]
 InterfaceChecksumItems: [48x1 struct]
```

The checksum details is a structure array with four fields. Two of the fields are the component checksums of the model checksum (these are called ContentsChecksum and InterfaceChecksum) and the other two are the corresponding checksum details. These details correspond to various information which went into to the computation of the two component checksums. The model [structural] checksum is a function of ContentsChecksum and InterfaceChecksum.

First, let's determine if the difference lies in the model's contents or the model's interface.

```
if (csdet1.ContentsChecksum.Value ~= csdet2.ContentsChecksum.Value)
 disp('Contents checksums are different')
else
 disp('Contents checksums are the same')
end
```

Contents checksums are different

```
if (csdet1.InterfaceChecksum.Value ~= csdet2.InterfaceChecksum.Value)
 disp('Interface checksums are different')
else
 disp('Interface checksums are the same')
end
```

Interface checksums are the same

### Use Details to Determine Why Checksum Changed

Now that we know the change is in the ContentsChecksum, we can look at the ContentsChecksumItems to see what has changed.

```

idxForDifferences=[];
for idx = 1:length(csdet1.ContentsChecksumItems)
 if (~strcmp(csdet1.ContentsChecksumItems(idx).Handle, ...
 csdet2.ContentsChecksumItems(idx).Handle))
 idxForDifferences=[idxForDifferences,idx];
 disp(['Handles different for item ',num2str(idx)]);
 end
 if (~strcmp(csdet1.ContentsChecksumItems(idx).Identifier, ...
 csdet2.ContentsChecksumItems(idx).Identifier))
 disp(['Identifiers different for item ',num2str(idx)]);
 idxForDifferences=[idxForDifferences,idx];
 end
 if(ischar(csdet1.ContentsChecksumItems(idx).Value))
 if (~strcmp(csdet1.ContentsChecksumItems(idx).Value, ...
 csdet2.ContentsChecksumItems(idx).Value))
 disp(['String Values different for item ',num2str(idx)]);
 idxForDifferences=[idxForDifferences,idx];
 end
 end
 if(isnumeric(csdet1.ContentsChecksumItems(idx).Value))
 if (csdet1.ContentsChecksumItems(idx).Value ~= ...
 csdet2.ContentsChecksumItems(idx).Value)
 disp(['Numeric values are different for item ',num2str(idx)]);
 idxForDifferences=[idxForDifferences,idx];
 end
 end
end
end

```

```
String Values different for item 40
```

Now that we know the differences are in the items at the indices listed in `idxForDifferences`, we can look at those items in the two `ContentsChecksumItems` arrays.

```

blk1 = csdet1.ContentsChecksumItems(idxForDifferences(1)).Handle

blk1 =
'slAccelDemoWhyRebuild/Integrator'

blk2 = csdet2.ContentsChecksumItems(idxForDifferences(1)).Handle

blk2 =
'slAccelDemoWhyRebuild/Integrator'

id1 = csdet1.ContentsChecksumItems(idxForDifferences(1)).Identifier

id1 =
'IgnoreLimit'

id2 = csdet2.ContentsChecksumItems(idxForDifferences(1)).Identifier

id2 =
'IgnoreLimit'

```

The Handle for both items is 'slAccelDemoWhyRebuild/Integrator', which indicates the block with the changing data. The identifier for both is 'IgnoreLimit' which tells us that this was the block setting which changed, resulting in a different checksum for the model. The setting for the Initial Condition of the block does not appear in the checksum detail. Therefore, we expect that if only the setting for the Initial Condition is modified, that no rebuild will occur.

## Avoid Rebuild on Successive Simulations

Now that we found the parameter which causes the checksums to differ for this workflow, we can validate the findings by keeping that parameter constant and seeing whether rebuild occurs on successive simulations.

Let's simulate the model in Accelerator mode again. We expect it to rebuild for this simulation because we changed the parameter ('IgnoreLimit') for the checksum computation above.

```
simOutput = evalc(['sim('',model,'')']);
if ~isempty(strfind(simOutput,'Building the Accelerator target for model'))
 disp('Built Simulink Accelerator mex file')
else
 disp('Did not build Simulink Accelerator mex file')
end
```

Built Simulink Accelerator mex file

Now let's only change the Initial Condition setting and simulate again. We expect that no rebuild should happen this time.

```
set_param([model,'/Integrator'],'InitialCondition','-3');
simOutput = evalc(['sim('',model,'')']);
if ~isempty(strfind(simOutput,'Building the Accelerator target for model'))
 disp('Built Simulink Accelerator mex file')
else
 disp('Did not build Simulink Accelerator mex file')
end
```

Did not build Simulink Accelerator mex file

As expected from the checksum analysis, changing the parameter for 'Initial Condition' does not cause a regeneration of code for simulation in Accelerator mode.

## Parallel Simulations Using Parsim: Test-Case Sweep

This example shows how you can run multiple Simulink® simulations corresponding to different test cases in the Signal Editor block using SimulationInput objects and the `parsim` command. The `parsim` command uses Parallel Computing Toolbox™, if it is available, to run simulations in parallel, otherwise the simulations are run in serial.

### Model Overview

The model `sldemo_suspn_3dof` shown below simulates the vehicle dynamics based on the road - suspension interaction for different road profiles. The vehicle dynamics are captured in three degrees of freedom: vertical displacement, roll, and pitch. The road profile data for the left and right tires is imported into the Signal Editor block as different test cases. The Road-Suspension Interaction subsystem calculates the suspension forces on the vehicle at the four tire locations based on the road data and the current vehicle state. In the Body Dynamics subsystem these forces and the resulting pitch and roll moments are used to determine the vehicle motion in three degrees of freedom: vertical displacement, roll, and pitch.

The suspension model is simulated using different road profiles to determine if the design meets desired performance goals. Parallel Computing Toolbox is used to speed up these multiple simulations, as illustrated below.

```
mdl = 'sldemo_suspn_3dof';
isModelOpen = bdIsLoaded(mdl);
open_system(mdl);
```

Copyright 2011-2018 The MathWorks, Inc.

### Set up Data Required for Multiple Simulations

Determine the number of cases in the Signal Editor block using the `NumberOfScenarios` parameter of the Signal Editor block. The number of cases is used to determine the number of iterations to run in step 3.

```
sigEditBlk = [mdl '/Road Profiles'];
numCases = str2double(get_param(sigEditBlk, 'NumberOfScenarios'));
```

Create an array of `Simulink.SimulationInput` objects to define the set of simulations to run. Each `SimulationInput` object corresponds to one simulation and will be stored as an array in a variable, `in`. The mask parameter, `ActiveScenario`, specifies the sweep value for the Signal Editor block scenario. The active scenario is set for each simulation.

```
for idx = numCases:-1:1
 in(idx) = Simulink.SimulationInput mdl;
 in(idx) = setBlockParameter(in(idx), sigEditBlk, 'ActiveScenario', idx);
end
```

Note that specifying the model parameter on the `SimulationInput` object does not apply it to the model immediately. The specified value will be applied during the simulation and reverted back to its original value, if possible, after the simulation finishes.

### Run Simulations in Parallel Using Parsim

Use the `parsim` function to execute the simulations in parallel. The array of `SimulationInput` objects, `in`, created in the last step is passed into the `parsim` function as the first argument. The output from the `parsim` command is an array of `Simulink.SimulationOutput` objects which is stored in the variable `out`. Set the `'ShowProgress'` option to `'on'` to print a progress of the simulations on the MATLAB command window.

```
out = parsim(in, 'ShowProgress', 'on');
```

```

[21-Feb-2021 01:45:34] Cleaning up parallel workers...
```

Each `SimulationOutput` object contains the logged signal along with the `SimulationMetadata`. When running multiple simulations using `parsim`, errors are captured so that subsequent simulations can continue to run. Any errors would show up in the `ErrorMessage` property of the `SimulationOutput` object.

## Plot Results

Plot the vertical vehicle displacement from the different simulations to see how the vehicle performed to the different road profiles. The signal is logged in the SimulationOutput object in the Dataset format. Use the get method to obtain the timeseries object containing the time and signal data from each element of out.

```

legend_labels = cell(1,numCases);
for i = 1:numCases
 simOut = out(i);
 ts = simOut.logout.get('vertical_disp').Values;
 ts.plot;
 legend_labels{i} = ['Run ' num2str(i)];
 hold all
end
title('Response of a 3-DoF Suspension Model')
xlabel('Time (s)');
ylabel('Vehicle vertical displacement (m)');
legend(legend_labels,'Location','NorthEastOutside');

```

## Close MATLAB Workers

Last, close the parallel pool and the model if they were not previously opened.

```

if(~isModelOpen)
 close_system mdl, 0);

```

```
end
delete(gcf('nocreate'));
```

## Parallel Simulations Using Parsim: Parameter Sweep in Normal Mode

This example shows how to run multiple simulations of a Monte Carlo study in parallel by using Parallel Computing Toolbox™. Parallel execution leverages the multiple cores of your host machine to run many simulations more quickly. These simulations could also be run in parallel on computer clusters using the MATLAB Parallel Server™. This example will work even if the Parallel Computing Toolbox™ or the MATLAB Parallel Server™ is not available, but the simulations will run in serial.

### Explore Example Model

The model `sldemo_suspn_3dof` simulates vehicle dynamics based on the interaction between road and suspension for different road profiles. The model captures vehicle dynamics in three degrees of freedom: vertical displacement, roll, and pitch. The Signal Editor block stores measured road profile data for the left and right tires as different test groups. The Road-Suspension Interaction subsystem calculates the suspension forces on the vehicle at the four tire locations based on the road data and the current vehicle state. The Body Dynamics subsystem uses these forces and the resulting pitch and roll moments to calculate the vehicle motion in each of the three degrees of freedom.

In this Monte Carlo study, you inspect the impact of the front suspension coefficients on the vehicle dynamics. You run multiple simulations, each with a different coefficient value.

```
mdl = 'sldemo_suspn_3dof';
isModelOpen = bdIsLoaded(mdl);
open_system(mdl);
```

Copyright 2011-2018 The MathWorks, Inc.

In the model, double-click the Road-Suspension Interaction block. The mask dialog box opens. The mask parameter **Front susp. damping** sets the value of the damping coefficient, 150.

For the Body Dynamics block, find the signal that exits the `Vertical disp` output port. This signal represents the vertical vehicle displacement over time, which the suspension damping coefficient influences.

Right-click the signal and select **Properties**.

In the Signal Properties dialog box, the **Logging and accessibility** tab has **Log signal data** checked on, indicating that the signal is configured for logging. After the simulation finishes, you can use the specified logging name, `vertical_disp`, to identify the signal and acquire the simulation output data from the `SimulationOutput` object.

### Prepare Parameter Inputs

Calculate the sweep values for the coefficient as percentages of the design value ranging from 5% to 95% in increments of 10%. Store the values in a variable, `Cf_sweep`, in the base workspace.

```
Cf_sweep = Cf*(0.05:0.1:0.95);
```

Determine the number of simulations to run, which is equal to the number of sweep values. Store the number in a variable, `numSims`.

```
numSims = length(Cf_sweep);
```

Use a `for` loop to:

- 1 Create `Simulink.SimulationInput` objects for the model. Create one object per simulation. Store the objects as an array in a variable, `in`.
- 2 Specify the sweep value for each simulation. Identify the target mask parameter by its underlying name, `Cf`.

```
for i = numSims:-1:1
 in(i) = Simulink.SimulationInput mdl;
 in(i) = setBlockParameter(in(i), [mdl '/Road-Suspension Interaction'], 'Cf', num2str(Cf_sweep(i)));
end
```

Note that specifying the block parameter on the `SimulationInput` object does not apply it to the model immediately. The specified value will be applied during the simulation and reverted back to its original value, if possible, after the simulation finishes.

### Run Simulations in Parallel Using Parsim

Use the `parsim` function to execute the simulations in parallel. The array of `SimulationInput` objects, `in`, created in the last step is passed into the `parsim` function as the first argument. The output from the `parsim` command is an array of `Simulink.SimulationOutput` objects which is stored in the variable `out`. Set the `'ShowProgress'` option to `'on'` to print a progress of the simulations on the MATLAB command window.

```
out = parsim(in, 'ShowProgress', 'on');
```

```
[20-Feb-2021 23:49:38] Checking for availability of parallel pool...

[20-Feb-2021 23:51:34] Completed 10 of 10 simulation runs
[20-Feb-2021 23:51:34] Cleaning up parallel workers...
```

Each `SimulationOutput` object contains the logged signal along with the `SimulationMetadata`. When running multiple simulations using `parsim`, errors are captured so that subsequent simulations can continue to run. Any errors would show up in the `ErrorMessage` property of the `SimulationOutput` object.

### Plot Results

Plot the vertical vehicle displacement from the different simulations to see how varying the damping coefficient affects the vehicle dynamics. The signal is logged in the `SimulationOutput` object in the `Dataset` format. Use the `get` method to obtain the `timeseries` object containing the time and signal data from each element of `out`.

```
legend_labels = cell(1,numSims);

for i = numSims:-1:1
 simOut = out(i);
 ts = simOut.logout.get('vertical_disp').Values;
 % 'ts' is a MATLAB 'timeseries' object that stores the time and
 % data values for the logged 'vertical_disp' signal.
 % Use the 'plot' method of the object to plot the data against the
 % time.
 plot(ts);
 legend_labels{i} = ['Run ' num2str(i)];
 hold all
end

title('Response of a 3-DoF Suspension Model')
xlabel('Time (s)');
ylabel('Vehicle vertical displacement (m)');
legend(legend_labels,'Location','NorthEastOutside');
```

### Close MATLAB Workers

Last, close the parallel pool and the model if they were not previously opened.

```
if(~isModelOpen)
 close_system mdl, 0);
end
delete(gcf('nocreate'));
```

Parallel pool using the 'local' profile is shutting down.

## Parallel Simulations Using Parsim: Parameter Sweep in Rapid Accelerator Mode

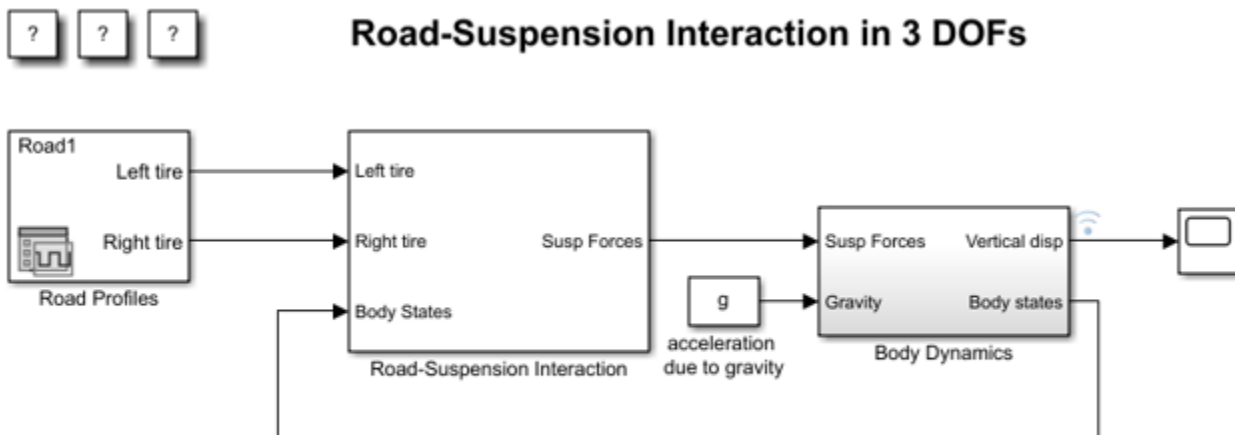

This example shows how to run multiple simulations of a Monte Carlo study in parallel by using Parallel Computing Toolbox™. Parallel execution leverages the multiple cores of your host machine to run many simulations more quickly. These simulations could also be run in parallel on computer clusters using the MATLAB Parallel Server™. This example will work even if the Parallel Computing Toolbox™ or the MATLAB Parallel Server™ is not available, but the simulations will run in serial.

### Explore Example Model

The model `sldemo_suspn_3dof` simulates vehicle dynamics based on the interaction between road and suspension for different road profiles. The model captures vehicle dynamics in three degrees of freedom: vertical displacement, roll, and pitch. The Signal Editor block stores measured road profile data for the left and right tires as different test groups. The Road-Suspension Interaction subsystem calculates the suspension forces on the vehicle at the four tire locations based on the road data and the current vehicle state. The Body Dynamics subsystem uses these forces and the resulting pitch and roll moments to calculate the vehicle motion in each of the three degrees of freedom.

In this Monte Carlo study, the vehicle mass is varied to study its effect on the vehicle dynamics. Parallel Computing Toolbox is used to speed up these multiple simulations, as illustrated below.

```
mdl = 'sldemo_suspn_3dof';
isModelOpen = bdIsLoaded(mdl);
open_system(mdl);
```

Copyright 2011-2018 The MathWorks, Inc.

### Setup to Build the Rapid Accelerator Target

The Rapid Accelerator executable for the model is built in the `SetupFcn` call using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function. The `buildRapidAcceleratorTarget` function returns the default run-time parameter set which is assigned to a global variable, `RTP`, in the `SetupFcn` and is used in the next step to modify the parameter values. Open `sldemo_parsim_paramsweep_suspn_raccel_setup` in the editor to inspect the

code. Note that the build process is optimized so that if the build files are already present and compatible with the model and machine architecture then it returns early.

### Set up Multiple Simulations Using SimulationInput Objects

Store the sweep values in a variable, `Mb_sweep`, in the base workspace.

```
Mb_sweep = Mb*(0.5:5:45.5);
```

Determine the number of simulations to run, which is equal to the number of sweep values. Store the number in a variable, `numSims`.

```
numSims = length(Mb_sweep);
```

Use a for loop to:

- 1 Create `Simulink.SimulationInput` objects for the model. Create one object per simulation. Store the objects as an array in a variable, `in`.
- 2 Specify the model parameters on the `SimulationInput` object.

```
for i = numSims:-1:1
 in(i) = Simulink.SimulationInput mdl;
 in(i) = in(i).setModelParameter('SimulationMode', 'rapid', ...
 'RapidAcceleratorUpToDateCheck', 'off');
 in(i).PreSimFcn = @(x) sldemo_parsim_paramsweep_suspn_raccel_presim(x, Mb_sweep(i));
end
```

The `SimulationInput` object is used to modify the model parameters. 'SimulationMode' is set to use rapid accelerator and 'RapidAcceleratorUpToDateCheck' model parameter is set to 'off' to skip up-to-date checks since there are no structural changes made to the model between simulations and the same build files can be used. Note that specifying the model parameter on the `SimulationInput` object does not apply it to the model immediately. The specified value will be applied during the simulation and reverted back to its original value, if possible, after the simulation finishes. Inspect the code in the `PreSimFcn`, `sldemo_parsim_paramsweep_suspn_raccel_presim`. It uses `modifyTunableParameters` from the `Simulink.BlockDiagram` package to change the parameter corresponding to vehicle mass. The first argument to the `PreSimFcn` is always the `SimulationInput` object, and is passed into the function by `Simulink@`. The `PreSimFunction` adds another model parameter to the `SimulationInput` object and returns it to be used for simulation.

### Run Simulations in Parallel Using Parsim

Use the `parsim` function to execute the simulations in parallel. The array of `SimulationInput` objects, `in`, created in the last step is passed into the `parsim` function as the first argument. The output from the `parsim` command is an array of `Simulink.SimulationOutput` objects which is stored in the variable `out`. Set the 'ShowProgress' option to 'on' to print a progress of the simulations on the MATLAB command window. As mentioned earlier, the `SetupFcn` is passed as a parameter to the `parsim` command to build the rapid accelerator target on the workers if required.

```
out = parsim(in, 'ShowProgress', 'on', ...
 'SetupFcn', @() sldemo_parsim_paramsweep_suspn_raccel_setup mdl);
```

```

```

Each `SimulationOutput` object contains the logged signal along with the `SimulationMetadata`. When running multiple simulations using `parsim`, errors are captured so that subsequent simulations can continue to run. Any errors would show up in the `ErrorMessage` property of the `SimulationOutput` object.

### Plot Results

Plot the vertical vehicle displacement from the different simulations to see how varying the vehicle mass affected the vehicle dynamics. Use the `get` method of the `SimulationOutput` object to obtain the time and signal data contained in each element of `simout`.

```
legend_labels = cell(1,numSims);
for i = 1:numSims
 simOut = out(i);
 ts = simOut.logout.get('vertical_disp').Values;
 ts.plot;
 legend_labels{i} = ['Run ' num2str(i)];
 hold all
end
title('Response of a 3-DoF Suspension Model')
xlabel('Time (s)');
ylabel('Vehicle vertical displacement (m)');
legend(legend_labels,'Location','NorthEastOutside');
```

### Close MATLAB Workers

Last, close the parallel pool and the model if they were not previously opened.

```
if(~isModelOpen)
 close_system mdl, 0);
end
delete(gcp('nocreate'));
```

Parallel pool using the 'local' profile is shutting down.

## Rapid Accelerator Simulations Using Parsim

This example shows the use of Rapid Accelerator in applications that require running parallel simulations for a range of input and parameter values.

The example uses a model that simulates the idle speed of an engine. The model input is the voltage of the bypass air valve. The output is the idle speed.

Use `parsim` to run parallel simulations with two sets of valve voltages. Independently vary two of the three transfer function gain parameters over a range of two values. The following table lists the eight simulations, along with the parameter values. In Step 2, create the external inputs, `inpSets`. The variables `gain2` and `gain3` correspond to the two gain parameters.

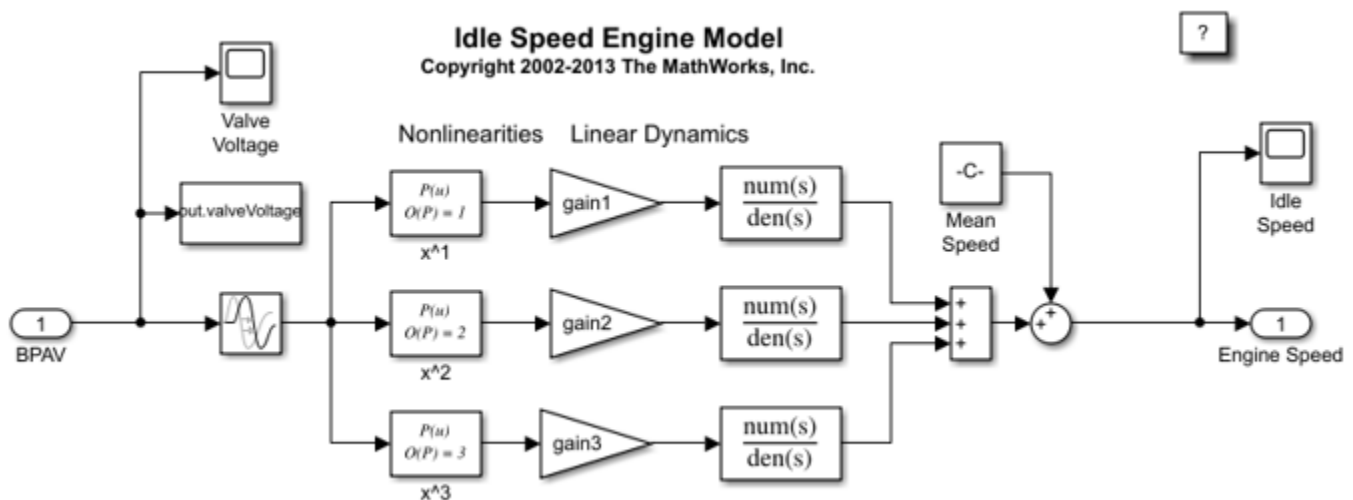

Run 1	<code>inpSets(1)</code>	<code>gain2 = 25</code>	<code>gain3 = 20</code>
Run 2	<code>inpSets(1)</code>	<code>gain2 = 25</code>	<code>gain3 = 30</code>
Run 3	<code>inpSets(1)</code>	<code>gain2 = 35</code>	<code>gain3 = 20</code>
Run 4	<code>inpSets(1)</code>	<code>gain2 = 35</code>	<code>gain3 = 30</code>
Run 5	<code>inpSets(2)</code>	<code>gain2 = 25</code>	<code>gain3 = 20</code>
Run 6	<code>inpSets(2)</code>	<code>gain2 = 25</code>	<code>gain3 = 30</code>
Run 7	<code>inpSets(2)</code>	<code>gain2 = 35</code>	<code>gain3 = 20</code>
Run 8	<code>inpSets(2)</code>	<code>gain2 = 35</code>	<code>gain3 = 30</code>

### Step 1: Preparation

First, open the model. The simulation mode is set to Rapid Accelerator. The default input data, and the required parameters are preloaded in the base workspace.

Open model:

```
mdl = 'sldemo_raccel_engine_idle_speed';
open_system(mdl);
```

## Step 2: Create Input Sets

Perturb the default input values vector to obtain a new input values vector.

```
inpSets(1) = timeseries(inpData, time);
rndPertb = 0.5 + rand(length(time), 1);
inpSets(2) = timeseries(inpData.*rndPertb, time);
numInpSets = length(inpSets);
```

## Step 3: Create Parameter Sets

Next, examine how the idle speed changes for different values of parameters `gain2` and `gain3`. Create an array of `Simulink.SimulationInput` objects to specify the different parameter values and external input for each simulation. The array of `SimulationInput` objects is preallocated for better performance. Note that you can directly specify the external input on the `SimulationInput` object instead of using a model parameter.

```
gain2_vals = 25:10:35;
gain3_vals = 20:10:30;

num_gain2_vals = length(gain2_vals);
num_gain3_vals = length(gain3_vals);

numSims = num_gain2_vals*num_gain3_vals*numInpSets;
in(1:numSims) = Simulink.SimulationInput mdl);

idx = 1;
for iG2 = 1:num_gain2_vals
 for iG3 = 1:num_gain3_vals
 for inpSetsIdx = 1:numInpSets
 in(idx) = in(idx).setModelParameter('SimulationMode', 'rapid', ...
 'RapidAcceleratorUpToDateCheck', 'off', ...
 'SaveTime', 'on', ...
 'SaveOutput', 'on');
 % Use setVariable to specify a new value for a variable during
 % simulations
 in(idx) = in(idx).setVariable('gain2', gain2_vals(iG2));
 in(idx) = in(idx).setVariable('gain3', gain3_vals(iG3));
 in(idx).ExternalInput = inpSets(inpSetsIdx);
 idx = idx + 1;
 end
 end
end
```

Note: This example uses the `setModelParameter` method of the `SimulationInput` object to set model parameters to run the simulations in Rapid Accelerator mode and enable logging. The Rapid Accelerator target is built using the `SetupFcn`. The Rapid Accelerator target is built once and used by all subsequent simulations, saving the time required for model compilation. Here is the code for the `SetupFcn`

```
function sldemo_parallel_rapid_accel_sims_script_setup mdl)
 % Temporarily change the current folder on the workers to an empty
 % folder so that any existing slprj folder on the client does not
 % interfere in the build process.
 currentFolder = pwd;
 tempDir = tempname;
 mkdir(tempDir);
```

```
 cd (tempDir);
 oc = onCleanup(@() cd (currentFolder));
 Simulink.BlockDiagram.buildRapidAcceleratorTarget mdl;
end
```

#### Step 4: Execute Simulations

Use the `parsim` function to execute the simulations in parallel. The array of `SimulationInput` objects, `in`, created in the last step is passed into the `parsim` function as the first argument. Store the simulation output data in a variable, `out`, whose value is an array of `SimulationOutput` objects. Each `SimulationOutput` object contains the logged signal along with the `SimulationMetadata`. When running multiple simulations using `parsim`, errors are captured so that subsequent simulations can continue to run. Any errors would show up in the `ErrorMessage` property of the `SimulationOutput` object.

```
out = parsim(in, 'ShowProgress', 'on', ...
 'SetupFcn', @() sldemo_parallel_rapid_accel_sims_script_setup mdl);
```

```

## Multiple Simulations Workflow Tips

The goal of this example is to provide helpful tips for running multiple simulations using parallel simulation tools. This example will work even if the Parallel Computing Toolbox™ is not available, but the simulations will run in serial. We will be using the model `sldemo_suspn_3dof`.

```
mdl = 'sldemo_suspn_3dof';
isModelOpen = bdIsLoaded(mdl);
open_system(mdl);
```

Copyright 2011-2018 The MathWorks, Inc.

### Initializing an Array of Simulink.SimulationInput Objects

Typically you will construct an array of `Simulink.SimulationInput` objects in order to run multiple simulations. There are several ways to initialize the array before populating it with data.

```
numSims = 5;
Cf_sweep = Cf*linspace(.05,.95, numSims);
```

#### Method 1: Initialize the array before the loop

```
in(numSims) = Simulink.SimulationInput;
for idx = 1:numSims
 % Need to populate the model name since we get any empty array by default
 in(idx).ModelName = 'sldemo_suspn_3dof';
 in(idx) = in(idx).setVariable('Cf', Cf_sweep(idx));
end
```

#### Method 2: Initialize the array in the loop

Note that the loop variable `idx` starts from the largest value so that the entire array is pre-allocated.

```
for idx = numSims:-1:1
 % Since we are indexing from 5 to 1, the first iteration will
 % initialize the array.
 in(idx) = Simulink.SimulationInput('sldemo_suspn_3dof');
```

```

 in(idx) = in(idx).setVariable('Cf', Cf_sweep(idx));
end

```

### Setting Model and Block Parameters

The `setModelParameter` and `setBlockParameter` methods use the same parameter-value pair syntax that the `set_param` API uses. This means that most values you pass in to these methods should be character arrays, not their literal value.

```

for idx = numSims:-1:1
 in(idx) = Simulink.SimulationInput('sldemo_suspn_3dof');

 % Incorrect
 in(idx) = in(idx).setModelParameter('StartTime', 5);

 % Correct
 in(idx) = in(idx).setModelParameter('StartTime', '3');
end

```

### Setting Variables

The `setVariable` method expects that you will pass the literal value you want to assign to a variable. The idea is that this closely reflects the `assignin` syntax.

```

for idx = numSims:-1:1
 in(idx) = Simulink.SimulationInput('sldemo_suspn_3dof');

 % Incorrect, Cf is expected to be a double, not a character array
 in(idx) = in(idx).setVariable('Cf', '2500');

 % Correct, Cf is a scalar double
 in(idx) = in(idx).setVariable('Cf', 2500);
end

```

### Diagnosing Runtime Errors

Assume that you've accidentally set up an array of `Simulink.SimulationInput` objects with an incorrect value.

```

Mb_sweep = linspace(0, 1500, numSims);
for idx = numSims:-1:1
 in(idx) = Simulink.SimulationInput('sldemo_suspn_3dof');

 % Accidentally set the Mass to 0 on the first iteration
 in(idx) = in(idx).setVariable('Mb', Mb_sweep(idx));

 % Shorten the stop time
 in(idx) = in(idx).setModelParameter('StopTime', '1');
end

```

Simulating these will cause a runtime error

```
out = sim(in);
```

```

[09-Dec-2021 11:45:05] Running simulations...
[09-Dec-2021 11:45:26] Completed 1 of 5 simulation runs. Run 1 has errors.
[09-Dec-2021 11:45:36] Completed 2 of 5 simulation runs
[09-Dec-2021 11:45:36] Completed 3 of 5 simulation runs

```

```

```

Fortunately, you can inspect the `Simulink.SimulationOutput` object to see any error messages that come from a simulation.

```
out(1).ErrorMessage
```

```
ans =
```

```
'Derivative of state '1' in block '<a href="matlab:open_and_hilite_hyperlink ('sldemo_suspn_3
```

This works to debug issues on parallel workers too.

```
for idx = numSims:-1:1
 in(idx) = Simulink.SimulationInput('sldemo_suspn_3dof');

 % Accidentally set the Mass to 0 on the first iteration
 in(idx) = in(idx).setVariable('Mb', Mb_sweep(idx));

 % Shorten the stop time
 in(idx) = in(idx).setModelParameter('StopTime', '1');
end
```

```
out = parsim(in);
```

```

## Streamline Simulink Blockset Authoring Process with Blockset Designer

This example shows how to manage artifacts associated with a Simulink® blockset using a single Blockset Designer Project.

Simulink Blockset Designer is a Project™ based environment to author a Simulink blockset. Simulink Blockset Designer allows you to develop and maintain Simulink blockset artifacts, such as source code, TLC-files, build scripts, test suites, libraries, models, and documentation, using a single tool. This example demonstrates how using Simulink Blockset Designer can streamline such a Simulink blockset project.

### Open the Example

Run `slexBlocksetDesignerExample` to open the Simulink Blockset Designer project. Then click the **Run All** button.

## Simplify Interface for Structured Data with FMU Import Block

This examples shows how to use the FMU block to simplify the Simulink interface for structured data. The FMU block imports existing functional mockup units (FMUs) into Simulink®.

This FMU file models a simple system that computes the weighted average of two input bus signals, `vehicle`, packed into an array of buses. Each of the input bus signals contains four bus elements, `wheel`. Each bus element contains two scalar signals, `position` and `speed`. The FMU accepts two structure parameters, `Weight` and `Bias`, and uses them to compute the weighted average `ev` of input signals:

$$ev.wheel(i).position = vehicle(1).wheel(i).position * Weight.v1 + Bias.v1 + vehicle(2).wheel(i).position * Weight.v2 + Bias.v2$$

$$ev.wheel(i).speed = vehicle(1).wheel(i).speed * Weight.v1 + Bias.v1 + vehicle(2).wheel(i).speed * Weight.v2 + Bias.v2$$

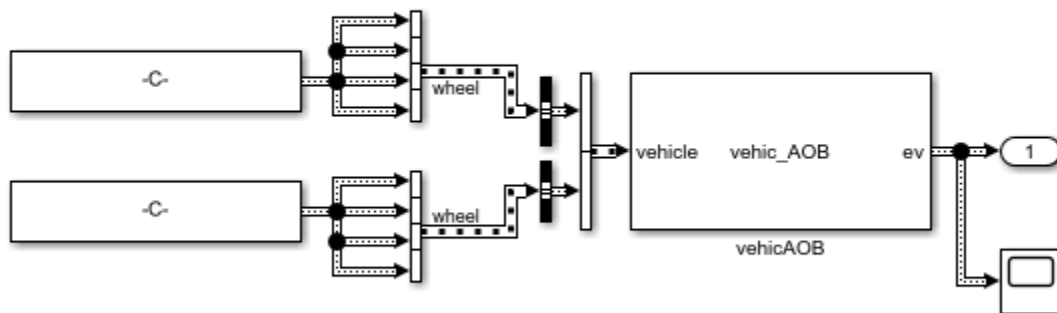

where

$$i = 1 \dots 4.$$

The FMU file supports FMI 1.0 Model Exchange mode.

The FMU Import block supports non-virtual bus types. You must create a bus object whose structure matches the associated structure in the FMU file. When naming the bus object structures, use the variable names defined in the `modelDescription.xml` of the FMU file.

## Co-Simulation Signal Compensation

This example shows how to use co-simulation and signal compensation for interfacing signals.

In co-simulation application, components simulate with local solvers. Local solvers maintain separate timelines and integrate from a previous time point to the current time using I/O data exchanged between components and integration model. Co-simulation components do not expose internal states to global solver.

When co-simulation components are integrated in Simulink, you can use periodic discrete rate to exchange I/O data between components. However, communication between co-simulation components may introduce error caused by one-step delay during data exchange. This may cause simulation to be less accurate or unstable.

To mitigate this issue, Simulink automatically identifies interfacing signals between these components that are eligible for numerical compensation. These signals are ideally continuous quantities that have to be discretized due to co-simulation. Simulink automatically compensate for these signals to reduce co-simulation error. A 'gear' icon is displayed on input port if a signal is compensated.

### **Two co-simulation components with PI Controller**

This example model contains two co-simulation components and a discrete PI controller. A monolithic system with two continuous rate systems and same PI controller is used as the baseline for result comparison.

### Co-Simulation Numerical Compensation for Components with Local Solvers

Plant #1, realized by an S-Function `cosim_plant1_sfcn.c`, is equivalent to a state-space model `cosim_plant1.slx`:

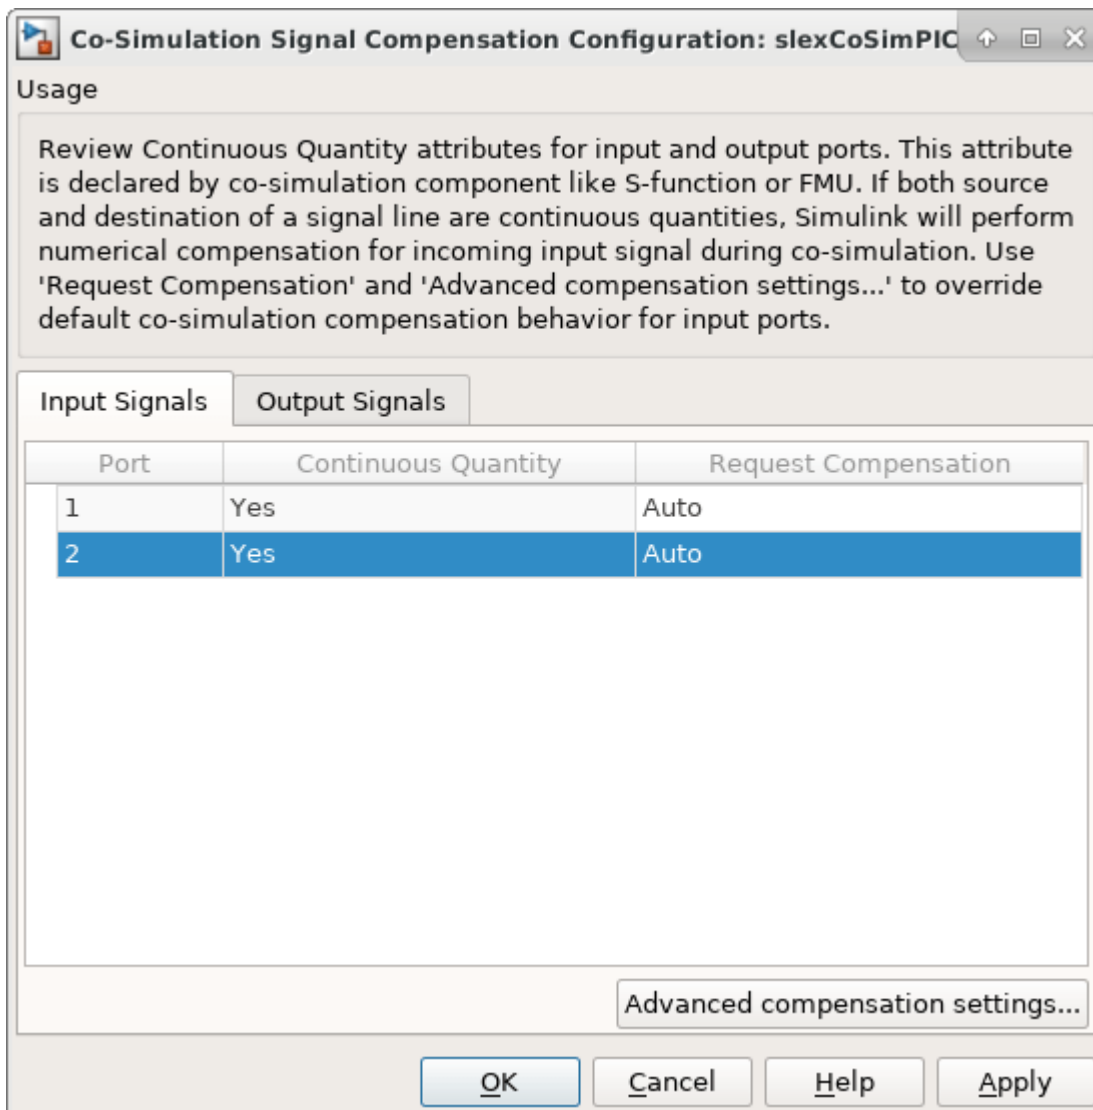

Plant #2, realized by a Co-Simulation FMU v2.0 `cosim_plant2_fmu.fmu`, is equivalent to a transfer function `cosim_plant2.slx`:

Both are causal systems where output signal does not directly depend on inputs. Local solver step size is 0.01. Communication step size is 0.3.

After updating integration model, a gear icon appears at the input ports of the two co-simulation components, indicating Simulink has identified a signal eligible for numerical compensation. Alternatively, you can right click on the icon (or block) and open 'Co-simulation Numerical Compensation' dialog:

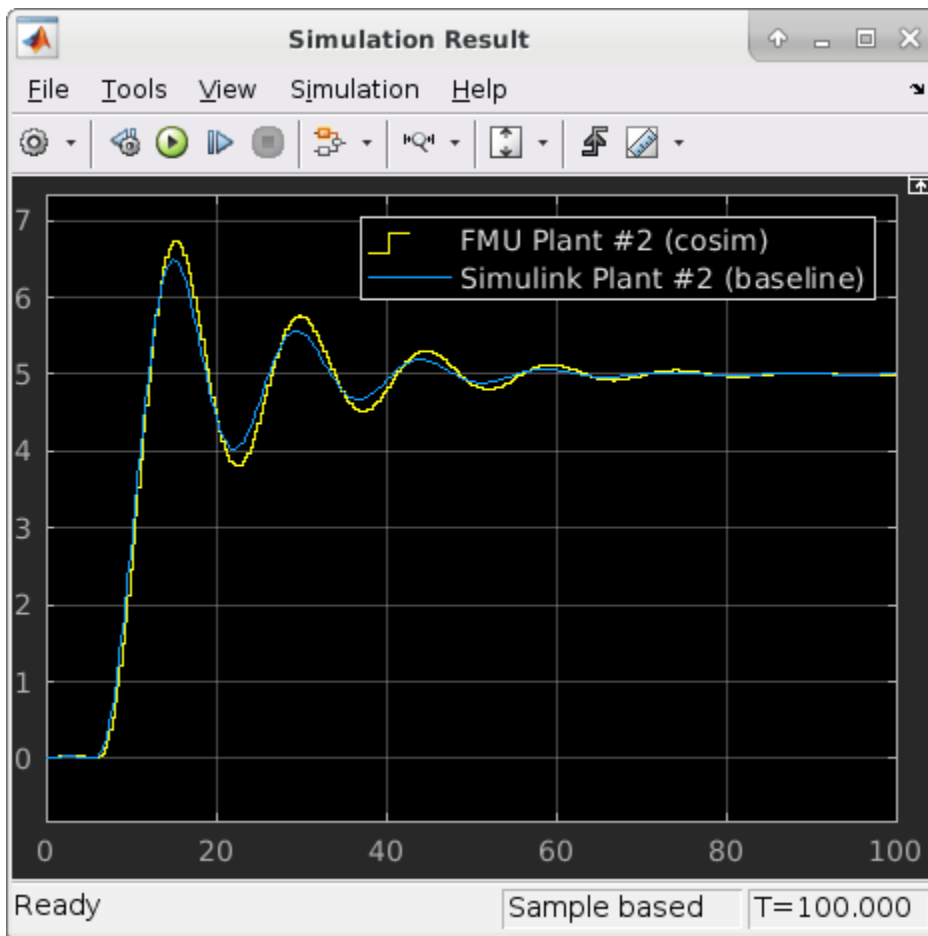

- **Continuous Quantity** column shows whether the co-simulation component itself has declared its I/O as continuous quantity. If both source and destination of this signal meet certain requirements, Simulink will mark it for auto-compensation. For example, input port 1 of Plant #1 is declared as continuous quantity, but its source, output port 1 of PI controller is a discrete rate control signal. As a result, input pot1 of Plant #1 will not be auto-compensated.
- **Request Compensation** column allows you to override this behavior by always allowing or disallowing numerical compensation. When a signal is marked as 'Always' or is already eligible, you can use **Advanced compensation settings...** button to configure more numerical compensation settings.

The following plots show the difference between enabling and disabling numerical compensation for this model. With numerical compensation turned on:

Accumulated error due to co-simulation is 0.4342.

Without numerical compensation:

Accumulated error due to co-simulation is 6.8520.

## Using Numerical Compensation for Co-Simulation Integration

This example shows how to reduce potential simulation errors introduced by co-simulation using numerical compensation.

### An Example Co-Simulation Component

A typical co-simulation component can be represented by a dynamic system with continuous states and a local solver that performs integration between communication time points. These functions export the standalone Co-Simulation FMU `cosim_component.fmu` from this model:

```
componentMdl = 'cosim_component';
open_system(componentMdl);
```

This model contains a transfer function and has a local fixed-step solver with step size  $ts=0.02s$ . You can use the generated FMU as a co-simulation component in an integration model.

Note that co-simulation components can only use input values given at communication time points. This requirement introduces a co-simulation error when the communication step is relatively large compared to the dynamic behavior of the component. Reducing the communication step size improves the simulation result but increases data transfer overhead. Changing local solver types or reducing local solver step size can give better integration results within a communication step, but cannot compensate for co-simulation error due to undersampling.

### Using Numerical Compensation in Integration Model

The co-simulation component is used in the following model for integration:

```
integrationMdl = 'cosim_integration';
open_system(integrationMdl);
set_param(integrationMdl, 'SimulationCommand', 'Update');
```

This model contains two connected FMU co-simulation components in the top branch. Both co-simulation components, FMU Cosim Component 1 and FMU Cosim Component 2, have their own local solver. They only exchange data at a discretized communication rate  $D2$ , where  $ts=0.2s$ . Two continuous-time Transfer Function blocks in the bottom branch are the monolithic, non-co-simulation approach of the same system, which uses the global solver and serves as the baseline for the simulation result. The two non-co-simulation components exchange data at a continuous rate, and the global solver step size is set to  $ts=0.02s$ . In this example, we focus on the numerical behavior of FMU Cosim Component 2 and assume that co-simulation discretization of its input signal is inevitable.

After updating block diagram, a gear icon appears at the input port for the second co-sim component, FMU Cosim Component 2. This indicates that Simulink has automatically determined that this input port needs numerical compensation because:

- Source (and destination) blocks declare their output (and non-directfeedthrough input) ports as continuous quantities.
- Source and destination blocks are co-simulation components (e.g. S-Function or Co-Simulation FMU)
- The signal has a double data type and periodic discrete sample rate

To turn off auto-compensation, left-click on the icon. Alternatively, to programmatically turn it off:

```
blk = 'cosim_integration/FMU Cosim Component 2';
p = get_param(blk, 'PortHandles')
```

```
p = struct with fields:
 Inport: 43.0005
 Outport: 69.0004
 Enable: []
 Trigger: []
 State: []
 LConn: []
 RConn: []
 Ifaction: []
 Reset: []
 Event: []
```

```
set_param(p.Inport, 'CoSimSignalCompensationMode', 'Auto_Off')
out_off = sim(integrationMdl);
```

Simulink does not compensate for co-simulation error on this input port when the gear icon appears as disabled. The following functions plot the result without numerical compensation:

```
figure(1); hold on;
plot(out_off.yout{1}.Values, 'r');
plot(out_off.yout{2}.Values, 'black');
plot(out_off.yout{3}.Values, 'g');
plot(out_off.yout{4}.Values, 'b');
legend({'cosim response(no compensation)', 'ideal response', 'cosim input', 'ideal input'}, 'Loca
```

The co-simulation input signal (a double-typed periodic discrete signal that represents a continuous quantity) jumps from 0 to a positive value at  $t=0.4\text{s}$ . The co-simulation response shows a delay to its input when compared to the ideal (non-co-simulation) response. The co-simulation scheme causes this delay, where the input signal cannot vary between two communication time points. For example, when co-simulation component FMU Cosim Component 2 pauses at communication time point  $t=0.4\text{s}$ , the local solver takes a positive input for integration; then the local solver integrates over communication step  $[0.4, 0.6]$ , and returns a positive output value at the next communication time point  $t=0.6\text{s}$ .

When numerical compensation is enabled, Simulink attempts to compute a better input value for co-simulation component FMU Cosim Component 2 so that the co-simulation input value is closer to the average non-co-simulation input between two communication time points. For example, instead of using the co-simulation input value  $y=0.165$  at  $t=0.4\text{s}$ , a better averaged input over communication step  $[0.4, 0.6]$  is somewhere around  $y=0.241$ , which is the midpoint of  $y=0.165$  ( $t=0.4\text{s}$ ) and  $y=0.316$  ( $t=0.6\text{s}$ ). This is like using the midpoint Riemann sum instead of the left sum to estimate the area under the curve of an ideal input signal.

However, at communication time point  $t=0.4\text{s}$ , the value of  $y=0.316$  ( $t=0.6\text{s}$ ) is still not available. To get an estimate of  $y$  value at  $t=0.6\text{s}$ , Simulink extrapolates the signal data as a polynomial based on earlier time points (e.g.  $t=0.2\text{s}$ ,  $t=0.4\text{s}$ ). You can select a different **extrapolation method** in **Co-simulation Numerical Compensation** dialog when right-clicking the icon. Alternatively, use the functions:

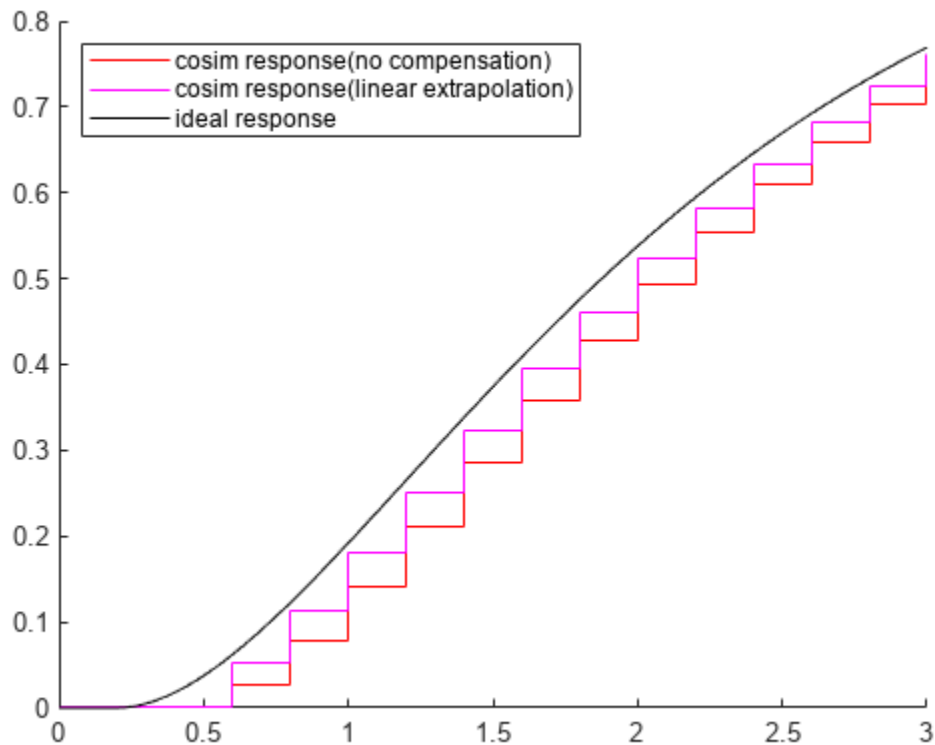

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "LinearExtrapolation"}');
```

The following plot compares the result of enabling or disabling the compensation:

```

set_param(p.Inport, 'CoSimSignalCompensationMode', 'Auto')
out_linear = sim(integrationMdl);
figure(2); hold on;
plot(out_off.yout{1}.Values, 'r')
plot(out_linear.yout{1}.Values, 'm')
plot(out_off.yout{2}.Values, 'black')
legend({'cosim response(no compensation)', 'cosim response(linear extrapolation)', 'ideal response'})

```

With numerical compensation, the co-simulation response at communication timepoints are much closer to the ideal non-co-simulation output. The numerical error (delay) introduced by co-simulation is reduced.

The following plot shows the impact of the different extrapolation methods:

```

set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "QuadraticExtrapolation"}')
out_quadratic = sim(integrationMdl);
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "CubicExtrapolation"}')
out_cubic = sim(integrationMdl);
figure(3); hold on;
plot(out_linear.yout{1}.Values, 'r')
plot(out_quadratic.yout{1}.Values, 'g')
plot(out_cubic.yout{1}.Values, 'b')
plot(out_off.yout{2}.Values, 'black')
legend({'cosim response(linear extrapolation)', 'cosim response(quadratic extrapolation)', 'cosim response(cubic extrapolation)', 'ideal response'})

```

The extrapolated output value introduces an estimation error, for example, when comparing extrapolated y value at  $t=0.6\text{s}$  (estimated at  $t=0.4\text{s}$ ) to the real y value at  $t=0.6\text{s}$  (recorded at  $t=0.6\text{s}$ ). Simulink can optionally compensate for this error in the following communication steps when you specify a non-zero **signal correction coefficient** in **Co-simulation Numerical Compensation** dialog. Alternatively, use these functions:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "LinearExtrapolation"
```

This coefficient is valid within  $[0, 1]$ , where 0 means the estimation error will be ignored, and 1 means estimation error is fully compensated in the following communication steps. Setting this value to 1 might be useful when the co-simulation signal represents, or is proportional to, a flux of some conserved quantity (e.g. current, mass or volumetric flow rate).

The following plot shows the impact of different values of the signal correction coefficient:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "LinearExtrapolation"
out_linear_0 = sim(integrationMdl);
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "LinearExtrapolation"
out_linear_0_5 = sim(integrationMdl);
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod": "LinearExtrapolation"
out_linear_1 = sim(integrationMdl);
figure(4); hold on;
plot(out_linear_0.yout{1}.Values, 'r')
plot(out_linear_0_5.yout{1}.Values, 'g')
plot(out_linear_1.yout{1}.Values, 'b')
plot(out_off.yout{2}.Values, 'black')
legend({'cosim response(coefficient: 0)', 'cosim response(coefficient: 0.5)', 'cosim response(coef
```

```
close_system(componentMdl, 0);
close_system(integrationMdl, 0);
```

## Multithread Co-Simulation

This example shows how to run co-simulation on multiple threads.

Simulink is an integration platform that supports co-simulation between components with local solvers or that involves simulation tools. For example, co-simulation can involve an S-function as a co-simulation gateway between Simulink and third-party tools or custom code. It can also involve an FMU in co-simulation mode imported to Simulink.

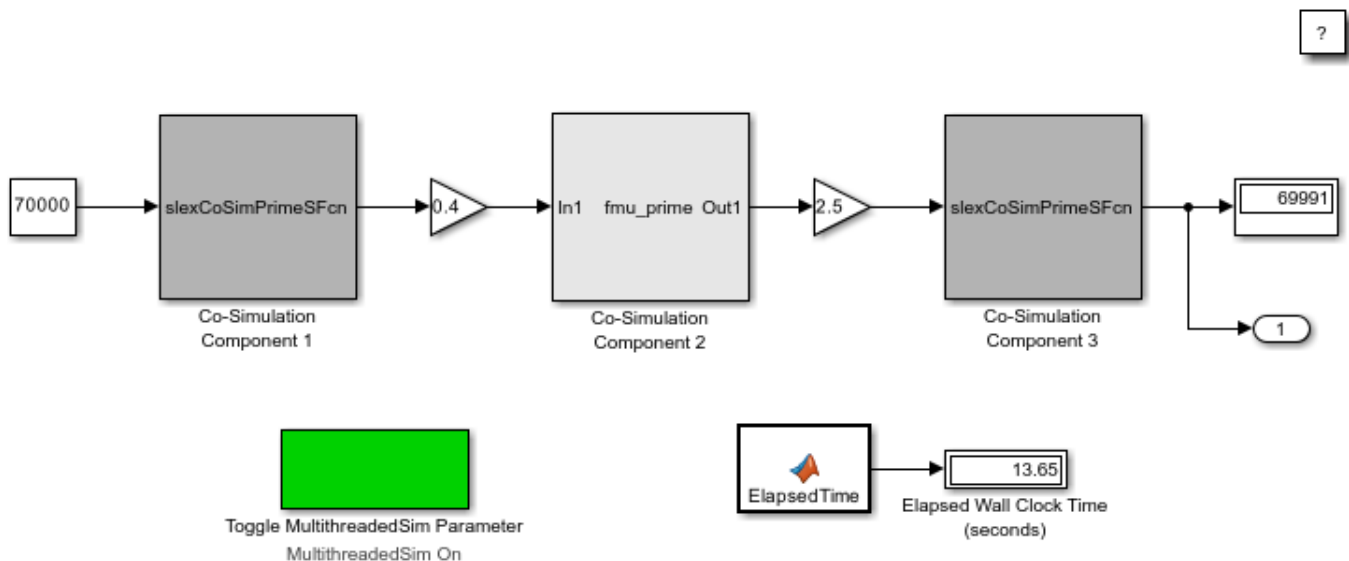

By default, Simulink configures all models to run on multiple threads with the `MultiThreadCoSim` parameter.

This example shows how to run multithreaded co-simulation of three components (two implemented in C-MEX S-Function, one implemented using FMU Co-Simulation v2.0). These components compute prime numbers to find the maximum prime number that is smaller than or equal to the given input.

Multithreaded co-simulation best suits models with computationally intensive and loosely coupled components. In this example, each component computes prime numbers using a brute-force search. The intensity of the computation is directly proportional to the given range, which is a block input that you can experiment with. Also, components exchange a scalar signal, which is the maximum prime number within the given range, at communication times.

Experiment toggling the `MultithreadedSim` parameter and measuring the wall clock time.

```
open_system('slexCoSimPrimeExample')
sim('slexCoSimPrimeExample');
```

## Pulse Width Modulation Using MATLAB System Block

This example shows how to use MATLAB System block to generate Pulse Width Modulation (PWM) signals based on the input period and duty cycle signals by using controllable sample time and `setNumTicksUntilNextHit`.

In this example, MATLAB System block registers a controllable sample time so that it can schedule the next hit while changing the output value. In this example, the MATLAB System block has two input ports and one output port. The first input port is the duty cycle signal and the second input port is the period signal. The MATLAB System block has two block parameters: the amplitude of the generated PWM signal and the resolution of the controllable sample time.

In this example, the MATLAB System block demonstrates the use of the function: `* createSampleTime(obj, 'Type', 'Controllable', 'TickTime', obj.Resolution)` to register a controllable sample time in `getSampleTimeImpl` method. The resolution must be a positive finite integer that defines the fundamental step size that the MATLAB System block can schedule the next hit for this sample time.

MATLAB System Block demonstrates the use of the method: `* setNumTicksUntilNextHit(obj, numTicks)` to schedule the next hit of the controllable sample time. The next hit happens after  $t = t_{\text{current}} + \text{numTicks} * \text{resolution}$ . `numTicks` must be a positive integer. The MATLAB System block can use this method to schedule the execution of the controllable sample time in `setupImpl` and `stepImpl`.

## Modeling Cyber-Physical Systems

Cyber-physical systems combine computer and physical systems to achieve design goals. Simulation of cyber-physical systems requires a combination of modeling techniques such as continuous-time, discrete-time, discrete-event, and finite state modeling. Simulink® and its companion products provide functionality to apply a wide range of modeling techniques and seamlessly integrate them in one simulation environment, which is ideal for modeling cyber-physical systems.

This example shows how continuous-time, discrete-event, and finite-state modeling techniques combine to simulate the behavior of a variable speed conveyor belt system. In SimEvents®, entities are discrete items of interest in a discrete-event simulation. Because passengers are discrete individuals, they are modeled by SimEvents® entities, created by the Entity Generator block. A Stateflow® chart models the operational modes and motor dynamics of the variable speed conveyor belt. Finally, the Entity Transport Delay block models passenger throughput as a function of conveyor belt dynamics, providing a bridge between the discrete-event and continuous-time domains.

**Note:** The example uses blocks from SimEvents® and Stateflow®. If you do not have a SimEvents or Stateflow license, you can open and simulate the model but only make basic changes such as modifying block parameters.

### Model Structure

The model includes these key components:

- **Passengers** — Models the arrival of passengers as a Poisson process. The output is a sequence of SimEvents® entities corresponding to the passengers who step on the conveyor belt. The distribution of inter-arrival time ( $\Delta t$ ) of a Poisson process is  $P(\Delta t) = \lambda e^{-\lambda \Delta t}$ , where  $\lambda$  is the arrival rate.  $\lambda$  is modeled by a MATLAB action in the Entity Generator block for *rush hour*, *normal hour*, and *free hour*. The passenger arrival rate changes with time as:

$$\lambda(t) = \begin{cases} 2, & \text{mod}(t, 300) \in [0, 180), \quad \text{rush hour} \\ 0.5, & \text{mod}(t, 300) \in [180, 240), \quad \text{normal hour} \\ 0.1, & \text{mod}(t, 300) \in [240, 300), \quad \text{free hour} \end{cases}$$

- **Entity Transport Delay** — Holds the passengers on the conveyor belt until they arrive at the other terminal, based on the time delay calculated by the Stateflow chart.
- **Dynamics of conveyor belt** — Models the operation of a variable speed conveyor belt. See the Conveyor Belt Dynamics section for more details.
- **Dashboard** — Shows the runtime status of the conveyor belt. The color of the Mode Lamp indicates the mode of the conveyor belt.

### Conveyor Belt Dynamics

A Stateflow® chart models the dynamics of the variable speed conveyor belt. Note in the chart that the velocity and power of the belt are plotted against a logarithmic scale of the load weight. The conveyor belt has these modes:

- **Idle** — The weight of the load is small. The belt maintains a low velocity to save energy. The Mode Lamp is gray in this mode.

- **OnDemand** — This is the normal operating mode, which maintains the optimal velocity for passenger comfort and throughput. The power will proportionally increase with the weight of the load. The Mode Lamp is green in this mode.
- **Max** — Maximum power mode. The weight of the load is too large for the conveyor belt to maintain the optimal velocity. The conveyor belt operates at the maximum possible velocity that does not exceed the maximum power. The Mode Lamp is red in this mode.

## Results

The Scope and blocks in the DashBoard show the simulation results.

Simulation results: 1. Number of passengers versus simulation time. 2. Velocity (blue) and power (red) versus simulation time.

Three operation cycles are observed within a time span of 900. Each cycle has a period of 300, which aligns with the period of the arrival rate. The top plot shows the number of passengers on the conveyor belt over time, and the bottom plot shows the velocity and power of the conveyor belt. The velocity and power are normalized for better visualization.

The first two thirds of each period correspond to *rush hour*, and the number of passengers on the conveyor belt increases dramatically. Consequently, the conveyor belt enters into the **Max** mode quickly, which is characterized by the maximum output power with a velocity that is inversely proportional to the number of passengers. In the last third of each period, the airport is in the *normal hour* followed by the *free hour*. Therefore, the number of passengers on the conveyor belt drops and even becomes zero for some time.

The conveyor belt then operates in **OnDemand** and **Idle** modes accordingly. In **OnDemand** mode, the velocity is locked to a default value, and the power is proportional to the number of passengers. In **Idle** mode, both the velocity and power are maintained at low values to reduce energy consumption. Overall, the conveyor belt operates according to the load of the airport.

## Power Analysis of Spring Mass Damper System

This example shows how to analyze the mechanical power and energy of a spring mass damper system using functionality available with the Powertrain Blockset™. The model subsystems contain Power Accounting Bus Creator blocks that report system power and energy consumption across the spring mass damper system.

### Run Simulation

Click **Run** to create an `autoblks.pwr.PlantInfo` object that analyzes the model energy consumption. Use the `PwrUnits` and `EnrgyUnits` properties to set the units.

```
SysName = 'powerAnalysis';
open(SysName);
SysPwrAnalysis = autoblks.pwr.PlantInfo(SysName);
SysPwrAnalysis.PwrUnits = 'kW';
SysPwrAnalysis.EnrgyUnits = 'MJ';
```

Use `run` method to turn on logging, run simulation, and add logged data to the object.

```
SysPwrAnalysis.run;
```

### Overall Summary

Display the final energy values for each subsystem.

```
SysPwrAnalysis.dispSysSummary
```

## Schedule an Export-Function Model Using the Schedule Editor

This example shows how to view and edit the order of function-calls in an export-function model using the Schedule Editor. As in all export-function models, the desired functionality is modeled as function-call subsystems. These function-call subsystems define the partitions that are scheduled by the Schedule Editor.

With the Schedule Editor, you can easily view and edit the schedule of the function-calls. The behavior of the system depends on the order of these partitions. In this example, we change the order and observe its effects on the behavior of the system by simulating the model. To see the impact of editing the schedule on the simulation, we compare the model simulations before and after scheduling.

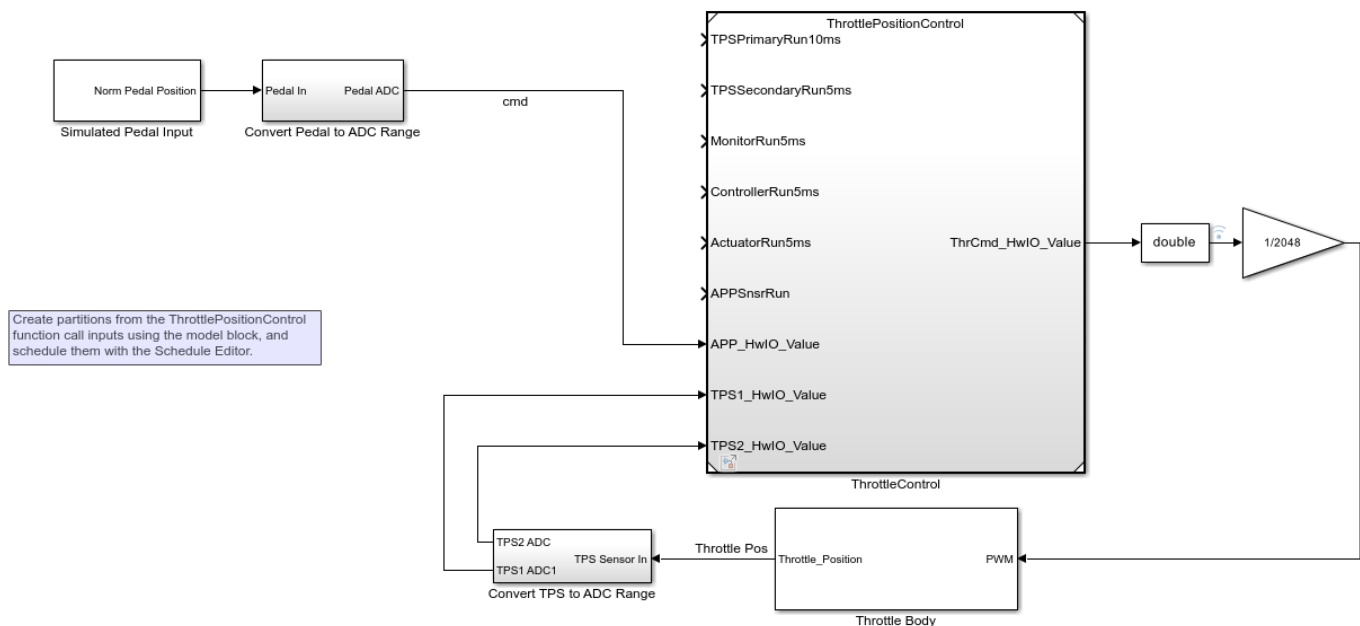

### Create Partitions from Referenced Export-Function Model

To view and edit the schedule of the export-function model, reference the model.

```
open_system('ThrottlePositionControlTop.slx');
```

### Schedule an Export-Function Model with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

ThrottlePositionControl is the referenced export-function model. By default, each function has an input port that can be used to trigger these functions. The Schedule Editor automatically handles these ports. To use the Schedule Editor, set the Schedule Rates With parameter to Schedule Editor.

```
set_param('ThrottlePositionControlTop/ThrottleControl', 'ScheduleRatesWith', 'Schedule Editor');
```

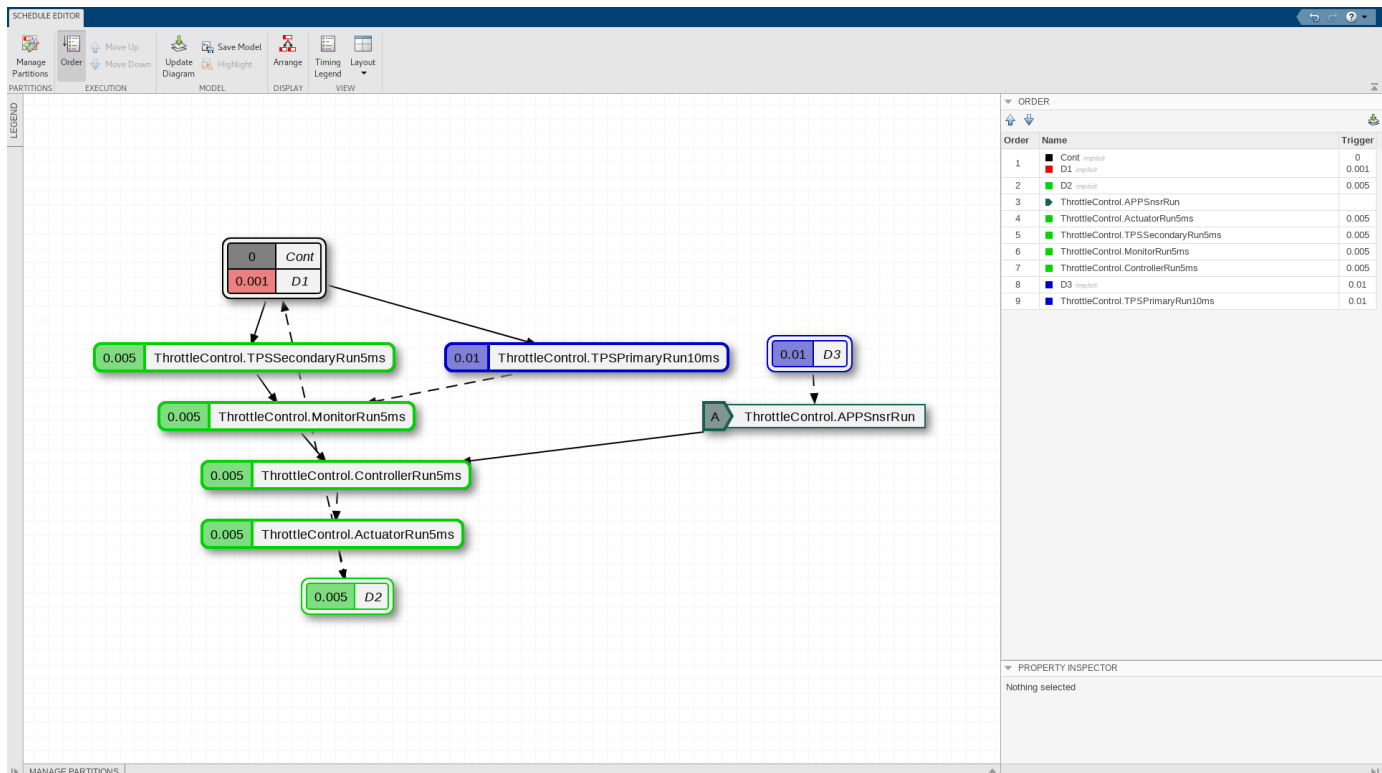

## Establish a Simulation Baseline

To observe the impact of scheduling on the model behavior, establish a baseline by simulating the model before editing the schedule. Simulate the model.

```
sim('ThrottlePositionControlTop');
```

## Open the Schedule Editor

To open the Schedule Editor, click **Schedule Editor** in the **Design** section of the **Modeling** tab. In the Schedule Editor, different components of the model are represented as partitions. Update the diagram to see the partitions. Partitions are the entry-points in the model. The Schedule Editor shows the order and data communications of these partitions. The arrows are data connections between the partitions that show the data flow. The dashed lines indicate that there is a delay because the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

## Edit Partition Schedule

The Order pane shows the order the partitions run in at a given time step. Assume that the order of the partitions is in an imperfect state. In this case, to remove the delay, you want to run the `ThrottleControl.ActuatorRun5ms` partition after the `ThrottleControl.ControllerRun5ms` partition.

Drag `ThrottleControl.ActuatorRun5ms` after the `ThrottleControl.ControllerRun5ms` in the Order pane. Observe that the delay between the `ThrottleControl.ControllerRun5ms` and the `ThrottleControl.ActuatorRun5ms` partitions changes to a dependency. Observe that now there is no delay between the executions of `ThrottleControl.ControllerRun5ms` and `ThrottleControl.ActuatorRun5ms`.

**Schedule the Execution of Aperiodic Partitions**

The export-function model contains an unconstrained partition, AccelerationPedalPositionSensor. Suppose you want to schedule an unconstrained partition to simulate as if it were discrete. Schedule ThrottleControl.APPSnrRun partition to run at [0:0.02:100] to observe its behavior at different instances of time. Click the unconstrained partition and enter [(1:5000)\*.02] for Trigger in the Property Inspector.

**Compare the Runs in Simulation Data Inspector**

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior.

## Graph-Based Multithread Simulation

This example shows how graph-based algorithms optimize simulation on multiple threads.

### Graph-based algorithm

This example contains four nondirect feedthrough blocks followed by four direct feedthrough blocks. Direct feedthrough means that the output port signal of a block is computed from the values of its input port signals in the same time step. The graph-based algorithm runs the four nondirect feedthrough blocks in parallel and groups the following direct feedthrough blocks into the same branch. Then, the model uses multithreading to run those four branches. Thus, the algorithm speeds up the simulation almost four times on a four or more core machine compared to a single-threaded simulation on the same machine.

### Open model and simulate

```
open_system('slexGraphBasedMultiThreadSimExample');

% Press "Toggle MultithreadedSim Parameter" block to turn off / on
% multithreaded simulation and compare the elapsed time.
```

Graph-based multithreaded simulation enables DirectFeedThrough blocks to run in parallel.

## Find Shortest Control Path in Simulink Model

### Model Description

This example shows how to find the shortest control path for a hybrid electrical vehicle using Signal Tracing Command-line API.

To open the model, enter this command in the example folder.

```
open_system('sldemo_hevc')
```

In this model, a hybrid electrical vehicle drives on a slope and the initial speed is 0 m/s. Set the target speed to 30 m/s. In **Driver**, a PID control compares the actual speed with the target speed and sends a command to increase or decrease speed to the power demand estimation module. **Power demand estimation** converts to the desired power, and the power is primarily provided by the electrical motor. If electrical motor is unable to provide enough torque, then the engine and provides additional torque. In **Vehicle Dynamic**, road resistance including rolling resistance and gravity resistance as well as the aero drag are calculated. The actual speed of the vehicle is constantly returned to **Driver** through the feedback loop until the vehicle reaches the target speed.

### Trace All Sources that Control the Actual Speed

Use the signal tracing API to find the shortest control path to the actual speed. Since the actual speed signal goes into the second inport of Scope, use Scope as the tracing origin.

```
g = sltrace('sldemo_hevc/Scope', 'source', 'port', '2', 'traceall', 'on');
highlight(g);
```

### Obtain the Trace Graph

The tracing results can be expressed as a MATLAB digraph. The trace graph includes edges and nodes.

A node in trace graph corresponds to a block port in a Simulink® model. The second port of Scope is a node. You can find the node information nodes table.

```
nodes = g.TraceGraph.Nodes;
```

The edges are shown as pair of node indexes in trace graph. You can access the node information from the nodes table with the corresponding node index. The Simulink® line between nodes is shown as segment handle(s).

```
edges = g.TraceGraph.Edges;
```

Compute the edges of the trace graph of the `sltrace.Graph` object and use built-in MATLAB® digraph features to plot the trace graph, as shown in the figure.

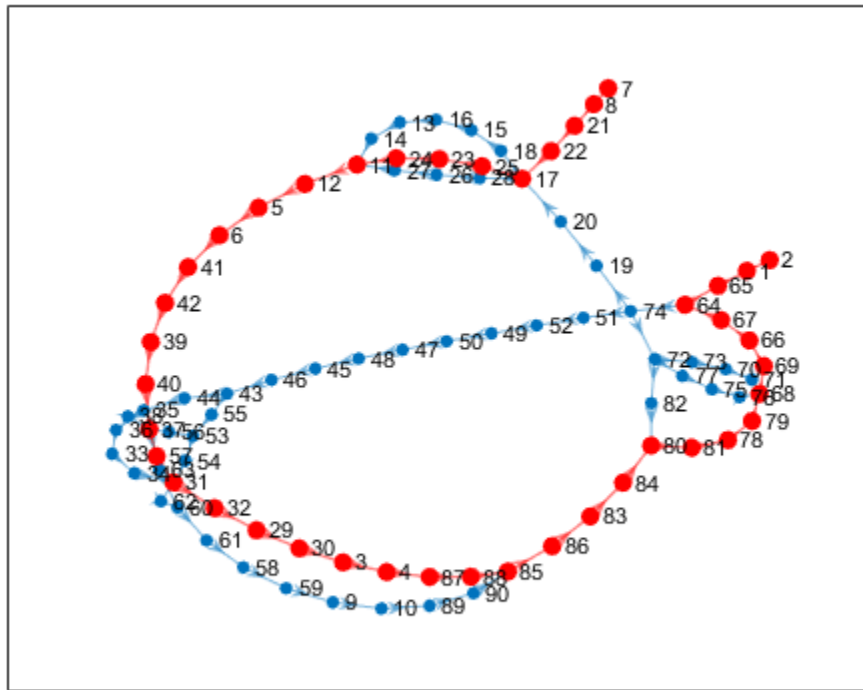

```
fig = g.TraceGraph.plot('Layout', 'force');
```

### Find the Shortest Path from trace graph

The start node is the outport of target speed [m/s], and the end node is the second inport of Scope. Use the nodes table to obtain the node indexes of the start node and end node and compute the shortest path between them, as shown in the figure.

```
startNode = 7;
endNode = 2;
shortestPath = g.TraceGraph.shortestpath(startNode, endNode);
highlight(fig, shortestPath, 'EdgeColor','r','NodeColor','r','MarkerSize',6,'LineWidth',1);
```

### Find the Shortest Control Path from the Simulink Model

The edges table contains two types of edges: real edges and virtual edges, including internal edges and hidden edges. First, filter out the virtual edges using the MATLAB find function.

```
realEdgeIdx = find(cellfun(@(x) ~ischar(x), edges.Segments) == 1);
realEdges = edges(realEdgeIdx, :);
```

Process each node in the shortest path to obtain the corresponding blocks and segments. Since one source node may be connected to multiple destination nodes, iterate over all the edges from the same source node and find the target destination node on the shortest path.

```
elements = [];
for i = 1:length(shortestPath) - 1
 srcNodeIdx = shortestPath(i);
 dstNodeIdx = shortestPath(i+1);
 srcBlockHandle = nodes.Block(srcNodeIdx);
 srcNodeEdgeIdx = find(realEdges.EndNodes(:,2) == dstNodeIdx);
 if length(srcNodeEdgeIdx) > 1
 dstNodeEdgeIdx = find(realEdges.EndNodes(srcNodeEdgeIdx, 2) == dstNodeIdx);
 edgeIdx = srcNodeEdgeIdx(dstNodeEdgeIdx);
 elseif length(srcNodeEdgeIdx) == 1
 edgeIdx = srcNodeEdgeIdx;
 else
 continue;
 end
 elements = [elements srcBlockHandle flip(realEdges.Segments{edgeIdx})];
end
```

Process the last node in the shortest path and highlight the shortest path in the Simulink model, as shown in the figure.

```
lastNodeIdx = shortestPath(end);
lastBlockHandle = nodes.Block(lastNodeIdx);
elements = [elements lastBlockHandle];
highlight(g, elements)
```

## Use Fixed-Step Zero-Crossing Detection for Faster Simulations

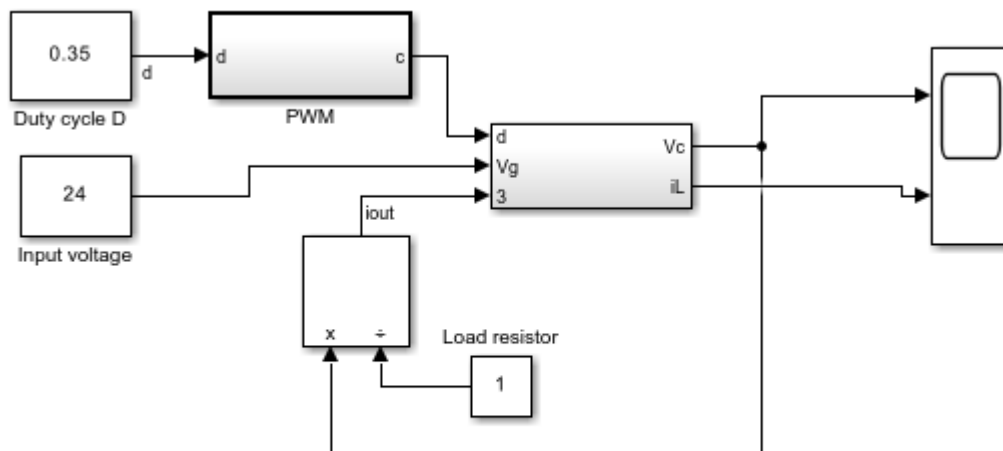

This example shows how fixed-step zero-crossing detection can be used to speed up simulation by increasing the fixed-step size without sacrificing simulation accuracy. Zero-crossing detection is essential if a system contains events that will change the equations in the system. The location and reaction to these events is important for accurate simulation.

### Load Model

This example uses a model of a buck converter, a DC-DC power converter. The converter is controlled via pulse width modulation (PWM), where a switch, represented by the Relay block in the PWM subsystem, is controlled by comparing the control voltage to a triangular voltage.

This model implements an open-loop version of the buck converter.

```
model = 'buck_ol';
open_system(model);
```

Copyright 2022 The MathWorks, Inc.

### Examine PWM Generation System

The buck converter in this model uses PWM to control the power transmitted to the load. The Relay block in the PWM subsystem represents a switch and is controlled by comparing the control voltage to a triangular voltage. The frequency of the triangle wave is 100 kHz. To accurately detect PWM switching, check that the solver takes steps smaller than  $1.0e-5$ . The relay block in a PWM system detects zero crossings when the triangle wave intersects with the duty cycle.

```
pwmGenSubsys = [model '/PWM'];
open_system(pwmGenSubsys);
```

### Simulate with a Variable-Step Solver

To achieve accurate simulation results, you must accurately locate the switching times that occur in the PWM subsystem. To see what the results should look like, you can first simulate the model using a variable-step solver with zero-crossing detection. Limit the max-step size of the solver to  $1e-6$  to ensure that you do not miss PWM switching events.

```
set_param(model, 'Solver', 'ode45', 'MaxStep', '1e-6', ...
 'ReturnWorkspaceOutputs', 'on')
simout = sim(model);
plot(simout.tout, simout.xout(:,1));
title('Output Voltage');
legend('Variable-step (expected)');
xlim([0 1e-3]);
```

### Use Fixed-Step Simulation

Now that you know what the expected simulation results should look like, you can simulate the model using a fixed-step solver. You should select the largest possible fixed-step size where the solver is still able to step near the PWM switching times. Using a large fixed-step size will result in the fastest possible simulation while still obtaining accurate results.

Use the simulation results generated by the variable-step solver to inform your choice for a fixed-step size. Start by using a fixed-step size of  $1.0\text{e-}6$ , similar to the maximum step size used for the variable-step simulation.

```
set_param(model, 'Solver', 'ode3', 'FixedStep', '1.0e-6');
set_param(model, 'EnableFixedStepZeroCrossing', 'off')

simout_FS_1ms = sim(model);

plot(simout.tout, simout.xout(:,1), ...
 simout_FS_1ms.tout, simout_FS_1ms.xout(:,1), '-s');
title('Output Voltage');
legend('Variable-step (expected)', 'Fixed-step: 1ms', ...
 'Location', 'southeast');
xlim([0 1e-3]);
```

### Reduce Fixed-Step Size

This plot shows that the results obtained with a fixed-step size of  $1.0e-6$  are not very accurate when compared to the variable-step baseline. Reducing the step size to  $5.0e-8$  produces more accurate results. Without zero-crossing detection,  $5.0e-8$  is the largest fixed-step size you can use for this model while still obtaining accurate simulation results.

```
set_param(model, 'FixedStep', '5.0e-8');
simout_FS_50ns = sim(model);

plot(simout.tout, simout.xout(:,1), ...
 simout_FS_50ns.tout, simout_FS_50ns.xout(:,1), '-s');
title('Output Voltage')
legend('Variable-step (expected)', 'Fixed-step: 50ns', ...
 'Location', 'southeast')
xlim([0 1e-3]);
```

### Enable Zero-Crossing Detection for fixed-step simulation

Open up the solver pane of the configuration parameters and select **Enable zero-crossing detection for fixed-step simulation**. Enabling this parameter allows Simulink to detect zero crossings between major time steps and apply corrections to continuous states in the model. Use the default value for **Maximum number of zero-crossings per step**.

Solver selection

Type:  Solver:

▼ Solver details

Fixed-step size (fundamental sample time):

Solver Jacobian method:

Number of Newton's iterations:

Zero-crossing options

Enable zero-crossing detection for fixed-step simulation

Zero-crossing control:

Maximum number of bracketing iterations:

Maximum number of zero-crossings per step:

```
set_param(model, 'EnableFixedStepZeroCrossing', 'on')
set_param(model, 'FixedStep', '1.0e-6', 'MaxZcPerStep', '2');
simout_FSZC_1ms = sim(model);
```

### Compare Results

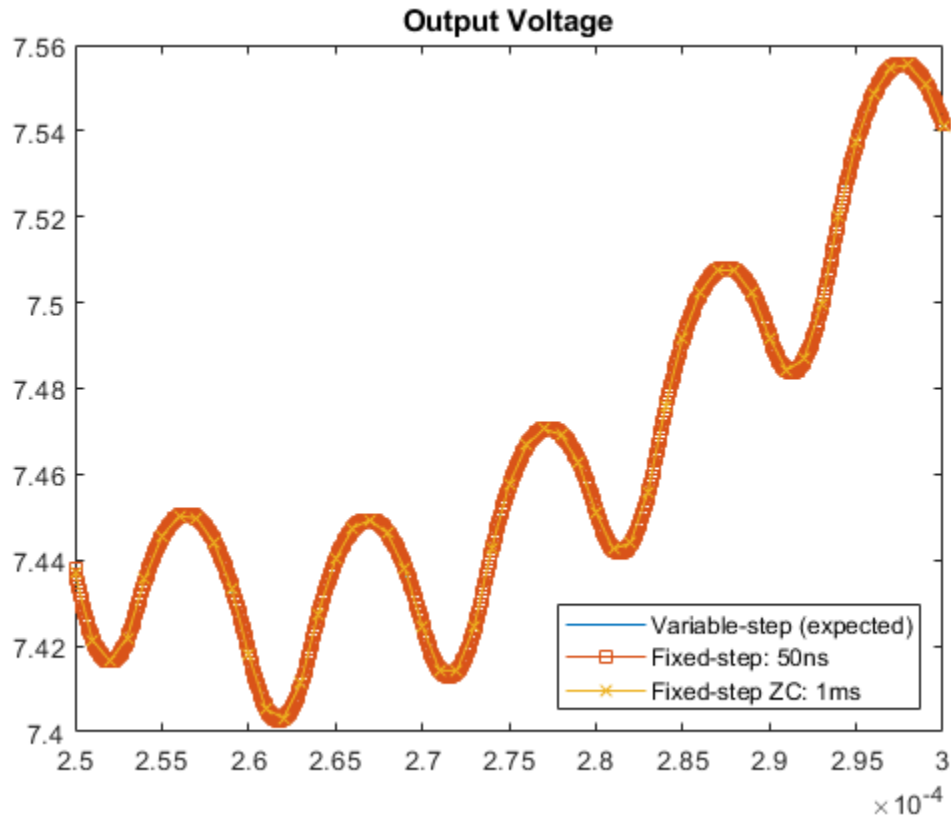

With zero-crossing detection enabled for fixed-step simulation, you can use a step size that is twenty times larger than the fixed step size used without zero-crossing detection and still obtain accurate results. This larger step size leads to faster simulation times.

```
figure()
state = 1;
plot(simout.tout, simout.xout(:,state), ...
 simout_FS_50ns.tout, simout_FS_50ns.xout(:,state), '-s' , ...
 simout_FSZC_1ms.tout, simout_FSZC_1ms.xout(:,state), '-x');
title('Output Voltage')
legend('Variable-step (expected)', 'Fixed-step: 50ns', 'Fixed-step ZC: 1ms', ...
 'Location', 'southeast')
xlim([0 1e-3]);
```

Zoom in to see that the results are accurate with zero crossing detection enabled, even with this larger step size.

```
xlim([2.5e-4 3e-4])
ylim([7.4 7.56])
```

Finally, note that the simulation time is faster at this larger step size with zero-crossing detection enabled.

```
bar([simout_FS_50ns.SimulationMetadata.TimingInfo.ExecutionElapsedWallTime, ...
 simout_FSZC_1ms.SimulationMetadata.TimingInfo.ExecutionElapsedWallTime])
xticklabels(gca, {'Zc Disabled @ 5.0e-8', 'ZC Enabled @ 1.0e-6'});
xtickangle(45);
ylabel("Wallclock Time (seconds)")
```
