## Create a New Project from a Folder

If you have many files that you want to organize into a project, with or without source control, use the following steps to create a new project.

---

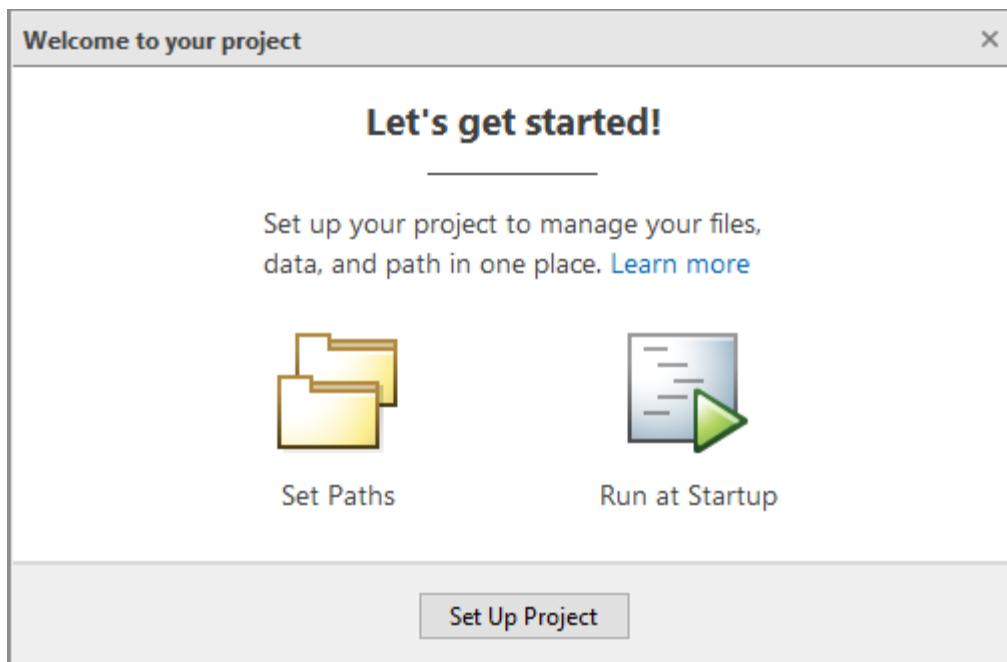

**Note** If you want to retrieve a project from a source control repository, see instead “Clone Git Repository” on page 19-31 or “Check Out SVN Repository” on page 19-32.

---

Easily convert a folder of files into a project by using the **Folder to Project** template in the Simulink start page. The template automatically adds your files to the project and prompts you to set up the path and startup files. This simple, quick process sets up your project to manage your files and introduces you to project features. When you open the project, it automatically puts the folders you need on the path, and runs any setup operations to configure your environment. Startup files automatically run (.m and .p files), load (.mat files), and open (Simulink models) when you open the project.

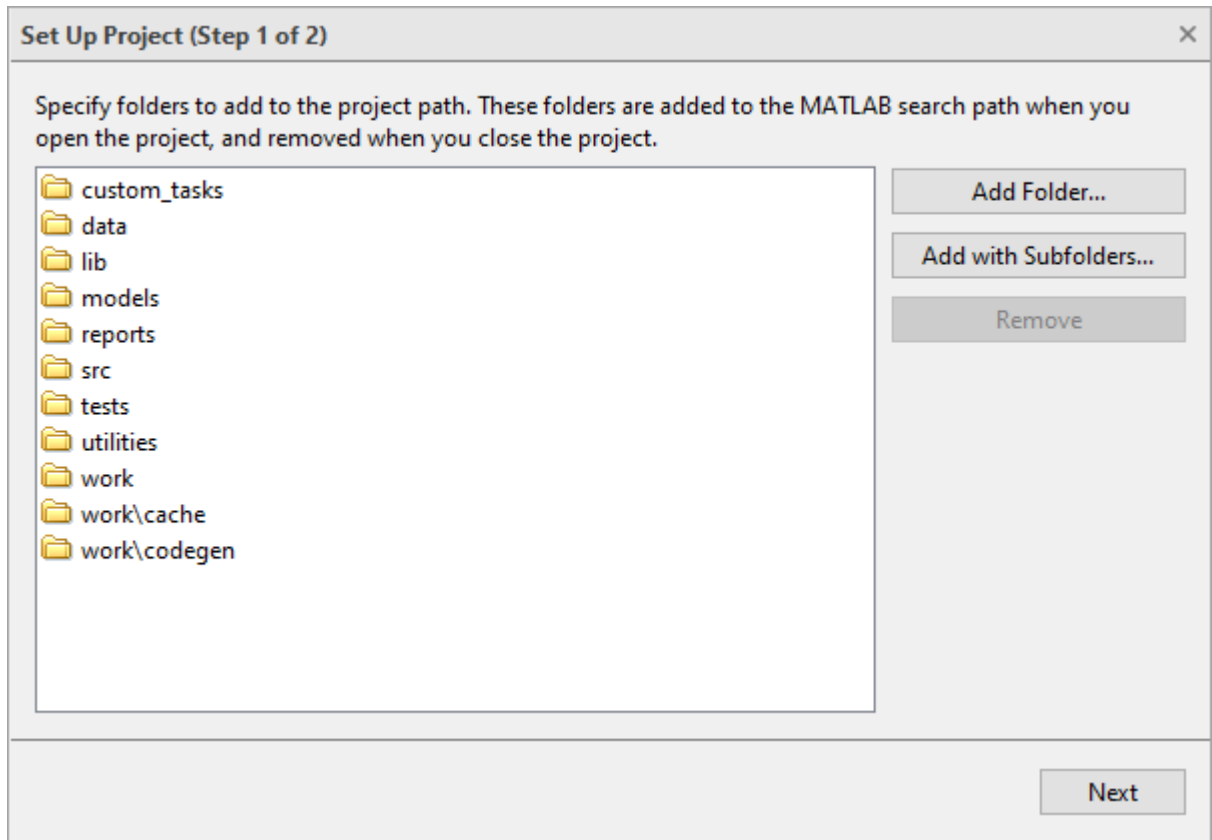

To create a new project to manage your files:

- On the MATLAB **Home** tab, select **New > Project > From Folder**.
  - Alternatively, in the Simulink start page, click the **Folder to Project** template. You can also, on the **Simulation** tab, select **New > Project > New Project** from the Model Editor.
- 1 In the New Project dialog box, enter a project name, browse to select the folder containing your files, and click **OK**.
  - 2 In the Welcome to your project dialog box, click **Set Up Project** to continue.

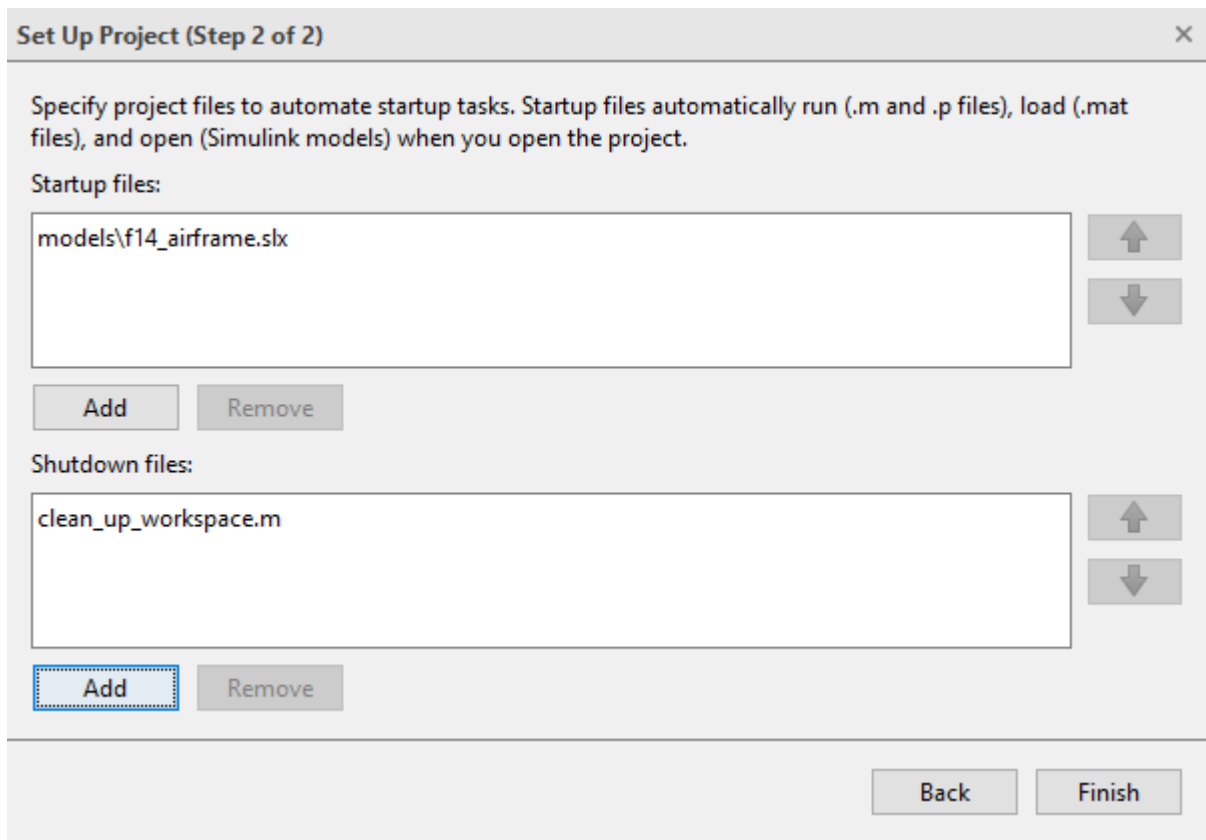

- 3 In the Set Up Project (Step 1 of 2) dialog box, optionally choose folders to add to the project path. When you open the project, it adds these folders to your MATLAB search path, and removes

them when you close the project. Add project folders to ensure dependency analysis detects project files. To add all project folders, click **Add with Subfolders** and then select the project folder containing all your subfolders. Alternatively, you can set up the project path later. Click **Next**.

- 4 In the Set Up Project (Step 2 of 2) dialog box, optionally specify startup and shutdown files.
  - Use startup files to configure settings when you open the project. Startup files automatically run (.m and .p files), load (.mat files), or open (Simulink models) when you open the project.
  - Use shutdown files to specify MATLAB code to run as the project shuts down. You do not need to use shutdown files to close models when you close a project, because it automatically closes any project models that are open, unless they are dirty. The project prompts you to save or discard changes.

Click **Add** to specify startup or shutdown files. Alternatively, you can setup these files later.

- 5 Click **Finish** and your new project opens. The **Folder to Project** template automatically adds all your files to the project. The template does not add derived files to your project.

For next steps, try dependency analysis to visualize the structure of your project, or consider adding source control to help you manage versions. For details, see “Run a Dependency Analysis” on page 18-7 or “Add a Project to Source Control” on page 19-5.

As alternatives to the **Folder to Project** template, you can:

- Create a project from a model by analyzing it for dependent files that you want to put in a project. See “Create a Project from a Model” on page 16-12
- Create projects manually, but then you need to add files to the project and configure the path, startup, and shutdown files. To examine the alternative templates, or to use your own templates:
  - 1 In the Simulink start page, click templates in the list to read the descriptions. If you selected a new project option to open the start page, the list shows only project templates, or you can filter the list for Project Templates using the list next to the Search box.
    - Select the **Blank Project** template if you are creating a project in a folder with existing files and want to set up the project manually. The **Blank Project** template creates a project in your selected folder and leaves any other files untouched. You must manually set up the project, for example by adding files to the project, configuring startup files, configuring the project path, etc.
    - Try the **Simple Project** template if you are creating a project in a new folder and want a blank model. The **Simple Project** template creates a simple project containing a blank model and some utilities. The model is a shortcut so you can open it from the toolstrip. The

project manages your path and the location of the temporary files (slprj folder) when you open and close the project. You can modify any of these files, folders, and settings later.

- You can create your own templates. See “Using Templates to Create Standard Project Settings” on page 16-35.
- 2** In the start page, select a template and click **Create Project**.
  - 3** In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**. You can control the default folder for new projects using the project preferences.

The Project displays the project files view for the specified project root. You need to add files to the project. See “Add Files to the Project” on page 16-21.

For next steps using your new project, try dependency analysis to visualize the structure of your files.

### More About

- “What Can You Do with Project Shortcuts?” on page 16-28

## Add Files to the Project

If you create a project from a folder, from a model, or with a Git or SVN template from the start page, then the project setup helps you add initial files to the project. If you create a new blank project, then the project files view is empty and you need to add files to the project.

To display all files in your project folder (or `projectroot`), in the **Files** view, click **All**. You might not want to include all files in your project. For example, you might want to exclude some files under `projectroot` from your project, such as SVN or CVS source control folders.

To add existing files to your project:

- 1 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Files**, click **Add Files**.
- 2 Select from the list of unmanaged files in the project folder.

Use **Add Files** any time you want to check for new files not yet added to the project.

Alternatively, you can use these methods to add files:

- In the **All** files view, select files or folders, right-click, and select **Add to Project** or **Add to Project (including child files)**.
- To add files to your project, cut and paste or drag and drop files from a file browser or the Current Folder browser onto the **Project** files view. If you drag a file from outside the project root, this moves the file and adds it to your project. You can drag files within project root to move them.
- Add and remove project files at the command line using `addFile`.

To create new files or folders in the project, right-click a white space in the **Files** view and select **New Folder** or **New File**. The new files are added to the project.

To learn how to set up your project with all required files, see “Run a Dependency Analysis” on page 18-7.

To add or remove project folders from the MATLAB search path, see “Specify Project Path” on page 16-27.

To configure your project to automatically run startup and shutdown tasks, see “Automate Startup Tasks” on page 16-29.

You can access your recent projects direct from MATLAB. See “Open Recent Projects” on page 16-25.

If you want to add source control, see “Add a Project to Source Control” on page 19-5.

## **More About**

- “What Can You Do with Project Shortcuts?” on page 16-28

## Create a New Project from an Archived Project

To create a new project from an archived project:

- 1 Locate and double-click the `mlproj` file in the Current Folder, Windows Explorer, or Apple Finder.

If you do not have a product that the project requires, you see a warning with a link to the Add-On Explorer to get missing products.

- 2 In the Extract Project to dialog box, specify the location of the new project and click **Select Folder**.

The new project opens. The current working folder is the location of the new project, which is a new subfolder of the extraction folder.

If you have a project archived in a zip file, double click or right click to extract the project. The current working folder, for example, `C:\myNewProject`, contains the imported project folders. If the zip project contains referenced projects, the project imports files into two subfolders, `main` and `refs`. The current working folder, for example, `C:\myNewProject\main` contains the project folders and `C:\myNewProject\refs` contains the referenced project folders. To open the project, navigate into `main` to locate and double-click the `prj` file.

- “Sharing Projects” on page 17-31

## Create a New Project Using Templates

In a project, you can use templates to create and reuse a standard project structure.

- 1 To browse for templates, click **Simulink** on the MATLAB Home tab, or on the Project tab, click **New**.
- 2 In the Simulink start page, click a template in the list to read the description. For example, click **Simple Project**.
- 3 The start page shows all project templates (\*.sltx) on the MATLAB path. If your templates do not appear, locate them by clicking **Open**. In the Open dialog box, make \*.sltx files visible by changing the file type list **Model Files** to **All MATLAB files**, and browse to your template.
- 4 In the start page, select a template and click **Create Project**.

Templates created in R2017b or later warn you if required products are missing. Click the links to open Add-On Explorer and install required products.

- 5 In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**.

### Use Project Templates from R2014a or Before

To use project templates created in R2014a or earlier (.zip files), upgrade them to .sltx files using `Simulink.exportToTemplate`.

After you upgrade the templates to .sltx and put them on the MATLAB path, you can use the templates from the start page.

- “Using Templates to Create Standard Project Settings” on page 16-35

## Open Recent Projects

You can use any of these methods to open recent projects:

- On the MATLAB **Home** tab, click **Simulink**, and select your project in the recent list.

If you select a recent model that is part of a project, you can choose to also open the project.

- On the MATLAB **Home** tab, click the **Open** arrow and select your project under the **Recent Projects** list.
- From the Current Folder browser, double-click the `.prj` file.
- In the Simulink Editor, if an open model, library, or chart belongs to a project, you can, on the **Simulation** tab, select **Project > View Project**.

If you already have an open project, to load another project, click on the **Project** tab and open a recent project with these methods:

- Click the **Open** arrow and select your project under the **Recent** list.
- Select **Open > Open**. Browse and select your project `.prj` file.

---

**Note** You can have one project open at a time, to avoid conflicts. If you open another project, any currently open project closes.

---

When you open a project, you are prompted if loaded files shadow your project model files. To avoid working on the wrong files, close the shadowing files. See “Manage Shadowed and Dirty Models and Other Project Files” on page 17-8.

## Specify Project Details, Startup Folder, and Derived Files Folders

On the Project tab, in the Environment section, click **Details**. Use the Project Details dialog box for the following tasks:

- Edit the project name or add a description.
- View the **Project root** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths. To change the current working folder to your project root, click **Set as Current Folder**.
- View or edit the **Start up folder**. By default, this is set to the project root. When you open the project, the current working folder changes to the project root folder. You can specify a different startup folder or click **Clear**.

You can also configure startup scripts that set the current folder and perform other setup tasks. If you configure startup files to set the current folder, your startup setting takes precedence over the startup folder at the Project Details dialog box. To set up startup files, see “Automate Startup Tasks” on page 16-29.

- View or edit the **Dependency cache file**. By default, the dependency cache file is stored in the preferences folder. You can create and specify a different cache file, for example, [project root]/dependencycache.graphml or click **Clear**.
- View or edit the **Generated Files** folders. You can set the **Simulation cache folder** and **Code generation folder**. For details, see “Manage Build Process Folders” (Simulink Coder).
- If you edit any project details, then click **OK** to save your changes.

If you are looking for source control information for your project, see instead the details button for your source control in the Source Control section of the Project tab, e.g., **SVN Details**. See “Add a Project to Source Control” on page 19-5.

### See Also

### Related Examples

## Specify Project Path

- When you open your project, it adds the project path to the MATLAB search path before applying startup shortcuts.
- When you close your project, it removes the project path from the MATLAB search path after applying shutdown shortcuts.

You can add or remove folders from the project path. Add project folders to ensure dependency analysis detects project files. On the **Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

In the **Project > Files** view, you can use the context menu to add or remove folders from the project path. Right-click a folder and select **Project Path > Add to Project Path**, or **Add to the Project Path (Including Subfolders)**, or one of the options to remove the folder from the path.

Folders on the project path display the project path icon in the **Status** column.

Name ^	Status	SVN	Revision	Type	Classification
batch_jobs			2	Folder	None
data			2	Folder	None
models			2	Folder	None
reports			2	Folder	None
src			2	Folder	None
tests			2	Folder	None
utilities			2	Folder	None
work				Folder	None

src (Folder)

### More About

- “What Is the MATLAB Search Path?”
- “What Can You Do with Project Shortcuts?” on page 16-28

## What Can You Do with Project Shortcuts?

In a project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. You can group shortcuts to organize them by type and annotate them to use meaningful names instead of cryptic file names.

Using the Project Shortcuts tab in the toolstrip, you can execute, group, or annotate shortcuts. Run shortcuts by clicking them in the Project Shortcuts tab or execute them manually from the context menu.

To automate tasks, use startup and shutdown files instead. You can use startup files to help you set up the environment for your project, and shutdown shortcuts to help you clean up the environment for the current project when you close it.

### See Also

#### Related Examples

- “Automate Shutdown Tasks” on page 16-31
- “Specify Project Path” on page 16-27

## Automate Startup Tasks

In a project, startup files help you set up the environment for your project.

Startup files are automatically run (.m and .p files), loaded (.mat files), and opened (Simulink models) when you open the project.

---

**Note** Startup scripts can have any name. You do not need to use `startup.m`

---

You can use a file named `startup.m` on the MATLAB path which runs when you start MATLAB. If your `startup.m` file calls the project with `currentProject`, an error appears because no project is loaded yet. To avoid the error, rename `startup.m` and use it as a project startup file instead.

Configure an existing file to run when you open your project.

- Right-click the file and select **Run at Startup**.
- Alternatively, on the Project tab, click **Startup Shutdown**. In the Manage Project Startup and Shutdown dialog box, you can add and remove startup and shutdown files. If execution order is important, change the order using the arrow buttons.

In the files view, the **Status** column displays an icon and tooltip indicating the file will run at startup.

---

**Note** Startup file settings are included when you commit modified files to source control. Any startup tasks you create run for all other project users.

---

To stop a file running at startup, change back by right-clicking it and selecting **Remove from Startup**.

On the Manage Project Startup and Shutdown dialog box, use the check boxes to specify environment options:

- **Start Simulink before this project starts**-This option starts Simulink when you open the project.
- **Refresh Simulink customizations**- This option runs `sl_customization` files on project startup and shutdown.

When you open the project, the startup files run. Also, the current working folder changes to the project startup folder. If you want to set the startup folder, on the Project tab, click **Details** and edit the **Start Up** folder. See “Specify Project Details, Startup Folder, and Derived Files Folders” on page 16-26.

You can create new startup and shutdown files interactively in the project or at the command line. For details, see `addStartupFile`.

### **More About**

- “What Can You Do with Project Shortcuts?” on page 16-28

## Automate Shutdown Tasks

In a project, shutdown files help you clean up the environment for the current project when you close it. Shutdown files should undo the settings applied in startup files.

Configure an existing file to run when you close your project.

- 1 Right-click the file and select **Run at Shutdown**.

The **Status** column displays an icon and tooltip indicating the file will run at shutdown.

---

**Note** Shutdown files are included when you commit modified files to source control. Any shutdown files you set run for all other project users.

---

To stop a file running at shutdown, change it back by right-clicking it and selecting **Remove from Shutdown**.

#### Related Examples

- “Automate Startup Tasks” on page 16-29
- “Specify Project Path” on page 16-27
- “Create Shortcuts to Frequent Tasks” on page 16-32
- “Use Shortcuts to Find and Run Frequent Tasks” on page 16-34

#### More About

- “What Can You Do with Project Shortcuts?” on page 16-28

## Create Shortcuts to Frequent Tasks

### In this section...

“Create Shortcuts” on page 16-32

“Group Shortcuts” on page 16-32

“Annotate Shortcuts to Use Meaningful Names” on page 16-33

“Customize Shortcut Icons” on page 16-33

### Create Shortcuts

In a project, create shortcuts for common project tasks and to make it easy to find and access important files and operations. For example, find and open top models, run code (for example, to load data), and simulate models. To run startup or shutdown code, see instead “Automate Startup Tasks” on page 16-29.

To configure an existing project file as a shortcut, use any of the following methods:

- In the **Files** view, right-click the project file and select **Create Shortcut**. In the Create New Shortcut dialog box, you can edit the shortcut name, choose an icon, and select a group if you have created a shortcut group you want to use. You can change shortcut group later. Click **OK**.
- Click **New Shortcut** on the Project Shortcuts tab on the toolstrip and browse to select a file.

The shortcut appears on the Project Shortcuts tab on the toolstrip.

In the files view, the **Status** column displays an icon and tooltip indicating the file is a shortcut.

---

**Note** Shortcuts are included when you commit your modified files to source control, so you can share shortcuts with other project users.

---

### Group Shortcuts

You can group shortcuts to organize them by type. For example, you can group shortcuts for loading data, opening models, generating code, and running tests.

You can select a shortcut group when creating shortcuts, or manage groups later on the Project Shortcuts toolstrip tab.

Create new shortcut groups to organize your shortcuts:

- On the Project Shortcuts tab, click **Organize Groups**.
- Click **Create**, enter a name for the group and click **OK**.

The new shortcut group appears on the Project Shortcuts tab.

To organize your shortcuts by group, either:

- Select a group when creating a shortcut.
- In the **Project** files view, right-click a file and select **Edit Shortcut**.

- On the Project Shortcuts tab, right-click a file and select **Edit Shortcut**.

The shortcuts are organized by group in the Project Shortcuts toolbar tab.

## Annotate Shortcuts to Use Meaningful Names

Annotating shortcuts makes their purpose visible, without changing the file name or location of the script or model the shortcut points to. For example, you can change a cryptic file name to a descriptive name for the shortcut. To put shortcuts in a workflow order on the toolbar, prefix the shortcut names with numbers.

When creating a shortcut, edit the **Name**. The shortcut name does not affect the file name or location.

Your specified shortcut name appears on the Project Shortcuts tab, to make it easier to find your shortcuts.

## Customize Shortcut Icons

You can specify an icon to use for your shortcut buttons on the Project Shortcuts tab. Icons such as "build" can aid other project users to recognize frequent tasks.

- 1 When creating a shortcut, choose an icon.
- 2 Select an image file. Images must be exactly 16 pixels square, and a png or a gif file.

### More About

- "What Can You Do with Project Shortcuts?" on page 16-28

## Use Shortcuts to Find and Run Frequent Tasks

In a project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. Shortcuts are available from any file view via the toolstrip.

If your project does not yet contain any shortcuts, see “Create Shortcuts to Frequent Tasks” on page 16-32.

To use shortcuts:

- In the Project Shortcuts toolstrip tab, click the shortcut. Clicking a shortcut in the toolstrip performs the default action for the file type, for example, run `.m` files, load `.mat` files, and open models. Hover over a shortcut to view the full path.

Choose which behavior you want when running shortcuts:

- If the script is not on the path, and you want to switch to the parent folder and run the script without being prompted, then click the shortcut in the Project Shortcuts toolstrip tab. If you use this option, the result of `pwd` in the script is the parent folder of the script.
- If you select **Run** in the **Files** view context menu, and the script is not on the path, then MATLAB asks if you want to change folder or add the folder to the path. This is the same behavior as running from the Current Folder browser. If you use this option, the result of `pwd` in the script is the current folder when you run the script.

## Create Templates for Standard Project Settings

### In this section...

“Using Templates to Create Standard Project Settings” on page 16-35

“Create a Template from the Current Project” on page 16-35

“Create a Template from a Project Under Version Control” on page 16-36

“Edit a Template” on page 16-36

“Remove a Template” on page 16-36

“Explore the Example Templates” on page 16-36

### Using Templates to Create Standard Project Settings

In a project, use templates to create and reuse a standard project structure. Templates help you make consistent projects across teams. You can use templates to create new projects that:

- Use a standard folder structure.
- Set up a company standard environment, for example, with company libraries on the path.
- Have access to tools such as company Model Advisor checks.
- Use company standard startup and shutdown scripts.
- Share labels and categories.

You can use templates to share information and best practices. You or your colleagues can create templates.

Create a template from a project when it is useful to reuse or share with others. You can use the template when creating new projects.

### Create a Template from the Current Project

In a project, when you create a template, it contains the structure and all the contents of the current project, enabling you to reuse scripts and other files for your standard project setup. You can choose whether to include the contents of referenced projects in the template.

- 1 Before creating the template, create a copy of the project, and edit the copy to contain only the files you want to reuse. Use the copy as the basis for the template.

---

**Note** If the project is under version control, see instead “Create a Template from a Project Under Version Control” on page 16-36.

---

- 2 On the **Project** tab, in the **File** section, select **Share > Simulink Template**.
- 3 On the Create Project Template dialog box, edit the name and author, select or create a group, and add a description to help template users.
- 4 If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
- 5 Click **Save As**. Choose a file location and click **Save**

## Create a Template from a Project Under Version Control

- 1 Get a new working copy of the project. See “Clone Git Repository” on page 19-31 or “Check Out SVN Repository” on page 19-32.
- 2 To avoid accidentally committing changes to your project meant only for the template, stop using source control with this sandbox as you work on the template. In the Source Control view, under **Available Source Control Integrations**, select **No Source Control Integration** and click **Reload**.
- 3 Remove the files that you do not want in the template. For example, you might want to reuse only the utility functions, startup and shutdown scripts, and labels. In the **Files** view, right-click unwanted files and select **Remove from Project**.
- 4 On the **Project** tab, in the **File** section, select **Share > Simulink Template** and use the dialog box to name and save the file.

To verify that your template behaves as you expect, create a new project that uses your new template. See “Create a New Project Using Templates” on page 16-24.

## Edit a Template

- 1 Create a new project that uses the template you want to modify. See “Create a New Project Using Templates” on page 16-24.
- 2 Make the changes.
- 3 On the **Project** tab, in the **File** section, select **Share > Simulink Template**.

Use the dialog box to create a new template or overwrite the existing one.

## Remove a Template

To remove a template from the Simulink start page:

- 1 Browse to the template location specified in the template details.
- 2 Delete the template or move it to another location.

## Explore the Example Templates

You can use the example templates as example structures for a new project.

You can explore the templates using the Simulink start page. To search for templates, use the start page search box. See “Create a New Project Using Templates” on page 16-24 and “Create a New Project from a Folder” on page 16-17.

## Group and Sort File Views

In a project, to group and sort the views in the Files view:

- Use the List or Tree options under **Layout** to switch between a flat list of files and a hierarchical tree of files.
- Click the Actions button  to specify display columns and sort order. For example, you can display columns for label categories that you created and sort files by label category.

### Related Examples

- “Search Inside Project Files and Filter File Views” on page 17-3

## Search Inside Project Files and Filter File Views

### In this section...

“Project-Wide Search” on page 17-3

“Filter Project File Views” on page 17-5

“More Ways to Search” on page 17-6

### Project-Wide Search

In a project, you can search inside all your models and supporting files. You can find matches inside model files, MATLAB files, data dictionaries, and other project files. You search only the current project. If you want to search referenced project files, open the referenced project.

- 1 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Files**, click **Search**. Alternatively, type in the file filter box, and the project provides a link to try searching inside files instead.

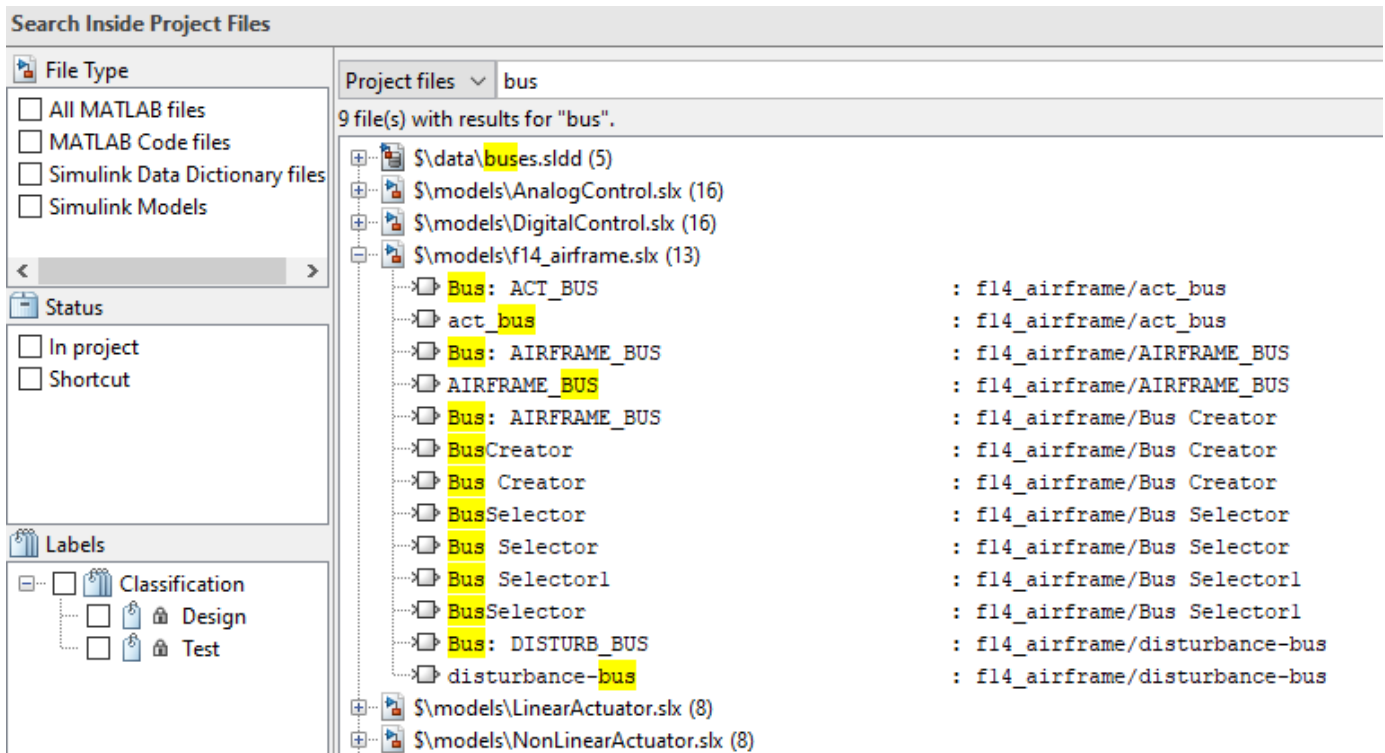

- 2 In the Search Inside Project Files dialog box, enter some characters to search for. Do not use quotes around phrases, or hyphens.
- 3 Expand files in the list to see results inside the file. Double-click results to locate specific items, e.g., highlight blocks in Simulink models, or highlight specific lines in MATLAB files.

- 4 Click **Filters** to refine results by file type, status, or label.

## Filter Project File Views

In a project, in the Files view and in the Custom Task dialog box, you can use the search box and filtering tools to specify file display.

- To view files, select the **Files** node. When the **Project (number of files)** view is selected, only the files in your project are shown. To see all the files in your sandbox, click **All**. This view shows all the files that are under the project root, not just the files that are in the project.
- To search, type a search term in the search box, for example, part of a file name or a file extension. You can use wildcards, for example, \*.m, or \*.m\*.

Click **X** to clear the search.

- To build a filter for the current view, click the filter button .

In the Filter Builder dialog box you can select multiple filter criteria to apply using names, file types, project status, and labels.

The dialog box reports the resulting filter at the bottom, for example:

```
Filter = file type is 'Model files (*.slx, *.mdl)' AND project status
is 'In project' AND has label 'Engine Type:Diesel'
```

When you click **Apply**, the search box shows the filter that you are applying.

A screenshot of a search bar interface. The search bar contains the text "name contains '.slx' AND has Label 'Review:To Review'". To the right of the text is a small blue square button with a white "x" icon, and further right is a grey funnel icon representing a filter.

## More Ways to Search

You can also search:

- Model contents without loading the models into memory. On the MATLAB **Home** tab, in the **File** section, click **Find Files**. You can search a folder or the entire path. However, you cannot highlight results in models from the results in the Find Files dialog box the same way you do with project search. See “Advanced Search for Files”.
- A model hierarchy. In the Simulink Editor, on the **Modeling** tab, click **Find**. Select options to look inside masks, links, and references. This search loads the models into memory. See Model Explorer
- For variables, block parameter values, or search a model hierarchy and contents using more options, using the Model Explorer. This search loads the models into memory. Use the Model Explorer to search for variables in workspaces and data dictionaries, and variable usage in a model. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 72-112

## See Also

**Model Explorer**

## Related Examples

- “Group and Sort File Views” on page 17-2

## Work with Project Files

In a project, in the **Files** view, use the context menus to perform actions on the files that you are viewing. Right-click a file (or selected multiple files) to perform project options such as:

- Open files.
- Add and remove files from the project.
- Add, change, and remove labels. See “Add Labels to Files” on page 17-17.
- Create entry point shortcuts (for example, code to run at startup or shutdown, open models, simulate, or generate code). See “Create Shortcuts to Frequent Tasks” on page 16-32.
- If a source control interface is enabled, you can also:
  - Refresh source control status.
  - Update from source control.
  - Check for modifications.
  - Revert.
  - Compare against revision (select a version to compare).

See “About Source Control with Projects” on page 19-2.

In the **Files** view, if you select, for example a model file, the bottom right-hand pane displays file information, a model preview, and file labels.

## Manage Shadowed and Dirty Models and Other Project Files

### In this section...

“Identify Shadowed Project Files When Opening a Project” on page 17-8

“Find Models and Other Project Files With Unsaved Changes” on page 17-8

“Manage Open Models and Data Dictionaries When Closing a Project” on page 17-9

### Identify Shadowed Project Files When Opening a Project

If there are two model files with the same name on the MATLAB path, then the one higher on the path is loaded, and the one lower on the path is shadowed. This shadowing applies to all models and libraries (SLX and MDL files).

A loaded model always takes precedence over unloaded ones, regardless of its position on the MATLAB path. Loaded models can interfere when you try to use other files of the same name, especially when models are loaded but not visible. Simulink warns when you try to load a shadowed model, because the other model is already loaded and can cause conflicts. The project checks for shadowed files when you open a project.

- 1 When you open a project, it warns you if any models of the same names as your project models are already loaded. This check enables you to find and avoid shadowed files before opening any project models.

The Configuring Project Environment dialog box reports the **Identify shadowed project files** check fails. Click **Details**.

- 2 In the dialog box, use the context menu to open or close individual files, or click **Close All** to close all potentially shadowing files. To avoid working on the wrong files, close the loaded models. The dialog box closes and you return to the Configuring Project Environment dialog box.
- 3 Inspect the other project loading tasks, then click **Continue** to view the project.

---

**Tip** To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

---

When you open a project with many referenced projects, identifying shadowed files can be time-consuming. You can turn off this check using the MATLAB project preference **Detect project files shadowed by open models**.

To learn more about shadowed files, see “Shadowed Files” on page 15-3.

### Find Models and Other Project Files With Unsaved Changes

You can check your project for models, data dictionaries and MATLAB files with unsaved changes. On the **Project** tab, click on the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Show Unsaved Changes**.

In the Unsaved Changes dialog box, you can see all dirty project models, data dictionaries, and MATLAB files. Project only detects unsaved changes edited in the MATLAB and Simulink editors.

Manually examine changes edited in other tools. If you have referenced projects, files are grouped by project. You can save or discard all detected changes.

## **Manage Open Models and Data Dictionaries When Closing a Project**

When you close a project, it closes any project models or data dictionaries, unless they are dirty.

When you close a project, if there are model files or data dictionaries with unsaved changes, a message prompts you to save or discard changes. You can see all dirty files, grouped by project if you have referenced projects. To avoid losing work, you can save or discard changes by file, by project, or globally.

Control this behavior using the project shutdown preferences.

## Move, Rename, Copy, or Delete Project Files

### In this section...

“Move or Add Files” on page 17-10

“Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-10

### Move or Add Files

To move or add project files, you can drag them to the project, or use clipboard operations.

- To add files to your project, you can paste files or drag them from your operating system file browser or the MATLAB Current Folder browser onto the **Project** files view in the project. When you drag a file to the **Project** files view, you add the file to the project. For projects under source control, you also add the file to source control.
- To move files within your project, cut and paste or drag files in the project.

See also “Add Files to the Project” on page 16-21.

### Automatic Updates When Renaming, Deleting, or Removing Files

When you rename, delete, or remove files or folders in a project, the project checks for impact in other project files. You can find and fix impacts such as changed library links, model references, and model callbacks. You can avoid refactoring pain tracking down other affected files. Automatic renaming helps to prevent errors that result from changing names or paths manually and overlooking or mistyping one or more instances of the name.

For example:

- When renaming a library, the project offers to automatically update all library links to the renamed library.
- When renaming a class, the project offers to automatically update all classes that inherit from it. If you rename a `.m` or `.mlx` file, the project offers to automatically update files and callbacks that call it. The project does not automatically update `.mlx` files. You need to update them manually.
- When deleting files or removing them from the project, the project prompts you if other files refer to them. You must decide how to fix the affected files manually.
- When renaming a C file, the project prompts you to update the S-function that uses it.
- When renaming buses or bus elements using the Simulink Type Editor, the project prompts you to update all usages in the project.

You can disable the project prompt and analysis when renaming buses or bus elements while keeping automatic updates enabled for other files. On the MATLAB **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project** and clear **Detect project-wide references when renaming Simulink buses and bus elements**.

You can disable the automatic updates when renaming, deleting, or removing files in a project. On the MATLAB **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project** and clear **Detect project-wide references when renaming, removing, and deleting files**.

To use automatic updates:

- 1 Rename a model, library, or MATLAB file in a project.

The project runs a dependency analysis to look for impacts in other files.

- 2 In the Rename dialog box, you can examine impacted files, choose to rename and update, just rename, or cancel renaming the file.
- 3 If you choose automatic updates, you can examine the results in updated files.

### Automatic Renaming Using the Power Window Project

- 1 Open the power window example project by entering in MATLAB:

```
slexPowerWindowStart
```

The project opens the top model, some scopes, and an animation window.

- 2 In a project, expand the `model` folder, and rename the `slexPowerWindowControl.slx` model to `slexPowerWindowControlSystem.slx`.

The project runs a dependency analysis to look for impacts in other files, and then the Rename dialog box reports impacted files.

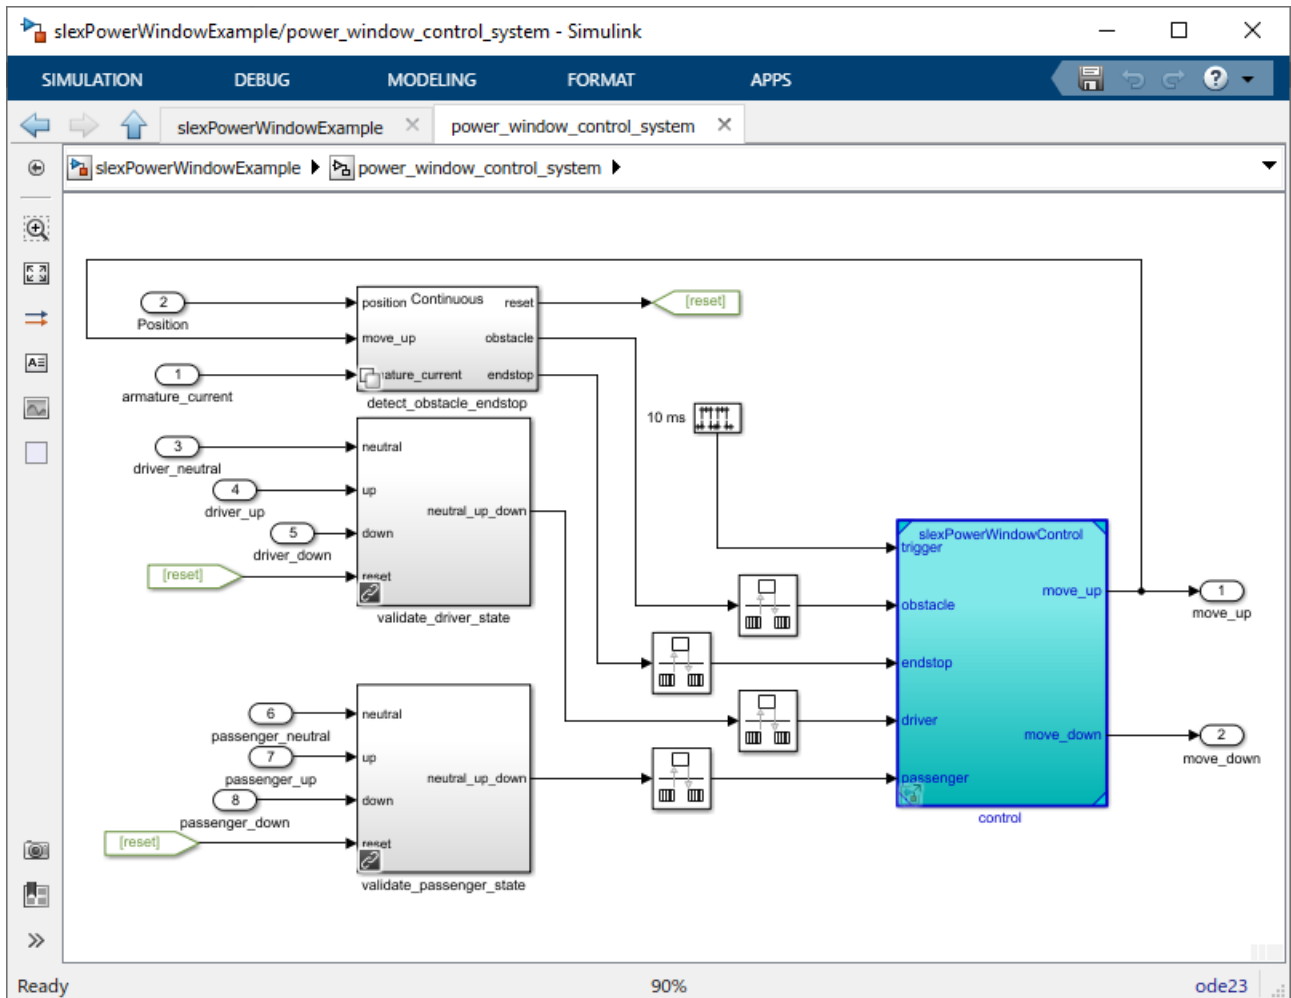

- 3 In the Rename dialog box, click **Show impacted files**. Expand the last impacted file to view the dependency, which is a model reference.

- 4 To view the dependency highlighted in the model, double-click the last **Model Reference** line in the Rename dialog box. Observe the model name on the highlighted control block, `sllexPowerWindowControl`.

- 5 In the Rename dialog box, click **Rename and Update**.

The project updates the impact files to use the new model name in model references. When the project can automatically rename items, it reports success with a check mark. With some impacts, you must decide how to fix the affected files manually.

- 6 Examine the results by double-clicking items in the Rename dialog box. Double-click the last **Model Reference** line. Check if the model name on the highlighted control block is updated to slexPowerWindowControlSystem.

## Related Examples

- “Work with Project Files” on page 17-7

## Back Out Changes

Similar to many applications, the project enables you to Undo and Redo, to back out recent changes.

- 1 Click the arrow next to the Undo or Redo button.
- 2 Select the actions you want to undo or redo. You can select multiple actions. Hover over each action to view details in a tooltip.

If you are using source control, you can revert to particular versions of files or projects. See “Revert Changes” on page 19-49.

### See Also

### Related Examples

- “Revert Changes” on page 19-49

## Create Labels

In a project, use labels to organize files and communicate information to project users. You can create these types of label categories:

- Single-valued — You can attach only one label from the category to a file.
- Multi-valued — You can attach multiple labels from the category to a file.

The **Labels** tree has built-in labels in the single-valued **Classification** category:

- You cannot rename or delete **Artifact**, **Convenience**, **Derived**, **Design**, **None**, **Test**, and **Other**.
- You cannot annotate built-in labels.

To create a label category:

- 1 In a project, right-click the **Labels** pane. Then select **Create New Category**.
- 2 In the Create Category dialog box, enter a name for the new category.
- 3 If you require a single-valued label category, select the **Single Valued** check box. The default is multi-valued.
- 4 If you want to specify a data type for the label other than `String`, from the **Type** list, select `Double`, `Integer`, `Logical`, or `None`.
- 5 Click **Create**.

To create a label in a category:

- 1 In the **Labels** pane, right-click the label category and select **Create New Label**.
- 2 In the Create Label dialog box, enter a name for the new label and click **OK**.

To rename or delete a category or label, right-click it and select **Rename** or **Remove**.

To create new labels at the command line, see “Automate Project Tasks Using Scripts” on page 17-19.

## See Also

### Related Examples

- “Add Labels to Files” on page 17-17
- “View and Edit Label Data” on page 17-18

## Add Labels to Files

In a project, use labels to organize files and communicate information to project users.

To add a label to a file, use one of these methods:

- Drag the label from the **Labels** pane onto the file.
- In the Files view, select the file. Then, drag the label from the **Labels** pane into the label editor.

To add a label to multiple files, in the **Files** view or Dependency Analyzer graph, select the files that require the label. Then right-click and select **Add Label**. Use the dialog box to specify the label.

To add labels programmatically, for example, in custom task functions, see “Automate Project Tasks Using Scripts” on page 17-19.

---

**Note** After you add a label to a file, the label persists across file revisions.

---

After you add labels, you can organize files by label in the Files view and dependency graph. See “Group and Sort File Views” on page 17-2 and “Perform an Impact Analysis” on page 18-17.

If the project is under SVN source control, adding tags to all your project files enables you to mark versions. See “Tag and Retrieve Versions of Project Files” on page 19-34.

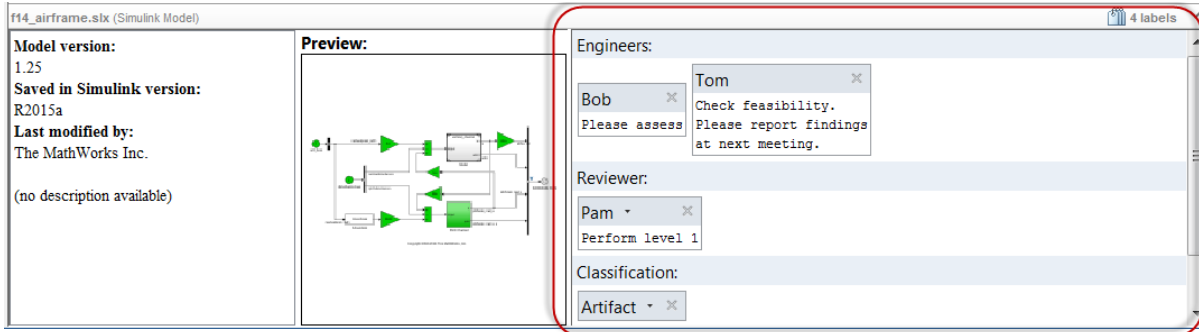

### See Also

#### Related Examples

- “Create Labels” on page 17-16
- “View and Edit Label Data” on page 17-18

## View and Edit Label Data

When you select a file in the project Files view, the file labels appear in the label editor view.

To change a label that belongs to a single-valued category, select the new value from the label list.

You can annotate labels from categories that you create. In the label, insert or modify text. Then, click **Apply**.

## Automate Project Tasks Using Scripts

This example shows how to use the project API to automate project tasks manipulating files, including working with modified files, dependencies, shortcuts, and labels.

### Get Project at the Command Line

Open the Airframe project and use `currentProject` to get a project object to manipulate the project at the command line.

```
proj = sldemo_slproject_airframe
```

```
Building with 'MinGW64 Compiler (C)'.
MEX completed successfully.
```

```
proj =
```

```
Project with properties:
```

```

        Name: "Airframe Example"
SourceControlIntegration: "Git"
  RepositoryLocation: "C:\workSpace\examples\repositories\airframe3"
SourceControlMessages: ["Branch status: Normal" ... ]
      ReadOnly: 0
      TopLevel: 1
    Dependencies: [1x1 digraph]
      Categories: [1x1 matlab.project.Category]
        Files: [1x32 matlab.project.ProjectFile]
      Shortcuts: [1x7 matlab.project.Shortcut]
    ProjectPath: [1x7 matlab.project.PathFolder]
ProjectReferences: [1x0 matlab.project.ProjectReference]
  StartupFiles: [1x0 string]
  ShutdownFiles: [1x0 string]
DefinitionFileType: FixedPathMultiFile
  Description: "This is an example project. Use the "Project Shortcuts" toolstrip
  RootFolder: "C:\workSpace\examples\airframe3"
SimulinkCodeGenFolder: "C:\workSpace\examples\airframe3\work\codegen"
ProjectStartupFolder: "C:\workSpace\examples\airframe3"
SimulinkCacheFolder: "C:\workSpace\examples\airframe3\work\cache"
```

### Find Project Commands

Find out what you can do with your project.

```
methods(proj)
```

```
Methods for class matlab.project.Project:
```

```

addFile                                listImpactedFiles
addFolderIncludingChildFiles            listModifiedFiles
addPath                                listRequiredFiles
addReference                           refreshSourceControl
addShortcut                             reload
addShutdownFile                        removeCategory
addStartupFile                          removeFile
```

```
addprop          removePath
close            removeReference
createCategory  removeShortcut
export           removeShutdownFile
findCategory     removeStartupFile
findFile        runChecks
isLoaded        updateDependencies
listAllProjectReferences
```

Call "methods('handle')" for methods of matlab.project.Project inherited from handle.

### Examine Project Files

After you get a project object, you can examine project properties such as files.

```
files = proj.Files
```

```
files =
```

```
1x32 ProjectFile array with properties:
```

```
Path
Labels
Revision
SourceControlStatus
```

Use indexing to access files in this list. The following command gets file number 10. Each file has properties describing its path and attached labels.

```
proj.Files(10)
```

```
ans =
```

```
ProjectFile with properties:
```

```
Path: "C:\workSpace\examples\airframe3\data\controller.sldd"
Labels: [1x1 matlab.project.Label]
Revision: "27b6d5ec735ea103997d4cf6fc7abe625665678b"
SourceControlStatus: Unmodified
```

Examine the labels of the 10th file.

```
proj.Files(10).Labels
```

```
ans =
```

```
Label with properties:
```

```
File: "C:\workSpace\examples\airframe3\data\controller.sldd"
DataType: 'none'
Data: []
Name: "Design"
```

```
CategoryName: "Classification"
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.slx')
```

```
myfile =
```

```
ProjectFile with properties:
```

```

    Path: "C:\workSpace\examples\airframe3\models\AnalogControl.slx"
    Labels: [1x1 matlab.project.Label]
    Revision: "27b6d5ec735ea103997d4cf6fc7abe625665678b"
    SourceControlStatus: Unmodified

```

Find out what you can do with the file.

```
methods(myfile)
```

```
Methods for class matlab.project.ProjectFile:
```

```
addLabel    findLabel    removeLabel
```

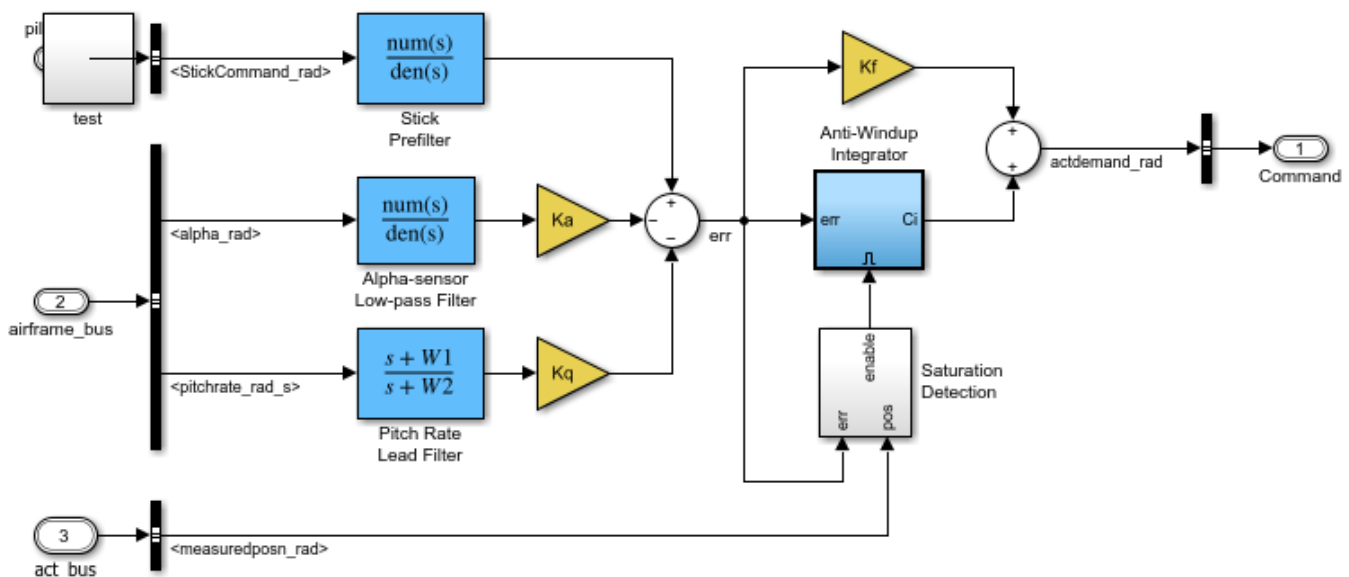

### Get Modified Files

Modify a project model file by adding an arbitrary block.

```

open_system('AnalogControl')
add_block('built-in/SubSystem', 'AnalogControl/test')
save_system('AnalogControl')

```

Copyright 1990-2018 The MathWorks, Inc.

Get all the modified files in the project. Observe two modified files. Compare with the Modified Files view in Project, where you can see a modified model file, and the corresponding project definition file.

```
modifiedfiles = listModifiedFiles(proj)
```

```
modifiedfiles =
```

```
    1x2 ProjectFile array with properties:
```

```
    Path
    Labels
    Revision
    SourceControlStatus
```

Get the second modified file. Observe the file SourceControlStatus property is Modified. Similarly, listModifiedFiles returns any files that are added, conflicted, deleted, etc., that show up in the Modified Files view in Project.

```
modifiedfiles(2)
```

```
ans =
```

```
    ProjectFile with properties:
```

```
        Path: "C:\workSpace\examples\airframe3\resources\project\uuid-08e31a06-2b0a-4..."
        Revision: ""
    SourceControlStatus: Added
```

Refresh source control status before querying individual files. You do not need to do before using listModifiedFiles .

```
refreshSourceControl(proj)
```

Get all the project files with a particular source control status. For example, get the files that are Unmodified .

```
proj.Files(ismember([proj.Files.SourceControlStatus], matlab.sourcecontrol.Status.Unmodified))
```

```
ans =
```

```
    1x23 ProjectFile array with properties:
```

```
    Path
    Labels
    Revision
    SourceControlStatus
```

### Get File Dependencies

Update the file dependencies. The project runs a dependency analysis to update the known dependencies between project files.

```
updateDependencies(proj)
```

Get the list of dependencies in the Airframe project. The Dependencies property contains the graph of dependencies between project files, stored as a MATLAB digraph object.

```
g = proj.Dependencies
```

```
g =
```

```
digraph with properties:
```

```
Edges: [21x1 table]
Nodes: [21x1 table]
```

Get the files required by a model.

```
requiredFiles = bfsearch(g, which('AnalogControl'))
```

```
requiredFiles =
```

```
3x1 cell array
```

```
{'C:\workSpace\examples\airframe3\models\AnalogControl.slx'}
{'C:\workSpace\examples\airframe3\data\controller.sldd' }
{'C:\workSpace\examples\airframe3\data\buses.sldd' }
```

Get the top-level files of all types in the graph.

```
g.Nodes.Name(indegree(g)==0);
```

Get the top-level files that have dependencies.

```
g.Nodes.Name(indegree(g)==0 & outdegree(g)>0)
```

```
ans =
```

```
4x1 cell array
```

```
{'C:\workSpace\examples\airframe3\models\DigitalControl.slx'}
{'C:\workSpace\examples\airframe3\models\LinearActuator.slx'}
{'C:\workSpace\examples\airframe3\models\slproject_f14.slx' }
{'C:\workSpace\examples\airframe3\tests\fl4_airframe_test.m' }
```

Find impacted (or "upstream") files by creating a transposed graph.

```
transposed = flipedge(g)
impacted = bfsearch(transposed, which('vertical_channel'))
```

```
transposed =
```

```
digraph with properties:
```

```
Edges: [21x1 table]
Nodes: [21x1 table]
```

```
impacted =  
  
4x1 cell array  
  
{'C:\workSpace\examples\airframe3\models\vertical_channel.slx'}  
{'C:\workSpace\examples\airframe3\models\f14_airframe.slx' }  
{'C:\workSpace\examples\airframe3\models\slproject_f14.slx' }  
{'C:\workSpace\examples\airframe3\tests\f14_airframe_test.m' }
```

Find files impacted by a data dictionary.

```
impacted2 = bfsearch(transposed, which('buses.slidd'))
```

```
impacted2 =  
  
11x1 cell array  
  
{'C:\workSpace\examples\airframe3\data\buses.slidd' }  
{'C:\workSpace\examples\airframe3\data\controller.slidd' }  
{'C:\workSpace\examples\airframe3\data\system_model.slidd' }  
{'C:\workSpace\examples\airframe3\tests\f14_airframe_test.m' }  
{'C:\workSpace\examples\airframe3\models\AnalogControl.slx' }  
{'C:\workSpace\examples\airframe3\models\DigitalControl.slx' }  
{'C:\workSpace\examples\airframe3\models\LinearActuator.slx' }  
{'C:\workSpace\examples\airframe3\models\NonLinearActuator.slx' }  
{'C:\workSpace\examples\airframe3\models\f14_airframe.slx' }  
{'C:\workSpace\examples\airframe3\models\slproject_f14.slx' }  
{'C:\workSpace\examples\airframe3\models\vertical_channel.slx' }
```

Get information on your files, such as the number of dependencies and orphans.

```
averageNumDependencies = mean(outdegree(g));  
numberOfOrphans = sum(indegree(g)+outdegree(g)==0);
```

If you want to make changes to a model hierarchy, starting from the bottom up, find the topological order.

```
ordered = g.Nodes.Name(flip(toposort(g)));
```

### Query Shortcuts

Examine the project's Shortcuts property.

```
shortcuts = proj.Shortcuts
```

```
shortcuts =
```

```
1x7 Shortcut array with properties:
```

```
Name  
Group  
File
```

Examine a shortcut in the array.

```
shortcuts(7)
```

```
ans =
```

```
Shortcut with properties:
```

```
    Name: "Rebuild Project's S-functions"
    Group: "Utility"
    File: "C:\workSpace\examples\airframe3\utilities\rebuild_s_functions.m"
```

Get the file path of a shortcut.

```
shortcuts(7).File
```

```
ans =
```

```
"C:\workSpace\examples\airframe3\utilities\rebuild_s_functions.m"
```

Examine all the files in the shortcuts cell array.

```
{shortcuts.File}'
```

```
ans =
```

```
7×1 cell array
```

```
{["C:\workSpace\examples\airframe3\custom_tasks\analyzeModelFiles.m"]}
{["C:\workSpace\examples\airframe3\custom_tasks\billOfMaterials.m" ]}
{["C:\workSpace\examples\airframe3\custom_tasks\checkCodeProblems.m"]}
{["C:\workSpace\examples\airframe3\custom_tasks\runUnitTest.m"      ]}
{["C:\workSpace\examples\airframe3\models\slproject_f14.slx"         ]}
{["C:\workSpace\examples\airframe3\reports\slproject_f14.pdf"       ]}
{["C:\workSpace\examples\airframe3\utilities\rebuild_s_functions.m" ]}
```

## Label files

Create a new category of labels, of type char. In the Project, the new Engineers category appears in the Labels pane.

```
createCategory(proj, 'Engineers', 'char')
```

```
ans =
```

```
Category with properties:
```

```
    Name: "Engineers"
    SingleValued: 0
    DataType: "char"
    LabelDefinitions: [1×0 matlab.project.LabelDefinition]
```

Find out what you can do with the new category.

```
category = findCategory(proj, 'Engineers');  
methods(category)
```

```
Methods for class matlab.project.Category:
```

```
createLabel findLabel removeLabel
```

Define a new label in the new category.

```
createLabel(category, 'Bob');
```

Get a label definition.

```
ld = findLabel(category, 'Bob')
```

```
ld =
```

```
LabelDefinition with properties:
```

```
    Name: "Bob"  
  CategoryName: "Engineers"
```

Attach a label to the retrieved file, myfile. If you select the file in Project, you can see this label in the label editor pane.

```
addLabel(myfile, 'Engineers', 'Bob');
```

Get a particular label and attach data to it, for example, some text.

```
label = findLabel(myfile, 'Engineers', 'Bob');  
label.Data = 'Please assess'
```

```
label =
```

```
Label with properties:
```

```
    File: "C:\workSpace\examples\airframe3\models\AnalogControl.slx"  
  DataType: 'char'  
    Data: 'Please assess'  
    Name: "Bob"  
  CategoryName: "Engineers"
```

You can specify a variable for the label data, for example:

```
mydata = label.Data
```

```
mydata =
```

```
    'Please assess'
```

Create a new label category with numeric data type.

```
createCategory(proj, 'Assessors', 'double');
category = findCategory(proj, 'Assessors');
createLabel(category, 'Sam');
```

Attach the new label to a specified file and assign data value 2 to the label.

```
myfile = proj.Files(14);
addLabel(myfile, 'Assessors', 'Sam', 2)
```

ans =

Label with properties:

```
File: "C:\workSpace\examples\airframe3\lib\timesthree.tlc"
DataType: 'double'
Data: 2
Name: "Sam"
CategoryName: "Assessors"
```

## Close Project

Closing the project at the command line is the same as closing the project using the Project tool. For example, the project runs shutdown scripts and checks for unsaved models.

```
close(proj)
```

## More Information

For more details on using the API, enter: `doc currentProject`.

To automate start and shutdown tasks, see “Automate Startup Tasks” on page 16-29.

## See Also

`currentProject` | `listModifiedFiles` | `refreshSourceControl` | `addLabel` | `createLabel`

## Related Examples

- “View and Edit Label Data” on page 17-18
- Automate Label Management in a Simulink Project

## Create a Custom Task Function

In a project, you can create functions and run them on selected project files.

For example custom task functions, see “Run Custom Tasks with a Project”.

To create a custom task function:

- 1 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**. In the Custom Task dialog box, click **Manage**.
- 2 In the Manage Custom Tasks dialog box, select **Add > Add Using New Function** or **Add Using Existing Function**.

Either browse to an existing script, or name and save the new file on your MATLAB path. The file is added to the project.

- 3 The MATLAB Editor opens the new file containing a simple example custom task function for you to edit. Edit the function to perform the desired action on each file. The instructions guide you to create a custom task with the correct function signature. Save the file.
- 4 To run your task, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**. In the Custom Task dialog box, select project files to include using the check boxes, select your custom task in the list, and click **Run Task**.
- 5 After your custom task function runs, view the results in the Custom Task Report.
- 6 To save the results in a file, click **Publish Report**.

### See Also

### Related Examples

- “Run a Project Custom Task and Publish Report” on page 17-29

## Run a Project Custom Task and Publish Report

- 1 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**, and then select the check boxes of project files you want to include in the custom task.

---

**Tip** If the function can identify the files to operate on, include all files. For example, the custom task function `saveModelFiles` in the `airframe` project checks that the file is a Simulink model and does nothing if it is not.

---

To select multiple files, **Shift** or **Ctrl**+click, and then right-click a file and select **Include** or **Exclude**.

- 2 Specify the custom task function to run in the **Custom task** box. Enter the name, or click **Browse**, or choose from a list of custom tasks.

If your project does not yet contain any custom task functions, see “Create a Custom Task Function” on page 17-28.

- 3 Click **Run Task**.

The project displays the results.

- 4 To view details of results for the currently selected file, click a file and check the Results pane.

You can publish a report of your custom task results. For example, try this custom task:

- 1 Open an example project by entering `sldemo_slproject_customtasks`.
- 2 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Custom Tasks**.
- 3 In the Custom Task dialog box, click the **Custom task** drop-down arrow to choose from a list of tasks, and select **Generate Bill of Materials Report**.
- 4 Click **Run Task**. Results appear.

- 5 Click **Publish Report**.
- 6 In the file browser, specify a name and location for the report, and choose a file type from HTML or Microsoft Word. If you have MATLAB Report Generator, you can also choose PDF.
- 7 View the results in the report.

The example custom task function **Generate Bill of Materials Report** creates a list of project files, their source control status, revision numbers, and MD5 checksums. You can view the code for this custom task in the file `billOfMaterials.m`.

- 8 To see the report file and add it to your project, switch to the **All** files view.

---

**Tip** To try example custom tasks in a project, see the example “Run Custom Tasks with a Project”.

## Sharing Projects

Projects help you collaborate. Use the **Share** menu to share your project in these ways:

- Archive your project in a single file.
- Share your project by email (Windows only).
- Create a template from your project.
- Package your project as a MATLAB toolbox.
- Make your project publicly available on GitHub.

You can also collaborate by using source control within projects.

### See Also

#### Related Examples

- “Create Templates for Standard Project Settings” on page 16-35
- “Share Project by Email” on page 17-32
- “Share Project as a MATLAB Toolbox” on page 17-33
- “Share Project on GitHub” on page 17-34

#### More About

- “About Source Control with Projects” on page 19-2

## Share Project by Email

To package and share project files on Windows, you can email your project as an archive file attachment. For example, you can share the project with people who do not have access to the connected source control tool.

- 1 With a project loaded, on the **Project** tab, select **Share > Email**.
- 2 (Optional) To export only the specified files, choose an **Export profile**. To exclude files with particular labels, select **Manage Export Profiles** and create an export profile.
- 3 If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
- 4 Click **Attach to Email**. The project opens a new email in your default email client with the project attached as an archive `.mlproj` file.
- 5 Edit and send the email.

### See Also

## Share Project as a MATLAB Toolbox

To package and share project files, you can create a MATLAB toolbox from your project.

- 1 With a project loaded, on the **Project** tab, select **Share > Toolbox**.

The packager adds all project files to the toolbox and opens the Package a Toolbox dialog box.

- 2 The **Toolbox Information** fields are populated with the project name, author, and description. Edit the information if needed.
- 3 If you want to include files not already included in the project files, edit the excluded files and folders.
- 4 Click **Package**.

#### Related Examples

- “Create and Share Toolboxes”

#### More About

- “Sharing Projects” on page 17-31

## Share Project on GitHub

To share your project, you can make your project publicly available on GitHub. You must first have a GitHub account.

You can share any project. Sharing adds Git source control to the open project. If your project is already under source control, sharing replaces the source control configuration with Git, and the project's remote repository is GitHub.

---

**Note** If you do not want to change your current source control in the open project, share a copy of the project instead. To create a copy to share, see “Archive Projects” on page 17-35.

---

- 1 With a project loaded, on the Project tab, select **Share > Change Share Options**.
- 2 Add the **GitHub** option to your **Share** menu. In the Manage Sharing dialog box, select **GitHub** and click **Close**.
- 3 Select **Share > GitHub**.
- 4 In the Create GitHub Repository dialog box, enter your GitHub user name and personal access token, and edit the name for the new repository. Click **Create**.

A warning prompts you to confirm that you want to create a public repository and modify the current project's remote repository location. To continue, click **Yes**.

- 5 The Create GitHub Repository dialog box displays the URL address for your new repository. Click the link to view the new repository on the GitHub website. The repository contains the initial commit of your project files.
- 6 The source control in your current project now references the new repository on GitHub as the remote repository. To use the project with the new repository, in the Create GitHub Repository dialog box, click **Reload Project**.

In the project, you can find the URL address for your remote repository on the Project tab, under **Source Control**, using the **Git Details** button.

If you have not already set up Git, you need some additional setup steps before you can merge branches. You can use other Git functionality without any additional installation. See “Set Up Git Source Control” on page 19-16.

## Archive Projects

To package and share project files, you can export all project files to an archive file. For example, you can share an archived project with people who do not have access to the connected source control tool.

- 1 With a project loaded, on the **Project** tab, select **Share > Archive**.
- 2 (Optional) To export only the specified files, choose an **Export profile**.
- 3 If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
- 4 Click **Save As**.
- 5 Use the file browser to specify a file path in the **File name** field. By default, the file *myProjectName.m\proj* is created in the current working folder. You can choose the file type project archive (.m\proj) or zip file.

If you want to exclude files from the archive, create an export profile to exclude files with particular labels.

- 1 Create labels and add them to the project files you want to exclude. See “Create Labels” on page 17-16.
- 2 Specify an export profile. On the **Project** tab, select **Share > Manage Export Profiles**.
  - a Click **+** and specify a name for the export profile.
  - b In the Files pane, click **+** and select the labels for the files you do not want to export, and click **OK**. You can also choose not to export custom labels.
  - c Click **Apply** and close the Manage Export Profiles dialog box.
- 3 When you share the project to an archive, in the **Export profile** list, select the name of your export profile to export only the specified files.

---

**Note** Export profiles do not apply changes to referenced projects. When you share your project, MATLAB exports the entire referenced projects.

---

Before sharing projects with other users, it can be useful to examine the required add-ons for your project. See “Find Required Products and Add-Ons” on page 18-19.

## Upgrade All Project Models, Libraries, and MATLAB Code Files

**Tip** Before upgrading, if you put your project under source control, you can easily revert changes later if you want. See “Add a Project to Source Control” on page 19-5.

Upgrade all models, libraries, and MATLAB code files in your project to the latest release using a simple workflow. The Upgrade Project tool can apply all fixes automatically when possible, upgrade all model hierarchies in the project at once, and produce a report. You do not need to open the Upgrade Advisor.

- 1 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Upgrade Project**.

- 2 In the Upgrade Project dialog box, to upgrade all files, run all checks, and apply fixes automatically where possible, click **Upgrade**. If you want to change the settings, use these options before clicking **Upgrade**:
  - If you want to run upgrade checks but not apply fixes automatically where possible, clear the check box **Apply upgrades automatically**.
  - If you want to change which files to upgrade and which checks to run, click **Change Options**. In the Upgrade Options dialog box, clear check boxes for models and checks you want to exclude from the upgrade. For example, you might want to exclude checks that require an **Update Diagram**.

When you click **Upgrade**, the tool runs the checks and applies fixes if specified. Upgrading can take several minutes.

- 3 Examine the Upgrade Project Report. The summary at the top shows how many files passed and how many files require attention.

The screenshot shows the 'Upgrade Project Report' window. At the top, a large green circle indicates '100% Passed'. Below this, a summary table shows the status of different components:

	Models	Libraries	MATLAB Code
Passed	7	1	7
Need attention	-	-	-

Below the summary, there are two dropdown menus: 'Show: All Files' and 'All Results'. The main area is divided into two panes. The left pane lists files, with 'AnalogControl.slx' selected. The right pane shows the check results for 'AnalogControl.slx' at the path '\$\models\AnalogControl.slx'. It includes a 'Rerun Checks' and 'View Changes' link. A table lists the checks and their results:

Check Name	Result
Turn off SLX file compression	✓
Return all simulation outputs as a single Simulink.SimulationOutput object	✓
Resave in current version of Simulink	✓
Identify variant blocks using variant objects with empty conditions	✓
Identify Model Variants blocks and convert those to Variant Subsystem blocks containing Model block choi...	✓
Identify Model Info blocks that can interact with external source control tools	✓
Identify masked blocks that specify tabs in mask dialog using MaskTabNames parameter	✓
Identify configurable subsystem template blocks having the instances in the model for converting to varia...	✓

At the bottom of the right pane, there is a 'Turn off SLX file compression' link with a 'Learn more' link, and a 'Passed' status indicator. The window footer shows 'Checks run on 08/08/2020 11:24' and a 'Close' button.

- a Select files in the left list to view check results on the right. By default, the left list shows any files that need attention. Show instead all files, files types, all results, files that passed, or files that passed with fixes, by using the **Show** controls.
- b Select checks in the right list to read details of results and any applied fixes in the lower pane. Examine checks marked as needing attention, with an orange circle in the **Result** column. For details of upgrading libraries, see “Upgrade Libraries” on page 17-38.
- c If your project is under source control, you can examine the upgrade changes in your files using a comparison report. To see the differences before and after upgrade, in the Upgrade Project Report, click **View Changes**.
- 4 The project saves an HTML report of the upgrade results in the project root folder. To open the published report, click the **Report** link at the top of the Upgrade Project Report.
- 5 To close the interactive report, click **Close**.

## Upgrade Libraries

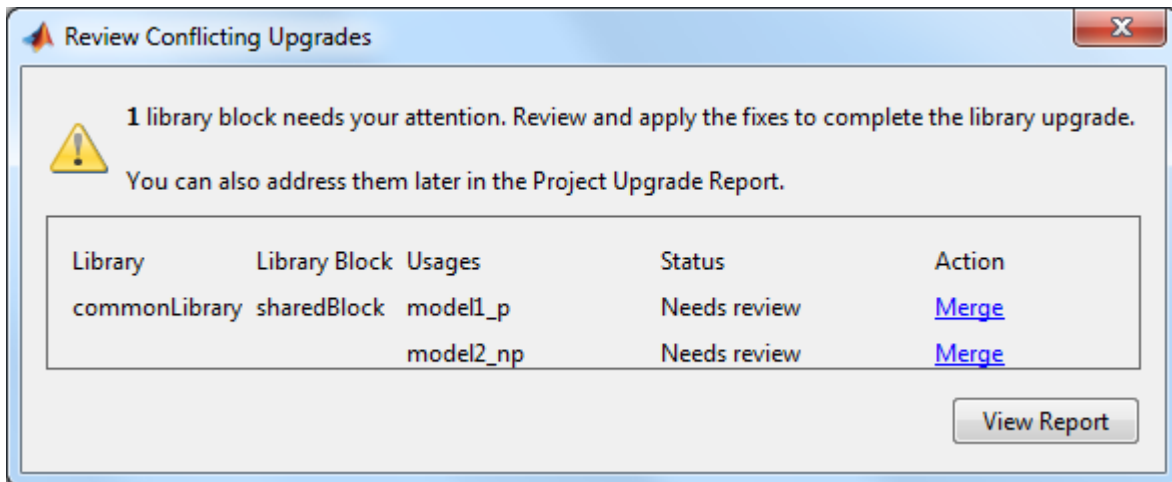

The project automatically runs all upgrade checks on multiple libraries, including any checks that require an Update Diagram.

You cannot run Update Diagram on a library, so project upgrade runs the Update Diagram checks in the models where the library blocks are used. This means that project upgrade can only fully upgrade library blocks that are used in a model. If the library block is used in a model, project upgrade automatically runs all checks, including Update Diagram checks, and then upgrades the block in the library.

If a library block is not used in any project model, then the check **Run checks that require Update Diagram on library blocks** is marked as needing attention, with an orange circle in the **Result** column. Select the check and in the details pane you see the message **Unable to upgrade blocks unused by a model**.

- To upgrade unused library blocks, use the blocks in a model and then upgrade.
- If you want to upgrade library blocks that use forwarding tables, disable the library link and save the model before upgrading, upgrade and then restore the link.

The upgrade of library blocks depends on the model context. The same library block might be used in multiple models. Linked library blocks inherit attributes from the surrounding models, such as data types and sample rate. The blocks' behavior can differ depending on the context where they are used, and this can lead to conflicting upgrades for Update Diagram checks. If models require a different upgrade of the same library block, you are prompted to view and resolve the upgrade conflict.

If you need to review conflicting upgrades, click **Merge**. Alternatively you can review conflicting upgrades later from the report. Review changes in the comparison report and choose which upgrades to save.

- “About Source Control with Projects” on page 19-2

## Analyze Model Dependencies

### In this section...

“Open and Explore Dependency Graph” on page 17-40

“Model Dependency Views” on page 17-41

“Find Required Products” on page 17-43

“Export Dependency Analysis Results” on page 17-43

“Create Project from the Dependency Graph” on page 17-44

Examine models, subsystems, and libraries referenced directly or indirectly by the model using the Dependency Analyzer. Use the dependency graph to identify all required files and products. To package, share, or put your design under source control, create a project from your model. For more details, see “Create Project from the Dependency Graph” on page 17-44.

### Open and Explore Dependency Graph

1. Open the `sldemo_mdhref_depgraph` model.
2. To open the model dependency graph, on the **Modeling** tab, click the down arrow to expand the **Design** section. Under **Dependencies**, click **Dependency Analyzer**.

The Dependency Analyzer opens the dependency graph using the **Model Hierarchy** view by default. To switch to the model instances view, in the **Views** section, click **Model Instances**. For more details, see “Model Dependency Views” on page 17-41.

After you run the first dependency analysis, subsequent analyses incrementally update the results. The Dependency Analyzer determines which files changed since the last analysis and updates the dependency data for those files. To perform a complete analysis, in the Dependency Analyzer, select **Analyze > Reanalyze All**.

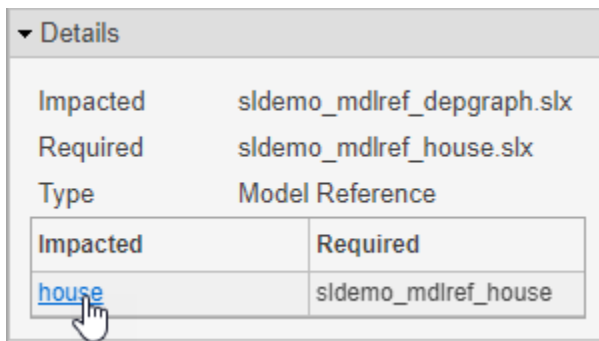

To analyze the dependencies inside add-ons, select **Analyze > Add-Ons**. For more details about available options, see “Analysis Scope” on page 18-4.

3. To view the dependencies laid out horizontally, in the **Layout** section, click **Horizontal**.
4. In the dependency graph, double-click a box to open the corresponding model in the Simulink® Editor.
5. To see more information about how two files are related, select their dependency arrow. In the **Properties** pane, in the **Details** section, you can see the full paths of the files you are examining, the dependency type, and where the dependency is introduced.

6. To open the file and highlight where the dependency is introduced, in the **Details** section, click the link under **Impacted**.

For example, to open the `sldemo_mdref_depgraph` model and highlight where the dependency to `sldemo_mdref_house` is introduced, select the dependency arrow between `sldemo_mdref_depgraph` and `sldemo_mdref_house`. In the **Properties** pane on the right, under **Impacted**, click house.

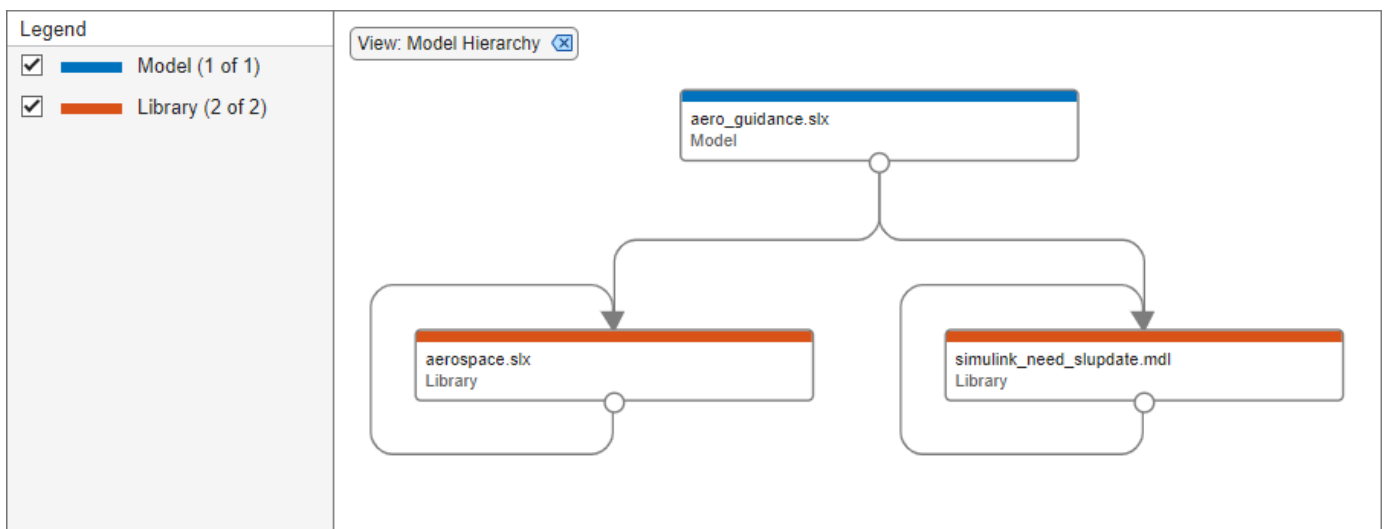

## Model Dependency Views

You can explore model dependencies using the model hierarchy or the model instances views.

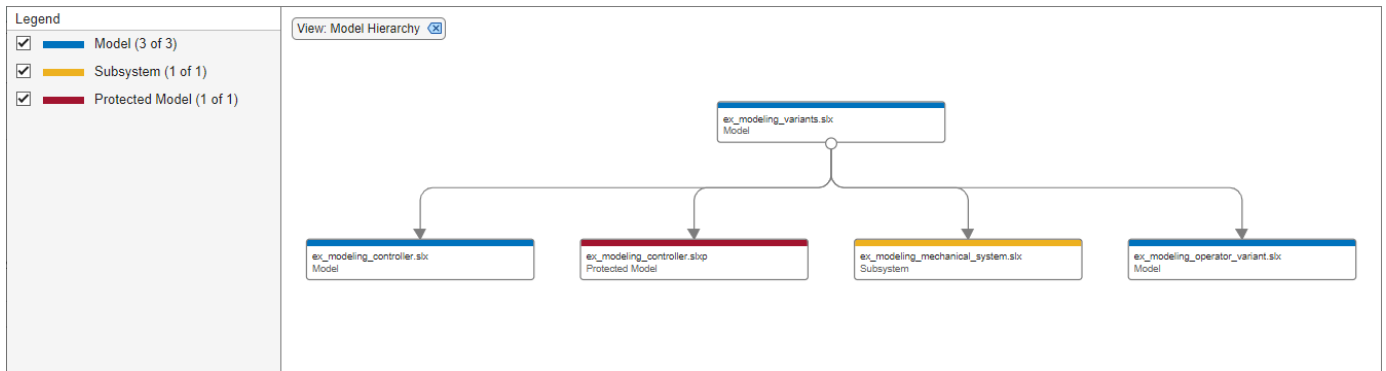

### Model Hierarchy View

The **Model Hierarchy** view shows the model, subsystem, library and data dictionary files referenced by a top model.

- A referenced file appears only once in the view even if it is referenced more than once in the model.
- Blue boxes represent model files, red boxes represent libraries, and yellow boxes represent subsystem references. Arrows represent dependencies. For example, the arrows in this example indicate that the `aero_guidance` model references two libraries: `aerospace` and `simulink_need_slupdate`.

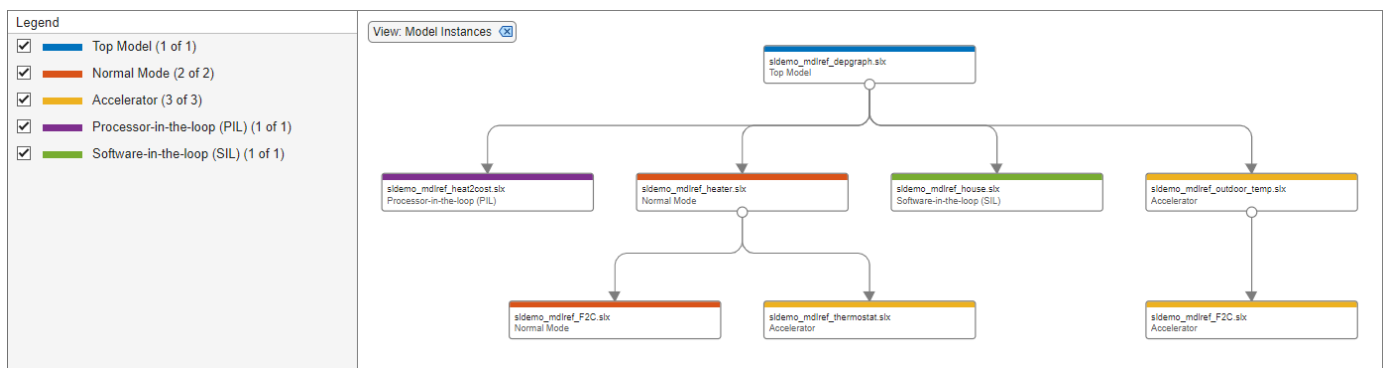

- An arrow from a library that points to itself indicates that the library references itself. Blocks in the library reference other blocks in that same library. The example view shows that the libraries `aerospace` and `simulink_need_slupdate` reference themselves.
- Dark red boxes represent protected models (.slxp files). You cannot open or edit protected referenced models. See “Reference Protected Models from Third Parties” on page 8-13.

### Model Instances View

The **Model Instances** view shows every reference to a model in a model reference hierarchy with the top model at the root of the hierarchy. Boxes represent the top model and its references. See “Model References”.

- If a model hierarchy references the same model more than once, the referenced model appears multiple times in the instance view, once for each reference. This example graph shows that the model reference hierarchy for `sldemo_mdref_depgraph` contains two references to the model `sldemo_mdref_F2C`.
- Yellow boxes represent accelerated-mode instances, red boxes represent normal-mode instances, purple boxes represent processor-in-the-loop mode instances, and green boxes represent software-in-the-loop mode instances. See “Choose Simulation Modes for Model Hierarchies” on page 8-39.

The previous example graph shows that one of the references to `sldemo_mdref_F2C` operates in normal mode and the other operates in accelerated mode.

- The Dependency Analyzer detects when a simulation mode is overridden and appends (Overridden) to the simulation mode. If a referenced model is configured to run in normal mode and it runs in accelerator mode, its simulation mode is overridden. This occurs when another model that runs in accelerator mode directly or indirectly references it.

## Find Required Products

To find required products and add-ons for a file in your design, select a box in the dependency graph. The Dependency Analyzer shows the list of required products by your selection in the **Products** section in the **Properties** pane.

To find required add-ons for the whole design, click the graph background to clear all selection. Examine the list of products in the **Products** section in the **Properties** pane.

To highlight files that use a certain product in the graph, for example *Simulink*, in the **Products**

section, in the **Properties** pane, point to product and click the magnifying glass icon .

To go through these files, use the arrows in the search box (e.g., **Files using "productName"**).

To undo the highlighting, close the search box.

To investigate further, you can list the files that use a product and examine where in these files the dependency is introduced. In the **Products** section, in the **Properties** pane, point to a product and

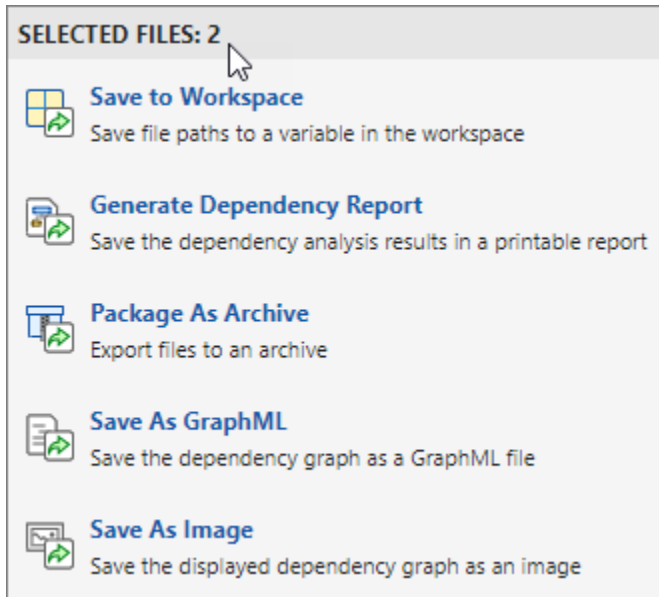

click the search folder icon .

## Export Dependency Analysis Results

To export all the files displayed in the dependency graph, click the graph background to clear the selection on all files. In the Dependency Analyzer toolstrip, in the **Export** section, click **Export**. Select from the available options:

- **Export to Workspace** — Save file paths to a variable in the workspace.
- **Generate Dependency Report** — Save dependency analysis results in a printable report (HTML, Word, or PDF).
- **Package As Archive** — Export files in the graph as an archive.
- **Save As GraphML** — Save dependency analysis results as a GraphML file.
- **Save As Image** — Save displayed dependency graph as an image.

You can also export a subset of files in the graph. Select the files, then click **Export**. The menu displays how many files are selected. The Dependency Analyzer exports only the selected files.

---

**Note** When you use **Package As Archive**, the Dependency Analyzer includes the selected files and all their dependencies in the archive.

---

## Create Project from the Dependency Graph

To package, share, or put your design under source control, create a project from your model. You can create a project from the model dependency graph.

To create a project from all the files displayed in the dependency graph, click the graph background. This action clears all selected files.

- 1 In the Dependency Analyzer toolstrip, in the **Export** section, click **Create Project**.
- 2 In the **New Project** window, click **Create**.

The Dependency Analyzer creates a project and reloads the graph.

You can also create a project from a subset of files in the graph. Select the files, then click **Create Project**. The Dependency Analyzer includes the selected files and all their dependencies in the project.

## View Requirements Toolbox Links Associated with Model Elements

### In this section...

“Highlight, Filter, and View Information for Links in a Model” on page 17-46

“Navigate to Externally Stored Requirements from a Model” on page 17-49

You can work with links that were added to the model with Requirements Toolbox when you use the **Requirements Viewer** app in Simulink. For all links, you can:

- Highlight model objects with links
- View information about a link
- Filter link highlighting based on specified keywords

For links to requirements that are stored in external documents, you can also navigate to the linked requirements.

### Highlight, Filter, and View Information for Links in a Model

This example shows how to work with a Simulink model that has links using the Requirements Viewer app. You can highlight links, view information about a link, and filter link highlighting based on specified keywords.

Open the `slvnvdemo_fuelsys_officereq` model.

```
open_system('slvnvdemo_fuelsys_officereq')
```

In the **Apps** tab, click **Requirements Viewer**.

#### Highlight Links in a Model

To highlight model objects that have associated outgoing links, in the **Requirements Viewer** tab, click **Highlight Links**.

Model objects that have associated outgoing links are highlighted in yellow, such as the block called `MAP sensor`.

Objects that contain child objects with associated outgoing links are highlighted with an orange outline, such as the `fuel rate controller` subsystem.

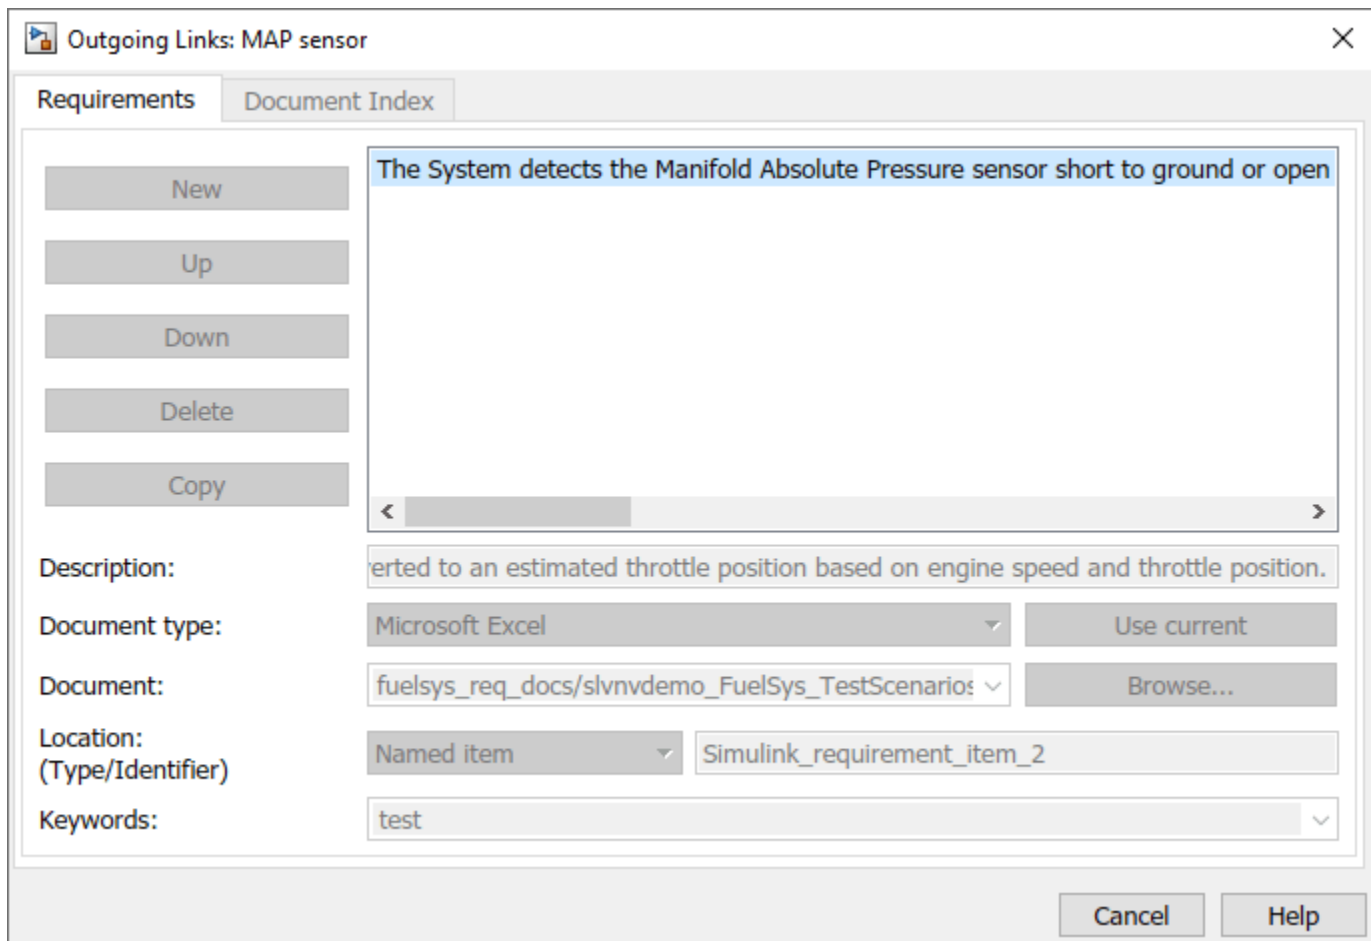

Model objects that do not have associated links are dimmed.

To remove highlighting, click the **Highlight Links** button again. When highlighting links, ensure that you don't have any keyword filters applied because this can prevent some objects from becoming highlighted. For more information, see Filter Highlighted Links on page 17-48.

### View Information About a Link

After you've identified the model objects that have associated outgoing links, you can view information about those links. Right-click the MAP sensor block and select **Requirements > Open Outgoing Links dialog**.

The Outgoing Links dialog displays information about the link and its destination. In this case, the link destination is a requirement stored in an external document. The dialog displays the:

- Link description
- Document type
- Document name and relative location
- Location identifier for link destination
- Link keywords

### Filter Highlighted Links

Links in your model can have associated keywords. You can categorize a link with a keyword. For example, the `slvnvdemo_fuelsys_officereq` model uses the keywords `design`, `requirement`, and `test`.

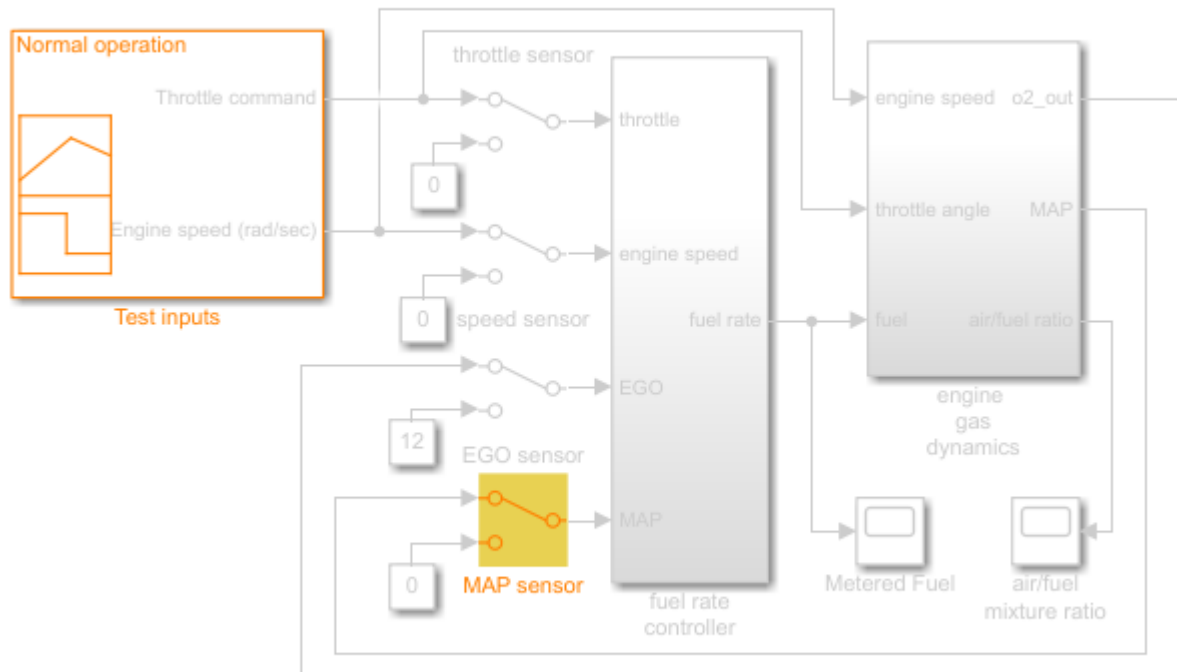

In the `slvnvdemo_fuelsys_officereq` model, the `MAP sensor` block has the specified keyword `test`, which was found in View Information about a Link on page 17-47. Filter the highlighted links so that only blocks that have associated links with the keyword `test` are highlighted:

- 1 In the **Requirements Viewer** tab, click **Link Settings**.
- 2 In the Requirement Settings dialog, in the **Filters** tab, select **Filter links by keywords when highlighting and reporting requirements**.

- 3 In the **Include links with any of these keywords** field, enter test.
- 4 Click **Close**.
- 5 In the **Requirements Viewer** tab, click **Highlight Links**.

Note that the fuel rate controller subsystem is not highlighted when the filter is applied.

## Fault-Tolerant Fuel Control System

Copyright 1997-2010 The MathWorks, Inc.

You can also use the **Exclude links with any of these keywords** field to omit blocks from highlighting that have associated links with the specified keyword. You can enter multiple keywords in the **Include links with any of these keywords** and **Exclude links with any of these keywords** fields. If you select **Apply same filters to link labels**, when you right-click blocks that have links but are not highlighted, the link is greyed out and you cannot navigate to the destination.

To clear the filter, clear **Filter links by keywords when highlighting and reporting requirements**, or remove all keywords from the **Include links with any of these keywords** and **Exclude links with any of these keywords** fields.

### Cleanup

Close the open models without saving changes.

```
bdclose all;
```

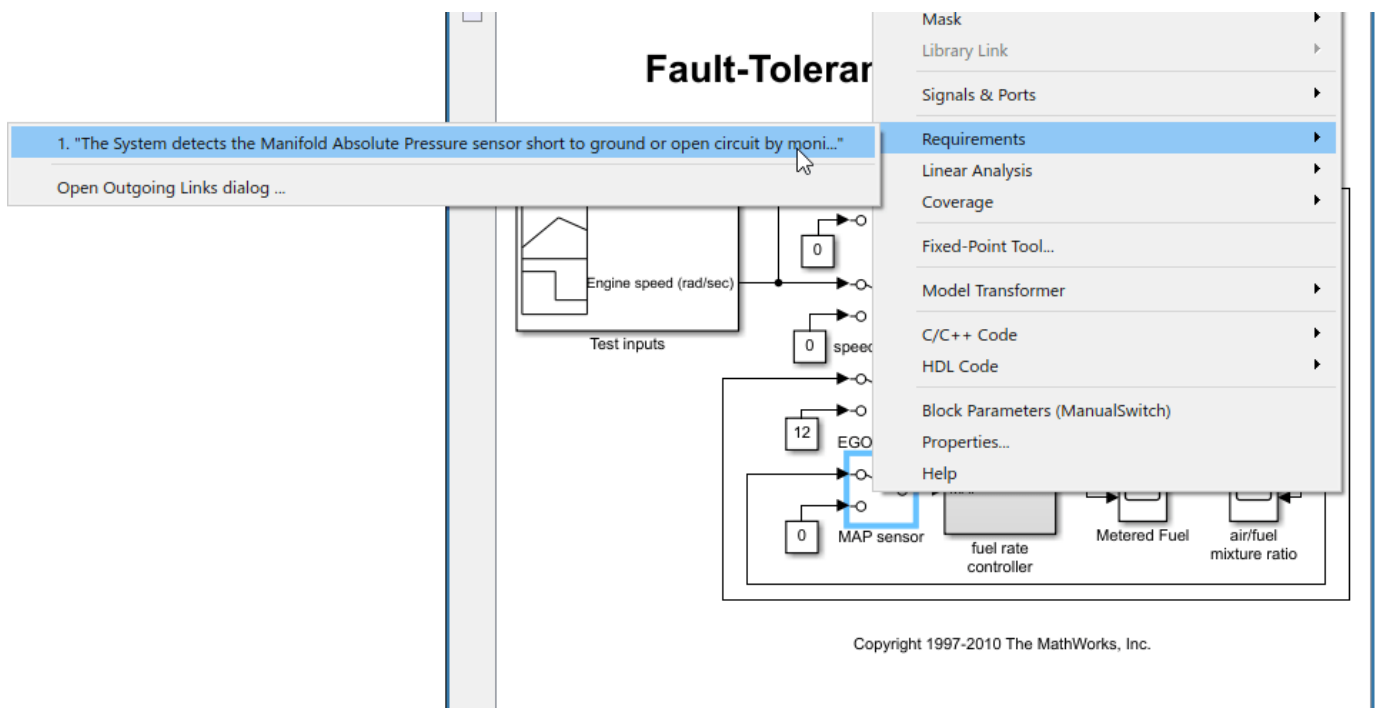

### Navigate to Externally Stored Requirements from a Model

This example shows how to navigate to linked requirements that are stored in an external document from a model using the **Requirements Viewer** app in Simulink®. If a model object is linked to a requirement that is stored in an external document, such as a Microsoft® Word or Microsoft Excel® file, or an IBM® Rational® DOORS® or IBM DOORS Next project, then you can navigate to the requirement in the external document from the associated block in Simulink.

Open the `slvnvdemo_fuelsys_officereq` model.

```
open_system('slvnvdemo_fuelsys_officereq')
```

The block called `MAP sensor` is linked to a requirement in a Microsoft Excel file. To navigate to the requirement in the Excel file, right-click the `MAP sensor` block, select **Requirements**, and click the link at the top of the context menu.

The associated requirement opens in Excel.

19	1.2.1.3 MAP Sensor failure	T1.2.1-3: Manifold Pressure Sensor Short to Ground, Open Circuit	During normal mode of operation the MAP sensor reading shows value below the callibratable treshold	The System detects the Manifold Absolute Pressure sensor short to ground or open circuit by monitoring when the signal is below a calibratable threshold. The failure is detected within 100mSec of the occurrence and the MAP sensor reading is reverted to an estimated throttle position based on engine speed and throttle position.
----	----------------------------	---	---	--

If you don't have Requirements Toolbox™ installed, then you cannot navigate to requirements that are stored in a Requirements Toolbox requirement set.

**Cleanup**

Close the open models without saving changes.

bdclose all;

# Project Dependency Analysis

---

- “What Is Dependency Analysis?” on page 18-2
- “Dependency Analyzer Scope and Limitations” on page 18-4
- “Run a Dependency Analysis” on page 18-7
- “Explore the Dependency Graph, Views, and Filters” on page 18-9
- “Perform an Impact Analysis” on page 18-17
- “Check Dependency Results and Resolve Problems” on page 18-23
- “Find Requirements Documents in a Project” on page 18-29
- “Export Dependency Analysis Results” on page 18-30

## What Is Dependency Analysis?

Every design, whether it is a Simulink model or a project, requires a set of files and products to run successfully. Dependencies include data files, model references, linked libraries, MATLAB and C/C++ code, Stateflow charts, and requirements documents.

### Dependency Analysis for Projects

You perform a dependency analysis to analyze project structure and discover required files and products. You can use the dependency graph to identify all required files and products, and perform an impact analysis.

On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**. For more details, see “Run a Dependency Analysis” on page 18-7.

With the Dependency Analyzer, you can:

- Find required products and add-ons. See “Find Required Products and Add-Ons” on page 18-19.
- Check project dependencies and problems before sharing, packaging, or submitting your project to source control. See “Check Dependency Results and Resolve Problems” on page 18-23.
- Perform an impact analysis to find the impact of changing particular files. See “Perform an Impact Analysis” on page 18-17.
- Export the dependency analysis results as workspace variables, or `.graphml` files, or send the files for custom task processing. Exporting the results enables further processing or archiving. See “Export Dependency Analysis Results” on page 18-30.

---

**Tip** For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see “Perform Impact Analysis with a Project”.

---

### Dependency Analysis for Models

You perform a dependency analysis to examine models, subsystems, and libraries referenced directly or indirectly by the model. You can use the dependency graph to identify all required files and products.

On the **Modeling** tab, on the far right of the **Design** section, click the arrow. Under **Dependencies**, click **Dependency Analyzer**.

- You can explore model dependencies using the model hierarchy or the model instances views. For more details, see “Analyze Model Dependencies” on page 17-40.
- To package, share, or put your design under source control, create a project from your model. For more details, see “Create a Project from a Model” on page 16-12. Perform a project dependency analysis to explore the dependency graph using source control and project-specific views.

## **See Also**

### **Related Examples**

- “Perform an Impact Analysis” on page 18-17
- “Find Requirements Documents in a Project” on page 18-29

## Dependency Analyzer Scope and Limitations

### Analysis Scope

The Dependency Analyzer identifies the required files and add-ons for your project or model. The analysis covers a wide range of dependencies, including model references, subsystem references, linked libraries, MATLAB and C/C++ code, Stateflow charts, data files, S-functions, and requirements documents.

When the Dependency Analyzer encounters MATLAB code, such as in a model or block callback, or in a .m file S-function, it attempts to identify the files it references. For more information, see “Analysis Limitations” on page 18-4.

For files under the MATLAB root folder, the Dependency Analyzer only shows required products. It does not analyze dependencies.

The Dependency Analyzer identifies dependencies inside user-defined add-ons and dependencies that were introduced by code generation or by MATLAB code in model parameters. These options are off by default because they can be time consuming for large designs.

To specify the scope of the analysis, in the Dependency Analyzer toolstrip, click **Analyze** and select one or more of the following options:

Option	Default	Description
<b>C/C++ Code</b>	On	Analyze dependencies introduced by C/C++ code files.
<b>Add-Ons</b>	Off	Analyze dependencies inside add-ons.
<b>Model Parameters</b>	Off	Analyze dependencies introduced by MATLAB code in model block parameters.
<b>Generated Code Traceability</b>	Off	Analyze dependencies introduced by code generated from a model.

### Analysis Limitations

- The Dependency Analyzer has limitations specific to MATLAB code analysis:
  - The Dependency Analyzer only identifies function input arguments when they are literal character vectors or strings:

```
load("mydatafile")
load mydatafile
```

If you define a file name as a variable and pass it to a function, the Dependency Analyzer is unable to identify the dependency. In the following example, since the code is not executed, the Dependency Analyzer does not have the value of `str`. The Dependency Analyzer might report a missing dependency.

```
str = "mydatafile";
load(str);
```

This limitation extends to functions similar to `load`, such as `fopen`, `xlsread`, `importdata`, `dlmread`, `eval`, or `imread`.

- The Dependency Analyzer does not always determine type automatically. Depending on the way you call an object method, the Dependency Analyzer might confuse a method with a function and report a missing dependency.

In MATLAB, you can call an object method in two different ways. For example, for an object `p`, you can call the method `addFile` using the function notation:

```
p = currentProject;
addFile(p, "myfile");
```

or by using the dot notation:

```
p = currentProject;
p.addFile("myfile");
```

If you do not declare the type of `p` explicitly, the Dependency Analyzer might confuse a method call that uses a function notation with a function call. The analyzer reports `addFile` as a missing dependency.

To work around this limitation, use dot notation to call a method or use arguments to explicitly declare the variable type in your function:

```
function myfunction(p)
    arguments
        p matlab.project.Project
    end
    addFile(p, "myfile");
end
```

- The Dependency Analyzer does not report a dependency to a class that is referenced using a method call.
- When analyzing a file, the Dependency Analyzer does not consider the context in which it is called. When a file *A* calls a file *B*, the Dependency Analyzer does not know about data used in *B* but defined in *A*. The Dependency Analyzer reports this data as a missing file. To work around this limitation, pass this data explicitly using function input arguments.

For example, when you analyze a Simulink subsystem that is referenced in a model that links to a data dictionary and the subsystem uses an enumeration that you define in the data dictionary, the analysis cannot access the enumeration and reports this data as a missing file.

- The Dependency Analyzer might not report certain blocksets required by a model.

The Dependency Analyzer is unable to detect blocksets that do not introduce dependencies on any files, such as Fixed-Point Designer™.

To include dependencies that the analysis cannot detect, add the file that introduces the dependency to your project. To create a project from your model, see “Create a Project from a Model” on page 16-12.

- The Dependency Analyzer might not detect required support packages. It lists required add-ons, including apps and toolboxes.
- The Dependency Analyzer might not report dependencies for dynamic content in masked blocks.

Based on the parameters of the masked blocks, dynamic masks can modify the masked subsystem and change the block dependencies. If the dynamic mask is in a library, the Dependency Analyzer is unable to detect the dynamic changes.

- The Dependency Analyzer does not support Simulink functions called from MATLAB function blocks.
- Some MathWorks products and add-ons share code and Simulink libraries. The Dependency Analyzer might report dependencies on all of them.

To investigate where shared code is used, in the **Properties** panel, in the **Products** section, point

to a product under **Shared Functionalities Among:** and click the search folder icon  .

- The Dependency Analyzer analyzes project code without evaluating its content, therefore:
  - The Dependency Analyzer does not add global variables in executed functions.
  - The Dependency Analyzer analyzes code inside logic statements, even if it is not executed. In the following example, the code is not executed but the Dependency Analyzer reports a missing dependency on Simulink.

```
if false
    load_system(vdp)
end
```

- “Find Requirements Documents in a Project” on page 18-29

## Run a Dependency Analysis

---

**Note** You can analyze only files that are in your project. If your project is new, add files to the project before running a dependency analysis. See “Add Files to the Project” on page 16-21.

---

To investigate dependencies, run a dependency analysis on your project. On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**. Alternatively, in the project **Views** pane, select **Dependency Analyzer** and click **Analyze**.

To analyze the dependencies of specific files, in the dependency graph, select the files. In the **Impact Analysis** section, click **All Dependencies** or use the context menu and select **Find All Dependencies**.

To analyze the dependencies inside add-ons, select **Analyze > Add-Ons**. For more details about available options, see “Analysis Scope” on page 18-4.

You can also check dependencies directly in Project. In the Project **Files** view, right-click the project files you want to analyze and select **Find Dependencies**.

After you run the first dependency analysis of your project, subsequent analyses incrementally update the results. The Dependency Analyzer determines which files changed since the last analysis and updates the dependency data for those files. However, if you update add-ons or installed products and want to discover dependency changes in them, you must perform a complete analysis. To perform a complete analysis, in the Dependency Analyzer, click **Analyze > Reanalyze All**.

---

**Note** In the Simulink Editor, if an open model, library, or chart belongs to a project, you can find file dependencies. On the **Simulation** tab, select **Project > Run Dependency Analysis**. Simulink analyzes the whole project and shows all dependencies for the file.

---

For next steps, see:

- “Find Required Products and Add-Ons” on page 18-19
- “Find Dependencies of Selected Files” on page 18-20
- “Check Dependency Results and Resolve Problems” on page 18-23

**Tip** To try a dependency analysis on example files, see “Perform Impact Analysis with a Project”.

## See Also

### Related Examples

## Explore the Dependency Graph, Views, and Filters

If you have not yet run an analysis, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

The dependency graph displays your project structure, dependencies, and how files relate to each other. Each item in the graph represents a file and each arrow represents a dependency. For more details, see “Investigate Dependency Between Two Files” on page 18-9.

By default, the dependency graph shows all files required by your project. To help you investigate dependencies or a specific problem, you can simplify the graph using one of the following filters:

- Use the **Views** to color the files in the graph by type, class, source control status, and label. See “Color Files by Type, Status, or Label” on page 18-10.
- Use the check boxes in the **Legend** pane to filter out a group of files.
- Use the **Impact Analysis** tools to simplify the graph. See “Find Dependencies of Selected Files” on page 18-20.

### Select, Pan, and Zoom

- To select an item in the graph, click it.

To select multiple files, press **Shift** and click the files.

To select all files of a certain type, hover the pointer over the corresponding item in the **Legend** pane and click the **Add to selection** icon.

To clear all selection, click the graph background.

To remove all files of a certain type from the current selection, hover the pointer over the corresponding item in the **Legend** pane and click the **Remove from selection** icon.

- To open a file, double-click it.
- To pan the dependency graph, hold the **Space** key, click and drag the mouse. Alternatively, press and hold the mouse wheel and drag.

For large graphs, navigate using the **Overview** pane.

- To zoom in and out, in the **Navigate** section, click **Zoom In** and **Zoom Out**. Alternatively, use the mouse wheel.
- To center and fit the dependency graph to view, in the **Navigate** section, click **Fit to View**. Alternatively, press the **Space** bar.

### Investigate Dependency Between Two Files

To see more information about how two files are related, select their dependency arrow. In the **Properties** pane, in the **Details** section, you can see the full paths of the files you are examining, the dependency type (such as function call, inheritance, S-function, data dictionary, model reference, and library link), and where the dependency is introduced.

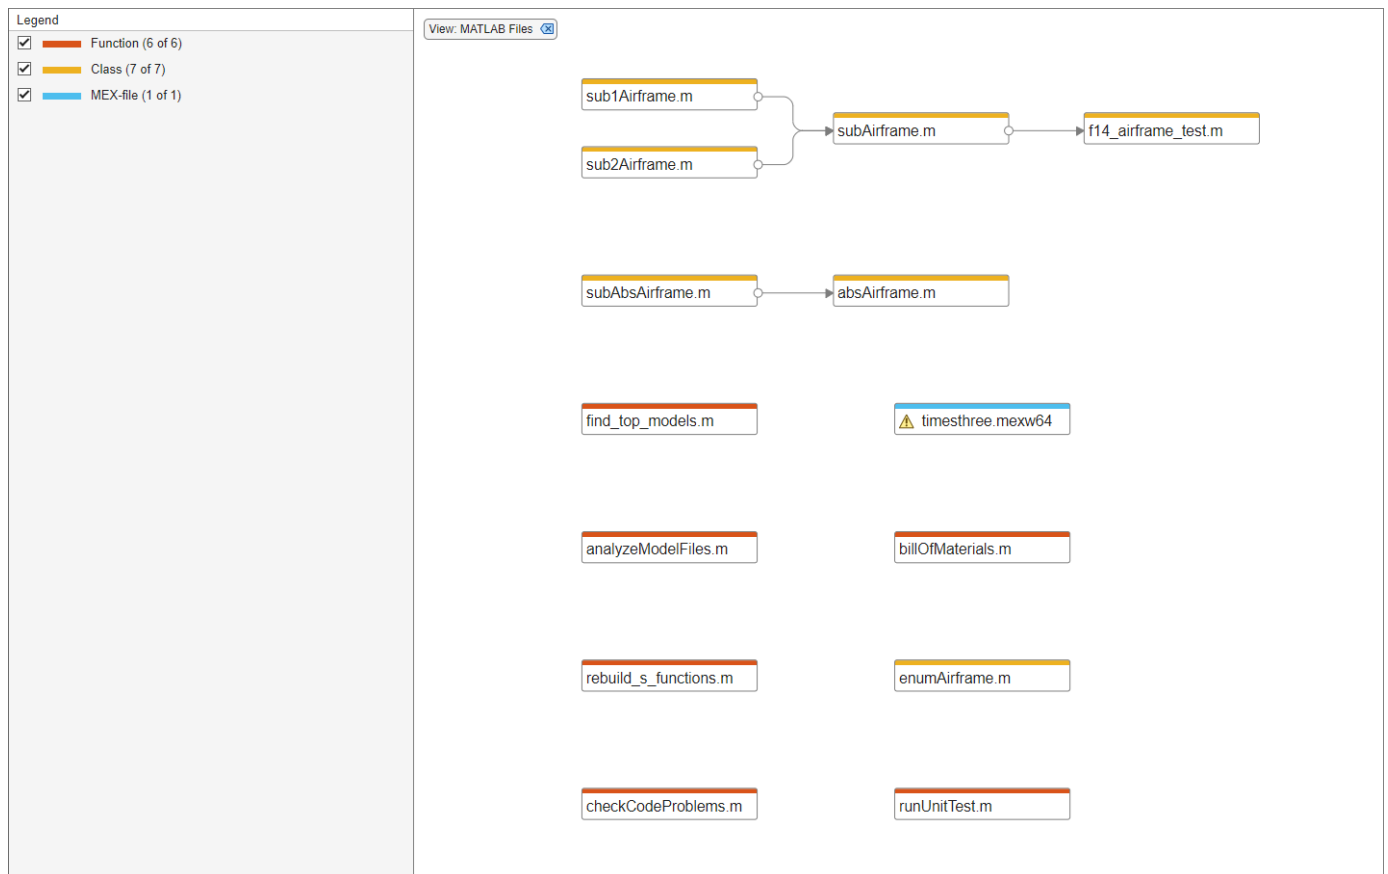

To open the file and highlight where the dependency is introduced, in the **Details** section, click the link under **Impacted**.

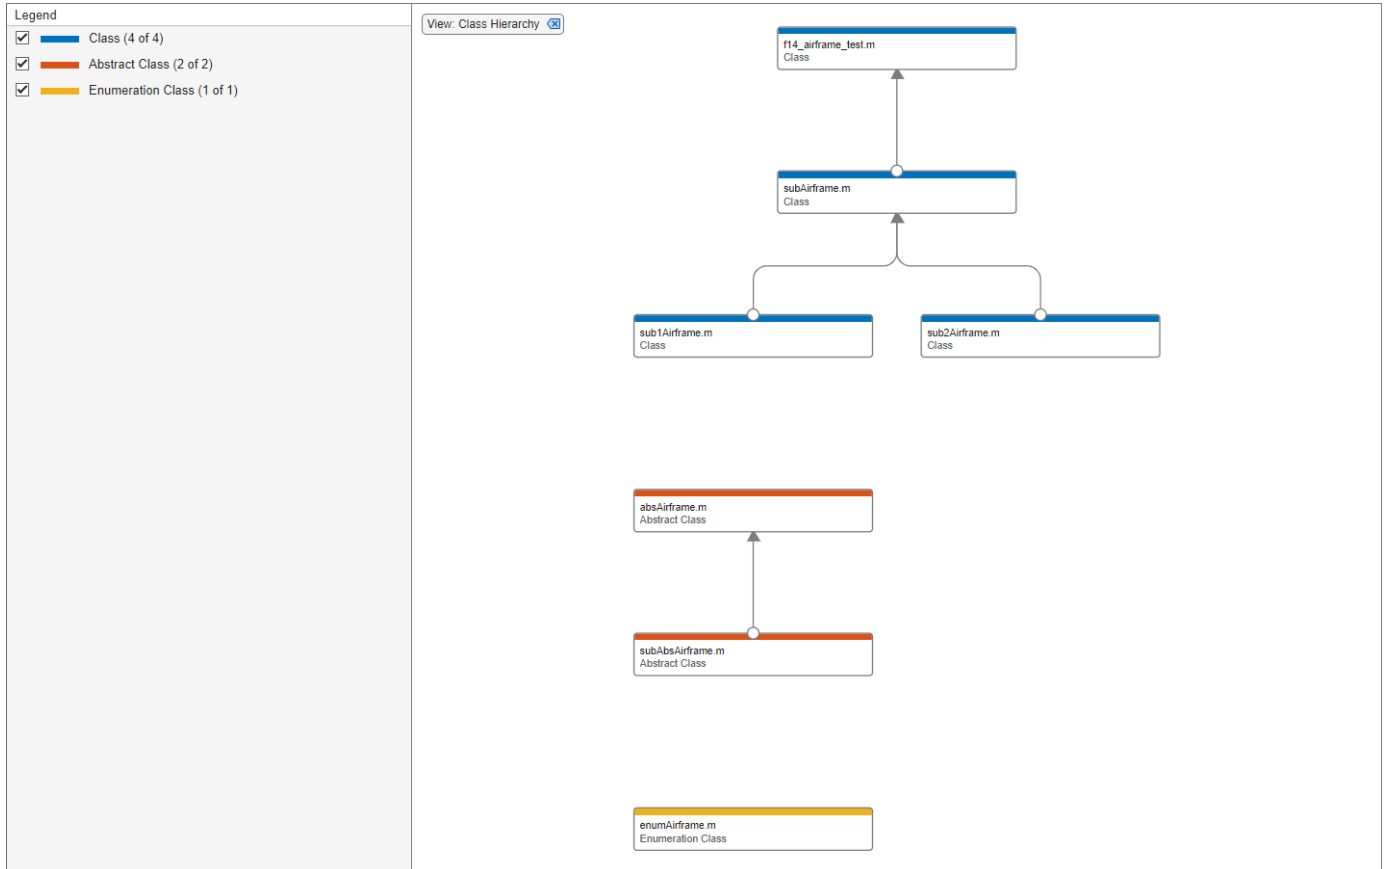

## Color Files by Type, Status, or Label

Explore the different views in the **Views** section of the Dependency Analyzer toolstrip to explore your project files dependencies.

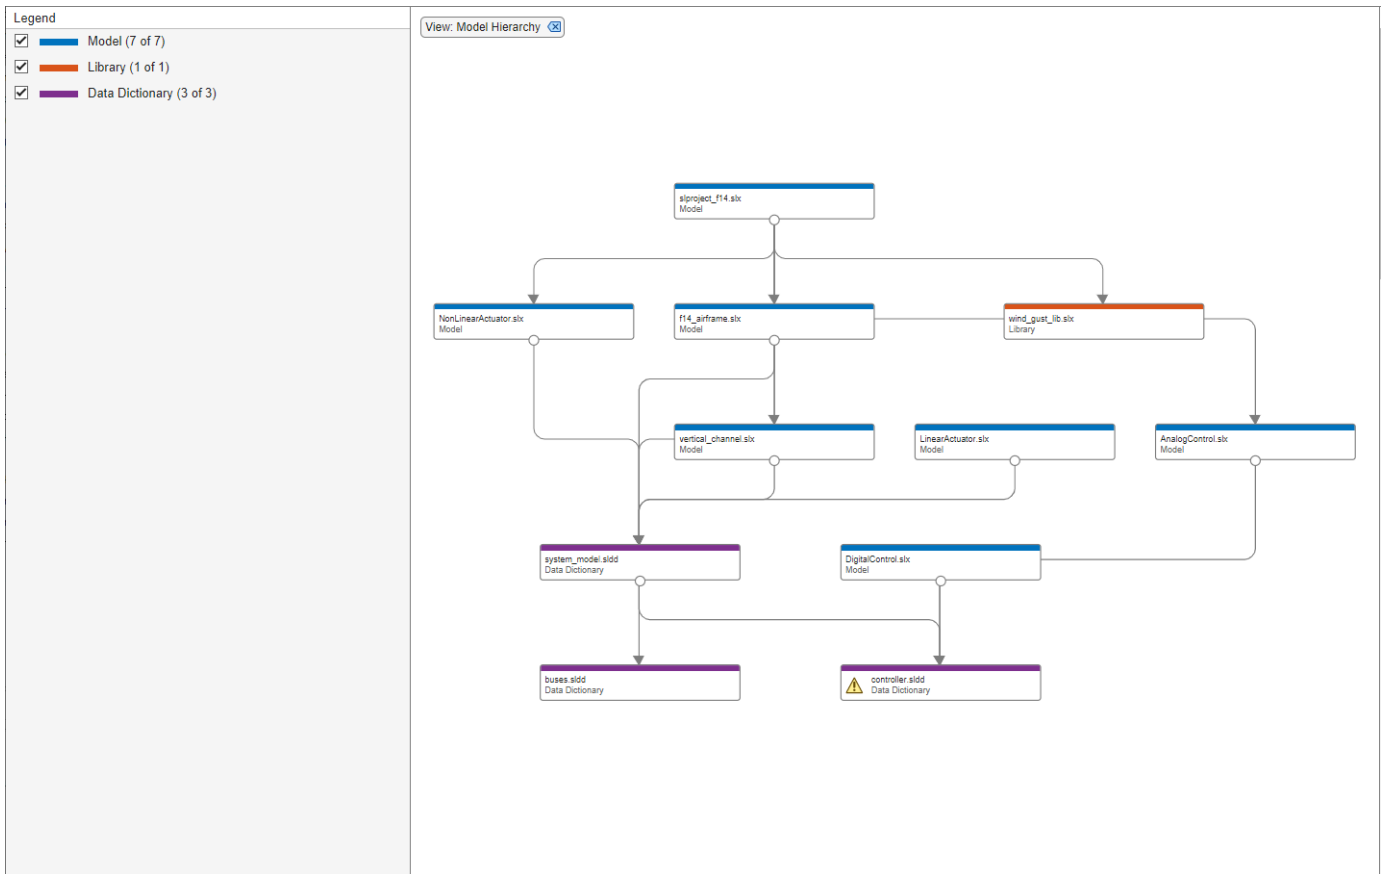

- The **MATLAB Files** view shows only MATLAB files (such as `.m`, `.mlx`, `.p`, `.mlapp`, `.fig`, `.mat`, and `.mex`) in the view and colors them by type.

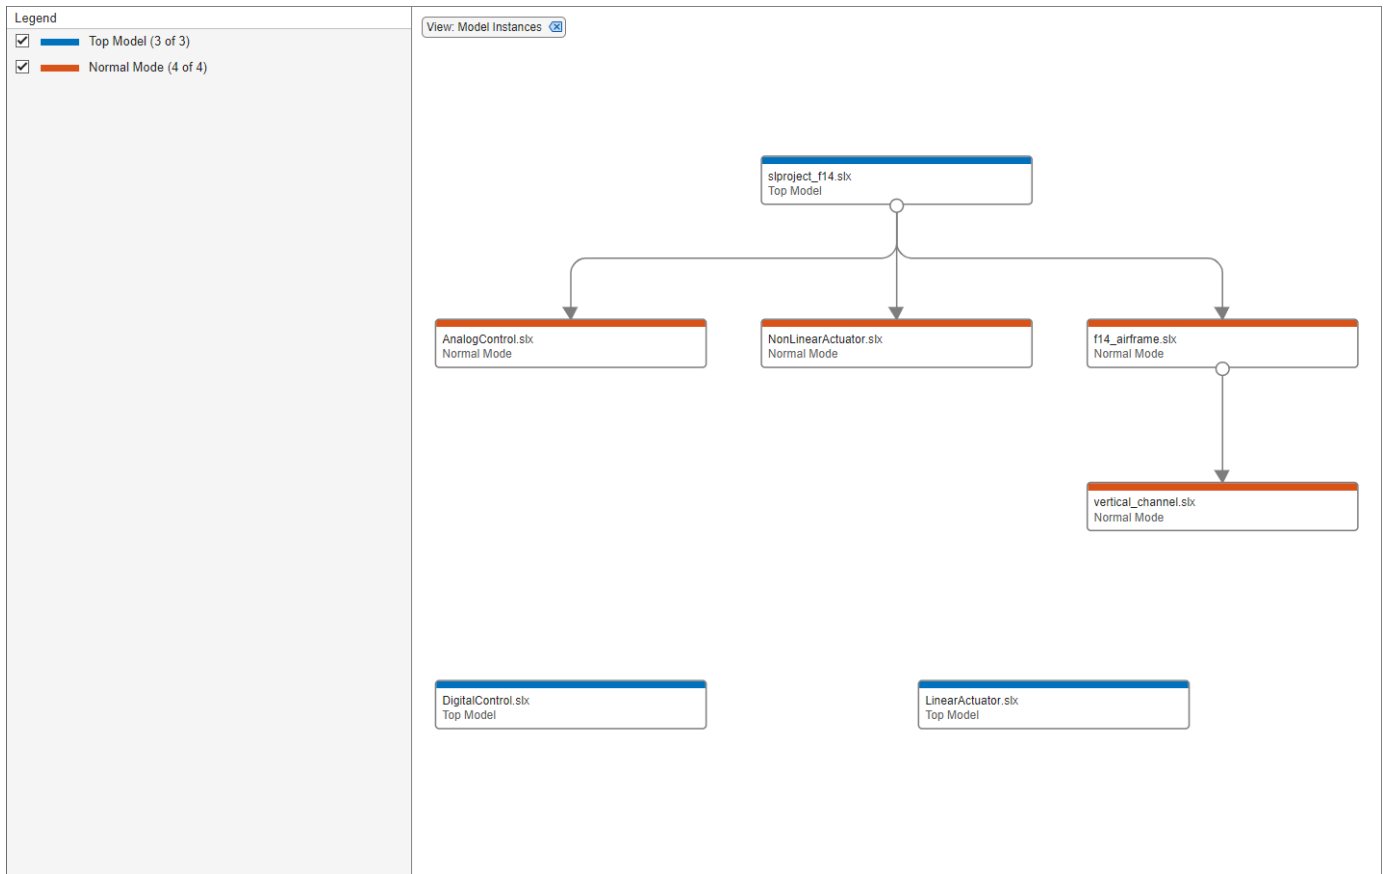

- The **Class Hierarchy** view shows the class inheritance graph and colors the files by type (class, enumeration class, or abstract class). If the class is not on the search path, the Dependency Analyzer cannot determine the class type.

- The **Model Hierarchy** view shows the model, subsystem, library and data dictionary files referenced by a top model. A referenced file appears only once in the view even if it is referenced more than once in the model. For more details, see "Model Hierarchy View" on page 17-41.

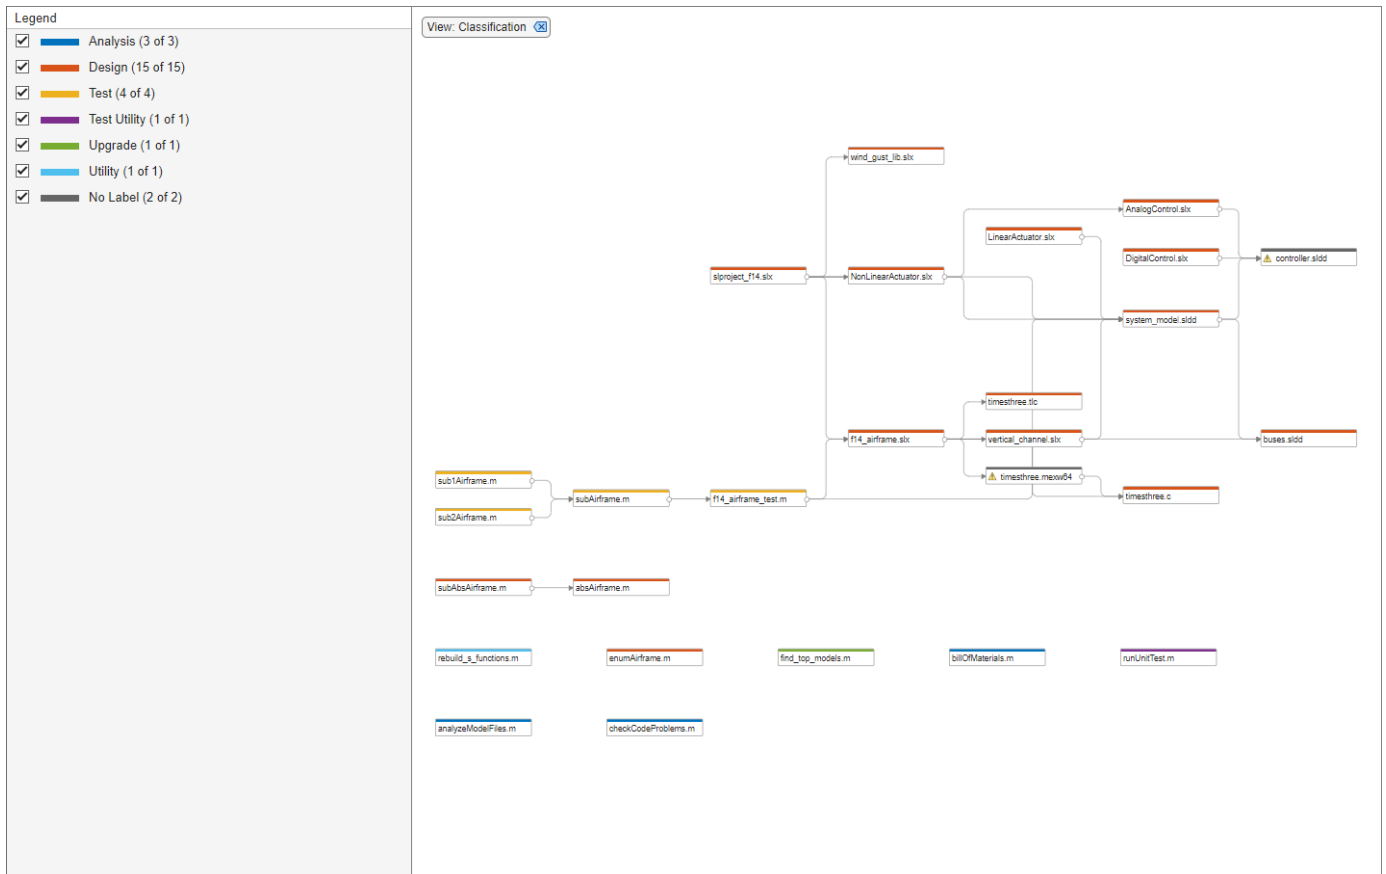

- The **Model Instances** view shows every instance to a model in a model reference hierarchy. A top model is at the root of this hierarchy. If a model hierarchy references the same model more than once, the referenced model appears multiple times in the instance view. For more details, see “Model Instances View” on page 17-42.

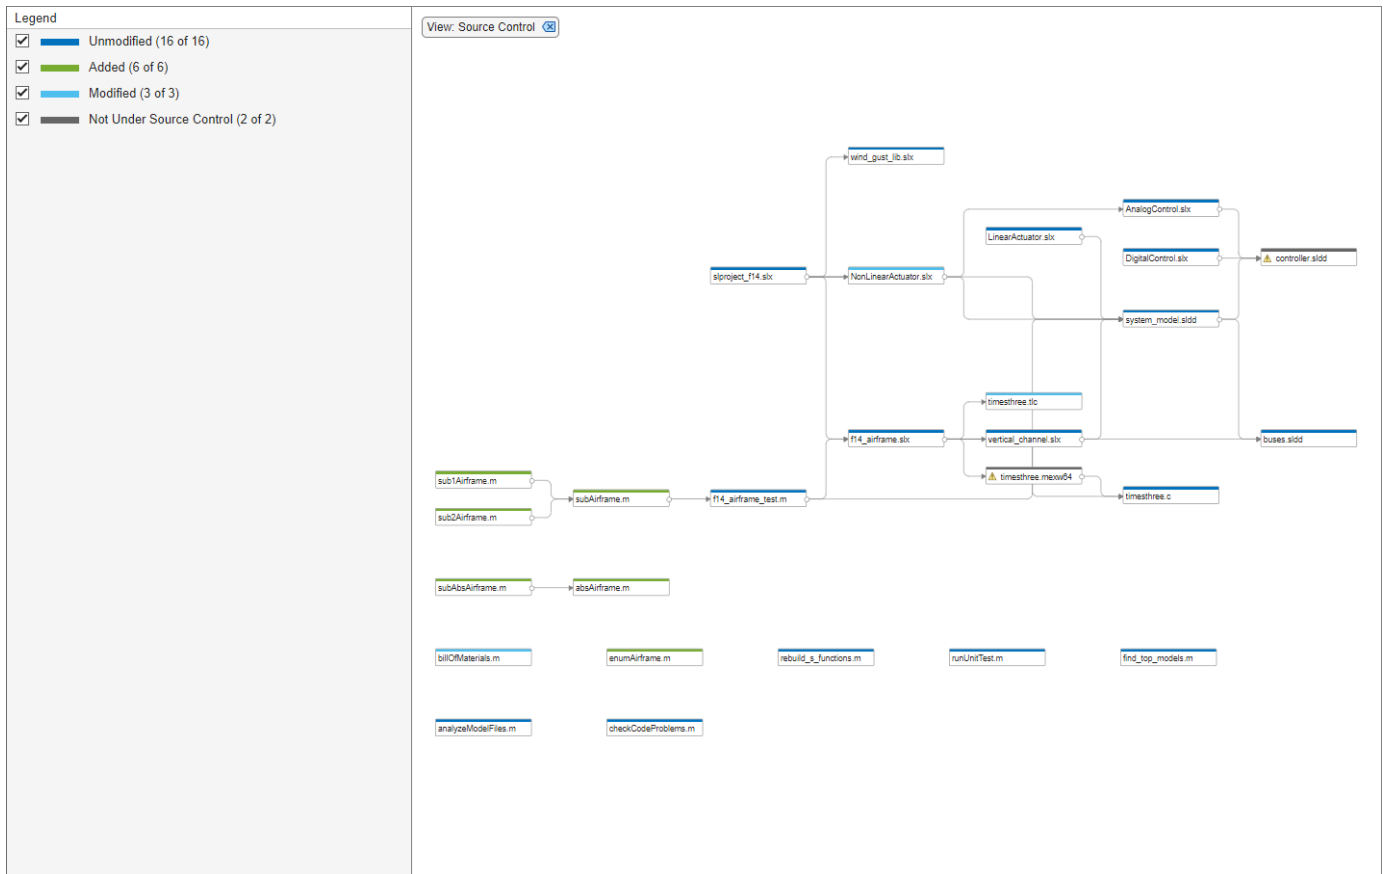

- The **Classification** view shows all files in the graph and colors them by file label (such as test, design, and artifact).

Use the classification view to identify which tests you need to run to validate the changes in your design. For more information, see “Identify Tests to Run” on page 18-21.

- The **Source Control** view shows all files in the graph and colors them by source control status. This view is only enabled if your project is under source control.

Use the source control view to find modified files in your project and to examine the impact of these changes on the rest of the project files. For more information, see “Investigate Impact of Modified Files” on page 18-21.

- **Restore to Default** clears all filters.

This is equivalent to manually removing all of the filters. Filters appear at the top of the graph. For example, if you have the **Source Control** view selected, you can remove it by clicking

## Apply and Clear Filters

In large projects, when investigating problems or dependencies, use the different filters to show only the files you want to investigate:

- To filter out a subgroup of files from the graph, such as files labeled *test* or modified files, use the check boxes in the **Legend** pane. To remove the legend filter, click the **Legend Filter**

- To color the files in the graph by type, class, label, or source control status, use the filtered **Views**. To remove the view filter, click **View: viewName** at the top of the graph. For example, if you have

the **Source Control** view selected, you can remove it by clicking

- To show only the dependencies of a specific file, select the file and, in the **Impact Analysis** section, click **All Dependencies**. The graph shows the selected file and all its dependencies. To

reset the graph to show all project dependencies, remove the filter at the top of the graph. For example, if you filtered by all dependencies of `NonLinearActuator.slx`, to remove the filter

click 

- To clear all filters and restore the graph to show all analyzed dependencies in the project, click **Restore to Default**. Alternatively, manually remove all filters at the top of the graph.

## Perform an Impact Analysis

### In this section...

“About Impact Analysis” on page 18-17  
 “Run a Dependency Analysis” on page 18-17  
 “Find Required Products and Add-Ons” on page 18-19  
 “Find Dependencies of Selected Files” on page 18-20

### About Impact Analysis

In a project, you can use impact analysis to find out the impact of changing particular files. Investigate dependencies visually and explore the structure of your project. Analyze selected or modified files to find their required files and the files they affect. Impact analysis can show you how a change affects other files before you make the change. For example, you can:

- Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
- Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification, and help you find the tests you need to run.

After performing dependency analysis, you can open or label the files, export the results as workspace variables, or reloadable files, or send files for custom task processing. Exporting the results enables further processing or archiving of impact analysis results.

---

**Tip** For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see “Perform Impact Analysis with a Project”.

---

### Run a Dependency Analysis

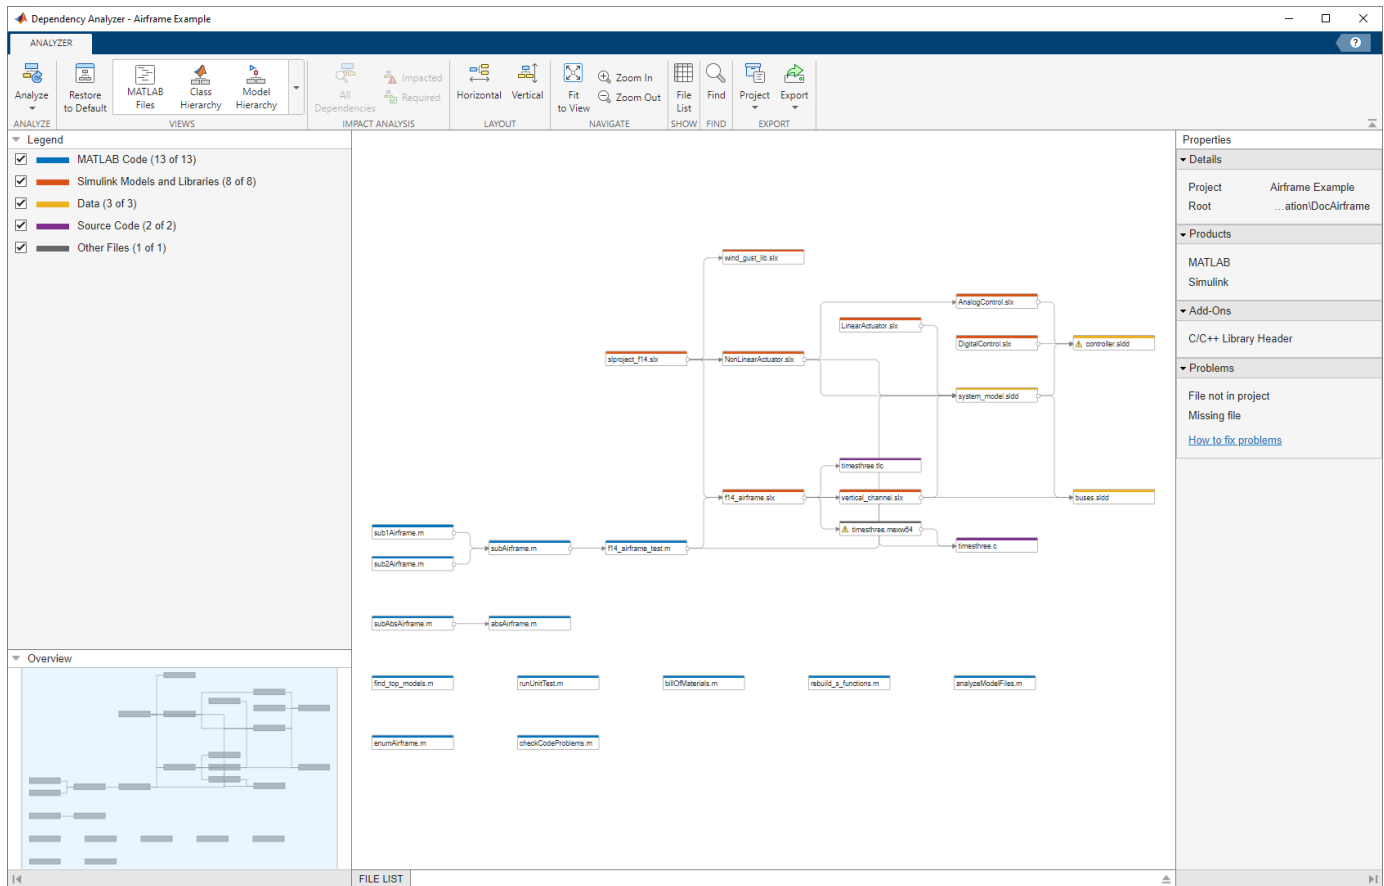

Before running a dependency analysis on a project, make sure that you have added all your files to the project. For more information, see “Add Files to the Project” on page 16-21.

To start analyzing your project, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**. Alternatively, in the project **Views** pane, select **Dependency Analyzer** and click **Analyze**.

To analyze the dependencies of specific files, in the dependency graph, select the files. In the **Impact Analysis** section, click **All Dependencies** or use the context menu and select **Find All Dependencies**.

To analyze the dependencies inside add-ons, select **Analyze > Add-Ons**. For more details about available options, see “Analysis Scope” on page 18-4.

You can also check dependencies directly in Project. In the Project **Files** view, right-click the project files you want to analyze and select **Find Dependencies**.

The dependency graph shows:

- Your project structure and its file dependencies, including how files such as models, libraries, functions, data files, source files, and derived files relate to each other.
- Required products and add-ons.
- Relationships between source and derived files (such as `.m` and `.p` files, `.slx` and `.slxp`, `.ssc` and `.sscp`, or `.c` and `.mex` files), and between C/C++ source and header files. You can see what code is generated by each model, and find what code needs to be regenerated if you modify a model.
- Warnings about problem files, such as missing files, files not in the project, files with unsaved changes, and out-of-date derived files.

You can examine project dependencies and problem files using the **File List**. In the toolbar, click **File List**.

After you run the first dependency analysis of your project, subsequent analyses incrementally update the results. The Dependency Analyzer determines which files changed since the last analysis and updates the dependency data for those files. However, if you update add-ons or installed products and want to discover dependency changes in them, you must perform a complete analysis. To perform a complete analysis, in the Dependency Analyzer, click **Analyze > Reanalyze All**.

For next steps:

- “Find Required Products and Add-Ons” on page 18-19
- “Find Dependencies of Selected Files” on page 18-20
- “Check Dependency Results and Resolve Problems” on page 18-23

**Tip** To try a dependency analysis on example files, see “Perform Impact Analysis with a Project”.

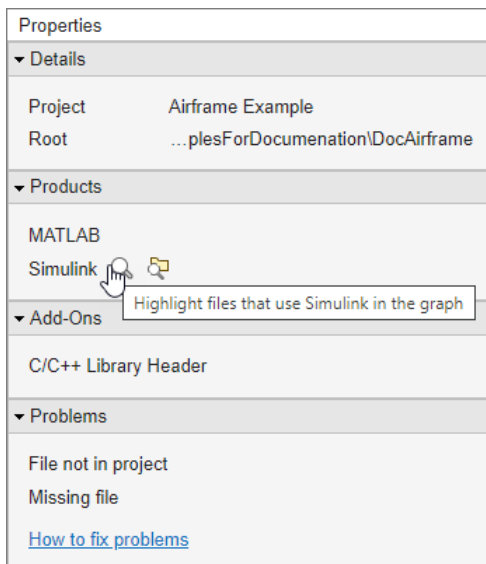

## Find Required Products and Add-Ons

After running a dependency analysis on a project, the graph shows the required add-ons for the whole project or for selected files. You can see which products are required to use the project or find which file is introducing a product dependency.

In the Dependency Analyzer, in the **Properties** pane, the **Product** section displays the required products for the whole project. To view products required by a specific file, select a file by clicking the graph.

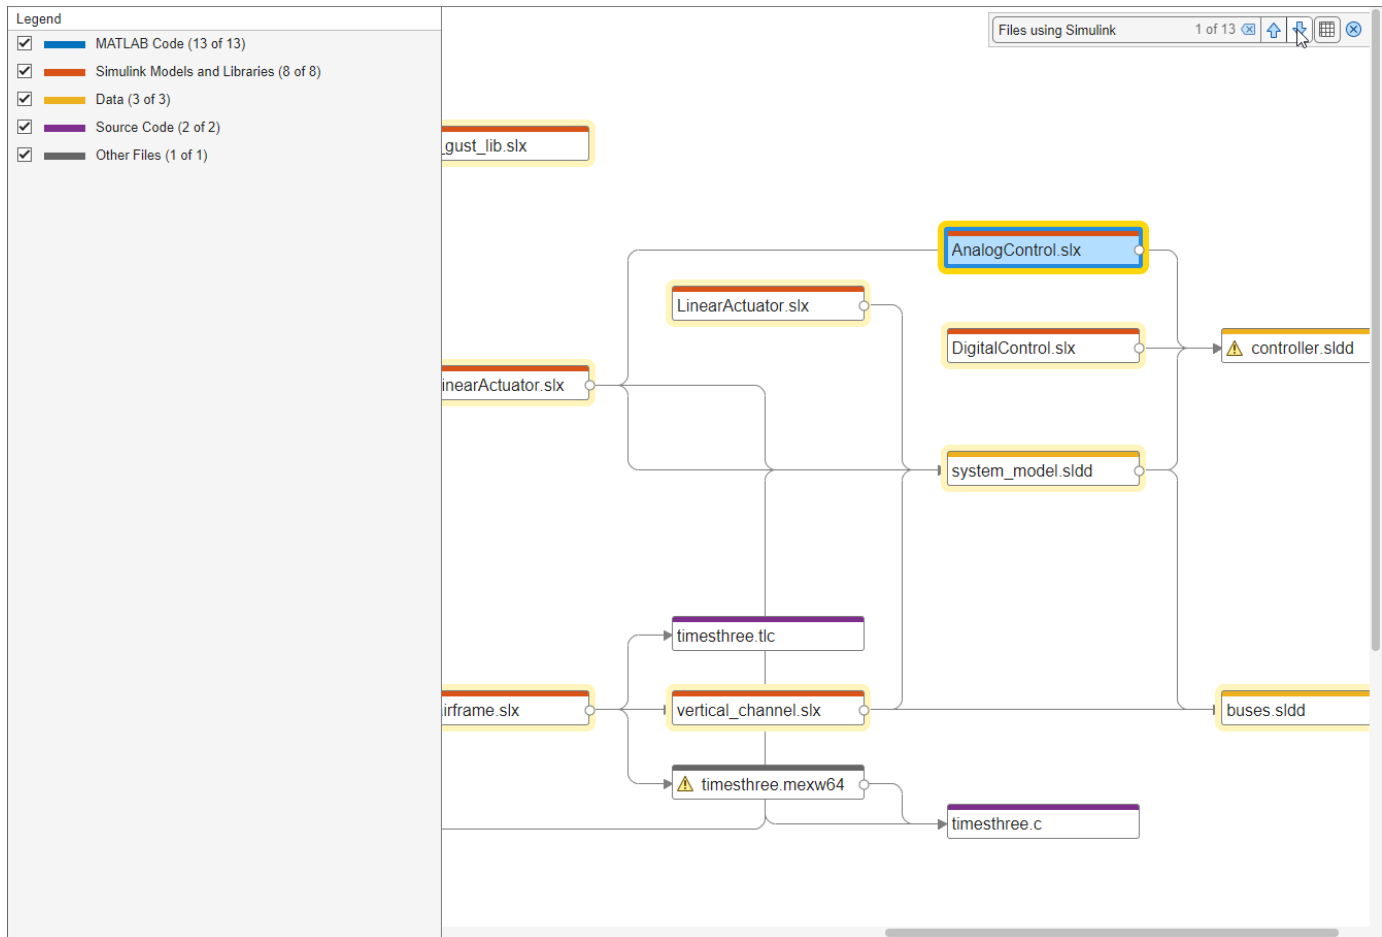

To find which file is introducing a product dependency, point to the product name and click the

magnifying glass icon . The graph highlights the files that use the selected product.

To go through these files, use the arrows in the search box (e.g., **Files using "productName"**).

To undo the highlighting, close the search box.

To investigate further, you can list the files that use a product and examine where the dependency is introduced. In the **Products** section, in the **Properties** pane, point to a product and click the search folder icon .

If a required product is missing, the products list labels it as missing. The product is also listed in the **Problems** section as **productName not installed**. To resolve a missing product, install the product and rerun the dependency analysis.

## Find Dependencies of Selected Files

After a dependency analysis, to find out the impact of particular files, select files in the dependency graph use the context menu, or use controls in the legend, **View** and **Impact Analysis** sections of the Dependency Analyzer. You can simplify the graph by investigating dependencies of particular files.

To investigate the dependencies of a file after running a dependency analysis, in the dependency graph, select a file.

- In the **Impact Analysis** section, click **All Dependencies**. The graph shows the selected file and all its dependencies.
- To show only files needed by the selected file to run properly, click **Required**.

- To show only files impacted by a potential change to the selected file, click **Impacted**.

Finding these dependencies can help you identify the impact of a change and identify the tests you need to run to validate your design before committing the changes.

To investigate the dependencies of multiple files, click files while holding the **Shift** key. The **Impact Analysis** section displays how many files are selected.

To reset the graph, click the filter at the top of the graph. For example, if you had filtered by files impacted by `f14_airframe.slx`, click Impacted: f14\_airframe.slx.

### Investigate Impact of Modified Files

To examine the impact of the changes you made on the rest of the project files, perform an impact analysis on the modified files in your project.

- In the **Views** section, select the **Source Control** view. The graph colors the files by their source control status. The modified files are in light blue.
- Select all the modified files in the graph.

Alternatively, add all modified files to selection by clicking the **Add to selection** icon of an item in the **Legend** pane.

**Tip** If you changed a large number of files, you can also use the file list.

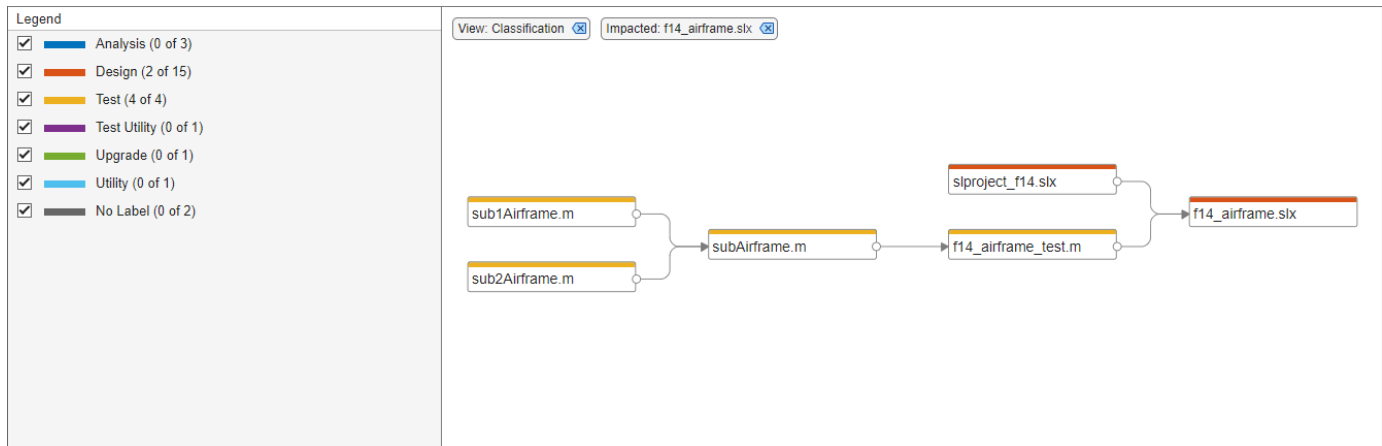

In the Dependency Analyzer toolstrip, click **File List**. Point to **Status** and click the arrow to sort the list by the source control status. Select all the modified files.

File Name	Status	File Path
billOfMaterials.m	Modified	custom_tasks\billOfMaterials.m
timesthree.tlc	Modified	lib\timesthree.tlc
NonLinearActuator.slx	Modified	models\NonLinearActuator.slx
absAirframe.m	Added	absAirframe.m
enumAirframe.m	Added	enumAirframe.m

- In the **Impact Analysis** section, click **Impacted**. Alternatively, use the context menu and select **Find Impacted**.

### Identify Tests to Run

To identify the tests you need to run to validate your design before committing the changes, use the **Classification** view when you perform an impact analysis on the file you changed.

- 1 In the **Views** section, select the **Classification** view. The graph colors the files by their project label.
- 2 Select the file you changed, for example `f14_airframe.slx`.
- 3 In the **Impact Analysis** section, click **Impacted**. Alternatively, use the context menu and select **Find Impacted**.

The example graph shows four tests you need to run to qualify the change made to `f14_airframe.slx`.

## See Also

### Related Examples

- “Run a Dependency Analysis” on page 18-7

- “Export Dependency Analysis Results” on page 18-30
- “Find Requirements Documents in a Project” on page 18-29
- “Automate Project Tasks Using Scripts” on page 17-19
- “Perform Impact Analysis with a Project”

## Check Dependency Results and Resolve Problems

If you have not yet run an analysis, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

When you run a dependency analysis, the Dependency Analyzer identifies problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. You can examine problem files using the dependency graph or the file list. When no file is selected, the **Properties** pane on the right shows the add-ons dependencies and a list of problems for the entire project.

Problem Message	Description	Fix
File not in project	The file is not in the project.	Right-click the problem file in the graph and select <b>Add to Project</b> .  To remove a file from the problem list without adding it to the project, right-click the file and select <b>Hide Warnings</b> .
Missing file	The file is in the project but does not exist on disk.	Create the file or recover it using source control.
	The file or variable cannot be found.	If this status is acceptable, right-click the file and select <b>Hide Warnings</b> .  Depending on the way you call an object method, the Dependency Analyzer might confuse a method with a function and report a missing dependency. See "Analysis Limitations" on page 18-4.
Outside project root	The file is outside the project root folder.	If this status is acceptable, right-click the file and select <b>Hide Warnings</b> . Otherwise, move it under the project root.  If required files are outside your project root, you cannot add these files to your project. This dependency might not indicate a problem if the file is on your path and is a utility or resource that is not part of your project. Use dependency analysis to ensure that you understand the design dependencies.
In unreferenced project	The file is within a project that is not referenced by the current project.	Add the project containing the file as a project reference
Unsaved changes	The file has unsaved changes in the MATLAB and Simulink editors.	Save the file.

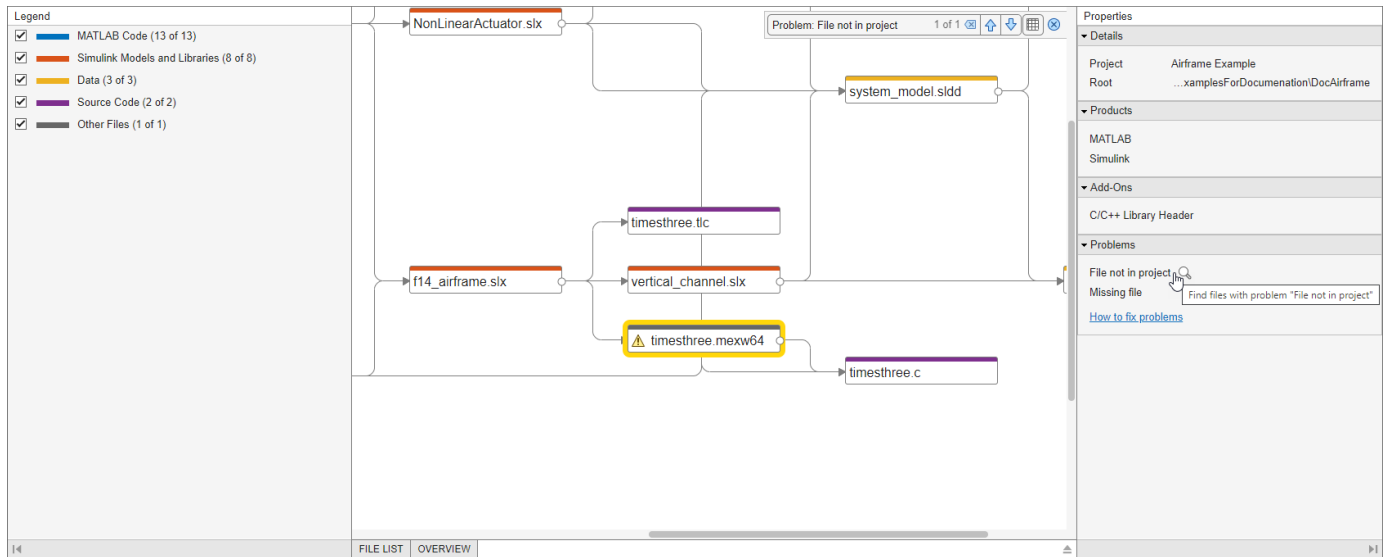

Problem Message	Description	Fix
Derived file out of date	The derived file is older than the source file it was derived from.	<p>Regenerate the derived file. If it is a .p file, you can regenerate it automatically by running the project checks. In MATLAB, on the <b>Project</b> tab, click the down arrow to expand the <b>Tools</b> gallery. Under <b>Project Checks</b>, click <b>Check Project</b>.</p> <p>If you rename a source file, the project detects the impact to the derived file and prompts you to update it.</p>
Created in a newer release	The file is created in a newer release than the one currently used. For example, the file is a Simulink model file created in a newer Simulink release. The Dependency Analyzer warns and does not analyze the file.	If this status is acceptable, right-click the file and select <b>Hide Warnings</b> . Otherwise, open the model in the release you used to create it and export to a previous version. See “Export Model to Previous Simulink Version” on page 1-32.
Not a valid file format	The file is not a format supported by MathWorks products. For example, the file has .slx extension but is not a valid Simulink model. The Dependency Analyzer warns and does not analyze the file.	If this status is acceptable, right-click the file and select <b>Hide Warnings</b> .
File with syntax error	The file contains a syntax error or the Dependency Analyzer cannot parse the file. For example, the file is an .m file that contains a syntax error. The Dependency Analyzer warns and does not analyze the file.	If this status is acceptable, right-click the file and select <b>Hide Warnings</b> . Otherwise, fix the syntax error and save the file.

Problem Message	Description	Fix
Product not installed	The project has a dependency on a missing product.	<p>Fix models by installing missing products.</p> <p>If you open a model that contains built-in blocks or library links from missing products, you see labels and links to help you fix the problem.</p> <ul style="list-style-type: none"> <li>• Blocks are labeled with missing products (for example, <b>SimEvents not installed</b>)</li> <li>• Tooltips include the name of the missing product</li> <li>• Messages provide links to open Add-On Explorer and install the missing products</li> </ul> <p>To find a link to open Add-On Explorer and install the product:</p> <ul style="list-style-type: none"> <li>• For built-in blocks, open the Diagnostic Viewer, and click the link in the warning.</li> <li>• For unresolved library links, double-click the block to view details and click the link.</li> </ul> <p>Product dependencies can occur in many other ways, for example in callbacks, so in this case you cannot easily see where the missing product is referenced. Fix models by installing missing products.</p>

## Investigate Problem Files in Dependency Graph

Use the graph to investigate problem files graphically.

- 1 In the **Properties** pane, in the **Problems** section, point to a problem, such as *File not in project*, and click the magnifying glass icon . The graph highlights the files with this specific problem.

To go through these files, use the arrows in the search box (e.g., **Problem: File not in project**).

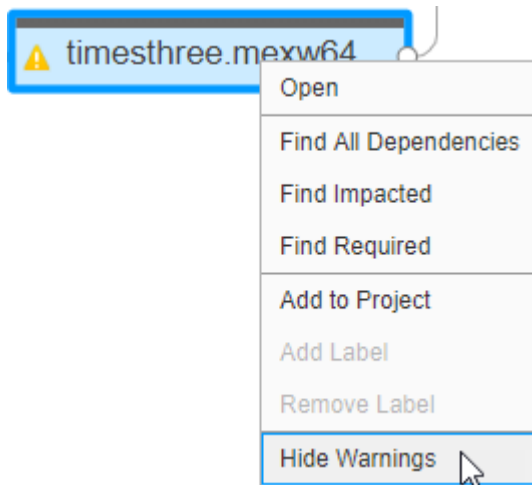

To undo the highlighting, close the search box.

- 2 To see more information about a specific problem file, select the file in the graph. In the **Properties** pane, in the **Problems** section, you can see details including the path, type, and the problems for this file.

Take actions to resolve the problem file. For example, if a file is *File not in project*, right-click the problem file in the graph and select **Add to Project**. To remove the file from the problem list without adding it to the project, right-click the file and select **Hide Warnings**.

- Investigate the next problem listed in the **Problems** section. Repeat the steps until you resolve all problems.

To update the graph and the **Problems** list, click **Analyze**.

---

**Tip** For large projects, viewing the results in a list can make navigation easier.

---

For more ways to work with the dependency graph, see “Perform an Impact Analysis” on page 18-17.

## Investigate Problem Files in File List

For large projects, use the **File List** to investigate your project problem files.

- In the Dependency Analyzer toolstrip, click **File List**.
- In the **Properties** pane, in the **Problems** section, point to a problem, such as *File not in project*, and click the magnifying glass icon .

The **File List** shows only files with the specific problem.

To fix the *File not in project* problem, select all the files in the list. Use the context menu and select **Add to Project**. To remove a file from the problem list without adding it to the project, right-click the file and select **Hide Warnings**.

- Investigate the next problem listed in the **Problems** section, for example *Missing file*. Repeat the steps until you resolve all problems.

To update the graph and the **Problems** list, click **Analyze**.

- “Perform an Impact Analysis” on page 18-17
- “Export Dependency Analysis Results” on page 18-30

## Find Requirements Documents in a Project

In a project, a dependency analysis finds requirements documents linked using the Requirements Management Interface.

- You can view and navigate to and from the linked requirements documents.
  - You can create or edit Requirements Management links only if you have Requirements Toolbox.
- 1 On the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

Alternatively, in the project **Views** pane, select **Dependency Analyzer** and click the **Analyze** button.

- 2 The dependency graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files are not visible in the graph.
- 3 Use the dependency graph legend to locate the requirements documents in the graph. Arrows connect requirements documents to the files with the requirement links.
- 4 To find the specific block containing a requirement link, select the arrow connecting requirements documents to the files. In the **Properties** pane, in the **Impacted** column of the table, click the file to open it and highlight the block containing the dependency.
- 5 To open a requirements document, double-click the document in the graph.

- “Perform an Impact Analysis” on page 18-17
- “Export Dependency Analysis Results” on page 18-30
- “View Requirements Toolbox Links Associated with Model Elements” on page 17-46

## Export Dependency Analysis Results

You can export dependency analysis results for your project in several formats. If you have not yet run an analysis, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

To export all the files displayed in the dependency graph, click the graph background to clear the selection on all files. In the Dependency Analyzer toolstrip, in the **Export** section, click **Export**. Select from the available options:

- **Save to Workspace** — Save file paths to a variable in the workspace.
- **Generate Dependency Report** — Save dependency analysis results in a printable report (HTML, Word, or PDF).
- **Package As Archive** — Export files in the graph as an archive.
- **Save As GraphML** — Save dependency analysis results as a GraphML file.

---

**Tip** You can open and compare different analysis results without having to repeat the analysis.

- To compare previously saved graphs, in MATLAB, in the **Current Folder**, right-click two GraphML files and select **Compare Selected Files/Folders**.
- To open saved dependency analysis results, use the `depview` function, then restore the view to default.

- 1 In the Command Window, type: `depview("myDepResults.graphml");`

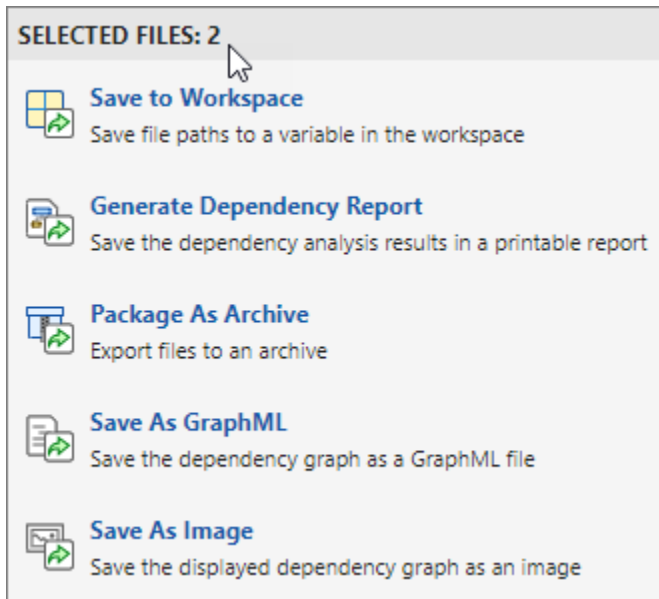

- 2 In the Dependency Analyzer toolstrip, in the **Views** section, click **Restore to Default**.

- 
- **Save As Image** — Save displayed dependency graph as an image.

To export a subset of files in the graph, select the files, then click **Export**.

- Use the **Legend** check boxes, the filtered **Views**, or the **Impact Analysis** tools to simplify the graph.
- To select multiple files, press **Shift** and select the files.
- To select all files in the filtered graph, press **Ctrl+A**.

The menu displays how many files are selected. The Dependency Analyzer exports only the selected files.

---

**Note** When you use **Package As Archive**, the Dependency Analyzer includes the selected files and all their dependencies in the archive.

---

Alternatively, you can work with the graph information programmatically. See “Automate Project Tasks Using Scripts” on page 17-19.

## Send Files to Project Tools

You can send files to other Project tools using the **Project** menu. The Dependency Analyzer exports only the selected files in the current filtered view.

Select the desired files. In the Dependency Analyzer toolstrip, in the **Export** section, click **Project**. Select from the available options:

- **Show in Project** — Switch to the project **Files** view with the files selected.
- **Send to Custom Task** — Run a project custom task on the selected files.

## About Source Control with Projects

You can use a project to work with source control. You can perform operations such as update, commit, merge changes, and view revision history directly from the project environment.

In MATLAB, projects have interfaces to:

- Git— See “Set Up Git Source Control” on page 19-16.
- Subversion (SVN) — See “Set Up SVN Source Control” on page 19-9.
- Software Development Kit (SDK) — You can use the SDK to integrate projects with third-party source control tools. See “Write a Source Control Integration with the SDK” on page 19-30.

---

**Tip** You can check for updated source control integration downloads on the projects Web page: <https://www.mathworks.com/products/simulink/projects.html>

---

To use source control in your project, use any of the following workflows:

- Add source control to a project. See “Add a Project to Source Control” on page 19-5.
- Retrieve files from an existing repository and create a new project. See “Clone Git Repository” on page 19-31 or “Check Out SVN Repository” on page 19-32.
- Create a new project in a folder already under source control and click **Detect**. See “Create a New Project from a Folder” on page 16-17.
- Make your project publicly available on GitHub. See “Share Project on GitHub” on page 17-34.

When your project is under source control, you can:

- “Clone Git Repository” on page 19-31 or “Check Out SVN Repository” on page 19-32
- “Compare Revisions” on page 19-44
- “Commit Modified Files to Source Control” on page 19-47

---

**Caution** Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Source Control Tools” on page 19-8.

---

To view an example project under source control, see “Explore Project Tools with the Airframe Project” on page 16-5.

## Classic and Distributed Source Control

This diagram represents the classic source control workflow (for example, using SVN).

Benefits of classic source control:

- Locking and user permissions on a per-file basis (e.g., you can enforce locking of model files)
- Central server, reducing local storage needs
- Simple and easy to learn

This diagram represents the distributed source control workflow (for example, using Git).

Benefits of distributed source control:

- Offline working
- Local repository, which provides full history
- Branching
- Multiple remote repositories, enabling large-scale hierarchical access control

To choose classic or distributed source control, consider these tips.

Classic source control can be helpful if:

- You need file locks.

- You are new to source control.

Distributed source control can be helpful if:

- You need to work offline, commit regularly, and need access to the full repository history.
- You need to branch locally.

## Add a Project to Source Control

### In this section...

“Add a Project to Git Source Control” on page 19-5

“Add a Project to SVN Source Control” on page 19-5

### Add a Project to Git Source Control

If you want to add version control to your project files without sharing with another user, it is quickest to create a local Git repository in your sandbox.

- 1 On the Project tab, in the Source Control section, click **Use Source Control**.
- 2 In the Source control Information dialog box, click **Add Project to Source Control**.
- 3 In the Add to Source Control dialog box, in the **Source control tool** list, select Git to use the Git source control tool provided by the project.
- 4 Click **Convert** to finish adding the project to source control.

Git creates a local repository in your sandbox project root folder. The project runs integrity checks.

- 5 Click **Open Project** to return to your project.

The Project node displays the source control name Git and the repository location Local Repository: *yoursandboxpath*.

- 6 Select the **Modified** files view and click **Commit** to commit the first version of your files to the new repository.

In the dialog box, enter a comment if you want, and click **Submit**.

---

**Tip** If you want to use Git and share with other users:

- To clone an existing remote Git repository, see “Clone Git Repository” on page 19-31.
  - To connect an existing project to a remote repository, on the Project tab, in the Source Control section, click **Remote** and specify a single remote repository for the origin branch.
  - To make your project publicly available on GitHub, see “Share Project on GitHub” on page 17-34.
- 

### Add a Project to SVN Source Control

---

**Caution** Before you start, check that your sandbox folder is on a local hard disc. Using a network folder with SVN is slow and unreliable.

---

This procedure adds a project to the built-in SVN integration that comes with the project. If you want to use a different version of SVN, see “Set Up SVN Source Control” on page 19-9.

- 1 On the Project tab, in the Source Control section, click **Use Source Control**.

- 2 In the Source control Information dialog box, click **Add Project to Source Control**.
- 3 In the Add to Source Control dialog box, select SVN as the **Source control tool**.
- 4 Next to **Repository path**, click **Change**.
- 5 In the Specify SVN Repository URL dialog box, to specify an existing repository, click the  button to browse for your repository, paste a URL into the box, or use the list to select a recent repository.
- 6 Click **Validate** to check the path to the selected repository.

When the path is valid, you can browse the repository folders. For example, select the trunk folder, and verify the selected URL at the bottom of the dialog box, as shown.

- 7 Click **OK** to return to the Add to Source Control dialog box.

If your repository has a file URL, a warning appears that file URLs are for single users. Click **OK** to continue.

- 8 Click **Convert** to finish adding the project to source control.

The project runs integrity checks.

- 9 After the integrity checks run, click **Open Project** to return to your project.

The Project node displays details of the current source control tool and the repository location.

---

**Caution** Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Subversion” on page 19-11.

---

### More About

- “About Source Control with Projects” on page 19-2

## Set Source Control Preferences

MathWorks source control integration, accessible through Projects and the Current Folder browser, is on by default.

To disable source control, on the **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > General > Source Control** and click **None**.

When you disable source control, MATLAB does not destroy repository information. For example, it does not remove the `.svn` folder. You can put the folder back under source control by enabling the source control integration again.

### Set Git Preferences in MATLAB Online

In MATLAB Online, you can use the Git source control preferences to specify your user name and email, remember credentials for the current MATLAB session, and enable SSH authentication.

On the **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Source Control > Git**. Then, adjust preference options as described in this table.

Preference	Usage
<b>User</b>	Specify your user name and email in <b>Name</b> and <b>Email</b> . This overrides information you already specified in your global Git configuration file.
<b>Credentials</b>	To configure MATLAB Online to remember user names and passwords when using Git, select <b>Remember credentials for the current MATLAB session</b> .
<b>SSH</b>	SSH authentication is disabled by default in MATLAB Online. To enable the use of SSH keys, select <b>Enable SSH</b> . This requires you to store the public and private key files on MATLAB Drive. Make sure your <b>Key is pass-phrase protected</b> when you generate your SSH keys.
	To specify the <b>Public key file</b> , browse to or paste the path to your public key file. For example, <code>/MATLAB Drive/.ssh/id_rsa.pub</code> .
	To specify the <b>Private key file</b> , browse to or paste the path to your private key file. For example, <code>/MATLAB Drive/.ssh/id_rsa</code> .
	To enable the use of a pass-phrase and receive a prompt once per session, select <b>Key is pass-phrase protected</b> .

- “Clone Git Repository” on page 19-31
- “Add a Project to Source Control” on page 19-5

## Register Model Files with Source Control Tools

If you use third-party source control tools, you must register your model file extensions (.mdl and .slx) as binary formats. If you do not, these third-party tools can corrupt your model files when you submit them, by changing end-of-line characters, expanding tokens, substituting keywords, or attempting to automerge. Corruption can occur whether you use the source control tools outside of Simulink or if you try submitting files from a project without first registering your file formats.

Also check that other file extensions are registered as binary to avoid corruption at check-in for files such as .mat, .mlx, .mlapp, .mdl, .slxp, .sldd, .p, MEX-files, .xlsx, .jpg, .pdf, .docx, etc.

For instructions with SVN, see “Register Model Files with Subversion” on page 19-11. You must register model files if you use SVN, including the SVN integration provided by the project.

For instructions with Git, see “Register Binary Files with Git” on page 19-16.

---

**Tip** You can reduce your Git repository size by saving Simulink models without compression. Turning off compression results in larger SLX files on disk but reduces repository size.

To use this setting with new SLX files, create your models using a model template with SLX Compression set to none. For existing SLX files, set compression and then save the model. For more information, see “Set SLX Compression Level” on page 4-72.

---

## Set Up SVN Source Control

### In this section...

“Set Up SVN Provided with Projects” on page 19-9

“Set Up Project SVN for SVN Version Already Installed” on page 19-10

“Set Up Project SVN for SVN Version Not Yet Provided with Projects” on page 19-10

“Register Model Files with Subversion” on page 19-11

“Enforce SVN Locking Model Files Before Editing” on page 19-13

“Share a Subversion Repository” on page 19-14

“Manage SVN Externals” on page 19-14

### Set Up SVN Provided with Projects

Projects provide SVN for use with Subversion (SVN) sandboxes and repositories at version 1.9. You do not need to install SVN to use this integration because it includes an implementation of SVN.

---

**Note** This integration ignores any existing SVN installation.

The project SVN supports secure logins.

---

To use the version of SVN provided with the project, do one of the following:

- On the MATLAB Home tab, select **New > Project > From SVN**.
- Alternatively, in the start page, select **Project from SVN** to retrieve from source control, or when you add a project to source control, select SVN in the **Source control tool** list

For instructions, see

- “Add a Project to Source Control” on page 19-5, or
- “Check Out SVN Repository” on page 19-32.

---

**Caution** Place your project sandbox folder on a local hard disc. Using a network folder with SVN is slow and unreliable. If you use a Windows network drive, SVN move operations can result in incorrect “not existing” status for files visible in file browsers.

---

When you create a new sandbox using the project SVN, the new sandbox uses the latest version of SVN provided by the project.

When your project is under source control, you can use these project features:

- “Check Out SVN Repository” on page 19-32
- “Compare Revisions” on page 19-44
- “Commit Modified Files to Source Control” on page 19-47

You can check out from a branch, but the project SVN does not support branch merging. Use an external tool such as TortoiseSVN to perform branch merging. You can use the project tools for

comparing and merging by configuring TortoiseSVN to generate a comparison report when you perform a diff on model files. See “Merge Simulink Models from the Comparison Report” on page 21-16.

Subversion is not supported in MATLAB Online.

## Set Up Project SVN for SVN Version Already Installed

If you want to use projects with an earlier SVN version you already have installed, create a new project in a folder already under SVN source control. The project detects SVN.

For example:

- 1 Create the sandbox using TortoiseSVN from Windows Explorer.
- 2 In MATLAB, create a new project in that folder. The project detects the existing source control. If the sandbox is version 1.6, for example, it remains a version 1.6 sandbox.

---

**Note** Before using source control, you must register model files with the tools. See “Register Model Files with Subversion” on page 19-11.

---

## Set Up Project SVN for SVN Version Not Yet Provided with Projects

If you need to use a later version of SVN than 1.9, you can use Command-Line SVN Integration (compatibility mode), but you must also install a command-line SVN client.

---

**Note** Select Command-Line SVN Integration (compatibility mode) only if you need to use a later version of SVN than 1.9. Otherwise, use SVN instead, for more features, improved performance, and no need to install an additional command-line SVN client.

---

Command-line SVN integration communicates with any Subversion (SVN) client that supports the command-line interface.

- 1 Install an SVN client that supports the command-line interface.

---

**Note** TortoiseSVN does not support the command-line interface unless you choose the option to install command-line tools. Alternatively, you can continue to use TortoiseSVN from Windows Explorer after installing another SVN client that supports the command-line interface. Ensure that the major version numbers match, for example, both clients are SVN 1.7.

---

You can find Subversion clients on this Web page:

<https://subversion.apache.org/packages.html>

- 2 In a project, select Command-Line SVN Integration (compatibility mode).

With Command-Line SVN Integration (compatibility mode), if you try to rename a file in a project and the folder name contains an @ character, an error appears because command-line SVN treats all characters after the @ symbol as a peg revision value.

---

**Tip** You can check for updated source control integration downloads on the projects Web page: <https://www.mathworks.com/products/simulink/projects.html>

---

## Register Model Files with Subversion

You must register model files if you use SVN, including the SVN integration provided by projects.

If you do not register your model file extension as binary, SVN might add annotations to conflicted Simulink files and attempt automerge. This corrupts model files so you cannot load the models in Simulink.

To avoid this problem when using SVN, register file extensions.

- 1 Locate your SVN config file. Look for the file in these locations:
  - C:\Users\myusername\AppData\Roaming\Subversion\config or C:\Documents and Settings\myusername\Application Data\Subversion\config on Windows
  - In ~/.subversion on Linux or Mac OS X
- 2 If you do not find a config file, create a new one. See “Create SVN Config File” on page 19-11.
- 3 If you find an existing config file, you have previously installed SVN. Edit the config file. See “Update Existing SVN Config File” on page 19-12.

### Create SVN Config File

- 1 If you do not find an SVN config file, create a text file containing these lines:

```
[miscellany]
enable-auto-props = yes
[auto-props]
*.mlx = svn:mime-type=application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.fig = svn:mime-type=application/octet-stream
*.mdl = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlapp = svn:mime-type= application/octet-stream
*.p = svn:mime-type=application/octet-stream
*.mdlp = svn:mime-type=application/octet-stream
*.slxp = svn:mime-type=application/octet-stream
*.sldd = svn:mime-type=application/octet-stream
*.slxc = svn:mime-type=application/octet-stream
*.mlproj = svn:mime-type=application/octet-stream
*.mldatx = svn:mime-type=application/octet-stream
*.slreqx = svn:mime-type=application/octet-stream
*.sfx = svn:mime-type=application/octet-stream
*.sltx = svn:mime-type=application/octet-stream
```

- 2 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as MEX-files (.mexa64, .mexmaci64, .mexw64), .xlsx, .jpg, .pdf, .docx, etc. Add a line to the attributes file for each file type you need. Examples:

```
*.mexa64 = svn:mime-type=application/octet-stream
*.mexw64 = svn:mime-type=application/octet-stream
*.mexmaci64 = svn:mime-type=application/octet-stream
*.xlsx = svn:mime-type=application/octet-stream
```

```
*.docx = svn:mime-type=application/octet-stream
*.pdf = svn:mime-type=application/octet-stream
*.jpg = svn:mime-type=application/octet-stream
*.png = svn:mime-type=application/octet-stream
```

**3** Name the file `config` and save it in the appropriate location:

- `C:\Users\myusername\AppData\Roaming\Subversion\config` or `C:\Documents and Settings\myusername\Application Data\Subversion\config` on Windows
- `~/.subversion` on Linux or Mac OS X

After you create the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, see “Register Models Already in Repositories” on page 19-13.

### Update Existing SVN Config File

If you find an existing config file, you have previously installed SVN. Edit the config file to register files as binary.

**1** Edit the config file in a text editor.

**2** Locate the `[miscellany]` section, and verify the following line enables auto-props with yes:

```
enable-auto-props = yes
```

Ensure that this line is not commented (that is, that it does not start with a #). Config files can contain example lines that are commented out. If there is a # character at the beginning of the line, delete it.

**3** Locate the `[auto-props]` section. Ensure that `[auto-props]` is not commented. If there is a # character at the beginning, delete it.

**4** Add the following lines at the end of the `[auto-props]` section:

```
*.mlx = svn:mime-type=application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.fig = svn:mime-type=application/octet-stream
*.mdl = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlapp = svn:mime-type= application/octet-stream
*.p = svn:mime-type=application/octet-stream
*.mdlp = svn:mime-type=application/octet-stream
*.slxp = svn:mime-type=application/octet-stream
*.sldd = svn:mime-type=application/octet-stream
*.slxc = svn:mime-type=application/octet-stream
*.mlproj = svn:mime-type=application/octet-stream
*.mldatx = svn:mime-type=application/octet-stream
*.slreqx = svn:mime-type=application/octet-stream
*.sfx = svn:mime-type=application/octet-stream
*.sltx = svn:mime-type=application/octet-stream
```

These lines prevent SVN from adding annotations to MATLAB and Simulink files on conflict and from automerging.

**5** Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as MEX-files (`.mexa64`, `.mexmaci64`, `.mexw64`), `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc. Add a line to the config file for each file type you need.

Examples:

```
*.mexa64 = svn:mime-type=application/octet-stream
*.mexw64 = svn:mime-type=application/octet-stream
*.mexmaci64 = svn:mime-type=application/octet-stream
*.xlsx = svn:mime-type=application/octet-stream
*.docx = svn:mime-type=application/octet-stream
*.pdf = svn:mime-type=application/octet-stream
*.jpg = svn:mime-type=application/octet-stream
*.png = svn:mime-type=application/octet-stream
```

## 6 Save the config file.

After you create or update the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, register them as described next.

## Register Models Already in Repositories

---

**Caution** Changing your SVN config file does not affect model files already committed to an SVN repository. If a model is not registered as binary, use `svn propset` to manually register models as binary.

---

To manually register a file in a repository as binary, use the following command with command-line SVN:

```
svn propset svn:mime-type application/octet-stream modelfilename
```

If you need to install a command-line SVN client, see “Set Up Project SVN for SVN Version Not Yet Provided with Projects” on page 19-10.

## Enforce SVN Locking Model Files Before Editing

To ensure users remember to get a lock on model files before editing, you can configure SVN to make specified file extensions read only. To locate your SVN config file, see “Register Model Files with Subversion” on page 19-11.

After this setup, SVN sets model files to read only when you open the project, so you need to select **Source Control > Get File Lock** before you can edit them. Doing so helps prevent editing of models without getting the file lock. When the file has a lock, other users know the file is being edited, and you can avoid merge issues.

- 1 To make SLX files read only, add a property to your SVN config file. Find this line in the [auto-props] section that registers SLX files as binary:

```
*.slx = svn:mime-type= application/octet-stream
```

- 2 Add the `needs-lock` property to the end of the existing `slx` line, separated by a semicolon, so the line looks like this:

```
*.slx = svn:mime-type=application/octet-stream;svn:needs-lock=yes
```

You can combine properties in any order, but multiple entries (e.g., for `slx`) must be on a single line separated by semicolons.

- 3 Recreate the sandbox for the config to take effect.
- 4 You need to select **Get File Lock** before you can edit model files. See “Get SVN File Locks” on page 19-39.

If you need to resolve merge issues, see “Resolve Conflicts” on page 19-59.

## Share a Subversion Repository

When you want to share a repository, you need to set up a server. You can use `svnserve` or the Apache SVN module. See the Web page references:

<https://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.svnserve>  
<https://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.httpd>

### Standard Repository Structure

Create your repository with the standard `tags`, `trunk`, and `branches` folders, and check out files from `trunk`. The Subversion project recommends this structure. See the Web page:

<https://svn.apache.org/repos/asf/subversion/trunk/doc/user/svn-best-practices.html>

---

**Note** In a production environment, do not rely on remote repositories via the file system using the `file:///` protocol. The file protocol is not safe. Concurrent access might corrupt repositories.

---

After you create a repository with this structure, to add tags to all your project files, on the Project tab, in the Source Control section, click **Tag**. See “Tag and Retrieve Versions of Project Files” on page 19-34.

## Manage SVN Externals

To get files into your project from another repository or from a different part of the same repository, use SVN externals.

- 1 In a project, right-click a project folder and select **Source Control > Manage Externals**.
- 2 In the Manage Externals dialog box, click **Add entry**. You can browse to and validate a repository location, specify the relative reference format, specify the subfolder, choose the revision, e.g., the HEAD node, etc.
- 3 After specifying the externals, click **OK**. The project displays the externals definition in the Manage Externals dialog box.

Alternatively, enter or paste an `svn:external` definition in the Manage Externals dialog box. The project applies an SVN version 1.6 compliant externals definition.

- 4 Click **Set** to validate and apply your changes.
- 5 To retrieve the external files, click **Update** to update the sandbox.

If two users modify the `svn:external` for a folder, you can get a conflict. To resolve the conflict, in the All Files View, locate the `.prej` file and examine the conflict details. Open the Manage Externals dialog box and specify the desired `svn:external`, mark the folder conflict resolved, and then commit the changes.

## **See Also**

## Set Up Git Source Control

You can use Git source control in MATLAB to manage your files and collaborate with others. Using Git, you can track changes to your files and recall specific versions later. For more information, see “Clone Git Repository” on page 19-31 and “Add a Project to Source Control” on page 19-5.

Before using Git, follow these steps to set it up for MATLAB:

- Register your binary files with Git to avoid file corruption. (Required for all systems)
- Configure MATLAB for Git on a Windows system. (Recommended for Windows Systems)
- Configure MATLAB to use Git SSH authentication or install a Git credential helper to prevent frequent login prompts. (Optional)
- Disable compression for Simulink models to reduce your Git repository size. (Optional)
- Configure Git to use Git LFS if you are working with large files. (Optional)
- Configure Git to use MATLAB for Diff and Merge. (Optional)

*Before R2020b, a command-line Git client must be installed to use Git to merge branches in MATLAB. For more information, see “Install Command-Line Git Client” on page 19-22.*

### Register Binary Files with Git

If you use third-party source control tools, you must register your MATLAB and Simulink file extensions such as `.mlx`, `.mat`, `.fig`, `.mlapp`, `.mdl`, `.slx`, `.mdlp`, `.slxp`, `.sldd`, and `.p` as binary formats. Also register extensions for MEX files, such as `.mexa64`, `.mexmaci64`, and `.mexw64`. If you do not register the extensions, these tools can corrupt your files when you submit them by changing end-of-line characters, expanding tokens, substituting keywords, or attempting to automerger. Corruption can occur if you use the source control tools outside of MATLAB or if you try submitting files from MATLAB without first registering your file formats.

Also check that other file extensions are registered as binary to avoid corruption at check-in. Check and register file extensions such as `.xlsx`, `.jpg`, `.pdf`, `.docx`, and so on.

To register your binary file extensions with Git, add them to a `.gitattributes` file. If you create a new project that uses Git source control or switch an existing project from another source control system to Git source control, MATLAB automatically creates a `.gitattributes` file and populates it with a list of common binary files to register.

If a `.gitattributes` file is not automatically created, you can create one that contains the list of common binary files to register. In the MATLAB Command Window, enter:

```
copyfile(fullfile(matlabroot,'toolbox','shared','cmlink','git','auxiliary_files', ...
'mwgitattributes'),fullfile(pwd,'.gitattributes'))
```

Alternatively, to create a blank `.gitattributes` file, enter:

```
edit .gitattributes
```

To register binary files that are not already included in the `.gitattributes` file, add a line to the file for each file type that you need. For example, `*.mlapp binary`.

### Configure MATLAB for Git on Windows

On Windows systems, if you are working with files that have long paths, enable support for long paths. In addition, to use Git hooks with MATLAB, install Cygwin and add it to the MATLAB library path. Git hooks are custom scripts that can be triggered by operations such as committing, merging, and receiving pushed commits.

### Enable Support for Long Paths (Recommended)

To enable support for long paths on a Windows system, run this command in MATLAB:

```
!git config --global core.longpaths true
```

### Install Cygwin (Optional)

To install Cygwin on a Windows system and add it to the MATLAB library path:

- 1 Download and run the installer from <https://www.cygwin.com/>.
- 2 In MATLAB, open `librarypath.txt`.

```
edit(fullfile(matlabroot, "toolbox", "local", "librarypath.txt"))
```

- 3 Add the Cygwin bin folder location to the end of `librarypath.txt`, for example, `C:\cygwin64\bin`.

```
##
## FILE: librarypath.txt
##
## Entries:
##   o path_to_jnifile
##   o [alpha,glx86,sol2,unix,win32,mac]=path_to_jnifile
##   o $matlabroot/path_to_jnifile
##   o $jre_home/path_to_jnifile
##
$matlabroot/bin/$arch
$matlabroot/sys/jxbrowser/$arch/lib
C:\cygwin64\bin
```

If you do not have permission to edit the `librarypath.txt` file, see “Locate Native Method Libraries”.

- 4 Restart MATLAB.

## Configure MATLAB to Use Git SSH Authentication

To prevent frequent login prompts when you interact with your remote repository using HTTPS, add a new public key and clone the repository using SSH instead. This table provides instructions on how to configure MATLAB to use SSH authentication based on your operating system.

Operating System	Instructions
Windows	<p><b>1</b> Install a command-line Git client and make it available system-wide. To check if Git is installed, enter the command <code>!git</code> in the MATLAB Command Window. If the command does not return anything, you need to install command-line Git. For more information, see “Install Command-Line Git Client” on page 19-22.</p> <p><b>2</b> Close all MATLAB sessions.</p> <p><b>3</b> Generate an SSH key using the <code>ssh-keygen</code> command. For example, at a Windows command prompt, enter this command:</p> <pre>ssh-keygen -t ed25519 -C "your_email@example.com"</pre> <p><code>ssh-keygen</code> prompts you to confirm where to save the key and asks for a passphrase. If you do not want to type a password when you use the key, leave the passphrase empty.</p> <p>If you already have keys in the specified folder, <code>ssh-keygen</code> asks if you want to override them.</p> <p><i>Before R2021a, specify the <code>-m PEM</code> option to generate an SSH key in the RSA format. Otherwise, <code>ssh-keygen</code> creates the SSH key using the default OpenSSH format, which is not supported in MATLAB versions before R2021a. For example, at a Windows command prompt, enter this command:</i></p> <pre>ssh-keygen -m PEM</pre> <p><i>If you generate an SSH key without specifying the <code>-m PEM</code> option, you can convert your key to the supported RSA format using this command, where <code>~/ .ssh/id_rsa</code> is the name of the SSH key file.</i></p> <pre>ssh-keygen -p -m PEM -f ~/ .ssh/id_rsa</pre> <p><b>4</b> Place your keys in the <code>USERPROFILE/ .ssh</code> or <code>HOME/ .ssh</code> folder. To verify which <code>USERPROFILE</code> folder MATLAB is working with, in the MATLAB Command Window, enter:</p> <pre>getenv('USERPROFILE')</pre> <p><i>Before R2021a, if you created the SSH key using the <code>-m PEM</code> option, you can skip step 5.</i></p> <p><b>5</b> To make sure that MATLAB detects the SSH keys, in the MATLAB Command Window, enter:</p> <pre>git = settings().matlab.sourcecontrol.git; git.PrivateKeyFile.PersonalValue = '/path/to/key'; git.PublicKeyFile.PersonalValue = '/path/to/key.pub';</pre> <p>If you entered a passphrase when generating the SSH key, configure MATLAB to use the passphrase and receive a prompt only once per session. To do so, use Pageant or, in the MATLAB Command Window, enter:</p> <pre>git.KeyHasPassphrase.PersonalValue = true;</pre>

Operating System	Instructions
	<p>To use multiple keys, use Pageant as the SSH agent. If Pageant is running, MATLAB looks for keys in Pageant before looking in USERPROFILE/.ssh.</p> <p><b>6</b> Configure your GitHub or GitLab® account to use the SSH keys. To do so, go to the .ssh folder and copy the contents of the .pub file. Then, go to your account settings, and in the <b>SSH keys</b> section, paste the contents of the .pub file into the <b>Add SSH key</b> field.</p>

Operating System	Instructions
Linux and macOS	<p><b>1</b> Close all MATLAB sessions.</p> <p><b>2</b> Generate an SSH key using the <code>ssh-keygen</code> command. For example, in a Terminal window, enter this command:</p> <pre>ssh-keygen -t ed25519 -C "your_email@example.com"</pre> <p><code>ssh-keygen</code> prompts you to confirm where to save the key and asks for a passphrase. If you do not want to type a password when you use the key, leave the passphrase empty.</p> <p>If you already have keys in the specified folder, <code>ssh-keygen</code> asks if you want to override them.</p> <p><i>Before R2021a, specify the <code>-m PEM</code> option to generate an SSH key in the RSA format. Otherwise, <code>ssh-keygen</code> creates the SSH key using the default OpenSSH format, which is not supported in MATLAB versions before R2021a. For example, in a Terminal window, enter this command:</i></p> <pre>ssh-keygen -m PEM</pre> <p><i>If you generate an SSH key without specifying the <code>-m PEM</code> option, you can convert your key to the supported RSA format using this command, where <code>~/ .ssh/id_rsa</code> is the name of the SSH key file.</i></p> <pre>ssh-keygen -p -m PEM -f ~/ .ssh/id_rsa</pre> <p><b>3</b> Place your keys in the <code>HOME/ .ssh</code> folder. To verify which <code>HOME</code> folder MATLAB is working with, in the MATLAB Command Window, enter:</p> <pre>getenv('HOME')</pre> <p><i>Before R2021a, if you created the SSH key using the <code>-m PEM</code> option, you can skip step 4.</i></p> <p><b>4</b> To make sure that MATLAB detects the SSH keys, in the MATLAB Command Window, enter:</p> <pre>git = settings().matlab.sourcecontrol.git; git.PrivateKeyFile.PersonalValue = '/path/to/key'; git.PublicKeyFile.PersonalValue = '/path/to/key.pub';</pre> <p>If you entered a passphrase when generating the SSH key, configure MATLAB to use the passphrase and receive a prompt only once per session. To do so, use an SSH agent or, in the MATLAB Command Window, enter:</p> <pre>git.KeyHasPassphrase.PersonalValue = true;</pre> <p>To use multiple keys, use an SSH agent. If an SSH agent is running, MATLAB looks for keys in the agent before looking in <code>HOME/ .ssh</code>.</p> <p><b>5</b> Configure your GitHub or GitLab account to use the SSH keys. To do so, go to the <code>.ssh</code> folder and copy the contents of the <code>.pub</code> file. Then, go to your account settings, and in the <b>SSH keys</b> section, paste the contents of the <code>.pub</code> file into the <b>Add SSH key</b> field.</p>

## Install Git Credential Helper

To configure MATLAB to remember user names and passwords when using Git, install a credential helper. The recommended credential helper for all platforms is Git Credential Manager Core.

For example, to install Git Credential Manager Core on a Windows system, download and run the Git for Windows installer using the instructions described in “Install Command-Line Git Client” on page 19-22. In the **Choose a credential helper** section of the installer, select **Git Credential Manager Core** as the credential helper.

To delete saved login information for Git repositories, follow instructions based on your operating system.

Operating System	Instructions
Windows	To reset the Git credentials for your repository, in the Credential Manager, in the <b>Windows Credentials</b> tab, delete the entries under <b>Generic Credentials</b> .
Linux and macOS	To reset the Git credentials for your repository, enter: <pre>echo "url=https://github.com/myrepo.git"   git credential reject</pre>

## Disable Compression for Simulink Models

You can reduce your Git repository size by saving Simulink models without compression. Turning off compression results in larger SLX files on disk but reduces repository size.

To use this setting with new SLX files, create your models using a model template with SLX Compression set to none. For existing SLX files, set the compression and then save the model. For more information, see “Set SLX Compression Level” on page 4-72.

## Configure Git to Use Git LFS

If you are working with large files, configure Git to use Git Large File Storage (LFS) by installing command-line Git and setting up LFS.

For example, to use Git LFS on a Windows system, download and run the Git for Windows installer using the instructions described in “Install Command-Line Git Client” on page 19-22. In the **Select Components** section of the Git for Windows installer, select the **Git LFS (Large File Support)** and **Associate .sh files to be run with Bash** options.

MATLAB does not support Git LFS locking. In addition, MATLAB does not support LFS commands such as `git lfs track`. Use `!git lfs track` instead.

---

**Note** Git LFS uses Git hooks. Make sure that you have Cygwin installed. For more information, see “Configure MATLAB for Git on Windows” on page 19-16.

---

## Configure Git to use MATLAB for Diff and Merge

You can configure Git to use the MATLAB Comparison Tool for diff and merge. The MATLAB Comparison Tool provides tools for merging MathWorks files such as live scripts, MAT, SLX, or MDL

files. You can use the automerge tool with Git to automatically merge branches that contain changes in different subsystems in the same SLX file.

For more information about how to configure Git to use the MATLAB Comparison Tool, see “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-64.

## Install Command-Line Git Client

To use Git LFS or a credential helper, you must install a command-line Git client and make it available system-wide. Before R2020b, a command-line Git client must be installed to use Git to merge branches in MATLAB.

To check if Git is installed, enter the command `!git` in the MATLAB Command Window. If the command does not return anything, you need to install command-line Git. This table provides instructions on how to install command-line Git based on your operating system.

Operating System	Instructions
Windows	<ol style="list-style-type: none"> <li><b>1</b> Download and run the installer from <a href="https://gitforwindows.org/">https://gitforwindows.org/</a>.</li> <li><b>2</b> In the <b>Adjusting your PATH environment</b> section, choose the install option <b>Git from the command line and also from 3rd-party software</b>. This option adds Git to your PATH variable and makes it available system-wide so that MATLAB can communicate with Git.</li> <li><b>3</b> In the section for configuring the line-ending conversions, choose the <b>Checkout Windows-style, commit Unix-style line endings</b> option. The line-ending format is not enforceable between machines and users, but you can support consistent line endings for text files in the <code>.gitattributes</code> file of each repository.</li> <li><b>4</b> Restart your system for the changes to take effect.</li> </ol>
Linux	<p>Git is available for most distributions. Install Git for your distribution. For example, on Debian®, install Git by entering:</p> <pre>sudo apt-get install git</pre>
macOS	<p>On Mavericks (10.9) or above, run Git from a Terminal window. If you do not have Git installed already, it will prompt you to install Xcode Command Line Tools. For more information, see <a href="https://git-scm.com/doc">https://git-scm.com/doc</a>.</p>

### Related Examples

- “Clone Git Repository” on page 19-31
- “Add a Project to Source Control” on page 19-5
- “Branch and Merge Files with Git” on page 19-55
- “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-64

## Add Git Submodules

To reuse code from another repository, you can specify Git submodules to include in your project.

To clone an external Git repository as a submodule:

- 1 On the Project tab, in the Source Control section, click **Submodules**.
- 2 In the Submodules dialog box, click **Add**.
- 3 In the Add Submodule dialog box, in the **Remote** box, specify a repository location. Optionally, click **Validate**.
- 4 In the **Path** box, specify a location for the submodule in your project and click **OK**. The Submodules dialog box displays the status and details of the submodule.
- 5 Check the status message, and click **Close** to return to your project.

---

**Tip** You can use Git submodules to populate a referenced project. For more information, see “Organize Projects into Components Using References and Git Submodules” and watch How to Organize Large Projects into Components (3 min, 32 sec).

---

## Update Submodules

After using **Pull** on the top-level project, check submodules are up to date by clicking Submodules and then click **Update**. If any submodule definition have changed, then the update ensures that the submodule folder contains the correct files. Update applies to all child submodules in the submodule hierarchy.

## Use Fetch and Merge with Submodules

When you want to manage a submodule, open the Submodules dialog box.

- 1 To get the latest version of a submodule, in the Submodules dialog box, click **Fetch**.
- 2 After fetching, you must merge. Check the **Status** message in the Submodules dialog box for information about your current branch relative to the remote tracking branch in the repository. When you see the message **Behind**, you need to merge in changes from the repository to your local branch.
- 3 Click **Branches** and merge in the origin changes to your local branch using the Branches dialog box. See “Pull, Fetch, and Merge” on page 19-52.

## Use Push to Send Changes to the Submodule Repository

If you make changes in your submodule and want to send changes back to the repository:

- 1 Perform a local commit in the parent project.
- 2 Open the Submodules dialog box and click **Push**.

If you want other project users to obtain your changes in the submodule when they clone the parent project, make sure the index and head match.

- 1 In the Submodules dialog box, check the index and head values. The index points to the head commit at the time you first cloned the submodule, or when you last committed the parent project repository. If the index and head do not match, you must update the index.
- 2 To update the index, commit your changes in the parent project, and then click **Push** in the Submodules dialog box. This action makes the index and head the same.

## See Also

### Related Examples

- How to Organize Large Projects into Components (3 min, 32 sec)
- “Branch and Merge Files with Git” on page 19-55

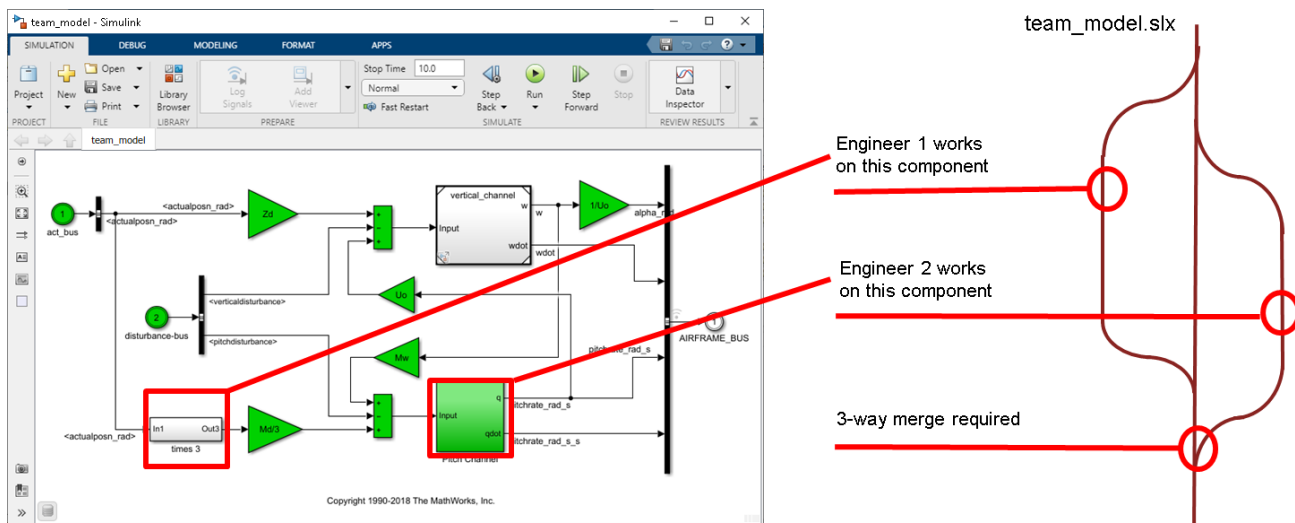

## Automatically Merge Models

You can enable MATLAB Git integration to automatically merge branches in your Git repository. MATLAB can automatically merge branches that contain changes in different subsystems, Stateflow charts, and configuration sets in the same SLX file.

**Tip** MATLAB automatically merges your model files and resolves conflict when you are working in different subsystems.

If you are not working in different subsystems, you need to merge and resolve conflicts manually. For more information, see “Merge Simulink Models from the Comparison Report” on page 21-16.

MATLAB Git integration automatically merges changes in a child subsystem of a modified subsystem. If the number of ports remains unchanged, child subsystems are independent of parent subsystems.

MATLAB does not report a conflict for nonfunctional changes such as, window positions, open Editor tabs, and other graphical details.

To enable automerge for models in your Git repository:

- 1 Run this command in MATLAB.

```
comparisons.ExternalSCMLink.setupGitConfig();
```

This command automatically populates the global `.gitconfig` file. For example:

```
[difftool "mLDiff"]
  cmd = \"C:/Program Files/MATLAB/R2022b/bin/win64/mLDiff.exe\" $LOCAL $REMOTE
[mergetool "mLMerge"]
  cmd = \"C:/Program Files/MATLAB/R2022b/bin/win64/mLMerge.exe\" $BASE $LOCAL $REMOTE $MERGED
[merge "mLAutoMerge"]
  driver = \"C:/Program Files/MATLAB/R2022b/bin/win64/mLAutoMerge.bat\" %0 %A %B %A
```

- 2 Configure your Git repository to use the `mLAutoMerge` executable file. Open the `.gitattributes` file in your repository and add:

```
*.slx binary merge=mlAutoMerge  
*.mdl binary merge=mlAutoMerge
```

Now, when you merge branches that contain changes in non-overlapping parts of the same SLX file, MATLAB Git integration handles the merge automatically.

You can also enable automerge for requirement files and links. Open the `.gitattributes` file in your repository and add:

```
*.slreqx binary merge=mlAutoMerge  
*.slmx binary merge=mlAutoMerge
```

For more details, see “Three-Way AutoMerge Solution for Requirement Set and Link Set” (Requirements Toolbox).

You can also customize external source control tools to use the MATLAB Comparison Tools and automerge functionality. For more details, see “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-64.

## See Also

### Related Examples

- “Merge Simulink Models from the Comparison Report” on page 21-16
- “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-64

## Create New GitHub Repository

Creating a GitHub repository adds Git source control to your new or existing project. The GitHub repository you create becomes the project remote repository. To create a GitHub repository, you must have a GitHub account.

To create a blank project and a GitHub remote repository:

- 1 On the **Home** tab, click **New > Project > From Git**.
- 2 Select **New > GitHub Repository**. In the GitHub dialog box, enter your **User name** and **Personal access token**. Fill the **Repository name** and **Description** fields and click **Create**.

MATLAB creates a new public GitHub repository and populates the **Repository path** field with information in the `https://github.com/myusername/mynewrepository` format.

- 3 In the **Sandbox** field, specify the location for your sandbox. The selected folder must be empty. Click **Retrieve** to create the sandbox.

To confirm the project name and creation, click **OK**.

After creating the GitHub repository and sandbox, add your files to the sandbox. Commit the first version of your files to your local repository, then push all modifications to your remote GitHub repository.

---

**Tip** If you want to create a remote GitHub repository for an existing project, share your project to GitHub instead.

With your project loaded, on the **Project** tab, select **Share > GitHub**. For detailed instructions, see “Share Project on GitHub” on page 17-34.

---

## Disable Source Control

Disabling source control is useful when you are preparing a project to create a template from it, and you want to avoid accidentally committing unwanted changes.

- 1 On the Project tab, in the Source Control section, click the **Details** button for your source control. For example, **SVN Details** or **Git Details**.
- 2 Change the selection from the current source control to `No source control integration`.
- 3 Click **Reload**.

---

**Note** Source control tools create files in the project folders (for example, SVN creates an `.svn` folder), so you can put the project back under the same source control only by selecting your previous source control from the list.

---

#### Related Examples

- “Change Source Control” on page 19-29
- “Create a Template from a Project Under Version Control” on page 16-36
- “Add a Project to Source Control” on page 19-5

## Change Source Control

Changing source control is useful when you want to create a new local repository for testing and debugging.

- 1 Prepare your project by checking for any updates from the existing source control tool repository and committing any local changes.
- 2 Save your project as an archive without any source control information.

On the **Project** tab, click **Share > Archive**. Click **Save As** and specify a file path and name in the **File name** field.

By default, the archive is a `.mlproj` file. You can choose to archive your project as a `.zip` file. Click **Save** to create the project archive.

- 3 On the **Project** tab, click **New**, and then in the start page, click **Archive** to create a new project from the archived project.
- 4 On the Project tab, in the Source Control section, click **Use Source Control**.
- 5 Click **Add Project to Source Control** and then select a new source control. For details, see “Add a Project to Source Control” on page 19-5.

---

**Tip** To avoid accidentally committing changes to the previous source control, delete the original sandbox.

---

## Write a Source Control Integration with the SDK

---

**Tip** You can check for updated source control integration downloads on the projects Web page: <https://www.mathworks.com/products/simulink/projects.html>

---

The file exchange provides a Software Development Kit (SDK) that you can use to integrate projects with third-party source control tools. See <https://www.mathworks.com/matlabcentral/fileexchange/61483-source-control-integration-software-development-kit>.

The SDK provides instructions for writing an integration to a source control tool that has a published API you can call from Java<sup>®</sup>.

You must create a `.jar` file that implements a collection of Java interfaces and a Java Manifest file, that defines a set of required properties.

The SDK provides example source code, Javadoc, and files for validating, building, and testing your source control integration. Build and test your own interfaces using the example as a guide. Then you can use your source control integration with projects. Download the SDK and follow the instructions.

After you write a source control integration, see “Add a Project to Source Control” on page 19-5.

- “About Source Control with Projects” on page 19-2

# Clone Git Repository

Create a new local copy of a project by retrieving files from Git source control.

- 1 On the **Home** tab, click **New > Project > From Git**. The New Project From Source Control dialog box opens.

Alternatively, on the Simulink start page, click the **Project from Git** template.

- 2 Enter your HTTPS repository path into the **Repository path** field.
- 3 In the **Sandbox** field, select the working folder where you want to put the retrieved files for your new project.
- 4 Click **Retrieve**.

If an authentication dialog box for your repository appears, enter the login information for your Git repository account -- for instance, your GitHub user name and personal access token.

If your repository already contains a project, then the project is ready when the tool finishes retrieving files to your selected sandbox folder.

If your sandbox does not yet contain a project, then a dialog box asks whether you want to create a project in the folder. To create a project, specify a project name and click **OK**. The Welcome screen appears to help you set up your new project. For more information about setting up a project, see "Create a New Project from a Folder" on page 16-17.

You can now add, delete, and modify your project files. For details on how to commit and push the modified project files, see "Commit Modified Files to Source Control" on page 19-47.

---

**Tip** Alternatively, to prevent frequent login prompts when you interact with your remote repository, you can clone a remote repository using SSH instead of HTTPS or install a credential helper. To avoid problems connecting using SSH, set the **HOME** environment variable and use it to store your SSH keys. For more information, see "Configure MATLAB to Use Git SSH Authentication" on page 19-17 and "Install Git Credential Helper" on page 19-21.

---

### More About

- "About Source Control with Projects" on page 19-2

## Check Out SVN Repository

Create a new local copy of a project by retrieving files from SVN source control.

- 1 On the MATLAB Home tab, select **New > Project > From SVN**.

Alternatively, on the Simulink start page, click the **Project from SVN** template.

- 2 If you know your repository location, enter it into the **Repository path** field and proceed to step 3.

Otherwise, to browse for and validate the repository path from which to retrieve files, click **Change**.

- a In the Specify SVN Repository URL dialog box, enter a URL using the list of recent repositories or the **Repository** button .

---

**Caution** Use `file://` URLs only for single-user repositories. For more information, see “Share a Subversion Repository” on page 19-14.

---

- b Click **Validate** to check the repository path.

If an authentication dialog box for your repository appears, enter the login information to continue.

- c If the path is invalid, check the URL against your source control repository browser.

If necessary, select a deeper folder in the repository tree. If your repository contains tagged versions of files, then you might want to check out from `trunk` or from a branch folder under `tags`. For more information, see “Tag and Retrieve Versions of Project Files” on page 19-34. You can check out from a branch, but the built-in SVN integration does not support branch merging. Use an external tool such as TortoiseSVN to perform branch merging.

- d When you have finished specifying the URL path you want to retrieve, click **OK**.

- 3 In the New Project From Source Control dialog box, in the **Sandbox** field, select the working folder where you want to put the retrieved files for your new project.

- 4 Click **Retrieve**.

If an authentication dialog box for your repository appears, enter the login information to continue.

---

**Caution** Use local sandbox folders. Using a network folder with SVN slows source control operations.

---

If your repository already contains a project, then the project is ready when the tool finishes retrieving files to your selected sandbox folder.

If your sandbox does not yet contain a project, then a dialog box asks whether you want to create a project in the folder. To create a project, specify a project name and click **OK**. The Welcome screen appears to help you set up your new project. For more information about setting up a project, see “Create a New Project from a Folder” on page 16-17.

**Note** To update an existing project sandbox from source control, see “Update Revisions of Project Files” on page 19-37.

---

- “Commit Modified Files to Source Control” on page 19-47

### More About

- “About Source Control with Projects” on page 19-2

## Tag and Retrieve Versions of Project Files

With SVN, you can use tags to identify specific revisions of all project files. Not every source control has the concept of tags. To use tags with SVN, you need the standard folder structure in your repository and you need to check out your files from `trunk`. See “Standard Repository Structure” on page 19-14.

- 1 On the Project tab, in the Source Control section, click **Tag**.
- 2 Specify the tag text and click **OK**. The tag is added to every project file.

Errors appear if you do not have a `tags` folder in your repository.

---

**Note** You can retrieve a tagged version of your project files from source control, but you cannot tag them again with a new tag. You must check out from `trunk` to create new tags.

---

To retrieve the tagged version of your project files from source control:

- 1 On the **Project** tab, click **New**, and then in the start page, click **Source Control**.
- 2 Click **Change** to select the Repository path that you want to retrieve files from.

The Specify SVN Repository URL dialog box opens.

- a Select a recent repository from the **Repository** list, or click the **Repository** button  to browse for the repository location.
  - b Click **Validate** to show the repository browser.
  - c Expand the `tags` folder in the repository tree, and select the tag version you want.
  - d Click **OK** to continue and return to the new project dialog box.
- 3 Select the local folder to receive the tagged files. You must use an empty project folder. (If you try to retrieve tagged files into an existing project folder, an error appears.)
  - 4 Click **Retrieve**.

Alternatively, you can use labels to apply any metadata to files and manage configurations. You can group and sort by labels, and create batch jobs to export files by label. See “Add Labels to Files” on page 17-17.

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-55.

### See Also

#### Related Examples

- “Standard Repository Structure” on page 19-14
- “Add Labels to Files” on page 17-17
- “Branch and Merge Files with Git” on page 19-55

## Refresh Status of Project Files

To check for locally modified project files, on the Project tab, in the Source Control section, click **Refresh**.

Refresh queries the local sandbox state and checks for changes made with another tool outside of MATLAB.

---

**Note** For SVN, **Refresh** does not contact the repository. To check the repository for later revisions, use **Check for Modifications** instead. To get the latest revisions, use **Update** instead. See “Check for Modifications” on page 19-36 and “Update Revisions of Project Files” on page 19-37.

---

The buttons in the Source Control section of the Project tab apply to the whole project.

**Refresh** refreshes the view of the source control status for all files under `projectroot`. Clicking **Refresh** updates the information shown in the **Revision** column and the source control status column (for example, **SVN**, or **Git** columns). Hover over the icon to see the tooltip showing the source control status of a file, e.g., **Modified**.

### See Also

#### Related Examples

- “Check for Modifications” on page 19-36
- “Update Revisions of Project Files” on page 19-37
- “Revert Changes” on page 19-49

## Check for Modifications

To check the status of individual files for modifications, right-click files in the project and select **Source Control > Check for Modifications**. Use this to find out if the repository version has moved ahead.

With SVN, this option contacts the repository to check for external modifications. The project compares the revision numbers of the local file and the repository version. If the revision number in the repository is larger than that in the local sandbox folder, then the project displays (**not latest**) next to the revision number of the local file.

If your local file is not the latest version, get the latest revisions from the repository by clicking **Update**. See “Update Revisions of Project Files” on page 19-37. You might need to resolve conflicts after updating. See “Resolve Conflicts” on page 19-59 and “Compare Revisions” on page 19-44.

To check for locally modified files, use **Refresh** instead. See “Refresh Status of Project Files” on page 19-35.

### See Also

#### Related Examples

- “Refresh Status of Project Files” on page 19-35

- “Revert Changes” on page 19-49

## Update Revisions of Project Files

In this section...
“Update Revisions with SVN” on page 19-37
“Update Revisions with Git” on page 19-37
“Update Selected Files” on page 19-38

### Update Revisions with SVN

In a project, to get the latest revisions of all project files from the source control repository, click **Update** in the source control section of the project tab.

Use **Update** to get other people’s changes from the repository and find out about any conflicts. If you want to back out local changes, use **Revert Project** instead. See “Discard Local Changes” on page 19-49.

After you update, the project displays a dialog box listing all the files that have changed on disk. You can control this behavior using the project preference **Show changes on source control update**.

When your project uses SVN source control, **Update** calls `svn update` to bring changes from the repository into your working copy. If there are other people’s changes in your modified files, SVN adds conflict markers to the file. SVN preserves your modifications.

---

**Caution** Ensure you have registered SLX files as binary with SVN before using **Update**. If you do not, SVN conflict markers can corrupt your SLX file. The project warns you about this when you first click **Update** to ensure you protect your model files. See “Register Model Files with Subversion” on page 19-11.

---

You must resolve any conflicts before you can commit. See “Resolve Conflicts” on page 19-59.

### Update Revisions with Git

If you are using Git source control, click **Pull** in the source control pane.

---

**Caution** Ensure you have registered SLX files as binary with Git before using **Pull**. If you do not, conflict markers can corrupt your SLX file. See “Set Up Git Source Control” on page 19-16.

---

Pull fetches the latest changes and merges them into your current branch. If you are not sure what is going to come in from the repository, use `fetch` to examine the changes first and then merge the changes manually.

Pull might fail if you have conflicts. With a complicated change you might want to create a branch from the origin, make some compatibility changes, then merge that branch into the main tracking branch. For next steps, see “Pull, Push, and Fetch Files with Git” on page 19-51.

## Update Selected Files

To update selected files, right-click and select the **Update** command for the source control system you are using. For example, if you are using SVN, select **Source Control > Update from SVN** to get fresh local copies of the selected files from the repository.

## See Also

### Related Examples

- “Register Model Files with Source Control Tools” on page 19-8
- “Resolve Conflicts” on page 19-59
- “Discard Local Changes” on page 19-49

## Get SVN File Locks

To ensure users remember to get a lock on model files before editing, you can configure SVN to make model files read only. Follow the steps in “Enforce SVN Locking Model Files Before Editing” on page 19-13. After you configure SVN to make files with certain extensions read only, then users must get a lock on these read-only files before editing.

- 1 In a project, in any Files view, select the files you want to check out.
- 2 Right-click the selected files and select **Source Control > Get File Lock**.

**Get File Lock** is for SVN. This option does not modify the file in your local sandbox. Git does not have locks.

A lock symbol appears in the SVN source control column. Other users cannot see the lock symbol in their sandboxes, but they cannot get a file lock or check in a change when you have the lock. To view or break locks, click **Locks** on the Project tab.

---

**Note** To get a fresh local copy of the file from the repository, select **Update from SVN**.

---

In the Simulink Editor, if an open model belongs to a project under SVN, you can get a lock by selecting **File > Project > Get File Lock**.

If you see an SVN message reporting a `working copy locked` error, remove stale locks by clicking **SVN Cleanup** in the Source Control section on the Project tab. SVN uses working copy locks internally and they are not the file locks you control using **Get File Lock**.

---

**Note** Starting in R2020a Update 5, SVN cleanup only removes stale locks and unfinished transactions. It does not remove unversioned or ignored files.

You can manually remove unversioned and ignored files.

- 1 In the **Files** view, in the **All** tab, click the **SVN** header to sort files by their SVN status.
  - 2 Select the **Not Under Source Control** files.
  - 3 Right-click and select **Delete**.
- 

## Manage SVN Repository Locks

To manage global SVN locks for a repository, on the Project tab, in the Source Control section, click **Locks**.

In the SVN Repository Locks dialog box, you can:

- View which users have locks on files.
- Right-click to break locks.
- Group locks by user or file.

## **See Also**

### **Related Examples**

- “Work with Project Files” on page 17-7
- “Enforce SVN Locking Model Files Before Editing” on page 19-13
- “View Modified Files” on page 19-41
- “Commit Modified Files to Source Control” on page 19-47

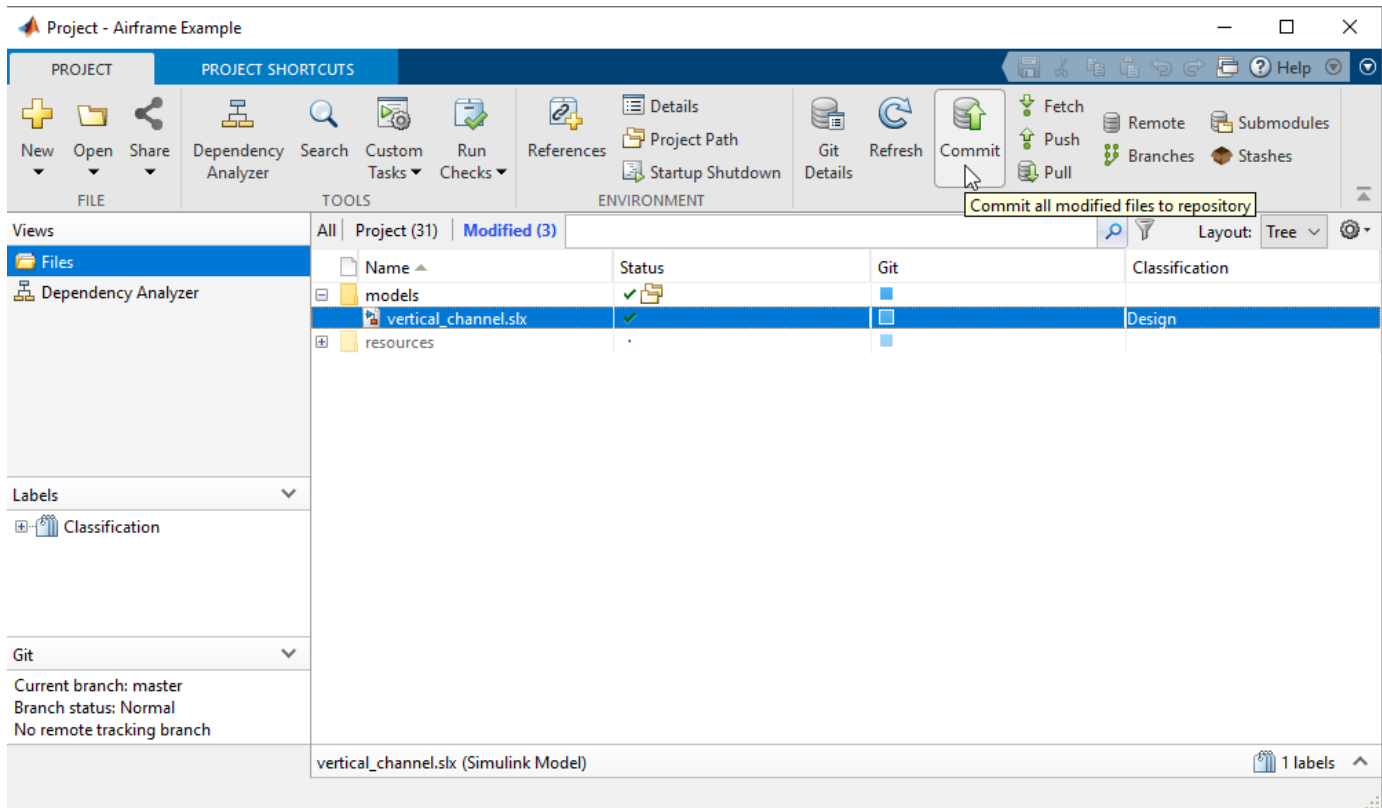

### **More About**

- “About Source Control with Projects” on page 19-2

## View Modified Files

To review, analyze, label, and commit modified project files, use the **Modified (number of files)** view. The modified files view is visible only if you are using source control with your project.

If you need to update the modified files list, click **Refresh** in the source control section.

Lists of modified files are sometimes called changesets. You can perform the same operations in the Modified files view as you can in other file views. To view changes, see “Compare Revisions” on page 19-44.

---

**Tip** In the **Modified** files view, it can be useful to switch to the **List** layout.

---

You can identify modified or conflicted folder contents using the source control summary status. In the Files views, folders display rolled-up source control status to help you locate changes in files, particularly conflicted files. Pause on the source control status (for example, the **SVN** or **Git** column) for a folder to see how many files inside are modified, conflicted, added, or deleted.

## Project Definition Files

The files in the resources/project folder are project definition files generated when you first create or make changes to your project. The project definition files enable you to add project metadata to files without checking them out. Some examples of metadata you can change this way

are shortcuts, labels, and project descriptions. Project definition files also specify the files added to your project. These files are not part of the project.

Any changes you make to your project generate changes in the `resources/project` folder. These files store the definition of your project in XML files whose format is subject to change.

You do not need to view project definition files directly, except when the source control tool requires a merge. The files are shown so that you know about all the files being committed to the source control system. See “Resolve Conflicts” on page 19-59.

Starting in R2020b, the default project definition file type is **Use multiple project files (fixed-path length)**. To change the project definition file management from the type selected when the project was created, use `matlab.project.convertDefinitionFiles`.  
`matlab.project.convertDefinitionFiles` preserves the source control history of your project.

---

**Warning** To avoid merge issues, do not convert the definition file type more than once for a project.

---

For releases before R2020b, if you want to change the project definition file management from the type selected when the project was created:

- 1 On the **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project** and in the **New Projects** section, select one of the options under **Project definition files**:
  - **Use multiple project files** - Helps to avoid file conflicts when performing merge on shared projects
  - **Use multiple project files (fixed-path length)** - Is better if you need to work with long paths
  - **Use a single project file (not recommended for source control)** - Is faster but is likely to cause merge issues when two users submit changes in the same project to a source control tool
- 2 Create a project archive file (`.mlproj`). For more information, see “Archive Projects” on page 17-35 or export.
- 3 Create a new project from the archived project. For more information, see “Create a New Project from an Archived Project” on page 16-23.

You can use the project preferences to change the project definition folder for new projects. Instead of `resources/project`, you can choose the `.SimulinkProject` or `_SimulinkProject` folder names adopted for releases before R2019a.

To stop managing your folder with a project and delete the `resources/project` folder, see `matlab.project.deleteProject`.

- “Discard Local Changes” on page 19-49
- “Commit Modified Files to Source Control” on page 19-47

## **More About**

- “About Source Control with Projects” on page 19-2

## Compare Revisions

To review changes in modified files in a project, select the **Modified (number of files)** tab.

If you need to update the modified files list, click **Refresh** in the source control section of the Project tab.

To review changes in modified files, right-click selected files in any view in a project and:

- Select **Compare > Compare to Ancestor** to run a comparison with the last checked-out version in the sandbox (SVN) or against the local repository (Git). The Comparison Tool displays a report.
- To compare other revisions of a file, select **Compare > Compare to Revision**. In the Compare to Revisions dialog box, you can view information about who previously committed the file, when they committed it, and the log messages. To view a comparison report, select the revisions you want to compare. You can:
  - Select a revision and click **Compare to Local**.
  - Select two revisions and click **Compare Selected**.
  - With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions..
- To browse the revision history of a file, select **Source Control > Show Revisions**. In the File Revisions dialog box, view information about who previously committed the file, when they committed it, and the log messages. With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions.

- To browse and compare files within committed SVN change sets, on the Project tab, in the Source Control section, select **Show Log**. In the File Revisions dialog box, select a revision to view a list of modified files. Right-click files in the lower list to view changes or save revisions.

---

**Note** In the Simulink Editor, if an open model, library, or chart belongs to a project under source control, you can view changes. To do so, on the **Simulation** tab, select **Project > Compare to Ancestor** or **Compare to Revision**.

---

When you compare to a revision or ancestor, the MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox with the selected revision or against its ancestor stored in the version control tool.

Comparison type depends on the file you select. If you select a Simulink model, this command runs a Simulink model comparison.

When reviewing changes, you can merge Simulink models from the Comparison Tool report. See “Merge Text Files” on page 19-60 and “Merge Models” on page 19-61.

To examine the dependencies of modified files, see “Perform an Impact Analysis” on page 18-17.

### More About

- “About Source Control with Projects” on page 19-2

## Run Project Checks

To run the project integrity checks, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Check Project**. The checks look for missing files, files to add to source control or retrieve from source control, and other issues.

For details on problems the checks can fix, see “Work with Derived Files in Projects” on page 19-63 and “Check Dependency Results and Resolve Problems” on page 18-23.

- Click **Check Project** to check the integrity of the project. For example, is everything under source control in the project? Are all project files under source control? A dialog box reports results. You can click for details and follow prompts to fix problems.
- If you want to check for required files, click **Dependency Analyzer** to analyze the dependencies of the modified files.

Use the dependency tools to analyze the structure of your project. See “Perform an Impact Analysis” on page 18-17.

---

**Note** The files in `resources/project` are project definition files generated by your changes. See “Project Definition Files” on page 19-41.

---

## Commit Modified Files to Source Control

Before you commit modified files, review changes and consider precommit actions. See “Compare Revisions” on page 19-44 and “Run Project Checks” on page 19-46.

- 1 In a project, select the **Modified (number of files)** view.

If you need to update the modified files list, click **Refresh** in the source control section of the Project tab.

- 2 To check in all files in the modified files list, on the Project tab, in the Source Control section, click **Commit**.

If you are using SVN source control, this commits changes to your repository.

If you are using Git source control, this commits to your local repository. To commit to the remote repository, see “Pull and Push” on page 19-51.

- 3 Enter comments in the dialog box if you want, and click **Submit**.
- 4 A message appears if you cannot commit because the repository has moved ahead. Before you can commit the file, you must update its revision up to the current HEAD revision. If you are using SVN source control, click **Update**. If you are using Git source control, click **Pull**. Resolve any conflicts before you commit.

**Note** You can commit individual files using the context menu, by selecting **Source Control > Commit**. However if you commit individual files, you risk not committing the related project

definition files that keep track of your files. Instead, use the **Modified** files view to see all changes, and on the Project tab, click **Commit** to commit all related changes.

---

## See Also

- “View Modified Files” on page 19-41
- “Run Project Checks” on page 19-46
- “Update Revisions of Project Files” on page 19-37
- “Pull, Push, and Fetch Files with Git” on page 19-51
- “Resolve Conflicts” on page 19-59
- “Revert Changes” on page 19-49

### More About

- “About Source Control with Projects” on page 19-2

## Revert Changes

### In this section...

“Discard Local Changes” on page 19-49

“Revert a File to a Specified Revision” on page 19-49

“Revert the Project to a Specified Revision” on page 19-50

### Discard Local Changes

With SVN, if you want to roll back local changes in a particular file, in a project, right-click the file and select **Source Control > Discard Local Changes and Release Locks** to release locks and revert to the version in the last sandbox update (that is, the last version you synchronized or retrieved from the repository).

In the Simulink Editor, if an open model belongs to a project under source control, you can revert changes. To do so, on the **Simulation** tab, select **Project > Discard Local Changes and Release Locks**.

To abandon all local changes, in a project select all the files in the **Modified** files list, then right-click and select **Discard Local Changes and Release Locks**.

With Git, right-click a file and select **Source Control > Revert Local Changes**. Git does not have locks. To remove all local changes, click **Branches** in the **Git** pane and click **Revert to Head**.

### Revert a File to a Specified Revision

- 1 Right-click a file and select **Source Control > Revert using SVN** or **Source Control > Revert using Git**.
- 2 In the Revert Files dialog box, choose a revision to revert to. Select a revision to view information about the change such as the author, date, log message.

With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions.

- 3 Click **Revert**.

The project reverts the selected file.

- 4 If you revert a file to an earlier revision and then make changes, you cannot commit the file until you resolve the conflict with the repository history.

With SVN, if you try to commit the file, you see a message that it is out of date. Before you can commit the file, you must update its revision up to the current HEAD revision. click **Update** in the source control section on the Project tab.

The project marks the file as conflicted because you have made changes to an earlier version of the file than the version in the repository.

- 5 With either SVN or Git, to examine conflicts, right-click and select **View Conflicts**.

Decide how to resolve the conflict or to keep your changes to the reverted file. See “Resolve Conflicts” on page 19-59.

- 6 After you have resolved the conflict, mark the conflict resolved, either by using the merge tool or manually by right-clicking the file and selecting **Source Control > Mark Conflict Resolved**.
- 7 Select the **Modified (number of files)** view to check changes, and on the **Project** tab, click **Commit**.

## Revert the Project to a Specified Revision

With SVN, inspect the project revision information by clicking **Show Log** in the in Source Control section on the Project tab. In the Log dialog box, each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, log message and the list of modified files.

To revert the project:

- 1 On the Project tab, in the Source Control section, click **Revert Project**.
- 2 In the Revert Files dialog box, choose a revision to revert to.

Each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, and the log message.

With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions.

- 3 Click **Revert**.

The project displays progress messages in the SVN pane as it restores the project to the state it was in when the selected revision was committed. Depending on the change set you selected, all files do not necessarily have a particular revision number or matching revision numbers. For example, if you revert a project to revision 20, all files will show their revision numbers when revision 20 was committed (20 or lower).

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-55.

## See Also

### Related Examples

- “Resolve Conflicts” on page 19-59

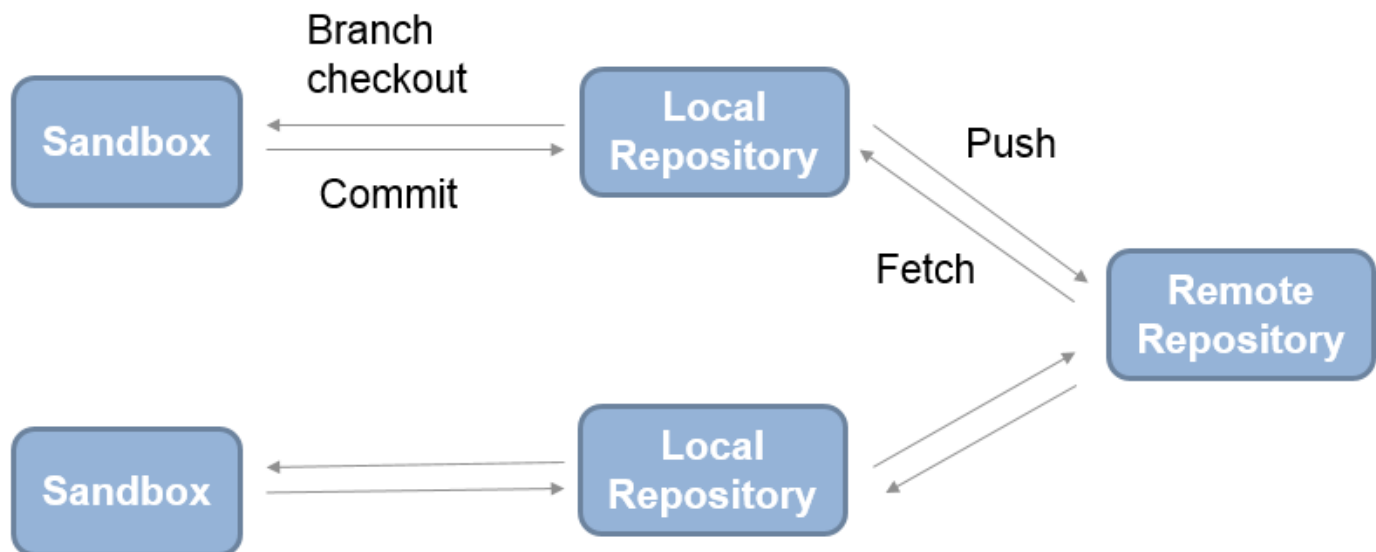

## Pull, Push, and Fetch Files with Git

### In this section...

“Pull and Push” on page 19-51  
 “Pull, Fetch, and Merge” on page 19-52  
 “Push Empty Folders” on page 19-54  
 “Use Git Stashes” on page 19-54

### Pull and Push

Use this workflow to work with a Git project connected to a remote repository. With Git, there is a two-step workflow: commit local changes, and then push to the remote repository. In a project, the only access to the remote repository is through the **Pull**, **Push**, and **Fetch** buttons. All other actions use the local repository (such as **Check for Modifications**, **Compare to Ancestor**, and **Commit**). This diagram represents the Git workflow.

- 1 To get the latest changes, on the Project tab, in the Source Control section, click **Pull**. Pull fetches the latest changes and merges them into your current branch.

**Note** Before you can merge, you must register model files as binary to prevent Git from inserting conflict markers. See “Register Model Files with Source Control Tools” on page 19-8.

- 2 To create branches to work on, on the Project tab, in the Source Control section, click **Branches**. Create branches in the Branches dialog box, as described in “Branch and Merge Files with Git” on page 19-55.
- 3 When you want to commit changes, select the Modified files view to view files, and on the **Project** tab, click **Commit**. The changes are committed to your current branch in your local repository. Check the **Git** pane for information about the current branch. You see the message Ahead when you commit local changes that have moved ahead of the remote tracking branch.

Current branch: master  
Branch status: SAFE  
Ahead of /origin/master

- 4 To send your local commits to the remote repository, on the Project tab, in the Source Control section, click **Push**.
- 5 A message appears if you cannot push your changes directly because the repository has moved on. Click **Fetch** to fetch changes from the remote repository. Merge branches and resolve conflicts, and then you can push your changes. See “Pull, Fetch, and Merge” on page 19-52.

## Pull, Fetch, and Merge

Use **Fetch** to get changes and merge manually. Use **Pull** instead to fetch the latest changes and merge them into your current branch.

---

**Note** Before you can merge branches, you must register model files as binary to prevent Git from inserting conflict markers. See “Register Model Files with Source Control Tools” on page 19-8.

---

Pull fetches the latest changes and merges them into your current branch. If you are not sure what is going to come in from the repository, use fetch instead to examine the changes, and then merge the changes manually.

Pull might fail if you have conflicts. With a complicated change you might want to create a branch from the origin, make some compatibility changes, then merge that branch into the main tracking branch.

To fetch changes from the remote repository, click **Fetch** on the Project tab.

Fetch updates all of the origin branches in the local repository.

---

**Note** When you click **Fetch**, your sandbox files are not changed. To see others’ changes, you need to merge in the origin changes to your local branches.

---

Check the Git pane for information about your current branch relative to the remote tracking branch in the repository. When you see the message **Behind**, you need to merge in changes from the repository to your local branch.

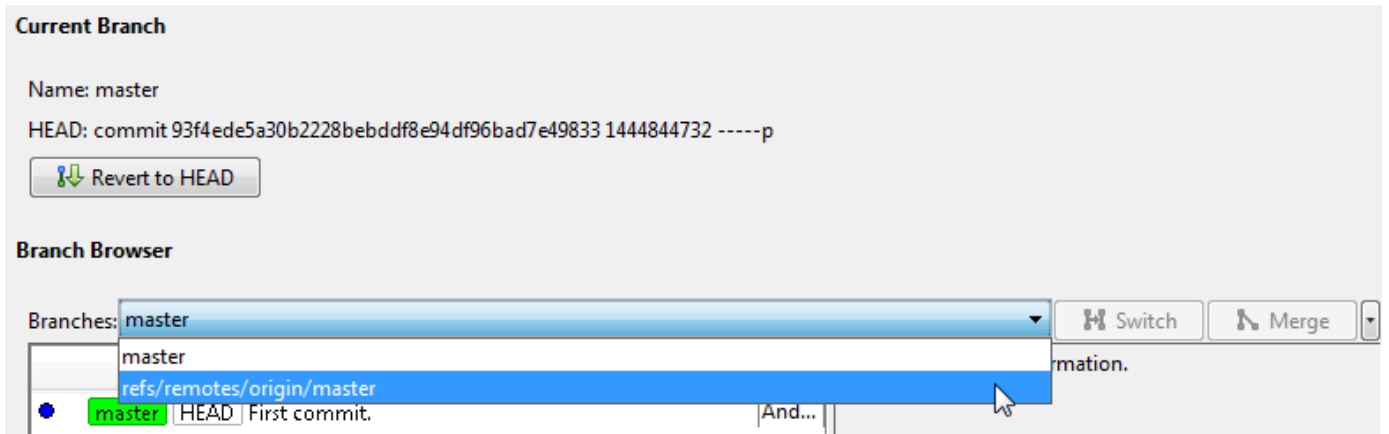

For example, if you are on the main branch and want to get changes from the main branch in the remote repository:

- 1 Click **Fetch**.

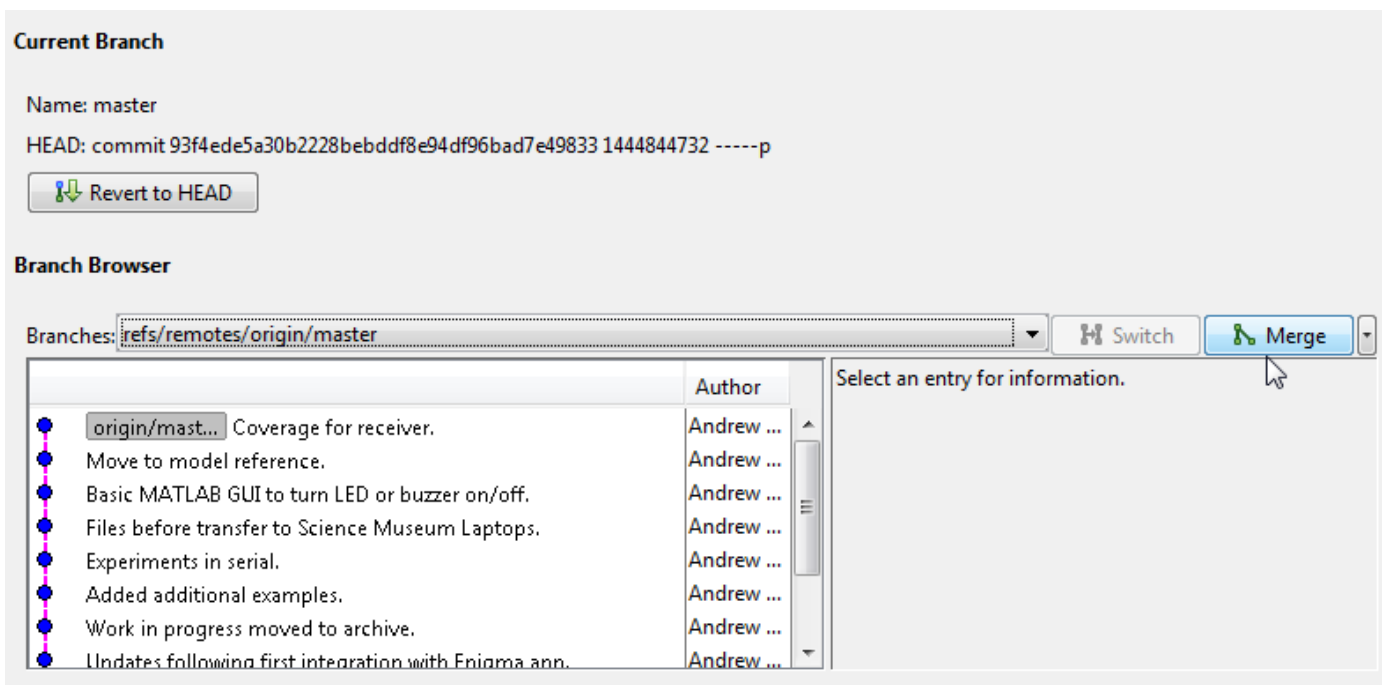

Observe the message in the Git pane, **Behind /origin/main**. You need to merge in the changes from the repository to your local branch, using **Branches**.

Current branch: master  
Branch status: SAFE  
Behind /origin/master

- 2 Click **Branches**.
- 3 In the Branches dialog box, in the **Branches** list, select **origin/main**.

- 4 Click **Merge**. This merges the origin branch changes into the main branch in your sandbox.

- 5 Close the Branches dialog box. Observe the message in the Git pane now says **Coincident with / origin/main**. You can now view the changes fetched and merged from the remote repository in your local sandbox files.

When you fetch and merge, you might need to resolve conflicting changes. If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. Resolve the conflicts before proceeding. See “Resolve Conflicts” on page 19-59.

## Push Empty Folders

Using Git, you cannot add empty folders to source control, so you cannot select **Push** and then clone an empty folder. You can create an empty folder in a project, but if you push changes and then sync a new sandbox, then the empty folder does not appear in the new sandbox. You can instead run **Check Project** which creates the empty folder for you.

Alternatively, to push empty folders to the repository for other users to sync, create a `gitignore` file in the folder and then push your changes.

## Use Git Stashes

Store uncommitted changes for later use by creating a Git stash. Use stashes to:

- Store modified files without committing them.
- Move changes easily to a new branch.
- Browse and examine the changes within a stash.

To create and manage stashes, on the **Project** tab, in the **Source Control** section, click **Stashes**. In the Stashes dialog box:

- To create a stash containing your currently modified files, click **New Stash**.
- To view modified files in a stash, select the stash under **Available Stashes**. Right-click modified files to view changes or save a copy.
- To apply the stash to your current branch and then delete the stash, click **Pop**.
- To apply the stash and keep it, click **Apply**.
- To delete the stash, click **Drop**.

- “Create a Branch” on page 19-55
- “Switch Branch” on page 19-56
- “Compare Branches and Save Copies” on page 19-57
- “Merge Branches” on page 19-57
- “Revert to Head” on page 19-58
- “Delete Branches” on page 19-58

### Create a Branch

- 1 In a project using Git source control, click **Branches** on the Project tab. The Branches dialog box appears, where you can view, switch, create, and merge branches.

---

**Tip** You can inspect information about each commit node. Select a node in the Branch Browser diagram to view the author, date, commit message, and changed files.

---

The **Branches** pane in this figure shows an example branch history.

- 2 Select a source for the new branch. Click a node in the Branch Browser diagram, or enter a unique identifier in the Source text box. You can enter a tag, branch name, or a unique prefix of the SHA1 hash (for example, 73c637 to identify a specific commit). Leave the default to create a branch from the head of the current branch.
- 3 Enter a name in the **Branch name** text box and click **Create**.
- 4 To work on the files on your new branch, switch your project to the branch.

In the **Branches** drop-down list, select the branch you want to switch to and click **Switch**.

- 5 Close the Branches dialog box to return to the project and work on the files on your branch.

For next steps, see “Pull, Push, and Fetch Files with Git” on page 19-51.

## Switch Branch

- 1 In a project, click **Branches**.
- 2 In the Branches dialog box, select the branch you want to switch to in the **Branches** list and click **Switch**.

- 3 Close the Branches dialog box to return to the project and work on the files on the selected branch.

## Compare Branches and Save Copies

From within your Git repository folder, right-click the white space of the Current Folder browser and select **Source Control > Branches**.

- To examine differences in a file between the current revision and its parent, right-click a file in the tree under **Differences from parent** and select **Show Difference**.
- To examine differences in a file between any two revisions including revisions on two different development branches, hold the **Ctrl** key and select the two different revisions. Right-click a file in the tree under **Differences from selection** and select **Show Difference**.

MATLAB opens a comparison report. You can save a copy of the selected file on either revision. Right-click a file and select **Save As** to save a copy of the file on the selected revision. Select **Save Original As** to save a copy of the file on the prior revision. This is useful if you want to test how the code ran in previous revisions or on other branches.

## Merge Branches

Before you can merge branches, you must register model files as binary to prevent Git from inserting conflict markers. See “Register Model Files with Source Control Tools” on page 19-8.

---

**Tip** After you use **Fetch**, you must merge. See “Pull, Fetch, and Merge” on page 19-52.

---

To merge any branches:

- 1 In a project, click **Branches**.
- 2 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to merge into the current branch, and click **Merge**.
- 3 Close the Branches dialog box to return to the project and work on the files on the current branch.

If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. The Branch status in the **Git** pane displays **MERGING**. Resolve the conflicts before proceeding.

---

**Caution** Do not move or delete files outside of MATLAB because this can cause errors on merge.

---

## Keep Your Version

- 1 To keep your version of the file, right-click the file and select **Mark Conflict Resolved**. The Branch status in **Git** pane displays **MERGE\_RESOLVED**. The Modified Files list is empty, because you have not changed any file contents. The local repository index version and your branch version are identical.
- 2 Click **Commit** to commit your change that marks the conflict resolved.

### **View Conflicts in Branch Versions**

If you merge a branch and there is a conflict in a model file, Git marks the file as conflicted and does not modify the contents. Right-click the file and select **View Conflicts**. The project opens a comparison report showing the differences between the file on your branch and the branch you want to merge into. Decide how to resolve the conflict. See “Resolve Conflicts” on page 19-59.

### **Revert to Head**

To remove all local changes, in the Branches dialog box, click **Revert to Head**.

### **Delete Branches**

- 1 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to delete. You cannot delete the current branch.
- 2 On the far right, click the down arrow and select **Delete Branch**.

---

**Caution** You cannot undo deleting a branch.

---

### **See Also**

#### **Related Examples**

- “Set Up Git Source Control” on page 19-16
- “Pull, Push, and Fetch Files with Git” on page 19-51
- “Resolve Conflicts” on page 19-59

#### **More About**

- “About Source Control with Projects” on page 19-2

## Resolve Conflicts

### In this section...

- “Resolve Conflicts” on page 19-59
- “Merge Text Files” on page 19-60
- “Merge Models” on page 19-61
- “Extract Conflict Markers” on page 19-61

## Resolve Conflicts

If you and another user change the same file in different sandboxes or on different branches, a conflict message appears when you try to commit your modified files. Extract conflict markers if necessary, compare the differences causing the conflict, and resolve the conflict.

- 1 Look for conflicted files in the **Modified (number of files)** tab.

Identify conflicted folder contents using source control summary status. Folders display rolled-up source control status. This makes it easier to locate changes in files, particularly conflicted files. You can hover over the source control status for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

**Tip** Use the **List** layout to view files without needing to expand folders.

- 2 Check the source control status column (**Git** or **SVN**) for files with a red warning symbol, which indicates a conflict.

Name	Status	Git	Classification
.SimulinkProject			
models	✓	⚠	None
AnalogControl.mdl	✓		Upgrade
DigitalControl.slx	✓		Design
slproject_f14.slx	✓	⚠ (both modified)	Design
tests	✓		None
f14_airframe_test.m	✓		Test
utilities	✓		None
clean_up_project.m	✓		Utility

- 3 Right-click the conflicted file and select **View Conflicts** to compare versions.
- 4 Examine the conflict. The project opens a comparison report showing the differences between the conflicted files.
  - For SVN, the comparison shows the differences between the file and the version of the file in conflict.
  - For Git, the comparison shows the differences between the file on your branch and the branch you want to merge into.
  - For model files, see “Merge Simulink Models from the Comparison Report” on page 21-16.

- 5 Use the comparison report to determine how to resolve the conflict.

To resolve conflicts you can:

- Use the report to merge changes between revisions.
- Decide to overwrite one set of changes with the other.
- Make changes manually from the project by editing files, changing labels, or editing the project description.

For details on using the Comparison Tool to merge changes between revisions, see “Merge Text Files” on page 19-60 and “Merge Models” on page 19-61.

- 6 When you have resolved the changes and want to commit the version in your sandbox, in a project, right-click the file and select **Source Control > Mark Conflict Resolved**. You can use the merge tool to mark the conflict resolved, or you can choose to manually mark the conflict resolved in the project.

For Git, the Branch status in the **Git** pane changes from MERGING to SAFE.

- 7 Select the **Modified (number of files)** tab to check changes. On the **Project** tab, click **Commit**.

## Merge Text Files

When comparing text files, you can merge changes from one file to the other. Merging changes is useful when resolving conflicts between different versions of files.

Conflict markers appear in a text comparison report like this:

```
<<<<<<< .mine
```

If your comparison report contains conflict markers, extract them before merging, as described in “Extract Conflict Markers” on page 19-61.

---

**Tip** You can merge only from left to right. When comparing to another version in source control, the right file is the version in your sandbox. The left file is either a temporary copy of the previous version or another version causing a conflict (e.g., *filename\_theirs*). Observe the file paths of the left and right file at the top of the comparison report. Merge differences from the left (temporary copy) file to the right file to resolve conflicts.

---

- 1 In the Comparison Tool report, select a difference in the report and click **Replace Content**. The selected difference is copied from the left file to the right file.

To undo the content replacement, click **Undo**.

Alternatively, use the inline **Replace Content** and **Undo** icons.

The merged file name at the top of the report displays the dirty flag (*filename.m\**) to show you that the file contains unsaved changes.

- 2 Click **Accept & Close** to save the merge changes and mark the conflicts resolved.

## Merge Models

In the Comparison Tool report, you can merge changes between revisions. For details, see “Merge Simulink Models from the Comparison Report” on page 21-16.

After merging to resolve conflicts, the merge tool can mark the conflict resolved for you, or you can choose to manually mark the conflict resolved. Then commit the changes, as described in “Resolve Conflicts” on page 19-59.

## Extract Conflict Markers

- “What Are Conflict Markers?” on page 19-61
- “Extract Conflict Markers” on page 19-62

### What Are Conflict Markers?

Source control tools can insert conflict markers in files that you have not registered as binary (e.g., text files). You can use project tools to extract the conflict markers and compare the files causing the conflict. This process helps you to decide how to resolve the conflict.

---

**Caution** Register model files with source control tools to prevent them from inserting conflict markers and corrupting models. See “Register Model Files with Source Control Tools” on page 19-8. If your model already contains conflict markers, the project tools can help you to resolve the conflict, but only if you open the model from the project. Opening a model that contains conflict markers from the Current Folder or from a file explorer can fail because Simulink does not recognize conflict markers.

---

Conflict markers have the following form:

```
<<<<<<["mine" file descriptor]
["mine" file content]
=====
["theirs" file content]
>>>>>>["theirs" file descriptor]
```

If you try to open a file marked conflicted that contains conflict markers, the Conflict Markers Found dialog box opens. Follow the prompts to fix the file by extracting the conflict markers. After you extract the conflict markers, resolve the conflicts as described in “Resolve Conflicts” on page 19-59.

To view the conflict markers, in the Conflict Markers Found dialog box, click **Load File**. Do not try to load model files, because Simulink does not recognize conflict markers. Instead, click **Fix File** to extract the conflict markers.

By default, the project checks only conflicted files for conflict markers. You can change this preference to check all files or no files. Click **Preferences** in the Project tab to change the setting.

### **Extract Conflict Markers**

When you open a conflicted file or select **View Conflicts**, the project checks files for conflict markers and offers to extract the conflict markers. The project checks only conflicted files for conflict markers unless you change your preferences setting.

However, some files that are not marked conflicted can still contain conflict markers. This can happen if you or another user marked a conflict resolved without removing the conflict markers and then committed the file. If you see conflict markers in a file that is not marked conflicted, you can remove the conflict markers.

- 1** In a project, right-click the file and select **Source Control > Extract Conflict Markers to File**.
- 2** Leave the default option to copy the “mine” revision over the conflicted file. Leave the **Compare** check box selected. Click **Extract**.
- 3** Use the Comparison Tool report as usual to continue to resolve the conflict.

## Work with Derived Files in Projects

Best practice is to omit derived and temporary files from your project or exclude them from source control. To check the integrity of the project, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Check Project**. If you add the `slprj` folder to a project, the project checks advise you to remove this from the project and offer to make the fix.

Best practice is to exclude derived files, such as `.mex*`, the contents of the `slprj` folder, `sccprj` folder, or other code generation folders from source control, because they can cause problems. For example:

- With a source control that can do file locking, you can encounter conflicts. If `slprj` is under source control and you generate code, most of the files under `slprj` change and become locked. Other users cannot generate code because of file permission errors. The `slprj` folder is also used for simulation via code generation (for example, with model reference or Stateflow), so locking these files can have an impact on a team. The same problems arise with binaries, such as `.mex*`.
- Deleting `slprj` is often required. However, deleting `slprj` causes problems such as “not a working copy” errors if the folder is under some source control tools (for example, SVN).
- If you want to check in the generated code as an artifact of the process, it is common to copy some of the files out of the `slprj` cache folder and into a separate location that is part of the project. That way, you can delete the temporary cache folder when you need to. See `packNGo` to discover the list of generated code files, and use the project API to add to the project with appropriate metadata.
- The `slprj` folder can contain many small files. This can affect performance with some source control tools when each of those files is checked to see if it is up-to-date.

## Customize External Source Control to Use MATLAB for Diff and Merge

### In this section...

“Finding the Full Paths for MATLAB Diff, Merge, and AutoMerge” on page 19-64

“Integration with Git” on page 19-65

“Integration with SVN” on page 19-66

“Integration with Other Source Control Tools” on page 19-67

You can customize external source control tools to use the MATLAB Comparison Tool for diff and merge. If you want to compare MATLAB files such as live scripts, MAT, SLX, or MDL files from your source control tool, then you can configure your source control tool to open the MATLAB Comparison Tool. For a more complete list of supported files, see `visdiff`. The MATLAB Comparison Tool provides tools for merging MathWorks files and is compatible with popular software configuration management and version control systems. You can use the `automerger` tool with Git to automatically merge branches that contain changes in different subsystems in the same SLX file.

To set up your source control tool to use MATLAB as the application for diff and merge, you must first determine the full paths of the `mldiff`, `mlmerge`, and `mlautomerger` executable files, and then follow the recommended steps for the source control tool you are using.

### Finding the Full Paths for MATLAB Diff, Merge, and AutoMerge

To get the required file paths and enable external source control tools to reuse open MATLAB sessions, run this command in MATLAB:

```
comparisons.ExternalSCMLink.setup()
```

This command sets the MATLAB preference, under **Comparison**, called **Allow external source control tools to use open MATLAB sessions for diffs and merges**.

This command also displays the file paths to copy and paste into your source control tool setup:

- On Windows:

Diff: `matlabroot\bin\win64\mldiff.exe`

Merge: `matlabroot\bin\win64\mlmerge.exe`

AutoMerge: `matlabroot\bin\win64\mlautomerger.bat`

- On Linux:

Diff: `matlabroot/bin/glnxa64/mldiff`

Merge: `matlabroot/bin/glnxa64/mlmerge`

AutoMerge: `matlabroot/bin/glnxa64/mlautomerger`

- On Mac:

Diff: `matlabroot/bin/maci64/mldiff`

Merge: `matlabroot/bin/maci64/mlMerge`

AutoMerge: `matlabroot/bin/maci64/mlAutoMerge`

where `matlabroot` is replaced with the full path to your installation, for example, `C:\Program Files\MATLAB\R2020b`.

---

**Note** Your diff and merge operations use open MATLAB sessions when available, and only open MATLAB when necessary. The operations only use the specified MATLAB installation.

---

## Integration with Git

### Command Line

To configure MATLAB diff and merge tools with command-line Git:

- 1 Run this command in MATLAB.

```
comparisons.ExternalSCMLink.setupGitConfig()
```

This command displays the full paths of the `mlDiff`, `mlMerge`, and `mlAutoMerge` executable files. It also automatically populates the global `.gitconfig` file. For example:

```
[difftool "mlDiff"]
  cmd = \"C:/Program Files/MATLAB/R2020b/bin/win64/mlDiff.exe\" $LOCAL $REMOTE
[mergetool "mlMerge"]
  cmd = \"C:/Program Files/MATLAB/R2020b/bin/win64/mlMerge.exe\" $BASE $LOCAL $REMOTE $MERGED
[merge "mlAutoMerge"]
  driver = \"C:/Program Files/MATLAB/R2020b/bin/win64/mlAutoMerge.bat\" %0 %A %B %A
```

---

**Note** You need to do step 1 only once for your Git setup.

---

- 2 Configure your repository to use the `mlAutoMerge` executable file. Open the `.gitattributes` file in your repository and add:

```
*.slx binary merge=mlAutoMerge
```

Now, when you merge branches that contain changes in different subsystems in the same SLX file, MATLAB handles the merge automatically.

To run the MATLAB diff and merge tools from command-line Git, use `git difftool` and `git mergetool`:

- To compare two revisions of a model using the MATLAB diff tool, type:

```
git difftool -t mlDiff <revisionID1> <revisionID2> myModel.slx
```

If you do not provide revision IDs, `git difftool` compares the working copy to the repository copy.

If you do not specify which model you want to compare, command-line Git will go through all modified files and ask you if you want to compare them one by one.

- To resolve a merge conflict in a model using the MATLAB merge tool, type:

```
git mergetool -t mlMerge myModel.slx
```

If you do not specify which model you want to merge, command-line Git will go through all files and ask you if you want to merge them one by one.

## SourceTree

SourceTree is an interactive GUI tool that visualizes and manages Git repositories for Windows and Mac.

- 1 Configure the MATLAB diff and merge tools as SourceTree external tools:
  - a With SourceTree open, click **Tools > Options**.
  - b On the **Diff** tab, under **External Diff / Merge**, fill the fields with the following information:

```
External Diff tool: Custom
Diff Command: C:\Program Files\MATLAB\R2020b\bin\win64\mLDiff.exe
Arguments: $LOCAL $REMOTE
Merge tool: Custom
Merge Command: C:\Program Files\MATLAB\R2020b\bin\win64\mLMerge.exe
Arguments: $BASE $LOCAL $REMOTE $MERGED
```

- 2 Configure your repository to automerge changes in different subsystems in the same SLX file using the `mLAutoMerge` executable file:

- a Open the global `.gitconfig` file and add:

```
[merge "mLAutoMerge"]
  driver = \"C:/Program Files/MATLAB/R2020b/bin/win64/mLAutoMerge.bat\" %0 %A %B %A
```

- b Open the `.gitattributes` file in your repository and add:

```
*.slx binary merge=mLAutoMerge
```

---

**Tip** Customize the full path of the `mLDiff`, `mLMerge`, and `mLAutoMerge` executables to match both the MATLAB installation and the operating system you are using. For more information, see “Finding the Full Paths for MATLAB Diff, Merge, and AutoMerge” on page 19-64.

---

To use the MATLAB diff tool from within SourceTree, right-click a modified file under **Unstaged files** and select **External Diff**.

To use the MATLAB merge tool when SourceTree detects a merge conflict, select the **Uncommitted changes** branch, right-click a modified file, and select **Resolve Conflicts > Launch External Merge Tool**.

## Integration with SVN

### TortoiseSVN

With TortoiseSVN, you can customize your diff and merge tools based on the file extension. For example, to use MATLAB diff and merge tools for SLX files:

- 1 Right-click in any file explorer window and select **TortoiseSVN > Settings** to open TortoiseSVN settings.
- 2 In the **Settings** sidebar, select **Diff Viewer**. Click **Advanced** to specify the diff application based on file extensions.
- 3 Click **Add** and fill the fields with the extension and the `mLDiff` executable path:

```
Filename, extension or mime-type: .slx
External Program: "C:\Program Files\MATLAB\R2020b\bin\win64\mLDiff.exe" %base %mine
```

- 4 Click **OK** and repeat the same steps to add another file extension.

- 5 In the **Settings** sidebar, select **Diff ViewerMerge Tool**. Click **Advanced** to specify the merge application based on file extensions.
- 6 Click **Add** and fill the fields with the extension and mLMerge executable path:
 

```
Filename, extension or mime-type: .slx
External Program: "C:\Program Files\MATLAB\R2020b\bin\win64\mLMerge.exe" %base %mine %theirs %merged
```
- 7 Click **OK** and repeat the same steps to add another file extension.

You can now use the MATLAB tools for diff and merge the same way you would use the TortoiseSVN default diff and merge applications.

---

**Note** Automerging binary files with SVN , such as SLX files, is not supported.

---

## Integration with Other Source Control Tools

### Perforce P4V

With Perforce® P4V, you can customize your diff and merge tools based on the file extension. To use MATLAB diff and merge tools for SLX files, for example:

- 1 In Perforce, click **Edit > Preferences**.
- 2 In the **Preferences** sidebar, select **Diff**. Under **Specify diff application by extension (overrides default)**, click **Add**.
- 3 In the **Add File Type** dialog box, enter the following information:
 

```
Extension: .slx
Application: C:\Program Files\MATLAB\R2020b\bin\win64\mLDiff.exe
Arguments: %1 %2
```
- 4 Click **Save**.
- 5 In the **Preferences** sidebar, select **Merge**. Under **Specify merge application by extension (overrides default)**, click **Add**.
- 6 In the **Add File Type** dialog box, enter the following information:
 

```
Extension: .slx
Application: C:\Program Files\MATLAB\R2020b\bin\win64\mLMerge.exe
Arguments: %b %2 %1 %r
```
- 7 Click **Save** and repeat the steps for other file extensions.

---

**Tip** Customize the full path of the mLDiff and mLMerge executables to match both the MATLAB installation and the operating system you are using. For more information, see “Finding the Full Paths for MATLAB Diff, Merge, and AutoMerge” on page 19-64.

---

You can now use the MATLAB tools for diff and merge the same way you would use the Perforce default diff and merge applications.

## See Also

### Related Examples

- “Compare Files and Folders and Merge Files”

- “Automatically Merge Models” on page 19-25

## Continuous Integration Using MATLAB Projects and Jenkins

### In this section...

“Prerequisites” on page 19-69

“Set Up MATLAB Project for Continuous Integration in Jenkins” on page 19-69

“Reduce Test Runtime Using Dependency Cache and Impact Analysis” on page 19-70

“Enhance Workflow” on page 19-71

This example shows how to set up a MATLAB project for continuous integration and run a suite of MATLAB unit tests with Jenkins.

- Configure a freestyle Jenkins project to access a MATLAB project hosted in a remote repository.
- Add a build step to the Jenkins project to run all project tests.
- Add a build step to the Jenkins project to run tests impacted by the latest change.
- Add a post-build step to archive and reuse the dependency analysis cache file to reduce test suite runtime when qualifying a change.
- Build the project and examine the test results.

**Note** You can use different continuous integration (CI) platforms such as Azure® DevOps, Bamboo®, and GitHub Actions to run MATLAB code and Simulink models as part of your automated workflow. For a list of supported CI platforms, see “Continuous Integration with MATLAB on CI Platforms”

### Prerequisites

Before you start:

- 1 Install Jenkins. See <https://www.jenkins.io/doc/book/installing/>.
- 2 Install the MATLAB plugin for Jenkins:
  - a From within Jenkins, on the **Manage Jenkins** page, click **Manage Plugins**.
  - b On the **Available** tab, search for "MATLAB".
  - c Download and install the plugin.

For more information, see Plugin Configuration Guide (GitHub).

- 3 Put your MATLAB project under Git source control and share on GitHub:
  - a With the project loaded, on the **Project** tab, select **Share > GitHub**.
  - b Enter your GitHub user name and personal access token, and edit the name for the new repository. Click **Create**.

Your MATLAB project is publicly available on GitHub. You can make your repository private by changing the settings in your GitHub account.

### Set Up MATLAB Project for Continuous Integration in Jenkins

Create a new Jenkins project:

- 1 In the Jenkins interface, in the left pane, click **New Item**.
- 2 Enter a name for your Jenkins project, select **Freestyle project**, and click **OK**.

Configure your Jenkins project. In the left pane, click **Configure**.

- 1 In the **Source Code Management** section, specify the **Repository URL** that hosts your MATLAB project. For example, `https://github.com/username/Airframe-Example.git`.
- 2 In the **Build Triggers** section, you can specify when and how frequently you want to run builds. For example, to build your project after every GitHub push notification, select **GitHub hook trigger for GITScm polling**.
- 3 In the **Build Environment** section, select **Use MATLAB Version** and specify the **MATLAB root**, for example, `C:\Program Files\MATLAB\R2022a`.
- 4 To specify the test suite you want to run, in the **Build** section, select **Add Build Step > Run MATLAB Tests**. To run all tests stored in a specific folder, select **By folder name** and specify the test folder name. For example, `tests`. By default, **Run MATLAB Tests** runs all test files in the MATLAB project.

Alternatively, use the **Run MATLAB Command** step to run all tests using the MATLAB project label. In the **Build** section, select **Add Build Step > Run MATLAB Command**. In the **Command** field, enter this script.

```
proj = openProject("ProjectAirframeExample.prj");
files = proj.Files;
testFiles = [findLabel(files, "Classification", "Test").File];

runtests(testFiles)
```

- 5 To save the Jenkins project configuration, click **Save**.
- 6 To build your project and run all tests, click **Build Now**. Jenkins triggers a build, assigns it a number under **Build History**, and runs the build. If the build is successful, a blue circle icon appears next to the build number. If the build fails, a red circle icon appears. For more information, see [Run MATLAB Tests on Jenkins Server \(GitHub\)](#).

## Reduce Test Runtime Using Dependency Cache and Impact Analysis

You can share the dependency cache file to reduce qualification time on local machines and CI servers. Using a prepopulated dependency cache file, you can perform an incremental impact analysis and run only the tests impacted by a change.

### Set MATLAB Project Dependency Cache File

To set the project dependency cache file, in MATLAB, on the **Project** tab, in the **Environment** section, click **Details**. In **Dependency cache file**, browse to and specify a GraphML file. If the cache file does not exist, the project creates it for you when you run a dependency analysis.

Alternatively, you can create and set the project dependency cache programmatically.

```
proj = currentProject;
proj.DependencyCacheFile = "work/dependencyanalysis/projectcache.graphml";
```

Commit and push the change to make it available on GitHub and Jenkins. On the **Project** tab, in the **Source Control** section, click **Commit**, then click **Push**.

## Generate and Archive Dependency Cache File on Jenkins

To configure your Jenkins project to generate and archive the dependency analysis cache file, on your Jenkins project configuration page:

- 1 Add a new build step. In the **Build** section, select **Add Build Step > Run MATLAB Command**. In the **Command** field, enter this script.

```
proj = openProject("ProjectAirframeExample.prj");
updateDependencies(proj);
```

This script launches MATLAB, loads your MATLAB project, runs a dependency analysis, and caches the results in the dependency cache file.

- 2 In the **Post-build Actions** section, under **Archive the artifacts**, in the **Files to archive** field, enter: `work/dependencyanalysis/*.graphml`. After the build, Jenkins copies the GraphML file from the Jenkins workspace to the build archive location.

## Share Cache for Faster Dependency Analysis on Local Machines

If you configured Jenkins to perform frequent builds, team members can sync their working copy based on the last successful build. Team members check out the design changes from Git, retrieve the associated dependency cache file from the build archive area, and place the GraphML file in the specified location.

On a local machine, MATLAB projects use the prepopulated dependency cache file to run an incremental dependency analysis. This action saves time for workflows running a dependency analysis in the background, such as automatic renaming, sharing a project, and performing an impact analysis.

## Run Impacted Tests and Reduce Qualification Runtime on CI Servers

On a CI server, for large projects, you can use the prepopulated dependency cache to perform an incremental impact analysis. You can configure your project build to run only impacted tests and significantly reduce runtime when qualifying a code change.

To configure your Jenkins project to only run tests impacted by the last change, in the **Build** section, select **Add Build Step > Run MATLAB Command**. In the **Command** field, enter this script.

```
proj = openProject("ProjectAirframeExample.prj");
[status,modifiedFiles] = system("git diff --name-only HEAD~1..HEAD :!resources");
updateDependencies(proj);
modifiedFiles = split(modifiedFiles);
modifiedFiles = modifiedFiles(1:(end-1));
impactedFiles = listImpactedFiles(proj,modifiedFiles);
files = proj.Files;
testFiles = [findLabel(files,"Classification","Test").File];
impactedTests = intersect(testFiles,impactedFiles);

runtests(impactedTests)
```

This script launches MATLAB, loads your MATLAB project, retrieves the list of files that changed in the last commit, runs an impact analysis to determine the subset of tests you need to run to qualify the change, and runs the list of impacted tests.

## Enhance Workflow

You can apply several additional steps to improve the workflow and make building and qualifying the project faster.

- Similar to the GraphML file, you also can generate and archive SLXC files to reuse and reduce simulation time. For more information, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.
- To easily manage SLXC and GraphML files from multiple Jenkins builds, you can use a database or a repository management tool such as JFrog Artifactory. For more information, see <https://www.jfrog.com/confluence/display/JFROG/JFrog+Artifactory>.
- You can set up a script to automatically retrieve the associated dependency cache file and place a copy in your working copy.

## Determine Order for Resolving Conflicts Using Dependency Analyzer

When collaborating on a project, a branch merge can lead to conflicted files. For a smoother merge, you can determine the optimal order in which to resolve conflicts by running a dependency analysis. Conflicts in files that are used by other files should be resolved first. Conflicts in files that do not have dependencies do not affect other files, so the conflict resolve order does not matter.

**Note** If the project dependency graph contains circular dependencies, there might not be an optimal order in which to resolve conflicts.

Name	Status	Git	Classification
custom_tasks	✓	.	
data	✓	.	
lib	✓	.	
readme.txt	✓	.	Design
timesthree.tlc	✓	! (both modified)	Design
models	✓	.	
AnalogControl.slx	✓	.	Design
DigitalControl.slx	✓	.	Design
f14_airframe.slx	✓	! (both modified)	Design
LinearActuator.slx	✓	.	Design
NonLinearActuator.slx	✓	! (both modified)	Design
slproject_f14.slx	✓	! (both modified)	Design
vertical_channel.slx	✓	.	Design
wind_gust_lib.slx	✓	.	Design
reports	✓	.	
src	✓	.	
timesthree.c	✓	! (both modified)	Design
tests	✓	.	
f14_airframe_test.m	✓	! (both modified)	Test
utilities	✓	.	
.gitattributes	✓	.	
.gitignore	✓	.	

You can use the Dependency Analyzer to programmatically determine the optimal order in which to resolve conflicts. In the MATLAB Command Window, run the `getProjectResolveOrder` function.

```
function fileOrder = getProjectResolveOrder()
    import matlab.sourcecontrol.Status;
    p = currentProject;
    conflictingFiles = p.Files([p.Files.SourceControlStatus] == Status.Conflicted);
    updateDependencies(p);
    graph = p.Dependencies;

    if ~isdag(graph)
        error('Unable to recommend an optimal resolve order. The dependency graph contains circular dependencies.');
    end

    topologicalOrder = toposort(graph);
    topologicalFiles = graph.Nodes.Name(topologicalOrder);
    fileIndices = ismember(topologicalFiles, [conflictingFiles.Path]);
    files = flip(topologicalFiles(fileIndices));
    nodedependencyFiles = setdiff(cellstr([conflictingFiles.Path]), files);
```

```
        fileOrder = [files;nodependencyFiles];
end

getProjectResolveOrder

ans =

    6×1 cell array

    {'C:\workSpace\examples\airframe\src\timesthree.c'      }
    {'C:\workSpace\examples\airframe\lib\timesthree.tlc'    }
    {'C:\workSpace\examples\airframe\models\NonLinearActuator.slx'}
    {'C:\workSpace\examples\airframe\models\f14_airframe.slx'}
    {'C:\workSpace\examples\airframe\models\slproject_f14.slx'}
    {'C:\workSpace\examples\airframe\tests\f14_airframe_test.m' }
```

Resolve conflicts according to the listed order. For more details, see “Resolve Conflicts” on page 19-59.

- “Manage Referenced Project Changes Using Checkpoints” on page 20-9

## Componentization Using Referenced Projects

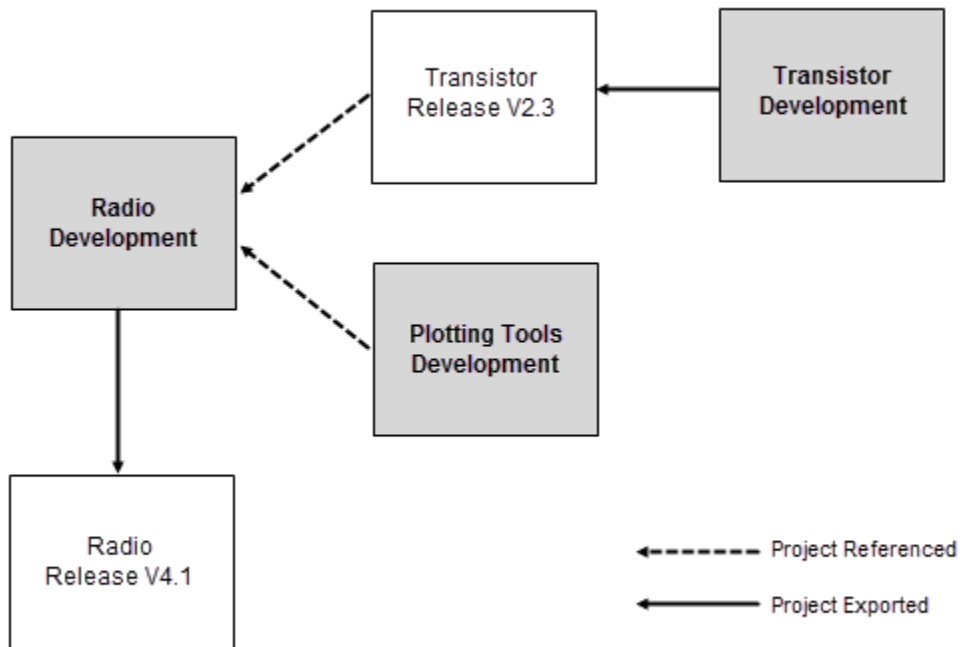

For a large modeling project, organizing the project into components facilitates:

- Component reuse
- Modular, team-based development
- Unit testing
- Independent release of components

Projects supports large-scale project componentization by allowing you to reference other projects from a parent project. A collection of parent and referenced projects constitutes a project reference hierarchy. Project referencing provides these benefits:

- A parent project has access to a referenced project's project paths, entry-point shortcuts, and source control information. For example, from a parent project, you can display the hierarchy of referenced projects. You can select a referenced project and then view, edit, and run files that belong to the referenced project.
- Through a referenced project, your team can develop a component independent of other components.
- In a referenced project, you can test the component separately.
- In a parent project, you can set a checkpoint and then compare the referenced project against the checkpoint to detect any changes.

This project hierarchy illustrates the use of parent and referenced projects as components of a large project.

Through the Transistor Development project, a team independently creates and tests a library of blocks. The team makes the library available to other developers by exporting release versions, for example, version 2.3.

Through the Radio Development project, another team develops and tests the Radio system. This team requires:

- Version 2.3 of the Transistor component. The team sets up the Radio Development project to reference the Transistor Release V2.3 project.
- Tools to plot signals, for example, MATLAB files that are not distributed to customers. The team sets up the Radio Development project to reference the Plotting Tools Development project.

When the Radio system is ready for customers, the team exports a release version, for example, version 4.1.

- “Manage Referenced Project Changes Using Checkpoints” on page 20-9
- “Organize Projects into Components Using References and Git Submodules”

## Add or Remove a Reference to Another Project

Add new components to your project by referencing other projects. The addition of referenced projects creates a project hierarchy. When the Project loads a referenced project in a project hierarchy, it:

- Adds project paths from the referenced project to the MATLAB search path.
- Runs startup shortcuts from the referenced project.

To reference a project:

1

On the Project tab, in the **Environment** section, click .

2 In the Add Reference dialog box, specify settings:

- **Referenced project location** -- Click **Browse** and navigate to the project folder. Then, in the project folder, select the required project (.prj) file.
- **Reference type** -- If your project hierarchy has a well-defined root relative to your project root, for example, a folder under source control, click **Relative**. If the project you want to reference is in a location accessible to your computers, for example, a network drive, click **Absolute**.
- **Set a checkpoint to detect future changes** -- To create a checkpoint, select the check box. To detect changes, you can compare the referenced project against this checkpoint.

3 Click **Add**. The Project creates a References view that displays the referenced project.

You can reference multiple projects in a hierarchical manner. In the References view, the Project displays the project reference hierarchy as a tree.

To view summary information about a referenced project, in the References tree, select the project.

To view files that belong to the referenced project, click .

To remove a referenced project from your project hierarchy, in the References tree, right-click the referenced project and select **Remove Reference**.

- “View, Edit, or Run Referenced Project Files” on page 20-6
- “Extract a Folder to Create a Referenced Project” on page 20-7
- “Organize Projects into Components Using References and Git Submodules”

## View, Edit, or Run Referenced Project Files

In a project that references other projects, use the References view to see, modify, or run files that belong to the referenced projects.

- 1 In a Project, select the References view.
- 2 In the References tree, select the required project reference.
- 3 Click **Show Files**. The Project displays files and folders from the referenced project.

- 4 Right-click a file, and then, from the context menu, select the required action.

## See Also

### Related Examples

- “Extract a Folder to Create a Referenced Project” on page 20-7
- “Organize Projects into Components Using References and Git Submodules”

## Extract a Folder to Create a Referenced Project

In a Project, you can partition a large project into components through the use of project references.

Consider the Airframe example project. Suppose you create a folder `Trial` and carry out development work within the folder. You produce:

- Shortcuts to a Simulink library, a MATLAB file, and a Readme document
- Design and source code folders
- Data files

Name	Status
batch_jobs	✓
data	✓
models	✓
reports	✓
src	✓
tests	✓
<b>Trial</b>	✓
DataBaseSourceCode	✓
Design Requirements	✓
ReallyComplicatedSource	✓
buses.mat	✓
DataLoggingLib.slx	✓ ↗
f14_digital_data.mat	✓
plotData.m	✓ ↗
Readme.pdf	✓ ↗
utilities	✓

For easier management, you want to convert the `Trial` folder into a separate component. In addition, you want access to the folder contents, for example, shortcuts to key files. To fulfill these requirements, extract the folder from the project and convert the folder into a referenced project.

- 1 In the Files view, right-click the `Trial` folder and select **Extract to Referenced Project**.
- 2 In the Extract Folder to New Project dialog box, specify these options:
  - **New Project Name** — For example, `DataLogging`.
  - **New Project Location** - For example, `C:\Work\DataLogging`.
  - **Reference type** - The default is `Relative` reference. Use the default if you specify the new project location with reference to the current project root. If you specify the full path for the new location, which is, for example, on a network drive, select `Absolute` reference.
- 3 Click **More Options**. If you want to disable any of the default content migration actions, clear the corresponding check box.
- 4 Click **Extract**.
- 5 In the two Warning dialog boxes that open, click **OK**.

The folder `Trial` and its contents are removed from the project. On the **Project Shortcuts** tab, the **Referenced Projects** section displays a new `DataLogging` button.

## Manage Referenced Project Changes Using Checkpoints

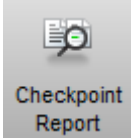

In a Project, you can create a checkpoint for a referenced project. You can then compare the referenced project against the checkpoint to detect changes.

- 1 In the project that contains the referenced project, select the References view.
- 2 In the References tree, select the referenced project. If a checkpoint does not exist for the project, in the Details view, the **Checkpoint** field displays **None**.

References	../refs/Signal Multiplier (Relative)
	Name: Signal Multiplier Checkpoint: None Description: This component project provides reusable functionality for amplifying signals.

- 3 To create a checkpoint, in the Checkpoint section, click . In the Details view, the Checkpoint field displays the timestamp of the check point.

References	../refs/Signal Multiplier (Relative)
	Name: Signal Multiplier Checkpoint: 18 July 2018 15:17:25 Description: This component project provides reusable functionality for amplifying signals.

In future, to detect changes in the referenced project, in the Checkpoint section, click . The Difference to Checkpoint dialog box shows files that have changed on disk since you created the checkpoint.

To remove the checkpoint, in the Checkpoint section, click .

## About Simulink Model Comparison

### In this section...

“Creating Model Comparison Reports” on page 21-2

“Examples of Model Comparison” on page 21-2

“Using Model Comparison Reports” on page 21-2

“Select Simulink Models to Compare” on page 21-3

### Creating Model Comparison Reports

In Simulink, you can compare Simulink models. Review and merge differences using three-way model merge or two-way model merge.

You can use models from any version of Simulink. Use the comparison report to explore the differences, view the changes highlighted in the original models, and merge differences.

For details, see “Compare Simulink Models” on page 21-6 and “Merge Simulink Models from the Comparison Report” on page 21-16.

You can access the comparison tool from:

- The MATLAB Current Folder browser context menu
- The MATLAB Comparison Tool
- The MATLAB command line
- The Simulink Editor **Compare** menu
- The Project view

You can use the comparison tool with both model file formats, SLX and MDL. If the selected files are .mdl files, or SLX files saved in a previous version, then the comparison tool first exports the .mdl files to SLX files in a temporary folder, and produces a comparison report based on the SLX files.

For more information on creating reports, see “Select Simulink Models to Compare” on page 21-3.

### Examples of Model Comparison

For examples with instructions, see:

- “Compare and Merge Simulink Models”
- “Compare and Merge Simulink Models Containing Stateflow”
- Resolve Conflicts with Simulink Three-Way Merge

For more information on using and understanding the comparison reports, see “Compare Simulink Models” on page 21-6.

### Using Model Comparison Reports

You can display comparison reports in the Comparison Tool. In the interactive report, you can click items in the report to display the corresponding items highlighted in the original models.

The comparison report shows a hierarchical view of the portions of the two files that differ. The report does not show sections of the files that are identical.

If the files are identical you see a message reporting there are no differences.

If files have not been saved, you see an error message informing you that you must save modified or newly created models before running a comparison.

---

**Note** It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

---

Change detection is based on a scoring algorithm. Items match if their score is above a threshold. The tool's algorithm uses a comparison pattern that defines the thresholds assigned to particular node types (e.g., block).

For more information on using the report, see “Compare Simulink Models” on page 21-6.

To control highlighting, see “Display Differences in Original Models” on page 21-14.

To merge differences, see “Merge Simulink Models from the Comparison Report” on page 21-16.

For more information about the Comparison Tool, see “Compare Files and Folders and Merge Files”.

## Select Simulink Models to Compare

- “Select Files from the Simulink Editor” on page 21-3
- “Select Files from the Current Folder Browser” on page 21-4
- “Select Files from a Project” on page 21-4
- “Select Files from the Comparison Tool” on page 21-4
- “Select Files from the Command Line” on page 21-4
- “Choose a Comparison Type” on page 21-4

To learn what you can do with comparison reports, see “About Simulink Model Comparison” on page 21-2.

### Select Files from the Simulink Editor

To compare files using the Simulink Editor:

- 1** On the **Modeling** tab, in the **Evaluate & Manage** section, select **Compare > Compare Models**.

The Select Files or Folders for Comparison dialog box opens.

- 2** If the Editor currently displays a model, the current model name and path appear automatically selected in the **First file or folder** edit box. Use the browse buttons to locate and select files for the first and second model files.
- 3** When you click **Compare**, the comparison tool performs the analysis, and displays the resulting report in the Comparison Tool.

### Select Files from the Current Folder Browser

To compare two files from the Current Folder browser:

- For two files in the same view, select two files, right-click and select **Compare Selected Files/Folders**.
- Alternatively, you can browse to select the second file to compare:
  - 1 Select a file, right-click and select **Compare Against**
  - 2 Select the second file to compare in the Select Files or Folders for Comparison dialog box.
  - 3 For models, leave the default **Comparison type**, Simulink Model Comparison.
  - 4 Click **Compare**.

For more information about comparisons of other file types (e.g., text, MAT, or binary) with the Comparison Tool, see “Compare Files and Folders and Merge Files”.

### Select Files from a Project

If you have a project using source control, you can create a model comparison report from the Modified Files view of the project. For details, see “Project Management”.

### Select Files from the Comparison Tool

To compare files using the Comparison Tool, from the MATLAB Toolstrip, in the **File** section, select the **Compare** button. In the dialog box select files to compare.

### Select Files from the Command Line

To compare XML files from the command line, enter

```
visdiff(filename1, filename2)
```

where `filename1` and `filename2` are XML files or Simulink models.

`visdiff` produces a report in the Comparison Tool.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

See “Export Results to the Workspace” on page 21-22 for information about the `xmlcomp.Edits` object.

### Choose a Comparison Type

To change comparison type, either create a new comparison from the Comparison Tool, or use the **Compare Against** option from the Current Folder browser. You can change comparison type in the Select Files or Folders for Comparison dialog box. For example, if you want the MATLAB text differences report for XML or model files, change the comparison type to `Text comparison` in the dialog before clicking **Compare**. Alternatively, see the `visdiff` function.

“Examples of Model Comparison” on page 21-12

“Limitations” on page 21-13

### Navigate the Simulink Model Comparison Report

You can compare models from any version of Simulink. The comparison tool produces a comparison report based on the SLX files, resaved in the current version if necessary. Use the report to explore the differences, view the changes highlighted in the original models, and merge differences.

The Comparison report shows changes only, not the entire file contents. The report shows a hierarchical view of the portions of the files that differ, and does not show sections of the files that are identical. To learn about the report, see “About Simulink Model Comparison” on page 21-2.

To *step through differences*, on the **Comparison** tab, in the **Navigate** section, click **Next** or **Previous**. See “Step Through Changes” on page 21-7.

You can also click to select items in the hierarchical trees and observe the following display features:

- Selected items appear highlighted in a box.
- If the selected item is part of a matched pair it is highlighted in a box in both left and right trees.
- When you select an item, the original model displays and the corresponding item is highlighted. See “Explore Changes in the Original Models” on page 21-8.

Report item highlighting indicates the nature of each difference as follows:

Type of report item	Highlighting	Notes
Modified	Purple	Modified items are matched pairs that differ between the two files. When you select a modified item it is highlighted in a box in both trees. Changed parameters for the selected pair are displayed underneath.
Inserted	Blue	When you select an unmatched item it is highlighted in a box in one tree only.

Type of report item	Highlighting	Notes
Deleted	Yellow	
Container	None	Rows with no highlighting indicate a container item that contains other modified or unmatched items.

Icons indicate the category of item, for example: model, subsystem, Stateflow machine or chart, block, line, parameter, etc.

To expand or filter the tree view, use the toolbar for the following functions:

- **Filter** — Use filters to show only the changes you are interested in. By default the report hides all nonfunctional changes, such as repositioning of items. Turn off filters to explore *all* differences including nonfunctional changes. See “Filter Comparison Reports” on page 21-9.
- **Find** — Opens the Find dialog box where you can search for items.
- If you want to swap the files, on the **Comparison** tab, select **Swap**. The report swaps the sides and reruns the comparison. **Refresh** also runs the analysis again.

To create a new report, see “Select Simulink Models to Compare” on page 21-3.

For examples with instructions, see also “Examples of Model Comparison” on page 21-2.

## Step Through Changes

On the **Comparison** tab, in the **Navigate** section, when you click the **Next** arrow button (or press the Down key when the report has focus), you step through groups of changes in the report, in the following order:

- 1 The first time you click **Next**, it selects the first changed (purple) or inserted (blue) node.
- 2 Step through the differences with the **Next** button.
  - When selected items have a match in the right tree then they are also highlighted.
  - Next skips white nodes with no color background, if they have no parameter changes underneath. White nodes are parts of the hierarchy that contain no differences.
  - If there is an insertion or deletion with child nodes, **Next** skips the child nodes if they are all also insertions or deletions. For example, if you insert a subsystem, **Next** selects the top subsystem node, then skips all the nodes inside the subsystem (if they are all also insertions) and selects the next difference.
  - **Next** minimizes context switching when highlighting in models. When you click **Next**, the report steps through all differences at the same level of the model, subsystem, or chart, in both left and right trees in the report, before moving to the next level of the report. For example, you step through all differences in a subsystem in the left and right trees, before moving to another subsystem.
- 3 When you have stepped through all changes, **Next** stops at the end.

If you click an item in the report, the **Next/Previous** controls will step through changes from the point you selected.

## Explore Changes in the Original Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting function to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Control the display by using the **Highlight Now** button and the **Always Highlight** check box.

For details, see “Display Differences in Original Models” on page 21-14.

## Merge Differences

To merge, on the **Comparison** tab, click **Merge Mode**. The Target pane appears at the bottom of the report. Use the buttons to select differences to keep in the target. For more information, see “Merge Simulink Models from the Comparison Report” on page 21-16.

## Open Child Comparison Reports for Selected Nodes

If additional comparisons are available for particular parameters, you see a **Compare** button to open a report for that pair of nodes. For example, if there are differences in the Model Workspace, you can click **Compare** to open a new report to explore differences in variables.

- You can open a new comparison for parameters when the report cannot display all the details, e.g., long strings or a script.
- If the original models contain MATLAB Function block components, and if differences are found, click the **Compare** button at the end of the MATLAB Function block report items to open new comparisons in the Comparison Tool, showing the text difference reports for the MATLAB Function block components. You can merge differences in MATLAB Function block code from the text comparison report. See “Merge Simulink Models from the Comparison Report” on page 21-16.
- If the original models contain truth tables, and if differences are found:
  - Click the **Compare** button at the end of the MATLAB Function node to see a summary of all changes.
  - Click the **truthtable** node to reverse annotate and display both truth table editors.
  - Click the **Compare** button on the parameter to open a new text comparison showing only Condition table differences.
  - Similarly click the **Compare** button for **Action Table** to view only Action changes.

## Understand the Report Hierarchy and Matching

---

**Note** It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

---

If you cannot see changes you expected to see in the report, turn off filters and see *all* identified changes. See “Filter Comparison Reports” on page 21-9.

## Filter Comparison Reports

You can define custom filters to simplify reports and focus on specified elements. You can import and export filters for sharing. Use built-in filters to control display of categories of changes. Turn off filtering to view all identified changes.

To see the available filters, and whether or not they apply to the current report, on the **Comparison** tab, in the **Filter** section, click the down arrow to expand the filter gallery. Click filter names to toggle whether they are applied. In the **Filter** section, click **Show** to include the selected filters changes in the report or **Hide** to exclude the selected filters changes from the report.

Use the filters to include only the changes you are interested in. By default the report hides all nonfunctional changes. These changes have no impact on the design behavior, such as repositioning of items. Turn off filters to explore all differences including nonfunctional changes. Try this if you cannot see changes you expected to see in the report.

Built-in filters include:

- **Lines.** Select all changes to signal lines, including functional changes.
- **Nonfunctional Changes.** The report identifies certain items in the model file as nonfunctional, for example, items representing parameters such as block, system, chart, or label positions; font and color settings for blocks and lines; and system print and display settings.
- **Block Defaults.** Block defaults rarely change and cause longer reports when there are added or deleted blocks. Often the report is simpler when you hide block defaults.

To show all changes, use either of these methods:

- Hide nothing - Click **Hide** and disable all filters in the gallery.
- Show everything - Create a custom filter. In the New Filter dialog box, delete the contents of the first column so it shows Any, then remove the rest of the row under **Parameter Name**. Click **Show** and enable the "everything" filter in the gallery.

To define a new custom filter:

- 1 On the **Comparison** tab, in the **Filter** section, click **New Filter**.
- 2 In the New Filter dialog box, define one or more rules for your new filter. For example, you can select parameters or blocks of particular types or values. Suggested values depend on the items in your comparison report. Specify a unique name for your filter and click **Apply**.
- 3 To check if your filter applies to the items you expect, enable only the new filter in the filter gallery and then click **Show**. This is often easier than checking that a filter is hiding the changes you expect to see in the report.

Observe how these custom filters are defined.

Purpose	Select Column	Parameter Name	Parameter Value
Filter out Annotation changes	Annotation	Click the minus button to clear the row.	Leave blank
Filter out Inport and Outport block changes	Block	BlockType	Inport
	To add a row, click <b>Add Rule</b> , then select <b>Block</b>	BlockType	Outport

Purpose	Select Column	Parameter Name	Parameter Value
Filter out sample time parameter changes	Parameter	SampleTime	Any

- Annotation changes:

- Inport and Outport block changes:

New Filter

Name:

Rules:

Select	Parameter Name	Parameter Value
Block ▼	BlockType	Inport ▼
	<input type="button" value="+"/> <input type="button" value="-"/>	
Block ▼	BlockType	Output ▼
	<input type="button" value="+"/> <input type="button" value="-"/>	

- Sample time parameter changes:

New Filter

Name:

Rules:

Select	Parameter Name	Parameter Value
Parameter ▼	SampleTime	Any ▼

## Exceptions

The report does *not* filter out changes to Block and System names, annotations, and Stateflow Notes as nonfunctional, even though changes to these items do not affect the outcome of simulation. The report always displays these changes to facilitate review of code changes, because they can contain important information about users' intentions.

In rare cases, the report filters out changes that can impact the behavior of the design. By default, moves are filtered as nonfunctional, but in these cases moves can change design behavior:

- Moving blocks can in some cases change the execution order.
- In a Stateflow chart, if you move states or junctions so that they intersect, the model fails to simulate.

To view these types of changes in the report, turn off the filter for nonfunctional changes.

## Change Color Preferences

You can change and save your diff color preferences for the Comparison tool. You can apply your color preferences to all comparison types.

- 1 On the MATLAB Home tab, click **Preferences**.
- 2 In the Preferences dialog box, under **MATLAB**, click **Comparison**.
- 3 Edit color settings as desired for differences and merges. View the colors in the **Sample** pane.

The **Active Settings** list displays **Default (modified)**.

- 4 To use your modified settings in the comparison, click **Apply** and refresh the comparison report.
- 5 To return to the default color settings, in the Preferences dialog box, click **Reset** and click **Apply**. Refresh the comparison report.
- 6 If you want to save your modified color preferences for use in future MATLAB sessions, click **Save As**. Enter a name for your color settings profile and click **OK**.

After saving settings, you can select them in the **Active Settings** list.

## Save Comparison Results

To save your comparison results, use these **Comparison** tab buttons:

- **Publish > HTML, Word, or PDF** — Open the Save dialog box, where you can choose to save a printable version of the comparison report. See “Save Printable Report” on page 21-22.
- **Publish > Workspace Variable** — Export comparison results to workspace. See “Export Results to the Workspace” on page 21-22.

Alternatively, you can publish a comparison report to a file using the `visdiff` function.

## Examples of Model Comparison

For examples with instructions, see:

- “Compare and Merge Simulink Models”

- “Compare and Merge Simulink Models Containing Stateflow”
- Resolve Conflicts with Simulink Three-Way Merge

## Limitations

MATLAB Online does not support functionalities such as publishing comparison reports, merging, or creating custom filters. In MATLAB Online, Model Comparison does not support Stateflow and test harness comparisons.

## See Also

`visdiff`

## Related Examples

- “Select Simulink Models to Compare” on page 21-3
- “Display Differences in Original Models” on page 21-14
- “Merge Simulink Models from the Comparison Report” on page 21-16
- “Compare Revisions” on page 19-44
- “Source Control in Projects”

## More About

- “About Simulink Model Comparison” on page 21-2
- “Comparing Models with Identical Names” on page 21-24
- “Work with Referenced Models and Library Links” on page 21-25

## Display Differences in Original Models

In this section...
“Highlighting in Models” on page 21-14
“Control Highlighting in Models” on page 21-14
“View Changes in Model Configuration Parameters” on page 21-15

### Highlighting in Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Click a report entry to view the highlighted item (or its parent) in the model:

- If the item occurs in both models, they both appear with highlighting.
- When there is no match in the other model, the report highlights the first matched ancestor to show the context of the missing item.
- If the comparison tool cannot highlight an item directly (e.g., configuration parameters), then it highlights the nearest ancestor of the selected node.

Try highlighting items in original models using the example “Compare and Merge Simulink Models Containing Stateflow”.

### Control Highlighting in Models

To control highlighting in models, in the Comparison Tool, select or clear the check box **Always Highlight**. You can click the **Highlight Now** button to highlight the currently selected report node at any time. This can be useful if you turn off automatic highlighting and only want to display specific nodes.

By default, models display to the right of the comparison report, with the model corresponding to the left side of the report on top, and the right below. If you move or resize the models your position settings are respected by subsequent model highlighting operations within the same session. The tool remembers your window positions.

If you want to preserve window positions across sessions, position the window, and then enter:

```
slxmlcomp.storeWindowPositions
```

This preserves the placement of any Simulink windows, Stateflow windows, and truth table windows.

To stop storing window positions and return to the defaults, enter:

```
slxmlcomp.clearWindowPositions
```

## View Changes in Model Configuration Parameters

You can use the report to explore differences in the model Configuration Parameters. If you select a Configuration Parameter item, the report displays the appropriate root node pane, if possible, of both Configuration Parameters dialog boxes.

Parameters display the label text from the dialog controls (or the parameter name if it is command line only), and the parameter values. You can merge selected parameters using merge mode.

### More About

- “About Simulink Model Comparison” on page 21-2

## Merge Simulink Models from the Comparison Report

### In this section...

“Resolve Conflicts Using Three-Way Model Merge” on page 21-16

“Use Three-Way Merge with External Source Control Tools” on page 21-19

“Open Three-Way Merge Without Using Source Control” on page 21-19

“Two-Way Model Merge” on page 21-20

“Merge MATLAB Function Block Code” on page 21-21

Merge tools enable you to:

- Resolve conflicts in model files under source control using three-way merge. Open by selecting **View Conflicts**.
- Merge any two model files using two-way merge. Open by selecting **Compare** context menu items.
- Merge MATLAB Function block code using text comparison reports.

### Resolve Conflicts Using Three-Way Model Merge

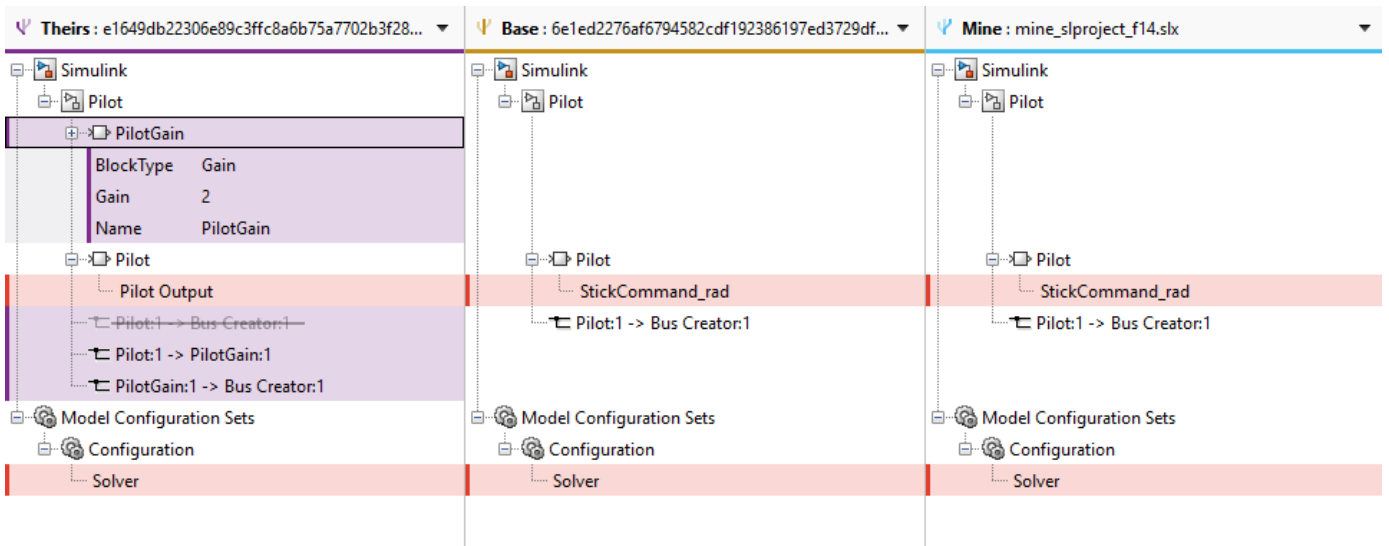

If you have a conflicted model file under source control in a project or in the Current Folder browser, right-click and select **View Conflicts**. You can resolve the conflicts in the Three-Way Model Merge tool. Examine your local file compared to the conflicting revision and the base ancestor file, and decide which changes to keep. You can resolve the conflict and submit your changes.

- 1 To try an example three-way merge, see Resolve Conflicts with Simulink Three-Way Merge.
- 2 In the project, locate the conflicted model file, right-click and select **View Conflicts**. You can only see **View Conflicts** in the context menu if your file is marked conflicted by the source control.

The Merge tool automatically resolves every difference that it can, and shows the results in the **Target** pane. Review the automerge choices, edit if desired, and decide how to resolve any remaining conflicts.

- 1 Examine the Merge report columns.
  - At the top, **Theirs**, **Base**, and **Mine** columns show the differences in the conflicting revision, your revision, and the base ancestor of both files.
  - Underneath, the **Target** shows the local file that you will merge changes into. The Merge tool already automerged the differences it can merge.

- Examine a difference by clicking **Next** or by clicking a row in the **Theirs**, **Base**, and **Mine** columns.

The merge tool displays two models (or if you selected a configuration setting, you see two model Configuration Parameters dialog boxes). By default, you see **Theirs** and **Target** models.

- Choose the models to display with the toolbar buttons on the **Merge** tab: **Top Model** or **Bottom Model**. View the models to help you decide what to merge.

**Note** If you open the merge tool using **View Conflicts**, then the models **Theirs**, **Base**, and **Mine** are temporary files showing the conflicting revisions. Examine them to decide how to merge. The **Target** model is a copy of **Mine** containing the results of your merges in the report.

- 4 Select a version to keep for each change by clicking the buttons in the **Target** pane. You can merge modified, added, or deleted nodes, and you can merge individual parameters. The Merge tool selects a choice for every difference it could resolve automatically. Review the selections and change them if you want.

Look for warnings in the Conflicts column. Select a button to use **Theirs**, **Base**, or **Mine** for each conflicted item.

**Tip** Merge blocks before lines, and merge states and junctions before merging transitions. Merge tool then attempts to connect all lines to blocks for you. See “Merging Tips” on page 21-20.

- 5 Some differences you must merge manually. In the **Target** pane, look for the manual merge icon in the Conflicts column that shows you must take action.

Make manual changes in the Editor. The comparison report cannot update to show any changes that you make in the Editor, so try to make manual changes after addressing all the simpler merges in the report.

After you have resolved the conflict using the Editor, in the **Target** pane, select the check option to mark the node as complete.

- Examine the summary table to see the number of automatic merges and remaining conflicts you need to resolve.

**Resolve remaining 5 changes**

Filtered View (3) All Changes (5)

TYPE	UNRESOLVED	RESOLVED
Conflict	1	0
Conflicted manual merge	0	0
Manual merge	2	0
Automatic	0	8
<b>Total</b>	<b>3</b>	<b>8</b>

Check for changes that are filtered out of the current view by looking at the summary table tab titles. The Filtered View and All Changes tab titles show the number of changes. By default the report hides all nonfunctional changes. Turn off active filters to view all identified changes.

- When you are happy with your merge selections and any manual merges in the **Target** file, click **Accept and Close**. This action saves the target file with all your merges and marks the conflicted file resolved in the source control tool.

To save and not mark the conflict resolved, select **Accept and Close > Save and Close**.

To learn more about resolving conflicts in a change list of modified files in a project, see “Resolve Conflicts” on page 19-59.

## Use Three-Way Merge with External Source Control Tools

If you are using source control outside of MATLAB, then you can customize external source control tools to open Three-Way Merge (or two-way merge for diffs).

For instructions, see “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-64.

## Open Three-Way Merge Without Using Source Control

If you are not using source control or you want to choose three files to merge, then you can open Three-Way Merge using the function `sxmlcomp.slMerge`. Specify the files to merge, for example:

```
sxmlcomp.slMerge(baseFile, mineFile, theirsFile, targetFile);
```

Three-Way Merge opens, where you can merge the changes in `baseFile`, `mineFile`, and `theirsFile` into the `targetFile`.

## Two-Way Model Merge

You can merge two Simulink models from a comparison report. The **Compare** context menu items from a project or the Current Folder browser open a two-way model merge. If you are using source control and want to resolve conflicts using a three-way model merge instead, see “Resolve Conflicts Using Three-Way Model Merge” on page 21-16.

The merge feature enables you to merge two versions of a design modeled in Simulink. You can merge individual parameters, blocks, or entire subsystems. Entire subsystems can only be merged as a whole if they are fully inserted or deleted subsystems.

- 1 On the **Comparison** tab, click **Merge Mode**. The Target pane appears at the bottom of the report.
- 2 Use the same workflow as three-way merge. Use the buttons to select the differences to keep in the target file.

---

**Tip** Merge blocks before lines, and merge states and junctions before merging transitions. See “Merging Tips” on page 21-20.

---

- 3 View the results in the report and the models. Click **Save File**. **Save File** copies the temporary target file over the right file in the comparison and reruns the comparison.
- 4 (Optional) To revert all merge operations, click **Close Merge** without saving the file.
- 5 Inspect your merge changes in the Simulink Editor. If necessary, connect any lines that the software did not connect automatically. The comparison report does not update to show any changes that you make in the Editor.

### Merging Tips

- In the Simulink part of the report, merge models in the following order. In the target file:
  - 1 Delete the lines you do not want to keep.
  - 2 Delete the blocks you do not want to keep.
  - 3 Add the blocks you want to keep.
  - 4 Add the lines you want to keep.
  - 5 Select the parameters you want to keep.

You must merge states and junctions before merging transitions, or the report cannot make the connections.

For an example showing how to merge a change involving multiple nodes, see “Compare and Merge Simulink Models Containing Stateflow”.

- Not all parameters can be merged. In this case, only one radio button is shown in the target pane indicating the version that is in the target model.
- For information on merging between models with identical names, see “Comparing Models with Identical Names” on page 21-24.

## Merge MATLAB Function Block Code

- 1 To merge differences in MATLAB Function block code, create a comparison report for the parent models.
- 2 Click the **Merge Mode** button.  
  
This creates and opens a third file called targetFile. It can contain the changes from either the left or right model.
- 3 Use the buttons in the right of the report to select changes you want in the target file.
- 4 Save these changes over the right model using the **Save File** toolbar button.

## Export, Print, and Save Model Comparison Results

### In this section...

“Save Printable Report” on page 21-22

“Export Results to the Workspace” on page 21-22

### Save Printable Report

To save a printable version of a model comparison report,

- 1 On the **Comparison** tab, select **Publish > HTML, Word, or PDF**.

The Save dialog box opens, where you can choose to save a printable version of the model comparison report.

- 2 Select a file name and location to save the report.

The report is a non-interactive document of the differences detected by the algorithm for printing, sharing, or archiving a record of the comparison. If you have applied filters, your filtered results appear in the printable report.

Alternatively, you can publish a comparison report to a file using the `visdiff` function.

### Export Results to the Workspace

To export the comparison results to the MATLAB base workspace,

- 1 On the **Comparison** tab, select **Publish > Workspace Variable**.

The Input Variable Name dialog box appears.

- 2 Specify a name for the export object in the dialog and click **OK**. This action exports the results of the model comparison to an `xmlcomp.Edits` object in the workspace.

The `xmlcomp.Edits` object contains information about the comparison including file names, filters applied, and hierarchical nodes that differ between the two files.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

Property of <code>xmlcomp.Edits</code>	Description
Filters	Array of filter structure arrays. Each structure has two fields, Name and Value.
LeftFileName	File name of left model.
LeftRoot	<code>xmlcomp.Node</code> object that references the root of the left tree.
RightFileName	File name of right model.
RightRoot	<code>xmlcomp.Node</code> object that references the root of the right tree.

Property of <code>xmlcomp.Edits</code>	Description
TimeSaved	Time when results exported to the workspace.
Version	MathWorks release-specific version number of <code>xmlcomp.Edits</code> object.

Property of <code>xmlcomp.Node</code>	Description
Children	Array of <code>xmlcomp.Node</code> references to child nodes, if any.
Edited	Boolean — If <code>Edited = true</code> then the node is either inserted or part of a modified matched pair.
Name	Name of node.
Parameters	Array of parameter structure arrays. Each structure has two fields, <code>Name</code> and <code>Value</code> .
Parent	<code>xmlcomp.Node</code> reference to parent node, if any.
Partner	If matched, <code>Partner</code> is an <code>xmlcomp.Node</code> reference to the matched partner node in the other tree. Otherwise empty [ ].

## See Also

`visdiff`

## Comparing Models with Identical Names

You can compare model files of the same name. To complete the operation, the comparison tool copies one of the models to a temporary folder, because Simulink cannot have two models of the same name in memory at the same time. The comparison tool creates a read-only copy of one model named *modelName\_TEMPORARY\_COPY*, and compares the resulting XML files.

---

**Warning** When you use highlighting from the report, one of the models displayed is a temporary copy with a new name. The temporary copy is read-only, to avoid making changes that can be lost.

---

Alternatively, you can run the comparison by renaming or copying one of the files.

If one of the models is open when you try to compare them, a dialog box appears where you can click **Yes** to close the file and proceed, or **No** to abort. You must close open models before the comparison tool can compare two models with the same name. The problem requiring you to close the loaded model is called “shadowed files”. In some cases, another model with the same name might be in memory, but not visible. See “Shadowed Files” on page 15-3 for more information.

If you want to automatically close open models of the same name when comparing them and not see the dialog box again, run these commands:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(true)
```

This is persistent across MATLAB sessions. To revert to default behavior and be prompted whether or not to close the open model every time, enter:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(false)
```

If you open a comparison report from a project (for example, using **Compare to Revision**), the project handles files of the same name and does not prompt you to close models.

## Work with Referenced Models and Library Links

The model comparison report applies only to the currently selected models, and does not include changes to any referenced models or linked libraries. The comparison report shows only changes in the files selected for comparison.

---

**Tip** If you want to examine your whole hierarchy instead, try using a project, where you can examine modified files and dependencies across your whole project, and compare to selected revisions. See “Project Management”.

---

If you are comparing models that contain referenced models with the same name, then your MATLAB path can affect the results. For example, this can happen if you generate a model comparison report for the current version of your model and a previous baseline. Make sure that your referenced models are not on your MATLAB path before you generate the report.

The reason why results can change is that Simulink records information in the top model about the interface between the top model and the child model. This interface information in the top model enables incremental loading and diagnostic checks without any need to load child models.

When you load a model (for example, to compare) then Simulink refreshes the interface information for referenced models if it can find the child model. Simulink can locate the child model if it is on the path. If another model of the same name is higher on the path, Simulink updates the interface information for that other model before comparing. This can produce entries for interface changes for model reference blocks in the comparison report. Make sure your referenced models are not on your path before you generate the report, to avoid these interface changes in the results. If both model versions are off the path, the interface information in the top model is not refreshed during the comparison process. Instead the cached information is used, resulting in a valid comparison report.

With library links, Simulink does not update the cached interface information when comparing, and so the report correctly captures library interfaces. However with both referenced models and library links, Simulink updates the information when displaying the model. When displaying report items in original models, you may see that Simulink finds another model or library that is higher in the path. To obtain the clearest results, make sure that the models and associated libraries are temporarily removed from the path. By removing the files from the path you will see unresolved library links and referenced models when you view the original models, but their interfaces will be correct and will correctly align with the comparison report.

## Compare Project or Model Templates

In this section...
“Compare Project Templates” on page 21-26
“Compare Model Templates” on page 21-26

### Compare Project Templates

You can compare project templates (SLTX files). If you select two project template files to compare, you see a comparison report showing differences in template properties and project metadata. You can open a new report to investigate project file and folder differences.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Expand the **Project Metadata** node to view metadata differences such as label changes.
- Next to **Project Files**, click **Compare** to open a folder comparison where you can investigate changed, added, or removed files and folders.

### Compare Model Templates

You can compare model templates (SLTX files). If you select two model template files to compare, you see a comparison report showing differences in template properties. You can open a new comparison report to compare the Simulink models.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Next to **Model**, click **Compare** to open a Simulink model comparison report where you can investigate differences.

### See Also

# Simulink Model Comparison for GitHub Pull Requests

## In this section...

“Prerequisites” on page 21-27

“Attach Diff Reports Using GitHub Actions” on page 21-27

Automate the generation of Simulink model diffs for GitHub pull requests and push events using GitHub Actions. Automatically attach the comparison reports to the pull request or push event for easy viewing outside of MATLAB and Simulink. Watch Simulink Model Comparison for GitHub Pull Requests (4min 46sec).

## Prerequisites

- 1 Download the MATLAB code and YAML files from <https://github.com/mathworks/Simulink-Model-Comparison-for-GitHub-Pull-Requests>.
- 2 Ensure that GitHub Actions is enabled for your repository.
- 3 The actions, defined in the YAML files, use a self-hosted runner. To add a self-hosted runner to your repository, follow the instructions at <https://docs.github.com/en/actions/hosting-your-own-runners>.
- 4 Ensure that you have MATLAB and Simulink installed on the self-hosted runner you are using.

## Attach Diff Reports Using GitHub Actions

GitHub Actions allows you to automate workflows that you define in YAML files. This example shows how to set up the workflows to be triggered on push and pull request to the main branch on GitHub. These workflows use the MATLAB code files to:

- 1 Get the list of modified model files and their ancestors using Git commands.
- 2 Compare every modified model to its ancestor and publish an HTML comparison report using `visdiff`.

---

**Tip** To peer review changes, use the DOCX file format instead of HTML when publishing the reports. Using DOCX files allows reviewers to leave detailed comments on different blocks or parameters.

---

- 3 Upload all model comparison reports to the job when it is complete.
- 4 Run all the project tests.

To set up the workflows on GitHub:

- 1 Add the MATLAB code files to your repository. Select **Add file > Upload** and upload the files. Then, click **Commit Changes**.
- 2 Create the new workflows:
  - a On the **Actions** tab, click **set up a workflow yourself**.

GitHub stores all workflows in the `.github/workflows` folder. If it does not exist already, GitHub automatically creates the `.github/workflows` folder in your repository.

- b** Copy the content of one of the YAML files you downloaded, for example, `Diff_runTests_pullrequest.yml`, and paste it in the **Edit new file** field.
- c** Rename the file and click **Start commit > Commit new file**.
- d** Repeat the steps for the second YAML file you downloaded.

Alternatively, if you already have a `.github/workflows` folder in your repository, upload the YAML files to `.github/workflows` and commit the changes.

Now, when you push your commits to the main branch or create a pull request to merge a development branch with main, it triggers the workflows you set up. When the job is successful, contributors and reviewers can access the model comparison reports in the **Artifacts** section of each job.

# Design Evolution Management

---

- “About Design Evolutions” on page 22-2
- “Manage Evolutions and Evolution Trees” on page 22-4
- “Inspect Properties of Evolutions and Compare Evolutions” on page 22-8
- “Use Design Evolution Manager with the Fixed-Point Tool” on page 22-10

## About Design Evolutions

Design evolutions help you model and analyze your engineering process. A design evolution is a snapshot of all files included in a project. When developing a new design or troubleshooting an existing design, you may add or remove files from the design, or create different versions of files in your design. By creating evolutions at key stages in your design process, you can manage and compare different versions of a design during the course of your work. The relationships between evolutions and the metadata associated with evolutions help you to understand the big-picture trajectory of your design process, including why certain design decisions were made.

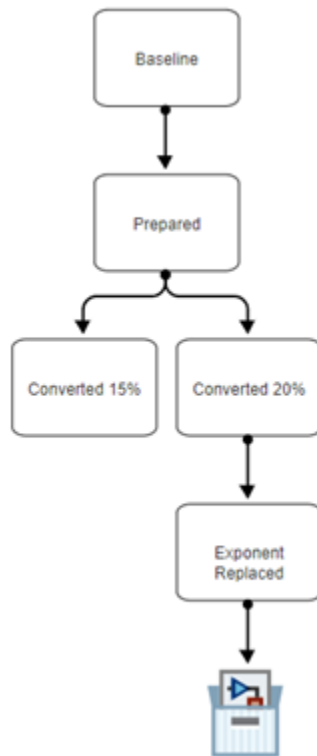

The Design Evolution Manager is available on MATLAB Online only and requires a Simulink license.

### Evolutions and Evolution Trees

Evolutions are alternative versions of project files that you have stored, similar to a revision control submission. An evolution is a snapshot of a particular version of your files contained in a project. Each evolution you create has metadata associated with it where you can add additional descriptive information about the version of the design that is captured in the evolution. An evolution tree is a visual representation of a collection of related but different versions of your design stored as evolutions.

This figure shows an example of a small evolution tree. An evolution tree has three important elements:

- A node representing the current open project, visualized as the icon at the bottom of the evolution tree.
- Evolution nodes, visualized as boxes in the evolution tree.
- Connectors between evolution nodes, visualized as arrows between evolutions. Connectors contain information about the changes between the design versions.

Evolutions have parent-child relationships in the evolution tree. The first evolution you create is the **Baseline** evolution, which is the reference point for the evolution tree. The **Baseline** evolution is parent to all following evolutions. Each subsequent evolution you create is a child of the previous evolution. A child evolution represents a change or set of changes made to the design since its parent evolution was saved. The connectors between evolutions contain metadata about the changes that have occurred between the parent evolution and the child evolution. You can create branches in your evolution tree by having multiple child evolutions under a single parent evolution.

The shape of the evolution tree visually maps to your design process. Your evolution tree may be linear, indicating that each evolution is a continuation of the same design path. Or, your evolution tree may branch if you explore multiple design directions within one evolution tree. You can use evolutions and branches in the evolution tree to explore different design ideas, perform trade studies, or troubleshoot an existing design. Evolutions can be used to record successful design directions and also to keep a record of unsuccessful design ideas. At any point, you can trace back through your evolution tree to understand why particular changes were made to the design.

## See Also

“Manage Evolutions and Evolution Trees” on page 22-4 | “Inspect Properties of Evolutions and Compare Evolutions” on page 22-8

## Related Examples

- “Use Design Evolution Manager with the Fixed-Point Tool” on page 22-10

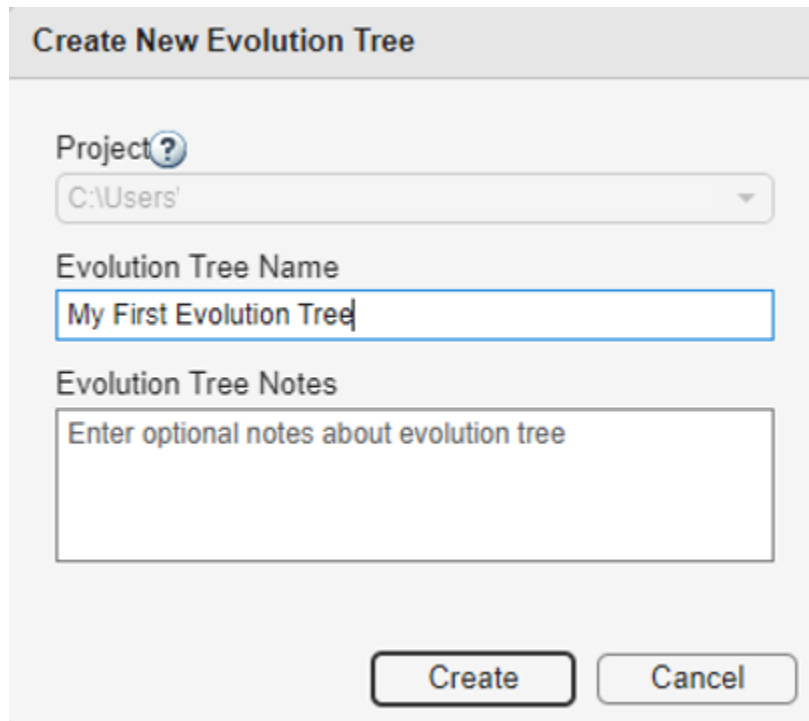

## Manage Evolutions and Evolution Trees

The files you want to organize and analyze with evolutions must be contained in a single project. For more information about creating a project, see “Create a New Project from a Folder” on page 16-17.

To open the Design Evolution Manager, first open the project containing your files. From the **Projects** tab, under **Tools**, select the **Design Evolution Manager** icon.

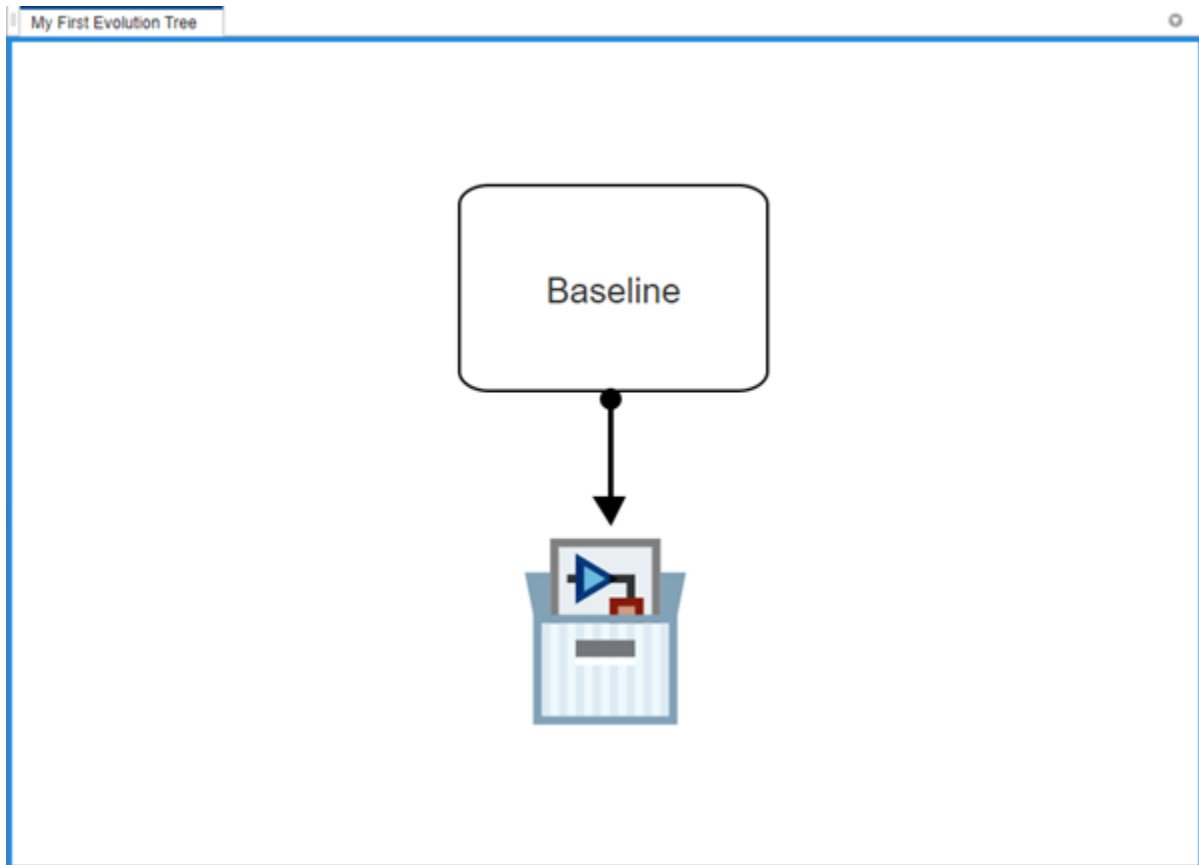

### Create Evolution Tree

When you open the Design Evolution Manager for the first time, or when you click the **New Tree** button in the Design Evolution Manager toolstrip, the Create New Evolution Tree dialog box guides you through the process of creating a new evolution tree. Select the project containing your design files and give the evolution tree a name. Optionally, add notes about the evolution tree.

The screenshot shows a dialog box titled "Create New Evolution Tree". It features three main input areas: a "Project?" dropdown menu currently showing "C:\Users'", an "Evolution Tree Name" text box containing "My First Evolution Tree", and an "Evolution Tree Notes" text box with the placeholder text "Enter optional notes about evolution tree". At the bottom of the dialog are two buttons: "Create" and "Cancel".

The app creates a new evolution tree containing the **Baseline** evolution. The **Baseline** evolution contains a copy of all files in the project in their current state. The node beneath the **Baseline** evolution represents the current state of the files in the project. Some or all of these files may diverge from the version stored in the **Baseline** evolution as you continue your design work. You can also add and remove files between evolutions.

The evolution tree you create will be saved as part of the project. All of your design files must be contained within a single project.

A project can contain multiple evolution trees. Use the **Change Tree** and **Delete Tree** buttons to manage evolution trees in your project. You can also right-click the canvas of the evolution tree to access these options.

## Create Evolution

After making changes to one or more files in your design, you can save the current state of the project files by clicking **Create Evolution**. The app creates a new evolution as a child of the **Baseline** evolution.

## Update Evolution

To update an existing evolution with additional changes made to files in the project, first select the evolution in the evolution tree, then click **Update Evolution**. Only the parent evolution of the project node can be updated. You cannot update an evolution that has multiple child evolutions.

To add a file to an evolution, first add the file to the project. Then, select the evolution in the evolution tree and click **Update Evolution**.

## Get Evolution into Project

At any point in the design process, you can return to a previous version of your design that was saved in an evolution. Select the evolution to which you want to return, then click **Get Evolution**. The Design Evolution Manager gets that version of the design files into the project. The evolution tree indicates this action visually by moving the project node to be a child of the selected evolution. You can then continue working with this previous version of the design files.

If you have added or deleted files between evolutions, the app warns you that these files will be added or removed from the project.

## Delete Evolutions

To delete an evolution, first select the evolution, then click **Delete Evolution**. The app deletes the evolution. If the deleted evolution had one child node, the child is reparented to the next-higher evolution in the tree. You cannot delete a parent evolution that has multiple child evolutions.

To delete a branch of the evolution tree, select the parent evolution and click **Delete Branch**. The app deletes the selected parent evolution and all child evolutions.

### **See Also**

“About Design Evolutions” on page 22-2 | “Inspect Properties of Evolutions and Compare Evolutions” on page 22-8

### **Related Examples**

- “Use Design Evolution Manager with the Fixed-Point Tool” on page 22-10

## Inspect Properties of Evolutions and Compare Evolutions

Use the **Property Inspector** pane of the Design Evolution Manager to inspect properties of the evolution tree, evolutions, and the connectors between evolutions and to compare evolutions.

### Inspect Properties of Evolution Tree, Evolutions, and Connectors

Select an evolution to display properties of the evolution. Use the **Properties** tab to rename the evolution. Use the **File List** tab to view the files that are stored in the evolution. Use the **Description** box of the **Info** tab to enter notes.

Select the evolution tree canvas to display properties of the evolution tree. Use the **Properties** tab to rename the evolution tree. Use the **Info** tab to enter notes.

Select a connector between evolutions to display what has changed between the parent and child evolution. Use the **Info** tab to enter notes. The **File List** tab displays files that have been added, deleted, or changed.

### Compare Evolutions

You can launch the Simulink Model Comparison Tool directly from the Design Evolution Manager to compare changes between evolutions.

To compare a parent and child evolution, first select the connector between the evolutions in the evolution tree. The **File List** tab of the **Property Inspector** pane displays a list of files that have been added, deleted, or changed between the parent and child evolution. Select the file you want to compare, then click **Compare Files**.

The app launches the Simulink Model Comparison Tool.

“About Design Evolutions” on page 22-2 | “Manage Evolutions and Evolution Trees” on page 22-4

## **Related Examples**

- “Use Design Evolution Manager with the Fixed-Point Tool” on page 22-10

## Use Design Evolution Manager with the Fixed-Point Tool

### Use Design Evolution Manager with Fixed-Point Tool

This example shows how to use the Design Evolution Manager to manage different design versions while using the Fixed-Point Tool and the Lookup Table Optimizer to convert a floating-point model to use fixed-point data types. While this example demonstrates the fixed-point conversion use case, the Design Evolution Manager can be used to organize and analyze any work in which you create different versions of files in your design.

In this example, the Fixed-Point Tool creates many versions of a design, including:

- The original floating-point model
- The model prepared for fixed-point conversion
- Various fixed-point versions of the model

Managing, analyzing, and moving between these different versions of a design can be challenging. The Design Evolution Manager helps you to organize different versions of the same design, understand the relationships between different versions, compare different versions, and store and review notes and data about the versions.

In this example, you

- 1 Convert your model files into a project.
- 2 Create an evolution tree to visually organize the different versions of your design that you store in evolutions.
- 3 Create a baseline evolution to store a snapshot of the initial state of the files in the project.
- 4 Convert the model to use fixed-point data types. Create evolutions to store snapshots of the design and notes you take at key points in the design process.
- 5 Compare evolutions and review your notes to understand changes that were made to the model, then choose which version of the design best meets your requirements.

The Design Evolution Manager is available on MATLAB® Online™ only and requires a Simulink® license. This example also requires a Fixed-Point Designer™ license.

### Set Up Example Files

To use the Design Evolution Manager, all of your design files be contained in a single project.

Create and open a working copy of the project example files. MATLAB® copies the files to an example folder so that you can edit them.

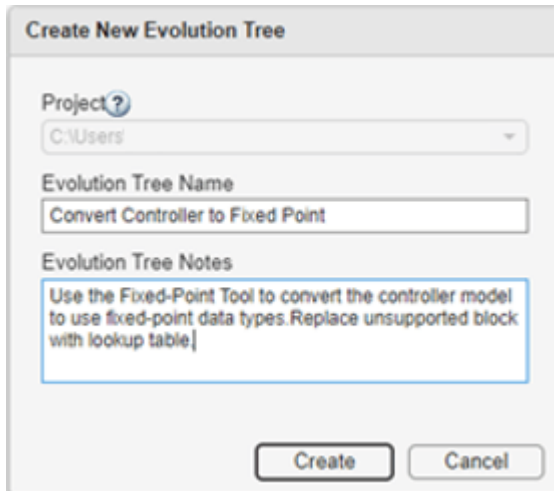

```
setupExample
```

The `setupExample` helper function creates and opens a project called `DEM_FPT_Example`, which contains a `controller_subsystem` model to convert to fixed point and a `controller_harness` model for testing.

## Create New Evolution Tree

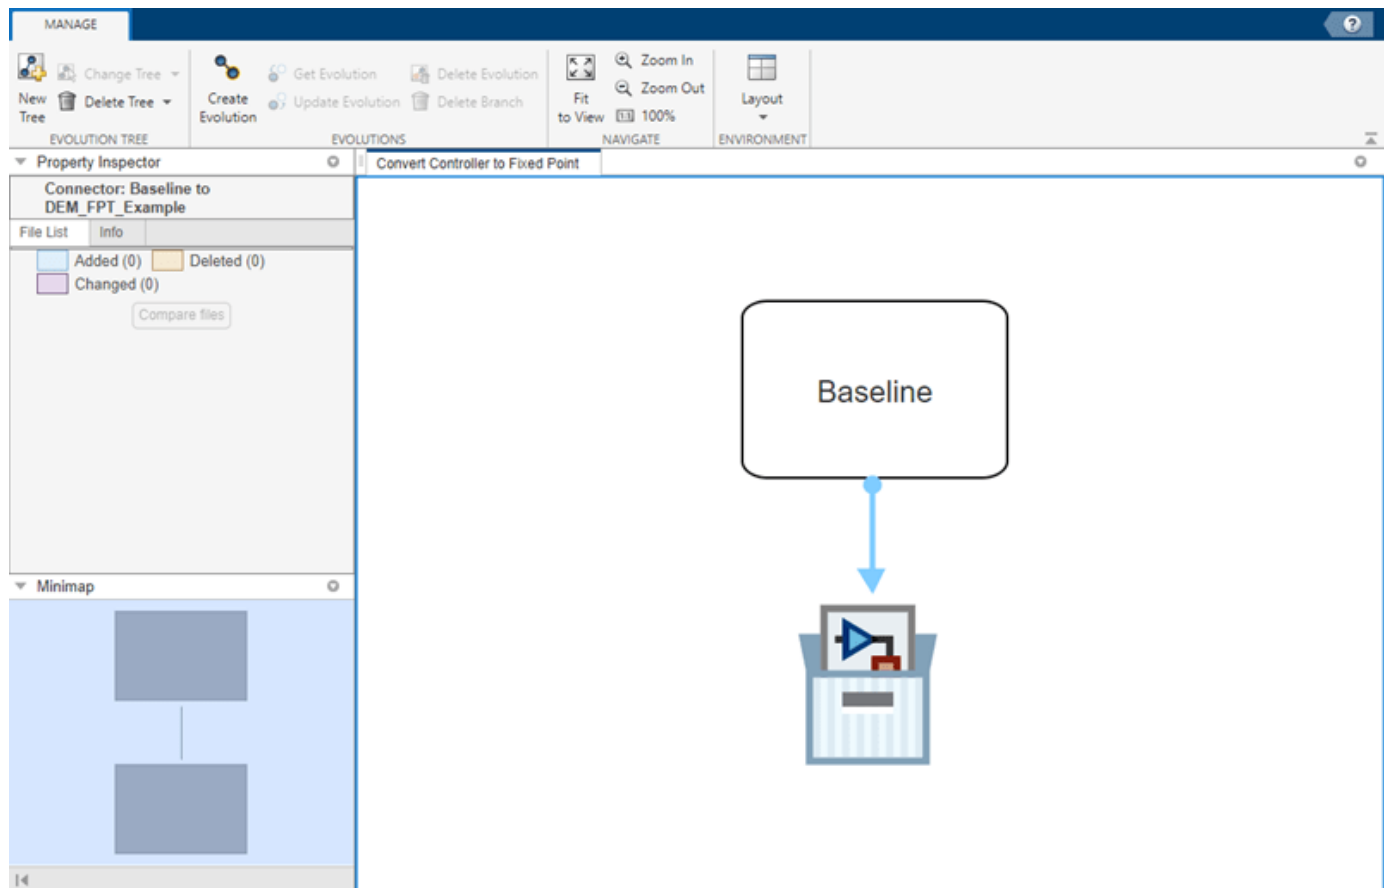

An evolution tree is a visual representation of a collection of related but different versions of your files stored as evolutions. Create a new evolution tree to keep track of different design versions created during conversion to fixed point.

1. On the **Project** tab, in the **Tools** section, expand the button arrow and select the **Design Evolution Manager** icon .
2. In the Create New Evolution Tree dialog box, under **Evolution Tree Name**, enter **Convert Controller to Fixed Point**. You can enter optional notes under **Evolution Tree Notes**.

3. Click **Create** to continue.

The Design Evolution Manager creates a new evolution tree containing the **Baseline** evolution. The **Baseline** evolution contains a copy of all files in the project in their current state. The project node  beneath the **Baseline** evolution represents the current state of the files in the project.

### Prepare for Fixed-Point Conversion

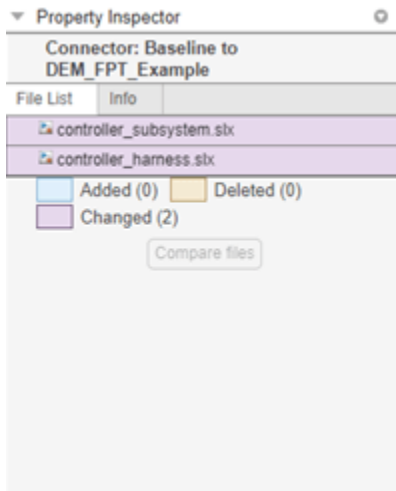

The first step in the fixed-point conversion process is to use the Fixed-Point Tool to prepare the `controller_subsystem` model for conversion to fixed point. The preparation step creates a new version of the model files that you may want to reference and return to later.

1. From the project, open the `controller_harness` model.
2. Open the Fixed-Point Tool. On the Simulink® **Apps** tab, under **Code Generation**, click the Fixed-Point Tool icon.
3. In the tool, select **New > Optimized Fixed-Point Conversion**.
4. Under **System Under Design (SUD)**, select `controller_subsystem` as the system to convert to fixed point.
5. In the toolstrip, click **Prepare**.
6. When the preparation checks are complete, save the changes to the `controller_subsystem` and `controller_harness` models.

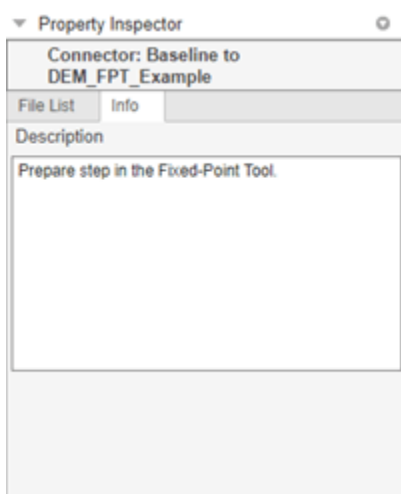

### Create Evolution

Use the Design Evolution Manager to check the state of your design and save the prepared model in a new evolution.

1. On the evolution tree, select the connector ↓ between the **Baseline** evolution and the project node. In the **Property Inspector** pane, the **File List** tab shows that the **controller\_subsystem.slx** and **controller\_harness.slx** model files have changed.

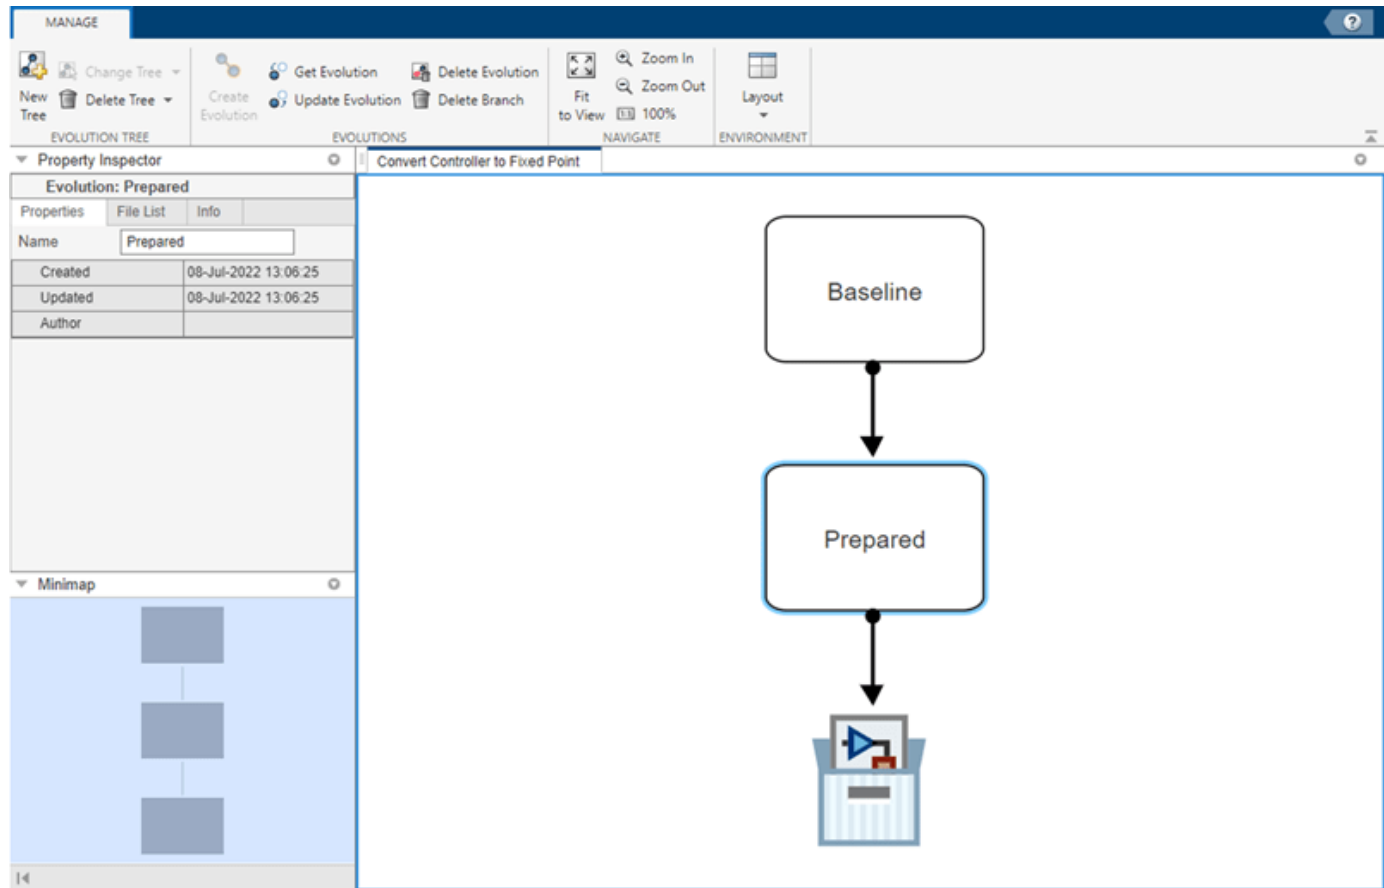

2. Select the **Info** tab for the connector. Add a note that these file changes are the result of running the preparation step in the Fixed-Point Tool.

3. Create a new evolution to store the prepared version of the model files. On the Design Evolution Manager toolstrip, click **Create Evolution**.

The shape of the evolution tree changes. An **Untitled** evolution appears beneath the **Baseline** evolution. This change indicates that the **Untitled** evolution was created from and is a child of the **Baseline** evolution.

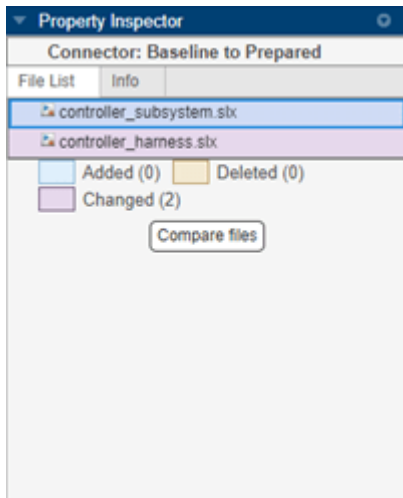

4. In the **Property Inspector** pane, on the **Properties** tab, name the new evolution **Prepared**.

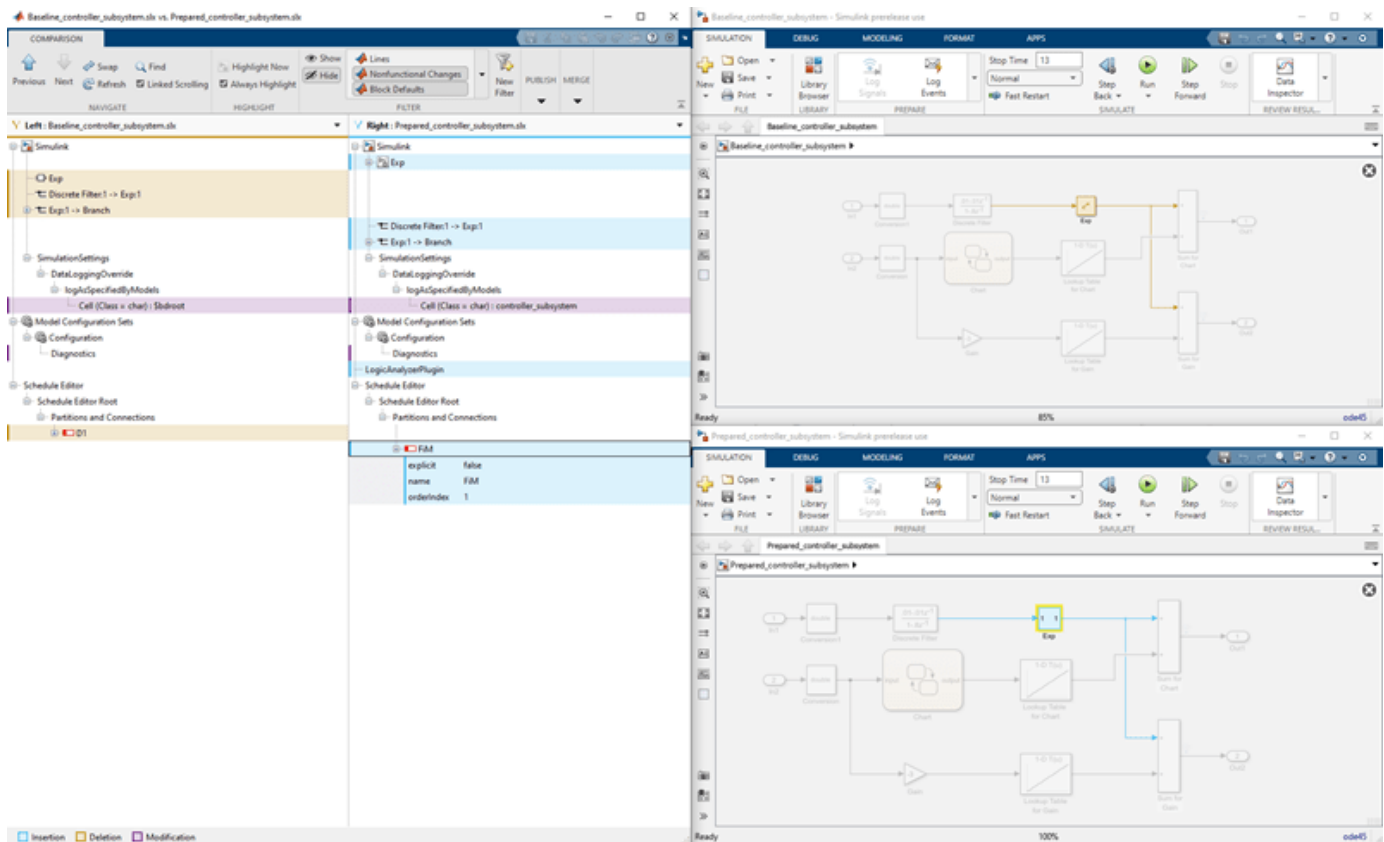

### Inspect Changes Between Evolutions

Use the Simulink Model Comparison Tool to compare the version of the files stored in the Baseline evolution to the version of the files stored in the Prepared evolution.

1. Select the connector ↓ between the Baseline and Prepared evolutions.
2. On the **Property Inspector** pane, on the **File List** tab, select the `controller_subsystem.slx` file from the list. Click **Compare Files**.

The **Comparison** tool launches. The version of the model stored in the **Baseline** evolution is shown in orange and the version of the model stored in the **Prepared** evolution is shown in blue. The comparison shows that the **Exp** block, which is not supported for fixed-point conversion, was automatically isolated during the prepare step in the Fixed-Point Tool.

3. In the Design Evolution Manager, select the **Prepared** evolution. In the **Property Inspector** pane, on the **Info** tab, add a note indicating that the **Exp** block has been isolated and needs to be replaced later.

### Convert to Fixed-Point and Store in Evolution

Use the Fixed-Point Tool to convert the controller model to fixed point. Use the Design Evolution Manager to track your work.

1. In the Fixed-Point Tool, from the **Workflow Browser** pane, select the **Setup** window.
2. Under **Signal Tolerances**, set the **Relative Tolerance** for the Sum:1 and Sum1:1 signals to 0.15.
3. Click **Optimize Data Types**.

The Fixed-Point Tool determines optimized fixed-point data types for the `controller_subsystem` based on the specified tolerances. The best solution found has a cost of 416. This solution is automatically applied to the `controller_subsystem` model.

4. To open the Simulation Data Inspector, click **Compare**. Visually confirm that the solution meets the specified tolerances for the logged signals.
5. Save the changes to the model.
6. In the Design Evolution Manager, create a new evolution to store this version of the design.
7. Name the new evolution `Converted 15%`.
8. Add a note to the evolution that the total cost of this design is 416.

### Update Evolution to Add Conversion Script

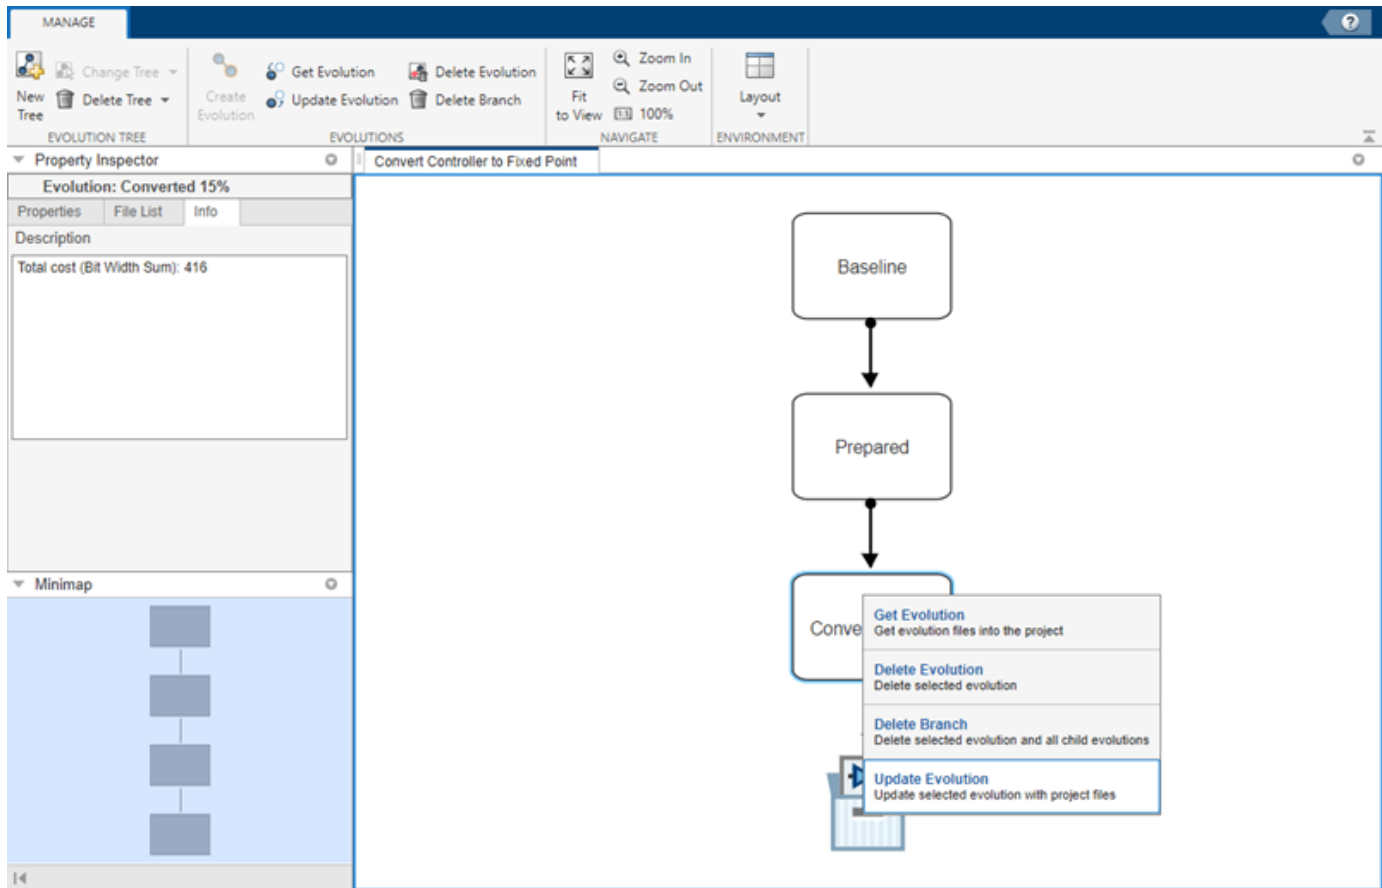

In addition to storing the fixed-point version of the model in an evolution, you can also add a copy of the script used to convert the model to fixed point to the `Converted 15%` evolution you just created.

1. Export the fixed point conversion script. In the Fixed-Point Tool, click **Export Script**.

The Fixed-Point Tool exports `fxpOptimizationScript.m` to the base workspace.

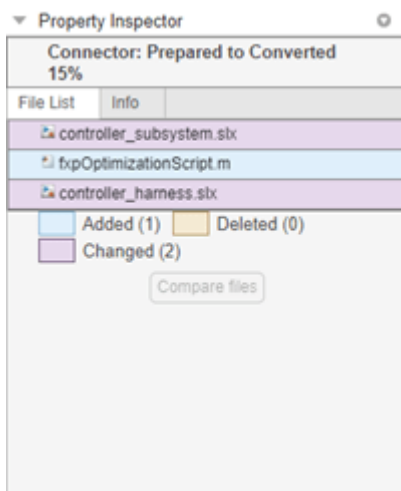

2. Add the fixed point conversion script to the project. In MATLAB, in the **Current Project** pane, right-click `fxpOptimizationScript.m` and select **Add to Project**.
3. Update the `Converted 15%` evolution to add the `fxpOptimizationScript` file to the evolution. In the Design Evolution Manager, right-click the `Converted 15%` evolution and select **Update Evolution**.

4. Click **OK**.

5. Confirm that the file was added to the evolution. Select the connector between the Prepared evolution and the Converted 15% evolution.

In the **Property Inspector** pane, the **File List** tab shows that the `fxpOptimizationScript.m` file was added. Additionally, it shows that the `controller_harness.slx` and

controller\_subsystem.slx model files were changed between the Prepared and Converted 15% evolutions.

### Create Branch in Evolution Tree to Explore Different Fixed-Point Types

Next, try the optimized fixed-point conversion workflow with a larger tolerance. Use the version of the files saved in the Prepared evolution to start from the version of the model files already prepared for fixed-point conversion. Then, run the optimization process again and track your work in a new branch in the evolution tree.

1. Return to the floating-point version of the design after it was prepared for fixed-point conversion. In the Design Evolution Manager, select the Prepared evolution. Click **Get Evolution**.

The dialog indicates that the fixed point conversion script, which was not present in the Prepared evolution, will be removed from the active project area.

2. Click **OK** to continue.

The files in the project are now the version of the design files as they previously were after preparation by the Fixed-Point Tool. The shape of the evolution tree has changed, showing that the active project node is now a child of the Prepared evolution.

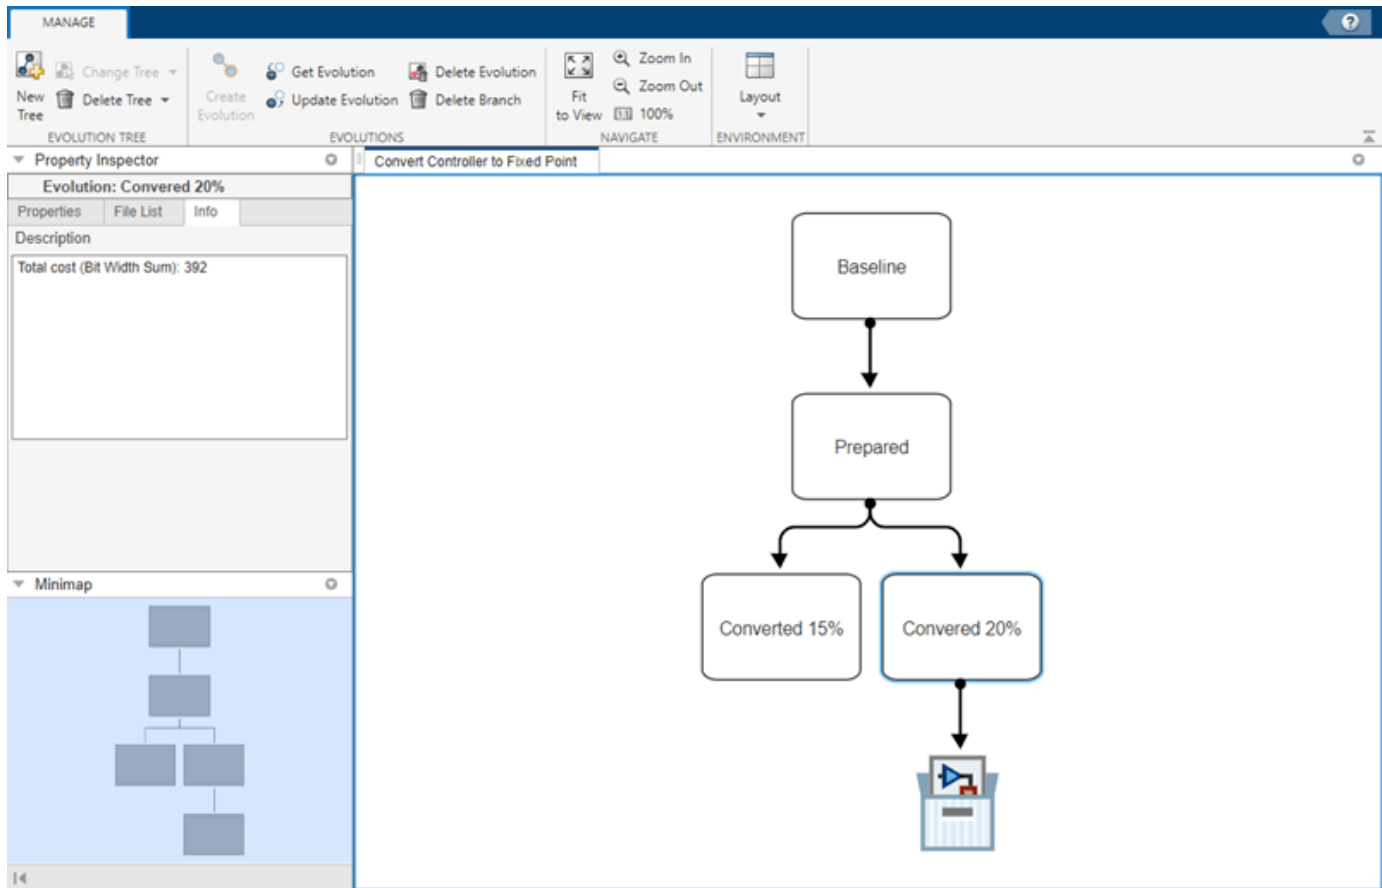

3. Use the Fixed-Point Tool to convert the controller\_subsystem to fixed point as before. This time, set the **Relative Tolerance** for both of the logged signals to 0.20.

Because you loaded the version of the model files from the Prepared evolution, you do not need to run the prepare step in the Fixed-Point Tool again.

4. Click **Optimize Data Types** to run the conversion.

The best solution found has a total cost of 392.

5. Save the changes to the model.
6. Save this version of the design in a new evolution named Converted 20%.
7. Export the fixed-point conversion script and add it to the evolution you just created.
8. Add a note to the Converted 20% evolution that the total cost of this version of the design is 392.

### Compare Alternate Versions of Design

The final step of fixed-point conversion is to replace the Exp block with a lookup table approximation. The fixed-point versions of the design stored in the Converted 15% and Converted 20% evolutions both produced acceptable results, with the logged signals meeting all specified tolerances. You can review your notes to confirm that the costs of these designs are 392 and 416, respectively. Because the Converted 20% version of the design has a lower cost, choose this branch of the evolution tree to continue your design work.

### Replace Unsupported Block with Lookup Table

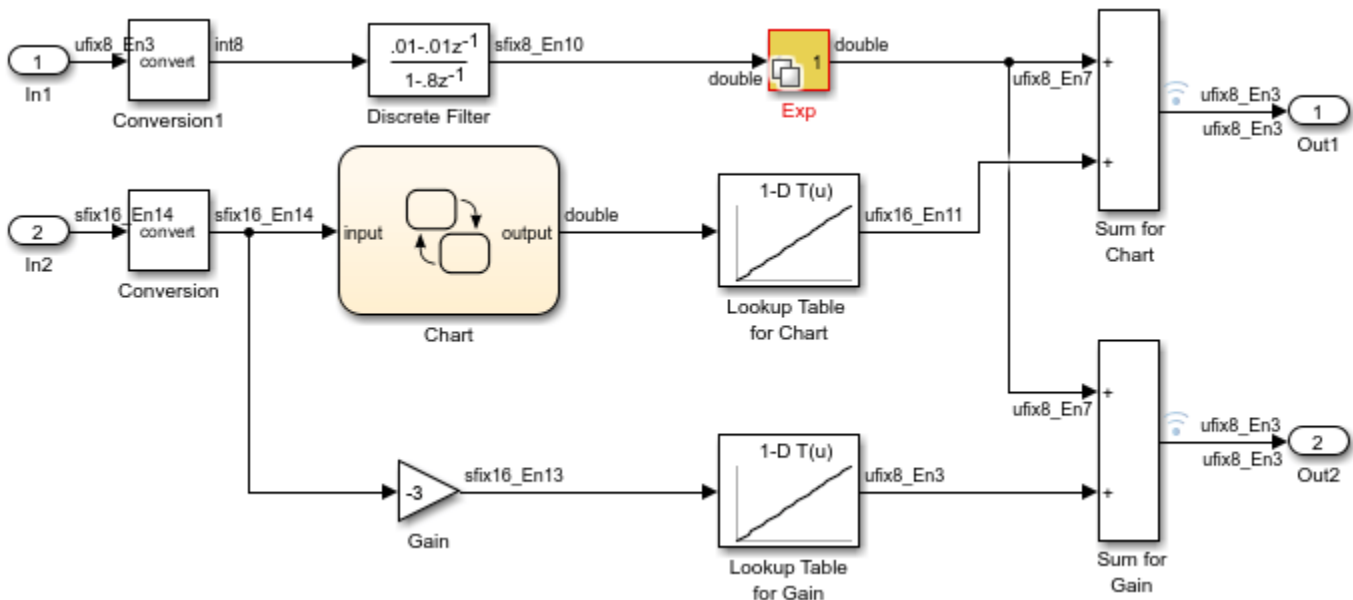

From the Converted 20% version of the design, replace the Exp block with a lookup table approximation.

1. Get the Converted 20% evolution into your active project area and open the `controller_harness` model.
2. In the model, navigate to the blue exponential subsystem under **controller\_harness > Model (controller\_subsystem) > Exp**. Select the Exp block that was isolated in the preparation stage of fixed-point conversion.

3. Open the Lookup Table Optimizer. On the Simulink **Apps** tab, under **Code Generation**, click the app icon.
4. In the Lookup Table Optimizer, select **Simulink block or subsystem**. Click **Next**.
5. Confirm that the Simulink block path is `controller_subsystem/Exp/ReplicaOfSource`. Click **Collect Current Values from Model**, then click **Next**.
6. Click **Optimize**, then click **Next**.
7. Click **Replace Original Function**.

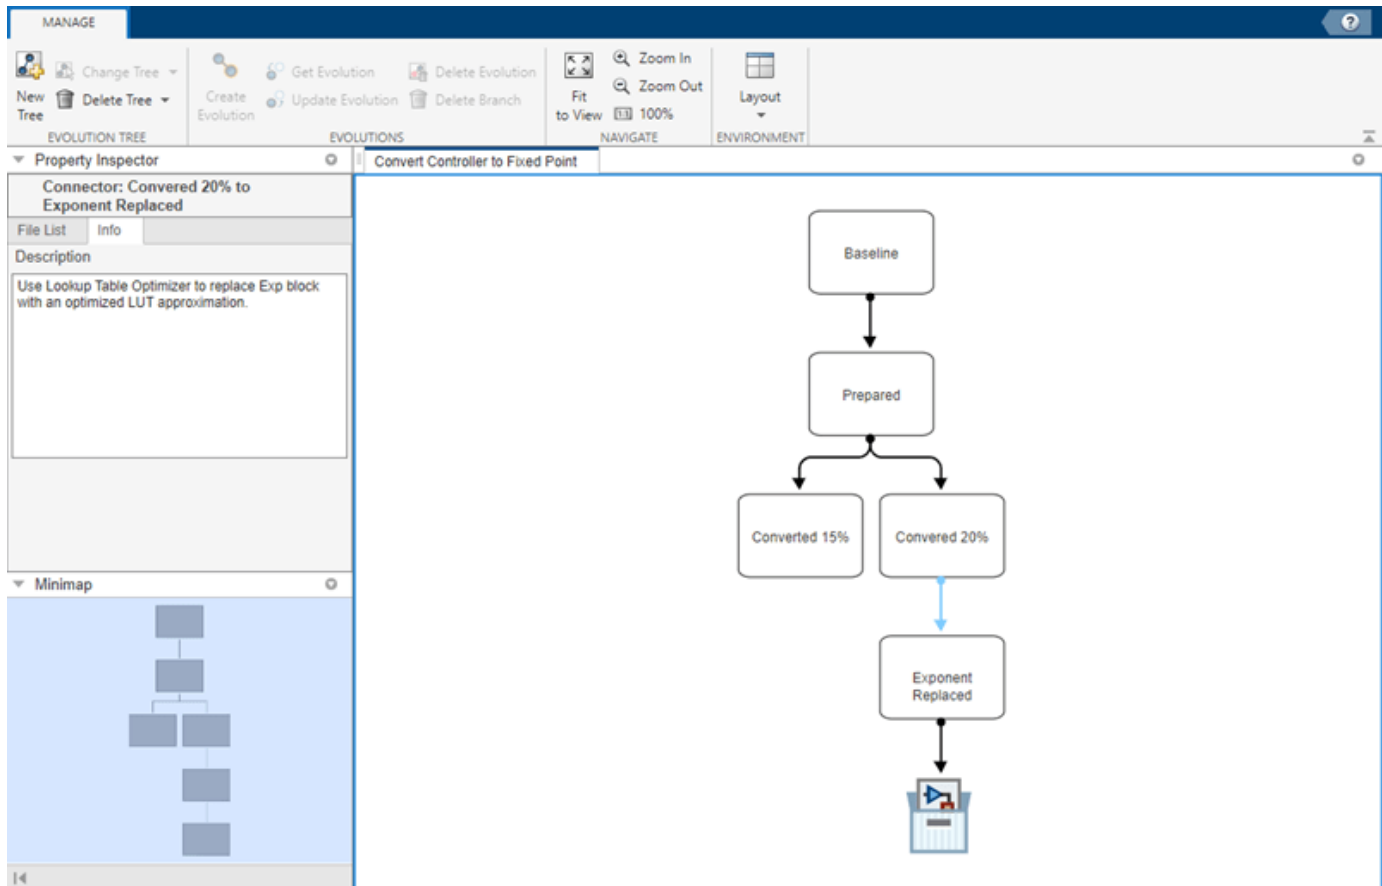

The Exp block is replaced with a lookup table approximation.

8. Save the changes to the model.

### Save Final Design in Evolution

1. In the Design Evolution Manager, create a new evolution to store this version of the design. Name the evolution `Exponent Replaced`.
2. Select the connector between the `Converted 20%` evolution and the `Exponent Replaced` evolution. Add a note that the action taken between these evolutions was to use the Lookup Table Optimizer to replace the Exp block with an optimized lookup table approximation.

## Review Design Process

The Design Evolution Manager shows the complete design process used in this example. Design decisions are represented visually by the evolution tree. You can select individual evolutions or connectors to review changes made during the design process and any notes you recorded.

## Close Project

Close the project. On the **Project** tab, in the **Close** section, click **Close Project**.

```
proj = currentProject;
close(proj);
```

## Component-Based Modeling Guidelines

Componentization benefits organizations developing Simulink models that consist of many functional pieces. Using model components can enable:

- Team-based development — Reduce file contention and elaborate components independently through well-defined interfaces.
- Reduced design complexity — Each component solves smaller problems.
- Component reuse — Reuse algorithms and environment models within a project and across multiple projects.
- Unit testing — Eliminate retesting for unchanged components and reduce the cost of verification.
- Performance benefits that scale — Reduce memory usage and the time required to load and simulate models.
- Component variants — Choose among multiple implementations of a component.
- Intellectual property protection — Limit functionality and content visibility for components that you share with third parties.

### Should You Create Model Components?

Considering the work required to define and manage components, you should use component-based modeling only when the benefits outweigh the cost.

Separating an existing Simulink model into components is analogous to taking a large piece of code (C, Java, or MATLAB code) and breaking it down into multiple functions. The conversion can require significant effort and extensive modifications if the design is not modular from the beginning.

Considering model scalability and potential requirements upfront makes separating a Simulink model into components easier. Identifying components upfront can help you avoid these difficulties:

- Poor component definition — The scope of subsystems that are grown over time can fail to meet component requirements. For example, they might contain too much or too little functionality to be reused, to generate code that integrates with legacy functionality, or to support hardware-in-the-loop tests.
- Merge conflicts — If additional engineers begin to work on a model that was originally designed for development by a single engineer, they can encounter time-consuming and error-prone merges.
- Algebraic loops — If a single engineer develops a model from the bottom up, they are likely to group blocks into subsystems as model complexity increases. The subsystems within the model are likely visual groupings that do not affect model execution. When you make these subsystems atomic, or convert them to referenced models, you can introduce unwanted algebraic loops that are difficult to diagnose and fix.

Components are also useful when a design becomes too complicated for one person to manage all of the details. For example, a complicated model can be a model that has:

- Thousands of blocks
- Hundreds of logical decisions
- Multiple variant configurations of the same functionality

Projects and source control can help you manage components. For more information, see “What Are Projects?” on page 16-3 and “Configuration Management” on page 23-23.

## Define Model Components

1. “Choose Among Types of Model Components” on page 23-4	Identify Simulink components that align with your high-level modeling requirements.
2. “Compare Capabilities of Model Components” on page 23-8	Investigate which types of model components meet your low-level modeling requirements.
3. “Define Interfaces of Model Components” on page 23-19	Configure design attributes at interfaces and manage data for model components.

## Choose Among Types of Model Components

Useful model components have a well-defined scope, perform functionality defined by requirements, and form part of a larger system.

As you define a component, consider these potential requirements.

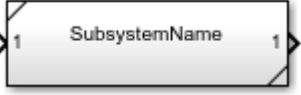

- **File contention** — You can have larger components if only one person is working on each. If you must share components between several people, you should divide the design into smaller logical pieces. If multiple people must edit the same file, see “Merge Simulink Models from the Comparison Report” on page 21-16.
- **Reusability** — If you expect to use a group of blocks multiple times in a model, define the group of blocks in a reusable component. By avoiding duplication, you make maintaining the model easier. To refactor an existing model with duplication, see “Refactor Models to Improve Component Reuse” (Simulink Check).
- **Code generation** — If you must generate standalone code for a physical component, such as a digital controller, you should have one component that represents the physical component and has a well-defined interface.
- **Verification cost** — If part of a model changes frequently and has high testing costs, you should manage this part of the model as a component in a separate file. When components are defined in separate files, you can control and trace changes using project source control. For more information on source control, see “Configuration Management” on page 23-23.
- **Simulation speed** — Using different solvers for components with different numerical properties can increase simulation speed. Similarly, grouping blocks based on their sample rate can increase simulation speed. For more information, see Solver Profiler and “Improve Simulation Performance Using Performance Advisor” on page 35-2.

Modeling requirements can influence the size of your components. For example, models with fewer than 500 blocks are easier to test than larger models. However, simulation can be faster for model hierarchies when referenced models contain more than 500 blocks.

## Simulink Components

The different types of Simulink components serve a variety of modeling requirements.

Type of Component	Definition	Source of Contents	Implementation in Model
Subsystem	A subsystem is a unique group of blocks with a dynamic interface that can inherit the properties of its inputs and outputs.	None — Contents must be manually added to each subsystem	Subsystem block 
Linked subsystem	A linked subsystem is a linked instance of a Subsystem block that is stored in a library. If you disable the library link, each instance of a linked block can be unique.	Library file (.slx or .mdl) that contains the parent library block, or prototype block	Subsystem block with a library link 

Type of Component	Definition	Source of Contents	Implementation in Model
Subsystem reference	A subsystem reference is a reference to a reusable group of blocks with a dynamic interface that can inherit the properties of its inputs and outputs.	Subsystem file (.slx or .mdl) that contains the referenced subsystem	Subsystem Reference block 
Model reference	A model reference is a reference to a model with a defined interface that specifies the properties of its inputs and outputs.	Model file (.slx, .mdl, or .slxp) that contains the referenced model, which may be a protected model	Model block 

Simulink models can use any combination of these components. For example, to minimize file contention for a large model, you can convert subsystems to referenced subsystems and models, both of which are saved in separate files.

When you drag a subsystem reference or model reference from a library into a model, it directly references the subsystem file or model file that defines its contents. It has a library link only when the parent library block has a mask applied directly to it. Typically, you should use model masks, which are saved in the referenced file and do not require a library link.

## High-Level Component Selection Guidelines

Each of the types of model components has an ideal use case:

- Subsystem — Ideal for simplifying the block diagrams of other components
- Linked subsystem — Ideal for utilities and blocksets
- Subsystem reference — Ideal for reducing file contention and merge issues
- Model reference — Ideal for code reuse, unit testing, parallel builds, and large components

The ideal use cases are a subset of the possible use cases for each type of component. For example, you can also reduce file contention and merge issues with a model reference, and you can also unit test a subsystem.

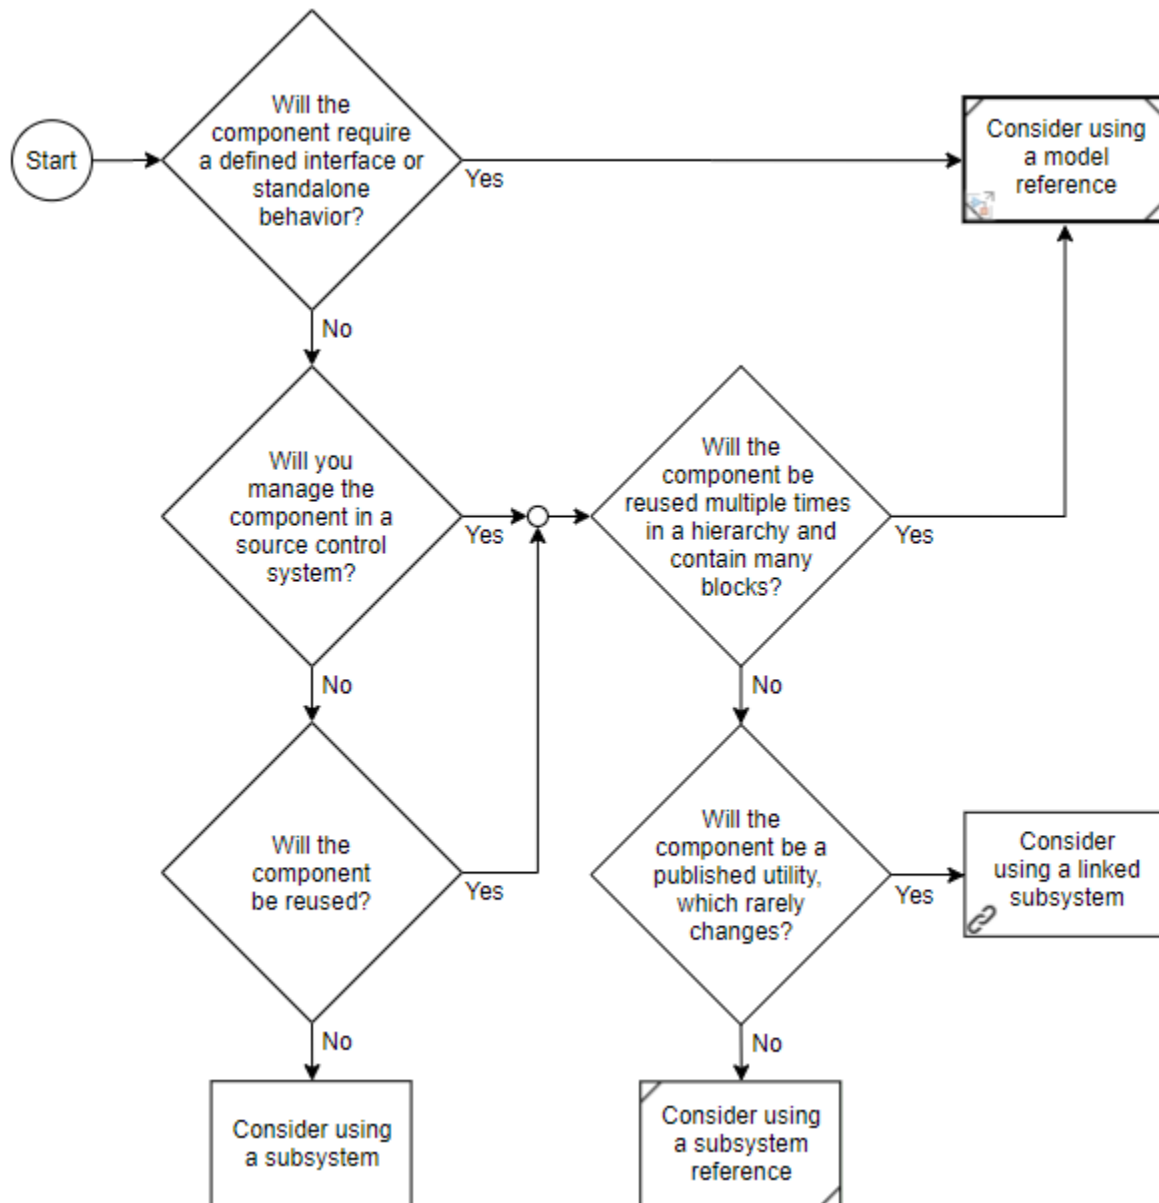

---

**Tip** If you expect a subsystem to grow, make it atomic so that it functionally groups the blocks. An atomic subsystem behaves like a single block, or atomic unit, when the parent model executes. Atomic behavior is necessary for you to convert a subsystem to a model reference.

---

For an overview of when to use different componentization techniques, see [Component-Based Modeling in Simulink \(4 min, 28 sec\)](#).

This flow chart provides a starting point for choosing a component type.

Consider a subsystem if the component meets all of these conditions:

- The component will not require a defined interface or standalone behavior.
- The component will not be managed in a source control system.
- The component will not be reused.

Consider a linked subsystem if the component meets all of these conditions:

- The component will not require a defined interface or standalone behavior.
- The component will either be managed in a source control system or be reused.
- The component will not contain enough blocks and be reused enough to benefit from accelerator mode simulation of referenced models.

- The component will be a published utility, which rarely changes.

Consider a subsystem reference if the component meets all of these conditions:

- The component will not require a defined interface or standalone behavior.
- The component will either be managed in a source control system or be reused.
- The component will not contain enough blocks and be reused enough to benefit from accelerator mode simulation of referenced models.
- The component will not be a published utility, which rarely changes.

Consider a model reference if the component meets either of these conditions:

- The component will require a defined interface or standalone behavior.
- The component will contain enough blocks and be reused enough to benefit from accelerator mode simulation of referenced models.

Whether a model hierarchy benefits from accelerator mode simulation of referenced models depends on many factors. For each referenced model that simulates in accelerator mode, Simulink must build and compile a simulation target. These targets are reused for additional instances of the referenced model, which accelerates simulation when the model hierarchy contains many instances of the referenced model. If the referenced model is unchanged, you can reuse its simulation target, which is stored in a Simulink cache file (.slxc). For more information, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.

## Modeling Requirement Considerations

Before implementing a component based on the high-level guidelines, consider additional modeling requirements. For example, if you require physical connections at the component interface, you must use a subsystem, linked subsystem, or referenced subsystem. If you require intellectual property protection, you must create a protected model, which can be referenced.

To determine whether a component meets your modeling requirements, see “Compare Capabilities of Model Components” on page 23-8.

## Define Interfaces of Model Components

Defining the interface of a model component, such as a Simulink subsystem, subsystem reference, or model reference, is a key first step before others can use it.

- Agreeing on an interface helps determine how to break down the functionality of a large system into components.
- After you define interfaces between components, you can develop the components in parallel. If the interface remains stable, then it is easy to integrate those components into a larger system.
- Changing the interface between components is expensive. Changing an interface requires changes to at least two components (the source and any sinks) and to any test harnesses. It also makes all previous versions of those components incompatible with the current and future versions.

Changing an interface is much easier if the components are stored under configuration management. You can track configurations of compatible component versions to prevent incompatible combinations of components.

---

**Note** This topic focuses on design interfaces for modeling and simulation. To configure an interface for code generation and deployment, see:

- “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder)
  - “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder)
  - “C Code Generation Configuration for Model Interface Elements” (Simulink Coder)
  - “Interactively Configure C++ Interface” (Embedded Coder)
  - “Programmatically Configure C++ Interface” (Embedded Coder)
- 

## Identify Component Boundaries

Base the boundaries of the components upon the boundaries of the corresponding real systems. This guideline is especially useful when the model contains:

- Both physical (plant and environment) and control systems
- Algorithms that run at different rates
- A system that you want to reuse multiple times

If you intend to add sensors or other components as you elaborate your model, create components to represent them. You can configure these components to pass signals straight through or perform a unit delay or name conversion.

## Simplify Interfaces with Buses

To simplify interfaces, group signals and messages into buses. Buses simplify subsystem and model interfaces by letting you associate multiple signals or messages with one port. They reduce line complexity and clutter in a block diagram and make it easier to change the interface incrementally. For example, if you must add or remove elements from a component interface, modifying a bus can be simpler than adding or removing ports. To logically group or define the properties of a portion of the interface, use multiple bus ports.

Buses are well suited for components that have many input and output signals and do not use all of the available signals. Buses pass only the required data to each component from the inputs and outputs. If you define the bus at the interface with a `Simulink.Bus` object, the interface requires data for the entire bus.

To access an element from an input bus, use an In Bus Element block. To create an output bus, use Out Bus Element blocks. For more information, see “Simplify Subsystem and Model Interfaces with Bus Element Ports” on page 81-23.

How you implement buses at an interface depends on your requirements.

Requirement	Bus Implementation
Provide name-based matching among elements at the interface and simplify line routing	Use virtual buses. While nonvirtual buses also satisfy this modeling requirement, virtual buses provide a simpler solution. For more information, see “Composite Interface Guidelines” on page 81-2.
Enable robust component integration with defined interfaces	Use <code>Simulink.Bus</code> objects to define the properties of the virtual buses at the interface. Use a rigorous naming convention for the bus elements and <code>Bus</code> objects.  To place the <code>Bus</code> objects under revision control, save them in a data dictionary, function, script, or MAT file.
Replicate structure type in generated code	Use nonvirtual buses to describe a structured data type for an element in the interface.
Package signals or parameters into structures that correspond to a <code>struct</code> type definition that your external C code defines	Import the type as a <code>Bus</code> object and use the object as a data type for buses and MATLAB structures. To create the object, use the <code>Simulink.importExternalCTypes</code> function.

## Partition Interface Data

Explicitly control the scope of data for your components with global and nonglobal parameters.

- Global parameters — A common approach in the automotive world is to completely separate parameter storage from model storage. The parameters for a model come from a database of calibration data, and the specific calibration file used becomes part of the configuration. The calibration data is treated as global data, and resides in the base MATLAB workspace. You can migrate base workspace data to a data dictionary for more control.
- Nonglobal parameters — Combining components that store their own parameter data has the risk of parameter name collisions. If you do not use a naming convention for parameters or a list of unique parameter names and definitions, then two components may use a parameter with the same name but with different meanings.

To store local parameter data:

- Partition data into reference dictionaries for each component.
- For referenced models, you can use model workspaces.

- Use parameter files (.m or .mat) and callbacks of the individual Simulink models (for example, the `preLoad` function).

You can also automatically load required data using project shortcuts.

- Use mask workspaces with or without the use of mask initialization functions.
- For subsystems, you can control the scope of data for a subsystem using the **Permit hierarchical resolution** parameter of the Subsystem block.

## Configure Data Interfaces

Explicitly configure design attributes of the interface, such as data type and numeric complexity, to prevent modeling errors and make component integration easier. You can configure the interface of a component before you develop the internal algorithm, in which case the component contains unconnected blocks. After you create the blocks that correspond to the component interface, use:

- The **Model Data Editor** to configure the design attributes of the blocks.

To open the Model Data Editor, on the **Modeling** tab of the Simulink Toolstrip, click **Model Data Editor**. On the **Inports/Outports** tab of the Model Data Editor, each row corresponds to an input or output block and the columns correspond to attributes that you can set for the blocks.

- The interface display perspective to view the component interface in its entirety and trace elements of the interface to usage points in the internal block algorithm.

To open the interface display perspective, on the **Modeling** tab, in the **Design** gallery, click **Model Interface**. For more information, see “Trace Connections Using Interface Display” on page 81-117.

By default, the **Change view** list of the Model Data Editor is set to **Design**, which configures the columns to correspond to design attributes. Use the columns to explicitly configure the design attributes of the interface. For example, specify minimum and maximum values for each block with the **Min** and **Max** columns.

Alternatively, you can specify a reusable set of design attributes at component interfaces instead of individually specifying each attribute.

- Use `Simulink.ValueType` objects to assign or validate properties of a signal based on application-specific value types such as wind velocity, tire pressure, or water temperature.
- Use `Simulink.Bus` objects to assign or validate the properties of each element of a bus.

To display the input and output blocks of the subsystems, select the **Change Scope** button . Alternatively, view only the input and output blocks at the root level of the model by excluding the blocks inside the subsystems.

# Configuration Management

**In this section...**

“Manage Designs Using Source Control” on page 23-23

“Determine the Files Used by a Component” on page 23-23

“Manage Model Versions” on page 23-24

“Create Configurations” on page 23-24

## Manage Designs Using Source Control

Projects can help you work with configuration management tools for team collaboration. You can use projects to help you manage all the models and associated files for model-based design.

You can control and trace the changes in each component using project source control. Using source control directly from a project provides these benefits:

- Engineers do not have to remember to use two separate tools, avoiding the common mistake of beginning work in Simulink without checking out the required files first.
- You can perform analysis within MATLAB and Simulink to determine the dependencies of files upon each other. Third-party tools are unlikely to understand such dependencies.
- You can compare revisions and use tools to merge models.

If each component is a single file, you can achieve efficient parallel development, where different engineers can work on the different components of a larger system in parallel. Using model components allows you to avoid or minimize time-consuming merging. One file per component is not strictly necessary to perform configuration management, but it makes parallel development much easier.

If you break down a model into components, it is easier to reuse those components in different projects. If the components are kept under revision control and configuration management, then you can reuse components in multiple projects simultaneously.

To find out about source control support, see “Source Control in Projects”.

## Determine the Files Used by a Component

You can use a project to determine the set of files you must place under configuration management. You can analyze the set of files that are required for the model to run, such as model references, library links, block and model callbacks (preload functions, init functions, etc.), S-functions, From Workspace blocks, etc. Any MATLAB code found is also analyzed to determine additional file dependencies. You can use the Dependency Analyzer to report which toolboxes are required by a model, which can be a useful artifact to store.

You can also perform a file dependency analysis of a model programmatically from MATLAB using `dependencies.fileDependencyAnalysis` to get a cell array of paths to required files.

For more information, see “Dependency Analysis”.

## Manage Model Versions

Simulink can help you to manage multiple versions of a model.

- Use a project to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Simulink notifies you if a model has changed on disk when updating, simulating, editing, or saving the model. Models can change on disk, for example, with source control operations and multiple users. Control this notification with the Model File Change Notification preference. See “Model File Change Notification” on page 4-70.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
  - Use the Model Properties dialog box to view and edit some of the version information stored in the model and specify history logging.
  - The Model Info block lets you display version information as an annotation block in a model diagram.
- Use `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

## Create Configurations

You can use a project to work with the revision control parts of the workflow: retrieving files, adding files to source control, checking out files, and committing edited files to source control.

To define configurations of files, you can label several files as a new mutually consistent configuration. Team members can get this set of files from the revision control system.

Configurations are different from revisions. Individual components can have revisions that work together only in particular configurations.

Tools for creating configurations in Simulink:

- Variant modeling. See “Variant Systems”.
- Project tools:
  - Label — Label project files. Use labels to apply metadata to files. You can group and sort by labels, label folders for adding to the path using shortcut functions, or create batch jobs to export files by label, for example, to manage files with the label `Diesel`. You cannot retrieve from source control by label, and labels persist across revisions.
  - Revision Log — Use Revert Project to choose a revision to revert to (SVN source control only).
  - Branch — Create branches of file versions, and switch to any branch in the repository (Git source control only).
  - Tag — You can tag all project files (SVN source control only) to identify a particular configuration of a project, and retrieve tagged versions from source control. However, continued development is limited. That is, you cannot tag again, and you must check out from trunk to apply tags.

- Archive — Package all project files in a zip file that you can create a project from. However, this packaging removes all source control information, because archiving is for exporting, sharing, and changing to another source control. You can commit the new zip file to source control.

### Study Power Windows

Automobiles use electronics for control operations such as:

- Opening and closing windows and sunroof
- Adjusting mirrors and headlights
- Locking and unlocking doors

These systems are subject to stringent operation constraints. Failures can cause dangerous and possibly life-threatening situations. As a result, careful design and analysis are needed before deployment.

This example focuses on the design of a power window system of an automobile, in particular, the passenger-side window. A critical aspect of this system is that it cannot exert a force of more than 100 N on an object when the window closes. When the system detects such an object, it must lower the window by about 10 cm.

As part of the design process, the example considers:

- Quantitative requirements for the window control system, such as timing and force requirements
- System requirements, captured in activity diagrams
- Data definitions for the signals used in activity diagrams

Other aspects of the design process that this example contains are:

- Managing the components of the system
- Building the model
- Validating the results of system simulation
- Generating code

## MathWorks Software Used in This Example

In addition to Simulink, this example uses these additional MathWorks products:

- DSP System Toolbox
- Fixed-Point Designer
- Simscape Multibody
- Simscape Electrical™
- Simscape
- Simulink 3D Animation™
- Simulink Real-Time
- Simulink Coverage
- Stateflow

## Quantitative Requirements

Quantitative requirements for the control are:

- The window must fully open and fully close within 4 s.
- If the up is issued for between 200 ms and 1 s, the window must fully open. If the down command is issued for between 200 ms and 1 s, the window must fully close.
- The window must start moving 200 ms after the command is issued.
- The force to detect when an object is present is less than 100 N.
- When closing the window, if an object is in the way, stop closing the window and lower the window by approximately 10 cm.

## Capturing Requirements in Activity and Context Diagrams

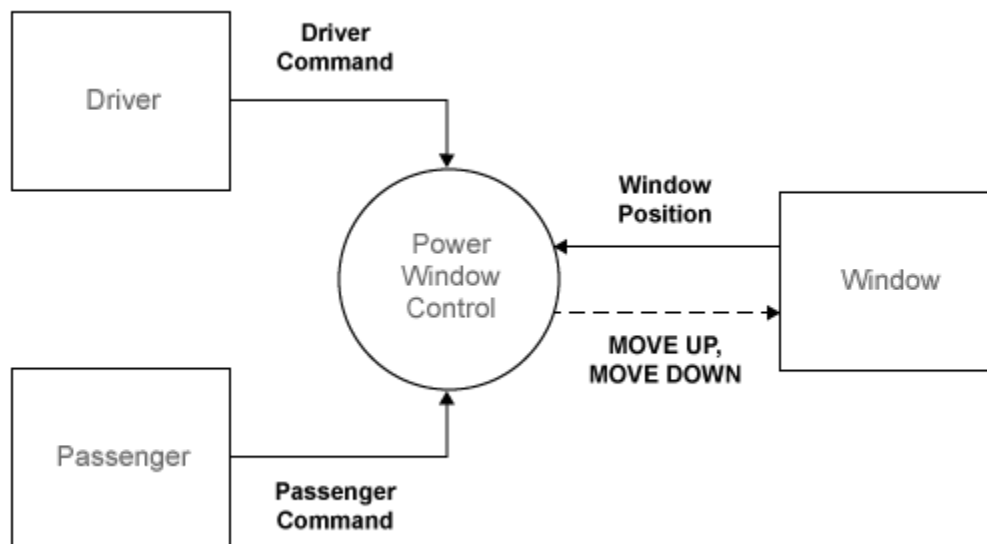

Activity diagrams help you graphically capture the specification and understand how the system operates. A hierarchical structure helps with analyzing even large systems. At the top level, a context diagram describes the system environment and its interaction with the system under study in terms of data exchange and control operations. Then you can decompose the system into an activity diagram with processes and control specifications (CSPEC).

The processes guide the hierarchical decomposition. You specify each process using another activity diagram or a primitive specification (PSPEC). You can specify a PSPEC in a number of

representations with a formal semantic, such as a Simulink block diagram. In addition, context diagrams graphically capture the context of system operation.

### Context Diagram: Power Window System

The figure represents the context diagram of a power window system. The square boxes capture the environment, in this case, the driver, passenger, and window. Both the driver and passenger can send commands to the window to move it up and down. The controller infers the correct command to send to the window actuator (e.g., the driver command has priority over the passenger command). In addition, diagram monitors the state of the window system to establish when the window is fully opened and closed and to detect if there is an object between the window and frame.

The circle (also known as a bubble) represents the power window controller. The circle is the graphical notation for a process. Processes capture the transformation of input data into output data. Primitive process might also generate. CSPECs typically consist of combinational or sequential logic to infer output control signals from input control.

For implementation in the Simulink environment, see “Implementation of Context Diagram: Power Window System” on page 24-26.

### Activity Diagram: Power Window Control

The power window control consists of three processes and a CSPEC. Two processes validate the driver and passenger input to ensure that their input is meaningful given the state of the system. For example, if the window is completely opened, the MOVE DOWN command does not make sense. The remaining process detects if the window is completely opened or completely closed and if an object is present. The CSPEC takes the control signals and infers whether to move the window up or down (e.g., if an object is present, the window moves down for about one second or until it reaches an endstop).

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Power Window Control” on page 24-11.

**Activity Diagram: Validate Driver**

Each process in the VALIDATE DRIVER activity chart is primitive and specified by the following PSPEC. In the MAKE EXCLUSIVE PSPEC, for safety reasons the DOWN command takes precedence over the UP command.

PSPEC 1.1.1: CHECK DOWN  
 CHECKED\_DOWN = DOWN and not RESET

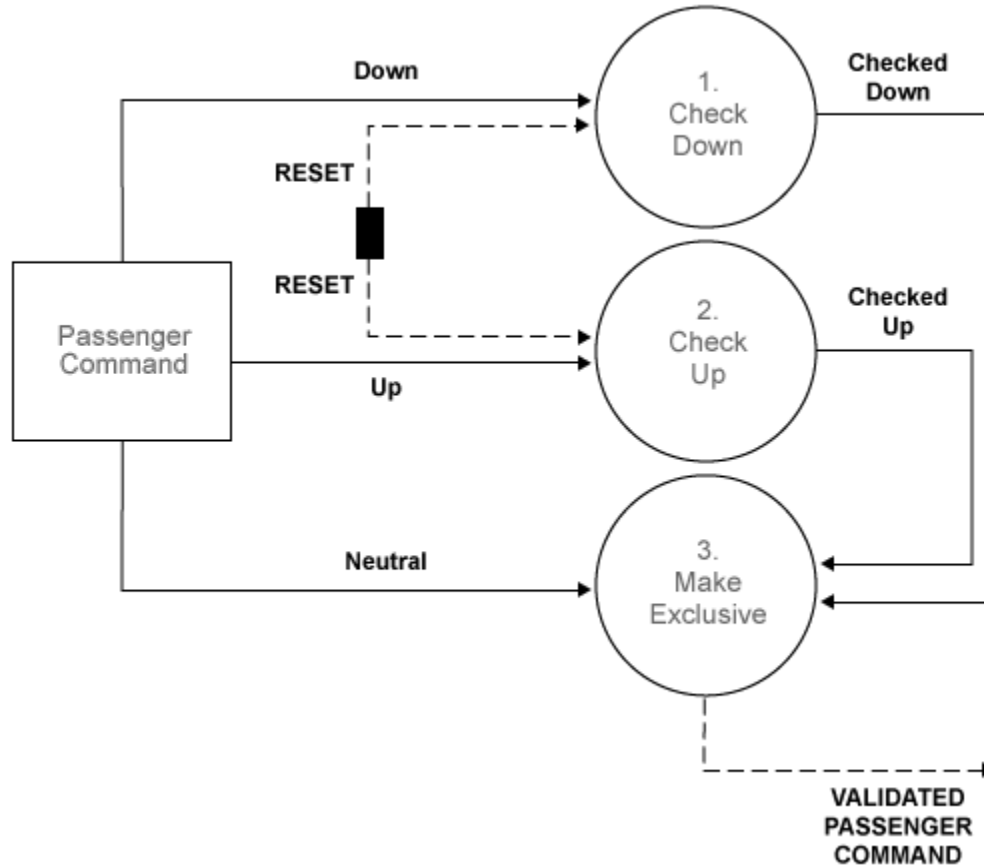

PSPEC 1.1.2: CHECK UP  
 CHECKED\_UP = UP and not RESET

PSPEC 1.1.3: MAKE EXCLUSIVE  
 VALIDATED\_DOWN = CHECKED\_DOWN  
 VALIDATED\_UP = CHECKED\_UP and not CHECKED\_DOWN  
 VALIDATED\_NEUTRAL = (NEUTRAL and not (CHECKED\_UP and not CHECKED\_DOWN))  
 or not (CHECKED\_UP or CHECKED\_DOWN)

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Validate” on page 24-28.

**Activity Diagram: Validate Passenger**

The internals of the VALIDATE PASSENGER process are the same as the VALIDATE DRIVER process. The only difference is the different input and output.

PSPEC 1.2.1: CHECK DOWN  
 CHECKED\_DOWN = DOWN and not RESET

PSPEC 1.2.2: CHECK UP  
 CHECKED\_UP = UP and not RESET

PSPEC 1.2.3: MAKE EXCLUSIVE  
 VALIDATED\_DOWN = CHECKED\_DOWN  
 VALIDATED\_UP = CHECKED\_UP and not CHECKED\_DOWN  
 VALIDATED\_NEUTRAL = (NEUTRAL and not (CHECKED\_UP and not CHECKED\_DOWN))  
 or not (CHECKED\_UP or CHECKED\_DOWN)

For implementation in the Simulink environment, see “Activity Diagram: Validate Passenger” on page 24-6.

### Activity Diagram: Detect Obstacle Endstop

The third process in the POWER WINDOW CONTROL activity diagram detects the presence of an obstacle or when the window reaches its top or bottom (ENDSTOP). The detection mechanism is based on the armature current of the window actuator. During normal operation, this current is within certain bounds. When the window reaches its top or bottom, the electromotor draws a large current (more than 15 A or less than -15 A) to try and sustain its angular velocity. Similarly, during normal operation the current is about 2 A or -2 A (depending on whether the window is opening or closing). When there is an object, there is a slight deviation from this value. To keep the window force on the object less than 100 N, the control switches to its emergency operation when it detects a current that is less than -2.5 A. This operations is necessary only when the window is rolling up, which

corresponds to a negative current in the particular wiring of this model. The DETECT OBSTACLE ENDSTOP activity diagram embodies this functionality.

CSPEC 1.3: DETECT OBSTACLE ENDSTOP  
 RESET = OBSTACLE or ENDSTOP

PSPEC 1.3.1: DETECT ENDSTOP  
 ENDSTOP = WINDOW\_POSITION > ENDSTOP\_MAX

PSPEC 1.3.2: DETECT OBSTACLE  
 OBSTACLE = (WINDOW\_POSITION > OBSTACLE\_MAX) and MOVE\_UP for 500 ms

For implementation in the Simulink environment, see “Activity Diagram: Detect Obstacle Endstop” on page 24-7.

### Data Definitions

The functional decomposition unambiguously specifies each process by its decomposition or primitive specification (PSPEC). In addition, it must also formally specify the signals in the activity diagrams. Use data definitions for these specifications.

The following tables are data definitions for the signals used in the activity diagrams.

For the associated activity diagram, see “Context Diagram: Power Window System” on page 24-4.

**Context Diagram: Power Window System Data Definitions**

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Power Window Control” on page 24-4.

**Activity Diagram: Power Window Control Data Definitions**

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Validate Driver” on page 24-5.

**Activity Diagram: Validate Driver Data Definitions**

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Validate Passenger” on page 24-6.

**Activity Diagram: Validate Passenger Data Definitions**

Signal	Information Type	Continuous/ Discrete	Data Type	Values
NEUTRAL	Data	Discrete	Boolean	'True', 'False'
UP	Data	Discrete	Boolean	'True', 'False'
DOWN	Data	Discrete	Boolean	'True', 'False'
CHECKED_UP	Data	Discrete	Boolean	'True', 'False'
CHECKED_DOWN	Data	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 24-7.

**Activity Diagram: Detect Obstacle Endstop Data Definitions**

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ENDSTOP_MIN	Data	Constant	Real	0.0 m
ENDSTOP_MAX	Data	Constant	Real	0.4 m
OBSTACLE_MAX	Data	Constant	Real	0.3 m

The model design iterates as we examine more detailed implementations. For information about how the model design iterates as you introduce more detail, see “Iterate on the Design” on page 24-35.

**Simulink Power Window Controller Project**

MATLAB and Simulink support Model-Based Design for embedded control design, from initial specification to code generation. To organize large projects and share your work with others, use “Project Management”.

“Power Window Control Project” shows how you can use MathWorks tools and the Model-Based Design process to go from concept through implementation for an automobile power window system. It uses projects to organize the files and other model components.

In addition, this example shows how to link models to system documentation.

**Explore the Power Window Controller Project**

- 1 To open the Power Window Controller project, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```

- 2 Explore the project folders. In particular, note the **task** folders. This folder contains scripts that run frequent tasks for a model. For the Power Window Controller Project, these scripts:

- Set up the model to control window movement on a controller area network (CAN).
- Set up the model to use the Stateflow and Simulink software to model discrete-event reactive behavior and continuous time behavior, with a low-order plant model.
- Set up the model with a more detailed plant model that includes power effects in the electrical and mechanical domains. The plant model validates the force exerted by the window on a trapped object.
- Set up the model with a model that includes other effects that may change the model, such as quantization of the measurements.

---

**Note** These scripts also simulate the model. To only configure the model, see the scripts in the **configureModel** folder.

---

- Use the increase coverage model to generate the model coverage report.
- 3** The **Project Shortcuts** section contains quick-access commands that you can double-click to perform common tasks such as:
- Add projects to MATLAB paths.
  - Perform interactive testing.
  - Validate model testing with model coverage.
  - Open the main model.
  - Simulate the model with various configurations.
  - Generate a model coverage report for increased coverage of the model.
  - Open the model used for increasing model coverage.

## Simulink Power Window Controller

- “Implementation of Activity Diagram: Power Window Control” on page 24-11
- “Interactive Testing” on page 24-13
- “Experimental Results from Interactive Testing” on page 24-14
- “Model Coverage” on page 24-22

### Implementation of Activity Diagram: Power Window Control

This topic describes the high-level discrete-event control specification for a power window control.

You can model the discrete-event control of the window with a Stateflow chart. A Stateflow chart is a finite state machine with hierarchy and parallelism. This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency. It models the state transitions and accounts for the precedence of driver commands over the passenger commands. It also includes emergency behavior that activates when the software detects an object between the window and the frame while moving up.

The initial Simulink model for the power window control, `slexPowerWindowControl`, is a discrete-event controller that runs at a given sample rate.

In this implementation, open the power window control subsystem and observe that the Stateflow chart with the discrete-event control forms the CSPEC, represented by the tilted thick bar in the bottom right corner. The `detect_obstacle_endstop` subsystem encapsulate the threshold detection mechanisms.

The discrete-event control is a Stateflow model that extends the state transition diagram notion with hierarchy and parallelism. State changes because of passenger commands are encapsulated in a *super state* that does not correspond to an active driver command.

Consider the control of the passenger window. The passenger or driver can move this window up and down.

This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency.

## Interactive Testing

### Control Input

The `slexPowerWindowCntlInteract` model includes this control input as switches. Double-click these switches to manually operate them.

Test the state machine that controls a power window by running the input test vectors and checking that it reaches the desired internal state and generates output. The power window has the following external inputs:

- Passenger input
- Driver input
- Window up or down
- Obstacle in window

Each input consists of a vector with these inputs.

**Passenger Input**

Element	Description
neutral	Passenger control switch is not depressed.
up	Passenger control switch generates the up signal.
down	Passenger control switch generates the down signal.

**Driver Input**

Element	Description
neutral	Driver control switch is not depressed.
up	Driver control switch generates the up signal.
down	Driver control switch generates the down signal.

**Window Up or Down**

Element	Description
0	Window moves freely between top or bottom.
1	Window is stuck at the top or bottom because of physical limitations.

**Obstacle in Window**

Element	Description
0	Window moves freely between top or bottom.
1	Window has obstacle in the frame.

Generate the passenger and driver input signals by mapping the up and down signals according to this table:

Inputs		Outputs		
up	down	up	down	neutral
0	0	0	0	1
0	1	0	1	0
1	0	1	0	0
1	1	0	0	1

The inputs explicitly generate the `neutral` event from the `up` and `down` events, generated by pressing a power window control switch. The inputs are entered as a truth table in the passenger `neutral, up, down` map and the driver `neutral, up, down` map.

**Experimental Results from Interactive Testing****Case 1: Window Up**

To observe the state machine behavior:

- 1 Open the `slexPowerWindowCntlInteract` model.

- Run the simulation and then double-click the passenger up switch.

If you press the physical window switch for more than one second, the window moves up until the up switch is released (or the top of the window frame is reached and the endstop event is generated).

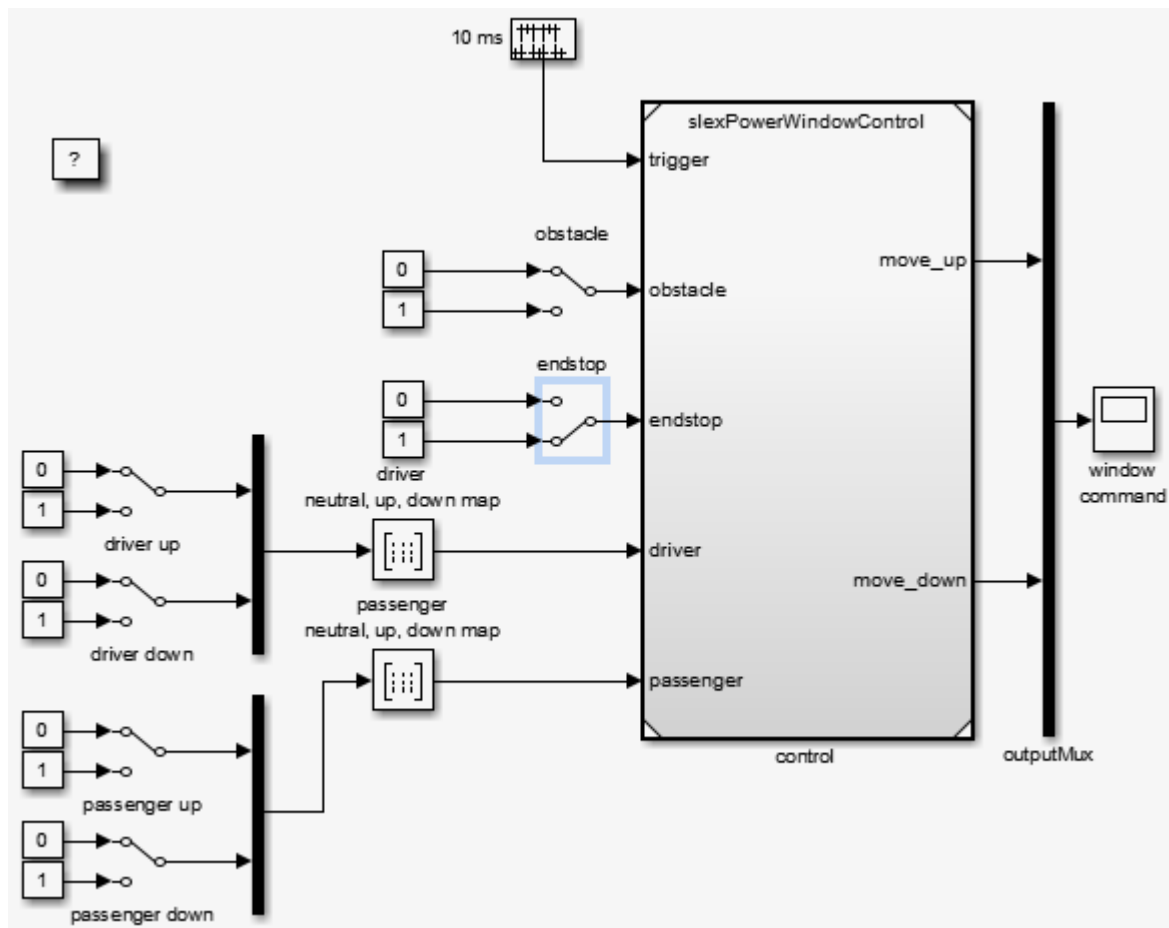

- Double-click the selected passenger up switch to release it.

4 Simulate the model.

Setting the endstop switch generates the endstop event.

### Case 2: Window Auto-Up

If you press the physical passenger window up switch for a short period of time (less than a second), the software activates auto-up behavior and the window continues to move up.

- 1 Press the physical passenger window up switch for a short period of time (less than a second).

Ultimately, the window reaches the top of the frame and the software generates the endstop event. This event moves the state machine back to its neutral state.

2 Simulate the model.

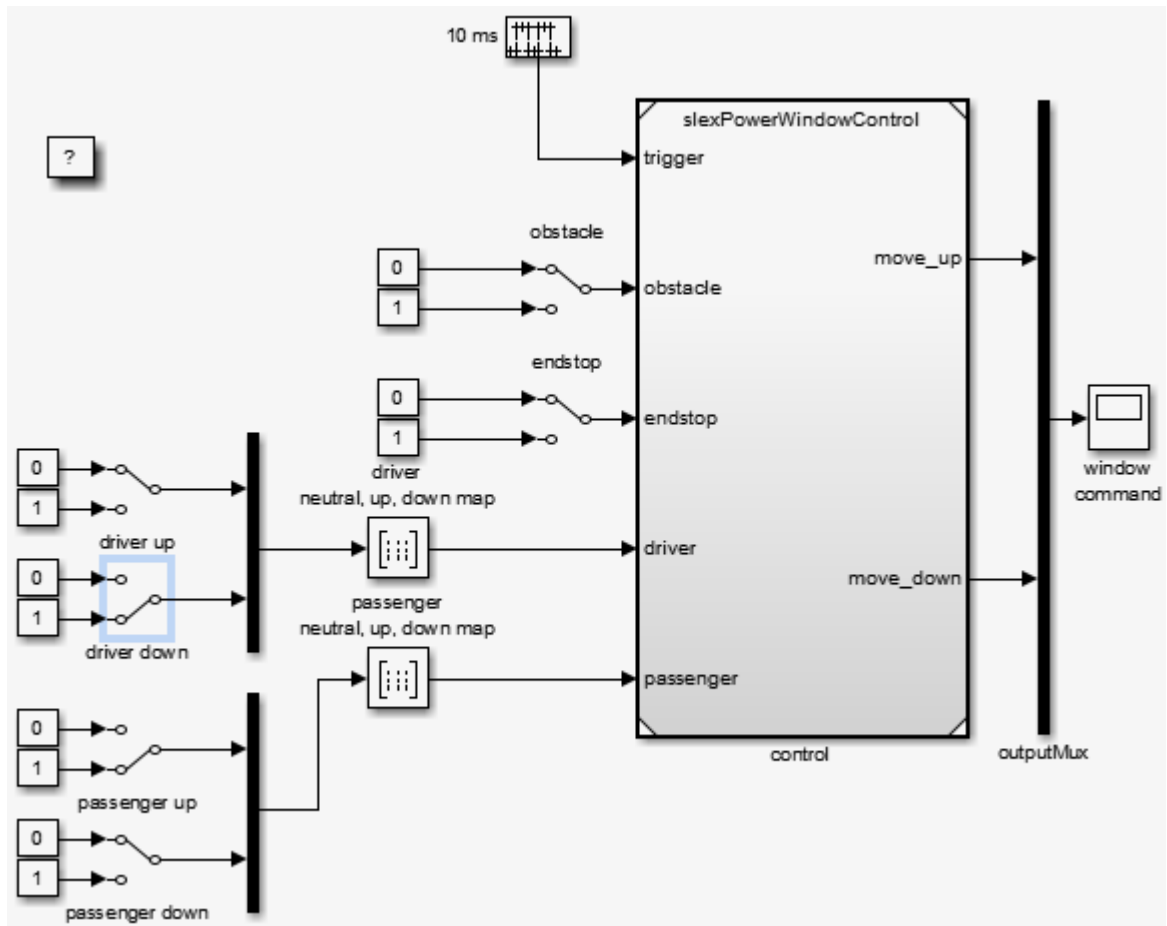

**Case 3: Driver-Side Precedence**

The driver switch for the passenger window takes precedence over the driver commands. To observe the state machine behavior in this case:

- 1 Run the simulation, and then move the system to the `passenger up` state by double-clicking the passenger window up switch.

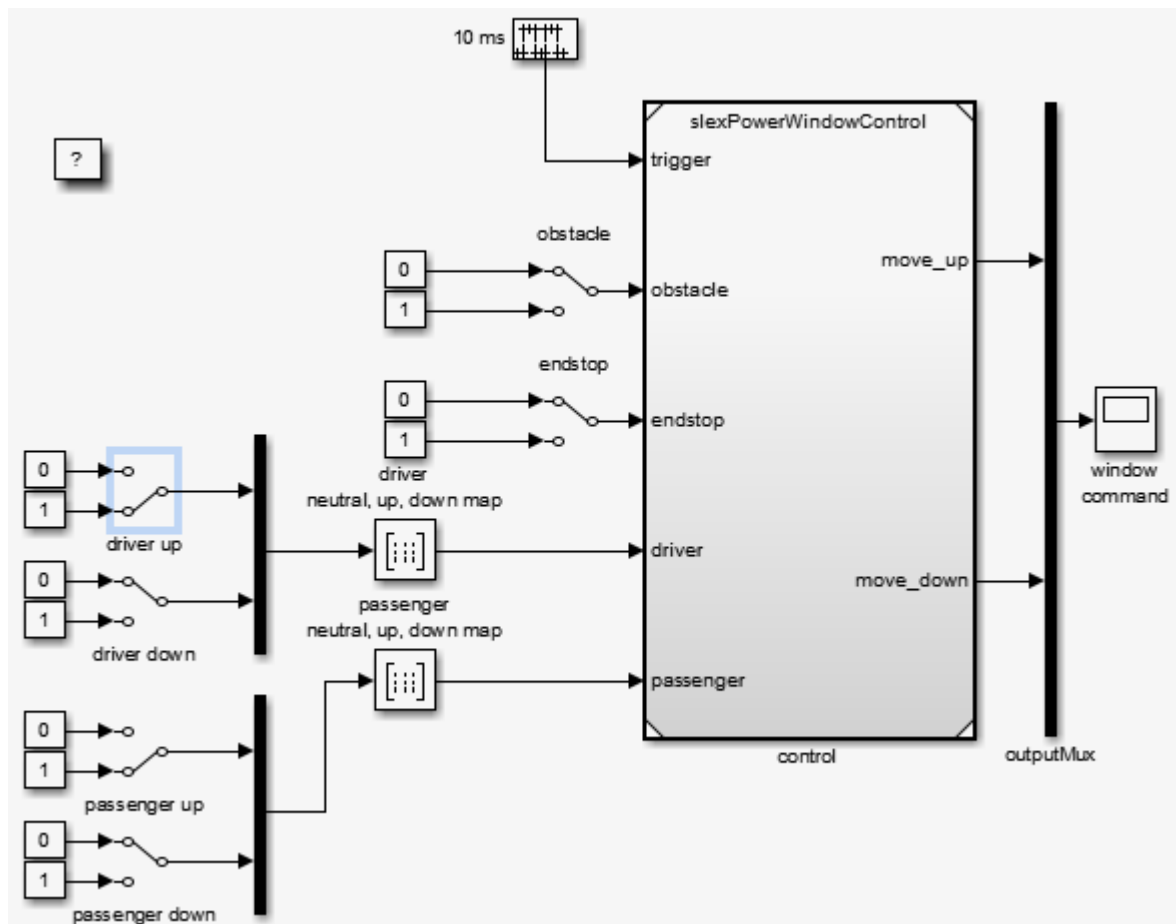

2 Double-click the driver down switch.

- 3 Simulate the model.
- 4 Notice how the state machine moves to the driver control part to generate the window down output instead of the window up output.
- 5 Double-click the driver control to driver up. Double-click the driver down switch.

The driver window up state is reached, which generates the window up output again, i.e.,  $windowUp = 1$ .

- 6 To observe state behavior when an object is between the window and the frame, double-click the obstacle switch.

## 7 Simulate the model.

On the next sample time, the state machine moves to its `emergencyDown` state to lower the window a few inches. How far the software lowers the window depends on how long the state machine is in the `emergencyDown` state. This behavior is part of the next analysis phase.

If a driver or passenger window switch is still active, the state machine moves into the up or down states upon the next sample time after leaving the emergency state. If the obstacle switch is also still active, the software again activates the emergency state at the next sample time.

## Model Coverage

### Validation of the Control Subsystem

Validate the discrete-event control of the window using the model coverage tool. This tool helps you determine the extent to which a model test case exercises the conditional branches of the controller. It helps evaluate whether all transitions in the discrete-event control are taken, given the test case, and whether all clauses in a condition that enables a particular transition have become true. Multiple clauses can enable one transition, e.g., the transition from emergency back to neutral occurs when either 100 ticks have occurred or if the endstop is reached.

To achieve full coverage, each clause evaluates to true and false for the test cases used. The percentage of transitions that a test case exercises is called its model coverage. Model coverage is a measure of how thoroughly a test exercises a model.

Using Simulink Coverage software, you can apply the following test to the power window controller.

Position	Step						
	0	1	2	3	4	5	6
Passenger up	0	0	0	0	0	0	0
Passenger down	0	0	0	1	0	1	1
Driver up	0	0	1	0	1	0	1
Driver down	0	1	0	0	1	1	0

With this test, all switches are inactive at time 0. At regular 1 s steps, the state of one or more switches changes. For example, after 1 s, the driver down switch becomes active. To automatically run these input vectors, replace the manual switches by prescribed sequences of input. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverage
```

- 2 Simulate the model to generate the Simulink Coverage coverage report.

For the `sllexPowerWindowCntlCoverage` model, the report reveals that this test handles 100% of the decision outcomes from the driver neutral, up, down map block. However, the test achieves only 50% coverage for the passenger neutral, up, down map block. This coverage means the overall

coverage for `slexPowerWindowCntlCoverage` is 45% while the overall coverage for the `slexPowerWindowControl` model is 42%. A few of the contributing factors for the coverage levels are:

- Passenger up block does not change.
- Endstop and obstacle blocks do not change.

### Increase Model Coverage

To increase total coverage to 100%, you need to take into account all possible combinations of driver, passenger, obstacle, and endstop settings. When you are satisfied with the control behavior, you can create the power window system. For more information, see “Create Model Using Model-Based Design” on page 24-26.

This example increases the model coverage for the validation of the discrete-event control of the window. To start, the example uses inputs from `slexPowerWindowCntlCoverage` as a baseline for the model coverage. Next, to further exercise the discrete-event control of the window, it creates more input sets. The spreadsheet file, `inputCntlCoverageIncrease.xlsx`, contains these input sets using one input set per sheet.

In the example, the `slexPowerWindowSpreadsheetGeneration` utility function, which creates a spreadsheet template from the controller model, `slexPowerWindowControl`, creates the `inputCntlCoverageIncrease.xlsx`. In `inputCntlCoverageIncrease.xlsx`, the function uses the block names in the controller model as signal names. `slexPowerWindowSpreadsheetGeneration` defines the sheet names. The `slexWindowSpreadsheetAddInput` utility function populates `inputCntlCoverageIncrease.xlsx` with signal data.

The sheet names of these input sets and their descriptions are:

Sheet Name	Description
Logged	Inputs logged from <code>slexPowerWindowCntlCoverage</code>
LoggedObstacleOffEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with ability to hit endstop
LoggedObstacleOnEndStopOff	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window
LoggedObstacleOnEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window and ability to hit endstop
DriverLoggedPassengerNeutral	Inputs logged from <code>slexPowerWindowCntlCoverage</code> for driver only and passenger takes no action
DriverDownPassengerNeutral	Driver is putting down window and passenger takes no action
DriverUpPassengerNeutral	Driver is putting up window and passenger takes no action
DriverAutoDownPassengerNeutral	Driver is putting down window for one second (auto-down) and passenger takes no action
DriverAutoUpPassengerNeutral	Driver is putting up window for one second (auto-up) and passenger takes no action
PassengerAutoDownDriverNeutral	Passenger is putting down window for one second (auto-down) and driver takes no action

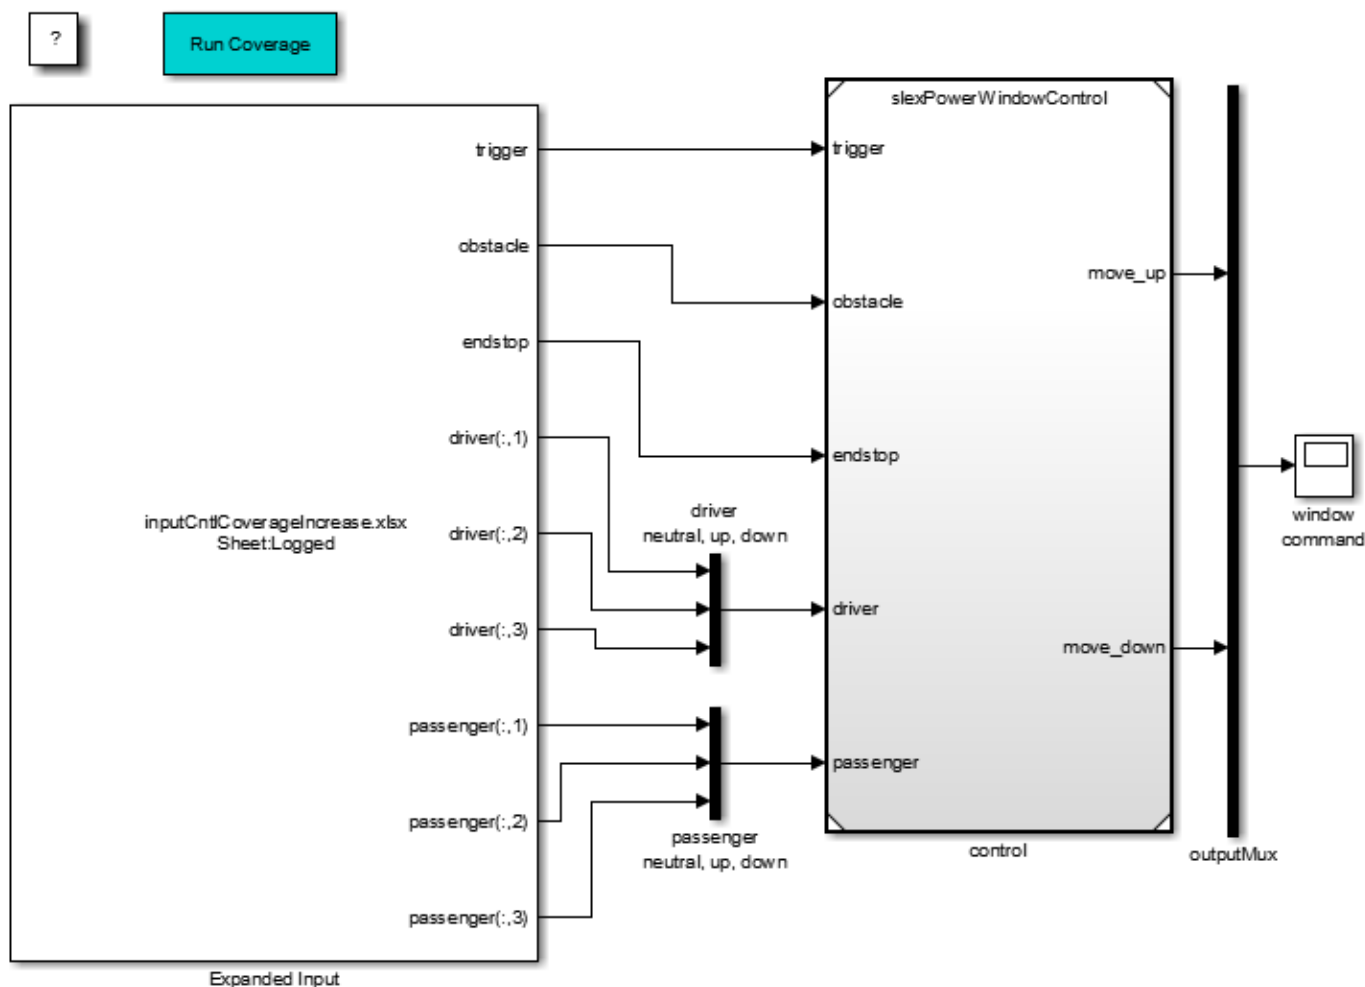

Sheet Name	Description
PassengerAutoUpDriverNeutral	Passenger is putting up window for one second (auto-up) and driver takes no action

To automatically run these input vectors, replace the inputs to the discrete-event control with the From Spreadsheet block using the file, `inputCntlCoverageIncrease.xlsx`. This file contains the multiple input sets. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverageIncrease
```

- 2 To generate the Simulink Coverage coverage report for multiple input set, double click the Run Coverage subsystem in the model.

For the `slexPowerWindowCntlCoverageIncrease` model, the report reveals that using multiple input sets has successfully raised the overall coverage for the `slexPowerWindowControl` model from 42% to 78%. Coverage levels are less than 100% because of missing input sets for:

- Passenger up state

- Driver up and down states
- Passenger automatic down and automatic up states

## **Create Model Using Model-Based Design**

- “Why Use Model-Based Design?” on page 24-26

- “Communication Protocols” on page 24-41

### **Why Use Model-Based Design?**

In Model-Based Design, a system model is at the center of the development process, from requirements development, through design implementation, and testing. Use Model-Based Design to:

- Use a common design environment across project teams.
- Link designs directly to requirements.
- Integrate testing with design to continuously identify and correct errors.
- Refine algorithms through multidomain simulation.
- Automatically generate embedded software code.
- Develop and reuse test suites.
- Automatically generate documentation for the model.
- Reuse designs to deploy systems across multiple processors and hardware targets.

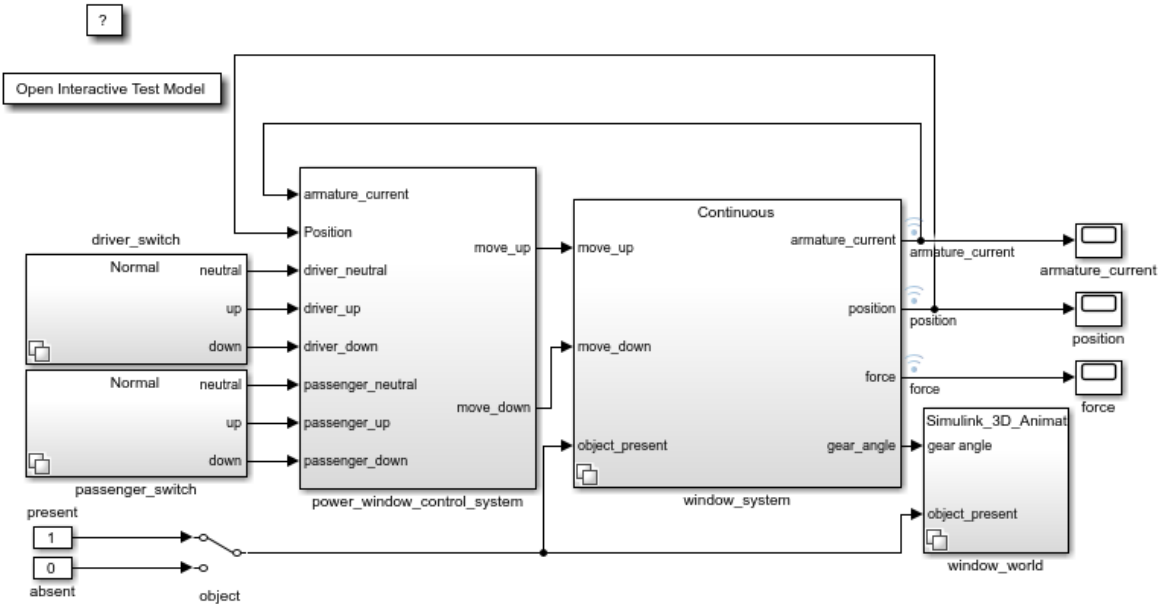

### **Implementation of Context Diagram: Power Window System**

For requirements presented as a context diagram, see “Context Diagram: Power Window System” on page 24-4.

Create a Simulink model to resemble the context diagram.

- 1** Place the plant behavior into one subsystem.
- 2** Create two subsystems that contain the driver and passenger switches.
- 3** Add a control mechanism to conveniently switch between the presence and absence of the object.
- 4** Put the control in one subsystem.
- 5** Connect the new subsystems.
- 6** To see an implementation of this model, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```

You can use the power window control activity diagram (“Activity Diagram: Power Window Control” on page 24-4) to decompose the power window controller of the context diagram into parts. This diagram shows the input and output signals present in the context diagram for easier tracing to their origins.

**Implement Power Window Control System**

To satisfy full requirements, the power window control must work with the validation of the driver and passenger inputs and detect the endstop.

For requirements presented as an activity diagram, see “Activity Diagram: Power Window Control” on page 24-4.

Double-click the `slexPowerWindowExample/power_window_control_system` block to open the following subsystem:

### Implementation of Activity Diagram: Validate

For requirements presented as activity diagrams, see “Activity Diagram: Validate Driver” on page 24-5 and “Activity Diagram: Validate Passenger” on page 24-6.

The activity diagram adds data validation functionality for the driver and passenger commands to ensure correct operation. For example, when the window reaches the top, the software blocks the up command. The implementation decomposes each validation process in new subsystems. Consider the validation of the driver commands (validation of the passenger commands is similar). Check if the model can execute the up or down commands, according to the following:

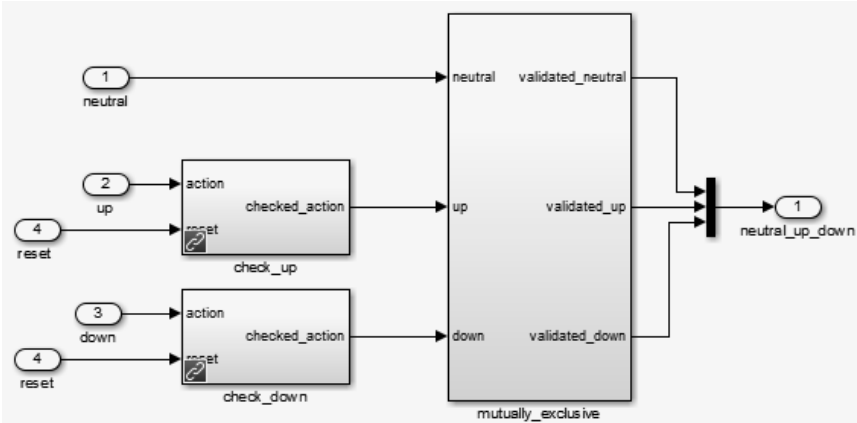

- The model allows the down command only when the window is not completely opened.
- The model allows the up command only when the window is not completely closed and no object is detected.

The third activity diagram process checks that the software sends only one of the three commands (`neutral`, `up`, `down`) to the controller. In an actual implementation, both up and down can be simultaneously true (for example, because of switch bouncing effects).

From the `power_window_control_system` subsystem, this is the `validate_driver_state` subsystem:

From the power\_window\_control\_system subsystem, this is the validate\_passenger\_state subsystem:

### Implementation of Activity Diagram: Detect Obstacle Endstop

For requirements presented as an activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 24-7.

In the slxPowerWindowExample model, the power\_window\_control\_system/detect\_obstacle\_endstop block implements this activity diagram in the continuous variant of the Variant Subsystem block. During design iterations, you can add additional variants.

Double-click the slxPowerWindowExample model power\_window\_control\_system/detect\_obstacle\_endstop/Continuous/verify\_position block:

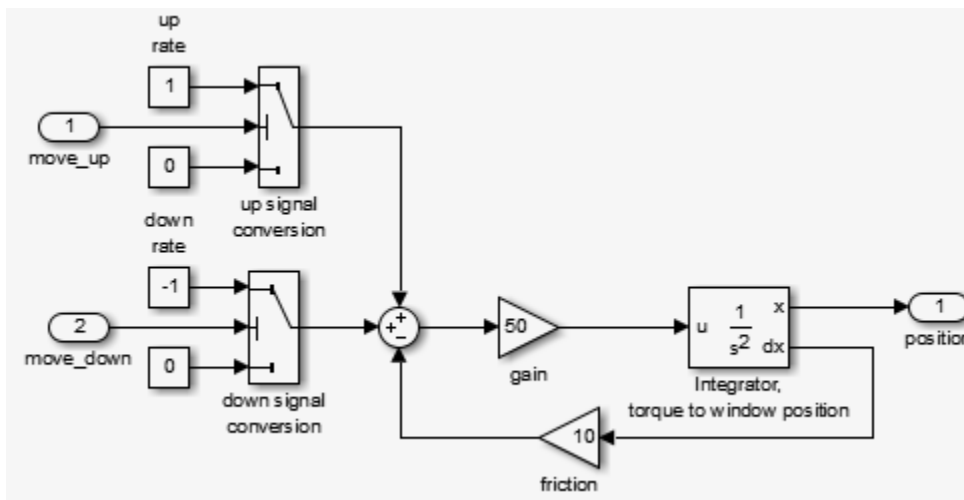

### Hybrid Dynamic System: Combine Discrete-Event Control and Continuous Plant

After you have designed and verified the discrete-event control, integrate it with the continuous-time plant behavior. This step is the first iteration of the design with the simplest version of the plant.

In the project, navigate to **Files** and click **Project**. In the **configureModel** folder, run the `slexPowerWindowContinuous` utility to open and initialize the model.

The `window_system` block uses the Variant Subsystem block to allow for varying levels of fidelity in the plant modeling. Double-click the `window_system/Continuous/2nd_order_window_system` block to see the continuous variant.

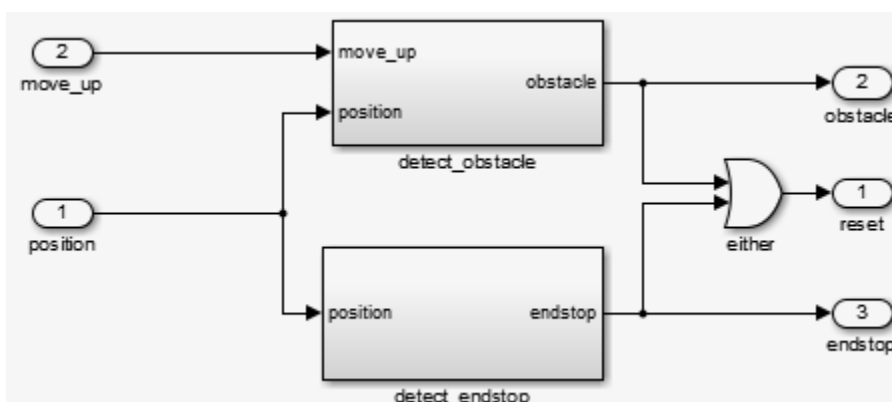

The plant is modeled as a second-order differential equation with step-wise changes in its input:

- When the Stateflow chart generates `windowUp`, the input is 1.
- When the Stateflow chart generates `windowDown`, the input is -1.
- Otherwise, the input is 0.

This phase allows analysis of the interaction between the discrete-event state behavior, its sample rate, and the continuous behavior of the window movement. There are threshold values to generate the window frame top and bottom:

- `endStop`
- Event when an obstacle is present, that is, `obstacle`
- Other events

Double-click the `slexPowerWindowExample` model `power_window_control_system/-detect_obstacle_endstop/Continuous/verify_position` block to see the continuous variant.

When you run the `slexPowerWindowContinuous` `configureModel` utility, the model uses the continuous time solver `ode23` (Bogacki-Shampine).

A structure analysis of a system results in:

- A functional decomposition of the system
- Data definitions with the specifics of the system signals
- Timing constraints

A structure analysis can also include the implementation architecture (outside the scope of this discussion).

The implementation also adds a control mechanism to conveniently switch between the presence and absence of the object.

**Expected Controller Response**

To view the window movement, in **Project Shortcuts**, double-click SimHybridPlantLowOrder. Alternatively, you can run the task `slexPowerWindowContinuousSim`.

The position scope shows the expected result from the controller. After 30 cm, the model generates the `obstacle` event and the Stateflow chart moves into its `emergencyDown` state. In this state, `windowDown` is output until the window lowers by about 10 cm. Because the passenger window up switch is still on, the window starts moving up again and this process repeats. Stop the simulation and open the position scope to observe the oscillating process. In case of an emergency, the discrete-event control rolls down the window approximately 10 cm.

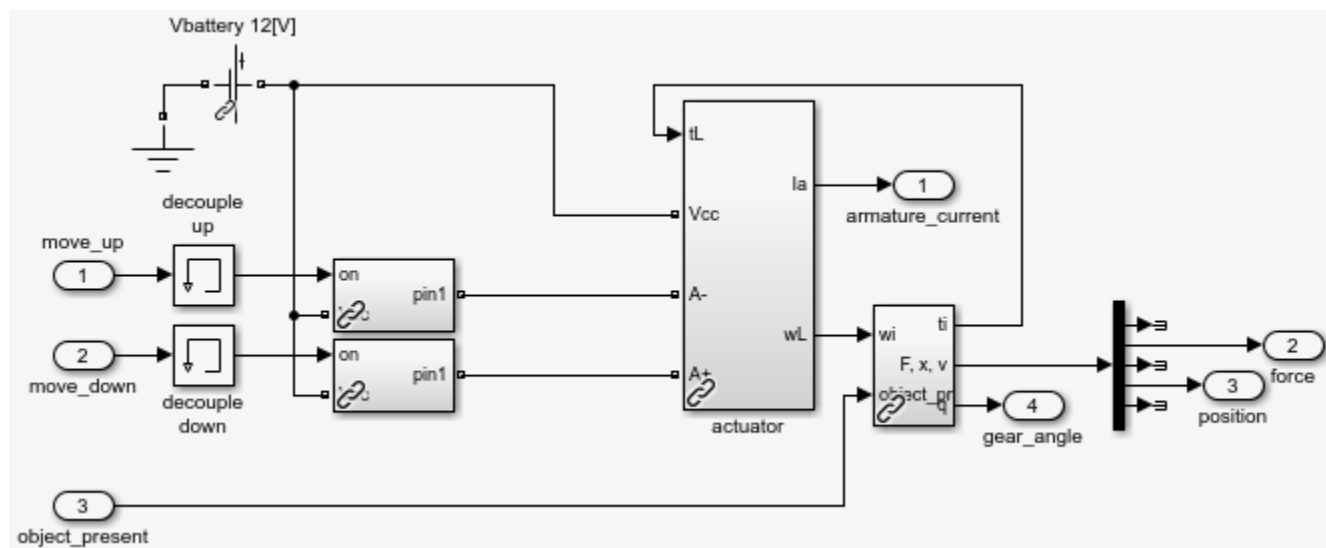

### Detailed Modeling of Power Effects

After an initial analysis of the discrete-event control and continuous dynamics, you can use a detailed plant model to evaluate performance in a more realistic situation. It is best to design models at such a level of detail in the power domain, in other words, as energy flows. Several domain-specific MathWorks blocksets can help with this.

To take into account energy flows, add a more detailed variant consisting of power electronics and a multibody system to the `window_system` variant subsystem.

To open the model and explore the more detailed plant variant, in the project, run `configureModel slexPowerWindowPowerEffects`.

Double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system` block.

### Power Electronics Subsystem

The model must amplify the control signals generated by the discrete-event controller to be powerful enough to drive the DC motor that moves the window.

The amplification modules model this behavior. They show that a switch either connects the DC motor to the battery voltage or ground. By connecting the battery in reverse, the system generates a negative voltage and the window can move up, down, or remain still. The window is always driven at maximum power. In other words, no DC motor controller applies a prescribed velocity.

To see the implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/amplification_up` block.

**Multibody System**

This implementation models the window using Simscape Multibody blocks.

To see the actuator implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/actuator` block.

To see the window implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant` block.

This implementation uses Simscape Multibody blocks for bodies, joints, and actuators. The window model consists of:

- A worm gear
- A lever to move the window holder in the vertical direction

The figure shows how the mechanical parts move.

### Iterate on the Design

An important effect of the more detailed implementation is that there is no window position measurement available. Instead, the model measures the DC motor current and uses it to detect the endstops and to see if an obstacle is present. The next stage of the system design analyzes the control to make sure that it does not cause excessive force when an obstacle is present.

In the original system, the design removes the obstacle and endstop detection based on the window position and replaces it with a current-based implementation. It also connects the process to the controller and position and force measurements. To reflect the different signals used, you must modify the data definition. In addition, observe that, because of power effects, the units are now amps.

PSPEC 1.3.1: DETECT ENDSTOP  
 $ENDSTOP = ARMATURE\_CURRENT > ENDSTOP\_MAX$

PSPEC 1.3.2: DETECT OBSTACLE  
 $OBSTACLE = (ARMATURE\_CURRENT > OBSTACLE\_MAX) \text{ and } MOVE\_UP \text{ for } 500 \text{ ms}$

PSPEC 1.3.3: ABSOLUTE VALUE  
 $ABSOLUTE\_ARMATURE\_CURRENT = abs(ARMATURE\_CURRENT)$

This table lists the additional signal for the Context Diagram: Power Window System data definitions.

### Context Diagram: Power Window System Data Definition Changes

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ARMATURE_CURRENT	Data	Continuous	Real	-20 to 20 A

This table lists the changed signals for the Activity Diagram: Detect Obstacle Endstop data definitions.

**Activity Diagram: Detect Obstacle Endstop Data Definition Changes**

Signal	Information Type	Continuous/ Constant	Data Type	Values
ABSOLUTE_ARMATURE_CURRENT	Data	Continuous	Real	0 to 20 A
ENDSTOP_MAX	Data	Constant	Real	15 A
OBSTACLE_MAX	Data	Constant	Real	2.5 A

To see the window subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window` block.

The implementation uses a lookup table and adds noise to allow evaluation of the control robustness. To see the implementation of the friction subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window/friction` block.

### Control Law Evaluation

The idealized continuous plant allows access to the window position for `endStop` and `obstacle` event generation. In the more realistic implementation, the model must generate these events from accessible physical variables. For power window systems, this physical variable is typically the armature current,  $I_a$ , of the DC motor that drives the worm gear.

When the window is moving, this current has an approximate value of 2 A. When you switch the window on, the model draws a transient current that can reach a value of approximately 10 A. When the current exceeds 15 A, the model activates endstop detection. The model draws this current when the angular velocity of the motor is kept at almost 0 despite a positive or negative input voltage.

Detecting the presence of an object is more difficult in this setup. Because safety concerns restrict the window force to no more than 100 N, an armature current much less than 10 A should detect an object. However, this behavior conflicts with the transient values achieved during normal operation.

Implement a control law that disables object detection during achieved transient values. Now, when the system detects an armature current more than 2 A, it considers an object to be present and enters the `emergencyDown` state of the discrete-event control. Open the force scope window (measurements are in newtons) to check that the force exerted remains less than 100 N when an object is present and the window reverses its velocity.

In reality, far more sophisticated control laws are possible and implemented. For example, you can implement neural-network-based learning feedforward control techniques to emulate the friction characteristic of each individual vehicle and changes over time.

### Visualization of the System in Motion

If you have Simulink 3D Animation software installed, you can view the geometrics of the system in motion via a virtual reality world. If the VR Sink block is not yet open, in the `slexPowerWindowExample/window_world/Simulink_3D_Animation` View model, double-click the VR Sink block.

To simulate the model with a stiff solver:

- 1 In a project, run the task, `slexPowerWindowPowerEffectsSim`. This batch job sets the solver to `ode23tb` (stiff/TR-BDF2).
- 2 In the `slexPowerWindowExample` model `passenger_switch/Normal` block, set the passenger up switch to on.
- 3 In the `slexPowerWindowExample` model `driver_switch/Normal` block, set the driver up switch to off.
- 4 Simulate the model.
- 5 Between 10 ms and 1 s in simulation time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block passenger up switch to initiate the auto-up behavior.

- 6 Observe how the window holder starts to move vertically to close the window. When the model encounters the object, it rolls the window down.
- 7 Double-click the `slexPowerWindowExample` model `passenger_switch/Normal` block driver down switch to roll down the window completely and then simulate the model. In this block, at less than one second simulation time, switch off the driver down switch to initiate the auto-down behavior.

- 8 When the window reaches the bottom of the frame, stop the simulation.
- 9 Look at the position measurement (in meters) and at the armature current ( $I_a$ ) measurement (in amps).

---

**Note** The absolute value of the armature current transient during normal behavior does not exceed 10 A. The model detects the obstacle when the absolute value of the armature current required to move the window up exceeds 2.5 A (in fact, it is less than -2.5 A). During normal operation, this is about 2 A. You might have to zoom into the scope to see this measurement. The model detects the window endstop when the absolute value of the armature current exceeds 15 A.

---

Variation in the armature current during normal operation is due to friction that is included by sensing joint velocities and positions and applying window specific coefficients.

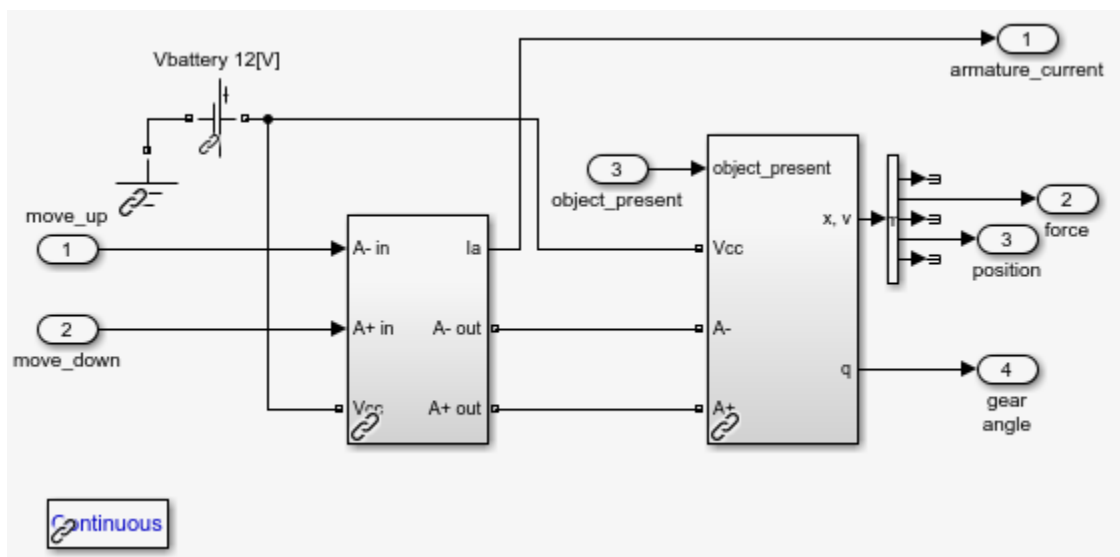

### Realistic Armature Measurement

The armature current as used in the power window control is an ideal value that is accessible because of the use of an actuator model. In a more realistic situation, data acquisition components must measure this current value.

To include data acquisition components, add the more realistic measurement variant to the window\_system variant subsystem. This realistic measurement variant contains a signal conditioning block in which the current is derived based on a voltage measurement.

To open a model and configure the realistic measurement, in the project, run the configureModel task `slexPowerWindowRealisticArmature`.

To view the contents of the Realistic Armature - Communications Protocol block, double-click the `SlexPowerWindowExample` model `window_system/Realistic Armature - Communications Protocol/detailed_window_system_with_DAQ`.

The measurement voltage is within the range of an analog-to-digital converter (ADC) that discretizes based on a given number of bits. You must scale the resulting value based on the value of the resistor and the range of the ADC.

Include these operations as fixed-point computations. To achieve the necessary resolution with the given range, 16 bits are required instead of 8.

Study the same scenario:

- 1 In the `slexPowerWindowExample/passenger_switch/Normal` block, set the passenger up switch.
- 2 Run the simulation.
- 3 After some time, in the `slexPowerWindowExample/passenger_switch/Normal` block, switch off the passenger up switch.
- 4 When the window has been rolled down, click the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.

- 5 After some time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.
- 6 When the window reaches the bottom of the frame, stop the simulation.
- 7 Zoom into the `armature_current` scope window and notice the discretized appearance.

### Communication Protocols

Similar to the power window output control, hardware must generate the input events. In this case, the hardware is the window control switches in the door and center control panels. Local processors generate these events and then communicate them to the window controller via a CAN bus.

To include these events, add a variant containing input from a CAN bus and switch components that generate the events delivered on the CAN bus to the driver switch and passenger switch variant subsystems. To open the model and configure the CAN communication protocols, run the `configureModel` task, `slexPowerWindowCommunicationProtocolSim`.

To see the implementation of the switch subsystem, double-click the `slexPowerWindowExample/driver_switch/Communication Protocol/driver window control switch` block.

Observe a structure that is very similar to the window control system. This structure contains a:

- Plant model that represents the control switch
- Data acquisition subsystem that includes, among other things, signal conditioning components
- Control module to map the commands from the physical switch to logical commands
- CAN module to post the events to the vehicle data bus

You can add communication effects, such as other systems using the CAN bus, and more realism similar to the described phases. Each phase allows analysis of the discrete-event controller in an increasingly realistic situation. When you have enough detail, you can automatically generate controller code for any specific target platform.

### Automatic Code Generation for Control Subsystem

You can generate code for the designed control model, `slexPowerWindowExample`.

- 1 Display the sample rates of the controller. In the Simulink Editor, on the **Debug** tab, select **Information Overlays > Sample Time > Colors**. Observe that the controller runs at a uniform sample rate.

- 2 Right-click the power\_window\_control\_system block and select **C/C++ Code > Build This Subsystem**.

## What are Partitions?

Partitions are components of a model that execute independently as atomic tasks. In multi-tasking models, partitions are created from model components. Periodic partitions are scheduled as a function of sample times in a model. In export-function models, the root function-call inputs are defined as partitions. These partitions have a schedule associated with it, which tells order in which the partitions execute.

With partitions, you can separate parts of the model which you can explicitly control. You can think of periodic partitions as components that run at specific rates in a model. Aperiodic partitions are components that run at specified hit times. The schedule of these partitions have an impact on simulation and code generation.

The Schedule Editor enables you to partition the model and interact with those partitions. The Schedule Editor shows partitions, the connections between them, and the ordering of the partitions

There are three types of partitions:

Types of Partitions	Image	Description
Implicit		Automatically created by Simulink. Blocks running at the base rate show up as an implicit partition.
Periodic		User-defined partitions from the atomic subsystems and/or Model blocks. Periodic partitions can also be defined by export-functions. These partitions execute based on their sample time and thus their execution is periodic.
Aperiodic		Aperiodic partitions are partitions which have no constraints and can be made to execute at any time. Specify the hit times in the <b>Property Inspector</b> of the Schedule Editor, at which you want to run the aperiodic partition. You can also use events in the Schedule Editor to schedule execution of the aperiodic partitions.

The blocks running at the base rate in the model is shown as an implicit partition in the Schedule Editor. The base rate is the fastest discrete rate in the model. *D1* denotes the base rate. *D1* annotation also appears in the Timing Legend. The *D1* partition or implicit partition always remains the first discrete partition in the order.

The default partitions that are already present in the model are also implicit partitions.

The partition colors match their rate.

## Create Partitions

### Partitioning a Model

Partitions are components of a model that execute independently as atomic tasks. In multi-tasking models, partitions are created from model components. Periodic partitions are scheduled as a function of sample times in a model. In export-function models, the root function-call inputs are defined as partitions. These partitions have a schedule associated with them, which tells what order the partitions execute.

With partitions, you can separate parts of the model which you can explicitly control. You can think of periodic partitions as components that run at specific rates in a model. Aperiodic partitions are components that run at specified hit times or specified events. The schedule of these partitions have an impact on simulation and code generation.

The Schedule Editor enables you to partition the model and interact with those partitions. The Schedule Editor shows partitions, the connections between them, and the order of the partitions.

There are three types of partitions:

Types of Partitions	Image	Description
Implicit		Automatically created by Simulink. Blocks running at the base rate show up as an implicit partition.
Periodic		User-defined partitions from the atomic subsystems and/or Model blocks. Periodic partitions can also be defined by export-functions. These partitions execute based on their sample time and thus their execution is periodic.
Aperiodic		Aperiodic partitions are partitions which have no constraints and can be made to execute at any time. Specify the hit times in the <b>Property Inspector</b> of the Schedule Editor, at which you want to run the aperiodic partition. You can also use events in the Schedule Editor to schedule execution of the aperiodic partitions.

The blocks running at the base rate in the model is shown as an implicit partition in the Schedule Editor. The base rate is the fastest discrete rate in the model. *D1* denotes the base rate. *D1* annotation also appears in the Timing Legend. The *D1* partition or implicit partition always remains the first discrete partition in the order.

The default partitions that are already present in the model are also implicit partitions.

The partition colors match their rate.

## Create Partitions from a Rate-Based Model

Partitioning is enabled only on multitasking, fixed-step and variable-step solver models. To choose multitasking execution mode, in Solver selection on the **Solver** pane, select the **Type** to be **Fixed-step** or **Variable-step**. Select the **Treat each discrete rate as a separate task** check box on the **Solver** pane of the Configuration Parameters dialog box. For more information on multitasking execution mode, see “Time-Based Scheduling and Code Generation” (Embedded Coder).

As a best practice, enable the **Automatically handle rate transition for data transfer** setting in the **Solver** pane. When you check **Automatically handle rate transition for data transfer**, Simulink inserts Rate Transition blocks between blocks when rate transitions are detected. Simulink handles rate transitions for asynchronous and periodic tasks. Simulink adds the hidden blocks configured to ensure data integrity and determinism for data transfers. When you check **Treat each discrete rate as a separate task**, Simulink selects multitasking execution for models operating at different rates. It also specifies that groups of blocks with the same execution priority are processed through each stage of simulation (for example, calculating output and updating states) based on task priority.

To see default partitions in the Schedule Editor, open the Schedule Editor. On the **Modeling** tab, click

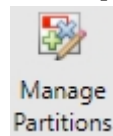

**Schedule Editor**. Update the diagram by clicking the  icon on the toolbar. The default partitions in the model are called implicit partitions. You can also create partitions in the model through an atomic subsystem or a model block.

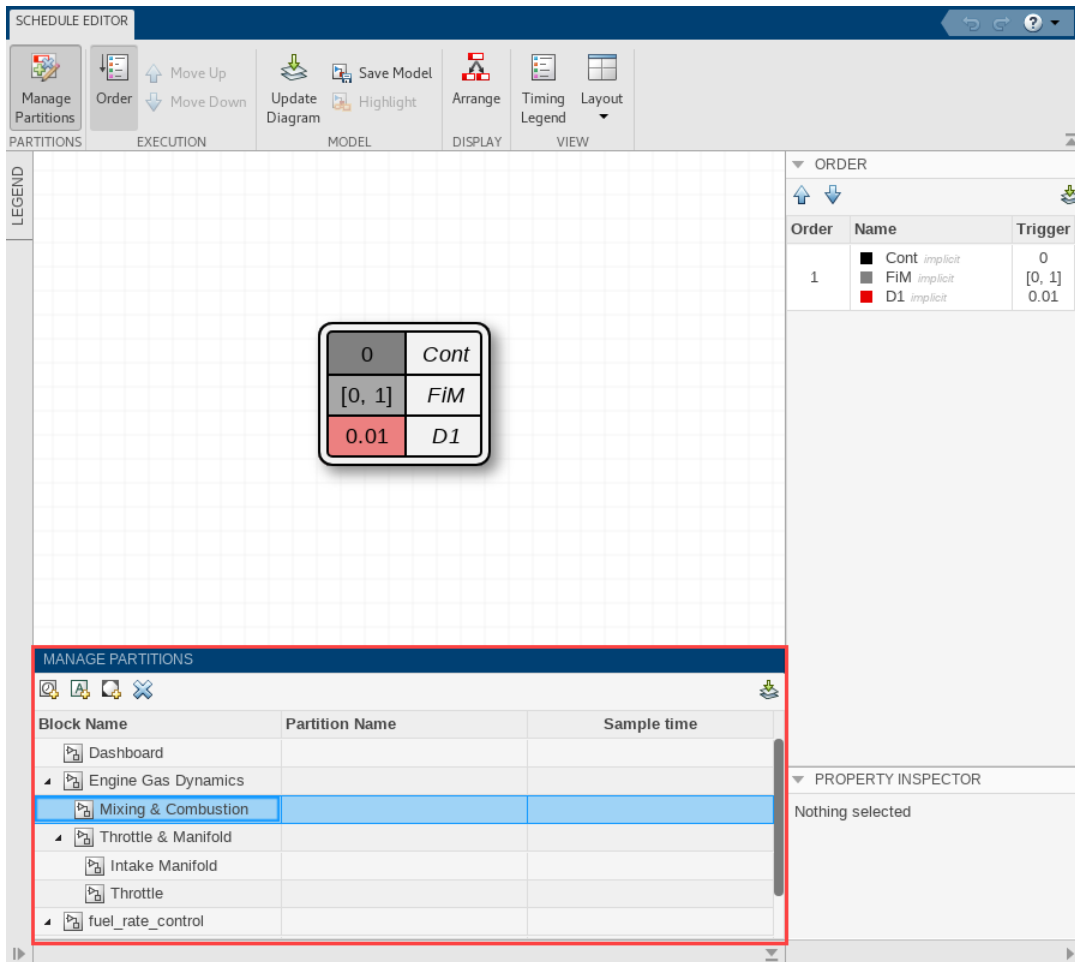

### Create Partitions Using Manage Partitions

In the Schedule Editor, use the **Manage Partitions** panel to create partitions. To open the **Manage**

**Partitions** panel, click **Manage Partitions**,  on the Schedule Editor toolbar. The changes made in **Manage Partitions** are applied to the model to create partitions after updating the diagram. **Manage Partitions** shows the model hierarchy with the Subsystem blocks and Model blocks which can be explicitly partitioned.

To create partitions from Subsystem blocks, select the subsystems and click the . To create partitions from Model blocks, select the Model blocks and click . Enter partition names in the column **Partition Name**, and sample times in the column **Sample Time**. Repeat the steps for all the subsystems and Model blocks in the model that you want to partition. Update the diagram to see the created partitions in the Schedule Editor. The partitions appear in the graph with their deduced data dependencies and order.

**Note** Creating partitions using the **Manage Partitions** panel makes changes to the subsystem or model block parameters.

The following example shows how to configure a model for partitioning and create partitions by using **Manage Partitions** panel in the Schedule Editor.

- 1 Open the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

- 2 Open the Schedule Editor.

Open the Schedule Editor On the **Modeling** tab, click **Schedule Editor**. To see the default partitions, click **Update Diagram** in the Schedule Editor. Two implicit partitions, created automatically by Simulink, are seen in the Schedule Editor.

- 3 Create partitions.

Open the **Manage Partitions** panel. In the panel, expand the `fuel_rate_control` subsystem.

Select the `airflow_calc` subsystem and click . To change the default partition name and sample time, click the default name and sample time.

To create a partition for the `fuel_calc` subsystem, select the `fuel_calc` subsystem and click .

The **Manage Partitions** panel gives you the default partition names and sample times.

Update the diagram to see the newly created partitions.

### Create Partitions from Atomic Subsystem Blocks

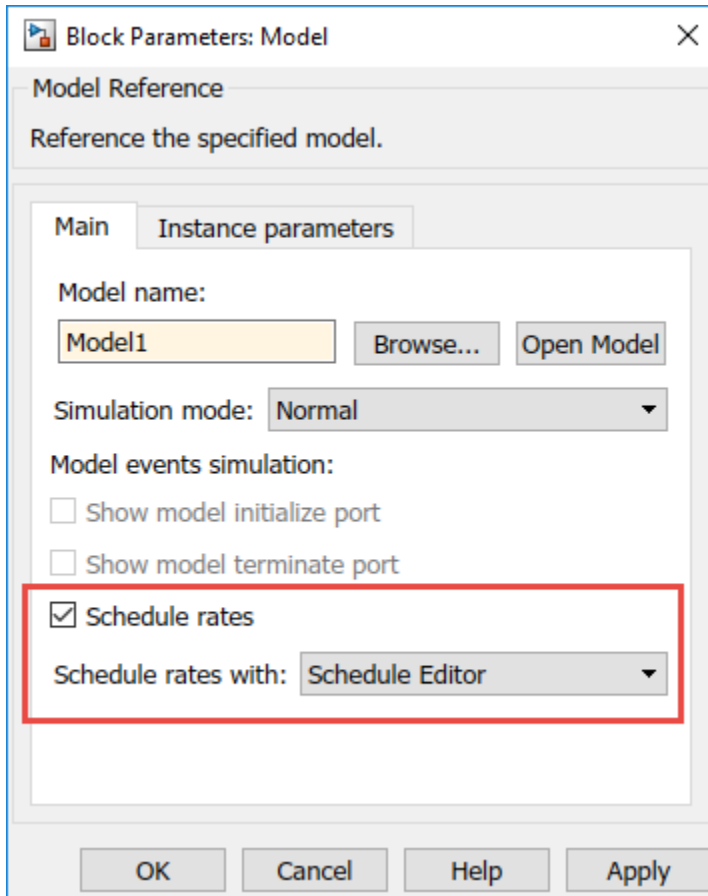

You can partition an atomic subsystem. An atomic subsystem is treated by Simulink as a unit when determining the execution order of block methods (partitioning is enabled only on multitasking, fixed-step and variable-step solver models). To create partitions from an atomic subsystem block, go to the Block Parameters dialog box. Select **Periodic partition** from the **Schedule as** drop-down. Give the partition a name and a discrete sample time and click OK. This creates an explicit partition for this block. To see this partition in the Schedule Editor, update the diagram. The partition appears in the graph and in the **Order** with the connections based on the signals in the model.

### Create Partitions from Model Blocks

To create partitions from a Model block, in the **Model events simulation**, select **Schedule rates** and **Schedule Editor** from the **Schedule rates with** drop-down. When you enable partitioning

from a referenced model, partitions are created from all the Model blocks present in the referenced model. These partitions are scoped by the model block name. To see this partition in the Schedule Editor, update the diagram. The partitions appear in the graph and in the **Order** column with the connections based on the design of your model.

## Export-Function Partitions

In export-function models, partitions are created from the function calls present in the model. To create partitions from the function calls in the export-function models, reference the export-function model in a top model. Schedule the Model block using the Schedule Editor through the block parameters. Partitions are then created from the function calls and their order is determined by the Schedule Editor.

- 1 Create an export-function model.
- 2 Add a Model block that references the export-function model.
- 3 Set the parameter to partition the export-function model.

Referencing an export-function model from a Model block allows you to partition the function calls without changing the model itself. To create the model for this example, see “Create an Export-Function Model” on page 10-71. Simulink functions in an export-functions model cannot be scheduled, and do not appear as partitions in the Schedule Editor.

- 1 Add a model block to a new Simulink model. In the **Model name** box, enter `export_function_model`. To enable the use of the Schedule Editor, configure the model to be multitasking. Open the Model Configuration Parameters. In **Solver selection** on the **Solver** pane, set the **Type** to **Fixed-step**. Check the **Treat each discrete rate as a separate task** and **Automatically handle rate transition for data transfer** parameters. Click **OK**. The model is enabled for partitioning.

---

**Note** Do not convert a subsystem into a model because it automatically creates Inport blocks.

---

- 2 Add Outport blocks to the **output\_100ms** and **output\_10ms** ports for saving simulation data to MATLAB. For this example, in the `export_function_model`, set the sample time of both the function calls to -1.
- 3 Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01.
- 4 To partition the function calls of the export-function model, in the Block Parameters of the model block, select **Schedule Editor** option from the **Schedule Rates with** drop-down menu.
- 5 Open the Schedule Editor and update the diagram to see the function calls as partitions.

The screenshot shows the Schedule Editor interface. The main workspace displays a flow diagram with three elements: a green arrow labeled 'A' pointing to 'Model.function\_call\_1', a red box containing '0.01' and 'D1', and a green arrow labeled 'A' pointing to 'Model.function\_call\_2'. An arrow points from the red box to the second call. The right sidebar contains an 'ORDER' table and a 'PROPERTY INSPECTOR' for the selected partition.

Order	Name	Trigger
1	D1 <i>implicit</i>	0.01
2	Model.function_call_1	[0:0.1:1]
3	Model.function_call_2	[0:0.01:

Partition	
Name	Model.function_call_1
Rate	A
Hit Times	[0:0.1:10]
Type	Explicit aperiodic partition

### Schedule Editor

## More About

- “Schedule the Partitions” on page 25-15
- “Generate Code from a Partitioned Model” on page 25-22

## Using the Schedule Editor

The Schedule Editor is a scheduling tool that represents the components in the model known as partitions, the data connections between them, and the order of those partitions.

Partitions are the components of the model that execute independently as tasks. The data connections between the partitions show the flow of the data between those partitions. The scheduling of these partitions is based on the rates and the events in the model. This schedule is shown in the **Order** table in the Schedule Editor.

Using the Schedule Editor you can:

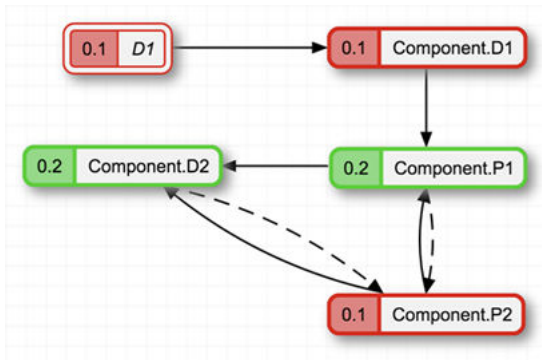

- Create partitions and specify their order
- Edit and analyze the schedule of the executable partitions without disturbing the structure of the model.
- Visualize how Simulink executes partitions

Changes made in the Schedule Editor affect both, simulation and code generation.

## Using the Schedule Editor

The Schedule Editor consists of two parts representing two different views of partitions in the model.

- A graph that shows the partitions and the data connections between them.

- A table that shows the order in which the partitions execute.

---

**Note** Aperiodic partitions are listed in the order of their priority.

---

ORDER		
Order	Name	Trigger
1	■ Cont <i>implicit</i>	0
	■ D1 <i>implicit</i>	0.001
2	■ D2 <i>implicit</i>	0.005
3	▶ ThrottleControl.APPSnsrRun	
4	■ ThrottleControl.ActuatorRun5ms	0.005
5	■ ThrottleControl.TPSSecondaryRun5ms	0.005
6	■ ThrottleControl.MonitorRun5ms	0.005
7	■ ThrottleControl.ControllerRun5ms	0.005
8	■ D3 <i>implicit</i>	0.01
9	■ ThrottleControl.TPSPrimaryRun10ms	0.01

Changing one of the views impacts the other.

To use the Schedule Editor, on the **Modeling** tab, click **Schedule Editor**. If the model is already partitioned, you can open the Schedule Editor by clicking the badge, , which appears above the blocks. To see the default partitions present in the model in the Schedule Editor, update the diagram with  icon, on the toolbar or by selecting **Ctrl+D**. As you create partitions in the model and update the diagram, partitions appear in the Schedule Editor.

To check how the partitions map to the model, right-click the partitions and select **Show Source**. The Simulink model window appears with every block corresponding to the partition highlighted.

### Order

The **Order** pane shows the order in which the partitions execute. To change the order, you can drag and drop the partitions. You can also use the **Up** and **Down** arrows on the toolbar. Partitions are sorted based on their rates. You can only reorder the partitions with the same rate. Clicking a partition in the **Order**, highlights the corresponding partition in the graph. On changing the order, the connections that are affected by this specified change get highlighted.

---

**Note** Aperiodic partitions are listed in the order of their priority.

---

3	▶ ThrottleControl.APPSnsrRun	
4	■ ThrottleControl.ActuatorRun5ms	0.005
5	■ ThrottleControl.TPSSecondaryRun5ms	0.005
6	■ ThrottleControl.MonitorRun5ms	0.005
7	■ ThrottleControl.ControllerRun5ms	0.005
8	■ D3 <i>implicit</i>	0.01
9	■ ThrottleControl.TPSPPrimaryRun10ms	0.01

## Connections

Connections between the partitions show data dependencies. You can right-click the connections between the partitions to change the constraints on data connections. The different types of connections illustrate how the partitions behave with each other.

The types of connections are:

- **Dependency** - Indicates that the source always runs before the destination. The dependency connection is a solid line.

- **Delay** - Indicates that the destination runs before the source. When the destination runs before the source, a scheduling delay is introduced. The delay connection is a dashed line.

You can put these types of constraints on connections:

- **Allow Delay** - Inserts a delay when required. When you specify this constraint for a connection, Simulink inserts a delay for that connection only when necessary. The unlock icon on the connections signifies an allowed delay. When you select this constraint on a connection, Simulink prefers these connections to be turned into a delay if necessary over other connections.

This constraint is displayed as one of these options.

- **Prevent Delay** - Prevents delay from being inserted in the connection. When you specify this constraint for a connection, Simulink ensures that the connection always remains as a dependency. The lock icon on the connection indicates that the connection is locked to be a dependency and is not changed to a delay.

- “Generate Code from a Partitioned Model” on page 25-22

## Schedule the Partitions

These two examples walk through the workflow of partitioning a model, scheduling the partitions and analyzing the simulations before and after editing the schedule of the partitions.

### Schedule an Export-Function Model Using the Schedule Editor

This example shows how to view and edit the order of function-calls in an export-function model using the Schedule Editor. As in all export-function models, the desired functionality is modeled as function-call subsystems. These function-call subsystems define the partitions that are scheduled by the Schedule Editor.

With the Schedule Editor, you can easily view and edit the schedule of the function-calls. The behavior of the system depends on the order of these partitions. In this example, we change the order and observe its effects on the behavior of the system by simulating the model. To see the impact of editing the schedule on the simulation, we compare the model simulations before and after scheduling.

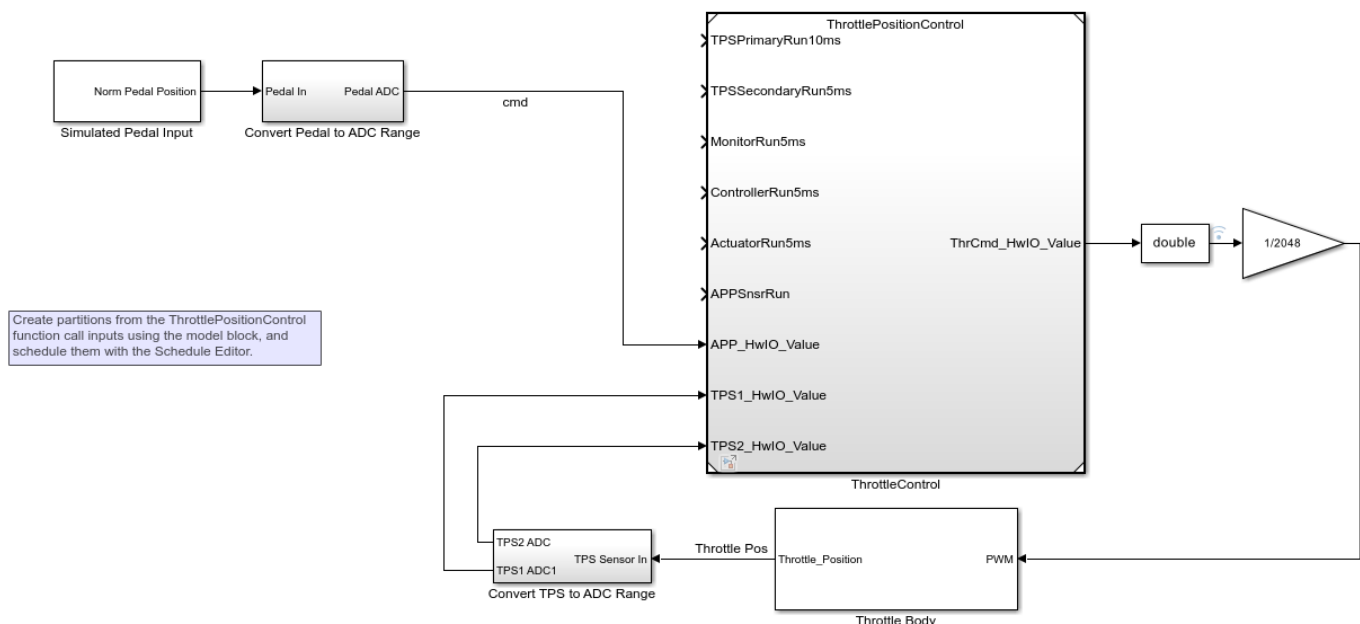

#### Create Partitions from Referenced Export-Function Model

To view and edit the schedule of the export-function model, reference the model.

```
open_system('ThrottlePositionControlTop.slx');
```

### Schedule an Export-Function Model with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

ThrottlePositionControl is the referenced export-function model. By default, each function has an input port that can be used to trigger these functions. The Schedule Editor automatically handles these ports. To use the Schedule Editor, set the Schedule Rates With parameter to Schedule Editor.

```
set_param('ThrottlePositionControlTop/ThrottleControl', 'ScheduleRatesWith', 'Schedule Editor');
```

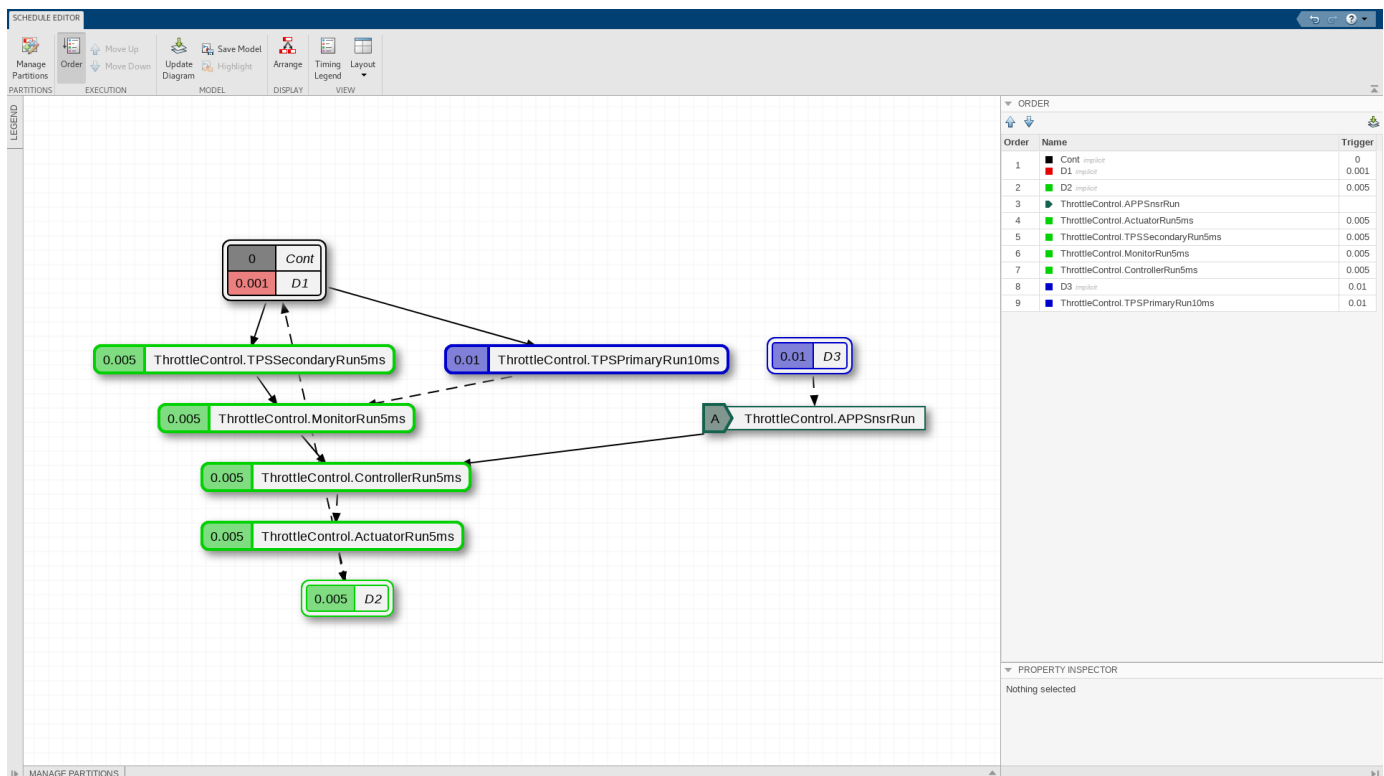

### Establish a Simulation Baseline

To observe the impact of scheduling on the model behavior, establish a baseline by simulating the model before editing the schedule. Simulate the model.

```
sim('ThrottlePositionControlTop');
```

### Open the Schedule Editor

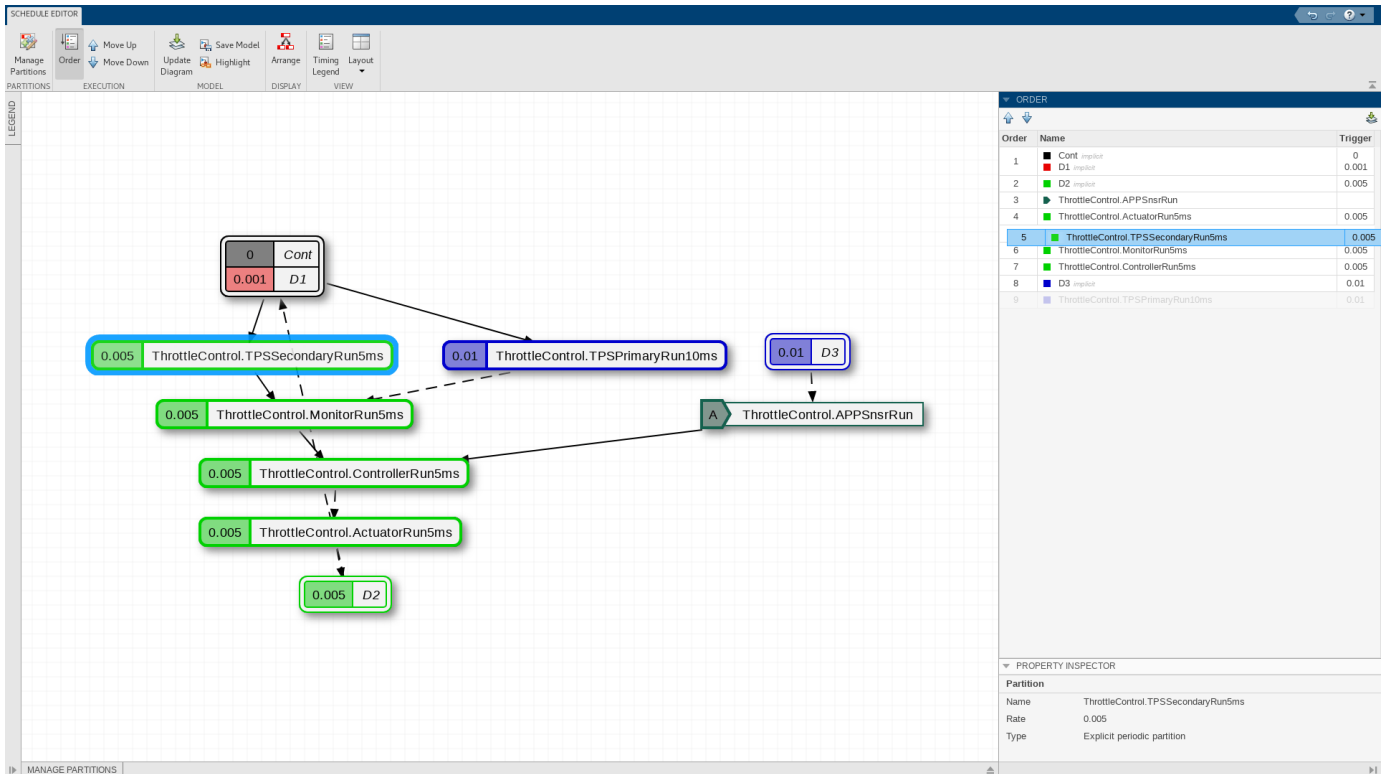

To open the Schedule Editor, click **Schedule Editor** in the **Design** section of the **Modeling** tab. In the Schedule Editor, different components of the model are represented as partitions. Update the diagram to see the partitions. Partitions are the entry-points in the model. The Schedule Editor shows the order and data communications of these partitions. The arrows are data connections between the partitions that show the data flow. The dashed lines indicate that there is a delay because the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

### Edit Partition Schedule

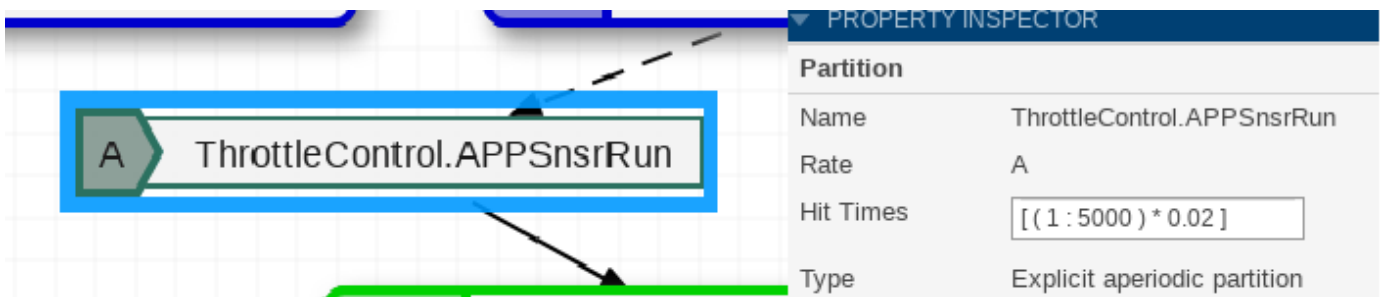

The Order pane shows the order the partitions run in at a given time step. Assume that the order of the partitions is in an imperfect state. In this case, to remove the delay, you want to run the ThrottleControl.ActuatorRun5ms partition after the ThrottleControl.ControllerRun5ms partition.

Drag `ThrottleControl.ActuatorRun5ms` after the `ThrottleControl.ControllerRun5ms` in the Order pane. Observe that the delay between the `ThrottleControl.ControllerRun5ms` and the `ThrottleControl.ActuatorRun5ms` partitions changes to a dependency. Observe that now there is no delay between the executions of `ThrottleControl.ControllerRun5ms` and `ThrottleControl.ActuatorRun5ms`.

### Schedule the Execution of Aperiodic Partitions

The export-function model contains an unconstrained partition, `AccelerationPedalPositionSensor`. Suppose you want to schedule an unconstrained partition to simulate as if it were discrete. Schedule `ThrottleControl.APPSnsrRun` partition to run at `[0:0.02:100]` to observe its behavior at different instances of time. Click the unconstrained partition and enter `[(1:5000)*.02]` for Trigger in the Property Inspector.

### Compare the Runs in Simulation Data Inspector

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior.

Copyright 2018-2019 The MathWorks, Inc.

## Schedule a Rate-Based Model Using the Schedule Editor

This example shows how to partition a rate-based model using the Schedule Editor. Partitions are the components of the model that can execute independently. In this example, we convert the subsystems into partitions and view and edit their schedule.

With the Schedule Editor, you can easily view and edit the schedule of the partitions. The behavior of the system depends on the order of these partitions. In this example, we observe the effects of scheduling this model on the simulation. To see the impact of partitioning and scheduling the model, we compare the model simulations before and after creating partitions and scheduling them.

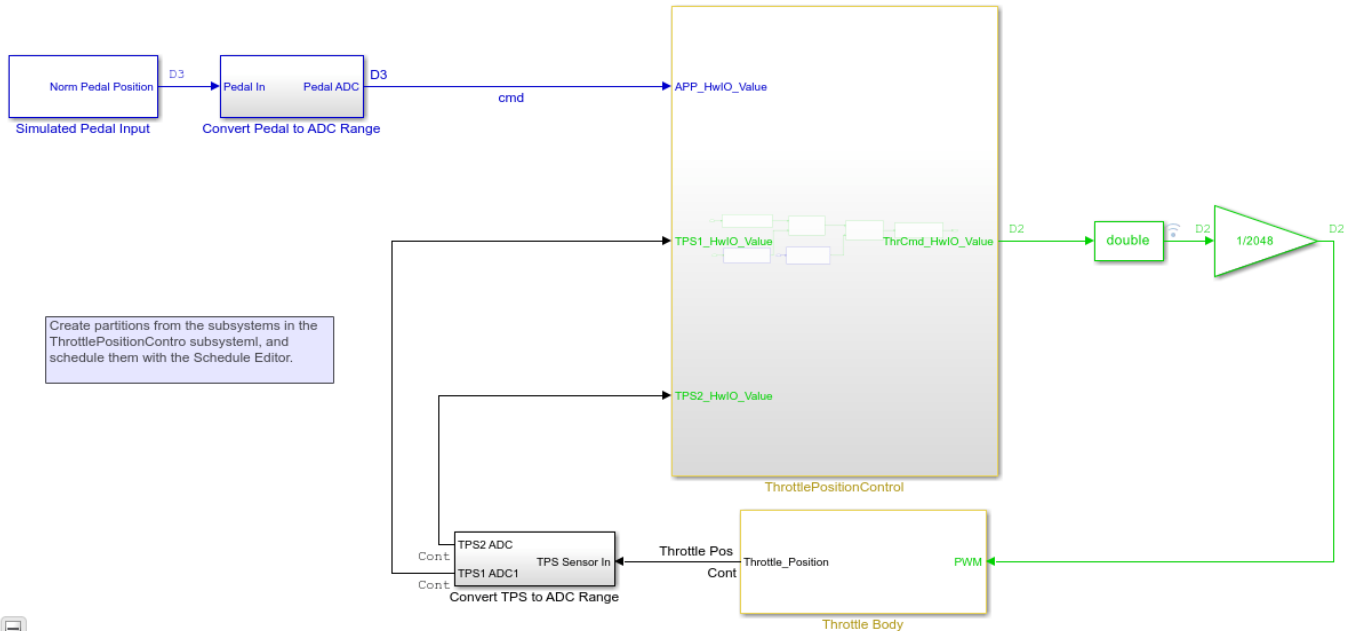

### Open the Model and Establish a Simulation Baseline

Open the model of a Throttle Position Control system and simulate it to establish a baseline for comparison

```
open_system('ScheduleEditorWithSubsystemPartitions');
sim('ScheduleEditorWithSubsystemPartitions');
```

## Schedule Subsystem Partitions with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

### Open the Schedule Editor and Create Partitions

To open the Schedule Editor, click **Schedule Editor** in the **Design** section of the **Modeling** tab. Use **Manage Partitions** to create partitions from the subsystems in your model. Select all the subsystems in **ThrottlePositionControl**, and click the **Create Partitions** icon on the top of the **Manage Partitions** panel. Specify the names for the partitions and their sample time. Update the diagram to see the partitions in the Schedule Editor.

The arrows are data connections between the partitions that show the data flow. The dashed lines always indicate that there is a delay as the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

Order	Name	Trigger
1	Cont_inptor	0
1	D1_inptor	0.001
2	TPSSecondaryRun5ms	0.005
3	MonitorRun5ms	0.005
4	ControllerRun5ms	0.005
5	ActuatorRun5ms	0.005
6	D2_inptor	0.005
7	D3_inptor	0.01
8	APPSnsrRun	0.01
9	TPSPPrimaryRun10ms	0.01

### Edit Partition Schedule

The Order shows the order the partitions run at a given time step. Assume that the order of the partitions is in an imperfect state. In this case, you want to run the ActuatorRun5ms partition before the ControllerRun5ms partition. Drag ActuatorRun5ms before the ControllerRun5ms in the order. Observe that the dependency between the ControllerRun5ms and the ActuatorRun5ms partitions changes to a delay.

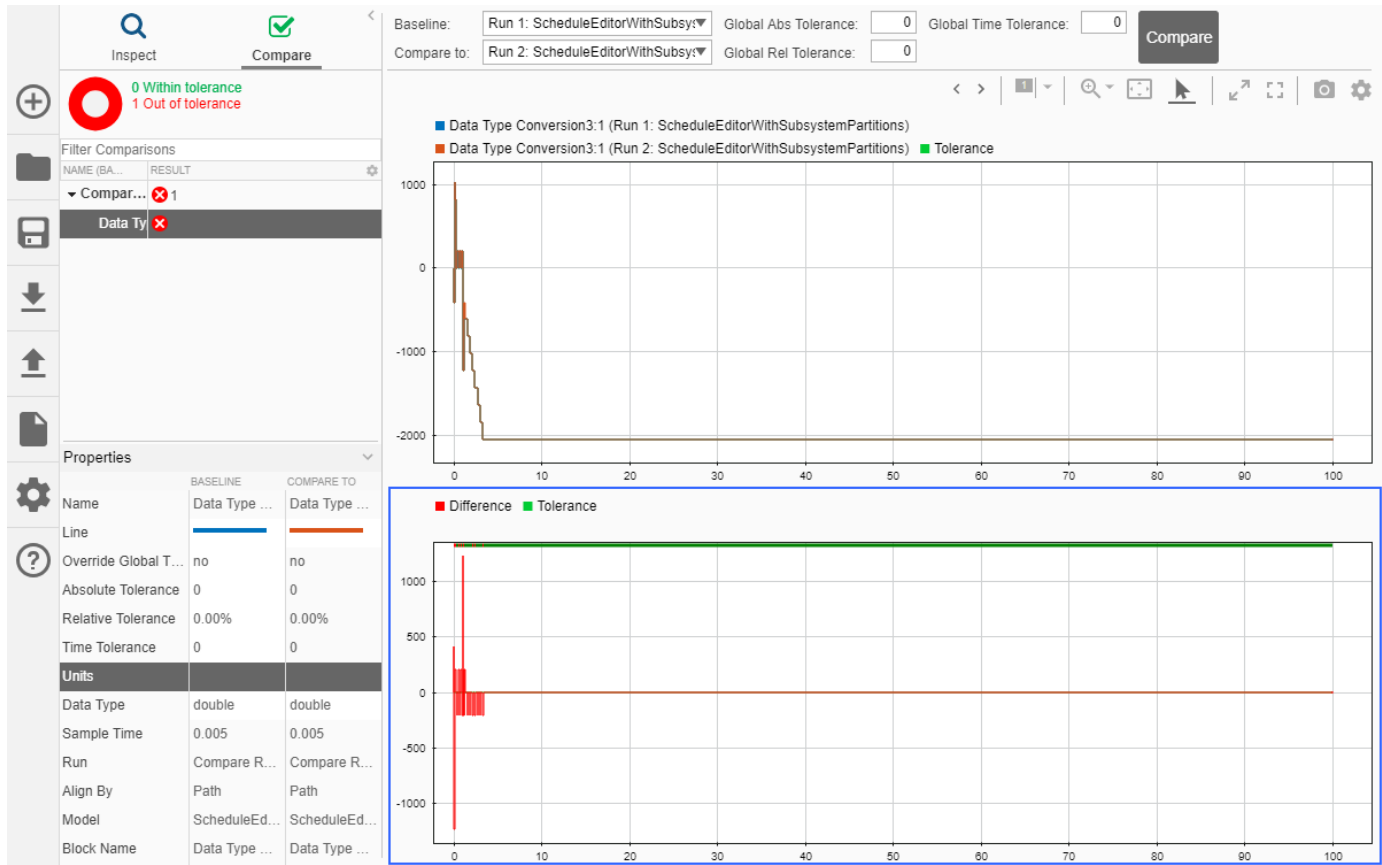

Order	Name	Trigger
1	Cont_inptor	0
1	D1_inptor	0.001
2	TPSSecondaryRun5ms	0.005
3	MonitorRun5ms	0.005
4	ActuatorRun5ms	0.005
5	ControllerRun5ms	0.005
6	D2_inptor	0.005
7	D3_inptor	0.01
8	APPSnsrRun	0.01
9	TPSPPrimaryRun10ms	0.01

## Compare Runs in Simulation Data Inspector

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior.

### Schedule Editor

## More About

- “Create Partitions” on page 25-4
- “Generate Code from a Partitioned Model” on page 25-22

## Generate Code from a Partitioned Model

Partitioning and scheduling a model has an impact on the order of the function calls in the generated code. Using the Schedule Editor to edit the schedule of a rate-based model or a referenced export-function model, the order of the functions in the generated code depends on the specified schedule in the Schedule Editor. The resulting code shows every partition as an entry point. The generated code does not include the scheduler and it must be provided by the user.

---

**Note** To use the code generation functionality, Embedded Coder and Simulink Coder are required.

---

To see the impact of the Schedule Editor on the generated code, use the model that is created in “Create A Rate-Based Model” on page 10-41.

- 1 Open the Schedule Editor from the **Design** section of the **Modeling** tab. Use the **Manage Partitions** panel to create partitions for Scheduled Subsystem 1 and Scheduled Subsystem 2 with 0.01 sample time. Update the diagram.
- 2 Change the order of the partitions by dragging Scheduled\_Subsystem\_2 above Scheduled\_Subsystem\_1.

The screenshot shows the SCHEDULE EDITOR interface. The main workspace is a grid containing three components, each with a red border and a rate of 0.01:

- D1**: A small red-bordered box with "0.01" and "D1".
- Scheduled\_Subsystem\_1**: A larger red-bordered box with "0.01" and "Scheduled\_Subsystem\_1".
- Scheduled\_Subsystem\_2**: A large blue-bordered box with "0.01" and "Scheduled\_Subsystem\_2".

The right-hand panel contains the following sections:

- ORDER**: A table with columns Order, Name, and Trigger.
 

Order	Name	Trigger
1	D1 <i>implicit, empty</i>	0.01
2	d_Subsystem_1	0.01
3	d_Subsystem_2	0.01
- PROPERTY INSPECTOR**: A section for the selected component.
 

Partition	
Name	Scheduled_Subsystem_2
Rate	0.01
Type	Explicit periodic partition

- 3 Generate code for the component model. From the **Apps** tab, select **C/C++ Code > Build Model**.

In the generated code, the order of the functions depends on the schedule specified in the Schedule Editor.

```

#include "rate_based_model.h"
#include "rate_based_model_private.h"

/* External inputs (root inport signals with default storage) */
ExtU_rate_based_model_T rate_based_model_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rate_based_model_T rate_based_model_Y;

/* Real-time model */
RT_MODEL_rate_based_model_T rate_based_model_M;
RT_MODEL_rate_based_model_T *const rate_based_model_M = &rate_based_model_M;

/* Model step function for TID0 */
void rate_based_model_step0(void) /* Sample time: [0.01s, 0.0s] */
{
    /* (no output/update code required) */
}

/* Model step function for TID2 */
void rate_based_model_step2(void) /* Explicit Task: Scheduled_Subsystem_1 */
{
    /* Outport: '<Root>/Out1' incorporates:
     * Inport: '<Root>/In1_10ms'
     */
    rate_based_model_Y.Out1 = rate_based_model_U.In1_10ms;
}

/* Model step function for TID1 */
void rate_based_model_step1(void) /* Explicit Task: Scheduled_Subsystem_2 */
{
    /* Outport: '<Root>/Out2' incorporates:
     * Inport: '<Root>/In2_100ms'
     */
    rate_based_model_Y.Out2 = rate_based_model_U.In2_100ms;
}

```

---

**Note** Changing the constraints on the connections does impact the generated code. The changes with respect to connections are useful to set preferences about delays and dependencies.

---

- “Create Partitions” on page 25-4
- “Schedule the Partitions” on page 25-15

## Export-Function Conversion

To use the **Schedule rates with** option with the Schedule Editor, the model can not be an export-function model. To enable **Schedule rates with** option, convert your model to a rate-based model. To convert your model to a rate-based model, remove the function call input ports. For more information, see “Export-Function Models” on page 10-48.

# Create and Analyze Random Schedules for a Model Using the Schedule Editor API

This example uses the Schedule Editor API to perform operations on the schedule. Then it uses a function to generate random schedules and analyze them in Simulation Data Inspector

## Open the Model and get the Schedule Object

Open a model of a Throttle Position Control system and use `get_param` to obtain the `simulink.schedule.OrderedSchedule` object. This object contains the current schedule.

```
model = 'ScheduleEditorAPIWithSubsystemPartitions';
open_system(model);
schedule = get_param(model, 'Schedule')
```

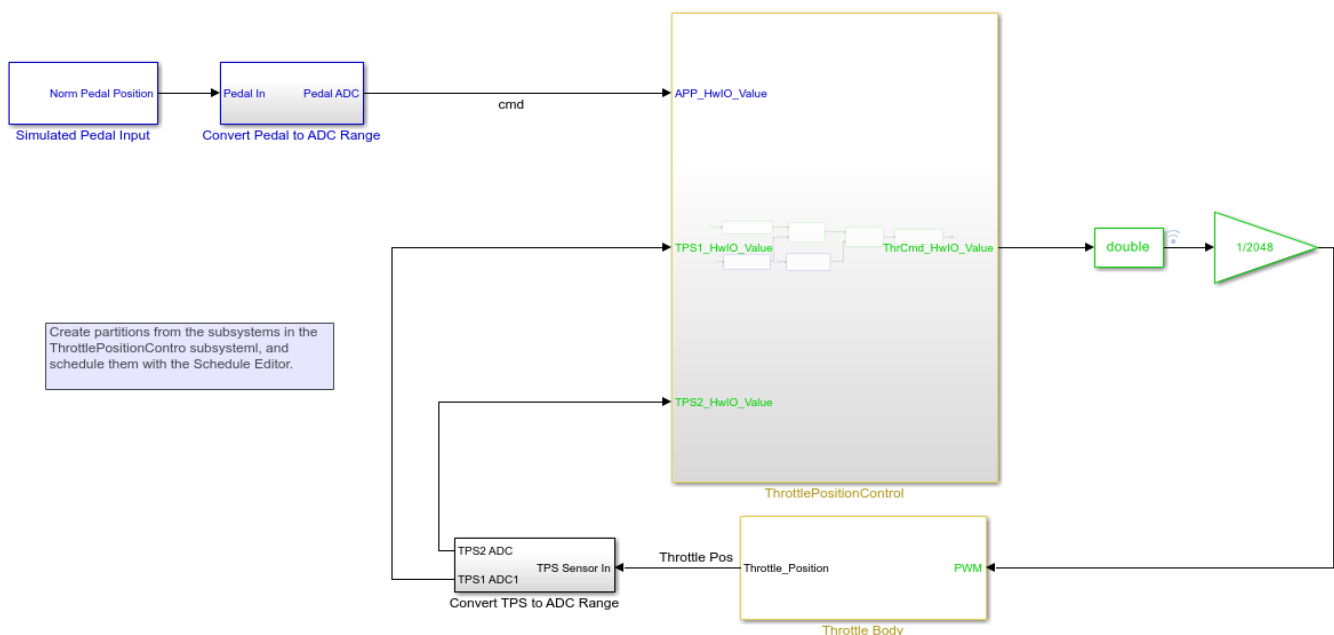

schedule =

OrderedSchedule with properties:

```
Order: [9x3 table]
RateSections: [3x1 simulink.schedule.RateSection]
Events: [0x1 simulink.schedule.Event]
Description: ''
```

## Schedule Subsystem Partitions with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

### Examine the Schedule Object

The schedule object has an `Order` property that contains the execution order of the partitions in the model. The `Order` property displays a table that contains partition names, their index, type, and their trigger.

```
schedule.Order
```

```
ans =
```

```
9x3 table
```

	Index	Type	Trigger
Cont	1	Periodic	"0"
TPSSecondaryRun5ms	2	Periodic	"0.005"
MonitorRun5ms	3	Periodic	"0.005"
ControllerRun5ms	4	Periodic	"0.005"
ActuatorRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"
D3	7	Periodic	"0.01"
APPSnsrRun	8	Periodic	"0.01"
TPSPPrimaryRun10ms	9	Periodic	"0.01"

Use the index variable in the `Order` table to change the execution order of the model

```
schedule.Order.Index('ActuatorRun5ms') = 2;  
schedule.Order
```

```
ans =
```

```
9x3 table
```

	Index	Type	Trigger
Cont	1	Periodic	"0"
ActuatorRun5ms	2	Periodic	"0.005"
TPSSecondaryRun5ms	3	Periodic	"0.005"
MonitorRun5ms	4	Periodic	"0.005"
ControllerRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"
D3	7	Periodic	"0.01"
APPSnsrRun	8	Periodic	"0.01"
TPSPPrimaryRun10ms	9	Periodic	"0.01"

Any moves within the `Order` property that are made to modify the schedule should result in valid schedule. To perform the schedule modifications and valid moves easier, each partition is grouped with partitions of the same rate in the `RateSections` property. Each element of the `RateSection` property contains an order table with partitions of the same rate.

```
schedule.RateSections(2)  
schedule.RateSections(2).Order
```

```
ans =
```

```
RateSection with properties:
```

```
Rate: "0.005"
Order: [5x3 table]
```

```
ans =
```

```
5x3 table
```

	Index	Type	Trigger
ActuatorRun5ms	2	Periodic	"0.005"
TPSSecondaryRun5ms	3	Periodic	"0.005"
MonitorRun5ms	4	Periodic	"0.005"
ControllerRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"

Use the index variable to move the partitions within RateSections.

```
schedule.RateSections(2).Order.Index('ActuatorRun5ms') = 5;
schedule.Order
```

```
ans =
```

```
9x3 table
```

	Index	Type	Trigger
Cont	1	Periodic	"0"
TPSSecondaryRun5ms	2	Periodic	"0.005"
MonitorRun5ms	3	Periodic	"0.005"
ControllerRun5ms	4	Periodic	"0.005"
ActuatorRun5ms	5	Periodic	"0.005"
D2	6	Periodic	"0.005"
D3	7	Periodic	"0.01"
APPSnsrRun	8	Periodic	"0.01"
TPSPPrimaryRun10ms	9	Periodic	"0.01"

## Create a Function to Generate Random Schedules

In this section, we create three different functions: `randomSchedule`, `generateSimulationInputs` and `simulateRandomSchedules`

`randomSchedule` function is used to create random schedules by using random permutations of index modifications in the `schedule` object. Using the `Order` and the `RateSections` properties of the `schedule` object, partitions in the schedules are moved around in different, random combinations. With these randomly created schedules, models are simulated and compared to study the effect of different schedules on simulation. In the function `randomSchedule`, the input is the model name. Then use `get_param` to obtain the `simulink.schedule.OrderedSchedule` object of

the model. The schedule object and its properties are used to modify and randomize the schedules. Create a variable `firstExecutionOrder` for the first rate section of the model. The `rateSections(1).ExecutionOrder = [firstExecutionOrder(1,:); reSchedule(firstExecutionOrder(2:end,:))]` line of code calls the function `reSchedule` which creates random permutations of the indexes.

type `randomSchedule`

```
function schedule = randomSchedule(model)
    % schedule = randomSchedule(model) Produces a
    % simulink.schedule.OrderedSchedule that has a randomized permutation
    % of the model's original execution order schedule

    arguments
        model char = bdroot
    end

    schedule = get_param(model, 'Schedule');

    rateSections = schedule.RateSections;
    firstOrder = rateSections(1).Order;

    % This assumes that the slowest discrete rate is at index 1. This may
    % not be the case for all models (ex. JMAAB-B).
    rateSections(1).Order = [firstOrder(1,:); reSchedule(firstOrder(2:end,:))];

    for i=2:length(rateSections)
        rateSections(i).Order = reSchedule(rateSections(i).Order);
    end

    schedule.RateSections = rateSections;
end

function out = reSchedule(in)
    numPartitions = height(in);
    in.Index = in.Index(randperm(numPartitions));
    out = in;
end
```

To analyze the effects of different schedules on the model, simulate the model with the different schedules. In this function, create an array of `Simulink.SimulationInput` objects. Through this array of `Simulink.SimulationInput` objects, you can apply the schedules to the model with the `setModelParameters` method of the `Simulink.SimulationInput` object.

type `generateSimulationInputs`

```
function in = generateSimulationInputs(model, numSimulations)
    % in = generateSimulationInputs(model, numSimulations) Generates
    % numSimulations Simulink.SimulationInput objects each containing a
    % different, randomized execution order schedule
    arguments
        model char = bdroot
        numSimulations double = 10
    end

    in(numSimulations) = Simulink.SimulationInput();
```

```

    in = in.setModelName(model);
    for idx = 1:numSimulations
        in(idx) = in(idx).setModelParameter('Schedule', randomSchedule(model));
    end
end

```

In the last function, use the array of `Simulink.SimulationInput` objects to run multiple simulations. Once the simulations are complete, you can plot the output of all the simulations in Simulation Data Inspector.

type `simulateRandomSchedules`

```

function out = simulateRandomSchedules(model, numSimulations)
    % out = simulateRandomSchedules(model, numSimulations) Simulates a
    % model numSimulations number of times. Each simulation has a
    % randomized execution order schedule.
    arguments
        model char = bdroot
        numSimulations double = 10
    end

    in = generateSimulationInputs(model, numSimulations);
    out = sim(in);
    plot(out);
end

```

### Execute the Functions

Now run the above functions for the `ScheduleEditorAPIWithSubsystemPartitions` model. First, use the `randomSchedule` function to create randomly generated schedules, then, use the `generateSimulationInputs` function to generate an array of `Simulink.SimulationInput` objects, and use the `simulateRandomSchedule` function to simulate the model with different schedules and plot their results for comparison. Let's run simulations with 15 randomly generated schedules.

```
simulateRandomSchedules(model, 15)
```

```

## Events in Schedule Editor

An event is a construct that represents an action, transition, or condition. You can broadcast events from within a model hierarchy. The Schedule Editor allows you to create and manage partitions and schedule the execution of your model. You can bind an event to an aperiodic partition that is scheduled, based on priority, for execution when the event is broadcast. Events simplify system creation and provide more flexibility during scheduling.

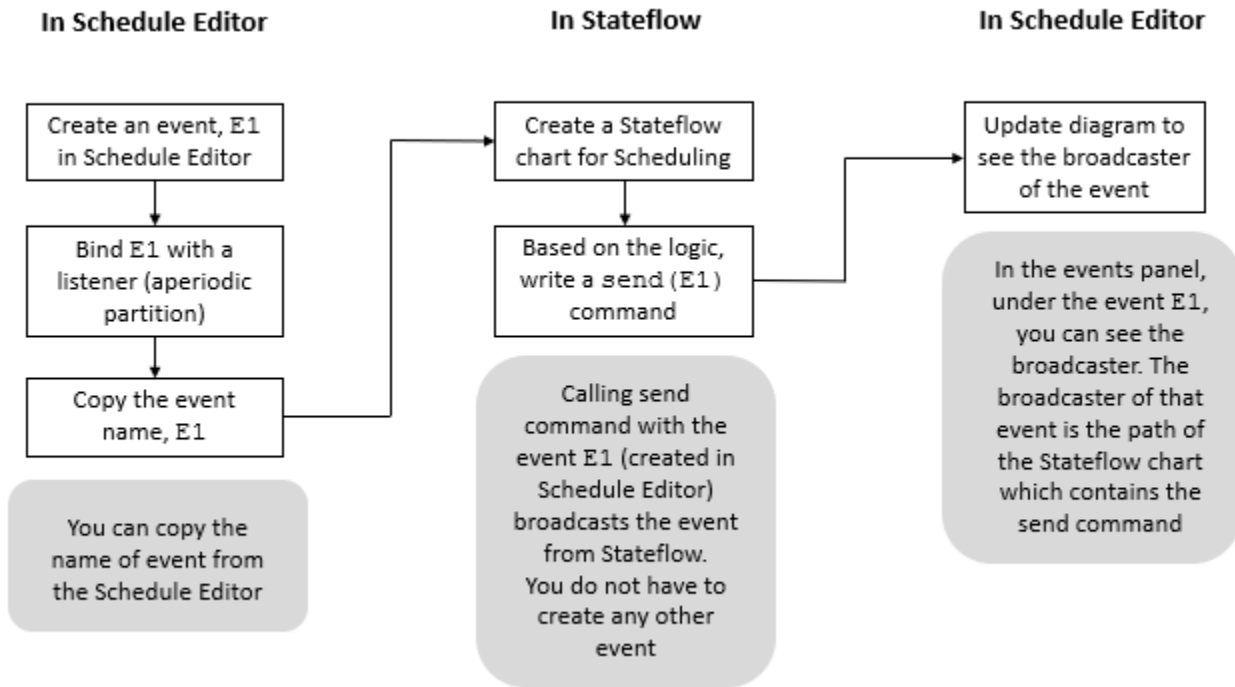

Events can connect blocks that detect important conditions with a partition to schedule the execution of the partition when the conditions occurs. You can send Schedule Editor events from Stateflow charts using the `send` keyword. You can also configure event triggers on the Inport or In Bus Element block, and manage the events in the Schedule Editor.

### Event Management in the Schedule Editor

Each model in a model hierarchy has its own **Events** panel in the Schedule Editor, that contains all the events present in the model and the model's children. When you open the Schedule Editor and update the diagram, all partitions and events present in the model appear in the Schedule Editor. Through the **Events** panel, you can:

- Create an event.
- Delete an event.
- Rename an event.
- Get an event.
- Bind an event to a partition.
- Unbind an event from a partition.

You can create a Stateflow chart for scheduling and use the `send` operator to broadcast an event. Then, in the Schedule Editor, in **Events**, create an event of the same name. Update the diagram to see the broadcaster of that event which is the Stateflow chart.

You can also configure event triggers on the Inport or In Bus Element block that represents the port. Then, in the Schedule Editor, specify the partition to execute in response to each event and schedule the priority of execution. By configuring event triggers on input ports, you can model and simulate quality of service effects. The table summarizes the event triggers you can configure on input ports. For each input port, you can configure one event trigger for each input event.

Input Event	Input Event Description	Event Trigger Object
Input write	Value for input port updates.	simulink.event.InputWrite
Input write timeout	Input port value does not update within a specified amount of time.	simulink.event.InputWriteTimeout
Input write lost	Input port value update overwrites unprocessed data.	simulink.event.InputWriteLost

The **Events** panel in the Schedule Editor shows you the event tree. Under every event, you can see the broadcasters and listeners of that event.

When an event is bound to a partition, the event name appears on the left side of the partition and in the **Trigger** column of the **Order** table.

The screenshot shows the Schedule Editor interface. On the left is the **EVENTS** panel with a search bar and a list of events. In the center is a diagram showing a hierarchy of events: PartitionA (green arrow) has two children, PartitionB (green arrow) and PartitionC (red arrow with '0.1'). On the right is the **ORDER** panel, which is a table listing the events in order.

Order	Name	Trigger
1	▶ PartitionA	
2	▶ PartitionB	
3	■ PartitionC	0.1

## Naming

Unique names are enforced for events within a model and within a model hierarchy. Within a model hierarchy, the model name prepends the event name. For example, if the model reference named `ModelName` contains an event, `E1`, then that event appears as `ModelName.E1` in the Schedule Editor.

## Scope

You can set the scope of the event in the **Events** panel. To set the scope of the event, right click the event in the **Events** panel.

There are two options:

**Global**,  - A global event indicates that an event is available for use anywhere in the model hierarchy. You can use and connect the global event anywhere within the model hierarchy. A global event is visible in the **Events** panel for the parent model. A global event with the name `E1`, that's present in the model named `ModelName.E1`, is displayed as `E1` in the **Events** panel of the parent model. All global events must have a unique name. You can use the global scope to combine multiple instances of the same event. These multiple instances of the events can then be triggered by the same Stateflow chart to unify scheduling.

**Scoped,**  - By default, the event is scoped, indicating that the event is used within the context of the parent model. A scoped event is visible in the **Events** panel for the parent model. A scoped event with the name E1, that's present in the model named ModelName, is displayed as ModelName.E1 in the **Events** panel.

## Execution of Aperiodic Partitions with Events

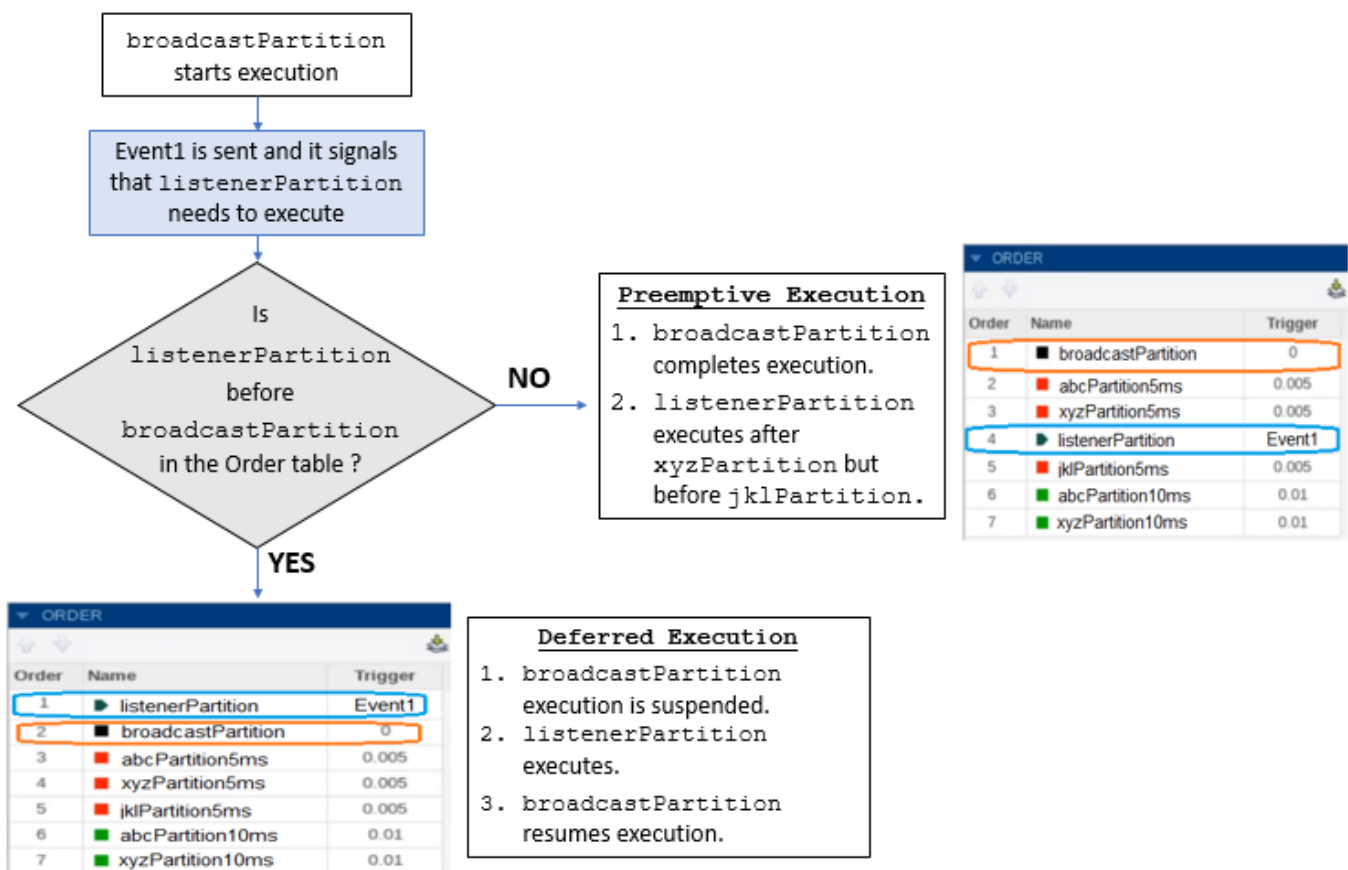

### Bind Events

An event and a partition can be bound together to indicate that the partition executes when the event is broadcast. A partition may only be bound to a single event.

### Priority Based Execution

If the event-bound partition is scheduled to run before the partition driving the event, then the event-bound partition execution preempts the execution of the partition driving the event. If the triggered partition is scheduled to run after the partition driving the event, then the triggered partition executes when the scheduler reaches its position in the execution order.

listenerPartition is an aperiodic partition and a listener to the event, Event1. Suppose that Event1 comes from a Stateflow Chart present in the model and is a part of the partition called, broadcastPartition. When broadcastPartition starts executing, Event1 occurs, which then triggers the execution of listenerPartition.

## Hit Times

You can trigger an aperiodic partition at specified hit times. If a partition has hit times and gets bound to an event, the hit times are replaced with the specified event. Likewise, if a partition is bound to an event and hit times are added, then the bound event is removed from the partition. Variables can also specify hit times for the aperiodic partitions. In case of ambiguous variable and events names, events are given precedence.

## Schedule Partitions with Events

This example shows how you can use events to schedule the execution of aperiodic partitions via a Stateflow chart. You can send events from Stateflow and use those events to control the execution of the partitions in the model by using events in Schedule Editor.

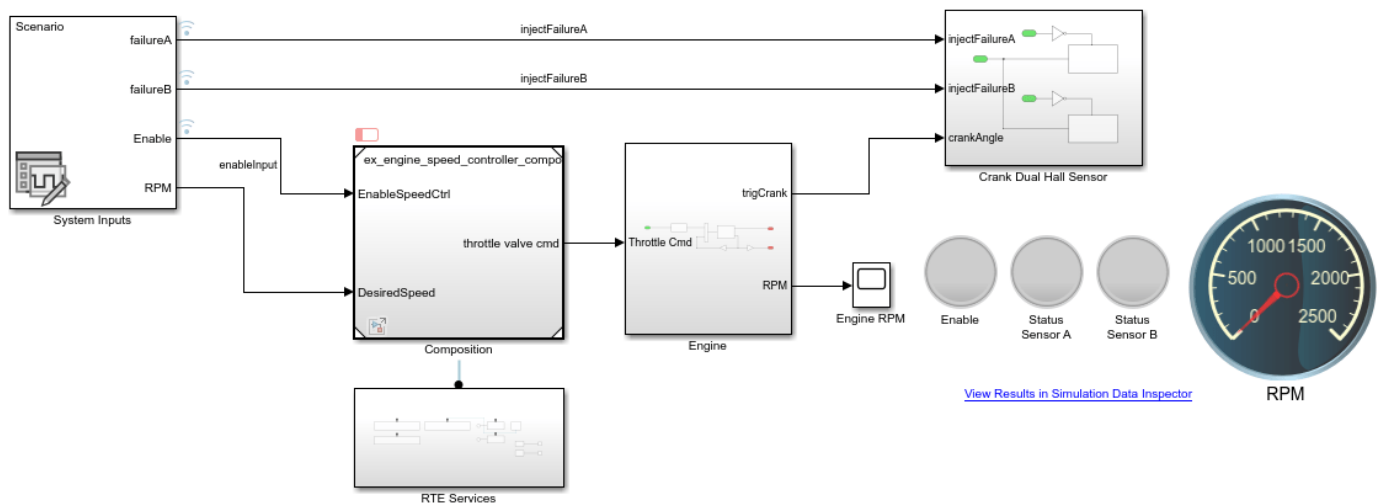

### Open the Model

In this example, we simulate the digital speed control of an internal combustion engine. In this model, the angular velocity of the engine is measured using two redundant Hall sensors, and we simulate the failure of the Hall sensors.

The model primarily contains the following main components:

- **System Inputs:** Inputs and signals to exercise the system.
- **Engine:** Simplified representation of internal combustion engine.
- **Composition:** Digital controller intended to deploy on an Engine Control Unit (ECU), with a Runtime Environment (RTE).
- **Crank Dual Hall Sensor:** Emulation of two redundant sensors, sensor A and sensor B.
- **RTE Services:** Emulation of the services provided by Engine Control Unit.

```
open_system("ex_engine_speed_control_system");
```

## System Inputs

The system inputs for this model are designed using the Signal Editor block. The `ex_engine_speed_control_external_inputs.mat` file contains the following scenario:

- The desired angular velocity is set to 2000 rpm for the entire simulation.
- At  $t = 01$  sec, the speed controller is enabled. As a result, Hall sensor A is being used to compute the angular velocity and the engine speed increases to 2000 rpm.
- At  $t = 06$  sec, a failure of the first Hall sensor is injected. As a result, Hall sensor B is now being used to compute the angular velocity, the engine speed remains at 2000 rpm.
- At  $t = 11$  sec, a failure of the second sensor is injected. As a result, the speed controller is disabled, the engine speed falls toward zero.
- At  $t = 15$  sec, the failure of sensors A and B gets resolved.
- At  $t = 21$  sec, the command to enable speed control is cycled back to zero for one second and back to one. As a result, the engine speed increases to 2000 rpm.

## Engine

The engine dynamics are represented by a Transfer Function that receives a throttle command and converts it into torque, and a Second Order Integrator to integrate the motion.

## Composition

`ex_engine_speed_controller_composition` implements the digital control algorithm. It contains the following components:

- **ComputeRPM\_A and ComputeRPM\_B:** Aperiodic partitions registered as hardware interrupts. Hall sensors A and B trigger these partitions when the engine shaft rotates by every increment of 10 degrees.
- **computeThrottle and actuatorProcessing:** Periodic partitions executing at 0.001 sec. `computeThrottle` interrogates the RTE at every time step.
- **monitorMalfunction:** Periodic partition executing at 0.01 sec. Monitors output signals of `ComputeRPM_A` and `ComputeRPM_B` to identify potential hardware failures. If a failure is detected, it calls a function provided by the RTE to register the failure.
- **checkForRecovery:** Aperiodic partition that is triggered by RTE once a failure has been detected. Upon detection, `checkForRecovery` is called by the RTE at a rate of 1 sec. It calls a function provided by the RTE if a recovery is detected.

Using the Schedule Editor, the events checkForRecovery, trigCrankA, and trigCrankB are created and bound to aperiodic partitions checkForRecovery, ComputeRPM\_A, and ComputeRPM\_B respectively. These events are broadcast from the top model.

### Crank Dual Hall Sensor

The Hall sensors are modeled using Hit Crossing blocks that generate a function-call every time the engine shaft rotates by increments of 10 degrees. When the Stateflow chart gets triggered, it sends events `trigCrankA` and `trigCrankB`, which have been bound to execute aperiodic partitions, `ComputeRPM_A` and `ComputeRPM_B` respectively.

## RTE Services

The RTE Services subsystem emulates functionalities available on the Run-time Environment onto which the code generated from the digital controller is deployed. For simulation purposes, those services are emulated using Simulink Functions.

- **sendFailureStatus** and **recoverFailureStatus** are called respectively by the `monitorMalfunctions` and `checkForRecovery` partitions when a failure or a recovery is detected. The global failure statuses are stored using Data Store Memory blocks for simulation purposes.
- **getFailureMode** is called by the `computeThrottle` to verify if a failure has been detected in one of the sensors.
- **getTimeA** and **getTimeB** simulate the RTE clock.
- **Check for Recovery** simulates the logic to determine when the `checkForRecovery` aperiodic partition of the digital controller should be triggered. Triggering is done by broadcasting the event `checkForRecovery`.

## Open the Schedule Editor

To open the Schedule Editor, on the **Modeling** tab in the **Design Section**, click **Schedule Editor**. Doing an Update Diagram compiles the models and shows you the existing partitions in the Schedule Editor.

The screenshot displays the Schedule Editor for the 'ex\_engine\_speed\_control\_system'. The interface includes a menu bar with options like 'Manage Partitions', 'Order', 'Update Diagram', 'Save Model', 'Highlight', 'Arrange', 'Timing Legend', and 'Layout'. Below the menu is a toolbar with icons for these functions. The main workspace shows a state transition diagram with nodes and transitions. A legend on the left lists events with their triggers and priorities. The right panel shows the 'ORDER' table and the 'PROPERTY INSPECTOR'.

Order	Name	Trigger
1	Composition.computeRPM_A	trigCrankA
2	Composition.computeRPM_B	trigCrankB
3	Composition.computeThrottle.D1	0
4	Composition.actuatorProcessing.D1	[0, 1]
5	Composition.checkForRecovery	0.01
6	Composition.D1	0.001
7	Composition.D1	0.001
8	Composition.Model.D1	0.01

### Events Panel in the Schedule Editor

The events broadcast by the send keyword in Stateflow are shown in the **Events** panel of the Schedule Editor, these events are bound to aperiodic partitions, so that these partitions can be triggered from the top model. In the **Events** panel, you can expand each event to see the listeners

and the broadcasters of that event. The icon,  indicates broadcaster of the event and the icon,  indicates the listener. In this example, the sender of the event checkForRecovery is the Stateflow Chart in RTE Services subsystem, the sender of the events trigCrankA and trigCrankB is the Stateflow chart in the Crank Dual Hall -> Sensor A and Sensor B.

In the **Order** panel, the partitions are arranged in the order of priority of execution. Since ComputerRPM\_A and ComputerRPM\_B are time sensitive, their priority is the highest. Therefore, when the events trigCrankA and trigCrankB are broadcast, the corresponding partitions ComputerRPM\_A and ComputerRPM\_B are executed immediately. In contrast, the aperiodic partition checkForRecovery is less time sensitive, and is lower in the priority order. Therefore, when the event checkForRecovery is broadcast, the execution of the corresponding partition checkForRecovery is deferred until all the partitions with higher priority complete execution.

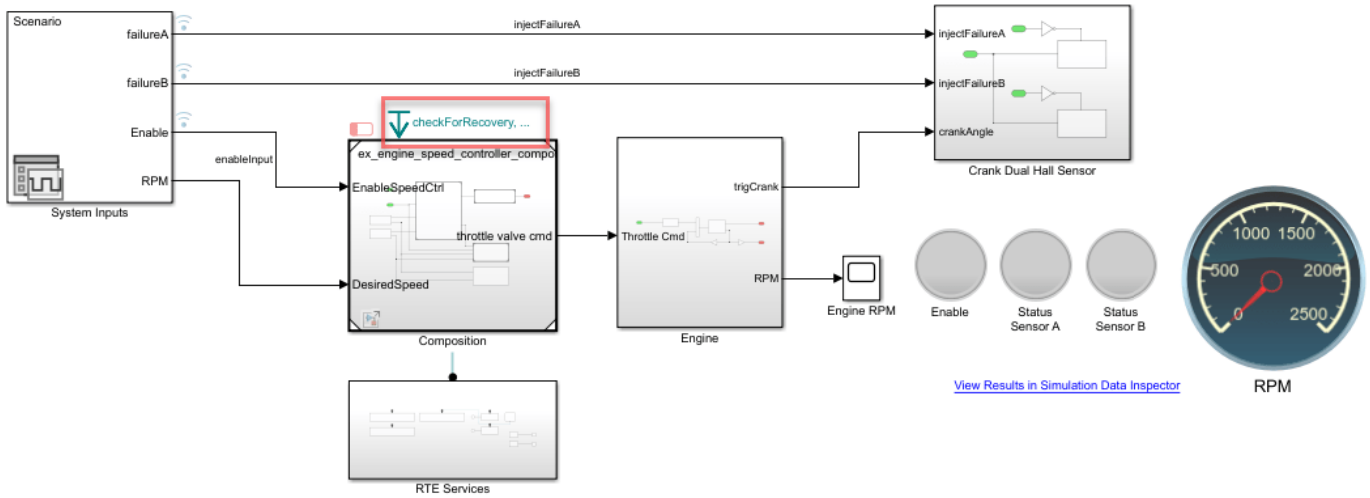

The screenshot displays the Schedule Editor for the 'ex\_engine\_speed\_control\_system'. The main workspace shows a diagram with event connections. A blue box highlights a connection from 'trigCrankA' to 'Composition.computeRPM\_A'. Below it, two red boxes highlight '0.001 Composition.computeThrottle.D1' and '0.001 Composition.actuatorProcessing.D1'. The 'EVENTS' pane on the left lists events like 'checkForRecovery', 'trigCrankA', and 'trigCrankB'. The 'ORDER' pane on the right shows a table of execution orders:

Order	Name	Trigger
1	computeRPM_A	trigCrankA
2	computeRPM_B	trigCrankB
3	Cont implicit	0
	FiM implicit	[0, 1]
	D2 implicit	0.01
	D3 implicit	1
4	uteThrottle.D1	0.001
5	Processing.D1	0.001
6	ckForRecovery	checkForRecovery
7	omposition.D1	0.001
8	ition.Model.D1	0.01

The 'PROPERTY INSPECTOR' at the bottom right shows the selected partition 'Composition.computeRPM\_A' with a rate of 'A' and trigger 'trigCrankA'.

You can view this event connection in the Simulink model, this connection conveys the flow of execution between a block broadcasting an event and another block listening to that event. To view this connection, on the Simulink Toolstrip, on the **Debug** tab, select **Information Overlays** in the

**Diagnostic** section. From the drop-down menu, select **Schedule Connectors**  in the **Blocks** section.

### Simulation Results

Click on **View Results in Simulation Data Inspector** in the model to view the results of the simulation.

## Test Harness Generation

You can use the Schedule Editor to generate a test harness for a model with events. Using events with test harnesses helps you avoid complex wiring between the test sequence block and the entire system.

The generated test harness gets its own Schedule Editor, which enables you to easily send events through the test harness. Through the test harness scheduler, you can test the model under different scenarios by triggering events at specific times.

The Events panel also allows you to bind existing events to other aperiodic partitions. You can do this by dragging and dropping the event over a valid aperiodic partition, or by adding the partition

directly using the dropdown. You can order the partitions that have events as their Trigger in the Order table relative to the other partitions. You can also create events in Schedule Editor. Click the plus icon. Double click **Add Row** to create a new event. You can use this event to send from Stateflow to schedule execution of an aperiodic partition.

## Limitations and Error Conditions

- Events in the Schedule Editor cannot be used in models with export-functions.
- Events do not support code generation and do not impact the generated code.

Events in the Schedule Editor use the following guidelines:

- An event cannot be sent before that event has processed.
- Duplicate event names in the parent model caused by giving two model references the same name are not allowed.
- Infinite looping is not allowed.
- A partition cannot send an event that triggers itself.

## Software Component Modeling

### In this section...

“Create Models of Software Components” on page 26-2

“Create Model of Target Environment” on page 26-6

“Test System by Simulating Composition Model” on page 26-7

“Integrate Components into Software Architectures” on page 26-7

“Design Software Architectures” on page 26-7

“Generate Code for Software Components” on page 26-8

Software modeling refers to modeling, simulating, and generating code for algorithms that run in software frameworks. Simulink provides a range of modeling abstractions, semantics, and configuration capabilities that help you create algorithm models that leverage the scheduling, communication, time, memory, diagnostic, and multicore support for these frameworks. For example, when designing a model, you can:

- Partition the design for time- and event-based scheduling.
- Design software component data interfaces.
- Represent call to target platform services such as diagnostic and memory services.
- Configure the model for concurrent execution on multicore systems.
- Create test harnesses and simulate model compositions.
- Integrate with standard middleware software, such as AUTOSAR and DDS.
- Represent complex power-cycle and mode-transition logic.

By using model reference, variant, and data management capabilities, you can design software components for reuse within an application and across software frameworks.

When you use Simulink with Simulink code generation and verification and testing products, you can specify, elaborate, test, and validate software components. You can:

- Model your system in Simulink.
- Simulate the system behavior in a target environment.
- Use Simulink Coder or Embedded Coder to generate code from your algorithm model for rapid prototyping or production, respectively.
- Call generated entry-point functions for initiating function execution and controlling initialization, resets, and shutdowns.
- Use code-sharing capabilities to deploy and integrate generated function-level source code, shared libraries, and application executable programs.

See “Modeling Guidelines” for application-specific guidelines for model architecture, design, and configuration.

### Create Models of Software Components

When you design the functionality of each component in a composition, it is useful to distinguish between the algorithms that are internal to the component and the interaction of the component with target environment software. The algorithm of each software component can be implemented in a

Simulink model, which is referenced as a Model block in the composition in Simulink or as a software component in the composition in System Composer. The model can be used in multiple instances in your design and used for simulation and code generation.

Within a model representing software component, you can further componentize your design. See “Component-Based Modeling Guidelines” on page 23-2. In your componentization, you can use subsystems to establish a hierarchical block diagram and to keep functionally related blocks together. For more information about subsystems, see “Create Subsystems” on page 4-17. You can also use model references to define a set of blocks once and use it repeatedly. Using model references instead of subsystems offers several advantages. For example, model references allow you to do modular development, during which you can develop a referenced model independently from the models that use it. Using model references also allows model protection, using multiple references of the same model, and incremental Simulink loading and code generation. For more information, see “Model Reference Basics” on page 8-2.

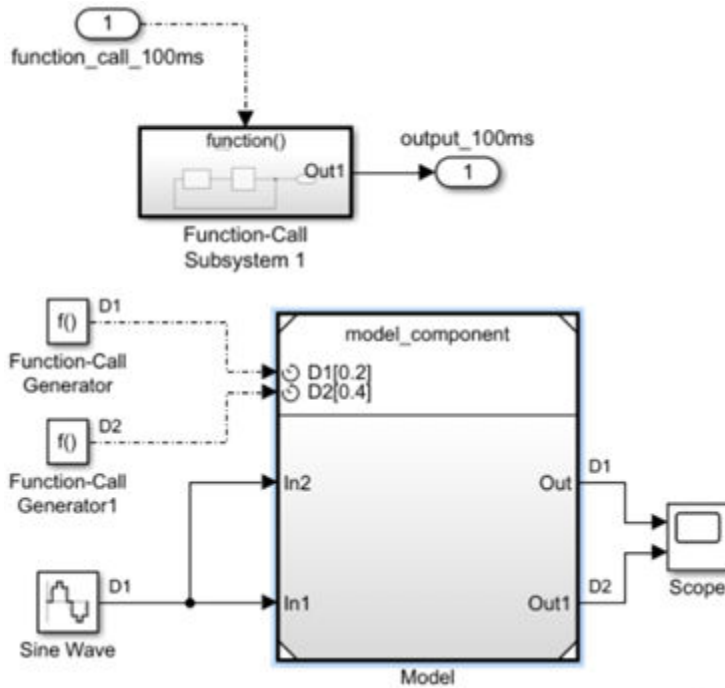

Component-Based Modeling with Model Reference

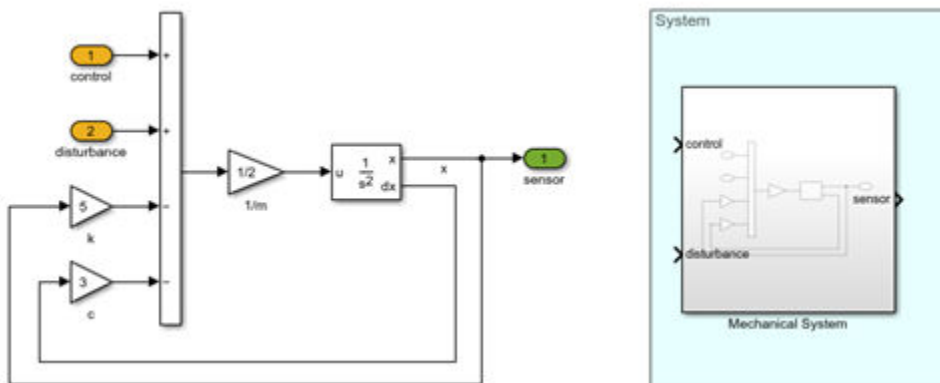

You can create your own custom library of blocks by using the instances of blocks from built-in Simulink libraries or from the blocks or components you create. You can create custom blocks by using legacy code or other custom code. See “Extend Modeling Functionality with Custom Blocks”. Using custom libraries is helpful for providing frequently used and seldom changed modeling utilities and for reusing components in a model or in multiple models. To learn more, see “Create Custom Library” on page 44-2.

To schedule and control the execution of your software component models, you can design each model as an export-function model or a rate-based model. For an export-function model, the code generator produces code for independent callable functions you can integrate with target environment software and a scheduler. See “Export-Function Models Overview” on page 10-96. With a rate-based model, Simulink schedules function execution based on sample times. The code generator produces a callable function for each rate represented in the model. Export-function models provide flexible entry points and customization support, which makes them useful for generating production code. For more information, see “Create an Export-Function Model” on page 10-71 and “Create A Rate-Based Model” on page 10-41.

When you design the interfaces of your components, use In Bus Element or Inport blocks to represent component inputs. A signal or a message arriving at an input port on a component flows out of the associated inport in that component. Similarly, use Out Bus Element or Outport blocks to represent component outputs.

To reduce visual complexity in a model, you can combine signals into buses that are composite signals. Buses contain elements that retain their separate identities, which allows you to extract them from the composite signal. When you group signals into a bus you can decide whether they affect simulation and code generation.

- A *virtual* composite signal simplifies the visual appearance of a model by combining two or more signal lines into one line. It does not group the signals in any functional sense and, therefore, does not affect simulation or code generation. By accessing elements directly, virtual composite signals execute faster than nonvirtual composite signals in simulations and generated code.
- A *nonvirtual* composite signal visually and functionally groups signals, affecting both simulation and code generation.

For more information, see “Choose Among Composite Interfaces” on page 81-5.

For models that include buses composed of many bus elements, consider using In Bus Element and Out Bus Element blocks. These blocks reduce signal line complexity and combine the functionality of Inport and Outport blocks with the ability to choose which elements of a bus to input and output. You can customize data interfaces to your components by defining and using custom bus types. See “Create Nonvirtual Buses” on page 81-34.

You can configure your components to call platform services, such as data sender and receiver and timer services, custom services, such as device drivers, and other component code, or other target environment software, as in a distributed service architecture. Use function call subsystems and function caller blocks together with function ports for this purpose. See “Call Simulink Functions in Other Models Using Function Ports” on page 10-164.

You can configure your components to run as concurrent systems on multicore processor and multiprocessor systems when they are deployed. This configuration can improve performance or enhance scalability of an embedded system. See “Concepts in Multicore Programming” on page 14-2 and “Multicore Programming with Simulink” on page 14-8.

To represent an area of RAM used by a component model, you can use a data store. A data store is a repository from which you can read and to which you can write data without connecting input or output signals to the store, analogous to a global variable in a program. Use Data Store Read and Data Store Write blocks to access data stores. See “Model Global Data by Creating Data Stores” on page 78-10 and “Determine Where to Store Variables and Objects for Simulink Models” on page 72-102.

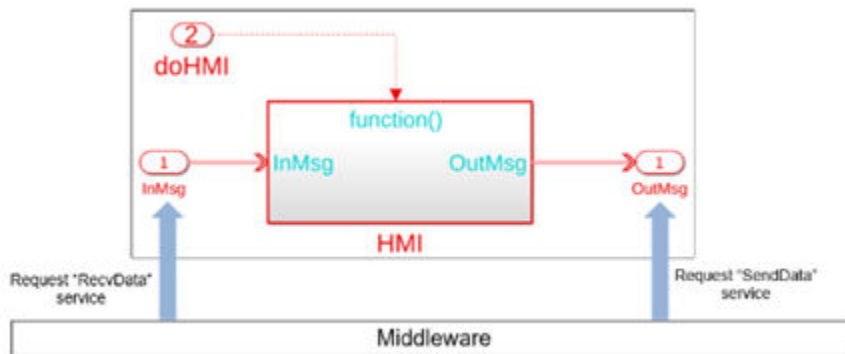

## Create Model of Target Environment

Once you create models of your software components, you can test your design by creating a model to emulate or mock the target environment in which the components will be deployed.

Use messages to model communication between Simulink components for the purpose of system integration.

You can use message-based communication instead of signals for component communication when modeling systems in which centralized architectures are replaced with distributed architectures. A message is a useful modeling artifact that combines events with related data. You can send and receive messages from the root input and output ports of a model and generate C/C++ code to connect to a middleware or an operating system communication programming interface.

For more information, see “Simulink Messages Overview” on page 11-2.

Use Simulink functions to represent callable services such as input and output, memory, diagnostics, and hardware peripherals. See “Simulink Functions Overview” on page 10-114.

To schedule the execution of your software components, you can use the Schedule Editor, a Stateflow chart, or other scheduling blocks such as Function-Call Generator. See “Test Export-Function Model Simulation Using Function-Call Generators” on page 10-78, “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81, and “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85. For rate-based models, you can use the Simulink built-in scheduler, which

schedules tasks based on sample time. For export-function models, you need to schedule execution with explicit calls. See “Create Partitions” on page 25-4.

If you have both export-function and rate-based components, you can use periodic function-call event ports for the rate-based components. You can also schedule them with the Schedule Editor.

You can use event functions to implement startup, shutdown, and mode transition behavior of your system. See “Using Initialize, Reinitialize, Reset, and Terminate Functions” on page 10-172.

## Test System by Simulating Composition Model

Once you have built a model of target environment around your software components, you can simulate the model to test and refine your design.

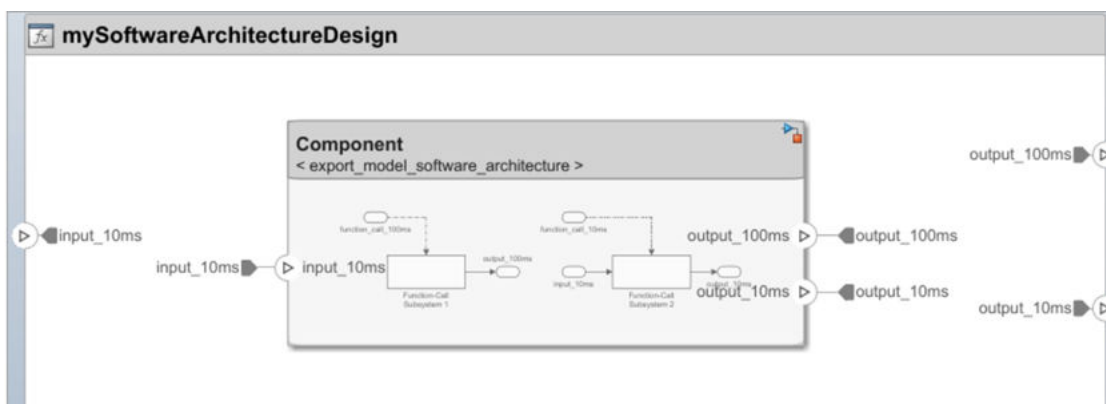

You can observe how the system behaves during simulation and view and analyze resulting data by using the Simulation Data Inspector. See “Investigate Signal Values” on page 80-9. You can also use the Sequence Viewer to visualize the flow of messages and function calls.

You can experiment with different parameter values or variant configurations as you test your system. See “Tune and Experiment with Block Parameter Values” on page 40-31 and “What Are Variants and When to Use Them” on page 12-4.

If you have a Simulink Test license, you can automatically create a test harness model to test your system.

## Integrate Components into Software Architectures

Once you create models in Simulink to represent your software components, you can integrate the components into a software architecture model in System Composer. Add software components to your software architecture model, then link the Simulink models to those components. You can use export-function and rate-based models. Define and create interfaces between components to build the composition. You can then use System Composer to view, analyze, and simulate the composition to help you further refine your design. See “Author Software Architectures” (System Composer).

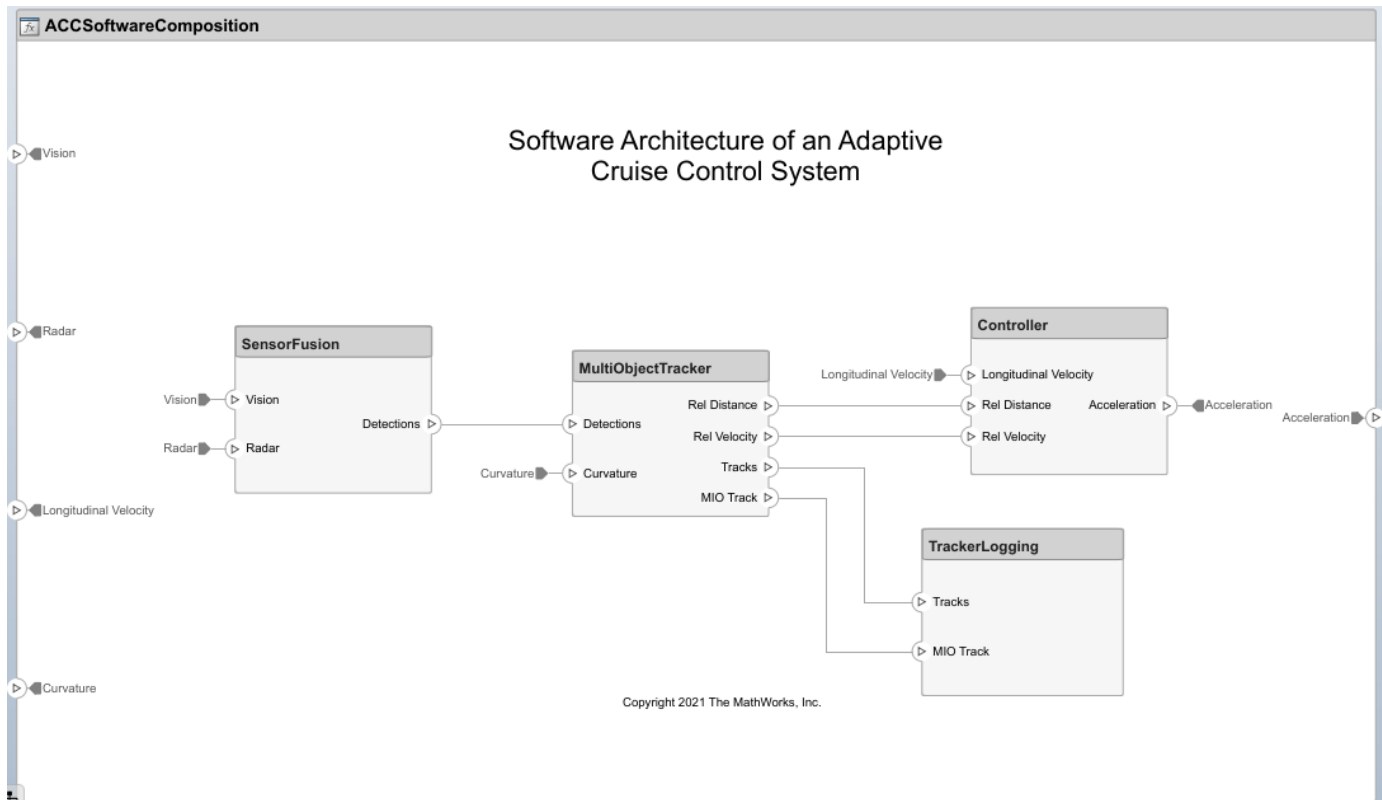

## Design Software Architectures

Before you design the software components themselves, designing the overall architecture of the system in which the components operate can be useful. You can model the high-level behavior of your

system by creating a software architecture model in System Composer. See “Design Software Architectures” (System Composer).

Using System Composer, you can define component interfaces, author functions for your components, analyze your design, and simulate the composition before fully implementing the functionality of your components. See “Author and Extend Functions for Software Architectures” (System Composer).

## Generate Code for Software Components

When you are ready to generate code for the software component, use Embedded Coder to prepare the model for code generation and generate C code. The code that you generate from a model includes entry-point functions, which are called from application code. These functions include an initialization function, execution functions, and, optionally, terminate and reset functions. The functions exchange data with your application code through a data interface that you control. To customize the data interface of the generated code, use the Embedded Coder Dictionary and Code Mappings editor. To test generated code, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer. The PIL simulation then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

To get started, see “Embedded Coder Fundamentals” (Embedded Coder).

## Simulate a Model Interactively

### Simulation Basics

You can simulate a model in the Simulink Editor using the **Run** button  on the toolbar. The **Run** button also appears in tools within the Simulink Editor. You can simulate from any tool that includes the button, such as the Scope viewer.

Before you start a simulation, you can specify options like simulation start time, stop time, and the solver for solving the model. (See “Solver Selection Criteria” on page 27-7) You specify these options in the Configuration Parameters dialog box, which you can open by clicking **Model Settings**  on the **Modeling** tab. These settings are saved with the model in a configuration set. You can create multiple configuration sets for each model and switch between them to see the effects of different settings. See “Model Configuration Sets”.

By default, simulations start at 0.0 s and end at 10.0 s.

---

**Note** In the Simulink software, time and all related parameters (such as sample times) are implicitly in seconds. If you choose to use a different time unit, scale parameters accordingly.

---

The **Solver** configuration pane allows you to specify other start and stop times for the currently selected simulation configuration. See “Solver Pane” for more information.

---

**Note** Simulation time and actual clock time are not the same. For example, if running a simulation for 10 s usually does not take 10 s as measured on a clock. The amount of time it actually takes to run a simulation depends on many factors including the complexity of the model, the step sizes, and the computer speed.

---

After you set your model configuration parameters, you can start the simulation. You can pause, resume, and stop simulation using toolbar controls. You can also simulate more than one model at a time, so you can start another simulation while one is running.

During simulation, you cannot make changes to the structure of the model, such as adding or deleting lines or blocks. However, you can make these changes while a simulation is running:

- Modify some configuration parameters, including the stop time and the maximum step size.
- Modify the parameters of a block, as long as you do not cause a change in:
  - Number of states, inputs, or outputs
  - Sample time
  - Number of zero crossings
  - Vector length of any block parameters
  - Length of the internal block work vectors
  - Dimension of any signals

You can also examine the model visually as it simulates. For example, you can click a line to see the signal carried on that line on a Floating Scope or Display block. You can also display port values as a model simulates. See “Display Port Values for Debugging” on page 39-18.

## Run, Pause, and Stop a Simulation

To start simulating your model, click the **Run** button . You can pause, resume, or stop a simulation using the corresponding controls on the toolbar.

The model starts simulating at the specified start time and runs until the specified end time. While the simulation is running, information at the bottom of the editor shows the percentage of simulation completed and the current simulation time.

- If an error occurs, simulation stops and a message appears. If a warning condition occurs, simulation completes. In both cases, click the diagnostics link at the bottom of the editor to see the message, which helps you to locate errors.
- Pausing takes effect after the current time step finishes executing. Resuming a paused simulation occurs at the next time step.
- If you stop a simulation, the current time step completes, and then simulation stops.
- If the model outputs to a file or to the workspace, stopping or pausing simulation writes the data.

## Use Blocks to Stop or Pause a Simulation

### Stop Simulation Using Stop Simulation Blocks

You can use the Stop Simulation block to stop a simulation when the input to the block is nonzero. If the block input is a vector, any nonzero element stops the simulation.

- 1 Add a Stop Simulation block to your model.
- 2 Connect the Stop Simulation block to a signal whose value becomes nonzero at the specified stop time.

For example, this model stops the simulation when the simulation time reaches 10.

## Pause Simulation Using Assertion Blocks

You can use an Assertion block to pause the simulation when the input signal to the block is zero. The Assertion block uses the `set_param` command to pause the simulation. See “Run Simulations Programmatically” on page 28-2 for more information on using the `set_param` command to control the execution of a Simulink model.

- 1 Add an Assertion block to your model.
- 2 Connect the Assertion block to a signal whose value becomes zero at the desired pause time.
- 3 In the Assertion block dialog box, clear the **Stop simulation when assertion fails** check box. Enter this command as the value of **Simulation callback when assertion fails**:

```
set_param(bdroot, 'SimulationCommand', 'pause'),
disp(sprintf('\nSimulation paused.'))
```

This model uses an Assertion block with these settings to pause the simulation when the simulation time reaches 5.

When the simulation pauses, a message appears that shows the time the block paused the simulation.

You can resume the simulation using **Continue** as you can for any paused simulation.

## Local Solver Basics

When a local solver is enabled, Simulink solves model reference as a separate differential equation with its own solver. Both a different solver and a different step size can be used. The top solver and local solver work together to integrate continuous states in the model. The local solver is responsible for all continuous states inside the model reference, while the top solver is responsible for all other states elsewhere in the model, including those in other model references that do not have a local solver.

At each step, the simulation loop executes output, update, and advance phases. Typically, states are integrated forward in the advance phase. When you use a local solver, the local states are integrated during the update phase for the model reference. The other states of the model are integrated during the advance phase. Because the states in the model reference with a local solver are integrated before the rest of the states in the model, advancing the local solver can require extrapolation. You can control the extrapolation method using the Input Signal Handling parameter.

When you use a local solver, you can specify both a different solver and a different step size, which means that the time steps taken by the local solver may not match the time steps taken by the solver for the top model. When the top solver and local solver take different time steps, the software interpolates the outputs of the model reference. You can control the interpolation method using the Output Signal Handling parameter.

The result of a simulation that uses a local solver might differ from the result of an equivalent simulation that solves the model with one solver, because using a local solver involves interpolation and extrapolation.

### Why Use Local Solver?

You can speed up simulation by using an inexpensive solver on a subset of the model. An inexpensive solver could be a lower-order solver, for example, using an `ode1` solver instead of `ode3`, or using a solver with a larger step size.

The choice of solver and step size involves a tradeoff between computational cost and accuracy. A local solver allows you to fine-tune this tradeoff for different subsections of the model.

### Tips

In addition to a cost-accuracy tradeoff, a local solver can introduce further inaccuracies due to the interpolations or extrapolations it requires to communicate with the rest of the model. Input and output signal handing can mitigate some of these effects, but are not always appropriate. Follow these guidelines to get the most out of local solver usage.

- Use the `Zero-Order Hold` option in the Input Signal Handling parameter for these situations:
  - To achieve lowest computational cost
  - When the model has no input ports, when the input ports do not drive continuous derivatives, or when a significant portion of the derivative is based on the state itself, for example, from feedback loops in the model.
  - To improve stability of the local solver at a given step size
- Use the `Auto` input signal handling option to apply extrapolation and improve accuracy.

- Use the Zero-Order Hold output signal handling option for lowest computational cost.
- Use the Auto output signal handling option to apply interpolation and potentially improve accuracy.
- Look for subsections of the model with time constants separated by several orders of magnitude. These subsections may often correspond to different modeling domains, such as electrical versus mechanical.

Additionally, you can easily apply a local solver if some states are completely disconnected from others, for example, if a model contains two dynamic systems in the model that do not interact.

- Local solvers are not supported for models that do not have continuous states. A local solver has no effect on discrete states, which always run at their registered sample time.

## Considerations

- The top solver can be fixed step or variable step. The local solver must be fixed step.
- If the top solver is fixed step, then the step size for the local solver must be greater than or equal to the step size for the top solver.
- Local solvers are supported only for the second level of the model hierarchy. You can configure a local solver for a model referenced by a Model block in the top model. You cannot configure a local solver on a Model block inside a model reference.
- To use a local solver, the model must have continuous states.
- The top solver must use the full perturbation solver Jacobian method, and this parameter only applies when the top solver is implicit. For more information on Jacobian methods, see “Choose a Jacobian Method for an Implicit Solver” on page 27-11.

## Choose a Solver

To simulate a dynamic system, you compute its states at successive time steps over a specified time span. This computation uses information provided by a model of the system. Time steps are time intervals when the computation happens. The size of this time interval is called step size. The process of computing the states of a model in this manner is known as solving the model. No single method of solving a model applies to all systems. Simulink provides a set of programs called solvers. Each solver embodies a particular approach to solving a model.

A solver applies a numerical method to solve the set of ordinary differential equations that represent the model. Through this computation, it determines the time of the next simulation step. In the process of solving this initial value problem, the solver also satisfies the accuracy requirements that you specify.

Mathematicians have developed a wide variety of numerical integration techniques for solving the ordinary differential equations (ODEs) that represent the continuous states of dynamic systems. An extensive set of fixed-step and variable-step continuous solvers are provided, each of which implements a specific ODE solution method (see “Compare Solvers” on page 3-6). Select solvers in the **Solver** pane of model configuration parameters.

All solvers provided by MATLAB and Simulink follow a similar naming convention: **ode**, followed by two or three numerals indicating the orders of the solver. Some solvers can solve stiff differential equations and the methods used by them are expressed by the **s**, **t**, or **tb** suffixes.

### Solver Selection Criteria

The appropriate solver for simulating a model depends on these characteristics:

- System dynamics
- Solution stability
- Computation speed
- Solver robustness

As such, the numerical solvers provided by Simulink can be broadly classified by two properties.

#### Computation Step Size Type

- Fixed-step solvers, as the name suggests, solve the model using the same step size from the beginning to the end of the simulation. You can specify the step size or let the solver choose it. Generally, decreasing the step size increases the accuracy of the results and the time required to simulate the system.
- Variable-step solvers vary the step size during the simulation. These solvers reduce the step size to increase accuracy at certain events during the simulation of the model, such as rapid state changes, zero-crossing events, etc. Also, they increase the step size to avoid taking unnecessary steps when the states of a model change slowly. Computing the step size adds to the computational overhead at each step. However, it can reduce the total number of steps, and hence the simulation time required to maintain a specified level of accuracy for models with zero-crossings, rapidly changing states, and other events requiring extra computation.

#### Model States

- Continuous solvers use numerical integration to compute continuous states of a model at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on individual blocks to compute the values of the discrete states of the model at each time step.
- Discrete solvers are primarily used for solving purely discrete models. They compute only the next simulation time step for a model. When they perform this computation, they rely on each block in the model to update its individual discrete state. They do not compute continuous states.

Use an iterative approach to choose a solver for your requirements. Compare simulation results from several solvers and select a solver that offers the best performance with minimal tradeoffs.

Select a solver for your model in these ways:

- Use auto solver. New models have their solver selection set to auto solver by default. Auto solver recommends a fixed-step or variable-step solver for your model as well as the maximum step size. For more information, see “Select Solver Using Auto Solver” on page 27-40.
- If you are not satisfied with the simulation results using auto solver, select a solver in the **Solver** pane in the model configuration parameters.

When you build and simulate a model, you can choose the solver based on the dynamics of your model. A variable-step solver is better suited for purely continuous models, like the dynamics of a mass spring damper system. A fixed-step solver is recommended for a model that contains several switches, like an inverter power system, due to the number of solver resets that would cause a variable-step solver to behave like a fixed-step solver.

---

**Note** When you deploy a model as generated code, you can use only a fixed-step solver. If you select a variable-step solver during simulation, use it to calculate the step size required for the fixed-step solver that you need at deployment.

---

This chart provides a broad classification of solvers in the Simulink library.

To tailor the selected solver to your model, see “Check and Improve Simulation Accuracy” on page 34-11.

Ideally, the solver you select should:

- Solve the model successfully.
- For variable-step solvers, provide a solution within the tolerance limits you specify.
- Solve the model in a reasonable duration.

A single solver might not meet all of these goals. Try simulating using different solvers before making a selection.

The Simulink library provides several solvers, all of which can work with the algebraic loop solver. For more information, see “How the Algebraic Loop Solver Works” on page 3-42.

Solver Type	Explicit/ Implicit	Discrete	Continuous	Variable-Order
Fixed-Step	Explicit	Not Applicable	“Fixed-Step Continuous Explicit Solvers” on page 27-24	Not Applicable

Solver Type	Explicit/ Implicit	Discrete	Continuous	Variable-Order

## Choose a Jacobian Method for an Implicit Solver

For implicit solvers, Simulink must compute the *solver Jacobian*, which is a submatrix of the Jacobian matrix associated with the continuous representation of a Simulink model. In general, this continuous representation is of the form:

$$\begin{aligned}\dot{x} &= f(x, t, u) \\ y &= g(x, t, u).\end{aligned}$$

The Jacobian,  $J$ , formed from this system of equations is:

$$J = \begin{pmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial u} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial u} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

In turn, the solver Jacobian is the submatrix,  $J_x$ .

$$J_x = A = \frac{\partial f}{\partial x}.$$

### Sparsity of Jacobian

For many physical systems, the solver Jacobian  $J_x$  is *sparse*, meaning that many of the elements of  $J_x$  are zero.

Consider the following system of equations:

$$\begin{aligned}\dot{x}_1 &= f_1(x_1, x_3) \\ \dot{x}_2 &= f_2(x_2) \\ \dot{x}_3 &= f_3(x_2).\end{aligned}$$

From this system, you can derive a sparsity pattern that reflects the structure of the equations. The pattern, a Boolean matrix, has a 1 for each  $x_i$  that appears explicitly on the right-hand side of an equation. Therefore, you obtain:

$$J_{x, pattern} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

The sparse perturbation and the sparse analytical methods may be able to take advantage of this sparsity pattern to reduce the number of computations necessary and improve performance.

### Solver Jacobian Methods

When you choose an implicit solver from the **Solver** pane of the configuration parameters dialog box, a parameter called **Solver Jacobian method** and a drop-down menu appear. This menu has five options for computing the solver Jacobian.

**Note** If you set **Automatic solver parameter selection** to **error** in the Solver Diagnostics pane, and you choose a different solver than that suggested by Simulink, you may receive an error.

## Limitations

The solver Jacobian methods have these limitations associated with them.

- If you select an analytical Jacobian method, but one or more blocks in the model do not have an analytical Jacobian, then Simulink applies a perturbation method.
- If you select sparse perturbation and your model contains data store blocks, Simulink applies the full perturbation method.

## Heuristic 'auto' Method

The default setting for the Solver Jacobian method is **auto**. Selecting this choice causes Simulink to determine which of the remaining four methods best suits your model. This flowchart depicts the algorithm.

Sparse methods are beneficial for models that have a large number of states. If 50 or more states exist in your model, `auto` chooses a sparse method. Unlike other implicit solvers, `ode23s` is a sparse method because it generates a new Jacobian at every time step. A sparse analytical or a sparse perturbation method is, therefore, advantageous. Selecting `auto` also ensures that the analytical methods are used only if every block in your model can generate an analytical Jacobian.

## Full and Sparse Perturbation Methods

The full perturbation method solves the full set of perturbation equations and uses LAPACK for linear algebraic operations. This method is costly from a computational standpoint, but remains a recommended method for establishing baseline results.

The sparse perturbation method attempts to improve the run-time performance by taking mathematical advantage of the sparse Jacobian pattern. Returning to the sample system of three equations and three states,

$$\dot{x}_1 = f_1(x_1, x_3)$$

$$\dot{x}_2 = f_2(x_2)$$

$$\dot{x}_3 = f_3(x_2).$$

The solver Jacobian is:

$$J_x = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} & \frac{\partial f_1}{\partial x_3} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} & \frac{\partial f_2}{\partial x_3} \\ \frac{\partial f_3}{\partial x_1} & \frac{\partial f_3}{\partial x_2} & \frac{\partial f_3}{\partial x_3} \end{pmatrix}$$

$$= \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2, x_3) - f_1}{\Delta x_1} & \frac{f_1(x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_2} & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ \frac{f_2(x_1 + \Delta x_1, x_2, x_3) - f_2}{\Delta x_1} & \frac{f_2(x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & \frac{f_2(x_1, x_2, x_3 + \Delta x_3) - f_2}{\Delta x_3} \\ \frac{f_3(x_1 + \Delta x_1, x_2, x_3) - f_3}{\Delta x_1} & \frac{f_3(x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & \frac{f_3(x_1, x_2, x_3 + \Delta x_3) - f_3}{\Delta x_3} \end{pmatrix}$$

It is, therefore, necessary to perturb each of the three states three times and to evaluate the derivative function three times. For a system with  $n$  states, this method perturbs the states  $n$  times.

By applying the sparsity pattern and perturbing states  $x_1$  and  $x_2$  together, this matrix reduces to:

$$J_x = \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_1} & 0 & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ 0 & \frac{f_2(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & 0 \\ 0 & \frac{f_3(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & 0 \end{pmatrix}$$

The solver can now solve columns 1 and 2 in one sweep. While the sparse perturbation method saves significant computation, it also adds overhead to compilation. It might even slow down the simulation if the system does not have a large number of continuous states. A tipping point exists for which you obtain increased performance by applying this method. In general, systems having a large number of continuous states are usually sparse and benefit from the sparse method.

The sparse perturbation method, like the sparse analytical method, uses UMFPACK to perform linear algebraic operations. Also, the sparse perturbation method supports both RSim and rapid accelerator mode.

## Full and Sparse Analytical Methods

The full and sparse analytical methods attempt to improve performance by calculating the Jacobian using analytical equations rather than the perturbation equations. The sparse analytical method, also uses the sparsity information to accelerate the linear algebraic operations required to solve the ordinary differential equations.

For details on how to access and interpret the sparsity pattern in MATLAB, see “Exploring the Solver Jacobian Structure of a Model”.

## **Code Generation Support**

While the sparse perturbation method supports RSim, the sparse analytical method does not. Consequently, regardless of which sparse method you select, any generated code uses the sparse perturbation method. This limitation applies to rapid accelerator mode as well.

## Variable Step Solvers in Simulink

Variable-step solvers vary the step size during the simulation, reducing the step size to increase accuracy when model states are changing rapidly and increasing the step size to avoid taking unnecessary steps when model states are changing slowly. Computing the step size adds to the computational overhead at each step but can reduce the total number of steps, and hence simulation time, required to maintain a specified level of accuracy for models with rapidly changing or piecewise continuous states.

When you set the **Type** control of the **Solver** configuration pane to **Variable-step**, the **Solver** control allows you to choose one of the variable-step solvers. As with fixed-step solvers, the set of variable-step solvers comprises a discrete solver and a collection of continuous solvers. However, unlike the fixed-step solvers, the step size varies dynamically based on the local error.

The choice between the two types of variable-step solvers depends on whether the blocks in your model define states and, if so, the type of states that they define. If your model defines no states or defines only discrete states, select the discrete solver. If the model has continuous states, the continuous solvers use numerical integration to compute the values of the continuous states at the next time step.

---

**Note** If a model has no states or only discrete states, Simulink uses the discrete solver to simulate the model even if you specify a continuous solver.

---

### Variable-Step Discrete Solver

Use the variable-step discrete solver when your model does not contain continuous states. For such models, the variable-step discrete solver reduces its step size in order to capture model events such as zero-crossings, and increases the step size when it is possible to improve simulation performance.

The model shown in the figure contains two discrete sine wave signals at 0.5 and 0.75 sample times. The graphs below show the signals in the model along with the solver steps for the variable-step discrete and the fixed-step discrete solvers respectively. You can see that the variable-step solver only

takes the steps needed to record the output signal from each block. On the other hand, the fixed-step solver will need to simulate with a fixed-step size—or fundamental sample time—of 0.25 to record all the signals, thus taking more steps overall.

## Variable-Step Continuous Solvers

Variable-step solvers dynamically vary the step size during the simulation. Each of these solvers increases or reduces the step size using its local error control to achieve the tolerances that you specify. Computing the step size at each time step adds to the computational overhead. However, it can reduce the total number of steps, and the simulation time required to maintain a specified level of accuracy.

You can further categorize the variable-step continuous solvers as one-step or multistep, single-order or variable-order, and explicit or implicit. See “One-Step Versus Multistep Continuous Solvers” on page 3-8 for more information.

### Variable-Step Continuous Explicit Solvers

The variable-step explicit solvers are designed for nonstiff problems. Simulink provides four such solvers:

- ode45
- ode23
- ode113
- odeN

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode45	X		Medium	Runge-Kutta, Dormand-Prince (4,5) pair
ode23	X		Low	Runge-Kutta (2,3) pair of Bogacki & Shampine

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode113		X	Variable, Low to High	PECE Implementation of Adams-Bashforth-Moulton
odeN	X		See <b>Order of Accuracy</b> in “Fixed-Step Continuous Explicit Solvers” on page 27-24	See <b>Integration Technique</b> in “Fixed-Step Continuous Explicit Solvers” on page 27-24

ODE Solver	When to Use
ode45	In general, the ode45 solver is the best to apply as a first try for most problems. The Runge-Kutta (4,5) solver is a fifth-order method that performs a fourth-order estimate of the error. This solver also uses a fourth-order interpolant, which allows for event location and smoother plots.  If the ode45 is computationally slow, the problem may be stiff and thus require an implicit solver.
ode113	For problems with stringent error tolerances or for computationally intensive problems, the Adams-Bashforth-Moulton PECE solver can be more efficient than ode45.
ode23	The ode23 can be more efficient than the ode45 solver at crude error tolerances and in the presence of mild stiffness. This solver provides accurate solutions by applying a cubic Hermite interpolation to the values and slopes computed at the ends of a step.
odeN	The odeN solver uses a nonadaptive Runge-Kutta integration whose order is determined by the <b>Solver order</b> parameter. odeN uses a fixed step size determined by the <b>Max step size</b> parameter, but the step size can be reduced to capture certain solver events, such as zero-crossings and discrete sample hits.

**Note** Select the odeN solver when simulation speed is important, for example, when

- The model contains lots of zero-crossings and/or solver resets
- The **Solver Profiler** does not detect any failed steps when profiling the model

## Variable-Step Continuous Implicit Solvers

If your problem is stiff, try using one of the variable-step implicit solvers:

- ode15s
- ode23s
- ode23t
- ode23tb

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Solver Reset Method	Max. Order	Method
ode15s		X	Variable, low to medium	X	X	Numerical Differentiation Formulas (NDFs)
ode23s	X		Low			Second-order, modified Rosenbrock formula
ode23t	X		Low	X		Trapezoidal rule using interpolant
ode23tb	X		Low	X		TR-BDF2

### Solver Reset Method

For ode15s, ode23t, and ode23tb a drop-down menu for the **Solver reset method** appears in the **Solver details** section of the Configuration pane. This parameter controls how the solver treats a reset caused, for example, by a zero-crossing detection. The options allowed are **Fast** and **Robust**. **Fast** specifies that the solver does not recompute the Jacobian for a solver reset, whereas **Robust** specifies that the solver does. Consequently, the **Fast** setting is computationally faster but it may use a small step size in certain cases. To test for such cases, run the simulation with each setting and compare the results. If there is no difference in the results, you can safely use the **Fast** setting and save time. If the results differ significantly, try reducing the step size for the fast simulation.

### Maximum Order

For the ode15s solver, you can choose the maximum order of the numerical differentiation formulas (NDFs) that the solver applies. Since the ode15s uses first- through fifth-order formulas, the **Maximum order** parameter allows you to choose orders 1 through 5. For a stiff problem, you may want to start with order 2.

### Tips for Choosing a Variable-Step Implicit Solver

The following table provides tips for the application of variable-step implicit solvers. For an example comparing the behavior of these solvers, see “Explore Variable-Step Solvers with Stiff Model”.

ODE Solver	Tips on When to Use
ode15s	ode15s is a variable-order solver based on the numerical differentiation formulas (NDFs). NDFs are related to, but are more efficient than the backward differentiation formulas (BDFs), which are also known as Gear's method. The ode15s solver numerically generates the Jacobian matrices. If you suspect that a problem is stiff, or if ode45 failed or was highly inefficient, try ode15s. As a rule, start by limiting the maximum order of the NDFs to 2.
ode23s	ode23s is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it can be more efficient than ode15s at crude tolerances. Like ode15s, ode23s numerically generates the Jacobian matrix for you. However, it can solve certain kinds of stiff problems for which ode15s is not effective.
ode23t	The ode23t solver is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if your model is only moderately stiff and you need a solution without numerical damping. (Energy is not dissipated when you model oscillatory motion.)

ODE Solver	Tips on When to Use
ode23tb	ode23tb is an implementation of TR-BDF2, an implicit Runge-Kutta formula with two stages. The first stage is a trapezoidal rule step while the second stage uses a backward differentiation formula of order 2. By construction, the method uses the same iteration matrix in evaluating both stages. Like ode23s, this solver can be more efficient than ode15s at crude tolerances.

**Note** For a stiff problem, solutions can change on a time scale that is very small as compared to the interval of integration, while the solution of interest changes on a much longer time scale. Methods that are not designed for stiff problems are ineffective on intervals where the solution changes slowly because these methods use time steps small enough to resolve the fastest possible change. For more information, see Shampine, L. F., *Numerical Solution of Ordinary Differential Equations*, Chapman & Hall, 1994.

## Error Tolerances for Variable-Step Solvers

### Local Error

The variable-step solvers use standard control techniques to monitor the local error at each time step. During each time step, the solvers compute the state values at the end of the step and determine the *local error*—the estimated error of these state values. They then compare the local error to the *acceptable error*, which is a function of both the relative tolerance (*rtol*) and the absolute tolerance (*atol*). If the local error is greater than the acceptable error for *any one* state, the solver reduces the step size and tries again.

- Relative tolerance measures the error relative to the size of each state. The relative tolerance represents a percentage of the state value. The default, 1e-3, means that the computed state is accurate to within 0.1%.
- Absolute tolerance is a threshold error value. This tolerance represents the acceptable error as the value of the measured state approaches zero.

The solvers require the error for the  $i$ th state,  $e_i$ , to satisfy:

$$e_i \leq \max(\text{rtol} \times |x_i|, \text{atol}_i).$$

The following figure shows a plot of a state and the regions in which the relative tolerance and the absolute tolerance determine the acceptable error.

### Absolute Tolerances

Your model has a global absolute tolerance that you can set on the Solver pane of the Configuration Parameters dialog box. This tolerance applies to all states in the model. You can specify `auto` or a

real scalar. If you specify `auto` (the default), Simulink initially sets the absolute tolerance for each state based on the relative tolerance. If the relative tolerance is larger  $1e-3$ , `abstol` is initialized at  $1e-6$ . However, for `reltol` smaller than  $1e-3$ , `abstol` for the state is initialized at `reltol * 1e-3`. As the simulation progresses, the absolute tolerance for each state resets to the maximum value that the state has assumed so far, times the relative tolerance for that state. Thus, if a state changes from 0 to 1 and `reltol` is  $1e-3$ , `abstol` initializes at  $1e-6$  and by the end of the simulation reaches  $1e-3$  also. If a state goes from 0 to 1000, then `abstol` changes to 1.

Now, if the state changes from 0 to 1 and `reltol` is set at  $1e-4$ , then `abstol` initializes at  $1e-7$  and by the end of the simulation reaches a value of  $1e-4$ .

If the computed initial value for the absolute tolerance is not suitable, you can determine an appropriate value yourself. You might have to run a simulation more than once to determine an appropriate value for the absolute tolerance. You can also specify if the absolute tolerance should adapt similarly to its `auto` setting by enabling or disabling the `AutoScaleAbsTol` parameter. For more information, see “Auto scale absolute tolerance”.

Several blocks allow you to specify absolute tolerance values for solving the model states that they compute or that determine their output:

- Integrator
- Second-Order Integrator
- Variable Transport Delay
- Transfer Fcn
- State-Space
- Zero-Pole

The absolute tolerance values that you specify for these blocks override the global settings in the Configuration Parameters dialog box. You might want to override the global setting if, for example, the global setting does not provide sufficient error control for all of your model states because they vary widely in magnitude. You can set the block absolute tolerance to:

- `auto`
- `-1` (same as `auto`)
- `positive scalar`
- `real vector` (having a dimension equal to the number of corresponding continuous states in the block)

### Tips

If you do choose to set the absolute tolerance, keep in mind that too low of a value causes the solver to take too many steps in the vicinity of near-zero state values. As a result, the simulation is slower.

On the other hand, if you set the absolute tolerance too high, your results can be inaccurate as one or more continuous states in your model approach zero.

Once the simulation is complete, you can verify the accuracy of your results by reducing the absolute tolerance and running the simulation again. If the results of these two simulations are satisfactorily close, then you can feel confident about their accuracy.

## Fixed Step Solvers in Simulink

Fixed-step solvers solve the model at regular time intervals from the beginning to the end of the simulation. The size of the interval is known as the step size. You can specify the step size or let the solver choose the step size. Generally, a smaller the step size increases the accuracy of the results but also increases the time required to simulate the system.

### Fixed-Step Discrete Solver

The fixed-step discrete solver computes the time of the next simulation step by adding a fixed step size to the current time. The accuracy and the length of time of the resulting simulation depends on the size of the steps taken by the simulation: the smaller the step size, the more accurate the results are but the longer the simulation takes. By default, Simulink chooses the step size or you can choose the step size yourself. If you choose the default setting of `auto`, and if the model has discrete sample times, then Simulink sets the step size to the fundamental sample time of the model. Otherwise, if no discrete rates exist, Simulink sets the size to the result of dividing the difference between the simulation start and stop times by 50.

### Fixed-Step Continuous Solvers

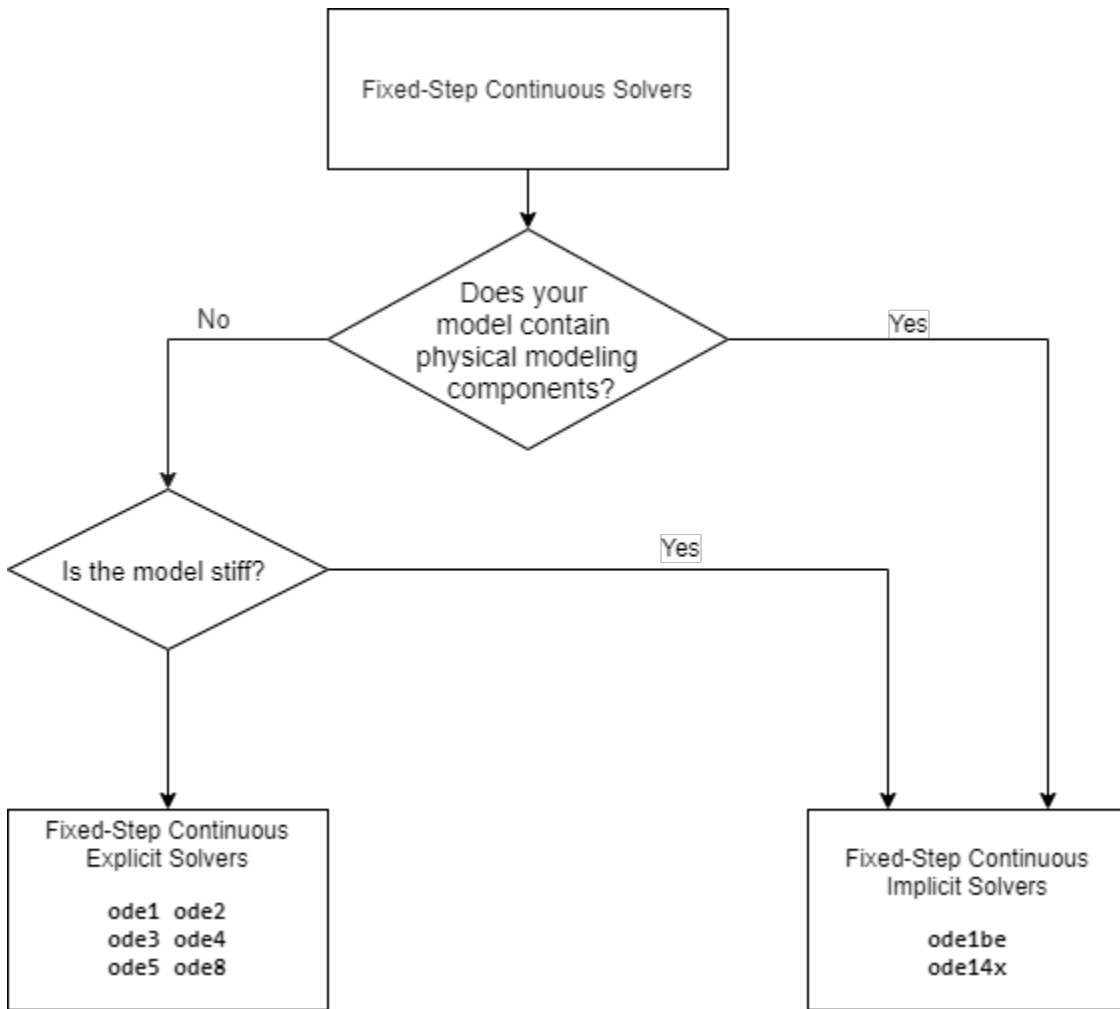

The fixed-step continuous solvers, like the fixed-step discrete solver, compute the next simulation time by adding a fixed-size time step to the current time. For each of these steps, the continuous solvers use numerical integration to compute the values of the continuous states for the model. These values are calculated using the continuous states at the previous time step and the state derivatives at intermediate points (minor steps) between the current and the previous time step.

---

**Note** Simulink uses the fixed-step discrete solver for a model that contains no states or only discrete states, even if you specify a fixed-step continuous solver for the model.

---

Simulink provides two types of fixed-step continuous solvers — explicit and implicit.

The difference between these two types lies in the speed and the stability. An implicit solver requires more computation per step than an explicit solver but is more stable. Therefore, the implicit fixed-step solver that Simulink provides is more adept at solving a stiff system than the fixed-step explicit solvers. For a comparison of explicit and implicit solvers, see “Explicit Versus Implicit Continuous Solvers” on page 3-8.

### Fixed-Step Continuous Explicit Solvers

Explicit solvers compute the value of a state at the next time step as an explicit function of the current values of both the state and the state derivative. A fixed-step explicit solver is expressed mathematically as:

$$x(n + 1) = x(n) + h * Dx(n)$$

where

- $x$  is the state.
- $Dx$  is a solver-dependent function that estimates the state derivative.
- $h$  is the step size.

- $n$  indicates the current time step.

Simulink provides a set of fixed-step continuous explicit solvers. The solvers differ in the specific numerical integration technique that they use to compute the state derivatives of the model. This table lists each solver and the integration technique it uses. The table lists the solvers in the order of the computational complexity of the integration methods they use, from the least complex (ode1) to the most complex (ode8).

Solver	Integration Technique	Order of Accuracy
ode1	Euler's method	First
ode2	Heun's method	Second
ode3	Bogacki-Shampine formula	Third
ode4	Fourth-order Runge-Kutta (RK4) formula	Fourth
ode5	Dormand-Prince (RK5) formula	Fifth
ode8	Dormand-Prince RK8(7) formula	Eighth

None of these solvers have an error control mechanism. Therefore, the accuracy and the duration of a simulation depend directly on the size of the steps taken by the solver. As you decrease the step size, the results become more accurate, but the simulation takes longer. Also, for any given step size, the higher the order of the solver, the more accurate the simulation results.

If you specify a fixed-step solver type for a model, then by default, Simulink selects the `FixedStepAuto` solver. Auto solver then selects an appropriate fixed-step solver that can handle both continuous and discrete states with moderate computational effort. As with the discrete solver, if the model has discrete rates (sample times), then Simulink sets the step size to the fundamental sample time of the model by default. If the model has no discrete rates, Simulink automatically uses the result of dividing the simulation total duration by 50. Consequently, the solver takes a step at each simulation time at which Simulink must update the discrete states of the model at its specified sample rates. However, it does not guarantee that the default solver accurately computes the continuous states of a model. Therefore, you may need to choose another solver, a different fixed step size, or both to achieve acceptable accuracy and an acceptable simulation time.

### Fixed-Step Continuous Implicit Solvers

An implicit solver computes the state at the next time step as an implicit function of the state at the current time step and the state derivative at the next time step, as described by the following expression.

$$x(n + 1) - x(n) - h * Dx(n + 1) = 0$$

Simulink provides two fixed-step implicit solvers: `ode14x` and `ode1be`. This solver uses a combination of Newton's method and extrapolation from the current value to compute the value of a state at the next time step. You can specify the number of Newton's method iterations and the extrapolation order that the solver uses to compute the next value of a model state. See "Fixed-step size (fundamental sample time)". The more iterations and the higher the extrapolation order that you select, the greater the accuracy you obtain. However, you simultaneously create a greater computational burden per step size.

## Choose a Fixed-Step Solver

This example shows an algorithmic method of selecting an appropriate fixed-step solver for your model. For simulation workflows in Simulink, the default setting for the **Solver** parameter in the Model Configuration Parameters is `auto`. The heuristics used by Simulink to select a variable-step solver is shown in the figure below.

**Auto Solver Heuristics**

The solver type is		The system has		Continuous states	
		Only discrete states			The system is an ordinary differential equation (ODE)
Fixed-Step	FixedStepDiscrete			ode3	
				ode14x	
Variable-Step	VariableStepDiscrete			The model is stiff	The model is non-stiff
				ode15s	ode45

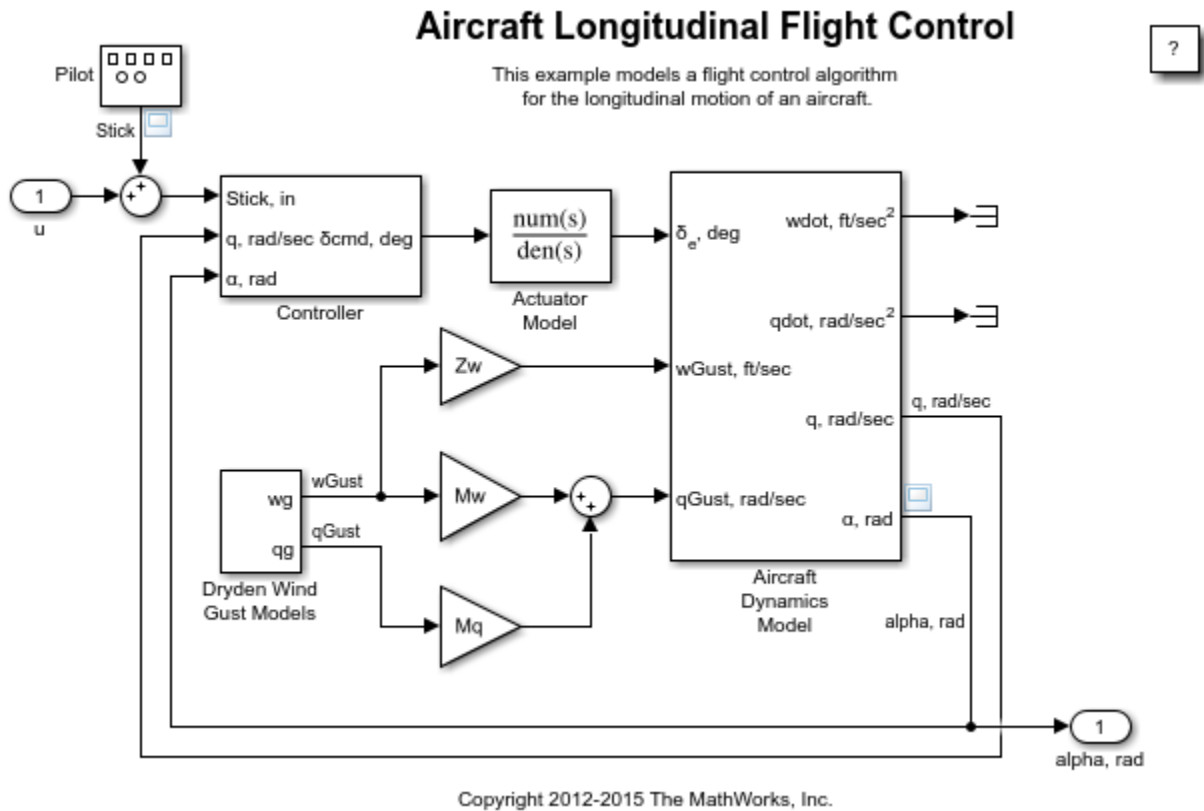

### When to Use a Fixed-Step Solver

One common case to use a fixed-step solver is for workflows where you plan to generate code from your model and run the code on a real-time system.

With a variable-step solver, the step size can vary from step to step, depending on the model dynamics. In particular, a variable-step solver increases or reduces the step size to meet the error tolerances that you specify and as such, the variable step sizes cannot be mapped to the real-time clock of a target system.

Any of the fixed-step continuous solvers in the Simulink product can simulate a model to any desired level of accuracy, given a small enough step size. Unfortunately, it is not possible or practical to decide without trial, the combination of solver and step size that will yield acceptable results for the continuous states in the shortest time. Determining the best solver for a particular model generally requires experimentation.

The example model represents the flight control algorithm for the longitudinal flight of an aircraft.

## Establish Baseline Results Using a Variable-Step Solver

Before you begin simulation, determine acceptable error tolerances for your variable-step solver. The model is currently set up with the default values of absolute and relative tolerances of  $1e-6$  and  $1e-4$  respectively.

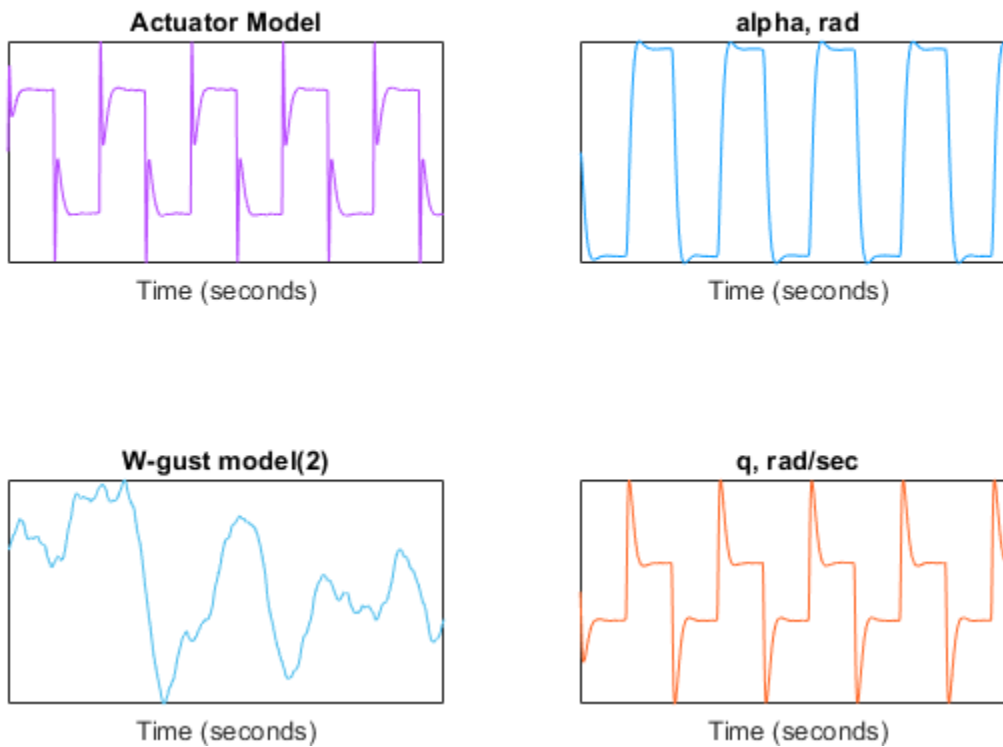

If these values are acceptable, continue with the example. Otherwise, you can change them to your specification using the Model Configuration Parameters.

Select a variable-step solver from the list of solvers in the **Solver** dropdown in the **Solver** pane of the Model Configuration Parameters to simulate the model. The default setting in Simulink for the **Solver** parameter is `VariableStepAuto`. Simulink selects a solver and the maximum step size of the simulation based on the contents and dynamics of the model.

Simulate the model using the auto solver, or pick another solver. Additionally, enable the **Save states**, **Save time**, and **Save outputs** parameters in the **Data Import/Export** pane of the Model Configuration Parameters. Set the logging format for your model to `Dataset` to allow the Simulation Data Inspector to log the signals.

The simulation results from this run will be designated the baseline results for this task. The model contains 13 signals, but this example focuses on only a few signals plotted below.

Profile the model using the **Solver Profiler** to find an appropriate step size for the candidate fixed-step simulations of the model. See Solver Profiler for information on how to launch and use the tool. For command-line usage, see `solverprofiler.profileModel`.

Note the maximum and average step sizes returned by the **Solver Profiler**.

```

solver: 'ode45'
tStart: 0
tStop: 60
absTol: 1.0000e-06
relTol: 1.0000e-04
hMax: 0.1000
hAverage: 0.0447
steps: 1342
profileTime: 0.0665
zcNumber: 0
resetNumber: 600
jacobianNumber: 0
exceptionNumber: 193

```

## Run Fixed-Step Simulations of the Model

Once you obtain the results of the variable-step simulation of the model, simulate it using one or more of the fixed-step solvers. In this example, the model is simulated using all the non-stiff fixed-step solvers: ode1, ode2, ode3, ode4, ode5, and ode8. You can also select a specific solver from the **Solver** dropdown in the Model Configuration Parameters to run against the variable-step baseline.

### Considerations for Selecting a Fixed Step Size

The optimal step size for a fixed-step simulation of your model strikes a balance between speed and accuracy, given constraints such as code-generation objectives, physics or dynamics of the model, and modeling patterns used. For example, code generation would dictate the step size must be greater than or equal to the clock speed of the processor (the reciprocal of the CPU frequency). For pure simulation objectives, the step size must be less than the discrete sample times specified by individual blocks in the model. For models with periodic signals, the step size must be such that the signal is sampled at twice its highest frequency; this is known as the Nyquist frequency.

For this specific example, set the fixed-step size of the solver to 0.1 (the maximum step size detected by the **Solver Profiler**). This takes into account the discrete sample time 0.1 of the Dryden Wind-Gust block, as well as the periodic nature of the stick movements and the aircraft response.

Make sure that the model states, outputs, and simulation time are enabled for logging and that the logging format is set to Dataset in the Model Configuration Parameters.

Simulate the model by selecting any one or all the non-stiff fixed-step solvers from the **Solver** dropdown of the Model Configuration Parameters when the solver **Type** is set to Fixed-step.

A Simulink.sdi.Run object is created for the fixed-step solver simulation(s) and stored in the fsRuns struct in the base workspace.

## Compare Fixed-Step Simulations with the Variable-Step Baseline

Use the **Simulation Data Inspector** to visualize and inspect logged signals in your model. You can also compare signals across simulations, or runs, using the **Compare** feature. For more information on using the **Simulation Data Inspector**, see *Simulation Data Inspector*. For more information on how to compare simulations using the Simulation Data Inspector, see “Compare Simulation Data” on page 31-193.

To compare signals, switch to the **Compare** tab in the **Simulation Data Inspector**. Set the **Baseline** run to the variable-step simulation and select a fixed-step simulation from the **Compare to** dropdown. Set the **Global Abs Tolerance**, **Global Rel Tolerance**, and **Global Time Tolerance** based on your requirements.

For this example, **Global Abs Tolerance** is set to  $0.065$ , **Global Rel Tolerance** is set to  $0.005$ , and **Global Time Tolerance** is set to  $0.1$ .

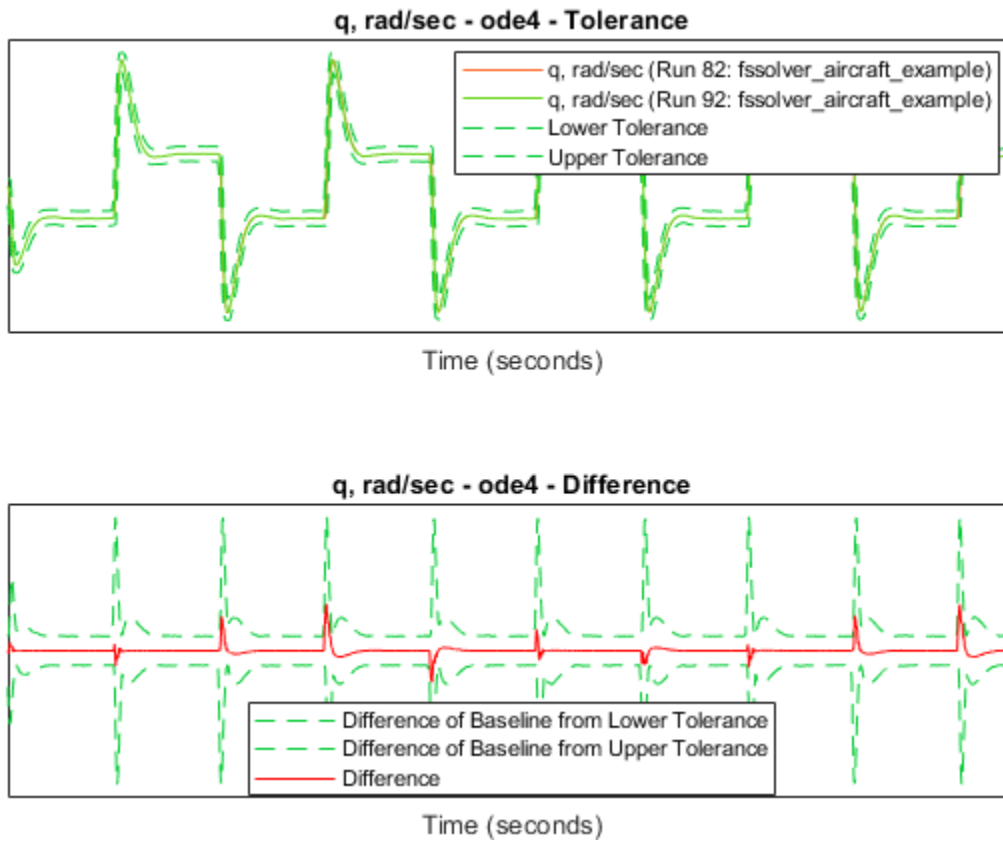

The comparison plots display the results for the lowest order fixed-step solver simulation where all signals fell within tolerance, when compared to the baseline variable-step simulation. For the selected solver, comparison results of a few of the signals are plotted below.

The lowest order with all signals within tolerance is determined to be ode4. Consider the results for the ode1 fixed-step solver, where the comparison results showed 11 signals out of tolerance. Observe that there are 11 signals out of tolerance when the signal comparison parameters are set as:

- **Signal Abs Tolerance:** 0.065
- **Signal Rel Tolerance:** 0.065
- **Signal Time Tolerance:** 0.1

Actuator Model - ode1 (11 signals out of tolerance) - Tolerance

## Select Solver Using Auto Solver

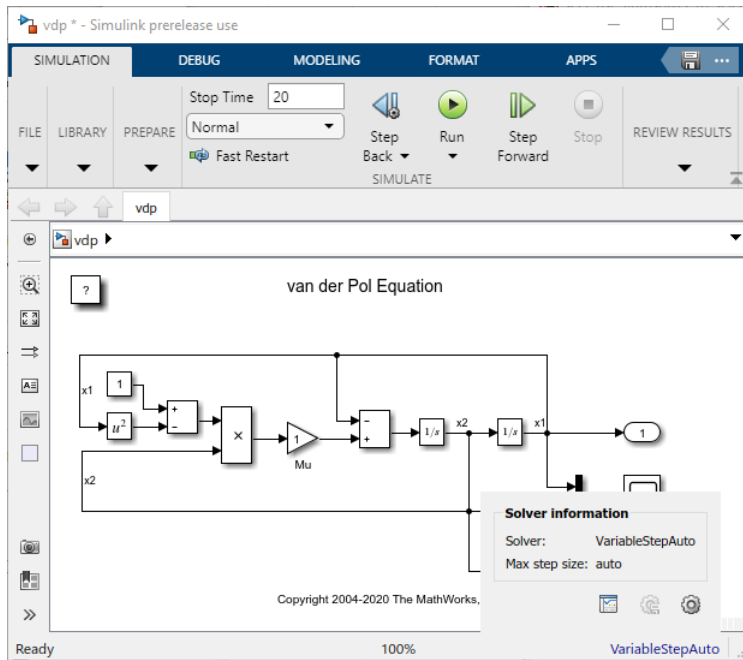

When you want Simulink to select a solver for simulating the model, use auto solver. Auto solver chooses a suitable solver and sets the maximum step size of the simulation.

For new models, Simulink selects auto solver and sets the type to variable-step by default. For an existing model, you can use auto solver to select a solver.

- 1 Open vdp and click the solver link in the lower-right corner.

- 2 In the **Solver Information** pane, click the **View solver settings** button  to open the **Solver** pane of the model configuration parameters.
- 3 Under **Solver selection**, set **Type** to fixed or variable-step according to your preference and set **Solver** to auto.
- 4 When you simulate the model, auto solver selects a fixed-step or variable-step solver according to your preference and calculates the maximum step size it recommends. To see the results, open the **Solver information** pane.

- 5 Click the **Accept suggested settings** button  to apply the recommendations of auto solver. To select different settings, click the **View solver settings** button and make changes in the configuration parameters **Solver** pane.

This chart describes the selection process of the auto solver.

### Auto Solver Heuristics

The solver type is		The system has	
		Only discrete states	Continuous states
Fixed-Step	FixedStepDiscrete	The system is an ordinary differential equation (ODE)	
		ode3	ode14x
Variable-Step	Variable StepDiscrete	The model is stiff	The model is non-stiff
		ode15s	ode45
		The system has differential algebraic equations (DAE)	
		ode23t	

- For Simscape Electrical models, auto solver selects **ode23tb**. These systems can have circuits with nonlinear models, especially circuit breakers and power electronics. Such nonlinear models require a stiff solver.

- If the number of continuous states in the model exceeds the `NumStatesForStiffnessChecking` value, auto solver uses `ode15s`. It does not calculate the stiffness of the model. The default value for this parameter is 1000. You can change this value using `set_param`.
- If the number of continuous states in the model is less than the `NumStatesForStiffnessChecking` value, auto solver calculates the stiffness of the model. A model is stiff if the stiffness exceeds the `StiffnessThreshold` value. The default value for this parameter is 1000. You can change this value using `set_param`.

## Use Model Operating Point for Faster Simulation Workflow

### In this section...

“Benefits of Using Operating Point” on page 27-44

“Save an Operating Point” on page 27-45

“Restore Operating Point” on page 27-45

To effectively design a system, you simulate a model iteratively, so you can analyze the system based on different inputs, boundary conditions, or operating conditions. In many applications, when performing multiple simulations, a startup phase with significant dynamic behavior is common. For example, the cold start takeoff of a gas turbine engine occurs before each set of aircraft maneuvers. In multiple simulations, you ideally:

- 1 Simulate the startup phase once.
- 2 Save a snapshot at the end of the startup phase that represents the operating point for the system.
- 3 Use this snapshot as the initial state for each in a set of simulations for different conditions or maneuvers.

To save a snapshot of a model at a given point in a simulation, save the final states with the operating point. The snapshot is saved as a `Simulink.op.ModelOperatingPoint` object you can specify as the initial state for subsequent simulations, which start from that operating point.

The model operating point contains information about:

- Logged states
- State of the solver and execution engine
- Zero-crossing signals for blocks that register zero crossings
- Output values of certain blocks in the model

Simulink analyzes block connections and other information to determine whether it is using the output values effectively as state information.

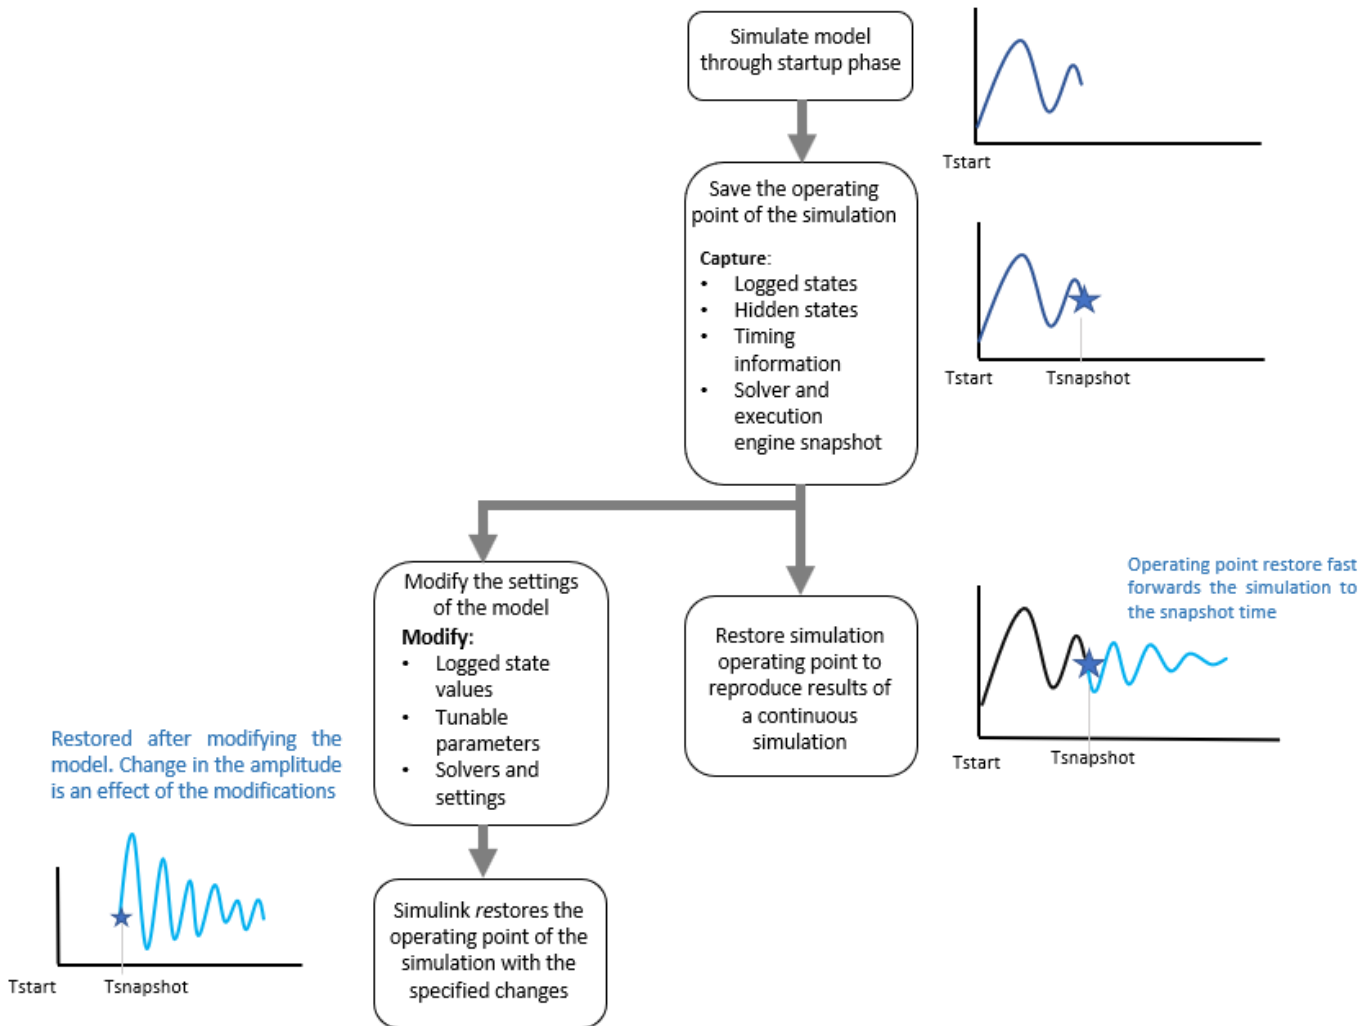

The model operating point also includes the hidden states of these blocks:

- Transport Delay
- Variable Transport Delay
- From Workspace
- For Each subsystem
- Conditionally executed subsystems
- Stateflow
- MATLAB System
- Simscape Multibody Second Generation

Because the model operating point includes complete information about the state of the system at that point in the simulation, the results of a simulation that starts from an initial operating point are the same as a simulation that runs from the beginning.

## Benefits of Using Operating Point

- Saving a model operating point creates a record of information in addition to the logged states in the model. Restore all of this information to ensure that the simulation matches the uninterrupted simulation. For example, if solver information affected the simulation, then specifying an initial state without the operating point can produce different results.
- You can save several operating points during a simulation, then resume the simulation from any of those operating points.
- You can use a model operating point to restore the state of blocks that are typically difficult to restore to a particular state, including the Transport Delay block. The state of the Transport Delay block is not saved in the structure format or the array format when you log data using the **Final states** configuration parameter. With dataset logging format, the answers returned by `ModelOperatingPoint` always match those returned by state logging (non-Operating Point save). Logged states for blocks inside of accelerator-mode model reference are visible and editable. Logged states for many blocks with custom operating point functions, for example, Simscape, model reference accel and variable transport delay are editable.

You can also save a simulation state by saving final states without the operating point. However, this option saves only the continuous and discrete states of blocks. These states are only subsets of the complete simulation state of the model. They do not include information about the solver, execution engine, or hidden states of blocks, which are required for the proper execution of a block.

## Save an Operating Point

Save an operating point at the beginning of the final step using one of these options:

- At the final **Stop time**.
- When you interrupt a simulation with the **Pause** or **Stop** button. You can also save an operating point when you pause a simulation using `get_param('modelName','CurrentOperatingPoint')`.
- When you use `set_param` or a block, like the Stop block, to stop a simulation.

### Interactive Save

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Final states** check box. The **Save final Operating Point** check box becomes available.
- 2 Select the **Save final Operating Point** check box.
- 3 In the **Final states** text box, enter a variable name for the `ModelOperatingPoint` object.
- 4 Simulate the model.

## Restore Operating Point

Restore the simulation snapshot using the `ModelOperatingPoint` object after modifying the model. The **Start time** does not change from the value in the simulation that generated the operating point. It is a reference value for all time and time-dependent variables in both the original and the current simulation. For example, a block can save and restore the number of sample time hits that occurred since the beginning of simulation as its `ModelOperatingPoint` object.

Consider a model that you ran from 0 to 100 s and that you now want to run from 100 to 200 s. The **Start time** is 0 s for both the original simulation and for the current simulation. The initial time of the current simulation is 100 s. Also, if the block had 10 sample time hits during the original simulation, Simulink recognizes that the next sample time hit is the 11th, relative to 0, not 100 s.

---

**Note** If you change the **Start time** before restoring the `ModelOperatingPoint`, Simulink overwrites the **Start time** with the value saved in the `ModelOperatingPoint`.

---

### Interactive Restore

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, under **Load from workspace**, select the **Initial state** check box. The text box becomes available.
- 2 Enter the name of the variable containing the `ModelOperatingPoint` in the text box.
- 3 Set the **Stop time** to a value greater than the time at which the operating point was saved.

### Restore from Different Simulink Versions

You can use `ModelOperatingPoint` objects saved in releases starting with R2010a to restore the `ModelOperatingPoint` of a model. However, this option restores only the logged states of the

model. To see the version of Simulink used to save the `ModelOperatingPoint`, examine the **version** parameter of the `ModelOperatingPoint` object.

Simulink detects if the `ModelOperatingPoint` object you provided as the initial state was saved in the current release. By default, Simulink displays an error message if the `ModelOperatingPoint` was not saved in the current release. You can configure the diagnostic to allow Simulink to display the message as a warning and try to restore as many of the values as possible. To enable this best-effort restoration, in the Configuration Parameters dialog box set the message for **Operating Point object from earlier release** to warning. Previously named `SimState` objects are loaded as `ModelOperatingPoint` objects in 19a.

### Objects

`Simulink.op.ModelOperatingPoint`

## Related Examples

- “Specify Initial State for Simulation” on page 27-50
- “Save Block States and Simulation Operating Points” on page 77-76
- “Operating Point Behavior” on page 27-47

## Operating Point Behavior

Use a model operating point with a block, S-functions and model changes.

### Change the States of a Block Within Operating Point

- Use the `loggedStates` property of the `Simulink.op.ModelOperatingPoint` object to get or set the states of blocks. If `xout` is the state log that Simulink exports to the workspace, then the `loggedStates` field has the same structure as `xout.signals`.
- With dataset logging, saving the model operating point captures the current logged states snapshot as saving the final states without the operating point would, and stores it on the `ModelOperatingPoint` object. When you query this logged state, a copy of the saved dataset is returned.
- With dataset logging format, the answers returned by `ModelOperatingPoint` always match those returned by state logging (non-Operating Point save). Logged states for blocks inside of accelerator-mode model reference are visible and editable. Logged states for many blocks with custom operating point functions, for example, Simscape, model reference accel and variable transport delay are editable.
- You cannot change the states that are not logged. Simulink does not allow this modification as it could cause the state to be inconsistent with the simulation.

### S-Functions

You can use APIs for C-MEX and Level-2 MATLAB S-functions to enable S-functions to leverage the model operating point. For information on how to implement this functionality in an S-function, see “S-Function Compliance with the `ModelOperatingPoint`”.

S-functions that have `PWork` vectors, which store pointers to data structures but do not declare their operating point compliance level or declare it to be unknown or disallowed do not support operating point. For more information, see “S-Function Compliance with the `ModelOperatingPoint`”.

### Model Changes and Operating Point Restore

After saving the operating point of a model, you can change the model and restore an operating point with those changes.

- You can rename a model between saving and restoring its operating point.
- The operating point interface checksum is primarily based on the configuration settings in a model and sample times used in the model. You can make some nonstructural changes to the model between saving and restoring an operating point. In the Configuration Parameters dialog box, in the **Diagnostics** pane, use the **Operating point interface checksum mismatch** diagnostic to track such changes. You can then find out if the interface checksum of the restored operating point matches the current interface checksum. See “Operating point restore interface checksum mismatch”.

You can make the following nonstructural changes to the model without affecting your ability to restore a previously saved operating point:

- Changes to model-level signal logging settings in the “Model Configuration Parameters: Data Import/Export”.

- Logging of specific signals.
- Addition and removal of Scope, Floating Scope and Scope Viewer, To Workspace, To File, and Display blocks.
- Addition and removal of Level-2 MATLAB or C S-Functions that are configured as simulation viewing devices and do not set the operating point compliance to Custom or Disallowed. See “S-Function Compliance with the ModelOperatingPoint” for more information.

---

**Note** These modifications may change the number of sample times in the model. This can cause the model's interface checksum to be different from the operating point save and restore checksum. Configure the **Operating point interface checksum mismatch diagnostic** to display a warning (default), error, or none to not compare the checksums.

---

- You cannot make structural changes to the model between the time you save the operating point and the time you restore the simulation using the operating point. Examples include, adding or removing a block after saving the operating point, changing the sample time of a model, and changing the type of solver from variable-step to fixed-step.
- Mismatches can occur when you try to simulate using a solver that is different from the one that generated the saved operating point. Simulink permits solver changes. For example, you can use the `ode15s` solver to solve the initial stiff portion of a simulation and save the final operating point. You can then continue the simulation with the restored operating point using `ode45`. In other words, this diagnostic helps you see the solver changes but does not signal a problem with the simulation.

---

**Note** When you use a variable-step solver with the maximum step size set to `auto`, Simulink uses the maximum step size from the restored `ModelOperatingPoint` object for the new simulation. To ensure that the concatenated operating point trajectory of two simulations matches that of an uninterrupted simulation, specify a value for the maximum step size.

---

## Limitations of Saving and Restoring Operating Point

---

**Note** In some cases, saving final states without the complete model operating point can avoid some of the limitations of using the model operating point. For more information, see “Save Block States and Simulation Operating Points” on page 77-76.

---

### Block Support

The following blocks do not support operating point:

- In the Stack and Queue blocks, the default setting for the **Push full stack** option is **Dynamic reallocation**. This default setting does not support `ModelOperatingPoint` object. Other settings (**Ignore**, **Warning** and **Error**) support `ModelOperatingPoint` object.
- Simscape Multibody First Generation blocks

Simulink tries to save the output of a block as part of an operating point. For S-functions, this happens even if the functions declare that no operating point is required. If the block output is of custom type, Simulink cannot save the operating point and displays an error. For more information about operating point use with S-functions, see “S-Functions” on page 27-47.

Model reference offers partial support for operating point. For details, see “Model Referencing” on page 27-49.

### **Simulation**

- You can use only the normal or the accelerator simulation mode.
- You cannot save operating point in normal mode and restore it in accelerator mode, or vice versa.
- You cannot change the states of certain blocks that are not logged. For more information, see “Change the States of a Block Within Operating Point” on page 27-47.

### **Code Generation**

The operating point feature does not support Simulink Coder or Embedded Coder code generation.

### **Model Referencing**

- You cannot modify logged states of blocks that are inside a referenced model in accelerator mode.
- The following blocks do not support operating point when included in a model referenced in accelerator mode:
  - Level-2 MATLAB S-Function
  - MATLAB System
  - n-D Lookup Table
  - S-Function (with custom operating point or PWork vectors)
  - To File

### **Model Name Programmatic Interface**

You cannot specify an operating point as the states input when you use the model name as a programmatic interface. For more information, see “Use Model Name as Programmatic Interface” on page 3-64.

## Specify Initial State for Simulation

This example shows the difference between specifying the initial state for a simulation using final states saved with and without the model operating point. Specifying initial states for a simulation can save time when you run a set of simulations. For example, suppose you need to simulate several scenarios for a system that has an initialization phase. If the initialization phase is the same for all scenarios, you can simulate the initialization phase once, save the operating point, and use that operating point as the initial state for all the simulations.

When you want to continue a simulation from a given state, use the model operating point. A model operating point contains complete information about the state of the model and simulation, including the simulation time for the snapshot and the state of the solver and execution engine. When you use a model operating point as the initial state for a simulation, the simulation results match results from a simulation without an initial state, and you do not need to specify the start time for the model. When you specify initial states without the operating point, the simulation results can differ from an equivalent simulation that does not run from an initial state.

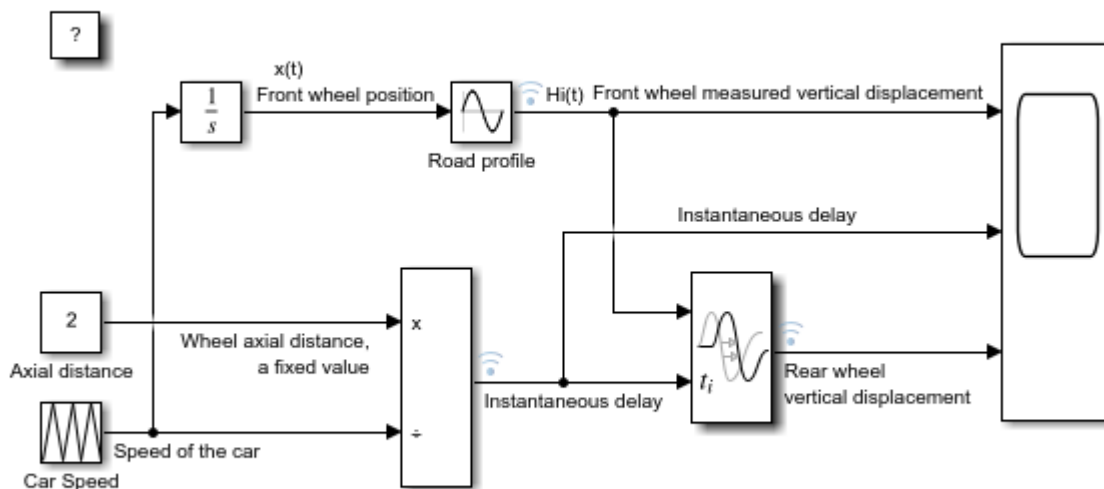

For more information about the difference between final states with and without the operating point, see “Save Block States and Simulation Operating Points” on page 77-76.

### Open and Simulate Model

Open the model `slexVariableTransportDelay`, which models the relationship between the vertical displacement of the front and rear wheels for a car. For more information about the model, see “Simulating Systems with Variable Transport Delay Phenomena”.

```
modelName = "slexVariableTransportDelay";
open_system(modelName)
```

### Vertical displacement of the wheels of a one dimensional car

Copyright 1990-2018 The MathWorks, Inc.

This example uses a model with the Variable Transport Delay block to illustrate a key difference between saving final states and saving final states with the operating point. Some blocks, including the Variable Transport Delay block, use information to compute output values that is not included in the logged block state. This information is included in the `Simulink.op.ModelOperatingPoint` object created when you save final states with the final operating point for the model.

Create a `Simulink.SimulationInput` object to specify model parameters to use in the baseline simulation. Configure the model to simulate from 0 to 10 seconds. Use the `OutputTimes` parameter to ensure that the model computes output values for simulation times of 0, 5, and 10.

```
siminBaseline = Simulink.SimulationInput(modelName);
siminBaseline = setModelParameter(siminBaseline,'StartTime','0','StopTime','10',...
    'OutputOption','AdditionalOutputTimes','OutputTimes',[0 5 10]);
```

Simulate the model to create baseline results.

```
baseline = sim(siminBaseline);
```

### Specify Initial State for Simulation Using Model Operating Point

To see how the model operating point allows you to resume a simulation, simulate the model for 5 seconds and save the final operating point. Then, simulate the model again from 5 seconds to 10 seconds using the operating point as the initial state for the model.

Create a `SimulationInput` object to specify model parameters to use in the first simulation. Configure the model to simulate from 0 seconds to 5 seconds, and save the final states with the final operating point.

```
siminOP1 = Simulink.SimulationInput(modelName);
siminOP1 = setModelParameter(siminOP1,'StartTime','0','StopTime','5',...
    'SaveFinalState','on','SaveOperatingPoint','on');
```

Simulate the model for the first five seconds.

```
op1 = sim(siminOP1);
```

Create a `SimulationInput` object to specify model parameters for the second part of the simulation. When you use an operating point as the initial state for a simulation, do not specify the start time for the simulation. The simulation runs from the time saved in the `snapshotTime` property of the `Simulink.op.ModelOperatingPoint` object that contains the operating point data.

```
siminOP2 = Simulink.SimulationInput(modelName);
siminOP2 = setModelParameter(siminOP2,'StopTime','10');
```

Specify the initial states for the second portion of the simulation as the operating point saved from the first part of the simulation. By default, the operating point is stored in a variable called `xFinal` and returned as part of the single simulation output as a field in a `Simulink.SimulationOutput` object.

```
siminOP2 = setInitialState(siminOP2,op1.xFinal);
```

Simulate the model from five seconds to ten seconds, using the final states without the operating point as the initial state.

```
op2 = sim(siminOP2);
```

Plot the results from the interrupted simulation that was resumed using the operating point alongside the results from the baseline simulation.

Get the `Simulink.SimulationData.Dataset` object that contains the signal data logged from the baseline simulation. The results are returned as a single `Simulink.SimulationOutput` object that contains the `Dataset` object with signal logging data in the variable `logouts`.

```
baselineResults = baseline.logouts;
```

Combine the logged signal data from the two segments of the interrupted simulation. First, create a copy of the logged signal data that will contain the combined simulation results.

```
opResults = op1.logouts;
```

In a `for` loop, access the `timeseries` objects that contain the time and signal data for each logged signal, and use the `append` function to concatenate the data in time. The `Dataset` object with the logged signal data contains a `Simulink.SimulationData.Signal` object for each signal. The `Values` property of the `Signal` object is a `timeseries` object that contains the data. This example uses curly braces (`{}`) to access the `Signal` objects in the `Dataset` objects by index.

```
for idx = 1:numElements(op1.logouts)
    ts1 = op1.logouts{idx}.Values;
    ts2 = op2.logouts{idx}.Values;
    opResults{idx}.Values = append(ts1,ts2);
end
```

Plot the data on a 3-by-1 MATLAB® figure using a `for` loop to iterate through the elements of the `Dataset` object. This example uses curly braces (`{}`) to access the elements of the `Dataset` objects by index.

```
fig2 = figure(2);
fig2.Name = "Simulation Resumed Using Operating Point";
for idx=1:numElements(baselineResults)
    ax = subplot(3,1,idx);
    plot(baselineResults{idx}.Values)
    hold on
    plot(opResults{idx}.Values, 'r--')
    hold off
    grid on
    ax.Title.String = baselineResults{idx}.Values.Name;
end
```

The results from the interrupted simulation that was resumed using the operating point match the results from the uninterrupted simulation.

### Specify Initial State for Simulation Using Final States

To see how using final states without the model operating point can affect simulation results, simulate the model for 5 seconds and save the final states without the operating point. Then, simulate the model again from 5 seconds to 10 seconds, using the final states as the initial state for the simulation.

Create a `SimulationInput` object to specify model parameters to use in the first simulation. Configure the model to simulate from 0 seconds to 5 seconds and save the final states without the operating point.

```
siminStates1 = Simulink.SimulationInput(modelName);
siminStates1 = setModelParameter(siminStates1, 'StartTime', '0', 'StopTime', '5', ...
    'SaveFinalState', 'on');
```

Simulate the model for the first five seconds.

```
finalStates1 = sim(siminStates1);
```

Create a `SimulationInput` object to specify model parameters for the second part of the simulation. Configure the model to simulate from 5 seconds to 10 seconds. When you use final states without the operating point as the initial state for a simulation, the simulation time is not restored from the final states data. You must specify the start time for the simulation.

```
siminStates2 = Simulink.SimulationInput(modelName);
siminStates2 = setModelParameter(siminStates2, 'StartTime', '5', 'StopTime', '10');
```

Specify the initial states for the second portion of the simulation as the final states saved from the first part of the simulation. By default, final states are stored in a variable called `xFinal` and returned as part of the single simulation output as a field in a `Simulink.SimulationOutput` object.

```
siminStates2 = setInitialState(siminStates2, finalStates1.xFinal);
```

Simulate the model from five seconds to ten seconds. Use the final states without the operating point as the initial state.

```
finalStates2 = sim(siminStates2);
```

Plot the results for all ten seconds of simulation time side by side to see how resuming the interrupted simulation using final states affects the simulation results.

Combine the logged signal data from the two segments of the interrupted simulation. First, create a copy of the logged signal data that will contain the combined simulation results.

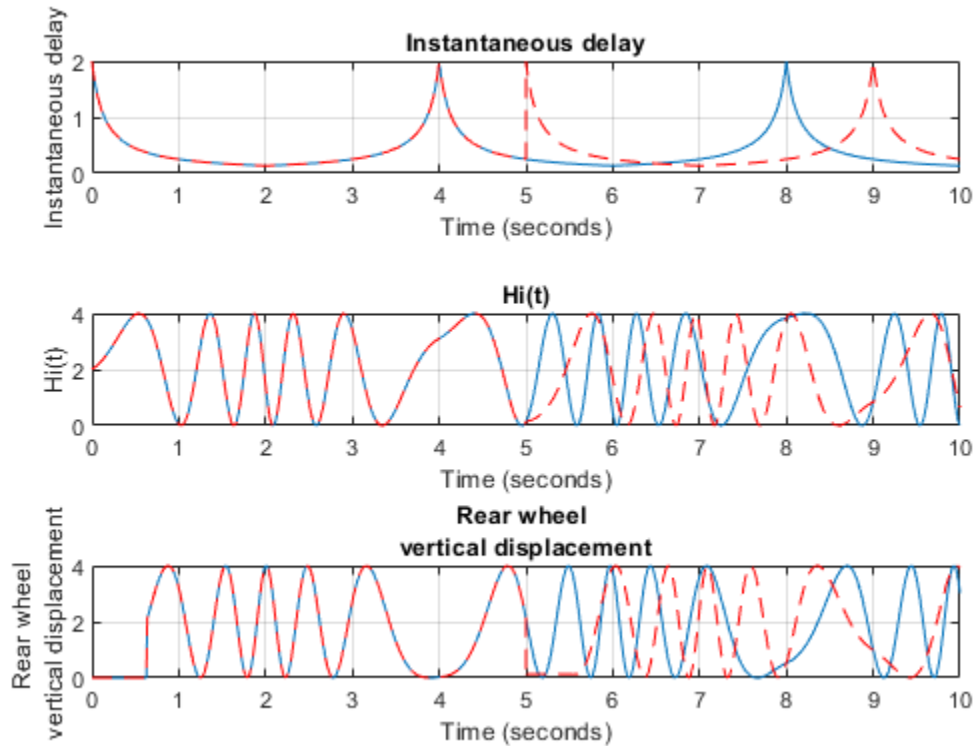

```
finalStatesResults = finalStates1.logout;
```

In a `for` loop, access the `timeseries` objects that contain the time and signal data for each logged signal, and use the `append` function to concatenate the data in time. The `Dataset` object with the logged signal data contains a `Simulink.SimulationData.Signal` object for each signal. The `Values` property of the `Signal` object is a `timeseries` object that contains the data. This example uses curly braces (`{}`) to access the `Signal` objects in the `Dataset` objects by index.

```
for idx = 1:numElements(finalStates1.logout)
    ts1 = finalStates1.logout{idx}.Values;
    ts2 = finalStates2.logout{idx}.Values;
    finalStatesResults{idx}.Values = append(ts1,ts2);
end
```

Plot the data on a 3-by-1 MATLAB figure using a `for` loop to iterate through the elements of the `Dataset` object. This example uses curly braces (`{}`) to access the elements of the `Dataset` objects by index.

```
fig1 = figure(1);
fig1.Name = "Simulation Resumed Using Final States Without Operating Point";
for idx=1:numElements(baselineResults)
    ax = subplot(3,1,idx);
    plot(baselineResults{idx}.Values)
    hold on
    plot(finalStatesResults{idx}.Values, 'r--')
    hold off
    grid on
    ax.Title.String = baselineResults{idx}.Values.Name;
end
```

The simulation results diverge in the interrupted simulation after the simulation is resumed using the final states without operating point information. For this model, the final states alone do not provide enough information to continue the simulation as though it was never interrupted.

## View Diagnostics

You can view and diagnose errors and warnings generated by your model using the **Diagnostic Viewer**. The **Diagnostic Viewer** displays three types of diagnostic messages: errors, warnings, and information. A model generates these messages during a runtime operation, like model load, simulation, or update diagram.

You can dock the diagnostic viewer to a model to view diagnostics specific to the model or you can have a standalone diagnostic viewer to view the diagnostics of all the models.

To dock the diagnostic viewer to a model, go to **Debug > Diagnostics > Docked Diagnostic Viewer** or go to **Modeling > Environment > Simulink Preference > Editor > Use docked Diagnostic Viewer**

**Note** Docking the diagnostic viewer is a system-wide operation. You cannot change the preferences model-wise.

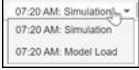

The diagnostic viewer window is divided into:

- **Toolbar menu:** Displays various commands to help you manage the diagnostic messages. For more information, see “Toolbar” on page 27-56.
- **Diagnostic Message pane:** Displays the error, warning, and information messages. For more information, see “Diagnostic Message Pane” on page 27-57.
- **Suggested Actions:** Displays suggestions and fixes to correct the diagnostic errors and warnings. For more information, see “Suggested Actions” on page 27-59.

### Toolbar

To manage the diagnostic messages, use the **Diagnostic Viewer** toolbar.

Menu	Action
	View all error messages
	View all warning messages

Menu	Action
	View all information messages
	Search messages for specific keywords and navigate between messages
	The time and the events appear in this drop-down. You can view diagnostic messages specific to an event by clicking on the event.
Reports	<p>You can</p> <ul style="list-style-type: none"> <li>• Expand or collapse messages</li> <li>• Save all or latest messages in a log file</li> <li>• Copy all or latest messages</li> </ul> <p><b>Note</b> You can right-click anywhere inside the messages to save or copy the messages specific to the event.</p>
Settings	Group similar warnings. Set maximum number of models to display in tabbed panes and the maximum number of events to display per model

## Diagnostic Message Pane

The diagnostic message pane displays the error, warning, and information messages in a tabbed format. These messages are color-coded for distinction and are hierarchical.

A new stage is generated for each successive event, you can save or clear stage. Each stage represents a single event such as model load, update diagram, or simulation.

Different types of diagnostic messages are:

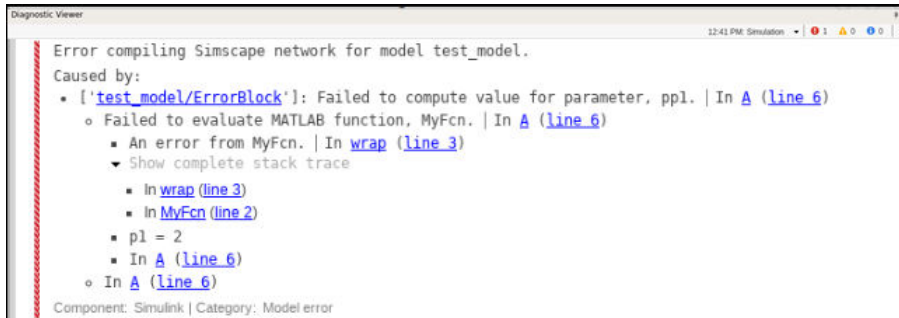

- Information message: Displays the information related to a model load. Information messages are marked as .
- High priority warning: Displays the errors encountered during model load as a high priority warning. Any subsequent operation, like update on the model without rectifying the high priority warning messages are marked as errors. High priority warnings are marked as .
- Warning: Displays the warnings associated during an operation on a model. Warnings are marked as .
- Error: Displays the errors associated during an operation on a model. Errors are marked as .

**Tip** To locate the source of error, click the hyperlink in the message. The source of error in the model is highlighted.

## Trace Diagnostics Location

The Diagnostic Viewer can trace the location of an error so that you can investigate the errors in your model easily. If the error is in a file that is being called from another file, the diagnostic shows up as an expandable stack. You can expand or collapse the stack, as required. Expanding the stack displays information about the file and the line in which the error or warning is located. You can click any of the links to go the error or warning. You can also see the same diagnostic message with stack trace enabled, while using the `sim` command in MATLAB.

**Note** Tracing the exact location of an error is not applicable for protected files.

## Identify Diagnostics from Custom Compilers

Diagnostic viewer can recognize errors and warnings from builds generated by custom compilers. You can specify compiler-specific patterns using the following directives:

```
% Here tool is the buildtool obtained from the toolchain
tool.setDirective ('WarningPattern', 'warning #(\d+):'); %Specifies warning patterns
tool.setDirective ('ErrorPattern', 'error:'); %Specifies error pattern
tool.setDirective ('FileNamePattern', '[^\\s]*\\w+\\. (c|h)'); %Specifies file name pattern
tool.setDirective ('LineNumberPattern', '\\(\\d+\\)'); %Specifies line number pattern
```

For more information about creating a `ToolchainInfo` object, see “Register Custom Toolchain and Build Executable” (Simulink Coder).

## Suppress Diagnostics

Use the **Suppression Manager** to suppress certain numerical diagnostics (for example, overflow, saturation, precision loss) for specific objects in your models. You can also suppress certain errors that have the diagnostic level set to error in the **Diagnostics** section of the Model Configuration Parameters. You can add a comment for the suppressed diagnostics.

To suppress a diagnostic from the specified source, click **Suppress** in the Diagnostic Viewer. Add appropriate comments to the suppressed diagnostic.

To view the suppressed diagnostic, on the **Debug** tab, click **Diagnostics > Suppression Manager**. To restore the suppressed diagnostic, select **Restore**. Diagnostic suppressions are saved with the model and persist across sessions.

The **Suppression Manager** displays the model name, suppression location, and comments of the diagnostic in tabular format. Using the **Actions** menu, you can add and edit comments, suppress a diagnostic, or move a diagnostic to the subsystem level from the block level (**Add to Parent Level**).

For more information, see “Suppress Diagnostic Messages Programmatically” on page 27-64.

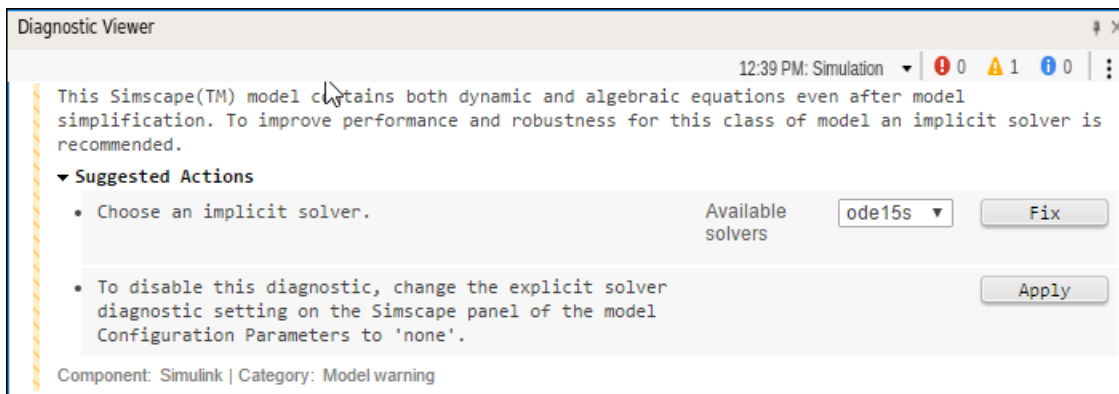

## Suggested Actions

Diagnostic viewer provides suggestions and fixes for diagnostic error and warning messages. These suggestions and fixes are provided in the **Suggested Actions** section of diagnostic message pane.

A diagnostic error or warning can have multiple fixes and suggestions. Each fix is associated with a **Fix** button.

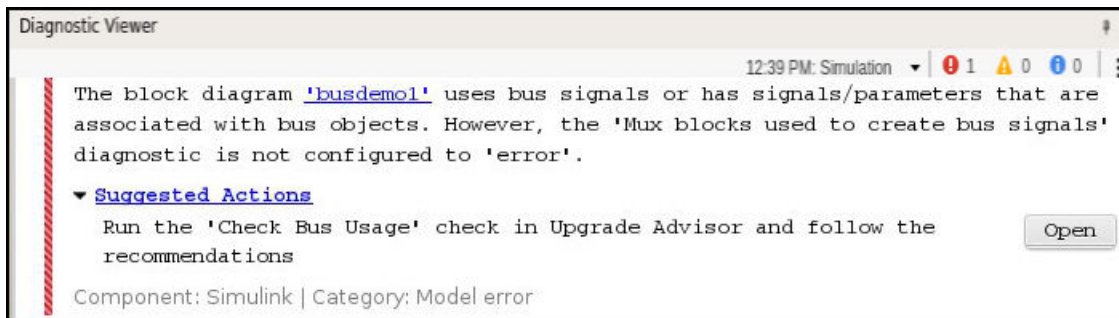

You can click the **Fix** button for the most suitable fix to rectify the error automatically. In some cases, you can provide the fix by one of these ways:

- Enter the values in the available edit boxes.
- Select a value from one of the listed values from a combo box.

The **Fix** buttons for a diagnostic error or warning are no longer available after a fix is successfully applied. If a fix was unsuccessful, a failure message is displayed in the **Suggested Actions** section.

Suggestions are provided for errors and warnings that cannot be fixed automatically.

**Note** The **Suggested Actions** section is available only for the diagnostic errors or warnings that have a predefined fix.

### Related Examples

- “Systematic Diagnosis of Errors and Warnings” on page 27-61
- “Customize Diagnostic Messages” on page 27-71
- “Report Diagnostic Messages Programmatically” on page 27-73

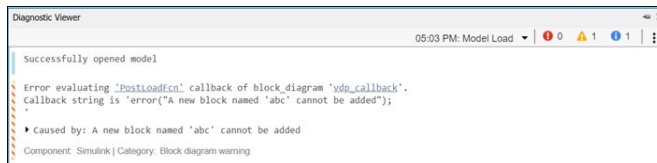

## Systematic Diagnosis of Errors and Warnings

This example shows how to use the Diagnostic Viewer to identify and locate simulation errors and warnings systematically.

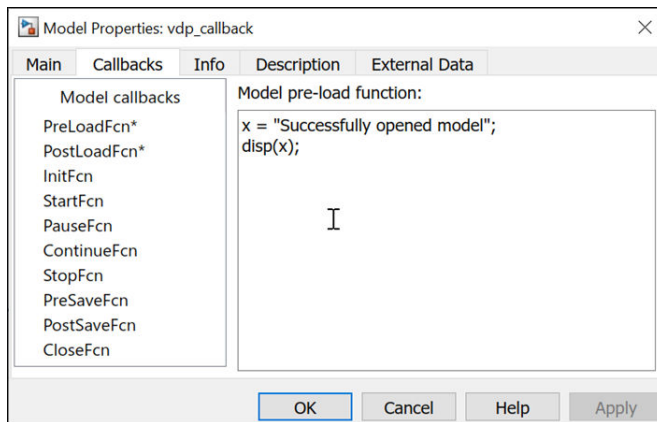

- 1 Open your model.

If your model contains errors related to callback functions, the **Diagnostic Viewer** opens and displays the following errors in **Model Load** stage.

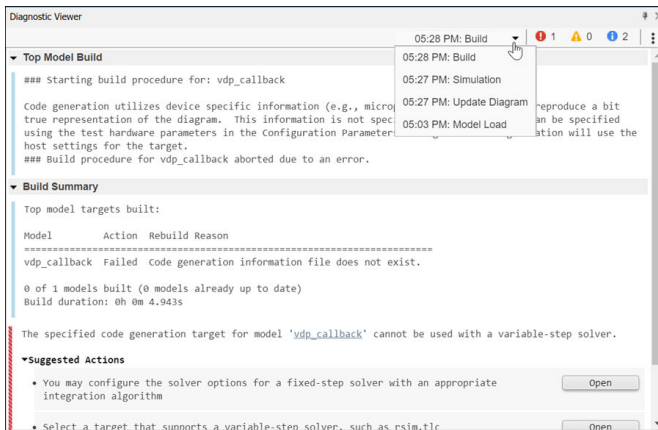

**Tip** To open the Diagnostic Viewer window, in the **Debug** tab, click **Diagnostics** or click the view errors or warnings link displayed at the bottom of the Simulink Editor window.

- 2 In the Simulink Editor, in the **Modeling** tab, select **Model Settings > Model Properties**, and examine the callback error.

- 3 After fixing any callback errors, simulate the model to diagnose simulation errors and warnings.

**Diagnostic Viewer** lists errors and warnings in stages. Each stage in **Diagnostic Viewer** represents a single event such as model load, update diagram, simulation, or build.

- 4 Filter out warnings by clicking  so that you can address errors first.
- 5 To locate the source of the error, click the hyperlink in the message. The model in the source is highlighted. If a block has multiple ports, you can hover over each port to see the port number.

- 6 After fixing all errors, simulate your model again and view the **Diagnostic Viewer** to identify remaining problems.

---

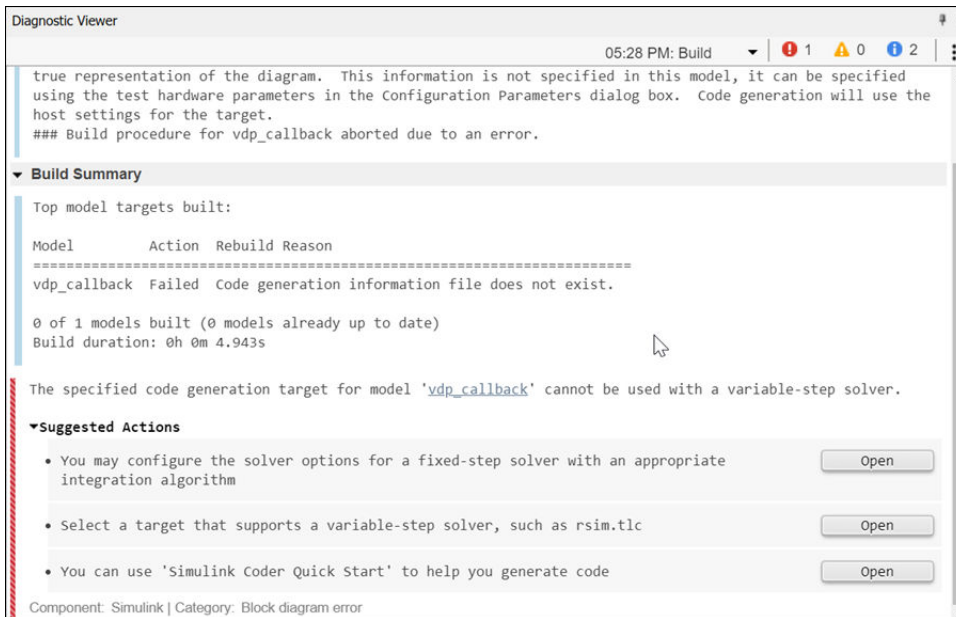

**Note** If an error or warning has a predefined fix, the diagnostic message pane displays a **Suggested Actions** section. You can use the **Fix** button provided in this section to rectify the related error or warning. For more information see, “Suggested Actions” on page 27-59.

---

- 7 If an object in your model generates a warning that you do not want to be notified of, sometimes, you can suppress the warning from the specified source using the **Suppress** button. You can restore the warning from that source using the **Restore** button. For example, if a Counter Free-Running block generates an overflow warning that is intentional in your design, you can suppress only overflow warnings from this particular block, without sacrificing notification of other overflows in your model.
- 8 To generate code for your model, in the **C Code** tab, click **Build**.

---

**Note** If there is a failure during code generation, Diagnostic Viewer provides hyperlinks for easy navigation to the source of the error or warning message.

## Suppress Diagnostic Messages Programmatically

The following examples show how to manage diagnostic suppressions programmatically.

### In this section...

“Suppress Diagnostic Messages Programmatically” on page 27-64

“Suppress Diagnostic Messages of a Referenced Model” on page 27-67

### Suppress Diagnostic Messages Programmatically

This example shows how to access simulation metadata to manage diagnostic suppressions and to restore diagnostic messages programmatically.

#### Create a New Folder and Copy Relevant Files

- 1 Create a local working folder, for example, `c:\diagnostic_suppressor_demo`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the `getDiagnosticObjects.m`, `suppressor_script.m`, and `Suppressor_CLI_Demo.slx` files to your local working folder.

The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model.

#### getDiagnosticObjects.m

```
function y = getDiagnosticObjects(in)
Warningdata = in.getSimulationMetadata.ExecutionInfo.WarningDiagnostics;
Errordata = in.getSimulationMetadata.ExecutionInfo.ErrorDiagnostic;

index = 1;

for i = 1 : numel(Warningdata)
    y(index) = Warningdata(i).Diagnostic;
    index = index + 1;
end

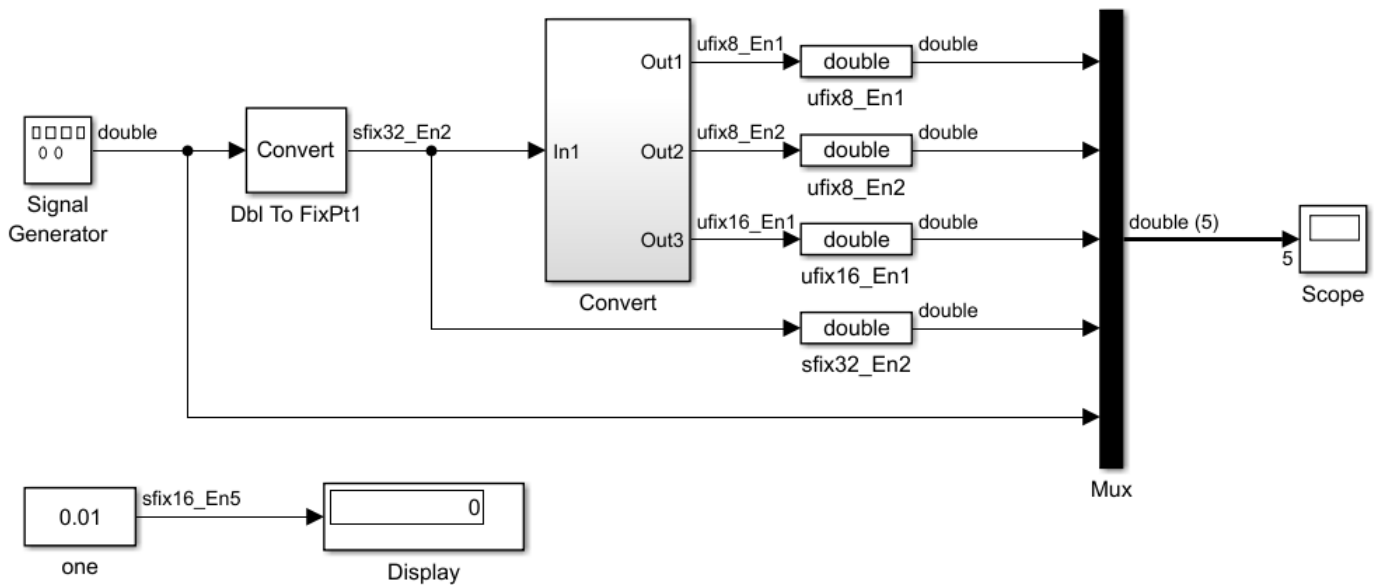

for i = 1 : numel(Errordata)
    y(index) = Errordata(i).Diagnostic;
    index = index + 1;
end
```

#### Open and Simulate the Model

Open the model. To access `Simulink.SimulationMetadata`, set the `ReturnWorkspaceOutputs` parameter value to `'on'`. Simulate the model.

```
model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);
```

### Fixed-Point to Fixed-Point Conversion

### Get Message Identifiers from Simulation Metadata

Find the names of diagnostic message identifiers using the simulation metadata stored in the `MSLDiagnostic` object.

```
if (exist('out', 'var'))
    diag_objects = getDiagnosticObjects(out);
end
```

Several warnings were generated during simulation, including a saturation of the Data Type Conversion block. Query the `diag_objects` variable to get more information on the identifiers.

```
diag_objects(5)
```

```
ans =
MSLDiagnostic with properties:
    identifier: 'SimulinkFixedPoint:util:Saturationoccurred'
    message: 'Saturation occurred. This originated from 'Suppressor_CLI_Demo/Con...'
    paths: {'Suppressor_CLI_Demo/Convert/FixPt To FixPt3'}
    cause: {}
    stack: [0x1 struct]
```

### Suppress Saturation Diagnostic on a Block

Use the `Simulink.suppressDiagnostic` function to suppress the saturation diagnostic on the data type conversion block only. Simulate the model.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', ...
'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

### Restore the Saturation Diagnostic

Use the `Simulink.restoreDiagnostic` function to restore the saturation diagnostic of the same block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3',...
'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

### Suppress Multiple Diagnostics on a Source

You can suppress multiple warnings on a single source by creating a cell array of message identifiers. Suppress the precision loss and parameter underflow warnings of the Constant block, one, in the model.

```
diags = {'SimulinkFixedPoint:util:fxpParameterPrecisionLoss',...
'SimulinkFixedPoint:util:fxpParameterUnderflow'};
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one', diags);
set_param(model, 'SimulationCommand', 'start');
```

### Restore All Diagnostics on a Block

Restore all diagnostics on a specified block using the `Simulink.restoreDiagnostic` function.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one');
set_param(model, 'SimulationCommand', 'start');
```

### Suppress a Diagnostic on Many Blocks

You can suppress one or more diagnostics on many blocks. For example, use the `find_system` function to create a cell array of all Data Type Conversion blocks in a system, and suppress all saturation warnings on the specified blocks.

```
dtc_blocks = find_system('Suppressor_CLI_Demo/Convert',...
'BlockType', 'DataTypeConversion');
Simulink.suppressDiagnostic(dtc_blocks, 'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

### Restore All Diagnostics Inside a Subsystem

You can also use the `Simulink.restoreDiagnostic` function to restore all diagnostics inside a specified subsystem.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert',...
'FindAll', 'On');
set_param(model, 'SimulationCommand', 'start');
```

### Add Comments and User Information to a Suppression

A `SuppressedDiagnostic` object contains information on the source of the suppression and the suppressed diagnostic message identifier. You can also include comments, and the name of the user who last modified the suppression.

```
Object = Simulink.SuppressedDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt1',...
'SimulinkFixedPoint:util:Saturationoccurred');
Object.Comments = 'Reviewed: John Doe';
Object.LastModifiedBy = 'Joe Schmoe';
set_param(model, 'SimulationCommand', 'start');
```

```
Object =
```

```
SuppressedDiagnostic with properties:
```

```
Source: 'Suppressor_CLI_Demo/Convert/FixPt To FixPt1'
Id: 'SimulinkFixedPoint:util:Saturationoccurred'
LastModifiedBy: 'Joe Schmoe'
Comments: 'Reviewed: John Doe'
LastModified: '2016-Jun-21 18:23:01'
```

## Get Suppression Data

To get suppression data for a certain subsystem or block, use the `Simulink.getSuppressedDiagnostics` function.

```
Object = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo/Convert/FixPt To FixPt1');  
set_param(model, 'SimulationCommand', 'start');
```

## Restore All Diagnostics on a Model

When a model contains many diagnostic suppressions, and you want to restore all diagnostics to a model, use the `Simulink.getSuppressedDiagnostics` function to return an array of `Simulink.SuppressedDiagnostic` objects. Then use the `restore` method as you iterate through the array.

```
Objects = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo');  
for iter = 1:numel(Objects)  
    restore(Objects(iter));  
end  
set_param(model, 'SimulationCommand', 'start');
```

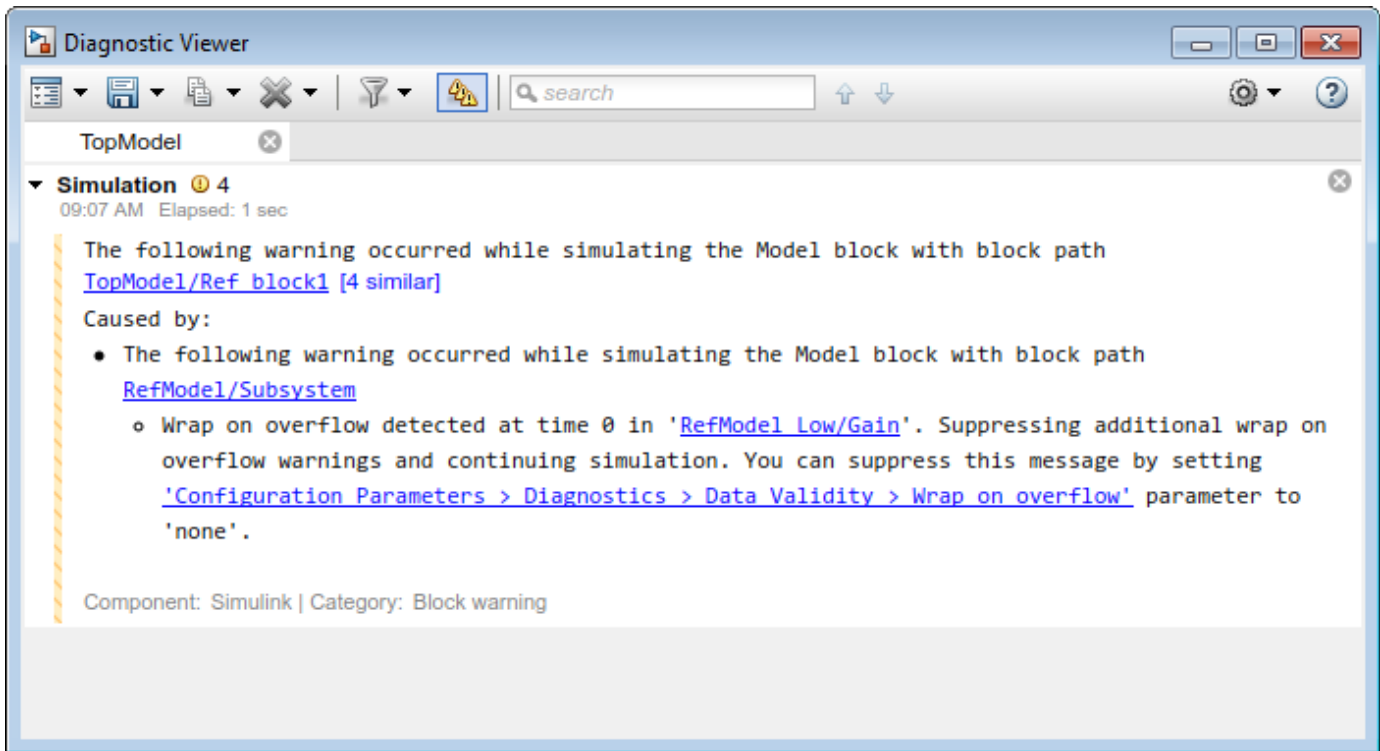

## Suppress Diagnostic Messages of a Referenced Model

This example shows how to suppress a diagnostic when the diagnostic originates from a referenced model. By accessing the `MSLDiagnostic` object of the specific instance of the warning, you can suppress the warning only for instances when the referenced model is simulated from the specified top model.

This example model contains two instances of the same referenced model, `RefModel`. The model `RefModel` references yet another model, `RefModel_Low`. `RefModel_Low` contains two Gain blocks that each produce a wrap on overflow warning during simulation. Suppress one of the four instances of this warning in the model by accessing the `MSLDiagnostic` object associated with the wrap on overflow warning produced by one of the Gain blocks in the `RefModel_Low` model only when it is referenced by `Ref_block1`.

Open the top model. Simulate the model and store the output in a variable, out.

```
out = sim('TopModel');
```

Access the simulation metadata stored in the MSLDiagnostic object.

```
diag = getDiagnosticObjects(out)
```

```
diag =
```

```
1x4 MSLDiagnostic array with properties:
```

```
    identifier
    message
    paths
    cause
    stack
```

You can view the diagnostics and their causes in the Diagnostic Viewer or at the command-line.

```
for i = 1 : numel(diag)
    disp(diag(i));
    disp(diag(i).cause{1});
end
```

Suppress one of the wrap on overflow warnings from RefModel\_Low only when it is simulated from TopModel/Ref\_block1 by accessing the specific diagnostic. Simulate the model.

```
Simulink.suppressDiagnostic(diag(1));
out = sim('TopModel')
```

Access the simulation metadata. This simulation produced only three warnings.

```
diag = getDiagnosticObjects(out)
diag =
    1×3 MSLDiagnostic array with properties:
        identifier
        message
        paths
        cause
        stack
```

Restore the diagnostic to the model.

```
Simulink.restoreDiagnostic(diag(1));
```

`Simulink.SimulationMetadata`

## Customize Diagnostic Messages

### In this section...

“Display Custom Text” on page 27-71

“Create Hyperlinks to Files, Folders, or Blocks” on page 27-71

“Create Programmatic Hyperlinks” on page 27-72

The **Diagnostic Viewer** displays the output of MATLAB error functions executed during simulation.

You can customize simulation error messages in the following ways by using MATLAB error functions in callbacks, S-functions, or MATLAB Function blocks.

### Display Custom Text

This example shows how you can customize the MATLAB function `check_signal` to display the text `Signal is negative`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

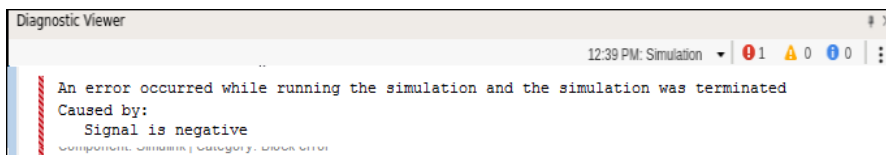

```

function y = check_signal(x)
    if x < 0
        error('Signal is negative');
    else
        y = x;
    end
  
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

### Create Hyperlinks to Files, Folders, or Blocks

To create hyperlinks to files, folders, or blocks in an error message, include the path to these items within customized text.

Example error message	Hyperlink
<code>error('Error reading data from "C:/Work/designData.mat"')</code>	Opens <code>designData.data</code> in the MATLAB Editor.
<code>error('Could not find data in folder "C:/Work"')</code>	Opens a Command Window and sets <code>C:\Work</code> as the working folder.
<code>error('Error evaluating parameter in block "myModel/Mu"')</code>	Displays the block <code>Mu</code> in model <code>myModel</code> .

## Create Programmatic Hyperlinks

This example shows how you can customize the MATLAB function `check_signal` to display a hyperlink to the documentation for `find_system`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

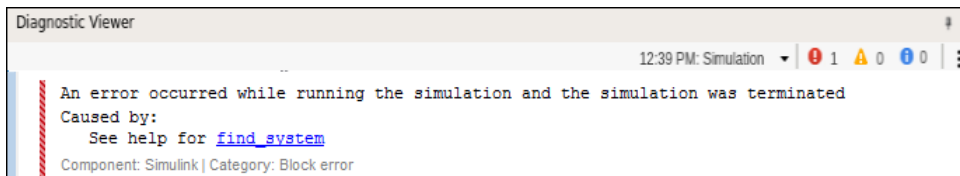

```

function y = check_signal(x)
    if x < 0
        error('See help for <a href="matlab:doc find_system">find_system</a>');
    else
        y = x;
    end
end
  
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

## Report Diagnostic Messages Programmatically

The `sldiagviewer` functions enable you to generate, display, and log diagnostic messages in the Diagnostic Viewer.

You can use these functions to report the diagnostic messages programmatically:

- Function to create a stage: `sldiagviewer.createStage`
- Functions to report diagnostic messages:
  - `sldiagviewer.reportError`
  - `sldiagviewer.reportWarning`
  - `sldiagviewer.reportInfo`
- Function to log the diagnostics: `sldiagviewer.diary`

### Create Diagnostic Stages

In the Diagnostic Viewer, errors, warnings, and information messages are displayed in groups based on the operation, such as model load, simulation, and build. These groups are called stages. The `sldiagviewer.createStage` function enables you to create stages. You can also create child stages for a stage object. A parent stage object must be active to create a child stage. When you create a stage object, Simulink initializes a stage. When you close the stage object, Simulink ends the stage. If you delete a parent stage object, the corresponding parent and its child stage close in the Diagnostic Viewer. The syntax for creating a stage is:

```
stageObject = sldiagviewer.createStage(StageName, 'ModelName', ModelNameValue)
```

In this syntax,

- `StageName` specifies the name of a stage and is a required argument, for example, `'Analysis'`.
- Use the `'ModelName', ModelNameValue` pair to specify the model name of a stage, for example `'ModelName', 'vdp'`. All the child stages inherit the model name from their parent.

#### Example to Create Stage

```
my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');
```

### Report Diagnostic Messages

You can use the `sldiagviewer` functions to report error, warning, or information messages in the Diagnostic Viewer. The syntaxes for reporting diagnostic messages are:

- `sldiagviewer.reportError(Message)`: Reports the error messages.
- `sldiagviewer.reportWarning(Message)`: Reports the warnings.
- `sldiagviewer.reportInfo(Message)`: Reports the information messages.

`Message` describes the error, warning, or build information and is a required argument. `Message` can have values in these formats:

- String

- MSLErrorException or MException object

Optionally, you can use the 'Component' argument and its corresponding value in the syntax to specify the component or product that generates the message, for example, 'Simulink' and 'Stateflow'.

### Example to Report Diagnostics

```
% Create a Stage to display all the messages

my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');

% Catch the error introduced in vdp as an exception.

try
sim('vdp');
catch error
% Report the caught exception as warning

sldiagviewer.reportWarning(error);
end

% Report a custom info message to Diagnostic Viewer

sldiagviewer.reportInfo('My Info message');
```

## Log Diagnostic Messages

You can use the `sldiagviewer.diary` function to log the simulation warning, error, and build information to a file. The syntaxes for generating log files are:

- `sldiagviewer.diary`: Intercepts the build information, warnings, and errors transmitted to the Diagnostic Viewer and logs them to a text file `diary.txt` in the current directory.
- `sldiagviewer.diary(filename)`: Toggles the logging state of the text file specified by `filename`.
- `sldiagviewer.diary(toggle)`: Toggles the logging ability. Valid values are 'on' and 'off'. If you have not specified a log file name, the toggle setting applies to the last file name that you specified for logging or to the `diary.txt` file.
- `sldiagviewer.diary(filename, 'UTF-8')`: Specifies the character encoding for the log file.

In this syntax,

- `filename` specifies the file to log the data to.
- `toggle` specifies the logging state 'on' or 'off'.

### Log Diagnostic Messages

```
% Start logging build information and simulation warnings and errors to diary.txt

sldiagviewer.diary
open_system('vdp')
set_param('vdp/Mu', 'Gain', 'xyz')
set_param('vdp', 'SimulationCommand', 'Start')
% This introduces an error and do UI simulation which you can see in the diary log

% Open diary.txt to view logs.

%### Starting build procedure for model: vdp
```

```
### Build procedure for model: 'vdp' aborted due to an error.
%...

% Set up logging to a specific file
% Make sure you have write permission for this location

sdiagviewer.diary('C:\MyLogs\log1.txt')

% Switch the logging state of a file

sdiagviewer.diary('C:\MyLogs\log2.txt') % Switch on logging and specify a log file.
open_system('vdp')
set_param('vdp/Mu', 'Gain', 'xyz')
set_param('vdp', 'SimulationCommand', 'Start')

sdiagviewer.diary('off') % Switch off logging.
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample',...
    'supportingfile','sldemo_fuelsys');
% Any operation you do after the previous command will not be logged
sim('sldemo_fuelsys')

sdiagviewer.diary('on') % Resume logging in the previously specified log file.

% Specify the filename to log to and character encoding to be used
sdiagviewer.diary('C:\MyLogs\log3.txt','UTF-8')
```

## View and Trace Callbacks in Models

You can view and trace all the callbacks executed in a model. To record all callbacks, on the Simulink toolstrip, on the **Debug** tab, under **Diagnostics**, select **Log Callbacks**. To view the callback report, go to **Debug > Diagnostics > Callback Tracer**.

The Callback Tracer report displays the **Order**, **Callback Type**, **Object Name**, **Callback Code**, and **Total Execution Time (s)**.

This is the call back tracer report for the vdp model.

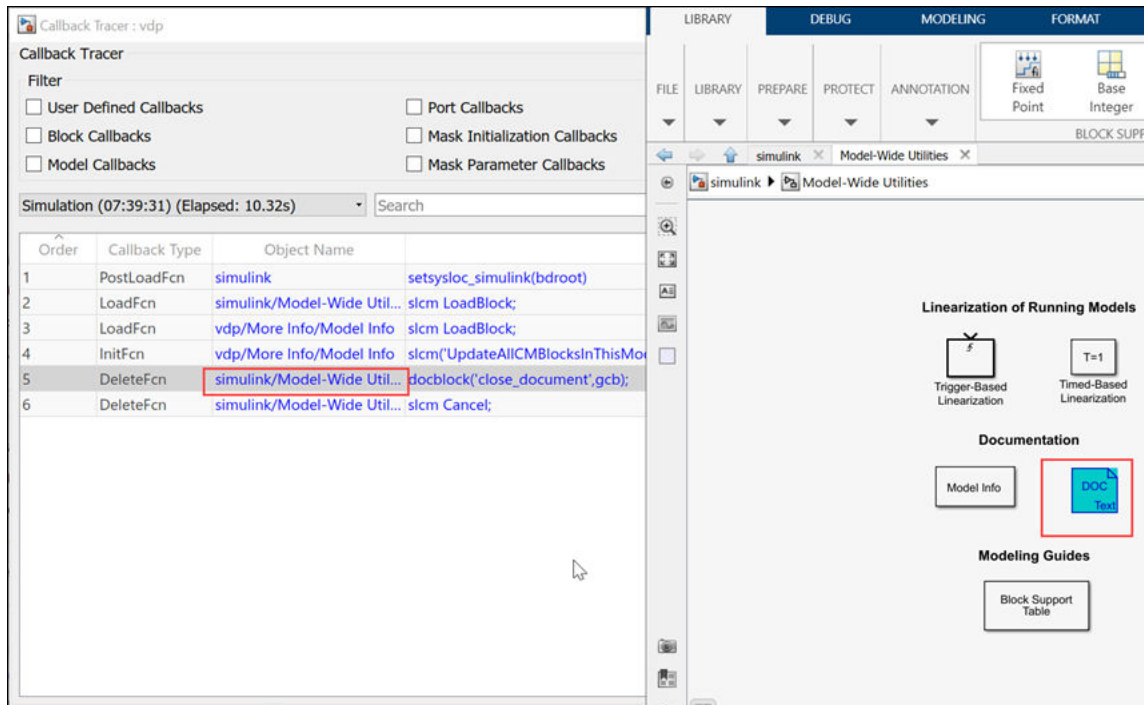

The screenshot shows the 'Callback Tracer' window with the following data:

Order	Callback Type	Object Name	Callback Code	Total Execution Time (s)
1	PostLoadFcn	<a href="#">simulink</a>	setsysloc_simulink(bdroot)	0.0181
2	LoadFcn	<a href="#">simulink/Model-Wide Util...</a>	slcm LoadBlock;	0.1400
3	LoadFcn	<a href="#">vdp/More Info/Model Info</a>	slcm LoadBlock;	0.0098
4	InitFcn	<a href="#">vdp/More Info/Model Info</a>	slcm('UpdateAllCMBlocksInThisModelInit')	0.0103
5	DeleteFcn	<a href="#">simulink/Model-Wide Util...</a>	docblock('close_document',gcb);	0.0636
6	DeleteFcn	<a href="#">simulink/Model-Wide Util...</a>	slcm Cancel;	0.0005

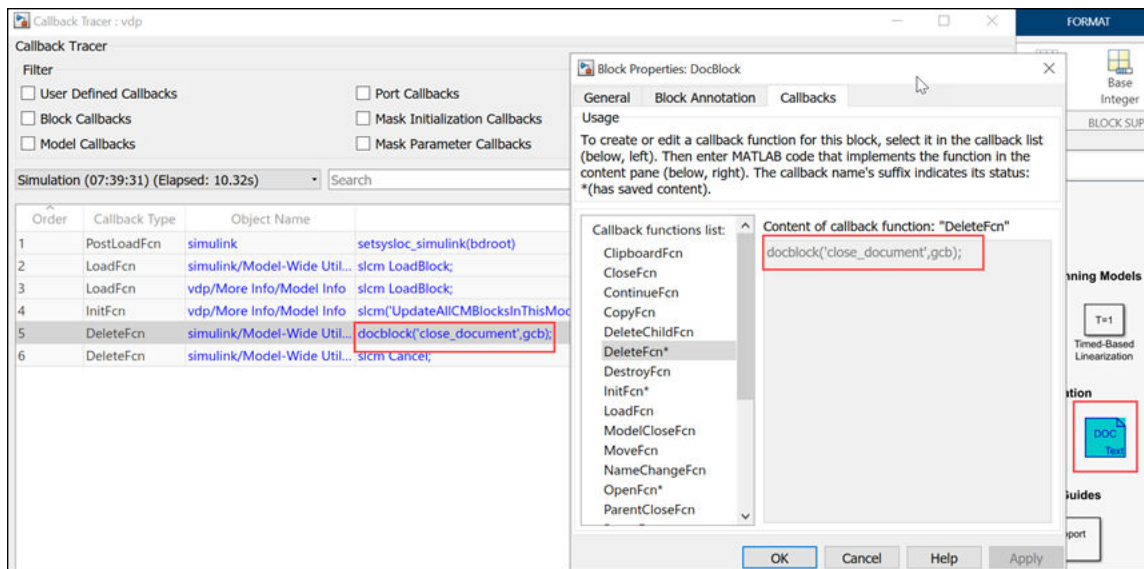

**Order:** The order in which callbacks are executed. You can sort this column in ascending or descending order.

**Callback Type:** Callbacks that are executed based on events, for example, PostLoadFcn, DeleteFcn, LoadFcn, InitFcn.

**Object Name:** The object that triggers the callback. The objects are hyper-linked. Click the hyper-linked object name to navigate to the object. The object is highlighted in the model, which helps you to identify the object without having to search for it.

**Callback Code:** The callback code is displayed in this column. The code is hyper-linked. Click the code to go to the callback code editor, where you can make code changes.

**Total Execution Time (s) :** The total time to execute the callback code. This column is sortable, which allows you to analyze the performance of the callback code and minimize time.

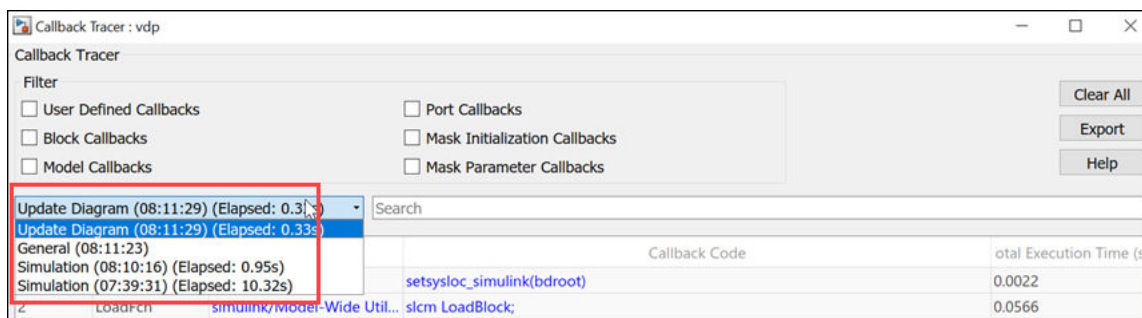

## Filters

You can filter callbacks based on type:

- “Block Callback”
- “Model Callback”
- “Port Callback”
- Mask Initialization Callbacks
- “Mask Parameter Callback”

## Stage-Specific Callbacks

The callbacks are recorded for each event, for example, Model Load, Simulation, Update Diagram. Click the stage pane and select an event to view callbacks specific to the event. The time stamp and the time taken for execution are recorded.

## Search

Use the **Search** box to search for specific keywords.

## Export

You can export the Callback Tracer report to a TXT or JSON file. To export the Callback Tracer report, click **Export**, then select the file format.

If you export the report in JSON format, use this code to read the contents of the JSON file.

```
fileName = 'vdp.json';
str = fileread(fileName);
data = jsondecode(str);
```

## Trace Callbacks Programmatically

To trace callbacks programmatically, enter `set_param(0, 'CallbackTracing', 'on')` in the MATLAB Command Window.

The `CallbackTracing` parameter causes the callbacks to appear in the MATLAB Command Window as they are invoked. This option applies to all Simulink models, not just models that are open when you enable the preference.

## Run Simulations Programmatically

You can simulate a model programmatically in two ways:

- Via `sim` command.
- Via the run button

When performing simulations with the `sim` command, you use the command line to perform operations on your simulation. Performing simulations with the **Run** button implies that you can interact with the simulation using the Simulink UI to perform any other additional operations. The following table elaborates the differences between these two approaches.

Actions	Non-Interactive Simulation ( <code>sim</code> Command Simulations)	Interactive Simulation (Run Button Simulations)
Allowed level of interaction	Low	High
Start a simulation	<code>sim</code> command	<b>Run</b> / <code>set_param mdl, 'SimulationCommand', 'Start'</code>
Stopping a simulation	<b>Ctrl-C</b> on the command line	<code>set_param mdl, 'SimulationCommand', 'Stop'</code> / <b>Stop</b>
Pausing a simulation	No	Yes. <code>set_param mdl, 'SimulationCommand', 'Pause'</code> / <b>Pause</b>
MATLAB prompt available while simulation runs	No	Yes
Scopes update while simulation runs	Yes, except in Rapid Accelerator Mode	Yes
Simulation Stepper	No	Yes, except in Rapid Accelerator Mode
Conditional Pauses	No	Yes, except in Rapid Accelerator Model
Port value displays available while simulation runs?	No	Yes
Supports simulation pacing	Yes	Yes
Supports Timeout option	Yes	No
Error handling	MATLAB exception, unless <code>CaptureErrors</code> is on	Reported to the Diagnostic Viewer

### sim Command Simulations

You can programmatically simulate a model with the `sim` function by using the specified techniques to specify parameter values. In addition to simulating a model, you can use the `sim` command to enable simulation timeout, capture simulation errors, and access simulation metadata when your simulation is complete.

## Specify Parameter Name-Value Pairs

This example shows how to programmatically simulate a model, specifying model parameters as name-value pairs.

Simulate the vdp model with parameter values specified as consecutive name-value pairs.

```
simOut = sim('vdp','SimulationMode','normal',...
            'SaveState','on','StateSaveName','xout',...
            'SaveOutput','on','OutputSaveName','yout',...
            'SaveFormat','Dataset');
outputs = simOut.yout
```

```
outputs =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
    Name: 'yout'
    Total Elements: 2
```

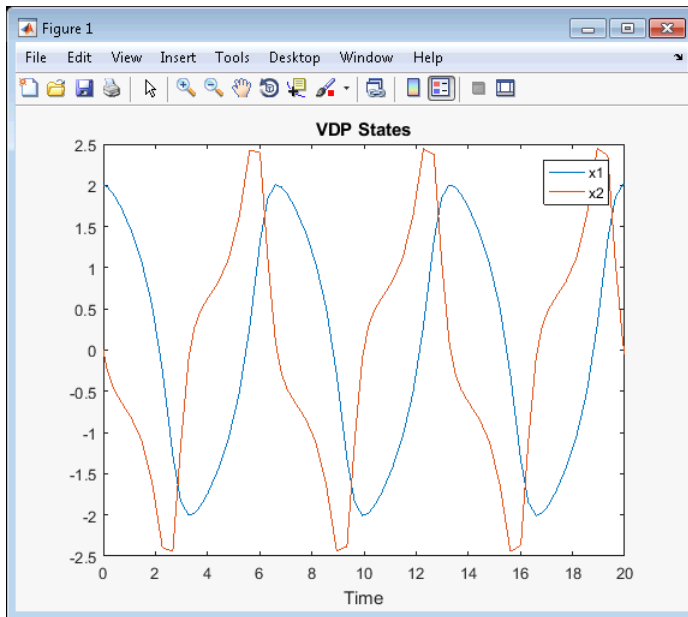

```
Elements:
    1 : 'x1'
    2 : 'x2'
```

```
-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.
```

You simulate the model in `Normal` mode, specifying an absolute tolerance for solver error. The `sim` function returns `SimOut`, a single `Simulink.SimulationOutput` object that contains all of the simulation outputs: logged time, states, and signals.

Plot the output signal values against time.

```
x1 = (outputs.get('x1').Values);
x2 = (outputs.get('x2').Values);
plot(x1); hold on;
plot(x2);
title('VDP States')
xlabel('Time'); legend('x1','x2')
```

### Enable Simulation Timeouts

If you are running multiple simulations in a loop and are using a variable-step solver, consider using `sim` with the `timeout` parameter. If, for some reason, a simulation hangs or begins to take unexpectedly small time steps, it will time out. Then, the next simulation can run.

```
N = 100;
simOut = repmat(Simulink.SimulationOutput, N, 1);
for i = 1:N
    simOut(i) = sim('vdp', 'timeout', 1000);
end
```

### Capture Simulation Errors

If an error causes your simulation to stop, you can see the error in the simulation metadata. In this case, `sim` captures simulation data in the simulation output object up to the time it encounters the error, enabling you to do some debugging of the simulation without rerunning it. To enable this feature, use the `CaptureErrors` parameter with the `sim` function.

Another advantage of this approach is that the simulation error does not also cause `sim` to stop. Therefore, if you are using `sim` in a `for` loop, for example, subsequent iterations of the loop will still run.

```
simOut = sim('my_model', 'CaptureErrors', 'on');
simOut.getSimulationMetadata.ExecutionInfo

ans =

    struct with fields:
        StopEvent: 'DiagnosticError'
        StopEventSource: []
        StopEventDescription: 'Division by zero in 'my_model/Divide''
```

```
ErrorDiagnostic: [1x1 struct]
WarningDiagnostics: [0x1 struct]
```

### Access Simulation Metadata

This example shows you how to access simulation metadata once your simulation is complete. You can run any kind of simulation and access its metadata.

This example simulates the model with parameter values specifies as name-value pairs. Run the simulation.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
            'SaveState','on','StateSaveName','xoutNew',...
            'SaveOutput','on','OutputSaveName','youtNew',...
            'SaveFormat','StructureWithTime');
```

Access the `ModelInfo` property, which has basic information about the model and solver.

```
simOut.getSimulationMetadata.ModelInfo
ans =
    struct with fields:
        ModelName: 'vdp'
        ModelVersion: '1.6'
        ModelFilePath: 'C:\MyWork'
        UserID: 'User'
        MachineName: 'MyMachine'
        Platform: 'PCWIN64'
        ModelStructuralChecksum: [4x1 uint32]
        SimulationMode: 'normal'
        StartTime: 0
        StopTime: 20
        SolverInfo: [1x1 struct]
        SimulinkVersion: [1x1 struct]
        LoggingInfo: [1x1 struct]
```

Inspect the solver information.

```
simOut.getSimulationMetadata.ModelInfo.SolverInfo
ans =
    struct with fields:
        Type: 'Variable-Step'
        Solver: 'ode45'
        MaxStepSize: 0.4000
```

Review timing information for your simulation, such as when your simulation started and finished, and the time the simulation took to initialize, execute, and terminate.

```
simOut.getSimulationMetadata.TimingInfo
ans =
    struct with fields:
```

```

WallClockTimestampStart: '2016-06-17 10:26:58.433686'
WallClockTimestampStop: '2016-06-17 10:26:58.620687'
InitializationElapsedWallTime: 0.1830
ExecutionElapsedWallTime: 1.0000e-03
TerminationElapsedWallTime: 0.0030
TotalElapsedWallTime: 0.1870

```

Add notes to your simulation.

```

simOut=simOut.setUserString('Results from simulation 1 of 10');
simOut.getSimulationMetadata

```

ans =

SimulationMetadata with properties:

```

ModelInfo: [1x1 struct]
TimingInfo: [1x1 struct]
ExecutionInfo: [1x1 struct]
UserString: 'Results from simulation 1 of 10'
UserData: []

```

You can also add your own custom data using the `UserData` property.

## Run-Button Simulations

For an interactive simulation, you can use `set_param` and `get_param`. With `set_param` and `get_param`, you can check the status of a running simulation and control how the simulation works by using block callbacks.

### Control and Check Status of Simulation

This example shows how to use `set_param` to control the status of your simulation. `set_param` allows you to update the variables dynamically as well as write data-logging variables to the workspace.

Start a simulation.

```

set_param('vdp', 'SimulationCommand', 'start')

```

When you start a simulation using `set_param` and the `'start'` argument, you must use the `'stop'` argument to stop it. Not using the `'stop'` argument causes the simulation to stop only once its finished.

Pause, continue, and stop a simulation.

```

set_param('vdp', 'SimulationCommand', 'pause')
set_param('vdp', 'SimulationCommand', 'continue')
set_param('vdp', 'SimulationCommand', 'stop')

```

When you use `set_param` to pause or stop a simulation, the simulation does not execute the commands immediately. You can use `set_param` to start a simulation after the `stop` command and to continue a simulation after the `pause` command. Simulink first completes uninterruptable work, such as solver steps and other commands that preceded the `set_param` command. Then, simulation starts, pauses, continues, or stops as specified by the `set_param` command.

Check the status of a simulation.

```
get_param('vdp', 'SimulationStatus')
```

The software returns 'stopped', 'initializing', 'running', 'paused', 'compiled', 'updating', 'terminating', or 'external' (used with the Simulink Coder product).

To update the changed workspace variables dynamically while a simulation is running, use the `update` command.

```
set_param('vdp', 'SimulationCommand', 'update')
```

Write all data-logging variables to the base workspace.

```
set_param('vdp', 'SimulationCommand', 'WriteDataLogs')
```

### Automate Simulation Tasks Using Callbacks

A callback executes when you perform various actions on your model, such as starting, pausing, or stopping a simulation. You can use callbacks to execute a MATLAB script or other MATLAB commands. For more information, see “Customize Model Behavior with Callbacks” on page 4-52 and “Block Callbacks” on page 4-59.

This example shows how to use the model `StartFcn` callback to automatically execute MATLAB code before the simulation starts.

Write a MATLAB script that finds Scope blocks in your model and opens them in the foreground when you simulate the model. Save the script in the current folder.

```
% openscopes.m
% Brings scopes to forefront at beginning of simulation.

blocks = find_system(bdroot, 'BlockType', 'Scope');

% Finds all of the scope blocks in the top level of your
% model. To find scopes in subsystems, provide the subsystem
% names. Type help find_system for more on this command.

for i = 1:length(blocks)
    set_param(blocks{i}, 'Open', 'on')
end

% Loops through all of the scope blocks and brings them
% to the forefront.
```

Set the `StartFcn` parameter for the model to call the `openscopes` script.

```
set_param('my_model', 'StartFcn', 'openscopes')
```

### Related Examples

- “Running Multiple Simulations” on page 29-2

## Run Parallel Simulations

The `parsim` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple simulations at the same time on different workers. `parsim` makes it easy for you to run the same model with different inputs or different parameter settings in scenarios such as Monte Carlo analyses, parameter sweeps, model testing, experiment design, and model optimization. Running a single simulation in parallel by decomposing the model into smaller components and running those individual pieces simultaneously on multiple workers is currently not supported.

To run the simulations in parallel with `parsim`, you need a Parallel Computing Toolbox for local workers. In addition, you can use MATLAB Parallel Server for multiple computer clusters, clouds, and grids. In the absence of Parallel Computing Toolbox and MATLAB Parallel Server, `parsim` runs the simulations in serial. For more information, see “Parallel Computing Toolbox” and “MATLAB Parallel Server”.

If no parallel pool exists, `parsim` creates a pool from the default cluster profile. To use a cluster other than the default, create a pool with that cluster profile before calling `parsim`.

This example runs multiple simulations in parallel for a set of sweep parameters.

```
% 1) Load model
openExample('sldemo_suspn_3dof');
model = 'sldemo_suspn_3dof';
load_system(model);

% 2) Set up the sweep parameters
Cf_sweep = 2500*(0.05:0.1:0.95);
numSims = numel(Cf_sweep);

% 3) Create an array of SimulationInput objects and specify the sweep value for each simulation
simIn(1:numSims) = Simulink.SimulationInput(model);
for idx = 1:numSims
    simIn(idx) = simIn(idx).setBlockParameter([model '/Road-Suspension Interaction'], 'Cf', num2str(Cf_sweep(idx)))
end

% 4) Simulate the model
simOut = parsim(simIn)
```

### How `parsim` works

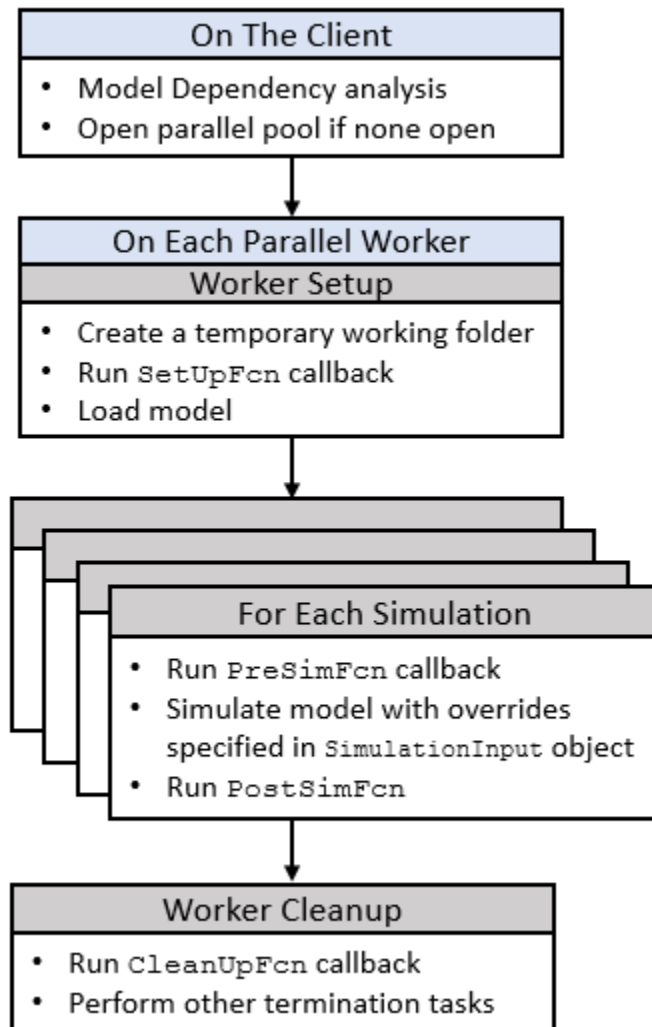

`parsim` runs simulations with different parameters and values based on the `Simulink.SimulationInput` object. Each `SimulationInput` object specifies one simulation of the model. An array of these objects can be created for multiple simulations. For more information, see “Running Multiple Simulations” on page 29-2.

You can use the following methods and properties on `Simulink.SimulationInput` object:

- `setVariables` - Change variables in base workspace, data dictionary, or model workspace
- `setBlockParameter` - Change block parameters
- `setModelParameter` - Change model parameters
- `setPreSimFcn` - Specify MATLAB functions to run before each simulation for customization and post-processing results on the cluster
- `setPostSimFcn` - Specify MATLAB functions to run after each simulation for customization and post-processing results on the cluster

- `InitialState` - Change the Initial State
- `ExternalInput` - Specify a numerical array, timeseries, or Dataset object as external inputs to the model

This flowchart shows a general sequence of events that occur when `parsim` is executed

Changes to model library blocks can be overwritten when using `parsim`. When models are set up on new workers, model inherits properties directly from the worker library. Use `SetupFcn` with `parsim` to transfer the model library block changes to the workers.

## Using sim function within parfor

---

**Note** Using `sim` function within `parfor` loop is no longer recommended. For running parallel simulations, use `parsim`. Please see “Run Parallel Simulations” on page 28-8.

---

### Overview of Calling sim from Within parfor

The `parfor` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple model simulations at the same time on different workers. Calling `sim` from within a `parfor` loop often helps for performing multiple simulation runs of the same model for different inputs or for different parameter settings. For example, you can save simulation time performing parameter sweeps and Monte Carlo analyses by running them in parallel. Note that running parallel simulations using `parfor` does not currently support decomposing your model into smaller connected pieces and running the individual pieces simultaneously on multiple workers.

Normal, Accelerator, and Rapid Accelerator simulation modes are supported by `sim` in `parfor`. (See “Choosing a Simulation Mode” on page 38-10 for details on selecting a simulation mode and “Design Your Model for Effective Acceleration” on page 38-14 for optimizing simulation run times.) For other simulation modes, you need to address any workspace access issues and data concurrency issues to produce useful results. Specifically, the simulations need to create separately named output files and workspace variables. Otherwise, each simulation overwrites the same workspace variables and files, or can have collisions trying to write variables and files simultaneously.

For information on code regeneration and parameter handling in Rapid Accelerator mode, see “Parameter Tuning in Rapid Accelerator Mode” on page 38-7.

Also, see `parfor`.

---

**Note** If you open models inside a `parfor` statement, close them again using `bdclose all` to avoid leaving temporary files behind.

---

### sim in parfor with Normal Mode

This code fragment shows how you can use `sim` and `parfor` in Normal mode. Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.

```
% 1) Load model and initialize the pool.
openExample('sldemo_suspn_3dof');
model = 'sldemo_suspn_3dof';
load_system(model);
parpool;

% 2) Set up the iterations that we want to compute.
Cf = evalin('base', 'Cf');
Cf_sweep = Cf*(0.05:0.1:0.95);
iterations = length(Cf_sweep);
simout(iterations) = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
```

```

% any code is generated for instance for StateFlow, or any other
% file artifacts are created by the model.
smpd
    % Setup tempdir and cd into it
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
smpd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcf('nocreate'));

```

### sim in parfor with Normal Mode and MATLAB Parallel Server Software

This code fragment is identical to the one in “sim in parfor with Normal Mode” on page 28-11

. Modify it as follows for using `sim` and `parfor` in Normal mode:

- In item 1, modify the `parpool` command as follows to create an object and use it to call a cluster name.
 

```
p = parpool('clusterProfile');
```

 % 'clusterProfile' is the name of the distributed cluster
- In item 1, find files on which the model depends and attach those files to the model for distribution to cluster workers on remote machines.
 

```
files = dependencies.fileDependencyAnalysis(modelName);
p.addAttachedFiles(files);
```
- If you do not have a MATLAB Parallel Server cluster, use your local cluster. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

Start your cluster before running the code.

```

% 1) Load model and initialize the pool.
openExample('sldemo_suspn_3dof');
model = 'sldemo_suspn_3dof';
load_system(model);

```

```

parpool;

% 2) Set up the iterations that we want to compute.
Cf                = evalin('base', 'Cf');
Cf_sweep          = Cf*(0.05:0.1:0.95);
iterations        = length(Cf_sweep);
simout(iterations) = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are created by the model.
spmd
    % Setup tempdir and cd into it
    addpath(pwd);
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));

```

### sim in parfor with Rapid Accelerator Mode

Running Rapid Accelerator simulations in `parfor` combines speed with automatic distribution of a prebuilt executable to the `parfor` workers. As a result, this mode eliminates duplication of the update diagram phase.

To run parallel simulations in Rapid Accelerator simulation mode using the `sim` and `parfor` commands:

- Configure the model to run in Rapid Accelerator simulation mode.
- Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.
- Ensure that the Rapid Accelerator target is already built and up to date.

- Disable the Rapid Accelerator target up-to-date check by setting the `sim` command option `RapidAcceleratorUpToDateCheck` to `'off'`.

To satisfy the second condition, you can change parameters only between simulations that do not require a model rebuild. In other words, the structural checksum of the model must remain the same. Hence, you can change only tunable block diagram parameters and tunable run-time block parameters between simulations. For a discussion on tunable parameters that do not require a rebuild subsequent to their modifications, see “Determine If the Simulation Will Rebuild” on page 38-7.

To disable the Rapid Accelerator target up-to-date check, use the `sim` command, as shown in this sample.

```
parpool;
% Load the model and set parameters
model = 'vdp';
load_system(model);
% Build the Rapid Accelerator target
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model,'SimulationMode', 'rapid',...
                  'RapidAcceleratorUpToDateCheck', 'off',...
                  'SaveTime', 'on',...
                  'StopTime', num2str(10*i));
    close_system(model, 0);
end

close_system(model, 0);
delete(gcf('nocreate'));
```

In this example, the call to the `buildRapidAcceleratorTarget` function generates code once. Subsequent calls to `sim` with the `RapidAcceleratorUpToDateCheck` option `off` guarantees that code is not regenerated. Data concurrency issues are thus resolved.

When you set `RapidAcceleratorUpToDateCheck` to `'off'`, changes that you make to block parameter values in the model (for example, by using block dialog boxes, by using the `set_param` function, or by changing the values of MATLAB variables) do not affect the simulation. Instead, use `RapidAcceleratorParameterSets` to pass new parameter values directly to the simulation.

## Workspace Access Issues

### Workspace Access for MATLAB worker sessions

By default, to run `sim` in `parfor`, a parallel pool opens automatically, enabling the code to run in parallel. Alternatively, you can also first open MATLAB workers using the `parpool` command. The `parfor` command then runs the code within the `parfor` loop in these MATLAB worker sessions. The MATLAB workers, however, do not have access to the workspace of the MATLAB client session where the model and its associated workspace variables have been loaded. Hence, if you load a model and define its associated workspace variables outside of and before a `parfor` loop, then neither is the model loaded, nor are the workspace variables defined in the MATLAB worker sessions where the `parfor` iterations are executed. This is typically the case when you define model parameters or external inputs in the base workspace of the client session. These scenarios constitute workspace access issues.

### Transparency Violation

When you run `sim` in `parfor` with `srcWorkspace` set to `current`, Simulink uses the `parfor` workspace, which is a transparent workspace. Simulink then displays an error for transparency violation. For more information on transparent workspaces, see “Ensure Transparency in `parfor`-Loops or `spmd` Statements” (Parallel Computing Toolbox).

### Data Dictionary Access

When a model is linked to a data dictionary (see “What Is a Data Dictionary?” on page 79-2), to write code in `parfor` that accesses a variable or object that you store in the dictionary, you must use the functions `Simulink.data.dictionary.setupWorkerCache` and `Simulink.data.dictionary.cleanupWorkerCache` to prevent access issues. For an example, see “Sweep Variant Control Using Parallel Simulation” on page 28-16.

### Resolving Workspace Access Issues

When a Simulink model is loaded into memory in a MATLAB client session, it is only visible and accessible in that MATLAB session; it is not accessible in the memory of the MATLAB worker sessions. Similarly, the workspace variables associated with a model that are defined in a MATLAB client session (such as parameters and external inputs) are not automatically available in the worker sessions. You must therefore ensure that the model is loaded and that the workspace variables referenced in the model are defined in the MATLAB worker session by using the following two methods.

- In the `parfor` loop, use the `sim` command to load the model and to set parameters that change with each iteration. (Alternative: load the model and then use the `g(s)et_param` command(s) to set the parameters in the `parfor` loop)
- In the `parfor` loop, use the MATLAB `evalin` and `assignin` commands to assign data values to variables.

Alternatively, you can simplify the management of workspace variables by defining them in the model workspace. These variables will then be automatically loaded when the model is loaded into the worker sessions. There are, however, limitations to this method. For example, you cannot store signal objects that use a storage class other than `Auto` in a model workspace. For a detailed discussion on the model workspace, see “Model Workspaces” on page 72-121.

### Specifying Parameter Values Using the `sim` Command

Use the `sim` command in the `parfor` loop to set parameters that change with each iteration.

```
%Specifying Parameter Values Using the sim Command
```

```
model = 'vdp';
load_system(model)

%Specifying parameter values.
paramName = 'StopTime';
paramValue = {'10', '20', '30', '40'};

% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model, ...
                    paramName, paramValue{i}, ...
                    'SaveTime', 'on'); %#ok
```

```
end
```

```
close_system(model, 0);
```

An equivalent method is to load the model and then use the `set_param` command to set the `paramName` in the `parfor` loop.

### Specifying Variable Values Using the `assignin` Command

You can pass the values of model or simulation variables to the MATLAB workers by using the `assignin` or the `evalin` command. The following example illustrates how to use this method to load variable values into the appropriate workspace of the MATLAB workers.

```
parfor i = 1:4
    assignin('base', 'extInp', paramValue{i})%#ok
    % 'extInp' is the name of the variable in the base
    % workspace which contains the External Input data
    simOut{i} = sim(model, 'ExternalInput', 'extInp'); %#ok
end
```

### Sweep Variant Control Using Parallel Simulation

To use parallel simulation to sweep a variant control (a `Simulink.Parameter` object whose value influences the variant condition of a `Simulink.Variant` object) that you store in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and variant control to match your application.

To sweep block parameter values or the values of workspace variables that you use to set block parameters, use `Simulink.SimulationInput` objects instead of the programmatic interface to the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'mySweepMdl';
dd = 'mySweepDD.sldd';

% Define the sweeping values for the variant control
CtrlValues = [1 2 3 4];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmc
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(CtrlValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
    % Create objects to interact with dictionary data
    % You must create these objects for every iteration of the parfor-loop
    dictObj = Simulink.data.dictionary.open(dd);
    sectObj = getSection(dictObj, 'Design Data');
    entryObj = getEntry(sectObj, 'MODE');
```

```

% Suppose MODE is a Simulink.Parameter object stored in the data dictionary

% Modify the value of MODE
temp = getValue(entryObj);
temp.Value = CtrlValues(index);
setValue(entryObj,temp);

% Simulate and store simulation output in the nondistributed array
simOut{index} = sim(model);

% Each worker must discard all changes to the data dictionary and
% close the dictionary when finished with an iteration of the parfor-loop
discardChanges(dictObj);
close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model

spsmd
    bdclose(model)
    Simulink.data.dictionary.cleanupWorkerCache
end

```

---

**Note** If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

---

## Data Concurrency Issues

Data concurrency issues refer to scenarios for which software makes simultaneous attempts to access the same file for data input or output. In Simulink, they primarily occur as a result of the nonsequential nature of the `parfor` loop during simultaneous execution of Simulink models. The most common incidences arise when code is generated or updated for a simulation target of a Stateflow, Model block or MATLAB Function block during parallel computing. The cause, in this case, is that Simulink tries to concurrently access target data from multiple worker sessions. Similarly, To File blocks may simultaneously attempt to log data to the same files during parallel simulations and thus cause I/O errors. Or a third-party blockset or user-written S-function may cause a data concurrency issue while simultaneously generating code or files.

A secondary cause of data concurrency is due to the unprotected access of network ports. This type of error occurs, for example, when a Simulink product provides blocks that communicate via TCP/IP with other applications during simulation. One such product is the HDL Verifier™ for use with the Mentor Graphics® ModelSim® HDL simulator.

## Resolving Data Concurrency Issues

The core requirement of `parfor` is the independence of the different iterations of the `parfor` body. This restriction is not compatible with the core requirement of simulation via incremental code generation, for which the simulation target from a prior simulation is reused or updated for the current simulation. Hence during the parallel simulation of a model that involves code generation (such as Accelerator mode simulation), Simulink makes concurrent attempts to access (update) the simulation target. However, you can avoid such data concurrency issues by creating a temporary

folder within the `parfor` loop and then adding several lines of MATLAB code to the loop to perform the following steps:

- 1 Change the current folder to the temporary, writable folder.
- 2 In the temporary folder, load the model, set parameters and input vectors, and simulate the model.
- 3 Return to the original, current folder.
- 4 Remove the temporary folder and temporary path.

In this manner, you avoid concurrency issues by loading and simulating the model within a separate temporary folder. Following are examples that use this method to resolve common concurrency issues.

#### **A Model with Stateflow, MATLAB Function Block, or Model Block**

In this example, either the model is configured to simulate in Accelerator mode or it contains a Stateflow, a MATLAB Function block, or a Model block (for example, `sf_bounce`, `sldemo_autotrans`, or `sldemo_mdhref_basic`). For these cases, Simulink generates code during the initialization phase of simulation. Simulating such a model in `parfor` would cause code to be generated to the same files, while the initialization phase is running on the worker sessions. As illustrated below, you can avoid such data concurrency issues by running each iteration of the `parfor` body in a different temporary folder.

```
parfor i=1:4
    cwd = pwd;
    addpath(cwd)
    tmpdir = tempname;
    mkdir(tmpdir)
    cd(tmpdir)
    load_system(model)
    % set the block parameters, e.g., filename of To File block
    set_param(someBlkInMdl, blkParamName, blkParamValue{i})
    % set the model parameters by passing them to the sim command
    out{i} = sim(model, mdlParamName, mdlParamValue{i});
    close_system(model,0);
    cd(cwd)
    rmdir(tmpdir, 's')
    rmpath(cwd)
end
```

Note the following:

- You can also avoid other concurrency issues due to file I/O errors by using a temporary folder for each iteration of the `parfor` body.
- On Windows platforms, consider inserting the `evalin('base', 'clear mex');` command before `rmdir(tmpdir, 's')`. This sequence closes MEX-files first before calling `rmdir` to remove `tmpdir`.

```
evalin('base', 'clear mex');
rmdir(tmpdir, 's')
```

#### **A Model with To File Blocks**

If you simulate a model with To File blocks from inside of a `parfor` loop, the nonsequential nature of the loop may cause file I/O errors. To avoid such errors during parallel simulations, you can either use

the temporary folder idea above or use the `sim` command in Rapid Accelerator mode with the option to append a suffix to the file names specified in the model To File blocks. By providing a unique suffix for each iteration of the `parfor` body, you can avoid the concurrency issue.

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
    parfor idx=1:4
        sim(model, ...
            'ConcurrencyResolvingToFileSuffix', num2str(idx),...
            'SimulationMode', 'rapid',...
            'RapidAcceleratorUpToDateCheck', 'off');
    end
```

## Error Handling in Simulink Using MSLException

### Error Reporting in a Simulink Application

Simulink allows you to report an error by throwing an exception using the `MSLException` object, which is a subclass of the MATLAB `MException` class. As with the MATLAB `MException` object, you can use a try-catch block with a `MSLException` object construct to capture information about the error. The primary distinction between the `MSLException` and the `MException` objects is that the `MSLException` object has the additional property of `handles`. These handles allow you to identify the object associated with the error.

### The MSLException Class

The `MSLException` class has five properties: `identifier`, `message`, `stack`, `cause`, and `handles`. The first four of these properties are identical to those of `MException`. For detailed information about them, see `MException`. The fifth property, `handles`, is a cell array with elements that are double array. These elements contain the handles to the Simulink objects (blocks or block diagrams) associated with the error.

### Methods of the MSLException Class

The methods for the `MSLException` class are identical to those of the `MException` class. For details of these methods, see `MException`.

### Capturing Information about the Error

The structure of the Simulink try-catch block for capturing an exception is:

```
try
    Perform one or more operations
catch E
    if isa(E, 'MSLException')
    ...
end
```

If an operation within the `try` statement causes an error, the `catch` statement catches the exception (`E`). Next, an `if isa` conditional statement tests to determine if the exception is Simulink specific, i.e., an `MSLException`. In other words, an `MSLException` is a type of `MException`.

The following code example shows how to get the handles associated with an error.

```
errHndls = [];
try
    sim('modelName', ParamStruct);
catch e
    if isa(e, 'MSLException')
        errHndls = e.handles{1}
    end
end
```

You can see the results by examining `e`. They will be similar to the following output:

```
e =
```

MSLErrorException

Properties:

```
handles: {[7.0010]}
identifier: 'Simulink:Parameters:BlkParamUndefined'
message: [1x87 char]
cause: {0x1 cell}
stack: [0x1 struct]
```

Methods, Superclasses

To identify the name of the block that threw the error, use the `getfullname` command. For the present example, enter the following command at the MATLAB command line:

```
getfullname(errHndls)
```

If a block named Mu threw an error from a model named *vdp*, MATLAB would respond to the `getfullname` command with:

```
ans =
vdp/Mu
```

# Multiple Simulations

---

## Running Multiple Simulations

For workflows that involve multiple parallel simulations and logging of large amounts of data, you can use the `parsim` or `batchsim` functions, or run the simulations with the **Multiple Simulations** panel in the Simulink Editor. This approach is useful in scenarios like model testing, experiment design, Monte Carlo analysis, and model optimization.

For the command line workflow (`parsim` or `batchsim` functions), you can create simulation sets by using an array of `Simulink.SimulationInput` objects to run multiple simulations. Alternatively, you can use the **Multiple Simulations** panel in Simulink.

In the **Multiple Simulations** panel, you can create design studies to make specify values for simulations. The panel allows you to specify values for block parameters, and variables for the simulations.

With the Parallel Computing Toolbox, you can also use the `parsim` and `batchsim` functions, and **Multiple Simulations** panel to run the simulations in parallel.

- To run multiple simulations with `Simulink.SimulationInput` object and `parsim` function, see “Run Parallel Simulations for a Thermal Model of a House Using `parsim`” on page 29-5. To learn more about how the `parsim` function runs simulations in parallel, see “Run Parallel Simulations” on page 28-8.
- To learn about running multiple simulations in batch, see `batchsim`.
- To understand the differences between the command line workflows and how they work, see “Comparison Between Multiple Simulation Workflows” on page 29-10.
- To use the graphical user interface for running multiple simulations, see “Configure and Run Simulations with Multiple Simulations Panel” on page 29-19.
- To learn how to monitor the simulations and view the results, see “Analyze Data from Multiple Simulations” on page 31-127.

---

**Note** When the pool is not already open and simulations are run for the first time, simulations take an additional time to start. Subsequent parallel simulations are faster.

---

### Multiple Simulations with Simulink Editor

The **Multiple Simulations** panel allows you to set up multiple simulations for different values of block parameters and variables. You can pick a block parameter of interest from the model canvas and specify values that you want to use for the simulations. You can also provide variables for simulations. To run the simulations that you have set up, first, select the design study, then click **Run All** button on **Simulation** tab on the Simulink toolstrip. To learn more, see the “Multiple Simulations Panel: Simulate for Different Values of Stiffness for a Vehicle Dynamics System” on page 29-26 example.

### Multiple Simulations with Parallel Computing Toolbox

The `parsim` function and the **Multiple Simulations** panel distributes each simulation to parallel pool workers to decrease your overall simulation time when running in parallel. Using the `parsim` function and the **Multiple Simulations** panel creates a parallel pool, which allows you to identify file dependencies and manage build artifacts for simulations in accelerator and rapid accelerator mode.

The `batchsim` function offloads the simulations to the compute cluster. The simulations are executed on the cluster, which allows you to carry out other tasks while the batch job is processing. You can also close the client MATLAB session and access the batch job later.

The `batchsim` function uses the Parallel Computing Toolbox™ license to run the simulations on compute cluster. The `batchsim` function runs the simulations in serial if a parallel pool cannot be created. Without the Parallel Computing Toolbox license, `batchsim` function gives an errors.

## Multiple Simulations with the `sim` Function

In the absence of a Parallel Computing Toolbox license, the `parsim` function and the **Multiple Simulations** panel behave like the `sim` command. The simulations run in serial.

## Multiple Simulations with `Simulink.SimulationInput` Object

In command line workflows, you can make changes to your model using the `Simulink.SimulationInput` object and run a simulation in parallel with those changes. Changing the values in the `Simulink.SimulationInput` object, overrides the values in the model, which allows you to modify the model without dirtying it. Through the `Simulink.SimulationInput` object, you can also specify MATLAB functions to run at the start and the end of each simulation by using the `PreSimFcn` and `PostSimFcn` functions, respectively. When you use `Simulink.SimulationInput` objects, the model parameters are restored after the simulation ends. See “Run Parallel Simulations for a Thermal Model of a House Using `parsim`” on page 29-5. The `Simulink.SimulationInput` object allows you to change these settings in your model:

- Initial state
- External inputs
- Model parameters
- Block parameters
- Variables

## Simulation Manager to Monitor Simulations

The Simulation Manager allows you to monitor multiple parallel simulations. It shows the progress of the runs as they are running in parallel. You can view the details of every run such as parameters, elapsed time, and diagnostics. The Simulation Manager acts as a useful tool by giving you the option to analyze and compare your results in the Simulation Data Inspector. You can also select a run and apply its values to the model. For more information, see **Simulation Manager**.

## The `parsim/batchsim` Function Capabilities

- Outputs errors in the simulation output object for easier debugging
- Compatible with rapid accelerator and fast restart
- Compatible with file logging (to facilitate big data)
- Compatible with MATLAB Parallel Server in addition to local parallel pools
- Capable of transferring base workspace variables to workers
- Avoids transparency errors

## Data Logging for Multiple Simulations

The resulting `Simulink.SimulationOutput` object, which contains the simulation outputs, captures error messages and the simulation metadata. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter, Simulink creates a `Simulink.SimulationData.DatasetRef` object for each `Dataset` stored in the resulting MAT file. You can use the `DatasetRef` object to access the data for a `Dataset` element. For simulations that are run using the `Simulink.SimulationInput` objects, the `DatasetRef` object is returned as part of the `SimulationOutput` object. As a result, you have quicker access to and do not need to create them.

Parallel simulations can produce more logged data than the MATLAB memory can hold. Consider logging to persistent storage for parallel simulations to reduce the memory requirement. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter (`LoggingToFile`), for parallel simulations in Simulink:

- Data is logged in Dataset format in a MAT-file
- A `Simulink.SimulationData.DatasetRef` object is created for each `Dataset` element (for example, `logout`) for each simulation

You can use `DatasetRef` objects to access data for a specific signal. You can create `matlab.io.datastore.SimulationDatastore` objects to use for streaming logged data from persistent storage in to a model.

### More About

- “Run Parallel Simulations” on page 28-8
- “Multiple Simulations Panel: Simulate for Different Values of Stiffness for a Vehicle Dynamics System” on page 29-26
- “Run Parallel Simulations for a Thermal Model of a House Using `parsim`” on page 29-5
- “Comparison Between Multiple Simulation Workflows” on page 29-10
- “Work with Big Data for Simulations” on page 77-30

Using the defined values, initialize an array of `Simulink.SimulationInput` objects. Use these `Simulink.SimulationInput` objects to specify the Set Point values. In this step, to preallocate the array, the loop index is made to start from the largest value.

```
for i = spv_length:-1:1
    in(i) = Simulink.SimulationInput('sldemo_househeat');
    in(i) = in(i).setBlockParameter('sldemo_househeat/Set Point',...
        'Value',num2str(SetPointValues(i)));
end
```

This example produces an array of 11 `Simulink.SimulationInput` objects, each corresponding to a different value of Set Point.

Now, run these multiple simulations in parallel using the command `parsim`. To monitor and analyze the runs, open the Simulation Manager by setting the `ShowSimulationManager` argument to `on`. The `ShowProgress` argument when set to `on` shows the progress of the simulations.

```
out = parsim(in, 'ShowSimulationManager', 'on', 'ShowProgress', 'on')
```

The output is generated as a `Simulink.SimulationOutput` object. To see all of the different set point values, open the plot of the Temperatures (Indoor and Outdoor) and the Heat Cost component. The constant block Avg Outdoor Temp specifies the average air temperature outdoors. The Daily Temp Variation Sine Wave block generates daily temperature fluctuations of outdoor temperature. The indoor temperature is derived from the House subsystem. The temperature outdoor varies sinusoidally, whereas the temperature indoors is maintained within 5 degrees Fahrenheit of the set point.

In the absence of the Parallel Computing Toolbox licenses, the `parsim` command behaves like the `sim` command. The simulations run in serial.

## View the Runs in the Simulation Manager

Setting the `ShowSimulationManager` argument to `on` enables the Simulation Manager. For more information, see **Simulation Manager**.

You can view the status of all the runs and detailed information about them.

## Comparison Between Multiple Simulation Workflows

When running a set of multiple simulations, you can run them in parallel on multiple MATLAB workers in a parallel pool. To run multiple simulations, you can use `parsim`, `parsim` with 'RunInBackground' option turned on, or `batchsim`.

The flow chart shows how running multiple simulations with `parsim`, `parsim` with `RunInBackground` and `batchsim` differ.

The `parsim` and `batchsim` commands use the Parallel Computing Toolbox license to run the simulations in parallel. `parsim` runs the simulations in serial if a parallel pool cannot be created or if the Parallel Computing Toolbox license is not available. `batchsim` commands cannot run without Parallel Computing Toolbox license.

## parsim Workflow

Using `parsim` command with Parallel Computing Toolbox to run multiple simulations sets up a parallel pool automatically and runs simulations in parallel. The client is always tied to the MATLAB workers.

### Basic parsim Workflow

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 Run `parsim(in)` to execute these multiple simulations in parallel. If a parallel pool does not exist, `parsim` creates it. `parsim` uses default settings.
- 4 You can open Simulation Manager by setting the `'SimulationManager'` argument to `'on'` with `parsim, parsim(in, 'SimulationManager', 'on')`. Simulation Manager enables you to monitor the simulations as they are running and gives you access to outputs of the simulations when they are ready. Simulation Manager provides you with information about the simulations running on the workers. For more information, see **Simulation Manager**.
- 5 Once all the simulations are complete, you get an array of `Simulink.SimulationOutput` objects.

### Limitations

- Closing the MATLAB session terminates simulations on the workers, disabling retrieval of partial results.

### parsim with RunInBackground Workflow

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.

- 3 Run `parsim` with `RunInBackground` option set to `'on'`:  
`parsim(in, 'RunInBackground', 'on')`. Setting the `'RunInBackground'` option to `'on'` runs the simulations asynchronously. This keeps the MATLAB command prompt available enabling you to work on other tasks.
- 4 With `'RunInBackground'` option set to `'on'`, `parsim` returns a `Simulink.Simulation.Future` object. You can poll this object to check the status of simulations, fetch the outputs of simulations when they are completed, or cancel simulations. For more information, see `Simulink.Simulation.Future`.

### Limitations

- Closing the MATLAB session terminates simulations on the workers, disabling retrieval of partial results. If the `future` object is cleaned, you are subsequently unable to access the results of the simulations.
- Using a `fetchNext` method loop on `Future` objects, along with Simulation Manager causes them to compete for retrieval of `Future` objects. Use either a `fetchNext` method loop or Simulation Manager to get the outputs of completed simulations.

### batchsim Workflow

A batch workflow typically means submitting jobs to run simulations on MATLAB workers and subsequently accessing the results of those simulations. When you run simulations in batches, you offload the execution of simulations onto a compute cluster. To learn more about batch processing, see “Simple Batch Processing” (Parallel Computing Toolbox).

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 To run on a cluster or desktop background, call `batchsim` to offload the execution of simulations. With `batchsim`, you can use most of the arguments that are compatible with `parsim` and `batch` commands. For more information, see `batchsim`.

Using `batchsim`, you offload simulations to a MATLAB worker. To run the batch job on multiple workers, specify a pool size, `N`, that is an integer specifying the number of workers to make into a parallel pool for the job: `batchsim(in, 'Pool', N)`. There must be at least `N+1` workers available on the cluster. If the pool size is not specified, `batchsim(in)` runs the simulations on a single worker in the cluster specified by the default cluster profile.

---

**Note** `batchsim` errors out when used with a pool size if Parallel Computing Toolbox license is not available.

---

- 4 `batchsim` offloads simulations to the compute cluster, enabling you to carry out other tasks while the batch job is processing, or close the client MATLAB and access the batch job later.
- 5 On submitting a batch job, `batchsim` returns a job object containing a job ID and other information that you can use to access the batch job at a later time. Access this job again to check the progress of simulations.

### Limitations

- Because the client session is not tied to the workers, you cannot access the outputs unless the job is finished.
- `batchsim` does not give you the ability to monitor simulations with Simulation Manager. For batch jobs, you can use a batch job monitor that tells you if the job is queued, in progress, or completed. For more information, see “Job Monitor” (Parallel Computing Toolbox)

## Analyze Results Using Simulation Manager

The Simulation Manager allows you to monitor multiple simulations, in serial or in parallel, and their progress. You can view the details of every run, such as parameters, elapsed time, and diagnostics. The Simulation Manager provides the option to analyze and compare your logged signal results in the **Simulation Data Inspector**. Through Simulation Manager, you can select a run and apply its values to the model. Simulation Manager opens when you run a `parsim` or a `sim` command with `ShowSimulationManager` argument set to `on`. For more information, see **Simulation Manager**.

The dimensions of the tank have an impact on the total cost of production of the product. For this example, we observe the behavior of `TotalCost` for different values of the width and the height. By analyzing the behavior of the parameters, we find the combination of `A` and `h` that results in lowest `TotalCost`. To solve this design problem, we run multiple simulations (in parallel or in serial) with different values of the parameters `A` and `h`.

This example shows how you can use the Simulation Manager to analyze the simulations and solve a design problem using a model of a continually stirred tank reactor. The reactors are specialized tanks that are used to mix various chemicals or compounds to create a product. The important variables used in this model are:

- Variable `A`, which represents the cross-sectional area of the tank (width).
- Variable `h`, which represents the height.
- Variable `TotalCost`, which represents the cost, in dollars, to produce a tankful of product.

Simulation Manager enables you to analyze the simulations as they are running. When the simulations are in progress, you can visualize the simulation data of the model by plotting the simulation outputs against the input parameters. Visualizing trend of the simulations as they are happening allows you to learn about the design space of the simulations and evaluate whether the simulations are running as required. You can stop the simulations if the progress is not as desired thus saving time.

### Open Simulation Manager

In this example, use a set of sweep parameters provided to the model through `Simulink.SimulationInput` objects and then use the `parsim` command to run the simulations in parallel.

Create a `PostSimFcn` function as follows in a MATLAB script to call later in the parameter sweep. Name the file `calculateCost.m`. The `PostSimFcn` function calculates `TotalCost` from the variables `A` and `h`, and its calculation can vary depending on the application.

```
function costOutput = calculateCost(out)

    costOutput.yout = out.yout;

    coolantOutput = out.yout.get('Coolant').Values.Data;
    costCoolant = abs(mean(coolantOutput - 294))/30;
    costOutput.costFromCoolant = costCoolant;

    concentrationOutput = out.yout.get('Residual Concentration').Values.Data;
    costConcentration = 10*std(concentrationOutput - 2);
    costOutput.costFromConcentration = costConcentration;

    costOutput.TotalCost = costCoolant + costConcentration;

end
```

Open the model.

```
openExample('simulink/OpenTheModelToUseWithSimulationManagerExample');
open_system('simManagerCSTR');
```

Create a sample of values for parameter sweep.

```
rangeA = [0.1, 5];
rangeH = [0.1, 5];

rng default;

numSamples = 60;
allAValues = rangeA(1) + (rangeA(2) - rangeA(1)).*rand(numSamples, 1);
allHValues = rangeH(1) + (rangeH(2) - rangeH(1)).*rand(numSamples, 1);
```

Create an array of Simulink.SimulationInput objects. For this example, the TotalCost is calculated and returned using the PostSimFcn.

```
in(1:numSamples) = Simulink.SimulationInput('simManagerCSTR');
in = in.setPostSimFcn(@(out) calculateCost(out));
```

Run the simulations in parallel and open the Simulation Manager.

```
for k = 1:numSamples
    in(k) = in(k).setVariable('A', allAValues(k), 'Workspace', 'simManagerCSTR');
    in(k) = in(k).setVariable('h', allHValues(k), 'Workspace', 'simManagerCSTR');
end

out = parsim(in, 'ShowSimulationManager', 'on');
```

The default view in the Simulation Manager shows a scatter plot with two parameters on its X and Y axes. In this case, the variable A is on the X-axis and variable h is on the Y-axis. When the simulations are running you can see dots appear on the plot, color coded according to the simulation status. Completed simulations are marked in green, in-progress simulations are blue, and simulations with errors are red.

The **Plot Properties** panel on the right enables you to edit and configure the data that plot shows. By selecting grid for X and Y axes, the plot appears with grid lines.

If a particular parameter is a time-series, the Simulation Manager plots only the last value of the time series.

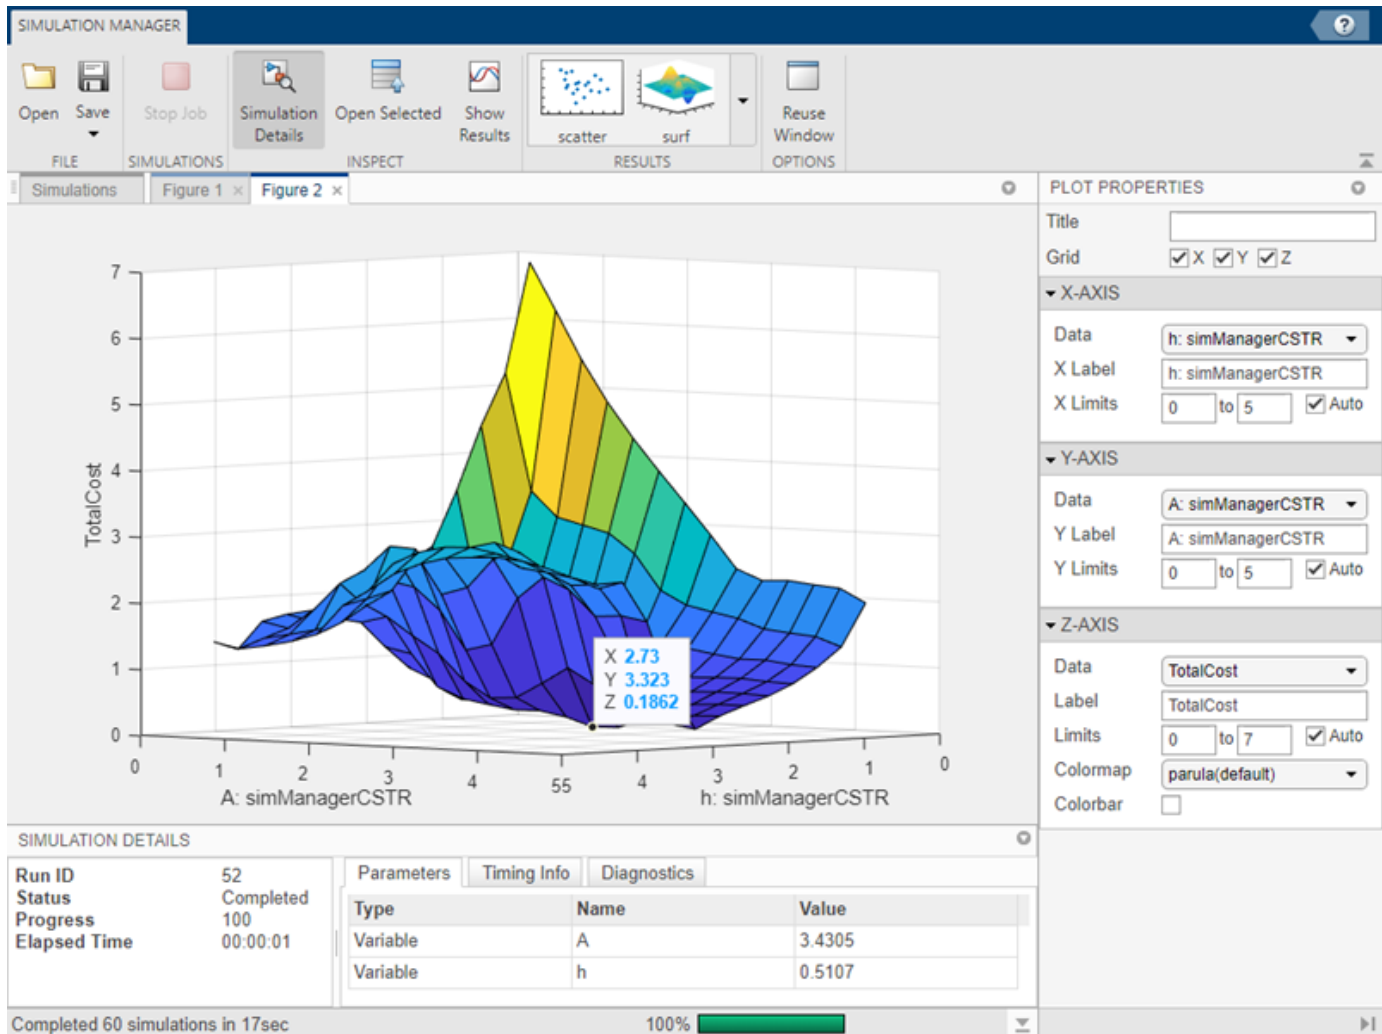

With the Simulation Manager, you can visualize the above data in a surf plot. Click the **surf** plot in the **Results** section of the toolbar.

## Add and Configure Plots

The **Results** section of the Simulation Manager allows you to add multiple plots and configure them. To add a plot, click the type of the plot in the **Results** section. For this example, click the **surf plot** in **Results** section of the Simulation Manager toolbar. Using the plot properties, change the parameters to display on the plots. You can change properties such as the plot labels, axes labels and you can add a colormap to denote the third parameter. You can also change the value limits of the colormap.

With the second plot and the first plot together, you can determine the value of the variables A and h, that gives the best TotalCost.

For the Z-axis of the surf plot, change the **Data** to TotalCost. By observing the surf plot, you can find the lowest point of TotalCost. Clicking the lowest point shows the values for X-axis and Y-axis, which is h and A, respectively.

## Save and Load Simulation Manager

Save the session information, which includes simulation data all the plot configurations. To save the session, click the **Save** button on the toolbar. The session saves as a `.mldatx` file. To reopen the saved session, navigate to the location where the file is saved and double-click the `.mldatx` file.

The Simulation Manager allows you to reuse the plot configuration when you want to run similar simulations with different sets of values. To reuse the plot configuration, click the **Reuse Window** button on the toolbar. Selecting the **Reuse Window** saves the plot configurations, such as labels, axis orientation, which parameters to display on which axis that you can reuse with the next simulation of the same model. When you use this functionality while running simulations for different models, the simulation errors out due to a limitation.

## Configure and Run Simulations with Multiple Simulations Panel

The **Multiple Simulations** panel allows you to set up multiple simulations for a block parameter that you want to vary, for example, for a parameter sweep or Monte-Carlo simulations. You can pick a block parameter of interest from the model canvas and specify values that you want to use for the simulations. With the Multiple Simulations panel, you can provide configurations such as **Use Parallel** to run your simulations in parallel. To run the simulations that you have set up, first, select the design study, then click **Run All** button on **Simulation** tab on the Simulink toolstrip. Once the simulations are complete, you can view and manage the results in **Simulation Manager**.

### Workflow for Multiple Simulations Panel

To configure and run multiple simulations from the Simulink Editor:

- 1 First, check that you have made all the desired changes to your model.
- 2 The **Multiple Simulations** panel allows you to perform similar operations as the `parsim` command line API, but through the Simulink Editor. To open the **Multiple Simulations** panel, navigate to the **Prepare** section on the Simulink toolstrip. In the **Inputs & Parameter Tuning**

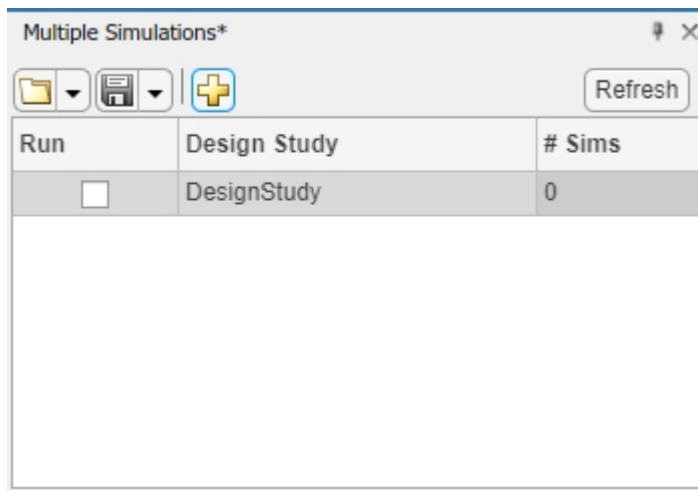

section, click **Multiple Simulations**.

- 3 The **Multiple Simulations** panel appears docked on the right side of the Simulink canvas.

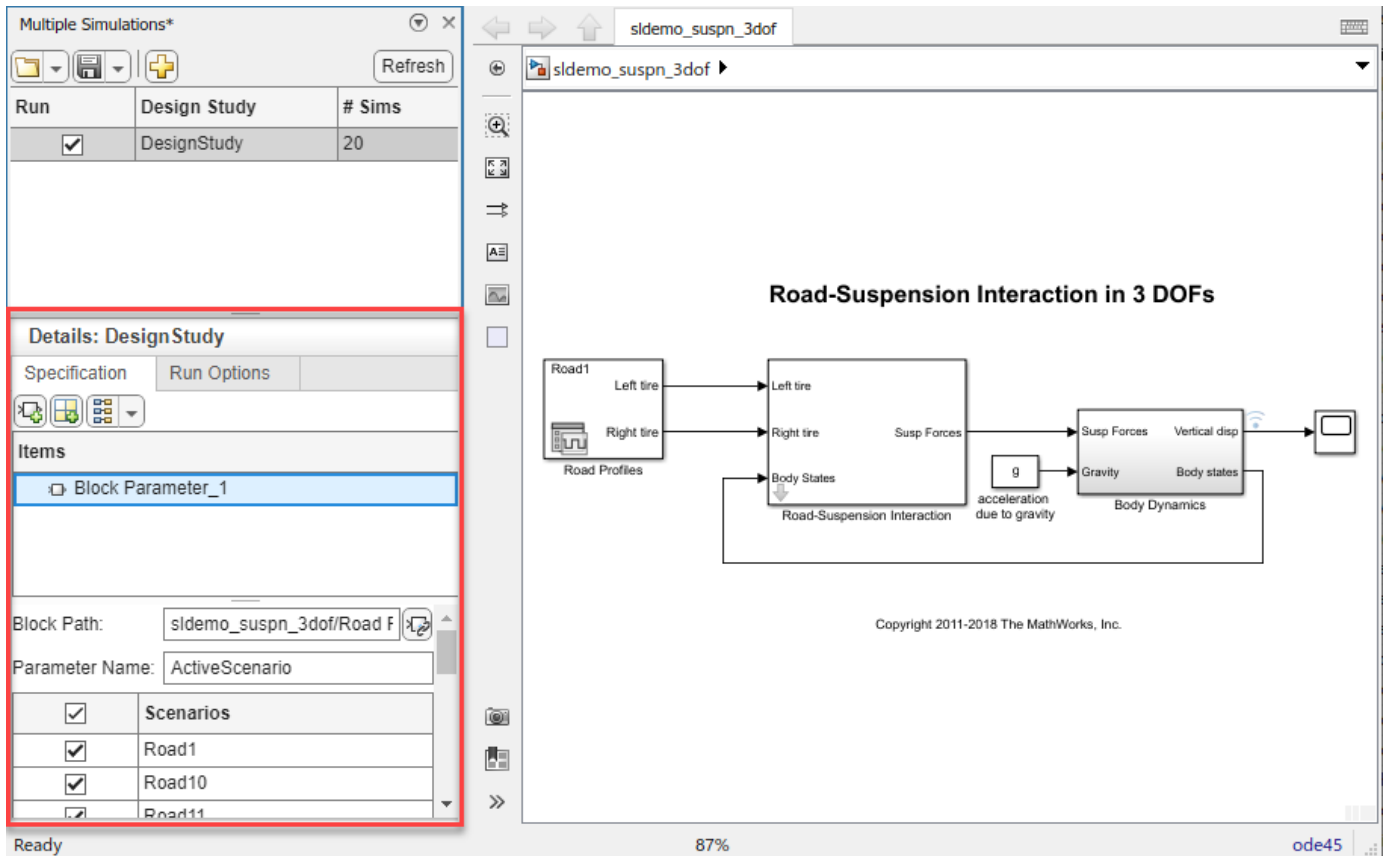

- 4 In the panel, click the right most button to create a new design study. A design study is an object that allows you to set up simulations. The name of the new design study is automatically populated as `DesignStudy`. To change the name, double-click on the name and enter your preferred name. Once you configure and enter the values for the simulations, select the design study and click **Run All** on the Simulink toolstrip to run the simulations.

5

Now, you can add a block parameter to the created design study. Click  to add a new block parameter to the design study. You can enter the block path or use a picker to select a block from the model canvas, or you can enter the block parameter name. Once you have added the block parameter, specify its values. If the block is a Signal Editor block, you can choose your specification from the list of scenarios. By default, all scenarios will be selected.

The screenshot shows the Simulink Multiple Simulations panel on the left and a Simulink model diagram on the right. The Multiple Simulations panel is titled "Multiple Simulations\*" and contains a table with the following data:

Run	Design Study	# Sims
<input checked="" type="checkbox"/>	DesignStudy	20

Below the table is the "Details: Design Study" section, which is highlighted with a red box. It includes a "Specification" tab, "Run Options" tab, and an "Items" list containing "Block Parameter\_1". The "Block Path" is set to "sldemo\_suspn\_3dof/Road F" and the "Parameter Name" is "ActiveScenario". Below this is a "Scenarios" table:

<input checked="" type="checkbox"/>	Scenarios
<input checked="" type="checkbox"/>	Road1
<input checked="" type="checkbox"/>	Road10
<input checked="" type="checkbox"/>	Road11

The Simulink model diagram on the right is titled "Road-Suspension Interaction in 3 DOFs". It shows a block diagram with inputs "Left tire" and "Right tire" from "Road Profiles" (containing "Road1" and "Road10") entering a "Road-Suspension Interaction" block. This block outputs "Susp Forces" and "Body States". The "Body States" block also receives "acceleration due to gravity" (g) and outputs "Body states". The "Susp Forces" block outputs "Vertical disp" and "Body states". The "Body states" block outputs "Body states".

You can also add variables for your simulations by clicking .

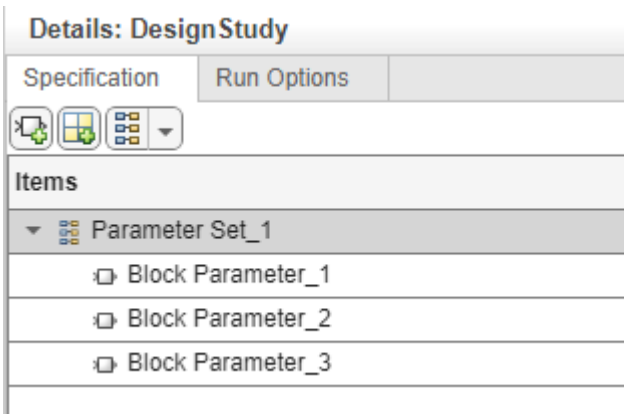

### Parameter Combinations

For the block parameters or variables that you add, you can use parameter combinations. Parameter combinations allow you to specify either an exhaustive combination or a sequential combination of the parameters. By default, all parameters at the top level are combined exhaustively.

To create an exhaustive combination, select the specified block parameters. Then, from the parameter combinations drop down list , select **Exhaustive combination**. An exhaustive combination is denoted by . An exhaustive combination creates all possible combinations from the parameter values. For example, if there are ten values of one parameter and five values of another, an exhaustive combination creates a total of  $10 \times 5 = 50$  different combinations.

To create a sequential combination, select the specified block parameters. Then, from the parameter combinations drop-down list , select **Sequential combination**. For example, if you have two properties that each specify ten different values, sequential combination creates total of ten different simulations, one for each set of values. A sequential combination is denoted by . A sequential combination combines values sequentially. The number of values specified for each parameter must be the same. You can choose the sequence in which parameters are combined.

You can also nest parameter combinations. Based on the parameter combination specification, the **Multiple Simulations** panel shows the number of simulations that correspond to the design study.

- 6 In the **Details: Design Study** section, on the **Run Options** tab, you can also specify the option to run in parallel.

- 7 Now that you have entered specifications, select the scenarios and the design study that you want to run. Once you select the design study, the **Run** button on the Simulink toolstrip changes to **Run All**. Click **Run All** to run the simulations.

- 8 Once the simulations complete, you can view and manage the results in the **Simulation Manager**. To open the Simulation Manager, click **Open Simulation Manager** on the status bar at the bottom of the canvas.
- 9 Click the save button in the **Multiple Simulations** panel to save the design study. The design study is saved in `.mldatx` format. To reuse the design study, open the **Multiple Simulations** panel, click the open button, and select the design study file from the file browser.

You can also save the Simulation Manager session information, which includes simulation data for all the plot configurations. To save the Simulation Manager session, use the save button on the Simulation Manager toolbar.

## Multiple Simulations Panel: Simulate for Different Values of Stiffness for a Vehicle Dynamics System

This example shows how to use the **Multiple Simulations** panel in the Simulink® Editor to run multiple simulations with varying values of stiffness of the suspension for a road profile that has a sinusoidal shape.

### Open the Model

The model simulates the vehicle dynamics based on the road-suspension interaction for different road profiles. The road profile data for the left and right tires is imported into the Signal Editor block as a sinusoidal shape. The Road-Suspension Interaction subsystem calculates the suspension forces on the vehicle at the four tire locations based on the road data and the current vehicle state. In the Body Dynamics subsystem, these forces and the resulting pitch and roll movements are used to determine the vehicle motion in three degrees of freedom: vertical displacement, roll, and pitch. The model is simulated using different values of stiffness of the suspension to determine if the design meets desired performance goals.

```
open_system('ex_multisim_sldemo_suspn_3dof');
```

### Set Up Simulations

To configure and set up simulations, use the **Multiple Simulations** panel. To open the **Multiple Simulations** panel, go to the **Prepare** section on the Simulink toolstrip. In the **Inputs & Parameter**

**Tuning** section, click **Multiple Simulations**. In the panel, click  to create a new design study.

The screenshot displays the MATLAB/Simulink environment. The top menu bar includes SIMULATION, DEBUG, MODELING, FORMAT, and APPS. The toolbar contains various simulation controls like 'Run', 'Step Back', and 'Step Forward'. On the left, the 'Multiple Simulations\*' panel shows a table with one entry: 'Design Study' with 0 simulations. Below this, the 'Details: Design Study' section has tabs for 'Specification' and 'Run Options'. The main workspace shows a Simulink model titled 'Road-Suspension Interaction in 3 DOFs'. The model includes blocks for 'SineWave' (Left tire, Right tire), 'Road Profiles', 'Body States', 'Road-Suspension Interaction', 'Suspension Forces', 'Gravity', 'Body Dynamics', and a 'max(u,y)' block. The status bar at the bottom indicates 'Ready', '100%', and 'ode45'.

A new design study object is added to the panel. The name of this design study is automatically populated. Double-click the design study to change the name. Use this design study to specify the parameters for the simulations. In this design study, we set up the values for the variable  $K$  which represents stiffness. By running multiple simulations, we want to see how the amplitude at which the car oscillates is affected by different values of stiffness.

To add variable to this design study, click  on the **Specification** tab of the **Details:Design Study** section. Once you add the variable, double-click to label the variable as **Suspension stiffness**. Specify the variable name as  $K$ , which is the stiffness of the suspension. Run simulations for multiple values of the stiffness,  $K$ . Simulate for values ranging from  $2e4$  to  $8e4$ , with one hundred separate points. Add `linspace(2e4, 8e4, 100)` as the values of the variable  $K$ .

### Run Multiple Simulations

Now that you have set up the values for our simulations, select the design study. The **Run** button in

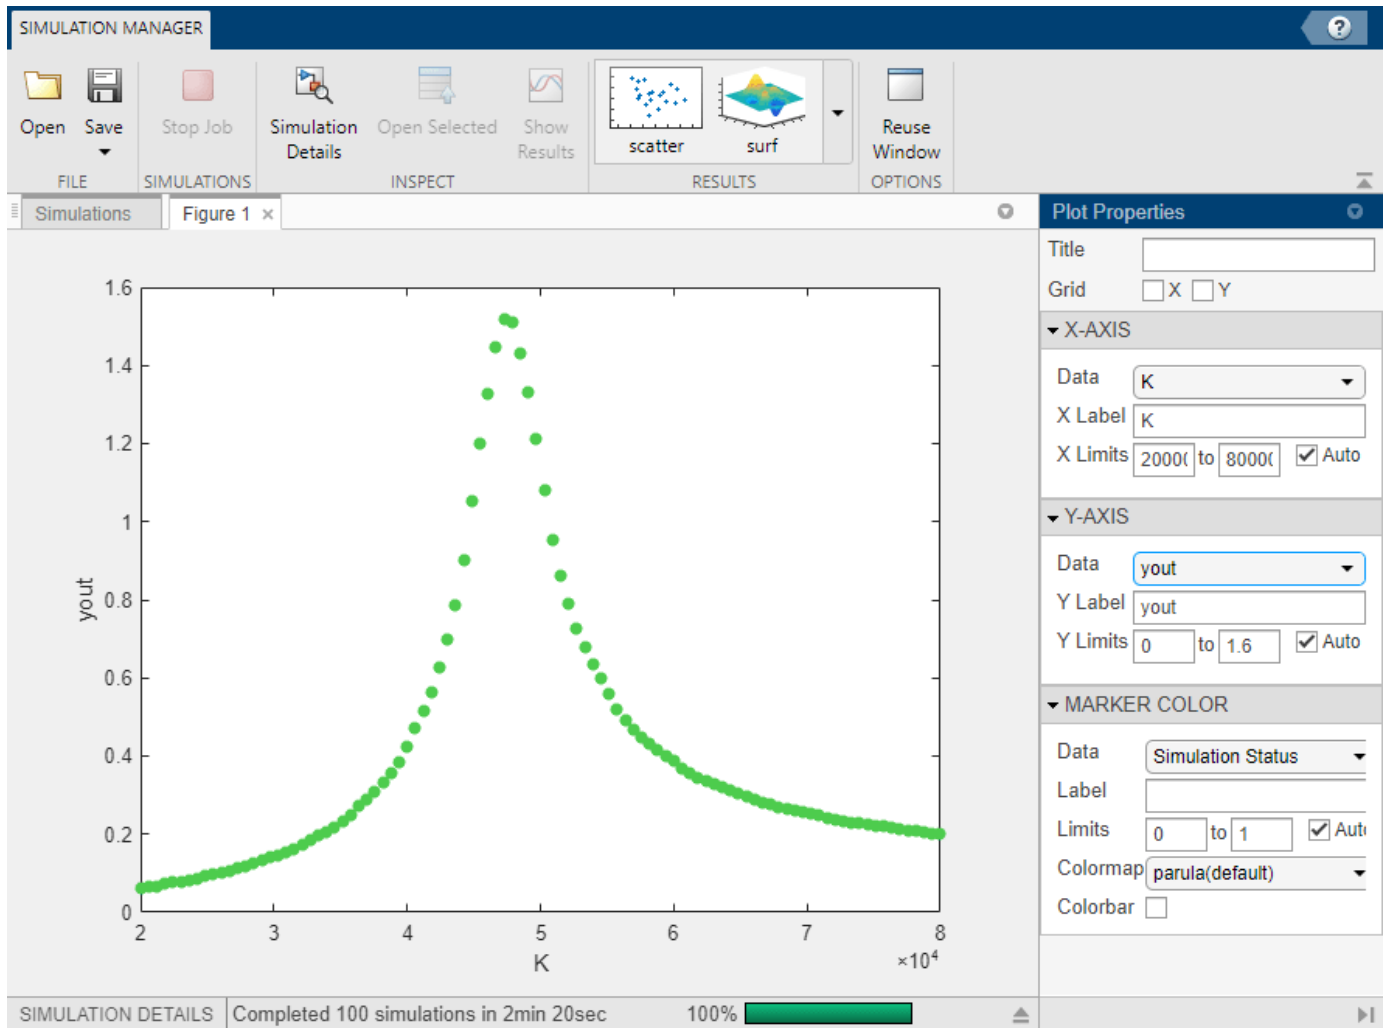

the Simulation section of the Simulink toolstrip changes to **Run All**, to indicate that you have setup multiple simulations. Click the **Run All** button to start the simulations. You can open Simulation Manager by clicking **Open Simulation Manager** on the Simulink status bar at the bottom of the canvas.

### View the Results in Simulation Manager

Inspect how the amplitude at which the car oscillates is affected by different values of stiffness. To see the plot, in **Plot Properties**, select `yout` from the list for Data for the Y-Axis. `yout` represents the resulting amplitude of oscillations. The road pattern for this simulation is a sine wave with fixed frequency. By varying the stiffness values, you vary the natural frequency of the system. Based on the stiffness values, you start below the natural frequency. As you increase the values of the stiffness, you cross the natural frequency, thus entering resonance. As you increase the stiffness values above the natural frequency, the amplitude starts to decrease again.

By configuring and specifying values through the Multiple Simulations panel, you can easily run many simulations with different values for parameter sweep and Monte-Carlo simulations directly through the Simulink Editor.

### Save the Design Study and the Plot

Click in the **Multiple Simulations** panel to save the design study that you have set up. The design study is saved in `mldatax` format. To reuse the design study, open the **Multiple Simulations** panel, click , and select the design study file from the file browser.

You can also save the Simulation Manager session information, which includes simulation data all the plot configurations. The Simulation Manager allows you to reuse the plot configuration when you want to run similar simulations with different sets of values. To reuse the plot configuration, click

on the Simulation Manager toolstrip. To reopen the saved session, navigate to the location where the file is saved and double-click the `.mldatx` file.

## Prototype and Debug Models with Scopes

Simulink scope blocks and viewers offer a quick and lightweight way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block. After simulating the model, you can use the results to validate your design. See “Scope Blocks and Scope Viewer Overview” on page 30-6 and “Model and Validate a System”.

A Scope block or Scope viewer opens to a Scope window where you can display and evaluate simulation data.

The toolbar contains controls for starting, stopping, and stepping forward through a simulation

. You can use these controls to debug a model by viewing signal data at each time interval. See “How Stepping Through a Simulation Works” on page 2-3.

Connect signal lines to a Scope block using multiple input ports, see “Number of input ports”.

Attach signals to a Floating Scope block or signal viewer directly from the model. See “Add Signals to an Existing Floating Scope or Scope Viewer” on page 30-74.

Use the oscilloscope-like tools available with a scope to debug your model. Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. See “Scope Triggers Panel” on page 30-12 and “Cursor Measurements Panel” on page 30-23.

Save or log signal data to the MATLAB workspace, and then plot data in a MATLAB figure window. Use MATLAB functions or your own scripts to analyze the data. See “Save Simulation Data from Floating Scope” on page 30-75.

## Scope Blocks and Scope Viewer Overview

### In this section...

“Overview of Methods” on page 30-6

“Simulink Scope Versus Floating Scope” on page 30-6

“Simulink Scope Versus DSP System Toolbox Time Scope” on page 30-8

### Overview of Methods

Simulink scopes provide several methods for displaying simulation data and capturing the data for later analysis. Symbols on your block diagram represent the various data display and data capture methods.

For more information about these methods:

- Scope and Floating Scope blocks — Scope, Floating Scope, “Common Scope Block Tasks” on page 30-51, “Floating Scope and Scope Viewer Tasks” on page 30-73.
- Scope Viewer — “Viewers and Generators Manager” on page 30-83, “Floating Scope and Scope Viewer Tasks” on page 30-73.
- Signal Logging — “Save Simulation Data from Floating Scope” on page 30-75.
- Signal Test Point — “Configure Signals as Test Points” on page 80-46.

### Simulink Scope Versus Floating Scope

Scope blocks and Floating Scope blocks both display simulation results, but they differ in how you attach signals and save data. Simulation behavior for a Floating Scope and a Scope Viewer is identical, but you manage them differently in your model.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
<b>Attaching signals</b>	Connect signal lines to a Scope block using input ports.	Attach signals interactively from the model before and during a simulation. See “Add Signals to an Existing Floating Scope or Scope Viewer” on page 30-74 and “Quickly Switch Visualization of Different Signals on a Floating Scope” on page 30-79.	Attach signals from the Viewers and Generators Manager, interactively from the toolstrip, or using the signal line context menu.
<b>Access to signals</b>	Because signals lines are connected to a Scope block, access signals at different levels of a model hierarchy using GoTo blocks.	Because signals are attached without signal lines, you do not have to route lines to a Floating Scope block.  You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.	Scope viewers are attached to signal lines.  You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.
<b>Data logging</b>	Save data to a MATLAB variable as an array, structure, or object.	Save data to a MATLAB variable as an object.	Save data to a MATLAB variable as an object.
<b>Simulation control</b>	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.
<b>Scale axes after simulation</b>	Toolbar buttons to scale X-axis and Y-axis limits  <b>Axes scaling</b> set to Auto for the X-axis and Y-axis.	Toolbar buttons to scale X-axis and Y-axis limits.  <b>Axes scaling</b> set to Auto for only the Y-axis.	Toolbar buttons to scale X-axis and Y-axis limits.  <b>Axes scaling</b> set to Auto for the X-axis and Y-axis.
<b>Add to model</b>	Add block from Simulink sinks library.	Add block from Simulink sinks library.	Add using “Viewers and Generators Manager” on page 30-83.
<b>Visual indication in model</b>	Scope block connected to signals.	Floating Scope block not attached to any signal lines.	Viewer icons located above signal lines for all attached signals.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
<b>Manage scopes centrally</b>	No.	No.	Use the Viewers and Generators Manager to add or delete viewers, and attach or remove signals.
<b>Manage scopes locally</b>	Attach signal lines to Scope block in ports.	Attach signals from the Floating Scope window.	Add viewers and attach additional signals within a model hierarchy using the context menus or from the Scope viewer window.
<b>Simulink Report Generator support</b>	Yes.	Yes.	No.
<b>Connecting Constant block with Sample time set to inf (constant sample time)</b>	Plots the data value at the first time step and anytime you tune a parameter.	Plots all data values.	Plots the data value at the first time step and anytime you tune a parameter.

### Simulink Scope Versus DSP System Toolbox Time Scope

If you have a Simulink and a DSP System Toolbox license, you can use either the Simulink Scope or DSP System Toolbox Time Scope. Choose the scope based on your application requirements, how the blocks work, and the default values of each block.

If you have a DSP System Toolbox license and you have been using Time Scopes, continue to do so in your applications. Using the Time Scope block requires a DSP System Toolbox license.

Feature	Scope	Time Scope
Location in block library	Simulink Sinks library	DSP System Toolbox Sinks library
Trigger and measurement panels	With Simulink only: <ul style="list-style-type: none"> <li>• Trigger</li> <li>• Cursor Measurement</li> </ul> With DSP System Toolbox or Simscape license: <ul style="list-style-type: none"> <li>• Signal Statistics</li> <li>• Bilevel Measurements</li> <li>• Peak Finder</li> </ul>	<ul style="list-style-type: none"> <li>• Trigger</li> <li>• Cursor Measurements</li> <li>• Signal Statistics</li> <li>• Bilevel Measurements</li> <li>• Peak Finder</li> </ul>

Feature	Scope	Time Scope
<p>Simulation mode support for block-based sample times</p> <p>For block-based sample times, all the inputs of the block run at the same rate.</p> <p>For rapid-accelerator mode, see “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 38-16.</p>	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Accelerator</li> <li>• Rapid-Accelerator</li> <li>• External</li> </ul>	<ul style="list-style-type: none"> <li>• Rapid-Accelerator</li> <li>• External</li> </ul>
<p>Simulation mode support for port-based sample times</p> <p>For port-based sample times, the input ports can run at different rates.</p>	No.	<ul style="list-style-type: none"> <li>• Normal</li> <li>• Accelerator</li> </ul>
Frame processing of signals	Included in Scope block with DSP System Toolbox license.	Included in Time Scope block.
Sample time propagation	If the different ports have different sample rates, the scope uses the greatest common divisor of the rates.	When using port-based sample times, the different ports of the Scope block inherit the different rates and plots the signals according to those rates.
Save model to previous Simulink release	If saving to a release before R2015a, the Scope block is converted to a scope with the features available in that release.	No change in features.

This table lists the differences in Configuration Property default values between the Scope and Time Scope blocks.

Property	Scope Default	Time Scope Default
Open at start of simulation	Cleared	Selected
Input processing	Elements as channels (sample based)	Columns as channels (frame based)
Maximize Axes	Off	Auto
Time Units	None	Metric (based on Time Span)
Time-axis labels	Bottom displays only	All
Show time-axis label	Cleared	Selected
Plot Type	Auto	Line
Title	%<Signal Label>	No title
Y label	No label	Amplitude

## **See Also**

Floating Scope | Scope | Scope Viewer | Time Scope

## **Related Examples**

## Scope Triggers Panel

### In this section...

- “What Is the Trigger Panel” on page 30-12
- “Main Pane” on page 30-12
- “Source/Type and Levels/Timing Panes” on page 30-13
- “Hysteresis of Trigger Signals” on page 30-21
- “Delay/Holdoff Pane” on page 30-22

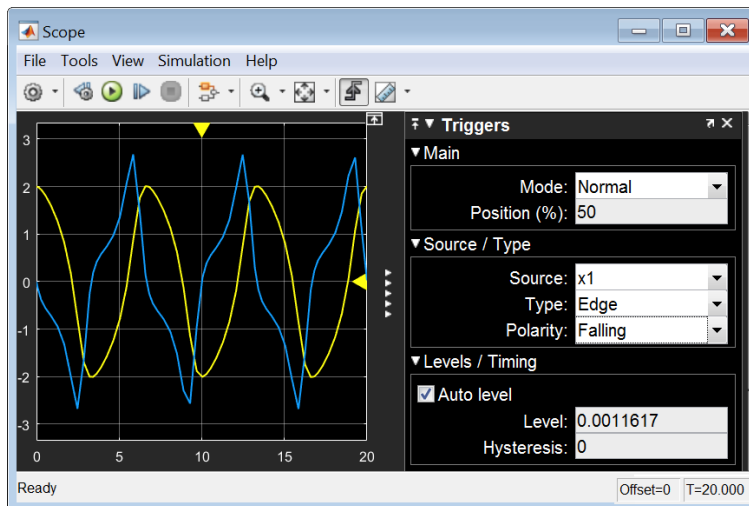

### What Is the Trigger Panel

The Trigger panel defines a trigger event to synchronize simulation time with input signals. You can use trigger events to stabilize periodic signals such as a sine wave or capture non-periodic signals such as a pulse that occurs intermittently.

To open the Trigger panel:

- 1 Open a Scope block window.
- 2 On the toolbar, click the Triggers button .
- 3 Run a simulation.

Triangle trigger pointers indicate the trigger time and trigger level of an event. The marker color corresponds to the color of the source signal.

### Main Pane

**Mode** — Specify when the display updates.

- **Auto** — Display data from the last trigger event. If no event occurs after one time span, display the last available data.

**Normal** — Display data from the last trigger event. If no event occurs, the display remains blank.

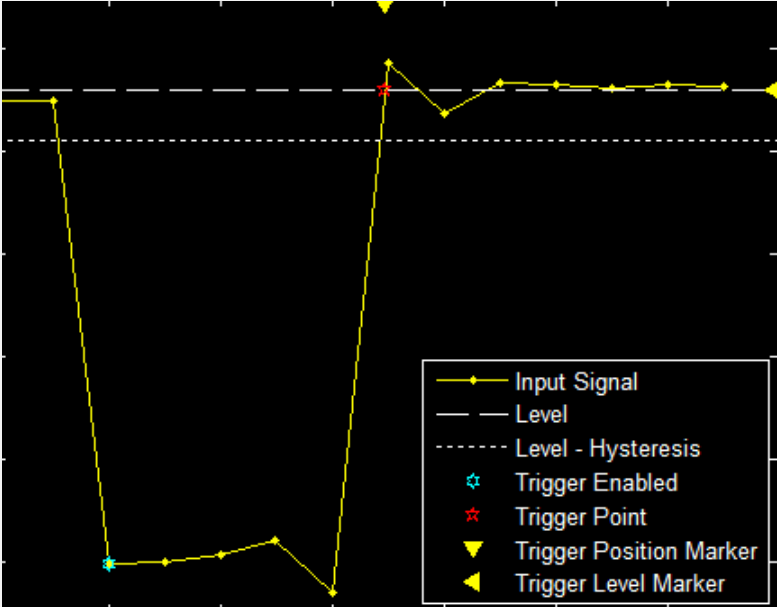

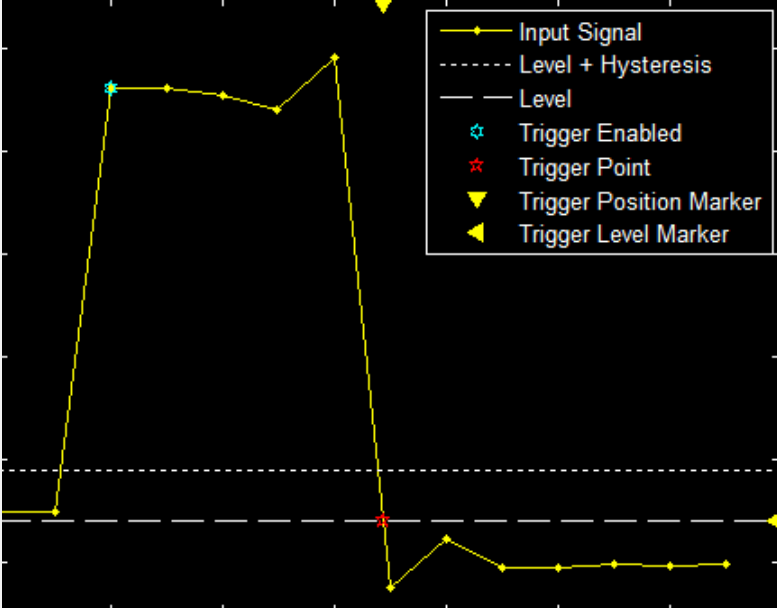

- **Once** — Display data from the last trigger event and freeze the display. If no event occurs, the display remains blank. Click the **Rearm** button to look for the next trigger event.
- **Off** — Disable triggering.

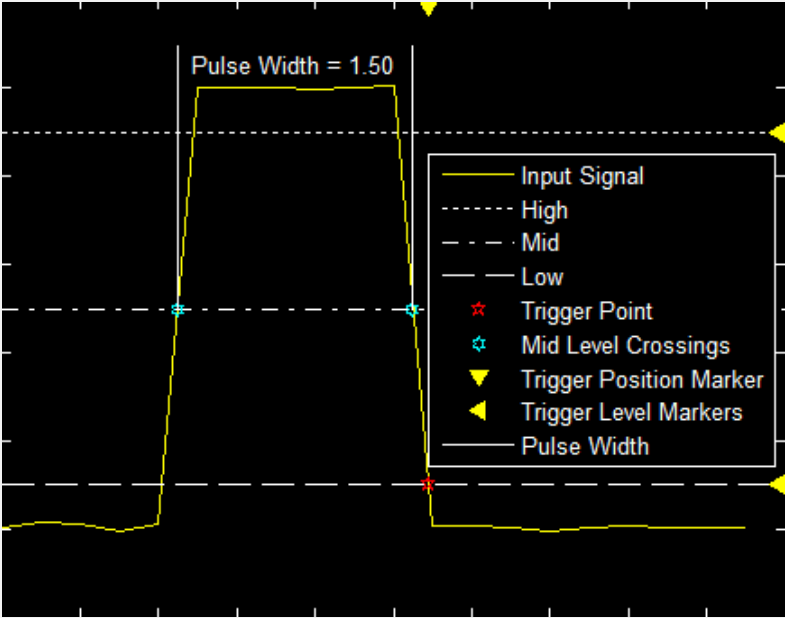

**Position (%)** — Specify the position of the time pointer along the y-axis. You can also drag the time pointer to the left or right to adjust its position.

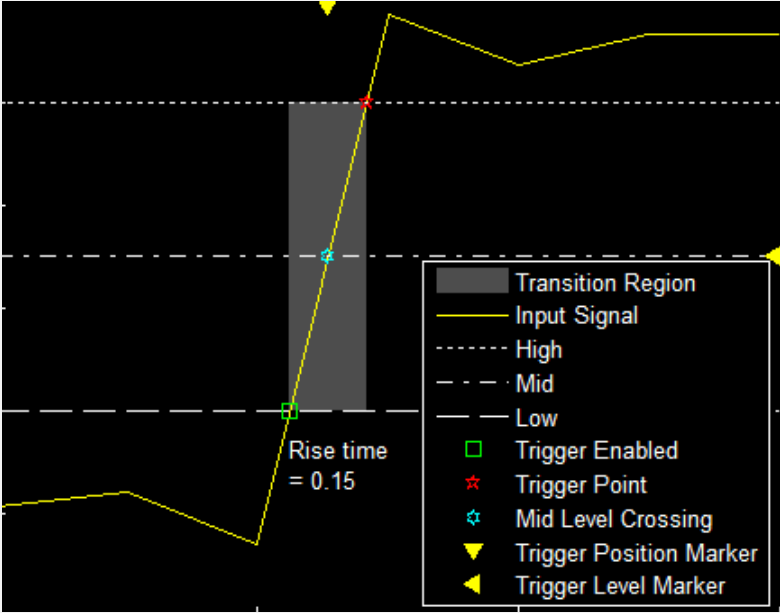

## Source/Type and Levels/Timing Panes

**Source** — Select a trigger signal. For magnitude and phase plots, select either the magnitude or the phase.

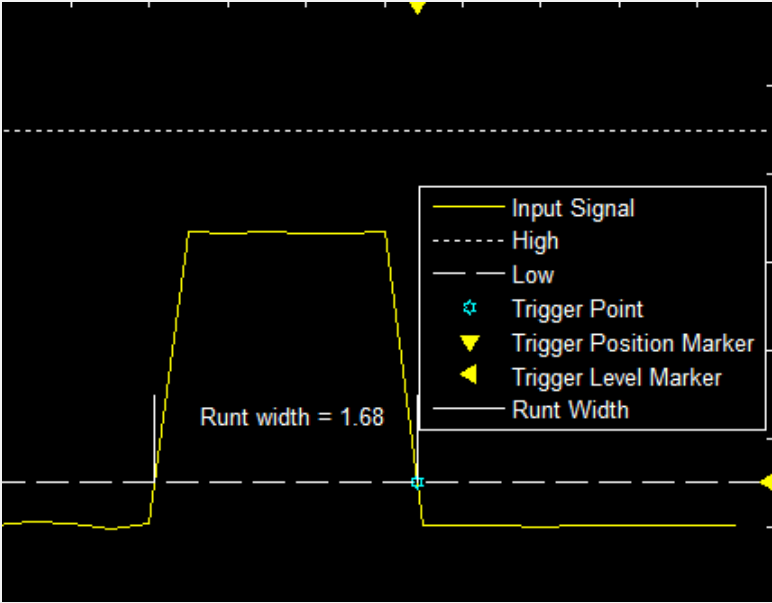

**Type** — Select the type of trigger.

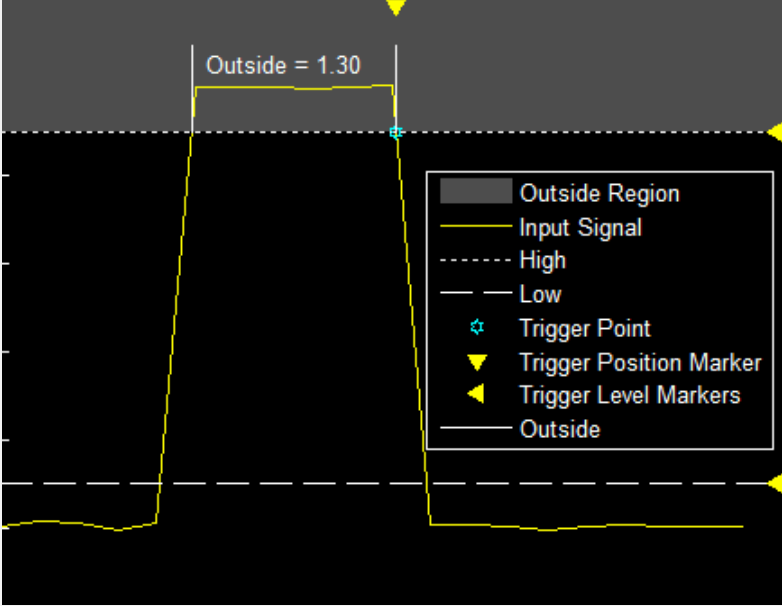

Trigger Type	Trigger Parameters
<p>Edge — Trigger when the signal crosses a threshold.</p>	<p><b>Polarity</b> — Select the polarity for an edge-triggered signal.</p> <ul style="list-style-type: none"> <li>• <b>Rising</b> — Trigger when the signal is increasing.</li> </ul> 
	<ul style="list-style-type: none"> <li>• <b>Falling</b> — Trigger when the signal value is decreasing.</li> </ul> 
	<ul style="list-style-type: none"> <li>• <b>Either</b> — Trigger when the signal is increasing or decreasing.</li> </ul> <p><b>Level</b> — Enter a threshold value for an edge triggered signal. <b>Auto level</b> is 50%</p>

Trigger Type	Trigger Parameters
<p>Pulse Width — Trigger when the signal crosses a low threshold and a high threshold twice within a specified time.</p>	<p><b>Hysteresis</b> — Enter a value for an edge-triggered signal. See “Hysteresis of Trigger Signals” on page 30-21</p> <p><b>Polarity</b> — Select the polarity for a pulse width-triggered signal.</p> <ul style="list-style-type: none"> <li>• <b>Positive</b> — Trigger on a positive-polarity pulse when the pulse crosses the low threshold for a second time.</li> </ul>  <ul style="list-style-type: none"> <li>• <b>Negative</b> — Trigger on a negative-polarity pulse when the pulse crosses the high threshold for a second time.</li> <li>• <b>Either</b> — Trigger on both positive-polarity and negative-polarity pulses.</li> </ul> <p><b>Note</b> A glitch-trigger is a special type of a pulse width-trigger. A glitch-trigger occurs for a pulse or spike whose duration is less than a specified amount. You can implement a glitch trigger by using a pulse width-trigger and setting the <b>Max Width</b> parameter to a small value.</p> <p><b>High</b> — Enter a high value for a pulse width-triggered signal. <b>Auto level</b> is 90%.</p> <p><b>Low</b> — Enter a low value for a pulse width-triggered signal. <b>Auto level</b> is 10%.</p> <p><b>Min Width</b> — Enter the minimum pulse-width for a pulse width triggered signal. Pulse width is measured between the first and second crossings of the middle threshold.</p> <p><b>Max Width</b> — Enter the maximum pulse width for a pulse width triggered signal.</p>

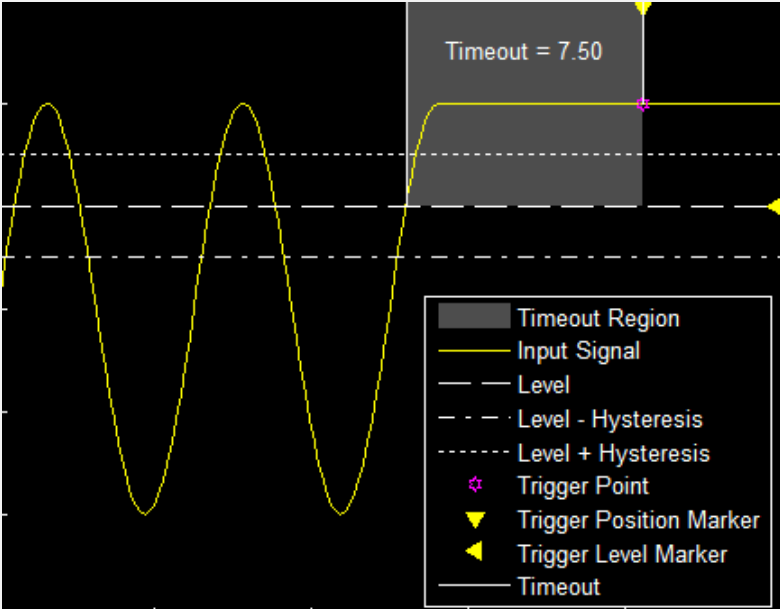

Trigger Type	Trigger Parameters
<p>Transition — Trigger on the rising or falling edge of a signal that crosses the high and low levels within a specified time range.</p>	<p><b>Polarity</b> — Select the polarity for a transition-triggered signal.</p> <ul style="list-style-type: none"> <li>• <b>Rise Time</b> — Trigger on an increasing signal when the signal crosses the high threshold.</li> </ul>  <ul style="list-style-type: none"> <li>• <b>Fall Time</b> — Trigger on a decreasing signal when the signal crosses the low threshold.</li> <li>• <b>Either</b> — Trigger on an increasing or decreasing signal.</li> </ul> <p><b>High</b> — Enter a high value for a transition-triggered signal. <b>Auto level</b> is 90%.</p> <p><b>Low</b> — Enter a low value for a transition-triggered signal. <b>Auto level</b> is 10%.</p> <p><b>Min Time</b> — Enter a minimum time duration for a transition-triggered signal.</p> <p><b>Max Time</b> — Enter a maximum time duration for a transition-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Runt— Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.</p>	<p><b>Polarity</b> — Select the polarity for a runt-triggered signal.</p> <ul style="list-style-type: none"> <li>• <b>Positive</b> — Trigger on a positive-polarity pulse when the signal crosses the low threshold a second time, without crossing the high threshold.</li> </ul>  <ul style="list-style-type: none"> <li>• <b>Negative</b> — Trigger on a negative-polarity pulse.</li> <li>• <b>Either</b> — Trigger on both positive-polarity and negative-polarity pulses.</li> </ul> <p><b>High</b> — Enter a high value for a runt-triggered signal. <b>Auto level</b> is 90%.</p> <p><b>Low</b> — Enter a low value for a runt-triggered signal. <b>Auto level</b> is 10%.</p> <p><b>Min Width</b> — Enter a minimum width for a runt-triggered signal. Pulse width is measured between the first and second crossing of a threshold.</p> <p><b>Max Width</b> — Enter a maximum pulse width for a runt-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Window — Trigger when a signal stays within or outside a region defined by the high and low thresholds for a specified time.</p>	<p><b>Polarity</b> — Select the region for a window-triggered signal.</p> <ul style="list-style-type: none"> <li> <p><b>Inside</b> — Trigger when a signal leaves a region between the low and high levels.</p>  </li> <li> <p><b>Outside</b> — Trigger when a signal enters a region between the low and high levels.</p>  </li> <li> <p><b>Either</b> — Trigger when a signal leaves or enters a region between the low and high levels.</p> </li> </ul>

Trigger Type	Trigger Parameters
	<p><b>High</b> — Enter a high value for a window-triggered signal. <b>Auto level</b> is 90%.</p> <p><b>Low</b> — Enter a low value for a window-trigger signal. <b>Auto level</b> is 10%.</p> <p><b>Min Time</b> — Enter the minimum time duration for a window-triggered signal.</p> <p><b>Max Time</b> — Enter the maximum time duration for a window-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Timeout — Trigger when a signal stays above or below a threshold longer than a specified time</p>	<p><b>Polarity</b> — Select the polarity for a timeout-triggered signal.</p> <ul style="list-style-type: none"> <li>• <b>Rising</b> — Trigger when the signal does not cross the threshold from below. For example, if you set <b>Timeout</b> to 7.50 seconds, the scope triggers 7.50 seconds after the signal crosses the threshold.</li> </ul>  <ul style="list-style-type: none"> <li>• <b>Falling</b> — Trigger when the signal does not cross the threshold from above.</li> <li>• <b>Either</b> — Trigger when the signal does not cross the threshold from either direction</li> </ul> <p><b>Level</b> — Enter a threshold value for a timeout-triggered signal.</p> <p><b>Hysteresis</b> — Enter a value for a timeout-triggered signal. See “Hysteresis of Trigger Signals” on page 30-21.</p> <p><b>Timeout</b> — Enter a time duration for a timeout-triggered signal.</p> <p>Alternatively, a trigger event can occur when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the threshold.</p>

## Hysteresis of Trigger Signals

**Hysteresis (V)** — Specify the hysteresis or noise reject value. This parameter is visible when you set **Type** to Edge or Timeout. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores the times that a signal crosses the trigger level within the hysteresis region.

You can reduce the hysteresis region size by decreasing the hysteresis value. In this example, if you set the hysteresis value to 0.07, the scope also considers the second rising edge to be a trigger event.

## Delay/Holdoff Pane

Offset the trigger position by a fixed delay, or set the minimum possible time between trigger events.

- **Delay (s)** — Specify the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event has occurred. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the relevant portion of a burst.

## Related Examples

- “Cursor Measurements Panel” on page 30-23

## Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

---

**Note** If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

---

Display screen cursors with signal times and values. To open the Cursor measurements panel:

- From the menu, select **Tools > Measurements > Cursor Measurements**.
- On the toolbar, click the Cursor Measurements  button.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

The Measurements pane displays time and value measurements.

	Time (secs)	Value
1	2.500	-9.027e+01
2	7.500	-1.175e+02
$\Delta T$	5.000 s	$\Delta Y$ 2.722e+01
$1 / \Delta T$		200.000 mHz
$\Delta Y / \Delta T$		5.444 (/s)

- **1** — View or modify the time or value at cursor number one (solid line cursor).
- **2** — View or modify the time or value at cursor number two (dashed line cursor).
- $\Delta T$  or  $\Delta X$  — Shows the absolute value of the time (x-axis) difference between cursor number one and cursor number two.
- $\Delta Y$  — Shows the absolute value of the signal amplitude difference between cursor number one and cursor number two.
- $1/\Delta T$  or  $1/\Delta X$  — Shows the rate. The reciprocal of the absolute value of the difference in the times (x-axis) between cursor number one and cursor number two.
- $\Delta Y/\Delta T$  or  $\Delta Y/\Delta X$  — Shows the slope. The ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times (x-axis) between cursors.

## Scope Signal Statistics Panel

**Note** The Signal Statistics panel requires a DSP System Toolbox or Simscape license.

Display signal statistics for the signal selected in the **Trace Selection** panel. To open the Signal Statistics panel:

- From the menu, select **Tools > Measurements > Signal Statistics**.
- On the toolbar, click the Signal Statistics  button.

	Value	Time (secs)
Max	1.000e+00	0.000e+00
Min	-1.000e+00	1.000
Peak to Peak	2.000e+00	
Mean	1.117e-05	
Median	2.945e-04	
RMS	7.084e-01	

The statistics shown are:

- **Max** — Maximum or largest value within the displayed portion of the input signal.
- **Min** — Minimum or smallest value within the displayed portion of the input signal.
- **Peak to Peak** — Difference between the maximum and minimum values within the displayed portion of the input signal.
- **Mean** — Average or mean of all the values within the displayed portion of the input signal.
- **Median** — Median value within the displayed portion of the input signal.
- **RMS** — Root mean squared of the input signal.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

## Bilevel Measurements

**Note** The Bilevel Measurements panel requires a DSP System Toolbox or Simscape license.

Display information about signal transitions, overshoots, undershoots, and cycles. To open the Bilevel Measurements panel:

- From the menu, select **Tools > Measurements > Bilevel Measurements**.
- On the toolbar, click the Bilevel Measurements  button.

## Settings

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level.

Bilevel Measurements	
Settings	
Transitions	
High	9.900e-01
Low	-9.900e-01
Amplitude	1.980e+00
+ Edges	1459
+ Rise Time	258.516 $\mu$ s
+ Slew Rate	8.296 (/ms)
- Edges	1459
- Fall Time	257.387 $\mu$ s
- Slew Rate	-8.309 (/ms)
Overshoots / Undershoots	
+ Preshoot	-0.243 %
+ Overshoot	-0.271 %
+ Undershoot	24.163 %
+ Settling Time	—
- Preshoot	-0.250 %
- Overshoot	24.424 %
- Undershoot	-0.276 %
- Settling Time	—
Cycles	
Period	1.739 ms
Frequency	575.040 Hz
+ Pulses	1458
+ Width	867.458 $\mu$ s
+ Duty Cycle	49.647 %
- Pulses	1459
- Width	873.184 $\mu$ s
- Duty Cycle	50.290 %

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel detects the high- and low- state levels of a bilevel waveform. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
  - **High** — Used to specify manually the value that denotes a positive polarity, or high-state level.

- **Low** — Used to specify manually the value that denotes a negative polarity, or low-state level.

- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, D, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

## Transitions Pane

Display calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or rising edge, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.

When there is a plus sign (+) next to a text label, the measurement is a rising edge, a transition from a low-state level to a high-state level.

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

When there is a minus sign (-) next to a text label, the measurement is a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. For the transition measurements to be valid, you must convert all input signals to volts.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

- - **Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- - **Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level.
- - **Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal.

## Overshoots / Undershoots Pane

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. Overshoot and undershoot refer to the amount that a signal respectively exceeds and falls below its final steady-state value. Preshoot refers to the amount before a transition that a signal varies from its initial steady-state value.

This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

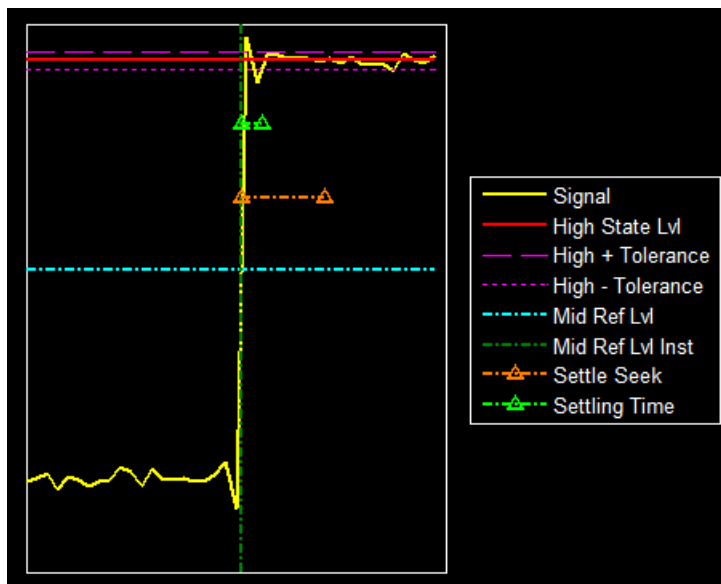

The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.

- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle-peek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

You can modify the settle-peek duration parameter in the **Settings** pane.

- - **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- - **Overshoot** — Average highest aberration in the region immediately following each falling transition.
- - **Undershoot** — Average lowest aberration in the region immediately following each falling transition.
- - **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle-peek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle-peek duration parameter in the **Settings** pane.

## Cycles Pane

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

Properties to set:

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal.

- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal.
- **- Pulses** — Number of negative-polarity pulses counted.
- **- Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal.
- **- Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

## Peak Finder Measurements Panel

---

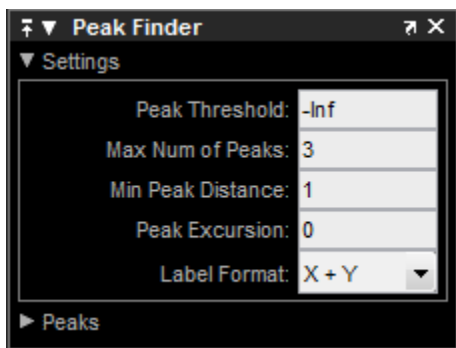

**Note** Peak Finder measurements require a DSP System Toolbox or Simscape license.

---

The **Peak Finder** panel displays the maxima, showing the x-axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion.

- From the menu, select **Tools > Measurements > Peak Finder**.
- On the toolbar, click the Peak Finder  button.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the `findpeaks` function reference.

Properties to set:

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.
- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The peak threshold is a minimum value necessary for a sample value to be a peak. The peak excursion is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both x-axis and y-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.
  - X+Y — Display both x-axis and y-axis values.
  - X — Display only x-axis values.
  - Y — Display only y-axis values.

The **Peaks** pane displays the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show or hide all the peak values on the display, use the check box in the top-left corner of the **Peaks** pane.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

## Spectrum Analyzer Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

**Note** If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

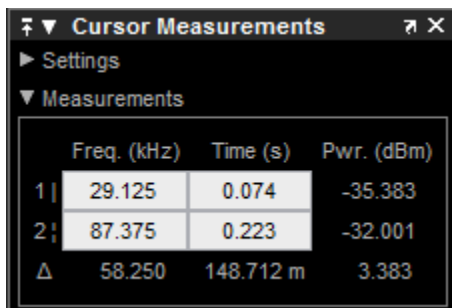

In the Scope menu, select **Tools > Measurements > Cursor Measurements**. Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel for the spectrum and dual view:

	Freq. (kHz)	Power (dBm)
1	29.125	-31.098
2	87.375	-32.501
Δ	58.250	1.402 dB
Channel Power:		27.000 dBm

The **Cursor Measurements** panel for the spectrogram view. You must pause the spectrogram display before you can use cursors.

	Freq. (kHz)	Time (s)	Pwr. (dBm)
1	29.125	0.074	-35.383
2	87.375	0.223	-32.001
Δ	58.250	148.712 m	3.383

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

The **Measurements** pane displays the frequency (Hz), time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

## Spectrum Analyzer Channel Measurements Panel

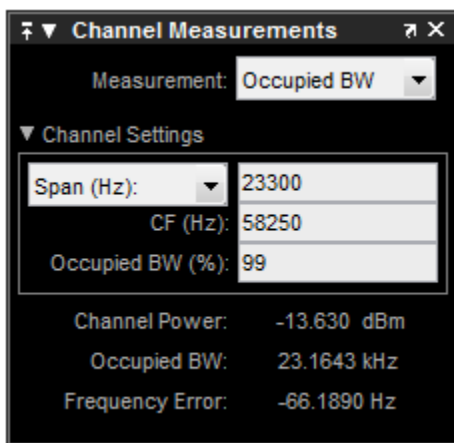

The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements.

- From the menu, select **Tools > Measurements > Channel Measurements**.
- On the toolbar, click the Channel Measurements  button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are Occupied BW or ACPR. See the 'Occupied BW' section in “Algorithms” (DSP System Toolbox) for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select Occupied BW as the **Measurement**, the following fields appear.

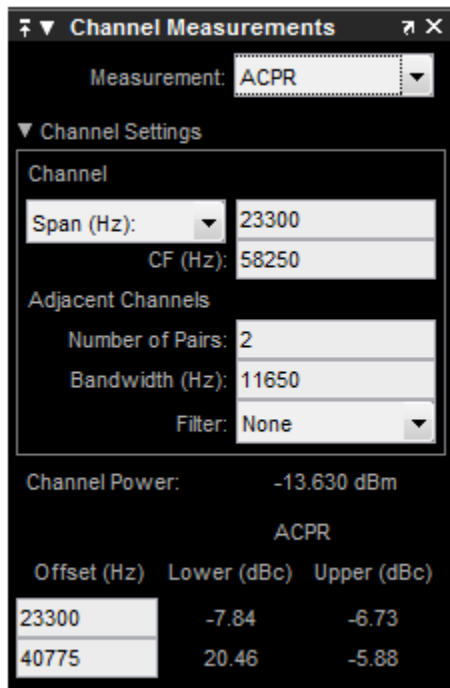

- **Channel Settings** — Modify the parameters for calculating the channel measurements.

### Channel Settings for Occupied BW

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.
- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select Occupied BW as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select Occupied BW as the **Measurement** type.

When you select ACPR as the **Measurement**, the following fields appear.

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

#### Channel Settings for ACPR

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Number of Pairs** — The number of pairs of adjacent channels.
- **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
- **Filter** — The filter to use for both main and adjacent channels. Available filters are None, Gaussian, and RRC (root-raised cosine).
- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.

## Spectrum Analyzer Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements.

- From the menu, select **Tools > Measurements > Distortion Measurements**.
- On the toolbar, click the Distortion Measurements  button.

The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

---

**Note** For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

---

- **Distortion** — The type of distortion measurements to display. Available options are **Harmonic** or **Intermodulation**. Select **Harmonic** if your system input is a single sinusoid. Select **Intermodulation** if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

See the 'Distortion Measurements' section in "Algorithms" (DSP System Toolbox) for information on how distortion measurements are calculated.

When you select **Harmonic** as the **Distortion**, the following fields appear.

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

**Note** To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Also, the noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100–300 db).

- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from 2 to 99. The default value is 6.

- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to 1 milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics,  $D$ , to the power in the fundamental frequency,  $S$ . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

$$THD = 10 \cdot \log_{10}(D/S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency,  $S$ , to the power of all nonharmonic content,  $N$ , including spurious signals, in decibels relative to the carrier (dBc).

$$SNR = 10 \cdot \log_{10}(S/N)$$

If you see — as the reported SNR, the total non-harmonic content of your signal is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency,  $S$  to all other content (including noise,  $N$ , and harmonic distortion,  $D$ ), in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10}\left(\frac{S}{N+D}\right)$$

- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency,  $S$ , to power of the largest spurious signal,  $R$ , regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

$$SNR = 10 \cdot \log_{10}(S/R)$$

When you select Intermodulation as the **Distortion**, the following fields appear.

The screenshot shows a software window titled "Distortion Measurements" with a dropdown menu set to "Intermodulation". Under the "Harmonics" section, there is a checkbox for "Label frequencies" which is checked. Below this is a table with two columns: "Freq. (kHz)" and "Power (dBm)". The table lists the following data:

	Freq. (kHz)	Power (dBm)
F1	10.9219	46.32
F2	45.9629	26.75
	Freq. (kHz)	Power (dBc)
2 F1 - F2	--	--
2 F2 - F1	80.7764	-62.03
TOI:	--	

The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products ( $2 \cdot F1 - F2$  and  $2 \cdot F2 - F1$ ).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency
- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

## Spectral Masks

Add upper and lower masks to the Spectrum Analyzer to visualize spectrum limits and compare spectrum values to specification values.

To open the **Spectral Mask** pane, in the toolbar, select the spectral mask button .

### Set Up Spectral Masks

In the Spectrum Analyzer window:

- 1 In the **Spectral Mask** pane, select a **Masks** option.
- 2 In the **Upper limits** or **Lower limits** box, enter the mask limits as a constant scalar, an array, or a workspace variable name.
- 3 (Optional) Select additional properties:
  - **Reference level** — Set a reference level for the mask. Enter a specific value or select Spectrum peak.
  - **Channel** — Select a channel to use for the mask reference.
  - **Frequency offset** — Set a frequency offset for mask.

From the command-line, to add a spectral mask to the `dsp.SpectrumAnalyzer` System object or the `SpectrumAnalyzerConfiguration` block configuration object:

- 1 Create a `SpectralMaskSpecification` object.
- 2 Set properties, such as `EnabledMasks`, `LowerMask`, or `UpperMask`.
- 3 In the `dsp.SpectrumAnalyzer` or `SpectrumAnalyzerConfiguration` object, set the `SpectralMask` property equal to your `SpectralMaskSpecification` object.

For example:

```
mask = SpectralMaskSpecification();
mask.EnabledMasks = 'Upper';
mask.UpperMask = 10;
scope = dsp.SpectrumAnalyzer();
scope.SpectralMask = mask;
scope.SpectralMask
```

ans =

SpectralMaskSpecification with properties:

```
    EnabledMasks: 'Upper'
      UpperMask: 10
      LowerMask: -Inf
    ReferenceLevel: 'Custom'
CustomReferenceLevel: 0
    MaskFrequencyOffset: 0
```

Events for class SpectralMaskSpecification: MaskTestFailed

## Check Spectral Masks

You can check the status of the spectral mask in several different ways:

- In the Spectrum Analyzer window, select the spectral mask button . In the **Spectral Mask** pane, the **Statistics** section shows statistics about how often the masks fail, which channels have caused a failure, and which masks are currently failing.
- To get the current status of the spectral masks, call `getSpectralMaskStatus`.
- To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events”.

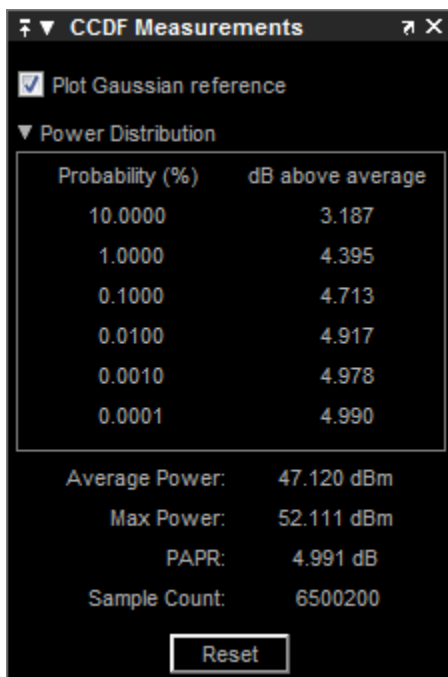

## Spectrum Analyzer CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of the instantaneous power of a signal being a specified level above the average power of the signal. These measurements are useful indicators of the dynamic range of a signal.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

To open this dialog box:

- From the menu, select **Tools > Measurements > CCDF Measurements**
- In the toolbar, click the CCDF Measurements  button.

- **Plot Gaussian reference** — Show the complex white Gaussian noise reference signal on the plot.
- **Probability (%)** — Percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — Expected minimum power level at the associated **Probability (%)**.
- **Average Power** — Average power level of the signal since the start of simulation or from the last reset.

**Max Power** — Maximum power level of the signal since the start of simulation or from the last reset.

- **PAPR** — Ratio of the peak power to the average power of the signal. PAPR should be less than 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — Total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

## Common Scope Block Tasks

### In this section...

“Connect Multiple Signals to a Scope” on page 30-51  
 “Save Simulation Data Using Scope Block” on page 30-53  
 “Pause Display While Running” on page 30-55  
 “Copy Scope Image” on page 30-55  
 “Plot an Array of Signals” on page 30-57  
 “Scopes in Referenced Models” on page 30-58  
 “Scopes Within an Enabled Subsystem” on page 30-62  
 “Modify x-axis of Scope” on page 30-63  
 “Show Signal Units on a Scope Display” on page 30-66  
 “Select Number of Displays and Layout” on page 30-68  
 “Dock and Undock Scope Window to MATLAB Desktop” on page 30-69

To visualize your simulation results over time, use a Scope block or Time Scope block

### Connect Multiple Signals to a Scope

To connect multiple signals to a scope, drag additional signals to the scope block. An additional port is created automatically.

To specify the number of input ports:

- 1 Open a scope window.
- 2 From the toolbar, select **File > Number of Input Ports > More**.
- 3 Enter the number of input ports, up to 96.

### Signals from Nonvirtual Buses and Arrays of Buses

You can connect signals from nonvirtual buses and arrays of buses to a Scope block. To display the bus signals, use normal or accelerator simulation mode. The Scope block displays each bus element

signal, in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened. For example, in this model the nestedBus signal has the const, subSignal, and step signals as elements. The subSignal sub-bus has the chirp and sine signals as its bus elements. In the Scope block, the two elements of the subSignal bus display between the const and step signals.

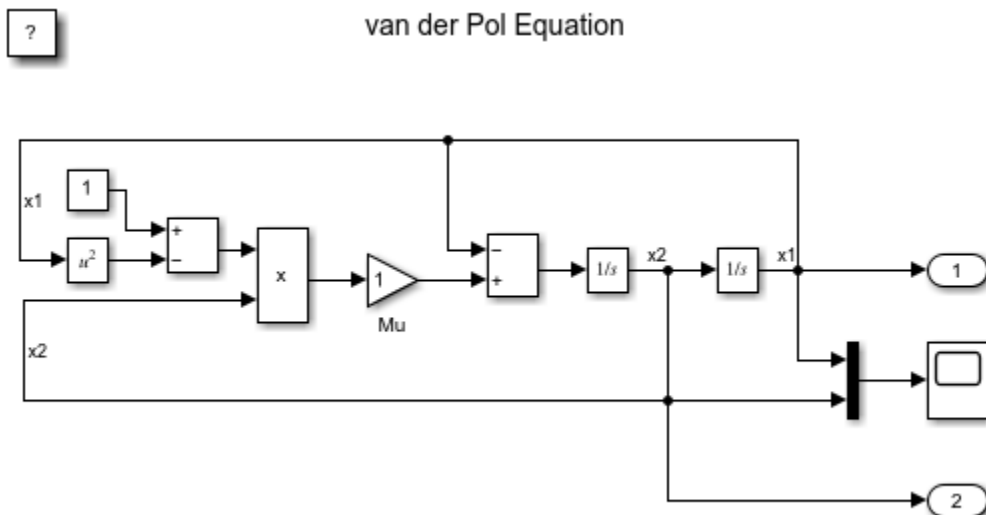

## Save Simulation Data Using Scope Block

This example shows how to save signals to the MATLAB Workspace using the Scope block. You can use these steps for the Scope or Time Scope blocks. To save data from the Floating Scope or Scope viewer, see “Save Simulation Data from Floating Scope” on page 30-75.

Using the vdp model, turn on data logging to the workspace. You can follow the commands below, or in the Scope window, click the Configuration Properties button and navigate to the Logging tab, turn on **Log data to workspace**.

```
vdp
scopeConfig = get_param('vdp/Scope', 'ScopeConfiguration');
scopeConfig.DataLogging = true;
scopeConfig.DataLoggingSaveFormat = 'Dataset';
out = sim('vdp');
```

Copyright 2004-2020 The MathWorks, Inc.

In the MATLAB Command window, view the logged data from the `out.ScopeData` structure.

```
x1_data = out.ScopeData{1}.Values.Data(:,1);  
x1_time = out.ScopeData{1}.Values.Time;  
plot(x1_time,x1_data)
```

## Pause Display While Running

Use the Simulink Snapshot to pause the scope display while the simulation keeps running in the background.

- 1 Open a scope window and start the simulation.
- 2 Select **Simulation > Simulink Snapshot**.

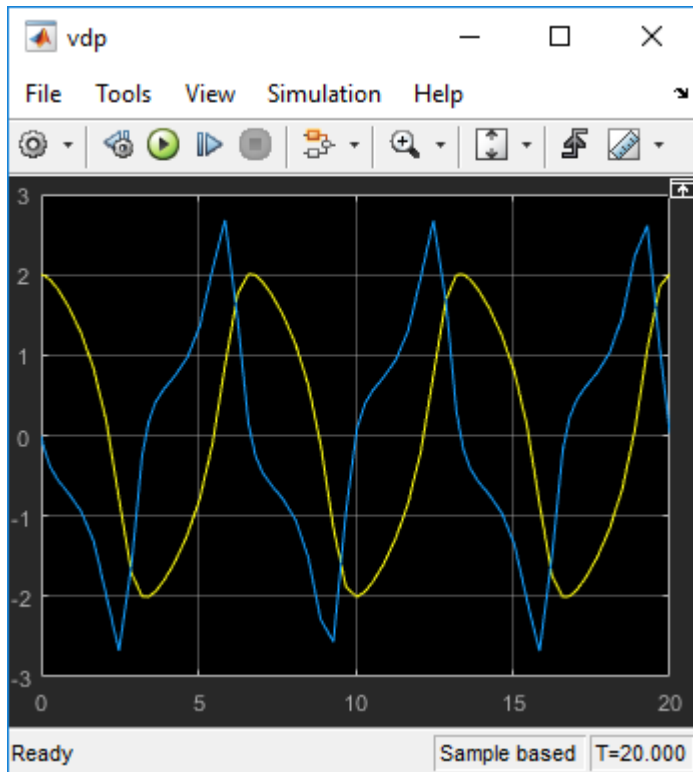

The scope window status in the bottom left is **Frozen**, but the simulation continues to run in the background.

- 3 Interact with the paused display. For example, use measurements, copy the scope image, or zoom in or out.
- 4 To unfreeze the display, select **Simulation > Simulink Snapshot** again.

## Copy Scope Image

This example uses the model vdp to demonstrate how to copy and paste a scope image.

- 1 Add a scope block to your model.
- 2 Connect signals to scope ports. See “Connect Multiple Signals to a Scope” on page 30-51. For example, in the vdp model, connect the signals x1 and x2 to a scope.
- 3 Open the scope window and run the simulation.

- 4 Select **File > Copy to Clipboard**.
- 5 Paste the image into a document.

The van der Pol Equation results from my model:

By default, **Copy to Clipboard** saves a printer-friendly version of the scope with a white background and visible lines. If you want to paste the exact scope plot displayed, select **View > Style**, then select the **Preserve colors for copy to clipboard** check box.

## Plot an Array of Signals

This example shows how the scope plots an array of signals.

Copyright 2019 The MathWorks, Inc.

In this simple model, a Sine Wave block is connected to a scope block. The Sine Wave block outputs four signals with the amplitudes [10, 20; 30 40]. The scope displays each sine wave in the array separately in the matrix order (1,1), (2,1), (1,2), (2,2).

## Scopes in Referenced Models

This example shows the behavior of scopes in referenced models. When you use a scope in a referenced model, you see different output in the scope depending on where you started the simulation: from the top model or the scope in the referenced model.

---

**Note** Scope windows display simulation results for the most recently opened top model. Playback controls in scope blocks and viewers simulate the model containing that block or viewer.

---

This example uses the `sldemo_mdref_counter` model both as a top model and as a referenced model from the `sldemo_mdref_basic` model.

Open the model:

```
openExample('sldemo_mdref_basic')
```

Double-click the CounterA block. The `sldemo_mdref_counter` model opens as a referenced model, as evidenced by the breadcrumb above the canvas.

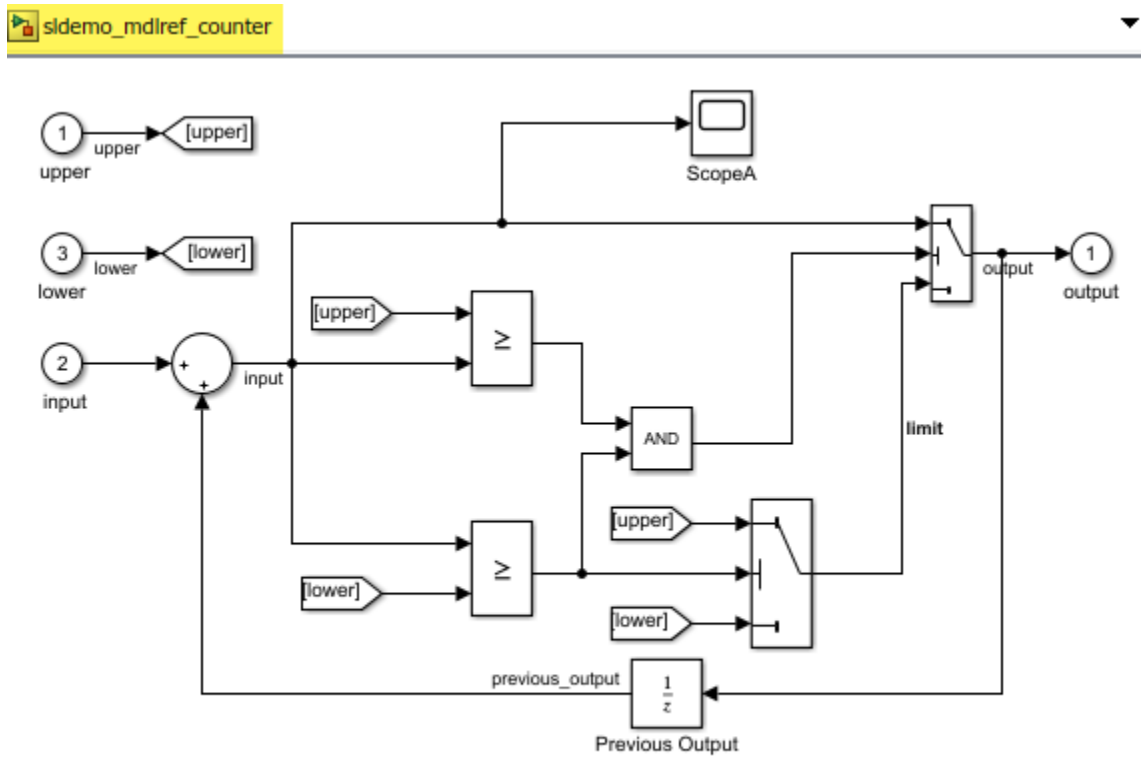

Copyright 1990-2014 The MathWorks, Inc.

Run the simulation using the main run button, then open up the ScopeA scope. The scope visualizes the data from the entire model.

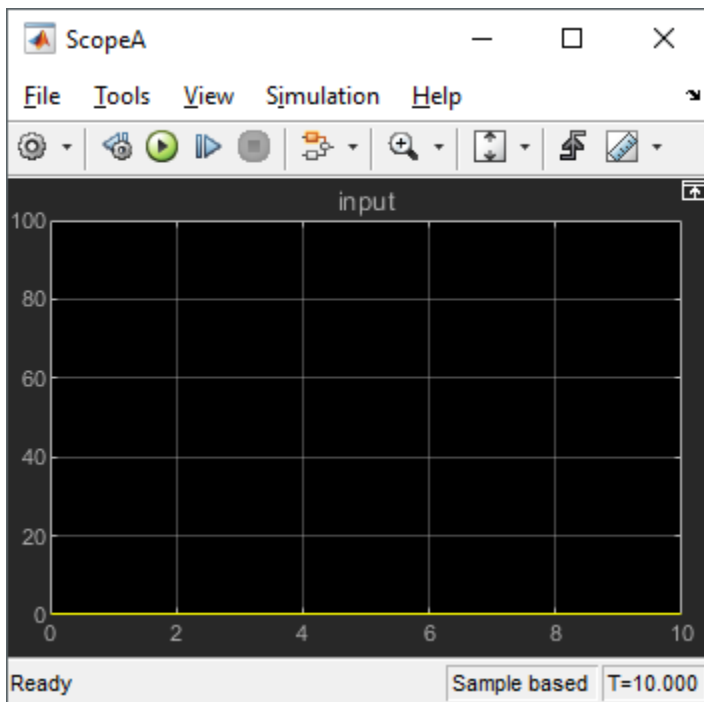

If you specifically want to visualize a referenced model in isolation, open the model as a top model. In this example, right-click the CounterA block and select `Open as Top Model`. The model opens in another window and the breadcrumb only shows the referenced model name.

Copyright 1990-2014 The MathWorks, Inc.

When you run the simulation from either the Simulink window or the scope window, the scope visualizes the model without any reference to another model. In this case, the model input is zero the entire time.

## Scopes Within an Enabled Subsystem

When placed within an Enabled Subsystem block, scopes behave differently depending on the simulation mode:

- Normal mode — A scope plots data when the subsystem is enabled. The display plot shows gaps when the subsystem is disabled.

- External, Accelerator, and Rapid modes — A scope plots data when the subsystem is enabled. The display connects the gaps with straight lines.

## Modify x-axis of Scope

This example shows how to modify the x-axis values of the Scope block using the **Time span** and **Time display offset** parameters. The **Time span** parameter modifies how much of the simulation time is shown and offsets the x-axis labels. The **Time display offset** parameter modifies the labels used on the x-axis.

You can also use this procedure for the Time Scope block, Floating Scope block, or Scope viewer.

Open the model and run the simulation to see the original scope output. The simulation runs for 10 time steps stepping up by 1 at each time step.

```
model = 'ModifyScopeXAxis';
open_system(model);
sim(model);
open_system([model, '/Scope']);
```

Copyright 2020 The MathWorks, Inc

### Modify Time Span Shown

Modify the **Time span** parameter to 2. You can follow the commands below, or in the Scope window, click the Configuration Properties button and navigate to the Time tab.

```
scopeConfig = get_param([model, '/Scope'], 'ScopeConfiguration');  
scopeConfig.TimeSpan = '2';  
sim(model);  
open_system([model, '/Scope']);
```

The x-axis of the scope now shows only the last 2 time steps and offsets the x-axis labels to show 0-2. The bottom toolbar shows that the x-axis is offset by 8. This offset is different from the **Time display offset** value.

The **Time span** parameter is useful if you do not want to visualize signal initialization or other start-up tasks at the beginning of a simulation. You can still see the full simulation time span if you click the **Span x-axis** button.

### Offset x-axis Labels

Modify the **Time display offset** parameter to 5. Again, use the commands below, or in the Scope window, click the Configuration Properties button and navigate to the Time tab.

```
scopeConfig.TimeDisplayOffset = '5';
sim(model);
open_system([model, '/Scope']);
```

Now, the same time span of 2 is shown in the scope, but the x-axis labels are offset by 5, starting at 5 and ending at 7. If you click the **Span x-axis** button, the x-axis labels still start at 5.

## Show Signal Units on a Scope Display

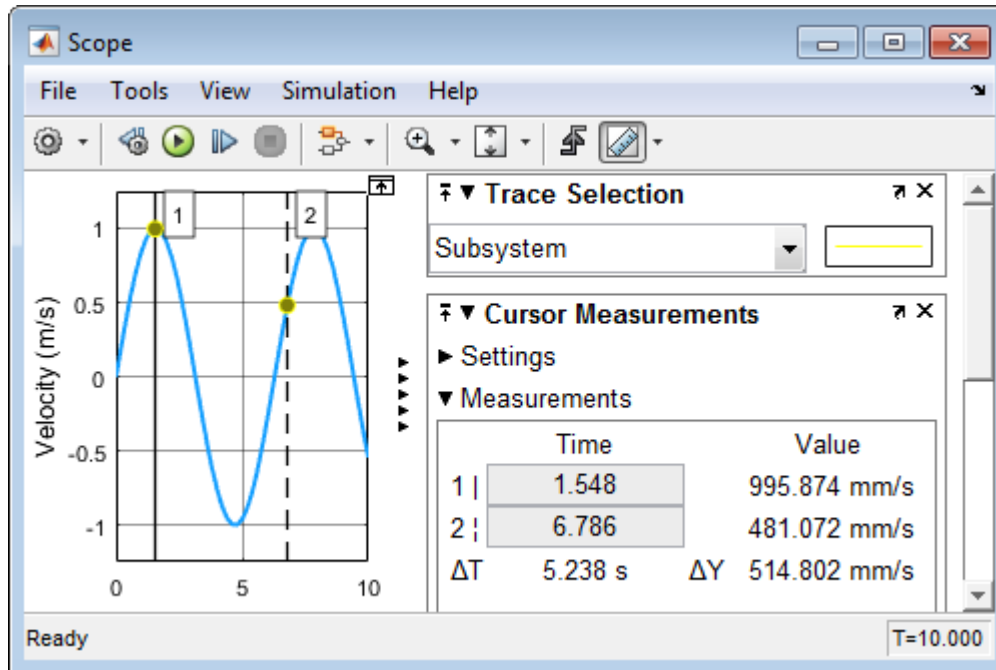

You can specify signal units at a model component boundary (Subsystem and Model blocks) using Inport and Outport blocks. See “Unit Specification in Simulink Models” on page 9-2. You can then connect a Scope block to an Outport block or a signal originating from an Outport block. In this example, the **Unit** property for the Out1 block was set to m/s.

## Show Units on a Scope Display

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties: Scope dialog box, select the **Display** tab.
- 3 In the **Y-label** box, enter a title for the y-axis followed by (%<SignalUnits>). For example, enter  
Velocity (%<SignalUnits>)
- 4 Click **OK** or **Apply**.

Signal units display in the y-axis label as meters per second (m/s) and in the Cursor Measurements panel as millimeters per second (mm/s).

From the Simulink toolstrip, you can also select **Debug > Information Overlays > Units**. You do not have to enter (%<SignalUnits>) in the **Y-Label** property.

### Show Units on a Scope Display Programmatically

- 1 Get the scope properties. In the Command Window, enter

```
load_system('my_model')
s = get_param('my_model/Scope', 'ScopeConfiguration');
```

- 2 Add a y-axis label to the first display.

```
s.ActiveDisplay = 1
s.YLabel = 'Velocity (%<SignalUnits>);'
```

You can also set the model parameter ShowPortUnits to 'on'. All scopes in your model, with and without (%<SignalUnits>) in the **Y-Label** property, show units on the displays.

```
load_system('my_model')
get_param('my_model', 'ShowPortUnits')

ans =
off

set_param('my_model', 'ShowPortUnits', 'on')

ans =
on
```

## Determine Units from a Logged Data Object

When saving simulation data from a scope with the `Dataset` format, you can find unit information in the `DataInfo` field of the timeseries object.

---

**Note** Scope support for signal units is only for the `Dataset` logging format and not for the legacy logging formats `Array`, `Structure`, and `Structure With Time`.

---

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties window, select the **Logging** tab.
- 3 Select the **Log data to workspace** check box. In the text box, enter a variable name for saving simulation data. For example, enter `ScopeData`.
- 4 From the Scope window toolbar, select the run button .
- 5 In the Command Window, enter

```
ScopeData.getElement(1).Values.DataInfo
```

```
Package: tsdata
Common Properties:
    Units: m/s (Simulink.SimulationData.Unit)
    Interpolation: linear (tsdata.interpolation)
```

## Connect Signals with Different Units to a Scope

When there are multiple ports on a scope, Simulink ensures that each port receives data with only one unit. If you try to combine signals with different units (for example by using a Bus Creator block), Simulink returns an error.

Scopes show units depending on the number of ports and displays:

- **Number of ports equal to the number of displays** — One port is assigned to one display with units for the port signal shown on the y-axis label.
- **Greater than the number of displays** — One port is assigned to one display, with the last display assigned the remaining signals. Different units are shown on the last y-axis label as a comma-separated list.

## Select Number of Displays and Layout

- 1 From a Scope window, select the Configuration Properties button .
- 2 In the Configuration Properties dialog box, select the **Main** tab, and then select the **Layout** button.
- 3 Select the number of displays and the layout you want.

You can select more than four displays in a row or column. Click within the layout, and then drag your mouse pointer to expand the layout to a maximum of 16 rows by 16 columns.

- Click to apply the selected layout to the Scope window.

## Dock and Undock Scope Window to MATLAB Desktop

- In the right corner of a Scope window, click the Dock Scope button.

The Scope window is placed above the Command Window in the MATLAB desktop.

- Click the Show Scope Actions button, and then click **Undock Scope**.

## View Values of Parameters Set as Variables

When you specify the value of a Simulink parameter as a variable or as an expression that contains variables, the Block Parameters dialog box and the Property Inspector display the value of the variable or the expression.

The text box where you enter the parameter value displays the variable or expression on the left and the value on the right.

**Note** Numerical values are displayed in the shortG format. For more information about the shortG format, see [format](#).

With this in-place display of parameter values, you can check the value of a parameter in the same text field where you define the parameter.

To see the value the variable or expression has during simulation, run the simulation and open the Block Parameters dialog box or the Property Inspector. The displayed value is the value of the variable or expression in the simulation at the time step when you open the Block Parameters dialog box or the Property Inspector.

If the variable represents a data type that cannot be evaluated, the data type or class is displayed instead of a value. For example, if the variable represents an object, the class is displayed.

### In-Place Parameter Value Display for Different Data Types

What the text field displays depends on the data type and dimensions of the parameter value. The table shows the display according to data type and, where relevant, dimension.

Data Type and Dimension	Display	Example
1-D or 2-D matrix with four elements or fewer	Values of all elements	x=[1,2;3,4]; x

Data Type and Dimension	Display	Example
Matrix with more than two dimensions or more than four elements	Dimensions and data type	<pre>x=[1 2 3 4 5];</pre> 
String	Value	<pre>x="position";</pre> 
Character vector	Value	<pre>x='position';</pre> 
Cell array	Dimensions and data type	<pre>x={'a', 'b', 'c'};</pre> 
Structure	Data type	<pre>x.a=1; x.b=2; x.c=3;</pre> 
Object	Class	<p>Create the <code>BasicClass</code> from the “Design Class” example.</p> <pre>x=BasicClass;</pre> 
	<p><b>Note</b> The class is displayed as a hyperlink. When you click the hyperlink, the MATLAB File Help for the class opens.</p>	

## In-Place Parameter Value Display for Variables Defined in Multiple Workspaces

To see how a variable is evaluated when the same variable name is used to represent different values in different workspaces, see “Symbol Resolution Process” on page 72-134.

## Turn Off In-Place Parameter Value Display

To turn the value display off, in the Simulink Toolstrip, on the **Modeling** tab, in the **Evaluate and Manage** section, click **Environment**, then click **Simulink Preferences**. Select **Editor**, then clear **Show evaluated value in place**.

**Note** Settings in the Simulink Preferences are applied to all Simulink windows and persist from one session to the next.

## **Limitations**

The display of variable values for Simulink parameters is not supported for Simscape blocks.

## Floating Scope and Scope Viewer Tasks

### In this section...

“Add Floating Scope Block to Model and Connect Signals” on page 30-73

“Add Scope Viewer to a Signal” on page 30-74

“Add Signals to an Existing Floating Scope or Scope Viewer” on page 30-74

“Save Simulation Data from Floating Scope” on page 30-75

“Add and Manage Viewers” on page 30-78

“Quickly Switch Visualization of Different Signals on a Floating Scope” on page 30-79

These tasks walk through frequently used Floating Scope and Scope Viewer procedures.

### Add Floating Scope Block to Model and Connect Signals

To add a Floating Scope block from the Simulink block library:

- 1 From the **Simulation** tab, click **Library Browser** .
- 2 From Simulink / Sinks, drag a copy of the Floating Scope block into your model.

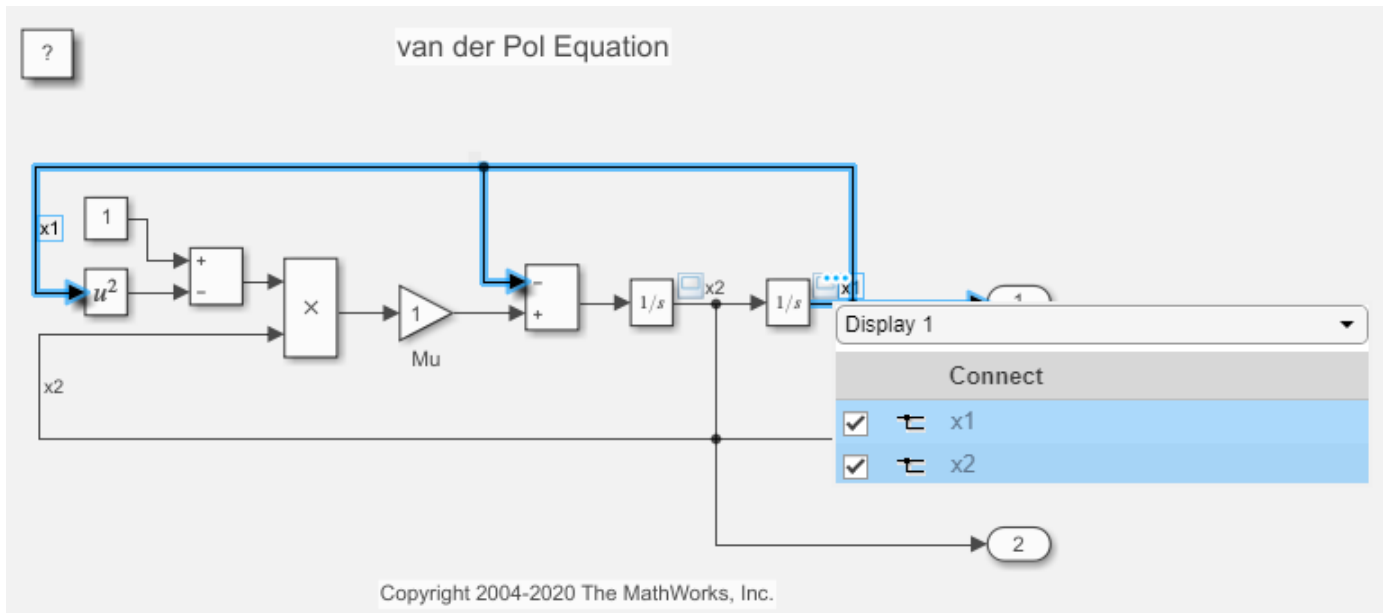

To connect signals to your floating scope:

- 1 Double-click the Floating Scope block.
- 2 In the scope window toolbar, click the signal selection button . You may need to select the dropdown next to the lock button to see signal selection.

The Simulink Editor canvas grays, indicating you can interactively select signals to connect to the scope.

- 3 Select the signals you want to connect to the scope. To select multiple signals, click and drag.
- 4 In the **Connect** pop-up, select the check box next to the signals you want to connect.

- 5 For scopes with multiple displays (subplots), select the desired display from the drop-down at the top of the Connect pop-up and connect the signals.
- 6 Click the **X** in the upper-right of the Simulink canvas.

Your signals are now connected to the floating scope. Run a simulation to see the plotted signals.

## Add Scope Viewer to a Signal

- 1 Select a signal to view.
- 2 In the **Simulation** tab, in the **Prepare** gallery, select **Add Viewer**.
- 3 From the Add Viewer window, select a viewer, for example **Scope**.

## Add Signals to an Existing Floating Scope or Scope Viewer

Connect signals to an existing Floating Scope or Scope viewer.

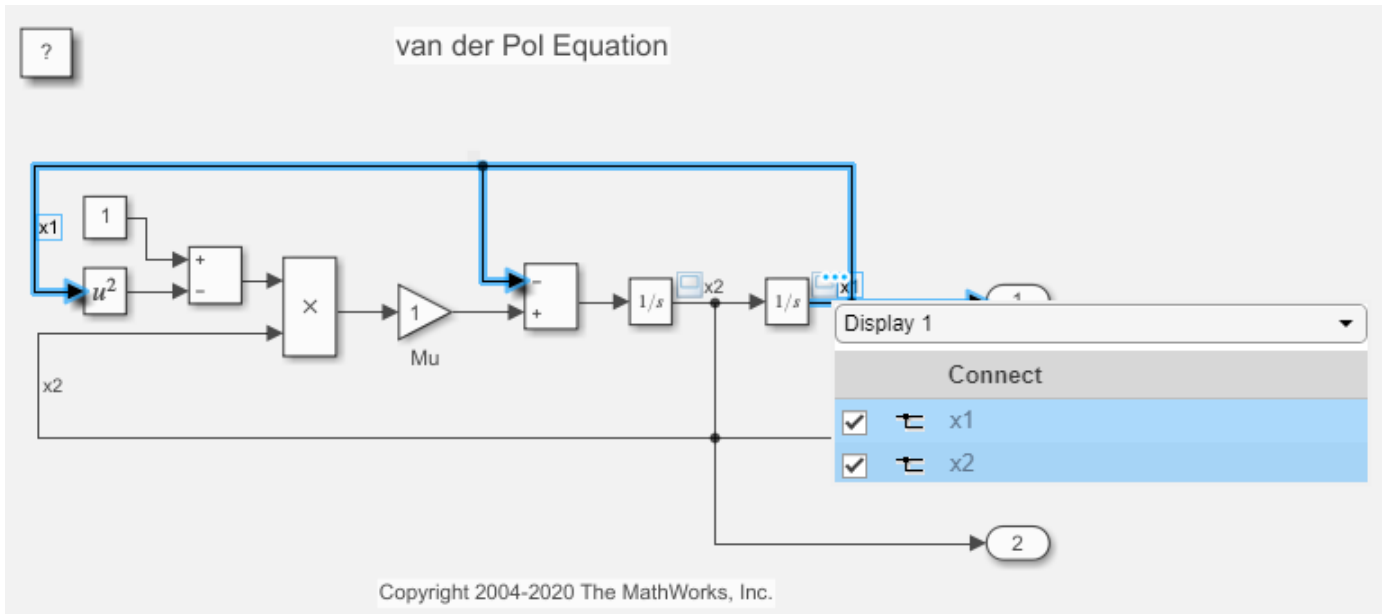

- 1 Open the scope by double-clicking a Floating Scope block or Scope viewer icon .
- 2 In the scope window toolbar, click the signal selection button . You may need to select the drop-down next to the lock button to see signal selection.

The Simulink Editor canvas grays, indicating you can interactively select signals to connect to the scope.

- 3 Select the signals you want to connect to the scope. To select multiple signals, click and drag.

- 4 In the **Connect** pop-up, select the check box next to the signals you want to connect.

- 5 For scopes with multiple displays (subplots), select the desired display from the drop-down at the top of the Connect pop-up and connect the signals.
- 6 Click the **X** in the upper-right of the Simulink canvas.

Your signals are now connected to the scope. Run a simulation to see the plotted signals.

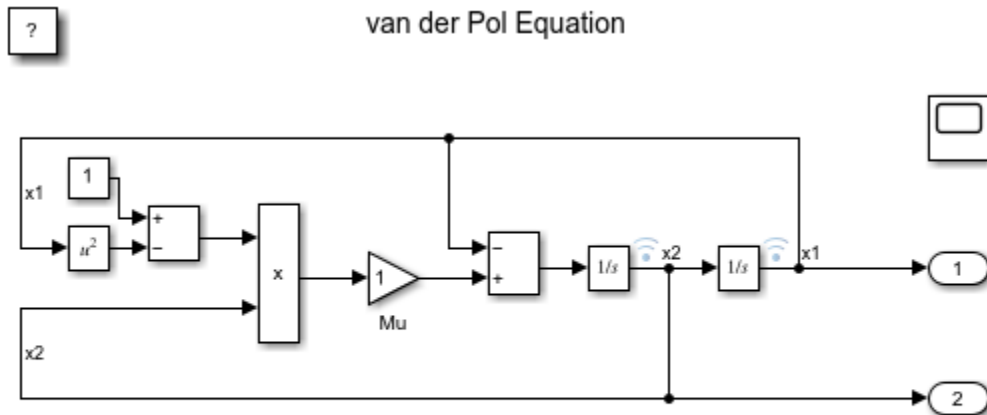

## Save Simulation Data from Floating Scope

This example shows how to save signals to the MATLAB® Workspace using a Floating Scope block. You can follow the same procedure to save data from a Scope Viewer. To save data from a Scope or Time Scope block, see “Save Simulation Data Using Scope Block” on page 30-53.

This example uses a modified version of the vdp model. In this example, a floating scope is connected to the x1 and x2 signals.

### Set Up Signal Logging from the Floating Scope

```
model = 'vdpFloatingScope';
open_system(model);
```

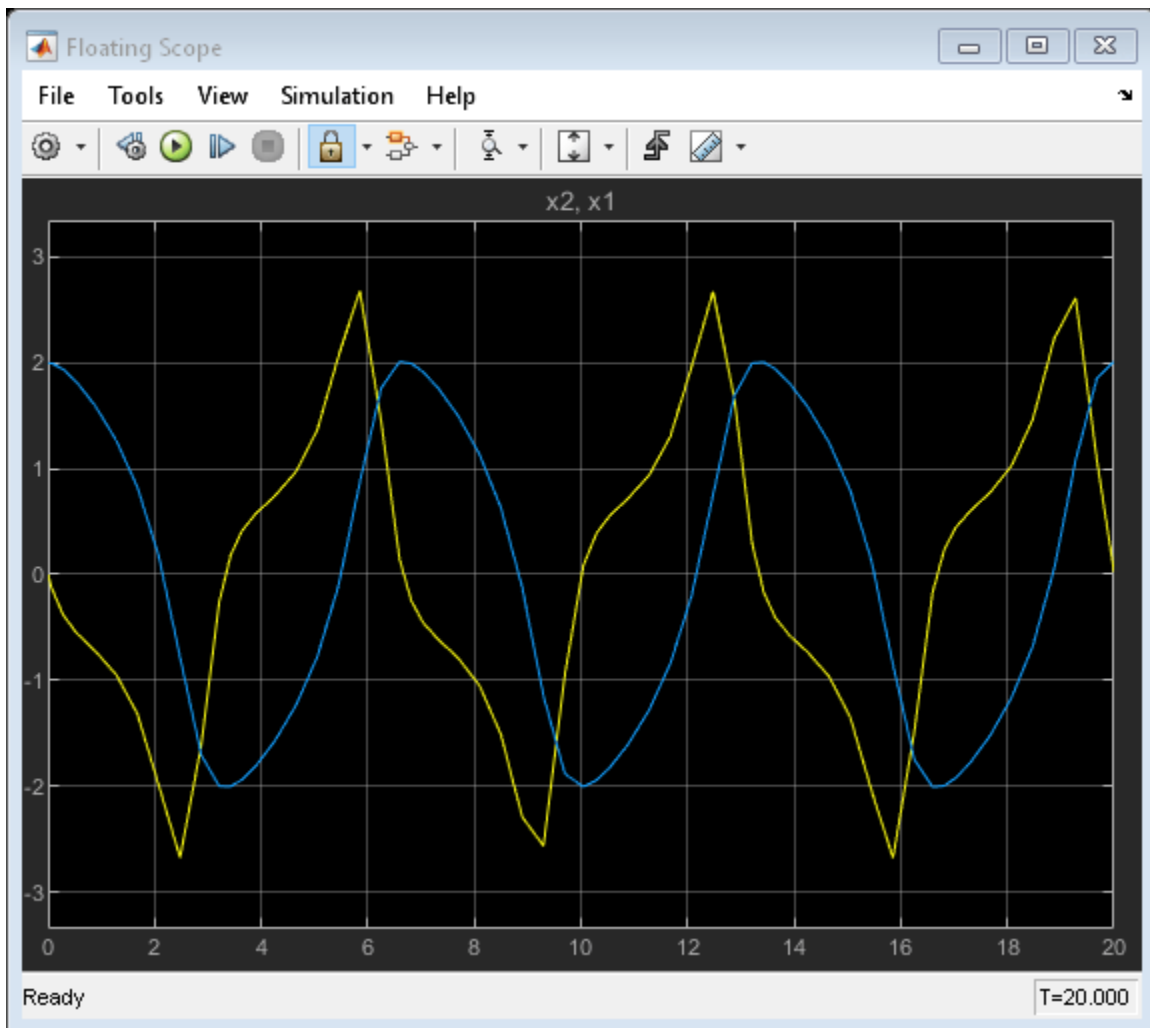

Copyright 2004-2019 The MathWorks, Inc.

- 1 From the Floating Scope window, select **View > Configuration Properties**.
- 2 On the **Logging** tab, select **Log/Unlog Viewer Signals to Workspace**. When you click this button, Simulink places logging symbols on the signals connected to the Floating Scope.
- 3 From the Simulink Editor, on the **Modeling** tab, click **Model Settings**.
- 4 In the Configuration Properties window, select **Data Import/Export**.
- 5 Select the **Signal logging** check box. You can also set the parameter name from this window. The default parameter name is `logout`.

### Use Saved Simulation Data

Run a simulation. Simulink saves data to the MATLAB Workspace in a variable `out`.

```
out = sim(model);
```

Simulink saves all logged or saved simulation data as one structure. In `out`, the scope data object `logscope` has one element for each logged signal.

In the MATLAB Command Window, plot the log data for `x1`.

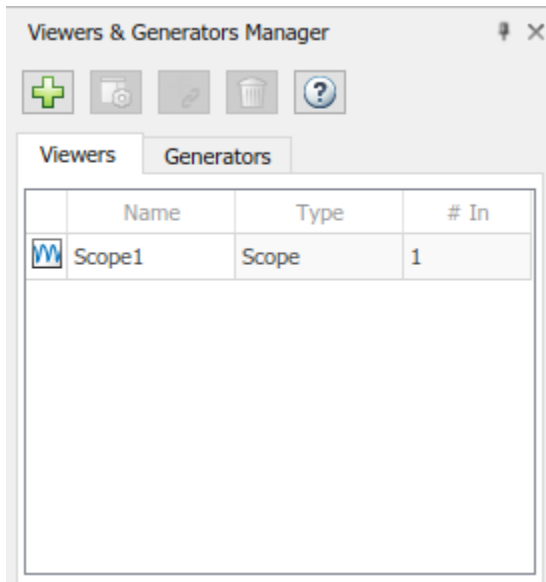

```
x1_data = out.logscope.get('x1').Values.Data;  
x1_time = out.logscope.get('x1').Values.Time;  
plot(x1_time,x1_data);
```

### Add and Manage Viewers

Open the Viewers and Generators Manager. From the Simulink toolstrip **Simulation** tab, expand the **Prepare** gallery and select **Viewers Manager**.

You can see any viewers or generators you added in the Viewers and Generators Manager.

- To add viewers or generators, click and choose a viewer. New viewers and generators are not connected to any signals.
- To connect signals, click on a viewer or generator, and click .
- To delete a viewer or generator, click .

## Quickly Switch Visualization of Different Signals on a Floating Scope

- 1 Open a Floating Scope window.
- 2 On the toolbar, click the Lock button so that the icon is unlocked .
- 3 In the model, click a signal line to select and highlight the signal line. To select multiple signals, hold down the **Shift** key while selecting signals.

After clicking on the canvas, the selected display removes connections to any previously selected signals.

- 4 Run a simulation. As long as the unlock icon is showing, you can click between signals to switch which signal appears in the Floating Scope.

## Generate Signals Without Source Blocks

Signal generators create signals without adding a block to your model. Generators are added and managed through the Viewers and Generators Manager.

### Attach Signal Generator

#### Context Menu

- 1 In the Simulink Editor, right-click the input to a block.
- 2 From the context menu, select **Create And Connect Generator** > *product* > *generator*.

The name of the generator you choose appears in a box connected to the block input.

#### Viewers and Generators Manager

- 1 From the **Simulation** tab, open the **Prepare** gallery and select **Viewers Manager**. The Viewers and Generators Manager panel opens to the side of the Simulink editor.
- 2 In the Viewers and Generators panel, select the **Generators** tab.
- 3 Click the  button and select a generator.

The generator is added to the list of generators.

- 4 Click the generator you just added from the list and select the  button.
- 5 The canvas grays, indicating you are now in connect mode. Click the block you want to connect the generator to and in the pop-up, select the check box for the input port you want to attach the generator to.
- 6 Close connect mode by clicking the **X** in the upper right corner of the canvas.

### Modify Signal Generator Parameters

#### Context Menu

- 1 Right-click the generator name and select **Generator Parameters**. In the Generator Parameters dialog box, enter parameters for this generator.
- 2 To rename a signal generator, double-click the generator label and type your new name for the generator.

#### Viewers and Generators Manager

- 1 From the Viewers and Generators Manager panel, select the generator from the **Generator** tab.
- 2 Click  and enter parameter values for this generator.
- 3 To rename a signal generator, double-click the generator name in the Generators list and type your new name for the generator.

## Remove Signal Generator

### Context Menu

- 1 Right-click a generator.
- 2 From the context menu, select **Disconnect Generator**.

To also delete the generator, select **Disconnect and Delete Generator**

### Viewers and Generators Manager

- 1 From the Viewers and Generators Manager panel, select the generator from the **Generator** tab.
- 2 Enter connect mode by selecting the  button
- 3 On the grayed canvas, select the generator and, in the pop-up, clear the check box next to the port you want to disconnect.
- 4 To delete the generator completely, in the Viewers and Generators Manager panel, also click .

## Viewers and Generators Manager

Using the Viewers and Generators Manager, you can manage viewers and generators from a central point.

Viewers and generators are not blocks. Blocks are dragged from the Library Browser and managed with block dialog boxes. Viewers and generators are mechanisms that create or visualize signals, but are added and managed through the Viewers and Generators Manager.

Symbols identify a viewer attached to a signal line, and signal names identify generators.

### Open the Viewers and Generators Manager

From the **Simulation** tab, open the **Prepare** gallery and select **Viewers Manager**. The Viewers and Generators Manager panel opens to the side of the Simulink editor.

You can also access the Viewers and Generators Manager by right-clicking a signal or block input and selecting **Viewers and Generators Manager**.

### Change Parameters

- 1 Open the Viewers and Generators Manager.
- 2 In the list of **Generators** or **Viewers**, select the viewer or generator you want to modify.
- 3 Select the  button.
  - For a generator, the parameters dialog box opens for that generator type.
  - For a viewer, either a parameter dialog opens or the viewer itself opens. If the viewer opens, you can access parameters from the  button.
- 4 Review and change parameters.

### Connect Viewers and Generators

Connect signals to a new viewer or generator using the Viewers and Generators Manager.

- 1 Open the Viewers and Generators Manager panel.
- 2 Select either the **Viewers** or **Generators** tab.
- 3 Click .

- 4 From the list of viewers or generators, select the viewer or generator you just added.
- 5 Select the  button. The canvas grays, indicating you are now in connect mode.
- 6 For generators, click the block you want to connect the generator to and in the pop-up, select the check box for the input port you want to attach to.

For viewers, click the signal or signals you want to visualize and in the pop-up, select the check box next to the signals you want to connect. If you have multiple displays or specific inputs, select the display you want to connect to from the drop down before selecting the check box.

- 7 Close connect mode by clicking the **X** in the upper right corner of the canvas.

## View Test Point Data

Use a Scope viewer available from the Viewers and Generators Manager to view any signal that is defined as a test point in a referenced model. A test point is a signal that you can always see when using a Scope viewer in a model.

---

**Note** With some viewers (for example, To Video Display, Matrix Viewer), you cannot use the Signal Selector to select signals with test points in referenced models.

---

For more information, see “Configure Signals as Test Points” on page 80-46.

## Customize Viewers and Generators Manager

You can add custom signal viewers or generators so that they appear in the Viewers and Generators Manager. This procedure adds a custom viewer named `newviewer` to the Viewers and Generators Manager:

- 1 Create a new Simulink library by selecting **Simulation > New > Library**.
- 2 Save the library as `newlib`.
- 3 In the MATLAB Command Window, set the library type to a viewer library:

```
set_param('newlib','LibraryType','SSMgrViewerLibrary')
```

To set the library type for generators, use the type `'SSMgrGenLibrary'`. For example:

```
set_param('newlib','LibraryType','SSMgrGenLibrary')
```

- 4 Set the display name of the library:

```
set_param('newlib','SSMgrDisplayString','My Custom Library')
```

- 5 Add your custom viewer or generator to the library by dragging and dropping into the Simulink canvas.

---

**Note** If the viewer is a compound viewer, such as a subsystem with multiple blocks, make the top-level subsystem an atomic one.

---

- 6 Set the `iotype` of the viewer. For example:

```
set_param('newlib/newviewer','iotype','viewer')
```

- 7 Save the library `newlib`.
- 8 Using the MATLAB editor, create a file named `sl_customization.m`. In this file, enter a directive to incorporate the new library as a viewer library.

For example, to save `newlib` as a viewer library, add these lines:

```
function sl_customization(cm)
cm.addSigScopeMgrViewerLibrary('newlib')
%end function
```

To add a library as a generator library, use this syntax instead:

```
cm.addSigScopeMgrGeneratorLibrary('newlib')
```

- 9 Add a corresponding `cm.addSigScope` line for each viewer or generator library you want to add.
- 10 Save the `sl_customization.m` file on your MATLAB path. Edit this file to add new viewer or generator libraries.
- 11 To see the new custom libraries, restart MATLAB and start the Viewers and Generators Manager.

## Control Scope Blocks Programmatically

This example shows how to control scopes with programming scripts.

### Use Simulink Configuration Object

Use a Scope Configuration object for programmatic access to scope parameters.

- Modify the title, axis labels, and axis limits
- Turn on or off the legend or grid
- Control the number of inputs
- Change the number of displays and which display is active

Create a model and add a Scope and Time Scope block. Then, use `get_param` to create the Scope Configuration object `myConfiguration`.

```
mdl = 'myModel';
new_system(mdl);
add_block('simulink/Sinks/Scope', [mdl '/myScope']);
add_block('dspsnks4/Time Scope', [mdl '/myTimeScope']);
myConfiguration = get_param([mdl '/myScope'],'ScopeConfiguration')
```

```
myConfiguration =
Scope configuration with properties:

                Name: 'myScope'
                Position: [360 302 560 420]
                Visible: 0
    OpenAtSimulationStart: 0
                DisplayFullPath: 0
    PreserveColorsForCopyToClipboard: 0
                NumInputPorts: '1'
                LayoutDimensions: [1 1]
                SampleTime: '-1'
    FrameBasedProcessing: 0
                MaximizeAxes: 'Off'
                MinimizeControls: 0
                AxesScaling: 'Manual'
    AxesScalingNumUpdates: '10'
                TimeSpan: 'Auto'
    TimeSpanOverrunAction: 'Wrap'
                TimeUnits: 'none'
                TimeDisplayOffset: '0'
                TimeAxisLabels: 'Bottom'
    ShowTimeAxisLabel: 0
                ActiveDisplay: 1
                Title: '%<SignalLabel>'
                ShowLegend: 0
                ShowGrid: 1
    PlotAsMagnitudePhase: 0
                YLimits: [-10 10]
                YLabel: ''
                DataLogging: 0
    DataLoggingVariableName: 'ScopeData'
    DataLoggingLimitDataPoints: 0
```

```
DataLoggingMaxPoints: '5000'
DataLoggingDecimateData: 0
DataLoggingDecimation: '2'
DataLoggingSaveFormat: 'Dataset'
```

Set a property.

```
myConfiguration.DataLoggingMaxPoints = '10000';
```

Find the Scope and Time Scope blocks.

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...
'AllBlocks', 'on', 'BlockType', 'Scope')
```

```
ans = 2x1 cell
    {'myModel/myScope' }
    {'myModel/myTimeScope' }
```

Find only Simulink Scope blocks.

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...
'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...
'Simulink.scopes.TimeScopeBlockCfg')
```

```
ans = 1x1 cell array
    {'myModel/myScope' }
```

Find only the DSP Time Scope blocks.

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...
'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...
'spbscopes.TimeScopeBlockCfg')
```

```
ans = 1x1 cell array
    {'myModel/myTimeScope' }
```

## Scope Configuration Properties

## Plot a Circle Using the XY Graph Block

This example shows how to plot data using the XY Graph block. The XY Graph block is an alternative configuration of the Record block that plots two input signals on an XY plot. The XY plot used by the Record block is also available in the Simulation Data Inspector. The XY Graph block has all the capabilities of the Record block, including the ability to log data to the workspace and a file.

The model computes  $x$  and  $y$  data to plot a circle using a third variable,  $\theta$ . Using a polar coordinate system, you can express the equation for a circle of radius  $a$  centered on the origin as:

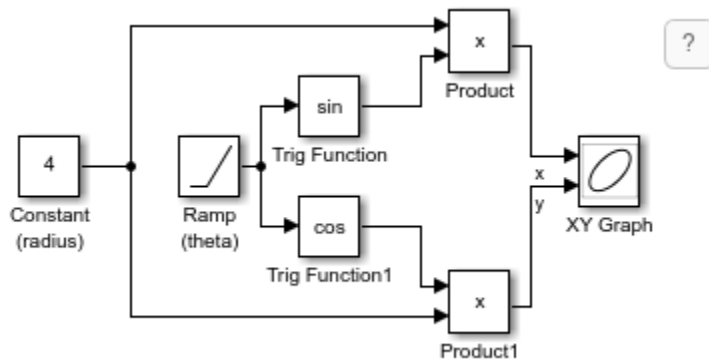

$$r(\theta) = a$$

Converting the equation to use Cartesian coordinates results in these equations for the  $x$  and  $y$  data:

$$x = a \cos(\theta)$$

$$y = a \sin(\theta)$$

The model computes the  $x$  data and the  $y$  data using Trigonometric Function blocks. The Ramp block provides the input,  $\theta$ , and the Constant block sets the radius of the circle.

To view the plotted results, simulate the model, then double-click the XY Graph block.

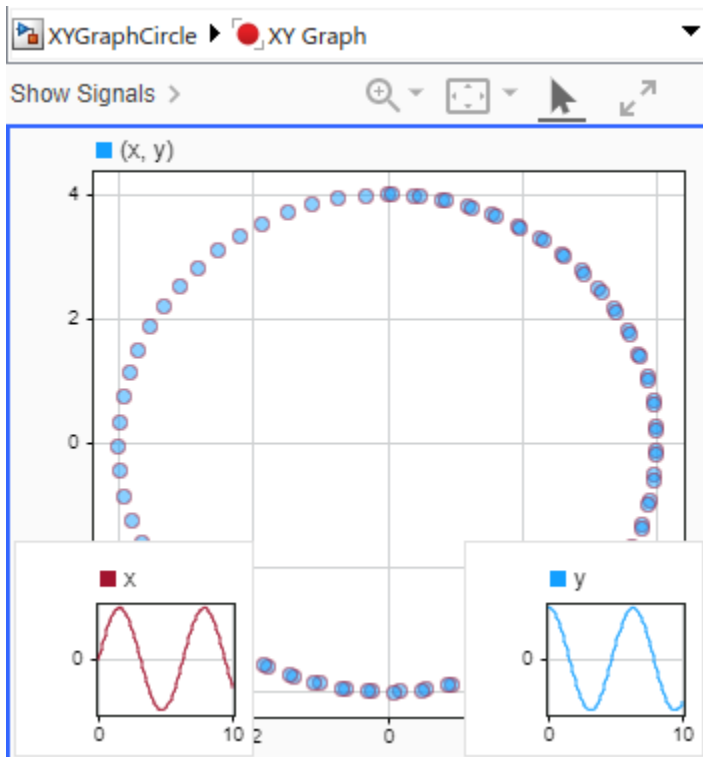

You can add subplots to the layout in the XY Graph block to view the  $x$  data and the  $y$  data variations against time. For example, select **Layouts**. Then, under **Overlays**, select **Bottom**. Click **Show Signals** to view the signals. To plot the  $x$  signal, select the left overlay, then select the check box next to the  $x$  signal. Then, to plot the  $y$  signal, select the right overlay, then select the  $y$  signal.

You can also update the styling of the data plotted on the XY plot. For example, remove the connecting line and add data markers. To add markers to the plot, on the **Format** tab, under **Markers**, click **Markers**. To remove the line from the plot, on the **Format** tab, under **Line**, click **Line**.

The XY plot supports other analysis and visualization features including trend lines and the ability to plot more than one series. For more information, see “Visualize Simulation Data on an XY Plot” on page 31-31 and “Analyze Data Using the XY Plot” on page 31-43.

## Sample Time with Scope Blocks

The Scope block and Time Scope block inherit and propagate sample time differently. This example helps you understand how sample time inheritance works when using a Scope block versus a Time Scope block. This example also shows what to do when you want to control the sample time propagation in the model.

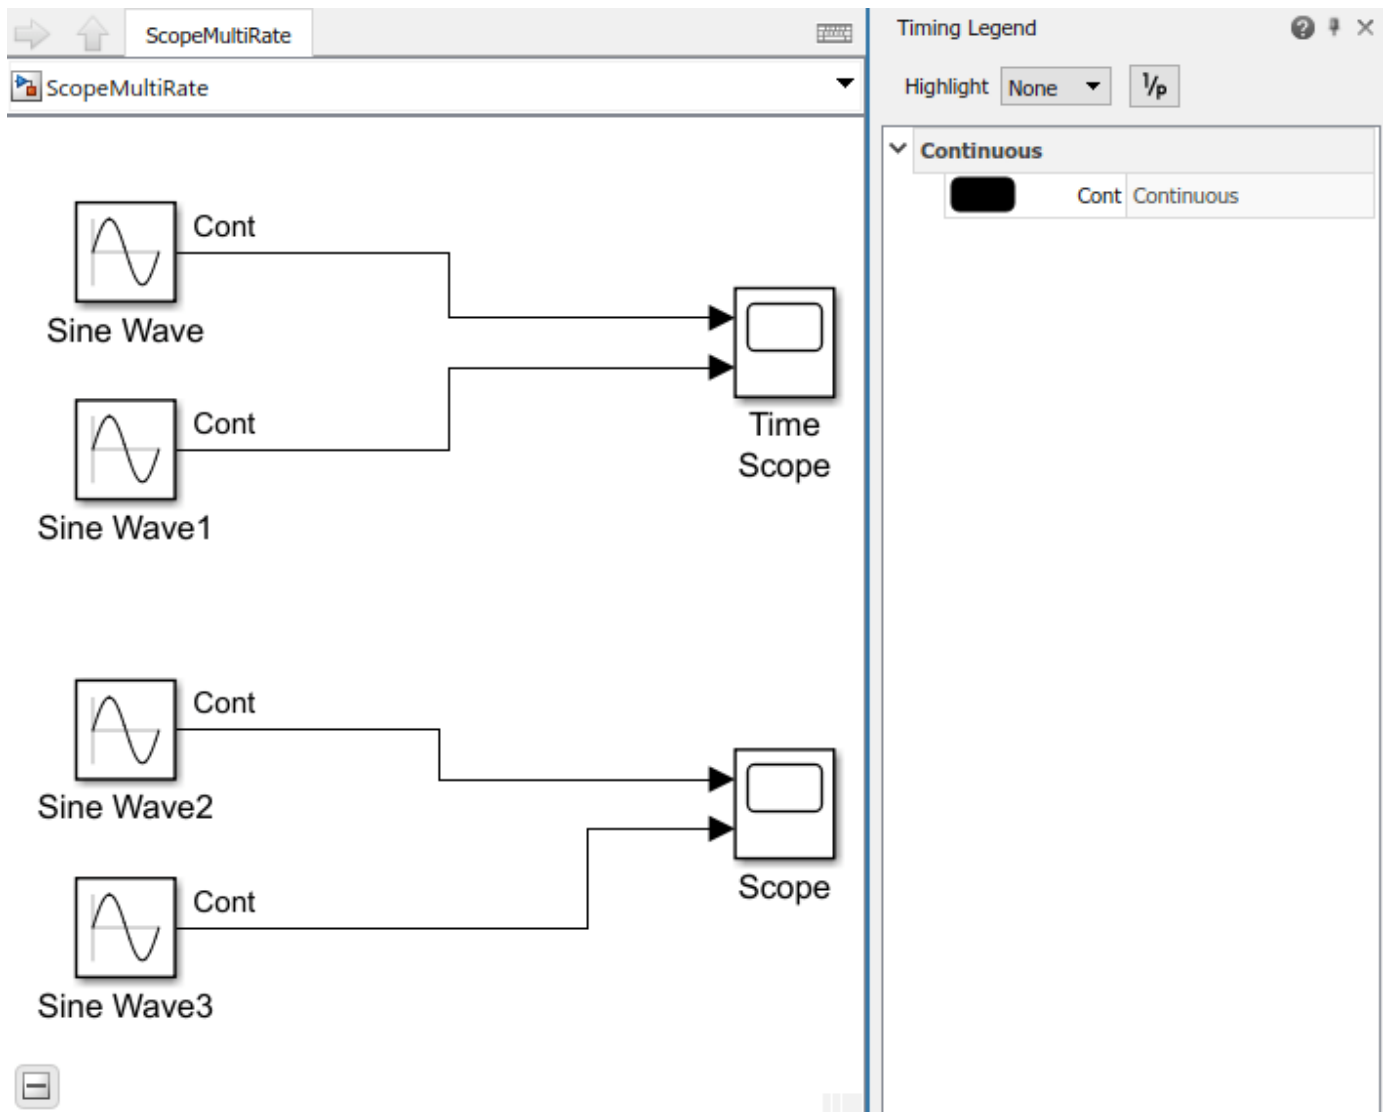

The Time Scope block is available with the DSP System Toolbox™.

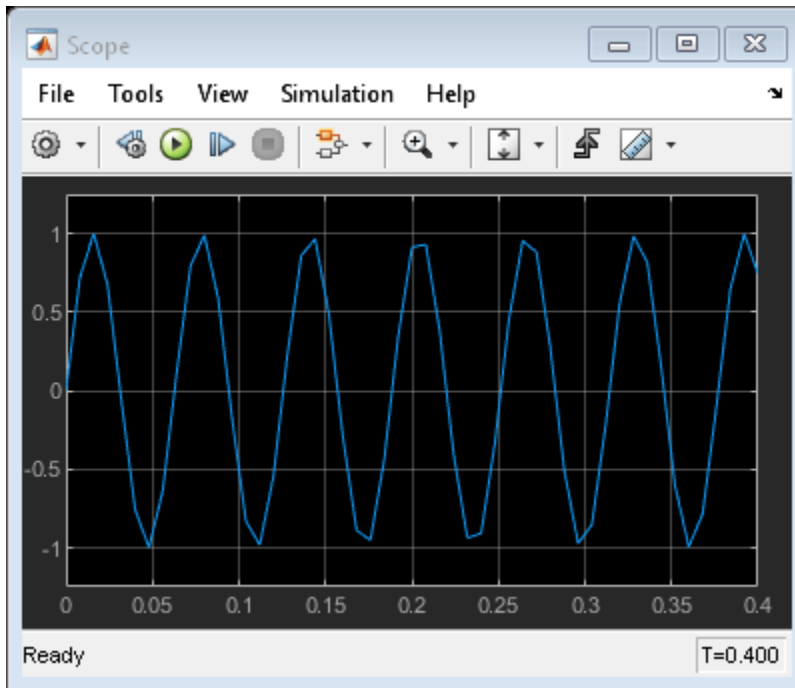

### Default Behavior with Inherited Sample Time

This model shows two sine waves connected to a Time Scope block. The same sine waves are also connected to a Scope block. All blocks have the default inherited sample time (the **Sample Time** parameter equal to -1).

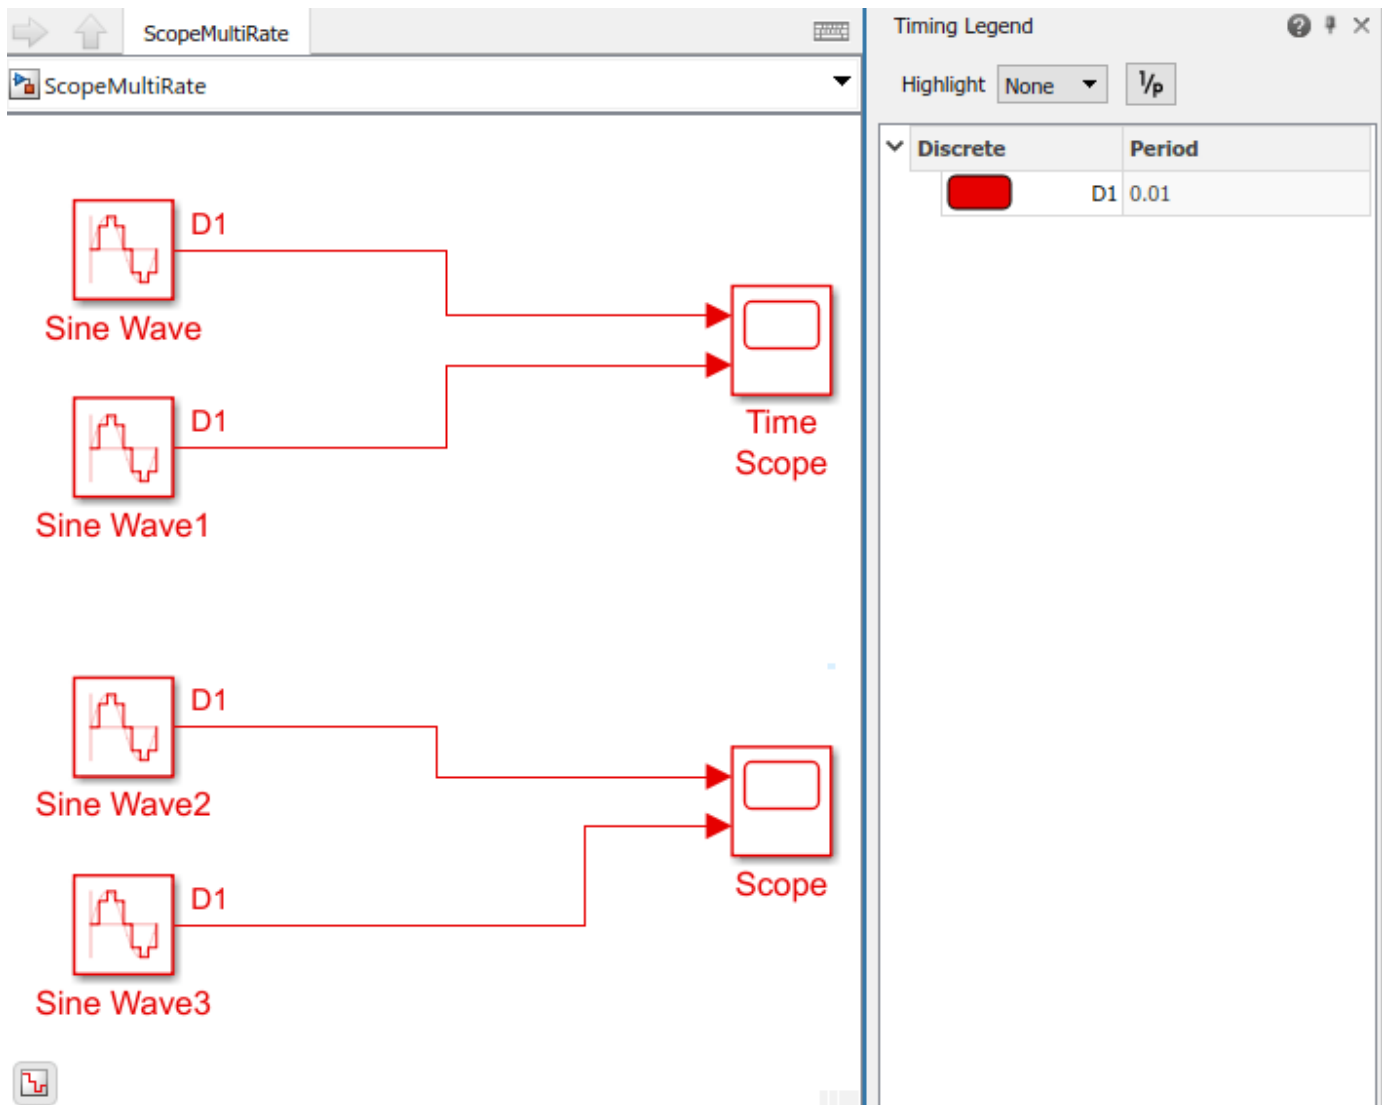

When you run this model, all blocks have continuous sample time. Continuous sample time occurs because the solver is set to variable step by default and all the blocks are set to inherited sample time. When you compile the model, Simulink® gives you four warnings that say, "Source block specifies that its sample time (-1) is back-inherited. You should explicitly specify the sample time of sources." This warning helps avoid unwanted sample time propagation from an incorrectly configured model. To improve clarity, these warnings have been hidden in this example.

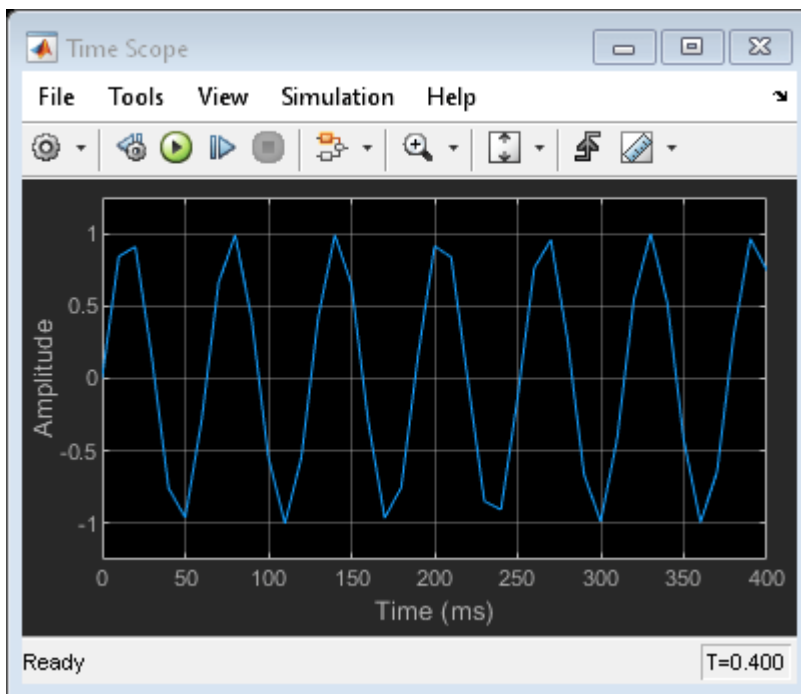

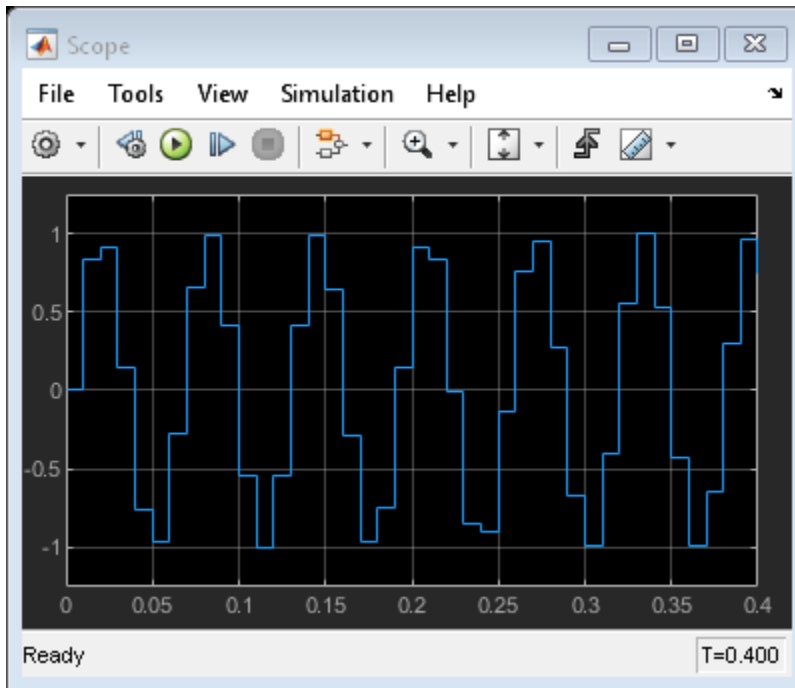

### Default Behavior with Fixed-Step Solver and Inherited Sample Time

Change the model to discrete sample time by setting the solver to fixed step.

The default plot type for the Scope block is Auto, which means that the plot changes type depending on the inputs. Because the sample time is now discrete, the Scope block shows a stair plot. The default plot type of the Time Scope block is a Line plot, so the signal visualization does not change when the sample time changes to discrete.

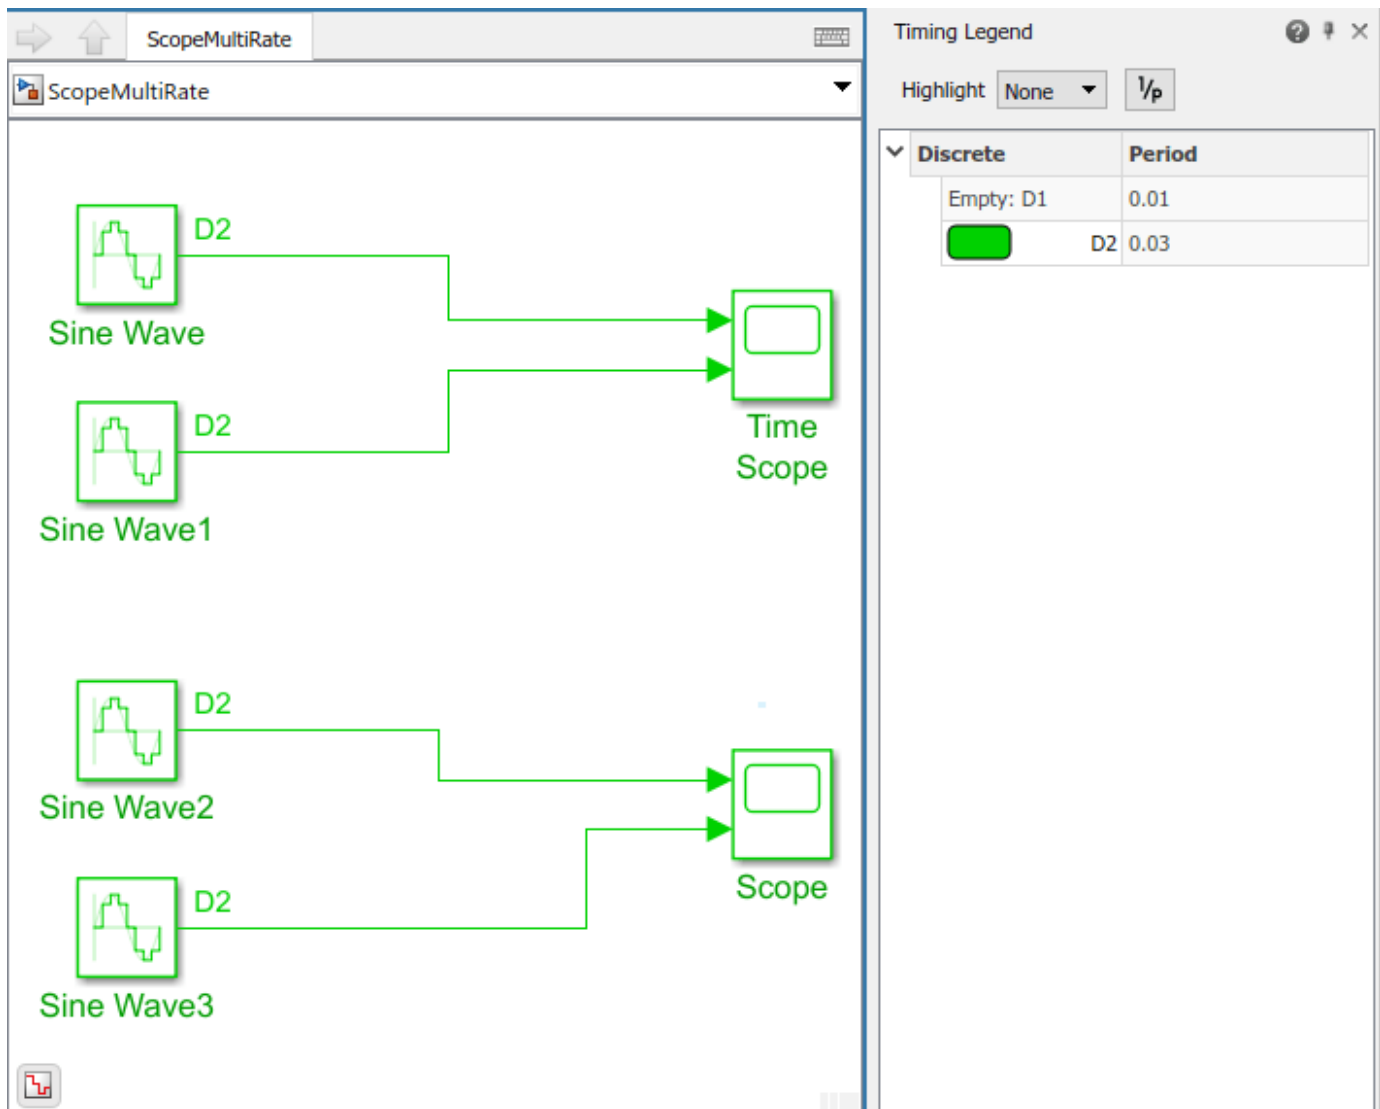

### One Specified Sample Time On the Model

Set the sample time of the first Sine Wave block to 0.03. Specifying one sample time changes the sample time of the entire model, changing the sample time for the blocks connected to the Sine Wave block and the ones not connected to the block. Simulink changes the sample rates for all the blocks in the model because the lowest specified sample time takes precedence over a solver-determined

sample time. The number of warnings drops to three. To improve clarity, these warnings have been hidden in this example.

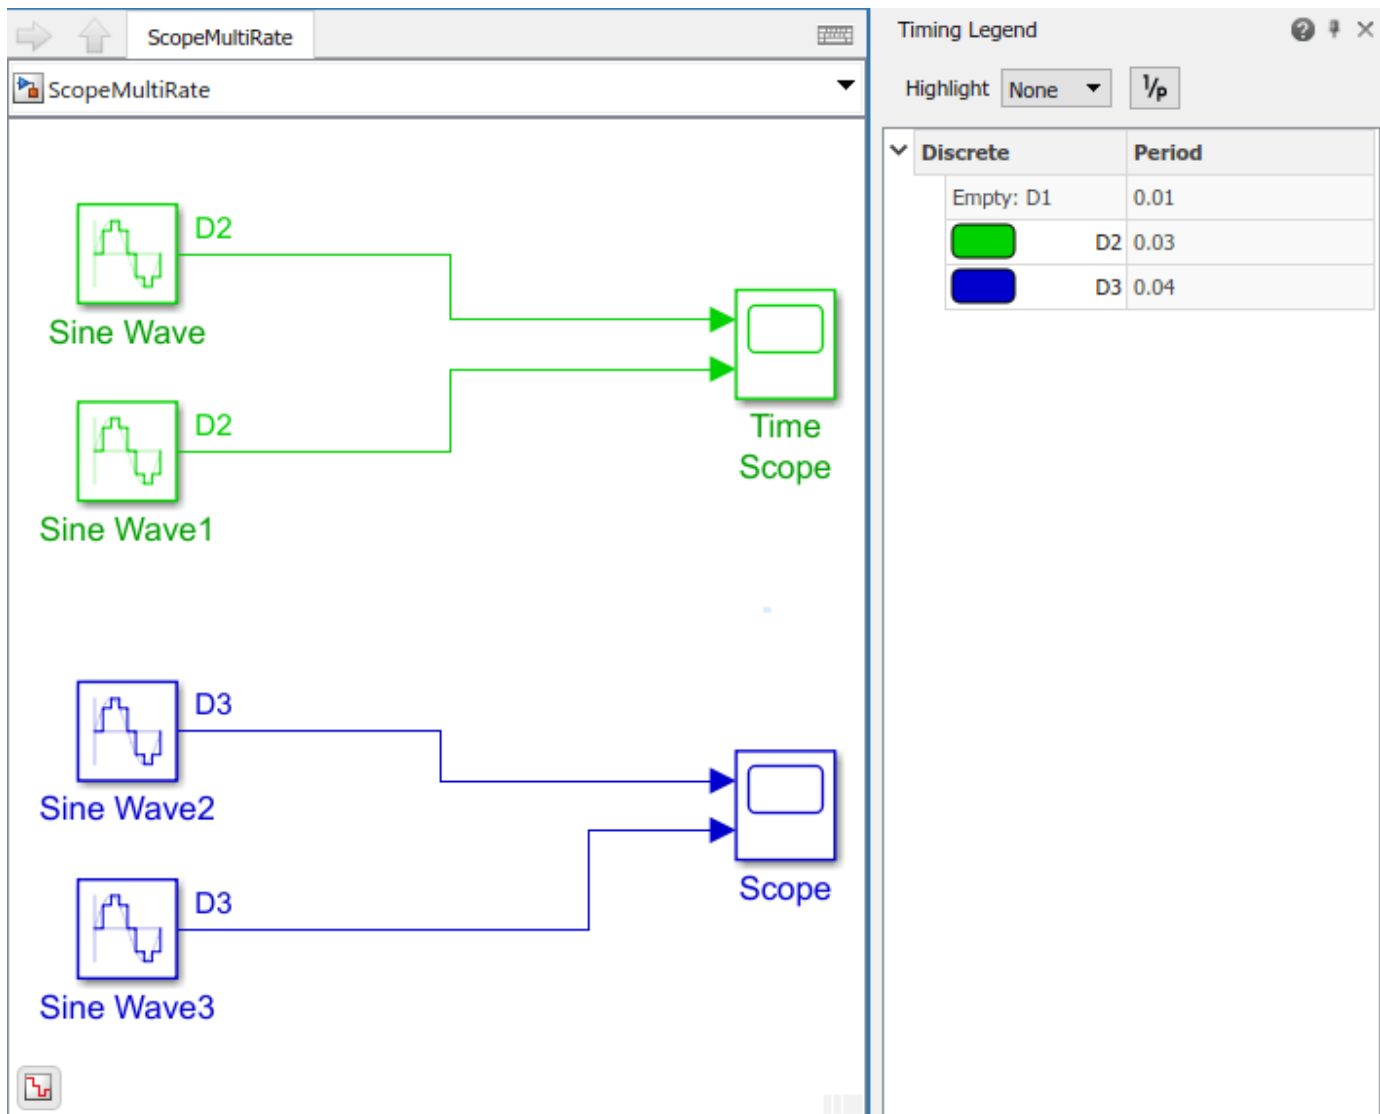

### One Scope Input with Specified Sample Time

Set the sample time of the Sine Wave2 block to 0.04. Now the Sine Wave and Sine Wave2 blocks have specified sample times of 0.03 and 0.04 respectively. The scope blocks and Sine Wave input blocks with inherited sample time, they inherit the sample from the Sine Wave block with the specified sample time. Now each submodel within this model has a different sample time. All sample times are based on the sample times specified in the Sine Wave and Sine Wave2 blocks. The number of warnings drops to two. To improve clarity, these warnings have been hidden in this example.

### All Inputs with Specified Sample Time

Set the sample time of the Sine Wave1 block to 0.03, and the sample time of the Sine Wave3 block to 0.04. Now the Sine Wave and Sine Wave1 blocks have a sample time of 0.03 and the Sine Wave2 and Sine Wave3 blocks have a sample time of 0.04. There are no warnings now because you have specified the sample times for all the source blocks.

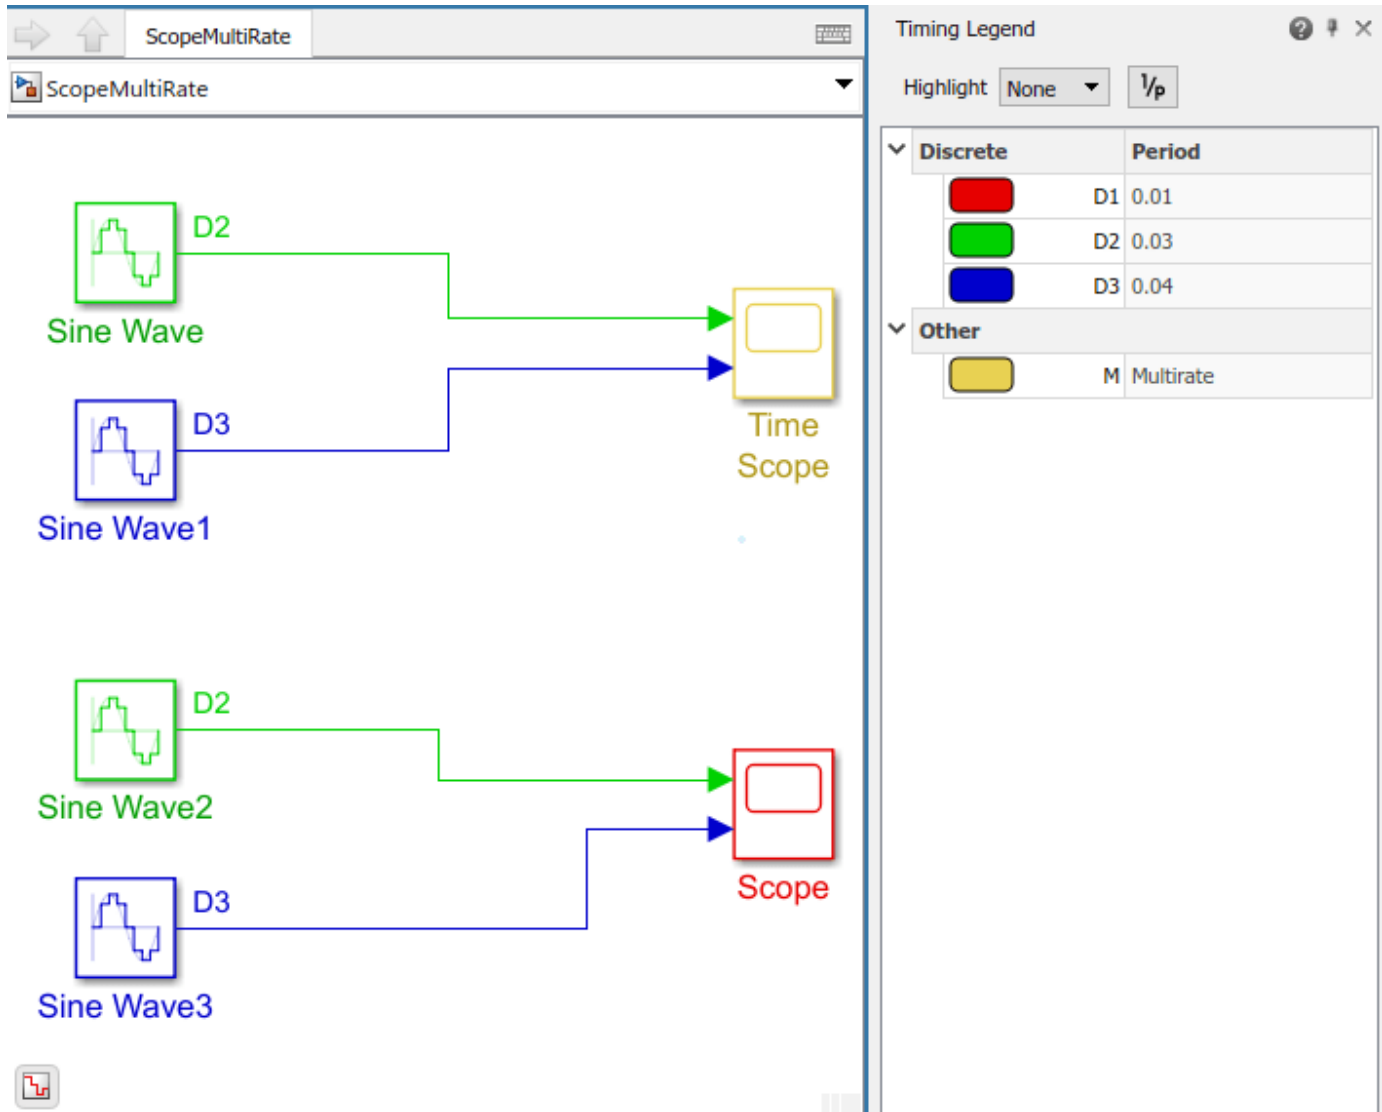

### Inputs with Different Sample Times

Set the sample time for the Sine Wave blocks so that the two inputs to each scope have a different sample time. Set the sample time in the Sine Wave and Sine Wave2 blocks to 0.03, and the sample time for the Sine Wave1 and Sine Wave3 blocks to 0.04. When you compile the model, you see that the Time Scope and Scope behave differently. The sample time for the Simulink Scope resolves to the fastest discrete rate (FDR). The FDR sample time is 0.01, the greatest common denominator of the two input rates 0.03 and 0.04. This smaller sample rate means that each signal is oversampled. By contrast, the sample time for the Time Scope resolves to multirate sample time, meaning each input is sampled at its own sample time.

In general, the DSP System Toolbox Time Scope uses port-based sample time, which processes the sample time for each input individually during initialization. Port-based sample time allows for multiple sample times and sample time offsets. The Simulink Scope uses block-based sample time, which resolves to a FDR sample time for the block as a whole during the initialization phase of the simulation.

During the simulation phase, the Scope block processes all inputs at the FDR sample rate. This sample rate can cause oversampling of some inputs. By contrast, during simulation, the Time Scope block processes a particular port only when a sample hit occurs for that port.

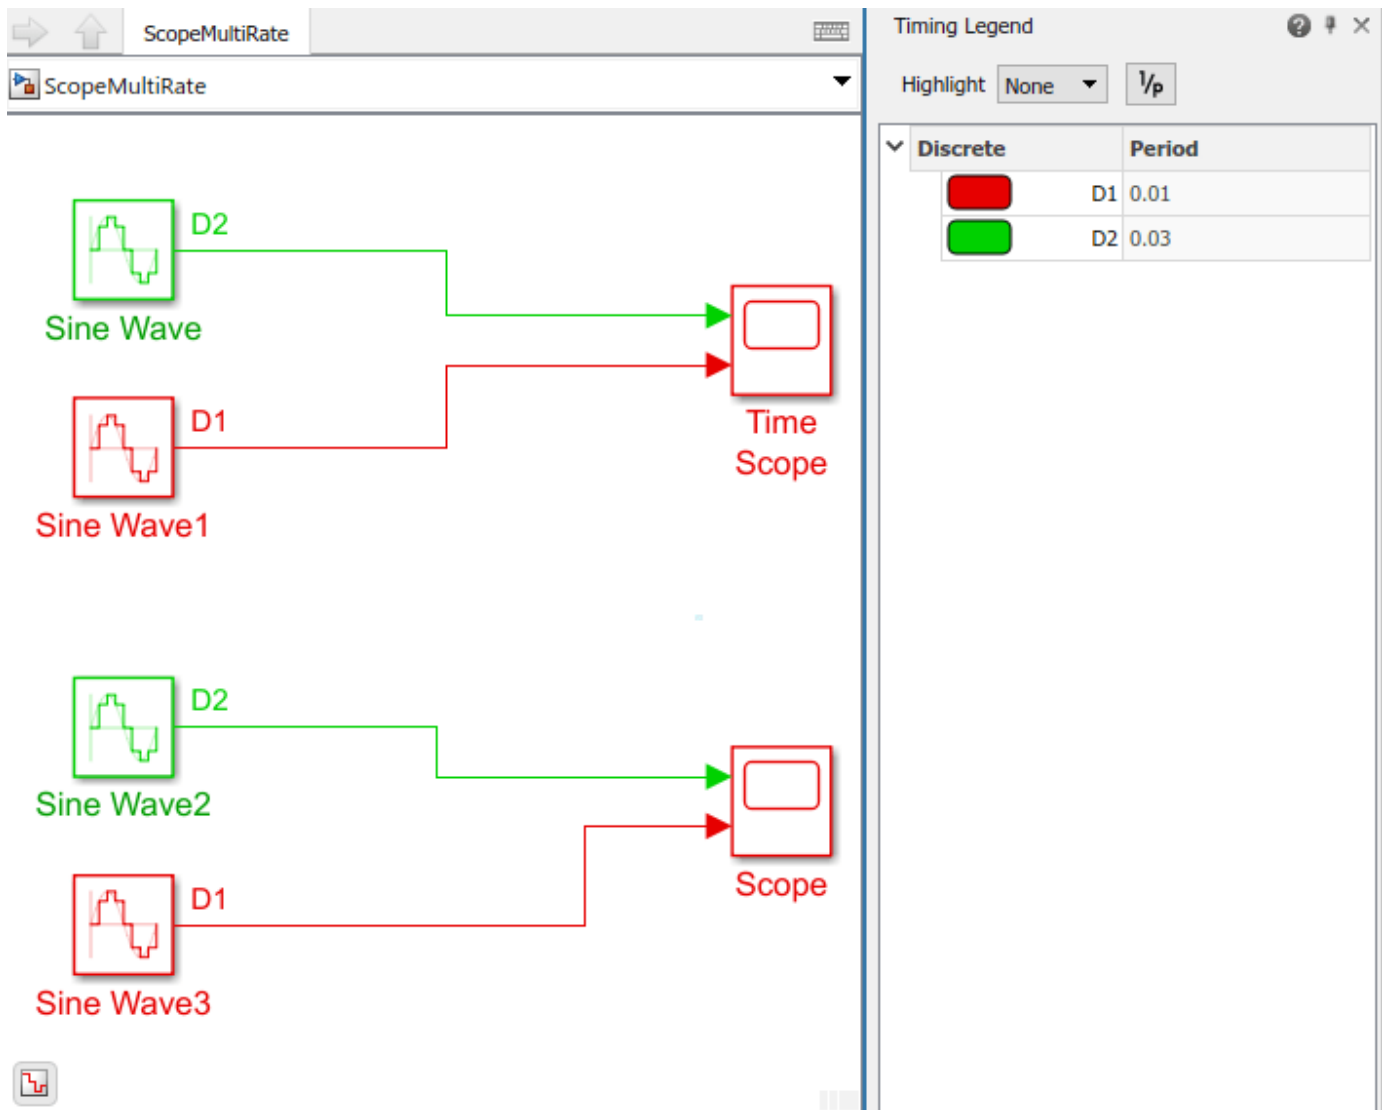

### Set Sample Time on Scope Blocks

Until now, the sample times for the scopes were inherited (-1). Set the sample time on both scopes to 0.01 the FDR in the previous section. Simulink issues two warnings, one per scope block, about "Inconsistent sample times." There is a mismatch between the specified sample time in the scopes and their input ports. The warning lets you know the scope decides the sample hits and not the Simulink engine.

### Inputs Inherit Sample Time From Scope

Set the sample time for the Sine Wave1 and Sine Wave4 blocks to inherited (-1). The scope blocks backpropagate their sample time of 0.01 to these Sine Wave blocks. This change causes the two inherited sample time warning messages to appear again.

### Avoid Backpropagation From Scope with Rate Transition Blocks

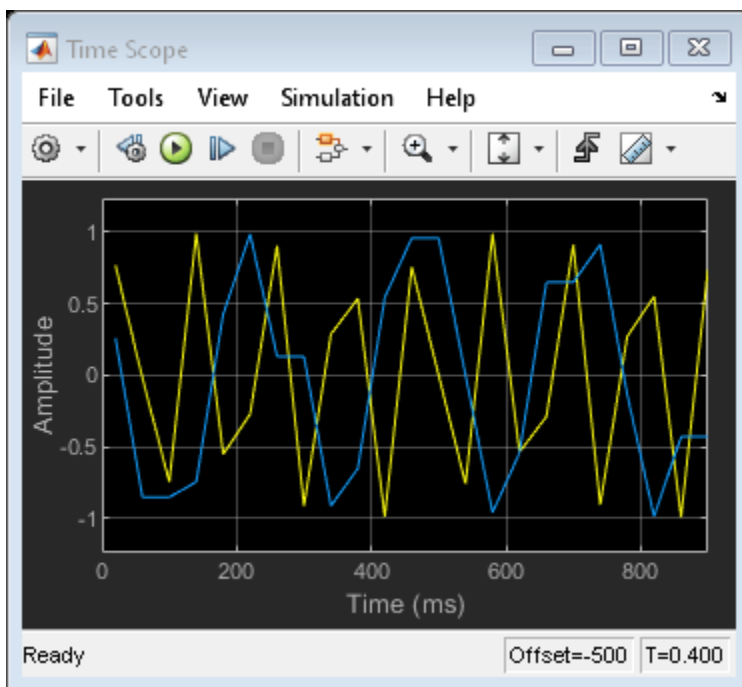

To avoid backpropagating sample time from the Scope to the blocks connected to it, either set the sample time on the connected blocks or use rate transition blocks. To specify the sample time on the connected blocks, set the sample time of Sine Wave1 and Sine Wave3 to 0.04 again.

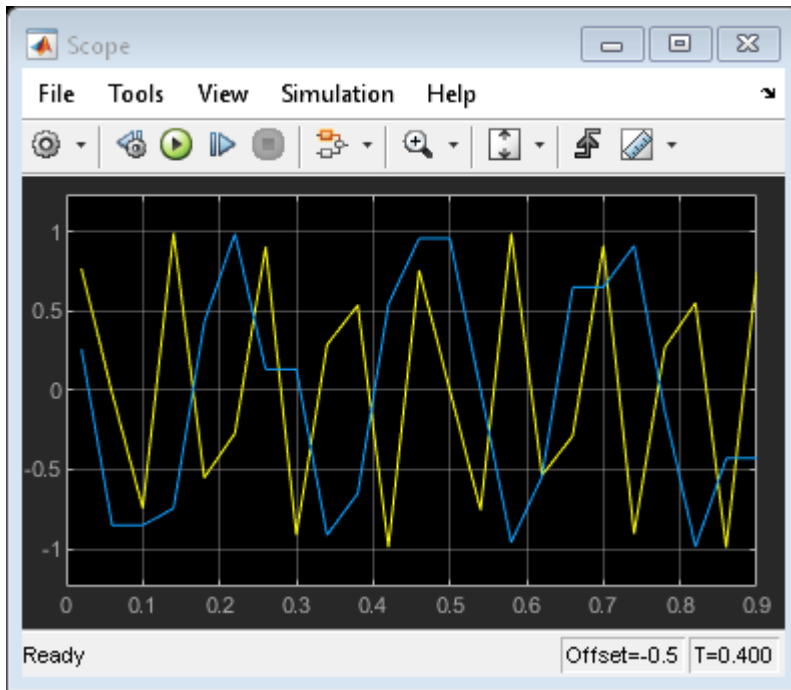

To use rate transition blocks, insert a Rate Transition block before the Scope and Time Scope blocks. When you add the rate transition blocks, the two scopes behave identically. Each source with a specified sample time is connected to a Rate Transition block that resamples the signals at the output port according to its own rules. A Rate Transition block also prevents propagation of sample times from one input to another through the scope block.

In this model, each input has a specified sample time and the scope blocks have inherited sample time.

## View Data in the Simulation Data Inspector

You can use the Simulation Data Inspector to visualize the data you generate throughout the design process. Simulation data that you log in a Simulink model logs to the Simulation Data Inspector. You can also import test data and other recorded data into the Simulation Data Inspector to inspect and analyze it alongside the logged simulation data. The Simulation Data Inspector offers several types of plots, which allow you to easily create complex visualizations of your data.

### View Logged Data

Logged signals as well as outputs and states logged using the `Dataset` format automatically log to the Simulation Data Inspector when you simulate a model. You can also record other kinds of simulation data so the data appears in the Simulation Data Inspector at the end of the simulation. To see states and output data logged using a format other than `Dataset` in the Simulation Data Inspector, open the Configuration Parameters dialog box and, in the **Data Import/Export** pane, select the **Record logged workspace data in Simulation Data Inspector** parameter.

---

**Note** When you log states and outputs using the `Structure` or `Array` format, you must also log time for the data to record to the Simulation Data Inspector.

---

The Simulation Data Inspector displays available data in the table in the **Inspect** pane. To plot a signal, select the check box next to the signal. You can modify the layout and add different visualizations to analyze the simulation data. For more information, see “Create Plots Using the Simulation Data Inspector” on page 31-152.

The Simulation Data Inspector manages incoming simulation data using the archive. By default, the previous run moves to the archive when you start a new simulation. You can plot signals from the archive, or you can drag runs of interest back into the work area.

## Import Data from the Workspace or a File

You can import data from the base workspace or from a file to view on its own or alongside simulation data. The Simulation Data Inspector supports all built-in data types and many data formats for importing data from the workspace. In general, whatever the format, sample values must be paired with sample times. The Simulation Data Inspector allows up to 8000 channels per signal in a run created from imported workspace data.

You can also import data from these types of files:

- MAT file
- CSV file — Format data as shown in “Import Data from a CSV File into the Simulation Data Inspector” on page 31-76.
- Microsoft Excel file — Format data as described in “Microsoft Excel Import, Export, and Logging Format” on page 31-68.

- **MDF file** — MDF file import is supported for Linux and Windows operating systems. The MDF file must have a `.mdf`, `.mf4`, `.mf3`, `.data`, or `.dat` file extension and contain data with only integer and floating data types.
- **ULG file** — Flight log data import requires a UAV Toolbox license.

To import data from the workspace or from a file that is saved in a data or file format that the Simulation Data Inspector does not support, you can write your own workspace data or file reader to import the data using the `io.reader` class. You can also write a custom reader to use instead of the built-in reader for supported file types. For examples, see:

- “Import Data Using a Custom File Reader” on page 31-17
- “Import Workspace Variables Using a Custom Data Reader” on page 31-11

To import data, select the **Import** button in the Simulation Data Inspector.

In the Import dialog, you can choose to import data from the workspace or from a file. The table below the options shows data available for import. If you do not see your workspace variable or file contents in the table, that means the Simulation Data Inspector does not have a built-in or registered reader that supports that data. You can select which data to import using the check boxes, and you can choose whether to import that data into an existing run or a new run.

When you import data into a new run, the run always appears in the work area. You can manually move imported runs to the archive.

## View Complex Data

To view complex data in the Simulation Data Inspector, import the data or log the signals to the Simulation Data Inspector. You can control how to visualize the complex signal using the **Properties** pane in the Simulation Data Inspector and in the **Instrumentation Properties** for the signal in the model. To access the **Instrumentation Properties** for a signal, right-click the logging badge for the signal and select **Properties**.

You can specify the **Complex Format** as Magnitude, Magnitude-Phase, Phase, or Real-Imaginary. If you select Magnitude-Phase or Real-Imaginary for the **Complex Format**, the Simulation Data Inspector plots both components of the signal when you select the check box for the signal. For signals in Real-Imaginary format, the **Line Color** specifies the color of the real component of the signal, and the imaginary component is a different shade of the **Line Color**. For example, the Rectangular QAM Modular Baseband signal on the lower graph displays the real component of

the signal in light blue, matching the **Line Color** parameter, and the imaginary component is shown in a darker shade of blue.

For signals in Magnitude-Phase format, the **Line Color** specifies the color of the magnitude component, and the phase is displayed in a different shade of the **Line Color**.

## View String Data

You can log and view string data with your signal data in the Simulation Data Inspector. For example, consider this simple model. The value of the sine wave block controls whether the switch sends a string reading Positive or Negative to the output.

The plot shows the results of simulating the model. The string signal is shown at the bottom of the graphical viewing area. The value of the signal is displayed inside a band, and transitions in the string signal's value are marked with criss-crossed lines.

You can use cursors to inspect how the string signal values correspond with the sine signal's values.

When you plot multiple string signals on a plot, the signals stack in the order they were simulated or imported, with the most recent signal positioned at the top. For example, you might consider the effect of changing the phase of the sine wave controlling the switch.

## View Frame-Based Data

Processing data in frames rather than point by point provides a performance boost needed in some applications. To view frame-based data in the Simulation Data Inspector, you have to specify that the signal is frame-based in the **Instrumentation Properties** for the signal. To access the **Instrumentation Properties** dialog for a signal, right-click the signal's logging badge and select **Properties**. To specify a signal as frame-based, select **Columns as channels (frame based)** for **Input processing**.

## View Event-Based Data

You can log or import event data to the Simulation Data Inspector. To view the logged event-based data, select the check box next to **Send: 1**. The Simulation Data Inspector displays the data as a stem plot, with each stem representing the number of events that occurred for a given sample time.

## Import Workspace Variables Using a Custom Data Reader

When your workspace data is in a format that built-in readers do not support, you can write a custom data reader to import the data into the Simulation Data Inspector. This example explains the parts of the class definition for a custom workspace reader and shows how to register the reader with the Simulation Data Inspector. Open the `SimpleStructReader.m` file to view the complete class definition.

### Create Workspace Data

First, create workspace data to import into the Simulation Data Inspector using the custom reader. Suppose you store each signal as a structure with fields for the data (`d`), the time values (`t`), and the signal name (`n`).

```
time = 0:0.1:100;
time = time';
lineData = 1/4*time;
sineWave = sin((2*pi)/50*time);
squareWave = square((2*pi)/30*time);

mySineVar.d = sineWave;
mySineVar.t = time;
mySineVar.n = "Sine Wave";

myLineVar.d = lineData;
myLineVar.t = time;
myLineVar.n = "Line";

mySquareVar.d = squareWave;
mySquareVar.t = time;
mySquareVar.n = "Square Wave";
```

### Write the Class Definition for a Custom Reader

Write a class definition that specifies how the custom reader extracts relevant data and metadata from the workspace variables. Save the class definition file in a location on the MATLAB™ path.

The class definition starts by inheriting from the `io.reader` class, followed by property and method definitions. The custom reader in this example defines the property `ChannelIndex`. You can use the reader to import individual structures or an array of structures from the workspace. The `ChannelIndex` property is used when importing an array of structures.

```
classdef SimpleStructReader < io.reader

    properties
        ChannelIndex
    end
```

Every custom reader must define the `getName`, `getTimeValues`, and `getDataValues` methods. When you write a custom reader to import data from the workspace, you must also define the `supportsVariable` method. The reader in this example also defines the `getChildren` method to support importing an array of structures.

The `supportsVariable` method checks which variables in the workspace are supported by the reader. In this example, the `supportsVariable` returns true when:

- 1 The structure contains the appropriate fields.
- 2 The n field of the structure contains a string or character array that represents the signal name.
- 3 The t field of the structure is a column vector of double data.
- 4 The d field contains numeric data.
- 5 The d field is the same size as the t field, meaning there is a sample value for each time step.

```
function supported = supportsVariable(~, val)
    % Support structure with fields t (time), d (data), and n (name)
    supported = ...
        isstruct(val) && ...
        isfield(val,'t') && ...
        isfield(val,'d') && ...
        isfield(val,'n');
    if supported
        for idx = 1:numel(val)
            varName = val(idx).n;
            time = val(idx).t;
            varData = val(idx).d;

            % Name must be string or character array
            if ~ischar(varName) && ~isstring(varName)
                supported = false;

            % Time must be double column vector
            elseif ~isa(time,'double') || ~iscolumn(time)
                supported = false;

            % Data size must match time size
            else
                timeSz = size(time);
                dataSz = size(varData);

                if ~isnumeric(varData) || ~isequal(dataSz, timeSz)
                    supported = false;
                end
            end
        end
    end
end
```

The `getChildren` method creates a `SimpleStructReader` object for each structure in an array of structures. When the variable to import is not scalar, the `getChildren` method assigns a value to the `ChannelIndex` property added to the class for the custom reader. The `VariableValue` property for each `SimpleStructReader` object returned by the `getChildren` method is the array of structures. Other methods use the `ChannelIndex` property to extract the appropriate signal name, signal data, and time values from each object.

```
function childObj = getChildren(obj)
    childObj = {};
    if ~isscalar(obj.VariableValue) && isempty(obj.ChannelIndex)
        numChannels = numel(obj.VariableValue);
        childObj = cell(numChannels,1);
        for idx = 1:numChannels
            childObj{idx} = SimpleStructReader;
            childObj{idx}.VariableName = sprintf('%s(%d)',obj.VariableName,idx);
            childObj{idx}.VariableValue = obj.VariableValue;
        end
    end
end
```

```

        childObj{idx}.ChannelIndex = idx;
    end
end
end

```

The `getName` method assigns the name stored in the `n` field of the structure to each imported signal. When the imported variable is scalar, the method gets the name from the `VariableValue` property of the `SimpleStructReader` object. When the imported data is an array of structures, the appropriate structure is extracted from the `VariableValue` property using the `ChannelIndex` property. The top-level node of the array is named `Signal Array`.

```

function retName = getName(obj)
    if isscalar(obj.VariableValue)
        retName = char(obj.VariableValue.n);
    elseif ~isempty(obj.ChannelIndex)
        varVal = obj.VariableValue(obj.ChannelIndex);
        retName = char(varVal.n);
    else
        retName = 'Signal Array';
    end
end
end

```

The `getTimeVals` and `getDataVals` methods handle scalar and nonscalar structures similar to how the `getName` method does. For a scalar structure, both methods extract the appropriate field from the `VariableValue` property of the `SimpleStructReader` object. For a nonscalar structure, both methods access the appropriate structure in the `VariableValue` property using the `ChannelIndex` property. Finally, for the top-level node of the array, time and data are both returned as empty.

```

function timeVals = getTimeValues(obj)
    if isscalar(obj.VariableValue)
        timeVals = obj.VariableValue.t;
    elseif ~isempty(obj.ChannelIndex)
        varVal = obj.VariableValue(obj.ChannelIndex);
        timeVals = varVal.t;
    else
        timeVals = [];
    end
end

function dataVals = getDataValues(obj)
    if isscalar(obj.VariableValue)
        dataVals = obj.VariableValue.d;
    elseif ~isempty(obj.ChannelIndex)
        varVal = obj.VariableValue(obj.ChannelIndex);
        dataVals = varVal.d;
    else
        dataVals = [];
    end
end
end

```

### Register a Custom Reader

After you write the class definition for the custom reader, you must register the reader before you can use it to import data into the Simulation Data Inspector. The Simulation Data Inspector does not store registered readers between MATLAB sessions, so you need to register a custom reader at the start of each new MATLAB session. To register the workspace data reader in this example, use the `registerWorkspaceReader` method.

```
registerWorkspaceReader(SimpleStructReader);
```

To confirm that the reader is registered, use the `io.reader.getRegisteredWorkspaceReaders` method.

```
io.reader.getRegisteredWorkspaceReaders
```

```
ans =  
"SimpleStructReader"
```

### **Import Workspace Data in a Custom Format**

Once you register the custom workspace data reader, you can import workspace variables stored using the custom format into the Simulation Data Inspector using the UI or the `Simulink.sdi.createRun` function.

To import data using the UI, open the Simulation Data Inspector. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector from the MATLAB Command Window. Then, select **Import**.

The Import dialog shows the data in the base workspace that the Simulation Data Inspector is able to import using built-in and registered custom readers. Because the custom reader is registered, the `Line`, `Sine Wave`, and `Square Wave` signals are available for import, while the `lineData`, `sineWave`, and `squareWave` variables are not. Select the data you want to import and select **Import**. The data imports into a run called `Imported_Data`.

To import data from the workspace programmatically, use the `Simulink.sdi.createRun` function.

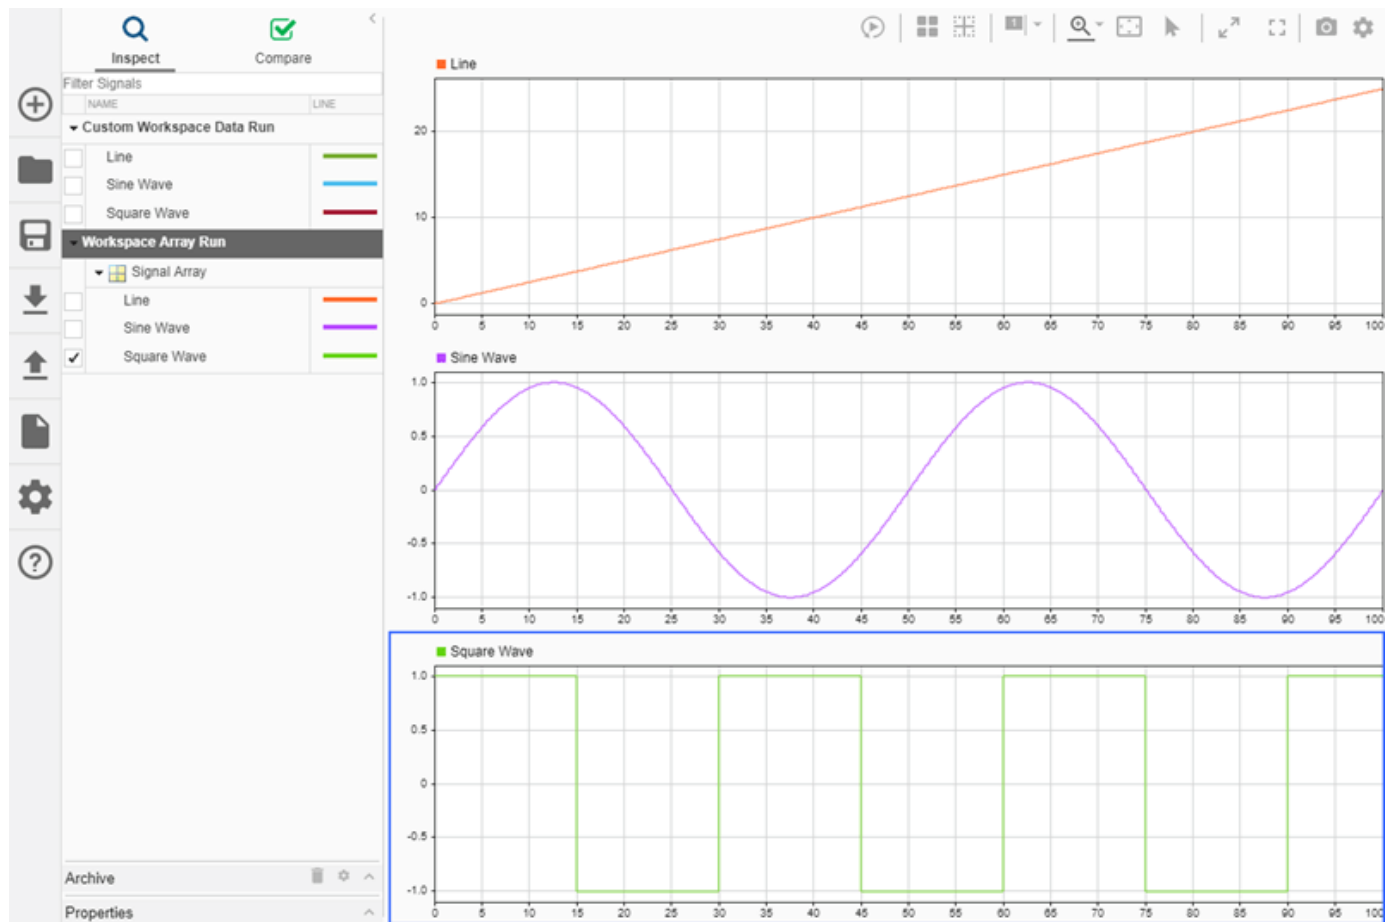

```
Simulink.sdi.createRun('Custom Workspace Data Run', 'vars', myLineVar, mySineVar, mySquareVar);
```

The custom reader in this example can also import an array of structures. Importing an array of workspace variables rather than importing them individually groups the variables together when you import the data to an existing run. Create an array that contains the `myLineVar`, `mySineVar`, and `mySquareVar` structures, and import the array using the `Simulink.sdi.createRun` function.

```
myVarArray = [myLineVar; mySineVar; mySquareVar];
Simulink.sdi.createRun('Workspace Array Run', 'vars', myVarArray);
```

### Inspect and Analyze Imported Data

After importing data, you can use the Simulation Data Inspector to inspect and analyze the imported data on its own or alongside related simulation data.

- “Import Data Using a Custom File Reader” on page 31-17

## Import Data Using a Custom File Reader

When you want to visualize data stored in a data or file format the Simulation Data Inspector does not support, you can use the `io.reader` class to write your own custom file reader for the Simulation Data Inspector. This example explains the parts of a class definition for a custom file reader and demonstrates how to register the reader with the Simulation Data Inspector. Open the `ExcelFirstColumnTimeReader.m` file to view the complete class definition.

### Write the Class Definition for a Custom Reader

Write a class definition that specifies how your custom reader extracts relevant data and metadata from files and variables that use custom formats. Save the class definition file in a location on the MATLAB™ path.

The custom reader in this example uses the `readtable` function to load data from a Microsoft Excel™ file and uses the first column in the file as time data.

The class definition starts by inheriting from the `io.reader` class, followed by method definitions that return required and relevant data and metadata.

```
classdef ExcelFirstColumnTimeReader < io.reader
```

Every custom reader must define the `getName`, `getTimeValues`, and `getDataValues` methods. Additional methods are available to access certain metadata that might exist in the custom file. The class definition for this example defines the abstract methods as well as the `supportsFile` and `getChildren` methods.

The `supportsFile` method checks the file contents to make sure the file contains signal data.

```
function supported = supportsFile(~,filename)
    try
        t = readtable(filename);
        supported = height(t) > 0 && numel(t.Properties.VariableNames) > 1;
    catch
        supported = false;
    end
end
```

To import multiple signals from a file, treat the data as hierarchical with the file being the top node. The reader uses the `getChildren` method to create an `ExcelFirstColumnTimeReader` object for each signal in the file.

```
function childObj = getChildren(obj)
    childObj = {};
    if isempty(obj.VariableName)
        t = readtable(obj.FileName);
        vars = t.Properties.VariableNames;
        vars(1) = [];
        childObj = cell(size(vars));
        for idx = 1:numel(vars)
            childObj{idx} = ExcelFirstColumnTimeReader;
            childObj{idx}.FileName = obj.FileName;
            childObj{idx}.VariableName = vars{idx};
        end
    end
```

```

    end
end

```

The `getTimeValues` method reads the data in the file using the `readtable` function and returns the data in the first column for the Simulation Data Inspector to use as time data.

```

function timeVals = getTimeValues(obj)
    timeVals = [];
    if ~isempty(obj.VariableName)
        t = readtable(obj.FileName);
        timeName = t.Properties.VariableNames{1};
        timeVals = t.(timeName);
    end
end

```

The `getName` method uses the file name as the name for the top-level node of the imported data. Signals are named using the `VariableName` property for the corresponding `ExcelFirstColumnTimeReader` object returned by the `getChildren` method.

```

function retName = getName(obj)
    if isempty(obj.VariableName)
        fullName = obj.FileName;
        [filepath,name,ext] = fileparts(fullName);
        retName = strcat(name,ext);
    else
        retName = obj.VariableName;
    end
end

```

The `getDataValues` method returns the data in each column that has data besides the first as signal data. Data for each signal is accessed using the `VariableName` property for the corresponding object returned by the `getChildren` method.

```

function dataVals = getDataValues(obj)
    dataVals = [];
    if ~isempty(obj.VariableName)
        t = readtable(obj.FileName);
        dataVals = t.(obj.VariableName);
    end
end

```

### Register a Custom Reader for the Simulation Data Inspector

After you write the class definition file for the custom data reader, you need to register the reader with the Simulation Data Inspector before you can use it to import data. The Simulation Data Inspector does not store registered readers between MATLAB sessions, so you need to register a custom reader at the start of each new MATLAB session. You can register a custom reader to read data from the workspace or to read data from a file. To register the file reader in this example, use the `registerFileReader` method.

```
registerFileReader(ExcelFirstColumnTimeReader,[".xlsx" "xls"]);
```

To confirm that the file reader is registered, use the `io.reader.getRegisteredFileReaders` method.

```
io.reader.getRegisteredFileReaders
```

```
ans =
"ExcelFirstColumnTimeReader"
```

### Import Data from a File in a Custom Format

Once you register the custom file reader, you can import data from a file in a custom format using the Simulation Data Inspector UI or using the `Simulink.sdi.createRun` function. This example imports a simple data set from a file that contains four columns of data. The custom file reader in this example always loads the first column, in this case `a`, as time data.

	A	B	C	D
1	a	b	c	d
2	1	6	6	1
3	2	5	4	7
4	3	4	2	6
5	4	3	6	1
6	5	2	7	3
7	6	1	2	4

To import the data using the UI, open the Simulation Data Inspector. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector from the MATLAB Command Window. Then, click the **Import** button.

In the Import dialog, select the **File** option and import the data from the file into a new run. Click the folder to browse the file system and select the file you want to import. The file for this example is called `CustomFile.xlsx`.

After you select a file with an extension that corresponds to one or more registered custom readers, an option to select the reader you want to use appears in the dialog. In this example, you can choose between the built-in Microsoft Excel file reader or the custom reader written for this example. By default, a custom reader is selected when one is available for the extension of the selected file.

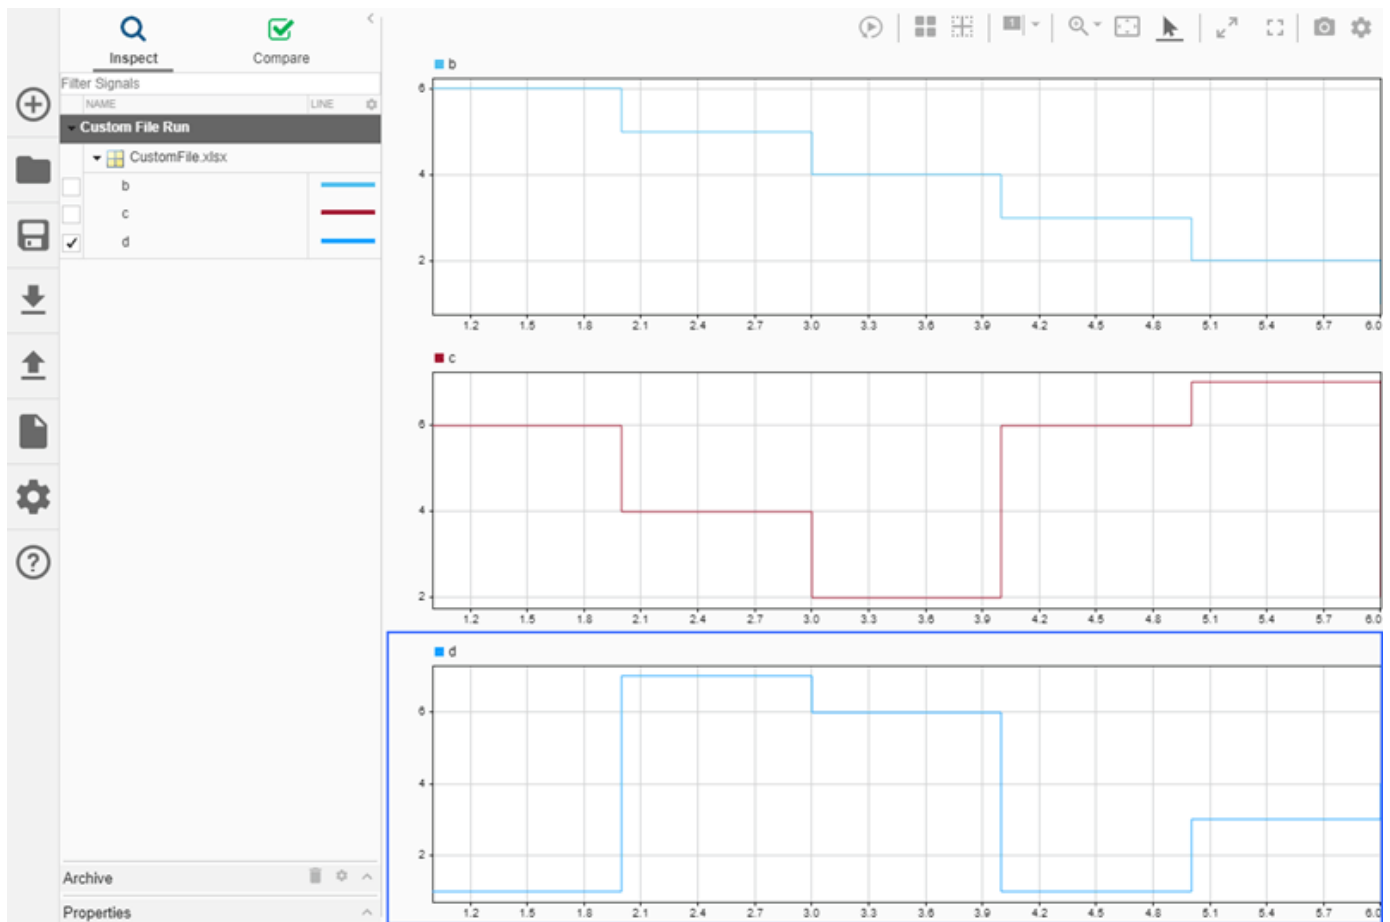

You can choose which signals you want to import from the file. After making your selection, click **Import**. The data is imported to a new run called `Imported_Data`.

To import data programmatically, you can use the `Simulink.sdi.createRun` function. The Simulation Data Inspector has a built-in reader for Microsoft Excel files. You can specify which reader to use to import the data in the call to the `Simulink.sdi.createRun` function. When you do not specify the reader you want to use to import the data, the Simulation Data Inspector uses the first custom reader that supports the file extension.

```
Simulink.sdi.createRun('Custom File Run','file','CustomFile.xlsx','ExcelFirstColumnTimeReader');
```

### Inspect and Analyze Imported Data

After importing your data, you can use the Simulation Data Inspector to inspect and analyze the imported data on its own or alongside related simulation data.

## See Also

### Classes

`io.reader`

### Functions

`Simulink.sdi.createRun`

## More About

- “View Data in the Simulation Data Inspector” on page 31-2

## View and Replay Map Data

This example shows how to use the map visualization in the Simulation Data Inspector to view routes of longitude and latitude data. The map data is synchronized with signal data, which allows you to analyze signal activity throughout the route by adding cursors and by replaying the data.

The map visualization used in this example is also available in the Record block. When you use the map visualization in the Record block, you add the visualization and configure the appearance using the toolstrip. You plot data on the map the same way shown in this example.

To view map data in the Simulation Data Inspector or Record block, you must have an active internet connection.

### Import Route Data into Simulation Data Inspector

If your model includes latitude and longitude signals, you can view logged data on the map during simulation. You can also import data from the workspace or a file.

Open the Simulation Data Inspector.

```
Simulink.sdi.view
```

The data for this example is stored in the Excel™ file `LoganTripGPSData.xlsx`. To import the data

using the user interface, click Import .

In the Import dialog box, under **Import from**, select **File**. Then, enter `LoganTripGPSData.xlsx` in the text box and click **Import**.

Alternatively, import the data programmatically using the `Simulink.sdi.createRun` function.

```
mapRun = Simulink.sdi.createRun("LoganTrip", "file", "LoganTripGPSData.xlsx");
```

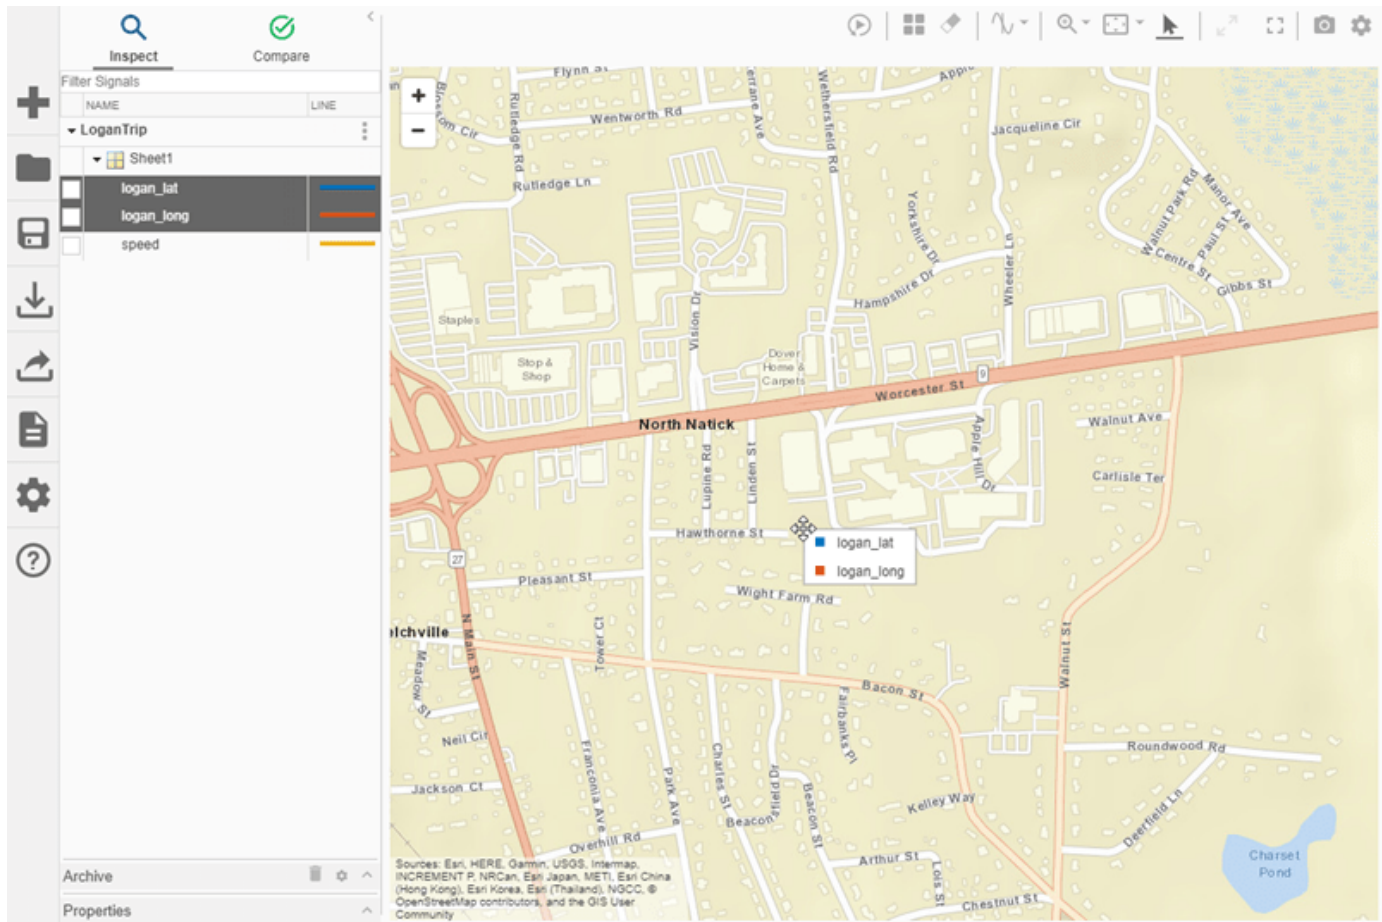

### Plot Route on Map

By default, the Simulation Data Inspector uses time plots for each subplot in the layout. To plot data on a map, you need to add the visualization to the layout.

To add a map to your layout, click Visualizations and layout . Then, drag the **Map** icon from **Visualizations** onto the subplot.

To plot a route on the map, select the signal with the latitude data and the signal with the longitude data in the table and drag them onto the map. Hold the **Shift** key or the **Ctrl** key to select more than one signal row in the table. Note that the check boxes next to the signal names remain clear when selecting multiple signals. For this example, select the rows for the `logan_lat` signal and the `logan_long` signal in the table, then drag the selection onto the map.

Specify which signal to use as the latitude data and which to use as the longitude data in the route menu that appears in the lower-right of the plot.

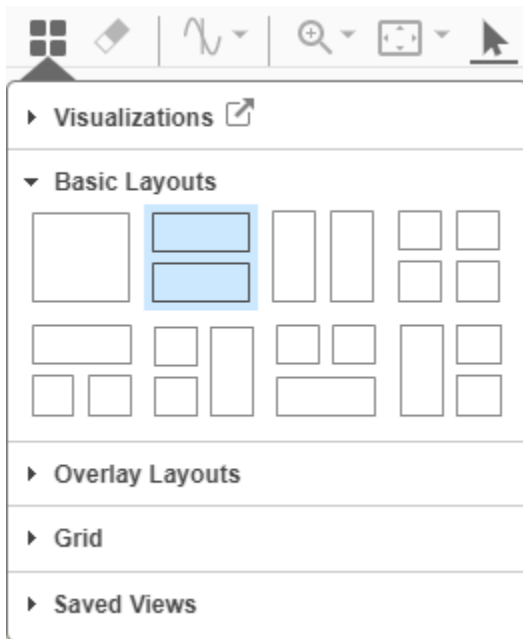

After making the selections, click **OK**.

### Plot Signal Data Alongside Route

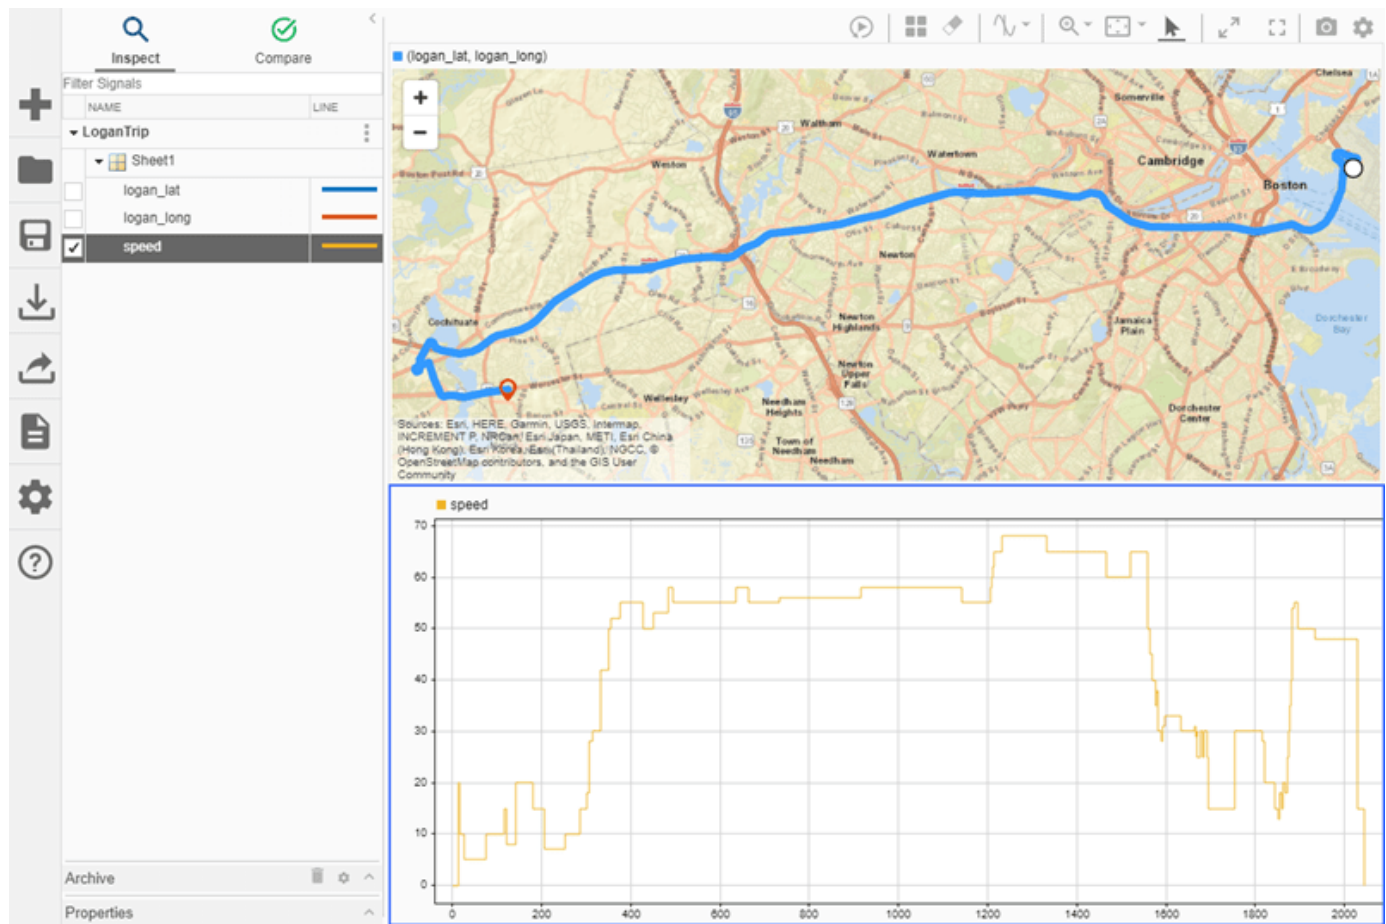

Change the subplot layout in the plot area to a 2-by-1 layout so you can plot the speed data alongside

the route. Click Visualizations and Layouts . Then, under **Basic Layouts**, select the subplot layout in a 2-by-1 configuration.

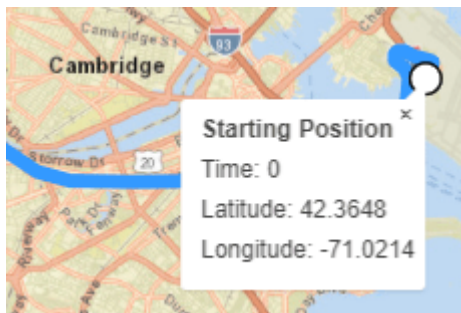

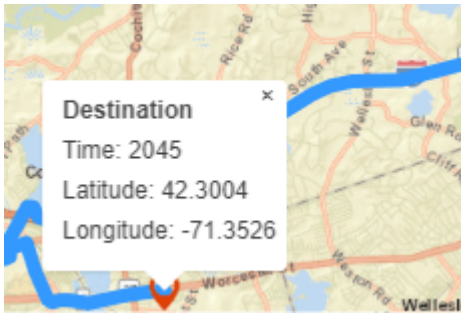

To plot the speed data on the bottom subplot, select the subplot, then select the check box next to the speed signal in the table.

Click the white circle to get more information about the **Starting Position**.

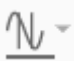

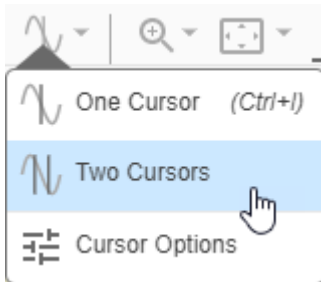

To get more information about the **Destination**, click the red marker.

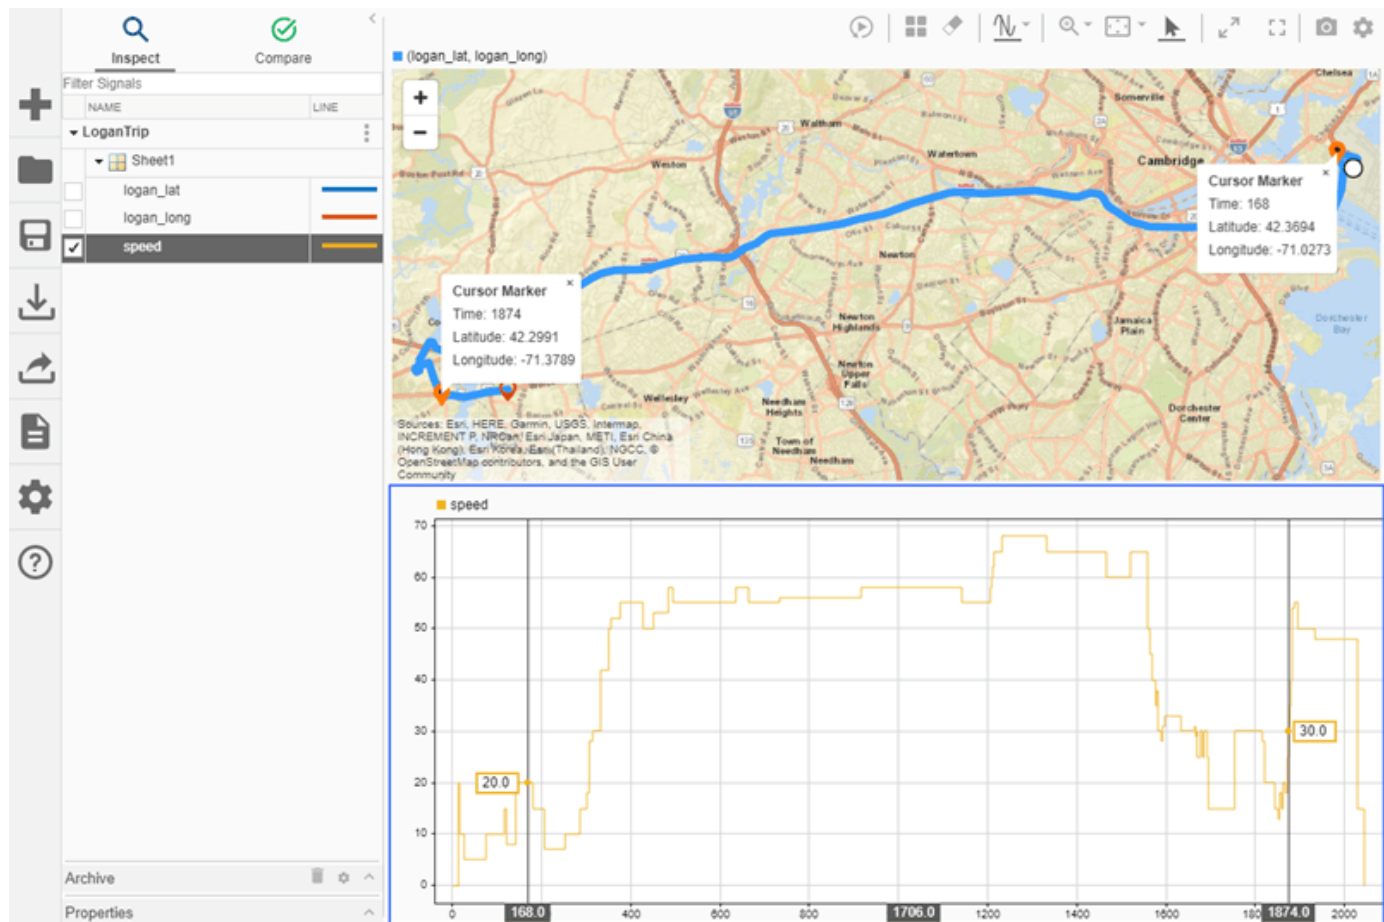

### Analyze Data Using Cursors

You can add cursors to the plots to analyze the relationship between the **speed** signal and the route shown on the map. To add two cursors to the layout, click the drop-down arrow on the Show/hide

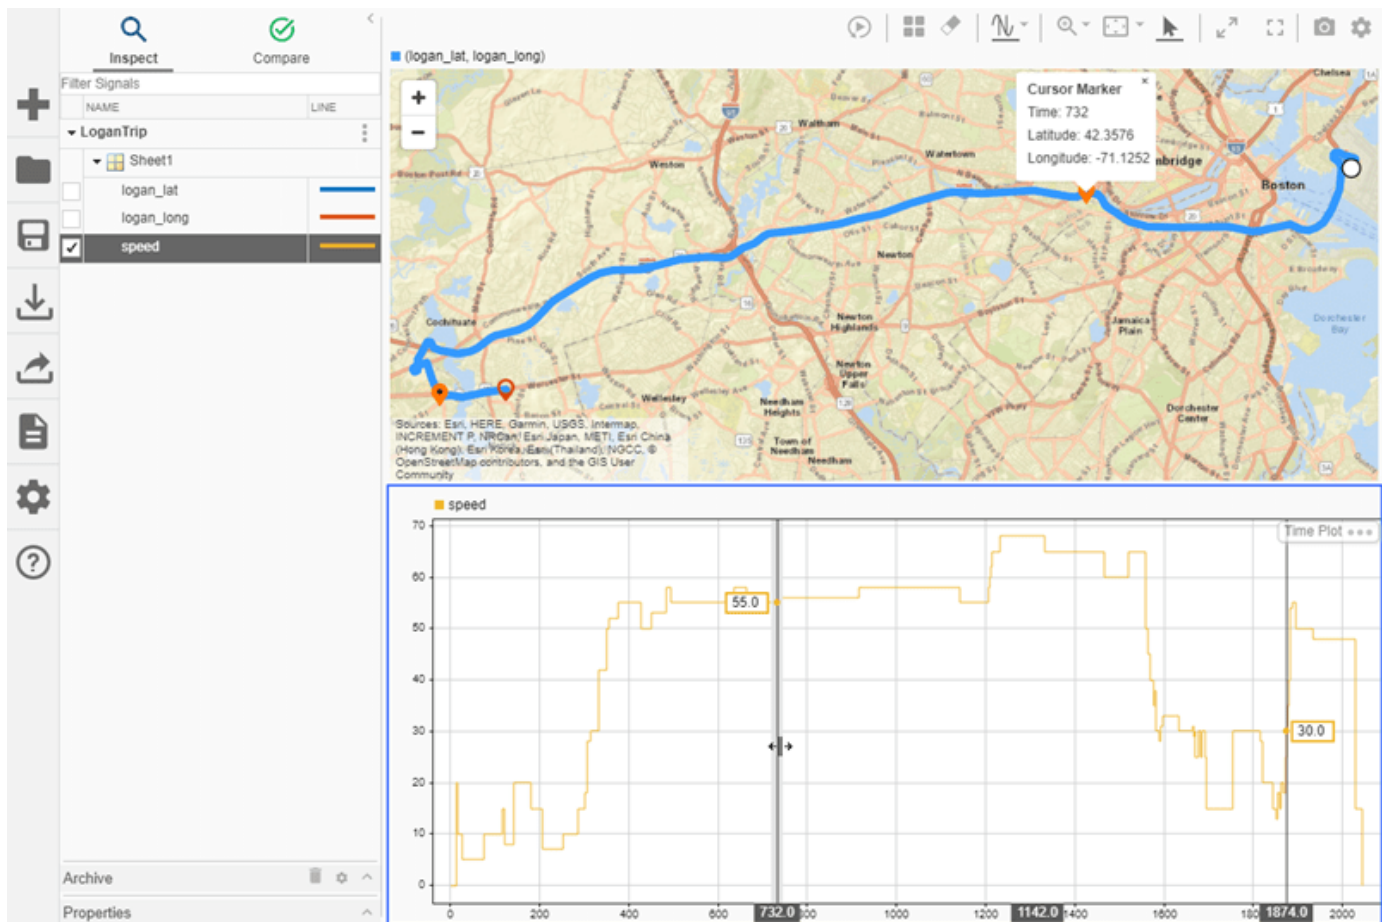

data cursors button  and select **Two Cursors**.

When you add cursors, additional orange markers appear on the map. The **Starting Position** and the **Destination** for the route have static markers. An additional marker corresponds to each cursor in the time plot.

In the lower subplot, move the cursor on the left. The marker on the right of the map moves as you move the left cursor because the route starts in Boston and moves from east to west over time.

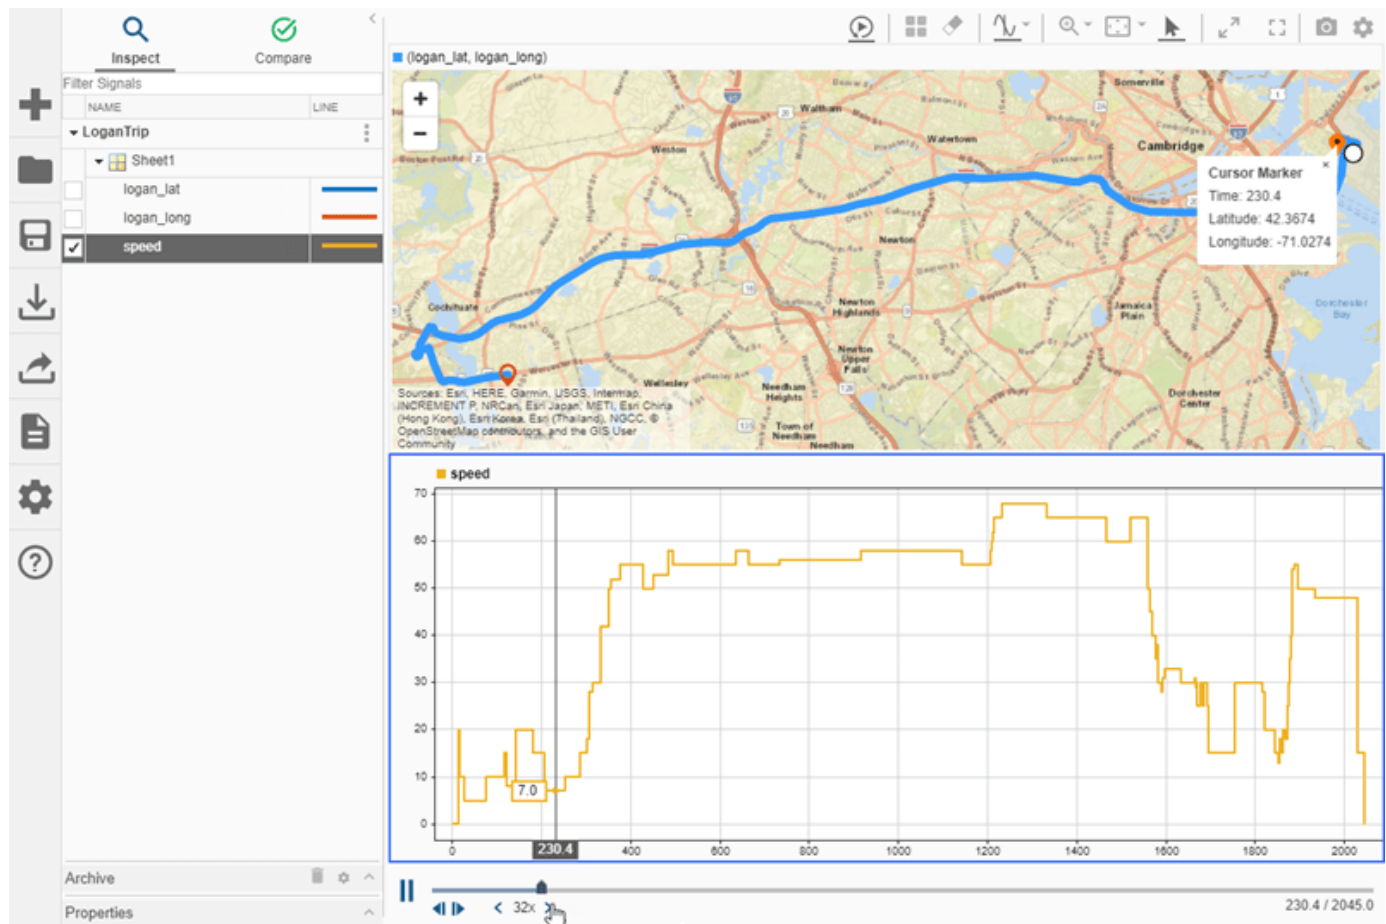

To remove the cursors from the plot, click Show/hide data cursors .

### Replay Route and Signal Data

In the Simulation Data Inspector, you can replay data to analyze relationships among plotted signals in your view. When you replay data in the Simulation Data Inspector, animated cursors sweep through the plotted data from the start time to the end time. To add the replay controls to the view, click

Show/hide replay controls . Then, click Replay .

A marker on the map and a cursor on the time plot sweep synchronously across the screen. By default, the Simulation Data Inspector replays data at one second per second, meaning that the cursor moves through one second of data in one second of clock time. The data for this trip spans approximately 34 minutes. You can increase the replay speed using the arrow to the right of the label or by clicking the label and typing the desired speed. Increase the replay speed to 32x using the arrow.

### Tools

**Simulation Data Inspector**

### Blocks

Record, XY Graph

### Functions

Simulink.sdi.createRun

## Related Examples

- “Replay Data in the Simulation Data Inspector” on page 31-188

## Visualize Simulation Data on an XY Plot

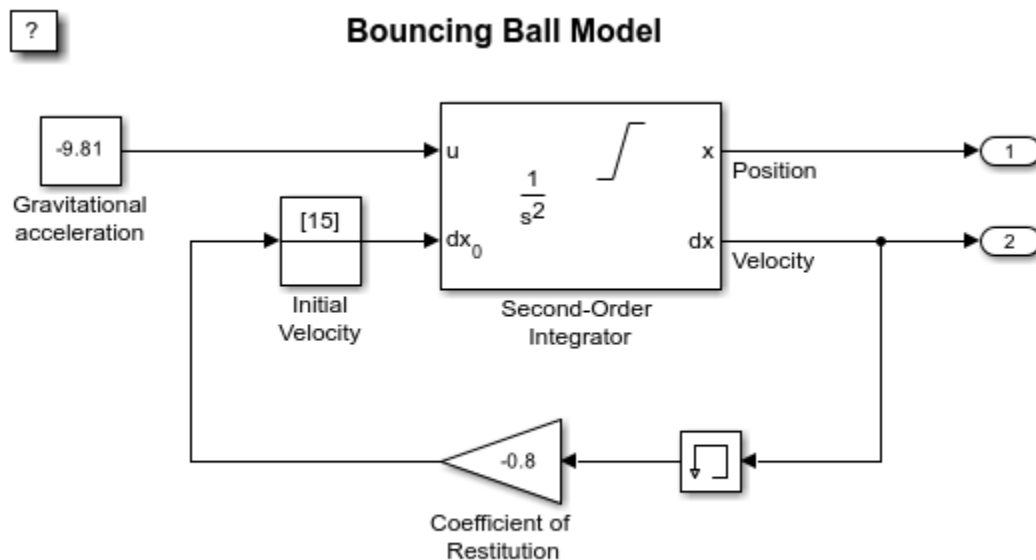

This example shows how to plot data on an XY plot in the Simulation Data Inspector and use the replay controls to analyze relationships among plotted signals. You run two simulations of the model `ex_sl-demo_bounce` and analyze the relationship between the position and velocity for a bouncing ball.

The XY plot used in this example is also available in the Record block and the XY Graph block. When you use the XY plot in the Record block and the XY Graph block, you add the visualization and configure the appearance using the toolstrip. You plot data on the XY plot the same way shown in this example.

### Simulate Model

Open the model `ex_sl-demo_bounce`, which simulates the dynamics of a bouncing ball.

```
open_system("ex_sl-demo_bounce")
```

Copyright 2004-2022 The MathWorks, Inc.

Because the model is configured to log output data, the position and velocity signals connected to the Output blocks log to the workspace and the Simulation Data Inspector.

To simulate the model, click **Run**. Then, under **Review Results**, click **Data Inspector** to open the Simulation Data Inspector.

Alternatively, you can simulate the model and open the Simulation Data Inspector programmatically.

```
out = sim("ex_sl-demo_bounce");
Simulink.sdi.view
```

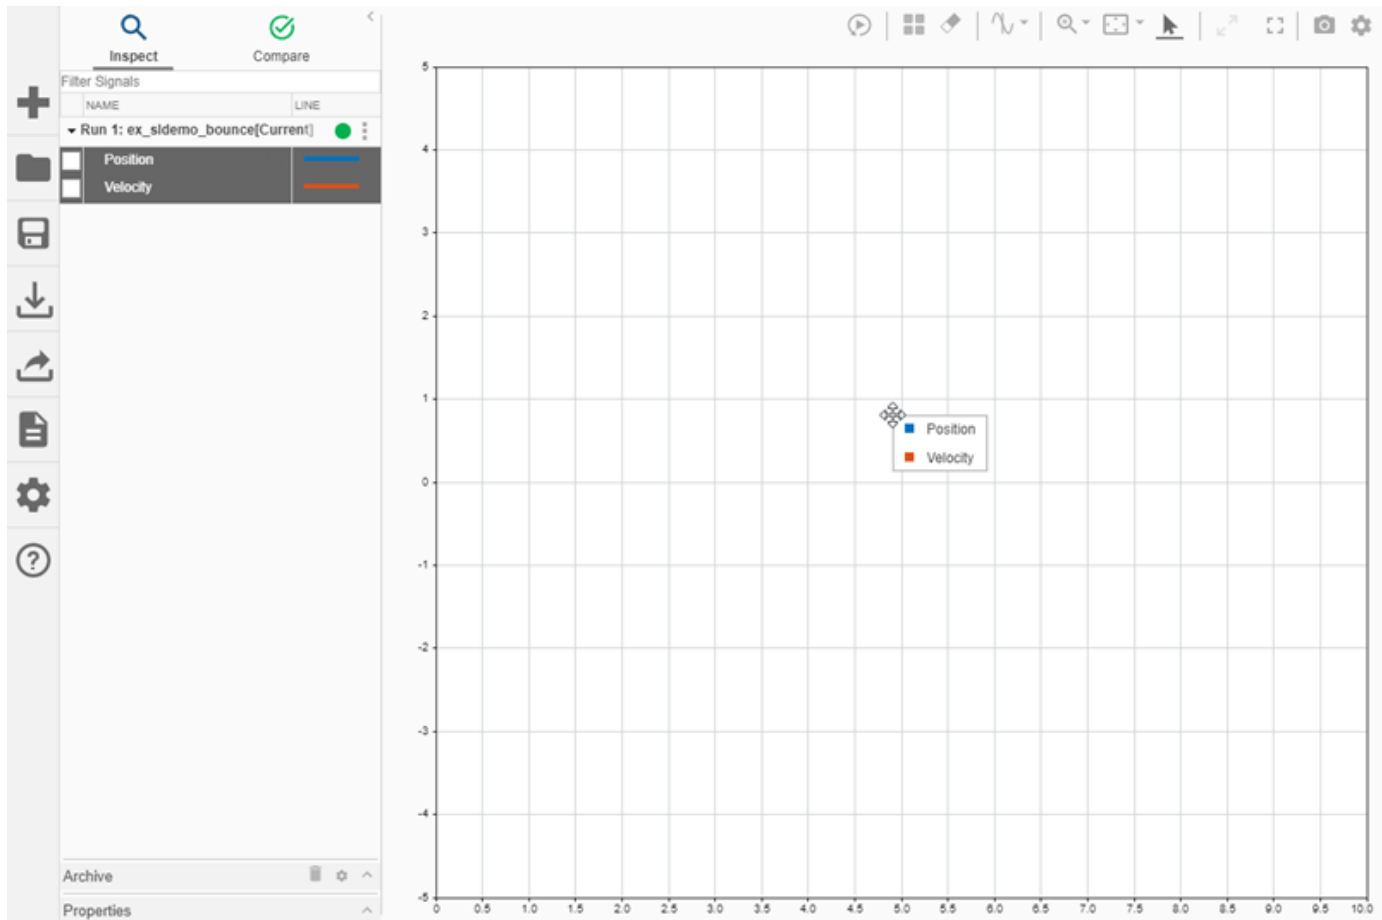

### Plot Data on XY Plot

By default, the Simulation Data Inspector uses time plots for each subplot in the layout. To plot the data on an XY plot, add the visualization to the layout. Click Visualizations and layouts, then drag the **XY** icon onto the subplot.

To plot the signals on the XY plot, select the rows for both the signals in the table and drag them onto the plot. Hold the **Shift** key or the **Ctrl** key to select more than one signal row in the table.

Specify which signal to use as the x data and which to use as the y data in the series menu that appears in the lower-right of the plot. Use the first drop-down list to select the signal that provides the x data, and use the second drop-down list to select the signal that provides the y-data. To swap the current x and y data selections, click the Swap button between the drop-down lists.

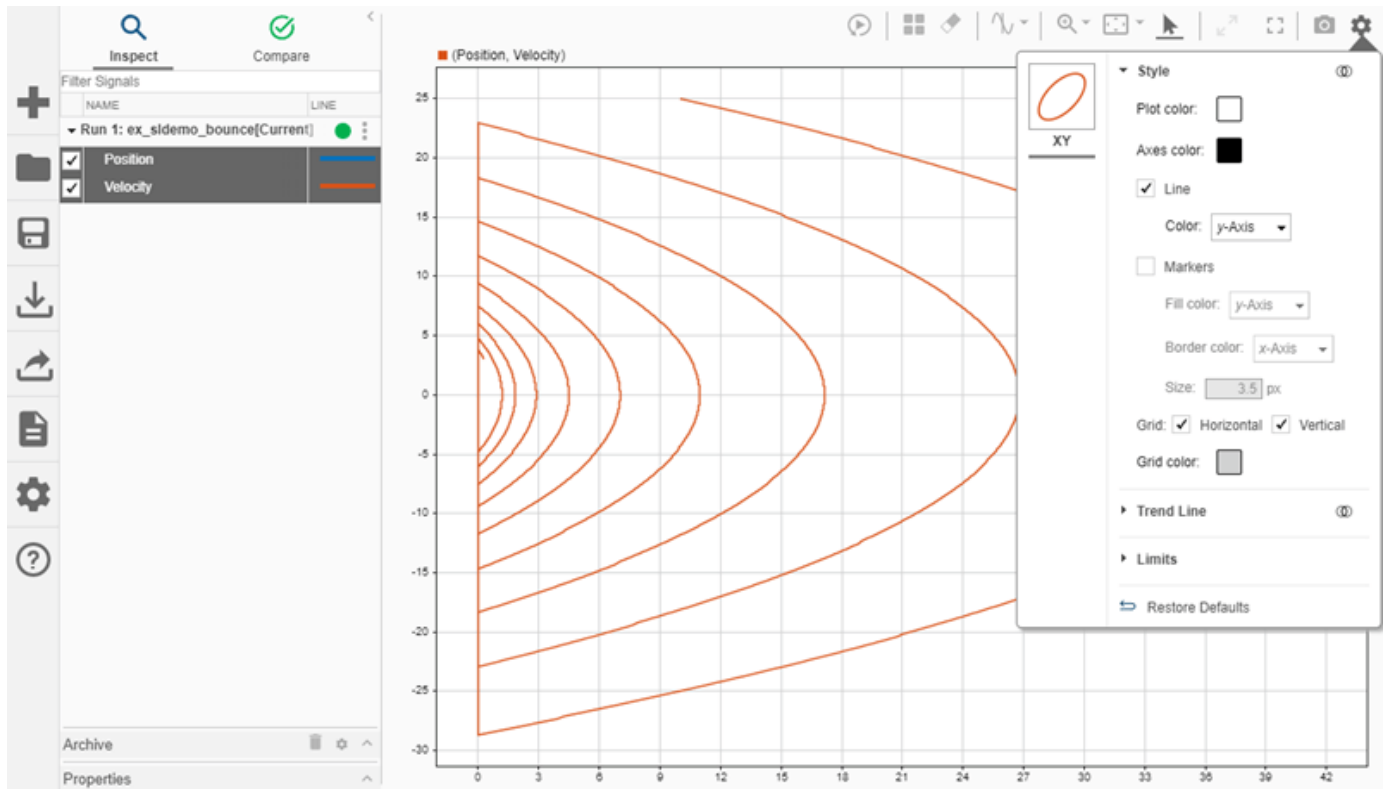

For this example, use Position as the x data and Velocity for the y data.

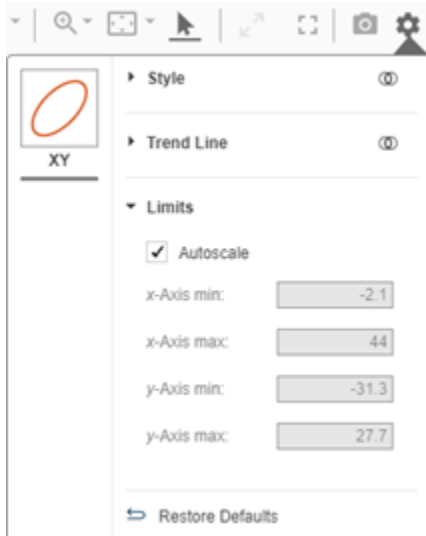

You can modify the appearance of the XY plot using the Visualization Settings. To access the Visualization Settings for the XY plot, click Visualization Settings.

The line and marker colors can match the color of the signal that provides the x data or the signal that provides the y data. By default, the line and markers both use the y-axis signal color. Specified settings apply for all XY plots in the layout.

You can also change the limits of the  $x$ -axis and  $y$ -axis from the Visualization Settings. To change the limits, first, clear **Autoscale**. Then, enter new values for the  $x$  and  $y$  limits. These limits apply to the currently selected XY subplot. By default, **Autoscale** is selected, which performs a fit-to-view on the XY subplot.

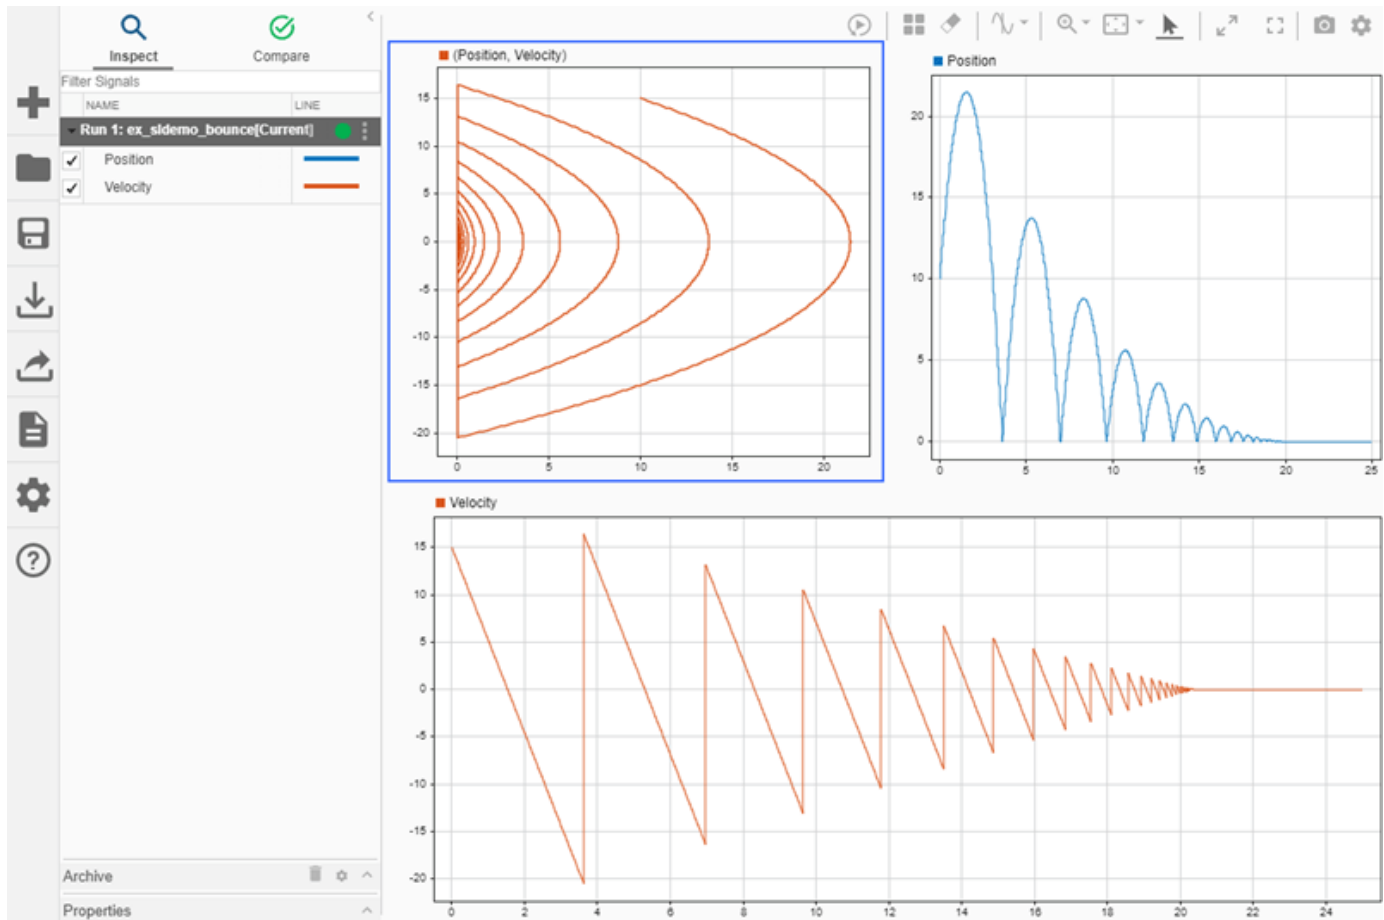

## Add Time Plots and Inspect Data

You can include multiple visualizations in a layout in the Simulation Data Inspector, Record block, or XY Graph block. For example, change to a layout with three subplots so you can see each signal on a time plot alongside the XY plot.

To change the subplot layout, click Visualizations and layouts. Then, in the **Basic Layouts** section, select the layout with two subplots on top of a third subplot.

Plot the **Position** signal on the upper-right time plot, and plot the **Velocity** signal on the bottom time plot. To plot a signal on a time plot, select the subplot where you want to plot the signal, then select the check box next to the signal you want to plot.

To inspect the data, add a cursor. In the XY plot, the vertical line of the cursor shows the x-axis value, and the horizontal line shows the y-axis value. The time that corresponds to the point is displayed in the upper-right of the plot.

Move the cursor in the XY plot along the plotted line. You can also move the cursor in the XY plot using the arrow keys on your keyboard or by pausing on a point on the line and clicking the highlighted point.

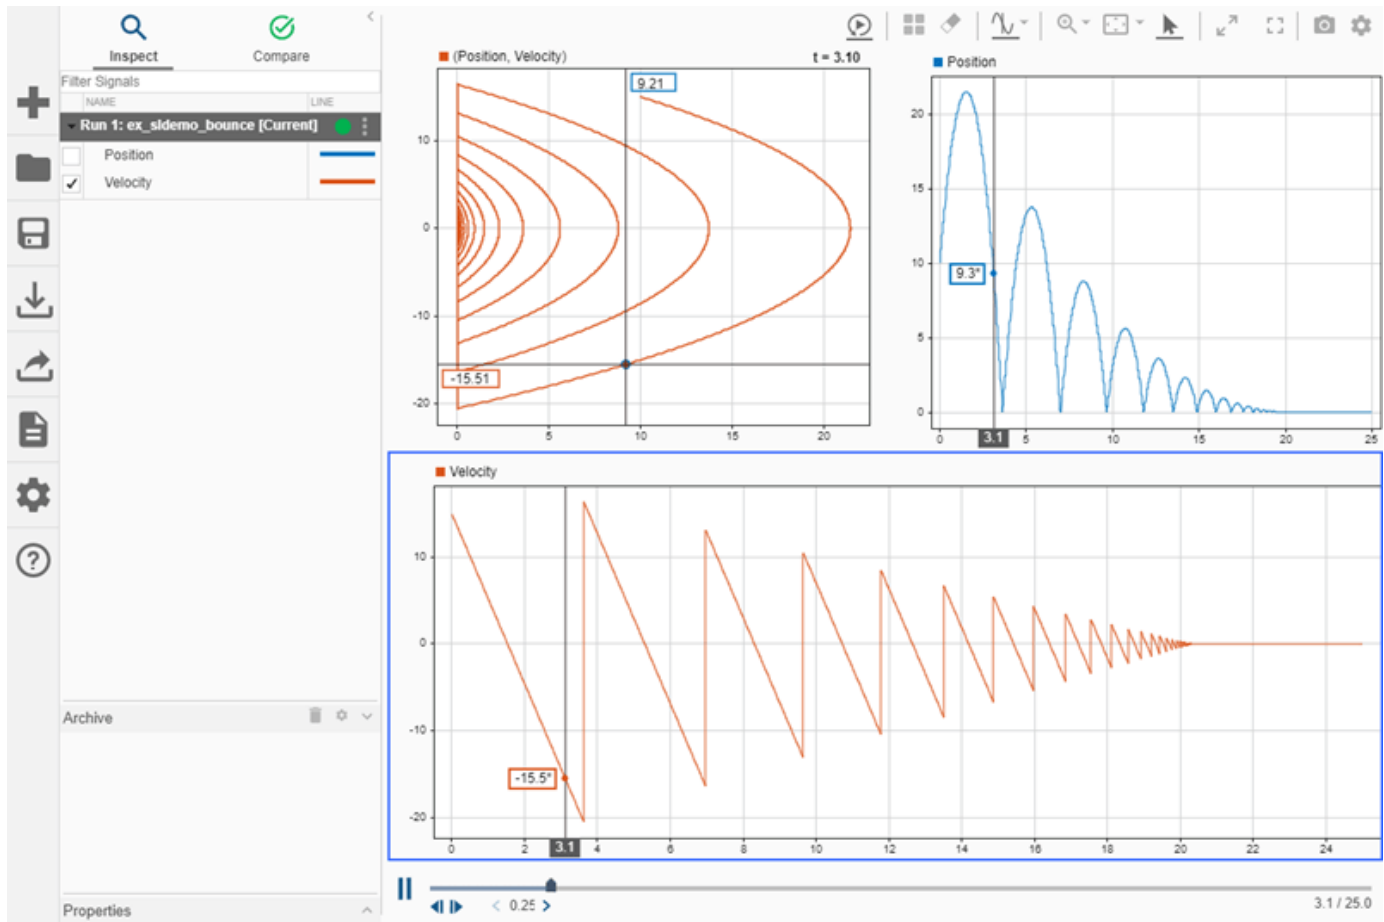

When you drag the cursor in a time plot, the cursor in the XY plot moves synchronously through the plotted data. The XY plot can only have one cursor. When you add two cursors to the layout, the XY cursor moves with the left cursor in the time plot.

### Replay Data

Now that you have a comprehensive visualization of the simulation data, replaying the data can help you understand the relationship between the signals. When you replay data in the Simulation Data Inspector, animated cursors sweep through the logged simulation data from the start time to the end time. Add the replay controls to the view by clicking Show/hide replay controls.

You can control the speed of the replay and pause at any time. By default, the Simulation Data Inspector replays data at one second per second, meaning the cursor moves through one second of data in one second of clock time. The data in this example spans 25 seconds. Slow the replay speed by clicking the arrow to the left of the label.

For more information about using replay controls, see “Replay Data in the Simulation Data Inspector” on page 31-188.

### Analyze Data from Multiple Simulations

To analyze how changes in simulation parameters affect the data, you can plot multiple series on an XY plot. Simulate the model again using a higher initial velocity for the ball.

Using the Simulink® Editor or the MATLAB™ Command Window, change the **Initial value** parameter of the Initial Velocity block to 25. Then, simulate the model.

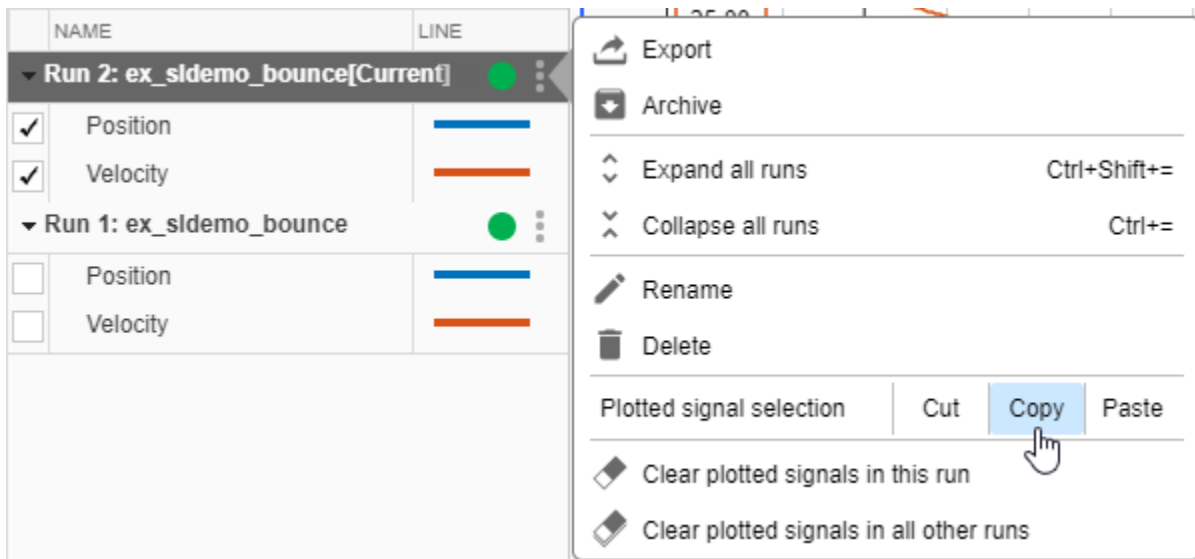

```
set_param("ex_sl-demo_bounce/Initial Velocity", 'Value', '25')
sim('ex_sl-demo_bounce');
```

The Simulation Data Inspector moves the first run to the archive and transfers the view to the new run. To adjust the zoom level for the signals from the new run, click Fit to View.

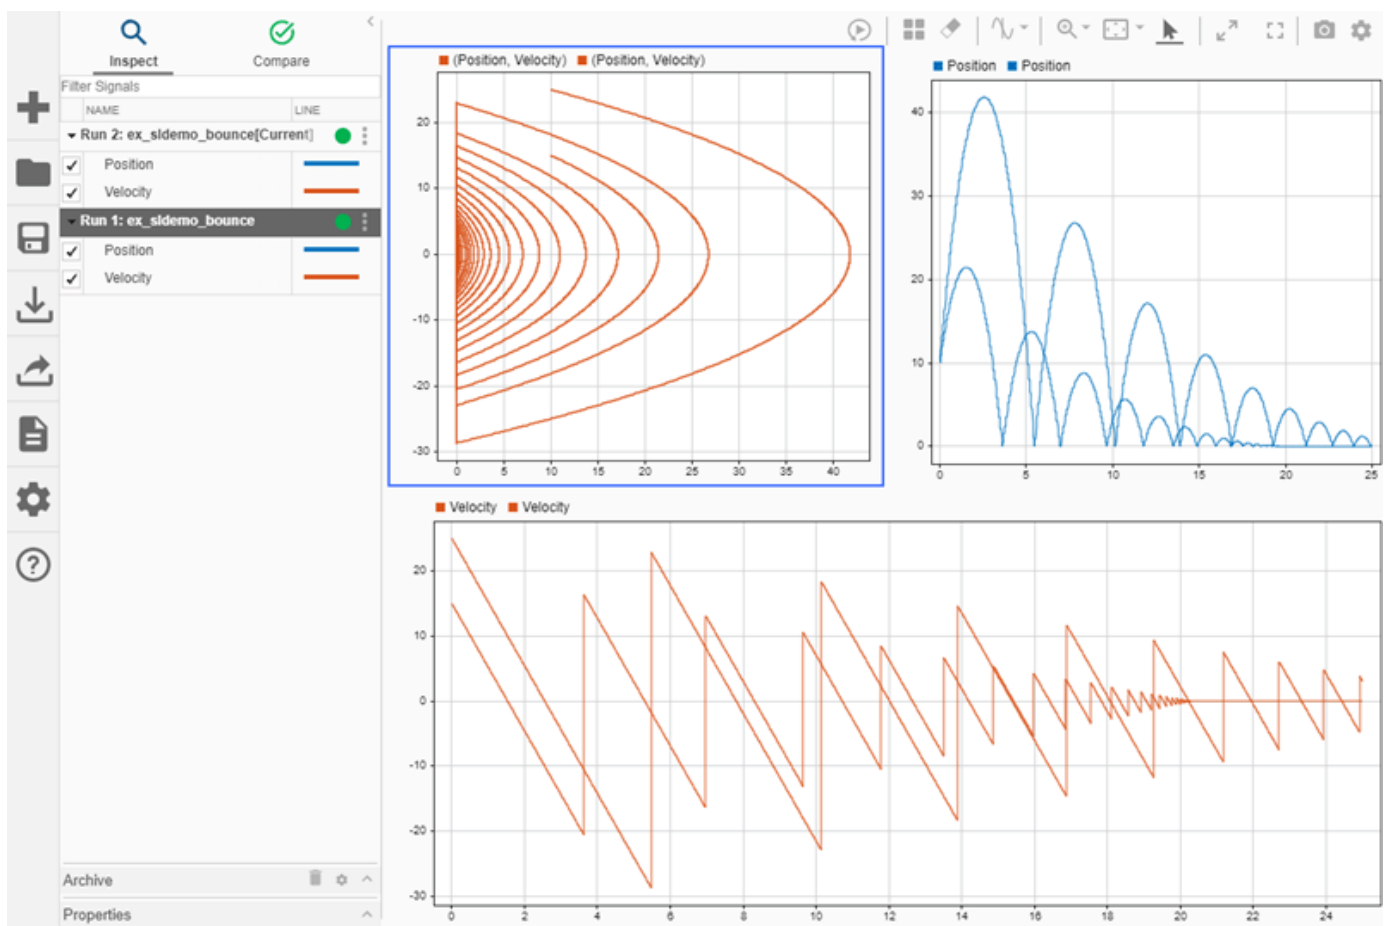

Drag the first run from the archive into the work area. Then, use the run actions menu to copy the plotted signal selection from the current run to the first run.

To copy the plotted signal selection from the current run, click the three dots on the right of the row for the current run. Then, under **Plotted signal selection**, select **Copy**.

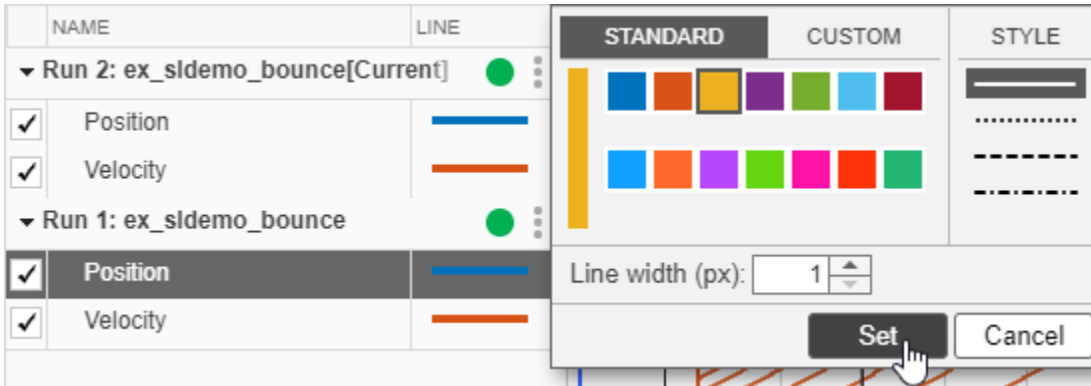

To plot data from the first run, paste the plotted signal selection onto the run. Click the three dots on the right of the row for the first run. Then, under **Plotted signal selection**, select **Paste**.

The signals in both runs have the same names and the same signal colors. Change the colors for the signals in the first run.

- 1 Click the representation of the line in the table.
- 2 Select a new color.
- 3 Click **Set**.

The signals in both runs also have the same name. To determine which run contains a plotted signal, you can use the tooltip in the legend.

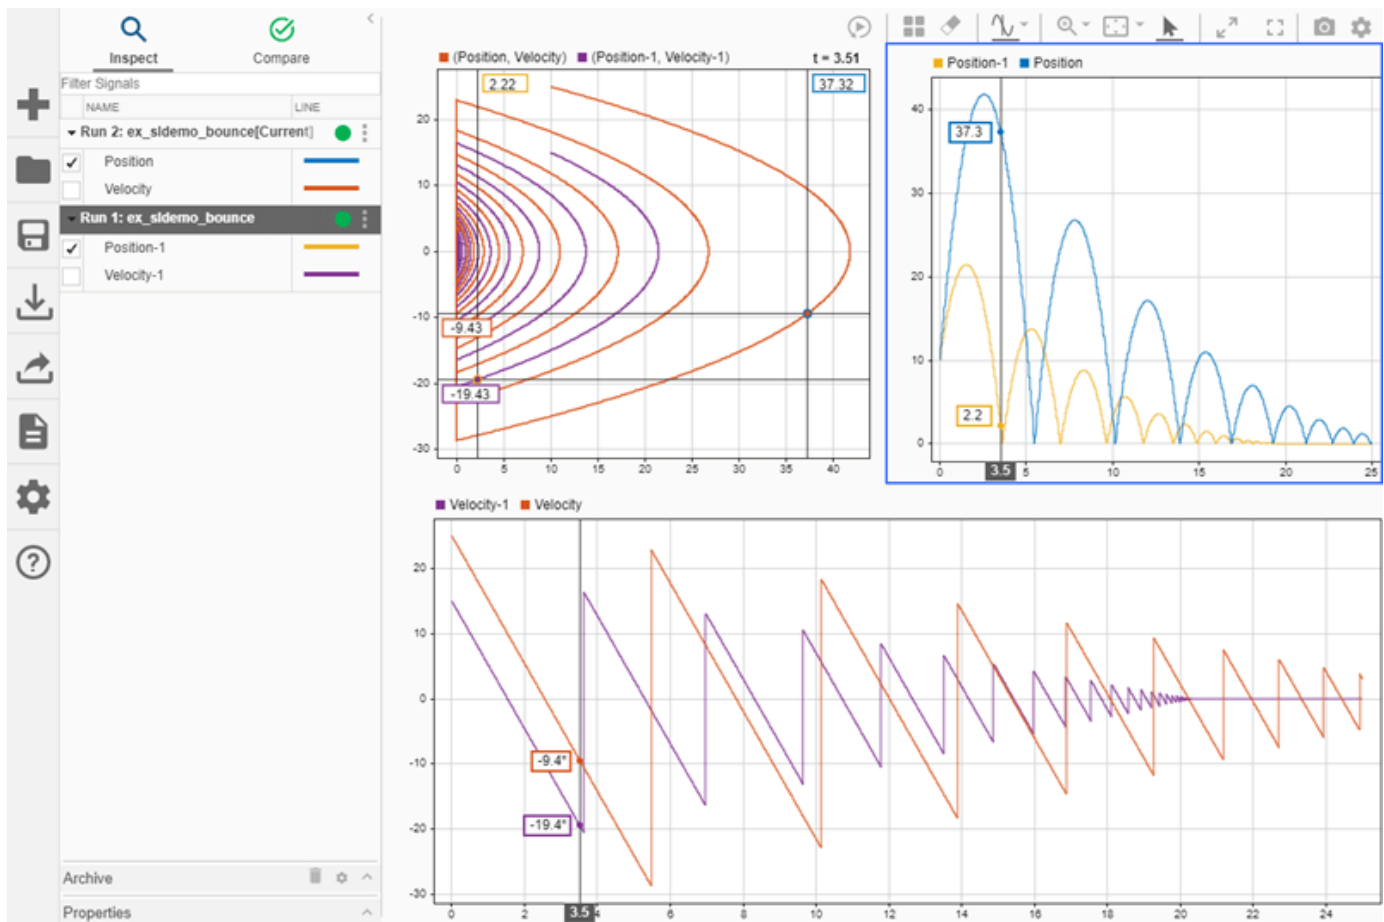

You can also rename the signals. For example, rename the signals in the first run to **Position-1** and **Velocity - 1**. To rename a signal, double-click the name in the table and enter a new name.

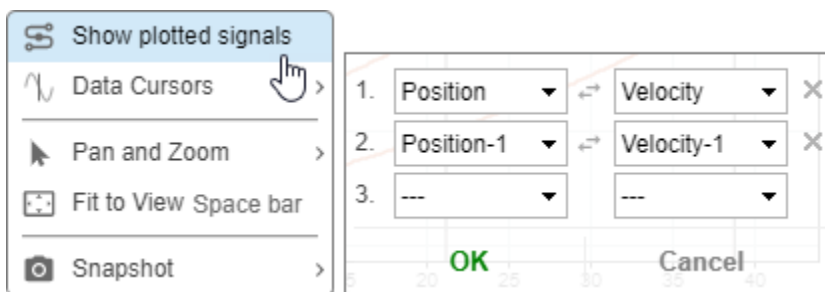

When you add multiple series to an XY plot, each series gets a cursor. All cursors on the XY plot move synchronously, so all signal values displayed on the cursors correspond to the same time.

You can manage the signals plotted on an XY plot using the subplot context menu. Right-click the XY plot and select Show plotted signals. Using the series menu, you can remove series from the plot or modify which signals provide the x-data and y-data for each series.

## Analyze Data Using the XY Plot

This example shows how to analyze data plotted on an XY plot in the Simulation Data Inspector using trend lines.

The XY plot used in this example is also available in the Record block and the XY Graph block. When you use the XY plot in the Record block and the XY Graph block, you add the visualization and configure the appearance using the toolstrip. You plot data on the XY plot the same way shown in this example.

### Import Data into Simulation Data Inspector

Open the Simulation Data Inspector.

```
Simulink.sdi.view
```

The data for this example is stored in the MAT file `XYData.mat`. To import the data using the UI,

click Import .

In the Import dialog box, under **Import from**, select **File**. Then, enter `XYData.mat` in the text box and click **Import**.

Alternatively, import the data programmatically using the `Simulink.sdi.createRun` function.

```
xyRunID = Simulink.sdi.createRun("XY signals", "file", "XYData.mat");
```

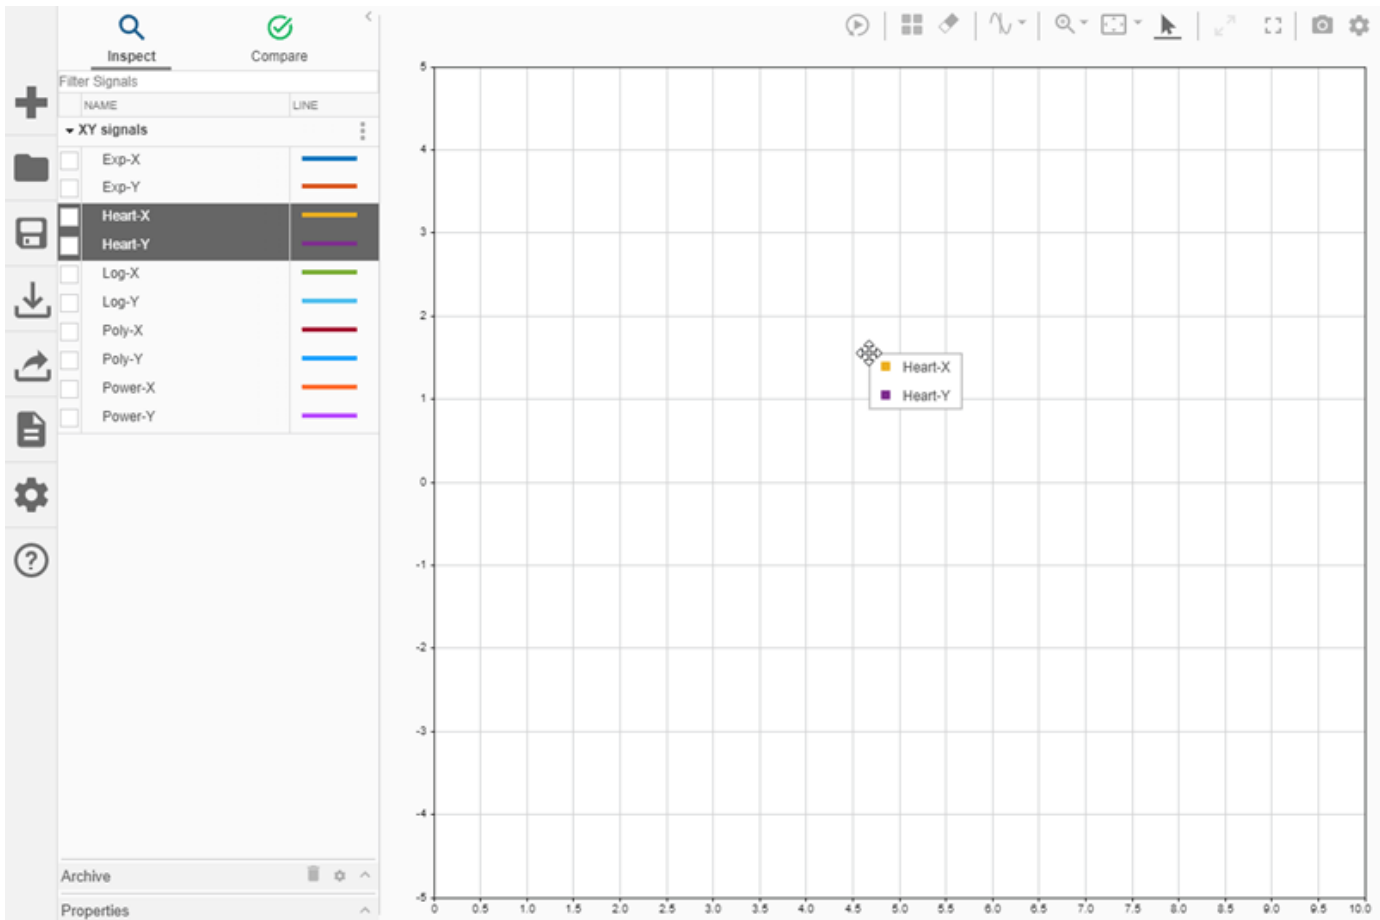

### Plot Data on XY Plot

By default, the Simulation Data Inspector uses time plots for each subplot in the layout. To plot the data on an XY plot, you need to add the visualization to the layout.

To add an XY plot to your layout, click Visualizations and layouts . Then, from **Visualizations**, drag the **XY** icon onto the subplot.

To plot signals on the XY plot, select two signals in the table and drag them onto the plot. For example, select the rows for the Heart -X and Heart -Y signals, then drag them onto the plot. Hold the **Shift** key or the **Ctrl** key to select more than one signal row in the table.

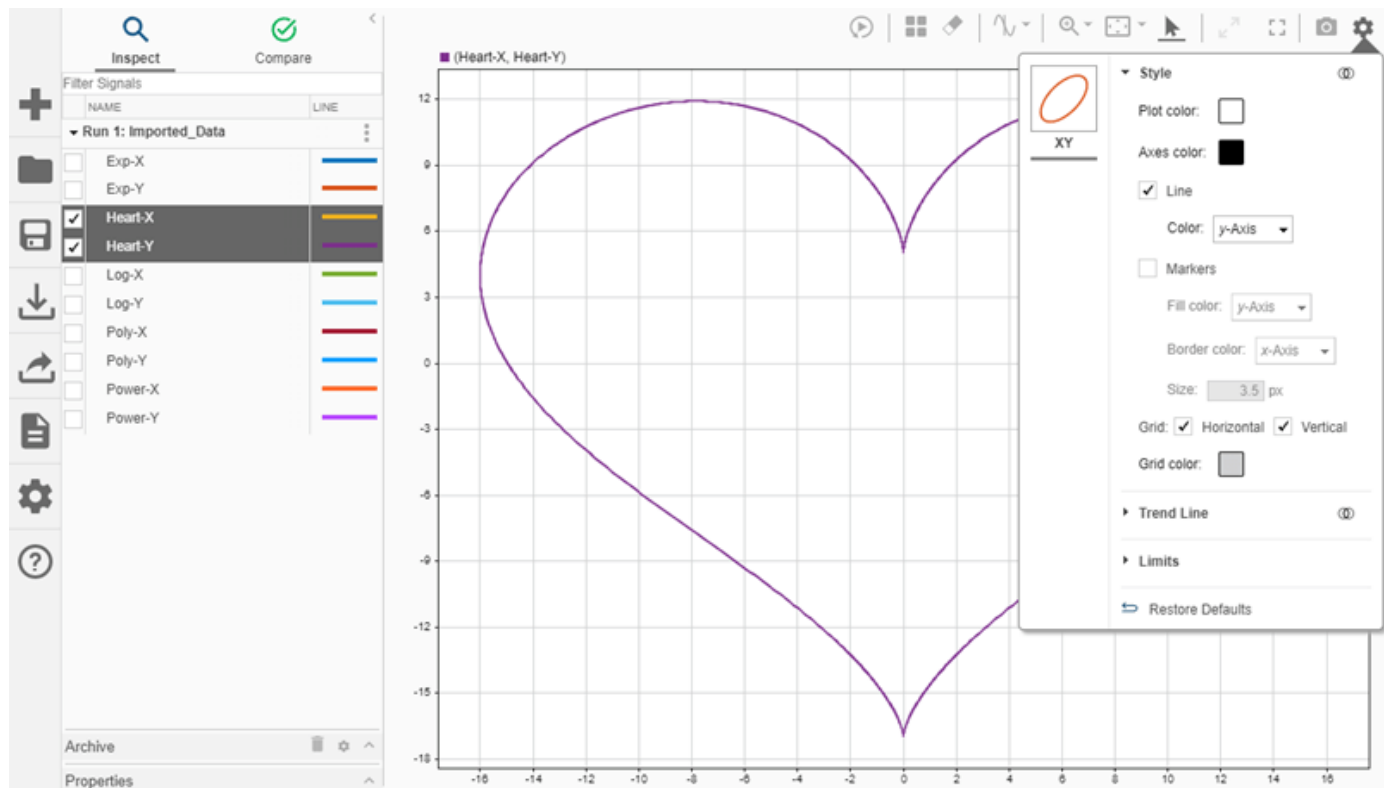

Specify which signal to use as  $x$ -data and which to use as  $y$ -data in the menu that appears in the lower-right of the plot. Use the first drop-down list to select the signal that provides the  $x$ -data, and use the second drop-down list to select the signal that provides the  $y$ -data. To swap the current  $x$ - and  $y$ - data selections, click the Swap  $\leftrightarrow$  button between the drop-down lists.

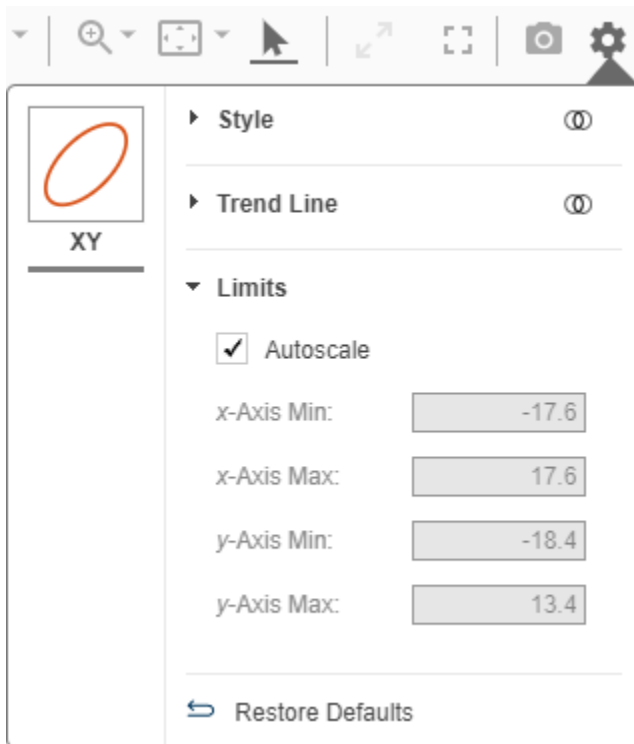

You can modify the appearance of XY plots in the layout using the Visualization Settings. To access the visualization settings for the XY plot, click Visualization Settings .

The line and marker colors can match the color for the signal that provides the  $x$  data or the color for the signal that provides the  $y$  data. By default, the line and markers both use the  $y$ -axis signal color. Specified settings apply for all XY plots in the layout.

You can also change the limits of the x-axis and y-axis from the Visualization Settings . To change the limits, first, clear **Autoscale**. Then, enter new values for the x and y limits. These limits apply to the currently selected XY subplot. By default, **Autoscale** is selected, which performs a fit-to-view on the XY subplot.

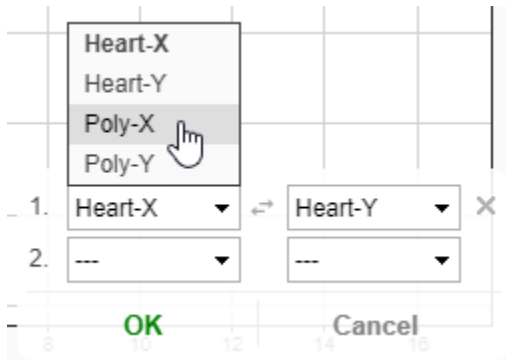

### Analyze XY Data Using Trend Lines

You can add a trend line to an XY plot to analyze the relationship between the  $x$ - and  $y$ -data. The trend line is most useful when the relationship can be expressed as a function. The Heart -X and Heart -Y data plotted in the prior section is not well-suited for analysis with trend lines because the  $y$ -data is not well correlated with the  $x$ -data.

The example data includes  $x$ - and  $y$ -data well-suited for each type of trend line available. You can try plotting each pair of signals to see how each trend line helps you analyze the data. For example, plot the Poly-X and Poly-Y signals on the XY plot:

- 1 Select the rows for both signals in the table. Hold the **Shift** key or the **Ctrl** key to select more than one signal row.
- 2 Drag the selected signals onto the plot.
- 3 In the menu that appears in the lower-right of the plot, specify which signal to use for the  $x$ -data and which to use for the  $y$ -data. In the first row, select Poly-X from the first drop-down list and select Poly-Y from the second drop-down list.
- 4 Click **OK**.

To add a trend line, click Visualization Settings  and select **Trend line**. From the **Type** list, select Polynomial.

By default, the Simulation Data Inspector computes the polynomial trend line in the form of a third-order polynomial. To see the equation for the trend line as well as information about how it fits the data, pause on the trend line. The tooltip for the trendline shows:

- The names of the signals that provide the  $x$ - and  $y$ - data for the series.
- The coordinates for the trend line point closest to the pointer.
- The trend line equation and R-squared value.

When you use a polynomial trend line, you can specify the order of the polynomial between 2 and 6, inclusive. For example, change the order of the polynomial trend line to 2 to see how it affects the fit of the trend line. Open the visualization settings for the XY plot. Then, in the text box next to the trend line type selection, enter 2.

When you use a second-order polynomial, the trend line does not fit the start of the data as well.

Try other trend line options to see how they fit the Poly-X and Poly-Y data. You can add these types of trend line to the XY plot:

- **Linear:** Trend line equation has the form  $y = mx + b$ .
- **Logarithmic:** Trend line equation has the form  $y = a \ln(x) + b$ . The x-data must not contain 0 or negative values.
- **Polynomial:** Trend line equation has the form  $y = b_6x^6 + \dots + b_2x^2 + b_1x + a$ , where the number of terms is determined by the specified order.
- **Exponential:** Trend line equation has the form  $y = ae^{bx}$ . The y-data must not contain 0 or negative values.
- **Power:** Trend line equation has the form  $y = ax^b$ . The x- and y-data must not contain 0 or negative values.

Try plotting other pairs of signals in the XY plot and explore how each trend line option fits each data set.

## View Many Signals Together Using Sparklines

This example shows how to use the sparklines visualization in the Simulation Data Inspector to easily plot and view many signals at once.

The sparklines visualization used in this example is also available in the Record block. When you use the sparklines plot in the Record block, you add the visualization and configure the appearance using the toolstrip. You plot data on the sparklines plot the same way shown in this example.

### Simulate Model

This example plots signals logged from a simulation of the model `sldemo_fuelsys`.

Open the model.

```
open_system('sldemo_fuelsys');
```

To simulate the model, click **Run**. Then, under **Review Results**, click **Data Inspector** to open the Simulation Data Inspector.

Alternatively, simulate the model and open the Simulation Data Inspector programmatically.

```
out = sim('sldemo_fuelsys');
Simulink.sdi.view
```

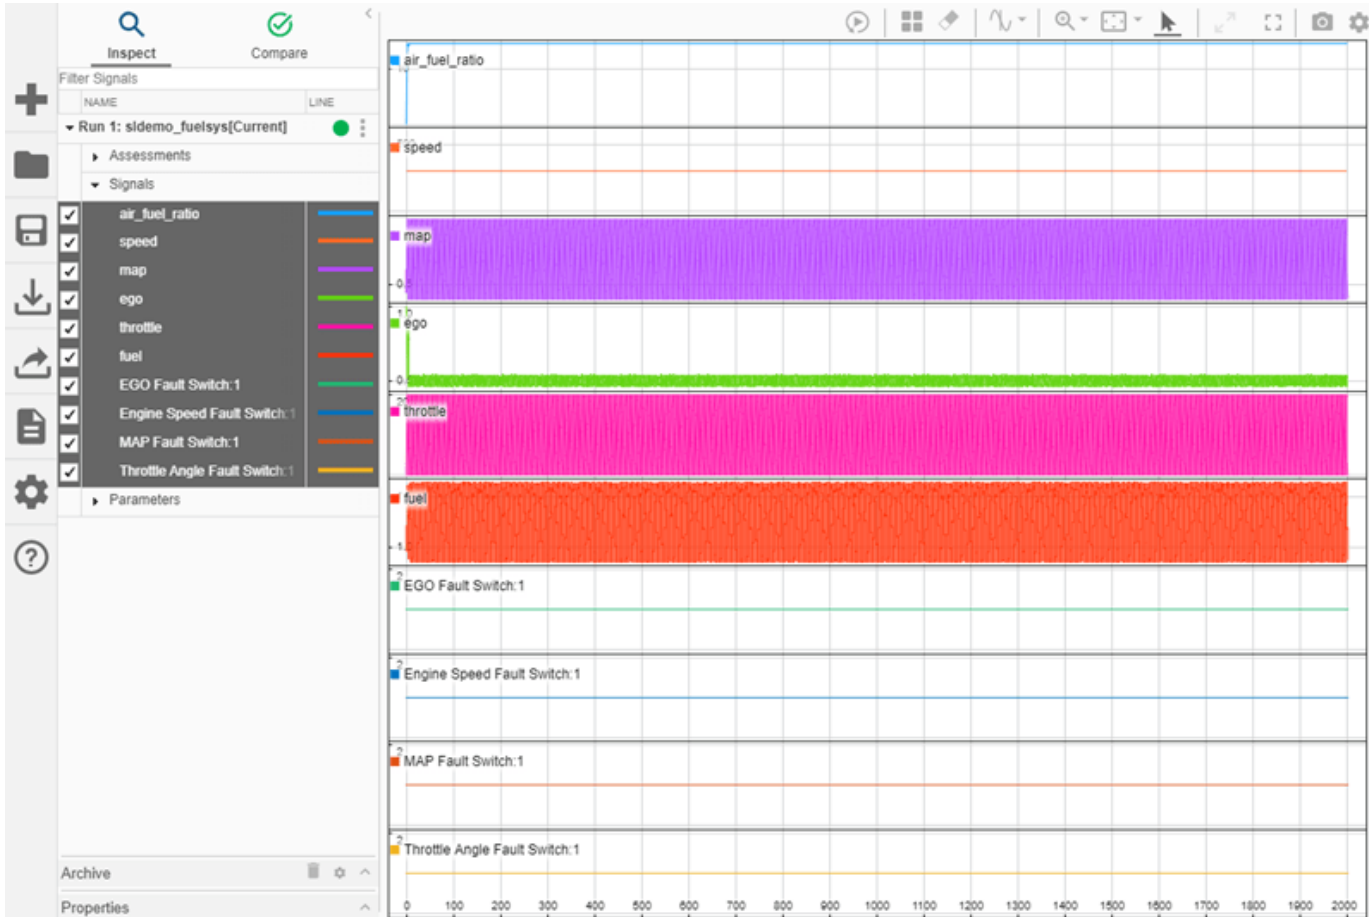

### Plot Data on Sparklines Plot

By default, the Simulation Data Inspector uses time plots for each subplot in the layout. To plot the

data on a sparklines plot, add the visualization to the layout. Click Visualizations and layouts . From **Visualizations**, drag the **Sparklines** icon onto the subplot.

The Simulation Data Inspector groups logged data by domain, which indicates the type or source of the data. Expand the **Signals** group. You can add sparklines for the signals one by one by selecting the check box next to each signal you want to plot, or you can select a group of signals to drag onto the plot. Each signal is shown on its own sparkline.

If you want to view more than one signal in a single sparkline, you can drag the signal line from one sparkline onto another. The sparkline for the signal you move disappears, and both signals are shown together on the sparkline where you drag the signal. For example, drag the **ego** signal into the top sparkline.

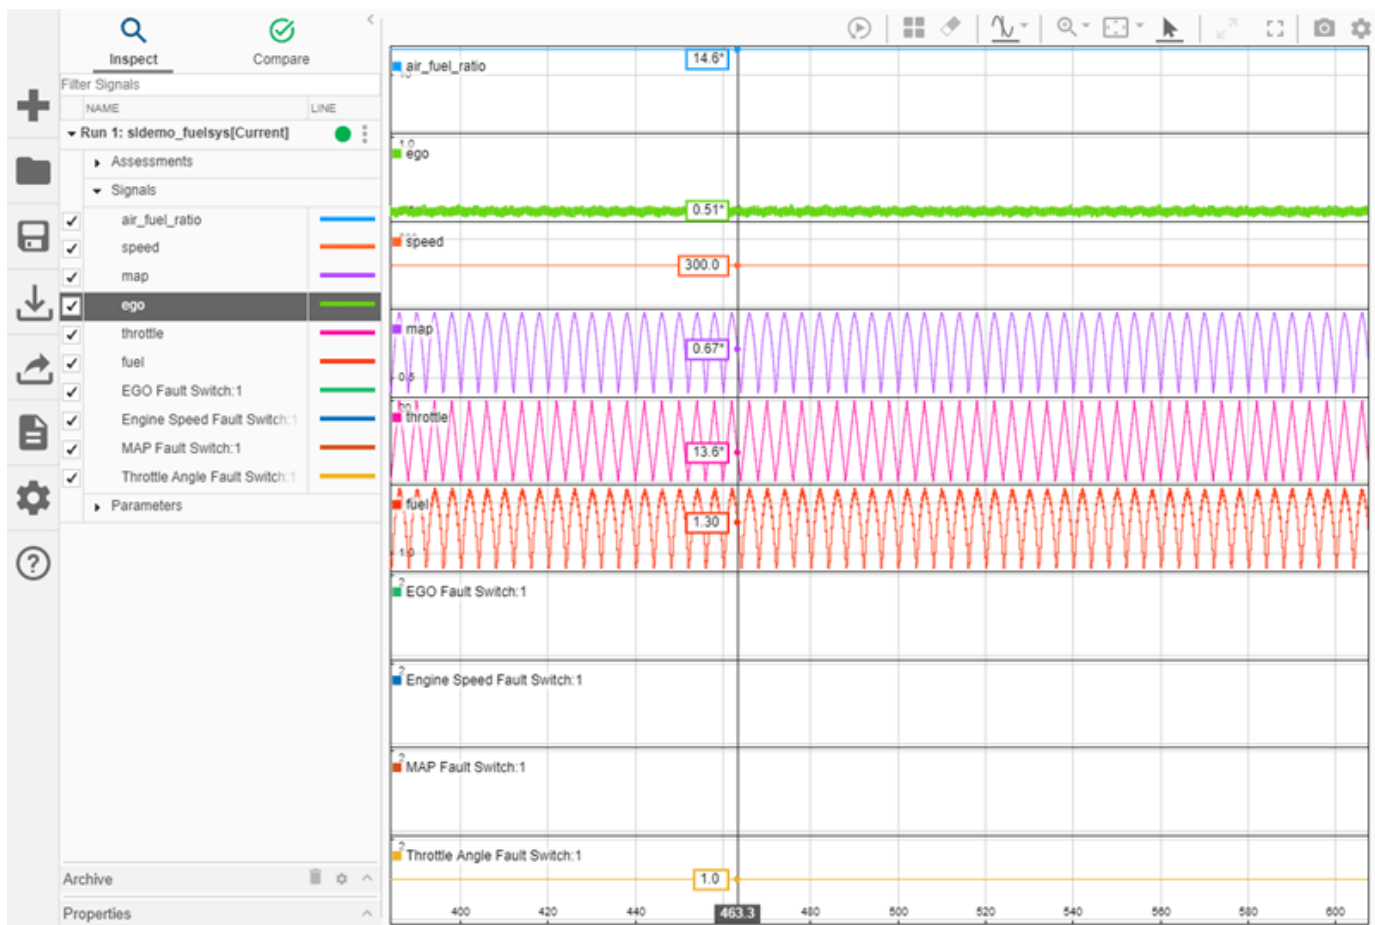

You can also reorder the sparklines by dragging the signal line and dropping it between two sparklines where you want that signal to appear. For example, drag the ego signal out of the top sparkline and drop it in between the first and second sparklines.

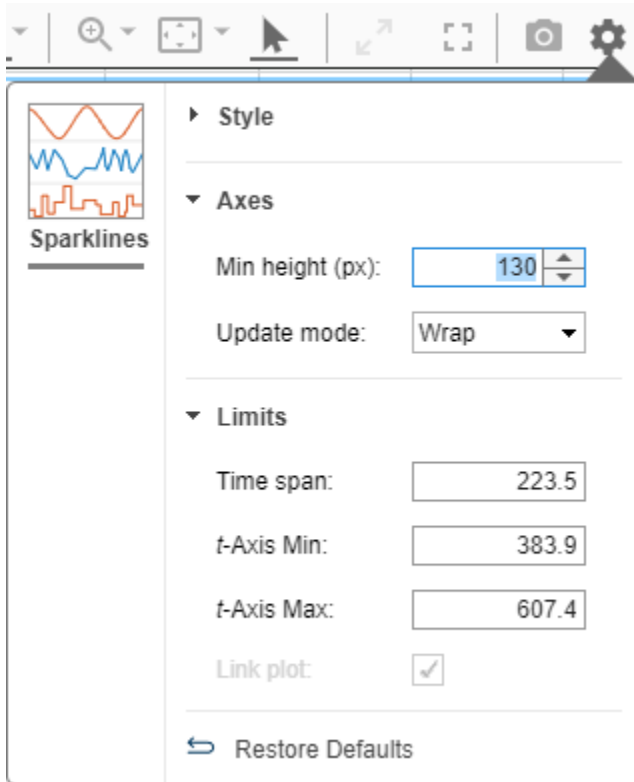

### Inspect Data on Sparklines

You can add cursors to the sparklines plot to see the value for each signal at a given time. You can also use the replay controls with sparklines to inspect how the signal values change relative to each other over time. When you pan or zoom in a given sparkline, all other sparklines remain synchronized.

You can modify the appearance of a sparklines plot using the Visualization Settings and the subplot menu. To access the Visualization Settings for the sparklines plot, click Visualization Settings .

For example, increase the minimum height for each sparkline to 130 px. The values you specify in the Visualization Settings are specific to a single sparklines visualization and apply to all sparklines within that sparklines plot.

With the larger minimum height, all the sparklines are not visible at once, and a scroll bar allows you to view all the signals. To scroll down, select the scroll bar with your mouse and drag.

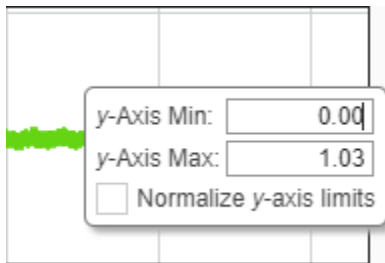

You can modify settings that apply only to a single sparkline within the sparklines plot using the subplot menu. For example, change the y-axis limits for the sparkline that displays the ego signal.

To open the subplot menu for the sparkline, pause on the sparkline then click the three dots that appear.

To open the sparkline-specific visualization settings, click Sparkline Settings . In the menu that appears, change the minimum value for the y-axis to 0.

To clear the Sparkline Settings menu, click outside the menu.

### View Data on a Sparklines Plot During Simulation

During simulation, plotted signals stream data to the sparklines visualization. You can control how the signal data is displayed as well as how and when the sparklines update using the **Update mode** and

**Time span** settings in the Visualization Settings . Change **Update mode** to **Scroll** and set **Time span** to 100. Then, simulate the model again.

```
out = sim('sldemo_fuelsys');
```

By default, the Simulation Data Inspector automatically moves the previous run into the archive and plots signals from the current simulation in the place of plotted signals from the prior simulation. To inspect a signal of interest during simulation, you can freeze the display by clicking Freeze display

Alternatively, you can use a trigger to control when the sparklines plot updates. For more information, see “Control Display of Streaming Data Using Triggers” on page 31-97

## View Multidimensional Signals Using the Array Plot

This example shows how to view and analyze data using an array plot in the Simulation Data Inspector. You can use an array plot to view multidimensional signals, including variable-size signals, that you log from simulation or import from another source into the Simulation Data Inspector. This example plots and analyzes imported data from a system that:

- 1 Samples a signal contaminated with noise using an analog to digital converter.
- 2 Performs a discrete Fourier transform (DFT) on the sampled signal.
- 3 Removes the noise from the signal in the frequency domain.
- 4 Performs an inverse DFT on the filtered signal to return to the time domain.

The signal samples are processed using frames, which buffer several samples into an array. You can use the array plot to view the frames of the time domain signal and to view the frequency domain representation of the signal.

### Import Data into Simulation Data Inspector

Open the Simulation Data Inspector.

```
Simulink.sdi.view
```

The data for this example is stored in the MAT file `NoiseFilteringData.mat`. To import the data

using the user interface, click Import .

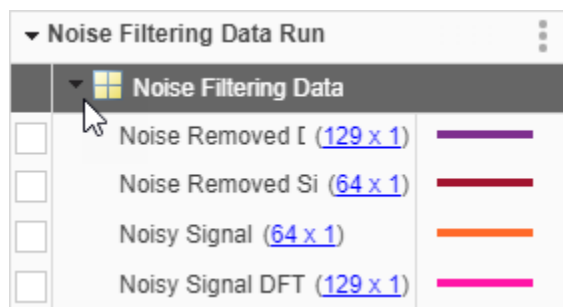

In the Import dialog box, under **Import from**, select **File**. Then, enter `NoiseFilteringData.mat` in the text box and click **Import**.

Alternatively, import the data programmatically using the `Simulink.sdi.Run.create` function.

```
runObj = Simulink.sdi.Run.create("Noise Filtering Data Run","file","NoiseFilteringData.mat");
```

### Plot Data Using Array Plot

By default, the Simulation Data Inspector groups signals according to data hierarchy, and groups of signals are collapsed. To view the signals that were imported, click the arrow next to **Noise Filtering Data**. Because the signals contain multidimensional data, the dimensions of each sample are indicated to the right of the signal name.

By default, the Simulation Data Inspector uses time plots for all subplots in the layout. Time plots do not support displaying multidimensional data. To plot `Noisy Signal`, select the check box next to it.

A menu appears in the plot area with actions you can perform on the multidimensional signal. To view the signal data, select **Change active subplot to array plot** and click **OK**.

Each 64-by-1 sample of **Noisy Signal** is a frame of time-domain data for a sine wave contaminated by noise. The array plot uses the row index within the sample as the x data and the sample value at that index as the y data.

Change the subplot layout to include four subplots so you can plot the other signals. Click

Visualizations and layouts . Then, under **Basic Layouts**, select the four-subplot layout.

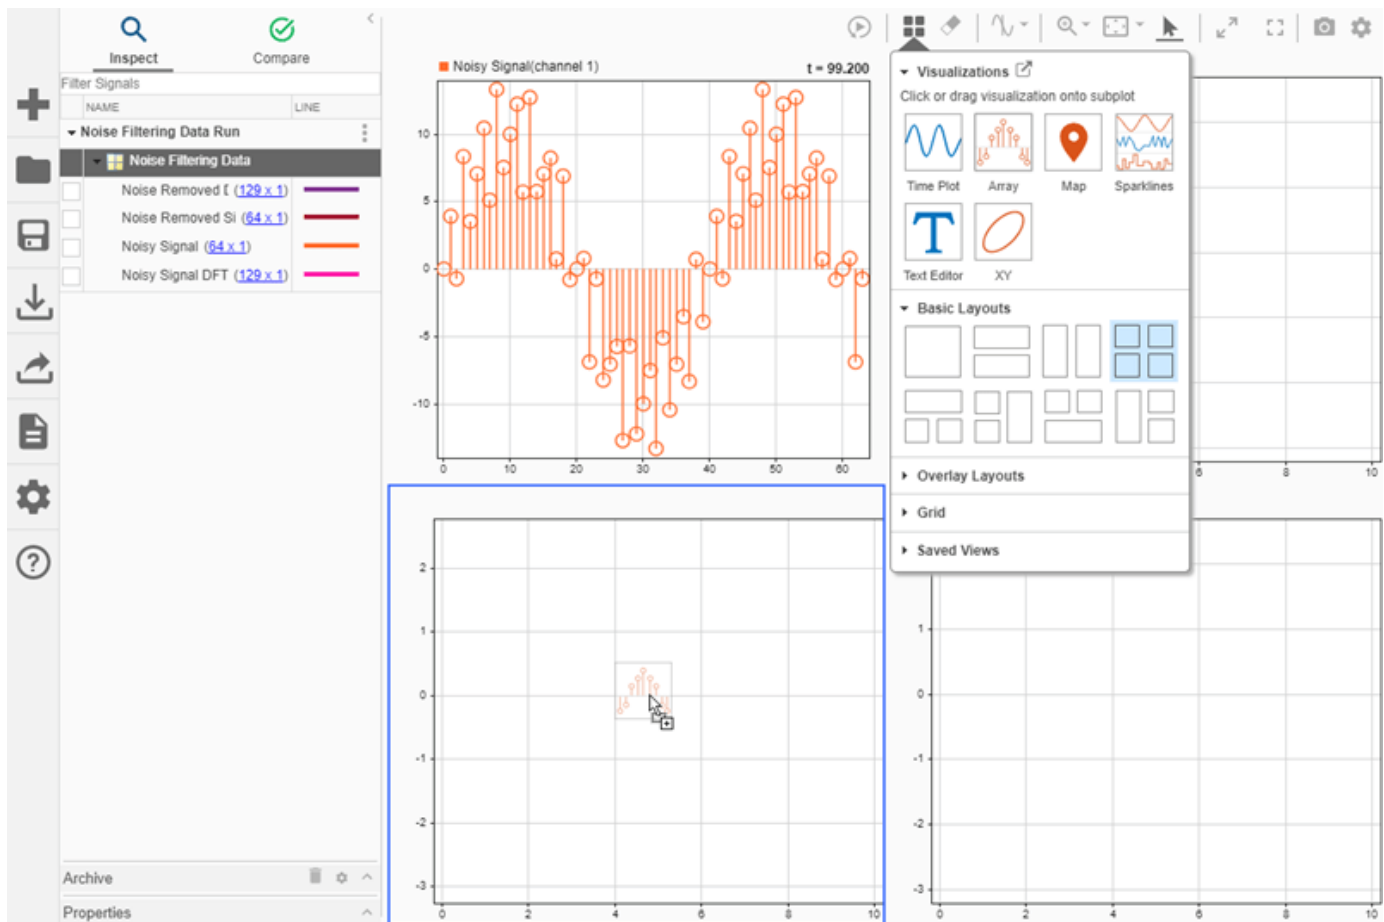

You can plot the other signals the same way as the first:

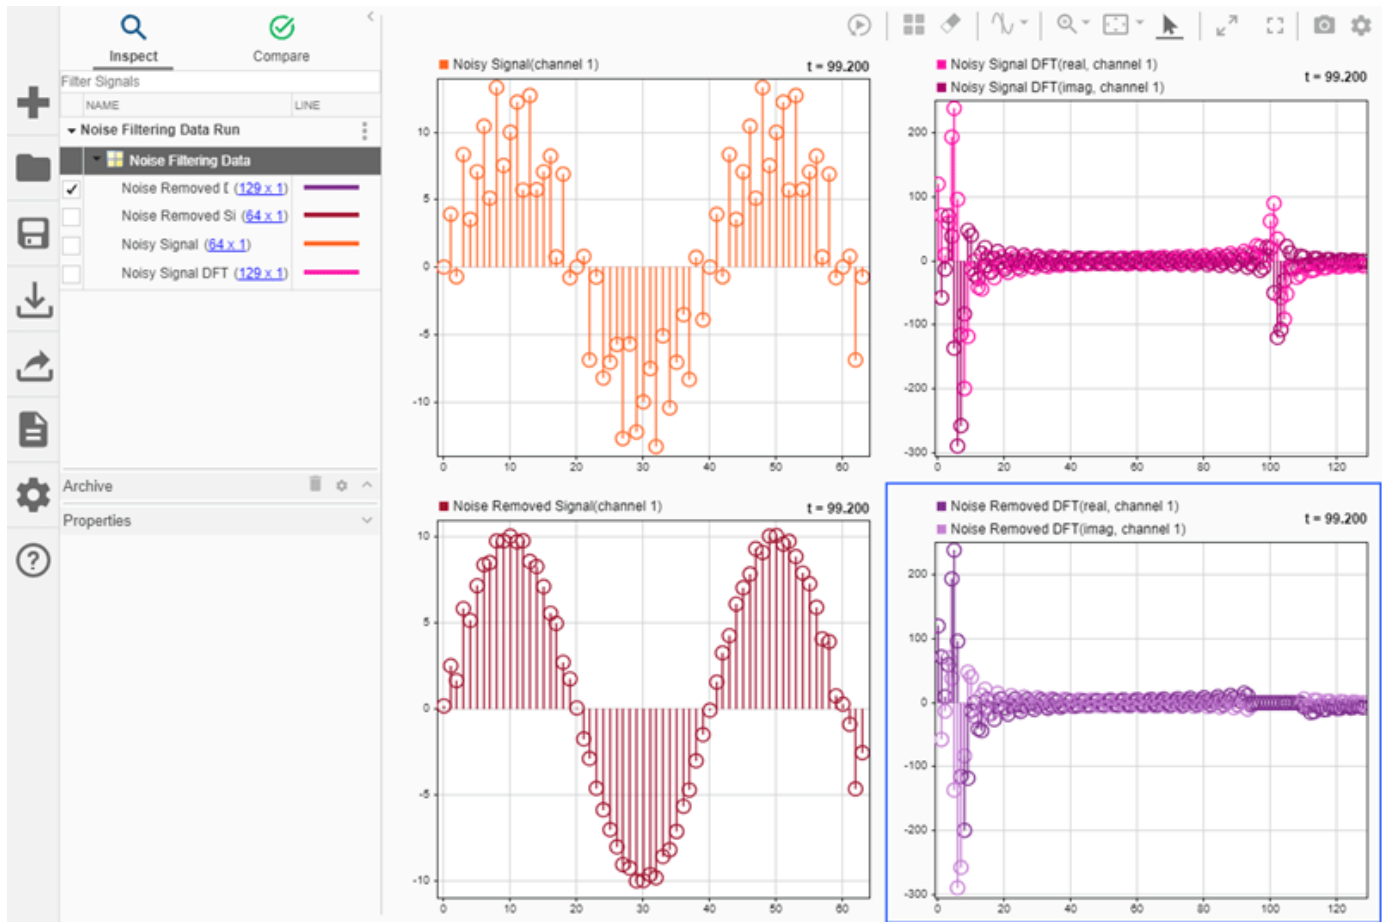

- 1 Select the subplot where you want to plot the signal.
- 2 Select the check box next to the signal you want to plot.
- 3 Select the option to change the active subplot to an array plot.
- 4 Click **OK**.

You can also manually change the time plots to array plots then plot the signals using the check boxes in the table.

To manually change a time plot to an array plot, click Visualizations and layouts  , then click or drag the **Array** icon onto a subplot.

Using either strategy, plot the remaining signals so the time-domain signals are on the left and the frequency-domain data is on the right. In the time domain, you can see the sine wave is smoother after the frequency domain processing. In the frequency domain, you can see the peak that corresponds to the high-frequency noise and its removal.

### Modify Array Plot Appearance

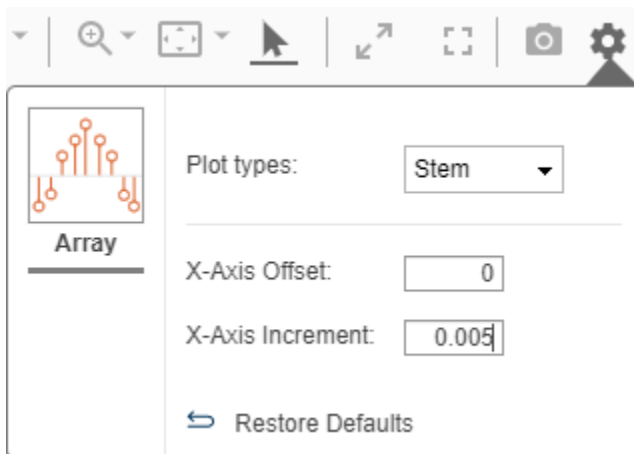

Using the array plot settings, you can change the plot type and control the values on the x-axis by specifying an offset and an increment value that defines the space between values on the x-axis. For example, change the settings for the time domain plots to better suit the plotted data.

By default, the array plot uses a stem plot type. Because the frequency domain data is discrete, a stem plot is well-suited. The time domain data represents an analog signal that is sampled, which is better represented as a stair plot. You can change the plot type using the subplot menu. To change the Noisy Signal and Noise Removed Signal array plot types to stair:

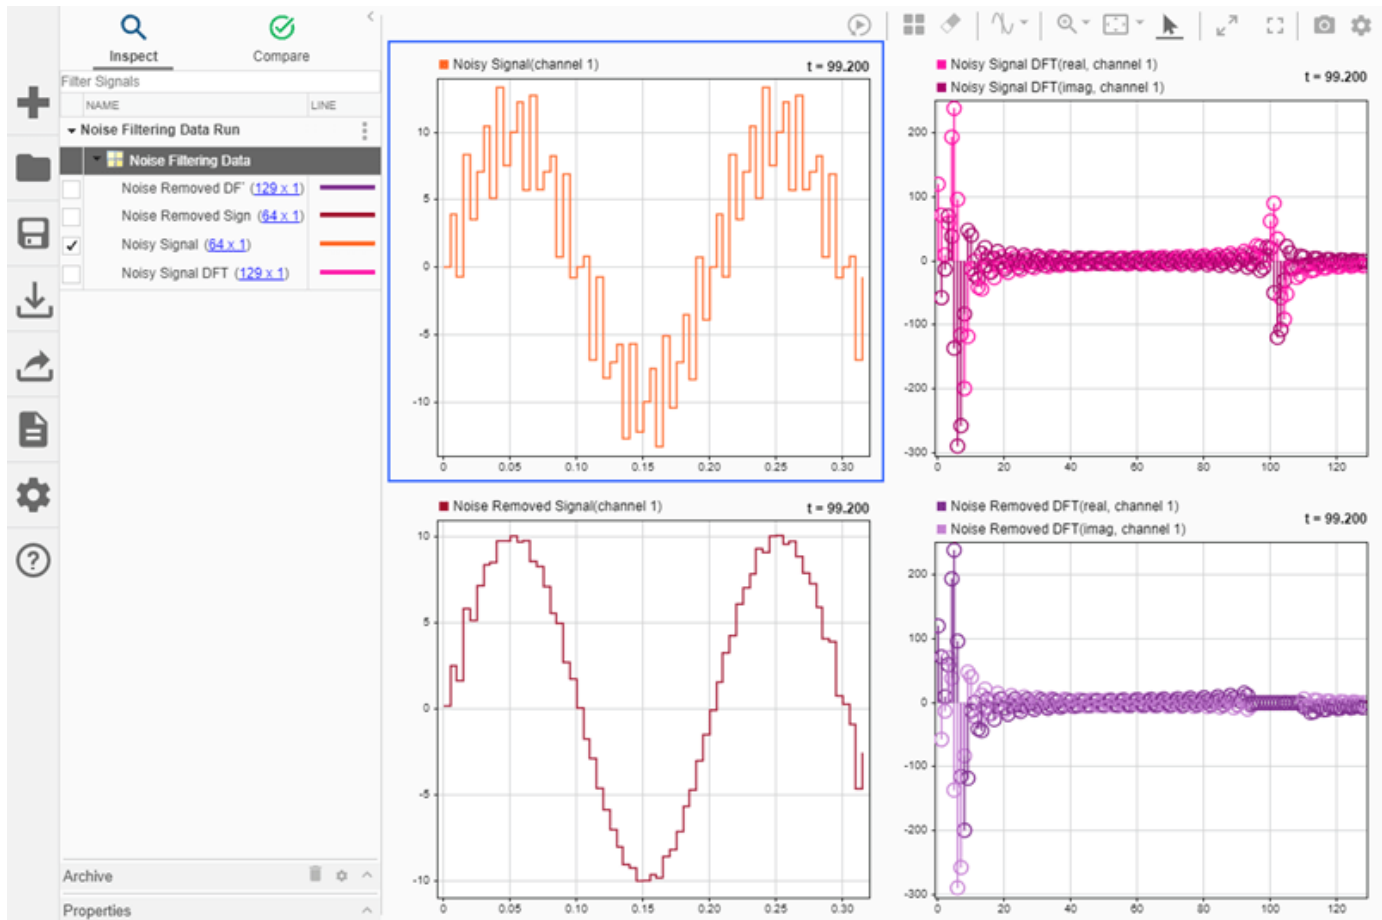

- 1 Pause on the subplot.
- 2 Click the three dots that appear.
- 3 Expand the Plot Type list and select Stair.

Next, adjust the x-axes for the time domain plots to accurately reflect the relative sample times for each frame. Using the Visualization Settings for the array plot, change the x-axis increment to match the sample rate of  $0.005\text{s}$  used to generate the data. First, select the subplot you want to modify, then click Visualization Settings  and specify the **X-Axis Increment** as  $0.005$ .

The x-axis labels update to indicate that each frame represents a bit more than 300ms of signal data.

You can also modify the appearance of the array plot by modifying properties on the plotted signal. Using the **Properties** pane, you can modify:

- The signal name, which appears in the legend.
- The line style and color.
- The format used to display complex data.

The frequency domain data is complex. By default, complex data is displayed in real-imaginary format, and the array plot uses different shades of the same color to display the real and imaginary components. You can control how complex data is plotted by changing the **Complex Format** parameter for the signal. To change the **Complex Format** for the Noisy Signal DFT and Noise Removed DFT signals to Magnitude:

- 1 Select the row for the signal in the table.
- 2 Expand the **Properties** pane.
- 3 From the **Complex Format** list, select Magnitude.

### Analyze Multidimensional Data Over Time

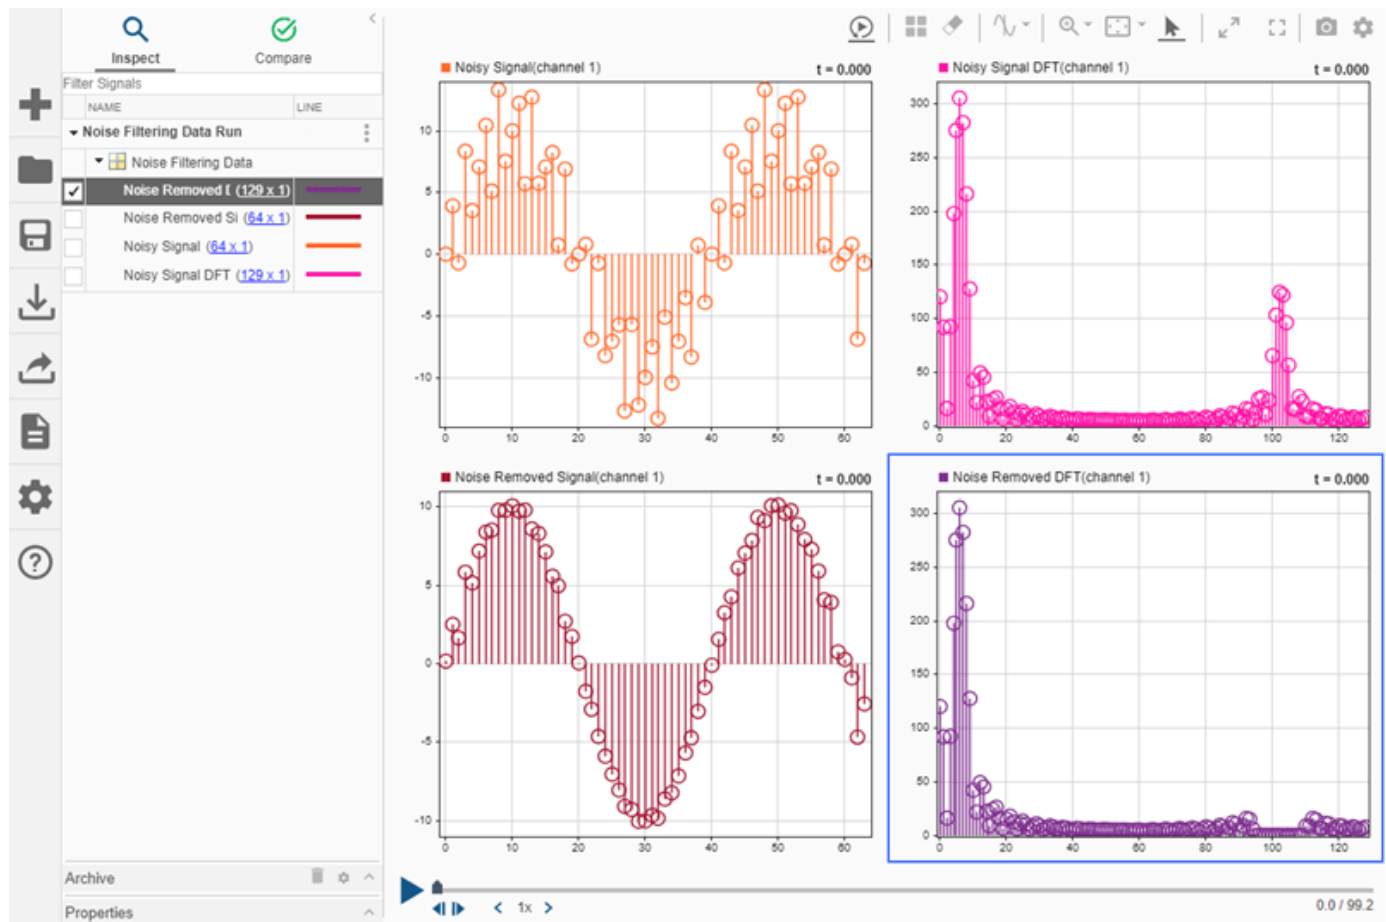

The array plot provides a two-dimensional representation of one sample of a multidimensional signal, plotting the values in a column evenly spaced along the  $x$ -axis. The signals also have a time component, and the data in each multidimensional sample can vary with time.

When a view contains visualizations that support cursors, the array plot synchronizes with the cursor to display the sample that corresponds to the cursor position in time. You can also use the replay controls to analyze the sample values on an array plot over time.

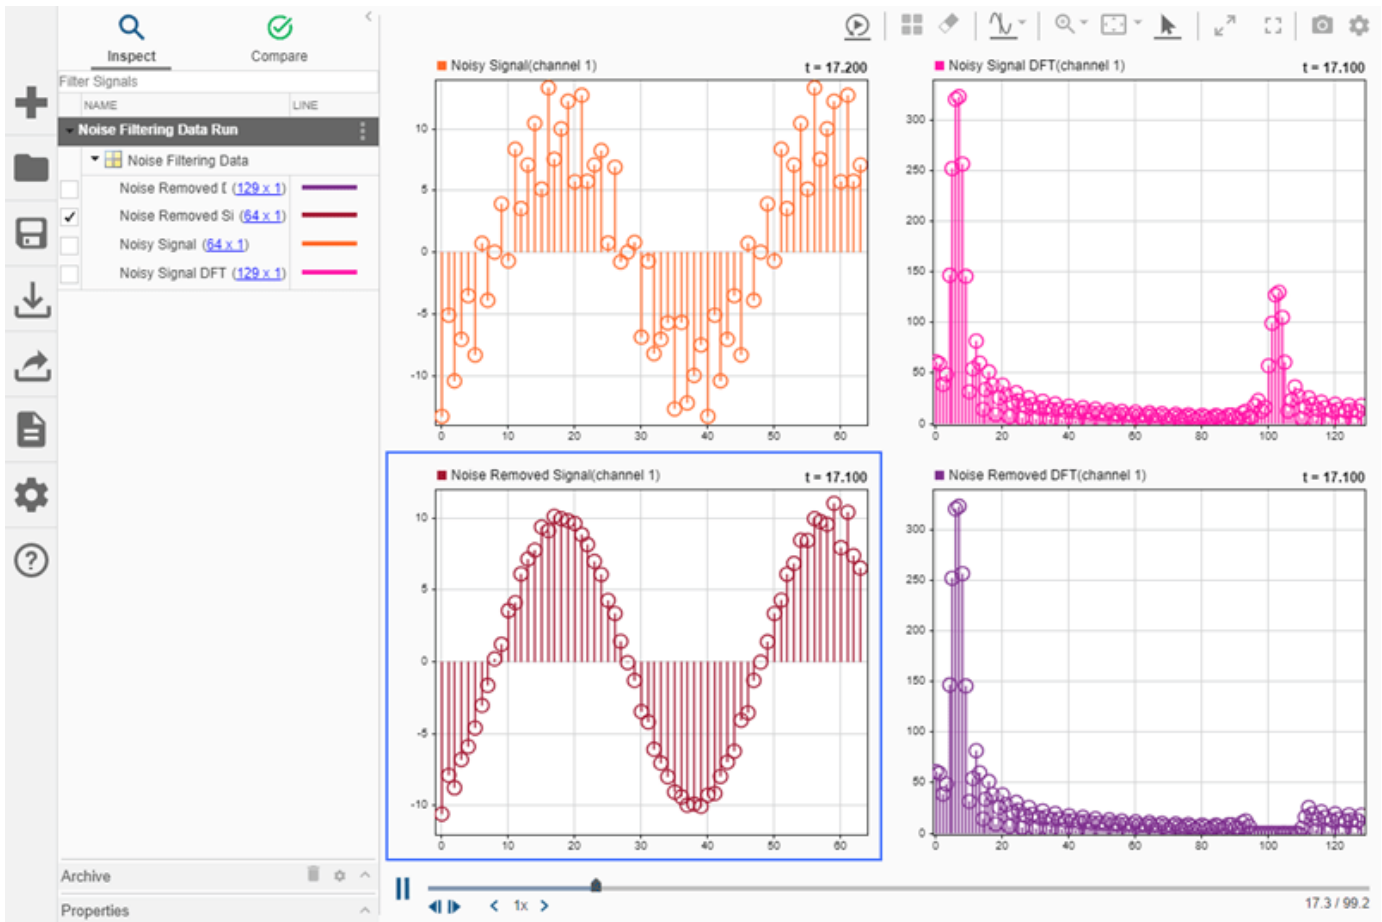

The array plot indicates the time that corresponds to the plotted sample in the upper-right of the plot. By default, the array plot displays the last sample of data. When you enable the replay controls, the array plots update to display the sample value for the first time point. To show the replay controls,

click Show/hide replay controls

You can manually control which sample is displayed on the plots using the Step forward  and Step backward  buttons or by dragging the progress indicator . To replay the data, click Replay .

The replay sweeps through the sample values at a rate you can adjust using the Decrease replay speed  $\leftarrow$  and Increase replay speed  $\rightarrow$  buttons on either side of the replay speed or specify by clicking the replay speed  $1x$  and entering a new value. By default, the replay updates plots at a rate of one second per second, meaning that the cursor moves through one second of data in one second of clock time.

As the plots update, you can see how the sine wave shifts within each frame and how that affects the results of the DFT.

`Simulink.sdi.Run.create`

### Tools

**Simulation Data Inspector**

## More About

- “View Data in the Simulation Data Inspector” on page 31-2

## Microsoft Excel Import, Export, and Logging Format

Using the Simulation Data Inspector or Simulink Test, you can import data from a Microsoft Excel file or export data to a Microsoft Excel file. You can also log data to an Excel file using the Record block. The Simulation Data Inspector, Simulink Test, and the Record block all use the same file format, so you can use the same Microsoft Excel file with multiple applications.

---

**Tip** When the format of the data in your Excel file does not match the specification in this topic, you can write your own file reader to import the data using the `io.reader` class.

---

### Basic File Format

In the simplest format, the first row in the Excel file is a header that lists the names of the signals in the file. The first column is time. The name for the time column must be `time`, and the time values must increase monotonically. The rows below the signal names list the signal values that correspond to each time step.

	A	B	C	D
1	<code>time</code>	<code>signal1</code>	<code>signal2</code>	<code>signal3</code>
2	0	1	1	4
3	1	2	4	8
4	2	3	9	15
5	3	3	9	16
6	3	4	16	23
7	4	5	25	42

The import operation does not support time data that includes `Inf` or `NaN` values or signal data that includes `Inf` values. Empty or `NaN` signal values imported from the Excel file render as missing data in the Simulation Data Inspector. All built-in data types are supported.

### Multiple Time Vectors

When your data includes signals with different time vectors, the file can include more than one time vector. Every time column must be named `time`. Time columns specify the sample times for signals to the right, up to the next time vector. For example, the first time column defines the time for `signal1` and `signal2`, and the second time column defines the time steps for `signal3`.

	A	B	C	D	E
1	<code>time</code>	<code>signal1</code>	<code>signal2</code>	<code>time</code>	<code>signal3</code>
2	0	1	1	0	4
3	1	2	4	2	8
4	2	3	9	3	15
5	3	3	9	5	16
6	3	4	16		
7	4	5	25		

Signal columns must have the same number of data points as the associated time vector.

## Signal Metadata

The file can include metadata for signals such as data type, units, and interpolation method. The metadata is used to determine how to plot the data, how to apply unit and data conversions, and how to compute comparison results. For more information about how metadata is used in comparisons, see “How the Simulation Data Inspector Compares Data” on page 31-204.

Metadata for each signal is listed in rows between the signal names and the signal data. You can specify any combination of metadata for each signal. Leave a blank cell for signals with less specified metadata.

	A	B	C	D	E
1	time	signal1	signal2	time	signal3
2		Interp: zoh			Interp: zoh
3		Type: int8	Type: int32		
4		Unit: m			Unit: m/s
5	0	1	1	0	4
6	1	2	4	2	8
7	2	3	9	3	15
8	3	3	9	5	16
9	3	4	16		
10	4	5	25		

Label each piece of metadata according to this table. The table also indicates which tools and operations support each piece of metadata. When an imported file does not specify signal metadata, double data type, linear interpolation, and union synchronization are used.

**Property Descriptions**

<b>Signal Property</b>	<b>Label</b>	<b>Values</b>	<b>Simulation Data Inspector Import</b>	<b>Record Block Logging and Simulation Data Inspector Export</b>	<b>Simulink Test Import and Export</b>
Data type	Type:	Built-in data type.	<b>Supported</b>	<b>Supported</b>	<b>Supported</b>
Units	Unit:	Supported unit. For example, Unit: m/s specifies units of meters per second.  For a list of supported units, enter showunitslist in the MATLAB Command Window.	<b>Supported</b>	<b>Supported</b>	<b>Supported</b>
Interpolation method	Interp:	linear, zoh for zero order hold, or none.	<b>Supported</b>	<b>Supported</b>	<b>Supported</b>

## User-Defined Data Types

In addition to built-in data types, you can use other labels in place of the `DataType: label` to specify fixed-point, enumerated, alias, and bus data types.

**Property Descriptions**

<b>Data Type</b>	<b>Label</b>	<b>Values</b>	<b>Simulation Data Inspector Import</b>	<b>Record Block Logging and Simulation Data Inspector Export</b>	<b>Simulink Test Import and Export</b>
Enumeration	Enum:	Name of the enumeration class.	<b>Supported</b> <i>Enumeration class definition must be saved on the MATLAB path.</i>	<b>Supported</b> <i>Enumeration class definition must be saved on the MATLAB path.</i>	<b>Supported</b> <i>Enumeration class definition must be saved on the MATLAB path.</i>
Alias	Alias:	Name of a Simulink.AliasType object in the MATLAB workspace.	<b>Supported</b> <i>For matrix and complex signals, specify the alias data type on the first channel.</i>	<b>Not Supported</b>	<b>Supported</b> <i>For matrix and complex signals, specify the alias data type on the first channel.</i>
Fixed-point	Fixdt:	<ul style="list-style-type: none"> <li>fixdt constructor.</li> <li>Name of a Simulink.NumericType object in the MATLAB workspace.</li> <li>Name of a fixed-point data type as described in “Fixed-Point Numbers in Simulink” (Fixed-Point Designer).</li> </ul>	<b>Supported</b>	<b>Not Supported</b>	<b>Supported</b>
Bus	Bus:	Name of a Simulink.Bus object in the MATLAB workspace.	<b>Supported</b>	<b>Not Supported</b>	<b>Supported</b>

When you specify the type using the name of a Simulink.Bus object and the object is not in the MATLAB workspace, the data still imports from the file. However, individual signals in the bus use data types described in the file rather than data types defined in the Simulink.Bus object.

## Complex, Multidimensional, and Bus Signals

You can import and export complex, multidimensional, and bus signals using an Excel file. The signal name for a column of data indicates whether that data is part of a complex, multidimensional, or bus signal. Excel file import and export do not support array of bus signals.

Multidimensional signal names include index information in parentheses. For example, the signal name for a column might be `signal1(2,3)`. When you import data from a file that includes multidimensional signal data, elements in the data not included in the file take zero sample values with the same data type and complexity as the other elements.

Complex signal data is always in real-imaginary format. Signal names for columns containing complex signal data include `(real)` and `(imag)` to indicate which data each column contains. When you import data from a file that includes imaginary signal data without specifying values for the real component of that signal, the signal values for the real component default to zero.

Multidimensional signals can contain complex data. The signal name includes the indication for the index within the multidimensional signal and the real or imaginary tag. For example, `signal1(1,3) (real)`.

Dots in signal names specify the hierarchy for bus signals. For example:

- `bus.y.a`
- `bus.y.b`
- `bus.x`

	A	B	C	D	E
1	time	bus.y.a	bus.y.b	time	bus.x
2		Interp: zoh			Interp: zoh
3		Type: int8	Type: int32		
4		Unit: m			Unit: m/s
5	0	1	1	0	4
6	1	2	4	2	8
7	2	3	9	3	15
8	3	3	9	5	16
9	3	4	16		
10	4	5	25		

---

**Tip** When the name of your signal includes characters that could make it appear as though it were part of a matrix, complex signal, or bus, use the **Name** metadata option to specify the name you want the imported signal to use in the Simulation Data Inspector and Simulink Test.

---

## Function-Call Signals

Signal data specified in columns before the first time column is imported as one or more function-call signals. The data in the column specifies the times at which the function-call signal was enabled. The imported signals have a value of 1 for the times specified in the column. The time values for function-call signals must be double, scalar, and real, and must increase monotonically.

When you export data from the Simulation Data Inspector, function-call signals are formatted the same as other signals, with a time column and a column for signal values.

## Simulation Parameters

You can import data for parameter values used in simulation. In the Simulation Data Inspector, the parameter values are shown as signals. Simulink Test uses imported parameter values to specify values for those parameters in the tests it runs based on imported data.

Parameter data is specified using two or three columns. The first column specifies the parameter names, with the cell in the header row for that column labeled `Parameter:`. The second column specifies the value used for each parameter, with the cell in the header row labeled `Value:`. Parameter data may also include a third column that contains the block path associated with each parameter, with the cell in the header row labeled `BlockPath:`. Specify names, values, and block paths for parameters starting in the first row that contains signal data, below rows used to specify signal metadata. For example, this file specifies values for two parameters, X and Y.

	A	B	C	D	E	F	G
1	time	signal1	signal2	time	signal3	Parameter: Value:	
2		Interp: zoh			Interp: zoh		
3		Type: int8	Type: int32				
4		Unit: m			Unit: m/s		
5	0	1	1	0	4 X		2
6	1	2	4	2	8 Y		1.2
7	2	3	9	3	15		
8	3	3	9	5	16		
9	3	4	16				
10	4	5	25				

## Multiple Runs

You can include data for multiple runs in a single file. Within a sheet, you can divide data into runs by labeling data with a simulation number and a source type, such as `Input` or `Output`. Specify the simulation number and source type as additional signal metadata, using the label `Simulation:` for the simulation number and the label `Source:` for the source type. The Simulation Data Inspector uses the simulation number and source type only to determine which signals belong in each run. Simulink Test uses the information to define inputs, parameters, and acceptance criteria for tests to run based on imported data.

You do not need to specify the simulation number and output type for every signal. Signals to the right of a signal with a simulation number and source use the same simulation number and source until the next signal with a different source or simulation number. For example, this file defines data for two simulations and imports into four runs in the Simulation Data Inspector:

- **Run 1** contains `signal1` and `signal2`.
- **Run 2** contains `signal3`, X, and Y.
- **Run 3** contains `signal4`.

- **Run 4** contains signal5.

	A	B	C	D	E	F	G	H	I	J
1	time	signal1	signal2	time	signal3	Parameter:	Values:	time	signal4	signal5
2		Interp: zoh			Interp: zoh					
3		Type: int8	Type: int32							
4		Unit: m			Unit: m/s					
5		Simulation: 1							Simulation: 2	
6		Source: Input			Source: Output				Source: Input	Source: Output
7	0	1	1	0	4 X		2	1	2	1
8	1	2	4	2	8 Y		1.2	2	6	3
9	2	3	9	3	15			3	4	5
10	3	3	9	5	16			4	8	7
11	3	4	16					5	10	2
12	4	5	25							

You can also use sheets within the Microsoft Excel file to divide the data into runs and tests. When you do not specify simulation number and source information, the data on each sheet is imported into a separate run in the Simulation Data Inspector. When you export multiple runs from the Simulation Data Inspector, the data for each run is saved on a separate sheet. When you import a Microsoft Excel file that contains data on multiple sheets into Simulink Test, you are prompted to specify how to import the data.

## More About

- “View Data in the Simulation Data Inspector” on page 31-2
- “Import Data from a CSV File into the Simulation Data Inspector” on page 31-76
- “Import Data Using a Custom File Reader” on page 31-17

## Import Data from a CSV File into the Simulation Data Inspector

To import data into the Simulation Data Inspector from a CSV file, format the data in the CSV file. Then, you can import the data using the Simulation Data Inspector UI or the `Simulink.sdi.createRun` function.

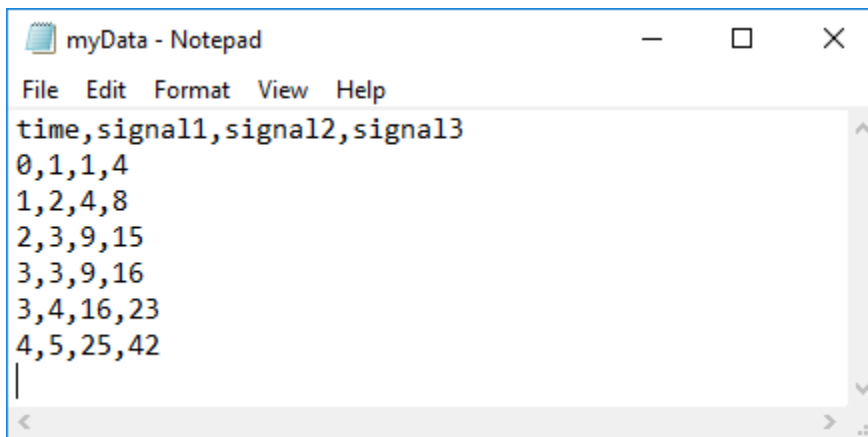

---

**Tip** When you want to import data from a CSV file where the data is formatted differently from the specification in this topic, you can write your own file reader for the Simulation Data Inspector using the `io.reader` class.

---

### Basic File Format

In the simplest format, the first row in the CSV file is a header that lists the names of the signals in the file. The first column is time. The name for the time column must be `time`, and the time values must increase monotonically. The rows below the signal names list the signal values that correspond to each time step.

```
myData - Notepad
File Edit Format View Help
time,signal1,signal2,signal3
0,1,1,4
1,2,4,8
2,3,9,15
3,3,9,16
3,4,16,23
4,5,25,42
```

The import operation does not support time data that includes `Inf` or `NaN` values or signal data that includes `Inf` values. Empty or `NaN` signal values render as missing data. All built-in data types are supported.

### Multiple Time Vectors

When your data includes signals with different time vectors, the file can include more than one time vector. Every time column must be named `time`. Time columns specify the sample times for signals to the right, up to the next time vector. For example, the first time column defines the time for `signal1` and `signal2`, and the second time column defines the time steps for `signal3`.

```

myData - Notepad
File Edit Format View Help
time,signal1,signal2,time,signal3
0,1,1,0,4
1,2,4,2,8
2,3,9,3,15
3,3,9,5,16
3,4,16
4,5,25

```

Signal columns must have the same number of data points as the associated time vector.

## Signal Metadata

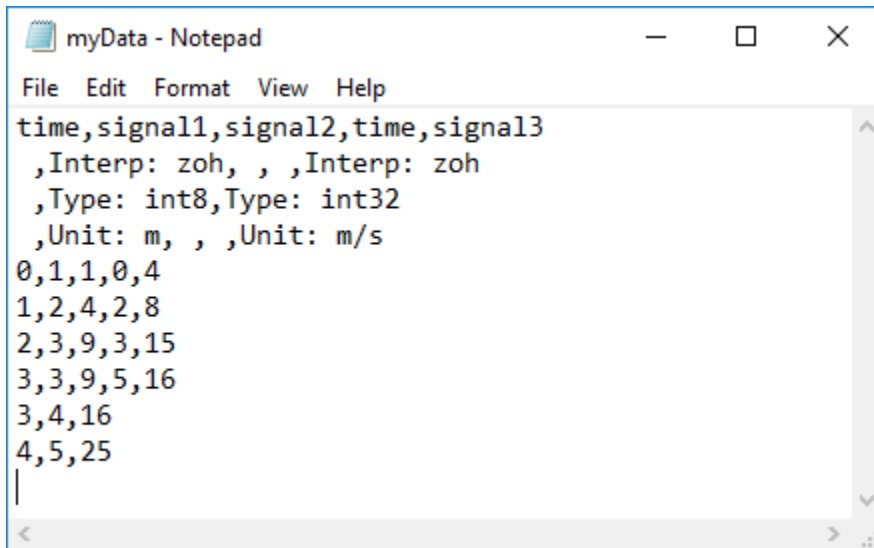

You can specify signal metadata in the CSV file to indicate the signal data type, units, interpolation method, block path, and port index. List metadata for each signal in rows between the signal name and the signal data. Label metadata according to this table.

Signal Property	Label	Value
Data type	Type:	Built-in data type.
Units	Unit:	Supported unit. For example, Unit: m/s specifies units of meters per second.  For a list of supported units, enter <code>showunitslist</code> in the MATLAB Command Window.
Interpolation method	Interp:	linear, zoh for zero order hold, or none.
Block Path	BlockPath:	Path to the block that generated the signal.
Port Index	PortIndex:	Integer.

You can also import a signal with a data type defined by an enumeration class. Instead of using the Type: label, use the Enum: label and specify the value as the name of the enumeration class. The definition for the enumeration class must be saved on the MATLAB path.

When an imported file does not specify signal metadata, the Simulation Data Inspector assumes double data type and linear interpolation. You can specify the interpolation method as linear, zoh (zero-order hold), or none. If you do not specify units for the signals in your file, you can assign units to the signals in the Simulation Data Inspector after you import the file.

You can specify any combination of metadata for each signal. Leave a blank cell for signals with less specified metadata.

```
myData - Notepad
File Edit Format View Help
time,signal1,signal2,time,signal3
,Interp: zoh, , ,Interp: zoh
,Type: int8,Type: int32
,Unit: m, , ,Unit: m/s
0,1,1,0,4
1,2,4,2,8
2,3,9,3,15
3,3,9,5,16
3,4,16
4,5,25
|
```

## Import Data from a CSV File

You can import data from a CSV file using the Simulation Data Inspector UI or using the `Simulink.sdi.createRun` function.

To import data using the UI, open the Simulation Data Inspector using the `Simulink.sdi.view` function or the **Data Inspector** button in the Simulink™ toolstrip. Then, click the **Import** button.

In the Import dialog, select the option to import data from a file and navigate in the file system to select the file. After you select the file, data available for import shows in the table. You can choose which signals to import and whether to import them to a new or existing run. This example imports all available signals to a new run. After selecting the options, click the **Import** button.

When you import data into a new run using the UI, the new run name includes the run number followed by `Imported_Data`.

When you import data programmatically, you can specify the name of the imported run.

```
csvRunID = Simulink.sdi.createRun('CSV File Run', 'file', 'csvExampleData.csv');
```

- “Microsoft Excel Import, Export, and Logging Format” on page 31-68
- “Import Data Using a Custom File Reader” on page 31-17

## Configure the Simulation Data Inspector

The Simulation Data Inspector supports a wide range of use cases for analyzing and visualizing data. You can modify preferences in the Simulation Data Inspector to match your visualization and analysis requirements. The preferences that you specify persist between MATLAB sessions.

By specifying preferences in the Simulation Data Inspector, you can configure options such as:

- How signals and metadata are displayed.
- Which data automatically imports from parallel simulations.
- Where prior run data is retained and how much prior data to store.
- How much memory is used during save operations.
- The system of units used to display signals.

To open the Simulation Data Inspector preferences, click Preferences.

---

**Note** You can restore all preferences in the Simulation Data Inspector to default values by clicking **Restore Defaults** in the Preferences menu or by using the `Simulink.sdi.clearPreferences` function.

---

### Logged Data Size and Location

By default, simulation data logs to disk with data loaded into memory on demand, and the maximum size of logged data is constrained only by available disk space. You can use the **Disk Management** settings in the Simulation Data Inspector to directly control the size and location of logged data.

The **Record mode** setting specifies whether logged data is retained after simulation. When you change the **Record mode** setting to **View during simulation only**, no logged data is available in the Simulation Data Inspector or the workspace after the simulation completes. Only use this mode when you do not want to save logged data. The **Record mode** setting reverts to **View and record data** each time you start MATLAB. Changing the **Record mode** setting can affect other applications, such as visualization tools. For details, see “View Data Only During Simulation” on page 77-26.

To directly limit the size of logged data, you can specify a minimum amount of free disk space or a maximum size for the logged data. By default, logged data must leave at least 100 MB of free disk space with no maximum size limit. Specify the required disk space and maximum size in GB, and specify 0 to apply no disk space requirement or no maximum size limit.

When you specify a minimum disk space requirement or a maximum size for logged data, you can also specify whether to prioritize retaining data from the current simulation or data from prior simulations when approaching the limit. By default, the Simulation Data Inspector prioritizes retaining data for the current run by deleting data for prior runs. To prioritize retaining prior data, change the **When low on disk space** setting to **Keep prior runs and stop recording**. You see a warning message when prior runs are deleted and when recording is disabled. If recording is disabled due to the size of logged data, you need to change the **Record Mode** back to **View and**

**record data** to continue logging data, after you have freed up disk space. For more information, see “Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data” on page 77-25.

The **Storage Mode** setting specifies whether to log data to disk or to memory. By default, data logs to disk. When you configure a parallel worker to log data to memory, data transfer back to the host is not supported. Logging data to memory is not supported for rapid accelerator simulations or models deployed using Simulink Compiler™.

You can also specify the location of the temporary file that stores logged data. By default, data logs to the temporary files directory on your computer. You may change the file location when you need to log large amounts of data and a secondary drive provides more storage capacity. Logging data to a network location can degrade performance.

### Programmatic Use

You can programmatically configure and check each preference value.

Preference	Functions
<b>Record mode</b>	Simulink.sdi.setRecordData Simulink.sdi.getRecordData
<b>Required Free Space</b>	Simulink.sdi.setRequiredFreeSpace Simulink.sdi.getRequiredFreeSpace
<b>Max Disk Usage</b>	Simulink.sdi.setMaxDiskUsage Simulink.sdi.getMaxDiskUsage
<b>When low on disk space</b>	Simulink.sdi.setDeleteRunsOnLowSpace Simulink.sdi.getDeleteRunsOnLowSpace
<b>Storage Mode</b>	Simulink.sdi.setStorageMode Simulink.sdi.getStorageMode
<b>Storage Location</b>	Simulink.sdi.setStorageLocation Simulink.sdi.getStorageLocation

### Archive Behavior and Run Limit

When you run multiple simulations in a single MATLAB session, the Simulation Data Inspector retains results from each simulation so you can analyze the results together. Use the Simulation Data Inspector archive to manage runs in the user interface and control the number of runs the Simulation Data Inspector retains.

You can configure a limit for the number of runs to retain in the archive and whether the Simulation Data Inspector automatically moves prior runs into the archive.

## Manage Runs Using the Archive

By default, the Simulation Data Inspector automatically archives simulation runs. When you simulate a model, the prior simulation run moves to the archive, and the Simulation Data Inspector updates the view to show data for aligned signals in the current run.

The archive does not impose functional limitations on the runs and signals it contains. You can plot signals from the archive, and you can use runs and signals in the archive in comparisons. You can drag runs of interest from the archive to the work area and vice versa whether **Automatically Archive** is selected or disabled.

To prevent the Simulation Data Inspector from automatically moving prior simulations runs to the archive, clear the **Automatically archive** setting. With automatic archiving disabled, the Simulation Data Inspector does not move prior runs into the **Archive** pane or automatically update plots to display data from the current simulation.

---

**Tip** To manually delete the contents of the archive, click Delete archived runs .

---

## Control Number of Runs Retained in Simulation Data Inspector

You can specify a limit for the number of runs to retain in the archive. When the number of runs in the archive reaches the limit, the Simulation Data Inspector deletes runs in the archive on a first-in, first-out basis.

The run limit applies only to runs in the archive. For the Simulation Data Inspector to automatically limit the data it retains by deleting old runs, select **Automatically archive** and specify a size limit.

By default, the Simulation Data Inspector retains the last 20 runs moved to the archive. To remove the limit, select **No limit**. To specify the maximum number of runs to store in the archive, select **Last n runs** and enter the limit. A warning occurs if you specify a limit that would delete runs already in the archive.

## Programmatic Use

You can programmatically configure and check the archive behavior and run limit.

Preference	Functions
<b>Automatically archive</b>	<code>Simulink.sdi.setAutoArchiveMode</code> <code>Simulink.sdi.getAutoArchiveMode</code>
<b>Size</b>	<code>Simulink.sdi.setArchiveRunLimit</code> <code>Simulink.sdi.getArchiveRunLimit</code>

## Incoming Run Names and Location

You can configure how the Simulation Data Inspector handles incoming runs from import or simulation. You can choose whether new runs are added at the top of the work area or the bottom and specify a naming rule to use for runs created from simulation.

By default, the Simulation Data Inspector adds new runs below prior runs in the work area. The **Archive** settings also affect the location of runs. By default, prior runs are moved to the archive when a new simulation run is created.

The run naming rule is used to name runs created from simulation. You can create the run naming rule using a mix of literal text that is used in the run name as-is and one or more tokens that represent metadata about the run. By default, the Simulation Data Inspector names runs using the run index and model name: Run <run\_index>: <model\_name>.

---

**Tip** To rename an existing run, double-click the name in the work area and enter the new name, or modify the run name in the **Properties** pane.

---

### Programmatic Use

You can programmatically configure and check incoming run names and locations.

Preference	Functions
<b>Add New Runs</b>	Simulink.sdi.appendRunToTop Simulink.sdi.getAppendRunToTop
<b>Naming Rule</b>	Simulink.sdi.setRunNamingRule Simulink.sdi.getRunNamingRule Simulink.sdi.resetRunNamingRule

### Signal Metadata to Display

You can control which signal metadata is displayed in the work area of the **Inspect** pane and in the results section on the **Compare** pane in the Simulation Data Inspector. You specify the metadata to display separately for each pane using the **Table Columns** preferences in the **Inspect** and **Compare** sections of the Preferences dialog, respectively.

#### Inspect Pane

By default, the signal name and the line style and color used to plot the signal are displayed on the **Inspect** pane. To display different or additional metadata in the work area on the **Inspect** pane, select the check box next to each piece of metadata you want to display in the **Table Columns** preference in the **Inspect** section. You can always view complete metadata for the selected signal in the **Inspect** pane using the **Properties** pane.

---

**Note** Metadata displayed in the work area on **Inspect** pane is included when you generate a report of plotted signals. You can also specify metadata to include in the report regardless of what is displayed in the work area when you create the report programmatically using the `Simulink.sdi.report` function.

---

## Compare Pane

By default, the **Compare** pane shows the signal name, the absolute and relative tolerances used in the signal comparison, and the maximum difference from the comparison result. To display different or additional metadata in the results on the **Compare** pane, select the check box next to each piece of metadata you want to display in the **Table Columns** preference in the **Compare** section. You can always view complete metadata for the signals compared for a selected signal result using the **Properties** pane, where metadata that differs between the compared signals is highlighted. Signal metadata displayed on the **Compare** pane does not affect the contents of comparison reports.

## Signal Selection on the Inspect Pane

You can configure how you select signals to plot on the selected subplot in the Simulation Data Inspector. By default, you use check boxes next to each signal to plot. You can also choose to plot signals based on selection in the work area. Use **Check Mode** when creating views and visualizations that represent findings and analysis of a data set. Use **Browse Mode** to quickly view and analyze data sets with a large number of signals.

For more information about creating visualizations using **Check Mode**, see “Create Plots Using the Simulation Data Inspector” on page 31-152.

For more information about using **Browse Mode**, see “Visualize Many Logged Signals” on page 31-115.

---

**Note** To use **Browse Mode**, your layout must include only **Time Plot** visualizations.

---

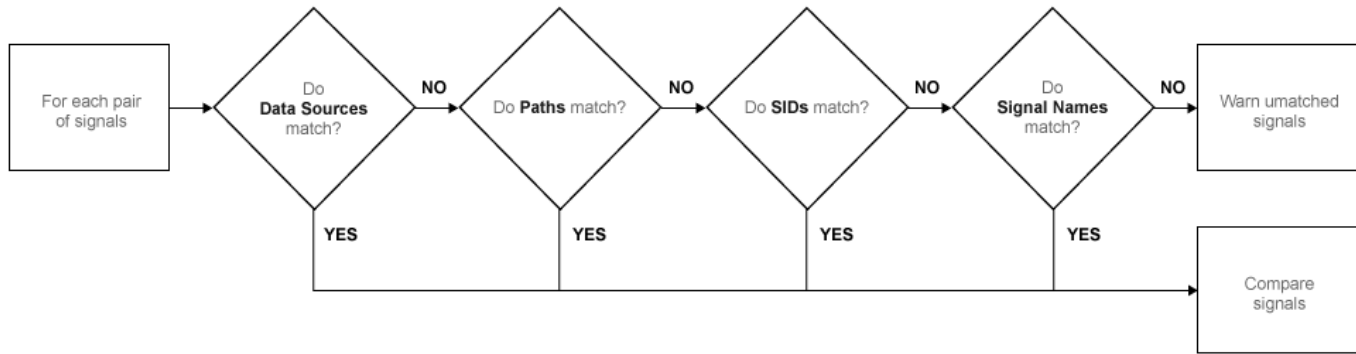

## How Signals Are Aligned for Comparison

When you compare runs using the Simulation Data Inspector, the comparison algorithm pairs signals for signal comparison through a process called alignment. You can align signals between the compared runs using one or more of the signal properties shown in the table.

Property	Description
Data Source	Path of the variable in the MATLAB workspace for data imported from the workspace
Path	Block path for the source of the data in its model
SID	Automatically assigned Simulink identifier
Signal Name	Name of the signal

You can specify the priority for each piece of metadata used for alignment. The **Align By** field specifies the highest priority property used to align signals. The priority drops with each subsequent **Then By** field. You must specify a primary alignment property in the **Align By** field, but you can leave any number of **Then By** fields blank.

By default, the Simulation Data Inspector aligns signals between runs according to this flow chart.

For more information about configuring comparisons in the Simulation Data Inspector, see “How the Simulation Data Inspector Compares Data” on page 31-204.

## Colors Used to Display Comparison Results

You can configure the colors used to display comparison results using the Simulation Data Inspector preferences. You can specify whether to use the signal color from the **Inspect** pane or a fixed color for the baseline and compared signals. You can also choose colors for the tolerance and the difference signal.

By default, the Simulation Data Inspector displays comparison results using fixed colors for the baseline and compared signals. Using a fixed color allows you to avoid the baseline signal color and compared signal color being either the same or too similar to distinguish.

## Signal Grouping

You can specify how to group signals within a run in the Simulation Data Inspector. The preferences apply to both the **Inspect** and **Compare** panes and comparison reports. You can group signals by:

- Domain — Signal type. For example, signals created by signal logging have a domain of **Signal**, while signals created from logging model outputs have a domain of **Outputs**.
- Physical System Hierarchy — Signal Simscape physical system hierarchy. The option to group by physical system hierarchy is available when you have a Simscape license.
- Data Hierarchy — Signal location within structured data. For example, data hierarchy grouping reflects the hierarchy of a bus.
- Model Hierarchy — Signal location within model hierarchy. Grouping by model hierarchy can be helpful when you log data from a model that includes model or subsystem references.

Grouping signals adds rows for the hierarchical nodes, which you can expand to show the signals within that node. By default, the Simulation Data Inspector groups signals by domain, then by physical system hierarchy (if you have a Simscape license), and then by data hierarchy.

To remove grouping and display a flat list of signals in each run, select **None** for all grouping options.

## Programmatic Use

To specify how to group signals programmatically, use the `Simulink.sdi.setTableGrouping` function.

## Data to Stream from Parallel Simulations

When you run parallel simulations using the `parsim` function, you can stream logged simulation data to the Simulation Data Inspector. A dot next to the run name in the **Inspect** pane indicates the status of the simulation that corresponds to the run, so you can monitor simulation progress while visualizing the streamed data. You can control whether data streams from a parallel simulation based on the type of worker the data comes from.

By default, the Simulation Data Inspector is configured for manual import of data from parallel workers. You can use the Simulation Data Inspector programmatic interface to inspect the data on the worker and decide whether to send it to the client Simulation Data Inspector for further analysis. To manually move data from a parallel worker to the Simulation Data Inspector, use the `Simulink.sdi.sendWorkerRunToClient` function.

You may want to automatically stream data from parallel simulations that run on local workers or on local and remote workers. Streaming data from both local and remote workers may affect simulation performance, depending on how many simulations you run and how much data you log. When you choose to stream data from local workers or all parallel workers, all logged simulation data automatically shows in the Simulation Data Inspector.

## Programmatic Use

You can configure Simulation Data Inspector support for parallel worker data programmatically using the `Simulink.sdi.enablePCTSupport` function.

## Options for Saving and Loading Session Files

You can specify a maximum amount of memory to use while loading or saving a session file. By default, the Simulation Data Inspector uses a maximum of 100 MB of memory when you load or save a session file. You can specify a memory use limit as low as 50 MB.

To reduce the size of the saved session file, you can specify a compression option.

- **None** — Do not compress saved data.
- **Normal** — Compress the saved file as much as possible.
- **Fastest** — Compress the saved file less than **Normal** compression for faster save time.

## Signal Display Units

Signals in the Simulation Data Inspector have two units properties: stored units and display units. The stored units represent the units of the data saved to disk. The display units specify how the Simulation Data Inspector displays the data. You can configure the Simulation Data Inspector to use a system of units to define the display units for all signals. You can choose either the **SI** or **US Customary** system of units, or you can display data using its stored units.

When you use a system of units to define display units for signals in the Simulation Data Inspector, the display units update for any signal with display units that are not valid for that unit system. For example, if you select **SI** units, the display units for a signal may update from ft to m.

---

**Note** The system of units you choose to use in the Simulation Data Inspector does not affect the stored units for any signal. You can convert the stored units for a signal using the `convertUnits` function. Conversion may result in loss of precision.

---

In addition to selecting a system of units, you can specify override units so that all signals of a given measurement type are displayed using consistent units. For example, if you want to visualize all signals that represent weight using units of kg, specify kg as an override unit.

---

**Tip** For a list of units supported by Simulink, enter `showunitslist` in the MATLAB Command Window.

---

You can also modify the display units for a specific signal using the **Properties** pane. For more information, see “Modify Signal Properties in the Simulation Data Inspector” on page 31-183.

### **Programmatic Use**

Configure the unit system and override units using the `Simulink.sdi.setUnitSystem` function. You can check the current units preferences using the `Simulink.sdi.getUnitSystem` function.

## **See Also**

## View Streaming Data in the Simulation Data Inspector

When streaming data to the Simulation Data Inspector, you can control how incoming data is displayed by specifying the behavior of the time axis. You can set a time span, choose how plot updates are drawn, and freeze the display to better view and analyze your streaming data. These options are helpful when working with real-time models or infinite simulation times or when you use simulation pacing to interact with the system. You can also use triggers to control when to draw the plot of a streaming signal in the Simulation Data Inspector. For more information, see “Control Display of Streaming Data Using Triggers” on page 31-97.

This example shows you how to control the time axis, display scaling, and display offset to better visualize your streaming data.

### Open and Simulate the Model

This model generates four logged signals: Sine Wave, Pulse, Sawtooth and Output. The Switch block is configured to allow the sine signal to pass through when the output of the Pulse Generator block is greater than zero. When the output of the Pulse Generator block is less than or equal to zero, the Switch block allows the sawtooth signal to pass through.

The model uses simulation pacing to slow down the simulation, which allows you to interact with the system. For more information, see “Simulation Pacing” on page 2-18.

- 1 Click **Run** to start a simulation.
- 2 When the simulation has finished, click **Data Inspector** to open the Simulation Data Inspector.
- 3 Plot the Output signal in the upper subplot.
- 4 Plot the Sawtooth and Sine Wave signals in the lower subplot.

By default, the Simulation Data Inspector groups signals by domain. The **Signals** grouping contains the output of the Pulse Generator block, the Signal Generator block, and the Sine Wave block. The **Outputs** grouping contains the logged model output from the Switch block. When you plot a signal after the simulation completes, the Simulation Data Inspector fits the view to display all the signal data.

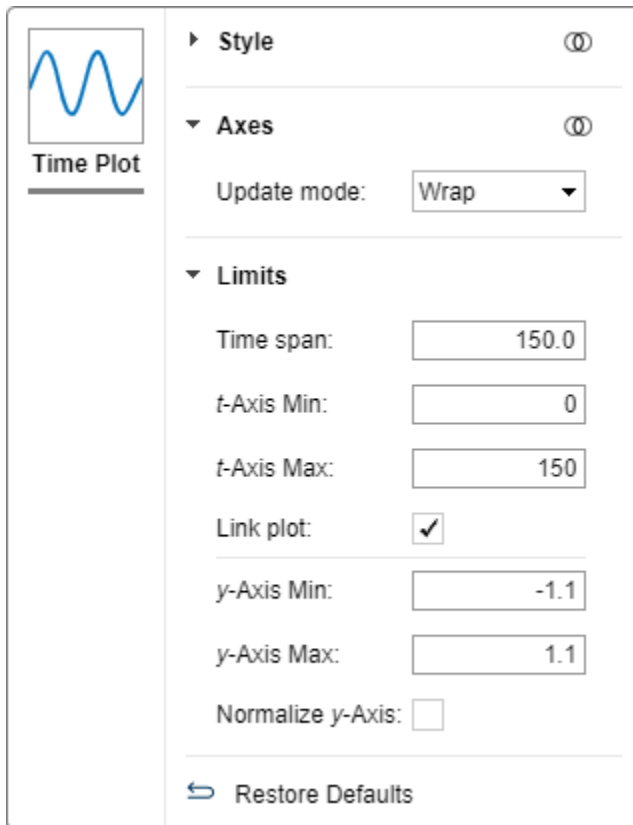

## Change Time Span

If the simulation time is finite, the **Time span** can be set to **auto**. When **Time span** is set to **auto**, the  $t$ -axis spans the full simulation time. However, when you view the entire simulation at once, the characteristics of the sine wave and sawtooth signals are hard to see. You can view a portion of the signal by setting the **Time span**. Before beginning the simulation, you can change the size of the

visible time interval by changing the **Time span** value. Click Visualization Settings . Then, in **Limits > Time span**, enter a value.

For example, set **Time span** to 150. Because the plots are linked, the  $t$ -axis has limits 0 to 150 at the start of the simulation for both subplots. When **Link plot** is selected, any changes made in Visualization Settings apply to all linked subplots. Subplots are linked by default. To unlink a subplot, select the subplot. Then, in the Visualization Settings, clear **Link plot**.

With the **Time span** set to 150, click **Run** to start the simulation. When the simulation starts, the span from 0 to 150 is visible on the *t*-axis. After reaching 150, the *t*-axis shifts to show 150 to 300.

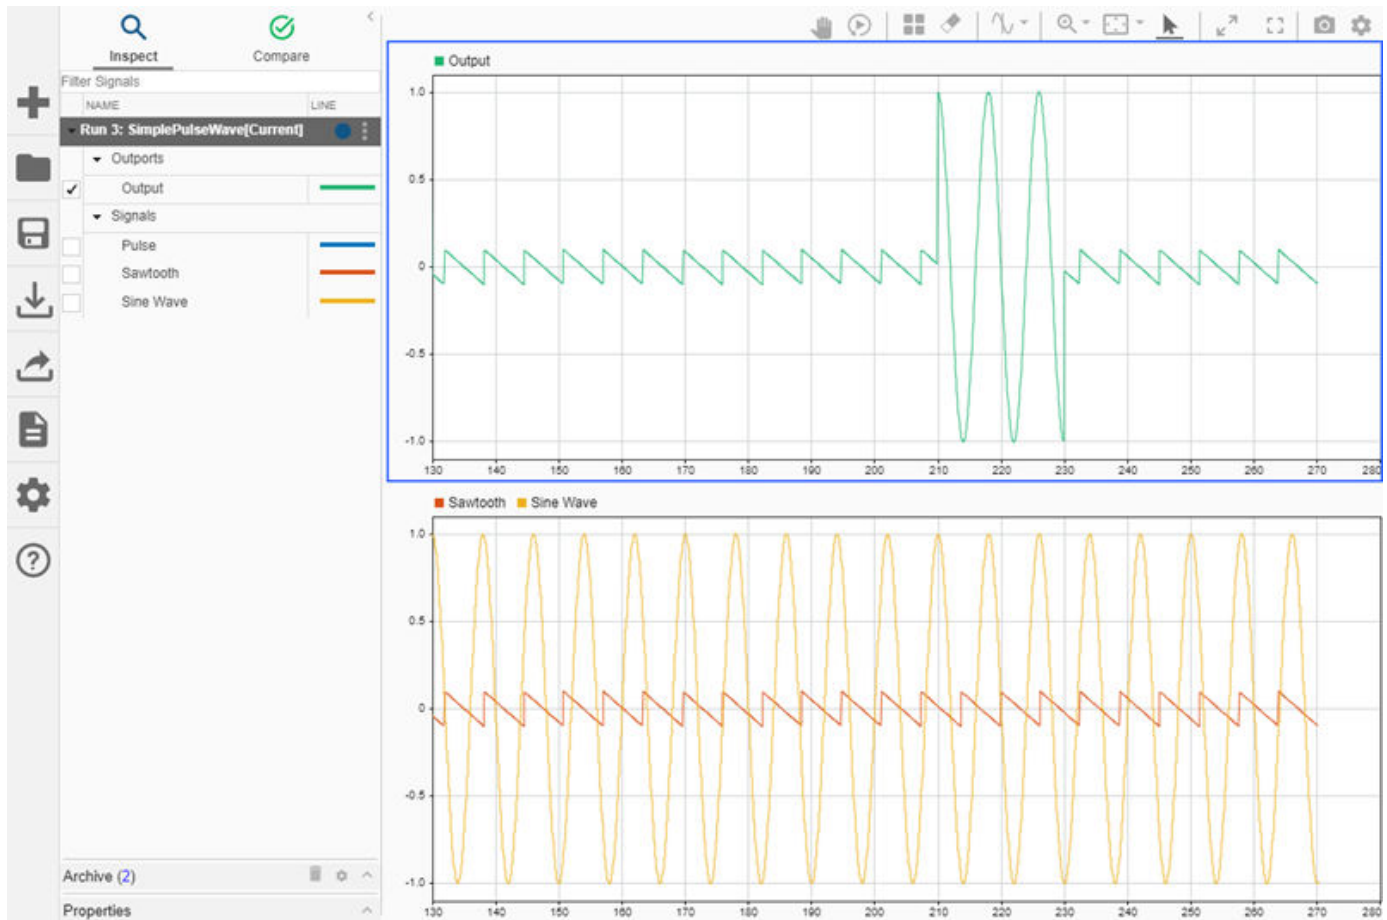

## Control Plot Update Behavior

You can change the way the Simulation Data Inspector updates subplots while streaming a signal.

Click Visualization Settings . Then, set **Axes > Update mode** to **Wrap** or **Scroll**. By default, the display updates by wrapping the plot.

In **Wrap** mode, the Simulation Data Inspector shows streaming data until it reaches the maximum  $t$ -axis limit. When the data reaches this limit, the minimum and maximum  $t$ -axis limits are increased by the **Time span** value.

Next, set **Update mode** to **Scroll**. Start a new simulation. In scroll mode, old data is moved out of view on the left as new data is plotted on the right. In this mode, instead of jumping by 150,  $t$ -axis scrolls with the streaming signal data.

## Freeze Display

You can inspect your signal while the simulation is running by freezing the display. Suppose you want to measure the period of the sine wave while data is streaming. You can freeze the display and use cursors to find the difference between two peaks.

- 1 To improve signal visibility, set **Time span** to 50.
- 2 Start the simulation.
- 3 Click Freeze display  to prevent wrapping or scrolling. You can also zoom in on previous data to freeze the display.
- 4 Click Show/hide data cursors . Then, select **Two Cursors**.
- 5 Drag the cursors to measure the difference between two peaks in the **Output** or **Sine Wave** signal.

When you finish measuring, click Unfreeze display  to return your view to the current simulation time. If the simulation ends while the display is frozen, the display jumps to the end.

**Note** The simulation continues to run when the display is frozen. To pause the simulation, click **Pause** in the model.

## Control Display Scaling and Display Offset

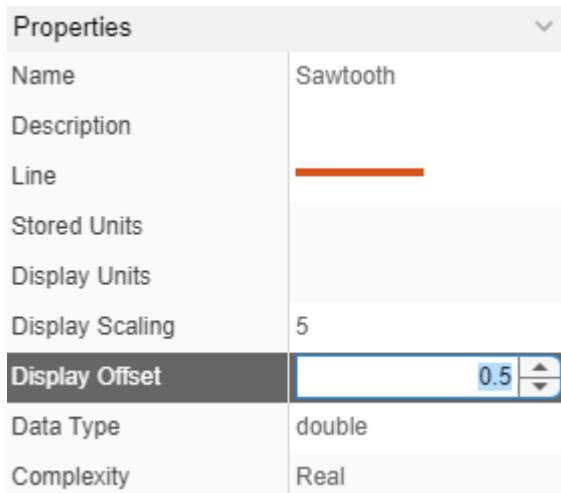

You can vertically scale and shift the display of individual signals from the **Properties** pane of the Simulation Data Inspector.

- Use the **Display Scaling** property to vertically scale the appearance of a plotted signal. The Simulation Data Inspector plots the signal values multiplied by the scaling value. By default, **Display Scaling** is 1.
- Use the **Display Offset** property to vertically shift the appearance of a plotted signal. The Simulation Data Inspector plots the summation of the offset value added to the signal values. By default, **Display Offset** is 0.

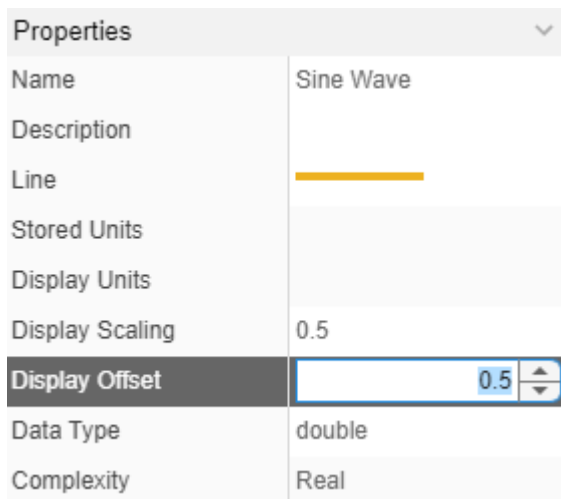

**Note** Changing the value of **Display Scaling** or **Display Offset** affects how the Simulation Data Inspector displays a signal. Signal values are unchanged.

For example, you can change the scaling and offset values for Sine Wave and Sawtooth such that both signals are displayed between y values of 0 and 1.

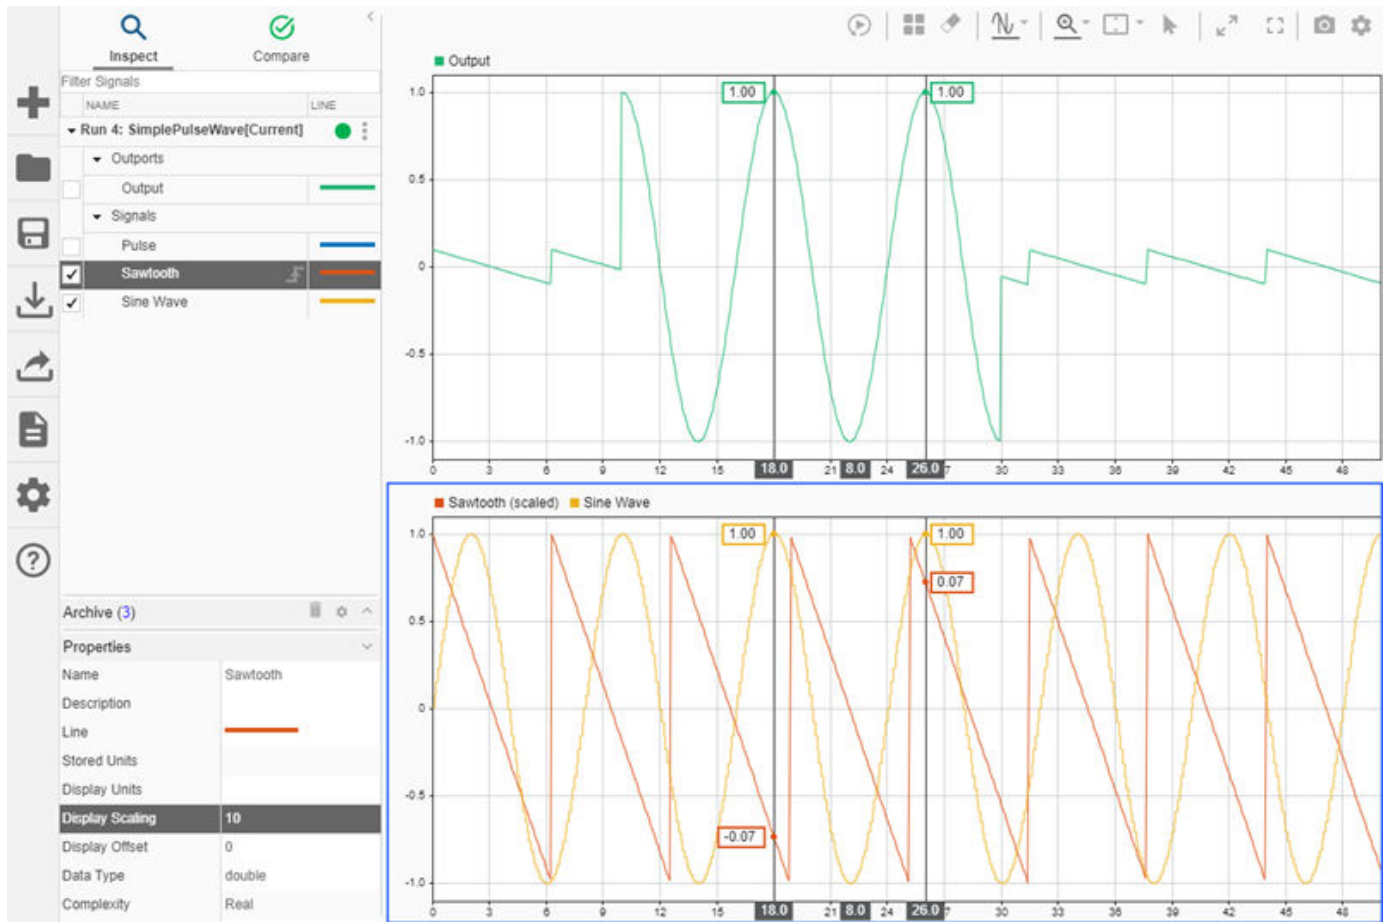

- 1 Select the signal Sawtooth. Then, in the **Properties** pane, set **Display Scaling** to 5 and **Display Offset** to 0.5.

- 2 Select the signal Sine Wave. Then, in the **Properties** pane, set **Display Scaling** to 0.5 and **Display Offset** to 0.5.

- 3 Select **Fit to View in Y**  to adjust the view.

Notice that the cursors display the original signal values. When you set **Display Scaling** or **Display Offset** to values other than the defaults, you change the appearance of the plot. However, cursors display the data value of the signal, which remains unchanged.

- “Control Display of Streaming Data Using Triggers” on page 31-97
- “Inspect Simulation Data” on page 31-169

## Control Display of Streaming Data Using Triggers

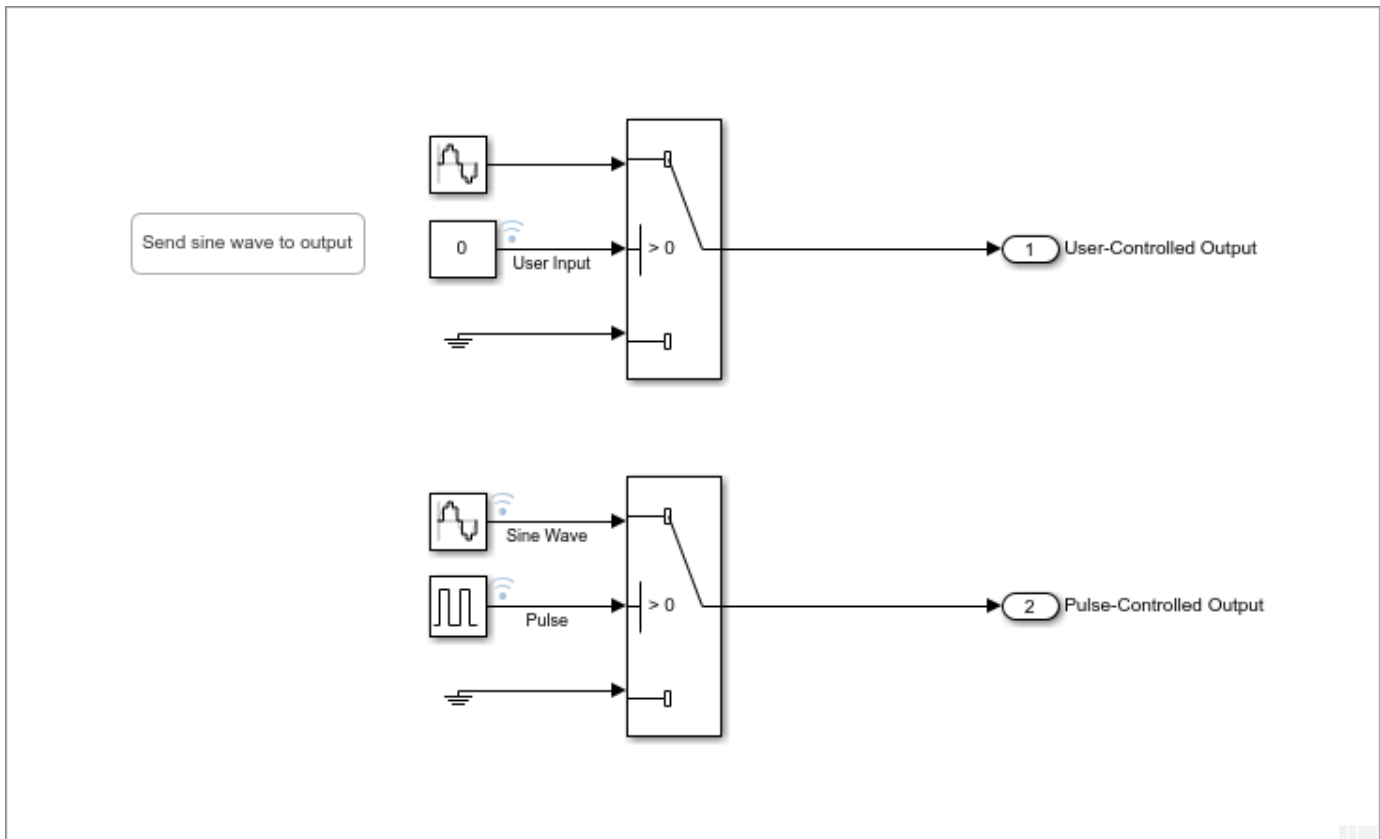

A *trigger* is an event that determines when to draw the plot of a streaming signal. Trigger settings specify criteria for the trigger event and where the trigger event is displayed within the updated data. Triggers facilitate viewing and analyzing streaming data by allowing you to capture transient changes in signals and stabilize the display of steady-state periodic signals. You can use triggers to inspect streaming data using several tools, such as the Scope block and the Simulation Data Inspector. This example uses the Simulation Data Inspector add, configure, and modify triggers on signals streaming from a model simulation.

**Note** The following examples add a trigger to signals that are plotted in the Simulation Data Inspector. However, you can add a trigger to a signal from the active simulation that is not plotted.

For complete descriptions of all trigger types and options, see “Scope Triggers Panel” on page 30-12.

### Examine the Model

The model in this example generates two logged output signals. Both signals are created by passing the output of a Sine Wave block through a switch. Both switches are configured to allow the sine signal through when the control signal is greater than zero. The switch for the first output is controlled by user input supplied using the Push Button block. The switch for the second output is controlled by the output of a Pulse Generator block.

The model uses simulation pacing so the model behavior and signal display are responsive to user interaction. Click **Run** to start a simulation. Then, click **Data Inspector** to open the Simulation Data Inspector. In the Simulation Data Inspector, change the layout to show two subplots. Plot the **User-Controlled Output** signal on the top subplot and the **User Input** signal on the bottom subplot. Press and hold the Push Button block periodically throughout the simulation to pass the Sine Wave block output to the Output block.

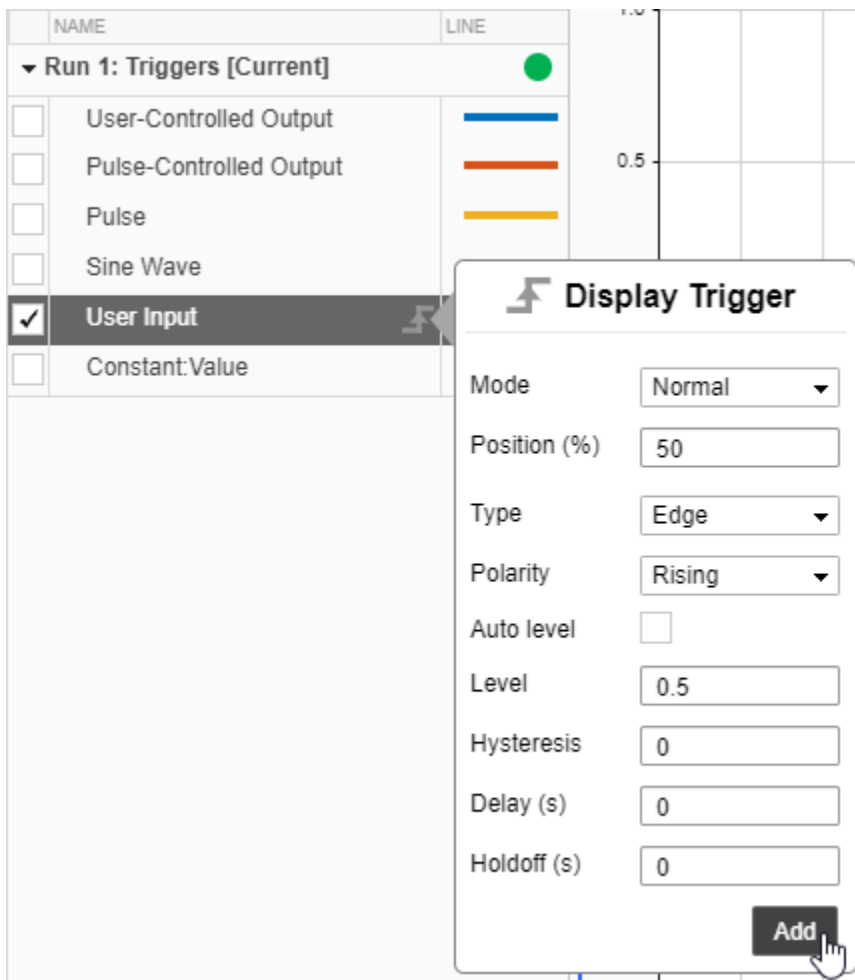

## Interactively Generate Trigger Events

The sine wave characteristics are difficult to see when you view the signals over the entire simulation time. When you use a trigger to control when the plot updates, you can view the streaming data over a smaller time range, which allows you to see the sine wave more clearly. Using the trigger ensures that you see the signal behavior of interest in the smaller time range. In this example, you want to see the change in the output signal when you press the Push Button block.

To trigger plot updates based on button presses, add a trigger to the **User Input** signal. To add a trigger, pause on the row for the **User Input** signal in the Simulation Data Inspector and click the trigger icon that appears.

The default settings in the Display Trigger dialog configure an auto-leveled rising-edge trigger, with the trigger event positioned in the middle of the displayed data. Change **Mode** to **Normal**, then clear the **Auto level** check box and set the **Level** to 0.5. Then, click **Add**.

Using normal mode for the trigger means that the plot only updates when a trigger occurs. In auto mode, the display also updates when a trigger is not detected for the duration of the time span. The trigger level of 0.5 puts the level in the middle of the signal range.

Before simulating the model, adjust the time range displayed in the plots. In the upper right, click Visualization Settings . Then, set **Time span** to 50.

Simulate the model and view the streaming signals in the Simulation Data Inspector. When you start a new simulation, the trigger configured in the Simulation Data Inspector automatically transfers to the corresponding signal in the current simulation. The display updates in response to the trigger events you cause by pressing the Push Button block in the model. On the smaller time span, you can see the shape of the sine wave in the output signal. The trigger position and level are marked with green triangles. You can click and drag the trigger markers to adjust the level and position. A new value is applied for the level or position when you let go of the marker after dragging.

Experiment with this configuration to test out different kinds of triggers and different trigger settings. For example, try using a falling-edge trigger. You can also adjust the simulation pacing in the model to explore how timing can affect trigger behavior. When the trigger occurs, the Simulation Data Inspector collects all the data to display before updating the plot. If you slow the simulation pacing closer to a rate where one simulation second takes one second of clock time, you can see the delay between causing a trigger by pressing the Push Button block and the plot update in the Simulation Data Inspector.

## Stabilize a Steady-State Periodic Signal

Using a trigger can stabilize the display of a periodic steady-state signal that you want to view and analyze. Because the trigger event is always in the stable position in the plot, a streaming periodic signal can appear still in the plot, rather than shifting or scrolling. When the display is stable, you can inspect and analyze signal characteristics, such as frequency and amplitude.

To see how a trigger can stabilize the display of a periodic signal, trigger display updates using the Sine Wave signal. Use the same settings to configure the rising-edge trigger in normal mode with a level of 0.5.

Before simulation, update the plot layout to show a single plot. Plot the Sine Wave signal, and set the **Time span** to 10.

Simulate the model. During simulation, you can add cursors in the Simulation Data Inspector and measure the amplitude and period of the signal.

To contrast, remove the trigger and simulate the model again. Notice the differences in how the display updates. Try simulating with the **Update mode** set to **Wrap** and then set to **Scroll**. Specify

**Update mode** in Visualization Settings .

## Synchronize Cursors in the Simulation Data Inspector with an App Designer App

You can use several functions from the Simulation Data Inspector programmatic interface to synchronize cursors between an App Designer app and the Simulation Data Inspector. Synchronized cursors allow you to easily analyze data plotted in the Simulation Data Inspector alongside data displayed on a custom visualization coded in the App Designer app.

The app in this example is simple and illustrates only the core function of passing information about cursors between the app and the Simulation Data Inspector. Cursor positions are shown on linear gauges in the app. You can use sliders in the app to reposition the cursors on the **Inspect** or **Compare** panes of the Simulation Data Inspector. When you move cursors in the Simulation Data Inspector, the new cursor positions are reflected on the sliders and linear gauges.

### Open and Run the Cursors App

The cursors app opens in App Designer, where you can explore and modify the layout of the user interface and the code that specifies the function of each user interface element.

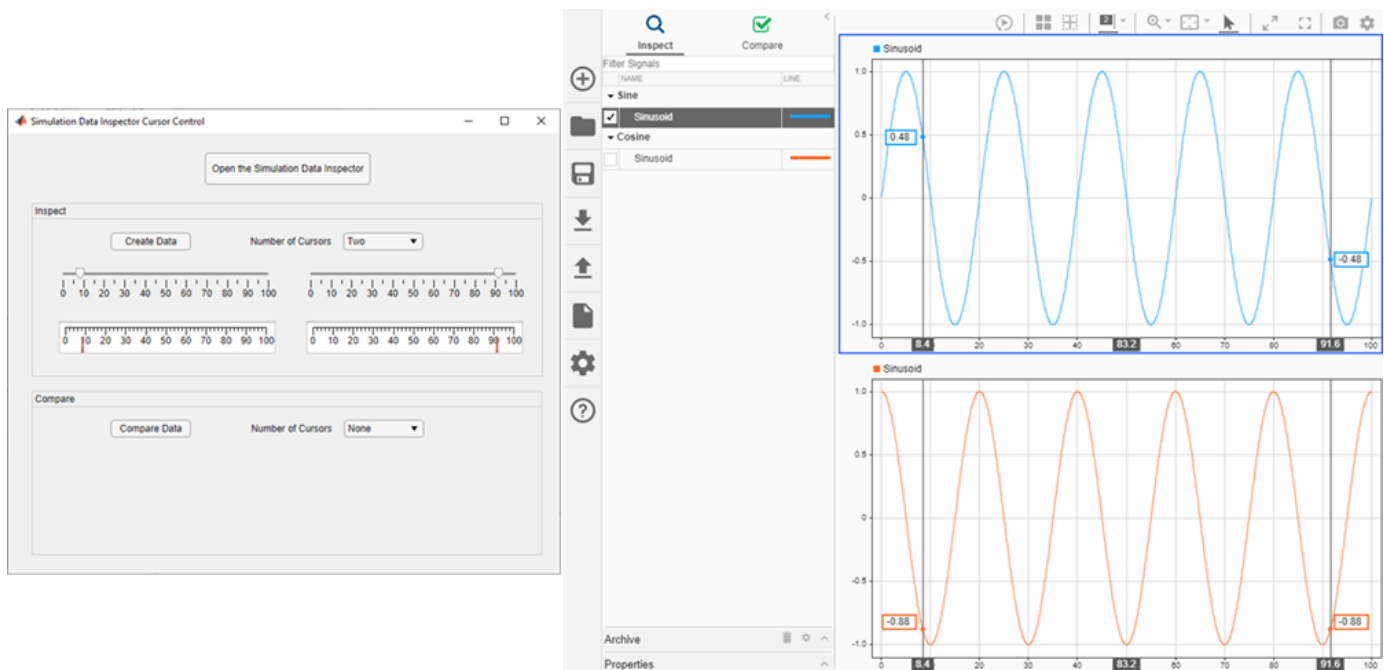

```
appdesigner('CursorsApp.mlapp');
```

To run the cursors app, click **Run**. A new window opens with the app user interface. To get started using the app, click **Open the Simulation Data Inspector**, then click **Create Data**. The **Create Data** button creates data for and plots two signals in the **Inspect** pane of the Simulation Data Inspector.

Next, add cursors. You can add cursors using the **Number of Cursors** control in the app or using the **Show/hide data cursors** option in the Simulation Data Inspector. The slider control and gauge display for each cursor becomes visible once the cursor is active in the Simulation Data Inspector. Try moving the cursors using the sliders in the app and by dragging them in the Simulation Data Inspector.

The app also includes controls and displays for cursors on the **Compare** pane of the Simulation Data Inspector. To interact with cursors on the **Compare** pane, start by clicking **Compare Data**. The

Simulation Data Inspector automatically shows the **Compare** pane when you compare data. Then, add cursors to the comparison plots using the app or the Simulation Data Inspector. Try moving the cursors in the Simulation Data Inspector and using the sliders in the app.

When you finish exploring the cursor synchronization, close the app window.

## Examine the App Code

To view the code in the App Designer window, click **Code View** in the upper-right of the app canvas.

The code view shows the code that specifies the function of the app. Code in grey areas is automatically programmed by the App Designer when you interactively add components and specify properties in the **Design View**. The code in white areas customizes the function of the app.

### Custom App Properties

The cursors app adds two custom properties to the app. The `callbackID` property saves the ID for the cursor callback registered with the Simulation Data Inspector so the app can unregister the callback when you close the app. The `runIDs` property saves the run IDs for the runs created when you click **Create Data**. The run IDs are then used to compare the runs when you click **Compare Data**.

### Custom OnCursorMove Method

The `OnCursorMove` function is the cursor callback that the app registers with the Simulation Data Inspector when you start the app. To keep the displays in sync, the function refreshes the app settings each time you move a cursor in the Simulation Data Inspector.

### Custom refreshSettings Method

The cursors app also includes the custom method `refreshSettings`, which keeps the values displayed in the app synchronized with the state of the Simulation Data Inspector. The `refreshSettings` method uses the `Simulink.sdi.getNumCursors` function to make sure the **Number of Cursors** controls display the correct number of cursors currently visible in the **Inspect** and **Compare** panes of the Simulation Data Inspector. The `refreshSettings` method also controls the visibility of the sliders and gauges using the cursor positions returned by the `Simulink.sdi.getCursorPositions` function. When a cursor is outside the range of its corresponding slider and gauge, the app hides the slider and gauge for that cursor.

### Callbacks That Handle Component Events

Each component in the app user interface has an associated function that implements the component response to user interactions. You can add one or more callbacks for a component in the **Design View**, and you write the code to define the component response in the **Code View**.

Method	Description of Functionality
startupFcn	When you open the cursors app, the app registers a callback for cursors in the Simulation Data Inspector and refreshes the app data. The OnCursorMove cursor callback for both the <b>Inspect</b> and <b>Compare</b> panes executes when you move a cursor in the Simulation Data Inspector. The callback IDs are saved in the callbackID property of the app.
OpentheSimulationDataInspectorButtonPushed	When you click the <b>Open the Simulation Data Inspector</b> button, the app opens the Simulation Data Inspector and refreshes the app data.
CreateDataButtonPushed	When you click the <b>Create Data</b> button, the app creates a sine signal and a cosine signal and plots the signals in the Simulation Data Inspector.
CompareDataButtonPushed	When you click the <b>Compare Data</b> button, the app compares the run with the sine signal and the run with the cosine signal.
SimulationDataInspectorCursorControlUIFigureCloseRequest	When you close the app, the app unregisters the callback functions for cursors in the Simulation Data Inspector.
NumberOfCursorsDropDownValueChanged CompNumCursorsDropDownValueChanged	When you use one of the <b>Number of Cursors</b> controls to change the number of cursors displayed in the Simulation Data Inspector, the app uses the Simulink.sdi.setNumCursors function to display the specified number of cursors in the Simulation Data Inspector.
LeftSliderValueChanging RightSliderValueChanging CompLeftSliderValueChanging CompRightSliderValueChanging	When you adjust a cursor position using the slider, the app uses the Simulink.sdi.setCursorPositions function to update the position of the cursor in the Simulation Data Inspector.

## Iterate Model Design Using the Simulation Data Inspector

The Simulation Data Inspector facilitates iterative design, debugging, and optimization by providing easy access to visualizations of logged data during simulation. Using the Simulation Data Inspector archive, you can maintain a focused work area and control data retention for multiple simulations. When you automatically archive simulation runs, you can create a view that is automatically applied to subsequent simulation runs. With **Browse Mode** enabled, you can inspect large amounts of logged signals on **Time Plot** visualizations more quickly.

### View and Inspect Signals During Simulation

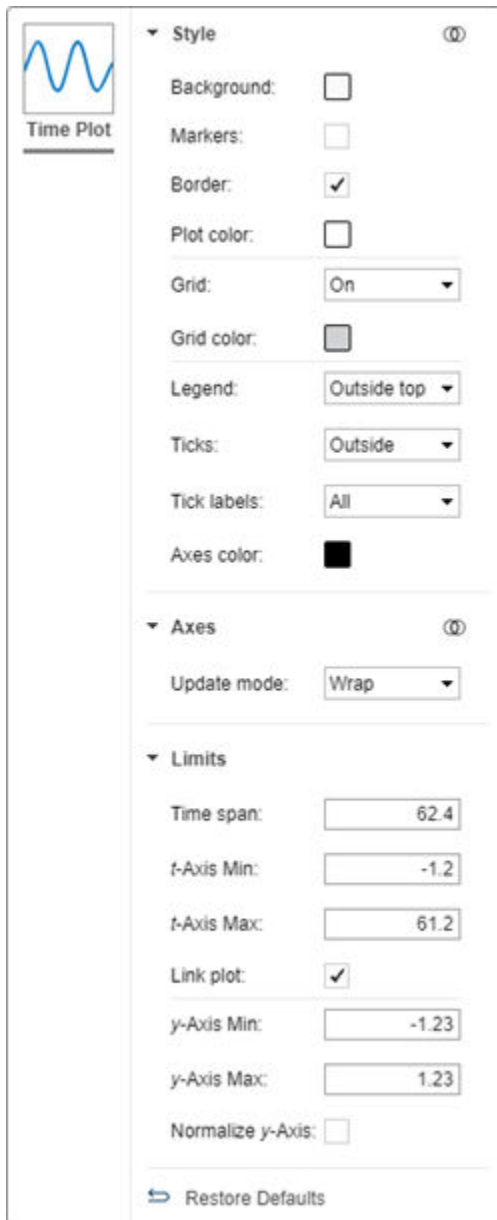

You can plot logged signals in the Simulation Data Inspector during simulation. Viewing signals during a simulation can help build understanding of the model and allow you to make decisions about model parameters without waiting for a simulation to complete.

When you plot data that is streaming from an active simulation, the Simulation Data Inspector automatically updates the time span of the plot to match the stop time for the simulation. To view the streaming data on a smaller time scale, change the **t-Axis max** value or zoom in time. To update the

**t-Axis max**, open the **Visualization Settings** . To zoom in time, select the **Zoom in Time** option from the **Zoom** menu and click and drag in the plot area to specify the time span.

Use the **Update mode** setting to specify whether the Simulation Data Inspector wraps or scrolls the plot after the streaming data reaches the maximum time you specified.

To closely examine signals throughout design iteration, add data cursors to your plots. You can add a data cursor to the plot during simulation, while a simulation is paused, or after the simulation has

finished. To add a data cursor, click the cursor button . Drag the data cursor across the plot to inspect signal values. When you display multiple signals on a plot, the data cursor indicates the value for each signal in a color-coded box.

Click the drop-down on the cursors button and select **Two Cursors** to add a second data cursor and explore temporal characteristics of your data. You can move each cursor independently, or you can move them together. The number between the two cursors displays the time difference between the cursors.

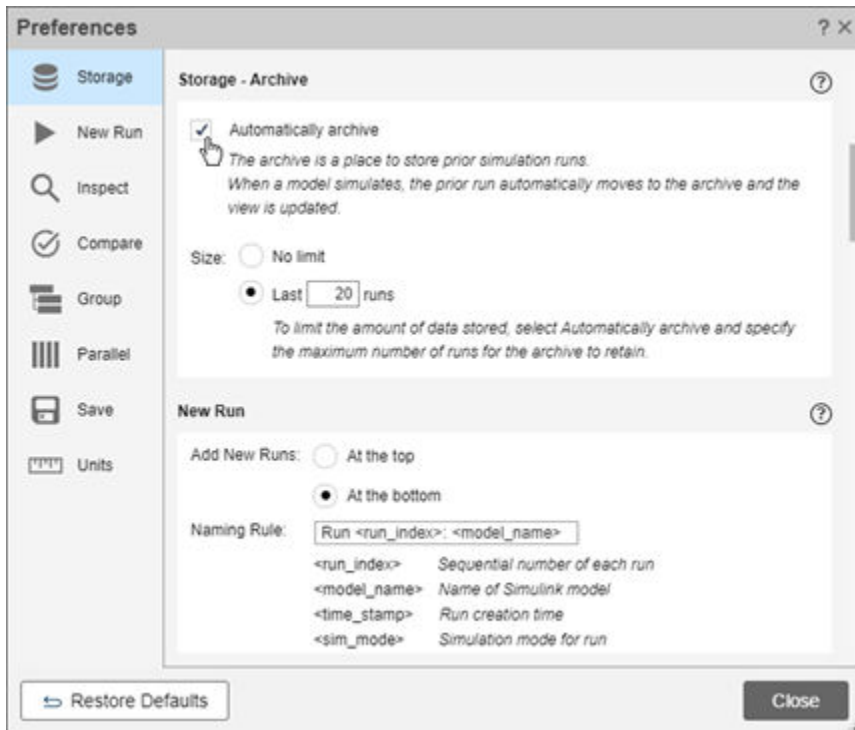

You can type directly into the box to specify a desired cursor separation. To move the cursors together, click and hold the middle number indicator, and drag it across the graphical viewing area to your desired position. For more information about using data cursors, see “Inspect Simulation Data” on page 31-169.

## Automatically Transfer View to Current Simulation

By default, the Simulation Data Inspector is configured to automatically archive simulation runs and transfer a view from the previous run to the current simulation. When you run a new simulation, the Simulation Data Inspector moves the prior simulation run to the archive and updates the view to show aligned signals from the current run. You can control archiving by toggling the **Automatically**

**archive** setting. Click Preferences . Then, navigate to the **Storage - Archive** pane.

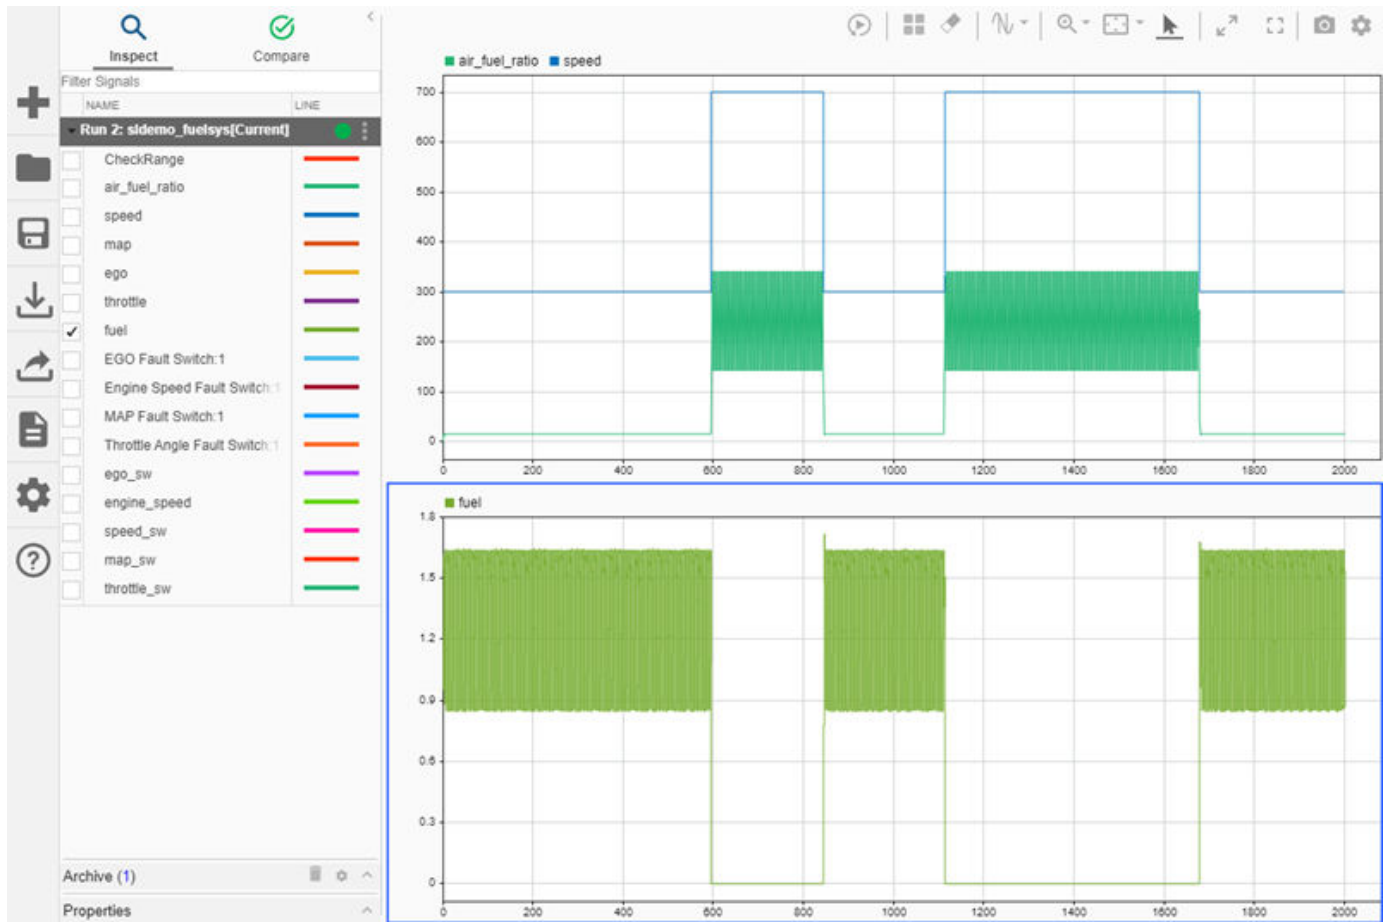

For example, open the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

Create a view of signals from the `sldemo_fuelsys` model. Then, simulate the `sldemo_fuelsys` model again. The signals from the previous run clear from the plots, and the Simulation Data Inspector plots data from the current simulation as the simulation runs. The previous run also moves into the archive, reducing clutter in the work area.

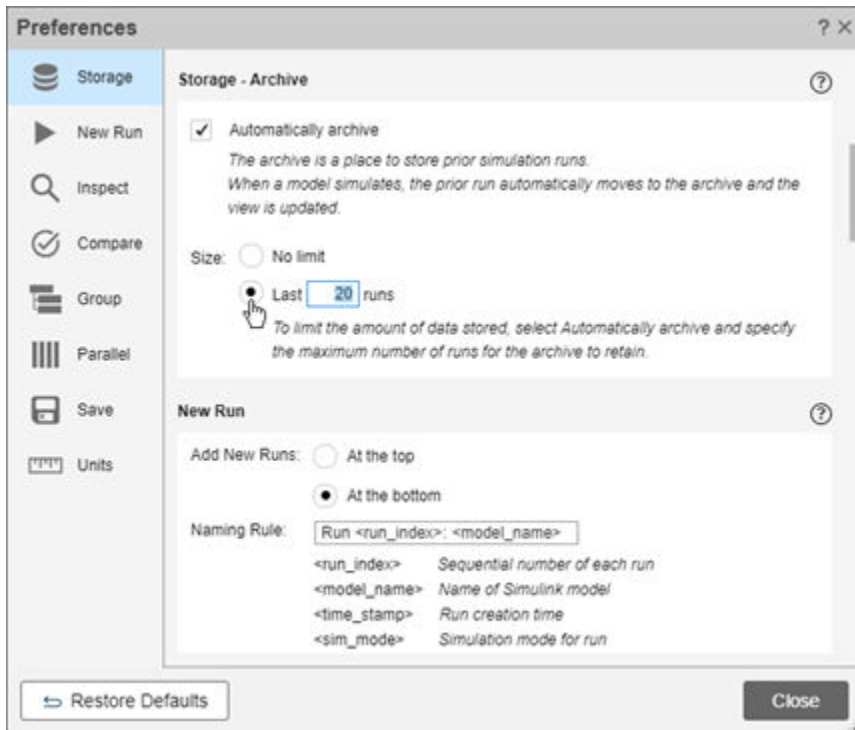

You can access and plot data from previous runs from within the archive, and you can drag runs of interest into the work area from the archive.

## Control Data Retention

Running many simulations with logged signals can create a lot of data, especially during iterative design and debugging workflows. To limit the amount of disk space occupied by logged data, you can limit the amount of data the Simulation Data Inspector stores in the archive from the **Storage -**

**Archive** pane in the Preferences  menu.

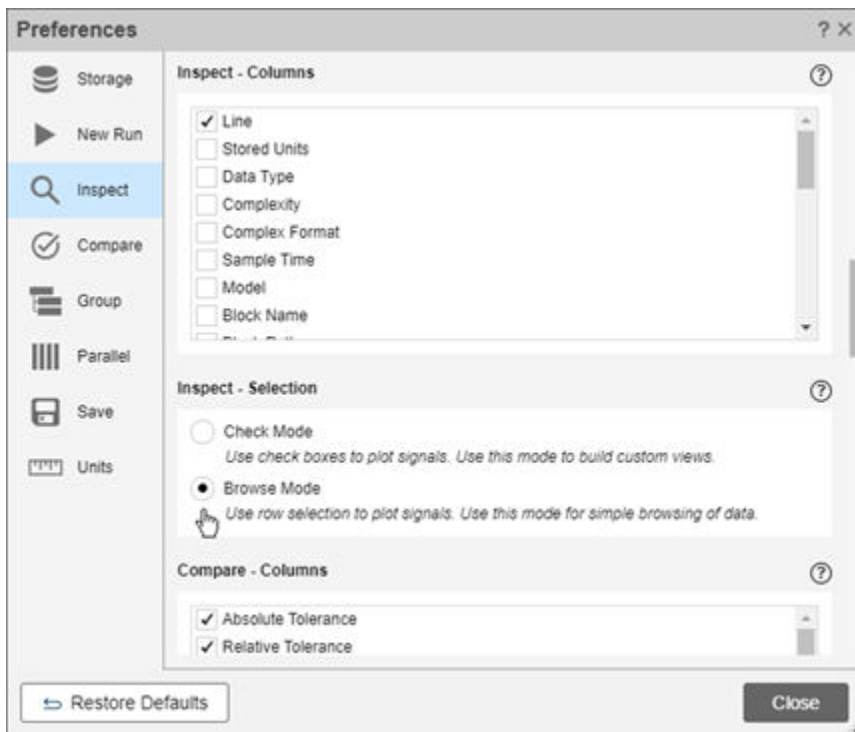

By default, the Simulation Data Inspector does not limit the number of runs stored in the archive. To impose a limit, select the **Last runs** radio button, and specify the desired limit. When the number of runs in the archive reaches the limit, the Simulation Data Inspector deletes the run that has been in the archive the longest. If the archive contains more runs than the limit you specify, the Simulation Data Inspector provides a warning before deleting your run data.

**Tip** When you do not want the Simulation Data Inspector to store run data, specify an archive limit of 0. With an archive limit of 0 and **Automatically archive** enabled, the Simulation Data Inspector automatically transfers your configured view to the current simulation and only retains the current simulation data.

## Visualize Many Logged Signals

You can use **Browse Mode** to inspect many signals quickly on **Time Plot** visualizations. To enable

**Browse Mode**, click Preferences . Then, select the **Browse Mode** radio button from the **Inspect - Selection** pane.

---

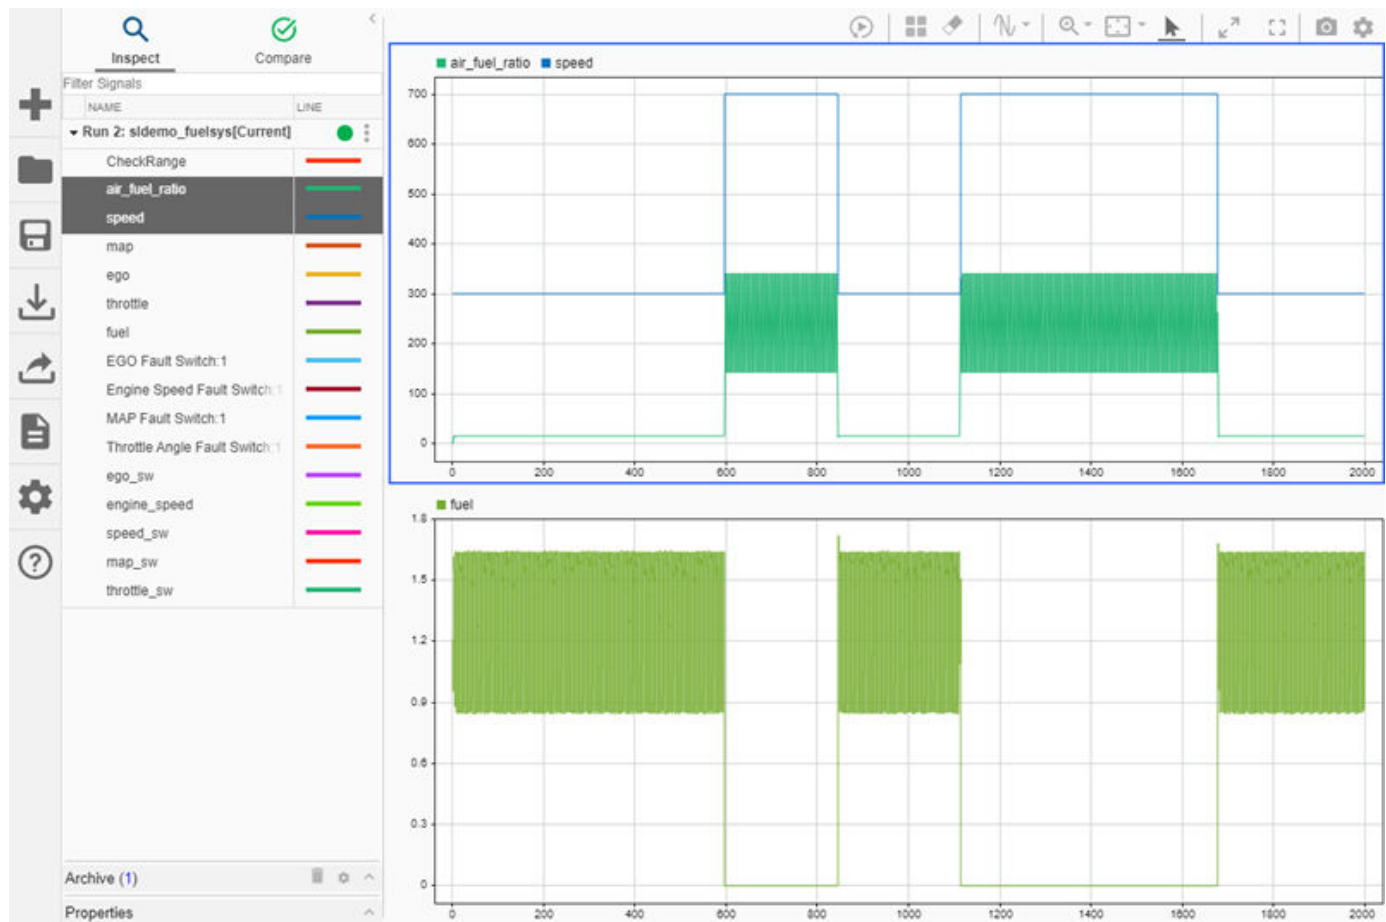

**Note** To use **Browse Mode**, all subplots, including hidden subplots, must be **Time Plot** visualizations.

---

In **Browse Mode**, signals selected in the navigation pane are plotted on the active **Time Plot**. You can use the arrow keys on your keyboard to change the selected signals, and you can select multiple signals by holding the **Shift** or **Ctrl** keys. When you select a row for a run or hierarchical organization, no signals are displayed in the graphical viewing area.

You can also use plot layouts in **Browse Mode** to make more complex visualizations. When the graphical viewing area contains multiple subplots, selecting new signals using the mouse or keyboard changes only the active plot.

When you finish browsing your simulation results, enable **Check Mode** from the **Inspect - Selection**

pane of the Preferences menu. For more information about creating plots with the Simulation Data Inspector, see “Create Plots Using the Simulation Data Inspector” on page 31-152.

## Access Data in a MATLAB Function During Simulation

You can stream signal data to a MATLAB callback function during simulation using the **Data Access** functionality in the **Instrumentation Properties** for a signal. The function you provide receives data in packets asynchronously throughout the simulation. The callback function executes each time it receives new data. You can write a callback function to process signal data during simulation or to create a custom visualization of a signal. The callback function does not affect signal values in your model. This example illustrates the steps required to access signal data during simulation using a simple callback function that plots the signal.

---

**Note** Data access does not support Rapid Accelerator mode, referenced models, fixed-point data, or virtual bus signals and only supports 1-D and 2-D matrix signals.

---

### Write a Callback Function for Data Access

The data access callback function always receives signal data as the first argument. You can choose whether to send the simulation time and a parameter. When you include all three arguments, simulation time is the second argument. Your callback function can be specific to a single signal, or you can use the same callback to process and visualize multiple signals. The callback function only has access to data for a single signal at a time. This example creates a callback function that receives signal data, time, and a parameter used to identify which signal the function is processing for a given call.

---

**Note** The data access callback function receives nonvirtual bus data as a structure of arrays that matches the hierarchy of the bus.

---

Author your callback function in an m-file with the same name as your function. For more information about writing MATLAB functions, see “Create Functions in Files”. The example callback function uses the optional parameter to assign a numerical identifier to each signal. The parameter is used to create a unique figure for each signal and assign each signal a different line color. To accumulate signal data on the plot, the callback includes `hold on`. For each call to the callback, the function receives a portion of the signal data. You can use the callback to accumulate the packets if desired.

```
function plotSignals(y,time,sigNum)

    figure(sigNum)

    if isequal(sigNum,1)
        marker = 'ro-';
    elseif isequal(sigNum,2)
        marker = 'go-';
    else
        marker = 'bo-';
    end

    hold on;
    plot(time,y,marker);

end
```

The callback function provides no return values. If you specify the function with returns, the return data is discarded.

---

**Tip** Use `assignin` to access data from the callback function in the base workspace.

---

Save the callback function in a location on the MATLAB path. If the location where you save the callback is not on the path, you can add it to the path. Right-click the directory containing the callback in the **Current Folder** section in MATLAB and select **Add to Path**.

## Configure Signals for Data Access

To access data for a signal with the data access callback, you need to log the signal. To mark a signal for logging, right-click the signal in your model and select **Log Selected Signals**. To configure data access for the signal, right-click the logging badge and select **Properties**. On the **Data Access** tab of the **Instrumentation Properties**, you can specify the name of your callback function, whether the callback function takes time as an argument, and the optional parameter value.

For example, open the `vdp` model and configure the `x1` and `x2` signals to use the callback from the previous section.

- 1 Enter `vdp` in the MATLAB **Command Window**.
- 2 Select the `x1` and `x2` signals. Then, right-click the selected signals and choose **Log Selected Signals** from the context menu.
- 3 To open the **Instrumentation Properties**, right-click the logging badge for `x1` and select **Properties**.
- 4 On the **Data Access** pane, enter the name of the callback, check **Include simulation time**, and enter 1 as the **Function parameter**.

- 5 Open the **Instrumentation Properties** for `x2` and configure the **Data Access** pane to use the `plotSignals` callback with a **Function parameter** value of 2.

Simulate the `vdp` model. The callback generates Figures 1 and 2 to display the `x1` and `x2` signals during simulation.

You can modify the callback function to create a custom visualization or to create a plot of processed signal data. Errors related to the data access callback function do not interrupt simulation. The errors surface in the **Diagnostic Viewer** as a warning.

### **More About**

- “View Data in the Simulation Data Inspector” on page 31-2

## Analyze Multidimensional Signal Data

When you log or import multidimensional signal data with fixed dimensions into the Simulation Data Inspector, you can choose to view and analyze data as:

- A single signal with multidimensional sample values
- A set of signals with scalar sample values: one signal, called a channel, for each element of the multidimensional data

Variable-sized signals are always represented as a single signal with multidimensional values.

When the multidimensional data is frame-based, you can also use the Simulation Data Inspector to remove the buffering from each frame.

You can control how you view and analyze multidimensional signal data using the Record block or the Simulation Data Inspector. When you change the representation of a multidimensional signal in the Record block, the change is reflected in the Simulation Data Inspector and vice versa.

### Convert Representation of Multidimensional Data

The way the Simulation Data Inspector initially represents a multidimensional signal with fixed dimensions depends on the number of elements in each sample of the signal. By default:

- Signals with samples that contain fewer than five elements are represented as channels.
- Signals with samples that contain five or more elements are represented as a single signal with multidimensional sample values.

---

**Note** Variable-sized signals are always represented as a single signal with multidimensional sample values and cannot be converted.

---

When the default behavior for a signal with fixed dimensions does not provide the representation you need for your analysis, you can convert the representation from a single signal to channels or from channels to a single signal.

For example, consider this output from a model that creates two composite signals using Mux blocks:

- `Large Mux` contains five elements and is displayed as a single signal by default.
- `Small Mux` contains two elements and is displayed as two channels by default.

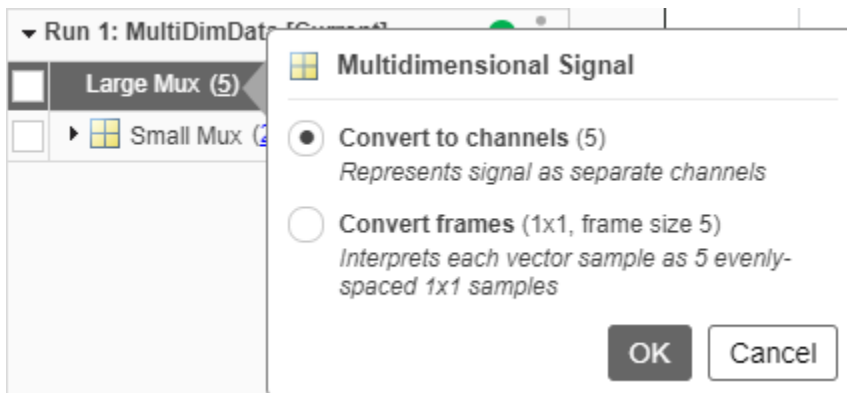

The run includes one row for the `Large Mux` signal and three rows for the `Small Mux` signal. By default, the Simulation Data Inspector groups signals by data hierarchy, so one row groups the signals for each channel in the `Small Mux` signal, and each channel has a row.

Dimensions are indicated as part of the signal name in the table of signals under each run.

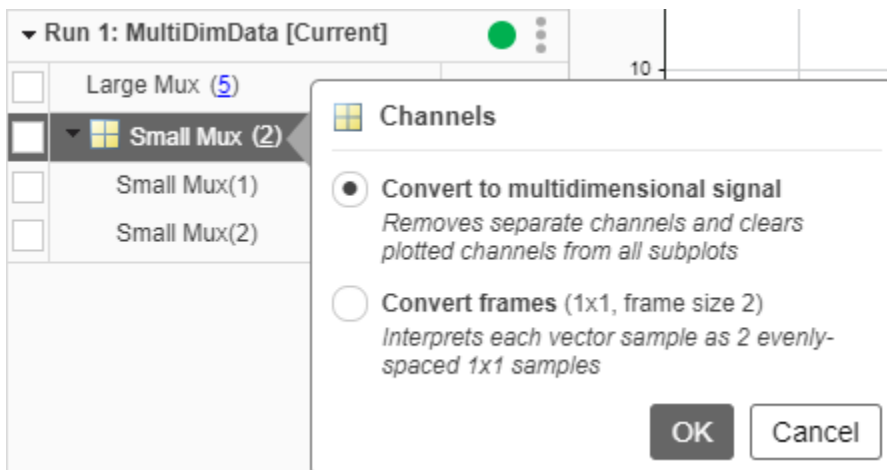

- When a multidimensional signal is represented as a single signal with multidimensional sample values, the signal name row indicates the dimensions.
- When a multidimensional signal is represented as channels, the grouping row indicates the dimensions.

To convert the representation of a signal with multidimensional data, you can click the dimensions and select an option from the menu. For example, to convert the **Large Mux** signal to channels, click the dimensions, **5**, and select **Convert to channels**.

To convert the **Small Mux** signal to a single signal, click the dimensions, **2**, for the grouping row and select **Convert to multidimensional signal**.

When you convert a signal from channels to a single signal, any plotted channels are cleared from the view because the signals for the channels no longer exist.

You can also convert the representation of multidimensional signals in the Simulation Data Inspector programmatically using the `expand` and `collapse` functions.

## Plot Multidimensional Signal Data

Most visualizations in the Simulation Data Inspector, including time plots, XY plots, maps, and sparklines, only support plotting scalar signals. To plot data from a multidimensional signal on one of these visualizations, convert the signal to channels. You can use the conversion menus that you access by clicking the signal dimensions or the menu that appears on a subplot that does not support multidimensional data when you try to plot the signal.

For example, if you try to plot the **Large Mux** signal on a time plot, the menu gives you the option to change the active subplot to an array plot, which does support multidimensional data, or to convert the representation of the signal.

To view multidimensional data, use the array plot in the Simulation Data Inspector. The array plot supports scalar and multidimensional signals, including variable-size signals. You can add an array plot to the subplot layout using the menu that appears when you try to plot a multidimensional signal on a plot that only supports scalar signals or using the **Visualization Gallery**. For more information about using the array plot, see “View Multidimensional Signals Using the Array Plot” on page 31-58. The Record block does not support the array plot.

Only time plots support plotting signals programmatically. You can plot channel data on a time plot programmatically. You cannot plot data for a signal with multidimensional sample values programmatically. Use the `expand` function to convert a single multidimensional signal to channels, which you can plot on a time plot programmatically using the `plotOnSubPlot` function.

## Compare Multidimensional Signals

By default, when you compare multidimensional signals represented as a single signal or runs that contain multidimensional signals represented as a single signal, the Simulation Data Inspector converts the multidimensional signal to channels and computes a comparison result for each channel. The conversion happens for the comparison only and does not affect the way the signal is represented on the **Inspect** pane. The Simulation Data Inspector does not support comparing variable-size signals or signals with multidimensional sample values.

If you do not want to compute comparison results for the channels in multidimensional signals, you can configure comparisons to skip multidimensional signals instead of computing the channel results. On the **Compare** pane, click **More**, then clear **Expand multidimensional channels**.

The screenshot shows the 'Compare' pane in the Simulation Data Inspector. At the top, there are two dropdown menus: 'Baseline:' set to 'Run 1: MultidimensionalData' and 'Compare to:' set to 'Run 2: MultidimensionalData'. Below this is the 'Global Tolerances' section with three input fields: 'Absolute:' (0), 'Relative:' (0), and 'Time:' (0). The 'Constraints' section contains several checkboxes: 'Expand multidimensional channels' (checked), 'Signal start and stop times must match' (unchecked), 'Signal data types must match' (unchecked), and 'Signal time vectors must match' (unchecked). At the bottom, there is a dropdown menu for 'Stop comparison on first mismatch of:' set to 'Metadata', and a '[ - ] Less' button.

You can also configure whether programmatic comparisons compute results for multidimensional signals using the `Simulink.sdi.compareRuns` function with the `ExpandChannels` name-value argument.

## Convert Representation of Frame-Based Data

Some applications buffer several samples of a signal into a frame to process with a single computation instead of processing each sample in the frame separately. When you work with frame-based signals, you can analyze the data frame by frame, or you can remove the buffering and analyze the signal without the frames.

You can remove frame buffering from signals logged to the Simulation Data Inspector using the menu that appears when you click the dimensions next to a multidimensional signal or the menu that appears when you try to plot multidimensional data on a plot that only supports scalar data.

For example, consider this run created by logging data for the analog to digital converter output in the model `sfcndemo_frame`. The model buffers the samples into a frame and performs a discrete Fourier transform on each frame. To remove the frame buffering in the Simulation Data Inspector, click the dimensions for the signal,  $64 \times 2$ , and select **Convert frames**. The conversion interprets each sample as 64 evenly spaced samples with dimensions 1-by-2. Because the unbuffered signal only contains two elements, conversion also displays the results as separate channels with scalar sample values.

You can also convert the frames for a frame-based signal in the Simulation Data Inspector programmatically using the `convertToFrames` function. The Simulation Data Inspector does not support converting frames for imported data.

When you log frame-based data from a model, you can control how the data is logged by specifying the **Input Processing** setting for the logged signal in the model using the **Instrumentation Properties** dialog box or the `Simulink.sdi.setSignalInputProcessingMode` function. You can configure the input processing for the signal as frame-based or sample-based.

- Sample-based — The logged data retains the buffering, and each sample of the logged signal represents a frame. The Simulation Data Inspector interprets the data as a multidimensional signal, where each element of a sample represents a separate channel.
- Frame-based — Logging removes the buffering and treats each column in the samples as a separate channel.

When you log frame-based signals as sample-based, you can still convert the frames in the Simulation Data Inspector after simulation.

## Analyze Data from Multiple Simulations

You can analyze data from multiple simulations by viewing the data from each simulation using the same visualizations and subplot layout. With the Simulation Data Inspector, you can save the subplot layout and configuration, including the plotted signal selection, as a view in an MLDATX file that you can load to visualize data from another simulation. When the Simulation Data Inspector contains multiple runs, you can also copy or cut the plotted signal selection from one run and then paste it onto another to plot data from different runs side by side or easily swap which run supplies the data for the plots.

This example shows how to use views and the cut, copy, and paste options in the Simulation Data Inspector to analyze data from several simulations of the model `sldemo_autotrans`. For information about analyzing simulation data using comparisons, see “Compare Simulation Data” on page 31-193.

### Open and Simulate the Model

Open the model `sldemo_autotrans`, which models a controller for an automatic transmission system. The model uses a Signal Editor block to load external input data to model the Throttle and Brake signals for different vehicle maneuvers. In this example, you run several simulations and analyze the system response to different vehicle maneuvers. For more information about the model and the system it represents, see “Modeling an Automatic Transmission Controller”.

Copyright 1990-2022 The MathWorks, Inc.

Simulate the model for the default input scenario, which represents a passing maneuver. On the **Simulation** tab, click **Run**.

### Create and Save Views to Analyze Simulation Results

After simulating the model, analyze the simulation results by plotting signals on multiple time plots in the Simulation Data Inspector. For example, visualize the input signals `Throttle` and `Brake`

alongside the EngineRPM and VehicleSpeed signals to see how the driver input to the vehicle affects the vehicle speed.

Open the Simulation Data Inspector. On the **Simulation** tab, under **Review Results**, click **Data Inspector**. Then, change the subplot layout in the Simulation Data Inspector to include four subplots, one for each signal. To change the subplot layout, click **Layout**. Then, under **Basic Layouts**, select the four-subplot layout.

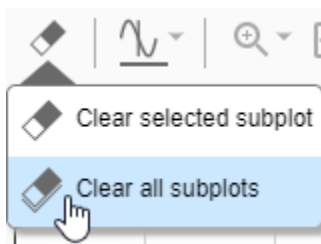

Plot the Throttle signal on the top-left subplot. To plot the signal, select the subplot where you want to plot the signal, then select the check box next to the signal. Plot the Brake signal on the subplot below the Throttle signal, then plot the EngineRPM and VehicleSpeed signals on the remaining subplots.

To facilitate building the same visualization for subsequent simulations, save the view. In the Simulation Data Inspector, click **Layout**, then select **Save current view**. Use the dialog box to specify a name for the view and browse to the location where you want to save the view file. Alternatively, you can save the view programmatically using the `Simulink.sdi.saveView` function. This example saves the view with the name `ThrottleBrakeVehicleSpeed`.

After saving the view, clear the subplots so you can visualize another set of signals. Click **Clear Subplot**, then select **Clear all subplots**.

Build another view to analyze the relationships among the `EngineRPM`, `OutputTorque`, `TransmissionRPM`, and `VehicleSpeed` signals.

Save the view using the `Simulink.sdi.saveView` function or using the Simulation Data Inspector UI. In the Simulation Data Inspector, click **Layout**, then select **Save current view**. This example saves the view with the name `RPMTorqueVehicleSpeed`.

## Load a View and Plot Signals Side by Side

Simulate the model again, using input data for the hard braking vehicle maneuver. To change the input scenario the Signal Editor block loads, double-click the `ManeuversGUI` block. Then, from the **Active scenario** list, select the `Hard_braking` scenario.

By default, when you simulate the model the second time, the Simulation Data Inspector updates the plots in the current view with data from the current simulation and moves the prior simulation run into the archive. To better understand the vehicle maneuver, load the first view that plots the `Throttle` and `Brake` signals using the Simulation Data Inspector or the `Simulink.sdi.loadView` function. To load the view using the Simulation Data Inspector UI:

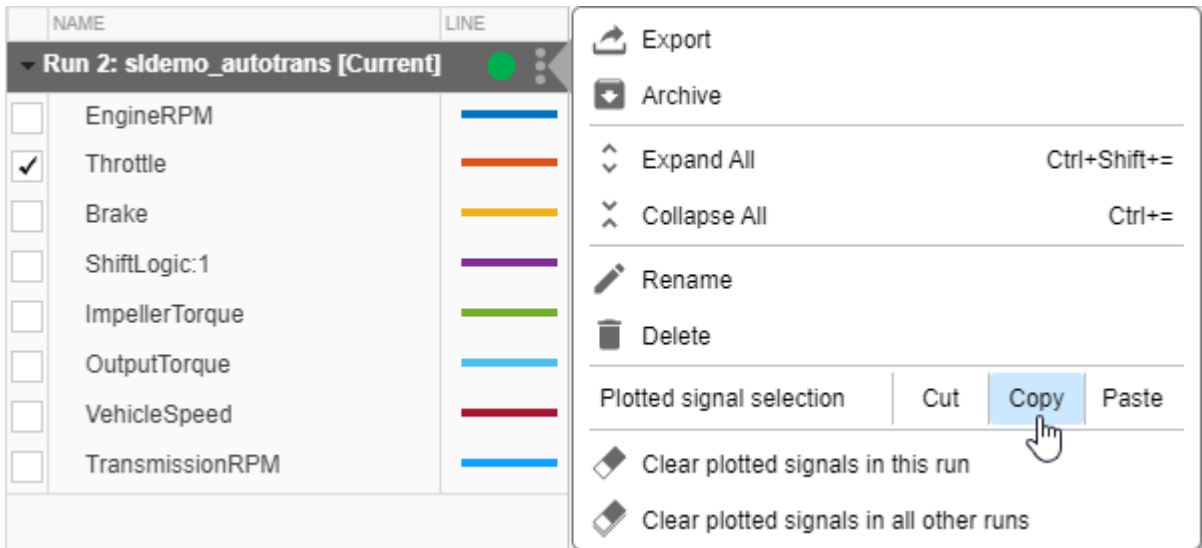

- 1 Click **Layout**, then select **Open saved view**.
- 2 In the dialog box, select `ThrottleBrakeVehicleSpeed.mldatx`.
- 3 Click **Open**.

To adjust the zoom level for the signals from the new run, click **Fit to View**  or press the space bar.

Analyze the differences between the passing maneuver and hard braking maneuver by plotting the same signals from each simulation side by side. Copy the plotted signal selection for the current run and paste it onto the prior run in the archive.

- 1 To open the run actions menu for the current run, click the three dots on the right of the row for the current run. Then, under **Plotted signal selection**, select **Copy**.

- 2 Click the arrow to expand the archive and access the prior run.

- 3 To open the run actions menu for the prior run, click the three dots on the right of the row for the prior run in the archive. Then, under **Plotted signal selection**, select **Paste**.

The cut, copy, and paste options work for all visualizations that plot signal data, including XY plots and Maps.

**Note** The map visualization only supports displaying one route. When you copy and paste the plotted signals selection for a view that includes a map, the map updates to display the route from the run where you pasted the plotted signal selection.

Analyze the differences between the passing maneuver and hard braking simulations using the second view.

- 1 Load the view `RPMTorqueVehicleSpeed.mldatx`.

Click **Layout**, then select **Open saved view**. Select the file `RPMTorqueVehicleSpeed.mldatx` and click **Open**.

- 2 Click **Fit to View**  or press the space bar.
- 3 Copy the plotted signal selection from the current run.
- 4 Paste the plotted signal selection from the current run onto the first run.

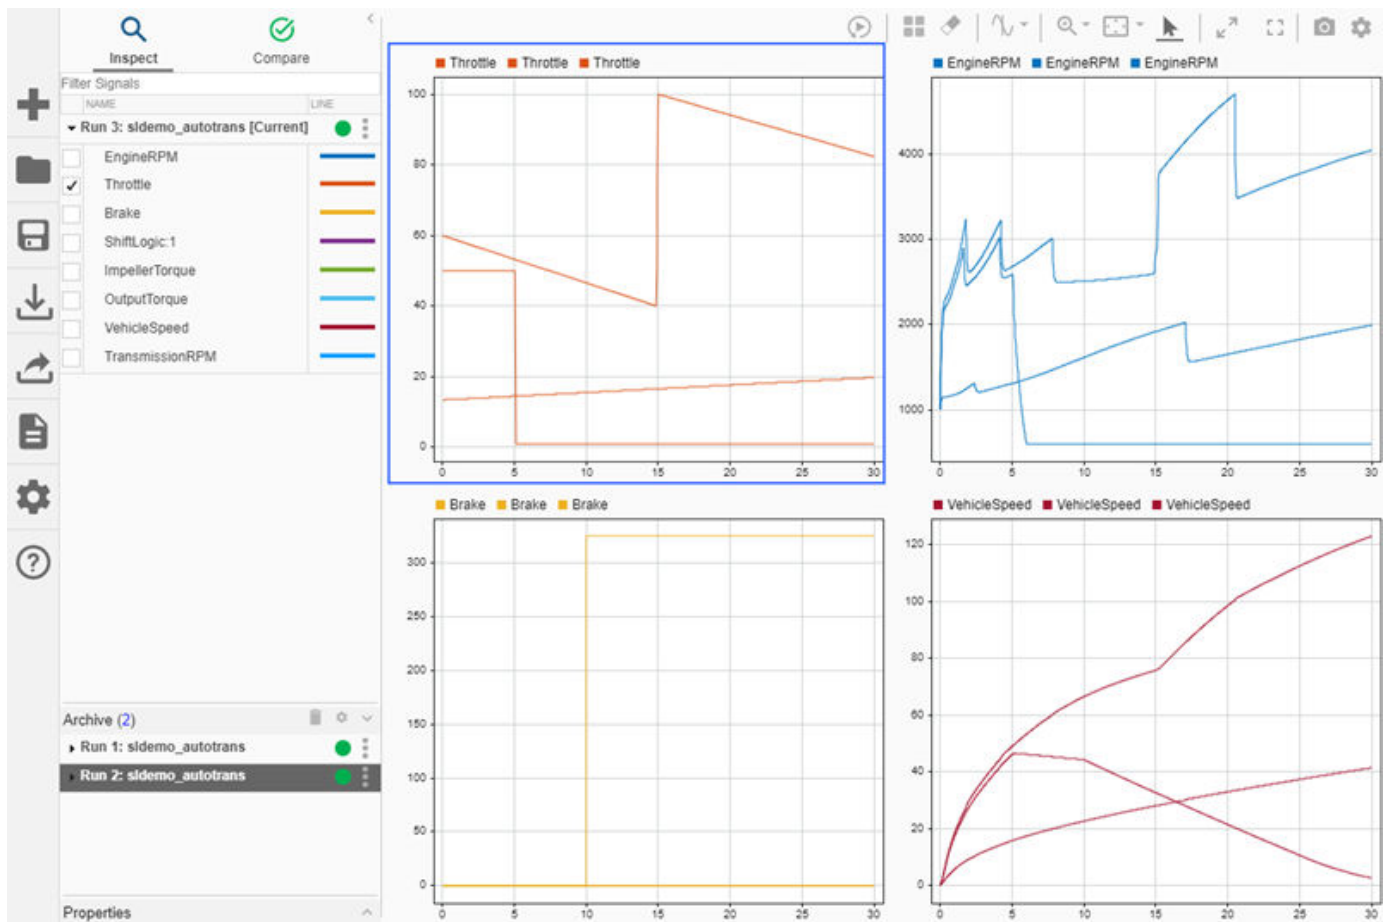

## Swap Source Run for Plotted Signals

Simulate the model again, using input data for the gradual acceleration maneuver. To change the input scenario the Signal Editor block loads, double-click the ManeuversGUI block. Then, from the **Active scenario** list, select the Gradual\_Acceleration scenario.

When you simulate the model again, the plots update to display data from the current run. To analyze the vehicle maneuver, load the first view. Click Layout, then select **Open saved view** and select the ThrottleBrakeVehicleSpeed view file. To adjust the axis limits for the new run data, click Fit to View  or press the space bar.

Suppose you want to view data from all three runs together. You can copy the plotted signal selection from the current run and paste it onto both prior runs.

- 1 Open the run actions menu for the current run. Then, under **Plotted signal selection**, select **Copy**.
- 2 Open the run actions menu for Run 1 in the archive. Then, under **Plotted signal selection**, select **Paste**.
- 3 Open the run actions menu for Run 2 in the archive. Then, under **Plotted signal selection**, select **Paste**.

Now suppose you want to analyze each vehicle maneuver on its own. Using the run actions menu, you can easily clear signals from a specific run from the view or clear signals from all runs except a specific run from the view. Then, you can use the cut and paste options to swap which run provides the data for the view.

To remove signals from the passing maneuver and hard braking maneuver simulations, open the run actions menu for the current run and select **Clear plotted signals in all other runs**.

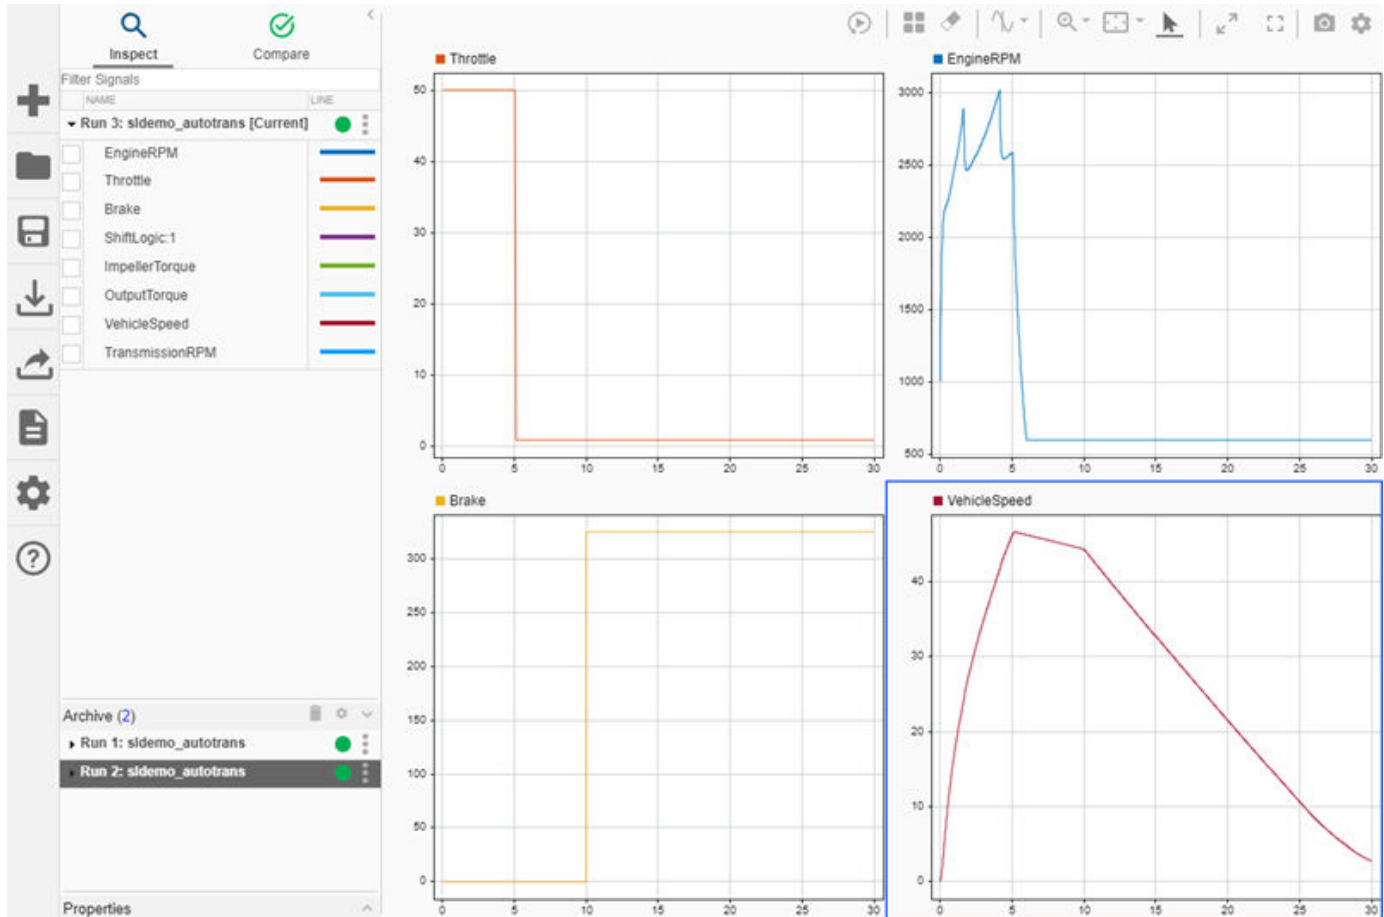

Only signals from the current run remain plotted.

To update the view to plot only signals from the hard braking maneuver simulation, cut the plotted signal selection from the current run and paste it onto Run 2 in the archive.

- 1 Open the run actions menu for the current run. Then, under **Plotted signal selection**, select **Cut**.
- 2 Open the run actions menu for Run 2. Then, under **Plotted signal selection**, select **Paste**.

To update the view to plot only signals from the passing maneuver simulation, cut the plotted signal selection from Run 2 and paste it onto Run 1.

- 1 Open the run actions menu for Run 2. Then, under **Plotted signal selection**, select **Cut**.
- 2 Open the run actions menu for Run 1. Then, under **Plotted signal selection**, select **Paste**.

You can repeat similar steps using the other view, `RPMTorqueVehicleSpeed`. Load the view using the `Simulink.sdi.loadView` function or by clicking **Layout** and then selecting **Open saved view**. Then, use the run actions menu to plot signals from each run side by side or on their own.

## Related Examples

- “Create Plots Using the Simulation Data Inspector” on page 31-152
- “Save and Share Simulation Data Inspector Data and Views” on page 31-139

## Save and Share Simulation Data Inspector Data and Views

After you inspect, analyze, or compare your data in the Simulation Data Inspector, you can share your results with others. The Simulation Data Inspector provides several options for sharing and saving your data and results, depending on your needs. With the Simulation Data Inspector, you can:

- Save your data and layout modifications in a Simulation Data Inspector session.
- Share your layout modifications in a Simulation Data Inspector view.
- Share images and figures of plots you create in the Simulation Data Inspector.
- Create a Simulation Data Inspector report.
- Export data to the workspace.
- Export data to a file.

### Save and Load Simulation Data Inspector Sessions

If you want to save or share data along with a configured view in the Simulation Data Inspector, save your data and settings in a Simulation Data Inspector session. You can save sessions as MAT- or MLDATX-files. The default format is MLDATX. When you save a Simulation Data Inspector session, the session file contains:

- All runs, data, and properties from the **Inspect** pane, including which run is the current run and which runs are in the archive.
- Plot display selection for signals in the **Inspect** pane.
- Subplot layout and line style and color selections.

---

**Note** Comparison results and global tolerances are not saved in Simulation Data Inspector sessions.

---

To save a Simulation Data Inspector session:

- 1 Hover over the save icon on the left side bar. Then, click **Save As**.

- 2 Name the file.
- 3 Browse to the location where you want to save the session, and click **Save**.

For large datasets, a status overlay in the bottom right of the graphical viewing area displays information about the progress of the save operation and allows you to cancel the save operation.

The **Save** tab of the Simulation Data Inspector preferences menu on the left side bar allows you to configure options related to save operations for MLDATX-files. You can set a limit as low as 50MB on the amount of memory used for the save operation. You can also select one of three **Compression** options:

- **None**, the default, applies no compression during the save operation.

- **Normal** creates the smallest file size.
- **Fastest** creates a smaller file size than you would get by selecting **None**, but provides a faster save time than **Normal**.

To load a Simulation Data Inspector session, click the open icon  on the left side bar. Then, browse to select the MLDATX-file you want to open, and click **Open**.

Alternatively, you can double-click the MLDATX-file. MATLAB and the Simulation Data Inspector open if they are not already open.

When the Simulation Data Inspector already contains runs and you open a session, all of the runs in the session move to the archive. The view updates to reflect show plotted signals from the session file. You can drag runs between the work area and archive as desired.

When the Simulation Data Inspector does not contain runs and you open a session, the Simulation Data Inspector puts runs in the work area and archive as specified in the file.

## Share Simulation Data Inspector Views

When you have different sets of data that you want to visualize the same way, you can save a view. A view saves the layout and appearance characteristics of the Simulation Data Inspector without saving the data. Specifically, a view saves:

- Plot visualization type, layout, axis ranges, linking characteristics, and normalized axes
- Location of signals in the plots, including plotted signals in the archive
- Signal grouping and columns on display in the **Inspect** pane
- Signal color and line styling

To save a view:

- 1 Click Visualizations and layouts .
- 2 In **Saved Views**, click **Save current view**.
- 3 In the dialog box, specify a name for the view and browse to the location where you want to save the MLDATX-file.
- 4 Click **Save**.

To load a view:

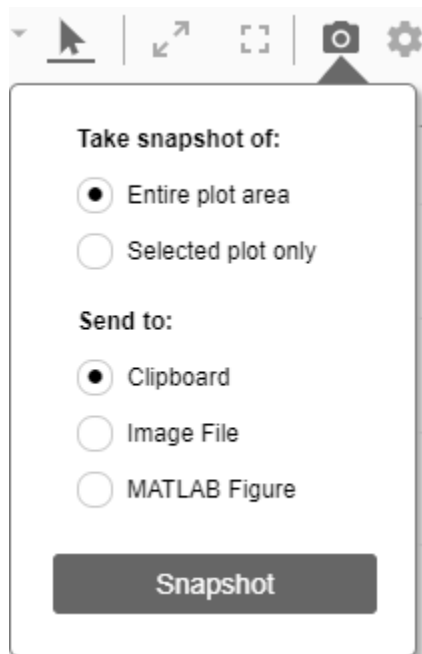

- 1 Click Visualizations and layouts .
- 2 In **Saved Views**, click **Open saved view**.
- 3 Browse to the view you would like to load, and click **Open**.

## Share Simulation Data Inspector Plots

Use the snapshot feature to share the plots you generate in the Simulation Data Inspector. You can export your plots to the clipboard to paste into a document, as an image file, or to a MATLAB figure.

You can choose to capture the entire plot area, including all subplots in the plot area, or to capture only the selected subplot.

Click the camera icon  on the toolbar to access the snapshot menu. Use the radio buttons to select the area you want to share and how you want to share the plot. After you make your selections, click **Snapshot** to export the plot.

If you create an image, select where you would like to save the image in the file browser.

You can create snapshots of your plots in the Simulation Data Inspector programmatically using `Simulink.sdi.snapshot`.

## Create Simulation Data Inspector Report

To generate documentation of your results quickly, create a Simulation Data Inspector report. You can create a report of your data in either the **Inspect** or the **Compare** pane. The report is an HTML file that includes information about all the signals and plots in the active pane. The report includes all signal information displayed in the signal table in the navigation pane. For more information about configuring the table, see “Inspect Metadata” on page 31-178.

To generate a Simulation Data Inspector Report:

1

Click the create report icon on the left bar.

2 Specify the type of report you want to create.

- Select **Inspect** to include the plots and signals from the **Inspect** pane.

- Select **Compare** to include the data and plots from the **Compare** pane. When you generate a **Compare Runs** report, you can choose to **Report only mismatched signals** or to **Report all signals**. If you select **Report only mismatched signals**, the report shows only signal comparisons that are not within the specified tolerances.

- 3 Specify a **File name** for the report, and navigate to the **Folder** where you want to save the report.
- 4 Click **Create Report**.

The generated report automatically opens in your default browser.

## Export Data to the Workspace or a File

You can use the Simulation Data Inspector to export data to the base workspace, a MAT file, or a Microsoft Excel file. You can export a selection of runs and signals, runs in the work area, or all runs in the **Inspect** pane, including the **Archive**.

When you export a selection of runs and signals, make the selection of data to export before clicking

the export button .

Only the selected runs and signals are exported. In this example, only the x1 signals from Run 1 and Run 2 are exported. The check box selections for plotting data do not affect whether a signal is exported.

When you export a single signal to the workspace or a MAT file, the signal is exported to a `timeseries` object. Data exported to the workspace or a MAT file for a run or multiple signals is stored as a `Simulink.SimulationData.Dataset` object.

To export data to a file, select the **File** option in the **Export** dialog. You can specify a file name and browse to the location where you want to save the exported file. When you export data to a MAT file, a single exported signal is stored as a `timeseries` object, and runs or multiple signals are stored as a `Simulink.SimulationData.Dataset` object. When you export data to a Microsoft Excel file, the data is stored using the format described in “Microsoft Excel Import, Export, and Logging Format” on page 31-68.

To export to a Microsoft Excel file, select the XLSX extension from the drop-down. When you export data to a Microsoft Excel file, you can specify additional options for the format of the data in the exported file. If the file name you provided already exists, you can choose to overwrite the entire file or to only overwrite sheets containing data that corresponds to the exported data. You can also choose which metadata to include and whether signals with identical time data share a time column in the exported file.

## Export Video Signal to an MP4 File

You can export a 2D or 3D signal that contains RGB or monochrome video data to an MP4 file using the Simulation Data Inspector. For example, when you log a video signal in a simulation, you can export the data to an MP4 file and view the video using a video player. To export a video signal to an MP4 file:

- 1 Select the signal you want to export.
- 2

Click **Export** in the toolbar on the left or right-click the signal and select **Export**.

- 3 In the Export dialog box, choose to export **Selected runs and signals** to a file.
- 4 Specify a file name and the path to the location where you want to save the file.
- 5 Select **MP4 video file** from the list and click **Export**.

For the option to export to an MP4 file to be available:

- You must export only one signal at a time.
- The selected signal must be 2D or 3D and contain RGB or monochrome video data.
- The selected signal must be represented in the Simulation Data Inspector as a single signal with multidimensional sample values.

You may need to convert the signal representation before exporting the signal data. For more information, see “Analyze Multidimensional Signal Data” on page 31-122.

- The data type for the signal values must be `double`, `single`, or `uint8`.

Exporting a video signal to an MP4 file is not supported for Linux operating systems.

- “Compare Simulation Data” on page 31-193

## Create Interactive Comparison Reports

This example shows how to create an interactive web-based comparison report to share and archive results for comparisons you perform using the Simulation Data Inspector. The report is a self-contained HTML file, and viewing the report only requires a web browser. You can use the report to analyze the comparison results similarly to how you would in the Simulation Data Inspector. You can change the layout of the report between the interactive view and a printable view.

This example shows how to create an interactive comparison report using data loaded into the Simulation Data Inspector from a session file. For information about importing data into the Simulation Data Inspector or logging data from a simulation, see “View Data in the Simulation Data Inspector” on page 31-2.

### Load and Compare Data

Open the Simulation Data Inspector and load the session file data into the Simulation Data Inspector.

```
Simulink.sdi.view
Simulink.sdi.load("dataToCompare.mldatx");
```

The session file contains data created by simulating the model `slexAircraftExample`. Both simulations use the square wave input from the Pilot block in the model. Each simulation uses a different time constant for the input filter. The first run contains simulation results for an input filter time constant of 0.1. The second run contains simulation results for an input filter time constant of 1.

To analyze the effect of changing the input filter time constant, compare the runs that contain the data for each simulation.

- 1 In the Simulation Data Inspector, navigate to the **Compare** tab.
- 2 From the **Baseline** list, select Run 1: `slexAircraftExample`.
- 3 From the **Compare to** list, select Run 2: `slexAircraftExample`.
- 4 Click **Compare**.

Alternatively, you can compare the runs programmatically using the `Simulink.sdi.compareRuns` function.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end-1);
runID2 = runIDs(end);

diffRes = Simulink.sdi.compareRuns(runID1,runID2);
```

### Generate Interactive Comparison Report

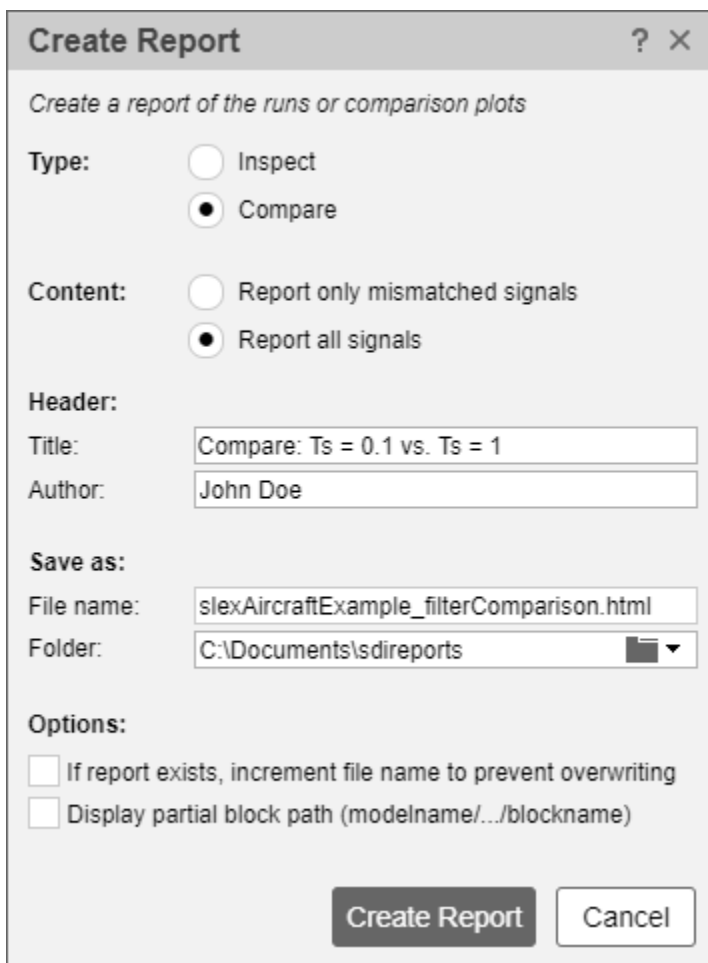

When you generate a comparison report to save the comparison results, specify:

- The data you want to include in the report.
- The title and author for the report.
- The file name and location.
- Options for avoiding overwriting existing reports and shortening block paths. Consider shortening block paths when you log data throughout a model hierarchy.

To create the report, click **Report** .

For this example:

- 1 Under **Type**, select **Compare**.
- 2 Under **Content**, select either option. In this example, all signals in the comparison do not match, so the contents of the report are the same for either option.
- 3 In the **Title** text box, enter Compare: Ts = 0.1 vs. Ts = 1.
- 4 In the **File name** text box, enter slexAircraftExample\_filterComparison.html.
- 5 Click **Create Report**.

**Create Report** ? X

Create a report of the runs or comparison plots

**Type:**  Inspect  
 Compare

**Content:**  Report only mismatched signals  
 Report all signals

**Header:**

Title: Compare: Ts = 0.1 vs. Ts = 1

Author: John Doe

**Save as:**

File name: slexAircraftExample\_filterComparison.html

Folder: C:\Documents\sdireports

**Options:**

If report exists, increment file name to prevent overwriting

Display partial block path (modelname/.../blockname)

Create Report Cancel

The generated report automatically opens in the system browser. By default, the Simulation Data Inspector saves the report in a folder called sdi reports in the working directory.

### Inspect Comparison Results Using Interactive Report

The interactive report information and layout is similar to what you see on the **Compare** pane of the Simulation Data Inspector. In the comparisons table, you can select the signal result you want to view in the plots.

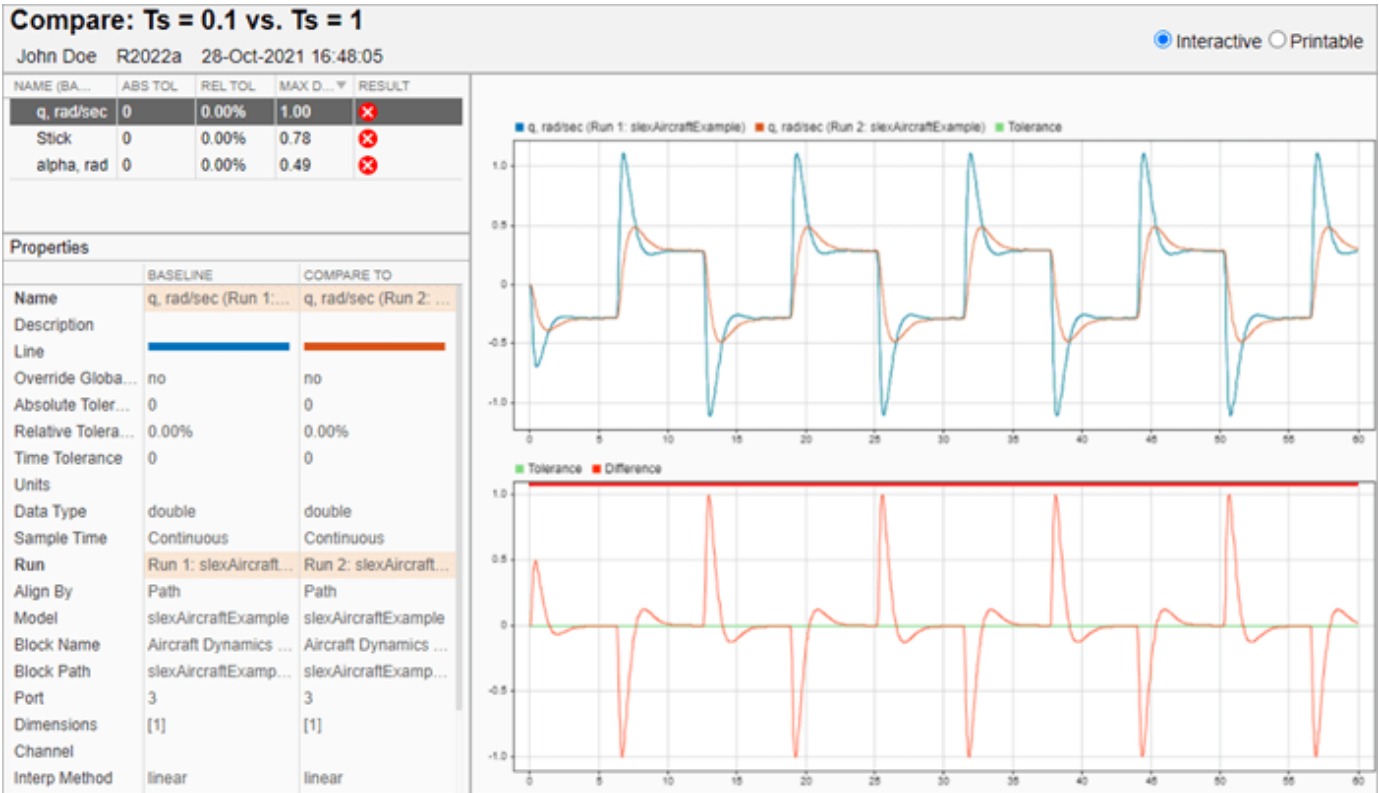

The **Properties** table shows the metadata for the compared signals and highlights metadata that differs. Scroll in the **Properties** table to see all the metadata. When the comparison contains more signals than fit in the results table, you can scroll in the comparison table to inspect the results for each signal comparison and sort the signals in the table by the data in each column.

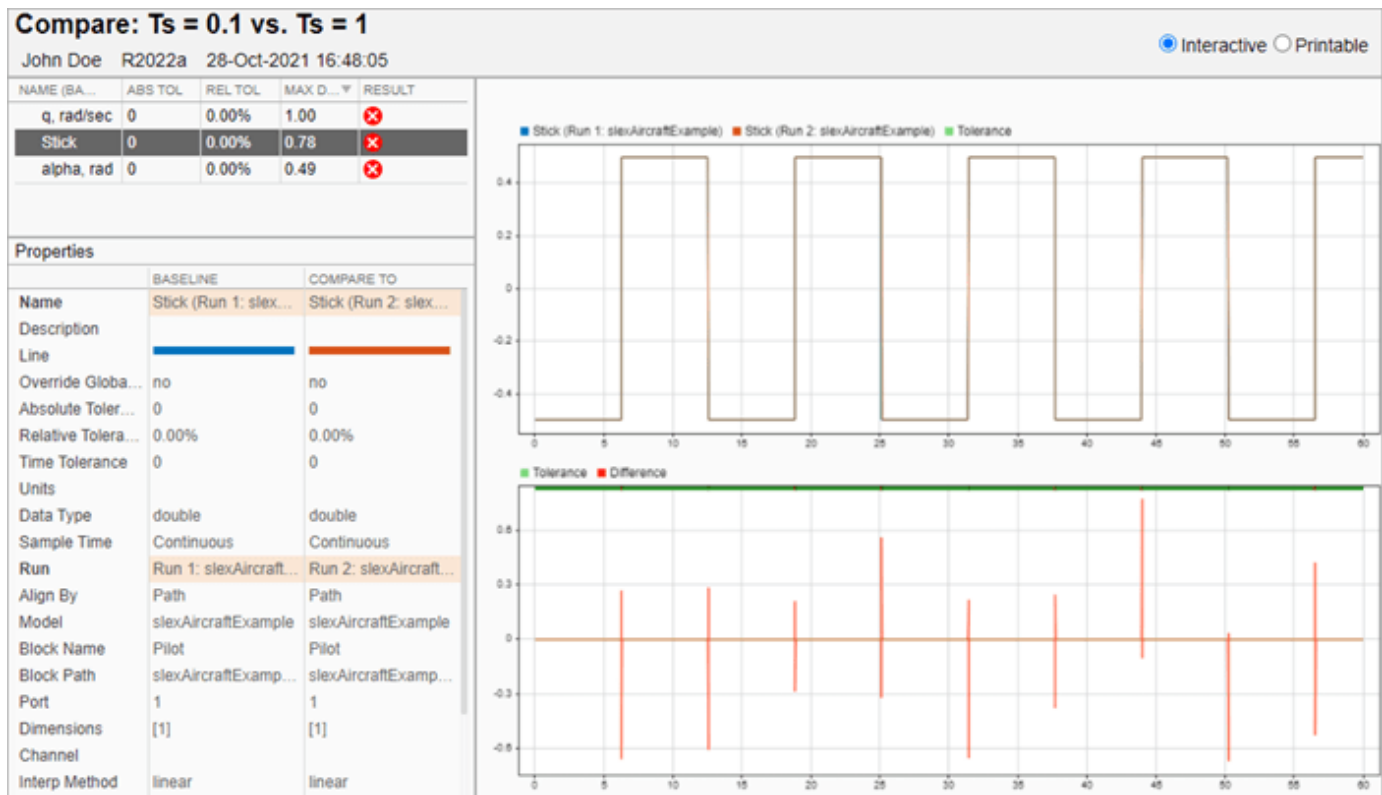

For example, to sort the results by the maximum difference, click the **Max Diff** column.

You can adjust the size of the panes in the report by dragging the borders and adjust the widths of the columns in each table by dragging the divisions between the column headings. For example, since the comparison table does not use all the space in the signals pane, you could make the **Properties** pane larger.

The information in the table indicates that the comparison results for the **Stick** signal are out of tolerance with a maximum difference of 0.78. In the model, the **Stick** signal is the output from a Signal Generator block, and the filter time constant should not affect the block output. Select the **Stick** signal to investigate the comparison results.

By inspecting the plots, you can see that the differences occur at the rising and falling edges of the square wave. The `slexAircraftExample` model uses a variable-step solver. The differences occur because the new time constant value changes the system dynamics, and the solver calculates slightly different time steps for the second simulation. The transition of the square wave is sharp, so small timing differences can result in large differences in magnitude.

Because the differences in the `Stick` signal are due to modeling rather than a real change in system dynamics, you could go back to the Simulation Data Inspector and specify a small time tolerance (for example,  $0.01$ ) for the `Stick` signal so the comparison results are within tolerance. To share the updated results, you can generate a new comparison report.

### Print Comparison Report

After finalizing the analysis and presentation of the comparison results, you can print a comprehensive view of the results using the interactive web report. To switch to the printable view, select the **Printable** radio button, or press **Ctrl+P** to see a print preview in the browser. In the printable view, the metadata and plots for all signals are stacked, with the summary table at the top.

## Create Plots Using the Simulation Data Inspector

Plots can help showcase important features or trends in your data and allow you to share your findings with others. The Simulation Data Inspector allows you to select from a variety of visualization types and layouts and customize plot and signal appearances to present your data most effectively.

### Add Visualizations

You can choose from several visualizations to use for your data in the Simulation Data Inspector.

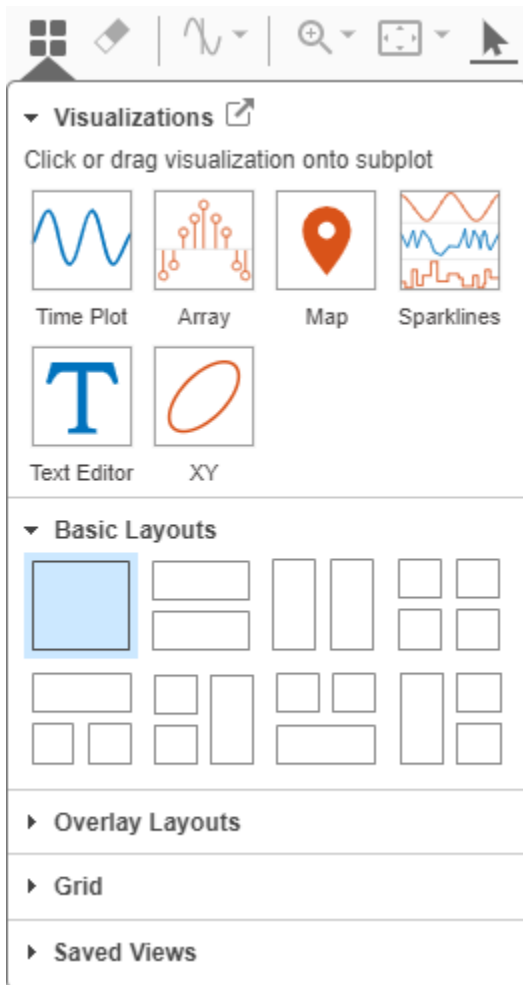

Icon	Visualization Name	Description
	<b>Time Plot</b>	Plot your signal data as a function of time. Time plots are the default visualization for each subplot.
	<b>Array</b>	Plot multidimensional data including variable-sized signals.  For an example, see “View Multidimensional Signals Using the Array Plot” on page 31-58.
	<b>Map</b>	Plot a route using longitude and latitude data on either a street or satellite view.  For an example, see “View and Replay Map Data” on page 31-22.
	<b>Sparklines</b>	Plot many signals at once.  For an example, see “View Many Signals Together Using Sparklines” on page 31-52.
	<b>XY</b>	Plot relationships between time-aligned signals.  For an example, see: <ul style="list-style-type: none"> <li>• “Visualize Simulation Data on an XY Plot” on page 31-31</li> <li>• “Analyze Data Using the XY Plot” on page 31-43</li> </ul>
	<b>Text Editor</b>	Add notes, observations, and conclusion to your data with a rich text editor.

To view available visualizations in the Simulation Data Inspector, click Visualizations and layouts

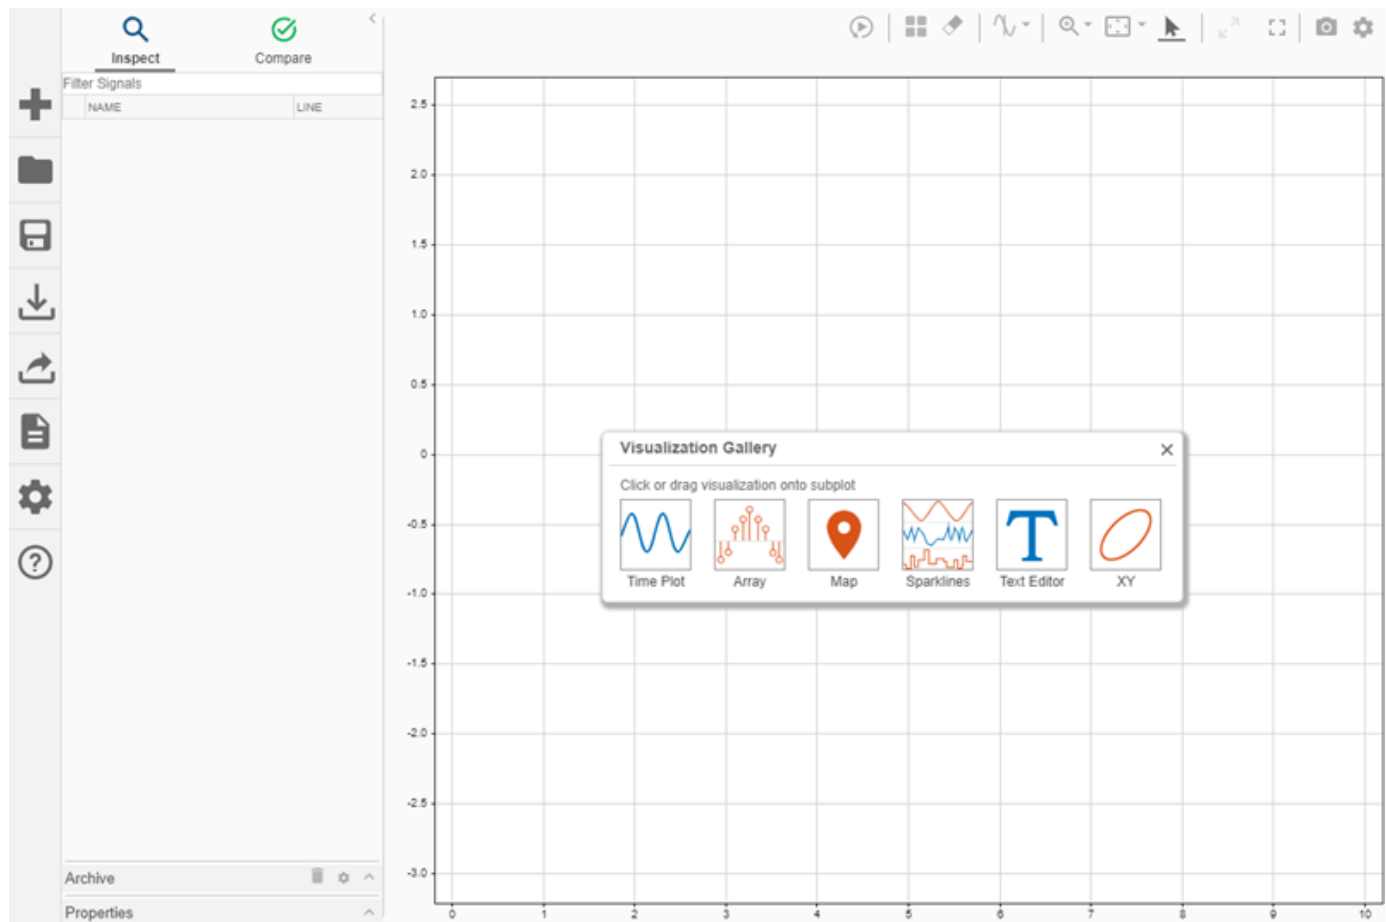

. To add a visualization, drag the visualization icon onto the subplot.

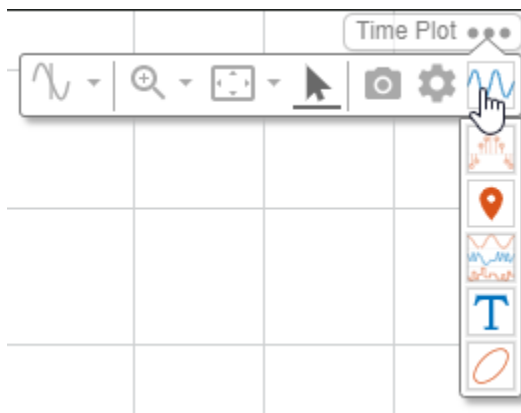

When you have many subplots, you can open the **Visualization Gallery** in a separate window and reposition it with the plot area. Click Undock Visualization Gallery , then move the **Visualization Gallery** to a different location.

You can also add a visualization to a subplot using the subplot menu.

- 1 Pause on the subplot you wish to change. The name of the visualization currently in use appears with three dots.
- 2 Click the three dots.
- 3 Choose a visualization from the Change Visualization drop-down list.

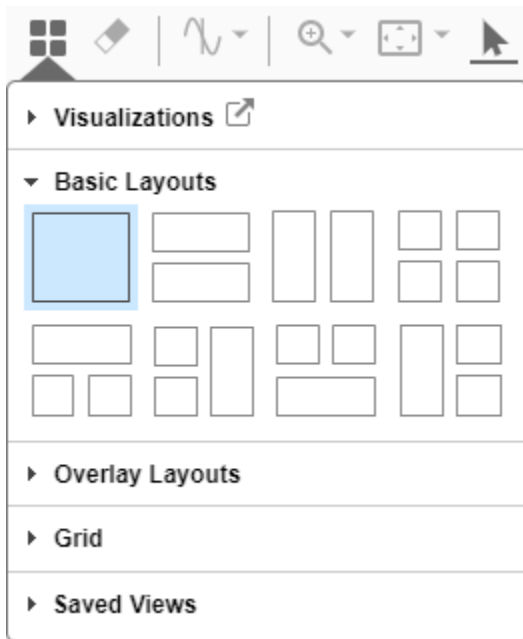

## Select Plot Layout

You can select from three types of layouts in the Simulation Data Inspector.

- **Basic Layouts** offer templates for layouts including up to four subplots.
- **Overlays** have overlay subplots in two corners of a main plot.
- **Grid** layouts create a grid of subplots according to dimensions you specify from 1×1 to 8×8.

To change the visualization, click Visualizations and layouts .

### Moving Between Subplot Layouts

When you plot a signal on a subplot, the Simulation Data Inspector links the signal to the subplot, identifying the subplot with a number. As you move between subplot layouts, the association between the signal and subplot remains, even as the shape or visibility of the subplot may change.

Subplots of **Grid** layouts follow column-wise numbering, from 1 at the top left subplot to 8 in the bottom left, to 64 at the bottom right. The number system is fixed, regardless of which subplot configuration you select. For example, if you display four subplots in a 2×2 configuration, the bottom right subplot of the configuration is numbered 10, not 4. The number is 10 because in the largest possible 8×8 matrix, that subplot is numbered 10 when you count the subplots in a column-wise manner.

**Basic Layouts** subplots also use the fixed 8×8 column-wise numbering as a base. For example, the top plot in this three-subplot layout is subplot 1, and the two subplots below it are 2 and 10.

In this three-subplot layout, the index for the right subplot is 9, and the indices for the two subplots on the left are 1 and 2.

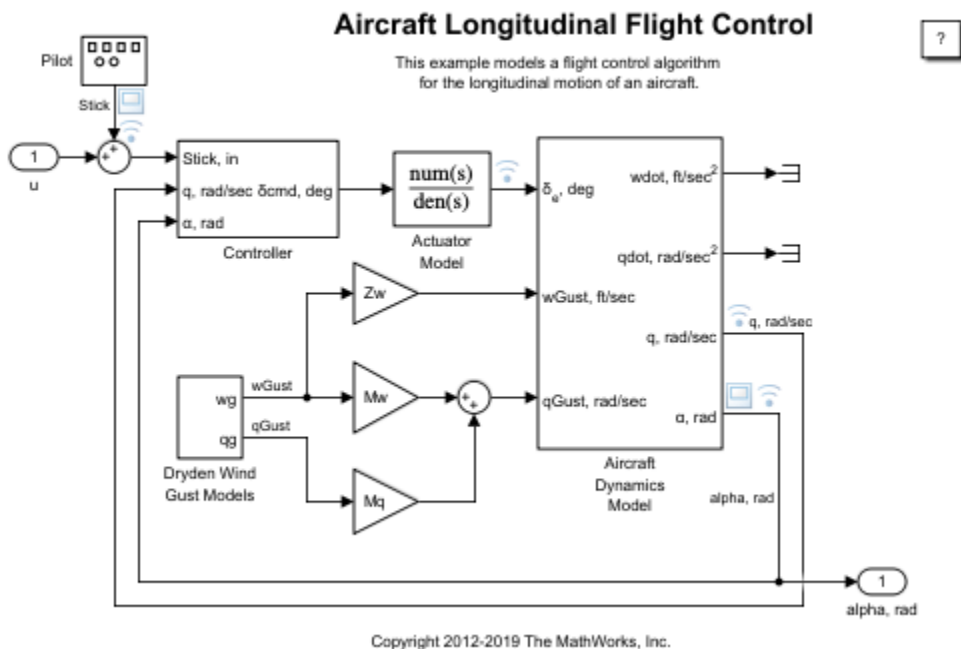

For the **Overlays** layouts, the index for the main plot is always 1, and the indices for the overlaid plots are 2 and 9.

## View Simulation Data Using Time Plot

This example shows how to plot time series data using the Simulation Data Inspector. Simulation data for this example is generated from a simulation of the `slexAircraftExample` model that logs the output of the Actuator Model block and the Stick,  $\alpha$ , rad, and  $q$ , rad/sec signals.

Open the model, mark signals for logging, and run a simulation.

- 1 Open the model.
- 2 To log the output of the Actuator Model block and the  $q$ , rad/sec, the Stick, and the  $\alpha$ , rad signals, select the signals in the model. Then, click **Log Signals**.
- 3 Click the **Data Inspector** button to open the Simulation Data Inspector.
- 4 Click **Run** to simulate the model.

Add the  $\alpha$ , rad signal to the time plot by selecting the check box next to the signal name or by dragging the signal onto the plot.

You can view more than one signal in a single time plot by selecting multiple check boxes. Add the Stick signal to your time plot of the alpha, rad signal.

## Add Text to Plot Layout

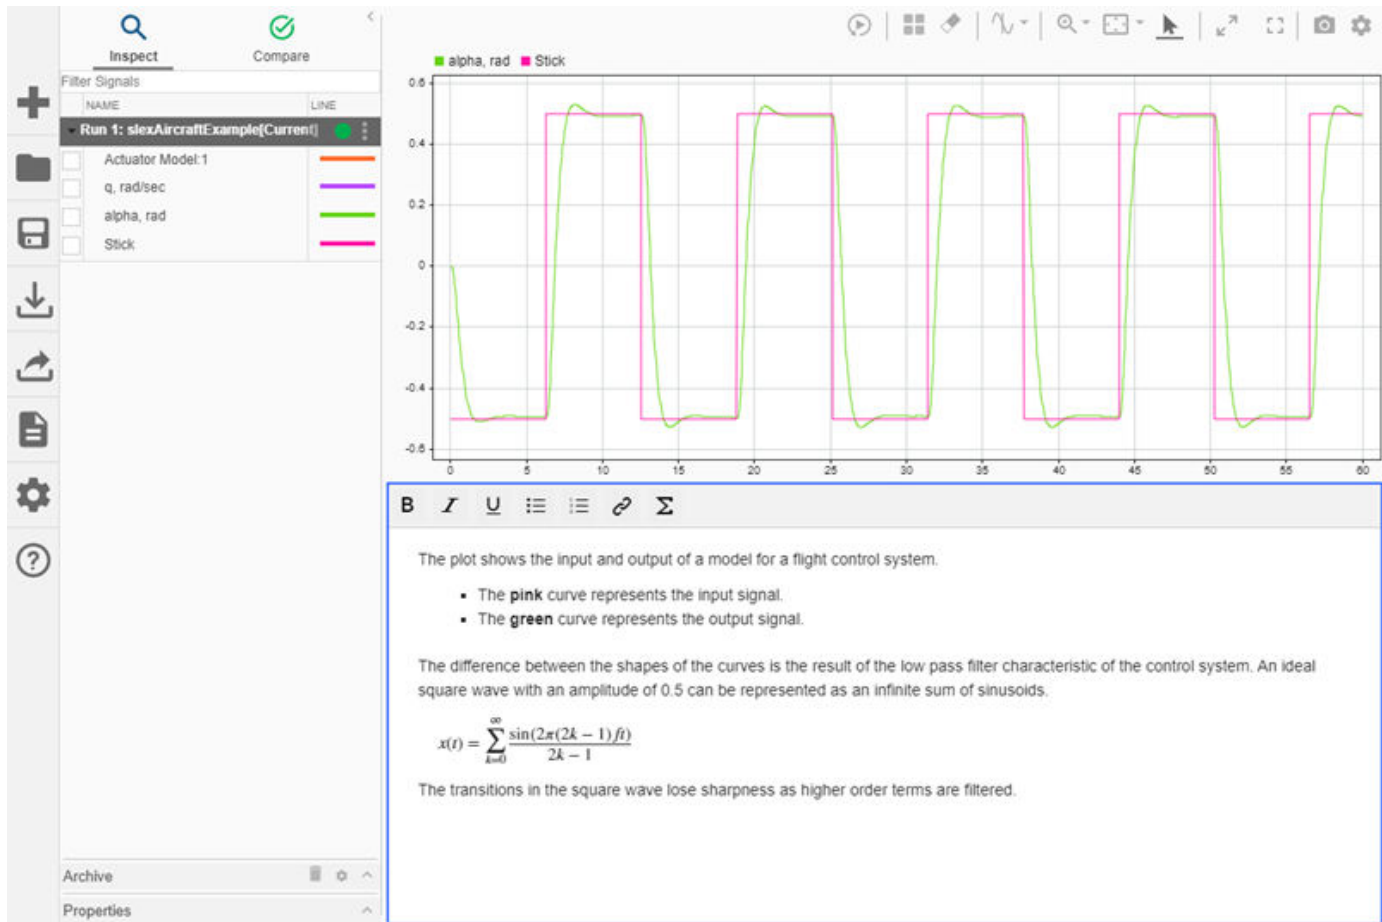

You can use text to make the results of your data more clear. For example, add a text editor to your plot layout when you want to present conclusions, descriptions, or observations alongside your data. Try adding a text editor below your time series data. First, to add a subplot below the time plot, click

Visualizations and layouts . Then, select the vertically aligned two-plot layout from **Basic**

**Layouts**. Next, drag the **Text Editor** icon from the Visualizations and layouts menu  onto the lower subplot.

The text editor includes a toolbar for rich text formatting, including:

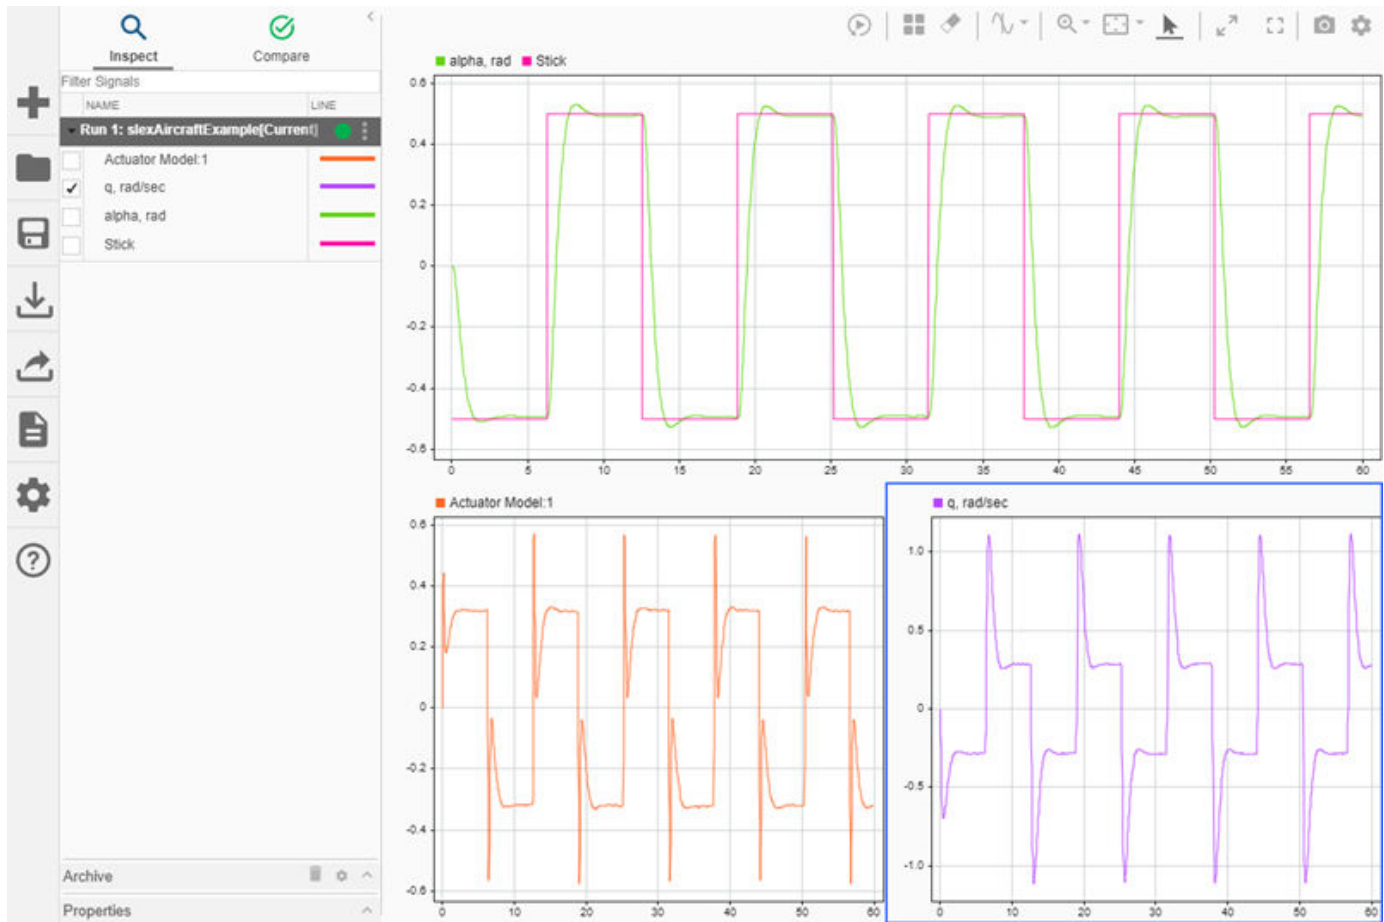

- Bullet points
- Numbered lists
- Hyperlinks
- LaTeX equations

## Add Subplots to Visualize Data

Select the plot layout that best highlights the characteristics of your data. For example, with a basic three-plot layout, you can use the large plot to show a main result and show intermediate signals on the smaller plots.

- 1 Click Visualizations and layouts . Then, from **Basic Layouts**, choose the layout with one large plot on top and two smaller plots below.
- 2 Drag the **Time Plot** icon from Visualizations and layouts  onto the lower left subplot.
- 3 Add the **Actuator Model: 1** signal to the lower left subplot by selecting the check box next to the signal name or by dragging the signal onto the plot.
- 4 Add the **q, rad/sec** signal to the lower right subplot.

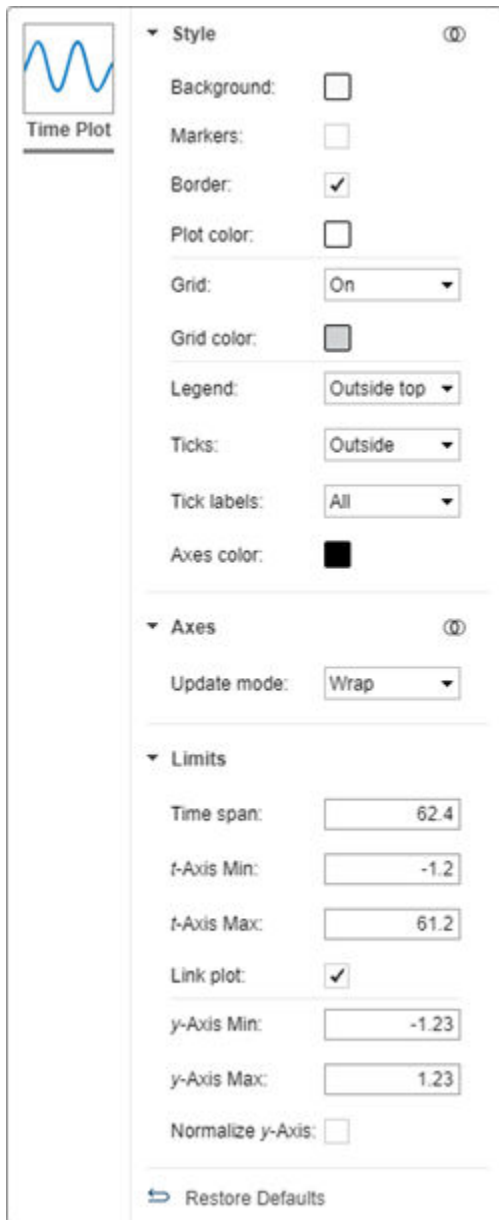

## Customize Time Plot Appearance

After you choose a plot layout, you can customize the appearance of each visualization. To view customization options, click Visualization Settings . The menu tabs correspond to the visualizations in your layout.

You can customize the appearance of time plots in the Simulation Data Inspector, including choosing custom colors, choosing to show or hide attributes such as the grid or legend, and specifying axes limits. To maximize the area in the visualization available for the plot, you can move the tick marks, tick mark labels, and legend inside the plot or hide them.

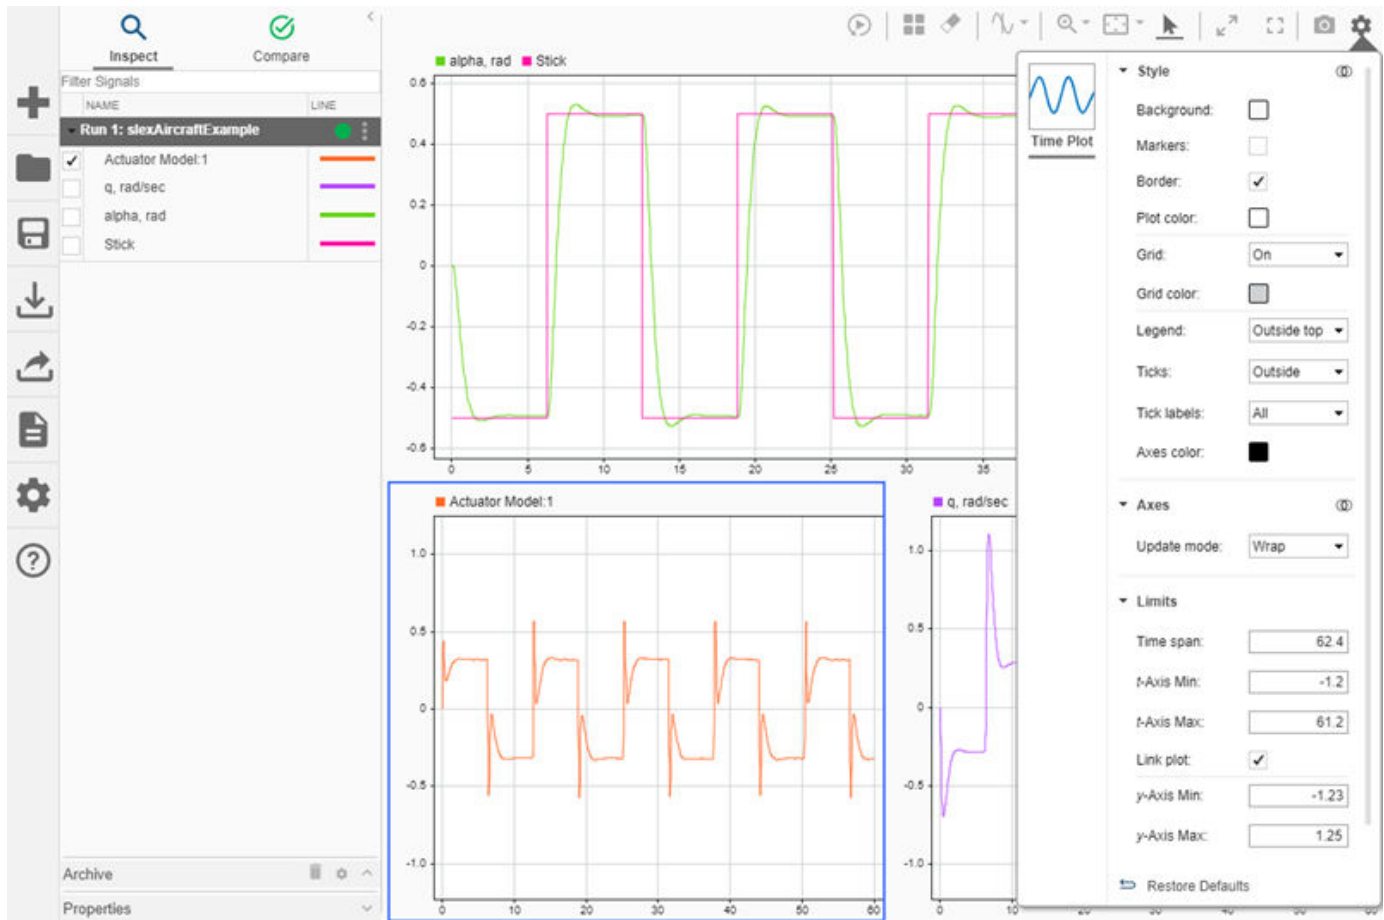

The **Limits** section gives you control over the limits of the  $t$ - and  $y$ -axes. You may also choose to normalize the  $y$ -axis. Except for the  $t$ -axis limits, the settings you configure in the **Limits** section apply to the active subplot. To configure  $t$ -axis limits individually for a subplot, unlink the subplot. For more information, see “Linked Subplots” on page 31-174.

To improve the plot you created in the previous section, change the  $y$ -axis limits of the left graph to match those on the right.

- 1 Select the  $q$ , rad/sec plot to view its  $y$ -axis limits in the **Limits** tab.
- 2 Select the Actuator Model: 1 plot as the active plot.
- 3 In the **Limits** section, change the  $y$ -axis limits of the Actuator Model: 1 plot to match the limits of the  $q$ , rad/sec plot.

## Customize Signal Appearance

The Simulation Data Inspector allows you to modify the color, style, and line width of each signal. You can select a signal color from a palette of standard colors or specify a custom color with RGB values.

You can access the line style menu for a signal in the Simulation Data Inspector or in the Simulink Editor:

- In the Simulation Data Inspector, click the graphic representation in the **Line** column of the work area or the **Line** row in the **Properties** pane.

- From the Simulink Editor, right-click the logging badge for a signal, and select **Properties** to open the **Instrumentation Properties** for the signal. Then, click the graphic representation of the **Line**.

From the **Instrumentation Properties**, you can also select subplots where you want to plot the signal. Changes made through the **Instrumentation Properties** take effect for subsequent simulations.

If a signal is connected to a Dashboard Scope block, you can also modify the signal line style and color using the **Block Parameters** dialog box. Changes to line style and color made in the Simulink Editor remain consistent for a signal. When you change the line style and color in the Simulation Data Inspector, the signal line style and color do not change in the Simulink Editor.

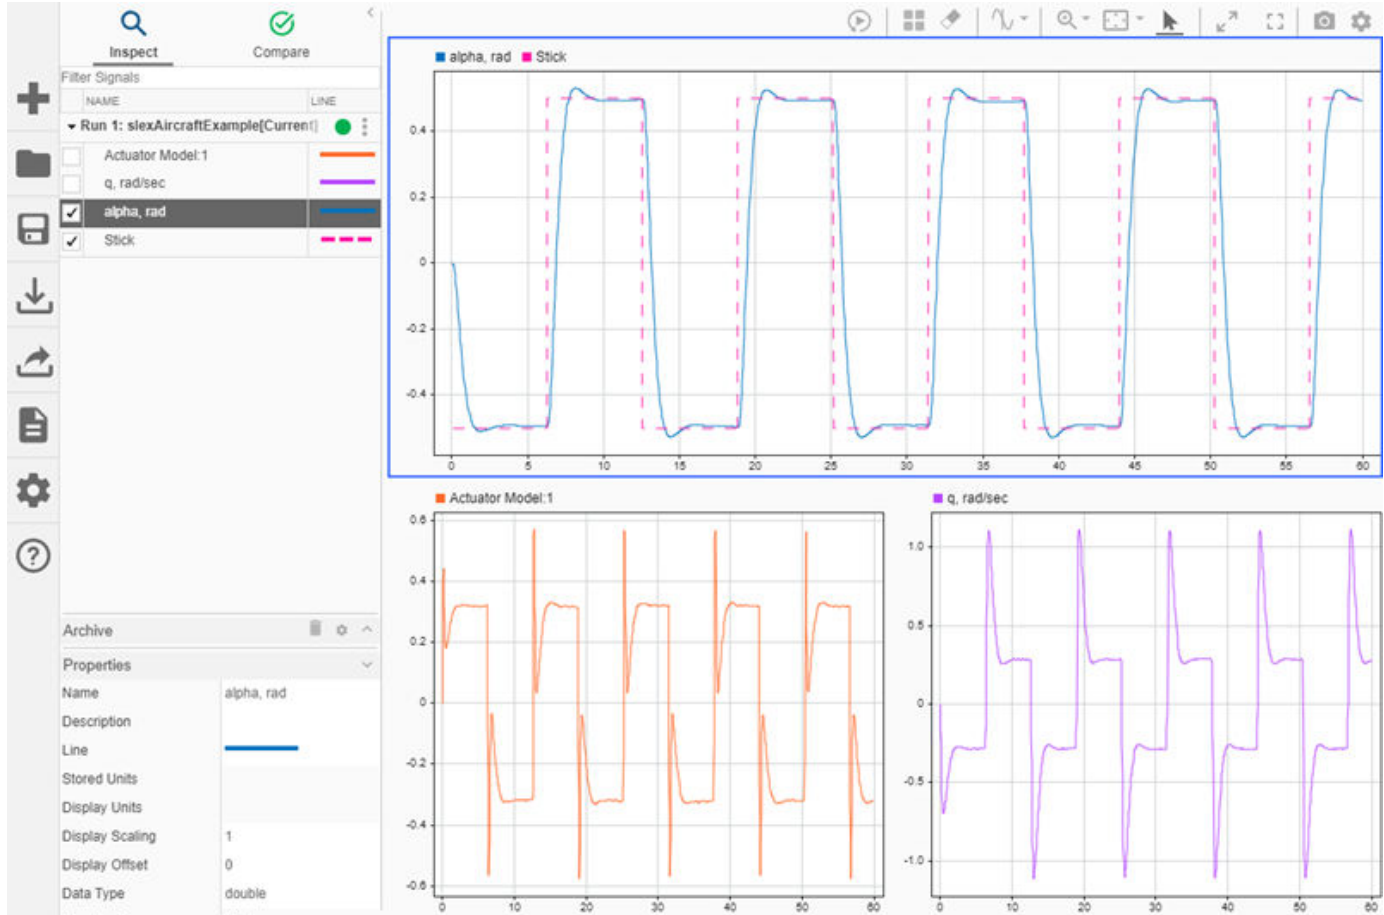

Line style customization can help emphasize differences between signals in your plot. For example, change the line style of the **Stick** signal to dashed to visually indicate that it is an ideal, rather than simulated, signal.

- 1 Click the **Line** column for the **Stick** signal.
- 2 Select the dashed option.
- 3 Click **Set**.

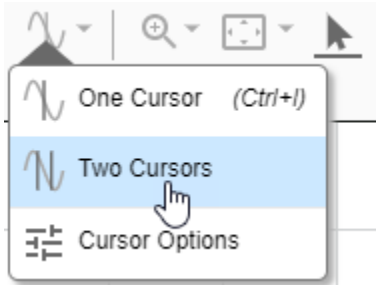

You can select easily distinguishable colors for all of the signals in your plot.

- 1 Click the **Line** column for the `alpha, rad` signal.
- 2 Specify the desired color. This example uses the dark blue in the standard palette.
- 3 Click **Set**.

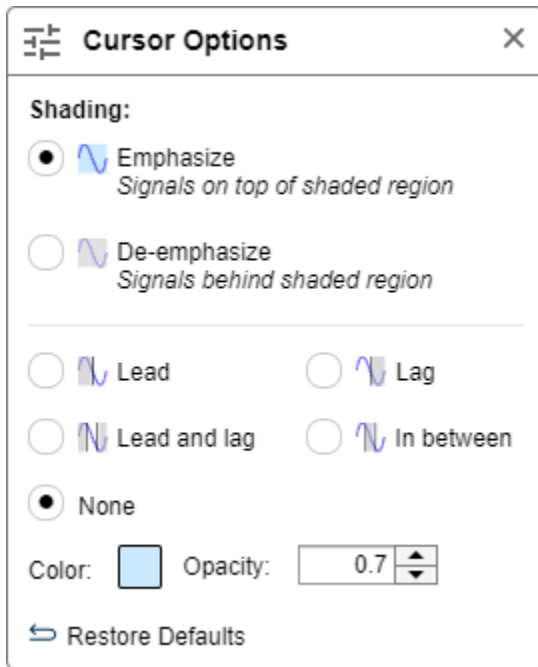

## Shade Signal Regions

You can shade an area of a time plot to draw attention to a region of interest in the plotted data. For example, you can highlight the area around a signal transition. First, add two cursors to the plot area by clicking the arrow next to the **Show/hide cursors** button and selecting **Two Cursors**.

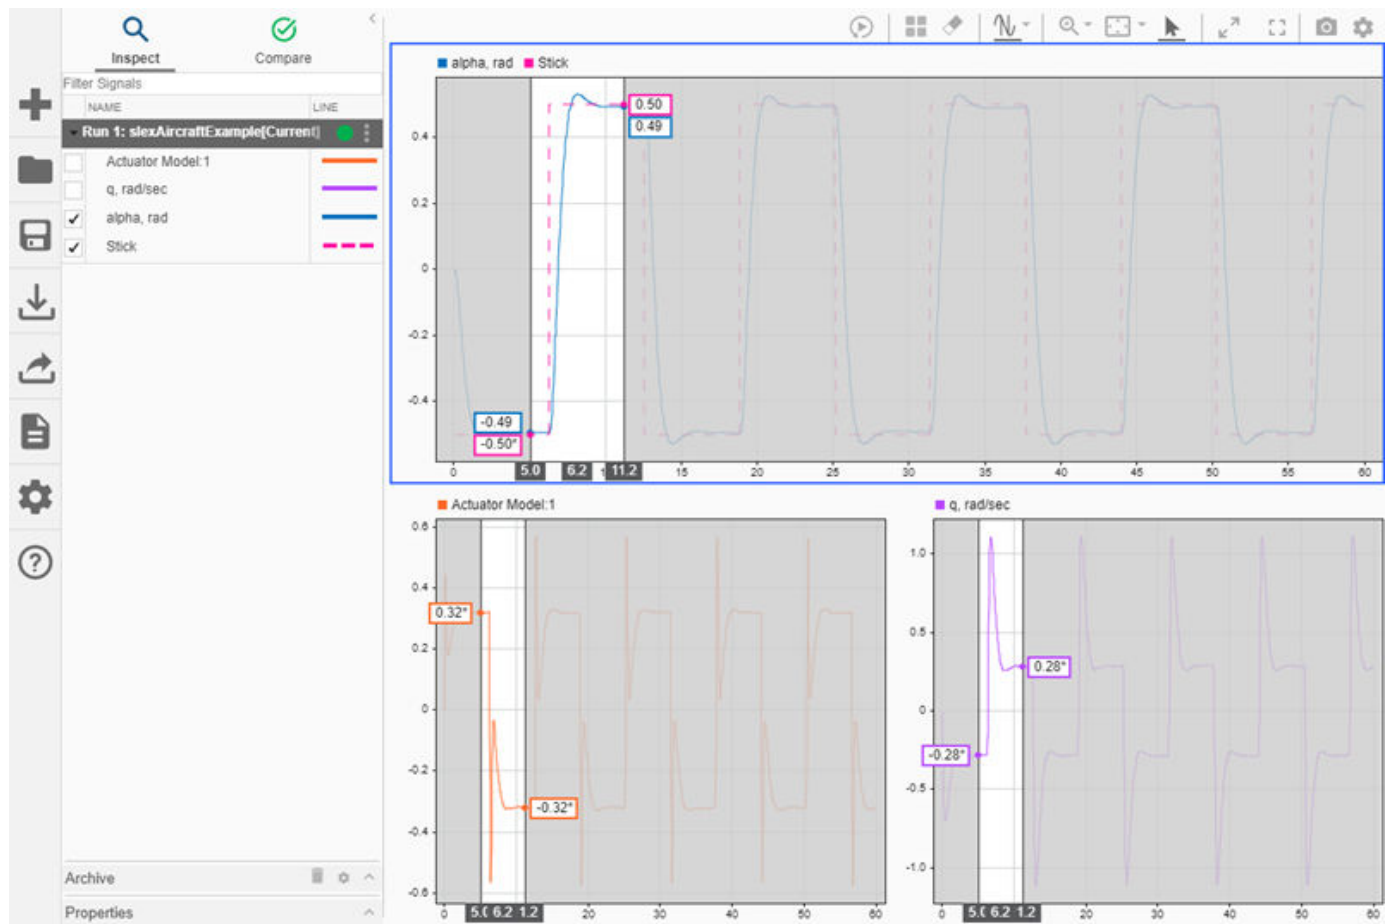

Next, click the arrow again and select **Cursor Options**. You can specify whether to emphasize or de-emphasize the shaded area, the area to shade relative to the cursors, and the shading color and

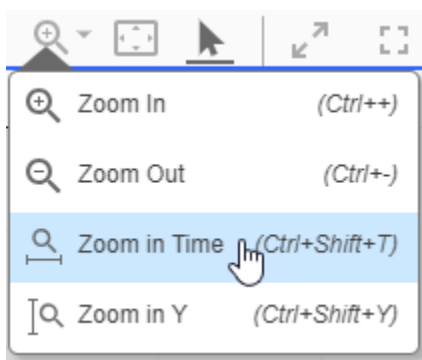

opacity. You can specify separate color and opacity settings for the **Emphasize** and **De-emphasize** options.

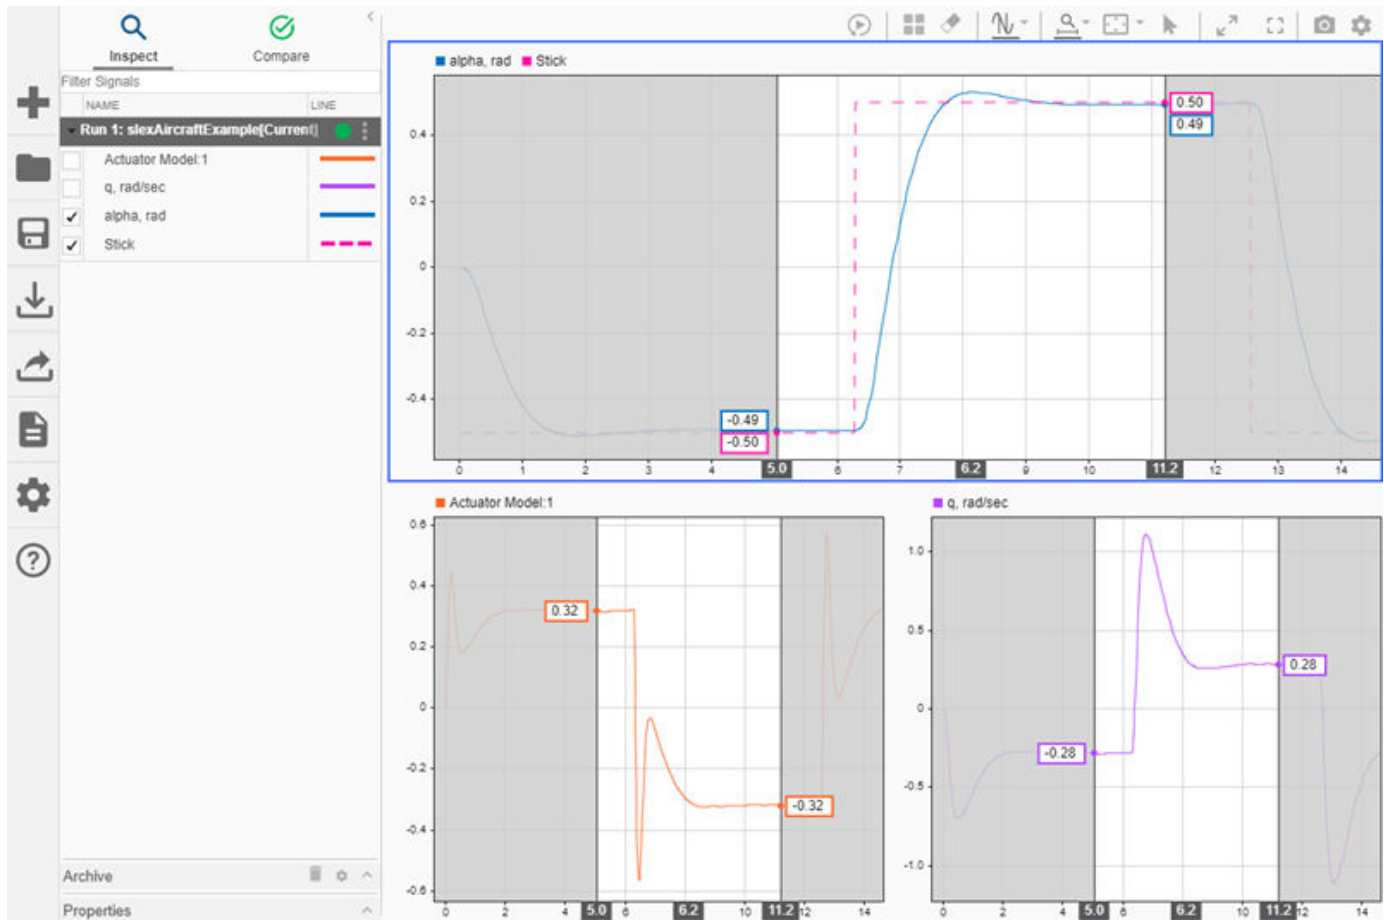

For this example, select the **De-emphasize** and **Lead and lag** options. Close the **Cursor Options** menu. The gray shading obscures the area outside of the cursors and highlights the signal region between the cursors. Move the cursors to highlight an area of interest, like the first rising edge of the waveform.

You can use the **Zoom in Time** option to zoom in synchronously on the region of interest. Select **Zoom in Time** from the **Zoom In** menu.

Then, click and drag to select a time span.

You can use the **Snapshot** menu to save snapshots of highlighted signal regions. For more information, see “Save and Share Simulation Data Inspector Data and Views” on page 31-139.

## Rename Signals

You can rename signals in the Simulation Data Inspector when a more descriptive name can help convey information. Changing a signal name in the Simulation Data Inspector does not affect signal names used in models. You cannot rename bus signals in the Simulation Data Inspector.

To change a signal name, double-click the signal name in the work area or archive, or edit the **Name** field in the **Properties** pane. Change the name of the **Actuator Model: 1** signal to **Actuator Output**.

## More About

- “Save and Share Simulation Data Inspector Data and Views” on page 31-139
- “Inspect Simulation Data” on page 31-169
- “Compare Simulation Data” on page 31-193

## Inspect Simulation Data

You can use the Simulation Data Inspector to view and inspect signals from simulations or imported data. The Simulation Data Inspector provides a comprehensive view of your data by allowing you to arrange data from multiple simulations and sources on multiple subplots. You can zoom and pan within plots and use data cursors for close examination of signal values, and you can replay data to analyze signal relationships.

This example shows you how to view and inspect signal data from the model `slexAircraftExample` using the Simulation Data Inspector.

### Configure Signals for Logging

This example uses signal logging to send data to the Simulation Data Inspector. You can also import signal data from the base workspace or a CSV, MDF, Microsoft Excel, or MAT-file. For more information, see “View Data in the Simulation Data Inspector” on page 31-2.

Open the model `slexAircraftExample`, mark several signals for logging, and run a simulation.

- 1 Open the model.
 

```
openExample('slexAircraftExample')
```
- 2 To log the `q`, `rad/sec`, the `Stick`, and the `alpha`, `rad` signals, select the signals in the model. Then, click **Log Signals**.

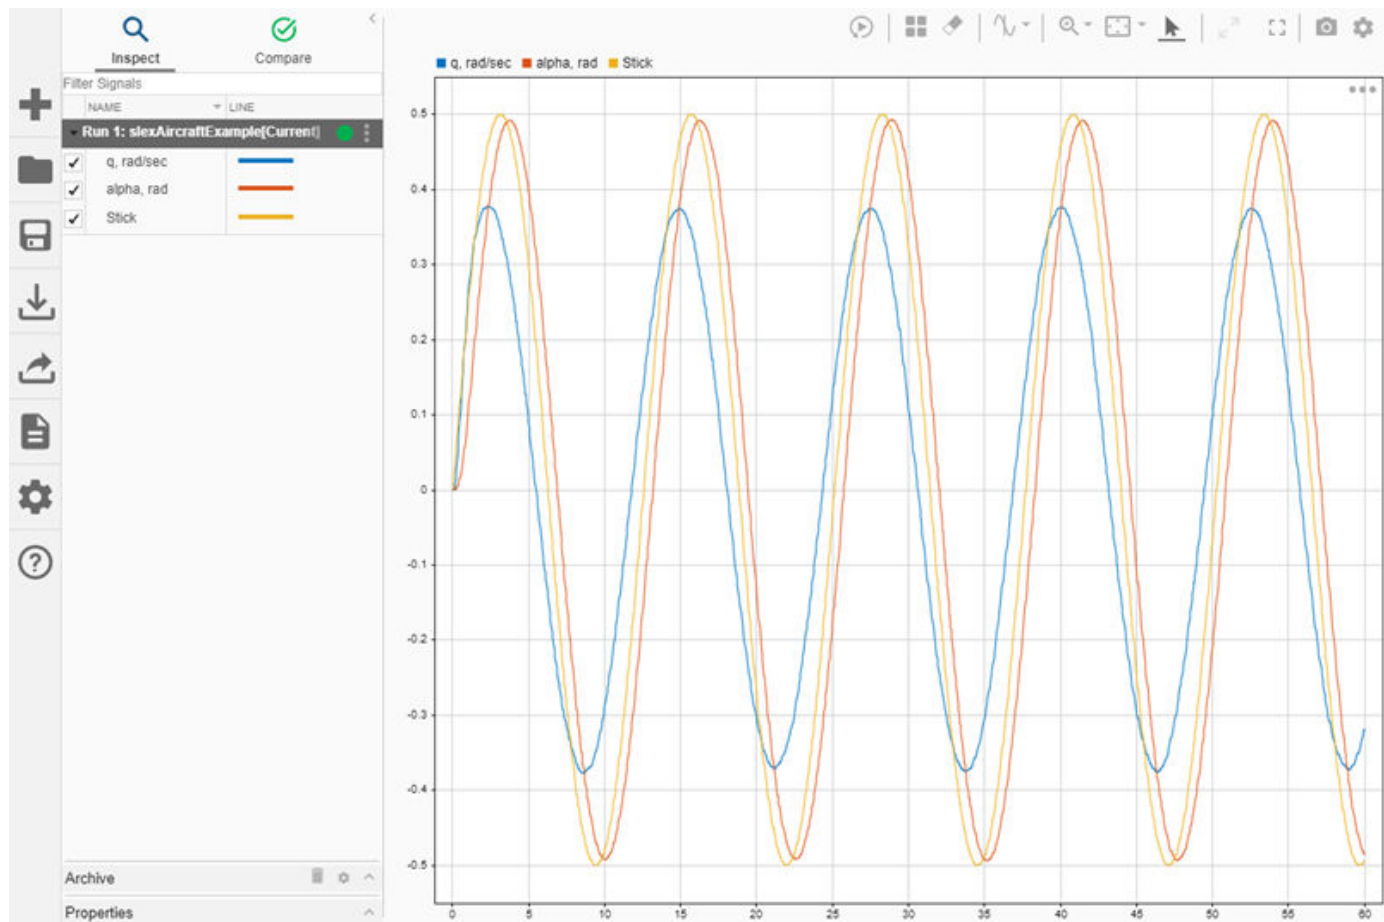

The logging badge  appears above each signal marked for logging.

- 3 Double-click the Pilot block. Set **Wave form** to `sine`. Click **OK**.
- 4 On the **Simulation** tab, click **Data Inspector** to open the Simulation Data Inspector.
- 5 Simulate the model. The simulation run appears in the Simulation Data Inspector.

By default, the **Inspect** pane lists all logged signals in rows, organized by simulation run. You can expand or collapse any of the runs to view the signals in a run. For more information on signal grouping, see “Configure the Simulation Data Inspector” on page 31-81.

### View Signals

To select signals you want to plot, use the check boxes next to the signals in the table. Select the check boxes next to the `q`, `rad/sec`, `Stick`, and `alpha`, `rad` signals. When the signal you want to plot is easier to find in the model, you can click the logging badge for the signal to plot it in the Simulation Data Inspector.

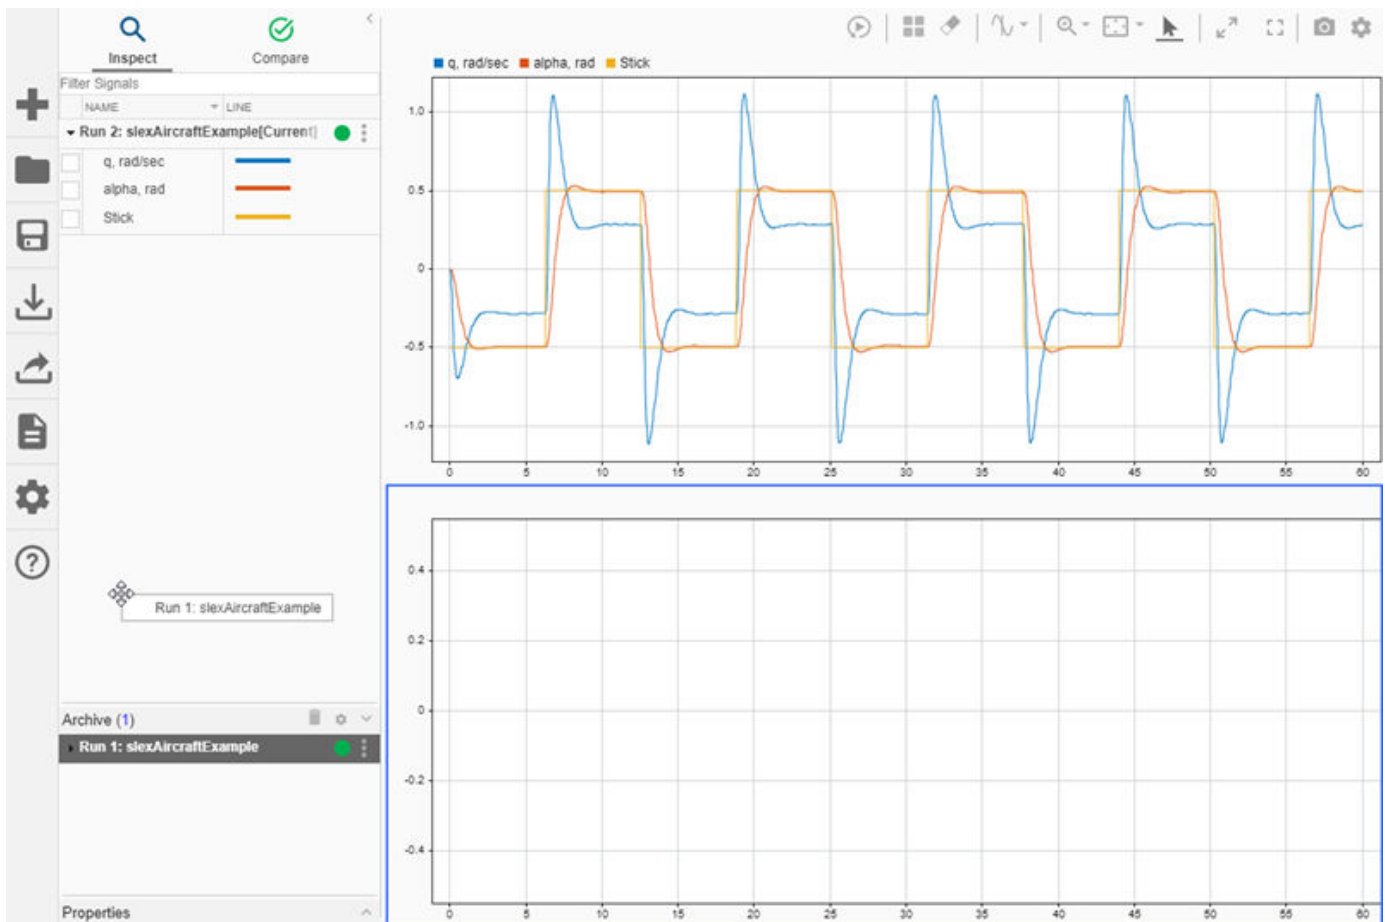

You can also use Browse Mode to quickly view all the signals in a run on time plots. For more information, see “Visualize Many Logged Signals” on page 31-115.

## View Signals on Multiple Plots

You can use subplot layouts to view groups of signals on different subplots. For example, you can arrange the same signal from different simulation runs on the same subplot or view signals that have a similar range of values.

- 1 In the model, double-click the Pilot block. Set **Wave form** to square. Click **OK**.
- 2 Simulate the model.
- 3 By default, the Simulation Data Inspector automatically moves prior runs into the archive and transfers the view to the current run. Drag Run 1 from the archive into the work area.

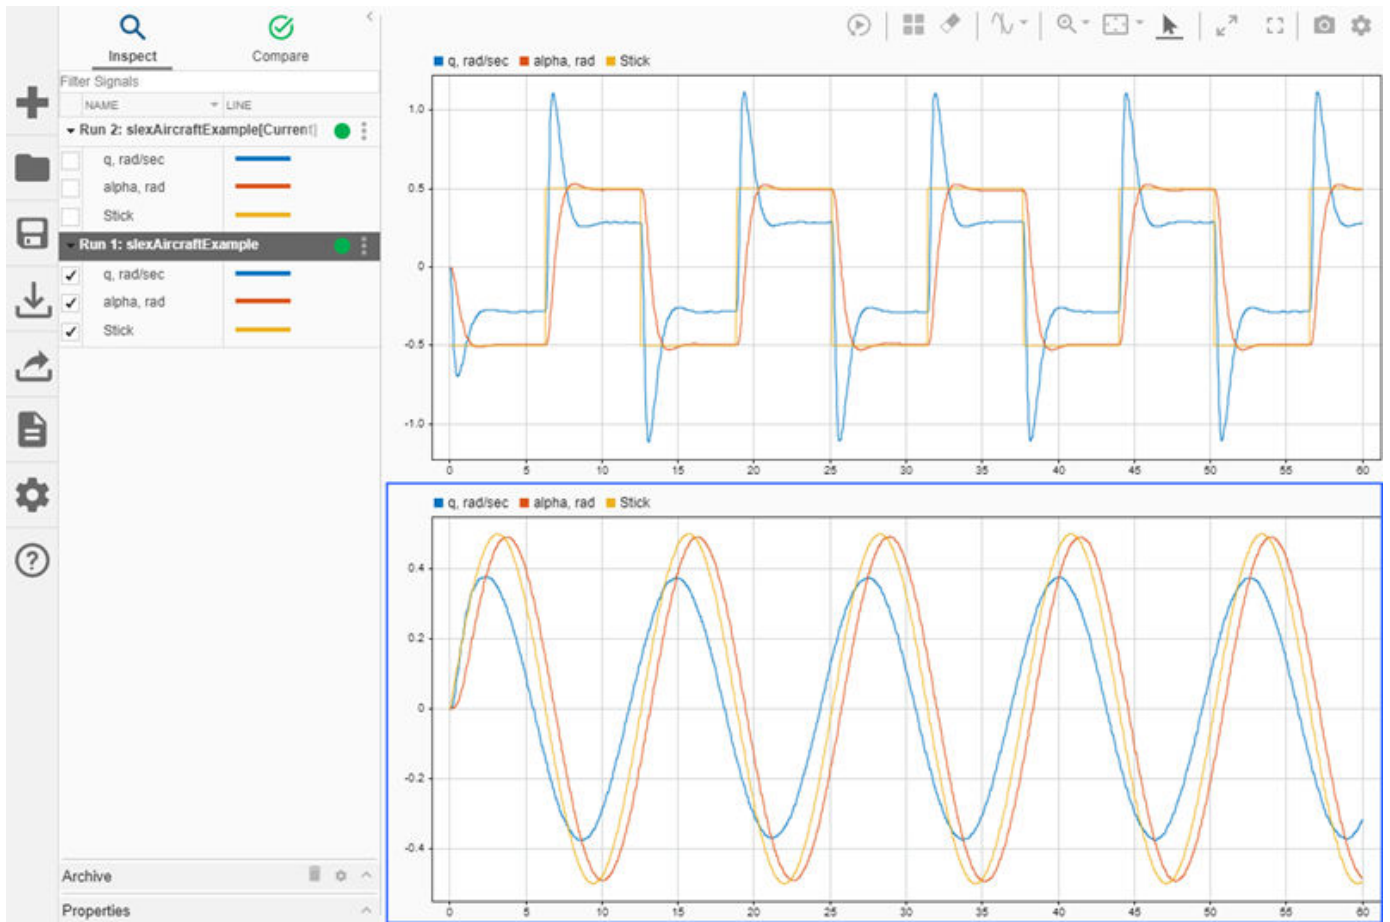

4

Click Layout  and select the 2×1 plot layout.

5 Click the lower subplot. In the **Inspect** pane, select the check boxes for the  $q$ , rad/sec, Stick, and  $\alpha$ , rad signals under Run 1.

The check boxes in the **Inspect** pane indicate the signals plotted in the selected subplot, outlined in blue.

You can also move signals graphically rather than using the check boxes. Drag the signal from the **Inspect** pane or another subplot to the subplot where you want to plot it.

For more information on working with plots, see “Create Plots Using the Simulation Data Inspector” on page 31-152.

## Zoom, Pan, and Resize Plots

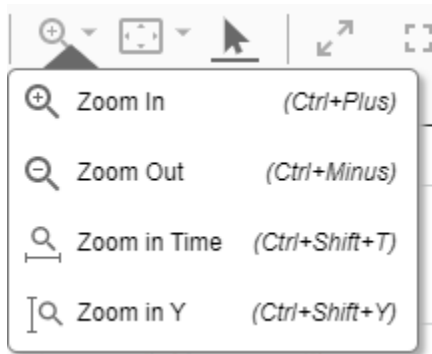

You can closely inspect signals in a larger viewing area by maximizing a subplot or expanding the view to full screen.

-  — Select Maximize to expand the active subplot to occupy the entire graphical viewing area.
-  — Select Full Screen to view your entire layout using your whole screen. The Simulation Data Inspector automatically collapses the navigation pane so the view of the layout is as large as possible.

You can zoom and pan within subplots that use a time plot visualization to inspect signal values and the relationships between signals. You can access the zoom and pan controls from the toolbar above the plots or from the subplot menu. Each icon allows you to control aspects of the plot using your

mouse .

- You can select the action for the zoom button from the drop-down list.

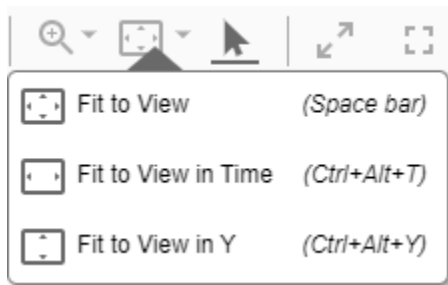

-  When you want to zoom in on a selected area in the plot, select **Zoom In**. While you have **Zoom In** selected, the Simulation Data Inspector adapts the zoom action it performs based on the area of the plot you select. To zoom only in the y dimension, drag vertically. When you drag horizontally, the Simulation Data Inspector zooms only in the  $t$  dimension. You can also click and drag to zoom in on a rectangular region.

You can click the graphical viewing area to zoom in a fixed amount on both axes. Scrolling with the mouse wheel zooms in and out on both axes.

-  Select **Zoom Out** to zoom out a fixed amount from the center of the subplot when you click inside the graphical viewing area. You can also use **Zoom Out** to undo a previous **Zoom In** operation.
-  Select **Zoom in Time** to make all mouse actions zoom on the  $t$ -axis. You can click the graphical viewing area to zoom in a fixed amount. You can click and drag the graphical viewing area to select a portion of the plot as the limits for the  $t$ -axis. Scrolling with the mouse wheel zooms in and out on the  $t$ -axis.
-  Select **Zoom in Y** to make all mouse actions zoom on the  $y$ -axis. You can click in the graphical viewing area to zoom in a fixed amount. You can also click and drag to select a portion of the plot as the limits for the  $y$ -axis. Scrolling with the mouse wheel zooms in and out on the  $y$ -axis.
-  With the mouse pointer selected, you can select signals by clicking them. Pan by clicking anywhere on the plot and dragging the mouse.

- You can select the fit action to scale the axes.

-  Select **Fit to View** to scale both the y and time axes to accommodate your plotted data.
-  Select **Fit to View in Time** to scale the *t*-axis to fit your data.
-  Select **Fit to View in Y** to scale the y-axis to fit your data.

### Linked Subplots

Subplots are linked by default. Linked plots have a synchronized response when you perform actions that change the time axis, including:

- Any pan operation involving the *t*-axis
- Any zoom operation involving the *t*-axis
- Any fit to view operation involving the *t*-axis
- Any adjustment to the *t*-axis limits

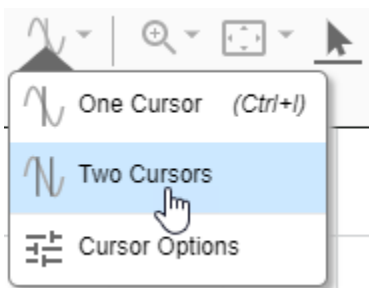

To inspect data independently in a subplot, you can unlink the subplot.

- 1 Select the subplot you want to unlink.
- 2 Click the Visualization Settings button in the upper right of the viewing area.
- 3 In the **Limits** section, clear the **Link plot** option.

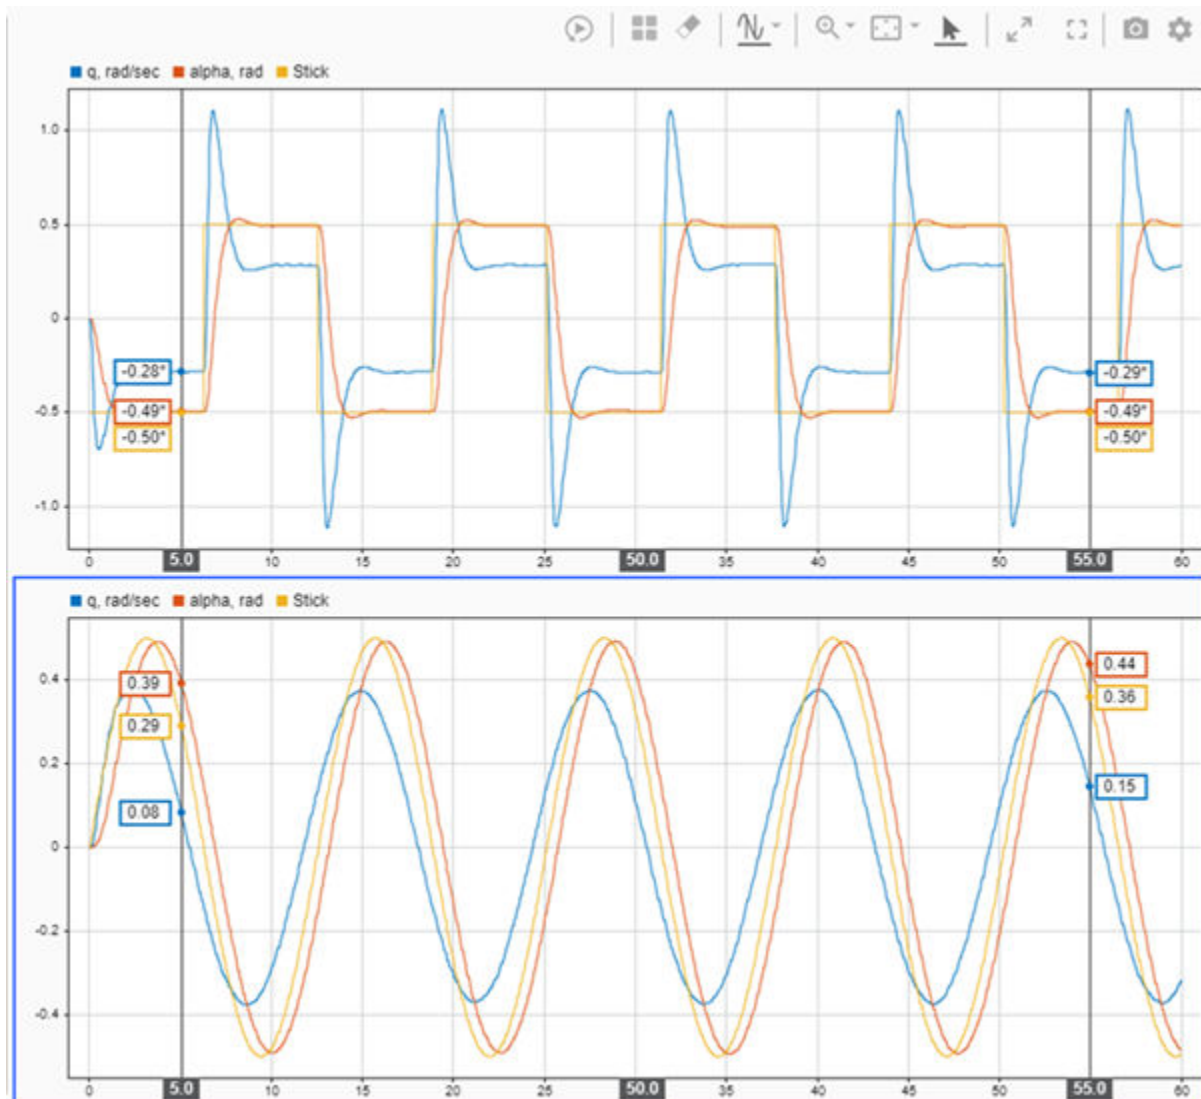

The broken link symbol  appears on the unlinked subplot.

### Inspect Simulation Data Using Cursors

In the Simulation Data Inspector, you can inspect signals using data cursors. You can use one or two cursors to inspect your data. To add two cursors, select **Two Cursors** from the Show/hide data cursors drop-down list.

With two cursors, three time values are displayed: the times that corresponded to each cursor position and the time spanned by the cursors. You can move the two cursors together by dragging the span label between the two cursors. You can also set the span by typing the desired value into the label field.

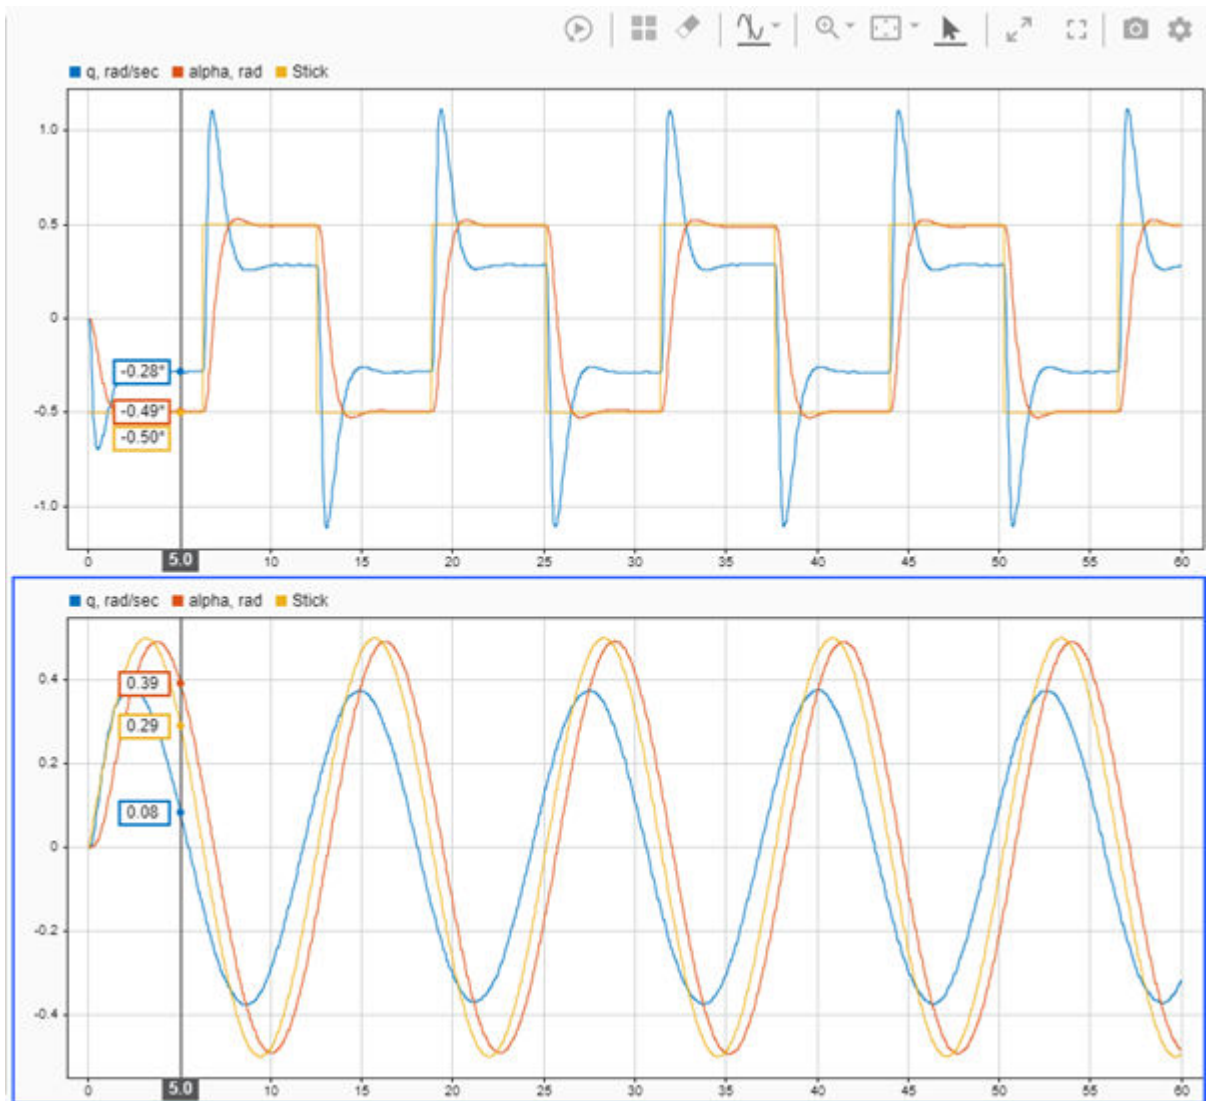

Practice inspecting data with cursors using one cursor.

1

Select **One Cursor** from the Show/hide data cursors drop-down list .

- 2 Drag the data cursor left or right to a point of interest. You can also use the arrow keys to move the data cursor from sample to sample.

To inspect the data at a specific point in time, click the cursor time field and enter the desired time value, for example, 40.33.

If the signal does not have a sample at the point of interest, the Simulation Data Inspector interpolates the value for the indicated time. An asterisk in the data cursor label indicates that the displayed value is interpolated. For information regarding interpolation methods, see “Interpolation” on page 31-206.

3

When you have finished inspecting the data, click Show/hide data cursors  to remove the cursor from the viewing area.

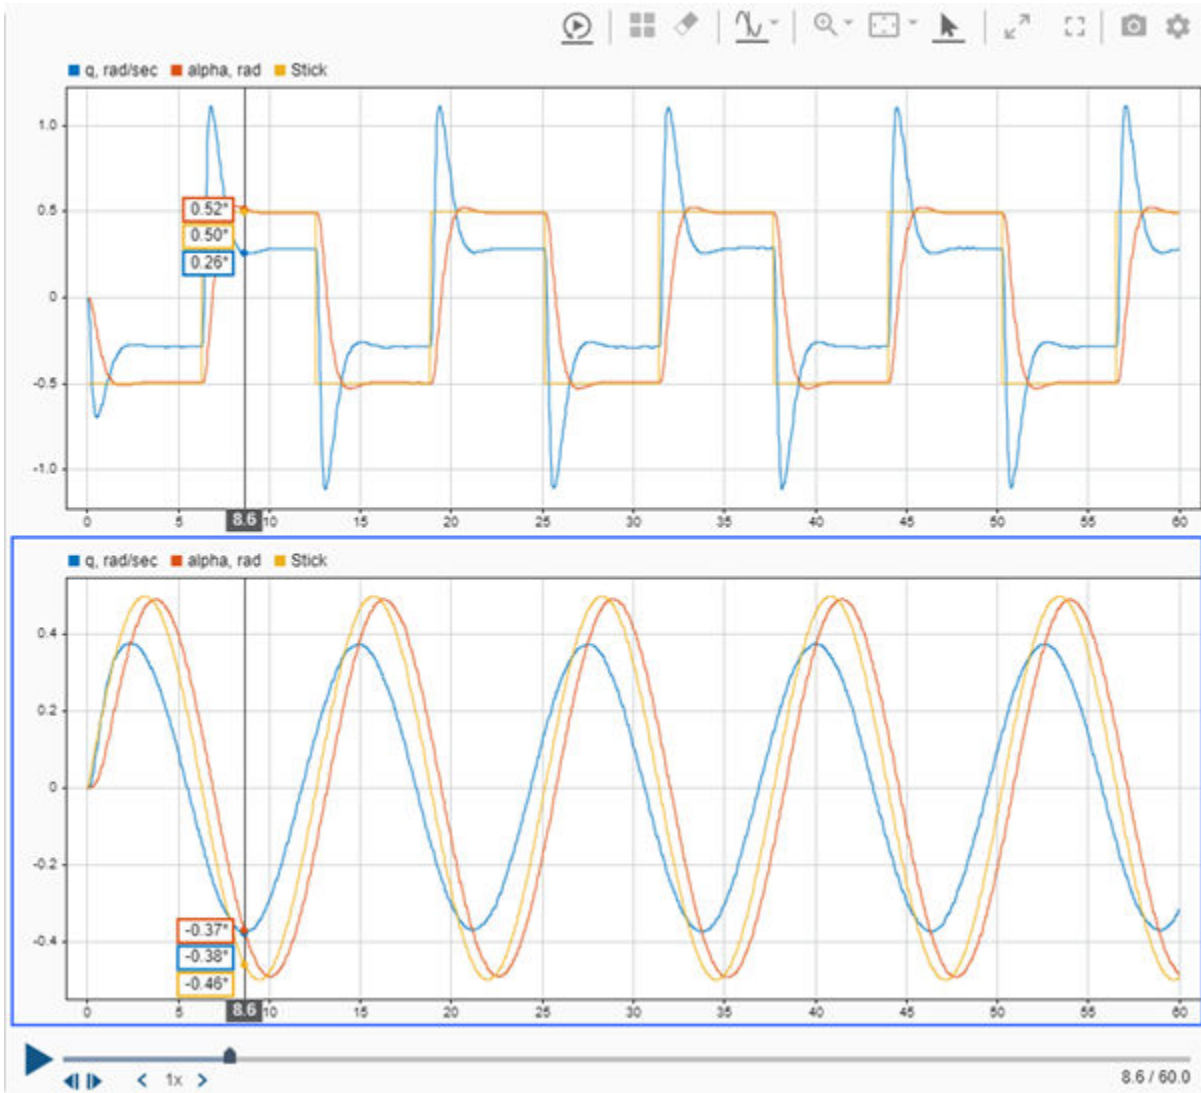

## Replay Data

You can replay data in the Simulation Data Inspector to inspect signal value changes and relationships between signals. Replaying data in the Simulation Data Inspector has no effect on any models or simulations. To replay data, first show the replay controls by clicking Show/hide replay

controls . Then, press Replay .

The Simulation Data Inspector synchronously sweeps a cursor displaying the signal value across all subplots in the view. By default, data replays at a rate of one second per second, which means that replaying one second of data takes one second of clock time. You can adjust the replay speed using the arrows on either side of the label or by clicking the label to type the desired speed. You can also pause the replay and use the step forward and step backward buttons to inspect signal values sample

by sample. For a detailed example, see “Replay Data in the Simulation Data Inspector” on page 31-188.

### Inspect Metadata

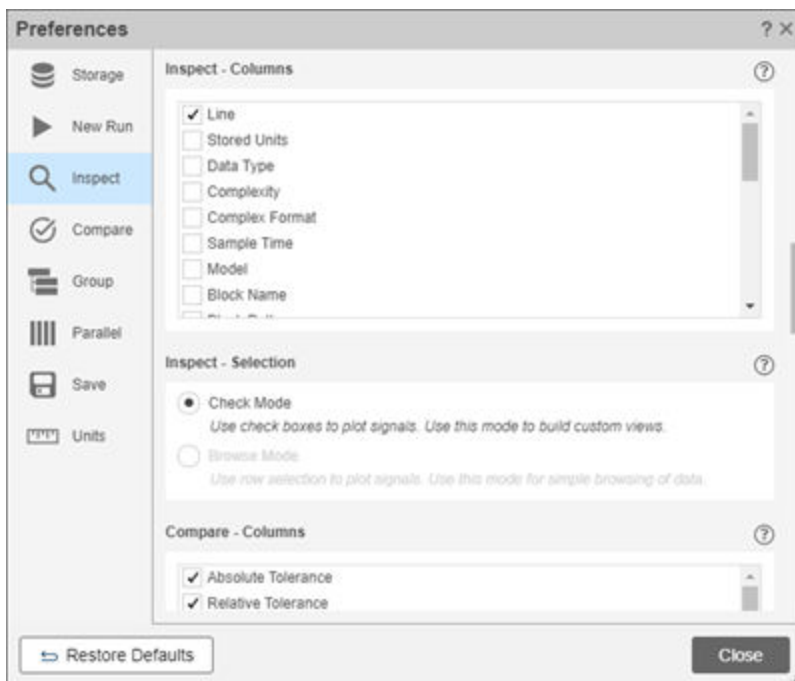

The Simulation Data Inspector allows you to view signal and run metadata in the **Properties** pane. In the column on the right, you can edit properties using the white box. When you view a comparison, the Simulation Data Inspector highlights metadata differences in red.

Properties	
Name	q, rad/sec
Description	
Line	
Stored Units	
Display Units	
Display Scaling	1
Display Offset	0
Data Type	double
Complexity	Real
Complex Format	Real-Imaginary
Sample Time	Continuous
Model	slexAircraftExample
Block Name	Aircraft Dynamics Model

You can also view metadata for signals as a table under each run in the **Inspect** pane. To choose

which signal properties to display, click Preferences and click **Inspect**. Select the columns you want to display from the **Inspect - Columns** list. Columns appear in the table in the order in which you select them.

The table describes the metadata properties.

**Property Descriptions**

<b>Property Name</b>	<b>Value</b>
<b>Line</b>	Signal line style and color
<b>Stored Units</b>	Signal measurement units
<b>Data Type</b>	Signal data type
<b>Complexity</b>	Signal type — real or complex
<b>Complex Format</b>	Format for visualizing complex data
<b>Sample Time</b>	Type of sampling
<b>Model</b>	Name of the model that generated the signal
<b>Block Name</b>	Name of the signal's source block
<b>Block Path</b>	Path to the signal's source block
<b>Port</b>	Index of the signal on the block's output port
<b>Dimensions</b>	Dimensions of the matrix containing the signal
<b>Channel</b>	Index of signal within matrix
<b>Run</b>	Name of the simulation run containing the signal
<b>Absolute Tolerance</b>	User-specified, positive-valued absolute tolerance for the signal
<b>Relative Tolerance</b>	User-specified, positive-valued relative tolerance for the signal
<b>Override Global Tolerance</b>	User-specified property that determines whether signal tolerances take priority over global tolerances
<b>Time Tolerance</b>	User-specified, positive-valued time tolerance for the signal
<b>Interp Method</b>	User-specified interpolation method used to plot the signal
<b>Sync Method</b>	User-specified synchronization method used to coordinate signals for comparison
<b>Time Series Root</b>	Name of the variable associated with signals imported from the MATLAB workspace
<b>Time Source</b>	Name of the array containing the time data for signals imported from the MATLAB workspace
<b>Data Source</b>	Name of the array containing the data for signals imported from the MATLAB workspace
<b>Description</b>	Description of signal
<b>Display Units</b>	Units used to display signal
<b>Domain</b>	Signal type for data created by logging simulation data
<b>Display Scaling</b>	Scaling used to display signal
<b>Display Offset</b>	Offset used to display signal

In the **Compare** pane, create a similar table of signal properties by choosing from the **Compare -**

**Columns** list in Preferences . Many parameters have a baseline signal and a comparison signal that you can display independently. When a parameter does not specify baseline or comparison signal, but both signals have the property, the column shows data for the baseline signal. In addition to the parameters listed for the **Inspect** pane, the **Compare** pane has columns specific to comparisons.

Property Name	Value
<b>Max Difference</b>	The maximum difference between the <b>Baseline</b> and <b>Compare to</b> signals
<b>Align By</b>	Primary signal alignment criterion specified in the <b>Compare - Alignment</b> tab of the Simulation Data Inspector <b>Preferences</b> menu

By default, the table displays a column for baseline name, absolute tolerance, relative tolerance, maximum difference, and results of the comparison. For more information, see “Compare Simulation Data” on page 31-193.

## Modify Signal Properties in the Simulation Data Inspector

You can modify signal display units, data type, and names in the Simulation Data Inspector. When you modify the data type for a signal, the Simulation Data Inspector converts the signal values stored on disk. Changes you make to signal properties in the Simulation Data Inspector do not affect any models, files, or workspace variables.

You may want to save the original signal data or export modified signal data to use as simulation input. You can export data from the Simulation Data Inspector to the workspace or a file. For more information, see “Export Data to the Workspace or a File” on page 31-142.

This example uses data from a simulation of the `slexAircraftExample` model. To generate the data for this example:

- 1 Open the model `slexAircraftExample`.  

```
openExample('slexAircraftExample')
```
- 2 To log the `q`, `rad/sec`, the `Stick`, and the `alpha`, `rad` signals to the Simulation Data Inspector, select the signals in the model. Then, right-click the selection, and select **Log Selected Signals** from the context menu.
- 3 Double-click the Pilot block. Set **Wave form** to `sine`, and click **OK**.
- 4 Simulate the model.

### Modify Signal Units

Signals in the Simulation Data Inspector have two unit properties: display units and stored units. To analyze sets of data using consistent units, modify the display units for a signal. The Simulation Data Inspector converts data when the stored units and display units for a signal differ such that signals are always plotted using values that correspond to the display units. The units you specify are properties of the signals in the Simulation Data Inspector only and do not affect the signal properties in models. To learn how to specify units in a model, see “Unit Specification in Simulink Models” on page 9-2.

The `slexAircraftExample` model does not specify units for its signals. However, some signal names indicate the intended units.

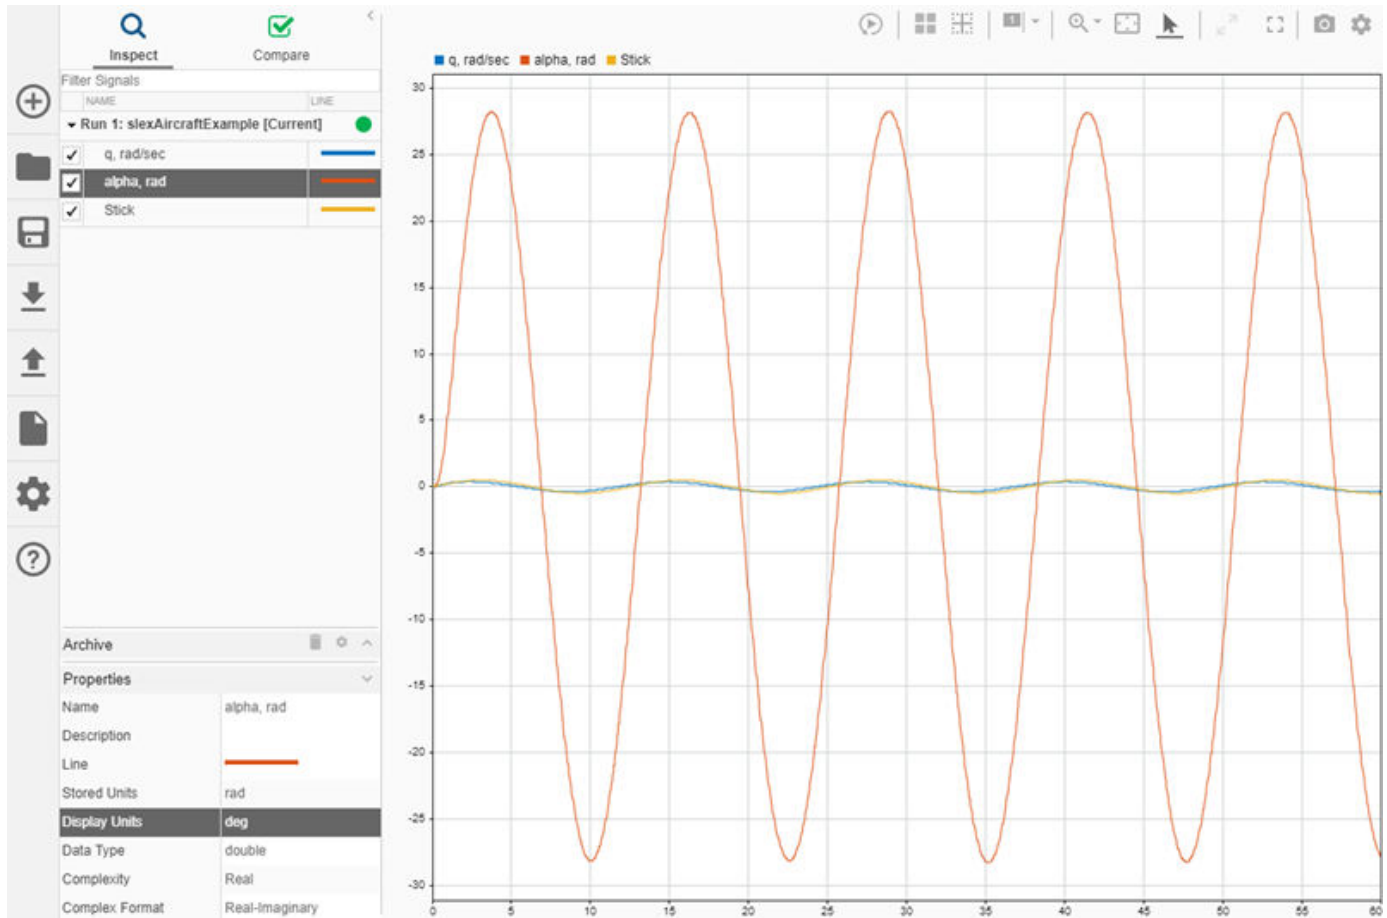

- 1 In the **Inspect** pane, select the `alpha`, `rad` signal.
- 2 To view the properties for the selected signal, expand the **Properties** pane.
- 3 To specify units of radians for the signal, in the **Properties** pane, type `rad` into the white text box next to the **Display Units** property.

For a list of units supported by Simulink, enter `showunitslist` into the MATLAB Command Window.

Now, the Simulation Data Inspector interprets the data for the `alpha`, `rad` signal as having units of `rad`. When you specify display units for a signal without units, the specified units also set the value for the stored units. Once a signal has units Simulink recognizes, you can convert the display units for the signal to supported compatible units using the Simulation Data Inspector. When you click the **Display Units** text box to modify the units, the Simulation Data Inspector provides a drop-down list of compatible units.

Change the alpha, rad signal display units to deg using the drop-down or by typing the new units into the **Display Units** field. When you change the units, the Simulation Data Inspector performs the conversion, and the plot updates to show the converted signal values.

You can also configure unit preferences in the Simulation Data Inspector to use units from a system of measurement or consistent units for a measurement type, such as length, for all logged and imported data. For more information, see “Signal Display Units” on page 31-87.

---

**Note** You can convert the stored units for a signal using the `convertUnits` function. Unit conversion does not support undo and may result in loss of precision.

---

## Modify Signal Data Type

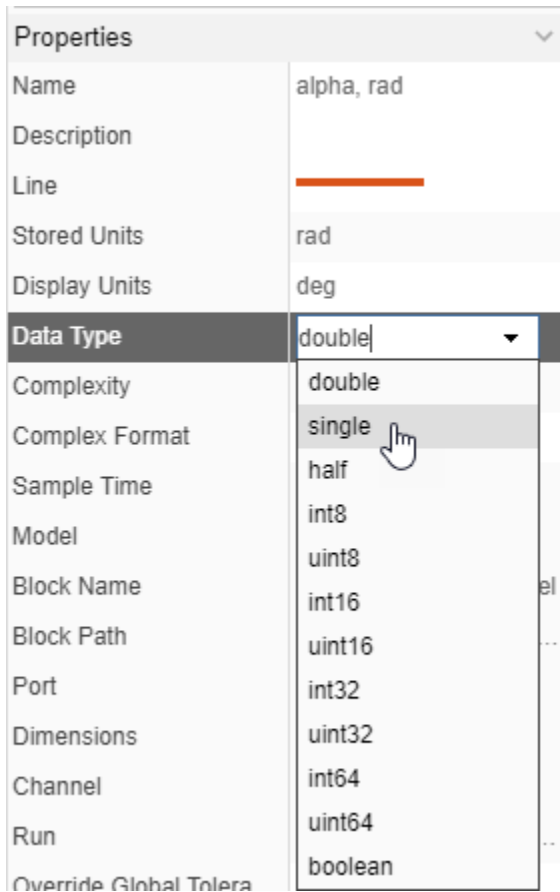

You can modify the data type for a signal to analyze the effect on signal values or to create a signal to use as simulation input. Converting the data type in the Simulation Data Inspector does not affect any signal properties in the model. You can convert signal data types to all built-in data types. If you have a license for Fixed-Point Designer, you can also convert to fixed-point data types. For a list of built-in data types, see “Data Types Supported by Simulink” on page 72-4.

---

**Note** When you convert to a lower precision data type, you lose precision in the data that cannot be recovered. You can save a copy of the data in the Simulation Data Inspector before changing signal data types. For more information, see “Save and Share Simulation Data Inspector Data and Views” on page 31-139.

---

The data type for the `alpha, rad` signal is `double`. Suppose you want to convert the data type to `single`. First, select the `alpha, rad` signal. Then, expand the **Properties** pane and click the white text field next to the **Data Type** property. You can type `single` or select it from the drop-down of data types. The Simulation Data Inspector converts the data when you click outside the drop-down.

Because the `single` data type has less precision than the `double` data type, the Simulation Data Inspector returns a warning about irreversible precision loss. Click **Continue**. The plot shows no visible difference in the signal. If you saved the data for the original signal, you can compare the converted signal to analyze the effect of changing the data type. For more information on comparing data in the Simulation Data Inspector, see “Compare Simulation Data” on page 31-193.

### Fixed-Point Conversions

If you have a license for Fixed-Point Designer, you can convert signal data types to fixed-point data types in the Simulation Data Inspector. Specify the data type in the **Data Type** property text box using the `fixdt` function.

### Modify Signal Names

You can modify the names of signals in the Simulation Data Inspector. Changing the name of a signal in the Simulation Data Inspector does not affect signal names specified in the model. You can specify a new name from the work area, the **Archive**, or the **Properties** pane. To modify the signal name, click the signal name and type the new name. For example, change the name of the `alpha, rad` signal to `alpha` because the **Units** property now has the units information.

	NAME	LINE	⚙
▼ Run 1: slexAircraftExample [Current]			
<input checked="" type="checkbox"/>	q, rad/sec		—
<input checked="" type="checkbox"/>	alpha		—
<input checked="" type="checkbox"/>	Stick		—

When you export data from the Simulation Data Inspector after modifying the name, the exported data uses the new name.

## Replay Data in the Simulation Data Inspector

This example shows how to replay data in the Simulation Data Inspector to inspect and build intuitive understanding of your data. When you replay data, a cursor sweeps synchronously across all the subplots in your view, displaying signal values. You can control the replay speed, pause to move the cursor sample-by-sample, and zoom to inspect your data. You can replay imported data and data logged from a simulation.

This example uses logged simulation data saved in a session. The session contains two runs of data logged from the `ex_vdp_mu` model. Data from Run 1: `ex_vdp_mu` is plotted in the viewing area.

Load the session and open the Simulation Data Inspector to view the data.

```
Simulink.sdi.load('ex_vdp_mu.mldatx');  
Simulink.sdi.view
```

### Replay Data

When you replay data, the Simulation Data Inspector animates synchronized cursors to move through a time period defined by the maximum time among the plotted signals. Replaying and pausing in the Simulation Data Inspector has no effect on any models or simulations.

To show the replay controls in the Simulation Data Inspector, click the **Show/hide replay controls**

button. 

Click the **Replay** button. 

Synchronized cursors sweep across the subplots, indicating the signal value as the cursor moves in time. By default, the Simulation Data Inspector replays data at a rate of one second per second, meaning that the cursor moves through one second of data in the span of one second of clock time. You can adjust the replay speed to suit the data you want to inspect. To change the speed, click one of the arrows on either side of the label or click the label and enter your desired replay speed.

The Simulation Data Inspector moves the cursor based on the maximum time in the plotted signals and the replay speed. The position of the cursor at a given time during replay does not depend on the time values for samples in the plotted signals. When the cursor position does not correspond with a sample in a plotted signal, the Simulation Data Inspector interpolates a value to display, using the method defined in the **Interpolation** property of the signal. An asterisk at the end of the cursor value indicates that the value is interpolated.

### Inspect Data Values During Replay

To inspect sample values in your data, you can pause the replay. When the replay is paused, you can use the **Step forward** and **Step backward** buttons to move the cursor sample-by-sample. The cursors move to the next time point among all plotted signals. When a plotted signal does not have a sample, the Simulation Data Inspector interpolates the value.

Pause the replay and use the **Step forward** and **Step backward** buttons to view the signal values.

### Zoom During Replay

You can zoom in on a region of your data during replay to inspect signal values and relationships more closely. Viewing a portion of your signal can be particularly useful when your data spans a long duration with a high sample rate. For example, plot the signals from Run 2: `ex_vdp_mu`.

The data in run 2 corresponds to a much longer simulation of the `ex_vdp_mu` model, where the value of `Mu` changed over the course of the simulation. Viewing the entire signal at once makes analyzing the changing characteristics of the curve difficult. Before replaying the data, change the **Time span** in the **Visualization settings** to 100 to show the first 100 seconds. You can also collapse the navigation pane to allow the viewing area to occupy more space. Then, replay the data.

When the cursor nears the end of the zoomed portion of the data, click the **Fit to view** button to show the complete signal. Then, you can use the **Zoom in time** option to select another region of the signal to inspect more closely during the replay.

When replaying a long simulation, you can also adjust the replay speed or drag the time marker to replay data in an area of interest.

## Compare Simulation Data

The Simulation Data Inspector can compare the data and metadata for runs and individual signals you import from the workspace or a file or log in a simulation. You can analyze comparison results using tolerances, and you can configure the comparison behavior by specifying signal properties and comparison constraints. This example uses data logged from simulations of the model `slexAircraftExample` and shows how to:

- Compare signals and runs.
- Analyze comparison results using the **Compare** pane in the Simulation Data Inspector.
- Specify signal tolerances and global tolerances.
- Configure comparison constraints.

For more information on tolerance calculations and signal properties that affect comparisons, see “How the Simulation Data Inspector Compares Data” on page 31-204. To compare data programmatically, use the `Simulink.sdi.compareRuns` function or the `Simulink.sdi.compareSignals` function.

### Setup

This example continues from “Inspect Simulation Data” on page 31-169. You can also use this script to generate the data required for the example.

```
load_system('slexAircraftExample')

% Configure signals to log
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 3, 'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4, 'on')

% Change Pilot signal to sine
set_param('slexAircraftExample/Pilot', 'WaveForm', 'sine')

% Simulate model
sim('slexAircraftExample')

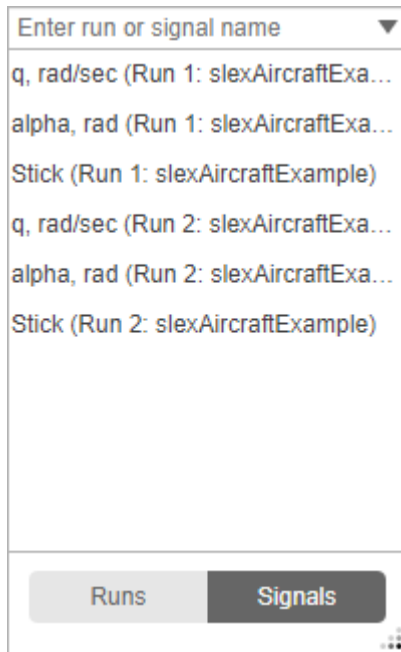

% Change Pilot signal to square
set_param('slexAircraftExample/Pilot', 'WaveForm', 'square')

% Simulate Model
sim('slexAircraftExample')
```

### Compare Signals

You can compare signals to analyze the relationship between two signals in a model. For example, compare the `Stick` input signal to the output signal, `alpha, rad`.

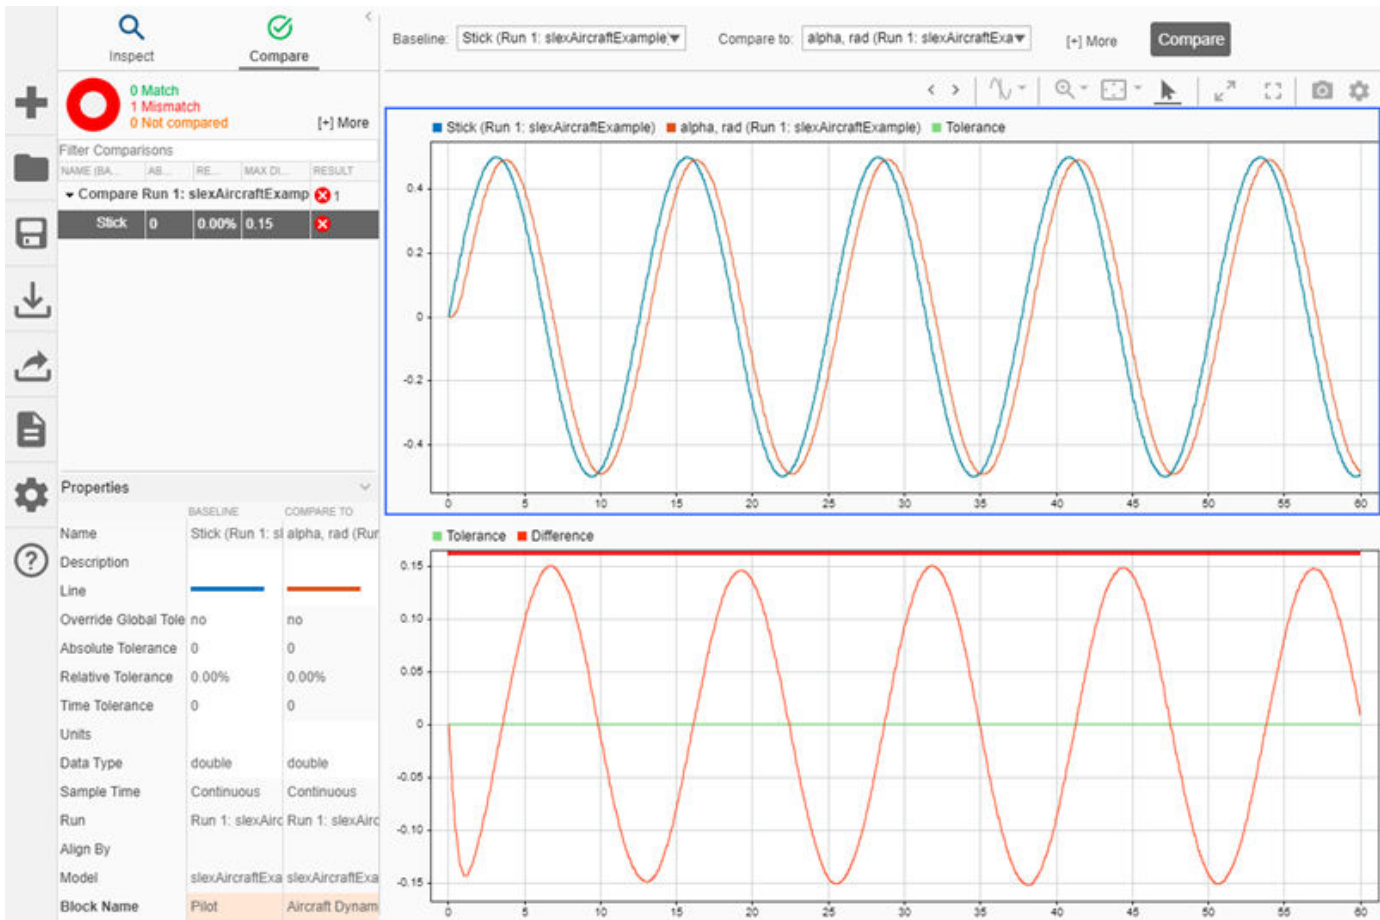

- 1 Navigate to the **Compare** pane.
- 2 To view a list of signals available for comparison, expand the **Baseline** drop-down and select **Signals**.

- 3 Select **Stick (Run 1: slexAircraftExample)**.
- 4 Expand the **Compare to** drop-down and select **alpha, rad (Run 1: slexAircraftExample)**.
- 5 Click **Compare**.

Alternatively, you can select the **Baseline** and **Compare to** signals using the context menu by right-clicking the signal in the **Inspect** pane.

The signals are not identical, so they do not match within the absolute, relative, and time tolerances, all set to 0 by default.

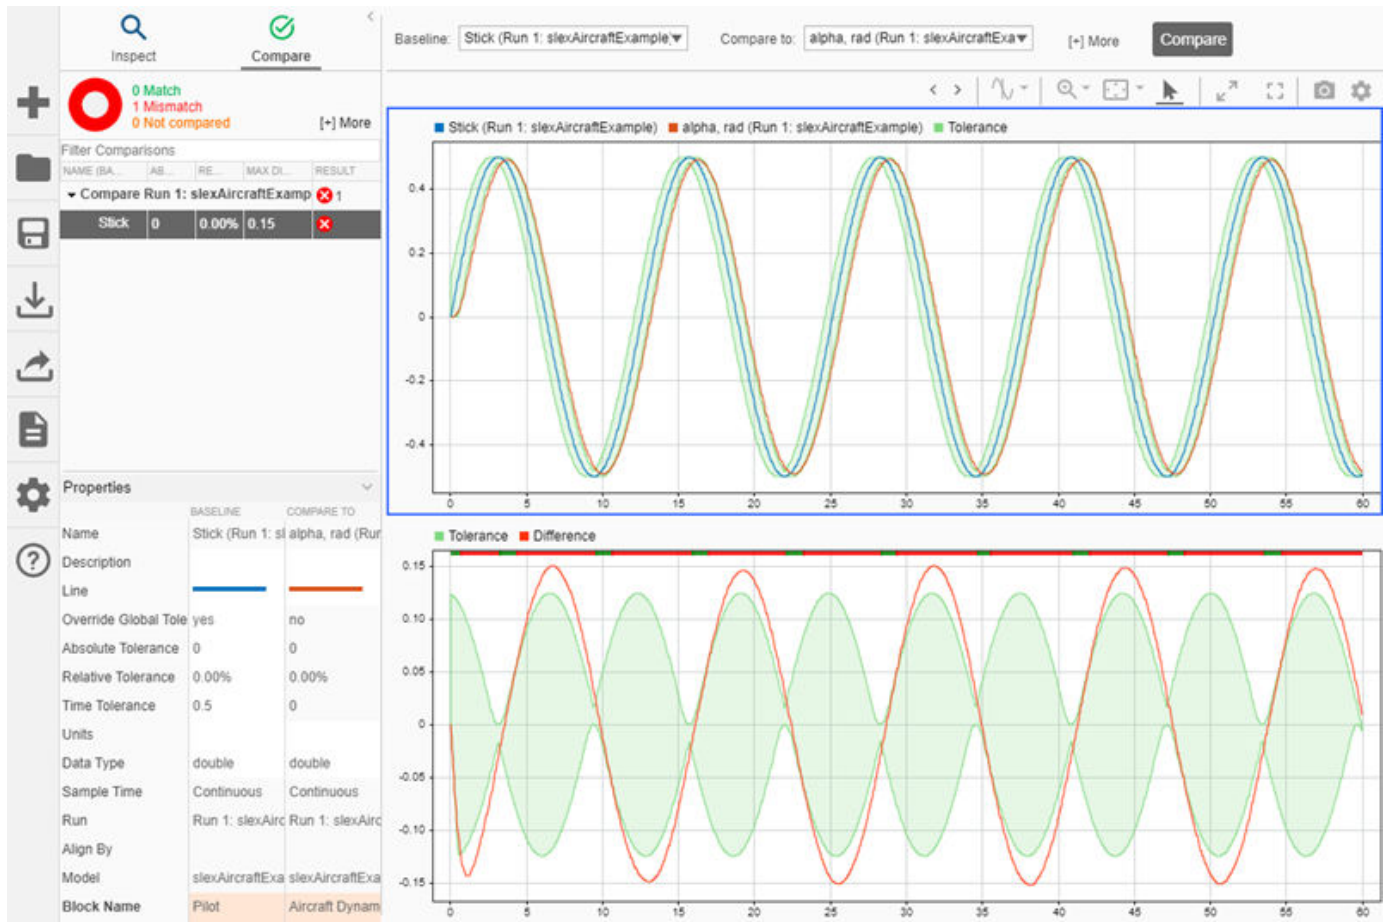

## Signal Time Tolerance

Looking at the top plot in the comparison view, you can see the `alpha, rad` signal lags the `Stick` signal. For signal comparisons, the Simulation Data Inspector uses tolerance values specified for the **Baseline** signal. Add a time tolerance to the `Stick` signal to account for the lag.

Select the `Stick` signal and enter 0.5 in the **Time Tolerance** field of the **Properties** pane. When you specify a tolerance for a **Baseline** signal, its **Override Global Tolerance** field automatically changes to yes. When you click away from the **Time Tolerance** field, the comparison runs again, using the signal-level tolerance you specified. If you want to use global tolerance values for the signal, click the **Override Global Tolerance** field and select no from the drop-down.

The Simulation Data Inspector draws the tolerance band around the plotted **Baseline** signal and around the signed difference signal displayed in the bottom subplot. The bar along the top of the difference plot shows regions within tolerance and out of tolerance for the comparison in green and red.

### Signal Magnitude Tolerance

The time tolerance covers the phase difference between the two signals, but the comparison still includes regions out of tolerance due to the amplitude difference. You can add a magnitude tolerance as either an **Absolute Tolerance** or **Relative Tolerance**.

To add an absolute tolerance to the `Stick` signal, enter `0.05` into the **Absolute Tolerance** field in the properties pane. With the combination of the absolute and time tolerances, the signal comparison passes.

**Note** The Simulation Data Inspector draws the tolerance region using the most lenient interpretation of the specified tolerances for each point. For more information on how the Simulation Data Inspector calculates the tolerance band, see “Tolerance Specification” on page 31-206.

## Compare Runs

You can also use the Simulation Data Inspector to compare all the signals in a run to all the signals in another run. Run comparisons can provide useful information about the effects of changing model parameters. For example, change the frequency cutoff of the filter for the control stick input signal. Then, evaluate the effect on the logged signals using the Simulation Data Inspector.

- 1 To access the data in the model workspace, on the **Modeling** tab, under **Design**, click **Model Explorer**.
- 2 Click the arrow next to the model name and select **Model Workspace**.
- 3 Change the value of  $T_s$  from 0.1 to 1 and close the **Model Explorer**.
- 4 Simulate the model with the new filter.
- 5 In the **Compare** pane in the Simulation Data Inspector, expand the **Baseline** drop-down, and select **Runs**.
- 6 From the list of runs, select Run 2: sllexAircraftExample.
- 7 Expand the **Compare to** drop-down and select Run 3: sllexAircraftExample.
- 8 Click **Compare**.

The **Compare** pane lists all signals from the compared runs and summarizes the results of the comparison in the **Results** column. In this example, all three signals aligned, and none matched. You

can click **More** to see the reason each signal comparison did not match. All three signals are out of tolerance.

 <span style="color: green;">0 Match</span> <span style="color: red;">3 Mismatch</span> <span style="color: red;">3 Out of tolerance</span> <span style="color: orange;">0 Not compared</span>				
[-] Less				
Filter Comparisons				
NAME (BA...	AB...	RE...	MAX DI...	RESULT
▼ Compare Run 3: slexAircraftExamp				✖ 3
q, rad/s	0	0.00%	1.00	✖
alpha, r	0	0.00%	0.49	✖
Stick	0	0.00%	0.78	✖

**Note** The Simulation Data Inspector only compares signals from the **Baseline** run that align with a signal from the **Compare To** run. If a signal from the **Baseline** run does not align with a signal from the **Compare To** run, the signal is listed in the **Compare** pane with a warning.  For more information on signal alignment, see “Signal Alignment” on page 31-204.

To plot a comparison result, select the signal you want to view in the **Compare** pane. For example, select the result for the q, rad/sec signal. The top plot shows the q, rad/sec signals from the **Baseline** and **Compare To** runs. The bottom plot shows the difference between the signals and the calculated tolerance band.

## Global Tolerances

To analyze the signals in the run comparison, you can specify global tolerances. To specify global tolerances, click **More**. Under **Global Tolerances**, enter 0.75 for the time tolerance and 0.075 for the absolute tolerance.

Baseline: Run 2: slxAircraftExample Compare to: Run 3: slxAircraftExample

**Global Tolerances**

Absolute: 0.075 Relative: 0 Time: 0.75

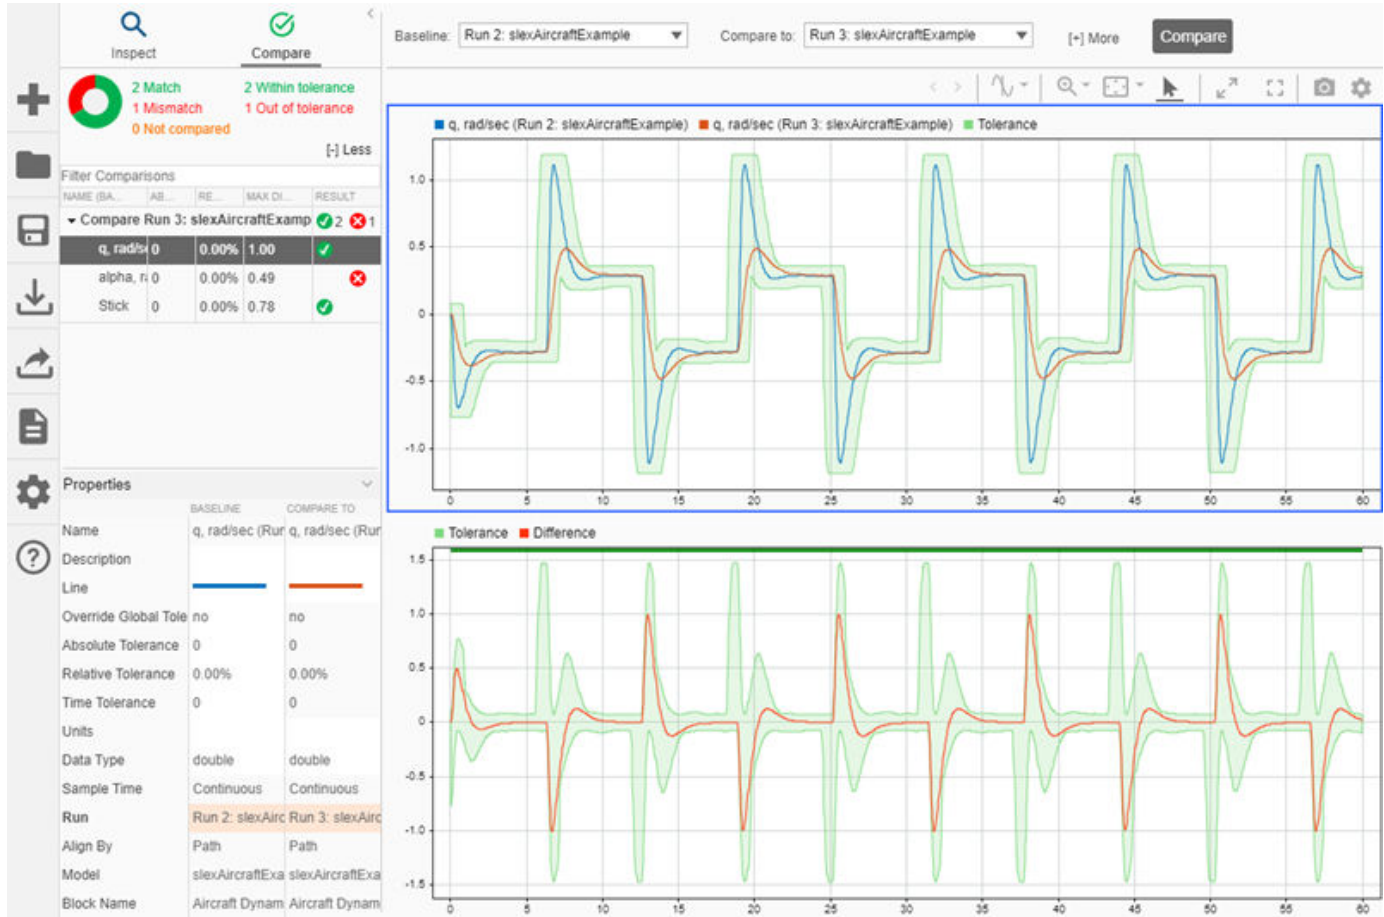

**Constraints**

Expand multidimensional channels  Signal start and stop times must match

Signal data types must match  Signal time vectors must match

Stop comparison on first mismatch of: Metadata [-] Less

Click the **Compare** button to run the comparison. The Simulation Data Inspector plots the tolerance band around the **Baseline** signal and on the signed difference plot. With the new tolerance values, the Stick and  $q$ , rad/sec signals pass the comparison.

View the  $\alpha$ , rad signal to analyze the out of tolerance regions in the comparison result. Click the arrow buttons  $\leftarrow$   $\rightarrow$  in the toolbar to navigate through the out of tolerance regions. Two cursors on the plot show the beginning and end of the first out of tolerance region. You can use your keyboard arrows to explore the signal and tolerance values throughout each out of tolerance region. To view the next out of tolerance region, click the right arrow button in the tool strip.

To resolve the out of tolerance regions, you can choose to modify the global tolerance values or to add a signal-specific tolerance to the  $\alpha$ , rad signal using the signal properties.

## Configure Comparison Constraints

You can also apply constraints to comparisons that affect whether the result is a match or mismatch. For example, you can specify that the time vectors for signals must match in order for the result to be a match. To specify the constraint, click **More**, then select **Signal time vectors must match**. To run a new comparison with this constraint, click **Compare**.

The comparison results show all signal results as mismatches now. The time vectors do not match for any of the signals because they were logged from simulations of a model that uses a variable-step solver, and the conditions changed between simulations. When the comparison result is a mismatch due to a constraint, the Simulation Data Inspector does not compute results for that signal. When you select a signal, the plot area shows an explanation of why the signal result is a mismatch.

The screenshot displays the Simulation Data Inspector (SDI) interface. At the top, there are tabs for 'Inspect' and 'Compare', with 'Compare' selected. Below the tabs, there are dropdown menus for 'Baseline' (Run 2: slx:AircraftExample) and 'Compare to' (Run 3: slx:AircraftExample), along with a 'Compare' button. A summary section shows '0 Match', '3 Mismatch', '3 Time mismatch', and '0 Not compared'. Below this is a table of comparison results:

NAME (BA...)	AB...	RE...	MAX DI...	RESULT
▼ Compare Run 3: slx:AircraftExamp 3				
q, rad/s	0	0.00%	0	✗
alpha, r	0	0.00%	0	✗
Stick	0	0.00%	0	✗

Below the table, a message states: 'Time vectors do not match (see [documentation](#))'. At the bottom, there is a table with two columns: 'RUN' and 'NAME'.

RUN	NAME
Run 2: slx:AircraftExample	alpha, rad
Run 3: slx:AircraftExample	alpha, rad

On the left side of the interface, there is a 'Properties' panel with a table comparing 'BASELINE' and 'COMPARE TO' settings for various parameters.

	BASELINE	COMPARE TO
Name	alpha, rad (Run 2: slx:AircraftExample)	alpha, rad (Run 3: slx:AircraftExample)
Description		
Line		
Override Global Tole	no	no
Absolute Tolerance	0	0
Relative Tolerance	0.00%	0.00%
Time Tolerance	0	0
Units		
Data Type	double	double
Sample Time	Continuous	Continuous
Run	Run 2: slx:Airc	Run 3: slx:Airc
Align By	Path	Path
Model	slx:AircraftExa	slx:AircraftExa
Block Name	Aircraft Dynam	Aircraft Dynam

You can configure these comparison constraints:

- **Signal data types must match**
- **Signal start and stop times must match**
- **Signal time vectors must match**

When you require a match in signal metadata, specifying a constraint can return a mismatch result more quickly because the comparison does not compute results when the specified metadata does not match.

You can also configure a comparison to stop computing results after detecting the first mismatch result. When you configure a comparison to stop on the first mismatch, the comparison always stops after detecting the first mismatch in the signal metadata. You can also choose to stop the comparison when the first mismatch result is due to an out-of-tolerance result when comparing the signal data.

The Simulation Data Inspector always aligns signals in the baseline and comparison runs and always checks whether signal units match. When you configure a comparison to stop on the first mismatch, signals that do not align and signals with units that do not match always cause a comparison to stop. You can specify additional metadata for the comparison to check by selecting one or more constraints.

## Cancel Comparisons

The runs and signals used in this example are relatively small, and comparisons run quickly. When you compare long signals or runs containing many signals, comparisons may take more time. The Simulation Data Inspector displays incremental progress indicators during comparison, and the **Compare** button becomes a **Cancel** button you can click to cancel the comparison at any point. For hierarchical data, the **Results** column in the comparison view summarizes the results on each hierarchical node.

 <span style="color: green;">37 Within tolerance</span> <span style="color: red;">82 Out of tolerance</span>				
Filter Comparisons

## How the Simulation Data Inspector Compares Data

You can tailor the Simulation Data Inspector comparison process to fit your requirements in multiple ways. When comparing runs, the Simulation Data Inspector:

- 1 Aligns signal pairs in the **Baseline** and **Compare To** runs based on the **Alignment** settings.

The Simulation Data Inspector does not compare signals that it cannot align.

- 2 Synchronizes aligned signal pairs according to the specified **Sync Method**.

Values for time points added in synchronization are interpolated according to the specified **Interpolation Method**.

- 3 Computes the difference of the signal pairs.
- 4 Compares the difference result against specified tolerances.

When the comparison run completes, the results of the comparison are displayed in the navigation pane.

Status	Comparison Result
	Difference falls within the specified tolerance.
	Difference violates specified tolerance.
	The signal does not align with a signal from the <b>Compare To</b> run.

When you compare signals with differing time intervals, the Simulation Data Inspector compares the signals on their overlapping interval.

### Signal Alignment

In the alignment step, the Simulation Data Inspector decides which signal from the **Compare To** run pairs with a given signal in the **Baseline** run. When you compare signals with the Simulation Data Inspector, you complete the alignment step by selecting the **Baseline** and **Compare To** signals.

The Simulation Data Inspector aligns signals using a combination of their Data Source, Path, SID, and Signal Name properties.

Property	Description
Data Source	Path of the variable in the MATLAB workspace for data imported from the workspace
Path	Block path for the source of the data in its model
SID	Automatically assigned Simulink identifier
Signal Name	Name of the signal in the model

With the default alignment settings, the Simulation Data Inspector aligns signals between runs according to this flow chart.

You can specify the priority for each of the signal properties used for alignment in the Simulation Data Inspector **Preferences**. The **Align By** field specifies the highest priority property used to align signals. The priority drops with each subsequent **Then By** field. You must specify a primary alignment property in the **Align By** field, but you can leave any number of the **Then By** fields blank.

## Synchronization

Often, signals that you want to compare don't contain the exact same set of time points. The synchronization step in Simulation Data Inspector comparisons resolves discrepancies in signals' time vectors. You can choose union or intersection as the synchronization method.

When you specify union synchronization, the Simulation Data Inspector builds a time vector that includes every sample time between the two signals. For each sample time not originally present in either signal, the Simulation Data Inspector interpolates the value. The second graph in the illustration shows the union synchronization process, where the Simulation Data Inspector identifies samples to add in each signal, represented by the unfilled circles. The final plot shows the signals after the Simulation Data Inspector has interpolated values for the added time points. The Simulation Data Inspector computes the difference using the signals in the final graph, so that the computed difference signal contains all the data points between the signals.

When you specify intersection synchronization, the Simulation Data Inspector uses only the sample times present in both signals in the comparison. In the second graph, the Simulation Data Inspector identifies samples that do not have a corresponding sample for comparison, shown as unfilled circles. The final graph shows the signals used for the comparison, without the samples identified in the second graph.

The choice between the synchronization options involves a trade off between speed and accuracy. The interpolation required by `union` synchronization takes time, but provides a more precise result. When you use `intersection` synchronization, the comparison finishes quickly because the Simulation Data Inspector computes the difference for fewer data points and does not interpolate. However, some data is discarded and precision is lost with `intersection` synchronization.

## Interpolation

The interpolation property of a signal determines how the Simulation Data Inspector displays the signal and how additional data values are computed in synchronization. You can choose to interpolate your data with a zero-order hold (`zoh`) or a linear approximation. You can also specify no interpolation.

When you specify `zoh` or `none` for the **Interpolation Method**, the Simulation Data Inspector replicates the data of the previous sample for interpolated sample times. When you specify `linear` interpolation, the Simulation Data Inspector uses samples on either side of the interpolated point to linearly approximate the interpolated value. Typically, discrete signals use `zoh` interpolation and continuous signals use `linear` interpolation. You can specify the **Interpolation Method** for your signals in the signal properties.

## Tolerance Specification

The Simulation Data Inspector allows you to specify the scope and value of the tolerance for your signal. You can define a tolerance band using any combination of absolute, relative, and time tolerance values, and you can specify whether the specified tolerance applies to an individual signal or to all the signals in a run.

## Tolerance Scope

In the Simulation Data Inspector, you can specify the tolerance for your data globally or for an individual signal. Global tolerance values apply to all signals in a run that do not have **Override Global Tol** set to yes. You can specify global tolerance values for your data at the top of the graphical viewing area in the **Compare** view. To specify signal specific tolerance values, edit the signal properties and ensure the **Override Global Tol** property is set to yes.

## Tolerance Computation

In the Simulation Data Inspector, you can specify a tolerance band for your run or signal using a combination of absolute, relative, and time tolerance values. When you specify the tolerance for your run or signal using multiple types of tolerances, each tolerance can yield a different answer for the tolerance at each point. The Simulation Data Inspector computes the overall tolerance band by selecting the most lenient tolerance result for each data point.

When you define your tolerance using only the absolute and relative tolerance properties, the Simulation Data Inspector computes the tolerance for each point as a simple maximum.

```
tolerance = max(absoluteTolerance, relativeTolerance*abs(baselineData));
```

The upper boundary of the tolerance band is formed by adding **tolerance** to the **Baseline** signal. Similarly, the Simulation Data Inspector computes the lower boundary of the tolerance band by subtracting **tolerance** from the **Baseline** signal.

When you specify a time tolerance, the Simulation Data Inspector evaluates the time tolerance first, over a time interval defined as  $[(t_{\text{samp}} - \text{tol}), (t_{\text{samp}} + \text{tol})]$  for each sample. The Simulation Data Inspector builds the lower tolerance band by selecting the minimum point on the interval for each sample. Similarly, the maximum point on the interval defines the upper tolerance for each sample.

If you specify a tolerance band using an absolute or relative tolerance in addition to a time tolerance, the Simulation Data Inspector applies the time tolerance first, and then applies the absolute and relative tolerances to the maximum and minimum points selected with the time tolerance.

`upperTolerance = max + max(absoluteTolerance, relativeTolerance*max)`

`lowerTolerance = min - max(absoluteTolerance, relativeTolerance*min)`

## Limitations

The Simulation Data Inspector does not support comparing:

- Signals of data types `int64` or `uint64`.
- Variable-size signals.

## Inspect and Compare Data Programmatically

You can harness the capabilities of the Simulation Data Inspector from the MATLAB command line using the Simulation Data Inspector API.

The Simulation Data Inspector organizes data in runs and signals, assigning a unique numeric identification to each run and signal. Some Simulation Data Inspector API functions use the run and signal IDs to reference data, rather than accepting the run or signal itself as an input. To access the run IDs in the workspace, you can use `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`. You can access signal IDs through a `Simulink.sdi.Run` object using the `getSignalIDByIndex` method.

The `Simulink.sdi.Run` and `Simulink.sdi.Signal` classes provide access to your data and allow you to view and modify run and signal metadata. You can modify the Simulation Data Inspector preferences using functions like `Simulink.sdi.setSubPlotLayout`, `Simulink.sdi.setRunNamingRule`, and `Simulink.sdi.setMarkersOn`. To restore the Simulation Data Inspector's default settings, use `Simulink.sdi.clearPreferences`.

### Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

#### Create Data for the Run

Create `timeseries` objects to contain data for a sine signal and a cosine signal. Give each `timeseries` object a descriptive name.

```
time = linspace(0,20,100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals,time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals,time);
cos_ts.Name = 'Cosine, T=8';
```

#### Create a Run and Add Data

Use the `Simulink.sdi.view` function to open the Simulation Data Inspector.

```
Simulink.sdi.view
```

To import data into the Simulation Data Inspector from the workspace, create a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.create` function. Add information about the run to its metadata using the `Name` and `Description` properties of the `Run` object.

```
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';
```

Use the `add` function to add the data you created in the workspace to the empty run.

```
add(sinusoidsRun, 'vars', sine_ts, cos_ts);
```

### Plot the Data in the Simulation Data Inspector

Use the `getSignalByIndex` function to access `Simulink.sdi.Signal` objects that contain the signal data. You can use the `Simulink.sdi.Signal` object properties to specify the line style and color for the signal and plot it in the Simulation Data Inspector. Specify the `LineColor` and `LineDashed` properties for each signal.

```
sine_sig = getSignalByIndex(sinusoidsRun,1);  
sine_sig.LineColor = [0 0 1];  
sine_sig.LineDashed = '-.';
```

```
cos_sig = sinusoidsRun.getSignalByIndex(2);  
cos_sig.LineColor = [0 1 0];  
cos_sig.LineDashed = '--';
```

Use the `Simulink.sdi.setSubPlotLayout` function to configure a 2-by-1 subplot layout in the Simulation Data Inspector plotting area. Then use the `plotOnSubPlot` function to plot the sine signal on the top subplot and the cosine signal on the lower subplot.

```
Simulink.sdi.setSubPlotLayout(2,1);
```

```
plotOnSubPlot(sine_sig,1,1,true);  
plotOnSubPlot(cos_sig,2,1,true);
```

### Close the Simulation Data Inspector and Save Your Data

When you have finished inspecting the plotted signal data, you can close the Simulation Data Inspector and save the session to an MLDATX file.

```
Simulink.sdi.close('sinusoids.mldatx')
```

## Compare Two Signals in the Same Run

You can use the Simulation Data Inspector programmatic interface to compare signals within a single run. This example compares the input and output signals of an aircraft longitudinal controller.

First, load the session that contains the data.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

Use the `Simulink.sdi.Run.getLatest` function to access the latest run in the data.

```
aircraftRun = Simulink.sdi.Run.getLatest;
```

Then, you can use the `Simulink.sdi.getSignalsByName` function to access the `Stick` signal, which represents the input to the controller, and the `alpha, rad` signal that represents the output.

```
stick = getSignalsByName(aircraftRun, 'Stick');  
alpha = getSignalsByName(aircraftRun, 'alpha, rad');
```

Before you compare the signals, you can specify a tolerance value to use for the comparison. Comparisons use tolerance values specified for the baseline signal in the comparison, so set an absolute tolerance value of 0.1 on the `Stick` signal.

```
stick.AbsTol = 0.1;
```

Now, compare the signals using the `Simulink.sdi.compareSignals` function. The `Stick` signal is the baseline, and the `alpha_rad` signal is the signal to compare against the baseline.

```
comparisonResults = Simulink.sdi.compareSignals(stick.ID,alpha.ID);
match = comparisonResults.Status
```

```
match =
    ComparisonSignalStatus enumeration
        OutOfTolerance
```

The comparison result is out of tolerance. You can use the `Simulink.sdi.view` function to open the Simulation Data Inspector to view and analyze the comparison results.

## Compare Runs with Global Tolerance

You can specify global tolerance values to use when comparing two simulation runs. Global tolerance values are applied to all signals within the run. This example shows how to specify global tolerance values for a run comparison and how to analyze and save the comparison results.

First, load the session file that contains the data to compare. The session file contains data for four simulations of an aircraft longitudinal controller. This example compares data from two runs that use different input filter time constants.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

To access the run data to compare, use the `Simulink.sdi.getAllRunIDs` function to get the run IDs that correspond to the last two simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end - 1);
runID2 = runIDs(end);
```

Use the `Simulink.sdi.compareRuns` function to compare the runs. Specify a global relative tolerance value of `0.2` and a global time tolerance value of `0.5`.

```
runResult = Simulink.sdi.compareRuns(runID1,runID2,'reltol',0.2,'timetol',0.5);
```

Check the `Summary` property of the returned `Simulink.sdi.DiffRunResult` object to see whether signals were within the tolerance values or out of tolerance.

```
runResult.Summary
ans = struct with fields:
    OutOfTolerance: 0
    WithinTolerance: 3
    Unaligned: 0
    UnitsMismatch: 0
    Empty: 0
    Canceled: 0
    EmptySynced: 0
    DataTypeMismatch: 0
```

```
TimeMismatch: 0
StartStopMismatch: 0
Unsupported: 0
```

All three signal comparison results fell within the specified global tolerance.

You can save the comparison results to an MLDATX file using the `saveResult` function.

```
saveResult(runResult, 'InputFilterComparison');
```

## Analyze Simulation Data Using Signal Tolerances

You can programmatically specify signal tolerance values to use in comparisons performed using the Simulation Data Inspector. In this example, you compare data collected by simulating a model of an aircraft longitudinal flight control system. Each simulation uses a different value for the input filter time constant and logs the input and output signals. You analyze the effect of the time constant change by comparing results using the Simulation Data Inspector and signal tolerances.

First, load the session file that contains the simulation data.

```
Simulink.sdi.load('AircraftExample.mldatx');
```

The session file contains four runs. In this example, you compare data from the first two runs in the file. Access the `Simulink.sdi.Run` objects for the first two runs loaded from the file.

```
runIDs = Simulink.sdi.getAllRunIDs;
runIDs1 = runIDs(end-3);
runIDs2 = runIDs(end-2);
```

Now, compare the two runs without specifying any tolerances.

```
noTolDiffResult = Simulink.sdi.compareRuns(runIDs1, runIDs2);
```

Use the `getResultByIndex` function to access the comparison results for the `q` and `alpha` signals.

```
qResult = getResultByIndex(noTolDiffResult, 1);
alphaResult = getResultByIndex(noTolDiffResult, 2);
```

Check the `Status` of each signal result to see whether the comparison result fell within our out of tolerance.

```
qResult.Status
```

```
ans =
  ComparisonSignalStatus enumeration
    OutOfTolerance
```

```
alphaResult.Status
```

```
ans =
  ComparisonSignalStatus enumeration
```

## OutOfTolerance

The comparison used a value of 0 for all tolerances, so the `OutOfTolerance` result means the signals are not identical.

You can further analyze the effect of the time constant by specifying tolerance values for the signals. Specify the tolerances by setting the properties for the `Simulink.sdi.Signal` objects that correspond to the signals being compared. Comparisons use tolerances specified for the baseline signals. This example specifies a time tolerance and an absolute tolerance.

To specify a tolerance, first access the `Signal` objects from the baseline run.

```
runTs1 = Simulink.sdi.getRun(runIDTs1);
qSig = getSignalsByName(runTs1, 'q, rad/sec');
alphaSig = getSignalsByName(runTs1, 'alpha, rad');
```

Specify an absolute tolerance of 0.1 and a time tolerance of 0.6 for the `q` signal using the `AbsTol` and `TimeTol` properties.

```
qSig.AbsTol = 0.1;
qSig.TimeTol = 0.6;
```

Specify an absolute tolerance of 0.2 and a time tolerance of 0.8 for the `alpha` signal.

```
alphaSig.AbsTol = 0.2;
alphaSig.TimeTol = 0.8;
```

Compare the results again. Access the results from the comparison and check the `Status` property for each signal.

```
tolDiffResult = Simulink.sdi.compareRuns(runIDTs1, runIDTs2);
qResult2 = getResultByIndex(tolDiffResult, 1);
alphaResult2 = getResultByIndex(tolDiffResult, 2);
```

```
qResult2.Status
```

```
ans =
  ComparisonSignalStatus enumeration
    WithinTolerance
```

```
alphaResult2.Status
```

```
ans =
  ComparisonSignalStatus enumeration
    WithinTolerance
```

## Keyboard Shortcuts for the Simulation Data Inspector

You can use several keyboard shortcuts to facilitate working with the Simulation Data Inspector. In the table, where the shortcut looks like **Ctrl+N**, hold the **Ctrl** key and then press the **N** key to use the shortcut.

---

**Note** On Macintosh platforms, use the **command** key instead of **Ctrl**.

---

### General Actions

Task	Shortcut
Start a new session	<b>Ctrl+N</b>
Open a session	<b>Ctrl+O</b>
Save a session	<b>Ctrl+S</b>
Compare	<b>Ctrl+E</b>
Link or unlink a subplot	<b>Ctrl+U</b>
Delete a run or signal	<b>Delete</b>

### Plot Zooming

Task	Shortcut
Zoom in time	<b>Ctrl+Shift+T</b>
Zoom in y	<b>Ctrl+Shift+Y</b>
Zoom in time and y	<b>Ctrl++</b> (Numeric keypad only)
Zoom out	<b>Ctrl+-</b> (Numeric keypad only)
Fit to view	<b>Space bar</b>
Fit to time	<b>Ctrl+Alt+T</b>
Fit to y	<b>Ctrl+Alt+Y</b>
Cancel zoom operation or signal dragging	<b>Esc</b>

### Data Cursors

Task	Shortcut
Show a data cursor	<b>Ctrl+I</b>
Hide all data cursors	<b>Shift+Del</b>
Move a selected data cursor to next data point	<b>Right arrow</b>
Move a selected data cursor to previous data point	<b>Left arrow</b>

<b>Task</b>	<b>Shortcut</b>
Activate first (left) cursor	<b>Ctrl+1</b>
Activate second (right) cursor	<b>Ctrl+2</b>

## **Import Dialog Box**

These actions pertain to the import table.

<b>Task</b>	<b>Shortcut</b>
Expand all nodes	<b>Shift+Ctrl+=</b>
Collapse all nodes	<b>Ctrl+=</b>
Select a node	<b>Space bar</b>
Expand a single node	<b>Right arrow</b>
Collapse a single node	<b>Left arrow</b>

## Tune and Visualize Your Model with Dashboard Blocks

### In this section...

“Explore Connections Within the Model” on page 32-2

“Simulate Changing Model States” on page 32-3

“View Signal Data” on page 32-4

“Tune Parameters During Simulation” on page 32-5

The blocks in the Dashboard library help you control and visualize your model during simulation and while the simulation is paused. This example uses the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys` to showcase the control and visualization capabilities of Dashboard blocks. To open the model, use this command:

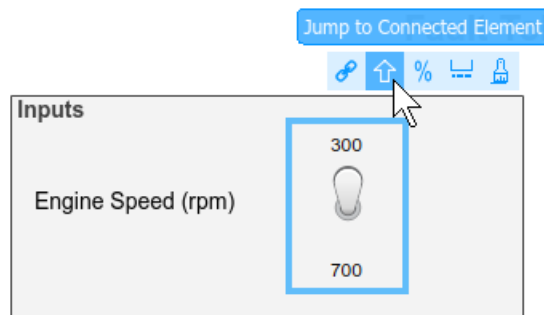

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
```

**Note** Dashboard blocks cannot connect to signals inside referenced models or subsystems.

### Explore Connections Within the Model

The Dashboard subsystem contains blocks for controlling and visualizing signals in the Fault-Tolerant Fuel Control System model. Explore the connections between the signals and Dashboard blocks. Click either a signal or a Dashboard block to highlight the connections.

From the Dashboard subsystem, click the Toggle Switch in the Fuel panel. Hover the mouse over the ellipsis above the block and then click the arrow above it to jump to the connected block or signal.

From the top level of the model, click the `air_fuel_ratio` signal and see the Dashboard subsystem, Quarter Gauge, and Half Gauge highlighted.

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2016 The MathWorks, Inc.

## Simulate Changing Model States

In the Dashboard subsystem, switches provide control over the state of the throttle angle, engine speed, EGO, and MAP signals. For each sensor signal, the switch toggles between normal and fail, allowing you to simulate the system response to each single-point failure. Clicking any one of these switches before simulation, during simulation, or while a simulation is paused changes the state in the model.

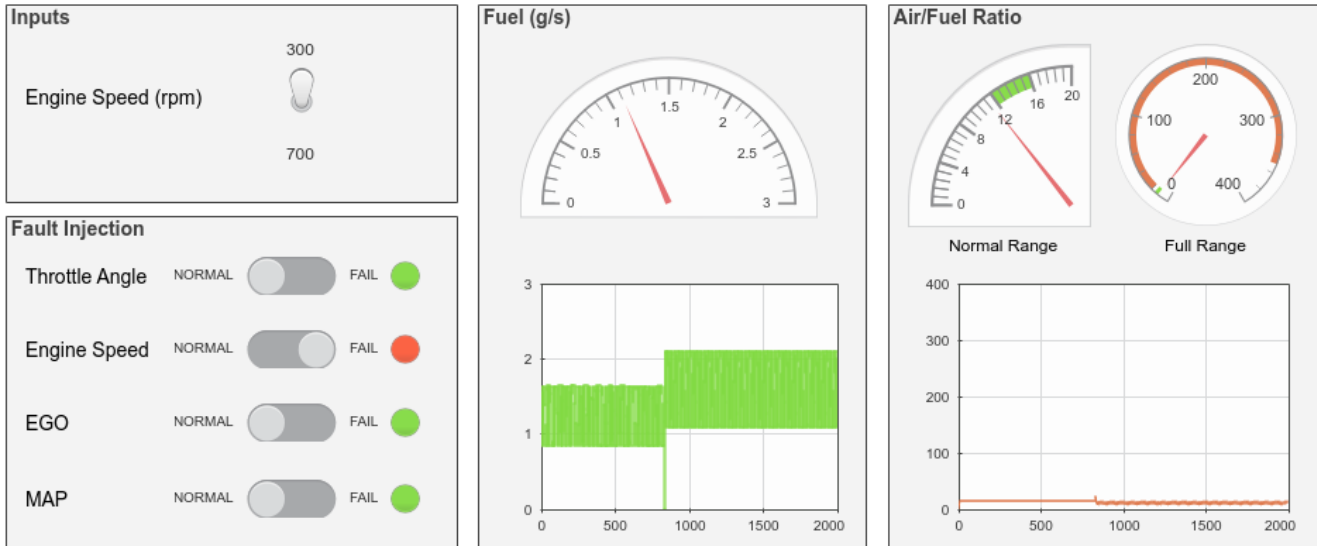

Run the simulation and observe the control system response to each single-point failure.

- 1 Start the simulation.
- 2 As the simulation runs, click one of the switches to simulate a component failure.

Observe the changes in the `fuel` and `air_fuel_ratio` signals in the Dashboard Scope and Gauge blocks when you flip each switch.

- 3 Stop the simulation when you are finished.

## Fault-Tolerant Fuel Control System Dashboard

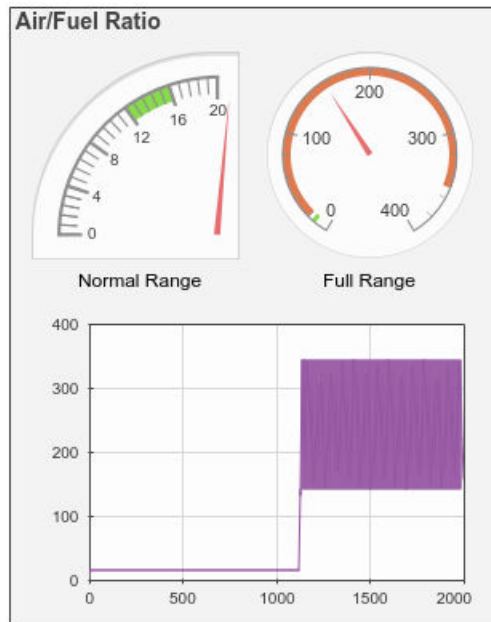

[Update Diagram](#) (Ctrl+D) to bind switches to model workspace variables.

## View Signal Data

Dashboard blocks allow you to view signal data using gauges, lamps, and dashboard scopes. In this example, the Dashboard blocks provide visual feedback about the fuel input and air-to-fuel ratio during simulation, after simulation, and while a simulation is paused.

To capture different types of information and more effectively visualize a signal, connect multiple Dashboard blocks to a single signal. For example, you can visualize the `air_fuel_ratio` signal using the Gauge, Quarter Gauge, and Dashboard Scope blocks.

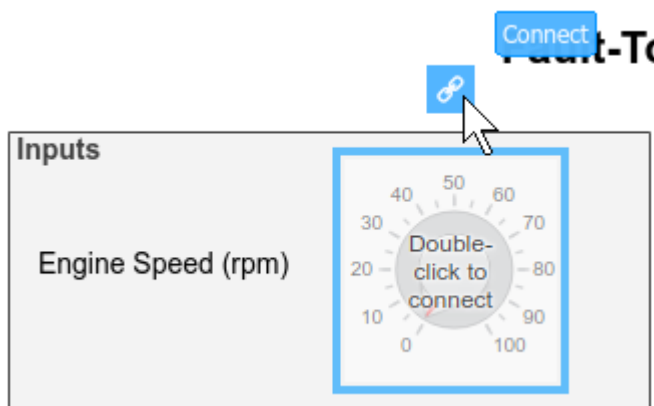

Use the Quarter Gauge block, labeled Normal Range in the example, to see small fluctuations in the instantaneous `air_fuel_ratio` signal while its value lies within the normal operational range. The Gauge block, labeled Full Range, allows you to see the behavior of the instantaneous `air_fuel_ratio` signal outside of the normal range. The Dashboard Scope block shows the variations of the `air_fuel_ratio` signal over time.

## Tune Parameters During Simulation

Dashboard blocks allow you to tune parameters in your model during a simulation. To explore the tuning capability within the fuel system model, replace the engine speed Toggle Switch block with a Knob:

- 1 Delete the engine speed Toggle Switch.
- 2 Add a Knob block from the Dashboard library.
- 3 Click the **Connect** button that appears when you pause on the Knob block. When you click the **Connect** button, the Simulink Editor enters connect mode, which facilitates connecting Dashboard blocks to signals and parameters in your model.

- 4 Navigate to the top level of the model and select the Engine Speed block. The Engine Speed block is a Constant block whose **Constant value** parameter you can tune with the Knob block.

When you select the Engine Speed block, the names of tunable parameters associated with the block appear in a table.

- 5 Select the option button next to `engine_speed` in the table. Then, to exit connect mode, click the **Exit** button in the upper-right of the model canvas.

Now that the Knob block is connected to the `engine_speed` parameter, you can set the tick interval and range to values that make sense for the simulation. Double-click the Knob block to access the block parameters. In this example, set **Minimum** to 75, **Maximum** to 750, and **Tick Interval** to 75. Then, click **OK**.

Simulate the model and tune the `engine_speed` parameter using the Knob.

- 1 Start the simulation.
- 2 As the simulation runs, drag the pointer on the Knob to adjust the value of `engine_speed`.

Notice as you use the Knob to adjust the value of `engine_speed`, the `air_fuel_ratio` value displayed on the Gauge blocks and in the Dashboard Scope block changes.

- 3 Stop the simulation when you have finished tuning the parameter.

## See Also

- “Decide How to Visualize Simulation Data” on page 33-2

## Interactively Design and Debug Models Using Panels

You can use a panel containing one or more Dashboard blocks to help you design and debug a model. A panel floats above the model canvas and follows you throughout a model hierarchy. With panels, you can control and monitor components of your model in place, without adding collections of Dashboard blocks throughout the model.

When you use panels, the blocks in the panel are not associated with the model in the same way as blocks in the canvas. For example, you cannot programmatically interact with blocks in panels using `get_param`, `set_param`, `gcb`, or `gcbh`. Otherwise, blocks promoted to panels retain their interactive behavior. You can connect Dashboard blocks in a panel using connect mode, inspect block properties using the Property Inspector, and modify connections during simulation.

This example uses the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys` to illustrate the steps required to create panels and how you can use panels to debug your models. To open the model, use this command:

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
```

### Create a New Panel

The `sldemo_fuelsys` model has a Dashboard subsystem that contains controls and indicators for interactively simulating the model. You can use panels in addition to or instead of using a Dashboard subsystem or including Dashboard blocks throughout your model. For example, you can create three panels, each containing a subset of the blocks in the Dashboard subsystem:

- A control panel, including the blocks in the **Inputs** and **Fault Injection** areas.
- A visualization panel for the `fuel` signal, including the blocks in the **Fuel (g/s)** area.
- A visualization panel for the `air_fuel_ratio` signal, including the blocks in the **Air/Fuel Ratio** area.

You do not need to separate controls and visualizations into different panels. A single panel can contain both kinds of blocks. For this example, the modular division allows you to have access to the controls while choosing which signal to monitor, depending on the subsystem you need to understand or debug.

Navigate inside the Dashboard subsystem, and create the controls panel:

- 1 Select the blocks inside the areas labeled **Inputs** and **Fault Injection**.
- 2 To promote the selection of blocks to a panel, pause on the ellipsis that appears at the end of the selection and select **Promote to Panel** from the menu that appears.

---

**Note** You can only promote Dashboard blocks and blocks in the Aerospace Blockset™ Flight Instruments library to a panel. When you try to promote a selection that contains model elements other than Dashboard blocks, only the Dashboard blocks promote to the panel.

---

When you promote blocks to a panel, the blocks move from the canvas into the panel. If you want to move a block back into the canvas from a panel, enter edit mode and drag the block out of the panel and into the canvas. To enter edit mode for a panel, select the panel, pause on the ellipsis that appears above the selected panel, and select **Edit Panel**.

Follow similar steps to create two more panels: one containing the blocks in the **Fuel (g/s)** area, and another containing the blocks in the **Air/Fuel Ratio** area.

## Fault-Tolerant Fuel Control System Dashboard

---

**Note** To use panels saved in a referenced model, open the referenced model as a top model.

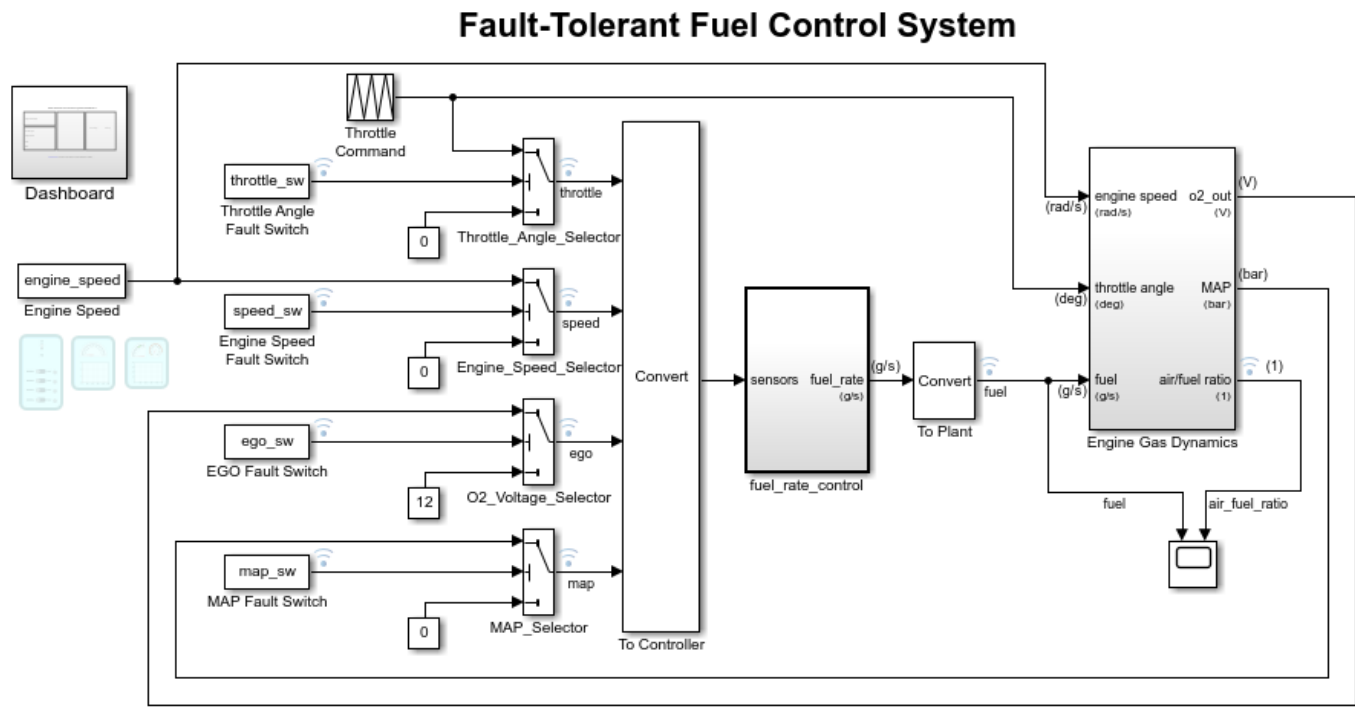

---

### Manage Panels in Your Model

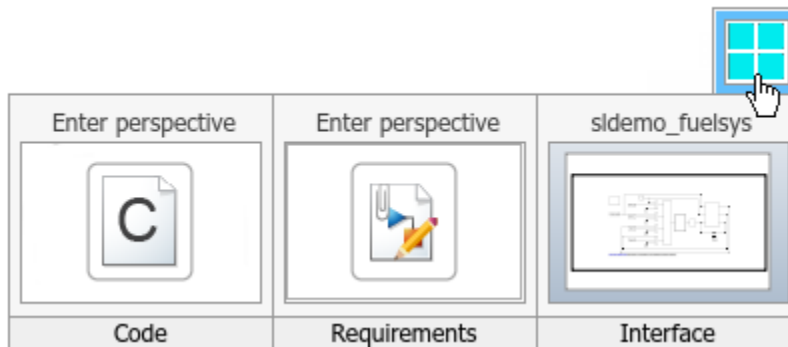

When you use panels in your model, the panel remains accessible, floating over the canvas, no matter where you are in a model hierarchy. For example, navigate to the top level of the `sldemo_fuelsys` model. The panels remain visible and in the same position, similar to a heads-up display.

You can adjust the size of a panel from the corners. When you resize a panel outside of edit mode, the contents of the panel scale proportionally. To resize a panel without scaling the contents, enter edit mode as described in “Edit and Annotate a Panel” on page 32-11. You can reposition a panel by selecting an empty area in the panel and dragging.

If you need to inspect or edit your model, you can minimize one or more panels by double-clicking each panel. Minimized panels remain visible in the model, represented by icons. You can move the icon to a convenient place in your model while you edit or inspect the model contents. When you need to use the panel, you can restore the panel by double-clicking the icon.

You can also use the **Manage Panels** dialog to control panel visibility in the model. To access all panels available in a model or change the visibility of a panel, select **Manage Panels** from the perspectives controls. You can access the perspectives controls by clicking the lower right corner of the Simulink Editor.

The **Manage Panels** dialog is only available when your model includes panels. If there are no panels in your model, the **Manage Panels** dialog does not show in the perspectives controls.

The **Manage Panels** dialog hovers over the canvas and displays an icon for each panel in the model. Because this model contains three panels, you see three icons. You can use the **Manage Panels** dialog to hide or show individual panels in your model, depending on the relevance of each panel to your present workflow. Click an icon to toggle the visibility for the corresponding panel. When panels are hidden, the icon becomes more transparent in the dialog, and the panel is not visible in the model. You can use the menu above the **Manage Panels** dialog to show or hide all panels in the model.

Because panels are positioned relative to the canvas and do not scale with zoom actions, you may lose track of one or more panels in the model as you design and debug. Use the **Fit Visible Panels to View** button to gather all visible panels in your model into the visible canvas.

## Edit and Annotate a Panel

You can edit and annotate panels using edit mode. To enter edit mode for a panel, select the panel, pause on the ellipsis that appears above the selected panel, and select **Edit Panel**.

In edit mode, you can resize panels without resizing the panel contents, delete a panel, and change the appearance of a panel. For example, you could specify a background image to use as the panel background, or you can add annotations to label the contents of the panel. You can also add and remove blocks in edit mode by dragging blocks into or out of the panel. When your model has multiple panels, you can move blocks and labels between panels in edit mode.

Add annotations to each panel to label each interactive element. To add an annotation, double-click an empty part of the panel and start typing. Use the rich text menu to modify the annotations. For example, make section labels bold. To edit another panel while in edit mode, select the next panel. Clicking outside of a panel exits edit mode.

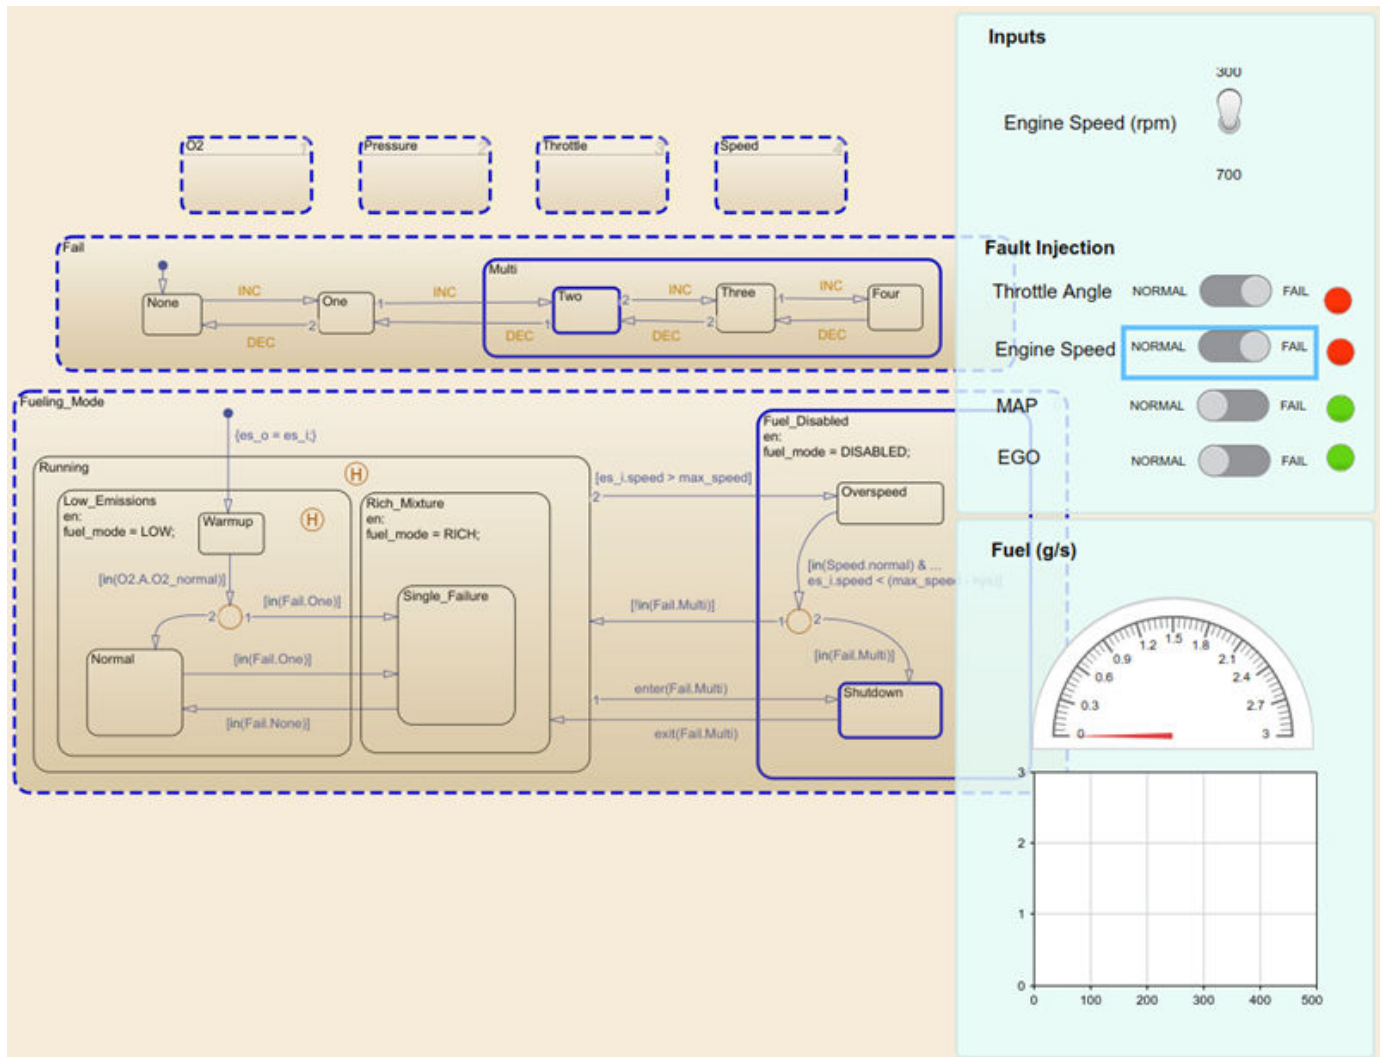

When you finish editing and annotating the panel, exit edit mode by selecting the **Done Editing** option in the menu above the panel or clicking outside of the panel.

## Interactively Simulate a Model Using Panels

Now you have modular panels to use while interactively simulating the `sldemo_fuelsys` model. Suppose you need to understand and debug the `fuel_rate_control` subsystem. In this subsystem, the controls panel and the panel that visualizes the `fuel` signal are most useful. Before starting a simulation, navigate inside the `fuel_rate_control` subsystem and then inside the `control_logic` Stateflow chart. Minimize or hide the panel that visualizes the `air_fuel_ratio` signal, and arrange the controls panel and fuel panel so you can see the contents of the chart.

Start a simulation. Once the simulation starts, modify the position for one or more **Fault Injection** Slider Switch blocks to induce a failure in the system. To modify the value a Dashboard block passes to the model, select the block and then click to select the new value. Observe the changes in the Stateflow chart as the system state changes in response to one or more failures.

**Tip** If the simulation progresses too quickly, you can use simulation pacing to slow the progression of simulation time relative to clock time. For more information, see “Simulation Pacing” on page 2-18.

## Create Tabbed Panels

Another way to manage multiple panels is by creating a tabbed panel. For example, you can create a tabbed panel that contains one panel for visualizing the fuel signal and another for visualizing the air\_fuel\_ratio signal.

To add a tab to the **Fuel** panel, select the panel and pause on the ellipsis that appears above it. Then, select **Add Tab**.

To add blocks to the new tab, enter edit mode by selecting the panel, pausing on the ellipsis above it, and selecting **Edit Panel**. Drag the contents of the **Air/Fuel Ratio** panel into the new tab you added to the **Fuel** panel. Panels do not support selecting more than one element, so you must move the blocks and labels one by one.

You can name the tabs of the panels using the Property Inspector. To show the Property Inspector, in the **Modeling** tab, under **Design**, select **Property Inspector**. Select the panel and type the name in the Property Inspector. The name applies to the active tab. To name the other tab, select the tab and type the name in the Property Inspector.

You can separate panels by dragging a tab away and combine panels by dragging tabs together.

- "Tune and Visualize Your Model with Dashboard Blocks" on page 32-2
- "Simulation Pacing" on page 2-18

## Design Custom Gauges

You can design custom gauges that look like displays in a real system or animate a signal using the Circular Gauge, Horizontal Gauge, and Vertical Gauge blocks. This example gives step-by-step guidance to design a thermometer using the Vertical Gauge block and an ammeter using the Circular Gauge block.

The model for this example includes several customized gauges connected to the output of a Sine Wave block. The example gives step-by-step instructions to design the gauge blocks in the canvas of the model. The model includes a panel that contains additional customized gauges you can explore on your own. The example directory includes a folder with all the SVG images used to create the gauges.

### Design a Thermometer Using the Vertical Gauge Block

The thermometer designed using the Vertical Gauge block uses a background image to define the shape of the thermometer and the value bar of the Vertical Gauge block to indicate the value of the connected signal during simulation. The Battery Level block in the panel uses a similar design strategy.

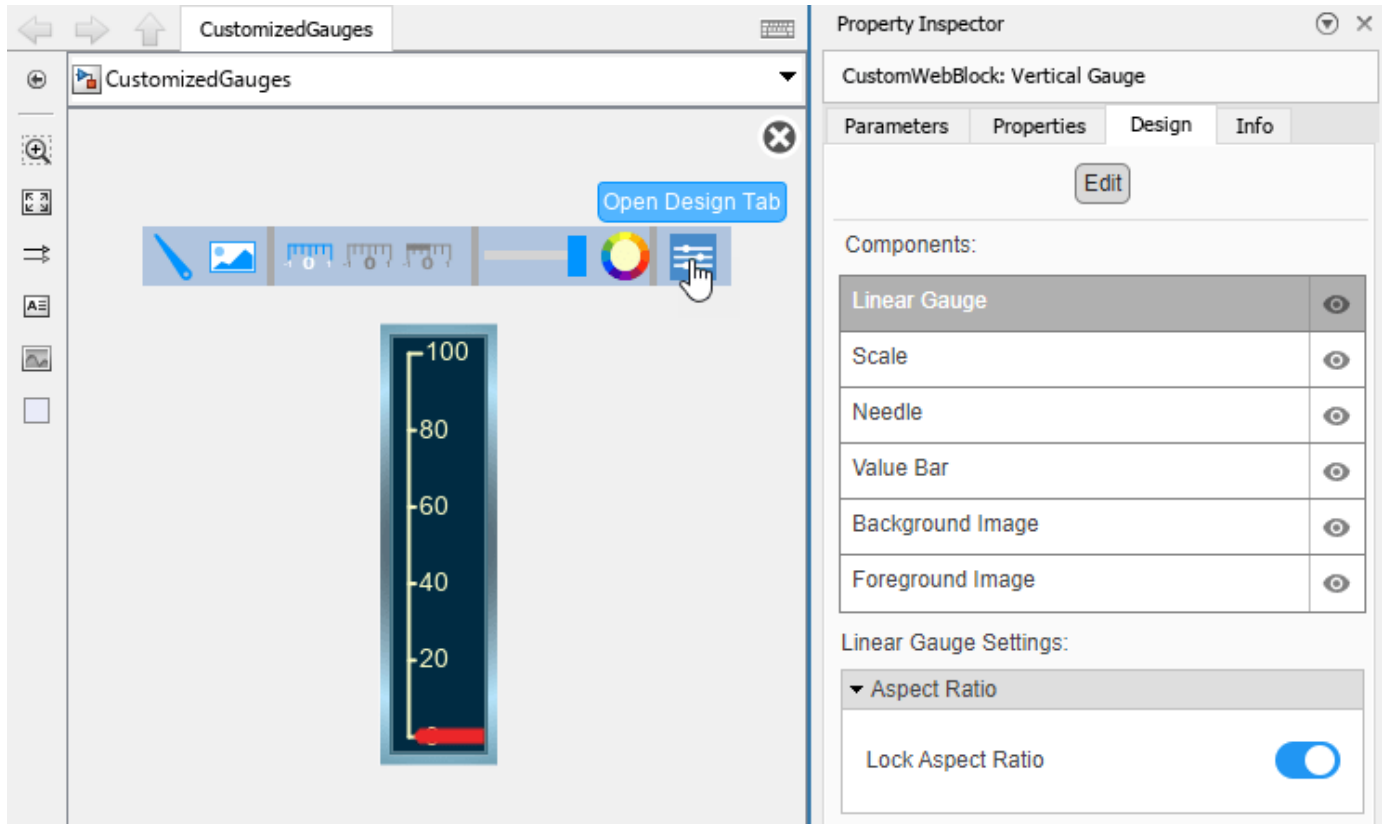

To design a thermometer, add a Vertical Gauge block to the model using the quick insert menu:

- 1 To open the quick insert menu, double-click in the canvas.
- 2 To search for the customizable Vertical Gauge block, type `Vertical Gauge`.
- 3 Select the search result with the library path `Simulink/Dashboard/Customizable Blocks`.

To modify the design of the Vertical Gauge block, enter design mode:

- 1 In the model canvas, select the Vertical Gauge block.
- 2 In the Simulink® Toolstrip, click the **Gauge** tab.

- 3 On the **Gauge** tab, click **Edit**. A toolbar appears above the Vertical Gauge block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**. In design mode, the **Design** tab of the Property Inspector is active.

Add the thermometer background image:

- 1 Select the **Background Image** component in the **Design** tab.
- 2 In the **Select Image** section, click the plus button.
- 3 Navigate inside the CustomGaugeImages folder and select the Thermometer .svg file.

The thermometer design uses the value bar, not the needle, to indicate the value of the connected signal. To remove the needle image, in the **Design** tab, select the **Needle** component. Then, in the **Select Image** section, click the X button.

Next, adjust the scale range, color, position, and size:

- 1 In the **Design** tab, select the **Scale** component.
- 2 In the **Range** section, change the **Maximum** to 50.
- 3 In the **Ticks** section and the **Labels** section, change **Color** to black so the tick marks are more visible on the white background.
- 4 Resize the scale so it fits inside the white column of the thermometer background image. You can adjust the width and height of the scale interactively on the block or by using the **Design** tab. When resizing interactively, you can maintain the aspect ratio of the scale by pressing **Shift** as you drag the corners of the block. To use the **Design** tab, in the **Size and Position** section, adjust the **Width** and **Height**.
- 5 Align the zero point on the scale with the top of the red area of the background image.

Finally, change the value bar width and color:

- 1 In the **Design** tab, select the **Value Bar** component.
- 2 In the **Value Preview** section, adjust the slider to preview what the value bar shows when the input value is greater than the minimum scale value.
- 3 In the **Value Bar** section, change **Color** to red.
- 4 Widen the value bar so it fills the majority of the thermometer. You can use interactive controls on the block or use the **Design** tab. In the **Design** tab, under **Value Bar**, adjust **Size**.
- 5 Decrease the value bar opacity so the labels are easier to read.

When you finish adjusting the design for the thermometer, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished thermometer to display a signal value. In the model, a Sine Wave block represents the temperature.

Connect the Vertical Gauge block to the Sine Wave with Offset signal:

- 1 Select the Vertical Gauge block.
- 2 Click the Connect button that appears above the block.
- 3 Select the Sine Wave with Offset signal.
- 4 Select the Sine Wave with Offset option in the table that appears below the selected signal.
- 5 Click the X in the upper right corner of the Simulink window.

To see the thermometer in action, simulate the model.

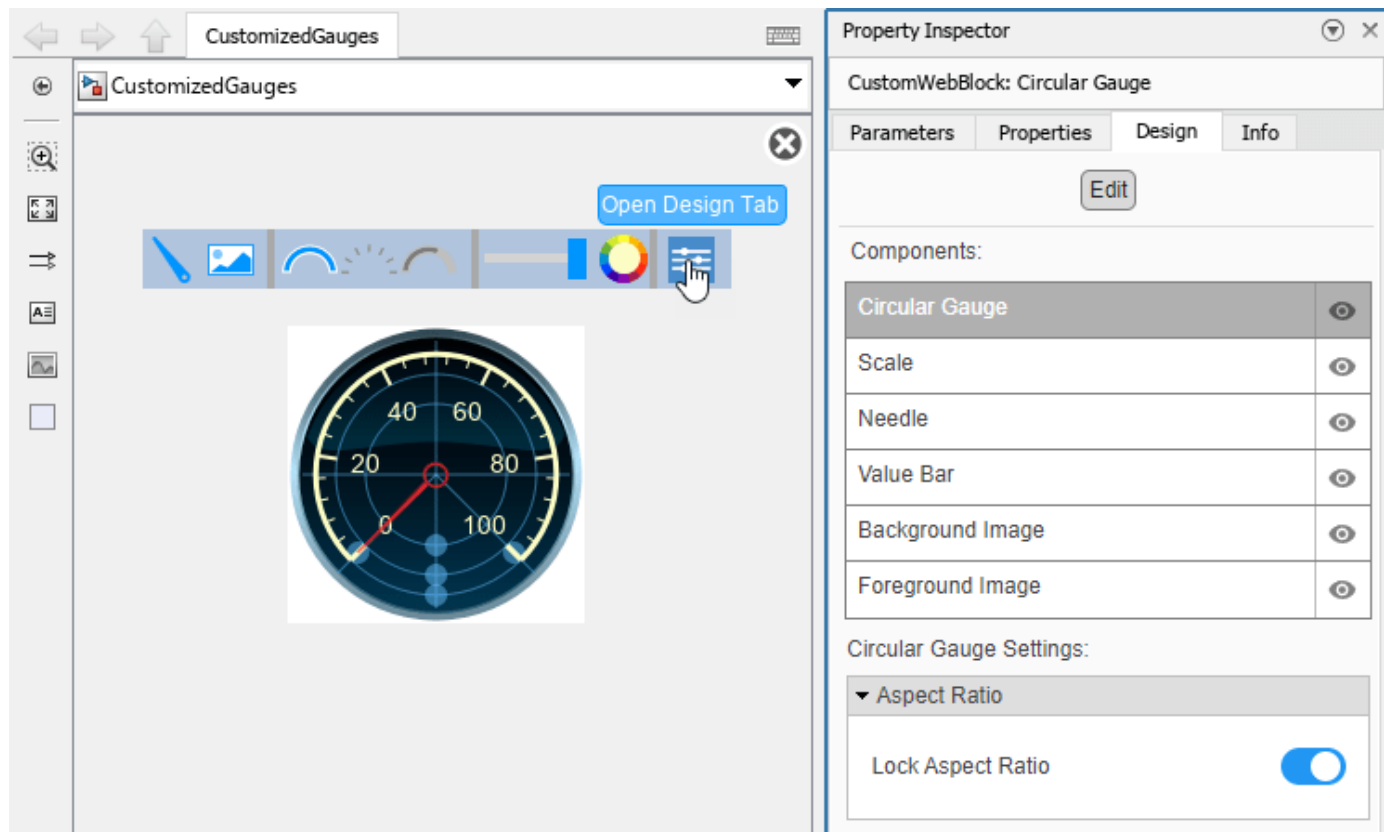

### Design an Ammeter Using the Circular Gauge Block

The ammeter designed using the Circular Gauge block uses a background image to define the appearance of the ammeter, and uses a needle image and a value bar to indicate the value of the connected signal during simulation. The Pressure Gauge block in the panel uses a similar design strategy.

To design an ammeter, add a Circular Gauge block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Circular Gauge block.
- 2 In the Simulink Toolstrip, click the **Gauge** tab.
- 3 On the **Gauge** tab, click **Edit**. A toolbar appears above the Circular Gauge block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the ammeter background image:

- 1 Select the **Background Image** component in the **Design** tab.
- 2 In the **Select Image** section, click the plus button.
- 3 Select the Ammeter .svg file.

Change the scale limits and color:

- 1 In the **Design** tab, select the **Scale** component.

- 2 In the **Range** section, change the **Minimum** to -50 and the **Maximum** to 50.
- 3 In the **Ticks** section and the **Labels** section, change the **Color** to black so the tick marks are more visible on the white background.

The ammeter scale starts and ends on the horizontal crosshairs. The scale **Start Angle** specifies the position for the scale minimum, and the scale **Arc** specifies the extent of the scale arc, both in degrees. In the **Design** tab, under **Range**, change the **Start Angle** and the **Arc** to 180.

Adjust the scale position so the entire scale fits within the display area of the ammeter background image, with the center of the needle positioned approximately at the center of the semicircle.

Replace the needle image:

- 1 In the **Design** tab, select the Needle component.
- 2 In the **Select Image** section, click the plus button.
- 3 Select the Needle .svg file.

The needle image is a straight black line. The saved image is too large for the size of the block and oriented so that the needle does not point to the zero point on the scale. To rotate the needle image, click the needle rotation button in the block. Then, use the needle grab handles in the block to resize and reposition the needle so it starts at the center of the semicircle in the background image and ends before the label for the scale minimum.

Preview the value bar:

- 1 Open the **Value Bar** component.
- 2 To see how the value bar grows as the needle moves, move the slider in the **Value Preview** section.

The value bar grows from the origin. By default, the origin is the minimum of the scale.

Change the origin to zero:

- 1 Open the **Scale** component.
- 2 In the **Range** section, set **Origin** to 0.

To see the change, open the **Value Bar** component, and move the slider in the **Value Preview** section. The value bar grows from zero, the new origin.

When you finish adjusting the design for the ammeter, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished ammeter to display a signal value. In the model, a Sine Wave block represents the input to the ammeter.

Connect the Circular Gauge block to the Sine Wave signal:

- 1 Select the Circular Gauge block.
- 2 Click the Connect button that appears above the block.
- 3 Select the Sine Wave block output signal.
- 4 Select the Sine Wave option in the table that appears below the selected signal.
- 5 Click the X in the upper right corner of the Simulink window.

To see the ammeter in action, simulate the model.

### **Explore More Customized Gauges**

The panel in the model contains more examples of customized gauges built using the Circular Gauge, Horizontal Gauge, and Vertical Gauge blocks. For more information on panels, see “Interactively Design and Debug Models Using Panels” on page 32-7. To view the panel, double-click the panel icon in the model. You can drag the panel into the canvas or resize the window to view the panel. To see how the gauges respond to changing input values, simulate the model. The CustomGaugeImages folder includes the SVG images used to create each gauge so you can try replicating the designs on your own.

## Design Custom Knobs

This example shows how to use the customizable Knob block to design three knobs that look like controls in real systems:

- The cabin temperature knob of a passenger car
- The volume knob of a radio
- A stove knob

Cabin Temp Knob

Volume Knob

Stove Knob

Each knob consists of a stationary component, the mounting, and a movable component, which is the handle that you turn to set the value.

The blocks in the model use PNG images to define the shapes of these components. You can find all images used to create the knobs in the example directory.

### Design Cabin Temperature Knob of Passenger Car

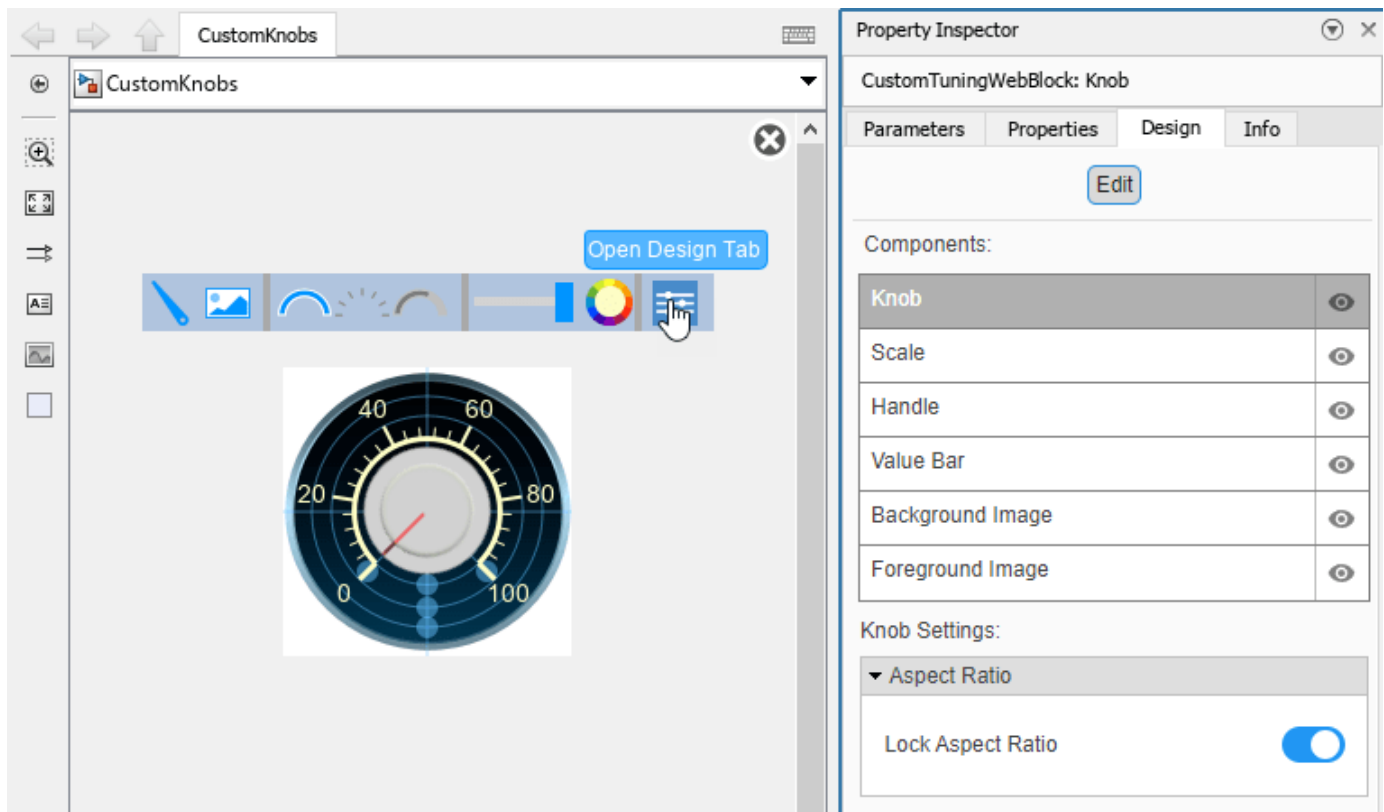

To design the cabin temperature knob, add a customizable Knob block to the model using the Simulink® quick insert menu:

- 1 To open the quick insert menu, double-click in the canvas.
- 2 To search for the customizable Knob block, type Knob.
- 3 Select the search result with the library path `Simulink/Dashboard/Customizable Blocks`.

To modify the design of the Knob block, enter design mode:

- 1 In the model canvas, select the Knob block.
- 2 In the Simulink Toolstrip, click the **Knob** tab.
- 3 On the **Knob** tab, click **Edit**. A toolbar appears above the Knob block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**. In design mode, the **Design** tab of the Property Inspector is active.

You can design a customizable knob using the toolbar or using the **Design** tab of the **Property Inspector**. This example uses both.

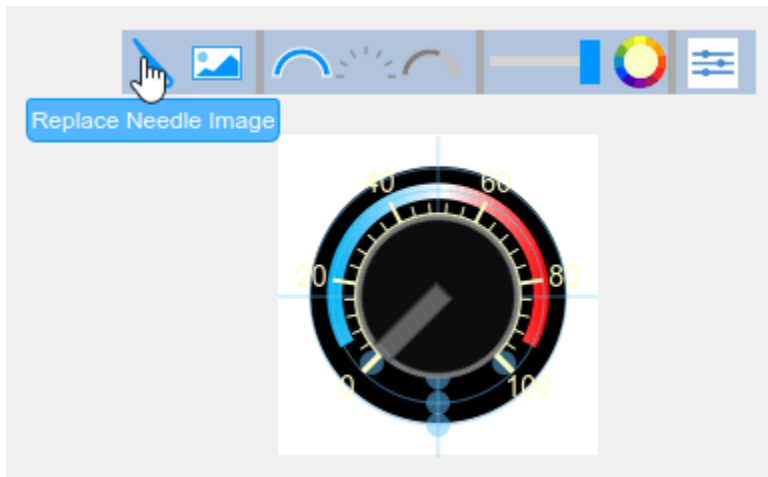

Add the background image for the cabin temperature knob:

- 1 In the toolbar, click the Replace Background Image button.
- 2 In the CustomKnobImages folder, select the `cabin-temp-knob-background.png` file.

Add the handle image for the cabin temperature knob:

- 1 In the toolbar, click the Replace Needle Image button.
- 2 In the CustomKnobImages folder, select the `cabin-temp-knob-handle.png` file.

Adjust the endpoints of the scale:

- 1 Adjust the start offset angle. On the tick mark that constitutes the left end of the scale, click and drag the blue marker so that the tick mark aligns with the blue end of the color bar on the background image. By default, the blue markers snap to angles located at 15 degree intervals. To avoid snapping to these angles, press **Shift** while dragging the marker.
- 2 Adjust the scale angle. On the tick mark that constitutes the right end of the scale, click and drag the blue marker so that the tick mark lines up with the red end of the color bar on the background image.

For the next two steps, return to the Property Inspector. To open the Design Tab of the Property Inspector, click **Open Design Tab** in the toolbar.

Hide the scale:

- 1 On the **Design** tab, select the **Scale** component.
- 2 In the **Ticks** section, clear **Show Ticks**.
- 3 In the **Ticks** section, clear **Show Span Line**.

- 4 In the **Labels** section, clear **Show Labels**.

The customizable Knob block has a value bar: a circular arc whose length serves as a visual representation of the value to which the knob is set. To see the value bar:

- 1 On the **Design** tab, select the **Value Bar** component.
- 2 In **Value Preview**, move the **Value** slider and see how the value bar changes as the handle of the knob moves.

The cabin temperature knob does not use the value bar. To hide the value bar, in the toolbar, move the Set Opacity slider to zero.

When you finish adjusting the design for the cabin temperature knob, to exit design mode, on the **Design** tab of the Property Inspector, click **Edit**.

You can use the finished cabin temperature knob to control a parameter. In the model, a Constant block represents the cabin temperature of a passenger car, and the cabin temperature knob controls the value of the constant.

Cabin Temp Knob

Connect the Knob block to the Value parameter of the Constant block:

- 1 Select the Knob block.
- 2 Click the Connect button that appears above the block.
- 3 Select the Constant block named Const1.
- 4 Select the Const1:Value option in the table that appears below the selected signal.
- 5 Click the X in the upper right corner of the Simulink window.

To use the cabin temperature knob:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 Click and drag the Knob block handle to change its value during simulation.
- 3 See the effect on the cabin temperature in the Dashboard Scope block.

### Design Volume Knob of Radio

To design the radio volume knob, add a customizable Knob block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Knob block.
- 2 In the Simulink Toolstrip, click the **Knob** tab.
- 3 On the **Knob** tab, click **Edit**. A toolbar appears above the Knob block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the volume knob:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomKnobImages folder, select the radio-knob-background.png file.

Add the handle image for the volume knob:

- 1 On the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomKnobImages folder, select the radio-knob-handle.png file.

Change the color of the value bar:

- 1 On the **Design** tab, select the **Value Bar** component.
- 2 In the **Value Preview** section, move the **Value** slider to preview the value bar.
- 3 In the **Value Bar** section, set the **Color** to turquoise.

The inner and outer radius of the value bar are the same as the inner and outer radius of the tick marks on the knob scale. Change the inner and outer radius of the value bar such that the bar covers the dark gray swoosh on the background image:

- 1 On the **Design** tab, select the **Scale** component.
- 2 In the **Range** section, adjust the **Inner Radius** slider to make the inner radius of the value bar smaller than that of the gray swoosh. The example uses an **Inner Radius** value of 0.55.
- 3 In the **Range** section, adjust the **Outer Radius** slider to make the outer radius of the value bar larger than that of the gray swoosh. The example uses an **Outer Radius** value of 0.78.

The scale is hard to read because the light yellow color of the tick marks and labels blends into the white background, and because the labels are half on and half off of the knob background. To make the scale readable so that you can adjust the arc length of the scale, set the color of the scale to black:

- 1 In the **Ticks** section, set the **Color** to black.
- 2 In the **Labels** section, set the **Color** to black.

In the **Labels** section, adjust the **Label Radius** slider to move the scale labels outside of the outer radius of the knob. The example uses a **Label Radius** value of 0.92.

Adjust the arc length of the scale:

- 1 In the **Range** section, set the **Start Angle** to 270 degrees to place the start point of the scale on the positive vertical axis. The angle is measured clockwise from the horizontal axis that bisects the right half of the knob.
- 2 In the **Range** section, set **Arc** to 90 degrees to place the end point of the scale one quarter of a full knob revolution from the start point.

Hide the scale:

- 1 In the **Ticks** section, clear **Show Ticks**.
- 2 In the **Ticks** section, clear **Show Span Line**.
- 3 In the **Labels** section, clear **Show Labels**.

Add the foreground image for the volume knob:

- 1 On the **Design** tab, select the **Foreground Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomKnobImages folder, select the radio-knob-foreground.png file.

When you finish adjusting the design for the volume knob, to exit design mode, on the **Design** tab, click **Edit**.

You can use the finished volume knob to control a parameter. In the model, a Sine Wave block represents a radio signal, and the volume knob controls the amplitude of the sine wave.

Volume Knob

Connect the Knob block to the **Amplitude** parameter of the Sine Wave block:

- 1 Select the Knob block.
- 2 Click the Connect button that appears above the block.
- 3 Select the Sine Wave block.
- 4 Select the Sine Wave:Amplitude option in the table that appears below the selected signal.
- 5 Click the X in the upper right corner of the Simulink window.

To use the volume knob:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 Click and drag the Knob block handle to change its value during simulation.
- 3 See the effect on the radio signal in the Dashboard Scope block.

### Design a Stove Knob

To design the stove knob, add a customizable Knob block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Knob block.
- 2 In the Simulink Toolstrip, click the **Knob** tab.
- 3 On the **Knob** tab, click **Edit**. A toolbar appears above the Knob block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the stove knob:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomKnobImages folder, select the stove-knob-background.png file.

Add the handle image for the stove knob:

- 1 On the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomKnobImages folder, select the stove-knob-handle.png file.

To edit the scale, make it readable by changing its color:

- 1 On the **Design** tab, select the **Scale** component.
- 2 In the **Ticks** section, set the **Color** to black.
- 3 In the **Labels** section, set the **Color** to black.

The range of the stove knob scale labels spans from 0 to 10. The minimum of the range is the default value of the Knob block. In the **Range** section, set the **Maximum** to 10.

The arc length of the stove knob scale is the default value, 270 degrees. The start angle of the scale is 315 degrees, measured clockwise from the horizontal axis that bisects the right half of the knob. In the **Range** section, set the **Start Angle** to 315.

Adjust the span line, tick marks, and labels of the scale so that they fit on the knob:

- 1 In the **Range** section, adjust the radius of the span line of the scale by moving the **Outer Radius** slider. Bring the span line close to the outer radius of the knob handle. The example uses an **Outer Radius** value of 0.55.
- 2 In the **Range** section, adjust the width of the tick marks of the scale by moving the **Inner Radius** slider. To keep the span line at the inner radius of the scale, set an **Inner Radius** value larger than that of the **Outer Radius**. Set the **Inner Radius** value such that the tick marks take up about a third of the radial distance between the outer radius of the knob handle, and the outer radius of the knob. The example uses an **Inner Radius** value of 0.63.
- 3 In the toolbar, on the **Format** tab, under **Font and Paragraph**, set the font size of the labels to 10.
- 4 On the **Design** tab, select the **Scale** component again.
- 5 In the **Labels** section, adjust the **Label Radius** slider to move the scale labels such that they are between the outer radius of the tick marks and the outer radius of the knob. The example uses a **Label Radius** value of 0.7.

Hide the value bar:

- 1 On the **Design** tab, select the **Value Bar** component.
- 2 In the **Value Bar** section, set the **Opacity** to zero.

When you finish adjusting the design for the stove knob, to exit design mode, on the **Design** tab, click **Edit**.

You can use the finished stove knob to control a parameter. In the model, a Constant block represents the heat setting of a stove, and the stove knob controls the value of the constant. The product of the heat setting and a gain represent the resulting stove temperature.

Stove Knob

Connect the Knob block to the Value parameter of the Constant block:

- 1 Select the Knob block.
- 2 Click the Connect button that appears above the block.
- 3 Select the Constant block named `Const2`.
- 4 Select the `Const2:Value` option in the table that appears below the selected signal.
- 5 Click the X in the upper right corner of the Simulink window.

To use the stove knob:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 Click and drag the Knob block handle to change its value during simulation.
- 3 See the effect on the stove temperature in the Dashboard Scope block.

- “Tune and Visualize Your Model with Dashboard Blocks” on page 32-2

## Design Custom Lamps

This example shows how to use the customizable Lamp block to design four lamps that look like displays in real systems:

- A dashboard light in a passenger car
- Elevator floor indicator lights
- Two pedestrian crossing lights

Each lamp consists of a translucent surface that the light of the lamp traverses and an icon on the translucent surface that blocks the light. When the lamp is turned on or off and when its mode of operation changes, the appearance of the translucent surface and the icon will also change. The discrete set of different looks that the translucent surface and icon can take on for a given lamp are the states of that lamp.

In addition to the translucent surface and the icon, some of the lamps have a background image, a foreground image, or both. These do not change as the lamp switches states.

The blocks in the model use PNG images to define the shapes of these components. You can find all images used to create the lamps in the example directory.

### Design Dashboard Light in Passenger Car

To design the dashboard light in a passenger car, add a customizable Lamp block to the model using the quick insert menu:

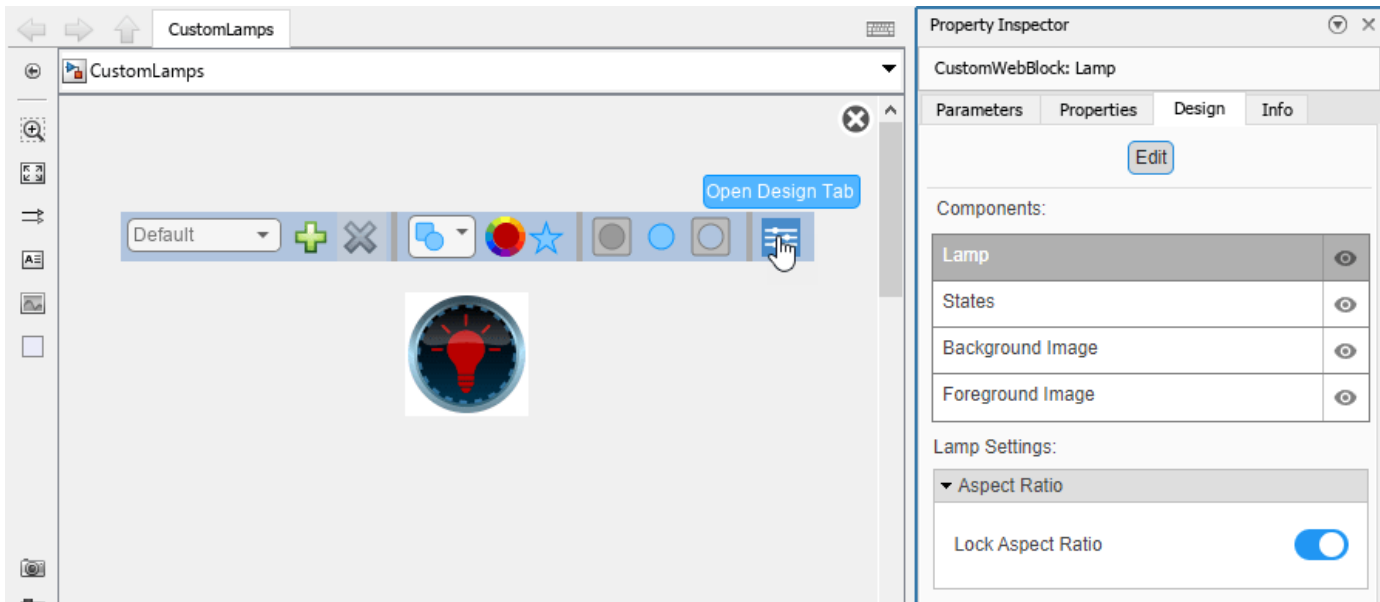

- 1 To open the quick insert menu, double-click in the canvas.
- 2 To search for the customizable Rocker Switch block, type Lamp.
- 3 Select the search result with the library path Simulink/Dashboard/Customizable Blocks.

To modify the design of the Lamp block, enter design mode:

- 1 In the model canvas, select the Lamp block.
- 2 In the Simulink® Toolstrip, click the **Lamp** tab.

- 3 On the **Lamp** tab, click **Edit**. A toolbar appears above the Lamp block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**. In design mode, the **Design** tab of the Property Inspector is active.

You can design a custom lamp using the toolbar or using the **Design** tab of the **Property Inspector**. This example uses both.

Change the background color to gray:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Background Color** section, turn on **Use Background Color**.
- 3 Change the **Color** to gray.

Delete the foreground image:

- 1 On the **Design** tab, select the **Foreground Image** component.
- 2 In the **Select Image** section, click the X button.

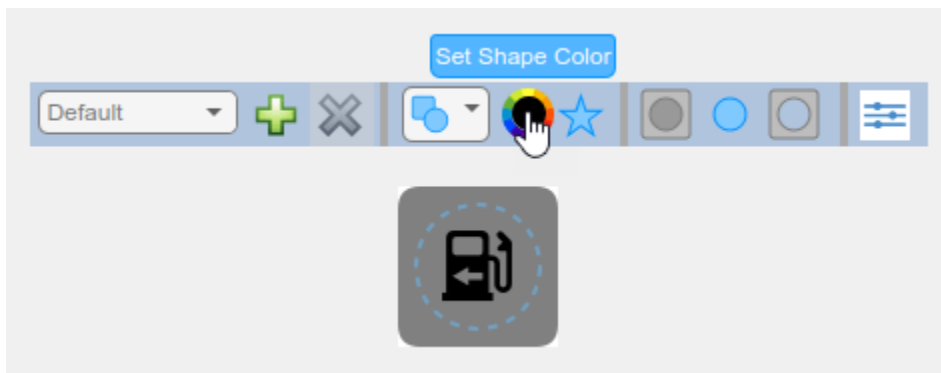

The Lamp block for the dashboard light has three states:

- It is in the first state when the percent fuel left in the tank is between 0 and 30.
- It is in the second state when the percent fuel left in the tank is between 30 and 100.
- It is in the default state when the block does not receive a parameter value that activates any other of the specified states.

When the Lamp block is in the default state, the fuel icon on the car dashboard is not lit.

Configure the appearance of the lamp for the default state:

- 1 On the **Design** tab, select the **States** component.
- 2 In the **Icon** section, open the drop-down menu and select **Automotive**.
- 3 Select the fuel icon.
- 4 In the toolbar, click the color wheel and set the color to black.

The toolbar color wheel sets the color of the translucent surface of the lamp. Since the default **Style** setting in the **Shape and Icon Combination** section is **Intersect**, the lamp shows only the area of the translucent surface that overlaps with the area of the icon. In this case, the translucent surface is the circle that is selected in the **Shape** section, and the icon is the fuel symbol that is selected in the **Icon** section. Since the overlapping area is the shape of the fuel symbol, the toolbar color wheel changes the color of that symbol.

By default, states are activated by a single parameter value. However, the fuel symbol on the dashboard is lit when the percent fuel left is in a certain range, not when the percent fuel left is equal to a certain value. If you enable **Specify State Values as Ranges**, you can specify a range of values to activate each state.

Specify the range of parameter values that activate the second state:

- 1 In the **Select State** section, open the drop-down menu and select **1 (State 2)**. The number in this drop-down menu option is the parameter value that activates the state specified in parentheses.
- 2 Turn on the **Specify State Values as Ranges** option. Observe that the drop-down menu option has changed from **1 (State 2)** to **1 to 1 (State 2)**. The numbers indicate the range of values that activate the state.
- 3 In the **Value and Color** section, enter **100** as the **Maximum** value of the range.
- 4 In the **Value and Color** section, enter **30** as the **Minimum** value of the range.

In the second state, the percent of fuel left in the tank is 30 to 100. The fuel icon on the car dashboard is not lit.

Configure the appearance of the lamp for the second state:

In the toolbar, click the color wheel and set the color for the icon to black.

Specify the range of parameter values that activate the first state:

- 1 On the **Design** tab of the Property Inspector, select the **States** component.
- 2 In the **Select State** section, open the drop-down menu and select  $\emptyset$  to  $\emptyset$  (State 1).
- 3 In the **Value and Color** section, enter 30 as the **Maximum** value of the range.

In the first state, the percent of fuel left in the tank is 0 to 30. The fuel icon on the car dashboard is lit.

Configure the appearance of the lamp for the first state:

In the toolbar, click the color wheel and set the color for the icon to yellow.

When you finish adjusting the design for the dashboard light, to exit design mode, on the **Design** tab, click **Edit**.

You can use the finished dashboard light to display a signal value. In the model, a Ramp block represents the percentage of fuel left in the tank of a car. The Ramp block has a slope of -10 and an initial output of 100.

Connect the Lamp block to the % Fuel in Tank signal:

- 1 Select the Lamp block.
- 2 Click the Connect button that appears above the block.
- 3 Select the signal line with the label % Fuel in Tank.
- 4 Select the % Fuel in Tank option in the table that appears below the selected signal line.
- 5 Click the X in the upper right corner of the Simulink window.

To use the dashboard light, simulate the model. This model uses simulation pacing to slow model execution so that you can clearly see the Lamp block respond to the value of the parameter that it connects to. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.

### Design Elevator Floor Indicator Lights

To design a simple set of elevator floor indicator lights, add a customizable Lamp block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Lamp block.
- 2 In the Simulink Toolstrip, click the **Lamp** tab.
- 3 On the **Lamp** tab, click **Edit**. A toolbar appears above the Lamp block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the floor indicator lights:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomLampImages folder, select the floor-indicator-background.png file.

Exit design mode by clicking **Edit** on the **Design** tab.

Resize the block in the canvas by dragging one of its corners outwards until the numbers on the background image are large enough to read.

To continue modifying the design of the Lamp block, enter design mode. In the Property Inspector, on the **Design** tab, click **Edit**.

Add the foreground image for the floor indicator lights:

- 1 On the **Design** tab, select the **Foreground Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomLampImages folder, select the floor-indicator-foreground.png file.

Hide the foreground image so that it is not in the way when you configure the lamp appearance for each state. On the **Design** tab, click the eye icon of the **Foreground Image** component. The eye icon now has a slash through it, indicating that the foreground image is hidden.

Using the eye icon only hides the corresponding block component while you are in design mode. If you exit design mode, the component will become visible again.

The Lamp block for the floor indicator lights has five states:

- It is in the first state when the elevator is on the ground floor, which corresponds to a parameter value of 0.
- It is in the second state when the elevator is on the first floor, which corresponds to a parameter value of 1.
- It is in the third state when the elevator is on the second floor, which corresponds to a parameter value of 2.
- It is in the fourth state when the elevator is on the third floor, which corresponds to a parameter value of 3.
- It is in the default state when the block does not receive a parameter value that activates any other of the specified states.

All states have the same setting in the **Shape and Icon Combination** and **Custom Icon** sections. The **Apply Default Settings to All States** option is on. Configure the common settings for all states simultaneously by configuring them in the default state.

Configure all states to show the icon on top of the translucent surface of the lamp:

- 1 On the **Design** tab, select the **States** component.
- 2 In the **Shape and Icon Combination** section, from **Style**, select Simple.

To delete the custom icon for all states, in the **Custom Icon** section, click the X button.

The opacity of the translucent surface of the lamp is also the same for all states, but the **Apply Default Settings to All States** option does not apply to the parameters in the **Value and Color** section. The remaining settings must be configured individually for each state.

In the **Select State** section, turn off the **Apply Default Settings to All States** option.

In the default state, all floor indicator lights are turned off.

In the **Custom Icon** section, set the **Opacity** to 0.

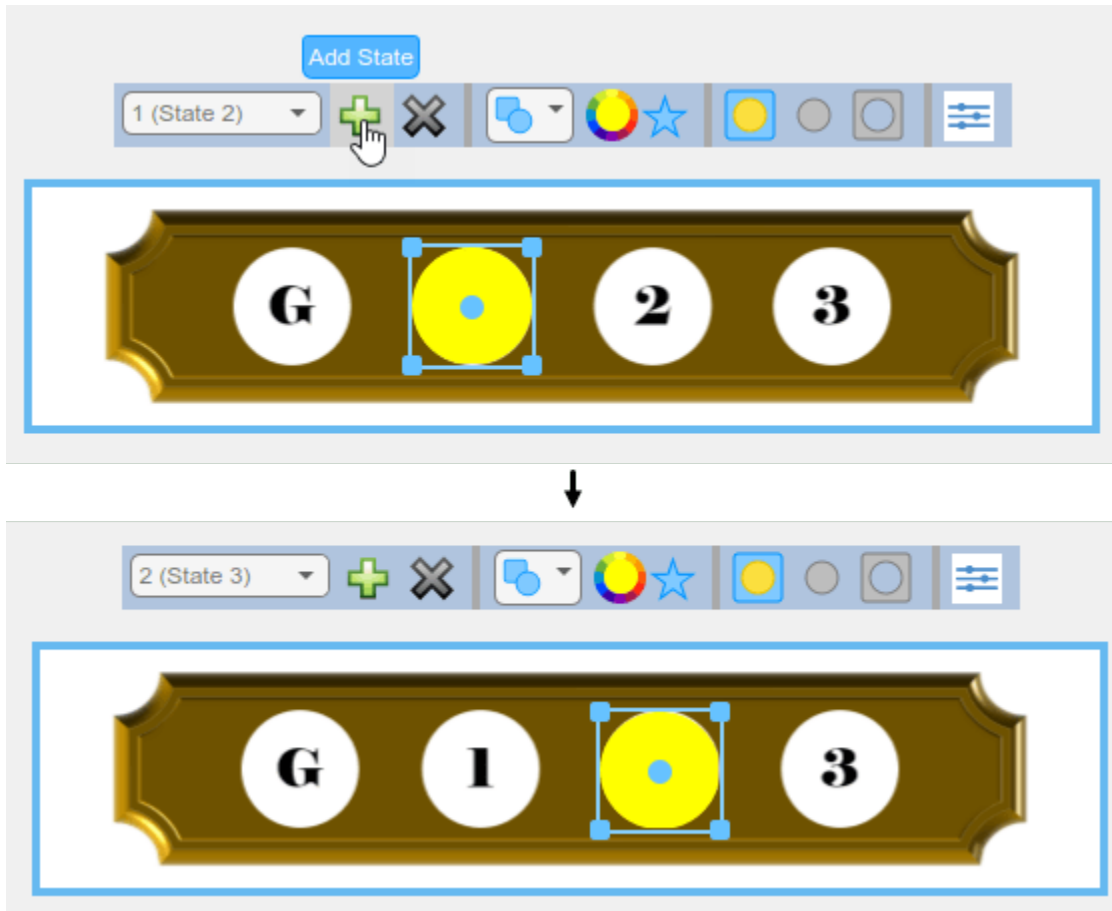

For each of the four non-default states, specify the parameter value that activates the state and configure the appearance of the lamp. In each state, the elevator reaches a different floor, and the corresponding floor indicator light turns yellow. To turn the light yellow, cover the labeled circle of the floor with a yellow circle.

For each non-default state:

- 1 In the **Select State** section, open the drop-down menu.
- 2 If the state is listed in the drop-down menu, select it. If not, click the plus button in the toolbar to add a new state. Then, in the **Select State** section of the Property Inspector, select the new state from the drop-down menu.
- 3 To turn the translucent surface of the light yellow, in the toolbar, click the color wheel and set the color to yellow.

- 4 To resize the surface, click and then drag one corner until the surface is the same size as the labeled circles on the background image. To maintain the aspect ratio of the surface, press **Shift** as you drag.
- 5 To position the surface, drag it on top of the labeled circle of the floor that the elevator reaches in the selected state.

To unhide the foreground image, on the **Design** tab, click the eye icon of the **Foreground Image** component. The eye icon no longer has a slash through it, indicating that the foreground image is visible again.

When you finish adjusting the design for the floor indicator lights, to exit design mode, on the **Design** tab, click **Edit**.

You can use the finished floor indicator lights to display a signal value. In the model, a Signal Builder block represents the input signal to the floor indicator light panel.

Connect the Lamp block to the Floor signal:

- 1 Select the Lamp block.
- 2 Click the Connect button that appears above the block.
- 3 Select the signal line with the label Floor.
- 4 Select the Floor option in the table that appears below the selected signal line.
- 5 Click the X in the upper right corner of the Simulink window.

To use the floor indicator lights, simulate the model. This model uses simulation pacing to slow model execution so that you can clearly see the Lamp block respond to the value of the parameter that it connects to. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.

### Design Pedestrian Crossing Light without Background Image

To design a pedestrian crossing light, add a customizable Lamp block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Lamp block.
- 2 In the Simulink Toolstrip, click the **Lamp** tab.
- 3 On the **Lamp** tab, click **Edit**. A toolbar appears above the Lamp block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Delete the background image:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the X button.

Delete the foreground image:

- 1 On the **Design** tab, select the **Foreground Image** component.
- 2 In the **Select Image** section, click the X button.

Configure the states for the pedestrian crossing light. In the model, the crossing light is controlled by the walk light timer, which counts the elapsed seconds at the crosswalk for one minute, and then resets. Over the first half of that minute, the stop sign is on. Over the second half, the walk sign is on. The Lamp block represents this with three states:

- It is in the first state when the value of the walk light timer signal is between 0 seconds and 30 seconds, the time range when pedestrians are not permitted to cross the street.
- It is in the second state when the value of the walk light timer signal is between 30 seconds and 60 seconds, the time range when pedestrians are permitted to cross the street.
- It is in the default state when the block does not receive a parameter value that activates any other of the specified states.

All states have the same settings in the **Shape and Icon Combination** and **Size and Position** sections. The **Apply Default Settings to All States** option is on. Configure the common settings for all states simultaneously by configuring them in the default state.

Configure all states to show the icon on top of the translucent surface of the lamp:

- 1 On the **Design** tab, select the **States** component.
- 2 In the **Shape and Icon Combination** section, from **Style**, select Simple.

To configure all states to maximize and center the icon within the area taken up by the block, in the **Size and Position** section:

- 1 Set the **X Offset** to 0.
- 2 Set the **Y Offset** to 0.
- 3 Set the **Width** to 1.
- 4 Set the **Height** to 1.
- 5 Set the **Icon Size** to 1.

The opacity of the translucent surface of the lamp is also the same for all states, but the **Apply Default Settings to All States** option does not apply to the parameters in the **Value and Color** section. The remaining settings must be configured individually for each state.

In the **Select State** section, turn off the **Apply Default Settings to All States** option.

In the default state, the crossing light is turned off. The Lamp block uses a custom icon to show this.

Configure the appearance of the lamp for the default state:

- 1 To render the translucent surface of the lamp invisible, in the **Value and Color** section, set the **Opacity** to 0.
- 2 To add the custom icon, in the **Custom Icon** section, click the plus button.
- 3 In the CustomLampImages folder, select the ped-xing-1-off.png file.

By default, states are activated by a single parameter value. However, the crosswalk light shows the walk signal over a certain time span, not at a certain time value. If you enable **Specify State Values as Ranges**, you can specify a range of values to activate each state.

Specify the range of parameter values that activate the second state:

- 1 In the **Select State** section, open the drop-down menu and select 1 (State 2). The number in this drop-down menu option is the parameter value that activates the state specified in parentheses.
- 2 Turn on the **Specify State Values as Ranges** option. Observe that the drop-down menu option has changed from 1 (State 2) to 1 to 1 (State 2). The numbers indicate the range of values that activate the state.
- 3 In the **Value and Color** section, enter 60 as the **Maximum** value of the range.
- 4 In the **Value and Color** section, enter 30 as the **Minimum** value of the range.

In the second state, the walk signal is lit. The Lamp block uses a custom icon to show the lit walk signal.

Configure the appearance of the lamp for the second state:

- 1 To render the translucent surface of the lamp invisible, in the **Value and Color** section, set the **Opacity** to 0.
- 2 To add the custom icon, in the **Custom Icon** section, click the plus button.
- 3 In the CustomLampImages folder, select the ped-xing-1-walk.png file.

Specify the range of parameter values that activate the first state:

- 1 On the **Design** tab of the Property Inspector, select the **States** component.
- 2 In the **Select State** section, open the drop-down menu and select  $\emptyset$  to  $\emptyset$  (State 1).
- 3 In the **Value and Color** section, enter 30 as the **Maximum** value of the range.

In the first state, the stop signal is lit. The Lamp block uses a custom icon to show the lit stop signal.

Configure the appearance of the lamp for the first state:

- 1 To render the translucent surface of the lamp invisible, in the **Value and Color** section, set the set the **Opacity** to  $\emptyset$ .
- 2 To add the custom icon, in the **Custom Icon** section, click the plus button.
- 3 In the CustomLampImages folder, select the ped-xing-1-stop.png file.

Resize the block:

- 1 Exit design mode by clicking **Edit** on the **Design** tab.
- 2 In the canvas, drag one corner of the block outwards until the block is large enough to clearly show the crossing light symbols.

You can use the finished crossing light to display a signal value. In the model, a Signal Builder block represents the walk light timer. The Signal Builder block is set up such that one minute at the crosswalk corresponds to 2 seconds of simulation time. In the model, the crosswalk light therefore switches between stop and walk every second.

Connect the Lamp block to the Walk Light Timer [s] signal:

- 1 Select the Lamp block.
- 2 Click the Connect button that appears above the block.
- 3 Select the signal line with the label Walk Light Timer [s].
- 4 Select the Walk Light Timer [s] option in the table that appears below the selected signal line.

- Click the X in the upper right corner of the Simulink window.

To use the crossing light, simulate the model. This model uses simulation pacing to slow model execution so that you can clearly see the Lamp block respond to the value of the parameter that it connects to. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.

### Design Pedestrian Crossing Light on Panel

If you want to design two lamps that share a common background but connect to different parameters, you can do so using panels. For more information on panels, see “Interactively Design and Debug Models Using Panels” on page 32-7.

To design a pedestrian crossing light with two lamps using this approach, add a customizable Lamp block to the model.

Configure this lamp to be the bottom lamp in the crossing light, which is the walk light.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- In the model canvas, select the Lamp block.
- In the Simulink Toolstrip, click the **Lamp** tab.
- On the **Lamp** tab, click **Edit**. A toolbar appears above the Lamp block.
- To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the bottom lamp of the crossing light:

- In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- In the **Select Image** section, click the plus button.
- In the CustomLampImages folder, select the ped-xing-2-walk-off.png file.

Delete the foreground image:

- On the **Design** tab, select the **Foreground Image** component.
- In the **Select Image** section, click the X button.

Configure the states for the bottom lamp of the crossing light. In model, the bottom lamp in the crossing light is controlled by the walk light timer, which counts the elapsed seconds at the crosswalk for one minute, and then resets. Over the first half of that minute, the stop sign is on. Over the second half, the walk sign is on. The Lamp block represents this with three states:

- It is in the first state when the value of the walk light timer signal is between 0 seconds and 30 seconds, the time range when pedestrians are not permitted to cross the street.
- It is in the second state when the value of the walk light timer signal is between 30 seconds and 60 seconds, the time range when pedestrians are permitted to cross the street.
- It is in the default state when the block does not receive a parameter value that activates any other of the specified states.

All states have the same settings in the **Shape and Icon Combination** and **Size and Position** sections. The **Apply Default Settings to All States** option is on. Configure the common settings for all states simultaneously by configuring them in the default state.

Configure all states to show the icon on top of the translucent surface of the lamp:

- 1 On the **Design** tab, select the **States** component.
- 2 In the **Shape and Icon Combination** section, open the **Style** drop-down menu, and select **Simple**.

To configure all states to maximize and center the icon within the area taken up by the block, in the **Size and Position** section:

- 1 Set the **X Offset** to 0.
- 2 Set the **Y Offset** to 0.
- 3 Set the **Width** to 1.
- 4 Set the **Height** to 1.
- 5 Set the **Icon Size** to 1.

The opacity of the translucent surface of the lamp is also the same for all states, but the **Apply Default Settings to All States** option does not apply to the parameters in the **Value and Color** section. The remaining settings must be configured individually for each state.

In the **Select State** section, turn off the **Apply Default Settings to All States** option.

In the default state, the crossing light is turned off. The Lamp block uses the background image to show the unlit walk signal.

Configure the appearance of the lamp for the default state:

- 1 In the **Custom Icon** section, click the X button.
- 2 In the **Value and Color** section, set the **Opacity** to 0.

By default, states are activated by a single parameter value. However, the crosswalk light shows the walk signal over a certain time span, not at a certain time value. If you enable **Specify State Values as Ranges**, you can specify a range of values to activate each state.

Specify the range of parameter values that activate the second state:

- 1 In the **Select State** section, open the drop-down menu and select 1 (State 2). The number in this drop-down menu option is the parameter value that activates the state specified in parentheses.
- 2 Turn on the **Specify State Values as Ranges** option. Observe that the drop-down menu option has changed from 1 (State 2) to 1 to 1 (State 2). The numbers indicate the range of values that activate the state.
- 3 In the **Value and Color** section, enter 60 as the **Maximum** value of the range.
- 4 In the **Value and Color** section, enter 30 as the **Minimum** value of the range.

In the second state, the walk signal is lit. The Lamp block uses a custom icon to show the lit walk signal.

Configure the appearance of the lamp for the second state:

- 1 To render the translucent surface of the lamp invisible, in the **Value and Color** section, set the **Opacity** to 0.
- 2 To add the custom icon, in the **Custom Icon** section, click the plus button.
- 3 In the CustomLampImages folder, select the ped-xing-2-walk-on.png file.

Specify the range of parameter values that activate the first state:

- 1 On the **Design** tab of the Property Inspector, select the **States** component.
- 2 In the **Select State** section, open the drop-down menu and select 0 to 0 (State 1).
- 3 In the **Value and Color** section, enter 30 as the **Maximum** value of the range.

In the first state, the walk signal is not lit. The Lamp block uses the background image to show the unlit walk signal.

Configure the appearance of the lamp for the first state:

- 1 In the **Custom Icon** section, click the X button.
- 2 In the **Custom Icon** section, set the **Opacity** to 0.

Exit design mode by clicking **Edit** on the **Design** tab.

Resize the block in the canvas by dragging one of its corners outwards until it is large enough to clearly show the walk symbol.

To configure the top lamp in the crossing light, copy and paste the Lamp block for the bottom lamp in the canvas. The copy represents the top lamp in the crossing light, which is the stop light.

To modify the design of the Lamp block, enter design mode:

- 1 On the **Modeling** tab, under **Design**, select **Property Inspector**.
- 2 In the model canvas, select the Lamp block.
- 3 In the Property Inspector, select the **Design** tab and click **Edit**.

Change the background image for the top lamp of the crossing light:

- 1 On the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomLampImages folder, select the ped-xing-2-stop-off.png file.

Configure the states for the top lamp of the crossing light. The top lamp is lit when the bottom lamp is off, and vice versa. In the model, the parameter value settings for the top lamp are the same as those for the bottom lamp, and the different timing of the two lamps is achieved by connecting the top lamp to a different timer, the stop light timer. This timer also counts the elapsed seconds at the crosswalk for one minute, and then resets. However, the signal of the stop light timer is offset from that of the walk light timer by 30 seconds.

Since both the top and bottom lamps of the crossing light have the same parameter value settings, you only need to configure the appearance of the top lamp for each state. Since the default state and the first state only show the background image, you do not need to modify these states.

In the second state, the stop signal is lit. The Lamp block uses a custom icon to show the lit stop signal.

Configure the appearance of the lamp for the second state:

- 1 To add the custom icon, in the **Custom Icon** section, click the plus button.
- 2 In the CustomLampImages folder, select the `ped-xing-2-stop-on.png` file.

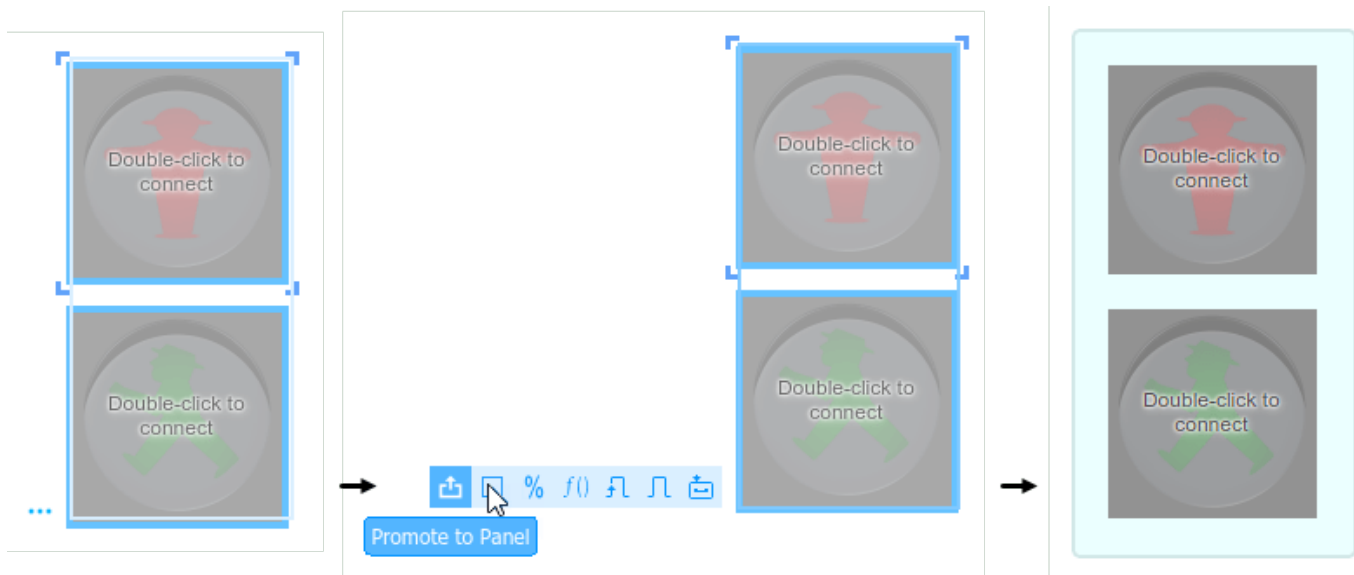

Exit design mode by clicking **Edit** on the **Design** tab.

Select and drag the Lamp block of the top lamp, the stop signal, to be directly above the bottom lamp, the walk signal.

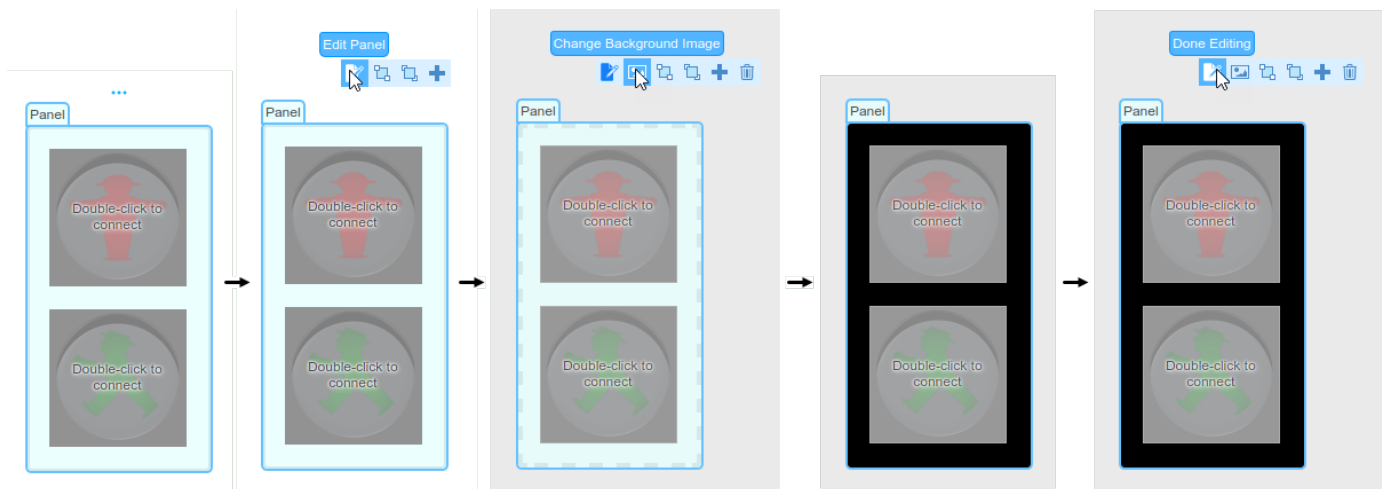

Promote both of the custom Lamp blocks for the crossing light to a panel:

- 1 Select both Lamp blocks in the canvas.
- 2 To open the action menu, click the three blue dots.
- 3 In the action menu, click the Promote to Panel button.

Change the background color of the panel to black:

- 1 Click the panel.
- 2 To open the action menu, click the three blue dots.
- 3 In the action menu, click the Edit Panel button.
- 4 In the action menu, click the Change Background Image button.
- 5 In the CustomLampImages folder, select the ped-xing-2-panel-background.png file.
- 6 Click the panel. In the action menu, click the Done Editing button.

When you finish adjusting the design for the crossing light, to exit design mode, on the **Design** tab, click **Edit**.

You can use the finished crossing light to display a signal value. In the model, two Signal Builder blocks represents the walk light and stop light timers. The Signal Builder blocks are set up such that one minute at the crosswalk corresponds to 2 seconds of simulation time. In the model, the crosswalk light therefore switches between stop and walk every second.

Connect the bottom Lamp block to the Walk Light Timer [s] signal:

- 1 Select the Lamp block.
- 2 Click the Connect button that appears above the block.
- 3 Select the signal line with the label Walk Light Timer [s].
- 4 Select the Walk Light Timer option in the table that appears below the selected signal line.
- 5 Click the X in the upper right corner of the Simulink window.

Connect the top Lamp block to the Stop Light Timer [s] signal:

- 1 Select the Lamp block.
- 2 Click the Connect button that appears above the block.
- 3 Select the signal line with the label Stop Light Timer [s].
- 4 Select the Stop Light Timer option in the table that appears below the selected signal line.
- 5 Click the X in the upper right corner of the Simulink window.

To use the Pedestrian Crossing Light 2 Lamp blocks, simulate the model. This model uses simulation pacing to slow model execution so that you can clearly see the Lamp block respond to the value of the parameter that it connects to. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.

## Design Custom Rocker, Slider, and Toggle Switches

This example shows how to use the customizable Rocker Switch, Slider Switch, and Toggle Switch blocks to design three switches that look like controls in real systems:

- A diff lock switch to lock the differential in a passenger vehicle, modeled as a rocker switch
- An automotive gearbox modeled as a slider switch
- An electromechanical toggle switch

Every switch has multiple states. A state pairs a State Value with a customizable State Label and block appearance. The block appearance of a state can, for example, include an image that appears on the block between the background and foreground or a particular font color for the State Label.

You can activate a state by clicking its click area. When you activate the state, the State Value is assigned to the Simulink® block diagram element to which the switch block is connected.

The blocks in the model use PNG images to define the appearance of states. You can find all images used to create the switches in the example directory.

### Design Diff Lock Rocker Switch

To design the diff lock switch, add a customizable Rocker Switch block to the model using the Simulink quick insert menu:

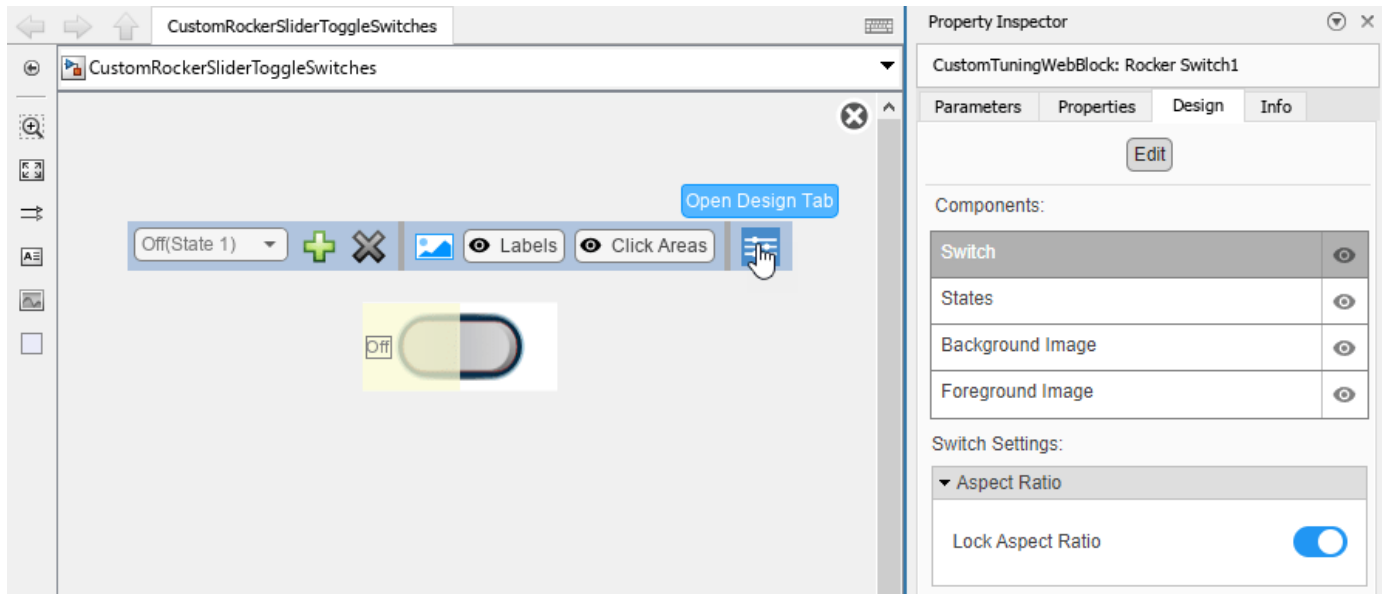

- 1 To open the quick insert menu, double-click in the canvas.
- 2 To search for the customizable Rocker Switch block, type `Rocker Switch`.
- 3 Select the search result with the library path `Simulink/Dashboard/Customizable Blocks`.

To modify the design of the Rocker Switch block, enter design mode:

- 1 In the model canvas, select the Rocker Switch block.
- 2 In the Simulink Toolstrip, click the **Switch** tab.
- 3 On the **Switch** tab, click **Edit**. A toolbar appears above the Rocker Switch block.

- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**. In design mode, the **Design** tab of the Property Inspector is active.

You can design a custom switch using the toolbar or using the **Design** tab of the **Property Inspector**. This example uses both.

Adding state images to a customizable dashboard block changes the aspect ratio of the state images to match the aspect ratio of the block.

Adding a background image to a customizable dashboard block changes the aspect ratio of the block to match the aspect ratio of the background image.

To prevent state images from being distorted, before you add the state images, you can use a transparent background image to set the aspect ratio of the block to be the same as the aspect ratio of the state image.

Add the transparent background image for the diff lock switch:

- 1 On the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomRockerSliderToggleSwitchImages folder, select the diff-lock-switch-background.png file.

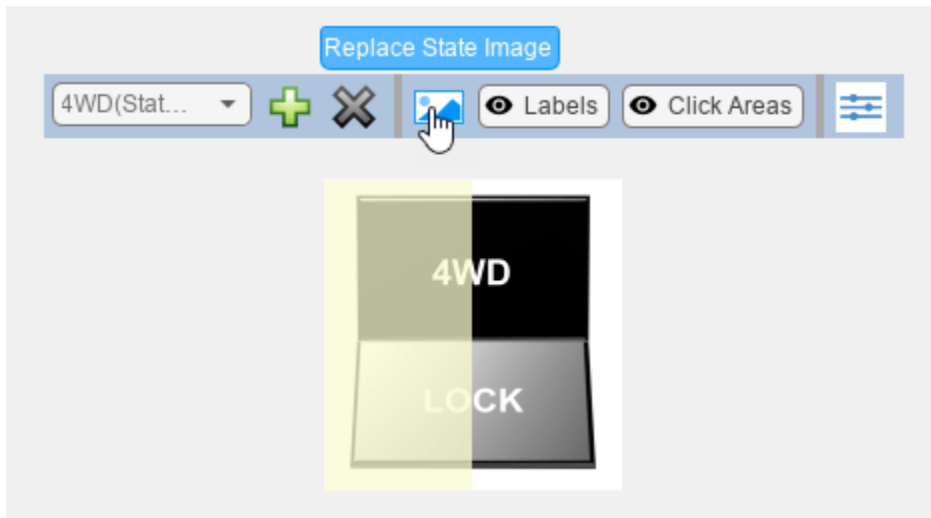

The Rocker Switch block for the diff lock switch has two states:

- In State 1, the car is in four-wheel drive mode. The Rocker Switch block has a State Value of 0 and the State Label 4WD.
- In State 2, the differential is locked. The Rocker Switch block has a State Value of 1 and the State Label Lock.

When the Rocker Switch block is in State 1, the half of the diff lock switch with the 4WD label is pressed down.

Configure the appearance of the diff lock switch for State 1:

- 1 On the **Design** tab, select the **States** component. The **Value** of the state is 0 by default.
- 2 To make the state identifiable in the **Select State** section drop-down list, in the **Label** section, enter the State Label 4WD in the **Text** field. When you click out of the **Text** field, the label appears in the **Select State** section drop-down list.
- 3 Since the diff lock switch settings are labeled in the background image, the block labels are redundant. In the **Label** section, turn off **Show Label**.
- 4 In the toolbar, click **Replace State Image**.
- 5 In the CustomRockerSliderToggleSwitchImages folder, select the diff-lock-switch-4wd.png file.

To configure the **Click Area** for State 1, in the canvas, click and drag the corners of the yellow rectangle to cover the upper half of the state image.

When the Rocker Switch block is in State 2, the half of the diff lock switch with the LOCK label is pressed down.

Configure the appearance of the diff lock switch for State 2:

- 1 In the **Select State** section, select On (State 2). The **Value** of the state is 1 by default.
- 2 In the **Label** section, enter the State Label Lock in the **Text** field.
- 3 In the **Label** section, turn off **Show Label**.
- 4 In the toolbar, click **Replace State Image**.
- 5 In the CustomRockerSliderToggleSwitchImages folder, select the diff-lock-switch-lock.png file.

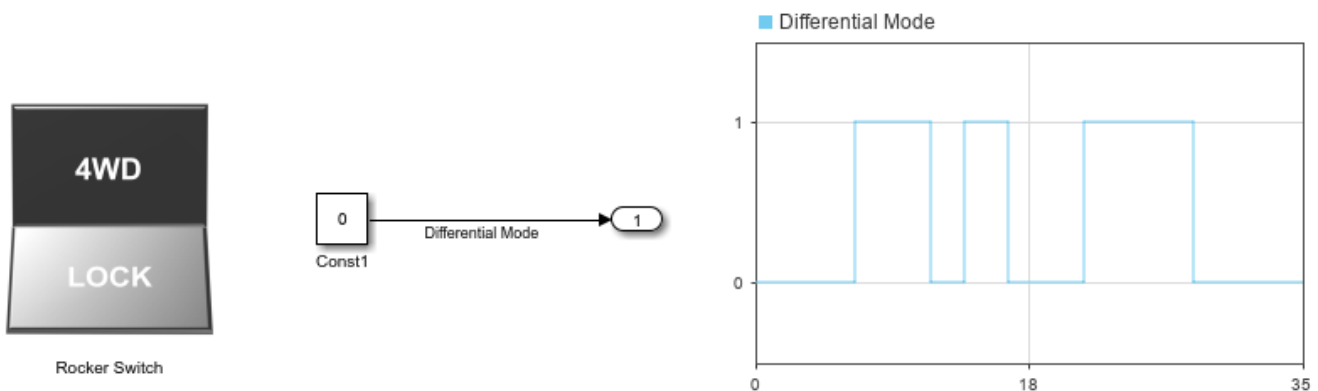

To configure the **Click Area** for State 2, in the canvas, click and drag the corners of the yellow rectangle to cover the lower half of the state image. To avoid overlap between the click areas of the first and second states, in the toolbar, click **Show All Click Areas**. You can now see the click areas of all states while editing the click area of the active state.

When you finish adjusting the design for the diff lock switch, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished diff lock switch to control a parameter. In the model, a Constant block represents the mode of operation of the differential, and the Rocker Switch block controls the value of the constant.

Connect the Rocker Switch block to the Value parameter of the Constant block:

- 1 Select the Rocker Switch block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named `Const1`.
- 4 In the table that appears below the selected signal, select `Const1:Value`.
- 5 Click the X in the upper right corner of the Simulink window.

To use the diff lock switch:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 During simulation, click the upper or on the lower half of the background image to flip the rocker switch.
- 3 See the effect on the mode of operation of the differential in the Dashboard Scope block.

### Design Gearbox Modeled as Slider Switch

To design the automotive gearbox, add a customizable Slider Switch block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Slider Switch block.
- 2 In the Simulink Toolstrip, click the **Switch** tab.
- 3 On the **Switch** tab, click **Edit**. A toolbar appears above the Slider Switch block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the gearbox:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomRockerSliderToggleSwitchImages folder, select the gearbox-background.png file.

The Slider Switch block for the gearbox has seven states:

- In State 1, the car is in first gear. The Slider Switch block has a State Value of 1 and the State Label **First Gear**.
- In State 2, the car is in second gear. The Slider Switch block has a State Value of 2 and the State Label **Second Gear**.
- In State 3, the car is in third gear. The Slider Switch block has a State Value of 3 and the State Label **Third Gear**.
- In State 4, the car is in fourth gear. The Slider Switch block has a State Value of 4 and the State Label **Fourth Gear**.
- In State 5, the car is in fifth gear. The Slider Switch block has a State Value of 5 and the State Label **Fifth Gear**.
- In State 6, the car is in reverse. The Slider Switch block has a State Value of -1 and the State Label **Reverse**.
- In State 7, the car is in neutral. The Slider Switch block has a State Value of 0 and the State Label **Neutral**.

When the Slider Switch block is in State 1, the gear lever is in the upper left slot of the gearbox.

Configure the appearance of the gearbox for State 1:

- 1 On the **Design** tab, select the **States** component.
- 2 The default Slider Switch block has two states. Since multiple states cannot be assigned the same State Value, before assigning the value for State 1, check the value for State 2 by expanding the **Select State** menu and selecting **On (State 2)**.
- 3 The State Value of State 2, shown in the **Value** section, is 1, but the State Value for State 1 of the diff lock switch is also 1. To change the State Value of State 2, in the **Value** section, set **Value** to 2.
- 4 To configure State 1, in the **Select State** menu, select **Off (State 1)**.
- 5 To make the state identifiable in the **Select State** section drop-down list, in the **Label** section, enter the State Label **First Gear** in the **Text** field. When you click out of the **Text** field, the label appears in the **Select State** section drop-down list.
- 6 Since the gears are labeled on the gearstick in the background image, the block labels are redundant. In the **Label** section, turn off **Show Label**.
- 7 In the toolbar, click **Replace State Image**.
- 8 In the CustomRockerSliderToggleSwitchImages folder, select the gearbox-gear-1.png file.

To exit design mode, on the **Design** tab, click **Edit**. Resize the block in the canvas by dragging one of its corners outwards until the numbers on the gear lever are large enough to read.

To reenter design mode, in the Property Editor, on the **Design** tab, click **Edit**.

To configure the **Click Area** for State 1, in the canvas, click and drag the corners of the yellow rectangle to cover the upper left slot on the gearbox in the background image.

To configure the other five states, for each state:

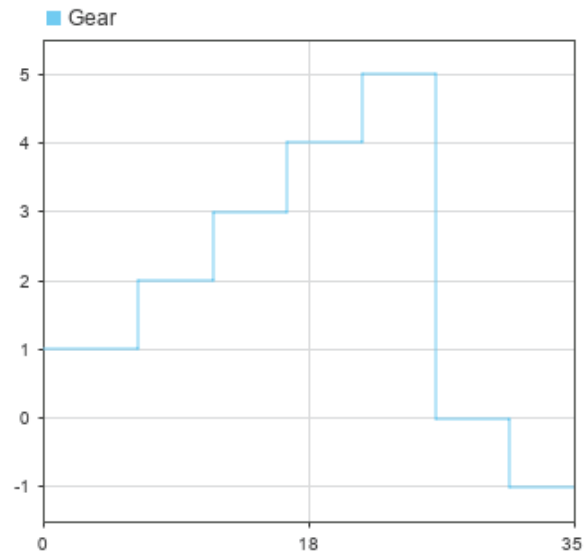

- 1 In the Property Inspector, on the **Design** tab, in the **States** component, in the **Select State** section, expand the drop-down list. If the state number is listed, select the corresponding state. If not, click the plus button to add a new state.
- 2 In the **Value** section, enter the State Value.
- 3 In the **Label** section, enter the State Label in the **Text** field.
- 4 If a State Label is visible in the canvas, in the **Label** section, turn off **Show Label**.
- 5 In the toolbar, click **Replace State Image**.
- 6 In the CustomRockerSliderToggleSwitchImages folder, select the gearbox-gear-N.png file, where N is the number of the gear. For reverse, select the gearbox-reverse.png file, and for neutral, select the gearbox-neutral.png file.
- 7 To configure the click area, in the canvas, click and drag the corners of the yellow rectangle. Use the image as a guide to size and position the click area. To avoid overlap between the click areas of different states, in the toolbar, click **Show All Click Areas**. You can now see the click areas of all states while editing the click area of the active state.

When you finish adjusting the design for the gearbox, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished gearbox to control a parameter. In the model, a Constant block represents the gear of a car. The Slider Switch block controls the value of the constant.

Connect the Slider Switch block to the Value parameter of the Constant block:

- 1 Select the Slider Switch block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named Const2.
- 4 In the table that appears below the selected signal, select Const2:Value.
- 5 Click the X in the upper right corner of the Simulink window.

To use the gearbox:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see "Simulation Pacing" on page 2-18.
- 2 During simulation, click the area of the background image to which you want to move the gear lever to change gears during simulation.
- 3 See the effect on the gear in the Dashboard Scope block.

### Design Electromechanical Toggle Switch

To design the electromechanical toggle switch, add a customizable Toggle Switch block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Toggle Switch block.
- 2 In the Simulink Toolstrip, click the **Switch** tab.

- 3 On the **Switch** tab, click **Edit**. A toolbar appears above the Toggle Switch block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the electromechanical switch:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomRockerSliderToggleSwitchImages folder, select the toggle-background.png file.

The Toggle Switch block for the electromechanical switch has three states:

- In State 1, the switch is on, the toggle is pointing down. The Toggle Switch block has a State Value of -1 and the State Label On, Down.
- In State 2, the switch is off, the toggle is centered. The Toggle Switch block has a State Value of 0 and the State Label Off.
- In State 3, when the switch is on, the toggle is pointing up. The Toggle Switch block has a State Value of 1 and the State Label On, Up.

When the Toggle Switch block is in State 1, the toggle is pointing down.

Configure the appearance of the electromechanical switch for State 1:

- 1 On the **Design** tab, select the **States** component.
- 2 In the **Value** section, set the **Value** to -1.
- 3 To make the state identifiable in the **Select State** section drop-down list, in the **Label** section, enter the State Label On, Down in the **Text** field. When you click out of the **Text** field, the label appears in the **Select State** section drop-down list.
- 4 Since the settings of the electromechanical switch are labeled in the background image, the block labels are redundant. In the **Label** section, turn off **Show Label**.
- 5 In the toolbar, click **Replace State Image**.
- 6 In the CustomRockerSliderToggleSwitchImages folder, select the toggle-down.png file.

To exit design mode, on the **Design** tab, click **Edit**. Resize the block in the canvas by dragging one of its corners outwards until the labels on the electromechanical switch are large enough to read.

To reenter design mode, in the Property Editor, on the **Design** tab, click **Edit**.

To configure the **Click Area** for State 1, in the canvas, click and drag the corners of the yellow rectangle to cover the electromechanical switch from the bottom to halfway between the OFF label and the lower ON label.

When the Toggle Switch block is in State 2, the toggle is centered.

Configure the appearance of the electromechanical switch for State 2:

- 1 On the **Design** tab, select the **States** component.
- 2 In the **Select State** section, select **On (State 2)**.
- 3 In the **Value** section, set the **Value** to **0**.
- 4 In the **Label** section, enter the State Label **Off** in the **Text** field.
- 5 In the **Label** section, turn off **Show Label**.
- 6 In the toolbar, click **Replace State Image**.
- 7 In the **CustomRockerSliderToggleSwitchImages** folder, select the **toggle-neutral.png** file.

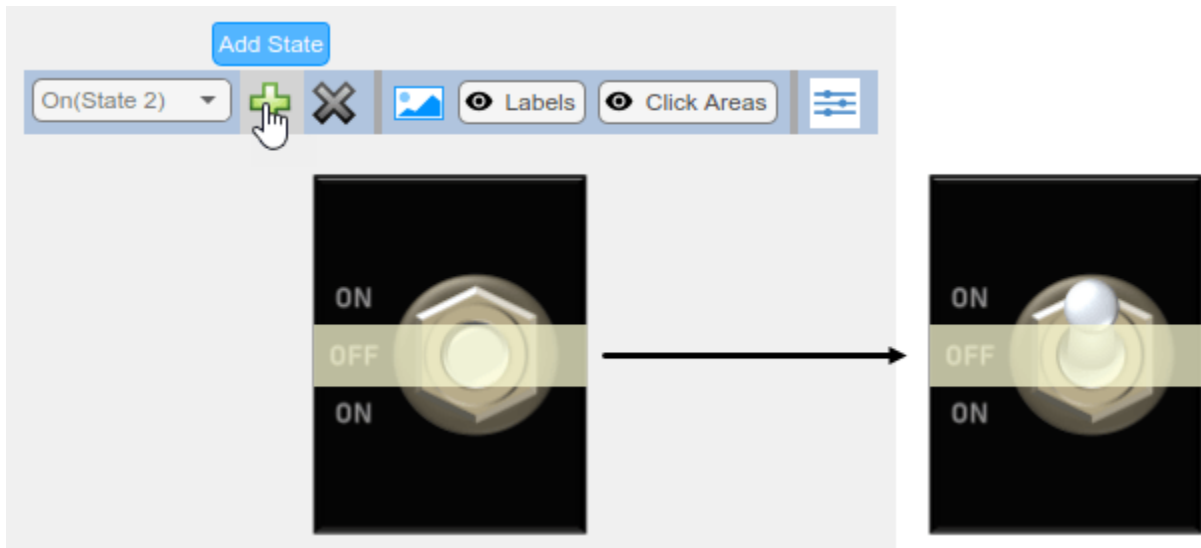

To configure the **Click Area** for State 2, in the canvas, click and drag the corners of the yellow rectangle to cover the switch from halfway between the **OFF** label and the lower **ON** label to halfway between the **OFF** label and the upper **ON** label. To avoid overlap between the click areas of State 1 and State 2, click **Show All Click Areas**. You can now see the click areas of all states while editing the click area of the active state.

When the Toggle Switch block is in State 3, the toggle is up.

Configure the appearance of the electromechanical switch for State 3:

- 1 In the Property Inspector, on the **Design** tab, select the **States** component.
- 2 To add a new state, in the **Select State** section, click the plus button.
- 3 In the **Value** section, set the **Value** to 1.
- 4 In the **Label** section, enter the State Label On, Up in the **Text** field.
- 5 In the toolbar, click **Replace State Image**.
- 6 In the CustomRockerSliderToggleSwitchImages folder, select the `toggle-up.png` file.

To configure the **Click Area** for State 3, in the canvas, click and drag the corners of the yellow rectangle to cover the switch from the top to halfway between the OFF label and the upper ON label.

When you finish adjusting the design for the electromechanical switch, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished switch to control a parameter. In the model, a Constant block represents the state of the electromechanical switch, and the Toggle Switch block controls the value of the constant.

Connect the Toggle Switch block to the Value parameter of the Constant block:

- 1 Select the Toggle Switch block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named Const3.
- 4 In the table that appears below the selected signal, select Const3:Value.
- 5 Click the X in the upper right corner of the Simulink window.

To use the electromechanical switch:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 During simulation, click the area of the background image to which you want to move the toggle to turn the switch on or off.
- 3 See the effect on the state of the switch in the Dashboard Scope block.

## Design Custom Rotary Switches

An engine order telegraph (EOT) is a device used on ships to communicate the commanded speed and direction of travel from the bridge to the engine room. Personnel on the bridge use the EOT to control the velocity of the ship from outside the engine room.

This example shows how to use the customizable Rotary Switch block to design two EOTs that look like controls in real systems:

- A traditional EOT
- A modern EOT

Each switch consists of a stationary component and a movable component. The stationary component is the mounting, and the movable component is the handle that you turn to set the value of the parameter that the switch controls.

The blocks in the model use PNG images to define the shapes of these components. You can find all images used to create the switches in the example directory.

Each switch has multiple states. A state pairs a State Value with a customizable State Label, a handle orientation, and a click area.

You can activate a state by clicking its click area or by dragging the handle and releasing it over the click area. When you activate the state, the State Value is assigned to the Simulink® block diagram element to which the switch block is connected.

You can specify the arc length the handle traverses when it moves from the first state to the last state. The state labels are evenly spaced over the arc length. The edges of the click areas bisect the angular distance between labels.

### Design Traditional EOT

To design the traditional EOT, add a customizable Rotary Switch block to the model using the Simulink quick insert menu:

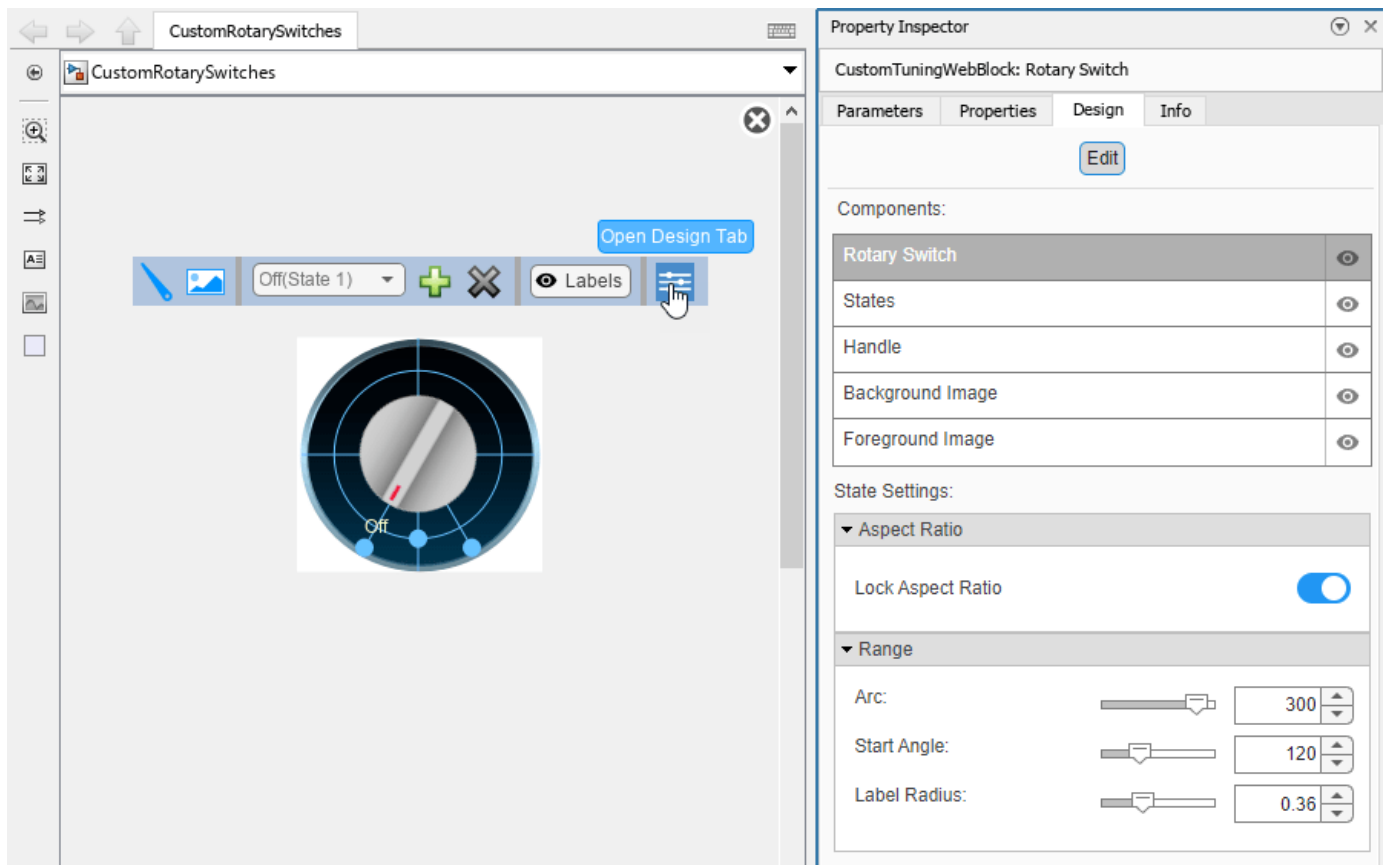

- 1 To open the quick insert menu, double-click in the canvas.
- 2 To search for the customizable Rotary Switch block, type Rotary Switch.
- 3 Select the search result with the library path Simulink/Dashboard/Customizable Blocks.

To modify the design of the Rotary Switch block, enter design mode:

- 1 In the model canvas, select the Rotary Switch block.
- 2 In the Simulink Toolstrip, click the **Switch** tab.
- 3 On the **Switch** tab, click **Edit**. A toolbar appears above the Rotary Switch block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**. In design mode, the **Design** tab of the Property Inspector is active.

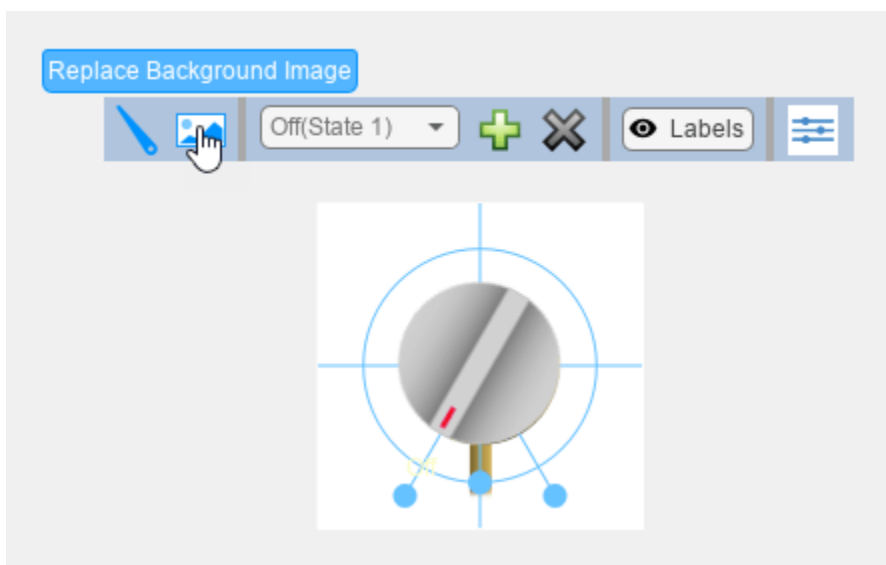

You can design a custom rotary switch using the toolbar or using the **Design** tab of the **Property Inspector**. This example uses both.

Add the background image for the traditional EOT:

- 1 In the toolbar, click **Replace Background Image**.
- 2 In the CustomRotarySwitchImages folder, select the eot - 1 - background . png file.

Resize the block to make the text on the EOT in the background image large enough to read:

- 1 Make the full background image visible by deleting the handle image. On the **Design** tab of the Property Inspector, click the **Handle** component. Then, in the **Handle** component, underneath the handle image, click the X button.
- 2 To resize the block, exit design mode. In the Property Editor, on the **Design** tab, click **Edit**.
- 3 Click and drag one of the corners of the block outwards until the text on the background image is large enough to read.

To continue modifying the design of the Rotary Switch block, enter design mode again.

Add the handle image for the traditional EOT:

- 1 On the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomRotarySwitchImages folder, select the eot - 1 - handle . png file. Note that the handle in the PNG file points to the right.

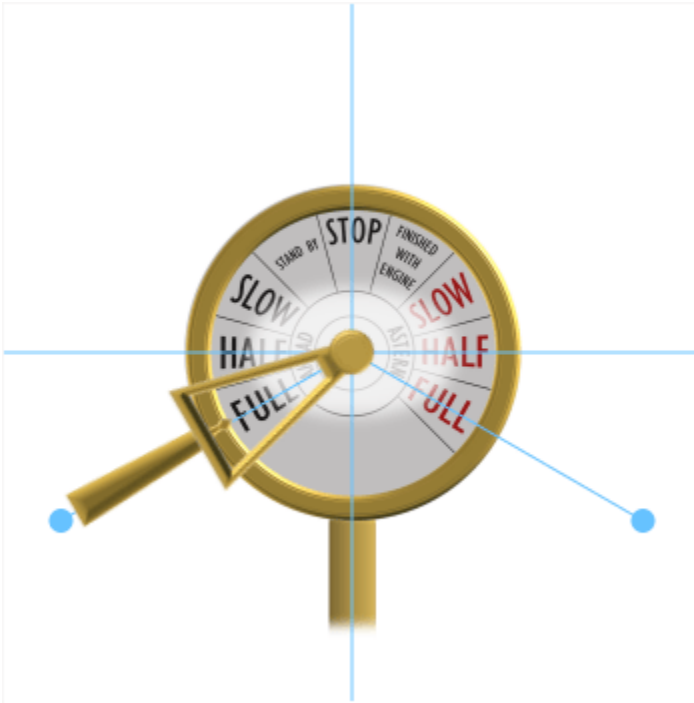

The states of the traditional EOT Rotary Switch block have this layout:

- The background image shows nine labels spaced at 30 degree intervals. Each label corresponds to an EOT state. The traditional EOT Rotary Switch block is split into nine corresponding state sections, shown in yellow.
- State 1 is the FULL ahead command on the background image.
- The **Arc** is the arc length the rotary switch handle traverses when it moves from the first state to the last state. For the traditional EOT Rotary Switch block, the arc length spans from the middle of the FULL ahead section to the middle of the FULL astern section, which is an angular distance of 240 degrees.
- The **Start Angle** is the angular location of the end of the arc length that is in State 1, measured clockwise from the positive horizontal axis pointing right. For the traditional EOT Rotary Switch block, the **Start Angle** is the angular location of the middle of the FULL ahead section relative to the positive horizontal axis, which is 150 degrees.
- Since the background image already has the labels for each section marked, the Rotary Switch block state labels are hidden.

Implement the state layout:

- 1 In the Property Inspector, on the **Design** tab, select the **Rotary Switch** component.
- 2 In the **Range** section, set **Arc** to 240 degrees.
- 3 In the **Range** section, set **Start Angle** to 150 degrees.
- 4 To hide the Rotary Switch blocks state labels, make the label radius large enough to move the labels out of view. In the **Range** section, set **Label Radius** to 1.

The Rotary Switch block for the traditional EOT has nine states:

- In State 1, the bridge orders the engine to travel ahead at the full engine speed. The Rotary Switch block has a State Value of 100 and the State Label Full Speed, Ahead.
- In State 2, the bridge orders the engine to travel ahead at 50 percent of the full engine speed. The Rotary Switch block has a State Value of 50 and the State Label Half Speed, Ahead.
- In State 3, the bridge orders the engine to travel ahead at 25 percent of the full engine speed. The Rotary Switch block has a State Value of 25 and the State Label Slow Speed, Ahead.
- In State 4, the bridge orders the engine to stand by. The Rotary Switch block has a State Value of 1 and the State Label Stand By.
- In State 5, the bridge orders the engine to stop, and the engine speed is 0. The Rotary Switch block has a State Value of 0 and the State Label Stop.
- In State 6, the bridge is finished with the main engine. The Rotary Switch block has a State Value of -1 and the State Label Finished with Engine.
- In State 7, the bridge orders the engine to travel astern at 25 percent of the full engine speed. The Rotary Switch block has a State Value of -25 and the State Label Slow Speed, Astern.
- In State 8, the bridge orders the engine to travel astern at 50 percent of the full engine speed. The Rotary Switch block has a State Value of -50 and the State Label Half Speed, Astern.
- In State 9, the bridge orders the engine to travel astern at the full engine speed. The Rotary Switch block has a State Value of -100 and the State Label Full Speed, Astern.

In the Property Inspector, on the **Design** tab, for each state:

- 1 In the **States** component, in the **Select State** section, expand the drop-down list. If the state number is listed, select the corresponding state. If not, click the plus button to add a new state.
- 2 In the **Value** section, enter the State Value.

- 3 To make the state identifiable in the **Select State** section drop-down list, in the **Label** section, enter the State Label in the **Text** field. When you click out of the **Text** field, the label appears in the **Select State** section drop-down list.

Note that the handle orientation for a given state not be correct until all nine states have been added because the Rotary Switch block does not recognize the labels on the background image. The Rotary Switch block spaces state labels at equal angular intervals, so the angular locations to which the handle snaps depend on the number of states. When there are nine states, the angular locations of the Rotary Switch block state labels coincide with the angular locations of the labels on the background image, and the handle takes on the correct orientation for all states.

When you finish adjusting the design for the traditional EOT, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished EOT to control a parameter. In the model, a Constant block represents the EOT signal that is sent to the engine room. The Rotary Switch block controls the value of the constant.

Traditional EOT

Connect the Rotary Switch block to the **Value** parameter of the Constant block:

- 1 Select the Rotary Switch block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named `Const1`.
- 4 In the table that appears below the selected signal, select the `Const1:Value`.
- 5 Click the X in the upper right corner of the Simulink window.

To use the traditional EOT:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 During simulation, click and drag the handle. To change the State Value of the Rotary Switch block, release the handle over any of the labels on the background image.
- 3 See the effect on the EOT signal in the Dashboard Scope block.

### Design Modern EOT

To design the modern EOT, add a customizable Rotary Switch block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Rotary Switch block.
- 2 In the Simulink Toolstrip, click the **Switch** tab.
- 3 On the **Switch** tab, click **Edit**. A toolbar appears above the Rotary Switch block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the modern EOT:

- 1 In the toolbar, click **Replace Background Image**.
- 2 In the CustomRotarySwitchImages folder, select the eot-2-background.png file.

Resize the block to make the text on the EOT in the background image large enough to read:

- 1 Make the full background image visible by deleting the handle image. On the **Design** tab of the Property Inspector, click the **Handle** component. Then, in the **Handle** component, underneath the handle image, click the X button.

- 2 To resize the block, exit design mode. In the Property Editor, on the **Design** tab, click **Edit**.
- 3 Click and drag one of the corners of the block outwards until the text on the background image is large enough to read.

To continue modifying the design of the Rotary Switch block, enter design mode again.

Add the handle image for the modern EOT:

- 1 On the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomRotarySwitchImages folder, select the eot-2-handle.png file. Note that the handle in the PNG file points to the right.
- 4 In the **Size** section, set the **Width** and **Height** to 1.

The states of the modern EOT Rotary Switch block have this layout:

- The background image shows eleven labels spaced at 30 degree intervals. Each label corresponds to an EOT state. The modern EOT Rotary Switch block is split into eleven corresponding state sections, shown in yellow.
- **State 1** is the FULL astern command on the background image.
- The **Arc** is the arc length the rotary switch handle traverses when it moves from the first state to the last state. For the modern EOT Rotary Switch block, the arc length spans from the middle of the FULL ahead section to the middle of the FULL astern section, which is an angular distance of 300 degrees.
- The **Start Angle** is the angular location of the end of the arc length that is in **State 1**, measured clockwise from the positive horizontal axis pointing right. For the modern EOT Rotary Switch block, the **Start Angle** is the angular location of the middle of the FULL ahead section relative to the positive horizontal axis, which is 120 degrees.
- Since the background image already has the labels for each section marked, the Rotary Switch block state labels are hidden.

**Arc** is 300 degrees by default. **Start Angle** is 120 degrees by default.

To hide the Rotary Switch blocks state labels, make the label radius large enough to move the labels out of view:

- 1 In the Property Inspector, on the **Design** tab, select the **Rotary Switch** component.
- 2 In the **Range** section, set **Label Radius** to 1.

The Rotary Switch block for the traditional EOT has eleven states:

- In State 1, the bridge orders the engine to travel astern at the full engine speed. The Rotary Switch block has a State Value of -100 and the State Label Full Speed, Astern.
- In State 2, the bridge orders the engine to travel astern at 50 percent of the full engine speed. The Rotary Switch block has a State Value of -50 and the State Label Half Speed, Astern.
- In State 3, the bridge orders the engine to travel astern at 25 percent of the full engine speed. The Rotary Switch block has a State Value of -25 and the State Label Slow Speed, Astern.
- In State 4, the bridge orders the engine to travel astern at 12.5 percent of the full engine speed. The Rotary Switch block has a State Value of -12.5 and the State Label Dead Slow Speed, Astern.
- In State 5, the bridge is finished with the main engine. The Rotary Switch block has a State Value of -1 and the State Label Finished with Engine.
- In State 6, the bridge orders the engine to stop, and the engine speed is 0. The Rotary Switch block has a State Value of 0 and the State Label Stop.
- In State 7, the bridge orders the engine to stand by. The Rotary Switch block has a State Value of 1 and the State Label Stand By.
- In State 8, the bridge orders the engine to travel ahead at 12.5 percent of the full engine speed. The Rotary Switch block has a State Value of 12.5 and the State Label Dead Slow Speed, Ahead.
- In State 9, the bridge orders the engine to travel ahead at 25 percent of the full engine speed. The Rotary Switch block has a State Value of 25 and the State Label Slow Speed, Ahead.
- In State 10, the bridge orders the engine to travel ahead at 50 percent of the full engine speed. The Rotary Switch block has a State Value of 50 and the State Label Half Speed, Ahead.
- In State 11, the bridge orders the engine to travel ahead at the full engine speed. The Rotary Switch block has a State Value of 100 and the State Label Full Speed, Ahead.

In the Property Inspector, on the **Design** tab, for each state:

- 1 In the **States** component, in the **Select State** section, expand the drop-down list. If the state number is listed, select the corresponding state. If not, click the plus button to add a new state.
- 2 In the **Value** section, enter the State Value.
- 3 To make the state identifiable in the **Select State** section drop-down list, in the **Label** section, enter the State Label in the **Text** field. When you click out of the **Text** field, the label appears in the **Select State** section drop-down list.

Note that the handle orientation for a given state not be correct until all eleven states have been added because the Rotary Switch block does not recognize the labels on the background image. The Rotary Switch block spaces state labels at equal angular intervals, so the angular locations to which the handle snaps depend on the number of states. When there are eleven states, the angular locations of the Rotary Switch block state labels coincide with the angular locations of the labels on the background image, and the handle takes on the correct orientation for all states.

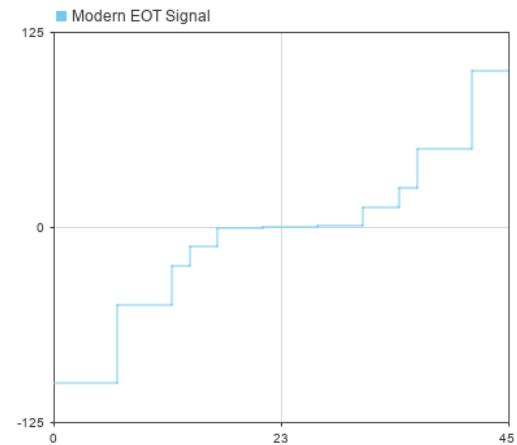

Add the foreground image for the modern EOT:

- 1 On the **Design** tab, select the **Foreground Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomRotarySwitchImages folder, select the eot-2-foreground.png file.

When you finish adjusting the design for the modern EOT, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

Use the finished EOT to control a parameter. In the model, a Constant block represents the EOT signal that is sent to the engine room, and the Rotary Switch block controls the value of the constant.

Connect the Rotary Switch block to the Value parameter of the Constant block:

- 1 Select the Rotary Switch block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named Const2.
- 4 In the table that appears below the selected signal, select Const2:Value.
- 5 Click the X in the upper right corner of the Simulink window.

To use the modern EOT:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 During simulation, click and drag the handle. To change the State Value of the Rotary Switch block, release the handle over any of the labels on the background image.
- 3 See the effect on the EOT signal in the Dashboard Scope block.

- “Interactively Design and Debug Models Using Panels” on page 32-7

## Design Custom Sliders

This example shows how to use the Horizontal Slider block and the Vertical Slider block to design three sliders that look like controls in real systems:

- A light dimmer switch
- A medical syringe
- A mixing desk slider

Each slider consists of a stationary component and a movable component. The stationary component is the mounting. The movable component is the handle that you turn to set the value of the parameter that the slider controls.

The blocks in the model use PNG images to define the shapes of these components. You can find all images used to create the sliders in the example directory.

## Design Light Dimmer Switch

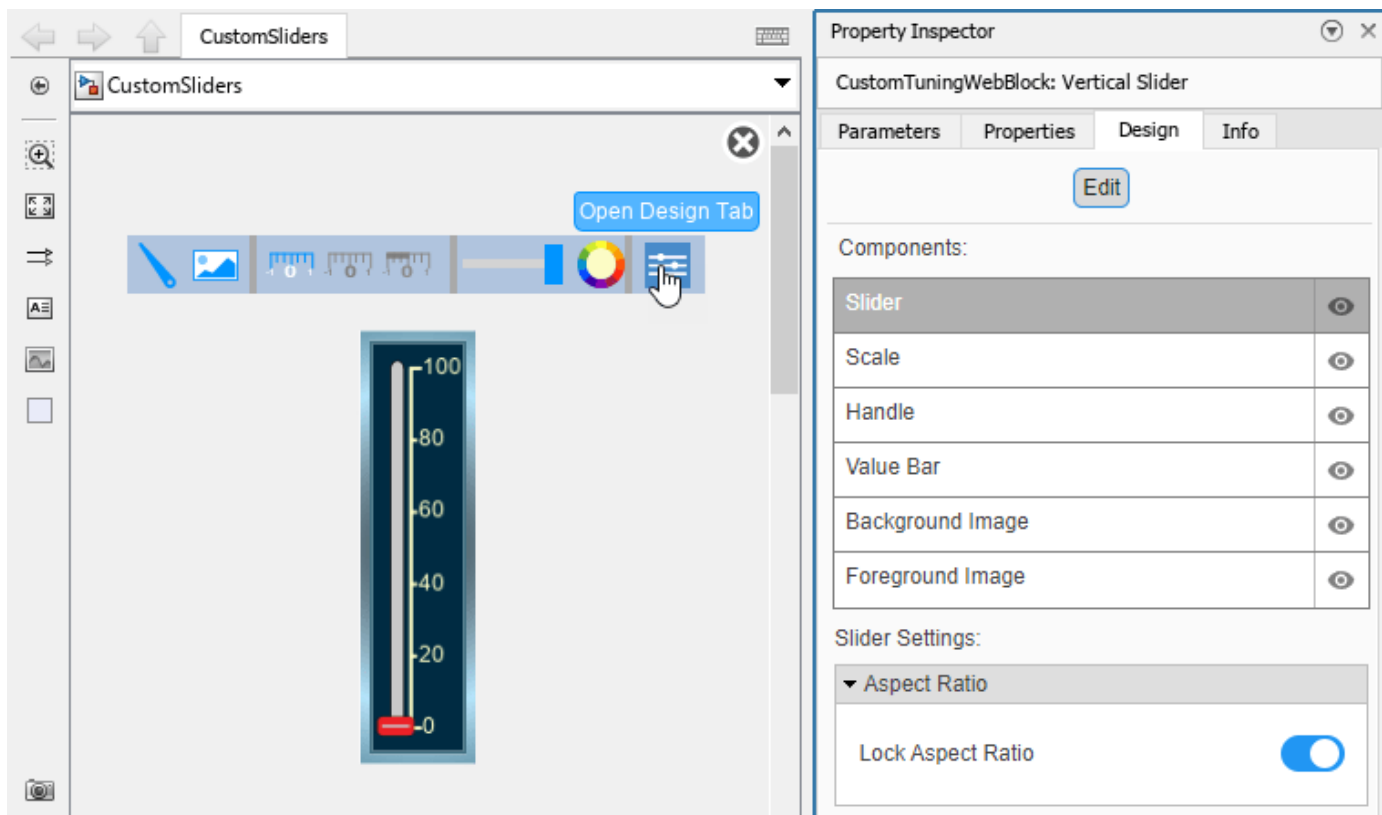

To design the light dimmer switch, add a Vertical Slider block to the model using the quick insert menu:

- 1 To open the quick insert menu, double-click in the canvas.
- 2 To search for the customizable Vertical Slider block, type `Vertical Slider`.
- 3 Select the search result with the library path `Simulink/Dashboard/Customizable Blocks`.

To modify the design of the Vertical Slider block, enter design mode:

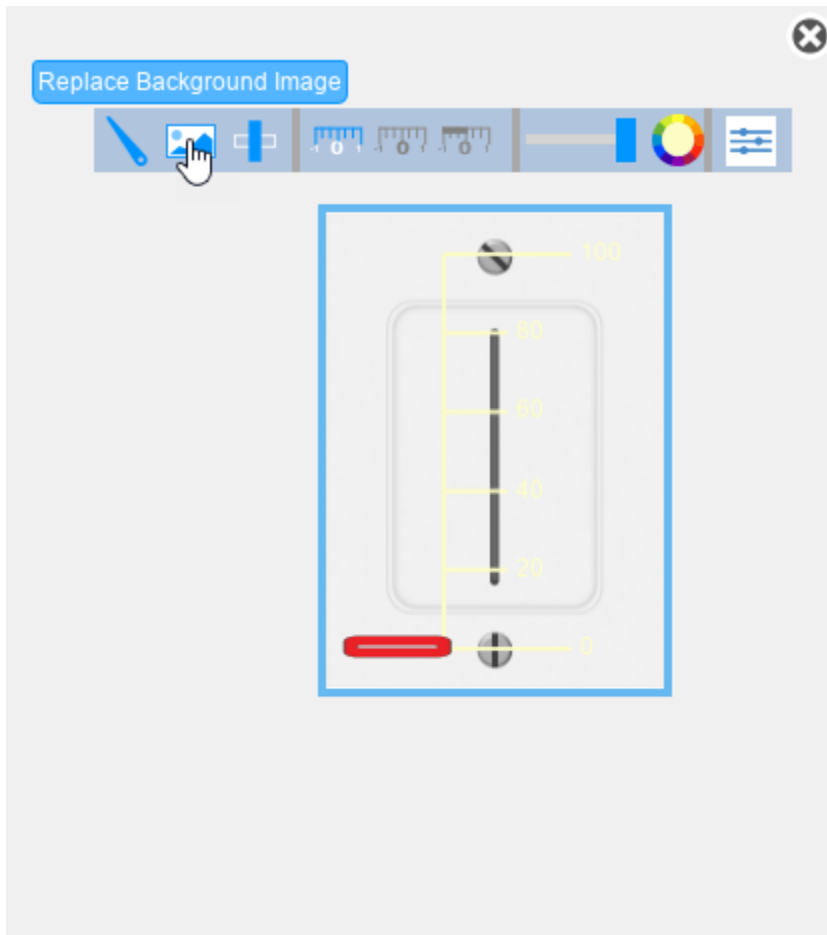

- 1 In the model canvas, select the Vertical Slider block.
- 2 In the Simulink® Toolstrip, click the **Slider** tab.
- 3 On the **Slider** tab, click **Edit**. A toolbar appears above the Vertical Slider block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**. In design mode, the **Design** tab of the Property Inspector is active.

You can design a custom slider using the toolbar or using the **Design** tab of the **Property Inspector**. This example uses both.

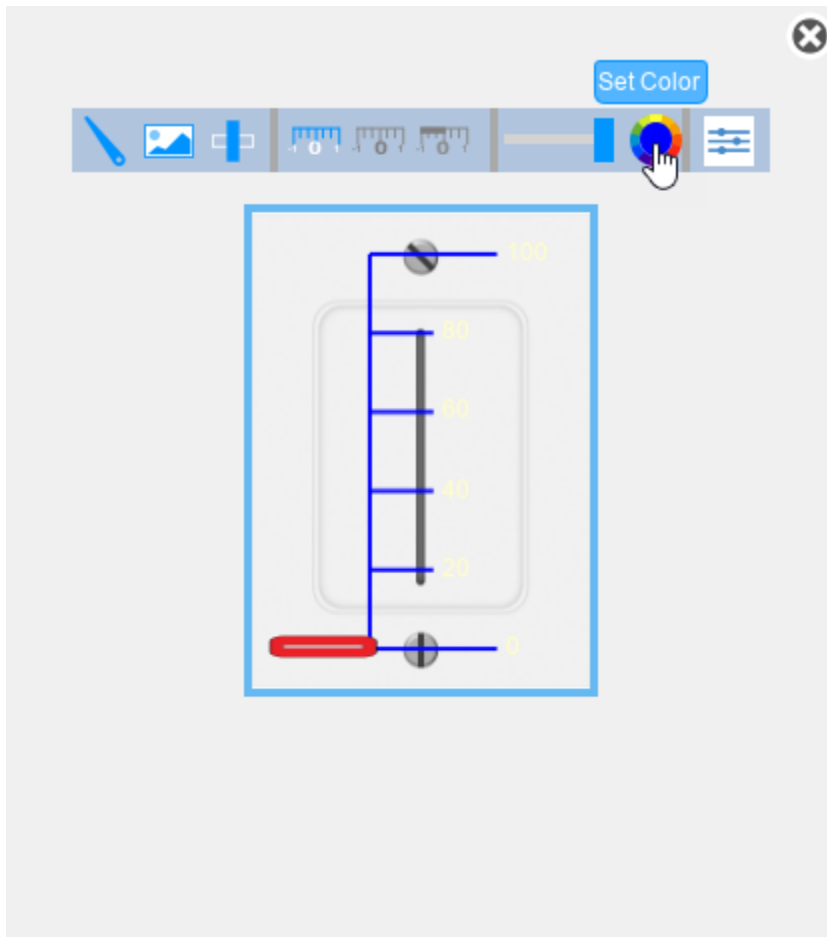

Add the background image for the light dimmer switch:

- 1 In the toolbar, click **Replace Background Image**.
- 2 In the CustomSliderImages folder, select the light-switch-background.png file.

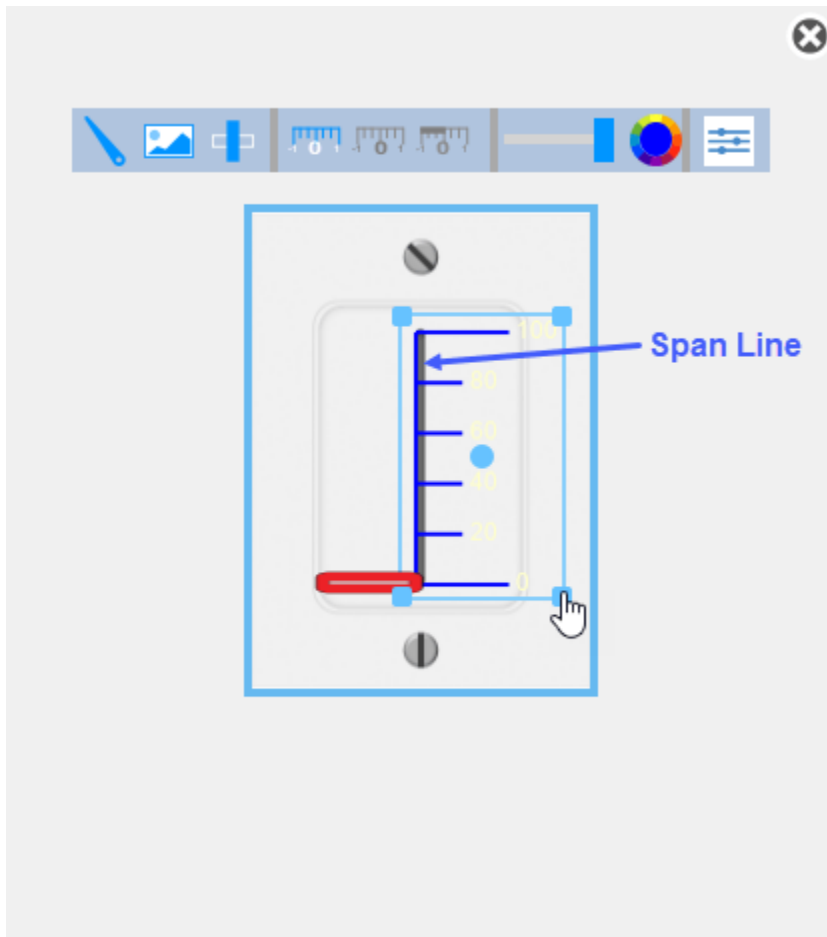

To make the scale easier to see, in the toolbar, click **Set Color**. Change the scale color to blue.

In the canvas, adjust the scale such that the span line exactly covers the slot in the light switch mounting shown on the background image:

- To move the scale, click and move the bounding box of the scale.
- To resize the scale, click and drag the corners of the bounding box of the scale.

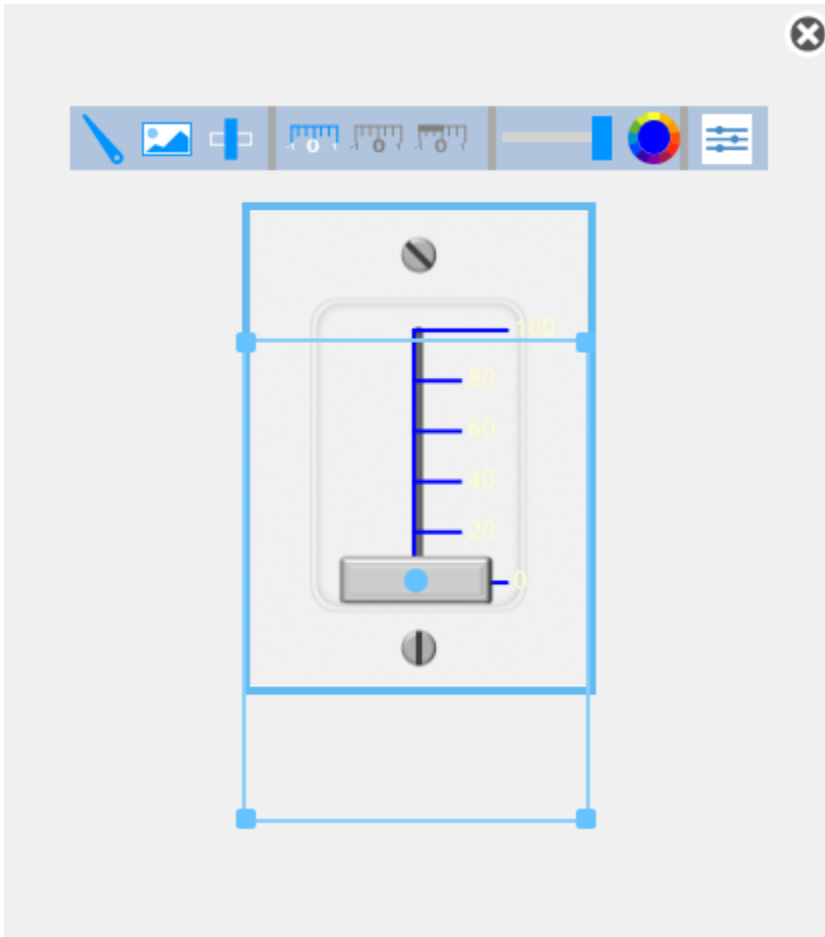

Add the handle image for the light dimmer switch:

- 1 In the Property Inspector, on the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomSliderImages folder, select the light-switch-handle.png file.
- 4 In the **Size** section, set the **Width** and **Height** to 1.

In the canvas, move the handle to the off position on the light switch mounting shown in the background image. The center of the handle image should be at the bottom of the slot in the light switch mounting.

Hide the scale ticks, span line, and labels:

- 1 In the Property Inspector, on the **Design** tab, select the **Scale** component.
- 2 In the **Ticks** section, turn off **Show Ticks** and **Show Span Line**.
- 3 In the **Labels** section, turn off **Show Labels**.

Hide the value bar:

- 1 On the **Design** tab, select the **Value Bar** component.
- 2 In the **Value Bar** section, set the **Opacity** to 0.

When you finish adjusting the design for the light dimmer switch, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished light dimmer switch to control a parameter. In the model, a Constant block represents the light intensity, and the Vertical Slider block controls the value of the constant.

Light Dimmer

Connect the Vertical Slider block to the Value parameter of the Constant block:

- 1 Select the Vertical Slider block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named Const1.
- 4 In the table that appears below the selected signal, select the Const1:Value.
- 5 Click the X in the upper right corner of the Simulink window.

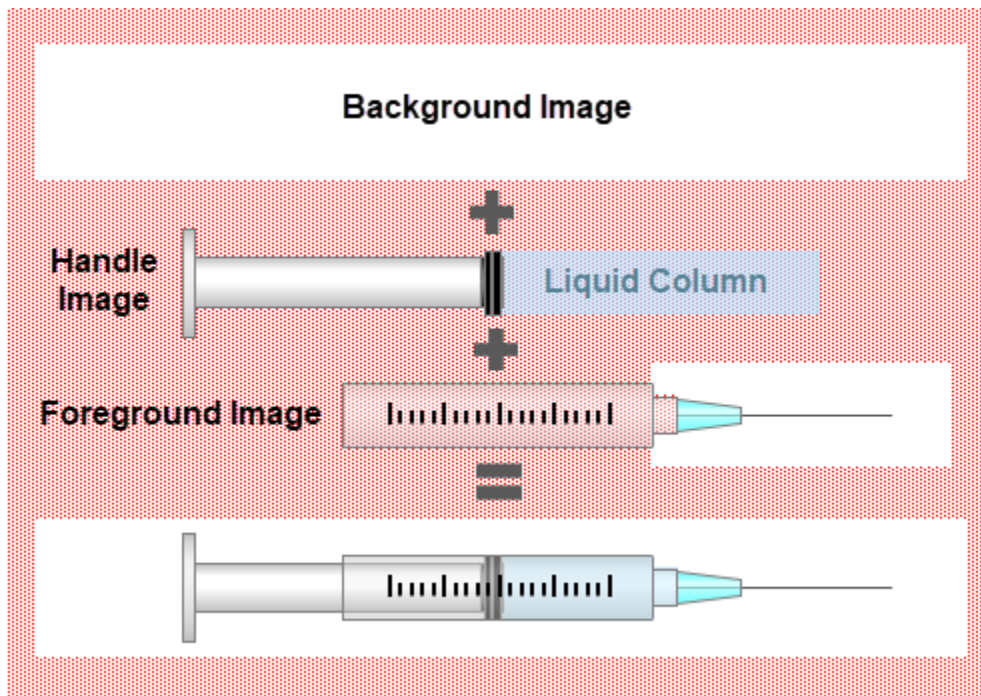

To use the light dimmer switch:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 Click and drag the Vertical Slider block handle to change the value of the Constant block during simulation.
- 3 See the effect on the light intensity in the Dashboard Scope block.

### Design Medical Syringe

The medical syringe is made with a Horizontal Slider block that has three components:

- A background image that is blank and serves only to properly scale the other images
- A handle image that shows the handle of the syringe attached to a column of liquid
- A foreground image that shows the casing of the syringe with tick marks to indicate the level of liquid inside

The visual effect that the liquid column vanishes when it passes the tip of the syringe needle is achieved with the opacity of the foreground image.

- To show the liquid inside of the syringe, the glass cylinder is transparent in the foreground image.
- To hide the part of the handle image liquid column that has moved past the needle tip, the area around the needle tip is opaque in the foreground image.

To design the medical syringe, add a Horizontal Slider block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Horizontal Slider block.
- 2 In the Simulink Toolstrip, click the **Slider** tab.
- 3 On the **Slider** tab, click **Edit**. A toolbar appears above the Horizontal Slider block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Adding a handle image to a customizable dashboard block changes the aspect ratio of the handle image to match the aspect ratio of the block.

Adding a background image to a customizable dashboard block changes the aspect ratio of the block to match the aspect ratio of the background image.

To prevent the handle image from being distorted, before you add the handle image, you can use a background image to set the aspect ratio of the block to be the same as the aspect ratio of the handle image.

You can prevent the foreground image from being distorted in the same way.

Since the handle and foreground images of the syringe have the same aspect ratio, a background image with that aspect ratio can be used to prevent both from being distorted.

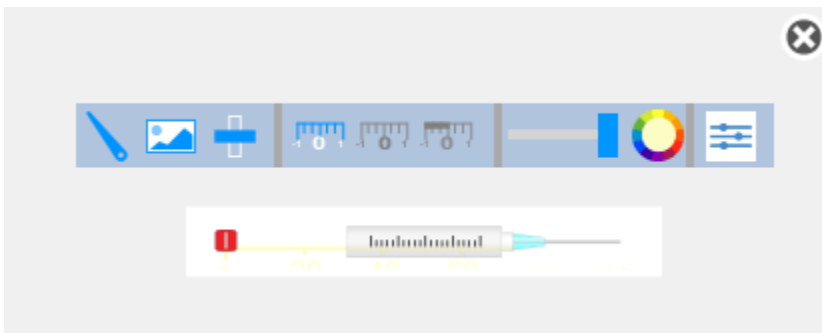

Add the transparent background image for the syringe:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomSliderImages folder, select the `medical-syringe-background.png` file.

Add the foreground image for the syringe:

- 1 On the **Design** tab, select the **Foreground** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomSliderImages folder, select the `medical-syringe-foreground.png` file.

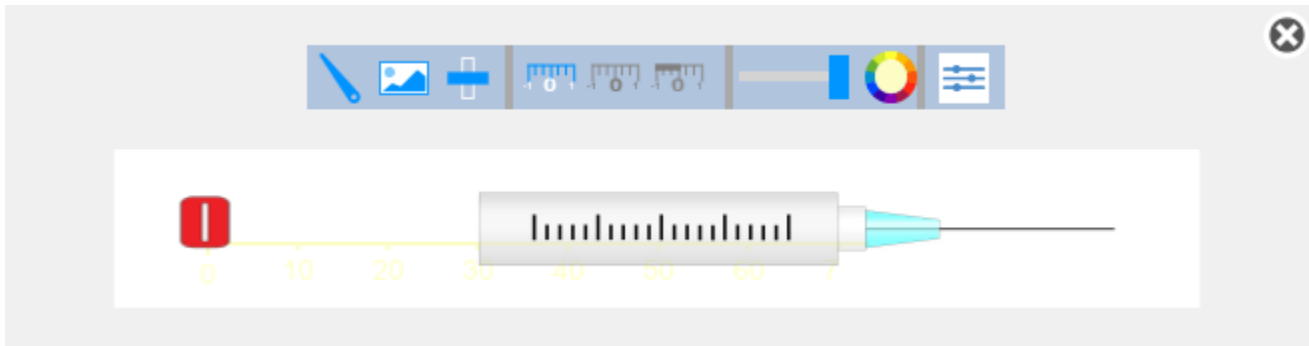

To exit design mode, on the **Design** tab, click **Edit**.

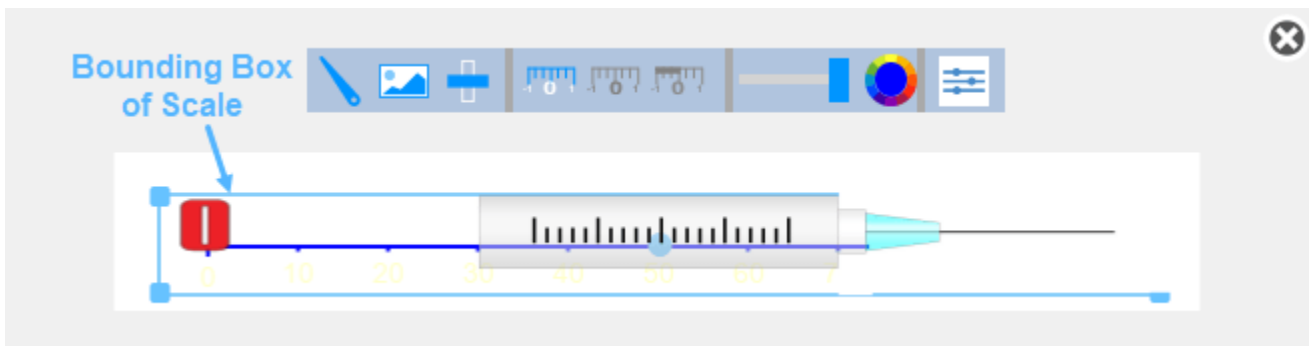

Resize the block in the canvas by dragging one of its corners outwards until the tick marks on the syringe shown in the foreground image are clearly visible.

To continue modifying the design of the Horizontal Slider block, enter design mode. In the Property Inspector, on the **Design tab**, click **Edit**.

Make the scale easier to see:

- 1 On the **Design** tab, select the **Scale** component.
- 2 In the **Ticks** section, change the **Color** to blue.

At this point, you cannot adjust the size or position the scale in the canvas because the foreground image is on top of the scale.

To make the scale of the Horizontal Slider block match the scale on the foreground image, the handles of the bounding box of the scale need to be outside of the foreground image so that you can adjust the scale with the foreground image visible.

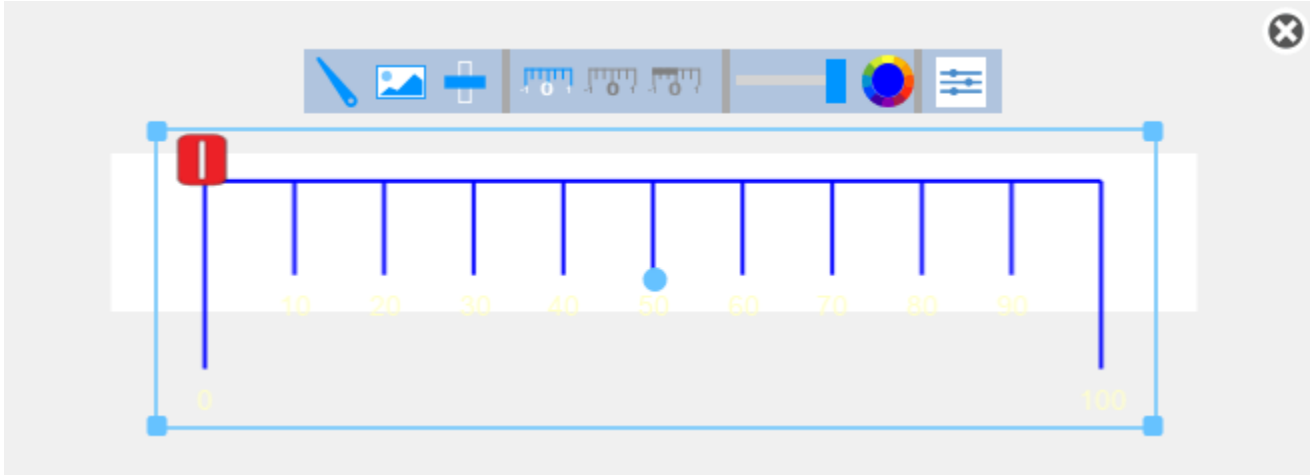

Hide the foreground image:

On the **Design** tab, click the eye icon of the **Foreground Image** component. The eye icon now has a slash through it, indicating that the foreground image is hidden.

Resize the scale such that you can still grab the handles of the bounding box of the scale when the foreground is visible again:

- 1 On the **Design** tab, click the **Scale** component.
- 2 In the canvas, click and drag the corners of the bounding box of the scale such that the top and bottom edges of the bounding box are outside of the white box that is the background image.

To make the foreground image visible again, on the **Design** tab, click the eye icon of the **Foreground Image** component.

In the canvas, click and drag the corners of the bounding box of the scale such that the left edge of the scale lines up with the leftmost tick mark on the syringe in the foreground image and the right edge lines up with the rightmost tickmark.

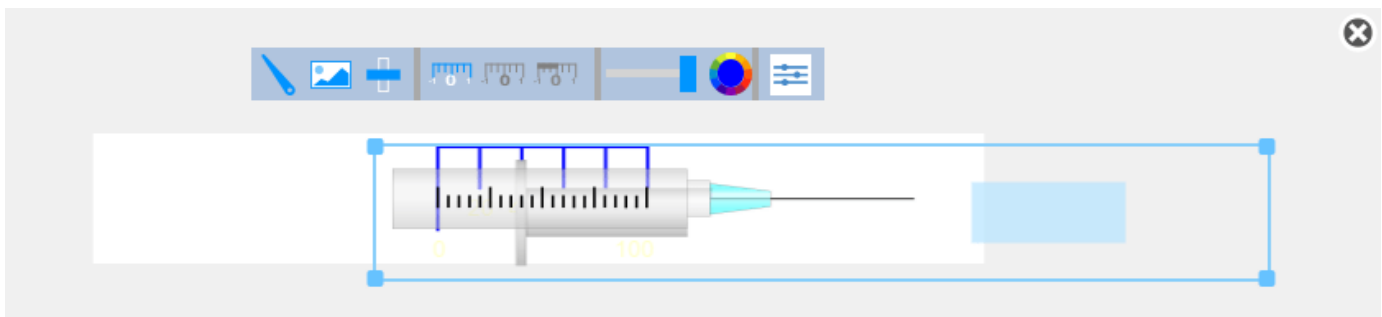

In the canvas, click and drag the corners of the bounding box of the scale such that the top and bottom edges of the bounding box line up with the top and bottom edges of the white box that is the background image.

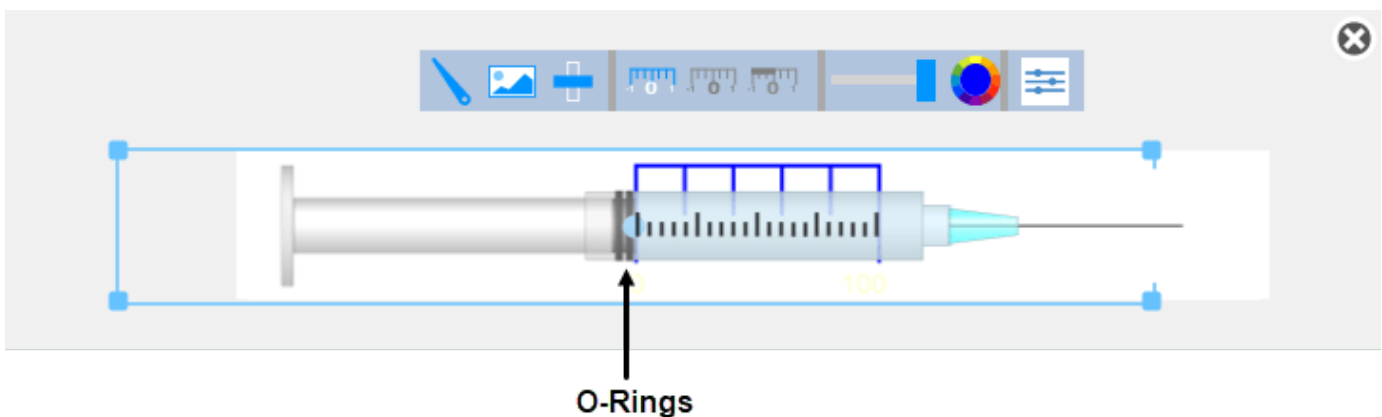

Add the handle image for the syringe:

- 1 On the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomSliderImages folder, select the `medical-syringe-handle.png` file.
- 4 In the **Size** section, set the **Width** and **Height** to 1.

In the canvas, click and drag the edges of the bounding box of the handle image to line up the right edge of the O-rings with the left edge of the scale. Then, line up the top and bottom edges of the handle and foreground images.

Hide the scale ticks, span line, and labels:

- 1 In the Property Inspector, on the **Design Tab**, select the **Scale** component.
- 2 In the **Ticks** section, turn off **Show Ticks** and **Show Span Line**.
- 3 In the **Labels** section, turn off **Show Labels**.

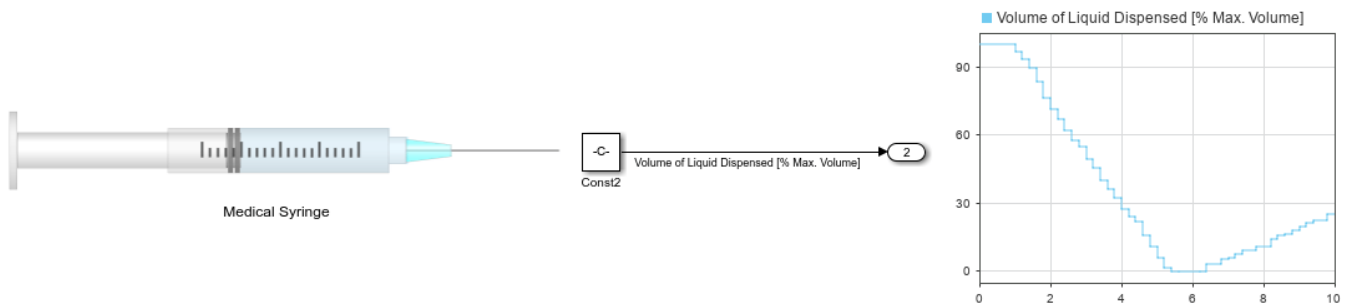

Hide the value bar:

- 1 In the Property Inspector, on the **Design Tab**, select the **Value Bar** component.
- 2 In the **Value Bar** section, set the **Opacity** to 0.

When you finish adjusting the design for the syringe, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished syringe to control a parameter. In the model, a Constant block represents the volume of liquid dispensed, and the Horizontal Slider block controls the value of the constant.

Connect the Horizontal Slider block to the **Value** parameter of the Constant block:

- 1 Select the Vertical Slider block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named **Const2**.
- 4 In the table that appears below the selected signal, select **Const2:Value**.
- 5 Click the X in the upper right corner of the Simulink window.

To use the syringe:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see “Simulation Pacing” on page 2-18.
- 2 Click and drag the Horizontal Slider block handle to change the value of the Constant block during simulation.
- 3 See the effect on the volume of liquid dispensed in the Dashboard Scope block.

### Design Mixing Desk Slider

To design the mixing desk slider, add a Vertical Slider block to the model.

If the Property Inspector is not open to the **Design** tab with the **Edit** button pressed:

- 1 In the model canvas, select the Vertical Slider block.
- 2 In the Simulink Toolstrip, click the **Slider** tab.
- 3 On the **Slider** tab, click **Edit**. A toolbar appears above the Vertical Slider block.
- 4 To open the Property Inspector, in the toolbar, click **Open Design Tab**.

Add the background image for the mixing desk slider:

- 1 In the Property Inspector, on the **Design** tab, select the **Background Image** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomSliderImages folder, select the `mixing-desk-slider-background.png` file.

To exit design mode, on the **Design** tab, click **Edit**.

Resize the block in the canvas by dragging one of its corners outwards until the text on the background image is large enough to read.

To continue modifying the design of the Horizontal Slider block, enter design mode. In the Property Inspector, on the **Design tab**, click **Edit**.

To adjust the scale, you need to be able to see all of the tick marks on the background image. To hide the handle, on the **Design** tab, click the eye icon of the **Handle** component. The eye icon now has a slash through it, indicating that the handle is hidden.

Make the scale easier to see:

- 1 On the **Design** tab, select the **Scale** component.
- 2 In the **Ticks** section, change the **Color** to black.
- 3 In the **Label** section, change the **Color** to black.

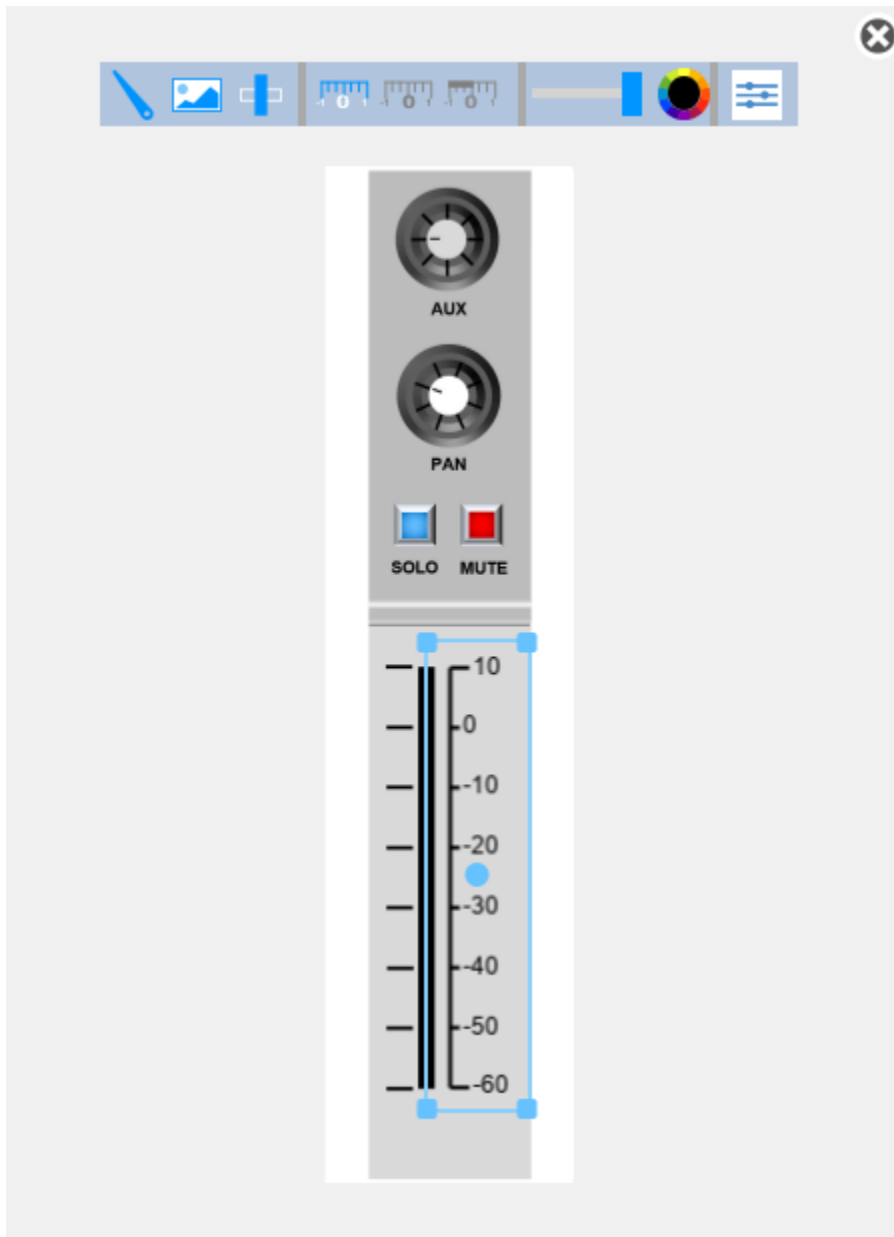

On the **Design** tab, in the **Handle** component, in the **Range** section, set the **Minimum** to -60 and the **Maximum** to 10.

In the canvas, click and drag the corners of the bounding box of the scale such that:

- The top tick mark of the scale lines up with the top tick mark in the background image.
- The bottom tick mark of the scale lines up with the bottom tick mark in the background image.
- The left edge of the scale bounding box lines up with the centerline of the slot shown in the background image.
- The right edge of the bounding box lines up with the right edge of the mixing desk surface shown in the background image.

To make the scale easier to read, adjust the height of the tick marks and the offset between the scale labels and the tick marks:

- 1 On the **Design** tab of the Property Inspector, select the **Scale** component.
- 2 To make the tick marks easier to see, in the **Ticks** section, set the **Minor Tick Height** to 1.
- 3 To increase the label offset to make the negative signs in front of scale labels distinguishable from the scale tick marks, in the **Labels** section, set the **Label Offset** to 0.15.

To make the handle visible again, on the **Design** tab, click the eye icon of the **Handle** component.

Add the handle image for the mixing desk slider:

- 1 On the **Design** tab, select the **Handle** component.
- 2 In the **Select Image** section, click the plus button.
- 3 In the CustomSliderImages folder, select the mixing-desk-slider-handle.png file.
- 4 The handle image is too large to fit on the scale without covering the labels. To make the handle fit, in the **Size** section, set the **Width** to 0.245 and **Height** to 0.088.

Click and drag the edges of the bounding box to position the handle such that:

- The white line shown on the handle image lines up with the -70 tick mark on the scale.
- The center point of the handle image is on the slot shown in the background image.

Hide the value bar:

- 1 In the Property Inspector, on the **Design Tab**, select the **Value Bar** component.
- 2 In the **Value Bar** section, set the **Opacity** to 0.

When you finish adjusting the design for the fader, to exit design mode, in the Property Inspector, on the **Design** tab, click **Edit**.

You can use the finished fader to control a parameter. In the model, a Constant block represents the volume of a channel, and the Vertical Slider block controls the value of the constant.

Connect the Vertical Slider block to the Value parameter of the Constant block:

- 1 Select the Vertical Slider block.
- 2 Click the **Connect** button that appears above the block.
- 3 Select the Constant block named `Const3`.
- 4 In the table that appears below the selected signal, select `Const3:Value`.
- 5 Click the X in the upper right corner of the Simulink window.

To use the fader:

- 1 Simulate the model. This model uses simulation pacing to slow model execution so you can interact with the model during simulation. For more information about simulation pacing, see "Simulation Pacing" on page 2-18.
- 2 Click and drag the Vertical Slider block handle to change the value of the Constant block during simulation.

- 3 See the effect on the channel volume in the Dashboard Scope block.

# Analyzing Simulation Results

---

- “Decide How to Visualize Simulation Data” on page 33-2
- “Linearizing Models” on page 33-8

## Decide How to Visualize Simulation Data

Visualizing simulation data throughout the modeling process helps you understand and tune model behavior. Simulink offers several complementary visualization tools you can use throughout the modeling process. Some visualization tools also offer the ability to save simulation data. Learn about each technique so you can choose the right tools to visualize your model data.

- Simulation Data Inspector — View, analyze, and compare logged data throughout the modeling process.
- Scope block, Floating Scope block, and Scope Viewer — Debug and analyze data using an environment and capabilities similar to a bench-top oscilloscope.
- Dashboard blocks — Build an interactive interface to tune and monitor a model.
- Port value displays — View instantaneous signal values while debugging.
- Custom MATLAB visualization — Write MATLAB code to visualize data.

### Simulation Data Inspector

You can use the **Simulation Data Inspector** for most visualization tasks. The Simulation Data Inspector integrates with data logging in your model and works well for visualizing many signals throughout a model. Use comparisons in the Simulation Data Inspector to prototype, debug, tune, calibrate, and test your models. The Simulation Data Inspector supports:

- Viewing signals during simulation
- Logging, importing, and exporting data
- Configurable subplot layouts and visualization settings
- Viewing data using multiple visualization options, including maps and XY plots
- Post-processing and data analysis using comparisons with tolerance values
- Saving plots and data to share or archive results

To visualize simulation data using the Simulation Data Inspector, log data in the model. When you log signals and outputs, the logged data is automatically available in the Simulation Data Inspector during and after simulation. In the model Configuration Parameters, select **Data Import/Export > Record logged workspace data in Simulation Data Inspector** to make logged states and Simscape data available in the Simulation Data Inspector after simulation. When you want to view signals without logging the data, consider using a Scope block, the Floating Scope block, or a Scope Viewer.

Open the Simulation Data Inspector from **Simulation > Data Inspector** or by clicking a signal logging badge. When you open the Simulation Data Inspector by clicking the logging badge on a signal, the signal is automatically plotted.

For more information, see **Simulation Data Inspector**.

## Scope Blocks and the Scope Viewer

Scope blocks, Floating Scope blocks, and the Scope Viewer visualize connected signals in a similar way as a bench-top oscilloscope. The scope blocks and Scope Viewer use the same interface to visualize and analyze connected signals. The interface is similar to other domain-specific tools, such as the Spectrum Analyzer and Array Plot blocks. Scope blocks are easy to add and connect in your model, and you do not need to log data in order to view signal data.

Scope blocks, Floating Scope blocks, and the Scope Viewer support:

- Viewing signals during simulation, including rapid accelerator simulations.
- Simple connection and accessibility for lightweight debugging.
- Signal visualization without logging.
- Optional signal logging.
- Starting simulations from the visualization interface using playback controls.
- Oscilloscope measurements, including cursors and triggers. Additional measurements are available when you have a Simscape or DSP System Toolbox license.
- Configurable plots and display.
- Configurable triggers to capture events.

Use the Scope block, the Floating Scope block, and the Scope Viewer for prototyping and lightweight debugging. For example, in the early stages of model development, you can connect a Scope block to a signal to quickly verify component behavior. By adding triggers, you can tune a specific peak or other artifact in a signal. A Scope block may or may not be permanent in your model.

When you need to view data for signals throughout a model hierarchy, consider using the Simulation Data Inspector, especially if you already log the signals you want to view.

For more information, see “Scope Blocks and Scope Viewer Overview” on page 30-6.

## Dashboard Blocks

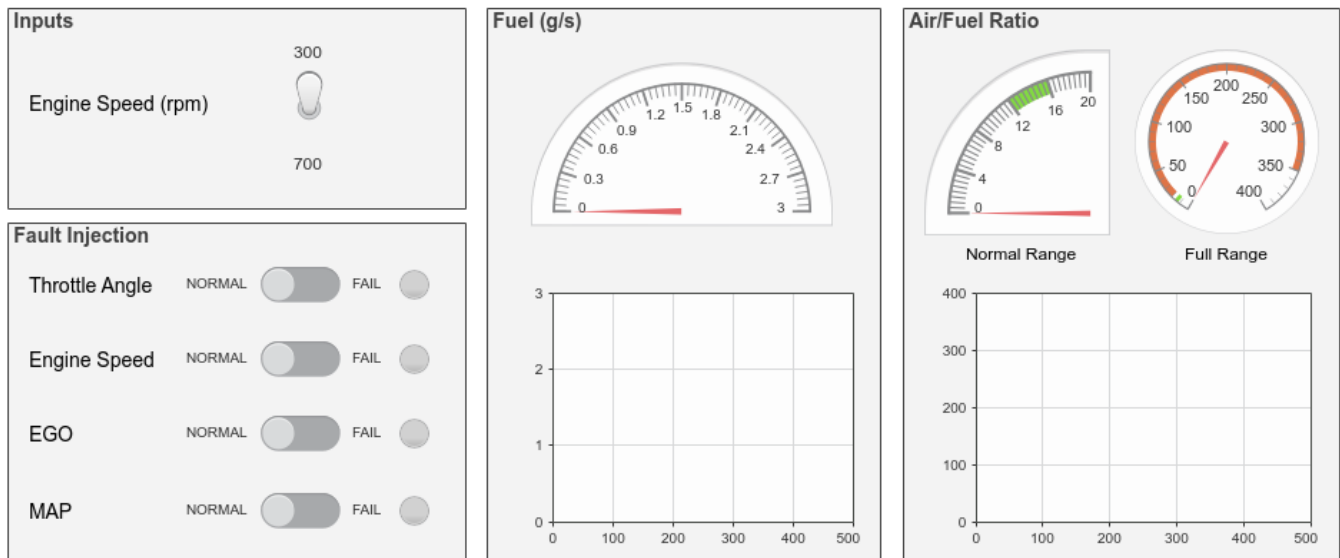

The Dashboard library includes control blocks you can use to tune variables and parameters in your model and visualization blocks you can use to view signal data. Use Dashboard blocks to view instantaneous signal data and build an interactive interface for your model.

You can use Dashboard block controls to modify the values of variables and tunable parameters in your model during simulation. Visualization Dashboard blocks are updated continuously throughout simulation. When you need to debug a model that uses Dashboard blocks, consider using simulation pacing or simulation stepping to slow the simulation so you can view the instantaneous signal values. You can also promote Dashboard blocks to one or more panels so the interactive dashboard can follow you throughout a model hierarchy as you design and debug your model. For more information, see:

- “Simulation Pacing” on page 2-18
- “Step Through a Simulation” on page 2-12
- “Interactively Design and Debug Models Using Panels” on page 32-7

## Fault-Tolerant Fuel Control System Dashboard

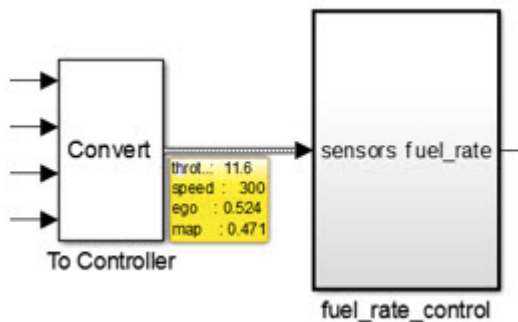

The Dashboard Scope block provides a simple view of a signal over time. You can zoom, pan, and add cursors to a Dashboard Scope block through the context menu. For more debugging and analysis capabilities, use a Scope block or log data to the Simulation Data Inspector.

For more information about using Dashboard blocks, see “Tune and Visualize Your Model with Dashboard Blocks” on page 32-2.

## Port Value Displays

You can enable port value displays to view a signal value at a given time point. Port value displays can supplement existing visualizations while prototyping and debugging models. For example, you can view signal values on port value displays as you step through a simulation while visualizing the temporal behavior using a Scope block. You can also use port value displays on their own to support debugging without adding any blocks to your model or logging data.

To display a signal value, right-click the signal and select **Show Value Label of Selected Port**.

When inspecting signal data by displaying the value on the port, consider using simulation pacing or stepping through the simulation. For more information, see “Simulation Pacing” on page 2-18 and “Step Through a Simulation” on page 2-12.

For more information, see “Display Port Values for Debugging” on page 39-18.

## Custom MATLAB Visualizations

When you log simulation data to the workspace or a file, you can write MATLAB code and scripts to create custom visualizations. You can log signals, outputs, and states in a model, and you can also enable data logging for signals connected to Scope Viewers, Floating Scope blocks and Scope blocks. For more information about logging data in your model, see “Export Simulation Data” on page 77-2.

---

**Note** When you post-process data using MATLAB code and scripts, you do not need to write custom MATLAB code to visualize the data. You can import the processed data into the Simulation Data Inspector for visualization alongside the logged data.

---

The visualization code you write can depend on the format of the logged data. By default, logging uses the `Dataset` format and produces a single simulation output. Logged data is returned to the workspace as a `Simulink.SimulationOutput` object that contains a `Simulink.SimulationData.Dataset` object for each type of logging used in the simulation. Each `Dataset` object contains `Simulink.SimulationData.Signal` objects that store the data for an individual signal as a `timeseries` object. For more information, see “Data Format for Logged Simulation Data” on page 77-6.

When you log a signal, you can visualize the signal during simulation using custom MATLAB code. For more information, see “Access Data in a MATLAB Function During Simulation” on page 31-119.

## Linearizing Models

The Simulink product provides the `linmod`, `linmod2`, and `dlinmod` functions to extract linear state-space models from Simulink models. However, these functions provide only basic linearization functionality. For full linearization functionality, use Simulink Control Design software. For more information, see “Choose Linearization Tools” (Simulink Control Design).

The `linmod`, `linmod2`, and `dlinmod` functions extract linear models in the form of the state-space matrices  $A$ ,  $B$ ,  $C$ , and  $D$ . State-space matrices describe the linear input-output relationship as

$$\begin{aligned}\dot{x} &= Ax + Bu \\ y &= Cx + Du,\end{aligned}$$

where  $x$ ,  $u$ , and  $y$  are state, input, and output vectors, respectively. For example, the following model is called `lmod`.

To extract the linear model of this system, enter this command.

```
[A,B,C,D] = linmod('lmod')
```

```
A =
  -2   -1   -1
   1    0    0
   0    1   -1
B =
   1
   0
   0
C =
   0    1    0
   0    0   -1
D =
   0
   1
```

Inputs and outputs must be defined using Inport and Outport blocks from the Ports & Subsystems library. Source and sink blocks do not act as inputs and outputs. Inport blocks can be used in conjunction with source blocks, using a Sum block. Once the data is in the state-space form or converted to an LTI object, you can apply functions in the Control System Toolbox product for further analysis:

- Conversion to an LTI object  
`sys = ss(A,B,C,D);`
- Bode phase and magnitude frequency plot  
`bode(A,B,C,D)` or `bode(sys)`
- Linearized time response  
`step(A,B,C,D)` or `step(sys)`  
`impulse(A,B,C,D)` or `impulse(sys)`  
`lsim(A,B,C,D,u,t)` or `lsim(sys,u,t)`

You can use other functions in the Control System Toolbox and the Robust Control Toolbox™ products for linear control system design.

When the model is nonlinear, an operating point can be chosen at which to extract the linearized model. Extra arguments to `linmod` specify the operating point.

```
[A,B,C,D] = linmod('sys', x, u)
```

For discrete systems or mixed continuous and discrete systems, use the function `dlinmod` for linearization. This function has the same calling syntax as `linmod` except that the second right-hand argument must contain a sample time at which to perform the linearization.

## How Optimization Techniques Improve Performance and Accuracy

The design of a model and choice of configuration parameters can affect simulation performance and accuracy. Solvers handle most model simulations accurately and efficiently with default parameter values. However, some models yield better results when you adjust solver parameters. Information about the behavior of a model can help you improve simulation performance, particularly when you provide this information to the solver. Use optimization techniques to better understand the behavior of your model and modify the model settings to improve performance and accuracy.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To learn more about accelerator modes for faster simulation, see “Acceleration”.

#### More About

- “Modeling Techniques That Improve Performance” on page 34-13

## Speed Up Simulation

Several factors can slow simulation. Check your model for some of these conditions.

- The model includes an Interpreted MATLAB Function block. When a model includes an Interpreted MATLAB Function block, the MATLAB execution engine is called at each time step, drastically slowing down the simulation. Use the Math Function block whenever possible.
- Your model includes a MATLAB file S-function. MATLAB file S-functions also call the MATLAB execution engine at each time step. Consider converting the S-function either to a subsystem or to a C-MEX file S-function.
- Your model includes a Memory block. Using a Memory block causes the variable-order solvers (ode15s and ode113) to reset back to order 1 at each time step.
- The maximum step size is too small. If you changed the maximum step size, try running the simulation again with the default value (`auto`).
- Your accuracy requirements are too high. The default relative tolerance (0.1% accuracy) is usually sufficient. For models with states that go to zero, if the absolute tolerance parameter is too small, the simulation can take too many steps around the near-zero state values. See the discussion of this error in “Maximum order” in the online documentation.
- The time scale is too long. Reduce the time interval.
- Your model represents a stiff system, but you are using a nonstiff solver. Try using `ode15s`. For more information, see “Stiffness of System” on page 34-15.
- Your model uses sample times that are not multiples of each other. Mixing sample times that are not multiples of each other causes the solver to take small enough steps to ensure sample time hits for all sample times.
- The model contains an algebraic loop. The solutions to algebraic loops are iteratively computed at every time step. Therefore, they severely degrade performance. For more information, see “Algebraic Loop Concepts” on page 3-39.

You can check the model blocks for the following conditions:

- Your model feeds a Random Number block into an Integrator block. For continuous systems, use the Band-Limited White Noise block in the Sources library.
- Your model contains a scope viewer that displays too many data points. Try adjusting the viewer property settings that can affect performance. For more information, see Scope Viewer.
- You need to simulate your model iteratively. You change tunable parameters between iterations but do not make structural changes to the model. Every iteration requires the model to compile again, thus increasing overall simulation time. Use fast restart to perform iterative simulations. In this workflow, the model compiles only once and iterative simulations are tied to a single compile phase. See “How Fast Restart Improves Iterative Simulations” on page 86-2 for more information.

## How Profiler Captures Performance Data

### In this section...

“How Profiler Works” on page 34-5

“Start Profiler” on page 34-6

“Save Profiler Results” on page 34-9

### How Profiler Works

Profiler captures performance data while your model simulates. It identifies the parts of your model that require the most time to simulate. Use the profiling information to decide where to focus your model optimization efforts.

**Note** You cannot use Profiler in Rapid Accelerator mode.

Simulink stores performance data in the *simulation profile report*. The data shows the time spent executing each function in your model.

The basis for Profiler is an execution model that this pseudocode summarizes.

```

Sim()
  ModelInitialize().
  ModelExecute()
    for t = tStart to tEnd
      Output()
      Update()
      Integrate()
        Compute states from derivs by repeatedly calling:
          MinorOutput()
          MinorDeriv()
        Locate any zero crossings by repeatedly calling:
          MinorOutput()
          MinorZeroCrossings()
      EndIntegrate
      Set time t = tNew.
    EndModelExecute
  ModelTerminate
EndSim

```

According to this conceptual model, Simulink runs a model by invoking the following functions zero, one, or many times, depending on the function and the model.

Function	Purpose	Level
sim	Simulate the model. This top-level function invokes the other functions required to simulate the model. The time spent in this function is the total time required to simulate the model.	System
ModelInitialize	Set up the model for simulation.	System

Function	Purpose	Level
ModelExecute	Execute the model by invoking the output, update, integrate, etc., functions for each block at each time step from the start to the end of simulation.	System
Output	Compute the outputs of a block at the current time step.	Block
Update	Update the state of a block at the current time step.	Block
Integrate	Compute the continuous states of a block by integrating the state derivatives at the current time step.	Block
MinorOutput	Compute block output at a minor time step.	Block
MinorDeriv	Compute the state derivatives of a block at a minor time step.	Block
MinorZeroCrossings	Compute zero-crossing values of a block at a minor time step.	Block
ModelTerminate	Free memory and perform any other end-of-simulation cleanup.	System
Nonvirtual Subsystem	Compute the output of a nonvirtual subsystem at the current time step by invoking the output, update, integrate, etc., functions for each block that it contains. The time spent in this function is the time required to execute the nonvirtual subsystem.	Block

Profiler measures the time required to execute each invocation of these functions. After the model simulates, Profiler generates a report that describes the amount of simulation time spent on each function.

## Start Profiler

- 1 Open the model.
- 2 On the **Debug** tab, select **Performance Advisor > Simulink Profiler**.
- 3 Simulate the model.

When simulation is complete, Simulink generates and displays the simulation profile for the model in a panel in the Simulink editor.

### Block Hierarchy View

The block hierarchy view of the report presents the profiling information of the model in a nested tree form. The first row of the table—which is the top of the tree—corresponds to the entire model. Subsequent rows at the first level of nesting correspond to blocks at the root level of the model.

sldemo_fuelsys_dd		47.126	13.354

## Save Profiler Results

You can save the Profiler report to a mat file. At a later time, you can import and review the report by either loading the saved mat file to the current workspace or import it into an existing profiler session.

To save a profiling report, select **Export to MAT** in the **Share** section of the **Profile** tab and optionally specify a name for the mat file.

To view a saved report in an open profiling session in the Simulink editor, select **Import from File** in the **Profile** tab.

To view a saved report in the command line, load the mat file containing the report. The profiling information is loaded into the current workspace as a `Simulink.profiler.Data` object. For more information, see `Simulink.profiler.Data`.

# Check and Improve Simulation Accuracy

## Check Simulation Accuracy

- 1 Simulate the model over a reasonable time span.
- 2 Reduce either the relative tolerance to 1e-4 (the default is 1e-3) or the absolute tolerance.
- 3 Simulate the model again.
- 4 Compare the results from both simulations.

If the results are not significantly different, the solution has converged.

If the simulation misses significant behavior at the start, reduce the initial step size to ensure that the simulation does not step over that behavior.

## Unstable Simulation Results

When simulation results become unstable over time,

- The system can be unstable.
- If you are using the ode15s solver, try restricting the maximum order to 2 (the maximum order for which the solver is A-stable). You can also try using the ode23s solver.

## Inaccurate Simulation Results

If simulation results are not accurate:

- For a model that has states whose values approach zero, if the absolute tolerance parameter is too large, the simulation takes too few steps around areas of near-zero state values. Reduce this parameter value in the **Solver pane** of model configuration parameters or adjust it for individual states in the function block parameters of the Integrator block.
- If reducing the absolute tolerances does not improve simulation accuracy enough, reduce the size of the relative tolerance parameter. This change reduces the acceptable error and forces smaller step sizes and more steps.

Certain modeling constructs can also produce unexpected or inaccurate simulation results.

- A Source block that inherits sample time can produce different simulation results if, for example, the sample times of the downstream blocks are modified (see “How Propagation Affects Inherited Sample Times” on page 7-37).
- A Derivative block found in an algebraic loop can result in a loss in solver accuracy.

## Modeling Techniques That Improve Performance

### In this section...

“Accelerate the Initialization Phase” on page 34-13

“Reduce Model Interactivity” on page 34-13

“Reduce Model Complexity” on page 34-14

“Choose and Configure a Solver” on page 34-15

“Save the Model Operating Point” on page 34-17

### Accelerate the Initialization Phase

Speed up a simulation by accelerating the initialization phase, using these techniques.

#### Simplify Graphics Using Mask Editor

Complex graphics and large images take a long time to load and render. Masked blocks that contain such images can make your model less responsive. Where possible, remove complex drawings and images from masked blocks.

If you want to keep the image, replace it with a smaller, low-resolution version. Use mask editor and edit the icon drawing commands to keep the image that is loaded by the call to `image()`.

For more information on mask editor, see “Mask Editor Overview”.

#### Consolidate Function Calls

When you open or update a model, Simulink runs the mask initialization code. If your model contains complicated mask initialization commands that contain many calls to `set_param`, consolidate consecutive calls into a single call with multiple argument pairs. Consolidating the calls can reduce the overhead associated with these function calls.

To learn more, see “Mask Callback Code” on page 42-13.

#### Load Data Using MAT-file

If you use MATLAB scripts to load and initialize data, you can improve performance by loading MAT-files instead. The data in a MAT-file is in binary and can be more difficult to work with than a script. However, the load operation typically initializes data more quickly than the equivalent MATLAB script.

For more information, see “MAT-Files for Signal Data” on page 75-4.

### Reduce Model Interactivity

In general, the more interactive a model is, the longer it takes to simulate. Use these techniques to reduce the interactivity of your model.

#### Disable Debugging Diagnostics

Some enabled diagnostic features can slow simulations considerably. Consider disabling them in the model configuration parameters **Diagnostics** pane.

---

**Note** Running **Array bounds exceeded** and **Solver data inconsistency** can slow down model runtime performance. For more information, see “Array bounds exceeded” and “Solver data inconsistency”.

---

### **Disable MATLAB Debugging**

After verifying that your MATLAB code works correctly, disable these checks in the model configuration parameters **Simulation Target** pane.

- **Enable debugging/animation**
- **Detect wrap on overflow (with debugging)**
- **Echo expressions without semicolons**

For more information, see “Model Configuration Parameters: Simulation Target”.

### **Use BLAS Library Support**

If your simulation involves low-level MATLAB matrix operations, use the Basic Linear Algebra Subprograms (BLAS) libraries to make use of highly optimized external linear algebra routines.

### **Disable Stateflow Animations**

By default, Stateflow charts highlight the current active states in a model and animate the state transitions that take place as the model simulates. This feature is useful for debugging, but it slows the simulation.

To accelerate simulations, either close all Stateflow charts or disable the animation. Similarly, consider disabling animation or reducing scene fidelity when you use:

- Simulink 3D Animation
- Simscape Multibody visualization
- FlightGear
- Any other 3D animation package

To learn more, see “Speed Up Simulation” (Stateflow).

### **Adjust Scope Viewer Properties**

If your model contains a scope viewer that displays a high rate of logging and you cannot remove the scope, adjust the viewer properties to trade off fidelity for rendering speed.

However, when you use decimation to reduce the number of plotted data points, you can miss short transients and other phenomena that you can see with more data points. To have more precise control over enabling visualizations, place viewers in enabled subsystems.

For more information, see Scope Viewer.

### **Reduce Model Complexity**

Use these techniques to improve simulation performance by simplifying a model without sacrificing fidelity.

## Replace Subsystems with Lower-Fidelity Alternatives

Replace a complex subsystem with one of these alternatives:

- A linear or nonlinear dynamic model that was created from measured input-output data using the System Identification Toolbox™.
- A high-fidelity, nonlinear statistical model that was created using the Model-Based Calibration Toolbox™.
- A linear model that was created using Simulink Control Design.
- A lookup table. For more information, see A lookup table.

You can maintain both representations of the subsystem in a library and use variant subsystems to manage them. Depending on the model, you can make this replacement without affecting the overall result. For more information, see “Optimize Generated Code for Lookup Table Blocks” on page 41-59.

## Reduce Number of Blocks

When you reduce the number of blocks in your model, fewer blocks require updates during simulations and simulation is faster.

- Vectorization is one way to reduce your block count. For example, if you have several parallel signals that undergo a similar set of computations, try to combine them into a vector using a Mux block and perform a single computation.
- You can also enable the **Block Reduction** parameter in the **Configuration Parameters** dialog.

## Use Frame-Based Processing

In frame-based processing, Simulink processes samples in batches instead of one at a time. If a model includes an analog-to-digital converter, for example, you can collect output samples in a buffer. Process the buffer in a single operation, such as a fast Fourier transform. Processing data in chunks this way reduces the number of times that the simulation needs to invoke blocks in your model.

In general, the scheduling overhead decreases as frame size increases. However, larger frames consume more memory, and memory limitations can adversely affect the performance of complex models. Experiment with different frame sizes to find one that maximizes the performance benefit of frame-based processing without causing memory issues.

## Choose and Configure a Solver

Simulink provides a comprehensive library of solvers, including fixed-step and variable-step solvers, to handle stiff and nonstiff systems. Each solver determines the time of the next simulation step. A solver applies a numerical method to solve ordinary differential equations that represent the model.

The solver you choose and the solver options you select can affect simulation speed. Select and configure a solver that helps boost the performance of your model using these criteria. For more information, see “Choose a Solver” on page 27-7.

## Stiffness of System

A stiff system has continuous dynamics that vary slowly and quickly. Implicit solvers are particularly useful for stiff problems. Explicit solvers are better suited for nonstiff systems. Using an explicit

solver to solve a stiff system can lead to incorrect results. If a nonstiff solver uses a very small step size to solve a model, this is a sign that your system is stiff.

### **Model Step Size and Dynamics**

When you are deciding between using a variable-step or fixed-step solver, keep in mind the step size and dynamics of your model. Select a solver that uses time steps to capture only the dynamics that are important to you. Choose a solver that performs only the calculations needed to work out the next time step.

You use fixed-step solvers when the step size is less than or equal to the fundamental sample time of the model. With a variable-step solver, the step size can vary because variable-step solvers dynamically adjust the step size. As a result, the step size for some time steps is larger than the fundamental sample time, reducing the number of steps required to complete the simulation. In general, simulations with variable-step solvers run faster than those that run with fixed-step solvers.

Choose a fixed-step solver when the fundamental sample time of your model is equal to one of the sample rates. Choose a variable-step solver when the fundamental sample time of your model is less than the fastest sample rate. You can also use variable-step solvers to capture continuous dynamics.

### **Decrease Solver Order**

When you decrease the solver order, you reduce the number of calculations that Simulink performs to determine state outputs, which improves simulation speed. However, the results become less accurate as the solver order decreases. Choose the lowest solver order that produces results with acceptable accuracy.

### **Increase Solver Step Size or Error Tolerance**

Increasing the solver step size or error tolerance usually increases simulation speed at the expense of accuracy. Make these changes with care because they can cause Simulink to miss potentially important dynamics during simulations.

### **Disable Zero-Crossing Detection**

Variable-step solvers dynamically adjust the step size, increasing it when a variable changes slowly and decreasing it when a variable changes rapidly. This behavior causes the solver to take many small steps near a discontinuity because this is when a variable changes rapidly. Accuracy improves, but often at the expense of long simulation times.

To avoid the small time steps and long simulations associated with these situations, Simulink uses zero-crossing detection to locate such discontinuities accurately. For systems that exhibit frequent fluctuations between modes of operation—a phenomenon known as chattering—this zero-crossing detection can have the opposite effect and thus slow down simulations. In these situations, you can disable zero-crossing detection to improve performance.

You can enable or disable zero-crossing detection for specific blocks in a model. To improve performance, consider disabling zero-crossing detection for blocks that do not affect the accuracy of the simulation.

For more information, see “Zero-Crossing Detection” on page 3-10.

## Save the Model Operating Point

Often, you run several simulations of the same model for different inputs, boundary conditions, and operating conditions. In some situations, these simulations share a common startup phase in which the model transitions from the initial state to another state. For example, you can bring an electric motor up to speed before you test various control sequences.

You can save the model operating point when the system transitions from the startup phase and use this operating point as the initial state for future simulations. This technique does not improve simulation speed, but it can reduce total simulation time for consecutive runs because the startup phase needs to be simulated only once. For more information, see “Use Model Operating Point for Faster Simulation Workflow” on page 27-43

## Understanding Total Time and Self Time in Profiler Reports

The Simulink Profiler displays the performance of the components of your model and their simulation phases. Each row of the Profiler Report pane presents the following information:

- **Path**
- **Time Plot (Dark Band = Self Time)**
- **Total Time (s)**
- **Self Time (s)**
- **Number of Calls**

An indicator of the model's performance is the number of times a block is called in conjunction with the time taken by each call. For a model component with any level of hierarchy, it is useful to know how much of its total execution time is taken up by its constituent blocks vis-a-vis the time taken by its own execution, or self-time.

Use the **Total Time(s)** information to identify subsystems or referenced models that are expensive to run within the current model. As subsystems and model references typically correspond to high-level

conceptual entities such as physical models and algorithms, you can identify which component of your model is slowing down overall performance.

The graphic below shows part of the Profiler Report pane for the `sldemo_fuelsys_dd` model.

- 1 To begin, recursively expand the hierarchy of the Engine Gas Dynamics subsystem. For the Throttle subsystem, tally the total time of its constituents (from threshold=0.5 to Sonic Flow), highlighted in red. Observe that the sum of their execution times, along with the self time for Throttle block, is the total time of the Throttle block, shown in yellow.
- 2 Collapse the Throttle row of the hierarchy. Repeat the previous step for the contents of the Throttle & Manifold subsystem—which is highlighted in yellow—and then the Engine Gas Dynamics subsystem.

Component	Self Time	Total Time
sldemo_fuelsys_dd	47.126	13.354
Engine Gas Dynamics	18.284	2.911
Throttle & Manifold	8.025	0.000
Throttle	5.652	0.000
threshold = 0.5	1.382	1.382
f(theta)	1.257	1.257
MinMax	1.128	1.128
g(pratio)	1.039	1.039
Product	0.211	0.211
Sum	0.202	0.202
Product1	0.178	0.178
Product2	0.142	0.142
direction	0.115	0.115
Sonic Flow	0.000	0.000
Intake Manifold	1.870	0.000
Limit to Positive	0.502	0.502
Atmospheric Pressure, Pa (bar)	0.000	0.000
Mixing & Combustion	3.738	0.000
sldemo_fuelsys_dd_plant	3.610	3.610

# Performance Advisor

---

- “Improve Simulation Performance Using Performance Advisor” on page 35-2
- “Perform a Quick Scan Diagnosis” on page 35-11
- “Improve vdp Model Performance” on page 35-12

## Improve Simulation Performance Using Performance Advisor

In this section...
“Performance Advisor Workflow” on page 35-2
“Prepare Your Model” on page 35-3
“Create a Performance Advisor Baseline Measurement” on page 35-4
“Run Performance Advisor Checks” on page 35-5
“View and Respond to Results” on page 35-6
“View and Save Performance Advisor Reports” on page 35-8

Whatever the level of complexity of your model, you can make systematic changes that improve simulation performance. Performance Advisor checks for configuration settings that slow down your model simulations. It produces a report that lists the suboptimal conditions or settings it finds and suggests better configuration settings where appropriate.

You can use the Performance Advisor to fix some of these suboptimal conditions automatically or you can fix them manually.

---

**Note** Use Performance Advisor on top models. Performance Advisor does not traverse referenced models or library links.

---

To learn about faster simulation using acceleration modes, see “Acceleration”.

### Performance Advisor Workflow

When the performance of a model is slower than expected, use Performance Advisor to help identify and resolve bottlenecks.

- 1 Prepare your model.
- 2 Create a baseline to compare measurements against.
- 3 Select the checks you want to run.
- 4 Run Performance Advisor with the selected checks and see recommended changes.
- 5 Make changes to the model. You can either:
  - Automatically apply changes.
  - Generate advice, and review and apply changes manually.
- 6 After applying changes, Performance Advisor performs a final validation of the model to see how performance has improved.
  - If the performance improves, the selected checks were successful. The performance check is complete.
  - If the performance is worse than the baseline, Performance Advisor reinstates the previous settings of the model.
- 7 Save your model.

---

**Caution** Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

---

## Prepare Your Model

Before running checks using Performance Advisor, complete the following steps:

- “Start Performance Advisor” on page 35-3
- “Enable Data Logging for the Model” on page 35-3
- “Select How Performance Advisor Applies Advice” on page 35-3
- “Select Validation Actions for the Advice” on page 35-4
- “Specify Runtime for Performance Advisor” on page 35-4

### Start Performance Advisor

To get started with Performance Advisor:

- 1 Make a backup of the model.
- 2 Verify that the model can simulate without error.
- 3 Close all applications, including web browsers. Leave only the MATLAB Command Window, the model you want to analyze, and Performance Advisor running.

Running other applications can hinder the performance of model simulation and the ability of Performance Advisor to measure accurately.

- 4 Open Performance Advisor. In the Simulink Editor, on the **Debug** tab, click **Performance Advisor**.

### Enable Data Logging for the Model

Make sure the model configuration parameters are set to enable data logging.

- 1 In the model, on the **Modeling** tab, click **Model Settings**.
- 2 In the Configuration Parameters dialog box, in the left pane, select **Data Import/Export**.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log** and select the signals to log.

---

**Note** Select only the signals you are most interested in. Minimizing the number of signals to log can help performance. Selecting too many signals can cause Performance Advisor to run for a longer time.

---

- 5 Click **OK** in the Configuration Parameters dialog box.
- 6 Run the model once to make sure that the simulation is successful.

### Select How Performance Advisor Applies Advice

Choose from these options to apply advice to the model:

- **Use check parameters.** Select the checks for which you want Performance Advisor to automatically apply advice. You can review the remaining checks and apply advice manually.

- **Automatically for all checks.** Performance Advisor automatically applies advice to all selected checks.
- **Generate advice only.** Review advice for each check and apply changes manually.

### Select Validation Actions for the Advice

For the checks you want to run, validate an improvement in simulation time and accuracy by comparing against a baseline measurement. Each validation action requires the model to simulate. Use these validation options as global settings for the checks you select:

- **Use check parameters.** From the checks you want to run, select the ones for which you want to validate an improvement in performance. Specify validation action for fixes using individual settings for these checks.
- **For all checks.** Performance Advisor automatically validates an improvement in performance for the checks you select.
- **Do not validate.** Performance Advisor does not validate an improvement in performance. Instead, you can validate manually. When you select this option and also specify for Performance Advisor to apply advice automatically, a warning appears before Performance Advisor applies changes without validation.

These global settings for validation apply to all checks in the left pane except the Final Validation check. The Final Validation check validates the overall performance improvement in a model after you have applied changes. In case you do not want to validate changes resulting from other check results, you can run the Final Validation check to validate model changes for simulation time and accuracy.

### Specify Runtime for Performance Advisor

You can specify a **Time Out** value in minutes if you want to limit the runtime duration of Performance Advisor. Use this option when running Performance Advisor on models with long simulation times.

If Performance Advisor times out before completing the checks you specify, in the left pane you can see the checks that failed.

## Create a Performance Advisor Baseline Measurement

A baseline measurement is a set of simulation measurements that Performance Advisor measures check results against.

---

**Note** Before creating a baseline measurement, set the model configuration parameters to enable data logging. For more information, see “Enable Data Logging for the Model” on page 35-12.

---

- 1 In the model, select **Performance Tools > Performance Advisor** to start Performance Advisor.
- 2 In the left pane, in the Baseline folder, select **Create Baseline**.
- 3 In the right pane, under **Input Parameters**, enter a value in the **Stop Time** field for the baseline.

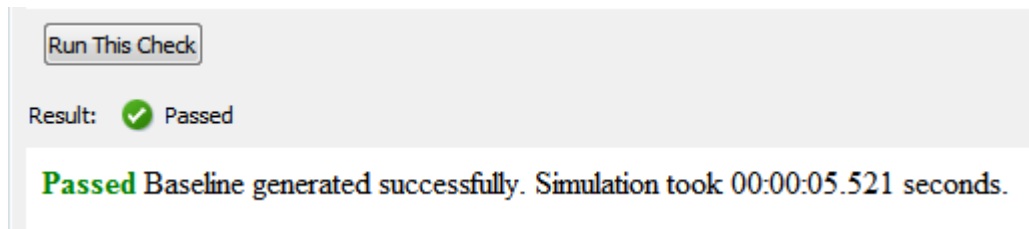

When you enter a Stop Time value in Performance Advisor, this overrides the value set in the model. A large stop time can create a simulation that runs longer.

If you do not enter a value, Performance Advisor uses values from the model. Performance Advisor uses values from the model that are less than 10. Performance Advisor rounds values from the model larger than 10 to 10.

- 4 Select the **Check to view baseline signals and set their tolerances** check box to start the Simulation Data Inspector after Performance Advisor runs a check. Using the Simulation Data Inspector, you can compare signals and adjust tolerance levels.
- 5 Click **Run This Check**.

When a baseline has been created, a message like the following appears under **Analysis**:

After the baseline has been created, you can run Performance Advisor checks.

## Run Performance Advisor Checks

- 1 After you have created a baseline measurement, select checks to run.
  - In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
  - In the folder, select the checks you want to run using the check boxes.

**Tip** If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- 2 Specify input parameters for selected checks. Use one of these methods:
  - Apply global settings to all checks to take action, validate simulation time and validate simulation accuracy.
  - Alternatively, for each check, in the right pane, specify input parameters.

Input Parameter	Description
<b>Take action based on advice</b>	automatically — Allow Performance Advisor to automatically make the change for you.  manually — Review the change first. Then manually make the change or accept Performance Advisor recommendations.
<b>Validate and revert changes if time of simulation increases</b>	Select this check box to have Performance Advisor rerun the simulation and verify that the change made based on the advice improves simulation time. If the change does not improve simulation time, Performance Advisor reverts the changes.

Input Parameter	Description
<b>Validate and revert changes if degree of accuracy is greater than tolerance</b>	Select this check box to have Performance Advisor rerun the simulation and verify that, after the change, the model results are still within tolerance. If the result is outside tolerance, Performance Advisor reverts the changes.
<b>Quick estimation of model build time</b>	Select this check box to have Performance Advisor use the number of blocks of a referenced model to estimate model build time.

- 3 To run a single check, click **Run This Check** from the settings for the check. Performance Advisor displays the results in the right pane.

You can also select multiple checks from the left pane and click **Run Selected Checks** from the right pane. Select **Show report after run** to display the results of the checks after they run.

- 4 To limit the run time of Performance Advisor, specify a **Time Out** value in minutes. Use this option for models with long simulation times. The default setting for this option is 60 minutes.

---

**Note** The **Time Out** setting does not apply to a Quick Scan diagnosis.

---

Performance Advisor also generates an HTML report of the current check results and actions in a file with a name in the form *model\_name\report\_#.html*

To view this report in a separate window, click the **Report** link in the right pane.

---

**Note** If you rename a system, you must restart Performance Advisor to check that system.

---

## View and Respond to Results

After you run checks with Performance Advisor, the right pane shows the results:

**Identify simulation target settings**

**Analysis**

Disabling simulation target settings, such as 'Echo expression without semicolons', can improve simulation speed.

Input Parameters

Take action based on advice:

Validate and revert changes if time of simulation increases

Validate and revert changes if degree of accuracy is greater than tolerance

Result: Warning

The simulation target setting 'Echo expressions without semicolons' is enabled. Disabling this setting might improve simulation speed. Review the following settings in the Model Configuration of model 'vdp'.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
	<a href="#">Simulation Target &gt; Echo expressions without semicolons</a>	on	off

**Action**

Review the action results

Result:

Summary of performance validations			
	Before this check	After this check	Improvement
<b>Performance</b>			
<b>Accuracy</b>	Within given tolerance	Within given tolerance <a href="#">Click to view</a>	
<b>Simulation Time</b>	00:00:34.970	00:00:02.036	94.18%

To view the results of a check, in the left pane, select the check you ran. The right pane updates with the results of the check. This pane has two sections.

The **Analysis** section contains:

- Information about the check
- Option to run the simulation
- Settings to take action based on advice from Performance Advisor
- Result of the check (Passed, Failed or Warning)

The **Action** section contains:

- A setting to manually accept all recommendations for the check
- Summary of actions taken based on the recommendations for the check

### Respond to Results

Use the **Take action based on advice** parameter in the **Analysis** section to select how to respond to changes that Performance Advisor suggests.

Value	Response
automatically	<ul style="list-style-type: none"> <li>Performance Advisor makes the change for you.</li> <li>You can evaluate the changes using the links in the summary table.</li> <li>The <b>Modify All</b> button in the <b>Action</b> section is grayed out since Performance Advisor has already made all recommended changes for you.</li> </ul>
manually	<ul style="list-style-type: none"> <li>Performance Advisor does not make the change for you.</li> <li>The links in the summary table show recommendations.</li> <li>Use the <b>Modify All</b> button in the <b>Action</b> section to implement all recommendations after reviewing them. Depending on how you set your validation input parameters before you ran the check, the button label can change to <b>Modify All and Validate</b>.</li> </ul>

## Review Actions

The **Action** section contains a summary of the actions that Performance Advisor took based on the **Input Parameters** setting. If the tool also performed validation actions, this section lists the results in a summary table. If performance has not improved, Performance Advisor reports that it reinstated the model to the settings it had before the check ran.

Summary of performance validations			
	Before this check	After this check	Improvement
<b>Performance</b>			✓
<b>Accuracy</b>	Within given tolerance	Within given tolerance <a href="#">Click to view</a>	✓
<b>Simulation Time</b>	00:00:04.276	00:00:02.412	43.59%

Severity	Description
✓	The actions succeeded. The table lists the percentage of improvement.
✗	The actions failed. For example, if Performance Advisor cannot make a recommended change, it flags it as failed. It also flags a check as failed if performance did not improve and reinstates the model to the settings it had before the check ran.

**Caution** Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

## View and Save Performance Advisor Reports

When Performance Advisor runs checks, it generates HTML reports of the results. To view a report, select a folder in the left pane and click the link in the **Report** box in the right pane.

As you run checks, Performance Advisor updates the reports with the latest information for each check in the folder. Time stamps indicate when checks ran.

In the pane for global settings, when you select **Show report after run**, Performance Advisor displays a consolidated set of check results in the report.

**Simulink Performance Advisor Report - vdp.slx**

Simulink version: 8.3      Model version: 1.7  
System: vdp      Current run: 24-Oct-2013 06:57:14

**Performance Advisor**

1 Baseline    1 ● 0 ● 0 ▲ 0 □ 0

**Create baseline**  
Passed Baseline generated successfully. Simulation took 00:00:00.580 seconds.

**Input Parameters Selection**

Name	Value
Stop Time	10
Check to view baseline signals and set their tolerances.	false

2 Simulation    2 ● 0 ● 0 ▲ 2 □ 8

2.1 Checks Occurring Before Update    1 ● 0 ● 0 ▲ 2 □ 6

**Identify resource-intensive diagnostic settings**

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Click link(s) to make changes manually. Alternatively, click the 'Modify all' button below to have Performance Advisor take necessary actions for you.

Severity	Diagnostics checked	Original Value	New Value
<span style="color: green;">●</span>	Solver > Diagnostics > Solver data inconsistency	none	none
<span style="color: orange;">▲</span>	Signals > Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
<span style="color: green;">●</span>	Signals > Diagnostics > Data Validity > Division by singular matrix	none	none
<span style="color: green;">●</span>	Signals > Diagnostics > Data Validity > Inf or nan block output	none	none
<span style="color: green;">●</span>	Signals > Diagnostics > Data Validity > Simulation range checking	none	none
<span style="color: green;">●</span>	Signals > Diagnostics > Data Validity > Array bounds exceeded	none	none
<span style="color: orange;">▲</span>	DSM Blocks > Diagnostics > Data Validity > Detect read before write	UseLocalSettings	DisableAll
<span style="color: orange;">▲</span>	DSM Blocks > Diagnostics > Data Validity > Detect write after read	UseLocalSettings	DisableAll

**Input Parameters Selection**

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

You can perform these actions using the Performance Advisor report:

- Use the check boxes under **Filter checks** to view only the checks with the status that you are interested in viewing. For example, to see only the checks that failed or gave warnings, clear the **Passed** and **Not Run** check boxes.
- Perform a keyword search using the search box under **Filter checks**.
- Use the tree of checks under **Navigation** to jump to the category of checks or a specific check result that interests you.
- Expand and collapse content in the right pane of the report to view or hide check results.

Some checks have input parameters that you specify in the right pane of Performance Advisor. For example, **Identify resource intensive diagnostic settings** has several input parameters. When you run checks that have input parameters, Performance Advisor displays the values of the input parameters in the report.

**Identify resource-intensive diagnostic settings**

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
<span style="color: green;">●</span>	Solver > Diagnostics > Solver data inconsistency	none	none
<span style="color: orange;">▲</span>	Signals > Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
<span style="color: green;">●</span>	Signals > Diagnostics > Data Validity > Division by singular matrix	none	none

More (3 rows)

**Input Parameters Selection**

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

## Save Performance Advisor Reports

You can archive a Performance Advisor report by saving it to a new location. Performance Advisor does not update the saved version of a report when you run checks again. Archived reports serve as good points of comparison when you run checks again.

- 1 In the left pane of the Performance Advisor window, select the folder of checks for the report you want to save.
- 2 In the **Report** box, click **Save As**.

- 3 In the **Save As** dialog box, navigate to where you want to save the report, and click **Save**. Performance Advisor saves the report to the new location.

## Perform a Quick Scan Diagnosis

Quick Scan is a fast method to diagnose settings in a model and deliver an approximate analysis of performance. A model can compile and simulate several times during a normal run in Performance Advisor. Quick Scan enables you to review performance issues without compiling or changing the model or validating any fixes. In models with long compile times, use Quick Scan to get a rapid analysis of possible improvements.

When you perform a Quick Scan diagnosis, Performance Advisor

- Does not perform a baseline measurement.
- Does not automatically apply advice to the model.
- Does not validate any changes you make to the model.
- Does not time out if the Quick Scan diagnosis takes longer than the **Time Out** duration you specify.

### Run Quick Scan on a Model

- 1 Select checks to run.

---

**Tip** If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

---

- In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
  - In the folder, select the checks you want to run using the check boxes.
- 2 Select the **Show report after run** check box to display the results of the checks after they run.
  - 3 Click **Quick Scan** on the right pane.

### Checks in Quick Scan Mode

- “Identify resource-intensive diagnostic settings”
- “Check optimization settings”
- “Identify inefficient lookup table blocks”
- “Check MATLAB System block simulation mode”
- “Identify Interpreted MATLAB Function blocks”
- “Identify simulation target settings”
- “Check model reference rebuild setting”

## Improve vdp Model Performance

### In this section...

“Enable Data Logging for the Model” on page 35-12  
 “Create Baseline” on page 35-12  
 “Select Checks and Run” on page 35-13  
 “Review Results” on page 35-13  
 “Apply Advice and Validate Manually” on page 35-15

This example shows you how to run Performance Advisor on the vdp model, review advice, and make changes to improve performance.

### Enable Data Logging for the Model

- 1 In the vdp model, on the **Modeling** tab, click **Model Settings**.
- 2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log**.
- 5 To select signals to log, select a signal in vdp. Right click and select **Properties**.
- 6 In the Signal Properties dialog box, check the **Log signal data** option and click **OK**.
- 7 Click **OK** in the Configuration Parameters dialog box.
- 8 Run the model once to make sure that the simulation is successful.

### Create Baseline

- 1 Open Performance Advisor. In the vdp model, on the **Debug** tab, click **Performance Advisor**.
- 2 In the right pane, under **Set Up**, select a global setting for **Take Action**. To automatically apply advice to the model, select **automatically for all checks**.
- 3 Select global settings to validate any improvements in simulation time and accuracy after applying advice. To select the default setting for validation, for **Validate simulation time** and **Validate simulation accuracy**, select **use check parameters**.

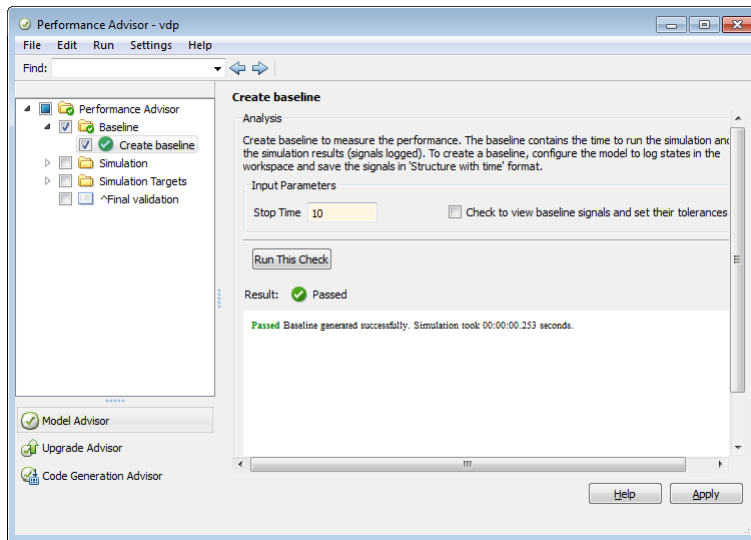

---

**Note** To validate any improvements automatically, change the global settings to **For all checks**. However, this can increase simulation time as validating all checks requires more simulation runs.

---

- 4 Select **Show report after run**. This opens an HTML report of check results.
- 5 In the left pane, select the **Create baseline** check. Clear the other checks.
- 6 In the **Create baseline** pane, set **Stop Time** to 10. Click **Apply**.
- 7 Click **Run This Check**. The right pane updates to show that the baseline was created successfully.

## Select Checks and Run

**Note** The global input parameters to take action and validate improvement apply to all the checks you select.

- 1 In the left pane, clear the baseline check. Select these checks:
  - In **Simulation > Checks Occurring Before Update**, select **Identify resource-intensive diagnostic settings**.
  - In **Simulation > Checks that Require Update Diagram**, select **Check model reference parallel build**.
  - In **Simulation Targets > Check Compiler Optimization Settings**, select **Select compiler optimizations on or off**.
  - Select **Final validation**.
- 2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to automatically, a result of **Take Action** being set to automatically for all checks.
- 3 Select a value for **Time Out** if you want to limit the runtime duration of Performance Advisor.
- 4 Click **Run Selected Checks**.

Performance Advisor runs the checks you selected and opens an HTML report with check results.

## Review Results

- 1 In the HTML report, filter the results to see only the checks that passed.

Simulink Performance Advisor Report - vdp.slx

Simulink version: 8.3  
System: vdp  
Treat as Referenced Model: off

Performance Advisor

- 1 Baseline 0 Passed 0 Failed 0 Warning 1 Not Run
- 2 Simulation 1 Passed 0 Failed 1 Warning 10 Not Run
  - 2.1 Checks Occurring Before Update 0 Passed 0 Failed 1 Warning 8 Not Run
  - 2.2 Checks that Require Update Diagram 1 Passed 0 Failed 0 Warning 1 Not Run
  - 2.3 Checks that Require Simulation to Run 0 Passed 0 Failed 0 Warning 1 Not Run
- 3 Simulation Targets 1 Passed 0 Failed 0 Warning 1 Not Run
  - 3.1 Check Simulation Modes Settings 0 Passed 0 Failed 0 Warning 1 Not Run
  - 3.2 Check Compiler Optimization Settings 1 Passed 0 Failed 0 Warning 0 Not Run

Final validation 1 Passed 0 Failed 0 Warning 0 Not Run

All of the selected checks passed successfully.

- Navigate to the results for a particular check, for example **Check model reference parallel build**. Use the navigation tree in the left pane or scroll to the results for this check in the right pane.
- Performance Advisor gives you information about this check, advice for performance improvement, as well as a list of related model configuration parameters.

✓ **Check model reference parallel build**

**Passed**

There are less than two reference models in your model. Parallel building is unnecessary. However, consider using model reference for large models. Use more than one model reference to take advantage of parallel building.

*Input Parameters Selection*

Name	Value
Quick estimation of model build time	true
Parallel build overhead time estimation factor	0.5

- Filter the results to display warnings. See results for the **Identify resource-intensive diagnostic settings** check.

Performance Advisor identified diagnostic settings that incur runtime overhead during simulation. It modified values for some of these diagnostics. A table in the report shows the diagnostics checked and whether Performance Advisor suggested a change to the value.

If the performance of the model improved, the HTML report gives you information about this improvement. If the performance has deteriorated, Performance Advisor discards all changes and reinstates the original settings in the model.

- See details for the **Final Validation** check.

✔ Final validation

Summary of performance validations			
Performance	Before this check	After this check	Improvement
Accuracy	Within given tolerance	Within given tolerance <a href="#">Click to view</a>	✔
Simulation Time	00:00:00.253	00:00:00.100	60.38%

**Passed**

Overall, Performance advisor has improved the performance of the model.

*Input Parameters Selection*

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

This check validates the overall performance improvement in the model. The check results show changes in simulation time and accuracy, depending on whether performance improved or degraded.

## Apply Advice and Validate Manually

Generate advice for a check, apply it, and validate any improvements manually.

- 1 In the left pane, click **Performance Advisor**. Select these settings and click **Apply**:
  - Set **Take Action** to generate advice only.
  - Set **Validate simulation time** to use check parameters.
  - Set **Validate simulation accuracy** to use check parameters.
- 2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to manually, a result of **Take Action** being set to generate advice only.
- 3 Select **Performance Advisor** in the left pane. Click **Run Selected Checks** in the Performance Advisor pane.

If the performance of the model has improved, the **Final Validation** check results show the overall performance improvement.

- 4 In the results for **Identify resource-intensive diagnostic settings**, Performance Advisor suggests new values for the diagnostics it checked. Review these results to accept or reject the values it suggests.

Alternatively, click **Modify all and Validate** to accept all changes and validate any improvement in performance.

## Examine Model Dynamics Using Solver Profiler

When model simulation slows down or stops responding, a close examination of the dynamics of the model can help you identify the factors affecting the simulation.

Understanding solver behavior enables you to interpret how the model simulates and what causes the solver to take small steps.

The Solver Profiler analyzes a model for patterns that affect its simulation. The Solver Profiler presents graphical and statistical information about the simulation, solver settings, events, and errors. You can use this data to identify locations in the model that caused simulation bottlenecks.

In addition, there are multiple factors that can limit the simulation speed. The Solver Profiler logs and reports all the major events that occur when simulating a model:

- Zero-crossing events
- Solver exception events
- Solver reset events
- Jacobian computation events

---

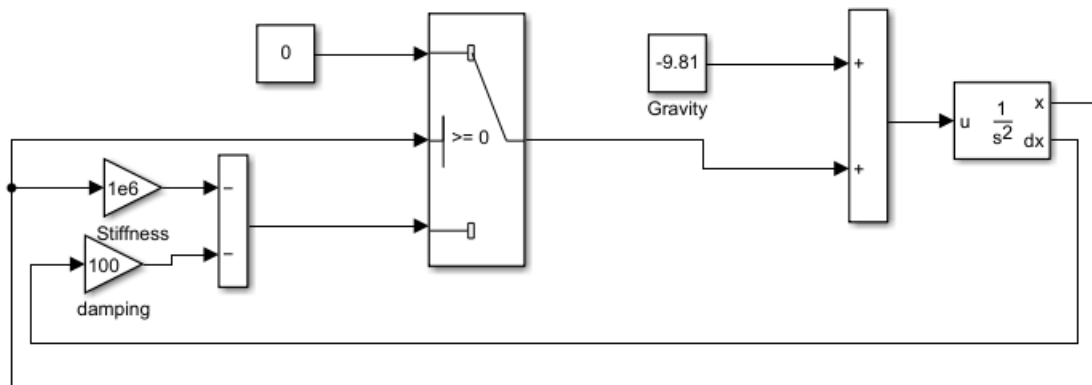

**Note** In order to accurately profile the solver performance, the **Solver Profiler** may temporarily modify some logging settings of your model. Your settings will be restored after profiling has been completed.

---

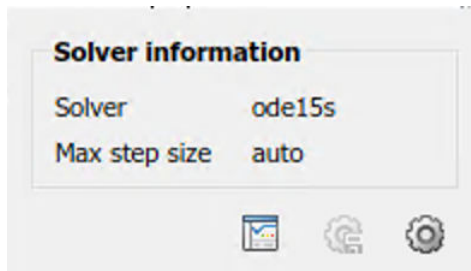

These events are common and necessary for an accurate simulation. However, they do incur computational cost and frequent occurrences can slow down or even stall the simulation.

To examine model dynamics and identify causes that affect the simulation:

- 1 Open the model that is simulating slowly or unsuccessfully. For example, open the `ex_spi_show_zc` model.

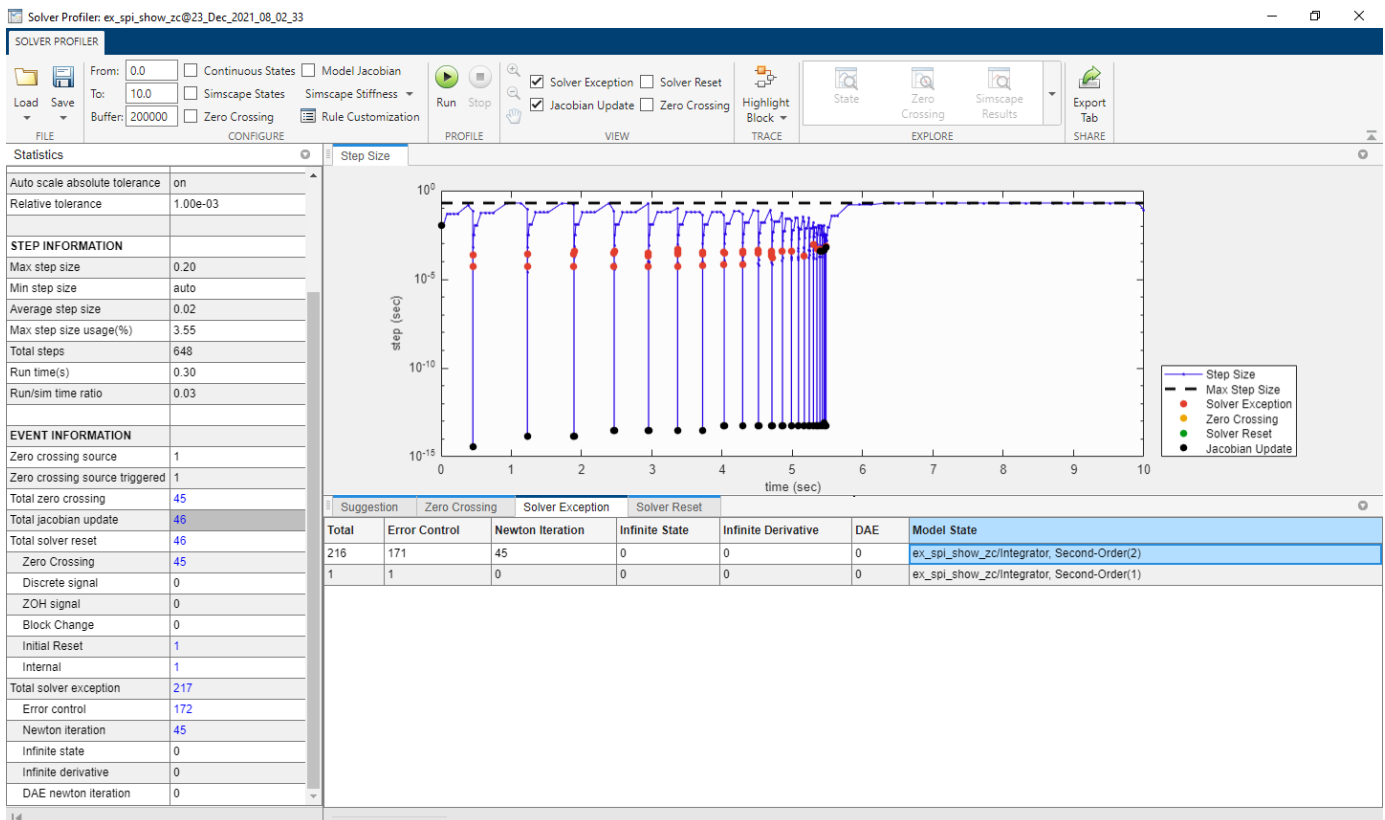

- 2 Open the Solver Profiler by clicking the hyperlink in the lower-right corner of the Simulink Editor.

- 3 The Solver Profiler provides smart logging and diagnostics of continuous model states and Simscape states. To enable this, select the **Continuous States**, **Zero Crossing** or **Simscape States** option before a run. Disable these options only if you are running out of memory. After the run, access the States Explorer, Zero Crossing Explorer, or Simscape Explorer to examine those states.
- 4 Click **Run**. The profiler simulates the model and starts capturing solver performance data.

When the simulation ends, the profiler displays the statistics and exceptions it captured over the duration of the simulation.

**Tip** You can pause or stop the simulation at any time to view the information captured until that point.

- 5 Use the profiler plot to highlight the parts of the model that caused generate the most events.
- 6 Click **Save** to capture your profiling session, or exit without saving.

**See Also**

Solver Profiler | Zero Crossing Explorer | States Explorer | `solverprofiler.profileModel`

## Zero-Crossing Events

The `ex_spi_show_zc` model simulates a ball bouncing on a hard surface.

Select the **Zero Crossing** option in **Configure** section of toolstrip, then click the **Run** button on the Solver Profiler. The model simulates in 648 steps and triggers 45 zero crossing events. To highlight the zero crossing events on the step size plot, click the **Zero Crossing** tab from the **Diagnostics** pane and select the `ex_spi_show_zc/Switch` block that is causing the zero-crossing events. Notice that the zero crossing events are displayed on the **Step Size** plot as yellow dots.

The result indicates that when the ball drops on the hard surface, it bounces 45 times before coming to a stop. The solver resets after each bounce, increasing the computational load. Having many resets improves accuracy at the cost of computation load. Therefore, it is important to know this tradeoff when modeling.

If this modeling construct belonged to a larger model, the Solver Profiler would help you locate it. You could then modify the model to improve solver performance. For example, you can decide to reduce the accuracy of the contact dynamic by increasing the damping factor, which would reduce the number of bounce events. Increasing the damping from 100 to 500 makes the ball bounce only 9 times, allowing the simulation to complete in only 161 steps.

You can observe more details about Zero Crossing events from **Zero Crossing Explorer**. To do this, ensure **Zero Crossing** option from **Configure** is selected before profiling the model. Then click **Zero Crossing** in the **Explore** section of the Solver Profiler toolbar. See Zero Crossing Explorer.

# Solver Exception Events

## Tolerance-Exceeding Events

This example simulates two identical nonlinear spring-damping systems. The two systems have different spring stiffness.

When you run the Solver Profiler on this model, you can see the tolerance-exceeding events in the **Solver Exception** tab.

The result indicates that the stiffer spring causes the solver tolerance to exceed the limit. Typically, model states that change the fastest tend to be closest to the solver tolerance limit.

The solver attempts to take the largest possible steps while optimally trading off between speed and accuracy. Occasionally, this tradeoff causes the solver to take steps that exceed the tolerance limit and forces it to reduce the step size. Exceeding the tolerance limit is not a poor modeling practice in itself. This profiler statistic is not meant to help you reduce tolerance exceeding events to zero.

This statistic can help you identify parts of your model that are close to exceeding the tolerance limit. You can identify model components that change the fastest or are the stiffest. You can decide to retain this model dynamic in the simulation or simplify it to speed up simulation.

The tolerance-exceeding statistic can also help you identify modeling errors. If you do not expect the highlighted states to change as fast, you can examine your model for errors. In this example, the modeling error could be that the stiffness of the stiffer spring is specified in N/m instead of N/mm. This error makes the spring 1000 times stiffer than expected.

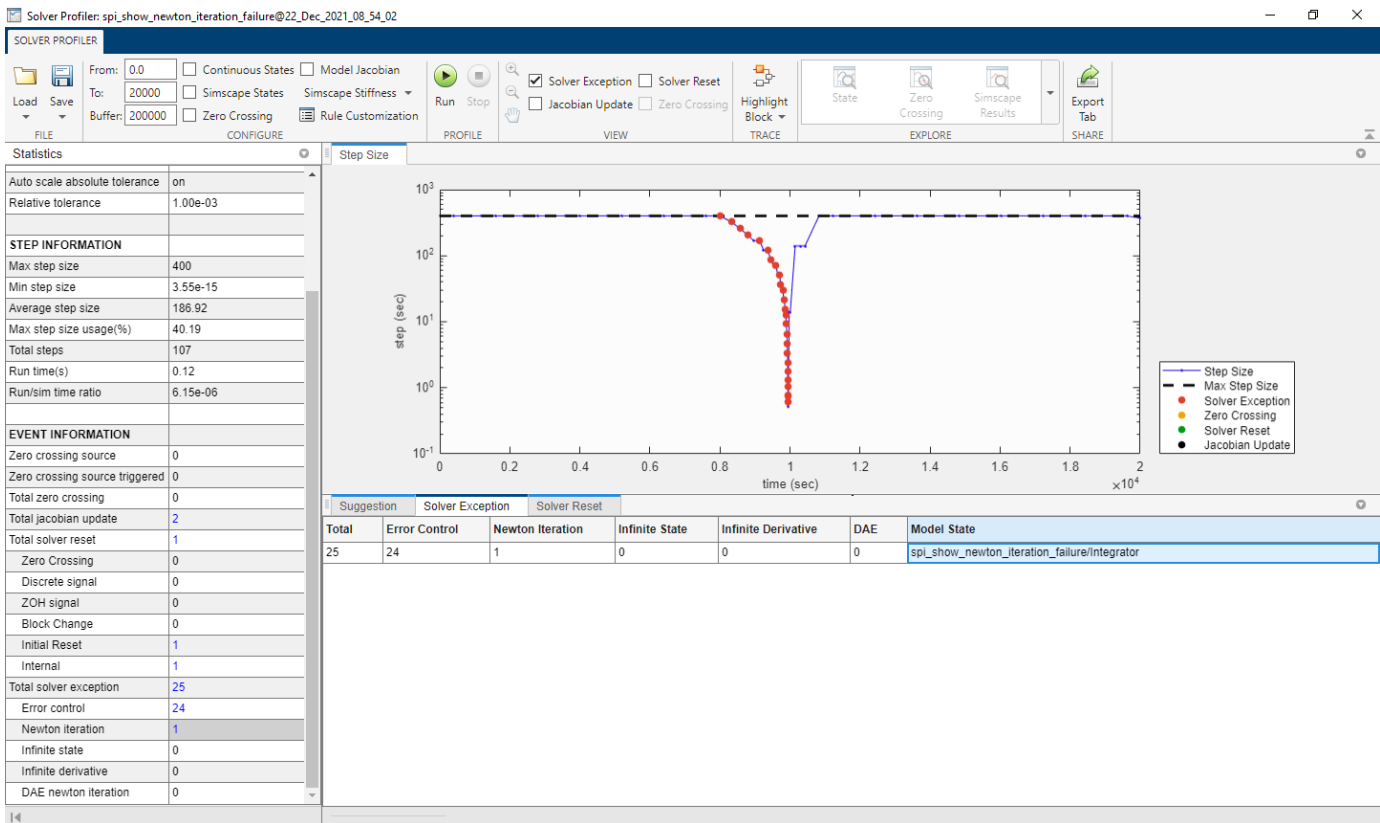

## Newton Iteration Failures

Newton iteration failures are specific to implicit solvers like `ode15s` and `ode23t`, and they result from Newton iterations not converging after a few trials. Similar to tolerance-exceeding events, these failures tend to occur when a system changes quickly.

This example simulates how the radius of a ball of flame changes when you strike a match. The ball of flame grows rapidly until it reaches a critical size, when the amount of oxygen consumed balances the growth in ball surface.

When you run the Solver Profiler on this model, you can see the Newton iteration failures in the **Solver Exception** tab.

The result indicates that when the combustion begins, the solver tolerance is exceeded multiple times. When equilibrium is attained, the system appears different, and a Newton iteration failure occurs. The Jacobian of the system is recomputed, and the solver continues to move forward.

Newton failures are not indicative of poor modeling practices. This profiler statistic is not meant to help you reduce these failures to zero. In this example, you can reduce the solver tolerance to prevent this failure. But the solver then takes small steps unnecessarily, which is counterproductive. Therefore, in this example, this failure is acceptable.

This type of failure becomes problematic when it occurs in large numbers over a short period, especially in Simscape models. Dense failures indicate that your model is not robust numerically. One way to improve numerical robustness is to tighten the solver tolerance. Another way is to modify the model to avoid rapid changes.

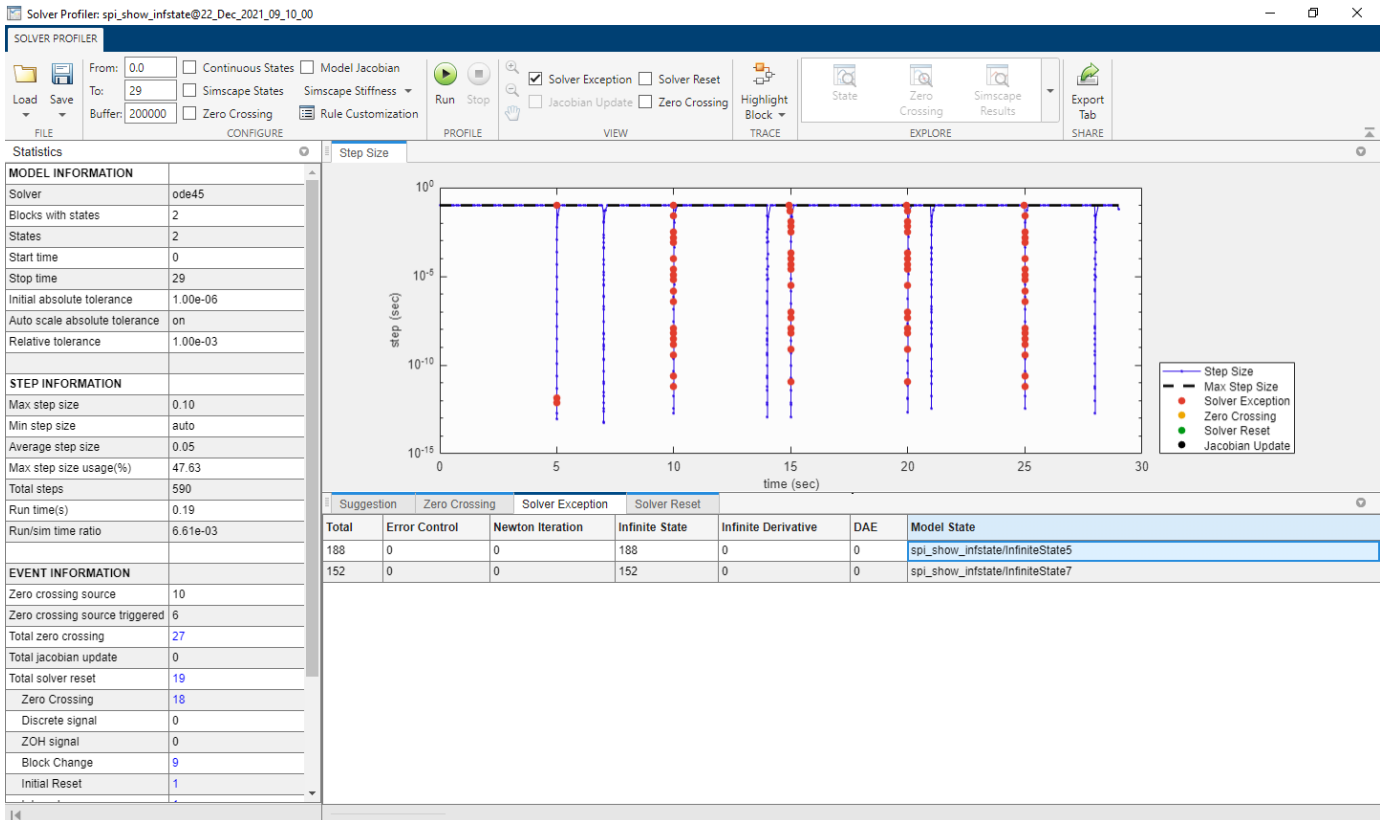

## Infinite State and Infinite Derivative Exceptions

An infinite state exception occurs when the magnitude of a state approaches infinity. Similarly, when the magnitude of the derivative of a state approaches infinity, an infinite derivative exception occurs. The solver reduces the step size and makes another attempt at integration.

This example shows a set of two Integrator Limited blocks that have initial conditions slightly less than  $\text{realmax}$ . As they integrate the Constant input of  $1\text{e}305$ , the solver quickly reaches the infinite state exception.

When you run the Solver Profiler for this model, you can see that the InfiniteState5 and InfiniteState7 blocks have 188 and 152 infinite state exceptions in the **Solver Exceptions** tab.

## Differential Algebraic Equation Failures

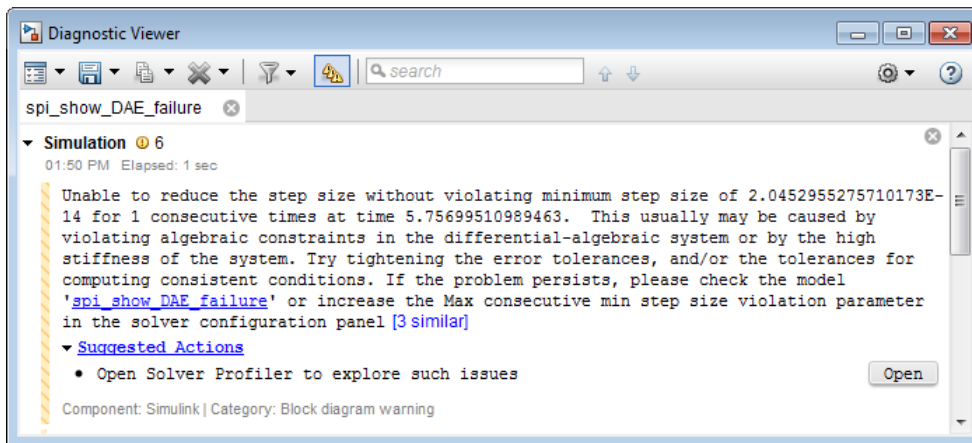

Most Simscape models use differential algebraic equations (DAEs), in contrast to Simulink models, which use ordinary differential equations.

The use of DAEs adds complexity to Simscape models. Solvers like ode15s and ode23t can handle many types of DAEs. However, when the algebraic constraints between Simscape components are complex and changing fast, the Newton iteration process fails to resolve to those constraints.

This example simulates a pressure source that can be directed toward one of two hydraulic chambers.

When you simulate this model, Simulink displays several warnings.

Typically, small models can handle such warnings and simulate to completion. However, this warning indicates that the model is not robust numerically. Minor changes to the model, or integration into a larger model, can result in errors.

When you run the Solver Profiler on this model, you can see the DAE failures in the **Solver Exception** tab.

In this case, the exception results from large solver tolerance. Tightening the solver tolerance forces the solver to take smaller steps and better capture the changes in algebraic constraints.

Alternatively, this exception can be avoided by removing the algebraic constraint. In this example, the **Check Valve** and the **4-Way Directional Valve** are directly connected. When their pressure-flow relationship changes rapidly, the solver is unable to capture the changes. Inserting a **Hydraulic Chamber** between those two components makes them compliant. To learn more about dry nodes, see Simscape documentation.

## Solver Resets

The Solver Profiler logs events that cause the solver to reset its parameters because solver resets do incur computational cost. In addition to the total number of resets, you can also see a breakdown by type of reset event.

---

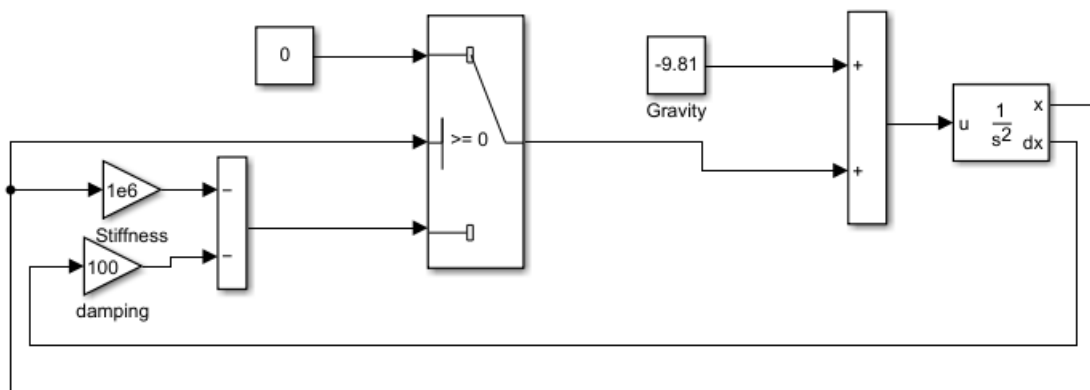

**Note** A solver reset event can have multiple causes. As a result, the number of **Total solver reset** events in the **Statistics** pane may be less than the sum of the solver resets of each type.

---

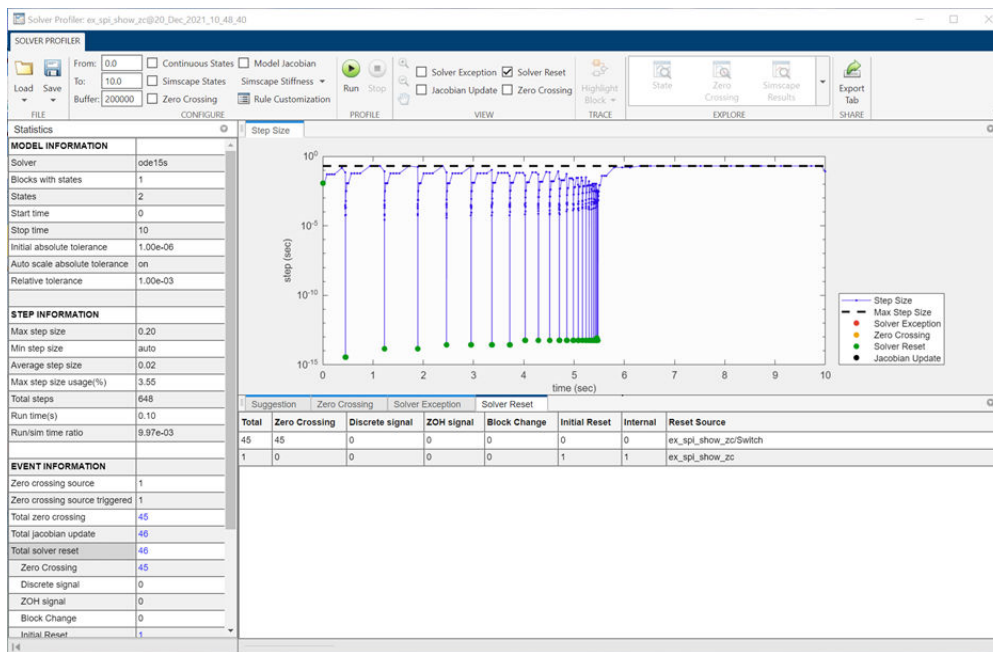

### Zero-Crossing

Some zero crossing events occur at discontinuities in the signal. Consider the example model of a bouncing ball from the “Zero-Crossing Events” on page 36-5 section.

Open the `ex_spi_show_zc` model and launch Solver Profiler.

The Solver Profiler records 46 solver resets, 45 of them are caused by Zero Crossing events from the `ex_spi_show_zc/Switch` block. The solver resets are displayed on the Step Size plot as green dots. Compare the step-size and the **Solver Reset** highlighting with the output  $x$  of the Second-Order Integrator block, which is the height of the ball from the ground. Observe that the solver resets occur when the ball bounces off the ground.

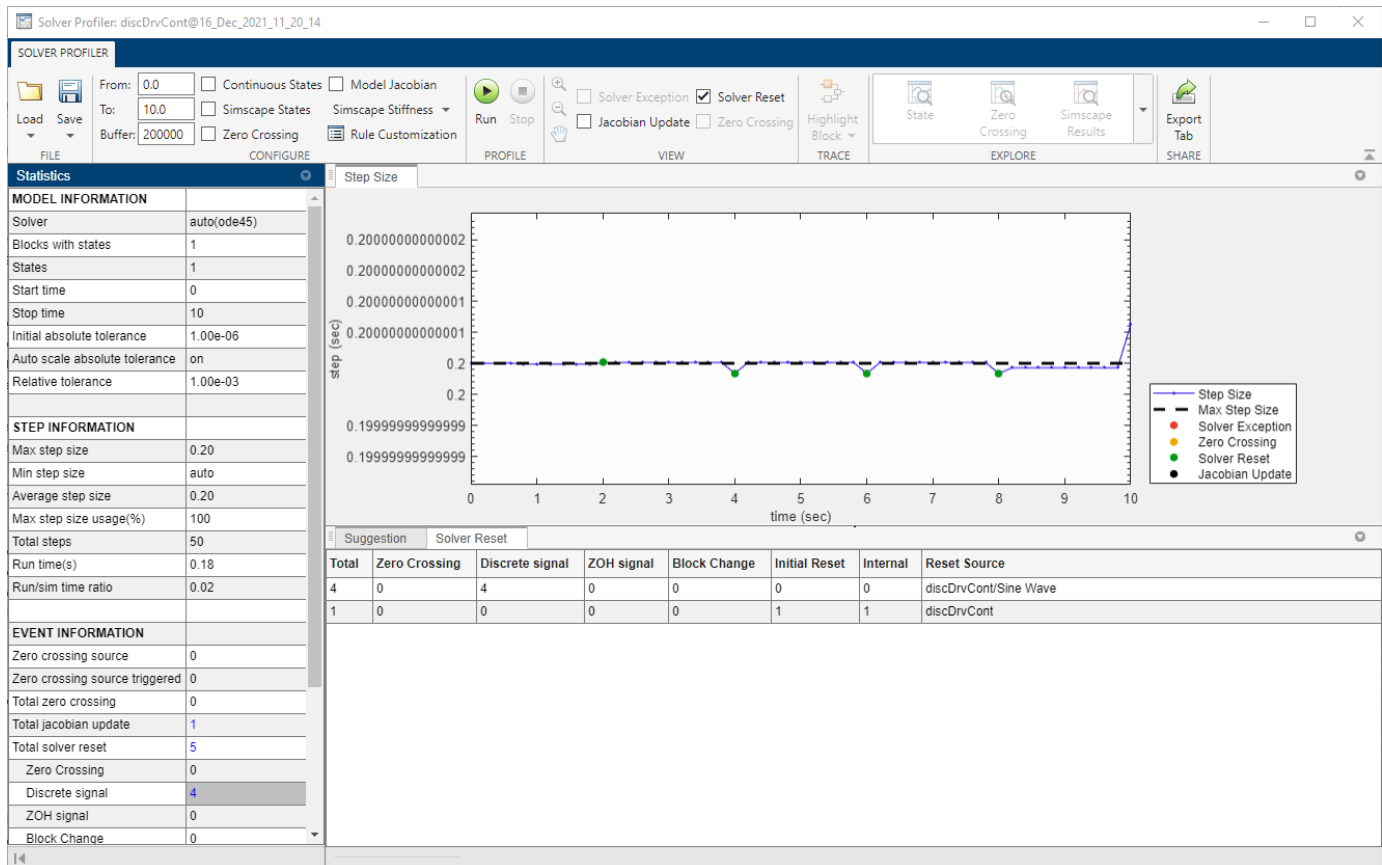

### Discrete Signal

Solver resets also occur when your model has a discrete signal driving a block with continuous states, as seen in this example model.

The discrete Sine Wave block outputs a 1 rad/s sine wave with a discrete sample time  $t_s = 2$ .

The Solver Profiler report shows that four solver resets occur due to discrete signals driving a continuous block. These resets occur at every execution of the Sine Wave block.

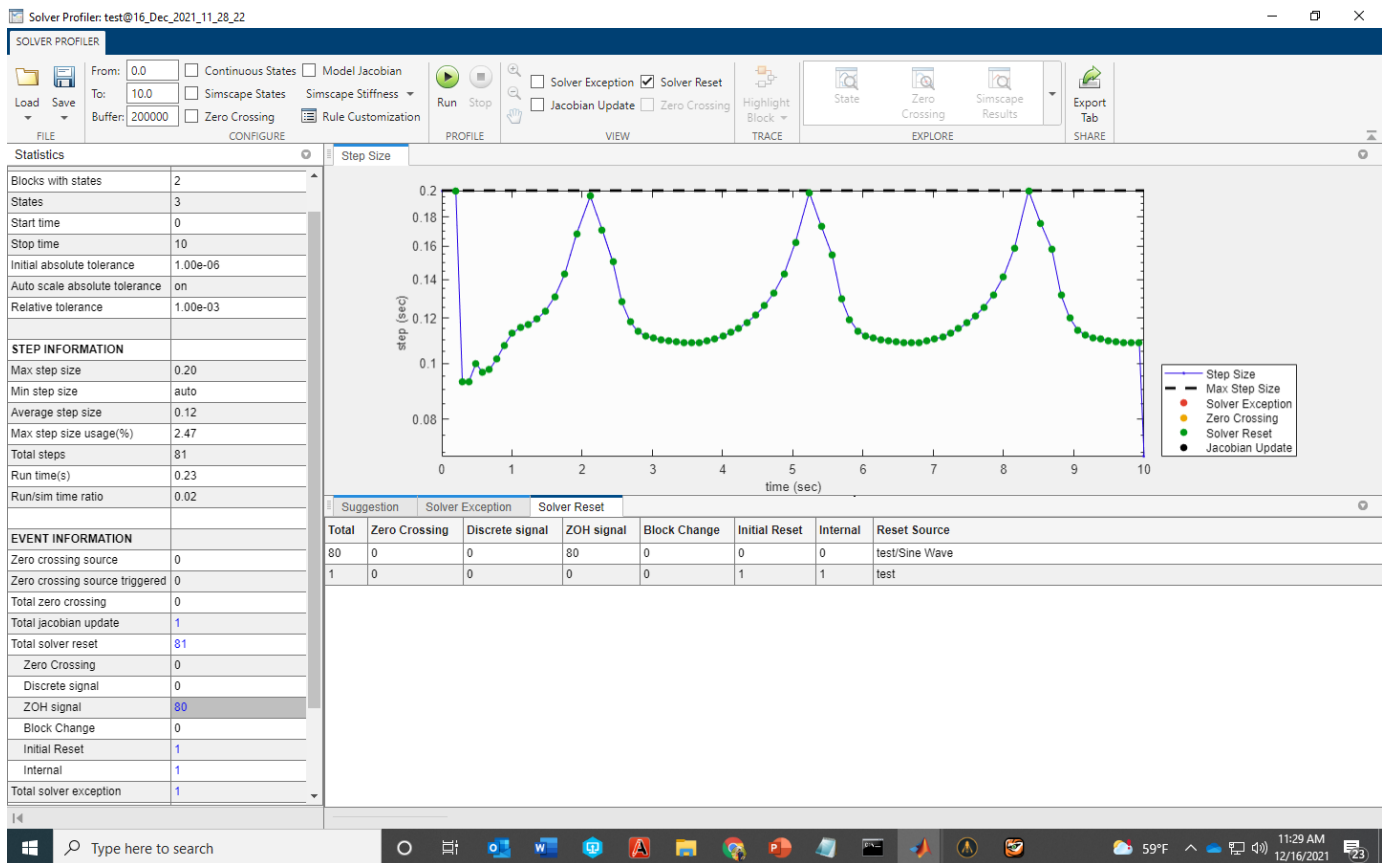

## ZOH Signal

This type of solver reset occurs when a block output is not executed during a trial or minor time step and gets updated only during the integration or major time step. As a result, the block output changes discontinuously from one major time step to the other. As a result the solver resets. See “Fixed-in-Minor-Step” on page 7-21 sample time.

This example model shows a simple plant and controller that tracks a sinusoidal reference signal. The source of this signal is a Sine Wave block whose sample time is specified to be fixed-in-minor-step.

Observe from the results of the profiling session that there are 80 **ZOH Signal** solver resets in the simulation.

**Note** When you select **Continuous States** for logging or enable the SaveStates parameter, the derivative of a continuous block driven by a Fixed-in-Minor-Step signal is NaN.

This is because the driving “Fixed-in-Minor-Step” on page 7-21 block updates its value only at every major time step. The signal driven to the continuous block is therefore discontinuous and the state is non differentiable.

The plot shows the outputs of the Sine Wave and Integrator blocks in the example model.

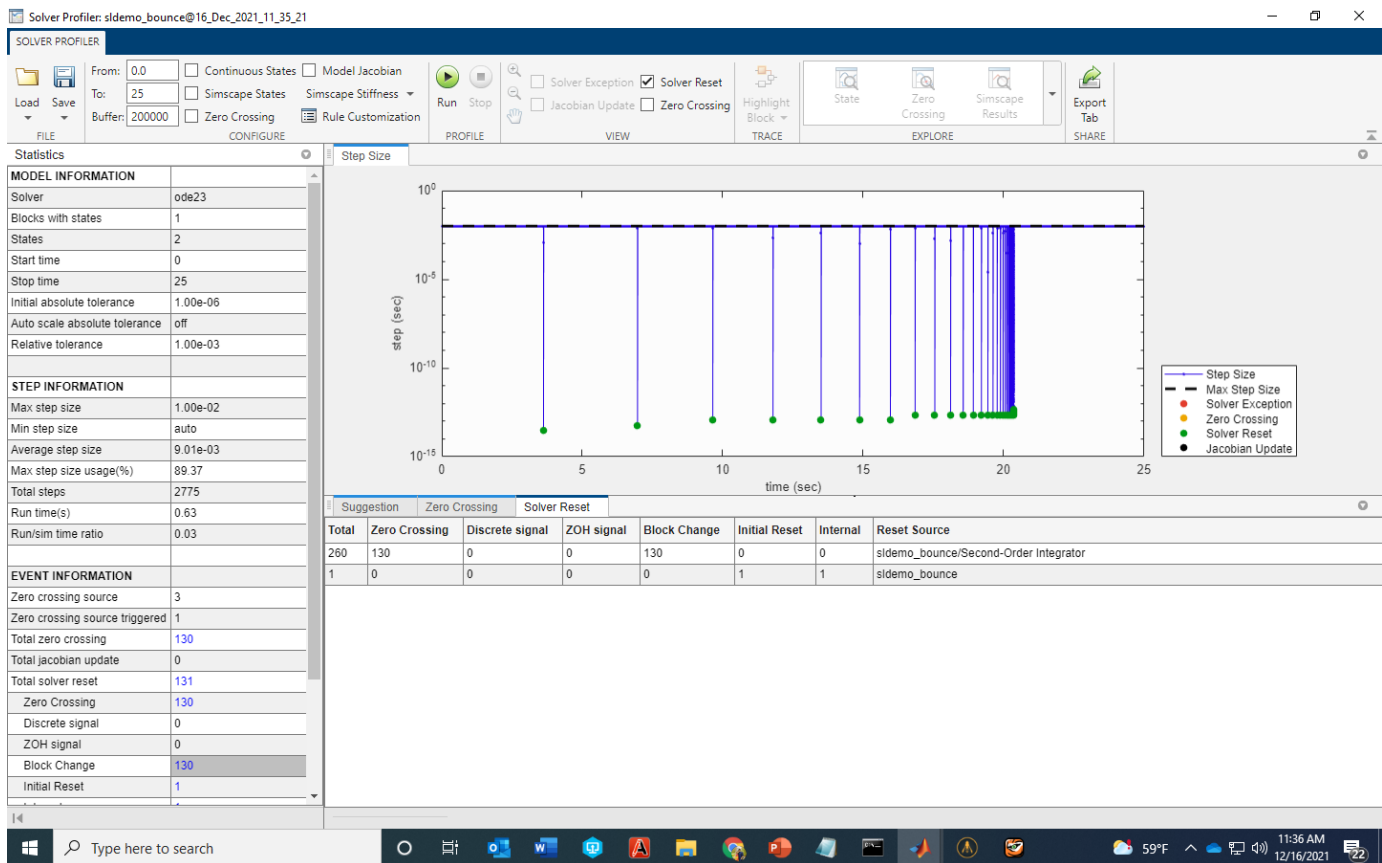

**Tip** Solver resets caused due to ZOH signals are serious compared to solver reset events caused by discrete signals and can significantly slow down the simulation. This is because ZOH signal reset events occur at every major step of the solver. Reconfigure your simulation to avoid these resets, if needed.

## Block Signal

Sometimes, the block can be configured to reset the solver when certain conditions are satisfied during its execution. Consider the `sldemo_bouncemodel` of a bouncing ball which can be found in the “Capture the Velocity of a Bouncing Ball with the Memory Block” example.

Observe from the profiling results that there are 130 solver resets triggered by a block. A solver reset event can have multiple causes. In this case, zero crossings and block changes cause a solver reset event.

One setting that causes the **Block Change** solver reset event is the **Reinitialize dx/dt when x reaches saturation** parameter. This setting is necessary to properly simulate the dynamics of a bouncing ball.

## Initial Reset

When you run a simulation, the solver needs to reset its parameters for the first time. This event is shown as the **Initial Reset** event in the Solver Profiler report. It occurs once at the start of the simulation.

## Internal

There are some reset events that are internal to the Simulink engine. These reset events are necessary for the engine to correctly configure itself for accurate simulation.

# Jacobian Logging and Analysis

The Solver Profiler supports Jacobian logging and analysis for implicit solvers.

Open the `ssc_pneumatic_actuator` model, click **Debug**, select Solver Profiler from the **Performance Advisor** drop down menu.

You can select the **Model Jacobian** check box in the Solver Profiler to log updates to the Jacobian matrix for the model. When you run the Solver Profiler on a model, you can see the logs in the **Jacobian Analysis** tab. Click **Run** to start simulation.

The **Jacobian Analysis** tab indicates the states in the model that are likely slowing down the solver.

Once the simulation completes, you should be able to find the logs in the **Jacobian Analysis** tab in the Suggestion Pane. The **Jacobian Analysis** tab indicates the states in the model that are likely slowing down the solver.

If you select **Jacobian Update** from the **View** section of the toolbar, you will see that the Jacobian updates are displayed on the **Step Size** plot as black dots.

The log shows 448 Jacobian updates in total. To highlight the target block in the model, select a row of the table in the **Jacobian Analysis** tab and click **Highlight Block**. The information displayed should be helpful to investigate the cause of each limiting state.

## See Also

## Related Examples

- “Examine Model Dynamics Using Solver Profiler” on page 36-2
- “Solver Resets” on page 36-14

- “Zero-Crossing Events” on page 36-5
- “Solver Exception Events” on page 36-7

## Modify Solver Profiler Rules

You can customize the suggestions that appear in the Solver Profiler in these ways:

- Change the thresholds of the Solver Profiler rules that detect failure patterns.
- Select which rules to apply during a profiling run.
- Author your own rule set as a MATLAB script.

### Change Thresholds of Profiler Rules

Click **Rule Customization** in the Solver Profiler to access the rule set. You can change the thresholds for most of these rules and also select which rules you want to apply selectively during a simulation run.

### Develop Profiler Rule Set

You can override the settings on the **Rule Set** dialog box by specifying a custom rule set.

Create a rule set as a MATLAB script and specify the path to the script in the **Custom Rule Set** section of the **Rule Set** dialog box.

A simple rule set example looks as follows:

```
function diagnosticsString = customRule(profilerData)
    if isempty(profilerData.zcEvents)
        diagnosticsString{1} = 'No zero crossing event detected.';
```

```

else
    diagnosticsString{1} = 'Zero-crossing events detected.';
end
end

```

The input to the function is an array of structures called `profilerData`. This array of structures organizes all the information that the Solver Profiler collects during a profiling run. It contains the following substructures.

Substructure	Fields
<code>stateInfo</code> : Stores information on block states	<ul style="list-style-type: none"> <li>• <code>name</code>: Block name</li> <li>• <code>value</code>: State values</li> <li>• <code>blockIdx</code>: Block ID</li> </ul>
<code>blockInfo</code> : Cross-reference of blocks and state IDs	<ul style="list-style-type: none"> <li>• <code>name</code>: Block name</li> <li>• <code>stateIdx</code>: State ID</li> </ul>
<code>zcSrcInfo</code> : Stores information on blocks causing zero crossing events	<ul style="list-style-type: none"> <li>• <code>name</code>: Block name</li> <li>• <code>blockIdx</code>: Block ID</li> </ul>
<code>zcEvents</code> : Cross-reference of the time stamps of zero crossing events and the corresponding state IDs	<ul style="list-style-type: none"> <li>• <code>t</code>: Event timestamp</li> <li>• <code>srcIdx</code>: Block ID</li> </ul>
<code>exceptionEvents</code> : Cross-reference of exception event timestamps, the ID of the corresponding state that caused the event, and the cause.	<ul style="list-style-type: none"> <li>• <code>t</code>: Event timestamp</li> <li>• <code>stateIdx</code>: State ID</li> <li>• <code>cause</code>: Cause of exception</li> </ul>
<code>resetTime</code> : Stores timestamps of solver resets.	None
<code>tout</code> : Stores simulation times.	None

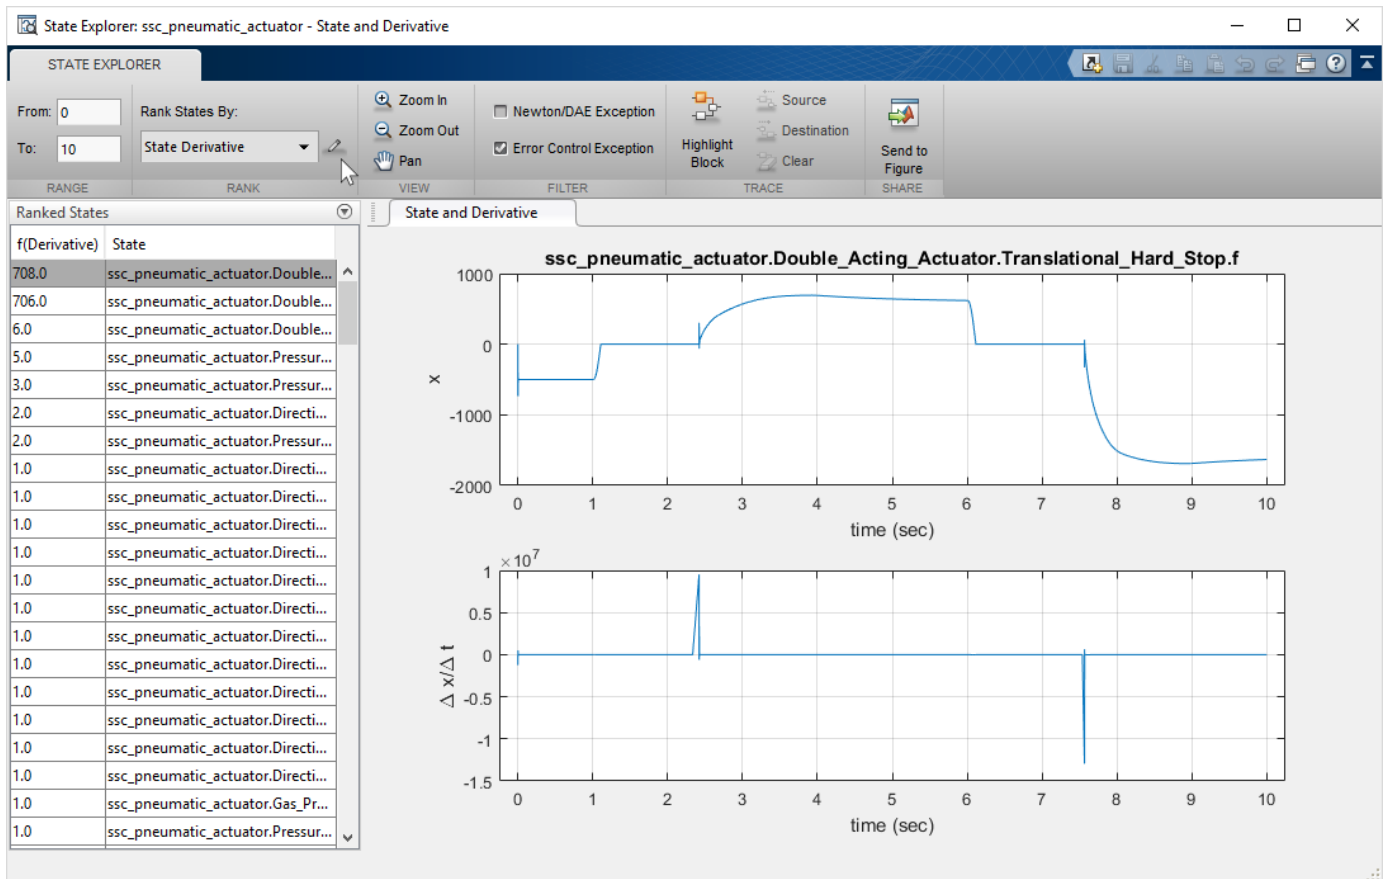

# Customize State Ranking

If you log continuous states in the Solver Profiler, you can open the State Explorer to investigate each continuous state. The State Explorer ranks continuous states by the following metrics:

- State Derivative
- Newton/DAE Exception
- State Value
- Error Control Exception
- State Name
- State Chatter

In addition to these ranking metrics, you can write and upload your own algorithm to determine how continuous states are ranked in the State Explorer.

- 1 Click the edit button next to the **Rank States By** dropdown.

- 2 In the Custom Algorithm dialog box that appears, click **Add** and upload a MATLAB script that contains your ranking algorithm.

A simple algorithm that ranks states by value looks as follows:

**Note** The structures referenced in this example organize information that the Solver Profiler collects during a profiling run. For more information on the structures, see “Develop Profiler Rule Set” on page 36-23.

---

```
function [index,score] = customRank(sd,tl,tr)

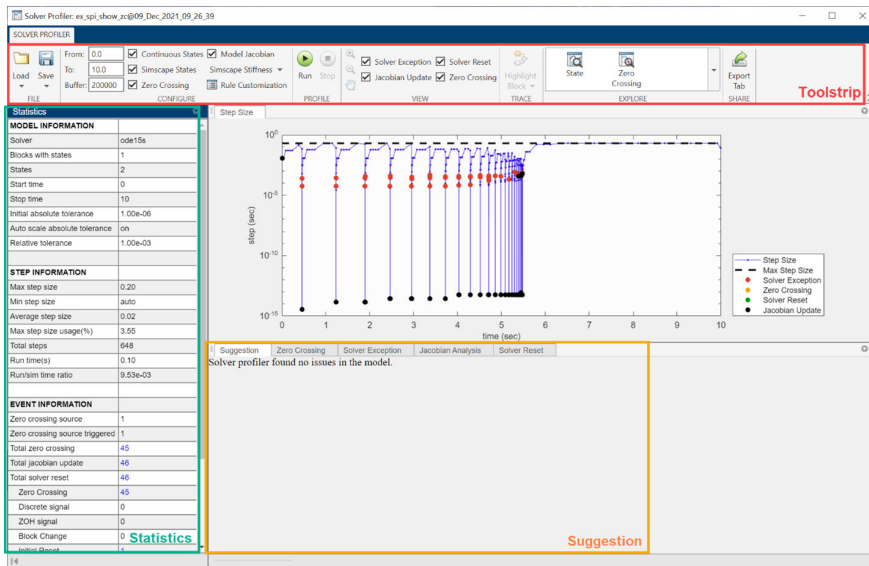

% Allocate storage for index and score list
nStates = length(sd.stateInfo);
index = 1:nStates;
score = zeros(nStates,1);

% Loop through each state to calculate score
for i = 1:nStates
    x = sd.stateInfo(i).value;
    % apply time range constraints
    x = x(sd.tout>=tl & sd.tout<=tr);
    if max(x) > 1
        score(i) = 1;
    else
        score(i) = 0;
    end
end

% Rank the states
[score, order] = sort(score, 'descend');
index = index(order);

end
```

# Solver Profiler Interface

The Solver Profiler enables you to:

- Start a profiling session, save a session, or open a saved session.
- Customize and filter the results displayed.
- Interact with the model and trace and highlight the states that contain exceptions.
- Open Simscape Explorer, Zero Crossing Explorer, or States Explorer to analyze simulation data further.
- Customize profiler suggestions using your own rules.

The Solver Profiler includes four panes. Use these panes to perform these functions.

- **Toolstrip** — Set parameters for the Solver Profiler to log and report events that occurred during simulation.
- **Step Size** — Display step size over simulation time plot. You can also observe maximum step size and events such as Zero Crossing, Solver Reset or Solver Exception from the plot.
- **Statistics** — Display statistical information on solver profiling including model information, step information and event information.
- **Suggestions** — Provide suggestions to improve the performance of the current model. You can also obtain detailed profiling information from other tabs such as **Zero Crossing**, **Solver Exception** or **Solver Reset**.

## Toolstrip

For more information on the Solver Profiler parameters, see "Parameters".

## Statistics Pane

The statistics pane displays information on model parameters, including:

- **Model Information** — Model configurations for the current simulation including Solver type, states, time, tolerance.
- **Step Information**
  - **Average step size** — A measure of how fast the solver advances. It is calculated as the total simulation time divided by the number of steps the solver used. It is bounded by the model configuration parameters **Max step size** and **Min step size**.
  - **Max step size usage** — The percentage of maximum step sizes used by the solver among all step sizes.
- **Event Information**
  - **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-10.
  - **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost. The solver reset statistics are broken down into **Zero Crossing**, **Discrete Signal**, **ZOH Signal**, **Block Change**, **Initial Reset**, and **Internal** solver reset events. For more information, see “Solver Resets” on page 36-14
  - **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
    - **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
    - **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
    - **Infinite state exception** — An event where one or more states solved by the solver are infinite.
    - **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

## Suggestions Pane

The Suggestions pane provides suggestions if issues are detected in the model. It also provides detailed statistic data on events such as Zero Crossing, Solver Exception or Solver Reset. Clicking on these events in the Statistics Pane will bring relevant tabs in the Suggestion Pane to the front. The suggestions and exceptions pane displays information on exceptions, including:

- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-10.

The Suggestions pane shows blocks that experience zero crossing events and number of those events that happened during simulation. To highlight the target block in the model, select the block from Zero Crossing table, then click **Highlight Block** from toolstrip.

- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost. The solver reset statistics are broken down into **Zero Crossing**, **Discrete Signal**, **ZOH Signal**, **Block Change**, **Initial Reset**, and **Internal** solver reset events. For more information, see “Solver Resets” on page 36-14.

The suggestions pane shows detailed statistic data on solver reset events and blocks that caused the solver to reset. To highlight the target block in the model, select the block from Solver Reset table, then click **Highlight Block** from toolbar.

- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.

The suggestions pane shows detailed statistic data on solver exception events and blocks that caused solver exceptions. To highlight the target block in the model, Select the block from Solver Exception table, then click **Highlight Block** from toolbar.

## Simulink Debugger Programmatic Interface

### In this section...

“Controlling the Debugger” on page 37-2

“Method ID” on page 37-2

“Block ID” on page 37-2

“Accessing the MATLAB Workspace” on page 37-2

### Controlling the Debugger

When you run the Simulink debugger programmatically, you control the debugger by entering commands at the debugger command line in the MATLAB Command Window. You must start the debugger programmatically using the `sldebug` function and not using the Simulink Toolstrip. The debugger accepts abbreviations for debugger commands.

---

**Note** You can repeat some commands by entering an empty command (by pressing the **Enter** key).

---

### Method ID

Some of the Simulink debugger commands and messages use method IDs to refer to methods. A method ID is an integer assigned to a method the first time the method is invoked. The debugger assigns method IDs sequentially, starting with 0.

### Block ID

Some of the debugger commands and messages use block IDs to refer to blocks. Block IDs are assigned to blocks while generating the sorted lists for the model during the compilation phase of the simulation. A block ID has the form `sysIdx:blkIdx`, where `sysIdx` is an integer that identifies the system that contains the block and `blkIdx` is the position of the block in the sorted list for the system. For example, the block ID `0:1` refers to the first block in the root system of a model. The `slist` function shows the block ID for each debugged block in the model.

### Accessing the MATLAB Workspace

You can enter any MATLAB expression at the `sldebug` prompt. For example, suppose you are at a breakpoint and you are logging time and output of your model as `tout` and `yout`. The following command creates a plot.

```
(sldebug ...) plot(tout, yout)
```

You cannot display the value of a workspace variable whose name is partially or entirely the same as that of a debugger command by entering it at the debugger command prompt. You can, however, use the `eval` command to work around this problem. For example, use `eval('s')` to determine the value of `s` rather than call the function `step` function.

## Debug Models Using Simulink Debugger

Using the Simulink debugger, you can run a simulation of a model method by method. Using breakpoints, you can stop after each method to examine execution results to trace problems in your model to specific blocks, parameters, or interconnections.

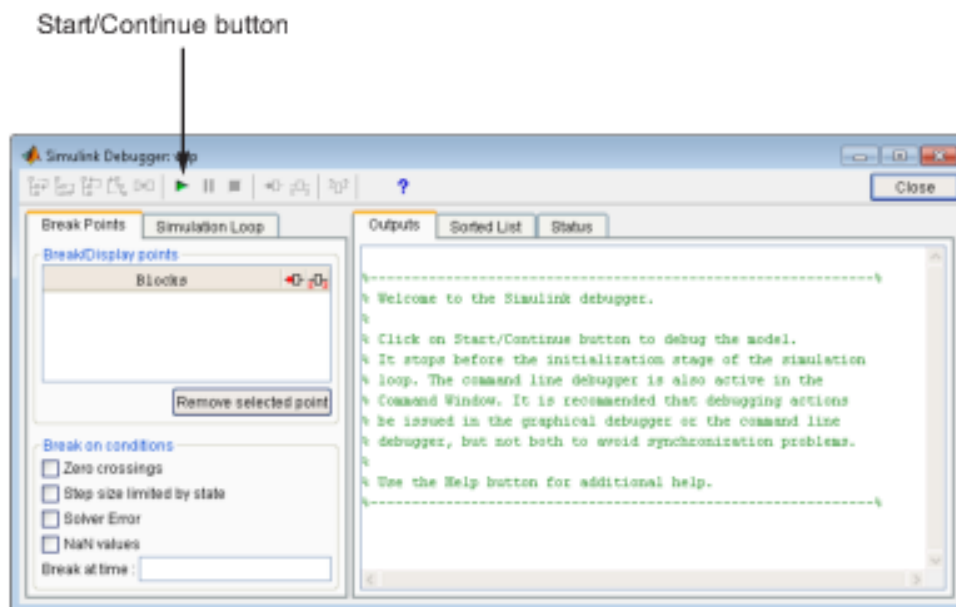

Methods are functions that the Simulink software uses to solve a model at each time step during simulation. Blocks consist of several methods.

The Simulink debugger has a graphical user interface and a programmatic interface. The graphical interface provides the most commonly-used features, and the programmatic interface provides access to additional debugging options. You can only use the Simulink debugger functions after starting a simulation in the debugger using the `sldebug` function.

### Start Simulation from User Interface

To open the Simulink debugger graphical interface, on the **Debug** tab, under **Breakpoints**, click the arrow next to **Breakpoints List** and select **Debug Model**.

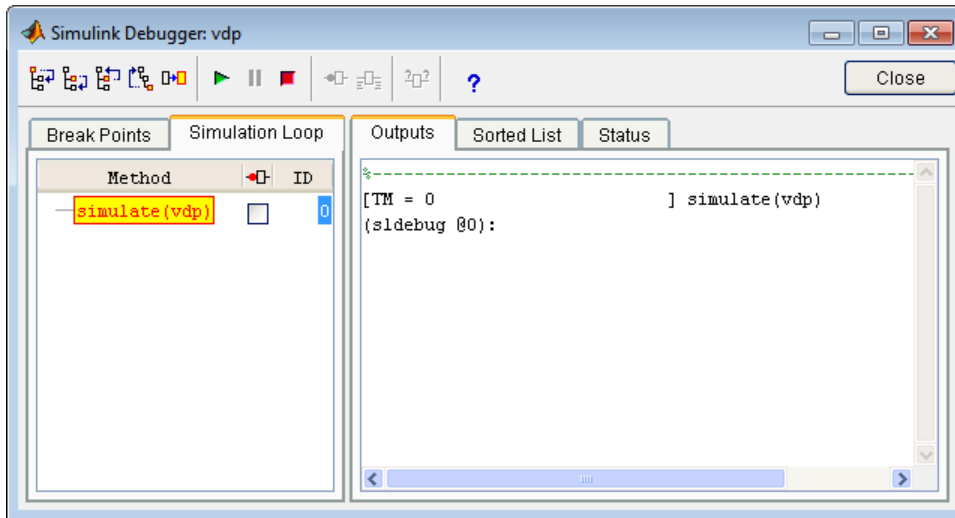

To start the simulation, click the **Start/Continue** button on the Simulink debugger toolbar.

The simulation starts and then stops at the first simulation method that is to be executed. The Simulink debugger displays the name of the method in its **Simulation Loop** pane. At this point, you can:

- Set breakpoints
- Run the simulation step by step
- Continue the simulation to the next breakpoint or end
- Examine data
- Perform other debugging tasks

The Simulink debugger displays the name of the method in the **Simulation Loop** pane.

The following sections explain how to use the debugger controls to perform these debugging tasks.

---

**Note** When you start the debugger using the Simulink Toolstrip, the debugger programmatic interface also activates in the MATLAB Command Window. To prevent synchronization errors between the graphical and programmatic interfaces, avoid using the programmatic interface.

---

- “Simulink Debugger Programmatic Interface” on page 37-2

## Run a Simulation Step by Step

### In this section...

“Block Data Output” on page 37-6

“Stepping Commands” on page 37-7

“Continuing a Simulation” on page 37-8

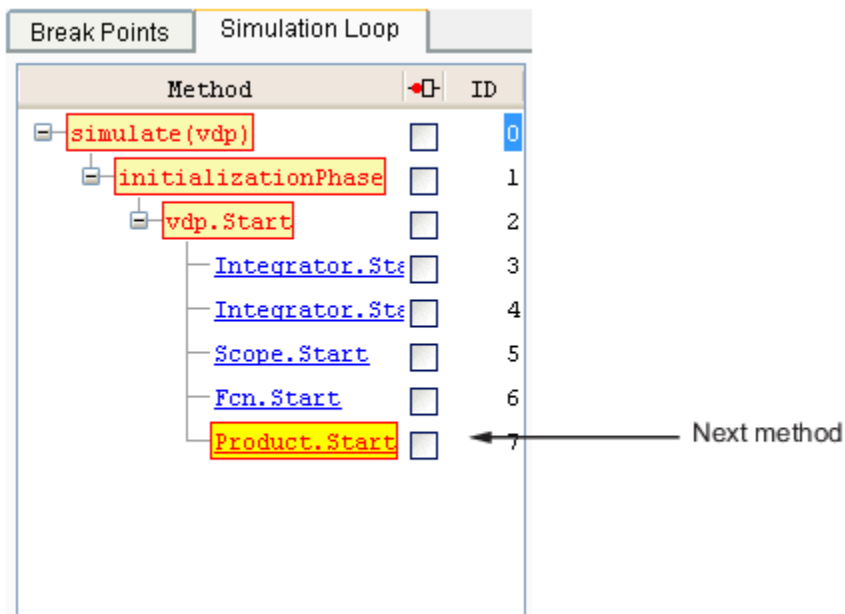

“Running a Simulation Nonstop” on page 37-8

The Simulink debugger provides functions you can use to advance a simulation from the method where it is currently paused by various increments. For example, you can advance the simulation:

- Into or over the next method
- Out of the current method
- To the top of the simulation loop

After each advance, the debugger displays information that enables you to determine the point to which the simulation has advanced and the results of advancing the simulation to that point.

For example, after each step command, the debugger highlights the current method call stack in the **Simulation Loop** pane. The call stack comprises the next method and the methods that invoked the next method directly or indirectly.

When you debug simulations programmatically, use the `where` function to display the method call stack.

### Block Data Output

After executing a block method, the debugger prints some or all of the following block data in the **Output** panel:

- $U_n = v$  —  $n$ th block input value
- $Y_n = v$  —  $n$ th block output value
- $CSTATE = v$  — Block continuous state vector
- $DSTATE = v$  — Block discrete state vector

The debugger also displays the current time, the ID and name of the next method to be executed, and the name of the block to which the method applies in the MATLAB Command Window. The following example illustrates typical Simulink debugger outputs after a step command.

```

Current time                                Next method
      ↓                                     ↓
-----
[Tm = 2.009509145207664e-05 ] 0:2 Integrator.Derivatives 'vdp/x2'
(sldebug @49):
Data of 0:2 Integrator block 'vdp/x2':
U1      = [-1.9998794294512876]
Y1      = [-4.0190182904153282e-05]
CSTATE  = [-4.0190182904153282e-05]
-----
[Tm = 3.014263717811496e-05 ] vdp.Outputs.Minor

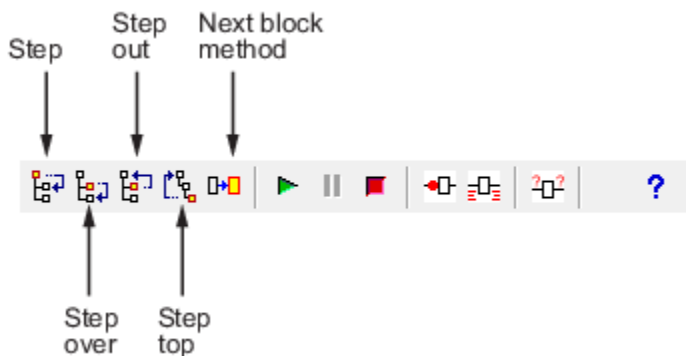

```

## Stepping Commands

When you debug a model programmatically, use these commands to advance a simulation incrementally.

Command	Stepping Behavior
step [in into]	Steps into the next method, stopping at the first method in the next method or, if the next method does not contain any methods, at the end of the next method
step over	Steps to the method that follows the next method, executing all methods invoked directly or indirectly by the next method
step out	Steps to the end of the current method, executing any remaining methods invoked by the current method
step top	Steps to the first method of the next time step
step blockmth	Steps to the next block method to be executed, executing all intervening model- and system-level methods
next	Same as step over

From the user interface, use the buttons in the toolbar to step through the simulation.

Clicking a button has the same effect as entering the corresponding command.

## Continuing a Simulation

When you start the debugger from the Simulink Toolstrip, the **Stop** button turns red when the debugger pauses the simulation for any reason. To continue the simulation, click the **Start/Continue** button. When you debug a model programmatically, enter `continue` to continue the simulation. By default, the Simulink debugger runs the simulation to the next breakpoint or to the end of the simulation, whichever comes first.

## Running a Simulation Nonstop

The `run` function runs a simulation to the end of the simulation, skipping any intervening breakpoints. At the end of the simulation, the Simulink debugger returns you to the MATLAB Command Prompt. To continue debugging a model, you must restart the debugger.

---

**Note** The user interface does not provide a graphical version of the `run` command. To run the simulation to the end, clear all breakpoints and then click **Start/Continue**.

---

## Set Breakpoints in Simulink Debugger

### In this section...

“Setting Unconditional Breakpoints” on page 37-9

“Setting Conditional Breakpoints” on page 37-11

The Simulink debugger allows you to define stopping points called breakpoints in a simulation. You can then run a simulation from breakpoint to breakpoint, using the `continue` function. You can define unconditional and conditional breakpoints. An unconditional breakpoint pauses simulation when the simulation reaches a specified method. A conditional breakpoint pauses simulation when the specified condition arises in the simulation. For example, you can specify a conditional breakpoint to pause the simulation when a signal has a certain value.

Breakpoints are useful when you know that a problem occurs at a certain point in your model or when a certain condition occurs. By defining an appropriate breakpoint and running the simulation using the `continue` function, you can skip immediately to the point in the simulation where the problem occurs.

---

**Note** When you stop a simulation at a breakpoint of a MATLAB S-function, to exit MATLAB, you must first quit the debugger.

---

### Setting Unconditional Breakpoints

You can set unconditional breakpoints from these locations:

- Debugger toolbar
- **Simulation Loop** pane
- MATLAB Command Window

### Setting Breakpoints from the Simulink Toolstrip

To add a breakpoint, enable the **Breakpoint** button.

- 1 Simulate the model.
- 2 Click the **Step over current method** button until `simulationPhase` is highlighted.
- 3 Click the **Step into current method** button.

The debugger displays the name of the selected block in the **Break/Display points** panel of the **Breakpoints** pane.

---

**Note** Clicking **Breakpoint** on the toolbar sets breakpoints on the invocations of the methods of the block in major time steps.

---

You can temporarily disable the breakpoints on a block by deselecting the check box in the breakpoints column of the panel. To clear the breakpoints on a block and remove its entry from the panel,

- 1 Select the entry.
- 2 Click the **Remove selected point** button.

---

**Note** You cannot set a breakpoint on a virtual block. A virtual block is purely graphical: it indicates a grouping or relationship among the computational blocks of a model. The debugger warns you if you try to set a breakpoint on a virtual block. You can get a listing of nonvirtual blocks of a model by using the `slist` command (see “Displaying a Model's Nonvirtual Blocks” on page 37-19).

---

### Setting Breakpoints from the Simulation Loop Pane

To set a breakpoint at a particular invocation of a method displayed in the **Simulation Loop** pane, select the check box next to the method name of the method in the breakpoint column.

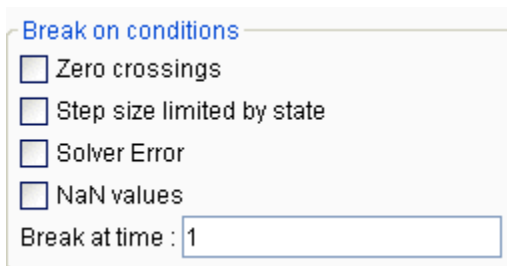

To clear the breakpoint, clear the check box.

### Setting Breakpoints from the Command Window

In command-line mode, use the `break` and `bafter` commands to set breakpoints before or after a specified method, respectively. Use the `clear` command to clear breakpoints.

### Setting Conditional Breakpoints

You can use the **Break on conditions** controls group on the debugger **Break Points** pane.

Use these functions to set conditional breakpoints.

Function	Breakpoint Behavior
<code>tbreak [t]</code>	Pauses simulation at specified simulation time step
<code>ebreak</code>	Pauses simulation at a recoverable error in the model
<code>nanbreak</code>	Pauses simulation at the occurrence of an underflow or overflow (NaN) or infinite (Inf) value
<code>xbreak</code>	Pauses simulation when the simulation reaches the state that determines the simulation step size

Function	Breakpoint Behavior
zcbreak	Pauses simulation when a zero crossing occurs between simulation time steps

### Setting Breakpoints at Time Steps

To set a breakpoint at a time step, enter a time in the debugger **Break at time** field or enter the time using the `tbreak` function. The debugger stops the simulation at the `Outputs.Major` method of the model at the first time step that follows the specified time. For example, starting `vdp` in debug mode and entering these commands causes the debugger to pause the simulation at the `vdp.Outputs.Major` method of time step 2.078.

```
tbreak 2
continue
```

```
%-----%
[ Tm = 2.034340153847549      ] vdp.Outputs.Minor
(sldebug @37):
```

### Breaking on Nonfinite Values

Selecting the debugger **NaN values** option or entering the `nanbreak` command causes the simulation to stop when a computed value is infinite or outside the range of values that is supported by the machine running the simulation. This option is useful for locating computational errors in a model.

### Breaking on Step-Size Limiting Steps

Selecting the **Step size limited by state** option or entering the `xbreak` command causes the debugger to stop the simulation when the model uses a variable-step solver and the solver encounters a state that limits the size of the steps that it can take. This command is useful in debugging models that appear to require an excessive number of simulation time steps to solve.

### Breaking at Zero Crossings

Selecting the **Zero crossings** option or entering the `zcbreak` command causes the simulation to halt when a nonsampled zero crossing is detected in a model that includes blocks where zero crossings can arise. After halting, the ID, type, and name of the block in which the zero crossing was detected is displayed. The block ID (`s:b:p`) consists of a system index `s`, block index `b`, and port index `p` separated by colons (see “Block ID” on page 37-2).

For example, setting a zero-crossing break at the start of execution of the `zeroxing` example model,

```
>> sldebug zeroxing
%-----%
%
[ TM = 0                      ] zeroxing.Simulate
(sldebug @0): >> zcbreak
Break at zero crossing events      : enabled
```

and continuing the simulation

```
(sldebug @0): >> continue
```

results in a zero-crossing break at

```
Interrupting model execution before running mdlOutputs at the left post of
(major time step just before) zero crossing event detected at the following location:
```

```
6[-0] 0:5:2 Saturate 'zeroxing/Saturation'  
%-----%  
[TzL= 0.3435011087932808 ] zeroxing.Outputs.Major  
(sldebug @16): >>
```

If a model does not include blocks capable of producing nonsampled zero crossings, the command prints a message advising you of this fact.

### Breaking on Solver Errors

Selecting the debugger **Solver Errors** option or entering the `ebreak` command causes the simulation to stop if the solver detects a recoverable error in the model. If you do not set or disable this breakpoint, the solver recovers from the error and proceeds with the simulation without notifying you.

## Display Information About the Simulation

### In this section...

“Display Block I/O” on page 37-14

“Display Algebraic Loop Information” on page 37-15

“Display System States” on page 37-16

“Display Solver Information” on page 37-16

### Display Block I/O

The debugger allows you to display block I/O by clicking the appropriate buttons on the debugger toolbar

or by entering the appropriate debugger command.

This command...	Displays a Blocks I/O...
probe	Immediately
disp	At every breakpoint any time execution stops
trace	Whenever the block executes

**Note** The two debugger toolbar buttons, Watch Block I/O (  ) and Display Block I/O (  ) correspond, respectively, to `trace gcb` and `probe gcb`. The `probe` and `disp` commands do not have a one-to-one correspondence with the debugger toolbar buttons.

### Displaying I/O of a Selected Block

To display the I/O of a block, select the block and click  in GUI mode or enter the `probe` command in command-line mode. In the following table, the `probe gcb` command has a corresponding toolbar button. The other commands do not.

Command	Description
probe	Enter or exit probe mode. Typing any command causes the debugger to exit probe mode.
probe gcb	Display I/O of selected block. Same as  .
probe s:b	Print the I/O of the block specified by system number <code>s</code> and block number <code>b</code> .

The debugger prints the current inputs, outputs, and states of the selected block in the debugger **Outputs** pane (GUI mode) or the Command Window of the MATLAB product.

The `probe` command is useful when you need to examine the I/O of a block whose I/O is not otherwise displayed. For example, suppose you are using the `step` command to run a model method by method. Each time you step the simulation, the debugger displays the inputs and outputs of the current block. The `probe` command lets you examine the I/O of other blocks as well.

### Displaying Block I/O Automatically at Breakpoints

The `disp` command causes the debugger to display a specified block's inputs and outputs whenever it halts the simulation. You can specify a block by entering its block index and entering `gcb` as the `disp` command argument. You can remove any block from the debugger list of display points, using the `undisp` command. For example, to remove block `0:0`, enter `undisp 0:0`.

---

**Note** Automatic display of block I/O at breakpoints is not available in the debugger GUI mode.

---

The `disp` command is useful when you need to monitor the I/O of a specific block or set of blocks as you step through a simulation. Using the `disp` command, you can specify the blocks you want to monitor and the debugger will then redisplay the I/O of those blocks on every step. Note that the debugger always displays the I/O of the current block when you step through a model block by block, using the `step` command. You do not need to use the `disp` command if you are interested in watching only the I/O of the current block.

### Watching Block I/O

To watch a block, select the block and click  in the debugger toolbar or enter the `trace` command. In GUI mode, if a breakpoint exists on the block, you can set a watch on it as well by selecting the check box for the block in the watch column  of the **Break/Display points** pane. In command-line mode, you can also specify the block by specifying its block index in the `trace` command. You can remove a block from the debugger list of trace points using the `untrace` command.

The debugger displays a watched block's I/O whenever the block executes. Watching a block allows you obtain a complete record of the block's I/O without having to stop the simulation.

### Display Algebraic Loop Information

The `atrace` command causes the debugger to display information about a model's algebraic loops (see "Algebraic Loop Concepts" on page 3-39) each time they are solved. The command takes a single argument that specifies the amount of information to display.

This command...	Displays for each algebraic loop...
<code>atrace 0</code>	No information
<code>atrace 1</code>	The loop variable solution, the number of iterations required to solve the loop, and the estimated solution error
<code>atrace 2</code>	Same as level 1
<code>atrace 3</code>	Level 2 plus the Jacobian matrix used to solve the loop
<code>atrace 4</code>	Level 3 plus intermediate solutions of the loop variable

## Display System States

The `states` debug command lists the current values of the system states in the MATLAB Command Window. For example, the following sequence of commands shows the states of the bouncing ball example (`sldemo_bounce`) after its first, second, and third time steps. However, before entering the debugger, open the Configuration Parameters dialog box and clear the **Block reduction** and **Signal storage reuse** check boxes.

```
sldebug sldemo_bounce
%-----%
[TM = 0 ] simulate(sldemo_bounce)
(sldebug @0): >> step top
%-----%
[TM = 0 ] sldemo_bounce.Outputs.Major
(sldebug @16): >> next
%-----%
[TM = 0 ] sldemo_bounce.Update
(sldebug @23): >> states

Continuous States:
Idx Value (system:block:element Name 'BlockName')
 0 10 (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
 1. 15 (0:4:1)

(sldebug @23): >> next
%-----%
[tm = 0 ] solverPhase
(sldebug @26): >> states

Continuous States:
Idx Value (system:block:element Name 'BlockName')
 0 10 (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
 1. 15 (0:4:1)

(sldebug @26): >> next
%-----%
[TM = 0.01 ] sldemo_bounce.Outputs.Major
(sldebug @16): >> states

Continuous States:
Idx Value (system:block:element Name 'BlockName')
 0 10.1495095 (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
 1. 14.9019 (0:4:1)
```

## Display Solver Information

The `strace` command allows you to pinpoint problems in solving a models differential equations that can slow down simulation performance. Executing this command causes the debugger to display solver-related information at the command line of the MATLAB product when you run or step through a simulation. The information includes the sizes of the steps taken by the solver, the estimated integration error resulting from the step size, whether a step size succeeded (i.e., met the accuracy requirements that the model specifies), the times at which solver resets occur, etc. If you are concerned about the time required to simulate your model, this information can help you to decide whether the solver you have chosen is the culprit and hence whether choosing another solver might shorten the time required to solve the model.

## Display Information About the Model

### In this section...

"Display Model's Sorted Lists" on page 37-18

"Display a Block" on page 37-19

### Display Model's Sorted Lists

In GUI mode, the debugger **Sorted List** pane displays lists of blocks for a model's root system and each nonvirtual subsystem. Each list lists the blocks that the subsystem contains sorted according to their computational dependencies, alphabetical order, and other block sorting rules. In command-line mode, you can use the `slist` command to display a model's sorted lists.

```

---- Sorted list for 'vdp' [11 nonvirtual block(s), directFeed=0]
      Total number of tasks = 2
- Sorted list of task index [0], 10 nonvirtual block(s)
(0)0:1  'vdp/x1' (Integrator)
        Input ports: [0]
        Output ports: [0]
(0)0:2  'vdp/Out1' (Outport)
        Input ports: [0]
        Output ports: []
(0)0:3  'vdp/x2' (Integrator)
        Input ports: [0]
        Output ports: [0]
(0)0:4  'vdp/Out2' (Outport)
        Input ports: [0]
        Output ports: []
(0)0:5  'vdp/Scope' (Scope)
        Input ports: [0]
        Output ports: []
(0)0:6  'vdp/Square' (Math)
        Input ports: [0]
        Output ports: [0]
(0)0:7  'vdp/Sum1' (Sum)
        Input ports: [0 1]
        Output ports: [0]
(0)0:8  'vdp/Product' (Product)
        Input ports: [0 1]
        Output ports: [0]
(0)0:9  'vdp/Mu' (Gain)
        Input ports: [0]
        Output ports: [0]
(0)0:10 'vdp/Sum' (Sum)
        Input ports: [0 1]
        Output ports: [0]

- Sorted list of task index [1], 1 nonvirtual block(s)
(1)0:1  'vdp/Constant' (Constant)
        Input ports: []
        Output ports: [0]

----- Task Index Legend -----
Task Index [0]: Cont

```

Task Index [1]: Constant

-----

These displays include the block index for each command. You can use them to determine the block IDs of the models blocks. Some debugger commands accept block IDs as arguments.

### Identifying Blocks in Algebraic Loops

If a block belongs to an algebraic list, the `slist` command displays an algebraic loop identifier in the entry for the block in the sorted list. The identifier has the form

```
algId=s#n
```

where `s` is the index of the subsystem containing the algebraic loop and `n` is the index of the algebraic loop in the subsystem. For example, the following entry for an Integrator block indicates that it participates in the first algebraic loop at the root level of the model.

```
0:1 'test/ss/I1' (Integrator, tid=0) [algId=0#1, discontinuity]
```

When the debugger is running, you can use the `ashow` command at the debugger command-line interface to highlight the blocks and lines that make up an algebraic loop. See “Displaying Algebraic Loops” on page 37-20 for more information.

## Display a Block

To determine the block in a models diagram that corresponds to a particular index, enter `bshow s:b` at the command prompt, where `s:b` is the block index. The `bshow` command opens the system containing the block (if necessary) and selects the block in the systems window.

### Displaying a Model's Nonvirtual Systems

The `systems` command displays a list of the nonvirtual systems in the model that you are debugging. For example, the `sldemo_clutch` model contains the following systems:

```
openExample('sldemo_clutch')
set_param(gcs, 'OptimizeBlockIOStorage','off')
sldebug sldemo_clutch
(sldebug @0): %-----%
[TM = 0 ] simulate(sldemo_clutch)
(sldebug @0): >> systems
0 'sldemo_clutch'
1 'sldemo_clutch/Locked'
2 'sldemo_clutch/Unlocked'
```

---

**Note** The `systems` command does not list subsystems that are purely graphical. That is, subsystems that the model diagram represents as Subsystem blocks but that are solved as part of a parent system. are not listed. In Simulink models, the root system and triggered or enabled subsystems are true systems. All other subsystems are virtual (that is, graphical) and do not appear in the listing from the `systems` command.

---

### Displaying a Model's Nonvirtual Blocks

The `slist` command displays a list of the nonvirtual blocks in a model. The listing groups the blocks by system. For example, the following sequence of commands produces a list of the nonvirtual blocks in the Van der Pol (`vdp`) example model.

```

sldebug vdp
%-----%
[TM = 0                               ] simulate(vdp)
sldebug @0): >> slist

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
 0:0   'vdp/x1' (Integrator)
 0:1   'vdp/Out1' (Outport)
 0:2   'vdp/x2' (Integrator)
 0:3   'vdp/Out2' (Outport)
 0:4   'vdp/Scope' (Scope)
 0:5   'vdp/Fcn' (Fcn)
 0:6   'vdp/Product' (Product)
 0:7   'vdp/Mu' (Gain)
 0:8   'vdp/Sum' (Sum)

```

---

**Note** The `slist` command does not list blocks that are purely graphical. That is, blocks that indicate relationships between or groupings among computational blocks.

---

### Displaying Blocks with Potential Zero Crossings

The `zclist` command displays a list of blocks in which nonsampled zero crossings can occur during a simulation. For example, `zclist` displays the following list for the clutch sample model:

```

(sldebug @0): >> zclist
 0 0:4:0 F HitCross 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Velocities Match'
 1 0:4:1 F
 2 0:10:0 F Abs 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Required Friction for Lockup/Abs'
 3 0:12:0 F RelationalOperator 'sldemo_clutch/Friction Mode
Logic/Lockup Detection/Required Friction for Lockup/Relational Operator'
 4 0:19:0 F Abs 'sldemo_clutch/Friction Mode Logic/Break Apart
Detection/Abs'
 5 0:20:0 F RelationalOperator 'sldemo_clutch/Friction Mode
Logic/Break Apart Detection/Relational Operator'
 6 2:3:0 F Signum 'sldemo_clutch/Unlocked/slip direction'

```

### Displaying Algebraic Loops

The `ashow` command highlights a specified algebraic loop or the algebraic loop that contains a specified block. To highlight a specified algebraic loop, enter `ashow s#n`, where `s` is the index of the system (see “Identifying Blocks in Algebraic Loops” on page 37-19) that contains the loop and `n` is the index of the loop in the system. To display the loop that contains the currently selected block, enter `ashow gcb`. To show a loop that contains a specified block, enter `ashow s:b`, where `s:b` is the block's index. To clear algebraic-loop highlighting from the model diagram, enter `ashow clear`.

### Displaying Debugger Status

In GUI mode, the debugger displays the settings of various debug options, such as conditional breakpoints, in its **Status** panel. In command-line mode, the `status` command displays debugger settings. For example, the following sequence of commands displays the initial debug settings for the `vdp` model:

```

sim('vdp', 'StopTime', '10', 'debug', 'on')
%-----%
[TM = 0                               ] simulate(vdp)
(sldebug @0): >> status
%-----%

```

```
Current simulation time           : 0.0 (MajorTimeStep)
Solver needs reset                : no
Solver derivatives cache needs reset : no
Zero crossing signals cache needs reset : no
Default command to execute on return/enter : ""
Break at zero crossing events     : disabled
Break on solver error             : disabled
Break on failed integration step  : disabled
Time break point                  : disabled
Break on non-finite (NaN,Inf) values : disabled
Break on solver reset request     : disabled
Display level for disp, trace, probe : 1 (i/o, states)
Solver trace level                : 0
Algebraic loop tracing level     : 0
Animation Mode                    : off
Execution Mode                    : Normal
Display level for etrace          : 0 (disabled)
Break points                      : none installed
Display points                    : none installed
Trace points                      : none installed
```

- “Comparing Performance” on page 38-27
- “How to Improve Performance in Acceleration Modes” on page 38-31

## What Is Acceleration?

*Acceleration* is a mode of operation in the Simulink product that you can use to speed up the execution of your model. The Simulink software includes two modes of acceleration: accelerator mode and rapid accelerator mode. Both modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where run time is long compared to the time associated with compilation and checking to see if the target is up to date.

Accelerator mode works with any model, but performance decreases if a model contains blocks that do not support acceleration. Accelerator mode supports the Simulink debugger and profiler. These tools help with debugging and determining relative performance of various parts of your model. For more information, see “Run Accelerator Mode with the Simulink Debugger” on page 38-25 and “How Profiler Captures Performance Data” on page 34-5.

Rapid accelerator mode works with only those models that contain blocks that support code generation of a standalone executable. For this reason, rapid accelerator mode does not support the debugger or profiler. However, this mode generally results in faster execution than accelerator mode. When used with dual-core processors, rapid accelerator mode runs Simulink and the MATLAB technical computing environment from one core while the rapid accelerator target runs as a separate process on a second core.

For more information about the performance characteristics of the accelerator and rapid accelerator modes, and how to measure the difference in performance, see “Comparing Performance” on page 38-27.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To employ modeling techniques that help achieve faster simulation, see “Manual Performance Optimization”.

## How Acceleration Modes Work

### In this section...

“Overview” on page 38-3

“Normal Mode” on page 38-3

“Accelerator Mode” on page 38-4

“Rapid Accelerator Mode” on page 38-5

### Overview

The accelerator and rapid accelerator modes use portions of the Simulink Coder product to create an executable.

The accelerator and rapid accelerator modes replace the interpreted code normally used in Simulink simulations, shortening model run time.

Although the acceleration modes use some Simulink Coder code generation technology, you do not need the Simulink Coder software installed to accelerate your model.

---

**Note** The code generated by the accelerator and rapid accelerator modes is suitable only for speeding the simulation of your model. Use Simulink Coder to generate code for other purposes.

---

### Normal Mode

In normal mode, the MATLAB technical computing environment is the foundation on which the Simulink software is built. Simulink controls the solver and model methods used during simulation. Model methods include such things as computation of model outputs. Normal mode runs in one process.

One Process

## Accelerator Mode

By default, accelerator mode uses Just-in-Time (JIT) acceleration to generate an execution engine in memory instead of generating C code or MEX files. You can also have your model fall back to the classic accelerator mode, in which Simulink generates and links code into a C-MEX S-function.

In accelerator mode, the model methods are separate from the Simulink software and are part of the *acceleration target code*, which is used in later simulations.

Simulink checks that the acceleration target code is up to date before reusing it. For more information, see “Code Regeneration in Accelerated Models” on page 38-7 .

There are two modes of operation in accelerator mode.

### Just-In-Time Accelerator Mode

In this default mode, Simulink generates an execution engine in memory for the top-level model only and not for referenced models. As a result, a C compiler is not required during simulation.

Because the acceleration target code is in memory, it is available for reuse as long as the model is open. Simulink also serializes the acceleration target code so that the model does not need rebuilding when it is opened.

### Classic Accelerator Mode

If you want to simulate your model using the classic, C-code generating, accelerator mode, run the following command:

```
set_param(0, 'GlobalUseClassicAccelMode', 'on');
```

In this mode, Simulink generates and links code into a shared library, which communicates with the Simulink software. The target code executes in the same process as MATLAB and Simulink.

## Rapid Accelerator Mode

Rapid accelerator mode creates a *rapid accelerator standalone executable* from your model. This executable includes the solver and model methods, but it resides outside of MATLAB and Simulink. It uses external mode (see “External Mode Communication” (Simulink Coder)) to communicate with Simulink.

MATLAB and Simulink run in one process, and if a second processing core is available, the standalone executable runs there.

## Code Regeneration in Accelerated Models

### In this section...

“Determine If the Simulation Will Rebuild” on page 38-7

“Parameter Tuning in Rapid Accelerator Mode” on page 38-7

Changing the structure of your model causes rapid accelerator mode to regenerate the standalone executable, and for the accelerator mode to regenerate the target code and update (overwrite) the existing MEX-file. Changing the value of a tunable parameter does not trigger a rebuild.

### Determine If the Simulation Will Rebuild

The accelerator and rapid accelerator modes use a checksum to determine if the model has changed, indicating that the code should be regenerated. The checksum is an array of four integers computed using an MD5 checksum algorithm based on attributes of the model and the blocks it contains.

- 1 Use the `Simulink.BlockDiagram.getChecksum` function to obtain the checksum for your model. For example:
 

```
cs1 = Simulink.BlockDiagram.getChecksum('myModel');
```
- 2 Obtain a second checksum after you have altered your model. The code regenerates if the new checksum does not match the previous checksum.
- 3 Use the information in the checksum to determine why the simulation target rebuilt.

For a detailed explanation of this procedure, see “Determine Why Simulink Accelerator Is Regenerating Code”.

### Parameter Tuning in Rapid Accelerator Mode

In model rebuilds, rapid accelerator mode handles block diagram and runtime parameters differently from other parameters.

#### Tuning Block Diagram Parameters

You can change some block diagram parameters during simulation without causing a rebuild. Tune these parameters using the `set_param` function or using the **Model Configuration Parameters** dialog box. These block diagram parameters include:

Solver Parameters		
AbsTol	MaxNumMinSteps	RelTol
ConsecutiveZCsStepRelTol	MaxOrder	StartTime
ExtrapolationOrder	MaxStep	StopTime
InitialStep	MinStep	ZCDetectionTol
MaxConsecutiveMinStep	OutputTimes	
MaxConsecutiveZCs	Refine	

Loading and Logging Parameters		
ConsistencyChecking	MinStepSizeMsg	SaveTime
Decimation	OutputOption	StateSaveName
FinalStateName	OutputSaveName	TimeSaveName
LimitDataPoints	SaveFinalState	
LoadExternalInput	SaveFormat	
MaxConsecutiveZCsMsg	SaveOutput	
MaxDataPoints	SaveState	

### Tuning Runtime Parameters

To tune runtime parameters for maximum acceleration in rapid accelerator mode, follow this procedure which yields better results than using `set_param` for the same purpose:

- 1 Collect the runtime parameters in a runtime parameter structure while building a rapid accelerator target executable using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function.
- 2 To change the parameters, use the `Simulink.BlockDiagram.modifyTunableParameters` function.
- 3 To specify the modified parameters to the `sim` function, use the `RapidAcceleratorParameterSets` and `RapidAcceleratorUpToDateCheck` parameters.

All other parameter changes can necessitate a rebuild of the model.

Parameter Changes	Passed Directly to <code>sim</code> function	Passed Graphically via Block Diagram or via <code>set_param</code> function
Runtime	Does not require rebuild	Can require rebuild
Block diagram (logging parameters)	Does not require rebuild	Does not require rebuild

For information about parameter tunability limitations with accelerated simulation modes, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 40-36.

## Choosing a Simulation Mode

### In this section...

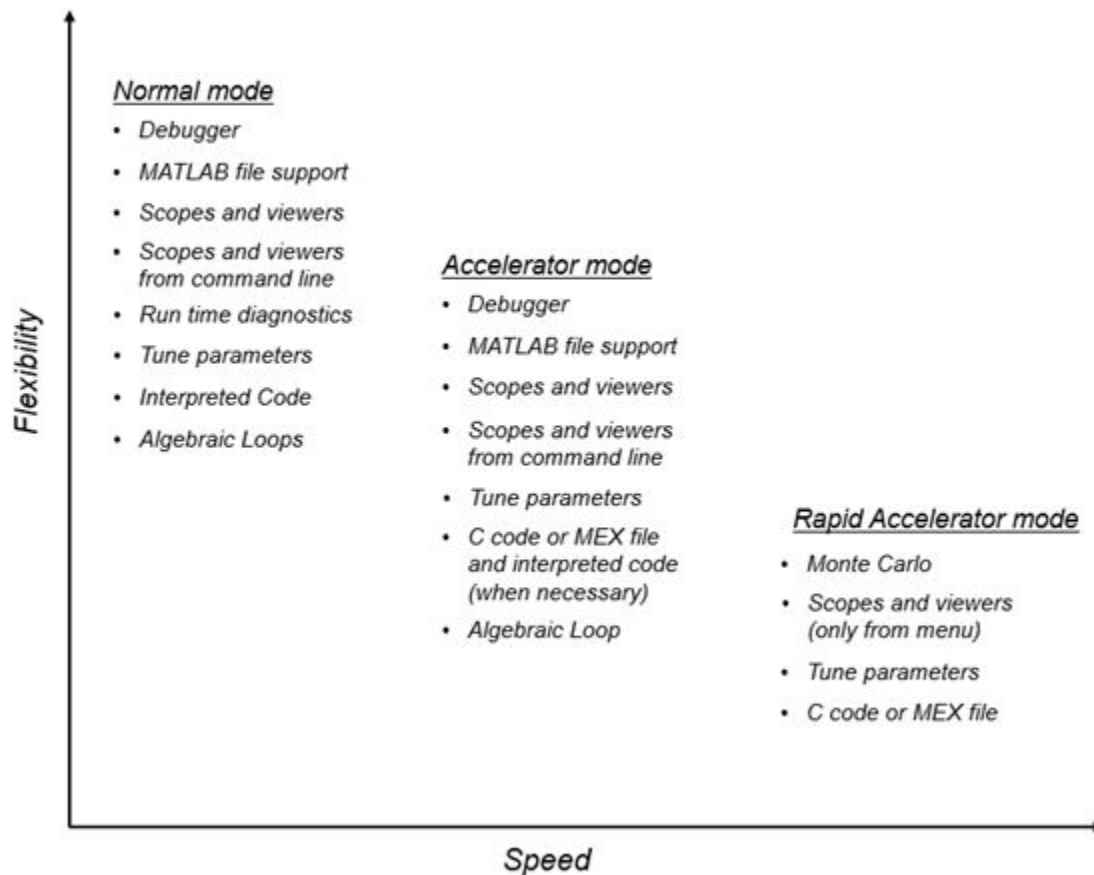

“Simulation Mode Tradeoffs” on page 38-10

“Comparing Modes” on page 38-11

“Decision Tree” on page 38-12

### Simulation Mode Tradeoffs

In general, you must trade off simulation speed against flexibility when choosing either accelerator mode or rapid accelerator mode instead of normal mode.

Normal mode offers the greatest flexibility for making model adjustments and displaying results, but it runs the slowest.

Accelerator mode lies between normal and rapid accelerator modes in performance and in interaction with your model. Accelerator mode does not support most runtime diagnostics.

Rapid accelerator mode runs the fastest, but this mode does not support the debugger or profiler, and works only with those models for which C code or MEX file is available for all of the blocks in the model.

**Note** An exception to this rule occurs when you run multiple simulations, each of which executes in less than one second in normal mode. For example:

```
for i=1:100
sim(model); % executes in less than one second in Normal mode
end
```

For this set of conditions, you will typically obtain the best performance by simulating the model in normal mode.

**Tip** To gain additional flexibility, consider using model referencing to componentize your model. If the top model uses normal mode, then you can simulate a referenced model in a different simulation mode than you use for other portions of a model. During the model development process, you can choose different simulation modes for different portions of a model. For details, see “Choose Simulation Modes for Model Hierarchies” on page 8-39.

## Comparing Modes

The following table compares the characteristics of normal mode, accelerator mode, and rapid accelerator mode.

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
<b>Performance</b>			
Run your model in a separate address space			✓
Efficiently run batch and Monte Carlo simulations			✓
<b>Model Adjustment</b>			
Change model parameters such as solver, stop time without rebuilding	✓	✓	✓
Change block tunable parameters such as gain	✓	✓	✓
For more information on configuration set parameters which can be modified without requiring rebuild, see “Code Regeneration in Accelerated Models” on page 38-7			
<b>Model Requirement</b>			
Accelerate your model even if C code or MEX file are not used for all blocks		✓	
Support Interpreted MATLAB Function blocks	✓	✓	
Support Non-Inlined MATLAB language or Fortran S-Functions	✓	✓	
Permit algebraic loops in your models	✓	✓	
Have your model work with the debugger or profiler	✓	✓	
Have your model include C++ code	✓	✓	
<b>Data Display</b>			

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Use scopes and signal viewers	✓	✓	See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 38-16
Use scopes and signal viewers when simulating your model programmatically	✓	✓	

---

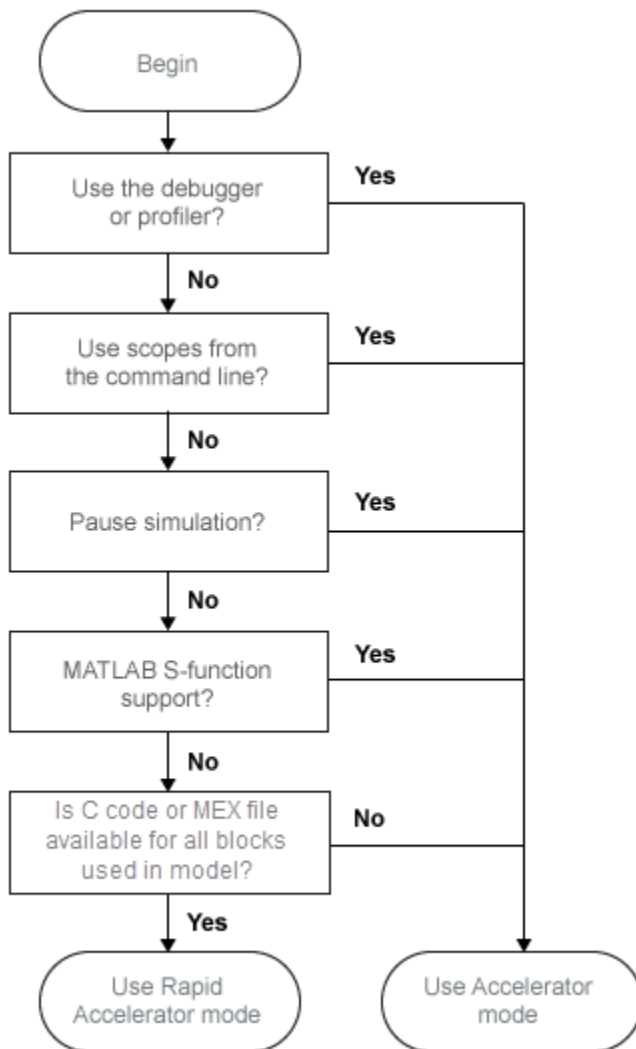

**Note** Scopes and viewers do not update if you run your model programmatically in rapid accelerator mode.

---

## Decision Tree

Use this decision tree to select between accelerator mode and rapid accelerator mode.

See “Comparing Performance” on page 38-27 to understand how effective acceleration will be in improving the performance of your model.

“Accelerator and Rapid Accelerator Mode Data Type Considerations” on page 38-15

“Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 38-16

“Factors Inhibiting Acceleration” on page 38-16

### Select Blocks for Accelerator Mode

Accelerator mode runs the following blocks as if you were running normal mode because these blocks do not generate code for the accelerator build. Consequently, if your model contains a high percentage of these blocks, accelerator mode may not increase performance significantly. All of these Simulink blocks use interpreted code.

- Display
- From File
- From Workspace
- Inport (root level only)
- Interpreted MATLAB Function
- Outport (root level only)
- Scope
- To File
- To Workspace

---

**Note** In some instances, normal mode output might not precisely match the output from accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

---

The following blocks can cause poor simulation runtime performance when run in the default JIT accelerator mode.

- Transport Delay
- Variable Transport Delay

### Select Blocks for Rapid Accelerator Mode

Blocks that do not support code generation (such as SimEvents) or blocks that generate code only for a specific target cannot be simulated in rapid accelerator mode.

Additionally, rapid accelerator mode does not work if your model contains any of the following blocks:

- Interpreted MATLAB Function
- Device driver S-functions, such as blocks from the Simulink Real-Time product, or those targeting Freescale™ MPC555

---

**Note** In some instances, normal mode output might not precisely match the output from rapid accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

---

## Control S-Function Execution

---

**Note** In the default JIT accelerator mode, inlining of user-written TLC S-Functions is not supported. If you run a model containing TLC S-Functions in the JIT accelerator mode, there is a possibility of the execution speed reducing. The code generation speed, however, will be high due to JIT acceleration.

---

Inlining S-functions using the Target Language Compiler increases performance with the classic accelerator mode by eliminating unnecessary calls to the Simulink API. By default, however, the classic accelerator mode ignores an inlining TLC file for an S-function, even though the file exists. The rapid accelerator mode always uses the TLC file if one is available.

A device driver S-Function block written to access specific hardware registers on an I/O board is one example of why this behavior was chosen as the default. Because the Simulink software runs on the host system rather than the target, it cannot access the target I/O registers and so would fail when attempting to do so.

To direct the classic accelerator mode to use the TLC file instead of the S-function MEX-file, specify `SS_OPTION_USE_TLC_WITH_ACCELERATOR` in the `mdlInitializeSizes` function of the S-function, as in this example:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* Code deleted */
ssSetOptions(S, SS_OPTION_USE_TLC_WITH_ACCELERATOR);
}
```

Rapid accelerator mode will make use of the MEX file if the S-Function C file is not present in the same folder.

---

**Note** To use the `.c` or `.cpp` code for your S-Function, ensure that they are in the same folder as the S-Function MEX-file. Otherwise, you can include additional files to an S-function or bypass the path limitation by using the `rtwmakecfg.m` file. For more information, see [Use `rtwmakecfg.m` API to Customize Generated Makefiles \(Simulink Coder\)](#).

---

## Accelerator and Rapid Accelerator Mode Data Type Considerations

- Accelerator mode supports fixed-point signals and vectors up to 128 bits.
- Rapid accelerator mode supports fixed-point parameters up to 128 bits.

- Rapid accelerator mode supports fixed-point root inputs up to 32 bits
- Rapid accelerator mode supports root inputs of Enumerated data type
- Rapid accelerator mode does not support fixed-point data for the From Workspace block.
- Rapid accelerator mode ignores the **Log fixed-point data as a fi object** parameter for the To Workspace block.
- Rapid accelerator mode supports bus objects as parameters.
- Accelerator mode and rapid accelerator mode store integers as compactly as possible.
- Fixed-Point Designer does not collect min, max, or overflow data in the accelerator or rapid accelerator modes.
- Accelerator mode supports a limited set of runtime diagnostics, including the assertion block.
- Rapid accelerator mode supports a limited set of runtime diagnostics, including the assertion block.

## Behavior of Scopes and Viewers with Rapid Accelerator Mode

Running the simulation programmatically or interactively determines the behavior of scopes and viewers in rapid accelerator mode.

Scope or Viewer Type	Simulation Run Interactively	Simulation Run Programmatically
Simulink Scope block	Same support as normal mode	<ul style="list-style-type: none"> <li>• Logging is supported</li> <li>• Scope window is not updated</li> </ul>
Simulink signal viewer scopes	Graphics are updated, but logging is not supported	Not supported
Other signal viewer scopes	Support limited to that available in external mode	Not supported
Signal logging	Supported.	Supported.
Visualizers with inputs from logging  (Such as the Simulation Data Inspector or Logic Analyzer)	Data not visualized during simulation.	Data not visualized during simulation.
Stateflow charts	Same support for chart animation as normal mode	Not supported

**Note** Although scopes and viewers do not update when you run rapid accelerator simulations programmatically, they do update when you run the simulation interactively. “Run Acceleration Mode from the User Interface” on page 38-19 shows how to run rapid accelerator mode from the menu. “Interact with the Acceleration Modes Programmatically” on page 38-22 shows how to run the simulation programmatically.

## Factors Inhibiting Acceleration

- You cannot use accelerator mode or rapid accelerator mode if your model:

- Passes array parameters to MATLAB S-functions that are not numeric, logical, or character arrays, are sparse arrays, or that have more than two dimensions.
- Uses Fcn blocks containing trigonometric functions having complex inputs.
- In some cases, changes associated with external or custom code do not cause accelerator or rapid accelerator simulation results to change. These include:
  - TLC code
  - S-function source code, including `rtwmakecfg.m` files
  - Integrated custom code
  - S-Function Builder

In such cases, consider force regeneration of code for a top model. Alternatively, you can force regeneration of top model code by deleting code generation folders, such as `slprj` or the generated model code folder.

---

**Note** With JIT acceleration, the acceleration target code is in memory. It is therefore available for reuse as long as the model is open, even if you delete the `slprj` folder.

---

### Rapid Accelerator Mode Limitations

- Rapid accelerator mode does not support:
  - Algebraic loops.
  - Targets written in C++.
  - Interpreted MATLAB Function blocks.
  - Noninlined MATLAB language or Fortran S-functions. You must write S-functions in C or inline them using the Target Language Compiler (TLC) or you can also use the MEX file. For more information, see “Write Fully Inlined S-Functions” (Simulink Coder).
  - Debugger or Profiler.
  - Run time objects for `Simulink.RunTimeBlock` and `Simulink.BlockCompOutputPortData` blocks.
- Model parameters must be one of these data types:
  - `boolean`
  - `uint8` or `int8`
  - `uint16` or `int16`
  - `uint32` or `int32`
  - `single` or `double`
  - Fixed-point
  - Enumerated
- You cannot pause a simulation in rapid accelerator mode.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In these cases, you must regenerate the code for the model. See “Code Regeneration in Accelerated Models” on page 38-7 for more information.
- For root inports, when you specify the minimum and maximum values that the block should output, rapid accelerator mode does not recognize these limits during simulation.

- In rapid accelerator mode, To File or To Workspace blocks inside function-call subsystems do not generate any logging files if the function-call port is connected to Ground or unconnected.
- Rapid accelerator mode does not support systems that run RHEL / CentOS 6.x or 7.x.

### Reserved Keywords

Certain words are reserved for use by the Simulink Coder code language and by accelerator mode and rapid accelerator mode. These keywords must not appear as function or variable names on a subsystem, or as exported global signal names. Using the reserved keywords results in the Simulink software reporting an error, and the model cannot be compiled or run.

The keywords reserved for the Simulink Coder product are listed in “Construction of Generated Identifiers” (Simulink Coder). Additional keywords that apply only to the accelerator and rapid accelerator modes are:

<code>muDoubleScalarAbs</code>	<code>muDoubleScalarCos</code>	<code>muDoubleScalarMod</code>
<code>muDoubleScalarAcos</code>	<code>muDoubleScalarCosh</code>	<code>muDoubleScalarPower</code>
<code>muDoubleScalarAcosh</code>	<code>muDoubleScalarExp</code>	<code>muDoubleScalarRound</code>
<code>muDoubleScalarAsin</code>	<code>muDoubleScalarFloor</code>	<code>muDoubleScalarSign</code>
<code>muDoubleScalarAsinh</code>	<code>muDoubleScalarHypot</code>	<code>muDoubleScalarSin</code>
<code>muDoubleScalarAtan</code>	<code>muDoubleScalarLog</code>	<code>muDoubleScalarSinh</code>
<code>muDoubleScalarAtan2</code>	<code>muDoubleScalarLog10</code>	<code>muDoubleScalarSqrt</code>
<code>muDoubleScalarAtanh</code>	<code>muDoubleScalarMax</code>	<code>muDoubleScalarTan</code>
<code>muDoubleScalarCeil</code>	<code>muDoubleScalarMin</code>	<code>muDoubleScalarTanh</code>

### See Also

#### Related Examples

- “Perform Acceleration” on page 38-19
- “How to Improve Performance in Acceleration Modes” on page 38-31
- “What Is Acceleration?” on page 38-2
- “How Acceleration Modes Work” on page 38-3
- “Choosing a Simulation Mode” on page 38-10

## Perform Acceleration

### In this section...

- “Customize the Build Process” on page 38-19
- “Run Acceleration Mode from the User Interface” on page 38-19
- “Making Run-Time Changes” on page 38-20
- “Switching Solvers between Runs” on page 38-21

### Customize the Build Process

Compiler optimizations are off by default. This results in faster build times, but slower simulation times. You can optimize the build process toward a faster simulation.

- 1 On the **Modeling** tab, under **Setup**, click **Model Settings**.
- 2 In the Configuration Parameters dialog box, from the **Compiler optimization level** drop-down list, select **Optimizations on (faster runs)**.

Code generation takes longer with this option, but the simulation runs faster.

- 3 Select **Verbose accelerator builds** to display progress information using code generation, and to see the compiler options in use.

### Changing the Location of Generated Code

By default, accelerator mode places the generated code in a subfolder of the working folder called `s\prj\accel\modelname` (for example, `s\prj\accel\f14`). To change the name of the folder into which accelerator mode writes generated code:

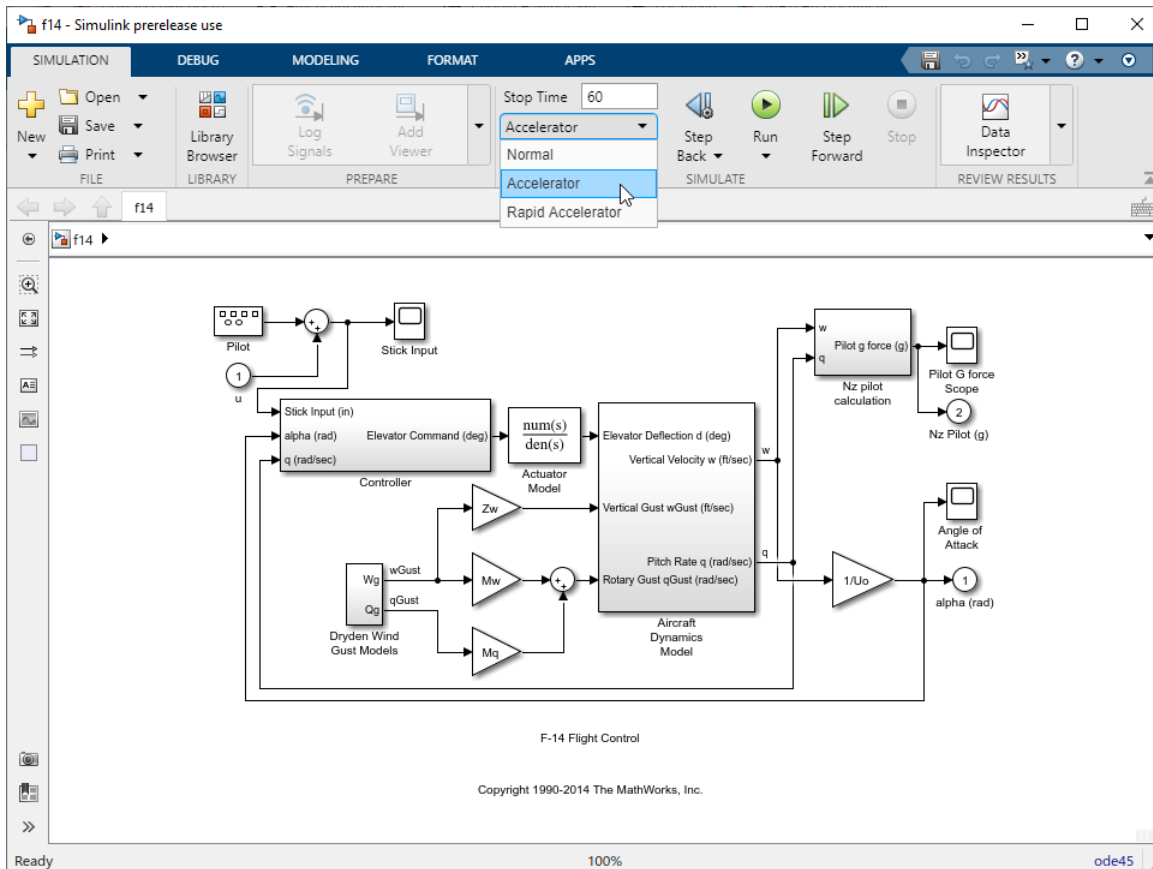

- 1 In the Simulink Editor window, on the **Modeling** tab, select **Environment > Simulink Preferences**.
- 2 In the Simulink Preferences window, navigate to the **Simulation cache folder** parameter.
- 3 Enter the absolute or relative path to your subfolder and click **Apply**.

### Run Acceleration Mode from the User Interface

To accelerate a model, first open it, and then on the **Simulation** tab, in the **Simulate** section, select **Accelerator** or **Rapid Accelerator** from the drop-down list. Then start the simulation.

The following example shows how to accelerate the already opened `f14` model using accelerator mode:

- 1 On the **Simulation** tab, in the **Simulate** section, select **Accelerator** from the drop-down list.

- 2 On the **Simulation** tab, click **Run**.

The accelerator and rapid accelerator modes first check to see if code was previously compiled for your model. If code was created previously, accelerator or rapid accelerator mode runs the model. If code was not previously built, they first generate and compile the C code, and then run the model.

For an explanation of why these modes rebuild your model, see “Code Regeneration in Accelerated Models” on page 38-7.

Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/modelname` (for example, `slprj/accel/f14`). If you want to change this path, see “Changing the Location of Generated Code” on page 38-19.

Rapid accelerator mode places the generated code in a subfolder of the working folder called `slprj/raccel/modelname` (for example, `slprj/raccel/f14`).

---

**Note** The warnings that blocks generate during simulation (such as divide-by-zero and integer overflow) are not displayed when your model runs in accelerator or rapid accelerator mode.

---

## Making Run-Time Changes

A feature of the accelerator and rapid accelerator modes is that simple adjustments (such as changing the value of a Gain or Constant block) can be made to the model while the simulation is still

running. More complex changes (for example, changing from a `sin` to `tan` function) are not allowed during run time.

The Simulink software issues a warning if you attempt to make a change that is not permitted. The absence of a warning indicates that the change was accepted. The warning does not stop the current simulation, and the simulation continues with the previous values. If you wish to alter the model in ways that are not permitted during run time, you must first stop the simulation, make the change, and then restart the simulation.

In general, simple model changes are more likely to result in code regeneration when in rapid accelerator mode than when in accelerator mode.

## Switching Solvers between Runs

You can switch variable-step solvers between runs and Simulink will automatically determine if a solver change will trigger a rebuild, based on the mathematical structure of the model, such as whether the model is an ordinary differential equation (ODE) or a differential algebraic equation (DAE) model, if the solver needs a Jacobian, whether it handles mass matrices, or if the model contains rate limiter blocks.

## Interact with the Acceleration Modes Programmatically

### In this section...

“Why Interact Programmatically?” on page 38-22

“Build JIT Accelerated Execution Engine” on page 38-22

“Control Simulation” on page 38-22

“Simulate Your Model” on page 38-22

“Customize the Acceleration Build Process” on page 38-23

### Why Interact Programmatically?

You can build an accelerated model, select the simulation mode, and run the simulation programmatically. With this flexibility, you can create accelerator mode MEX-files in batch mode, allowing you to build the C code and executable before running the simulations. When you use accelerator mode interactively at a later time, it will not be necessary to generate or compile MEX-files at the start of the accelerated simulations.

### Build JIT Accelerated Execution Engine

With the `accelbuild` command, you can build a JIT accelerated execution engine without actually simulating the model. For example, to build an accelerator mode simulation of `myModel`:

```
accelbuild myModel
```

### Control Simulation

You can control the simulation mode programmatically using the `set_param` command:

```
set_param('modelName', 'SimulationMode', 'mode')
```

The simulation mode can be `normal`, `accelerator`, `rapid`, or `external`.

For example, to simulate your model using accelerator mode, you would use:

```
set_param('myModel', 'SimulationMode', 'accelerator')
```

However, a preferable method is to specify the simulation mode using the `sim` function:

```
simOut = sim('myModel', 'SimulationMode', 'accelerator');
```

You can use `bdroot` to set parameters for the currently active model (that is, the active model window) rather than `modelName` if you do not wish to explicitly specify the model name.

For example, to simulate the currently opened system using rapid accelerator mode, you would use:

```
simOut = sim(bdroot, 'SimulationMode', 'rapid');
```

### Simulate Your Model

You can use `set_param` to configure the model parameters (such as the simulation mode and the stop time), and use the `sim` command to start the simulation:

```
sim('modelName', 'ReturnWorkspaceOutputs', 'on');
```

However, the preferred method is to configure model parameters directly using the `sim` command, as shown in the previous section.

You can substitute `gcs` for `modelName` if you do not want to explicitly specify the model name.

Unless target code has already been generated, the `sim` function first builds the executable and then runs the simulation. However, if the target code has already been generated and no significant changes have been made to the model (see “Code Regeneration in Accelerated Models” on page 38-7 for a description), the `sim` function executes the generated code without regenerating the code. This process lets you run your model after making simple changes without having to wait for the model to rebuild.

### Simulation Example

The following sequence shows how to programmatically simulate `myModel` in rapid accelerator mode for 10,000 seconds.

First open `myModel`, and then type the following in the Command Window:

```
simOut = sim('myModel', 'SimulationMode', 'rapid', ...
'StopTime', '10000');
```

Use the `sim` function again to simulate after making a change to your model. If the change is minor (adjusting the gain of a gain block, for instance), the simulation runs without regenerating code.

## Customize the Acceleration Build Process

You can programmatically control the accelerator mode and rapid accelerator mode build process and the amount of information displayed during the build process. See “Customize the Build Process” on page 38-19 for details on why doing so might be advantageous.

### Controlling the Build Process

Use `SimCompilerOptimization` to set the degree of optimization used by the compiler when generating code for acceleration. The permitted values are `on` or `off`. The default is `off`.

Enter the following in the Command Window to turn on compiler optimization:

```
set_param('myModel', 'SimCompilerOptimization', 'on')
```

When `SimCompilerOptimization` is set to `on` in JIT accelerated mode, the simulation time for some models improves, while the build time can become slower.

### Controlling Verbosity During Code Generation

Use the `AccelVerboseBuild` parameter to display progress information during code generation. The permitted values are `on` or `off`. The default is `off`.

Enter the following in the Command Window to turn on verbose build:

```
set_param('myModel', 'AccelVerboseBuild', 'on')
```

## Run Accelerator Mode with the Simulink Debugger

### In this section...

“Advantages of Using Accelerator Mode with the Debugger” on page 38-25

“How to Run the Debugger” on page 38-25

“When to Switch Back to Normal Mode” on page 38-25

### Advantages of Using Accelerator Mode with the Debugger

Using accelerator mode can shorten the length of your debugging sessions if you have large and complex models. For example, you can use accelerator mode to simulate a large model and quickly reach a break point.

For more information, see “Accelerator Mode” on page 38-4.

---

**Note** You cannot use rapid accelerator mode with the debugger.

---

### How to Run the Debugger

To simulate your model using accelerator mode with the debugger:

- 1 On the **Simulation** tab, in the **Simulate** section, select **Accelerator** from the drop-down menu.
- 2 In the MATLAB Command Window, enter:  

```
sldebug modelname
```
- 3 At the debugger prompt, set a time break:  

```
tbreak 10000  
continue
```
- 4 Once you reach the breakpoint, use the debugger command `emode` (execution mode) to toggle between accelerator and normal mode.

### When to Switch Back to Normal Mode

You must switch to Normal mode to step through the simulation by blocks, and when you want to use the following debug commands:

- `trace`
- `break`
- `zcbreak`
- `nanbreak`

## Comparing Performance

### In this section...

“Performance When Target Must Be Rebuilt” on page 38-27

“Performance When Targets Are Up to Date” on page 38-28

“Analyze Performance of Simulation Modes” on page 38-28

When simulation execution time exceeds the time required for code generation, accelerator and rapid accelerator simulation modes give speed improvement compared to normal mode. Accelerator and rapid accelerator modes generally perform better than normal mode when simulation execution times are several minutes or more. However, models with a significant number of Stateflow or MATLAB Function blocks might show only a small speed improvement over normal mode because these blocks also simulate through code generation in normal mode.

Including tunable parameters in your model can also increase the simulation time.

The figure shows the relative performance of normal mode, accelerator mode, and rapid accelerator mode simulations in general terms for a hypothetical model.

### Performance When Target Must Be Rebuilt

The solid lines, labeled **all targets out of date**, in the figure show performance when the target code must be rebuilt. For this hypothetical model, the time scale is on the order of minutes. However, the time scale could be longer for more complex models.

Compiling a model in normal mode generally requires less time than building the accelerator target or the rapid accelerator executable. For small simulation stop times, normal mode results in quicker overall simulations compared to the accelerator and rapid accelerator modes.

The crossover point where accelerator mode or rapid accelerator mode results in faster overall simulation depends on the complexity and content of your model. For example, models that contain large numbers of blocks that use interpreted code might not run much faster in accelerator mode than they would in normal mode unless the simulation stop time is very large. For more information, see “Select Blocks for Accelerator Mode” on page 38-14. Similarly, models with a large number of Stateflow charts or MATLAB Function blocks might not show much speed improvement over normal mode unless the simulation stop time is large. You can speed up the simulation of models with Stateflow or MATLAB Function blocks through code generation.

The figure represents a model with a large number of Stateflow charts or MATLAB Function blocks. The curve labeled **Normal** would have a much smaller initial elapsed time than shown if the model did not contain these blocks.

## Performance When Targets Are Up to Date

The dashed lines, labeled **all targets up to date**, in the figure show that the time to determine whether the accelerator target or the rapid accelerator executable is up to date is significantly smaller than the time required to generate code, which is represented by the solid lines, labeled **all targets out of date**. You can take advantage of this characteristic when you wish to test various design tradeoffs.

For instance, you can generate the accelerator mode target once and use it to simulate your model with a series of gain settings. This method is especially efficient for the accelerator or rapid accelerator modes because this type of change does not result in the target code being regenerated. The target code is generated the first time the model runs, but on subsequent runs, the software spends only the time necessary to verify that the target is up to date. This process is much faster than generating code, so subsequent runs can be significantly faster than the initial run.

Because checking the targets is quicker than code generation, the crossover point is smaller when the target is up to date than when code must be generated. Subsequent runs of your model might simulate faster in accelerator or rapid accelerator mode when compared to normal mode, even for small stop times.

## Analyze Performance of Simulation Modes

To see the effect of using accelerator or rapid accelerator mode for simulations of your model, you can run equivalent simulations using different simulation modes and inspect the timing information captured in the simulation metadata.

This example uses the model `sldemo_fuelsys`. For more information about the model, see “Modeling a Fault-Tolerant Fuel Control System”.

```
model = "sldemo_fuelsys";
```

To configure the baseline simulation, create a `Simulink.SimulationInput` object. Set the stop time to 10000.

```
simIn = Simulink.SimulationInput(model);
simIn = setModelParameter(simIn, "StopTime", "10000");
```

To capture baseline timing information, simulate the model using normal mode.

```
simOut = sim(simIn);
```

The `Simulink.SimulationOutput` object contains a `Simulink.SimulationMetadata` object with information about the simulation, including a structure of timing information, `TimingInfo`.

```
normalMode = simOut.SimulationMetadata.TimingInfo;
```

From the timing information, extract the initialization time, execution time, and total elapsed time for the simulation.

```
normalInit = normalMode.InitializationElapsedWallTime;
normalExec = normalMode.ExecutionElapsedWallTime;
normalTotal = normalMode.TotalElapsedWallTime;
```

Simulate the model again using rapid accelerator mode. The first time you simulate a model in rapid accelerator mode, the rapid accelerator target builds during the initialization phase.

```
simIn = setModelParameter(simIn, "SimulationMode", "rapid");
simOut = sim(simIn);
```

```
### Building the rapid accelerator target for model: sldemo_fuelsys
### Successfully built the rapid accelerator target for model: sldemo_fuelsys
```

```
Build Summary
```

```
Top model rapid accelerator targets built:
```

Model	Action	Rebuild Reason
sldemo_fuelsys	Code generated and compiled	Code generation information file does not exist.

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 48.581s
```

Access the timing information for the first rapid accelerator simulation. Then, extract the initialization time, execution time, and total elapsed time for the simulation.

```
rapidAccel = simOut.SimulationMetadata.TimingInfo;
rapidBuildInit = rapidAccel.InitializationElapsedWallTime;
rapidBuildExec = rapidAccel.ExecutionElapsedWallTime;
rapidBuildTotal = rapidAccel.TotalElapsedWallTime;
```

Simulate again to see the benefit of rapid accelerator mode for a simulation that does not build the rapid accelerator target.

```
simOut = sim(simIn);
```

```
Build Summary
```

```
0 of 1 models built (1 models already up to date)
Build duration: 0h 0m 1.7911s
```

Access the timing information for the rapid accelerator simulation that ran without building the target. Then, extract the initialization time, the execution time, and the total elapsed time for the simulation.

```

rapidAccelNoRebuild = simOut.SimulationMetadata.TimingInfo;
rapidInit = rapidAccelNoRebuild.InitializationElapsedWallTime;
rapidExec = rapidAccelNoRebuild.ExecutionElapsedWallTime;
rapidTotal = rapidAccelNoRebuild.TotalElapsedWallTime;

```

Build a table to compare the timing for each simulation.

```

InitializationTime = [normalInit;rapidBuildInit;rapidInit];
ExecutionTime = [normalExec;rapidBuildExec;rapidExec];
TotalSimulationTime = [normalTotal;rapidBuildTotal;rapidTotal];

simNames = ["Normal Mode";"Rapid Accelerator";"Rapid Accelerator No Rebuild"];
timingTable = table(TotalSimulationTime,InitializationTime, ...
    ExecutionTime,RowNames=simNames);

```

In the first rapid accelerator simulation, the initialization time increases because the rapid accelerator target builds during the initialization phase. For this model and simulation duration, using rapid accelerator mode reduces the execution time so much that the first rapid accelerator simulation is still faster than using normal mode.

timingTable

timingTable=3×3 table

	TotalSimulationTime	InitializationTime	ExecutionTime
Normal Mode	92.268	5.8193	86.356
Rapid Accelerator	61.405	50.257	10.895
Rapid Accelerator No Rebuild	12.662	2.2544	10.33

## How to Improve Performance in Acceleration Modes

### In this section...

“Techniques” on page 38-31  
 “C Compilers” on page 38-31

### Techniques

To get the best performance when accelerating your models:

- Verify that the Configuration Parameters dialog box settings are as follows:

Set...	To...
<b>Solver data inconsistency</b>	none
<b>Array bounds exceeded</b>	none
<b>Signal storage reuse</b>	selected

- Disable Stateflow debugging and animation.
- When logging large amounts of data (for instance, when using the Workspace I/O, To Workspace, To File, or Scope blocks), use decimation or limit the output to display only the last part of the simulation.
- Customize the code generation process to improve simulation speed. For details, see “Customize the Build Process” on page 38-19.

### C Compilers

On computers running the Microsoft Windows operating system, the accelerator and rapid accelerator modes use the default 64-bit C compiler supplied by MathWorks to compile your model. If you have a C compiler installed on your PC, you can configure the mex command to use it instead. You might choose to do this if your C compiler produces highly optimized code since this would further improve acceleration.

**Note** For an up-to-date list of 32- and 64-bit C compilers that are compatible with MATLAB software for all supported computing platforms, see:

[https://www.mathworks.com/support/compilers/current\\_release/](https://www.mathworks.com/support/compilers/current_release/)

## Nonvirtual and Virtual Blocks

Simulink blocks fall into two basic categories: nonvirtual blocks and virtual blocks.

- Nonvirtual blocks play an active role in the simulation of a system. If you add or remove a nonvirtual block, you change the model behavior.
- Virtual blocks help organize a model graphically. While they play no active role in the simulation, they can affect the execution order of other blocks.

Some Simulink blocks are virtual in some circumstances and nonvirtual in others. Such blocks are called conditionally virtual blocks.

The table lists Simulink virtual and conditionally virtual blocks.

Block Name	Condition Under Which Block Is Virtual
Bus Assignment	Virtual if input bus is virtual.
Bus Creator	Virtual if output bus is virtual.
Bus Selector	Virtual if input bus is virtual.
Demux	Always virtual.
Enable	Virtual unless connected directly to an Outport block.
From	Always virtual.
Goto	Always virtual.
Goto Tag Visibility	Always virtual.
Ground	Always virtual.
In Bus Element	Virtual <i>unless</i> input bus is nonvirtual <i>and</i> contains a variable-size signal.
Inport	Virtual <i>unless</i> the block resides in a conditionally executed or atomic subsystem <i>and</i> has a direct connection to an Outport block.
Mux	Always virtual.
Out Bus Element	Virtual <i>unless</i> output bus is nonvirtual.
Outport	Virtual when the block resides within any subsystem (conditional or not), and does <i>not</i> reside in the root (top-level) Simulink window.
Selector	Virtual only when <b>Number of input dimensions</b> specifies 1 and <b>Index Option</b> specifies Select all, Index vector (dialog), or Starting index (dialog).
Signal Specification	Always virtual.
Subsystem	Virtual unless the block is conditionally executed or the <b>Treat as atomic unit</b> check box is selected.  You can check if a block is virtual with the <code>IsSubsystemVirtual</code> block property. See “Block-Specific Parameters”.
Terminator	Always virtual.
Trigger	Virtual when the output port is <i>not</i> present.

## Specify Block Properties

For each block in a model, you can set general block properties, such as:

- A description of the block
- The block execution priority
- A block annotation
- Block callback functions

To set block properties, use the Property Inspector. You can set properties in the **Properties** and **Info** tabs of the Property Inspector when the block is selected. Alternatively, you can use the Block Properties dialog box.

### Set Block Annotation Properties

In the Property Inspector, use the **Block Annotation** section to display the values of selected block parameters in an annotation. The annotation appears below the block icon.

Enter the text of the annotation in the text box. You can use a block property token in the annotation. The value for the property replaces the token in the annotation in the model. To display a list of tokens that you can use in an annotation, type % in the text box. The parameters that are valid for the selected block appear. See “Common Block Properties” and “Block-Specific Parameters”.

Suppose that you specify the following annotation text and tokens for a Product block:

```
Multiplication = %<Multiplication>
Sample time = %<SampleTime>
```

In the Simulink Editor, the block displays this annotation:

You can also create block annotations programmatically. See “Create Block Annotations Programmatically” on page 39-6.

### Specify Block Callbacks

Use the **Callbacks** section to specify block callbacks. Callbacks are MATLAB commands that execute when a specific model action occurs, such as when you select or delete a block. For more information on callbacks, see “Customize Model Behavior with Callbacks” on page 4-52.

- 1 Select the block whose callback you want to set.
- 2 In **Properties** tab of the Property Inspector, in the **Callbacks** section, select the function that you want to assign the callback to. For example, select `OpenFcn` to specify a behavior for double-clicking a block.

- 3 In the text box, enter the command that you want to execute when that block function occurs.

After you assign a callback to a function, the function displays an asterisk next to it in the list. The asterisks helps you to see the functions that have callbacks assigned to them.

---

**Note** After you add an `OpenFcn` callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select **Block Parameters** from the block context menu.

---

### Set a Block Callback Programmatically

This example shows how to use the `OpenFcn` callback to execute MATLAB scripts when you double-click a block. For example, in a MATLAB script you can define variables or open a plot of simulated data.

To create a callback programmatically, select the block to which you want to add this property. Then, at the MATLAB command prompt, enter a command in this form:

```
set_param(gcf, 'OpenFcn', 'myfunction')
```

In this example, `myfunction` represents a valid MATLAB command or a MATLAB script on your MATLAB search path.

### Specify Block Execution Priority and Tag

In the **Advanced Properties** section of the block properties, you can specify the block priority and identify the block by assigning a value to the **Tag** property.

- **Priority** — Specify the execution priority of the block relative to other blocks. Specify a numerical value. A smaller number indicates a higher priority.
- **Tag** — Specify an identifier for the block. Specify text to assign to the block **Tag** property. Setting this property is useful for finding the block in the model by searching or programmatically using `find_system`. See “Explore Model Hierarchy”.

---

**Note** In determining execution priority, Simulink compares the **Priority** of blocks only to that of other blocks in the same block diagram, even if the block diagram is a virtual subsystem, and only to other blocks that have their **Priority** explicitly set.

---

### Use Block Description to Identify a Block

The **Info** tab displays information about the block type. The block author provides this description.

You can also enter a description in the **Description** box to provide information about the block instance.

- If you add a description, you can set up your model display so that the description appears in a tooltip when you hover over the block. To enable this tooltip, on the **Debug** tab, select **Information Overlays > Description in Tooltip**.
- The **Description** property can help you to find a block by searching. See **Simulink Editor**.

## Create Block Annotations Programmatically

You can use a block `AttributesFormatString` parameter to display specified block parameter values below the block. “Common Block Properties” and “Block-Specific Parameters” describe the parameters that a block can have. Use the Simulink `set_param` function to set this parameter to the attributes format that you want.

The attributes format can be any text that has embedded parameter names. An embedded parameter name is a parameter name preceded by `%<` and followed by `>`, for example, `%<priority>`. Simulink displays the attributes format text below the block icon, replacing each parameter name with the corresponding value. You can use line-feed characters (`\n`) to display each parameter on a separate line. For example, select a Gain block and enter this command at the MATLAB command prompt:

```
set_param(gcf, 'AttributesFormatString', 'pri=%<priority>\ngain=%<Gain>')
```

The Gain block displays this block annotation:

If a parameter value is not text or an integer, N/S (for not supported) appears in place of the value. If the parameter name is not valid, Simulink displays ??? in place of the value.

### More About

- “Add Blocks and Set Parameters” on page 1-13
- “Customize Model Behavior with Callbacks” on page 4-52

## Format a Model

As you build a model, you can adjust block positions, change block colors, place block names and ports on any side of the block, adjust fonts, and add elements that help to improve model readability. These changes can help to organize the model visually and help others understand the model.

You can make these types of changes to your model format:

- Improve the model layout. See “Improve Model Layout” on page 39-7.
- Flip or rotate blocks or groups of blocks. These adjustments help blocks to fit in the model and connect with other blocks. See “Flip or Rotate Blocks” on page 39-9.
- Reposition or hide block names, edit port labels, and move ports to any side of the block. See “Manage Block Names and Ports” on page 39-12.
- Add colors to blocks and to the background. See “Specify Model Colors” on page 39-13.
- Adjust aesthetics by changing fonts and deepening the intensity of drop shadows. See “Specify Fonts in Models” on page 39-14 and “Increase Drop Shadow Depth” on page 39-15.
- Surround groups of blocks with a box to show that the blocks are related. See “Box and Label Areas of a Model” on page 39-15.
- Copy formatting from a block, line, or area to another model element. See “Copy Formatting Between Model Elements” on page 39-16.
- Document a model using text, image, and math annotations. See “Describe Models Using Notes and Annotations” on page 4-4.
- Annotate a block. See “Set Block Annotation Properties” on page 39-4.
- Change the block icon. For example, you can use a mask to display a graphic on a block. A mask also enables you to design a custom interface for a block. To learn about masks, see “Masking Fundamentals” on page 42-2.

### Improve Model Layout

To improve your diagram layout and appearance, on the **Format** tab, click **Auto Arrange**, or, press **Ctrl+Shift+A**. This option:

- Aligns blocks in your model from left to right, starting with inputs and ending with outputs
- Resizes blocks, such as the Constant block, to display long parameter values
- Standardizes block size among similar blocks
- Straightens signal lines by moving blocks

Alternatively, you can try improving the shapes of individual signal lines. Select the signal line and, from the action bar, select **Auto-route Line**. The line redraws if a better route between model elements is possible.

You can try to improve multiple lines by using **Auto-route Lines**. To access **Auto-route Lines** from the action bar, select a block or select multiple model elements by dragging a box around the elements.

### Move Multiple Model Elements Together

To move multiple model elements while maintaining their relationship with each other:

- 1 Select the model elements by dragging a selection box around them.
- 2 Move the model elements by dragging an edge of the selection box to a new position.

The contents of the selection box move as a unit. The relationship among lines, blocks, and other elements in the selection box remains the same as you move them. Line segments outside of the selection box reroute.

For example, suppose you have this model:

When you drag a selection box that includes line bends, the included line bends remain the same when you move the selection.

When you drag a selection box that excludes line bends, the excluded line bends may change when you move the selection.

To move multiple lines together, drag the selection box around the line segments you want to move.

## Flip or Rotate Blocks

You can change the orientation of a block or a group of blocks by rotating blocks in 90-degree increments or by flipping the blocks. Rotating or flipping blocks can help them fit better in the model, such as in feedback loops, where the blocks are connected to each other in a loop. You might also need to rotate a block so that the block input ports align with output ports or to make better use of the model canvas.

The figure shows a Gain block flipped to simplify a feedback loop diagram.

To rotate a block, select the block and, on the **Format** tab, click the **Rotate 90 clockwise** button  or the **Rotate 90 counterclockwise** button .

Blocks automatically rotate when you place them on a signal line that has an orientation other than left to right. For example, if the signal goes from bottom to top and you place a block on it, the block rotates to align with the signal.

To flip a block, select the block and, on the **Format** tab, click **Flip left-right** button  or **Flip up-down** button . You can flip a block horizontally or vertically based on the orientation of the block ports. For example, if the ports are on the sides, the block flips left to right.

To rotate or flip a group of blocks, select multiple blocks before rotating or flipping them. You can only flip groups of blocks to the left or right.

After you rotate or flip a group of blocks, you can improve the readability of the model by editing the signal lines. The **Auto Arrange** option might improve the appearance of signals. (For information on rotation with multiple ports, see “Port Location After Rotating or Flipping” on page 39-11.)

For example, suppose you rotate these selected blocks clockwise.

After you rotate the blocks, the model might contain overlapping elements.

With the blocks and signals selected, on the **Format** tab, select **Auto Arrange**.

### Port Location After Rotating or Flipping

Rotating moves block ports from the sides to top and bottom or the reverse, depending on the placement of the ports. The resulting positions of the block ports depend on the block port rotation type.

Rotating can reposition the ports on some blocks to maintain left-to-right or top-to-bottom port numbering order. A block whose ports are reordered after a rotation has the default port rotation type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. The figure shows the effect of clockwise rotation on a block with the default port rotation policy.

A masked block can specify that ports keep their order after rotation (see “Icon drawing commands”). These blocks have a physical port rotation type. This policy helps when designing blocks to use when modeling physical systems and other applications where diagrams do not have a preferred orientation. The figure shows the effect of clockwise rotation on a block with a physical port rotation type.

Flipping a block moves the ports to the opposite side of the block, creating a mirror image, regardless of port rotation type.

## Manage Block Names and Ports

You can manage block names by displaying or hiding them and by changing their location on the block.

---

**Note** Copying and pasting blocks whose names follow numeric order (Gain1, Gain2, and so on) creates names that follow standard sorting order conventions for ASCII characters. This sorting order can result in a sequence of numbers on the block names that is hard to understand. If the numbering scheme is important to you, name your blocks explicitly such that copying and pasting them creates names that follow a typical reading order. To do so, use a leading zero in the block names, for example Gain001, Gain002, and so on.

---

### Hide or Display Block Names

The Simulink Editor names blocks when you create them. The first occurrence of the block is the library block name, for example, Gain. The next occurrence is the block name with a number appended. Each new block increments the number, for example, Gain1, Gain2, and so on. These names are called automatic names. By default, the editor hides these names.

You can choose whether to hide or display block names. You can:

- Display all automatic names. Select one or multiple blocks and, on the **Format** tab, select the button that says **Auto Name, Name On**, or **Name Off** depending on its current setting. Then, clear **Hide Automatic Block Names**.
- Temporarily display a hidden automatic block name by selecting the block.
- Name the block explicitly. The **Hide Automatic Names** setting does not affect blocks that you name explicitly. To name a block, select it, double-click the name, and type a new name.

In addition, you can explicitly hide or display any block name. Explicitly hidden or displayed block names are not affected by the **Hide Automatic Block Names** setting. To explicitly hide or display a block name, select the block, then on the **Format** tab, select the button that says **Auto Name, Name On**, or **Name Off** depending on its current setting. Then, select:

- **Name On** to always display the block name.
- **Name Off** to always hide the block name.
- **Auto Name** to return to the default state. If the block has a default name, the **Hide Automatic Block Names** setting affects the block.

---

**Tip** You can pause on a block to display the block name irrespective of the name settings at the block and model levels. You can edit the block name when it displays.

---

To display and hide block names programmatically, use `set_param` with the `'HideAutomaticNames'` option for models and the `'HideAutomaticName'` and `'ShowName'` options for blocks. For more information on these parameters, see “Common Block Properties”. The table shows how these parameters interact.

'ShowName' (block setting)	'HideAutomaticName' (block setting)	'HideAutomaticNames' (model setting)	Result
'off'	Any	Any	Name is hidden
'on'	'on'	'on'	Name is hidden
'on'	'off'	Any	Name is shown
'on'	'on'	'off'	Name is shown

### Move Block Names

By default, block names appear below blocks whose ports are on the sides and to the left on blocks whose ports are on the top and bottom. To change the location of a block name, you can:

- Drag the block name to any side of the block.
- Select the block and, on the **Format** tab, click **Flip Name**.

### Move Ports

You can put ports in any order on any side of these blocks:

- Subsystem block
- Subsystem Reference block
- Model block
- Chart block
- Truth Table block
- State Transition Table block

You can move ports by clicking and dragging the port. For Subsystem blocks, the port index will automatically be renumbered after each move. For port label editing on Subsystem blocks, see “Edit Port Labels on Subsystems” on page 4-21.

### Specify Model Colors

You can specify the outline and interior colors of any block, and you can change the background color for any system in a model. You can also change the text color and background color for annotations and the background fill color for areas.

This subsystem uses color to identify the input ports.

- To change the outline color of a block, text color in an annotation, or interior color for an area, select the element, and then, on the **Format** tab, select a color from the **Foreground** menu. Changing the foreground color of a block also changes the color of its output signals.
- To change the interior color of a block or background color in an annotation, select the element, and then, on the **Format** tab, select a color from the **Background** menu.
- To change a background color in a system, open the system and, on the **Format** tab, select a color from the **Background** menu.

You can select a color from the menu or select the **Custom Color** button  to define your own color.

You can also use the Property Inspector to change color for an area or an annotation. To specify colors programmatically, see “Specify Colors Programmatically” on page 1-6

## Specify Fonts in Models

Change the font family, style, and size for any model element to make your model easier to read or to comply with company standards. You can modify the font for selected blocks, signal labels, areas, and annotations. Some blocks display text according to the font style settings, and some blocks have fixed fonts and styles. To increase the font size of those blocks, zoom in.

You can also change the default font for the model. The default font affects any elements whose font you have not changed and any new elements you create. If you want to use the same default font in all new models, change the default model font in your default template. See “Set Default Template for New Models” on page 1-9.

- To change the font of a block, signal label, area, or annotation, select the element, and then specify font information on the **Format** tab in the **Font & Paragraph** section.

- To change the default fonts for the model, on the **Format** tab, click the **Font Properties** button arrow , then click **Fonts for Model**. Use the Font Styles dialog box to specify the font information.

You can also use the Property Inspector to change font for an area or an annotation.

### Select Font Dialog Box on Linux Machines

On Linux machines configured for English, the **Font style** list in the Select Font dialog box can appear out of order or in another language in some fonts. If the characters in your **Font style** list appear in another language, set the LANG environment variable to `en_US.utf-8` before you start MATLAB. For example, at a Linux terminal, enter:

```
setenv LANG en_US.utf-8
matlab
```

### Increase Drop Shadow Depth

By default, blocks have a drop shadow. To make the block stand out more against the background, you can increase the depth of the drop shadow.

Select the blocks whose drop shadow depth you want to increase and, on the **Format** tab, click **Shadow**.

---

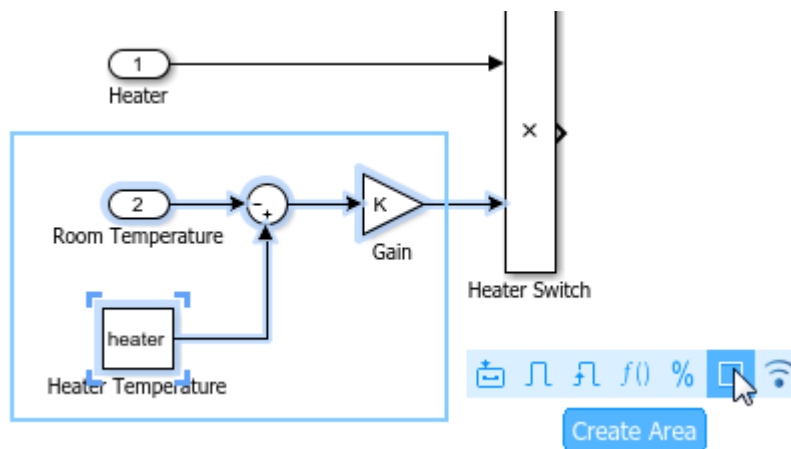

**Tip** To remove the default drop shadow for all blocks, in the Simulink Toolstrip, on the **Modeling** tab, select **Environment > Simulink Preferences**. In the **Editor** pane of the Simulink Preferences dialog box, select **Use classic diagram theme**.

---

### Box and Label Areas of a Model

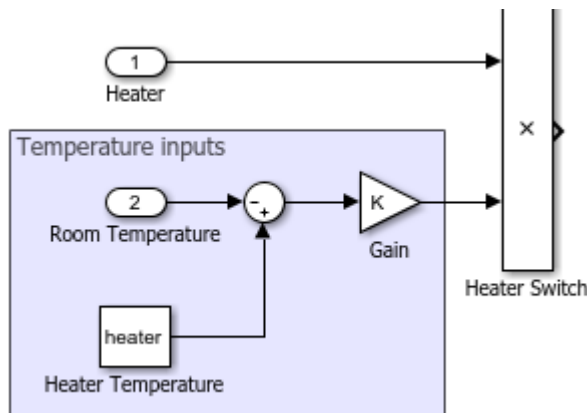

Add an area to your model to visually group related model elements in a box. An area can move with the blocks it surrounds. You can add text to an area to briefly describe or label the area.

- 1 Drag a box around the area of interest in the model. Alternatively, drag on a blank area of the canvas to draw the area shape.
- 2 From the action bar, select the option to create an area.

- 3 Type the name of the area. The name appears in the upper-left corner of the area.

To enter the name later, select the area, click the **?**, and start typing, or use the **Name** property in the Property Inspector.

- 4 Optionally, add a description of the area contents using the Property Inspector.
- 5 To move the area and its contents, drag the area near the border.

---

**Tip** To move an area without moving its contents, hold **Alt** (**option** on a Mac) and drag.

---

### Convert Area to a Subsystem

An area is similar to a subsystem in that it is a way to group related blocks. However, a subsystem creates a hierarchy, replacing multiple blocks in a model with a single block. You can initially group related blocks in an area and later decide to put those blocks in a subsystem by converting the area to a subsystem. The resulting subsystem has the same name, blocks, description, and requirements traceability information as the area.

To convert an area to a subsystem, right-click the area and select **Create Subsystem from Area**.

### Copy Formatting Between Model Elements

If you have applied formatting to a block, signal line, or area in a model, you can copy the formatting and apply it to another model element. Examples of formatting include font changes, foreground and background color selections, and drop shadow effects.

- 1 Select the block, line, or area whose formatting you want to copy.
- 2 From the action bar, select **Copy Formatting**. The cursor becomes a paintbrush.

- 3 Using the paintbrush, click each element that you want to copy the formatting to.
- 4 To cancel the paintbrush cursor, click a blank spot on the canvas or press **Esc**.

## Display Port Values for Debugging

### In this section...

“Display Port Values for Easy Debugging” on page 39-18

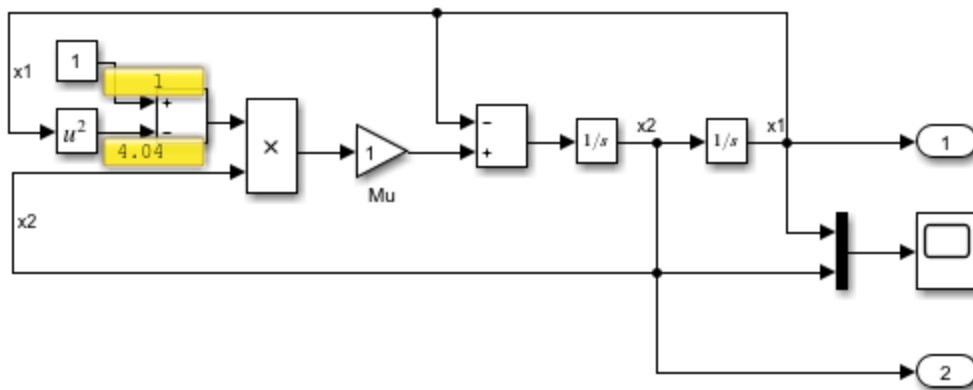

“Display Value for a Specific Port” on page 39-21

“Display Port Values for a Model” on page 39-24

“Port Value Display Limitations” on page 39-25

### Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the ports on the Constant and Math blocks, output values of 1 and 4.04.

If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the text *optimized*.

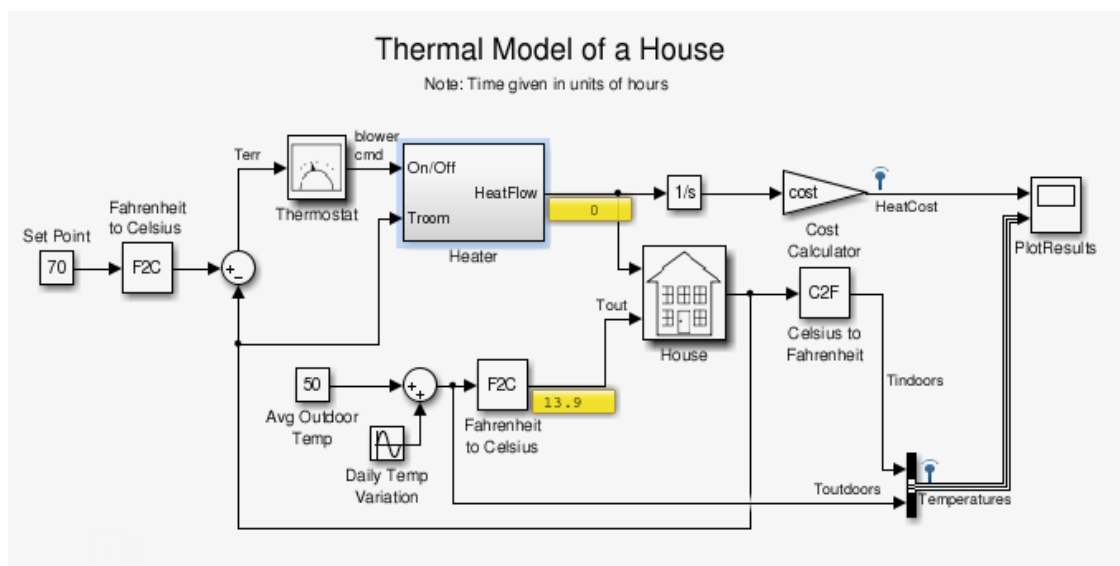

Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.

These results suggest a problem with the model because:

- The heating cost is 0 at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is 0 at every time step.

To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at 0.

This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you monitor a signal value during simulation. However, these labels are not saved with a model.

For nonnumeric data display, Simulink uses these values:

Message	Explanation
action	The signal executes action subsystems.
fcn-call	The signal is a function-call signal, e.g., Function Call Generator output.
ground	The signal is coming from a Ground block.
not a data signal	The signal does not contain valid data, e.g., the signal is from a block that is commented out.

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these values.

Message	Explanation
...	The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see "Display Port Values for a Model" on page 39-24.
(no message)	The simulation data available is insufficient. Step forward or press play to obtain more data.
click to add signals	You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.
inaccessible	Simulink cannot obtain the port value. For an example, see "Signal Storage Reuse" on page 39-25.
[m*n]	This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.

Message	Explanation
no data yet	This message appears when: <ul style="list-style-type: none"> <li>The simulation data is not available. Start the simulation to see values.</li> <li>If the model contains subsystems (for example, an enabled subsystem) and model references and they are not executed during a simulation.</li> </ul>
not used	Simulink cannot obtain the signal value due to optimization.
removed	Simulink cannot obtain the signal value due to block reduction.
optimized	Simulink cannot obtain the signal value due to optimization. In Normal mode, this message appears for blocks with <b>Conditional input branch execution</b> enabled. For more information, see “Conditionally Executed Subsystems Overview” on page 10-3.
unavailable	The simulation data available is insufficient. For example, see “Simulation Stepper” on page 39-26.

---

**Note** You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

---

## Display Value for a Specific Port

To display the value of a specific port or port values for a block before simulation, select one or more signals, right-click the selection, and select **Show Value Label of Selected Port**.

By default, Simulink displays the value of a signal when you click it during simulation. You can control this behavior. On the **Debug** tab, select the **Remove all simulation output Value Displays from**

**canvas** button arrow , then select **Options**. In the Value Label Display Options dialog box, select **Enable by default during simulation**.

---

**Note** To remove all data tips, on the **Debug** tab, select the **Remove all simulation output Value Displays from canvas** button arrow , then select **Remove Value Displays**.

---

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label has no data; it displays values when you simulate the model.

When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog. You can also click on another signal to display its value.

**Note** Simulink does not save the values of a signal when you remove the port value label.

## Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

- 1 In the model whose port values you want to display, on the **Debug** tab, select the **Remove all simulation output Value Displays from canvas** button arrow , then select **Options**.
- 2 In the Value Label Display Options dialog box, specify your preferences for:
  - The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
  - The display mode
  - Floating-point or fixed-point format

## Port Value Display Limitations

### Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

### Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

Accelerated Mode	Port Values
Accelerator	<ul style="list-style-type: none"> <li>Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as <b>optimized</b>. For more information, see “Display Port Values for Easy Debugging” on page 39-18.</li> <li>Model reference blocks simulated in Accelerator mode do not get their port value displays updated.</li> </ul>
Rapid Accelerator	Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

### Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as **inaccessible**. You can disable signal storage reuse using the **Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

### Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

### Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Outputport block displays the value of the Outputport block, depending on the **Output when disabled** setting.

- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

### **Simulation Stepper**

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the `unavailable` label is displayed.

### **Refine Factor**

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Additional parameters > Refine factor**) because Simulink updates port value displays only during major time steps.

### **Signal Specification Block and Inport Block**

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

### **Command-Line Simulations**

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

### **Merge Block**

Simulink does not display the input values to the merge block. To see this value, refer to the source block.

### **Command Line Interface**

You cannot specify port value displays through the command line interface.

### **Non-Simulink signals**

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

- “Access Block Data During Simulation” on page 39-40
- “Block Libraries”

## Control and Display Execution Order

The execution order for a model is the order in which Simulink invokes the block output methods during simulation. Simulink determines this order during a model update, which you can initiate by clicking **Update Model** on the **Modeling** tab. Simulink also updates the model during simulation.

You cannot set the execution order, but you can assign priorities to nonvirtual blocks to indicate their execution order relative to other blocks in the corresponding block diagram.

Some nonvirtual blocks do not support block priorities. For example, Simulink ignores priorities set on these blocks:

- Merge blocks
- Blocks with function-call input ports, such as Function-Call Subsystem blocks and Model blocks that reference export-function models
- Blocks with action ports, such as If Action Subsystem and Switch Case Action Subsystem blocks

If a priority is set on these blocks, the **Block priority violation** configuration parameter setting determines whether you receive a warning or error.

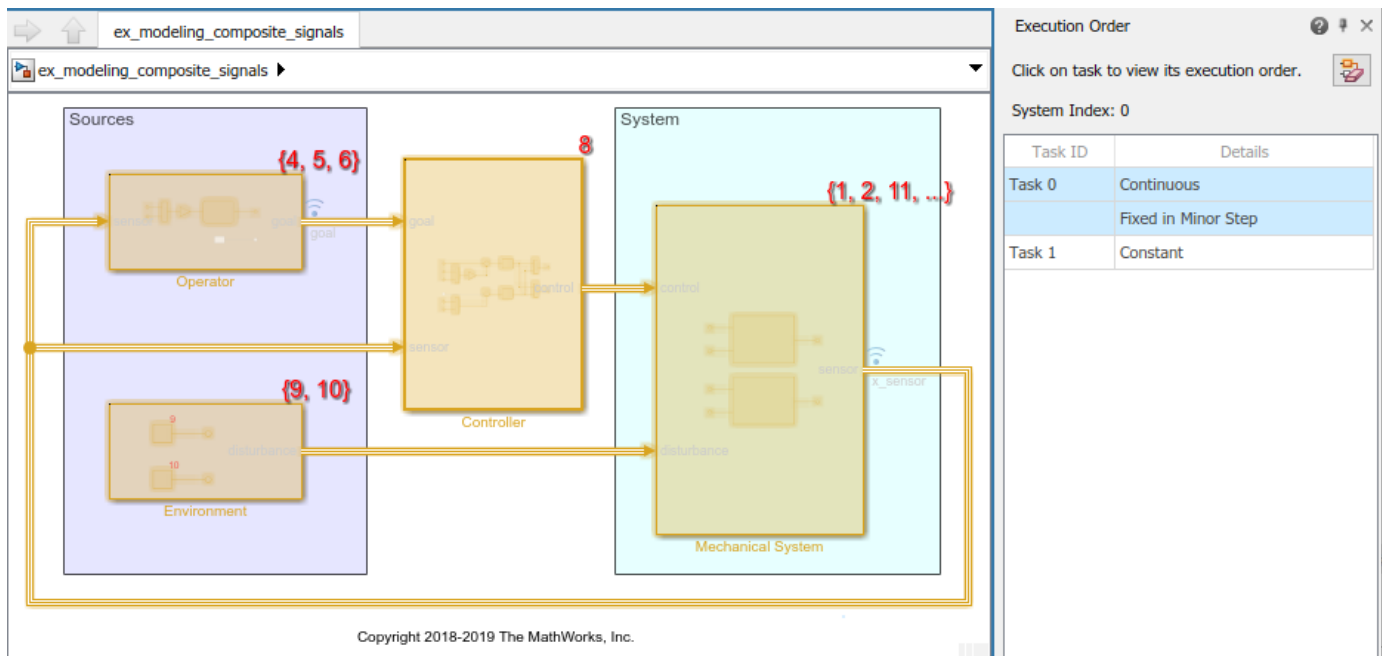

Simulink tries to honor block priority settings unless there is a conflict with data dependencies. To confirm the results of the priorities you have set or to debug your model, display and review the execution order of your nonvirtual blocks and subsystems.

For more information about block methods and execution, see:

- “Block Methods”
- “Conditionally Executed Subsystems Overview” on page 10-3
- “Specify Block Execution Priority and Tag” on page 39-5

### Execution Order Viewer

On the **Debug** tab, select **Information Overlays > Execution Order**. The Execution Order viewer opens in a pane on the right side of the Simulink Editor.

The Execution Order viewer displays a list of tasks for the current system.

Each nonvirtual subsystem has its own **System Index** value that is unique within the model. Blocks that are directly inside the nonvirtual subsystem have the same **System Index** value as the subsystem. In model reference hierarchies, the same **System Index** value may be used multiple times, but it remains unique within each model in that hierarchy. To determine whether subsystems are part of the same system within a model, compare their **System Index** values.

Each task listed in the **Task ID** column corresponds to a group of blocks that execute in the same task. For fixed-step sizes, the **Treat each discrete rate as a separate task** configuration parameter determines whether Simulink executes blocks with discrete rates in one or multiple tasks.

Selecting a task in the Execution Order viewer highlights the blocks that belong to the task and displays their execution order. By default, Simulink selects the first task that corresponds to the active block diagram.

When the active block diagram does not contain any blocks that execute as part of a given task, you cannot select the task in the Execution Order viewer. The active block diagram may contain virtual blocks, such as Inport blocks, that are part of this task.

To hide the highlighting and execution order, click the **Clear Highlighting** button .

## Navigation from Blocks to Tasks

To display the tasks in which a block executes, click on a block.

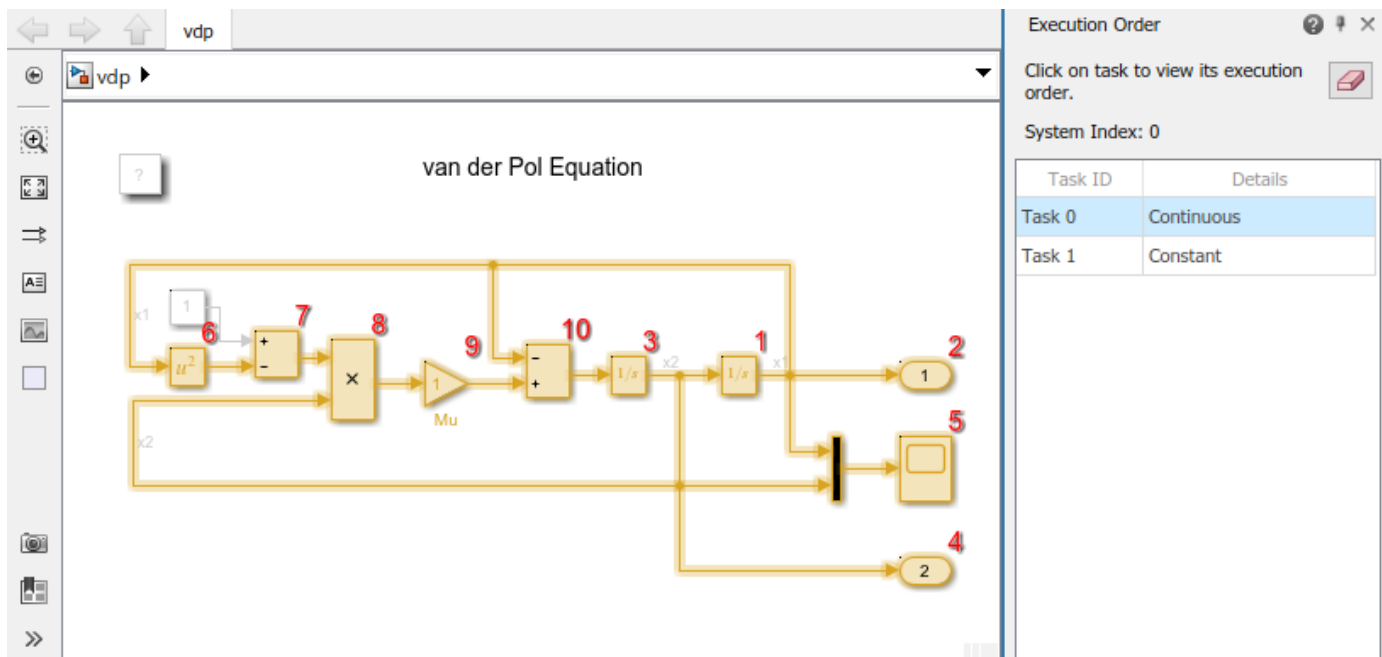

The task numbers in the label are links that you can click to select the corresponding task in the Execution Order viewer. When a model has many tasks, these links provide an alternative to scrolling through the list of tasks in the Execution Order viewer.

To compare tasks among blocks, select multiple blocks.

## Execution Order Notation

Simulink displays a number at the top-right corner of each nonvirtual block. These numbers indicate the order in which the blocks execute. The first block to execute has the lowest execution order, which is usually 1. The displayed execution order may skip numbers, but the blocks always execute in order of the visible numbers. Suppose a task displays execution orders 1, 2, and 4. The block labeled 1 executes before the block labeled 2, which executes before the block labeled 4.

For example, in the vdp model, the block execution order ranges from 1 to 9, with each nonvirtual block receiving an execution order.

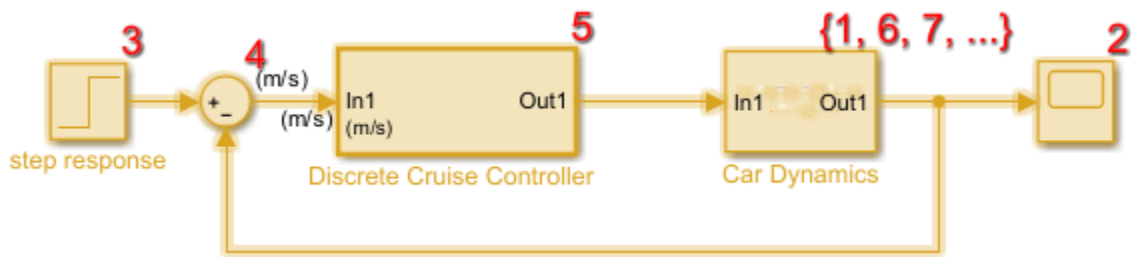

## Virtual and Nonvirtual Subsystems

Virtual Subsystem blocks exist only graphically and do not execute. Consequently, they are not part of the execution order. Creating virtual subsystems can affect the execution order of blocks when the

blocks are sorted by block path. Each block within a virtual subsystem executes as an atomic unit and has an execution order in the context of the root-level model or, if the virtual subsystem is inside a nonvirtual subsystem, in the context of the parent nonvirtual subsystem. For virtual subsystems, block execution order within the subsystem is listed in curly brackets {}.

Nonvirtual Subsystem blocks exist functionally and execute as a unit. They have a single execution order and a different system index than the root-level model or any parent nonvirtual subsystem. The blocks inside a nonvirtual subsystem have their own execution orders, which are independent of the root-level model or any parent nonvirtual subsystem.

For example, this model contains a virtual subsystem named Car Dynamics and an atomic, nonvirtual subsystem named Discrete Cruise Controller.

The virtual Car Dynamics subsystem shows a list of execution orders within curly brackets for the blocks it contains. The blocks it contains execute at the same level as the Step, Sum, and Scope blocks and the Discrete Cruise Controller nonvirtual subsystem. The Integrator block executes first and sends its output to the Scope block, which executes second.

The nonvirtual Discrete Cruise Controller subsystem has a single execution order (5), which indicates that the subsystem and the blocks within it are the fifth to execute relative to the blocks at the same level.

**Note** Depending on your model configuration, Simulink can insert hidden, nonvirtual subsystems in your model. As a result, the visible blocks inside the hidden Subsystem block can have a system index that is different from the current system index. For example, if you select the **Conditional input branch execution** configuration parameter, Simulink may create hidden, nonvirtual subsystems for optimization, which can affect the sorted execution order.

### Algebraic Loops

Blocks within an algebraic loop are moved into a hidden nonvirtual subsystem. Simulink first determines the execution order of the hidden subsystem within the context of the other blocks, then determines the execution order of the blocks within the hidden subsystem. See “Algebraic Loop Concepts” on page 3-39.

### Function-Call and Action Subsystems

For function-call and action subsystems, the execution of the subsystem is controlled by the execution of its initiator. The subsystem and its initiator therefore share an execution order.

Simulink ignores any block priority set on Function-Call Subsystem, If Action Subsystem, or Switch Case Action Subsystem blocks, but you can set the block priority on the blocks that initiate these subsystems.

At the root-level of export-function models, function-call execution orders have an F prefix.

For more information, see “Export-Function Models Overview” on page 10-96.

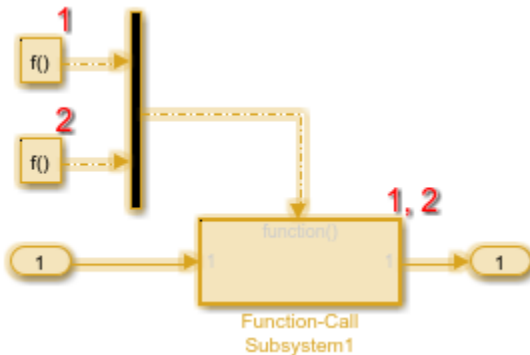

### Buses and Multiple Initiators

A block has multiple execution orders when the block executes multiple times based on different execution paths to that block. For example:

- A block connected to a bus has an execution order corresponding to each signal that the bus contains.

- A function-call or action subsystem with multiple initiators has an execution order corresponding to each initiator.

### How Simulink Determines Execution Order

Simulink uses task-based sorting to set the execution order of blocks and ports based on their derived sample time information. Task-based sorting provides an efficient and simpler process for determining the execution order of blocks.

With task-based sorting:

- Tasks are sorted individually based on sample time.
- Multiple sorted lists are generated instead of one flattened, sorted list of blocks across all tasks.
- Rate transition handling is simplified.
- False data dependency violations involving blocks in different tasks are avoided.
- Code generation results are in efficient rate groupings.
- One subsystem can belong to different sorted lists in multiple tasks.

### Direct-Feedthrough Input Impact on Execution Order

To ensure that the execution order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* input. See “Algebraic Loop Concepts” on page 3-39. Examples of blocks that have direct-feedthrough inputs include:

- Gain
- Product
- Sum

Examples of blocks without direct-feedthrough inputs include:

- Integrator
- Unit Delay
- Constant

### Rules for Determining Block Execution Order

To sort blocks, Simulink uses these rules:

- If a block drives the direct-feedthrough input of another block, the driving block must appear in the execution order ahead of the block that it drives.

This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block output methods that require current inputs.

- If a block drives the input of another block that is not a direct-feedthrough input, there is no data dependency between the two blocks, so their relative execution order does not matter.

This model illustrates this result.

- The Integrator block  $1/s$  in the Car Dynamics virtual subsystem has no direct-feedthrough input. Therefore, even though its input is connected to the Gain block  $1/m$ , the Integrator block is sorted before the Gain block  $1/m$ . The output of the Integrator block drives the input of the Gain block  $b$ , so the Integrator block is sorted before that Gain block.

- In the root-level model, the Step block `step` response drives a Sum block, so the Step block is sorted before the Sum block. The Sum block drives the direct-feedthrough input of the Discrete Cruise Controller nonvirtual subsystem, so the subsystem is sorted after the Sum block.

The Discrete Cruise Controller nonvirtual subsystem is treated as a block with a direct-feedthrough input because its output depends on the current value of the input via the branch with the  $K_p$  Gain block. Inside the subsystem, all the Gain blocks, which have direct-feedthrough inputs, run before the Sum block that they drive.

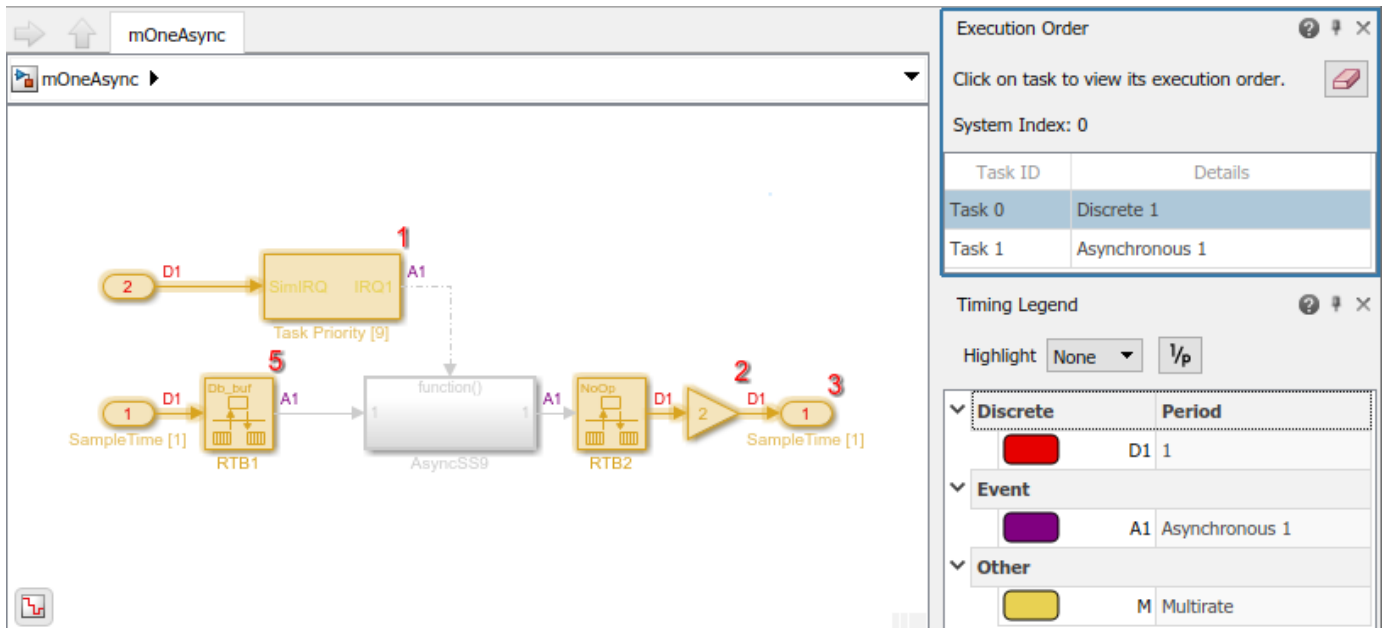

### Rules for Determining Block Execution Order in Models Containing Asynchronous Tasks

In simulation, asynchronous function call initiators have the highest priority when determining block sorting order within a task. For more information, see “Asynchronous Sample Time” on page 7-22 and “Rate Transitions and Asynchronous Blocks” (Simulink Coder).

To determine the block execution order in models containing asynchronous sample times, Simulink uses these rules:

- If an asynchronous function call initiator is triggered by a discrete rate shared by the corresponding rate transition block, then in the task of the common discrete rate, the asynchronous function call initiator will be sorted first.

For example, in the below model, there is one asynchronous function call initiator that is triggered by the discrete rate D1. Within the discrete task, the asynchronous function call initiator is sorted first. The Rate Transition blocks convert between the asynchronous rate, A1, and the discrete rate, D1.

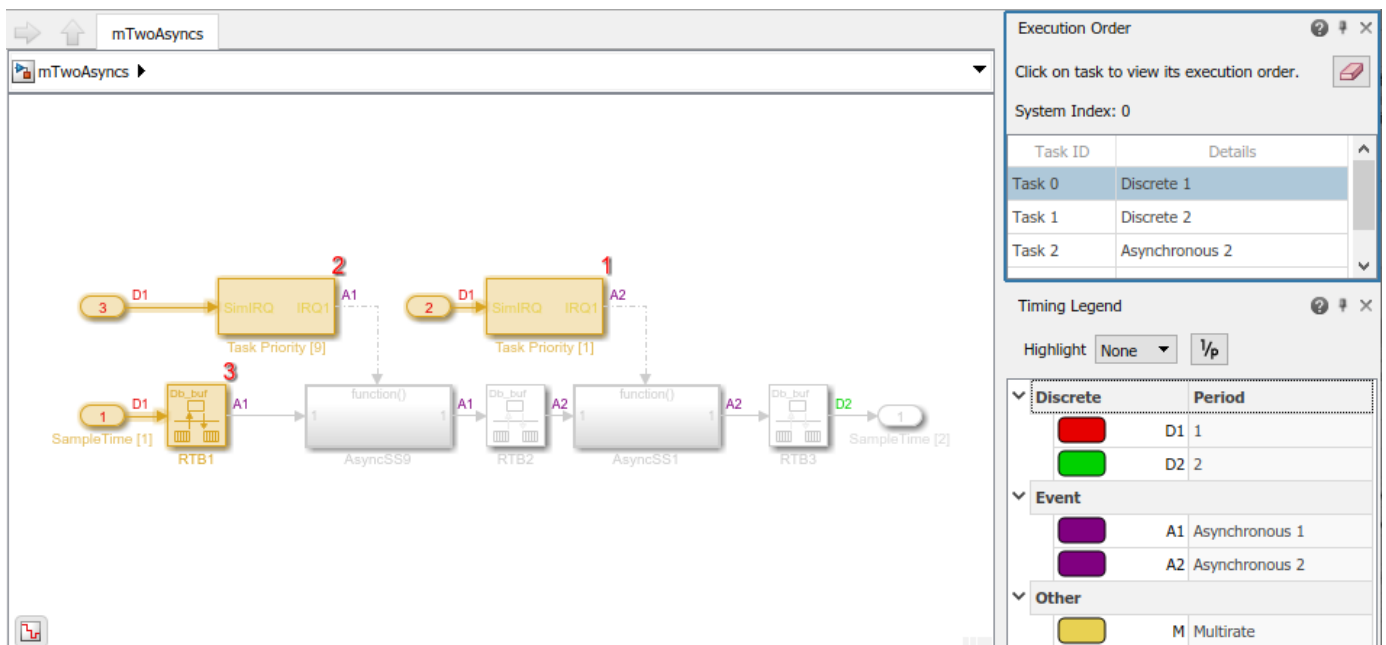

- If a Rate Transition block is reduced to NoOp, the Rate Transition block does not execute, and its position in the sorted order within the discrete task is transferred to the upstream or downstream discrete block to which it is connected.

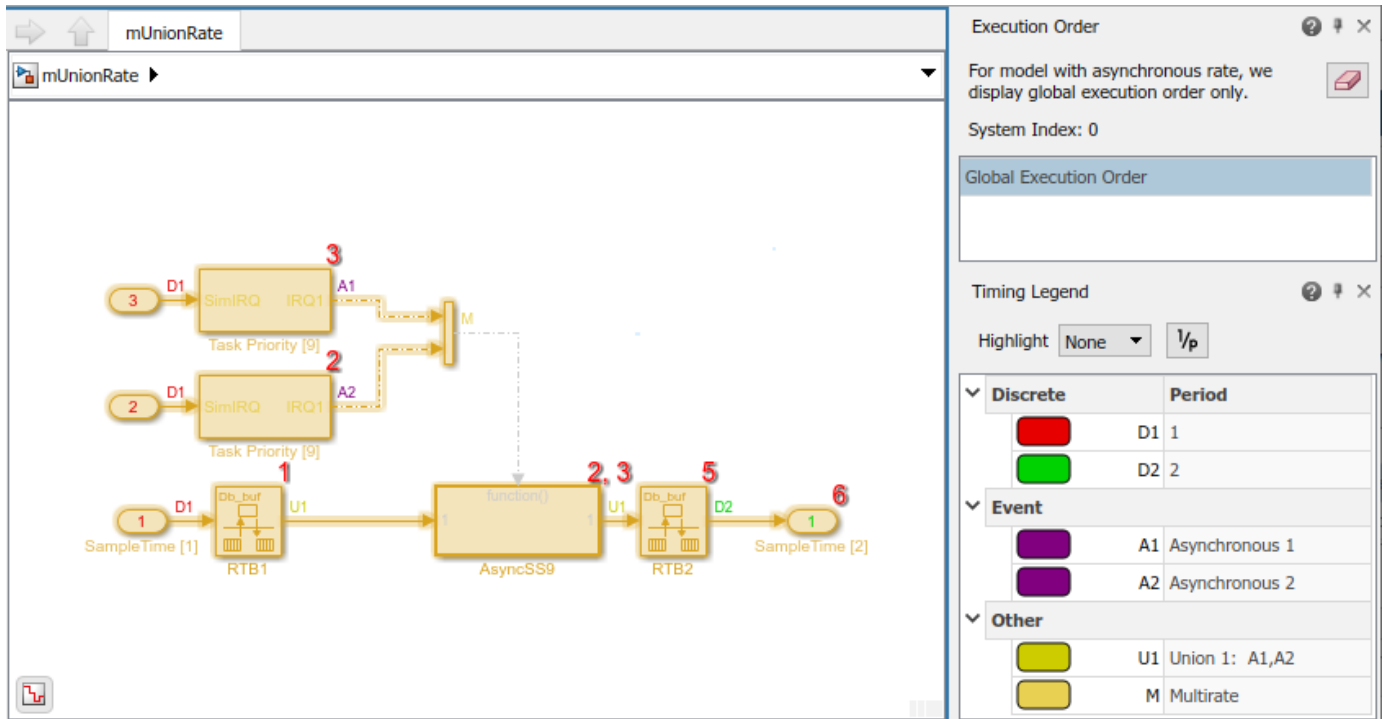

For example, in the above model, RTB2 is reduced to NoOp, so its position in the sorted order is transferred to the downstream Gain block.

- If two asynchronous function call initiators share a common discrete rate task, then asynchronous function call initiator with higher priority executes first within the discrete rate task.

For example, in the below model, two asynchronous function call initiators are triggered by the same discrete rate, D1. The one with higher task priority is sorted first.

- The union of asynchronous sample times is not supported by task-based sorting. Models containing the union of multiple asynchronous sample times default to a global execution order, in which all blocks are sorted within a single task.

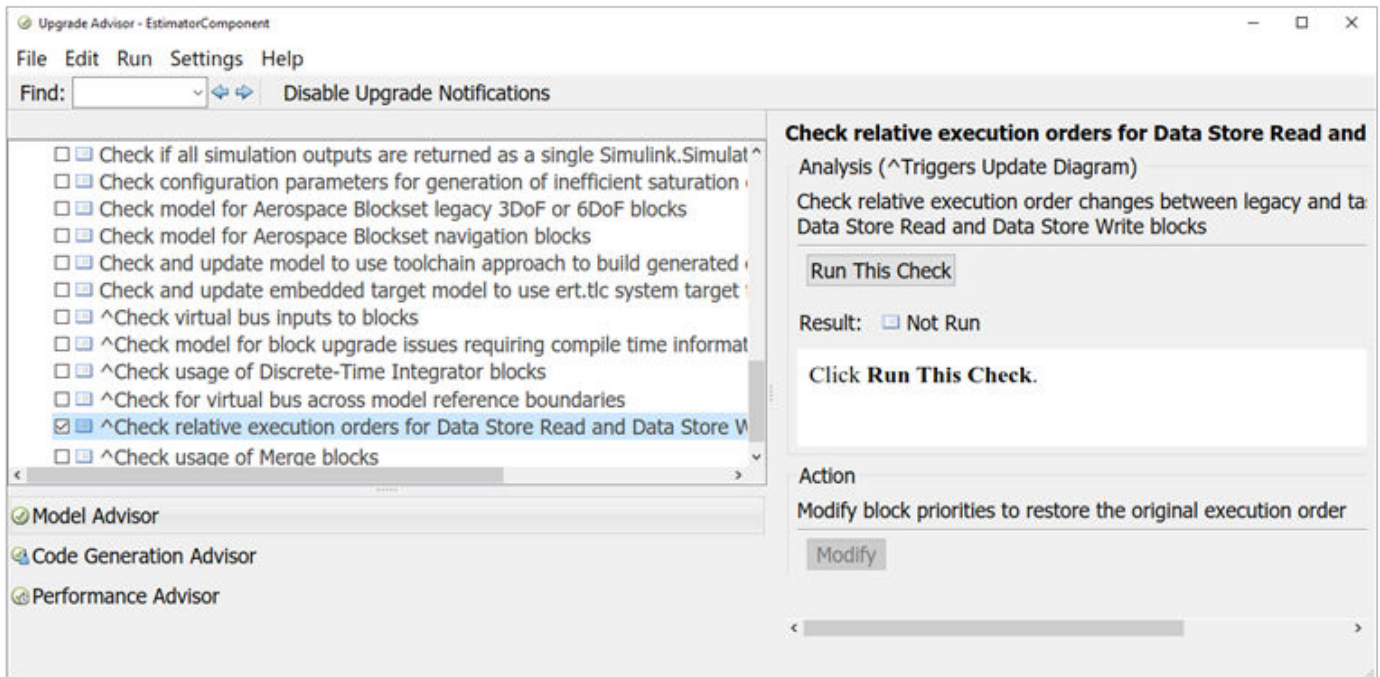

## Checks for Execution Order Changes Involving Data Store Memory Blocks

### Model Upgrades

Using task-based sorting instead of legacy (block) sorting can change the relative execution order involving Data Store Memory blocks. An Upgrade Advisor check detects the changes and provides an option to keep the original execution order when upgrading your model from earlier versions of Simulink.

- 1 Open the Upgrade Advisor. On the **Modeling** tab, select **Model Advisor > Upgrade Advisor**.
- 2 Select the check box for **Check relative execution orders for Data Store Read and Data Store Write blocks**.

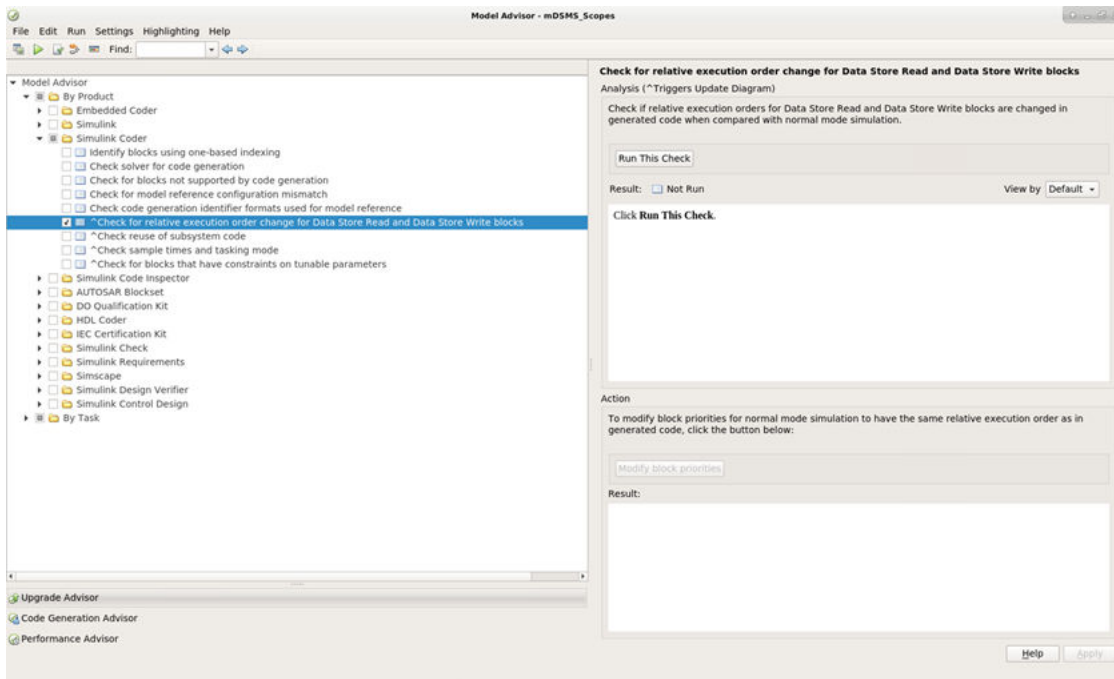

- 3 Click **Run This Check**.
- 4 Review any changes in the **Result** table. If you want to keep the original execution order, click **Modify**.

### Code Generation

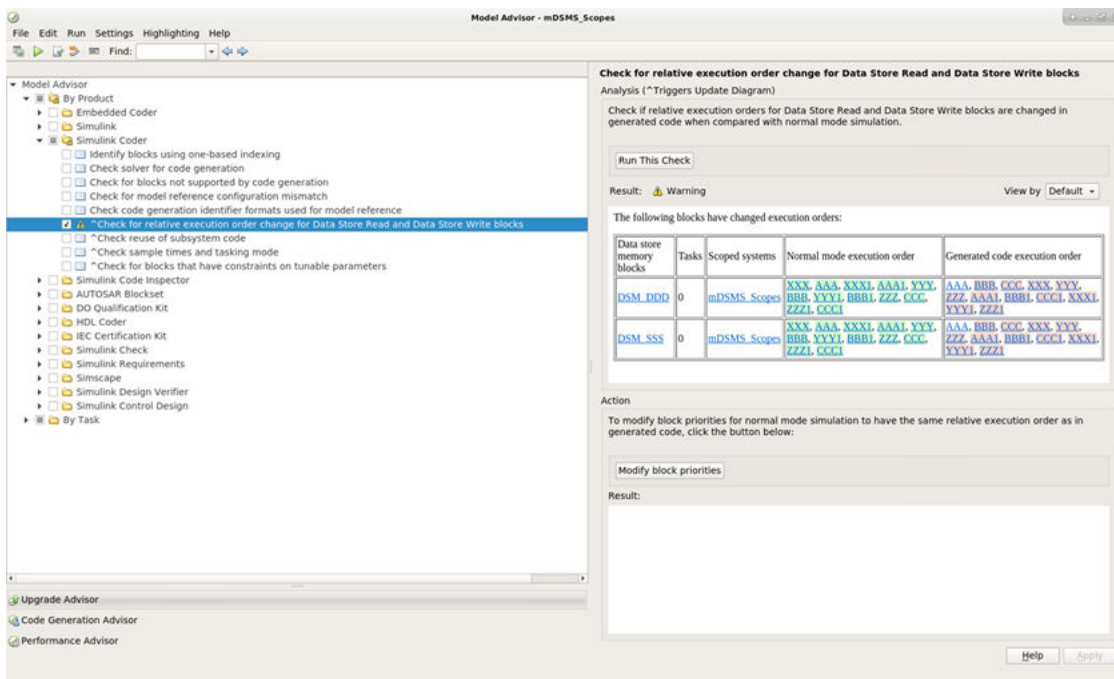

When a model is compiled for code generation, the relative execution order of Data Store Read and Data Store Write blocks can differ in the generated code from the order in normal simulation mode. A Model Advisor check detects these differences and provides an option to change the execution order in normal simulation mode to match the order in the generated code.

- 1 Open the Model Advisor. On the **Modeling** tab, select **Model Advisor > By Product > Simulink Coder**.
- 2 Select the check box for **Check for relative execution order change for Data Store Read and Data Store Write blocks**.

3 Click **Run This Check**.

4 Review any changes in the **Result** table. If there are discrepancies listed and you want to change the execution order in normal simulation to conform with the execution order in generated code, click **Modify block priorities**.

## Access Block Data During Simulation

### In this section...

“About Block Run-Time Objects” on page 39-40

“Access a Run-Time Object” on page 39-40

“Listen for Method Execution Events” on page 39-40

“Synchronizing Run-Time Objects and Simulink Execution” on page 39-41

### About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” in the online Simulink documentation).

---

**Note** You can use this interface even when the model is paused or is running or paused in the debugger.

---

The block run-time interface consists of a set of Simulink data object classes (see “Data Objects” on page 72-61) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

### Access a Run-Time Object

Every nonvirtual block in a running model has a `RuntimeObject` parameter whose value, while the simulation is running, is a handle for the run-time object of the block. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb, 'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

---

**Note** Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 39-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see “Block reduction”). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

---

### Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such

applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function `adapt_lms.m`, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's `DWork` vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h = add_exec_event_listener(blk, ...
    'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's `DWork` vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot = get_param(block.BlockHandle,'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2),'YData',est);
drawnow('expose');
```

## Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcf,'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the `Data` field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box (see Signal storage reuse (Simulink Coder)).

## Set Block Parameter Values

Blocks have numeric parameters that determine how they calculate output values. To control the calculations that blocks perform, you can specify parameter values. For example, a Gain block has a **Gain** parameter, and a Transfer Fcn block has multiple parameters that represent the transfer function coefficients.

You can use numbers, variables, and expressions to set block parameter values. Choose a technique based on your modeling goals. For example, you can:

- Share parameter values between blocks and models by creating variables.
- Control parameter characteristics such as data type and dimensions by creating parameter objects.
- Model an algorithm as code by using mathematical expressions.

Set block parameters using the **Parameters** tab in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), or the block dialog box. For more information, see “Add Blocks and Set Parameters” on page 1-13. To set block sample times, see “Specify Sample Time” on page 7-10.

---

**Tip** You can use the Model Explorer to make batch changes to many block parameter values at once. For more information, see **Model Explorer**.

---

## Programmatically Access Parameter Values

To programmatically access block parameter values, use the `get_param` and `set_param` functions. You can use this technique to:

- Construct a model programmatically.
- Adjust parameter values during a simulation run when you simulate a model programmatically.

To sweep parameter values between simulation runs by using a script, use `Simulink.SimulationInput` objects instead of `get_param` and `set_param`. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.

Suppose you create a model named `myModel` that contains a Constant block named `My Constant`. Next, you use the block dialog box to set the **Constant value** parameter to 15. To programmatically return the parameter value, use the function `get_param`. You specify the block path and the equivalent programmatic parameter name, `Value`.

```
paramValue = get_param('myModel/My Constant', 'Value')
```

```
paramValue =
```

```
15
```

To programmatically change the value, for example to 25, use the function `set_param`. Use the character vector `'25'` as the input to the function.

```
set_param('myModel/My Constant', 'Value', '25')
```

For a list of programmatic names of block parameters, see “Block-Specific Parameters”.

For more information about programmatic simulation, see “Run Simulations Programmatically” on page 28-2.

To avoid using the `get_param` and `set_param` functions, use the name of a MATLAB variable or `Simulink.Parameter` object as the parameter value, and change the value of the variable or object at the command prompt. See “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9.

## Specify Parameter Values

Goal	Block Parameter Value	Description
Store the parameter value in the model file.	2.3 [1.2 2.3 4.5; 7.9 8.7 6.5] 2 + 3i	Literal numeric value. Specify a scalar, vector, matrix, or multidimensional array. Use <code>i</code> to specify complex values.
<ul style="list-style-type: none"> <li>Access the parameter value without having to locate or identify the block in the model.</li> <li>Change the parameter value without having to modify the model file.</li> <li>Share the parameter value between blocks or between models.</li> <li>Identify the parameter by a specific name when sweeping or tuning the value.</li> </ul>	myVar	<p>MATLAB variable that exists in a workspace.</p> <p>For more information, see “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9.</p>
<ul style="list-style-type: none"> <li>Avoid name clashes between workspace variables.</li> <li>Organize parameter values using hierarchies and meaningful names.</li> <li>Reduce the number of workspace variables that a model uses.</li> </ul>	myParam.a.SpeedVect	<p>Field of parameter structure.</p> <p>For more information, see “Organize Related Block Parameter Definitions in Structures” on page 40-19.</p>
Use a portion of a matrix or array variable. For example, set the parameters of a n-D Lookup Table block.	myMatrixParam(:,2)	Index operation.

Goal	Block Parameter Value	Description
<ul style="list-style-type: none"> <li>Define parameter characteristics, such as data type, complexity, units, allowed value range, and dimensions, separately from the parameter value.</li> <li>Define a system constant with custom documentation.</li> <li>Create a tunable parameter in the generated code.</li> <li>Set the value of a variable to a mathematical expression involving constants and other variables.</li> </ul>	<p>myParam</p>	<p>Parameter object.</p> <p>For more information, see “Use Parameter Objects” on page 40-4.</p>
<ul style="list-style-type: none"> <li>Express a parameter value as a mathematical relationship between known physical constants instead of as an unidentifiable literal number.</li> <li>Reduce block population in a model.</li> <li>Model an obscure or trivial calculation by using code instead of blocks.</li> <li>Use MATLAB operators and functions to perform calculations.</li> <li>Write a custom MATLAB function that calculates parameter values.</li> </ul>	<p>5<sup>3.2</sup> - 1/3</p> <p>myParam * myOtherparam + sin(0.78*pi)</p> <p>myFun(15.23)</p>	<p>Expression or custom function.</p> <p>For more information, see “Use Mathematical Expressions, MATLAB Functions, and Custom Functions” on page 40-5.</p>
<p>Specify a block parameter value by using a data type other than double.</p>	<p>15.23</p> <p>single(15.23)</p> <p>myParam</p>	<p>Typed or untyped expression, numeric MATLAB variable, or parameter object.</p> <p>For more information about controlling parameter data types, see “Control Block Parameter Data Types” on page 40-44.</p>

### Use Parameter Objects

Parameter objects are `Simulink.Parameter` objects and objects of the subclasses that you create. The parameter object exists in a workspace such as the base workspace or a data dictionary.

You can use parameter objects to define system constants. For example, use a parameter object to represent the radius of the Earth. Use the properties of the object to specify the physical units and to document the purpose of the value.

Create parameter objects to prepare your model for code generation. You can configure parameter objects to appear as tunable global variables in the generated code. You can also control the parameter data type through the object.

To create and use parameter objects in models, see “Data Objects” on page 72-61. For information about using variables to set block parameter values, see “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9.

### Use Mathematical Expressions, MATLAB Functions, and Custom Functions

You can set a block parameter value to an expression that calls MATLAB functions and operators such as `sin` and `max`. You can also call your own custom functions that you write on the MATLAB path.

Suppose that a section of your block algorithm uses variables to calculate a single constant number used by the rest of the algorithm. You can perform the calculation by creating multiple blocks.

Instead, create a single Constant block that uses an expression written in MATLAB code. This technique reduces the size of the block algorithm and improves readability.

You can model a complicated portion of an algorithm by using an expression instead of many blocks. To operate on an existing signal, use a mathematical expression as the value of a parameter in an algorithmic block, such as the **Gain** parameter of a Gain block.

With expressions, you can also call your custom functions to set block parameter values. Suppose that you write a MATLAB function that calculates optimal P, I, and D parameters for a control algorithm by accepting a single input number.

```

paramFcn.m  x  +
1  function paramValue = paramFcn(performance,parameter)
2  %PARAMVALUE = paramFcn(PERFORMANCE,PARAMETER) returns the P, I, or D
3  %value PARAMVALUE that you request using PARAMETER. Specify performance
4  %criteria using PERFORMANCE.
5
6  % Initialize output.
7  paramValue = [];
8
9  % Calculate parameter value.
10 switch parameter
11     case 'P'
12         paramValue = performance*3;
13     case 'I'
14         paramValue = sqrt(performance)/0.175;
15     case 'D'
16         paramValue = performance^0.25;
17
18 % Validation

```

You can parameterize a PID Controller block by using the function to set the parameter values.

Controller parameters

Proportional (P):

Integral (I):

Derivative (D):

To make the best use of expressions, consider these tips:

- If you use variables and parameter objects, you can explicitly model the algebraic relationships between the real-world quantities that the variables and objects represent. Use expressions in parameter objects as described in “Set Variable Value by Using a Mathematical Expression” on page 40-10.
- While you edit an expression in a block parameter value, to navigate to the documentation for a function, use the button  next to the parameter value. You can also navigate to the source code of a custom function.

## Considerations for Other Modeling Goals

Choose a technique to set block parameter values based on your modeling goals.

Goal	Features or Products	Best Practice
Run multiple simulations quickly.	Simulink.SimulationInput objects and the sim function	Use variables or parameter objects to set block parameter values. This technique helps you to assign meaningful names to the parameters and to avoid having to identify or locate the blocks in the model. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.
Sweep parameter values during testing.	Simulink Test	Use variables or parameter objects to set block parameter values. Use iterations and parameter overrides to run multiple tests. See “Parameter Overrides” (Simulink Test) and “Test Iterations” (Simulink Test).
Estimate and optimize parameter values.	Simulink Design Optimization™	Use variables or parameter objects to set block parameter values.  To estimate or optimize a parameter that uses a data type other than double, use a parameter object to separate the value from the data type.  For parameter estimation, see “Parameter Estimation” (Simulink Design Optimization). For response optimization, see “Optimize Model Response” (Simulink Design Optimization).

Goal	Features or Products	Best Practice
Generate code from a model. Simulate an external program through SIL/PIL or External mode simulations.	Simulink Coder	<p>Use parameter objects to set block parameter values. This technique helps you to declare and identify tunable parameters in the generated code and to control parameter data types. See “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).</p> <p>When you use expressions to set block parameter values, avoid using operators and functions that result in loss of tunability in the generated code. See “Tunable Expression Limitations” (Simulink Coder).</p>

## Share and Reuse Block Parameter Values by Creating Variables

To set a block parameter value, such as the **Gain** parameter of a Gain block, you can use numeric variables that you create and store in workspaces such as the base workspace, a model workspace, or a Simulink data dictionary. You can use the variable to set multiple parameter values in multiple blocks, including blocks in different models. To change the values of the block parameters, you change the value of the variable in the workspace.

Using a variable to set a block parameter value also enables you to:

- Change the parameter value without having to modify the model file (if you store the variable outside the model workspace).
- Identify the parameter by a specific, meaningful name when sweeping or tuning the value.

For basic information about setting block parameter values, see “Set Block Parameter Values” on page 40-2.

### Reuse Parameter Values in Multiple Blocks and Models

You can create a numeric MATLAB variable in a workspace, such as the base workspace or a data dictionary, and use it to specify one or more block parameter values.

If a block parameter value is set to a simple numeric expression, you can create a variable for that expression in the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). Click  in the right side of the cell that corresponds to the value, then select **Create variable**. In the Create New Data dialog box, set the name and location for the new variable, then click **Create**. The cell now displays the new variable.

You can also create a variable to represent a constant that is used in multiple expressions. The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number `14.6`, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters. In this example, to share the number between the blocks, you create a variable named `myParam`.

- 1 Open the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

- 2 In the model, on the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 3 In the model, navigate into the subsystem.

```
open_system(...
    'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
```

- 4 In the Model Data Editor, in the **Filter contents** box, enter `14.6`.

The data table contains two rows, which correspond to the **Constant value** parameters of two of the Constant blocks in the subsystem.

- 5 Use the **Value** column to replace the literal number `14.6` with `myParam`. Perform the replacement for both parameters.

- 6 In the **Filter contents** box, enter `myParam`.
- 7 While editing the value of one of the parameters, click the action button  and select **Create**.
- 8 In the **Create New Data** dialog box, set **Value** to `14.6` and click **Create**.

The variable, `myParam`, appears in the base workspace.

Because the variable exists in the base workspace, you can use it in multiple models. However, when you end your MATLAB session, you lose the contents of the base workspace. Consider permanently storing the variable in a model workspace or data dictionary.

## Define a System Constant

To define a system constant, such as a variable that represents the radius of the Earth, consider creating a `Simulink.Parameter` object instead of a numeric MATLAB variable. Parameter objects allow you to specify physical units and custom documentation as well as other characteristics.

- To create and use parameter objects in models, see “Data Objects” on page 72-61.
- Typically, the value of a system constant influences the values of other parameters and signals through mathematical relationships. To model these relationships explicitly, set the values of the dependent data by using expressions. See “Set Variable Value by Using a Mathematical Expression” on page 40-10.

## Set Variable Value by Using a Mathematical Expression

You can set the value of a variable to an expression involving literal numbers and other variables. With expressions, you can:

- Express the value as a relationship between known physical constants instead of as an unidentifiable literal number.
- Explicitly model algebraic dependencies between parameter data. When you change the values of independent data, you do not need to remember to adjust the values of dependent data.

### General Technique

Convert the variable to a `Simulink.Parameter` object. Then, set the `Value` property of the object by using an expression:

- Interactively — For example, with the Model Data Editor or the Model Explorer, precede the expression with an equals sign, `=`. The figure shows how to specify the expression `myVar + myOtherVar`.

- Programmatically — Use the `slexpr` function, specifying the expression in a character vector or string. For example, to set the value of a parameter object named `myParam` to the expression `myVar + myOtherVar`:

```
myParam.Value = slexpr('myVar + myOtherVar')
```

### Explicitly Model Algebraic Relationship Between Variables

The example `sldemo_metro` (see “Exploring the Solver Jacobian Structure of a Model”) models a system of three identical, pointlike metronomes suspended from a moving platform. Blocks in the model use these MATLAB variables from the base workspace:

- `m` — Mass of each metronome, initial value 0.1 kg
- `r` — Length of each metronome, initial value 1.0 m
- `J` — Moment of inertia of each metronome, initial value 0.1 kg/m<sup>2</sup>

These variables share an algebraic relationship: the moment of inertia of each metronome is equal to the mass times the length squared. In this example, you record this relationship in the value of `J`.

- 1 Open the model.

```
sldemo_metro
```

- 2 Update the block diagram. A model callback creates the variables in the base workspace.
- 3 To prevent the callback from overwriting changes that you make to the variables, for this example, remove the callback code.

```
set_param('sldemo_metro','InitFcn','')
```

- 4 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 5 On the Model Data Editor **Parameters** tab, activate the **Change scope** button.

The blocks that use the variables are in the subsystems, so you must configure the Model Data Editor to show data in subsystems.

- 6 Click the **Show/refresh additional information** button.

The data table contains rows that correspond to the variables in the base workspace.

- 7 In the **Filter contents** box, enter `J`.
- 8 In the data table, find the row that corresponds to `J`. In the **Value** column, set the value of the variable to `Simulink.Parameter(J)`.

Simulink converts `J` to a `Simulink.Parameter` object.

- 9 In the **Value** column, set the value of the parameter object to `=m*r^2`.
- 10 Optionally, simulate the model with different metronome masses and lengths. As you change the values of `m` and `r`, you do not have to remember to correct the value of `J`.

### Limitations and Considerations for Other Modeling Goals

- If the expression contains fixed-point data or data of an enumerated type, the expression can operate on only one variable or object.
- You cannot set the data type (`DataType` property) of the parameter object that uses the expression to `auto` (the default) and set the data types of parameter objects that appear in the expression to a value other than `auto`. For example, in the expression `J = m*r^2`, you cannot set the data type of `J` to `auto` and the data types of `m` and `r` to `single`.

- To retain the benefits of `auto` (described in “Context-Sensitive Data Typing” on page 40-44) for the object that uses the expression, set the data types of the objects in the expression to `auto`. In other words, use `auto` for all of the involved objects. The objects in the expression acquire the same data type as the object that uses the expression.
- To use a value other than `auto` for an object that appears in the expression, set the data types of all dependent parameter objects to a value other than `auto`. In other words, do not use `auto` for any involved objects.

You must use the same data type for all objects used in the expression.

- If you have Simulink Coder and Embedded Coder licenses, you can generate code that initializes a global variable by using the expression. However, the code generator can preserve the expression only if it conforms to certain requirements. See “Expression Preservation” (Simulink Coder).

## Control Scope of Parameter Values

The scope of a variable is the set of models and blocks that can use the variable. For example, variables that you create in the base workspace have global scope because all blocks in all open models can use the variables. Variables that you store in a model workspace have limited scope because only the blocks in the host model can use the variables.

You cannot create two variables that have the same name in the same scope. Controlling the scope of a variable helps you to avoid name conflicts and establish clear ownership of the variable.

The table describes the different ways that you can control the scope of a reusable parameter value.

Scope	Technique
All open models	Create a variable in the base workspace.
One or more targeted models	Create a variable in a data dictionary. To reuse the variable in multiple models, create a referenced dictionary. See “What Is a Data Dictionary?” on page 79-2
One model, including all subsystems in the model	Create a variable in the model workspace. See “Model Workspaces” on page 72-121.
Multiple blocks inside a subsystem, including blocks in nested subsystems	<p>Mask the subsystem and create a mask parameter instead of a workspace variable.</p> <p>To prevent blocks inside a subsystem from using workspace variables, in the subsystem block dialog box, set <b>Permit Hierarchical Resolution</b> to <b>None</b>. This technique allows you to use the same name to create both a variable in a workspace and a mask parameter in the subsystem mask. The blocks in the subsystem can use only the mask parameter.</p> <p>For information about subsystems, see <i>Subsystem</i>. For information about masking, see “Masking Fundamentals” on page 42-2.</p>

To avoid name conflicts when you have a large model with many variables in the same scope, consider packaging the variables into a single structure. For more information, see “Organize Related Block Parameter Definitions in Structures” on page 40-19.

For basic information about how blocks use the variable names that you specify, see “Symbol Resolution” on page 72-134.

## Permanently Store Workspace Variables

Variables that you create in the base workspace do not persist between MATLAB sessions. However, you can store the variables in a MAT-file or script file, and load the file whenever you open the model using a model callback. A model callback is a set of commands that Simulink executes when you interact with a model in a particular way, such as opening the model. You can use a callback to load variables when you open the model. Use this technique to store variables while you learn about Simulink and experiment with models.

- 1 In a model that contains a Gain block, set the value of the **Gain** parameter to K.
- 2 At the command prompt, create a variable K in the base workspace.

```
K = 27;
```

- 3 In the Workspace browser, right-click the variable and select **Save As**.

To save multiple variables in one file, select all of the target variables in the Workspace browser, and then right-click any of the selected variables.

- 4 In the dialog box, set **Save as type** to MATLAB Script. Set **File name** to loadvar and click **Save**.

The script file loadvar.m appears in your current folder. You can open the file to view the command that creates the variable K.

- 5 In the model, on the **Modeling** tab, select **Model Settings > Model Properties**.
- 6 In the **Callbacks** tab of the Model Properties dialog box, select PreLoadFcn as the callback that you want to define. In the **Model pre-load function** pane, enter loadvar and click **OK**.
- 7 Save the model.

The next time that you open the model, the PreloadFcn callback loads the variable K into the base workspace. You can also save the variable to a MAT-file, for example loadvar.mat, and set the model callback to load loadvar.

To learn about callbacks, see “Customize Model Behavior with Callbacks” on page 4-52. To programmatically define a callback for loading variables, see “Programmatically Store Workspace Variables for a Model” on page 40-13.

When you save variables to a file, you must save the changes that you make to the variables during your MATLAB session. To permanently store variables for a model, consider using a model workspace or a data dictionary instead of a MAT-file or script file. For more information about permanently storing variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-102.

### Programmatically Store Workspace Variables for a Model

In the example above, you define a model callback that creates variables when you open a model. You can programmatically save the variable and set the model callback.

- 1 At the command prompt, create the variable K in the base workspace.

```
K = 27;
```

- 2 Save the variable to a new script file named `loadvar.m`.

```
matlab.io.saveVariablesToScript('loadvar.m','K')
```

- 3 Set the model callback to load the script file.

```
set_param('myModel','PreloadFcn','loadvar')
```

- 4 Save the model.

```
save_system('myModel')
```

The function `matlab.io.saveVariablesToScript` saves variables to a script file. To save variables to a MAT-file, use the function `save`. To programmatically set model properties such as callbacks, use the function `set_param`.

## Manage and Edit Workspace Variables

When you use variables to set block parameter values, you store the variables in a workspace or data dictionary. You can use the command prompt, the Model Explorer, and the Model Data Editor to create, move, copy, and edit variables. You can also determine where a variable is used in a model, list all of the variables that a model uses, and list all of the variables that a model does not use. For more information, see “Create, Edit, and Manage Workspace Variables” on page 72-108.

## Package Shared Breakpoint and Table Data for Lookup Tables

To share breakpoint vectors or table data between multiple n-D Lookup Table, Prelookup, and Interpolation Using Prelookup blocks, consider storing the data in `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of MATLAB variables or `Simulink.Parameter` objects. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data.

### Store Standalone Lookup Table in `Simulink.LookupTable` Object

A standalone lookup table consists of a set of table data and one or more breakpoint vectors. You do not share the table data or any of the breakpoint vectors with other lookup tables.

When you share a standalone lookup table, you use all of the table and breakpoint data together in multiple n-D Lookup Table blocks. To store this data in a `Simulink.LookupTable` object:

- 1 Create the object in a workspace or data dictionary. For example, at the command prompt, enter:

```
myLUTObj = Simulink.LookupTable;
```

- 2 Use the properties of the object to store the values of the table and breakpoint data.
- 3 Use the properties of the object to configure a unique name for the structure type in the generated code. In the property dialog box, under **Struct Type definition**, specify **Name**.
- 4 In the n-D Lookup Table blocks, set **Data specification** to `Lookup table object`.
- 5 To the right of **Data specification**, set **Name** to the name of the `Simulink.LookupTable` object.

For ways to create and configure `Simulink.LookupTable` objects, see `Simulink.LookupTable`

## Store Shared Data in Simulink.LookupTable and Simulink.Breakpoint Objects

When you use Prelookup and Interpolation Using Prelookup blocks to more finely control the lookup algorithm, you can share breakpoint vectors and sets of table data. For example, you can share a breakpoint vector between two separate sets of table data. With this separation of the breakpoint data from the table data, you can share individual parts of a lookup table instead of sharing the entire lookup table.

To store breakpoint and table data:

- 1 Create a `Simulink.LookupTable` object for each unique set of table data. Create a `Simulink.Breakpoint` object for each unique breakpoint vector, including breakpoint vectors that you do not intend to share.
- 2 Use the properties of the objects to store the values of the table and breakpoint data.
- 3 Configure the `Simulink.LookupTable` objects to refer to the `Simulink.Breakpoint` objects for breakpoint data. In the `Simulink.LookupTable` objects, set **Specification** to Reference. Specify the names of the `Simulink.Breakpoint` objects.
- 4 In the Interpolation Using Prelookup blocks, set **Specification** to Lookup table object. Set **Name** to the name of a `Simulink.LookupTable` object.

In the Prelookup blocks, set **Specification** to Breakpoint object. Set **Name** to the name of a `Simulink.Breakpoint` object.

The example model `fxpdemo_lookup_shared_param` contains two Prelookup and two Interpolation Using Prelookup blocks. Configure the blocks so that each combination of a Prelookup and an Interpolation Using Prelookup block represents a unique lookup table. Share the breakpoint vector between the two lookup tables. In this case, each lookup table has unique table data but shared breakpoint data.

- 1 Open the example model.
- 2 In the Prelookup block dialog box, set **Specification** to Breakpoint object. Set **Name** to `sharedBkpts`.
- 3 Click the button  next to the value of the **Name** parameter. Select **Create Variable**.
- 4 In the **Create New Data** dialog box, set **Value** to `Simulink.Breakpoint` and click **Create**.

A `Simulink.Breakpoint` object appears in the base workspace.

- 5 In the property dialog box for `sharedBkpts`, specify **Value** as a vector such as `[1 2 3 4 5 6 7 8 9 10]`. Click **OK**.
- 6 In the Prelookup block dialog box, click **OK**.
- 7 In the Prelookup1 block dialog box, set **Specification** to Breakpoint object. Set **Name** to `sharedBkpts`.
- 8 In the Interpolation Using Prelookup block dialog box, set **Specification** to Lookup table object. Set **Name** to `dataForFirstTable`.
- 9 Click the button  next to the value of the **Name** parameter. Select **Create Variable**.
- 10 In the **Create New Data** dialog box, set **Value** to `Simulink.LookupTable` and click **Create**.

A `Simulink.LookupTable` object appears in the base workspace.

- 11 In the property dialog box for `dataForFirstTable`, specify **Value** as a vector, such as `[10 9 8 7 6 5 4 3 2 1]`.

- 12** Set **Specification** to Reference.
- 13** In the table under **Specification**, set **Name** to sharedBkpts and click **OK**.
- 14** In the Interpolation Using Prelookup block dialog box, click **OK**.
- 15** Configure the Interpolation Using Prelookup1 block to use a Simulink.LookupTable object named dataForSecondTable. In the object property dialog box, specify **Value** as a vector, such as [0 0.5 1 1.5 2 2.5 3 3.5 4 4.5]. Configure the object to refer to sharedBkpts for the breakpoint data.

The model now represents two unique lookup tables:

- A combination of sharedBkpts and dataForFirstTable.
- A combination of sharedBkpts and dataForSecondTable.

These lookup tables share the same breakpoint data through sharedBkpts.

## Parameter Interfaces for Reusable Components

You can use subsystems, referenced models, and custom library blocks as reusable components in other models. For guidelines to help you decide how to componentize a system, see “Choose Among Types of Model Components” on page 23-4.

Typically, a reusable algorithm requires that numeric block parameters, such as the **Gain** parameter of a Gain block, either:

- Use the same value in all instances of the component.
- Use a different value in each instance of the component. Each value is instance specific.

By default, if you use a literal number or expression to set the value of a block parameter, the parameter uses the same value in all instances of the component. If you set multiple block parameter values by using a MATLAB variable, Simulink.Parameter object, or other parameter object in a workspace or data dictionary, these parameters also use the same value in all instances of the component.

### Referenced Models

If you use model referencing to create a reusable component, to set parameter values that are specific to each instance, configure model arguments for the referenced model. When you instantiate the model by adding a Model block to a different model, you set the values of the arguments in the Model block. When you add another Model block to the same parent model or to a different model, you can set different values for the same arguments. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If a model has many model arguments, consider packaging the arguments into a single structure. Instead of configuring many arguments, configure the structure as a single argument. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of model argument values that you must set in each instance of the component.

For more information about model arguments, see “Parameterize Instances of a Reusable Referenced Model” on page 8-63.

### Subsystems

If you use subsystems or custom libraries to create reusable components, to set parameter values that are specific to each instance, use masks, mask parameters, and parameter promotion. When you instantiate the component in a model, you set the values of the mask parameters in the Subsystem block. When you instantiate the component again in the same model or a different model, you can set different values for the same mask parameters. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If the subsystem has many mask parameters, consider packaging the parameters into a single structure. Instead of configuring many mask parameters, configure the structure as a single parameter. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of mask parameter values that you must set in each instance of the component.

For more information about subsystems, see Subsystem. For more information about custom block libraries, see “Design and Create a Custom Block” on page 43-12. For more information about

masks, see “Masking Fundamentals” on page 42-2. For more information about structures, see “Organize Related Block Parameter Definitions in Structures” on page 40-19.

## Organize Related Block Parameter Definitions in Structures

When you use numeric MATLAB variables to set block parameter values in a model, large models can accumulate many variables, increasing the effort of maintenance and causing the variable names to grow in length.

Instead, you can organize these parameter values into structures. Each structure is a single variable and each field of the structure stores a numeric parameter value. You can assign meaningful names to the structures, substructures, and fields to indicate the purpose of each value.

Use structures to:

- Reduce the number of workspace variables that you must maintain.
- Avoid name conflicts between workspace variables.

You cannot create two variables that have the same name in the same scope, such as in the base workspace. When you create structures, you must provide each field a name, but multiple structures can each contain a field that uses the same name. Therefore, you can use each structure and substructure as a namespace that prevents the field names from conflicting with each other and with other variable names in the same scope.

- Logically group sets of block parameter values. For example, use nested structures to clearly identify the parameter values that each subsystem or referenced model uses.

If you use mask parameters or model arguments to pass parameter values to the components of a system, you can use structures to reduce the number of individual mask parameters or model arguments that you must maintain. Instead of passing multiple variables, you can pass a single structure variable.

For basic information about creating and manipulating MATLAB structures, see [Structures](#). For basic information about setting block parameter values in a model, see “Set Block Parameter Values” on page 40-2.

To use structures to initialize bus signals, see “Specify Initial Conditions for Bus Elements” on page 81-64.

### Create and Use Parameter Structure

This example shows how to create and use a parameter structure in a model.

The example model `f14` uses multiple variables from the base workspace to set block parameter values. For example, when you open the model, it creates the variables `Zw`, `Mw`, and `Mq` in the base workspace. To organize these variables into a single structure variable:

- 1 At the command prompt, open the example model.

```
f14
```

- 2 At the command prompt, create the parameter structure `myGains`. Set the field values by using the values of the target variables.

```
myGains.Zw = Zw;  
myGains.Mw = Mw;  
myGains.Mq = Mq;
```

- 3 In the Model Explorer, on the **Model Hierarchy** pane, click **Base Workspace**. In the **Contents** pane, right-click the variable `Mq` and select **Find Where Used**.
- 4 In the **Select a system** dialog box, click the node **f14** and click **OK**. Click **OK** when asked about updating the diagram.
- 5 In the **Contents** pane, right-click the row corresponding to the block labeled `Gain1` and select **Properties**. The `Gain1` block dialog box opens.
- 6 Change the value of the **Gain** parameter from `Mq` to `myGains.Mq` and click **OK**.
- 7 In the **Contents** pane, right-click the row corresponding to the `Transfer Fcn.1` block and select **Properties**.
- 8 Change the value of the **Denominator coefficients** parameter from `[1, -Mq]` to `[1, -myGains.Mq]` and click **OK**.
- 9 In the **Model Hierarchy** pane, click **Base Workspace**. Use **Find Where Used** to locate the blocks that use the variables `Mw` and `Zw`. In the block dialog boxes, replace the references to the variable names according to the table.

Variable Name	Replacement Name
<code>Mw</code>	<code>myGains.Mw</code>
<code>Zw</code>	<code>myGains.Zw</code>

- 10 Clear the old variables.

```
clear Zw Mw Mq
```

Each of the modified block parameters now uses a field of the `myGains` structure. The numeric value of each structure field is equal to the value of the corresponding variable that you cleared.

You can migrate a model to use a single parameter structure instead of multiple workspace variables.

## Store Data Type Information in Field Values

To use a structure or array of structures to organize parameter values that use a data type other than `double`, you can explicitly specify the type when you create the structure. When you create the structure, use typed expressions such as `single(15.23)` to specify the field values.

```
myParams.Gain = single(15.23);
```

If you want to change the field value later, you must remember to explicitly specify the type again. If you do not specify the type, the field value uses the data type `double` instead:

```
myParams.Gain = 15.23;
% The field 'Gain' now uses the data type 'double' instead of 'single'.
```

To preserve the type specification, you can use subscripted assignment to assign a new value to the field:

```
% Assign value of type 'single'.
myParams.Gain = single(15.23);

% Assign new value while retaining type 'single'.
myParams.Gain(:) = 11.79;
```

To match a fixed-point data type, set the field value by using an `fi` object.

## Control Field Data Types and Characteristics by Creating Parameter Object

A `Simulink.Parameter` object allows you to separate the value of a block parameter from its data type. If you use a parameter object to store a structure or array of structures, you can create a `Simulink.Bus` object to use as the data type of the entire structure.

You can use the bus object and the parameter object to explicitly control:

- The data type of each field. When you use this technique, you do not have to remember to use typed expressions or subscripted assignment to set the field values.
- The complexity, dimensions, and units of each field.
- The minimum and maximum value of each field if the field represents a tunable parameter value.
- The shape of the entire structure. The shape of the structure is the number, names, and hierarchy of fields.
- The tunability of the structure in the code that you generate from the model.

- 1 Create a parameter structure `myParams`.

```
myParams = struct(...
    'SubsystemA', struct(...
        'Gain', 15.23, ...
        'Offset', 89, ...
        'Init', 0.59), ...
    'SubsystemB', struct(...
        'Coeffs', [5.32 7.99], ...
        'Offset', 57, ...
        'Init1', 1.76, ...
        'Init2', 2.76) ...
);
```

- 2 Use the function `Simulink.Bus.createObject` to create `Simulink.Bus` objects that represent the structure and substructures.

```
Simulink.Bus.createObject(myParams)
```

Because `myParams` contains two unique substructures, the function creates three `Simulink.Bus` objects: one named `s1Bus1` to represent the parent structure `myParams`, one named `SubsystemA` for the substructure `SubsystemA`, and one named `SubsystemB` for the substructure `SubsystemB`.

- 3 Rename the bus object `s1Bus1` as `myParamsType`.

```
myParamsType = s1Bus1;
clear s1Bus1
```

- 4 Store the structure `myParams` in a `Simulink.Parameter` object.

```
myParams = Simulink.Parameter(myParams);
```

The `Value` property of the parameter object contains the structure.

- 5 Set the data type of the parameter object to the bus object `myParamsType`.

```
myParams.DataType = 'Bus: myParamsType';
```

- 6 Open the Type Editor to view the bus objects.

```
typeditor
```

- 7 In the table, expand the bus object named `SubsystemA`. Then, set the data types according to the figure.

Name	Type
▼ SubsystemA	
— Gain	single
— Offset	int8
— Init	single
> SubsystemB	
> myParamsType	

- 8 Optionally, change the data types for the bus object named `SubsystemB`.

The parameter object `myParams` stores the parameter structure. The data type of the parameter object is the bus object `myParamsType`. Prior to simulation and code generation, the parameter object casts the field values to the data types that you specified in the bus object.

To use one of the fields to set a block parameter value, specify an expression such as `myParams.SubsystemB.Init1`.

To access the field values at the command prompt, use the `Value` property of the parameter object. Because the bus object controls the field data types, you do not need to use a typed expression to set the field value.

```
myParams.Value.SubsystemA.Gain = 12.79;
```

The bus object strictly controls the field characteristics and the shape of the structure. For example, if you set the value of the two-element field `myParams.SubsystemB.Coeffs` to a three-element array, the model generates an error when you set a block parameter value. To change the dimensions of the field, modify the element `Coeffs` in the bus object `SubsystemB`.

To manipulate bus objects after you create them, see “Create and Specify Simulink.Bus Objects” on page 81-59 and “Save Simulink.Bus Objects” on page 81-60.

### Match Field Data Type with Signal Data Type

Suppose that you use the field `myParams.SubsystemA.Gain` to set the value of the **Gain** parameter in a Gain block. If you want the data type of the field to match the data type of the output signal of the block, you cannot rely on context-sensitive data typing (see “Context-Sensitive Data Typing” on page 40-44). Consider using a `Simulink.AliasType` or a `Simulink.NumericType` object to set the data type of the field and the signal. If you do not use a data type object, you must remember to change the data type of the field whenever you change the data type of the signal.

- 1 In the MATLAB Command Window, create a `Simulink.AliasType` object that represents the data type `single`.

```
myType = Simulink.AliasType;
myType.BaseType = 'single';
```

- 2 In the Gain block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myType`.
- 3 In the MATLAB Command Window, open the Type Editor.

```
typeeditor
```

- 4 Select the bus object named `SubsystemA`. Then, set the data type of the element named `Gain` to `myType`.

Now, both the output signal of the `Gain` block and the structure field `myParams.SubsystemA.Gain` use the data type that you specify by using the `BaseType` property of `myType`.

For more information about data type objects, see `Simulink.AliasType` and `Simulink.NumericType`.

## Manage Structure Variables

To create, modify, and inspect a variable whose value is a structure, you can use the Variable Editor. For more information, see “Modify Structure and Array Variables Interactively” on page 72-109.

## Define Parameter Hierarchy by Creating Nested Structures

To further organize block parameter values, create a hierarchy of nested structures.

For example, suppose that you create subsystems named `SubsystemA` and `SubsystemB` in your model. You use variables such as `Offset_SubsystemA` and `Offset_SubsystemB` to set block parameter values in the subsystems.

```
Gain_SubsystemA = 15.23;
Offset_SubsystemA = 89;
Init_SubsystemA = 0.59;

Coeffs_SubsystemB = [5.32 7.99];
Offset_SubsystemB = 57;
Init1_SubsystemB = 1.76;
Init2_SubsystemB = 2.76;
```

Create a parameter structure that contains a substructure for each subsystem. Use the values of the existing variables to set the field values.

```
myParams = struct(...
    'SubsystemA', struct(...
        'Gain', Gain_SubsystemA, ...
        'Offset', Offset_SubsystemA, ...
        'Init', Init_SubsystemA), ...
    'SubsystemB', struct(...
        'Coeffs', Coeffs_SubsystemB, ...
        'Offset', Offset_SubsystemB, ...
        'Init1', Init1_SubsystemB, ...
        'Init2', Init2_SubsystemB)...
);
```

The single structure variable `myParams` contains all of the parameter information for the blocks in the subsystems. Because each substructure acts as a namespace, you can define the `Offset` field more than once.

To use the `Offset` field from the substructure `SubsystemB` as the value of a block parameter, specify the parameter value in the block dialog box as the expression `myParams.SubsystemB.Offset`.

## Group Multiple Parameter Structures into an Array

To organize parameter structures that have similar characteristics, you can create a single variable whose value is an array of structures. This technique helps you to parameterize a model that contains multiple instances of an algorithm, such as a library subsystem or a referenced model that uses model arguments.

Suppose that you create two identical subsystems in a model.

Suppose that the blocks in each subsystem require three numeric values to set parameter values. Create an array of two structures to store the values.

```
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
```

```
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;
```

Each structure in the array stores the three parameter values for one of the subsystems.

To set the value of a block parameter in one of the subsystems, specify an expression that references a field of one of the structures in the array. For example, use the expression `myParams(2).Init`.

### Organize Parameter Values for Reusable Components and Iterative Algorithms

You can also partition an array of structures in a For Each Subsystem block. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example by iterating the algorithm over a vector signal. For an example, see “Repeat an Algorithm Using a For-Each Subsystem” on page 81-84.

If you use model arguments to specify different parameter values across multiple instances of a referenced model, you can use arrays of structures to organize the model argument values. In the referenced model workspace, create a structure variable and configure the model to use the structure as a model argument. Use the fields of the structure to set block parameter values in the model. Then, create an array of structures in the base workspace or a data dictionary to which the parent model or models are linked. In the parent model or models, use each of the structures in the

array as the value of the model argument in a Model block. Each structure in the array stores the parameter values for one instance of the referenced model.

The model `sldemo_mdhref_datamngt` contains three instances (Model blocks) of the masked referenced model `sldemo_mdhref_counter_datamngt`. The base workspace variables `IC1`, `IC2`, `Param1`, and `Param2` are `Simulink.Parameter` objects whose values are structures. The parent model uses these variables to set the values of mask parameters on the Model blocks. Since `IC1` is structurally identical to `IC2`, and `Param1` to `Param2`, you can combine these four structures into two arrays of structures.

- 1 Open the example parent model.

```
openExample('sldemo_mdhref_datamngt')
```

The model creates the four `Simulink.Parameter` objects in the base workspace.

- 2 Open the example referenced model.

```
sldemo_mdhref_counter_datamngt
```

The model workspace defines two model arguments, `CounterICs` and `CounterParams`, whose values are structures. The blocks in the model use the fields of these structures to set parameter values.

- 3 In the model `sldemo_mdhref_datamngt`, open the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). In the Model Data Editor, inspect the **Parameters** tab.
- 4 In the model, click one of the Model blocks.

The Model Data Editor highlights rows that correspond to two mask parameters on the selected Model block. The block uses the mask parameters to set the values of the two model arguments defined by the referenced model, `sldemo_mdhref_counter_datamngt`. Each Model block uses a different combination of the four parameter objects from the base workspace to set the argument values.

- 5 In the Model Data Editor **Value** column, click one of the cells to begin editing the value of the corresponding mask parameter (for example, `IC1`). Next to the parameter value, click the action button  and select **Open**. The property dialog box for the parameter object opens.
- 6 In the property dialog box, next to the **Value** box, click the action button and select **Open Variable Editor**.

The Variable Editor shows that the parameter object stores a structure. The structures in `Param2` and `IC2` have the same fields as the structures in `Param1` and `IC1` but different field values.

- 7 At the command prompt, combine the four parameter objects into two parameter objects whose values are arrays of structures.

```
% Create a new parameter object by copying Param1.
Param = Param1.copy;
```

```
% Use the structure in Param2 as the second structure in the new object.
Param.Value(2) = Param2.Value;
% The value of Param is now an array of two structures.
```

```
% Delete the old objects Param1 and Param2.
clear Param1 Param2
```

```
% Create a new parameter object by copying IC1.
% Use the structure in IC2 as the second structure in the new object.
IC = IC1.copy;
```

```
IC.Value(2) = IC2.Value;
clear IC1 IC2
```

- 8 In the parent model, in the Model Data Editor, use the **Value** column to replace the values of the mask parameters according to the table

Previous Value	New Value
Param1	Param(1)
IC1	IC(1)
Param2	Param(2)
IC2	IC(2)

Each Model block sets the value of the model argument CounterICs by using one of the structures in the array IC. Similarly, each block sets the value of CounterParams by using one of the structures in Param.

### Enforce Uniformity in an Array of Structures

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array. You can use a parameter object and a bus object to enforce this uniformity among the structures.

To use a parameter object to represent an array of parameter structures, set the value of the object to the array of structures:

```
% Create array of structures.
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;

% Create bus object.
Simulink.Bus.createObject(myParams);
myParamsType = slBus1;
clear slBus1

% Create parameter object and set data type.
myParams = Simulink.Parameter(myParams);
myParams.DataType = 'Bus: myParamsType';
```

To use one of the fields to set a block parameter value, specify an expression such as `myParams(2).Offset`.

To access the field values at the command prompt, use the `Value` property of the parameter object.

```
myParams.Value(2).Offset = 129;
```

### Create a Structure of Constant-Valued Signals

You can use a structure in a Constant block to create a single bus that transmits multiple numeric constants. For more information, see `Constant`. For information about buses, see “Composite Interface Guidelines” on page 81-2.

## Considerations Before Migrating to Parameter Structures

- Before you migrate a model to use parameter structures, discover all of the blocks in the target model and in other models that use the variables that you intend to replace.

For example, suppose two blocks in a model use the workspace variable `myVar`. If you create a structure `myParams` with a field `myVar`, and set the parameter value in only one of the blocks to `myParams.myVar`, the other block continues to use the variable `myVar`. If you delete `myVar`, the model generates an error because the remaining block requires the deleted variable.

To discover all of the blocks that use a variable:

- 1 Open all models that might use the variable. If the models are in a model reference hierarchy, you can open only the top model.
- 2 In the Model Data Editor or in the Model Explorer **Contents** pane, right-click the variable and select **Find Where Used**. The Model Explorer displays all of the blocks that use the variable.

You can discover variable usage only in models that are open. Before you migrate to parameter structures, open all models that might use the target variables. For more information about determining variable usage in a model, see “Finding Blocks That Use a Specific Variable” on page 72-113.

Alternatively, you can refrain from deleting `myVar`. However, if you change the value of the `myParams.myVar` structure field, you must remember to change the value of `myVar` to match.

- You can combine multiple separate variables or parameter objects (such as `Simulink.Parameter`) into a structure that you store in a single variable or parameter object (to combine parameter objects, see “Combine Existing Parameter Objects Into a Structure” on page 40-27). However, the resulting variable or object acts as a single entity. As a result, you cannot apply different code generation settings, such as storage classes, to individual fields in the structure.

## Combine Existing Parameter Objects Into a Structure

When you use parameter objects to set block parameter values (for example, so you can apply storage classes), to combine the objects into a single structure:

- 1 Create a MATLAB structure and store it in a variable. To set the field values, use the parameter values that each existing parameter object stores.
- 2 Convert the variable to a parameter object. Create and use a `Simulink.Bus` object as the data type of the parameter object (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 40-21).
- 3 Choose a storage class to apply to the resulting parameter object. You can choose only one storage class, which applies to the entire structure.
- 4 Transfer parameter metadata, such as the `Min` and `Max` properties of the existing parameter objects, to the corresponding properties of the `Simulink.BusElement` objects in the bus object.

For example, suppose you have three individual parameter objects.

```
coeff = Simulink.Parameter(17.5);
coeff.Min = 14.33;
coeff.DataType = 'single';
coeff.StorageClass = 'ExportedGlobal';
```

```

init = Simulink.Parameter(0.00938);
init.Min = -0.005;
init.Max = 0.103;
init.DataType = 'single';
init.StorageClass = 'Model default';

offset = Simulink.Parameter(199);
offset.DataType = 'uint8';
offset.StorageClass = 'ExportedGlobal';

```

- 1 Create a structure variable.

```

myParams.coeff = coeff.Value;
myParams.init = init.Value;
myParams.offset = offset.Value;

```

- 2 Convert the variable to a parameter object.

```

myParams = Simulink.Parameter(myParams);

```

- 3 Create a bus object and use it as the data type of the parameter object.

```

Simulink.Bus.createObject(myParams.Value);
paramsDT = copy(slBus1);

```

```

myParams.DataType = 'Bus: paramsDT';

```

- 4 Transfer metadata from the old parameter objects to the bus elements in the bus object.

```

% coeff
paramsDT.Elements(1).Min = coeff.Min;
paramsDT.Elements(1).DataType = coeff.DataType;

```

```

% init
paramsDT.Elements(2).Min = init.Min;
paramsDT.Elements(2).Max = init.Max;
paramsDT.Elements(2).DataType = init.DataType;

```

```

% offset
paramsDT.Elements(3).DataType = offset.DataType;

```

To help you write a script that performs this transfer operation, you can use the `properties` function to find the properties that the bus elements and the old parameter objects have in common. To list the structure fields so that you can iterate over them, use the `fieldnames` function.

- 5 Apply a storage class to the parameter object.

```

myParams.StorageClass = 'ExportedGlobal';

```

Now, you can use the fields of `myParams`, instead of the old parameter objects, to set the block parameter values.

## Parameter Structures in the Generated Code

You can configure parameter structures to appear in the generated code as structures and arrays of structures. For information about generating code with parameter structures, see “Organize Data into Structures in Generated Code” (Simulink Coder).

## Parameter Structure Limitations

- The value of a field that you use to set a block parameter must be numeric or of an enumerated type. The value of a field can be a real or complex scalar, vector, or multidimensional array.
- If the value of any of the fields of a structure is a multidimensional array, you cannot tune any of the field values during simulation.
- All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:
  - Field name
  - Numeric data type, such as `single` or `int32`
  - Complexity
  - Dimensions

Suppose that you define an array of two structures.

```
paramStructArray = ...
[struct('sensor1',int16(7),'sensor2',single(9.23)) ...
 struct('sensor1',int32(9),'sensor2',single(11.71))];
```

You cannot use any of the fields in a block parameter because the field `sensor1` uses a different data type in each structure.

- Parameter structures do not support context-sensitive data typing in the generated code. If the parameter structure is tunable in the code, the fields of the structure use the numeric data types that you specify by using either typed expressions or a `Simulink.Bus` object. If you do not use typed expressions or a `Simulink.Bus` object, the fields of the structure use the `double` data type.

## Package Shared Breakpoint and Table Data for Lookup Tables

When you share data between lookup table blocks, consider using `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of structures to store and group the data. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data. See “Package Shared Breakpoint and Table Data for Lookup Tables” on page 40-14.

## Create Parameter Structure According to Structure Type from Existing C Code

You can create a parameter structure that conforms to a `struct` type definition that your existing C code defines. Use this technique to:

- Replace existing C code with a Simulink model.
- Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool). For an example, see “Integrate C Function Whose Arguments Are Pointers to Structures”.
- Generate C code (Simulink Coder) that you can compile with existing C code into a single application. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” (Embedded Coder).

In MATLAB, store the parameter structure in a parameter object and use a bus object as the data type (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 40-21). To create the bus object according to your C-code `struct` type, use the `Simulink.importExternalCTypes` function.

## Tune and Experiment with Block Parameter Values

As you construct a model you can experiment with block parameters, such as the coefficients of a Transfer Fcn block, to help you decide which blocks to use. You can simulate the model with different parameter values, and capture and observe the simulation output.

You can change the values of most numeric block parameters during a simulation. To observe the effects, you can visualize the simulation output in real time. This technique allows you to quickly test parameter values while you develop an algorithm. You can visually:

- Tune and optimize control parameters.
- Calibrate model parameters.
- Test control robustness under different conditions.

When you begin a simulation, Simulink first updates the model diagram. This operation can take time for larger models. To test parameter values without repeatedly updating the model diagram, you can tune the parameter values during a single simulation run.

Alternatively, to avoid updating the model diagram, use Fast Restart. For more information about Fast Restart, see “Get Started with Fast Restart” on page 86-5.

If you cannot visually analyze the simulation output in real time, or if you must run many simulations, consider using a programmatic approach to sweeping parameter values. You can capture the simulation output data and perform analysis later. For more information, see “Optimize, Estimate, and Sweep Block Parameter Values” on page 40-38.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 40-2.

### Iteratively Adjust Block Parameter Value Between Simulation Runs

This example shows how to prototype a model by changing block parameter values between simulation runs. You can experiment with parameter values and observe simulation results to help you decide which blocks to use and how to build your model.

The “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number 14.6, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters.

Suppose that you want to change the design value of the ideal air-to-fuel ratio from 14.6 to 17.5 to observe the effect on the fuel demand. To store the design value in the model, you can modify the value in the block dialog boxes. Alternatively, you can store the value in a variable with a meaningful name, which allows you to reuse the value in the two blocks.

To observe the change in simulation outputs by changing the value in the block dialog boxes:

- 1 Open the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

- 2 Set the model simulation time from 2000 to 50 for a faster simulation.

- 3 In the model, open the Scope block dialog box.

- 4 Simulate the model. Resize the window in the Scope dialog box to see all of the simulation results.

The scope display shows that throughout the simulation, the `fuel` signal oscillates between approximately 0.9 and 1.6. The `air_fuel_ratio` signal quickly climbs to 15 without overshoot.

- 5 In the model, open the Model Data Editor. On the **Modeling** tab, click **Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 6 In the model or at the command prompt, navigate to the target subsystem.

```
open_system(...
    'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
```

- 7 In the Model Data Editor, use the **Value** column to change the **Constant value** (Value) parameter of the Constant block labeled `rich` from  $1/(14.6*0.8)$  to  $1/(17.5*0.8)$ .
- 8 Similarly, change the **Constant value** parameter of the block labeled `normal` from  $1/14.6$  to  $1/17.5$ .
- 9 Simulate the model.

The scope display shows that the signals now respond differently.

To replace the literal values in the block dialog boxes with a numeric variable:

- 1 Use the Model Data Editor to set the value of the `normal` Constant block to  $1/mixture$ .
- 2 Set the value of the `rich` block to  $1/(mixture*0.8)$ .
- 3 While editing the `rich` value, next to  $1/(mixture*0.8)$ , click the action button  and select **Create**.
- 4 In the **Create New Data** dialog box, set **Value** to 17.5 and click **Create**.

The numeric variable `mixture` appears in the base workspace with value 17.5. Between simulation runs, you can change the value of `mixture` in the base workspace instead of changing the parameter values in the block dialog boxes.

## Tune Block Parameter Value During Simulation

This example shows how to observe the effect of changing a block parameter value during a simulation. This technique allows you to avoid updating the model diagram between simulation runs and to interactively test and debug your model.

The example model `sldemo_fuelsys` contains a Constant block, `Throttle Command`, that represents the throttle command. To observe the effect of increasing the magnitude of the command during simulation:

- 1 Open the “Modeling a Fault-Tolerant Fuel Control System” example model `sldemo_fuelsys`.

```
openExample('simulink_automotive/ModelingAFaultTolerantFuelControlSystemExample')
sldemo_fuelsys
```

- 2 In the model, open the Scope block dialog box.

- 3 Begin a simulation.

The model is configured to simulate 2000 seconds. During the simulation, the values of the `fuel` and `air_fuel_ratio` signals appear on the scope graph in real time.

- 4 In the model, when the status bar indicates approximately 1000 (1000 seconds), click the Pause button  to pause the simulation.
- 5 In the scope display, the **fuel** graph plots the simulation output prior to the pause time.
- 6 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 7 In the Model Data Editor, select the **Parameters** tab.
- 8 In the model, select the Throttle Command block.
- 9 In the Model Data Editor, select the `rep_seq_y` row. Make sure that you do not select the `rep_seq_t` row as well.
- 10 For the `rep_seq_y` row, change the value in the **Value** column from `[10 20 10]` to `[10 30 10]`.
- 11 Click the Step Forward button  to advance the simulation step by step. Click the button about 15 times or until you see a change in the **fuel** graph in the scope display.

The plot of the signal `fuel` indicates a sharp increase in fuel demand that corresponds to the increased throttle command.

- 12 In the model, resume the simulation by clicking the Continue button .

The scope display shows the significant periodic increase in fuel demand, and the periodic reduction in the air-to-fuel ratio, throughout the rest of the simulation.

During the simulation, you must update the model diagram after you change the value of a workspace variable. For more information about updating the model diagram, see “Update Diagram and Run Simulation” on page 1-24.

## Prepare for Parameter Tuning and Experimentation

- Use workspace variables to set block parameter values.

To access the value of a block parameter, such as the **Constant value** parameter of a Constant block, you must navigate to the block in the model and open the block dialog box, search for the block by using the Model Explorer, or use the function `set_param` at the command prompt.

Alternatively, if you set the block parameter value by creating a workspace variable, you can change the value of the variable by using the command prompt, the MATLAB Workspace browser, or the Model Explorer. You can also create a variable to set the same value for multiple block parameters. When you change the variable value, all of the target block parameters use the new

value. For more information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 40-2.

- Visualize simulation output.

To observe simulation output in real time while you tune block parameter values, you can use blocks in a model such as the Scope block. You can also capture simulation output at the end of a simulation run, and view the data in the Simulation Data Inspector. For more information, see “Decide How to Visualize Simulation Data” on page 33-2.

- Specify value ranges for block parameters that you expect to tune during simulation.

If you expect another person to use your model and tune the parameter, you can control the allowed tuning values by specifying a range. Also, it is a best practice to specify value ranges for all fixed-point block parameters that you expect to tune. To specify block parameter value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 40-52.

- Control simulation duration and pace.

A simulation run can execute so quickly that you cannot tune block parameter values. Also, if you want to change a parameter value at a specific simulation time, you must learn to control the simulation pace. You can configure the simulation to run for a specific duration or to run forever, and pause and advance the simulation when you want to. For more information, see “Simulate a Model Interactively” on page 27-2 and “Run Simulations Programmatically” on page 28-2.

## Interactively Tune Using Dashboard Blocks

You can tune block parameter values by adding blocks from the Dashboard library to your model. Dashboard blocks allow you to adjust the parameter values of other blocks, and to observe simulation output in real time, by interacting with knobs, switches, and readouts that mimic the appearance of industrial controls. You can interact with the Dashboard blocks without having to locate the target block parameters in the model. For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 32-2.

## Which Block Parameters Are Tunable During Simulation?

Nontunable block parameters are parameters whose values you cannot change during simulation. For example, you cannot tune the **Sample time** block parameter. If a parameter is nontunable, you cannot change its value during simulation by changing the value in the block dialog box or by changing the value of a workspace variable.

Nontunable block parameters include:

- Sample times.
- Parameters that control the appearance or structure of a block such as the number of inputs of a Sum block.
- Priority, which allows you to control block execution order.
- Parameters that control the block algorithm, such as the **Integrator method** parameter of a Discrete-Time Integrator block.

To determine whether a block parameter is tunable during simulation, use one of these techniques:

- Begin a simulation and open the block dialog box. If the value of the target block parameter is gray during simulation, you cannot tune the parameter.

- At the command prompt, determine whether the flags `read-write` and `read-only-if-compiled` describe the parameter.
  - 1 Select the block in the model.
  - 2 At the command prompt, use the function `get_param` to return information about the block dialog box parameters. The function returns a structure that has a field for each parameter in the block dialog box.

```
paramInfo = get_param(gcf, 'DialogParameters');
```

Alternatively, rather than locating and selecting the block in the model, you can replace `gcb` with the block path, such as `'myModel/mySubsystem/myBlock'`.

- 3 View the information about the target block parameter. For example, to view the information about the **Sample time** parameter of a block, view the value of the field `SampleTime`, which is also a structure.

```
paramInfo.SampleTime
```

```
ans =
```

```

    Prompt: 'Sample time:'
    Type: 'string'
    Enum: {}
    Attributes: {'read-write' 'read-only-if-compiled' 'dont-eval'}
```

- 4 Inspect the structure's `Attributes` field, whose value is a cell array of character vectors. If the flag `read-write` appears in the cell array, you can modify the parameter value. However, if the flag `read-only-if-compiled` also appears in the cell array, you cannot modify the parameter value during simulation.

If you use masks to create custom interfaces for blocks and subsystems, you can control the tunability of individual mask parameters. If you use model arguments to parameterize referenced models, you can tune the value of each model argument in each Model block.

## Why Did the Simulation Output Stay the Same?

If the output of your simulation does not change after you change a parameter value, use these troubleshooting techniques:

- Locate the definition of a workspace variable.

If you use a workspace variable to set block parameter values, determine where the variable definition resides. For example, if you define a variable `myVar` in a model workspace and use it to set a block parameter value in the model, you cannot change the parameter value by changing the value of a variable named `myVar` in the base workspace. You must access the variable definition in the model workspace.

To locate the definition of a variable, while editing the value of a block parameter that uses the variable, click the nearby action button  and select **Explore**. A dialog box opens, such as the Model Explorer, which displays the definition of the variable in the appropriate workspace. For more information about how models use variables, see “Symbol Resolution” on page 72-134.

- Specify value ranges for fixed-point parameters that you want to tune during simulation.

If the block parameter you want to tune uses a fixed-point data type with best-precision scaling, specify a minimum and maximum value for the parameter so that Simulink can calculate and apply an appropriate scaling. If you do not specify a value range, Simulink might apply a scaling that excludes the tuning values that you want to use. To specify value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 40-52.

- Update the model diagram during a simulation run. If you use a workspace variable to set the value of one or more block parameters, after you change the value of the variable during a simulation, you must update the model diagram.

To learn how to update a model diagram, see “Update Diagram and Run Simulation” on page 1-24.

## Tunability Considerations and Limitations for Other Modeling Goals

### Referenced Models

When you use Model blocks, these parameter tunability limitations apply:

- If you set the simulation mode of a Model block to an accelerated mode or if you simulate the parent model in an accelerated mode, you cannot tune block parameters in the referenced model during simulation. However, if the referenced model uses variables in the base workspace or a data dictionary to set parameter values, you can tune the values of the variables.
- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use a Model block to refer to this model:
  - And you set the simulation mode of the Model block to an accelerated mode or simulate the parent model in an accelerated mode, you cannot change the value of the variable or object during the simulation.
  - When you simulate the parent model in an accelerated mode, changing the value of the variable or object between simulation runs causes Simulink to regenerate code.
  - And you use additional Model blocks to refer to the model multiple times in the parent model, you can choose a different simulation mode for each Model block. If at least one block uses normal simulation mode and any other block uses a different simulation mode, you cannot change the value of the variable or object during simulation. Also, when you simulate the parent model with fast restart on, you cannot change the value of the variable or object between fast-restart simulation runs.

As a workaround, move the variable or object to the base workspace or a data dictionary.

### Accelerator and SIL/PIL Simulations

These tunability limitations apply to accelerator, rapid accelerator, SIL, and PIL simulations:

- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use the `sim` function to simulate the model in rapid accelerator mode and set the `RapidAcceleratorUpToDateCheck` pair argument to `'off'`, you cannot use the `RapidAcceleratorParameterSets` pair argument to specify different values for the variable or object. The structure returned by `Simulink.BlockDiagram.buildRapidAcceleratorTarget` does not contain information about the variable or object.
- If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation, such as by using the function `set_param`. Instead, you can tune the values of the referenced variables.

Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see “Tuning Runtime Parameters” on page 38-8.

For more information about parameter tunability during accelerated simulations, see “Tuning Runtime Parameters” on page 38-8 and “sim in parfor with Rapid Accelerator Mode” on page 28-13. For more information about parameter tunability during SIL and PIL simulations, see “Tunable Parameters and SIL/PIL” (Embedded Coder).

### Fast Restart

For more information about parameter tunability when you use fast restart, see “Get Started with Fast Restart” on page 86-5 .

### Code Generation and Simulation of External Programs

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. If you simulate an external program by using SIL, PIL, or External mode simulation, parameter tunability during the simulation and between simulation runs can depend on your code generation settings.

To control parameter tunability in the generated code, you can adjust the code generation settings for a model by using the configuration parameter **Default parameter behavior**. You can also adjust settings for individual MATLAB variables, Simulink.Parameter objects, and other parameter objects. For more information, see “Preserve Variables in Generated Code” (Simulink Coder).

### Stateflow Charts

To debug a Stateflow chart by changing data during simulation, see “Set Breakpoints to Debug Charts” (Stateflow).

### See Also

set\_param

- “Switch Between Sets of Parameter Values During Simulation and Code Execution” on page 40-56

## Optimize, Estimate, and Sweep Block Parameter Values

When you sweep one or more parameters, you change their values between simulation runs, and compare and analyze the output signal data from each run. Use parameter sweeping to tune control parameters, estimate unknown model parameters, and test the robustness of a control algorithm by taking into consideration uncertainty in the real-world system.

You can sweep block parameter values or the values of workspace variables that you use to set the parameter values. Use the **Parameters** tab on the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), the Property Inspector (on the **Modeling** tab, under **Design**, click **Property Inspector**), the command prompt, or scripts to change parameter values between simulation runs.

If you want to repeatedly change the value of a block parameter, consider creating a variable in a workspace. You can use the Model Explorer or programmatic commands to change the value of the variable instead of locating or identifying the block in the model. Also, several features and products that facilitate parameter optimization, estimation, and sweeping require that you set block parameter values by creating workspace variables.

To learn how to manipulate parameter values during the iterative process of creating a model, see “Tune and Experiment with Block Parameter Values” on page 40-31.

For basic information about accessing and setting block parameter values as you design a model, see “Set Block Parameter Values” on page 40-2. For basic information about programmatically simulating a model, such as by using a script, see “Run Simulations Programmatically” on page 28-2.

### Sweep Parameter Value and Inspect Simulation Results

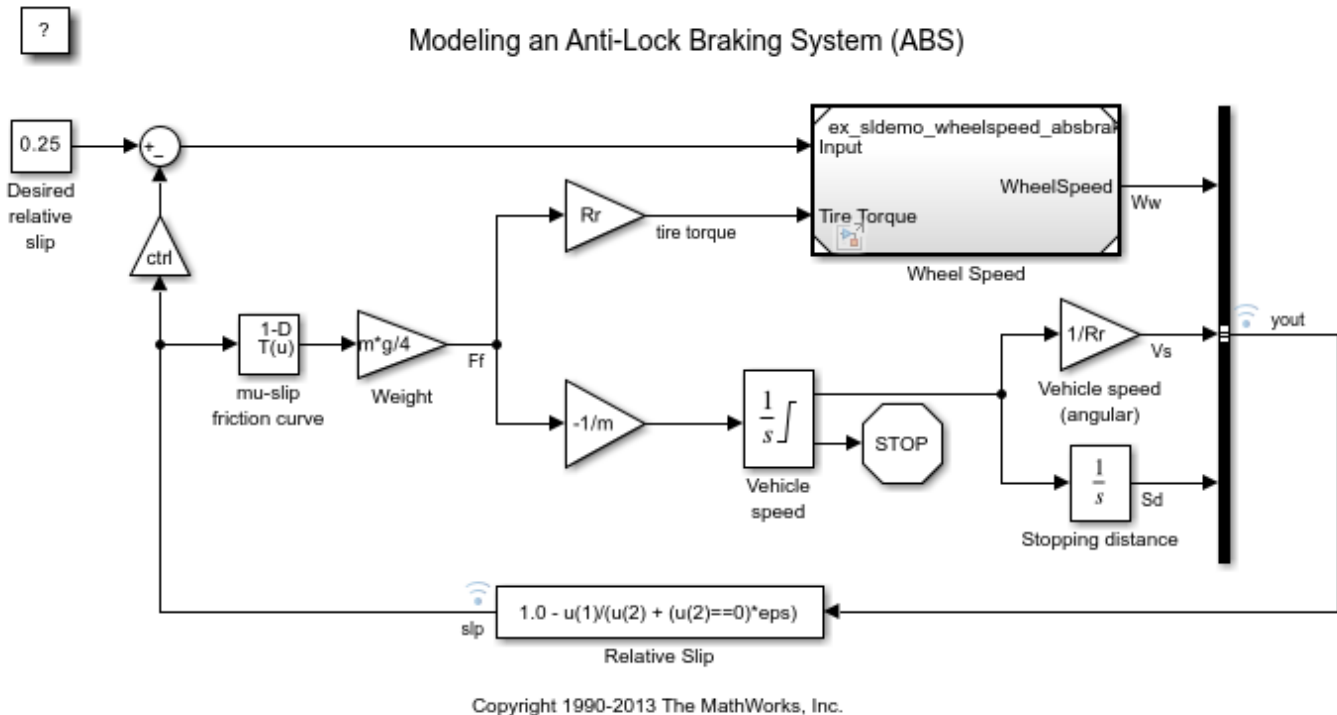

This example shows how to change a block parameter value between multiple programmatic simulation runs. Use this technique to determine an optimal parameter value by comparing the output signal data of each run.

The example model `ex_slldemo_absbrake` uses a Constant block to specify a slip setpoint for an anti-lock braking system. Simulate the model with two different slip setpoint values, 0.24 and 0.25, and compare the output wheel speed of each simulation run.

To store the setpoint value, create a variable in the base workspace. This technique enables you to assign a meaningful name to the value.

Open the example model.

```
open_system('ex_slldemo_absbrake');
```

On the **Modeling** tab, click **Model Data Editor**.

In the Model Data Editor, select the **Signals** tab.

Set the **Change view** drop-down list to **Instrumentation**. The **Log Data** column shows that the signals `yout` (which is a virtual bus) and `slp` are configured for logging. When you simulate the model, you can collect and later inspect the values of these signals by using the Simulation Data Inspector.

In the Model Data Editor, select the **Parameters** tab. Set **Change view** to **Design**.

In the model, select the Constant block labeled `Desired relative slip`. The Model Data Editor highlights the row that corresponds to the **Constant value** parameter of the block.

Use the **Value** column to set the parameter value to `relSlip`.

While editing the value, next to `relSlip`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `0.2` and click **Create**. A variable, whose value is `0.2`, appears in the base workspace. The model now acquires the relative slip setpoint from this variable.

Alternatively, you can use these commands at the command prompt to create the variable and configure the block:

```
relSlip = 0.2;
set_param('ex_slidemo_absbrake/Desired relative slip','Value','relSlip')
```

At the command prompt, create an array to store the two experimentation values for the relative slip setpoint, 0.24 and 0.25.

```
relSlip_vals = [0.24 0.25];
```

Create a `Simulink.SimulationInput` object for each simulation that you want to run (in this case, two). Store the objects in a single array variable, `simIn`. Use the `setVariable` method of each object to identify each of the two experimentation values.

```
for i = 1:length(relSlip_vals)
    simIn(i) = Simulink.SimulationInput('ex_sl_demo_absbrake');
    simIn(i) = setVariable(simIn(i), 'relSlip', relSlip_vals(i));
end
```

Use the `sim` function to simulate the model. Optionally, store the output in a variable named `simOutputs`.

```
simOutputs = sim(simIn);
```

```
[01-Sep-2022 12:16:09] Running simulations...
[01-Sep-2022 12:16:13] Completed 1 of 2 simulation runs
[01-Sep-2022 12:16:15] Completed 2 of 2 simulation runs
```

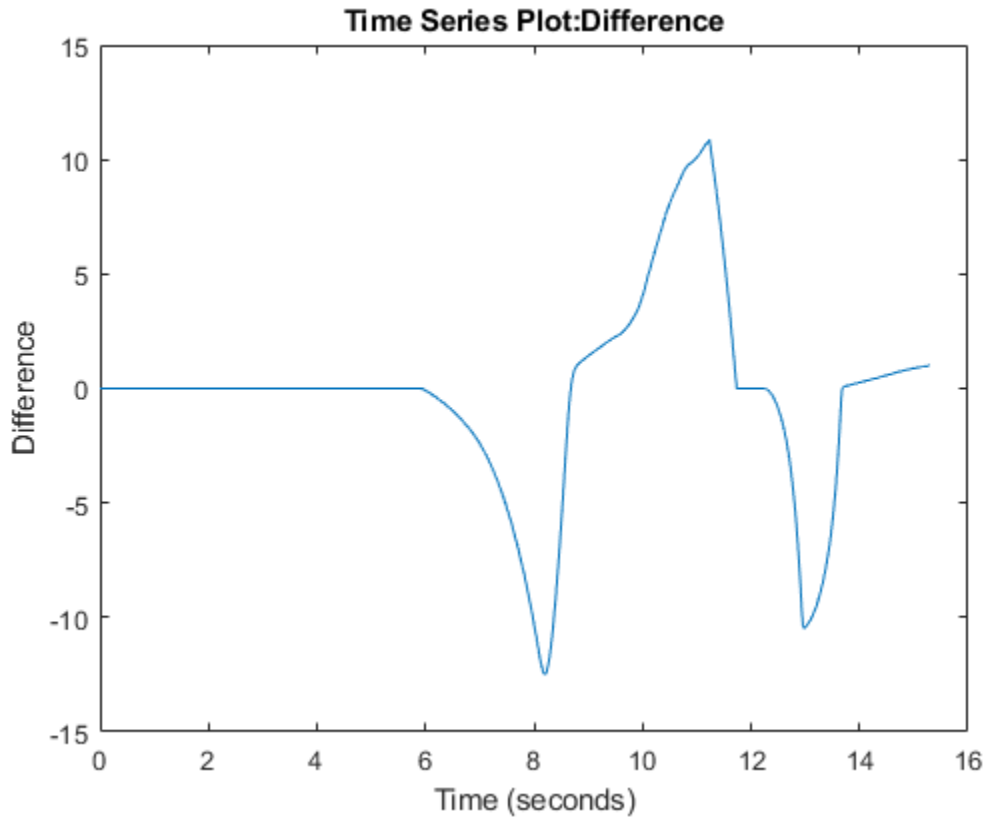

The model streams the logged signals, `yout` and `slp`, to the Simulation Data Inspector. You can view the signal data in the Simulation Data Inspector.

Compare the output data of the two latest simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs();
runResult = Simulink.sdi.compareRuns(runIDs(end-1), runIDs(end));
```

Plot the difference between the values of the `Ww` signal (which is an element of the virtual bus signal `yout`) by specifying the result index 1.

```
signalResult = getResultByIndex(runResult,1);
plot(signalResult.Diff);
```

## Store Sweep Values in Simulink.SimulationInput Objects

When you write a script to run many simulations, create an array of `Simulink.SimulationInput` objects (one object for each simulation that you want to run). Use the `setVariable` and `setBlockParameter` methods of each object to identify the parameter values to use for the corresponding simulation run. With this technique, you avoid having to use the `set_param` function to modify block parameter values and assignment commands to modify workspace variable values between simulation runs.

For more information about using `Simulink.SimulationInput` objects to run multiple simulations, see `sim`.

## Sweep Nonscalars, Structures, and Parameter Objects

If you use nonscalar variables, structure variables, or `Simulink.Parameter` objects to set block parameter values, use the `setVariable` method of each `Simulink.SimulationInput` object. Refer to the examples in the table.

Scenario	Example
MATLAB variable, <code>myArray</code> , whose value is an array. You want to set the third element in the array (assuming one-based indexing).	<code>setVariable(simIn, 'myArray(3)', 15.23)</code>

Scenario	Example
MATLAB variable, myStruct, that has a field named field1.	<code>setVariable(simIn, 'myStruct.field1', 15.23)</code>
Parameter object, myParam, whose Value property is a scalar.	<code>setVariable(simIn, 'myParam.Value', 15.23)</code>
Parameter object, myArrayParam, whose Value property is an array. You want to set the third element in the array.	<code>setVariable(simIn, 'myArrayParam.Value(3)', 15.23)</code>
Parameter object, myStructParam, whose Value property is a structure. The structure has a field named field1.	<code>setVariable(simIn, 'myStructParam.Value.field1', 15.23)</code>

### Sweep Value of Variable in Model Workspace

If you use the model workspace to store variables, when you use the `setVariable` method of a `Simulink.SimulationInput` object to modify the variable value, use the `Workspace` pair argument to identify the containing model:

```
setVariable(simIn, 'myVar', 15.23, 'Workspace', 'myModel')
```

### Capture and Visualize Simulation Results

Each simulation run during a parameter sweep produces outputs, such as signal values from Output blocks and from logged signals.

You can capture these outputs in variables and objects for later analysis. For more information, see “Export Simulation Data” on page 77-2.

To visualize simulation output data so you can compare the effect of each parameter value, see “Decide How to Visualize Simulation Data” on page 33-2.

### Improve Simulation Speed

To perform many simulations that each use different parameter values, you can use accelerated simulation modes. For larger models, accelerated simulations take less time to execute than normal simulations. If you also have Parallel Computing Toolbox, you can use the multiple cores of your processor to simultaneously execute simulations. Use arguments of the `sim` and `parsim` functions.

To improve the simulation speed of your model by using accelerated simulations and other techniques, see “Optimize Performance”. For examples and more information, see “Running Multiple Simulations” on page 29-2.

### Sweep Parameter Values to Test and Verify System

If you have Simulink Test, you can confirm that your model still meets requirements when you use different parameter values. Parameter overrides and test iterations enable you to set different parameter values for each test case. For more information, see “Parameter Overrides” (Simulink Test) and “Test Iterations” (Simulink Test).

## Estimate and Calibrate Model Parameters

If you have Simulink Design Optimization, you can estimate model parameter values so that simulation outputs closely fit the data that you measure in the real world. Use this technique to estimate the real-world values of parameters in a plant model, which represents the dynamics of a real-world system, when you cannot directly measure the values. This estimation improves the accuracy of the plant model. For more information, see “Estimate Parameters from Measured Data” (Simulink Design Optimization).

## Tune and Optimize PID and Controller Parameters

If you have Simulink Control Design, you can use PID Tuner to tune the parameters of a PID Controller block. For more information, see “PID Controller Tuning in Simulink” (Simulink Control Design).

If you have Simulink Design Optimization, you can optimize control parameter values so that simulation outputs meet response requirements that you specify. For more information, see “Design Optimization to Meet Step Response Requirements (GUI)” (Simulink Design Optimization).

- “Switch Between Sets of Parameter Values During Simulation and Code Execution” on page 40-56

## Control Block Parameter Data Types

A block parameter, such as the **Gain** parameter of a Gain block, has a data type in the same way that a signal has a data type (see “Control Data Types of Signals” on page 72-6). MATLAB variables, `Simulink.Parameter` objects, and other parameter objects that you use to set block parameter values also have data types. Control block parameter data types to:

- Accurately simulate the execution of your control algorithm on hardware.
- Generate efficient code.
- Integrate the generated code with your custom code.
- Avoid using data types that your target hardware does not support.

### Reduce Maintenance Effort with Data Type Inheritance

By default, block parameters, numeric MATLAB variables that use the data type `double`, and `Simulink.Parameter` objects acquire a data type through inherited and context-sensitive data typing. For example, if the input and output signals of a Gain block use the data type `single`, the **Gain** parameter typically uses the same data type. If you use a `Simulink.Parameter` object to set the value of the block parameter, by default, the object uses the same data type as the parameter. You can take advantage of this inheritance to avoid explicitly specifying data types for parameters.

Some inheritance rules choose a parameter data type other than the data type that the corresponding signals use. For example, suppose that:

- The input and output signals of a Gain block use fixed-point data types with binary-point-only scaling.
- On the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default).
- On the **Parameter Attributes** tab, you specify a minimum and maximum value for the parameter by using **Parameter minimum** and **Parameter maximum**.

The data type setting `Inherit: Inherit via internal rule` can cause the block to choose a different data type, with a different word length or scaling, than the data type that the signals use. The minimum and maximum values that you specified for the parameter influence the scaling that the block chooses.

When you select internal rules (`Inherit: Inherit via internal rule`) to enable Simulink to choose data types, before simulating or generating code, configure the characteristics of your target hardware. The internal rules can use these settings to choose data types that yield efficient generated code.

### Context-Sensitive Data Typing

When you use a MATLAB variable or `Simulink.Parameter` object to set the value of a block parameter, you can configure the variable or parameter object to use context-sensitive data typing. When you simulate or generate code, the variable or parameter object uses the same data type as the block parameter. With this technique, you can match the data type of the variable or parameter object with the data type of the block parameter. To control the data type of the block parameter and the variable or object, you specify only the data type of the block parameter.

To use context-sensitive data typing, set the value of a MATLAB variable to a double value. For a `Simulink.Parameter` object, set the `Value` property by using a double value and set the `DataType` property to `auto` (the default).

### Context-Sensitive Data Typing for Structure Fields

As described in “Organize Related Block Parameter Definitions in Structures” on page 40-19, you can organize multiple block parameter values into a structure.

The fields of parameter structures do not support context-sensitive data typing. However, to match the data type of a field with the data type of another data item in a model, you can use a bus object and a data type object.

- 1 Use a `Simulink.Bus` object as the data type of the structure.
- 2 Use a `Simulink.AliasType` or `Simulink.NumericType` object as the data type of the element in the bus object and as the data type of the target data item.

### Techniques to Explicitly Specify Parameter Data Types

Many blocks supported for discrete-time simulation and code generation (such as those in the built-in Discrete library) enable you to explicitly specify parameter data types. For example, in an **n-D Lookup Table** block dialog box, on the **Data Types** tab, you can specify a data type for the lookup table data by using the **Table data** parameter. In a Gain block dialog box, use the **Parameter Attributes** tab to set **Parameter data type**, which controls the data type of the **Gain** parameter.

Some blocks, such as those in the Continuous library, do not enable you to specify parameter data types. These block parameters use internal rules to choose a data type. To indirectly control the data type of such a parameter, apply the data type to a `Simulink.Parameter` object instead.

When you use a `Simulink.Parameter` object or other parameter object to set the value of a block parameter, you can use the `DataType` property of the object to specify a data type.

If you use model arguments, you can specify a data type:

- For the model argument that you store in the model workspace.
- With some blocks (such as those in the Discrete library), for the block parameter that uses the model argument.
- For the argument value that you specify in a Model block.

The default settings for these data types typically use inheritance and context-sensitive data typing. For example, the default value of the `DataType` property of a `Simulink.Parameter` object is `auto`, which causes the parameter object to acquire a data type from the block parameter or parameters that use the object.

To explicitly specify a data type, you can use the Data Type Assistant in block dialog boxes and property dialog boxes. For information about the Data Type Assistant, see “Specify Data Types Using Data Type Assistant” on page 72-30.

### Use the Model Data Editor for Batch Editing

Using the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), you can specify the same data type for multiple block parameters simultaneously. On the **Parameters** tab, set the **Change view** drop-down list to **Design** and specify data types by using the **Data Type** column.

For more information, see **Model Data Editor**.

## Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters

When you apply fixed-point data types to a model, you can use the Data Type Assistant and the Fixed-Point Tool to calculate best-precision scaling for tunable block parameters. A block parameter, `Simulink.Parameter` object, or other parameter object is tunable if it appears in the generated code as a variable stored in memory.

The chosen scaling must accommodate the range of values that you expect to assign to the parameter. To enable the tools to calculate an appropriate scaling, specify the range information in the block or in a parameter object. Then, use one of these techniques to calculate the scaling:

- Use the Fixed-Point Tool to autoscale the entire model or subsystem. The tool can propose and apply fixed-point data types for data items including block parameters, `Simulink.Parameter` objects, signals, and states.
- Configure individual block parameters or parameter objects to calculate their own scaling.

When you later change value ranges for parameters, this technique enables you or the model to recalculate the scaling without having to autoscale the entire model. However, if changing the value range of the parameter also changes the value range of an associated signal, you must manually calculate and apply a new scaling for the signal or use the Fixed-Point Tool to autoscale the model or subsystem.

For basic information about fixed-point data types, block parameters, and other tools and concepts, use the information in the table.

Topic	More Information
Fixed-point data types and scaling	"Fixed-Point Numbers in Simulink" (Fixed-Point Designer)
How to specify value range information for block parameters and parameter objects	"Specify Minimum and Maximum Values for Block Parameters" on page 40-52
How to use the Data Type Assistant	"Specify Data Types Using Data Type Assistant" on page 72-30
Tunability and block parameter representation in the generated code	"How Generated Code Stores Internal Signal, State, and Parameter Data" (Simulink Coder) and "Create Tunable Calibration Parameter in the Generated Code" (Simulink Coder)

### Autoscale Entire Model by Using the Fixed-Point Tool

You can use the Fixed-Point Tool to autoscale data items in your model, including tunable parameters and signals whose values depend on those parameters. If you use this technique:

- To configure parameters as tunable, use parameter objects (for example, `Simulink.Parameter`) instead of the Model Parameter Configuration dialog box. The Fixed-Point Tool can autoscale parameter objects, but cannot autoscale numeric variables that you select through the Model Parameter Configuration dialog box.

If your model already uses the Model Parameter Configuration dialog box, use the `tunablevars2parameterobjects` function to create parameter objects instead.

- When you use `Simulink.Parameter` objects to set block parameter values, specify the value range information in the objects instead of the blocks. The Fixed-Point Tool uses the range information in each object to propose a data type for that object.
- To enable the tool to autoscale parameter values that you store as fields of a structure, use a `Simulink.Bus` object as the data type of the entire structure. Specify the range information for each field by using the `Min` and `Max` properties of the corresponding element in the bus object. The tool can then apply a data type to each element by using the `DataType` property.

To use a bus object as the data type of a parameter structure, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 40-21.

- Before you apply the data types that the Fixed-Point Tool proposes, clear the proposals for parameters and parameter objects whose data types you do not want the tool to change. For example, clear the proposals for these entities:
  - Parameter objects that you import into the generated code from your own handwritten code by applying a storage class such as `ImportedExtern`.
  - `Simulink.Parameter` model arguments in a model workspace.

Alternatively, before autoscaling the model, consider replacing these parameter objects with numeric MATLAB variables to prevent the Fixed-Point Tool from autoscaling them.

Allowing the tool to autoscale model arguments can increase the risk of unintentional data type mismatches between the model argument values (which you specify in Model blocks in a parent model), the model arguments in the model workspace, and the client block parameters in the model.

- Parameter objects whose `DataType` property is set to `auto` (context-sensitive). Clear the proposals if you want the parameter objects to continue to use context-sensitive data typing.

For more information about using the Fixed-Point Tool to autoscale `Simulink.Parameter` objects, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

### Calculate Best-Precision Scaling for Individual Parameters

You can configure a block parameter or `Simulink.Parameter` object to calculate its own best-precision scaling. First, specify value range information for the target parameter or parameter object. Then, use the Data Type Assistant or the function `fixdt` to apply a data type to the parameter or object. Use these techniques when you do not want to use the Fixed-Point Tool to autoscale the model.

#### Enable Block Parameter to Automatically Calculate Best-Precision Scaling

You can enable the parameters of some blocks (typically blocks in the Discrete library) to automatically calculate best-precision fixed-point scaling. Use this technique to store the range and data type information in the model instead of a parameter object. When you use this technique, if you later change the range information, the block parameter automatically recalculates best-precision scaling.

In the block dialog box, use the function `fixdt` to specify a fixed-point data type with unspecified scaling. For example, use best-precision scaling for lookup table data, and store the data in a 16-bit word:

- 1 On the **Data Types** tab of an n-D Lookup Table block, under the **Minimum** and **Maximum** columns, specify a value range for the elements of the table data.
- 2 Under the **Data Type** column, set the table data type to `fixdt(1,16)`.
- 3 If you use a tunable `Simulink.Parameter` object to set the value of the table data parameter, set the `DataType` property of the object to `auto`. In the generated code, the parameter object uses the same scaling as the block parameter.

When you simulate or generate code, the lookup table data uses a signed 16-bit fixed-point data type whose binary-point scaling depends on the range information that you specify. The calculated scaling allows the fixed-point type to represent values that lie within the range. If you later change the minimum or maximum values, the block recalculates the scaling when you simulate or generate code.

### Calculate Scaling for Parameter Object

If you use a `Simulink.Parameter` object to set the values of multiple block parameters, and if the block parameters use different data types (including different fixed-point scaling), you cannot set the `DataType` property of the object to `auto` (the default). Instead, you can calculate best-precision fixed-point scaling for the parameter object by specifying range and data type information in the object. You can also use this technique to store range and data type information in a parameter object instead of a block dialog box. When you use this technique, if you later change the range information, you must recalculate the best-precision scaling by using the Data Type Assistant.

Suppose that you create a parameter object to represent the value `15.25`, and that the design range of the value is between `0.00` and `32.00`. To calculate best-precision scaling, use the Data Type Assistant.

- 1 At the command prompt, create a parameter object in the base workspace whose value is `15.25`.
 

```
myParam = Simulink.Parameter(15.25);
```
- 2 In the MATLAB Workspace browser, double-click the object `myParam`. The property dialog box opens.
- 3 Specify range information in the object. For example, set **Minimum** to `0.00` and **Maximum** to `32.00`.
- 4 Set **Data type** to `fixdt(0,16,0)`.
- 5 Expand the Data Type Assistant and click **Calculate Best-Precision Scaling**.

The data type changes from `fixdt(0,16,0)` to `fixdt(0,16,10)`.

The calculated scaling (a fraction length of 10 bits) enables the fixed-point data type to represent parameter values that lie within the range that you specified.

If you specify range and data type information in a parameter object, consider removing the range and data type information from the blocks that use the object. Some tools, such as the Fixed-Point Tool, ignore the range information that you specify in the block and use only the information in the parameter object. Removing the information from the block prevents confusion and user errors.

For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Set **Parameter data type** to an inherited data type such as `Inherit: Inherit from 'Gain'` so that the block parameter uses the same data type as the parameter object.

## Detect Numerical Accuracy Issues Due to Quantization and Overflow

When the data type of a block parameter, MATLAB variable, or parameter object cannot represent the value that you specify, the data type quantizes the value, compromising numerical accuracy. For example, the 32-bit floating-point data type `single` (`float` in C code) cannot exactly represent the parameter value 1.73. When the real-world value of a data item lies outside the range of values that the data type can represent, overflow can cause loss of information.

To detect these issues, use the diagnostic configuration parameters under **Configuration Parameters > Diagnostics > Data Validity > Parameters**. Set the values of these diagnostic configuration parameters to warning or error:

- **Detect downcast**
- **Detect precision loss**
- **Detect underflow**
- **Detect overflow**

## Reuse Custom C Data Types for Parameter Data

In a model, you can create parameter data that conform to custom C data types, such as structures, that your existing C code defines. Use these data to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for a structure that you store in a `Simulink.Parameter` object. See “Organize Related Block Parameter Definitions in Structures” on page 40-19.
- For an enumeration, create an enumeration class and use it as the data type for block parameters. See “Use Enumerated Data in Simulink Models” on page 73-6.
- To match a `typedef` statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for block parameters. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

If a MATLAB Function block or Stateflow chart in your model uses an imported enumeration or structure type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 49-116 (for a MATLAB Function block) and “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow) and “Integrate Custom Structures in Stateflow Charts” (Stateflow) (for a chart).

## Data Types of Mathematical Expressions

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

Suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a Constant block.

```
int8Param = Simulink.Parameter(3);
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```

The Constant block determines the data type of the **Constant value** parameter using these steps:

- 1 Each parameter object casts the specified numeric value to the specified data type.

Parameter object	Data type	Numeric value	Result
<code>int8Param</code>	<code>int8</code>	3	<code>int8(3)</code>
<code>doubleParam</code>	<code>double</code>	9.36	<code>double(9.36)</code>

- 2 The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a `double` data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

If you use an expression to set the value of a parameter object (such as `Simulink.Parameter`), parameter objects used in the expression follow different data typing rules. The `auto` setting of the `DataType` property has a slightly different meaning. See “Set Variable Value by Using a Mathematical Expression” on page 40-10.

## Block Parameter Data Types in the Generated Code

For more information about controlling parameter data types in the generated code, see “Parameter Data Types in the Generated Code” (Simulink Coder).

- “Specify Minimum and Maximum Values for Block Parameters” on page 40-52
- “Tune and Experiment with Block Parameter Values” on page 40-31

- “Model Configuration Parameters: Data Validity Diagnostics”

## Specify Minimum and Maximum Values for Block Parameters

You can protect your model design by preventing block parameters from using values outside of a range. For example, if the value of a parameter that represents the angle of an aircraft aileron cannot feasibly exceed a known magnitude, you can specify a design maximum for the parameter in the model.

Fixed-Point Designer enables Simulink to use your range information to calculate best-precision fixed-point scaling for:

- Tunable parameters.
- Signals, by taking into consideration the range of values that you intend to assign to tunable parameters.

For basic information about block parameters, see “Set Block Parameter Values” on page 40-2.

### Specify Parameter Value Ranges

When you specify a value range for a block parameter, typically, you can choose to store the information in the block (the model file) or in an external variable or parameter object. Choose a technique based on your modeling goals.

- Use other parameters of the same block, if available. For example, you can control the value range of the **Gain** parameter of a Gain block by using the **Parameter minimum** and **Parameter maximum** parameters in the **Parameter Attributes** tab in the block dialog box. For other blocks, such as n-D Lookup Table and PID Controller, use the **Data Types** tab.

Use this technique to:

- Store the range information in the model file.
- Store the range information when you store fixed-point data type information in the block (for example, by setting the **Parameter data type** parameter of a Gain block to a fixed-point type, including best-precision scaling). This technique more clearly associates the range information with the data type information.
- Use parameter objects (for example, `Simulink.Parameter`) to set the parameter value. You can specify the range information in the object, instead of the block, by using the `Min` and `Max` properties of the object.

Use this technique to:

- Specify range information for blocks that cannot store minimum or maximum information, for example, many blocks in the Continuous library.
- Specify range information for a single value that you share between multiple block parameters (see “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9). Instead of using a numeric MATLAB variable, use a parameter object so that you can specify the `Min` and `Max` properties.
- Store the range information when you store fixed-point data type information in a parameter object (by setting the `DataType` property to a fixed-point type instead of `auto`). This technique more clearly associates the range information with the data type information.

If you specify the range information in a parameter object, consider removing the range information from the block. For example, on the **Parameter Attributes** tab of a Gain block dialog

box, set **Parameter minimum** and **Parameter maximum** to `[]`. Some tools, such as the Fixed-Point Tool, use the range information that you specify in the block only if you do not specify the range information in the parameter object. If you specify the range information in the parameter object, the tools ignore the range information that you specify in the block.

For basic information about creating and using data objects, see “Data Objects” on page 72-61.

### Specify Valid Range Information

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with double data type. For example, you can specify a minimum value for the **Gain** parameter in a Gain block by setting **Parameter minimum**:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see “Share and Reuse Block Parameter Values by Creating Variables” on page 40-9) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

However, you cannot use variables to set the **Min** or **Max** properties of a parameter object.

To leave the minimum or maximum of a block parameter or parameter object unspecified, use an empty matrix `[]`, which is the default value.

### Specify Range Information for Nonscalar Parameters

If the value of a block parameter is a vector or matrix, the range information that you specify applies to each element of the vector or matrix. If the value of any of the elements is outside the specified range, the model generates an error.

If the value of a block parameter is a structure or a field of a structure, specify range information for the structure fields by creating a `Simulink.Parameter` object whose data type is a `Simulink.Bus` object. Specify the range information by using the properties of the signal elements in the bus object. For more information, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 40-21.

### Specify Range Information for Complex-Valued Parameters

If the value of a block parameter is complex (i), the range information that you specify applies separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is outside the range, the model generates an error.

### Specify Ranges for Multiple Parameters by Using the Model Data Editor

Using the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**), you can specify value ranges for multiple block parameters and variables with a searchable, sortable table. On the **Parameters** tab, set the **Change view** drop-down list to **Design** and specify values in the **Min** and **Max** columns.

For more information, see **Model Data Editor**.

### Restrict Allowed Values for Block Parameters

To protect your design by preventing block parameters from using values outside of a range, you can specify the minimum and maximum information by using other parameters of the same block. If you

or your users set the value of the target parameter outside the range that you specify, the model generates an error.

Whether a block allows you to specify a value range for a parameter, consider using a parameter object (for example, `Simulink.Parameter`) to set the value of the target parameter. Use the properties of the object to specify the range information. This technique helps you to specify range information for a variable that you use to set multiple block parameter values.

## Specify Range Information for Tunable Fixed-Point Parameters

When you use fixed-point data types in your model, you can enable Simulink to choose a best-precision scaling for block parameters and `Simulink.Parameter` objects. If you intend to tune such a parameter by changing its value during simulation or during execution of the generated code, the fixed-point scaling chosen by Simulink must accommodate the range of values that you expect to assign to the parameter.

Also, if you expect to change the value of a parameter, signal data types in the model must accommodate the corresponding expanded range of possible signal values. If you use the Fixed-Point Tool to propose and apply fixed-point data types for a model, to allow the tool to accurately autoscale the signals, specify range information for tunable parameters.

To specify range information for tunable parameters, see “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” on page 40-46. To learn how the Fixed-Point Tool autoscales signals by taking into account the value ranges of tunable parameters, see “Derive Ranges for `Simulink.Parameter` Objects” (Fixed-Point Designer).

## Unexpected Errors or Warnings for Data with Greater Precision or Range than double

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the `nondouble` data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the `nondouble` type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the command prompt, calculate the next number furthest from zero that `double` can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)

ans =

    98.884769234850921
```

Use the resulting number, `98.884769234850921`, to replace the maximum value.

## Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see [Optimize using the specified minimum and maximum values \(Embedded Coder\)](#).

## Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

### Explore Example Model

Open the example model.

```
open_system('sldemo_fuelsys_dd_controller')
```

Copyright 1990-2022 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
            'switchable_compensation'])
```

## Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
            'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the model data badge, then click the **Data Dictionary** link. The data dictionary for this model, `sldemo_fuelsys_dd_controller.slidd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the Simulink.NumericType objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

### Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a Simulink.Parameter object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
            'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
             'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));
params.richNumerator = eval(get_param(richBlock, 'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

### Create Variable to Switch Between Parameter Sets

Create a Simulink.Parameter object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

### Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

### Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

### Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.slidd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.slidd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
```

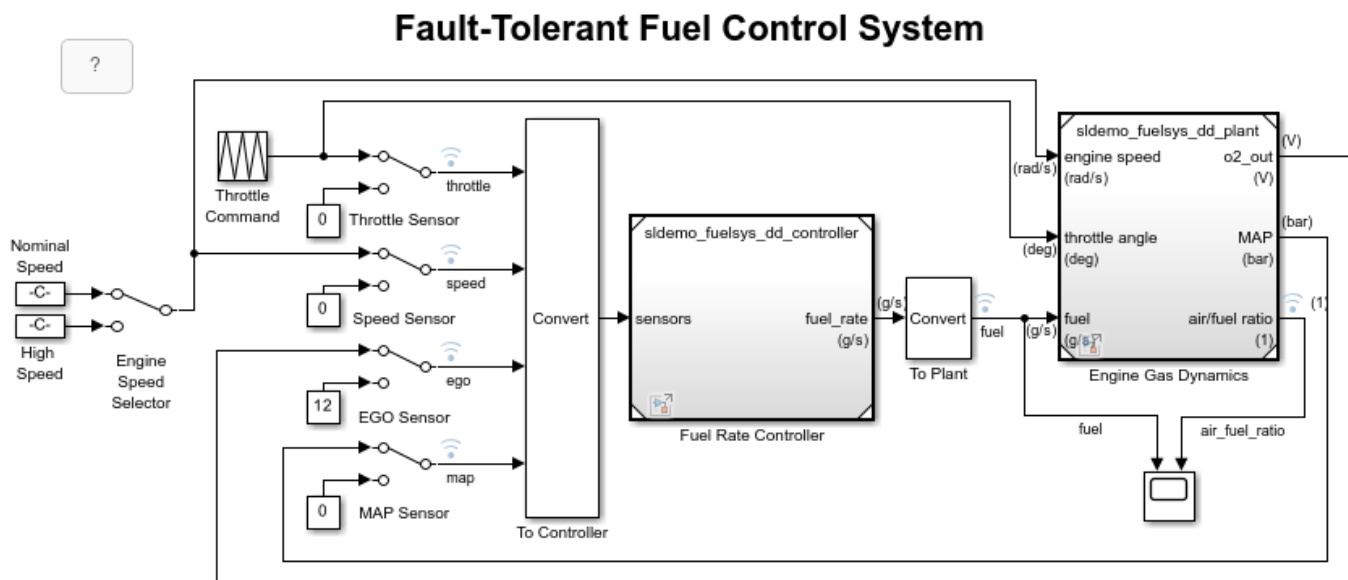

```
addEntry(sectObj, 'params', params)
addEntry(sectObj, 'paramsType', paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” on page 79-14.

### Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

The sensor switches simulate any combination of sensor failures. The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2022 The MathWorks, Inc.

Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

## Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, params);

tempEntryObj = getEntry(sectObj, 'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
slbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for: sldemo_fuelsys_dd_controller
### Successful completion of code generation for: sldemo_fuelsys_dd_controller
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
sldemo_fuelsys_dd_controller	Code generated.	Code generation information file does not exist.

1 of 1 models built (0 models already up to date)

Build duration: 0h 1m 26.21s

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', ...
    '/* Forward declaration for rtModel */', 1, 0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_
```

```
typedef enum {
    Weak = 1, /* Default value */
```

```
    Aggressive
} FilterCoeffs;
```

```
#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_paramsType_', ...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', 1, 0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_
```

```
typedef struct {
    real32_T lowNumerator[2];
    real32_T richNumerator[2];
} paramsType;
```

```
#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file, 'FilterCoeffs Ctrl = Aggressive;', ...
    '/* Block signals (default storage) */', 1, 0)
```

```
FilterCoeffs Ctrl = Aggressive;          /* Variable: Ctrl
                                           * Referenced by:
                                           *   '<S12>/Discrete Filter'
                                           *   '<S13>/Discrete Filter'
                                           */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file, '/* Exported block parameters */', ...
    '/* Variable: params', 1, 1)
```

```
/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
}, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
} } ;                                     /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

Close the connections to the data dictionary. This example discards unsaved changes. To save the changes, use the '-save' option.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd_controller.sldd', '-discard')
```

## About Lookup Table Blocks

A lookup table is an array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a lookup operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding, where:

- An interpolation is a process for estimating values that lie between known data points.
- An extrapolation is a process for estimating values that lie beyond the range of known data points.
- A rounding is a process for approximating a value by altering its digits according to a known rule.

A lookup table block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a “lookup” operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function  $y = x^3$ . The lookup table defines its output ( $y$ ) data discretely over the input ( $x$ ) range  $[-3, 3]$ . The following table and graph illustrate the input/output relationship:

An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's  $x$  values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest adjacent data points  $(x_i, y_i)$  and  $(x_{i+1}, y_{i+1})$ . For example, given these two points:

- $(x_i, y_i)$  is (-2, -8)
- $(x_{i+1}, y_{i+1})$  is (-1, -1)

The lookup table estimates and returns a value of -4.5.

Similarly, although the lookup table does not include data for  $x$  values beyond the range of  $[-3, 3]$ , the block can extrapolate values using a pair of data points at either end of the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points  $(2, 8)$  and  $(3, 27)$  to estimate an output value of 46.

Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

## Anatomy of a Lookup Table

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or breakpoint data sets and an array, referred to as table data, constitute the lookup table.

A breakpoint is a single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped. Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

A breakpoint data set is a vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.

Table data is an array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value.

## Guidelines for Choosing a Lookup Table

### In this section...

“Data Set Dimensionality” on page 41-5

“Data Set Numeric and Data Types” on page 41-5

“Data Accuracy and Smoothness” on page 41-5

“Dynamics of Table Inputs” on page 41-5

“Efficiency of Performance” on page 41-6

“Summary of Lookup Table Block Features” on page 41-6

### Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the 1-D Lookup Table or Lookup Table Dynamic block. If you are approximating a two-dimensional function, consider the 2-D Lookup Table block. Blocks such as the n-D Lookup Table and Direct Lookup Table (n-D) allow you to approximate a function of  $N$  variables.

### Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the Direct Lookup Table (n-D), 1-D Lookup Table, 2-D Lookup Table, and n-D Lookup Table blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to double and single data types.

---

**Note** For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

---

### Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation and extrapolation, improving the accuracy of values that fall between or outside of the table data, respectively. For instance, the Lookup Table Dynamic block performs linear interpolation and extrapolation, while the n-D Lookup Table block performs either linear, cubic spline interpolation and extrapolation, or Akima spline interpolation and extrapolation. In contrast, the Direct Lookup Table (n-D) block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the Prelookup block with the Interpolation Using Prelookup block.

### Dynamics of Table Inputs

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The 1-D Lookup Table,

2-D Lookup Table, n-D Lookup Table, and Prelookup blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the Prelookup block with the Interpolation Using Prelookup block.

## Efficiency of Performance

When the efficiency with which lookup tables operate is important, consider using the Prelookup block with the Interpolation Using Prelookup block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the Interpolation Using Prelookup block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

## Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

Feature	1-D Lookup Table	2-D Lookup Table	Lookup Table Dynamic	n-D Lookup Table	Direct Lookup Table (n-D)	Prelookup	Interpolation Using Prelookup

## Breakpoint and Table Size Features in Lookup Tables

Simulink supports multiple size related features in lookup tables. This topic summarizes these features and describes when to use them.

### Tunable Size

Lookup tables consist of breakpoint and table arrays that lookup table blocks use to look up inputs and interpolate table data. These arrays have fixed sizes once the simulation starts. They appear as arrays in generated C/C++ code. Tunable sizes enable you to work with a smaller range of active breakpoints, also known as active region, within the larger fixed size of the breakpoint array. Use tunable sizes when you need to tune or calibrate your lookup table without needing to resize the arrays and regenerate code. With this feature, the generated C/C++ code includes a tunable size variable, whose value you can change, between compile runs or during program execution by writing into its memory location. As of R2022b, this feature is available only in code generation. To use the tunable size feature, select the **Support tunable size** check box on the “Advanced” tab of the Simulink.LookupTable property dialog box.

In this example, the breakpoint array of the lookup table is of size 10.  $N$  denotes the tunable size.

### Symbolic Dimensions

Symbolic dimensions let you create breakpoint and table arrays using sizes represented by symbolic values in simulation and generated C/C++ code. Symbolic dimensions allow you to easily change the size of your lookup table data between compile runs. In generated C/C++ code, these symbolic values appear as macros used to declare the breakpoint and table C arrays. The symbolic values represent the larger fixed sizes of the breakpoints and table. Use the tunable size feature with symbolic dimensions to choose a smaller active region within the symbolic size in the generated C/C++ code. To use symbolic dimensions, see the **Dimensions** parameter on the “Table and Breakpoints” tab of the Simulink.LookupTable property dialog box.

In this example, the breakpoint and table arrays of the lookup table are of size  $S$ .  $S$  is a macro that can represent different sizes between compile runs.

## Reusable Struct Data Types for Different Breakpoint and Table Array Sizes

`Simulink.LookupTable` objects let you create struct data types with fields to represent breakpoint and table data. Lookup table objects also provide for customization of the struct data type definition. The reusable struct data types feature lets you use the same struct data type to represent multiple lookup table objects, each with different lookup table array sizes.

In simulation, you can have multiple n-D Lookup Table blocks, each with objects having different table and breakpoint sizes with the same struct data type name. You can also pass these differently sized array objects via model arguments in a model reference hierarchy, setting up a size-independent interface between models for your lookup table data types. In the generated C/C++ code, the struct data type represents the breakpoint and table fields as pointer data types instead of array data types.

Without this feature, achieving the same behavior requires padding the differently sized arrays to the maximum size of the arrays of the participating lookup table objects. Padding in this manner has several disadvantages, such as wasted memory and slower breakpoint search speed.

Starting in R2022b, to work with different breakpoint and table array sizes, use the **Allow multiple instances of this type to have different table and breakpoint sizes** check box on the “Advanced” tab of the `Simulink.LookupTable` property dialog box.

As an example, the **Two Lookup Table Objects with Differently Sized Arrays** graphic shows two lookup table objects, each with different breakpoint and table array sizes.

- *LUT object 1* has breakpoint and table arrays of size [1x4].
- *LUT object 2* has breakpoint and table arrays of size [1x6].

We would like to have the same struct data type, *lookup\_type*, represent both objects. As presented, the configuration issues an error during model update diagram.

### Two Lookup Table Objects with Differently Sized Arrays

To resolve the sizing discrepancy, in releases before R2022b, the workaround was to use padding to match the array sizes of the participating lookup table objects. This approach is not optimal.

The **Lookup Table Object with Padding Applied** graphic shows the padding workaround. Breakpoint and table arrays of *LUT object 1* are padded to match the size of the breakpoint and table arrays of *LUT object 2*. Notice how the struct data type, `lookup_type`, generated in the C/C++ code, has breakpoint and table fields as arrays of size 6. With this, the struct data type can represent both *LUT object 1* and *LUT object 2* using padding.

```
typedef struct {
    uint32_T N1;
    l_T BP1[6];
    real_T T[6];
} lookup_type;
```

### Lookup Table Object with Padding Applied

Starting in R2022b, to solve the size discrepancy, use the **Allow multiple instances of this type to have different table and breakpoint sizes** check box in the Simulink.LookupTable object. This feature allows the same struct data type to represent different breakpoint and table sizes.

The **Lookup Table Object with Differently Sized Tables and Breakpoints Enabled** graphic shows the same lookup table object configuration, but with the **Allow multiple instances of this type to have different table and breakpoint sizes** check box selected. The struct data type, `lookup_type`, in the generated C/C++ code, has breakpoint and table fields as pointers instead of arrays. As a result, the struct data type can represent *LUT object 1* and *LUT object 2* without requiring any padding.

```
typedef struct {
    uint32_T N1;
    real_T *BP1;
    real_T *T;
} lookup_type;
```

## Characteristics of Lookup Table Data

### In this section...

“Sizes of Breakpoint Data Sets and Table Data” on page 41-12

“Monotonicity of Breakpoint Data Sets” on page 41-13

“Formulation of Evenly Spaced Breakpoints” on page 41-13

### Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

Vector of input values: [-3 -2 -1 0 1 2 3]  
 Vector of output values: [-3 -1 0 -1 0 1 3]

In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

Row index input values: [1 2 3]  
 Column index input values: [1 2 3 4]  
 Table data: [11 12 13 14; 21 22 23 24; 31 32 33 34]

	1	2	3	4
1	11	12	13	14
2	21	22	23	24
3	31	32	33	34

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

## Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be strictly monotonically increasing, that is, each successive element is greater than its preceding element. For example, the vector

$$A = [0 \quad 0.5 \quad 1 \quad 1.9 \quad 2.1 \quad 3]$$

is a valid breakpoint data set as each element is larger than its predecessors.

---

**Note** Although a breakpoint data set is strictly monotonic in double format, it might not be so after conversion to a fixed-point data type.

---

## Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

Formulation	Example	When to Use This Formulation
<code>[first_value:spacing:last_value]</code>	<code>[10:10:200]</code>	The lookup table does <i>not</i> use double or single.
<code>first_value + spacing * [0:(last_value-first_value)/spacing]</code>	<code>1 + (0.02 * [0:450])</code>	The lookup table uses double or single.

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for double and single. For example, use `1 + (0.02 * [0:450])` instead of `[1:0.02:10]`. For a list of lookup table blocks that support evenly spaced breakpoints, see “Summary of Lookup Table Block Features” on page 41-6.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- “Effects of Spacing on Speed, Error, and Memory Usage” (Fixed-Point Designer)
- “Identify questionable fixed-point operations” (Embedded Coder)

---

**Tip** Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

## Methods for Approximating Function Values

### In this section...

“About Approximating Function Values” on page 41-15

“Interpolation Methods” on page 41-15

“Extrapolation Methods” on page 41-16

“Rounding Methods” on page 41-17

“Example Output for Lookup Methods” on page 41-17

### About Approximating Function Values

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

### Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- **Flat** — Disables interpolation and uses the rounding operation titled `Use Input Below`. For more information, see “Rounding Methods” on page 41-17.
- **Nearest** — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- **Linear point-slope** — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input. This is the equation for linear point-slope, where  $x$  is the input data,  $y$  is the output table data ( $x_i, y_i$  is the coordinate of the table data), and  $f$  is the fraction. For more information on  $x_i, y_i$ , see “About Lookup Table Blocks” on page 41-2.

$$f = \frac{x - x_i}{x_{i+1} - x_i}$$

$$y = y_i + f(y_{i+1} - y_i)$$

- **Cubic spline** — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.
- **Linear Lagrange** — Fits a line between the adjacent breakpoints using first-order Lagrange interpolation, and returns the point on that line corresponding to the input. This is the equation for linear Lagrange, where  $x$  is the input data,  $y$  is the output table data, and  $f$  is the fraction.  $f$  is constrained to range from 0 to less than 1 ( $[0, 1)$ ). For more information on  $x$  and  $y$ , see “About Lookup Table Blocks” on page 41-2.

$$f = \frac{x - x_i}{x_{i+1} - x_i}$$

$$y = (1 - f)y_i + f y_{i+1}$$

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

- **Akima spline** — Fits an Akima spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input. The interpolation method works only with the **Akima spline** extrapolation method. The modified Akima cubic Hermite interpolation method has these properties:
  - It produces fewer undulations than **Cubic spline**.
  - It is more efficient for real-time applications than **Cubic spline**.
  - Unlike **Cubic spline**, it does not produce overshoots.
  - Unlike **Cubic spline**, it supports nonscalar signals.

---

**Note** The **Lookup Table Dynamic** block does not let you select an interpolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

---

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces smooth results. Akima spline produces the smoothest results.

## Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- **Clip** — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- **Linear** — If the interpolation method is **Linear**, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is **Cubic spline** or **Akima spline**, this extrapolation method fits a linear surface using the slope of the interpolation at the first or last breakpoint, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

- **Cubic spline** — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

- **Akima spline** — Fits an Akima spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

---

**Note** The Lookup Table Dynamic block does not let you select an extrapolation method. The Interpolation-Extrapolation option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

---

In addition to these methods, some lookup table blocks, such as the n-D Lookup Table block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

## Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the Lookup Table Dynamic block lets you select one of the following rounding methods:

- **Use Input Nearest** — Returns the output value corresponding to the nearest input value.
- **Use Input Below** — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- **Use Input Above** — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

## Example Output for Lookup Methods

In the following model, the Lookup Table Dynamic block accepts a vector of breakpoint data given by  $[-5:5]$  and a vector of table data given by  $\sinh([-5:5])$ .

The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

Lookup Method	Input	Output	Comment
Interpolation- Extrapolation	1.4	2.156	N/A
	5.2	83.59	N/A
Interpolation- Use End Values	1.4	2.156	N/A
	5.2	74.2	The block uses the value for $\sinh(5.0)$ .
Use Input Above	1.4	3.627	The block uses the value for $\sinh(2.0)$ .
	5.2	74.2	The block uses the value for $\sinh(5.0)$ .
Use Input Below	1.4	1.175	The block uses the value for $\sinh(1.0)$ .
	-5.2	-74.2	The block uses the value for $\sinh(-5.0)$ .
Use Input Nearest	1.4	1.175	The block uses the value for $\sinh(1.0)$ .

## Use the Lookup Table Editor

To manage the lookup tables in your environment, use the Lookup Table Editor.

- Visualize and edit lookup table data in a consistent way similar to a spreadsheet editor, regardless of the data source. A variable data source can be from the MATLAB base workspace, model workspace, or data dictionary.
- Explore lookup tables from multiple models, subsystems, and blocks loaded in the current MATLAB session.
- Generate reports containing lookup table data and plots.
  - For 1-D data, the report generates line plots.
  - For more than 1-D data, the report generates surface plots, one plot for each 2-D slice of data.
- Add custom lookup table blocks to the Lookup Table Editor, enabling you to work with them as you do other lookup table blocks.

This graphic is a view of the Lookup Table Editor for the Throttle Estimation lookup table block in the “Modeling a Fault-Tolerant Fuel Control System” example `sldemo_fuel_sys` model. For this view, the heatmap is enabled and the mesh and contours for the data are plotted. Observe that the red dots in the plots represent the data in the selected area of the blue rectangle in the tabular area.

## Start the Lookup Table Editor

Access the Lookup Table Editor in one of these ways:

- In Simulink Editor, on the **Modeling** tab, click **Lookup Table Editor**. From this interface, you can open the **Lookup Table Editor** for Simulink, AUTOSAR Blockset, and Simscape lookup table blocks. The Lookup Table Editor can also open for empty models. The Lookup Table Editor also recognizes any custom lookup table blocks that you have registered.
- From the Simulink blocks 1-D Lookup Table, 2-D Lookup Table, Direct Lookup Table (n-D), n-D Lookup Table, Interpolation Using Prelookup, and Prelookup, click the edit lookup table button.
- From the AUTOSAR Blockset blocks Curve, Curve Using Prelookup, Map, and Map Using Prelookup, click the edit lookup table button.
- In the MATLAB Command Window, type `lookupTableEditor`.
- In Simulink Editor, click a Simulink or AUTOSAR Blockset lookup table block. In the **Lookup Table** tab that appears, click **Lookup Table Editor**.

Lookup Table Editor enables you to:

- Enter the path to models and subsystems that contain lookup table blocks and the path to lookup table blocks themselves in the lookup table path browser to see them in the list in the **Lookup Table Blocks** path pane.

In the tabular area, the Lookup Table Editor contains the same lookup table spreadsheet that is available through the `Simulink.LookupTable` property dialog box. See “Edit Lookup Table Data with Lookup Table Spreadsheet” on page 41-23.

10	350	0	3.50	5.83	7.42	8.69

- Generate line, plot, surface, and contour plots for the data.

- Enable heatmap overlays for data.

## Edit Lookup Tables

You can edit a lookup table using:

- Lookup Table Editor — Edit one or more lookup tables without navigating to the blocks, models, or subsystems that contain them.
- Lookup Table block dialog box — Edit lookup tables from within a lookup table block.

For more information, see “Enter Breakpoints and Table Data” on page 41-35

## Lookup Table Editor Limitations

- The Lookup Table Editor does not support lookup tables containing data specified as `Simulink.VariantVariable`. When you try to open a lookup table that contains this data type, the lookup table block returns an error in a pop-up window.
- The Lookup Table Editor overwrites expressions set in the block dialog unless they are non-variable names or pure structure field references. For example, if an expression `myDataSet.MyLookupTable.Breakpoints` is set as the parameter value, the Lookup Table Editor updates the value of `myDataSet`.
- If the Lookup Table Editor has a data source that is specified more than once, for example, if the same model workspace variable `myVar` is used for both breakpoints and table, the entire lookup table is read-only.
- If the lookup table contains data passed in through a model argument, the Lookup Table Editor treats the local model variable as the data source.
- The Lookup Table Editor supports report generation only for the n-D Lookup Table, 1-D Lookup Table, n-D Lookup Table, Interpolation Using Prelookup, Prelookup, and Direct Lookup Table n-D blocks.
- The Lookup Table Editor does not support runtime tunability of parameters.
- The Lookup Table Editor shows breakpoints for the Interpolation Using Prelookup block only when the Interpolation Using Prelookup block is directly connected to one or more Prelookup blocks.

## Edit Lookup Table Data with Lookup Table Spreadsheet

You can use a lookup table spreadsheet to view lookup table and breakpoint data. The lookup table spreadsheet is shared by multiple interfaces, including the `Simulink.LookupTable` property dialog box and the Lookup Table Editor. This topic and its examples are presented using the `Simulink.LookupTable` property dialog box. Here is lookup table data spreadsheet as seen through the `Simulink.LookupTable` property dialog box. The spreadsheet is highlighted.

When the **Breakpoints specification** property is set to `Explicit values`, use the lookup table spreadsheet at the bottom to:

- View, add, manipulate, and remove table and breakpoint data.
- Create or modify table or breakpoint data using MATLAB expressions.

Alternatively, you can copy and paste the contents of a Microsoft Excel spreadsheet or any spreadsheet application.

- View and edit 2-D slices of data from multiple dimensions.

This topic describes:

- Supported data types for the lookup table spreadsheet
- How to create, edit, and view table and breakpoint data in the tabular interface
- How to view multidimensional 2-D slices
- How the tabular interface handles data overflows
- How the tabular interface handles invalid data
- Supported keyboard shortcuts

## Lookup Table Spreadsheet Data Type Support

The spreadsheet supports these data types:

- Built-in data types (int8, uint8, int16, uint16, int32, uint32, double, single, boolean)

- Fixed-point data types
- `uint64`, `int64`
- `half`

It does not support other data types that Simulink supports.

## Create Simulink.LookupTable Objects

To start working with a `Simulink.LookupTable` object, create one at the MATLAB command line:

```
LUTObj = Simulink.LookupTable;
```

## How to Open the Simulink.LookupTable Object Property Dialog Box

To work with the `Simulink.LookupTable` object, start its property dialog box in one of these ways from the MATLAB Command Window:

- In the workspace, double-click the `Simulink.LookupTable` object.
- In the Model Explorer, double-click the object in the specific workspace for the object.
- In the command line, use the `open` function, for example:

```
open LUTObj
```

## Create Table and Breakpoint Data

Generate data and manipulate it using standard table editing actions. You can generate lookup table data in multiple ways, such as in the workspace, from Microsoft Excel, and so forth, and copy that data into the lookup table spreadsheet. For `Simulink.LookupTable` objects, you can also generate data from within the property dialog box using MATLAB expressions.

This example describes how to create data in the MATLAB Command Window workspace and how to set up the property dialog box lookup table spreadsheet using an example with that data.

- 1 To create table and breakpoint data, at the MATLAB command line, type:

```
LUTObj.Breakpoints(1).Value = fi(linspace(1000,5000,5),1,16,2);  
LUTObj.Breakpoints(2).Value = single(linspace(1,2,5));  
LUTObj.Table.Value = uint16(rand(5,5)*60*60);
```

- 2 Set up the **Unit** and **Field name** properties for the object.

```
LUTObj.Breakpoints(1).Unit = 'rpm';  
LUTObj.Breakpoints(2).Unit = 'Nm';  
LUTObj.Table.Unit = 'kg/hr';  
LUTObj.Breakpoints(1).FieldName = 'Corr_Speed';  
LUTObj.Breakpoints(2).FieldName = 'Prs_ratio';  
LUTObj.Table.FieldName = 'Mass_Flow_Rate';
```

- 3 Open the property dialog box.

```
open LUTObj;
```

Simulink.LookupTable: LUTObj

Table and Breakpoints | Code Generation

OK Cancel Help Apply

- 4 From within the tabular area, you can perform typical table edits on particular breakpoint data, such as copying and pasting. Data that has been edited but not applied is outlined in yellow. When you are done, click **Apply**. Observe that the yellow outline for the data is gone.

**Tip** To create this data directly in the lookup table spreadsheet:

- 1 Set **Number of table dimensions** to 2.
- 2 Set the first breakpoint to `fi(linspace(1000,5000,5),1,16,2);`.
- 3 Set the second breakpoint to `single(linspace(1,2,5));`.
- 4 Set **Table** to `uint16(rand(5,5)*60*60);`.

## View Multidimensional Slices of Data

The spreadsheet lets you view and edit 2-D slices of data. This example describes how to use the slice selector to navigate through the 2-D slices of 3-D data.

To view a multidimensional slice, use the dropdown lists under the MATLAB expression parameter. There is a dropdown list for each breakpoint. To view a two-dimensional slice, choose a combination of the breakpoint data from the vertical and horizontal dropdown lists.

- 1 Change the table dimensions to 3.

Mass_Flow_Rate		Type MATLAB expression and press Enter				
Prs_ratio (Nm)		BP3				
		1				
kg/hr	Nm	1	2	3	4	5
rpm		1	1.25	1.5	1.75	2
1	1e+3	2.93e+3	351	567	511	2.36e+3
2	2e+3	3.26e+3	1.00e+3	3.49e+3	1.52e+3	129
3	3e+3	457	1.97e+3	3.45e+3	3.30e+3	3.06e+3
4	4e+3	3.29e+3	3.45e+3	1.75e+3	2.85e+3	3.36e+3
5	5e+3	2.28e+3	3.47e+3	2.88e+3	3.45e+3	2.44e+3

- 2 In the tabular area at the bottom, change the horizontal breakpoint slice to BP3. Observe the changed view of the slice of data.

Mass_Flow_Rate		Type MATLAB expression and press Enter	
BP3		Prs_ratio (Nm)	
		1	
kg/hr	Nm	1	2
rpm		1	2
1	1e+3	2.93e+3	0
2	2e+3	3.26e+3	0
3	3e+3	457	0
4	4e+3	3.29e+3	0
5	5e+3	2.28e+3	0

## Edit Table and Breakpoint Data with MATLAB Expressions

Edit table and breakpoint data using standard table editing actions, such as cutting or copying and pasting, or directly editing table cells. You can also edit table and breakpoint data with MATLAB expressions.

This example shows how to replace the table and breakpoint using a MATLAB expression.

- 1 In the spreadsheet, select BP3 from the horizontal dimension dropdown list.
- 2 In the MATLAB expression field, enter `linspace(1000,9999,5)`.
- 3 Observe the changed view of the slice of data.

		linspace(1000,9999,5)				
		Prs_ratio (Nm) 1				
		1	2	3	4	5
	kg/hr					
	rpm	1e+3	3.25e+3	5.50e+3	7.75e+3	1.00e+4
Corr_Speed (rpm)	1	1e+3	2.93e+3	0	0	0
	2	2e+3	3.26e+3	0	0	0
	3	3e+3	457	0	0	0
	4	4e+3	3.29e+3	0	0	0
	5	5e+3	2.28e+3	0	0	0

### Edit Table and Breakpoint Data

You can perform standard table edits in the spreadsheet. This example shows how to apply the same value to multiple cells.

Replace a column of data with the same value.

- 1 In the spreadsheet, select row 1, column 2 of the table data.
- 2 Select the entire column by dragging down the column.
- 3 Enter 324.
- 4 Press **Ctrl+Enter**.
- 5 Observe that the entire column of data is now 324.

		linspace(1000,9999,5)				
		Prs_ratio (Nm) 1				
		1	2	3	4	5
	kg/hr					
	rpm	1e+3	3.25e+3	5.50e+3	7.75e+3	1.00e+4
Corr_Speed (rpm)	1	1e+3	324	0	0	0
	2	2e+3	324	0	0	0
	3	3e+3	457	324	0	0
	4	4e+3	3.29e+3	324	0	0
	5	5e+3	2.28e+3	324	0	0

Add a row to the table.

- 1 In the spreadsheet, right-click the last row of the table and select **Insert > Insert Row Below**.

		1	2	3	4	5
kg/hr						
rpm		1e+3	3.25e+3	5.50e+3	7.75e+3	1.00e+4
1	1e+3	2.93e+3	324	0	0	0
2	2e+3	3.26e+3	324	0	0	0
3	3e+3	457	324	0	0	0
4	4e+3	3.29e+3	324	0	0	0
5	5e+3	2.28e+3	324	0	0	0
6	0	0	0	0	0	0

Delete a column in the table.

- 1 In the spreadsheet, right-click the last column of the table and select **Delete > Delete Column**.

		1	2	3	4
kg/hr					
rpm		1e+3	3.25e+3	5.50e+3	7.75e+3
1	1e+3	2.93e+3	324	0	0
2	2e+3	3.26e+3	324	0	0
3	3e+3	457	324	0	0
4	4e+3	3.29e+3	324	0	0
5	5e+3	2.28e+3	324	0	0
6	0	0	0	0	0

Select and paste a region in the table.

- 1 In the spreadsheet, select the top-left cell of your selection and drag to the bottom-right of your selection.

BP3    linspace(1000,9999,5)

BP3    Prs\_ratio (Nm)    1

		1	2	3	4
kg/hr					
rpm		1e+3	3.25e+3	5.50e+3	7.75e+3
1	1e+3	2.93e+3	324	0	0
2	2e+3	3.26e+3	324	0	0
3	3e+3	457	324	0	0
4	4e+3	3.29e+3	324	0	0
5	5e+3	2.28e+3	324	0	0
6	0	0	0	0	0

- 2 Copy the selected area with **Ctrl+C**.
- 3 Select another area of the table. Paste the selected data with **Ctrl+V**.

BP3    linspace(1000,9999,5)

BP3    Prs\_ratio (Nm)    1

		1	2	3	4
kg/hr					
rpm		1e+3	3.25e+3	5.50e+3	7.75e+3
1	1e+3	2.93e+3	324	2.93e+3	324
2	2e+3	3.26e+3	324	3.26e+3	324
3	3e+3	457	324	457	324
4	4e+3	3.29e+3	324	3.29e+3	324
5	5e+3	2.28e+3	324	0	0
6	0	0	0	0	0

## Enable Heatmap for Table Data

You can view heatmaps for your data. Right-click any cell in the table and select **Heatmap On**.

The screenshot shows the Simulink Lookup Table Spreadsheet dialog box. At the top, there are two dropdown menus, both set to 'BP3'. The first dropdown is followed by the MATLAB expression 'linspace(1000,9999,5)'. The second dropdown is followed by 'Prs\_ratio (Nm)' and a value of '1'. Below these is a table with the following data:

		1	2	3	4	
kg/hr						
rpm		1e+3	3.25e+3	5.50e+3	7.75e+3	
Corr_Speed (rpm)	1	1e+3	2.93e+3	324	2.93e+3	324
	2	2e+3	3.26e+3	324	3.26e+3	324
	3	3e+3	457	324	457	324
	4	4e+3	3.29e+3	324	3.29e+3	324
	5	5e+3	2.28e+3	324	0	0
	6	0	0	0	0	0

## Overflow Handling

The `Simulink.LookupTable` object property dialog box handles data overflows in the lookup table spreadsheet by automatically changing values to ones that do not cause overflows. For example, if you enter a value of 70000 in a cell for a data type of `uint16`, the property dialog box automatically changes the value to 65535, which is the maximum number for `uint16`. For a list of supported `Simulink.LookupTable` object property dialog box data types, see “Lookup Table Spreadsheet Data Type Support” on page 41-25.

## Data Validation

The lookup table spreadsheet performs data validation when you enter a table cell value and press **Enter**. For example, if you enter `NaN`, `Inf` or `-Inf` as a table cell value, an error is displayed.

The MATLAB expression area also validates expressions. For example, if you enter an invalid expression, the text box is outlined in red and displays an error message on an expected expression. If you enter an expression for fixed-point data with a bias, the software evaluates and, as necessary, saturates the value to the nearest available fixed-point value before displaying the corrected value in the table.

- “Use the Lookup Table Editor” on page 41-19
- “Enter Breakpoints and Table Data” on page 41-35

## Enter Breakpoints and Table Data

### In this section...

“Enter Data in Block Parameter Dialog Box” on page 41-35

“Enter Data in Lookup Table Editor” on page 41-35

“Enter Data for Multiple Lookup Tables in Lookup Table Editor” on page 41-37

“Enter Data Using Inports of Lookup Table Dynamic Block” on page 41-37

### Enter Data in Block Parameter Dialog Box

This example shows how to populate a 1-D Lookup Table block using the parameter dialog box. The lookup table in this example approximates the function  $y = x^3$  over the range  $[-3, 3]$ .

- 1 Add a 1-D Lookup Table block to a model.
- 2 In the 1-D Lookup Table block dialog box, enter the table dimensions and table data:
  - Set **Number of table dimensions** to 1.
  - Set **Table data** to  $[-27 \ -8 \ -1 \ 0 \ 1 \ 8 \ 27]$ .

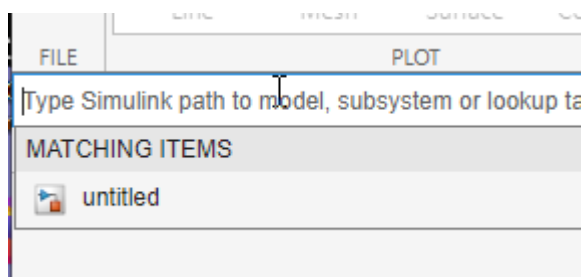

Alternatively, to use an existing lookup table (Simulink.LookupTable) object, select **Data specification > Lookup table object**.

- 3 Enter the breakpoint data set using one of two methods:
  - To specify evenly spaced data points, set **Breakpoint specification** to `Even spacing`. Set **First point** to `-3` and **Spacing** to `1`. The block calculates the number of evenly spaced breakpoints based on the table data.
  - To specify breakpoint data explicitly, set **Breakpoint specification** to `Explicit values` and set **Breakpoints 1** to  $[-3:3]$ .

### Enter Data in Lookup Table Editor

This example shows how to populate a 2-D Lookup Table block using the Lookup Table Editor. In this example, the lookup table approximates the function  $z = x^2 + y^2$  over the input ranges  $x = [0, 2]$  and  $y = [0, 2]$ .

- 1 Add a 2-D Lookup Table block to a model.
- 2 Open the Lookup Table Editor. For example, open the block dialog and click **Edit table and breakpoints**.
- 3 Click in the lookup table path browser. Any models that contain lookup tables appear.

- 4 Select `untitled` and press **Enter**.
- 5 In the hierarchy pane, navigate to the 2-D Lookup Table block.

The lookup table spreadsheet appears on the right.

- 6 In the spreadsheet, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.
  - In the cells associated with the **BreakpointsForDimension1**, enter each of the values [0 1 2].
  - In the cells associated with the **BreakpointsForDimension2**, enter each of the values [0 1 2].
  - In the table data cells, enter the values in the array [0 1 4; 1 2 5; 4 5 8].
- 7 Notice that each value you edit appears as a red dot in the plot to the right. As you click a value in the table, the corresponding plot point is highlighted with a red dot.

The screenshot shows the 'LOOKUP TABLE EDITOR' window. The 'Spreadsheet' tab is active, displaying a table with the following data:

	1	2	3
1	0	0	1
2	1	1	2
3	2	4	5

The 'Plot - Mesh' tab shows a 3D surface plot with a red dot at the top peak. The axes are labeled 'BreakpointsForDimension1' and 'BreakpointsForDimension2'. The 'Data Source - 2-D Lookup Table' table at the bottom is as follows:

Source Type	Source	Name
block dialog	untitled/2-D Lookup Table	BreakpointsForDimension1
block dialog	untitled/2-D Lookup Table	BreakpointsForDimension2

- 8 In the Lookup Table Editor toolstrip, click **Apply** to update the data in the 2-D Lookup Table block. If the parameter value in the source is specified as a variable name, the applied data updates the variable data, but does not overwrite the string set in the block dialog.

For more information on using the lookup table spreadsheet, see “Edit Lookup Table Data with Lookup Table Spreadsheet” on page 41-23.

## Enter Data for Multiple Lookup Tables in Lookup Table Editor

This example builds on the “Enter Data in Lookup Table Editor” on page 41-35 example.

- 1 Open another model that contains one or more lookup tables, for example, `openExample('sldemo_fuelsys')`.
- 2 In the lookup table path browser, type the name of the new model, for example, `sldemo_fuelsys`.
- 3 Select `sldemo_fuelsys`, then press **Enter**.

The hierarchy contains two systems that contain lookup tables.

- 4 Navigate through the `sldemo_fuelsys` node and select a lookup table to edit.

## Enter Data Using Inports of Lookup Table Dynamic Block

This example shows how to populate a Lookup Table Dynamic block using the inports of the block. In this example, the lookup table approximates the function  $y = 3x^2$  over the range  $[0, 10]$ .

- 1 Add a Lookup Table Dynamic block to a model.
- 2 Copy the blocks needed to implement the equation  $y = 3x^2$  to the Simulink model:
  - One Constant block to define the input range, from the Sources library
  - One Math Function block to square the input range, from the Math Operations library
  - One Gain block to multiply the signal by 3, also from the Math Operations library
- 3 Assign these values to the Constant, Math Function, and Gain blocks using their dialog boxes.

Block	Parameter	Value
Constant	Constant value	0:10
Math Function	Function	square
Gain	Gain	3

- 4 Input the breakpoint data set to the Lookup Table Dynamic block by connecting the output port of the Constant block to the input port labeled **xdat** of the Lookup Table Dynamic block. This signal is the input breakpoint data set for  $x$ .
- 5 Input the table data to the Lookup Table Dynamic block by branching the output signal from the Constant block and connecting it to the Math Function block. Then connect the Math Function block to the Gain block. Finally, connect the Gain block to the input port of the Lookup Table Dynamic block labeled **ydat**. This signal is the table data for  $y$ .

## Import Lookup Table Data from MATLAB

### In this section...

“Import Standard Format Lookup Table Data” on page 41-39

“Propagate Standard Format Lookup Table Data” on page 41-40

“Import Nonstandard Format Lookup Table Data” on page 41-40

“Propagate Nonstandard Format Lookup Table Data” on page 41-42

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

### Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [ 1 2 3 4; 5 6 7 8];
table3d_map(:,:,2) = [ 11 12 13 14; 15 16 17 18];
table3d_map(:,:,3) = [ 111 112 113 114; 115 116 117 118];
bp3d_z = [ 0 10 20];
bp3d_x = [ 0 10 20 30];
bp3d_y = [ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d\_map
- Breakpoints 1: bp3d\_y
- Breakpoints 2: bp3d\_x
- Breakpoints 3: bp3d\_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

## Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File > Update Block Data**.

You can also use the Lookup Table Editor to edit the table data and breakpoint data set of `Simulink.LookupTable` and the breakpoint data set of `Simulink.Breakpoint` objects and propagate the changes back to the object.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in “Import Standard Format Lookup Table Data” on page 41-39. For example, change the value of the data in (1,1,1) from 1 to 33. To propagate this change back to `table3d_map` in the workspace, in the Lookup Table Editor toolstrip, click **Apply**.

## Import Nonstandard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);
table3d_map_custom = [ 1 2 3 4; 5 6 7 8;
11 12 13 14; 15 16 17 18;
111 112 113 114; 115 116 117 118];
bp3d_z = [ 0 10 20];
bp3d_x = [ 0 10 20 30];
bp3d_y = [ 400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the reshape command.

- Table data: `reshape(table3d_map_custom,[2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

The screenshot shows the Lookup Table Editor interface. The top toolbar includes options for File, Plot (Line, Mesh, Surface, Contour), Overlay, Edit (Insert, Delete), Data Source, Reload, Apply, Generate Report, and Register Custom. The main workspace is titled 'untitled/n-D Lookup Table' and contains two tabs: '2-D Lookup Table' and 'n-D Lookup Table'. The 'n-D Lookup Table' tab is active, showing a 'Spreadsheet' view of the table data and a 'Plot - Mesh' view of a 3D surface plot.

The 'Spreadsheet' view shows the following table data:

		1	2	3
		0	10	20
1	400	1	11	111
2	6.4e+3	5	15	115

The 'Plot - Mesh' view shows a 3D surface plot with axes labeled 'bp3d\_x', 'bp3d\_y', and 'Table'. The 'Table' axis ranges from 0 to 100, 'bp3d\_x' from 0 to 5000, and 'bp3d\_y' from 0 to 30.

The 'Data Source - N-D Lookup Table' section at the bottom shows the following table:

Source Type	Source	Name
base workspace	base workspace	bp3d_y
base workspace	base workspace	bp3d_x
base workspace	base workspace	bp3d_z
block dialog	untitled/n-D Lookup Table	Table

Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, in the Lookup Table Editor toolstrip, click **Reload**. To update the MATLAB workspace variables with the edited data, in the Lookup Table Editor toolstrip, click **Apply**. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides on the MATLAB search path. For details, see “Propagate Nonstandard Format Lookup Table Data” on page 41-42.

## Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from “Import Nonstandard Format Lookup Table Data” on page 41-40 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable `table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

- 1 Create a file named `sl_customization.m` with these contents.

```
function sl_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

In this function:

- The argument `cm` is the handle to a customization manager object.
- The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.

- 2 In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk,tableStr)
    blkInfo.allowTableConvertLocal = true;
    blkInfo.tableWorkSpaceVarName = 'table3d_map_custom';
    blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

- `allowTableConvertLocal` — Allows table data conversion for a block.
- `tableWorkSpaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
- `tableConvertFcnHandle` — Specifies the handle for the conversion function.

When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkSpaceVarName`. The conversion function corresponds to the handle that `tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

- 3 In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* \* *Columns* \* *Height* to a two-dimensional variable of size *(Rows\*Height) \* Columns*.

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)

% Determine the row and column number of the 3D table data
mapDim = size(data);
numCol = mapDim(2);
numRow = mapDim(1)*mapDim(3);
cMap = zeros(numRow, numCol);
% Transform data back to a 2-dimensional matrix
cMap = reshape(data,[numRow,numCol]);
end
```

- 4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see “Behavior with Multiple Customization Functions” on page 41-43.
- 5 Refresh Simulink customizations at the MATLAB command prompt.

```
sl_refresh_customizations
```

- 6 Open the Lookup Table Editor for your lookup table block and select **File > Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.
- 7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =
```

```

    33     2     3     4
     5     6     7     8
    11    12    13    14
    15    16    17    18
   111   112   113   114
   115   116   117   118
```

The change in the Lookup Table Editor has propagated to the workspace variable.

---

**Note** If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

---

### Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

## Copy and Paste Lookup Table Data from Excel

This example shows how to copy data from an Excel spreadsheet or any spreadsheet application into a lookup table.

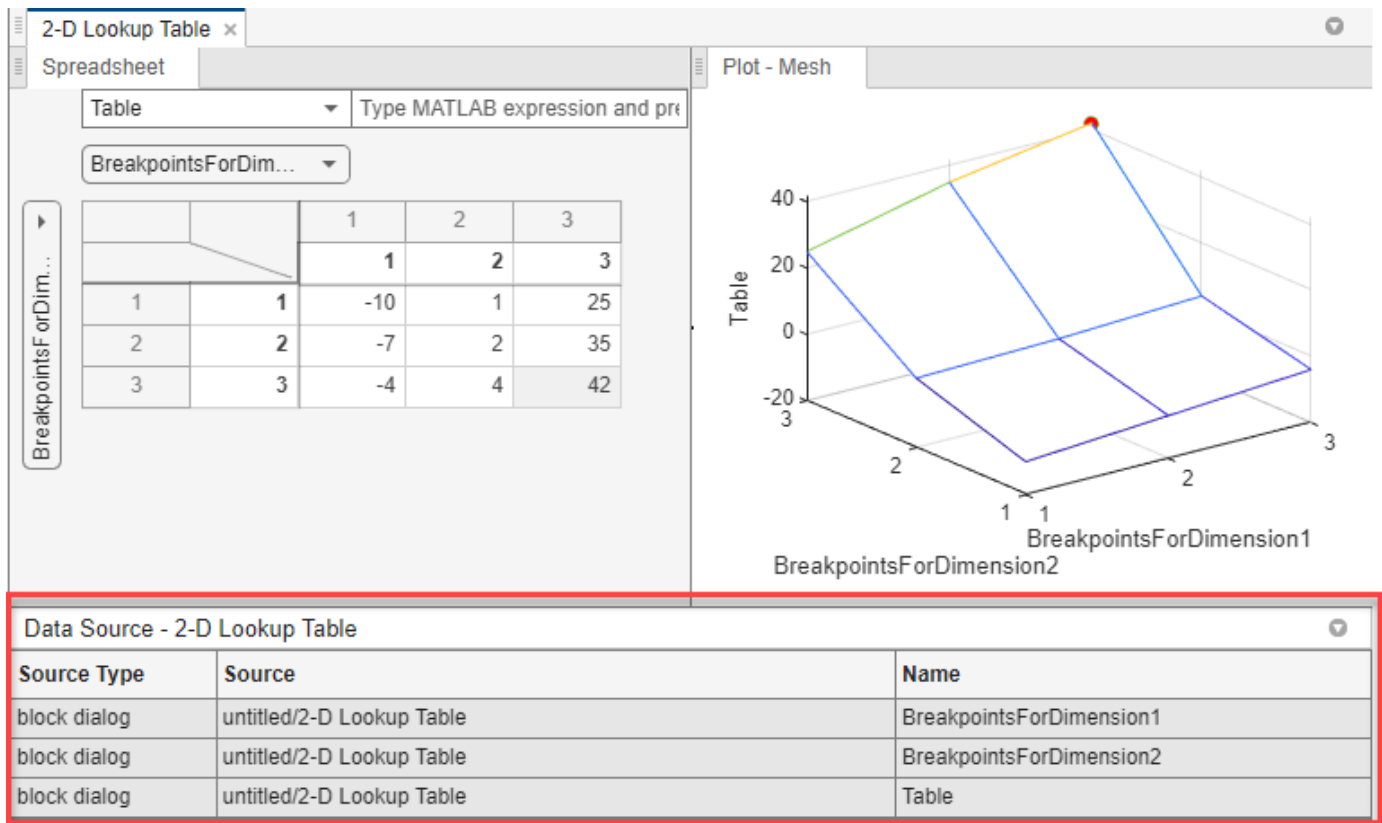

- 1 Add a 2-D Lookup Table block to a model.
- 2 Open the Lookup Table Editor. For example, open the block dialog and click **Edit table and breakpoints**.
- 3 Create or open an existing Excel spreadsheet, for example, an Excel spreadsheet that contains this data.

-10	1	25
-7	2	35
-4	4	42

- 4 Copy and paste the contents of the Excel spreadsheet into the lookup table spreadsheet.

- 5 Notice that the pasted elements in the lookup table spreadsheet have a yellow border. This yellow border indicates that the data has not yet been saved. To save the data to the data source, click **Apply**. In this example, the data source is the 2-D Lookup Table block.
- 6 At the bottom of the Lookup Table Editor is a table of sources for the data.

To display and hide this table, click **Data Source** in the toolstrip.

- 7 To get the data from the data source into the Lookup Table Editor, click **Reload**. If you do not click **Apply** before clicking **Reload**, the editor discards the spreadsheet before loading the data from the data source.
- 8 To save the data from Lookup Table Editor spreadsheet to the data source, click **Apply**.

- “Import Lookup Table Data from Excel Using readtable” on page 41-47

## Import Lookup Table Data from Excel Using readtable

This example shows how to use the `readtable` function in a model to import data into a lookup table.

---

**Tip** Instead of importing data into a lookup table, you can also copy and paste the contents of an Excel spreadsheet into a Lookup Table spreadsheet (see “Copy and Paste Lookup Table Data from Excel” on page 41-45).

---

- 1 Save the Excel file in a folder on the MATLAB path.
- 2 Open the model containing the lookup table block and in the **Modeling** tab, select **Model Settings**.
- 3 In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
- 4 Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `readtable` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = readtable('MySpreadsheet', 'Sheet', Sheet1);
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

- 5 Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

## Visualize Data Through Plots

This example shows how to use the plots to visualize the data in the Lookup Table Editor.

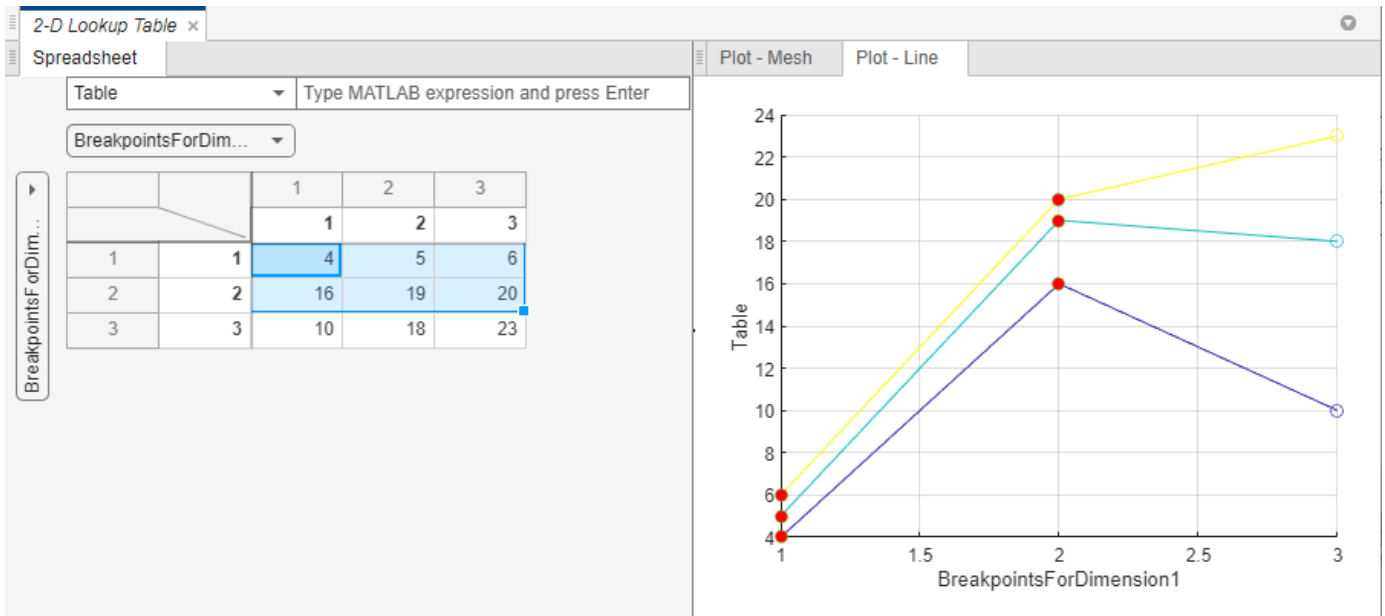

- 1 Add a 2-D Lookup Table block to a model.
- 2 Open the Lookup Table Editor. For example, open the block dialog and click **Edit table and breakpoints**.
- 3 By default, the 2-D Lookup Table block has this data as an example.

- 4 To create two tabs, one for the spreadsheet and one for the plot, pause between the spreadsheet and plot and click the red X. To view or tile the panes, drag the panes as you want to position them.
- 5 Click the data points in the spreadsheet and observe the corresponding red dot in the plot.

- From the toolstrip, click another plot type, such as **Line**, **Surface**, or **Contour**, and reselect the same data. These plots are the equivalent of the MATLAB functions `line`, `mesh`, `line`, `surface`, and `contour`, using the table and breakpoint data.

Each plot type and data selection gives you another view of the data on that plot type.

- To view heatmaps of your data, click **Heatmap** in the toolstrip.

## Generate Report of Lookup Table

Generate a report of one or more lookup tables in a model. Lookup Table Editor supports report generation only for the n-D Lookup Table, 1-D Lookup Table, n-D Lookup Table, Interpolation Using Prelookup, Prelookup, and Direct Lookup Table blocks. Lookup Table Editor returns a message for blocks for which it does not generate a report.

- 1 Start the model `sldemo_fuelsys`.  
`openExample('sldemo_fuelsys')`
- 2 Open the Lookup Table Editor. For example, type `lookupTableEditor` in the MATLAB Command Window.
- 3 In the lookup table path browser, type `openExample('sldemo_fuelsys')` and press **Enter**.

The `sldemo_fuelsys` model and the subsystems that contain lookup table blocks display in the Lookup Table Blocks pane.

- 4 Select `fuel_rate_control`, then click **Generate Report**.
- 5 The software evaluates the number of lookup tables in the model (5). Click **OK**.
- 6 The software generates an HTML file, saved to `current_folder/lookupTableReport.html`. Each numbered section of the file contains a report of a lookup table, including information such as:
  - Breakpoint data BP1 versus BP2.
  - A plot of the lookup table outputs against the breakpoints
  - Data types
  - Notes about the report generation.

## Register Custom Lookup Table Blocks

You can use the Lookup Table Editor to register custom lookup table blocks that you have created. Configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

**Tip** Entries must be valid MATLAB variable names.

- 1 In the Lookup Table Editor toolstrip, click **Register Custom**. The **Lookup Table Blocks Type Configuration** dialog box appears.

The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

- 2 Click **Add Row** on the dialog box. A new row appears at the bottom of the block type table.
- 3 Enter information for the custom block in the new row under these headings. You must enter an entry for each table cell.

Field Name	Description
Block type	Block type of the custom block. The block type is the value of the <code>BlockType</code> parameter of the block.
Mask type	Mask type of the custom block. The mask type is the value of the <code>MaskType</code> parameter of the block.

Field Name	Description
Breakpoint Parameter(s)	Names of the block parameters that are used as breakpoints. Separate multiple breakpoints with commas.
Table Parameter	Names of the block parameters that store the table.

The Lookup Table Editor uses the information in the **Block Type** and **Mask Type** columns to identify the block type. The editor uses the information in the **Breakpoint Parameters** and **Table Parameter** to find the lookup table data.

- 4 Click **OK**.
  - To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Delete Row**.
  - To automatically populate a table row with the mask characteristics of a masked block, select the block in the model and click **Autopopulate for Current Block**. Clicking this button also enables the autocompletion of the block and table name fields.

- “Guidelines for Choosing a Lookup Table” on page 41-5
- “Visualize and Edit N-Dimensional Data Using Mask Lookup Table Control” on page 42-96

## Visualize Lookup Tables Visualized Through Lookup Table Control

If you use the Lookup Table Control on page 42-96 to visualize and edit  $N$ -dimensional lookup table data in mask dialogs, the Lookup Table Editor can display these tables without registration. For example, the `slxMaskLookupTableControlExample` model has multiple custom lookup tables.

- 1 Open the model.  

```
openExample('simulink_masking/MaskLookupTableControlExample')
```
- 2 Open the Lookup Table Editor for the 2-D Table Lookup Table S-Function lookup table.  

```
lookupTableEditor('slxMaskLookupTableControlExample/2-D Table Lookup S-Function')
```

- 3 In the **Lookup Table Blocks** hierarchy pane, expand **2-D Table Lookup S-Function**.

- 4 In the hierarchy pane, click `fuelflowmap`.

- 5 Compare this Lookup Table Editor view with the custom lookup table block.

## See Also

## Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

- 1 Copy the following blocks to a Simulink model:
  - One Constant block to input the signal, from the Sources library
  - One n-D Lookup Table block to approximate the common logarithm, from the Lookup Tables library
  - One Display block to display the output, from the Sinks library
- 2 Assign the table data and breakpoint data set to the n-D Lookup Table block:
  - a In the **Number of table dimensions** field, enter 1.
  - b In the **Table data** field, enter [0 .301 .477 .602 .699 .778 .845 .903 .954 1].
  - c In the **Breakpoints 1** field, enter [1:10].
  - d Click **Apply**.

The dialog box looks something like this:

- 3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to 5. Click **OK** to apply the changes and close the dialog box.
- 4 Connect the blocks as follows.

## 5 Start simulation.

The following behavior applies to the n-D Lookup Table block.

Value of the Constant Block	Action by the n-D Lookup Table Block	Example of Block Behavior	
		Input Value	Output Value
Equals a breakpoint	Returns the corresponding output value	5	0.699
Falls between breakpoints	Linearly interpolates the output value using neighboring breakpoints	7.5	0.874
Falls outside the range of the breakpoint data set	Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set	10.5	1.023

For the n-D Lookup Table block, the default settings for **Interpolation method** and **Extrapolation method** are both **Linear**.

## Prelookup and Interpolation Blocks

The following examples show the benefits of using Prelookup and Interpolation Using Prelookup blocks.

Action	Benefit	Example
Use an index search to relate inputs to table data, followed by an interpolation and extrapolation stage that computes outputs	Enables reuse of index search results to look up data in multiple tables, which reduces simulation time	For more information, see “Using the Prelookup and Interpolation Blocks”.
Set breakpoint and table data types explicitly	Lowers memory required to store: <ul style="list-style-type: none"> <li>• Breakpoint data that uses a smaller type than the input signal</li> <li>• Table data that uses a smaller type than the output signal</li> </ul>	For more information, see “Saving Memory in Prelookup and Interpolation Blocks by Using Smaller Data”.
	Provides easier sharing of: <ul style="list-style-type: none"> <li>• Breakpoint data among Prelookup blocks</li> <li>• Table data among Interpolation Using Prelookup blocks</li> </ul>	For more information, see “Sharing Parameters in Prelookup and Interpolation Blocks” (Fixed-Point Designer).
	Enables reuse of utility functions in the generated code	For more information, see “Shared Utility Functions for Prelookup Blocks” (Fixed-Point Designer).
Set the data type for intermediate results explicitly	Enables use of higher precision for internal computations than for table data or output data	For more information, see “High Precision Calculations in Interpolation Block” (Fixed-Point Designer).

### More About

- “About Lookup Table Blocks” on page 41-2
- “Anatomy of a Lookup Table” on page 41-4
- “Guidelines for Choosing a Lookup Table” on page 41-5

## Optimize Generated Code for Lookup Table Blocks

In this section...
“Remove Code That Checks for Out-of-Range Inputs” on page 41-59
“Optimize Breakpoint Spacing in Lookup Tables” on page 41-60
“Reduce Data Copies for Lookup Table Blocks” on page 41-60
“Efficient Code for Row-Major Array Layout” on page 41-61

### Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Prelookup
- Interpolation Using Prelookup

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

Block	Check Box to Select
1-D Lookup Table	<b>Remove protection against out-of-range input in generated code</b>
2-D Lookup Table	
n-D Lookup Table	
Prelookup	
Interpolation Using Prelookup	<b>Remove protection against out-of-range index in generated code</b>

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

Model Advisor Check	When to Run the Check
<b>By Product &gt; Embedded Coder &gt; Identify lookup table blocks that generate expensive out-of-range checking code</b>	For code efficiency
<b>By Product &gt; Simulink Check &gt; Modeling Standards &gt; DO-178C/DO-331 Checks &gt; Check usage of lookup table blocks</b>	For safety-critical applications

For more information about the Model Advisor, see “Check Your Model Using the Model Advisor” on page 5-2 in the Simulink documentation.

## Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

Factor	Even Power of 2 Spaced Data	Evenly Spaced Data	Unevenly Spaced Data
Execution speed	The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation.	The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division.	The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations.
Error	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy.	The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy.
ROM usage	Uses less command ROM, but more data ROM.	Uses less command ROM, but more data ROM.	Uses more command ROM, but less data ROM.
RAM usage	Not significant.	Not significant.	Not significant.

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see “Check Your Model Using the Model Advisor” on page 5-2 in the Simulink documentation.

## Reduce Data Copies for Lookup Table Blocks

When you use workspace variables to store table and breakpoint data for Lookup Table blocks, and then configure these variables for tunability, you can avoid data copies by using the same data type for the block parameter and variable. Workspace variables include numeric MATLAB variables and Simulink.Parameter objects that you store in a workspace, such as the base workspace, or in a

data dictionary. If the data type of the variable is smaller than the data type of the block parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. This implicit cast requires a data copy which can potentially significantly increase RAM consumption and slow down code execution speed for large vectors or matrices.

For more information, see “Parameter Data Types in the Generated Code” (Embedded Coder) and “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

## Efficient Code for Row-Major Array Layout

To generate efficient code for row-major array layout, select the model configuration parameter **Math and Data Types > Use algorithms optimized for row-major array layout**. The row-major algorithms perform with the best speed and memory usage when operating on table data with row-major array layout. Similarly, the default column-major algorithms perform best with column-major array layout. Consider using the algorithm that is optimized for the specified array layout to achieve best performance. For example, use row-major algorithms when array layout is set as row-major during code generation.

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	Recommended
Row-major	Row-major	Recommended
Row-major	Column-major	Not recommended
Column-major	Row-major	Not recommended

For more information, see “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder).

## More About

- “Check Your Model Using the Model Advisor” on page 5-2
- “Guidelines for Choosing a Lookup Table” on page 41-5
- “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder)

## Row-Major Algorithm in Existing Models Containing Lookup Table Blocks

The Direct Lookup Table (n-D), Interpolation Using Prelookup, and n-D Lookup Table blocks have algorithms that work with row-major array layouts or column-major array layouts. This capability requires a Simulink Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Prior to R2018b, lookup table blocks supported only column-major array layouts. When selecting algorithms optimized for row-major array layout for a model previously configured for algorithms optimized for column-major array layout, you may need to preserve lookup table block semantics. For example, if a model contains lookup table blocks configured like these:

- An Interpolation Using Prelookup block configured with a subtable selection before interpolation.
- A Direct Lookup Table (n-D) configured for a vector or 2-D matrix output

Use the `permute` function to rearrange the dimensions of the array and preserve the semantics.

For an example of preserving semantics by using table permutations, see “Direct Lookup Table Algorithm for Row-Major Array Layout” (Simulink Coder) .

For an example of converting column-major arrays to row-major arrays see “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder).

## Update Lookup Table Blocks to New Versions

### In this section...

“Comparison of Blocks with Current Versions” on page 41-63

“Compatibility of Models with Older Versions of Lookup Table Blocks” on page 41-64

“How to Update Your Model” on page 41-64

“What to Expect from the Model Advisor Check” on page 41-65

### Comparison of Blocks with Current Versions

In R2011a, the following lookup table blocks were replaced with newer versions in the Simulink library:

Block	Changes	Enhancements
Lookup Table	<ul style="list-style-type: none"> <li>Block renamed as 1-D Lookup Table</li> <li>Icon changed</li> </ul>	<ul style="list-style-type: none"> <li>Default integer rounding mode changed from <code>Floor</code> to <code>Simplest</code></li> <li>Support for the following features: <ul style="list-style-type: none"> <li>Specification of parameter data types different from input or output signal types</li> <li>Reduced memory use and faster code execution for nontunable breakpoints with even spacing</li> <li>Cubic-spline interpolation and extrapolation</li> <li>Table data with complex values</li> <li>Fixed-point data types with word lengths up to 128 bits</li> <li>Specification of data types for fraction and intermediate results</li> <li>Specification of index search method</li> <li>Specification of diagnostic for out-of-range inputs</li> </ul> </li> </ul>

Block	Changes	Enhancements
Lookup Table (2-D)	<ul style="list-style-type: none"> <li>Block renamed as 2-D Lookup Table</li> <li>Icon changed</li> </ul>	<ul style="list-style-type: none"> <li>Default integer rounding mode changed from Floor to Simplest</li> <li>Support for the following features: <ul style="list-style-type: none"> <li>Specification of parameter data types different from input or output signal types</li> <li>Reduced memory use and faster code execution for nontunable breakpoints with even spacing</li> <li>Cubic-spline interpolation and extrapolation</li> <li>Table data with complex values</li> <li>Fixed-point data types with word lengths up to 128 bits</li> <li>Specification of data types for fraction and intermediate results</li> <li>Specification of index search method</li> <li>Specification of diagnostic for out-of-range inputs</li> </ul> </li> <li>Check box for <b>Require all inputs to have the same data type</b> now selected by default</li> </ul>
Lookup Table (n-D)	<ul style="list-style-type: none"> <li>Block renamed as n-D Lookup Table</li> <li>Icon changed</li> </ul>	<ul style="list-style-type: none"> <li>Default integer rounding mode changed from Floor to Simplest</li> </ul>

## Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to add the *current* versions of the blocks to your model, change the source block path for `add_block`:

Block	Old Block Path	New Block Path
Lookup Table	simulink/Lookup Tables/Lookup Table	simulink/Lookup Tables/1-D Lookup Table
Lookup Table (2-D)	simulink/Lookup Tables/Lookup Table (2-D)	simulink/Lookup Tables/2-D Lookup Table
Lookup Table (n-D)	simulink/Lookup Tables/Lookup Table (n-D)	simulink/Lookup Tables/n-D Lookup Table

## How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

Step	Action	Reason
1	Run the Upgrade Advisor.	Identify blocks that do not have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks.
2	For each block that does not have compatible settings: <ul style="list-style-type: none"> <li>Decide how to address each warning.</li> <li>Adjust block parameters as needed.</li> </ul>	Modify each Lookup Table or Lookup Table (2-D) block to ensure compatibility with the current versions.
3	Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.	Ensure that block replacement works for the entire model.

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the 1-D Lookup Table and 2-D Lookup Table blocks. For more information about the Upgrade Advisor, see “Model Upgrades”.

## What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have incompatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have repeated breakpoints

### Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

Lookup Method in the Lookup Table or Lookup Table (2-D) Block	Parameter Settings After Automatic Block Replacement	
	Interpolation	Extrapolation
Interpolation-Extrapolation	Linear	Linear
Interpolation-Use End Values	Linear	Clip
Use Input Below	Flat	Not applicable

Depending on breakpoint spacing, one of two index search methods can apply.

Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block	Index Search Method After Automatic Block Replacement
Not evenly spaced	Binary search
Evenly spaced and tunable	A prompt appears, asking you to select Binary search or Evenly spaced points.
Evenly spaced and not tunable	

### Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

Incompatibility Warning	Recommended Action	What Happens for Automatic Block Replacement
The <b>Lookup Method</b> is Use Input Nearest or Use Input Above. The replacement block does not support these lookup methods.	Change the lookup method to one of the following options: <ul style="list-style-type: none"> <li>• Interpolation - Extrapolation</li> <li>• Interpolation - Use End Values</li> <li>• Use Input Below</li> </ul>	The <b>Lookup Method</b> changes to Interpolation - Use End Values.  In the replacement block, this setting corresponds to: <ul style="list-style-type: none"> <li>• <b>Interpolation</b> set to Linear</li> <li>• <b>Extrapolation</b> set to Clip</li> </ul>
The <b>Lookup Method</b> is Interpolation - Extrapolation, but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type.	Change the extrapolation method or the port data types of the block.	You also see a message that explains possible numerical differences.
The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.	None	You see a message that explains possible numerical differences.

### Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

## Masking Fundamentals

A mask is a custom interface for a block that hides the block content, making it appear as an atomic block with its own icon and parameter dialog box. It encapsulates the block logic, provides controlled access to the block data, and simplifies the graphical appearance of a model.

When you mask a block, a mask definition is created and saved along with the block. A mask changes only the block interface, and not the underlying block characteristics. You can provide access to one or more underlying block parameters by defining corresponding mask parameters on the mask.

Mask a Simulink block to:

- Display a meaningful icon on a block
- Provide a customized dialog box for the block
- Provide a dialog box that enables you to access only select parameters of the underlying blocks
- Provide users customized description that is specific to the masked block
- Initialize parameters using MATLAB code

Consider the model `masking_example` that represents the equation of line  $y = mx + b$ .

Each block has its own dialog box, making it complicated to specify the values for the line equation variables. To simplify the user interface, a mask is applied on the top-level subsystem block.

Here the variable  $m$  represents slope and the variable  $b$  represents the intercept for the line equation  $y = mx + b$ .

The mask dialog box displays the fields for **Slope** and **Intercept** that are internally mapped to variables  $m$  and  $b$ .

Masked blocks do not support content preview. To preview the contents of a subsystem, see “Preview Content of Model Components” on page 1-35.

**Tip** For masking examples, see Simulink Masking Examples. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

Examples of few blocks that cannot be masked are:

- Scope blocks
- Simulink Function block
- Initialize, Terminate and Reset Function blocks
- Gauge blocks

## Masking Terminology

Term	Description
Mask icon	The masked block icon generated using drawing commands. Mask icon can be static or change dynamically with underlying block parameter values.
Mask parameters	The parameters that are defined in the Mask Editor and appear on the mask dialog box. Setting the value of a mask parameter on the mask dialog box sets the corresponding block parameter value.
Mask initialization code	MATLAB Code that initializes a masked block or reflects current parameter values. Add mask initialization code in the <b>Initialization</b> pane of the Mask Editor dialog box. For example, add initialization code to set a parameter value automatically.
Mask dialog callback code	MATLAB Code that runs in the base workspace when the value of a mask parameter changes. Use callback code to change the appearance of a mask dialog box dynamically and reflect current parameter values. For example, enable visible parameters on the dialog box.
Mask documentation	Description and usage information for a masked block defined in the Mask Editor.
Mask dialog box	A dialog box that contains fields for setting mask parameter values and provides mask description.
Mask workspace	Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores the evaluated values of the mask parameters and temporary values used by the mask.

### More About

- “Create Block Masks”
- “Create a Simple Mask” on page 42-6
- “Mask Editor Overview”

- Set mask parameters
- Creating a Mask: Masking Fundamentals (3 min, 46 sec)

## Create a Simple Mask

You can mask a block interactively by using the Mask Editor or mask it programmatically. This example describes how to mask a block by using the **Mask Editor**. To mask a block programmatically, see “Control Masks Programmatically” on page 42-26.

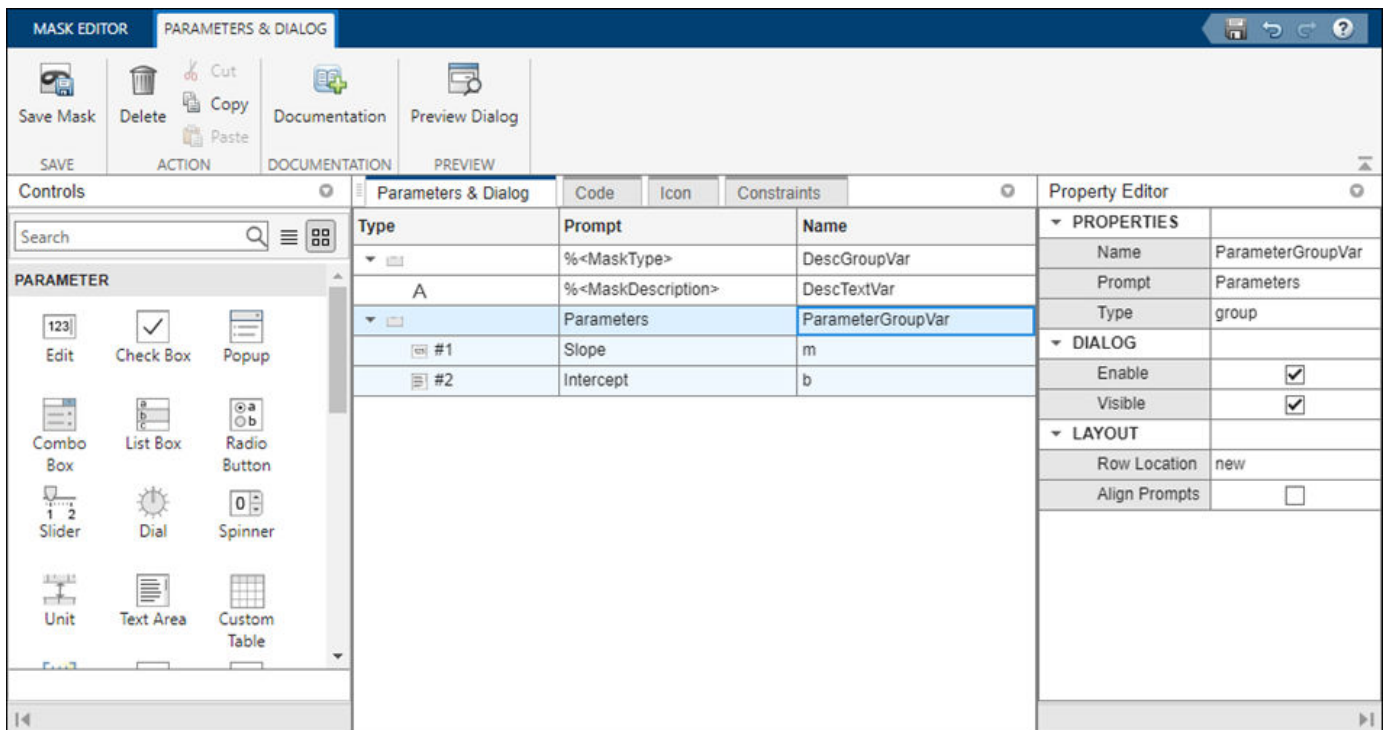

For masking examples, see Simulink Masking Examples.

### Step 1: Open Mask Editor

- 1 Open the model in which you want to mask a block. For example, open `subsystem_example`.

This model contains a Subsystem block that models the equation for a line:  $y = mx + b$ .

- 2 Select the Subsystem block and on the **Subsystem** tab, in the **Mask** group, click **Create Mask**.

### Step 2: Define the Mask

The **Mask Editor** contains four tabs that enable you to define the block mask and customize the dialog box for the mask.

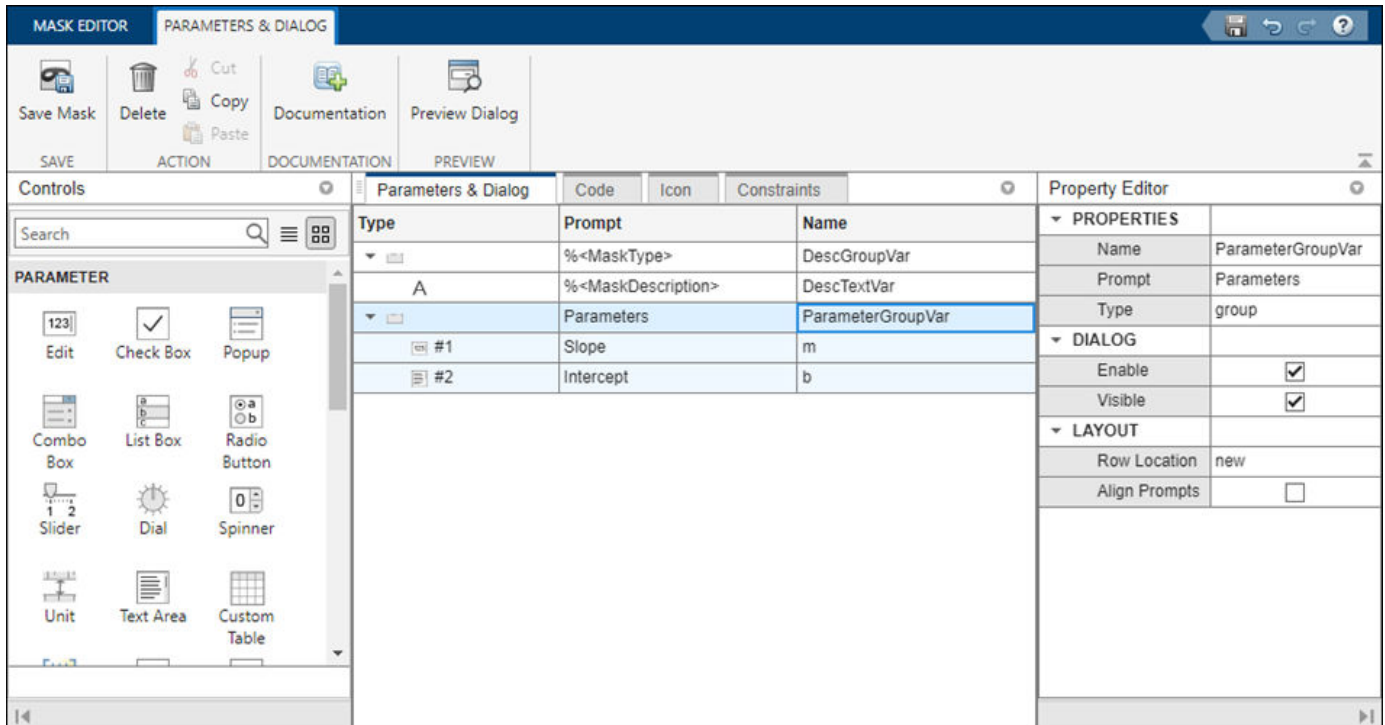

For detailed information on each pane, see “Mask Editor Overview”.

#### Parameters & Dialog Tab

Use this tab to add controls like parameters, displays, and action items to the mask dialog box.

To add **Edit** boxes to the block mask.

- 1 In the left pane, under **Parameter**, click **Edit** twice to add two new rows in the **Dialog box** pane.
- 2 Type **Slope** and **Intercept** in the **Prompt** column for the two **Edit** parameters. The value that you enter in **Prompt** column appears on the mask dialog box. Similarly, type **m** and **b** in the **Name** column. The value you enter in **Name** column is the mask parameter name. The mask parameter name must be a valid MATLAB name.
- 3 In the right pane, under **Property editor**, provide values in the **Properties**, **Dialog**, and **Layout** sections.
- 4 Click **Apply**.

- 5 To preview the mask dialog box without exiting the Mask Editor, click **Preview**.

For detailed information, see "Parameters & Dialog Pane".

---

**Note** A Simulink mask parameter cannot reference another parameter on the same mask.

---

### Code Pane

Use this pane to specify MATLAB code to control the mask parameters. For example, you can provide a predefined value for a mask parameter.

Consider the equation  $y = mx + b$  in the example. To set the value of the child block corresponding to 'm', you can use the `set_param` function in the code pane.

---

**Note** For detailed information, see “Code Pane”.

---

### Icon Pane

Use this tab to create an icon for the block mask. Mask Editor provides you with two modes of authoring block icon.

- 1 Graphical
- 2 Mask Drawing Commands

**Graphical Icon Editor:** You can create and edit the mask icon of a block through a graphical environment. The various features in Graphical Icon Editor helps you to create icons with ease. Launch Graphical Icon Editor from Mask Editor.

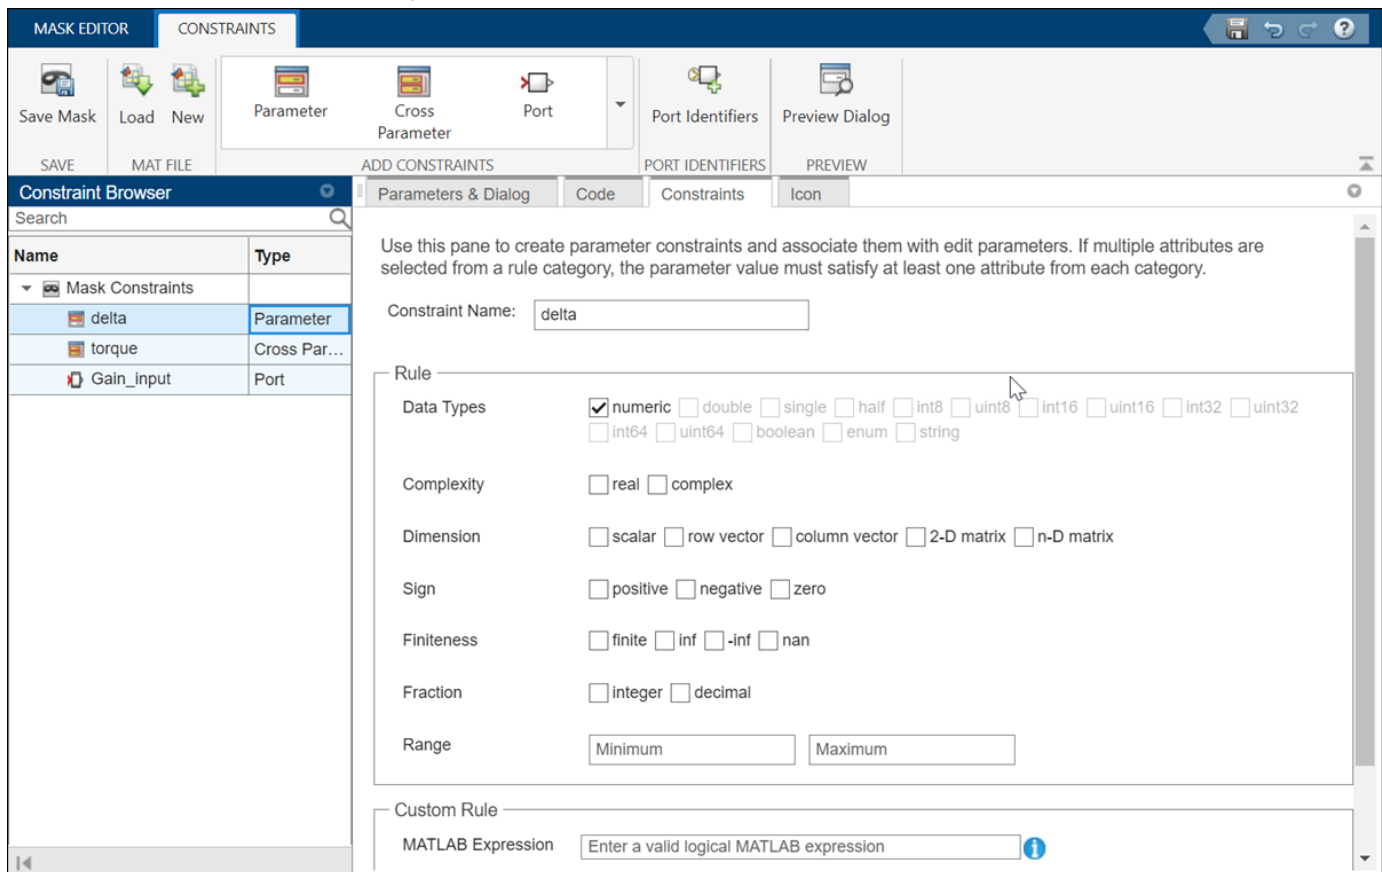

The interactive graphical environment provides graphical tools like pen, curvature, text, scissor, connector, and equation (which supports LaTeX) to create rich graphical icons. Grids, smart guides, and rulers help you to create pixel-perfect icons. Apart from the drawing tools, a few built-in shapes, such as Resistor, Inductor, and Rotational Damper, are readily available. For more information, see “Create and Edit Masked Block Icon Using Graphical Icon Editor” on page 42-110

**Mask Drawing Commands:** Use a set of mask drawing commands to create masked block icon. You can use the **Properties** pane on the left to specify icon properties and icon visibility. For detailed information, see “Icon drawing commands”.

You can create static or dynamic block mask icons. For more information, see “Draw Mask Icon” on page 42-16 and `slexMaskDisplayAndInitializationExample`.

## Constraints Pane

Mask parameter constraints help you to create validations on a mask parameter without having to write your own validation code. There are three types of constraints, Parameter Constraint, Cross Parameter Constraints, and Port Constraints.

**Parameter Constraint:** A mask can contain parameters that accept user input values. You can provide input values for mask parameters using the mask dialog box. Constraints ensure that the input for the mask parameter is within a specified range. For example, consider a masked Gain block. You can set a constraint where the input value must be between 1 and 10. If you provide an input that is outside the specified range, an error displays. Constraint Browser on the left pane helps you to manage Shared Constraints.

**Cross Parameter Constraint:** Cross-parameter constraints are applied among two or more **Edit** or **Combobox** type mask parameters. You can use a cross parameter constraint when you want to specify scenarios such as, Parameter1 must be greater than Parameter2.

**Port Constraint:** You can specify constraints on the input and output ports of a masked block. The port attributes are checked against the constraints when you compile the model.

### Step 3: Operate on Mask

- 1 You can preview the mask and choose to unmask the block or edit the block mask.
- 2 Double-click the masked block.

The mask dialog box appears.

- 3 Type values in the **Slope** and **Intercept** boxes of the mask dialog box. To view the output, simulate the model.
- 4 Click **OK**.
- 5 To edit the mask definition, select the subsystem block and click **Edit Mask** from the **Subsystem** tab in the Toolstrip. For more information, see “Manage Existing Masks” on page 42-11.
- 6 Select the masked block and on the **Subsystem Block** tab, in the **Mask** group, click **Look Under Mask** to view:
  - The blocks inside the masked subsystem
  - The built-in block dialog box of a masked block
  - The base mask dialog box of a linked masked block

### See Also

#### More About

- “Create Block Masks”
- Creating a Mask: Masking Fundamentals (3 min, 46 sec)
- “Mask Editor Overview”
- “Masking Fundamentals” on page 42-2

## Manage Existing Masks

### Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

- 1 Select the masked block.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, click **Apply** to preserve the changes.

### View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, select the block and on the **Block** tab, in the **Mask** group, click **Mask Parameters**.

---

**Tip** Each block has a block parameter dialog box. To view the block parameters dialog box of a masked block, right-click the masked block and select **Block Parameters (BlockType)**.

---

### Look Under Block Mask

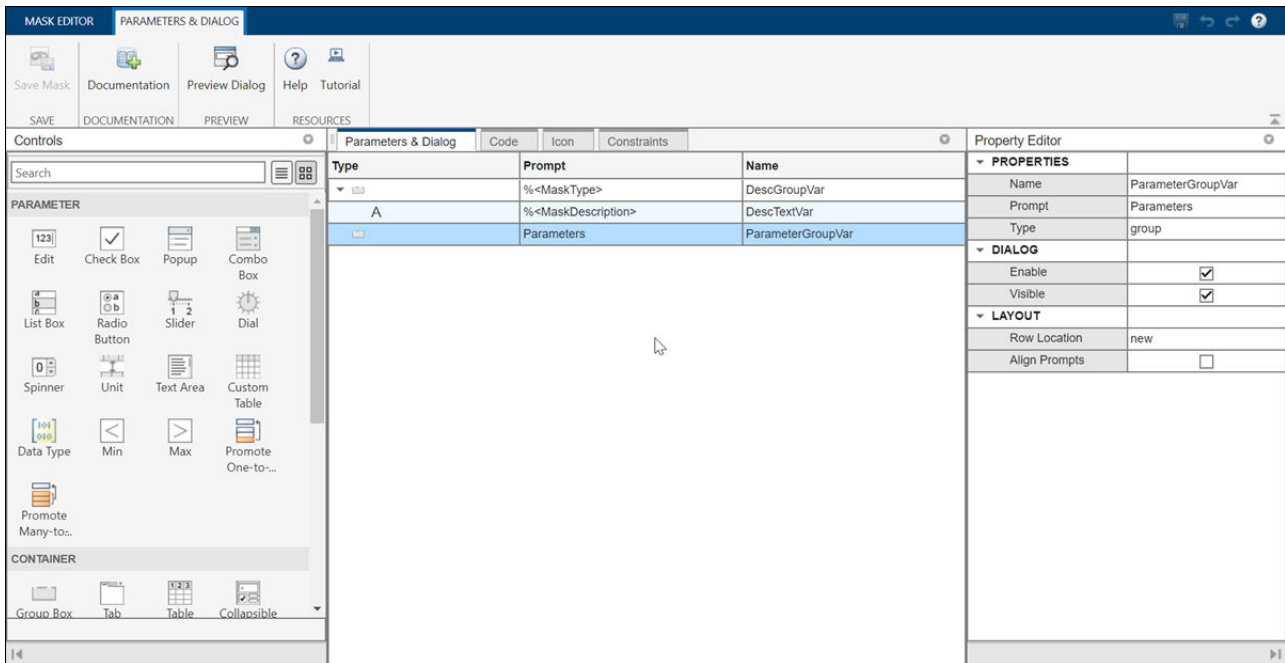

To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, select the block and on the **Subsystem** tab, click **Look Under Mask**.

### Remove Mask

To remove a mask from a block,

- 1 Select the block.
- 2 On the **Block** tab, in the **Mask** group, click **Edit Mask**.

The Mask Editor opens and displays the existing mask, for example:

3 Click **Delete Mask** in the of the Mask Editor.

The Mask Editor removes the mask from the block.

## See Also

### More About

- “Create a Simple Mask” on page 42-6

## Mask Callback Code

In this section...
“Add Mask Code” on page 42-13
“Execute Drawing Command” on page 42-13
“Execute Initialization Command” on page 42-13
“Execute Callback Code” on page 42-14

### Add Mask Code

You can use MATLAB code to initialize a mask and to draw mask icons. Since the location of code affects model performance, add your code to reflect the functionality you need.

Purpose	Add in Mask Editor	Programmatic Specification
Initialize the mask	<b>Initialization</b> pane	MaskInitialization parameter
Draw mask icon	<b>Icon</b> pane	MaskDisplay parameter
Callback code for mask parameters	<b>Parameters &amp; Dialog</b> pane	MaskCallbacks parameter

### Execute Drawing Command

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon** pane. Simulink executes these commands sequentially to redraw the mask icon when:

- Block is rendered first on the Mask Editor canvas.
- Mask parameters and values that depend on drawing commands change.
- Block appearance is altered due to rotation or other changes.

---

**Note** Placing MATLAB code for drawing mask icons in the **Initialization** section affects model performance. This behavior is because Simulink redraws the icon each time the masked block is evaluated in the model.

---

### Execute Initialization Command

Initialization commands for all masked blocks in a model run when you:

- Update the diagram
- Start simulation
- Start code generation
- Apply mask changes
- Change any of the parameters that define the mask, such as MaskDisplay and MaskInitialization, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.

- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem.

Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

---

**Note** Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands during model load.

---

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-2 and `load_system` for information about loading a model without displaying it.

---

**Note** The non-tunable parameters of a masked block are not evaluated if the model is already compiled (initialized).

---

## Execute Callback Code

Mask parameter callback codes are executed in a temporary workspace and not in the base workspace. If you need a variable created in the callback to be available later(not during callback processing), you must explicitly assign those variables to the base workspace.

Simulink executes the callback commands when:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor location. For example, you press the **Tab** key or click into another field in the dialog box after changing the parameter value.
- You modify the parameter value by using the `set_param` command, the callback commands execute.
- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands. For more information, see “Code Pane”.
- You hover over a masked block to see the tool tip for the block, when the tool tip contains parameter names and values.

---

**Note** Callback commands do not execute if the mask dialog box is open when the block tool tip appears.

---

- You update a diagram by pressing **Ctrl+D** or by clicking **Update Model** on the **Modeling** tab in the Simulink Editor.
- If you close a mask dialog box without saving the changes, the Callback command for parameters is executed sequentially.

---

**Note** Buttons on mask dialog box are unavailable when the callback code associated with the button is being executed.

---

For related Simulink example models, see:

- Sequence mask callbacks
- Unsafe mask callbacks
- Unsafe nested mask callbacks

## See Also

### More About

- “Create Block Masks”
- “Initialize Mask” on page 42-19

## Draw Mask Icon

Create icons for the masked blocks. You can either create static or dynamic icons. Static icons remain unchanged. Dynamic icons are created with the mask parameters, hence the icon changes with a change in the mask parameters. This example shows how to use drawing commands to create a mask icon.

### In this section...

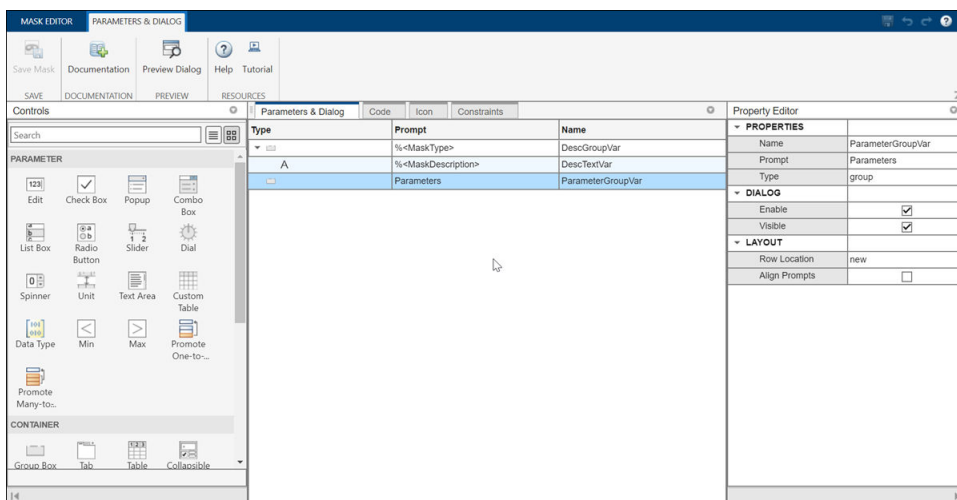

“Draw Static Icon” on page 42-16

“Draw Dynamic Icon” on page 42-17

## Draw Static Icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

- 1 Select the masked block that requires the icon.
- 2 On the **Block** tab, in the **Mask** group, click **Edit Mask**.

- 3 In the **Icons** tab, enter this command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

The image file must be on the MATLAB path.

For more examples of drawing command syntax, see “Icon drawing commands”.

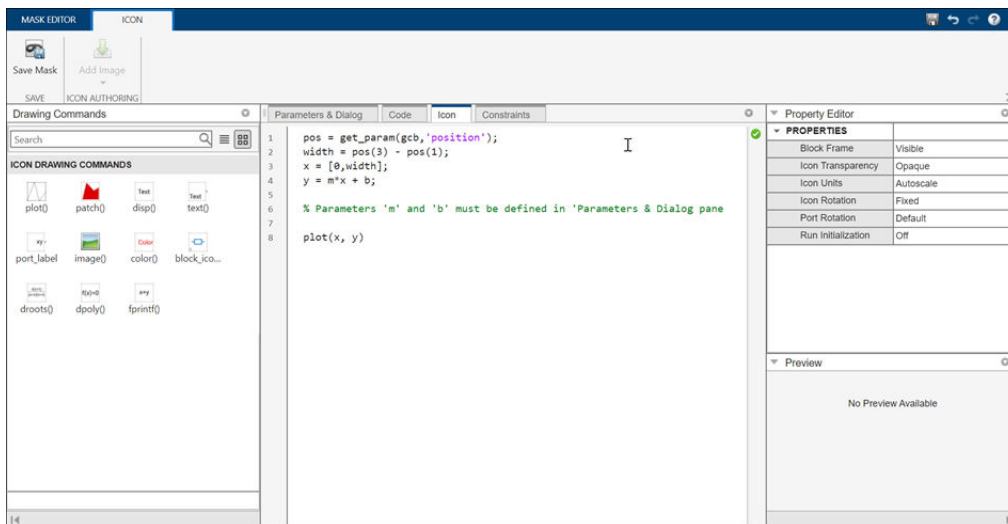

Images in formats `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd`, `.svg` cannot be used as block mask images. However, you can use images in these formats if you wrap the file name in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient. However, it is still supported for backward compatibility.

## Draw Dynamic Icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

- 1 Select the masked block that requires the icon.
- 2 On the **Block** tab, in the **Mask** group, click **Edit Mask**.

The Mask Editor opens.

- 3 In the **Icon** tab, enter this command in the **Icon Drawing commands** pane. Alternatively, you can click on the commands available in the left pane and fill in the data.

```

pos = get_param(gcf, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
% Parameters 'm' and 'b' must be defined in 'Parameters & Dialog' pane.
plot(x,y)

```

- 4 Under **Options**, set **Icon Units** to **Pixels**.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

- 5 Click **Apply**. To view the icon generated, see `model_masking_example`.

---

**Note** If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (? ? ?) appear on the mask.

---

See `slexMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- Static mask
- Dynamic shape mask
- Dynamic text mask
- Image mask

## **See Also**

### **More About**

- “Create and Edit Masked Block Icon Using Graphical Icon Editor” on page 42-110
- “Create Block Masks”

## Initialize Mask

You can add MATLAB code in the Initialization pane of the Mask Editor to initialize a masked block. Simulink executes these initialization commands to initialize a masked subsystem at critical times, such as model loading and start of a simulation run. For more information, see “Execute Initialization Command” on page 42-13.

You can add mask initialization code for these cases:

- To specify the initial values of mask parameters. For example to specify an initial value of parameter `a`, type `a = 5` in the Initialization pane.
- To specify the value of a child block. For example,

```
set_param('Child block Name','Parameter name','Parameter Value')
```

- To create a self-modifiable mask. For more information, see Self-Modifying Mask.

The initialization code of a masked subsystem can refer only to the variables in its local workspace.

When you reference a block with, or copy a block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

Ensure that the mask parameters used in the mask initialization code are defined. Errors in mask initialization are displayed when editing the mask initialization commands, but this is only possible if all the mask parameter values are evaluated without errors.

---

### Note

- Avoid unconditionally modifying the contents of a subsystem from the mask initialization code. Such unconditional modification does not work properly when using model reference.
  - When you use `set_param` in the mask initialization code of a Subsystem block, all the child blocks are also evaluated.
- 

Use the Mask Editor **Code** pane to add MATLAB commands that initialize a masked block.

The **Code** pane contains these sections:

- **Initialization & Callback**
- **Parameter**

## Dialog Variables

The **Dialog variables** section displays the names of the variables associated with the mask parameters of the masked block that are defined in the **Parameters** pane.

You can copy the name of a parameter from this list and paste it into the **Initialization Code** section.

You can change the name of the mask parameter variable in the list by double-clicking and editing the name.

## Initialization Code

You can add the initialization commands in this section. The initialization code must be a valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

To avoid echoing results to the MATLAB Command Window, terminate initialization commands with a semicolon.

To view related examples, see

- Define mask display and initialization

- Use MATLAB graphics in masking

## Mask Initialization Best Practices

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (Dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are intended for this purpose. For more information, see “Dynamic Mask Dialog Box” on page 42-35.
- Do not use initialization code to add or delete blocks during model load time.
- For nested masked subsystem, do not use `set_param` on a parent block from a child block. The child block mask and the parent block mask both could be initializing the same parameter of the block leading to unexpected behavior. For more information, see Unsafe Mask Callback Error.
- Do not use `set_param` commands on blocks that reside in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains a masked subsystem B which contains Gain block C, whose `Gain` parameter references a variable defined by B. Suppose also that subsystem A has initialization code that contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:
  - `Simulink.Parameter` and subclasses
  - `Simulink.Signal` and subclasses
- Do not add initialization code to delete the same masked block.
- Use mask initialization code to control direct child blocks only.

---

**Note** Do not use mask initialization code to comment or uncomment a block.

---

## Promote Block Parameters on a Mask

Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. You can promote any underlying parameter of a block either to a block mask or to a subsystem mask. For any subsystem, you have a single view of all the nested blocks, the block parameters, and internal parameters. You can click on any node to access any promotable parameter within the nested blocks. By promoting parameters from the block dialog box to the mask you can:

- Customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- Reuse a library block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each block.
- Simplify the interface and specify the parameters that the user of the block can view and set.

These options are available for promoting parameters:

**Promote One-to-One:** Use this option on the Mask Editor for one-to-one correspondence between the block parameter and the mask parameter. For each block parameter, one mask parameter is created. For example, consider the block dialog box of the **Gain** block, which has parameters such as **Gain**, **Multiplication**. To expose only the **Gain** parameter, mask the **Gain** block and promote the **Gain** parameter to the mask dialog box.

**Promote Many-to-One:** Use this option to create a many-to-one correspondence between the block parameter and the mask parameter. You can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single parameter on your mask.

### Note:

- If the parameter is of data type popup or `DataType`, the options must also be the same for the parameters to be promoted.
- The `Evaluate` attribute must be the same for all the promoted parameters.
- You can also change the attributes of a promoted parameter. For example, you can make a promoted parameter read-only or hidden. For more information on attributes, see “Property editor”.

### Explore the Model

The model contains two subsystem blocks: one for promoting on-to-one parameters, `Selective Promotion of Parameters` and one for promoting many to one parameters, `Promote Many to One`.

## Parameter Promotion

This subsystem comprises 3 gain blocks sharing a common gain value. For this, 3 gain parameters of the underlying gain blocks are promoted as a single parameter on the subsystem mask.

This subsystem comprises 3 gain blocks. However, the value of one of the gain blocks is fixed for all possible configurations. To simplify the user interface, the parameters of the variable gain blocks are promoted to the mask and the parameter of the static gain block is set in the mask initialization.

Copyright 2012 The MathWorks, Inc.

### Promote One-to-One

You can create an one-to-one correspondence for each underlying block parameters and the mask parameter.

Consider the model containing the subsystem **Selective Promotion of Parameters**, which contains three **Gain** blocks. The value of one of the **Gain** blocks is fixed. To simplify the user interface, the parameters of the variable **Gain** blocks are promoted to the mask.

To promote the parameters:

1. Go to **Mask Editor > Parameters & Dialog > Parameter > Promote One-to-One**.
2. Select the variable **Gain** parameters **Gain** and **Gain1**, then click **Promote**.

**Note:** You can modify the prompt of the promoted parameter.

3. Save the mask and simulate the model. Note that the value of the Gain1 block is taken from the mask parameter gain1\_promoted.

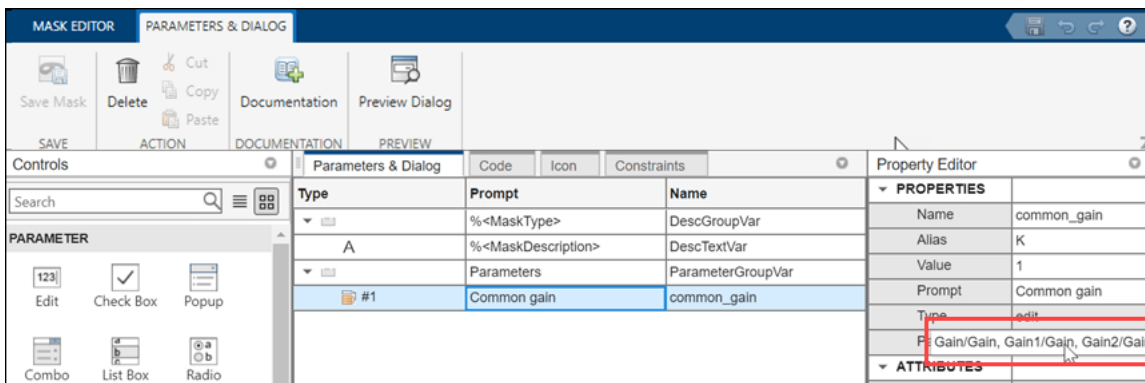

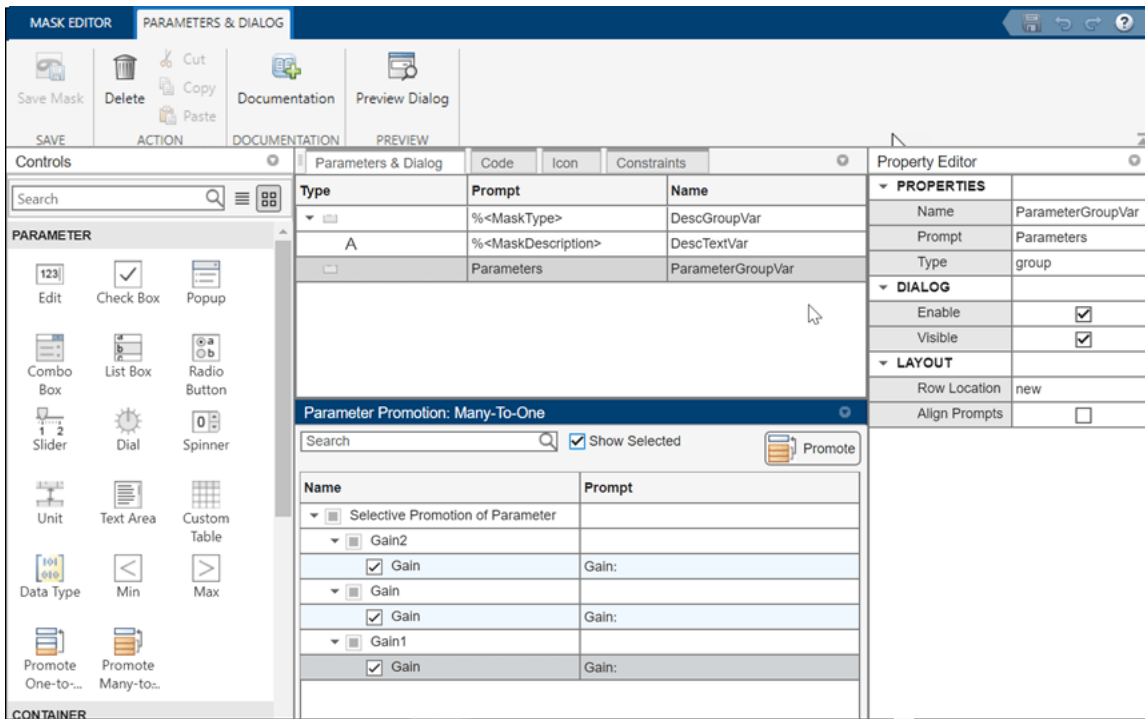

4. Simulate the model. Notice that the value of the Gain3 block is fixed and set in the initialization. The variable **Gain** parameters appear in the mask dialog box.

### Promote Many-to-One

Use the option **Promote-Many-to-One** in the Mask Editor to promote multiple block parameters to a single mask parameter. For example, this model contains a subsystem named Promote Many to One that has three **Gain** blocks ( **Gain1**, **Gain2**, and **Gain3** ). The variable K represents the **Gain** parameter for these **Gain** blocks. You can promote only the **Gain** parameter of each of these **Gain** blocks to the block mask as a single parameter. When you do so, the parameter K is available on the mask for editing, and its value will be applied to **Gain1**, **Gain2**, and **Gain3** blocks.

1. Go to **Mask Editor > Parameters & Dialog > Promote-Many-to-One**.
2. Select the **Gain** parameters Gain1, Gain2, and Gain3.
3. Click **Promote**.

4. Simulate the model. Notice that the value 4 is passed from the mask to the underlying blocks **Gain1**, **Gain2**, and **Gain3**. In this case, the output shows 64.

## Control Masks Programmatically

Simulink® defines a set of parameters that help in setting and editing masks. To set and edit a mask from the MATLAB® command line, you can use `Simulink.Mask` and `Simulink.MaskParameter` class methods. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use delimiters that do not support Unicode® (Non-English) characters it is recommended that you use methods of the `Simulink.Mask` and `Simulink.MaskParameter` class methods to control masks.

### Use `Simulink.Mask` and `Simulink.MaskParameter`

Use methods of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
- Create, edit, and delete mask parameters
- Determine the block that owns the mask
- Get workspace variables defined for a mask
- In this example the `Simulink.Mask.create` method is used to create a block mask:

```
new_system('mask_example');
add_block('built-in/subsystem','mask_example/subsystem');
save_system;
open_system('mask_example');
maskObj = Simulink.Mask.create(gcf);
```

In this example, the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```
maskObj = Simulink.Mask.get(gcf);
maskObj
```

```
maskObj =
  Mask with properties:
      Type: ''
  Description: ''
      Help: ''
 Initialization: ''
 SelfModifiable: 'off'
   ImageFile: ''
     Display: ''
   IconFrame: 'on'
   IconOpaque: 'opaque'
 RunInitForIconRedraw: 'analyze'
   IconRotate: 'none'
   PortRotate: 'default'
   IconUnits: 'autoscale'
   Parameters: [0x0 Simulink.MaskParameter]
 PortIdentifiers: [0x0 Simulink.Mask.PortIdentifier]
 ParameterConstraints: [0x0 Simulink.Mask.Constraints]
 CrossParameterConstraints: [0x0 Simulink.Mask.CrossParameterConstraints]
   PortConstraints: [0x0 Simulink.Mask.PortConstraint]
```

```
BaseMask: [0x0 Simulink.Mask]
```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks, see `Simulink.Mask` and `Simulink.MaskParameter`.

### Use `get_param` and `set_param`

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```
set_param(gcf, 'MaskStyleString', 'edit,edit', ...
'MaskVariables', 'maskparameter1=@1;maskparameter2=&2;', ...
'MaskPromptString', 'Mask Parameter 1:|Mask Parameter 2:', ...
'MaskValues', {'1', '2'});
get_param(gcf, 'MaskStyleString');
set_param(gcf, 'MaskStyles', {'edit', 'edit'}, 'MaskVariables', ...
'maskparameter1=@1;maskparameter2=&2;', 'MaskPrompts', ...
{'Mask Parameter 1:', 'Mask Parameter 2:'}, ...
'MaskValueString', '1|2');
get_param(gcf, 'MaskStyles');
```

where

- `|` separates individual character vector values for the mask parameters.
- `@` indicates that the parameter field is evaluated.
- `&` indicates that the parameter field is not evaluated but assigned as a character vector.

### Note

- When you use `get_param` to get the Value of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog box but not applied are not reflected when you use the `get_param` command.
- To specify the value of a mask parameter programmatically, it is recommended to use `set_param` command on the **mask parameter** instead of using `set_param` on **MaskValues**.

To control the mask properties programmatically for a release before R2014a, see “Mask Parameters”.

### Restrictions Using `set_param` and Mask Object APIs on Linked Blocks

Simulink imposes certain constraints while modifying the mask parameters using `set_param` and mask object APIs on linked blocks. On a non-self-modifiable linked block, you can change the properties of a mask parameter such as Value, Visible, and Enable. On a self-modifiable linked block, you can change few other properties in addition to Value, Visible, and Enable.

### Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.

**Step 1:** Create the mask for a block you selected in the model.

**Step 2:** To customize the dialog and to use tabs instead of the default group, remove the **Parameters** group box.

```
maskObj.removeDialogControl('ParameterGroupVar');
open_system('mask_example/subsystem');
```

Simulink preserves the child dialog controls—the two check boxes in this example—even when you delete the ParametersGroupVar group surrounding them. These controls are parameters that cannot be deleted using dialog control methods.

You can delete parameters using methods such as `removeAllParameters`, which belongs to the `Simulink.Mask` class.

**Step 3:** Create a tab container and get its handle.

```
tabgroup = maskObj.addDialogControl('tabcontainer','tabgroup');
```

**Step 4:** Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab','tab1');
tab1.Prompt = 'First';
maskObj.addParameter('Type','checkbox','Prompt','Option 1',...
    'Name','option1','Container','tab1');
maskObj.addParameter('Type','checkbox','Prompt','Option 2',...
    'Name','option2','Container','tab1');
tab2 = tabgroup.addDialogControl('tab','tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab','tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off';
tab3
```

```
tab3 =
  Tab with properties:
      Name: 'tab3'
      Prompt: 'Third (invisible)'
      Enabled: 'on'
      Visible: 'off'
      AlignPrompts: 'off'
      DialogControls: [0x0 Simulink.dialog.Control]
```

You can change the location and other properties of the parameters on the dialog by using the `Simulink.dialog.Control` commands.

For example, to change the dialog layout options, consider a Gain block with a Popup parameter named Parameter2 added. To set the dialog layout options of the parameter, you can use an instance of `Simulink.dialog.parameter.Popup` class. The following code shows how to set the prompt location in dialog layout:

```
add_block('built-in/gain','mask_example/gain2');
maskobj = Simulink.Mask.create(gcb);
set_param(gcb,'MaskStyleString','popup',...
'MaskVariables','maskparameter2=&2;',...
'MaskPromptString','Mask Parameter 2:');
a = Simulink.Mask.get('mask_example/gain2');
```

```
d = a.Parameters(1).DialogControl;
d
```

```
d =
  Popup with properties:
      Name: 'Parameter1'
  PromptLocation: 'left'
      Row: 'new'
  HorizontalStretch: 'on'
      Tooltip: ''
```

Now, to set the `PromptLocation` property, use the command:

```
d.PromptLocation = 'left';
```

This sets the `PromptLocation` as 'left'. The available values are 'left' and 'top'. The output confirms the change of the `PromptLocation` property value to left:

```
d
d =
  Popup with properties:
      Name: 'Parameter1'
  PromptLocation: 'left'
      Row: 'new'
  HorizontalStretch: 'on'
      Tooltip: ''
```

```
save_system;
```

For more information on dialog controls and their properties, see `Simulink.dialog.Control`.

## Pass Values to Blocks Under the Mask

A masked block can pass values to the block parameters under the mask. The underlying blocks use the passed values during simulation to execute the block logic.

A masked block has variables associated with mask parameters. These variables are stored in the mask workspace for a model and can correspond to a block parameter under the mask. When such a block is evaluated, the block variables look for matching values in the mask workspace to get a value.

The mapping of variables from the mask workspace to the base workspace must be correct. A correct mapping ensures that the right block variable is assigned the value that is passed from the mask.

Use any of these options to pass values to blocks under the mask:

- Parameter promotion (recommended)
- Mask initialization
- Referencing block parameters using variable names (For the Edit Parameter only)

### Parameter Promotion

When you promote a block parameter to its mask, the block parameter becomes accessible from the mask dialog box, allowing you to pass a value for the block parameter. Parameter promotion ensures correct mapping of parameter values and is a recommended way to pass values to the block from the mask dialog box. Note that, when you promote parameters of an in-built block, the internal callbacks associated with these parameters are also inherited in the new parameter. For more information on promoting a parameter, see “Promote Block Parameters on a Mask” on page 42-22.

### Mask Initialization

You can use MATLAB code in the Initialization pane of the Mask Editor to assign or pass values to the block parameters under the mask. You can assign a fixed value to a block parameter, specify an acceptable range for the input values, or specify a value for the child block. For more information, see “Initialize Mask” on page 42-19.

### Referencing Block Parameters Using Variable Names

You can add an Edit parameter to the mask dialog box and pass values to the block parameters through it. The values that you provide for the Edit parameter in the mask dialog box automatically becomes associated with the block parameter, by using the techniques described in “Symbol Resolution” on page 72-134.

Consider the model `masking_example`, which contains a masked Subsystem block and governs the equation  $y = mx + b$ . Here,  $m$  and  $b$  are variables controlling the slope and intercept of the equation and are associated with the Gain and the Constant block, respectively.

The variables **m** and **b** are assigned to the mask parameters **Slope** and **Intercept**, respectively, as parameter names in the Mask Editor.

When you type values for **Slope** and **Intercept** in the mask dialog box, these values are internally assigned to the variables **m** and **b**. When the model is simulated, the Gain block and the Constant block search for numeric values of **m** and **b** and apply them to resolve the equation  $y = mx + b$ .

## Mask Linked Blocks

### In this section...

“Guidelines for Mask Parameters” on page 42-33

“Mask Behavior for Masked, Linked Blocks” on page 42-33

“Mask a Linked Block” on page 42-34

Simulink libraries can contain blocks that have masks. An example of this type of block is the Ramp block. These blocks become library links when copied to a model or another library. You can add a mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

You can also apply a mask to a block, then include the block in a library. Masking a block that is later included in a library requires no special provisions. For more information, see “Create Custom Library” on page 44-2.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Block C to Library B. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.

For Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.

- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

Creating or changing a library block mask changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that exist as separate copies.

To view related example, see [Use self-modifying library masks](#).

## Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the `Promote` type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

## Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The `MaskType` and the `MaskSelfModifiable` parameters are inherited from the base mask.
- The mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose `MaskIconFrame` parameter is set to `opaque`.
- The mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **Save > Export Model to > Previous Version** on the **Simulation** tab, the `SourceBlock` parameter is modified to point to the library block having the bottom-most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
  - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
  - If you break the link to the library block, the block becomes a standalone block.
  - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

## Mask a Linked Block

### Step 1: Create Custom Library with Masked Linked Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Library**.
- 2 Open the Ramp block in the Library editor window.
- 3 Select the Ramp block and on the **Block** tab, in the **Mask** group, click **Create Mask**.

The **Mask Editor** opens.

- 4 In the **Icons** pane, type:

```
plot ([0:10],[0,1:10])
```

- 5 In the **Parameter & Dialog** pane, select  **Promote** to promote the Slope and Initial Output parameters.
- 6 Click **OK**.
- 7 Rename the block to Derived Ramp block.

### Step 2: Add a Mask to the Masked, Link Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Model**. The Model editor window opens.
- 2 Drag the Derived Ramp block from the Library editor to the Model editor.

The Derived Ramp block in the model has multiple masks on it. You can set parameters of the derived mask.

### Step 3: View Masks Below the Top Mask

- Right-click the Derived Ramp block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

- “Create Block Masks”
- “Linked Blocks” on page 44-12

## Dynamic Mask Dialog Box

### In this section...

- “Show Parameter” on page 42-35
- “Enable Parameter” on page 42-35
- “Create Dynamic Mask Dialog Box” on page 42-35
- “Set Up Nested Masked Block Parameters” on page 42-37

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include:

- Visibility of parameter controls — Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.
- Enabled state of parameter controls — Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.
- Parameter values — Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

---

**Note** Mask parameter addition, deletion, or modification is restricted from mask callback.

---

Creating a dynamic masked dialog box entails using the Mask Editor with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Execute Callback Code” on page 42-14). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 42-35). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see [Create dynamic mask dialog boxes](#).

### Show Parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

### Enable Parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

### Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: 2, 5, or User-defined. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

- 1 Select a subsystem and on the **Subsystem Block** tab, in the **Mask** group, click **Create Mask**.
- 2 Select the **Parameters & Dialog** pane on the Mask Editor.
- 3 Drag and drop a **Popup** parameter and select it in the **Dialog box** pane.

- a In the **Prompt** field, enter Gain.
- b In the **Name** field, enter gainpopup.
- c In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
- d In the **Type options** field, click the **Edit** button to enter these three values in the Popup Options dialog box:

```
2
5
User-defined
```

- 4 Enter this code in the **Dialog callback** field:

```
% Get the mask parameter values. This is a cell
% array of character vectors.
maskStr = get_param(gcb,'gainpopup');

% The pop-up menu is the first mask parameter.
% Check the value selected in the pop-up
if strcmp(maskStr(1),'U'),

    % Set the visibility of both parameters on when
    % User-defined is selected in the pop-up.

    set_param(gcb,'MaskVisibilities',{'on';'on'}),

else

    % Turn off the visibility of the Value field
    % when User-defined is not selected.

    set_param(gcb,'MaskVisibilities',{'on';'off'}),

    % Set the character vector in the Values field equal to the
    % character vector selected in the Gain pop-up menu.

    %maskStr{2}=maskStr{1};
    set_param(gcb,'editvalue',maskStr);
end
```

- 5 Drag and drop an **Edit** parameter and select it in the **Dialog box** pane.
  - a In the **Prompt** field, enter Value.
  - b In the **Name** field, enter editvalue.
  - c In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.
- 6 Click **Apply**.

- 7 To open the mask dialog box, double-click the masked subsystem.

If you select 2 or 5 as the **Gain**, Simulink hides the **Value**. If you select **User-defined** as the **Gain** the **Value** is visible.

## Set Up Nested Masked Block Parameters

If lower-level masked subsystems reference symbols defined by higher-level masked subsystems and you try to set parameters of blocks in lower-level masked subsystems, unresolved symbol errors can occur. Therefore, avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem being initialized. Trying if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

## Dynamic Masked Subsystem

### In this section...

“Allow Library Block to Modify Its Contents” on page 42-38

“Create Self-Modifying Masks for Library Blocks” on page 42-38

“Passing Mask Parameter Values from Parent Subsystem to Child Block” on page 42-40

### Allow Library Block to Modify Its Contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcb, 'MaskSelfModifiable', 'on');
```

Then save the block.

### Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

Simulink runs the mask-initialization code for a self-modifiable library block when you load the block. If the mask-initialization code controls the number of input/output ports for a block, mark the block as self-modifiable. Otherwise, the mask-initialization code will not execute and will not set the right number of ports, which will disconnect the block.

### Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

- 1 Unlock the library (see “Lock and Unlock Libraries” on page 44-6).
- 2 Select the block in the library.
- 3 On the **Block** tab, in the **Mask** group, click **Edit Mask**. The Mask Editor opens.
- 4 In the Mask Editor **Code** pane, select the **Allow library block to modify its contents** option.
- 5 Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see “Add Mask Code” on page 42-13). Doing so triggers an error when you edit the parameter.

- 6 Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.
- 7 Lock the library.

## Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

- 1 Unlock the library using the following command:  

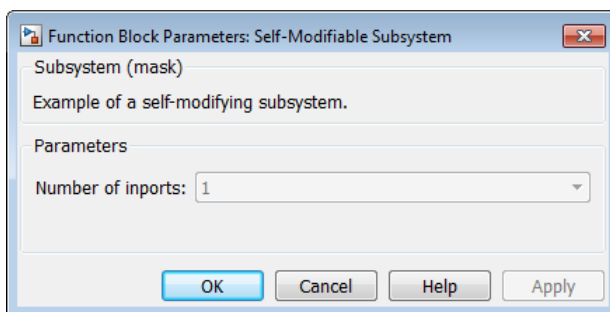

```
set_param(gcs, 'Lock', 'off')
```
- 2 Specify that the block is self-modifying by using the following command:  

```
set_param(block_name, 'MaskSelfModifiable', 'on')
```

where `block_name` is the full path to the block in the library.

## Create Self-Modifying Mask

The library `selfModifying_example` contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

- 1 In the Library window, on the **Library** tab, click **Locked Library** to unlock the library.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Edit Mask**. The Mask Editor opens.
- 3 The Mask Editor **Parameters & Dialog** pane defines a parameter `numIn` that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.

- 4 To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Code** pane is selected. If this option is not selected, copy of the library block could not modify their structural contents. Also, changing the selection in the **Number of inports** list would produce an error.

## Passing Mask Parameter Values from Parent Subsystem to Child Block

You can pass mask parameter values from a parent subsystem to a child block in three ways:

- Using parameter promotion.

- Using the mask initialization code. This is done by using the `set_param` command on the child block.
- Having the child block parameters reference the parent mask parameter name. This is applicable only for the edit parameters.

## Debug Masks That Use MATLAB Code

<b>In this section...</b>
“Code Written in Mask Editor” on page 42-42
“Code Written Using MATLAB Editor/Debugger” on page 42-42

### Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor by:

- Removing the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Placing a keyboard command in the code to stop execution and give control to the keyboard.

---

**Tip** To stop debugging the mask initialization callback code when an error is encountered, use the command `dbstop if caught error`.

---

### Code Written Using MATLAB Editor/Debugger

---

**Note** You cannot debug icon drawing commands using the MATLAB Editor/Debugger. For information on icon drawing commands syntax, see “Icon drawing commands”.

---

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

## Introduction to System Mask

A system mask can be applied to a model or a subsystem block diagram. A model consists of multiple blocks, with each block containing its own parameter and block dialog box. Simulink enables you to mask a model. By masking a model you encapsulate the model to have its own mask parameter dialog box. You can customize the mask parameter dialog box. When you mask a model, the model arguments become the mask parameters. Referencing a masked model helps in having a better user interface for a model with ease of controlling the model parameters through the mask.

When you reference a masked model from a Model block, a mask is generated automatically on the Model block. The generated mask on the Model block is a copy of the model mask that it is referencing. You can reference a masked model from multiple Model block instances.

Consider a model that represents the DC motor equation. `Plant` in this model is a Model block that references a masked model, simplifying the user interface.

The `Plant` block contains the same mask as that of the masked model and the mask is uneditable. The mask can only be edited from the Mask Editor dialog box of the masked model.

- “Add a System Mask for Subsystem Reference” on page 4-36
- “Masking Fundamentals” on page 42-2

## Create and Reference a Masked Model

This example shows how to mask a model and reference the masked model from the Model block.

### Step 1: Define Mask Arguments

- 1 Open the model in Simulink. For example, consider a simple model containing two Gain blocks, a Constant block, and a Display block.

- 2 On the **Modeling** tab, under **Design**, click **Model Explorer > Model Workspace**.
- 3 Click **Add > MATLAB Variable**. A variable of data type `double` is created in the Model Workspace.
- 4 Select the **Argument** check box corresponding to the MATLAB variables to make it a model argument, for example, `k` and `l`.

### Step 2: Create Model Mask

- 1 In the **Model Workspace** pane, click **Create System Mask**.

Alternatively, in Simulink, on the **Modeling** tab, under **Component**, click **Create Model Mask**, or right-click the model, and select **Mask > Create System Mask**.

The Mask Editor dialog box opens.

- 2 Click the **Parameters & Dialog** tab. The model arguments that you select in Model Explorer appear in the Mask Editor dialog box as mask parameters.

**Tip** Ensure that the model arguments you have selected in the Model Explorer dialog box are added as block parameters in the model. For example, the arguments *k* and *l* are passed to *Gain A* and *Gain B* blocks, respectively.

**Note** The Mask Editor dialog box for system mask does not contain the **Code** tab. Initialization code can alter the model and other model reference blocks, and thus affect the simulation results.

- 3 Select a mask parameter (*k* or *l*) on the **Dialog box** pane and edit its properties in the Property editor, as required. For example, you can change the prompt name, parameter type, value, or orientation.

By default, the **Edit** parameter type is assigned to a model mask parameter. You can change the parameter type by editing the **Type** property in the **Property editor** section.

#### Note

- Simulink supports only the **Edit**, **Slider**, **Dial**, and **Spinbox** parameter types for system mask.
- System mask supports all types of display and action controls.

- 4 Click **OK**. The Simulink model is now masked and contains the model arguments as the mask parameter.
- 5 Save the model.

### Step 3: View System Mask Parameters

- 1 To view the mask parameter dialog box, on the **Component** tab, under **System Mask**, click **Mask Parameters**.

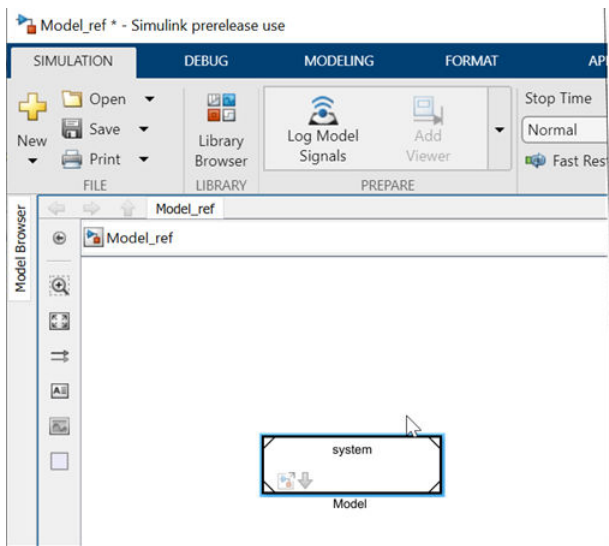

**Tip** To edit the system mask parameters, on the **Component** tab, under **System Mask**, click **Edit System Mask**.

- 2 Save the masked model.

### Step 4: Reference Masked Model

- 1 Open a blank model in Simulink and add the Model block from the library.
- 2 To reference the masked model from the Model block, specify the name of the masked model as the **Model name** in the **Block parameter** dialog box.

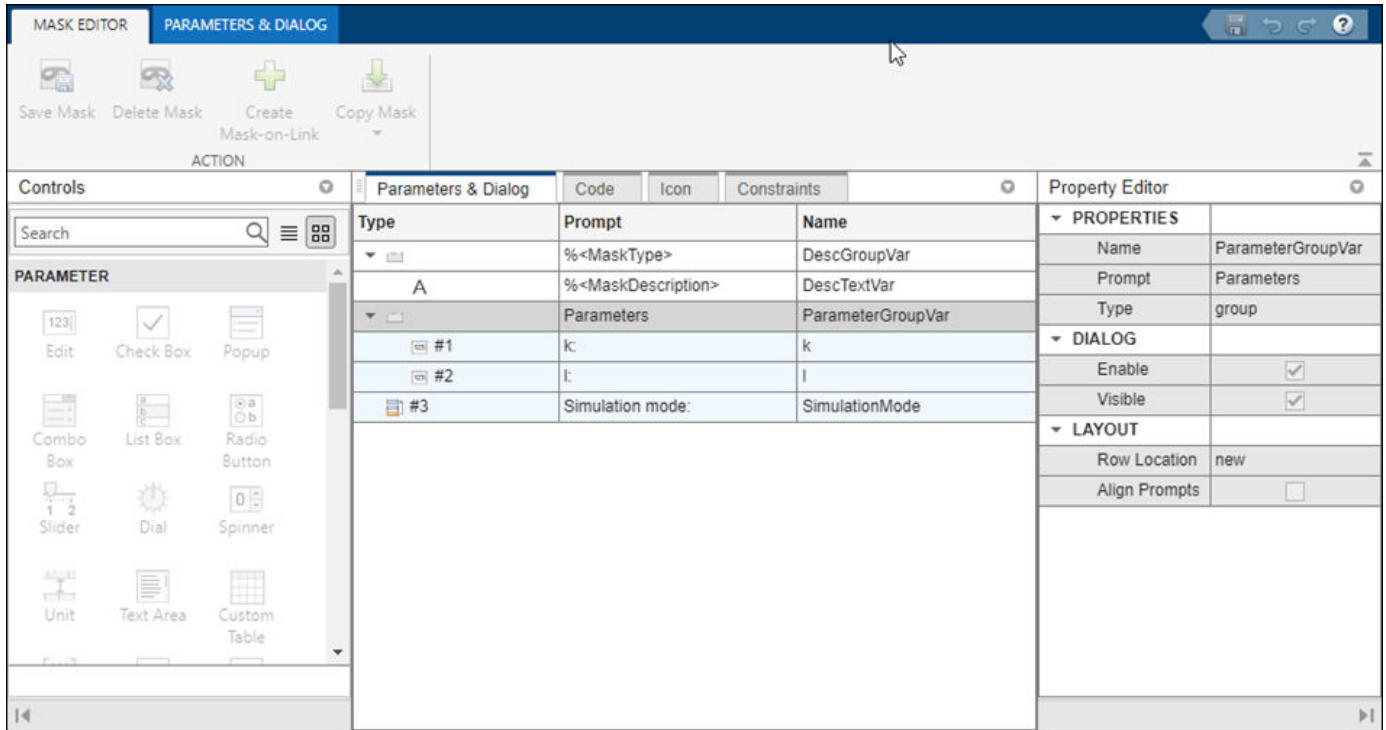

Masked model referenced by the Model block

- 3 To view the parameter dialog box of the referenced model, right-click the Model block, and in the context menu, click **Mask > Mask Parameters**. Alternatively, double-click the Model block.
- 4 Type 2 and 3 as the parameter values for k and l respectively.

- 5 Click **OK**.

- 6 Simulate the model and view the result on the display block.
- 7 To view the referenced model from the Model block, click **Mask > Look Under Mask**.
- 8 To view the mask, select the Model block and click **Mask > View Mask**. The **Mask Editor** dialog box opens. The Mask Editor dialog box displays the uneditable mask parameters of the referenced model.

## See Also

### More About

- “Introduction to System Mask” on page 42-43
- “Control System Mask Programmatically” on page 42-48
- “Masking Fundamentals” on page 42-2

## Control System Mask Programmatically

Simulink® defines a set of parameters to configure and edit a system mask.

- `addParameter`
- `removeParameter`
- `removeAllParameters`
- `MaskParameter.Name`

### Note:

- *Adding, removing, and renaming parameters on a system mask using these methods is not supported for a model mask.*

### Simulink.Mask.create

Use the `Simulink.Mask.create` method to create mask on a model. The syntax to mask a model,

- Using the model name

```
Simulink.Mask.create(ModelName)
```

- Using the system handle

```
SystemHandle = get_param(gcs, 'Handle') %To get the system handle
```

```
Simulink.Mask.create(SystemHandle) %To create mask using system handle
```

### Example:

```
new_system('vdp');
save_system;
maskObj = Simulink.Mask.create('vdp')
```

```
maskObj =
```

```
Mask with properties:
```

```

        Type: 'vdp'
      Description: ''
         Help: ''
 Initialization: ''
 SelfModifiable: 'off'
   ImageFile: ''
     Display: ''
   IconFrame: 'on'
   IconOpaque: 'opaque'
RunInitForIconRedraw: 'analyze'
   IconRotate: 'none'
   PortRotate: 'default'
   IconUnits: 'autoscale'
   Parameters: [0x0 Simulink.MaskParameter]
PortIdentifiers: [0x0 Simulink.Mask.PortIdentifier]
ParameterConstraints: [0x0 Simulink.Mask.Constraints]
CrossParameterConstraints: [0x0 Simulink.Mask.CrossParameterConstraints]
   PortConstraints: [0x0 Simulink.Mask.PortConstraint]
```

```
BaseMask: [0x0 Simulink.Mask]
```

### Simulink.Mask.get

Use the `Simulink.Mask.get` method to get the mask on a model as a mask object. The syntax to get the existing mask of a model,

- Using the model name

```
Simulink.Mask.get(ModelName)
```

- Using the system handle

```
SystemHandle = get_param(gcs,'Handle') %To get the system handle
```

```
Simulink.Mask.get(SystemHandle) %To create mask using system handle
```

### Example:

```
maskObj = Simulink.Mask.get('vdp')
```

```
maskObj =
```

```
Mask with properties:
```

```

        Type: 'vdp'
      Description: ''
         Help: ''
  Initialization: ''
  SelfModifiable: 'off'
      ImageFile: ''
        Display: ''
      IconFrame: 'on'
      IconOpaque: 'opaque'
RunInitForIconRedraw: 'analyze'
      IconRotate: 'none'
      PortRotate: 'default'
      IconUnits: 'autoscale'
      Parameters: [0x0 Simulink.MaskParameter]
  PortIdentifiers: [0x0 Simulink.Mask.PortIdentifier]
  ParameterConstraints: [0x0 Simulink.Mask.Constraints]
CrossParameterConstraints: [0x0 Simulink.Mask.CrossParameterConstraints]
      PortConstraints: [0x0 Simulink.Mask.PortConstraint]
      BaseMask: [0x0 Simulink.Mask]
```

**Note:**

*To get the model mask as a mask object in the mask callback, you can use `Simulink.Mask.get()` without passing a system name or system handle. Simulink fallback for `tm_simulink` does not require the system name (`gcb`) or the system handle (`gcs`) to query the mask object for the model mask.*

## Handling Large Number of Mask Parameters

The **Table** control in Mask Editor dialog box allows you to organize large number of mask parameters. The **Table** control can handle large (500+) number of mask parameters. You can include **Edit**, **Checkbox**, and **Popup** parameters within a **Table**.

You can also add large number of mask parameters in a **Table** programmatically. An example follows,

```
% Get mask object.
aMaskObj = Simulink.Mask.get(gcbh);

% Add Table controls to the mask.
aMaskObj.addDialogControl('Table', 'MyTable');

% Add parameters to table container.
for i = 1:length(Parameters) % To import values from an array called 'Parameters'
    aMaskObj.addParameter('Name', Parameters(i).Name, 'Type', Parameters(i).Type, 'Container', 'MyTable');
end
```

## Customize Tables for Masked Blocks

The **Custom Table** parameter allows you to add customized table with structured data on a mask dialog box without writing custom codes. As a mask parameter, the custom table widget supports parameter promotion unlike the tables created using custom block dialog code.

You can provide input to the **Custom Table** parameter as a string in the cell array format.

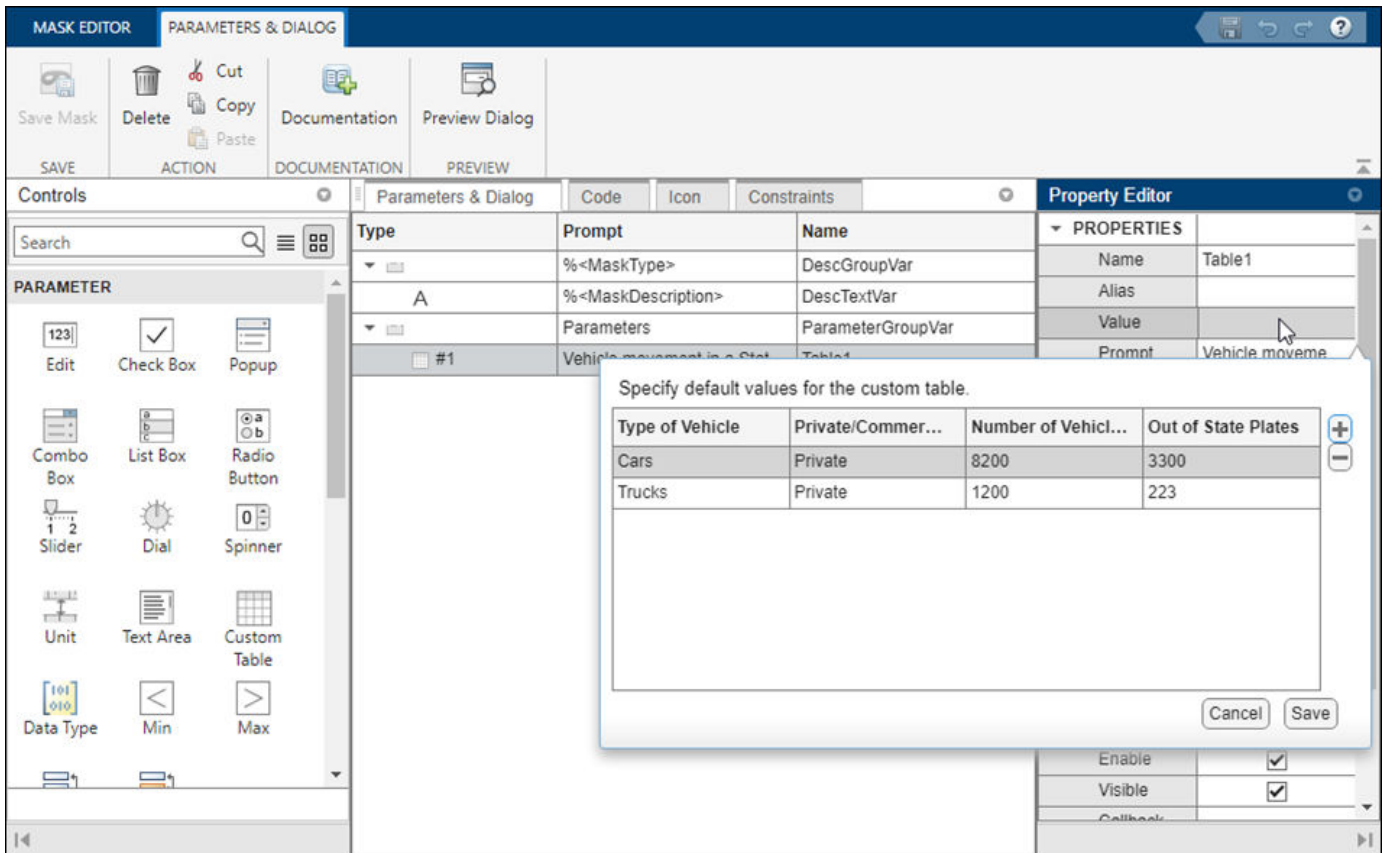

### Adding a Custom Table Parameter

- 1 Open a Simulink model.
- 2 Select any block and on the **Block** tab, in the **Mask** group, click **Create Mask**. The Mask Editor opens.
- 3 In the **Parameters & Dialog** tab, click **Custom Table** to add it to the mask as a parameter. Specify a name and prompt for the parameter, as required.
- 4 In the **Property Editor** pane, click the **Columns** field to enter the column properties, such as the name of each column, type of column, visibility and expression evaluation. The available column types are **edit**, **checkbox**, and **popup**. Use the **Add** button to add a column and **Remove** button to remove an existing column.

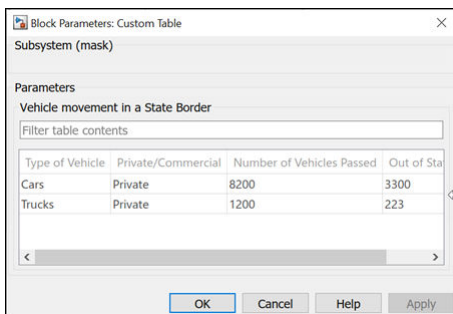

The screenshot shows the Mask Editor interface with the **PARAMETERS & DIALOG** tab selected. The **Property Editor** pane is open, showing the **Columns** field. A dialog box titled "Specify columns for the custom table" is open, displaying a table with the following data:

Name	Type	Type Options	Enabled	Visible	Evaluate	Width
Type of Vehicle	edit		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	0
Private/Com...	edit		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	0
Number of Ve...	edit		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	0
Out of State P...	edit		<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>	0

- 5 In the **Property Editor** pane, click the **Value** field and add the required number of rows by clicking **+**. If required, enter default values in the newly added rows. Click **Save** to save your changes.

- Click **Save Mask** to save the changes to the mask. Double-click the block to view this custom table.

If you want to edit the custom table, right-click the block and select **Mask > Edit Mask**.

## See Also

## More About

- “Control Custom Table Programmatically” on page 42-54

## Control Custom Table Programmatically

Use a programmatic interface to control custom tables. You can add a custom table on the mask dialog box programmatically and control its properties using programmatic interface. For information on creating a custom table from the Mask Editor, see “Customize Tables for Masked Blocks” on page 42-52.

### Add a Custom Table Parameter

You can add a custom table parameter to a mask dialog box using these commands:

```
new_system('mask_custom_table');
```

Warning: The model name 'mask\_custom\_table' is shadowing another name in the MATLAB workspace or

```
add_block('built-in/subsystem','mask_custom_table/subsystem');
save_system;
open_system('mask_custom_table');
% Mask Object
maskObj = Simulink.Mask.create(gcf);

% Add custom table parameter
tableParam = maskObj.addParameter( 'Name', 'myTable', 'Type', 'customtable' );
```

### Add Columns to a Table

You can add columns to a custom table using the addColumn command:

```
tableControl = maskObj.getDialogControl('myTable');
tableControl.addColumn( 'Name', 'HDL Name', 'Type', 'edit' );
tableControl.addColumn( 'Name', 'I/O Mode', 'Type', 'popup', 'TypeOptions', {'Input', 'Output'} );
tableControl.addColumn( 'Name', 'Sample Time', 'Type', 'edit' );
tableControl.addColumn( 'Name', 'Data Type', 'Type', 'popup', 'TypeOptions', {'Inherit', 'FixedP'} );
tableControl.addColumn( 'Name', 'Sign', 'Type', 'checkbox' );
tableControl.addColumn( 'Name', 'Fraction Length', 'Type', 'edit' );
tableControl.Columns(2).Width=500
```

```
tableControl =
  CustomTable with properties:
        Name: 'myTable'
         Row: 'new'
HorizontalStretch: 'on'
        Tooltip: ''
      ShowFilter: 'on'
      Multiselect: 'on'
        Sortable: 'off'
      Columns: [1x6 Simulink.Mask.TableParamColumnInfo]
```

```
% Add values to the table
tableParam.Value = join( [
    '{'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';", ...
    " 'sig2', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';", ...
    " 'sig3', 'Output', '10', 'Inherit', 'off', 'Inherit';", ...
    " 'sig4', 'Output', '10', 'Inherit', 'off', 'Inherit'}" ] );
```

**Note:**

- You can use the **Width** property to specify initial column width for a custom table.

**Set and Get Table Properties**

You can fetch the value of a cell if it had a change and set a new value for a cell in the table using these commands:

```
% get values of the changed cell
open_system('mask_custom_table/subsystem')

% get value of a particular cell
tableControl.getValue( [1 3] );

% Set value for a particular cell
tableControl.setValue( [1 3], '20' );

changedCells = tableControl.getChangedCells();
```

**Set and Get Cell Level Specifications**

You can set and fetch the value of a particular cell in a custom table. The commands used are:

```
% set value for a particular table cell
tableControl.setTableCell( [1 3], 'Type', 'checkbox', 'Value', 'off', 'Enabled', 'off' )

% get value from a particular table cell
tableCell = tableControl.getTableCell( [1 5] )

tableCell =
  CustomTableParamCellObject with properties:

      Value: 'on'
      Type: 'checkbox'
  Enabled: 'on'
  TypeOptions: {0x1 cell}
```

**Note:**

- The `setTableCell` and `getTableCell` APIs must be used as part of mask parameter call backs while getting the number of rows in a table.
- The `setTableCell` and `getTableCell` APIs displays the correct result only when the dialog with the custom table parameter is opened.

**Edit Rows in a Custom Table**

You can insert, remove, swap, and get the value of a specific row in a custom table. The commands used are:

```
% add a row to the table
tableControl.addRow( 'sig5', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit' )

% Insert a row at a specific location in the table
tableControl.insertRow( 4, 'insertSig4', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit' )

% Remove a particular row
```

```
tableControl.removeRow( 2 )  
  
% Swap two rows  
tableControl.swapRows( 3, 4 )  
  
tableControl.getSelectedRows()
```

### Get and Set Table Parameter

You can use the `set_param` and `get_param` commands to set or get the values of the custom table parameter you created in a mask dialog box.

```
get_param( gcb, 'myTable' )  
  
ans =  
'{sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit'; 'sig2', 'Input', 'Inherit', 'Inherit'  
  
set_param( gcb, 'myTable', "{ 'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit' }" )
```

### Edit Columns in a Custom Table

You can insert, remove, swap, and get the value of a specific column in a custom table. The commands used are:

```
% add a column to the table  
tableControl.addColumn( 'Name', 'Hardware Name', 'Type', 'edit' );  
% Remove a column from the table  
tableControl.removeColumn( 1 );  
% Insert a column at a particular location in the table  
tableControl.insertColumn( 1, 'Name', 'HDL Name', 'Type', 'edit' );  
tableControl.getColumn( 4 );
```

### Insert Column and Enable Evaluation of the Column Cells

Insert a new column with the **Evaluate** check box selected. The command used is:

```
tableControl.insertColumn( 2, 'Name', 'Counter', 'Type', 'edit', 'Evaluate', 'on' );
```

- “Customize Tables for Masked Blocks” on page 42-52
- `slexMaskParameterOptionsExample`

## Add Images in Masks

You can add images as icons on a Simulink mask and save them in the SLX file.

- 1 Select any masked block and on the **Block** tab, click **Add Image**.
- 2 In the **Add mask icon image** dialog box, click **Browse** to select an image from your local repository. You can also set the transparency using the **Icon transparency** field. Available options are: Opaque, Transparent, and Opaque with ports.

- 3 Select the **Store a copy of the image in the SLX file** check box if you want to store the mask image in the SLX file.
- 4 Click **OK** to save your changes.

### Store Mask Images Programmatically

- Convert mask image to internal for one block  
`Simulink.Mask.convertToInternalImage`
- Convert mask image to internal for the whole model  
`Simulink.Mask.convertToInternalImages`
- Convert mask image to external for one block  
`Simulink.Mask.convertToExternalImage`

## Create Hierarchical List in Mask Dialog

You can use the **Tree Control** option available in the **Display** section of the Mask Editor to create the hierarchical list of data in mask dialog box.

Consider a scenario in which you want to create a parent-child hierarchy on a mask dialog box as shown here:

To do so,

- 1 Right-click a block and in the content menu click **Mask > Create Mask** or **Mask > Edit Mask**.
- 2 In the **Parameters & Dialog** pane, click **Tree Control** from the **Display** section.
- 3 In the **Property editor** section, specify these in the **Tree Items** field:

```
{ 'Node1', {'ChildNode1', 'ChildNode2'}, 'Node2', {'ChildNode1',
'ChildNode2'}, 'Node3', {'ChildNode1', 'ChildNode2'}, 'Node4',
{'ChildNode1', 'ChildNode2'}}
```

- 4 Click **Apply**.

## Validating Mask Parameters Using Constraints

A mask can contain parameters that accept user input values. You can provide input values for mask parameters using the mask dialog box. Mask parameter constraints help you to create validations on a mask parameter without having to write your own validation code. Constraints ensure that the input for the mask parameter is within a specified range. For example, consider a masked Gain block. You can set a constraint where the input value must be between 1 and 10. If you provide an input that is outside the specified range, an error displays.

### Create and Associate a Constraint

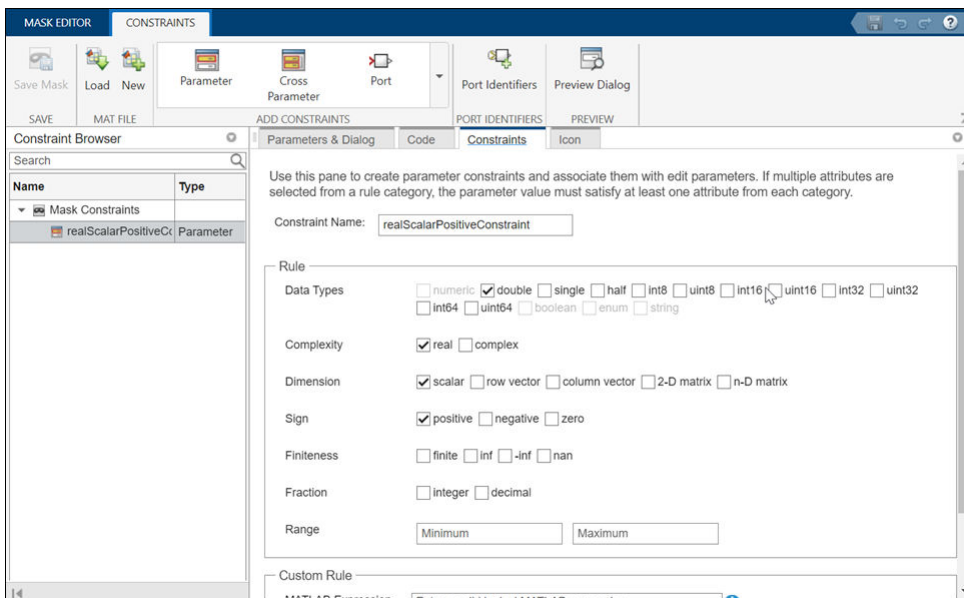

Constraint Manager is embedded inside Mask Editor with attributes and options to create your constraints. Click **Constraints** tab to create or load an existing constraint.

#### Create a Constraint

You can create constraints according to your specification using the built-in attributes in the Constraint Manager. To create a constraint:

- 1 In the Mask Editor, click **Constraints** tab and then click **New** in the toolstrip to create a constraint.
- 2 Select attributes for the constraint in the **Rule** section. Based on the data type selection, the applicable rule attributes gets enabled/disabled.

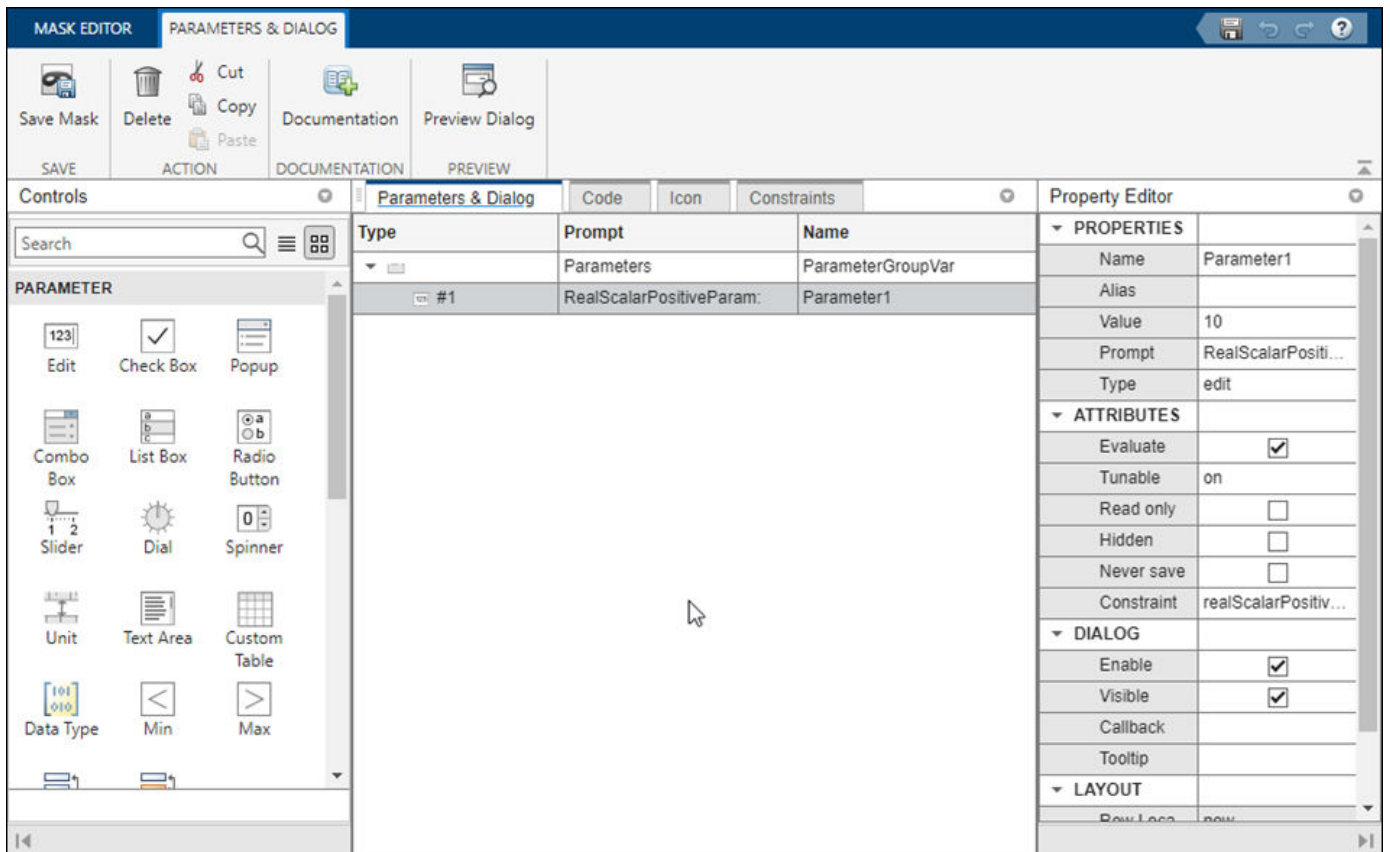

For more details on rule attributes, see “Rule Attributes” on page 42-62.

#### Associate the Constraint to a Mask Parameter

Once a constraint is created, you can associate it with any **Edit** or **Combobox** parameters in the **Mask Editor**.

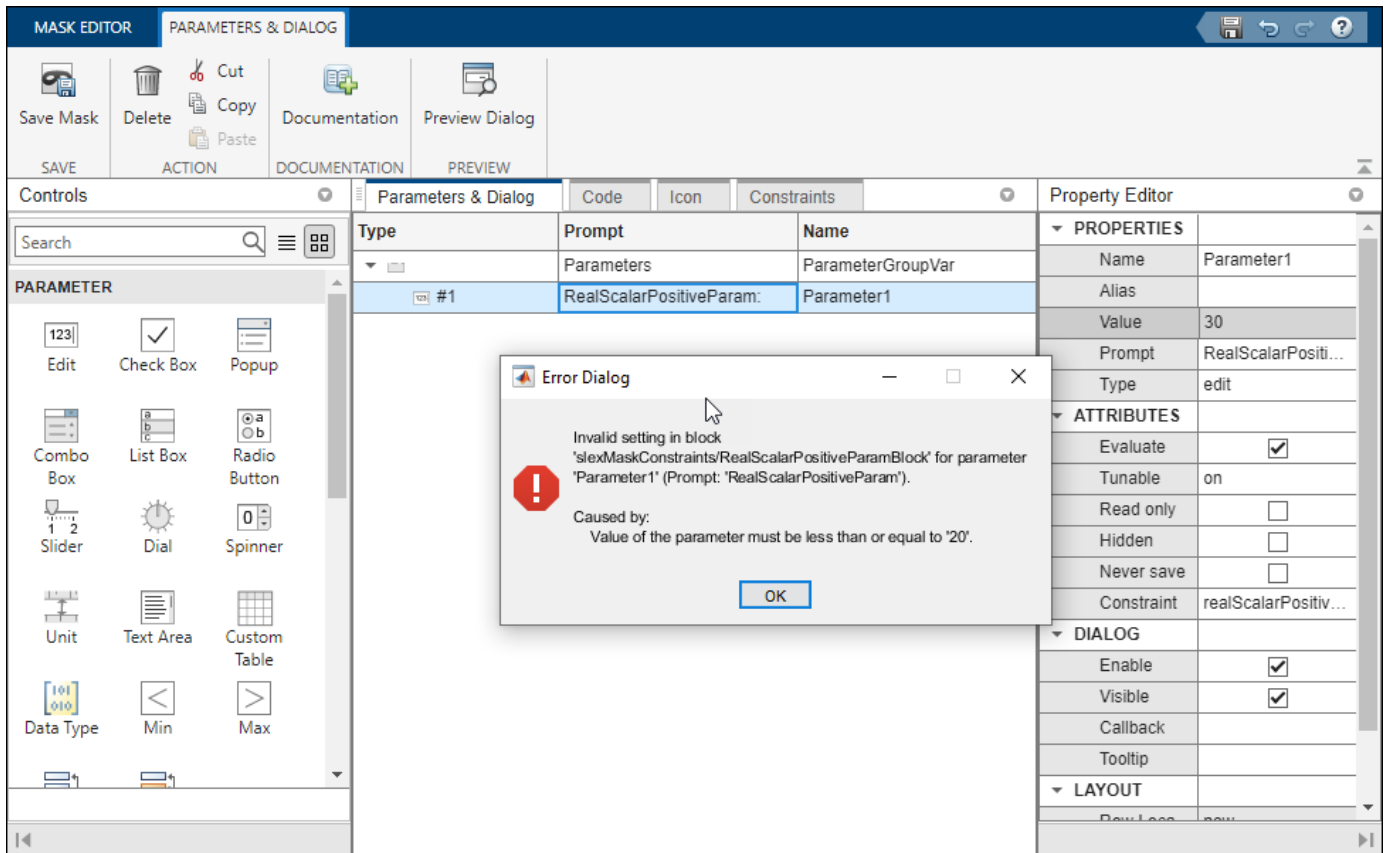

- 1 In the **Mask Editor**, select the parameter you want to associate a constraint with.
- 2 Select the constraint name from the **Constraint** drop-down menu.

### Validate the Constraint

To check if the parameter is in adherence with the associated constraint:

- 1 Select a parameter with a constraint associated with it.
- 2 Provide the input values for the parameter in the Property editor. If the input is outside the specification for the associated constraint, an error displays.

**Note** The parameter callback code gets executed after validating the parameter value against the associated constraint. If the validation fails, the callback code is not executed.

## Create a Cross-Parameter Constraint

Cross-parameter constraints are applied among two or more **Edit** or **Combobox** type mask parameters. You can use a cross parameter constraint when you want to specify scenarios such as, Parameter1 must be greater than Parameter2.

- 1 In the Mask Editor, click **Constraints** tab.
- 2 Click **Cross-Parameter Constraints**.
- 3 Click **Create Constraint**. A new cross-parameter constraint is created with a default name (Constraint\_1). You can change the constraint name.
- 4 Specify the following values for the new constraint:
  - Name - Specify a name for the constraint
  - MATLAB Expression - Specify a valid MATLAB expression. This expression is evaluated during edit time and simulation
  - Error Message - Specify the error message to be displayed when the constraint rule is not met. If no error message is specified, a default error message displays.

## Rule Attributes

Rule attributes to create constraints are shown in the table:

Rule Attribute	Attribute Value	Description
<b>Data type</b>	numeric, double, single, half, int8, uint8, int16, uint16, int32, uint32, int64, uint64 boolean, enum, string	Specify the acceptable data type of the mask parameter value. You can choose multiple data types. To validate the parameter value against a specific range, use the <b>Minimum</b> and <b>Maximum</b> properties because the <b>Data Type</b> property does not validate the parameter value against the range. For example, to validate the parameter value against the data type numeric and range 0 - 127, select numeric in <b>Data Type</b> and enter 0 and 127 in the <b>Minimum</b> and <b>Maximum</b> properties respectively.
<b>Complexity</b>	real, complex	Specify if the mask parameter value can be a real or complex number.
<b>Dimensions</b>	scalar, row vector, column vector, 2-D matrix, n-D matrix	Specify the acceptable dimensions for the mask parameter.
<b>Sign</b>	positive, negative, zero	Specify if the input value must be positive, negative, or zero.
<b>Finiteness</b>	finite, inf, -inf, NaN	Specify the acceptable finiteness of mask parameter value.
<b>Fraction</b>	integer, decimal	Specify if the input value must be an integer or decimal.
<b>Range</b>	Minimum, Maximum	Specify the acceptable range of mask parameter value.
<b>Custom Rule</b>	Valid MATLAB expression	Specify custom constraint for the mask parameter using a valid MATLAB expression. You can use the value token to parameterize the expression. During validation, the evaluated value of the parameter replaces the value token.

Rule Attribute	Attribute Value	Description
<b>Error Message</b>	Character vector	Specify a custom error message for the custom constraint. You can specify the error message as character vector or as a message catalog ID.

- “Share Parameter Constraints Across Multiple Block Masks” on page 42-68
- “Custom Constraint for Mask Parameter” on page 42-64

## Custom Constraint for Mask Parameter

A mask can contain parameters that accept user input values. You can provide input values for mask parameters using the mask dialog box. Mask parameter constraints help you to create validations on a mask parameter without having to write your own validation code. Constraints ensure that input value for the mask parameter satisfies the rules associated with the constraints. For example, consider a masked Subsystem block. You can set a constraint where the input value must be even number. If you provide an input that is not an even number, an error is displayed. If the rule you want specify is not present as one of the attributes, then specify a MATLAB® expression that returns a scalar.

### Explore Model

The example model contains a subsystem block whose block parameters `evenNoParam1` and `evenNoParam2` must be an even number. You have custom the constraint using MATLAB expression as the rule you want to specify is not present as one of the attributes.

```
open_system("slexMaskConstraints.slx");
```

Define and associate constraint to mask edit parameter

Create constraints using the Constraint Manager dialog box in the Mask Editor. Use the Constraint attribute in the Property editor pane of the Mask Editor to associate a constraint to a parameter. In this example, the mask parameter `RealScalarPositiveParam` is associated with the constraint `realScalarPositiveConstraint`. This constraint has attributes `real`, `scalar`, and `positive`. Error is thrown if the parameter value violates any of these attributes.

Single constraint to edit and combobox parameters

You can associate a single constraint with edit and combo box parameters. For combo box parameter, the attribute "Evaluator" must be set before associating a constraint. In this example, `numericConstraint` is associated to `numericParam1` and `numericParam2`. `int8Constraint` is associated to `int8Param1` and `int8Param2`.

Cross parameter constraint

If the validation involves multiple mask parameters, create cross parameter constraint. In this example, "GreaterThanOrConstraint" validates that value of Parameter1 must be greater than Parameter2.

Custom Constraint

Create a custom constraint in the Constraint Manager if the attributes provided does not suite your needs. Create the constraint by providing a MATLAB expression and Error Message(optional) in the Custom Constraint section and associate it with the mask parameter.

If the custom constraint needs to be associated with multiple parameters, you can provide an argument named "value" as a place holder in the MATLAB expression. During constraint validation, this argument is replaced with evaluated value of the parameter.

Error Message accepts these values

- No value is provided- default error message is shown.
- Valid message catalog id- the corresponding message from message catalog is shown.
- String- the same is shown.

In this example, `evenNumberConstraint` is associated to `evenNoParam1` and `evenNoParam2`.

Shared constraint

Create shared constraints to reuse constraints across blocks or models. Use the Constraint manager to create and save the constraints to a mat file present in the MATLAB path. You can browse the mat file and load the constraint using the Constraint attribute in the Property Editor pane of the Mask Editor.

In this example, `realScalarPositiveConstraint` is present in the mat file `sharedConstraint.mat`. This constraint is associated with `RealScalarPositiveParam1` of `SharedConstraintBlock1` and `RealScalarPositiveParam2` of `SharedConstraintBlock2`.

### Create Custom Constraint

In the example model, refer to the Custom Constraint section.

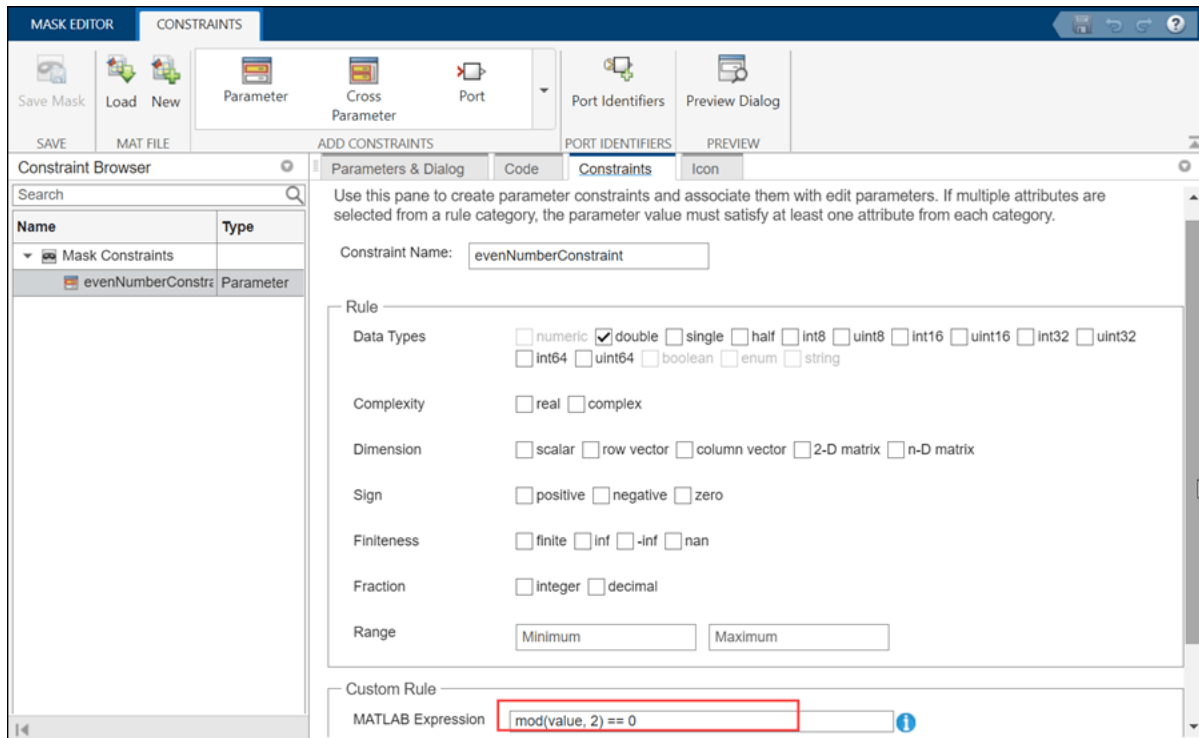

To create a custom constraint:

1. Create a mask on the subsystem block.
2. In the Mask Editor, select **Constraints > Parameter**.
  - i. Enter the name of the constraint as `evenNumberConstraint`.
  - ii. Enter the **MATLAB expression** as `mod(value,2)==0`.

**Note:** You can use the value token to parameterize the expression, which helps in assigning a constraint to multiple parameters. During validation, the evaluated value of the parameter replaces

the value token. For example, if the MATLAB expression for a constraint is `value > 100` and is associated with the edit type mask parameter, `Parameter1`, then the MATLAB expression evaluates as `Parameter1 > 100`. This helps in assigning the constraint to multiple parameters.

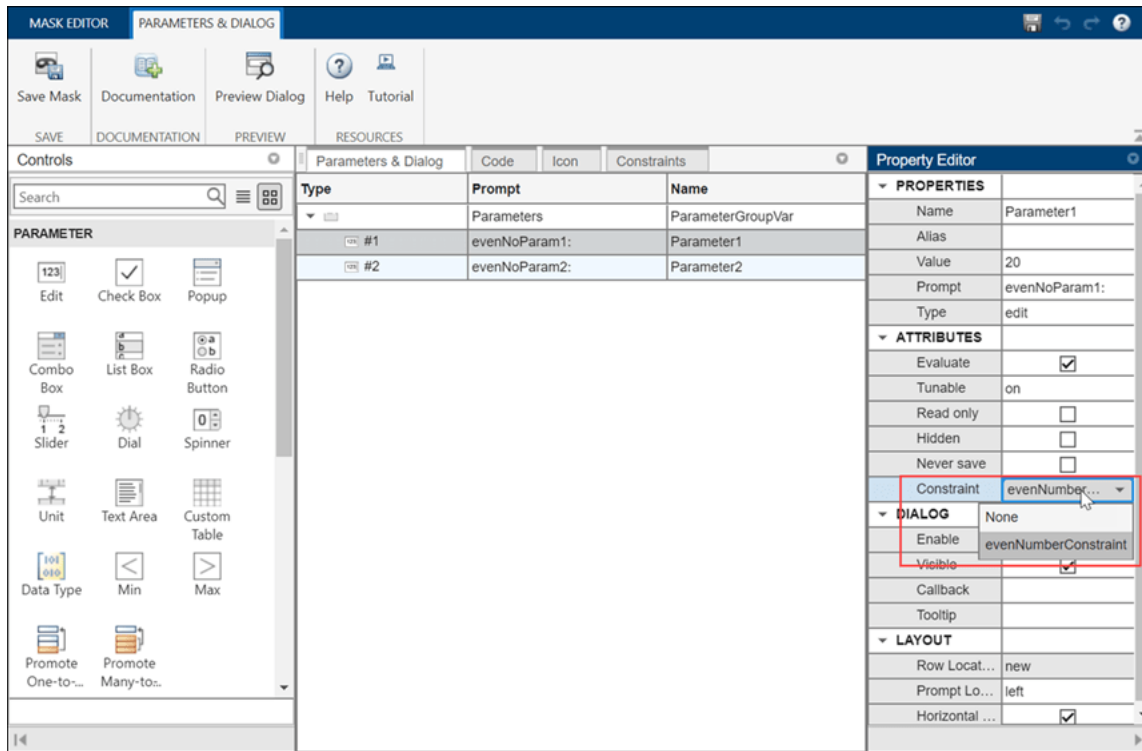

**iii. In Error Message**, enter The value of the parameter must be even number.. Save the mask.

### Associate Custom Constraint to Mask Parameters

You must associate constraints to mask parameters. You can associate the same constraint among multiple mask parameters.

1. In the Mask Editor, click the **Parameters & Dialog** tab.
2. Click the mask parameter.
3. In the **Property Editor**, go to the **Attributes** section, and select the constraint from the **Constraint**.

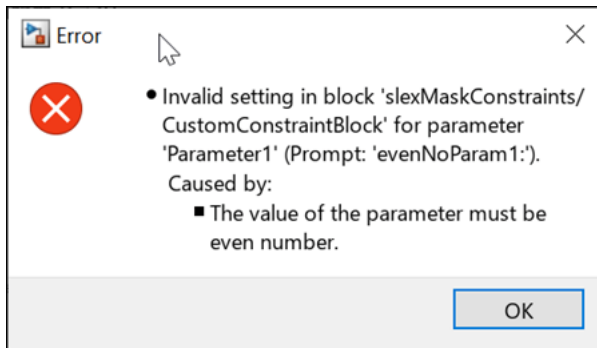

**Note:** You can associate the same constraints with multiple mask parameters. The **Constraints Browser** helps you to manage constraints. If you want to create a constraint that involves multiple parameters, use cross-parameter constraints instead of custom constraints.

### Validate Constraint

To check if a parameter adheres to the associated constraint:

1. Go to the Mask Editor and select the parameter.
2. In the **Property Editor**, provide input values that are outside of the range specified in the associated constraint. An error displays.

- “Validating Mask Parameters Using Constraints” on page 42-59

## Share Parameter Constraints Across Multiple Block Masks

This example shows you how to create a parameter constraint and share it across masks of different blocks in the same model or different models. You can save the parameter constraint in a MAT file and associate the constraint across multiple block masks.

A mask can contain parameters that accept user input values. You can provide input values for mask parameters using the mask dialog box. Mask parameter constraints help you to create validations on a mask parameter without having to write your own validation code. Constraints ensure that input value for the mask parameter satisfies the rules associated with the constraints. For example, consider a masked Subsystem block. You can set a constraint where the input value must be between 1 and 10. If you provide an input that is outside the specified range, an error is displayed. For information on mask parameter constraints, see “Validating Mask Parameters Using Constraints” on page 42-59.

### Explore the Model

This model has two subsystem blocks named `SharedConstraintBlock1` and `SharedConstraintBlock2`. The value of the block parameters on each subsystem block must be a real scalar. Instead of creating separate constraints for these blocks, you can create a single constraint in a MAT file and share it across the two subsystem blocks.

```
open_system("slexMaskConstraints.slx");
```

Define and associate constraint to mask edit parameter

Create constraints using the Constraint Manager dialog box in the Mask Editor. Use the Constraint attribute in the Property editor pane of the Mask Editor to associate a constraint to a parameter. In this example, the mask parameter `RealScalarPositiveParam` is associated with the constraint `realScalarPositiveConstraint`. This constraint has attributes `real`, `scalar`, and `positive`. Error is shown if the parameter value violates any of these attributes.

Custom Constraint

Create a custom constraint in the Constraint Manager if the attributes provided does not suite your needs. Create the constraint by providing a MATLAB expression and Error Message(optional) in the Custom Constraint section and associate it with the mask parameter.  
If the custom constraint needs to be associated with multiple parameters, you can provide an argument named "value" as a place holder in the MATLAB expression. During constraint validation, this argument is replaced with evaluated value of the parameter.  
Error Message accepts these values  
- No value is provided- default error message is shown.  
- Valid message catalog id- the corresponding message from message catalog is shown.  
- String- the same is shown.  
In this example, `evenNumberConstraint` is associated to `evenNoParam1` and `evenNoParam2`.

Single constraint to edit and combobox parameters

You can associate a single constraint with edit and combo box parameters. For combo box parameter, the attribute 'Evaluate' must be set before associating a constraint. In this example, `numericConstraint` is associated to `numericParam1` and `numericParam2`. `int8Constraint` is associated to `int8Param1` and `int8Param2`.

Cross parameter constraint

If the validation involves multiple mask parameters, create cross parameter constraint. In this example, `GreaterThanConstraint` validates that value of Parameter1 must be greater than Parameter2.

Shared constraint

Create shared constraints to reuse constraints across blocks or models. Use the Constraint manager to create and save the constraints to a mat file present in the MATLAB path. You can browse the mat file and load the constraint using the Constraint attribute in the Property Editor pane of the Mask Editor.

In this example, `realScalarPositiveConstraint` is present in the mat file `sharedConstraint.mat`. This constraint is associated with `RealScalarPositiveParam1` of `SharedConstraintBlock1` and `RealScalarPositiveParam2` of `SharedConstraintBlock2`.

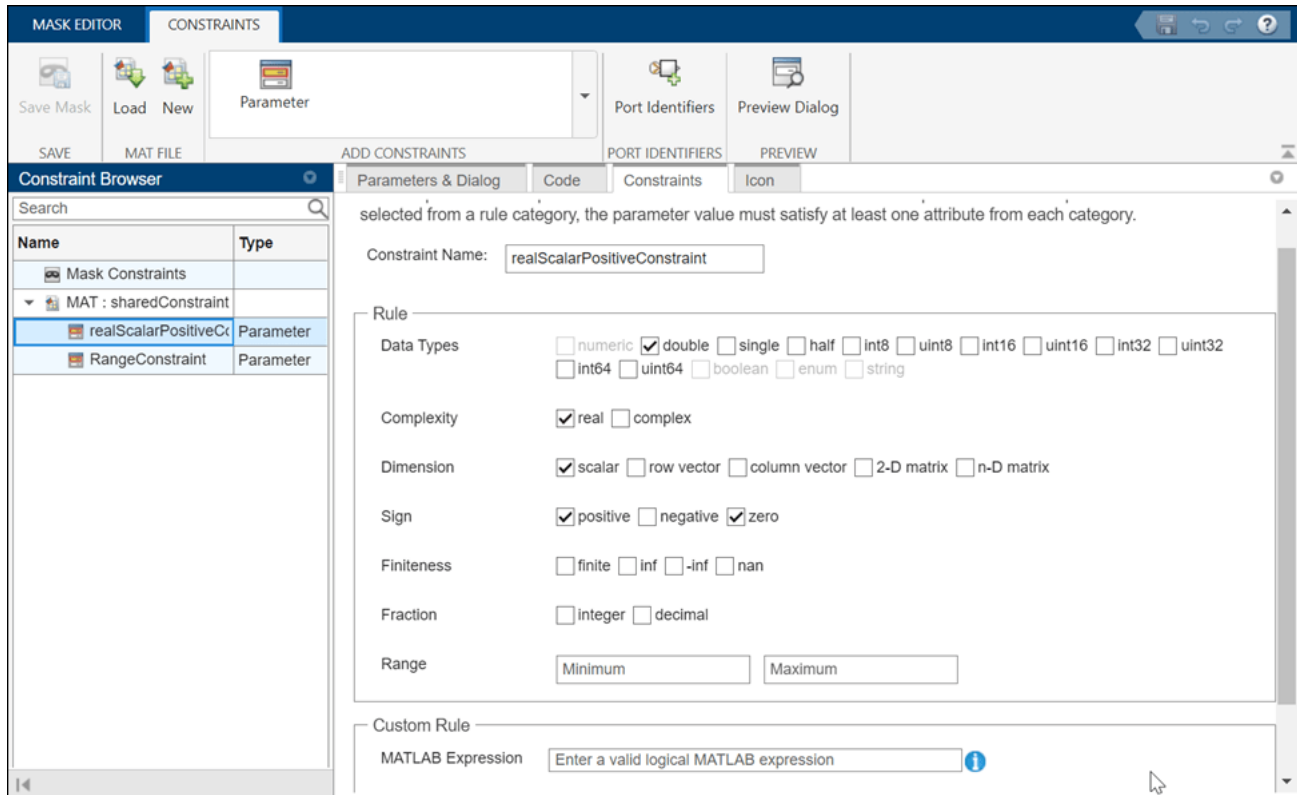

### Create Shared Constraint

In the example model, refer the shared constraint blocks `SharedConstraintBlock1` and `SharedConstraintBlock2`

To create a shared constraint:

1. Create a mask on the `SharedConstraintBlock1` block.
2. Go to **Mask Editor** and click the **Constraints** tab.
  - i. Click **New** and enter the name for the MAT file as shared.

ii. Now, create the parameter constraint in the MAT file. Click **Parameter Constraint** and specify the attributes for the constraint. The **Constraint Browser** helps you to manage shared constraint.

iii. Go to the **Parameters & Dialog** tab and click the parameter on which the constraint needs to be applied.

iv. Go to **Property Editor > Attributes > Constraint** and select the MAT file constraint.

### Associate Constraint Across Multiple Blocks or Models

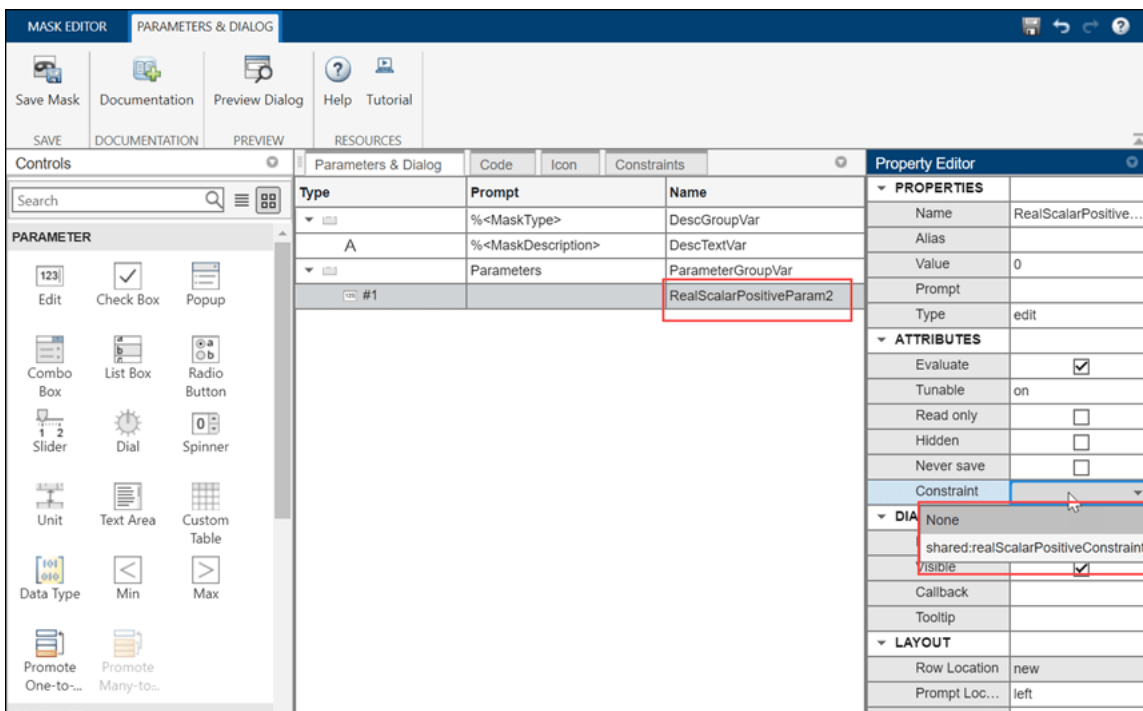

To reuse the constraint `shared:realScalarPositiveConstraint` in the `SharedConstraintBlock2` block:

1. Create a mask on the `SharedConstraintBlock2` block.
2. To load the constraint, go to **Mask Editor > Constraint > Load**. Select the MAT file and save the mask.

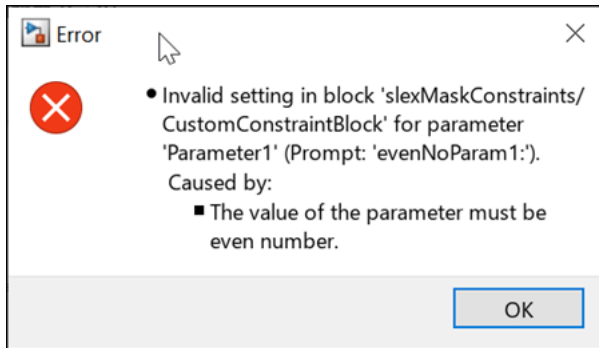

3. Go to the **Parameters & Dialog** tab and click the parameter.

4. Go to **Property Editor > Attributes > Constraints** and select the MAT file.

### Validate the Constraint

Provide an invalid value to the parameter using mask dialog. Observe that an error dialog is displayed on Apply.

## Control Constraints Programmatically

You can create a custom constraint programmatically from the MATLAB command window

To create a custom constraint:

```
% Get mask constraint handle
paramConstraint = maskObj.getParameterConstraint('const1');

% Add rules to the constraint.
paramConstRule = paramConstraint.addParameterConstraintRule('CustomConstraint','mod(value,2) ==0')
```

This creates a custom constraint:

ans =

ParameterConstraintRules with properties:

```
    DataType: ''
    Dimension: {0x1 cell}
    Complexity: {0x1 cell}
        Sign: {0x1 cell}
    Finiteness: {0x1 cell}
        Minimum: ''
        Maximum: ''
    CustomConstraint: 'mod(value,2) ==0'
```

You can create and save constraints in a MAT file and load constraints from a MAT file programmatically from the MATLAB command window:

To save a constraint in a MAT file:

```
uint16Constraint = Simulink.Mask.Constraints;
uint16Constraint.Name = 'uint16Constraint';
uint16Constraint.addParameterConstraintRule('DataType', 'uint16');
save('constraintList.mat', 'uint16Constraint','-append'); % appends 'uint16Constraint'
save('constraintList.mat', 'uint16Constraint') % overwrites the MAT file with 'uint16Constraint'
```

---

**Note** It is recommended that the constraint name (for example, `uint16Constraint.Name = 'uint16Constraint'`) and the variable used for storing the constraint (for example, `uint16Constraint = Simulink.Mask.Constraints`) have the same name.

---

To load a constraint from a MAT file:

```
myConstraints = load('constraintList') % loads constraints into the variable 'myConstraints'
```

## Define Measurement Units for Masked Blocks

Measurement units translate the amount of entities supplied to your computations. They are also crucial when diverse users using different systems of measurement are using the same equation. You can add measuring units to a Simulink model to enhance the usability and to avoid confusion while analyzing equations.

To specify measuring units for masked blocks, you can:

- Promote a `Unit` parameter from the underlying block to the mask. For more information, see “Promote Block Parameters on a Mask” on page 42-22.
- Add a **Unit** parameter to the mask dialog box as shown in the following steps:
  - 1 Open a Simulink Model.
  - 2 Select the block to be masked and press **Ctrl+M**. The Mask Editor opens.
  - 3 In the Mask Editor, click the **Parameters & Dialog** tab.
  - 4 In the Parameters section, click **Unit**.
  - 5 Click the **Code** tab in the Mask Editor dialog box.
  - 6 To define the measurement unit for the **Unit** parameter, specify the initialization command by using the following syntax:

```
set_param([gcb '/<blockname>'], '<unit parameter name>', get_param(gcb, '<unit parameter name>'));
```

For example, to associate the **Unit** parameter with the measuring unit of the Inport block, use:

```
set_param([gcb '/In1'], 'Unit', get_param(gcb, 'Unit'));
```

For more information, see `slexMaskParameterOptionsExample`.

## Create a Custom Table in the Mask Dialog

This example shows how to create a custom table in a mask dialog. This model includes a Subsystem block with a mask on it. The mask has a callback that modifies the table content based on the values provided in the cells. The callback comes from an external supporting file. To create this table, start by adding a mask to the block or editing an existing mask.

### Add and Configure a Custom Table parameter

To add a Custom Table parameter, open the Mask Editor, go to the **Parameters & Dialog** tab and click **Custom Table**. Then, add values in the **Property editor** section. For this example, in the **Value** field, add:

```
{ 'sig1', 'Input', 'Inherit', 'Inherit', 'Signed', 'Inherit'; 'sig2',
'Input', 'Inherit', 'Inherit', 'Signed', 'Inherit'; 'sig3', 'Output', '10',
'Inherit', 'Signed', 'Inherit'; 'sig4', 'Output', '10', 'Inherit', 'Signed',
'Inherit' }.
```

In the **Columns** field, click the Edit icon and add the name of columns. The column names used in this example are: HDL Name, I/O Mode, Sample Time, Data Type, Sign, and Fraction Length.

In the **Dialog** section, edit the **Callback** field to add your callback. The callback used in this example is from an external file named `CustomTableCallback.m`. Enter the filename in the callback field. This callback defines how the values change in a cell based on the value from other cells and columns.

The screenshot shows the Mask Editor interface with the 'PARAMETERS & DIALOG' tab selected. The main workspace displays a table with the following data:

Type	Prompt	Name
	Simulink and Incisive Cosim...	DescGroupVar
A	Cosimulate hardware compo...	DescTextVar
	Parameters	ParameterGroupVar
	(N/A)	Container3
	Ports	Container4
<input checked="" type="checkbox"/> #1	Enable direct feedthrough	Checkbox
A	If this block is in a feedback l...	Control2
	Auto Fill	Control3
A	Use the 'Auto Fill' button to a...	Control4
	(N/A)	Container9
A		Control9
	New	Control5
	Delete	Control6
	Up	Control7
	Down	Control8
A		Control10
	(N/A)	Container10
	#2	CustomTable
	Clocks	Container5
	Timescales	Container6

The Property Editor on the right shows the following settings for the selected 'CustomTable' parameter:

PROPERTIES	
Name	ParameterGroupVar
Prompt	Parameters
Type	group
DIALOG	
Enable	<input checked="" type="checkbox"/>
Visible	<input checked="" type="checkbox"/>
LAYOUT	
Row Location	new
Align Prompts	<input type="checkbox"/>

### Add Buttons and Options to Control the Custom Table

In this example, four buttons are added to add a new row, delete a selected row, and move a row up or down. To add the buttons, in the **Action** section click the Button parameter four times. Name the buttons as **New**, **Delete**, **Up**, and **Down**. To configure the buttons, edit the **Callback** field in the Property editor and add the appropriate callbacks. The callback used for each button is:

#### New

```
maskObj = Simulink.Mask.get(gcf);
tableControl = maskObj.getDialogControl( 'CustomTable' );

hdlName = 'sig';
rowIndex = tableControl.getNumberOfRows();
hdlName = strcat( 'sig', num2str( rowIndex + 1 ) );
tableControl.addRow( hdlName, 'Input', 'Inherit', 'Inherit', 'Signed', 'Inherit' )
```

#### Delete

```
maskObj = Simulink.Mask.get(gcf);
tableControl = maskObj.getDialogControl( 'CustomTable' );

rowIndex = tableControl.getSelectedRows();
hdlName = 'sig';

if ( ~isempty(rowIndex) )
    tableControl.removeRow( rowIndex(1) );
end
```

#### Up

```
maskObj = Simulink.Mask.get(gcf);
tableControl = maskObj.getDialogControl( 'CustomTable' );

rowIndex = tableControl.getSelectedRows();

if ( ~isempty(rowIndex) )
    tableControl.swapRows( rowIndex(1)-1, rowIndex(1) );
end
```

#### Down

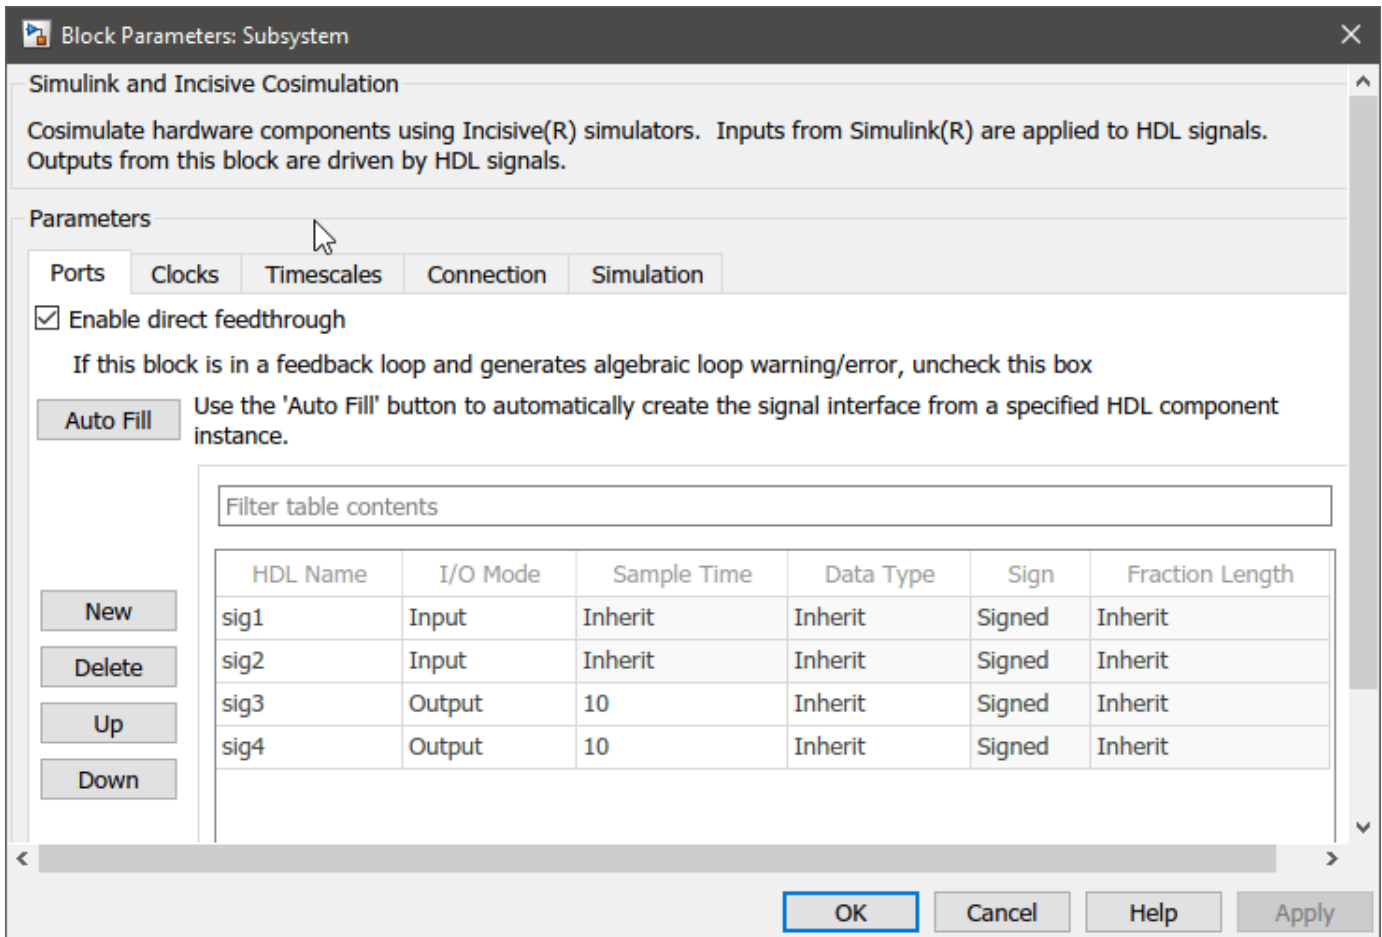

```
maskObj = Simulink.Mask.get(gcf);
tableControl = maskObj.getDialogControl( 'CustomTable' );

rowIndex = tableControl.getSelectedRows();

if ( ~isempty(rowIndex) )
    tableControl.swapRows( rowIndex(1)+1, rowIndex(1) );
end
```

In addition to these buttons, the table also has a check box to enable direct feedthrough and an autofill button that automatically creates the signal interface from a specified HDL component instance. To add these options, add a check box and a button control and add the appropriate configurations.

After adding all the values, click **OK** to save the changes. You can preview the table using the **Preview** button. This is a preview of the final table created in this example:

## Create a Block Mask Icon

You can create block icons on mask using various mask drawing commands. This model contains a collection of subsystem blocks, each showing a particular mask drawing command in use. To create a mask icon on a block, you must create a mask and add the icon drawing command to the mask in the mask editor. To create a mask:

- 1 Select a **Subsystem block** . For example, the Graph as Icon block.
- 2 On the **Subsystem Block** tab, in the **Mask** group, click **Create Mask/Edit Mask**.
- 3 In the Mask Editor dialog box, click the **Icon & Ports** tab.
- 4 Enter the command in the Icon drawing commands pane on the right. You can set the Run Initialization value to On, Off or Analyze based on the dependency on mask workspace.

### Plotted function as Icon

This command let you plot a graph and set it as the mask icon. Select the subsystem Graph as Icon. In the Mask Editor > Icon and Ports tab, enter **plot([10 20 30 40], [10 20 10 15])**. Run Initialization can be set to Off as there is no mask workspace dependency.

### Transfer Function as Icon

This command helps to set a Transfer function as the mask icon. Select the subsystem Transfer Function as Icon. In the Mask Editor > Icon and Ports tab, enter **droots([-1], [-4 -5], 4)**. Run Initialization can be set to Off as there is no mask workspace dependency.

### Color patch as Icon

This command lets you to set a color patch as mask icon. Select the subsystem Color patch as Icon. In the Mask Editor > Icon and Ports tab, enter **patch([0 10 20 30 30 0], [10 30 20 25 10 10],[1 0 0])**. Run Initialization can be set to Off as there is no mask workspace dependency.

### Image as Icon

This command lets you to set a color patch as mask icon. Select the subsystem Image as Icon. In the Mask Editor > Icon and Ports tab, enter **image('maskimage.png','center')**. Run Initialization is set to On. Make sure the image is available in the current folder in MATLAB.

### Contained block icon as Icon

This command lets you promote the icon of a block contained in a subsystem to the subsystem mask. Select the subsystem Promoted block Icon . In the Mask Editor > Icon and Ports tab, enter **block\_icon(Assertion)**.

```
open_system('mask_icon_drawing_example');
```

# Mask Icon Drawing Commands

Plotted Function as Icon

Port Label as icon

Transfer Function as Icon

Contained block icon as Icon

Color Patch as Icon

Image as Icon

## Promote Block Parameters on a Mask

Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. You can promote any underlying parameter of a block either to a block mask or to a subsystem mask. For any subsystem, you have a single view of all the nested blocks, the block parameters, and internal parameters. You can click on any node to access any promotable parameter within the nested blocks. By promoting parameters from the block dialog box to the mask you can:

- Customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- Reuse a library block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each block.
- Simplify the interface and specify the parameters that the user of the block can view and set.

These options are available for promoting parameters:

**Promote One-to-One:** Use this option on the Mask Editor for one-to-one correspondence between the block parameter and the mask parameter. For each block parameter, one mask parameter is created. For example, consider the block dialog box of the **Gain** block, which has parameters such as **Gain**, **Multiplication**. To expose only the **Gain** parameter, mask the **Gain** block and promote the **Gain** parameter to the mask dialog box.

**Promote Many-to-One:** Use this option to create a many-to-one correspondence between the block parameter and the mask parameter. You can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single parameter on your mask.

### Note:

- If the parameter is of data type popup or `DataType`, the options must also be the same for the parameters to be promoted.
- The `Evaluate` attribute must be the same for all the promoted parameters.
- You can also change the attributes of a promoted parameter. For example, you can make a promoted parameter read-only or hidden. For more information on attributes, see “Property editor”.

### Explore the Model

The model contains two subsystem blocks: one for promoting on-to-one parameters, `Selective Promotion of Parameters` and one for promoting many to one parameters, `Promote Many to One`.

## Parameter Promotion

This subsystem comprises 3 gain blocks sharing a common gain value. For this, 3 gain parameters of the underlying gain blocks are promoted as a single parameter on the subsystem mask.

This subsystem comprises 3 gain blocks. However, the value of one of the gain blocks is fixed for all possible configurations. To simplify the user interface, the parameters of the variable gain blocks are promoted to the mask and the parameter of the static gain block is set in the mask initialization.

Copyright 2012 The MathWorks, Inc.

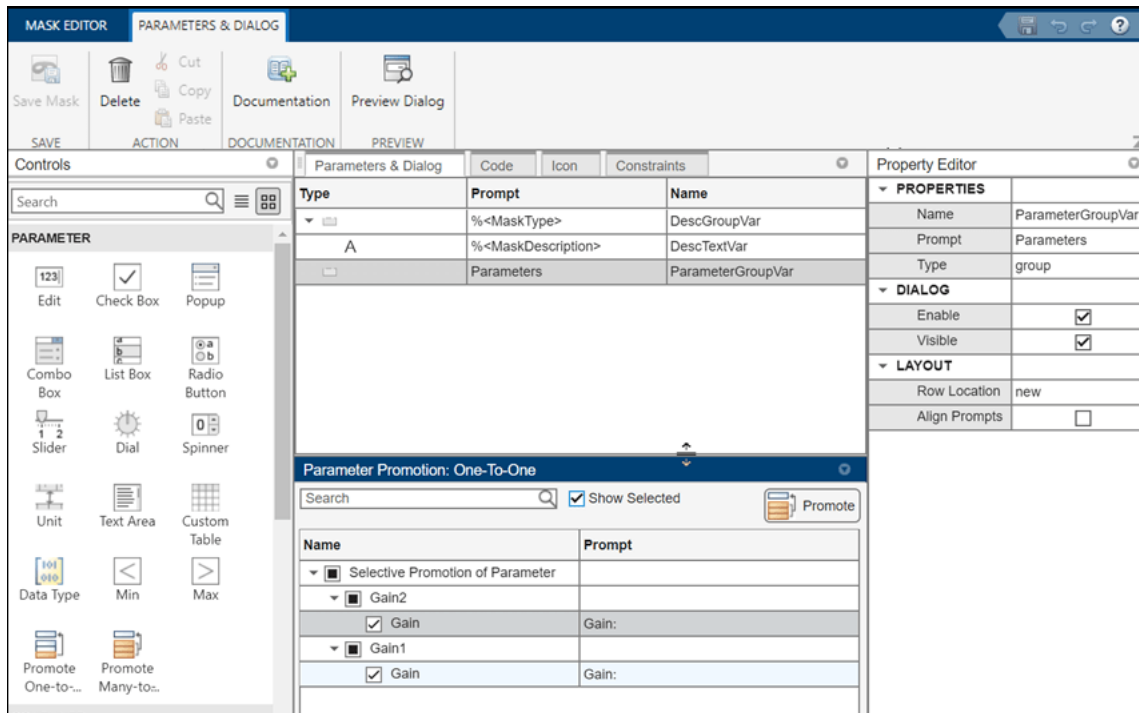

### Promote One-to-One

You can create an one-to-one correspondence for each underlying block parameters and the mask parameter.

Consider the model containing the subsystem **Selective Promotion of Parameters**, which contains three **Gain** blocks. The value of one of the **Gain** blocks is fixed. To simplify the user interface, the parameters of the variable **Gain** blocks are promoted to the mask.

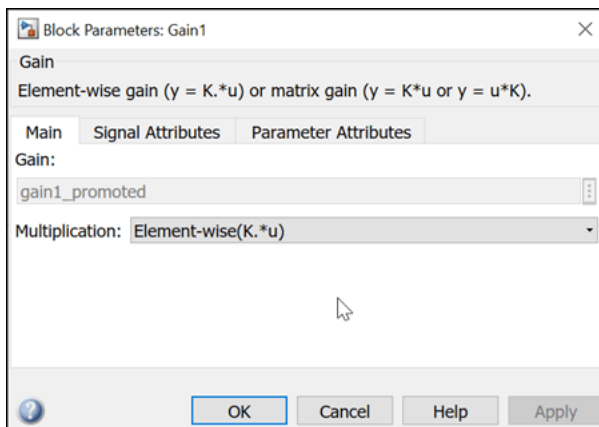

To promote the parameters:

1. Go to **Mask Editor > Parameters & Dialog > Parameter > Promote One-to-One**.
2. Select the variable **Gain** parameters **Gain** and **Gain1**, then click **Promote**.

**Note:** You can modify the prompt of the promoted parameter.

3. Save the mask and simulate the model. Note that the value of the Gain1 block is taken from the mask parameter gain1\_promoted.

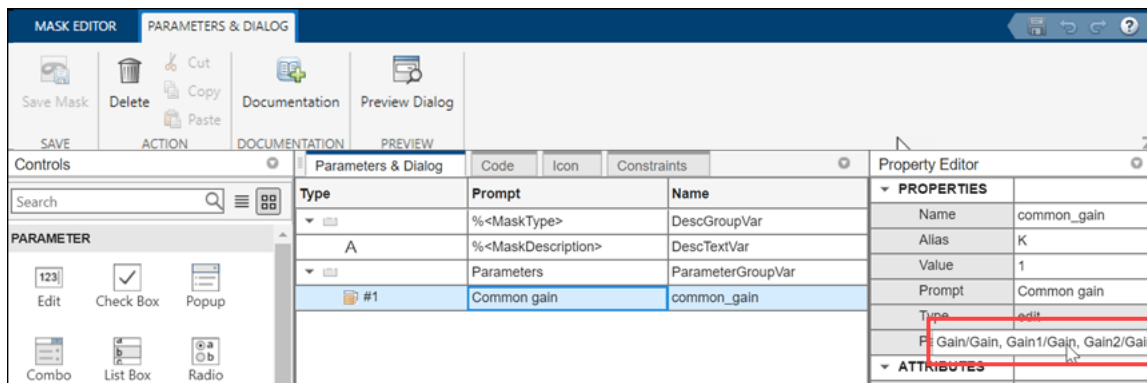

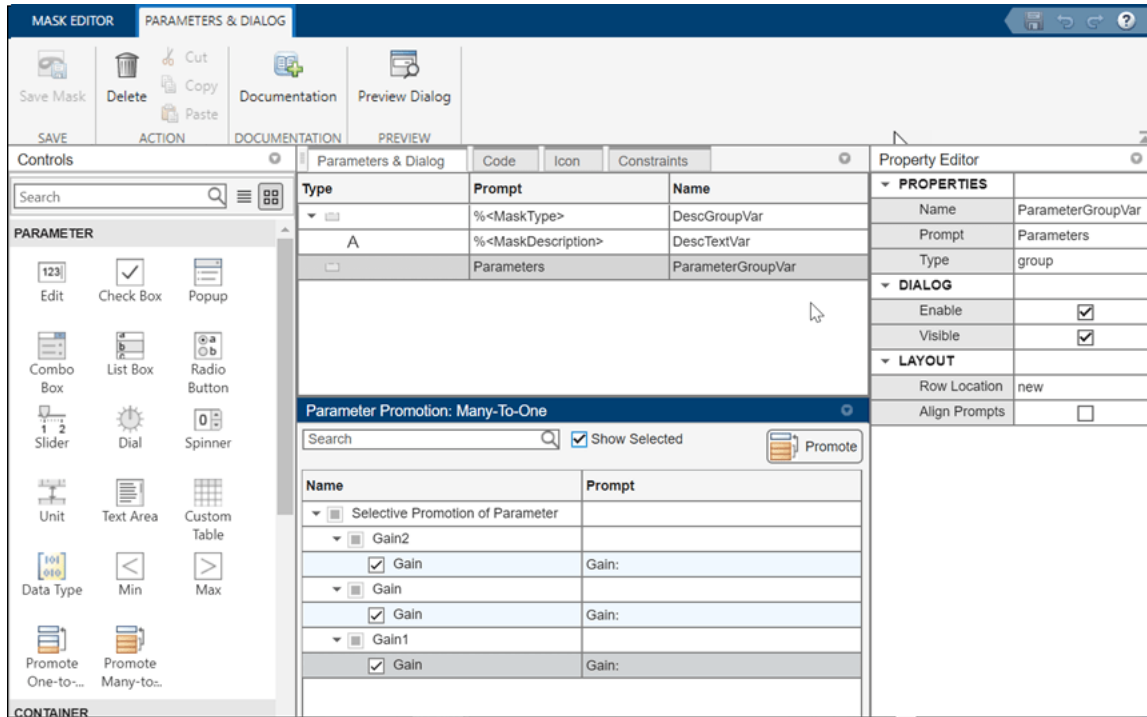

4. Simulate the model. Notice that the value of the Gain3 block is fixed and set in the initialization. The variable **Gain** parameters appear in the mask dialog box.

### Promote Many-to-One

Use the option **Promote-Many-to-One** in the Mask Editor to promote multiple block parameters to a single mask parameter. For example, this model contains a subsystem named Promote Many to One that has three **Gain** blocks ( **Gain1**, **Gain2**, and **Gain3** ). The variable K represents the **Gain** parameter for these **Gain** blocks. You can promote only the **Gain** parameter of each of these **Gain** blocks to the block mask as a single parameter. When you do so, the parameter K is available on the mask for editing, and its value will be applied to **Gain1**, **Gain2**, and **Gain3** blocks.

1. Go to **Mask Editor > Parameters & Dialog > Promote-Many-to-One**.
2. Select the **Gain** parameters Gain1, Gain2, and Gain3.
3. Click **Promote**.

4. Simulate the model. Notice that the value 4 is passed from the mask to the underlying blocks **Gain1**, **Gain2**, and **Gain3**. In this case, the output shows 64.

## Mask a Variant Subsystem

This example shows how to use a masked Variant Subsystem block in a Simulink model. Click the **Open Model** button located on the top right corner to view the related example model. This example model references masked library blocks.

### Masking a Variants Subsystem

This model contains masked Subsystem block (MaskedSubsystem) as a linked block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code in the Variant Subsystem block mask sets the variant choice that is passed from the Subsystem block (MaskedSubsystem). Parameter promotion is used to record the variant choice (V1 & V2) on the masked Subsystem block.

This model contains a masked Variant Subsystem (VariantSubsystem2) as a linked block. Initialization code in the mask sets the variant choice that is passed from the mask. Popup mask parameter is used to record variant choice V1 and V2.

This model contains a Subsystem block (Subsystem3) as a linked block. This block contains linked Variant Subsystem block nested within, in two levels. lv1\_1 and lv1\_2 are the variant choices of first level nested Variant Subsystem block and lv2\_1 and lv2\_2 are the variant choices of second level nested Variant Subsystem block. Popup mask parameter is used to record variant choices lv1\_1, lv1\_2, lv2\_1, and lv2\_2.

This model contains masked Subsystem block (MaskedSubsystem1) as a linked block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code in the Variant Subsystem block mask sets the parameter value that is passed from the Subsystem block (MaskedSubsystem1). Parameter promotion is used to record the choice from the parent block on the masked Subsystem block.

Copyright 2015 - 2022 The MathWorks, Inc.

When you mask a Variant Subsystem block, you can specify the variant choice from the mask dialog box. The variant choice that you specify on the mask dialog box is applied on the underneath Variant Subsystem block.

To pass the variant choice from the mask to the Variant Subsystem block, you can either use the `set_param` command or the parameter promotion option.

Let us consider the cases described in the example model.

- Case 1: The mask parameter promotion option is used to promote the Variant Subsystem block parameter to the mask. The Variant Subsystem block is wrapped within a masked Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice which is further passed on to the mask on the Subsystem block using parameter promotion. This promoted parameter records the variant choice specified from the masked Subsystem block.
- Case 2: The Popup mask parameter is used to create the choice option on the top level masked Subsystem block. This masked Subsystem block contains a Variant Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice. The value that you specify as a variant choice from the mask dialog box (**Popup** parameter) is transferred to the underneath Variant Subsystem block to set its choices.
- Case 3: This case is similar to Case 2 with an additional layer of Variant Subsystem block in the model. Initialization code (`set_param`) in the Subsystem block is used to define the variant choice.
- Case 4: Parameter promotion is used to record the choice from the parent block on the masked Subsystem block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code (`set_param`) in the Variant Subsystem block mask sets the parameter value that is passed from the Subsystem block (MaskedSubsystem1).

## Tune Mask Popup Parameters by Referencing an External Enumeration File

You can visualize the behavior of a Simulink® model under different conditions by tuning block parameter values. This example shows how to associate values with popup parameters and achieve code generation time tunability. Referencing an external enumeration file to tune a mask popup parameter allows you to:

- Associate numeric values with the popup options.
- Associate a variable with the popup parameter.
- Simulate and generate code corresponding to the selected popup option.

Consider this example where a subsystem containing a Constant block is connected to an output port.

### Associate External Enumeration File to Popup Parameter

An external enumeration file can have multiple members with different display names and values. When the enumeration file is associated with a popup parameter:

- The display name of the enumeration member becomes the popup parameter option.
- The enumeration member value becomes the value assigned to the popup parameter.

In this example, numeric values are associated with pop-up options from the enumerated file `Xfactor.m`. The enumeration class of the file `Xfactor`, is derived from `Simulink.Mask.EnumerationBase`. The class has three enumeration members, `alpha`, `beta`, and `gamma`. These enumerated members have numeric values `.001`, `.0001`, and `.00001`.

```

classdef XFactor < Simulink.Mask.EnumerationBase
    enumeration
        alpha(.001, 'alpha (.001)')
        beta (.0001, 'beta (.0001)')
        gamma(.00001, 'gamma (.00001)')
    end
end

```

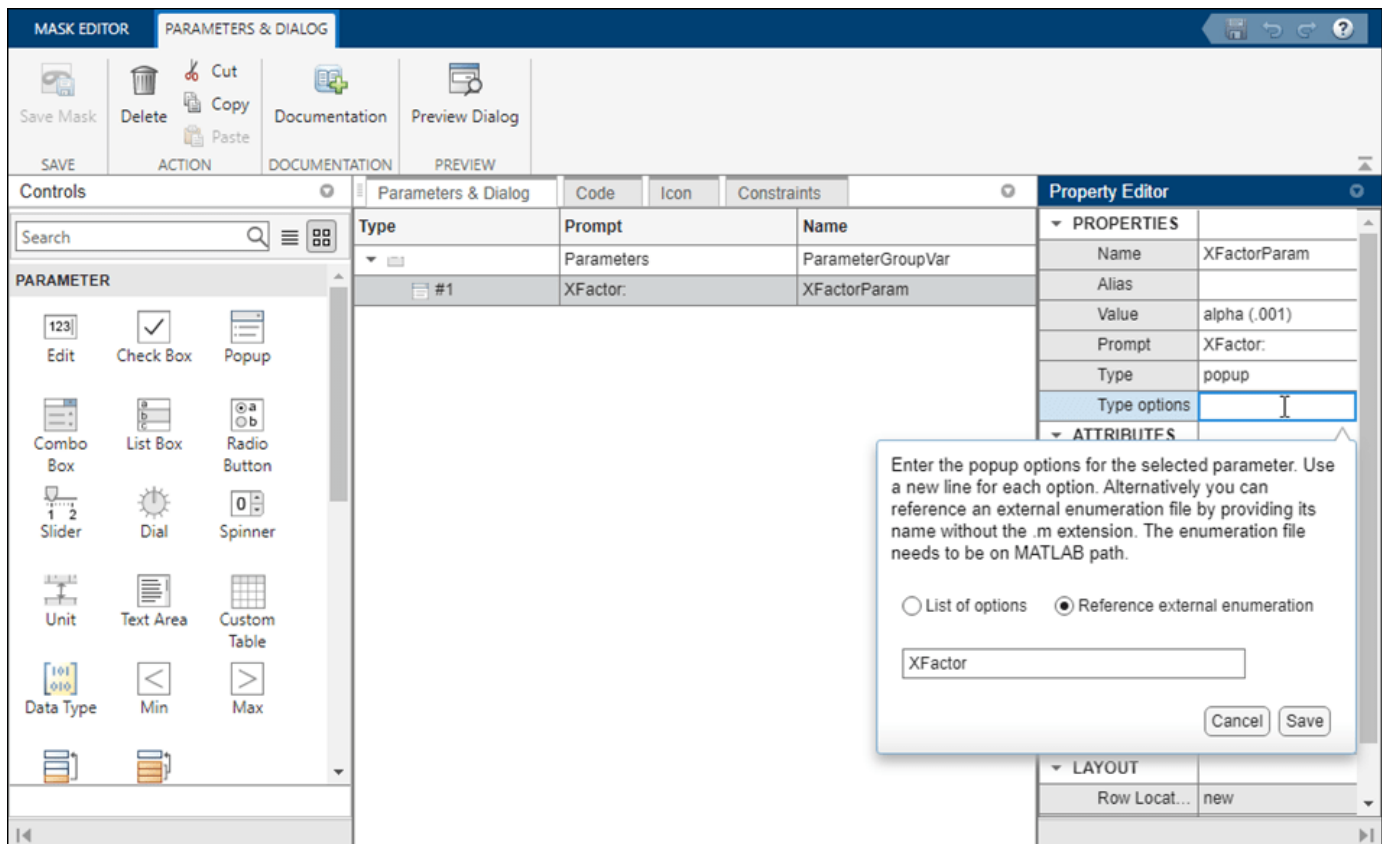

### Specify data type for numerical values associated with the enumeration member

In the generated code, the default data type for the enumeration member is double. Alternatively, you can also specify a data type for the enumeration members. For example, `alpha(int32(0.001), 'alpha (.001)')`. All members of the enumeration class must be of the same data type.

### Associate Numeric Values to Popup Parameter Options

1. In the Mask Editor of the Tunable Popup Subsystem block, create a popup parameter named XFactorParam.
2. In the **Property editor**, select the **Reference external enumeration** option and specify the name of the enumeration class that was created in the previous step. In this example, the name of the enumeration class is Xfactor.

**Note:** The referencing enumeration class Xfactor must be in the MATLAB® path.

Upon referencing the enumeration class file, the options for the popup parameter in the mask dialog box of the Subsystem block are populated with the display names in the enumeration file.

### Reference the Popup Parameter in Child Blocks

The parameter value is evaluated as the enumeration member corresponding to the display name you select. For example, if you select `alpha(.0001)` from the Parameters drop-down, the value of `XFactorParam` is set to `XFactor.alpha`. During model compilation, in order to get the numeric value corresponding to an option, Simulink creates an internal array that holds the value corresponding to each option. Therefore, when you select an option, the value corresponding to the option is selected from the array.

In this example, the array appears `XFactorValues = {.001, .0001, .00001}`

**Note:** To get the value corresponding to the selected option, use this format:

```
<enumerationClassName>Values(<ParameterName>)
```

`enumerationClassName` is the name of the enumeration class, and `ParameterName` is the name of the pop-up parameter that you specified in the mask editor.

In this example, the value of the **Constant** parameter inside the subsystem is set as `XFactorValues(XFactorParam)`. During model compilation, `XFactorValues(XFactorParam)` evaluates to `XFactorValues(XFactor.alpha)`, thus setting the value of the **Constant** parameter to `.001`.

You can customize a name for the array in the enumeration file as the return value of the `getValueArrayName()` function.

```
classdef XFactor < Simulink.Mask.EnumerationBase
    enumeration
        alpha(.001, 'alpha (.001)')
        beta (.0001, 'beta (.0001)')
```

```

        gamma(.00001, 'gamma (.00001)')
    end
    methods(Static)
        function valueArrayName = getValueArrayName()
            valueArrayName = 'customValueArrayName';
        end
    end
end
end

```

### Tune Parameter During Simulation and Code Generation

Change the value of the parameter in the dialog between alpha (0.001), beta (0.0001), and gamma (0.00001) and observe that during simulation, the value corresponding to the selected option appears as the output of the simulation.

You can generate code using Simulink Coder or Embedded Coder™. In the generated code:

- The value array XFactorValues is generated in the modelName.c file.

```
const real_T XFactorValues[3] = { 0.001, 0.0001, 1.0E-5 } ;
```

- Enumeration is generated in the code corresponding to the referenced enumeration file.

```
typedef enum {
XFactor_alpha = 1,           /* Default value */
XFactor_beta,
XFactor_gamma
} XFactor;
```

- The mask parameter (XFactorParam) appears in the parameter structure.

```
/* Parameters (default storage) */
struct P_slexMaskTunablePopupExample_T_ {
XFactor TunablePopup_XFactorParam; /* Mask Parameter: TunablePopup_XFactorParam
* Referenced by: '<S1>/Constant'
*/
};
```

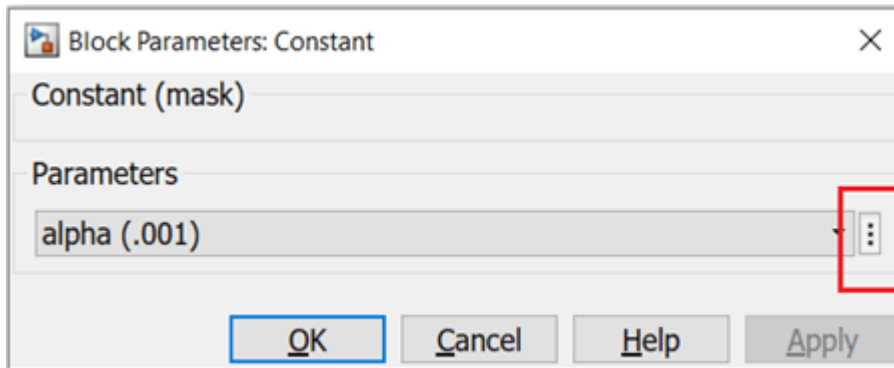

- Tunable variable XFactorParam is referenced while generating the output. You can specify different values to XFactorParam and thus tunability is achieved.

```
/* Model step function */
void slexMaskTunablePopupExample_step(void)
{
/* Output: '<Root>/Out1' incorporates:
* Constant: '<S1>/Constant'
*/
slexMaskTunablePopupExample_Y.Out1 = XFactorValues[(int32_T)
slexMaskTunablePopupExample_P.TunablePopup_XFactorParam - 1];
}
```

## Create and Associate Variables Using the Mask Dialog

When the default parameter behavior in the code generation optimization is inlined, all the parameters are inlined in the generated code. To achieve tunability for a specific parameter, create a variable of type `Simulink.Parameter` with specific storage class (anything other than `Auto`) in the workspace and associate with the mask popup parameter.

1. Open the mask dialog. Click the action widget (...).

2. You can associate an existing variable with the popup parameter or create the variable in one of the available locations and associate with the popup parameter.

After associating the variable with the popup parameter, the variable appears next to the popup option.

The value of the associated variable and the pop-up value are always synchronized. For example, if you change the popup option from `alpha (.001)` to `beta (.0001)`, the `workspaceVar` is updated to `XFactor.beta`. Similarly, when you change the value of the variable, the value of the parameter reflects the change in the mask dialog.

## Generate Code With the Associated Variable

The associated variable value appears in the parameter structure corresponding to the tunable popup parameter.

```
/* Block parameters (default storage) */
P_slexMaskTunablePopupExample_T slexMaskTunablePopupExample_P = {
```

```

/* Variable: workspaceVar
 * Referenced by: '<S2>/Constant'
 */
XFactor_alpha,
};

```

The associated variable is referenced in the step function to generate output.

```

/* Model step function */
void slexMaskTunablePopupExample_step(void)
{
    /* Outport: '<Root>/Out2' incorporates:
     * Constant: '<S2>/Constant'
     */
    slexMaskTunablePopupExample_Y.Out2 = XFactorValues[(int32_T)
        slexMaskTunablePopupExample_P.workspaceVar - 1];
}

```

### Use APIs to Reference External Enumeration File

Create a type option object using this API.

```

enumObj =
Simulink.Mask.EnumerationTypeOptions(ExternalEnumerationClass,
'<enumName>')

```

Create an instance of `Simulink.Mask.EnumerationTypeOptions` to parse the information from the enumeration file into the object `enumObj`.

Example

```

>> enumObj = Simulink.Mask.EnumerationTypeOptions('ExternalEnumerationClass', 'XFactor')

enumObj =
    EnumerationTypeOptions with properties:
        ExternalEnumerationClass: 'XFactor'
        EnumerationMembers: [1*3 Simulink.Mask.EnumerationMembers]

>> enumObj.EnumerationMembers(1)

ans =
    EnumerationMembers with properties:
        MemberName: 'alpha'
        DescriptiveName: 'alpha (.001)'
        Value: 0.001

```

Associate the enum object with the **Type Options** attribute.

```

maskobj = Simulink.Mask.create(<blockName>);
maskobj.addParameter('Type','popup','TypeOptions', enumObj );

```

If a mask parameter already exists, use the these APIs.

```

maskobj = Simulink.Mask.get(<blockName>);
paramHandle = maskobj.getParameter('<parameterName>');
paramHandle.TypeOptions = enumObj

```

Use this command to associate the variable to the value of the parameter.

```

set_param(<blockName>, '<ParameterName>', 'workspaceVar')

```

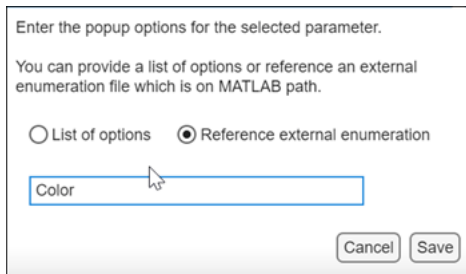

**Note:** Use `slResolve` to get the evaluated value of the parameter in case it is referencing a workspace variable.

### Associate Enumeration File Derived from `Simulink.IntEnumType`

If you have an existing enumeration class derived from `Simulink.IntEnumType`, you can use the enumeration file to associate numeric values to the popup parameter instead of creating a new enumeration class derived from `Simulink.Mask.EnumerationBase`. To associate enumeration file derived from `Simulink.IntEnumType`, follow these steps.

```
classdef Color < Simulink.IntEnumType
    enumeration
        red(1)
        green(100)
        blue(1000)
    end
    methods(Static)
        function aOut = addClassNameToEnumNames()
            aOut = false;
        end
    end
end
```

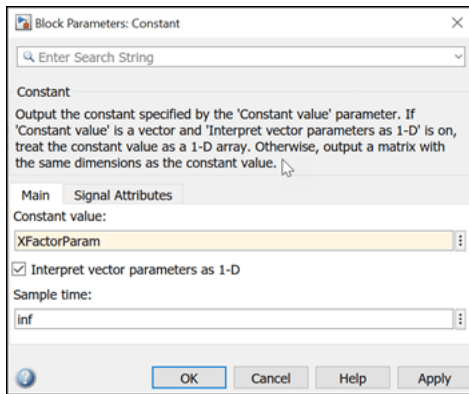

1. Specify the name of the enumeration class.

2. The popup options will be populated with enumeration members prefixed with the enumeration class name.

3. Set the **Constant** parameter value to the popup parameter `XFactorParam`.

## Visualize and Edit N-Dimensional Data Using Mask Lookup Table Control

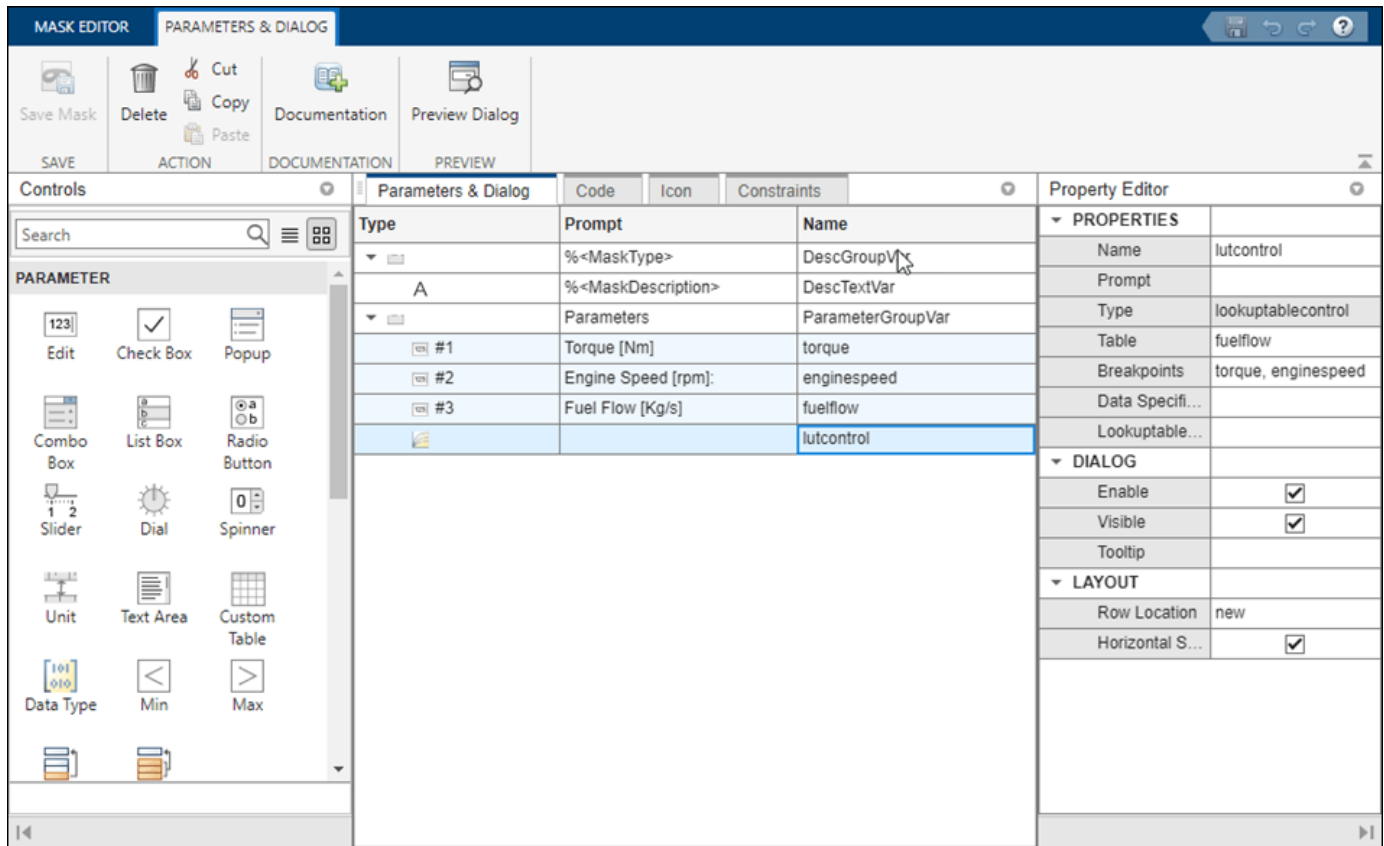

You can visualize and edit N-dimensional lookup table data in mask dialog using the lookup table control. Lookup tables approximate the functions and significantly reduce the computation time using simple lookup operations.

### Visualize and Edit Table and Breakpoint Data Using the Lookup Table Control

Consider a scenario where the fuel flow is determined by the torque and engine Speed. To specify the data explicitly for table data and breakpoint parameters:

1. Right-click on the block, click **Edit Mask** to open the Mask Editor. In the Mask Editor go to **Parameters & Dialog** pane, create edit parameters Torque and Engine Speed for breakpoints. In the **Property editor** pane, enter the values for the breakpoints in the **Values** box.
2. Create an Edit parameter Fuel Flow for table data in the **Property editor** pane, enter the values in the **Value** box.
3. Add a lookup table control. Enter the table properties **Table Parameter**, **Table Unit**, **Table Display Name**, **Breakpoint Parameters**, **Breakpoint Units**, and **Breakpoints Display Name**. Click **OK**.

4. Double-click the masked block to view the lookup table. Click on a cell to edit the value.

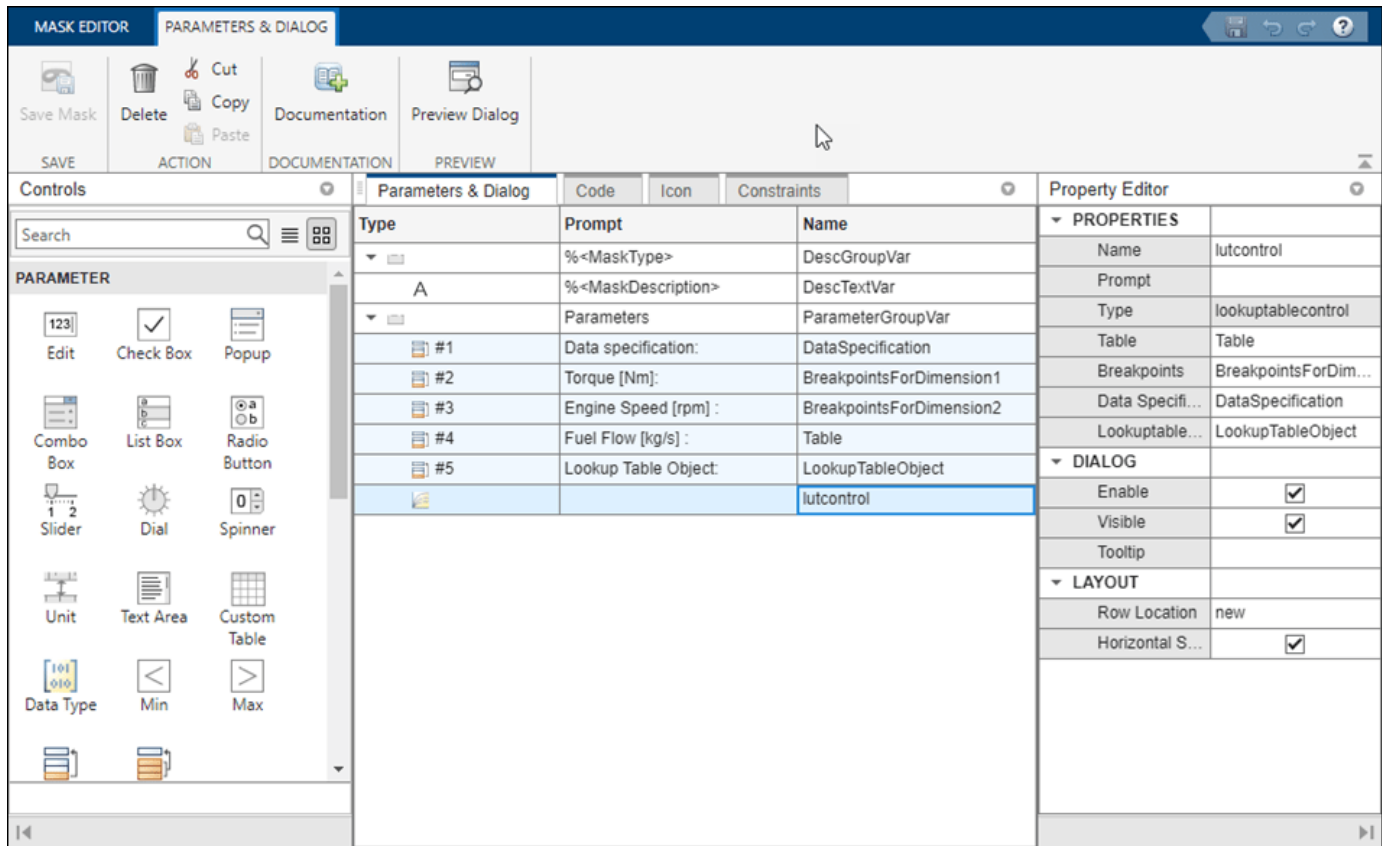

To view the heat map of the table, right-click on a cell, then click **Heatmap On**.

### Reference Promoted Parameters for Table and Breakpoint Data

You can follow the same steps to reference promoted parameters to build a lookup table.

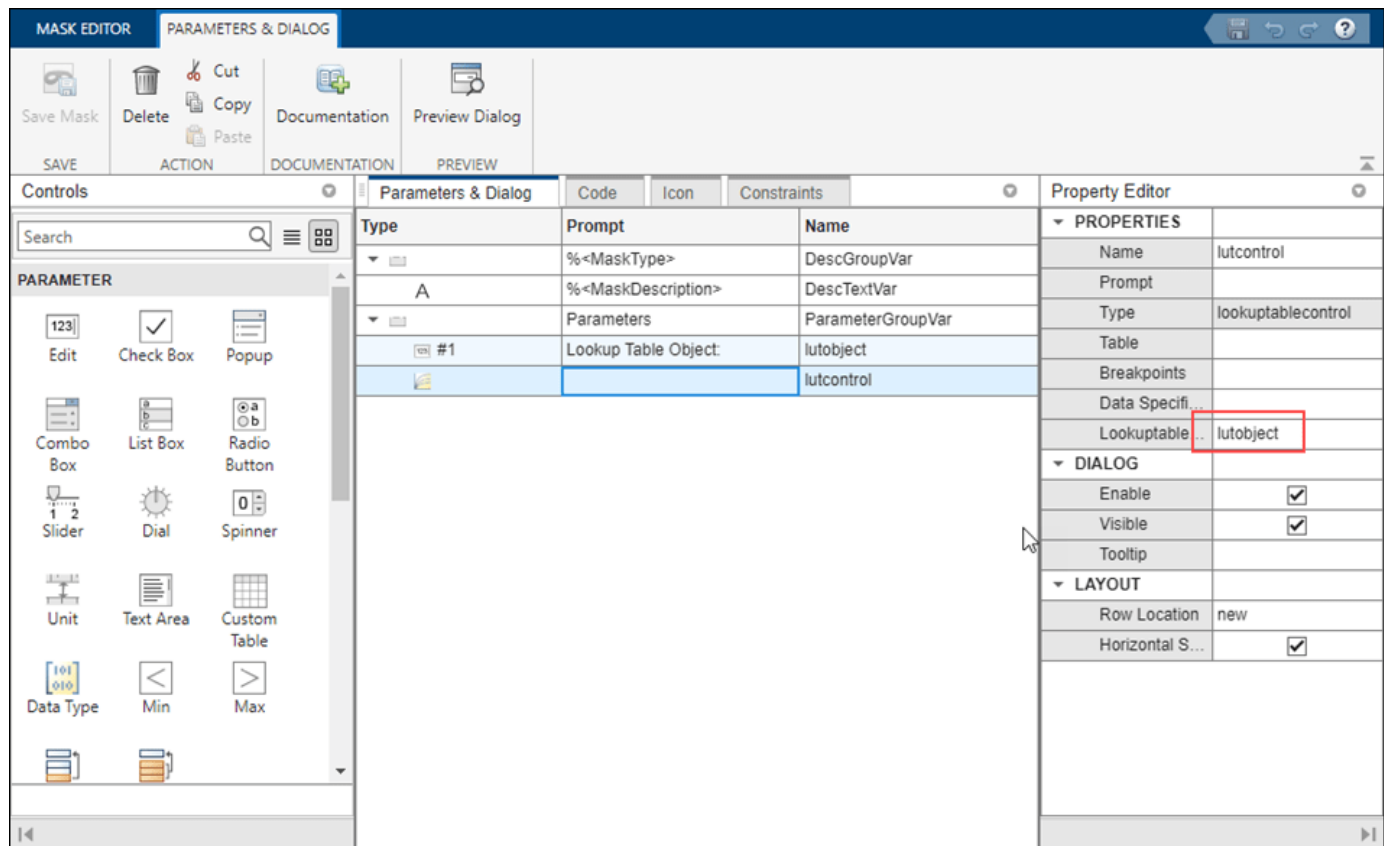

### Specify Table Data and Breakpoint Data Using Lookup Table Object

To reference an object in the Lookup Table Control:

1. Create an object named `lutobject` in the model or base workspace with table and breakpoint data.
2. Create an Edit parameter and enter the **Value** as `lutobject` created in the model workspace.
3. Create the lookup table control, `lutcontrol` and reference the Edit parameter.
4. The lookup table is now populated with the table and breakpoints data.

### Switch Between Explicit Data Specification Mode and Data Referencing Mode

You can switch between Explicit data specification mode and Data referencing mode using a Popup parameter. Create a Popup parameter and use it in the lookup table control to choose between explicit data specification mode and object referencing mode.

Use callback code for the Popup parameter.

```

dataspec_paramName = 'dataspec';
bp1_paramName = 'torque';
bp2_paramName = 'enginespeed';
tbl_paramName = 'fuelflow';
lutobj_paramName = 'lutobject';
underlyingLUTblock = 'slexMaskLookupTableControlExample/LUT Control with Data Specification Mo

dataSpec = get_param(gcf, dataspec_paramName);
maskObj = Simulink.Mask.get(gcf);
lutoParam = maskObj.getParameter(lutobj_paramName);
bp1Param = maskObj.getParameter(bp1_paramName);
bp2Param = maskObj.getParameter(bp2_paramName);
tableParam = maskObj.getParameter(tbl_paramName);
set_param(underlyingLUTblock, 'DataSpecification', dataSpec);

if strcmp(dataSpec, 'Lookup table object')
    bp1Param.Visible = 'off';
    bp2Param.Visible = 'off';
    tableParam.Visible = 'off';
    lutoParam.Visible = 'on';

```

```

else
  bp1Param.Visible = 'on';
  bp2Param.Visible = 'on';
  tableParam.Visible = 'on';
  lutoParam.Visible = 'off';
end
    
```

The screenshot displays the MASK EDITOR interface with the 'PARAMETERS & DIALOG' tab active. The central table lists the following parameters:

Type	Prompt	Name
	%<MaskType>	DescGroupVar
A	%<MaskDescription>	DescTextVar
Parameters		ParameterGroupVar
#1	Lookup Table Object:	lutobject
		lutcontrol

The Property Editor on the right shows the following settings for the selected 'lutobject':

Horizontal S...	<input checked="" type="checkbox"/>

### Share Explicit Breakpoint Data Between Lookup Tables

Many applications use the same breakpoints for different kinds of data. You can create multiple lookup tables by sharing breakpoint data. For example, **Exhaust Temperature**, **Air Pressure**, and **Fuel Flow** use the same breakpoints **Torque** and **Engine Speed**. Create multiple containers in the Mask Editor for each lookup table and use the same breakpoints in each table.

## Visualize Multidimensional Data

To visualize multidimensional data, create Edit parameters for table and breakpoints and enter the values. To visualize the data for a dimension, select the parameter for that dimension from the list.

The screenshot shows the MASK EDITOR interface with the PARAMETER GROUPS & DIALOGS window open. The window has a toolbar with 'Save Mask', 'Delete Mask', 'Create Mask-on-Link', and 'Copy Mask' buttons. Below the toolbar is a 'PARAMETER' list on the left and a 'PROPERTY EDITOR' on the right. The main area displays a table of parameters.

Type	Prompt	Name

### Add Lookup Table Control Programmatically

To add a mask lookup table control programmatically:

1. Get the mask object.

```
maskObj = Simulink.Mask.get(blkhndl);
```

2. Add table data and breakpoint parameters to the mask.

```
maskObj.addParameter('Name', 'torque', 'Prompt', 'Torque:', 'Type', 'edit');
maskObj.addParameter('Name', 'speed', 'Prompt', 'Engine speed:', 'Type', 'edit');
maskObj.addParameter('Name', 'fuelflowtable', 'Prompt', 'Fuel Flow Map:', 'Type', 'edit');
```

3. Set the table properties.

```
lutControl.Table.Name = 'fuelflowtable';
lutControl.Table.Unit = 'kg/s';
lutControl.Table.FieldName = 'Fuel Flow';
```

Set breakpoint properties of Dimension 1.

```
lutControl.Breakpoints(1).Name = 'torque';
lutControl.Breakpoints(1).Unit = 'Nm';
lutControl.Breakpoints(1).FieldName = 'Torque';
```

Set Breakpoint properties of Dimension 2

```
lutControl.Breakpoints(2).Name = 'speed';
lutControl.Breakpoints(2).Unit = 'rpm';
lutControl.Breakpoints(2).FieldName = 'Speed';
```

4. Add lookup table control.

```
lutControl = maskObj.addDialogControl('Name', 'fuelflowlut', 'Type', 'lookuptablecontrol');
```

## Validate Input and Output Port Signals Using Port Constraints

You can validate compile-time signal attributes on the input and output ports of a masked block by using port constraints. Compile-time signal attributes include data type, complexity, and dimensions. You can define the rules to validate the data types, the complexity (real or complex), and dimensions (scalar, vector, or 2-D matrix) of port signals. You can also add parameter conditions to the constraint. The port constraints are active on the associated port only when it satisfies all the parameter conditions. Port constraints allow you to check that signal attributes satisfy the specified rules without having to write validation code. The mask identifies each port with port identifiers. You associate the port constraint to a port identifier.

### Explore Model

This example has a subsystem with two input ports and two output ports. The port constraints mypc, mypc2, and mypc3 validate input and output signals.

Copyright MathWorks 2021

### Create Port Identifiers

First, create port identifiers to associate with the port constraint. To create port identifiers, right-click `subsys_mask` > **Edit Mask** > **Constraints** > **Port Identifiers**. The **Port Identifiers** pane lists the port identifiers for the masked Subsystem block `subsys_mask`.

**Name:** Enter the name for the port. This name uniquely identifies the port identifier in the mask. Multiple ports can have the same port identifier.

**Type:** Select the type of the port as either Input or Output.

**Identifier Type:** Select the type of identifier as name or index. Select name if you want to identify the ports using names. Select index, if you want to identify the ports using numbers.

**Identifier(s):** Enter the name of the port in case Identifier Type is name. Each port name in a block is unique. Enter indices in case Identifier Type is index. You can map multiple ports to one port identifier when the identifier type is index.

**Note:** If you select name as the **Identifier Type**, then you do not need to select the Type of port, because each port name is unique.

### Create Port Constraints

Next, create port constraints for the masked block. Create mask on the block. Go to **Constraints** > **Port**. The list of port constraints appears in the **Constraint Browser**.

**Constraint Name:** Enter the name for the constraint.

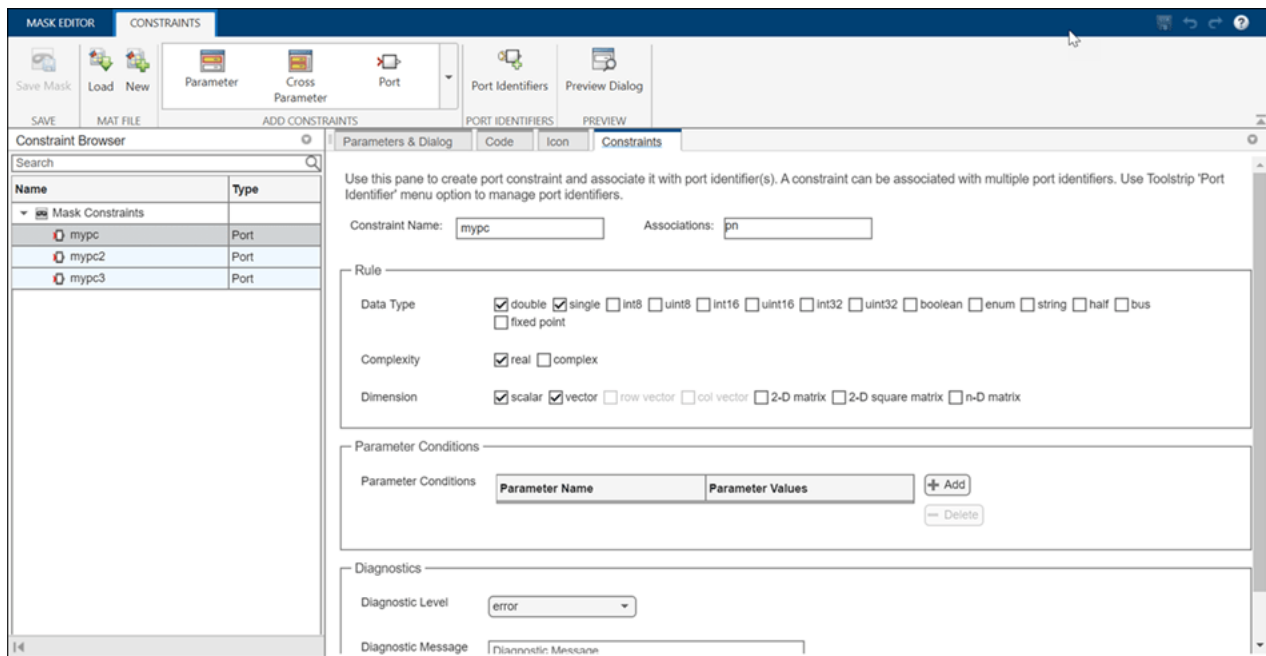

**Associations:** Select the port from the list. The list of port identifiers created appears here. You can select any port identifier to associate it with the constraint.

**Rule:** Set the rules for the constraint. You can set the permitted **Data Types**, **Complexity**, and **Dimensions** for the port values. When you set the **Data Type** as fixed point, you can also select the **Signedness**, **Scaling**, and **Wordlength**.

**Parameter Conditions:** Set mask parameter conditions for the constraints. The port constraints are active on the associated port only when the port satisfies all the parameter conditions. To add parameter conditions in the **Parameter Conditions** section, click **Add**. In **Parameter Name**, select the parameter name. In **Parameter Values**, specify the permitted values as comma-separated list.

**Diagnostic Level:** If the port constraint is not satisfied, you can display an error or a warning message during compile time. Select error or warning.

**Diagnostic Message:** You can specify an error or a warning message that will be displayed if the port constraint validation fails.

### Validate Port Constraints

Simulate the model. During the compilation stage, the compile process validates specified port constraints for the associated port. If the port constraint validation fails, then the error or warning message entered in the port constraint is displayed in the Diagnostic Viewer.

=== Simulation (Elapsed: 3 sec) ===

Error:Data at 'Input Port 1' of block 'slexMaskPortConstraints/subsys\_mask' is invalid.  
Caused by:

Expected data types for the port must be double. However, the port data type is single.  
'To meet constraints of the mask'.

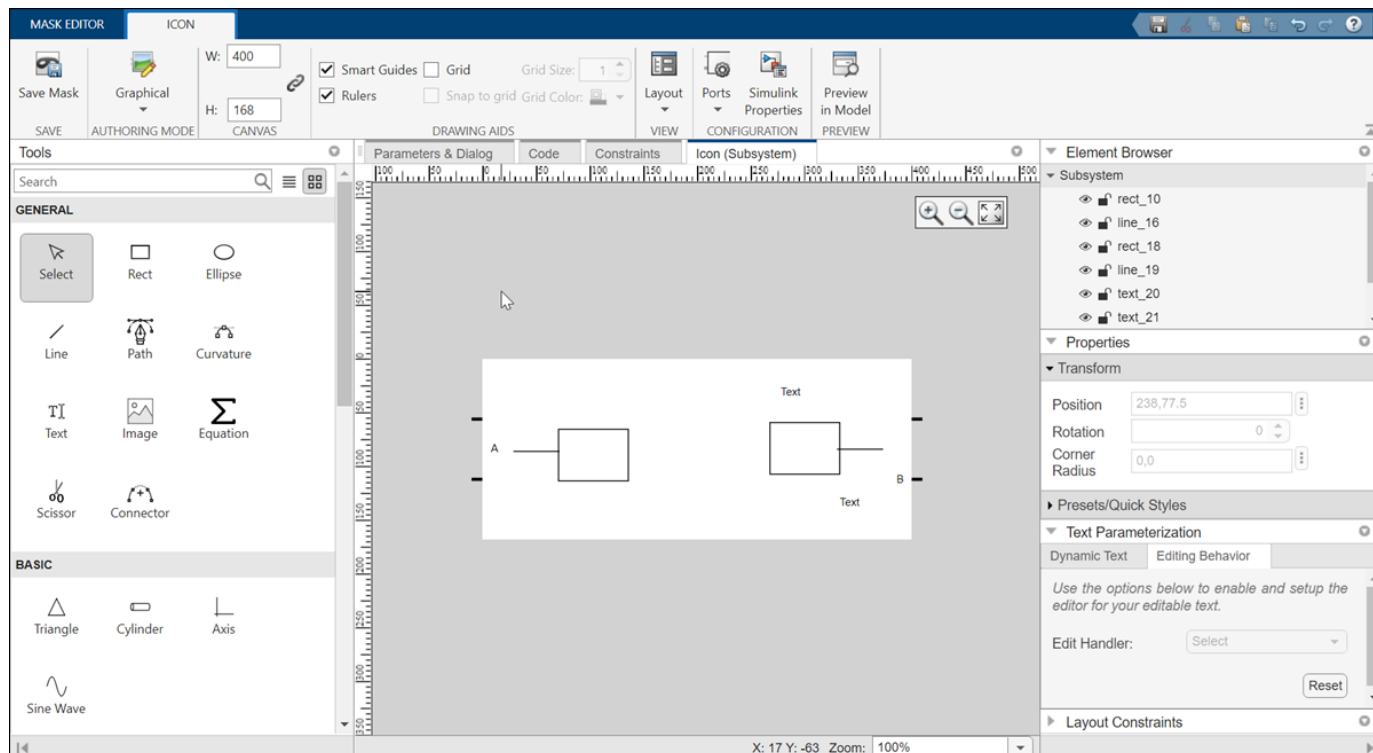

Error:An error occurred while propagating data type 'single' from 'slexMaskPortConstraints/In4',

- “Custom Constraint for Mask Parameter” on page 42-64

## Create and Edit Masked Block Icon Using Graphical Icon Editor

You can create and edit the mask icon of a block using a graphical environment. The features in Graphical Icon Editor helps you to easily create icons. Launch Graphical Icon Editor from Mask Editor. You can also create and edit the block mask icons through a set of drawing commands. For more information, see “Draw Mask Icon” on page 42-16.

Using the Graphical Icon Editor, you can:

- Preview the icon to check how it appears when the icon is horizontally stretched, flipped or scaled.
- Use Grid and Snap to Grid to achieve perfectly positioned icon elements.
- Name the elements and hide, lock, arrange, and regroup the icon.
- Hide or unhide specific elements in the icon based on conditions on the block parameters or mask parameters.
- Position each element on the icon relative to the canvas.

### Edit the Properties of Block Mask Icon and Its Elements

The graphical mode of authoring has a set of tabbed panes that help you to author block mask icons. The options available in these tabbed panes are context sensitive.

- **Icon** - Use the options in the Icon tab to control the properties of the icon such as the canvas height and width.

- **Element** - All the properties specific to an element of the icon are available in the Element tab, for example, alignment options and transformation options.

### Icon Properties

Section	Property	Functionality
Save	Save Mask	Save the mask.
Authoring Mode	Toggle Editor	Switch between the command and graphical editors.
Canvas	Height	Set the height of the canvas.
	Width	Set the width of the canvas.
Drawing Aids	Grid and Snap to grid	Enable these options to create perfectly positioned elements. It helps you to visualize the number of pixels each element scales. Snap to grid allows helps to snap the element to the nearest grid.
	Grid Size	Control the spacing between the grids.
	Grid Color	Select a color for the grid.
	Smart Guides and Rulers	Use smart guides and ruler to align or position an element with respect to all other elements in the icon as well as the canvas.
Configuration	Ports	Define the number of ports on the left, right, top, and bottom of the icon.
	Simulink Properties	Set Simulink properties such as aspect ratio, foreground, orientation.
Preview	Preview in Model	This option helps you to visualize the icon in its original scale and transformations like scaling, horizontally and vertical stretching, clockwise and, counterclockwise rotation.

### Element Properties

Section	Property	Functionality
Transform	X, Y	Set the X and Y coordinates of the element.
	H, W	Set the height and width of the element.
Shape	Stroke, Stroke Width, Bold, Italics, Underline, and Fill	These properties are enabled or disabled depending on the element.
Arrange	Group and Ungroup	Group and Ungroup elements in the icon.
	Flip Horizontal	Flip the selected element horizontally.
	Flip Vertical	Flip the selected element vertically.
Order	Send Backward	Send the element one spot backwards.
	Send to Back	Send the element to the back.
	Bring Forward	Bring the element to the front.
	Bring Front	Bring the element one spot forward.
Align	Align Left	Align the selected elements to the left. Select multiple elements to enable this option and the others in this section.
	Align Horizontal Center	Align the selected elements to the horizontal center.
	Align Right	Align the selected elements to the right.
	Align Bottom	Align the selected elements to the bottom.
	Align Top	Align the selected elements to the top.
	Align Vertical Center	Align the selected elements to the vertical center.
Port Binding	Bind Port or Unbind Port	Bind or unbind port labels and icon elements to a port. To bind the port and label or element, select the port and the label or element. Specify the port using Select Port. To know the number of elements bound to a port, click the port to highlight all the elements bound to the port. You can bind multiple elements to a port, but you cannot bind a single element to multiple ports. Select Unbind Port to unbind a label or element to a port. Binding the elements and labels to a port ensures that the elements and the labels are always with the port.

Section	Property	Functionality
Path	Convert to Path and Edit Path	Select multiple elements and convert them to a path using Convert to Path. To edit the path of the element, select the element and click <b>Edit Path</b> . Add or delete points along the path in the element. Convert a smooth point to a corner point or a corner point to smooth point. You can also close a path or open a closed path.

### Drawing Tools

Tool	Functionality
Path Tool	Create a path. Click and move on the canvas to draw straight lines. Click and hold for curved line. Double-click to end the path.
Curvature	This tool simplifies path creation. To draw curves, click on the canvas in two separate locations to create anchor points. Drag the center point to draw the curve. Drag the edge points of the curve to enlarge it. You can also rotate the curve to form loops.
Equation Tool	Create LaTeX equations. This tool is similar to the equation tool present in MATLAB® and Simulink.
Scissor	Split a path or elements on the canvas at an anchor point or along a segment. Click a point on the path you want to split. To modify the object, select the anchor points that are created due to splitting.
Connector	Connect two or more open paths. This connection creates a single path element. Click the tool and drag to connect open paths.

**Note** Along with using these tools to draw shapes, you can use predefined shapes from Electrical, Translational, and Rotational libraries. There are also basic shapes like Cylinder, Triangle, Axis, and Sine Wave.

### Other Menu Options

Menu	Property	Functionality
Element Browser		<p>The element browser provides you the following functionalities:</p> <ul style="list-style-type: none"> <li>• For icons having many elements, it helps to identify each element using unique names.</li> <li>• Hide or unhide an element so that it does not interfere while modifying other elements.</li> <li>• Lock or unlock an element so that the position of the element gets locked in the icon.</li> <li>• Arrange elements within the group.</li> <li>• Delete elements.</li> <li>• Maintain a stack order for the elements.</li> </ul>
Properties	Transform	Change the position, rotation, and corner radius of an element in the icon.
	Presets/Quick Styles	A set of standard styles such as fill color, stroke, and font is predefined for the elements. You can customize these styles using the Shape/Element section.
Shape/Element	Fill	Choose color for primary and secondary elements. The color of the secondary element is usually a lighter shade of the primary element.
	Stroke	Choose stroke color and transparency for primary and secondary elements. Set the stroke width and style (solid, dashed, and so on).
	Cap type	Select the cap type of the ends of the stroke.
	Join type	Select the style of the joints that connect the strokes.

Menu	Property	Functionality
	End points	Choose the beginning arrowhead and ending arrowhead of an open element.

## Add Dynamic Behavior to Masked Icons

Add dynamic behavior to your icon with Conditional Visibility, Text Parameterization, Layout Constraints, and First-fit features. The effect of these features are visible only when you preview the icon in Simulink.

### Hide or Unhide Elements in the Icon Based Block or Mask Parameters Values

Hide or unhide elements in the icon by applying certain conditions to the block parameters.

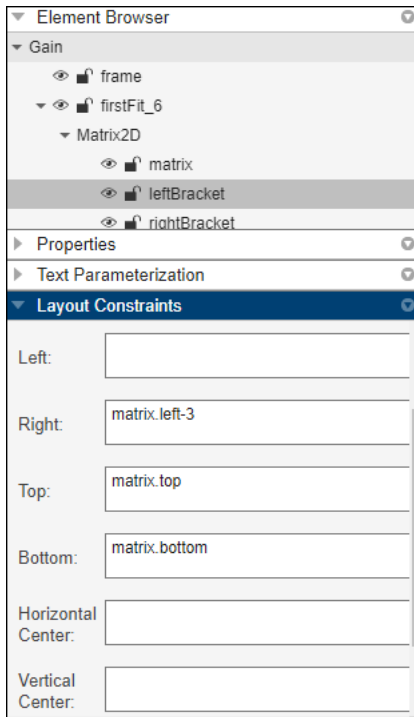

For example, the condition `iiin` in the following figure sets `uvec` element in a **Gain** block to be visible only when the value of the **Multiplication** parameter is `Matrix_Ku_Vector`.

### Position Elements Relatively Using Layout Constraints

Layout constraints help you to position each element relative to other elements on the canvas. Select the source and relative elements from the drop-down in the pinning panel. Select the **Source** element and the **Relative to** element. Pin both the source element and the relative to element using the pinning panel. Specify the **offset**. The available options are left, right, top, bottom, horizontal center, and vertical center. You can also use complex conditions to set the relative position of elements. Click **More** to specify complex conditions. You must preview the icon in Simulink to see the effect of layout constraints.

For example, the constraints in the following figure force the **Gain**, the left bracket of the matrix to be three pixels to the left of the last element of the matrix.

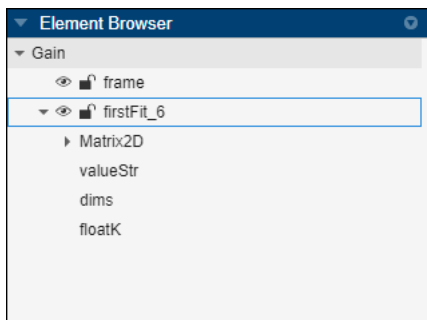

### Text Parameterization

You can view the evaluated value of a block parameter on the block icon. Enter the parameter name, the evaluated value of the parameter appears on the block icon during runtime. Enter the block parameter name or a placeholder in **Parameter/Value** that will return the text or value during runtime. To see the evaluated value of a block parameter on the block icon, preview the icon on Simulink canvas.

### Display Elements That Fit Size of Icon

You can create a block icon that dynamically changes sizes when you resize the block. Each element in the canvas is stored as an array. The element that exactly fits in the block size gets rendered.

For example, the following figure shows the **Gain** block with four elements of different sizes that are grouped under a first-fit element. When you resize the block, the element that fits in the size of the **Gain** block appears as the icon of the block.

## Create Block Mask Icon

Block mask icons can be created using Graphical Icon Editor and Mask Drawing commands. You can toggle between the two modes from Mask Editor. This example shows how to draw a block icon with the following features using the Graphical Icon Editor.

- The icon has the elements as shown in the following image.
- Depending on the value of the block parameter `FieldType`, the permanent magnet or the spring is visible on the icon.
- The text that appears in the center of the icon takes the value of the block parameter `CenterText` defined in the Mask Editor.

To create the block icon:

- 1 Add a Subsystem block. To create mask on the block, right-click the block, then select **Mask > Create**.
- 2 Select **Icon > Graphical** in the **Icon Authoring** tab.
- 3 Draw the icon.

- Select the **Rect** tool from the drawing tools and draw a square.

---

**Note** Enable the **Grid** and **Snap to grid** options to help shapes perfectly align with each other.

---

- Select the **Line** to draw a horizontal line touching the middle of the square.

---

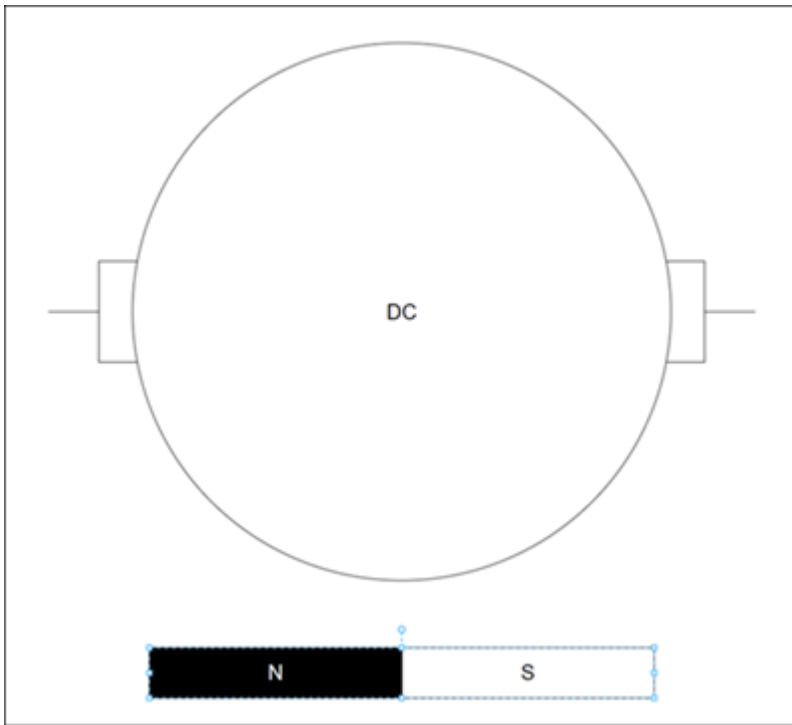

**Note** Enable the **Rulers** and **Smart Guides** options to align the element relative to other elements in the canvas.

---

- Select the square and line elements and make a copy of them. Flip the copies horizontally.

- Select **Ellipse** to draw a circle joining the two squares.
- Add the text element DC in the center of the icon.
- To draw the magnet, select **Rect** and draw a rectangle. Make a copy of the rectangle and place the rectangles next to each other. Fill the left rectangle.

- You can hide the magnet element to position the spring element in the place of the magnet. To hide the magnet, select the magnet element, right-click, and select **Hide**. To draw the spring element, select **Inductor** and place it on the canvas. Flip the inductor element to achieve a spring shape. Adjust the loops of the inductor element.

**Note** You can rename the elements in the **Element Browser** for easy identification. You can also group or ungroup elements as per your requirements.

**4** Bind ports to the icon.

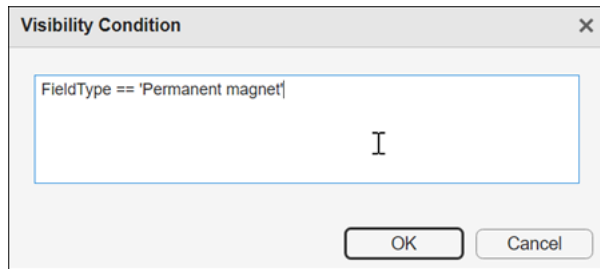

- Enter the labels for the left and right ports using the text element.
- Bind the ports and port labels of the icon to align the port labels to the port in the canvas, so that even when you resize the icon the ports and port labels remain intact. To bind the port to the port labels, select the port label, go to **Port Binding** and select the port. You can also unbind the port.

**5** Hide or unhide spring and magnet elements based on the block parameter condition.

Configure the spring element to be visible when the `FieldType` parameter is `Wound` and the magnet element to be visible when the parameter is `Permanent magnet`

- Right-click the magnet element and select **Conditional Visibility > Add Condition**.
- Enter the condition `FieldType=='Permanent magnet'`.

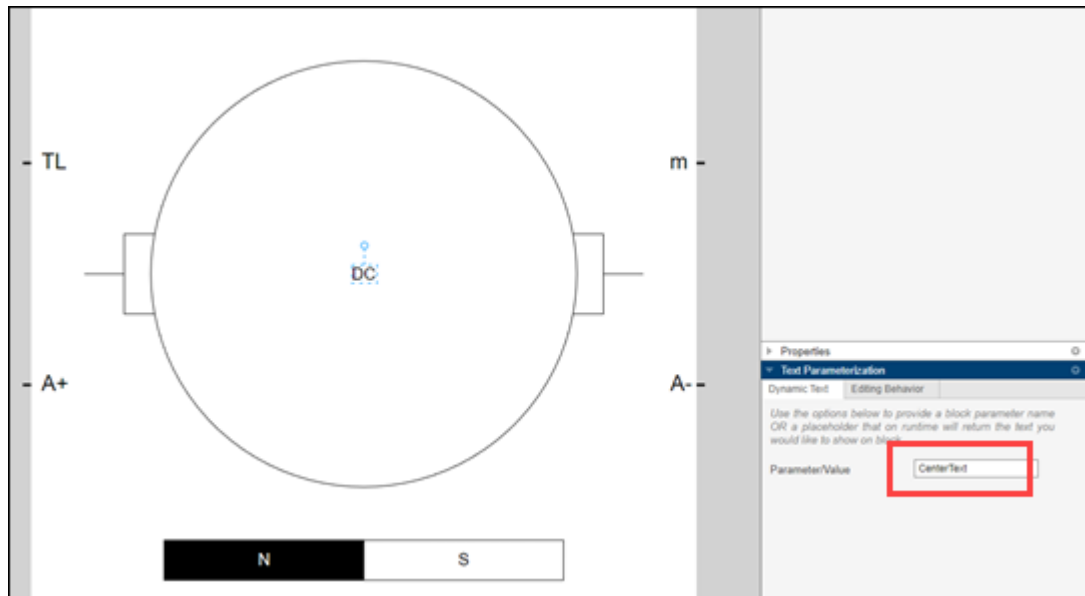

- Similarly, enter the condition `FieldType=='Wound'` for the spring element.

## 6 Parameterize text.

- Define the mask block parameter `CenterText` in the Mask Editor. The value of this block parameter appears in the center of the icon.

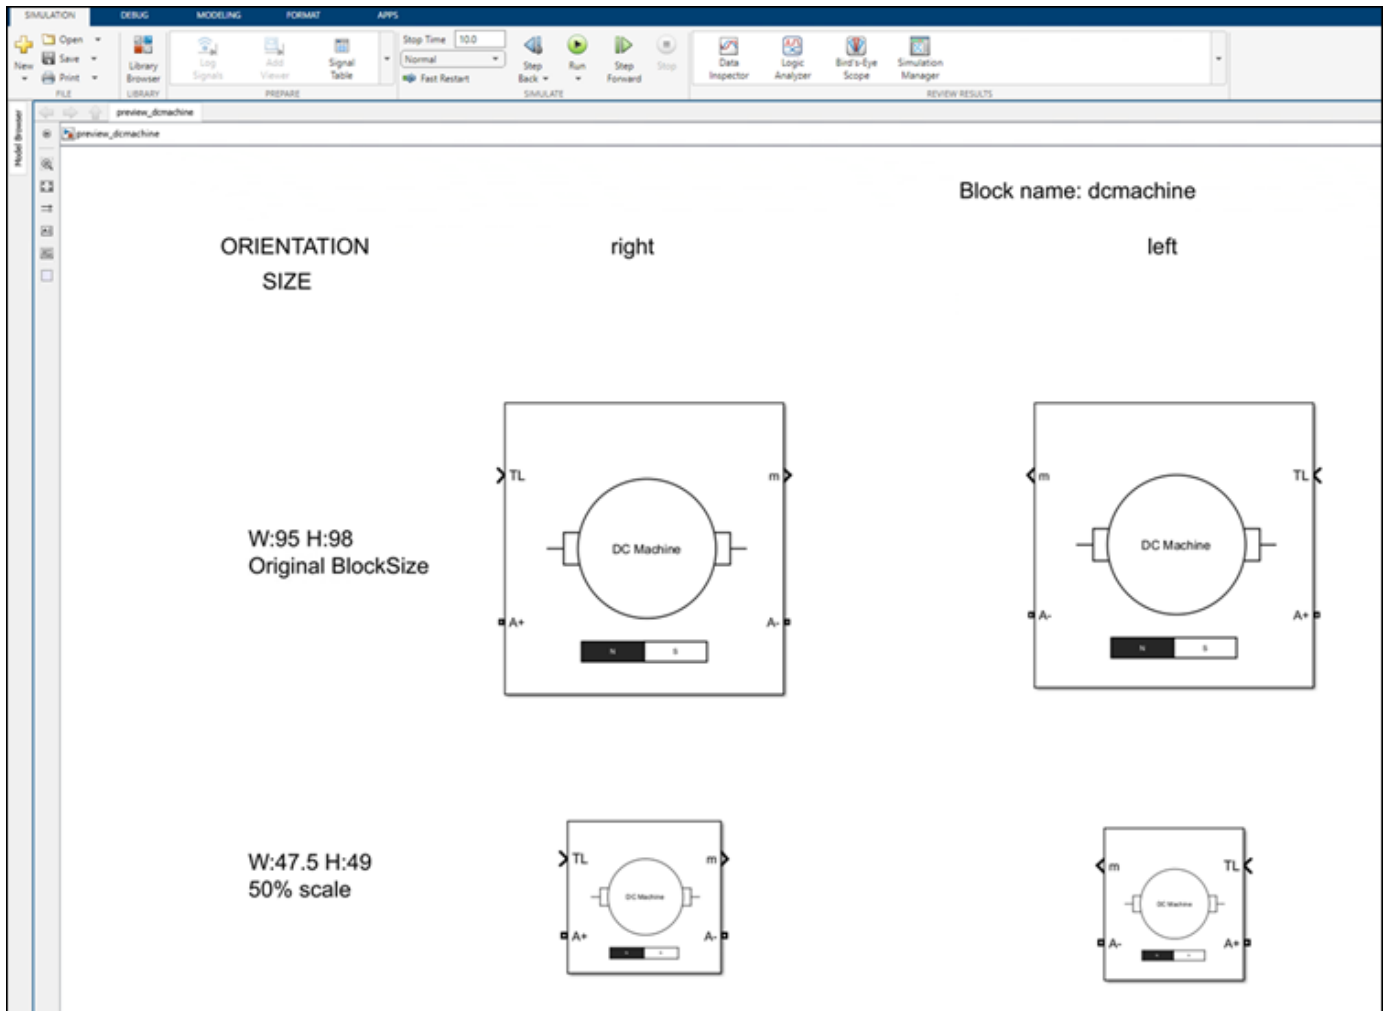

- Select the text element and click **Text Parameterization**.
- Enter the mask block parameter name `CenterText` in **Parameter/Value**.

**Parameter/Value** returns the text or value during runtime. To see the evaluated value of a block parameter on the block icon, preview the icon on the Simulink canvas.

- 7 Preview the icon in Simulink.

- 8 Click **Save Mask** to save the mask. Mask editor also allows you to save the icon separately as a SVG file.

---

**Note** If you have changes in both Command Editor and Graphical Editor, you can save the changes in either one of the modes.

---

# Creating Custom Blocks

---

- “Types of Custom Blocks” on page 43-2

## Types of Custom Blocks

### In this section...

“MATLAB Function Blocks” on page 43-2

“MATLAB System Blocks” on page 43-2

“Subsystem Blocks” on page 43-2

“C Caller Block” on page 43-3

“C Function Block” on page 43-3

“S-Function Blocks” on page 43-3

“Masked Blocks” on page 43-4

### MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The Interpreted MATLAB Function block allows you to use a MATLAB function to define a SISO block.
- The MATLAB Function block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks.

### MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

### Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

- 1 Masking the block to hide the block contents and provide a custom block dialog box.
- 2 Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Custom Libraries” and “Create Block Masks”.

## C Caller Block

The C Caller block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- Your C functions do not read or write global/static variables.
- You want blocks to easily integrate with other Simulink features, such as Simulink Coverage, Simulink Test, and Simulink Coder.
- You are not modeling dynamic systems.

## C Function Block

The C Function block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- You want to call multiple C functions from the block, or call C functions conditionally.
- You want to include C code to preprocess and postprocess data before and after calling C functions.
- You want to specify different code for simulation and code generation.
- You are not modeling dynamic systems with continuous states.

## S-Function Blocks

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The Level-2 MATLAB S-Function block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The S-Function block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “Implement C/C++ S-Functions”).
- The S-Function Builder block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “Implement C/C++ S-Functions”).
- The Legacy Code Tool transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”).

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Use S-Function Target for Model or Subsystem” (Simulink Coder) in the Simulink Coder User's Guide for details and limitations on using the S-function target.

## Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see “Create Block Masks”.

## Comparison of Custom Block Functionality

In this section...
"Model State Behavior" on page 43-6
"Simulation Performance" on page 43-6
"Code Generation" on page 43-8
"Multiple Input and Output Ports" on page 43-9
"Speed of Updating the Simulink Diagram" on page 43-9
"Callback Methods" on page 43-10
"Comparing MATLAB S-Functions to MATLAB Functions for Code Generation" on page 43-10
"Expanding Custom Block Functionality" on page 43-11

When creating a custom block, consider:

- Does the block model continuous or discrete state behavior on page 43-6?
- Is the simulation performance on page 43-6 important?
- Do you need to generate code on page 43-8 for a model containing the custom block?

This table shows how each custom block type addresses the three concerns.

### Modelling Considerations

Custom Block Type	Model State Dynamics on page 43-6	Simulation Performance on page 43-6	Code Generation on page 43-8
Interpreted MATLAB Function	No	Less fast	Not supported
Level-2 MATLAB S-Function	Yes	Less fast	Requires a TLC file
MATLAB Function	No	Fast	Supported with exceptions
MATLAB System	Yes	Fast	Supported with exceptions
S-Function	Yes	Fast	Requires a TLC file or non-inline S-Function support
C Caller	No	Fast	Supported
C Function	Yes	Fast	Supported
S-Function Builder	Yes	Fast	Supported
Simulink Function	Yes	Fast	Supported
Subsystem	Yes	Fast	Supported

For detailed design of custom blocks, consider:

- Does the custom block need multiple input and output ports on page 43-9?
- What are the callback methods on page 43-10 to communicate with the Simulink engine and which custom blocks let you implement all or a subset of these callback methods?
- How important is the effect of the custom block on the speed of updating the Simulink diagram on page 43-9?

## Model State Behavior

You need to model the state behavior for a block that requires some or all of its previous outputs to compute its current outputs. See “State variables” for more information.

Custom Block Type	Notes
Interpreted MATLAB Function, C Caller	Does not allow you to model state behavior.
MATLAB Function, C Function	Allows you to model a discrete state using <code>persistent</code> variables.
Level-2 MATLAB S-Function	Allows you to model both continuous and discrete state behavior using the <code>ContStates</code> or <code>Dwork</code> run-time object methods in combination with block callback methods. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Allows you to model discrete state behavior using <code>DiscreteState</code> properties of the <code>System</code> object, in combination with block callback methods. This block uses <code>System</code> object methods for callback methods: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ), <code>mdlInitializeConditions</code> ( <code>resetImpl</code> ), <code>mdlStart</code> ( <code>setupImpl</code> ), <code>mdlTerminate</code> ( <code>releaseImpl</code> ). For more information see “What Are System Objects?”.
C MEX S-Function, S-Function Builder	Allows you to model both continuous and discrete state behavior in combination with block callback methods. For more information, see “Callback Methods for C MEX S-Functions”
Simulink Function	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries. When multiple calls to this function originate from different callers, the state values are also persistent between these calls. For more information, see “Call a Simulink Function Block from Multiple Sites” on page 10-133.
Subsystem	Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries.

## Simulation Performance

For most applications, all custom block types provide satisfactory simulation performance. Use the Simulink profiler to get the actual performance indication. See “How Profiler Captures Performance Data” on page 34-5 for more information.

The two categories of performance indication are the interface cost and the algorithm cost. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

Custom Block Type	Notes
Interpreted MATLAB Function	<p>Has a slower performance due to the interface, but has the same algorithm cost as a MATLAB function.</p> <p>When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as frames or arrays, the performance can be substantially slow.</p> <p>Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function.</p>
Level-2 MATLAB S-Function	<p>Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Since MATLAB S-Functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement, whereas the Interpreted MATLAB Function block calls the MATLAB execution engine only for the <b>Outputs</b> method.</p>
MATLAB Function	<p>Performs simulation through code generation and incurs the same interface cost as other Simulink built-in blocks.</p> <p>The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and the MATLAB function run at about the same speed.</p> <p>If the MATLAB Function block has code that uses <code>coder.extrinsic</code> to call out to the MATLAB execution engine, it incurs all the costs that the MATLAB S-Function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally.</p> <p>To reduce the algorithm cost, you can disable debugging for all MATLAB Function blocks.</p>
MATLAB System	<p>In the interpreted execution mode, performance is similar to that of the Level-2 MATLAB S-function because the model simulates the block using the MATLAB execution engine. In the code generation mode, performance is similar to that of the MATLAB Function because the model simulates the block using the generated code. For more information, see the MATLAB Function entry in this table.</p>
C Caller, C Function	<p>First time model simulation with could be slower due to parsing and building of the custom code. To speed up the simulation after the first compile, from <b>Configuration parameters</b>, select <b>Faster Builds</b> for faster compile and select <b>Faster Runs</b> for faster simulation.</p>
C MEX S-Function	<p>Simulates via the compiled code and incurs the same interface cost as Simulink built-in blocks. The algorithm cost depends on the complexity of the S-Function.</p>
S-Function Builder	<p>This block only builds an S-Function from the specifications and C code you supply. You can also use this block as a wrapper for the generated S-Function in models. The algorithm cost of this block compared to C MEX S-Function is incurred only from the wrapper.</p>

Custom Block Type	Notes
Simulink Function, Subsystem	<p>If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.</p> <p>Performance is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model did not use libraries.</p>

## Code Generation

You need code generation if your model is part of a bigger system. Not all custom block types support code generation with Simulink Coder.

Custom Block Type	Notes
Interpreted MATLAB Function	Does not support code generation.
C Caller, C Function	Supports code generation.
Level-2 MATLAB S-Function	Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-Function in the interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-Function is <code>SimViewingDevice</code> , the Simulink Coder product automatically omits the block during code generation.
MATLAB Function, MATLAB System	Supports code generation. However, if your block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.
C MEX S-Function, S-Function Builder	<p>Both supports code generation.</p> <ul style="list-style-type: none"> <li>For non-inlined S-Functions, the Simulink Coder product uses the C MEX function during code generation.</li> <li>In the case of C MEX S-Functions, if you need to either inline the S-Function or create a wrapper for handwritten code, you must write a TLC file for the S-Function.</li> <li>In the case of S-Function Builder, you can choose the Generate wrapper TLC option to automatically generate a TLC file.</li> </ul> <p>See “S-Functions and Code Generation” (Simulink Coder) for more information.</p>
Simulink Function	Supports code generation.
Subsystem	Supports code generation as long as the blocks contained within the subsystem support code generation. For more information, see “Subsystems” (Simulink Coder).

## Multiple Input and Output Ports

These types of custom blocks support multiple input and output ports.

Custom Block Type	Notes
Interpreted MATLAB Function	Supports only a single input and a single output port.
MATLAB Function	Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 49-65 for more information.
MATLAB System	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on system object properties using the <code>getNumInputs</code> and <code>getNumOutputs</code> methods.
C Caller, C Function	Supports multiple input and output ports, including bus signals.
Level-2 MATLAB S-Function, C MEX S-Function, S-Function Builder	Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. The C MEX S-Function and S-Function Builder support bus signals.
Simulink Function	Supports multiple input and output ports, including bus signals.
Subsystem	Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifiable Linked Subsystems” on page 44-18 for more information.

## Speed of Updating the Simulink Diagram

Simulink updates the diagram before every simulation and when requested by the user. Every block introduces some overhead into the diagram update process.

Custom Block Type	Notes
Interpreted MATLAB Function	Low diagram update cost.
MATLAB Function, C Caller, C Function	Simulation is performed through code generation, so this blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
MATLAB System	Faster than MATLAB Function because code is not generated to update the diagram. Since, code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.
C MEX S-Function, Level-2 MATLAB S-Function	Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in “Simulink Engine Interaction with C S-Functions”. When updating the diagram, Simulink invokes all relevant methods in the model initialization phase up to, but not including, <code>mdlStart</code> .

Custom Block Type	Notes
Simulink Function, Subsystem	The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model does not use libraries.

## Callback Methods

Simulink blocks communicate with the Simulink engine through block callback methods, which fully specify the behavior of blocks (except the Simulink Function block). Each custom block type allows you to implement a different set of callback methods. To learn how blocks interact with Simulink engine, see “Simulink Engine Interaction with C S-Functions”. This table uses “S-Function Callback Methods” names as equivalents.

Custom Block Type	Notes
Interpreted MATLAB Function, MATLAB Function, C Caller	All create a <code>mdlOutputs</code> method to calculate the value of outputs given the value of inputs. You cannot implement any other callback methods using one of these blocks and, therefore, cannot model state behavior.
C Function	Allows implementation of start, output, and terminate callback methods. Allows modeling of discrete states with persistent data.
Level-2 MATLAB S-Function	Allows implementation of a larger subset of callback methods, including methods you can use to model continuous and discrete states. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.
MATLAB System	Uses System object methods for callback methods: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ), <code>mdlInitializeConditions</code> ( <code>resetImpl</code> ), <code>mdlStart</code> ( <code>setupImpl</code> ), <code>mdlTerminate</code> ( <code>releaseImpl</code> ). For more information, see “Simulink Engine Interaction with System Object Methods” on page 50-26
C MEX S-Function	Allows implementation of a complete set of callback methods.
S-Function Builder	Allows implementation of <code>mdlOutputs</code> , <code>mdlDerivatives</code> and <code>mdlUpdate</code> .
Simulink Function	Packaged as a standalone function. Any caller to this function becomes part of one of the callback methods based on the caller’s location.
Subsystem	Communicates directly with the engine. You can model state behaviors using appropriate blocks from the continuous and discrete Simulink block libraries.

## Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC file.

- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C/C++ Code Generation” on page 54-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

## Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and MATLAB graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Block Callbacks” on page 4-59.

App Designer, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” for more information on using App Designer.

## Design and Create a Custom Block

### In this section...

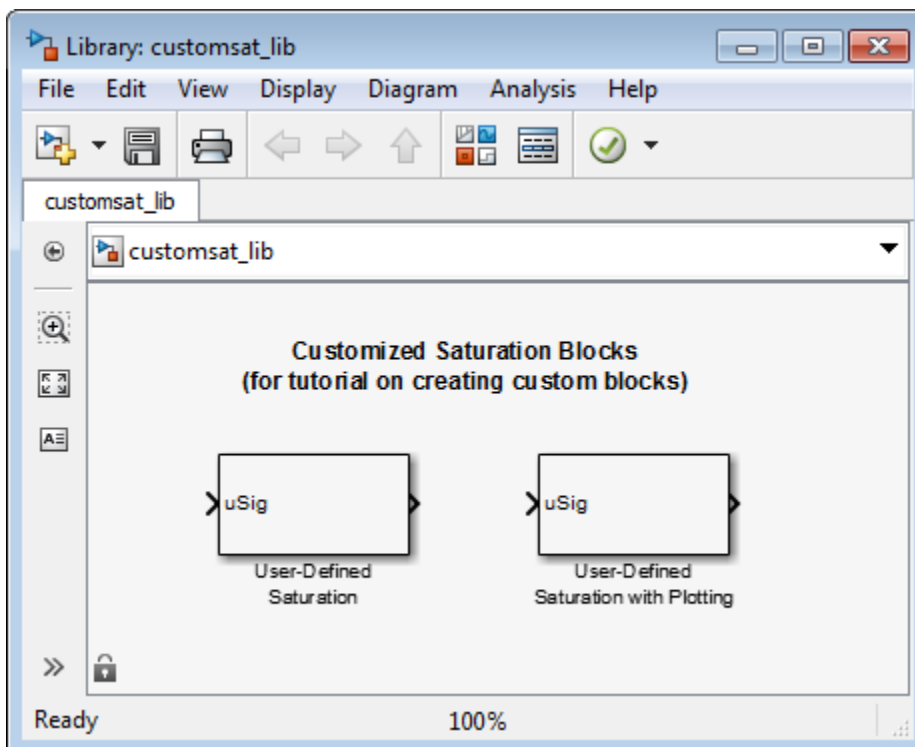

- “How to Design a Custom Block” on page 43-12
- “Defining Custom Block Behavior” on page 43-13
- “Deciding on a Custom Block Type” on page 43-14
- “Placing Custom Blocks in a Library” on page 43-17
- “Adding a User Interface to a Custom Block” on page 43-19
- “Adding Block Functionality Using Block Callbacks” on page 43-24

### How to Design a Custom Block

In general, use the following process to design a custom block:

- 1 “Defining Custom Block Behavior” on page 43-13
- 2 “Deciding on a Custom Block Type” on page 43-14
- 3 “Placing Custom Blocks in a Library” on page 43-17
- 4 “Adding a User Interface to a Custom Block” on page 43-19

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `ex_customsat_lib` contains the two versions of the customized saturation block.

The example model `sldemo_customsat` uses the basic version of the block.

## Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.
- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

## Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 43-5 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

### Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

### Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```

function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
    lowMode    = block.DialogPrm(1).Data;
    upMode     = block.DialogPrm(3).Data;
    numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
    numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms    = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
    'Tunable'};

% Register continuous sample times [0 offset]

    elseif isequal(lowMode,3), % Set via an input port
        lowVal = block.InputPort(lowPortNum).Data;
    else
        lowVal = -inf;
    end

    % Assign new value to signal
    if sigVal > upVal,
        sigVal = upVal;
    elseif sigVal < lowVal,
        sigVal=lowVal;
    end

    block.OutputPort(1).Data = sigVal;

%end Outputs function

```

## Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. If your custom block requires a bus as an interface, you can share the bus object with library users by creating the bus object in a data dictionary and attaching the dictionary to the library (See “Link Data Dictionary to Custom Libraries” on page 79-37).

This example places the custom saturation block into a library.

- 1 In the Simulink Editor, in the **Simulation** tab, select **New > Library**.
- 2 From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.

- 3 Save your library with the filename `saturation_lib`.
- 4 Double-click the block to open its Function Block Parameters dialog box.
- 5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2, -1, 2, 1`.

- 6 Click **OK**.

You have created a custom saturation block that you can share with other users.

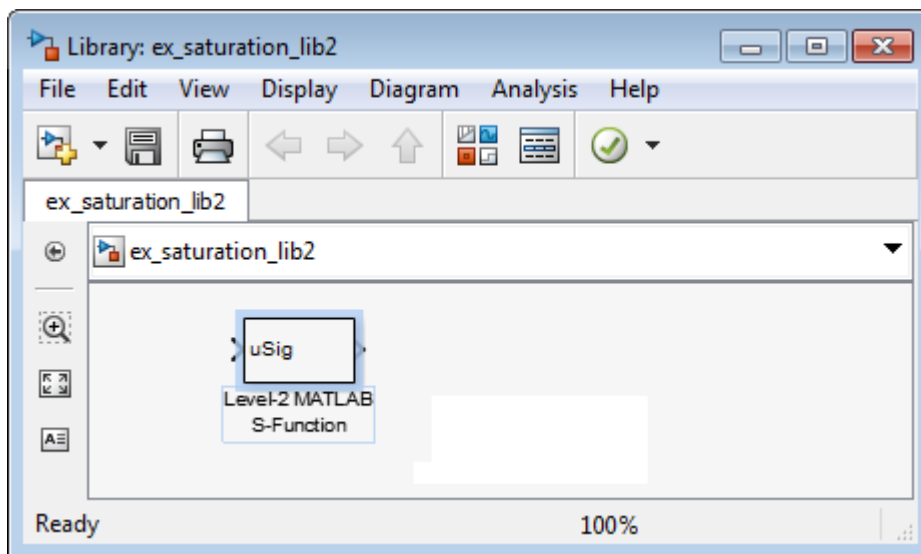

You can make the block easier to use by adding a customized user interface.

## Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

- 1 Open the library `saturation_lib` that contains the custom block you created,
- 2 Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
- 3 On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input',1,'uSig')`, and then click **Apply**.

This command labels the default port as the input signal under saturation.

- 4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Upper boundary:	upMode	✓		No limit Enter limit as parameter Limit using input signal	customsat_callback('upperbound_callback', gcb)
edit	Upper limit:	upVal	✓	✓	N/A	customsat_callback('upperparam_callback', gcb)

Type	Prompt	Name	Evaluate	Tunable	Popup options	Callback
popup	Lower boundary: :	lowMode	✓		No limit  Enter limit as parameter  Limit using input signal	customsat_callback('lowerbound_callback', gcb)
edit	Lower limit:	lowVal	✓	✓	N/A	customsat_callback('lowerparam_callback', gcb)

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a character vector indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.

- In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.
- In the **Documentation** pane:

- In the **Mask type** field, enter  
Customized Saturation
  - In the **Mask description** field, enter  
Limit the input signal to an upper and lower saturation value  
set either through a block parameter or input signal.
- 7 Click **OK**.
  - 8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.
  - 9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.

- 10 Click **OK**. Save and close the library to exit the edit mode.
- 11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.

To create a more complicated user interface, place a MATLAB graphics user interface on top of the masked block. The block `OpenFcn` invokes the MATLAB graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

### Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block, 'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisibilities`. This call returns a cell array of character vectors indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label text.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

% Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
```

```

function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label('input',1,'uSig')}';
switch vals{1}
    case 'No limit'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
    case 'Enter limit as parameter'
        set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
    case 'Limit using input signal'
        set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
        portStr = [portStr;{'port_label('input',2,'up')}'];
end
if strcmp(vals{3},'Limit using input signal'),
    portStr = [portStr;{'port_label('input',',num2str(length(portStr)+1), ...
        ', 'low')'}]];
end
set_param(block,'MaskDisplay',char(portStr));

```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```

%% Function: setup =====
function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
%    set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
%    or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
%    set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into

```

```

% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%endfunction

```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```

%% Function: Get Port Visibilities =====
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle,'MaskValues');
switch vals{1}
    case 'No limit'
        ud(2) = 1;
    case 'Enter limit as parameter'
        ud(2) = 2;
    case 'Limit using input signal'
        ud(2) = 3;
end

switch vals{3}
    case 'No limit'
        ud(1) = 1;
    case 'Enter limit as parameter'
        ud(1) = 2;
    case 'Limit using input signal'
        ud(1) = 3;
end

```

## Adding Block Functionality Using Block Callbacks

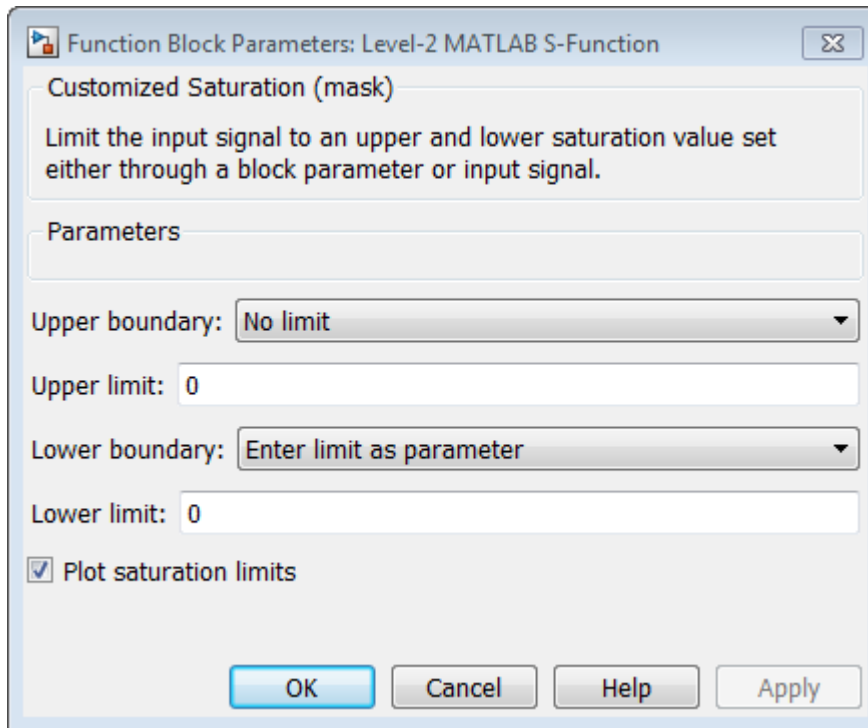

The User-Defined Saturation with Plotting block in `ex_customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

- 1 Add a check box to the mask parameter dialog box to toggle the plotting option on and off.
  - a Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask + Create Mask**.
  - b On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

Prompt	Name	Type	Tunabl e	Type options	Callback
Plot saturation limits	plotcheckbox	checkbox	No	NA	customsat_callback('plotsaturation',gcb)

- c Click **OK**.

- 2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```

%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block,'MaskValues');
ud = struct('time',[],'upBound',[],'upVal',[],'lowBound',[],'lowVal',[]);

if strcmp(vals{1},'No limit'),
    ud.upBound = 'off';
else
    ud.upBound = 'on';
end

if strcmp(vals{3},'No limit'),
    ud.lowBound = 'off';
else
    ud.lowBound = 'on';
end

set_param(gcb,'UserData',ud);

```

- 3 Update the MATLAB S-function `Outputs` method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the `Outputs` method in `custom_sat_plot.m` over the original `Outputs` method in `custom_sat_final.m`

```

%% Function: Outputs =====
function Outputs(block)

lowMode    = block.DialogPrm(1).Data;

```

```

upMode      = block.DialogPrm(3).Data;
sigVal      = block.InputPort(1).Data;
vals = get_param(block.BlockHandle,'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode,2)
    upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3)
    upVal = block.InputPort(2).Data;
    lowPortNum = 3; % Move lower boundary down one port number
else
    upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2),
    lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3)
    lowVal = block.InputPort(lowPortNum).Data;
else
    lowVal = -inf;
end

% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
    ud = get_param(block.BlockHandle,'UserData');
    ud.lowVal = [ud.lowVal;lowVal];
    ud.upVal = [ud.upVal;upVal];
    ud.time = [ud.time;block.CurrentTime];
    set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
    sigVal = upVal;
elseif sigVal < lowVal,
    sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction

```

- 4 Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```

function plotSat(block)

% PLOTSAT contains the plotting routine for custom_sat_plot
% This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
    if strcmp(ud.upBound,'on')
        fig = figure;
        plot(ud.time,ud.upVal,'r');
        hold on
    end
    if strcmp(ud.lowBound,'on')
        if isempty(fig),
            fig = figure;
        end
        plot(ud.time,ud.lowVal,'b');
    end
    if ~isempty(fig)
        title('Upper bound in red. Lower bound in blue.')
    end
end

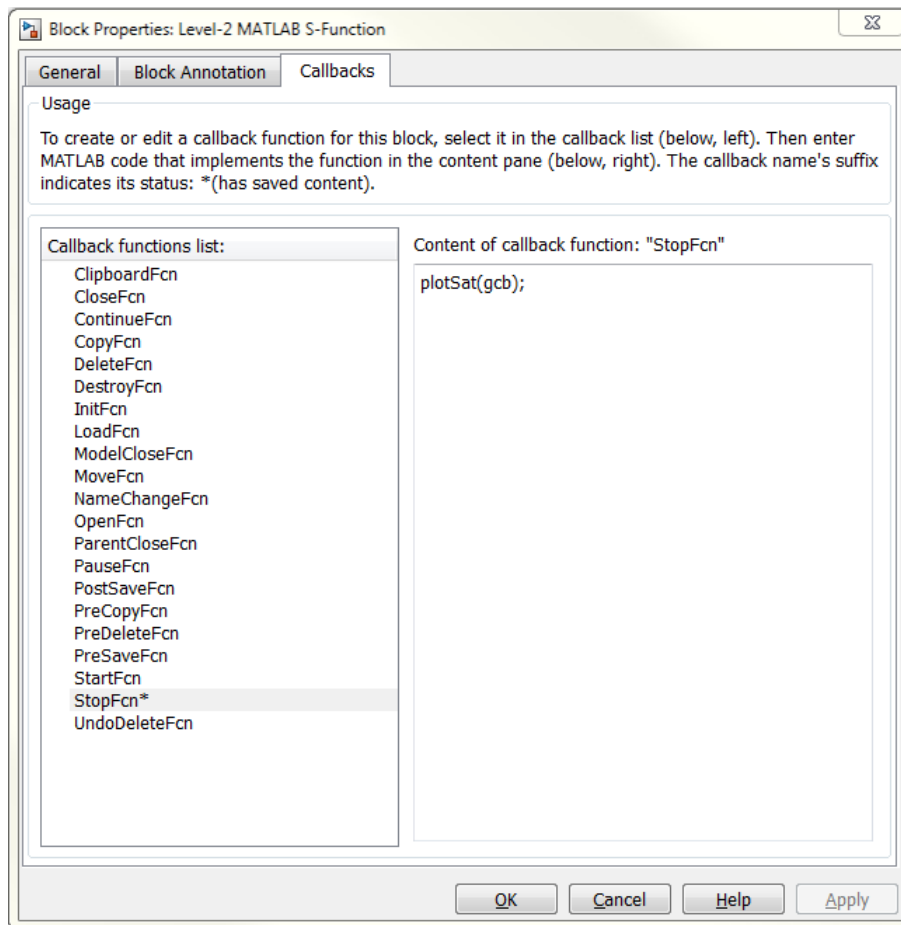

```

```

% Reinitialize userdata
ud.upVal=[];
ud.lowVal=[];
ud.time = [];
set_param(block, 'UserData', ud);
end

```

- 5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the StopFcn to call the plotting callback as shown in the following figure, then click **OK**.

## Integrate Python GPS Text Message Parsing Algorithms in Simulink

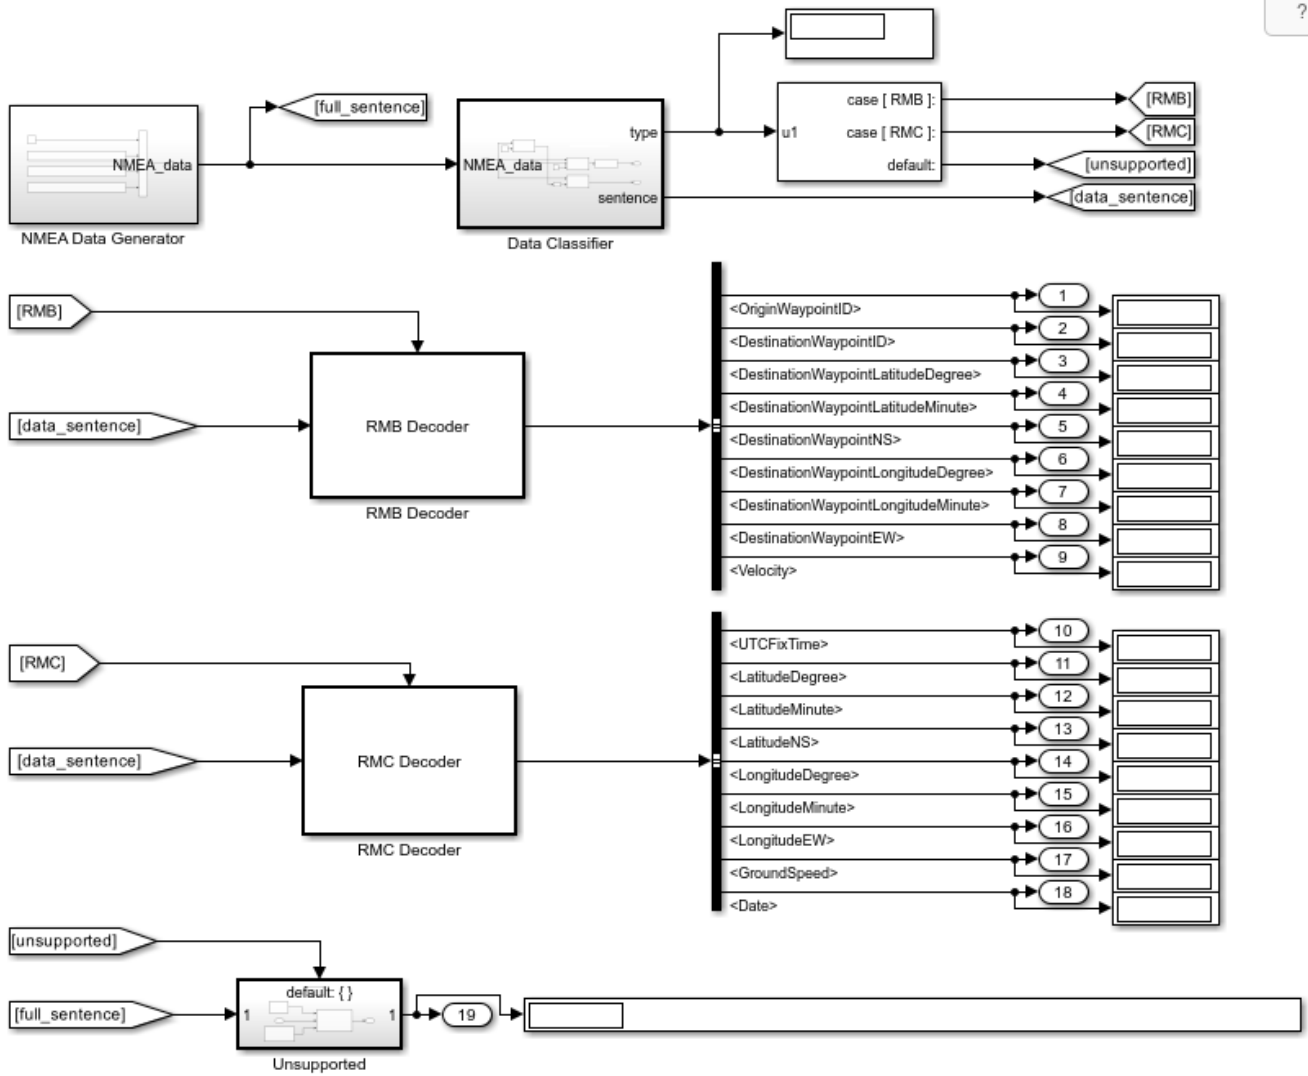

This example shows how to parse text messages in NMEA GPS format using Simulink® string blocks and Python®. NMEA sentences are used for communication between marine devices, and the model in the example decodes RMB and RMC sentences in NMEA. RMB is the sentence for the recommended navigation data for GPS. RMC is the sentence for the recommended minimum data for GPS sentences.

In the model, you can choose to decode RMB and RMC sentences using Simulink or by incorporating Python code. This example explains the details of incorporating Python for decoding. For more information about the model and using Simulink® blocks for decoding, see “Simulink Strings” on page 72-43. For more on using Python in MATLAB®, see “Access Python Modules from MATLAB - Getting Started”.

MATLAB supports the reference implementation of Python, often called CPython. If you are on a Mac or Linux® platform, you already have Python installed. If you are using Windows®, you need to install a distribution, such as those found at <https://www.python.org/downloads>. For more information, see “Configure Your System to Use Python”.

### Explore the Model

In the model, the subsystem named `NMEA Data Generator` generates data and sends the data to the subsystem named `Data Classifier`. The `Data Classifier` classifies the sentences as RMB, RMC, or unsupported. The sentences are then sent to `RMB Decoder`, `RMC decoder`, or `Unsupported`, depending on their type.

Copyright 2022 The MathWorks, Inc.

### Model RMB and RMC Decoders Using Python or Simulink String Blocks

If you double-click the block named RMB Decoder, you can choose to model the decoder using Simulink string blocks or Python code.

Look under the mask. Observe that when you select Python, the decoder is modeled by using a MATLAB System block.

Open the source code. Observe that the Python code to decode the message is incorporated into the `setupImpl` and `stepImpl` functions.

```
function setupImpl(obj)
    py.importlib.import_module('RMBDecode');
end

function y = stepImpl(obj,sentence)
    % convert sentence to python string
    pstr = py.str(sentence);

    % call python module for string processing
    plist = py.RMBDecode.parseRMBSentence(pstr);

    % assign python list elements to Simulink bus
    y.Status = string(plist{1});
    y.Error = str2double(string(plist{2}));
    y.ErrorDirection = string(plist{3});
    y.OriginWaypointID = uint16(str2double(string(plist{4})));
    y.DestinationWaypointID = uint16(str2double(string(plist{5})));
    y.DestinationWaypointLatitudeDegree = uint16(str2double(string(plist{6})));
    y.DestinationWaypointLatitudeMinute = str2double(string(plist{7}));
    y.DestinationWaypointNS = string(plist{8});
    y.DestinationWaypointLongitudeDegree = uint16(str2double(string(plist{9})));
    y.DestinationWaypointLongitudeMinute = str2double(string(plist{10}));
    y.DestinationWaypointEW = string(plist{11});
```

```

y.RangeToDestination = str2double(string(plist{12}));
y.TrueBearing = str2double(string(plist{13}));
y.Velocity = str2double(string(plist{14}));
y.ArrivalAlarm = string(plist{15});
y.Checksum = string(plist{16});
end

```

### Simulate Model and Review Results

Simulate the model and observe the decoded RMB and RMC sentences.

## Create Custom Library

You can create your own library and, optionally, add it to the Simulink **Library Browser**. You save a library as a `.slx` file similar to the way you save a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 44-6.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.

---

**Note** The Library Browser only supports libraries. You cannot display the contents of a model in the Library Browser.

---

- 2 (Optional) Define data types to be used on block interfaces in a Simulink data dictionary. Then, attach the data dictionary to the library. Library users automatically gain access to the data contained in the dictionary when they drag a block from the library into their model.
- 3 Add blocks to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as `Subsystem_Name1/Subsystem_Name2/Subsystem_Name1`.

- 4 Add annotations or images. Right-click the ones you want to appear in the library in the Library Browser and select **Show in Library Browser**.
- 5 If you plan to add the library to the Library Browser, you can order the blocks and annotations in your library. By default, they appear alphabetically in the Library Browser, with subsystems first, then blocks, and then annotations. The user of your library can use the Library Browser context menu to choose between viewing them in alphabetical order or the order you specified. When the user selects this option, the order in which they appear in your library determines the order they appear on the grid in the library in the Library Browser.
- 6 If you want the library to appear in the Library Browser, enable the `EnableLBRepository` library property before you save the library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 7 Save the library.

Where you save the library depends on how you plan to use it. If you want to add it to the Library Browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the Library Browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example that shows complete steps for adding a library to the browser, see “Add Libraries to Library Browser” on page 44-8.

---

**Note** To update the Library Browser with your custom libraries, right-click anywhere in the Library Browser library list and select **Refresh Library Browser**. Refreshing the Library Browser also updates the quick insert menu to include the blocks in custom libraries currently in effect. The quick insert menu lets you add blocks to a model without leaving the canvas. Click the canvas and start typing to add blocks from the quick insert menu.

---

## Data Dictionary for Custom Libraries

When you define data types — such as bus and enumeration types — to be used on block interfaces, you can make these data types available to users by storing them in a data dictionary that is attached to the library. When a user drags a block from the library into their model, the model automatically gains access to the data contained in the dictionary.

- 1 Create a data dictionary.
- 2 In the dictionary, define bus objects, enumeration types, or other data objects that you will use for the interface definitions of your library blocks.
- 3 Attach the dictionary as an external data source for your library programmatically by using `set_param` or in the UI by using the **External Data** tab in the Library Properties dialog box. The Model Explorer displays the attached dictionary and its content as an external data source for the library.
- 4 To save the data dictionary specifications, save the library.

The types that you defined in the library are now available to you while developing library blocks. See “Link Data Dictionary to Custom Libraries” on page 79-37.

## Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See “Design and Create a Custom Block” on page 43-12.

You can create blocks in custom libraries with settings for specific purposes.

### Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a Subsystem block in the parent library.

- 1 In the library you want to add a sublibrary to, add a Subsystem block.
- 2 Inside the Subsystem block, delete the default input and output ports.
- 3 If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary purpose.
- 4 In the subsystem block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see “Create a Simple Mask” on page 42-6.

### Prevent Library Block from Linking to Instance

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block’s `CopyFcn` callback.

```
set_param(gcbh, 'LinkStatus', 'none');
```

### Include Block Description in Linked Block

To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block's properties do not appear on the linked block.

### Configure Block with Keywords for Quick Insert

You can add one or more keywords to a block in your library. The keyword lets you add the block to your model from the quick insert menu by entering the keyword or the block name.

For example, suppose you have a custom Gain block in your library. You can add the keyword **My Gain** to the block. Then, you can add the block to your model by entering **My Gain** at the quick insert menu.

---

**Note** You cannot add keywords to the blocks from **Commonly Used Blocks** as they are a place to view frequently used blocks from various libraries. If you want to add keywords to a block available in **Commonly Used Blocks**, make sure that you set it in the library where the block is defined.

---

To add the keyword to the block in your library, use `set_param` with the `'BlockKeywords'` parameter. You can use a character vector, string scalar, or string array as the value. For example:

```
set_param(gcb, 'BlockKeywords', {"My Gain", "Your Gain"})
set_param(gcb, 'BlockKeywords', 'My Integrator')
```

---

**Note** The supported special characters in keywords are '&', '(', ')', '+', '@', '!'.  

---

**Note** The quick insert menu also supports searching for blocks in languages other than English by using internationalized keywords.  

---

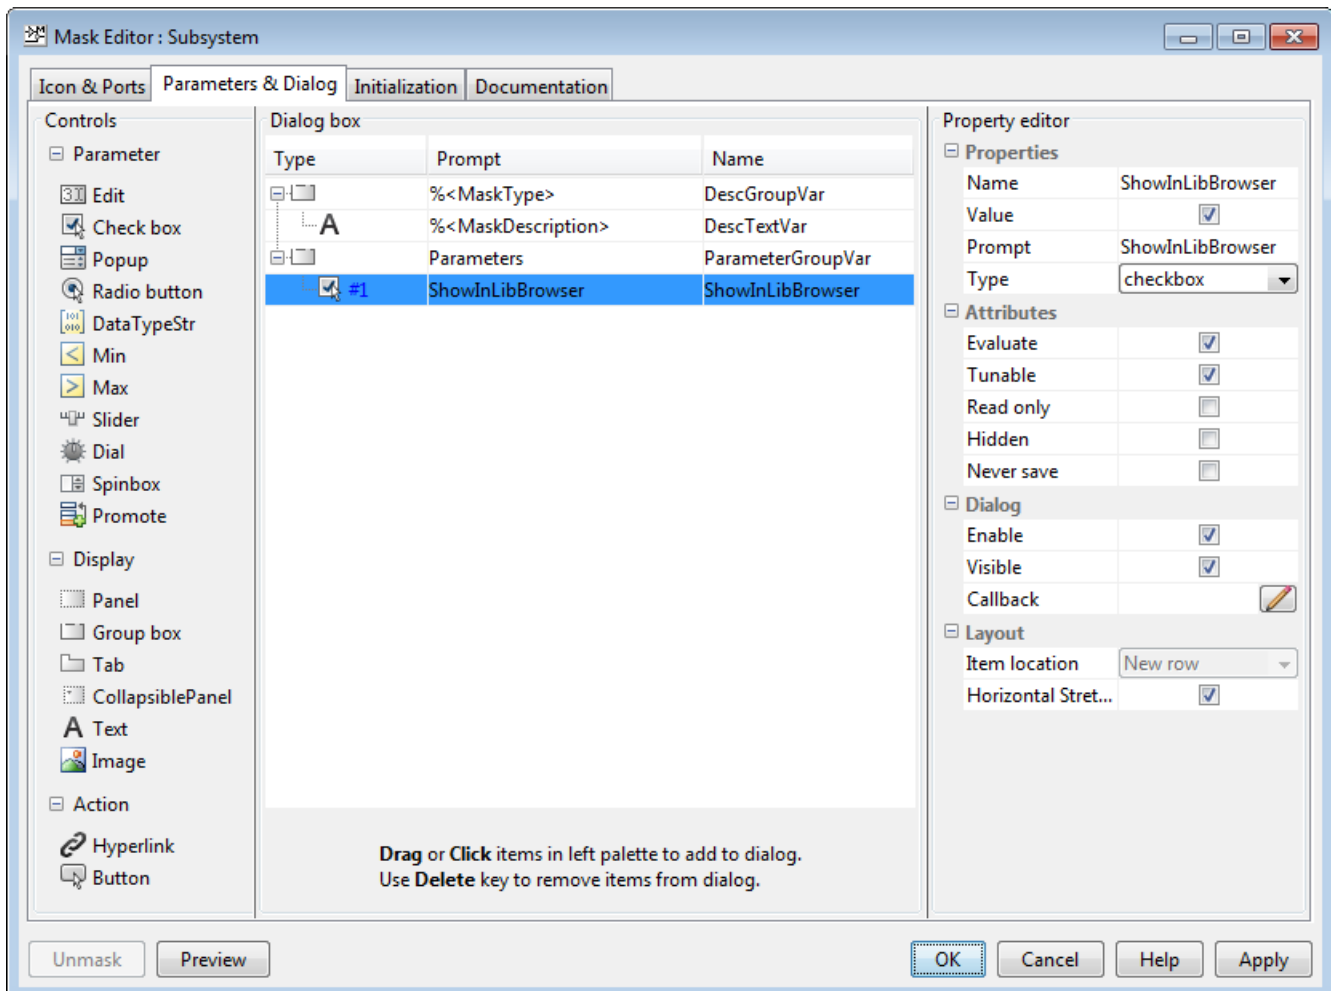

### Configure Subsystems with OpenFcn Callback for Library Browser

A common use of a Subsystem block in a custom library is to set the `OpenFcn` callback property to open a library, creating a library hierarchy. However, you can use the `OpenFcn` callback property of a Subsystem block for other purposes, for example to run MATLAB code or to open a link.

If a Subsystem block in a library is empty and its `OpenFcn` callback contains code that performs an action other than point to a library, then you need to add a `'ShowInLibBrowser'` mask parameter to the subsystem to have it appear in the Library Browser.

- 1 Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.

- 2 In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.
- 3 In the **Dialog box** pane, set the prompt and name for the new check box to **ShowInLibBrowser** and click **OK**.

## Annotations in Custom Libraries

You can add annotations in your custom library and optionally have them appear in the Library Browser. For example, you can add an annotation that documents the library. You can also add annotations that the user of your library can add to their model from the Library Browser. Annotations can contain text and images or display an equation. Annotations can also perform an action when clicked. Learn more about annotations in “Describe Models Using Notes and Annotations” on page 4-4.

You can add callout lines from annotations to blocks in your library. However, the callouts do not appear in the Library Browser.

If you want the annotation to appear in the Library Browser, after you add it to your library, right-click it and select **Show in Library Browser**. If you want a description to appear in a tooltip when the user hovers over the annotation in the Library Browser, add the description to the annotation programmatically. At the MATLAB command prompt, enter:

```
set_param(annotationHandle,'Description','descriptionText')
```

To get the annotation handle, use `find_system`. This example gets all the annotations in the library `mylib`:

```
ann = find_system('mylib','FindAll','on','Type','annotation');
```

To get a specific annotation, turn on regular expression search and specify part of the annotation text with the `'Name'` argument:

```
ann = find_system('mylib2','FindAll','on','RegExp',...  
'on','Type','annotation','Name','matchingText');
```

“Add Libraries to Library Browser” on page 44-8 includes instructions for adding an annotation that appears in the Library Browser.

## Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a message prompts you to unlock it.

You can unlock a library programmatically. At the MATLAB command prompt, enter:

```
set_param('library_name','Lock','off');
```

To lock the library programmatically, enter:

```
set_param('library_name','Lock','on');
```

## Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling links, you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, on the **Library** tab, click **Lock Links**.

To understand how the block user interacts with blocks from locked libraries, see “Lock Links to Blocks in a Library” on page 44-24.

## Add Libraries to Library Browser

This example shows how to create a block library and add it to the Simulink **Library Browser**. This example also shows how to add a sublibrary.

To specify information about your library, you create a function named `slblocks`.

### Add Library to Library Browser

- 1 On the Simulink start page, in the search box, type `library`. Select **Blank Library**, then click **Create Library**.

---

**Note** The Library Browser only supports libraries. You cannot display the contents of a model in the Library Browser.

---

- 2 Add a Gain block to the library.
- 3 In the MATLAB Command Window, enter this command to set the `EnableLBRepository` library property to `'on'`. Your library will appear in the Library Browser only if this property is enabled when you save your library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 4 Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.
- 5 In the MATLAB Current Folder Browser, open the folder that contains `mylib`, then, in the MATLAB Toolstrip, click **New Script**.
- 6 In the MATLAB Editor that opens, add this function, which specifies that the library `mylib` should appear in the Library Browser with the name **My Library**.

```
function blkStruct = slblocks
% This function specifies that the library 'mylib'
% should appear in the Library Browser with the
% name 'My Library'

    Browser.Library = 'mylib';
    % 'mylib' is the name of the library

    Browser.Name = 'My Library';
    % 'My Library' is the library name that appears
    % in the Library Browser

    blkStruct.Browser = Browser;
```

- 7 Save the function as `slblocks.m`.

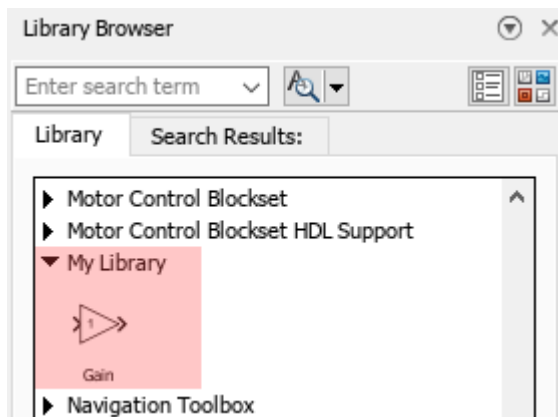

---

**Note** You can save the function as an `.m` or `.mlx` file. You cannot save the function as a P-code file.

---

- 8 To open the Library Browser, in the Simulink Toolstrip, click **Library Browser**.
- 9 To see the new library in the Library Browser, right-click the library list and select **Refresh Library Browser**.

The figure shows the example library `mylib` with the Library Browser name **My Library**.

**Note** If you save your library without setting 'EnableLBRepository' to 'on', a message appears at the top of the Library Browser.

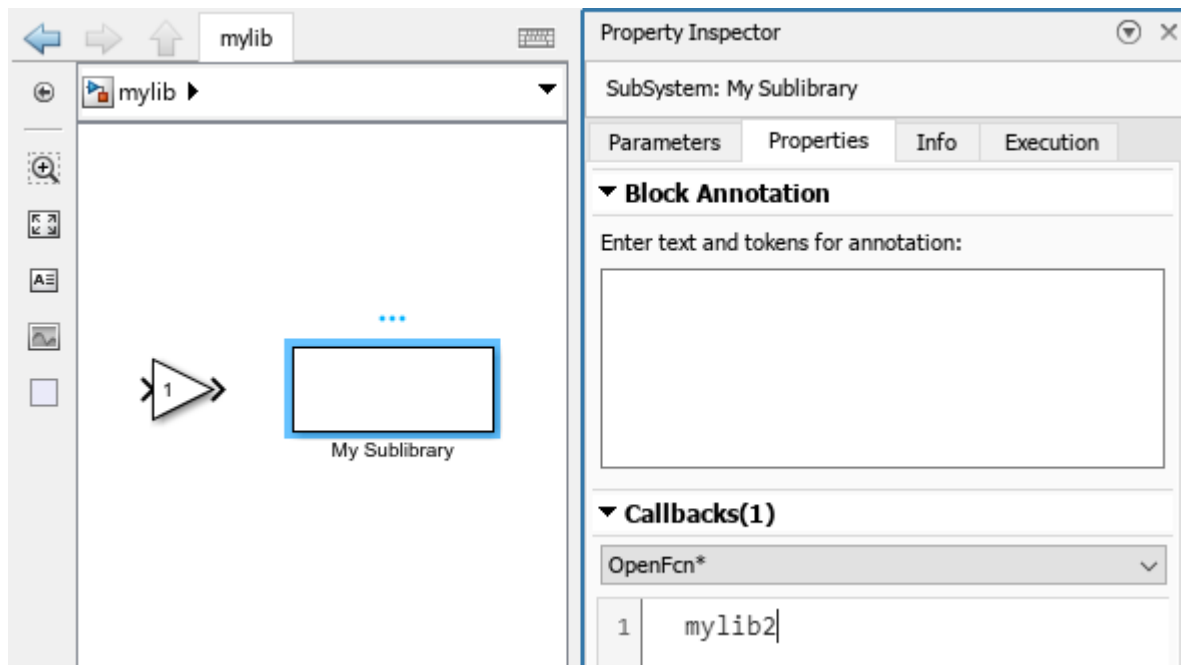

Click **Fix** and respond to the prompt as appropriate.

## Add Sublibrary to Library Browser

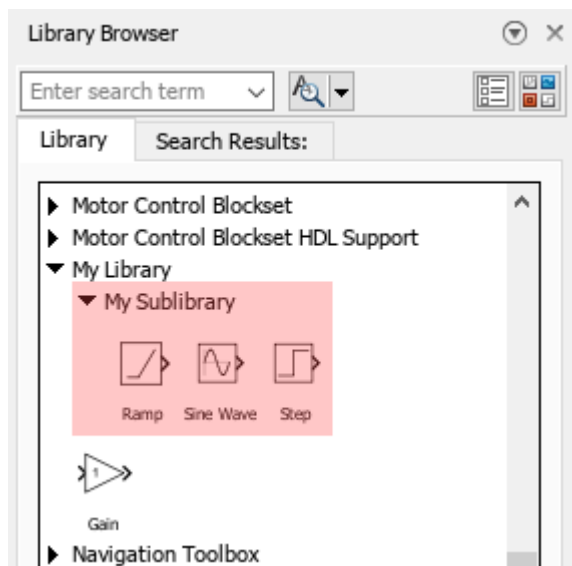

Follow these steps to add a sublibrary named `mylib2` to your `mylib` library.

- 1 Create a library named `mylib2`. Add some blocks to it.
- 2 In the MATLAB Command Window, set the `EnableLBRepository` library property to 'on' for the new library.
 

```
set_param(gcs, 'EnableLBRepository', 'on');
```
- 3 Save `mylib2` to the folder that contains `mylib`.
- 4 Add a Subsystem block to the `mylib` library.
- 5 Remove the input and output ports from the subsystem by deleting the Inport and Outport blocks inside the subsystem.
- 6 Name the Subsystem block `My Sublibrary`.
- 7 To link the Subsystem block to the sublibrary, set the `OpenFcn` callback to `mylib2` by using the Property Inspector.

- 8 Save mylib.
- 9 To see the new sublibrary in the Library Browser, right-click the library list and select **Refresh Library Browser**.

The figure shows the example sublibrary mylib2 with the Library Browser name **My Sublibrary**.

Because of the callback you created, expanding **My Sublibrary** displays the contents of the mylib2 library.

## Specify Library Order in Library List

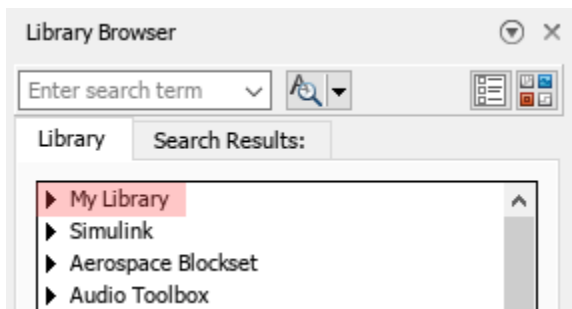

You can specify the order of your library relative to the other libraries in the list by adding a `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});
end
```

To make the customization take effect immediately, in the MATLAB Command Window, enter:

```
sl_refresh_customizations
```

## Linked Blocks

### In this section...

“Rules for Linked Blocks” on page 44-13

“Linked Block Terminology” on page 44-13

When you add a masked library block or a Subsystem block from a library to a Simulink model, a referenced instance of the library block is created. Such referenced instance of a library block is called a linked block and contains link or path to the parent library block. The link or path allows the linked block to update when the library block is updated.

To optimize the performance, the child blocks (and the parameters) of a linked block are not saved with the Simulink model. When such a model is loaded and viewed, the child blocks are referenced from the parent library. If you change the parameter value of a child block of such a linked block, the changed information is saved as linked data in the model.

To locate the parent library block of a linked block, right-click the block and select **Library Link > Go To Library Link** (Ctrl + L). This option is available only for the blocks that are linked and not for the Simulink built-in blocks. To prevent unintentional disabling of library links, use the locked links option on the library. For more information, see “Lock Links to Blocks in a Library” on page 44-24.

**Note** The tooltip for a linked block shows the name of the referenced masked library block.

When you edit a library block (either in Simulink Editor or at the command line), Simulink updates the changes in the linked blocks. The outdated links are updated when you:

- Simulate or update the model.
- Use the `find_system` command.
- On the **Modeling** tab, select **Update Model > Refresh Blocks** (or press **Ctrl+K**).
- Load the model or library (only the visible links are updated).
- Use `get_param` to query the link status of the block (see “Control Linked Block Programmatically” on page 44-34).

You can use the `LinkStatus` parameter or the `StaticLinkStatus` parameter to query the link status.

- `LinkStatus`: First updates the linked block and then returns the link status.
- `StaticLinkStatus`: Returns the link status without updating the linked block.

Selective usage of `StaticLinkStatus` over `LinkStatus` can result in better Simulink performance. For more information on `StaticLinkStatus` and `LinkStatus`, see “Control Linked Block Programmatically” on page 44-34.

## Rules for Linked Blocks

- You can change the values of a linked block parameter (including the existing mask) in the mask dialog box.
- To allow the library block initialization code to change the values of a linked block parameter, select the **Allow library block to modify its contents** check box in the **Initialization** pane of the library block.
- It is not recommended to set callback parameters for a linked block.
- If the reference library block of a linked block is a subsystem, you can make nonstructural changes such as changing the parameter value of the linked subsystem. To make structural changes to a linked block, disable the link of the linked block from its library block (See “Disable or Break Links to Library Blocks” on page 44-22).

## Linked Block Terminology

Terminology	Definition
Parent library block	Library block from which the linked blocks are referenced.
Linked block	Reference instance of a library block that contains links or path to its parent library block.
Locked links	Prevents unintentional modification of a linked block. For more information, see “Lock Links to Blocks in a Library” on page 44-24.
Disabled links	Library links that are temporarily disconnected from their parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 44-22.
Restore links	Restores the disabled link of a linked block to their parent library block. For more information, see “Restore Disabled Links” on page 44-26.
Break links	Permanently breaks the link of a linked block from its parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 44-22.
Self-modifiable links	Linked block with the ability to have structural changes in a linked Subsystem block. For more information, see “Self-Modifiable Linked Subsystems” on page 44-18.
Parameterized links	Created when the parameter values of a linked block are modified using the MATLAB command prompt. For more information, see “Parameterized Links and Self-Modifiable Linked Subsystems” on page 44-15.
Forwarding Tables	Maps the old library block path to new library block path. For more information, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 44-37.

<b>Terminology</b>	<b>Definition</b>
Transformation function	Corrects the mismatch of parameters in the <code>InstanceData</code> of the new and old library links to ensure that the library links continue to work. For more information, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 44-37.

## Parameterized Links and Self-Modifiable Linked Subsystems

You can use the MATLAB command prompt to change the value of a parameter in a linked block. Such parameter changes on the linked block result in parameterized links.

Similarly, you can also modify the structure of a linked Subsystem block without changing the parent library block. Such changes can be applied using the mask initialization code and is called self-modifiable linked subsystem.

### Parameterized Links

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block.

A parameterized link allows you to have a different parameter value for the linked block and the parent library block. For such library blocks, the link to the parent block is still retained.

---

**Note** Changing the mask value of a parent library block does not create a parameterized link.

---

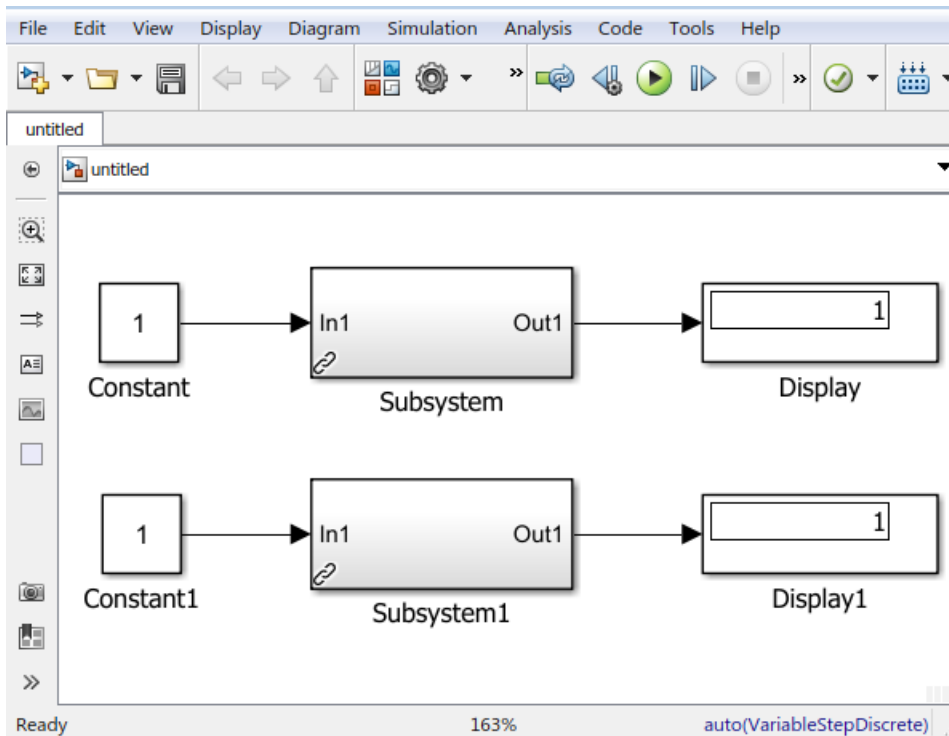

For example, you can use the `set_param` command to set a parameter value in the child blocks of a linked subsystem block. The `set_param` command overrides the parameter values of the child blocks of the subsystem linked block. Thus, differentiating the child block value from its parent library block and creating a parameterized link.

Consider a Subsystem library block (see “Subsystem Library Block” on page 44-15) that contains a Gain block within with its parameter value as 1.

### Subsystem Library Block

Use this Subsystem block as a linked block in a model.

You can modify the parameter values of the child blocks of the linked block without changing the value of the parent library block. For example, you can change the parameter value of the Gain block within the Subsystem linked block.

To change the Gain parameter value of the Gain block within the Subsystem linked block to 100, sequentially type these commands at MATLAB command prompt:

```
pathName = [modelName, '/Gain_Subsystem1/Gain'];
set_param(pathName, 'Gain', '100')
```

A parameterized link is now created, overriding the parameter value (see “Parameterized Linked Block” on page 44-17). Similarly, change the Gain parameter value of the Subsystem1 linked block.

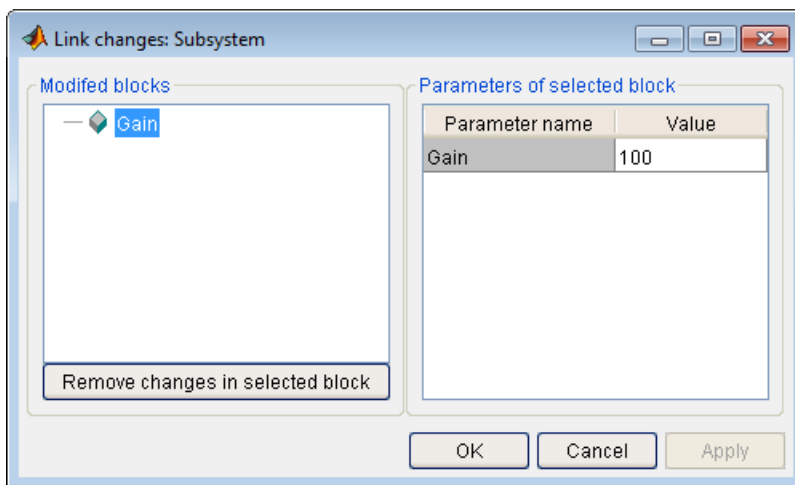

### Parameterized Linked Block

When you save a model containing a parameterized link, Simulink saves the changes to a local copy of the Subsystem with the path to the parent library. When you reopen the model, Simulink copies the library block into the loaded model and applies the saved changes.

**Note** To view the parameterized changes on a block, right-click the block, and on the context menu, select **View Changes**. The **Link changes** dialog box opens displaying the list of modified blocks. You can also use this dialog box to remove parameterized changes from a block.

## Identifying Parameterized Links

A parameterized link displays these identifications:

- The link badge of a parameterized link contains a black link with a red star icon, . For more information, see “Display Library Links” on page 44-20.
- The tooltip of a parameterized linked block displays **Modified parameter in link**.

- Block dialog box of a linked Subsystem block contains **parameterized link**.

## Self-Modifiable Linked Subsystems

---

**Tip** We recommend using variant blocks over self-modifiable linked subsystems.

---

A self-modifiable linked subsystem is a linked block with the ability to have structural changes in the subsystem without disabling the link. A self-modifiable linked subsystem is created when you use a library block containing a self-modifiable mask as a linked block. You can use the mask initialization code to change the structural contents.

For more information, see “Dynamic Masked Subsystem” on page 42-38 and Self-Modifiable Mask on page 44-19.

## See Also

### More About

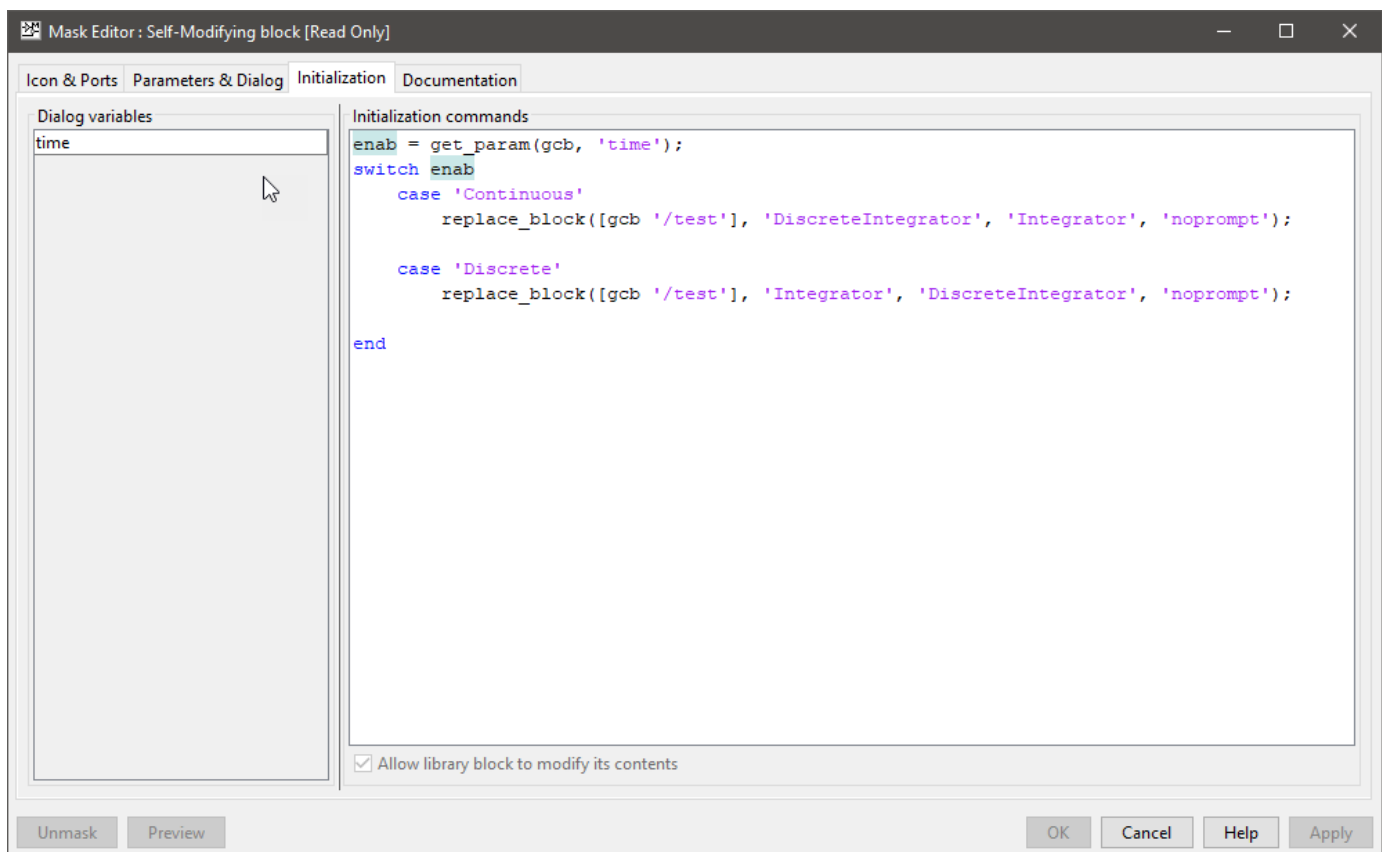

- “Linked Blocks” on page 44-12

- “Restore Disabled Links” on page 44-26

## Create a Self-Modifiable Library Block

A self-modifiable linked block is created when you add a self-modifiable masked subsystem block from the library to your model. Such linked blocks allow structural changes within the subsystem block.

You can observe that in this example, if you change the 'Time domain' on the mask dialog box, the block within the Subsystem is replaced accordingly. For example, if you select the 'Time domain' as 'Discrete', the continuous integrator block is replaced with a discrete integrator block and vice-versa.

This dynamic change in the structure of the self-modifiable linked block is controlled using the MATLAB code that is added in the Initialization pane of the Mask Editor.

The structural changes take place only if the option 'Allow library block to modify its contents' available on the Initialization pane is selected.

```
open_system('self_modifiable_mask_example');
```

## Display Library Links

Each linked block has a link badge associated with it. The badge makes it easier to identify the linked block in a model and also displays its link status.

To control the display of library link badges in a Simulink model, on the **Debug** tab, select **Information Overlays** and then one of these options:

- **Hide All Links** — Displays no links.
- **Disabled Links** — Displays only disabled links (the default for new models).
- **User-Defined Links** — Displays only links to user libraries.
- **Show All Links** — Displays all links.

If activated, link badges are displayed at the bottom left corner of a linked block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link.

Link Badge	Status
Black links 	Active link
Gray separated links 	Inactive link
Black links with a red star icon 	Active and modified (parameterized link)
White links, black background 	Locked link

### More About

- “Linked Blocks” on page 44-12

- “Disable or Break Links to Library Blocks” on page 44-22
- “Restore Disabled Links” on page 44-26

## Disable or Break Links to Library Blocks

Structural changes in a model include addition or deletion of blocks or adding ports while non-structural changes include changes in parameter value.

A linked block does not allow structural changes to it. You can disable the link of a linked block from its parent library block and perform required modifications. A disabled linked block behaves like a local instance of a block and allows you to make structural and nonstructural changes.

To disable a link, right-click the linked block and select **Library Link > Disable Link**. The **Disable Link** menu choice is made available only if the parent block of the linked block is disabled. If the menu option is grayed out, you must disable the link of the parent block first.

Alternatively, you can right-click the link icon in the graph on the bottom left corner of the canvas and click **Disable Link**. This action recursively disables the links of all the blocks up in the hierarchy.

To prevent unintentional disabling of a linked block, you can lock its links to the library. To lock a link, in the Library window, on the **Library** tab, click **Lock Links**. You can later choose to unlock the locked link by clicking **Links Locked**.

---

**Note** Simulink offers to disable the library links (unless the link is locked) when you try to make structural changes to a block that contains active library links.

Do not use `set_param` to make structural changes to an active link. The result of this type of change is undefined.

---

A disabled link of a linked block can be restored. For more information, see “Restore Disabled Links” on page 44-26.

Disabled links can cause merge conflicts and failure to update all instances of the same model component. In a hierarchy of links, you can accidentally disable all links without being aware of it, and only restore one link while leaving others disabled.

### Break Links

You can permanently break links to the parent library. Before you break a library link, the link must first be disabled. When you break a link, the linked block is converted to a standalone block, and you cannot detect what the block linked to previously.

To break a link, use any of these options:

- For disabled links, right-click the linked block and select **Library Link > Break Link**.
- To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. The locked links are ignored and not broken.
- When you save the model, you can break links by supplying arguments to the `save_system` command. For more information, see `save_system`.

---

**Note**

- Some models can contain blocks from third-party libraries or optional Simulink block sets. Breaking the link for such models does not guarantee that you can run the model standalone. It is possible that a library block invokes functions supplied with the library and hence can run only if the library is installed on the system running the model.
  - Breaking a link can cause a model to fail when you install a new version of the library on a system. For example, if a model block invokes a function that is supplied from a library. If you break the link for such a block, the function can no longer be invoked from the model, causing simulation to fail. To avoid such problems, avoid breaking links to libraries.
- 

**See Also**

“Linked Blocks” on page 44-12 | “Restore Disabled Links” on page 44-26

## Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links prevent unintentional disabling of these links. Lockable libraries ensure robust usage of mature stable libraries.

To lock links to a library, in the Library window, on the **Library** tab, click **Lock Links**. The link from the linked block to its parent library is now locked. When you refresh the model, you see a change in the link badge. The locked link badges have a black background.

Locked linked block links cannot be disabled from the parent library block. Such links can only be disabled from the command line by changing the LinkStatus to inactive. For more information, see “Control Linked Block Programmatically” on page 44-34.

The context menu of a locked linked block displays **Locked Library Link** and not **Library Link**. Also notice that the only enabled option on this menu is **Go To Library Block**.

If you open a locked linked block, the window title displays **Locked Link: *blockname***. The bottom left corner shows a lock icon and a link badge. You can also hover over the link badge to view lock information.

To unlock links from the Library window, on the **Library** tab, click **Links Locked**. If the library is locked, the option to lock or unlock the links is disabled. You must unlock the library to enable the option.

### Rules for Locked Links

- Locked links cannot be edited. If you try to make a structural change to a locked link (such as editing the diagram), you see a message that you cannot modify the link because it is either locked or inside another locked link.
- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.

- When you copy a block, the library status determines the status of a link (locked or not). If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh the links.
- If you use sublibraries, when you lock links to a library, lock links to the sublibraries.

## **See Also**

## **More About**

- “Linked Blocks” on page 44-12

## Restore Disabled Links

You can restore a disabled linked block or push a linked block value to the parent library block either individually or hierarchically.

### Restore Disabled Links Individually

When you push or restore a disabled block in individual mode, the disabled or edited block is pushed to or restored from the library, preserving the changes inside the block without acting on the hierarchy. All other links are unaffected. You can restore or push individual disabled blocks in three ways:

- Select the disabled linked block and in the Simulink toolstrip, on the **Subsystem Block** tab, select **Push Link** or **Restore Link**.

- Right-click a disabled linked block and from the context menu, select **Library Links** and click **Push Link** to push the changes or **Restore Link** to restore the values from the parent library block.
- Right-click the link badge on the bottom-left corner of a disabled linked block and from the context menu, click **Push Links** to push the changes or **Restore Link** to restore the values from the parent library block.

## Restore Disabled Links Hierarchically

When you push or restore disabled links in the hierarchy mode, the operation is applied to the whole hierarchy of links. To push or restore in hierarchy mode, use the Library Link Manager tool. The Library Link Manager displays all the disabled and parameterized linked blocks in the model.

You can launch the Library Link Manager in two ways:

- In the Simulink toolstrip, on the **Modeling** Tab, under the **System Design** section, click **Library Link Manager**.
- or
- Select any disabled linked block and in the Simulink toolstrip, on the **Subsystem Block** tab, click **Library Link Manager**.

The Library Link Manager window appears. It has two tabs showing disabled Links and parameterized links in the model. By default, the **Disabled Links** tab is selected.

The table shows two columns where the **Linked Block** column displays the list of linked blocks that have disabled links and the **Library Block** column displays the parent library block of the corresponding linked blocks.

To push or restore disabled blocks,

- 1 Select the disabled block or blocks as per your requirement.
- 2 Click **Push** to replace the version of the block in the library with the version in the model or **Restore** to replace the version of the linked block in the model with the version in the library.

You can use the **Filter Blocks** field to filter the displayed linked blocks based on your preference. This is useful when you have a huge number of blocks in the model.

## Pushing or Restoring Link Hierarchies

Pushing a hierarchy of disabled links affects the disabled links inside and outside the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if unchanged. This operation does not affect outer (parent) links with changes unless you also explicitly selected them for push. The Library Link Manager starts to push from the lowest inside links and then moves up in the hierarchy.

For examples:

- 1 Link A contains link B and both have changes.
  - Push A. The Links Tool pushes both A and B.
  - Push B. The Links Tool pushes B and not A.
- 2 Link A contains link B. A has no changes, and B has changes.
  - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Library Links Manager can manipulate only the top level.

---

**Tip** To compare files and view structural changes, in the **Modeling** tab, select **Compare > Compare Models**.

---

### More About

- “Linked Blocks” on page 44-12
- “Restore Parameterized Links” on page 44-30

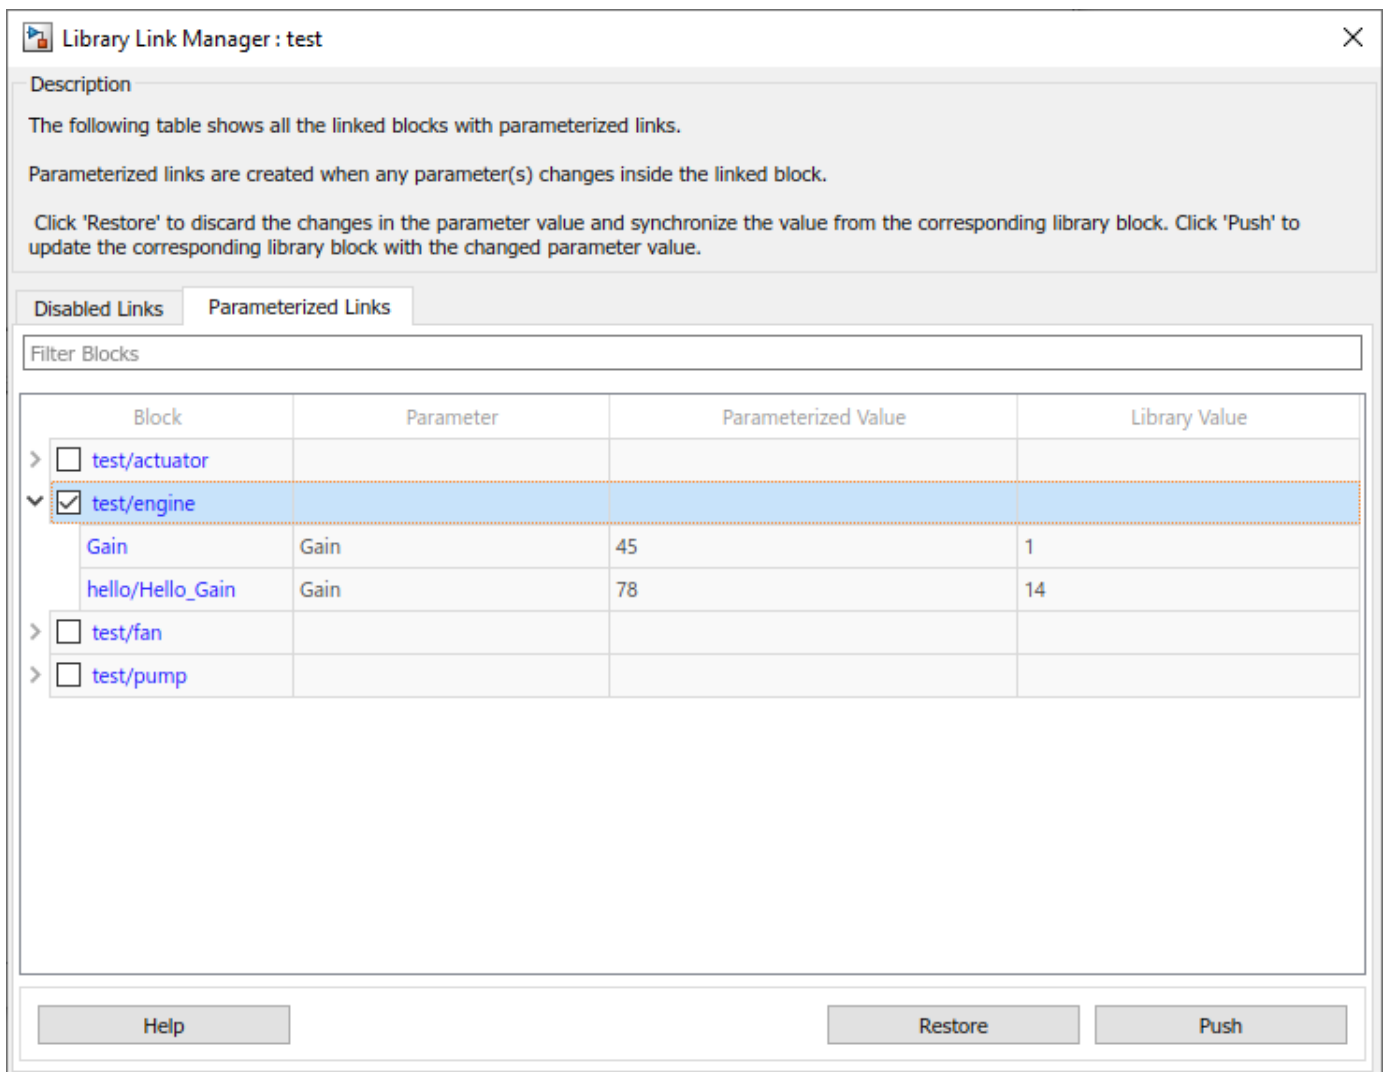

## Restore Parameterized Links

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block. You can choose to push the new values from the linked block to the parent block or restore the linked block with values from the parent block. You can push or restore parameterized links using the Library Links Manager.

To restore or push parameterized links:

- 1 Select the parameterized link and in the Simulink toolstrip, on the **Subsystem Block** tab, click **Library Link Manager**.

The Library Link manager opens. Click the **Parameterized Links** tab to display all the parameterized link in the model.

The table has the following columns:

- **Block** - Displays the block name.
  - **Parameter** - The name of the parameter in the block.
  - **Parameterized Value** - The changed value of any edited parameter in the model.
  - **Library Value** - The original value of the parameter in the parent library block.
- 2 Select the blocks you want to push or restore.
  - 3 Click **Push** to replace the value of the block in the library with the parameterized value in the model or **Restore** to replace the version of the linked block in the model with the version in the library.

- “Restore Disabled Links” on page 44-26

## Fix Unresolved Library Links

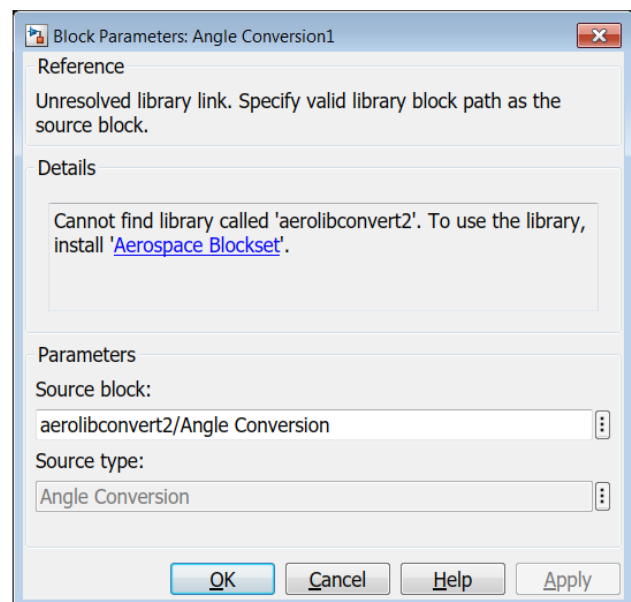

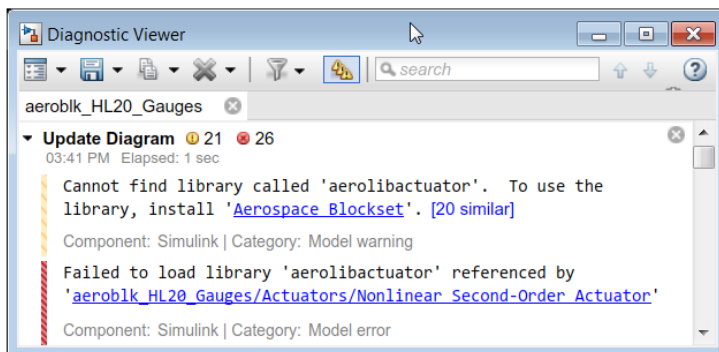

If Simulink is unable to find either the library block or the source library on your MATLAB path during a linked block update, the link becomes unresolved. Simulink changes the appearance of these blocks.

## Install Missing Product

Simulink helps you find and install missing products that a model needs to run.

- Blocks are labeled with missing products (for example, **SimEvents not installed**).
- Tooltips include the name of the missing product.
- Diagnostic messages provide links to open the Add-On Explorer and install any missing products.
- When you double-click the block, the dialog box provides a link to open the Add-On Explorer and install any missing products.

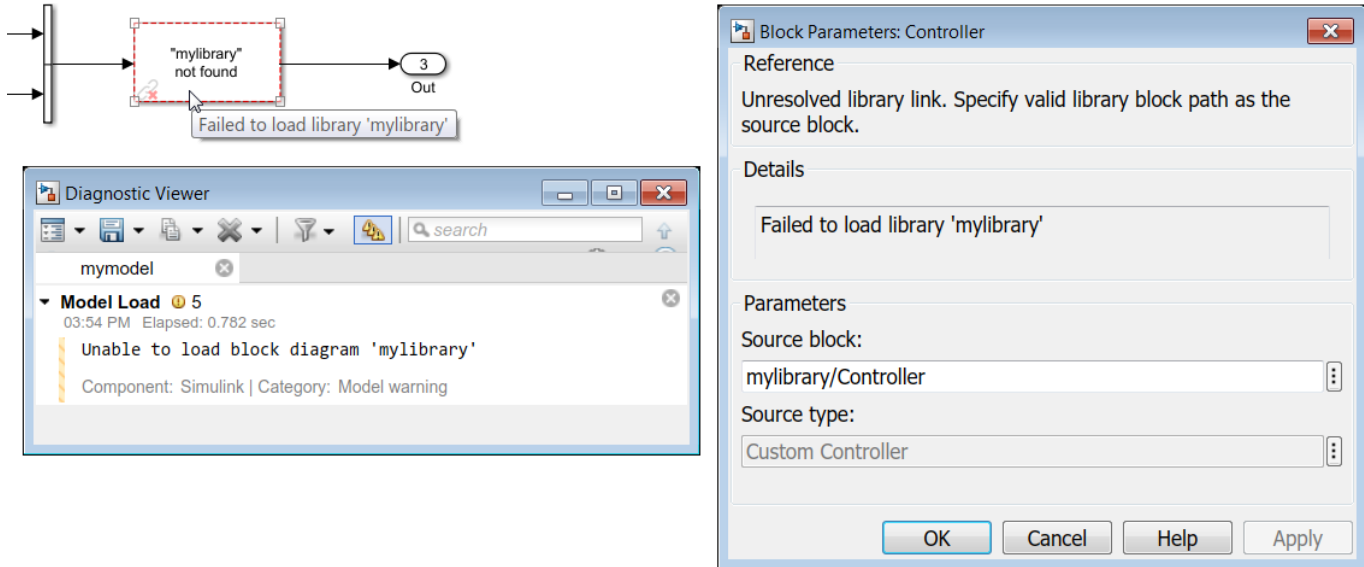

## Resolve Path to Source Block

If Simulink is unable to find the library, you can fix the unresolved link using one of these methods:

- Fix the reference to point to the correct location of the library block. Double-click the block to open its dialog box. Then, correct the path of the library block in the **Source block** text box and click **OK**.

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path. Then, on the **Modeling** tab, click **Update Model**.

## Specify Unresolved Block Details for Custom Libraries

You can customize the description that appears in the dialog box for an unresolved link to a custom library. Use the `set_param` function to set the `libraryinfo` property of the library. For example, this command customizes the description to include a URL.

```
set_param(library1, 'libraryinfo', 'https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

## Control Linked Block Programmatically

### Linked Block Information

Use the `libinfo` command to get information about the linked blocks in the model. `libinfo` also provides information about the parent library blocks of a linked block.

For example, here is a model with linked blocks:

Masking variant blocks

When you execute the `libinfo(gcb)` command on this block:

```
Block: 'slexMaskVariantExample/VariantSubsystem2' %Linked block
      Library: 'slexMaskingVariants_libraryblock' %Parent library block
      ReferenceBlock: 'slexMaskingVariants_libraryblock/VariantSubsystem2'
      LinkStatus: 'resolved' %Link status
```

The `ReferenceBlock` property gives the path of the library block to which a block links. You can change this path programmatically by using the `set_param` command. For example:

```
set_param('slexMaskVariantExample/VariantSubsystem2','ReferenceBlock','slexMaskVariantExample2/VariantSubsystem')
```

Here, `slexMaskVariantExample/VariantSubsystem2` is the original library block path and `slexMaskVariantExample2/VariantSubsystem` is the new library block path.

---

**Note** It is not recommended to change the properties of a referenced block by using the `set_param` command in the mask initialization code or callback code of the same block. For such modeling patterns, you can use Variant blocks (Masking variant blocks) or use the `ReferenceBlock` parameter on the callback code or the mask initialization code of the parent block of the reference block.

---

### Lock Linked Blocks

Use the `LockLinksToLibrary` command to lock or unlock a linked block in a library from the command line. When you set the value of `LockLinksToLibrary` to `on`, the linked block links to the library are locked.

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'on') %Lock links
```

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'off') %Unlock links
```

### Link Status

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter to indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating the linked blocks. You can use `StaticLinkStatus` to query the status of a linked block that is either active or outdated.

Use `get_param` to send a query to get the value of the `LinkStatus`.

Get LinkStatus Value	Description
none	Block is not a linked block.
resolved	Resolved link.
unresolved	Unresolved link.
implicit	Block resides in library block and is itself not a link to a library block. Suppose that A is a link to a subsystem in a library that contains the Gain block. If you open A and select the Gain block, <code>get_param(gcb, 'LinkStatus')</code> returns <code>implicit</code> .
inactive	Disabled link.

Use `set_param` to set the `LinkStatus`.

Set LinkStatus Value	Description
none	Breaks link. Use <code>none</code> to break a link, for example, <code>set_param(gcb, 'LinkStatus', 'none')</code> .
<code>breakWithoutHierarchy</code>	Breaks links in place without breaking the nested parent hierarchy of link. For example, <code>set_param(gcb, 'LinkStatus', 'breakWithoutHierarchy')</code> .
inactive	Disables link. Use <code>inactive</code> to disable a link, for example, <code>set_param(gcb, 'LinkStatus', 'inactive')</code> .
restore	Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, <code>set_param(gcb, 'LinkStatus', 'restore')</code> replaces the selected block with a link to a library block of the same type. It discards any changes in the local copy of the library block.  <code>restore</code> is equivalent to <code>Restore Individual</code> in the Links Tool.
propagate	Pushes any changes made to the disabled link to the library block and re-establishes its link. <code>propagate</code> is equivalent to <code>Push Individual</code> in the Links Tool.
restoreHierarchy	Restores all disabled links in the hierarchy with their corresponding library blocks. <code>restoreHierarchy</code> is equivalent to <code>Restore</code> in hierarchy mode in the Links Tool.
propagateHierarchy	Pushes all links with changes in the hierarchy to their libraries. <code>propagateHierarchy</code> is equivalent to <code>Push</code> in the <b>Hierarchy</b> mode of the Links Tool. See “Restore Disabled Links” on page 44-26.

#### Note

- When you use `get_param` to query the link status of a block, the outdated block links also resolve.
- Using the `StaticLinkStatus` command to query the link status when `get_param` is being used in the callback code of a child block is recommended. `StaticLinkStatus` command does not resolve any outdated links.

If you call `get_param` on a block inside a library link, Simulink resolves the link wherever necessary. Executing `get_param` can involve loading part of the library and executing callbacks.

## Maintain Compatibility of Library Blocks Using Forwarding Tables

Forwarding Table allow you to check that the changes to blocks in a library do not break the model if you have saved the model with an older version of the library block. Forwarding tables help you to maintain compatibility of library blocks when you change the path or name of the library, or add, remove, or rename the parameters in the library block. For more information see, “Create Custom Library” on page 44-2.

Create a forwarding table entry for mapping old library blocks to new library blocks. When you open the model, the links to the old library block are updated automatically without losing data or functionality. Forwarding tables are executed when you open a model, close a model, or when you execute the `add_block` or `replace_block` command.

Create a forwarding table entry when you:

- Rename a block.
- Move a block from one library to another library.
- Add or remove parameters from the block.
- Split the functionality of a block.

### Forwarding Table Entry for a Renamed Block

Consider an example where the block name in a library `testlib` is renamed from `ss1` to `ss2`.

- 1 Open the locked library `Lib1`.
- 2 In the Library window, on the **Library** tab, click **Locked Library**. The library is now unlocked for editing.
- 3 On the **Modeling** tab, click **Library Properties**. The **Library Properties** dialog box opens.
- 4 Click the **Forwarding Table** tab.
- 5 Click Add New entry. A new row is added in the forwarding table.
- 6 Specify the name of the old block in **Old Block Path** and the corresponding new block path in the **New Block Path**. If you do not know the path, select the block in the model and click **Get gcb** button. The path of the block is automatically populated in the respective columns.

The mapping of the old path to new path is created in the forwarding table. Now, open a model that contains links to the library. The links to the old library blocks in the model are updated automatically. You can use the search bar above the table to filter the table contents. You can sort the columns in ascending or descending order. You can also group columns by their values.

### Assign Version Numbers to Library Blocks

In the **Version** column, you can specify a version number for the library block.

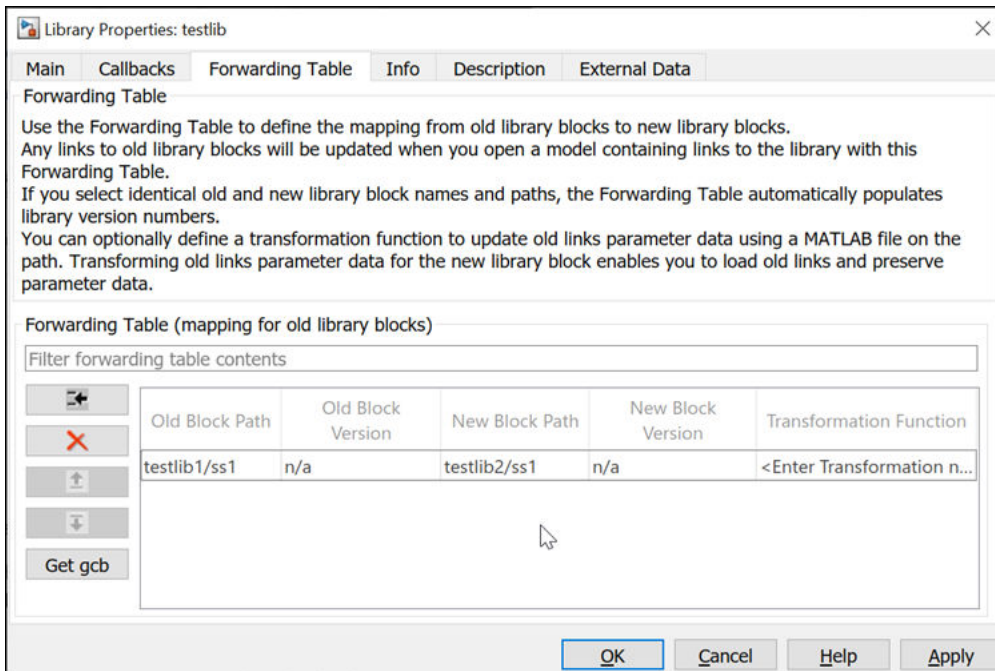

If the old block name is the same as new block name, the forwarding table populates the version number automatically. The initial value of the library version `LibraryVersion` is derived from the `ModelVersion` property of the library at the time the library link is created. Any subsequent updates to the library block will update the library version to match the model version of the library.

The version number:

- Must be a numeric value.
- Must be of the format `<major_version>. <minor_version>` when the old and the new block paths are the same.
- Must not have more than one dot notation. For example, a version number of 1.3 is acceptable. A version number 1.3.1 is not acceptable.
- Format is not critical when you use a forwarding table to move a library block from one library to another.

### Move Block from One Library to Another

Consider an example where a block `ss1` is moved from `testlib1` to `testlib2`. The forwarding table entry in this case is shown here:

## Add or Remove Parameters from the Block

Consider an example where the **Gain** parameter of `ss1` in library `testlib` is removed, and two other parameters `Initial condition` and `Delay length` are added to it.

To handle this change we use a transformation function. A transformation function corrects the mismatch of parameters between the new and old library links, which ensures that the library links continue to work. You can define a transformation function using a `.m` function file on MATLAB path, then call the function in the **Transformation Function** column of the **Forwarding Table**.

A linked block contains an instance of the block parameters in the form of name-value arguments to instantiate the block. This instance data is passed to transformation function as `InstanceData` along with forwarding entry. This data is stored as `struct` fields.

When you create versions of a library block, parameters are added or removed from the `InstanceData`. In this example, the `InstanceData` before removal of the **Gain** parameter and after the addition of initial condition and delay length looks like this

### Before:

```
'RTWMemSecFuncInitTerm' 'Inherit from model'
'RTWMemSecFuncExecute' 'Inherit from model'
```

```
'RTWMemSecDataConstants' 'Inherit from model'  
'RTWMemSecDataInternal' 'Inherit from model'  
'RTWMemSecDataParameters' 'Inherit from model'  
'ContentPreviewEnabled' 'on'  
'Gain' '0'
```

**After:**

```
'RTWMemSecFuncInitTerm'      'Inherit from model'  
'RTWMemSecFuncExecute'     'Inherit from model'  
'RTWMemSecDataConstants'   'Inherit from model'  
'RTWMemSecDataInternal'   'Inherit from model'  
'RTWMemSecDataParameters'  'Inherit from model'  
'ContentPreviewEnabled'    'on'  
'DelayLength'              '1'  
'InitialCondition'         '0'
```

This is the syntax for transformation function.

```
function outData = TransformationFcn(inData)
```

In this function syntax:

- `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`. `ForwardingTableEntry` is also a structure.
- • The `ForwardingTableEntry` has the old name, new name, old path, and new path of a block. Refer to the code to access the members of the `ForwardingTableEntry`.
- `outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

To add or remove parameters from a block:

- 1 Obtain the instance data and the forwarding table entry.
- 2 Extract the list of name-value pair and block names.
- 3 Get the old and new block names.
- 4 Check if the old and new block names are same. If so, then extract the versions of the block.
- 5 Check if the old version is 1.1 and the new version is 1.2. Then, remove the `Gain` parameter and add the parameters `Delay length` and `Initial condition`.

---

**Note** You can have only one transformation function for one library or block. However, you can have multiple functions.

---

To add or remove parameters, use this transformation function.

```
function [outData] = txFcnTestlib(inData)  
    outData.NewBlockPath = '';  
    outData.NewInstanceData = [];  
  
    % Get linked block instance data and forwarding entry for which  
    % function is called  
    instanceData = inData.InstanceData;  
    forwardingTableEntry = inData.ForwardingTableEntry;  
  
    % Get list of name value pair and block names
```

```

[ParamNames{1:length(instanceData)}] = instanceData.Name;

% Get old and new block paths or simply names
oldName = forwardingTableEntry('__slOldName__');
newName = forwardingTableEntry('__slNewName__');

% If block names are same and its subsys block in the lib
if strcmp(oldName, newName)
    % Get old and new block versions from forwarding table
    oldVer = forwardingTableEntry('__slOldVersion__');
    newVer = forwardingTableEntry('__slNewVersion__');

    % Each forwarding entry with different version can have separate
    % entry. Here, for one single entry in forwarding table i.e.
    % 1.2->1.3 or 1.3->2.0, we have separate transformation making one
    % TX Fcn for one library or block.
    if strcmp(oldName, 'testlib/ssl')
        % Forwarding with same block name ssl
        if oldVer == '1.1' && newVer == '1.2'
            % Remove gain param
            if (ismember('Gain',ParamNames))
                for (i = 1:length(instanceData))
                    if (strcmp(instanceData(i).Name,'Gain') == true)
                        instanceData(i) = [];
                        break;
                    end
                end
            end
        end

        % Add delay length param
        if (ismember('DelayLength',ParamNames))
            for (i = 1:length(instanceData))
                if (strcmp(instanceData(i).Name,'Value') == true)
                    instanceData(i).Value = '5';
                    break;
                end
            end
        else
            instanceData(end+1).Name = 'DelayLength';
            instanceData(end).Value = '1';
        end

        % Add initial condition param
        if (ismember('InitialCondition',ParamNames))
            for (i = 1:length(instanceData))
                if (strcmp(instanceData(i).Name,'InitialCondition') == true)
                    instanceData(i).Value = '0';
                    break;
                end
            end
        else
            instanceData(end+1).Name = 'InitialCondition';
            instanceData(end).Value = '0';
        end
    elseif (oldVer == '1.2' && newVer == '1.3')
        % Do version 1.2 to 1.3 specific changes
    elseif (oldVer == '1.3' && newVer == '2.0')
        % Do version 1.3 to 2.0 specific changes
    end
end

```

```

        else
            % Do default changes not applicable to any version if
            % required
        end
    elseif strcmp(oldName, 'testlib/ss2')
        % Forwarding for block ss2 with version upgrade
    end
elseif strcmp(oldName, 'testlib/oldblk') && strcmp(newName, 'testlib2/newblk')
    % Block moved to new library or just block is renamed within same
    % library, no version is checked here. Do transformation is
    % required i.e. is block has been modified while renaming or moving
    % to new lib.
elseif strcmp(oldName, 'testlib/blkX') && isempty(newName)
    % We are splitting the block into 2 different blocks. Hence, kept
    % newName empty in fwd table. Using one of the block param from its
    % instance data (which is name-value pair of all block params) to
    % decide how and what to divide.

    % Get the index of param we are interested in i.e. param X
    i = find(contains({instanceData.Name}, 'X'), true);

    % Based on its value, do block splitting
    switch (instanceData(i).Value)
        case 'op1'
            newName = 'newlibX/blkX';
            % Remove existing param or add new param or modify existing
            % params etc.
        case 'op2'
            newName = 'newlibY/blkX';
        otherwise
            newName = oldName;
    end
end

% Return new instance data and new block path
outData.NewInstanceData = instanceData;
outData.NewBlockPath = newName;
end

```

## Split Block Functionality

Splitting the functionality of a block involves adding, removing, or modifying the existing parameter of the block and adding it to the new block. To split the functionality of a block:

- 1 Leave the newName argument empty.
- 2 Get the index and value of the parameter.
- 3 Split the block based on its value.
- 4 Return the NewBlockPath with the updated InstanceData if required.

## Create Mask Parameter Aliases

If you rename a mask parameter, you must ensure that the existing MATLAB scripts that use the old parameter names, continues to work. To check compatibility, you can create an alias for a mask parameter name. An alias allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models.

Consider a masked block that contains an **Edit** parameter. The mask parameter name for this **Edit** parameter is `p1`.

```
MaskObj = Simulink.Mask.get(gcb);
hEdit = MaskObj.getParameter('p1');
```

```
hEdit=
% MaskParameter with properties:
```

```
    Type: 'edit'
TypeOptions: {0x1 cell}
    Name: 'p1'
    Prompt: 'p1'
    Value: '0'
    Evaluate: 'on'
    Tunable: 'on'
NeverSave: 'off'
    Hidden: 'off'
    Enabled: 'on'
    Visible: 'on'
    ToolTip: 'on'
    Callback: ''
    Alias: ''
```

Notice that the **Edit** mask parameter does not have an alias. To add an alias for the mask parameter, set a value for the **Alias** mask parameter property.

```
MaskObj.Alias = 'pa'
```

You can either use the mask parameter name or the alias to do a function call on the mask parameter. For example, you can either use `set_param(gcb, 'p1', '10')` (mask parameter name) or `set_param(gcb, 'pa', '10')` (mask parameter alias) to set a value for the **Edit** mask parameter.
