The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

### Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See [www.mathworks.com/trademarks](http://www.mathworks.com/trademarks) for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

### Patents

MathWorks products are protected by one or more U.S. patents. Please see [www.mathworks.com/patents](http://www.mathworks.com/patents) for more information.

## Revision History

November 1990	First printing	New for Simulink 1
December 1996	Second printing	Revised for Simulink 2
January 1999	Third printing	Revised for Simulink 3 (Release 11)
November 2000	Fourth printing	Revised for Simulink 4 (Release 12)
July 2002	Fifth printing	Revised for Simulink 5 (Release 13)
April 2003	Online only	Revised for Simulink 5.1 (Release 13SP1)
April 2004	Online only	Revised for Simulink 5.1.1 (Release 13SP1+)
June 2004	Sixth printing	Revised for Simulink 5.0 (Release 14)
October 2004	Seventh printing	Revised for Simulink 6.1 (Release 14SP1)
March 2005	Online only	Revised for Simulink 6.2 (Release 14SP2)
September 2005	Eighth printing	Revised for Simulink 6.3 (Release 14SP3)
March 2006	Online only	Revised for Simulink 6.4 (Release 2006a)
March 2006	Ninth printing	Revised for Simulink 6.4 (Release 2006a)
September 2006	Online only	Revised for Simulink 6.5 (Release 2006b)
March 2007	Online only	Revised for Simulink 6.6 (Release 2007a)
September 2007	Online only	Revised for Simulink 7.0 (Release 2007b)
March 2008	Online only	Revised for Simulink 7.1 (Release 2008a)
October 2008	Online only	Revised for Simulink 7.2 (Release 2008b)
March 2009	Online only	Revised for Simulink 7.3 (Release 2009a)
September 2009	Online only	Revised for Simulink 7.4 (Release 2009b)
March 2010	Online only	Revised for Simulink 7.5 (Release 2010a)
September 2010	Online only	Revised for Simulink 7.6 (Release 2010b)
April 2011	Online only	Revised for Simulink 7.7 (Release 2011a)
September 2011	Online only	Revised for Simulink 7.8 (Release 2011b)
March 2012	Online only	Revised for Simulink 7.9 (Release 2012a)
September 2012	Online only	Revised for Simulink 8.0 (Release 2012b)
March 2013	Online only	Revised for Simulink 8.1 (Release 2013a)
September 2013	Online only	Revised for Simulink 8.2 (Release 2013b)
March 2014	Online only	Revised for Simulink 8.3 (Release 2014a)
October 2014	Online only	Revised for Simulink 8.4 (Release 2014b)
March 2015	Online only	Revised for Simulink 8.5 (Release 2015a)
September 2015	Online only	Revised for Simulink 8.6 (Release 2015b)
October 2015	Online only	Rereleased for Simulink 8.5.1 (Release 2015aSP1)
March 2016	Online only	Revised for Simulink 8.7 (Release 2016a)
September 2016	Online only	Revised for Simulink 8.8 (Release 2016b)
March 2017	Online only	Revised for Simulink 8.9 (Release 2017a)
September 2017	Online only	Revised for Simulink 9.0 (Release 2017b)
March 2018	Online only	Revised for Simulink 9.1 (Release 2018a)
September 2018	Online only	Revised for Simulink 9.2 (Release 2018b)
March 2019	Online only	Revised for Simulink 9.3 (Release 2019a)
September 2019	Online only	Revised for Simulink 10.0 (Release 2019b)
March 2020	Online only	Revised for Simulink 10.1 (Release 2020a)
September 2020	Online only	Revised for Simulink 10.2 (Release 2020b)
March 2021	Online only	Revised for Simulink 10.3 (Release 2021a)
September 2021	Online only	Revised for Simulink 10.4 (Release 2021b)
March 2022	Online only	Revised for Simulink 10.5 (Release 2022a)
September 2022	Online only	Revised for Simulink 10.6 (Release 2022b)

## Introduction to Simulink

### 1

### Simulink Basics

<b>Programmatic Modeling Basics</b> .....	<b>1-2</b>
Load a Model .....	1-2
Create a Model and Specify Parameter Settings .....	1-2
Programmatically Load Variables When Opening a Model .....	1-3
Programmatically Add and Connect Blocks .....	1-3
Programmatically Comment Out or Comment Through Blocks .....	1-5
Name a Signal Programmatically .....	1-5
Arrange Model Layouts Automatically .....	1-5
Open the Same Model in Multiple Windows .....	1-6
Locate Diagram Elements Using Highlighting .....	1-6
Specify Colors Programmatically .....	1-6
<b>Build and Edit a Model Interactively</b> .....	<b>1-8</b>
Create a Model .....	1-8
Set Default Template for New Models .....	1-9
Open a Model .....	1-10
Set Favorite Files .....	1-10
Clear Recent Files .....	1-10
Load Variables When Opening a Model .....	1-10
Open a Model That Has Different Character Encoding .....	1-11
Simulink Model File Types .....	1-11
<b>Add Blocks and Set Parameters</b> .....	<b>1-13</b>
Add Blocks to the Model .....	1-13
Align and Connect Blocks .....	1-14
Set Block Parameters .....	1-14
Edit Block Parameters on Block Icons .....	1-15
<b>Extend the Model and Create Subsystems</b> .....	<b>1-18</b>
Add More Blocks .....	1-18
Branch a Connection .....	1-18
Organize Your Model into Components .....	1-21
<b>Update Diagram and Run Simulation</b> .....	<b>1-24</b>
Simulate the Model and View Results .....	1-24
Update the Diagram While Editing .....	1-25
<b>Refine the Model</b> .....	<b>1-27</b>
Comment Out and Comment Through Blocks .....	1-29

<b>Save the Model</b> .....	<b>1-30</b>
Save a Model .....	<b>1-30</b>
How Simulink Saves Models .....	<b>1-31</b>
Save Models in the SLX File Format .....	<b>1-31</b>
Export Model to Previous Simulink Version .....	<b>1-32</b>
Save from Earlier Simulink Version to Another Earlier Version .....	<b>1-33</b>
<b>Preview Content of Model Components</b> .....	<b>1-35</b>
<b>Collaborate by Adding Comments to Blocks</b> .....	<b>1-37</b>
Determine Whether Model Has Open Comments .....	<b>1-37</b>
View Comments .....	<b>1-38</b>
Add Comments .....	<b>1-38</b>
Edit, Reply to, and Resolve Comments .....	<b>1-39</b>
Hide and Delete Comments .....	<b>1-39</b>
<b>Bookmark Parts of Model with Viewmarks</b> .....	<b>1-40</b>
Create a Viewmark .....	<b>1-41</b>
Open and Navigate Viewmarks .....	<b>1-41</b>
Manage Viewmarks .....	<b>1-41</b>
Save a Viewmark to the Model .....	<b>1-41</b>
Refresh a Viewmark .....	<b>1-42</b>
<b>Print Model Diagrams</b> .....	<b>1-43</b>
Print Models Using Default Settings .....	<b>1-43</b>
Specify Paper Size and Orientation .....	<b>1-43</b>
Specify Background Color .....	<b>1-44</b>
Specify Print Frames .....	<b>1-44</b>
Select the Systems to Print .....	<b>1-45</b>
Print Large Diagrams on Multiple Pages .....	<b>1-45</b>
Add Log of Printed Models .....	<b>1-46</b>
Add Sample Time Legend .....	<b>1-47</b>
Configure Print Job .....	<b>1-47</b>
Print Models to PDFs .....	<b>1-48</b>
Copy Diagrams as Images .....	<b>1-48</b>
<b>Print Model Reports</b> .....	<b>1-49</b>
<b>Programmatically Print Models from MATLAB Command Window</b> .....	<b>1-51</b>
Printing Commands .....	<b>1-51</b>
Print Systems with Multiline Names or Names with Spaces .....	<b>1-53</b>
Set Paper Orientation and Type .....	<b>1-53</b>
Position and Size a System .....	<b>1-53</b>
Use Tiled Printing .....	<b>1-54</b>
Print Models to Image File Formats .....	<b>1-55</b>
<b>Keyboard Shortcuts and Mouse Actions for Simulink Modeling</b> .....	<b>1-56</b>
Use Context-Sensitive Hints Panels to Look Up Keyboard Shortcuts .....	<b>1-56</b>
Perform File and Clipboard Operations .....	<b>1-57</b>
Zoom and Pan .....	<b>1-58</b>
Navigate Model .....	<b>1-58</b>
Modify Block Diagram Contents .....	<b>1-59</b>
Select Block Diagram Elements .....	<b>1-59</b>

Modify Block Diagram Elements .....	1-60
Name Block Diagram Elements .....	1-62
Modify Block Diagram Appearance .....	1-62
Perform Actions .....	1-63
Update, Simulate, and Generate Code for Models .....	1-63
Debug Models .....	1-64

## Simulation Stepping

### 2

<b>How Simulation Stepper Helps With Model Analysis</b> .....	2-2
<b>How Stepping Through a Simulation Works</b> .....	2-3
Simulation Snapshots .....	2-3
How Simulation Stepper Uses Snapshots .....	2-3
How Simulation Stepper Differs from Simulink Debugger .....	2-5
<b>Use Simulation Stepper</b> .....	2-7
Simulation Stepper Access .....	2-7
Simulation Stepper Pause Status .....	2-7
Tune Parameters .....	2-8
Referenced Models .....	2-8
Simulation Stepper and Interval Logging .....	2-8
Simulation Stepper and Stateflow Debugger .....	2-8
<b>Simulation Stepper Limitations</b> .....	2-10
Interface .....	2-10
Model Configuration .....	2-10
Blocks .....	2-10
<b>Step Through a Simulation</b> .....	2-12
Step Forward and Back .....	2-12
<b>Set Conditional Breakpoints for Stepping a Simulation</b> .....	2-14
Setting Conditional Breakpoints .....	2-14
Observe Conditional Breakpoint Values .....	2-16
<b>Simulation Pacing</b> .....	2-18
Use Simulation Pacing .....	2-18
Use Simulation Pacing with Dashboard Blocks .....	2-19
Limitations .....	2-20

## How Simulink Works

### 3

<b>Simulation Phases in Dynamic Systems</b> .....	3-2
Model Compilation .....	3-2
Link Phase .....	3-2
Simulation Loop Phase .....	3-3

<b>Compare Solvers</b> .....	<b>3-6</b>
Fixed-Step Versus Variable-Step Solvers .....	3-6
Continuous Versus Discrete Solvers .....	3-7
Explicit Versus Implicit Continuous Solvers .....	3-8
One-Step Versus Multistep Continuous Solvers .....	3-8
Single-Order Versus Variable-Order Continuous Solvers .....	3-9
<b>Zero-Crossing Detection</b> .....	<b>3-10</b>
Demonstrating Effects of Excessive Zero-Crossing Detection .....	3-10
Preventing Excessive Zero Crossings .....	3-18
How the Simulator Can Miss Zero-Crossing Events .....	3-19
Zero-Crossing Detection in Blocks .....	3-22
<b>Zero-Crossing Detection with Fixed-Step Simulation</b> .....	<b>3-25</b>
Effects of Zero-Crossing Detection in Fixed-Step .....	3-25
Simulate in Fixed-Step Without Zero-Crossing Detection .....	3-26
Enable Fixed-Step Zero-Crossing Detection .....	3-28
Set Parameters for Zero-Crossing Detection .....	3-29
<b>Zero-Crossing Algorithms</b> .....	<b>3-37</b>
Signal Threshold for Adaptive Zero-Crossing Detection .....	3-37
<b>Algebraic Loop Concepts</b> .....	<b>3-39</b>
Mathematical Interpretation .....	3-40
Physical Interpretation .....	3-40
Artificial Algebraic Loops .....	3-41
How the Algebraic Loop Solver Works .....	3-42
Implications of Algebraic Loops in a Model .....	3-44
<b>Identify Algebraic Loops in Your Model</b> .....	<b>3-45</b>
Highlight Algebraic Loops in the Model .....	3-46
Use the Algebraic Loop Diagnostic .....	3-46
<b>Remove Algebraic Loops</b> .....	<b>3-48</b>
Introduce a Delay to Remove Algebraic Loops .....	3-48
Solve Algebraic Loops Manually .....	3-50
How Simulink Eliminates Artificial Algebraic Loops .....	3-50
Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems .....	3-55
Bundled Signals That Create Artificial Algebraic Loops .....	3-56
Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops .....	3-59
Block Reduction and Artificial Algebraic Loops .....	3-59
<b>Modeling Considerations with Algebraic Loops</b> .....	<b>3-62</b>
Managing Large Models with Artificial Algebraic Loops .....	3-62
Model Blocks and Direct Feedthrough .....	3-62
Changing Block Priorities When Using Algebraic Loop Solver .....	3-63
<b>Use Model Name as Programmatic Interface</b> .....	<b>3-64</b>
Model Requirements .....	3-64
Input Arguments .....	3-64
Execute Size Computation Phase .....	3-65
Execute Compilation Phase .....	3-65
Compute Discrete State Values .....	3-66

Compute Output Values .....	3-66
Compute Continuous State Derivatives .....	3-66
Execute Termination Phase .....	3-67

## Modeling Dynamic Systems

### Creating a Model

# 4

<b>Create Template from Model</b> .....	4-2
Edit a Template .....	4-2
<b>Describe Models Using Notes and Annotations</b> .....	4-4
Create, Edit, and Read Notes .....	4-4
Create Text Annotations .....	4-5
Add Equations to Annotations .....	4-5
Create Image Annotations .....	4-8
Resize Annotations .....	4-8
Associate Annotations with Blocks and Areas .....	4-9
Hide Annotations .....	4-9
Make Annotations Interactive .....	4-10
<b>Create and Edit Annotations Programmatically</b> .....	4-12
Create Annotation Programmatically .....	4-12
Programmatically Find and Modify Existing Annotations .....	4-12
Delete Annotation .....	4-13
Create Annotations That Contain Hyperlinks .....	4-13
Add Image to Model .....	4-14
Create Area Programmatically .....	4-14
Create and Hide Markup Annotation .....	4-15
Find Annotation Executing Callback Function .....	4-15
<b>Create Subsystems</b> .....	4-17
Types of Subsystems .....	4-17
Create Subsystems .....	4-18
Add Ports to Subsystems .....	4-19
Edit Port Labels on Subsystems .....	4-21
Configure Subsystems .....	4-24
Restrict Subsystem Access .....	4-24
<b>Expand Subsystem Contents</b> .....	4-25
Why Expand a Subsystem? .....	4-26
What Subsystems Can You Expand? .....	4-26
Expand a Subsystem .....	4-27
Results of Expanding a Subsystem .....	4-27
<b>Navigate Model Hierarchies</b> .....	4-29
Open Model Component in Current Tab .....	4-29
Open Model Component in New Tab .....	4-29
Open Model Component in New Window .....	4-30

Open Referenced Model as Top Model in New Window .....	4-30
<b>Subsystem Reference .....</b>	<b>4-32</b>
Create a Subsystem Block Diagram .....	4-32
Reference a Subsystem File in a Model .....	4-33
Convert an Existing Subsystem to a Referenced Subsystem .....	4-34
Edit and Save Referenced Subsystem .....	4-35
Add a System Mask for Subsystem Reference .....	4-36
Simulate a Subsystem Block Diagram with a Test Harness .....	4-36
Subsystem Reference Compatibility with Previous Versions .....	4-37
Control Referenced Subsystem Programmatically .....	4-38
Best Practices .....	4-39
<b>Reference a Subsystem File in a Model .....</b>	<b>4-40</b>
<b>Change Subsystem Reference Component Dynamically Using InitFcn</b> .....	<b>4-42</b>
<b>Use Control Flow Logic .....</b>	<b>4-45</b>
What is a Control Flow Subsystem .....	4-45
Equivalent C Language Statements .....	4-45
Conditional Control Flow Logic .....	4-45
While and For Loops .....	4-47
<b>Customize Model Behavior with Callbacks .....</b>	<b>4-52</b>
What You Can Do with Callbacks .....	4-52
Types of Callbacks .....	4-52
Callback Limitations .....	4-52
<b>Model Callbacks .....</b>	<b>4-54</b>
Create Model Callbacks .....	4-54
Model Callback Parameters .....	4-55
Referenced Model Callbacks .....	4-57
<b>Block Callbacks .....</b>	<b>4-59</b>
Block Opening Callback Parameters .....	4-59
Block Editing Callback Parameters .....	4-59
Block Compilation and Simulation Callback Parameters .....	4-61
Block Saving and Closing Callback Parameters .....	4-61
Subsystem Block Callback Parameters .....	4-62
<b>Port Callbacks .....</b>	<b>4-65</b>
<b>Initialization Function .....</b>	<b>4-66</b>
Model InitFcn Callback .....	4-66
Block InitFcn Callback .....	4-68
<b>Manage Model Versions and Specify Model Properties .....</b>	<b>4-70</b>
Model File Change Notification .....	4-70
Manage Model Properties .....	4-70
Access Model Information Programmatically .....	4-72
<b>Model Discretizer .....</b>	<b>4-75</b>
What Is the Model Discretizer? .....	4-75
Requirements .....	4-75

Discretize a Model with the Model Discretizer .....	4-75
View the Discretized Model .....	4-80
Discretize Blocks from the Simulink Model .....	4-83
Discretize a Model with the sldiscmdl Function .....	4-90

<b>Use modelfinder to Index Simulink Models and Improve its Discoverability within an Organization .....</b>	<b>4-91</b>
Search example models matching the search string .....	4-91
Register and Unregister folder path to search index of modelfinder .....	4-92
<b>Create Model That Performs Neighborhood Processing .....</b>	<b>4-93</b>
Import Image and Output Results .....	4-93
Configure Neighborhood Processing Subsystem .....	4-93
Simulate and View Results .....	4-94

## Model Advisor

<b>5</b>	<b>Check Your Model Using the Model Advisor .....</b>	<b>5-2</b>
	Model Advisor Overview .....	5-2
	Run Model Advisor Checks and Review Results .....	5-4
	Run Model Checks Programmatically .....	5-5
	<b>Find Model Advisor Check IDs .....</b>	<b>5-6</b>
	<b>Address Model Check Results .....</b>	<b>5-7</b>
	Fix a Model Advisor Check Warning or Failure .....	5-7
	<b>Save and View Model Advisor Check Reports .....</b>	<b>5-8</b>
	Save Model Advisor Check Reports .....	5-8
	View Model Advisor Check Reports .....	5-8

## Upgrade Advisor

<b>6</b>	<b>Consult the Upgrade Advisor .....</b>	<b>6-2</b>
	Upgrade Programmatically .....	6-2
	Upgrade Advisor Checks .....	6-3

## Working with Sample Times

<b>7</b>	<b>What Is Sample Time? .....</b>	<b>7-2</b>
	<b>What Is Union Sample Time? .....</b>	<b>7-3</b>

<b>Specify Sample Time</b> .....	<b>7-10</b>
Designate Sample Times .....	7-10
Specify Block-Based Sample Times Interactively .....	7-12
Specify Port-Based Sample Times Interactively .....	7-13
Specify Block-Based Sample Times Programmatically .....	7-14
Specify Port-Based Sample Times Programmatically .....	7-14
Access Sample Time Information Programmatically .....	7-14
Specify Sample Times for a Custom Block .....	7-14
Determining Sample Time Units .....	7-14
Change the Sample Time After Simulation Start Time .....	7-14
<b>View Sample Time Information</b> .....	<b>7-16</b>
Inspect Sample Time Using Timing Legend .....	7-16
Inspect Sample Times Throughout a Model .....	7-18
<b>Types of Sample Time</b> .....	<b>7-20</b>
Discrete Sample Time .....	7-20
Continuous Sample Time .....	7-20
Inherited Sample Time .....	7-21
Fixed-in-Minor-Step .....	7-21
Constant Sample Time .....	7-21
Variable Sample Time .....	7-22
Controllable Sample Time .....	7-22
Triggered Sample Time .....	7-22
Asynchronous Sample Time .....	7-22
<b>Blocks for Which Sample Time Is Not Recommended</b> .....	<b>7-24</b>
Best Practice to Model Sample Times .....	7-24
Appropriate Blocks for the Sample Time Parameter .....	7-24
Specify Sample Time in Blocks Where Hidden .....	7-25
<b>Block Compiled Sample Time</b> .....	<b>7-26</b>
<b>Sample Times in Subsystems</b> .....	<b>7-29</b>
<b>Sample Times in Systems</b> .....	<b>7-30</b>
Purely Discrete Systems .....	7-30
Hybrid Systems .....	7-32
<b>Resolve Rate Transitions</b> .....	<b>7-34</b>
Automatic Rate Transition .....	7-34
Visualize Inserted Rate Transition Blocks .....	7-34
<b>How Propagation Affects Inherited Sample Times</b> .....	<b>7-37</b>
Process for Sample Time Propagation .....	7-37
Simulink Rules for Assigning Sample Times .....	7-37
<b>Backpropagation in Sample Times</b> .....	<b>7-39</b>
<b>Specify Execution Domain</b> .....	<b>7-40</b>
Domain Specification Badge .....	7-40
Types of Execution Domains .....	7-40
Set Execution Domain .....	7-42
Enforce Discrete Execution Domain for a Subsystem .....	7-43

<b>Model Reference Basics</b> .....	<b>8-2</b>
Model Reference Advantages .....	8-2
Model Hierarchies .....	8-3
Model Block and Referenced Model Interface .....	8-3
Model Workspaces and Data Dictionaries .....	8-4
Referenced Model Execution .....	8-4
Referenced Model Simulation and Code Generation .....	8-5
<b>Model Reference Requirements and Limitations</b> .....	<b>8-6</b>
Model Reuse .....	8-6
Model Masks .....	8-6
S-Functions in Referenced Models .....	8-7
Model Architecture Requirements and Limitations .....	8-8
Signal Requirements and Limitations .....	8-9
Simulation Requirements and Limitations .....	8-10
Code Generation Requirements and Limitations .....	8-10
<b>Reference Existing Models</b> .....	<b>8-11</b>
<b>Reference Protected Models from Third Parties</b> .....	<b>8-13</b>
Load Supporting Files for Protected Model .....	8-13
Verify Digital Signature of Protected Model .....	8-13
View Protected Model Contents .....	8-14
Test Protected Model in Isolated Environment .....	8-14
Reference Protected Model .....	8-14
Use Models Protected in Previous Releases .....	8-15
<b>Convert Subsystems to Referenced Models</b> .....	<b>8-18</b>
Prepare Subsystem for Conversion .....	8-18
Convert Subsystems to Referenced Models .....	8-20
Conversion Results .....	8-21
Compare Simulation Results Before and After Conversion .....	8-21
Revert Conversion .....	8-22
Integrate Referenced Model into Parent Model .....	8-22
<b>Conditionally Execute Referenced Models</b> .....	<b>8-24</b>
Conditional Models .....	8-24
Requirements for Conditional Models .....	8-25
Modify a Referenced Model for Conditional Execution .....	8-26
<b>Inspect Model Hierarchies</b> .....	<b>8-28</b>
Content Preview .....	8-28
Model Dependency Graph .....	8-28
List of Model References .....	8-29
Model Version Numbers .....	8-29
<b>Model Reference Interface and Boundary</b> .....	<b>8-31</b>
Refresh Model Blocks .....	8-32
Signal Propagation .....	8-33
Signal Logging in Referenced Models .....	8-33
Sample Time Requirements .....	8-33

Share Data Among Referenced Model Instances .....	8-34
<b>Referenced Model Sample Times .....</b>	<b>8-35</b>
How Sample-Time Inheritance Works for Model Blocks .....	8-35
Conditions for Inheriting Sample Times .....	8-35
Determining Sample Time of a Referenced Model .....	8-35
Blocks That Depend on Absolute Time .....	8-36
Blocks Whose Outputs Depend on Inherited Sample Time .....	8-36
Sample Time Consistency .....	8-37
Sample Rates and Solvers .....	8-38
<b>Choose Simulation Modes for Model Hierarchies .....</b>	<b>8-39</b>
Model Reference Simulation Modes .....	8-39
Overridden Simulation Modes .....	8-42
<b>Simulate Conditionally Executed Referenced Models .....</b>	<b>8-43</b>
Triggered, Enabled, and Triggered and Enabled Models .....	8-43
Function-Call Models .....	8-43
<b>Simulate Multiple Referenced Model Instances in Normal Mode ..</b>	<b>8-44</b>
Normal Mode Visibility .....	8-44
Examine Models with Multiple Referenced Model Instances .....	8-44
Configure Models with Multiple Referenced Model Instances .....	8-45
Determine Which Instance Has Normal Mode Visibility .....	8-46
Specify the Instance Having Normal Mode Visibility .....	8-47
<b>Manage Simulation Targets for Referenced Models .....</b>	<b>8-50</b>
Reduce Time Spent Checking For Changes .....	8-50
Specify Programming Language of Simulation Targets .....	8-51
Use Custom Code for Simulation Targets .....	8-51
Control Location of Simulation Targets .....	8-51
<b>Reduce Update Time for Referenced Models by Using Parallel Builds</b> .....	<b>8-53</b>
<b>Share Simulink Cache Files for Faster Simulation .....</b>	<b>8-54</b>
Inspect Simulink Cache File Contents .....	8-54
Use Simulink Cache Files .....	8-56
Check for Simulink Cache Files in Projects .....	8-57
<b>Set Configuration Parameters for Model Hierarchies .....</b>	<b>8-59</b>
Manage Configuration Parameters by Using Configuration References .....	<b>8-59</b>
Configuration Requirements for All Referenced Model Simulation .	<b>8-59</b>
Diagnostics That Are Ignored in Accelerator Mode .....	<b>8-61</b>
<b>Parameterize Instances of a Reusable Referenced Model .....</b>	<b>8-63</b>
Specify a Different Value for Each Instance of a Reusable Model ...	<b>8-63</b>
Define Model Arguments Without Specifying a Default Value .....	<b>8-63</b>
Combine Multiple Arguments into a Structure .....	<b>8-64</b>
Parameterize a Referenced Model .....	<b>8-64</b>
Change Model Argument Name or Value .....	<b>8-69</b>
Customize User Interface for Reusable Components .....	<b>8-70</b>
Configure Instance-Specific Data for Simulink.LookupTable and Simulink.Breakpoint Objects .....	<b>8-70</b>

<b>Parameterize a Referenced Model Programmatically</b> .....	<b>8-76</b>
<b>Group Multiple Model Arguments into a Single Structure</b> .....	<b>8-78</b>
<b>Configure Instance-Specific Data for Lookup Tables Programmatically</b> .....	<b>8-81</b>

## Simulink Units

### 9

<b>Unit Specification in Simulink Models</b> .....	<b>9-2</b>
Guidelines for Unitless, Dimensionless, and No Unit Quantities .....	<b>9-3</b>
Specify Physical Quantities .....	<b>9-4</b>
Specify Units in Objects .....	<b>9-4</b>
Specify Units for Temperature Signals .....	<b>9-5</b>
Specify Units in MATLAB Function Blocks .....	<b>9-6</b>
Specify Units in Constant Blocks .....	<b>9-6</b>
Specify Units for Logging and Loading Signal Data .....	<b>9-6</b>
Restricting Unit Systems .....	<b>9-6</b>

## Conditional Subsystems

### 10

<b>Conditionally Executed Subsystems Overview</b> .....	<b>10-3</b>
---	-------------

<b>Ensure Output is Virtual</b> .....	<b>10-5</b>
Conditional Output Signal .....	<b>10-5</b>
Partial Write Signals With a Merge Block .....	<b>10-7</b>
<b>Using Enabled Subsystems</b> .....	<b>10-10</b>
Create an Enabled Subsystem .....	<b>10-10</b>
Blocks in Enabled Subsystems .....	<b>10-11</b>
Alternately Executing Enabled Subsystem Blocks .....	<b>10-13</b>
Model Examples .....	<b>10-16</b>
<b>Using Triggered Subsystems</b> .....	<b>10-17</b>
Create a Triggered Subsystem .....	<b>10-17</b>
Triggering with Discrete Time Systems .....	<b>10-18</b>
Triggered Model Versus a Triggered Subsystem .....	<b>10-19</b>
Blocks in a Triggered Subsystem .....	<b>10-19</b>
Model Examples .....	<b>10-19</b>
<b>Using Enabled and Triggered Subsystems</b> .....	<b>10-20</b>
Creating an Enabled and Triggered Subsystem .....	<b>10-21</b>
Blocks in an Enabled and Triggered Subsystem .....	<b>10-22</b>
Model Examples .....	<b>10-22</b>
<b>Select Subsystem Execution</b> .....	<b>10-24</b>
Models with If-Else Structures .....	<b>10-24</b>
Models with Switch Case Structure .....	<b>10-25</b>
<b>Iterate Subsystem Execution with While Iterator and For Iterator Subsystems</b> .....	<b>10-28</b>
Models with While Structures .....	<b>10-28</b>
Model with For Structures .....	<b>10-30</b>
<b>Using Function-Call Subsystems</b> .....	<b>10-34</b>
Creating a Function-Call Subsystem .....	<b>10-34</b>
Sample Time Propagation in a Function-Call Subsystem .....	<b>10-35</b>
Latched Input Data for Function-Call Subsystems .....	<b>10-35</b>
<b>Conditional Subsystem Initial Output Values</b> .....	<b>10-38</b>
Inherit Initial Output Values from Input Signals .....	<b>10-38</b>
Specify Initial Output Values Using Dialog Parameters .....	<b>10-39</b>
<b>Rate-Based Models Overview</b> .....	<b>10-40</b>
<b>Create A Rate-Based Model</b> .....	<b>10-41</b>
Multi-Tasking and Multi-Rate Model for Code Generation .....	<b>10-41</b>
<b>Test Rate-Based Model Simulation Using Function-Call Generators</b> .....	<b>10-44</b>
Create Test Model That References a Rate-Based Model .....	<b>10-44</b>
Simulate Rate-Based Model .....	<b>10-45</b>
<b>Generate Code from Rate-Based Model</b> .....	<b>10-47</b>
<b>Sorting Rules for Explicitly Scheduled Model Components</b> .....	<b>10-48</b>
Export-Function Models .....	<b>10-48</b>
Test Harness for Export Function Models with Strict Scheduling .....	<b>10-49</b>

Test Harness for Export-Function Models Without Strict Scheduling	10-49
Data Dependency Error Caused by Data Sorting Rules	10-50
Test Harness for Models with Initialize, Reset, and Terminate Function Blocks	10-52
Initiators for Model Block in Test Harness	10-52
<b>Conditional Subsystem Output Values When Disabled</b>	<b>10-55</b>
<b>Simplified Initialization Mode</b>	<b>10-56</b>
When to Use Simplified Initialization	10-56
Set Initialization Mode to Simplified	10-56
<b>Classic Initialization Mode</b>	<b>10-57</b>
Set Initialization Mode to Classic	10-57
Classic Initialization Issues and Limitations	10-57
Identity Transformation Can Change Model Behavior	10-58
Inconsistent Output with Discrete-Time Integrator or S-Function Block	10-60
Execution Order Affecting Merge Block Output	10-62
Tunable Parameters	10-68
State	10-68
Simulink does not provide correct consistency check	10-69
<b>Convert from Classic to Simplified Initialization Mode</b>	<b>10-70</b>
Blocks to Consider	10-70
<b>Create an Export-Function Model</b>	<b>10-71</b>
Designate Model as Export-Function Model and Satisfy Export-Function Model Requirements	10-71
Create Model Algorithms	10-71
Add Function-Call Inputs	10-72
Test Model	10-73
<b>Test Export-Function Model Simulation Using Input Matrix</b>	<b>10-74</b>
Create Function-Call Inputs and Data Inputs	10-74
Simulate Export-Function Model	10-75
<b>Test Export-Function Model Simulation Using Function-Call Generators</b>	<b>10-78</b>
Create Referenced Export-Function Model	10-78
Create Test Model (Harness) for Simulation	10-78
Simulate Export Function Model	10-79
<b>Test Export-Function Model Simulation Using Stateflow Chart</b>	<b>10-81</b>
Create Referenced Export-Function Model	10-81
Create Periodic Scheduler Using Stateflow Chart	10-81
Create Test Model (Harness) for Simulation	10-82
Simulate Export Function Model	10-83
<b>Test Export-Function Model Simulation Using Schedule Editor</b>	<b>10-85</b>
Create Test Model (Harness) for Simulation	10-85
Create Function-Call Events Using the Schedule Editor	10-86
Simulate Export Function Model	10-87

<b>Generate Code for Export-Function Model</b> .....	<b>10-89</b>
Generate Code for Exported Functions .....	<b>10-89</b>

Supported Multicore Targets .....	<b>14-44</b>
Supported Heterogeneous Targets .....	<b>14-44</b>
<b>Limitations with Multicore Programming in Simulink</b> .....	<b>14-46</b>

## Modeling Best Practices

# 15

<b>General Considerations when Building Simulink Models</b> .....	<b>15-2</b>
Avoiding Invalid Loops .....	<b>15-2</b>
Shadowed Files .....	<b>15-3</b>
Model Building Tips .....	<b>15-5</b>
<b>Model a Continuous System</b> .....	<b>15-6</b>

<b>Best-Form Mathematical Models</b> .....	<b>15-9</b>
Series RLC Example .....	15-9
Solving Series RLC Using Resistor Voltage .....	15-9
Solving Series RLC Using Inductor Voltage .....	15-10
<b>Model a Simple Equation</b> .....	<b>15-12</b>
<b>Model Differential Algebraic Equations</b> .....	<b>15-14</b>
Overview of Robertson Reaction Example .....	15-14
Simulink Model from ODE Equations .....	15-14
Simulink Model from DAE Equations .....	15-16
Simulink Model from DAE Equations Using Algebraic Constraint Block .....	15-18
<b>Basic Modeling Workflow</b> .....	<b>15-22</b>
<b>Model a System Algorithm</b> .....	<b>15-24</b>
<b>Create Model Components</b> .....	<b>15-26</b>
<b>Manage Signal Lines</b> .....	<b>15-29</b>
<b>Manage Model Data</b> .....	<b>15-34</b>
<b>Reuse Model Components from Files</b> .....	<b>15-36</b>
<b>Create Interchangeable Variations of Model Components</b> .....	<b>15-39</b>
<b>Set Up a File Management System</b> .....	<b>15-41</b>

## Project Setup

# 16

<b>Organize Large Modeling Projects</b> .....	<b>16-2</b>
<b>What Are Projects?</b> .....	<b>16-3</b>
<b>Explore Project Tools with the Airframe Project</b> .....	<b>16-5</b>
Explore the Airframe Project .....	16-5
Set Up Project Files and Open the Project .....	16-5
View, Search, and Sort Project Files .....	16-6
Open and Run Frequently Used Files .....	16-6
Review Changes in Modified Files .....	16-7
Run Dependency Analysis .....	16-8
Run Project Integrity Checks .....	16-10
Commit Modified Files .....	16-10
View Project and Source Control Information .....	16-10
<b>Create a Project from a Model</b> .....	<b>16-12</b>
<b>Set MATLAB Projects Preferences</b> .....	<b>16-14</b>

<b>Create a New Project from a Folder</b> .....	<b>16-17</b>
<b>Add Files to the Project</b> .....	<b>16-21</b>
<b>Create a New Project from an Archived Project</b> .....	<b>16-23</b>
<b>Create a New Project Using Templates</b> .....	<b>16-24</b>
Use Project Templates from R2014a or Before .....	<b>16-24</b>
<b>Open Recent Projects</b> .....	<b>16-25</b>
<b>Specify Project Details, Startup Folder, and Derived Files Folders</b> .....	<b>16-26</b>
<b>Specify Project Path</b> .....	<b>16-27</b>
<b>What Can You Do with Project Shortcuts?</b> .....	<b>16-28</b>
<b>Automate Startup Tasks</b> .....	<b>16-29</b>
<b>Automate Shutdown Tasks</b> .....	<b>16-31</b>
<b>Create Shortcuts to Frequent Tasks</b> .....	<b>16-32</b>
Create Shortcuts .....	<b>16-32</b>
Group Shortcuts .....	<b>16-32</b>
Annotate Shortcuts to Use Meaningful Names .....	<b>16-33</b>
Customize Shortcut Icons .....	<b>16-33</b>
<b>Use Shortcuts to Find and Run Frequent Tasks</b> .....	<b>16-34</b>
<b>Create Templates for Standard Project Settings</b> .....	<b>16-35</b>
Using Templates to Create Standard Project Settings .....	<b>16-35</b>
Create a Template from the Current Project .....	<b>16-35</b>
Create a Template from a Project Under Version Control .....	<b>16-36</b>
Edit a Template .....	<b>16-36</b>
Remove a Template .....	<b>16-36</b>
Explore the Example Templates .....	<b>16-36</b>

## Project File Management

# 17

<b>Group and Sort File Views</b> .....	<b>17-2</b>
<b>Search Inside Project Files and Filter File Views</b> .....	<b>17-3</b>
Project-Wide Search .....	<b>17-3</b>
Filter Project File Views .....	<b>17-5</b>
More Ways to Search .....	<b>17-6</b>
<b>Work with Project Files</b> .....	<b>17-7</b>

<b>Manage Shadowed and Dirty Models and Other Project Files</b> . . . . .	<b>17-8</b>
Identify Shadowed Project Files When Opening a Project . . . . .	<b>17-8</b>
Find Models and Other Project Files With Unsaved Changes . . . . .	<b>17-8</b>
Manage Open Models and Data Dictionaries When Closing a Project . . . . .	<b>17-9</b>
<b>Move, Rename, Copy, or Delete Project Files</b> . . . . .	<b>17-10</b>
Move or Add Files . . . . .	<b>17-10</b>
Automatic Updates When Renaming, Deleting, or Removing Files . . . . .	<b>17-10</b>
<b>Back Out Changes</b> . . . . .	<b>17-15</b>
<b>Create Labels</b> . . . . .	<b>17-16</b>
<b>Add Labels to Files</b> . . . . .	<b>17-17</b>
<b>View and Edit Label Data</b> . . . . .	<b>17-18</b>
<b>Automate Project Tasks Using Scripts</b> . . . . .	<b>17-19</b>
<b>Create a Custom Task Function</b> . . . . .	<b>17-28</b>
<b>Run a Project Custom Task and Publish Report</b> . . . . .	<b>17-29</b>
<b>Sharing Projects</b> . . . . .	<b>17-31</b>
<b>Share Project by Email</b> . . . . .	<b>17-32</b>
<b>Share Project as a MATLAB Toolbox</b> . . . . .	<b>17-33</b>
<b>Share Project on GitHub</b> . . . . .	<b>17-34</b>
<b>Archive Projects</b> . . . . .	<b>17-35</b>
<b>Upgrade All Project Models, Libraries, and MATLAB Code Files</b> .	<b>17-36</b>
Upgrade Libraries . . . . .	<b>17-38</b>
<b>Analyze Model Dependencies</b> . . . . .	<b>17-40</b>
Open and Explore Dependency Graph . . . . .	<b>17-40</b>
Model Dependency Views . . . . .	<b>17-41</b>
Find Required Products . . . . .	<b>17-43</b>
Export Dependency Analysis Results . . . . .	<b>17-43</b>
Create Project from the Dependency Graph . . . . .	<b>17-44</b>
<b>View Requirements Toolbox Links Associated with Model Elements</b> . . . . .	<b>17-46</b>
Highlight, Filter, and View Information for Links in a Model . . . . .	<b>17-46</b>
Navigate to Externally Stored Requirements from a Model . . . . .	<b>17-49</b>

<b>What Is Dependency Analysis?</b> .....	<b>18-2</b>
Dependency Analysis for Projects .....	<b>18-2</b>
Dependency Analysis for Models .....	<b>18-2</b>
<b>Dependency Analyzer Scope and Limitations</b> .....	<b>18-4</b>
Analysis Scope .....	<b>18-4</b>
Analysis Limitations .....	<b>18-4</b>
<b>Run a Dependency Analysis</b> .....	<b>18-7</b>
<b>Explore the Dependency Graph, Views, and Filters</b> .....	<b>18-9</b>
Select, Pan, and Zoom .....	<b>18-9</b>
Investigate Dependency Between Two Files .....	<b>18-9</b>
Color Files by Type, Status, or Label .....	<b>18-10</b>
Apply and Clear Filters .....	<b>18-15</b>
<b>Perform an Impact Analysis</b> .....	<b>18-17</b>
About Impact Analysis .....	<b>18-17</b>
Run a Dependency Analysis .....	<b>18-17</b>
Find Required Products and Add-Ons .....	<b>18-19</b>
Find Dependencies of Selected Files .....	<b>18-20</b>
<b>Check Dependency Results and Resolve Problems</b> .....	<b>18-23</b>
Investigate Problem Files in Dependency Graph .....	<b>18-25</b>
Investigate Problem Files in File List .....	<b>18-27</b>
<b>Find Requirements Documents in a Project</b> .....	<b>18-29</b>
<b>Export Dependency Analysis Results</b> .....	<b>18-30</b>
Send Files to Project Tools .....	<b>18-31</b>

<b>About Source Control with Projects</b> .....	<b>19-2</b>
Classic and Distributed Source Control .....	<b>19-2</b>
<b>Add a Project to Source Control</b> .....	<b>19-5</b>
Add a Project to Git Source Control .....	<b>19-5</b>
Add a Project to SVN Source Control .....	<b>19-5</b>
<b>Set Source Control Preferences</b> .....	<b>19-7</b>
Set Git Preferences in MATLAB Online .....	<b>19-7</b>
<b>Register Model Files with Source Control Tools</b> .....	<b>19-8</b>
<b>Set Up SVN Source Control</b> .....	<b>19-9</b>
Set Up SVN Provided with Projects .....	<b>19-9</b>

Set Up Project SVN for SVN Version Already Installed .....	19-10
Set Up Project SVN for SVN Version Not Yet Provided with Projects .....	19-10
Register Model Files with Subversion .....	19-11
Enforce SVN Locking Model Files Before Editing .....	19-13
Share a Subversion Repository .....	19-14
Manage SVN Externals .....	19-14
<b>Set Up Git Source Control .....</b>	<b>19-16</b>
Register Binary Files with Git .....	19-16
Configure MATLAB for Git on Windows .....	19-16
Configure MATLAB to Use Git SSH Authentication .....	19-17
Install Git Credential Helper .....	19-21
Disable Compression for Simulink Models .....	19-21
Configure Git to Use Git LFS .....	19-21
Configure Git to use MATLAB for Diff and Merge .....	19-21
Install Command-Line Git Client .....	19-22
<b>Add Git Submodules .....</b>	<b>19-23</b>
Update Submodules .....	19-23
Use Fetch and Merge with Submodules .....	19-23
Use Push to Send Changes to the Submodule Repository .....	19-23
<b>Automatically Merge Models .....</b>	<b>19-25</b>
<b>Create New GitHub Repository .....</b>	<b>19-27</b>
<b>Disable Source Control .....</b>	<b>19-28</b>
<b>Change Source Control .....</b>	<b>19-29</b>
<b>Write a Source Control Integration with the SDK .....</b>	<b>19-30</b>
<b>Clone Git Repository .....</b>	<b>19-31</b>
<b>Check Out SVN Repository .....</b>	<b>19-32</b>
<b>Tag and Retrieve Versions of Project Files .....</b>	<b>19-34</b>
<b>Refresh Status of Project Files .....</b>	<b>19-35</b>
<b>Check for Modifications .....</b>	<b>19-36</b>
<b>Update Revisions of Project Files .....</b>	<b>19-37</b>
Update Revisions with SVN .....	19-37
Update Revisions with Git .....	19-37
Update Selected Files .....	19-38
<b>Get SVN File Locks .....</b>	<b>19-39</b>
Manage SVN Repository Locks .....	19-39
<b>View Modified Files .....</b>	<b>19-41</b>
Project Definition Files .....	19-41
<b>Compare Revisions .....</b>	<b>19-44</b>

<b>Run Project Checks</b> .....	<b>19-46</b>
<b>Commit Modified Files to Source Control</b> .....	<b>19-47</b>
<b>Revert Changes</b> .....	<b>19-49</b>
Discard Local Changes .....	<b>19-49</b>
Revert a File to a Specified Revision .....	<b>19-49</b>
Revert the Project to a Specified Revision .....	<b>19-50</b>
<b>Pull, Push, and Fetch Files with Git</b> .....	<b>19-51</b>
Pull and Push .....	<b>19-51</b>
Pull, Fetch, and Merge .....	<b>19-52</b>
Push Empty Folders .....	<b>19-54</b>
Use Git Stashes .....	<b>19-54</b>
<b>Branch and Merge Files with Git</b> .....	<b>19-55</b>
Create a Branch .....	<b>19-55</b>
Switch Branch .....	<b>19-56</b>
Compare Branches and Save Copies .....	<b>19-57</b>
Merge Branches .....	<b>19-57</b>
Revert to Head .....	<b>19-58</b>
Delete Branches .....	<b>19-58</b>
<b>Resolve Conflicts</b> .....	<b>19-59</b>
Resolve Conflicts .....	<b>19-59</b>
Merge Text Files .....	<b>19-60</b>
Merge Models .....	<b>19-61</b>
Extract Conflict Markers .....	<b>19-61</b>
<b>Work with Derived Files in Projects</b> .....	<b>19-63</b>
<b>Customize External Source Control to Use MATLAB for Diff and Merge</b> .....	<b>19-64</b>
Finding the Full Paths for MATLAB Diff, Merge, and AutoMerge ..	<b>19-64</b>
Integration with Git .....	<b>19-65</b>
Integration with SVN .....	<b>19-66</b>
Integration with Other Source Control Tools .....	<b>19-67</b>
<b>Continuous Integration Using MATLAB Projects and Jenkins</b> ...	<b>19-69</b>
Prerequisites .....	<b>19-69</b>
Set Up MATLAB Project for Continuous Integration in Jenkins ...	<b>19-69</b>
Reduce Test Runtime Using Dependency Cache and Impact Analysis	<b>19-70</b>
.....	<b>19-70</b>
Enhance Workflow .....	<b>19-71</b>
<b>Determine Order for Resolving Conflicts Using Dependency Analyzer</b>	<b>19-73</b>
.....	<b>19-73</b>

## Project Reference

<b>Componentization Using Referenced Projects</b> .....	<b>20-2</b>
---	-------------

<b>Add or Remove a Reference to Another Project</b> .....	<b>20-5</b>
<b>View, Edit, or Run Referenced Project Files</b> .....	<b>20-6</b>
<b>Extract a Folder to Create a Referenced Project</b> .....	<b>20-7</b>
<b>Manage Referenced Project Changes Using Checkpoints</b> .....	<b>20-9</b>

## Compare Simulink Models

# 21

<b>About Simulink Model Comparison</b> .....	<b>21-2</b>
Creating Model Comparison Reports .....	<b>21-2</b>
Examples of Model Comparison .....	<b>21-2</b>
Using Model Comparison Reports .....	<b>21-2</b>
Select Simulink Models to Compare .....	<b>21-3</b>
<b>Compare Simulink Models</b> .....	<b>21-6</b>
Navigate the Simulink Model Comparison Report .....	<b>21-6</b>
Step Through Changes .....	<b>21-7</b>
Explore Changes in the Original Models .....	<b>21-8</b>
Merge Differences .....	<b>21-8</b>
Open Child Comparison Reports for Selected Nodes .....	<b>21-8</b>
Understand the Report Hierarchy and Matching .....	<b>21-8</b>
Filter Comparison Reports .....	<b>21-9</b>
Change Color Preferences .....	<b>21-12</b>
Save Comparison Results .....	<b>21-12</b>
Examples of Model Comparison .....	<b>21-12</b>
Limitations .....	<b>21-13</b>
<b>Display Differences in Original Models</b> .....	<b>21-14</b>
Highlighting in Models .....	<b>21-14</b>
Control Highlighting in Models .....	<b>21-14</b>
View Changes in Model Configuration Parameters .....	<b>21-15</b>
<b>Merge Simulink Models from the Comparison Report</b> .....	<b>21-16</b>
Resolve Conflicts Using Three-Way Model Merge .....	<b>21-16</b>
Use Three-Way Merge with External Source Control Tools .....	<b>21-19</b>
Open Three-Way Merge Without Using Source Control .....	<b>21-19</b>
Two-Way Model Merge .....	<b>21-20</b>
Merge MATLAB Function Block Code .....	<b>21-21</b>
<b>Export, Print, and Save Model Comparison Results</b> .....	<b>21-22</b>
Save Printable Report .....	<b>21-22</b>
Export Results to the Workspace .....	<b>21-22</b>
<b>Comparing Models with Identical Names</b> .....	<b>21-24</b>
<b>Work with Referenced Models and Library Links</b> .....	<b>21-25</b>
<b>Compare Project or Model Templates</b> .....	<b>21-26</b>
Compare Project Templates .....	<b>21-26</b>

Compare Model Templates .....	21-26
<b>Simulink Model Comparison for GitHub Pull Requests .....</b>	<b>21-27</b>
Prerequisites .....	21-27
Attach Diff Reports Using GitHub Actions .....	21-27

## Design Evolution Management

# 22

<b>About Design Evolutions .....</b>	<b>22-2</b>
Evolutions and Evolution Trees .....	22-2
<b>Manage Evolutions and Evolution Trees .....</b>	<b>22-4</b>
Create Evolution Tree .....	22-4
Create Evolution .....	22-5
Update Evolution .....	22-6
Get Evolution into Project .....	22-6
Delete Evolutions .....	22-6
<b>Inspect Properties of Evolutions and Compare Evolutions .....</b>	<b>22-8</b>
Inspect Properties of Evolution Tree, Evolutions, and Connectors .....	22-8
Compare Evolutions .....	22-8
<b>Use Design Evolution Manager with the Fixed-Point Tool .....</b>	<b>22-10</b>
Use Design Evolution Manager with Fixed-Point Tool .....	22-10

## Large-Scale Modeling

# 23

<b>Component-Based Modeling Guidelines .....</b>	<b>23-2</b>
Should You Create Model Components? .....	23-2
Define Model Components .....	23-3
<b>Choose Among Types of Model Components .....</b>	<b>23-4</b>
Simulink Components .....	23-4
High-Level Component Selection Guidelines .....	23-5
Modeling Requirement Considerations .....	23-7
<b>Compare Capabilities of Model Components .....</b>	<b>23-8</b>
Development Process .....	23-9
Performance Requirements .....	23-14
Features .....	23-15
<b>Define Interfaces of Model Components .....</b>	<b>23-19</b>
Identify Component Boundaries .....	23-19
Simplify Interfaces with Buses .....	23-19
Partition Interface Data .....	23-20
Configure Data Interfaces .....	23-21

<b>Configuration Management</b> .....	<b>23-23</b>
Manage Designs Using Source Control .....	<b>23-23</b>
Determine the Files Used by a Component .....	<b>23-23</b>
Manage Model Versions .....	<b>23-24</b>
Create Configurations .....	<b>23-24</b>

## Power Window Example

# 24

<b>Power Window</b> .....	<b>24-2</b>
Study Power Windows .....	<b>24-2</b>
MathWorks Software Used in This Example .....	<b>24-3</b>
Quantitative Requirements .....	<b>24-3</b>
Simulink Power Window Controller Project .....	<b>24-10</b>
Simulink Power Window Controller .....	<b>24-11</b>
Create Model Using Model-Based Design .....	<b>24-26</b>
Automatic Code Generation for Control Subsystem .....	<b>24-41</b>
References .....	<b>24-42</b>

## Schedule Editor

# 25

<b>What are Partitions?</b> .....	<b>25-2</b>
<b>Create Partitions</b> .....	<b>25-4</b>
Partitioning a Model .....	<b>25-4</b>
Create Partitions from a Rate-Based Model .....	<b>25-5</b>
Export-Function Partitions .....	<b>25-8</b>
<b>Using the Schedule Editor</b> .....	<b>25-11</b>
Using the Schedule Editor .....	<b>25-11</b>
<b>Schedule the Partitions</b> .....	<b>25-15</b>
Schedule an Export-Function Model Using the Schedule Editor ..	<b>25-15</b>
Schedule a Rate-Based Model Using the Schedule Editor .....	<b>25-18</b>
<b>Generate Code from a Partitioned Model</b> .....	<b>25-22</b>
<b>Export-Function Conversion</b> .....	<b>25-26</b>
<b>Create and Analyze Random Schedules for a Model Using the Schedule Editor API</b> .....	<b>25-27</b>
<b>Events in Schedule Editor</b> .....	<b>25-33</b>
Event Management in the Schedule Editor .....	<b>25-33</b>
Schedule Partitions with Events .....	<b>25-37</b>
Test Harness Generation .....	<b>25-44</b>
Limitations and Error Conditions .....	<b>25-45</b>

<b>Software Component Modeling</b> .....	<b>26-2</b>
Create Models of Software Components .....	<b>26-2</b>
Create Model of Target Environment .....	<b>26-6</b>
Test System by Simulating Composition Model .....	<b>26-7</b>
Integrate Components into Software Architectures .....	<b>26-7</b>
Design Software Architectures .....	<b>26-7</b>
Generate Code for Software Components .....	<b>26-8</b>

## Simulating Dynamic Systems

### Running Simulations

<b>Simulate a Model Interactively</b> .....	<b>27-2</b>
Simulation Basics .....	<b>27-2</b>
Run, Pause, and Stop a Simulation .....	<b>27-3</b>
Use Blocks to Stop or Pause a Simulation .....	<b>27-3</b>
<b>Local Solver Basics</b> .....	<b>27-5</b>
Why Use Local Solver? .....	<b>27-5</b>
Tips .....	<b>27-5</b>
Considerations .....	<b>27-6</b>
<b>Choose a Solver</b> .....	<b>27-7</b>
Solver Selection Criteria .....	<b>27-7</b>
<b>Choose a Jacobian Method for an Implicit Solver</b> .....	<b>27-11</b>
Sparsity of Jacobian .....	<b>27-11</b>
Solver Jacobian Methods .....	<b>27-11</b>
Heuristic 'auto' Method .....	<b>27-12</b>
Full and Sparse Perturbation Methods .....	<b>27-13</b>
Full and Sparse Analytical Methods .....	<b>27-14</b>
Code Generation Support .....	<b>27-15</b>
<b>Variable Step Solvers in Simulink</b> .....	<b>27-16</b>
Variable-Step Discrete Solver .....	<b>27-16</b>
Variable-Step Continuous Solvers .....	<b>27-17</b>
Variable-Step Continuous Explicit Solvers .....	<b>27-18</b>
Variable-Step Continuous Implicit Solvers .....	<b>27-19</b>
Error Tolerances for Variable-Step Solvers .....	<b>27-21</b>
<b>Fixed Step Solvers in Simulink</b> .....	<b>27-23</b>
Fixed-Step Discrete Solver .....	<b>27-23</b>
Fixed-Step Continuous Solvers .....	<b>27-23</b>

<b>Choose a Fixed-Step Solver</b> .....	<b>27-27</b>
When to Use a Fixed-Step Solver .....	27-27
Establish Baseline Results Using a Variable-Step Solver .....	27-28
Run Fixed-Step Simulations of the Model .....	27-30
Compare Fixed-Step Simulations with the Variable-Step Baseline .....	27-31
<b>Select Solver Using Auto Solver</b> .....	<b>27-40</b>
<b>Use Model Operating Point for Faster Simulation Workflow</b> .....	<b>27-43</b>
Benefits of Using Operating Point .....	27-44
Save an Operating Point .....	27-45
Restore Operating Point .....	27-45
<b>Operating Point Behavior</b> .....	<b>27-47</b>
Change the States of a Block Within Operating Point .....	27-47
S-Functions .....	27-47
Model Changes and Operating Point Restore .....	27-47
Limitations of Saving and Restoring Operating Point .....	27-48
<b>Specify Initial State for Simulation</b> .....	<b>27-50</b>
<b>View Diagnostics</b> .....	<b>27-56</b>
Toolbar .....	27-56
Diagnostic Message Pane .....	27-57
Trace Diagnostics Location .....	27-58
Identify Diagnostics from Custom Compilers .....	27-58
Suppress Diagnostics .....	27-58
Suggested Actions .....	27-59
<b>Systematic Diagnosis of Errors and Warnings</b> .....	<b>27-61</b>
<b>Suppress Diagnostic Messages Programmatically</b> .....	<b>27-64</b>
Suppress Diagnostic Messages Programmatically .....	27-64
Suppress Diagnostic Messages of a Referenced Model .....	27-67
<b>Customize Diagnostic Messages</b> .....	<b>27-71</b>
Display Custom Text .....	27-71
Create Hyperlinks to Files, Folders, or Blocks .....	27-71
Create Programmatic Hyperlinks .....	27-72
<b>Report Diagnostic Messages Programmatically</b> .....	<b>27-73</b>
Create Diagnostic Stages .....	27-73
Report Diagnostic Messages .....	27-73
Log Diagnostic Messages .....	27-74
<b>View and Trace Callbacks in Models</b> .....	<b>27-76</b>
Filters .....	27-78
Stage-Specific Callbacks .....	27-79
Search .....	27-79
Export .....	27-79
Trace Callbacks Programmatically .....	27-79

<b>Run Simulations Programmatically</b> .....	<b>28-2</b>
sim Command Simulations .....	28-2
Run-Button Simulations .....	28-6
<b>Run Parallel Simulations</b> .....	<b>28-8</b>
How parsim works .....	28-8
<b>Using sim function within parfor</b> .....	<b>28-11</b>
Overview of Calling sim from Within parfor .....	28-11
<b>Error Handling in Simulink Using MSLErrorException</b> .....	<b>28-20</b>
Error Reporting in a Simulink Application .....	28-20
The MSLErrorException Class .....	28-20
Methods of the MSLErrorException Class .....	28-20
Capturing Information about the Error .....	28-20

## Multiple Simulations

<b>Running Multiple Simulations</b> .....	<b>29-2</b>
Multiple Simulations with Simulink Editor .....	29-2
Multiple Simulations with Parallel Computing Toolbox .....	29-2
Multiple Simulations with the sim Function .....	29-3
Multiple Simulations with Simulink.SimulationInput Object .....	29-3
Simulation Manager to Monitor Simulations .....	29-3
The parsim/batchsim Function Capabilities .....	29-3
Data Logging for Multiple Simulations .....	29-4
<b>Run Parallel Simulations for a Thermal Model of a House Using parsim</b> .....	<b>29-5</b>
Run Multiple Parallel Simulations with Different Set Points .....	29-5
View the Runs in the Simulation Manager .....	29-6
<b>Comparison Between Multiple Simulation Workflows</b> .....	<b>29-10</b>
parsim Workflow .....	29-11
batchsim Workflow .....	29-12
<b>Analyze Results Using Simulation Manager</b> .....	<b>29-14</b>
Open Simulation Manager .....	29-14
Add and Configure Plots .....	29-16
Save and Load Simulation Manager .....	29-17

Lookup Table Spreadsheet Data Type Support .....	41-25
Create Simulink.LookupTable Objects .....	41-26
How to Open the Simulink.LookupTable Object Property Dialog Box .....	41-26
Create Table and Breakpoint Data .....	41-26
View Multidimensional Slices of Data .....	41-28
Edit Table and Breakpoint Data with MATLAB Expressions .....	41-28
Edit Table and Breakpoint Data .....	41-29
Enable Heatmap for Table Data .....	41-31
Overflow Handling .....	41-32
Data Validation .....	41-32
Lookup Table Spreadsheet Tabular Interface Shortcuts .....	41-33
<b>Enter Breakpoints and Table Data</b> .....	<b>41-35</b>
Enter Data in Block Parameter Dialog Box .....	41-35
Enter Data in Lookup Table Editor .....	41-35
Enter Data for Multiple Lookup Tables in Lookup Table Editor ...	41-37
Enter Data Using Inports of Lookup Table Dynamic Block .....	41-37
<b>Import Lookup Table Data from MATLAB</b> .....	<b>41-39</b>
Import Standard Format Lookup Table Data .....	41-39
Propagate Standard Format Lookup Table Data .....	41-40
Import Nonstandard Format Lookup Table Data .....	41-40
Propagate Nonstandard Format Lookup Table Data .....	41-42
<b>Copy and Paste Lookup Table Data from Excel</b> .....	<b>41-45</b>
<b>Import Lookup Table Data from Excel Using readtable</b> .....	<b>41-47</b>
<b>Visualize Data Through Plots</b> .....	<b>41-48</b>
<b>Generate Report of Lookup Table</b> .....	<b>41-51</b>
<b>Register Custom Lookup Table Blocks</b> .....	<b>41-52</b>
<b>Visualize Lookup Tables Visualized Through Lookup Table Control</b> .....	41-54
<b>Create a Logarithm Lookup Table</b> .....	<b>41-56</b>
<b>Prelookup and Interpolation Blocks</b> .....	<b>41-58</b>

<b>Optimize Generated Code for Lookup Table Blocks</b> .....	<b>41-59</b>
Remove Code That Checks for Out-of-Range Inputs .....	<b>41-59</b>
Optimize Breakpoint Spacing in Lookup Tables .....	<b>41-60</b>
Reduce Data Copies for Lookup Table Blocks .....	<b>41-60</b>
Efficient Code for Row-Major Array Layout .....	<b>41-61</b>
<b>Row-Major Algorithm in Existing Models Containing Lookup Table Blocks</b> .....	<b>41-62</b>
<b>Update Lookup Table Blocks to New Versions</b> .....	<b>41-63</b>
Comparison of Blocks with Current Versions .....	<b>41-63</b>
Compatibility of Models with Older Versions of Lookup Table Blocks .....	<b>41-64</b>
.....	<b>41-64</b>
How to Update Your Model .....	<b>41-64</b>
What to Expect from the Model Advisor Check .....	<b>41-65</b>

## Working with Block Masks

# 42

<b>Masking Fundamentals</b> .....	<b>42-2</b>
Masking Terminology .....	<b>42-4</b>
<b>Create a Simple Mask</b> .....	<b>42-6</b>
Step 1: Open Mask Editor .....	<b>42-6</b>
Step 2: Define the Mask .....	<b>42-6</b>
Step 3: Operate on Mask .....	<b>42-10</b>
<b>Manage Existing Masks</b> .....	<b>42-11</b>
Change a Block Mask .....	<b>42-11</b>
View Mask Parameters .....	<b>42-11</b>
Look Under Block Mask .....	<b>42-11</b>
Remove Mask .....	<b>42-11</b>
<b>Mask Callback Code</b> .....	<b>42-13</b>
Add Mask Code .....	<b>42-13</b>
Execute Drawing Command .....	<b>42-13</b>
Execute Initialization Command .....	<b>42-13</b>
Execute Callback Code .....	<b>42-14</b>
<b>Draw Mask Icon</b> .....	<b>42-16</b>
Draw Static Icon .....	<b>42-16</b>
Draw Dynamic Icon .....	<b>42-17</b>
<b>Initialize Mask</b> .....	<b>42-19</b>
Dialog Variables .....	<b>42-20</b>
Initialization Code .....	<b>42-20</b>
Mask Initialization Best Practices .....	<b>42-21</b>
<b>Promote Block Parameters on a Mask</b> .....	<b>42-22</b>
<b>Control Masks Programmatically</b> .....	<b>42-26</b>

<b>Pass Values to Blocks Under the Mask</b> .....	<b>42-30</b>
Parameter Promotion .....	42-30
Mask Initialization .....	42-30
Referencing Block Parameters Using Variable Names .....	42-30
<b>Mask Linked Blocks</b> .....	<b>42-32</b>
Guidelines for Mask Parameters .....	42-33
Mask Behavior for Masked, Linked Blocks .....	42-33
Mask a Linked Block .....	42-34
<b>Dynamic Mask Dialog Box</b> .....	<b>42-35</b>
Show Parameter .....	42-35
Enable Parameter .....	42-35
Create Dynamic Mask Dialog Box .....	42-35
Set Up Nested Masked Block Parameters .....	42-37
<b>Dynamic Masked Subsystem</b> .....	<b>42-38</b>
Allow Library Block to Modify Its Contents .....	42-38
Create Self-Modifying Masks for Library Blocks .....	42-38
Passing Mask Parameter Values from Parent Subsystem to Child Block .....	42-40
<b>Debug Masks That Use MATLAB Code</b> .....	<b>42-42</b>
Code Written in Mask Editor .....	42-42
Code Written Using MATLAB Editor/Debugger .....	42-42
<b>Introduction to System Mask</b> .....	<b>42-43</b>
<b>Create and Reference a Masked Model</b> .....	<b>42-44</b>
Step 1: Define Mask Arguments .....	42-44
Step 2: Create Model Mask .....	42-44
Step 3: View System Mask Parameters .....	42-45
Step 4: Reference Masked Model .....	42-46
<b>Control System Mask Programmatically</b> .....	<b>42-48</b>
<b>Handling Large Number of Mask Parameters</b> .....	<b>42-51</b>
<b>Customize Tables for Masked Blocks</b> .....	<b>42-52</b>
Adding a Custom Table Parameter .....	42-52
<b>Control Custom Table Programmatically</b> .....	<b>42-54</b>
<b>Add Images in Masks</b> .....	<b>42-57</b>
Store Mask Images Programmatically .....	42-57
<b>Create Hierarchical List in Mask Dialog</b> .....	<b>42-58</b>
<b>Validating Mask Parameters Using Constraints</b> .....	<b>42-59</b>
Create and Associate a Constraint .....	42-59
Create a Cross-Parameter Constraint .....	42-61
Rule Attributes .....	42-62
<b>Custom Constraint for Mask Parameter</b> .....	<b>42-64</b>

<b>Share Parameter Constraints Across Multiple Block Masks</b> . . . . .	<b>42-68</b>
<b>Control Constraints Programmatically</b> . . . . .	<b>42-73</b>
<b>Define Measurement Units for Masked Blocks</b> . . . . .	<b>42-74</b>
<b>Masking Example Models</b> . . . . .	<b>42-75</b>
<b>Create a Custom Table in the Mask Dialog</b> . . . . .	<b>42-77</b>
<b>Create a Block Mask Icon</b> . . . . .	<b>42-80</b>
<b>Promote Block Parameters on a Mask</b> . . . . .	<b>42-82</b>
<b>Mask a Variant Subsystem</b> . . . . .	<b>42-86</b>
<b>Tune Mask Popup Parameters by Referencing an External Enumeration File</b> . . . . .	<b>42-88</b>
<b>Visualize and Edit N-Dimensional Data Using Mask Lookup Table Control</b> . . . . .	<b>42-96</b>
<b>Validate Input and Output Port Signals Using Port Constraints</b>	<b>42-107</b>
<b>Create and Edit Masked Block Icon Using Graphical Icon Editor</b> . . . . .	<b>42-110</b>
Edit the Properties of Block Mask Icon and Its Elements . . . . .	<b>42-110</b>
Add Dynamic Behavior to Masked Icons . . . . .	<b>42-115</b>
Create Block Mask Icon . . . . .	<b>42-117</b>

## Creating Custom Blocks

# 43

<b>Types of Custom Blocks</b> . . . . .	<b>43-2</b>
MATLAB Function Blocks . . . . .	<b>43-2</b>
MATLAB System Blocks . . . . .	<b>43-2</b>
Subsystem Blocks . . . . .	<b>43-2</b>
C Caller Block . . . . .	<b>43-3</b>
C Function Block . . . . .	<b>43-3</b>
S-Function Blocks . . . . .	<b>43-3</b>
Masked Blocks . . . . .	<b>43-4</b>
<b>Comparison of Custom Block Functionality</b> . . . . .	<b>43-5</b>
Model State Behavior . . . . .	<b>43-6</b>
Simulation Performance . . . . .	<b>43-6</b>
Code Generation . . . . .	<b>43-8</b>
Multiple Input and Output Ports . . . . .	<b>43-9</b>
Speed of Updating the Simulink Diagram . . . . .	<b>43-9</b>
Callback Methods . . . . .	<b>43-10</b>
Comparing MATLAB S-Functions to MATLAB Functions for Code Generation . . . . .	<b>43-10</b>
Expanding Custom Block Functionality . . . . .	<b>43-11</b>

<b>Design and Create a Custom Block</b> .....	<b>43-12</b>
How to Design a Custom Block .....	43-12
Defining Custom Block Behavior .....	43-13
Deciding on a Custom Block Type .....	43-14
Placing Custom Blocks in a Library .....	43-17
Adding a User Interface to a Custom Block .....	43-19
Adding Block Functionality Using Block Callbacks .....	43-24
 <b>Integrate Python GPS Text Message Parsing Algorithms in Simulink</b> .....	 <b>43-28</b>

## Working with Block Libraries

# 44

<b>Create Custom Library</b> .....	<b>44-2</b>
Data Dictionary for Custom Libraries .....	44-3
Blocks for Custom Libraries .....	44-3
Annotations in Custom Libraries .....	44-5
Lock and Unlock Libraries .....	44-6
Prevent Disabling of Library Links .....	44-6
 <b>Add Libraries to Library Browser</b> .....	 <b>44-8</b>
Add Library to Library Browser .....	44-8
Add Sublibrary to Library Browser .....	44-9
Specify Library Order in Library List .....	44-11
 <b>Linked Blocks</b> .....	 <b>44-12</b>
Rules for Linked Blocks .....	44-13
Linked Block Terminology .....	44-13
 <b>Parameterized Links and Self-Modifiable Linked Subsystems</b> ...	 <b>44-15</b>
Parameterized Links .....	44-15
Self-Modifiable Linked Subsystems .....	44-18
 <b>Create a Self-Modifiable Library Block</b> .....	 <b>44-19</b>
 <b>Display Library Links</b> .....	 <b>44-20</b>
 <b>Disable or Break Links to Library Blocks</b> .....	 <b>44-22</b>
Break Links .....	44-22
 <b>Lock Links to Blocks in a Library</b> .....	 <b>44-24</b>
Rules for Locked Links .....	44-24
 <b>Restore Disabled Links</b> .....	 <b>44-26</b>
Restore Disabled Links Individually .....	44-26
Restore Disabled Links Hierarchically .....	44-27
 <b>Restore Parameterized Links</b> .....	 <b>44-30</b>
 <b>Fix Unresolved Library Links</b> .....	 <b>44-32</b>
Install Missing Product .....	44-32

Resolve Path to Source Block .....	44-32
Specify Unresolved Block Details for Custom Libraries .....	44-33
<b>Control Linked Block Programmatically .....</b>	<b>44-34</b>
Linked Block Information .....	44-34
Lock Linked Blocks .....	44-34
Link Status .....	44-34
<b>Maintain Compatibility of Library Blocks Using Forwarding Tables</b> .....	<b>44-37</b>
Forwarding Table Entry for a Renamed Block .....	44-37
Move Block from One Library to Another .....	44-38
Add or Remove Parameters from the Block .....	44-39
Split Block Functionality .....	44-42
Create Mask Parameter Aliases .....	44-42

## Integrating Custom C/C++ Code

### 45

<b>Debug Custom C/C++ Code .....</b>	<b>45-2</b>
In-Process and Out-of-Process Simulation .....	45-4

## Integrate C Code in Simulink Models

### 46

<b>Integrate C Code Using C Caller Blocks .....</b>	<b>46-2</b>
Specify Source Code and Dependencies .....	46-2
N-D Array Handling .....	46-4
Call C Caller Block and Specify Ports .....	46-5
Map C Function Arguments to Simulink Ports .....	46-5
Create a FunctionPortSpecification Object and Edit C Caller Block Properties .....	46-10
Create a Custom C Caller Library .....	46-10
Debug Custom Code .....	46-11
Generate Code from Model .....	46-11
Limitations .....	46-11
<b>Use C Caller Block with Conditional Execution .....</b>	<b>46-13</b>

## Integrate Algorithms Using C Function Blocks

### 47

<b>Integrate External C/C++ Code into Simulink Using C Function Blocks .....</b>	<b>47-2</b>
Write External Source Files .....	47-2
Enter the External Code Into Simulink .....	47-3

Specify Simulation or Code Generation Code .....	47-5
Specify Declaration for Target-Specific Function for Code Generation .....	47-6
<b>Interface with C++ Classes Using C Function Block .....</b>	<b>47-7</b>
Create Source Code Files .....	47-7
Configure the C Function Block .....	47-8
Limitations .....	47-10
<b>Modify States of a C Function Block Using Persistent Symbols ..</b>	<b>47-12</b>
<b>Change Values of Signals Using C Function Block and Buses ....</b>	<b>47-14</b>
<b>Access Elements of a Matrix Using Output Code in a C Function Block .....</b>	<b>47-16</b>
<b>Use External Functions with Matrix Input in a C Function Block .....</b>	<b>47-18</b>
<b>Define an Alias Type in a C Function Block .....</b>	<b>47-21</b>
<b>Use Enumerated Data in a C Function Block .....</b>	<b>47-23</b>
<b>Use Inherited Sizes in a C Function Block .....</b>	<b>47-25</b>
<b>Call a Legacy Lookup Table Function Using C Caller block .....</b>	<b>47-27</b>
<b>Start and Terminate Actions Within a C Function Block .....</b>	<b>47-29</b>
<b>Call C++ Class Methods Using a C-style Wrapper Function From a C Function Block .....</b>	<b>47-31</b>
<b>Call C++ Class Methods Directly From a C Function Block .....</b>	<b>47-33</b>
<b>Call Legacy Lookup Table Functions Using C Function Block ....</b>	<b>47-34</b>
<b>Use C Function Block Within For Each Subsystem .....</b>	<b>47-36</b>

## Simulink Code Importer

# 48

<b>Import Custom Code Using the Simulink Code Importer Wizard .....</b>	<b>48-2</b>
---	-------------

<b>Implement MATLAB Functions in Simulink with MATLAB Function Blocks</b> .....	<b>49-3</b>
Calculate Mean and Standard Deviation with a MATLAB Function Block .....	<b>49-3</b>
Program the MATLAB Function Block .....	<b>49-3</b>
Check Properties for MATLAB Function Block Variables .....	<b>49-5</b>
Build the Function .....	<b>49-6</b>
Prepare the Block for Code Generation .....	<b>49-6</b>
<b>Configure MATLAB Function Blocks Programmatically</b> .....	<b>49-7</b>
Call MATLAB Function Objects .....	<b>49-7</b>
Programmatically Configure Block Properties .....	<b>49-7</b>
Access Block Inputs, Outputs, and Properties .....	<b>49-7</b>
Programmatically Access MATLAB Function Reports .....	<b>49-8</b>
<b>Code Generation Readiness Tool</b> .....	<b>49-10</b>
Issues Tab .....	<b>49-10</b>
Files Tab .....	<b>49-11</b>
<b>Check Code Using the Code Generation Readiness Tool</b> .....	<b>49-13</b>
Run Code Generation Readiness Tool at the Command Line .....	<b>49-13</b>
Run the Code Generation Readiness Tool From the Current Folder Browser .....	<b>49-13</b>
<b>Debug MATLAB Function Blocks</b> .....	<b>49-14</b>
Debug an Example Function .....	<b>49-14</b>
Set Conditions on Breakpoints .....	<b>49-16</b>
Watch Function Variables During Simulation .....	<b>49-17</b>
Check for Data Range Violations .....	<b>49-19</b>
Debug MATLAB Function Blocks in Initialize Function and Terminate Function Blocks .....	<b>49-19</b>
<b>Prevent Algebraic Loop Errors in MATLAB Function, Chart, and Truth Table Blocks</b> .....	<b>49-21</b>
<b>Manage Function Call Outputs of a MATLAB Function Block</b> .....	<b>49-23</b>
Create Function Call Outputs .....	<b>49-23</b>
Enable a Function-Call Subsystem with a MATLAB Function Block .....	<b>49-23</b>
Considerations When Triggering Function-Call Subsystems .....	<b>49-24</b>
Set Function Call Output Properties .....	<b>49-25</b>
<b>Manage the Input Trigger of a MATLAB Function Block</b> .....	<b>49-27</b>
Create an Input Trigger .....	<b>49-27</b>
Enable a MATLAB Function Block with an Input Trigger .....	<b>49-27</b>
Set Input Trigger Properties .....	<b>49-28</b>
<b>Create and Define MATLAB Function Block Variables</b> .....	<b>49-31</b>
Create and Delete MATLAB Function Block Variables .....	<b>49-31</b>
Set General Variable Properties .....	<b>49-31</b>
Set Limit Range Properties .....	<b>49-34</b>

Set Description Properties .....	49-34
<b>Specify MATLAB Function Block Properties .....</b>	<b>49-36</b>
MATLAB Function Block Properties .....	49-36
Fixed-Point Properties .....	49-37
Description and Document Link Properties .....	49-38
Programmatically Specify Block Properties .....	49-39
<b>MATLAB Function Reports .....</b>	<b>49-40</b>
Open a MATLAB Function Report .....	49-40
Analyze MATLAB Source Code .....	49-40
View Error and Warning Messages .....	49-41
View MATLAB Variables .....	49-41
Report Limitations .....	49-43
<b>Define and Modify Variable Data Types .....</b>	<b>49-44</b>
Specify Variable Data Types .....	49-44
Inheriting Data Types .....	49-45
Built-In Data Types .....	49-45
Fixed-Point Designer Data Type Properties .....	49-46
Specify Data Types with Expressions .....	49-50
<b>Specify Size of MATLAB Function Block Variables .....</b>	<b>49-52</b>
Inherit Size from Simulink .....	49-52
Customize Data Sizes .....	49-52
<b>Configure MATLAB Function Block Parameter Variables .....</b>	<b>49-54</b>
Control Parameter Variables with Masks .....	49-54
Control Parameter Variables in Workspaces .....	49-55
<b>Resolve Signal Objects for Output Variables .....</b>	<b>49-57</b>
Implicit Signal Resolution .....	49-57
Eliminating Warnings for Implicit Signal Resolution in the Model .....	49-57
Disabling Implicit Signal Resolution for a MATLAB Function Block .....	49-57
Forcing Explicit Signal Resolution for an Output Signal .....	49-57
<b>Types of Structures in MATLAB Function Blocks .....</b>	<b>49-59</b>
<b>Attach Bus Signals to MATLAB Function Blocks .....</b>	<b>49-60</b>
Structures in a MATLAB Function Block .....	49-60
Structure Definitions in Example .....	49-60
Bus Objects Define Structure Inputs and Outputs .....	49-61
Write Buses From Data Store Memory to a MATLAB Function Block .....	49-62
<b>How Structure Inputs and Outputs Interface with Bus Signals ..</b>	<b>49-65</b>
Working with Virtual and Nonvirtual Buses .....	49-65
<b>Rules for Defining Structures in MATLAB Function Blocks .....</b>	<b>49-66</b>
<b>Index Substructures and Fields .....</b>	<b>49-67</b>

<b>Create Structures in MATLAB Function Blocks</b> .....	<b>49-68</b>
Use Nonvirtual Buses with MATLAB Function Blocks .....	<b>49-69</b>
<b>Assign Values to Structures and Fields</b> .....	<b>49-71</b>
<b>Initialize a Matrix Using a Nontunable Structure Parameter</b> ....	<b>49-72</b>
<b>Define and Use Structure Parameters</b> .....	<b>49-74</b>
Defining Structure Parameters .....	<b>49-74</b>
FIMATH Properties of Nontunable Structure Parameters .....	<b>49-74</b>
<b>Limitations of Structures and Buses in MATLAB Function Blocks</b> .....	<b>49-75</b>
<b>Control Support for Variable-Size Arrays in a MATLAB Function Block</b> .....	<b>49-76</b>
<b>Declare Variable-Size MATLAB Function Block Variables</b> .....	<b>49-77</b>
Output Variables .....	<b>49-77</b>
Other Scope Types .....	<b>49-77</b>
Use a Variable-Size Signal in a Filtering Algorithm .....	<b>49-77</b>
<b>Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block</b> .....	<b>49-83</b>
Provide Upper Bounds for Variable-Size Arrays .....	<b>49-83</b>
Disable Dynamic Memory Allocation for MATLAB Function Blocks .....	<b>49-83</b>
Modify the Dynamic Memory Allocation Threshold .....	<b>49-83</b>
<b>Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block</b> .....	<b>49-85</b>
Create Model .....	<b>49-85</b>
Configure Model for Dynamic Memory Allocation .....	<b>49-85</b>
Simulate Model Using Dynamic Memory Allocation .....	<b>49-86</b>
Use Dynamic Memory Allocation for Bounded Arrays .....	<b>49-86</b>
Generate C Code That Uses Dynamic Memory Allocation .....	<b>49-87</b>
<b>Code Generation for Enumerations</b> .....	<b>49-88</b>
Define Enumerations for MATLAB Function Blocks .....	<b>49-88</b>
Allowed Operations on Enumerations .....	<b>49-89</b>
MATLAB Toolbox Functions That Support Enumerations .....	<b>49-90</b>
<b>Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block</b> .....	<b>49-92</b>
<b>Use Enumerations to Control an LED Display</b> .....	<b>49-93</b>
Enumerations in a MATLAB Function Block .....	<b>49-93</b>
Enumeration Class Definitions .....	<b>49-93</b>
MATLAB Function Block Function .....	<b>49-94</b>
Simulation .....	<b>49-94</b>
<b>Share Data Globally</b> .....	<b>49-95</b>
When Do You Need to Use Global Data? .....	<b>49-95</b>
Using Global Data with the MATLAB Function Block .....	<b>49-95</b>
Choosing How to Store Global Data .....	<b>49-96</b>

Storing Data Using Data Store Memory Blocks .....	49-96
Storing Data Using Simulink.Signal Objects .....	49-97
Using Data Store Diagnostics to Detect Memory Access Issues ...	49-99
Limitations of Using Shared Data in MATLAB Function Blocks ...	49-99
<b>Initialize Persistent Variables in MATLAB Functions .....</b>	<b>49-100</b>
MATLAB Function Block with No Direct Feedthrough .....	49-101
State Control Block in Synchronous Mode .....	49-102

## 58

### Code Generation for Variable-Size Data

<b>Code Generation for Variable-Size Arrays</b> .....	<b>58-2</b>
Memory Allocation for Variable-Size Arrays .....	<b>58-2</b>
Enabling and Disabling Support for Variable-Size Arrays .....	<b>58-3</b>
Variable-Size Arrays in a MATLAB Function Report .....	<b>58-3</b>
<b>Specify Upper Bounds for Variable-Size Arrays</b> .....	<b>58-5</b>
Specify Upper Bounds for MATLAB Function Block Inputs and Outputs .....	<b>58-5</b>
Specify Upper Bounds for Local Variables .....	<b>58-5</b>
<b>Define Variable-Size Data for Code Generation</b> .....	<b>58-7</b>
Use a Matrix Constructor with Nonconstant Dimensions .....	<b>58-7</b>
Assign Multiple Sizes to the Same Variable .....	<b>58-7</b>
Define Variable-Size Data Explicitly by Using <code>coder.ysize</code> .....	<b>58-8</b>
<b>Diagnose and Fix Variable-Size Data Errors</b> .....	<b>58-12</b>
Diagnosing and Fixing Size Mismatch Errors .....	<b>58-12</b>
Diagnosing and Fixing Errors in Detecting Upper Bounds .....	<b>58-14</b>
<b>Incompatibilities with MATLAB in Variable-Size Support for Code Generation</b> .....	<b>58-15</b>
Incompatibility with MATLAB for Scalar Expansion .....	<b>58-15</b>
Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays .....	<b>58-16</b>
Incompatibility with MATLAB in Determining Size of Empty Arrays .....	<b>58-16</b>
Incompatibility with MATLAB in Determining Class of Empty Arrays .....	<b>58-18</b>
Incompatibility with MATLAB in Matrix-Matrix Indexing .....	<b>58-18</b>
Incompatibility with MATLAB in Vector-Vector Indexing .....	<b>58-19</b>
Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation .....	<b>58-19</b>

Incompatibility with MATLAB in Concatenating Variable-Size Matrices .....	58-20
Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements .....	58-20
<b>Variable-Sizing Restrictions for Code Generation of Toolbox Functions .....</b>	<b>58-22</b>
Common Restrictions .....	58-22
Toolbox Functions with Restrictions for Variable-Size Data .....	58-22
<b>Generate Code With Implicit Expansion Enabled .....</b>	<b>58-27</b>
Output Size .....	58-27
Additional Code Generation .....	58-27
Performance Variation .....	58-29
<b>Optimize Implicit Expansion in Generated Code .....</b>	<b>58-31</b>
Disable Implicit Expansion in Specified Function by Using coder.noImplicitExpansionInFunction .....	58-33
Disable Implicit Expansion for Specific Binary Operation by Using coder.sameSizeBinaryOp .....	58-34
Disable Implicit Expansion in your Project .....	58-35
<b>Representation of Arrays in Generated Code .....</b>	<b>58-36</b>
Customize Interface Generation .....	58-38
<b>Control Memory Allocation for Fixed-Size Arrays .....</b>	<b>58-40</b>
Enable Dynamic Memory Allocation for All Fixed-Size Arrays .....	58-40
Enable Dynamic Memory Allocation for Arrays Bigger Than a Threshold .....	58-40
<b>Resolve Error: Size Mismatches .....</b>	<b>58-41</b>
Issue .....	58-41
Possible Solutions .....	58-41

## Code Generation for MATLAB Structures

59

<b>Structure Definition for Code Generation .....</b>	<b>59-2</b>
<b>Structure Operations Allowed for Code Generation .....</b>	<b>59-3</b>
<b>Define Scalar Structures for Code Generation .....</b>	<b>59-4</b>
Restrictions When Defining Scalar Structures by Assignment .....	59-4
Adding Fields in Consistent Order on Each Control Flow Path .....	59-4
Restriction on Adding New Fields After First Use .....	59-4
<b>Define Arrays of Structures for Code Generation .....</b>	<b>59-6</b>
Ensuring Consistency of Fields .....	59-6
Using repmat to Define an Array of Structures with Consistent Field Properties .....	59-6
Defining an Array of Structures by Using struct .....	59-6
Defining an Array of Structures Using Concatenation .....	59-7

<b>Index Substructures and Fields</b> .....	<b>59-8</b>
<b>Assign Values to Structures and Fields</b> .....	<b>59-10</b>
<b>Pass Large Structures as Input Parameters</b> .....	<b>59-11</b>

## Code Generation for Cell Arrays

# 60

<b>Code Generation for Cell Arrays</b> .....	<b>60-2</b>
Homogeneous vs. Heterogeneous Cell Arrays .....	<b>60-2</b>
Controlling Whether a Cell Array Is Homogeneous or Heterogeneous .....	<b>60-2</b>
Cell Arrays in Reports .....	<b>60-3</b>
<b>Control Whether a Cell Array Is Variable-Size</b> .....	<b>60-4</b>
<b>Cell Array Limitations for Code Generation</b> .....	<b>60-6</b>
Cell Array Element Assignment .....	<b>60-6</b>
Variable-Size Cell Arrays .....	<b>60-7</b>
Definition of Variable-Size Cell Array by Using cell .....	<b>60-7</b>
Cell Array Indexing .....	<b>60-10</b>
Growing a Cell Array by Using {end + 1} .....	<b>60-11</b>
Cell Array Contents .....	<b>60-12</b>
Passing Cell Arrays to External C/C++ Functions .....	<b>60-12</b>
Use in MATLAB Function Block .....	<b>60-12</b>

## Code Generation for Categorical Arrays

# 61

<b>Code Generation for Categorical Arrays</b> .....	<b>61-2</b>
Define Categorical Arrays for Code Generation .....	<b>61-2</b>
Allowed Operations on Categorical Arrays .....	<b>61-2</b>
MATLAB Toolbox Functions That Support Categorical Arrays .....	<b>61-3</b>
<b>Define Categorical Array Inputs</b> .....	<b>61-6</b>
Define Categorical Array Inputs at the Command Line .....	<b>61-6</b>
Representation of Categorical Arrays .....	<b>61-6</b>
<b>Categorical Array Limitations for Code Generation</b> .....	<b>61-8</b>

## Code Generation for Datetime Arrays

# 62

<b>Code Generation for Datetime Arrays</b> .....	<b>62-2</b>
Define Datetime Arrays for Code Generation .....	<b>62-2</b>

Allowed Operations on Datetime Arrays .....	62-2
MATLAB Toolbox Functions That Support Datetime Arrays .....	62-2
<b>Define Datetime Array Inputs .....</b>	<b>62-5</b>
Define Datetime Array Inputs at the Command Line .....	62-5
Representation of Datetime Arrays .....	62-5
<b>Datetime Array Limitations for Code Generation .....</b>	<b>62-7</b>

## Code Generation for Duration Arrays

### 63

<b>Code Generation for Duration Arrays .....</b>	<b>63-2</b>
Define Duration Arrays for Code Generation .....	63-2
Allowed Operations on Duration Arrays .....	63-2
MATLAB Toolbox Functions That Support Duration Arrays .....	63-3
<b>Define Duration Array Inputs .....</b>	<b>63-6</b>
Define Duration Array Inputs at the Command Line .....	63-6
Representation of Duration Arrays .....	63-6
<b>Duration Array Limitations for Code Generation .....</b>	<b>63-8</b>

## Code Generation for Tables

### 64

<b>Code Generation for Tables .....</b>	<b>64-2</b>
Define Tables for Code Generation .....	64-2
Allowed Operations on Tables .....	64-2
MATLAB Toolbox Functions That Support Tables .....	64-3
<b>Define Table Inputs .....</b>	<b>64-5</b>
Define Table Inputs at the Command Line .....	64-5
Representation of Tables .....	64-5
<b>Table Limitations for Code Generation .....</b>	<b>64-7</b>
Creating Tables Limitations .....	64-7
Modifying Tables Limitations .....	64-7
Using Table Functions Limitations .....	64-9

## Code Generation for Timetables

### 65

<b>Code Generation for Timetables .....</b>	<b>65-2</b>
Define Timetables for Code Generation .....	65-2
Allowed Operations on Timetables .....	65-2

MATLAB Toolbox Functions That Support Timetables .....	65-3
<b>Define Timetable Inputs</b> .....	65-5
Define Timetable Inputs at the Command Line .....	65-5
Representation of Timetables .....	65-5
<b>Timetable Limitations for Code Generation</b> .....	65-8
Creating Timetables Limitations .....	65-8
Modifying Timetables Limitations .....	65-9
Using Timetable Functions Limitations .....	65-11

## Code Generation for MATLAB Classes

# 66

<b>MATLAB Classes Definition for Code Generation</b> .....	66-2
Language Limitations .....	66-2
Code Generation Features Not Compatible with Classes .....	66-3
Defining Class Properties for Code Generation .....	66-4
Inheritance from Built-In MATLAB Classes Not Supported .....	66-6
<b>Classes That Support Code Generation</b> .....	66-7
<b>Generate Code for MATLAB Value Classes</b> .....	66-8
<b>Generate Code for MATLAB Handle Classes and System Objects</b> .....	66-12
<b>Code Generation for Handle Class Destructors</b> .....	66-15
Guidelines and Restrictions .....	66-15
Behavioral Differences of Objects in Generated Code and in MATLAB .....	66-16
<b>Class Does Not Have Property</b> .....	66-18
Solution .....	66-18
<b>Passing By Reference Not Supported for Some Properties</b> .....	66-20
<b>Handle Object Limitations for Code Generation</b> .....	66-21
A Variable Outside a Loop Cannot Refer to a Handle Object Allocated Inside a Loop .....	66-21
A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object .....	66-22
References to Handle Objects Can Appear Undefined .....	66-23
<b>System Objects in MATLAB Code Generation</b> .....	66-25
Usage Rules and Limitations for System Objects for Generating Code .....	66-25
System Objects in codegen .....	66-27
System Objects in the MATLAB Function Block .....	66-27
System Objects in the MATLAB System Block .....	66-27
System Objects and MATLAB Compiler Software .....	66-27

<b>Work Around Language Limitation: Code Generation Does Not Support Object Arrays</b> .....	<b>66-28</b>
Issue .....	<b>66-28</b>
Possible Solutions .....	<b>66-28</b>

## Code Generation for Function Handles

### 67

<b>Function Handle Limitations for Code Generation</b> .....	<b>67-2</b>
--	-------------

## Defining Functions for Code Generation

### 68

<b>Code Generation for Variable Length Argument Lists</b> .....	<b>68-2</b>
<b>Generate Code for arguments Block That Validates Input Arguments</b> .....	<b>68-3</b>
Supported Features .....	<b>68-3</b>
<b>Code Generation for Anonymous Functions</b> .....	<b>68-4</b>
Anonymous Function Limitations for Code Generation .....	<b>68-4</b>
<b>Code Generation for Nested Functions</b> .....	<b>68-5</b>
Nested Function Limitations for Code Generation .....	<b>68-5</b>

## Calling Functions for Code Generation

### 69

<b>Resolution of Function Calls for Code Generation</b> .....	<b>69-2</b>
Key Points About Resolving Function Calls .....	<b>69-2</b>
Compile Path Search Order .....	<b>69-2</b>
When to Use the Code Generation Path .....	<b>69-2</b>
<b>Resolution of File Types on Code Generation Path</b> .....	<b>69-4</b>
<b>Compilation Directive %#codegen</b> .....	<b>69-5</b>
<b>Use MATLAB Engine to Execute a Function Call in Generated Code</b> .....	<b>69-6</b>
When To Declare a Function as Extrinsic .....	<b>69-6</b>
Use the coder.extrinsic Construct .....	<b>69-7</b>
Call MATLAB Functions Using feval .....	<b>69-9</b>
Working with mxArray .....	<b>69-9</b>
Restrictions on Using Extrinsic Functions .....	<b>69-11</b>

<b>Code Generation for Recursive Functions</b> .....	<b>69-12</b>
Compile-Time Recursion .....	<b>69-12</b>
Run-Time Recursion .....	<b>69-12</b>
Disallow Recursion .....	<b>69-13</b>
Disable Run-Time Recursion .....	<b>69-13</b>
Recursive Function Limitations for Code Generation .....	<b>69-13</b>
<b>Force Code Generator to Use Run-Time Recursion</b> .....	<b>69-14</b>
Treat the Input to the Recursive Function as a Nonconstant .....	<b>69-14</b>
Make the Input to the Recursive Function Variable-Size .....	<b>69-15</b>
Assign Output Variable Before the Recursive Call .....	<b>69-16</b>
<b>Avoid Duplicate Functions in Generated Code</b> .....	<b>69-17</b>
Issue .....	<b>69-17</b>
Cause .....	<b>69-17</b>
Solution .....	<b>69-17</b>

## Improve Run-Time Performance of MATLAB Function Block

### 70

<b>Avoid Data Copies of Function Inputs in Generated Code</b> .....	<b>70-2</b>
<b>Inline Code</b> .....	<b>70-4</b>
<b>Unroll for-Loops and parfor-Loops</b> .....	<b>70-5</b>
Force for-Loop Unrolling by Using coder.unroll .....	<b>70-5</b>
<b>Generate Reusable Code</b> .....	<b>70-7</b>
<b>LAPACK Calls for Linear Algebra in a MATLAB Function Block</b> ...	<b>70-8</b>
<b>BLAS Calls for Matrix Operations in a MATLAB Function Block</b> ..	<b>70-9</b>
<b>FFTW calls for fast Fourier transform functions in a MATLAB Function Block</b> .....	<b>70-10</b>

## Troubleshooting MATLAB Code in MATLAB Function Blocks

### 71

<b>Compile-Time Recursion Limit Reached</b> .....	<b>71-2</b>
Issue .....	<b>71-2</b>
Cause .....	<b>71-2</b>
Solutions .....	<b>71-2</b>
Force Run-Time Recursion .....	<b>71-2</b>
Increase the Compile-Time Recursion Limit .....	<b>71-4</b>

<b>Output Variable Must Be Assigned Before Run-Time Recursive Call . . .</b>	<b>71-5</b>
Issue . . . . .	71-5
Cause . . . . .	71-5
Solution . . . . .	71-5
<b>Unable to Determine That Every Element of Cell Array Is Assigned . . . .</b>	<b>71-8</b>
Issue . . . . .	71-8
Cause . . . . .	71-8
Solution . . . . .	71-9
<b>Nonconstant Index into varargin or varargout in a for-Loop . . . . .</b>	<b>71-12</b>
Issue . . . . .	71-12
Cause . . . . .	71-12
Solution . . . . .	71-12
<b>Unknown Output Type for coder.ceval . . . . .</b>	<b>71-14</b>
Issue . . . . .	71-14
Cause . . . . .	71-14
Solution . . . . .	71-14

Guidelines for Importing a Test Case .....	75-33
Example of Test Case Data .....	75-33
Use From Workspace Block for Test Case .....	75-34
Use Signal Editor Block for Test Case .....	75-35
<b>Load Data to Root-Level Input Ports</b> .....	<b>75-36</b>
Specify Input Data .....	75-36
Forms of Input Data .....	75-37
Time Values for the Input Parameter .....	75-38
Data Loading .....	75-38
Loading Dataset Data to Root-Level Inputs .....	75-38
Loading MATLAB Timeseries Data to Root-Level Inputs .....	75-39
Loading MATLAB Timetable Data to Root-Level Inputs .....	75-40
Loading Data Structures to Root-Level Inputs .....	75-40
Loading Data Arrays to Root-Level Inputs .....	75-43
Loading MATLAB Time Expressions to Root Inputs .....	75-45
<b>Load Bus Data to Root-Level Input Ports</b> .....	<b>75-47</b>
Imported Bus Data Requirements .....	75-47
Import Bus Data to a Top-Level Inport .....	75-48
Get Information About Bus Objects .....	75-50
Create Structures of Timeseries Objects from Buses .....	75-50
Import Array of Buses Data .....	75-50
<b>Load Input Data for a Bus Using In Bus Element Blocks</b> .....	<b>75-56</b>
<b>Load Signal Data That Uses Units</b> .....	<b>75-60</b>
Loading Bus Signals That Have Units .....	75-60
<b>Load Data Using the From File Block</b> .....	<b>75-61</b>
<b>Load Data Using the From Workspace Block</b> .....	<b>75-66</b>
<b>Load Data Using Playback Block</b> .....	<b>75-72</b>
<b>Load State Information</b> .....	<b>75-79</b>
Import Initial States .....	75-79
Initialize a State .....	75-79
Initialize States in Referenced Models .....	75-81

## Load Simulation Inputs Using the Root Inport Mapper

# 76

<b>Map Data Using Root Inport Mapper Tool</b> .....	<b>76-2</b>
The Model .....	76-2
Create Signal Data .....	76-3

Import and Visualize Workspace Signal Data .....	76-3
Map the Data to Imports .....	76-4
Save the Mapping and Data .....	76-5
Simulate the Model .....	76-5
<b>Map Root Import Signal Data .....</b>	<b>76-7</b>
Open the Root Import Mapper Tool .....	76-7
Command-Line Interface .....	76-7
Import and Mapping Workflow .....	76-8
Choose a Map Mode .....	76-8
Root Import Mapper Keyboard Shortcuts .....	76-8
View and Inspect Signal Data .....	76-9
<b>Create Signal Data for Root Import Mapping .....</b>	<b>76-11</b>
Choose a Source for Data to Import and Map .....	76-11
Choose a Naming Convention for Signals and Buses .....	76-11
Choose a Base Workspace and MAT-File Format .....	76-11
Bus Signal Data for Root Import Mapping .....	76-13
Create Signal Data in a MAT-File for Root Import Mapping .....	76-13
Supported Microsoft Excel File Formats .....	76-14
<b>Import Signal Data for Root Import Mapping .....</b>	<b>76-16</b>
Import Signal Data .....	76-16
Import Bus Data .....	76-17
Import Signal Data from Other Sources .....	76-18
Import Data from Signal Editor .....	76-18
Import Test Vectors from Simulink Design Verifier Environment ..	76-18
<b>Map Signal Data to Root Input Ports .....</b>	<b>76-19</b>
Select Map Mode .....	76-19
Set Options for Mapping .....	76-20
Select Data to Map .....	76-20
Map Data .....	76-21
Understand Mapping Results .....	76-22
Alternative Workflows to Load Mapping Data .....	76-24
<b>Preview Signal Data .....</b>	<b>76-26</b>
<b>Generate MATLAB Scripts for Simulation with Scenarios .....</b>	<b>76-28</b>
<b>Create and Use Custom Map Modes .....</b>	<b>76-29</b>
Create Custom Mapping File Function .....	76-29
<b>Root Import Mapping Scenarios .....</b>	<b>76-31</b>
Open Scenarios .....	76-31
Save Scenarios .....	76-32
Open Existing Scenarios .....	76-32
Work with Multiple Scenarios .....	76-33
<b>Load Data with Interchangeable Scenarios .....</b>	<b>76-34</b>
Load Data with Interchangeable Scenarios Using Signal Editor Block .....	76-34
Explore the Signal Editor Block .....	76-35
Get Number of Scenarios and Signals .....	76-36

<b>Migrate from Signal Builder Block to Signal Editor Block</b> . . . . .	<b>76-37</b>
Replace Signal Builder Block with Signal Editor Block . . . . .	<b>76-37</b>
Replace Programmatic Use of signalbuilder . . . . .	<b>76-38</b>

## Importing and Exporting Simulation Data

# 77

<b>Export Simulation Data</b> . . . . .	<b>77-2</b>
Simulation Data . . . . .	<b>77-2</b>
Logging Simulation Data . . . . .	<b>77-2</b>
Enable Simulation Data Export . . . . .	<b>77-4</b>
View Logged Data Using Simulation Data Inspector . . . . .	<b>77-4</b>
Memory Performance . . . . .	<b>77-5</b>
<b>Data Format for Logged Simulation Data</b> . . . . .	<b>77-6</b>
Data Format for Block-Based Logged Data . . . . .	<b>77-6</b>
Data Format for Model-Based Logged Data . . . . .	<b>77-6</b>
Signal Logging Format . . . . .	<b>77-6</b>
Logged Data Store Format . . . . .	<b>77-6</b>
Time, State, and Output Data Format . . . . .	<b>77-6</b>
<b>Dataset Conversion for Logged Data</b> . . . . .	<b>77-11</b>
Why Convert to Dataset Format? . . . . .	<b>77-11</b>
Results of Conversion . . . . .	<b>77-11</b>
Dataset Conversion Limitations . . . . .	<b>77-13</b>
<b>Convert Logged Data to Dataset Format</b> . . . . .	<b>77-14</b>
Convert Workspace Data to Dataset . . . . .	<b>77-14</b>
Convert Structure Without Time to Dataset . . . . .	<b>77-15</b>
Programmatically Access Logged Dataset Format Data . . . . .	<b>77-18</b>
<b>Log Signal Data That Uses Units</b> . . . . .	<b>77-23</b>
<b>Limit the Size of Logged Data</b> . . . . .	<b>77-25</b>
Limit the Number of Runs Retained in the Simulation Data Inspector Archive . . . . .	<b>77-25</b>
Specify a Minimum Disk Space Requirement or Maximum Size for Logged Data . . . . .	<b>77-25</b>
View Data Only During Simulation . . . . .	<b>77-26</b>
Reduce the Number of Data Points Logged from Simulation . . . . .	<b>77-26</b>
<b>Specify Signal Values to Log</b> . . . . .	<b>77-27</b>
Decimation . . . . .	<b>77-27</b>
Log Last n Signal Values . . . . .	<b>77-28</b>
Specify Logging Intervals . . . . .	<b>77-28</b>
<b>Work with Big Data for Simulations</b> . . . . .	<b>77-30</b>
Big Data Workflow . . . . .	<b>77-30</b>
<b>Log Data to Persistent Storage</b> . . . . .	<b>77-32</b>
When to Log to Persistent Storage . . . . .	<b>77-32</b>
Log to Persistent Storage . . . . .	<b>77-33</b>

Enable Logging to Persistent Storage Programmatically . . . . .	77-33
How Simulation Data Is Stored . . . . .	77-34
Save Logged Data from Successive Simulations . . . . .	77-34
<b>Analyze Big Data from a Simulation . . . . .</b>	<b>77-36</b>
Create DatasetRef Objects to Access Logged Datasets . . . . .	77-36
Use SimulationDatastore Objects to Access Signal Data . . . . .	77-36
Create Timetables for MATLAB Analysis . . . . .	77-36
Create Tall Timetables . . . . .	77-37
Access Persistent Storage Metadata . . . . .	77-37
Access Error Information . . . . .	77-37
<b>Samples to Export for Variable-Step Solvers . . . . .</b>	<b>77-39</b>
Output Options . . . . .	77-39
Refine Output . . . . .	77-39
Produce Additional Output . . . . .	77-39
Produce Specified Output Only . . . . .	77-40
<b>Export Signal Data Using Signal Logging . . . . .</b>	<b>77-42</b>
Signal Logging . . . . .	77-42
Signal Logging Workflow . . . . .	77-42
Signal Logging Limitations . . . . .	77-43
<b>Configure a Signal for Logging . . . . .</b>	<b>77-44</b>
Mark a Signal for Logging . . . . .	77-44
Specify Signal-Level Logging Name . . . . .	77-45
Limit Data Logged . . . . .	77-46
Set Sample Time for a Logged Signal . . . . .	77-47
<b>View the Signal Logging Configuration . . . . .</b>	<b>77-49</b>
Approaches for Viewing the Signal Logging Configuration . . . . .	77-49
View Signal Logging Configuration Using the Simulink Editor . . . . .	77-50
View Logging Configuration Using the Signal Logging Selector . . . . .	77-51
View Signal Logging Configuration Using the Model Explorer . . . . .	77-52
Programmatically Find Signals Configured for Logging . . . . .	77-53
<b>Enable Signal Logging for a Model . . . . .</b>	<b>77-54</b>
Enable and Disable Logging at the Model Level . . . . .	77-54
Specify Format for Dataset Signal Elements . . . . .	77-54
Specify a Name for Signal Logging Data . . . . .	77-56
<b>Override Signal Logging Settings . . . . .</b>	<b>77-57</b>
Benefits of Overriding Signal Logging Settings . . . . .	77-57
Two Interfaces for Overriding Signal Logging Settings . . . . .	77-57
Scope of Signal Logging Setting Overrides . . . . .	77-57
Override Signal Logging Settings with Signal Logging Selector . . . . .	77-58
Override Signal Logging Settings from MATLAB . . . . .	77-62
<b>View and Access Signal Logging Data . . . . .</b>	<b>77-67</b>
Signal Logging Object . . . . .	77-67
Access Data Programmatically . . . . .	77-67
Handling Spaces and Newlines in Logged Names . . . . .	77-68
Access Logged Signal Data in ModelDataLogs Format . . . . .	77-70

<b>Log Signals in For Each Subsystems</b> .....	77-71
Log Signal in Nested For Each Subsystem .....	77-71
Log Bus Signals in For Each Subsystem .....	77-73
<b>Save Block States and Simulation Operating Points</b> .....	77-76
Choose Which State Information to Log .....	77-76
Choose Format for Logged State Information .....	77-81
<b>Save State Information</b> .....	77-83
Save State Information for Each Simulation Step .....	77-83
Save Partial Final State Information .....	77-83
Examine State Information Saved Without the Operating Point ..	77-83
Save Final State Information with Operating Point .....	77-85
<b>Log Data to the Workspace and a File Using the Record Block</b> ..	77-86

## Working with Data Stores

# 78

<b>Data Store Basics</b> .....	78-2
When to Use a Data Store .....	78-2
Local and Global Data Stores .....	78-2
Data Store Diagnostics .....	78-3
Specify Initial Value for Data Store .....	78-9
<b>Model Global Data by Creating Data Stores</b> .....	78-10
Data Store Examples .....	78-10
Create and Apply Data Stores .....	78-12
Data Stores with Data Store Memory Blocks .....	78-13
Data Stores with Signal Objects .....	78-16
Access Data Stores with Simulink Blocks .....	78-17
Order Data Store Access .....	78-19
Data Stores with Buses and Arrays of Buses .....	78-22
Accessing Specific Bus and Matrix Elements .....	78-23
Rename Data Stores .....	78-26
Customized Data Store Access Functions in Generated Code ....	78-27
<b>Log Data Stores</b> .....	78-29
Logging Local and Global Data Store Values .....	78-29
Supported Data Types, Dimensions, and Complexity for Logging Data Stores .....	78-29
Data Store Logging Limitations .....	78-29
Logging Data Stores Created with a Data Store Memory Block ...	78-30
Logging Icon for the Data Store Memory Block .....	78-30
Logging Data Stores Created with a Simulink.Signal Object .....	78-30
Accessing Data Store Logging Data .....	78-31

<b>What Is a Data Dictionary?</b> .....	<b>79-2</b>
Dictionary Capabilities .....	79-2
Sections of a Dictionary .....	79-3
Dictionary Usage for Models Created with Different Versions of Simulink .....	79-4
Manage and Edit Entries in a Dictionary .....	79-5
Dictionary Referencing .....	79-5
Import and Export File Formats .....	79-5
Allow Access to Base Workspace .....	79-5
 <b>Migrate Models to Use Simulink Data Dictionary</b> .....	 <b>79-7</b>
Migrate Single Model to Use Dictionary .....	79-7
Migrate Model Reference Hierarchy to Use Dictionary .....	79-7
Considerations Before Migrating to Data Dictionary .....	79-8
Continue to Use Shared Data in the Base Workspace .....	79-11
Migrate Complicated Model Hierarchy with Shared Data .....	79-12
 <b>Enumerations in Data Dictionary</b> .....	 <b>79-14</b>
Migrate Enumerated Types into Data Dictionary .....	79-14
Manipulate Enumerations in Data Dictionary .....	79-16
Remove Enumerated Types from Data Dictionary .....	79-17
 <b>Import and Export Dictionary Data</b> .....	 <b>79-19</b>
Import Data to Dictionary from File .....	79-19
Export Design Data from Dictionary .....	79-22
 <b>View and Revert Changes to Dictionary Data</b> .....	 <b>79-24</b>
View and Revert Changes to Dictionary Entries .....	79-24
View and Revert Changes to Entire Dictionary .....	79-26
 <b>Partition Dictionary Data Using Referenced Dictionaries</b> .....	 <b>79-28</b>
 <b>Partition Data for Model Reference Hierarchy Using Data Dictionaries</b> .....	 <b>79-30</b>
Create a Dictionary for Each Component .....	79-30
Strategies to Discover Shared Data .....	79-35
 <b>Link Data Dictionary to Custom Libraries</b> .....	 <b>79-37</b>
Author Library Blocks with Data Types Defined in Attached Data Dictionary .....	79-37
Use Blocks From a Library with Attached Data Dictionary .....	79-38
Considerations When Using a Library Dictionary .....	79-39
 <b>Store Data in Dictionary Programmatically</b> .....	 <b>79-41</b>
Add Entry to Design Data Section of Data Dictionary .....	79-41
Rename Data Dictionary Entry .....	79-42
Increment Value of Data Dictionary Entry .....	79-42
Data Dictionary Management .....	79-42
Dictionary Section Management .....	79-43
Dictionary Entry Manipulation .....	79-44
Transition to Using Data Dictionary .....	79-44

Programmatically Migrate Single Model to Use Dictionary . . . . .	79-45
Import Directly From External File to Dictionary . . . . .	79-45
Programmatically Partition Data Dictionary . . . . .	79-47
Make Changes to Configuration Set Stored in Dictionary . . . . .	79-47

## Managing Signals

# 80

## Working with Signals

<b>Signal Basics</b> . . . . .	<b>80-2</b>
Signal Line Styles . . . . .	80-2
Signal Properties . . . . .	80-3
Signal Names and Labels . . . . .	80-4
Signal Display Options . . . . .	80-5
Store Design Attributes of Signals and States . . . . .	80-5
Test Signals . . . . .	80-6
<b>Signal Types</b> . . . . .	<b>80-7</b>
Control Signals . . . . .	80-7
Composite Signals . . . . .	80-8
Virtual and Nonvirtual Signals . . . . .	80-8
<b>Investigate Signal Values</b> . . . . .	<b>80-9</b>
Initialize Signal Values . . . . .	80-9
View Signal Values . . . . .	80-9
Display Signal Values in Model Diagrams . . . . .	80-10
Signal Data Types . . . . .	80-10
Complex Signals . . . . .	80-10
Exporting Signal Data . . . . .	80-11
<b>Signal Label Propagation</b> . . . . .	<b>80-12</b>
Blocks That Support Signal Label Propagation . . . . .	80-12
How Simulink Propagates Signal Labels . . . . .	80-13
Display Propagated Signal Labels . . . . .	80-16
Special Cases of Signal Propagation . . . . .	80-17
<b>Determine Signal Dimensions</b> . . . . .	<b>80-19</b>
Simulink Blocks that Support Multidimensional Signals . . . . .	80-20
Determine the Output Dimensions of Source Blocks . . . . .	80-20
Determine the Output Dimensions of Nonsource Blocks . . . . .	80-21
Signal and Parameter Dimension Rules . . . . .	80-21
Scalar Expansion of Inputs and Parameters . . . . .	80-21
<b>Highlight Signal Sources and Destinations</b> . . . . .	<b>80-26</b>
Highlight Signal Source . . . . .	80-26
Highlight Signal Destination . . . . .	80-27
Choose the Path of a Trace . . . . .	80-27
Trace a Signal To and From Subsystems . . . . .	80-28
Show All Possible Paths of a Trace . . . . .	80-29

Display Port Values Along a Trace . . . . .	80-29
Remove Highlighting . . . . .	80-30
Resolve Incomplete Highlighting to Library Blocks . . . . .	80-31
Signal Highlighting in Variant Systems . . . . .	80-31
Limitations . . . . .	80-32
Bus Element Tracing and Highlighting . . . . .	80-32
<b>Specify Signal Ranges . . . . .</b>	<b>80-34</b>
Blocks That Allow Signal Range Specification . . . . .	80-34
Work with Signal Ranges in Blocks . . . . .	80-35
Troubleshoot Signal Range Errors . . . . .	80-36
Unexpected Errors or Warnings for Data with Greater Precision or Range than double . . . . .	80-38
<b>Initialize Signals and Discrete States . . . . .</b>	<b>80-40</b>
Using Block Parameters to Initialize Signals and Discrete States . . . . .	80-40
Use Signal Objects to Initialize Signals and Discrete States . . . . .	80-41
Using Signal Objects to Tune Initial Values . . . . .	80-43
Initialization Behavior Summary for Signal Objects . . . . .	80-43
<b>Configure Signals as Test Points . . . . .</b>	<b>80-46</b>
What Is a Test Point? . . . . .	80-46
Displaying Test Point Indicators . . . . .	80-47
<b>Specify Application-Specific Signal Properties . . . . .</b>	<b>80-48</b>
Determine Whether To Use Value Types . . . . .	80-48
Create Value Types . . . . .	80-49
Specify Value Types . . . . .	80-49
Save Value Types . . . . .	80-50
Map Value Types to Models . . . . .	80-51
<b>Display Signal Attributes . . . . .</b>	<b>80-52</b>
Ports & Signals Menu . . . . .	80-52
Port Data Types . . . . .	80-53

# Introduction to Simulink

# Simulink Basics

---

The following sections explain how to perform basic tasks when using the Simulink product.

- “Programmatic Modeling Basics” on page 1-2
- “Build and Edit a Model Interactively” on page 1-8
- “Add Blocks and Set Parameters” on page 1-13
- “Extend the Model and Create Subsystems” on page 1-18
- “Update Diagram and Run Simulation” on page 1-24
- “Refine the Model” on page 1-27
- “Save the Model” on page 1-30
- “Preview Content of Model Components” on page 1-35
- “Collaborate by Adding Comments to Blocks” on page 1-37
- “Bookmark Parts of Model with Viewmarks” on page 1-40
- “Print Model Diagrams” on page 1-43
- “Print Model Reports” on page 1-49
- “Programmatically Print Models from MATLAB Command Window” on page 1-51
- “Keyboard Shortcuts and Mouse Actions for Simulink Modeling” on page 1-56

## Programmatic Modeling Basics

### In this section...

“Load a Model” on page 1-2  
 “Create a Model and Specify Parameter Settings” on page 1-2  
 “Programmatically Load Variables When Opening a Model” on page 1-3  
 “Programmatically Add and Connect Blocks” on page 1-3  
 “Programmatically Comment Out or Comment Through Blocks” on page 1-5  
 “Name a Signal Programmatically” on page 1-5  
 “Arrange Model Layouts Automatically” on page 1-5  
 “Open the Same Model in Multiple Windows” on page 1-6  
 “Locate Diagram Elements Using Highlighting” on page 1-6  
 “Specify Colors Programmatically” on page 1-6

You can perform most Simulink modeling basics programmatically at the MATLAB® Command Window, such as creating models, adding blocks to models, and setting parameters. These examples show some of these commands and how you can use them.

### Load a Model

Loading a model brings it into memory but does not open it in the Simulink Editor for editing. After you load a model, you can work with it programmatically. You can use the Simulink Editor to edit the model only if you open the model.

To load a system, use the `load_system` command. For example, to load the `vdp` model, at the MATLAB command prompt, enter:

```
load_system('vdp')
```

### Create a Model and Specify Parameter Settings

You can write a function that creates a model and uses the settings that you prefer. For example, this function creates a model that has a green background and uses the `ode3` solver:

```
function new_model(modelname)
% NEW_MODEL Create a new, empty Simulink model
%   NEW_MODEL('MODELNAME') creates a new model with
%   the name 'MODELNAME'. Without the 'MODELNAME'
%   argument, the new model is named 'my_untitled'.

if nargin == 0
    modelname = 'my_untitled';
end

% create and open the model
open_system(new_system(modelname));

% set default screen color
set_param(modelname, 'ScreenColor', 'green');
```

```
% set default solver
set_param(modelname, 'Solver', 'ode3');

% save the model
save_system(modelname);
```

## Programmatically Load Variables When Opening a Model

If you assign a variable as a block parameter value, you must define the value of the variable in the model. See “Create a Model” on page 1-8. You can define the variable programmatically using the `PreloadFcn` callback with the `set_param` function. Use the function in this form:

```
set_param('mymodel', 'PreloadFcn', 'expression')
```

`expression` is a MATLAB command or a MATLAB script on your MATLAB search path. This command sets the model `PreloadFcn` callback to the value that you specify. Save the model to save the setting.

For example, when you define the variables in a MATLAB script `loadvar.m` for the model `modelname.slx`, use this command:

```
set_param('modelname', 'PreloadFcn', 'loadvar')
```

To assign the variable `K` the value 15, use this command:

```
set_param('modelname', 'PreloadFcn', 'K=15')
```

After you save the model, the `PreloadFcn` callback executes when you next open the model.

## Programmatically Add and Connect Blocks

This example shows how to use functions to add blocks and connect the blocks programmatically. Once you have added blocks to the model, you use three different approaches to connect them: routed lines, port handles, and port IDs. Routed lines allow you to specify the exact (x,y) coordinates of all connecting line segment endpoints. Port handles and port IDs allow connecting lines to block ports without having to know the port location coordinates.

Create and open a blank model named ‘`mymodel`’.

Add blocks, including a subsystem block. Use the `position` array in the `set_param` function to set the size and position of the blocks. Set the upper left and lower right block corners using (x,y) coordinates.

```
add_block('simulink/Sources/Sine Wave', 'mymodel/Sine1');
set_param('mymodel/Sine1', 'position', [140,80,180,120]);
add_block('simulink/Sources/Pulse Generator', 'mymodel/Pulse1');
set_param('mymodel/Pulse1', 'position', [140,200,180,240]);
add_block('simulink/Ports & Subsystems/Subsystem', 'mymodel/Subsystem1');
set_param('mymodel/Subsystem1', 'position', [315,120,395,200]);
add_block('simulink/Sinks/Scope', 'mymodel/Scope1');
set_param('mymodel/Scope1', 'position', [535,140,575,180]);
```

Inside `Subsystem1`, delete the default connection between `In1` and `Out1`. Also, add a second input port by copying and renaming `In1` from the block library.

```
delete_line('mymodel/Subsystem1','In1/1','Out1/1');  
add_block('simulink/Sources/In1','mymodel/Subsystem1/In2');
```

Reposition the internal input and output port blocks inside Subsystem1.

```
set_param('mymodel/Subsystem1/In1','position',[50,50,90,70]);  
set_param('mymodel/Subsystem1/In2','position',[50,130,90,150]);  
set_param('mymodel/Subsystem1/Out1','position',[500,80,540,100]);
```

Insert and position an Add block inside Subsystem1.

```
add_block('simulink/Math Operations/Add','mymodel/Subsystem1/Add1');  
set_param('mymodel/Subsystem1/Add1','position',[250,80,290,120]);
```

Next, add lines to connect all the blocks in the model. Start by connecting the Sine1 and Pulse1 blocks using routed lines.

Find the (x,y) coordinates of the Sine1 output port.

```
Sine1_Port = get_param('mymodel/Sine1','PortConnectivity')
```

```
Sine1_Port =
```

```
struct with fields:  
    Type: '1'  
    Position: [185 100]  
    SrcBlock: []  
    SrcPort: []  
    DstBlock: [1x0 double]  
    DstPort: [1x0 double]
```

get\_param shows that the port Position is [185 100].

Find the (x,y) coordinates of the Pulse1 output port.

```
Pulse1_Port = get_param('mymodel/Pulse1','PortConnectivity')
```

```
Pulse1_Port =
```

```
struct with fields:  
    Type: '1'  
    Position: [185 220]  
    SrcBlock: []  
    SrcPort: []  
    DstBlock: [1x0 double]  
    DstPort: [1x0 double]
```

get\_param shows that the port position is [185 220].

Connect the output of Sine1 to the first input of Subsystem1 using three segments of routed line.

```
add_line('mymodel',[185 100; 275 100]);  
add_line('mymodel',[275 100; 275 140]);  
add_line('mymodel',[275 140; 310 140]);
```

Connect the output of Pulse1 to the second input of Subsystem1 using three segments of routed line.

```
add_line('myModel', [185 220; 275 220]);
add_line('myModel', [275 220; 275 180]);
add_line('myModel', [275 180; 310 180]);
```

Use `get_param` to get the port handles of the blocks being connected. Then use the block port handles to connect the output of `Subsystem1` to the input of `Scope1`.

```
SubsysPortHandles = get_param('myModel/Subsystem1', 'PortHandles');
ScopePortHandles = get_param('myModel/Scope1', 'PortHandles');
add_line('myModel', SubsysPortHandles.Outputport(1), ...
ScopePortHandles.Inport(1));
```

Use port names and IDs to connect the `Add1` block inside `Subsystem1` to the subsystem inputs and outputs. Simulink uses the most direct path to connect the ports.

```
add_line('myModel/Subsystem1', 'In1/1', 'Add1/1');
add_line('myModel/Subsystem1', 'In2/1', 'Add1/2');
add_line('myModel/Subsystem1', 'Add1/1', 'Out1/1');
```

## Programmatically Comment Out or Comment Through Blocks

To view or change the commented state of a block programmatically, use the `get_param` and `set_param` commands.

- To view the commented state of a block:

```
get_param(gcb, 'commented');
```

- To comment out a block:

```
set_param(gcb, 'commented', 'on');
```

- To comment through a block:

```
set_param(gcb, 'commented', 'through');
```

- To uncomment a block:

```
set_param(gcb, 'commented', 'off');
```

## Name a Signal Programmatically

- 1 Select the block that is the source for the signal line.
- 2 Use `get_param` to assign the port handle of the currently selected block to the variable `p`. Use `get_param` to assign the handle of the line connected to that port to the variable `l`. Then set the name of the signal line to `'s9'`.

```
p = get_param(gcb, 'PortHandles')
l = get_param(p.Outputport, 'Line')
set_param(l, 'Name', 's9')
```

## Arrange Model Layouts Automatically

You can use the `Simulink.BlockDiagram.arrangeSystem` command to lay out your model. This command aligns input blocks on the left, output blocks on the right, and model elements in columns between the inputs and outputs. The command affects only one layer at a time.

You can use the `Simulink.BlockDiagram.routeLine` command to route existing lines of your model. Routing existing lines improves line route quality and avoids overlaps of a line with other lines and obstacles in the model.

While you can use these commands with any open model, they are particularly useful with models you build programmatically. For an example, see “Arrange Programmatically Populated Model”.

## Open the Same Model in Multiple Windows

When you open a model, the model appears in a Simulink Editor window. For example, if you have one model open and then you open a second model, the second model appears in a second window.

To open the same model in two Simulink Editor windows, at the MATLAB command prompt, enter the `open_system` command and use the `window` argument. For example, if you have the `vdp` model open, to open another instance of the `vdp` model, enter:

```
open_system('vdp','window')
```

## Locate Diagram Elements Using Highlighting

To highlight a block, line, port, or annotation in an open model, use `hilite_system`.

## Specify Colors Programmatically

You can use the `set_param` command at the MATLAB command line or in a MATLAB program to set parameters that determine the background color of a diagram and the background color and foreground color of diagram elements. The following table summarizes the parameters that control block diagram colors.

Parameter	Determines
<code>ScreenColor</code>	Block diagram background
<code>BackgroundColor</code>	Block and annotation background
<code>ForegroundColor</code>	Block and annotation foreground

Set the color parameter to either a named color or an RGB value.

- Named color: 'automatic', 'black', 'white', 'red', 'green', 'blue', 'cyan', 'magenta', 'yellow', 'gray', 'lightBlue', 'orange', 'darkGreen'
- RGB value: '[r,g,b]'

where `r`, `g`, and `b` are the red, green, and blue components of the color normalized to the range 0.0 to 1.0.

For example, the following command sets the background color of the currently selected system or subsystem to a light green color:

```
set_param(gcs,'ScreenColor','[0.3, 0.9, 0.5]')
```

## Build and Edit a Model Interactively

Learn the basics of how to create a model, add blocks to a model, connect blocks, and simulate a model. You also learn how to organize your model with subsystems, name parts of a model, and modify a model.

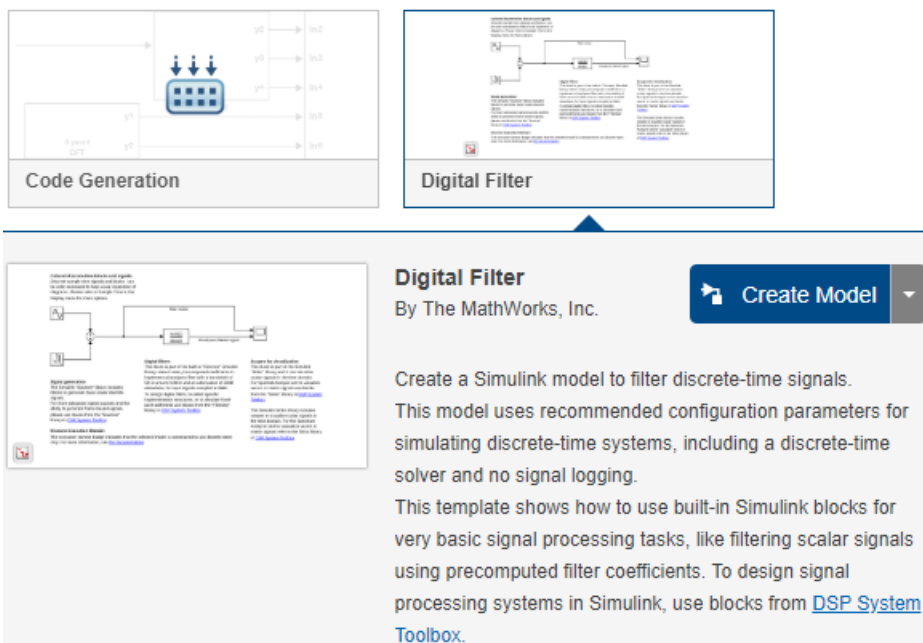

For a summary of how to connect blocks and add ports interactively, see “Keyboard Shortcuts and Mouse Actions for Simulink Modeling” on page 1-56.

### Create a Model

- 1 On the MATLAB **Home** tab, click **Simulink**.
- 2 On the Simulink Start Page, choose a template or search the templates.

Model templates are starting points that you can use to apply common modeling approaches. They help you reuse settings and block configurations. Use model and project templates to ensure your designs are applying best practices and to take advantage of previous modeling solutions.

Click the title of a template to read the description.

The image shows a selection of Simulink templates. At the top, two thumbnails are visible: 'Code Generation' (showing a block diagram with a blue controller block) and 'Digital Filter' (showing a block diagram of a filter). Below these, a larger view of the 'Digital Filter' template is shown. It includes a block diagram on the left, a title 'Digital Filter' by The MathWorks, Inc., and a 'Create Model' button. The description text reads: 'Create a Simulink model to filter discrete-time signals. This model uses recommended configuration parameters for simulating discrete-time systems, including a discrete-time solver and no signal logging. This template shows how to use built-in Simulink blocks for very basic signal processing tasks, like filtering scalar signals using precomputed filter coefficients. To design signal processing systems in Simulink, use blocks from [DSP System Toolbox](#).'

Search for templates by entering text in the search box. You can enter flexible search options, including OR, AND, NOT, use wildcards, do a fuzzy search (~), and more. Use the Lucene search engine query parser syntax.

To locate templates that are not on the MATLAB search path, click **Open**. Model templates have the extension `.sltx`.

- 3 After selecting the template you want, click **Create Model**.

To use a template without reading the description, click the template image. Alternatively, press **Ctrl+N** to use your default template.

A new model using the template settings and contents opens in the Simulink Editor.

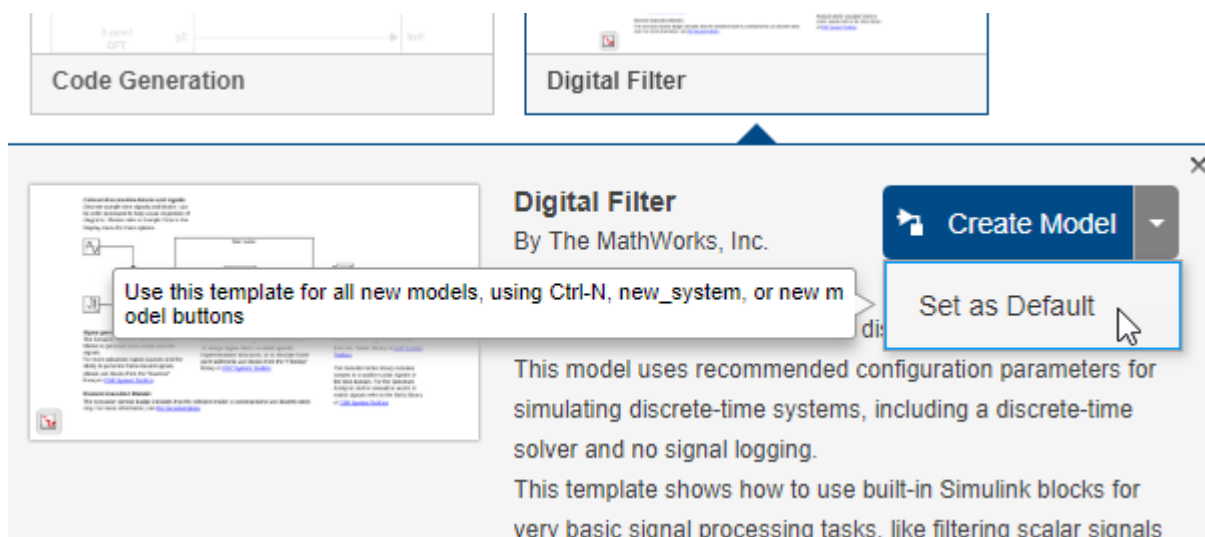

If the built-in templates do not meet your needs, try searching on the **Examples** tab or creating your own templates. See “Create Template from Model” on page 4-2. On the **Examples** tab, enter search terms to search the titles and descriptions of the examples, or open examples on the web by clicking **View All** next to a product name.

## Set Default Template for New Models

You can specify a model template to use for all new models.

- 1 Create a model with the configuration settings and blocks you want, then export the model to a template. See “Create Template from Model” on page 4-2.
- 2 To reuse these settings in every new model, make the new template your default model template by using the Simulink Start Page or the `Simulink.defaultModelTemplate` function.

On the Start Page, click the title of a template to expand the description, then click the down arrow next to **Create Model** and select **Set As Default**.

After you set a default model template, every new model uses that template, for example, when you press **Ctrl+N**, when you use new model buttons, or when you use `new_system`. In the Simulink Editor, your default template appears at the top of the list when, on the **Simulation** tab, you select **New**.

The default template shows a check mark on the Start Page.

## Open a Model

Opening a model loads the model into memory and displays it in the Simulink Editor. Use any of these techniques:

- On the MATLAB Toolstrip, on the **Home** tab, click **Simulink**. On the Simulink Start Page, select a recent model or project from the list, or click **Open**.
- In the Simulink Toolstrip, on the **Simulation** tab, select **Open** and click **Recent Files** to open recent files or **Open** to search for a model.
- At the MATLAB Command Window, enter the name of the model without a file extension, for example, `vdp`. The model must be in the current folder or on the MATLAB search path.
- In the Simulink Library Browser, click the **Open** button .
- Open the model using the Current Folder browser or your operating system file browser.

---

**Note** To open a model created in a later version of Simulink software in an earlier version, first export the model to the earlier version. See “Export Model to Previous Simulink Version” on page 1-32.

---

## Set Favorite Files

Set favorites to easily find your favorite models and projects on the Simulink Start Page.

In the **Recent** list, you can add files to favorites. The **Favorites** list then appears above recent files on the Start Page, so you can easily reopen your favorite models and projects.

## Clear Recent Files

To edit or clear the list of recent files on the Start Page, right-click a recent file and click **Remove from List** or **Clear List**.

Alternatively, use `Simulink.history.clear` to clear the Simulink history programmatically.

## Load Variables When Opening a Model

As you build models, you sometimes define variables for a model. For example, suppose that you have a model that contains a Gain block. You can specify the variable `K` as the gain rather than setting the

value on the block. When you use this approach, you must define the variable K for the model to simulate.

You can use a model callback to load variables when you open a model.

- 1 In a model that uses the Gain block, set the block **Gain** value to K.
- 2 Define the variable in a MATLAB script. In MATLAB, select **New > Script**. In the script, enter your variable definitions:
 

```
K=27
```
- 3 Save the script as `loadvar.m`.
- 4 In the model, open the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 5 At the top level of a model, click an empty space in the Simulink Editor canvas to ensure nothing is selected.
- 6 On the **Properties** tab, in the **Callbacks** section, select `PreLoadFcn`, then enter `loadvar`.
- 7 Save the model.

The next time that you open the model, the `PreLoadFcn` callback loads the variables into the MATLAB workspace.

You can also use the Model Properties dialog box instead of the Property Inspector. On the **Modeling** tab, click **Model Settings > Model Properties**.

To learn about callbacks, see “Customize Model Behavior with Callbacks” on page 4-52. To define a callback for loading variables programmatically, see “Programmatically Load Variables When Opening a Model” on page 1-3.

## Open a Model That Has Different Character Encoding

If you open an MDL file created in a release prior to R2021b in a MATLAB session that uses different encoding, you receive a warning. For example, suppose you create an MDL file in a MATLAB session configured for `Shift_JIS` and open it in a session configured for `windows-1252`. The warning message displays the encoding of the current session and the encoding used to create the model. Starting in R2021b, MDL files, similar to SLX files, can store characters from any encoding. Resave your model files as MDL or SLX files.

## Simulink Model File Types

New models have the `.slx` extension by default. Models created before R2012b have the extension `.mdl`. You can edit models with either the `.slx` or `.mdl` extension, depending on when they were created and whether you converted them. See “Save Models in the SLX File Format” on page 1-31.

`.slxp` and `.mdlp` extensions denote protected models that you cannot open or edit. See “Reference Protected Models from Third Parties” on page 8-13. Model templates have the extension `.sltx`.

Simulink libraries and subsystems can also use the `.slx` extension. To learn more, see “Choose Among Types of Model Components” on page 23-4.

- “Save the Model” on page 1-30

## Add Blocks and Set Parameters

### Add Blocks to the Model

A basic model takes an input signal, operates on it, and outputs the result. In the Library Browser, in the Simulink library, the Sources sublibrary contains blocks that represent different types of inputs. The Sinks sublibrary has blocks for capturing and displaying outputs. The other sublibraries contain blocks you can use for a variety of purposes, such as math operations.

In this example of a basic model, you use a sine wave for an input, multiply the signal value, and output the result. Try different techniques to explore the library and to add blocks to your model.

- 1 Open the Library Browser in docked mode. In the Simulink Toolstrip, on the **Simulation** tab, click the **Library Browser** button.
- 2 In the tree view of the Library Browser, expand the **Simulink** library, then expand the **Sources** sublibrary.
- 3 In the **Sources** sublibrary, pause on the Sine Wave block to see a tooltip describing its purpose.
- 4 Add a block to your model using the context menu. Right-click the Sine Wave block and select **Add block to model**. To learn more about the block, right-click the block and select **Help**.

---

**Tip** If the blocks are in the single-column layout, to make the block easier to click, you can switch to the responsive layout, which has larger block icons. To switch, on the Library Browser, click the Responsive layout button .

---

- 5 Add a block to your model by dragging. In the library tree view, in the Simulink library, expand the **Math Operations** sublibrary. In the **Math Operations** sublibrary, locate the Gain block and drag it to your model to the right of the Sine Wave block.
- 6 In the Simulink library, expand the **Sinks** sublibrary, locate the Scope block and add it to your model using the context menu or by dragging it.

The figure shows your model so far.

---

**Note** The Simulink Editor names blocks as you add them. For example, it names the first Gain block that you add Gain, the next Gain1, and so on. By default, the Simulink Editor hides these names. However, you can see the name by selecting the block. To make block names visible, you can:

- Name the block.
- Select the block. On the **Format** tab, select **Auto Name > Name On**.
- Change the model setting for displaying block names. On the **Debug** tab, select **Information Overlays** and clear **Hide Automatic Block Names**.

For more information on displaying block names, see “Manage Block Names and Ports” on page 39-12.

---

## Align and Connect Blocks

Connect the blocks to create relationships between model elements to make the model operate. Reading the model is easier when you line up blocks according to how they interact with each other. Shortcuts help you to align and connect blocks.

- 1 Drag a Gain block so it lines up with the Sine Wave block. An alignment guide appears when the blocks line up horizontally.
- 2 Release the block, and a blue arrow appears to suggest a connection.

- 3 To make the connection, click the arrow. A solid line appears.
- 4 Line up and connect the Scope block to the Gain block using the same technique. Additional guides appear when multiple blocks are within range.

- 5 To connect the Gain block to the Scope block, drag a line from the output port of the Gain block to the input port of the Scope block.

---

**Tip** For additional alignment options, select multiple blocks. On the **Format** tab, click options in the **Align** section.

---

## Set Block Parameters

You can set parameters on most blocks. Parameters allow you to specify how a block operates in the model. You can use the default values or set your own values in these ways:

- Use the Property Inspector to set parameters.
- Double-click most blocks to set the parameters using the Block Parameters dialog box.
- Edit block parameter values on the block icon. See “Edit Block Parameters on Block Icons” on page 1-15.

In your model, set the sine wave amplitude.

- 1 Display the Property Inspector. On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 2 Select the Sine Wave block.
- 3 In the Property Inspector, set the **Amplitude** parameter to 2.

In a block dialog box or in the Property Inspector, when you set a block parameter value to a variable or function, Simulink provides a list based on the current text typed in the edit field. The suggestions include variables or objects from every workspace (base, model, and mask), data dictionary, and referenced dictionary visible to the block parameter. Autocomplete is available for variables, fields of structures and objects, and for functions on the MATLAB path.

## Edit Block Parameters on Block Icons

For blocks that display parameter value on the block icon, you can edit the value interactively on the icon.

In your model, edit the gain value.

- 1 Select the Gain block. Pause on the block. A blue underline appears under the parameter value, which indicates that the parameter is editable.
- 2 Set the **Gain** parameter to 300000. Click the underlined number, delete it, and enter 300000.

Blocks such as Constant and Gain blocks display a parameter value only when it fits on the block icon.

- 3 To resize the block so that it displays the parameter value, click the interactive cue.

Alternatively, use one of these options to resize the block so that it displays the parameter value:

- In the Simulink Toolstrip, on the **Format** tab, select **Fit to Content**.
- In the Simulink Editor, on the action bar that appears when you select the block and pause on the ellipsis, select **Fit to Content**.

You can also edit enumerated block parameter values on the block icon.

- Fixed parameter enumeration — For the block parameters that have a fixed set of values, you can select the value from a list of allowed values using the cursor or arrow keys.

For example, consider a Rounding Function block that allows a list of values for the **Function** parameter.

- 1 Select the block and point to the block icon. The editable parameter value appears underlined.

- 2 Click the underlined text to edit the value. A list appears with allowed values for the **Function** parameter. Select the required value from the list to update the block parameter value.

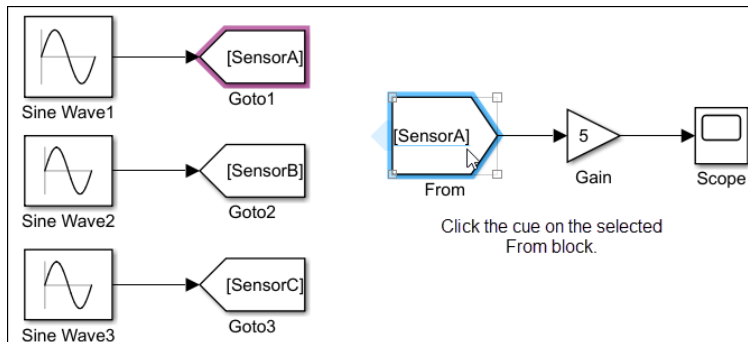

This feature is enabled for these blocks:

- Logical Operator
- Rounding Function
- MinMax
- Sqrt
- Relational Operator
- Math Function
- Complex to Real-Imag
- Dynamic parameter enumeration — For block parameters that allows dynamic values, you can select a value from the list, or you can type the new value. Typing a new value removes unmatched values from the list.

The feature is currently enabled for the From block.

For example, consider a From block with three values for the **GoTo Tag** parameter.

- “Save the Model” on page 1-30

## Extend the Model and Create Subsystems

### Add More Blocks

Suppose that you want to multiply the absolute value of the output from the Sine Wave block. To do this, you can add an Abs block and another Gain block to the model by using different techniques to locate and add blocks.

- 1 If you know the name of the block that you want to add, you can use the quick insert menu. Double-click where you want to add the block, and type the block name. In this case, enter **gain**.

The suggestions are dynamically ranked based on your recent block usage history.

- 2 Click the block name or, with the block name highlighted, press **Enter**. You can use the arrow keys to highlight the block name if it is not first in the list.
- 3 Some blocks display a prompt for you to enter a value for one of the block parameters. The Gain block prompts you to enter the **Gain** value. Type 3 and press **Enter**.
- 4 To perform an absolute value, add an Abs block. Suppose you do not know the library a block is in or the full name of the block. You can search for it using the search box in the Library Browser. Open the Library Browser. In the search box, type **abs** and press **Enter**. When you find the Abs block, add it to the left of the new Gain block.
- 5 Add another Scope block. You can right-click the existing Scope block and drag to create a copy or use the **Copy** and **Paste** commands.

The figure shows the current state of the model.

### Branch a Connection

The input to the second Gain block is the absolute value of the output from the Sine Wave block. To use a single Sine Wave block as the input to both gain operations, create a branch from the Sine Wave block output signal.

- 1 For the first set of blocks in your model, you used the horizontal alignment guides to help you align and connect them. You can also use guides to align blocks vertically. Drag the second Scope block so that it lines up under the first one. Release it when the vertical alignment guide shows that the blocks are aligned.

- 2 You can click a port to identify compatible ports that can be connected to it. The port hint symbol  appears near the compatible elements.
  - a Click the output port of the Gain block.

- b Point to  to see the connection cue.

- c Click the cue to connect the Gain block to the Scope block.

- d Connect the output port of the Abs block to the input port of the Gain block.

- 3 Create a branch from the Sine Wave block output to the Abs block. Click the input port of the Abs block. Move the cursor toward the output signal line from the Sine Wave block. A preview line appears. Click to create the branch.

Alternatively, you can start the branch by clicking the line segment and then moving the cursor toward the port.

- 4 Name the signals. Double-click the signal line between the bottom Gain block and Scope block and type Scope. The label appears next to the signal line.

Try these methods to add or connect blocks:

- To get a list of recommended blocks to connect to an unconnected signal line, drag from a block port and release so that a red, dotted line appears. Double-click the end of the line to use the quick insert menu. Suggested blocks for the current context appear on the menu. You can select one of the listed blocks.

To improve the menu suggestions based on your model designs, see “Improve Quick Block Insert Results” on page 83-54.

- To search for a block by name, double-click the canvas and then type the name of a block to get a list of blocks that starts with the characters you typed. For custom library blocks, you can type the block keyword, if the library author assigned one. The list is ranked based on your recent block usage history.
- To connect one port to multiple blocks, click a port, then hold **Shift** before you click another port. Holding **Shift** lets you make multiple, consecutive connections. For example, while holding **Shift**, you can branch a new signal line and connect it to another port or signal line with one click.
- To connect blocks, select the first block and **Ctrl+click** the block you want to connect it to. This technique is useful when you want to connect blocks that have multiple inputs and outputs, such as multiple blocks to a bus or two subsystems with multiple ports. As with clicking two ports, this technique is useful when you do not want to align blocks. The signal line bends as needed to make the connection.

To make a diagonal line from line segments, press **Shift** and drag a vertex.

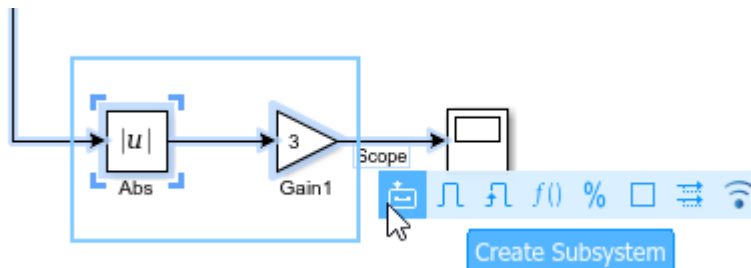

**Tip** To improve the shape of a signal line, select the line and pause on the ellipsis that appears. From the action bar, select **Auto-route Line**. The line redraws if a better route between model elements is possible. To improve line routing for a selected block or for multiple model elements selected by dragging a selection box, select **Auto-route Lines** from the action bar.

## Organize Your Model into Components

You can group blocks in subsystems and label blocks, subsystems, and signals. For more information about subsystems, see “Create Subsystems” on page 4-17.

- 1 Drag a selection box around the Abs block and the Gain block next to it.
- 2 Move the cursor over the ellipsis that appears at the corner of the selection box. From the action bar, select **Create Subsystem**.

A Subsystem block appears in the model in place of the selected blocks. On the Subsystem block icon, labels describe the input and output ports by index or name.

---

**Note** You can place a port on any side of the Subsystem block. To move a port, click and drag it around the block.

---

To resize the Subsystem block for the best fit in your model, drag the block handles.

- 3 Give the subsystem a meaningful name. Select the block, double-click the name, and type **Absolute Value**. Naming a block causes the name to appear in the model.
- 4 Open the Absolute Value subsystem by double-clicking it. Alternatively, right-click the subsystem and select **Open in New Tab**.

The subsystem contains the blocks and signal that you selected as the basis of the subsystem. They are connected in sequence to two new blocks: an Inport block and an Outport block. Inport and Outport blocks correspond to the input and output ports on the subsystem. Creating the subsystem from a selection that includes a named signal adds the name of the signal to the corresponding Inport or Outport block.

- 5 Click the **Up to Parent** button  to return to the top level of the model.

---

**Tip** You can use the Explorer Bar to navigate the model hierarchy. For example, to return to the parent model, click the name of the parent model.

---

The figure shows the model after you create the subsystem and name it.

## Update Diagram and Run Simulation

You can leave many attributes of a block diagram, such as signal data types and sample times, unspecified. The Simulink software then infers the values of block diagram attributes based on the block connectivity and attributes that you specify. The process that Simulink uses is known as updating the diagram.

Simulink attempts to infer the most appropriate values for attributes that you do not specify. If Simulink cannot infer an attribute, it halts the update and displays an error.

Simulink updates the diagram at the start of a simulation. The updated diagram provides the simulation with the results of the latest changes that you have made to a model.

### Simulate the Model and View Results

Simulating performs the operations specified by the blocks in the model and its specific configuration and produces results. See “Simulation” for complete information, such as how to configure your model for simulation.

Use either of these methods to simulate a model:

- Press **Ctrl+T**.
- Click **Run** .

In this example, the simulation runs for 10 seconds, which is the default setting.

Double-click both Scope blocks to open them and view the results.

The figures show the two results. In the second plot, the absolute value of the sine wave is always positive.

## Update the Diagram While Editing

You can also update the diagram at any point while you create a model. Updating the diagram periodically can help you to identify and fix potential simulation issues as you develop the model. This approach can make it easier to identify the sources of problems by focusing on a set of recent changes. Also, updating the diagram takes less time than performing a simulation, so you can identify issues more quickly.

To update the diagram, from the **Modeling** tab, click **Update Model**. Alternatively, press **Ctrl+D**.

To see the effects of updating the diagram.

- 1 On the **Debug** tab, select **Information Overlays > Base Data Types**.

The data types of the output ports of the blocks appear. The data type of the ports is **double**, the default value.

- 2 Double-click the Abs block.
- 3 In the Block Parameters dialog box, on the **Signal Attributes** tab, set **Output data type** to **single** and click **OK**.

The data type overlays on the block diagram do not show this change.

- 4 On the **Modeling** tab, click **Update Model**.

The updated block diagram shows the changes to the output data types of the Abs and Gain blocks.

The data type of the Gain block changes because the output data type of a Gain block is based on the data types of the input signal and the **Gain** parameter. In this example, the block uses the same data type as the input signal.

### Related Examples

- “Simulate a Model Interactively” on page 27-2
- “Running Multiple Simulations” on page 29-2
- “Run Simulations Programmatically” on page 28-2
- “Refine the Model” on page 1-27
- “Save the Model” on page 1-30

## Refine the Model

You can add blocks to a signal, remove blocks from models, comment out and comment through blocks, and redraw connections. Suppose you want to add a bias to the input to both branches of your model and export the results to the MATLAB workspace instead of a Scope block. Suppose you also want to add more blocks and another output to the subsystem.

- 1 Add a Bias block to the model and set the **Bias** parameter to 2.
- 2 Drag the block onto the signal line after the Sine Wave block but before the branch. If you need to make room for the block, drag the Sine Wave block to the left or move the end of the branch by dragging it to the right.

When you drag the block onto the signal line, the block connects to the signal line at both ends. Release the block when you are satisfied with the position.

- 3 Remove the top Scope block. If you want to disconnect it from the model, but do not want to delete it, press and hold **Shift** and drag the block. Cut or delete it by pressing **Ctrl+X** or the **Delete** key. The broken connection appears as a red dotted line.

**Tip** When you delete a block that has one input and one output, a blue line appears to suggest a connection between the broken lines. Click the blue line to connect the signals.

- 4 Add a To Workspace block at the end of the broken connection. The To Workspace block outputs the results to a variable in the MATLAB workspace.
- 5 Add a Sine Wave block to the model and set the amplitude to 5. Place it to the left of the subsystem.
- 6 Add another input to the subsystem. Drag a line from the new Sine Wave block to the left side of the subsystem. A new port appears on the subsystem.

Alternatively, click the side of the block and select the type of port to create.

For certain blocks, these actions add an input port or output port. For example, a port appears on a subsystem when you connect a line to it. Other blocks that add ports include the Bus Creator, Scope, Add, and Product blocks.

- 7 Add an output to the subsystem. Add another To Workspace block to the model and place it to the right of the subsystem. Drag a line from its input port to the right side of the subsystem. A new port appears on the subsystem.

- 8 Open the subsystem and rename the Out2 block Workspace. Add a Manual Switch block to the subsystem. Resize it and connect it as shown. Branch the signal after the Gain block to direct the output to the To Workspace block.

Then, return to the top level of the model. The figure shows the current model.

- 9 Simulate the model.
  - The `out` variable appears in the MATLAB workspace. Double-click the variable to explore the results.
  - If you want to use the second sine wave as the input to the subsystem, open the subsystem and double-click the switch. The input changes to the In2 block. Simulate again.

---

**Tip** To simulate the model without the effects of the Bias block, right-click the Bias block and select **Comment Through**. The block stays in the model, but does not affect the operation. Right-click the Bias block and select **Uncomment** to enable the block. The **Comment Out** command comments out the block output signal, so signal data does not pass through.

---

## Comment Out and Comment Through Blocks

You can use the **Comment Out** and **Comment Through** commands in Simulink to exclude blocks from simulation without physically removing the blocks from the model.

- **Comment Out:** Excludes the selected block from simulation. The signals are terminated and grounded. When you comment out a block, the signal names at the output port of the block are ignored. To include such signals during simulation, add the signal name at the input port of the block.
- **Comment Through:** Excludes the selected block from simulation. The signals are passed through. To comment through, a block must have the same number of input and output ports and no control or connection ports.

To comment out or comment through, right-click the block and select **Comment Out** or **Comment Through** based on your modeling requirement. Alternatively, select the block and press **Ctrl+Shift+X** to comment out, or press **Ctrl+Shift+Y** to comment through.

These Simulink blocks do not support the **Comment Out** and **Comment Through** commands:

- Inport
- Outport
- Connection ports
- Argument Inport
- Argument Outport
- Data Store Memory
- Goto Tag Visibility

The Signal Generator block does not support the **Comment Through** command.

- “Update Diagram and Run Simulation” on page 1-24
- “Save the Model” on page 1-30
- “Comment Out Objects in a Stateflow Chart” (Stateflow)

## Save the Model

You can tell that a model has unsaved changes by looking at the title bar in the Simulink Editor. An asterisk (also known as the dirty flag) appears in the title bar when a model has unsaved changes..

To determine programmatically whether a model has unsaved changes, you can query the value of the model parameter `Dirty` with the `get_param` function. For example, this command saves the current system (`gcs`) if it is dirty:

```
if strcmp(get_param(gcs, 'Dirty'), 'on')
    save_system;
end
```

## Save a Model

To save a model for the first time, in the Simulink Editor, on the **Simulation** tab, click **Save**. Provide a location and name for the model file. To see the naming requirements, see “Model Names” on page 1-30.

To save a previously saved model, follow one of these processes:

- To save the model using the current file name, in the Simulink Editor, on the **Simulation** tab, click **Save**.
- To save the contents of the top model to a new name or location, or to change the model format, in the Simulink Editor, on the **Simulation** tab, select **Save > Save As**.

---

**Note** For details about the SLX format, see “Convert File Format to SLX” on page 1-31.

---

- To save the contents of a referenced model to a new name, location, or format, open the referenced model as a top model. Then, on the **Simulation** tab, select **Save > Save As**.
- To save the top model in a format compatible with an earlier Simulink version, on the **Simulation** tab, select **Save > Previous Version**. See “Export Model to Previous Simulink Version” on page 1-32.

## Model Names

Model file names must start with a letter and can contain letters, numbers, and underscores. The file name must not be:

- A language keyword (for example, `if`, `for`, `end`)
- A reserved name: `'simulink'`, `'sl'`, `'sf'`
- A MATLAB software command

The total number of characters in the model name must not be greater than a certain maximum, usually 63 characters. To find the maximum file name length for your system, use the MATLAB `namelengthmax` command.

To understand how MATLAB determines which function to call when you specify a model name, see “Function Precedence Order”.

## How Simulink Saves Models

When you save a model, Simulink saves the block diagram, block properties, and other information associated with the model in the model file.

If you have any pre-save or post-save callbacks, they execute in this order:

- 1 All block `PreSaveFcn` callback routines execute, then the model `PreSaveFcn` callback routine executes.
- 2 Simulink writes the model file.
- 3 All block `PostSaveFcn` callback routines execute, then the model `PostSaveFcn` executes.

During the save process, Simulink maintains a temporary backup copy (named *modelName.bak*) that it uses to restore the model in case of an error. If an error occurs during saving or during any callback during the save process, Simulink:

- Restores the original file
- Writes any content saved before the error occurred in a file named *modelName.err*
- Issues an error message

When saving a model loaded from an SLX file, the original SLX file must still be present. Simulink performs incremental loading and saving of SLX files, so if the original file is missing at save-time, Simulink warns that it cannot fully reconstruct the file.

## Save Models in the SLX File Format

### Save New Models as SLX

Simulink saves new models and libraries in the SLX format by default, with file extension `.slx`. The SLX format is a compressed package that conforms to the Open Packaging Conventions (OPC) interoperability standard. The SLX format stores model information using Unicode® UTF-8 in XML and other international formats. Saving Simulink models in the SLX format:

- Typically reduces file size compared to MDL files. The file size reduction between MDL and SLX varies depending on the model.
- Enables incremental loading and saving. Simulink optimizes performance and memory usage by loading only required parts of the model and saving only modified parts of the model.

You can specify your file format for saving new models and libraries with the Simulink preference “File format for new models and libraries”.

### Convert File Format to SLX

If you convert an MDL file to the SLX file format, the file contains the same information as the MDL file. Functions that works with MDL files, such as `get_param` and `set_param`, also work with the SLX file format. If you convert an MDL file to the SLX file format without changing the model name or location, then Simulink creates a backup file by renaming the MDL file (if the file is writable).

If you save an existing MDL file by clicking **Save** on the **Simulation** tab, Simulink saves your model in MDL format.

To save an existing MDL file in the SLX file format:

- 1** On the **Simulation** tab, select **Save > Save As**.
- 2** Leave the default **Save as type** as SLX, and click **Save**.

Simulink saves your model in SLX format and creates a backup file by renaming the MDL file (if the file is writable) to `mymodel.mdl.releasename`, for example, `mymodel.mdl.R2010b`.

Alternatively, use `save_system`:

```
save_system mymodel mymodel.slx
```

This command creates `mymodel.slx`, and if the existing file `mymodel.mdl` is writable, it is renamed `mymodel.mdl.releasename`.

SLX files take precedence over MDL files, so if both exist with the same name and you do not specify a file extension, you load the SLX file.

**Caution** If you use third-party source control tools, register the model file extension `.slx` as a binary file format. If you do not, these third-party tools might corrupt SLX files when you submit them.

The following table describes operations with possible compatibility considerations when using SLX files.

Operations with Possible Compatibility Considerations when Using SLX	What Happens	Action
Hard-coded references to file names with the extension <code>.mdl</code>	Scripts cannot find or process models saved with the new file extension, <code>.slx</code> .	Make your code work with both the <code>.mdl</code> and <code>.slx</code> extension.  Use functions like <code>which</code> and <code>what</code> instead of file names.
Third-party source control tools that assume a text format by default	The binary format of SLX files can cause third-party tools to corrupt the files when you submit them.	Register the <code>.slx</code> and <code>.mdl</code> extensions as binary file formats with third-party source control tools. See "Register Model Files with Source Control Tools" on page 19-8.

The format of content within MDL and SLX files is subject to change. To operate on model data, use documented functions (such as `get_param`, `find_system`, and `Simulink.MDLInfo`).

## Export Model to Previous Simulink Version

You can export a model created with the latest version of the Simulink software in a format used by an earlier version. For example, you can share a model with colleagues who only have access to a previous version of Simulink.

To export a model in an earlier format:

- 1 In the Simulink Editor, on the **Simulation** tab, click **Save**. This saves a copy in the latest version of Simulink. This step avoids compatibility problems.
- 2 In the Simulink Editor, on the **Simulation** tab, select **Save > Previous Version**.
- 3 In the Export to Previous Version dialog box, from the **Save as type** list, select the previous version to which to export the model. The list supports seven years of previous releases.
- 4 Click **Save**.

When you export a model to a format of a previous version, the model is saved in the earlier format, regardless of whether the model contains blocks and features that were introduced after that version. If the model contains blocks or uses features that postdate the earlier version, the model might not give correct results when you run it in the earlier version of Simulink software. In addition, Simulink converts blocks that postdate an earlier version into yellow, empty, masked Subsystem blocks. For example, if you use `save_system` to export a model to Release R2007b, and the model contains Polynomial blocks, Simulink converts the Polynomial blocks into yellow, empty, masked Subsystem blocks. Simulink also removes any unsupported functionality from the model. See `save_system`.

## Save from Earlier Simulink Version to Another Earlier Version

You can open a model created in an earlier version of Simulink and export that model to a different earlier version. To prevent compatibility problems, use the following procedure:

- 1 Use the current version of Simulink to open the model created with the earlier version.
- 2 Before you make any changes, save the model in the current version by clicking **Save** on the **Simulation** tab.

After saving the model in the current version, you can change and resave it as needed.

- 3 Save the model in the earlier version of Simulink. On the **Simulation** tab, select **Save > Previous Version**.
- 4 Start the earlier Simulink version and use it to open the model that you exported to that earlier version.
- 5 Save the model in the earlier version.

You can now use the model in the earlier version of Simulink exactly as you could if it had been created in that version.

These Simulink preferences can help you work with models from earlier versions:

- “Do not load models created with a newer version of Simulink”
- “Save backup when overwriting a file created in an older version of Simulink”

## See Also

`save_system`

## **Related Examples**

- “Add Blocks and Set Parameters” on page 1-13
- “Extend the Model and Create Subsystems” on page 1-18
- “Update Diagram and Run Simulation” on page 1-24
- “Refine the Model” on page 1-27

## Preview Content of Model Components

To display a representation of the contents of a hierarchical model element, such as a subsystem, on the block, you can use content preview. Content preview helps you see the contents of a hierarchical element without navigating the hierarchy. Content preview shows blocks, signals, signal and block labels, sample time color coding, signal highlighting, and Stateflow® animations.

By default, content preview is on for new hierarchical elements. You can change this setting by using Simulink Preferences. To open the Simulink Preferences dialog box, on the **Modeling** tab, select **Environment > Simulink Preferences**. On the **Editor** pane, you can clear the **Content preview displays for new hierarchical elements** option.

To toggle content preview for a hierarchical element, select the block that you want to enable or disable content preview for, and then on the **Format** tab, click **Content Preview**. Content preview settings for blocks apply across Simulink sessions.

In this figure, the Throttle & Manifold subsystem has content preview enabled.

Simulink scales the content preview to fit the size of the block. To improve the readability of the content preview, you can zoom in on or resize the block.

You can enable content preview on:

- Subsystem blocks
- Model blocks
- Variant Subsystem blocks
- Stateflow charts, subcharts, and graphical functions

In some cases, content preview does not appear when it is enabled. Content preview does not appear for:

- Hierarchical block icons when they are smaller than their default size in the Library Browser
- Masked blocks whose **Icon transparency** property is set to **Opaque** or **Opaque with ports**
- Masked blocks that have a mask icon image
- Subsystem blocks when they have the **Read/Write permissions** block parameter set to **NoReadOrWrite**
- Model blocks whose referenced models are protected models
- Model blocks whose referenced models are not loaded
- Models that have the classic diagram theme enabled in Simulink Editor preferences

---

**Note** A slight delay can occur when drawing models with many hierarchical elements that contain many blocks and have content preview enabled.

---

## **Programmatic Use**

**Parameter:** ContentPreviewEnabled

**Type:** character vector

**Value:** 'on' | 'off'

**Default:** 'on'

## **See Also**

Model | Subsystem | Variant Subsystem, Variant Model

## Collaborate by Adding Comments to Blocks

Comments provide an interface for teams to review, iterate, and develop block diagrams. With comments, you can collaborate directly in the Simulink Editor. Team members can add comments to provide feedback, ask questions, and suggest alternative designs.

You can also use comments to record action items as you develop a block diagram. For example, you can add comments to remind yourself of design ideas and to indicate where you may need to change a parameter value.

The screenshot displays the Simulink Editor interface. The top menu bar includes SIMULATION, DEBUG, MODELING, FORMAT, APPS, and REVIEW. Below the menu is a toolbar with icons for Add Comment, Next, Previous, and Comment List. The main workspace shows a block diagram titled "van der Pol Equation" with various blocks like gain blocks (1, Mu), summing junctions (+, -), and integrators (1/s). A comments panel is open on the right, showing a list of comments for blocks "Mu", "Sum", and "Sum1". The "Sum1" comment is selected, showing its text and action buttons: Edit, Reply, Resolve, and Show in Model.

To add descriptive notes and annotations that are not actionable, see “Describe Models Using Notes and Annotations” on page 4-4.

To mark up a printed copy of the block diagram, see “Print Model Diagrams” on page 1-43.

### Determine Whether Model Has Open Comments

When you close a model, subsystem, or library file that has comments, the comments are saved in an MLDATX file with a `_comments` suffix. For example, for a model named `mymodel.slx`, the comments file is named `mymodel_comments.mldatx`. To access the comments, the corresponding comments file must be on the MATLAB path. When the comments file is accessible and the model has open

comments, a badge (  ) appears in the lower-left corner of the Simulink Editor canvas.

## View Comments

To view comments, open the **Review Manager** perspective by performing one of these actions:

- In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, select **Review Manager**.
- In the lower-right corner of the Simulink Editor canvas, click the perspectives control and select the **Review Manager** perspective.

- If the model has open comments, click the **Model has open review comments** badge  in the lower-left corner of the Simulink Editor canvas.

These actions open the **Review** tab and the **Comments** pane.

When a block has comments associated with it, a comment icon appears on the block. Click the comment icon to highlight the related comments in the **Comments** pane. To see the most recent comment for the block as a tooltip, pause on the comment icon.

## Add Comments

To add a comment:

- 1 Open the **Review Manager** perspective by performing one of these actions:
  - In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, select **Review Manager**.
  - In the lower-right corner of the Simulink Editor canvas, click the perspectives control and select the **Review Manager** perspective.

- If the model has open comments, click the **Model has open review comments** badge  in the lower-left corner of the Simulink Editor canvas.
- 2 Select a block in the Simulink Editor canvas, then perform one of these actions:
    - Pause on the ellipsis, then click the **Add Comment** button  in the action bar.
    - On the **Review** tab, click **Add Comment**.
  - 3 Enter the comment in the text box that appears in the **Comments** pane.

To enter multiline comments in the **Comments** pane, press **Shift+Enter** while editing a comment.

When you rename a block that has comments, the **Comments** pane updates to display the new block name. Blocks are sorted alphabetically by name in the **Comments** pane. Renaming a block can change the position of the comments in the pane.

When you close the parent model, subsystem, or library file, the comments are saved in an MLDATX file in the same location as the parent. Suppose you add comments to a model named `mymodel.slx`, which previously had no comments associated with it. Closing the model creates a comments file named `mymodel_comments.mldatx`.

To add comments to blocks in other files, open the files separately. For example, open a referenced model as a top model by clicking the **Open As Top Model** icon on a Model block that references it.

## Edit, Reply to, and Resolve Comments

In the **Comments** pane, pause on a committed comment to receive options to edit it, reply to it, resolve it, and show the block that corresponds to it. Clicking **Show in Model** highlights the block to facilitate finding the block in the block diagram.

When you pause on a resolved comment, you receive options to reopen the comment and to show the block that corresponds to the comment.

## Hide and Delete Comments

To display fewer comments in the **Comments** pane, on the **Review** tab, clear **Comment List > Show resolved comments**. Alternatively, permanently delete all resolved comments by selecting **Comment List > Delete all resolved comments**.

When the comments file is on the MATLAB path, deleting a block that has comments also deletes the corresponding comments. If you undo the deletion of a block, the block and its comments are restored.

## Related Examples

- “Bookmark Parts of Model with Viewmarks” on page 1-40
- “Describe Models Using Notes and Annotations” on page 4-4
- “Create a Project from a Model” on page 16-12
- “Print Model Diagrams” on page 1-43
- “Print Model Reports” on page 1-49

## Bookmark Parts of Model with Viewmarks

You can use viewmarks to bookmark parts of a model, or to capture graphical views of a model so you can navigate directly to that view. You can capture viewmarks for specific levels in a model hierarchy. You can also pan and zoom to capture a point of interest.

Some examples of ways you can use viewmarks include:

- Navigate to specific locations in complex models without opening multiple Simulink Editor tabs or windows.
- Review model designs.
- Visually compare versions of a model.
- Share views of a model by storing viewmarks within the model.

You manage viewmarks in the viewmarks gallery. By default, viewmarks are stored locally on your computer. If you want to include a viewmark to share with a model, see “Save a Viewmark to the Model” on page 1-41. The figure shows the viewmark gallery.

## Create a Viewmark

- 1 Navigate to the part of the model that you want to capture in a viewmark.
- 2 Pan and zoom to the part of the system that you want to capture.
- 3 Resize the Simulink Editor window so that it frames the part of the model you want to capture.
- 4 In the palette, click the **Viewmark This View** button .

The viewmark displays briefly and becomes part of the viewmarks gallery.

## Open and Navigate Viewmarks

- 1 In the Simulink Editor palette, click the **Viewmarks** button .

The viewmarks gallery has two tabs. The **Personal** tab consists of viewmarks that you created in a model and are stored locally on your computer. The **Model** tab consists of viewmarks that are saved in the Simulink model file.

- 2 Select the tab (**Personal** or **Model**) that contains your viewmark, and then click the viewmark.

The Simulink Editor opens the model, if necessary, and displays the part of the model captured in the viewmark.

## Manage Viewmarks

In the viewmarks gallery, you can rename viewmarks, add or edit a description for viewmark, and delete viewmarks. You also use the viewmarks gallery to save viewmarks with the model. You can manage viewmarks only in models saved in SLX format. In models saved in MDL format, the **Manage** button appears dimmed.

- To rename a viewmark, click the name and edit it.
- To add a description, pause on the viewmark, click the **Description** button , and enter a description.
- To delete a viewmark, pause on the viewmark and click the **Delete** button  on the viewmark. To delete all the viewmarks for a model, pause on the model name and click **Delete**.

## Save a Viewmark to the Model

- 1 In the Simulink Editor palette, click the **Viewmarks** button .
- 2 In the viewmarks gallery, click **Manage**.
- 3 Select the check box in the viewmarks you want to copy to the model.
- 4 Click the **Add viewmarks to model** button .

These viewmarks become part of the model.

## Refresh a Viewmark

A viewmark is a static view of a part of a model. For currently loaded models, you can refresh a viewmark so that it reflects the current model. Open the viewmark gallery and click the **Refresh** button  on the viewmark.

If the viewmark shows a subsystem that has been removed, then the viewmark appears dimmed.

“Print Models to PDFs” on page 1-48

## Print Model Diagrams

You can print a block diagram:

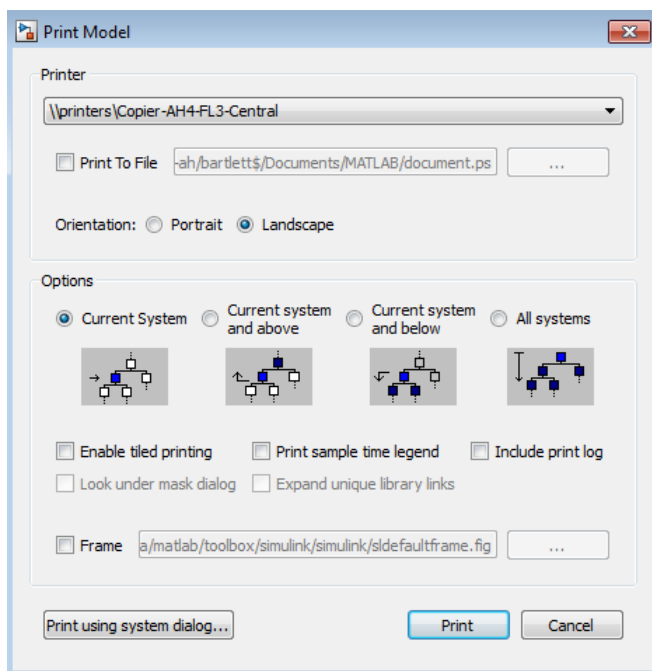

- Interactively, in the Simulink Editor. On the **Simulation** tab, click **Print**.
- Programmatically. In the MATLAB Command Window, use the `print` function.

To control some additional aspects of printing a block diagram, use the `set_param` command with model parameters. You can use `set_param` with the interactive and programmatic printing interface.

### Print Models Using Default Settings

The default print settings produce good quality printed output for quickly capturing a model in printed form.

- 1 Open your model.
- 2 In the Simulink Editor, on the **Simulation** tab, click **Print**.
- 3 In the Print Model dialog box, use the default settings. Click **Print**.

The model as it appears in the Simulink Editor prints on a single page using portrait orientation and without a print frame.

### Specify Paper Size and Orientation

Use the Print Model dialog box to specify the page orientation (portrait or landscape) for the current printing session.

To specify paper size and orientation without printing, use the Page Setup dialog box. To open the dialog box, on the **Simulation** tab, select **Print > Page Setup**. Only the paper size and orientation are used.

## Specify Background Color

By default, the canvas (background) of the printed model is white. To match the color of the model, set the **Simulink Preferences > General > Print**.

## Specify Print Frames

Print frames are borders of a printed page that contain information about a block diagram, such as the model name or the date of printing.

To print using a print frame, specify an existing print frame. If you want to build a print frame, see “Create Print Frames for Printed Pages” on page 84-2.

---

**Note** If you enable the print frame option, then Simulink does not use tiled printing.

---

- 1 In the Simulink Editor or Stateflow Editor, on the **Simulation** tab, click **Print**.
- 2 In the Print Model dialog box, select the **Frame** check box.

- 3 Supply the file name for the print frame you want to use. Either type the path and file name directly in the edit box, or click the ... button and select a print frame file you saved using the **PrintFrame Editor**. The default print frame file name, `sldefaultframe.fig`, appears in the file name edit box until you specify a different file name.
- 4 Specify other printing options in the Print Model dialog box.

---

**Note** The paper orientation you specify with the **PrintFrame Editor** does not control the paper orientation used for printing. For example, assume you specify a landscape-oriented print frame in the **PrintFrame Editor**. If you want the printed page to have a landscape orientation, you must specify that using the Print Model dialog box.

---

- 5 Click **OK**.

The block diagram prints with the print frame that you specify.

## Select the Systems to Print

To print the system in the currently open Simulink Editor tab, on the **Simulation** tab, click **Print**.

For models with subsystems, use the Simulink Editor and the Print Model dialog box to specify the subsystems to print.

---

**Note** To print a model reference hierarchy, you must print each referenced model separately. You cannot print the contents of protected models.

---

By default, Simulink does not print masked subsystems or subsystems linked to libraries.

- To print the contents of masked subsystems, in the Print Model dialog box, click **Look under mask dialog**.
- To print the contents of library links, in the Print Model dialog box, click **Expand unique library links**. Simulink prints one copy, regardless of how many copies of the block the model contains.
- If a subsystem is a masked subsystem linked to a library, Simulink uses the **Look under mask dialog** setting and ignores the **Expand unique library links** setting.

To print all of the subsystems in a model:

- 1 Display the top-level of a model in the currently open Simulink Editor tab.
- 2 In the Simulink Editor, on the **Simulation** tab, click **Print**.
- 3 In the Print Model dialog box, select **All systems**.
- 4 Click **Print**.

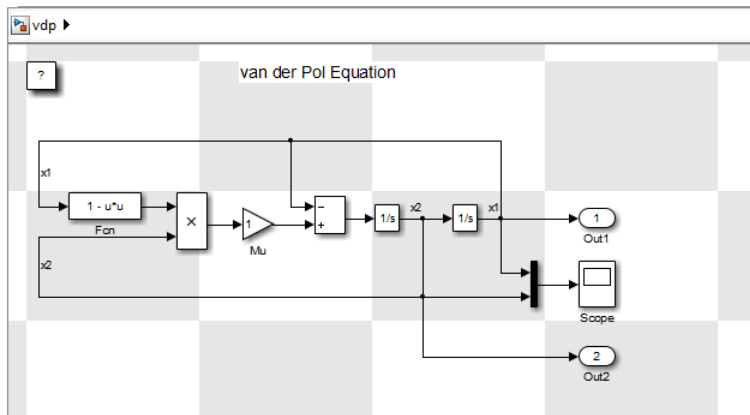

To print a subset of the subsystems in a model:

- 1 In the current tab of the Simulink Editor, display the subsystem level that you want to use as the starting point for printing the subsystem hierarchy.
- 2 In the Print Model dialog box, select one of the following:
  - **Current system and below**
  - **Current system and above**
- 3 Click **Print**.

## Print Large Diagrams on Multiple Pages

By default, each block diagram is scaled during the printing process so that it fits on a single page. In the case of a large diagram, this automatic scaling can make the printed image difficult to read.

Tiled printing enables you to print even the largest block diagrams without sacrificing clarity and detail. Tiled printing allows you to distribute a block diagram over multiple pages. For example, you can use tiling to divide a model as shown in the figure, with each white box and each gray box representing a separate printed page.

You can control the number of pages over which Simulink prints the block diagram.

You can also set different tiled-print settings for each of the systems in your model.

---

**Note** If you enable the print frame option, then Simulink does not use tiled printing.

---

To print multiple pages for large model:

- 1 In the Simulink Editor, open the model in the current tab.
- 2 On the **Simulation** tab, click **Print**.
- 3 In the Print Model dialog box, select **Enable tiled printing**.

---

**Note** The default **Enable tiled printing** setting in the Print Model dialog box is the same as the **Print > Enable Tiled Printing** setting. If you change the Print Model dialog box **Enable tiled printing** setting, the Print Model dialog box setting takes precedence.

---

- 4 Confirm that tiling divides the model into separate pages the way you want it to appear in the printed pages. In the Simulink Editor, on the **Simulation** tab, select **Print > Show Page Boundaries**. The gray and white squares indicate the page boundaries.
- 5 Optionally, from the MATLAB Command Window, specify the model scaling, tile margins, or both. See "Set Tiled Page Margins" on page 1-54.
- 6 Optionally, specify a subset of pages to print. In the Print Model dialog box, specify the **Page Range**.
- 7 Click **Print**.

## Add Log of Printed Models

A print log lists the blocks and systems you have printed. To print the print log when you print a model:

- 1 In the Simulink Editor, open the model whose print job you want to log.
- 2 On the **Simulation** tab, click **Print**.
- 3 In the Print Model dialog box, select **Include print log**.
- 4 Click **Print**.

The print log appears on the last page.

For example, here is the print log for the `sldemo_enginewc` model, with **All systems** enabled and **Enable tiled printing** cleared.

```

Page      System Name
-----
1         sldemo_enginewc
2         sldemo_enginewc/Combustion
3         sldemo_enginewc/Compression
4         sldemo_enginewc/Controller
5         sldemo_enginewc/Engine Dynamics
6         sldemo_enginewc/More Info
7         sldemo_enginewc/Throttle & Manifold
8         sldemo_enginewc/Throttle & Manifold/Intake Manifold
9         sldemo_enginewc/Throttle & Manifold/Throttle
10        sldemo_enginewc/drag torque
11        sldemo_enginewc/valve timing
12        sldemo_enginewc/valve timing/TDC and BDC detection
13        sldemo_enginewc/valve timing/positive edge to dual
edge conversion

```

## Add Sample Time Legend

You can print a legend that contains sample time information for your entire system, including any subsystems. The legend appears on a separate page from the model. To print a sample time legend:

- 1 In the Simulink Editor, on the **Modeling** tab, click **Update Model**.
- 2 On the **Simulation** tab, click **Print**.
- 3 In the Print Model dialog box, select **Print sample time legend**.
- 4 Click **Print**.

A sample time legend appears on the last page. For example, here is the sample time legend for the `sldemo_enginewc` model, with **All systems** enabled.

### Sample Times for 'sldemo\_enginewc'

Color	Description	Value
	Continuous	0
	Fixed in Minor Step	[0,1]
	Constant	Inf
	Triggered	Source: FIM

For more information on sample times, see “View Sample Time Information” on page 7-16.

## Configure Print Job

To open the print dialog box for your operating system, in the Print Model dialog box, click **Print using system dialog**. The operating system print dialog box provides additional printing options for models, such as page range, copies, double-sided printing, printing in color (if your print driver supports color printing), and nonstandard paper sizes.

## Print Models to PDFs

You can print a model to a .pdf file. Simulink creates one file for all of the systems in the model.

- 1 In the Simulink Editor, on the **Simulation** tab, click **Print**.
- 2 Select **Print to File**.
- 3 Specify a location and file name to save the new .pdf file. Include the extension .pdf in the file name.
- 4 Click **Print**.

## Copy Diagrams as Images

On Microsoft® Windows® platforms, you can copy the current view of your model in either a bitmap or metafile format. You can then paste the clipboard image to a third-party application, such as word processing software.

On Macintosh platforms, when you copy a model view to the clipboard, Simulink saves the model in a scalable format in addition to a bitmap format. When you paste from the clipboard to a third-party application, the application selects the format that best meets its requirements.

- 1 To copy a Simulink model to the operating system clipboard, in the Simulink Editor, on the **Format** tab, select **Screenshot**, then select the desired format.
- 2 Navigate out of Simulink and into a third-party application with image capabilities. Paste the model from the clipboard to the third-party application. Export the model image using the correct procedure for the application.

---

**Note** The quality of the exported image will depend on the third-party application. Results may vary based on individual cases.

---

By default, the canvas (background) of the copied model matches the color of the model. To use a white or transparent canvas for copied model files, set the **Simulink Preferences > General > Clipboard** preference. For more information, see Simulink Preferences.

print

## More About

- “Create Print Frames for Printed Pages” on page 84-2
- “Print Model Reports” on page 1-49
- “Programmatically Print Models from MATLAB Command Window” on page 1-51

## Print Model Reports

A model report is an HTML document that describes the structure and content of a model. The report includes block diagrams of the model and its subsystems and the settings of its block parameters.

**Tip** If you have the Simulink Report Generator™ installed, you can generate a detailed report about a system. In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, select **System Design Report**. For more information, see “System Design Description” (Simulink Report Generator).

To generate a model report for the current model:

- 1 In the Simulink Editor, on the **Simulation** tab, select **Print > Print Details**.
- 2 In the Print Details dialog box, select report options.

Report Option	Description
<b>Directory</b>	The folder where the HTML report is stored. The options include your system's temporary folder (the default), your system's current folder, or another folder whose path you specify in the adjacent edit field.
<b>Increment filename to prevent overwriting old files</b>	Creates a unique report file name each time you generate a report for the same model in the current session. This preserves each report.
<b>Current object</b>	Include only the currently selected object in the report.
<b>Current and above</b>	Include the current object and all levels of the model above the current object in the report.
<b>Current and below</b>	Include the current object and all levels below the current object in the report.
<b>Entire model</b>	Include the entire model in the report.
<b>Look under mask dialog</b>	Include the contents of masked subsystems in the report.
<b>Expand unique library links</b>	Include the contents of library blocks that are subsystems. The report includes a library subsystem only once even if it occurs in more than one place in the model.

- 3 Click **Print**.

The Simulink software generates the HTML report and displays the report in your default HTML browser.

While generating the report, Simulink displays status messages on a messages pane that replaces the options pane on the Print Details dialog box.

Select the detail level of the messages from the list at the top of the messages pane. When the report generation process begins, the **Print** button changes to a **Stop** button. To stop the report generation, click **Stop**. When the report generation process finishes, the **Stop** button changes to an **Options** button. Clicking this button redisplay the report generation options, allowing you to generate another report without having to reopen the Print Details dialog box.

# Programmatically Print Models from MATLAB Command Window

**In this section...**

“Printing Commands” on page 1-51

“Print Systems with Multiline Names or Names with Spaces” on page 1-53

“Set Paper Orientation and Type” on page 1-53

“Position and Size a System” on page 1-53

“Use Tiled Printing” on page 1-54

“Print Models to Image File Formats” on page 1-55

## Printing Commands

The MATLAB `print` command provides several options for printing Simulink models. For example, print the `Compression` subsystem in the `sldemo_enginewc` model to your default printer:

```
openExample('sldemo_enginewc');  
print -sCompression
```

---

**Tip** When you use the `print` command, you can print only one system. To print multiple levels in a model, use multiple `print` commands, one for each system that you want to print. To print multiple systems in a model, consider using the Print Model dialog box in the Simulink Editor. For details, see “Select the Systems to Print” on page 1-45.

---

You can use `set_param` and the following parameters to specify printing options for models.

**Model Parameters for Printing**

Parameter	Description	Values
PaperOrientation	Printing paper orientation.	'portrait'   {'landscape'}
PaperPosition	When PaperPositionMode is set to manual, this parameter determines the position and size of a diagram on paper and the size of the diagram exported as a graphic file in the units specified by PaperUnits.	vector — [left, bottom, width, height]
PaperPositionMode	<p>Paper position mode.</p> <ul style="list-style-type: none"> <li>• auto</li> </ul> <p>When printing, Simulink software sizes the diagram to fit the printed page. When exporting a diagram as a graphic image, Simulink software sizes the exported image to be the same size as the diagram's normal size on screen.</p> <ul style="list-style-type: none"> <li>• manual</li> </ul> <p>When printing, Simulink software positions and sizes the diagram on the page as indicated by PaperPosition. When exporting a diagram as a graphic image, Simulink software sizes the exported graphic to have the height and width specified by PaperPosition.</p> <ul style="list-style-type: none"> <li>• tiled</li> </ul> <p>Enables tiled printing.</p> <p>See “Print Large Diagrams on Multiple Pages” on page 1-45 for more information.</p>	{'auto'}   'manual'   'tiled'
PaperSize	Size of PaperType in PaperUnits.	vector — [width height] (read only)

Parameter	Description	Values
PaperType	Printing paper type.	'usletter'   'uslegal'   'a0'   'a1'   'a2'   'a3'   'a4'   'a5'   'b0'   'b1'   'b2'   'b3'   'b4'   'b5'   'arch-A'   'arch-B'   'arch-C'   'arch-D'   'arch-E'   'A'   'B'   'C'   'D'   'E'   'tabloid'
PaperUnits	Printing paper size units.	'normalized'   {'inches'}   'centimeters'   'points'
TiledPaperMargins	Controls the size of the margins associated with each tiled page. Each element in the vector represents a margin at the particular edge.	vector — [left, top, right, bottom]

You can use `orient` to control the paper orientation.

## Print Systems with Multiline Names or Names with Spaces

To print a system whose name appears on multiple lines, assign the newline character to a variable and use that variable in the `print` command. This example shows how to print a subsystem whose name, `Aircraft Dynamics Model`, appears on three lines.

```
open_system('f14');
open_system('f14/Aircraft Dynamics Model');
sys = sprintf('f14/Aircraft\nDynamics\nModel');
print (['-s' sys])
```

To print a system whose name includes one or more spaces, specify the name as a character vector. For example, to print the `Throttle & Manifold` subsystem, enter:

```
openExample('sldemo_enginewc');
open_system('sldemo_enginewc/Throttle & Manifold');
print (['-sThrottle & Manifold'])
```

## Set Paper Orientation and Type

To set just the paper orientation, use the MATLAB `orient` command.

You can also set the paper orientation by using `set_param` with the `PaperOrientation` model parameter. Set the paper type with the `PaperType` model parameter.

## Position and Size a System

To position and size the model diagram on the printed page, use `set_param` command with the `PaperPositionMode` and `PaperPosition` model parameters.

The value of the `PaperPosition` parameter is a vector of form `[left bottom width height]`. The first two elements specify the bottom-left corner of a rectangular area on the page, measured from the bottom-left corner. The last two elements specify the width and height of the rectangle.

If you set the `PaperPositionMode` parameter to `manual`, Simulink positions (and scales, if necessary) the model to fit inside the specified print rectangle. If `PaperPositionMode` is `auto`, Simulink centers the model on the printed page, scaling the model, if necessary, to fit the page.

For example, to print the `vdp` model in the lower-left corner of a U.S. letter-size page in landscape orientation:

```
open_system('vdp');
set_param('vdp', 'PaperType', 'usletter');
set_param('vdp', 'PaperOrientation', 'landscape');
set_param('vdp', 'PaperPositionMode', 'manual');
set_param('vdp', 'PaperPosition', [0.5 0.5 4 4]);
print -svdp
```

## Use Tiled Printing

### Enable Tiled Printing

- 1 Use `set_param` to set the `PaperPositionMode` parameter to `tiled`.
- 2 Use the `print` command with the `-tileall` argument.

For example, to enable tiled printing for the `Compression` subsystem in the `sldemo_enginewc` model:

```
openExample('sldemo_enginewc');
set_param('sldemo_enginewc/Compression', 'PaperPositionMode', ...
'tiled');
print('-ssldemo_enginewc/Compression', '-tileall')
```

### Display Tiled Page Boundaries

To display the page boundaries programmatically, use the `set_param` command, with the model parameter `ShowPageBoundaries` set to `on`. For example:

```
openExample('sldemo_enginewc');
set_param('sldemo_enginewc', 'ShowPageBoundaries', 'on')
```

### Set Tiled Page Margins

By decreasing the margin sizes, you can increase the printable area of the tiled pages. To specify the margin sizes associated with tiled pages, use the `set_param` function with the `TiledPaperMargins` parameter. Each margin is 0.5 inches by default. The value of `TiledPaperMargins` is a vector that specifies margins in this order: [left top right bottom]. Each element specifies the size of the margin at a particular edge of the page. The value of the `PaperUnits` parameter determines the units of measurement for the margins.

### Specify Range of Tiled Pages to Print

To specify a range of tiled page numbers programmatically, use `print` with the `-tileall` argument and the `-pages` argument. Append to `-pages` a two-element vector that specifies the range.

---

**Note** Simulink uses a row-major scheme to number tiled pages. For example, the first page of the first row is 1, the second page of the first row is 2, and so on.

---

For example, to print the second, third, and fourth pages:

```
open_system('vdp');  
print('-svdp','-tileall','-pages[2 4]')
```

## Print Models to Image File Formats

To print your model to an image file format such as .png or .jpeg, use the `-device` argument with the MATLAB `print` command. For example, to print the `vdp` model to a .png format, use this command:

```
print -dpng -svdp vdp_model.png
```

To programmatically export a model into an image format:

- Call your model in the MATLAB command line.  

```
model %model is your model name
```
- Use the `print` command to save your model in a .jpeg format.

```
print('-smodel', '-djpeg', 'new_name')
```

By default, the canvas (background) of the exported model matches the color of the model. To use a white or transparent canvas for model files that you export to another file format, set the **Simulink Preferences > General > Export** preference. For more information, see Simulink Preferences.

## Keyboard Shortcuts and Mouse Actions for Simulink Modeling

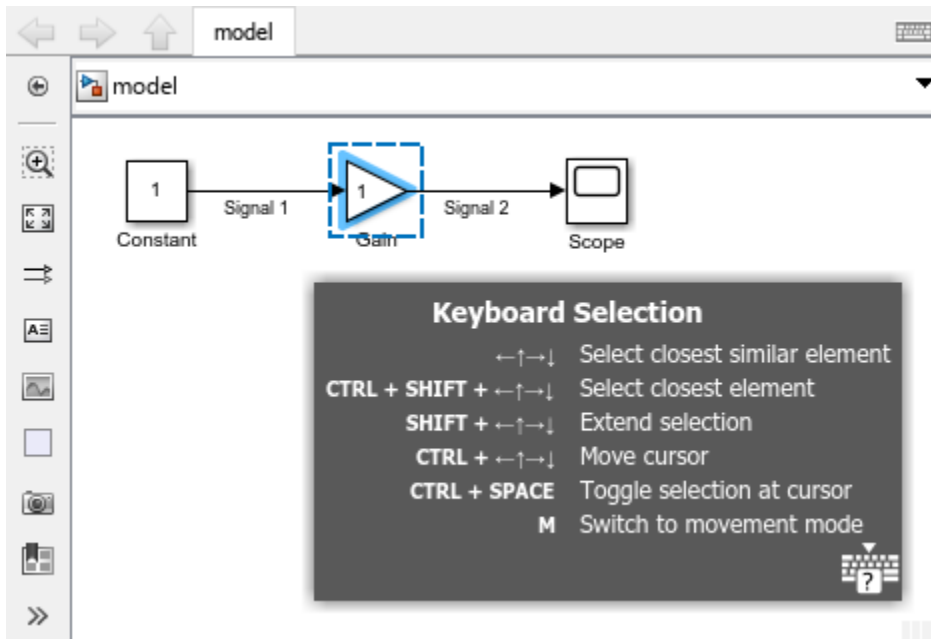

Keyboard shortcuts and mouse actions can help you efficiently model systems in Simulink. To open this page from a model, press **Shift+?** or click the **Keyboard Shortcuts** button  on the navigation bar.

**Note** When you use these keyboard shortcuts on a Mac, press **command** (⌘) instead of **Ctrl**.

### Use Context-Sensitive Hints Panels to Look Up Keyboard Shortcuts

When you are in any of these modes, you can view a hints panel that displays keyboard shortcuts specific to the active mode.

Mode	Definition	How to Enter Mode	How to View Hints Panel
Selection	Use the arrow keys to select a different block.	Select a block in your model. Press <b>M</b> to switch from movement mode (the default) to selection mode.	The panel appears when you enter selection mode.
Movement	Use the arrow keys to move the selected block.	When you open Simulink, you are in movement mode by default.  To switch from selection mode to movement mode, press <b>M</b> .	The panel appears when you switch from selection mode to movement mode.  To hide the panel, click the canvas.
Signal highlighting	Highlight signal lines between the selected block and the signal source or destination.  Display port values.	Click a signal in your model. Pause on the ellipsis that appears. In the action menu that expands, click either <b>Highlight Signal to Source</b>  or <b>Highlight Signal to Destination</b>  .	The panel appears when you enter signal highlighting mode.
Pan and zoom	Pan to move the view over the model. Zoom to change how close the model appears.	When you open Simulink, you are in pan and zoom mode by default.	Press and hold the space bar until the hints panel expands. If the panel is minimized, press and hold the space bar until the <b>?</b> button  appears.  To hide the panel, click the canvas.

To minimize the panel, press **?** on your keyboard. When the panel is minimized, only the **?** button  is visible.

To restore the panel, press **?** on your keyboard.

---

**Note** The hints panel of each mode preserves its state, minimized or expanded, across MATLAB sessions.

---

## Perform File and Clipboard Operations

Task	Shortcut
Open model	<b>Ctrl+O</b>
Create model	<b>Ctrl+N</b>
Print model	<b>Ctrl+P</b>
Save all modified models in current model hierarchy	<b>Ctrl+S</b>
Save current referenced model	<b>Ctrl+Shift+S</b>
Close model	<b>Ctrl+W</b>
Cut	<b>Ctrl+X</b>
Paste	<b>Ctrl+V</b>
Duplicate	<b>Ctrl+C, Ctrl+V</b>
Undo	<b>Ctrl+Z</b>
Redo	<b>Ctrl+Y, Ctrl+Shift+Z ( Simulink Online™ )</b>

Task	Shortcut
Find search string	<b>Ctrl+F</b>

## Zoom and Pan

Task	Action
Fit diagram to window	Space bar
Fit selection to window	Space bar + <b>F</b>
Zoom in	<b>Ctrl+Plus (+)</b> or space bar + <b>Plus (+)</b>
Zoom out	<b>Ctrl+Minus (-)</b> or space bar + <b>Minus (-)</b>
Zoom to 100%	<b>Ctrl+0</b> , <b>Alt+1</b> , or space bar + <b>0</b>
Zoom with scroll wheel	Scroll wheel  <b>Ctrl</b> + scroll wheel when <b>Scroll wheel controls zooming</b> is cleared
Zoom in on block diagram element	Drag the <b>Zoom</b> button  from the palette to the element.
View visible portion of block diagram relative to full block diagram with miniature map	Zoom or pan to part of the block diagram.  Press and hold the space bar when only part of the block diagram is visible.
View different portion of block diagram	Click the destination in the miniature map.
Pan	Drag the highlighted area in the miniature map.  Drag with middle button.  Space bar + drag.  Space bar + left, right, up, or down arrow
Pan vertically	<b>Ctrl</b> + scroll wheel
Pan horizontally	<b>Shift</b> + scroll wheel
Pan by page	<b>Shift</b> + space bar + left, right, up, or down arrow

## Navigate Model

Task	Shortcut
Open model	Double-click.  <b>Enter</b>
Change tabs	<b>Ctrl+Shift+Tab</b>
Go to parent of current subsystem, referenced model, or Stateflow state	<b>Esc</b>
Look under block mask	<b>Ctrl+U</b>

Task	Shortcut
For linked blocks, go to library of parent block	<b>Ctrl+L</b>
Open the <b>Model Explorer</b>	<b>Ctrl+H</b>

## Modify Block Diagram Contents

Task	Action
Insert block at current location with the quick insert menu	<p>Double-click the Simulink Editor canvas and start typing the block name, then select the block from the menu.</p> <p><b>Ctrl+Period (.)</b> twice and start typing the block name, then press the down arrow to select the block from the list and <b>Enter</b> to insert the block.</p> <p>On AZERTY keyboards, press <b>Ctrl+Shift+Period (.)</b> instead of <b>Ctrl+Period (.)</b>.</p>
Get prompted for suggested block based on context	Double-click the end of a line drawn from an existing block, then select a suggestion from the list or start typing to select one from the library.
Open the <b>Library Browser</b>	<b>Ctrl+Shift+L</b>
Insert annotation at current location with the quick insert menu	<p>Double-click the Simulink Editor canvas and type the annotation content, then select the annotation option.</p> <p><b>Ctrl+Period (.)</b> twice and type the annotation content, then press the down arrow to select the annotation option and <b>Enter</b> to insert the annotation.</p> <p>On AZERTY keyboards, press <b>Ctrl+Shift+Period (.)</b> instead of <b>Ctrl+Period (.)</b>.</p>
Copy selected block diagram elements	<p>Drag elements with the right mouse button.</p> <p><b>Ctrl</b> + drag.</p>
Copy selected block diagram elements between Simulink Editor windows	Drag elements between windows.
Delete selected block diagram elements	<b>Delete</b> or <b>Backspace</b>

## Select Block Diagram Elements

Selected elements have a solid blue outline. The most recently selected element has blue corner brackets in addition to the outline. To represent the cursor when you use the keyboard for selection, a blue box with dashed lines surrounds the element.

Task	Action
After clicking or moving elements, access keyboard shortcuts for selecting elements	<b>M</b> to toggle between modifying selection and moving selected elements.
Change selection to closest similar element in a direction	Left, right, up, or down arrow
Move cursor to closest element in a direction, regardless of similarity	<b>Ctrl+Shift</b> + left, right, up, or down arrow
Change selection to element at top-left of canvas	<b>Ctrl+Home</b> On a Mac, press <b>home</b> .
Change selection to element at bottom-right of canvas	<b>Ctrl+End</b> On a Mac, press <b>end</b> .
Change selection to leftmost element relative to cursor	<b>Home</b> On a Mac, press <b>control+left</b> .
Change selection to rightmost element relative to cursor	<b>End</b> On a Mac, press <b>control+right</b> .
Select additional adjacent elements	Drag from empty position. <b>Shift</b> + left, right, up, or down arrow
Select additional elements that are not adjacent	<b>Shift</b> + click.  <b>Ctrl</b> + left, right, up, or down arrow to change the current element. <b>Ctrl</b> + space bar to add the current element to the selection.  On a Mac, to add the current element to the selection, press <b>command+shift</b> + space bar or <b>shift</b> + space bar.
Select all blocks, lines, and annotations	<b>Ctrl+A</b>
Select ports	Point to the port region of a connected port to view and interact with the underlying port instead of the signal line.
Clear selection	<b>Ctrl+Alt+A</b>

## Modify Block Diagram Elements

Task	Shortcut
Set main parameter for selected block	<b>Alt+Enter</b>

Task	Shortcut
Open or hide the <b>Property Inspector</b>	<b>Ctrl+Shift+I</b>
Connect blocks	<p>Click a port. Click the blue chevron symbol  that appears near a compatible port you want to connect to.</p> <p>Select the first block, then <b>Ctrl</b> + click a second block.</p> <p>Drag from port to port.</p> <p>Click a port and hold <b>Shift</b> as you connect to the next port. Hold <b>Shift</b> to make multiple, consecutive connections.</p>
Branch line	<p>Click a port, move the cursor near the line you want to branch, and then click after you see the preview.</p> <p>Select a line, move the cursor toward the element you want to connect with, and then click the blue chevron symbol  that appears near the port.</p> <p><b>Ctrl</b> + drag line.</p> <p>Right mouse button + drag.</p>
Add ports to blocks that take multiple inputs	<p>Drag toward the port from a compatible block or signal line.</p> <p>Drag from the edge of the block that you want to add the port to.</p> <p>Click the edge of the port, and then drag.</p> <p>Click the edge of the port, move the cursor over the signal type — signal, bus, or connector — from the menu, and drag.</p>
Comment through selected blocks	<b>Ctrl+Shift+Y</b>
Comment out or uncomment selected blocks	<b>Ctrl+Shift+X</b>
Disconnect selected blocks	<p><b>Shift</b> + drag block.</p> <p>After selecting blocks with the keyboard, press <b>M</b> then <b>Shift</b> + left, right, up, or down arrow.</p>

## Name Block Diagram Elements

Task	Action
Rename selected block diagram element	Click or double-click the label.  Select the element and press <b>F2</b> .  On a Mac, press <b>command+return</b> instead of <b>F2</b> .
Name signal line	Double-click the signal and type its name.
Display name on branch of a named signal line	Double-click the branch.
Name every branch of a signal	Right-click the signal, select <b>Properties</b> , and use the dialog box.
Delete signal label and name	Delete characters in the label, or delete the name in Signal Properties dialog box.
Delete signal label only	Right-click the label and select <b>Delete Label</b> .
Copy signal label	<b>Ctrl</b> + drag the signal label.
Edit port labels on subsystem blocks	Point to the port label and click the interactive cue (blue box surrounding the label).  Select the port. Click the port label cue or press <b>F2</b> .  To switch between block name and signal name when editing labels on signal ports, press <b>Ctrl +1,2</b> .  To make successive port label edits on a subsystem block: <ul style="list-style-type: none"> <li>• Select a port on the block, edit the label and press <b>Enter</b>. This enables keyboard selection of ports.</li> <li>• Use up or down arrow keys to select adjacent ports and press <b>F2</b> for quick editing.</li> </ul>

## Modify Block Diagram Appearance

Task	Action
Move any block diagram element, including signal labels	Drag element.
Move selected elements	Drag one of the selected elements.  Drag selection box.  After selecting elements with the keyboard, press <b>M</b> then the left, right, up, or down arrow.
Automatically arrange block diagram	<b>Ctrl+Shift+A</b>

Task	Action
Resize block, maintaining ratio of width and height	<b>Shift</b> + drag handle
Resize block from the center	<b>Ctrl</b> + drag handle
Route lines around blocks	<b>Shift</b> + drag while drawing
Rotate blocks clockwise	<b>Ctrl+R</b>
Rotate blocks counterclockwise	<b>Ctrl+Shift+R</b>
Flip blocks	<b>Ctrl+I</b>
Create subsystem from selection	<b>Ctrl+G</b>
Create subsystem or area from empty selection	To create the highlighted option, which you can change by using the arrow keys or mouse: <ul style="list-style-type: none"> <li>• Click inside the selection box.</li> <li>• Press <b>Enter</b>.</li> </ul> Press the number key associated with an option.
Change signal label font	Select the signal line (not the label), then on the <b>Format</b> tab, click the <b>Font Properties</b> button arrow, then click <b>Fonts for Model</b> .
Mask block	<b>Ctrl+M</b>
Refresh Model blocks	<b>Ctrl+K</b>

## Perform Actions

Task	Shortcut
Perform generic action with the quick action search menu	Double-click the Simulink Editor canvas, select the <b>Actions</b> tab, and start typing the action name or description, then select the action from the list.  <b>Ctrl+Period (.)</b> and start typing the action name or description, then press the down arrow to select the action and <b>Enter</b> to perform it.  On AZERTY keyboards, press <b>Ctrl+Shift+Period (.)</b> instead of <b>Ctrl+Period (.)</b> .
Perform context-sensitive action	Before opening the quick action search menu, select a block diagram element.

## Update, Simulate, and Generate Code for Models

Task	Shortcut
Open Configuration Parameters dialog box	<b>Ctrl+E</b>
Update model	<b>Ctrl+D</b>

<b>Task</b>	<b>Shortcut</b>
Start simulation	<b>Ctrl+T</b>
Stop simulation	<b>Ctrl+Shift+T</b>
Build model (for code generation)	<b>Ctrl+B</b>

## **Debug Models**

<b>Task</b>	<b>Shortcut</b>
Step	<b>F10</b>
Step in	<b>F11</b>
Step out	<b>Shift+F11</b>
Run	<b>F5</b>
Set or clear breakpoint	<b>F12</b>

# How Simulation Stepper Helps With Model Analysis

Simulation Stepper enables you to step through major time steps of a simulation. Using discrete time steps, you can step forward or back to a particular instant in simulation time. At each time step, Stepper displays all of the simulation data the model produces.

Use Simulation Stepper to analyze your model in these ways:

- Step forward and back through a simulation.
- Pause a simulation in progress and step back.
- Continue running a simulation after stepping back.
- Analyze plotted data in your model at a particular moment in simulation time.
- Set conditions before and during simulation to pause a simulation.

## How Stepping Through a Simulation Works

### In this section...

“Simulation Snapshots” on page 2-3

“How Simulation Stepper Uses Snapshots” on page 2-3

“How Simulation Stepper Differs from Simulink Debugger” on page 2-5

These topics explain how Simulation Stepper steps through a simulation.

### Simulation Snapshots

When you set up Simulation Stepper, you specify:

- The number of time steps where Stepper creates snapshots
- The number of steps to skip between snapshots
- The total number of snapshots stored

A simulation snapshot contains simulation operating point and information related to logged data and visualization blocks. Simulation Stepper stores simulation states in snapshots at the specified interval of time steps when it steps forward through a simulation.

A Simulation Stepper step is not the same as a simulation time step. A simulation time step is the fixed amount of time by which the simulation advances. A Simulation Stepper step is where Simulation Stepper creates a snapshot. Each step that Simulation Stepper takes consists of one or more simulation time steps.

When you step back through a simulation, the software uses simulation snapshots, stored as `Simulink.op.ModelOperatingPoint` objects, to display previous states of the simulation. The model does not simulate in reverse when stepping back. Therefore, to enable the step back capability, you must first simulate the model or step it forward to save snapshots.

Snapshots for stepping back are available only during a single simulation. The Simulation Stepper does not save the steps from one simulation to the next.

### How Simulation Stepper Uses Snapshots

A simulation snapshot captures all the information required to continue a simulation from that point. When you set up simulation stepping, you specify:

- The maximum number of snapshots to capture while simulating forward. The greater the number, the more memory the simulation uses and the longer the simulation takes to run.
- The number of time steps to skip between snapshots. This setting enables you to save snapshots of simulation state when stepping forward at periodic intervals, such as every three steps. This interval is independent of the number of forward or backward time steps taken. Because taking simulation snapshots affects simulation speed, saving snapshots less frequently can improve simulation speed.

The figure shows how you can step through a simulation depending on how you set the parameters in the Simulation Stepping Options dialog box. Because you can change the stepping parameters as you

step through the simulation, you can step through a simulation as shown in this figure: sometimes by single steps and sometimes by two or more steps.

In the figure, the interval for snapshot captures is three.

This next figure shows the advantage of changing the stepping options while stepping forward. At the fourth step, the interval between stored steps changed the snapshot steps from three to one. This enables you to capture more snapshots around a simulation time of interest.

The next figure shows how the snapshot settings of Simulation Stepper can change what happens when stepping back. Suppose that the interval between snapshots is set to three, and starting at state six, the stepper **Move back/forward by** setting is set to one. The stepper first restores the simulation state to the last saved snapshot (state three), and then simulates two major times steps to arrive at the desired state (state five).

Thus, when you step back to a particular time step in a simulation, Simulation Stepper restores the last saved snapshot before that time step. Then, it steps forward to the time step you specify. This capability is helpful for memory usage and simulation performance.

## How Simulation Stepper Differs from Simulink Debugger

Simulation Stepper and Simulink Debugger both enable you to start, stop, and step through a model simulation. Both tools allow you to use breakpoints as part of a debugging session. However, you use Simulation Stepper and Simulink Debugger for different purposes. The table shows the actions you can perform with each tool.

Action	Simulation Stepper	Simulink Debugger
Look at state of system after executing a major time step.	✓	✓
Observe dynamics of the entire model from step to step.	✓	
Step simulation back.	✓	
Pause across major steps.	✓	
Control a Stateflow debugging session.	✓	
Step through simulation by major steps.	✓	
Monitor single block dynamics (for example, output and update) during a single major time step.		✓
Look at state of system while executing a major time step.		✓
Observe solver dynamics during a single major step.		✓
Show various stages of Simulink simulation.		✓
Pause within a major step.		✓
Step through a simulation block by block.		✓
Access via a command-line interface.		✓

Understanding the simulation process can help you to better understand the differences between Simulation Stepper and Simulink Debugger.

## Use Simulation Stepper

### In this section...

“Simulation Stepper Access” on page 2-7

“Simulation Stepper Pause Status” on page 2-7

“Tune Parameters” on page 2-8

“Referenced Models” on page 2-8

“Simulation Stepper and Interval Logging” on page 2-8

“Simulation Stepper and Stateflow Debugger” on page 2-8

### Simulation Stepper Access

You run Simulation Stepper and access the settings from the Simulink Toolstrip.

Click the **Configure simulation stepping** button  to open the Simulation Stepping Options dialog box.

Use the dialog box to enable stepping back through a simulation. When stepping back is enabled, after you start the simulation, you can use the **Step Back** button  to step back.

If you clear the **Enable previous stepping** check box, the software clears the stored snapshot cache.

### Simulation Stepper Pause Status

The status bar at the bottom of the Simulink Editor displays the simulation time of the last completed simulation step. While a simulation is running, the editor updates the time display to indicate the simulation progress. This display is approximate because the status bar updates only at every major time step and not at every simulation time step. When you pause a simulation, the status bar display time catches up to the actual time of the last completed step.

The value (the time of the last completed step) that is displayed on the status bar is not always the same as the time of the solver. This happens because different solvers use different ways to propagate the simulation time in a single iteration of the simulation loop. Simulation Stepper pauses at a single position within the simulation loop. Some solvers perform their time advance before Simulation Stepper pauses. However, other solvers perform their time advance after Simulation Stepper pauses, and the time advance then becomes part of the next step. As a result, for continuous and discrete solvers, the solver time is always one major step ahead of the time of the last model output.

When this condition occurs, and the simulation is paused, the status bar time displays an asterisk. The asterisk indicates that the solver in this simulation has already advanced past the displayed time (which is the time of the last completed simulation step).

### Tune Parameters

While using Simulation Stepper, when the simulation is paused, you can change tunable parameters, including some solver settings. However, changes to the solver step size take effect when the solver advances the simulation time. For some solvers, this occurs after the next simulation step is taken.

Simulation Stepper takes into account the size of a movement (**Move back/forward by**) and the frequency of saving steps (**Interval between stored back steps**). If you specify a frequency that is larger than the step size, Simulation Stepper first steps back to the last saved step and then simulates forward until the total step count difference reaches the size of the desired movement. Simulation Stepper applies values for tunable parameters when simulating forward. For this reason, if you change any tunable parameter before stepping back, the resulting simulation output might not match the previous simulation output at that step before the parameter change. This can cause unexpected results when stepping forward from the snapshot to the chosen time step.

For example, assume a snapshot save frequency of three and a step size of one. The stepper first steps back to the last saved step, up to three steps, and then simulates forward until the total step count difference reaches one. If you change tunable parameters before stepping back, the resulting simulation output might not match the previous simulation output at that step.

### Referenced Models

When using Simulation Stepper and the Model block, the referenced model shares the stepping options of the top model throughout a simulation. As a result, changing Simulation Stepper settings for the referenced model during simulation changes the Simulation Stepper settings of the top model. When the simulation ends, the settings of the referenced model revert to the original values; the Stepper settings of the top model stay at the changed settings.

- When the model is not simulating, the top model and referenced model retain their own independent stepping options.
- When the model is simulating and you change a referenced model stepping option, the top model stepping option changes to the same value.
- When the model is simulating and you change a top model stepping option, the referenced model stepping option changes to the same value.
- When the model stops simulating, the referenced model stepping options revert to how they were set before simulation started; the top model keeps the values set during simulation.

### Simulation Stepper and Interval Logging

When you change the logging interval of a simulation before rolling back, Simulink does not log data for time steps that were outside the original logging interval until the first forward step after a rollback operation. For more information, see “Logging intervals”.

### Simulation Stepper and Stateflow Debugger

When you debug a Stateflow chart (for example, when the simulation stops at a Stateflow breakpoint), Simulation Stepper adds buttons to control the Stateflow debugging session. When the

Stateflow debugging session ends, the Simulation Stepper interface returns to the default. For more information about controlling the Stateflow debugger using the Simulink Toolstrip, see “Control Chart Execution After a Breakpoint” (Stateflow).

- “Simulation Stepper Limitations” on page 2-10

## Simulation Stepper Limitations

### In this section...

“Interface” on page 2-10

“Model Configuration” on page 2-10

“Blocks” on page 2-10

### Interface

- There is no command-line interface for Simulation Stepper.

### Model Configuration

- Simulation stepping (forward and backward) is available only for Normal and Accelerator modes.
- The step back capability relies on the model operating point for saving and restoring the state of a simulation. As a result, the step back capability is available only for models that support saving the model operating point. For more information, see “Use Model Operating Point for Faster Simulation Workflow” on page 27-43.
- Simulation Stepper steps through the major time steps of a simulation without changing the course of a simulation. Choosing a refine factor greater than unity produces loggable outputs at times between the major time steps of the solver. These times are not major time steps, and you cannot step to a model state at those times.
- If you run a simulation with stepping back enabled, the Simulink software checks whether the model can step back. If it cannot, a warning appears at the MATLAB command prompt. For some simulations, Simulink cannot step back. The step back capability is then disabled until the end of that simulation. Then the setting resets to the value you requested.
- When you place custom code in **Configuration Parameters > Simulation Target > Custom Code > Initialize function** in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in Simulation Stepper.

### Blocks

- Some blocks do not support stepping back for reasons other than model operating point support. These blocks are:
  - S-functions that have P-work vectors but do not declare their model operating point compliance level or declare it to be unknown or disallowed. For more information, see “S-Function Compliance with the ModelOperatingPoint”.
  - Simscape™ Multibody™ First Generation blocks
  - Legacy (pre-R2016a) SimEvents® blocks
- MATLAB Function blocks generally support stepping back. However, the use of certain constructs in the MATLAB code of these blocks can prevent the block from supporting stepping back. These scenarios prevent the MATLAB Function blocks from stepping back:
  - Persistent variables of opaque data type. Attempts to step back under this condition cause an error message based on the specific variable type.
  - Extrinsic functions calls that can contain state (such as properties of objects or persistent data of functions). No warnings or error messages appear, but the result likely will be incorrect.

- Calls to custom C code (through MEX function calls) that do not contain static variables. No warnings or error messages appear, but the result likely will be incorrect.
- Some visualization blocks do not support stepping back. Because these blocks are not critical to the state of the simulation, no errors or warnings appear when you step back in a model that contains these blocks:
  - Auto Correlator
  - Cross Correlator
  - Spectrum Analyzer
  - Averaging Spectrum Analyzer
  - Power Spectral Density
  - Averaging Power Spectral Density
  - Floating Bar Plot
  - 3Dof Animation
  - MATLAB Animation
  - VR Sink
  - Any blocks that implement custom visualization in their output method (for example, an S-function that sends output to a MATLAB figure) are not fully supported for stepping back because the block method `Output` does not execute while stepping back. While the state of such blocks remains consistent with the simulation time (if the blocks comply with model operating point), the visualization component is inconsistent until the next step forward in the simulation.

Because these blocks do not affect the numerical result of a simulation, stepping back is not disabled for these blocks. However, the values these blocks output are inaccurate until the simulation steps forward again.

## Step Through a Simulation

### Step Forward and Back

This example shows how to step forward and back through a simulation.

- 1 At the MATLAB prompt, type  
vdp
- 2 In the Simulink Editor for the vdp model, click  to open the Simulation Stepping Options dialog box.
- 3 In the dialog box, select the **Enable stepping back** check box, and then click **OK**.
- 4 On the **Simulation** tab, click the **Step Forward** button  one time.

The simulation simulates one step, and the software stores a simulation snapshot for that step.

- 5 Click the Step Forward button again to step forward again and store simulation data. A total of 25 forward steps produces these simulation results:

- 6 You must step forward to create the simulation state that the step backward operation requires. This means you must first step forward before you can step backward through the same steps.

On the **Simulation** tab, click the **Step Back** button  four times to step backward to the simulation snapshot shown below.

## Set Conditional Breakpoints for Stepping a Simulation

A conditional breakpoint is triggered based on a specified expression evaluated on a signal. When the breakpoint is triggered, the simulation pauses.

Set conditional breakpoints to stop Simulation Stepper when a specified condition is met. One example of a use for conditional breakpoints is when you want to examine results after a certain number of iterations in a loop.

Simulation Stepper allows you to set conditional breakpoints for scalar signals. These breakpoints appear for signals:

Breakpoint	Description
	Enabled breakpoint. Appears when you add the conditional breakpoint.
	Enabled breakpoint hit. Appears when the simulation reaches the condition specified and triggers the breakpoint.
	Disabled breakpoint. Appears when you disable a conditional breakpoint.
	Invalid breakpoint. Appears when the software determines that a breakpoint is invalid for the signal. An enabled breakpoint image changes to this one when, during simulation, the software determines that the conditional breakpoint is invalid.

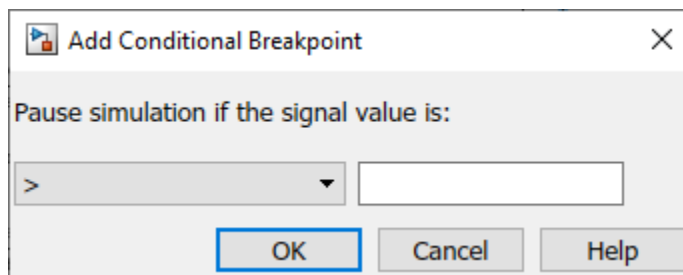

When setting conditional breakpoints, keep in mind that:

- When simulation arrives at a conditional breakpoint, simulation does not stop when the block is executed. Instead, simulation stops after the current simulation step completes.
- You can add multiple conditional breakpoints to a signal line.

### Setting Conditional Breakpoints

To add the breakpoints:

- Simulate the model.
- Select the signal or the block for which you want to add a breakpoint.
- In the **Debug** tab of the Simulink toolstrip, click **Add Breakpoint**. You can enter the conditions in the dialog box that appears.

## Breakpoint List

The Breakpoint List displays all the breakpoints that you set in the model. To open the Breakpoints List, in the **Debug** tab of the Simulink Toolstrip, click **Breakpoints List**. The list opens at the bottom in the Simulink Editor.

Source	Enabled	Source Type	Condition	Hits
slidemo_fuelsys/Engine Speed:1	<input checked="" type="checkbox"/>	Signal	> 10	0
slidemo_fuelsys/Throttle Command:1	<input checked="" type="checkbox"/>	Signal	= 5	0

The Breakpoint List contains the following columns:

- **Source** - Path to the model element for which the breakpoint is set. Selecting the name of the breakpoint highlights the specific element location in the model
- **Enabled** - Check box to indicate if the breakpoint is enabled or disabled. You can use the

button on the top to enable or disable breakpoints.

- **Source Type** - String that indicates the breakpoint type, such as `Signal` for conditional breakpoints or `onStateEntry` (During/Exit) for Stateflow state breakpoints.
- **Condition** - If applicable, an editable field describing the condition of a conditional breakpoint. This column is empty for unconditional breakpoints.
- **Hits** - Number of times the breakpoint is hit during a simulation. Hits restart at 0 for any subsequent simulations.

The  button allows you to delete a selected breakpoint. The drop-down arrow next to the  button also gives an option of deleting all the breakpoints together. The  button opens the Stateflow breakpoint and watch list. For more information on Stateflow breakpoints, see [. \(Stateflow\)](#)

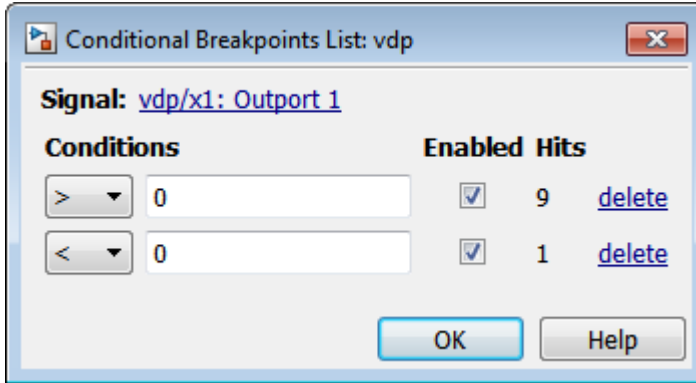

For signal breakpoints, when a breakpoint is hit, the icon on the signal displays a green play button. The model is in a paused state. The relevant breakpoint row is highlighted in light green.

### Add and Edit Conditional Breakpoints Through Right-Click

- 1 In a model, right-click a signal and select **Add Conditional Breakpoint**.
- 2 In the **Add Conditional Breakpoint** dialog box, from the drop-down list, select the condition for the signal. For example, select greater than or less than.
- 3 Enter the signal value where you want simulation to pause and click **OK**. For the condition values:
  - Use numeric values. Do not use expressions.
  - Do not use NaN.

The affected signal line displays a conditional breakpoint icon: .

- Click the breakpoint to view and edit all conditions set for the signal.

- Simulate the model and notice that the model pauses as simulation steps through the conditional breakpoints.

### Conditional Breakpoints Limitations

- You can set conditional breakpoints only on real scalar signals of these data types:
  - double
  - single
  - int
  - bool
  - fixed point (based on the converted double value)
- You cannot set conditional breakpoints (or port value display labels) on non-Simulink signals, such as Simscape or SimEvents signals.
- Conditional breakpoints also have the limitations that port value display have (“Port Value Display Limitations” on page 39-25).
- Conditional Breakpoints only work on the first iteration of For Each Subsystems

### Observe Conditional Breakpoint Values

To observe a conditional breakpoint value of a block signal, use data tips to display block port values. You can add data tips before or after you add conditional breakpoints.

- Enable the value display for a signal. Right-click the signal line that has a conditional breakpoint and select **Show Value Label of Selected Port**.

The data tip for the value display appears.

- 2 Simulate the model and observe the conditional breakpoint and data tip when the simulation triggers the breakpoint.

## Simulation Pacing

Simulation pacing enables you to slow down a simulation to understand and observe the system's behavior. Visualizing simulations at a slower rate makes it easier to understand underlying system design, identify design issues and demonstrate near real-time behavior. You can view the results and inspect your system while the simulation is in progress. Slow down animations in scopes, to observe how and when the system changes state.

Simulation pacing is useful in scenarios where one simulation-second is completed in a few wall clock time milliseconds. You can also manually interact with the model while it is running at a slower rate, which can help you to explore how your changes affect the simulation behavior. Note that the simulation will run at an approximation of the specified pace.

To start, specify the rate of simulation. This rate is a ratio of elapsed simulation time to elapsed wall clock time.

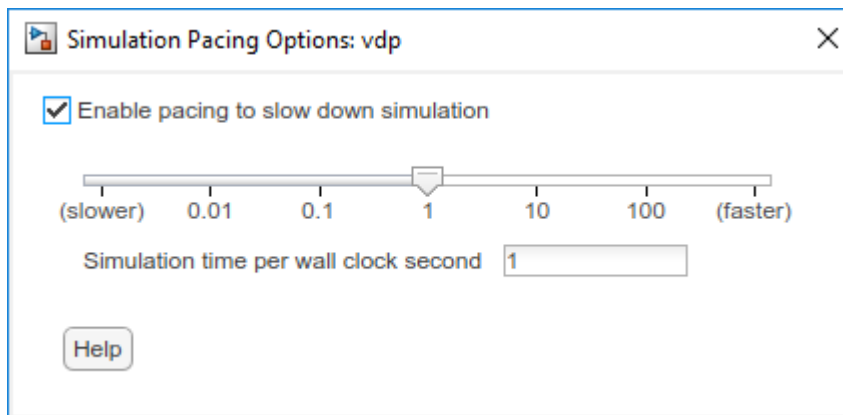

### Use Simulation Pacing

This example shows how to use simulation pacing during a simulation.

- 1 Open the vdp model.

vdp

- 2 In the **Simulation** tab, select **Run > Simulation Pacing**

- 3 In the Simulation Pacing Options dialog, select **Enable pacing to slow down simulation**. On enabling, the specified pace gets automatically applied to the simulation.
- 4 Select the pace at which the model should run by using the slider or entering the pace in the **Simulation time per wall clock second** field. This field also accepts values outside of the range on the slider. The value entered in the field can only be a finite positive number.
- 5 On simulating the model, you can watch the simulation progress at the specified pace in the scope. You can also change the pace through the dialog box and enable/disable pacing while your simulation is running.

To enable Pacing from the command line, use `set_param(model, 'EnablePacing', 'on')` command. To enter the value use `set_param(model, 'PacingRate', value)` where the value is a finite positive number.

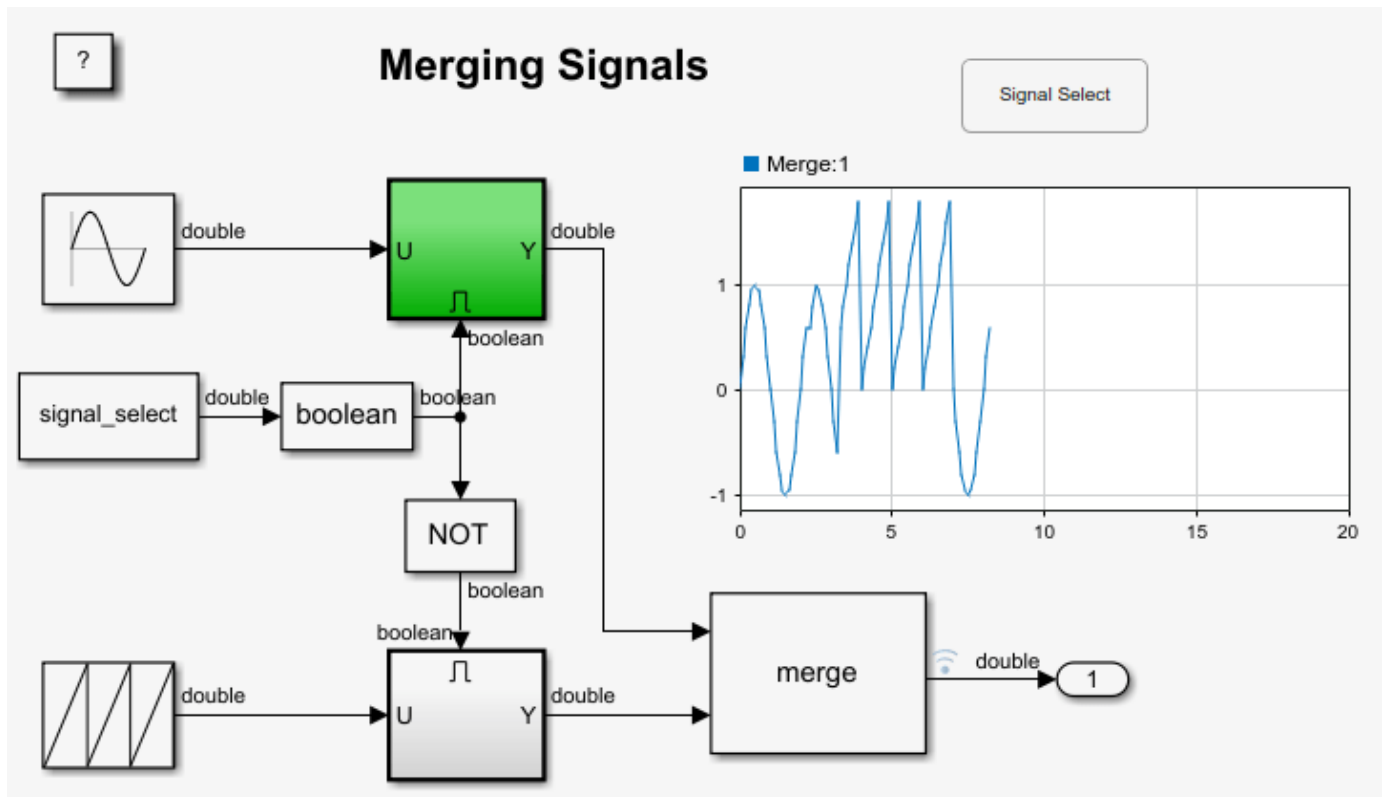

The run button changes to  , when a simulation is run with Pacing enabled. The status bar indicates if a simulation is running with pacing enabled. It also indicates if the simulation can not run at the specified pace.

## Use Simulation Pacing with Dashboard Blocks

You can use Dashboard blocks to view signals and tune variables and parameters in your model while slowing a simulation using simulation pacing. Using Dashboard blocks with simulation pacing allows you to build an intuitive understanding of your model and how it responds to changes as you tune parameters in your model.

The example model uses simulation pacing to slow the simulation pace to approximately equivalent to wall clock time, or one simulation second per one wall clock second. You can push the Signal Select button to select whether the sine wave or sawtooth input signal passes to the output, which is visualized using a Dashboard Scope block.

Open the model and run a simulation. During the simulation, press and release the Signal Select button and observe the effect on the output signal.

For more information about creating the example model, see “Control Merging Signals with the Push Button Block”.

### **Limitations**

- Simulation pacing is not compatible with:
  - Simulation stepper
  - Profiler

## Simulation Phases in Dynamic Systems

<b>In this section...</b>
“Model Compilation” on page 3-2
“Link Phase” on page 3-2
“Simulation Loop Phase” on page 3-3

### Model Compilation

The first phase of simulation occurs when the system’s model is open and you simulate the model. In the Simulink Editor, click **Run**. Running the simulation causes the Simulink engine to invoke the model compiler. The model compiler converts the model to an executable form, a process called compilation. In particular, the compiler:

- Evaluates the model's block parameter expressions to determine their values.
- Determines signal attributes, e.g., name, data type, numeric type, and dimensionality, not explicitly specified by the model and checks that each block can accept the signals connected to its inputs.
- Propagates the attributes of a source signal to the inputs of the blocks that it drives in order to compute previously unspecified attributes in the blocks.
- Performs block reduction optimizations.
- Flattens the model hierarchy by replacing virtual subsystems with the blocks that they contain (see “Compare Solvers” on page 3-6).
- Determines the block execution order by task-based sorting.
- Determines the sample times of all blocks in the model whose sample times you did not explicitly specify (see “How Propagation Affects Inherited Sample Times” on page 7-37).

These events are essentially the same as what occurs when you update a diagram (“Update Diagram and Run Simulation” on page 1-24). The difference is that the Simulink software starts model compilation as part of model simulation, where compilation leads directly into the linking phase, as described in “Link Phase” on page 3-2. In contrast, you start an explicit model update as a standalone operation on a model.

When you compile a model or model hierarchy, you can cancel model compilation by clicking the **Cancel** button next to the progress bar.

### Link Phase

In this phase, the Simulink engine allocates memory needed for working areas (signals, states, and run-time parameters) for execution of the block diagram. It also allocates and initializes memory for data structures that store run-time information for each block. For built-in blocks, the principal run-time data structure for a block is called the SimBlock. It stores pointers to a block's input and output buffers and state and work vectors.

### Method Execution Lists

In the Link phase, the Simulink engine also creates method execution lists. These lists list the most efficient order in which to invoke a model's block methods to compute its outputs. The block

execution order lists generated during the model compilation phase are used to construct the method execution lists.

### **Block Priorities**

You can assign update priorities to blocks. The output methods of higher priority blocks are executed before those of lower priority blocks. These priorities are honored only if they are consistent with its block execution order.

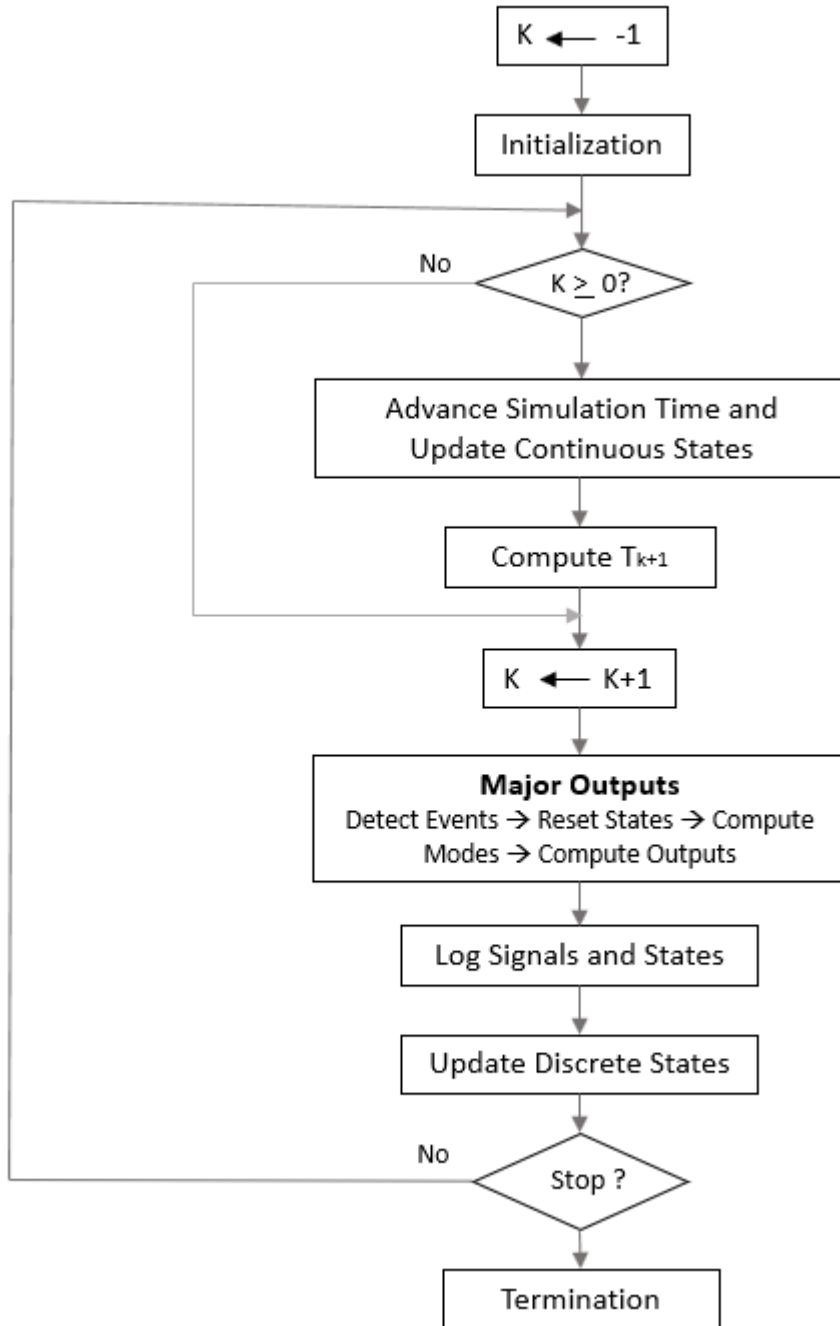

## **Simulation Loop Phase**

Once the Link Phase completes, the simulation enters the simulation loop phase. In this phase, the Simulink engine successively computes the states and outputs of the system at intervals from the simulation start time to the finish time, using information provided by the model. The successive time points at which the states and outputs are computed are called time steps. The length of time between steps is called the step size. The step size depends on the type of solver (see “Compare Solvers” on page 3-6) used to compute the system's continuous states, the system's fundamental sample time (see “Sample Times in Systems” on page 7-30), and whether the system's continuous states have discontinuities (see “Zero-Crossing Detection” on page 3-10).

The Simulation Loop phase has two subphases: the Loop Initialization phase and the Loop Iteration phase. The initialization phase occurs once, at the start of the loop. The iteration phase is repeated once per time step from the simulation start time to the simulation stop time.

At the start of the simulation, the model specifies the initial states and outputs of the system to be simulated. At each step, new values for the system's inputs, states, and outputs are computed, and the model is updated to reflect the computed values. At the end of the simulation, the model reflects the final values of the system's inputs, states, and outputs. The Simulink software provides data display and logging blocks. You can display and/or log intermediate results by including these blocks in your model.

The following flowchart explains how the simulation loop works where  $k$  denotes the major step

counter:

**Loop Iteration**

At each time step, the Simulink engine:

- 1 Computes the model outputs.

The Simulink engine initiates this step by invoking the Simulink model Outputs method. The model Outputs method in turn invokes the model system Outputs method, which invokes the

Outputs methods of the blocks that the model contains in the order specified by the Outputs method execution lists generated in the Link phase of the simulation (see “Compare Solvers” on page 3-6).

The system Outputs method passes the following arguments to each block Outputs method: a pointer to the block's data structure and to its SimBlock structure. The SimBlock data structures point to information that the Outputs method needs to compute the block's outputs, including the location of its input buffers and its output buffers.

**2** Computes the model's states.

The Simulink engine computes a model's states by invoking a solver. Which solver it invokes depends on whether the model has no states, only discrete states, only continuous states, or both continuous and discrete states.

If the model has only discrete states, the Simulink engine invokes the discrete solver selected by the user. The solver computes the size of the time step needed to hit the model's sample times. It then invokes the Update method of the model. The model Update method invokes the Update method of its system, which invokes the Update methods of each of the blocks that the system contains in the order specified by the Update method lists generated in the Link phase.

If the model has only continuous states, the Simulink engine invokes the continuous solver specified by the model. Depending on the solver, the solver either in turn calls the Derivatives method of the model once or enters a subcycle of minor time steps where the solver repeatedly calls the model's Outputs methods and Derivatives methods to compute the model's outputs and derivatives at successive intervals within the major time step. This is done to increase the accuracy of the state computation. The model Outputs method and Derivatives methods in turn invoke their corresponding system methods, which invoke the block Outputs and Derivatives in the order specified by the Outputs and Derivatives methods execution lists generated in the Link phase.

**3** Optionally checks for discontinuities in the continuous states of blocks.

A technique called zero-crossing detection is used to detect discontinuities in continuous states. See “Zero-Crossing Detection” on page 3-10 for more information.

**4** Computes the time for the next time step.

Steps 1 through 4 are repeated until the simulation stop time is reached.

## Compare Solvers

A dynamic system is simulated by computing its states at successive time steps over a specified time span, using information provided by the model. The process of computing the successive states of a system from its model is known as solving the model. No single method of solving a model suffices for all systems. Accordingly, Simulink provides a set of programs, known as *solvers*, each of which embodies a particular approach to solving a model. The Configuration Parameters dialog box allows you to choose the solver best suited to your model.

### Fixed-Step Versus Variable-Step Solvers

You can choose the solvers provided by Simulink based on the way they calculate step size: fixed-step and variable-step.

*Fixed-step solvers* solve the model at regular time intervals from the beginning to the end of the simulation. The size of the interval is known as the step size. You can specify the step size or let the solver choose the step size. Generally, decreasing the step size increases the accuracy of the results while increasing the time required to simulate the system.

*Variable-step solvers* vary the step size during the simulation. They reduce the step size to increase accuracy when a model's states are changing rapidly and increase the step size to avoid taking unnecessary steps when the model's states are changing slowly. Computing the step size adds to the computational overhead at each step but can reduce the total number of steps, and hence the simulation time required to maintain a specified level of accuracy for models with rapidly changing or piecewise continuous states.

Fixed-step and variable-step solvers compute the next simulation time as the sum of the current simulation time and the step size. The **Type** control on the **Solver** configuration pane allows you to select the type of solver. With a fixed-step solver, the step size remains constant throughout the simulation. With a variable-step solver, the step size can vary from step to step, depending on the model dynamics. In particular, a variable-step solver increases or reduces the step size to meet the error tolerances that you specify.

The choice between these types depends on how you plan to deploy your model and the model dynamics. If you plan to generate code from your model and run the code on a real-time computer system, choose a fixed-step solver to simulate the model. You cannot map the variable-step size to the real-time clock.

If you do not plan to deploy your model as generated code, the choice between a variable-step and a fixed-step solver depends on the dynamics of your model. A variable-step solver might shorten the simulation time of your model significantly. A variable-step solver allows this saving because, for a given level of accuracy, the solver can dynamically adjust the step size as necessary. This approach reduces the number of steps required. The fixed-step solver must use a single step size throughout the simulation, based on the accuracy requirements. To satisfy these requirements throughout the simulation, the fixed-step solver typically requires a small step.

The `ex_multirate` example model shows how a variable-step solver can shorten simulation time for a multirate discrete model.

The model generates outputs at two different rates: every 0.5 s and every 0.75 s. To capture both outputs, the fixed-step solver must take a time step every 0.25 s (the *fundamental sample time* for the model).

```
[0.0 0.25 0.5 0.75 1.0 1.25 1.5 ...]
```

By contrast, the variable-step solver has to take a step only when the model generates an output.

```
[0.0 0.5 0.75 1.0 1.5 ...]
```

This scheme significantly reduces the number of time steps required to simulate the model.

## Continuous Versus Discrete Solvers

Simulink provides both continuous and discrete solvers.

When you select a solver type, you can also select a specific solver. Both sets of solvers include discrete and continuous solvers. Discrete and continuous solvers rely on the model blocks to compute the values of any discrete states. Blocks that define discrete states are responsible for computing the values of those states at each time step. However, unlike discrete solvers, continuous solvers use numerical integration to compute the continuous states that the blocks define. When choosing a solver, determine first whether to use a discrete solver or a continuous solver.

If your model has no continuous states, then Simulink switches to either the fixed-step discrete solver or the variable-step discrete solver. If your model has only continuous states or a mix of continuous and discrete states, choose a continuous solver from the remaining solver choices based on the dynamics of your model. Otherwise, an error occurs.

*Continuous solvers* use numerical integration to compute a model's continuous states at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on the individual blocks to compute the values of the model's discrete states at each time step.

*Discrete solvers* exist primarily to solve purely discrete models. They compute the next simulation time step for a model and nothing else. In performing these computations, they rely on each block in the model to update its individual discrete states. They do not compute continuous states.

The solver library contains two discrete solvers: a fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses the step size and simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This

adjustment can avoid unnecessary steps and shorten simulation time for multirate models. See “Sample Times in Systems” on page 7-30 for more information.

---

**Note** You must use a continuous solver to solve a model that contains both continuous and discrete states because discrete solvers cannot handle continuous states. If, on the other hand, you select a continuous solver for a model with no states or discrete states only, Simulink software uses a discrete solver.

---

## Explicit Versus Implicit Continuous Solvers

You represent an explicit system by an equation

$$\dot{x} = f(x)$$

For any given value of  $x$ , you can compute  $\dot{x}$  by substituting  $x$  in  $f(x)$  and evaluating the equation.

Equations of the form

$$F(\dot{x}, x) = 0$$

are considered to be implicit. For any given value of  $x$ , you must solve this equation to calculate  $\dot{x}$ .

A linearly implicit system can be represented by the equation

$$M(x) \cdot \dot{x} = f(x)$$

$M(x)$  is called the mass matrix and  $f(x)$  is the forcing function. A system becomes linearly implicit when you use physical modeling blocks in the model.

While you can apply an implicit or explicit continuous solver to solve all these systems, implicit solvers are designed specifically for solving stiff problems. Explicit solvers solve nonstiff problems. An ordinary differential equation problem is said to be stiff if the desired solution varies slowly, but there are closer solutions that vary rapidly. The numerical method must then take small time steps to solve the system. Stiffness is an efficiency issue. The more stiff a system, the longer it takes to for the explicit solver to perform a computation. A stiff system has both slowly and quickly varying continuous dynamics.

When compared to explicit solvers, implicit solvers provide greater stability for oscillatory behavior. However, implicit solvers are also computationally more expensive. They generate the Jacobian matrix and solve the set of algebraic equations at every time step using a Newton-like method. To reduce this extra cost, the implicit solvers offer a **Solver Jacobian method** parameter that allows you to improve the simulation performance of implicit solvers. See “Choose a Jacobian Method for an Implicit Solver” on page 27-11 for more information. Implicit solvers are more efficient than explicit solvers for solving a linearly implicit system.

## One-Step Versus Multistep Continuous Solvers

The Simulink solver library provides both one-step and multistep solvers. The one-step solvers

estimate  $Y(t_n)$  using the solution at the immediately preceding time point,  $Y(t_{n-1})$ , and the values of the derivative at multiple points between  $t_n$  and  $t_{n-1}$ . These points are minor steps.

Multistep solvers use the results at several preceding time steps to compute the current solution. Simulink provides one explicit multistep solver, `ode113`, and one implicit multistep solver, `ode15s`. Both are variable-step solvers.

## Single-Order Versus Variable-Order Continuous Solvers

This distinction is based on the number of orders that the solver uses to solve the system of equation. Two variable-order solvers, `ode15s` and `ode113`, are part of the solver library. They use multiple orders to solve the system of equations. Specifically, the implicit, variable-step `ode15s` solver uses first-order through fifth-order equations, while the explicit, variable-step `ode113` solver uses first-order through thirteenth-order equations. For `ode15s`, you can limit the highest order applied via the **Maximum Order** parameter. For more information, see “Maximum Order” on page 27-20.

### See Also

“Zero-Crossing Detection” on page 3-10 | “Simulink Models” | “Simulation Phases in Dynamic Systems” on page 3-2

## Zero-Crossing Detection

A variable-step solver dynamically adjusts the time step size, causing it to increase when a variable is changing slowly and to decrease when the variable changes rapidly. This behavior causes the solver to take many small steps in the vicinity of a discontinuity because the variable is rapidly changing in this region. This improves accuracy but can lead to excessive simulation times.

Simulink uses a technique known as *zero-crossing detection* to accurately locate a discontinuity without resorting to excessively small time steps. Usually this technique improves simulation run time, but it can cause some simulations to halt before the intended completion time.

Simulink uses two algorithms for this purpose: nonadaptive and adaptive. For information about these techniques, see “Zero-Crossing Algorithms” on page 3-37.

### Demonstrating Effects of Excessive Zero-Crossing Detection

This example provides three models that illustrate zero-crossing behavior: `example_bounce_two_integrators`, `example_doublebounce`, and `example_bounce`.

The `example_bounce_two_integrators` model demonstrates how excessive zero crossings can cause a simulation to halt before the intended completion time unless you use the adaptive algorithm.

The `example_bounce` model uses a better model design, implementing the dynamics of the ball using a double integrator, than `example_bounce_two_integrators`.

The `example_doublebounce` model demonstrates how the adaptive algorithm successfully solves a complex system with two distinct zero-crossing requirements.

Consider the `example_bounce_two_integrators` model. It uses two single integrators to compute the vertical velocity and position of the ball over the time of the simulation.

- 1 Open the model by running `open_system('example_bounce_two_integrators')` at the command line.
- 2 Once the block diagram appears, set the **Solver details > Zero-crossing options > Algorithm** parameter in the **Solver** pane of the Model configuration parameters to **Nonadaptive**. Set the stop time of the model to 20 s. You can change this setting in the Simulink toolstrip or the **Solver** pane of the model configuration parameters.
- 3 Simulate the model.

## Bouncing Ball Model

Two separate Integrators are less efficient than a single Second-Order Integrator for simulating a bouncing ball.  
[Click here to see slidemo\\_bounce for the recommended modeling approach.](#)

Copyright 1990-2013 The MathWorks, Inc.

You can now view and analyze the simulation results.

Simulation Results Using Nonadaptive Zero-Crossing Algorithm

Upon closer examination of the last portion of the simulation, you will see that velocity hovers just above zero.

Change the simulation **Stop time** to 25 s and simulate the model. The simulation stops with an error due to excessive consecutive zero-crossing events at the Compare To Zero and Position blocks.

Simulink will stop the simulation of model 'example\_bounce\_two\_integrators' because the 2 zero c

```
-----
Number of consecutive zero-crossings : 1000
    Zero-crossing signal name : RelopInput
        Block type : RelationalOperator
        Block path : 'example_bounce_two_integrators/Compare To Zero/Compare'
```

```
-----
Number of consecutive zero-crossings : 500
    Zero-crossing signal name : IntgLoLimit
        Block type : Integrator
        Block path : 'example_bounce_two_integrators/Position'
```

Although you can increase this limit by adjusting the **Model Configuration Parameters > Solver > Number of consecutive zero crossings** parameter, making that change still does not allow the simulation to go on for 25 s.

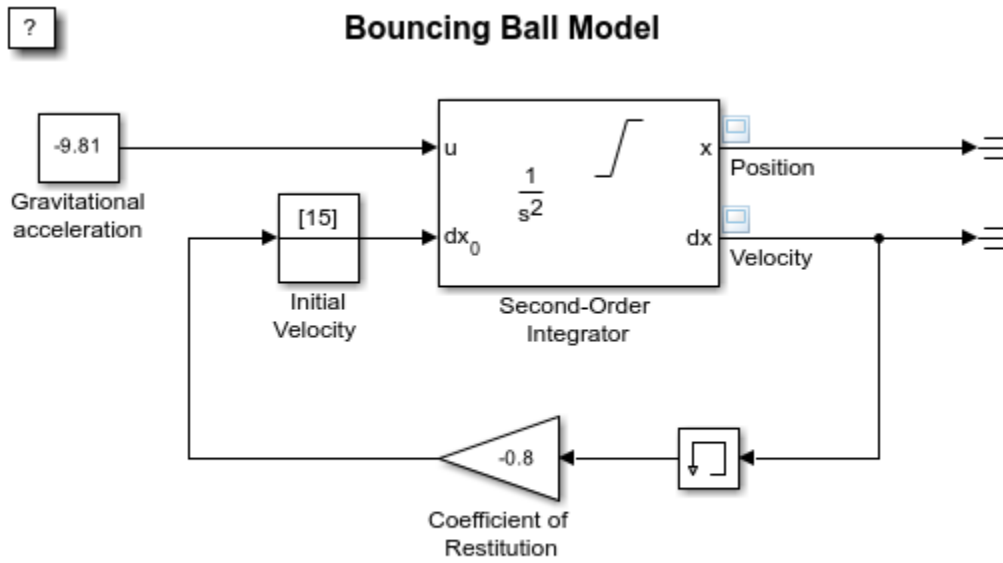

Change the **Solver details > Zero-crossing options > Algorithm** parameter in the **Solver** pane of the Model configuration parameters to Adaptive and simulate the model again for 25 s.

Zooming in on the last 5 seconds of the simulation, you can see that the results are more complete and closer to the expected analytical solution of the dynamics of a bouncing ball. The amount of chatter you see is a consequence of the system's states approaching zero and is expected in numerical simulations.

The `example_bounce` model uses a Second-Order Integrator block to model the dynamics of the bouncing ball. This is the preferred method to model the double integration of the ball's dynamics for solver performance. To compare the solver performance for `example_bounce_two_integrators` and `example_bounce`, try running the Solver Profiler on both models. For a detailed comparison of both models, see “Simulation of Bouncing Ball”.

### Preventing Excessive Zero Crossings

Use the following table to prevent excessive zero-crossing errors in your model.

Change Type	Change Procedure	Benefits
Increase the number of allowed zero crossings	Increase the value of the <b>Number of consecutive zero crossings</b> . option on the <b>Solver</b> pane in the Configuration Parameters dialog box.	This may give your model enough time to resolve the zero crossing.
Relax the <b>Signal threshold</b>	Select <b>Adaptive</b> from the <b>Algorithm</b> pull down and increase the value of the <b>Signal threshold</b> option on the <b>Solver</b> pane in the Configuration Parameters dialog box.	The solver requires less time to precisely locate the zero crossing. This can reduce simulation time and eliminate an excessive number of consecutive zero-crossing errors. However, relaxing the <b>Signal threshold</b> may reduce accuracy.

Change Type	Change Procedure	Benefits
Use the <b>Adaptive</b> algorithm	Select <b>Adaptive</b> from the <b>Algorithm</b> drop-down on the <b>Solver</b> pane in the Configuration Parameters dialog box.	This algorithm dynamically adjusts the zero-crossing threshold, which improves accuracy and reduces the number of consecutive zero crossings detected. With this algorithm you have the option of specifying both the <b>Time tolerance</b> and the <b>Signal threshold</b> .
Disable zero-crossing detection for a specific block	<ol style="list-style-type: none"> <li>1 Clear the <b>Enable zero-crossing detection</b> check box on the block's parameter dialog box.</li> <li>2 Select <b>Use local settings</b> from the <b>Zero-crossing control</b> pull down on the <b>Solver</b> pane of the Configuration Parameters dialog box.</li> </ol>	Locally disabling zero-crossing detection prevents a specific block from stopping the simulation because of excessive consecutive zero crossings. All other blocks continue to benefit from the increased accuracy that zero-crossing detection provides.
Disable zero-crossing detection for the entire model	Select <b>Disable all</b> from the <b>Zero-crossing control</b> pull down on the <b>Solver</b> pane of the Configuration Parameters dialog box.	This prevents zero crossings from being detected anywhere in your model. A consequence is that your model no longer benefits from the increased accuracy that zero-crossing detection provides.
If using the <code>ode15s</code> solver, consider adjusting the order of the numerical differentiation formulas	Select a value from the <b>Maximum order</b> pull down on the <b>Solver</b> pane of the Configuration Parameters dialog box.	For more information, see "Maximum order".
Reduce the maximum step size	Enter a value for the <b>Max step size</b> option on the <b>Solver</b> pane of the Configuration Parameters dialog box.	The solver takes steps small enough to resolve the zero crossing. However, reducing the step size can increase simulation time, and is seldom necessary when using the adaptive algorithm.

## How the Simulator Can Miss Zero-Crossing Events

The bounce and double-bounce models, in "Simulation of Bouncing Ball" and "Double Bouncing Ball: Use of Adaptive Zero-Crossing Location" show that high-frequency fluctuations about a discontinuity (chattering) can cause a simulation to prematurely halt.

It is also possible for the solver to entirely miss zero crossings if the solver error tolerances are too large. This is possible because the zero-crossing detection technique checks to see if the value of a signal has changed sign after a major time step. A sign change indicates that a zero crossing has occurred, and the zero-crossing algorithm searches for the precise crossing time. However, if a zero crossing occurs within a time step, but the values at the beginning and end of the step do not indicate a sign change, the solver steps over the crossing without detecting it.

The following figure shows a signal that crosses zero. In the first instance, the integrator steps over the event because the sign has not changed between time steps. In the second, the solver detects sign change and therefore detects the zero-crossing event.

Consider the two-integrator implementation of the bounce model.

Profiling of the last 0.5 s of the simulation using the Solver Profiler shows that the simulation detects 44 zero-crossing events at the Compare To Zero block and 22 events at the output of the Position block.

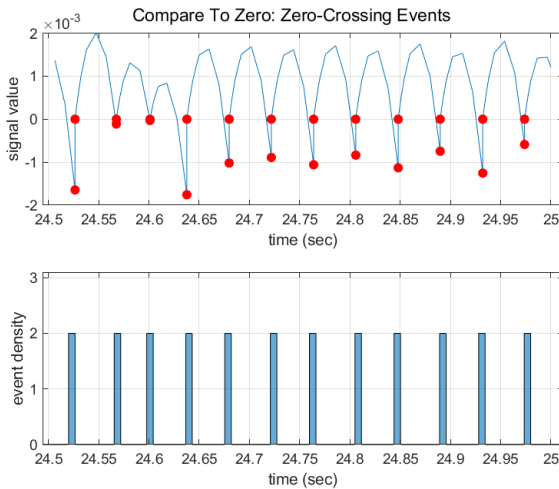

Increase the value of the **Relative tolerance** parameter to  $1e-2$  instead of the default  $1e-3$ . You can change this parameter in the **Solver Details** section of the **Solver** pane in the **Configuration Parameters** dialog or using `set_param` to specify `RelTol` as `'1e-2'`.

Profiling the last 0.5 s of the simulation with the new relative tolerance of the solver shows that it detects only 24 zero-crossing events at the Compare To Zero block and 12 events at the output of the Position block.

## Zero-Crossing Detection in Blocks

A block can register a set of zero-crossing variables, each of which is a function of a state variable that can have a discontinuity. The zero-crossing function passes through zero from a positive or negative value when the corresponding discontinuity occurs. The registered zero-crossing variables are updated at the end of each simulation step, and any variable that has changed sign is identified as having had a zero-crossing event.

If any zero crossings are detected, the Simulink software interpolates between the previous and current values of each variable that changed sign to estimate the times of the zero crossings, that is, the discontinuities.

**Note** The Zero-Crossing detection algorithm can bracket zero-crossing events only for signals of data type double.

### Blocks That Register Zero Crossings

The following table lists blocks that register zero crossings and explains how the blocks use the zero crossings.

Block	Number of Zero Crossing Detections
Abs	One, to detect when the input signal crosses zero in either the rising or falling direction.
Backlash	Two, one to detect when the upper threshold is engaged, and one to detect when the lower threshold is engaged.
Compare To Constant	One, to detect when the signal equals a constant.
Compare To Zero	One, to detect when the signal equals zero.
Dead Zone	Two, one to detect when the dead zone is entered (the input signal minus the lower limit), and one to detect when the dead zone is exited (the input signal minus the upper limit).

Block	Number of Zero Crossing Detections
Enable	One, If an Enable port is inside of a Subsystem block, it provides the capability to detect zero crossings. For details, “Using Enabled Subsystems” on page 10-10.
From File	One, to detect when the input signal has a discontinuity in either the rising or falling direction
From Workspace	One, to detect when the input signal has a discontinuity in either the rising or falling direction
Hit Crossing	One or two. If there is no output port, there is only one zero crossing to detect when the input signal hit the threshold value. If there is an output port, the second zero crossing is used to bring the output back to 0 from 1 to create an impulse-like output.
If	One, to detect when the If condition is met.
Integrator	If the reset port is present, to detect when a reset occurs.  If the output is limited, there are three zero crossings: one to detect when the upper saturation limit is reached, one to detect when the lower saturation limit is reached, and one to detect when saturation is left.
MinMax	One, for each element of the output vector, to detect when an input signal is the new minimum or maximum.
Relational Operator	One, to detect when the specified relation is true.
Relay	One, if the relay is off, to detect the switch-on point. If the relay is on, to detect the switch-off point.
Saturation	Two, one to detect when the upper limit is reached or left, and one to detect when the lower limit is reached or left.
Second-Order Integrator	Five, two to detect when the state $x$ upper or lower limit is reached, two to detect when the state $dx/dt$ upper or lower limit is reached, and one to detect when a state leaves saturation.
Sign	One, to detect when the input crosses through zero.
Signal Editor	One, to detect when the input signal has a discontinuity in either the rising or falling direction
Step	One, to detect the step time.
Switch	One, to detect when the switch condition occurs.
Switch Case	One, to detect when the case condition is met.
Trigger	One, If a Triggered port is inside of a Subsystem block, it provides the capability to detect zero crossings. For details, see “Using Triggered Subsystems” on page 10-17.
Enabled and Triggered Subsystem	Two, one for the enable port and one for the trigger port. For details, see: “Using Enabled and Triggered Subsystems” on page 10-20
From Spreadsheet	One, to detect when the input signal has a discontinuity in either the rising or falling direction.

**Note** Zero-crossing detection is also available for a Stateflow chart that uses continuous-time mode. See “Configure a Stateflow Chart for Continuous-Time Simulation” (Stateflow) for more information.

### Implementation Example: Saturation Block

An example of a Simulink block that registers zero crossings is the Saturation block. Zero-crossing detection identifies these state events in the Saturation block:

- The input signal reaches the upper limit.
- The input signal leaves the upper limit.
- The input signal reaches the lower limit.
- The input signal leaves the lower limit.

Simulink blocks that define their own state events are considered to have *intrinsic zero crossings*. Use the Hit Crossing block to receive explicit notification of a zero-crossing event. See “Blocks That Register Zero Crossings” on page 3-22 for a list of blocks that incorporate zero crossings.

The detection of a state event depends on the construction of an internal zero-crossing signal. This signal is not accessible by the block diagram. For the Saturation block, the signal that is used to detect zero crossings for the upper limit is  $zcSignal = UpperLimit - u$ , where  $u$  is the input signal.

Zero-crossing signals have a direction attribute, which can have these values:

- *rising* — A zero crossing occurs when a signal rises to or through zero, or when a signal leaves zero and becomes positive.
- *falling* — A zero crossing occurs when a signal falls to or through zero, or when a signal leaves zero and becomes negative.
- *either* — A zero crossing occurs if either a rising or falling condition occurs.

For the Saturation block upper limit, the direction of the zero crossing is *either*. This enables the entering and leaving saturation events to be detected using the same zero-crossing signal.

## Zero-Crossing Detection with Fixed-Step Simulation

Models with both continuous states and discontinuous signals may require a small fixed-step size to obtain accurate simulation results near discontinuities. With fixed-step zero crossing enabled, Simulink can automatically detect and locate discontinuities and correct the continuous states in the model. This functionality allows you to use a larger step size and enables faster simulation times without affecting simulation accuracy.

You may find fixed-step zero-crossing detection useful if your model contains:

- Continuous states
- Blocks with zero-crossings driven by signals with continuous sample time
- Frequent switching or other events that limit solver step-size

### Effects of Zero-Crossing Detection in Fixed-Step

Consider a self-resetting integrator that can be used to generate a sawtooth wave where the state is reset to 1/3 each time it reaches a value of 1. Simulating in variable-step with zero-crossing detection shows the expected results, or baseline, for this model.

```
model = 'mSelfResetIntegrator';
open_system(model);

set_param(model, 'Solver', 'ode23');
simoutVS = sim(model);
figure();
plot(simoutVS.tout, simoutVS.xout);
legend('Variable-Step (baseline)', ...
      'Location', 'southeast');
```

The sawtooth wave generated using variable-step simulation is used as a baseline.

### Simulate in Fixed-Step Without Zero-Crossing Detection

You can use a fixed-step solver like `ode3` to simulate this model with default fixed-step size equal to 0.2. However, the simulation results are not very accurate for this step size. The fixed-step size must be decreased to about 0.001 for the simulation results that align with the expected result.

```
set_param(model, 'Solver', 'ode3', ...
    'FixedStep', '0.2');
simoutFS = sim(model);

plot(simoutVS.tout, simoutVS.xout, ...
    simoutFS.tout, simoutFS.xout, '-x');
title('Fixed-step size = 0.2');
legend('Variable-Step (baseline)', 'Fixed-step (Zero-Crossing Disabled)',...
    'Location', 'southeast');
```

```

set_param(model, 'FixedStep', '.001');
simoutFS2 = sim(model);

plot(simoutVS.tout, simoutVS.xout, ...
      simoutFS2.tout, simoutFS2.xout, '-x');
title('Fixed-step size = 0.001');
legend('Variable-Step (baseline)', 'Fixed-step (Zero-Crossing Disabled)',...
       'Location', 'southeast');

```

## Enable Fixed-Step Zero-Crossing Detection

Zero-crossing detection can be enabled for this model by selecting “Enable zero-crossing detection for fixed-step solver”. You can also set the step size back to 0.2 and simulate. Note that despite this substantial increase in step size, each state value in this simulation coincides with the expected result. Thus, zero-crossing detection for fixed-step simulation results in faster simulation times for this model.

```
set_param(model, 'FixedStep', '0.2', ...
    'EnableFixedStepZeroCrossing', 'on');

simoutFSZC = sim(model);
plot(simoutVS.tout, simoutVS.xout, ...
    simoutFSZC.tout, simoutFSZC.xout, '-x');
title('Fixed-step size = 0.2');
legend('Variable-Step (baseline)', 'Fixed-step (Zero-Crossing Enabled)',...
    'Location', 'southeast');
```

## Set Parameters for Zero-Crossing Detection

You use two main parameters to control zero crossing for fixed-step simulation. These parameters help ensure that the detection and location of zero-crossing events is fixed-cost. Go to the **Solver Details > Zero-crossing options** section of the configuration parameters to access the parameters.

<input checked="" type="checkbox"/>	Enable zero-crossing detection for fixed-step simulation
Zero-crossing control:	Use local settings
Maximum number of bracketing iterations:	10
Maximum number of zero-crossings per step:	2

### Maximum Number of Bracketing Iterations

The **Maximum number of bracketing iterations** parameter limits the number of search iterations used by Simulink for locating a zero-crossing event once the event has been detected. In general, a higher number of bracketing iterations will provide a more accurate event location, but this option is computationally costly.

Consider this model with a sine wave driving a Hit Crossing block. Zero-crossings are detected when the Hit Crossing block detects that its input signal has crossed zero, which should occur at multiples of  $\pi$ . The scope displays this result.

```
model = 'mFixedStepZcParameters';
open_system(model);
set_param(model, 'Solver', 'VariableStepAuto');
sim(model);
```

Too few bracketing iterations results in locating zero crossings with less accuracy. To see the number of bracketing iterations simulation results, enable fixed-step zero-crossing, change to a fixed-step solver, and set the **Maximum number of zero-crossings per step** parameter to 2. Use a fixed-step size of 0.5.

```
set_param(model, 'EnableFixedStepZeroCrossing', 'on', ...
    'MaxZcBracketingIterations', '2', ...
    'SolverName', 'ode3', ...
    'FixedStep', '0.5');
```

Increasing the number of bracketing iterations to 4 results in more accurate location of the events in this model. The zero crossing is located closer to the expected value of pi.

```
set_param(model, 'MaxZcBracketingIterations', '4');
```

### Maximum Number of Zero-Crossings per Step

Use **Maximum number of zero-crossings per step** parameter to limit the maximum number of zero crossings that Simulink will locate in one simulation time step. Once this maximum number is reached in a step, any additional zero-crossings that occur within that step are ignored. To see how this can affect simulation results, consider the following example. Set the Sine Wave block to output two sine waves that are slightly offset by using scalar expansion on the 'Bias' parameter of the sine wave block. Two zero crossing events should be located near pi.

```
sineWaveBlock = [model '/Sine Wave'];
set_param(sineWaveBlock, 'Bias', '[0.0 0.1]');
set_param(model, 'Solver', 'ode45');
simoutVS = sim(model);
```

Setting the maximum number of zero-crossings to locate per step to 1 will restrict Simulink to only locating the first zero crossing that occurs within a single time step. In this example, Simulink only locates the first zero-crossing in the step at  $\pi$  in the step from  $t = 3$  to  $t = 3.5$ . As a result, the second state of the Integrator block is less accurate due to the missed zero crossing.

```
set_param(model, 'Solver', 'ode3',...
    'EnableFixedStepZeroCrossing', 'on',...
    'MaxZcPerStep', '1');
simoutFS_1ZC = sim(model);
f = figure();
tiledlayout(f, 'flow', 'TileSpacing', 'compact', 'Padding', 'compact');
nexttile;
plot(simoutVS.tout, simoutVS.xout.signals(1).values(:, 1),...
    simoutFS_1ZC.tout, simoutFS_1ZC.xout.signals(1).values(:, 1), '-x');
title('State 1')
nexttile;
plot(simoutVS.tout, simoutVS.xout.signals(1).values(:, 2),...
    simoutFS_1ZC.tout, simoutFS_1ZC.xout.signals(1).values(:, 2), '-x');
title('State 2')
legend('Variable-Step (Expected Result)', 'Fixed-Step with One Zc Per Step',...
    'Location', 'northwest');
```

Since you know to expect a maximum of two zero crossings to be located within the fixed-step size of 0.5, setting the **Maximum number of zero-crossings per step** parameter to 2 should yield more accurate simulation results. This plot shows that both continuous states of the Integrator block match the expected result.

```

set_param(model, 'MaxZcPerStep', '2')
simoutFS_2ZC = sim(model);
f = figure();
tiledlayout(f, 'flow', 'TileSpacing', 'compact', 'Padding', 'compact');
nexttile;
plot(simoutVS.tout, simoutVS.xout.signals(1).values(:, 1), ...
     simoutFS_2ZC.tout, simoutFS_2ZC.xout.signals(1).values(:, 1), '-x');
title('State 1')
nexttile;
plot(simoutVS.tout, simoutVS.xout.signals(1).values(:, 2), ...
     simoutFS_2ZC.tout, simoutFS_2ZC.xout.signals(1).values(:, 2), '-x');
title('State 2')
legend('Variable-Step (Expected Result)', 'Fixed-Step with Two Zc Per Step', ...
      'Location', 'northwest');

```

## Zero-Crossing Algorithms

The Simulink software includes two zero-crossing detection algorithms: Nonadaptive and Adaptive.

To choose the algorithm, either use the **Algorithm** option in the Solver pane of the Configuration Parameter dialog box, or use the `ZeroCrossAlgorithm` command. The command can either be set to 'Nonadaptive' or 'Adaptive'.

The Nonadaptive algorithm is provided for backwards compatibility with older versions of Simulink and is the default. It brackets the zero-crossing event and uses increasingly smaller time steps to pinpoint when the zero crossing has occurred. Although adequate for many types of simulations, the Nonadaptive algorithm can result in very long simulation times when a high degree of 'chattering' (high frequency oscillation around the zero-crossing point) is present.

The Adaptive algorithm dynamically turns the bracketing on and off, and is a good choice when:

- The system contains a large amount of chattering.
- You wish to specify a guard band (tolerance) around which the zero crossing is detected.

The Adaptive algorithm turns off zero-crossing bracketing (stops iterating) if either of the following are satisfied:

- The zero crossing error is exceeded. This is determined by the value specified in the **Signal threshold** option in the Solver pane of the Configuration Parameters dialog box. This can also be set with the `ZCThreshold` command. The default is Auto, but you can enter any real number greater than zero for the tolerance.
- The system has exceeded the number of consecutive zero crossings specified in the **Number of consecutive zero crossings** option in the Solver pane of the Configuration Parameters dialog box. Alternatively, this can be set with the `MaxConsecutiveZCs` command.

### Signal Threshold for Adaptive Zero-Crossing Detection

The Adaptive algorithm automatically sets a tolerance for zero-crossing detection. Alternatively, you can set the tolerance by entering a real number greater than or equal to zero in the Configuration Parameters Solver pane, `Signal threshold` pull down. This option only becomes active when the zero-crossing algorithm is set to Adaptive.

This graphic shows how the Signal threshold sets a window region around the zero-crossing point. Signals falling within this window are considered as being at zero.

The zero-crossing event is bracketed by time steps  $T_{n-1}$  and  $T_n$ . The solver iteratively reduces the time steps until the state variable lies within the band defined by the signal threshold, or until the number of consecutive zero crossings equals or exceeds the value in the Configuration Parameters Solver pane, Number of consecutive zero crossings pull down.

It is evident from the figure that increasing the signal threshold increases the distance between the time steps which will be executed. This often results in faster simulation times, but might reduce accuracy.

## Algebraic Loop Concepts

### In this section...

“Mathematical Interpretation” on page 3-40

“Physical Interpretation” on page 3-40

“Artificial Algebraic Loops” on page 3-41

“How the Algebraic Loop Solver Works” on page 3-42

“Implications of Algebraic Loops in a Model” on page 3-44

In a Simulink model, an algebraic loop occurs when a signal loop exists with only direct feedthrough blocks within the loop. Direct feedthrough means that Simulink needs the value of the block’s input signal to compute its output at the current time step. Such a signal loop creates a circular dependency of block outputs and inputs in the same time-step. This results in an algebraic equation that needs solving at each time-step, adding computational cost to the simulation.

Some examples of blocks with direct feedthrough inputs are:

- Math Function
- Gain
- Product
- State-Space, when the D matrix coefficient is nonzero
- Sum
- Transfer Fcn, when the numerator and denominator are of the same order
- Zero-Pole, when the block has as many zeros as poles

*Nondirect feedthrough* blocks maintain a State variable. Two examples are Integrator and Unit Delay.

---

**Tip** To determine if a block has direct feedthrough, read the **Characteristics** section of the block reference page.

---

The figure shows an example of an algebraic loop. The Sum block is an algebraic variable  $x_a$  that is constrained to equal the first input  $u$  minus  $x_a$  (for example,  $x_a = u - x_a$ ).

The solution of this simple loop is  $x_a = u/2$ .

## Mathematical Interpretation

Simulink contains a suite of numerical solvers for simulating ordinary differential equations (ODEs), which are systems of equations that you can write as

$$\dot{x} = f(x, t),$$

where  $x$  is the state vector and  $t$  is the independent time variable.

Some systems of equations contain additional constraints that involve the independent variable and the state vector, but not the derivative of the state vector. Such systems are called differential algebraic equations (DAEs),

The term algebraic refers to equations that do not involve any derivatives. You can express DAEs that arise in engineering in the semi-explicit form

$$\begin{aligned} \dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}, \mathbf{x}_a, t) \\ 0 &= \mathbf{g}(\mathbf{x}, \mathbf{x}_a, t), \end{aligned}$$

where:

- $\mathbf{f}$  and  $\mathbf{g}$  can be vector functions.
- The first equation is the differential equation.
- The second equation is the algebraic equation.
- The vector of differential variables is  $\mathbf{x}$ .
- The vector of algebraic variables is  $\mathbf{x}_a$ .

In Simulink models, algebraic loops are algebraic constraints. Models with algebraic loops define a system of differential algebraic equations. Simulink solves the algebraic equations (the algebraic loop) numerically for  $x_a$  at each step of the ODE solver.

The model in the figure is equivalent to this system of equations in semi-explicit form:

$$\begin{aligned} \dot{x} &= f(x, x_a, t) = x_a \\ 0 &= g(x, x_a, t) = -x + u - 2x_a. \end{aligned}$$

At each step of the ODE solver, the algebraic loop solver must solve the algebraic constraint for  $x_a$  before calculating the derivative  $\dot{x}$ .

## Physical Interpretation

Algebraic constraints:

- Occur when modeling physical systems, often due to conservation laws, such as conservation of mass and energy
- Occur when you choose a particular coordinate system for a model
- Help impose design constraints on system responses in a dynamic system

Use Simscape to model systems that span mechanical, electrical, hydraulic, and other physical domains as physical networks. Simscape constructs the DAEs that characterize the behavior of a model. The software integrates these equations with the rest of the model and then solves the DAEs directly. Simulink solves the variables for the components in the different physical domains simultaneously, avoiding problems with algebraic loops.

## Artificial Algebraic Loops

An *artificial algebraic loop* occurs when an atomic subsystem or Model block causes Simulink to detect an algebraic loop, even though the contents of the subsystem do not contain a direct feedthrough from the input to the output. When you create an atomic subsystem, all Inport blocks are direct feedthrough, resulting in an algebraic loop.

Start with the included model, which represents a simple proportional control of the plant described by

$$G(s) = \frac{1}{s^2 + 2s + 1}$$

which can be rewritten in state-space form as

$$\dot{x} = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u$$

$$y = \begin{bmatrix} 0 & 1 \end{bmatrix} x$$

The system has neither algebraic variables nor direct feedthrough and does not contain an algebraic loop.

Modify the model as described in the following steps:

- 1 Enclose the Controller and Plant blocks in a subsystem.
- 2 In the subsystem dialog box, select **Treat as atomic unit** to make the subsystem atomic.
- 3 In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic Loop** parameter to error.

When simulating this model, an algebraic loop occurs because the subsystem is direct feedthrough, even though the path within the atomic subsystem is not direct feedthrough. Simulation stops with an algebraic loop error.

### How the Algebraic Loop Solver Works

When a model contains an algebraic loop, Simulink uses a nonlinear solver at each time step to solve the algebraic loop. The solver performs iterations to determine the solution to the algebraic constraint, if there is one. As a result, models with algebraic loops can run more slowly than models without algebraic loops.

Simulink uses a dogleg trust region algorithm to solve algebraic loops. The tolerance used is smaller than the ODE solver `RelTol` and `Abstol`. This is because Simulink uses the “explicit ODE method” to solve Index-1 differential algebraic equations (DAEs).

For the algebraic loop solver to work,

- There must be one block where the loop solver can break the loop and attempt to solve the loop.
- The model should have real double signals.
- The underlying algebraic constraint must be a smooth function

For example, suppose your model has a Sum block with two inputs—one additive, the other subtractive. If you feed the output of the Sum block to one of the inputs, you create an algebraic loop where all of the blocks include direct feedthrough.

The Sum block cannot compute the output without knowing the input. Simulink detects the algebraic loop, and the algebraic loop solver solves the loop using an iterative loop. In the Sum block example, the software computes the correct result this way:

$$x_a(t) = u(t) / 2. \tag{3-1}$$

The algebraic loop solver uses a gradient-based search method, which requires continuous first derivatives of the algebraic constraint that correspond to the algebraic loop. As a result, if the algebraic loop contains discontinuities, the algebraic loop solver can fail.

For more information, see Solving Index-1 DAEs in MATLAB and Simulink <sup>1</sup>

## Trust-Region and Line-Search Algorithms in the Algebraic Loop Solver

The Simulink algebraic loop solver uses one of two algorithms to solve algebraic loops:

- Trust-Region
- Line-Search

By default, Simulink chooses the best algebraic loop solver and may switch between the two methods during simulation. To explicitly enable automatic algebraic loop solver selection for your model, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'Auto');
```

To switch to the trust-region algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'TrustRegion');
```

If the algebraic loop solver cannot solve the algebraic loop with the trust-region algorithm, try simulating the model using the line-search algorithm.

To switch to the line-search algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'LineSearch');
```

For more information, see:

- "Trust-Region Methods for Nonlinear Minimization" (Optimization Toolbox).
- "Line Search" (Optimization Toolbox).

## Limitations of the Algebraic Loop Solver

Algebraic loop solving is an iterative process. The Simulink algebraic loop solver is successful only if the algebraic loop converges to a definite answer. When the loop fails to converge, or converges too slowly, the simulation exits with an error.

The algebraic loop solver cannot solve algebraic loops that contain any of the following:

- Blocks with discrete-valued outputs
- Blocks with nondouble or complex outputs
- Discontinuities
- Stateflow charts

## Implications of Algebraic Loops in a Model

If your model contains an algebraic loop:

- You cannot generate code for the model.
- The Simulink algebraic loop solver might not be able to solve the algebraic loop.
- While Simulink is trying to solve the algebraic loop, the simulation can execute slowly.

For most models, the algebraic loop solver is computationally expensive for the first time step. Simulink solves subsequent time steps rapidly because a good starting point for  $x_a$  is available from the previous time step.

### More About

- “Identify Algebraic Loops in Your Model” on page 3-45
- “Remove Algebraic Loops” on page 3-48
- “Modeling Considerations with Algebraic Loops” on page 3-62

## Identify Algebraic Loops in Your Model

If Simulink reports an algebraic loop in your model, the algebraic loop solver may be able to solve the loop. If Simulink cannot solve the loop, there are several techniques to eliminate the loop.

Use this workflow to decide how you want to eliminate an algebraic loop.

## Highlight Algebraic Loops in the Model

Use `getAlgebraicLoops` to identify algebraic loops in a model and highlight them in the Simulink Editor. With this approach:

- You can traverse multiple layers of model hierarchy to locate algebraic loops.
- You can identify real and artificial algebraic loops.
- You can visualize all loops in your model simultaneously.
- You do not need to drill in and out of the model, across boundaries.
- You do not need to detect loops in serial order. Also, you do not need to compile the model every time you detect and solve a loop. Therefore you can solve loops quickly.

You perform algebraic loop highlighting on an entire model, not on specific subsystems.

- 1 Open the model.
- 2 In the **Diagnostics** pane of Model Configuration Parameters, set **Algebraic loop** to none or warning. Setting this parameter to error prevents the model from compiling.
- 3 Compile the model without any errors. The model must compile before you can highlight any algebraic loops.
- 4 At the MATLAB command prompt, enter:

```
Simulink.BlockDiagram.getAlgebraicLoops(bdroot)
```

The `getAlgebraicLoops` function highlights algebraic loops in the model, including algebraic loops in subsystems. It also creates a report with information about each loop:

- Solid lines represent real algebraic loops.
- Dotted lines represent artificial algebraic loops.
- A red highlight appears around a block assigned with an algebraic variable.
- The **Loop ID** helps you identify the system that contains a particular loop.

Customize the report by selecting or clearing the **Visible** check box for a loop.

Once you have identified algebraic loops in a model, you can remove them by editing the model. Close the highlight report and make changes to the model. You can edit the model only after you close the report.

Simulink does not save loop highlighting. Closing the model or exiting the display removes the loop highlighting.

## Use the Algebraic Loop Diagnostic

Simulink detects algebraic loops during simulation initialization, for example, when you update your diagram. You can set the Algebraic loop diagnostic to report an error or warning if the software detects any algebraic loops in your model.

In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter:

- none -- Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.

## Remove Algebraic Loops

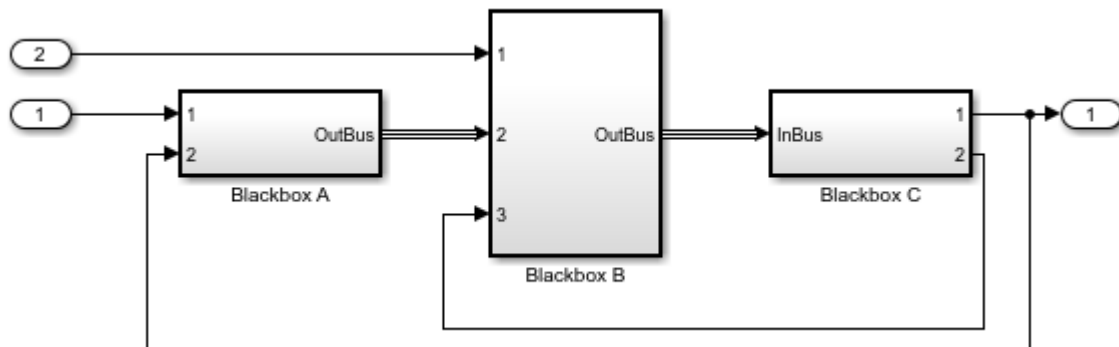

Use these techniques to remove algebraic loops in a model.

### Introduce a Delay to Remove Algebraic Loops

This example demonstrates how to remove algebraic loops in a model by introducing delays between blocks in a loop. This is one approach to remove algebraic loops in larger models where such loops can occur due to feedback between atomic subsystems.

Consider the model attached with this example. There are two algebraic loops caused by the atomic subsystems in the model

- Blackbox A -> Blackbox B -> Blackbox C -> Blackbox A
- Blackbox B -> Blackbox C -> Blackbox B

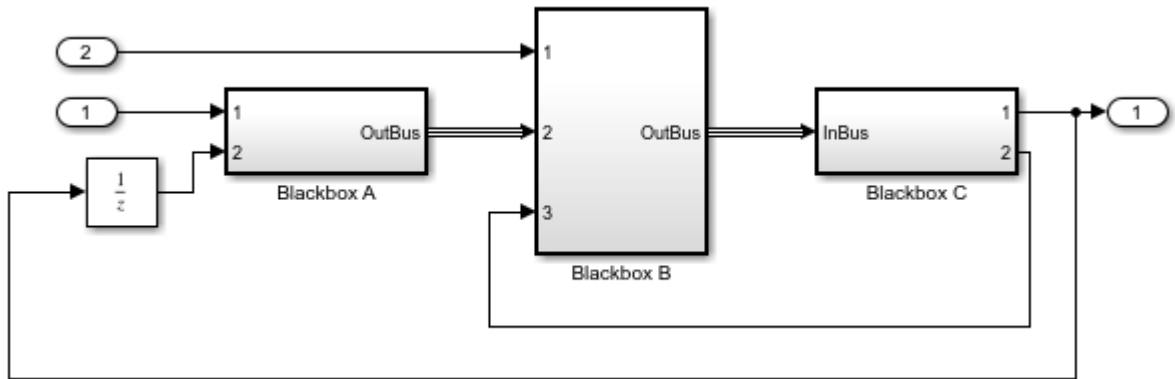

When you update this model, Simulink® detects the loop Blackbox A -> Blackbox B -> Blackbox C -> Blackbox A

Since you do not know the contents of these subsystems, break the loops by adding a Unit Delay block outside the subsystems. There are three ways to use the Unit Delay block to break these loops:

- Add a Unit Delay between Blackbox A and Blackbox C.
- Add a Unit Delay between Blackbox B and Blackbox C.
- Add Unit Delay blocks to both algebraic loops.

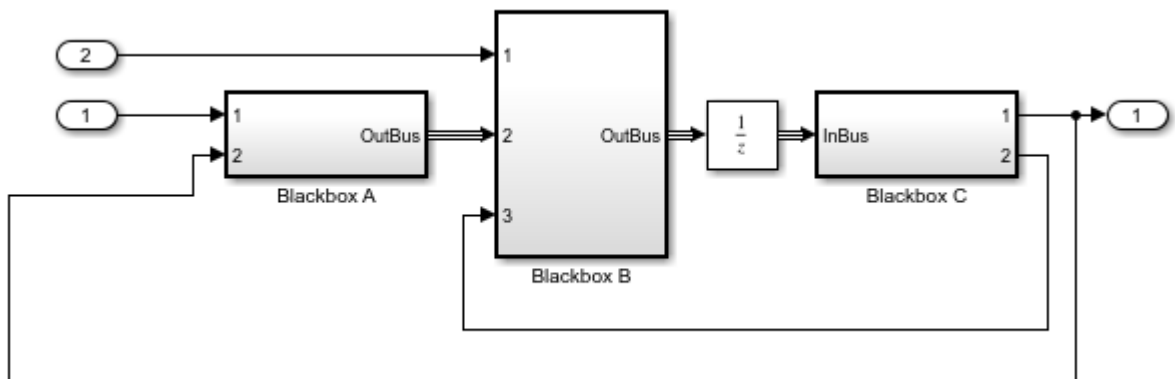

#### Add a unit delay between BlackBox A and BlackBox C

If you add a unit delay on the feedback signal between the subsystems Blackbox A and Blackbox C, you introduce the minimum number of unit delays (1) to the system. By introducing the delay before Blackbox A, Blackbox B and Blackbox C use data from the current time step.

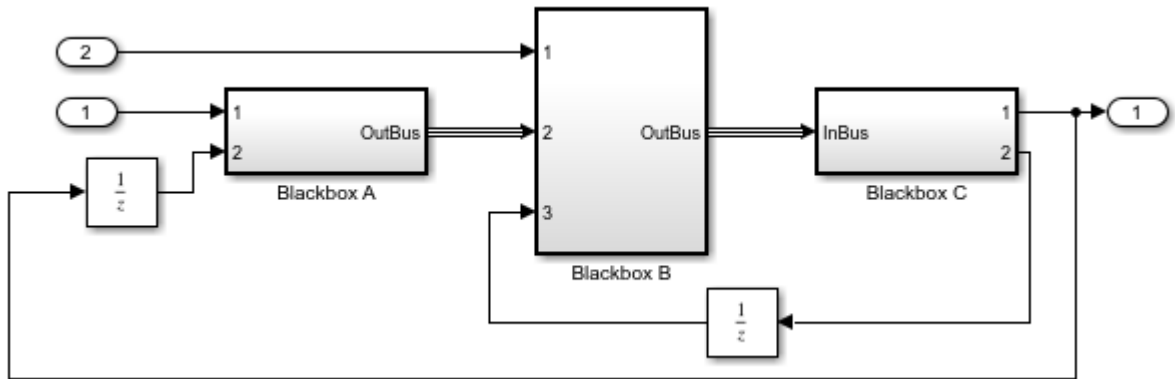

### Add a unit delay between BlackBox B and BlackBox C

If you add a unit delay between the subsystems Blackbox B and Blackbox C, you break the algebraic loop between Blackbox B and Blackbox C. In addition, you break the loop between Blackbox A and Blackbox C, because that signal completes the algebraic loop. By inserting the Unit Delay block before Blackbox C, Blackbox C now works with data from the previous time step only.

### Add unit delays to both algebraic loops

In the example here, you insert Unit Delay blocks to break both algebraic loops. In this model, BlackBox\_A and BlackBox\_B use data from the previous time step. BlackBox\_C uses data from the current time step.

### Solve Algebraic Loops Manually

If Simulink cannot solve the algebraic loop, the software reports an error. Use one of these techniques to solve the loop manually:

- Restructure the underlying DAEs using techniques such as differentiation or change of coordinates. These techniques put the DAEs in a form that is easier for the algebraic loop solver to solve.
- Convert the DAEs to ODEs, which eliminates any algebraic loops.
- “Create Initial Guesses Using the IC and Algebraic Constraint Blocks” on page 3-50

### Create Initial Guesses Using the IC and Algebraic Constraint Blocks

Your model might contain loops for which the loop solver cannot converge without a good, initial guess for the algebraic states. You can specify an initial guess for the algebraic state variables, but use this technique only when you think the loop is legitimate.

There are two ways to specify an initial guess:

- Place an IC block in the algebraic loop.
- Specify an initial guess for a signal in an algebraic loop using an Algebraic Constraint block.

### How Simulink Eliminates Artificial Algebraic Loops

When you enable **Minimize algebraic loop occurrences**, Simulink tries to eliminate artificial algebraic loops. In this example, the model contains an atomic subsystem that causes an artificial algebraic loop.

The contents of the atomic subsystem are not direct feedthrough, but Simulink identifies the atomic subsystem as direct feedthrough.

If the **Algebraic loop** diagnostic is set to error, simulating the model results in an error because the model contains an artificial algebraic loop involving its atomic subsystem.

To eliminate this algebraic loop,

- 1 Create the model from the preceding graphics, with the atomic subsystem that causes the artificial algebraic loop.
- 2 In the **Diagnostics** pane of Model Configuration Parameters, set the **Algebraic loop** parameter to warning or none.
- 3 To display the block execution order for this model and the atomic subsystem, in the **Debug** tab, select **Information Overlays > Execution Order**.

Reviewing the execution order can help you understand how to eliminate the artificial algebraic loop.

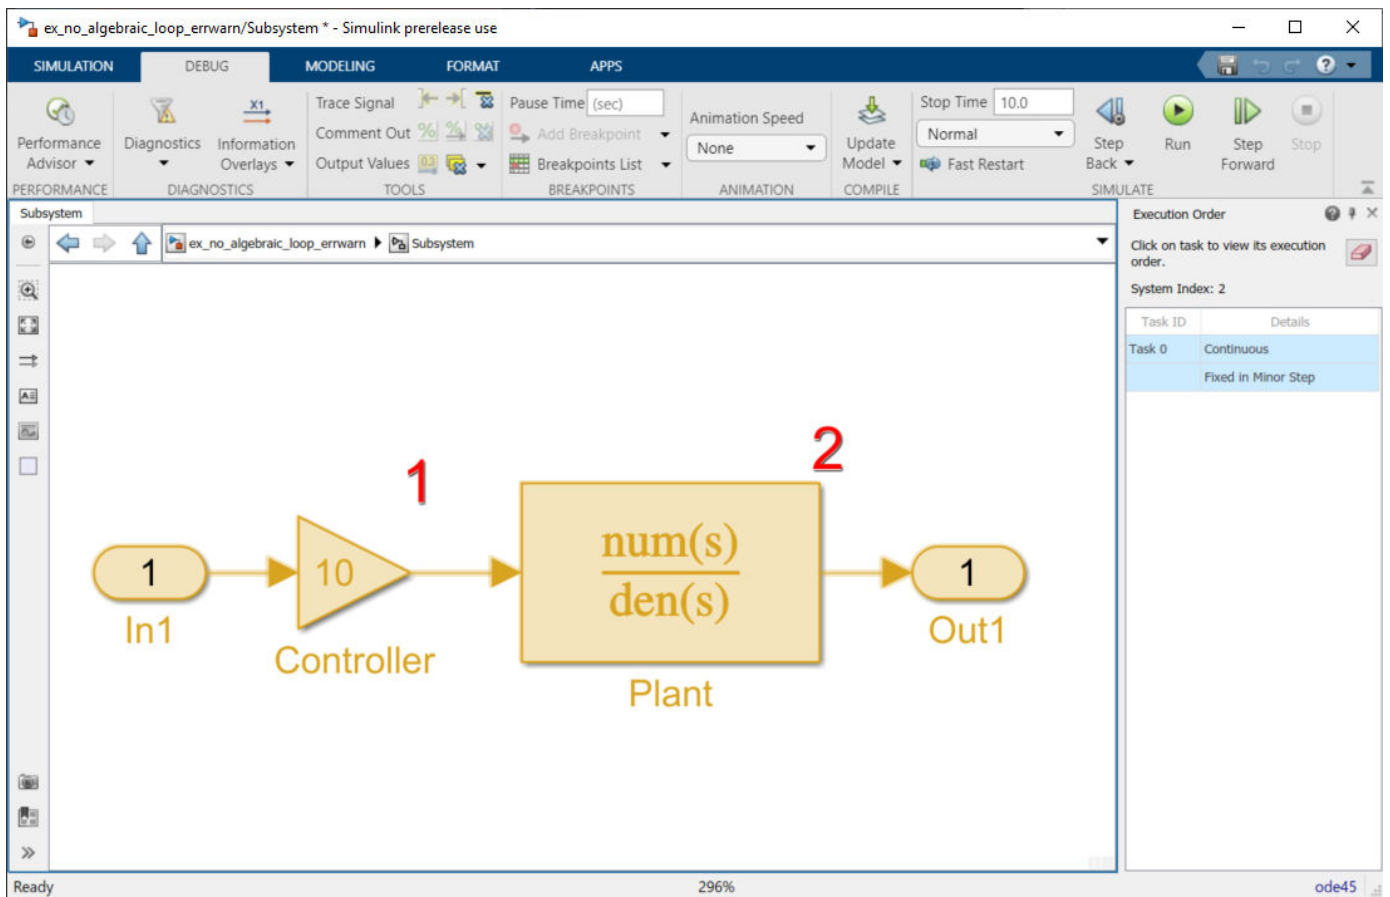

All the blocks in the subsystem execute at the same level: 1. (0 is the lowest level, indicating the first blocks to execute.)

**Note** For more information about block execution order, see “Control and Display Execution Order” on page 39-27.

- 4 In the top-level model’s **Subsystem Parameters** dialog box, select **Minimize algebraic loop occurrences**. This parameter directs the software to try to eliminate the algebraic loop that contains the atomic subsystem when you simulate the model.
- 5 Save the changes.
- 6 In the **Modeling** tab, click **Update Model** to recalculate the execution order.

Now there are two levels of execution order inside the subsystem: 1 and 2.

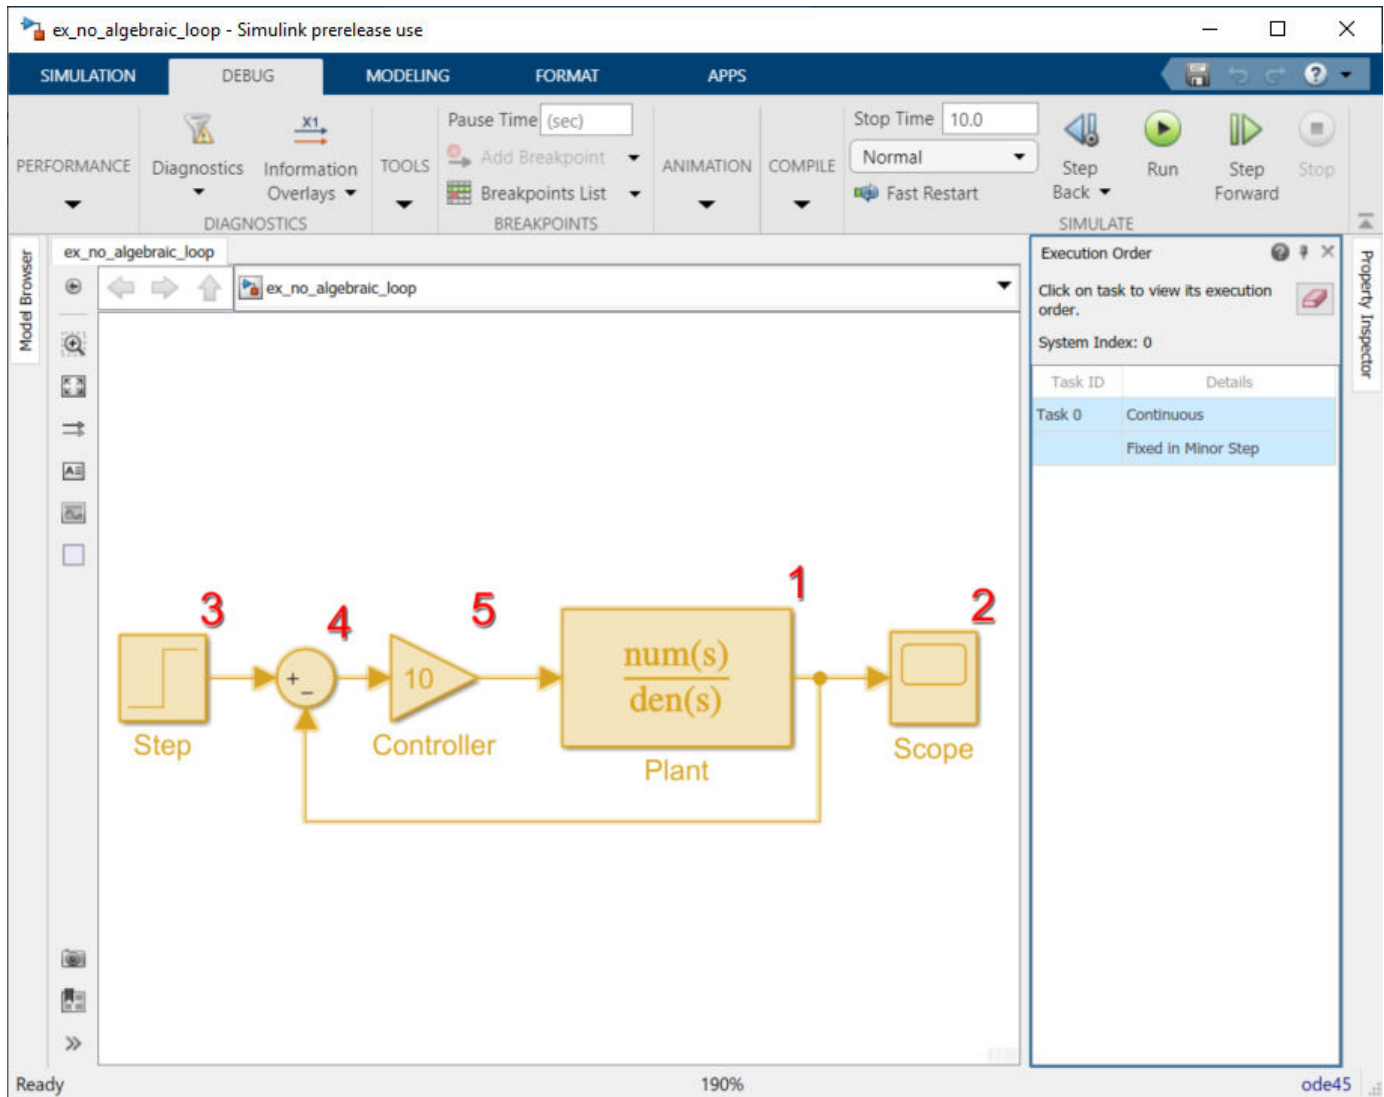

To eliminate the artificial algebraic loop, the software tries to adjust the execution order so that the subsystem or model reference does not have direct feedthrough.

When you simulate a model, all blocks execute methods in this order:

- 1 mdlOutputs
- 2 mdlDerivatives
- 3 mdlUpdate

In the original version of this model, the execution of the mdlOutputs method starts with the Plant block because the Plant block does not have direct feedthrough. The execution finishes with the Controller block.

For more information about these methods, see “Simulink Models”.

If you enable the **Minimize algebraic loop occurrences** parameter for the atomic subsystem, the software divides the subsystem into two atomic units.

These conditions are true:

- Atomic unit 2 does not have direct feedthrough.
- Atomic unit 1 has only a `mdlOutputs` method.

Only the `mdlDerivatives` or `mdlUpdate` methods of Atomic unit 2 need the output of Atomic unit 1. Simulink can execute what normally would have been executed during the `mdlOutput` method of Atomic unit 1 in the `mdlDerivatives` methods of Atomic unit 2.

The new execution order for the model is:

- 1 `mdlOutputs` method of model
  - a `mdlOutputs` method of Atomic unit 2
  - b `mdlOutputs` methods of other blocks
- 2 `mdlDerivatives` method of model
  - a `mdlOutputs` method of Atomic unit 1
  - b `mdlDerivatives` method of Atomic unit 2
  - c `mdlDerivatives` method of other blocks

For the **Minimize algebraic loop occurrences** technique to be successful, the subsystem or referenced model must have a non-direct-feedthrough block connected directly to an Inport and must not contain any signals designated as test points. The software can then set the `DirectFeedthrough` property of the block Inport to `false` to indicate that the input port does not have direct feedthrough.

## Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems

If an atomic subsystem causes an artificial algebraic loop, convert the atomic subsystem to a virtual subsystem. When the subsystem is atomic and you simulate the model, Simulink invokes the algebraic loop solver. The solver terminates after one iteration. The algebraic loop is automatically solved because there is no algebraic constant. After you make the subsystem virtual, Simulink does not invoke the algebraic loop solver during simulation.

To convert an atomic subsystem to a virtual subsystem:

- 1 Open the model that contains the atomic subsystem.
- 2 Right-click the atomic subsystem and select **Subsystem Parameters**.
- 3 Clear the **Treat as atomic unit** parameter.
- 4 Save the changes.

If you replace the atomic subsystem with a virtual subsystem and the simulation still fails with an algebraic loop error, examine the model for one of these:

- An algebraic constraint
- An artificial algebraic loop that was not caused by this atomic subsystem

## Bundled Signals That Create Artificial Algebraic Loops

Some models bundle signals together. This bundling can cause Simulink to detect an algebraic loop, even when an algebraic constraint does not exist. If you redirect one or more signals, you may be able to remove the artificial algebraic loop.

In this example, a linearized model simulates the dynamics of a two-tank system fed by a single pump. In this model:

- Output  $q_1$  is the rate of the fluid flow into the tank from the pump.
- Output  $h_2$  is the height of the fluid in the second tank.
- The State-Space block defines the dynamic response of the tank system to the pump operation:

Block Parameters: State-Space2

State Space

State-space model:

$$\frac{dx}{dt} = Ax + Bu$$
$$y = Cx + Du$$

Parameters

A:

 ⋮

B:

 ⋮

C:

 ⋮

D:

 ⋮

Initial conditions:

 ⋮

Absolute tolerance:

 ⋮

State Name: (e.g., 'position')

OK Cancel Help Apply

- The output from the State-Space block is a vector that contains  $q_1$  and  $h_2$ .

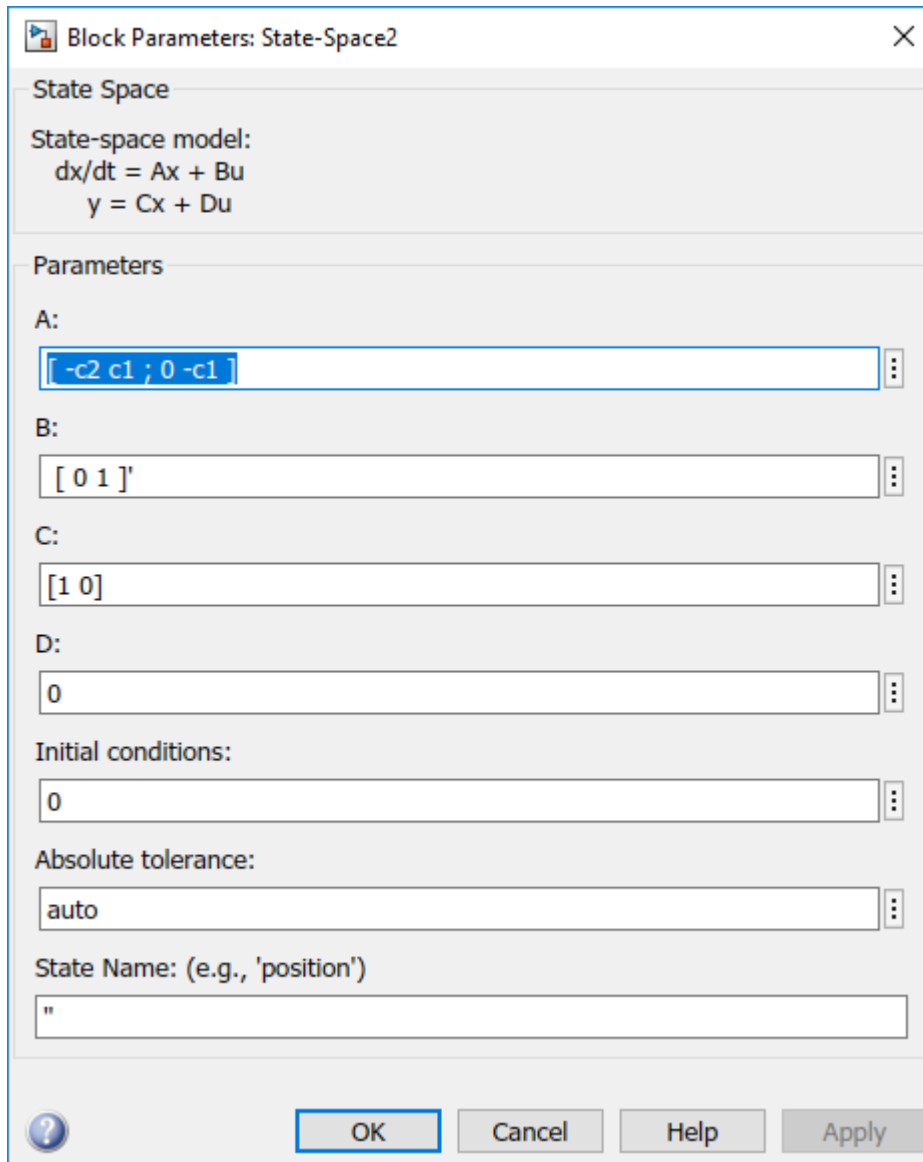

If you simulate this model with the **Algebraic loop** parameter set to warn or error, Simulink identifies the algebraic loop.

To eliminate this algebraic loop:

- 1 Change the C and D matrices as follows:

- 2 Pass q1 directly to the Scope instead of through the State-Space block.

Now, the input (q1) does not pass directly to the output (the D matrix is 0), so the State-Space block no longer has direct feedthrough. The feedback signal has only one element now, so the Selector block is no longer necessary, as you can see in the following model.

## Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops

There are two parameters to consider when you think that your model has an artificial algebraic loop:

- **Minimize algebraic loop occurrences** parameter — Specify that Simulink try to eliminate any artificial algebraic loops for:
  - Atomic subsystems — In the Subsystem Parameters dialog box, select **Minimize algebraic loop occurrences**.
  - Model blocks — For the referenced model, in the **Model Referencing** pane of Configuration Parameters, select **Minimize algebraic loop occurrences**.
- **Minimize algebraic loop** parameter — Specifies what diagnostic action Simulink takes if the **Minimize algebraic loop occurrences** parameter has no effect.

The **Minimize algebraic loop** parameter is in the **Diagnostics** pane of Configuration Parameters. The diagnostic actions for this parameter are:

Setting	Simulation Response
none	Simulink takes no action.
warning	Simulink displays a warning that the <b>Minimize algebraic loop occurrences</b> parameter has no effect.
error	Simulink terminates the simulation and displays an error that the <b>Minimize algebraic loop occurrences</b> parameter has no effect.

## Block Reduction and Artificial Algebraic Loops

When you enable the **Block reduction** optimization in Model Configuration Parameters, Simulink collapses certain groups of blocks into a single, more efficient block, or removes them entirely. Enabling block reduction results in faster execution during model simulation and in generating code.

Enabling block reduction can also help Simulink solve artificial algebraic loops.

Consider the following example model.

Initially, block reduction is turned off. When you simulate this model, the Atomic Unit subsystem and Gain and Compare to Constant blocks are part of an algebraic loop that Simulink cannot solve.

If you enable block reduction and execution order, and simulate the model again, Simulink does not display the execution order for blocks that have been reduced. You can now quickly see which blocks have been reduced.

The Compare to Constant and Gain blocks have been eliminated from the model, so they no longer generate an algebraic loop error. The Atomic Unit subsystem generates a warning:

Warning: If the inport 'ex\_aloop\_block\_reduction\_errwarn/Atomic Unit/In1' of subsystem 'ex\_aloop\_block\_reduction\_errwarn/Atomic Unit' involves direct feedback, then an algebraic loop exists, which Simulink cannot remove. Consider clearing the 'Minimize algebraic loop occurrences' parameter to avoid this warning.

---

**Tip** Use Bus Selector blocks to pass only the required signals into atomic subsystems.

## Modeling Considerations with Algebraic Loops

### Managing Large Models with Artificial Algebraic Loops

Adopt these design techniques for large models with algebraic loops:

- Avoid creating loops that contain discontinuities or nondouble data types. The Simulink algebraic loop solver is gradient-based and must solve algebraic constraints to high precision.
- Develop a scheme for clearly identifying atomic subsystems as direct feedthrough or not direct feedthrough. Use a visual scheme such as coloring the blocks or defining a block-naming convention.
- If you plan to generate code for your model, enable the **Minimize algebraic loop occurrences** parameter for all atomic subsystems. When possible, make sure that the input ports for the atomic subsystems are connected directly to non-direct-feedthrough blocks.
- Avoid combining non-direct-feedthrough and direct-feedthrough paths using the Bus Creator or Mux blocks. Simulink may not be able to eliminate any resulting artificial algebraic loops. Instead, consider clustering the non-direct-feedthrough and direct-feedthrough objects in separate subsystems.

Use Bus Selector blocks to pass only the required signals into atomic subsystems.

### Model Blocks and Direct Feedthrough

When a Model block is part of a cycle, and the block is a direct feed through block, an algebraic loop can result. An algebraic loop in a model is not necessarily an error, but it can give unexpected results. See:

- “Highlight Algebraic Loops in the Model” on page 3-46 for information about seeing algebraic loops graphically.
- “Display Algebraic Loop Information” on page 37-15 for information about tracing algebraic loops in the debugger.
- The “Model Configuration Parameters: Diagnostics” pane “Algebraic loop” option for information on detecting algebraic loops automatically.

### Direct Model Block Feedthrough Caused by Referenced Model Structure

A Model block can be a direct feed through block due to the structure of the referenced model. Where direct feed through results from sub model structure, and causes an unwanted algebraic loop, you can:

- Automatically eliminate the algebraic loop using techniques described in:
  - “Minimize algebraic loop”
  - “Minimize algebraic loop occurrences”
  - “Remove Algebraic Loops” on page 3-48
- Manually insert the number of Unit Delay blocks needed to break the algebraic loop.

## Direct Model Block Feedthrough Caused by Model Configuration

Generic Real Time (grt) and Embedded Real Time (ert) based targets provide the **Single output/update function** option on the **Configuration Parameters** dialog. This option controls whether generated code has separate output and update functions, or a combined output/update function. See:

- “Configure Generated C Function Interface for Model Entry-Point Functions” (Simulink Coder) for information about separate and combined output and update functions.
- “Single output/update function” (Simulink Coder) for information about specifying whether code has separate or combined functions.

When **Single output/update function** is enabled (default), a Model block has a combined output/update function. The function makes the block a direct feed through block for all inports, regardless of the structure of the referenced model. Where an unwanted algebraic loop results, you can:

- Disable **Single output/update function**. The code for the Model block then has separate output and update functions, eliminating the direct feed through and hence the algebraic loop.
- Manually insert one or more Unit Delay blocks as needed to break the algebraic loop.

## Changing Block Priorities When Using Algebraic Loop Solver

During the updating phase of simulation, Simulink determines the simulation execution order of block methods. This block invocation ordering is the execution order.

If you assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks, the algebraic loop solver does not honor these priorities when attempting to solve any algebraic loops.

## Use Model Name as Programmatic Interface

You can use the name of a model as a programmatic interface for executing a specified simulation phase and computing values for individual states and times that you specify.

This functionality is not intended for running a model step by step, simulating a model programmatically, or for debugging. For those purposes, consider these alternatives:

- To step through a simulation, use the **Step Forward** and **Step Back** buttons.

For more information, see “Use Simulation Stepper” on page 2-7.

- To simulate a model programmatically, use the `sim`, `parsim`, and `batchsim` functions.
- For low-level debugging, use the Simulink debugger.

## Model Requirements

This functionality ignores the effects of state transitions and conditional execution. Use this functionality only for models that implement simple dynamic systems. Such systems must meet these requirements:

- All states in the model must have built-in non-bus data types.

For more information about built-in data types, see “About Data Types in Simulink” on page 72-2.

- The model must contain a minimal amount of state logic, such as Stateflow charts and conditionally-executed subsystems.
- The model must contain only blocks from Simulink libraries. The model cannot contain S-functions or Simscape blocks.
- When you specify the state values as a vector, states in the model must have real double values.

Using this functionality for models that do not meet these requirements and models that use multitasking execution can produce unexpected results. For more information about multitasking and single task execution, see “Time-Based Scheduling and Code Generation” (Simulink Coder).

## Input Arguments

To use this functionality, you use the name of your model as though it were the name of a function. You always provide four inputs:

- `t` — Simulation time, specified as a real, double scalar.
- `x` — State values, specified as a vector of real double values or as a structure.

Specifying the states as a `Simulink.op.ModelOperatingPoint` object is not supported.

- `u` — Input data, specified as a vector of real, double values.
- `phase` — Simulation phase to execute, specified as one of these options:
  - `'sizes'` — Size computation phase, in which the software determines the sizes for the model input, output, and state vectors
  - `'compile'` — Compilation phase, in which the software propagates signal and sample time attributes

- 'update' — Update phase, in which the model computes the values of discrete states
- 'outputs' — Output phase, in which the model computes block and model output values
- 'derivs' — Derivatives phase, in which the model computes the derivatives for continuous states
- 'term' — Termination phase

The number, type, and dimensions of the output arguments depend on which simulation phase you execute.

When you use this functionality, you must manually execute each simulation phase in the appropriate order. For more information about how simulations run, see “Simulation Phases in Dynamic Systems” on page 3-2. This functionality is not meant to run a simulation step by step or as a replacement for the typical simulation workflow.

## Execute Size Computation Phase

To run the sizes phase, use this syntax, specifying [] for the first three input arguments.

```
[sys,x0,blks,st] = modelName([],[],[], 'sizes');
```

The sizes phase returns four output arguments:

- **sys** — System information, returned as a vector with seven elements:
  - **sys(1)** — Number of continuous states in the system
  - **sys(2)** — Number of discrete states in the system
  - **sys(3)** — Number of model outputs
  - **sys(4)** — Number of model inputs
  - **sys(5)** — Reserved
  - **sys(6)** — Direct feedthrough flag for system. A value of 1 indicates that the system has direct feedthrough. A value of 0 indicates that the system does not have direct feedthrough.
  - **sys(7)** — Number of continuous, discrete, fixed-in-minor-step, and controllable sample times in the system. The value at this index indicates the number of rows in the **ts** output.
- **x0** — Vector that contains the initial conditions for system states
- **blks** — Vector that contains the names of blocks associated with the system states. The order of elements in **blks** matches the order of elements in **x0**.
- **st** — *m*-by-2 array of sample time information for the system, where *m* is equal to the value of **sys(7)**. The first column of the array indicates the sample time and the second column indicates the offset. For more information about sample time, see “Types of Sample Time” on page 7-20.

## Execute Compilation Phase

To run the compilation phase, use this syntax, specifying [] for the first three input arguments.

```
[sys,x0,blks,st] = modelName([],[],[], 'compile');
```

The compilation phase returns the same four output arguments as the sizes phase:

- **sys** — System information, returned as a vector with seven elements:

- `sys(1)` — Number of continuous states in the system
- `sys(2)` — Number of discrete states in the system
- `sys(3)` — Number of model outputs
- `sys(4)` — Number of model inputs
- `sys(5)` — Reserved
- `sys(6)` — Direct feedthrough flag for system. A value of 1 indicates that the system has direct feedthrough. A value of 0 indicates that the system does not have direct feedthrough.
- `sys(7)` — Number of continuous, discrete, fixed-in-minor-step, and controllable sample times in the system. The value at this index indicates the number of rows in the `ts` output.
- `x0` — Vector that contains the initial conditions for system states
- `blks` — Vector that contains the names of blocks associated with the system states. The order of elements in `blks` matches the order of elements in `x0`.
- `st` —  $m$ -by-2 array of sample time information for the system, where  $m$  is equal to the value of `sys(7)`. The first column of the array indicates the sample time and the second column indicates the offset. For more information about sample time, see “Types of Sample Time” on page 7-20.

After running the compilation phase, you must run the termination phase before you can close the model.

## Compute Discrete State Values

To execute the update phase and compute the discrete state values, use this syntax. You specify the time at which you want to calculate the discrete states and the current state and input values to use in the computation.

```
dStates = modelName(x,u,t, 'update');
```

The update phase returns the discrete state values `dStates` as a structure or an array, depending on how you specify the current state values, `x`.

- When you specify `x` as empty (`[]`) or a structure, the update phase returns `dStates` as a structure that contains both discrete and continuous state values for all states with built-in data types.
- When you specify `x` as a vector or an array, the update phase returns `dStates` as a vector or an array that contains only the discrete state values for states that have real, double values.

## Compute Output Values

To compute the model outputs, use this syntax. You specify the time at which you want to calculate the discrete states and the current state and input values to use in the computation.

```
out = modelName(x,u,t, 'outputs');
```

## Compute Continuous State Derivatives

To compute the derivatives for continuous states, use this syntax. You specify the time at which you want to calculate the discrete states and the current state and input values to use in the computation.

```
derivs = modelName(x,u,t, 'derivs');
```

## Execute Termination Phase

When you are done analyzing the model behavior, use this syntax to execute the termination phase so you can close the model. Specify [] for the first three input arguments.

```
modelName([], [], [], 'term');
```

## Create Template from Model

Create a Simulink template from a model to reuse or share the settings and contents of the model without copying the model each time. Create templates only from models that do not have external file dependencies, for example, model references, data dictionary, scripts, S-functions, or other file dependencies. If you want to include other dependent files, use a project template instead. See “Using Templates to Create Standard Project Settings” on page 16-35.

- 1 In the model, on the **Simulation** tab, select **Save > Template**.
- 2 In the Export *modelName* to Model Template dialog box, edit the template title, select or create a group, and enter a description of the template.

The Simulink Start Page displays the title and description you specify and stores the template under the group you select, for example, *My Templates*.

- 3 In the **File location** box, specify a file name and location for the template SLTX file.

---

**Tip** Save the template on the MATLAB path to make it visible on the Simulink Start Page. If you save the template to a location that is not on the path, the new template is visible on the Start Page only in the current MATLAB session. Saving the template does not add the destination folder to the path.

---

- 4 Optionally, specify a thumbnail image for the template, click **Change**, then select an image file.
- 5 Click **Export**.

## Edit a Template

To edit a model file template, open the template from the **Current Folder** or from the Simulink Start Page. Make the desired changes.

- 1 Open the template for editing.
  - From the **Current Folder**, navigate to the template (\*.sltx). Right-click the template and select **Open Template for Editing**.
  - From the Simulink Start Page, point to the template and click the arrow to see the template information. On the **Create** button, click the arrow and select **Edit Template**.
- 2 Make the changes you want.
- 3 You can also edit the template properties.
  - For a model template, on the **Simulation** tab, click **Template Properties**.
  - For a subsystem template, on the **Subsystem** tab, click **Template Properties**.
  - For a library template, on the **Library** tab, click **Template Properties**.
- 4 Save the template for your changes to take effect.

## Describe Models Using Notes and Annotations

You can describe your model with notes and annotations to help others to understand it. You can add notes to any system in the model hierarchy by entering text, showing website content, or inheriting note content from the parent system. For each system, you can also choose not to show any notes.

Annotations are visual elements that you can use to add descriptive notes and callouts to your model. You can also add annotations that perform an action when you click them.

Text annotations can contain any combination of:

- Text
- Images
- Equations using LaTeX and MathML commands
- Hyperlinks that open a website or perform MATLAB functions

Also, you can create an image annotation.

### Create, Edit, and Read Notes

In the Simulink Toolstrip, on the **Modeling** tab, click **Notes**. The **Notes** pane opens. As you navigate the hierarchy, notes for each system appear. If the model does not have notes, the pane includes instructions to get started.

To add notes:

- 1** In the **Notes** pane, click **Create a notes file**.

Notes are stored in a file with the extension `.mldatx`. If you want your model to have notes, first create the notes file. After you create the file, the notes you add are saved automatically.

The `.mldatx` file is saved separate from the model. If you move your model to a different folder, the `.mldatx` file does not also move, but the association remains if the file is on the MATLAB path.

- 2** Enter a name for the notes file, or use the default name, and click **Save**.

You can have multiple notes files associated with the same model, for example, for users with different roles. The person using the model can then select among notes files. Notes files contain the model name and version information to ensure the notes file and model match.

- 3** The **Notes** pane is in editing mode. You can add notes in these ways:

- Enter text in the text editor.
- From the menu, select **Use URL for Notes** and enter a URL whose content you want to use as notes for the current system.
- Navigate to a different system in the model and use the menu to select whether to enter text, use a URL, or show parent notes.
- Select **No Notes**.

- 4 When you have finished adding and editing, click the **Read Notes** button  to toggle the notes to reading mode.

Use the **Read Notes** or **Edit Notes** button  to switch between the reading and editing modes. When you click **Edit Notes**, the editing features are enabled. When you click **Read Notes**, the editing features are not available, and the notes display in read-only format. As you navigate the model, the **Notes** pane updates with the content for the current system.

## Create Text Annotations

To create a text annotation, use one of these options:

- Double-click the canvas where you want to create the annotation and select **Create Annotation** from the menu.
- Click the annotation box  on the Simulink Editor palette and then click the canvas.
- Drag the annotation box  on the Simulink Editor palette to the canvas.
- Drag text from another application to the canvas.
- Paste text from the clipboard. Right-click the canvas and select **Paste**.

When you edit the text annotation, you can:

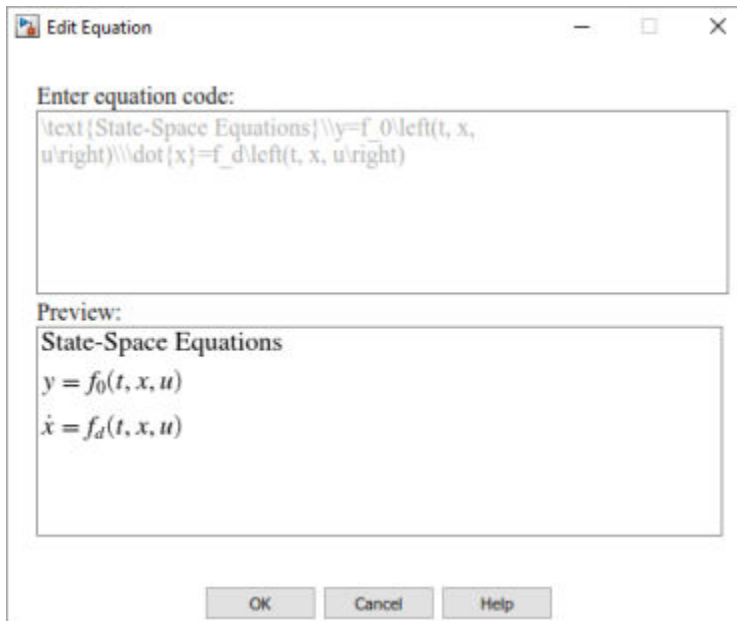

- Apply formatting changes to text or insert an image, table, or equation using the formatting toolbar.
- Apply additional formatting by right-clicking the annotation and selecting **Paragraph** from the context menu. For example, you can create bulleted and numbered lists from this menu.
- Add hyperlinks using the context menu. You can use hyperlinks to open a website or make an annotation interactive by using MATLAB commands.
- Apply properties using the Property Inspector. To view the Property Inspector, in the **Modeling** tab, under **Design**, click **Property Inspector**.

## Add Equations to Annotations

You can add equations to your annotation by clicking the **Insert Equation** button in the annotation formatting toolbar.

In the Edit Equation dialog box, enter LaTeX or MathML code to generate equations. For supported LaTeX commands, see “Insert LaTeX Equation”.

To edit equation code, double-click the equation in the annotation. You can format equations in annotations by using the formatting toolbar. You can change the font color, text highlight color, font size, and location of equations in annotations.

You can also type TeX formatting commands directly into the text of an annotation for mathematical and other symbols and Greek letters.

- 1 Add supported TeX commands to your annotation. For example, add this text:

```
\sigma \kappa \mu
```

- 2 With the annotation selected, or with the text cursor in the annotation, in the Property Inspector, under **Appearance**, select **Enable TeX commands**.

When you click outside the annotation, the TeX commands appear as symbols in the annotation.

The table shows the TeX characters that you can type directly into the text of a Simulink annotation.

Supported TeX Characters		
alpha	forall	supseteq
beta	exists	supset
gamma	ast	subseteq
delta	cong	subset
epsilon	sim	int
zeta	leq	in
eta	infty	o
theta	clubsuit	copyright
vartheta	diamondsuit	0
iota	heartsuit	ldots
kappa	spadesuit	varpi
lambda	leftarrow	times
mu	uparrow	cdot
nu	rightarrow	vee
xi	downarrow	wedge
pi	circ	perp
rho	pm	mid
sigma	geq	Leftarrow
varsigma	propto	Rightarrow
tau	partial	Uparrow
upsilon	bullet	Downarrow
phi	div	prime
chi	neq	nabla
psi	equiv	surd
omega	approx	angle
Gamma	aleph	neg
Delta	Im	lceil
Theta	Re	rceil

Supported TeX Characters		
Lambda	otimes	lfloor
Xi	oplus	rfloor
Pi	oslash	langle
Sigma	cap	rangle
Upsilon	cup	
Phi		
Psi		
Omega		

## Create Image Annotations

When you want to resize or move an image independently from text, create an image annotation. For example, you can size and position your company logo at a particular location in the model. To add an annotation that contains an image, drag an image from your local file system to the Simulink Editor canvas.

---

**Tip** To include an image such as a logo in every new model, add the image to your default template. See “Create Template from Model” on page 4-2.

---

Alternatively, you can drag an **Image** box  from the palette onto the canvas. Then you can either:

- Double-click the image box and browse to an image.
- Paste an image from the clipboard. Right-click the image box and select **Paste Image**.

---

**Tip** If you resize an image, you can reset it to its original size. Right-click the image and select **Format > Restore Size**.

---

## Resize Annotations

An annotation resizes as you enter content. You can also resize an annotation by dragging the corners. To resize proportionally, press **Shift** as you drag.

After you resize an annotation, the annotation stays that size until you resize it again, regardless of the content size. To revert to the original height or width of the annotation, in the Property Inspector, under **Appearance**, clear the **Fixed height** or **Fixed width** check box.

## Associate Annotations with Blocks and Areas

You can add a line between an annotation and a block or area in a model. These annotation connectors attach dynamically at both ends, so that they move and resize as necessary to maintain the connection.

- 1 Place the cursor over the annotation outline where you want the line to start.

- 2 When the cursor is a crosshair, drag the line to the block or area where you want the line to end.

---

**Tip** To specify the color or width of an annotation connector, right-click the connector and use the **Format** menu.

---

## Hide Annotations

By default, all annotations appear in the model. To hide an annotation, first configure it for hiding by converting it to markup. Then, in the **Format** tab, click **Show Markup**.

You can configure an annotation so that you can hide or display it.

- 1 Right-click the annotation.
- 2 From the context menu, select **Convert to Markup**.

A markup annotation has a light-blue background, regardless of the background color you set. If you change a markup annotation to a regular annotation, the annotation returns to the background color you set.

To change a markup annotation to a regular annotation (one that you cannot hide), right-click the annotation and select **Convert to Annotation**.

To hide all markup annotations, in the **Format** tab, disable **Show Markup**.

To display hidden markup annotations, in the **Format** tab, enable **Show Markup**.

---

**Note** In a model reference hierarchy, **Show Markup** and **Hide Markup** apply only to the current model reference level.

---

## Make Annotations Interactive

To make an annotation interactive, use a hyperlink on any content in a text annotation.

- 1 In the annotation, select the content that you want to make interactive.
- 2 Right-click and select **Hyperlink** from the context menu.
- 3 In the Hyperlink dialog box, either:
  - Select **URL Address** and enter the web address in the **Code** box.
  - Select **MATLAB Code** and enter MATLAB functions in the **Code** box.
- 4 Click **OK**.

Alternatively, you can associate these callback functions with text or image annotations.

<b>Annotati on Callback Function</b>	<b>Description</b>
Click Function	<p>A click function is a MATLAB function that Simulink invokes when you click an annotation.</p> <p>To associate a click function with an annotation:</p> <ol style="list-style-type: none"> <li>1 Open the Annotation Properties dialog box. Right-click the annotation and select <b>Properties</b>.</li> <li>2 On the <b>ClickFcn</b> tab, use one of these options:                             <ul style="list-style-type: none"> <li>• In the text box under <b>ClickFcn</b>, enter the MATLAB code that defines the click function.</li> <li>• Use the annotation text as the click function. Select the <b>Use annotation text as click callback</b> check box.</li> </ul> </li> <li>3 Click <b>OK</b>.</li> </ol> <p>The text for annotations associated with a click function appears in blue.</p> <p>If you associate an annotation with a click function, clicking invokes the function rather than selecting the annotation. To select it instead, drag a selection box around it. To edit it, right-click it and select <b>Edit Text</b> or <b>Properties</b>.</p>
Load Function	<p>A load function is a MATLAB function that Simulink invokes when you load the model that contains the associated annotation.</p> <p>To associate a load function with an annotation, programmatically set the <b>LoadFcn</b> property of the <b>Simulink.Annotation</b> object to the desired function.</p>

<b>Annotati on Callback Function</b>	<b>Description</b>
Delete Function	A delete function is a MATLAB function that Simulink invokes before you delete an annotation.  To associate a delete function with an annotation, programmatically set the <code>DeleteFcn</code> property of the <code>Simulink.Annotation</code> object to the desired function.

`Simulink.Annotation`

## Related Examples

- “Create and Edit Annotations Programmatically” on page 4-12

## Create and Edit Annotations Programmatically

Annotations are visual elements that you can use to add descriptive notes and callouts to your model. In addition to text-only annotations, you can create annotations that:

- Open websites
- Perform MATLAB commands
- Display images
- Visually differentiate areas of block diagrams

The following examples show how to programmatically create, edit, and delete annotations.

### Create Annotation Programmatically

Programmatically create, modify, and view an annotation.

Open a new model.

```
open_system(new_system)
```

Create an annotation with default properties using the `Simulink.Annotation` function.

```
a = Simulink.Annotation(gcs, 'This is an annotation.');
```

After creating the annotation, use dot notation to set property values. For example, apply an 18-point font and light blue background to the annotation.

```
a.FontSize = 18;  
a.BackgroundColor = 'lightBlue';
```

To view and briefly highlight the new annotation, use the `view` function.

```
view(a)
```

### Programmatically Find and Modify Existing Annotations

Programmatically find and modify the properties of an annotation.

Open the `vdp` model.

```
vdp
```

To find the annotations in the model, use the `find_system` function.

```
h = find_system(gcs, 'FindAll', 'on', 'Type', 'annotation');
```

To identify the annotations, query the text inside the annotations by using the `get_param` function.

```
get_param(h, 'PlainText')  
  
ans = 2x1 cell  
    {'Copyright 2004-2020 The MathWorks, Inc.'}
```

```
{'van der Pol Equation' }
```

Suppose you want to apply a light blue background color to the 'van der Pol Equation' annotation.

Get the `Simulink.Annotation` object by specifying the corresponding index of the array.

```
a = get_param(h(2), 'Object');
```

Use dot notation to set the value of the `BackgroundColor` property.

```
a.BackgroundColor = 'lightBlue';
```

## Delete Annotation

Programmatically delete an annotation.

Open the vdp model.

```
vdp
```

To get the handles for the annotations in the model, use the `find_system` function.

```
h = find_system(gcs, 'FindAll', 'on', 'Type', 'annotation');
```

To identify the annotations, query the text inside the annotations.

```
get_param(h, 'PlainText')
ans = 2x1 cell
    {'Copyright 2004-2020 The MathWorks, Inc.'}
    {'van der Pol Equation' }
```

To delete the title of the model ('van der Pol Equation'), get the `Simulink.Annotation` object that corresponds to the second handle.

```
a = get_param(h(2), 'Object');
```

Delete the annotation from the model.

```
delete(a)
```

## Create Annotations That Contain Hyperlinks

For rich-text annotations, you can use HTML formatting to add a hyperlink to text within the annotation.

Open a new model.

```
open_system(new_system)
```

Create two annotations, moving one of the annotations so that it does not overlap the other.

```
a1 = Simulink.Annotation(gcs, 'This is an annotation.');
```

```
a2 = Simulink.Annotation(gcs, 'This is another annotation.');
```

```
a2.Position = [0 20 28 34];
```

To create a hyperlink in the annotation, set `Interpreter` to `'rich'` and define the hyperlink in the `Text` property.

```
a1.Interpreter = 'rich';
```

```
a1.Text = 'Go to <a href="www.mathworks.com">www.mathworks.com</a>.';
```

You can also embed MATLAB functions in the hyperlink.

```
a2.Interpreter = 'rich';
```

```
a2.Text = '<a href="matlab:magic(4)">Generate magic square</a>.';
```

For more information, see “Create Hyperlinks that Run Functions”.

## Add Image to Model

Add an image to your model, such as a logo, by creating an image-only annotation.

Open a new model and create an annotation in it.

```
open_system(new_system)
```

```
a = Simulink.Annotation(gcs, 'This is an annotation.');
```

Change the annotation to display only the specified image.

```
img = fullfile(matlabroot, 'toolbox', 'matlab', 'imagesci', 'peppers.png');
```

```
setImage(a, img)
```

## Create Area Programmatically

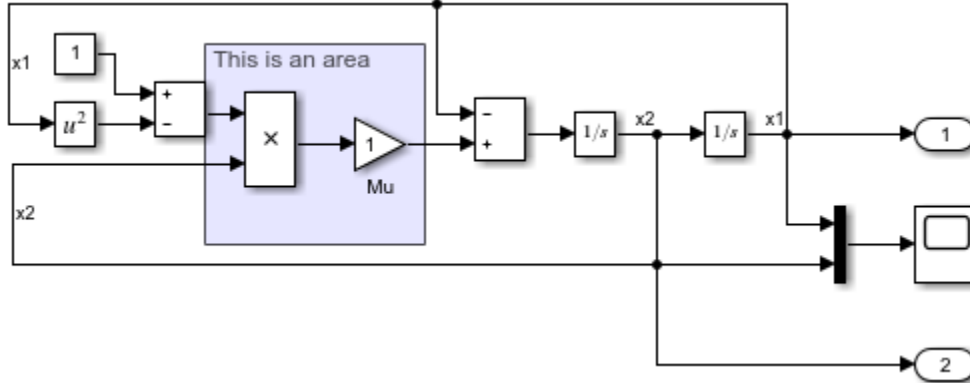

Create an area annotation in a model.

Open the `vdp` model.

```
open_system('vdp')
```

Create an area that includes some of the blocks in the model.

```
add_block('built-in/Area', 'vdp/This is an area', 'Position', [120, 100, 230, 200])
```

## Create and Hide Markup Annotation

To create annotations that can be easily hidden, create markup annotations.

Open a new model.

```
open_system(new_system)
```

Create two annotations, and move the second annotation so that it does not overlap the first annotation.

```
a1 = Simulink.Annotation(gcs, 'This is a model annotation. ');
a2 = Simulink.Annotation(gcs, 'This is a markup annotation. ');
a2.Position = [0 20 28 34];
```

By default, you create model annotations, which appear in the model.

Change the second annotation to a markup annotation.

```
a2.MarkupType = 'markup';
```

Configure the current model to hide markup annotations.

```
set_param(gcs, 'ShowMarkup', 'off');
```

Both annotations remain, despite the markup annotation being hidden.

```
ah = find_system(gcs, 'FindAll', 'on', 'Type', 'annotation');
at = get_param(ah, 'Text')
```

```
at = 2x1 cell
    {'This is a markup annotation.'}
    {'This is a model annotation.' }
```

## Find Annotation Executing Callback Function

If an annotation invoked a currently executing callback function, use the `getCallbackAnnotation` to determine which annotation invoked it. The function returns the corresponding Annotation

object. This function is also useful if you write a callback function in a separate MATLAB file that contains multiple callback calls.

## Create Subsystems

As a model increases in size and complexity, you can simplify it by grouping blocks into subsystems. A subsystem is a set of blocks that you group into a single Subsystem block.

Using subsystems:

- Establishes a hierarchical block diagram where a Subsystem block is on one layer and the blocks that make up the subsystem are on another.
- Keeps functionally related blocks together.
- Helps reduce the number of blocks displayed in your model window.
- Establishes an interface with inputs and outputs.

When you make a copy of a subsystem, that copy is independent of the source subsystem. To reuse the contents of a subsystem across a model or across models, consider referenced subsystems, referenced models, or subsystems linked to a block in a custom library. For more information, see “Choose Among Types of Model Components” on page 23-4.

### Types of Subsystems

A subsystem can be virtual or nonvirtual. A virtual subsystem provides graphical hierarchy in a model. A nonvirtual subsystem provides graphical hierarchy and executes as a unit within a model.

---

**Tip** For controllers and other standalone components, define a hard boundary around the related blocks by using a nonvirtual subsystem or referenced model. Defining a hard boundary upfront avoids costly refactoring when you want to generate code for the component.

---

Simulink classifies nonvirtual subsystems into these types:

Type of Subsystem	Description
Atomic Subsystem	Subsystem that executes as a single unit.
Enabled Subsystem	Subsystem whose execution is enabled by external input.
Triggered Subsystem	Subsystem whose execution is triggered by external input.
Function-Call Subsystem	Subsystem whose execution is controlled by an external function-call input.
Enabled and Triggered Subsystem	Subsystem whose execution is enabled and triggered by external inputs.
Message Triggered Subsystem and Message Polling Subsystem	Subsystem whose execution is triggered by message input.
Resettable Subsystem	Subsystem whose block states reset with an external trigger.
If Action Subsystem	Subsystem whose execution is enabled by an If block.

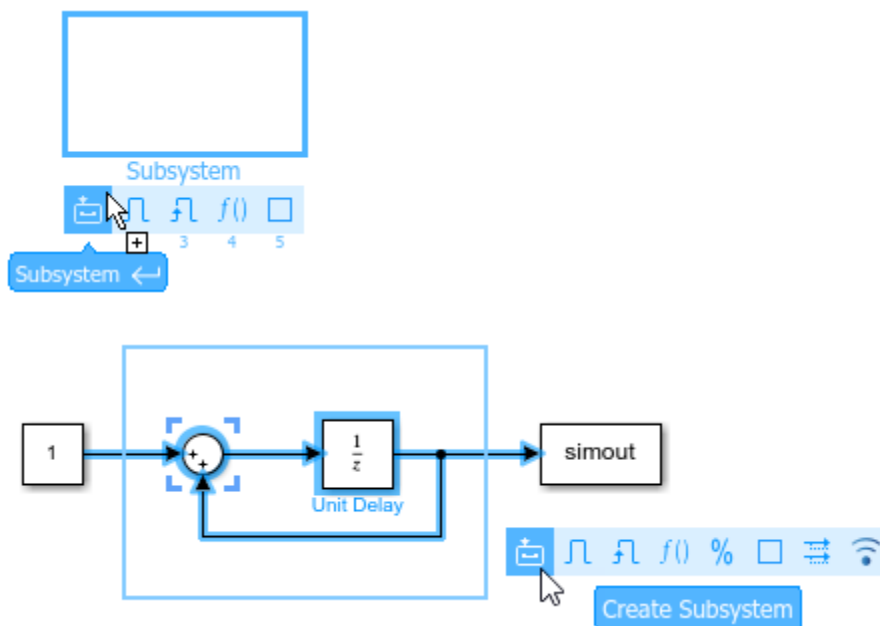

Type of Subsystem	Description
Switch Case Action Subsystem	Subsystem whose execution is controlled by a Switch Case block.
While Iterator Subsystem	Subsystem that repeats execution during a simulation time step while a logical condition is true.
For Iterator Subsystem	Subsystem that repeats execution during a simulation time step for a specified number of iterations.
For Each Subsystem	Subsystem that repeats execution on each element or subarray of input signal and concatenates results.

## Create Subsystems

To create a subsystem, you can:

- In the Simulink Editor, double-click and start typing the subsystem type, then select the corresponding block from the menu.
- In the Simulink Editor, drag a selection box to outline the subsystem that you want to create, then select the subsystem type.
- Drag a Subsystem block from the Library Browser.
- Copy and paste a Subsystem block from a model.

When you create a subsystem from a selection box, the selection can be empty or can contain multiple blocks in one area of the model.

From the action bar, select the type of subsystem that you want to create.

When the selection contains blocks that correspond to input and output ports, the new subsystem includes copies of those blocks. The new subsystem does not contain copies of blocks that correspond to control ports.

You can change the type of subsystem after creation.

- To make a subsystem execute as a unit, click the Subsystem block. On the **Subsystem** tab, select **Is Atomic Subsystem**.
- To make a subsystem execute conditionally, add a block that corresponds to a control port.
- To make a subsystem execute unconditionally, remove blocks that correspond to control ports.

---

**Note** If you no longer want to use a subsystem, you can replace the subsystem with its contents. For more information, see “Expand Subsystem Contents” on page 4-25.

---

## Add Ports to Subsystems

The ports on a Subsystem block correspond to blocks inside the subsystem.

For example, this Subsystem block has two input ports and one output port.

The subsystem contains two Inport blocks, In1 and In2, and one Outport block, Out1, that correspond to the ports on the Subsystem block.

To automatically add ports to a Subsystem block:

- Click the edge of the Subsystem block, then select the type of port to create.

- Drag a line to the edge of the Subsystem block.

- The corresponding port blocks are added inside the subsystem.

**Tip** After automatic port creation, the port label on the Subsystem block is enabled for quick editing. See, “Edit Port Labels on Subsystems” on page 4-21.

To manually add ports, open the subsystem by double-clicking the Subsystem block, then add the corresponding blocks to the subsystem.

Type of Port	Corresponding Block
Signal port, input	Inport block
Signal port, output	Outport block
Bus port, input	In Bus Element block
Bus port, output	Out Bus Element block
Control port, enabled	Enable block
Control port, triggered	Trigger block
Control port, function-call	Trigger block with <b>Trigger type</b> set to function-call
Control port, reset	Reset block
Control port, action	Action Port block
Connection port	Connection Port block

To change the location of a port on a Subsystem block, drag the port to a new location on any side of the Subsystem block.

By default, Simulink labels the ports on a Subsystem block. To specify how Simulink labels the ports of a subsystem:

- 1 Select the Subsystem block.
- 2 On the **Format** tab of the Simulink Toolstrip, select one of the labeling options from the **Port Labels** menu. For more information, see **Show port labels**.

## Edit Port Labels on Subsystems

You can directly edit the port labels on these types of subsystem blocks:

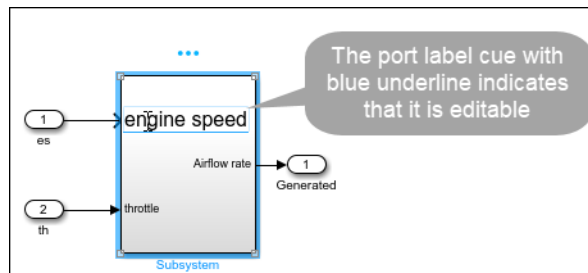

- Regular subsystem
- Subsystem with mask
- Variant subsystem
- Chart subsystem

To edit the port label on a subsystem block in the current model:

- 1 Point to the port label. An interactive *port label cue* (blue box surrounding the port label) appears. Click the cue.

Alternatively, select the port and press **F2**. The cue enters edit mode.

Creating a new port on a Subsystem block using automatic port creation also enables the port label cue for quick editing.

- 2 A *port selector cue* appears above the port label cue to indicate the port label information (port block name, signal name, bus port, or connection port) that is being edited. For signal ports, you can edit both the port block name and the port signal name from the port label. To switch between the values, click the respective icon in the selector cue or use the keyboard shortcuts **Ctrl+1,2**.
- 3 Enter a value in the port label cue and press **Enter** or **Esc**, or click away.

- 4 After the port label is edited, Simulink automatically updates the name of the related port or signal within the subsystem.

**Tip** To make successive port label edits on a subsystem block:

- Select a port on the block.
- Edit the port label and press **Enter**. This action enables keyboard selection of ports.
- You can select adjacent ports using the up arrow or down arrow key and pressing **F2** for quick editing.

This table lists the update action depending on the type of port label defined on the subsystem block.

Type of port label	Action
None	Editing not supported.

Type of port label	Action
Port icon	<p>Updates the names of elements in the subsystem depending on the <b>Icon display</b> parameter of the port.</p> <p>For example, if the value of the <b>Icon display</b> parameter of the port is <b>Signal name</b>, then both the icon on the port block and the name of the linked signal are updated.</p> <hr/> <p><b>Note</b> For this type of port label, the information shown on the port label after an edit depends on the final edit performed on the label using the selector cue:</p> <ul style="list-style-type: none"> <li>• If the initial port label shows the port block name, and the final edit is on the signal name, then the <b>Icon display</b> parameter for the underlying port block automatically updates to <b>Signal name</b>. So, after the edit, the port label shows the signal name by default.</li> <li>• If the initial port label shows the port signal name, and the final edit is on the port block name, then the <b>Icon display</b> parameter for the underlying port block automatically updates to <b>Port number</b>. So, after the edit, the port label shows the block name by default.</li> </ul>
Port block name	Updates the block name of the port in the subsystem. For this type of port label, you can edit only the port block name using the port selector cue.
Signal name	Updates the name of the signal linked to the port.

### Note

- Simulink does not show the port selector cue for Chart blocks.
- Editing port labels on Subsystem blocks with a mask icon is not supported.
- Editing port numbers from the port label is not supported. You can still edit the port block name and signal name using the port label cue.
- Editing name of propagated signals from the port label is not supported. You can still edit the port block name and internal signal name using the port label cue. When you click the cue, the port signal name field is empty because the internal signal does not have a name.

Subsystem port labels show the name of propagated signals when all these conditions are true:

- The value of the **Icon display** parameter for the underlying port block is `Signal name`.
  - The internal signal within the subsystem is connected but does not have a name.
  - The propagated signal has a name.
- 

### Configure Subsystems

You can change the name of the Subsystem block and modify the block the way that you do with any other block. For example, you can:

- Apply block masks to hide the subsystem content, making it appear as an atomic block with its own icon and parameter dialog box. For more information, see “Masking Fundamentals” on page 42-2.
- Use block callbacks to perform actions in response to subsystem modeling actions such as handling an error, deleting a block or line in a subsystem, or closing a subsystem. For more information on block properties, such as callbacks, see “Specify Block Properties” on page 39-4.

### Restrict Subsystem Access

The **Read/Write permissions** parameter of a Subsystem block controls the level of access allowed for the subsystem.

---

**Note** Restricting read or write access does not prevent the access restrictions from being changed. To hide proprietary information, consider using a protected model. For more information, see “Explore Protected Model Capabilities”.

---

When a subsystem is stored in a custom library, you can use the **Read/Write permissions** parameter on the parent library block to control access for the linked instances of the block. As long as the library link remains intact, the restricted access can prevent people from viewing or modifying the contents of the subsystem while still allowing them to employ it in a model. For more information, see “Linked Blocks” on page 44-12.

### More About

- “Navigate Model Hierarchies” on page 4-29
- “Expand Subsystem Contents” on page 4-25
- “Conditionally Executed Subsystems Overview” on page 10-3

## Expand Subsystem Contents

To move the contents of a subsystem into the containing system, you can expand the subsystem.

For example, the `sldemo_enginewc` model includes the Combustion subsystem.

After you expand the Combustion subsystem, the top level of the `sldemo_enginewc` model includes the blocks and signals of the Combustion subsystem. The expansion removes the Subsystem block and the Inport and Outport blocks.

## Why Expand a Subsystem?

Expand a subsystem if you want to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expanding a subsystem is useful when refactoring a model. Flattening a model hierarchy can be the end result, or just one step in refactoring. For example, you could pull a set of blocks up to the parent system by expanding the subsystem, deselect the blocks that you want to leave in the parent, and then create a subsystem from the remaining selected blocks.

## What Subsystems Can You Expand?

You can expand virtual subsystems that are not masked, linked, or commented. If you try to expand a masked, linked, or commented subsystem using the Simulink Editor, a message gives you the option of having Simulink modify the subsystem so that you can then expand it.

Kind of Subsystem	Modification
Masked subsystem	Removes all masking information
Library links	Breaks the link
Commented-out subsystem	Uncomments the subsystem

You cannot expand these subsystems:

- Atomic subsystems
- Conditional subsystems
- Configurable subsystems
- Variant subsystems
- Subsystems with the **Read/Write permissions** parameter set to ReadOnly or NoReadOrWrite
- Subsystems with an InitFcn, StartFcn, PauseFcn, ContinueFcn, or StopFcn callback
- Subsystems with linked requirements (using Requirements Toolbox™ software)

## Expand a Subsystem

To interactively expand a subsystem, right-click a Subsystem block and, from the context menu, select **Subsystem & Model Reference > Expand Subsystem**.

To programmatically expand a subsystem, use the `Simulink.BlockDiagram.expandSubsystem` function.

---

**Tip** Subsystem expansion applies to the currently selected subsystem level. Simulink does not expand other subsystems in a nested subsystem hierarchy.

To improve readability when you expand nested subsystems, start by expanding the highest-level subsystem that you want to expand, and then work your way down the hierarchy as far as you want to expand.

---

## Results of Expanding a Subsystem

When you expand a subsystem, Simulink:

- Removes the Subsystem block
- Removes the root Inport, root Outport, and Simscape Connection Port blocks that were in the subsystem
- Connects the signal lines that went to the input and output ports of the subsystem directly to the ports of the blocks in the model that connected to the subsystem
- Distributes blocks and routes signals for readability.

### Block Paths

The paths for blocks that were in the subsystem that you expanded change. After expansion, update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

### Signal Names and Properties

If you expand a subsystem with a missing connection on the outside or inside of the subsystem, Simulink keeps the line labels, but uses the signal name and properties from just one of the lines. For lines corresponding to:

- A subsystem input port, Simulink uses the signal name and properties from the signal in the system in which the subsystem exists
- A subsystem output port, Simulink uses the signal name and properties from the subsystem

### Display Layers

The display layers of blocks (in other words, which blocks appear in front or in back for overlapping blocks) does not change after expansion. Blocks in front of the Subsystem block remain above the expanded contents, and blocks below the Subsystem block remain under the expanded contents.

### **Execution Order and Block Priorities**

When you compile a model, Simulink sorts the blocks in terms of the order of block execution. Expanding a subsystem can change block path names, which, in rare cases, can impact the block execution order.

If you explicitly set block execution order by setting block priorities within a subsystem, Simulink removes those block priority settings when you expand that subsystem.

### **Data Stores**

Expanding a subsystem that contains a Data Store Memory block that other subsystems read from or write to can change the required data store write and read sequence. You may need to restructure your model. For details, see “Order Data Store Access” on page 78-19.

### **See Also**

#### **More About**

- “Types of Subsystems” on page 4-17
- “Create Subsystems” on page 4-17
- “Navigate Model Hierarchies” on page 4-29

## Navigate Model Hierarchies

Model components, such as subsystems and referenced models, allow you to create a hierarchical model composed of many layers. You can navigate this hierarchy by opening model components in the current tab, new tabs, and new windows.

For information on the types of model components, see “Choose Among Types of Model Components” on page 23-4.

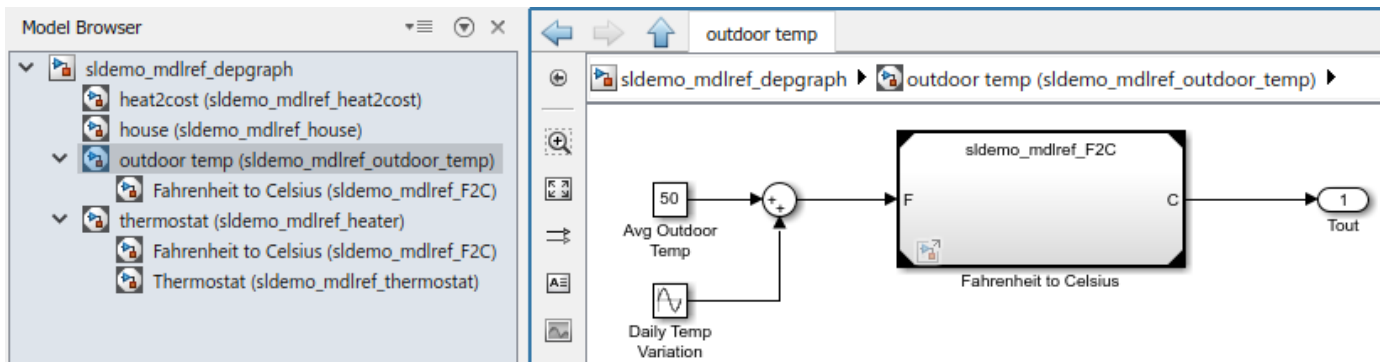

### Open Model Component in Current Tab

To navigate among model components in the current tab, perform any of these actions:

- Double-click a block that corresponds to a model component in the Simulink Editor. For example, double-click a Subsystem or Model block.
- Click a block name in the Model Browser.

To open the Model Browser, click the **Hide/Show Model Browser** button  at the bottom left corner of the window. Expand a node to see the children of a component.

- In the explorer bar that appears above the Simulink Editor canvas, click the name of a component.
- Use the **Back**, **Forward**, and **Up to Parent** arrows  .

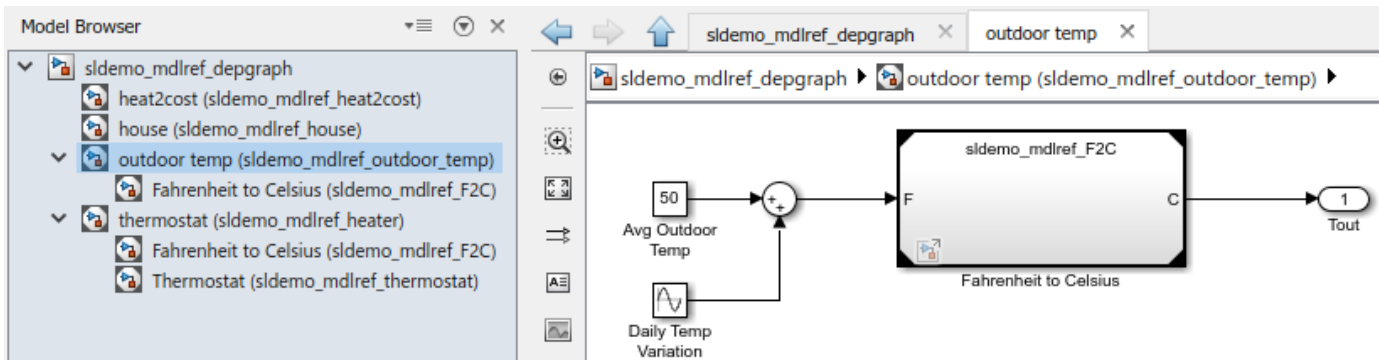

The address bar provides the path from the top model in the hierarchy to the component you have open. In this example, the address bar shows the top model (sldemo\_mdhref\_depgraph) followed by the Model block (outdoor temp) and its referenced model (sldemo\_mdhref\_outdoor\_temp).

When you navigate up to a parent subsystem or model, the model component from which you navigated is highlighted.

### Open Model Component in New Tab

To open a model component in a new tab, press **Ctrl** while double-clicking the block or clicking the node in the Model Browser. Alternatively, right-click the block in the Simulink Editor or the block name in the Model Browser. Then, select **Open In New Tab**.

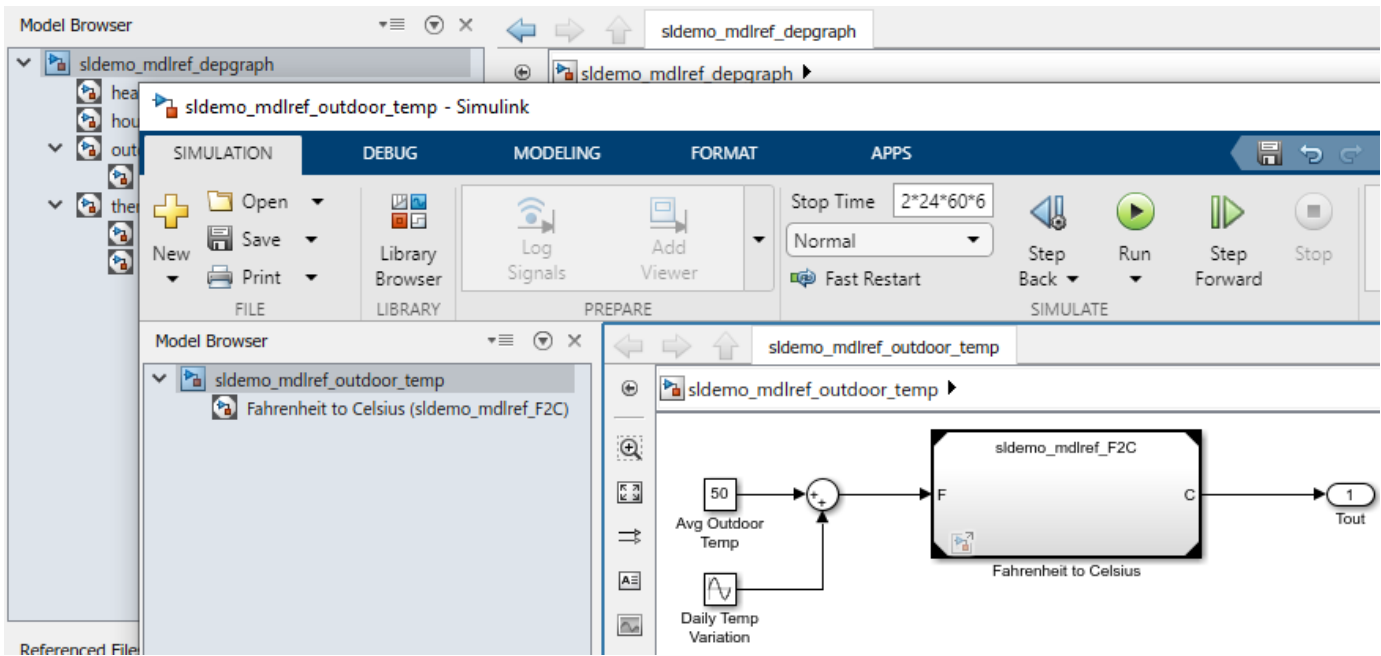

### Open Model Component in New Window

To open a model component in a new window, press **Shift** while double-clicking the block or clicking the node in the Model Browser. Alternatively, right-click the block in the Simulink Editor or the block name in the Model Browser. Then, select **Open In New Window**.

### Open Referenced Model as Top Model in New Window

To open a referenced model as a top model in a new window, click the **Open As Top Model** badge on the Model block. To open a referenced model that does not have a visible Model block, right-click the block name in the Model Browser, and select **Open As Top Model**.

The top model in the new window is `sldemo_mdref_outdoor_temp`, not `sldemo_mdref_depgraph`. The Model Browser shows the models in the current model hierarchy.

When you select **Run** in the toolstrip, the `sldemo_mdref_outdoor_temp` model hierarchy simulates.

When you edit the `sldemo_mdref_outdoor_temp` model, the changes affect the same model file regardless of whether the model is open as a referenced model or top model.

- “Component-Based Modeling Guidelines” on page 23-2

## Subsystem Reference

Subsystem reference allows you to save the contents of a subsystem in a separate file and reference it using a Subsystem Reference block. You can create multiple instances referencing the same subsystem file. When you edit any instance of a referenced subsystem, the changes are saved in the separate file in which the subsystem is stored and all the referenced instances of that file are synchronized.

---

**Note** Subsystem reference is compatible with SLX and MDL file formats.

---

When you save a subsystem to a separate file you can reuse it multiple times by using **Subsystem Reference** blocks referencing the same subsystem file.

You can identify a Subsystem Reference block by the triangles in the opposite corners of the block icon.

A referenced subsystem supports all the semantics of a regular subsystem. A referenced subsystem adapts itself to the context of the parent model and has identical execution behavior when compared to a nonreferenced subsystem.

### Create a Subsystem Block Diagram

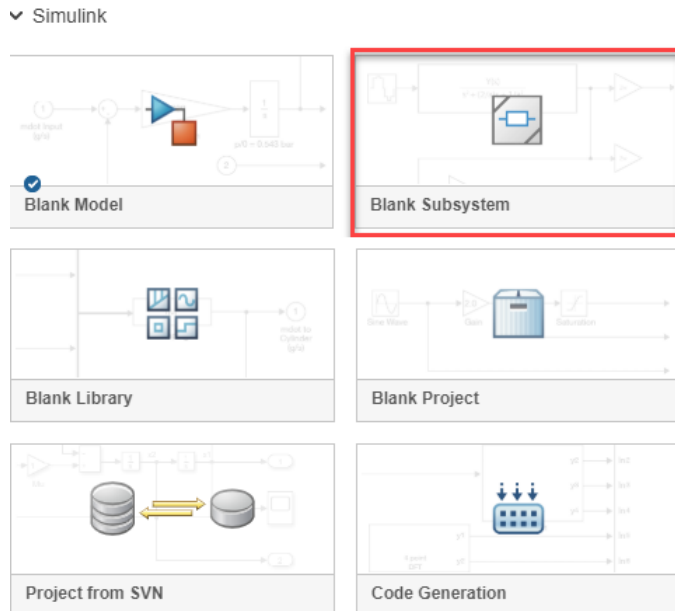

A subsystem file stores the content of a subsystem block diagram in a file.

A subsystem file:

- Cannot be simulated.
- Does not have a full configuration set.
- Does not have a model workspace.
- Does not have code generation capability.

To create a subsystem block diagram:

- 1 Open Simulink.
- 2 On the Start Page, in the Simulink product group, click **Blank Subsystem**.

Alternatively, in the Simulink toolstrip, on the **Simulation** tab, select **New** and click **Blank Subsystem**. A Subsystem window opens.

- 3 Add content and click **Save** .
- 4 Specify a file name in the **Save As** dialog box. The file name must be a valid MATLAB name.

This creates a new subsystem file at the location specified.

To create a subsystem file programmatically, use the command:

```
new_system(subsystemfilename, 'subsystem')
```

Once you create the subsystem file programmatically, it appears in the MATLAB File Browser as:

For more information on controlling subsystem files programmatically, see “Control Referenced Subsystem Programmatically” on page 4-38.

## Reference a Subsystem File in a Model

- 1 Open a model in which you want to reference a subsystem block diagram.
- 2 Add a Subsystem Reference block using the Simulink Library Browser or the Quick Block Insert menu. An empty Subsystem Reference block is added to the Simulink canvas.
- 3 In the Simulink toolstrip, on the **Referenced Subsystem** tab, specify the name of the subsystem block diagram file in the **File Name** field, or click **Browse** to navigate to it.

Alternatively, you can double-click the **Subsystem Reference** block to specify the subsystem block diagram file.

- 4 Click **OK** to save the changes.

## Convert an Existing Subsystem to a Referenced Subsystem

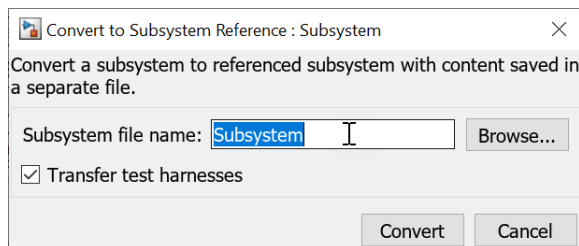

You can convert an existing Subsystem block to a Subsystem Reference block.

Consider a model with two Subsystem blocks as shown.

In this model, you have two Subsystem blocks - a Controller subsystem and a Plant subsystem. To convert the Controller Subsystem block to a referenced subsystem:

- 1 Select the Controller Subsystem block and on the **Subsystem Block** tab, select **Convert** and click **Convert to Subsystem Reference**.

- 2 Specify a name for the subsystem component in the **Subsystem file name** field. The name must be a valid MATLAB name. The conversion creates a subsystem file in the current directory. To create the file in a specific location, click **Browse** and navigate to the save location. Next, transfer existing test harnesses to the subsystem block diagram. To transfer the test harnesses, select the **Transfer test harnesses** check box then, click **Convert**.

The Subsystem block changes into a Subsystem Reference block with the name of the subsystem file displayed at the top of the block icon.

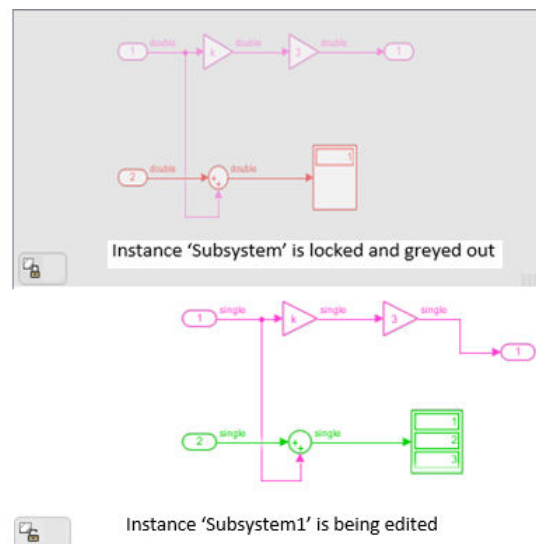

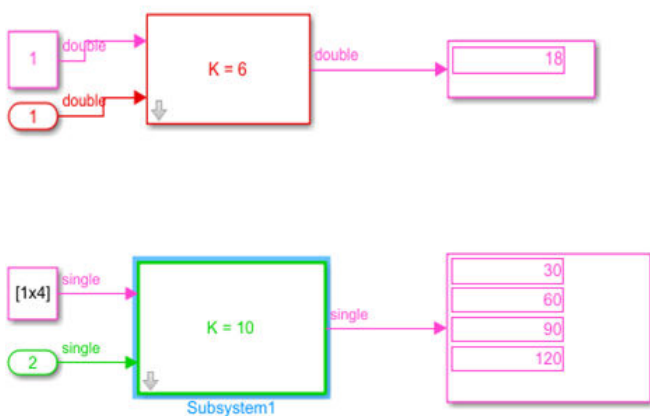

**Tip** When you convert a linked block to a referenced subsystem, do so in the parent library block of that linked block. Once you convert a parent library block to a referenced subsystem, all its linked block instances are also converted to referenced subsystems.

You cannot convert a subsystem to a referenced subsystem when the subsystem:

- Has no read/write permissions.
- Has a mask that is trying to modify its contents.

## Edit and Save Referenced Subsystem

In a model containing multiple instances of a referenced subsystem, you can edit any instance and upon saving the changes the updates propagate to all the referenced instances. When you actively edit an instance of a referenced subsystem, all the other referenced instances are locked and are unavailable for edit.

A badge is shown at the bottom left corner of an open subsystem file to denote the availability of the file for edit. The badge shows two states:

-  indicates that the subsystem file is available for edit. Right-click the badge to see all the active instances of that subsystem and to navigate to each of them.
-  indicates that the subsystem file is unavailable for edit, as another instance is being actively edited. Right-click the badge to open the instance being edited.

Once you have edited an instance in a model, you can save the changes from the **Save** option available in the **Simulation** tab of the model window. The **Save All** drop-down gives you two options to save your changes:

- **Save All** - To save all the updates in the current model.
- **Save Specific Referenced File** - To save a specific subsystem file when you have made changes to multiple subsystem files.

## Add a System Mask for Subsystem Reference

You can mask a subsystem file using a system mask. When you create a system mask for a subsystem file, all the referenced instances share the same system mask.

To mask a subsystem file:

- 1 Open the subsystem file to be masked.
- 2 In the Simulink toolstrip, on the **Subsystem** tab, click **Create System Mask**. Alternatively, right-click anywhere on the canvas and select **Mask** and click **Create System Mask**. The Mask Editor dialog opens.
- 3 Add mask parameters and click **OK**.

---

### Note

- You cannot directly mask a Subsystem Reference block. To mask a Subsystem Reference block, select the block. On the **Referenced Subsystem** tab, click **Create System Mask**. This action opens the subsystem file being referenced and creates a mask on it.
  - You cannot set parameters using `set_param` in a call back code of a masked subsystem. However if the subsystem is referenced from a library you can do so.
- 

For more information on creating and editing System masks, see “Introduction to System Mask” on page 42-43.

## Simulate a Subsystem Block Diagram with a Test Harness

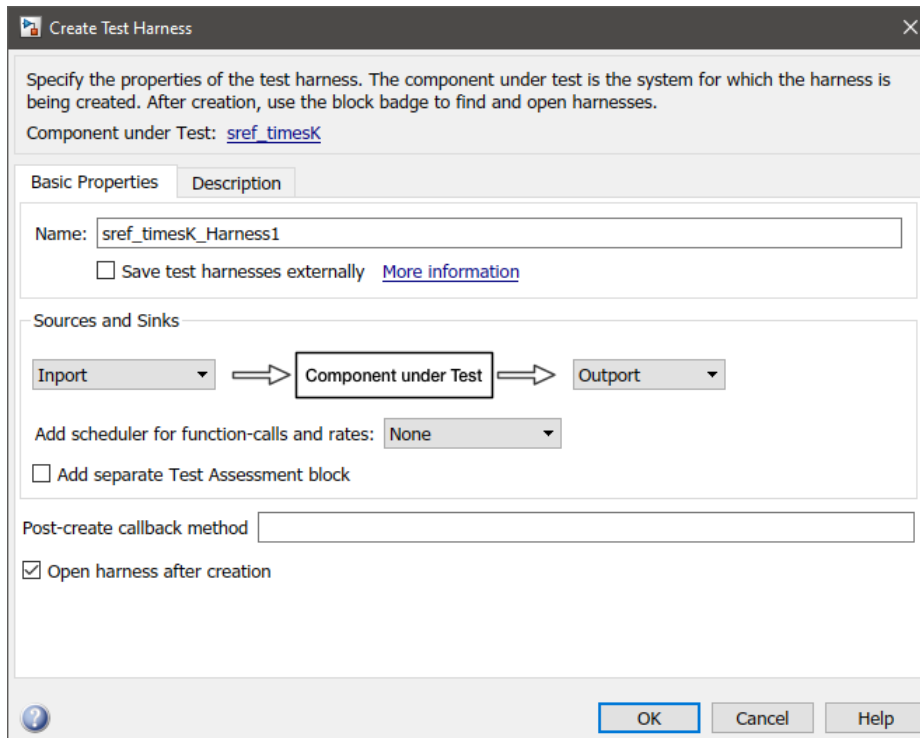

A subsystem block diagram cannot be simulated like a model or subsystem. However, you can create test harnesses on a subsystem block diagram and simulate the test harness. This action helps you to check for any errors or discrepancies while editing a subsystem block diagram. You can associate more than one test harness to a subsystem file and set a default test harness for the subsystem from a set of available test harnesses.

To simulate with a test harness:

- 1 Open a subsystem block diagram.
- 2 In the Simulink toolstrip, on the **Subsystem** tab, click **Add Test Harness**.

The **Create Test Harness** window appears.

- 3 Specify a name for the new test harness and click **OK**. This becomes the default test harness.
- 4 Click **Run with Test Harness** on the toolstrip to run the test harness on the subsystem without opening the test harness. Click the **Open Harness on Run** check box, to automatically open the test harness while running it on the subsystem.

### Set the Test harness using the Command line

You can set the default test harness of a subsystem block diagram using the command:

```
set_param('<subsystemfilename>', 'DefaultTestHarness', '<testHarnessName>');
```

## Subsystem Reference Compatibility with Previous Versions

When you export a model containing referenced subsystems to a version prior to R2019b, all the Subsystem Reference blocks are converted to independent Subsystem blocks.

Subsystem files created in R2019b cannot be exported to a prior version. For information on how to export a Simulink model to a previous version, see “Export Model to Previous Simulink Version” on page 1-32.

## Control Referenced Subsystem Programmatically

You can create a referenced subsystem, find available referenced subsystems in a model, change the referenced subsystem file in a block, and check the block diagram type of the file using a command-line interface.

### Create a Referenced Subsystem

You can create a referenced subsystem using the `new_system` command:

```
new_system(subsystemfilename, 'SubSystem')
```

### Find Subsystem Reference in a Model

You can find if a model contains a referenced subsystem using the `Simulink.findBlocksOfType` function:

```
Simulink.findBlocksOfType(bdroot, 'SubSystem', 'ReferencedSubsystem', '.', Simulink.FindOptions('Re
```

You can also use the `find_system` command:

```
find_system(bdroot, 'RegExp', 'on', 'BlockType', 'SubSystem', 'ReferencedSubsystem', '.')
```

Both return the number of Subsystem Reference blocks in the model. By default, `find_system` lists all the child blocks inside a subsystem reference instance.

If you do not want `find_system` to look inside a referenced subsystem, use `find_system` with `LookInsideSubsystemReference` set to `off`. By default, `LookInsideSubsystemReference` is set to `on`.

### Change the Referenced File for a Subsystem

You can change the subsystem file being referenced in a Subsystem Reference block through command-line interface using the `set_param` command:

```
set_param(gcf, 'ReferencedSubsystem', '<subsystemfilename>')
```

This command changes the file being currently referenced by the Subsystem Reference block and replaces it with the new subsystem file you specify.

### Check if the SLX or MDL File is a Subsystem Block Diagram Type

You can check if an SLX or MDL file is a subsystem block diagram type that can be placed in a **Subsystem Reference** block using any of these commands:

```
bdIsSubsystem(bdname)
```

This command returns `logical 1` if `bdname.slx` is a Subsystem block diagram type and `logical 0` if it is not. When using this command, make sure that `bdname.slx` is loaded.

```
get_param(bdname, 'BlockDiagramType')
```

This command returns `Subsystem` if `bdname.slx` is a Subsystem block diagram type. When using this command, make sure that `bdname.slx` is loaded.

```
Simulink.MDLInfo(bdname)
```

This command gives the entire model information where the `BlockDiagramType` property is shown as `Subsystem` if `bdname.slx` is a Subsystem block diagram type.

## Best Practices

While using a referenced subsystem in a model:

- To mask a referenced subsystem, use a System mask.
- Do not reference a parent subsystem because it creates a reference loop.
- Only the subsystem file type can be referenced by a Subsystem Reference block.

- “Reference a Subsystem File in a Model” on page 4-40

## Reference a Subsystem File in a Model

You can save a subsystem in an SLX or MDL file and reference it from a model. Such a modeling pattern helps re-usability. Consider the `slexSubsystemReferenceContextAdapting` model. This model contains two subsystems referencing the same subsystem file - `slexTimesK.slx`. The `slexTimesK.slx` subsystem contains Inport, Gain, and Outport blocks and is masked using Model Mask. An **Input for Gain** parameter is added to the mask to pass value using the variable `k`. This model is configured to demonstrate these capabilities of a referenced subsystem.

### Instance Specific Parameterization

You can specify different parameter values for each instance of a referenced subsystem. For example, here the input value (`k`) for the **Input for Gain** parameter from Subsystem1 and Subsystem2 are 5 and 10 respectively.

### Instance Specific Debugging

In this example, you have two instances of subsystem, referencing the saved subsystem file, `slexTimesK`. Each instance is driven by its own set of inputs in the top model. When you need to debug a referenced subsystem, you can dive into each instance and look for errors and debug them.

### Dimension Adaptability

While referencing subsystems, the top model can drive multiple dimensions. In this model, the Subsystem1 instance is driven by a one-dimensional signal and the Subsystem2 instance is driven by a four-dimensional signal. In both instances, you can see that the referenced subsystems adapt to have one dimension and four dimensions respectively in the output.

This example demonstrates

#### Instance Specific Parametrization

You can specify different parameter values for each instance of a referenced subsystem. For example, here the input value (`k`) for the "Edit" parameter from Subsystem Reference1 and Subsystem Reference2 are |5| and |10| respectively.

#### Context Specific Adaptability

While referencing subsystems, the top model can drive multiple dimensions. In this model, the Subsystem Reference1 instance is driven by an one-dimensional signal and the Subsystem Reference2 instance is driven by a four-dimensional signal. In the instances, you can see that the referenced subsystems adapt to scalar and matrix input respectively.

## Change Subsystem Reference Component Dynamically Using InitFcn

This example shows how to dynamically change the subsystem reference component using the “Initialization Function” on page 4-66. `InitFcn` is used to change the implementation of the model without having to change the contents. This example model simulates the front and rear wipers of a vehicle. The front wiper is sensor-based and it senses rain and fog. The rear wiper is controlled by the driver.

### Explore the Model

This example shows how to change subsystem reference component dynamically through model init.

This model is used to simulate front and rear wiper of a vehicle. It uses three subsystem based components. The front wiper is sensor based. It uses one subsystem component to convert the sensor input(voltage) to the right level(low, medium and high) to feed the wiper controller. The wiper speed controller component controls the speed of the wiper(cycles per second) based on the input level. The value of low, medium and high wiper speed can be parametrized through the system mask dialog of "Wiper Speed Controller".

The sensor component can be a "Fog" sensor or "Rain" sensor. Double-click the blue subsystem on top left corner to switch the sensor to "Rain" based sensor. It is going to create a variable "SensorInput = Rain" in the model workspace. During simulation, the init function of the model is going to read the "SensorInput" variable and based on its value, it is going to change the sensor component to "slexRainSensor" or "slexFogSensor".

Copyright 2021 The MathWorks, Inc.

**Inputs:** The wipers are turned on during rain or fog. Double-click **Turn on Fog Sensor** or **Turn on Rain Sensor** component on the top left corner of the model to select the type of input. Based on the selection, the sensor input variable `SensorInput` is created in the model workspace.

**Wiper speed controller:** During simulation the `InitFcn` is executed and calls the `switchSensor` function. This function reads the variable `SensorInput` from the model workspace and changes the subsystem to `slexRainSensor` or `slexFogSensor` according to your input selection. The subsystem reference component (Rain or Fog) converts the input voltage into speed levels low, medium, and high. The wiper speed controller converts the front and rear wiper speed levels into the appropriate speed in cycles per second.

Use this code in the InitFcn call back

```
function wiperController(bd, option)
    switch option
        case 'PostLoad'
            createWiperConstants(bd);
        case 'Init'
            switchSensor(bd);
        otherwise
    end
end

function switchSensor(bd)
    mws = get_param(bdroot, 'modelworkspace');
    si = mws.getVariable('SensorInput');
    blockpath = [bd '/SensorBasedSpeedController'];
    if strcmp(si, 'Fog')
        set_param(blockpath, 'ReferencedSubsystem', 'slexFogSensor');
    elseif strcmp(si, 'Rain')
        set_param(blockpath, 'ReferencedSubsystem', 'slexRainSensor');
    end
end
```

## Use Control Flow Logic

### In this section...

“What is a Control Flow Subsystem” on page 4-45

“Equivalent C Language Statements” on page 4-45

“Conditional Control Flow Logic” on page 4-45

“While and For Loops” on page 4-47

### What is a Control Flow Subsystem

A *control flow subsystem* executes one or more times at the current time step when enabled by a control flow block. A control flow block implements control logic similar to that expressed by control flow statements of programming languages (e.g., `if-then`, `while-do`, `switch`, and `for`).

### Equivalent C Language Statements

You can use block diagrams to model control flow logic equivalent to the following C programming language statements:

- `for`
- `if-else`
- `switch`
- `while`

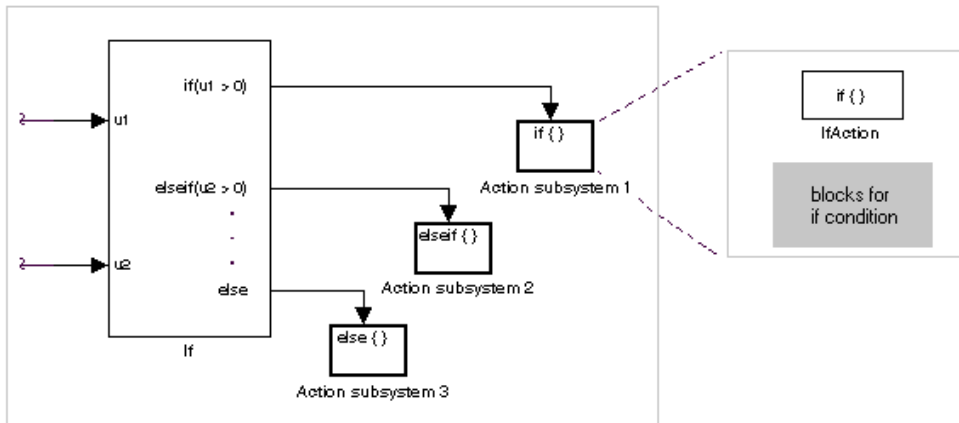

### Conditional Control Flow Logic

You can use the following blocks to perform conditional control flow logic.

C Statement	Equivalent Blocks
<code>if-else</code>	If, If Action Subsystem
<code>switch</code>	Switch Case, Switch Case Action Subsystem

#### If-Else Control Flow

The following diagram represents `if-else` control flow.

Construct an `if-else` control flow diagram as follows:

- 1 Provide data inputs to the If block for constructing if-else conditions.

In the If block parameters dialog box, set inputs to the If block. Internally, the inputs are designated as `u1`, `u2`, ..., `un` and are used to construct output conditions.

- 2 In the If block parameters dialog box, set output port if-else conditions for the If block.

In the If block parameters dialog box, set Output ports. Use the input values `u1`, `u2`, ..., `un` to express conditions for the if, elseif, and else condition fields in the dialog box. Of these, only the if field is required. You can enter multiple elseif conditions and select a check box to enable the else condition.

- 3 Connect each condition output port to an Action subsystem.

Connect each if, elseif, and else condition output port on the If block to a subsystem to be executed if the port's case is true.

Create these subsystems by placing an Action Port block in a subsystem. This creates an atomic Action subsystem with a port named Action, which you then connect to a condition on the If block.

Once connected, the subsystem takes on the identity of the condition it is connected to and behaves like an enabled subsystem.

For more detailed information, see the If and Action Port blocks.

---

**Note** All blocks in an Action subsystem driven by an If or Switch Case block must run at the same rate as the driving block.

---

### Switch Control Flow

The following diagram represents `switch` control flow.

Construct a switch control flow statement as follows:

- 1 Provide a data input to the argument input of the Switch Case block.

The input to the Switch Case block is the argument to the switch control flow statement. This value determines the appropriate case to execute. Noninteger inputs to this port are truncated.

- 2 Add cases to the Switch Case block based on the numeric value of the argument input.

Using the parameters dialog box of the Switch Case block, add cases to the Switch Case block. Cases can be single or multivalued. You can also add an optional default case, which is true if no other cases are true. Once added, these cases appear as output ports on the Switch Case block.

- 3 Connect each Switch Case block case output port to an Action subsystem.

Each case output of the Switch Case block is connected to a subsystem to be executed if the port's case is true. You create these subsystems by placing an Action Port block in a subsystem. This creates an atomic subsystem with a port named Action, which you then connect to a condition on the Switch Case block. Once connected, the subsystem takes on the identity of the condition and behaves like an enabled subsystem. Place all the block programming executed for that case in this subsystem.

For more detailed information, see documentation for the Switch Case and Action Port blocks.

---

**Note** After the subsystem for a particular case executes, an implied break executes, which exits the switch control flow statement altogether. Simulink switch control flow statement implementations do not exhibit the “fall through” behavior of C switch statements.

---

## While and For Loops

Use the following blocks to perform while and for loops.

C Statement	Equivalent Blocks
do-while	While Iterator Subsystem
for	For Iterator Subsystem
while	While Iterator Subsystem

## While Loops

The following diagram illustrates a `while` loop.

In this example, Simulink repeatedly executes the contents of the While subsystem at each time step until a condition specified by the While Iterator block is satisfied. In particular, for each iteration of the loop specified by the While Iterator block, Simulink invokes the update and output methods of all the blocks in the While subsystem in the same order that the methods would be invoked if they were in a noniterated atomic subsystem.

---

**Note** Simulation time does not advance during execution of a While subsystem's iterations. Nevertheless, blocks in a While subsystem treat each iteration as a time step. As a result, in a While subsystem, the output of a block with states (that is, a block whose output depends on its previous input), reflects the value of its input at the previous iteration of the `while` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a While subsystem outputs the value of its input at the previous iteration of the `while` loop, not the value at the previous simulation time step.

---

Construct a `while` loop as follows:

- 1 Place a While Iterator block in a subsystem.

The host subsystem label changes to `while { . . . }`, to indicate that it is modeling a while loop. These subsystems behave like triggered subsystems. This subsystem is host to the block programming that you want to iterate with the While Iterator block.

- 2 Provide a data input for the initial condition data input port of the While Iterator block.

The While Iterator block requires an initial condition data input (labeled IC) for its first iteration. This must originate outside the While subsystem. If this value is nonzero, the first iteration takes place.

- 3 Provide data input for the conditions port of the While Iterator block.

Conditions for the remaining iterations are passed to the data input port labeled `cond`. Input for this port must originate inside the While subsystem.

- 4 (Optional) Set the While Iterator block to output its iterator value through its properties dialog.

The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

- (Optional) Change the iteration of the While Iterator block to `do-while` through its properties dialog.

This changes the label of the host subsystem to `do { ... } while`. With a `do-while` iteration, the While Iteration block no longer has an initial condition (IC) port, because all blocks in the subsystem are executed once before the condition port (labeled `cond`) is checked.

- Create a block diagram in the subsystem that defines the subsystem's outputs.

---

**Note** The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (`-1`) or constant (`inf`).

---

For more information, see the While Iterator block.

### Modeling For Loops

The following diagram represents a `for` loop:

In this example, Simulink executes the contents of the For subsystem multiples times at each time step. The input to the For Iterator block specifies the number of iterations. For each iteration of the `for` loop, Simulink invokes the update and output methods of all the blocks in the For subsystem in the same order that it invokes the methods if they are in a noniterated atomic subsystem.

---

**Note** Simulation time does not advance during execution of a For subsystem's iterations. Nevertheless, blocks in a For subsystem treat each iteration as a time step. As a result, in a For subsystem, the output of a block with states (that is, a block whose output depends on its previous input) reflects the value of its input at the previous iteration of the `for` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a For subsystem outputs the value of its input at the previous iteration of the `for` loop, not the value at the previous simulation time step.

---

Construct a `for` loop as follows:

- Drag a For Iterator Subsystem block from the Library Browser or Library window into your model.
- (Optional) Set the For Iterator block to take external or internal input for the number of iterations it executes.

Through the properties dialog of the For Iterator block you can set it to take input for the number of iterations through the port labeled N. This input must come from outside the For Iterator Subsystem.

You can also set the number of iterations directly in the properties dialog.

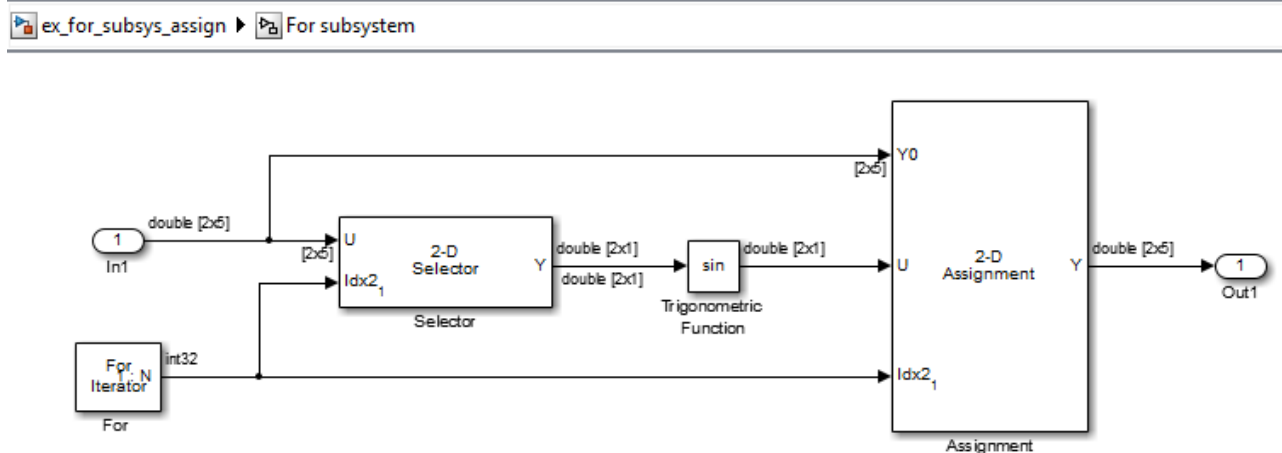

- 3 (Optional) Set the For Iterator block to output its iterator value for use in the block programming of the For Iterator Subsystem.

The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

- 4 Create a block diagram in the subsystem that defines the subsystem's outputs.

**Note** The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (-1) or constant (inf).

The For Iterator block works well with the Assignment block to reassign values in a vector or matrix. The following example shows the use of a For Iterator block. Note the matrix dimensions in the data being passed.

The above example outputs the sine value of an input 2-by-5 matrix (2 rows, 5 columns) using a For subsystem containing an Assignment block. The process is as follows.

- 1 A 2-by-5 matrix is input to the Selector block and the Assignment block.
- 2 The Selector block strips off a 2-by-1 matrix from the input matrix at the column value indicated by the current iteration value of the For Iterator block.

- 3 The sine of the 2-by-1 matrix is taken.
- 4 The sine value 2-by-1 matrix is passed to an Assignment block.
- 5 The Assignment block, which takes the original 2-by-5 matrix as one of its inputs, assigns the 2-by-1 matrix back into the original matrix at the column location indicated by the iteration value.

The rows specified for reassignment in the property dialog for the Assignment block in the above example are [1,2]. Because there are only two rows in the original matrix, you could also have specified -1 for the rows, (that is, all rows).

---

**Note** The Trigonometric Function block is already capable of taking the sine of a matrix. The above example uses the Trigonometric Function block only as an example of changing each element of a matrix with the collaboration of an Assignment block and a For Iterator block.

---

## Customize Model Behavior with Callbacks

Callbacks are commands you can define that execute in response to a specific modeling action, such as opening a model or stopping a simulation. Callbacks define MATLAB expressions that execute when the block diagram or a block is acted upon in a particular way.

Simulink provides model, block, and port callback parameters that identify specific kinds of model actions. You provide the code for a callback parameter. Simulink executes the callback code when the associated modeling action occurs.

For example, the code that you specify for the `PreLoadFcn` model callback parameter executes before the model loads. You can provide code for `PreLoadFcn` that loads the variables that model uses into the MATLAB workspace.

### What You Can Do with Callbacks

Callbacks are a powerful way to customize your Simulink model. A callback executes when you perform actions on your model, such as double-clicking a block or starting a simulation. You can use callbacks to execute MATLAB code. You can use model, block, or port callbacks to perform common tasks, for example:

- “Load Variables When Opening a Model” on page 1-10
- “Automate Simulation Tasks Using Callbacks” on page 28-7

### Types of Callbacks

Simulink provides many types of callbacks, including:

- Model callbacks — Model callbacks execute at specified action points, for example, after you load or save the model. See “Model Callbacks” on page 4-54.
- Block callbacks — Block callbacks execute for block events, such as when a block is loaded, opened, or edited. See “Block Callbacks” on page 4-59.
- Block mask callbacks — Block mask callbacks execute when the value of a mask parameter changes. See “Mask Parameter Callback”.
- Port callbacks — A port callback executes every time the connectivity of the corresponding port changes. See “Port Callbacks” on page 4-65.
- Annotation callbacks — An annotation can execute a callback when you click the annotation. See `Simulink.Annotation`.
- Callback Button block callbacks — The Callback Button block executes a callback when you click the block.

### Callback Limitations

Do not call the `run` command from within model or block callback code. Doing so can result in unexpected behavior such as errors or incorrect results if you load, compile, or simulate a Simulink model.

For limitations of specific callbacks, see their documentation.

## **See Also**

### **Related Examples**

- “View and Trace Callbacks in Models” on page 27-76
- “Fast Restart Methodology” on page 86-8

## Model Callbacks

Model callbacks execute at specified action points, for example, after you load or save the model.

You can use model callbacks to perform common tasks, such as:

- “Load Variables When Opening a Model” on page 1-10
- “Automate Simulation Tasks Using Callbacks” on page 28-7

You can set most of the same callbacks for libraries. Only the callbacks that can execute for a library are available to set for a library. For example, you cannot set the `InitFcn` callback for a library, which is called as part of simulation, because you cannot simulate a library.

### Create Model Callbacks

- 1** In the Simulink Toolstrip, on the **Modeling** tab, in the **Design** gallery, click **Property Inspector**.
- 2** With no selection at the top level of your model or referenced model, on the **Properties** tab, in the **Callbacks** section, select the callback you want to set.

---

**Note** Block callbacks differ from model callbacks. Do not select a Model block to set model callbacks for a referenced model.

---

- 3** In the box, enter the functions you want the callback to perform.

To programmatically create a model callback, use the `set_param` function to assign MATLAB code to a model callback parameter.

## Model Callback Parameters

Model Callback Parameter	When Executed
PreLoadFcn	<p>Before the model is loaded.</p> <p>Do not use model parameters in a PreLoadFcn model callback because parameters are loaded after the model is loaded. Instead, use a PostLoadFcn callback to work with model parameters when the model is loaded.</p> <p>Defining a callback code for this parameter is useful for loading variables that the model uses.</p> <p>If you want to call your model from a MATLAB file without opening your model, use the <code>load_system</code> function so that the PreLoadFcn executes.</p> <p>For an example, see “Load Variables When Opening a Model” on page 1-10.</p> <p>Limitations include:</p> <ul style="list-style-type: none"> <li>• For the PreLoadFcn callback, <code>get_param</code> does not return the model parameter values because the model is not yet loaded. Instead, <code>get_param</code> returns: <ul style="list-style-type: none"> <li>• The default value for a standard model parameter such as <code>solver</code></li> <li>• An error message for a model parameter added with <code>add_param</code></li> </ul> </li> <li>• Programmatic access to Scopes is not supported.</li> </ul>
PostLoadFcn	<p>After the model is loaded.</p> <p>Defining callback code for this parameter may be useful for generating an interface requiring a loaded model.</p> <p>Limitations include:</p> <ul style="list-style-type: none"> <li>• If you make structural changes with PostLoadFcn, the function does not set the model <code>Dirty</code> flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save.</li> <li>• Programmatic access to Scopes is not supported.</li> </ul> <p>Because the Simulink Editor opens after this callback executes, the PostLoadFcn callback is not suitable for setting up the model view, for example, setting a zoom factor. Save zoom information with the model to open it with a particular zoom factor.</p>

Model Callback Parameter	When Executed
InitFcn	<p>During the update phase before block parameters are evaluated. This callback is called during model update and simulation.</p> <p>Avoid InitFcn model callbacks that edit the structure of the model. Simulink may execute or ignore these callbacks based on the model load status.</p> <p>Avoid InitFcn model callbacks that edit the contents of a referenced model. Doing so can result in unexpected behavior such as errors or incorrect results when you simulate a Simulink model.</p> <p>For more information on the InitFcn callback, see “Initialization Function” on page 4-66.</p> <p>For an example, see “Call MATLAB Function Files in MATLAB Function Blocks” on page 49-119.</p>
StartFcn	<p>Before the simulation phase. This callback is not called during model update.</p> <p>For an example, see “Automate Simulation Tasks Using Callbacks” on page 28-7.</p> <p>This callback is called for every simulation in fast restart.</p>
PauseFcn	<p>After the simulation pauses.</p>
ContinueFcn	<p>Before the simulation continues.</p>
StopFcn	<p>After the simulation stops.</p> <p>Output is written to workspace variables and files before the StopFcn is executed.</p> <p>Simulation outputs are not available in the StopFcn callbacks for command-line simulations.</p> <p>This callback is called for every simulation in fast restart.</p>
PreSaveFcn	<p>Before the model is saved.</p>
PostSaveFcn	<p>After the model is saved.</p> <p>If you make structural changes with PostSaveFcn, the function does not set the model Dirty flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save.</p>
CloseFcn	<p>Before the block diagram is closed.</p> <p>Any ModelCloseFcn and DeleteFcn callbacks set on blocks in the model are called prior to the model CloseFcn callback. The DestroyFcn callback of any blocks in the model is called after the model CloseFcn callback.</p>

## Referenced Model Callbacks

In a model hierarchy, the execution of callbacks reflects the order in which the top model and the models it references execute their callbacks. For example, suppose:

- Model A:
  - References model B in accelerator mode.
  - Has a `PostLoadFcn` callback that creates variables in the MATLAB workspace.
  - Has the **Rebuild** configuration parameter set to `Always`, `If changes detected`, or `If any changes in known dependencies detected`.
- Model B:
  - Has a `CloseFcn` callback that clears the MATLAB workspace.
  - Has not been built or is out of date.

Simulating model A triggers a rebuild of referenced model B. When Simulink rebuilds model B, it opens and closes model B, which invokes the model B `CloseFcn` callback. `CloseFcn` clears the MATLAB workspace, including the variables created by the model A `OpenFcn` callback.

Instead of using a `CloseFcn` callback for model B, you can use a `StopFcn` callback in model A to clear the variables used by the model from the MATLAB workspace. Alternatively, you can use a data dictionary for the data to avoid the need to have variables in the base workspace.

The simulation mode of a Model block affects when the model callbacks of the referenced model execute.

Simulation Mode of Model Block	Behavior
Normal	<p>During model compilation, Simulink loads each referenced model that is configured to simulate in normal mode and is not already loaded.</p> <p>In most cases, Simulink compiles each normal-mode referenced model once, regardless of the number of Model blocks that reference it.</p> <p>The <code>InitFcn</code>, <code>StartFcn</code>, <code>PauseFcn</code>, <code>ContinueFcn</code>, and <code>StopFcn</code> model callbacks execute for each executable form of the model created by the model compiler.</p> <p>The referenced models remain loaded after model compilation.</p>

Simulation Mode of Model Block	Behavior
Accelerator	<p data-bbox="557 327 1471 453">During model compilation, Simulink may open and close referenced models that are configured to simulate in accelerator mode based on their <b>Rebuild</b> settings and simulation targets. Models that are open before model compilation remain open.</p> <p data-bbox="557 485 1068 512">Simulink does not execute some callbacks.</p> <ul data-bbox="557 541 1463 768" style="list-style-type: none"> <li data-bbox="557 541 1463 667">• If everything is up to date and the <b>Rebuild</b> configuration parameter is set to <i>If any changes in known dependencies detected</i>, then the referenced model does not compile and its <code>InitFcn</code> callbacks do not execute.</li> <li data-bbox="557 678 1463 768">• Callbacks such as <code>StartFcn</code> and <code>StopFcn</code> do not execute because referenced models in accelerator mode use an S-function, which starts and stops instead of the referenced model.</li> </ul>

For more information about model reference simulation modes, see “Choose Simulation Modes for Model Hierarchies” on page 8-39.

- “Fast Restart Methodology” on page 86-8

## Block Callbacks

You can specify block callbacks that execute MATLAB code for block events, such as when a block is loaded, opened, or edited.

- 1 On the **Modeling** tab, under **Design**, click **Property Inspector**.
- 2 Select the block whose callback you want to specify.
- 3 On the **Properties** tab of the Property Inspector, in the **Callbacks** section, select the callback you want to define.
- 4 In the box, enter the functions you want the callback to perform.

To specify a block callback programmatically, use `set_param` to assign MATLAB code to the block callback parameter.

If a block callback executes before or after a modeling action takes place, that callback occurs immediately before or after the action.

### Block Opening Callback Parameters

Block Callback Parameter	When Executed
OpenFcn	<p>When the block is opened.</p> <p>Generally, use this parameter with Subsystem blocks.</p> <p>The callback executes when you double-click the block or when you use <code>open_system</code> with the block as an argument. The <code>OpenFcn</code> parameter overrides the normal behavior associated with opening a block, which is to display the block dialog box or to open the subsystem. Examples of tasks that you can use <code>OpenFcn</code> for include defining variables for a block, making a call to MATLAB to produce a plot of simulated data, or generating a graphical user interface.</p> <p>After you add an <code>OpenFcn</code> callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select <b>Block Parameters</b> from the block context menu.</p>
LoadFcn	<p>After the block diagram is loaded.</p> <p>For Subsystem blocks, the <code>LoadFcn</code> callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a <code>LoadFcn</code> callback defined.</p>

### Block Editing Callback Parameters

Block Callback Parameter	When Executed
MoveFcn	When the block is moved or resized.

Block Callback Parameter	When Executed
NameChangeFcn	<p>After a block name or path changes.</p> <p>When a Subsystem block path changes, the Subsystem block calls the NameChangeFcn callback of its descendant blocks and then calls the NameChangeFcn callback on itself.</p>
PreCopyFcn	<p>Before a block is copied. The PreCopyFcn is also executed if add_block is used to copy the block.</p> <p>If you copy a Subsystem block that contains a block for which the PreCopyFcn callback is defined, that callback executes also.</p> <p>The block CopyFcn callback is called after all PreCopyFcn callbacks are executed.</p>
CopyFcn	<p>After a block is copied. The callback is also executed if add_block is used to copy the block.</p> <p>If you copy a Subsystem block that contains a block for which the CopyFcn parameter is defined, the callback is also executed.</p>
ClipboardFcn	<p>When the block is copied or cut to the system clipboard.</p>
PreDeleteFcn	<p>Before a block is graphically deleted (for example, when you graphically delete the block or invoke delete_block on the block).</p> <p>The PreDeleteFcn is not called when the model containing the block is closed. The block's DeleteFcn is called after the PreDeleteFcn, unless the PreDeleteFcn invokes the error command, either explicitly or via a command used in the PreDeleteFcn.</p>
DeleteFcn	<p>After a block is graphically deleted (for example, when you graphically delete the block, invoke delete_block on the block, or close the model containing the block).</p> <p>When the DeleteFcn is called, the block handle is still valid and can be accessed using get_param. If the block is graphically deleted by invoking delete_block or by closing the model, after deletion the block is destroyed from memory and the block's DestroyFcn is called.</p> <p>For Subsystem blocks, the DeleteFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a DeleteFcn callback defined.</p>
DestroyFcn	<p>When the block has been destroyed from memory (for example, when you invoke delete_block on either the block or a subsystem containing the block or close the model containing the block).</p> <p>If the block was not previously graphically deleted, the blockDeleteFcn callback is called prior to the DestroyFcn. When the DestroyFcn is called, the block handle is no longer valid.</p>
UndoDeleteFcn	<p>When a block deletion is undone.</p>

## Block Compilation and Simulation Callback Parameters

Block Callback Parameter	When Executed
InitFcn	Before the block diagram is compiled and before block parameters are evaluated. For more information on InitFcn callback, see "Initialization Function" on page 4-66.
StartFcn	After the block diagram is compiled and before the simulation starts.  In the case of an S-Function block, StartFcn executes immediately before the first execution of the block's mdlProcessParameters function. For more information, see "S-Function Callback Methods".
ContinueFcn	Before the simulation continues.
PauseFcn	After the simulation pauses.
StopFcn	At any termination of the simulation.  In the case of an S-Function block, StopFcn executes after the block's mdlTerminate function executes. For more information, see "S-Function Callback Methods".

## Block Saving and Closing Callback Parameters

Block Callback Parameter	When Executed
PreSaveFcn	Before the block diagram is saved.  For Subsystem blocks, the PreSaveFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a PreSaveFcn callback defined.
PostSaveFcn	After the block diagram is saved.  For Subsystem blocks, the PostSaveFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a PostSaveFcn callback defined.
CloseFcn	When the block is closed using close_system.  The CloseFcn is not called when you interactively close the block parameters dialog box, when you interactively close the subsystem or model containing the block, or when you close the subsystem or model containing a block using close_system.  For example, to close all open MATLAB windows, use a command such as:  <code>set_param('my_model','CloseFcn','close all')</code>

Block Callback Parameter	When Executed
ModelCloseFcn	<p>Before the block diagram is closed.</p> <p>When the model is closed, the block's ModelCloseFcn is called prior to its DeleteFcn.</p> <p>For Subsystem blocks, the ModelCloseFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a ModelCloseFcn callback defined.</p>

## Subsystem Block Callback Parameters

You can use the other block callback parameters with Subsystem blocks, but the callback parameters in this table are specific to Subsystem blocks.

---

**Note** A callback for a masked subsystem cannot directly reference the parameters of the masked subsystem (see “Create Block Masks”). Simulink evaluates block callbacks in the MATLAB base workspace, whereas the mask parameters reside in the masked subsystem's private workspace. A block callback, however, can use `get_param` to obtain the value of a mask parameter. For example, here `gain` is the name of a mask parameter of the current block:

```
get_param(gcf, 'gain')
```

---

Block Callback Parameter	When Executed
DeleteChildFcn	<p>After a block or line is deleted in a subsystem.</p> <p>If the block has a DeleteFcn or DestroyFcn callback, those callbacks execute prior to the DeleteChildFcn callback.</p>

Block Callback Parameter	When Executed
ErrorFcn	<p>When an error has occurred in a subsystem.</p> <p>Use the following form for the callback code for the ErrorFcn parameter:</p> <pre>newException = errorHandler(subsys, ... errorType, originalException)</pre> <p>where</p> <ul style="list-style-type: none"> <li>• errorHandler is the name of the function.</li> <li>• subsys is a handle to the subsystem in which the error occurred.</li> <li>• errorType is a character vector indicating the type of error that occurred.</li> <li>• originalException is an MSLException (see “Error Handling in Simulink Using MSLException” on page 28-20).</li> <li>• newException is an MSLException specifying the error message to be displayed to the user.</li> </ul> <p>If you provide the original exception, then you do not need to specify the subsystem and the error type.</p> <p>The following command sets the ErrorFcn of the subsystem subsys to call the errorHandler callback:</p> <pre>set_param(subsys, 'ErrorFcn', 'errorHandler')</pre> <p>In such calls to set_param, do not include the input arguments of the callback code. Simulink displays the error message returned by the callback.</p>
ParentCloseFcn	<p>Before closing a subsystem containing the block or when the block is made part of a new subsystem using either:</p> <ul style="list-style-type: none"> <li>• The new_system function</li> <li>• The <b>Create Subsystem</b> icon on the <b>Multiple</b> tab, in the Simulink Editor.</li> </ul> <p>When you close the model, Simulink does not call the ParentCloseFcn callbacks of blocks at the root model level.</p>

- “Fast Restart Methodology” on page 86-8

## Port Callbacks

Block input and output ports have a single callback parameter, `ConnectionCallback`. This parameter allows you to set callbacks on ports that are triggered every time the connectivity of these ports changes. Examples of connectivity changes include adding a connection from the port to a block, deleting a block connected to the port, and deleting, disconnecting, or connecting branches or lines to the port.

Use `get_param` to get the port handle of a port and `set_param` to set the callback on the port. The callback code must have one input argument that represents the port handle. The input argument is not included in the call to `set_param`.

For example, suppose the currently selected block has a single input port. The following code sets `foo` as the connection callback on the input port.

```
phs = get_param(gcf, 'PortHandles');  
set_param(phs.Inport, 'ConnectionCallback', 'foo');
```

`foo` is defined as:

```
function foo(portHandle)
```

- “Fast Restart Methodology” on page 86-8

## Initialization Function

An initialization function (InitFcn) is a type of callback that is executed or evaluated at the beginning of model compilation. You can specify the InitFcn callback as a model or block callback.

---

**Note** Variant controls can be defined only in a model InitFcn callback.

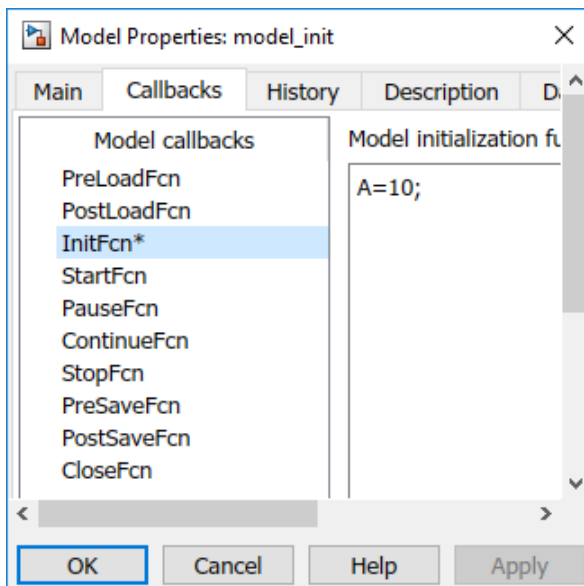

---

### Model InitFcn Callback

Use the model InitFcn callback to initialize parameters and environment settings that are specific to the model, for example:

- Variables used in model parameters
- License checks for the required software

In the Simulink Toolstrip, on the **Modeling** tab, click the **Model Settings** arrow, then click **Model Properties**. In the Model Properties dialog box, the model InitFcn callback is on the **Callbacks** tab.

Do not use the model InitFcn callback to:

- Get the simulation status. If you simulate a model with the `slbuild` function or use software-in-the-loop (SIL) or rapid accelerator mode, the model InitFcn callback status may show as 'stopped'.
- Run simulation commands. For example, do not use commands such as `set_param(ModelName, 'SimulationCommand', 'start')` or `set_param(ModelName, 'SimulationCommand', 'update')` in the model InitFcn callback.
- Modify other models. Similarly, the block InitFcn callback of a Model block must not modify the parameters or structure of the referenced model.
- Overwrite any variables used in a referenced model. For example, if the top model and a referenced model use the variable `k`, the model InitFcn callback of the top model must not

modify  $k$  for the referenced model. In such modeling patterns, use different variable names or a data dictionary.

- Edit the structure of the model, except to define variant controls. For example, do not use functions such as `add_line` or `delete_line` in the model `InitFcn` callback.

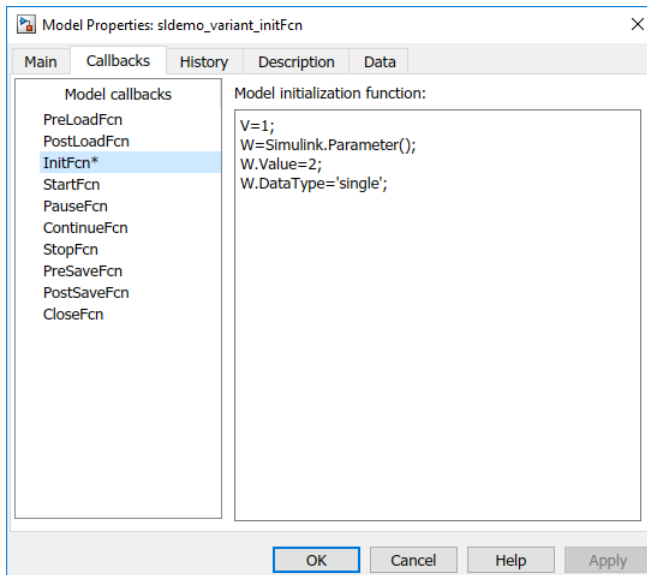

If you use the `InitFcn` callback for a model, edit-time checking for missing variables in block parameters is disabled for the entire model.

For examples of the model `InitFcn` callback with variants, open the `sldemo_variant_initFcn` model. Then, double-click the green block to open a model that uses the recommended workflow. The model that opens contains Variant Subsystem and Variant Source blocks.

### Variants with Model `InitFcn`

In this model, the model `InitFcn` callback is used to initialize parameters for the model.

While you can define these parameters in the model `PreLoadFcn` or `PostLoadFcn` callbacks, these callbacks execute before or after the model loads. Suppose you clear the parameters from the MATLAB workspace and simulate the model. The model `PreLoadFcn` and `PostLoadFcn` callbacks do not re-create the parameters. When you define the parameters in the model `InitFcn` callback, model update and simulation re-create the parameters.

## Block `InitFcn` Callback

Use the block `InitFcn` callback to initialize parameters and settings of the block.

Right-click the block. Then, click **Properties**. In the Block Properties dialog box, the block `InitFcn` callback is on the **Callbacks** tab.

Do not use the block `InitFcn` callback to:

- Modify the parameters (or variables) of other blocks, except in the case where you use the `InitFcn` callback of a Subsystem block to modify the parameters of its direct child blocks.
- Make structural changes. For example, do not use functions such as `add_block` or `delete_block` in the block `InitFcn` callback.
- Modify any global variables or variables in the model workspace that another block uses.
- Modify the parameters, structure, or settings of a model referenced by a Model block.

If you use an `InitFcn` callback for a block, edit-time checking for missing variables in block parameters is disabled for that block.

### Related Examples

- “Customize Model Behavior with Callbacks” on page 4-52
- “Model Callbacks” on page 4-54
- “Block Callbacks” on page 4-59
- “Manage Model Versions and Specify Model Properties” on page 4-70

## Manage Model Versions and Specify Model Properties

In Simulink, you can manage multiple versions of a model using these techniques:

- Use projects to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Use model file change notifications to manage work with source control operations and multiple users. See “Model File Change Notification” on page 4-70.
- Use `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

### Model File Change Notification

You can use a Simulink preference to specify whether to notify you if the model has changed on disk. You can receive this notification when updating or simulating the model, first editing the model, or saving the model. The model can change on disk, for example, with source control operations and multiple users.

In the Simulink Editor, on the **Modeling** tab, select **Environment > Simulink Preferences**. In the **Model File** pane, under **Change Notification**, you can select these options:

- If you select **First editing the model**, the file has changed on disk, and the block diagram is unmodified in Simulink:
  - Any interactive operation that modifies the block diagram (for example, adding a block) causes a warning to appear.
  - Any command-line operation that modifies the block diagram (such as a call to `set_param`) causes a warning to appear.
- If you select **Saving the model**, and the file has changed on disk:
  - Saving the model in the Simulink Editor causes a message to appear.
  - The `save_system` function reports an error, unless you use the `OverwriteIfChangedOnDisk` option.

To programmatically check whether the model has changed on disk since it was loaded, use the function `slIsFileChangedOnDisk`.

For more options that help you work with source control and multiple users, see “Project Management”.

### Manage Model Properties

You can use the Property Inspector to view and edit model version properties, description, and callback functions. To open the Property Inspector, in the **Modeling** tab, under **Design**, click **Property Inspector**. Model properties or, if you are in a library model, library properties, appear in the Property Inspector when nothing is selected at the top level of a model.

## Specify the Current User

When you create or update a model, your name is logged in the model. Simulink assumes that your name is specified by at least one of the `USER`, `USERNAME`, `LOGIN`, or `LOGNAME` environment variables. If your system does not define any of these variables, Simulink does not update the user name in the model.

UNIX® systems define the `USER` environment variable and set its value to the name you use to log in to your system. Thus, if you are using a UNIX system, you do not have to take further action for Simulink to identify you as the current user.

Windows systems can define environment variables for user name that Simulink expects, depending on the version of Windows installed on your system and whether it is connected to a network. Use the MATLAB function `getenv` to determine which of the environment variables is defined. For example, at MATLAB Command Window, enter:

```
getenv('user')
```

This function determines whether the `USER` environment variable exists on your Windows system. If it does not, set it.

## Model Information

The **Info** tab summarizes information about the current version of the model, such as modifications, version, and the last saved date. You can view and edit model information and enable, view, and edit the model change history.

Use the **Description** section to enter a description of the model. You can then view the model description by entering `help` followed by the model name at the MATLAB Command Window.

- **Model version**

Version number for this model. The major model version is incremented by the number of releases passed since the model was last saved. The minor model version is reset to zero for every new release of Simulink and is incremented by one each time you save the model within the same release.

- **Created by**

Name of the person who created this model based on the value of the `USER` environment variable when the model is created.

- **Created on**

Date and time this model was created. Do not change this value.

- **Last saved by**

Name of the person who last saved this model based on the value of the `USER` environment variable when the model is saved.

- **Last saved on**

Date that this model was last saved, based on the system date and time.

### Properties

You can view the source file location, set the model compression level, specify where to save model design data, and define callbacks in the **Properties** tab of the model properties.

---

**Note** Library properties also enable you to specify the mapping from old library blocks to new library blocks. For information on using forwarding tables for this purpose, see “Maintain Compatibility of Library Blocks Using Forwarding Tables” on page 44-37.

---

### Set SLX Compression Level

In the **Properties** tab of the **Property Inspector**, you can select one of three **SLX Compression** options:

- **None** applies no compression during the save operation.
- **Normal**, the default, creates the smallest file size.
- **Fastest** creates a smaller file size than you would get by selecting **None**, but provides a faster save time than **Normal**.

To set the compression level programmatically, use `SLXCompressionType`.

---

**Tip** You can reduce your Git™ repository size by saving Simulink models without compression. Turning off compression results in larger SLX files on disk, but reduces repository size.

To use this setting with new SLX files, create your models using a model template with **SLX Compression** set to **None**. See “Create Template from Model” on page 4-2. For existing SLX files, set the compression and then save the model.

---

### Define Location of Design Data

Use the **External Data** section to specify the location of the design data that your model uses. You can define design data in the base workspace or in a data dictionary. See “Migrate Single Model to Use Dictionary” on page 79-7.

### Callbacks

Use the **Callbacks** section to specify functions to invoke at specific points during the simulation of the model. Select the callback from the list. In the box, enter the function you want to invoke for the selected callback. For information on these callbacks, see “Create Model Callbacks” on page 4-54.

## Access Model Information Programmatically

Some version information is stored as model parameters in a model. You can access this information programmatically using the Simulink `get_param` function.

The table describes the model parameters used by Simulink to store version information.

Property	Description
BlockDiagramType	Returns <code>model</code> if it is in an open Simulink block diagram. Returns <code>library</code> if it is a Simulink library.
Created	Date created.
Creator	Name of the person who created this model.
Description	User-entered description of this model. In the Property Inspector, on the <b>Info</b> tab, enter or edit a description for the model in the <b>Description</b> box. To view the model description at the MATLAB Command Window, enter:  <code>help 'mymodelName'</code>
Dirty	If the value of this parameter is on, the model has unsaved changes.
FileName	Absolute path where the model is saved.
LastModifiedBy	Name of the user who last saved the model.
LastModifiedDate	Date when the model was last saved.
MetaData	Names and attributes of arbitrary data associated with the model. For more details, see <code>Simulink.MDLInfo.getMetadata</code> .
ModifiedByFormat	Format of the <code>ModifiedBy</code> parameter. The value can include the tag <code>%&lt;Auto&gt;</code> . The Simulink software replaces the tag with the current value of the <code>USER</code> environment variable.
ModifiedDateFormat	Format used to generate the value of the <code>LastModifiedDate</code> parameter. The value can include the tag <code>%&lt;Auto&gt;</code> . Simulink replaces the tag with the current date and time when saving the model.
ModelVersion	The major model version is incremented by the number of releases passed since the model was last saved. The minor model version is reset to zero for every new release of Simulink and is incremented by one each time you save the model within the same release.
ModelVersionFormat	The value contains the model format version as <code>%&lt;AutoIncrement:#. #&gt;</code> where <code>#</code> is an integer. Simulink increments the model version by <code>#</code> when saving the model.
PreviousFileName	When a <code>PreSaveFcn</code> or <code>PostSaveFcn</code> callback is running, <code>PreviousFileName</code> indicates the absolute path of the model before the save operation started.  To find the current absolute path of the model, use <code>FileName</code> instead.
SavedSinceLoaded	Indicates whether the model has been saved since it was loaded. 'on' indicates the model has been saved.
VersionLoaded	Simulink version that last saved the model, e.g., '7.6'.

<b>Property</b>	<b>Description</b>
EnableAccessToBaseWorkspace	Whether the model has access to design data and configuration sets in the base workspace, specified as 'true' or 'false'.

LibraryVersion is a block parameter for a linked block. LibraryVersion is the ModelVersion of the library at the time the link was created.

For source control version information, see “Project Management”.

# Model Discretizer

## In this section...

- “What Is the Model Discretizer?” on page 4-75
- “Requirements” on page 4-75
- “Discretize a Model with the Model Discretizer” on page 4-75
- “View the Discretized Model” on page 4-80
- “Discretize Blocks from the Simulink Model” on page 4-83
- “Discretize a Model with the sldiscmdl Function” on page 4-90

## What Is the Model Discretizer?

Model Discretizer selectively replaces continuous Simulink blocks with discrete equivalents. Discretization is a critical step in digital controller design and for hardware in-the-loop simulations.

You can use the Model Discretizer to:

- Identify a model's continuous blocks
- Change a block's parameters from continuous to discrete
- Apply discretization settings to all continuous blocks in the model or selected blocks
- Create variant subsystems that contain multiple discretization candidates along with the original continuous block(s)
- Switch among the different discretization candidates and evaluate the resulting model simulations

The Model Discretizer does not support masked subsystems.

## Requirements

To use Model Discretizer

- You must have a Control System Toolbox™ license, Version 5.2 or later.
- Make sure your model does not contain any obsolete blocks and is upgraded to the current Simulink version. For more information, see “Model Upgrades”
- You must convert configurable subsystem blocks in existing models to Variant Subsystem. For more information, see “Convert Configurable Subsystem to Variant Subsystem” on page 12-141.

## Discretize a Model with the Model Discretizer

To discretize a model:

- 1 “Start Model Discretizer” on page 4-76.
- 2 “Specify the Transform Method” on page 4-76.
- 3 “Specify the Sample Time” on page 4-77.
- 4 “Specify the Discretization Method” on page 4-77.

5 “Discretize the Blocks” on page 4-79.

The f14 model shows the steps in discretizing a model.

**Start Model Discretizer**

To open the tool, in the Simulink Editor, on the **Apps** tab, under **Apps**, under **Control Systems**, click **Model Discretizer**.

The **Simulink Model Discretizer** opens.

Alternatively, you can open Model Discretizer from the MATLAB Command Window using the `slmdliscui` function.

The following command opens the **Simulink Model Discretizer** window with the f14 model:

```
slmdliscui('f14')
```

To open a new model or library from Model Discretizer, select **File > Load model**.

**Specify the Transform Method**

The transform method specifies the type of algorithms used in the discretization. For more information on the different transform methods, see the Control System Toolbox.

The **Transform method** list contains the following options:

Transform Method	Description
Zero-order hold	Zero-order hold on the inputs.
First-order hold	Linear interpolation of inputs.
Tustin	Bilinear (Tustin) approximation.
Tustin with prewarping	Tustin approximation with frequency prewarping.

Transform Method	Description
Matched pole-zero	Matched pole-zero method (for SISO systems only).

### Specify the Sample Time

Enter the sample time in the **Sample time** field. For the Model Discretizer, this value must be numeric.

You can specify an offset time by entering a two-element vector for discrete blocks or variant subsystems. The first element is the sample time and the second element is the offset time. For example, an entry of [1.0 0.1] would specify a 1.0 second sample time with a 0.1 second offset. If no offset is specified, the default is zero.

You can enter workspace variables when discretizing blocks in the s-domain. See “Discrete blocks (Enter parameters in s-domain)” on page 4-77.

### Specify the Discretization Method

Specify the discretization method in the **Replace current selection with** field. The options are

Discretization Method	Description
“Discrete blocks (Enter parameters in s-domain)” on page 4-77	Creates a discrete block whose parameters are retained from the corresponding continuous block.
“Discrete blocks (Enter parameters in z-domain)” on page 4-78	Creates a discrete block whose parameters are “hard-coded” values placed directly into the block's dialog.
“Variant subsystem (Enter parameters in s-domain)” on page 4-79	Create multiple discretization candidates using s-domain values for the current selection.
“Variant subsystem (Enter parameters in z-domain)” on page 4-79	Create multiple discretization candidates in z-domain for the current selection.

### Discrete blocks (Enter parameters in s-domain)

Creates a discrete block whose parameters are retained from the corresponding continuous block. The sample time and the discretization parameters are also on the block's parameter dialog box.

The block is implemented as a masked discrete block that uses `c2d` to transform the continuous parameters to discrete parameters in the mask initialization code.

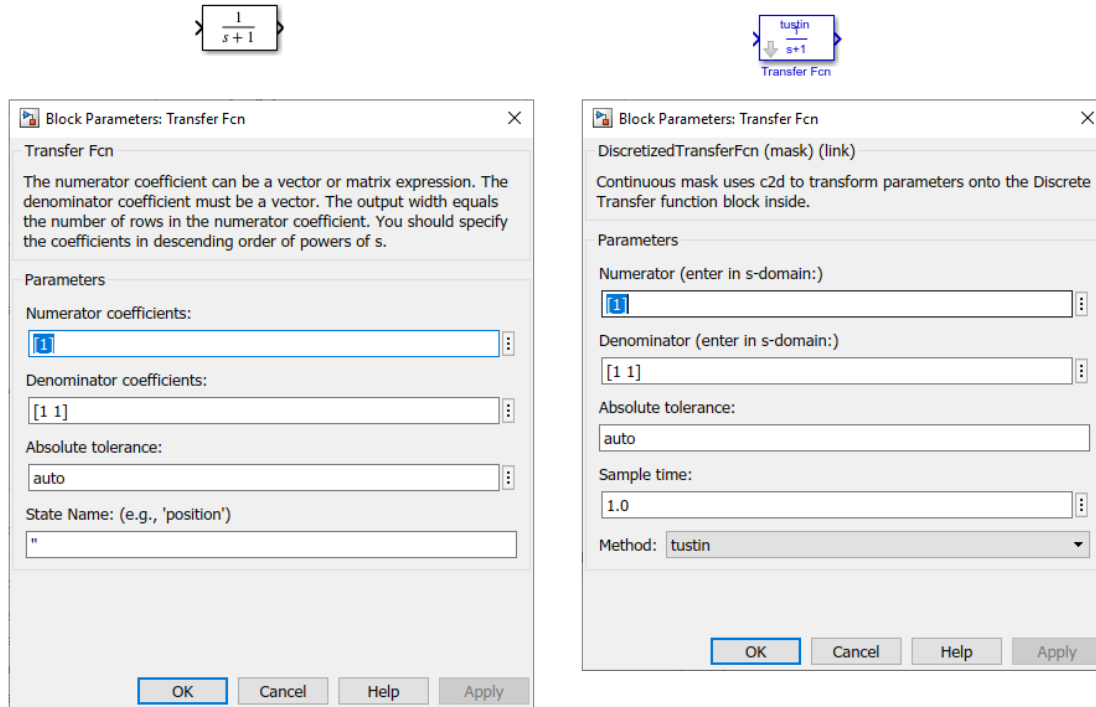

These blocks have the unique capability of reverting to continuous behavior if the sample time is changed to zero. Entering the sample time as a workspace variable ( ' Ts ', for example) allows for easy changeover from continuous to discrete and back again. See “Specify the Sample Time” on page 4-77.

---

**Note** If you generated code from a model, parameters are not tunable when **Default parameter behavior** is set to `Inlined` in the model's Configuration Parameters dialog box.

---

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the s-domain with the Tustin transform method. The block parameters dialog box for each block appears below the block.

#### Discrete blocks (Enter parameters in z-domain)

Creates a discrete block whose parameters are “hard-coded” values placed directly into the block's dialog box. Model Discretizer uses the `c2d` function to obtain the discretized parameters, if needed.

For more help on the `c2d` function, type the following in the Command Window:

```
help c2d
```

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the z-domain. The block parameters dialog box for each block appears below the block.

$$\frac{1}{s+1}$$

$$\frac{1}{z+0.5}$$

Block Parameters: Transfer Fcn

Transfer Fcn

The numerator coefficient can be a vector or matrix expression. The denominator coefficient must be a vector. The output width equals the number of rows in the numerator coefficient. You should specify the coefficients in descending order of powers of s.

**Note** If you want to recover exactly the original continuous parameter values after the Model Discretization session, you should enter parameters in the s-domain.

### Variant subsystem (Enter parameters in s-domain)

Create multiple discretization candidates using s-domain values for the current selection. Creates a discrete block whose parameters are retained from the corresponding continuous block.

The **Location for block in Variant Subsystem** field becomes active when this option is selected. This option allows you to either create a new variant subsystem.

### Variant subsystem (Enter parameters in z-domain)

Create multiple discretization candidates in z-domain for the current selection. Creates a discrete block whose parameters are "hard-coded" values placed directly into the block's dialog.

The **Location for block in Variant Subsystem** field becomes active when this option is selected. This option allows you to either create a new variant subsystem.

### Discretize the Blocks

To discretize blocks that are linked to a library, you must either discretize the blocks in the library itself or disable the library links in the model window.

You can open the library from Model Discretizer by selecting **Load model** from the **File** menu.

You can disable the library links by right-clicking on the block and selecting **Library Link > Disable Link** from the context menu.

There are two methods for discretizing blocks:

- “Select Blocks and Discretize” on page 4-80
- “Store the Discretization Settings and Apply Them to Selected Blocks in the Model” on page 4-80

### Select Blocks and Discretize

- 1 Select a block or blocks in the Model Discretizer tree view pane.

To choose multiple blocks, press and hold the **Ctrl** button on the keyboard while selecting the blocks.

---

**Note** You must select blocks from the Model Discretizer tree view. Clicking blocks in the editor does not select them for discretization.

---

- 2 Select **Discretize current block** from the **Discretize** menu if a single block is selected or select **Discretize selected blocks** from the **Discretize** menu if multiple blocks are selected.

You can also discretize the current block by clicking the **Discretize** button, shown below.

### Store the Discretization Settings and Apply Them to Selected Blocks in the Model

- 1 Enter the discretization settings for the current block.
- 2 Click **Store Settings**.

This adds the current block with its discretization settings to the group of preset blocks.

- 3 Repeat steps 1 and 2, as necessary.
- 4 Select **Discretize preset blocks** from the **Discretize** menu.

### Deleting a Discretization Candidate from a Variant Subsystem

You can delete a discretization candidate from a variant subsystem by selecting it in the **Location for block in Variant Subsystem** field and clicking the **Delete** button.

### Undoing a Discretization

To undo a discretization, click the **Undo discretization** button.

Alternatively, you can select **Undo discretization** from the **Discretize** menu.

This operation undoes discretizations in the current selection and its children. For example, performing the undo operation on a subsystem will remove discretization from all blocks in all levels of the subsystem's hierarchy.

## View the Discretized Model

Model Discretizer displays the model in a hierarchical tree view.

### Viewing Discretized Blocks

The block's icon in the tree view becomes highlighted with a “z” when the block has been discretized.

The following figure shows that the Aircraft Dynamics Model subsystem has been discretized into a variant subsystem with two discretization candidates.

The other blocks in this f14 model have not been discretized.

The following figure shows the Aircraft Dynamics Model subsystem of the f14 example model after discretization into a variant subsystem containing the original continuous model and two discretization candidates.

The following figure shows the Aircraft Dynamics Model variant subsystem with the two discretization candidates.

### Refreshing Model Discretizer View of the Model

To refresh the Model Discretizer tree view of the model when the model has been changed, click the **Refresh** button.

Alternatively, you can select **View > Refresh**.

## Discretize Blocks from the Simulink Model

You can replace continuous blocks in a Simulink software model with the equivalent blocks discretized in the s-domain using the Discretizing library.

The procedure below shows how to replace a continuous Transfer Fcn block in the Aircraft Dynamics Model subsystem of the f14 model with a discretized Transfer Fcn block from the Discretizing Library. The block is discretized in the s-domain with a zero-order hold transform method and a two second sample time.

- 1 Open the f14 model.
- 2 Open the Aircraft Dynamics Model subsystem in the f14 model.

- 3 Open the Discretizing library window.  
Enter `discretizing` at the MATLAB command prompt.  
The **Library: discretizing** window opens.

This library contains s-domain discretized blocks.

- 4 Add the Discretized Transfer Fcn (with initial states) block to the **f14/Aircraft Dynamics Model** window.
  - a Click the Discretized Transfer Fcn block in the **Library: discretizing** window.
  - b Drag it into the **f14/Aircraft Dynamics Model** window.

- 5 Open the parameter dialog box for the Transfer Fcn.1 block.

Double-click the Transfer Fcn.1 block in the **f14/Aircraft Dynamics Model** window.

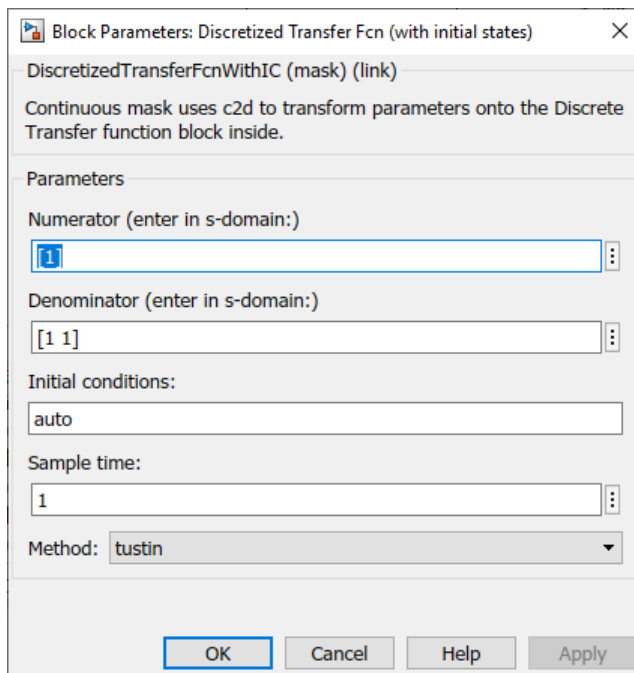

The Block Parameters: Transfer Fcn.1 dialog box opens.

- 6 Open the parameter dialog box for the Discretized Transfer Fcn block.

Double-click the Discretized Transfer Fcn block in the **f14/Aircraft Dynamics Model** window.

The Block Parameters: Discretized Transfer Fcn dialog box opens.

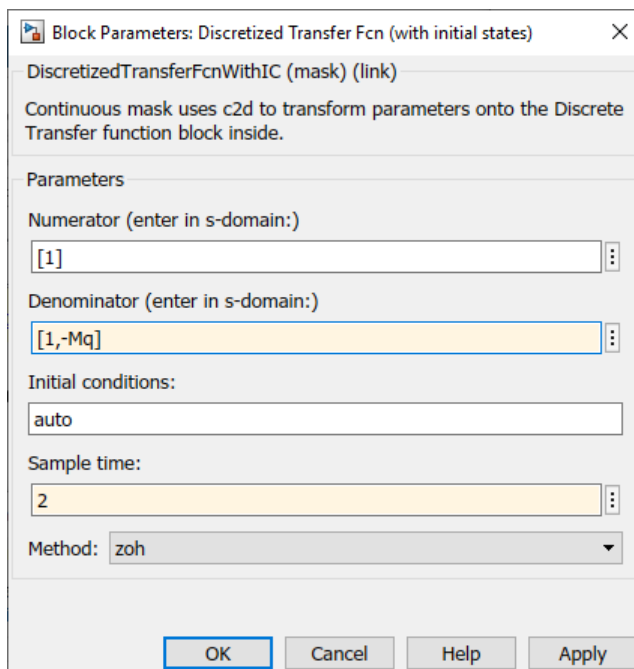

Copy the parameter information from the Transfer Fcn.1 block dialog box to the Discretized Transfer Fcn block's dialog box.

- 7 Enter 2 in the **Sample time** field.
- 8 Select zoh from the **Method** dropdown list.

The parameter dialog box for the Discretized Transfer Fcn now looks like this.

- 9 Click **OK**.

The **f14/Aircraft Dynamics Model** window now looks like this.

**10** Delete the original Transfer Fcn.1 block.

- a** Click the Transfer Fcn.1 block.
- b** Press the **Delete** key.

The **f14/Aircraft Dynamics Model** window now looks like this.

**11** Add the Discretized Transfer Fcn block to the model.

- a Click the Discretized Transfer Fcn block.
- b Drag the Discretized Transfer Fcn block into position to complete the model.

The **f14/Aircraft Dynamics Model** window now looks like this.

## Discretize a Model with the sldiscmdl Function

Use the `sldiscmdl` function to discretize Simulink software models from the MATLAB Command Window. You can specify the transform method, the sample time, and the discretization method with the `sldiscmdl` function.

For example, the following command discretizes the `f14` model in the s-domain with a 1-second sample time using a zero-order hold transform method:

```
sldiscmdl('f14',1.0,'zoh')
```

- “Variant subsystem (Enter parameters in s-domain)” on page 4-79
- “Variant subsystem (Enter parameters in z-domain)” on page 4-79

## Use modelfinder to Index Simulink Models and Improve its Discoverability within an Organization

You can now use `modelfinder` to search example models that matches the specified string. By default, `modelfinder` searches for example models in the MATLAB path. You can customize `modelfinder` to search for example models developed by your organization. Use `modelfinder.register` to index all the example models in the specified path. Similarly, use `modelfinder.unregister` to exclude all the example models in a specific path.

### Search example models matching the search string

Specify the search string to search for a model. If there are more than one match, then all matching items are displayed as a list, and you are prompted to select one of them. For example, to search for models that have `autosar` in their name run the command:

```
modelfinder('autosar')
```

```
1. AUTOSARCounterExample
   2. AuthorAUTOSARCompositionsInArchitectureModelExample
   3. > autosar_tpc_actuator
   4. > autosar_tpc_composition
   5. > autosar_tpc_controller
   6. > autosar_tpc_pedal_sensor
   7. > autosar_tpc_system
   8. > autosar_tpc_throttle_sensor1
   9. > autosar_tpc_throttle_sensor2
  10. > autosar_tpc_throttle_sensor_monitor
  11. ConfigureAndSimulateAUTOSARFiMServiceCallsExample
  12. > autosar_bsw_fim
  13. > autosar_bsw_fimmonitor
  14. > autosar_bsw_fimoperationcycle
  15. > autosar_bsw_fimsensor1
  16. > autosar_bsw_fimsensor2
  17. CreateAndConfigureAUTOSARAdaptiveSoftwareComponentExample
  18. DesignAUTOSARComponentsExample
  19. > autosar_composition
  20. > autosar_swc_actuator
  21. > autosar_swc_controller
  22. > autosar_swc_monitor
  23. > autosar_swc_pedal_sensor
  24. > autosar_swc_throttle_sensor
  25. > autosar_system
Showing 1-25 of 68 matches. Enter (m) for more results.
Enter the example number you want to open (choose number) OR
see more results (m) OR quit (q)
```

If there are more than three words in the search term, then `modelfinder` treats it as natural language query and finds models that satisfies the natural language query. For example, to search for solar panel models in Simulink

```
modelfinder('solar panel models in simulink')
```

```
1. GenerateHDLFromMultipleSimscapeNetworksExample
   2. > Solar_Power_Inverter_Multiple_Network_HDL
   3. > Solar_Power_Inverter_Multiple_Network_StateSpace
```

```
4. HybridSolarPanelExample
   > sscv_hybrid_solar_panel
5. PartitionLargeNetworkIntoMultipleSmallerNetworksExample
   > Solar_Power_Inverter_Single_Network_HDL
6. ee_mars_helicopter_system
7. ee_solar_boostconverter_maxpowerpoint
8. ee_solar_generator
9. ee_solar_gridconnected_singlephase
10. ee_solar_gridconnected_threephase
11. ee_solar_inverter
12. ee_solar_panel
13. ee_solar_standalone_acsystem_withbatterybackup
14. ee_solar_standalone_dcsystem_withbatterybackup
15. power_microgrid
16. sm_solar_tracker
Enter the example number you want to open (choose number) OR quit (q) :
```

See `modelfinder`, for all the search options and filters.

### Register and Unregister folder path to search index of `modelfinder`

The `modelfinder` function indexes the models in the search path. Specify the path of the models that needs to be included for indexing. For example, if you want to search for models in the path `~/Desktop/myFolder`, run the command

```
modelfinder.registerFolder("~/Desktop/myFolder");
```

This registers all models in the `~/Desktop/myFolder` path to `modelfinder` search result. It will look for models recursively within the specified folder.

To exclude models from the search results, you must unregister model from the `modelfinder` search index so that the models does not appear in search results. For example, if you want to exclude models from the search results in the path `~/Desktop/myFolder`, run the command:

```
modelfinder.unregisterFolder("~/Desktop/myFolder");
```

## Create Model That Performs Neighborhood Processing

### In this section...

“Import Image and Output Results” on page 4-93  
 “Configure Neighborhood Processing Subsystem” on page 4-93  
 “Simulate and View Results” on page 4-94

This example shows how to create a model that performs neighborhood processing by using the Neighborhood Processing Subsystem block to blur an image. Neighborhood processing algorithms operate on images by iteratively processing windows of pixels, called neighborhoods, within the image.

### Import Image and Output Results

The Neighborhood Processing Subsystem block operates on image data. You can use Computer Vision Toolbox™ blocks to import image data and render images.

- 1 Create a model that contains a Neighborhood Processing Subsystem block.
- 2 To import an image, add the Image From File (Computer Vision Toolbox) block to your model. Double-click the block to open the block dialog. To prevent precision loss, in the **Data Types** tab, set the **Output data type** block parameter to **double**.
- 3 Connect the output port of the Image From File block to the input port of the Neighborhood Processing Subsystem block.
- 4 To display images, use the Video Viewer (Computer Vision Toolbox) block. Use two Video Viewer blocks to display the image before and after the Neighborhood Processing Subsystem block.

### Configure Neighborhood Processing Subsystem

The Neighborhood Processing Subsystem block accepts a matrix as input and produces a matrix as output. Inside the subsystem, build an algorithm that accepts a neighborhood of the input matrix as input and produces a scalar as output. The block handles the processes of iteratively passing each neighborhood and assembling the output scalars into an output matrix.

- 1 Open the Neighborhood Processing Subsystem block.
- 2 The Neighborhood control block in the subsystem configures the behavior of the subsystem. Open the Neighborhood block parameters.
- 3 Set the **Neighborhood size** parameter to [5 5 1]. The Neighborhood Processing Subsystem block iterates over 5-by-5 windows for each color channel in the input image. A larger window size produces more blur.
- 4 Place a Gain block between the Inport and Output blocks. Set the **Gain** value to 1/25.
- 5 Place a Sum of Elements block between the Gain and Output blocks. The Sum of Elements block converts a matrix to a scalar. By multiplying the 25 elements of the neighborhood by 1/25 and summing the values, the subsystem computes the average value of the neighborhood. This creates a blur effect by blending nearby pixels together.

### Simulate and View Results

Simulate the model. The processed image is blurry compared to the original image.

# Model Advisor

---

## Check Your Model Using the Model Advisor

### Model Advisor Overview

The Model Advisor checks your model or subsystem for modeling conditions and configuration settings that cause inaccurate or inefficient simulation of the system that the model represents. The Model Advisor checks can help you verify compliance with industry standards and guidelines. By using the Model Advisor, you can implement consistent modeling guidelines across projects and development teams.

Upon completing the analysis of your model, the Model Advisor produces a report that lists the suboptimal conditions, settings, and modeling techniques and proposes solutions, when applicable.

You can use the Model Advisor to check your model in these ways:

- Interactively run Model Advisor checks
- Configure the Model Advisor to automatically run edit-time checks (requires Simulink Check™)

These limitations apply when you use the Model Advisor to check your model. For limitations that apply to specific checks, see the Capabilities and Limitations section in the check documentation.

- If you rename a system, you must restart the Model Advisor to check that system.
- In systems that contain a variant subsystem, the Model Advisor checks the active subsystem. To check both the active and inactive subsystems, set the `Advisor.Application (Simulink Check)` property, `AnalyzeVariants`, to `true`.
- Model Advisor does not analyze commented blocks.
- Checks do not search in model blocks or subsystem blocks with the block parameter **Read/Write** set to `NoReadorWrite`. However, on a check-by-check basis, Model Advisor checks do search in library blocks and masked subsystems.
- Unless specified otherwise in the documentation for a check, the Model Advisor does not analyze the contents of a Model block. To run checks on referenced models, use instances of the `Advisor.Application` class (Simulink Check license required).

---

**Note** Software is inherently complex and may not be free of errors. Model Advisor checks might contain bugs. MathWorks® reports known bugs brought to its attention on its Bug Report system at <https://www.mathworks.com/support/bugreports/>. The bug reports are an integral part of the documentation for each release. Examine bug reports for a release as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

While applying Model Advisor checks to your model increases the likelihood that your model does not violate certain modeling standards or guidelines, their application cannot guarantee that the system being developed will be safe or error-free. It is ultimately your responsibility to verify, using multiple methods, that the system being developed provides its intended functionality and does not include unintended functionality.

---

## Model Advisor Checks Documentation

The Model Advisor only displays the checks for your installed products. This table provides links to the product-specific check documentation. A product license may be required to review some of the documentation.

## Run Model Advisor Checks and Review Results

You can use the Model Advisor to check your model interactively against modeling standards and guidelines. The following example uses the `sldemo_mdadv` model to demonstrate the execution of the Model Advisor checks using the Model Advisor.

- 1 Open the Model Advisor example model `sldemo_mdadv`.
- 2 To open the Model Advisor, in the Simulink editor, click the **Modeling** tab and select **Model Advisor**. A **System Selector — Model Advisor** dialog box opens. Select the model or system that you want to review and click **OK**.
- 3 In the left pane of the Model Advisor, select the checks you want to run on your model:
  - a You can select the checks by using the **By Product** or **By Task** folders.
    - **Show By Product Folder** — Displays checks available for each product
    - **Show By Task Folder** — Displays checks related to specific tasks

Checks with the icon  trigger an update of the model diagram.

Checks with the icon  trigger an extensive analysis of the model. Checks that trigger extensive analysis of the model use additional analysis techniques, such as analysis with Simulink Design Verifier.

- 4 Click on the folder that contains the checks and, on the toolstrip, select **Run Checks** to execute the analysis. To run a single check, right-click the check in the folder and select **Run This Check**.
- 5 View the results on the Model Advisor User Interface. This table shows the common check status results; notice that different icons are used depending on the parameter set for **Check result when issues are flagged** in the Model Advisor Configuration Editor (requires a Simulink Check license). For more information about this parameter, see "Specify Parameters for Check Customization" (Simulink Check).

Check Result Status	Icon	Description
Passed		Model does not have any violations for the given check(s).
Failed		Check has identified severe violations.
Warning		Check has identified violations.
Justified		Check violations are justified.
Not Run		Check not selected for Model Advisor analysis.

Check Result Status	Icon	Description
Incomplete		Check analysis is incomplete or check execution has resulted in exceptions.

- 6 Fix the warnings or failures as desired. For more information, see “Address Model Check Results” on page 5-7.
- 7 Use the **Exclusions** tab to review checks that were marked for exclusion from the analysis.
- 8 View and save the report. For additional information, see “Save and View Model Advisor Check Reports” on page 5-8 and “Generate Model Advisor Reports” (Simulink Check).

## Run Model Checks Programmatically

If you have Simulink Check, you can create MATLAB scripts and functions so that you can run the Model Advisor programmatically. For example, you can create a `ModelAdvisor.run` function to check whether your model passes a specified set of the Model Advisor checks every time that you open the model and start a simulation.

## Find Model Advisor Check IDs

An *ID* is a unique identifier for a Model Advisor check. You find check IDs in the Model Advisor, using check context menus.

To Find	Do This
Check Title, ID, or location of the MATLAB source code	<ol style="list-style-type: none"> <li>1 On the model window toolbar, in the <b>Modeling</b> tab, select <b>Model Advisor</b> to open the Model Advisor.</li> <li>2 Select a check from the <b>Check Selector</b> window.</li> <li>3 In the right pane of the Model Advisor window, the Model Advisor window displays the check Title, TitleID, and location of the MATLAB source code for the check.</li> </ol>
Check ID	<ol style="list-style-type: none"> <li>1 In the left pane of the Model Advisor, select the check.</li> <li>2 Right-click the check name and select <b>Send Check ID to Workspace</b>. The ID is displayed in the Command Window and sent to the base workspace.</li> </ol>
Check IDs for selected checks in a folder	<ol style="list-style-type: none"> <li>1 In the left pane of the Model Advisor, select the checks for which you want IDs. Clear the other checks in the folder.</li> <li>2 Right-click the folder and select <b>Send Check ID to Workspace</b>. An array of the selected check IDs are sent to the base workspace.</li> </ol>

If you know a check ID from a previous release, you can find the current check ID using the `ModelAdvisor.lookupCheckID` function. For example, the check ID for Check for root Outports with missing range definitions prior to Release 2018b was `mathworks.iec61508.OutportRange`. Using the `ModelAdvisor.lookupCheckID` function returns:

```
>> NewID = ModelAdvisor.lookupCheckID('mathworks.iec61508.OutportRange')

NewID =
'mathworks.hism.hisl_0026'
```

### See Also

`ModelAdvisor.lookupCheckID`

### Related Examples

### More About

- “Check Your Model Using the Model Advisor” on page 5-2

## Address Model Check Results

After you run the Model Advisor checks on page 5-4 to find warnings or failures in your model, you can use the Model Advisor to fix check warnings or failures manually or by using the Model Advisor.

### Fix a Model Advisor Check Warning or Failure

The Model Advisor check results identify model elements that are being flagged by the Model Advisor check. You can either manually fix the issues or use the Model Advisor to automatically apply a fix.

For more information on why a specific check does not pass, see the documentation for that check.

- 1 In the Model Advisor results, review the results of the analysis.
- 2 Fix the warning or failure by using one of these methods:
  - a To manually fix an issue, use the hyperlinks from the **Result Details > Failing Element** to open model elements that are being flagged by the Model Advisor check. You can also apply batch changes to model parameters from the command line.
  - b To use the Model Advisor to automatically fix an issue, from the toolstrip, click **Fix**. The **Action Report** box displays a table of changes.
- 3 To verify that the check passes, rerun the check.

---

**Note** After you finish addressing all warnings or failures, it is important that you rerun all checks to verify that there are no additional issues.

---

#### More About

- “Check Your Model Using the Model Advisor” on page 5-2

## Save and View Model Advisor Check Reports

When the Model Advisor runs checks, it generates an HTML report of check results. By default, the HTML report is in the `slprj/modeladvisor/model_name` folder.

If you have Simulink Check, you can generate reports in Adobe® PDF and Microsoft Word Word formats.

### Save Model Advisor Check Reports

The Model Advisor uses the `slprj` folder in the Simulink cache folder to store reports and other information. If the `slprj` folder does not exist in the Simulink cache folder, the Model Advisor creates it.

You can save a Model Advisor report to a new location.

- 1 In the Model Advisor window, navigate to the folder with the checks that you ran.
- 2 Select the folder. The right pane of the Model Advisor window displays information about that folder.
- 3 From the toolstrip, click **Report**.

**Save Report** dialog box appears.

- 4 In the **Save Report** dialog box, enter the path to the folder where you want to generate the report. Provide a file name.
- 5 Click **Save**. The Model Advisor saves the report in HTML format to the location that you specified.

---

**Note** To change the Report format PDF or WORD, from the toolstrip, use the **Report** drop-down options. Simulink Online does support report generation in PDF or WORD format for Model Advisor.

---

If you rerun the Model Advisor, the report is updated in the working folder, not in the location where you archived the original report.

The full path to the report is in the title bar of the report window.

### View Model Advisor Check Reports

Access a report by selecting a folder and clicking the link in the **Report** box.

---

**Tip** Use the options in the Model Advisor window to interactively fix warnings and failures. Model Advisor reports are best for viewing a summary of checks.

---

As you run checks, the Model Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, an informational message appears in the report. Timestamps indicate when checks have been run. The time of the current run appears at the top right of the report. Checks that occurred during previous runs have a timestamp following the check name.

Goal	Action
Display results for checks that pass, warn, or fail.	Use the <b>Filter checks</b> check boxes. For example, to display results for only checks that warn, in the left pane of the report, select the Warning check box. Clear the <b>Passed</b> , <b>Failed</b> , and <b>Not Run</b> check boxes.
Display results for checks with keywords or phrases in the check title.	Use the <b>Keywords</b> field. Results for checks without the keyword in the check title are not displayed in the report. For example, to display results for checks with only “setting” in the check title, in the <b>Keywords</b> field, enter “setting”.
Quickly navigate to sections of the report.	Select the links in the table-of-contents navigation pane.
Expand and collapse content in the check results.	Click <b>Show/Hide check details</b> .
Scroll to the top of the report.	Click <b>Scroll to top</b> .
Minimize folder results in the report.	Click the minus sign next to the folder name.

Printed versions of the report do not contain:

- Filtering checks, Navigation, or View panes.
- Content hidden due to filtering or keyword searching.

Some checks have input parameters specified in the right pane of the Model Advisor. For example, **Check Merge block usage** has an input parameter for **Maximum analysis time (seconds)**. When you run checks with input parameters, the Model Advisor displays the values of the input parameters in the HTML report. For more information, see the `EmitInputParametersToReport` property of the `Simulink.ModelAdvisor` class.

# Upgrade Advisor

---

## Consult the Upgrade Advisor

Use the Upgrade Advisor to help you upgrade and improve models with the current release. The Upgrade Advisor can identify cases where you can benefit by changing your model to use new features and settings in Simulink. The Advisor provides advice for transitioning to new technologies, and upgrading a model hierarchy.

The Upgrade Advisor can also help identify cases when a model will not work because changes and improvements in Simulink require changes to a model.

The Upgrade Advisor offers options to perform recommended actions automatically or instructions for manual fixes.

You can open the Upgrade Advisor in the following ways:

- From the Model Editor, on the **Modeling** tab, select **Model Advisor > Upgrade Advisor**
- From the MATLAB command line, use the `upgradeadvisor` function:

```
upgradeadvisor modelName
```

- Alternatively, from the Model Advisor, click **Upgrade Advisor**. This action closes the Model Advisor and opens the Upgrade Advisor.

In the Upgrade Advisor, you create reports and run checks in the same way as when using the Model Advisor.

- Select the top Upgrade Advisor node in the left pane to run all selected checks and create a report.
- Select each individual check to open a detailed view of the results in the right pane. View the analysis results for recommended actions to manually fix warnings or failures. In some cases, the Upgrade Advisor provides mechanisms for automatically fixing warnings and failures.

---

**Caution** When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Upgrade Advisor might report an invalid check result.

---

You must run upgrade checks in this order: first the checks that do not require compile time information and do not trigger an Update Diagram, then the compile checks. To guide you through upgrade checks to run both non-compile and compile checks, run the check **Analyze model hierarchy and continue upgrade sequence**. See “Analyze model hierarchy and continue upgrade sequence”.

For models with no hierarchy, select and run all checks except the **Analyze model hierarchy and continue upgrade sequence** check.

For more information on individual checks, see

- “Model Upgrades” for upgrade checks only
- “Simulink Checks” for all upgrade and advisor checks

## Upgrade Programmatically

To analyze and upgrade models programmatically, use the `upgradeadvisor` function.

---

**Tip** For an example showing how to upgrade a whole project programmatically, see “Upgrade Simulink Models Using a Project”.

---

## Upgrade Advisor Checks

For advice on upgrading and improving models with the current release, use the following Model Advisor checks in the Upgrade Advisor.

- “Check model for block upgrade issues”
- “Check usage of function-call connections”
- “Identify Model Info blocks that can interact with external source control tools”
- “Check for calls to slDataTypeAndScale”
- “Identify masked blocks that specify tabs in mask dialog using MaskTabNames parameter”
- “Identify Variant blocks using Variant objects with empty conditions”
- “Check that the model or library is saved in current version”
- “Check if SLX file compression is off”
- “Check model for SB2SL blocks”
- “Check Model History properties”
- “Identify Model Info blocks that use the Configuration Manager”
- “Identify configurable subsystem blocks for converting to variant subsystem blocks”
- “Check and update masked blocks in library to use promoted parameters”
- “Check and update mask image display commands with unnecessary imread() function calls”
- “Check Rapid accelerator signal logging”
- “Check get\_param calls for block CompiledSampleTime”
- “Check model for parameter initialization and tuning issues”
- “Check model for block upgrade issues requiring compile time information”
- “Check usage of Merge blocks”
- “Check usage of Output blocks”
- “Check Delay, Unit Delay and Zero-Order Hold blocks for rate transition”
- “Check usage of Discrete-Time Integrator blocks”
- “Check model settings for migration to simplified initialization mode”
- “Check model for legacy 3DoF or 6DoF blocks”
- “Check model for Aerospace Blockset navigation blocks”

## What Is Sample Time?

The sample time of a block is a parameter that indicates when, during simulation, the block produces outputs and if appropriate, updates its internal state. The internal state includes but is not limited to continuous and discrete states that are logged.

---

**Note** Do not confuse the Simulink usage of the term sample time with the engineering sense of the term. In engineering, sample time refers to the rate at which a discrete system samples its inputs. Simulink allows you to model single-rate and multirate discrete systems and hybrid continuous-discrete systems through the appropriate setting of block sample times that control the rate of block execution (calculations).

---

For many engineering applications, you need to control the rate of block execution. In general, Simulink provides this capability by allowing you to specify an explicit `SampleTime` parameter in the block dialog or at the command line. Blocks that do not have a `SampleTime` parameter have an implicit sample time. You cannot specify implicit sample times. Simulink determines them based upon the context of the block in the system. The Integrator block is an example of a block that has an implicit sample time. Simulink automatically sets its sample time to 0.

Sample times can be port based or block based. For block-based sample times, all of the inputs and outputs of the block run at the same rate. For port-based sample times, the input and output ports can run at different rates. To learn more about rates of execution, see “Types of Sample Time” on page 7-20.

## What Is Union Sample Time?

The union sample time of a system is one sample time that unites two or more event sample times.

In the figure,  $E_1$  and  $E_2$  are independent events that do not preempt each other. The sample time of  $C$  is  $E_3$  which is computed using  $E_3 = \text{union}(E_1, E_2)$ . For example, if an Output block receives a union sample time of 2 and 3, then the block runs twice at 0 sample time, once for sample time 2, once for sample time 3, then at 2, 3, 4, twice again at 6, and so on. For more details on sample time, see “What Is Sample Time?” on page 7-2.

You can expect union sample time in these scenarios:

- **Root-level Inport block** - When “Allow multiple tasks to access inputs and outputs” is enabled for non-export function models, or when a root-level Inport block has multiple destinations in at least two different tasks. Union sample time may occur these situations.
- Two destinations have different discrete rates and the model setting “Treat each discrete rate as a separate task” is enabled.

- Two destinations have different explicit partitions.

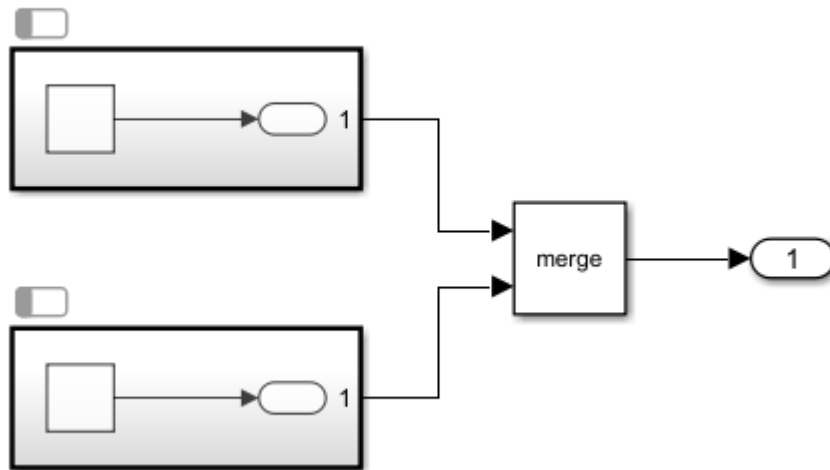

- Two destinations have exported function-call subsystems in an export-function model.

- **Root-level Output block and Merge block** - When a Merge block receives input from sources in at least two different tasks and is connected to the root Output block. Union sample times may occur in these situations:
  - Two blocks with discrete rates have the model setting "Treat each discrete rate as a separate task" enabled, such that the blocks in different tasks, and write to a Merge block connected to a root Output block.

- Two explicit partitions write to a Merge block that is connected to the root output.

- Two exported function-call systems write to the root output via a Merge block.

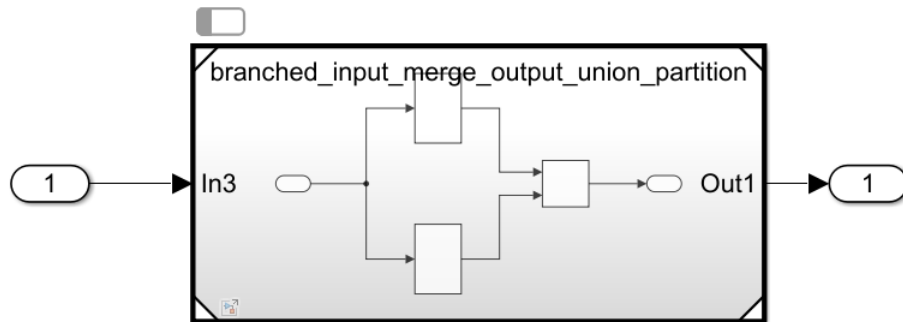

- **Model block** - When “Allow multiple tasks to access inputs and outputs” is enabled for non-export function models, or when ports of the Model block are accessed in multiple tasks inside the referenced model. Union sample time may occur in these situations:
  - Two discrete rates read or write from the root inports or outports of the referenced model, and “Allow multiple tasks to access inputs and outputs” is enabled in the referenced model. In this case, the model block will get a union rate on its ports if “Treat each discrete rate as a separate task” is enabled in both the referenced and the top models.

- Two explicit partitions access the inports or outports in a referenced model. In this case, the model block inputs or outputs will get a union rate.

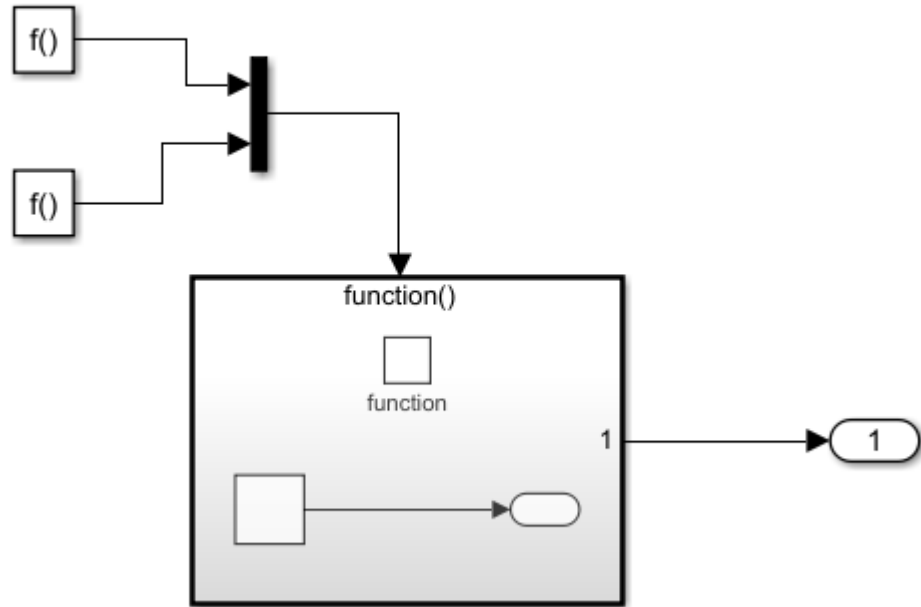

- Two exported functions access the inputs or outputs in a referenced export function model. In this case, the model block will have a union rate if "Allow multiple tasks to access inputs and outputs" is enabled in the top model.

- **Function-call subsystem** and **Model block with function-call ports** - When the function-call ports are fed by a mixed signal containing functions calls with different sample times. Union sample time may occur in these situations:
  - A function-call subsystem is called by two callers.

- A function-call port on a model block is called by two callers.

- A Simulink function has two callers that have different rates in different tasks.

### Designate Sample Times

Simulink allows you to specify a block sample time directly as a numerical value or symbolically by defining a sample time vector. In the case of a discrete sample time, the vector is  $[T_s, T_o]$  where  $T_s$  is the sampling period and  $T_o$  is the initial time offset. For example, consider a discrete model that produces its outputs every two seconds. If your base time unit is seconds, you can directly set the discrete sample time by specifying the numerical value of 2 as the `SampleTime` parameter. Because the offset value is zero, you do not need to specify it; however, you can enter  $[2, 0]$  in the **Sample time** field.

For nondiscrete blocks, the components of the vector are symbolic values that represent one of the types in “Types of Sample Time” on page 7-20. The following table summarizes these types and the corresponding sample time values. The table also defines the explicit nature of each sample time type and designates the associated color and annotation. Because an *inherited sample time* is explicit, you can specify it as  $[-1, 0]$  or as  $-1$ . Whereas, a triggered sample time is implicit; only Simulink can assign the sample time of  $[-1, -1]$ . (For more information about colors and annotations, see “View Sample Time Information” on page 7-16.)

## Designations of Sample Time Information

Sample Time Type	Sample Time	Color	Annotation	Explicit
Discrete	$[T_s, T_o]$	In descending order of speed: red, green, blue, light blue, dark green, orange	D1, D2, D3, D4, D5, D6, D7,... Di	Yes
Continuous	$[0, 0]$	black	Cont	Yes
Fixed in minor step	$[0, 1]$	gray	FiM	Yes
Inherited	$[-1, 0]$	N/A	N/A	Yes
Constant	$[\text{Inf}, 0]$	magenta	Inf	Yes
Variable	$[-2, T_{v0}]$	brown	V1, V2,... Vi	No
Controllable	$[\text{base}, -2i], i = 0, 1, 2, \dots,$	brown	Ctrl1, Ctrl2, Ctrl3, .... Ctrli	Yes
Hybrid	N/A	yellow	N/A	No
Triggered	Source: D1, Source: D2, ...Source: Di	cyan	T1, T2,... Ti	No
Asynchronous	$[-1, -n]$	purple	A1, A2,... Ai	No
Dataflow	N/A	light purple	N/A	No

The color that is assigned to each block depends on its sample time relative to other sample times in the model. This means that the same sample time may be assigned different colors in a parent model and in models that it references. (See “Model References”.)

For example, suppose that a model defines three sample times: 1, 2, and 3. Further, suppose that it references a model that defines two sample times: 2 and 3. In this case, blocks operating at the 2 sample rate appear as green in the parent model and as red in the referenced model.

It is important to note that Mux and Demux blocks are simply grouping operators; signals passing through them retain their timing information. For this reason, the lines emanating from a Demux block can have different colors if they are driven by sources having different sample times. In this case, the Mux and Demux blocks are color coded as hybrids (yellow) to indicate that they handle signals with multiple rates.

Similarly, Subsystem blocks that contain blocks with differing sample times are also colored as hybrids, because there is no single rate associated with them. If all the blocks within a subsystem run at a single rate, the Subsystem block is colored according to that rate.

You can use the explicit sample time values in this table to specify sample times interactively or programmatically for either block-based or port-based sample times.

The following model, `ex_specify_sample_time`, serves as a reference for this section.

### ex\_specify\_sample\_time

In this example, set the sample time of the input sine wave signal to 0.1. The goal is to achieve an output sample time of 0.2. The Rate Transition block serves as a zero-order hold. The resulting block diagram after setting the sample times and simulating the model is shown in the following figure. (The colors and annotations indicate that this is a discrete model.)

### ex\_specify\_sample\_time after Setting Sample Times

## Specify Block-Based Sample Times Interactively

To set the sample time of a block interactively:

- 1 In the Simulink model window, double-click the block. The block parameter dialog box opens.
- 2 Enter the sample time in the **Sample time** field.
- 3 Click **OK**.

Following is a figure of a parameters dialog box for the Sine Wave block after entering 0.1 in the **Sample time** field.

Parameters

Sine type: Time based

Time (t): Use simulation time

Amplitude: 1

Bias: 0

Frequency: 1

Phase (rad): 0

Sample time: 0.1

Interpret vector parameters as 1-D

OK Cancel Help Apply

Enter the sample time value in this field

To specify and inspect block-based sample times throughout a model, consider using the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). On the **Inports/Outports**, **Signals**, and **Data Stores** tabs, set the **Change view** drop-down list to Design and use the **Sample Time** column. For more information, see **Model Data Editor**.

## Specify Port-Based Sample Times Interactively

The Rate Transition block has port-based sample times. You can set the output port sample time interactively by completing the following steps:

- 1 Double-click the Rate Transition block. The parameters dialog box opens.
- 2 Leave the drop-down menu choice of the **Output port sample time options** as **Specify**.
- 3 Replace the -1 in the **Output port sample time** field with 0.2.

Parameters

Ensure data integrity during data transfer

Ensure deterministic data transfer (maximum delay)

Initial conditions: 0

Output port sample time options: Specify

Output port sample time: 0.2

OK Cancel Help Apply

Enter sample time in Output port sample time field

**4** Click **OK**.

For more information about the sample time options in the Rate Transition parameters dialog box, see the Rate Transition reference page.

## Specify Block-Based Sample Times Programmatically

To set a block sample time programmatically, set its `SampleTime` parameter to the desired sample time using the `set_param` command. For example, to set the sample time of the Gain block in the `Specify_Sample_Time` model to inherited (-1), enter the following command:

```
set_param('Specify_Sample_Time/Gain','SampleTime','[-1, 0]')
```

As with interactive specification, you can enter just the first vector component if the second component is zero.

```
set_param('Specify_Sample_Time/Gain','SampleTime','-1')
```

## Specify Port-Based Sample Times Programmatically

To set the output port sample time of the Rate Transition block to 0.2, use the `set_param` command with the parameter `OutPortSampleTime`:

```
set_param('Specify_Sample_Time/Rate Transition',...  
'OutPortSampleTime', '0.2')
```

## Access Sample Time Information Programmatically

To access all sample times associated with a model, use the API `Simulink.BlockDiagram.getSampleTimes`.

To access the sample time of a single block, use the API `Simulink.Block.getSampleTimes`.

## Specify Sample Times for a Custom Block

You can design custom blocks so that the input and output ports operate at different sample time rates. For information on specifying block-based and port-based sample times for S-functions, see “Specify S-Function Sample Times” in *Writing S-Functions* of the Simulink documentation.

## Determining Sample Time Units

Since the execution of a Simulink model is not dependent on a specific set of units, you must determine the appropriate base time unit for your application and set the sample time values accordingly. For example, if your base time unit is second, then you would represent a sample time of 0.5 second by setting the sample time to 0.5.

## Change the Sample Time After Simulation Start Time

To change a sample time after simulation begins, you must stop the simulation, reset the `SampleTime` parameter, and then restart execution.

## View Sample Time Information

### In this section...

“Inspect Sample Time Using Timing Legend” on page 7-16

“Inspect Sample Times Throughout a Model” on page 7-18

Simulink models can display color coding and annotations that represent specific sample times. Each sample time type has one or more colors associated with it. You can display the blocks and signal lines in color, the annotations in black, or both. To select one of these options:

- 1 To enable colors, in the Simulink model window, on the **Debug** tab, select **Information Overlays > Colors**.
- 2 To enable annotations, on the **Debug** tab, select **Information Overlays > Text**.

Selecting both **Colors** and **Text** displays both the colors and the annotations. Regardless of your choice, Simulink performs an **Update Model** automatically.

To turn off the colors and annotations:

- 1 On the **Debug** tab, select **Information Overlays > Colors** to disable colors.
- 2 On the **Debug** tab, select **Information Overlays > Text** to disable annotations.

Simulink performs another **Update Model** automatically.

Your Sample Time Display choices directly control the information that the Timing Legend displays.

---

**Note** The discrete sample times in the table Designations of Sample Time Information represent a special case. Five colors indicate the speed through the fifth fastest discrete rate. A sixth color, orange, represents all rates that are slower than the fifth discrete rate. You can distinguish between these slower rates by looking at the annotations on their respective signal lines.

---

## Inspect Sample Time Using Timing Legend

You can view the Timing Legend for an individual model or for multiple models. Additionally, you can prevent the legend from automatically opening when you select options on the **Sample Time** menu.

To assist you with interpreting a block diagram, the Timing Legend contains the sample time color, annotation, and value for each sample time in the model. To view the legend:

- 1 In the Simulink model window, on the **Modeling** tab, click **Update Model**.
- 2 On the **Debug** tab, select **Information Overlays > Legend** or press **Ctrl + J**.

In addition, when you select **Colors** or **Text**, Simulink updates the model diagram and opens the legend by default. The legend contents reflect your choices. If you turn colors on, the legend displays the color and the value of the sample time. Similarly, if you turn annotations on, the annotations appear in the legend.

The legend displays sample times present in the model, classified by the type of the sample time.

Sine\_sampletimes

Sine\_sampletimes

Timing Legend

Highlight All

This rate is introduced by Simulink and not visible on any blocks.

Discrete	Period
D1	1
D2	3

The legend provides two types of highlighting options:

- Highlighting the blocks and signals that the sample time originates from.
- Highlighting all the blocks and signals that contain the selected sample time.

To enable highlighting of the origin of the sample times, click the **Origin** option from the **Highlight** menu. You can also click the type of the sample time to highlight all sources of a particular type of sample time.

Sine\_sampletimes

Sine\_sampletimes

Timing Legend

Highlight Origin

Click the rate/type to highlight its origin.

Discrete	Period
D1	1
D2	3

Sine\_sampletimes

Sine\_sampletimes

Timing Legend

Highlight Origin

Click the rate/type to highlight its origin.

Discrete	Period
D1	1
D2	3

To enable highlighting of all the blocks that contain a selected sample time, click the **All** option from the **Highlight** menu. You can also click the type of the sample time to highlight all the blocks and signals that contain the select type of sample time.

The None option from the **Highlight** menu clears current highlighting.

The button  shows discrete value as 1/period when the discrete sample time is present. When clicked, the discrete period is displayed as 1/period; for a nonzero offset, it displays as offset/period. The image shows 1/period values and the corresponding highlighted block in the model.

**Note** The Timing Legend displays all of the sample times in the model, including those that are not associated with any block. For example, if the fixed step size is 0.1 and all of the blocks have a sample time of 0.2, then both rates (0.1 and 0.2) appear in the legend.

For subsequent viewings of the legend, update the diagram to access the latest known information.

If you do not want to view the legend upon selecting **Sample Time Display**:

- 1 In the Simulink Editor, on the **Modeling** tab, select **Environment > Simulink Preferences**
- 2 In the **General** pane, clear **Open the timing legend when the sample time display is changed** and click **Apply**.

## Inspect Sample Times Throughout a Model

The Model Data Editor (on the **Modeling** tab, click **Model Data Editor**) shows information about model data (signals, parameters, and states) in a sortable, searchable table. The **Sample Time** column shows the sample time specified for each signal in a model. After you update the block diagram, the column also shows the specific sample that each signal uses (for example, for signals for which you specify inherited sample time, -1). You can also use this column to specify sample times.

For more information, see **Model Data Editor**.

 “Variable Sample Time” on page 7-22  
 “Controllable Sample Time” on page 7-22  
 “Triggered Sample Time” on page 7-22  
 “Asynchronous Sample Time” on page 7-22

### Discrete Sample Time

Given a block with a discrete sample time, Simulink executes the block output or update method at times

$$t_n = nT_s + |T_o|,$$

where the sample time period  $T_s$  is always greater than zero and less than the simulation time  $T_{sim}$ . The number of periods ( $n$ ) is an integer that must satisfy

$$0 \leq n \leq \frac{T_{sim}}{T_s}.$$

As simulation progresses, Simulink computes block outputs only once at each of these fixed time intervals of  $t_n$ . These simulation times at which Simulink executes the output method of a block for a given sample time are called sample time hits. Discrete sample times are the only type for which sample time hits are known *a priori*.

If you need to delay the initial sample hit time, you can define an offset,  $T_o$ .

The Unit Delay block is an example of a block with a discrete sample time.

### Continuous Sample Time

Continuous sample time hits are divided into major time steps and minor time steps. Minor time steps are subdivisions of the major time steps. The solver produces a result at each major time step. The solver uses results at the minor time steps to improve the accuracy of the result at the major time step.

The ODE solver you choose integrates all continuous states from the simulation start time to a given major or minor time step. The solver determines the times of the minor steps and uses the results at the minor time steps to improve the accuracy of the results at the major time steps. You see the block output only at the major time steps.

To specify continuous sample time for a block, such as the Derivative block, for the **Sample time** parameter, enter  $[0, 0]$  or  $0$ .

## Inherited Sample Time

If a block sample time is set to  $[-1 \ 0]$  or  $-1$ , the sample time is inherited, and Simulink determines the best sample time for the block based on the context of the block within the model. Simulink determines the sample time for blocks with inherited sample time during compilation. Because the inherited setting is overwritten in compilation, the Sample Time Legend never shows inherited sample time  $[-1 \ 0]$  in a compiled model. For more information, see “View Sample Time Information” on page 7-16.

Some blocks inherit sample time by default. For these blocks, the parameter is not visible unless you specify a noninherited value. For example, the Gain and Rounding Function blocks do not have a visible sample time parameter and have inherited sample time by default. As a best practice, do not change the **Sample time** parameter for these blocks. For more information, see “Blocks for Which Sample Time Is Not Recommended” on page 7-24.

All inherited blocks are subject to the process of sample time propagation. For more information, see “How Propagation Affects Inherited Sample Times” on page 7-37.

## Fixed-in-Minor-Step

If the sample time of a block is  $[0 \ 1]$ , the block has fixed-in-minor-step sample time. For this sample time, the block does not execute at the minor time steps. The block executes only at major time steps. Fixed-in-minor-step sample time eliminates unnecessary computations of blocks with outputs that cannot change between major steps.

While you can explicitly set a block to fixed-in-minor-step sample time, more often the software sets this condition as either an inherited sample time or as an alteration to a specification of continuous sample time. Fixed-in-minor-step sample time is equivalent to the fastest discrete rate in a system that uses a fixed-step solver. When you use a fixed-step solver, fixed-in-minor-step sample time is converted to the fastest discrete sample time.

## Constant Sample Time

In Simulink, a constant is a symbolic name or expression whose value you can change only outside the algorithm or through supervisory control. Blocks whose outputs do not change during normal execution of the model, such as the Constant block, are always considered to be constant.

Simulink assigns constant sample time to these blocks. They run the block output method:

- At the start of a simulation
- In response to runtime changes in the environment, such as tuning a parameter

For constant sample time, the block sample time assignment is  $[inf \ 0]$  or  $inf$ .

For a block to allow constant sample time, the block must not have continuous or discrete states and must not drive an output port of a conditionally executed subsystem. For more information, see “Using Enabled Subsystems” on page 10-10.

The Simulink block library includes several blocks whose ports can produce outputs at different sample rates, such as the MATLAB S-Function block, the Level-2 MATLAB S-Function block, and the C S-Function block. Some ports of these blocks can have a constant sample time.

## Variable Sample Time

Blocks that use a variable sample time have an implicit sample time parameter that the block specifies. The block tells the software when it executes. The compiled sample time is  $[-2 T_{vo}]$ , where  $T_{vo}$  is a unique variable offset.

The Hit Scheduler block and the Pulse Generator block both have variable sample time. Variable sample time is supported only for variable-step solvers. The Hit Scheduler block is not supported for fixed-step solvers. When you use a fixed-step solver to simulate a model that contains a Pulse Generator block, the block specifies a discrete sample time.

To learn how to write your own block that uses a variable sample time, see “C MEX S-Function Examples”.

## Controllable Sample Time

You can configure a block to use a controllable sample time with a resolution  $T_{base}$ .  $T_{base}$  is the smallest allowable time interval between block executions. To set  $T_{base}$  in your own C S-Function block, use the `ssSetControllableSampleTime` function.

When a block uses controllable sample time, you can dynamically configure the block to execute at  $n$  multiples of  $T_{base}$ . The time of the next block execution is

$$T_{next} = n T_{base} + T$$

You can set  $n$  in your C S-Function block using the `ssSetNumTicksToNextHitForControllableSampleTime` function.

## Triggered Sample Time

If a block is inside a triggered subsystem, such as a function-call- or enabled subsystem, the block may be constant or have a triggered sample time, except in the case of an asynchronous function call. You cannot specify the triggered sample time type explicitly. To achieve a triggered sample time during compilation, set the block sample time to inherited (–1). The software then determines the specific times at which the block executes during simulation.

## Asynchronous Sample Time

An asynchronous sample time is similar to a triggered sample time. In both cases, you need to specify an inherited sample time because the Simulink engine does not regularly execute the block. Instead, a runtime condition determines when the block executes. For an asynchronous sample time, an S-function makes an asynchronous function call.

The differences between these sample time types are:

- Only a function-call subsystem can have an asynchronous sample time. See “Using Function-Call Subsystems” on page 10-34.
- The source of the function-call signal is an S-function that has the option `SS_OPTION_ASYNCHRONOUS`.
- The asynchronous sample time can also occur when a virtual block is connected to an asynchronous S-function or an asynchronous function-call subsystem.

- The asynchronous sample time is important to certain code generation applications. See “Asynchronous Events” (Simulink Coder) in the *Simulink Coder User's Guide*.
- The sample time is  $[-1, -n]$ .

For an explanation of how to use blocks to model and generate code for asynchronous event handling, see “Rate Transitions and Asynchronous Blocks” (Simulink Coder) in the *Simulink Coder User's Guide*.

## Blocks for Which Sample Time Is Not Recommended

### In this section...

“Best Practice to Model Sample Times” on page 7-24

“Appropriate Blocks for the Sample Time Parameter” on page 7-24

“Specify Sample Time in Blocks Where Hidden” on page 7-25

Some blocks do not enable you to set the **Sample Time** parameter by default. However, you can see and set the **Sample Time** parameter for these blocks in an existing model if the sample time is set to a value other than the default of -1 (inherited sample time). The **Sample Time** parameter is not available on certain blocks because specifying a sample time that is not -1 on blocks such as the Gain, Sum, and n-D Lookup Table causes sample rate transition to be implicitly mixed with block algorithms. This mixing can often lead to ambiguity and confusion in Simulink models.

In most modeling applications, you specify rates for a model on the boundary of your system instead of on a block within the subsystem. You specify the system rate from incoming signals or the rate of sampling the output. You can also decide rates for events you are modeling that enter the subsystem as trigger, function-call, or enable/disable signals. Some global variables (such as Data Store Memory blocks) might need additional sample time specification. If you want to change rate within a system, use a Rate Transition block, which is designed specifically to model rate transitions.

In a future release, you might not be able to see or set this parameter on blocks where it is not appropriate.

### Best Practice to Model Sample Times

Use these approaches instead of setting the **Sample Time** parameter in the blocks where it is not appropriate:

- Adjust your model by specifying **Sample Time** only in the blocks listed in “Appropriate Blocks for the Sample Time Parameter” on page 7-24, and set **Sample Time** to -1 for all other blocks. To change the sample time for multiple blocks simultaneously, use Model Explorer. For more information, see **Model Explorer**.
- Use the Rate Transition block to model rate transitions in your model.
- Use the Signal Specification block to specify sample time in models that don’t have source blocks, such as algebraic loops.
- Specify the simulation rate independently from the block sample times, using the Model Parameter dialog box.

Once you have completed these changes, verify whether your model gives the same outputs as before.

### Appropriate Blocks for the Sample Time Parameter

Specify sample time on the boundary of a model or subsystem, or in blocks designed to model rate transitions. Examples include:

- Blocks in the Sources library

- Blocks in the Sinks library
- Trigger ports (if **Trigger type** is set to `function-call`) and Enable ports
- Data Store Read and Data Store Write blocks, as the Data Store Memory block they link to might be outside the boundary of the subsystem
- Rate Transition block
- Signal Specification block
- Blocks in the Discrete library
- Message Receive block
- Function Caller block

## Specify Sample Time in Blocks Where Hidden

You can specify sample time in the blocks that do not display the parameter on the block dialog box. If you specify value other than `-1` in these blocks, no error occurs when you simulate the model. However, a message appears on the block dialog box advising to set this parameter to `-1` (inherited sample time). If you promote the sample time block parameter to a mask, this parameter is always visible on the mask dialog box.

To change the sample time in this case, use the `set_param` command. For example, select a block in the Simulink Editor and, at the command prompt, enter:

```
set_param(gcf, 'SampleTime', '2');
```

## Block Compiled Sample Time

During the compilation phase of a simulation, Simulink determines the sample time of a block from the `SampleTime` parameter (if the block has an explicit sample time), the block type (if it has an implicit sample time), or by the model content. This compiled sample time determines the sample rate of a block during simulation. You can determine the compiled sample time of any block in a model by first updating the model and then getting the block `CompiledSampleTime` parameter, using the `get_param` command.

For example, consider the model `ex_compiled_sample_new`.

Use `get_param` to obtain the block `CompiledSampleTime` parameter for each of the blocks in this example.

```
get_param('model_name/block_name','CompiledSampleTime');
```

For the Sine Wave3 block,

```
get_param('ex_compiled_sample_new/Sine Wave3','CompiledSampleTime');
```

displays

```
0.5000  0
```

The atomic subsystem contains sine wave blocks with sample times of 3 and 4.

When calculating the block `CompiledSampleTime` for this subsystem, Simulink returns a cell array of the sample times present in the subsystem.

```
3  0
4  0
```

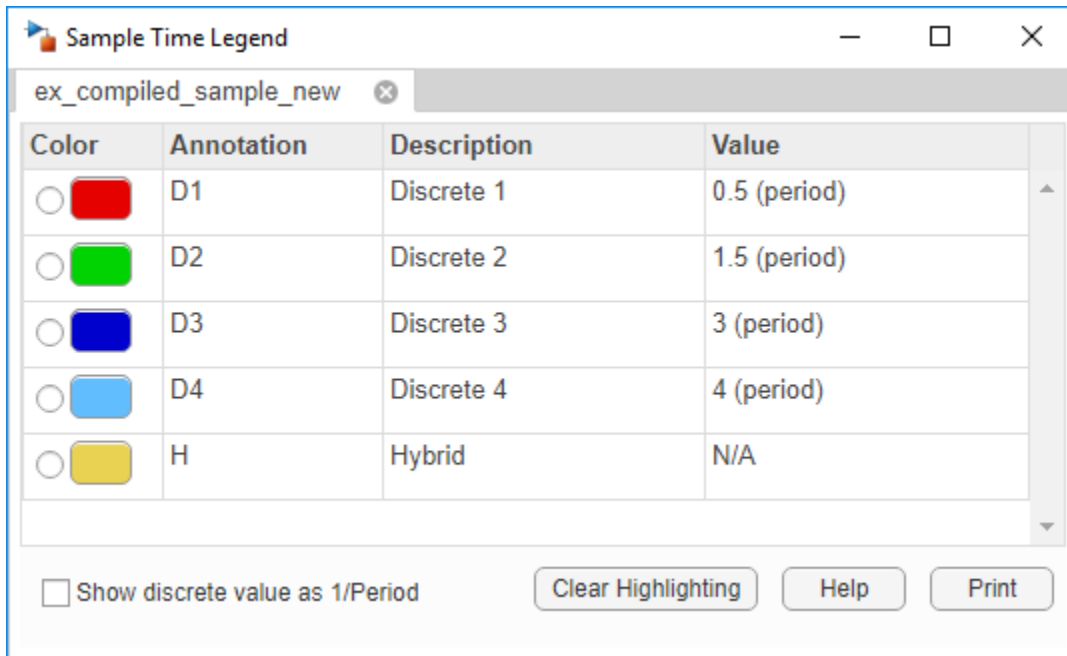

The greatest common divisor (GCD) of the two rates is 1. However, this is not necessarily one of the rates in the model.

The Rate Transition block in this model serves as a Zero-Order Hold. Since the `Sample Time Multiple` parameter is set to 3, the input to the rate transition block has a sample rate of 0.5 while the output has a rate of 1.5.

```
rt=get_param('ex_compiled_sample_new/Rate Transition',...
'CompiledSampleTime');
rt{:}
```

```
0.5000  0
1.5000  0
```

The Sample Time Legend shows all of the sample rates present in the model.

To inspect compiled sample times throughout a model, you can use the Model Data Editor (on the **Modeling** tab, click **Model Data Editor**). After you update the block diagram, the right side of the **Sample Time** column shows compiled sample times for signals and data stores. For more information, see **Model Data Editor**.

## Sample Times in Subsystems

Subsystems fall into two categories: triggered and non-triggered. For triggered subsystems, in general, the subsystem gets its sample time from the triggering signal. One exception occurs when you use a Trigger block to create a triggered subsystem. If you set the block **Trigger type** to **function-call** and the **Sample time type** to **periodic**, the `SampleTime` parameter becomes active. In this case, you specify the sample time of the Trigger block, which in turn, establishes the sample time of the subsystem.

There are four non-triggered subsystems:

- Virtual
- Enabled
- Atomic
- Action

Simulink calculates the sample times of virtual and enabled subsystems based on the respective sample times of their contents.

The atomic subsystem is a special case in that the subsystem block has a `SystemSampleTime` parameter. Moreover, for a sample time other than the default value of `-1`, the blocks inside the atomic subsystem can have only a value of `Inf`, `-1`, or the identical (discrete) value of the subsystem `SampleTime` parameter. If the atomic subsystem is left as inherited, Simulink calculates the block sample time in the same manner as the virtual and enabled subsystems. However, the main purpose of the subsystem `SampleTime` parameter is to allow for the simultaneous specification of a large number of blocks, within an atomic subsystem, that are all set to inherited. To obtain the sample time set on an atomic subsystem, use this command at the command prompt:

```
get_param(AtomicSubsystemBlock, 'SystemSampleTime');
```

Finally, the sample time of the action subsystem is set by the If block or the Switch Case block.

For non-triggered subsystems where blocks have different sample rates, Simulink returns the Compiled Sample Time for the subsystem as a cell array of all the sample rates present in the subsystem. To see this, use the `get_param` command at MATLAB prompt.

```
get_param(subsystemBlock, 'CompiledSampleTime')
```

## Sample Times in Systems

### In this section...

“Purely Discrete Systems” on page 7-30

“Hybrid Systems” on page 7-32

### Purely Discrete Systems

A purely discrete system is composed solely of discrete blocks and can be modeled using either a fixed-step or a variable-step solver. Simulating a discrete system requires that the simulator take a simulation step at every sample time hit. For a *multirate discrete system*—a system whose blocks Simulink samples at different rates—the steps must occur at integer multiples of each of the system sample times. Otherwise, the simulator might miss key transitions in the states of the system. The step size that the Simulink software chooses depends on the type of solver you use to simulate the multirate system and on the fundamental sample time.

The *fundamental sample time* of a multirate discrete system is the largest double that is an integer divisor of the actual sample times of the system. For example, suppose that a system has sample times of 0.25 and 0.50 seconds. The fundamental sample time in this case is 0.25 seconds. Suppose, instead, the sample times are 0.50 and 0.75 seconds. The fundamental sample time is again 0.25 seconds.

The importance of the fundamental sample time directly relates to whether you direct the Simulink software to use a fixed-step or a variable-step discrete solver to solve your multirate discrete system. A fixed-step solver sets the simulation step size equal to the fundamental sample time of the discrete system. In contrast, a variable-step solver varies the step size to equal the distance between actual sample time hits.

The following diagram illustrates the difference between a fixed-step and a variable-step solver.

Fixed-Step Solver

Variable-Step Solver

In the diagram, the arrows indicate simulation steps and circles represent sample time hits. As the diagram illustrates, a variable-step solver requires fewer simulation steps to simulate a system, if the fundamental sample time is less than any of the actual sample times of the system being simulated. On the other hand, a fixed-step solver requires less memory to implement and is faster if one of the system sample times is fundamental. This can be an advantage in applications that entail generating code from a Simulink model (using Simulink Coder). In either case, the discrete solver provided by

Simulink is optimized for discrete systems; however, you can simulate a purely discrete system with any one of the solvers and obtain equivalent results.

Consider the following example of a simple multirate system. For this example, the DTF1 Discrete Transfer Fcn block **Sample time** is set to  $[1 \ 0.1]$ , which gives it an offset of  $0.1$ . The **Sample time** of the DTF2 Discrete Transfer Fcn block is set to  $0.7$ , with no offset. The solver is set to a variable-step discrete solver.

Running the simulation and plotting the outputs using the stairs function

```
set_param(bdroot,'SolverType','Variable-Step','SolverName','VariableStepDiscrete','SaveFormat','/');
simOut = sim(bdroot,'Stoptime','3');
stairs(simOut.tout,simOut.yout,'-*','LineWidth',1.2);
xlabel('Time (t)');
ylabel('Outputs (out1,out2)');
legend('t_s = [1, 0.1]','t_s = 0.7','location','best')
```

produces the following plot.

(For information on the sim command, see “Run Simulations Programmatically” on page 28-2. )

As the figure demonstrates, because the DTF1 block has a 0.1 offset, the DTF1 block has no output until  $t = 0.1$ . Similarly, the initial conditions of the transfer functions are zero; therefore, the output of DTF1,  $y(1)$ , is zero before this time.

## Hybrid Systems

Hybrid systems contain both discrete and continuous blocks and thus have both discrete and continuous states. However, Simulink solvers treat any system that has both continuous and discrete sample times as a hybrid system. For information on modeling hybrid systems, see “Modeling Hybrid Systems”.

In block diagrams, the term hybrid applies to both hybrid systems (mixed continuous-discrete systems) and systems with multiple sample times (multirate systems). Such systems turn yellow in color when you perform an **Update Diagram** with Sample Time Display **Colors** turned 'on'. As an example, consider the following model that contains an atomic subsystem, “Discrete Cruise Controller”, and a virtual subsystem, “Car Dynamics”. (See `ex_execution_order`.)

### Car Model

With the **Sample Time** option set to **All**, an **Update Diagram** turns the virtual subsystem yellow, indicating that it is a hybrid subsystem. In this case, the subsystem is a true hybrid system since it has both continuous and discrete sample times. As shown below, the discrete input signal, D1, combines with the continuous velocity signal, v, to produce a continuous input to the integrator.

### Car Model after an Update Diagram

### Car Dynamics Subsystem after an Update Diagram

Now consider a multirate subsystem that contains three Sine Wave source blocks, each of which has a unique sample time — 0.2, 0.3, and 0.4, respectively.

### Multirate Subsystem after an Update Diagram

An **Update Diagram** turns the subsystem yellow because the subsystem contains more than one sample time. As shown in the block diagram, the Sine Wave blocks have discrete sample times D1, D2, and D3 and the output signal is fixed in minor step.

In assessing a system for multiple sample times, Simulink does not consider either constant  $[\text{inf}, 0]$  or asynchronous  $[-1, -n]$  sample times. Thus a subsystem consisting of one block that outputs constant value and one block with a discrete sample time will not be designated as hybrid.

The hybrid annotation and coloring are very useful for evaluating whether or not the subsystems in your model have inherited the correct or expected sample times.

- “Blocks for Which Sample Time Is Not Recommended” on page 7-24
- “View Sample Time Information” on page 7-16

## Resolve Rate Transitions

In general, a rate transition exists between two blocks if their sample times differ, that is, if either of their sample-time vector components are different. The exceptions are:

- Blocks that output constant value never have a rate transition with any other rate.
- A continuous sample time (black) and the fastest discrete rate (red) never has a rate transition if you use a fixed-step solver.
- A variable sample time and fixed in minor step do not have a rate transition.

You can resolve rate transitions manually by inserting rate transition blocks and by using two diagnostic tools. For the single-tasking execution mode, the **Single task data transfer** diagnostic allows you to set the level of Simulink rate transition messages. The **Multitask data transfer** diagnostic serves the same function for multitasking execution mode. These execution modes directly relate to the type of solver in use: Variable-step solvers are always single-tasking; fixed-step solvers may be explicitly set as single-tasking or multitasking.

### Automatic Rate Transition

Simulink can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is **Whenever possible**, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer”. To use other modes, you must insert Rate Transition blocks and set their modes manually.

### Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.

You can show or hide badge labels. On the **Debug** tab, select **Information Overlays > Automatic Rate Transitions**.

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.
- You can set the **Initial Conditions** of these blocks.
- You can change data transfer and sample time block parameters.

Validate the changes to your model by updating your diagram.

Displaying inserted Rate Transition blocks is not compatible with export-function models.

To learn more about the types of Rate Transition blocks, see [Rate Transition](#).

---

**Note** Suppose you automatically insert rate transition blocks and there is a virtual block specifying sample time upstream of the block you insert. You cannot click the badge of the inserted block to configure the block and make it visible because the sample time on the virtual block causes a rate transition as well. In this case, manually insert a rate transition block before the virtual block. To learn more about virtual blocks, see [“Nonvirtual and Virtual Blocks”](#) on page 39-2.

## How Propagation Affects Inherited Sample Times

During a model update, for example at the beginning of a simulation, Simulink uses a process called sample time propagation to determine the sample times of blocks that inherit their sample times. The figure below illustrates a Discrete Filter block with a sample time period  $T_s$  driving a Gain block.

Because the output of the Gain block is the input multiplied by a constant, its output changes at the same rate as the filter. In other words, the Gain block has an effective sample rate equal to the sample rate of the filter. The establishment of such effective rates is the fundamental mechanism behind sample time propagation in Simulink.

### Process for Sample Time Propagation

Simulink uses the following basic process to assign sample times to blocks that inherit their sample times:

- 1 Propagate known sample time information forward.
- 2 Propagate known sample time information backward.
- 3 Apply a set of heuristics to determine additional sample times.
- 4 Repeat until all sample times are known.

### Simulink Rules for Assigning Sample Times

A block having a block-based sample time inherits a sample time based on the sample times of the blocks connected to its inputs, and in accordance with the following rules:

Rule	Action
All of the inputs have the same sample time and the block can accept that sample time	Simulink assigns the sample time to the block
The inputs have different discrete sample times and all of the input sample times are integer multiples of the fastest input sample time	Simulink assigns the sample time of the fastest input to the block. (This assignment assumes that the block can accept the fastest sample time.)
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, and the model uses a variable-step solver	Simulink assigns a fixed-in-minor-step sample time to the block.

<b>Rule</b>	<b>Action</b>
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, the model uses a fixed-step solver, and Simulink can compute the greatest common integer divisor (GCD) of the sample times coming into the block	Simulink assigns the GCD sample time to the block. Otherwise, Simulink assigns the fixed step size of the model to the block.
The sample times of some of the inputs are unknown, or if the block cannot accept the sample time	Simulink determines a sample time for the block based on a set of heuristics.

## **See Also**

### **More About**

- “Blocks for Which Sample Time Is Not Recommended” on page 7-24
- “Backpropagation in Sample Times” on page 7-39

## Backpropagation in Sample Times

When you update or simulate a model that specifies the sample time of a source block as inherited (-1), the sample time of the source block may be backpropagated; Simulink may set the sample time of the source block to be identical to the sample time specified by or inherited by the block connected to the source block. For example, in the model below, the Simulink software recognizes that the Sine Wave block is driving a Discrete-Time Integrator block whose sample time is 1; so it assigns the Sine Wave block a sample time of 1.

You can verify this sample time setting by selecting **Information Overlays > Colors** from the **Debug** tab of the Simulink toolstrip and noting that both blocks are red. Because the Discrete-Time Integrator block looks at its input only during its sample hit times, this change does not affect the results of the simulation, but does improve the simulation performance.

Now replacing the Discrete-Time Integrator block with a continuous Integrator block, as shown in the model below, causes the Sine Wave and Gain blocks to change to continuous blocks. You can test this change by, on the **Modeling** tab, selecting **Update Model** to update the colors. Both blocks now appear black.

**Note** Backpropagation makes the sample times of model sources dependent on block connectivity. If you change the connectivity of a model whose sources inherit sample times, you can inadvertently change the source sample times. For this reason, when you update or simulate a model, by default, Simulink displays warnings at the command line if the model contains sources that inherit their sample times.

## Specify Execution Domain

Execution domain specification allows you to set a model and its subsystems and referenced models to simulate as discrete-time or data-driven systems. Use this setting to separate the discrete dynamics from the rest of its dynamics, for example, in the design of a deployable controller for a plant that is modeled with continuous-time dynamics.

To simulate a computationally intensive signal processing or multirate signal processing system, you can also assign a dataflow domain. Dataflow domains simulate using a model of computation synchronous dataflow, which is data-driven and statically scheduled. For more information, see “Dataflow Domain” (DSP System Toolbox).

You can create subsystems that maintain their discrete execution domain irrespective of their environment. By constraining a subsystem to be discrete, you can increase reusability of your subsystem as a component. To improve code generation, this specification reduces unnecessary update methods, reduces major time step checks, and increases reusability of generated code.

### Domain Specification Badge

The domain specification badge indicates the execution domain computed to a model or subsystem when you update the model diagram. You can toggle the visibility of the domain specification badge by turning on the **Sample Time Display**. For more information on visualizing sample time, see “View Sample Time Information” on page 7-16. The badge is visible at the bottom left corner of the Simulink Editor.

The model below shows a discrete Sine Wave block whose rate is reduced by the Rate Transition block before driving the Gain block.

Observe that the model receives the *Discrete* execution domain because its contents are all discrete.

You can also toggle the visibility of the badge by enabling or disabling the **Set Domain Specification** parameter in the **Execution** tab of the **Property Inspector**.

### Types of Execution Domains

You can instruct Simulink to assign the execution domain, along with the allowed sample times, via the **Property Inspector**.

Specification	Discrete	Other	Dataflow
Deduce from contents	X	X	-
Discrete	X	-	-
Dataflow	-	-	X
Export function	X	-	-

-  **Deduce from contents** Let Simulink assign the execution domain based on the contents of the subsystem.
-  **Discrete** Constrain all blocks in a subsystem to be discrete.
-  **Dataflow** Simulate a computationally-intensive signal processing or multi-rate signal processing system. This setting requires the DSP System Toolbox™.
-  **Export function** Specify that the model is to be treated as an export-function model. When you specify a model as an export-function model, Simulink automatically sets the **Solver selection** in the Model Configuration Parameters to **Fixed-step** and **auto**. See “Export-Function Models Overview” on page 10-96 for more information.

When you update the model diagram or simulate the model, the badge displays the computed execution domain for the model component. There are three execution domains in Simulink:

-  **Discrete** Blocks have discrete states and sample times. Allowed samples times include “Discrete Sample Time” on page 7-20, “Controllable Sample Time” on page 7-22, and “Asynchronous Sample Time” on page 7-22.
-  **Dataflow** Dataflow domains simulate using computation synchronous dataflow, which is data-driven and statically scheduled. This execution domain requires the DSP System Toolbox. For more information, see “Specifying Dataflow Domains” (DSP System Toolbox).
-  **Other** Blocks are not strictly discrete.

Subsystems that receive the **Other** execution domain include:

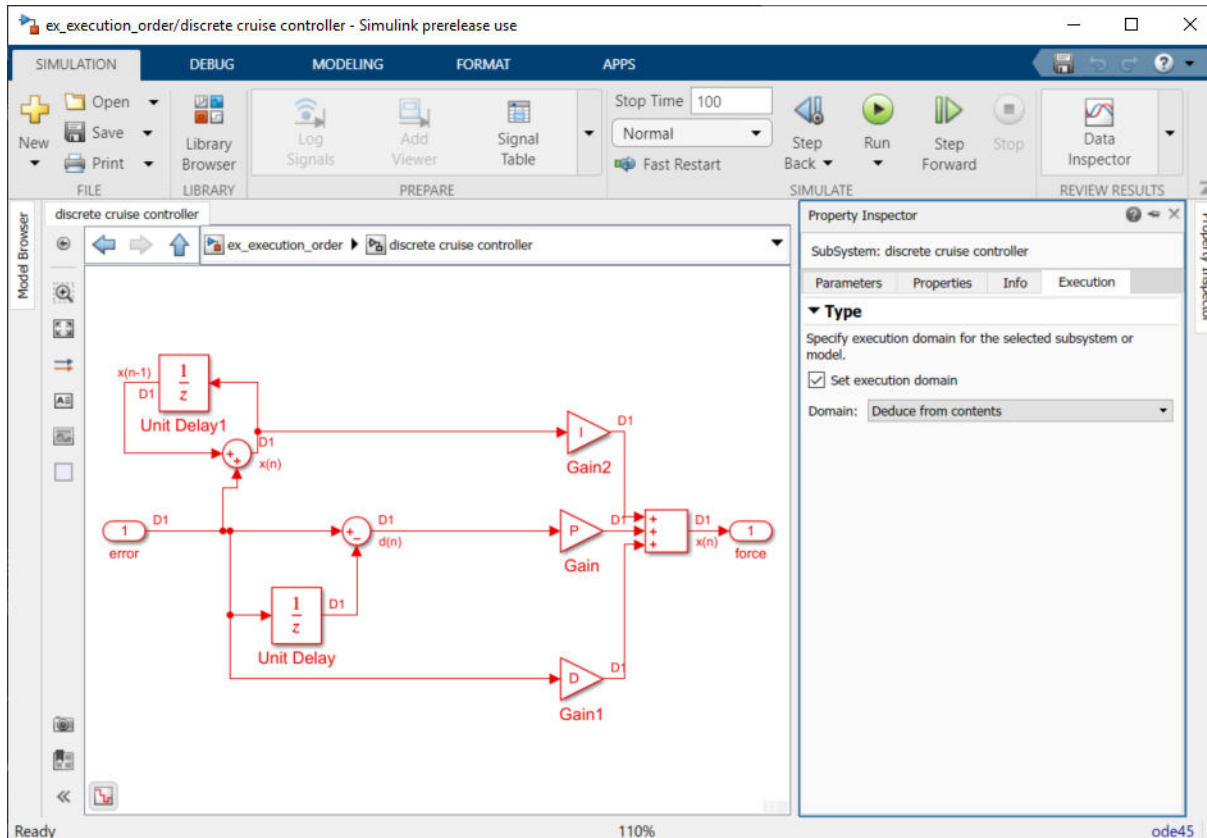

- Subsystems whose blocks have continuous states and sample times, including “Continuous Sample Time” on page 7-20, “Fixed-in-Minor-Step” on page 7-21, and “Variable Sample Time” on page 7-22
- Subsystems with a mixture of continuous and discrete sample times.
- Subsystems with “Asynchronous Sample Time” on page 7-22.
- Triggered Subsystem
- Function-Call Subsystem
- Enabled and Triggered Subsystem
- Initialize Function
- Reset Function
- Terminate Function
- If Action Subsystem

If a subsystem has continuous, variable, fixed-in-minor step, “Constant Sample Time” on page 7-21, or a mixture of sample times, you can use the badge to enable or disable domain specification. The subsystem still receives the **Other** time domain.

The domain specification badge is not actionable when the currently selected subsystem or model is a linked block, inside a library block, or a conditionally executed subsystem that receives the **Other** domain. To change the execution domain of a linked library block, break the link to the parent library block. See “Disable or Break Links to Library Blocks” on page 44-22.

## Set Execution Domain

You can set the domain specification per subsystem and at the root level of the model using the **Execution** tab of the Property Inspector. To enable the Property Inspector for the model, on the **Modeling** tab, under **Design**, click **Property Inspector**, or press **Ctrl+Shift+I** on your keyboard. If the domain specification badge is displayed, you can also open the **Execution** settings in the Property Inspector by clicking the badge. See “Domain Specification Badge” on page 7-40.

Select the **Set Execution Domain** check box. You can now specify the **Domain**.

**Note** Changing the domain specification at the root level of the model does not change the setting for its child subsystems.

You can also enable this setting from the command line using `set_param` to set the `SetExecutionDomain` parameter 'on' or 'off'.

Once enabled, the default setting for the **Domain** parameter is **Deduce from contents**. When you update the diagram, the execution domain is deduced from the characteristics of the blocks in the currently open subsystem. For example, a system that has only discrete blocks is in the **Discrete** execution domain. See “Types of Execution Domains” on page 7-40.

The badge shows the current specification setting. If you set the subsystem domain to **Deduce from contents**, the badge text displays **Deduce** until you update the diagram. Once you update the model

diagram, the badge shows the computed execution domain, as described in “Types of Execution Domains” on page 7-40. When you enable **Set domain specification** and **Domain** is set to **Deduce from Contents**, Simulink computes the execution domain of the currently focused subsystem based on the blocks and sample times inside the subsystem.

To set the **Domain** parameter from the command line, use `set_param` to change `ExecutionDomainType` to either 'Deduce' or 'Discrete'. You can also get the computed execution domain after you update the diagram using the `CompiledExecutionDomain` parameter of the subsystem.

## Enforce Discrete Execution Domain for a Subsystem

This model shows how to specify execution domains for the constituent subsystems of a model. The model has a discrete cruise controller subsystem that tracks the reference speed set in the Desired Speed block. A car dynamics subsystem models the continuous-time dynamics of the car.

Notice that the discrete cruise controller of the model has a hybrid sample time due to the presence of a continuous-time signal from the output of the car dynamics at the input port of the controller.

To enforce discrete-time execution of the controller, select the subsystem and open the **Execution** tab of the **Property Inspector** by clicking on the Domain badge at the bottom-left corner of the Simulink Editor.

Enable the **Set execution domain** parameter and set **Domain** to Discrete. Update the model diagram or simulate the model.

Note that the discrete cruise controller subsystem is now discrete.

You can also set the execution domain of the car dynamics to **Deduce** from **Contents**. The car dynamics subsystem receives the Hybrid sample time and the **Other** execution domain. If you wish, set the **Sample Time** parameter of the Inport block in this subsystem to 0.

## Model Reference Basics

You can include one model in another by using a Model block. Each instance of a Model block is a model reference. For simulation and code generation, blocks within a referenced model execute together as a unit. The model that contains a referenced model is a parent model. A collection of parent and referenced models constitutes a model hierarchy.

A model can function as both a standalone model and a referenced model, without changing the model or any entities derived from it. To use a referenced model as a standalone model, the referenced model cannot depend on data that is available only from a higher-level model.

### Model Reference Advantages

Like subsystems, model references allow you to organize large models hierarchically. Like libraries, model references allow you to define a set of blocks once and use it repeatedly. Model references provide several advantages that are unavailable with subsystems and libraries. Several of these advantages result from referenced models compiling independent from the context of the Model block, including:

- **Modular development**

You can develop a referenced model independently from the models that use it.

- **Model protection**

With a Simulink Coder license, you can obscure the contents of a referenced model, allowing you to distribute the model without revealing its intellectual property.

With a Simulink license, you can reference a protected model provided by a third party. Depending on the granted protected-model permissions, you can view, simulate, and generate code for the protected model.

- **Inclusion by reference**

You can reference a model multiple times without making redundant copies, and multiple models can reference the same model.

- **Incremental loading**

Simulink software loads a referenced model when it is needed, which speeds up model loading.

- **Accelerated simulation**

Simulink software can convert a referenced model to code and simulate the model by running the code, which is faster than interactive simulation.

- **Incremental code generation**

Accelerated simulation generates code only if the model has changed since the code was previously generated.

- **Independent configuration sets**

The configuration set used by a referenced model can differ from the configuration set of its parent or other referenced models.

For a video summarizing model reference advantages, see [Modular Design Using Model Referencing](#) (2 min, 50 sec).

To compare model references, subsystems, and libraries, see “Choose Among Types of Model Components” on page 23-4. You can use multiple componentization techniques in the same model.

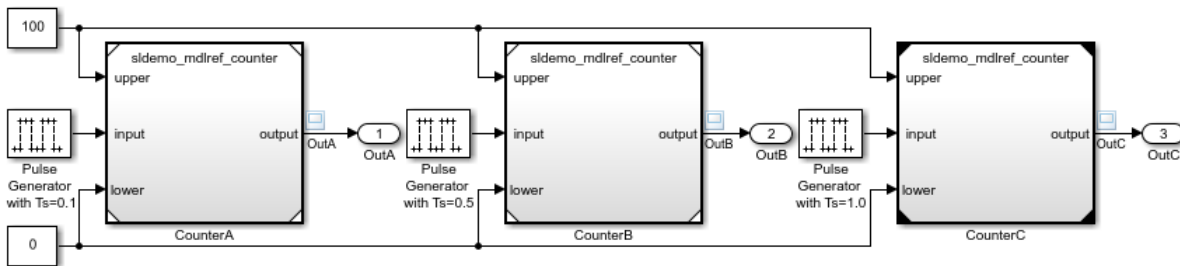

### Model Hierarchies

Referenced models can contain Model blocks that reference lower-level models. The top model is the top model in a hierarchy of referenced models. Where only one level of model reference exists, the parent model and top model are the same. To prevent cyclic inheritance, a Model block cannot refer directly or indirectly to a model that is superior to it in the model hierarchy. This figure shows cyclic inheritance.

A parent model can contain multiple Model blocks that reference the same model, as long as the referenced model does not define global data. For example, the `sldemo_mdref_basic` model contains three Model blocks that reference the `sldemo_mdref_counter` model.

Component-Based Modeling with Model Reference

The referenced model can also appear in other parent models at any level.

### Model Block and Referenced Model Interface

A Model block displays input, output, and control ports that correspond to root-level input, output, and control ports of the model it references. To connect the referenced model to other elements of the parent model, use these Model block ports. Connecting a signal to a Model block port connects the signal to the corresponding port in the referenced model.

In model `sldemo_mdref_basic`, each Model block has three inputs: two Constant blocks and a Pulse Generator block. Each Model block has one output signal logged to a scope. Because the input signal from each Pulse Generator block uses a different sample time, the output signal from each Model block differs for each model instance.

To connect to the parent model, referenced model `sldemo_mdref_counter` includes three Inport blocks (**upper**, **lower**, and **input**) and one Outport block (**output**).

Signal attributes in the referenced model are independent from the context of the Model block. For example, signal dimensions and data types do not propagate across the Model block boundary. To define signal attributes in the referenced model, define block parameters for root-level Inport and In Bus Element blocks.

For more information, see “Model Reference Interface and Boundary” on page 8-31.

## Model Workspaces and Data Dictionaries

Each model has its own workspace for storing variable values. In a model hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. To share data among models, you can use a data dictionary.

Duplicate data definitions can exist in a model reference hierarchy under these conditions:

- Each model in the hierarchy can see only one definition.
- Definitions must be the same across models in the hierarchy.

For more information on where you can store variables and objects, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-102.

## Referenced Model Execution

To use an external signal to control whether a Model block executes during simulation, see “Conditionally Execute Referenced Models” on page 8-24.

Variant Subsystem blocks can contain Model blocks as variant systems. For information on variant systems, see “What Are Variants and When to Use Them” on page 12-4.

By default, a block parameter has the same value in each Model block instance of a reusable referenced model. To specify a different block parameter value for each instance of a reusable referenced model, create model arguments. For example, if you add a Gain block to model

`sldemo_mdhref_counter`, model arguments allow each of the three instances of this model to use different gain values. See “Parameterize Instances of a Reusable Referenced Model” on page 8-63.

With a model mask, you can control the appearance of Model blocks and customize the way the blocks display model arguments. For model mask requirements, see “Model Masks” on page 8-6.

## Referenced Model Simulation and Code Generation

You can simulate a referenced model either interpretively (in normal mode) or by compiling the referenced model to code and executing the code (in accelerator mode). For details, see “Choose Simulation Modes for Model Hierarchies” on page 8-39.

Simulink cache files contain build artifacts that can speed up simulation and code generation. For more information and an example workflow, see “Share Simulink Cache Files for Faster Simulation” on page 8-54.

To learn about generating code for a model reference hierarchy, see “Generate Code for Model Reference Hierarchy” (Simulink Coder).

- “Reference Protected Models from Third Parties” on page 8-13
- “Convert Subsystems to Referenced Models” on page 8-18

## Model Reference Requirements and Limitations

Before referencing models, consider model reference requirements and limitations. By understanding the requirements and limitations upfront, you are better prepared to reference models successfully.

### Model Reuse

You can reference a model more than once in a model hierarchy unless the referenced model has any of these properties:

- The model references another model that is set to single instance.
- The model contains To File blocks.
- The model contains an internal signal or state with a storage class that is not supported for multi-instance models. Internal signals and states must have the storage class set to `Auto` or `Model default` and the default storage class for internal data must be a multi-instance storage class.
- The model uses any of these Stateflow constructs:
  - Exported Stateflow graphical functions
  - Machine-parented data
- The referenced model executes in accelerator mode and contains an S-function that is either not inlined or is inlined but does not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`.
- The model contains a function-call subsystem that:
  - Simulink forces to be a function
  - Is called by a wide signal

If the referenced model has any of these properties, only one instance of the model can appear in the model hierarchy. The model must have **Total number of instances allowed per top model** set to `One`.

### Model Masks

You can use masked blocks in a referenced model. Also, you can mask a referenced model (see “Create and Reference a Masked Model” on page 42-44).

To successfully use masks, consider these requirements and limitations:

- If a mask specifies the name of a referenced model, the mask must provide the name of the referenced model directly. You cannot use a workspace variable to provide the name.
- The mask workspace of a Model block is not available to the referenced model. Any variable that the referenced model uses must resolve to either of these workspaces:
  - A workspace that the referenced model defines
  - The MATLAB base workspace
- Mask callbacks cannot add Model blocks, change the Model block name, or change the Model block simulation mode.

## S-Functions in Referenced Models

Different types of S-functions provide different levels of support for model references.

S-Function Type	Models Referenced in Normal Mode	Models Referenced in Accelerator Mode and Protected Models
Level-1 MATLAB S-function	Not supported	Not supported
Level-2 MATLAB S-function	Supported	Supported — requires a TLC file
Handwritten C MEX S-function	Supported — can be inlined with a TLC file	Supported — can be inlined with a TLC file
S-Function Builder	Supported	Supported
Legacy Code Tool	Supported	Supported

When you use S-functions in referenced models, consider these requirements and limitations.

S-Function Consideration	Requirements and Limitations
Sample Time Inheritance	If an S-function depends on an inherited sample time, the S-function must explicitly declare a dependence on the inherited sample time. To control sample-time inheritance, use <code>ssSetModelReferenceSampleTimeInheritanceRule</code> differently based on whether an S-function permits or precludes inheritance. For details, see “S-Functions That Specify Sample Time Inheritance Rules” (Simulink Coder).
Models Referenced in Accelerator Mode	<p>For accelerator mode referenced models that contain an S-function that requires inlining using a Target Language Compiler (TLC) file, the S-function must use the <code>ssSetOptions</code> macro to set the <code>SS_OPTION_USE_TLC_WITH_ACCELERATOR</code> option in its <code>mdlInitializeSizes</code> method. The simulation target does not inline the S-function unless the S-function sets this option.</p> <p>A referenced model cannot use noninlined S-functions in these cases:</p> <ul style="list-style-type: none"> <li>The model is referenced more than once in the model hierarchy. To work around this limitation, use normal mode or: <ol style="list-style-type: none"> <li>Make copies of the referenced model.</li> <li>Assign different names to the copies.</li> <li>Reference a different copy at each location that needs the model.</li> </ol> </li> <li>The S-function uses character vector parameters.</li> </ul> <p>A referenced model in accelerator mode cannot use S-functions generated by Simulink Coder software.</p>

S-Function Consideration	Requirements and Limitations
Models Referenced in Normal Mode	<p>Under certain conditions, when a C S-function appears in a referenced model that executes in normal mode, successful execution is impossible. For details, see “S-Functions in Normal Mode Referenced Models”.</p> <p>To specify whether an S-function can be used in a normal mode referenced model, use the <code>ssSetModelReferenceNormalModeSupport</code> SimStruct function.</p> <p>For an S-function to work with multiple instances of referenced models in normal mode, the S-function must indicate explicitly that it supports multiple <code>exec</code> instances. For details, see “Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode”.</p>
Protected Models	<p>For protected models that contain an S-function that requires inlining using a Target Language Compiler (TLC) file, the S-function must use the <code>ssSetOptions</code> macro to set the <code>SS_OPTION_USE_TLC_WITH_ACCELERATOR</code> option in its <code>mdlInitializeSizes</code> method.</p>

## Model Architecture Requirements and Limitations

Element	Requirements and Limitations
Goto and From blocks	Goto and From blocks cannot cross model reference boundaries.
Iterator subsystems	If the referenced model contains Assignment blocks, you can place the Model block in an iterator subsystem only if the Assignment blocks are also in an iterator subsystem.
Configurable subsystems	In a configurable subsystem with a Model block, during model update, do not change the subsystem that the configurable subsystem selects.
InitFcn callback	An <code>InitFcn</code> callback in a top model cannot change parameters used by referenced models.
Printing referenced models	You cannot print a referenced model from a top model.

## Signal Requirements and Limitations

Signal	Requirements and Limitations
0-based or 1-based indexing information propagation	<p>In two cases, Simulink does not propagate 0-based or 1-based indexing information to referenced model root-level ports connected to blocks that:</p> <ul style="list-style-type: none"> <li>• Accept indexes (such as the Assignment block)</li> <li>• Produce indexes (such as the For Iterator block)</li> </ul> <p>An example of a block that accepts indexes is the Assignment block. An example of a block that produces indexes is the For Iterator block.</p> <p>The two cases result in a lack of propagation that can cause Simulink to fail to detect incompatible index connections. These two cases are:</p> <ul style="list-style-type: none"> <li>• If a root-level input port of the referenced model connects to index inputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level Inport block.</li> <li>• If a root-level output port of the referenced model connects to index outputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level Outport block.</li> </ul>
Asynchronous rates	<p>Referenced models can only use asynchronous rates if the model meets <i>both</i> of these conditions:</p> <ul style="list-style-type: none"> <li>• An external source drives the asynchronous rate through a root-level Inport block.</li> <li>• The root-level Inport block outputs a function-call signal. See Asynchronous Task Specification.</li> </ul>
User-defined data type input or output	<p>A referenced model can input or output only the user-defined data types that are fixed point or that <code>Simulink.DataType</code> or <code>Simulink.Bus</code> objects define.</p>
Buses	<p>If you use a virtual bus as an input or an output for a referenced model, the bus cannot contain a variable-sized signal element. See “Use Buses at Model Interfaces” on page 81-31.</p>
Signal objects	<p>A signal that connects to a Model block is functionally the same signal outside and inside the block. Therefore, that signal is subject to the restriction that a given signal can have at most one associated signal object. See <code>Simulink.Signal</code> for more information.</p>

## Simulation Requirements and Limitations

Simulation Property	Requirements and Limitations
Continuous sample time propagation	A continuous sample time cannot be propagated to a Model block that is sample-time independent.
Sample times and solvers	The solver of the top model controls all continuous sample times in a model hierarchy. For example, for a fixed-step solver, all continuous rates in referenced models run at the fixed-step size of the top model. For information about how sample times impact solvers, see “Types of Sample Time” on page 7-20.
State initialization	To initialize the states of a model that references other models with states, specify the initial states in structure or structure with time format.
Parameter tunability	When you simulate a model that references other models, under some circumstances, you lose some tunability of block parameters (for example, the <b>Gain</b> parameter of a Gain block). For more information, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 40-36.

## Code Generation Requirements and Limitations

By understanding code generation requirements and limitations upfront, you are better prepared to properly set up the model hierarchy for code generation. See “Set Configuration Parameters for Code Generation of Model Hierarchies” (Simulink Coder) and “Code Generation Limitations for Model Reference” (Simulink Coder).

- “Code Generation Limitations for Model Reference” (Simulink Coder)

## Reference Existing Models

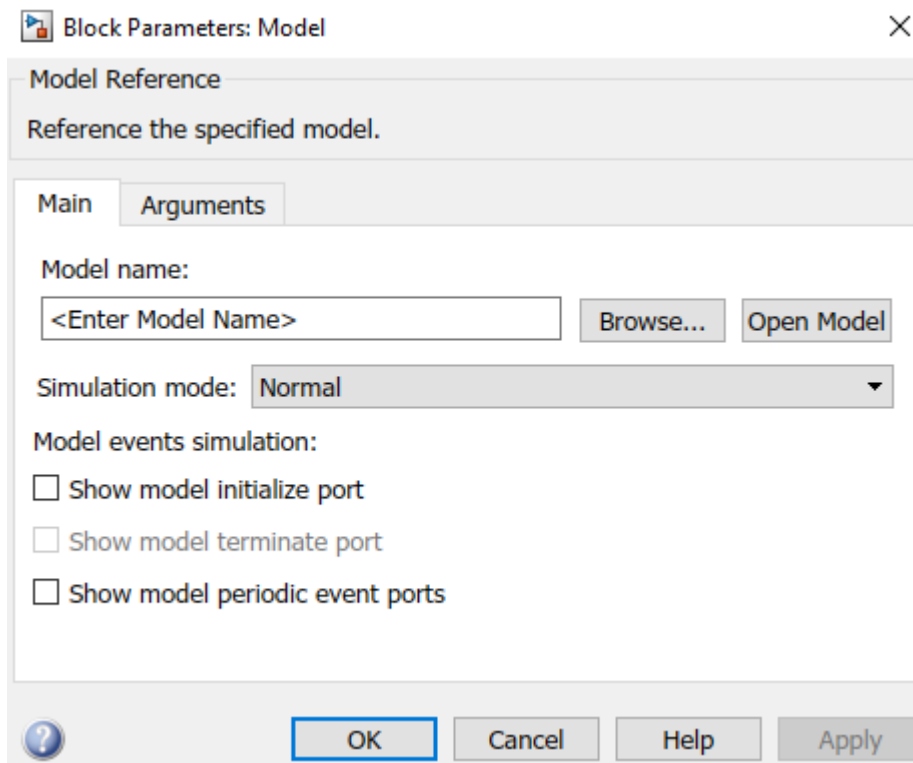

A model becomes a referenced model when a Model block in another model references it. Any model can function as a referenced model, and can continue to function as a separate model.

To reference an existing model in another model, follow these steps.

- 1 If the folder containing the model you want to reference is not on the MATLAB path, add the folder to the MATLAB path.
- 2 In the referenced model, set **Total number of instances allowed per top model** to:
  - One to use the model at most once in a model hierarchy.
  - Multiple to use the model more than once in a model hierarchy. To reduce overhead, specify Multiple only when necessary.
  - Zero to preclude referencing the model.
- 3 Create an instance of the Model block in the parent model. The new block is initially unresolved because it does not specify a referenced model.

- 4 To open the Block Parameters dialog box, double-click the unresolved Model block.

- 5 Enter the name of the referenced model in the **Model name** field. This name must contain fewer than 60 characters, exclusive of the file extension.

- 6 Click **OK**. If the referenced model contains root-level inputs or outputs, the Model block displays corresponding input and output ports.
- 7 Use the Model block ports to connect referenced model signals to ports in the parent model. See “Model Reference Interface and Boundary” on page 8-31.

---

**Note** When a Model block references another model, double-clicking the Model block opens the referenced model. To open the Block Parameters dialog box for a Model block, select the Model block. In the Simulink Toolstrip, on the **Model Block** tab, click **Block Parameters**.

---

### More About

- “Inspect Model Hierarchies” on page 8-28
- “Model Reference Requirements and Limitations” on page 8-6
- “Reference Protected Models from Third Parties” on page 8-13
- “Convert Subsystems to Referenced Models” on page 8-18
- “Conditionally Execute Referenced Models” on page 8-24

## Reference Protected Models from Third Parties

To deliver a model without revealing its intellectual property, third parties can protect the model before delivery. A protected model is a referenced model that does not support editing. The protected model author chooses whether to enable read-only view, simulation, code generation, and password protection. When an operation is password-protected, the AES-256 encryption technology protects the supporting file contents.

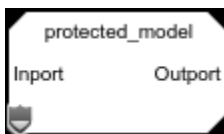

---

**Note** Creating a protected model requires a Simulink Coder license.

---

To identify protected models, look for:

- Files in the MATLAB Current Folder browser with a badge icon  and an `.slxp` extension. Protected models do not appear in the model hierarchy in the Model Explorer.
- Model blocks in the Simulink Editor with a badge icon in the lower left corner:

If available, a protected model report describes the supported functionality. To open the report, use one of these options:

- In the MATLAB Current Folder browser, right-click the protected model and click **Open Report**.
- In the Simulink Editor, right-click the protected-model badge icon on the Model block and click **Display Report**.

### Load Supporting Files for Protected Model

You may receive the protected model on its own, in a project archive, or in a package.

- If you receive a project archive (`.mlproj`), extract the protected model and any supporting files. Double-click the project archive (`.mlproj`) in the Current Folder browser and specify the destination folder. Alternatively, right-click on the project archive and click **Extract Here**. The project opens, and the extracted files are in a new folder named after the project archive.
- If you receive a protected model or supporting files by another method, follow any provided instructions. For example, you might need to load a MAT-file that contains workspace definitions. You can configure a callback function, such as `LoadFcn`, to load the MAT-file automatically. See “Customize Model Behavior with Callbacks” on page 4-52.

### Verify Digital Signature of Protected Model

If the author signed the protected model, verify the digital signature. In the Current Folder browser, double-click the protected model. In the **Details** pane, the **Signed by** field indicates the publisher that signed the model and whether the signature is verified by a trusted certificate authority. Verification fails in the following cases:

- The protected model was changed after it was signed.
- The protected model was not signed.
- The protected model was signed with an expired certificate.
- The protected model was self-signed with a certificate issued by the author.
- The protected model was signed with a missing or invalid certificate.
- The certificate of the CA is missing in your system or is invalid.

To verify the signature on protected models by default, in the Simulink Preferences dialog box, select **Verify digital signature of protected model before opening**.

## View Protected Model Contents

Web view allows you to view this protected model information:

- System contents
- Block parameters
- Signal properties

To open the read-only view, you can double-click the Model block referencing the protected model or the `.slxp` file in the Current Folder browser. If the read-only view is password protected, right-click the protected-model badge icon and select **Authorize**. In the **Model view** box, enter the password, then click **OK**.

You can navigate the model hierarchy by double-clicking Model or Subsystem blocks. Alternatively, you can navigate to the **View All** tab and select the system that you want to view. You cannot view the content of protected referenced models in the protected model.

To view block parameters and signal properties, select a block or a signal line, respectively.

To search in Web view, click the search button, then enter the name or value that you want to search in the box that appears. The elements of the model that the search returns appear highlighted. The search results include the name and parent of each returned element.

## Test Protected Model in Isolated Environment

With the protected model, you may receive a harness model, which typically has the suffix `_harness`. A harness model provides an isolated environment for you to test the protected model. If any supporting files are missing, simulating or generating code for the harness model can help identify them.

To create a harness model, right-click the protected model file in the Current Folder browser, then click **Create Harness Model**. The created harness model is set up for simulation of the protected model.

## Reference Protected Model

To reference a protected model:

- 1 Ensure that the protected model is on the MATLAB path.
- 2 If you have a harness model, copy the Model block from the harness model into your model. Otherwise, reference the protected model in a new Model block. Open the Block Parameters dialog box and enter the name of the protected model in the **Model name** field.

When a Model block references a protected model, the **Simulation mode** of the block becomes **Accelerator**. You cannot change this mode or use this Model block in External mode.

- 3 If the protected model is password protected, right-click the protected-model badge icon on the Model block and click **Authorize**. In the **Model view** box, enter the password, then click **OK**.
- 4 Connect signal lines to the Model block that match its input and output port requirements. See “Model Reference Interface and Boundary” on page 8-31.

Note that the protected model cannot use noninlined S-functions directly or indirectly.

- 5 Provide any needed model argument values. See “Parameterize a Referenced Model” on page 8-64.

If you plan to simulate the protected model, use the same platform used to create the protected model. The software stores the protected model as a compiled MEX binary.

## Use Models Protected in Previous Releases

Check that the Simulink release you are using supports the protected model.

If available, the protected model report shows the release versions used to create the protected model. Use the same Simulink release that was used to create the protected model unless the protected model also supports later releases, as described by this table.

Modeling Requirement	Cross-Release Protected Model Support
Read-only view	<b>Supported with limitations</b> — R2019a and later releases <ul style="list-style-type: none"> <li>• Protected model must have been created in R2018b or a later release.</li> </ul>
Simulation in normal mode	<b>Supported with limitations</b> — R2019a and later releases <ul style="list-style-type: none"> <li>• Protected model must have been created in R2018b or a later release.</li> </ul>

Modeling Requirement	Cross-Release Protected Model Support
Simulation in accelerator mode	<p><b>Supported with limitations</b> — R2020a and later releases</p> <ul style="list-style-type: none"> <li>Protected model must have been created in R2018b or a later release.</li> <li>You must directly simulate the parent of the protected model. Simulating a model hierarchy that contains the parent model as a referenced model is not supported. To interactively simulate the parent model, you must open it as the top model in its own window. For more information, see “Navigate Model Hierarchies” on page 4-29.</li> <li>The protected model must use Just-in-Time acceleration and must not require C code generation. For more information on acceleration modes, see “How Acceleration Modes Work” on page 38-3.</li> </ul>
Simulation in SIL or PIL mode	<p><b>Supported with limitations</b> — R2020b and later releases</p> <ul style="list-style-type: none"> <li>Protected model contains ERT, ERT-based, AUTOSAR, GRT, or GRT-based code generated in R2018b or a later release. You can run Model block SIL and PIL simulations that reference the protected model. For more information, see “Use Protected Models from Previous Releases to Perform SIL Testing and Generate Code” (Embedded Coder).</li> </ul> <p>If ERT or AUTOSAR code in the protected model requires shared utility code, use <code>sharedCodeUpdate</code> to copy the required code to an existing shared utility code folder. For more information, see “Cross-Release Shared Utility Code Reuse” (Embedded Coder).</p> <ul style="list-style-type: none"> <li>You cannot use <code>Simulink.ModelReference.ProtectedModel.addTarget</code> or <code>Simulink.ModelReference.ProtectedModel.removeTarget</code> to add or remove generated code from a protected model created in a different release.</li> </ul>
Simulation in rapid accelerator mode	<p><b>Not supported</b></p>

Modeling Requirement	Cross-Release Protected Model Support
Code generation	<p><b>Supported with limitations</b> — R2020b and later releases</p> <ul style="list-style-type: none"> <li>Protected model contains ERT, ERT-based, AUTOSAR, GRT, or GRT-based code generated in R2018b or a later release, with a <code>Model</code> reference code interface. For more information, see “Use Protected Models from Previous Releases to Perform SIL Testing and Generate Code” (Embedded Coder).</li> </ul> <p>If ERT or AUTOSAR code in the protected model requires shared utility code, use <code>sharedCodeUpdate</code> to copy the required code to an existing shared utility code folder. For more information, see “Cross-Release Shared Utility Code Reuse” (Embedded Coder).</p> <ul style="list-style-type: none"> <li>You cannot use <code>Simulink.ModelReference.ProtectedModel.addTarget</code> or <code>Simulink.ModelReference.ProtectedModel.removeTarget</code> to add or remove generated code from a protected model created in a different release.</li> </ul>

## Convert Subsystems to Referenced Models

Model reference offers benefits for modeling large, complex systems and for team-based development. Many large models use a combination of subsystems and referenced models. To decide whether to convert a subsystem to a referenced model, see “Choose Among Types of Model Components” on page 23-4.

### Prepare Subsystem for Conversion

Preparing a subsystem for conversion can eliminate or reduce the number of issues identified during conversion. Addressing these issues before conversion can be more efficient than switching repeatedly between the diagnostic messages and the Simulink Editor.

To prepare the subsystem:

- 1 Set the **Signal resolution** configuration parameter to `Explicit only` or `None`.

---

**Tip** You can automatically fix this issue during conversion.

---

- 2 Configure the Subsystem block interface.

---

**Tip** You can automatically fix these interface issues during conversion.

---

Subsystem Interface	What to Look For	Model Modification
Goto or From blocks	Goto or From blocks crossing the subsystem boundary	<p>Replace From blocks that have a corresponding Goto block that crosses the subsystem boundary with an Inport block.</p> <p>Replace each Goto block that has corresponding From blocks that cross the subsystem boundary with an Outport block.</p> <p>Connect the Inport and Outport blocks to the corresponding subsystem ports.</p>
Data stores	Data Store Memory blocks accessed by Data Store Read or Data Store Write blocks from outside of the subsystem	Replace the Data Store Memory block with a global data store. Define a global data store using a <code>Simulink.Signal</code> object. For details, see “Data Stores with Signal Objects” on page 78-16.

Subsystem Interface	What to Look For	Model Modification
Tunable parameters	Global tunable parameters in the dialog box opened using the <b>Configuration Parameters &gt; Code Generation &gt; Optimization &gt; Configure</b> button	To create a <code>Simulink.Parameter</code> object for each tunable parameter, use <code>tunablevars2parameterobjects</code> .  The <code>Simulink.Parameter</code> objects must have a storage class other than <code>Auto</code> .  For more information, see “Parameterize Instances of a Reusable Referenced Model” on page 8-63 and “Tunable Parameters” on page 10-68.

### 3 Configure the Subsystem block contents.

Subsystem Configuration	What to Look For	Model Modification
Block execution order	Virtual subsystem that does not force contained blocks to execute consecutively.	Select the Subsystem block, and then on the <b>Subsystem Block</b> tab, select <b>Is Atomic Subsystem</b> .
Function calls	Function-call signals that cross virtual subsystem boundaries	Move the Function-Call Generator block into the subsystem that you want to convert.  <b>Note</b> If you convert an export-function subsystem, then you do not need to move the Function-Call Generator block.
	Function-call outputs	Change the function-call outputs to data triggers.
	Wide function-call ports	Eliminate wide signals for function-call subsystems.
Sample times	An Inport block sample time that does not match the sample time of the block driving the Inport block	Insert Rate Transition blocks where appropriate.
Inport blocks	Merged Inport blocks	Configure the model to avoid merged Inport blocks. See the Merge block documentation.
Constant blocks	Constant blocks that provide input for subsystems	Move Constant blocks into the subsystem.
Buses	Buses that enter and exit a subsystem	Match signal names and bus element names for blocks inside the subsystem.  To find signal names that do not match bus element names, use the <b>Signal label mismatch</b> diagnostic.

Subsystem Configuration	What to Look For	Model Modification
	Duplicate signal names in buses	Make signal names of bus elements unique.
	Signal names that are not valid MATLAB identifiers. A valid identifier is a character vector that meets these conditions: <ul style="list-style-type: none"> <li>The name contains letters, digits, or underscores.</li> <li>The first character is a letter.</li> <li>The length of the name is less than or equal to the value returned by the <code>namelengthmax</code> function.</li> </ul>	Change any invalid signal names to be valid MATLAB identifiers.

- 4 Make sure that the model containing the subsystem that you want to convert compiles successfully.

## Convert Subsystems to Referenced Models

To convert a subsystem to a referenced model:

- 1 Select the Subsystem block you want to convert.
- 2 In the Simulink Toolstrip, on the **Subsystem Block** tab, select **Convert > Model Block**.

The **Model Reference Conversion Advisor** opens and lets you interactively specify conversion parameters and fix issues that the advisor finds.

To make the conversion process faster:

- In the Model Reference Conversion Advisor, select **Fix errors automatically (if possible)**. This option automatically fixes some conversion issues, but you do not control the fixes.
- Close any open Scope block windows before starting the conversion.

To leave the Subsystem block in place and create a separate model from the contents of the Subsystem block, clear **Replace the content of a subsystem with a Model block**.

To compare top-model simulation results before and after conversion:

- Enable signal logging for output signals of interest.
- Select **Check simulation results after conversion** and **Replace the content of a subsystem with a Model block**.
- Set the **Stop time**, **Absolute tolerance**, and **Relative tolerance**.
- Set the **Model block simulation mode** option in the advisor to the same simulation mode as the original model.

After you set the conversion settings, click **Convert** and address any identified issues.

Alternatively, in the MATLAB command window, use the `Simulink.SubSystem.convertToModelReference` function. You can convert multiple Subsystem blocks using one `Simulink.SubSystem.convertToModelReference` command. However, you cannot convert a parent subsystem and a child of that subsystem at the same time.

## Conversion Results

After all conversion checks pass, Simulink:

- Creates a referenced model from the subsystem.
- Creates the `Simulink.Bus` objects, `Simulink.Signal` objects, and tunable parameters that the referenced model requires.
- By default, replaces the Subsystem block with a Model block that references the new model.
- Inserts the Model block in a Subsystem block if the automatic fixes added ports to the Model block interface.
- Creates an HTML conversion summary report in the `slprj` folder. This report summarizes the results of the conversion process, including the results of the fixes that the advisor performed. This report also describes the elements that it copies.
- Optionally checks the consistency of simulation results before and after conversion.

Simulink copies the following elements from the original model to the new referenced model.

- **Configuration set** — If the parent model uses:
  - A configuration set that is not a referenced configuration set, the advisor copies the entire configuration set to the referenced model
  - A referenced configuration set, then both the parent and referenced models use the same referenced configuration set
- **Variables** — The advisor copies only the model workspace variables that the subsystem used in the original model to the model workspace of the referenced model. If the model that contained the subsystem uses a data dictionary, then the referenced model uses the same data dictionary.
- **Requirements links** — The advisor copies requirements links created with Requirements Toolbox software to the Model block from the original Subsystem block.

## Compare Simulation Results Before and After Conversion

After you successfully complete conversion, use the [Click here to view the comparison results](#) link. The results display in the **Simulation Data Inspector**. A green check mark indicates that simulation results are within tolerance between the baseline model and the model with the new referenced model.

For more information, see “Compare Simulation Data” on page 31-193.

## Revert Conversion

If you are not satisfied with the conversion results, you can restore the model to its initial state. Use one of these approaches:

- At any point during the conversion, select **File > Load Restore Point**.
- After you successfully run the **Complete conversion** check, use the **Click here to restore the original model** link.

## Integrate Referenced Model into Parent Model

After you complete the conversion, update the model as necessary to meet your modeling requirements. For example, you can manually replace a Subsystem block with a Model block that references the created referenced model.

If you want to simulate the model with external data, check that the root Inport blocks in the new referenced model have the appropriate **Interpolate data** parameter setting. See the documentation for the **Interpolate data** parameter of the Inport block.

## Conditionally Execute Referenced Models

A conditionally executed referenced model, or conditional model, allows you to control its execution with an external signal. The external signal, called the control signal, is attached to the control input port. Conditional models are useful when you create complex model hierarchies that contain components whose execution depends on other components.

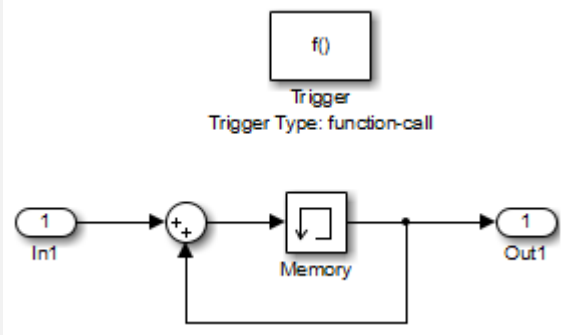

### Conditional Models

You can set up referenced models to execute conditionally, similar to conditional subsystems. For information about conditional subsystems, see “Conditionally Executed Subsystems Overview” on page 10-3.

Simulink software supports these conditional model types:

Conditional Model	Description
Enabled	<p>An enable port executes a referenced model at each simulation step for which the control signal has a positive value. To add an enable port to a Model block, insert an Enable block in the referenced model.</p>  <p>For an example of an enabled <i>subsystem</i>, see “Enabled Subsystems”. A corresponding enabled referenced model uses the same blocks as are in the enabled subsystem.</p>
Triggered	<p>A trigger port executes a referenced model each time a trigger event occurs. To add a trigger port to a Model block, insert a Trigger block in the referenced model.</p> 

Conditional Model	Description
Triggered and Enabled	A Model block can have both trigger and enable ports. If the enable control signal has a positive value at the time step for which a trigger event occurs, a triggered and enabled model executes once.
Function-Call	<p>A function-call port executes a referenced model each time a function-call event occurs. To add a function-call port to a Model block, insert a Trigger block in the referenced model. Then, open the Block Parameters dialog box and set the <b>Trigger type</b> to function-call.</p> <p>A Stateflow chart, a Function-Call Generator block, a Hit Crossing block, or an appropriately configured custom S-function can provide function-call events. See “Using Function-Call Subsystems” on page 10-34.</p>  <p>For an example of a function-call model, see “Model Reference Function-Call”.</p>

## Requirements for Conditional Models

Conditional models must meet the requirements for:

- Conditional subsystems (see “Conditionally Executed Subsystems and Models”)
- Referenced models (see “Reference Existing Models” on page 8-11)

Conditional models must also meet the requirements specific to each type of conditional model.

Conditional Model	Requirements
Enabled	<ul style="list-style-type: none"> <li>• Multi-rate enabled models cannot use multi-tasking solvers. Use single-tasking.</li> <li>• For models with enable ports at the root, if the model uses a fixed-step solver, the fixed-step size of the model must not exceed the rate for any block in the model.</li> <li>• Signal attributes of the enable port in the referenced model must be consistent with the input that the Model block provides to that enable port.</li> </ul>
Triggered	Signal attributes of the trigger port in the referenced model must be consistent with the input that the Model block provides to that trigger port.
Triggered and Enabled	See requirements for triggered models and enabled models.

Conditional Model	Requirements
Function-Call	<ul style="list-style-type: none"> <li>• A function-call model cannot have an output port driven only by Ground blocks, including hidden Ground blocks inserted by Simulink. To meet this requirement, do the following:               <ol style="list-style-type: none"> <li><b>1</b> Insert a Signal Conversion block into the signal connected to the output port.</li> <li><b>2</b> Enable the <b>Exclude this block from 'Block reduction' optimization</b> option of the inserted block.</li> </ol> </li> <li>• The parent model must trigger the function-call model at the rate specified by the <b>Configuration Parameters &gt; Solver 'Fixed-step size'</b> option if the function-call model meets both these conditions:               <ul style="list-style-type: none"> <li>• It specifies a fixed-step solver.</li> <li>• It contains one or more blocks that use absolute or elapsed time.</li> </ul> <p>Otherwise, the parent model can trigger the function-call model at any rate.</p> </li> <li>• A function-call model must not have direct internal connections between its root-level input and output ports. Simulink does not honor the None and Warning settings for the <b>Invalid root Inport/Outport block connection</b> diagnostic for a referenced function-call model. It reports all invalid root port connections as errors.</li> <li>• If the <b>Sample time type</b> is periodic, the sample-time period must not contain an offset.</li> <li>• The signal connected to a function-call port of a Model block must be scalar.</li> </ul>

## Modify a Referenced Model for Conditional Execution

- 1** At the root level of the referenced model, insert one of the following blocks:

Type of Model	Blocks to Insert
Enabled	Enable
Triggered	Trigger
Triggered and Enabled	Trigger and Enable
Function-Call	Trigger

For an enabled model, go to Step 3.

- 2** For the Trigger block, set the **Trigger type** parameter:

Type of Model	Trigger Type Parameter Setting
Triggered	One of the following:
Triggered and enabled	<ul style="list-style-type: none"> <li>• rising</li> <li>• falling</li> <li>• either</li> </ul>

Type of Model	Trigger Type Parameter Setting
Function-Call	function-call

- 3 Use the Model block ports to connect the referenced model to other ports in the parent model.
  - The top of the Model block displays an icon that corresponds to the control signal type expected by the referenced model. For a triggered model, the top of the Model block displays this icon.

## See Also

Enable | Trigger | Function-Call Subsystem

- “Conditionally Executed Subsystems Overview” on page 10-3
- “Export-Function Models Overview” on page 10-96

## Inspect Model Hierarchies

To better understand a model hierarchy, you can use Simulink tools, functions, parameters, or preferences to:

- Preview model contents
- Visualize the model hierarchy
- List referenced models and Model blocks
- Display model version numbers

### Content Preview

Content preview displays a representation of the contents of a referenced model on the Model block. This preview helps you to understand at a glance the kind of processing performed by the referenced model without opening the referenced model. See “Preview Content of Model Components” on page 1-35.

### Model Dependency Graph

The Dependency Analyzer shows the structure of the model hierarchy and lets you open constituent models. The **Model Instances** view displays Model blocks differently to indicate Normal, Accelerator, SIL, and PIL modes. See “Analyze Model Dependencies” on page 17-40.

The depview function opens the model dependency graph.

## List of Model References

The `find_mdhrefs` function lists all models that are directly or indirectly referenced by a given model. This function also provides the paths to the related Model blocks.

### Find Referenced Models in Model Hierarchy

Find referenced models and Model blocks for all models referenced by the specified model.

```
load_system('sldemo_mdhref_basic');
[myModels,myModelBlks] = find_mdhrefs('sldemo_mdhref_basic')

myModels = 2x1 cell
    {'sldemo_mdhref_counter'}
    {'sldemo_mdhref_basic' }

myModelBlks = 3x1 cell
    {'sldemo_mdhref_basic/CounterA'}
    {'sldemo_mdhref_basic/CounterB'}
    {'sldemo_mdhref_basic/CounterC'}
```

## Model Version Numbers

To display the version numbers of referenced models, in the parent model, on the **Debug** tab, click **Information Overlays**, then under **Blocks**, select **Ref. Model Version**. The version of each Model block instance appears on each Model block.

For information on model versions, see “Manage Model Versions and Specify Model Properties” on page 4-70.

## See Also

`find_mdhrefs` | `deview`

## More About

- “Export Signal Data Using Signal Logging” on page 77-42

## Model Reference Interface and Boundary

A Model block has input, output, and control ports that correspond to root-level input, output, and control ports of the model it references. A referenced model can include Inport, Outport, In Bus Element, Out Bus Element, Trigger, and Enable blocks to get input from the parent model and to provide output to the parent model. The input signals for the Model block must be valid for the corresponding input blocks of the referenced model. The output signals for the Model block are the referenced model root-level output block signals.

In `sldemo_mdhref_basic`, each Model block has three inputs: two Constant blocks and a Pulse Generator block. Each Model block has one output signal logged to a scope. Because the input signal from each Pulse Generator block uses a different sample time, the output signal from each Model block differs for each model instance.

Component-Based Modeling with Model Reference

To connect to the parent model, referenced model `sldemo_mdhref_counter` includes three Inport blocks (**upper**, **lower**, and **input**) and one Outport block (**output**).

To view how the output signal for each Model block differs, you can use the **Simulation Data Inspector**.

## Refresh Model Blocks

Refreshing a Model block updates its internal representation to reflect changes to the interface of the referenced model. For example, when the referenced model gains or loses a port, refreshing the Model block updates its ports.

By default, when a referenced model is loaded, the Model blocks that reference it automatically refresh. When a referenced model is not loaded, the corresponding Model blocks refresh when you perform actions such as:

- Opening the parent model
- Selecting a Model block
- Simulating the model hierarchy
- Generating code for the model hierarchy

When you select a Model block, you can refresh all Model blocks in the model hierarchy by clicking the **Refresh** button arrow on the **Model Block** tab, then clicking **Refresh Blocks**.

To be notified when Simulink detects Model blocks that might not match their referenced models, change the default setting for these diagnostic configuration parameters:

- **Model block version mismatch**
- **Port and parameter mismatch**

When these configuration parameters are set to `error` for a model, the Model blocks in that model do not automatically refresh. To refresh a Model block when these configuration parameters are set to `error`:

- Select the Model block. On the **Model Block** tab, click **Refresh**.
- Use the `Simulink.ModelReference.refresh` function.

## Signal Propagation

Signal attributes in a referenced model are independent from the context of the Model block. For example, signal dimensions and data types do not propagate across the Model block boundary. To define signal attributes in a referenced model, define block parameters for root-level Inport and In Bus Element blocks.

For signals that connect to Outport blocks to propagate out of a referenced model to the parent model, the signal names must explicitly appear on the signal lines.

For buses at interfaces, use In Bus Element and Out Bus Element blocks instead of Inport and Bus Selector blocks for inputs and Outport and Bus Creator blocks for outputs. In Bus Element and Out Bus Element blocks support multirate virtual buses and do not require `Simulink.Bus` objects at model interfaces, unlike Inport and Outport blocks. They also provide cleaner bus interfaces. For more information, see “Simplify Subsystem and Model Interfaces with Bus Element Ports” on page 81-23.

For an example of a model hierarchy that uses buses with Inport blocks, see “Interface Specification Using Bus Objects”.

A referenced model can only provide input or get output for user-defined data types that are fixed point or that `Simulink.DataType` or `Simulink.Bus` objects define.

## Signal Logging in Referenced Models

In a referenced model, you can log any signal configured for signal logging. Use the Signal Logging Selector to select a subset or all the signals configured for signal logging in a model hierarchy. For details, see “Override Signal Logging Settings” on page 77-57.

You can use the Simulation Data Inspector to view and analyze signals logged in referenced models. You can view signals on multiple plots, zoom, and use data cursors to understand and evaluate the data. Also, you can compare signal data from multiple simulations. For an example of viewing signals with referenced models, see “Viewing Signals in Model Reference Instances”.

## Sample Time Requirements

The first nonvirtual block that connects to a referenced model root-level input or output block must have the same sample time as the related port. If the sample times are different, use Rate Transition blocks to match input and output sample times, as shown in this diagram.

## Share Data Among Referenced Model Instances

By default, each Model block instance reads from and writes to a separate copy of the signals and block states in the model. Therefore, the instances do not interact with each other through shared signal or state data.

To share a piece of data between all of the instances (for example, an accumulator or a fault indicator), model the data as a data store.

- To restrict access to data so that only the blocks in the referenced model can read from and write to it, use a Data Store Memory block in the model and select the **Share across model instances** parameter. For an example, see “Share Data Store Between Instances of a Reusable Algorithm”.
- To allow access to data outside the referenced model, use a global data store, which is a `Simulink.Signal` object in the base workspace or a data dictionary. Data outside the referenced model can be in the parent model or in other referenced models.

For more information about data stores, see “Model Global Data by Creating Data Stores” on page 78-10.

# Referenced Model Sample Times

## How Sample-Time Inheritance Works for Model Blocks

The sample times of a Model block are the sample times of the model that it references. If the referenced model must run at specific rates, the model specifies the required rates. Otherwise, the referenced model inherits its sample time from the parent model.

Placing a Model block in a triggered, function call, or iterator subsystem relies on the ability to inherit sample times. Also, allowing a Model block to inherit sample time maximizes its reuse potential. For example, a model can fix the data types and dimensions of all its input and output signals. You could reuse the model with different sample times (for example, discrete at 0.1 or discrete at 0.2, triggered).

## Conditions for Inheriting Sample Times

A referenced model inherits its sample time if the model:

- Does not have any continuous states
- Specifies a fixed-step solver and the **Fixed-step size** is `auto`
- Contains no blocks that specify sample times (other than inherited or constant)
- Does not contain any S-functions that use their specific sample time internally
- Has only one sample time (not counting constant and triggered sample time) after sample time propagation
- Does not contain any blocks, including Stateflow charts, that use absolute time, as listed in “Blocks That Depend on Absolute Time” on page 8-36
- Does not contain any blocks whose outputs depend on inherited sample time, as listed in “Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-36.

You can use a referenced model that inherits its sample time anywhere in a parent model. By contrast, you cannot use a referenced model that has intrinsic sample times in a triggered, function call, or iterator subsystem. To avoid rate transition errors, ensure that blocks connected to a referenced model with intrinsic sample times operate at the same rates as the referenced model.

---

**Note** A continuous sample time cannot be propagated to a Model block that is sample-time independent.

---

For more information, see “Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-36.

## Determining Sample Time of a Referenced Model

To determine whether a referenced model can inherit its sample time, set the **Periodic sample time constraint** configuration parameter to `Ensure sample time independent`. If the model is unable to inherit sample times, this setting causes Simulink to display an error message when building the model. See “Periodic sample time constraint” for more about this option.

To determine the intrinsic sample time of a referenced model, or the fastest intrinsic sample time for multirate referenced models:

- 1 Update the model that references the model
- 2 Select a Model block within the parent model
- 3 Enter the following at the MATLAB command line:

```
get_param(gcf, 'CompiledSampleTime')
```

## Blocks That Depend on Absolute Time

The following Simulink blocks depend on absolute time, and therefore preclude a referenced model from inheriting sample time:

- Backlash (only when the model uses a variable-step solver and the block uses a continuous sample time)
- Chirp Signal
- Clock
- Derivative
- Digital Clock
- Discrete-Time Integrator (only when used in triggered subsystems)
- From File
- From Workspace
- Pulse Generator
- Ramp
- Rate Limiter
- Repeating Sequence
- Signal Generator
- Sine Wave (only when the **Sine type** parameter is Time-based)
- `stateflow` (when the chart uses absolute-time temporal logic, or the reserved word `t` to reference time)
- Step
- To File
- To Workspace (only when logging to Timeseries or Structure With Time format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

Some blocks other than Simulink blocks depend on absolute time. See the documentation for the blocksets that you use.

## Blocks Whose Outputs Depend on Inherited Sample Time

Using a block whose output depends on an inherited sample time in a referenced model can cause simulation to produce unexpected or erroneous results. When building a referenced model that does

not need a specified rate, Simulink checks for blocks whose outputs are functions of the inherited sample time. This checking includes examining S-Function blocks. If Simulink finds any such blocks, it specifies a default sample time. If you have set the **Configuration Parameters > Solver > Periodic sample time constraint** to **Ensure sample time independent**, Simulink displays an error. See “Periodic sample time constraint” for more about this option.

The outputs of the following built-in blocks depend on inherited sample time. The outputs of these blocks preclude a referenced model from inheriting its sample time from the parent model:

- Discrete-Time Integrator
- From Workspace (if it has input data that contains time)
- Probe (if probing sample time)
- Rate Limiter
- Rate Limiter Dynamic
- Sine Wave

Simulink assumes that the output of an S-function does not depend on inherited sample time unless the S-function explicitly declares the contrary. See “Specify S-Function Sample Times” for information on how to create S-functions that declare whether their output depends on their inherited sample time.

In referenced models that inherit their sample time, avoid S-functions in referenced models that fail to declare whether output depends on inherited sample time. Excluding those kinds of S-functions helps to avoid simulation errors. By default, Simulink warns you if your model contains such blocks when you update or simulate the model. See “Unspecified inheritability of sample time” for details.

## Sample Time Consistency

Use consistent sample time rates to promote the reliable use of a model referenced by another model. Make the rates of root Inport and Outport blocks in a referenced model consistent with the rates of blocks reading from and writing to those blocks. Simulink generates an error when there are sample time mismatches between:

- The sample times of root Inport blocks and the sample times of blocks to which the Inport block inputs.
- The sample times of root Outport blocks and the sample times of blocks that input to the Outport block.

To address an error that flags a sample time inconsistency in a referenced model, you can use one of these approaches.

Top-Level Inport or Outport Block Sample Time	Possible Solution
Different from all the blocks to which it connects, and those blocks all have the same sample time as each other	Set the sample time of the Inport or Outport block so that it matches the sample time of the block to which it connects.
Different from one or more blocks and the same as one or more blocks	For blocks that do not match the Inport or Outport block, insert Rate Transition blocks on the signal that connects to the Inport or Outport block.

## **Sample Rates and Solvers**

The solver of the top model controls all continuous sample times in a model hierarchy. For example, for a fixed-step solver, all continuous rates in referenced models run at the fixed-step size of the top model. For information about how sample times impact solvers, see “Types of Sample Time” on page 7-20.

## Choose Simulation Modes for Model Hierarchies

When you simulate a model hierarchy, you should consider how top models and referenced models execute.

- Top model — Supports all Simulink simulation modes. To speed up execution of a top model, you can use Simulink accelerator or rapid accelerator mode.
- Referenced model — Although you can specify any simulation mode for a model, when you reference that model, the Model block for each instance of the referenced model controls the simulation mode of the instance. The simulation mode of a parent model can override the simulation mode of a Model block.

For information on simulation modes, see “Choosing a Simulation Mode” on page 38-10 and “How Acceleration Modes Work” on page 38-3.

For information on selecting solvers for models in a model hierarchy, see “Set Configuration Parameters for Model Hierarchies” on page 8-59.

### Model Reference Simulation Modes

You can specify any of these simulation modes for a Model block:

- Normal
- Accelerator
- Software-in-the-loop (SIL) — requires Embedded Coder
- Processor-in-the-loop (PIL) — requires Embedded Coder

When you choose between normal and accelerator mode, you must make a tradeoff between flexibility and speed. Normal mode supports more Simulink and Stateflow features in referenced models, such as scopes, port value display, and debugging tools. Accelerator mode supports fewer features in referenced models, but simulates model hierarchies faster.

Modeling Requirement	Normal Mode	Accelerator Mode
Simulation speed	Models execute slower in normal mode than accelerator mode. However, referenced models that execute in normal mode do not delay simulation to build and compile simulation targets because normal mode executes referenced models interpretively.	Models execute faster in accelerator mode than normal mode. Before simulating the model, Simulink must build and compile simulation targets, which can be undesirable for prototyping. For more information, see “Manage Simulation Targets for Referenced Models” on page 8-50.

Modeling Requirement	Normal Mode	Accelerator Mode
Debugging	<p>With the Simulink Debugger, you can set a breakpoint inside a referenced model that executes in normal mode. For more information, see “Simulink Debugger”.</p> <p>With the Simulink Profiler, you can enable profiling for a referenced model that executes in normal mode. Enabling profiling on a parent model does not enable profiling for referenced models. See “How Profiler Captures Performance Data” on page 34-5.</p>	For referenced models that execute in accelerator mode, specifications made and actions taken by the Simulink Debugger and Simulink Profiler are ignored.
Testing	Simulink Coverage™ model coverage analysis supports referenced models that execute in normal mode.	Simulink Coverage model coverage analysis ignores referenced models that execute in accelerator mode.
Tunability	You can tune block parameters during simulation for referenced models that execute in normal mode.	For referenced models that execute in accelerator mode, if the referenced model uses variables in the base workspace or a data dictionary to set parameter values, you can tune the values of the variables. You cannot tune block parameters in the referenced model during simulation. For more information, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 40-36.
Data logging	Data logging provides extensive support for referenced models that execute in normal mode.	For referenced models that execute in accelerator mode, To Workspace blocks log data only if they use the <code>Timeseries</code> format for saving.

Modeling Requirement	Normal Mode	Accelerator Mode
Data visualization	<p>You can view simulation results for all instances of the referenced model with the <b>Simulation Data Inspector</b>.</p> <p>You can view instance-specific simulation results for each instance with Display blocks in the referenced model.</p> <p>Scopes and port value labels display data for only the instance of the referenced model that has normal mode visibility enabled. For more information, see “Simulate Multiple Referenced Model Instances in Normal Mode” on page 8-44.</p>	<p>You can view simulation results for all instances of the referenced model with the Simulation Data Inspector.</p> <p>These visualization methods show no data for referenced models that execute in accelerator mode.</p> <ul style="list-style-type: none"> <li>• Scope, Floating Scope, and Scope Viewer blocks in the referenced model</li> <li>• Runtime displays, such as port value labels</li> </ul> <p>Top model Scope blocks can display data for referenced models that execute in accelerator mode if you use the Viewers &amp; Generators Manager to add test points in the referenced model. Adding or removing a test point requires rebuilding the model reference simulation target for a model.</p>
Diagnostics	Configuration parameter settings are applied as specified.	For models referenced in accelerator mode, Simulink can ignore some configuration parameter settings. For details, see “Diagnostics That Are Ignored in Accelerator Mode” on page 8-61.
Runtime checks	Runtime checks are enabled.	Some blocks include runtime checks that are disabled when you include the block in a referenced model in accelerator mode. Examples of these blocks include Assignment, Selector, MATLAB Function, and MATLAB System blocks.
Linearization analysis and optimization	Normal mode allows block-by-block linearization of a referenced model, which achieves an accurate linearization.	<p>In accelerator mode, discrete states of model references are not exposed to linearization. These discrete states are not perturbed during linearization and, therefore, are not truly free in the trimming process.</p> <p>The outputs of random blocks are not kept constant during trimming. Outputs that are not kept constant can affect the optimization process.</p>

<b>Modeling Requirement</b>	<b>Normal Mode</b>	<b>Accelerator Mode</b>
Extrinsic functions	A MATLAB Function block in a referenced model that executes in normal mode can call MATLAB functions that are declared extrinsic for code generation.	A MATLAB Function block in a referenced model that executes in accelerator mode cannot call MATLAB functions that are declared extrinsic for code generation.
S-Functions	Referenced models that execute in normal mode support more S-functions than referenced models that execute in accelerator mode. For more information see, “S-Functions in Referenced Models” on page 8-7.	Referenced models that execute in accelerator mode support fewer S-functions than referenced models that execute in normal mode. For more information see, “S-Functions in Referenced Models” on page 8-7.

SIL and PIL simulation modes execute referenced models by generating production code for embedded processors. SIL mode provides a convenient alternative to PIL simulation because it can run on a host platform when the target hardware is not available. For more information, see “SIL and PIL Simulations” (Embedded Coder).

## Overridden Simulation Modes

The simulation mode of the parent model can override the simulation mode of a Model block. This table shows which simulation mode Simulink uses for a referenced model instance based on the simulation mode of the parent model and related Model block.

<b>Simulation Mode Used by Parent Model</b>	<b>Simulation Mode of Model Block</b>	
	<b>Normal</b>	<b>Accelerator</b>
<b>Normal</b>	Compatible — Referenced model simulates in normal mode.	Compatible — Referenced model simulates in accelerator mode.
<b>Accelerator</b>	Overridden — Referenced model simulates in accelerator mode.	Compatible — Referenced model simulates in accelerator mode.
<b>Rapid accelerator</b> (top model only)		Compatible — Referenced model simulates in accelerator mode.

For information on SIL and PIL, see “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder).

- “Simulate Multiple Referenced Model Instances in Normal Mode” on page 8-44
- “Choosing a Simulation Mode” on page 38-10

## Simulate Conditionally Executed Referenced Models

You can run a standalone simulation of a conditionally executed referenced model, or conditional model. A standalone simulation is useful for unit testing because it provides consistent data across simulations in terms of data type, dimension, and sample time. Use normal, accelerator, or rapid accelerator mode to simulate a conditional model.

### Triggered, Enabled, and Triggered and Enabled Models

Triggered, enabled, and triggered and enabled models require an external input to drive the Trigger or Enable blocks. In the **Signal Attributes** pane of the Trigger or Enable block dialog box, specify values for the signal data type, dimension, and sample time.

To run a standalone simulation, specify the inputs using the **Input** configuration parameter. For details about how to specify the input, see “Comparison of Signal Loading Techniques” on page 75-21. The following conditions apply when you use the **Input** parameter for Trigger and Enable block inputs:

- Use the last data input for the trigger or enable input. For a triggered and enabled model, use the last data input for the trigger input.
- If you do not provide any input values, the simulation uses zero as the default values.

You can log data to determine which signal caused the model to run. For the Trigger or Enable block, in the **Main** pane of the Block Parameters dialog box, select **Show output port**.

### Function-Call Models

When you simulate a function-call model, the Model block conditionally executes when it receives a function-call event. A Stateflow chart, Function-Call Generator block, or S-Function block can provide function-call events.

You can also configure the model to calculate output at specific times using a variable-step solver. For more information, see “Samples to Export for Variable-Step Solvers” on page 77-39.

## Simulate Multiple Referenced Model Instances in Normal Mode

### In this section...

“Normal Mode Visibility” on page 8-44

“Examine Models with Multiple Referenced Model Instances” on page 8-44

“Configure Models with Multiple Referenced Model Instances” on page 8-45

“Determine Which Instance Has Normal Mode Visibility” on page 8-46

“Specify the Instance Having Normal Mode Visibility” on page 8-47

### Normal Mode Visibility

All instances of a referenced model that simulate in normal mode are part of the simulation. However, only one normal-mode instance of the referenced model supports all data visualizations. For example, scopes and port value labels display data for only the instance that has normal mode visibility enabled. To view simulation results for all instances of the referenced model, use the **Simulation Data Inspector**. To view instance-specific data for each instance of the model that simulates in normal mode, use Display blocks in the referenced model.

To set normal mode visibility, in the top model, on the **Simulation** tab, in the **Prepare** gallery, under **Signal Monitoring**, click **Normal Mode Visibility**. This setting determines the instance that has normal mode visibility enabled. If you do not specify normal mode visibility for an instance of a referenced model, Simulink software selects which instance of the referenced model has normal mode visibility enabled.

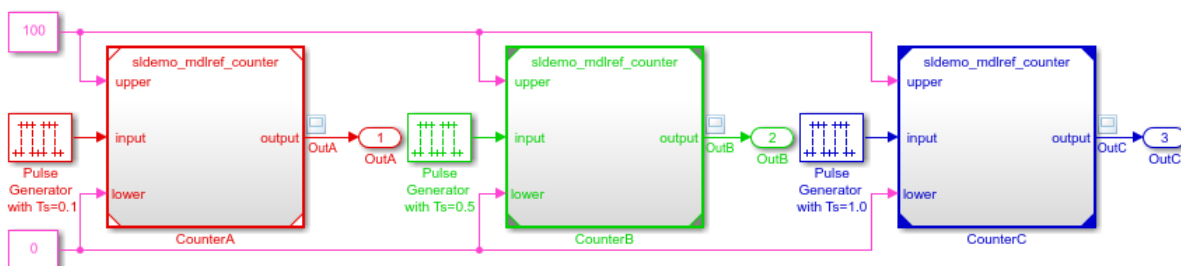

After a simulation, if you try to open a referenced model from a Model block that does not have normal mode visibility, Simulink software displays a warning.

To set up your model to control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see “Specify the Instance Having Normal Mode Visibility” on page 8-47.

### Examine Models with Multiple Referenced Model Instances

The `sldemo_mdhref_basic` model has Model blocks named CounterA, CounterB, and CounterC that each reference the `sldemo_mdhref_counter` model. If you update the diagram, `sldemo_mdhref_basic` displays different icon corners for each of the Model blocks.

Component-Based Modeling with Model Reference

Model Block	Icon Corners	Simulation Mode and Normal Mode Visibility Setting
CounterA	White	Normal mode, with normal mode visibility enabled
CounterB	Gray corners	Normal mode, with normal mode visibility disabled
CounterC	Black corner	Accelerator mode (normal mode visibility is not applicable)

Open and simulate `sldemo_mdref_basic`. Double-click the Model block named CounterA and open the Scope block named ScopeA.

The scope displays the simulation results for the Model block named CounterA, which has normal mode visibility enabled.

If you open the `sldemo_mdref_counter` model by double-clicking the Model block named CounterB, the scope in `sldemo_mdref_counter` still shows the results of the Model block named CounterA because that block has normal mode visibility enabled.

For more information on `sldemo_mdref_basic`, see “Component-Based Modeling with Model Reference”.

For an example that uses the Dependency Analyzer for a model hierarchy that contains multiple instances of a referenced model in normal mode, see “Visualize Model Reference Hierarchies”.

## Configure Models with Multiple Referenced Model Instances

- 1 Set the **Total number of instances allowed per top model** parameter to `Multiple`.
- 2 Set each instance of the referenced model so that it uses normal mode. In the block parameters dialog box for the Model block that references the instance, set the **Simulation Mode** parameter to `Normal`. Ensure that all the ancestors in the hierarchy for that Model block are in normal mode.

The corners of icons for Model blocks that are in normal mode can be white (empty). The corners turn gray after you update the diagram or simulate the model.

- 3 If necessary, modify S-functions used by the model so that they work with multiple instances of referenced models in normal mode. For details, see “Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode”.

By default, Simulink assigns normal mode visibility to one of the instances. After you complete the configuration steps, you can specify a non-default instance to have normal mode visibility.

For more information about encapsulating a reusable algorithm in a referenced model, see “Model Reuse” on page 8-6.

## Determine Which Instance Has Normal Mode Visibility

To determine which instance currently has normal mode visibility enabled:

- 1 To apply the normal mode visibility setting, update the diagram and make no other changes to the model.
- 2 Examine the Model blocks that reference the model that you are interested in. The Model block that has white corners has normal mode visibility enabled.

When you are editing a model or during compilation, after updating the diagram, use the `ModelReferenceNormalModeVisibilityBlockPath` parameter. The result is a `Simulink.BlockPath` object that is the block path for the Model block that references the model that has normal mode visibility enabled. For example:

```
get_param('sldemo_mdref_counter',...  
'ModelReferenceNormalModeVisibilityBlockPath')
```

```
ans =
```

```
Simulink.BlockPath  
Package: Simulink  
  
Block Path:  
'sldemo_mdref_basic/CounterA'
```

For a top model that you are simulating or that is in a compiled state, you can use the `CompiledModelBlockNormalModeVisibility` parameter. For example:

```
a = get_param('sldemo_mdref_depgraph',...  
'CompiledModelBlockNormalModeVisibility')
```

```
a =
```

```
struct with fields:  
  
sldemo_mdref_F2C: [1×1 Simulink.BlockPath]  
sldemo_mdref_heater: [1×1 Simulink.BlockPath]
```

When you create a `Simulink.BlockPath` object for specifying normal mode visibility:

- The first character vector must represent a block that is in the top model of the model reference hierarchy.
- Character vectors must represent Model blocks that are in normal mode.
- Character vectors that represent variant models or variant subsystems must refer to an active variant.

## Specify the Instance Having Normal Mode Visibility

---

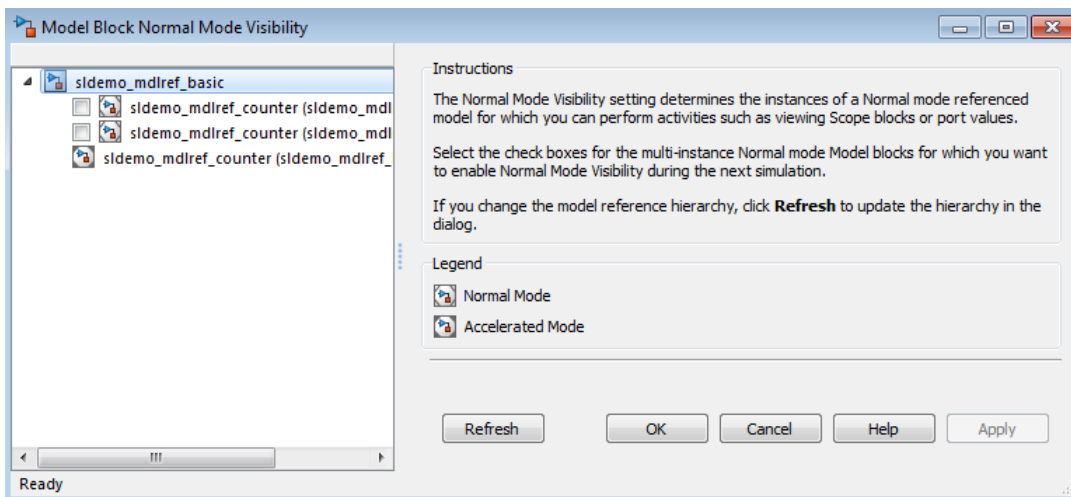

**Note** You cannot change normal mode visibility during simulation.

---

To enable normal mode visibility for a different instance of the referenced model than the instance that currently has normal mode visibility:

- 1 Navigate to the top model.
- 2 On the **Simulation** tab, in the **Prepare** section, under **Signal Monitoring**, select **Normal Mode Visibility**.

The Model Block Normal Mode Visibility dialog box appears. For example, here is the dialog box for the `sldemo_mdhref_basic` model, with the hierarchy pane expanded:

The model hierarchy pane shows a partial model hierarchy for the model from which you opened the dialog box. The hierarchy stops at the first Model block that is not in normal mode. The model hierarchy pane does not display Model blocks that reference protected models.

The dialog box shows the complete model hierarchy for the top model. The normal mode instances of referenced models have check boxes.

---

**Tip** To have the model hierarchy pane of the Model Block Normal Mode Visibility dialog box reflect the current model hierarchy, click **Refresh**.

---

- 3 Select the instance of the model that you want to have normal mode visibility.

Simulink selects all ancestors of the model and clears all other instances of that model. When a model is cleared, Simulink clears all children of that model.

---

**Tip** To open a model from the Model Block Normal Mode Visibility dialog box, right-click the model in the model hierarchy pane and then click **Open**.

---

- 4 To apply the normal mode visibility setting, simulate the top model in the model hierarchy.

As an alternative to using the Model Block Normal Mode Visibility dialog box, at the MATLAB command line you can use the `ModelBlockNormalModeVisibility` parameter. For input, you can specify one of these values:

- An array of `Simulink.BlockPath` objects. For example:
 

```
bp1 = Simulink.BlockPath({'mVisibility_top/Model', ...
    'mVisibility_mid_A/Model'});
bp2 = Simulink.BlockPath({'mVisibility_top/Model1', ...
    'mVisibility_mid_B/Model1'});
bps = [bp1, bp2];
set_param(topMdl, 'ModelBlockNormalModeVisibility', bps);
```
- A cell array of cell arrays of character vectors, with the character vectors being paths to individual blocks and models. This example produces the same effect as the object array example:

```
p1 = {'mVisibility_top/Model', 'mVisibility_mid_A/Model'};
p2 = {'mVisibility_top/Model1', 'mVisibility_mid_B/Model1'};
set_param(topMdl, 'ModelBlockNormalModeVisibility', {p1, p2});
```

- An empty array, to specify the use of the Simulink default selection of the instance that has normal mode visibility. For example:

```
set_param(topMdl, 'ModelBlockNormalModeVisibility', []);
```

Using an empty array is equivalent to clearing all the check boxes in the Model Block Normal Mode Visibility dialog box.

## Manage Simulation Targets for Referenced Models

A simulation target, or SIM target, is an automatically generated MEX-file that implements a referenced model that executes in accelerator mode. Simulink invokes the simulation target as needed during simulation to compute the behavior and outputs of the referenced model. Simulink uses the same simulation target for all instances of the referenced model that execute in accelerator mode. Instances of the referenced model that execute in normal mode do not use the simulation target.

To create model reference simulation targets, Simulink generates code that imposes some requirements and limitations on referenced models that execute in accelerator mode. Aside from these constraints, you can generally ignore simulation targets when you execute a referenced model in accelerator mode. For information on these constraints, see “Choose Simulation Modes for Model Hierarchies” on page 8-39.

By default, Simulink generates the simulation target for a referenced model that executes in accelerator mode if:

- The simulation target does not exist when you update the diagram of a direct or indirect parent of the referenced model or simulate the model hierarchy.
- The simulation target is out of date with structural changes in the referenced model.

While generating a simulation target, the MATLAB command window displays status messages so that you can monitor the simulation target generation process.

To programmatically build a model reference simulation target, use the `slbuild` function.

---

**Note** If you have a Simulink Coder license, be careful not to confuse the simulation target of a referenced model with these other types of targets:

- Hardware target — A platform for which Simulink Coder generates code
  - System target — A file that tells Simulink Coder how to generate code for particular purpose
  - Rapid Simulation target (RSim) — A system target file supplied with Simulink Coder
  - Model reference target — A library module that contains Simulink Coder code for a referenced model
- 

## Reduce Time Spent Checking For Changes

You can reduce the time that Simulink spends checking whether simulation targets require rebuilding by setting configuration parameter values as follows:

- In all referenced models throughout the hierarchy, set the **Signal resolution** configuration parameter to `Explicit only` or `None`.
- In the top model of the model hierarchy, set the **Rebuild** configuration parameter to `If any changes in known dependencies detected`. Alternatively, you can use this parameter to specify that Simulink always or never rebuilds simulation targets.

These parameters exist in the configuration set of the model; they are not parameters of the Model block. Setting these parameters for any instance of a referenced model sets it for all instances of that model.

## Specify Programming Language of Simulation Targets

To specify the programming language for model reference simulation targets, use the **Language** configuration parameter on the **Simulation Target** tab of the Configuration Parameters dialog box.

## Use Custom Code for Simulation Targets

To use custom code with Stateflow or with MATLAB Function blocks when building a model reference simulation target, use the **Include custom code for referenced models** configuration parameter.

---

**Caution** Using custom code for referenced models in accelerator mode can produce different results than when you simulate the model without using custom code. If the custom code includes declarations of structures for buses or enumerations, the simulation target generation fails if the build results in duplicate declarations of those structures. Also, if custom code uses a structure that represents a bus or enumeration, you can get unexpected simulation results.

---

## Control Location of Simulation Targets

Simulink creates simulation targets in the `s\prj` build folder of the current folder. If the `s\prj` folder does not exist, Simulink creates it.

---

**Note** Simulink Coder code generation also uses the `s\prj` folder. Subfolders in `s\prj` provide separate places for simulation code, Simulink Coder code, and other files. For details, see “Manage Build Process Folders” (Simulink Coder).

---

You can place generated files in a different root folder than the current working folder. This option allows you to:

- Store generated files separate from the models and other source materials used to generate them.
- Reuse or share previously built simulation targets without having to set the current working folder to a previous working folder.
- Separate generated simulation artifacts from generated production code.

The simulation cache folder is the root folder in which to place artifacts used for simulation.

To specify a simulation cache folder to use instead of the current folder (`pwd`), in the **Simulink Preferences > General** dialog box, set the **Simulation cache folder** by entering or browsing to a folder path.

This preference provides the initial defaults for MATLAB session parameters.

Alternatively, you can set the `CacheFolder` MATLAB session parameter using the `set_param` function.

```
>> set_param(0, 'CacheFolder', fullfile('C:', 'Work', 'MyModelSimCache'))  
>> get_param(0, 'CacheFolder')
```

```
ans =
```

```
C:\Work\MyModelSimCache
```

To override or restore the **Simulation cache folder** preference only for the current MATLAB session, use the `Simulink.fileGenControl` function. The values you set using `Simulink.fileGenControl` expire at the end of the current MATLAB session.

### More About

- “Choose Simulation Modes for Model Hierarchies” on page 8-39
- “Share Simulink Cache Files for Faster Simulation” on page 8-54
- “Reduce Update Time for Referenced Models by Using Parallel Builds” on page 8-53

## Reduce Update Time for Referenced Models by Using Parallel Builds

For models with large model reference hierarchies, you can increase the speed of diagram updates by building in parallel referenced models that are configured to run in accelerator mode. With Parallel Computing Toolbox™ software, you can distribute the code generation and compilation for referenced models across a parallel pool of MATLAB workers. If you also have MATLAB Parallel Server™ software, you can distribute the code generation and compilation across remote workers in your MATLAB Parallel Server configuration.

To configure parallel building of referenced models:

- 1 Open the Configuration Parameters dialog box for the top model of the model hierarchy.
- 2 Select the **Enable parallel model reference builds** check box.
- 3 For each MATLAB worker, you can set up a MATLAB environment that is consistent with the MATLAB environment of the client. From the **MATLAB worker initialization for builds** drop-down list, select one of these values:
  - None -- Simulink does not initialize workers.
  - Copy base workspace -- Simulink attempts to copy the base workspace to each MATLAB worker.
  - Load top model -- Simulink loads the top model onto each MATLAB worker.

If the Parallel Computing Toolbox parallel preference **Automatically create a parallel pool (if one doesn't already exist) when parallel keywords (e.g., parfor) are executed** is selected, a parallel pool of MATLAB workers is automatically started. For more information, see “Specify Your Parallel Preferences” (Parallel Computing Toolbox).

If a parallel pool is not running when you update your model, MATLAB automatically opens a parallel pool of workers by using the default cluster profile. To change the default behaviour of the worker cluster, you can modify properties of the cluster profile. If you have not touched your parallel preferences, the default profile is `local`. Control parallel behavior with the parallel preferences, including scaling up to a cluster, automatic pool creation, and preferred number of workers. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

## Share Simulink Cache Files for Faster Simulation

Simulink cache files contain build artifacts that can speed up simulation and code generation. To generate these build artifacts and automatically package them in Simulink cache files, perform one of these actions:

- Update the diagram for a model hierarchy that contains models referenced in accelerator mode
- Simulate a model hierarchy that contains models referenced in accelerator mode
- Simulate a top model in accelerator or rapid accelerator mode
- Generate code for a model or model hierarchy

The second time that you perform any of these actions, Simulink builds only the out-of-date files as long as the **Rebuild** configuration parameter is set to `If any changes detected` (default) or `If any changes in known dependencies detected`. With fewer files to build, the actions complete faster.

---

**Note** While you can avoid all referenced model rebuilds by setting the **Rebuild** configuration parameter to `Never`, using this setting can produce invalid simulation results.

---

Team members or continuous integration (CI) systems can generate Simulink cache files for models that you use. To reduce the time it takes when you build those models for the first time, you can copy the corresponding Simulink cache files to your local folder specified by the **Simulation cache folder** preference. Simulink extracts any Simulink cache file contents that differ from the contents on disk. If Simulink generates or updates the build artifacts on disk, it locally updates the corresponding Simulink cache files.

You can identify a Simulink cache file by its `.slxc` extension. Its file name matches the name of the corresponding model.

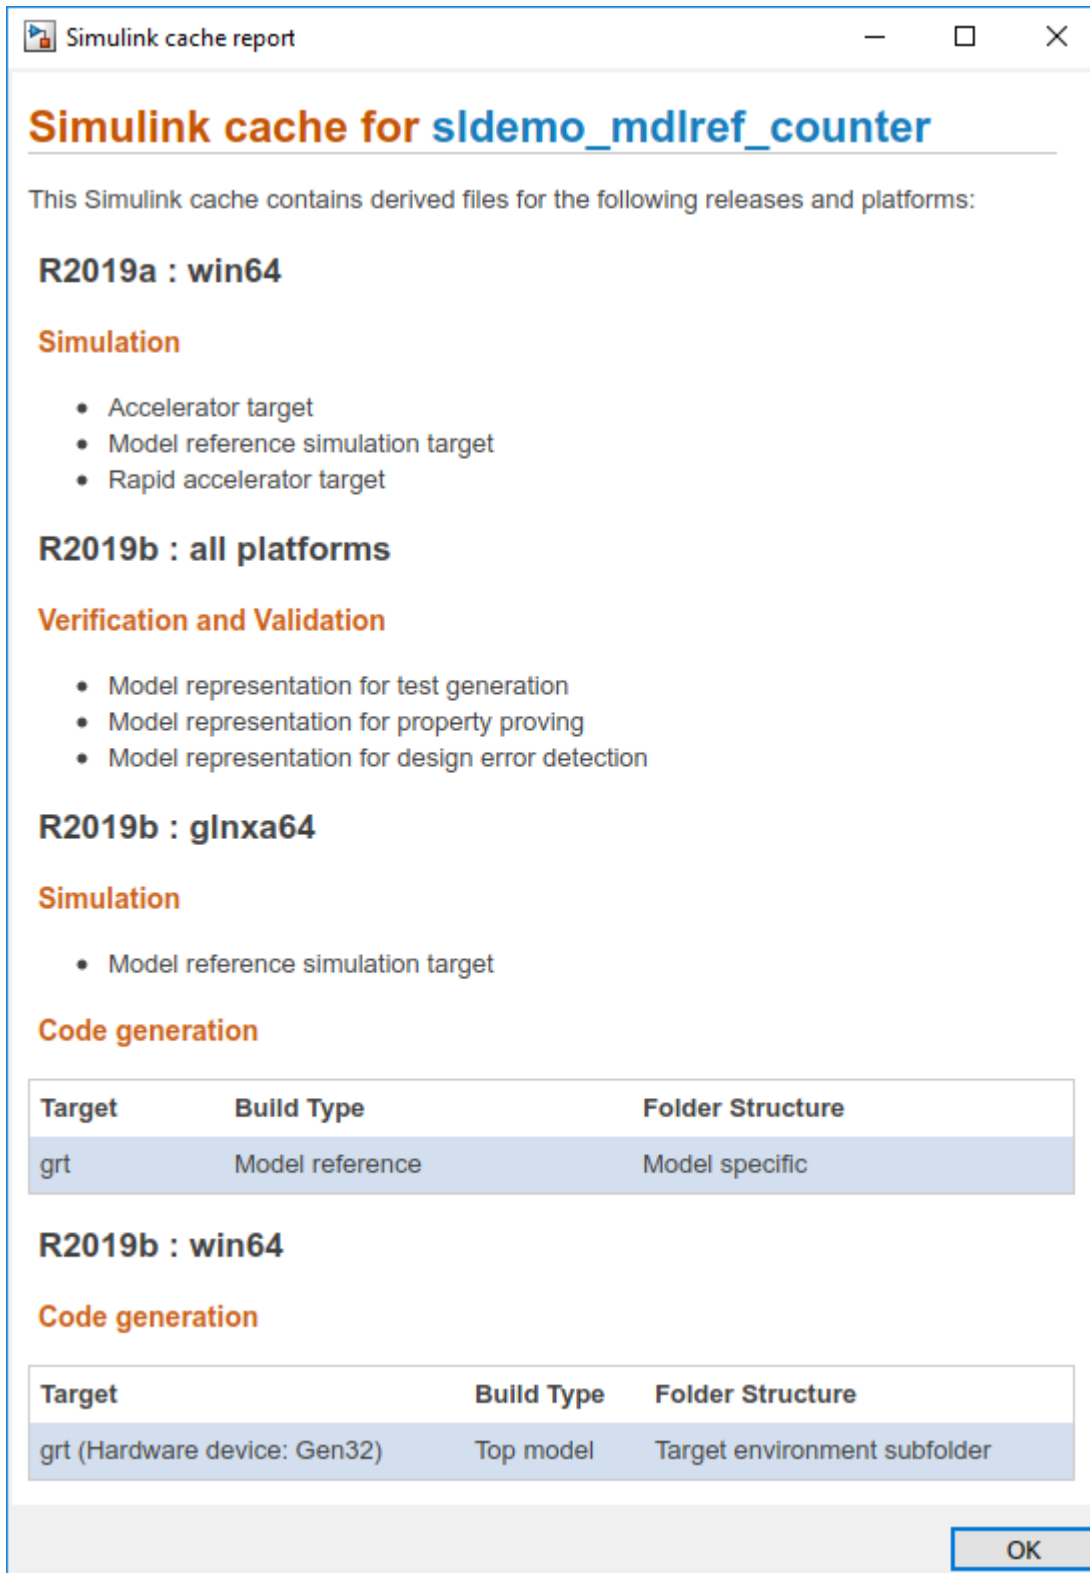

## Inspect Simulink Cache File Contents

Simulink cache files can contain multiple types of build artifacts, including:

- Accelerator targets
- Rapid accelerator targets
- Model reference simulation targets
- Variable usage information
- Code generation targets (Simulink Coder, Embedded Coder)
- Model representations (Simulink Design Verifier)
- Web views (Simulink Report Generator)

Simulink cache files accumulate build artifacts for multiple platforms and Simulink releases.

To learn what a specific Simulink cache file contains, open the report by double-clicking the file.

Alternatively, to get the contents of the Simulink cache file in a MATLAB table, use the `slxcinfo` function.

You can reuse build artifacts that support the platform and release that you are using. For example, suppose that you use a Windows machine and the R2019a Simulink release. In the Simulink cache file described by this report, you can use the simulation targets under **R2019a : win64**. A team member that uses a Linux<sup>®</sup> machine and R2019b can use the simulation and code generation targets under **R2019b : glnxa64** and the model representations under **R2019b : all platforms**.

A Simulink cache file can accumulate build artifacts for the release in which it was created and later releases. Suppose you create a Simulink cache file in R2019b. You would not be able to use that Simulink cache file in R2019a.

## Use Simulink Cache Files

While most teams can benefit from using Simulink cache files, a development environment with these features is best suited for using Simulink cache files.

- A model hierarchy that contains many referenced models.
- A top model that simulates in accelerator or rapid accelerator mode, causing Simulink to generate a simulation target for the top model and all referenced models.
- A standardized platform, compiler, and Simulink release for the entire development team.
- Relative paths or consistent absolute paths, which you specify with the **Include directories** configuration parameter, for the entire development team.
- A source control system, such as Git, that manages design files. See “Set Up Git Source Control” on page 19-16.

---

**Note** Since Simulink cache files are derived files, you should not manage them under source control. Even if you share Simulink cache files by storing them in a source control system, you cannot diff or merge different versions of these files.

---

- A CI system, such as Jenkins<sup>®</sup>, which periodically builds the latest version of the model hierarchy using a pool of parallel workers.

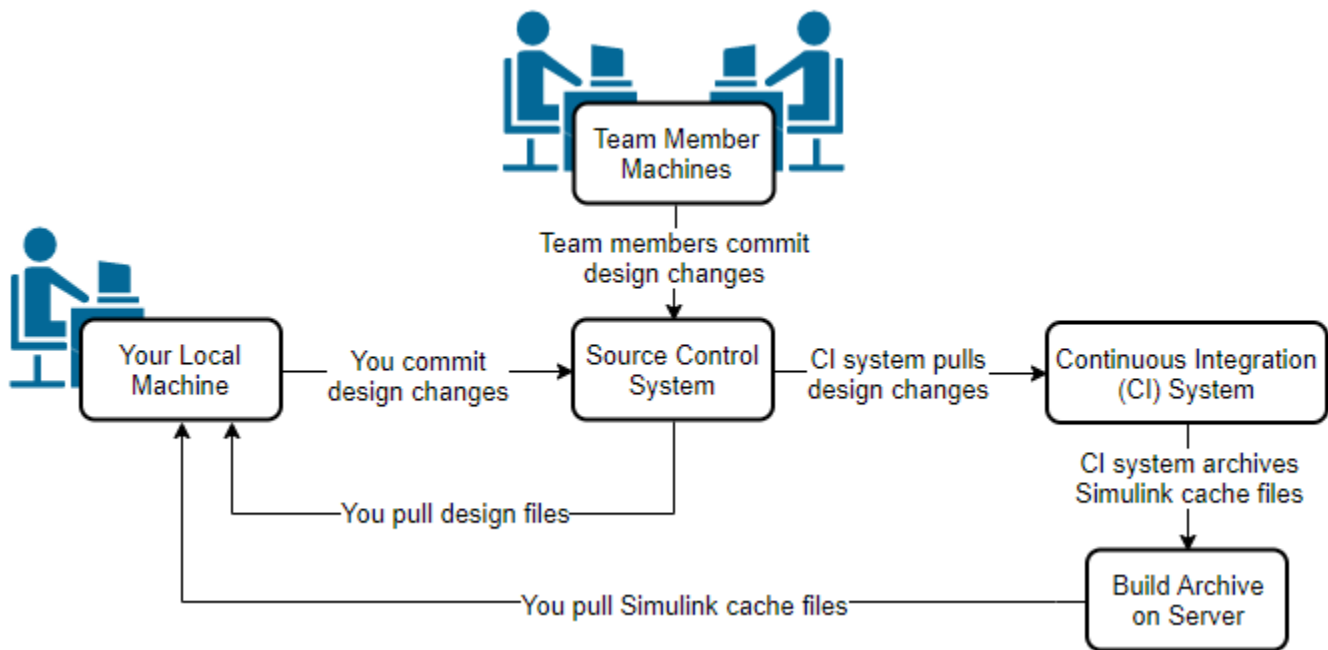

---

**Note** To avoid unnecessary rebuilds for simulation and coder targets that use custom code, map the CI system directories to named volumes or symbolic links that are the same in team member sandboxes. For example, have the CI system and team members store custom code in a mapped directory such as `B:\path\customcode`.

---

In this development environment, you interact with files in the source control system and build archive.

To reduce the amount of time that you spend updating simulation targets, follow these steps.

- 1 Pull the latest version of all design files from the source control system.
- 2 Copy the latest version of all Simulink cache files from the build archive and place them in your **Simulation cache folder**.
- 3 Open the top model and simulate it.

Simulink extracts the required build artifacts from the Simulink cache files. The simulation completes without rebuilding any models as long as the models have not changed since the most recent build completed by the CI system.

---

**Note** To unpack the simulation and code generation targets from the Simulink cache files without updating, simulating, or generating code for the model hierarchy, use the `s_lxcunpack` function.

---

- 4 Change a model and simulate the model hierarchy again.

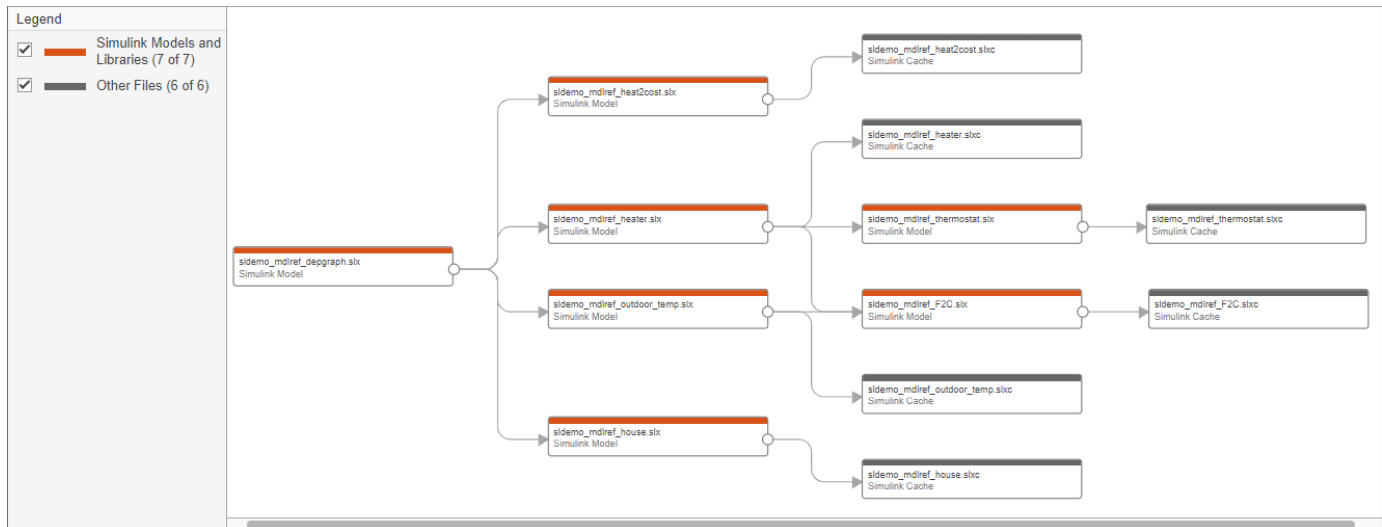

Simulink rebuilds the necessary models and updates the local copy of the corresponding Simulink cache file.

- 5 Commit the updated model to the source control system. You do not commit the Simulink cache file, which is a derived file.

## Check for Simulink Cache Files in Projects

When you create a project from a top model, the project includes the corresponding Simulink cache files for the model and its referenced models.

To view Simulink cache file dependencies in a model hierarchy, you can select **Dependency Analyzer** in the **Views** pane of the corresponding project.

For more information, see “What Is Dependency Analysis?” on page 18-2

## Set Configuration Parameters for Model Hierarchies

A referenced model uses a configuration set the same way that it would if the model executed independently. By default, every model in a hierarchy has its own configuration set. When you open a referenced model in the context of a model hierarchy, access its configuration parameters by clicking the **Model Settings** button arrow, then selecting **Model Settings** under **Referenced Model**.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model references. The Simulink response to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, or a trivial resolution without risk exists, Simulink ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, Simulink resolves the conflict silently, resolves it with a warning, or generates an error. See “Diagnostics That Are Ignored in Accelerator Mode” on page 8-61 for details.
- Where no acceptable resolution is possible, Simulink generates an error. Change some or all parameter values to eliminate the problem.

### Manage Configuration Parameters by Using Configuration References

To assign an externally stored configuration set to multiple models, you can use configuration references. Configuration references help you eliminate configuration parameter incompatibilities.

You can propagate the configuration reference of a top model to an individual referenced model or to all referenced models in the model hierarchy. For an example, see “Share a Configuration Across Referenced Models” on page 13-18.

### Configuration Requirements for All Referenced Model Simulation

Some configuration parameter options can cause incompatibilities in model hierarchies. Where possible, Simulink resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

Dialog Box Pane	Option	Requirement
Solver	<b>Start time</b>	The compiled start time of the top model and all referenced models must be the same.  The compiled start time is the first simulation step after the specified start time. Simulation steps are increments of the fastest discrete rate in the model, beginning from zero.
	<b>Stop time</b>	Simulink uses the <b>Stop time</b> of the top model for simulation, overriding any differing <b>Stop time</b> in a referenced model.

Dialog Box Pane	Option	Requirement
	<b>Type</b>	The <b>Type</b> and <b>Solver</b> of the top model apply throughout the hierarchy. See “Solver Settings” on page 8-60.
	<b>Solver</b>	
<b>Data Import/Export</b>	<b>Initial state</b>	Can be selected for the top model, but must be cleared for a referenced model.
<b>Math and Data Types</b>	<b>Application lifespan (days)</b>	For code generation, the setting must be the same for the parent and referenced models.  For simulation, the setting can be different for the parent and referenced models.
<b>Model Referencing</b>	<b>Total number of instances allowed per top model</b>	Must not be Zero in a referenced model. Specifying One rather than Multiple is preferable or required sometimes. See “Number of Model Instances Setting” on page 8-61.
<b>Code Generation &gt; Optimization</b>	<b>Default parameter behavior</b>	If the parent model has this option set to Inlined, then the referenced model cannot be set to Tunable.

### Solver Settings

Model referencing works with both fixed-step and variable-step solvers. All models in a model hierarchy use the same solver, which is always the solver specified by the top model. An error occurs if the solver type specified by the top model is incompatible with the solver type specified by any referenced model.

Top Model Solver Type	Referenced Model Solver Type	Compatibility
Fixed-step	Fixed-step	Allowed
Variable-step	Variable-step	Allowed
Variable-step	Fixed-step	Allowed unless the referenced model is multirate and specifies both a discrete sample time and a continuous sample time
Fixed-step	Variable-step	Error

If an incompatibility exists between the top model solver and any referenced model solver, one or both models must change to use compatible solvers. For information about solvers, see “Compare Solvers” on page 3-6 and “Solver Selection Criteria” on page 27-7.

## Number of Model Instances Setting

A referenced model must specify that it is available to be referenced, and whether it can be referenced at most once or can have multiple instances. The **Total number of instances allowed per top model** parameter provides this specification. The possible values for this parameter are:

- **Zero** — A model cannot reference this model. An error occurs if a reference to the model occurs in another model.
- **One** — A model hierarchy can reference the model at most once. An error occurs if more than one instance of the model exists. This value is sometimes preferable or required.
- **Multiple** — A model hierarchy can reference the model more than once, if it contains no constructs that preclude multiple references. An error occurs if the model cannot be referenced multiple times, even if only one reference exists.

Setting **Total number of instances allowed per top model** to **Multiple** for a model that is referenced only once can reduce execution efficiency slightly. However, this setting does not affect data values that result from simulation or from executing code Simulink Coder generates. Specifying **Multiple** when only one model instance exists avoids having to change or rebuild the model when reusing the model:

- In the same hierarchy
- Multiple times in a different hierarchy

Some model properties and constructs require setting **Total number of instances allowed per top model** to **One**. For details, see “Model Reuse” on page 8-6.

## Diagnostics That Are Ignored in Accelerator Mode

For models referenced in accelerator mode, Simulink ignores the values of these configuration parameter settings if you set them to a value other than **None**:

- **Array bounds exceeded** (ArrayBoundsChecking)
- **Inf or NaN block output** (SignalInfNanChecking)
- **Simulation range checking** (SignalRangeChecking)
- **Division by singular matrix** (CheckMatrixSingularityMsg)
- **Wrap on overflow** (IntegerOverflowMsg)

Also, for models referenced in accelerator mode, Simulink ignores these **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than **Disable all**. For details, see “Data Store Diagnostics” on page 78-3.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

During model reference simulation in accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to **None**, if they are set to **Warning** or **Error**. You can use the Model Advisor to check for parameters that change. For details, see “Diagnostics That Are Ignored in Accelerator Mode” on page 8-61.

You can use the Model Advisor to identify models referenced in accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 On the **Modeling** tab, click **Model Advisor**.
- 2 Select the top model, then click **OK**.
- 3 Select **By Task > Model Referencing > Check diagnostic settings ignored during accelerated model reference simulation**.
- 4 Click the **Run This Check** button.

To see the results of running the identified diagnostics with settings to produce warnings or errors, simulate the model in normal mode. Inspect the diagnostic warnings and then simulate in accelerator mode.

---

**Note** Configuration parameters on the **Code Generation** pane of the Configuration Parameters dialog box do not affect simulation in either normal or accelerator mode. **Code Generation** parameters affect only code generation by Simulink Coder itself. Accelerator mode simulation requires code generation to create a simulation target. Simulink uses default values for all **Code Generation** parameters when generating the target, and restores the original parameter values after code generation is complete.

---

- “Set Configuration Parameters for Code Generation of Model Hierarchies” (Simulink Coder)

## Parameterize Instances of a Reusable Referenced Model

When you reference the same model using multiple Model blocks, you can configure a block parameter to use either the same value or a different value for each instance of the model. For example, you can configure the **Gain** parameter of a Gain block. To use different values, create and use a model argument to set the value of the block parameter. For some applications, you can reuse a referenced model only if you can configure each instance to use a different value for a block parameter (such as the setpoint of a controller or a filter coefficient).

### Specify a Different Value for Each Instance of a Reusable Model

For a block parameter in a reusable referenced model, to specify a different value for each instance of the model:

- 1 Create a MATLAB variable or `Simulink.Parameter` object in the model workspace of the referenced model.
  - Use a MATLAB variable for ease of maintenance.
  - Use a `Simulink.Parameter` object for greater control over the minimum and maximum value, the data type, and other properties of the model argument.
- 2 Set the block parameter value by using the variable or parameter object. Optionally, use the same variable or object to set other block parameter values.
- 3 Configure the variable or object as a model argument by selecting the **Argument** property.
- 4 Specify a default value for the variable or `Simulink.Parameter` object. When you simulate this model directly, the block parameters use the value that the variable or object stores in the model workspace. When this model is simulated as a referenced model, a parameter configured as a model argument gets its value from its parent model.

Optionally, you can leave the value for a `Simulink.Parameter` object empty. See “Define Model Arguments Without Specifying a Default Value” on page 8-63.

- 5 In each Model block that refers to the reusable model, specify an instance-specific value for the block parameter. The dimensions and data type of the instance-specific value must match that of the model argument definition. If you do not specify a value, the argument uses the last value specified below it in the model hierarchy. In the top model, you can configure the diagnostic configuration parameter **No explicit final value for model arguments** to generate an error or warning when the topmost Model block that can set the value for a model argument uses this default value instead of providing an explicit value.
- 6 In intermediate models, in addition to specifying an instance-specific value for the block parameter, you can specify if the parameter can be overridden at the next level of the hierarchy.

### Define Model Arguments Without Specifying a Default Value

If you use a `Simulink.Parameter` object to set the block parameter value, you can compile and simulate the model as a referenced model with the value for the object left empty (**Value** set to `[]`) as long as you provide an explicit value somewhere in the parent model reference hierarchy. In this case, you cannot simulate the model directly. When the value is empty, you must provide the **Data Type** and **Dimensions** for the object. You can also specify the **Min**, **Max**, and **Complexity** properties. Although you have specified an empty value, Simulink still synthesizes a **Value** using the properties you have specified (see `Simulink.Parameter`).

## Combine Multiple Arguments into a Structure

When you configure a model to use multiple model arguments, consider using a structure instead of separate variables in the model workspace. This technique reduces the effort of maintenance when you want to add, rename, or delete arguments. Instead of manually synchronizing the arguments in the model workspace with the argument values in Model blocks, you modify structures by using the Variable Editor or the command prompt.

If you have a Simulink Coder license, this technique can also reduce the ROM consumed by the formal parameters of the referenced model functions, such as the output (step) function.

To create and use structures to set block parameter values, see “Organize Related Block Parameter Definitions in Structures” on page 40-19.

## Parameterize a Referenced Model

This example shows how to interactively configure multiple instances of a referenced model to use different values for the same block parameter. For an example that parameterizes a referenced model using only the command prompt, see “Parameterize a Referenced Model Programmatically” on page 8-76. For an example that involves code generation, see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” (Simulink Coder).

### Configure Referenced Model to Use Model Arguments

To configure model arguments for a referenced model, you must create MATLAB variables or `Simulink.Parameter` objects in the model workspace. This example configures `Simulink.Parameter` objects as model arguments without storing a default value in the object and instead relies on the parent model reference hierarchy to provide explicit values. Without a default value, the model cannot be simulated directly and must be simulated as referenced model.

Create a model `ex_model_arg_ref` that contains a Gain block and a Discrete Filter block.

To configure the **Gain** parameter of the Gain block and the **Numerator** parameter of the Discrete Filter block as model arguments:

- 1 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Parameters** tab.
- 3 Use the **Value** column to set the value of the **Gain** parameter to a variable, for example, `gainArg`.
- 4 Next to `gainArg`, click the action button  and select **Create**.

- 5 In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and **Location** to `Model Workspace`. Click **Create**.
- 6 In the `Simulink.Parameter` property dialog box, set **Data Type** to `double` and **Dimensions** to `1`. Leave the value empty (**Value** set to `[]`). Specifying the **Min**, **Max**, **Complexity** values for the object is optional.
- 7 To configure the object as a model argument, select **Argument**.
- 8 Click **OK**.
- 9 Repeat steps 4 through 9 for the **Numerator** parameter of the Discrete Filter block. In this case, create a `Simulink.Parameter` object named `coeffArg`.

Remember that the model by itself does not compile successfully without values set for the parameter objects.

### Set Model Argument Values in Parent Model

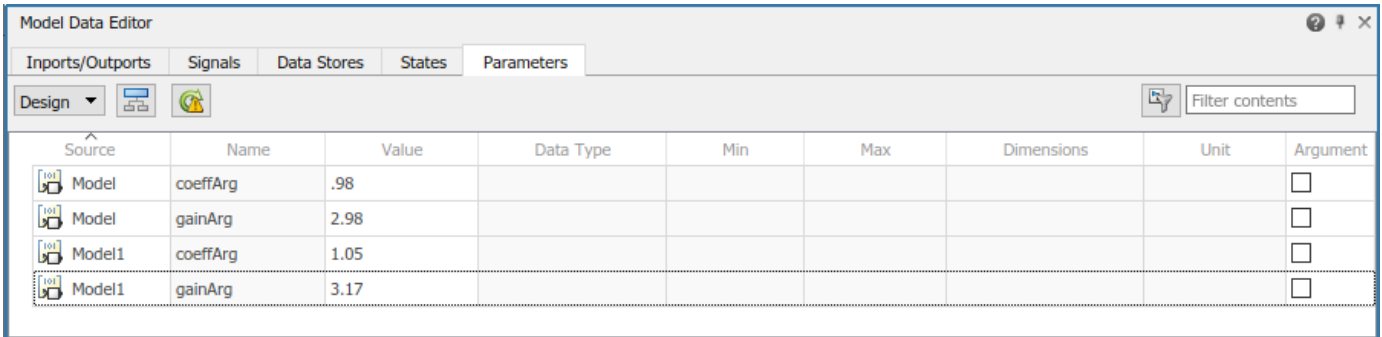

When you simulate a parent model, each instance of a reusable referenced model uses the parameter values that you specify in the parent model. This example shows how you can expose a model argument as a tunable parameter on the Model block at each level of the model hierarchy.

Create a model `ex_model_arg` that uses multiple instances of the reusable model `ex_model_arg_ref` from the previous example.

To set instance-specific values for your model arguments in the model reference hierarchy:

- 1 In the model, on the **Modeling** tab, click **Model Data Editor**.
- 2 In the Model Data Editor, select the **Parameters** tab. The Model Data Editor shows four rows that correspond to the instance-specific parameters that you can specify for the two Model blocks.
- 3 Use the Model Data Editor to set values for the parameters in `Model` and `Model1`. By default, a model argument uses the last value specified below it in the model hierarchy (indicated by the value `<from below>`). Replace the default with the values in this figure.

Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model	coeffArg	.98						<input type="checkbox"/>
Model	gainArg	2.98						<input type="checkbox"/>
Model1	coeffArg	1.05						<input type="checkbox"/>
Model1	gainArg	3.17						<input type="checkbox"/>

- To override the value of these parameters at the next level of the model hierarchy, select the check box in the **Argument** column. By default, the check box is not selected.

You can also configure instance-specific parameters at each Model block. In the block dialog box, select the **Instance parameters** tab.

**Tip** Model instance parameters are not supported when Use local solver when referencing model is enabled in the “Solver Pane”.

- Create a model `ex_model_arg_top` that contains a Model block that references `ex_model_arg`.

- 6 In the Model Data Editor, click the **Show/refresh additional information** button. On the **Parameters** tab, you can see each instance-specific parameter that is exposed as a tunable parameter in the referenced models. From here, you can create a parameter value set for all instances of the `coeffArg` and `gainArg` parameters in the model hierarchy.

Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model:Model	coeffArg	<from below> 0.98						<input type="checkbox"/>
Model:Model	gainArg	<from below> 2.98						<input type="checkbox"/>
Model:Model1	coeffArg	<from below> 1.05						<input type="checkbox"/>
Model:Model1	gainArg	<from below>						<input type="checkbox"/>

By default, each instance uses the last value specified below it in the model hierarchy. In this case, the Model Data Editor displays `<from_below>`. If you select the **Argument** check box to expose a parameter to a parent model, the **Value** displays as `<inherited>` to indicate that the runtime value now comes from that parent.

After you update the model diagram, the editor also displays the compiled value for the instance. To navigate to this default value, click the button with the three vertical dots next to the compiled value and select **Navigate to default value from below**. The referenced model where the value was last specified opens in a new tab in the model canvas, and the Model Data Editor highlights the row that contains the block parameter.

**Note** You can use a Parameter Writer block to change values of model instance parameters or model workspace variables during simulation. See “Initialize and Reset Parameter Values” on page 10-190.

### Group Multiple Model Arguments into Single Structure

You can use structures to reduce the effort of maintenance when you want to add, rename, or delete arguments. With structures, the mathematical functionality of the models is the same.

To replace the parameter values with structures for `ex_model_arg_ref` and `ex_model_arg`, follow these steps:

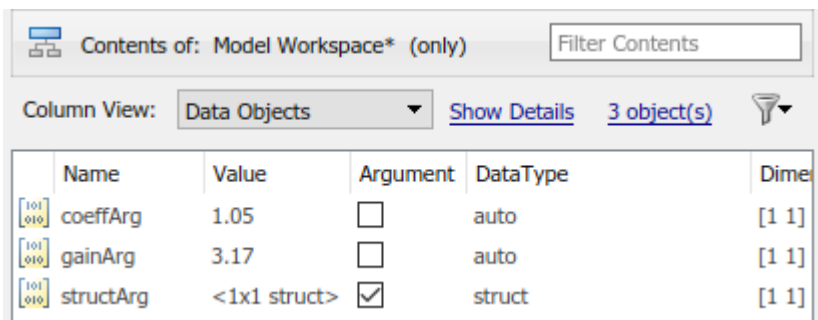

- 1 At the command prompt, create a structure. Add one field for each of the parameter objects in the `ex_model_arg_ref` workspace.

```
structForInst1.gain = 3.17;
structForInst1.coeff = 1.05;
```

- 2 Store the structure in a `Simulink.Parameter` object.

```
structForInst1 = Simulink.Parameter(structForInst1);
```

- 3 Open the Model Explorer. In the referenced model, `ex_model_arg_ref`, on the **Modeling** tab, click **Model Explorer**.
- 4 Use the Model Explorer to copy the parameter object from the base workspace into the `ex_model_arg_ref` model workspace.
- 5 In the model workspace, rename `structForInst1` as `structArg`.
- 6 In the **Contents** pane, configure `structArg` as the only model argument.

The screenshot shows the 'Contents of: Model Workspace\* (only)' pane. It has a 'Filter Contents' search box and a 'Column View' dropdown set to 'Data Objects'. Below the table are links for 'Show Details' and '3 object(s)'. The table lists three objects: 'coeffArg', 'gainArg', and 'structArg'. The 'Argument' column has checkboxes, with 'structArg' checked.

	Name	Value	Argument	DataType	Dimension
[101 010]	coeffArg	1.05	<input type="checkbox"/>	auto	[1 1]
[101 010]	gainArg	3.17	<input type="checkbox"/>	auto	[1 1]
[101 010]	structArg	<1x1 struct>	<input checked="" type="checkbox"/>	struct	[1 1]

- 7 In the `ex_model_arg_ref` model, in the Model Data Editor **Parameters** tab, set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`.

- 8 Save the model.

- 9 At the command prompt, copy the existing structure in the base workspace as `structForInst2`.

```
structForInst2 = copy(structForInst1);
```

- 10 Set the field values in the two structures by using the same numbers that you used to set the model argument values in the Model blocks.

```
structForInst1.Value.gain = 2.98;
structForInst1.Value.coeff = 0.98;
```

```
structForInst2.Value.gain = 3.34;
structForInst2.Value.coeff = 1.11;
```

- 11 In the top model, `ex_model_arg`, use the Model Data Editor to set the argument values as shown in this figure.

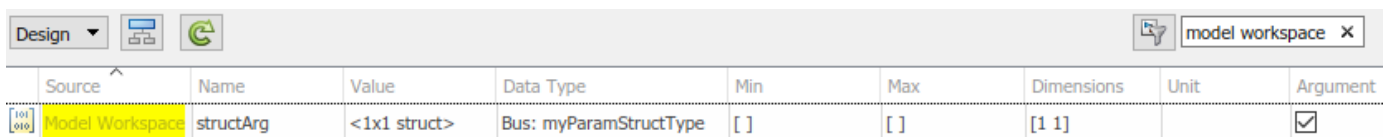

Model Data				
Inports/Outports	Signals	Data Stores	States	Parameters
Design  				
Source	Name	Value		
Model	structArg	structForInst1		
Model1	structArg	structForInst2		

## Use Bus Object as Data Type of Structures

You can use a `Simulink.Bus` object as the data type of the structures. The object ensures that the characteristics of the instance-specific structures, such as the names and order of fields, match the characteristics of the structure in the model workspace.

- At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.  
`Simulink.Bus.createObject(structForInst1.Value);`
- Rename the bus object as `myParamStructType` by copying it.  
`myParamStructType = copy(slBus1);`
- In the Model Data Editor for `ex_model_arg`, click the **Show/refresh additional information** button. The Model Data Editor now contains rows that correspond to the parameter objects in the base workspace, `structForInst1` and `structForInst2`.
- Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.
- In the Model Data Editor for `ex_model_arg_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`.

Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model Workspace	structArg	<1x1 struct>	Bus: myParamStructType	[ ]	[ ]	[1 1]		<input checked="" type="checkbox"/>

## Change Model Argument Name or Value

To rename a model argument in the context of the referenced model:

- Find all Model blocks that refer to the model and save the instance-specific parameter values that each block specifies. Use the `get_param` function to query the `InstanceParameters` parameter of each block, which is a structure array. The structure contains four fields: `Name`, `Value`, `Path`, and `Argument`.

You must save the instant-specific parameter values because the renaming operation discards the values in the Model blocks.

- In the Model Data Editor, right-click the variable or object in the model workspace of the referenced model and select **Rename All**. The renaming operation changes the name of the

variable or object and changes references to it throughout the model. For more information, see “Create, Edit, and Manage Workspace Variables” on page 72-108.

- Reapply the argument values to the Model blocks by using the new name of the argument. To programmatically set argument values in a Model block, see “Instance parameters”.

## Customize User Interface for Reusable Components

When you design a reusable referenced model for use by other members of a team, you can apply a mask to the entire referenced model. You can then customize the way that your users interact with Model blocks, including setting instance-specific values.

Using this technique also makes it easier to programmatically specify instance-specific values. If you create and use a mask parameter named `gainMask` to programmatically set the value to `0.98` for an instance of the model named `myModelBlock`, your users can use this command at the command prompt:

```
set_param('myModelBlock','gainMask','0.98')
```

If you apply a mask to the referenced model, the model mask shows only the instance-specific parameters from the direct child model. It does not show instance-specific parameters promoted up from descendant models.

If you do not mask the model, to set the instance-specific value, use the `InstanceParameters` parameter of the block. For more information, see “Parameterize a Referenced Model Programmatically” on page 8-76.

For information about masking models, see “Introduction to System Mask” on page 42-43.

## Configure Instance-Specific Data for Simulink.LookupTable and Simulink.Breakpoint Objects

When you use `Simulink.LookupTable` objects to store and configure lookup table data for ASAP2 or AUTOSAR code generation, for example, `STD_AXIS` or `CURVE`, you can configure the objects as model arguments. You can also configure a `Simulink.Breakpoint` object that is referenced by a `Simulink.LookupTable` as a model argument. You can then specify unique table data and breakpoint data for each instance of a component.

You can specify the instance-specific value of a `Simulink.LookupTable` argument as a new `Simulink.LookupTable` object in the parent model or as a simple MATLAB structure or array.

Specify an instance-specific value for a `Simulink.LookupTable` object based on the value of the **Breakpoints specification** property.

- When the **Breakpoints specification** property is set to `Explicit` values or `Even spacing`, the instance-specific value of the lookup table object can be:
  - A `Simulink.LookupTable` object
  - The name of a valid MATLAB structure variable, such as `Model1_LUT2`
  - A literal structure expression, such as `struct('Table', ..., 'BP1', ..., 'BP2', ...)`
  - Other expressions that return a valid structure, such as `Params.Model1.LUT2` or a call to a MATLAB function

- When the **Breakpoints specification** property is set to Reference, the instance-specific value of the `Simulink.LookupTable` object can be:
  - A `Simulink.LookupTable` object. In this case, Simulink passes only the **Table** property of the lookup table object to the child model. This allows you to configure model arguments for `Simulink.LookupTable` objects and `Simulink.Breakpoint` objects independently of each other and reuse these objects as instance parameters for multiple Model blocks.
  - A literal numeric array value, such as `[1 5 7; 2 8 13]`.
  - The name of a numeric array variable, such as `Model1_LUT2`.
  - Other expressions that return a valid numeric array, such as `Params.Model1.LUT2` or a call to a MATLAB function.

In this case, if you configure the `Simulink.Breakpoint` object that is referenced by the `Simulink.LookupTable` as a model argument, the instance-specific value for the `Simulink.Breakpoint` object can be:

- A `Simulink.Breakpoint` object.
- An array of numeric values that define the breakpoints. The array must match the design definition for the breakpoint object. Simulink synthesizes a `Simulink.Breakpoint` object by using the values in the array.
- The name of a numeric array variable or a field of a structure.

When you specify the instance-specific value of a `Simulink.LookupTable` argument as a structure, these rules apply:

- Each field of the model argument definition must be specified in the structure, and the number of fields and the names of the fields must match. For example, while only the table data from a `Simulink.LookupTable` object of type Reference is passed to the child model, you must still specify the breakpoint data in your structure or Simulink reports an error.
- The dimensions of the table and the breakpoint data in the structure must match that of the model argument definition.
- If the data type of a structure field is `double`, the value is cast to the data type of the corresponding model argument field. Otherwise, the value must match the data type of the corresponding model argument field.

You can specify the value of a `Simulink.LookupTable` object as a simple numeric value for any simulation mode and for code generation. For code generation, if you configure the model argument with a storage class of `Auto`, the structure or numeric array variable is not preserved in the generated code. If you set the storage class to any other value, the value of the structure or numeric array is used to initialize the tunable argument in the generated code, similar to other model arguments.

### Specify Instance-Specific Value of `Simulink.LookupTable` Object

This example shows how to specify the instance-specific value of a `Simulink.LookupTable` argument as a new `Simulink.LookupTable` and as a MATLAB structure.

For an example that parameterizes a referenced model by using lookup tables and the command prompt, see “Configure Instance-Specific Data for Lookup Tables Programmatically” on page 8-81.

First, create a model that represents a reusable algorithm. Configure a `Simulink.LookupTable` object as a model argument to be used by your model.

- 1 Create a model `ex_arg_LUT_ref`, which represents a reusable algorithm.

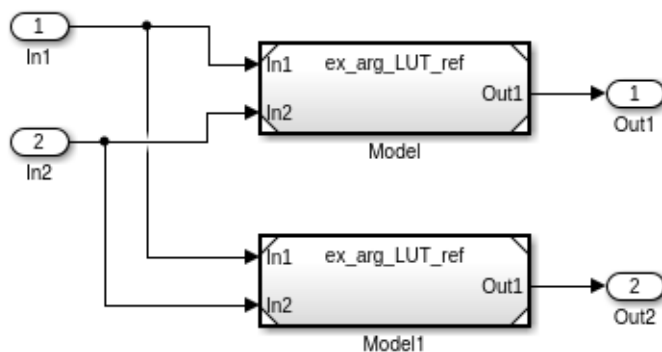

- 2 Using the Model Explorer, add a `Simulink.LookupTable` object in the model workspace. You can use the **Add Simulink LookupTable** button . Name the object `LUTArg`.
- 3 In the **Contents** pane, for `LUTArg`, select the check box in the **Argument** column.
- 4 Set **Number of table dimensions** to 2. In the **Table** and **Breakpoints** tabular area, specify values for the **Table**, **BP1**, and **BP2** data. For example, configure the table and breakpoint data by entering these values in the MATLAB expression box.
  - Table — `[3 4;1 2]`
  - BP1 — `[1 2]`
  - BP2 — `[3 4]`

When you simulate or generate code directly from `ex_arg_LUT_ref`, the model uses these values.

- 5 Under **Struct Type definition**, set **Name** to `LUTArg_Type`.
- 6 Click **Apply**.
- 7 In the **Contents** pane, for `LUTArg`, select the check box in the **Argument** column.
- 8 In the referenced model, in the n-D Lookup Table block, set **Data specification** to `Lookup table object`. Set **Name** to `LUTArg`.
- 9 Save the model.

Next, create a model that uses the reusable algorithm and specify instance-specific values for the `Simulink.LookupTable` object.

- 1 Create a model `ex_arg_LUT`, which uses the reusable algorithm twice.

- At the command prompt, create a `Simulink.LookupTable` object in the model workspace. Alternatively, you can create the `Simulink.LookupTable` object in a data dictionary or in the base workspace.

```
LUTForInst1 = Simulink.LookupTable;
```

- Specify breakpoint and table data for the object.

```
LUTForInst1.Table.Value = [8 7; 6 5];
LUTForInst1.Breakpoints(1).Value = [5 6];
LUTForInst1.Breakpoints(2).Value = [3 4];
```

- Specify a structure type name. Match this name to the name specified by the object in the referenced model workspace.

```
LUTForInst1.StructTypeInfo.Name = 'LUTArg_Type';
```

- Use a structure to create the instance-specific argument value for the second Model block. Specify the breakpoint and table data for the structure.

```
StructForInst2.Table = [9 8; 7 7];
StructForInst2.BP1 = [3 4];
StructForInst2.BP2 = [5 6];
```

- In the `ex_arg_LUT` model, for model instance `Model`, on the **Instance parameters** tab, set the value of `LUTArg` to `LUTForInst1`.
- For model instance `Model1`, set `LUTArg` to `StructForInst2`.

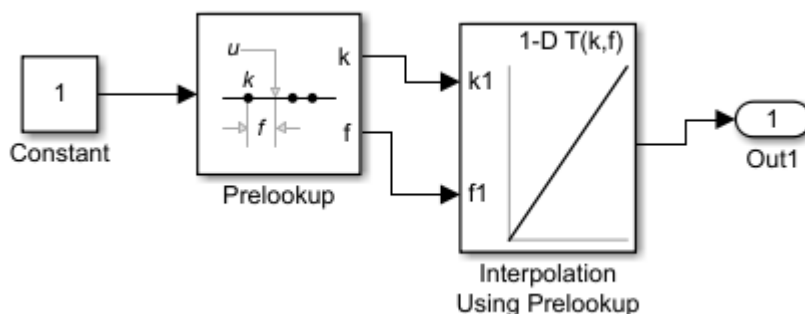

One instance of `ex_arg_LUT_ref` uses the table and breakpoint data stored in the `Simulink.LookupTable` object in the model workspace. The other instance uses the table and breakpoint data stored in the structure.

### Specify Instance-Specific Values for `Simulink.LookupTable` and `Simulink.Breakpoint` Object

This example shows how to specify an instance-specific value of a `Simulink.LookupTable` object as a new `Simulink.LookupTable` object. The example also shows how to specify an instance-specific value for a `Simulink.Breakpoint` object that is referenced by the `Simulink.LookupTable` object.

First, create a model that represents a reusable algorithm. Configure both a `Simulink.Breakpoint` object and the `Simulink.LookupTable` object that references the `Simulink.Breakpoint` object as model arguments.

- Create a model `ex_arg_BP_ref`, which represents a reusable algorithm.

- 2 Using the Model Explorer, add a `Simulink.LookupTable` object in the model workspace. You can use the **Add Simulink LookupTable** button . Name the object `LUTArg`.
- 3 In the **Contents** pane, for `LUTArg`, select the check box in the **Argument** column.
- 4 Set **Number of table dimensions** to 1.
- 5 Specify the value of the table data as `[1 2]`.
- 6 Set **Breakpoints specification** to Reference.
- 7 In the **Breakpoints** section, set the **Names** to `BP1`.
- 8 Add a `Simulink.Breakpoint` object in the model workspace. Name the object `BP1` and specify the value as `[3 4]`.
- 9 In the **Contents** pane, for `BP1`, select the check box in the **Argument** column.

Next, create a model that uses the reusable algorithm and specify instance-specific values for the `Simulink.LookupTable` object and the `Simulink.Breakpoint` object.

- 1 Create a model `ex_arg_BP`, which uses the reusable algorithm twice.

- 2 At the command prompt, for model instance `Model`, create a `Simulink.LookupTable` object and a `Simulink.Breakpoint` object in the model workspace. Alternatively, you can create these objects in a data dictionary or the base workspace.

```
LUTForInst1 = Simulink.LookupTable;
BPForInst1 = Simulink.Breakpoint;
```

- 3 Specify breakpoint and table data for the objects. You must specify breakpoint information for `LUTForInst1` so that the specification of the instance-specific value matches the model argument specifications. However, only the table data is pushed to the child model.

```
LUTForInst1.Table.Value = [7 8];
LUTForInst1.BreakpointsSpecification = 'Reference';
LUTForInst1.Breakpoints = {'BPForInst1'};
BPForInst1.Breakpoints.Value = [5 6];
```

- 4 In the `ex_arg_BP` model, for model instance `Model`, on the **Instance parameters** tab, set the value of **LUTArg** to `LUTForInst1` and the value of **BP1** to `BPForInst1`.
- 5 For model instance `Model1`, create another `Simulink.LookupTable` object in the model workspace and specify the table and breakpoint data. Alternatively, you can create the `Simulink.LookupTable` object in a data dictionary or in the base workspace.

```
LUTForInst2 = Simulink.LookupTable;
BPForInst2 = Simulink.Breakpoint;
```

```
BPForInst2.Breakpoints.Value = [11 12];  
LUTForInst2.Table.Value = [9 10];  
LUTForInst2.BreakpointsSpecification = 'Reference';  
LUTForInst2.Breakpoints = {'BPForInst2'};
```

- 6 For this model instance, use an array to specify the instance-specific value for the `Simulink.Breakpoint` object.

```
BPArrayForInst2 = [11 12];
```

- 7 In the `ex_arg_BP` model, for model instance `Model1`, on the **Instance parameters** tab, set the value of **LUTArg** to `LUTForInst2`. For this model instance, set the value of `BP1` to the array `BPArrayForInst2`.

## Parameterize a Referenced Model Programmatically

This example shows how to programmatically configure multiple instances of a referenced model to use different values for the same block parameter.

### Configure Referenced Model to Use Model Arguments

When you simulate a model, the parameter objects in the model workspace use the values that you specify for the `Simulink.Parameter` objects, `Simulink.LookupTable` objects, or MATLAB® variables. The block parameters also use these values.

To configure the **Gain** parameter of a Gain block and the **Numerator** parameter of a Discrete Filter block as model arguments, follow these steps.

Open model `ex_model_arg_ref`. This model represents a reusable algorithm.

```
open_system('ex_model_arg_ref')
```

Copyright 2021 The MathWorks, Inc.

For the Gain block, set the value of the **Gain** parameter to a `Simulink.Parameter` object in the model workspace with a numeric value. For this example, name the `Simulink.Parameter` object `gainArg` and assign a value of 3.17.

```
set_param('ex_model_arg_ref/Gain', 'Gain', 'gainArg')
modelWorkspace = get_param('ex_model_arg_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'gainArg', Simulink.Parameter(3.17));
```

For the Discrete Filter block, set the value of the **Numerator** parameter to a `Simulink.Parameter` object in the model workspace with a numeric value. For this example, name the `Simulink.Parameter` object `coeffArg` and assign a value of 1.05.

```
set_param('ex_model_arg_ref/Discrete Filter', 'Numerator', 'coeffArg')
assignin(modelWorkspace, 'coeffArg', Simulink.Parameter(1.05));
```

Specify `gainArg` and `coeffArg` as model arguments.

```
set_param('ex_model_arg_ref', 'ParameterArgumentNames', 'coeffArg,gainArg')
```

## Set Model Argument Values in Parent Model

When you simulate a parent model, each instance of a reusable referenced model uses the argument values that you specify in the parent model. In this example, in the upper instance of `ex_model_arg_ref`, the parameter object `gainArg` uses the value `2.98`.

Model `ex_model_arg` contains two Model blocks that reference `ex_model_arg_ref`. To set different parameter values for the two instances of the model, follow these steps.

Open model `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

```
open_system('ex_model_arg')
```

Copyright 2021 The MathWorks, Inc.

For both instances of model `ex_model_arg`, set values for the model arguments. If you decide to promote these arguments, set the `Argument` field to `true`. By default, the `Argument` field is `false`.

```
instSpecParams = get_param('ex_model_arg/Model','InstanceParameters');
instSpecParams1 = get_param('ex_model_arg/Model1','InstanceParameters');
```

```
instSpecParams(1).Value = '.98';
instSpecParams(2).Value = '2.98';
instSpecParams1(1).Value = '1.11';
instSpecParams1(2).Value = '3.34';
instSpecParams(1).Argument = true;
instSpecParams(2).Argument = true;
instSpecParams1(1).Argument = true;
instSpecParams1(2).Argument = true;
```

```
set_param('ex_model_arg/Model','InstanceParameters',instSpecParams);
set_param('ex_model_arg/Model1','InstanceParameters',instSpecParams1);
```

## Group Multiple Model Arguments into a Single Structure

This example shows how to programmatically configure multiple instances of a referenced model to use different values for the same block parameter by using structures.

### Configure Referenced Model to Use Model Arguments Grouped Into Structure

You can use structures to reduce the effort of maintenance when you want to add, rename, or delete arguments. With structures, the mathematical functionality of the models is the same.

To replace the parameter values with structures for `ex_model_arg_ref` and `ex_model_arg`, follow these steps.

Open model `ex_model_arg_ref`. This model represents a reusable algorithm.

```
open_system('ex_model_arg_ref')
```

Copyright 2021 The MathWorks, Inc.

Create a structure that contains one field for each of the parameter objects that exist in the `ex_model_arg_ref` workspace. Specify a value for each field.

```
structForInst1.gain = 3.17;
structForInst1.coeff = 1.05;
```

Store the structure in a `Simulink.Parameter` object.

```
structForInst1Param = Simulink.Parameter(structForInst1);
```

Copy the `Simulink.Parameter` object into the `ex_model_arg_ref` model workspace. For this example, name the copy of the object `structArg`.

```
modelWorkspace = get_param('ex_model_arg_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'structArg', copy(structForInst1Param));
```

Configure `structArg` as the only model argument.

```
set_param('ex_model_arg_ref', 'ParameterArgumentNames', 'structArg')
```

In the `ex_model_arg_ref` model, set the **Gain** parameter of the Gain block to `structArg.gain` and set the **Numerator** parameter of the Discrete Filter block to `structArg.coeff`.

```
set_param('ex_model_arg_ref/Gain', 'Gain', 'structArg.gain')
set_param('ex_model_arg_ref/Discrete Filter', ...
    'Numerator', 'structArg.coeff')
```

Copy the existing structure as structForInst2Param.

```
structForInst2Param = copy(structForInst1Param);
```

Set the field values in the two structures to the same numbers that you used to set the model argument values in the Model blocks.

```
structForInst1Param.Value.coeff = 0.98;
structForInst1Param.Value.gain = 2.98;
structForInst2Param.Value.coeff = 1.11;
structForInst2Param.Value.gain = 3.34;
```

Open model `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

```
open_system('ex_model_arg')
```

Copyright 2021 The MathWorks, Inc.

For model instance `Model`, set **structArg** to `structForInst1Param`. For model instance `Model1`, set **structArg** to `structForInst2Param`.

```
instSpecParamsStruct = get_param('ex_model_arg/Model', 'InstanceParameters');
instSpecParamsStruct1 = get_param('ex_model_arg/Model1', 'InstanceParameters');
```

```
instSpecParamsStruct(1).Value = 'structForInst1Param';
instSpecParamsStruct1(1).Value = 'structForInst2Param';
```

```
set_param('ex_model_arg/Model', 'InstanceParameters', instSpecParamsStruct);
set_param('ex_model_arg/Model1', 'InstanceParameters', instSpecParamsStruct1);
```

### Use Bus Object as Data Type of Structures

You can use a `Simulink.Bus` object as the data type of the structures. The bus object makes sure that the characteristics of the instance-specific structures, such as the names and order of fields, match the characteristics of the structure in the model workspace.

To set the data type of the structures to bus objects, follow these steps.

Use the `Simulink.Bus.createObject` function to create the bus object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1Param.Value);
```

Rename the bus object by copying it.

```
myParamStructType = copy(slBus1);
```

Set the data type of the parameter objects in the base workspace by using the bus object.

```
structForInst1Param.DataType = 'Bus: myParamStructType';  
structForInst2Param.DataType = 'Bus: myParamStructType';
```

For the `structArg` object, set `DataType` to `Bus: myParamStructType`.

```
temp = getVariable(modelWorkspace, 'structArg');  
temp = copy(temp);  
temp.DataType = 'Bus: myParamStructType';  
assignin(modelWorkspace, 'structArg', copy(temp));  
close_system('ex_model_arg_ref', 0)  
close_system('ex_model_arg', 0)
```

### More About

- “Parameterize a Referenced Model Programmatically” on page 8-76

## Configure Instance-Specific Data for Lookup Tables Programmatically

When you use `Simulink.LookupTable` objects to store and configure lookup table data for ASAP2 or AUTOSAR code generation (for example, `STD_AXIS` or `CURVE`), you can configure the objects as model arguments. You can then specify unique table data and breakpoint data for each instance of a component.

This example shows how to configure multiple instances of a referenced model to use different values for the same block parameter by using lookup tables and the command prompt.

### Configure Model Arguments in Referenced Model

Open model `ex_arg_LUT_ref`, which represents a reusable algorithm.

```
open_system('ex_arg_LUT_ref')
```

Create a `Simulink.LookupTable` object in the base workspace. For this example, name the object `LUTArg`.

```
temp = Simulink.LookupTable;
```

Specify values for the table and breakpoint data. When you simulate or generate code directly from `ex_arg_LUT_ref`, the model uses these values.

```
temp.Table.Value = [3 4; 1 2];
temp.Breakpoints(1).Value = [1 2];
temp.Breakpoints(2).Value = [3 4];
```

Set the structure name to `LUTArg_Type`.

```
temp.StructTypeInfo.Name = 'LUTArg_Type';
```

Copy the structure to the model workspace.

```
mdlwks = get_param('ex_arg_LUT_ref', 'ModelWorkspace');
assignin(mdlwks, 'LUTArg', copy(temp))
```

Specify `LUTArg` as a model argument.

```
set_param('ex_arg_LUT_ref', 'ParameterArgumentNames', 'LUTArg')
```

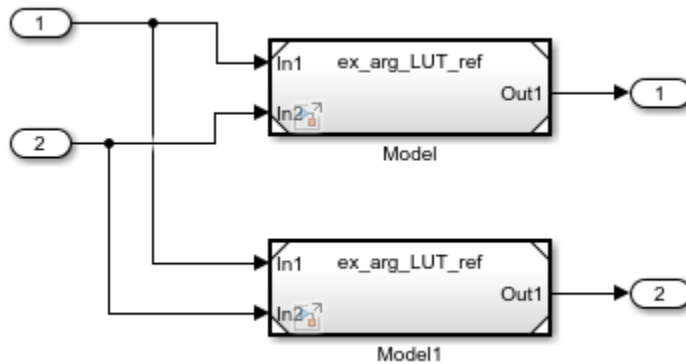

For the n-D Lookup Table block, set 'Data specification' to 'Lookup table object' and set the name to `LUTArg`.

```
set_param('ex_arg_LUT_ref/n-D Lookup Table',...
          'DataSpecification','Lookup table object','LookupTableObject','LUTArg')
```

### Create Instance-Specific Argument Values

Open model `ex_arg_LUT`, which uses the reusable algorithm twice.

```
open_system('ex_arg_LUT')
```

Create a `Simulink.LookupTable` object in the base workspace.

```
LUTForInst1 = Simulink.LookupTable;
```

Specify table and breakpoint data for the object.

```
LUTForInst1.Table.Value = [8 7; 6 5];
LUTForInst1.Breakpoints(1).Value = [5 6];
LUTForInst1.Breakpoints(2).Value = [3 4];
```

Specify the structure name to match the name specified by the object in the referenced model workspace.

```
LUTForInst1.StructTypeInfo.Name = 'LUTArg_Type';
```

Use a structure to create the instance-specific argument value for the second `Model` block. Specify the breakpoint and table data for the structure.

```
StructForInst2.Table = [9 8; 7 7];
StructForInst2.BP1 = [3 4];
StructForInst2.BP2 = [5 6];
```

In the `ex_arg_LUT` model, for model instance `Model`, set the value of `LUTArg` to `LUTForInst1`. For model instance `Model1`, set the value of `LUTArg` to `StructForInst2`.

```
instSpecParams = get_param('ex_arg_LUT/Model','InstanceParameters');
instSpecParams(1).Value = 'LUTForInst1';
instSpecParams1 = get_param('ex_arg_LUT/Model1','InstanceParameters');
instSpecParams1(1).Value = 'StructForInst2';
set_param('ex_arg_LUT/Model','InstanceParameters',instSpecParams);
set_param('ex_arg_LUT/Model1','InstanceParameters',instSpecParams1);
```

One instance of `ex_arg_LUT_ref` uses the table and breakpoint data stored in the `Simulink.LookupTable` object in the base workspace and the other instance uses the table and breakpoint data stored in the structure.

---

## Unit Specification in Simulink Models

Simulink enables you to specify physical units as attributes on signals at the boundaries of model components. Such components can be:

- Subsystems
- Referenced Simulink models
- Simulink-PS Converter and PS-Simulink Converter blocks that interface between Simulink and components developed in Simscape and its associated physical modeling products
- Stateflow charts, state transition tables, or truth tables
- MATLAB Function blocks
- Constant blocks
- Data Store Memory, Data Store Read, and Data Store Write blocks

By specifying, controlling, and visualizing signal units, you can ensure the consistency of calculations across the various components of your model. For example, this added degree of consistency checking is useful if you are integrating many separately developed components into a large, overall system model.

In Simulink models, you specify units from a unit database. The unit database comprises units from the following unit systems:

- SI — International System of Units
- SI (extended) — International System of Units (extended)
- English — English System of Units
- CGS — Centimetre-gram-second System of Units

Based on the type of system you are modeling, you can use any combination of units from these supported unit systems. For more information about supported unit systems and the units they contain, see [Allowed Units](#).

You can assign units to signals through these blocks:

- Inport
- In Bus Element
- Outport
- Out Bus Element
- Signal Specification
- MATLAB Function
- Chart

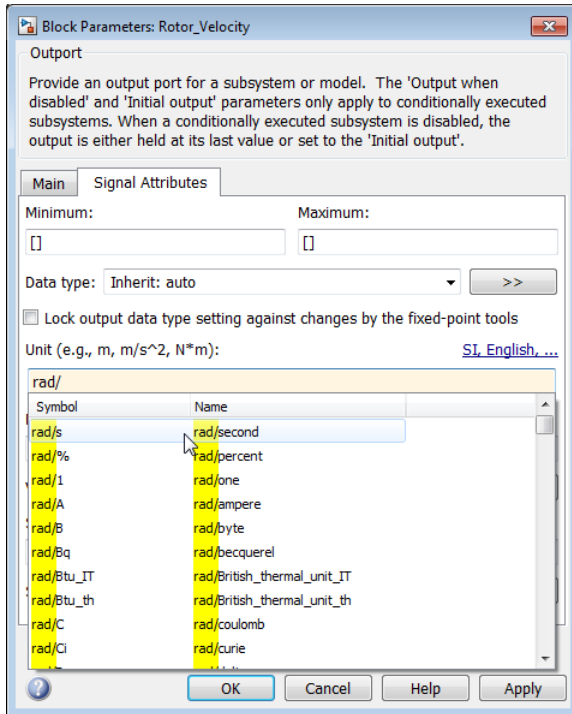

You can assign units to signals through these objects:

- `Simulink.ValueType`
- `Simulink.Signal`
- `Simulink.BusElement`

- Simulink.Parameter

When you add a supported block to your model, the **Unit** parameter on the block is set to `inherit` by default. This setting means that the block inherits the unit from a connecting signal that has an explicitly specified unit.

You can explicitly specify units for signals using the **Unit** parameter of a supported block. For this parameter, the dialog box provides matching suggestions to help you:

If you do not provide a correctly formed unit expression, you get an error. Correctly formed unit expressions are a combination of unit names or symbols with properly balanced parentheses and `*`, `/`, and `^` characters. Special characters such as `[`, `]`, `{`, `}`, `<`, `>`, `\`, `"`, `&`, and so forth are not supported.

By default, a block port has an empty (that is, unspecified) unit and the **Unit** parameter is set to `inherit`. When you specify a unit for one port, Simulink checks the unit setting of any port connected to it. If a port has an empty unit, you can connect it to another port that has any supported unit. If a port unit parameter is set to `inherit`, it inherits the unit from a connected port that has a specified unit.

To display the units on the Simulink lines in the model, on the **Debug** tab, click **Information Overlays > Units**.

## Guidelines for Unitless, Dimensionless, and No Unit Quantities

When dealing with unitless, dimensionless, or no unit quantities, consider these guidelines:

- Pure numbers with no units

Consider using `1`, the SI standard dimensionless unit. Simulink checks the unit to make sure other dimensionless quantities are propagated in. You can add, multiply, and otherwise manipulate these types of numbers.

- Unspecified units

Consider using an empty unit, where the **Unit** parameter is blank. When this parameter is blank, Simulink accepts any unit that propagates to the port without returning a warning.

- Integer counting number unit

Consider using `count` to denote an integer counting number unit. Use this unit for quantities that are difficult to describe, but that are considered unitless or dimensionless, such as thermally accessible states or PWM count. For more information, see `count` in Allowed Units.

- Dimensionless physical quantities

Dimensionless physical quantities represent a specific physical quantity. Consider using the physical quantities `velocity_factor`, `refractive_index`, `relative_permeability`, `strain`, `Reynolds_number`, and `logical`. Some of these physical quantities, `strain` and `Reynolds_number`, have corresponding units. To specify units for the other physical quantities, use a format such as `1@physical_quantity`, for example, `1@refractive_index`. Simulink performs a physical quantity check at propagation. For example, if a model tries to add dimensional physical quantities, Simulink returns a warning.

- Pure scaled numbers

Consider using `ppm`, `ppb`, `ppt`.

## Specify Physical Quantities

When you model a physical system, it is possible to use the same unit expression for two or more signals that represent different physical quantities. For example, a unit expression of  $N*m$  can represent either torque or energy. To prevent mistaken connection of two ports with the same unit but representing different physical quantities, you can add a physical quantity to the unit expression. For example, for the same unit of  $N*m$ , you can specify different physical quantities of  $N*m@torque$  and  $N*m@energy$ . Similar to units, the dialog box provides suggestions as you type the names of physical quantities.

Physical quantities help you to enforce an extra degree of unit consistency checking between connected ports. When you attempt to connect ports with different physical quantities, the model displays a warning.

## Specify Units in Objects

By default, `Simulink.ValueType`, `Simulink.Signal`, `Simulink.BusElement`, and `Simulink.Parameter` objects have empty units. In the case of a:

- `Simulink.ValueType` object, the object does not attach a unit to the corresponding signals.
- `Simulink.Signal` object, the empty unit means that the corresponding signal can inherit a unit from an upstream or downstream port.
- `Simulink.BusElement` object, the empty unit means that the corresponding bus element also has an empty unit. You can connect the element to a port with any unit, but the element does not inherit a unit from the port.

- `Simulink.Parameter` object, the object does not attach a unit to the corresponding parameter value.

If you specify a unit in a `Simulink.ValueType`, `Simulink.Signal`, or `Simulink.BusElement` object, Simulink applies the attribute to the corresponding signal line when:

- The `Simulink.ValueType` object specifies the properties for a signal in the model.
- The `Simulink.Signal` object resolves to a signal in the model.
- The `Simulink.BusElement` object is associated with a `Simulink.Bus` object and you use the corresponding bus element with a Bus Creator, Bus Selector, or Bus Assignment block that applies the `Simulink.Bus` object.

For the `Simulink.Parameter` object, Simulink does not apply any attribute. For all objects, if the **Unit** parameter has a value that is not formed correctly, you see an error. If the unit is formed correctly but is undefined, you see a warning when you compile the model. If the unit expression contains special characters such as [ , ], { , }, < , > , \ , " , & , and so forth, Simulink replaces them with underscores ( \_ ).

### Custom Unit Properties

Notes on the `Unit` and `DocUnits` properties starting in R2016a:

- The `DocUnits` property is now `Unit` for `Simulink.Parameter` and `Simulink.Signal` objects. If, in a previous release, you used the `DocUnits` parameter of a `Simulink.Parameter` or `Simulink.Signal` object to contain text that does not now comply with units specifications, simulation returns a warning when the model simulates.

To suppress these warnings, set the configuration parameter “Units inconsistency messages” to none. This setting suppresses all units inconsistency check warnings.

- If you have a class that derives from `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.BusElement` with a previously defined `Unit` property, Simulink returns an error like the following:

```
Cannot define property 'Unit' in class 'classname' because
the property has already been defined in the superclass 'superclass'.
```

If you use this property to represent the physical unit of the signal, delete the `Unit` property from the derived class in the R2016a or later release. Existing scripts continue to work, unless you are assigning incorrectly formed unit expressions to the `Unit` field. In this case, replace the use of `Unit` with `DocUnits` to continue to be able to assign the unit expression.

---

**Note** If you store existing data in a MAT- or `.sldd` file, in a release prior to R2016a, copy the contents of the `Unit` property to the `DocUnits` first. Then, save the file in the earlier release before loading the model in R2016a or later release.

---

## Specify Units for Temperature Signals

When modeling absolute temperature quantities, use units such as K, degC, degF, and degR. When modeling temperature *difference* quantities, use units such as deltaK, deltadegC, deltadegF, and deltadegR. If you connect a signal that has a temperature difference unit to a block that specifies an *absolute* temperature unit, Simulink detects the mismatch.

## Specify Units in MATLAB Function Blocks

You specify the units for the inputs and outputs of a MATLAB Function block by specifying the units in the **Unit (e.g., m, m/s<sup>2</sup>, N\*m)** parameter in the Property Inspector. Double-click the MATLAB Function block to open the MATLAB Function Block Editor. In the **Modeling** tab, in the Design section, click **Symbols Pane**. Right-click the variable name and select **Inspect**. By default, this property is **inherit**, which means that the unit equals the signal sent to the port. If you select the **Data must resolve to signal object** property for an output, the signal connected to the output port determines the port unit and the other properties except for the **Name** and **Scope**.

MATLAB Function blocks check if the Simulink signal unit matches the unit assigned to the corresponding input or output of the block. If the units do not match, Simulink displays a warning when you update the model. Otherwise, unit settings do not affect MATLAB Function block execution.

## Specify Units in Constant Blocks

You can specify units for output data of Constant blocks by using the **Unit** property in the `Simulink.Parameter` object.

## Specify Units for Logging and Loading Signal Data

You can include units in signal data that you log or load.

You specify units for logging and loading using `Simulink.SimulationData.Unit` objects. When you log using `Dataset` or `Timeseries` format, Simulink stores the unit information using `Simulink.SimulationData.Unit` objects. If you create MATLAB timeseries data to load, you can specify `Simulink.SimulationData.Unit` object for the `Units` property of the `timeseries` object.

For details, see “Log Signal Data That Uses Units” on page 77-23 and “Load Signal Data That Uses Units” on page 75-60.

## Restricting Unit Systems

By default, you can specify units from any of the supported unit systems. However, in large modeling projects, to enforce consistency, you might want to restrict the unit systems that certain components of your model can use. To specify available unit systems for a model, in the configuration parameter **Allowed unit systems**, enter `all` or a comma-separated list containing one or more of `SI`, `SI (extended)`, `CGS`, and `English`. Do not use quotation marks. If your model contains referenced models, you can use the **Allowed unit systems** to restrict units in each of those referenced models. If your model contains subsystems, you can use the Unit System Configuration block to restrict units in the subsystems. You can also optionally use a Unit System Configuration block in a model. In this case, the settings in the Unit System Configuration block override whatever you specify in **Allowed unit systems**.

To restrict unit systems in a model:

- 1 In the **Unit** parameter of the Inport, Outport, or Signal Specification block, click the link.

If a Unit System Configuration block exists in your model, this link opens the block dialog box. Otherwise, the link opens the **Allowed unit systems** configuration parameter.

- 2 Specify one or more the desired unit systems, `SI`, `SI (extended)`, `English`, or `CGS`, in a comma-delimited list, or `all`, without quotation marks.

In a parent-child relationship (for example, a top model with a referenced model or subsystem), you can specify different unit systems for each component. However, if a child propagates a unit into a parent that is not in the unit systems specified for the parent, you get a warning.

To check whether there are unit mismatches caused by restricted unit systems in your model hierarchy:

- Press **Ctrl+D** and visually inspect the model for warning badges.
- Use the Model Advisor check **Identify disallowed unit systems**.

- “Displaying Units” on page 9-8
- “Unit Consistency Checking and Propagation” on page 9-10
- “Converting Units” on page 9-14
- “Troubleshooting Units” on page 9-26

## Displaying Units

To display signal units in your model, on the **Debug** tab, select **Information Overlays > Units**. To select this option programmatically, use the command-line property `ShowPortUnits`.

With this option selected, the model dynamically updates port and signal labels to show any changes that you make to units. You do not need to press **Ctrl+D** to update the model. When you simulate your model, the Scope block displays units for connected signals as y-axis labels.

**Note** When you explicitly specify units on input or output blocks, block port labels and signal lines display those units. If a port is set to inherit units or has empty units, port labels and signal lines do not show labels.

**Note** With the option to display units cleared, you do not see port and signal labels, even when you press **Ctrl+D** to update your model. However, you do see warning or error badges for any unit inconsistency problems that exist in the model.

You can also see units in the interface view of your model. On the **Modeling** tab, under **Design**, click **Model Interface**.

- [“Unit Consistency Checking and Propagation”](#) on page 9-10
- [“Converting Units”](#) on page 9-14
- [“Troubleshooting Units”](#) on page 9-26

## Unit Consistency Checking and Propagation

Simulink performs unit consistency checking between components. Ports that you connect together — sometimes via intermediate blocks that propagate units — must have the same units. For example, you cannot connect a port with unit  $\text{ft/s}$  to a port with unit  $\text{m/s}^2$ .

By default, Simulink shows the mismatch warning  when it detects a mismatch in units between two connected ports. You can press **Ctrl+D** to show mismatched units in your model.

To make this connection valid, you can:

- Explicitly set both port units to the same unit.

- Set the **Unit** parameter of one of the connecting ports to `inherit`.
- Insert a Unit Conversion block between the mismatched units if they are separated by a scaling factor or offset, or if they are inverse units. These units are convertible. For more information, see “Converting Units” on page 9-14.
- Select the **Allow automatic unit conversions** configuration parameter. For more information, see “Converting Units” on page 9-14.

---

**Note** Simulink supports variations on unit expressions. For example, one port can have a unit of  $m/s^2$  and a connected port can have a unit of  $m/s/s$ . In these cases, Simulink does not display a warning for mismatched units.

---

When Simulink detects one of these conditions, it displays the inconsistency warning :

- Disallowed unit system
- Undefined unit

Simulink checks the consistency of unit settings and propagates units across component boundaries. In a model that contains a referenced model, Simulink compiles the referenced model independently of the top model. This independent compilation means that the referenced model cannot inherit units from the top model.

If a port in a referenced model has **Unit** set to `inherit`, it can inherit a unit from any upstream or downstream block in the referenced model. If the port does not inherit a unit from an upstream or downstream block, you can connect it to a port in the top model with any unit.

Simulink passes units through the following blocks that do not change data, known as noncomputation blocks:

- Bus Creator
- Bus Selector
- Bus to Vector
- Data Type Conversion
- Demux
- From
- Goto
- Inport
- Merge
- Model
- Mux
- Outport
- Rate Transition
- Signal Conversion
- Signal Specification
- Subsystem
- Variant Sink

- Variant Source

---

**Note** If you supply two or more signals with different units to a Mux block, Simulink applies empty units to the vector signal that the Mux block outputs. Vector signals must have a common unit.

---

---

**Note** If you have a nonvirtual bus in your model (see “Composite Interface Guidelines” on page 81-2), Simulink sets the unit of the bus to empty. A nonvirtual bus cannot have a unit. However, if the bus element signals themselves have units, Simulink does not change these.

---

Simulink does not propagate units through blocks that produce new data as output. When signals with units pass through these blocks, the units of these signals become empty. Examples of blocks that do not preserve units because they produce new data as an output include:

- Sum
- Gain
- Filter
- Product

## Unit Propagation Between Simulink and Simscape

When modeling physical systems, you might want to integrate components developed in Simulink with components developed in Simscape and its associated physical modeling products. Simscape components use physical signals instead of regular Simulink signals. Therefore, you need Simulink-PS Converter and PS-Simulink Converter converter blocks to connect signals between Simulink and Simscape components.

To specify units for the input and output signals of your Simscape component, you can explicitly specify the units on the converter blocks. When you specify units on a PS-Simulink Converter block that converts a signal from Simscape to Simulink, Simulink propagates the unit settings to the connected Simulink port. However, Simulink cannot propagate a signal unit from Simulink into your Simscape component. To do that, you must explicitly specify the unit on the Simulink-PS Converter block. For more information, see “Physical Units” (Simscape).

- “Displaying Units” on page 9-8

- “Converting Units” on page 9-14
- “Troubleshooting Units” on page 9-26

## Converting Units

Simulink can convert units between ports when it detects discrepancies that have known mathematical relationships such as:

- Scaling factors
- Conversion factors and offsets, such as °F (Fahrenheit) to °C (Celsius)
- Scaled, inverse units, such as mpg (miles per gallon) and L/km (liters per kilometer).

For example, if you connect one port with a unit of cm to one with a unit of mm, Simulink can automatically scale one unit to work with the other.

To enable Simulink to convert unit mismatches in your model automatically, select the **Allow automatic unit conversions** configuration parameter.

- When Simulink successfully converts signal units at a block port, it displays .
- When Simulink detects that an automatic conversion is not possible, it displays .

To manually convert units separated by a conversion factor or offset:

- 1 Clear the **Allow automatic unit conversions** configuration parameter.
- 2 Insert a Unit Conversion block between the ports whose units you want to convert.

---

**Tip** Automatic conversion of units is a convenience. For better control of units, when Simulink detects a mismatch, consider modifying the units specified at one or the other of the two connected ports.

---

## Automatic Unit Conversion Limitations

Simulink does not support automatic conversion:

- At the root level of models configured for concurrent execution or export-function models. For more information, see “Configure Your Model for Concurrent Execution” on page 14-20 and “Export-Function Models Overview” on page 10-96.
- For fixed-point and integer signals.
- At an input port of a Merge block.
- At any port of an asynchronous Rate Transition block.
- At an input port of a function-call subsystem.
- For bus signals.

## Update an Existing Model to Use Units

This example shows how to add units to an existing model. You see how to:

- Use an incremental workflow to add units to components in your model
- Integrate components that use different unit systems
- Specify units for individual elements of a bus object
- Troubleshoot unit mismatch problems

The model in the example is a fuel control system. The controller (Fuel Rate Controller) and plant (Engine Gas Dynamics) components of the model are nonvirtual subsystems. Nonvirtual subsystems have the **Treat as atomic unit** parameter selected. You introduce units to the plant before introducing units to the controller and connecting signals. You also specify units for the individual elements of a bus object in the model.

Open the `ex_units_fuelsys` example model.

For the top model, the **Allowed unit systems** configuration parameter determines the unit systems the model can use. For each of the plant and controller subsystems, a Unit System Configuration block determines the allowed unit systems.

Component	Allowed Unit Systems
Top model	SI
Fuel Rate Controller subsystem (controller)	all
Engine Gas Dynamics subsystem (plant)	all

In the plant subsystem, on the **Signal Attributes** tab of each Inport block dialog box, set the **Unit** parameter to a value appropriate for the connected physical signal.

Block	Physical Signal	Unit Parameter Setting
1	engine speed	rad/s (radians per second)
2	throttle angle	deg (degrees)
3	fuel rate	g/s (grams per second)

To display units on ports and signals in the model, on the **Debug** tab, select **Information Overlays > Port Units**.

In the plant subsystem, you see units on the Inport blocks and connected signals.

Navigate back to the top model. To compile the model, press **Ctrl+D**, which also performs unit consistency checking.

The model displays a warning to indicate that there is a disallowed unit for the throttle angle signal. Clicking the warning icon displays a link to a Model Advisor report that gives you more detail.

The model also displays the warning at the bottom of the model editing window.

In the plant subsystem, you specified a unit of deg (degrees) for the throttle angle signal. However, the warning message indicates that degrees are not in the SI unit system. As determined by the **Allowed unit systems** configuration parameter, SI is the only unit system that the top model currently allows. To resolve this warning, you have two options:

- In the plant subsystem, specify a unit for the `throttle` angle signal that the SI unit system supports. For more information about supported unit systems and the units they contain, see [Allowed Units](#).
- In the top model, change the **Allowed unit systems** configuration parameter to expand the set of allowed unit systems.

In this case, a unit of `deg` for the `throttle` angle signal is appropriate. Instead, to resolve the warning, expand the set of allowed unit systems for the top model. Set the **Allowed unit systems** configuration parameter of the top model to `all`. To recompile the model, press **Ctrl+D**.

The top model no longer displays warnings.

Now that you have introduced units to the plant and successfully resolved unit inconsistency problems, you can add units to the controller. In the Fuel Rate Controller subsystem, set the **Unit** parameter of the `fuel_rate` Outputport block to `kg/s` (kilograms per second).

Navigate back to the top model. To recompile it, press **Ctrl+D**.

The top model now shows a warning for mismatched units between the controller and plant. To resolve this error, you can:

- Explicitly insert a Unit Conversion block between the two components.
- Select the **Allow automatic unit conversions** configuration parameter.

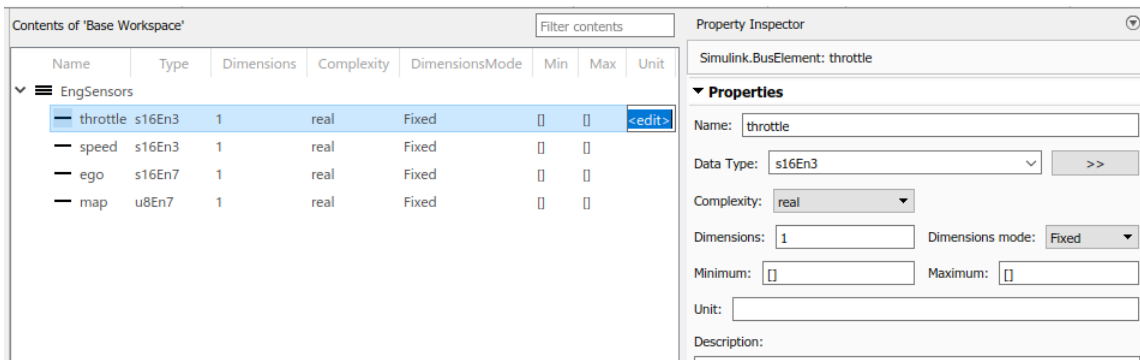

Both options convert units in the same way. A situation in which you might disallow automatic conversions and insert conversion blocks instead is when you are integrating many components in a large system model. In that case, manually inserting conversion blocks can give you an added degree of control of unit conversions in the model. Also, with a conversion block, you can control the data type of the converted signal. This is useful, for instance, when you are modeling for fixed-point precision.

In this case, to enable Simulink to resolve the unit mismatch automatically, select **Allow automatic unit conversions**. To recompile the model, press **Ctrl+D**.

Simulink automatically converts units between the controller and the plant. An automatic conversion icon replaces the warning.

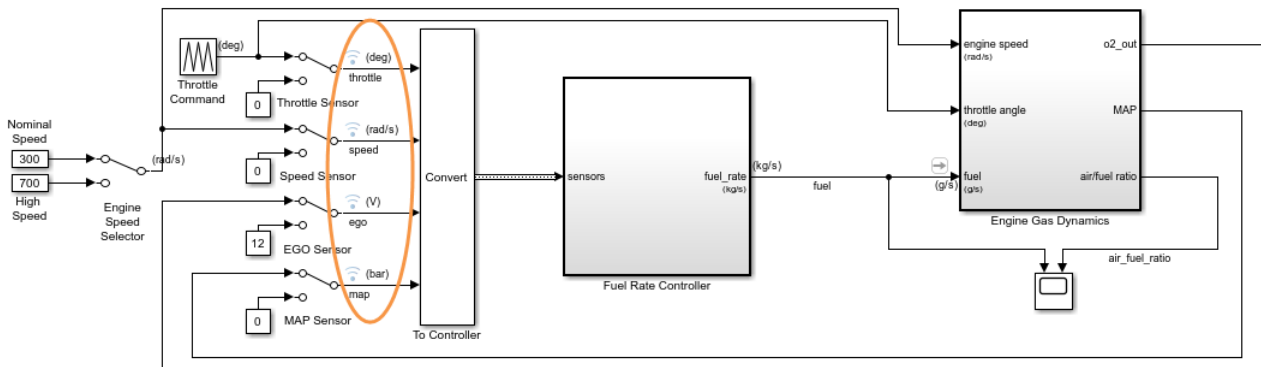

The top model includes a Simulink.Bus object named EngSensors that passes various sensor signals as a composite signal to the controller. To use the Type Editor to add units to individual elements of the bus object, on the **Modeling** tab, under **Design**, click **Type Editor**. Then, specify the units in the table or in the **Property Inspector** pane.

For the EngSensors bus object, set the **Unit** parameter of each element.

Signal	Unit Parameter Setting
throttle	deg (degrees)
speed	rad/s (radians per second)
ego	V (volts)
map	bar (bars)

To recompile the model, press **Ctrl+D**.

The model shows units on the individual elements of the bus object.

You can also see the units in the interface view of your model. On the **Modeling** tab, under **Design**, click **Model Interface**.

The `airflow_calc` block of the controller subsystem displays units on the individual elements of the bus object, both at the component interface and within the component.

After you introduce units incrementally and resolve inconsistency and mismatch issues, you can simulate the model.

For the `fuel` signal that is connected to the scope, the plot window displays the associated units of `kg/s` as a y-axis label.

## Working with Custom Unit Databases

In Simulink models, you specify units from a unit database. The unit database comprises units from the following unit systems:

- SI — International System of Units
- SI (extended) — International System of Units (extended)
- English — English System of Units
- CGS — Centimetre-gram-second System of Units

By default, Simulink supports only the units and unit systems listed in Allowed Units. To introduce additional units from other unit systems at a system-wide level and use those new units as you would those listed in Allowed Units, create and load a new unit database with these functions:

- `createCustomDBFromExcel` — Creates a custom unit database file from an Excel spreadsheet that contains definitions for the custom unit database. On all supported platforms, the `createCustomDBFromExcel` function supports: `.xls` and `.xlsx` files.
- `rehashUnitDBs` — Loads custom unit databases by rehashing unit database files on the MATLAB path.

### Custom Units Spreadsheet Format

Spreadsheets must have these columns in any order:

- **name** — Unit name, using any graphical Unicode characters except @, \*, /, ^, (, ), +, \, ", ', {, }, [, ], <, >, &, -, ::, and white space.
- **symbol** — Symbol of unit, using any graphical Unicode characters except @, \*, /, ^, (, ), +, \, ", ', {, }, [, ], <, >, &, -, ::, and white space.
- **asciiSymbol** — Symbol of unit, in ASCII.
- **displayName** — Name of unit displayed in model in LaTeX format.
- **definitionExpression** — Definition of the unit in terms of predefined units, such as seven base SI units.
- **conversionFactor** — Conversion factor between the unit and its definition.
- **conversionOffset** — Conversion offset between the unit and its definition.
- **physicalQuantity** — Valid physical quantities. See table 'Physical Quantities' in `showunitslist`.
- **provenance** — Optional column. List of unit provenances, separated by commas.

Follow these guidelines when developing spreadsheets:

- If the input spreadsheet contains more than one worksheet, you must name the worksheets with the prefixes `unit`, `physicalQuantity`, or `provenance`.
- If there are multiple instances of a prefix in a worksheet, the function uses all of the worksheets to create the database:
  - `unit` — Creates units
  - `physicalQuantity` — Creates physical quantities
  - `provenance` — Creates provenances

Optionally, you can define physical quantities in another worksheet of the input spreadsheet. A worksheet defining physical quantities contains these columns in any order:

- **name** — Physical quantity name, using any graphical Unicode characters except @, \*, /, ^, (, ), +, \, ", ', {, }, [, ], <, >, &, -, ::, and white space.
- **definitionExpression** — Definition of physical quantity in terms of predefined physical quantities.
- **provenance** — Optional. List of physical quantity provenances, separated by commas.

Optionally, you can also define provenances in another worksheet of the input spreadsheet. A worksheet defining provenances contains these columns in any order:

- **identifier** — Identifier of provenance
- **title** — Title of provenance
- **subTitle** — Subtitle of provenance
- **organization** — Organization of provenance
- **fullName** — Full name of provenance
- **urlList** — List of URL links of provenance
- **edition** — Provenance edition
- **year** — Provenance year

## Define Custom Units in Excel Spreadsheet

First, create an Excel spreadsheet following the guidelines in “Custom Units Spreadsheet Format” on page 9-23. Use unit definitions, one per row, such as:

	A	B	C	D	E	F	G	H
1	<u>name</u>	<u>symbol</u>	<u>asciiSymbol</u>	<u>displayName</u>	<u>definitionExpression</u>	<u>conversionFactor</u>	<u>conversionOffset</u>	<u>physicalQuantity</u>
2	ounce_force	ozf	ozf	{\rm{}oz_{force}}	oz*gn	1	0	force
3	troy_oz	ozt	ozt	{\rm{}oz_{troy}}	oz	1	0	mass
4	hogshead	Hhd	Hhd	{\rm{}Hhd}	gal	79	0	volume

Save this spreadsheet in a file such as `unitsDB.xlsx`. You can then create the database and load it.

## Create and Load Custom Unit Database

This example shows how to create a custom units database and then load it.

Create the database using the spreadsheet included in this example.

```
createCustomDBFromExcel('unitsDB.xlsx')
```

The function creates `unitsDB.slunitdb.mldatx` in the current folder.

Load the new units database into memory.

```
rehashUnitDBs
```

To verify that the new database has been loaded, open the `slex_customunits` model and apply custom units on any of the output ports:

slex\_customunits

 “Unsuccessful Automatic Unit Conversions” on page 9-27  
 “Simscape Unit Specification Incompatible with Simulink” on page 9-27

To help you troubleshoot issues with unit settings, Simulink uses Model Advisor checks to generate a report useful for larger models.

By default, Simulink flags unit usage issues, such as mismatched units, with warnings. Warnings enable you to continue working despite mismatched units. You can reduce the number of warnings you see by setting the configuration parameter **Units inconsistency messages** to none.

### Undefined Units

Simulink does not support custom unit specifications. For more information about supported unit systems and the units they contain, see Allowed Units.

The Model Advisor check “Identify undefined units in the model” identifies undefined units.

### Overflow and Underflow Errors or Warning

You can get overflow and underflow errors or warnings when using the Unit Conversion block. If you get:

- Overflow messages, change the data type at the output port to one with a better range
- Underflow messages, change the data type at the output port to one with better precision

### Mismatched Units Detected

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover over the warning badge. If the unit is convertible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

### Mismatched Units Detected While Loading

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover the warning badge. When possible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

## Disallowed Unit Systems

Simulink supports only the unit systems listed in the tables of allowed units.

The Model Advisor check “Identify disallowed unit systems in the model” identifies unit systems that are not allowed in the configured units systems.

## Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. Simulink flags automatically converted units with the  badge.

For a list of the automatic unit conversions, use the Model Advisor check “Identify automatic unit conversions in the model”.

## Unsuccessful Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. If Simulink cannot perform the automatic unit conversion, Simulink returns a warning (). In such cases, consider manually specifying the unit.

---

**Tip** Automatic unit conversion is a convenience. For better control of units, you can manually set the units for two connecting ports.

---

## Simscape Unit Specification Incompatible with Simulink

If these are true:

- You define a new unit to your unit registry by using the `pm_addunit` function.
- You use the new unit with the Simulink-PS Converter or PS-Simulink Converter block.
- Your new unit conflicts with an existing one in the Simulink database.

Simulink returns a warning about a potential incorrect calculation (.

## Conditionally Executed Subsystems Overview

A conditionally executed subsystem is a nonvirtual subsystem that allows you to control its execution with an external signal. The external signal, called the control signal, is attached to the control input port. Conditional subsystems are useful when you create complex models that contain components whose execution depends on other components.

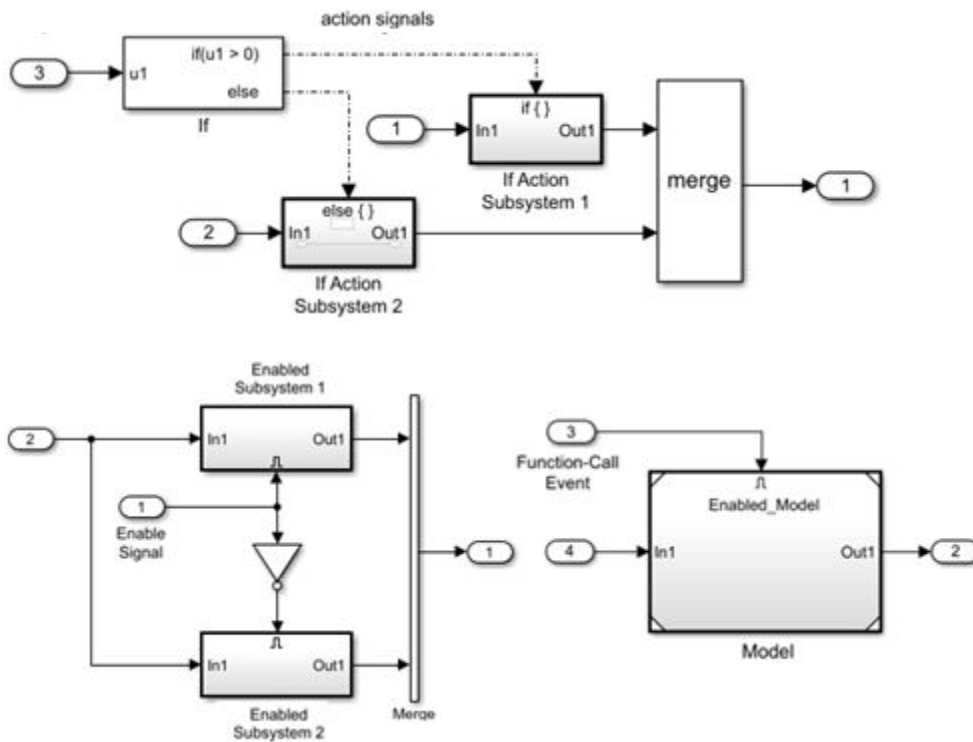

Simulink supports these types of conditional subsystems:

- **Enabled Subsystem** — Executes at each time step while the control signal is positive. Execution starts at the time step when the control signal crosses zero from the negative to the positive direction. See “Using Enabled Subsystems” on page 10-10.
- **Triggered Subsystem** — Executes at each time step when the control signal rises or falls to zero or crosses zero. See “Using Triggered Subsystems” on page 10-17.
- **Enabled and Triggered Subsystem** — Executes at the time step when the enable control signal has a positive value and the trigger control signal rises or falls to zero. See “Using Enabled and Triggered Subsystems” on page 10-20.
- **Message Triggered Subsystem** — Uses messages as a control signal, and executes whenever a message is available at the control port, independent of the block sample time. See “Using Message Polling and Message Triggered Subsystems” on page 11-85.
- **Message Polling Subsystem** — Uses messages as a control signal, and executes at each time step when a message is available at the control port. See “Using Message Polling and Message Triggered Subsystems” on page 11-85.
- **Function-Call Subsystem** — Executes when the control signal receives a function-call event. Events can occur one or more time during a time step. A Stateflow chart, Function-Call Generator block, S-Function block, or Hit Crossing block can provide function-call events. See “Using Function-Call Subsystems” on page 10-34.

A conditionally executed subsystem or conditionally executed referenced model runs:

- Once at the current time step when enabled by a control block. A control block implements control logic similar to that expressed by a programming language statement such as `if-then-else` or `switch`.
- Once at the current time step when enabled or triggered by a control signal or an action signal.
- One or more times during a time step when receiving a function-call event.

For example models, see “Simulink Subsystem Semantics”.

## Ensure Output is Virtual

In some situations Simulink adds a "hidden signal buffer" before the Outport block in a conditional subsystem or before an Outport block at the top-level of a model. In effect, Simulink inserts a Signal Copy block at that location, although the block does not appear on the canvas. This buffer ensures consistent initialization of the Outport block signal.

In a few cases, adding this signal buffer with a conditional output signal or partial write signal can cause a different simulation result. The parameter **Ensure output is virtual** is an option on an Outport block to remove the buffer. Select this option when you are concerned with conditional or partial write signals.

### Conditional Output Signal

Consider the following model. To open model, see `ex_conditional_write`.

The Merge block combines its inputs into a single signal whose value at any time is equal to the most recently computed output of its driving blocks.

For the case with most models, clear the **Ensure output is virtual** check box on the Outport block connected to Enabled Subsystem C.

- The Output block follows non-virtual semantics. A hidden buffer is inserted if needed before the Output block.
- The buffer provides consistent initialization of the Output block signal.

Time 0: A runs, C does not run, but because the buffer is in A, it runs and copies the initial value of zero to the Output block. B does not run. The merge signal is zero from the output from A.

Time 0.5: A does not run. B runs and outputs a sine wave. The merge signal is the sine wave from B.

Time 1: A runs, C does not run, but the buffer again runs and copies over the initial value of zero to the Output block. B does not run. The merge signal is again the initial value of A, not the last value from B.

Simulating the model with a fixed-step, produces the following result.

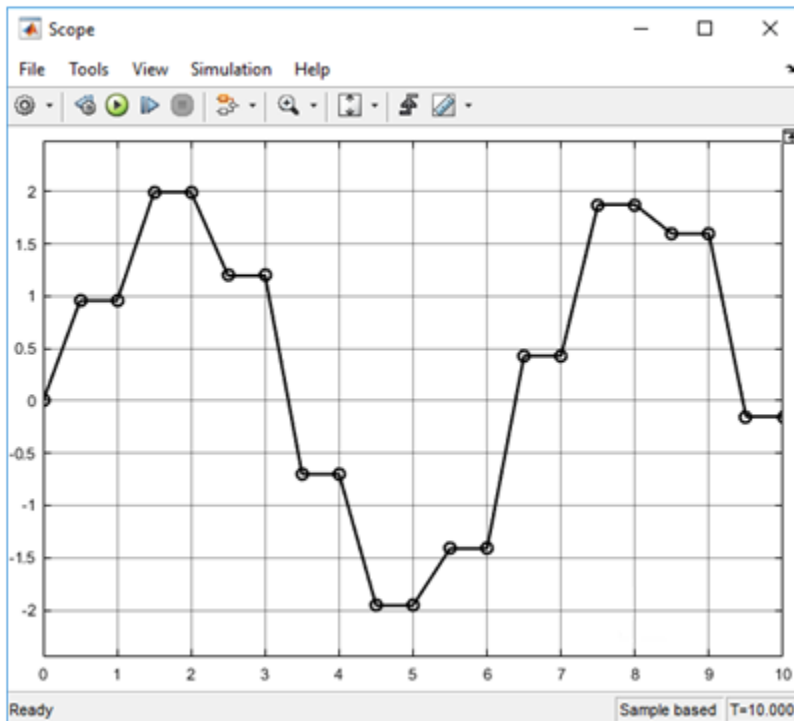

For the case where you are concerned with conditional and partial writes, select (check) the **Ensure output is virtual** check box for the Output block connected to Enabled Subsystem C.

- The Output block follows virtual semantics.
- A hidden buffer is not inserted before the Output block of the Subsystem.
- If Simulink determines a buffer is needed, an error is displayed.

Time 0: A runs, C does not run. B does not run. Merge signal is the initial value of the signal.

Time 0.5 sec: A does not run. B runs and outputs a sine wave. The merge signal is the value of the sine wave from B.

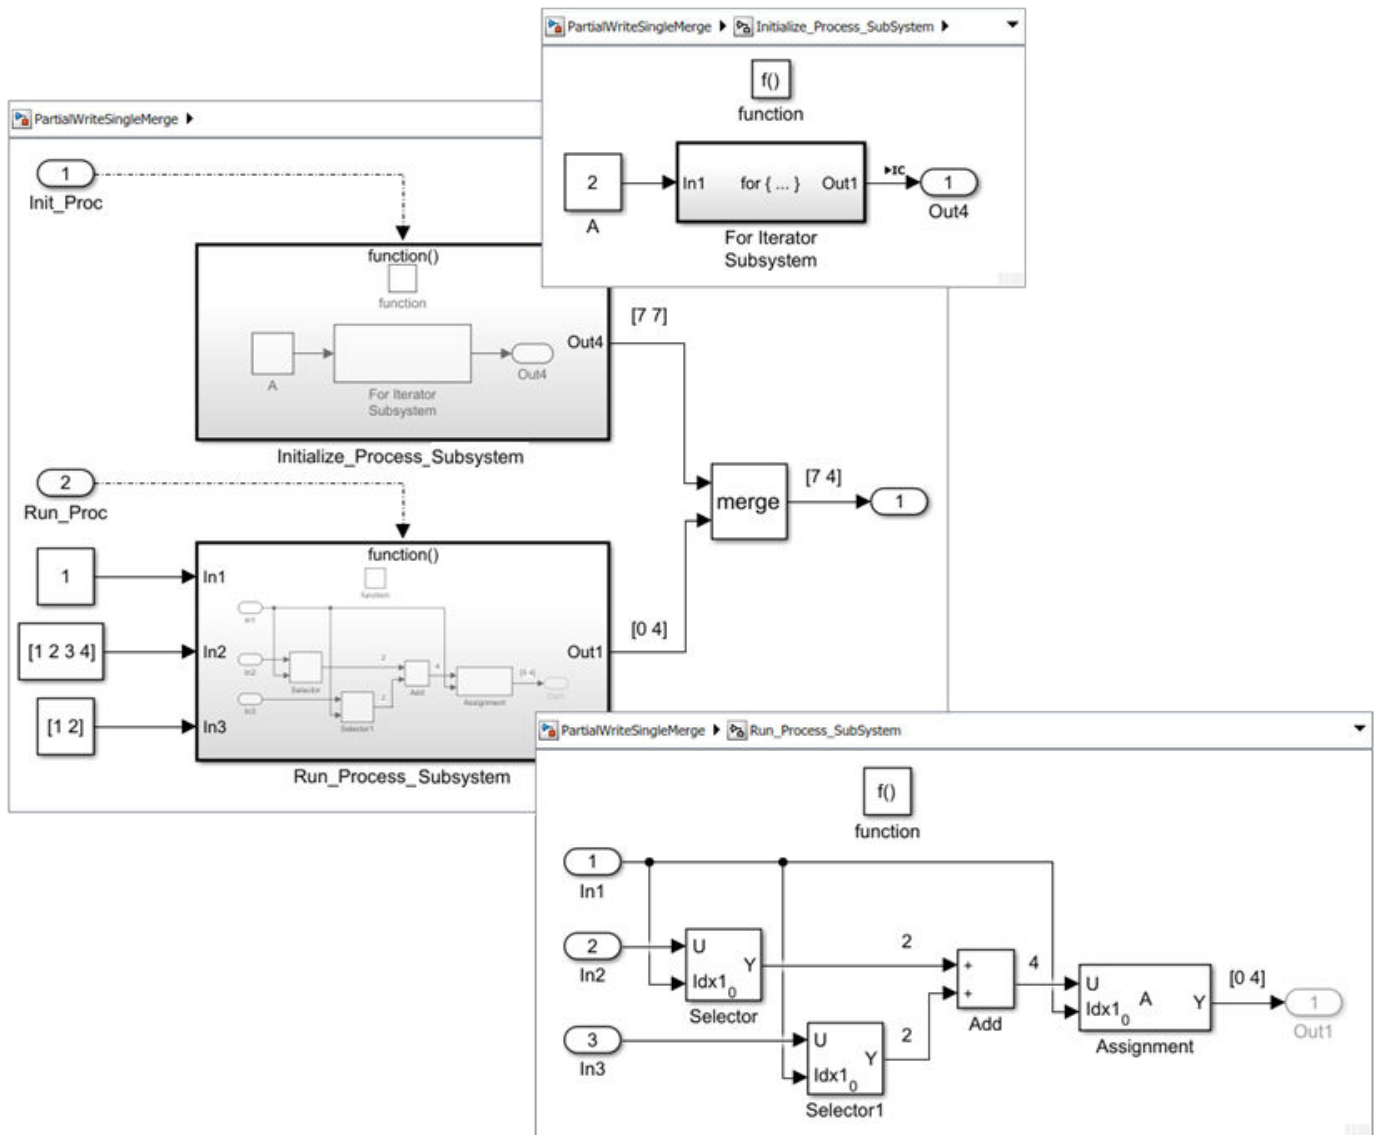

Time 1: A runs, C does not run. B does not run. The merge signal is the most recently computed output which was the sine wave from B.

## Partial Write Signals With a Merge Block

A typical modeling pattern is where you want to initialize a vector signal and then periodically update partial elements of the signal based upon certain conditions or inputs. One way of modeling this pattern is to use a Merge block whose inputs are from two Function-Call Subsystem blocks. One subsystem is the initialize task while the other subsystem is a periodic write task.

The model below demonstrates this pattern. The `Initialize_Process_Subsystem` is called once at the beginning of a simulation to initialize a vector signal. The `Run_Process_Subsystem` is called to partially write to elements of the vector. However, the output from the Assignment block needs a path where hidden buffers do not make copies of the vector. Selecting the **Ensure output is virtual** check box on the Output block removes a hidden buffer. If Simulink determines the buffer is needed an error is displayed. To open model, see `ex_partial_write_single_merge`.

The Initialize\_Process\_SubSystem

- Initializes each element of a 2 element vector with a value of 7.
- Outputs the vector [7 7].

The Run\_Process\_SubSystem

- Inputs an index value of 1, but because the **Index mode** parameter for the Selector blocks is set to Zero-based, they select the 2nd elements from the input vectors.
- Adds the output scalar values from the Selector blocks for a result of 4.
- Because the Assignment block **Index mode** parameter is set to Zero-based and the input index Idx1 is 1, the output signal needs to be a vector with length 2. After setting the **Output size** parameter to 2, the Assignment block is able to write to the 2nd element.
- Selecting the **Ensure output is virtual** check box removes the hidden buffer.

Code generated from this model includes two functions. Init\_Proc and Run\_Proc.

```
/* Model step function */
void Init_Proc(void)
{
    int32_T s3_iter;

    /* Initialize signal vector elements with 7.0 */
    for (s3_iter = 0; s3_iter < 2; s3_iter++) {
        PartialWriteSingleMerge_DW.Assignment[s3_iter] = 7.0;
    }

    for (s3_iter = 0; s3_iter < 2; s3_iter++) {
        PartialWriteSingleMerge_Y.Out4[s3_iter] =
            PartialWriteSingleMerge_DW.Assignment[s3_iter];
    }
}

/* Model step function */
void Run_Proc(void)
{
    /* Write to element 1 of the output signal vector */
    PartialWriteSingleMerge_Y.Out4[1] = 4.0;
}
```

## Using Enabled Subsystems

An enabled subsystem is a conditionally executed subsystem that runs once at each major time step while the control signal has a positive value. If the signal crosses zero during a minor time step, the subsystem is not enabled or disabled until the next major time step.

The control signal can be either a scalar or a vector.

- If a scalar value is greater than zero, the subsystem executes.
- If any one of the vector element values is greater than zero, the subsystem executes.

## Create an Enabled Subsystem

To create an enabled subsystem:

- 1 Add an Enabled Subsystem block to your model.
  - Copy a block from the Simulink Ports & Subsystems library to your model.
  - Click the model diagram, start typing `enabled`, and then select Enabled Subsystem.

- 2 Set initial and disabled values for the Outputport blocks. See “Conditional Subsystem Initial Output Values” on page 10-38 and “Conditional Subsystem Output Values When Disabled” on page 10-55.

- 3 Specify how subsystem states are handled when the subsystem is enabled.

Open the subsystem block, and then open the parameter dialog box for the Enable port block. From the **States when enabling** drop-down list, select:

- **held** — States maintain their most recent values.
- **reset** — If the subsystem is disabled for at least one time step, states revert to their initial conditions.

---

**Note** If the subsystem contains a Stateflow chart that contains a Simulink Function block, blocks inside the Simulink Function block do not revert to their initial conditions. For a more generic reinitialize functionality, consider using the Reinitialize Function block.

---

In simplified initialization mode (default), the subsystem elapsed time is always reset during the first execution after becoming enabled. This reset happens regardless of whether the subsystem is configured to reset on being enabled. See “Underspecified initialization detection”.

For nested subsystems whose Enable blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.

- 4 Output the control signal from the Enable block.

In the parameter dialog box for the Enable Block, select the **Show output port** check box.

Selecting this parameter allows you to pass the control signal into the enabled subsystem. You can use this signal with an algorithm that depends on the value of the control signal.

## Blocks in Enabled Subsystems

### Discrete Blocks

Discrete blocks in an enabled subsystem execute only when the subsystem executes, and only when their sample times are synchronized with the simulation sample time.

Consider the `ex_enabled_subsys_1` model, which contains four discrete blocks and a control signal. The discrete blocks are:

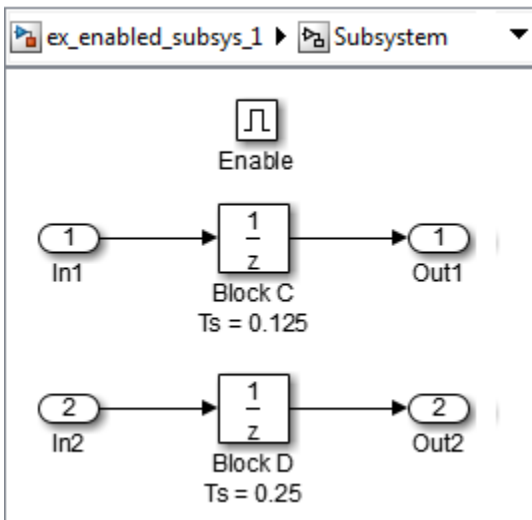

- Block A, with the sample time of 0.25 seconds
- Block B, with the sample time of 0.5 seconds

Signal E is the enable control signal generated by a Pulse Generator with a sample time of 0.125. Its output changes value from 0 to 1 at 0.375 seconds and returns to 0 at 0.875 seconds.

The discrete blocks in the enabled subsystem are:

- Block C, within the enabled subsystem, with the sample time of 0.125 seconds
- Block D, also within the enabled subsystem, with the sample time of 0.25 seconds

Discrete blocks execute at sample times shown.

Blocks A and B execute independently of the enable control signal because they are not part of the enabled subsystem. When the enable control signal becomes positive, blocks C and D execute at their assigned sample rates until the enable control signal becomes zero again. Block C does not execute at 0.875 seconds when the enable control signal changes to zero.

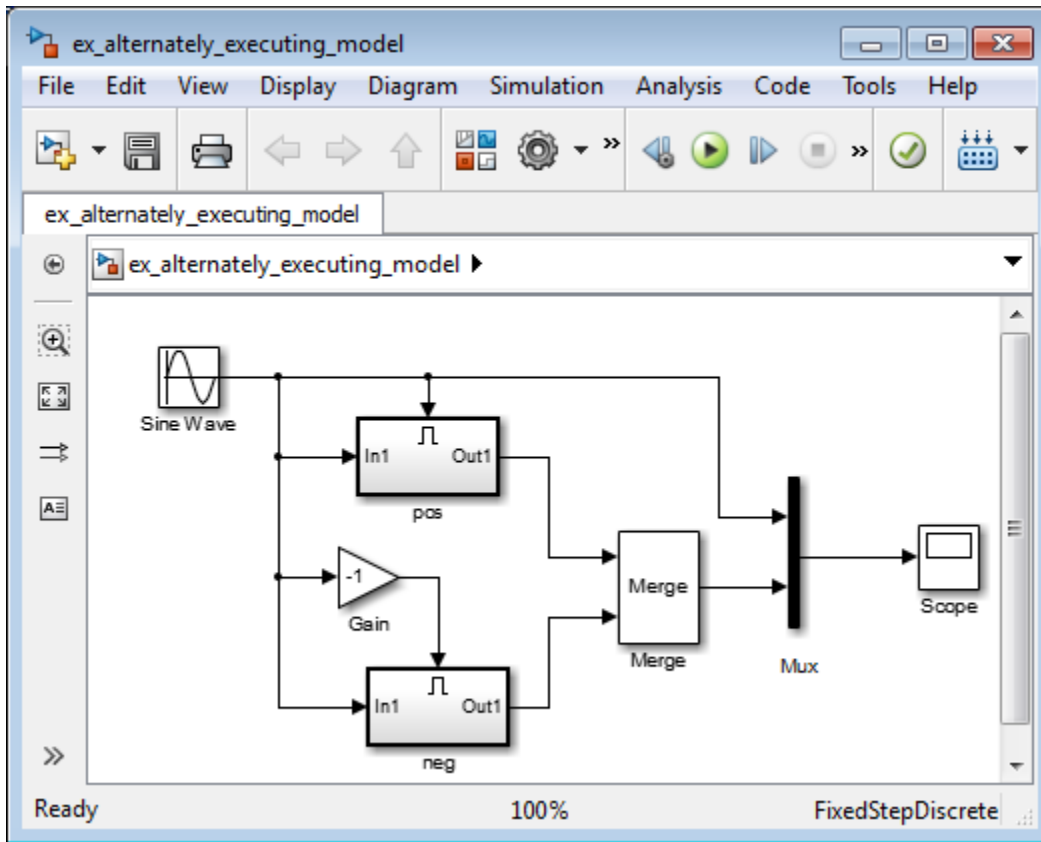

### Goto Blocks

Enabled subsystems can contain Goto blocks. However, only output ports for blocks with state can connect to Goto blocks. For an example of using Goto blocks in an enabled subsystem, see the Locked subsystem in the `sldemo_clutch` model.

### Alternately Executing Enabled Subsystem Blocks

You can use conditional subsystems with Merge blocks to create sets of subsystems that execute alternately, depending on the current state of the model.

Consider a model that uses two Enabled Subsystem blocks and a Merge block to model a full-wave rectifier (a device that converts AC current to pulsating DC current). To open model, see `ex_alternately_executing_model`.

Open the pos subsystem. The subsystem is enabled when the AC waveform is positive and passes the waveform unchanged to its output.

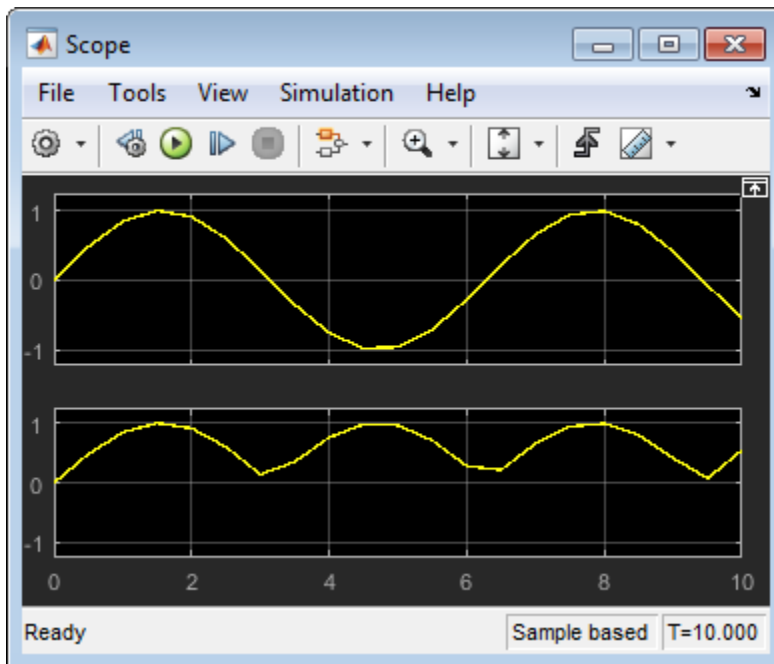

Open the neg subsystem. The subsystem is enabled when the waveform is negative and inverts the waveform.

The Merge block passes the output of the currently enabled subsystem along with the original waveform to the Scope block.

Running a simulation and then open the Scope block.

## Model Examples

For model examples, see:

- “Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-111

## Using Triggered Subsystems

A triggered subsystem is a conditionally executed atomic subsystem that runs each time the control signal (trigger signal):

- Either rises from a negative value to a positive value or zero, or rises from a zero value to a positive value.
- Either falls from a positive value to a negative value or zero, or falls from a zero value to a negative value.
- Rises or falls through or to a zero value.

Unlike an Enabled Subsystem block, a Triggered Subsystem block always holds its outputs at the last value between triggers. Also, triggered subsystems cannot reset block states when executed; the states of any discrete block are held between triggers.

### Create a Triggered Subsystem

To create a triggered subsystem:

- 1 Add a Triggered Subsystem block to your model.
  - Copy a block from the Simulink Ports & Subsystems library to your model.
  - Click the model diagram, start typing `trigger`, and then select Triggered Subsystem.

- 2 Set initial and disabled values for the Output blocks. See “Conditional Subsystem Initial Output Values” on page 10-38 and “Conditional Subsystem Output Values When Disabled” on page 10-55.
- 3 Set how the control signal triggers execution.

Open the subsystem block, and then open the parameter dialog box for the Trigger port block. From the **Trigger type** drop-down list, select:

- **rising** — Trigger execution of the subsystem when the control signal rises from a negative or zero value to a positive value.
- **falling** — Trigger execution of the subsystem when the control signal falls from a positive or zero value to a negative value.
- **either** — Trigger execution of the subsystem with either a rising or falling control signal.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers.

- 4 Output the enable control signal from the Trigger port block. Open the Trigger port block. Select the **Show output port** check box to pass the control signal into the triggered subsystem.

You can use this signal with an algorithm that depends on the value of the control signal.

- 5 From the **Output data type** drop-down list, select **auto**, **int8**, or **double**.

The **auto** option causes the data type of the output signal to be the data type (either **int8** or **double**) of the block port connected to the signal.

## Triggering with Discrete Time Systems

For a discrete time system, the trigger control signal must remain at zero for more than one time step. This triggering strategy eliminates false triggers caused by control signal sampling.

In the following timing diagram for a discrete system, a rising trigger signal (R) does not occur at time step 3. The trigger signal remains at zero for only one time step before the signal increases from zero.

## Triggered Model Versus a Triggered Subsystem

You can place a Trigger port block in a Model block (referenced model) to simplify your model design instead of using one of these blocks:

- A Triggered Subsystem block in a Model block.
- A Model block in a Triggered Subsystem block.

For information about using Trigger port blocks in referenced models, see “Conditionally Execute Referenced Models” on page 8-24.

To convert a subsystem to use model referencing, see “Convert Subsystems to Referenced Models” on page 8-18.

## Blocks in a Triggered Subsystem

All blocks in a triggered subsystem must have **Sample time** set to inherited (-1) or constant (inf). This requirement allows the blocks in a triggered subsystem to run only when the triggered subsystem itself runs. This requirement also means that a triggered subsystem cannot contain continuous blocks, such as an Integrator block.

## Model Examples

For model examples, see:

- “Simulink Subsystem Semantics”
- “Triggered Subsystems”
- “Modeling Engine Timing Using Triggered Subsystems”

## See Also

Enabled Subsystem | Triggered Subsystem | Enabled and Triggered Subsystem | Function-Call Subsystem

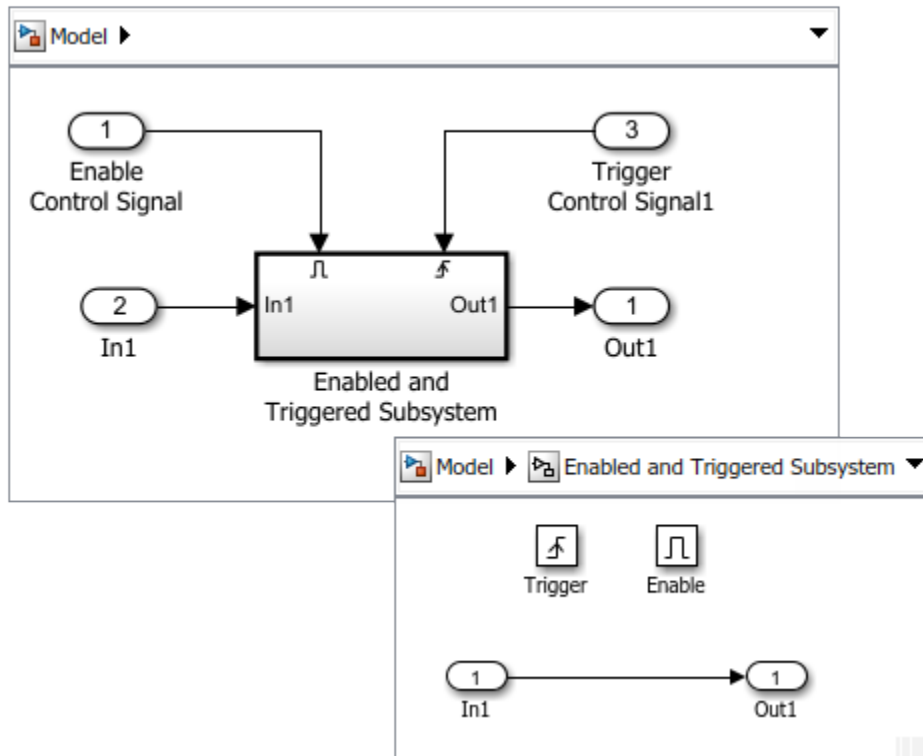

## Related Examples

- “Conditionally Executed Subsystems Overview” on page 10-3
- “Using Enabled Subsystems” on page 10-10

- “Using Function-Call Subsystems” on page 10-34
- “Conditional Subsystem Initial Output Values” on page 10-38
- “Conditional Subsystem Output Values When Disabled” on page 10-55

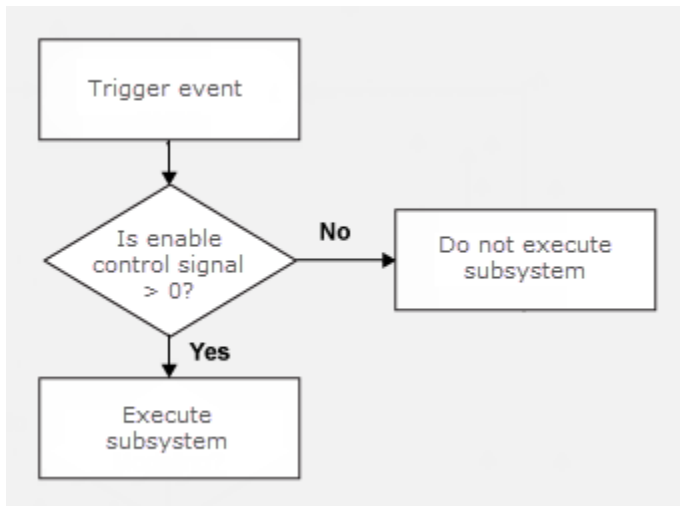

## Using Enabled and Triggered Subsystems

An Enabled and Triggered Subsystem is a conditionally executed subsystem that runs once at each simulation time step when both these conditions apply:

- Enabled control signal has a positive value.
- Trigger control signal rises or falls through zero.

An Enabled and Triggered Subsystem block contains both an Enable port block and a Trigger port block. When a trigger signal rises or falls through zero, the enable input port is checked to evaluate the enable control signal. If its value is greater than zero, the subsystem is executed. When both inputs are vectors, the subsystem executes if at least one element of each vector is nonzero.

## Creating an Enabled and Triggered Subsystem

To create an enabled and triggered subsystem:

- 1 Add an Enabled and Triggered Subsystem block to your model.
  - Copy a block from the Simulink Ports & Subsystems library to your model.
  - Click the model diagram, start typing `enabled`, and then select Enabled and Triggered Subsystem.

- 2 Set initial and disabled values for the Output blocks. See “Conditional Subsystem Initial Output Values” on page 10-38 and “Conditional Subsystem Output Values When Disabled” on page 10-55.
- 3 Set how the control signal triggers execution.

Open the subsystem block, and then open the block parameters dialog box for the Trigger port block. From the **Trigger type** drop-down list, select:

- **rising** — Trigger execution of the subsystem when the control signal rises from a negative or zero value to a positive value.
- **falling** — Trigger execution of the subsystem when the control signal falls from a positive or zero value to a negative value.
- **either** — Trigger execution of the subsystem with either a rising or falling control signal.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers.

- 4 Specify how subsystem states are handled when enabled.

Open the subsystem, and then open the Enable port block. From the **States when enabling** drop-down list, select:

- **held** — States maintain their most recent values.
- **reset** — States revert to their initial conditions if the subsystem is disabled for at least one time step.

In simplified initialization mode, the subsystem elapsed time is always reset during the first execution after becoming enabled. This reset happens regardless of whether the subsystem is configured to reset when enabled. See “Underspecified initialization detection”.

For nested subsystems whose Enable blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.

## Blocks in an Enabled and Triggered Subsystem

All blocks in an enabled and triggered subsystem must have **Sample time** set to inherited (-1 or constant (*inf*)). This requirement allows the blocks in a triggered subsystem to run only when the triggered subsystem itself runs. This requirement also means that a triggered subsystem cannot contain continuous blocks, such as an Integrator block.

## Select Subsystem Execution

A logically executed subsystem block runs one or more times at the current time step when enabled by a control block. A control block implements control logic similar to that expressed by a programming language statement (e.g., if-then, switch, while, for).

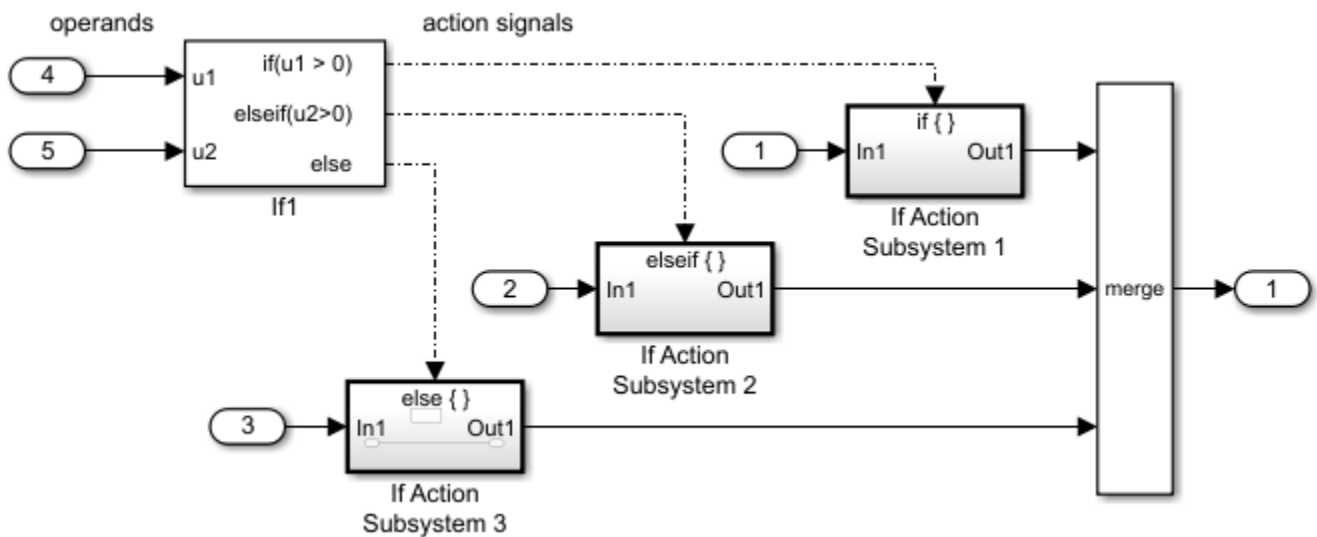

Selector subsystems are one type of logically executed subsystem that execute once during a time step in response to an action signal from a control block located external to the subsystem. Simulink supports two selector subsystem structures, if-else and switch-case.

### Models with If-Else Structures

The If Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is enabled by an If block.

An external If block controls execution. The If block evaluates a logical expression and then, depending on the result of the evaluation, outputs an action signal to a If Action Subsystem block.

Consider the following model. To open model, see `ex_if_block`.

In this model, the inputs to the If block provide the operand values for the logical expressions represented as output ports. Each output port is attached to an If Action Subsystem block. The expressions in the If block are evaluated top down starting with the `if` expression. When an expression evaluates to true, its corresponding If Action Subsystem is executed and the remaining expressions are not evaluated.

The *if-else* structure in the model can be represented with the following pseudo code.

```
IF u1 > 0 THEN
  Subsystem 1
ELSEIF u2 > 0
  Subsystem 2
ELSE
  Subsystem 3
END IF
```

## Create Model with If-Else Structure

To create the example model, use the following procedure.

- 1 Place an If block in the Simulink Editor. Double-click the block to open the block parameters dialog box.
- 2 In the **Number of inputs** box, enter 2.

Two input ports are added to the block. The inputs ports are for signals containing operand values, not necessary the number of operands. An input signal can be a vector. For example, you could specify the fifth element of a vector  $u$  in an expression as  $u(5) > 0$ .

- 3 In the **If expression** text box, enter  $u1 > 0$ .

An output port is added to the block with the label  $if(u1 > 0)$ . This port is the only required output for an If block.

- 4 In the **Elseif expressions** text box, enter  $u2 > 0$ .

You can enter multiple elseif expressions with a comma separating the expressions. Each expression adds an output port to the If block with a label of the form  $elseif(expression)$ .

- 5 Check the **Show else condition** check box.

An output port is added to the block with the label `else`.

- 6 Add three If Action Subsystem blocks.

These blocks are Subsystem blocks with an Action Port block. When you place an Action Port block inside a subsystem, an input port named Action is added to the block.

- 7 Connect each output port from the If block to the action port of an If Action Subsystem block.

When you make the connection, the icon for the If Action Subsystem block is renamed to the type of expression that attached to it.

- 8 In each If Action Subsystem block, enter the Simulink blocks to be executed for the condition it handles.
- 9 Connect outputs from If Action Subsystem blocks to a Merge block.
- 10 Run a simulation.

The action signal lines between the If block and the If Action Subsystem blocks change from a solid to a dashed line.

---

**Note** All blocks in an If Action Subsystem block driven by an If block must run at the same rate as the driving block.

---

## Models with Switch Case Structure

The Switch Case Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is enabled by a Switch Case block.

An external Switch Case block controls execution. The Switch Case block evaluates a case index and then, depending on the selected case, outputs an action signal to a Switch Case Action Subsystem block.

Consider the following model with a *switch* structure. To open model, see `ex_switch_case_block`.

In this model, the input to the Switch Case block provides the index value for selecting a case represented as output ports. Each output port is attached to an If Action Subsystem block. When a case is selected, its corresponding If Action Subsystem is executed.

The *switch* structure in the model can be represented with the following pseudo code.

```

CASE u1
  u1 = 1:
    subsystem_1
    break
  u1 = 2 or 3:
    subsystem_2_3
    break
  u1 = OTHER VALUES:
    subsystem_default
    break
END CASE

```

### Create Model with Switch Case Structure

To create the example model, use the following procedure.

- 1 Place a Switch Case block in the Simulink Editor. Double-click the block to open the block parameters dialog box.
- 2 In the **Case conditions** box, enter {1, [2,3]}.

Two cases are defined. The first case when the input value is 1, and the second case when the input value is 2 or 3. Cases can be single or multivalued and appear as output ports on the Switch Case block. Non-integer input values are truncated to integers.

- 3 Select the **Show default case** check box.

An output port labeled `default:` is added to the block. This port sends an action signal if no other cases are selected.

- 4 Add three Switch Case Action Subsystem blocks.

These blocks are Subsystem blocks with an Action Port block. When you place an Action Port block inside a subsystem, an input port named Action is added to the block.

- 5 Connect each output port from the Switch Case block to the action port of an Switch Case Action Subsystem block.

When you make the connection, the icon for the Switch Case Action Subsystem block is renamed to the type of expression attached to it.

- 6 In each Switch Case Action Subsystem block, enter the Simulink blocks to be executed for the case it handles.
- 7 Run a simulation.

The action signal lines between the Switch Case block and the Switch Case Action Subsystem blocks change from a solid to a dashed line.

---

**Note** After the subsystem for a particular case executes, an implied break terminates the execution of the Switch Case block. Simulink Switch Case blocks do not exhibit the fall-through behavior of C switch statements.

## Iterate Subsystem Execution with While Iterator and For Iterator Subsystems

### In this section...

“Models with While Structures” on page 10-28

“Model with For Structures” on page 10-30

*Iterator subsystems*, such as the While Iterator and For Iterator subsystems, are a type of logically executed subsystem that executes one or more times during a time step in response to a control block internal to the subsystem block. The control block implements control logic similar to that expressed by a programming language construct such as a `while` loop or a `for` loop.

For information about the For Each subsystem, which partitions input signals or mask parameters into individual elements or subarrays and applies an algorithm to each, see For Each Subsystem.

**Note** The While Iterator Subsystem and For Iterator Subsystem blocks must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all blocks within the subsystem must be either inherited (-1) or constant (inf).

### Models with While Structures

The While Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step while a logical (Boolean) expression is true.

Open the model `ex_while_iterator_block`.

An input of 1 (true) to the While Iterator block activates the subsystem. At each time step, the current iterative number is added to a running total until a maximum sum is reached.

The *while* structure in the model can be represented with the following pseudo code.

```

maximum_sum = 10
sum = 0
iteration_number = 1
condition = TRUE

WHILE (condition is TRUE) AND (iteration_number <= maximum_iterations)
    sum = sum + iteration_number
    IF (sum > maximum_sum) THEN
        condition = FALSE
    END IF
    iteration_number = iteration_number + 1
END WHILE

```

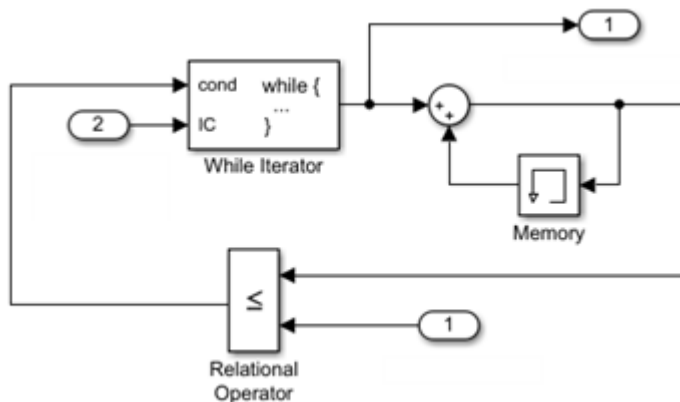

### Create Model with While Structure

To create the example model, use the following procedure.

- 1 Place a While Iterator Subsystem block in the Simulink Editor. Double-click the subsystem block to display its contents.

- 2 Double-click the While Iterator block to open its block parameters dialog box. Set the **Maximum number of iterations** to 20 and **States when starting** to reset. Select the **Show iteration number** port check box.
- 3 Add Memory, Relational Operator, and Sum blocks. Connect blocks as shown. For the Memory block, select the **Inherit sample time** check box.

The iteration number from the output of the While Iterator block is added to its previous value until the sum is greater or equal to the maximum sum from Inport block 1.

- 4 Navigate to the top level of the model.
- 5 Connect a Constant block to input port 2. This block provides the *initial logical condition* value for the While Iterator block. Set the **Constant value** to any non-zero number.

The While Iterator block requires an initial logical condition (input port labeled IC) for its first iteration. This signal enables the While Iterator Subsystem block and must originate from outside the subsystem. If this value is nonzero, the first iteration takes place.

- 6 Connect a second Constant block to input port 1. This block provides a maximum value for the iterative algorithm. The algorithm adds successive integers until a maximum value is reached.
- 7 Connect a Display block to output port 1. This block shows the number of iterations from the While Iterator block output port.
- 8 Run a simulation.

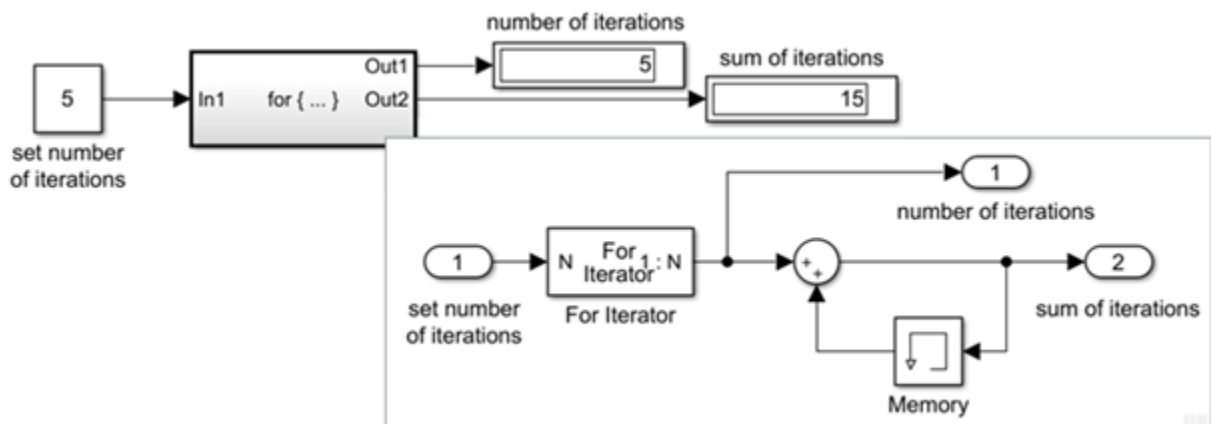

During a single time step, the first four iteration numbers are added for a total sum (10). With the fifth iteration, the sum (15) is greater than the maximum sum (10), the iterations stop, and the block waits for the next time step.

**Note** Simulation time does not advance during iterative executions of a While Iterator Subsystem block. Nevertheless, blocks in the subsystem treat each iteration as a time step. As a result, in a While Iterator Subsystem block, the output of a block with states (that is, a block whose output depends on its previous input), reflects the value of its input at the previous iteration of the `while` loop. The output does *not* reflect the block input at the previous simulation time step. For example, a Unit Delay block in a While Iterator subsystem outputs the value of its input at the previous iteration of the `while` loop, not the value at the previous simulation time step.

## Model with For Structures

The For Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step for a specified number of iterations.

Open the model `ex_for_iterator_block`.

The input to the For Iterator block specifies the number of iterations. At each time step, the current iterative number is added to a running total for 5 iterations.

The `for` structure in the model can be represented with the following pseudo code.

```
number_of_iterations = 5
sum = 0
```

```

FOR iteration_number = 1 TO number_of_iterations
    sum = sum + iteration_number
END FOR

```

### Create Model With For Structure

To create the example model, use the following procedure.

- 1 Place a For Iterator Subsystem block in the Simulink Editor. Double-click the subsystem block to display its contents.

- 2 Double-click the For Iterator block to open its block parameters dialog box. Set **States when starting** to reset and **Iteration limit source** to external.
- 3 Add Memory, Sum, and Outport blocks. Connect blocks as shown. For the Memory block, select the **Inherit sample time** check box.

The iteration number from the output of the For Iterator block is added to its previous value for the specified number of iterations from Inport block 1.

- 4 Navigate to the top level of the model.
- 5 Connect a Constant block to input port 1. This block provides the number of iterations for the For Iterator block. Set the **Constant value** to 5.
- 6 Connect Display blocks to output ports 1 and 2. These blocks shows the number of iterations from the For Iterator block output port and the sum from the Memory block.
- 7 Run a simulation.

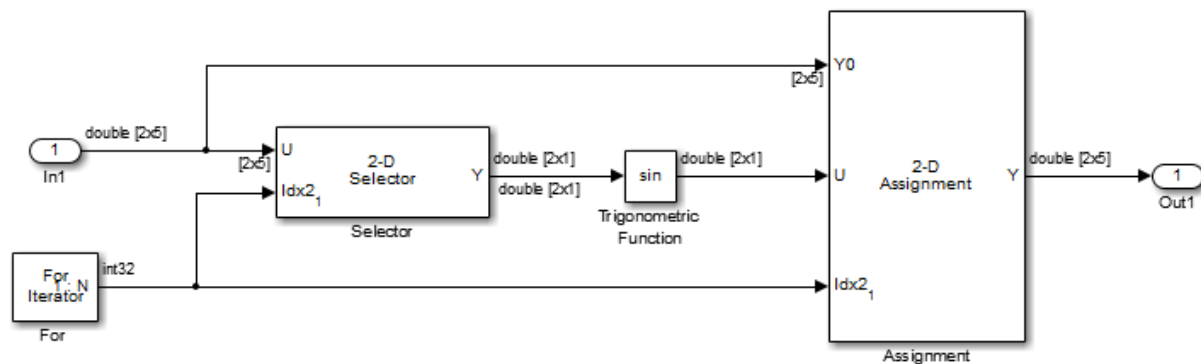

During each time step, the first five iteration numbers are added for a total sum (15).

### Using Assignment Blocks

The For Iterator block works well with the Assignment block to reassign values in a vector or matrix. The following example shows the use of a For Iterator block. Note the matrix dimensions in the data being passed.

ex\_for\_subsys\_assign ▶ For subsystem

The example outputs the sine value of an input 2-by-5 matrix (2 rows, 5 columns) using a For Iterator subsystem containing an Assignment block. The process is as follows.

- A 2-by-5 matrix is input to a Selector block and an Assignment block.
- The Selector block strips off a 2-by-1 matrix from the input matrix at the column value indicated by the current iteration value of the For Iterator block.
- The sine of the 2-by-1 matrix is taken.
- The sine value 2-by-1 matrix is passed to the Assignment block.
- The Assignment block, which takes the original 2-by-5 matrix as one of its inputs, assigns the 2-by-1 matrix back into the original matrix at the column location indicated by the iteration value.

Note that the Assignment block copies the first input ( $Y0$ ) to the output ( $Y$ ) only on the first iteration. The value of the second input ( $U$ ) is copied to the output on the first and each subsequent iteration. All of these operations take place during a single time step.

The rows specified for reassignment in the parameter dialog box for the Assignment block in the example are [1,2]. Because there are only two rows in the original matrix, you could also have specified -1 for the rows (that is, all rows).

**Note** The Trigonometric Function block is already capable of taking the sine of a matrix. The example uses the Trigonometric Function block only as an example for changing each element of a matrix with the collaboration of an Assignment block and a For Iterator block.

## Using Function-Call Subsystems

A Function-Call Subsystem block is a conditionally executed subsystem that runs each time the control port receives a function-call event. A Stateflow chart, Function-Call Generator block, MATLAB Function block, S-Function block, or Hit Crossing block can provide function-call events.

A function-call subsystem is analogous to a function in a procedural programming language. Invoking a function-call subsystem executes the output methods of the blocks within the subsystem in execution order. For an explanation of the Function-Call Subsystem block parameters, see [Subsystem](#).

### Creating a Function-Call Subsystem

To create a function-call subsystem:

- 1 Add a Function-Call Subsystem block to your model.
- 2 Open the subsystem block. Add a block diagram defining the algorithm that is executed when the subsystem receives a function-call event.
- 3 Set initial and disabled values for the Outputport blocks. See “Conditional Subsystem Initial Output Values” on page 10-38 and “Conditional Subsystem Output Values When Disabled” on page 10-55.
- 4 Set how subsystem states are handled when the subsystem is executed:

Open the subsystem block, then open the block parameters dialog box for the Trigger block. From the **States when enabling** drop-down list, select an option:

- held — States maintain their most recent values.
- reset — States set to their initial conditions.

- **inherit** — Use the held or reset setting from the parent subsystem initiating the function-call.

For nested subsystems whose Function-Call Subsystem blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem. See Trigger.

- 5 Attach a function-call initiator to the function-call input port.

If you attach an Inport block, open the block, select the Signal Attributes tab, then select the **Output function call** check box.

## Sample Time Propagation in a Function-Call Subsystem

Configure a Function-Call Subsystem block by setting the **Sample time type** of its Trigger Port block to **triggered** or **periodic**.

- A triggered (aperiodic) function-call subsystem can execute zero, one, or multiple times during a time step.

If a function-call subsystem is executed by a root-level function-call Inport block with a discrete sample time, multiple function-calls during a time step are not allowed. To allow multiple function-calls, set **Sample time** to **-1** (inherited), and set the sample time for all blocks in the function-call subsystem to **-1** (inherited).

- A periodic function-call subsystem executes once during each time step when it receives a function-call signal, and does not execute at a time step when it does not receive a function-call signal. Set the sample time for all blocks in the function-call subsystem to **-1** (inherited).

---

**Note** During range checking, the minimum and maximum parameter settings are back-propagated to the actual source port of the function-call subsystem, even when the function-call subsystem is not enabled.

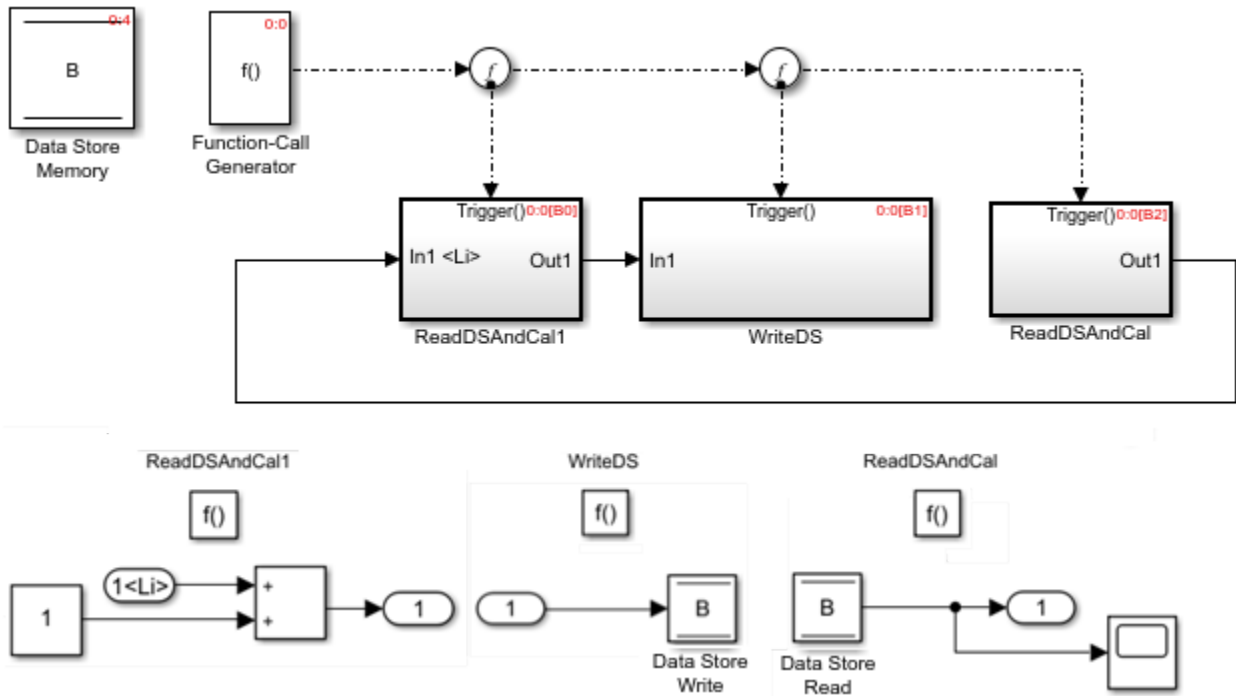

To prevent this back propagation:

- 1 Add a Signal Conversion block and a Signal Specification block after the source port.
  - 2 Set the **Output** of the Signal Conversion block to **Signal copy**.
  - 3 Specify the minimum and maximum values for the Signal Specification block instead of specifying them on the source port.
- 

## Latched Input Data for Function-Call Subsystems

You can latch input data for Inport blocks within Function-Call Subsystem blocks to ensure data integrity. To latch input data, in the Inport block parameters, select **Latch input for feedback signals of function-call subsystem outputs**.

In the following model, input data for the Inport block in the function-call subsystem `ReadDSAndCall` is latched (indicated by `<Li>`) and cannot change during the execution of the subsystem. The Data Store Read and Data Store Write blocks are called within each function-call subsystem. The first and second function-calls write data and the last function-call reads data to the Data Store Memory block.

**Note** The root-level data Inport block connected to an internal Inport block is also latched if all of the blocks connected to the root-level block are latched. For more information, see “Option to latch input for feedback signals of function-call subsystem outputs”.

**Note** Data transfer signals are unprotected in the generated code by default. Use custom storage classes to prevent data corruption in these signals due to preemption of the current task in the target environment.

- “Conditionally Executed Subsystems Overview” on page 10-3
- “Conditional Subsystem Initial Output Values” on page 10-38
- “Conditional Subsystem Output Values When Disabled” on page 10-55

## Conditional Subsystem Initial Output Values

To initialize the output values for a conditional subsystem, initialize Outputport blocks within the subsystem by using one of these methods:

- Inherit initial output values from input signals connected to the Outputport blocks.
- Specify initial output values using Outputport block parameters.

---

**Note** If the conditional subsystem is driving a Merge block in the same model, you do not need to specify an initial condition for the subsystem Outputport block.

---

### Inherit Initial Output Values from Input Signals

Simulink attempts to use input signals connected to conditional subsystem Outputport blocks to initialize output values. This behavior is seen after setting the Outputport block parameter **Source of initial output value** to `Input signal`. The same behavior is seen when **Source of initial output value** is set to `Dialog` and **Initial output** is set to `[]`.

Valid input signals for setting initial output values include:

- Output ports from another conditionally executed subsystem.
- Output ports from a Model block with a Trigger block with the **Trigger type** set to `function-call`.
- Merge blocks.
- Constant blocks.
- IC (initial condition) blocks.
- Simulink signal objects attached to the signal line connected to the Outputport block. If the `InitialValue` parameter is defined, Simulink uses this value.
- Stateflow charts.
- C Function blocks.

If the input signal is from a block not listed here, the Outputport block uses the default initial value of the output data type.

When a conditional subsystem Outputport block inherits its initial output value, after the model has been updated or run, an **IC** badge is displayed next to the Outputport block.

You can also determine whether a conditional subsystem Outport block inherits its initial output value by using the `Simulink.getOutportInheritsInitialValue` function.

---

**Note** If you are using classic initialization mode, selecting `Input signal` causes an error. To inherit the initial output value from an input signal, set the **Source of initial output value** parameter to `Dialog`, set **Output when disabled** to `held`, and set **Initial output** to the empty matrix `[]`. The  badge is not displayed in classic initialization mode. See “Classic Initialization Mode” on page 10-57.

---

## Specify Initial Output Values Using Dialog Parameters

Explicitly set the initial output values in cases where you want to:

- Test the behavior of a model with various initial values.
- Set initial values to steady state and reduce simulation time.
- Eliminate having to trace input signals to determine the initial output values.

To specify initial output values:

- 1 Open the dialog box for an Outport block within a conditional subsystem.
- 2 From the **Source of initial output value** list, select `Dialog`.
- 3 In the **Initial output** box, enter the initial value.

## Rate-Based Models Overview

You can control the execution of model components (Subsystem and Model blocks) by using export-function models or rate-based models. Benefits of scheduling components are:

- Full control over scheduling of model components rather than letting Simulink implicitly schedule the components.
- No need to deal with data dependency issues between components. That is, there are only data transfers.

### See Also

### More About

- “Sorting Rules for Explicitly Scheduled Model Components” on page 10-48

## Create A Rate-Based Model

A rate-based model is a model with explicitly scheduled subsystems. You can schedule a subsystem with a periodic execution rate by specifying the **Sample time** parameter for an Inport block connected to the Subsystem block, the Subsystem block, or a block within the Subsystem block where Sample time can be specified (for example, a Delay block).

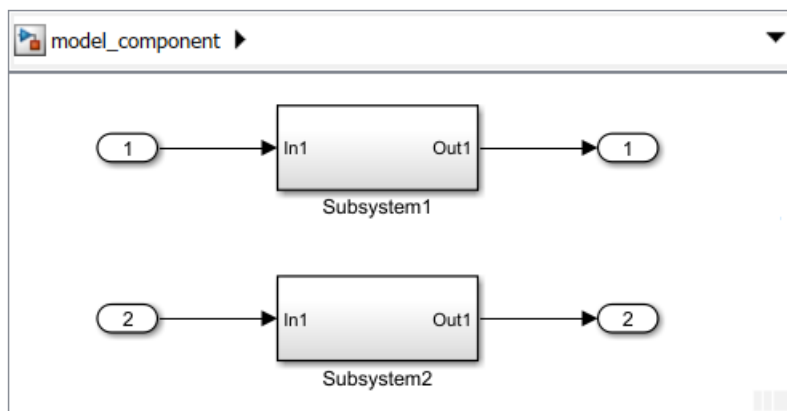

To open a completed rate-based model, see `ex_rate_based_model`.

---

**Note** Using Continuous time blocks such as Integrator blocks are not allowed. Instead use discrete time equivalent blocks

---

Consider the following model with two atomic Subsystem blocks. Subsystem1 multiplies its input by 2 while Subsystem2 multiplies its input by 4.

- 1 Open the Inport 1 dialog box. On the Signal Attributes tab, set the **Sample time** to 0.2.
- 2 Open the Inport 2 dialog box. On the Signal Attributes tab, set the **Sample time** to 0.4.
- 3 If a rate-based model has multiple rates, single tasking is not allowed. Select the check box for the configuration parameter **Treat each discrete rate as a separate task**.

### Multi-Tasking and Multi-Rate Model for Code Generation

Selecting single-tasking versus multi-tasking and single-rate versus multi-rate controls entry points in the generated code.

Configuration Parameter	Explicitly Scheduled Rates	Generated Code Entry Points
Single-tasking <input type="checkbox"/> Treat each discrete rate as a separate task	Single-rate Subsystem1 Sample time (-1 for inherited): <input type="text" value="0.2"/> Subsystem2 Sample time (-1 for inherited): <input type="text" value="0.2"/>	One entry-point function called periodically every 0.2 seconds <pre>void model_component_step(void) {     model_component_Y.Out1 = 2.0 * model     model_component_Y.Out2 = 4.0 * model }</pre>
Single-tasking <input type="checkbox"/> Treat each discrete rate as a separate task	Multi-rate Subsystem1 Sample time (-1 for inherited): <input type="text" value="0.2"/> Subsystem2 Sample time (-1 for inherited): <input type="text" value="0.4"/>	One entry-point function called periodically every 0.2 seconds, a schedule counter in the function determines which rates execute at which sample times. <pre>void model_component_step(void) {     model_component_Y.Out1 = 2.0 * model     if (model_component_M-&gt;Timing.TaskCo         model_component_Y.Out2 = 4.0 * m     rate_scheduler(); }</pre>
Multi-tasking <input checked="" type="checkbox"/> Treat each discrete rate as a separate task	Single-rate Subsystem1 Sample time (-1 for inherited): <input type="text" value="0.2"/> Subsystem2 Sample time (-1 for inherited): <input type="text" value="0.2"/>	One entry-point function, the same code as single-tasking with a single-rate. Not a use case, but the code generates without an error

Configuration Parameter	Explicitly Scheduled Rates	Generated Code Entry Points
Multi-tasking <input checked="" type="checkbox"/> Treat each discrete rate as a separate task	Multi-rate Subsystem1 Sample time (-1 for inherited): <input type="text" value="0.2"/> Subsystem2 Sample time (-1 for inherited): <input type="text" value="0.4"/>	Two entry-point functions one called periodically every 0.2 seconds and the other called periodically every 0.4 seconds. Rates are executed using a prioritized preemptive multitasking scheme. Faster rates are assigned higher priorities and thus executed first. <pre> void model_component_step0(void) {     model_component_Y.Out1 = 2.0 * model }  void model_component_step1(void) {     model_component_Y.Out2 = 4.0 * model }                     </pre>

## Test Rate-Based Model Simulation Using Function-Call Generators

<b>In this section...</b>
---------------------------

“Create Test Model That References a Rate-Based Model” on page 10-44
--

“Simulate Rate-Based Model” on page 10-45
---

This topic describes how to reference a rate-based model in a test model, and then add periodic function-call event ports to the test model for simulation. To open a completed test harness model, see `ex_model_test_harness_with_subsystems`.

### Create Test Model That References a Rate-Based Model

Testing a rate-based model includes referencing the model from a Model block in a test model, adding periodic function-call event ports to the Model block, and then connecting function-calls to the ports.

- 1 Create a Simulink model.
- 2 Add a Model block and open its Block Parameters dialog box.
- 3 In the **Model name** box, enter the file name for the rate-based model.
- 4 Select the **Schedule rates** check box.

Periodic function-call event ports are added to the Model block with the sample times you specified for the Inport blocks connected to the Subsystem blocks.

- 5 Specify the execution rate using function-call initiators (Function-Call Generator blocks or Stateflow charts). The function-call events and scheduling of the events are located outside of the Model block referencing the rate-based model.

In this example, add Function-Call Generator blocks. Open the Block Parameters dialog boxes for the blocks and specify **Sample time**.

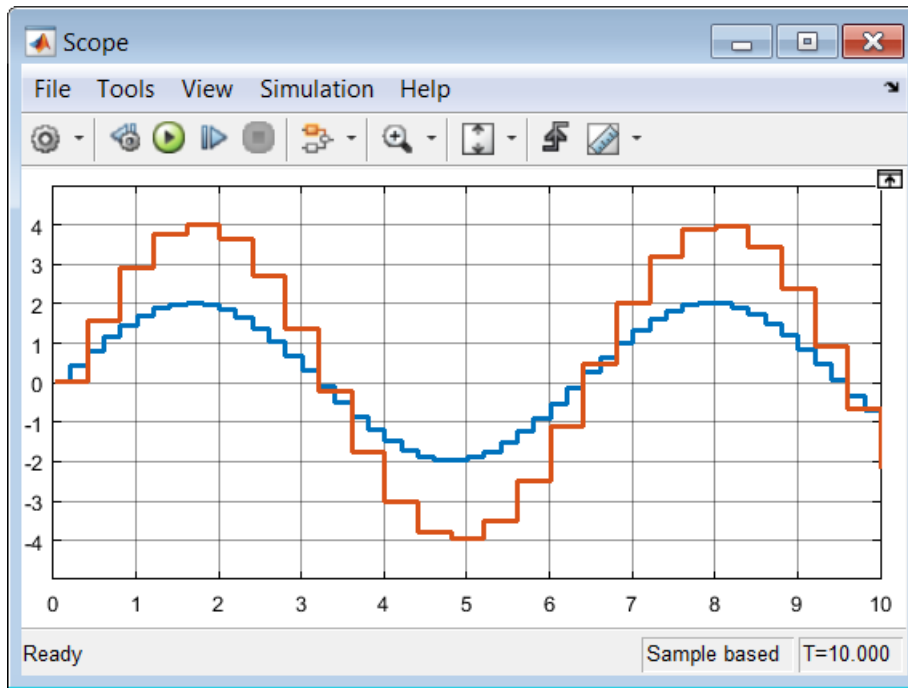

Subsystems or referenced models in a rate-based model with the same sample time must have a common rate initiator. This requirement includes periodic scheduled subsystems and event-driven Function-Call Subsystem blocks with the same rate.

- 6 Use a fixed-step solver for simulation. Set the configuration parameters **Type** to Fixed-step, **Solver** to auto, and **Fixed-step size** to auto.

## Simulate Rate-Based Model

Simulate the behavior of a rate-based model from the test model.

- 1 Run a simulation. Some common compile and run-time errors are caused by:
  - A periodic event port that is not connected to a function-call initiator with the same specified sample time.
  - A scheduled Inport block (**Sample time** parameter set to a value) in the referenced component model that does not specify one of the periodic function-call event port rates (sample times specified in the **Port discrete rates** table).
- 2 Observe the behavior of the component model. Open the Scope block.

## Generate Code from Rate-Based Model

Generate code from the rate-based model, not from the model test harness. For scheduled subsystems with different discrete rates, multi-tasking is required and the resulting code has separate entry points.

- 1 Generate code for the component model. Display the **C Code** tab by selecting the **Apps** tab, and then in the **Apps** section, select **Embedded Coder** . On the **C Code** tab, select **Generate Code** .
- 2 Open the code generation report. On the **C Code** tab, select **Open Latest Report**.

Function: <a href="#">model_component_step</a>

Function: <a href="#">model_component_step</a>				
Prototype	<b>void model_component_step(int_T tid)</b>			
Description	Output entry point of generated code			
Timing	Must be called periodically, every 0.4 seconds			
Arguments	<b>#</b>	<b>Name</b>	<b>Data Type</b>	<b>Description</b>
	<b>1</b>	tid	int_T	TID1
Return value	None			
Header file	<a href="#">model_component.h</a>			

## Sorting Rules for Explicitly Scheduled Model Components

Simulink determines the execution order for model components, that is, subsystems and referenced models.

### Export-Function Models

Export-function models include Function-Call Subsystem blocks, function-call Model blocks, Simulink Function blocks at the root level, and S-Function blocks invoked by function-call root Inport blocks.

Root function-call Inport blocks are sorted with the following rules:

- First compare block priorities. The block with the highest priority (smallest number) is sorted before the others.
- If block priorities are the same, compare sample times. The block with a faster rate (smaller sample time value) is sorted before the other.
- If sample times are the same, compare input port numbers. The block with the smaller port number is sorted before the other.
- If the `OrderFunctionsByDependency` parameter is set to 'on', blocks that have the same sample times are further sorted based on any relative data dependency of the functions to which the blocks are connected. See "Execution Order for Root-Level Function-Call Inport Blocks" on page 10-100.

Root Simulink Function blocks are sorted after root function-call Inport blocks.

## Test Harness for Export Function Models with Strict Scheduling

Reference the export-function model in a test harness and connect ports to Function Generator blocks.

If you select the check box for the configuration parameter **Enable strict scheduling checks for referenced models**, both compile time and run-time checks ensure initiators will invoke function-calls based on the pre-defined scheduling order. Initiators are sorted based on their sample time priorities. For this example, the scheduling order and the sample time priorities do not match. The model `mHarness_ExpFcnMdl` displays an error.

The Model block '[mHarness\\_ExpFcnMdl/Model](#)' requires that function-call input port 'fcIn2' execute before function-call input port 'fcIn3'. However, this execution order cannot be honored because the task priority of the sample time for function-call input port 'fcIn2' is lower than that of function-call input port 'fcIn3'. The two function-call input ports are driven by the function-call initiator blocks, '[mHarness\\_ExpFcnMdl/FcnCallGenOp4](#)' and '[mHarness\\_ExpFcnMdl/FcnCallGenOp3](#)', respectively. Consider using a function-call initiator with faster sample time (higher priority) or higher asynchronous task priority for function-call input port 'fcIn2'.

▼ **Suggested Actions**

- To disable this error message, clear the parameter 'Enable strict scheduling checks for referenced models' in the Model Referencing page of the Configuration Parameters dialog. Fix
- Alternatively, consider using a Function-Call Split block or a common function-call initiator block such as a Stateflow chart to schedule function-calls for these two input ports in the required order.

## Test Harness for Export-Function Models Without Strict Scheduling

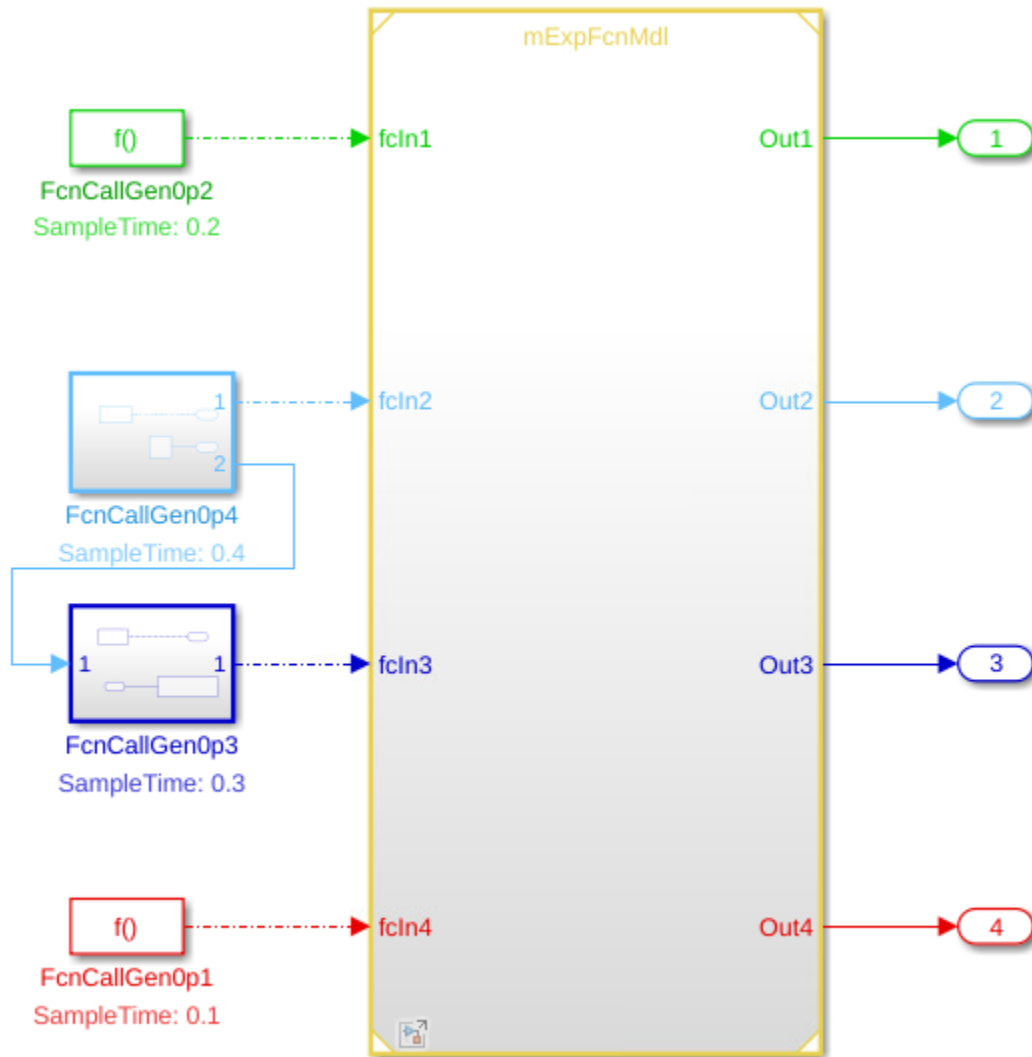

Reference the export-function model in a test harness and connect ports to Function-Call Generator blocks.

If you clear the check box for the configuration parameter **Enable strict scheduling checks for a referenced model** and the test harness model is in signal taking mode, the function-call initiators are sorted based on their sample time priorities. For this example, the execution order is `FcnCallGen0p1 > FcnCallGen0p2 > FcnCallGen0p3 > FcnCallGen0p1`.

### Data Dependency Error Caused by Data Sorting Rules

Consider a model where the output from one function-call initiator is the input to another.

The function-call initiator `FcnCallGen0p3` should be executed before `FcnCallGen0p4` based on their sample times. However, because `FcnCallGen0p4` is also a source for `FcnCallGen0p3` a data dependency occurs and Simulink displays an error.

## ▼ Update Diagram 4

11:24 PM Elapsed: 0.441sec

The function-call initiators invoking the export-function model referenced by Model block '[#Harness\\_ExpFcnMdl\\_Loop/Model](#)' must execute in the order of their sample times or task priorities. In a model with a single task, this implies that '[#Harness\\_ExpFcnMdl\\_Loop/FcnCallGen0p3](#)' must execute before '[#Harness\\_ExpFcnMdl\\_Loop/FcnCallGen0p4](#)'. However, applying this rule caused a data dependency violation. Consider clearing the 'Configuration Parameters' > 'Solver' > 'Treat each discrete rate as a separate task' option or tracing the data connections between the blocks listed below to resolve the data dependency loop.

Component: Simulink | Category: Model error

Block '[#Harness\\_ExpFcnMdl\\_Loop/FcnCallGen0p3](#)' is involved in the loop.

Component: Simulink | Category: Model error

Block '[#Harness\\_ExpFcnMdl\\_Loop/FcnCallGen0p4](#)' is involved in the loop.

Component: Simulink | Category: Model error

Block '[#Harness\\_ExpFcnMdl\\_Loop/Model](#)' is involved in the loop.

## Test Harness for Models with Initialize, Reset, and Terminate Function Blocks

If a Model block references a model that has an initialize, reset, or terminate ports, the function-call initiators connected to these ports have a higher priority than other function-call input ports. For example, export-function models, rate-based models, and JMAAB-B (Simulink Coder) models can have other function-call input ports. Simulink sorts function-call initiators in the following order:

- Initialize, reset, and then terminate ports.
- If there is more than one reset port, initiators to those reset ports are not sorted. For example, if a model has one initialize port driven by block A, two reset ports driven by blocks B and C, and one terminate port driven by block D, then Simulink sorts in the order A, B or C, and then D. B and C are sorted using general sorting rules.

## Initiators for Model Block in Test Harness

Add function-call event ports to a Model block in a test harness that references a rate-based model or JMAAB-B model by selecting the Model block parameter **Schedule rates**.

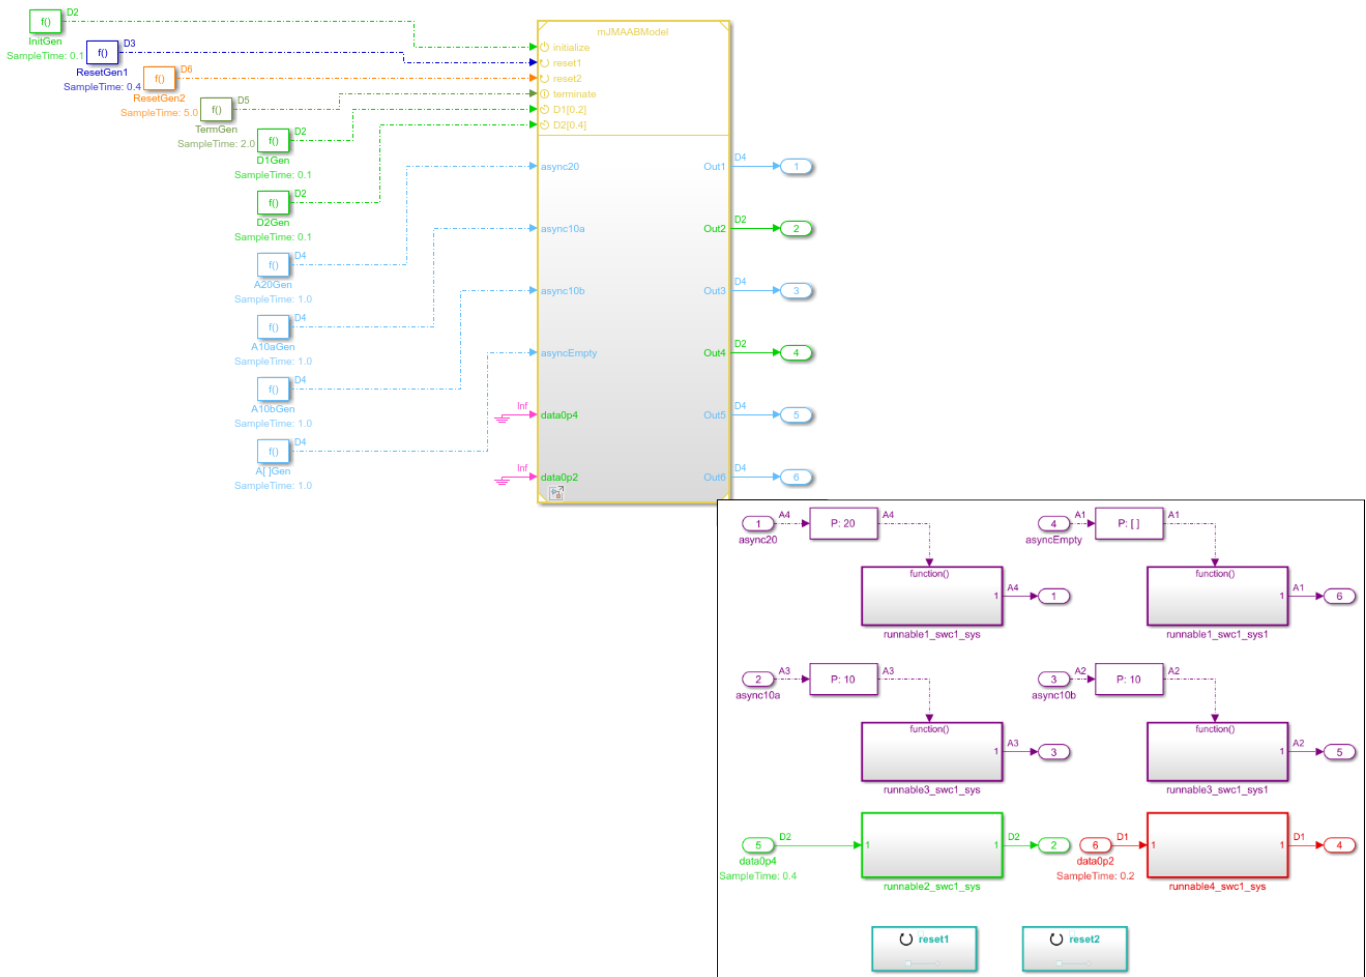

In a single tasking model, all discrete rates are in the same task. In a multi-tasking model, discrete rates with the same value execute in the same task. Simulink sorts test harness initiators in the same task in the following order:

- Initialize, reset, and then terminate ports.
- Function-call input ports mapped to asynchronous function-call root Inport blocks if adapted model is a JMAAB-B model. Among those "async" function-call input ports, use the task priorities specified by the Asynchronous Task Specification block connected to the function-call root Inport block inside the referenced model to compare ports. In the following cases, do not compare ports:
  - For two "async" function-call input ports with the same task priorities.
  - For "async" function-call input ports with an empty (unspecified) task priority

- Periodic function-call event input ports mapped to discrete rates. Use rate monotonic scheduling (RMS) rules to compare.

In a single tasking model, all initiators are in the same task:

- InitGen > ResetGen1 or ResetGen2 > TermGen > A10aGen or A10bGen or A[]Gen > D1Gen > D2Gen
- A10aGen or A10bGen > A20Gen
- Could swap relative ordering of (ResetGen1, ResetGen2) or (A10aGen, A10bGen), or (A[]Gen, A20Gen), etc.

In a multi-tasking model, initiators of the same color are in the same task.

- InitGen > D1Gen > D2Gen
- A10aGen or A10bGen > A20Gen

## Conditional Subsystem Output Values When Disabled

Although a conditional subsystem does not execute while it is disabled, the output signal is still available to other blocks. When a conditional subsystem is disabled and you have specified not to inherit initial conditions from an input signal, you can hold the subsystem outputs at their previous values or reset them to their initial conditions.

To specify output values when disabled:

- 1 Open the dialog box for an Output block in a conditional subsystem.
- 2 From the **Source of initial output value** drop-down list, select **Dialog**.
- 3 From the **Output when disabled** drop-down list, select one of these options:
  - **held** — Maintain the most recent value.
  - **reset** — Use the initial condition.

---

**Note** If you are connecting the output of a conditionally executed subsystem to a Merge block, set **Output when disabled** to **held** to ensure consistent simulation results.

If you are using simplified initialization mode, you must select **held** when connecting a conditionally executed subsystem to a Merge block. For more information, see “Underspecified initialization detection”.

---

- 4 In the **Initial output** box, enter the initial value.

---

**Note** If an Output block in an Enabled Subsystem resets its output when disabled at a different rate from the execution of the subsystem contents, both the disabled and execution outputs write to the subsystem output. This behavior can cause unexpected results.

---

## Simplified Initialization Mode

Initialization mode controls how Simulink handles:

- Initialization values for conditionally executed subsystems.
- Initial values for Merge blocks.
- Discrete-Time Integrator blocks.
- Subsystem elapsed time.

The default initialization mode for a model is simplified. This mode uses enhanced processing to improve consistency of simulation results and helps to:

- Attain the same simulation results with the same inputs when using the same blocks in a different model.
- Avoid unexpected changes to simulation results as you modify a model.

### When to Use Simplified Initialization

Use simplified initialization mode for models that contain one or more of the following blocks:

- Conditional subsystem blocks.
- Merge blocks. If a root Merge block has an empty matrix ([]) for its initial output value, simplified mode uses the default ground value of the output data type.
- Discrete-Time Integrator blocks. Simplified mode always uses the initial value as both the initial and reset value for output from a Discrete-Time Integrator block.

Use simplified mode if your model uses features that require simplified initialization mode, such as:

- Specify a structure to initialize a bus.
- Branch merged signals inside a conditional subsystem.

### Set Initialization Mode to Simplified

Simplified mode is the default initialization mode when creating a new Simulink model. If your model is using classic mode, you might need to make changes after you select simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-70.

- 1 Open the Configuration Parameters dialog box. On the **Modeling** tab and from the **Setup** section, select **Model Settings** .
- 2 In the search box, enter **Underspecified initialization detection**.
- 3 From the drop-down list, select **Simplified**.

### See Also

#### More About

- “Conditionally Executed Subsystems Overview” on page 10-3

## Classic Initialization Mode

Initialization mode controls how Simulink handles the initialization values for conditionally executed subsystems.

Classic mode was the default initialization mode for Simulink models created in R2013b or before. You can continue to use classic mode if:

- The model does not include any modeling elements affected by simplified mode.
- The behavior and requirements of simplified mode do not meet your modeling goals.
- The work involved in converting to simplified mode is greater than the benefits of simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-70.

### Set Initialization Mode to Classic

To set classic initialization mode:

- 1 Open the Configuration Parameters dialog box. On the **Modeling** tab and from the **Setup** section, select **Model Settings** .
- 2 In the search box, enter **Underspecified initialization detection**.
- 3 From the drop-down list, select **Classic**.

### Classic Initialization Issues and Limitations

Using classic initialization mode can result in one or more of the following issues. You can address these issues by using simplified mode. The description of each issue includes an example of the behavior in classic mode, the behavior when you use simplified mode, and a summary of the changes you must make to use simplified mode.

- “Identity Transformation Can Change Model Behavior” on page 10-58.

Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of the following apply:

- The model uses classic initialization mode.
- One or more of the identical subsystems outputs to an identity transformation block.
- “Inconsistent Output with Discrete-Time Integrator or S-Function Block” on page 10-60

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

- “Execution Order Affecting Merge Block Output” on page 10-62

The execution order of conditional subsystems that used classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results.

- When you rename the Merge block source subsystem blocks, the initial output of the Merge block can change.

When two or more subsystems are feeding different initial output values to a Merge block that does not specify its own initial output value, renaming one of the subsystems can affect the initial output of the Merge block in classic initialization mode.

- “Simulink does not provide correct consistency check” on page 10-69

Simulink does not provide the correct consistency check for settings between two Outport blocks connected through a model reference boundary.

For additional information about the tasks involved to convert a model from classic to simplified mode, see “Convert from Classic to Simplified Initialization Mode” on page 10-70.

## Identity Transformation Can Change Model Behavior

Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of the following apply:

- The model uses classic initialization mode.
- One or more of the identical subsystems outputs to an identity transformation block.

An identity transformation block is a block that does not change the value of its input signal. Examples of identify transform blocks are a Signal Conversion block or a Gain block with a value of 1.

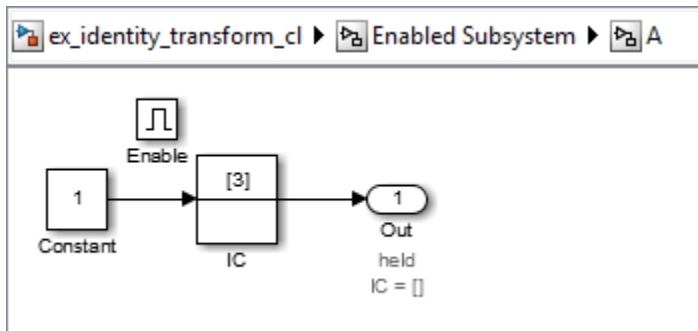

In the `ex_identity_transform_cl` model, subsystems A and B are identical, but B outputs to a Gain block, which in turn outputs to an Outport block.

`ex_identity_transform_cl` ▶

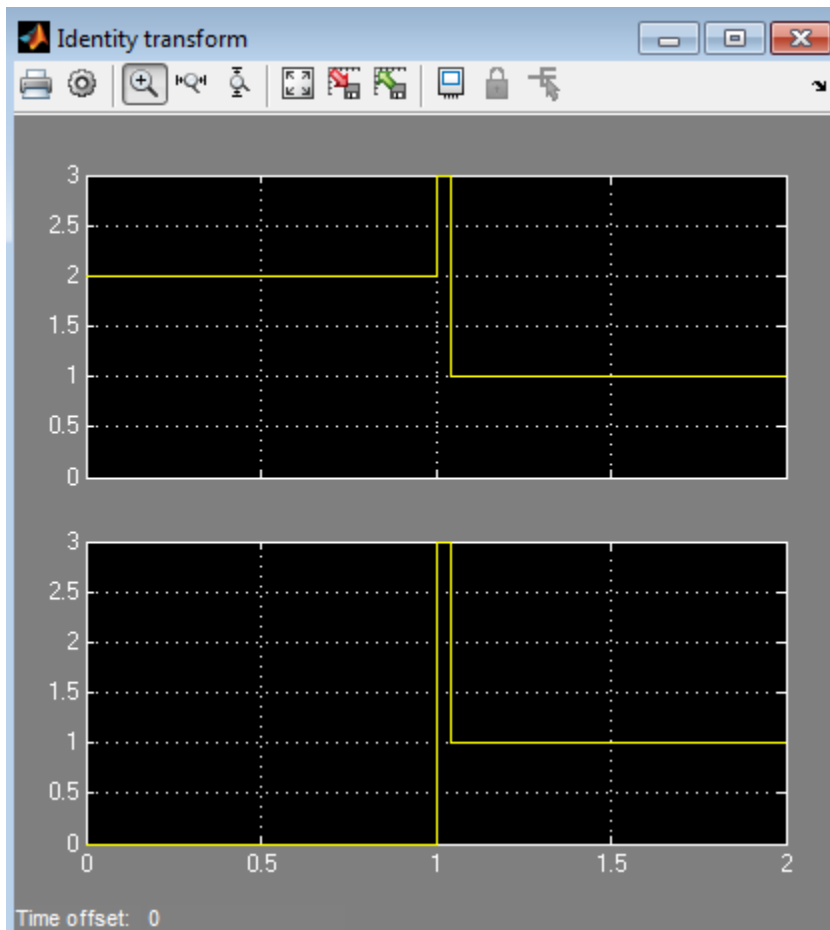

`ex_identity_transform_cl` ▶ Enabled Subsystem ▶

When you simulate the model, the initial value for A (the top signal in the Scope block) is 2, but the initial value of B is 0, even though the subsystems are identical.

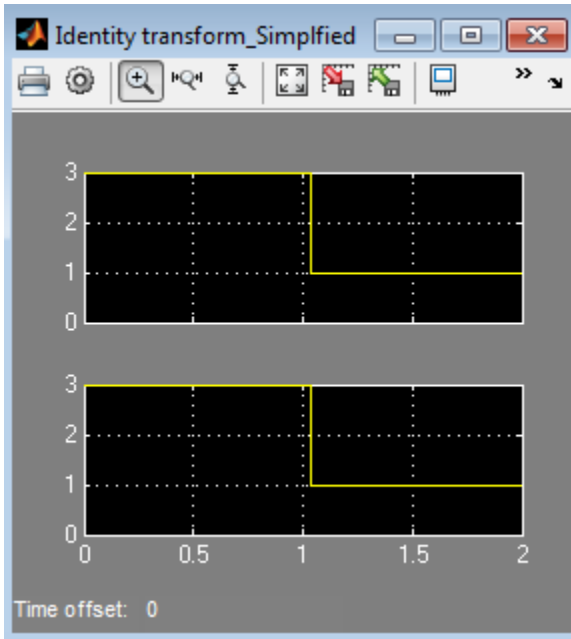

If you update the model to use simplified initialization mode (see `ex_identity_transform_simpl`), the model looks the same. The steps required to convert `ex_identity_transform_cl` to `ex_identity_transform_simpl` are:

- 1 Set **Underspecified initialization detection** to Simplified.
- 2 For the Output blocks in subsystems A and B, set the **Source of initial output value** parameter to Input signal.

You can also get the same behavior by setting the **Source of initial output value** parameter to Dialog and the **Initial output** parameter to 3.

When you simulate the updated model, the connection of an identity transformation does not change the result. The output is consistent in both cases.

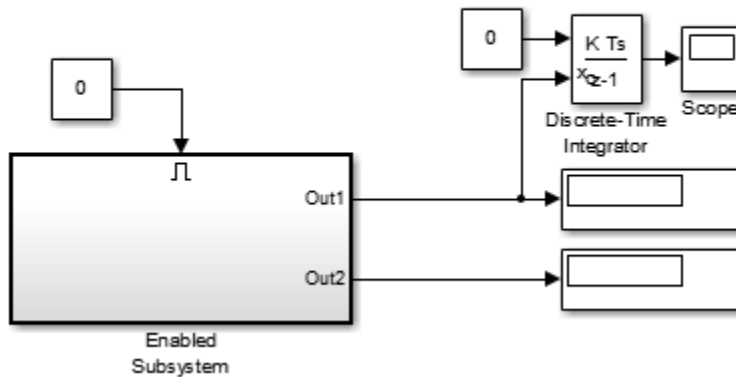

### Inconsistent Output with Discrete-Time Integrator or S-Function Block

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

In the `ex_discrete_time_cl` model, the enabled subsystem includes two Constant blocks and outputs to a Discrete-Time Integrator block. The enabled subsystem outputs to two Display blocks.

`ex_discrete_time_cl` ▶

When you simulate the model, the two display blocks show different values.

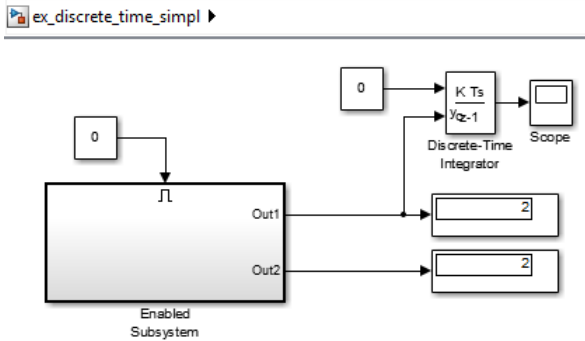

The Constant1 block, which is connected to the Discrete-Time Integrator block, executes, even though the conditional subsystem is disabled. The top Display block shows a value of 2, which is the value of the Constant1 block. The Constant2 block does not execute, so the bottom Display block shows a value of 0.

If you update the model to use simplified initialization mode (see `ex_discrete_time_simpl`), the model looks the same. The updated model corrects the inconsistent output issue by using simplified mode. The steps required to convert `ex_discrete_time_cl` to `ex_discrete_time_simpl` are:

- 1 Set **Underspecified initialization detection** to Simplified.
- 2 For the Output blocks Out1 and Out2, set the **Source of initial output value** parameter to `Input signal`. This setting explicitly inherits the initial value, which in this case is 2.

You can also get the same behavior by setting the **Source of initial output value** parameter to `Dialog` and the **Initial output** parameter to 2.

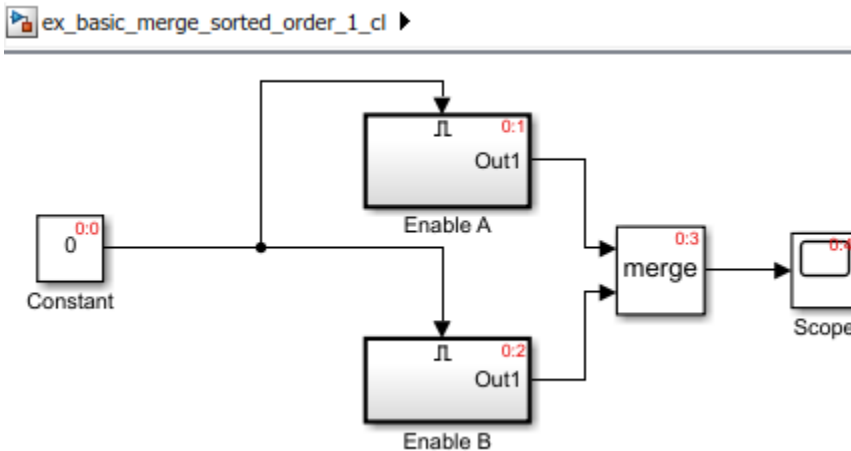

When you simulate the updated model, the Display blocks show the same output. The output value is 2 because both Output blocks inherit their initial value.

### Execution Order Affecting Merge Block Output

The execution order of conditional subsystems that use classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results. The behavior depends on how you set the **Output When Disabled** parameter.

The `ex_basic_merge_sorted_order_1_cl` model has two identical enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

ex\_basic\_merge\_sorted\_order\_1\_cl ▶ Enable A

When you simulate the model, the Scope block looks like the following:

The `ex_basic_merge_sorted_order_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

- 1 Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to 2.
- 2 Set the **Priority** of the Enable B subsystem to 1.

When you simulate the model using the different execution order, the Scope block looks like the following:

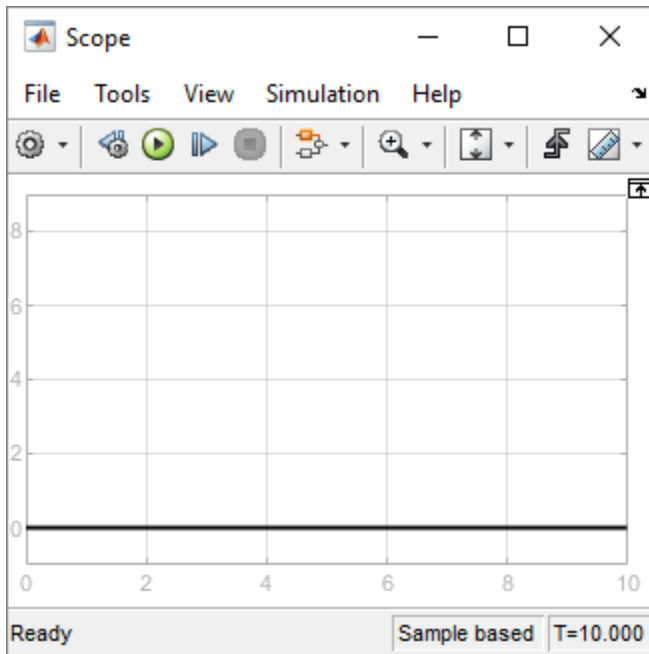

The change in execution order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_basic_merge_sorted_order_1_simpl` and `ex_basic_merge_sorted_order_2_simpl`):

- 1 Set **Underspecified initialization detection** to Simplified.

The **Initial Output** parameter of the Merge block is an empty matrix, [], by default. Hence, the initial output value is set to the default initial value for this data type, which is 0. For information on default initial value, see “Initialize Signal Values” on page 80-9. When you simulate each simplified mode model, both models produce the same results.

### Using Output When Disabled Parameter Set to Reset

The `ex_merge_sorted_1_cl` model has two enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

ex\_merge\_sorted\_1\_cl ▶ Enable A

ex\_merge\_sorted\_1\_cl ▶ Enable B

When you simulate the model, the Scope block looks like the following:

The `ex_merge_sorted_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

- 1 Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to 2.
- 2 Set the **Priority** of the Enable B subsystem to 1.

When you simulate the model using the different execution order, the Scope block looks like:

The change in execution order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_merge_sorted_1_simpl` and `ex_merge_sorted_2_simpl`):

- 1 Set **Underspecified initialization detection** to Simplified.
- 2 For the Output blocks in Enable A and Enable B, set the **Output when disabled** parameter to held. Simplified mode does not support reset for output ports of conditional subsystems driving Merge blocks.

When you simulate each simplified mode model, both models produce the same results.

## Tunable Parameters

Many block parameters are tunable. A *tunable parameter* is a parameter whose value can be changed without recompiling the model (see “Model Compilation” on page 3-2 for more information on compiling a model). For example, the gain parameter of the Gain block is tunable. You can alter the block's gain while a simulation is running. If a parameter is not tunable and the simulation is running, the dialog box control that sets the parameter is disabled.

When you change the value of a tunable parameter, the change takes effect at the start of the next time step.

## State

Typically the current values of some system, and hence model, outputs are functions of the previous values of temporal variables. Such variables are called states. Computing a model's outputs from a block diagram hence entails saving the value of states at the current time step for use in computing the outputs at a subsequent time step. This task is performed during simulation for models that define states.

Two types of states can occur in a Simulink model: discrete and continuous states. A continuous state changes continuously. Examples of continuous states are the position and speed of a car. A discrete state is an approximation of a continuous state where the state is updated (recomputed) using finite (periodic or aperiodic) intervals. An example of a discrete state would be the position of a car shown on a digital odometer where it is updated every second as opposed to continuously. In the limit, as the discrete state time interval approaches zero, a discrete state becomes equivalent to a continuous state.

Blocks implicitly define a model's states. In particular, a block that needs some or all of its previous outputs to compute its current outputs implicitly defines a set of states that need to be saved between time steps. Such a block is said to have states.

The following is a graphical representation of a block that has states:

Blocks that define continuous states include the following standard Simulink blocks:

- Integrator
- State-Space
- Transfer Fcn
- Variable Transport Delay
- Zero-Pole

The total number of a model's states is the sum of all the states defined by all its blocks. Determining the number of states in a diagram requires parsing the diagram to determine the types of blocks that it contains and then aggregating the number of states defined by each instance of a block type that defines states. This task is performed during the Compilation phase of a simulation.

## Simulink does not provide correct consistency check

Simulink does not provide the correct consistency check for settings between two Output blocks connected through a model reference boundary.

Simulink either throws a false warning or no warning when all of the following conditions are true:

- The option **Underspecified initialization detection** is set to `Classic`.
- The model contains a Model block.
- In the referenced model, a root Output block is driven directly (or indirectly through virtual blocks) by a conditionally executed subsystem. In this scenario, the Output block corresponding to the conditionally executed subsystem output is a *source* Output block.
- In the top model, the output port of the Model block that is driven by the source Output block, in turn, drives a *destination* Output block of a conditionally executed subsystem.

If both the source and destination Output blocks are in the same model, and the settings **Initial output** and **Output when disabled** (if applicable) for both Output blocks differ, Simulink throws an error. However, in the case described above, Simulink either throws a false warning when the two Output blocks have the same settings or throws no warning or error when they are different.

## Convert from Classic to Simplified Initialization Mode

If you switch the initialization mode from classic to simplified mode, you can encounter several issues that you must fix. For most models, the following approach helps you to address conversion issues more efficiently.

- 1 Save the existing model and simulation results for the model.
- 2 Simulate the model and address any warnings.
- 3 In the Model Advisor, in the Simulink checks section, run the checks in the folder “Migrating to Simplified Initialization Mode Overview”.
- 4 Address the issues that Model Advisor identifies.
- 5 Simulate the model to make sure that there are no errors.
- 6 Rerun the Model Advisor checks in the folder “Migrating to Simplified Initialization Mode Overview” check to confirm that the modified model addresses the issues related to initialization.

For examples of models that have been converted from classic initialization mode to simplified initialization mode, see “Classic Initialization Issues and Limitations” on page 10-57.

### Blocks to Consider

#### Discrete-Time Integrator Blocks

Discrete-Time Integrator block behaves differently in simplified mode than it does in classic mode. The changes for simplified mode promote more robust and consistent model behavior. For details, see “Behavior in Simplified Initialization Mode” in the Discrete-Time Integrator block reference documentation.

#### Library Blocks

Simulink creates a library assuming that classic mode is in effect. If you use a library block that is affected by simplified mode in a model that uses simplified mode, then use the Model Advisor to identify changes you must make so that the library block works with simplified mode.

## Create an Export-Function Model

The first step for creating independent functions in the generated code from a Simulink model is to define the functions in the context of an export-function model. See “Export-Function Models Overview” on page 10-96.

To open a completed export-function model, see `ex_export_function_model`.

### Designate Model as Export-Function Model and Satisfy Export-Function Model Requirements

- 1 Designate the model as an export-function model. Click the canvas to clear the selection from any blocks, then open the **Property Inspector** and go to the **Execution** tab. Select the **Set execution domain** check box and, from the **Domain** list, select **Export function**.
- 2 Open the Configuration Parameters dialog box. On the **Modeling** tab and from the **Setup** section, select **Model Settings** .
- 3 In the **Solver** pane, set Solver selection **Type** to **Fixed-step**, **Solver** to **auto**, and **Fixed-step size** to **auto**.
- 4 In the **Code Generation** pane, set **System target file** to `ert.tlc`. This step requires an Embedded Coder license.

### Create Model Algorithms

At the top-level of an export-function model, functions are modeled within Function-Call Subsystem, function-call Model, Simulink Function, and S-Function blocks. This example uses Function-Call Subsystem blocks to model two functions.

- 1 Add two Function-Call Subsystem blocks.
- 2 In the first subsystem, model a unit delay that increments by 0.05 at each time step.

- 3 In the second subsystem, model the square of an input signal.

- 4 Add Inport and Output blocks.

## Add Function-Call Inputs

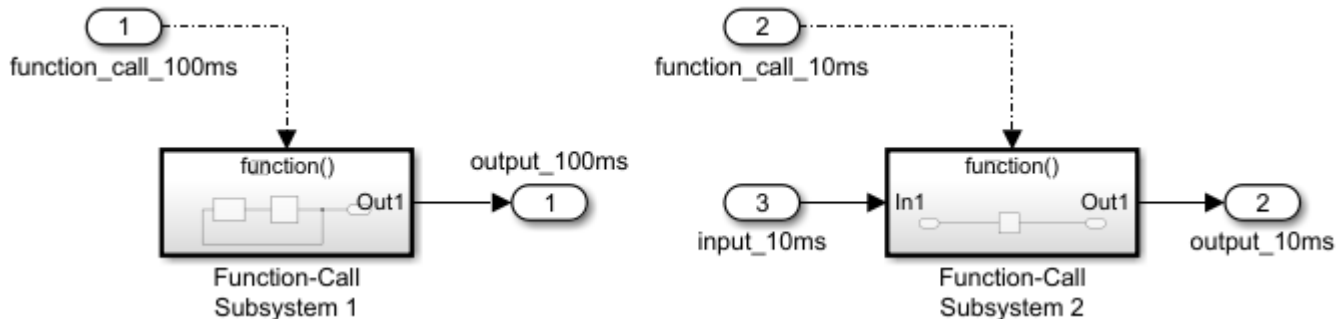

Inport blocks configured to output function-call signals control the execution of Function-Call Subsystem blocks during a simulation. The function-call Inport blocks also create an entry point function in the generated code.

- 1 Attach Inport blocks to the `function()` input ports on the Function-Call Subsystem blocks.
- 2 Specify sample times. Open the Inport block dialogs and select the **Signal Attributes** tab. Select the **Output function call** check box. Set **Sample time** for the delay function to 0.1 (100 ms), and the square function to 0.01 (10 ms).

Setting the sample time is only for simulation testing. Sample time values do not affect the generated code. However, comments are added in the code identifying the rate you should call the functions.

You could set the sample times to -1 and allow any function-call rate (periodic or aperiodic) during simulation. By setting sample times, Simulink checks the calling rate with the specified rate and displays an error if there is a mismatch.

- 3 Rename blocks. The names help to identify signals in the generated code.
- 4 Update the model (Ctrl-D). Dotted-and-dashed lines identify function-call signals.

## Test Model

After you create an export-function model, you can test it with simulations. Choose one of these simulation testing methods: “Test Export-Function Model Simulation Using Input Matrix” on page 10-74, “Test Export-Function Model Simulation Using Function-Call Generators” on page 10-78, or “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81.

## See Also

Function-Call Subsystem

- “Test Export-Function Model Simulation Using Input Matrix” on page 10-74
- “Test Export-Function Model Simulation Using Function-Call Generators” on page 10-78
- “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81
- “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85
- “Generate Code for Export-Function Model” on page 10-89

## Test Export-Function Model Simulation Using Input Matrix

When function-call sequencing is simple enough to be specified as a model input, simulation using an input matrix is the preferred method for testing an export-function model.

- Create time vectors that specify function-call times.
- Create a matrix that adds input data to the time vectors.
- Run simulation.

To create the model in this example, see “Create an Export-Function Model” on page 10-71.

### Create Function-Call Inputs and Data Inputs

Create time-vectors indicating when events occur for root-level function-call Inport blocks and data-vectors for root-level data Inport blocks.

- 1 For function-call Inport blocks 1 and 2, create column vectors with time steps of 0.1 and 0.01. In the MATLAB Command Window, enter

```
t1 = [0:0.1:10]';  
t2 = [0:0.01:10]';
```

- The time vector must be monotonically increasing and of double data type.
- If the sample time for a function-call Inport block is specified, the values in the corresponding time vector must all be integer multiples of the specified value.
- To specify multiple function-calls at a given time step, repeat the time value accordingly. For example, to specify three events at  $t = 0.1$  and 2 events at  $t = 0.5$ , list 0.1 three times and 0.5 twice in your time vector, `t1 = [0.1 0.1 0.1 0.5 0.5]'`.
- To use nonperiodic sample times, set the Inport block **Sample time** to -1 and provide a nonuniform time vector, e.g. `t1 = [0, 0.1, 0.2, 0.4, 0.8]`.

- 2 Create a matrix with time steps and data values for data Inport block 3.

```
sine_data = sin(0:0.01:10)';  
d3 = [t2,sine_data];
```

The data input can use any supported format as described in “Forms of Input Data” on page 75-37.

The following table provides additional information for specifying the time vector `t`.

Sample time type for internal Trigger Port block set to:	Root-level Function-Call Inport block with inherited sample time (-1)	Root-level Function-Call Inport block with discrete sample time
triggered	<p>Nondecreasing column vector.</p> <p>The function-call subsystem executes at the times specified by the column vector. The sample times can be periodic or aperiodic.</p> <p>If you specify an empty matrix ([ ]), the function-call subsystem does not execute.</p>	<p>Nondecreasing column vector. Each element in the column vector must be an integer multiple of the sample time specified by the Inport block.</p> <p>The function-call subsystem executes at the times specified by the column vector.</p> <p>Alternatively, specify an empty matrix ([ ]) and the function-call subsystem executes once at every sample time specified by the Inport block.</p>
periodic	Configuration not allowed	<p>Empty matrix([ ]).</p> <p>The function-call subsystem executes at the times specified by the Inport block calling it.</p>

## Simulate Export-Function Model

Simulate the export-function model to test and observe its behavior before generating code.

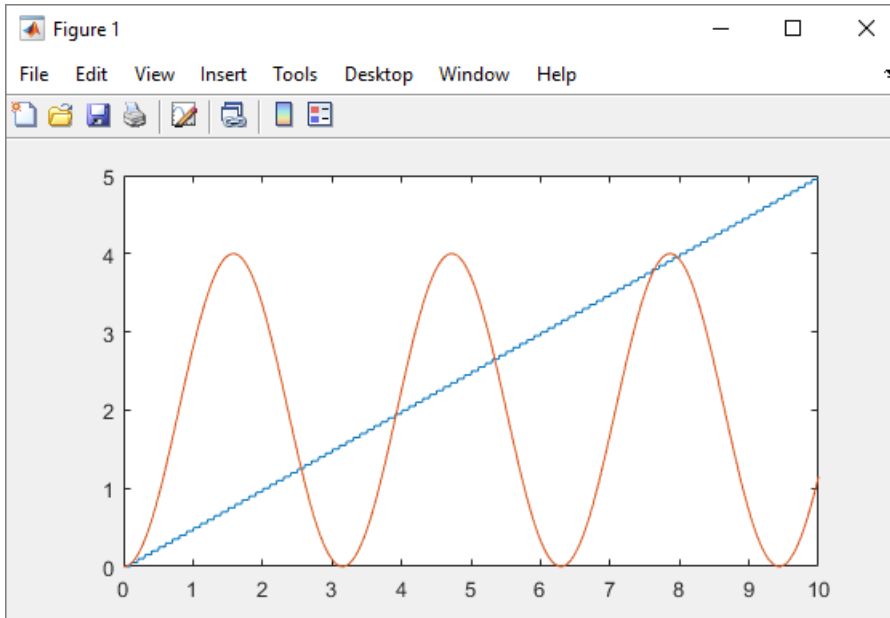

- 1 Import time and data from the MATLAB workspace.

On the **Modeling** tab, select **Model Settings** . In the Configuration Parameters dialog box, select the **Data Import/Export** pane and set the **Input** parameter to **t1, t2, d3**.

**t1** and **t2** are column vectors containing event times for the function-call Inport blocks 1 and 2. **d3** is a table of input values versus time for the data Inport block 3.

- 2 Run simulation.
- 3 Plot results. In the MATLAB Command Window, enter:

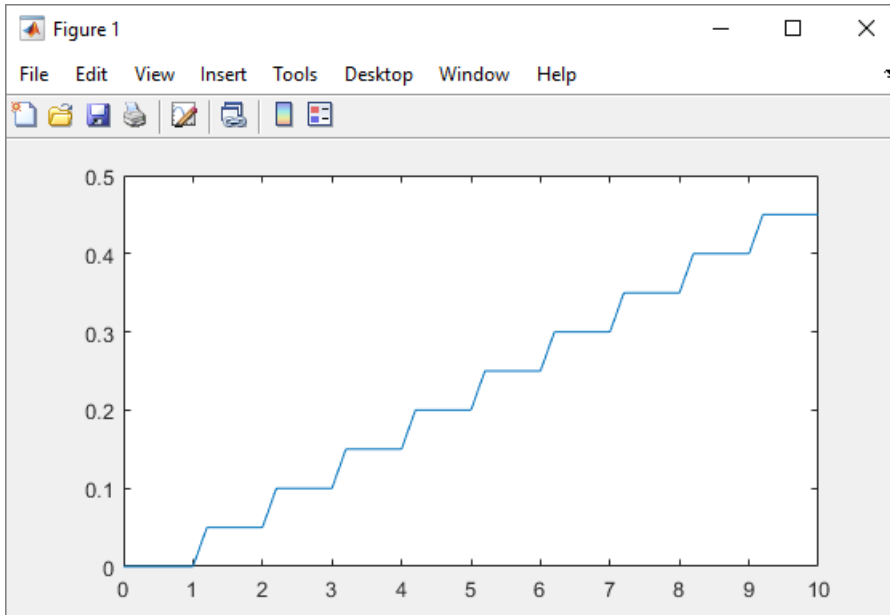

```
plot(yout.time, yout.signals(1).values)
hold
plot(yout.time, yout.signals(2).values)
```

- 4 Change `t1` to provide events every 0.5 seconds (0.5 is an integer multiple of the sample time of 0.1 specified in Inport block 1).

```
t1 = [0:0.5:10]';
```

- 5 Rerun simulation.

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-89.

- “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81
- “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85
- “Generate Code for Export-Function Model” on page 10-89

## Test Export-Function Model Simulation Using Function-Call Generators

Use multiple Function-Call Generator blocks with distinct sample times and let Simulink schedule the function-call components for simulation. This strategy is useful when the rate-monotonic scheduling behavior in Simulink is similar to the target OS behavior.

- Create a new Simulink model.
- Add a Model block that references the export-function model.
- Specify function-call events using Function-Call Generator blocks.
- Specify data inputs.
- Run simulation.

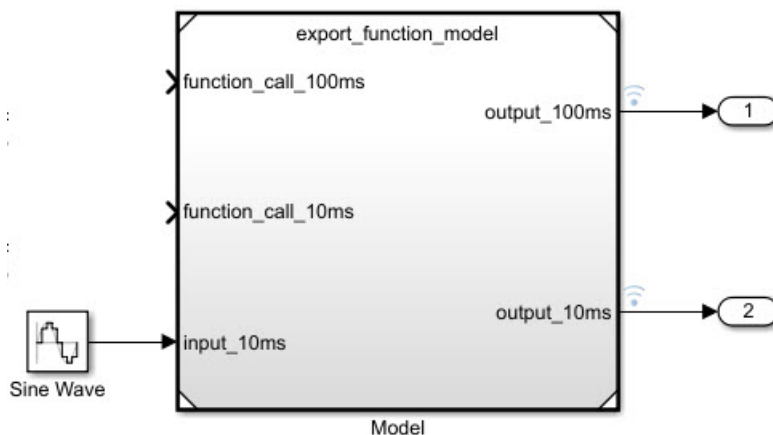

To create the model for this example, see “Create an Export-Function Model” on page 10-71.

To open a completed test model, see `ex_export_function_test_model_with_function_call_generators`.

### Create Referenced Export-Function Model

Referencing an export-function model from a Model block allows the addition of function-call events and logging of data signals for testing without changing the model itself.

- 1 Add a Model block to a new Simulink model. In the **Model name** box, enter `export_function_model`.
- 2 Add Outport blocks to the **output\_100ms** and **output\_10ms** ports on the Model block.
- 3 Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01. Connect the block to the **input\_10ms** input port on the Model block.

### Create Test Model (Harness) for Simulation

You use a Simulink test model only for simulation. After simulation testing, generate code from the export-function model, and then integrate exported function code with an externally coded scheduler.

- 1 Add a Function-Call Generator block. Set **Sample time** to  $0.1$ . Connect the block to the **function\_call\_100ms** input port.
- 2 Add a second Function-Call Generator block. Set **Sample time** to  $0.01$ . Connect the block to the **function\_call\_10ms** input port.

### Scheduling Restrictions for Referenced Export-Function Models

If a test model references an export-function model, there are some restrictions to ensure consistency with simulation results.

For the test model:

- You cannot use two Function-Call Generator blocks with the same sample time.
- Function-calls to the input ports on the Model block must follow the execution order of the root-level function-call Inport blocks in the referenced export-function model. Function-Call Generator blocks with smaller sample times execute first.

If the test model calls the referenced model functions out of order at any time step, Simulink displays an error. For information on sorted execution order, see “Control and Display Execution Order” on page 39-27. To disable this restriction, clear the check box for the configuration parameter **Enable strict scheduling checks for referenced model**.

- You can use a Mux block to connect signals from the Function-Call Generator blocks with different sample times before connecting them to the referenced export-function model. In the Configuration Parameters dialog box, clear the check box for the parameter **Treat each discrete rate as a separate task**.

For the export-function model:

- The sample times for the root-level function-call Inport blocks must be set to inherited (-1) or match the sample time of the Function-Call Generator blocks that drive them.

### Simulate Export Function Model

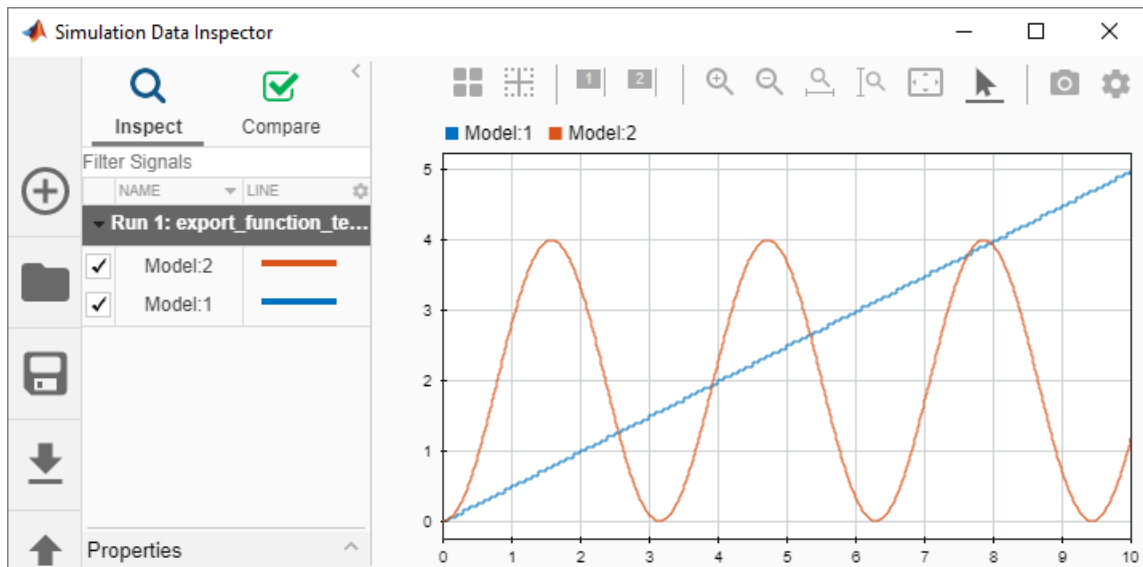

Simulate the export-function model to test and observe its behavior before generating code.

---

**Note** Simulink does not simulate preempting function-calls.

---

- 1 Set configuration parameters for the test model. On the **Modeling** tab and from the **Setup** section, select **Model Settings** . Select the Model Referencing pane. Clear the check box for the configuration parameter **Enable strict scheduling check for referenced models**.
- 2 Verify the configuration parameters for Solver Type is set to **Fixed-step**, Solver set to **discrete (no continuous states)**, and Fixed-step size (fundamental sample time) set to **auto**.
- 3 Set up logging of signals. Right-click output port signals and select **Log selected signal**.
- 4 Run simulation.
- 5 Open the Simulation Data Inspector by clicking the toolstrip icon .

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-89.

## See Also

Function-Call Subsystem

## Related Examples

- “Export-Function Models Overview” on page 10-96
- “Create an Export-Function Model” on page 10-71
- “Test Export-Function Model Simulation Using Input Matrix” on page 10-74
- “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81
- “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85
- “Generate Code for Export-Function Model” on page 10-89

## Test Export-Function Model Simulation Using Stateflow Chart

Use a Stateflow chart to provide a function-call scheduler where you can fully control the scheduling process for periodic (synchronous) or aperiodic (asynchronous) call sequences.

- Create a new Simulink model.
- Add a Model block that references the export-function model.
- Specify function-call Inputs using a Stateflow chart.
- Specify data inputs.
- Run simulation.

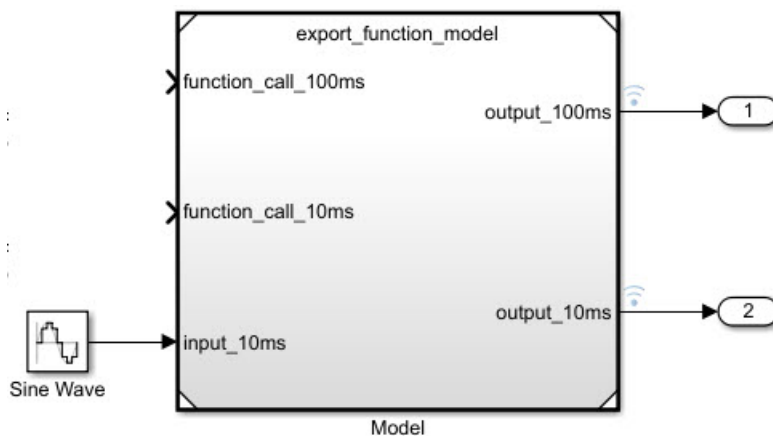

To create the model for this example, see “Create an Export-Function Model” on page 10-71.

To open a completed test model, see `ex_export_function_test_model_with_stateflow_chart`.

### Create Referenced Export-Function Model

Referencing an export-function model from a Model block allows the addition of function-calls events from a Stateflow chart and the logging of data signals for testing without changing the model itself.

- 1 Add a Model block to a new Simulink model. In the **Model name** box, enter `export_function_model`.
- 2 Add Outport blocks to the **output\_100ms** and **output\_10ms** ports for saving simulation data to MATLAB.
- 3 Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01. Connect the block to the **input\_10ms** input port on the Model block.

### Create Periodic Scheduler Using Stateflow Chart

- 1 Create a new Stateflow chart. This step requires a Stateflow license.
- 2 On the **Modeling** tab and from the **Design** section, select **Model Explorer** . In the **Model Hierarchy** pane, select Chart.

- 3 Add function-call events with output ports to the chart. From the menu, select **Add > Event**. In the **Name** box, enter `out_100ms`. From the **Scope** list, select **Output to Simulink**. Repeat step to create a function-call event and output port for `out_10ms`.

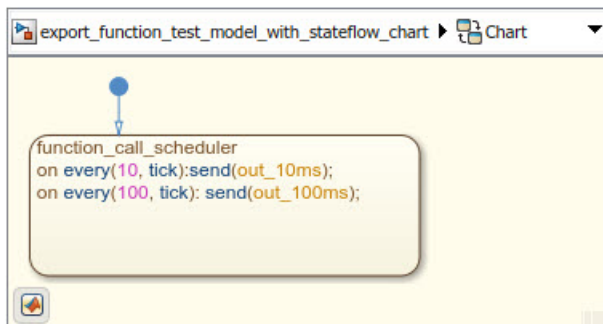

- 4 Open the chart by double-clicking the block. Add a State block and a Default transition arrow.

- 5 Rename the state to `function_call_scheduler`.
- 6 Add periodic function-calls every 10 and 100 milliseconds. In the state block, enter the following commands.

```
on every(10, tick):send(out_10ms);
on every(100, tick):send(out_100ms);
```

The keyword `tick` is an implicit event that counts the number of simulation steps while `send` is an explicit event that outputs a function-call event to the output ports.

## Create Test Model (Harness) for Simulation

You use a Simulink test model only for simulation. After simulation testing, generate code from the export-function model, and then integrate exported function code with an externally coded scheduler.

- 1 Add a Stateflow chart to your test model.

- 2 Connect the Stateflow Chart outputs to Model block inputs.

### Scheduling Restrictions for Referenced Export-Function Models

If a test model references an export-function model, there are some restrictions to ensure consistency with simulation results.

For the test model:

- Function-calls to the input ports on the Model block must follow the execution order of the root-level function-call Inport blocks in the referenced export-function model.

If the test model calls the referenced model functions out of order at any time step, Simulink displays an error. For information on sorted execution order, see “Control and Display Execution Order” on page 39-27. To disable this restriction, clear the check box for the configuration parameter **Enable strict scheduling checks for referenced models**.

For the export-function model:

- The sample times for the root-level function-call Inport blocks must be set to inherited (-1) or match the sample time of the function-calls from the Stateflow chart that drives them.

### Simulate Export Function Model

Simulate the export-function model to test and observe its behavior before generating code.

---

**Note** When using export-function models in top-model simulations, do not change the enable/disable status of the model during simulation. Enable it at the start of simulation and use function-calls to call it.

---

- 1 Set configuration parameters for the test model. On the **Modeling** tab and from the **Setup** section, select **Model Settings** . Select the Model Referencing pane. Clear the check box for the configuration parameter **Enable strict scheduling check for referenced models**.
- 2 Verify the configuration parameters **Solver Type** is set to Fixed-step, **Solver** set to discrete (no continuous states) and Fixed-step size (fundamental sample time) set to auto.

- 3 Right-click output port signals on the Model block and select **Log selected signal**.
- 4 Run simulation.
- 5 Open the Simulation Data Inspector by clicking the icon .

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-89.

- “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85
- “Generate Code for Export-Function Model” on page 10-89

## Test Export-Function Model Simulation Using Schedule Editor

Use the Schedule Editor to schedule the function-call components for simulation. This strategy is useful when you want to set the order of execution for function-call components and view data dependencies between components.

- Create a new Simulink model.
- Add a Model block that references the export-function model.
- Specify function-call events using the Schedule Editor.
- Specify data inputs.
- Run a simulation.

To create the model for this example, see “Create an Export-Function Model” on page 10-71.

To open a completed test model, see `ex_export_function_test_model_with_schedule_editor`.

### Create Test Model (Harness) for Simulation

A Simulink test model is used only for simulation. After simulation testing, generate code from the export-function model, and then manually integrate exported function code with an externally coded scheduler. Referencing an export-function model from a Model block allows the addition of function-call events and logging of data signals for testing without changing the model itself.

1 Create a new Simulink model.

2 On the **Modeling** tab and from the **Setup** section, select **Model Settings** .

In the left pane of the Configuration Parameters dialog box, select Solver. In the right pane, select the Solver details arrow to display additional parameters. Select the check boxes for **Treat each discrete rate as a separate task** and **Automatically handle rate transition for data transfer**.

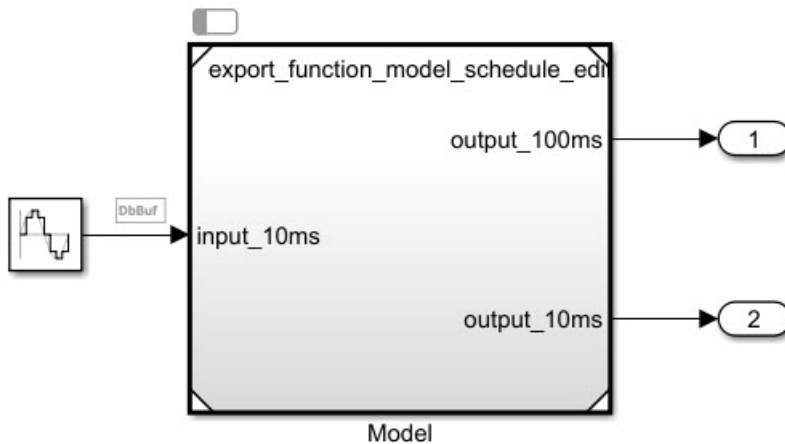

3 Add a Model block to your model

4 On the **Modeling** tab, select the **Design** section, and then select **Property Inspector** .

In the **Model name** box, enter `export_function_model`. Select the **Schedule rates** check box. From the **Schedule rates** drop-down list, select `Schedule Editor`.

5 Add Outport blocks to the **output\_100ms** and **output\_10ms** ports on the Model block.

6 Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01. Connect the block to the **input\_10ms** input port on the Model block.

## Create Function-Call Events Using the Schedule Editor

Use the Schedule Editor to provide function-call events by defining time-vectors that indicate when events occur for root-level function-call Import blocks

- 1 Open the Schedule Editor. On the **Modeling** tab and from the **Design** section, select **Schedule Editor** . The Schedule Editor partitions the function-call Import blocks and names the partitions using the block names.

Order	Name	Rate
1	■ D1	0.01
2	■ Model.function_call_2	-1
3	■ Model.function_call_1	-1

- 2 Select the function\_call\_2 partition. In the **Hit Times** box, enter a matrix with values that begin at 0, periodically increase by 0.01 to 10. You could also test asynchronous behavior by entering a matrix with random values that are multiples of 0.01.

Order	Name	Rate
1	■ D1	0.01
2	■ Model.function_call_2	-1
3	■ Model.function_call_1	-1

Partition	
Name	Model.function_call_2
Rate	-1
Hit Times	[0:0.01:10]

- 3 Select the function\_call\_1 partition. In the **Hit Times** box, enter a matrix with values that begin at 0, increase by 0.1 to 10.

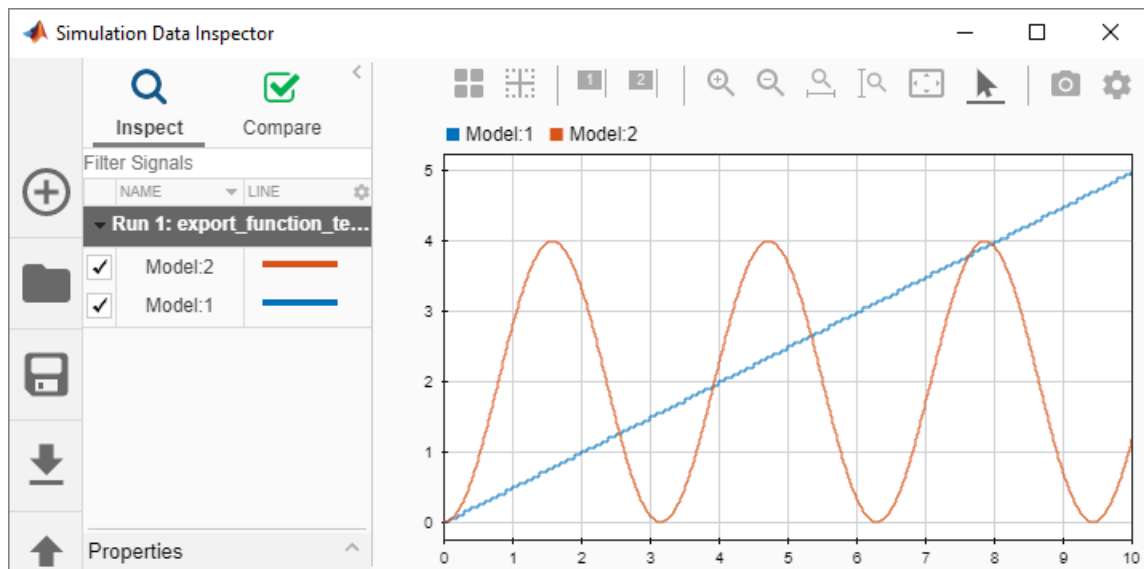

Order	Name	Rate
1	■ D1	0.01
2	■ Model.function_call_2	-1
3	■ Model.function_call_1	-1

Partition	
Name	Model.function_call_1
Rate	-1
Hit Times	[0:0.1:10]

## Simulate Export Function Model

Simulate the export-function model to test and observe its behavior before generating code.

- 1 Verify the configuration parameters for Solver Type is set to Fixed-step, Solver set to discrete (no continuous states) or auto (Automatic solver selected), and **Fixed-step size (fundamental sample time)** is set to auto.
- 2 Set up logging of data signals. Right-click output port signals and select the **Log selected signal** check box.
- 3 On the **Simulation** tab, select the run button .
- 4 Open the Simulation Data Inspector by clicking the toolstrip icon .

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-89.

## Generate Code for Export-Function Model

You generate code for independent functions from an export-function model, not the simulation test model (harness). After generating the function code, you can integrate the functions with a scheduler that you hand-code externally from Simulink.

To create the model for this example, see “Create an Export-Function Model” on page 10-71.

### Generate Code for Exported Functions

Generate code from the model that contains the functions.

- 1 Open an export-function model.
- 2 On the **Simulation** tab and from the **Prepare** section, select **Model Settings** .

In the Solver pane, set **Solver Type** to Fixed-step. In the Code generation pane, set **System target file** to `ert.tlc`. Requires an Embedded Coder license.

- 3 Display the **C Code** tab by selecting the **Apps** tab, and then in the **Apps** section, select **Embedded Coder** . On the **C Code** tab, select **Generate Code** . Wait for the code building process to complete.
- 4 On the **C Code** tab, select **Open Latest Report**.

#### Entry-Point Functions

Function: [function\\_call\\_100ms](#)

Prototype	<b>void function_call_100ms(void)</b>
Description	Exported function: <a href="#">&lt;Root&gt;/function_call_100ms</a>
Timing	Must be called periodically, every 0.1 seconds
Arguments	None
Return value	None
Header file	<a href="#">export_function_model.h</a>

Function: [function\\_call\\_10ms](#)

Prototype	<b>void function_call_10ms(void)</b>
Description	Exported function: <a href="#">&lt;Root&gt;/function_call_10ms</a>
Timing	Must be called periodically, every 0.01 seconds
Arguments	None
Return value	None
Header file	<a href="#">export_function_model.h</a>

In the generated code, each root-level function-call Inport block generates a void-void function. The function name is the name of the output signal from the block. If there is no signal name, then the function name is derived from the name of the block. In this example, the function name was derived from the block name.

**File: [export\\_function\\_model.c](#)**

```

36  /* Model step function for TID1 */
37  void function_call_10ms(void)          /* Sample time: [0.01s, 0.0s]
38  {
39      /* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor
40      * SubSystem: '<Root>/Function-Call_Subsystem_2'
41      */
42      /* Output: '<Root>/output_10ms' incorporates:
43      * Inport: '<Root>/input_10ms'
44      * Math: '<S2>/Square'
45      */
46      export_function_model_Y.output_10ms = export_function_model_U.input
47      export_function_model_U.input_10ms;
48
49      /* End of Outputs for RootInportFunctionCallGenerator: '<Root>/Root
50  }
51
52  /* Model step function for TID2 */
53  void function_call_100ms(void)        /* Sample time: [0.1s, 0.0s] *
54  {
55      /* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor
56      * SubSystem: '<Root>/Function-Call_Subsystem_1'
57      */
58      /* Output: '<Root>/output_100ms' incorporates:
59      * UnitDelay: '<S1>/Unit Delay'
60      */
61      export_function_model_Y.output_100ms =
62      export_function_model_DW.UnitDelay_DSTATE;
63
64      /* Bias: '<S1>/Bias' incorporates:
65      * Output: '<Root>/output_100ms'
66      * UnitDelay: '<S1>/Unit Delay'
67      */
68      export_function_model_DW.UnitDelay_DSTATE =
69      export_function_model_Y.output_100ms + 0.05;
70
71      /* End of Outputs for RootInportFunctionCallGenerator: '<Root>/Root
72  }

```

## Generate Code for Export-Function Model with Rate-Based Model

You can generate code from a model that includes both function-call subsystems and scheduled subsystems. Create a rate-based model with scheduled subsystems, and then add the model to an export-function model by reference from a Model block.

To open a completed model, see `ex_export_function_model04`.

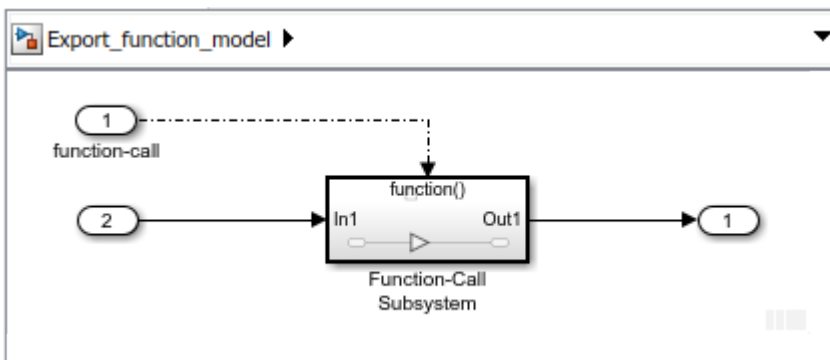

### Create Export-Function Model with Scheduled Subsystems

Create a model with function-call and scheduled subsystems.

- 1 Begin by creating a rate-based model with scheduled subsystems. In this example, the **Sample time** for the Scheduled Subsystem is set to `0.01`. See “Create A Rate-Based Model” on page 10-41.

- 2 Create an export-function model with function-call subsystems. See “Create an Export-Function Model” on page 10-71.

- 3 Include the rate-based model in the export-function model by reference from a Model block.

- 4 Display periodic event ports on the Model block by selecting the **Schedule rates** check box.

Connect Inport blocks to the periodic event ports.

- 5 In the Inport block dialog box, select the **Output function-call** parameter check box and specify the Sample time with the same sample time from the scheduled subsystem. In this example, the **Sample time** for the function-call 10ms Inport block is set to 0.01

## Generate Code for Exported Functions

Generate code from the model that contains the functions.

- 1 On the **Simulation** tab and from the **Prepare** section, select **Model Settings** . In the Solver pane, set **Solver Type** to Fixed-step. In the Code generation pane, set **System target file** to `ert.tlc`. Requires an Embedded Coder license.
- 2 Display the **C Code** tab by selecting the **Apps** tab, and then in the **Apps** section, select **Embedded Coder** . On the **C Code** tab, select **Generate Code** . Wait for the code building process to complete.
- 3 On the **C Code** tab, select **Open Latest Report**.

In the generated code, each root-level function-call Inport block generates a void-void function. The function name is the name of the output signal from the block. If there is no signal name, then the function name is derived from the name of the block. In this example, the function name was derived from the block name.

**File: [Export\\_function\\_model.c](#)**

```

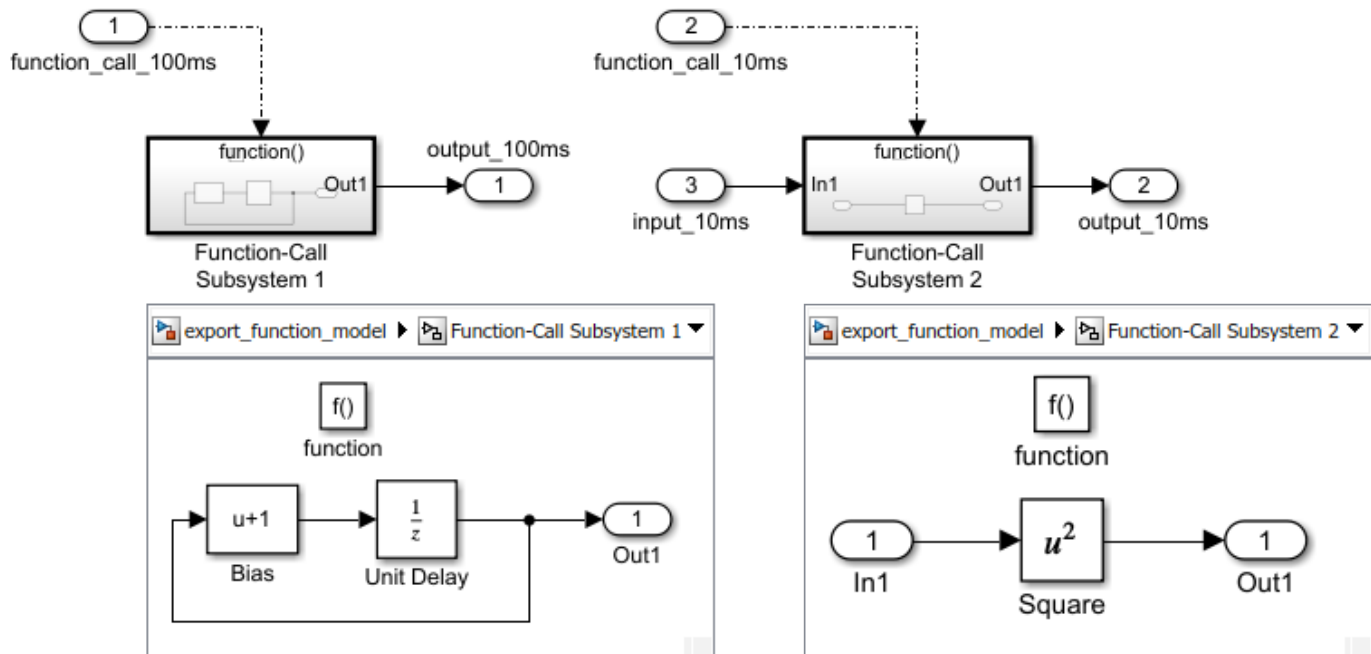

36 /* Model step function for TID1 */
37 void function_call_10ms(void)           /* Explicit Task: function_call_10ms */
38 {
39   /* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor_function_
40   rate\_based\_model\(&Export\_function\_model\_U.In1, &Export\_function\_model\_Y.Out1\)
41   */
42   /* End of Outputs for RootInportFunctionCallGenerator: '<Root>/RootFcnCall_In
43   */
44
45   /* Output function */
46   void function_call(void)
47   {
48     /* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor_function_
49     * SubSystem: '<Root>/Function-Call Subsystem'
50     */
51     /* Outport: '<Root>/Out2' incorporates:
52     * Gain: '<S1>/Gain'
53     * Inport: '<Root>/In4'
54     */
55     Export\_function\_model\_Y.Out2 = 3.0 \* Export\_function\_model\_U.In4;
56
57     /* End of Outputs for RootInportFunctionCallGenerator: '<Root>/RootFcnCall_In
58     */

```

## Export-Function Models Overview

Export-function models are Simulink models that generate code for independent functions that can be integrated with an external environment and scheduler. Functions are defined using Function-Call Subsystem, function-call Model, Simulink Function, Message Triggered Subsystem, and S-Function blocks.

The following export-function model contains two functions defined with Function-Call Subsystem blocks. For a step-by-step procedure to create this model, see “Create an Export-Function Model” on page 10-71.

Code generated from this model has two independent functions, one for a delay function and the other for a square function.

```

/*
 * File: export_function_model.c
 * Code generated for Simulink model 'export_function_model'.
 */

void function_call_100ms(void)          /* Sample time: [0.1s, 0.0s] */
{
    export_function_model_Y.output_100ms =
        export_function_model_DW.UnitDelay_DSTATE;

    export_function_model_DW.UnitDelay_DSTATE =
        export_function_model_Y.output_100ms + 1.0;
}

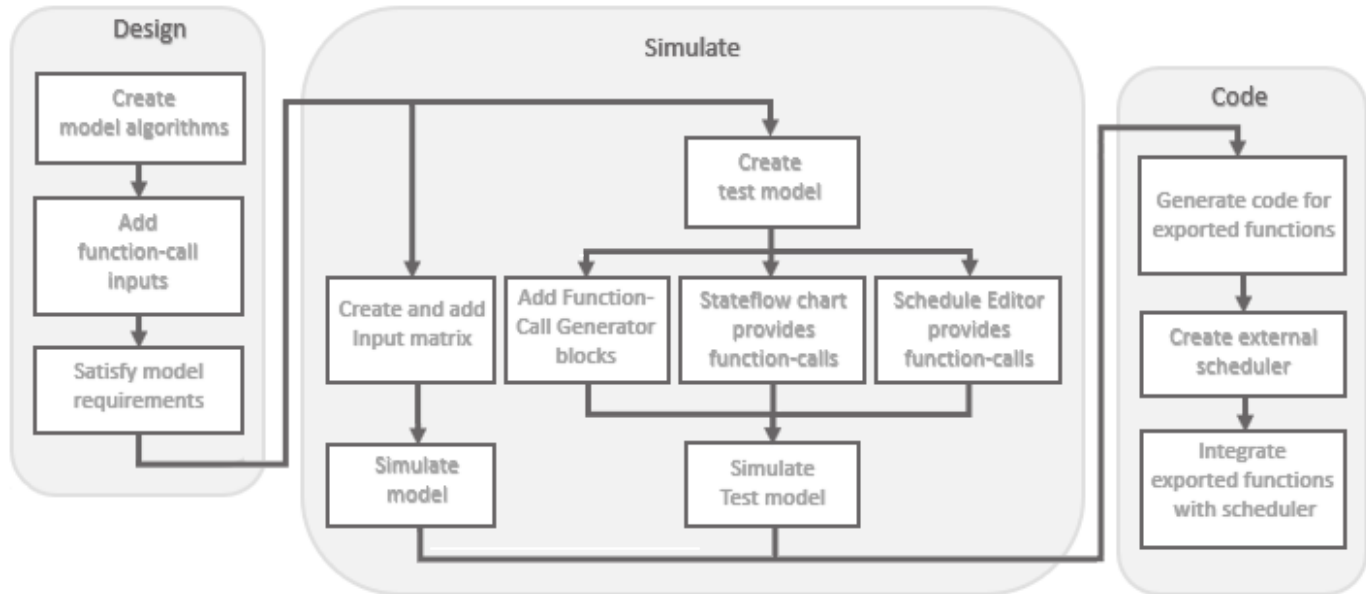

void function_call_10ms(void)          /* Sample time: [0.01s, 0.0s] */
{
    export_function_model_Y.output_10ms = export_function_model_U.input_10ms *
        export_function_model_U.input_10ms;
}

```

## Workflows for Export-Function Models

Four common processes for creating export-function models differ in how you simulate and test your model before generating code for the functions.

When function-call sequencing is simple enough to be specified as a model input, simulation using an input matrix is the preferred method for testing an export-function model. See “Test Export-Function Model Simulation Using Input Matrix” on page 10-74.

When function-call sequencing is too complicated to specify with an input matrix, create a test model (harness) to mimic the target environment behavior. Use this test model to provide function-call inputs to the export-function model. See “Test Export-Function Model Simulation Using Function-Call Generators” on page 10-78, “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85 and “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81.

## Allowed Blocks

At the top-level, an export-function model is limited to virtual blocks, blocks with constant (`inf`) sample time, and the following blocks:

- Inport
- Outport
- Bus Creator
- Bus Selector
- In Bus Element
- Out Bus Element
- Function-Call Subsystem
- Model with function-call input ports
- Simulink Function

- Function Element
- Function Element Call
- Message Triggered Subsystem
- Initialize Function
- Reinitialize Function
- Reset Function
- Terminate Function
- Data Store Memory
- Merge
- S-Function with function-call input port
- Function-Call Split
- Display
- Scope

See “Nonvirtual and Virtual Blocks” on page 39-2.

## Requirements for Export-Function Models

For an export-function model to successfully generate function code, the following requirements must be met.

Model Configuration Parameters:

- Solver **Type** set to Fixed-step.
- **Solver** set to auto or discrete.
- Code Generation **System target file** set to `ert.tlc`. Selecting `ert.tlc` requires an Embedded Coder license.
- For function-call Model blocks, **Periodic sample time constraint** for the referenced model set to `Ensure sample time independent`.

Root-level function-call Inport blocks:

- **Output function call** check box selected.
- Cannot receive a signal from an Asynchronous Task Specification block.

Root-level Outport blocks must be connected to one of these blocks or left unconnected or grounded:

- Function-call block driven by root-level function-call Inport block. This block can be a Function-Call Subsystem block, a function-call Model block, or an S-Function block with function-call input.
- Simulink Function block.
- Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block.
- Merge or Mux block driven exclusively by such blocks.

Root-level data Inport and Outport blocks cannot connect to virtual bus data signals.

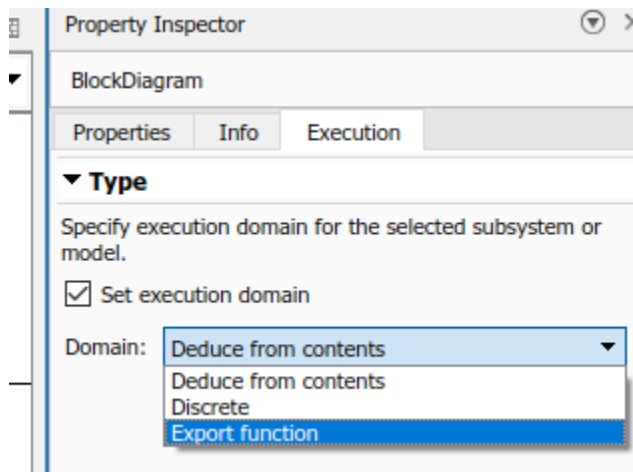

Root-level Function-Call Subsystem blocks and function-call Model blocks:

- All internal blocks within the block must support code generation.
- If the Trigger block **Sample time type** is set to:
  - **triggered**, internal blocks must have **Sample time** set to -1.
  - **periodic**, the root-level function-call Inport block must have its **Sample time** set to a specified discrete time and all internal blocks must have **Sample time** set to -1 or the specified discrete time.

## Designating an Export-Function Model

When you create an export-function model, tell Simulink to treat your model as an export-function model by designating it as an export-function model.

To designate a model as an export-function model, open the **Property Inspector**. With the root level of the model displayed and with no blocks highlighted, go to the **Execution** tab and select the **Set execution domain** check box. Then, from the **Domain** list, select **Export function**.

You can also designate a model as an export-function model by setting the `IsExportFunctionModel` parameter of the model.

```
set_param(ModelName, 'IsExportFunctionModel', 'on')
```

Simulink displays a  badge in the lower-left corner of the canvas to indicate that a model is specified as an export-function model.

After you designate a model as an export-function model, Simulink performs compile-time checks to warn you if the model does not meet export-function model requirements.

If you load a model that was created and saved in a release prior to R2022a, Simulink designates the model as an export-function model if the model meets the requirements to be an export-function model. In some cases, you may need to manually designate such a model as an export-function model.

## Sample Time for Function-Call Subsystems

In an export-function model, you can specify sample time for root-level function-call Inport blocks and the Trigger block inside a root-level Function-Call Subsystem block or function-call Model block. The following table shows how to specify these sample times.

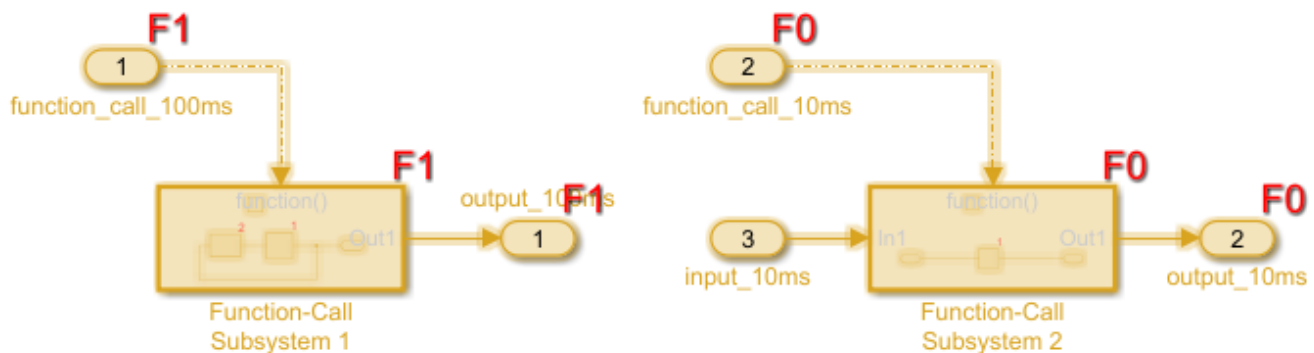

Trigger block <b>Sample time type</b>	Trigger block <b>Sample time</b>	Inport block <b>Sample time</b>	Function-call rate during simulation
Triggered	Not specified, parameter is inactive.	-1 (inherited)	For simulation, the function-call initiator connected to the Inport block sets the rate of simulation.
		Specified discrete time	Function-call initiator, in test model, connected to Inport block must have a sample time equal to the specified discrete time for the Inport block.  For simulation, component executes at the specified discrete rate. If a function-call source uses a different sample, Simulink displays an error message.
Periodic  Periodic function-call run-time checks apply if the export-function model is referenced from a Model block.	-1 (inherited) or the specified discrete time for the Inport block.	-1 (inherited)	This configuration is not allowed. Simulink displays an error message.
		Specified discrete time.	For simulation, component executes at the specified discrete sample time. If a function-call source uses a different sample time, Simulink displays an error message.

## Execution Order for Root-Level Function-Call Inport Blocks

By specifying sample time and priority for function-call Inport blocks you can control the execution order of function-call subsystems and function-call models during simulation. Alternatively, you can use the Schedule Editor or a Stateflow chart to test scheduling. See “Test Export-Function Model Simulation Using Schedule Editor” on page 10-85 and “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-81.

- 1 Specify sample time for simulation execution. Right-click a function-call Inport block, then select **Block parameters**.
- 2 Select the Signal Attributes tab. In the **Sample time** box, enter a discrete time.
- 3 Specify the block priority for simulation. Right-click a function-call Inport block, then select **Properties**.
- 4 In the **Priority** box, enter a priority value.
- 5 Display block execution order for simulation. On the **Debug** tab, select **Information Overlays** , then from the drop-down dialog, select **Execution Order**. This display has no impact on the generated code.

In the following export-function model, Function-Call Subsystem 2 with **Sample time** for Inport block 2 set to 0.01 (10 ms) runs before Function-Call Subsystem 1 with **Sample time** for Inport block 1 set to 0.1 (100 ms).

### Determine Relative Execution Order

Simulink compares function-call Inport block properties to determine their relative execution order using the following rules:

- 1 Priority - higher priority (smaller number) executes first
- 2 Sample time - smaller sample time executes first
- 3 Port number - smaller port number executes first
- 4 If the `OrderFunctionsByDependency` parameter for the model is set to 'on', blocks that have the same sample times are further sorted based on the relative data dependency of the functions to which the blocks are connected.

To see the effect of the `OrderFunctionsByDependency` parameter, consider the following model.

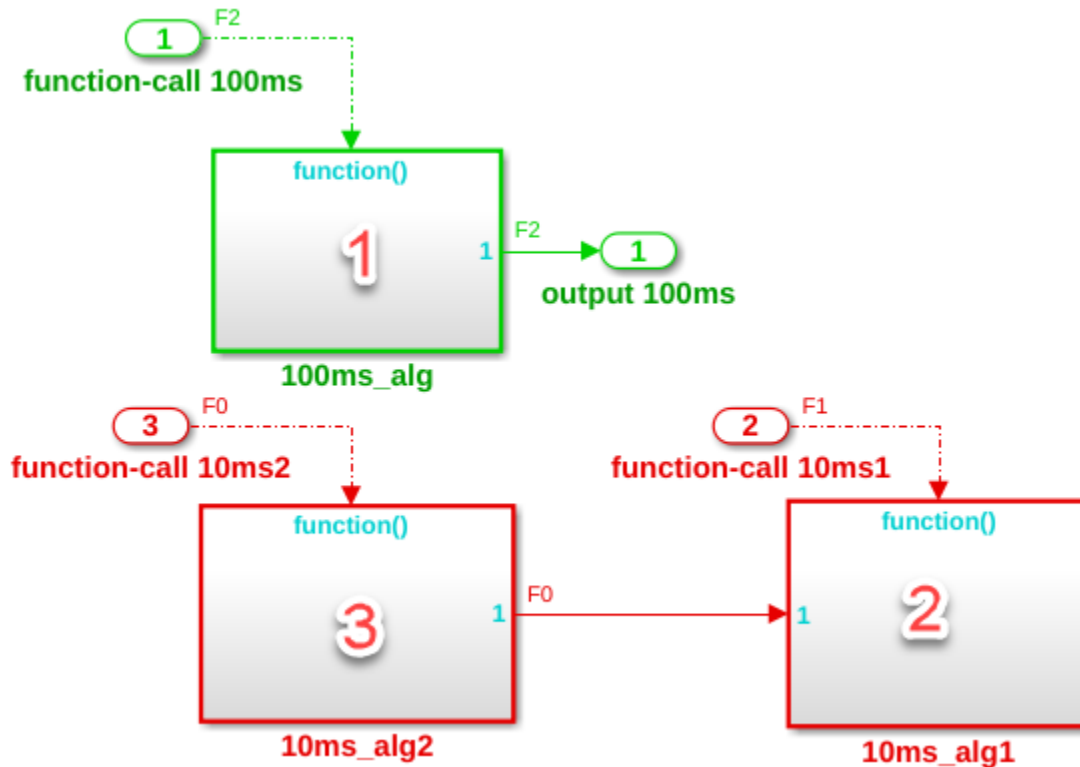

Inport block 1 executes last because it has a longer sample time than Inport blocks 2 and 3, which have the same sample time. If `OrderFunctionsByDependency` is set to 'off', Inport block 2 executes before Inport block 3 based on their port numbers. The execution order is 2, 3, 1.

The `OrderFunctionsByDependency` parameter is set to 'off' by default. To turn it on, use this command.

```
set_param(ModelName, 'OrderFunctionsByDependency', 'on')
```

With the `OrderFunctionsByDependency` set to 'on', Inport block 3 executes before Inport block 2 because of the data dependency between function-call subsystems 2 and 3. The execution order is 3, 2, 1.

Note that the `OrderFunctionsByDependency` parameter affects only the model for which it is set. The parameter does not propagate into referenced models.

When two blocks have different values for the **Priority** parameter, the block with the higher priority executes first. If the **Priority** parameter is equal, the block with the faster rate (smaller sample time) executes first. If **Priority** and sample time are the same for both of the blocks, the block with the lower port number executes first. The exception is when a data dependency exists between the blocks and `OrderFunctionsByDependency` is set to 'on', in which case the dependent block executes after the block on which it depends.

**Note** When the simulation mode of the top model is accelerator or rapid accelerator, Simulink does not perform run-time simulation checks for the execution order of root-level function-call Inport blocks inside referenced export-function models.

Suppose that an export-function model has five root-level function-call Inport blocks, A to E, with block properties as shown in the table. The blocks have no data dependencies, or `OrderFunctionsByDependency` is set to 'off'. To determine their relative execution order, Simulink compares their **Priority** parameters, sample times (if distinct and non-inherited), and port numbers.

Root-level function-call Inport block	A	B	C	D	E
Priority	10	30	40	40	30

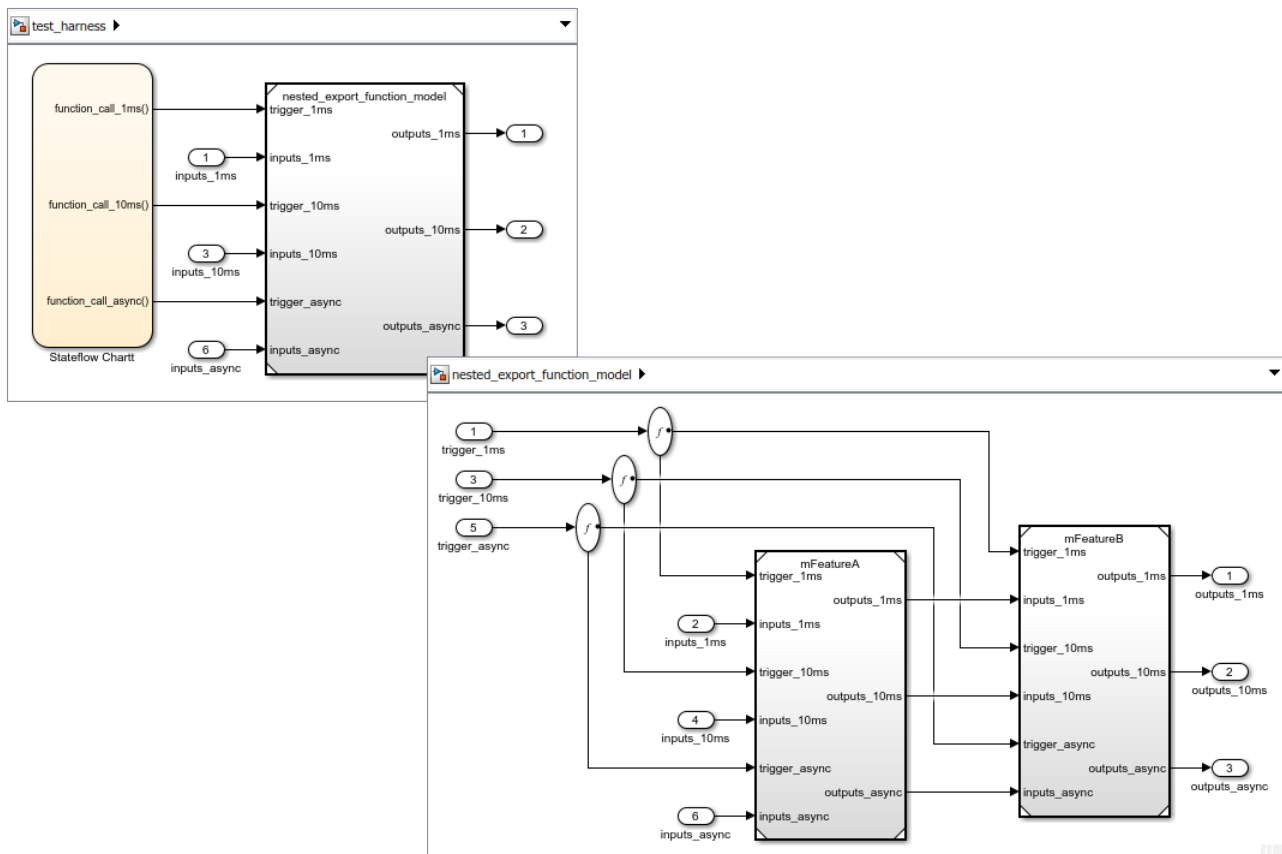

Root-level function-call Inport block	A	B	C	D	E
Sample Time	-1	0.2	0.1	0.1	-1
Port Number	5	4	3	2	1

- Block A has the highest priority of the five blocks. A executes first.
- B and E execute after A but before C and D. Since B and E have the same priority, Simulink compares their sample times to determine execution order. E has a sample time of -1 (inherited), which is smaller than 0.2, the sample time of B. E executes before B.
- C and D have the same priority and the same distinct, non-inherited sample times. The port number for D (2) is smaller than C (3), so D executes before C.

The relative execution order for these function-call Inport blocks is A, E, B, D, C.

### Nested Export-Function Models

Nested export-function models provide an additional layer of organization. The following model has two referenced export-function models that are referenced from a Model block.

**Note** An export-function model cannot contain a referenced model with asynchronous function-call inputs, but can contain function-call subsystems and function-call models. A model with asynchronous

function-call inputs can contain an export-function model, a function-call subsystem, or a function-call model.

## Export-Function Model with a Multi-Instanced Function-Call Model

You can use Function-Call Subsystem blocks or function-call Model blocks within an export-function model. If you use a function-call Model block, you can also create multiple instances of the model.

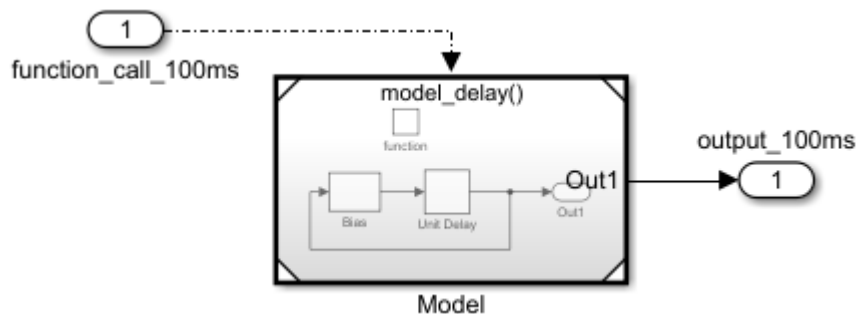

- 1 Define your algorithm with a model that contains a Trigger block. Set **Trigger type** to function-call.

- 2 Reference the model from a Model block. The result is a function-call model.

- 3 Connect a function-call Inport block and select the **Output function call** check box. Add signal Inport and Output blocks. Update the model (Ctrl-D). The result is an export-function model with a function-call model.

- 4 Copy the referenced model and port blocks to create a second instance of the model. The two instances are called by different root-level function-call Inport blocks in different tasks.

## Export-Function Models and Models with Asynchronous Function-Call Inputs

Export-function model capability is available for models with asynchronous function-call input ports, also referred to as JMAAB-B models. You use these models primarily in the Simulink environment where the Simulink scheduler calls the functions.

Comparison Characteristic	Export-Function Models	Models with Asynchronous Function-Call Inputs
Definition	These models have root-level function-call Inport blocks that are not connected to an Asynchronous Task Specification block. These Inport blocks trigger function-call subsystems or function-call models (Model block with Trigger block).	These models have root-level function-call Inport blocks connected to Asynchronous Task Specification blocks. These Inport blocks trigger function-call subsystems or function-call models.
Root-level blocks	Only blocks executing in a function-call context are allowed at the root level.	Blocks executing in a non-function-call context are also allowed.
Data transfer	Use data transfer indicators to interpret simulation results. Data transfer in export-function models is not protected by default in generated code. For more details, see “Latched Input Data for Function-Call Subsystems” on page 10-35.	Use Rate Transition blocks to protect data transferred between function-call subsystems running at different rates. For more information, see Rate Transition.
Simulation support	These models support standalone simulation and test model simulation in all simulation modes.	These models support test model simulation in all simulation modes and standalone simulation in Normal, Accelerator, and Rapid Accelerator modes.
Code generation support	Top-model and standalone code generation are supported.	Top-model and standalone code generation are supported.

## Using Resettable Subsystems

### Behavior of Resettable Subsystems

Use resettable subsystems when you want to conditionally reset the states of all blocks within a subsystem to their initial condition. A resettable subsystem executes at every time step but conditionally resets the states of blocks within it when a trigger signal occurs at the reset port. This behavior is similar to the reset behavior of blocks with reset ports, except that a resettable subsystem resets the states of all blocks inside it.

Using resettable subsystems over other methods of resetting states of your block or subsystem has these advantages:

- When you want to reset the states of multiple blocks in a subsystem, displaying and connecting the reset port of each block is cumbersome and makes the block diagram hard to read. Instead, place all the blocks in a resettable subsystem and configure the Reset block in the subsystem.
- Some blocks, such as the Discrete State-Space block, have states but do not have reset ports. You cannot reset these blocks individually, and you must reset the subsystem they are inside. In such cases, it is useful to place these blocks in a resettable subsystem.
- You can also reset blocks in enabled subsystems by setting the **States when enabling** parameter on the enable port to **reset**. However, for this behavior, you must disable the subsystem and then reenble it at a later time step. To reset your block states at the same time step, use resettable subsystems. For more information, see “Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-111.

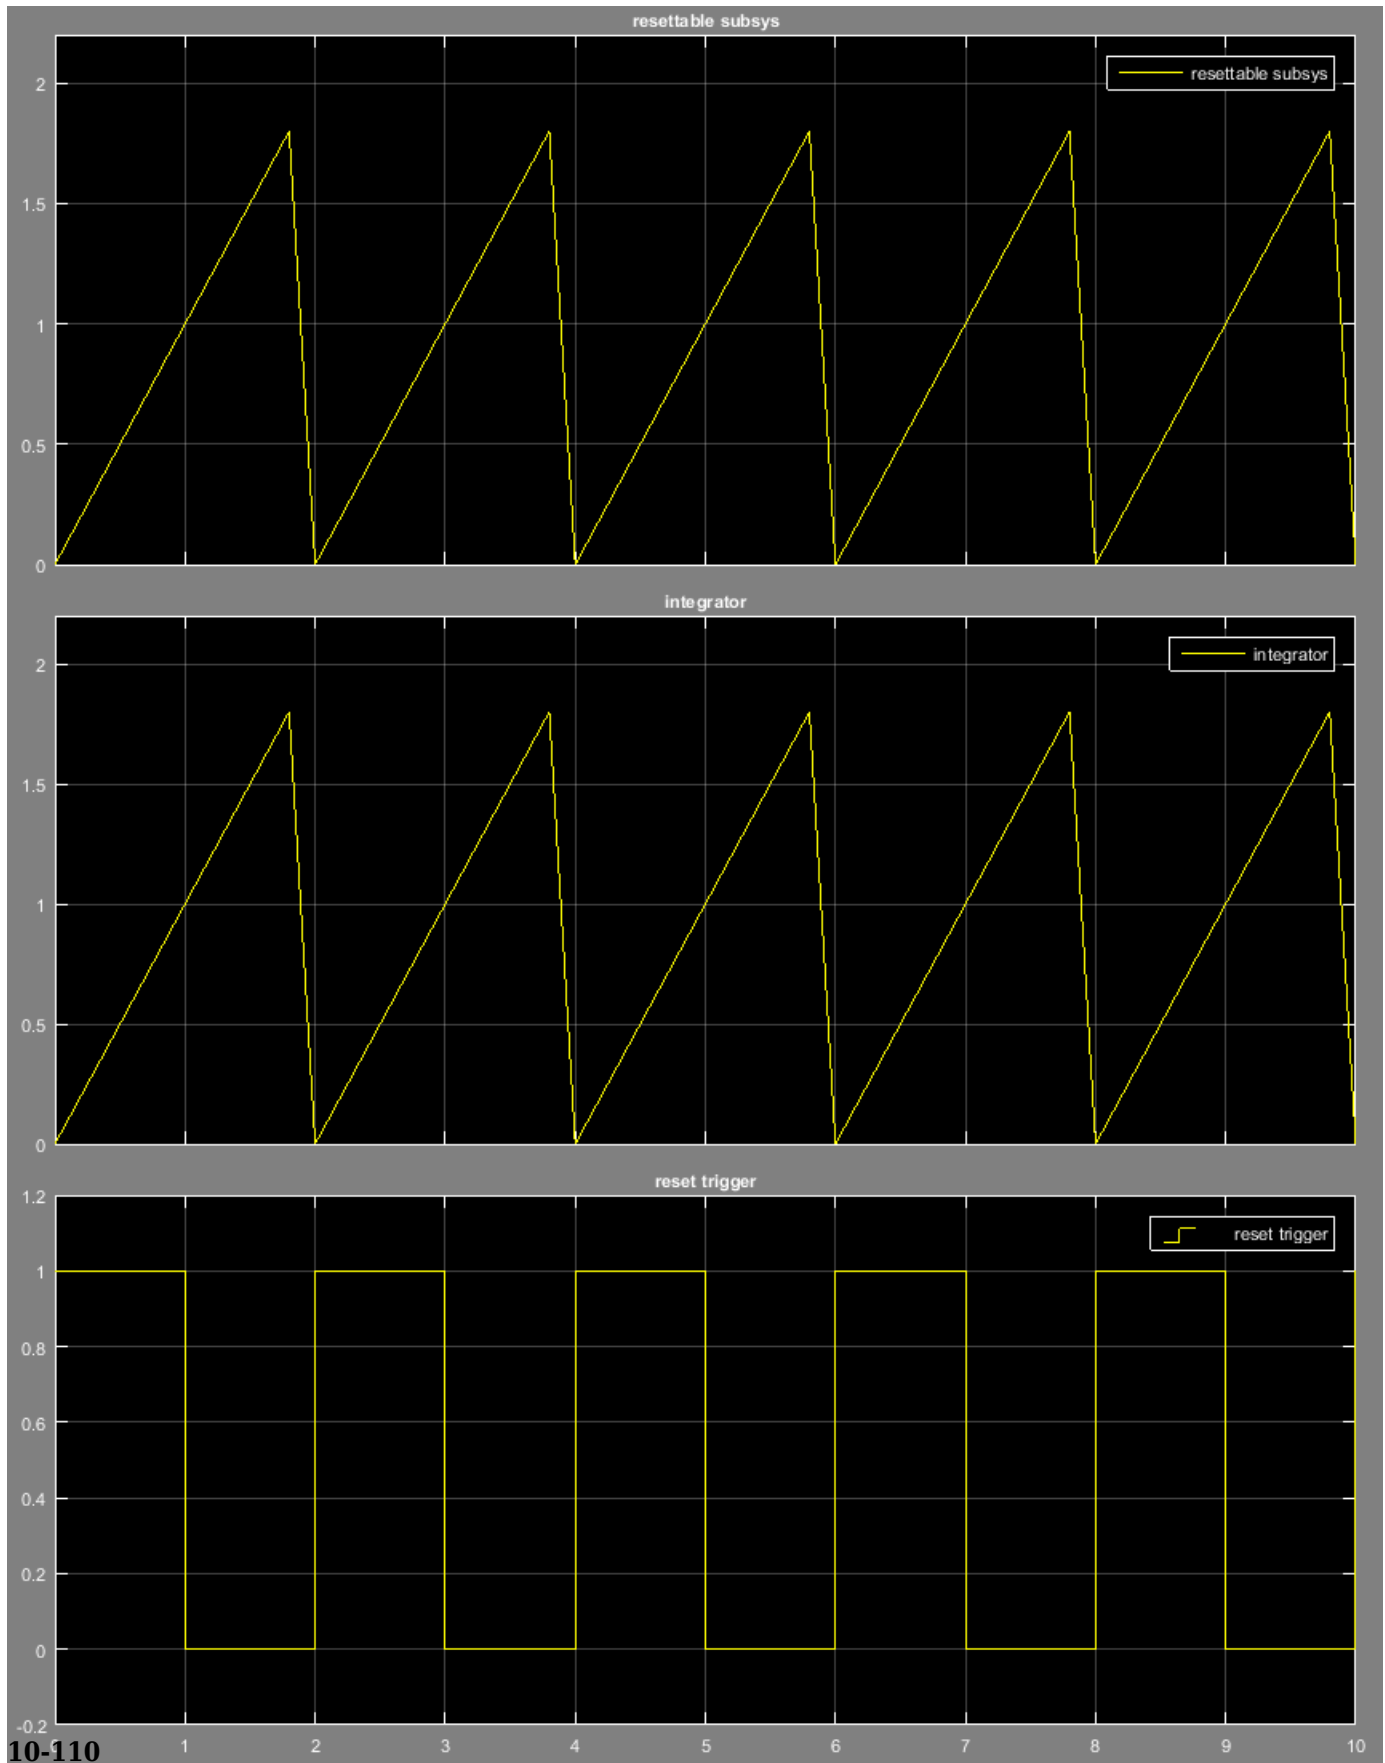

All blocks in a resettable subsystem must have the same sample time, and they execute at every sample time hit of the subsystem. Resettable subsystems and the model use a common clock.

---

**Note** If a resettable subsystem contains a Stateflow chart that contains a Simulink Function block, blocks inside the Simulink Function block do not revert to their initial conditions when the resettable subsystem executes.

---

This model shows that the behavior of block reset ports and resettable subsystems is the same. A resettable subsystem enables you to reset the states of all blocks inside it. The resettable subsystem contains an integrator block that is configured similar to the root-level Integrator block, but the block does not have a reset port. The subsystem resets the states of the integrator block inside it in the same manner as the reset port of the Integrator block. You can see this behavior by running the model and viewing the output in the scope.

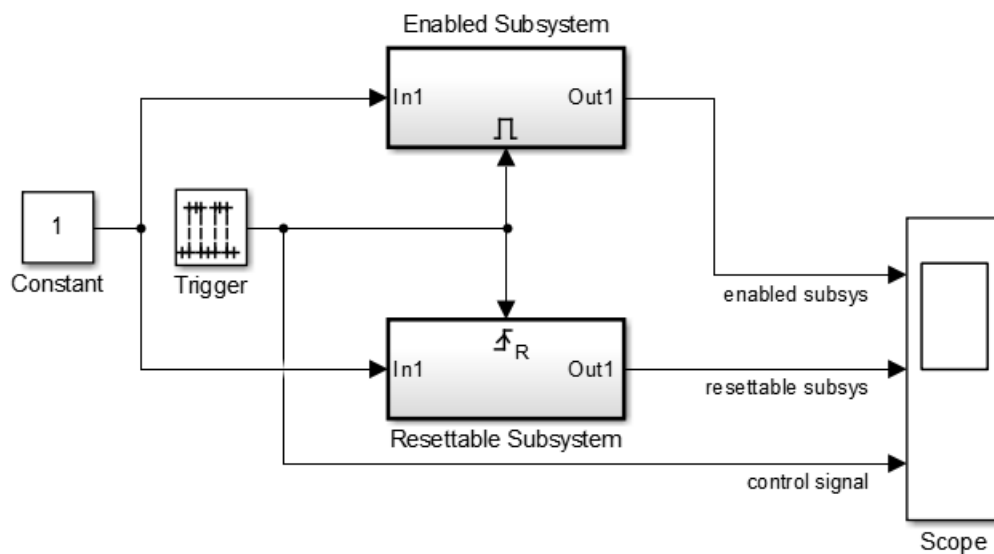

## Comparison of Resettable Subsystems and Enabled Subsystems

If you set **States when enabling** for the Enable block to **reset**, the enabled subsystem resets the states of all blocks in the subsystem. However, you must disable the subsystem for at least one time step and then reenable it for the states to reset.

In contrast, resettable subsystems always execute and reset the states of their blocks instantaneously.

This model shows the difference in the execution behavior of these subsystems. It contains an enabled subsystem and a resettable subsystem whose control ports are connected to pulse generator. The resettable subsystem is set to reset on the rising edge of the control signal, and the enabled subsystem has the **States when enabling** parameter set to **reset** in the enable port.

The subsystems contain identical Discrete-Time Integrator blocks, whose input is the Constant block at the root level of the model. The figure shows the contents of the resettable subsystem.

The figure shows the simulation output.

When the control signal is 0, the enabled subsystem is disabled and the integrator does not change its output while the resettable subsystem is executing. The rising edge of the control signal triggers the reset port of the resettable subsystem and enables the enabled subsystem. Both subsystems reset their states at this time step.

Notice that the enabled subsystem must be disabled for at least one time step before its states can be reset. The resettable subsystem does not have this limitation.

## Simulink Functions Overview

### What Are Simulink Functions?

A Simulink function is a computational unit that calculates a set of outputs when provided with a set of inputs. The function header uses a notation similar to programming languages such as MATLAB and C++. You can define and implement a Simulink function in several ways:

- **Simulink Function block** — Function defined using Simulink blocks within a Simulink Function block.
- **Exported Stateflow graphical function** — Function defined with state transitions within a Stateflow chart, and then exported to a Simulink model.
- **Exported Stateflow MATLAB function** — Function defined with MATLAB language statements within a Stateflow chart, and then exported to a Simulink model.
- **S-function** — Function defined using an S-function block. For an example with an S-function, open `sfcdemo_simulinkfunction_getset`.

### What Are Simulink Function Callers?

A Simulink function caller invokes the execution of a Simulink function from anywhere in a model or chart hierarchy.

- **Function Caller block** — Call a function defined in Simulink or exported from Stateflow. See Function Caller.
- **Stateflow chart transition** — In a Stateflow chart, call a function defined in Simulink or exported from Stateflow.
- **MATLAB Function block** — Call a function from a MATLAB language script.
- **S-Function block** — Call a function using system methods. See `ssDeclareFunctionCaller` and `ssCallSimulinkFunction`.
- **MATLAB System block** — Call a function using a System object™ and the MATLAB language.

### Connect to Local Signals

In addition to Argument Inport and Argument Outport blocks, a Simulink Function block can interface to signals in the local environment of the block through Inport or Outport blocks. These signals are hidden from the caller. You can use port blocks to connect and communicate between two Simulink Function blocks or connect to root Inport and Outport blocks that represent external I/O.

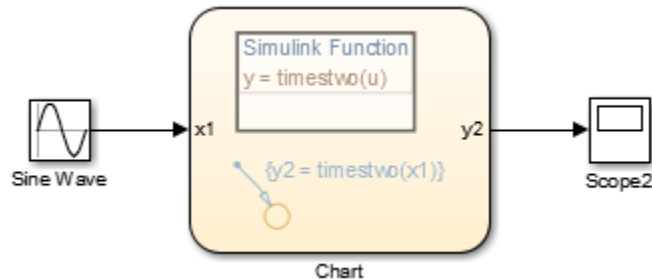

You can also connect the Outport blocks to sink blocks that include logging (To File, To Workspace) and viewing (Scope, Display) blocks. However, these blocks execute last after all other blocks.

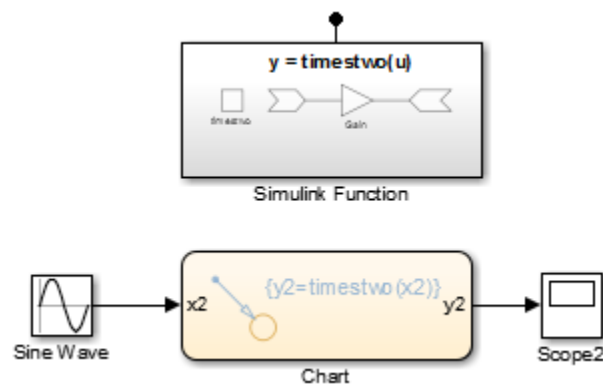

A Simulink Function block can output a function-call event to an Outport block.

## Reusable Logic with Functions

Use functions when you need reusable logic across a model hierarchy. Consider an example where a Simulink Function with reusable logic is defined in a Stateflow chart.

You can move the reusable logic from inside the Stateflow chart to a Simulink Function block. The logic is then reusable by function callers in Simulink subsystems (Subsystem and Model blocks) and in Stateflow charts at any level in the model hierarchy.

The result is added flexibility for structuring your model for reuse.

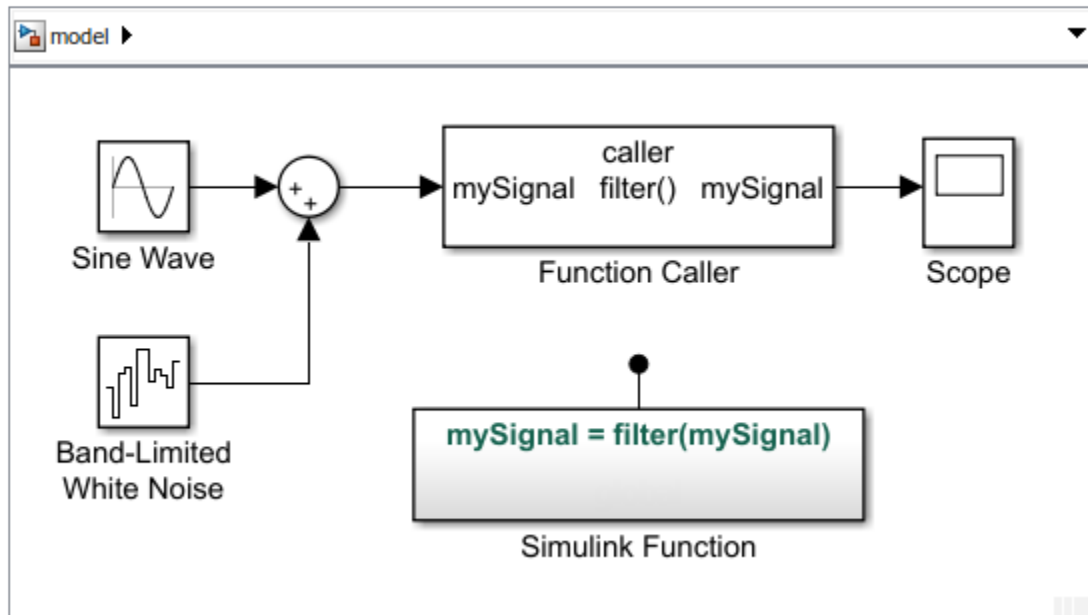

**Note** Input and output argument names (x2, y2) for calling a function from a Stateflow chart do not have to match the argument names in the function prototype (u, y) of a Simulink Function block.

## Input/Output Argument Behavior

The function prototype for a Simulink Function block can have identical input and output arguments. For example, a function that filters noise could input a signal and then return the signal after filtering.

```
mySignal = filter(mySignal)
```

You can call the function with a Function Caller block and add noise to a test signal to verify the function algorithm.

When generating code for this model, the input argument for the Simulink Function block passes a pointer to the signal, not a copy of the signal value.

```
void filter(real_T *rtuy_mySignal)
{
    . . .
    *rtuy_mySignal = model_P.DiscreteFilter_NumCoef * DiscreteFilter_tmp;
}
```

## Shared Resources with Functions

Use functions when you model a shared resource, such as a printer. The model `slexPrinterExample` uses Simulink Function blocks as a common interface between multiple computers and a single Stateflow chart that models a printer process.

## How a Function Caller Identifies a Function

The function interface uses MATLAB syntax to define its input and output arguments. The name of the function is a valid ANSI® C identifier. The model hierarchy can contain only one function definition with the identified function name. Simulink verifies that:

- The arguments in the **Function prototype** parameter for a Function Caller block matches the arguments specified in the function. For example, a function with two input arguments and one output argument appears as:  
 $y = \text{MyFunction}(u1, u2)$
- The data type, dimension, and complexity of the arguments must agree. For a Function Caller block, you can set the **Input argument specifications** and **Output argument specifications** parameters, but usually you do not need to specify these parameters manually. Simulink derives the specification from the function.

The only case where you must specify the argument parameters is when the Function Caller block cannot find the function in the model or in any child model it references. This situation can happen when the Function Caller block and called function are in separate models that are referenced by a common parent model. See “Simulink Function Blocks in Referenced Models” on page 10-139 and “Argument Specification for Simulink Function Blocks” on page 10-136.

## Reasons to Use a Simulink Function Block

Function-Call Subsystem blocks with direct signal connections for triggering provide better signal traceability than Simulink Function blocks, but Simulink Function blocks have other advantages.

- **Eliminate routing of signal lines.** The Function Caller block allows you to execute functions defined with a Simulink Function block without a connecting signal line. In addition, functions and their callers can reside in different models or subsystems. This approach eliminates signal routing problems through a hierarchical model structure and allows greater reuse of model components.
- **Use multiple callers to the same function.** Multiple Function Caller blocks or Stateflow charts can call the same function. If the function contains state (for example, a Unit Delay block), the state is shared between the different callers.
- **Separate function interface from function definition.** Functions separate their interface (input and output arguments) from their implementation. Therefore, you can define a function using a Simulink Function block, an exported graphical function from Stateflow, or an exported MATLAB function from Stateflow. The caller does not need to know how or where the function was implemented.

## Choose a Simulink Function or Reusable Subsystem

A consideration for using a Simulink Function block or a Subsystem block has to do with shared state between function calls. A Simulink Function block has shared state while a Subsystem block, even if specified as a reusable function, does not.

- For a Simulink Function block, when one block has multiple callers, code is always generated for one function. If the Simulink Function block contains blocks with state (for example, Delay or Memory), the state is persistent and shared between function callers. In this case, the order of calls is an important consideration.
- For a Subsystem block, when a block has multiple instances and is configured as a reusable function, code is usually generated for one function as an optimization. If the Subsystem block contains blocks with state, code is still generated for one function, but a different state variable is passed to the function. State is not shared between the instances.

## When Not to Use a Simulink Function Block

Simulink Function blocks allow you to implement functions graphically, but sometimes using a Simulink Function block is not the best solution.

For example, when modeling a PID controller or a digital filter and you have to model the equations defining the dynamic system. Use an S-Function, Subsystem, or Model block to implement systems of equations, but do not use a Simulink Function block, because these conditions can occur:

- **Persistence of state between function calls.** If a Simulink Function block contains any blocks with state (for example, Unit Delay or Memory), then their state values are persistent between calls to the function. If there are multiple calls to that function, the state values are also persistent between the calls originating from different callers.
- **Inheriting continuous sample time.** A Simulink Function block cannot inherit a continuous sample time. Therefore, do not use this block in systems that use continuous sample times to model continuous system equations.

## Tracing Simulink Functions

Visually display connections between a Simulink function and their callers with lines that connect callers to functions:

- Turning on/off tracing lines — On the **Debug** tab, select **Information Overlays** . From the drop-down box, select **Function Connectors** .
- Direction of tracing lines — Lines connected at the bottom of a block are from a function caller. Lines connected at the top of a block are to a Simulink function or a subsystem containing the function.

- Navigation to functions — A function caller can be within a subsystem.

Navigate from a caller in a subsystem to a function by first opening the subsystem, and then clicking a link to the function.

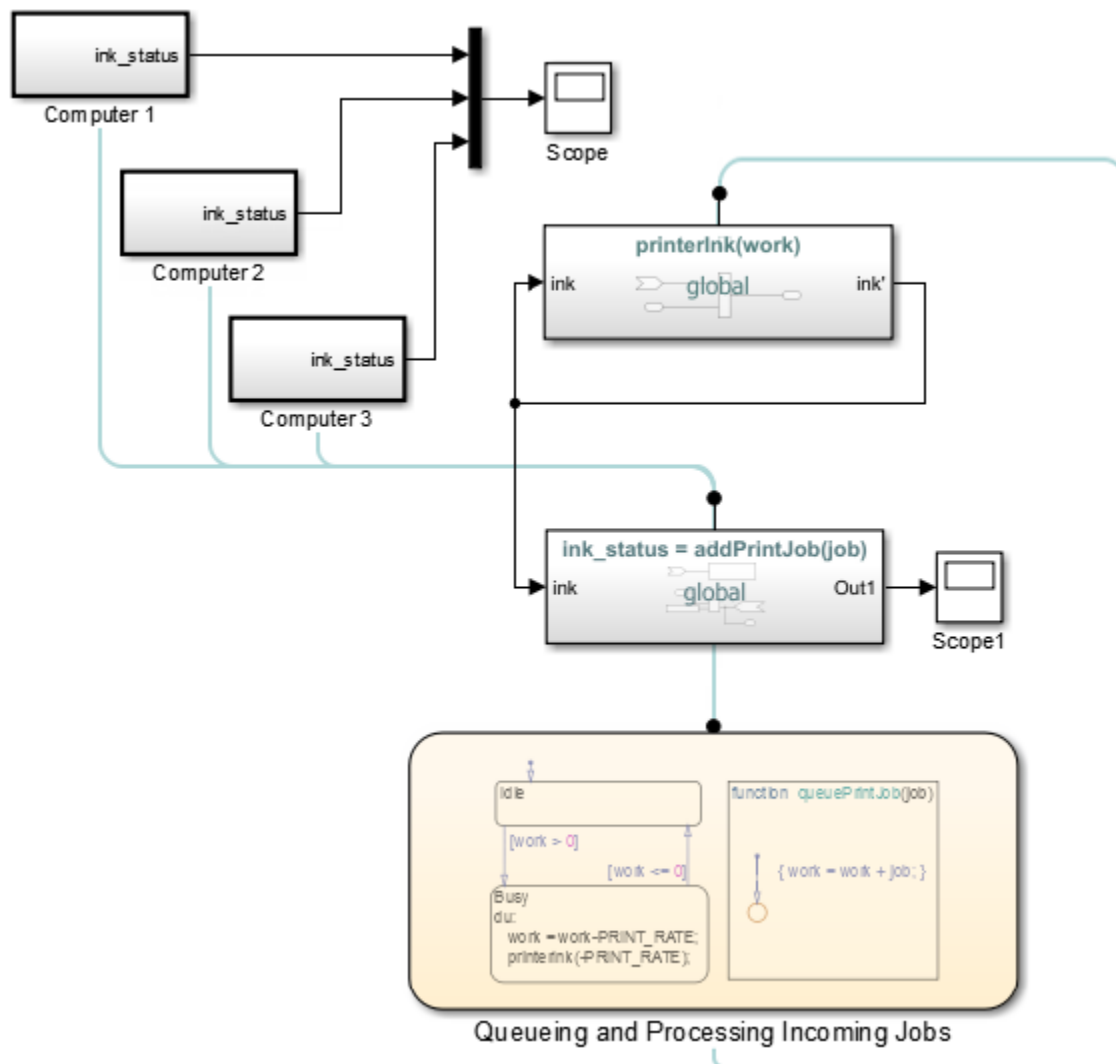

If the function is at the root level of a model, the function opens. If the function is within a subsystem, the subsystem containing the function opens.

### Monitor Ink Status on a Shared Printer Using Simulink Functions

After selecting **Function Connectors**, the model `slexPrinterExample` shows the relationships between callers and functions.

In this example, the Function Caller in the Simulink Function block `addPrintJob`, calls the exported Stateflow function `queuePrintJob`. The subchart `Busy` calls the Simulink Function block `printerInk`. Tracing lines are drawn into and out of the Stateflow chart.

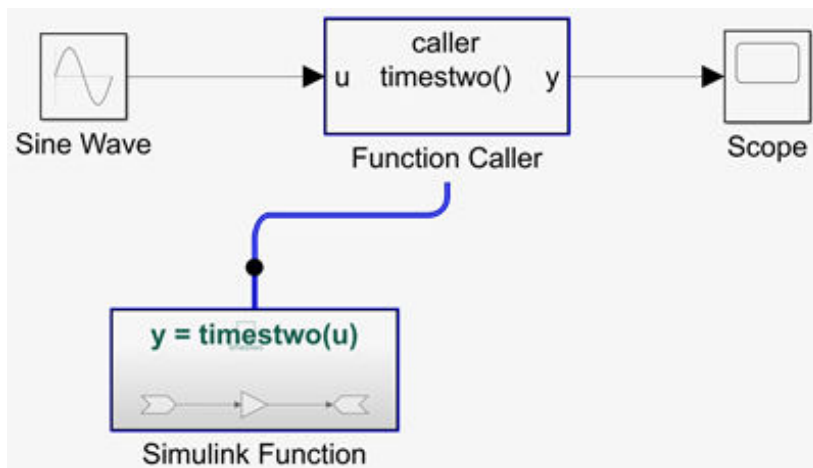

## Highlight and Animate Function Calls

Use animation to highlight function calls.

This example shows a still of an animated Simulink function call.

To access animation, in the toolstrip, on the **Debug** tab, in the **Event Animation** section, set the animation speed to **Slow**, **Medium**, or **Fast**.

**Event Animation** is visible when you have event blocks in your model, such as blocks from the Messages & Events library, Stateflow charts, Function-Call Subsystem blocks, Simulink functions, or SimEvents blocks.

## Add a Simulink Function to a Model

Simulink functions have an interface with input and output arguments similar to programming languages. You can create the function definition for a Simulink function using:

- Simulink blocks within a Simulink Function block
- Stateflow state transitions in a graphical function exported from a Stateflow chart.
- MATLAB code in a MATLAB function exported from a Stateflow chart.

The following sections show how to create a Simulink function for the function  $y = \text{timestwo}(x)$ . The function multiplies a value ( $x$ ) from a caller by 2, and then sends the calculated value ( $y$ ) back to the caller. To call the function, see “Call a Simulink Function from a Model” on page 10-129.

To open completed model with Simulink functions and function callers, see `ex_simulink_functions_and_function_callers`.

### Create a Simulink function using a Simulink Function Block

Set up a Simulink Function block to receive data through an input argument from a function caller, and then pass a calculated value back through an output argument.

- 1 Add a Simulink Function block to your model.
- 2 On the block face, enter the function prototype.

```
y = timestwo(x)
```

- 3 Double-click the block to open the subsystem defining the function algorithm.
- 4 Add a Gain block and set the **Gain** parameter to 2.

### Create a Simulink function using an exported graphical function from a Stateflow chart

Set up a graphical function in a Stateflow chart to receive data through an input argument from a function caller and pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

### Define a graphical function In a Stateflow chart

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

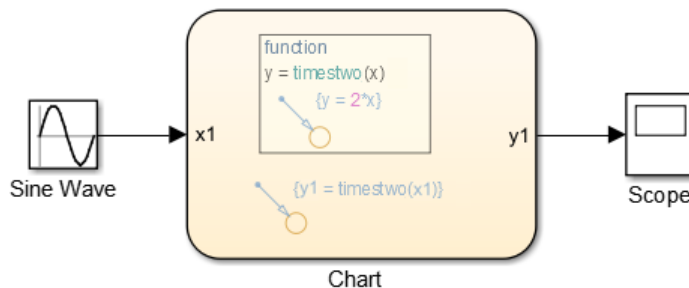

- 1 Add a Stateflow Chart to your Simulink model. Double-click on the Simulink block diagram. In the search box, enter `chart`, and then from the search results, select `Chart`.
- 2 Double-click to open the chart.
- 3 Add a graphical function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.
- 4 Define the function interface. In the function box, replace the ? with the function interface `y = timestwo(x)`.
- 5 Define the function algorithm. Click the transition arrow and replace the ? with `{y = 2*x}`.

### Test the graphical function

Test the graphical function within the Stateflow chart before exporting to a Simulink model.

- 1 Add a default transition in the chart for testing the function. From the left-side toolbar, click and drag a default transition arrow  onto the chart.
- 2 Double-click the arrow and replace the ? with `{y1 = timestwo(x1)}`.
- 3 Add an input port to the chart. Open the Model Explorer. In the left pane, select `Chart`. From the menu, select **Add > Data**. Set **Name** to `x1` and **Scope** to `Input`.
- 4 Add an output port to the chart. From the menu, select **Add > Data**. Set **Name** to `y1` and **Scope** to `Output`.
- 5 Add a Sine Wave block to provide test data for the input and a Scope block to view results from the output..

- 6 Run a simulation.

### Set argument parameters for a graphical function

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

- 1 Open the Model Explorer. On the **Modeling** tab and from the **Design** section, select **Model Explorer** .
- 2 In the left pane, select the graphical function.

- 3 From the **Column View** list in the middle pane, select **Stateflow**. Select the filter icon , and then from the toggle list, select **All Stateflow Objects**. From the center pane table, select an input or output argument.

- 4 In the right pane, set Size to 1 (scalar), Set **Complexity** to Off (real number), and set **Type** to double.

- 5 Repeat steps 2 and 3 with the output function argument y.

### Set export function parameters for a graphical function

Set parameters to export a graphical function to a Simulink model from a Stateflow chart during a simulation.

- 1 Open the Model Explorer.
- 2 In the left pane, select the chart containing the graphical function.

- 3 In the property dialog box on the right side, select the **Export Chart Level Functions** check box, click the **Apply** button, and then select the **Treat Exported Functions as Globally Visible** check box.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Treat Exported Functions as Globally Visible** check box.

## Create a Simulink function using an exported MATLAB function from a Stateflow chart

Set up a MATLAB function in a Stateflow chart to receive data through an input argument from a function caller and then pass a calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

### Define a MATLAB function in a Stateflow chart

Create a MATLAB function in a Stateflow chart. Define the function interface and function definition.

- 1 Add a Stateflow Chart to your Simulink model. Double-click on the block diagram. In the search box, enter `chart`, and then from the search results, select `Chart`.
- 2 Open the chart.
- 3 Add a MATLAB function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.
- 4 Define the function interface. In the function box, replace the ? with the function interface `y = timestwo(x)`.

- 5 Double-click the function box to open the MATLAB code editor. Define the function algorithm with the MATLAB code.

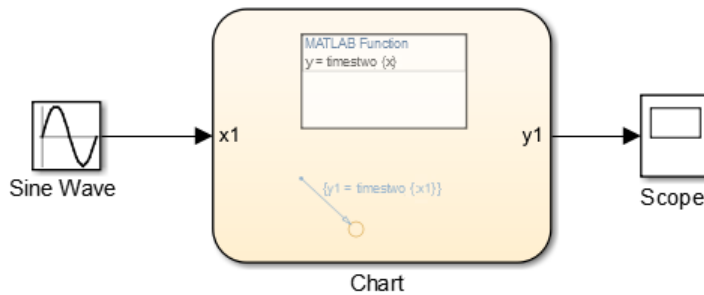

### Test the MATLAB function

Test the MATLAB function within a Stateflow chart before exporting to a Simulink model.

- 1 Add a default transition in the chart for testing the function. From the left-side toolbar, click and drag a default transition arrow  onto the chart.
- 2 Double-click the arrow and replace the ? with `{y1 = timestwo(x1)}`.

- 3 Add an input port to the chart. Open the Model Explorer. In the left pane, select Chart. From the menu, select **Add > Data**. Set **Name** to x1 and **Scope** to Input.
- 4 Add an output port to the chart. From the menu, select **Add > Data**. Set **Name** to y1 and **Scope** to Output.
- 5 Add a Sine Wave block to provide test data for the input and a Scope block to view results from the output..

- 6 Run a simulation.

### Set the argument parameters for a MATLAB function

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

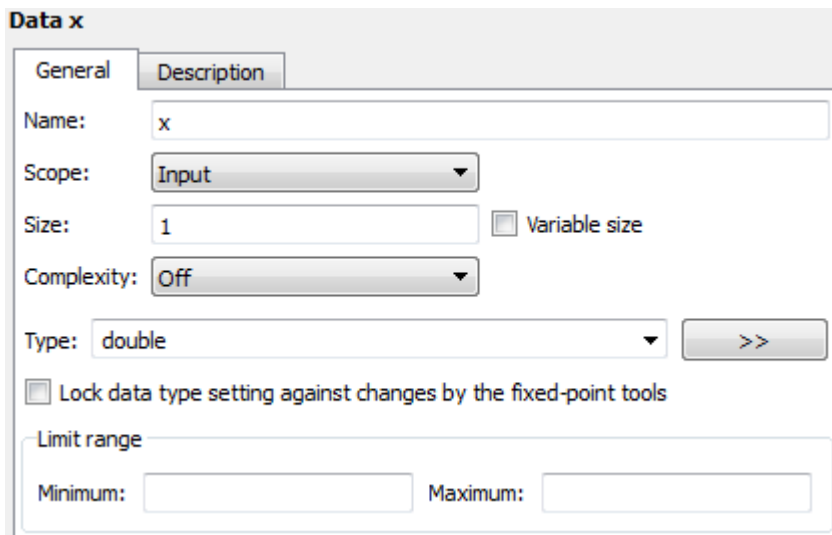

- 1 Open the Model Explorer. On the **Modeling** tab and from the **Design** section, select **Model Explorer** .
- 2 In the left pane, select the MATLAB function.

- 3 From the **Column View** list in the middle pane, select **Stateflow**. Select the filter icon , and then from the toggle list, select **All Stateflow Objects**. From the center pane table, select an input or output argument.

- 4 In the right pane, set **Size** to 1 (scalar), Set **Complexity** to Off (real number), and set **Type** to double.

- 5 Repeat steps 2 and 3 with the output function argument *y*.

### Set export function parameters for a MATLAB function

Set parameters to export a MATLAB function from a Stateflow chart during a simulation.

- 1 Open the Model Explorer.
- 2 From the left pane, select the chart containing the MATLAB function.

- 3 In the property dialog box on the right side, select the **Export Chart Level Functions** check box, click the **Apply** button, and then select the **Treat Exported Functions as Globally Visible** check box.

If you are calling the exported MATLAB function from another Stateflow chart (not the chart that exported the MATLAB function), you do not need to select the **Treat Exported Functions as Globally Visible** check box.

- “Diagnostics Using a Client-Server Architecture” on page 10-168

## Call a Simulink Function from a Model

Simulink functions have an interface with input and output arguments similar to programming languages. Simulink function callers send data through input arguments to Simulink functions, execute the function, and then receive data back from the function through output arguments. You can call a Simulink function using:

- Function Caller blocks
- MATLAB Function blocks
- Stateflow charts

The following sections show how to call a Simulink function. The function `y = timestwo(x)` multiplies a value (`x`) from a caller by 2, and then sends the calculated value (`y`) back to the caller. To create the functions, see “Add a Simulink Function to a Model” on page 10-123.

To open completed model with Simulink functions and function callers, see `ex_simulink_functions_and_function_callers`.

### Use a Function Caller Block to Call a Simulink Function Block

Set up a Function Caller block to send data through an input argument to a Simulink Function block, and receive data back from the function through an output argument.

- 1 Add a Function Caller block to your model.
- 2 Open the Function Caller dialog box. In the **Function prototype** box, enter `y = timestwo(x)`. This function prototype creates an input port `x` and output port `y` on the Function Caller block.

---

**Note** Typing in a blank text box displays a list of previously created function prototypes that match the text you are typing.

---

- 3 Add and setup a Simulink Function block as described in “Create a Simulink function using a Simulink Function Block” on page 10-123.

---

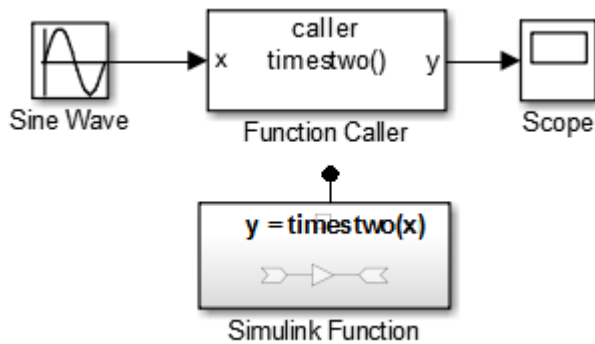

**Note** The function and argument names for the Simulink Function block and the **Function prototype** for the Function Caller block must match exactly.

---

**Test the function call**

- 1 Add a Sine Wave block to provide test data for the input and a Scope block to view results from the output.

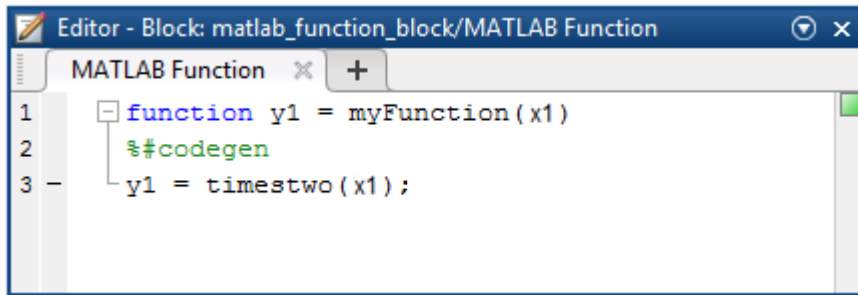

- 2 Run a simulation. The input sine wave with an amplitude of 2 is doubled.

**Use a MATLAB Function Block to Call a Simulink Function Block**

Set up a MATLAB Function block to send data through an input argument to a Simulink Function block, and receive data back from the function through an output argument.

- 1 Add a MATLAB Function block to your model.
- 2 Double-click the block, which opens the MATLAB editor. Enter the function call `y1 = timestwo(x1)`.

```

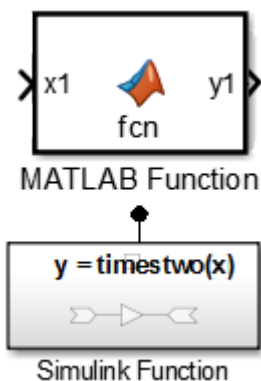

Editor - Block: matlab_function_block/MATLAB Function
MATLAB Function
1 function y1 = myFunction(x1)
2     %#codegen
3     y1 = timestwo(x1);

```

**Note** The argument names for the function you define in the MATLAB Function block do not have to match the argument names for the function that you define with a Simulink Function block. For a Function Caller block that calls a Simulink Function block, argument names must match.

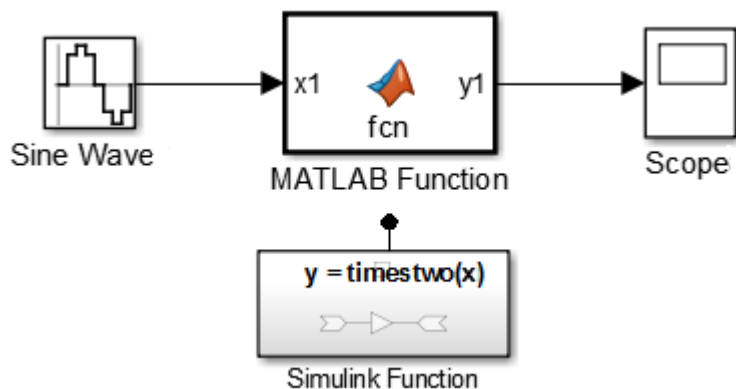

**Note** MATLAB Function blocks only support discrete and fixed-in-minor sample times.

- 3 Add and setup a Simulink Function block as described in “Create a Simulink function using a Simulink Function Block” on page 10-123.

### Test the function call

- 1 Add a Sine Wave block to provide test data for the input and a Scope block to view results from the output.

- 2 For the Sine Wave block, set the **Sample time** to 0.01. For the model, open the Configuration Parameters dialog box to the solver pane. Set **Type** to Fixed-step and **Fixed-step size** to 0.01.
- 3 Run a simulation.

## Use a Stateflow Chart to Call a Simulink Function Block

Set up a Stateflow chart to send data through an input argument to a Simulink Function block, and receive data back from the function through an output argument.

- 1 Add a Stateflow chart to your Simulink model. Double-click on the Simulink block diagram. In the search box, enter `chart`, and then from the search results, select `Chart`.
- 2 Double-click the chart to open it.
- 3 From the left-side toolbar, click and drag the default transition icon  onto the chart.
- 4 Add an input port to the chart. Open the Model Explorer. In the left pane, select `Chart`. From the menu, select **Add > Data**. Set **Name** to `x1` and **Scope** to `Input`.

---

**Note** The argument names for the function you define in the Stateflow chart do not have to match the argument names for the function that you define with a Simulink Function block. For a Function Caller block that calls a Simulink Function block, argument names must match.

---

- 5 Add an output port to the chart. From the menu, select **Add > Data**. Set **Name** to `y1` and **Scope** to `Output`.
- 6 Add a Sine Wave block and connect signal output to the chart input port. Add a Scope block and connect input to the chart output port.
- 7 Edit transition code to call a function. For example, to call the Simulink Function block, enter:

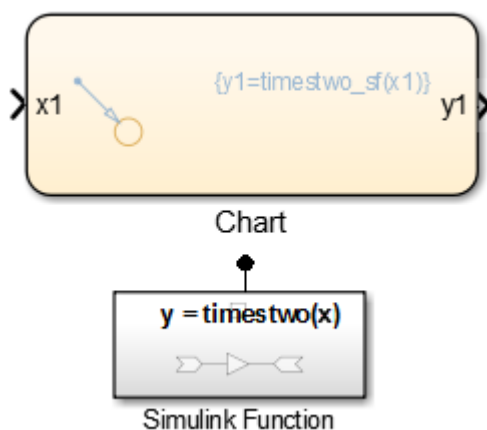

```
{y1=timestwo_sf(x1);}
```

---

**Note** Input signals to a Stateflow chart can be either continuous or discrete.

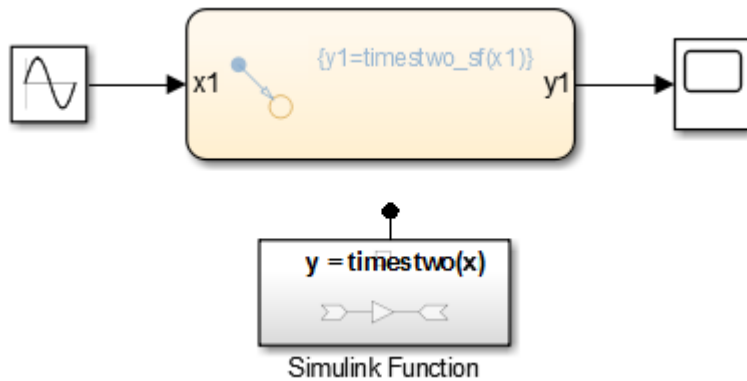

---

- 8 Add and setup a Simulink Function block as described in “Create a Simulink function using a Simulink Function Block” on page 10-123.

### Test the function call

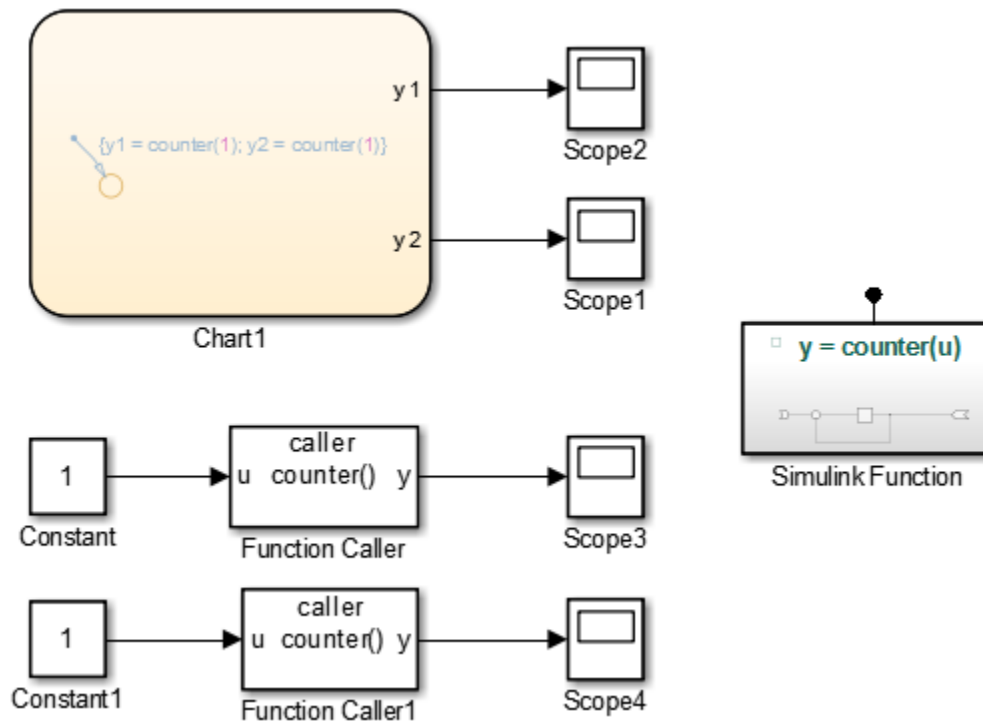

- 1 Add a Sine Wave block to provide test data for the input and a Scope block to view results from the output.

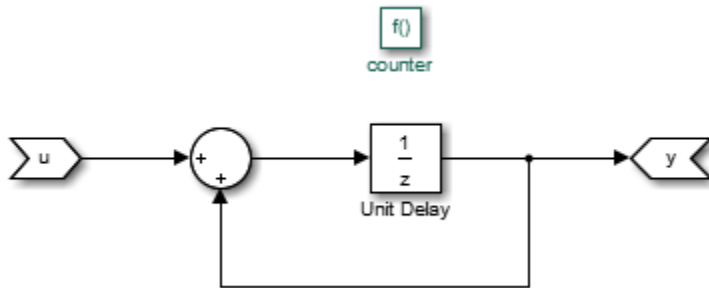

- 2 For the Sine Wave block, set the **Sample time** to `0.01`. For the model, open the Configuration Parameters dialog box to the solver pane. Set **Type** to Fixed-step and **Fixed-step size** to `0.01`.
- 3 Run a simulation.

### Call a Simulink Function Block from Multiple Sites

If you call a Simulink Function block from multiple sites, all call sites share the state of the function. For example, suppose that you have a Stateflow chart with two calls and two Function Caller blocks with calls to the same function.

A function defined with a Simulink Function block is a counter that increments by 1 each time it is called with an input of 1.

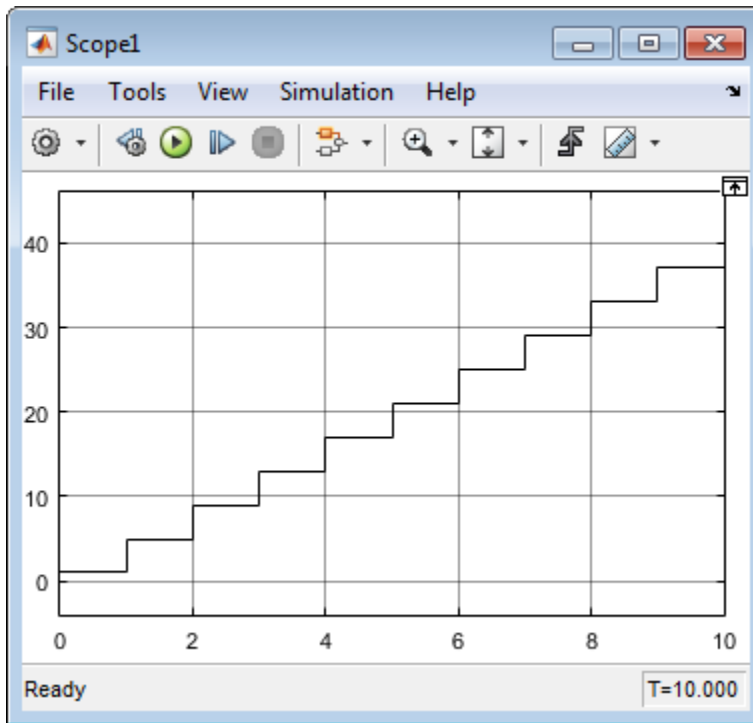

The Unit Delay block has state because the block value is persistent between calls from the two Function Caller blocks and the Stateflow chart. Conceptually, you can think of this function being implemented in MATLAB code:

```
function y = counter(u)
persistent state;
if isempty(state)
    state = 0;
end
y = state;
state = state + u;
```

Simulink initializes the state value of the Unit Delay block at the beginning of a simulation. After that, each time the function is called, the state value is updated.

In this example, the output observed in Scope1 increments by 4 at each time step. Scope2, Scope3, and Scope4 show a similar behavior. The only difference is a shift in the observed signal due to the execution sequence of the function calls.

### Diagnostic Settings With Multiple Callers

For multiple callers that share a function and have different sample time rates, data integrity and consistency of real-time code might be a problem. Consider controlling the severity of diagnostics.

Select a Fixed-step solver. Set the **Treat each discrete rate as a separate task** parameter to:

- Clear (single-tasking), and then set the **Single task data transfer** parameter to none (default), warning, or error.
- Select (multi-tasking), and then set the **Multitask data transfer** parameter to error (default) or warning.

## Argument Specification for Simulink Function Blocks

When a Simulink Function block is within the scope of a Function Caller block, you do not have to specify the parameters. In such a case, the Function Caller block can determine the input and output argument specifications.

You must specify arguments when a Simulink Function block is outside the scope of a Function Caller block. A Simulink Function block is considered to be out of scope of a Function Caller block when the two blocks are in separate models referenced by a common parent model.

### Example Argument Specifications for Data Types

This table lists possible input and output argument specifications.

Simulink Function Block Data Type	Function Caller Block Expression	Description
double	<code>double(1.0)</code>	Double-precision scalar.
double	<code>double(ones(12,1))</code>	Double-precision column vector of length 12.
single	<code>single(1.0)</code>	Single-precision scalar.
int8, int16, int32	<code>int8(1), int16(1), int32(1)</code>	Integer scalars.
	<code>int32([1 1 1])</code>	Integer row vector of length 3.
	<code>int32(1+1i)</code>	Complex scalar whose real and imaginary parts are 32-bit integers.
uint8, int16, int32	<code>uint8(1), uint16(1), uint32(1)</code>	Unsigned integer scalars.
boolean	<code>boolean(true),boolean(false)</code>	Boolean, initialized to true (1) or false (0).
<code>fixdt(1,16)</code> <code>fixdt(signed, word_length)</code>	<code>fi(0,1,16)</code> <code>fi(value, signed, word_length)</code>	16-bit fixed-point signed scalar with binary point set to zero. Fixed-point numbers can have a word size up to 128 bits.
<code>fixdt(1,16,4)</code>	<code>fi(0,1,16,4)</code>	16-bit fixed-point signed scalar with binary point set to 4.
<code>fixdt(1,16,2^0,0)</code>	<code>fi(0,1,16,2^0,0)</code>	16-bit fixed-point signed scalar with slope set to $2^0$ and bias set to 0.
Bus: <object name>	bus object name	Simulink.Bus object
Enum: <class name>	enumerated value	Enumerated type set to an enumerated value.
<alias name>	parameter object name	Simulink.Parameter object with the DataType parameter set to a Simulink.AliasType object and the Value parameter set to a value.

## Input Argument Specification for Bus Data Type

Create a bus with two signals, and then specify the **Input argument specification** parameter for a Function Caller block. The Function Caller block calls a Simulink Function block that accepts the bus as input.

A bus input to a Function Caller block must be a nonvirtual bus using a bus object.

- 1 Create a Simulink bus object `myBus`.

```
myBus = Simulink.Bus;
```

- 2 Add elements A and B.

```
myBus.Elements(1).Name = 'A';
myBus.Elements(2).Name = 'B';
```

- 3 For the Function Caller block dialog box, set the **Input argument specification** parameter to `myBus`.
- 4 For the dialog box of an Argument Inport block within the Simulink Function block, set the **Data type** parameter to `Bus: myBus`.

## Input Argument Specification for Enumerated Data Type

Create an enumerated data type for the three primary colors, and then specify the **Input argument specifications** parameter for a Function Caller block. The Function Caller block calls a Simulink Function block that accepts a signal with the enumerated type as input.

- 1 Create a MATLAB file for saving the data type definition. On the MATLAB toolstrip, select **New > Class**.
- 2 In the MATLAB editor, define the elements of an enumerated data type. The class `BasicColors` is a subclass of the class `Simulink.IntEnumType`.

```
classdef BasicColors < Simulink.IntEnumType
    enumeration
        Red(0)
        Yellow(1)
        Blue(2)
    end
end
```

- 3 Save the class definition in a file named `BasicColors.m`.
- 4 For the Function Caller block dialog box, set the **Input argument specifications** to `BasicColors(0)`.
- 5 For the dialog box of an Argument Inport block within the Simulink Function block, set the **Data type** parameter to `Enum: BasicColors`.

## Input Argument Specification for an Alias Data Type

Create an alias name for the data type single, and then specify the **Input argument specification** parameter for a Function Caller block. The Simulink Function block called by the Function Caller block also uses the alias name to define the input data type.

- 1 Create a Simulink alias data type object `myAlias`.

```
myAlias = Simulink.AliasType;
```

- 2 Assign a data type.

```
myAlias.BaseType = 'single';
```

- 3 Create a Simulink parameter object `myAlias_parameter` and assign the alias name to the `DataType` parameter.

```
myAlias_parameter = Simulink.Parameter;  
myAlias_parameter.DataType = 'myAlias';  
myAlias_parameter.Value = 1;
```

- 4 For the Function Caller block dialog box, set the **Input argument specification** parameter to `myAlias_parameter`.
- 5 For the dialog box of an Argument Inport block dialog box within the Simulink Function block, set the **Data type** parameter to `myAlias`.

## Simulink Function Blocks in Referenced Models

You can place Simulink Function blocks and function callers (such as Function Caller blocks and Stateflow charts) in a referenced model, but doing so requires some special considerations:

- The referenced model must follow export-function model rules and be designated as an export-function model. See “Export-Function Models Overview” on page 10-96.
- Sometimes, you must explicitly define the argument data types for a Function Caller block.

These examples show four relationships between Function Caller blocks, Simulink Function blocks, and referenced models.

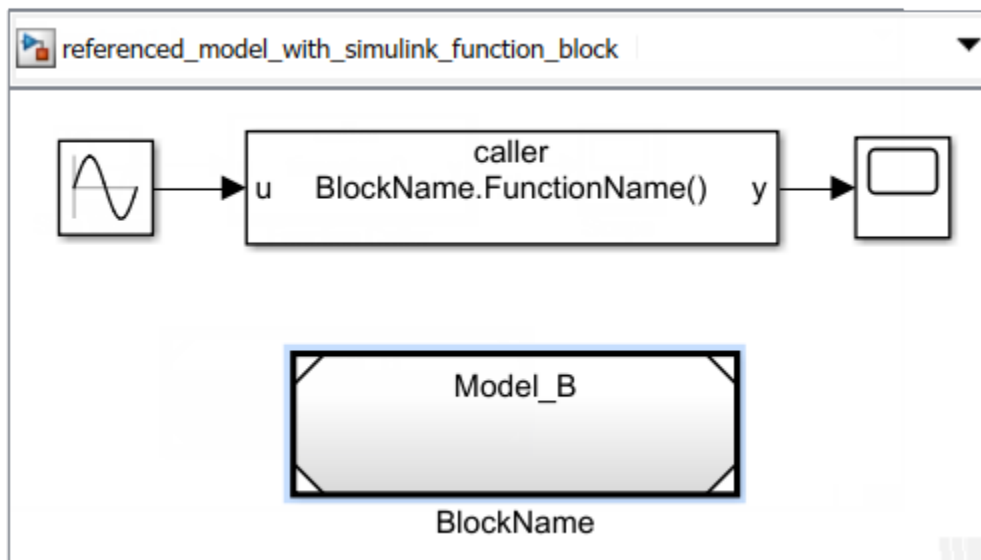

### Simulink Function Block in Referenced Model

In this example, the parent model contains a Function Caller block, and the referenced model, `Model_B`, contains a Simulink Function block. `Model_B` must follow export-function model rules.

The Function Caller block can determine the argument data types of the function. In the Function Caller block, you do not need to define the **Input argument specification** and **Output argument specification** parameters.

But since, by default, the Simulink Function block is scoped to the model, you must qualify a call to the function name with the Model block name.

To open a completed model, see `ex_referenced_model_with_simulink_function_block`.

`Model_B` contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models Overview” on page 10-96.

For Model\_B, set the Configuration Parameters for the solver to satisfy export-function model rules:

- **Type:** Fixed-step.
- **Solver:** discrete (no continuous states).

### Simulink Function Block in Referenced Model Placed in Subsystem

Once the Simulink Function block is identified as global by setting **Function visibility** to global, there are no limitations on where this referenced model can be placed.

For example, you could place Model\_B with a Simulink Function block in a Subsystem block.

## Function Caller Block in Referenced Model

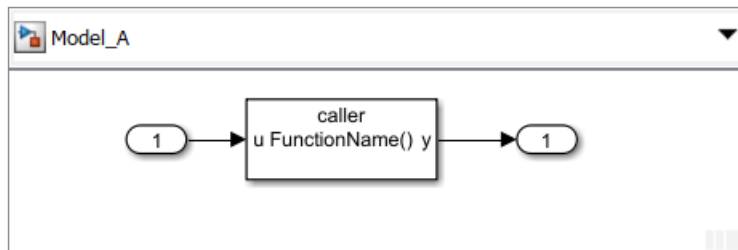

In this example, the parent model contains a Simulink Function block, and a referenced model, `Model_A`, contains a Function Caller block. If you want to use this modeling patterning, the **Function visibility** parameter for the Trigger port block in the Simulink Function block must be set to `global`.

For the parent model, set the solver type to `Variable-step` or `Fixed-step`.

To open a completed model, see `ex_referenced_model_with_function_caller_block`.

Model\_A contains a Function Caller block.

Since the Function Caller block cannot find the function in Model\_A, you must set the **Function visibility** parameter for the Trigger block to `global` and specify the Function Caller block argument parameters:

- **Input argument specification:** Specify to match the Simulink Function block input argument data types, for example, `double(1.0)`.

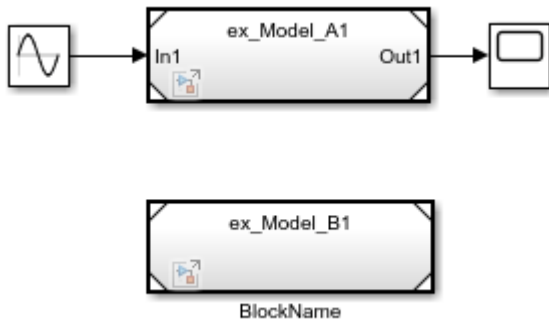

Specify the argument specification for a Simulink Function block with the **Data type** parameter in the Input Argument and Output Argument blocks.

- **Output argument specification:** Specify to match the Simulink Function block output argument data types, for example, `double(1.0)`.

## Function and Function Caller Blocks in Separate Referenced Models

### Function and Function Caller blocks in separate referenced models

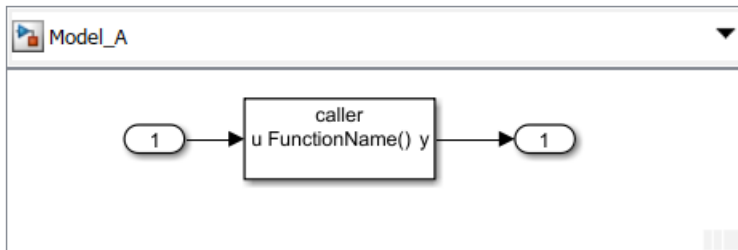

This example shows a parent model containing two referenced models. Model\_A is a referenced model with a Function Caller block. Model\_B is a referenced model with a scoped Simulink Function block. Only Model\_B with a Simulink Function block must follow export-function rules.

### Inside the referenced models

For `Model_A`, provide the argument specification as you do for the referenced model in “Function Caller Block in Referenced Model” on page 10-141. For `Model_B`, specify parameters as you do for the referenced model in “Simulink Function Block in Referenced Model” on page 10-139.

`Model_A` contains a Function Caller block. If the function is set to `global`, define the Input and Output Argument Specification parameters. If the function is set to `scoped`, provide the file name, not the block name, of the model where the function is expected to be resolved to as `y = Model_B.FunctionName(u)`.

`Model_B` contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models Overview” on page 10-96.

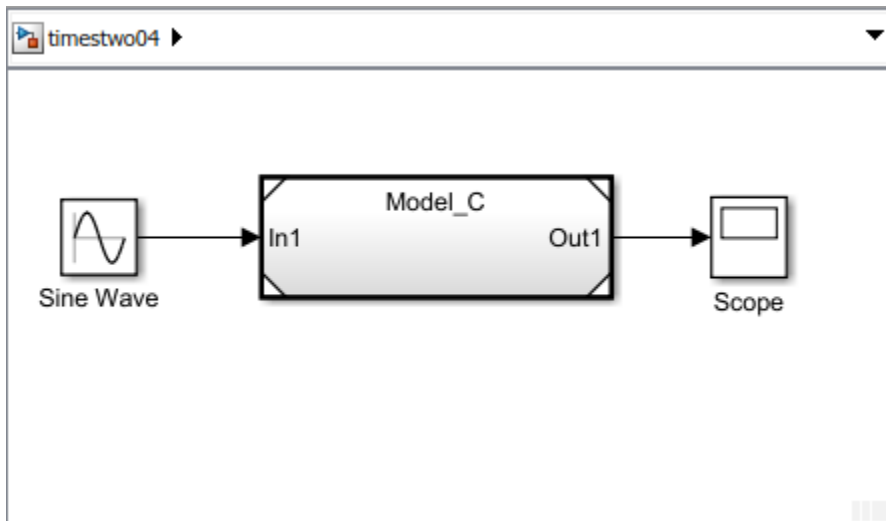

You can also use function ports to call a Simulink function in a referenced model from another referenced model. See “Call Simulink Functions in Other Models Using Function Ports” on page 10-164.

### Function and Function Caller in the Same Model

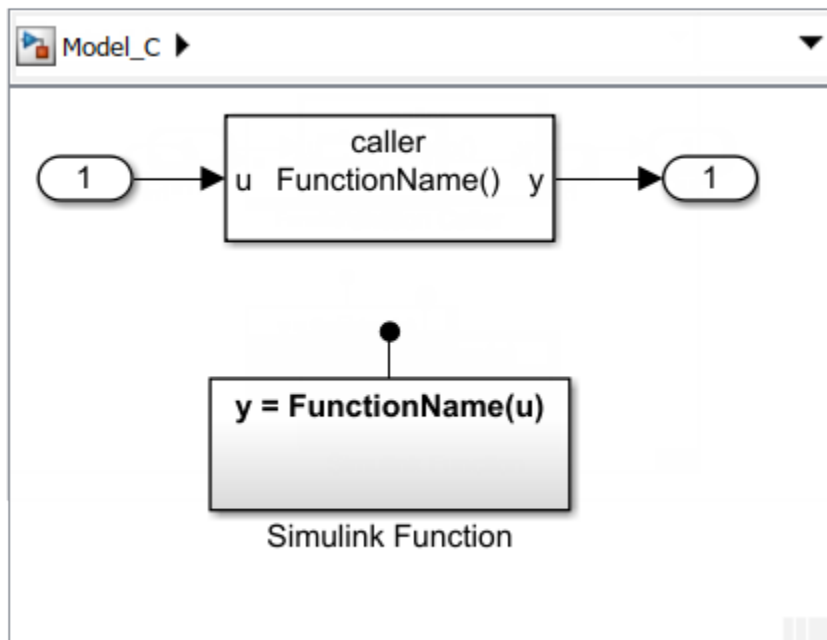

In this example, the parent model contains one referenced model, Model\_C, with both a Function Caller block and a scoped Simulink Function block.

- If there is only one instance of Model\_C, and the Configuration Parameter **Total number of instances allowed per top model** is set to One, the parent model simulates without error. Since Model\_C does not export the function, it does not need to follow export-function rules.
- If the Configuration Parameter **Total number of instances allowed per top model** is set to Multiple, Model\_C exports the function regardless if there is a single instance or multiple instances of the model. In both cases, Simulink displays an error. The model needs to follow export-function rules, but it does not because a Function Caller block is not allowed at the top-level of an export-function model.

`Model_C` contains both a Function Caller block and a scoped Simulink Function block. If you want to use this modeling pattern, only one instance of `Model_C` is allowed in the parent model.

## Scoped, Global, and Port-Scoped Simulink Function Blocks Overview

Defining the visibility of functions can help you to avoid name space conflicts when integrating your referenced models. A Simulink Function block defines the visibility of its function in relationship to the subsystem or model containing the block as either scoped, global, or port-scoped. By default, Simulink Function blocks are scoped.

- *Function Visibility.* A scoped function is visible in its hierarchy. A function caller located at the same level as the function, or one or more levels below can refer to the function. A global function is visible across a model hierarchy. This means that a function caller located anywhere in the current model or in the parent model hierarchy can refer to the function. A port-scoped function is visible only to a particular exporting function port in the current model, and is not visible elsewhere in the model hierarchy. The function can be called only from outside the current model, and only through the exporting function port.
- *Function accessibility* is determined by the visibility of a function and the location of the function caller relative to the Simulink Function block. For function callers one hierarchical level above the function, qualify the function name with the virtual Subsystem block name or Model block name.
- *Function exporting* refers to functions exported from models. A function with global visibility, placed anywhere in an export-function model, is exported to the top level of a model hierarchy in addition to the model interface. A function with scoped visibility at the root level of an export function model is exported to the model interface. In both these cases, you can access the exported function outside of the model. A function with port-scoped visibility must be placed at the root level of an export-function model, and can be accessed by function callers in other export-function models only through a connection between function ports in the respective models.

Use the **Function visibility** parameter for the Trigger block within a Simulink Function block to set the function visibility to either `scoped`, `global`, or `port`. For a port-scoped function, specify the name of the port in the **Scope to port** field.

**Summary of Simulink Function Block Visibility and Access**

	<b>Function visibility</b>	<b>Function accessibility</b>	<b>Function exporting</b>
<b>Virtual Subsystem</b>	scoped Function name does not have to be unique	function caller inside hierarchy or at parent level.  function caller inside Subsystem block hierarchy - unqualified, <code>fcn()</code> . See Resolve to a Function Hierarchically in “Scoped Simulink Function Blocks in Subsystems” on page 10-150.  function caller at parent level - qualified with subsystem block name, <code>subsystem.fcn()</code> . See Resolve to a Function by Qualification in “Scoped Simulink Function Blocks in Subsystems” on page 10-150.	Does not apply
	global Function name must be unique	function caller at any level of hierarchy down or up.  function caller at any level of hierarchy - unqualified, <code>fcn()</code>	Function at any level of model exported to the global name space of the top-level model
	port visibility not allowed	Does not apply	Does not apply
<b>Atomic Subsystem</b>	scoped Function name does not have to be unique	function caller only inside hierarchy  function caller inside Subsystem block hierarchy - unqualified, <code>fcn()</code> . See Resolve to a Function Hierarchically in “Scoped Simulink Function Blocks in Subsystems” on page 10-150.  function caller at parent level - not allowed	Does not apply
	global visibility not allowed	function call not allowed	Does not apply

## Scoped Simulink Function Blocks in Subsystems

The scope of a Simulink function is defined in its parent subsystem within the context of a model. If you place a function in any Subsystem block, access to the function from outside the model is prohibited by default. In both cases, the Trigger block **Function visibility** parameter is set to **scoped**. The Simulink Function block can be located:

- In a virtual subsystem — Call the function from within the containing Subsystem block hierarchy without qualifying the function name, or call the function from outside the subsystem by qualifying the function name with the subsystem block name.
- In an atomic or non-virtual subsystem — Call the function from within the containing Subsystem block hierarchy without qualifying the function name. Accessing the function from outside of the subsystem is prohibited.

### Resolve to a Function Hierarchically

Placing a scoped Simulink Function block within any Subsystem block (virtual or atomic) limits access to the function and removes the function name from the global name space. When a function caller resolves to a function hierarchically, it looks for the function using the following rules:

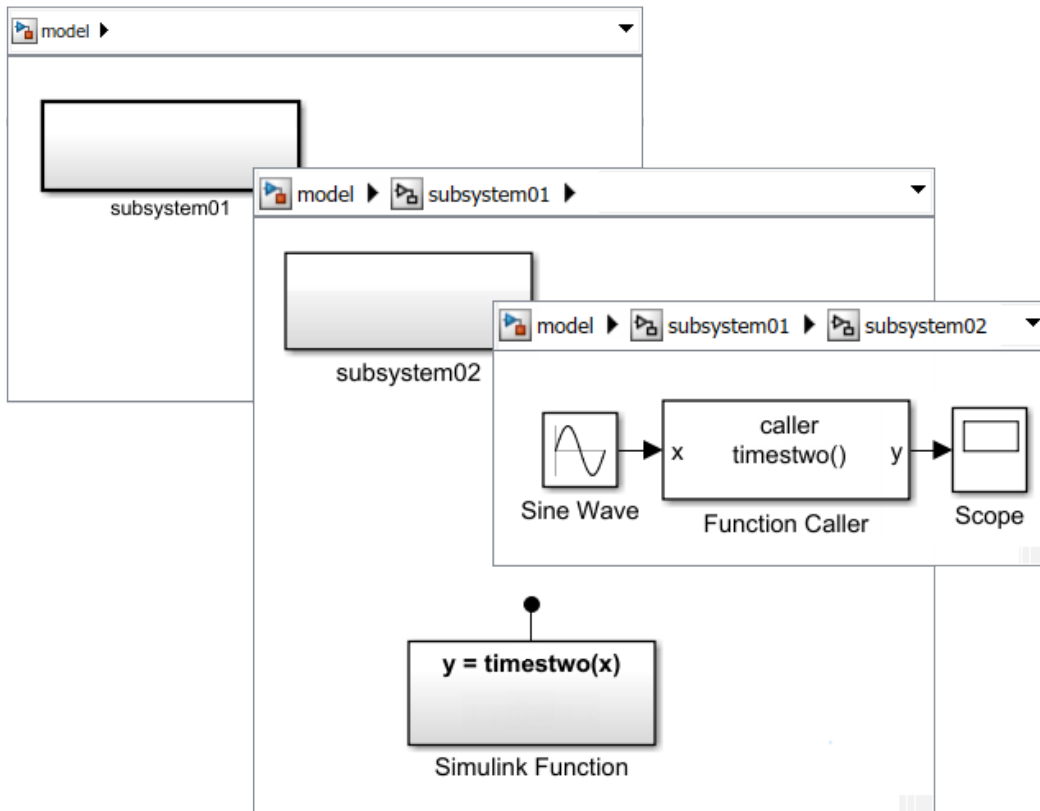

- Resolution Rule 1: Is the scoped Simulink Function block in the current Subsystem block with the function caller?
- Resolution Rule 2. If the scoped function is not in the current subsystem, is the scoped Simulink Function block in a parent or grandparent Subsystem block one or more levels above the function caller, or in a parent Model?

If a function caller resolves to a function hierarchically, you can call the function without qualifying the function name:

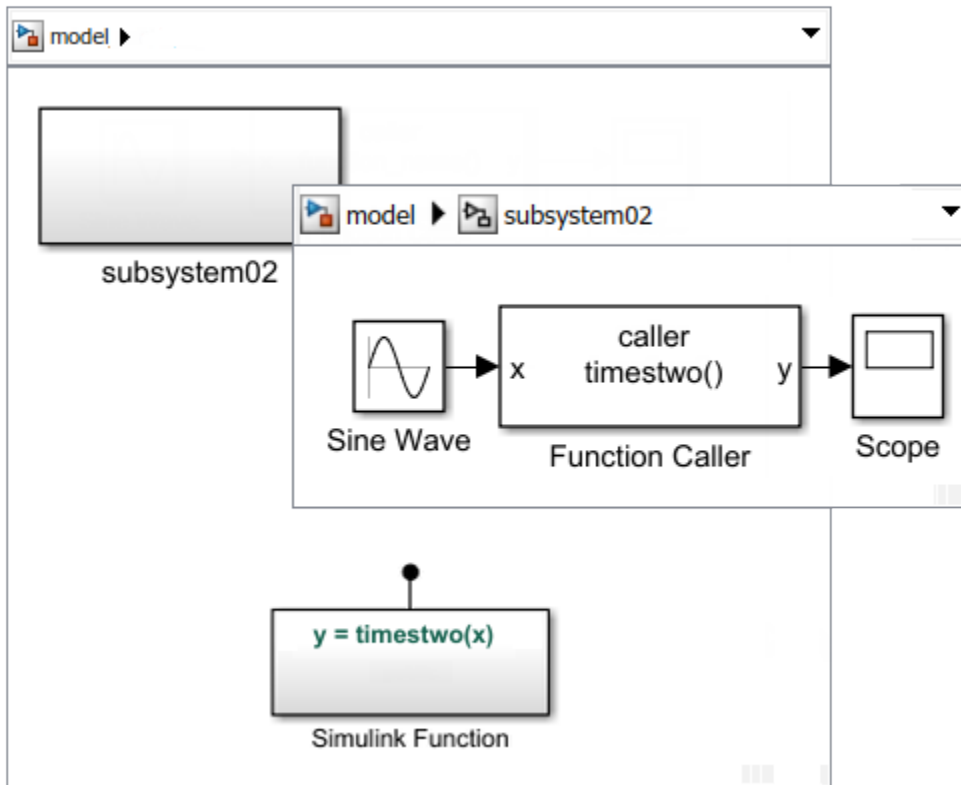

- Function caller located at the same hierarchic level as the function. In this case, the function caller finds the scoped function in the current subsystem (Resolution Rule 1).

- Function caller located in a Subsystem block one or more Subsystem block levels below the hierarchic level of the Simulink Function block. The function caller hierarchy cannot include a Model block since the function caller cannot cross model reference boundaries. In this case, the function caller didn't find the scoped function in the current subsystem, but it found the function in the parent subsystem (Resolution Rule 2).

In this case, the function caller didn't find the scoped function in the current subsystem, but it found the function in the parent model (Resolution Rule 2).

- You can also call a Simulink Function block in a Subsystem block without qualification from a MATLAB Function block or a Stateflow chart within the block.

## Resolve to a Function by Qualification

When you place a Simulink Function block in a virtual Subsystem block, the function name is not visible outside of the subsystem. However, you can call the function by qualifying the function name with the Subsystem block name. When a function caller resolves to a qualified function hierarchically, it looks for the virtual Subsystem block containing the function using the following rules:

- Resolution Rule 1: Is the virtual Subsystem block in the current component with the function caller? A component can be a Subsystem block or Model.
- Resolution Rule 2. If the virtual Subsystem block is not in the current component, is the virtual Subsystem block in a parent or grandparent component one or more levels above the function caller?

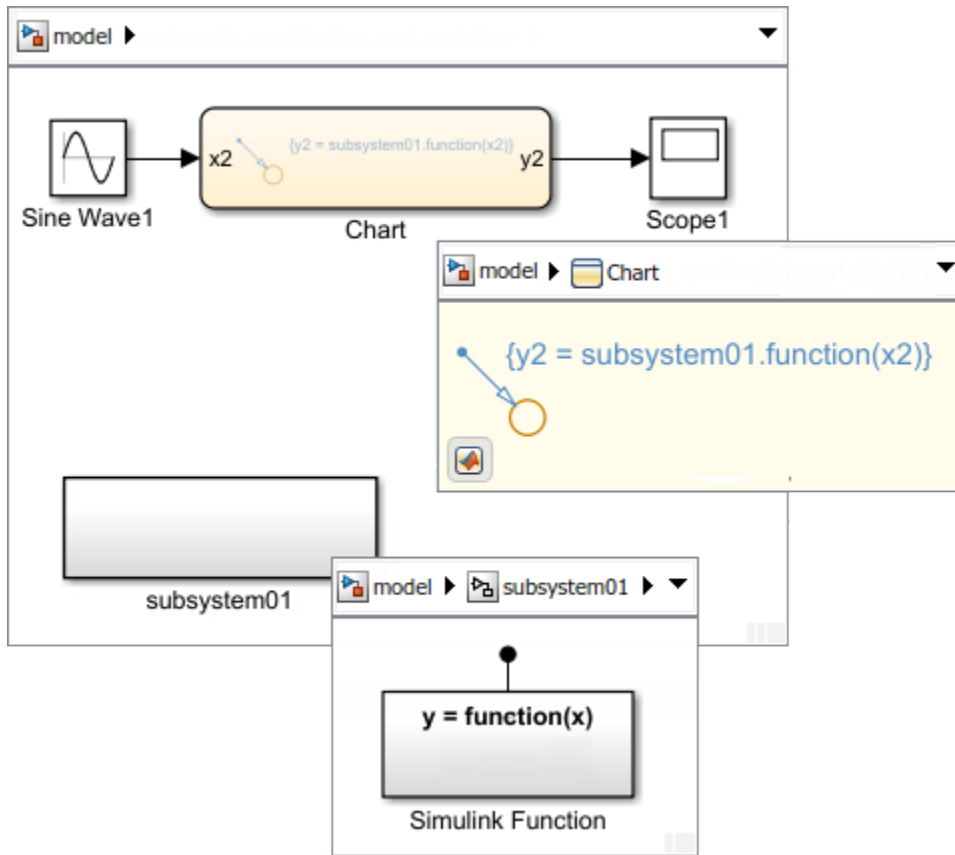

If a function caller resolves to a virtual Subsystem block with a scoped function, you can call the function by qualifying the function name:

- Function caller located outside of the subsystem one hierarchic level above the function. In this case, the function caller finds the Subsystem block with the scoped function in the current model (Resolution Rule 1).

- Calling the function from a Stateflow chart outside the subsystem one hierarchic level above the function. In this case, the function caller finds the Subsystem block with the scoped function in the current model (Resolution Rule 1).

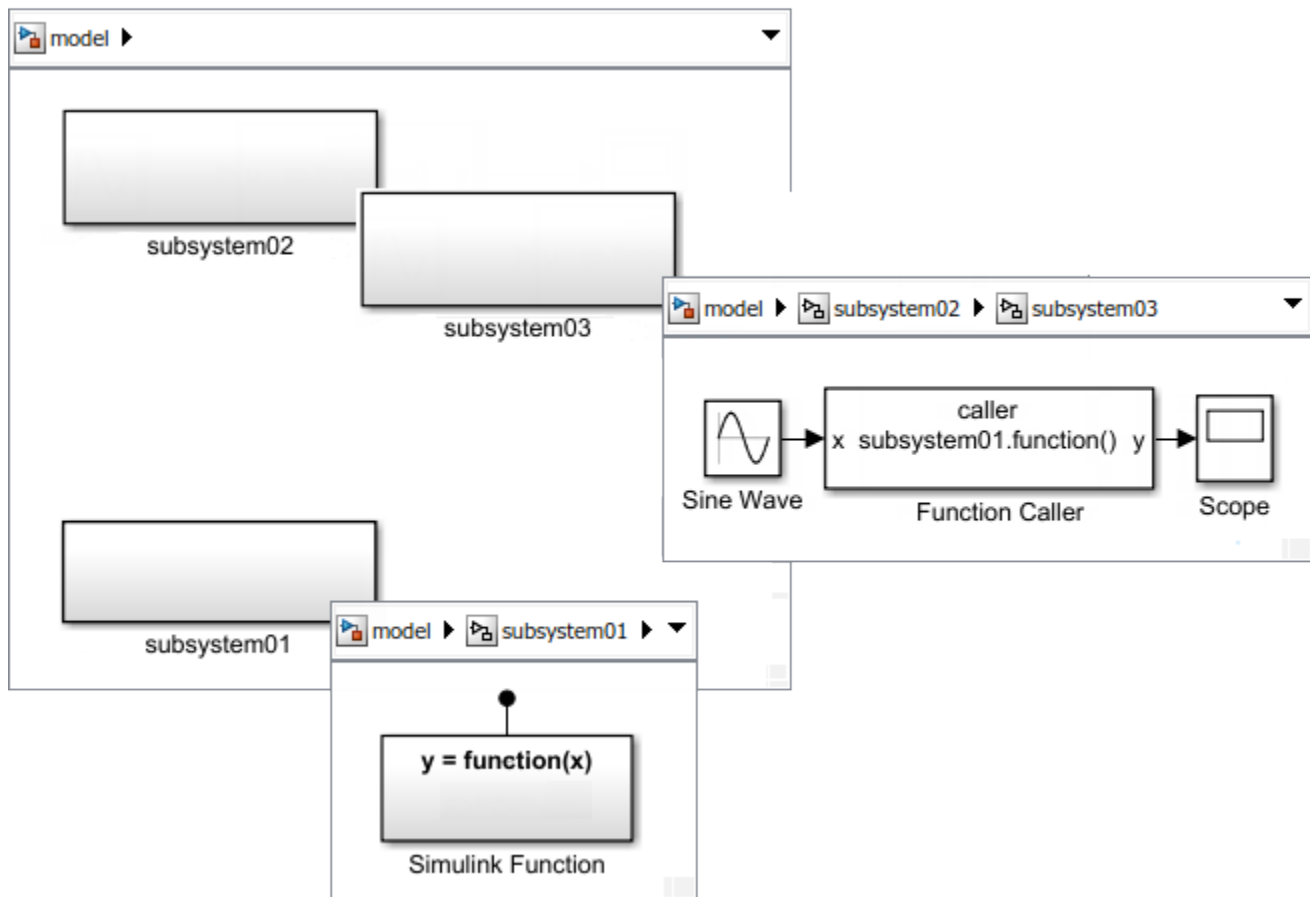

- Function caller is in another subsystem at the same hierarchic level as the function. In this case, the function caller didn't find the Subsystem block with the scoped function in the current subsystem, but it found the Subsystem block in the parent model (Resolution Rule 2).

- Function caller is in another subsystem one or more subsystem levels below the hierarchic level of the function. In this case, the function caller didn't find the Subsystem block with the scoped function in the current subsystem, but it found the Subsystem block in the grandparent model (Resolution Rule 2).

The function caller hierarchy cannot include a Model block since the function caller cannot cross model reference boundaries.

## Scoped Simulink Function Blocks in Models

The scope of a Simulink function is defined in the context of a model. If you place a Simulink Function block in a model at the root level, the function is scoped to the model by default. The Trigger block **Function visibility** parameter is set to `scoped`. Access the function with a function caller located:

- Within the model hierarchy containing the function. Call the function without qualifying the function name.
- Outside the model. Call the function by qualifying the function name with the Model block instance name, not the model file name.

Setting **Function visibility** for a Simulink Function block to `global` allows you to access the function from anywhere in the model or a parent model. As a result, models with a Simulink Function block set to `global` cannot be multi-instanced because function names must be unique.

### Resolve to a Function Hierarchically

Placing a scoped Simulink Function block within a model at the root level limits access to the function and removes the function name from the global name space.

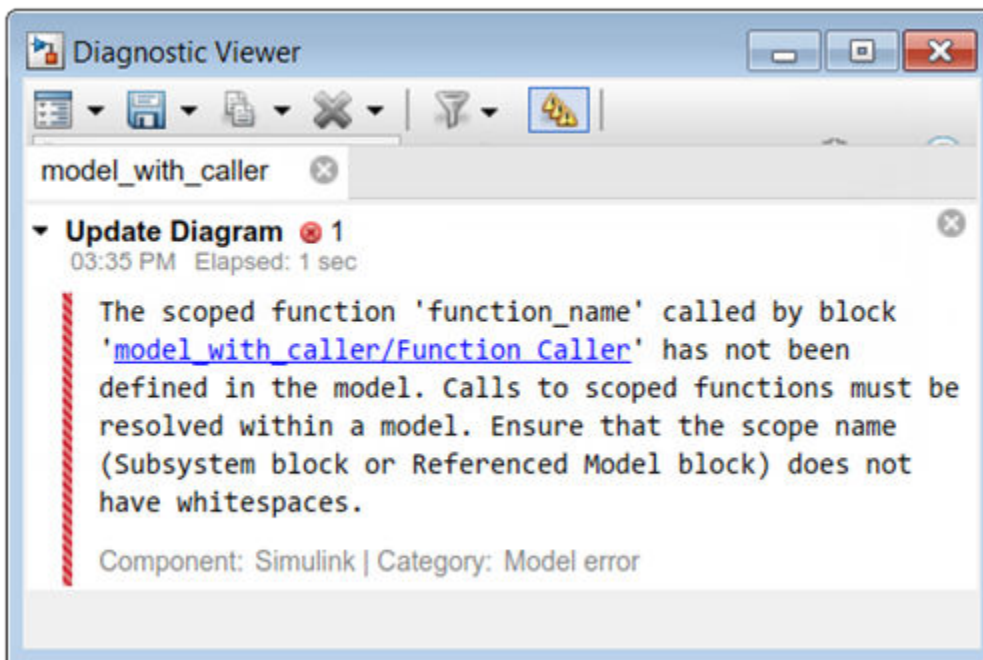

- Function caller located in the current model.

- You cannot place a function caller inside a Model block and the Simulink Function block in the parent model,

If you place a function caller inside a Model block, Simulink displays an error. This error occurs because the model containing the caller does not know the name of the function. Function calls cannot cross model reference boundaries.

## Resolve to a Function by Qualification

When you place a Simulink Function block in a Model block, the function name is not accessible outside the model. However, you can call a function by qualifying the function name with the Model block name. When a function caller resolves to a qualified function hierarchically, it looks for the Model block containing the function using the following rules:

- Resolution Rule 1: Is the Model block in the current model with the function caller?

- Resolution Rule 2: If the Model block is not in the current model or subsystem, is the Model block in a parent or grandparent model one or more levels above the function caller?

If a function caller resolves to a Model block with a scoped function, you can call the function by qualifying the function name:

- Function caller located outside of the Model block one hierarchic level above the function. In this case, the function caller finds the Model block with the scoped function in the current model (Resolution Rule 1).

- Function caller in a subsystem at the same hierarchic level as the function. In this case, the function caller didn't find the Model block in the current subsystem, but it found the Model block in the parent model (Resolution Rule 2).

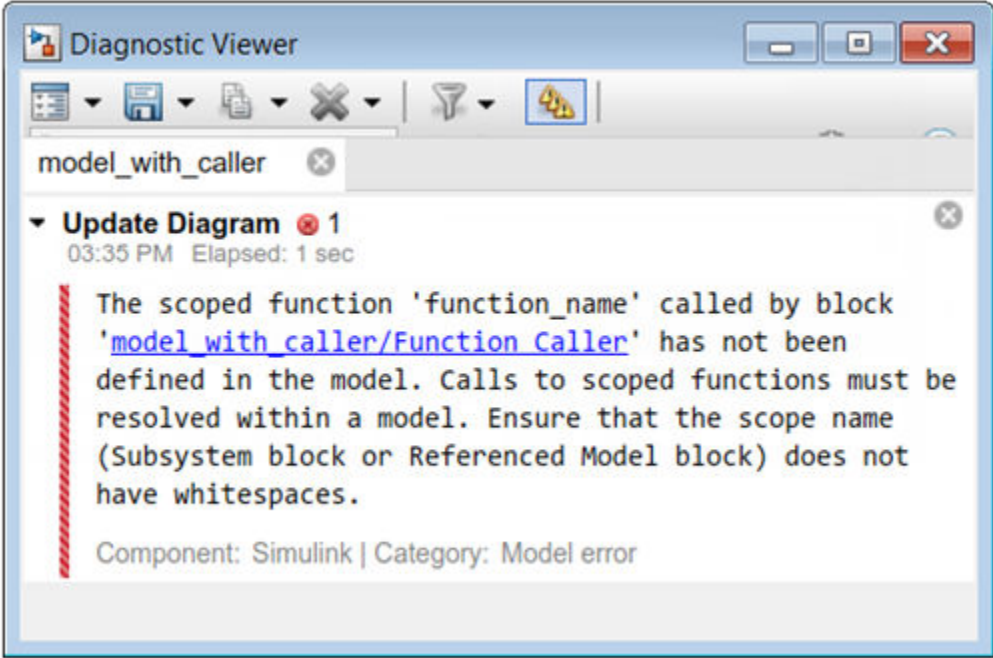

- You cannot place a Simulink Function block in one Model block and the function caller in another Model block.

If you place a Simulink Function block in a referenced model and a function caller in another referenced model, Simulink displays an error. This error occurs because the qualified function name using the Model block name is not visible to the model containing the caller.

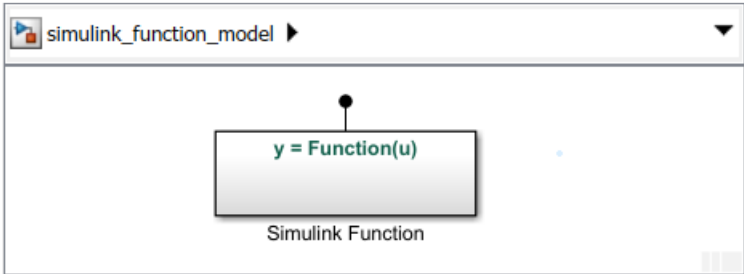

If you want to access the function using this modeling pattern, see the section Function Caller Block in Referenced Model and Function and the section Function Caller in Separate Models in the topic “Simulink Function Blocks in Referenced Models” on page 10-139.

### Multi-Instance Modeling with Simulink Functions

Setting **Function visibility** for a Simulink Function block to `scoped` encapsulates the function within the model, allowing you to multi-instance the model. Adding the model instance name to the function name creates a qualified function name that is unique within the parent model.

- 1 Create a model containing Simulink Function blocks.

By default, the **Function visibility** parameter for the Trigger block within the Simulink Function block is set to `scoped`.

- 2 Reference the model with Simulink functions from multiple Model blocks. Add a Function-Call Subsystem block to schedule calls to the functions.

- 3 Add Function Caller blocks to the Function-Call Subsystem block. Access the function in separate model instances by qualifying the function name with the block name.

- 4 On the **Debug** tab, select **Information Overlays** . From the drop-down box, select **Function Connectors** .

Tracing lines are drawn to help you navigate from a function caller to the function.

For a model using Simulink Function blocks with multiple instances, see “Model Reusable Components Using Multiply Instantiated Simulink Functions”.

## Call Simulink Functions in Other Models Using Function Ports

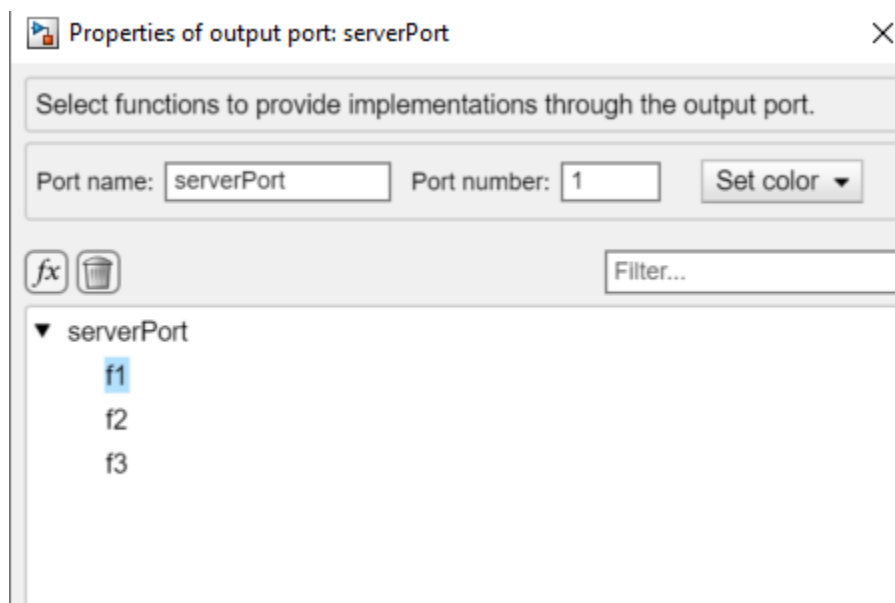

Function ports allow a referenced model to call a Simulink function defined in a second referenced model. A model can issue a function call through an invoking function port to invoke a function that is defined and exported in another model with an exporting function port block. You can use function ports to model client and server components in a distributed service architecture as well as to facilitate data sharing using a functional interface between component models.

### Connect Client and Server Models with Function Ports

A model that uses function ports must be an export-function model. See “Export-Function Models Overview” on page 10-96.

To create an exporting function port, add a Function Element block to your model, specify a name for the port, and specify one or more function elements.

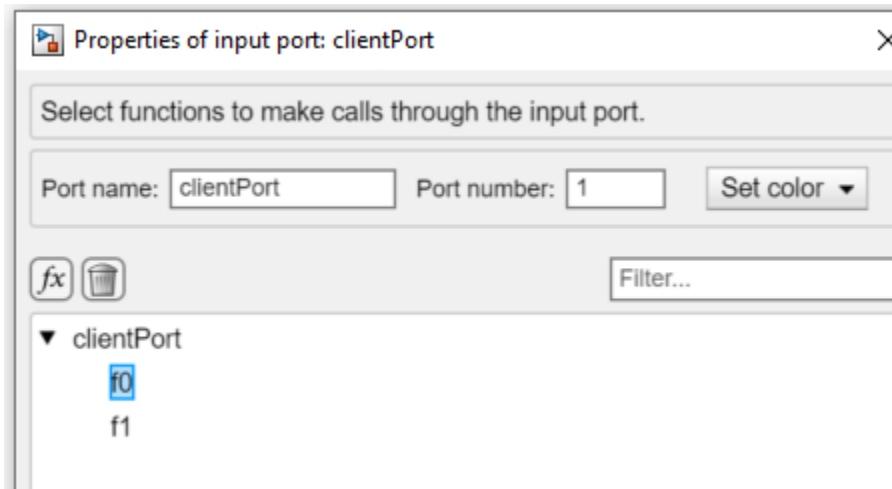

For each function element, add a Simulink Function block to the model and implement the desired algorithm inside the Simulink Function block. To connect the Simulink Function block to the function port, set the **Function visibility** parameter of the Trigger block inside the Simulink Function block to **port**, and enter the port name in the **Scope to port** box.

Because the block is scoped to the port, it is not visible elsewhere within the model hierarchy and can be called only through the port. The block icon indicates the port scope.

To create an invoking function port, add a Function Element Call block to your model, specify a name for the port, and specify one or more function elements.

For each function element, add a Function-Call Subsystem block, and place a Function Caller block inside the subsystem. To associate the Function Caller block with the port, use dot notation: *PortName.FunctionElementName*. The block icon indicates the association with the port.

**Note** To display green connector lines from the Function Element Call blocks to the Function-Call Subsystem blocks, on the toolstrip, navigate to **Debug > Information Overlays > Blocks** and select **Function Connectors**.

You can associate function ports with service interfaces authored in System Composer™ using the Function Element and Function Element Call blocks that correspond to the port.

When you reference a model with a function port, the port displays on Model block. To allow functions to be called through the ports, add a line between them. A ball icon appears at the end of the line next to the exporting function port. The attributes of the ports must match in number, names, and prototypes of function elements. Function ports can connect only to function ports and not to any other signal.

## Configure Asynchronous Interfaces with Function Ports

*Asynchronous execution* occurs when the caller (client) makes a request to call the function (server). The function is executed based on the ordering defined in the **Schedule Editor** and then returns the output arguments to the caller. The block outputs these arguments using a message output port.

- If there is one function output argument, the output argument becomes the message payload.
- If there is more than one function output argument, the Function Caller block bundles the output arguments as a structure that becomes the message payload.

Connect the message output port to a Message Triggered Subsystem in immediate mode. The Message Triggered Subsystem acts as a callback for the function.

For the server model, in the Simulink Function block, configure the Trigger block parameters. From the **Trigger type** list, select function-call, then select the **Treat as a Simulink Function** check box. Then, from the **Function visibility** list, select port. Select the Execute function call asynchronously check box on the Trigger block parameters dialog.

In the client model, configure the Function Caller block to execute function calls asynchronously. Select the `Execute function call asynchronously` check box on the Function Caller block parameters dialog.

For more information, see “Simulate Asynchronous Services for Vehicle Headlight Management” (System Composer).

## Diagnostics Using a Client-Server Architecture

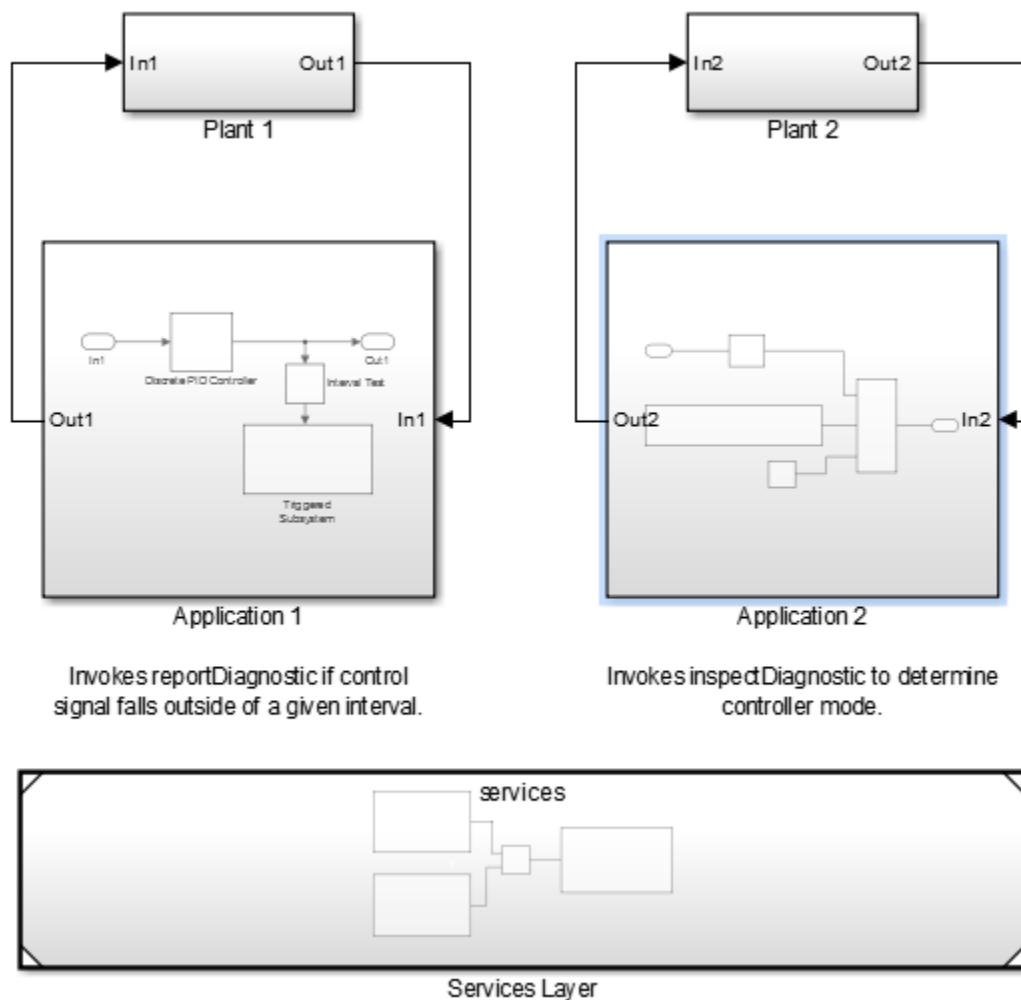

### Diagnostic Messaging with Simulink Functions

Use Simulink functions when you define a diagnostic service where callers pass an error code. The service tracks error codes for all errors that occur. One way to implement this service is to use an indexed Data Store Memory block. A diagnostic monitoring system can then periodically check for the occurrence of specific errors and modify system behavior accordingly.

### Client-Server Architecture

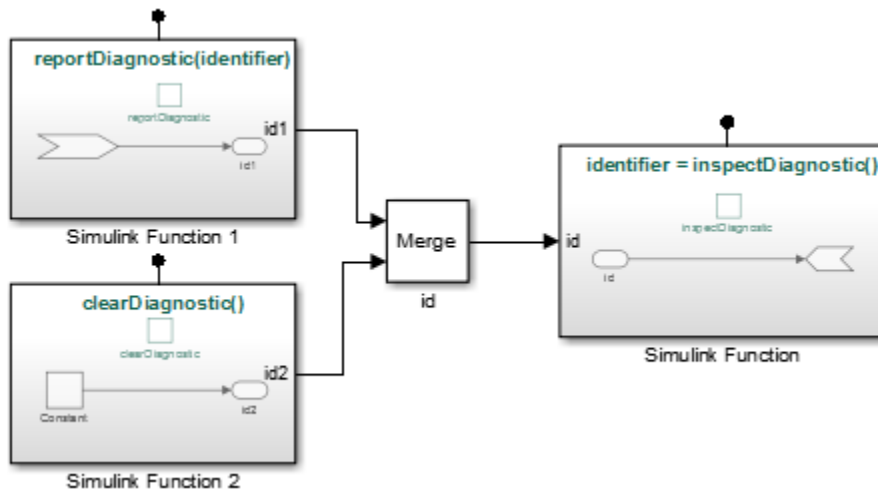

You can use Simulink Function blocks and Function Caller blocks to model client-server architectures. Uses for this architecture include memory storage and diagnostics.

As an example, create a model of a simple distributed system consisting of multiple control applications (clients), each of which can report diagnostics throughout execution. Since client-server architectures are typically constructed in layers, add a service layer to model the diagnostic interface.

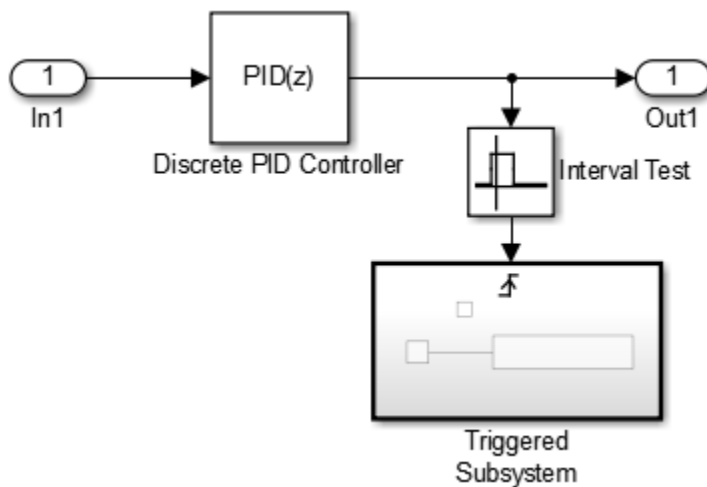

The services (servers), modeled using Simulink Function blocks, are in a separate model. Add the service model to your system model as a referenced model.

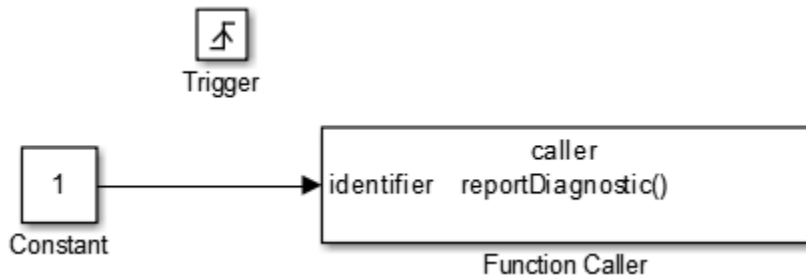

The control applications (clients) interact with the diagnostic interface using Function Caller blocks.

## Modifier Pattern

Application 1 reports a diagnostic condition by invoking the `reportDiagnostic` interface within the service layer. The application calls this function while passing in a diagnostic identifier.

The interval test determines when to create a diagnostic identifier.

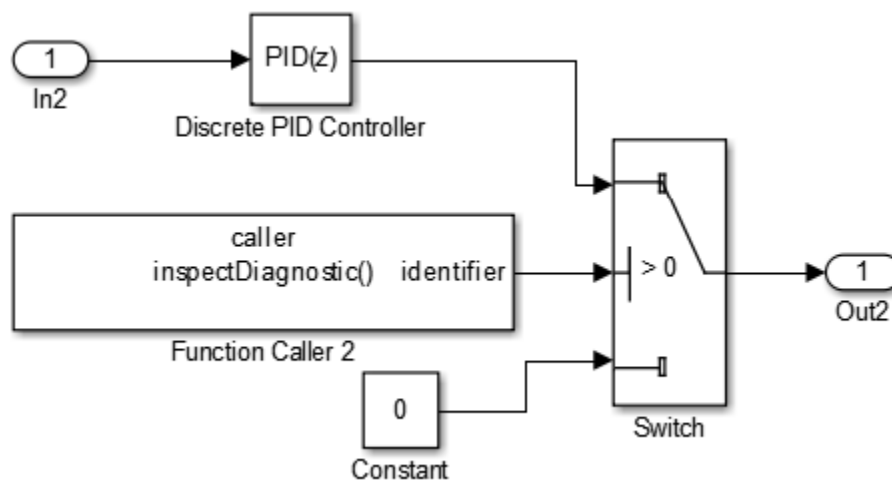

The implementation of the function (Simulink Function 1) tracks the passed-in identifier by transferring the value to a graphical output of the function. A graphical output is a server-side signal that is not part of the server interface but facilitates communication between service functions through function arguments. The value of graphical outputs is held between function invocations.

The reportDiagnostic function is an example of a modifier pattern. This pattern helps to communication of data from the caller to the function and later computations based on that data.

### Observer Pattern

Application 2 invokes the inspectDiagnostic interface within the service layer to inspect whether diagnostics were reported.

The implementation of the function (Simulink Function) uses a graphical input (id) to observe the last reported diagnostic and transfer this value as an output argument (identifier) to the caller. A graphical input is a server-side signal that is not part of the server interface.

The `inspectDiagnostic` function is an example of an observer pattern. This pattern helps to communication of data from the function to the caller.

- “Scoped Simulink Function Blocks in Subsystems” on page 10-150
- “Scoped Simulink Function Blocks in Models” on page 10-157

## Using Initialize, Reinitialize, Reset, and Terminate Functions

Some blocks maintain state information that they use during a simulation. For example, the Unit Delay block uses the current state of the block to calculate the output signal value for the next simulation time step.

Subsystem blocks have default initialize and termination routines. You can add custom routines to the default routines using Initialize Function, Reinitialize Function, and Terminate Function blocks to change or read block states. You can also implement custom routines using Reset Function blocks. These function blocks contain:

- An Event Listener block that executes the combined routine when receiving an initialize, reinitialize, or terminate function-call event, or the custom routine when receiving a reset function-call event.
- A State Writer block to initialize or set a block state or a State Reader block to read the state.

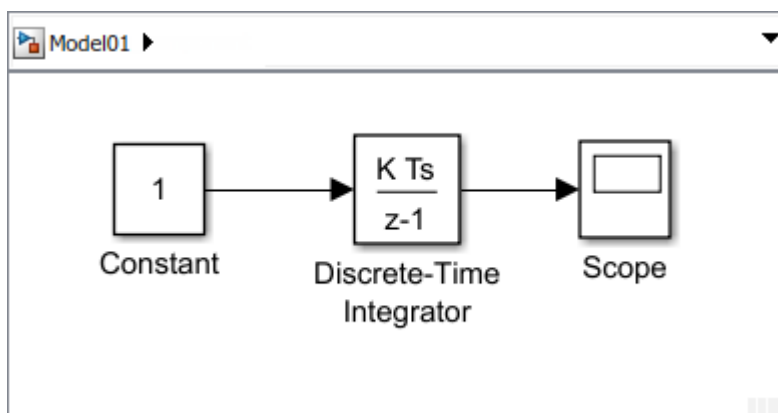

To define the custom routine, edit the contents of the block. For example:

- Set the **State owner block** parameter of the State Writer or State Reader block.
- Add additional State Writer or State Reader blocks.
- Add Parameter Writer blocks to set the value of block parameters. See “Initialize and Reset Parameter Values” on page 10-190.
- Add Data Store Write blocks to write or Data Store Read blocks to read data in a data store. See “Model Global Data by Creating Data Stores” on page 78-10.
- Add blocks and signal lines to supply the values for State Writer, Parameter Writer, and Data Store Write blocks to write, or to save the values read by State Reader or Data Store Read blocks.

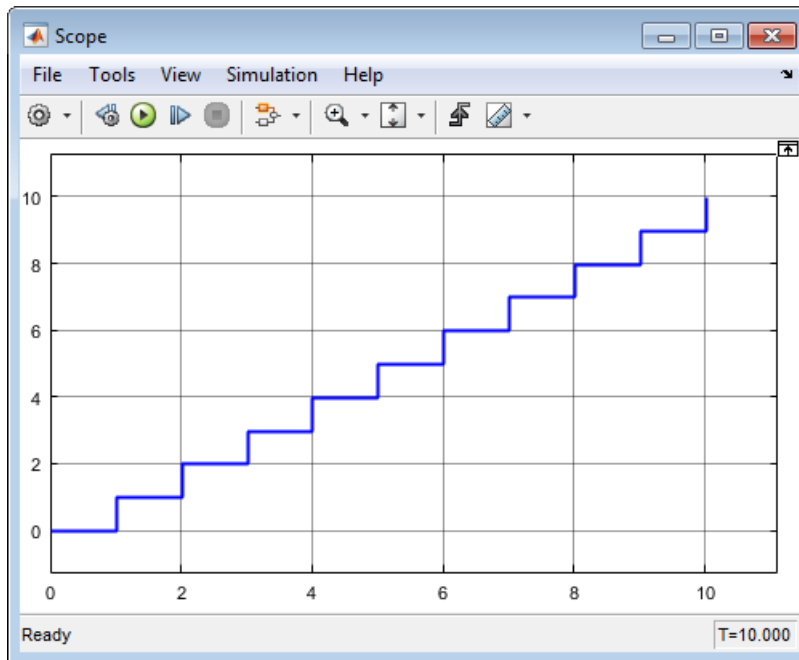

## Create Model Component with State

You can define model algorithms using Simulink blocks. In this example, a single Discrete-Time Integrator block defines the algorithm for integrating an input signal.

- 1 Open a new Simulink model. Save this model with the name Model01.
- 2 Add a Discrete-Time Integrator block. Verify the default parameter values are 1.0 for **Gain value**, 0 for **Initial condition**, Auto for **Initial condition setting**, and -1 for **Sample time**.
- 3 Connect a Constant block to the input of the Discrete-Time Integrator block to model an input signal. Connect a Scope block to the output signal.

- 4 Open the Configuration Parameters dialog box. Set the simulation parameters for the Solver **Type** to Fixed-step, **Solver** to auto, and **Fixed-step size** to 1.
- 5 Open the Scope block, and then run simulation. The output signal increases by 1 at each time step.

## Initialize Block State

Some model algorithms contain states that you can initialize. For example, with an algorithm that reads a sensor value, you can perform a computation to set the initial sensor state.

At the beginning of a simulation, initialize the state of a block using a State Writer block. To control when initialization occurs, use an Initialize Function block that includes the State Writer block.

- 1 Add an Initialize Function block.

By default, the Initialize Function block includes an Event Listener block with the **Event type** parameter set to `Initialize`. The block also includes a State Writer block, and a Constant block as a placeholder for the source of the initial state value.

- 2 Model initial conditions. In this example, set the **Constant value** parameter for the Constant block to 4.
- 3 Connect the state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree, select Discrete-Time Integrator, and then click **Apply**.

The State Writer block displays the name of the state owner block. The state owner block displays a tag indicating a link to a State Writer block. If you click the label above the tag, a list opens with a link for navigating to the State Writer block.

- 4 Run simulation to confirm that your model simulates without errors.

The Initialize Function block executes at the beginning of a simulation. The output signal starts with an initial value of 4 and then increases by 1 until the end of the simulation.

## Reset Block State

During a simulation, you can reset the state of a block using a State Writer block. To control when reset occurs, use a Reset Function block.

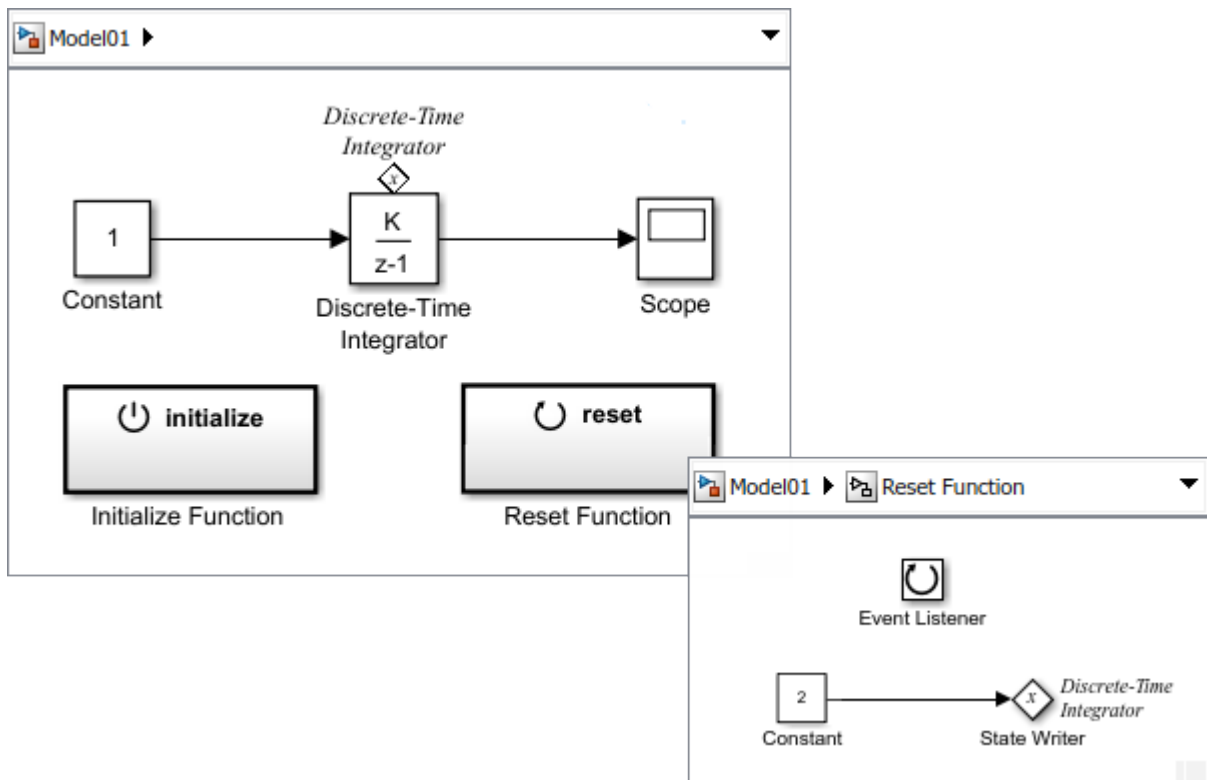

---

**Note** You can use either a Reinitialize Function block or a Reset Function block to reset the state of a block. Both the Reinitialize Function block and the Reset Function blocks can write to block states or perform whatever actions you specify when you configure the blocks. The difference between the blocks is that a Reinitialize Function first implicitly resets the states of all blocks in the model back to their initial conditions and then carries out whatever other actions, including writing to block states, you specify when you configure the block. By contrast, a Reset Function block, carries out only the actions that you specify when you configure the block. In this example, since the model contains no other blocks with state besides the Discrete-Time Integrator block, a Reinitialize Function block could be used in place of the Reset Function block with no difference in results.

---

- 1 Add a Reset Function block.
- 2 Open the Reset Function block.
- 3 Model reset conditions. In this example, set the **Constant value** parameter for the Constant block to 2.
- 4 Connect state writer with the state owner. Open the State Writer block dialog box. Expand the State Owner Selector Tree, select **Discrete-Time Integrator**, and then click **Apply**.
- 5 The event name for the Reset Function block, **reset**, is displayed on the face of the block.

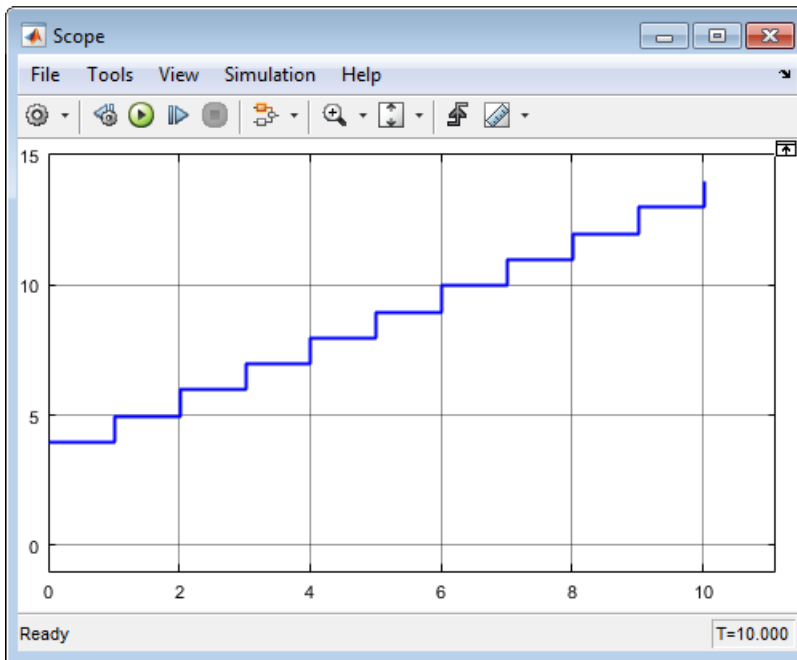

If you click above the tag, a list opens with a link for navigating to the State Writer blocks located in the Initialize Function block and the Reset Function block.

**Note** If the Reset Function block were replaced by a Reinitialize Function block, then the Reinitialize Function block would first set the state of the Discrete-Time Integrator block back to its initial condition of 0, as specified in the Discrete-Time Integrator block dialog. The Reinitialize Function block would then use the State Writer block to set the state of the Discrete-Time Integrator block to 2, which would override the implicit reinitialization to 0. This sequence of actions has the same effect as the Reset Function block, which simply sets the state of the Discrete-Time Integrator block to 2.

If a Reinitialize Function block were used without a State Writer block, then it would set the state of the Discrete-Time Integrator block to its initial condition of 0. If a Reset Function block were used without a State Writer block, it would have no effect on the state of any other block.

- 6 Run a simulation to confirm that your model simulates without errors.

The Reset Function block does not execute during the simulation. The block needs a function-call event signal.

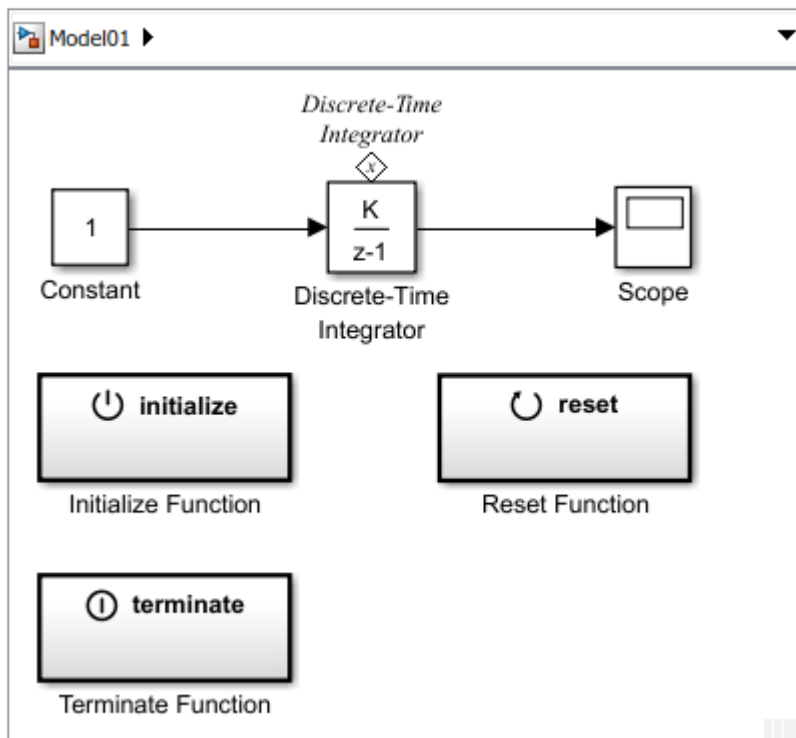

To create a function-call event signal for the Reset Function block, see “Create Test Harness to Generate Function Calls” on page 10-185.

## Read and Save Block State

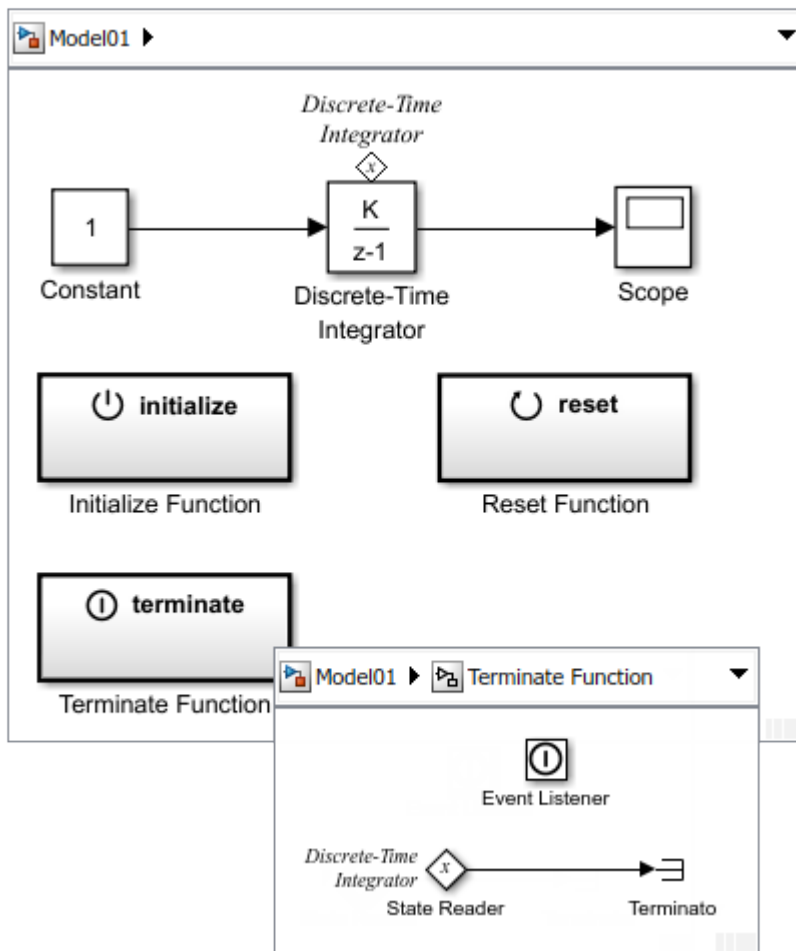

At the end of a simulation, you can read the state of a block, and save that state.

- 1 Add a Terminate Function block.

By default, the Terminate Function block includes an Event Listener block with the parameter **Event type** set to **Terminate**. The block also includes a State Reader block, and a Terminator block as a placeholder for saving the state value.

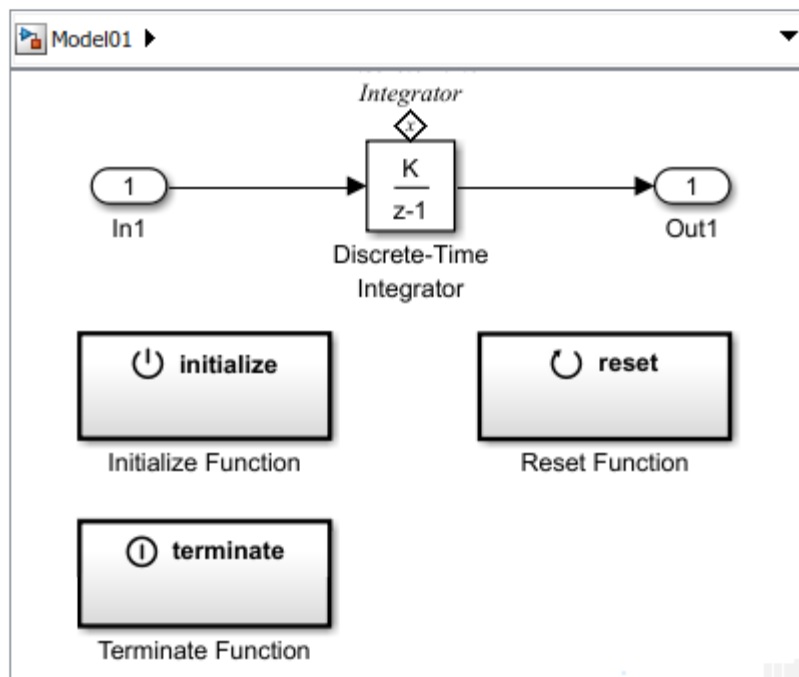

- 2 Connect the state reader with the state owner. Open the State Reader block dialog box. From the State Owner Selector Tree, select Discrete-Time Integrator, and then click **Apply**.

- 3 Run a simulation to confirm that your model simulates without errors. The Terminate Function block executes at the end of a simulation.

- 4 Delete the blocks that you added for testing. Replace the Constant block with an Inport block and the Scope block with an Output block.

## Prepare Model Component for Testing

Make the following changes to avoid simulation errors when the component model is placed in an export-function model for simulation testing.

- 1 Open the Block Parameters dialog box for the Discrete-Time Integrator block. Set **Integrator method** to Accumulation:Forward Euler.
- 2 Open the Model Configuration Parameters dialog box. Confirm the solver **Type** is set to Fixed-step and **Solver** is set to auto. Change the **Fixed-step size** from 1 to auto.

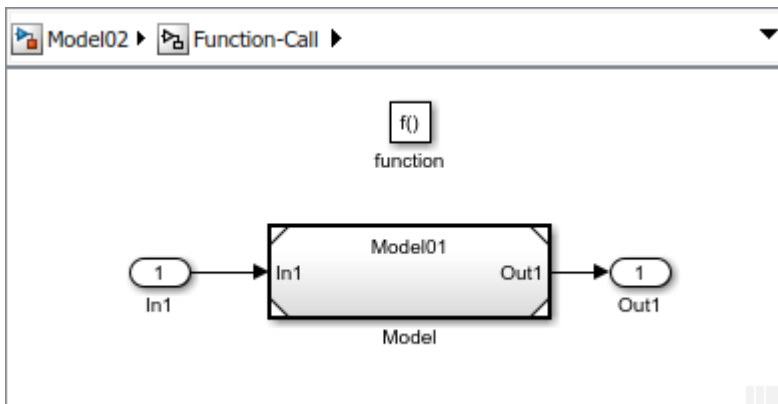

This change avoids a simulation error caused by having multiple sample times in a Function-Call Subsystem.

## Create an Export-Function Model

Placing a model component in a test harness for testing the initialize, reset, and terminate functions requires the model to follow export-function rules. See “Export-Function Models Overview” on page 10-96 and “Create Test Harness to Generate Function Calls” on page 10-185.

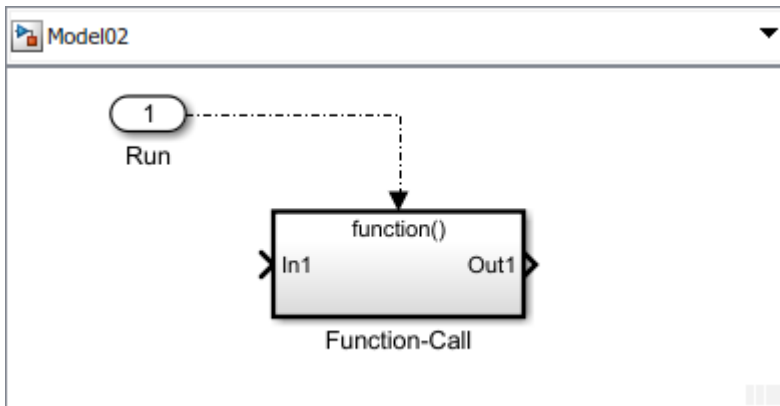

To create an export-function model, place the model component in a Function-Call Subsystem block using a Model block. Connect input and output ports from the model to the subsystem input and output ports.

- 1 Create a Simulink model. Save this model with the name Model02.
- 2 Open the Configuration Parameters dialog box. Set the simulation parameter for the Solver **Type** to Fixed-step. Confirm **Solver** is set to auto and **Fixed-step size** is set to auto.
- 3 Add a Function-Call Subsystem block. Open the subsystem by double-clicking the block.
- 4 Add a Model block to the subsystem and set **Model name** to Model01. Add Inport and Output blocks.

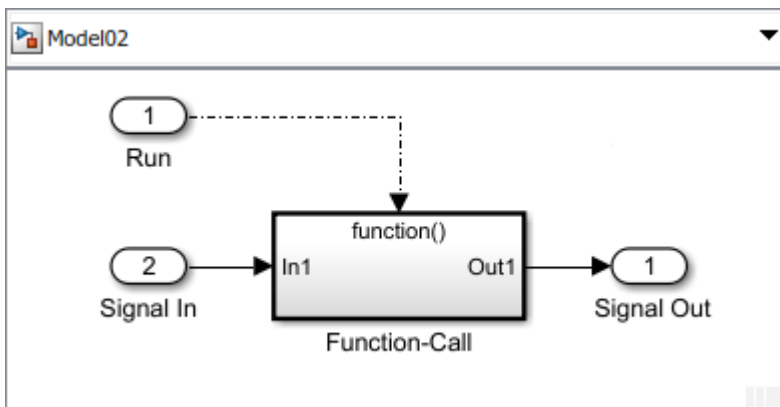

- 5 Navigate to the top level of the model.
- 6 Add an Inport block. This block is the control signal for executing the subsystem. Change the block name to Run and connect it to the `function()` port.

Open the Inport block dialog box and on the **Signal Attributes** tab, select the **Output function call** check box.

- 7 Add a second Inport block and rename it to `Signal In`. Connect it to the `In1` port of the subsystem. This block is the signal for the integration algorithm.

Add an Outport block, rename it to `Signal Out`, and then connect it to the `Out1` port of the subsystem. This block is the integrated signal.

- 8 Designate the model as an export-function model by going to the Property Inspector and setting the execution domain of the model to `Export function`. See "Designating an Export-Function Model" on page 10-99.
- 9 Open the Configuration Parameters dialog box. On the **Model Referencing** pane, set the **Total number of instances allowed per top model** to one.
- 10 Update your model and confirm that there are no errors by pressing **Ctrl-D**.

The next step is create a test harness. See "Create Test Harness to Generate Function Calls" on page 10-185.

- Initialize and Terminate Functions (3 min, 12 sec)

## Create Test Harness to Generate Function Calls

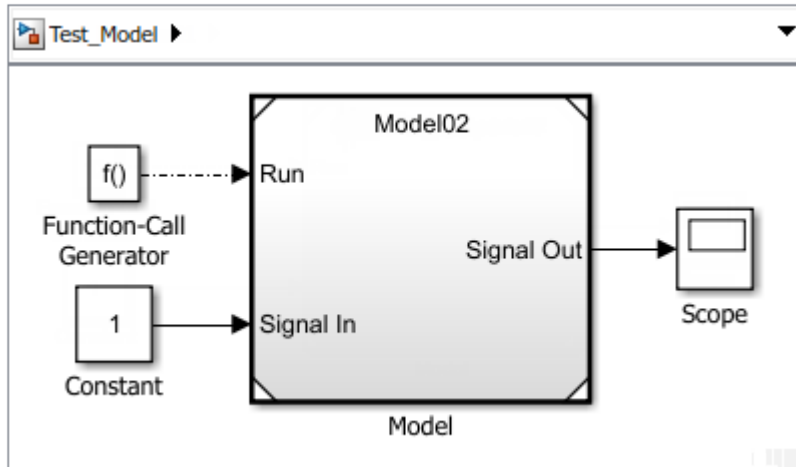

After you create a model component to initialize, reinitialize, reset, and terminate the state of blocks (see “Using Initialize, Reinitialize, Reset, and Terminate Functions” on page 10-172), you can place the model in a simulation test harness. A test harness is a Simulink model that you use to develop, test, and debug a model component.

To create the test harness, reference the export-function model containing the model component in a new model, and then add a Stateflow chart to model a function-call event scheduler.

### Reference the Export-Function Model

The export-function model contains the model component for testing. To create the export function model, see “Create an Export-Function Model” on page 10-182.

- 1 Create a Simulink model. Save this model with the name `Test_Model`.
- 2 Set configuration parameters for solver **Type** to `Fixed-step`, Solver to `auto`, and **Fixed-step size** to 1.
- 3 Add a Model block. Open the Block Parameters dialog box. In the **Model name** text box, enter the name of your export-function model. In this example, enter `Model02`.
- 4 Test the referenced model component by connecting a Function-Call Generator block to the `Run` port. Connect a Constant block to the `Signal In` port and a Scope block to the `Signal Out` port.

- 5 Run simulation to verify your model simulates correctly from the parent model. When the model is simulated without function-call event ports, the Initialize Function block executes at the beginning of a simulation and the Terminate Function block executes at the end of the simulation.

- 6 Expose function-call input ports on the Model block. Right-click the Model block and select **Block Parameters**. In the Block Parameters dialog box, select **Show model initialize port**, **Show model reset port**, and **Show model terminate port**.
- 7 Delete the Function-Call Generator block and update the model by pressing **Ctrl+D**.

When you activate the initialize function-call input port on a Model block, the model has to receive an initialize function call on the `initialize` port before it can execute. The reception of a function call triggers the execution of the default model initialize routine, and then the execution of the Initialize Function block contents.

The reception of a function call on the Reset port triggers the execution of the Reset Function block contents.

The reception of a function call on the Terminate port triggers the execution of the Terminate Function block contents, and then the execution of the default model terminate routine. The

model then stops running. To execute the model again, you have to reinitialize the model by sending a function-call event to the `initialize` port.

## Model an Event Scheduler

Use a Stateflow chart to model an event schedule and generate the initialize and terminate function call signals.

- 1 Add a Stateflow chart. Click the model diagram and start typing `Chart`. From the search list,

select .

- 2 Open the chart and add two state blocks, one above the other.

- 3 Add a default transition and connect it to the top state block. Edit the label:

```
{step = 0}
```

- 4 Add a transition from the top block to the bottom block. Edit the label:

```
[step == 2]/{Initialize}
```

- 5 Add a transition from the bottom block and back to the bottom block. Edit the label:

```
[step == 5]/{Reset}
```

- 6 Add a transition from the bottom block to top block. Edit the label:

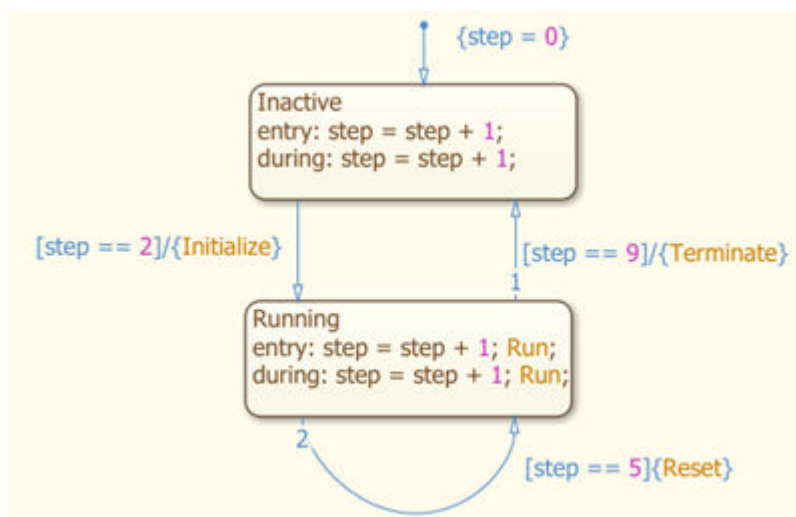

```
[step == 9]/{Terminate}
```

- 7 Edit the content of the top block:

```
Inactive
entry: step = step + 1;
during: step = step + 1;
```

- 8 Edit the content of the bottom block:

```
Running
entry: step = step + 1; Run;
during: step = step + 1; Run;
```

## Connect Chart to Test Model

Create function-call output ports on the chart to control and run the model component.

- 1 Open Model Explorer. On the **Modeling** tab and from the **Design** section, select **Model**

**Workspace** 

- 2 Create index variable. From the menu, select **Add > Data**. In the Data dialog box, enter Step for the **Name**.
- 3 Create function-call output ports. For each function-call event you create, select **Add > Event** and in the Event dialog box, enter, and select the following values.

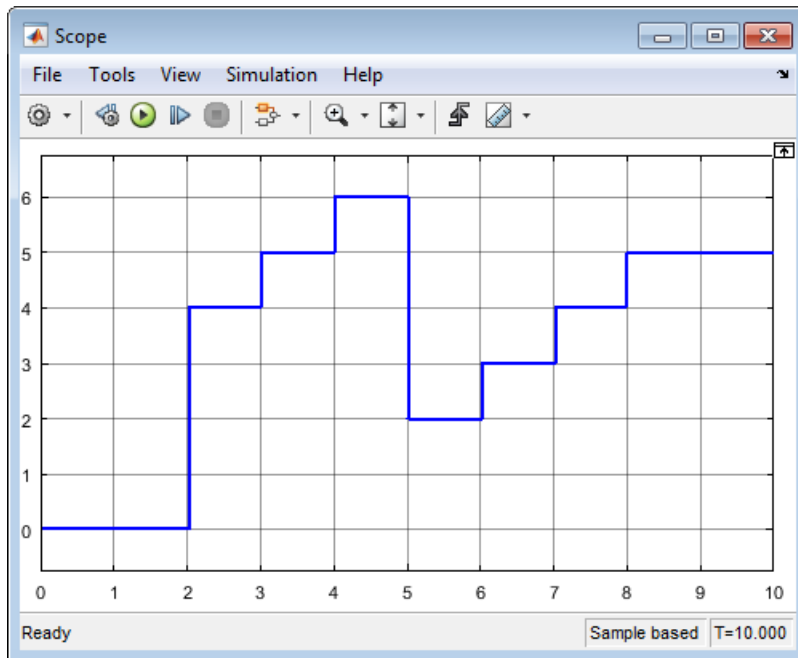

Enter in Event Text Box	Set Scope	Set Trigger
Initialize	Output to Simulink	Function call
Reset	Output to Simulink	Function call
Terminate	Output to Simulink	Function call
Run	Output to Simulink	Function call

- 4 Navigate to the top level of the model. Connect the Initialize, Reset, Terminate, and Run ports on the chart to the initialize, reset, terminate, and Run input ports on the Model block.

- 5 Run simulation.

The model cannot execute until the second time step, when the block state is initialized to 4. At the fifth time step, a reset function call to the reset port triggers the Reset Function block to execute. At the ninth time step, the subsystem stops executing, and the block state remains constant.

If the model receives a function call to run before an initialize function call, a simulation error occurs.

## Initialize and Reset Parameter Values

During a simulation, you can respond to an event such as reading an environment sensor value, and then update an algorithm with a new parameter value.

The Initialize Function, Reinitialize Function, and Reset Function blocks can respond to events while the Parameter Writer block can change parameter values. The Parameter Writer block can change parameters in these ways:

- Writing directly to a parameter of a block that is tunable during simulation
- Writing to an instance parameter belonging to a Model block referencing a model, thus affecting block parameters inside the referenced model
- Writing to a masked subsystem parameter, thus affecting block parameters inside the subsystem
- Writing to a model workspace variable, thus affecting block parameters that are based on that variable

### Adding a Parameter Writer Block

You can use a Parameter Writer block inside an Initialize Function, Reinitialize Function, or Reset Function block to write a parameter value in response to events. You can also use a Parameter Writer block inside a conditionally executed subsystem to write a parameter value whenever the subsystem executes.

A block with a parameter that can be written by a Parameter Writer block is called a parameter owner block. A parameter owner block can be a block with a tunable parameter, a Model block, or a masked subsystem block.

To add a Parameter Writer block to your model, click on a parameter owner block to highlight it. Then, from the current block tab of the Simulink toolstrip, click **Parameter Writer**. Alternatively, click **Reader-Writer**, then select Parameter Writer Block from the list.

---

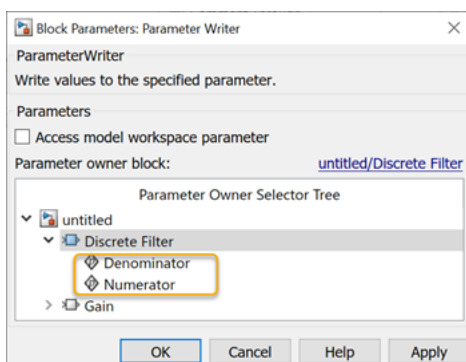

**Note** The current block tab of the toolstrip might be labeled with the name of the highlighted block, for example, **Constant**, or it might be labeled **Block**, depending on the type of block you highlight.

---

If the parameter owner block has multiple parameters to which the Parameter Writer block can write, then the Parameter Writer block dialog box opens. Select a parameter from the **Parameter Owner Selector Tree**.

After you add a Parameter Writer block, a  $p$  badge and the name of the parameter being written to appear above the parameter owner block. The names of the parameter owner block and the parameter appear next to the Parameter Writer block.

After you add a Parameter Writer block, cut and paste it to move it to the desired location within the model hierarchy.

Alternatively, you can add a Parameter Writer block to your model from the Simulink Library Browser, then select a parameter owner block or a model workspace parameter from the block dialog.

---

**Note** When you create a library block with a Parameter Writer block, you must also include the corresponding parameter owner block in the library block.

---

## Writing to Tunable Block Parameters

A Parameter Writer block can write directly to a parameter of a block that is tunable during simulation. See “Which Block Parameters Are Tunable During Simulation?” on page 40-34 The

parameter must take its value from the block dialog box and not from a port. Initial condition parameters are not included. The Parameter Writer block must be in the same model as the block whose parameter it is writing.

## Writing to Model Instance Parameters

A Parameter Writer block can change the value of a block parameter inside a referenced model by writing to an instance parameter of the model. This example shows how to use the Parameter Writer block to change a parameter value for a Gain block inside a referenced model.

- 1 Create a model with a writable parameter, which is a block parameter that you can define with a model parameter. In the example, add Constant, Gain, and Outport blocks to a new model. Connect the blocks. Save the model with the name ParamRw\_Sub.

- 2 Add a Simulink parameter to the Model Workspace. On the **Modeling** tab, in the **Design** section, select **Model Workspace** . From the Model Explorer menu, select **Add > Simulink Parameter**. Set **Name** to Parameter\_1 and **Value** to 1. Select the **Argument** check box. Click **Apply**.

- 3 Open the Gain Block Parameters dialog box. Set **Gain** to Parameter\_1.
- 4 Create a model that initializes the parameter. Add an Initialize Function and Model block to a new model. Save the model with the name ParamRw\_Top.

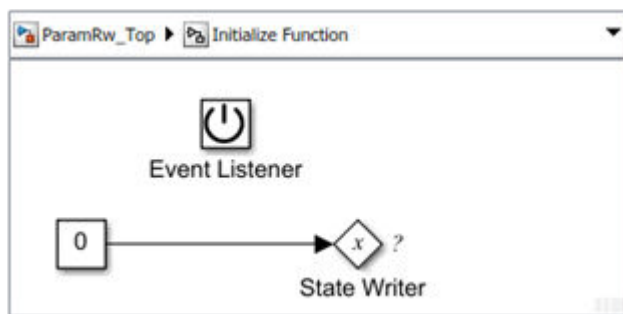

- 5 Rename the Model block to Model\_1. Open the Model Block Parameters dialog box. In the **Model name** box, enter ParamRw\_Sub. Select the **Instance parameters** tab. Set the **Value** for Parameter\_1 to 1. The model uses this default value before the Parameter Writer block updates this parameter with a new value.

- 6 Double-click the Initialize Function block. The block is preconfigured with a State Writer block.

- 7 Replace the State Writer block with a Parameter Writer block. Open the Parameter Writer Block Parameters dialog box. From the **Parameter Owner Selector Tree**, select Parameter\_1.

- 8 Open the Constant Block Parameters dialog box. Set **Constant value** to 3. This value sets the gain with the Parameter Writer block.
- 9 Click **OK** to close the dialog. The Parameter Writer block displays a label indicating it writes to the model instance parameter Parameter\_1 for Model\_1.

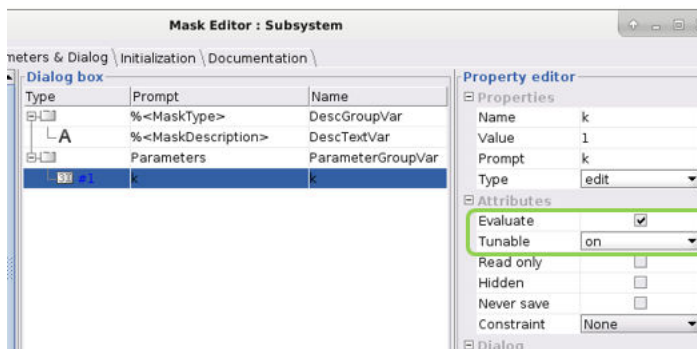

- 10 Click the ParamRw\_Top tab. The Model block displays a badge , indicating a value is written to Parameter\_1.

## Writing to Masked Subsystem Parameters

A Parameter Writer block can change the value of a block parameter inside a masked subsystem by writing to a parameter of the subsystem. The mask parameter must have **Evaluate** selected and **Tunable** set to on or run-to-run. See “Mask Editor Overview”. The subsystem can be atomic or virtual.

## Writing to Model Workspace Variables

A Parameter Writer block can directly write the value of a model workspace variable. The block must be in the same model as the workspace variable, and the variable must not be configured as a model argument. You can write only to model workspace variables and not to variables in the base MATLAB workspace or data dictionaries. The variable written to can be a regular MATLAB variable or a `Simulink.Parameter` object.

To write to a model workspace variable, in the block dialog box, select **Access model workspace parameter** and enter the variable name in **Model workspace parameter name**. Note that the **Parameter Owner Selector Tree** does not appear.

## Initialize, Reinitialize, Reset, and Terminate Function Limitations

Initialize Function, Reinitialize Function, Reset Function, and Terminate Function blocks do not support certain blocks, signals, and modeling patterns.

### Unsupported Blocks and Signals

This table describes whether the Initialize Function, Reinitialize Function, Reset Function, and Terminate Function blocks support the given blocks and signals.

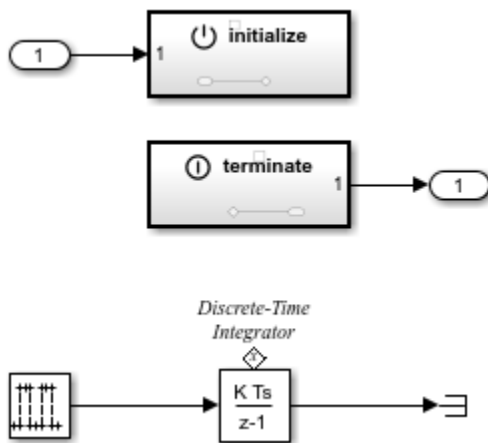

Block or Signal	Support
Model blocks	Not supported.
Custom code blocks	Not supported.
Stateflow charts	Supported by only Reset Function blocks.
Resettable Subsystem blocks	Not supported.
Blocks with states, for example, Unit Delay blocks	Supported by only Reset Function blocks.
Blocks with absolute time, for example, Clock blocks	Not supported.
MATLAB System blocks	Not supported.
MATLAB Function blocks	Initialize Function, Reinitialize Function, and Terminate Function blocks support only MATLAB Function blocks without persistent or global data.  Reset Function blocks support MATLAB Function blocks with or without persistent or global data.
Simulink Function blocks	Initialize Function, Reinitialize Function, Reset Function, and Terminate Function blocks can call Simulink Function blocks as long as the Simulink Function blocks do not have: <ul style="list-style-type: none"> <li>• Input or output ports</li> <li>• An Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block</li> <li>• Unsupported blocks</li> </ul>
Variable-size signals	Not supported.

### Unsupported Modeling Patterns

This table describes requirements for model components that contain Initialize Function, Reinitialize Function, Reset Function, and Terminate Function blocks.

Modeling Pattern	Requirement
Nonvirtual blocks between Initialize Function block and root input port block	<p>When a model contains an Initialize Function block that has an input port, the input port must connect to the root input port block without intervening nonvirtual blocks. Virtual blocks, such as Inport and From blocks, may intervene between the input port of the Initialize Function block and the root input port block.</p> <p>When a harness model simulates the initialization of a referenced model with an <b>initialize</b> port on a Model block, the input ports of the Model block may connect to nonvirtual blocks in the harness model.</p>
Nonvirtual blocks between Terminate Function block and root output port block	<p>When a model contains a Terminate Function block that has an output port, the output port must connect to the root output port block without intervening nonvirtual blocks. Virtual blocks, such as Outport and Goto blocks, may intervene between the output port of the Terminate Function block and the root output port block.</p> <p>When a harness model simulates the termination of a referenced model with a <b>terminate</b> port on a Model block, the output ports of the Model block may connect to nonvirtual blocks in the harness model.</p>
Branched input signal in export-function model	In an export-function model, a signal from a root Inport block to an Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block must not branch to a Simulink Function block.
Branched input signal in a model that is not an export-function model	In a model that is not an export-function model, a signal from a root Inport block to an Initialize Function, Reinitialize Function, Reset Function, or Terminate Function block must not branch to any other block.

For example, suppose you have a model that contains Initialize Function and Terminate Function blocks.

The Initialize Function block connects to a root Inport block. The Terminate Function block connects to a root Outport block. The signal from the root Inport block to the Initialize Function block does not branch to any other blocks.

A harness model can simulate the model behavior.

To simulate the initialization of the referenced model, a control signal connects to the **initialize** port of the Model block, which corresponds with the Initialize Function block in the referenced model.

To simulate the termination of the referenced model, a control signal connects to the **terminate** port of the Model block, which corresponds with the Terminate Function block in the referenced model.

To provide an environment for the referenced model, nonvirtual blocks in the harness model connect to the Model block input and output ports.

## Reinitialize States of Blocks in Subsystem

The Reinitialize Function block allows you set the state of all blocks in a referenced model or subsystem back to their initial condition, as well as to explicitly set block states or block parameters, at any time during model simulation. This example demonstrates the use of the Reinitialize Function block in a subsystem.

The model contains a subsystem with a reinitialize port. A Function-Call Generator block sends a function-call signal to the port at time step 5.

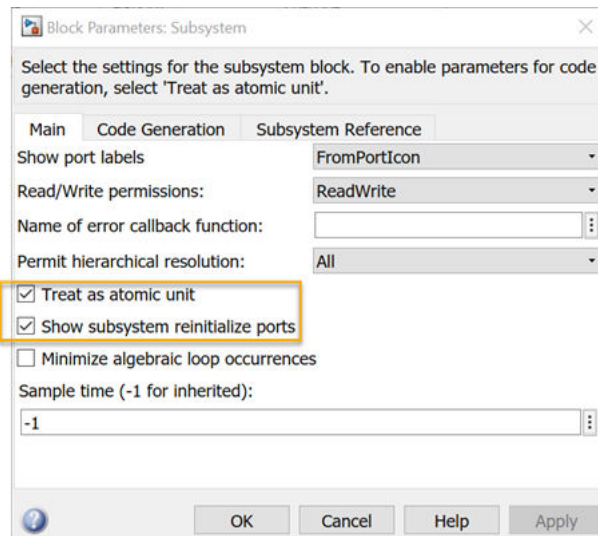

Inside the subsystem, two Discrete-Time Integrator blocks integrate the input signal and output the result. The blocks are identically configured, with the **Initial condition** set to 0.

The subsystem contains a Reinitialize Function block. Inside the Reinitialize Function block is a State Writer block that is configured to set the state of one of the two Discrete-Time Integrator blocks to 10.

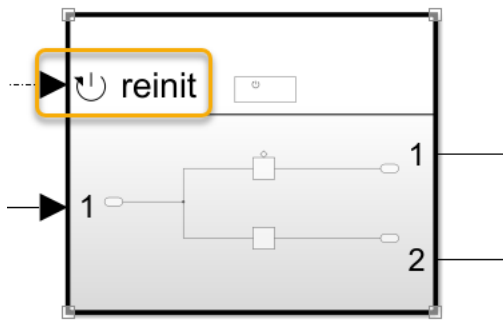

The Reinitialize Function block executes only when the subsystem receives a reinitialize event, that is, when a function-call event is set to the reinitialize port of the subsystem. To expose a reinitialize port on the subsystem block, in the Subsystem block parameters dialog box, select **Treat as atomic unit** and then select **Show subsystem reinitialize ports**.

**Note** You can also use the Reinitialize Function block inside conditional subsystems. In such cases, you do not need to select **Treat as atomic unit**.

A port is displayed on the Subsystem block with the reinitialize icon  and the label `reinit`. This label corresponds to the **Event name** specified in the Event Listener block inside the Reinitialize Function block.

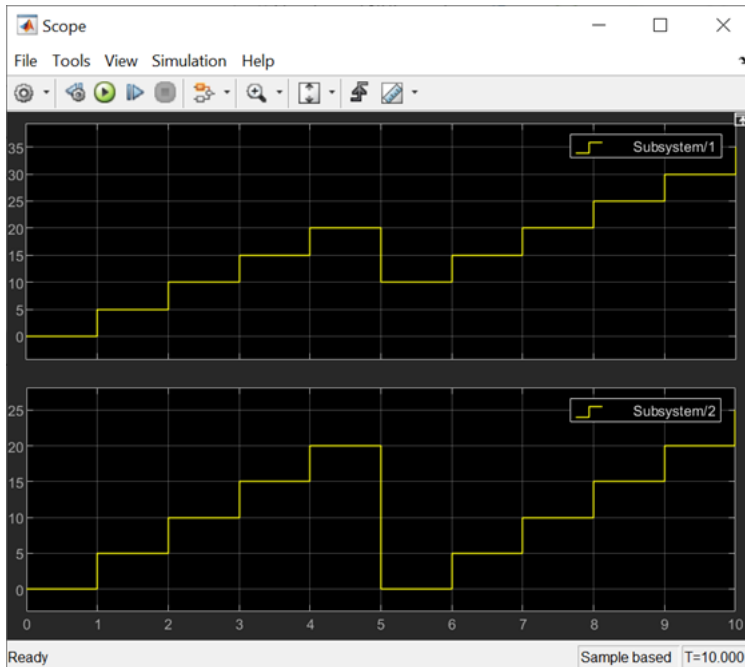

Sending a function-call event to the reinitialize port generates a subsystem reinitialize event, which has these effects:

- 1 For each block with a state in the subsystem, the state is set to the initial condition, as specified in the block parameters. In this example, the states of both Discrete-Time Integrator blocks are set to 0.
- 2 The contents of the Reinitialize Function block corresponding to the port are executed. In this example, the State Writer block sets the state of one of the Discrete-Time Integrator blocks to 10, overriding the value set in the previous step.

**Note** In addition to or instead of using State Writer blocks to set block states, you can configure a Reinitialize Function block to take other actions, such as setting a block parameter value with a Parameter Writer block or setting a data store value with a Data Store Write block.

In this example, a constant value of 5 is sent to both Discrete-Time Integrator blocks and integrated, and a function-call event is sent to the reinitialize port at time step 5, generating a subsystem reinitialize event. After you simulate the model, the Scope output shows that the first signal is reset to 10 and the second signal is reset to 0 at time step 5.

## Model A House Heating System

This tutorial shows how to model and simulate a dynamic system using Simulink software. The model is for a heating system that includes a heater (plant model), controlled by a thermostat (controller model), to heat a room (environment model) to a set temperature. While this is a simple model, the processes for creating model structure and algorithm design are the same processes you will use for more complex models.

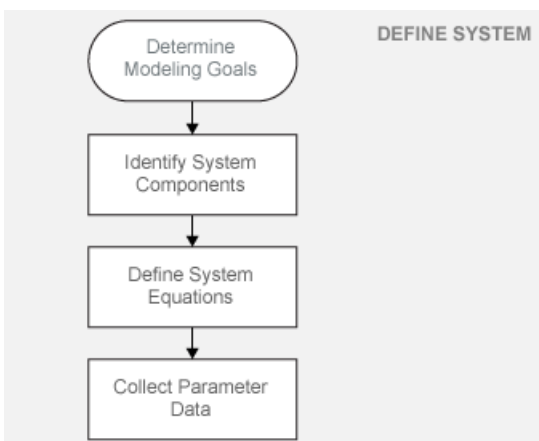

To review a completed model, in the MATLAB Command Window, enter

```
open_system(fullfile(matlabroot,...
'help', 'toolbox', 'simulink', 'examples', 'ex_househeat_modeling'))
```

### Define a House Heating System

Modeling begins with completion of tasks that are outside of the Simulink software environment. Define model requirements and derive mathematical equations. Collect data for model parameters and output signal data measurements to validate simulation results.

#### Determine Modeling Goals

Before designing a model, consider your goals and requirements. The goals for modeling the house heating system are:

- Observe how the changing outdoor temperature affects the indoor temperature.
- Examine the effect of changing parameters on the indoor temperature.

### Identify System Components

Once you understand your modeling requirements, you can begin to identify the components of the system.

The house heating system in this tutorial defines a heating system and its relationship to a room. It includes:

- Thermal characteristics of a house
- Thermal characteristics of a heater
- A thermostat to control the heater
- Outdoor environment
- Indoor environment

The thermostat monitors the room temperature regularly and turns the heater on or off, depending on the difference between the set temperature and the room temperature.

The model for this system includes three components: heater, thermostat, and room.

### Define System Equations

Three time-dependent variables define the heat exchange in the room:

- Temperature of the room ( $T_{room}$ )
- Heat gain: Thermal energy transferred from the heater ( $Q_{gain}$ ) to the room
- Heat loss: Thermal energy transferred from the room ( $Q_{loss}$ ) to the outdoor environment

A differential equation defines the relationship between these variables, but since heat transfer is defined in terms of changing temperature, only room temperature is a state variable.

### Rate of Heat Gain Equation

The temperature of the air in the heater is constant at  $T_{heater}$  and the room temperature is  $T_{room}$ . Thermal energy gain to the room is by convection of heated air from the heater, with a heat capacity

of  $c_{air}$ . Heat gain for a mass of air in the heater,  $m_{heaterair}$ , is proportional to the temperature difference between the heater and the room:

$$Q_{gain} = m_{heaterair}c_{air}(T_{heater} - T_{room}).$$

The rate of thermal energy gain from the heater is

$$\frac{dQ_{gain}}{dt} = \frac{dm_{heaterair}}{dt}c_{air}(T_{heater} - T_{room}).$$

A fan takes room air, and passes it through the heater and back to the room. A constant amount of air,  $M_{heaterair}$ , flows through the heater per unit time, and replacing  $dm_{heaterair}/dt$  with that constant simplifies the equation to

$$\frac{dQ_{gain}}{dt} = M_{heaterair}c_{air}(T_{heater} - T_{room}).$$

### Rate of Heat Loss Equation

Thermal energy loss from the room is by conduction through the walls and windows, and is proportional to the temperature difference between the room temperature and the outside temperature:

$$Q_{loss} = \frac{kA(T_{room} - T_{outside})t}{D}.$$

The rate of thermal energy loss is

$$\frac{dQ_{loss}}{dt} = \frac{kA(T_{room} - T_{outside})}{D}.$$

Replacing  $kA/D$  with  $1/R$  where  $R$  is the thermal resistance simplifies the equation to

$$\frac{dQ_{loss}}{dt} = \frac{(T_{room} - T_{outside})}{R}.$$

### Changing Room Temperature Equation

Define the rate of temperature change in the room by subtracting the rate of heat loss from the rate of heat gain:

$$\frac{dT_{room}}{dt} = \frac{1}{m_{roomair}c_{air}} \left( \frac{dQ_{gain}}{dt} - \frac{dQ_{loss}}{dt} \right).$$

### Collect Parameter Data

Most of the parameter values needed for the house heating model are published in standard property tables. The flow rate for the heater is from a manufacturer data sheet.

List the variables and coefficients from your equations and check for dimensional consistency between the units. Since the unit of time for the model is hours, convert published values for the thermal property of materials from units of seconds to hours.

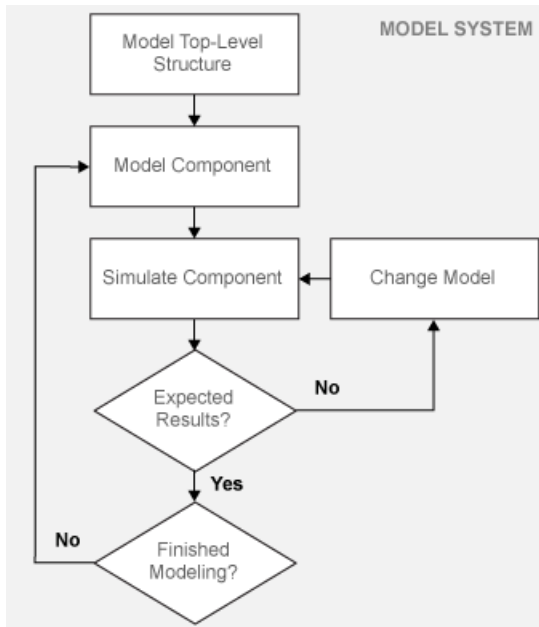

### Equation Variables and Constants

You can use the constant names and values in this table when building the model.

Equation Variable or Coefficient	Description	Units
$A$	Area of wall or window surface $A_{\text{wall}} = 914, A_{\text{window}} = 6$	square meter
$D$	Depth of wall or window $D_{\text{wall}} = 0.2, D_{\text{window}} = 0.01$	meter
$Q$	Thermal energy transferred	joule
$dQ/dt$	Rate of thermal energy transferred	joule/hour
$k$	Thermal conductivity; property of a material to conduct heat transfer $k_{\text{fiberglass}} = 136.8, k_{\text{glass}} = 2808$	joule/meter·hour·degree
$r$	Thermal resistivity; property of a material to resist heat transfer $r = 1/k$	meter·hour·degree/joule
$R$	Thermal resistance $R = D/kA = (T_1 - T_2)/Q$ $R_{\text{wall}} = 1.599\text{e-}6, R_{\text{window}} = 5.935\text{e-}7$ $R_{\text{equivalent}} = (R_{\text{wall}} * R_{\text{window}})/(R_{\text{wall}} + R_{\text{window}}) = 4.329\text{e-}7$	hour·degree/joule
$m$	Mass of air in the room or heater $m_{\text{room\_air}} = 1470$ The mass of the heater $m_{\text{heater\_air}}$ is not needed for this model.	kilogram
$dm/dt$	Rate of air mass passing through the heater	kilogram/hour
$M$	Constant rate of air mass passing through the heater $M_{\text{heater\_air}} = 3600$	kilogram/hour
$c$	Specific heat capacity $c_{\text{air}} = 1005.4$	joule/kilogram·degree
$T_{\text{heater}}$	Constant air temperature from heater $T_{\text{heater}} = 50$	degree Celsius
$T_{\text{room}}$	Initial air temperature of room $T_{\text{roomIC}} = 20$	degree Celsius

## Model House Heating System

Model the top-level structure with components that including interfaces for passing data between individual components. Your model should be organized into a hierarchical structure that corresponds to the components of the system.

### Model Top-Level Structure

At the top level of the house heating model, use Subsystem blocks to organize your model and create the structure. The model includes the subsystems Thermostat, Heater, and Room.

- 1 Open a new Simulink model: "Open New Model".
- 2 Open the Library Browser: "Open Simulink Library Browser"
- 3 Add Subsystem blocks. Drag three Subsystem blocks from the Ports & Subsystems library to the new model in the Simulink Editor.

- 4 Open a Subsystem block. Double-click the block.

Each new Subsystem block contains one Inport (In1) and one Outport (Out1) block. These blocks define the signal interface with the next higher level in a model hierarchy.

Each Inport block creates an input port on the Subsystem block, and each Outport block creates an output port. Add more blocks for additional input and output signals.

- 5 On the Simulink Toolstrip, click the **Navigate Up To Parent** button  to return to the top level. Rename the Subsystem blocks as shown. Double-click a block name and type the new name.

For each component, model the equations, define parameters, prepare the subsystem for simulation, and simulate to verify its behavior.

### Model Heater Component

Let's start by modeling the heater system component. The heater model:

- Takes the current temperature from the room and a control signal from the thermostat as inputs
- Calculates the heat gain from the heater
- Outputs the heat gain when the control signal is on

To model the heater subsystem, model the rate of heat gain equation with Simulink blocks:

$$\frac{dQ_{gain}}{dt} = M_{heaterair}c_{air}(T_{heater} - T_{room}).$$

### Subtract Room Air Temperature from Heater Air Temperature

The temperature difference is the current room temperature subtracted from the constant temperature of the heater ( $T_{heater}$ ).

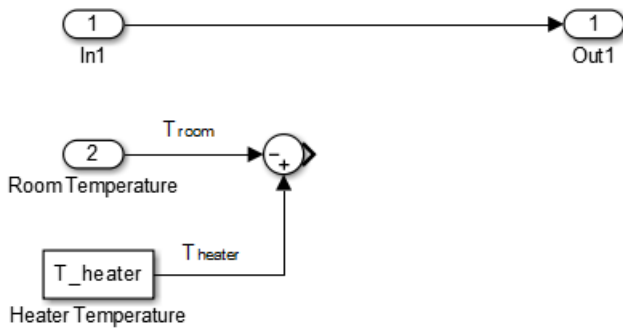

- 1 Open the Heater subsystem.
- 2 Click the model and type Sum to display a list of blocks with Sum in the name. Click the Sum block on the list. When prompted for a list of signs, type | - + to place - and + input ports on the block, and press **Enter**.

The vertical bar (|) changes the position of input ports by inserting spaces between the ports. A vertical bar at the beginning of the sign list, places a space at the top of the block and shifts the ports counter clockwise.

- 3 Add a Constant block to model the constant air temperature from the heater. Set the block **Constant value** parameter to  $T_{heater}$ . You will define the value of  $T_{heater}$  in the Model Workspace.

If the block displays -C-, resize the block to display the variable name.

- 4 Add a second Inport block to take the room temperature signal from another part of your model.
- 5 Add a Gain block to the Heater subsystem. Set the **Gain** parameter to  $M_{heater\_air} * c_{air}$ . You will define the values of these variables in the Model Workspace.
- 6 Connect the output of the Sum block to the input of the Gain block.
- 7 Add labels to the signal lines to help trace model components to the equations and model requirements. Double-click above a signal line and enter a label.

8 Rename the blocks and connect them as shown in the figure.

### Model a Heater Switch

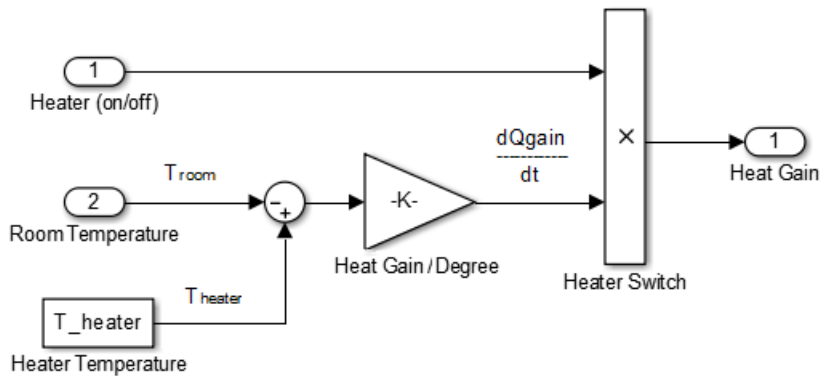

The thermostat sends an on/off signal equal to 1 (on) or 0 (off) to the heater. Because the input signal is binary, you can use a Product block to model a switch.

- 1 Remove the connection between the In1 and Out1 blocks. Select the line and press **Delete**.
- 2 Add a Product block. Resize the block vertically to align the block in your diagram. Connect the In1 block to the first block input and the block output to the Out1 block. Rename the blocks as shown.

- 3 Connect the output from the Gain block to the second input. Move all the connected blocks together. Draw a selection box around the blocks you want to move, and then drag them to the new location.
- 4 Rename blocks and add labels to signals as shown in the figure.

The Inport and Outport blocks create ports that connect this subsystem to other subsystems in your model.

### Define Heater Model Parameters

You can define parameters in the MATLAB Workspace and then enter their names in the block parameter dialog boxes. However, a more robust method is to use the Simulink Model Workspace because variable values are saved with the model.

- 1 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Model Workspace**.
- 2 In Model Explorer, select **Add > MATLAB Variable**. In the middle pane, click the new variable Var and enter the variable name for a block parameter. For this example, enter T\_heater.

Name	Value	DataType	Min	Max	Dimensions
T_heater	0	double (auto)			

- 3 Click the 0 value and enter the value for this variable. For this example, enter 50 degrees.

Name	Value	DataType	Min	Max	Dimensions
T_heater	50	double (auto)			

- 4 Using the same approach, add the variable M\_heater\_air with a value of 3600 kilogram/hour and c\_air with a value of 1005.4 joule/kilogram· degree.

### Prepare Heater Model for Simulation

Set up the heater model for simulation. Think about the expected behavior and how you can test that behavior with a simulation. When the thermostat output is 1 (on), and assuming constant room temperature of 25, the expected output from the gain is  $(50 - 25) \times 3600 \times 1005.3 = 9.05 \times 10^7$ . Verify this output by running the model with these inputs:

- Heater on/off signal that changes from 0 to 1 after the 4<sup>th</sup> hour
- Room temperature constant at 25

- 1 From the Heater subsystem, click the **Navigate Up To Parent** button  to navigate to the top level of your model. You can resize the Heater block as shown in the figure.

Notice the Heater block has a second input port and that each port corresponds to an Inport block or Outport block in the subsystem.

- 2 Add a Constant block to represent the room temperature, and set the value to 25 (degrees Celsius). Add a Step block for a temporary Heater (on/off) signal. Set **Step time** to 4.
- 3 Add a Scope block and connect it to the Heat Gain output.

### Simulate Heater Model and Evaluate Results

Use the default simulation settings to validate your model design.

- 1 Double-click the Scope block to open it.
- 2 Simulate the model. Click the **Run** button .

As the simulation runs, the Scope plots the results.

- 3 View the scope trace.

- 4 Determine if this result is what you expected.

When the heater on/off signal flips from 0 to 1 at 4 hours, the heater outputs  $9.05 \times 10^7$  joule/hour. The simulation validates the expected behavior.

- 5 Remove Constant, Step, and Scope blocks you added for testing the Heater component.

### Model Thermostat Component

You can model a thermostat without using system equations. Requirements for this component:

- When the room temperature is below the set temperature, heater is on and the control signal equals 1. When the room temperature is above the set temperature, the control signal equals 0.
- To avoid repeated switching around the set temperature, the thermostat allows a hysteresis of 2 degrees Celsius around the temperature set point. If the thermostat is on, the room temperature must increase 2 degrees above the set temperature before turning off. If the thermostat is off, the room temperature must drop 2 degrees below the set temperature before turning on.

This component models the operation of a thermostat, determining when the heating system is on or off. It contains only one Relay block but logically represents the thermostat in the model.

#### Subtract Set Room Temperature from Room Temperature

If the set room temperature is warmer than the room temperature, the thermostat model sends an “on” signal to the heater model. To determine if this is the case, begin by subtracting the room temperature from the set temperature.

- 1 Open the Thermostat subsystem. Add a Sum block. Set the parameter **List of signs** to  $|+-$ .
- 2 Connect the Inport block to the + input of the Sum block. The Inport block sets the room temperature.
- 3 Add a second Inport block and connect it to the - input of the Sum block. This second Inport block is the current room temperature from the room subsystem. Move the output port to the top of the block. Select the block. In the toolstrip, on the **Format** tab, select **Rotate 90 counterclockwise** . If you want, you can reshape the block as shown in the figure by dragging the handles.
- 4 Rename the blocks as shown.

#### Model Thermostat Signal

Model the signal from the thermostat with a hysteresis value of 2 degrees Celsius.

- 1 In the Thermostat subsystem, add a Relay block. Set the **Switch on point** parameter to 2, and the **Switch off point** parameter to -2.
- 2 Connect and rename the blocks as shown in the figure.

### Prepare Thermostat Model for Simulation

Prepare the Thermostat subsystem for simulation. Think about the expected behavior of the thermostat and how you can test that behavior with a simulation. When the room temperature rises above the thermostat setting by 2 degrees, the thermostat output is 0. When the room temperature moves below the thermostat setting by 2 degrees, the thermostat output is 1.

- 1 From the Thermostat subsystem, click the **Navigate Up To Parent** button  to navigate to the top level of your model. Resize the Thermostat block as shown in the figure.

Notice the Thermostat subsystem now has a second input port. Each input port corresponds to an Inport block in the subsystem.

- 2 Add a Constant block for the set temperature. Set the **Constant** parameter to 25 (degrees Celsius).
- 3 Add a Sine Wave block to represent the changing room temperature. Set the **Amplitude** parameter to 10, the **Bias** to 20, and the **Frequency** to 0.5. These parameters give a variation above and below the temperature set point of 25.
- 4 Create and connect Scope Viewer at the Heater port. See “Add Signal Viewer”.
- 5 Connect the two input signals to the Scope Viewer.

### Simulate Thermostat Model and Evaluate Results

Use the default simulation settings to validate your model design.

- 1 Simulate the model. As the simulation runs, the Scope Viewer plots the results.
- 2 Open the Scope to view the scope trace.

- 3 Determine if this result is what you expected.

Initially the room temperature is below the set temperature and the relay is on. When the room temperature reaches the set temperature, the relay continues to be on until the room temperature increases by 2 more degrees. Simulation validates the expected behavior.

### Model Room Component

Inputs to the room component are heat flow from the heater component and the external air temperature. The room component uses these inputs to compute heat loss through the walls, heat loss through the windows, and the current room temperature.

To design the room subsystem, use the Rate of Heat Loss equation and the Changing Room Temperature Equation.

### Model Changing Room Temperature

The rate of temperature change in the room ( $dT_{room}/dt$ ) is defined by the equation

$$\frac{dT_{room}}{dt} = \frac{1}{m_{room}c_{air}} \left( \frac{dQ_{gain}}{dt} - \frac{dQ_{loss}}{dt} \right)$$

The term  $dQ_{gain}/dt$  is a signal from the Heater subsystem.

- 1 Open the Room subsystem block. In the Room subsystem, add a Sum block. Set the **List of signs** parameter to |+-.
- 2 Connect In1 to the + input. The input is the heat gain ( $dQ_{gain}/dt$ ) from the heater component. The - input connects to the heat loss ( $dQ_{loss}/dt$ ) from the room.
- 3 Add a Gain block. Set the **Gain** parameter to  $1/(m_{room}c_{air})$ . Connect the output of the Sum block to the input of the Gain block. Label signals as shown in the figure. Dotted signal lines are signals you will connect later.

### Model Room Temperature

The output of the Gain block is the change in room temperature ( $dT_{room}/dt$ ). To get the current room temperature ( $T_{room}$ ), integrate the signal.

- 1 Add an Integrator block. Set the **Initial condition** parameter to  $T_{room\_IC}$ .
- 2 Connect the output of the Integrator block to Out1 as shown.

### Model Heat Loss Through Walls and Windows

This equation is the rate of thermal energy loss through the walls and windows:

$$\frac{dQ_{loss}}{dt} = \frac{(T_{room} - T_{outside})}{R}$$

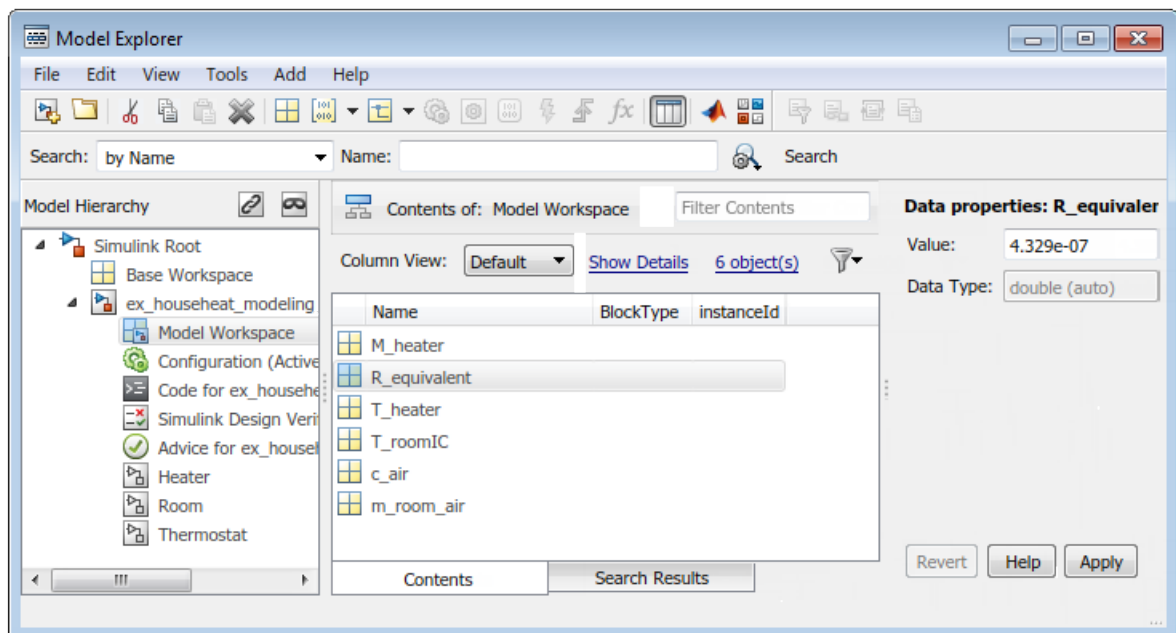

- 1 In the Room subsystem, add a Sum block. Set the **List of signs** parameter to |+-|. Select the block. In the toolbar, on the **Format** tab, click **Flip left-right** .
- 2 Connect  $T_{room}$  to the Sum block. Click the signal line for  $T_{room}$  and the + input on the Sum block.
- 3 Add another Inport block and connect it to the - input of the Sum block. Rename it to Outside Temperature.
- 4 Add another Gain block. Set the **Gain** parameter to  $1/R_{equivalent}$ . Select the block. In the toolbar, on the **Format** tab, click **Flip left-right** .
- 5 Connect the blocks as shown in the figure.

### Define Room Model Parameters

You can define parameters in the MATLAB Workspace and then enter their names in the block parameter dialog boxes. However, a more robust method is to use the Simulink Model Workspace, which saves parameter values with the model.

- 1 In the Simulink Editor, on the **Modeling** tab, under **Design**, click **Model Workspace**.
- 2 In the Model Explorer, select **Add > MATLAB Variable**.
- 3 In the middle pane, click the new variable Var and enter the name `m_room_air`. In the right pane, enter the value 1470 (kilograms).
- 4 Add the variables `T_roomIC = 20` (degrees Celsius) and `R_equivalent = 4.329e-7` (hour-degree/joule).

### Prepare Room Model for Simulation

Prepare the Room subsystem for simulation. Think about the expected behavior and how you can test that behavior with a simulation. When the heater is off (Heat Gain = 0) and the initial temperature of

the room (20) is above the outside temperature (10), heat loss should continue until the room temperature is equal to the outside temperature.

- 1 From the Room subsystem, click the **Navigate Up To Parent** button  to navigate to the top level of your model. Resize the Room block as shown in the figure.

The Room block now has a second input port. Each input port corresponds to an Inport block in the subsystem.

- 2 Add a Constant block and connect it to the Heat Gain input. Set the **Constant value** parameter to 0 (degrees Celsius) to mean that the heater is turned off.
- 3 Add another Constant block and connect it to the Outside Temperature input. Set the **Constant value** parameter to 10 (degrees Celsius).
- 4 Add and connect a Scope block to view the changing room temperature.

### Simulate Room Model and Evaluate Results

- 1 In the toolstrip, set the **Stop Time** to 20.
- 2 Simulate the model.
- 3 Open the Scope and click the **Autoscale** button  to view the scope trace.

- 4 Determine if this result is what you expected.

The room temperature starts at the initial room temperature set in the Integrator block. Because the heat gain is 0, the signal decays to the outside temperature (10). The simulation validates the expected behavior.

#### Prepare Room Model for Second Simulation

Set the constant outside temperature to a value above the initial room temperature (20).

In the Constant block that is connected to the Outside Temperature input, set **Constant value** to 30 (degrees Celsius).

#### Simulate Model and Evaluate Results

- 1 Simulate the model.
- 2 Open the Scope and click the **Autoscale** button  to view the scope trace.

- 3 Determine if this result is what you expected.

Room temperature starts at the initially set temperature of 20, but with the heater off (heat gain = 0) the room temperature rises to the outside temperature — a behavior that the model did not explicitly specify, and might be considered unexpected.

The equation that models the heat loss also models the heat gain when the outside temperature is above the inside room temperature. While the model did not explicitly specify this behavior when the heater is turned off, the result makes sense physically.

## Integrate a House Heating Model

Connect model components, add realistic input, and then simulate the model behavior over time to validate the model design.

## Integrate Heater and Thermostat Components

To simulate the heater and thermostat subsystems without the Room subsystem, you need a signal for the changing room temperature. Use a Constant block to set the thermostat temperature and a Sine Wave block for a realistic outside temperature signal.

### Prepare Model for Simulation

- 1 Open your model with the completed subsystems. Remove any blocks you added to test the separate components.
- 2 Open the Room subsystem. Double-click the Inport block labeled Heat Gain. In the Inport block dialog box, set **Port number** to 2. The Heat Gain port moves to the bottom of the Room subsystem.

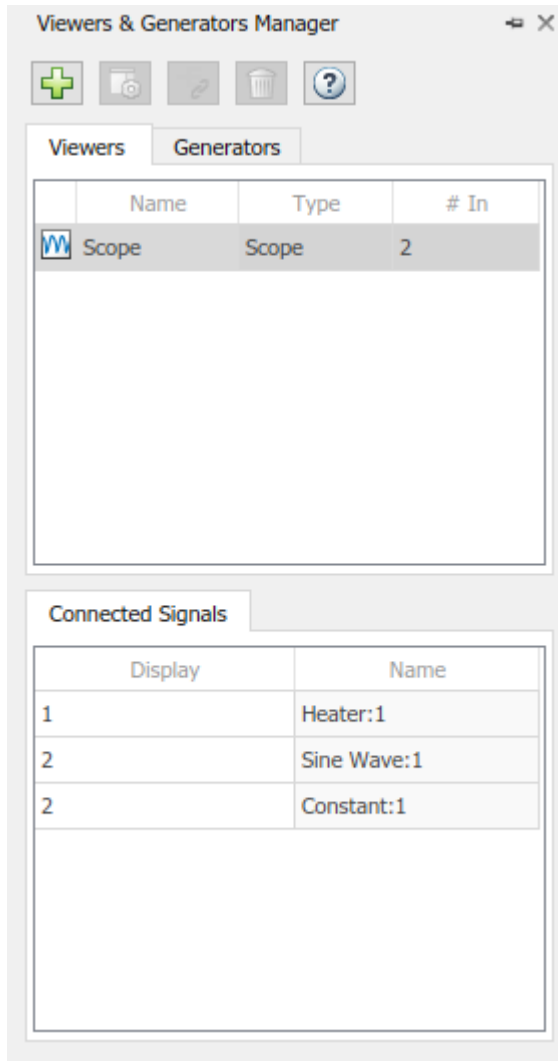

- 3 Connect the Heater (on/off) signal from the Thermostat subsystem output to the Heater subsystem input.
- 4 Add a Constant block to set the thermostat room temperature. Set **Constant** value to 20 (degrees Celsius).
- 5 Add a Sine Wave block to represent the changing room temperature. Set the parameters **Amplitude** to 10 (degrees Celsius), **Bias** to 15, and **Frequency** to 0.5.
- 6 Connect the blocks as shown in the figure.

- 7 Add a Scope viewer and add the output signals from Heater, Constant, and Sine Wave blocks. See "Add Signal Viewer".
- 8 On the Scope viewer window, in the **Configuration Properties** button  click the arrow and then click **Layout** icon . Select two boxes. A second empty graph appears below the first.
- 9 In the **Simulation** tab under **Prepare**, select **Viewers Manager**.

- 10 From the Viewers and Generators Manager, select the **Scope**. Under Connected Signals, in the rows for **Constant** and **Sine Wave**, select the Display entry and change the Display to **2**.

### Simulate Model and Evaluate Results

Simulate the model using the default stop time of 10.

- 1 Simulate the model.
- 2 Open the Scope Viewer and view the simulation results. The top graph is the heater gain while the lower graph shows the changing room temperature modeled with a sine wave.

- 3 Determine if this result is what you expected.

From about 0 to 1.5 hours, the heater is turned on. Heat gain is not constant but changes because heat gain is a function of the difference between the heater air temperature and the room air temperature. From 1.5 to 5.6 hours, the heater is turned off and the heat gain (top graph) is zero. The simulation confirms the expected behavior.

### Integrate Room Component

To simulate the Heater and Thermostat subsystems with the Room subsystem, you need a signal for the changing outside temperature. Simulating the model allows you to observe how the thermostat setting and outdoor temperature affect the indoor temperature.

#### Prepare Model for Simulation

- 1 Open your model with completed subsystems. Remove any blocks you added to test the separate components.

- 2 Connect the subsystems as shown.

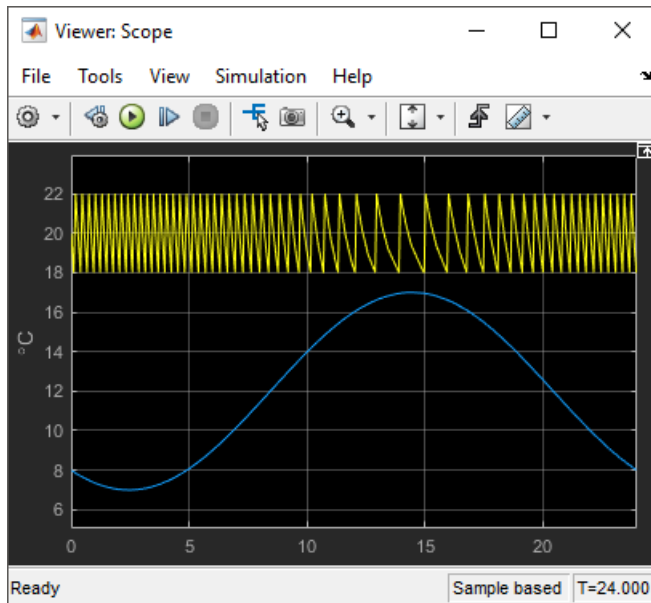

- 3 Add a Constant block for setting the room temperature. Set **Constant value** parameter to 20 (degrees Celsius).
- 4 Add a Sine Wave block to represent the changing outside temperature. Set **Amplitude** to 5, **Bias** to 12, **Frequency** to  $2\pi/24$ , and **Phase** to 180.

- 5 Add a Scope Viewer block to view simulation results.
- 6 In the Signal Viewer, click the **Signal Selector** button . In the Signal Selector dialog box and in the left pane, select the top model hierarchy. In the right pane, select the Room and Sine Wave signals.

**Simulate Model and Evaluate Results**

- 1 Set the simulation stop time to 24 (hours) to represent a day.
- 2 Simulate the model.
- 3 Open the Scope Viewer and view results.

- 4 Determine if the simulation result matches your expectation.

When the outside temperature is below the set room temperature, the room temperature fluctuates 2 degrees above and below the set temperature. Since the thermostat subsystem includes a 2 degree hysteresis, this simulation result is expected.

- 5 You can compare your results with an example model. In the MATLAB Command Window, enter

```
open_system(fullfile(matlabroot,...
    'help','toolbox','simulink','examples','ex_househeat_modeling_prepared'))
```

or click `ex_househeat_modeling_prepared.slx`.

### Refine Model Parameters

With Simulink models, you can interactively change model parameters and then observe changes in the behavior of your model. This approach allows you to evaluate your model quickly and validate your design.

Change the outside temperature in the Sine Wave block so that upper values are above the set temperature.

- 1 In the Sine Wave dialog box, set **Amplitude** to 5 and **Bias** to 19. These settings show what happens when outside temperature is higher than inside temperature.
- 2 Simulate the model and view the results.

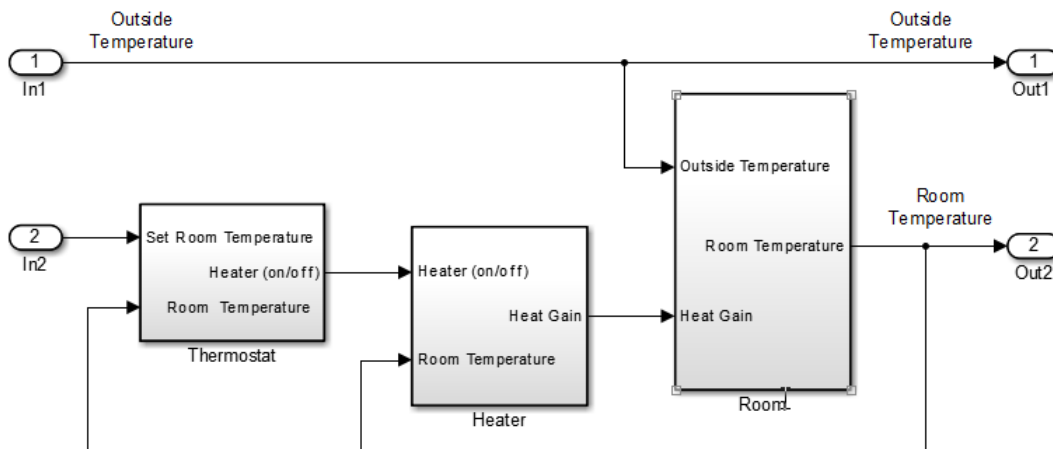

- 3 Determine if the results match your expectations.

When the outside temperature is above the set temperature, the room temperature follows the outside temperature with a slight delay. In this case, heat loss works in the reverse direction - and represents the loss of heat from the outside environment into the room.

### Model External Interface

Model the external interface for further testing and possible use in a larger model. In Simulink, you model the external interface using Inport and Outport blocks.

- 1 Add Inport blocks to read data from the outside temperature and thermostat set temperature into your model.
- 2 Add Outport blocks to connect the outside temperature and room temperature to a larger model or to visualize results.

## Specify Physical Units

By specifying physical units for model signals, you ensure the consistency of calculations across model components. In Simulink, you specify signal units through Inport and Outport blocks.

- 1 Double-click the In1 block to open the Block Parameters dialog box. Select the **Signal Attributes** tab.
- 2 In the **Unit** box, start typing degree. From the list of symbols and names, select °C degree\_Celsius.

For the remaining temperature Inport and Outport blocks, set the **Unit** parameter to °C degree\_Celsius.

- 3 Display units on block ports. On the **Debug** tab, select **Information Overlays > Units**.
- 4 Double-click the Heater Subsystem block. Double-click the Heat Gain Output block to open the Block Parameters dialog box. Select the **Signal Attributes** tab.

- 5 In the **Unit** box, start typing joule/hour. From the list of symbols and names, select joule/h joule/hour.
- 6 Update the model. Press **Ctrl+D**.

Your next step is to verify the correctness of the model by comparing simulations with real system data.

## Prepare for Simulation

After initial simulations, you can use the results to improve the model to match model behavior to measured data. After you prepare the model for simulation, you can use an interface to input measured system data and set room temperature.

To load the finished example model, in the MATLAB Command Window, enter

```
copyfile(fullfile(matlabroot,...
'help', 'toolbox', 'simulink', 'examples', 'ex_househeat_measured_data.mat'))
open_system(fullfile(matlabroot,...
'help', 'toolbox', 'simulink', 'examples', 'ex_househeat_simulation_prepared'))
```

Verify that a simulation represents the behavior of the system you modeled. Begin by experimentally measuring physical characteristics of the system that have comparable signals in your model:

- Collect data from physical system
- Prepare model for simulation

### Collect and Plot System Data

Measure the dynamic characteristics from an actual house heating system. You will use the measured data with model simulations to verify the behavior and accuracy of your model.

- 1 Measure the outside and inside temperatures of a house every 6 minutes for 24 hours.
- 2 Enter the measured data into a Microsoft Excel worksheet or open an example spreadsheet. In the MATLAB Command Window, enter

```
winopen(fullfile(matlabroot,...
'help', 'toolbox', 'simulink', 'examples', 'ex_househeat_measured_data.xls'))
```

	A	B	C
	Time (hours)	Inside Temperature	Outside Temperature
1			
2	0.00	25.20	6.60
3	0.10	21.00	6.50
4	0.20	20.00	6.60
5	0.30	19.70	6.60
6	0.40	24.60	6.60
7	0.50	25.30	6.40
8	0.60	21.30	6.60
9	0.70	19.80	7.00
10	0.80	22.80	6.70

- 3 Review a plot of the measured data. The inside temperature data shows temperature spikes when the hot air heater turns on. This pattern is typical for a hot air heating system.

### Prepare Model for Simulation

Prepare a model for simulation by adding an external interface for data input and input control signals.

- 1 Use the model you created in the tutorial Model House Heating System or open the example model. In the MATLAB Command Window, enter

```
open_system(fullfile(matlabroot,...
'help', 'toolbox', 'simulink', 'examples', 'ex_househeat_modeling'))
```

- 2 Replace the Inport block In2 with a Constant block and set the **Constant** parameter to 20. The Constant block sets the thermostat temperature.
- 3 Add an Inport block. Set **Port number** to 1. This action also sets the **Port number** of the outside temperature signal to 2.
- 4 Rename the first Inport block to Inside Temperature. Rename the second Inport block to Outside Temperature.
- 5 Add an Outport block and connect it to the first Inport block (Inside Temperature). The Outport blocks are needed for saving (logging) the signals. Set **Port number** to 1.

## Run and Evaluate Simulation

Verify the accuracy of the model and optimize parameters. Some parameters to consider for optimization are heater hysteresis, temperature offset, and the resistance of the house to heat loss. Follow these steps to verify your model:

- Import data
- Run simulation

- Evaluate simulation result
- Change model parameters
- Rerun simulation

### Import Data with Root Inport Mapping

You can use the Root Inport Mapper tool to bring measured signal data from an Excel spreadsheet into a Simulink model.

- 1 Open any Inport block. Click the **Connect Inputs** button to open the Root Inport Mapper.
- 2 On the toolstrip, click **From Spreadsheet**.
- 3 In the From Spreadsheet dialog box, click the browse button. Browse to and select the file `matlabroot\help\toolbox\simulink\examples\ex_househeat_measured_data.xls`. Click **Open**. Click **OK** to import the spreadsheet.
- 4 On the left side, select Sheet1. The **Scenario Signal** column shows the two signals from the Excel spreadsheet and an icon  indicating the signals are unmapped.

Source	Scenario Dataset	Map Mo...	Status
	Sheet1		

**SIMULATION READINESS**

Total Scenario Datasets: 1  1: Not Mapped  0: Will Simulate  
Applied to Model:

**SCENARIO DETAILS**

Source:  Sheet1 - ex\_househeat\_measured\_data.xls

Status	Scenario Signal	Port
	Inside Temperature (degree Celsius)	
	Outside Temperature (degree Celsius)	

- 5 On the toolstrip, select the **Map Mode Port Order** option. From the **Options** drop-down list, select the **Update Model Automatically** check box.
- 6 From the **Check Map Readiness** dropdown list, select **Map Unconnected**. The mapping summary shows the signals from the Excel spreadsheet mapped to the Input port blocks.

Source	Scenario D...	Map Mo...	Status
	Sheet1	Port Order	

**SIMULATION READINESS**

Total Scenario Datasets: 1  0: Not Mapped  0: Will Simulate  0: Might Simulate  0: Will Not Simulate  
Applied to Model:  Sheet1

**SCENARIO DETAILS**

Source:  Sheet1 - ex\_househeat\_measured\_data.xls  
Use Strong Data Typing with Spreadsheets: Off  
Mode: Port Order

Status	Scenario Signal	Port	Block Name	Mapped Sig...
	Inside Temperature (degree Celsius)	1	In1	Sheet1.getElem...
	Outside Temperature (degree Celsius)	2	In2	Sheet1.getElem...

The mapping summary shows Sheet1 is marked for simulation and a Dataset object is created in the MATLAB Workspace.

- 7 Save the signal data in a MAT-file. In the MATLAB Command Window, type  

```
save('ex_househeat_measured_data.mat', 'Sheet1')
```

### Configure Model to Load Signal Data

Signal data mapped to input ports is located in a MATLAB workspace variable. With each new MATLAB session, you have to manually reload the data or let the model preload function do it for you.

- 1 From the Simulink Editor, on the **Modeling** tab, select **Model Settings > Model Properties** to open the Model Properties dialog box.
- 2 Select the **Callbacks** tab.
- 3 In the **Model callbacks** section, select PreLoadFcn.
- 4 In the **Model pre-load function** box, enter  

```
load('ex_househeat_measured_data.mat')
```
- 5 Click **OK**.

### Configure Model to Save Simulation Results

Configure your model to save (log) signal data during a simulation. You can then view logged signals from a simulation using the Simulation Data Inspector.

- 1 In the model, on the **Modeling** tab, click **Model Settings**.
- 2 In the left pane, select **Data Import/Export**.
- 3 In the right pane, clear the **Time** and **Output** check boxes.
- 4 Select the **Signal logging** check box.
- 5 Select the **Record logged workspace data in Simulation Data Inspector** check box.
- 6 Click **OK**.

### Select Signals to Save

Identify signals to display in the Simulation Data Inspector, name the signals if they are unnamed, and set the logging parameters.

- 1 Right-click the Inside Temperature signal line and select **Properties**.
- 2 In the **Signal name** box, enter Measured Room Temperature. Select the **Log signal data** check box. A logging badge  appears above the signal line.
- 3 Name and select logging for these signals.

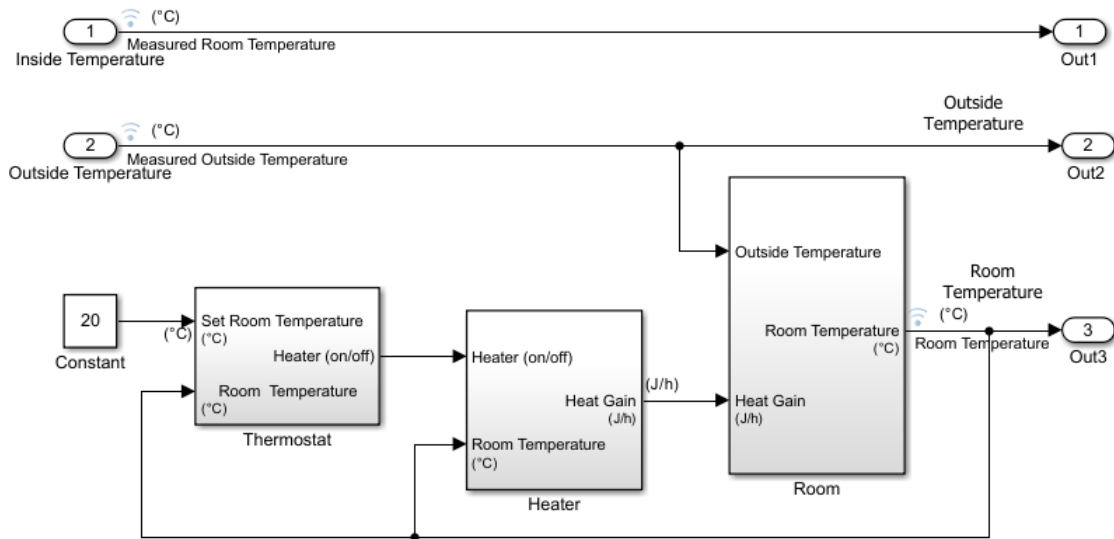

Location of signal	Signal name
Outside Temperature from output port 2.	Measured Outside Temperature
Room Temperature from Room subsystem output port	Room Temperature

### Run Simulation

After importing data and enabling logging of data for the signals, you can run a simulation.

- 1 Use the model you prepared for simulation or open the example model. In the MATLAB Command Window, enter

```
open_system(fullfile(matlabroot,...
'help', 'toolbox', 'simulink', 'examples', 'ex_househeat_simulation_prepared'))
```

- 2 On the Simulink Toolstrip, set **Stop Time** to 24 (hours).
- 3 Click the **Run** button .

The model simulation runs from 0.0 to 24.0 hours using the outside temperature data from the root import block as input.

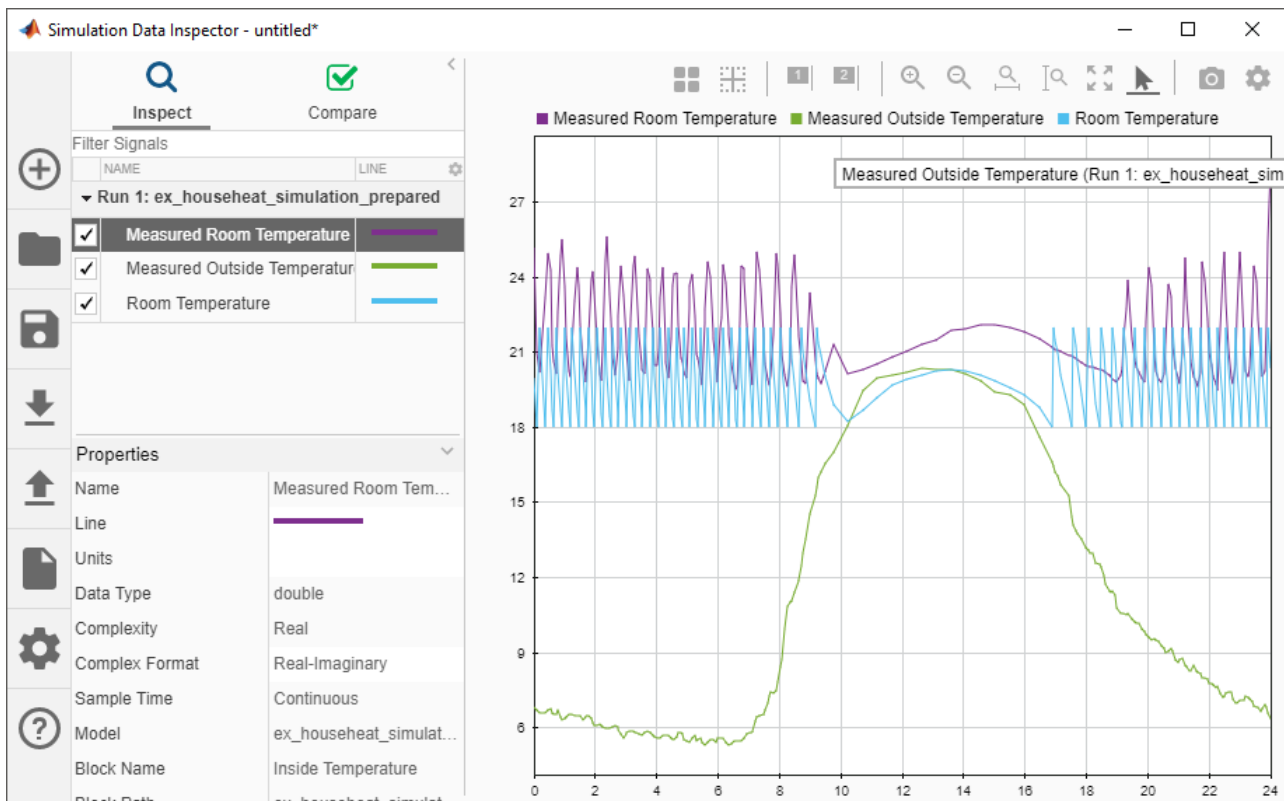

### Compare Simulation Results with Measured System Data

Use the Simulation Data Inspector to compare the simulated output signals with measured data.

- 1 On the Simulink Toolstrip, click the **Simulation Data Inspector** button .

A separate run appears in the **Runs** pane each time you simulate the model.

- 2 Select all the signal check boxes. The graph show the plot of each signal you select.

The top signal is the Measured Room Temperature. The middle signal is the Measured Outside Temperature. The bottom signal is the simulated Room Temperature.

### Determine Changes to Model

One obvious change to the model is the hysteresis of the thermostat. The simulated room temperature oscillates 18–22 degrees around the temperature set point of 20 degrees. The measured room temperature oscillates 20–25 degrees with the same set point.

- 1 Open the Relay block in the Thermostat subsystem.
- 2 Change **Switch on point** from 2 to 0 because the difference between the room temperature and set point is 0.
- 3 Change **Switch off point** from -2 to -5. When the room temperature is 5 degrees above the set point, you want to turn off the heater. The set point is 5 degrees below the room temperature.

### Compare Results Between Simulations

Use the Simulation Data Inspector to compare differences between two simulations that use different model parameters. This comparison shows how changes improve the accuracy of your model.

- 1 Simulate the model.
- 2 Open the Simulation Data Inspector.
- 3 Expand the list of logged signals by selecting the arrow to the left of the run. For **Run1**, select the Measured Outside Temperature and Measured Room Temperature check boxes. For **Run2**, select the Room Temperature check box.

- Review the signals. The minimum and maximum values for the simulated room temperature now match the measured room temperature values.

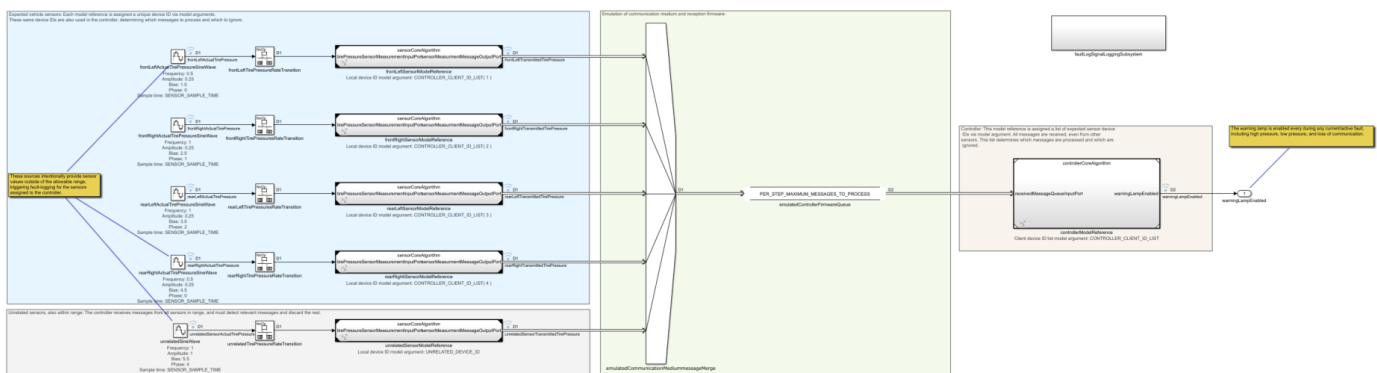

## Wireless Tire Pressure Monitoring System with Fault Logging

This example shows how to design, model, and simulate a distributed monitoring system. In this system, multiple sensors communicate wirelessly with a controller. The controller takes action when it detects a fault condition and maintains a log of fault conditions. The example uses a model of an automotive tire pressure monitoring system with identical pressure sensors at each wheel that communicate wirelessly with a controller in the vehicle using a unique device ID that is known to the controller. The controller checks the pressure readings against the acceptable range. If a pressure reading is out of range, or if the controller has lost communication with one of the sensors, the controller activates a warning lamp, and records the fault in a log.

Run this command to create and open a working copy of the project files for this example:

```
slexTirePressureMonitoringSystem
```

### Model Overview

The model contains four identical tire pressure sensors modeled by multi-instanced Model blocks that represent sensors on the four tires of a vehicle. The sensors periodically send messages to the controller. Each message consists of a tire pressure reading and the device ID of the sensor. All messages are routed to the controller via a Message Merge block and are buffered by a Queue block.

Messages in Simulink® combine events with related data. Messages are used to model communication between components in a distributed system, such as the communication between the sensors and the controller in this system. See “Simulink Messages Overview” on page 11-2.

The controller may also receive communications from sensors on other vehicles nearby. The controller has the list of the device IDs of the relevant sensors so that it can determine which communications to examine and which ones to reject.

To model the external environment in which the system operates, the model contains a fifth instance of the sensor model, representing a tire pressure sensor on a nearby vehicle, and which transmits messages that are received by the controller.

## Controller Unit

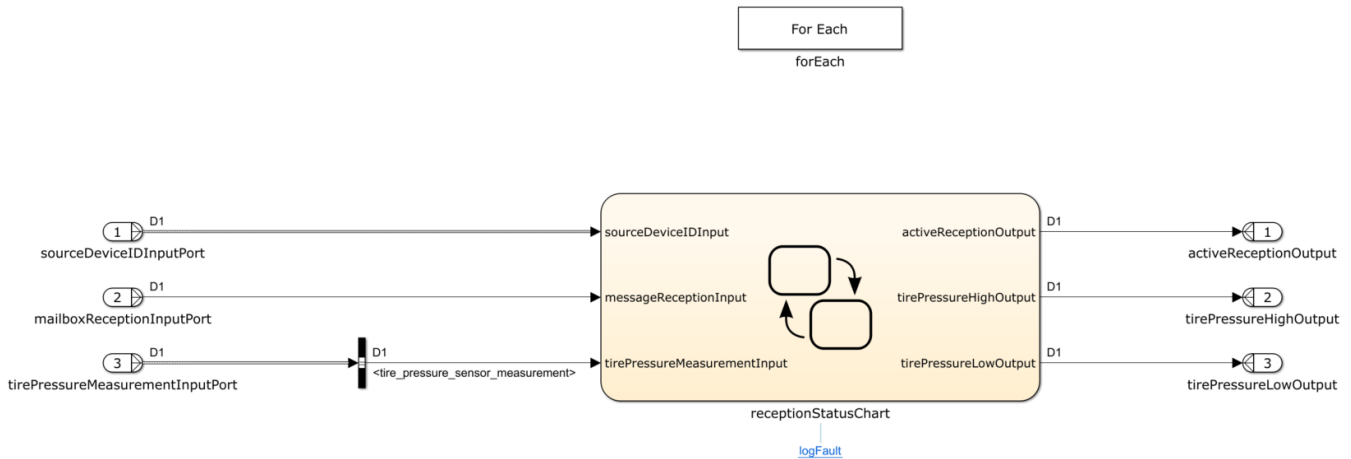

The controller receives discrete communications from each of the sensors as they are sent via wireless communication, middleware, or a combination of both. Each communication consists of a tire pressure reading from the physical hardware together with the unique device ID of the sensor unit. The combination of pressure data and device ID form a composite signal of different data types (double and character vector). This type of signal is reused throughout the model. Thus, defining a `Simulink.Bus` type for this combination makes sense. The communications may or may not be received periodically, so they are treated as asynchronous. The asynchronous communications are modeled as messages in Simulink, with the bus as the message payload.

The controller may also receive communications from sensors on other vehicles nearby. These communications are also modeled as messages with the same bus type. The controller model `controllerCoreAlgorithm.slx` receives as a model argument the list of the device IDs of the relevant sensors so that it can determine which communications to examine and which ones to reject.

Incoming communications from sensors are received and buffered in a Stateflow® chart and then passed to a MATLAB Function block. The MATLAB Function block checks each the device ID in each message against the valid device ID list, rejects messages with no match, and outputs these vectors at each time step:

- A four-element logical vector indicating whether a current sensor reading was received from each tire
- A four-element data vector containing the sensor readings

These vectors are passed to a for-each subsystem, which applies the same algorithm to each sensor. Both of these inputs to the for-each subsystem are partitioned, along with the valid device ID list.

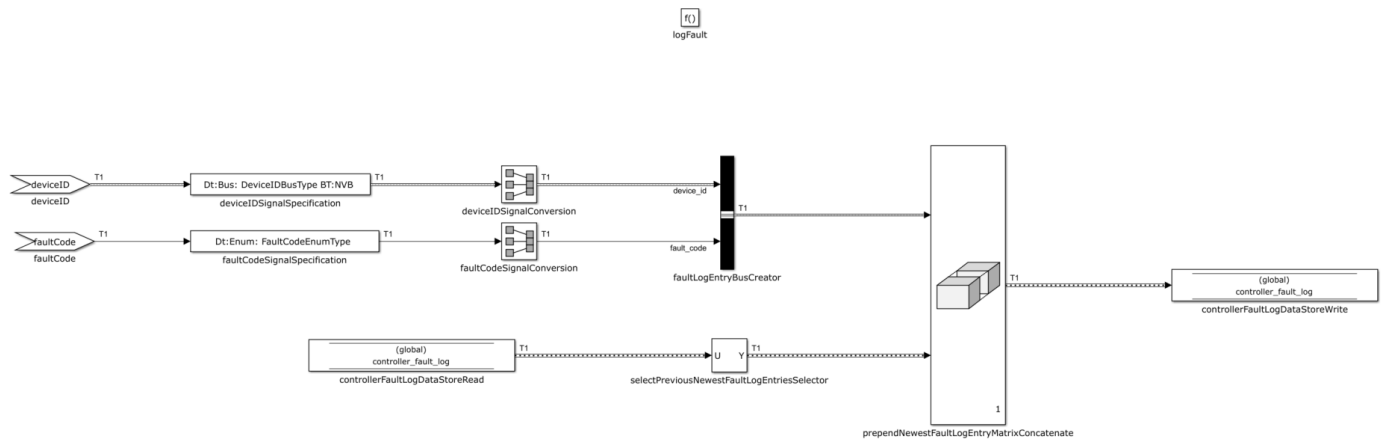

The controller model arguments include:

- The acceptable range for the tire pressure data measured by the sensors
- How frequently the sensors are expected to transmit data in order not to be considered to have timed out.

Within the for-each subsystem, a Stateflow chart is used to model the temporal logic of checking for timeouts as well as to check whether the pressure reading is within the valid range.

When the controller detects a fault, the fault is recorded in a fault log, which is modeled by a Data Store Memory block, representing an area of RAM in the controller. Each log entry consists of the device ID and the type of fault: pressure too high, pressure too low, lost contact with sensor. The type of fault is an enumerated data type defined for this purpose. The combination of device ID and type of fault used in the fault log entries form a composite signal type, is defined using a `Simulink.bus` type with these two fields. The Simulink function `logFault` performs the fault logging by prepending the new fault information to the fault log. The Stateflow chart calls this function each time it detects a fault.

The Stateflow chart `receptionStatusChart` outputs a logical signal for each of the possible fault conditions, and the for-each subsystem concatenates these output signals into logical vectors. These signals are combined with logical operators into a single, scalar, logical output for the controller that

indicates the presence or absence of a fault condition. This signal can be used to trigger a warning lamp or audible alarm when there is a fault condition.

The list of acceptable sensor device IDs is an instance parameter of the controller model, as are the minimum and maximum acceptable values for tire pressure and the timeout interval. The controller algorithm can be deployed in different applications with different values of these parameters.

## Sensor Units

Each sensor measures data from the physical environment, that is, tire pressure. In the sensor model, this input is modeled with a root Inport block. The pressure measurement is combined with the unique device ID into a bus signal using the `Simulink.bus` type defined for this purpose. The bus signal is the payload of the message output of the sensor, which is created by a Message Send block and sent to the root Outport. The sensors are designed to transmit readings periodically. However, the communications are treated as asynchronous to account for uncertainty in transmission and reception. Each message represents a discrete, asynchronous transmission sent through wireless communication, middleware, or a combination of both.

The unique device ID is an instance parameter of the sensor model, which is multi-instantiated to represent the multiple tires of the vehicle. The sensor models are identical apart from this instance parameter.

## System Model

In the system model, the controller unit is represented by a referenced model, and the sensor units are represented by a multi-instantiated referenced model. The communication between the sensors and the controller is modeled with messages in Simulink. The messages are combined with a Message Merge block into a single channel and buffered by a Queue block that represents a queue in the reception firmware.

The inputs to the system are the sensor readings from the physical environment, which are fed into the input ports of the sensor models. Source blocks can be used to model sensor readings. Here, varying inputs are modeled using Sine Wave blocks, with a sample time based on the frequency of pressure measurements. The output of the system is the control signal, which indicates the presence or absence of a fault condition.

In addition to the control signal at the outport, the system maintains a log of recorded fault conditions. The log is internal to the system, but it represents in effect part of the system output that can be examined and tested.

An additional sensor model represents a sensor on a nearby vehicle. The transmissions of this sensor model can be received by the controller, though the device ID of this sensor is not on the list of valid device IDs used by the controller. This model is also driven by a Sine Wave block. The message

outputs of this sensor unit are merged with the messages from the vehicle sensors and sent to the controller unit.

Data types such as `Simulink.bus` types and enumerated types that are used by the models are stored in a shared data dictionary `commonData.sldd`, which allows all models to have access to the definitions. See “What Is a Data Dictionary?” on page 79-2.

### Simulating the Model

The Sine Wave blocks used as inputs are configured so that some inputs are outside the acceptable tire pressure range, which triggers a fault condition. After simulating the model, you can observe the results in the Simulation Data Inspector.

The bottom plot shows when the control signal that activates the warning lamp is enabled. The warning lamp is activated when the rear right tire pressure is in excess of the maximum acceptable value of 4.5 and when the front left tire pressure is less than the minimum acceptable value of 1.25, but the unrelated sensor does not trigger the warning lamp.

## Prepare Sensor and Controller Models in a Distributed Monitoring System for Code Generation

This example shows how to take a Simulink® model containing a reusable algorithm and prepare that model to generate code that is deployable on a target hardware platform where the algorithm is implemented in a component as part of a system. The algorithms are contained in the controller and sensor models from the tire pressure monitoring system described in “Wireless Tire Pressure Monitoring System with Fault Logging” on page 10-234. The algorithms themselves do not depend on the hardware platform, but the inputs and outputs at the component interfaces are platform-dependent. The example shows how to integrate custom code to handle these aspects of the operation of the components:

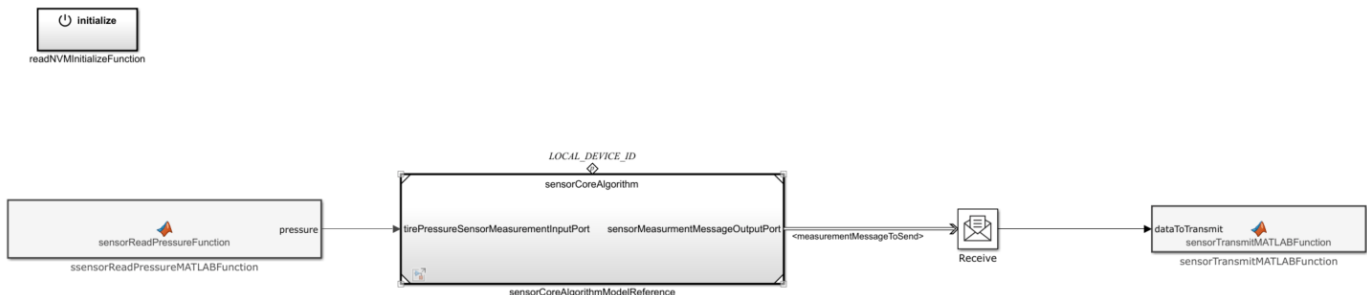

- Receiving data from the physical environment
- Communication between components
- Sending signals to other systems
- Interacting with non-volatile memory (NVM)

NVM is used to store the unique device IDs of the sensors in the system and to maintain the fault log between power cycles. By using NVM, the same code can be burnt into the CPU on multiple devices during manufacturing, and the unique IDs can be subsequently flashed into NVM.

Run this command to create and open a working copy of the project files for this example:

```
slexTirePressureMonitoringSystem
```

### Sensor Wrapper Model

To generate code for the sensor units, the sensor model `sensorCoreAlgorithm` is placed inside a wrapper model that is used as the top-level model for code generation. The local device ID parameter of the sensor model is a dummy value. The wrapper model contains an Initialize Function block that reads the local device ID for the sensor from NVM on power-up and writes it to the sensor model local device ID parameter using a Parameter Writer block. Reading from NVM is performed by a MATLAB Function block, which calls custom code for this purpose.

Similarly, MATLAB Function blocks that call custom code are used to retrieve tire pressure measurement data from the sensor and to send the data to the controller. The measurement data are fed as input to the sensor model. A Message Receive block receives the messages that are output from the sensor model and extracts the payload, which is passed to a MATLAB Function block for transmission to the controller via wireless communication, middleware, or a combination of both.

The file `SensorTargetSpecificCodeExternalDependency.m` defines the MATLAB class `SensorTargetSpecificCodeExternalDependency` as a subclass of the `coder.ExternalDependency` (MATLAB Coder) class. The `coder.ExternalDependency` class is a base class that is useful for interfacing with external C/C++ code from MATLAB code. See “Develop Interface for External C/C++ Code” (MATLAB Coder). The `classdef` defines public methods to read from NVM, read pressure data, and transmit data. The MATLAB Function blocks in the sensor wrapper model call these methods to perform these functions. These methods in turn call custom C code functions using `coder.ceval` (MATLAB Coder). These custom code functions are defined in `sensor_hand_code_header.h` and `sensor_hand_code_source.c`. For the purpose of this example, these files contain stub functions, which allow the model to compile and to generate code that implements the desired algorithm using generic driver calls. To generate and deploy code on a particular hardware target, replace the stubs with the corresponding target-specific code.

### Controller Wrapper Model

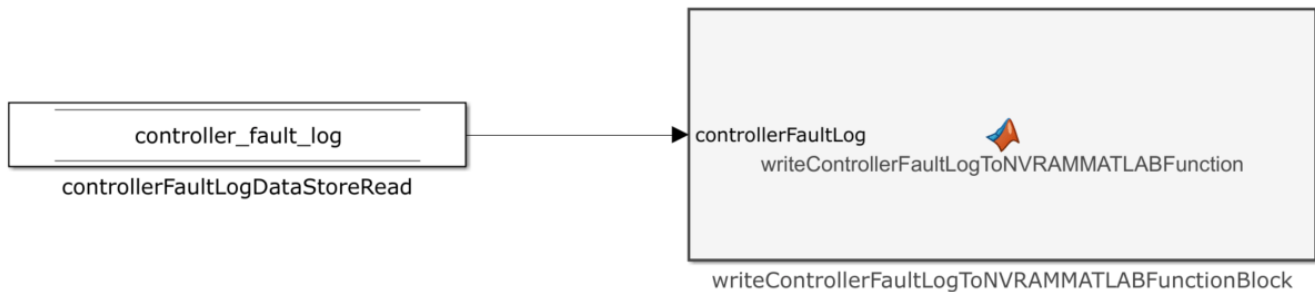

To generate code for the controller units, the controller model `controllerCoreAlgorithm` is placed inside a wrapper model that is used as the top-level model for code generation. The sensor device ID list parameter of the controller model is a dummy value. The wrapper model contains an Initialize Function block that reads the sensor device ID list for the system from NVM on power-up and writes it to the sensor device ID list parameter using a Parameter Writer block. The Initialize Function block also reads the previously saved contents of the fault log from NVM and loads them into RAM by using a Data Store Write block to write them to the data store that is used for the fault log while the system is operating.

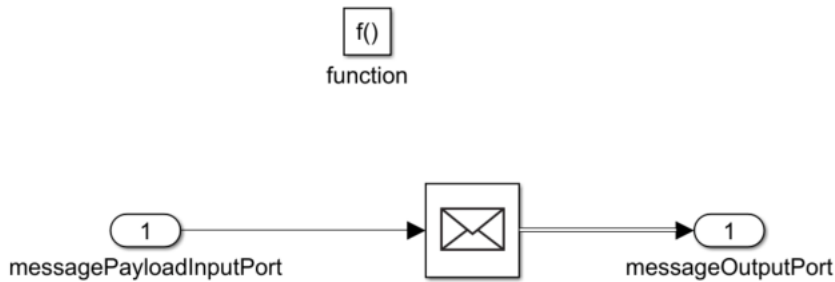

The wrapper model contains a Terminate Function block that executes on power-down. The Terminate Function block reads the updated contents of the fault log using a Data Store Read block and writes these contents to NVM. In this way, the fault log contents are maintained between power cycles.

Reading from and writing to NVM are performed by MATLAB Function blocks, which call custom code for this purpose. Interacting with NVM only on startup and shutdown and using RAM for memory needs during operation minimizes wear and tear on NVM.

The controller wrapper model contains a MATLAB Function block that calls custom code to receive message communications from the sensors. At one output, the block outputs a function call signal each time a message is received and outputs the message payload at the other output. These outputs are used to drive a function-call subsystem, which uses a Message Send block to send a message containing the payload each time it receives a function-call signal.

This message is sent to the controller model message input port through a Queue block that represents a LIFO, overwriting-type queue. The function-call subsystem and the Queue block implement an internal queue in the code that is generated for deployment to the controller hardware.

The logical output signal of the controller block is fed into a MATLAB Function block in order to enable a warning lamp and again calls custom code for this purpose.

The file `ControllerTargetSpecificCodeExternalDependency.m` defines the MATLAB class `ControllerTargetSpecificCodeExternalDependency` as a subclass of the `coder.ExternalDependency` class. The `classdef` defines public methods to read from and write to NVM, receive message communications, and enable a warning lamp. The MATLAB Function blocks in the controller wrapper model call these methods to perform these functions. These methods in turn call custom C code functions using `coder.ceval`. These custom code functions are defined in `controller_hand_code_header.h` and `controller_hand_code_source.c`. For the purpose of this example, these files contain stub functions, which allow the model to compile and to generate code that implements the desired algorithm using generic driver calls. To generate and deploy code on a particular hardware target, replace the stubs with the corresponding target-specific code.

## Simulink Messages Overview

Message-based communication is necessary in various applications, such as control system architectures in which centralized architectures are replaced with distributed architectures due to the complexity of the systems. In a distributed architecture, multiple components of the system communicate via a shared network.

A distributed architecture has these three elements:

- **Component** — Represents partitions of a design that performs a set of functionalities or algorithms with defined I/O interfaces. Generally, components generate events and data asynchronously.
- **Interface** — Provides a shared boundary through which components of the system communicate. To provide asynchronous communication, messages are useful modeling artifacts that combine events with related data.
- **Middleware** — Provides the services needed by the components to support asynchronous communication across the shared network.

Below is an illustration that shows the composition of a distributed architecture and its elements.

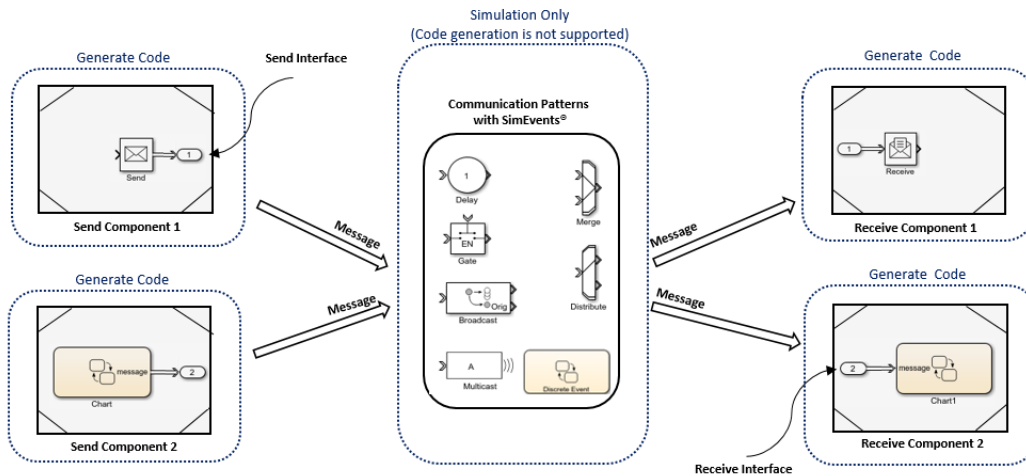

**Composition of a Distributed Architecture**

When modeling such an architecture, you typically model components that are clearly identifiable, reusable, and deployable. To achieve asynchronous event-based communication between components, use message send and receive interfaces. Model the middleware to facilitate the network topology that represents the connectivity of components, such as one-to-many, many-to-one, or many-to-many based on the number of message sending and receiving components. For an example, see “Build a Shared Communication Channel with Multiple Senders and Receivers” on page 11-31.

To learn how to model a distributed architecture, using Simulink, SimEvents, and Stateflow, see the illustration below. The illustration includes two message sending and two message receiving components that are created as referenced models. Model components with send and receive interfaces using Simulink Send and Receive blocks. If your send and receive interfaces involve states or require decision logic, use a Stateflow chart.

### Modeling Composition of a Distributed Architecture

After you model your components and interfaces:

- Simulate the behavior of your distributed architecture by modeling the middleware using SimEvents. Using the blocks from the SimEvents library, you can model custom routing and communication patterns, such as merging, delaying, distributing, and broadcasting messages, and investigate the effects of middleware on your communication network.
- Generate code for your components, including the interface, and connect to your middleware or an operating system communication API.

## Model Message Send and Receive Interfaces and Generate Code

Let us start by understanding how message blocks work. To create a model that uses messages, use Send blocks to convert data and send messages and Receive blocks to receive and convert messages to data. For a simple example that shows how Send and Receive blocks work, see “Animate and Understand Sending and Receiving Messages” on page 11-5.

Use Send and Receive blocks to model message send and receive interfaces for your components. For a simple example that shows the basics of creating send and receive interfaces, see “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22. To learn how to generate code for the same model, see “Generate C++ Messages to Communicate Data Between Simulink Components” (Embedded Coder).

You can further modify send and receive interfaces for custom behavior. For example, you can synchronize when a receive interface executes to when data is available. For more information, see “Model a Message Receive Interface that Runs on Message Availability” on page 11-26.

After modeling, generate code for your send and receive interfaces and connect them to the middleware or an operating system communication API. For an example that generates code for a top model and allows your application to communicate in a distributed system that uses an external message protocol service (for example, DDS, ROS, SOMEIP, or POSIX messages), see “Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware” (Embedded Coder).

## Simulate Middleware Effects on a Distributed Architecture

Use Queue blocks to store, sort and queue messages. The Queue block allows you to specify message storage capacity and the overwriting and sorting policies for message transitions. For a simple example that shows how a Queue block works, see “Use a Queue Block to Manage Messages” on page 11-12.

You can also use SimEvents to model and simulate middleware effects on your communication network. Use the blocks provided by the SimEvents library to model message routing, peer-to-peer communication, wireless communication, packet loss, and channel delays. For more information about SimEvents, see “Discrete-Event Simulation in Simulink Models” (SimEvents).

For basic communication patterns that can be modeled by SimEvents, see “Modeling Message Communication Patterns with SimEvents” on page 11-29. You can use combinations of these patterns to create more complex communication behavior. For an example of a system with multiple message sending and receiving components and an ideal shared channel with delay, see “Build a Shared Communication Channel with Multiple Senders and Receivers” on page 11-31. To see a model with shared wireless channel with channel failure and packet loss, see “Model Wireless Message Communication with Packet Loss and Channel Failure” on page 11-37.

To see an example that shows how to model more complex network behavior, such as an Ethernet communication network with CSMA/CD protocol, see “Model an Ethernet Communication Network with CSMA/CD Protocol” on page 11-47.

---

**Note** SimEvents blocks do not support code generation.

## Animate and Understand Sending and Receiving Messages

This example shows how to send, receive, and visualize messages. The example also shows how to use Simulation Data Inspector, Sequence Viewer, Animation, and Storage Inspector to understand how messages flow in your model.

Copyright 2019 The MathWorks, Inc.

### Model Description

The SimpleMessagesModel contains these blocks:

- Sine Wave — The signal source. The **Sample time** parameter of the block is set to 0.1.
- Send — Converts data signals and send messages. The specified value for the **Sample time** parameter of the Sine Wave block determines the rate at which the Send block sends messages. Therefore, the Send block sends one message every 0.1 simulation time.
- Queue — Stores messages. Observe the message line between the Send block and the Queue block. The default capacity of the queue is 16, which means the Queue block can store at most 16 messages. The default message sorting behavior is LIFO, which means incoming messages are sorted based on last-in-first-out policy. By default, the **Overwrite the oldest element if queue is full** check box is selected. When the queue is full, an incoming message overwrites the oldest message in the queue. For more information about using the Queue block, see “Use a Queue Block to Manage Messages” on page 11-12.
- Receive — Receives messages and converts them to signal data. In the block, **Sample time** parameter is set to 0.1. The Receive block receives a message every 0.1 simulation time.
- Scope — Visualizes messages received by the Receive block.

### Simulate the Model and Review Results

In the model, data logging is enabled for the signal and message lines among Sine Wave, Send, Queue, Receive, and Scope blocks.

Simulate the SimpleMessagesModel and observe from the Simulation Data Inspector that:

- The Sine Wave block generates the sine wave signal (green).
- Every 0.1 simulation time, Send block converts the value of the signal to a message and sends it to the Queue block. Simulation Data inspector displays messages as stem plots. Observe the Simulation Data Inspector displaying sent messages (purple).

- The Queue block sends messages to the Receive block (blue).
- Receive block output is the reconstructed sine wave signal (orange).

### Use Sequence Viewer to Visualize Messages

You can use the Sequence Viewer tool or the Sequence Viewer block to visualize messages, events, and Simulink function calls. The Sequence Viewer displays message transition events and the data that the messages carry. In the Sequence Viewer window, you can view event data related to Stateflow chart execution and the exchange of messages between Stateflow charts.

To use the Sequence Viewer tool:

- To activate logging events, in the Simulink Toolstrip, on the **Simulation** tab, in the **Prepare** section, click **Log Events**.

- Simulate your model. To open the Sequence Viewer tool, on the **Simulation** tab, in the **Review Results** section, click **Sequence Viewer**.

The **Log events** and **Sequence Viewer** buttons are visible when your model has blocks from the Simulink® Messages & Events library, a Stateflow chart, Function-Call Subsystem, Simulink Function, or SimEvents® blocks.

The Sequence Viewer window shows messages as they are created, sent, forwarded, received, and destroyed at different times during model execution. The Sequence Viewer window also displays state activity, transitions, and function calls to Stateflow graphical functions, Simulink functions, and MATLAB functions.

You can also add the Sequence Viewer block to your model for visualizing message transitions. For more information, see “Use a Queue Block to Manage Messages” on page 11-12.

## Use Animation and Storage Inspector

You can use **Animation** to animate the model and observe the message flow between model components. You can specify the speed of the animation as **Slow**, **Medium**, or **Fast**. The option **None** disables the model animation.

In the toolstrip, on the **Debug** tab, locate the **Event Animation** section.

From the **Event Animation** section, set the animation speed to **Slow**.

Simulate the model again. Observe the highlighted message lines representing message flow between the blocks.

Animation highlights message lines and Simulink function calls based on events rather than time passed. Within one simulation time, more than one message flow or Simulink function call event can be highlighted.

Pause the animation. In the Simulink Toolstrip, on the **Debug** tab, click **Pause**. Observe that the last highlighted message line is highlighted in violet.

The Storage Inspector allows you to visualize the details of the stored messages in Queue block. When you pause the simulation, the Storage Inspector magnifying glass icon appears on the Queue block. To open the Storage Inspector, click the magnifying glass.

The Storage Inspector does not show any stored messages because messages arriving at the Queue block are simultaneously received by the Receive block at the same simulation time.

To create a scenario with stored messages, stop the simulation and change the **Sample time** parameter of the Receive block to 0.5. Now the Send block sends one message every 0.1 simulation time, but the Receive block receives messages every 0.5 simulation time. This causes a backlog of messages that are stored in the Queue block.

Simulate the model again with animation speed set to *Slow*, and pause the simulation to check the status in the Storage Inspector. An entity in the Storage Inspector represents stored elements in the Queue block, in this case, messages. **Storage Inspector** lists the messages stored in the Queue block with their ID and data value carried by each message.

### Display Message Payload as Port Value Labels

To display message data as port value labels, right-click the message line emerging from a block and select **Show Value Label of Selected Port**.

In the example below, the port values are displayed for the message line connecting the Send block to the Queue block.

If a message carries data as a bus object, you can also select the elements to be displayed as the port values.

The `SimpleMessagesPortValueModel` is a variation of the `SimpleMessagesModel` where the input to the Send block comes from a Bus Creator block. In this example, a bus object `Data_message` is created with two elements, `sinewave` and `constant`.

To open this model, enter:

```
open_system('SimpleMessagesPortValueModel');
```

Right-click the message line emerging from the Send block, click `Show Value Label of Selected Port`, and select `constant`.

Only the values of the constant signal are displayed as port values.

Copyright 2019 The MathWorks, Inc.

If the message transmission stops on a message line, the port value display keeps displaying the last message payload value.

## Use a Queue Block to Manage Messages

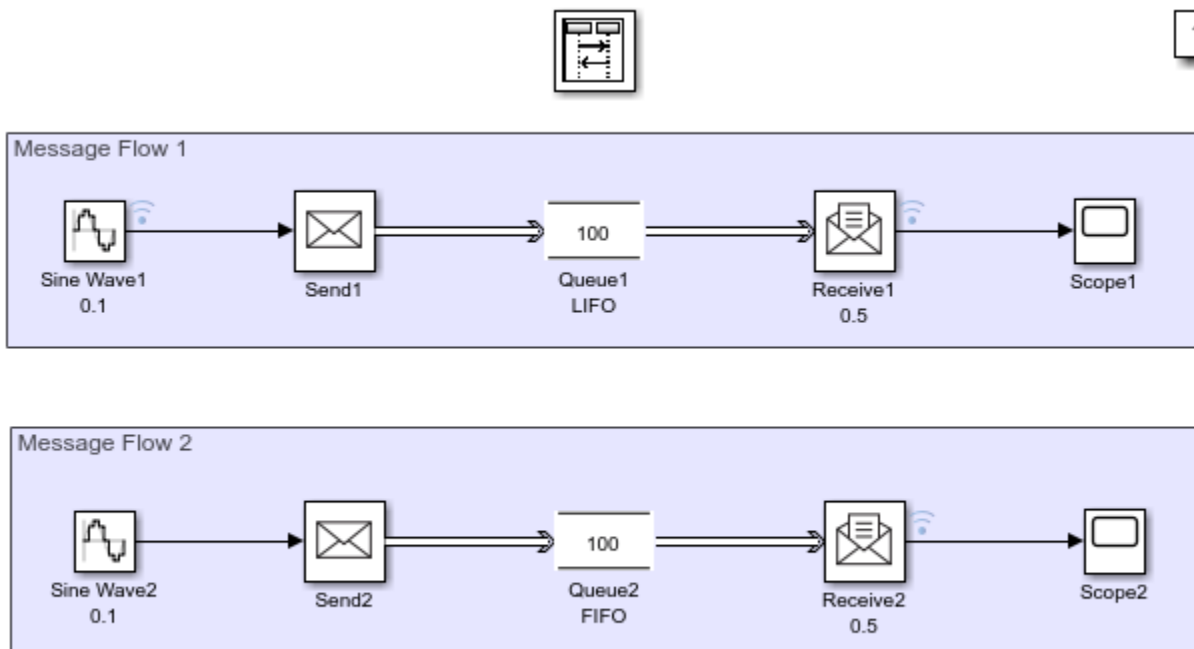

This example shows how to use a Queue block to store and queue messages. The Queue block allows you to specify message storage capacity, overwriting policy, and sorting policy during message transitions.

### Manipulate Message Transitions Using Queue Sorting Policies

The Queue block supports three message sorting policies:

- Last-in-first-out (LIFO) — The newest message in the storage departs first.
- First-in-first-out (FIFO) — The oldest message in the storage departs first.
- Priority — Messages are sorted based on their priority. The priority queue can be used only when the **Overwrite the oldest element if queue is full** check box is cleared.

This example uses a simple message-based communication model that is introduced in “Animate and Understand Sending and Receiving Messages” on page 11-5. The model includes Message Flow 1 and Message Flow 2 in which messages flow from Sine Wave1 to Scope1 and Sine Wave2 to Scope2.

Copyright 2019 The MathWorks, Inc.

### Model Description

In Message Flow 1 and Message Flow 2:

- The **Sample time** parameter of Sine Wave1 and Sine Wave2 are set to 0.1. They are identical sine wave sources.

- The **Sample time** parameter of Receive1 and Receive2 are set to 0.5. They are identical Receive blocks.
- The capacity of the Queue1 and Queue2 are 100. Both queues have the same capacity.
- The sorting policy of the Queue1 is LIFO and Queue2 is FIFO, which is displayed under the block labels. The only difference between two message flow scenarios is the queue sorting policy.
- The signals among Sine Wave1, Receive1, and Receive2 are logged.

### Simulate the Model and Review the Results

Simulate the model and observe the results in the Simulation Data Inspector.

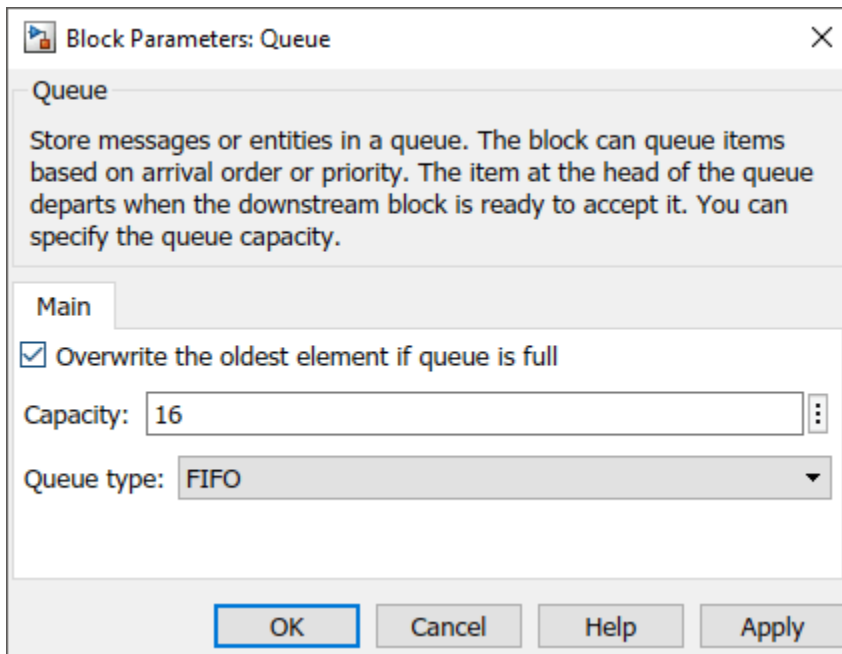

Observe the output from Sine Wave1. The output from SineWave2 is not displayed because it is identical to SineWave1. Also observe that the signal from Receive1 is the representation of the sine wave but with longer intervals between samples. However, the signal from Receive2 is the first part of the sine wave reaching to the positive peak because the sorting policy of the Queue block is set to FIFO and its capacity is large enough to store messages.

## Queue Block Message Overwriting Policies

You can also specify the Queue block message overwriting policy when the queue is full:

- By default, the **Overwrite the oldest element if queue is full** check box is selected. The block is set to always accept an incoming message, overwriting the oldest message in the storage. In this case, the block overwrites the oldest message, but the message departing the block is determined by the queue sorting policy.

In this example of queue behavior, messages are enumerated based on their arrival time at the FIFO and LIFO queues with capacity 8. A new message with number 9 arrives. In FIFO and LIFO cases, message 9 replaces message 1 because it is the oldest element in the queue. However, observe the change of head and tail of the queue during this process. In the FIFO queue, message 2 departs first because it is the oldest message after message 1 is replaced. In the LIFO queue, message 9 departs first because it is the last message that arrives at the storage. After the message departure, a new message 10 arrives. The queue accepts the new messages to its empty storage bin.

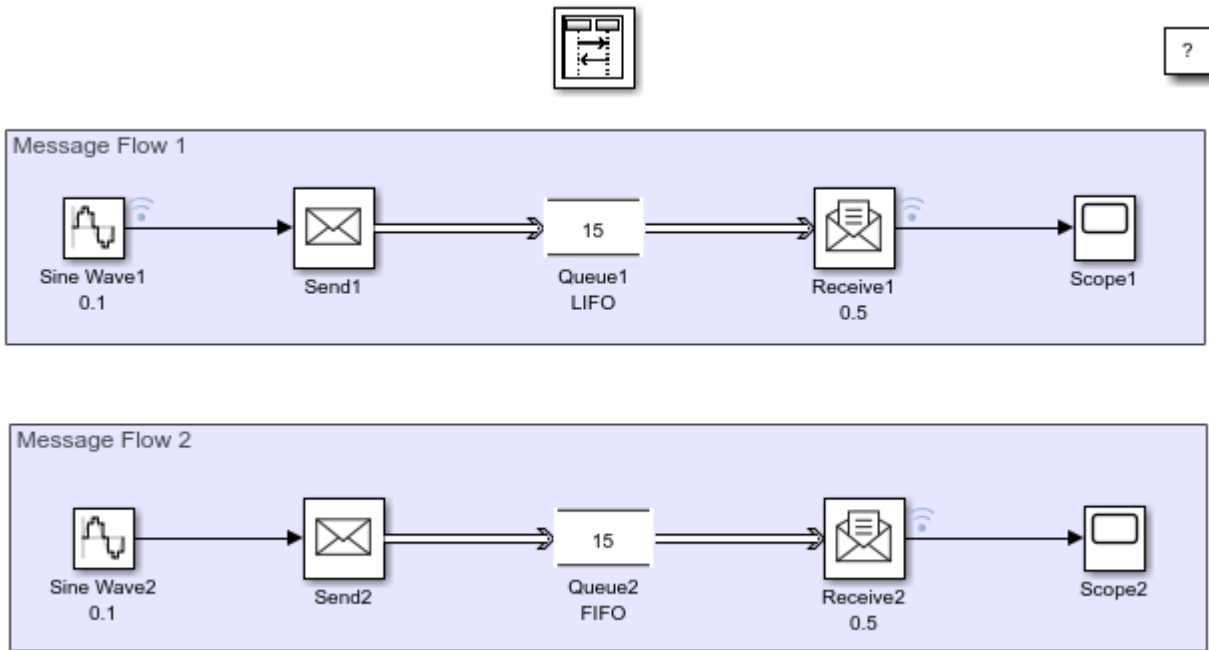

- If the **Overwrite the oldest element if queue is full** check box is cleared, the icon of the Queue block changes and the block does not accept new messages when the queue is full. This is a blocking queue behavior.

### Queue Block with Overwriting Policy Enabled

In the QueueSortingPoliciesModelSequenceViewer model, the capacities of the Queue blocks in Message Flow 1 and Message Flow 2 are changed to 15. Decreasing the capacity causes the incoming messages to overwrite the existing ones in the storage.

Copyright 2019 The MathWorks, Inc.

Simulate the model and open the Sequence Viewer block. In the Sequence Viewer block, scroll up or click the **Go to first event** icon on the left. Observe the messages departing the block based on FIFO and LIFO policies.

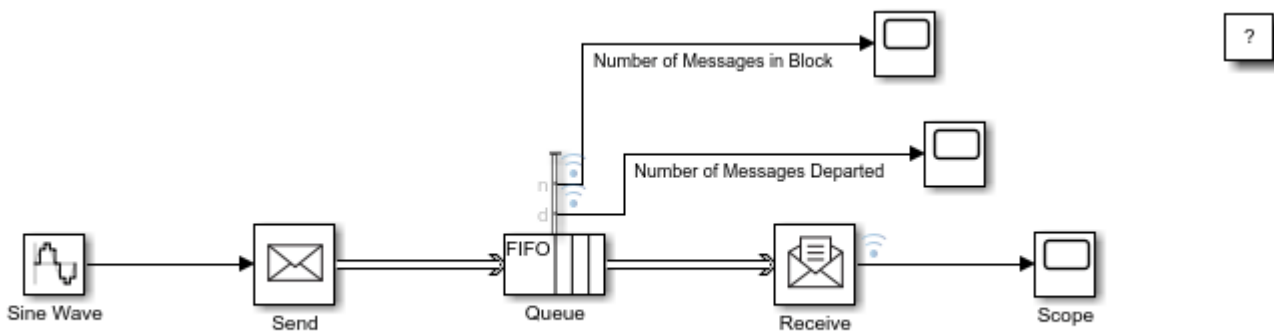

Both Queue blocks have limited capacity. When their capacity is full, a new incoming message overwrites the oldest existing message in the queue. Scroll down and observe that the Sequence Viewer block displays the messages that overwrite the existing ones.

**An Example of a Blocking Queue Behavior**

Open the QueueOverWritingPolicyModel to inspect the blocking queue behavior.

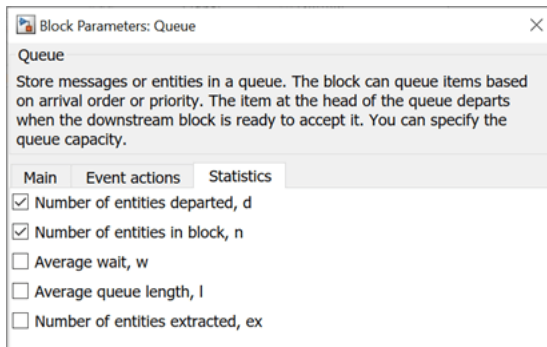

Copyright 2019 The MathWorks, Inc.

In the Receive block, set the **Sample time** parameter to 0.5.

Observe that in the Queue block:

- The **Overwrite the oldest element if queue is full** check box is cleared. Observe the block icon change.
- The **Capacity** parameter is set to 16.
- In the **Statistics** tab, the **Number of entities departed, d** and **Number of entities in block, n** check boxes are selected.

### Simulate the Model and Review Results

Simulate the model. Observe the warning displayed in the Diagnostic Viewer. Messages sent by the Send block were dropped during simulation.

```
Unable to send message from output port 1 of block 'QueueOverWritingPolicyModel/Send' because the output port is blocked. 65 messages were dropped during this simulation. To prevent messages from being dropped, increase the capacity of message storage connected to this output port.
```

Component: Simulink | Category: Block warning

The Queue block blocks the messages when the **Overwrite the oldest element if queue is full** check box is cleared. You can increase the capacity of the Queue block to prevent message dropping.

### Use Statistics to Analyze Queue Behavior

When the **Overwrite the oldest element if queue is full** check box is cleared the **Statistics** tab is enabled. Use **Statistics** tab to enable output ports and observe the Queue block statistics. Statistics are not supported for code generation.

Observe the signals labeled Number of Messages in Block and Number of Messages Departed. Up to simulation time 2, there are 16 messages in the storage, which is the queue capacity. After that, Number of Messages in Block takes values 15 and 16 because messages depart every 0.5 simulation time and a new message arrives.

At simulation time 10, a total of 21 messages departs the block.

### Use Event Actions

You can also use **Event actions**, when the **Overwrite the oldest element if queue is full** check box is cleared. Event actions are not supported for code generation. For more information, see “Events and Event Actions” (SimEvents).

Use **Event actions** to specify the behavior of the message in certain events. For instance, the **Entry** and the **Exit** actions are called just after the message entry and just before message exit. The **Blocked** action is called after a message is blocked.

For more information, see “Model a Message Receive Interface that Runs on Message Availability” on page 11-26.

You can also model more complex communication policies by using blocks from the SimEvents® library, which requires a SimEvents® license.

## Establish Message Send and Receive Interfaces Between Software Components

This example shows how to model message-based communication between software components that run in different applications. The example also shows how to prepare model components for C++ code generation.

In this example, the message-based communication is constructed between two components. Send component sends data and receive component consumes data. In this scenario, after send component sends messages, they are stored in a queue. Receive component pulls a message based on the logic it represents.

Copyright 2019 The MathWorks, Inc.

Two Model blocks, labeled Send Component and Receive Component, represent the components connected by a message line. Message-based communication is achieved using a Send block and a Receive block that are connected to the root-level Output and Input blocks.

For more information about generating C or C++ code for the model, see “Generate C++ Messages to Communicate Data Between Simulink Components” (Embedded Coder) and “Generate C Messages to Communicate Data Between Simulink Components” (Embedded Coder).

You can also generate C++ code for each component, and the code contains necessary software interfaces that are sufficient for you to connect with an operating system or message middleware. For more information, see “Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware” (Embedded Coder).

### Send Component

The algorithm in the Send Component can contain logic of any complexity. In the example, a simple Sine Wave block is used in a subsystem as the signal source. The **Sample time** parameter of the block is set to 0.1.

To prepare the Send Component for message-based communication, a Send block is connected to the root-level Outport block. The Send block converts data signals and send messages.

To prepare the Send Component for code generation, in the Model Configuration Parameters:

- 1 In the **Solver** pane, in the **Solver selection** section, the **Type** is set to Fixed-step.
- 2 The **Fixed-step size** is set to 0.1.
- 3 In the **Code Generation** pane, the **System target file** is set to `ert.tlc` and **Language** to C++.
- 4 The model is saved as `mSend`.

### Receive Component

In the Receive Component, a Scope block is used to represent the algorithm that receives messages.

To prepare the Receive Component, the Inport block is connected to a Receive block. The Receive block receives messages and converts them to signal data. By default, the **Sample time** parameter of the Receive block is -1.

To prepare the Receive Component for code generation, in the Model Configuration Parameters:

- 1 In the **Solver** pane, in the **Solver selection** section, the **Type** is set to Fixed-step.
- 2 The **Fixed-step size** is set to 0.1.
- 3 In the **Code Generation** pane, the **System target file** is set to `ert.tlc` and **Language** to C++.
- 4 The model is saved as `mReceive`.

### Visualize Message Transitions Between Components Using the Sequence Viewer Block

This is a composition model with Send and Receive components. The Model blocks, Send Component and Receive Component, refer to models `mSend` and `mReceive`, respectively.

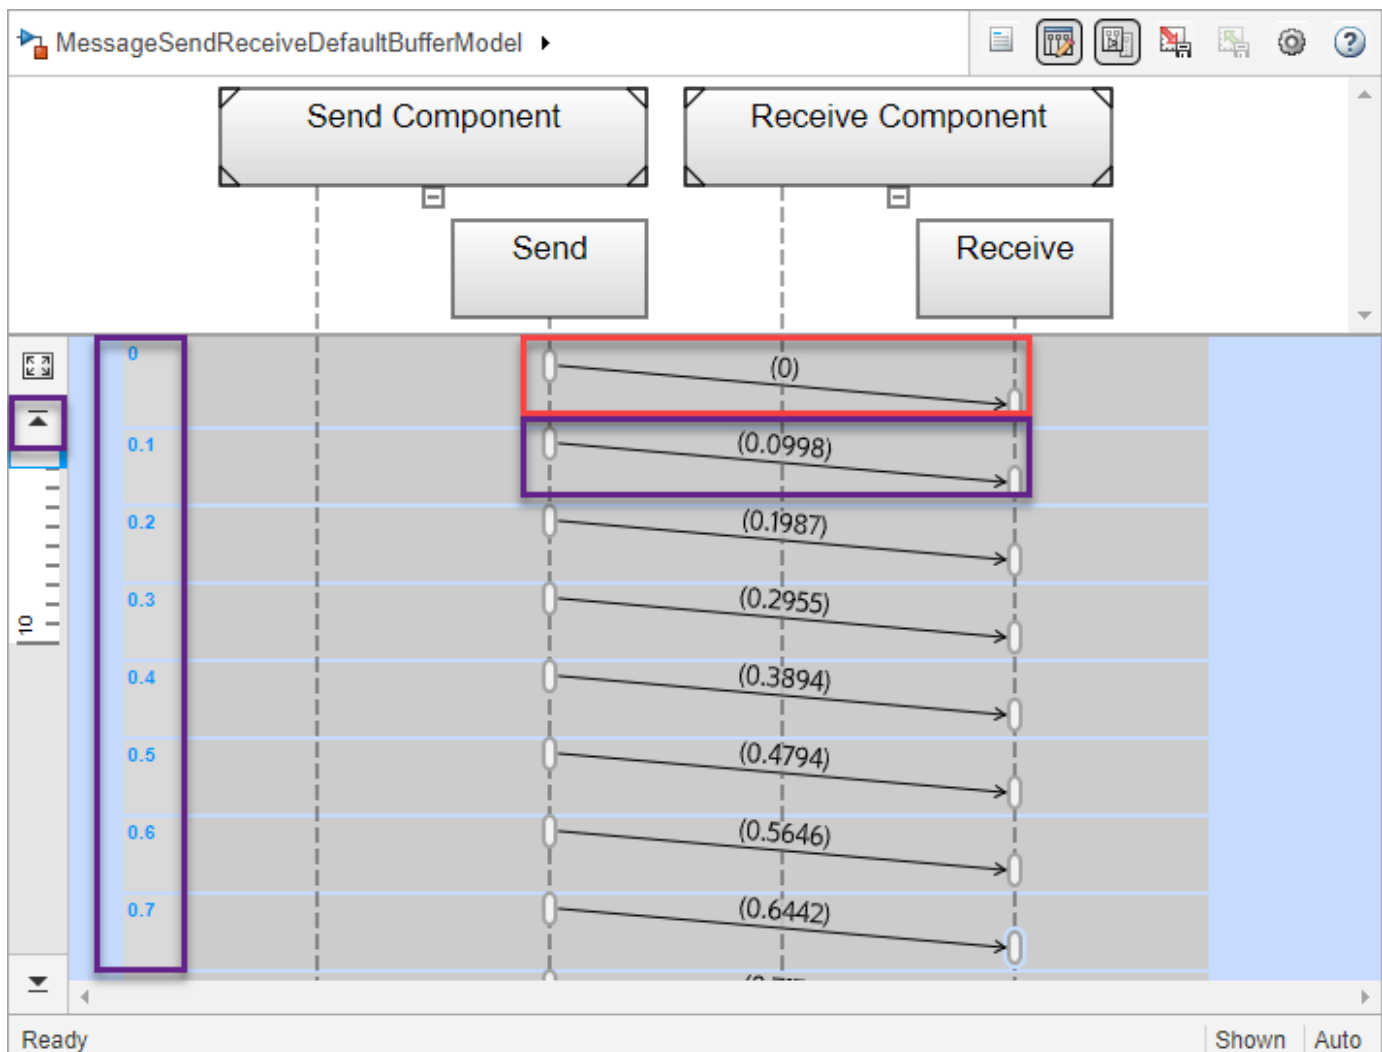

Simulate the model. Observe the queue inserted by default. An icon above the message line represents the default queue. The capacity of the default queue is 1 and the message overwriting policy is enabled. You can customize the queue by using a Queue block between components. For more information, see “Use a Queue Block to Manage Messages” on page 11-12.

Open the Sequence Viewer block. The block allows you to visualize message transition events and the data that the messages carry.

The Sequence Viewer block window shows the simulation time in the left vertical bar. Each time grid row contains events that occur at the same simulation time. Each message transition event is represented by an arrow that is labeled with the message data value. For more information about the Sequence Viewer block, see “Use the Sequence Viewer to Visualize Messages, Events, and Entities” on page 11-76.

In the Sequence Viewer block, scroll up or click **Go to first event** icon on the left. Observe that at time zero the Send block sends a message with data value 0 to the Receive block, and at time 0.1 the block sends another message with data value 0.0998. The block sends a message in every 0.1 simulation time.

## Model a Message Receive Interface that Runs on Message Availability

This example shows how to synchronize execution with data availability in message-based systems. We show how to model this behavior using events and actions. This example builds on another example, “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22, where two software components communicate using messages.

As with the previous example, the code generation process should apply to the SendComponent and the ReceiveComponent. The Message Storage models the middleware and data notification events provided by the middleware.

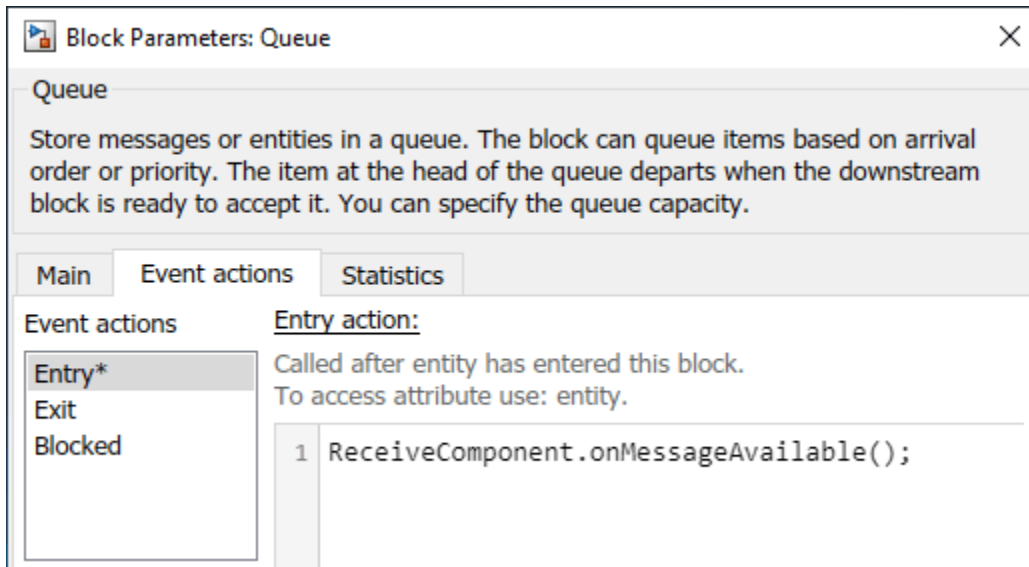

Below is the composition model with a SendComponent and a ReceiveComponent created by using two Model blocks. These two Model blocks are connected through a Queue block with message lines.

When a message arrives at the Queue block, its arrival is communicated to the ReceiveComponent by using Queue entry event action. This activates the Simulink Function block inside the ReceiveComponent to accept a new message for processing.

To achieve this behavior, in the Queue block, in the **Event action** tab, in the **Entry** field, the block calls the Simulink Function `onMessageAvailable()`. See “Event Action Languages and Random Number Generation” (SimEvents) for more information on Event Actions.

When the The Simulink Function block is activated, it accepts a message and converts it to a signal.

As a result, messages sent from the SendComponent trigger execution within the ReceiveComponent. To observe this behavior, use the Sequence Viewer block.

For example, observe the simulation time 0:

- 1 The arrow from the Send block to the Queue block represents that a message is sent with a data value of 0.
- 2 The arrow from the Queue block to the Simulink Function block indicates a call to the `onMessageAvailable()` function.
- 3 An arrow from the Queue block illustrates that the message with data value 0 is received by the Receive block within this function call.
- 4 The horizontal, dashed arrow from the Simulink Function block to the Queue block indicates the return of function `onMessageAvailable()`.

For more information about the Sequence Viewer block, see “Use the Sequence Viewer to Visualize Messages, Events, and Entities” on page 11-76.

# Modeling Message Communication Patterns with SimEvents

This example shows how to create common communication patterns using SimEvents®. In message-based communication models, you can use SimEvents® to model and simulate middleware, and investigate the effects of communication and the environment on your distributed architecture.

The systems in this example represent common communication patterns created by using SimEvents® blocks that can be used to simulate various network types, such as cabled or wireless communication, and channel behavior such as failure, or packet loss.

## Modeling Message Communication Patterns with SimEvents

### Merge messages from multiple senders

### Broadcast messages to multiple receivers

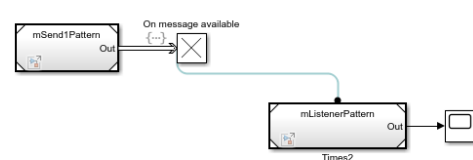

### Distribute work to multiple receivers

### Multicast messages among multiple senders and multiple receivers

### Run based on message availability

### Delay messages for a set amount of time

**Note:** This example uses blocks from SimEvents(R). If you do not have a SimEvents license, you can open and simulate the model but only make basic changes such as modifying block parameters.

Copyright © 2019 The MathWorks, Inc.

The communication patterns involve:

- Merging messages from multiple senders.
- Broadcasting messages to multiple receivers.
- Distributing work to multiple receivers.
- Multicasting messages among multiple senders and multiple receivers.
- Running a component based on message availability and data.
- Delaying messages for a set amount of time.

To create more complex networks and channel behavior, use combinations of these simple patterns.

By using these patterns, you can model:

- $N$ -to- $n$  communication with multiple senders and receivers with an ideal channel with communication delay. For an example, see “Build a Shared Communication Channel with Multiple Senders and Receivers” on page 11-31.

- *N* -to- *n* communication with channel failure and packet loss. For an example, see “Model Wireless Message Communication with Packet Loss and Channel Failure” on page 11-37.
- An *N* -to- *n* Ethernet communication network with an inter-component communication protocol. For an example, see “Model an Ethernet Communication Network with CSMA/CD Protocol” on page 11-47.

## Build a Shared Communication Channel with Multiple Senders and Receivers

This example shows how to model communication through a shared channel with multiple senders and receivers by using Simulink® messages, SimEvents®, and Stateflow®.

For an overview about messages, see “Simulink Messages Overview” on page 11-2.

In this model, there are two software components that send messages and two components that receive messages. The shared channel transmits messages with an added delay. SimEvents® blocks are used to create custom communication behavior by merging the message lines, and copying and delaying messages. A Stateflow chart is used in a send component to send messages based on a decision logic.

### Create Components to Send Messages

In the model, there are two software components that output messages, Send and StateflowSend.

In the Send component, the Sine Wave block is the signal source. The block generates a sine wave signal with an amplitude of 1. The sample time for the block is 0.1. The Send block converts the signal to a message that carries the signal value as data. The Send component sends messages to Send Buffer 1.

In the StateflowSend component, another Sine Wave block generates a sine wave signal and a Noise block injects noise into the signal. The Noise block outputs a signal whose values are generated from a Gaussian distribution with mean of 0 and variance of 1. The sample time of the block is 0.1.

The Stateflow chart represents a simple logic that filters the signal and decides whether to send messages. If the value of the signal is greater than 0.5 for a duration greater than 0.1, then the chart sends a message that carries the signal value. If the signal value is below 0, then the chart transitions to the ReceiveSignal state. The StateflowSend component sends messages to Send Buffer 2.

For more information about creating message interfaces, see “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22.

### Create Components to Receive Messages

In the model, there are two software components that receive messages, Receive and Listener.

In the Receive component, a Receive block receives messages and converts the message data to signal values.

In the Listener component, there is a Simulink Function block. The block displays the function, `onOneMessage(data)`, on the block face.

When a message arrives at Receive Buffer 2, the Listener block is notified and it takes the argument `data`, which is the value from the message data, as the input signal. In the block, `data` values are multiplied by 2. The block outputs the new data value.

### Routing Messages using SimEvents®

In the shared channel, the message paths originating from the two message-sending components are merged to represent a shared communication channel.

A SimEvents® Entity Input Switch block merges the message lines. In the block:

- **Number of input ports** specifies the number of message lines to be merged. The parameter value is 2 for two message paths.
- **Active port selection** specifies how to select the active port for message departure. If you select `All`, all of the messages arriving at the block are able to depart the block from the output port. If you select `Switch`, you can specify the logic that selects the active port for message departure. For this example, the parameter is set to `All`.

A SimEvents® Entity Server block is used to represent message transmission delay in the shared channel. In the block:

- **Capacity** is set to 1, which specifies how many messages can be processed at a time.

- **Service time value** is set to 1, which specifies how long it takes to process a message

A SimEvents® Entity Replicator block is used to generate identical copies of messages. In the block:

- **Replicas depart from** specifies if the copies leave the block from separate output ports or the same output port as the original messages. The parameter is set to **Separate output ports**.
- **Number of replicas** is set to 1, which specifies the number of copies generated for each message.
- **Hold original entity until all replicas depart** holds the original message in the block until all of its copies depart the block.

A SimEvents® Entity Terminator block is used to model Receive Buffer 2. In the block:

- Under the **Event actions** tab, in the **Entry action** field, you can specify MATLAB code that performs calculations or Simulink® function calls that are invoked when the message enters the block. In this example, `onOneMessage(entity)` is used to notify the Simulink Function block in the Listener component. To visualize the function call, under **Debug** tab, select **Information Overlays** and then **Function Connectors**.

### Simulate the Model and Review Results

Simulate the model. Observe that the animation highlights the messages flowing through the model. You can turn off the animation by right-clicking on the model canvas and setting **Animation Speed** to **None**.

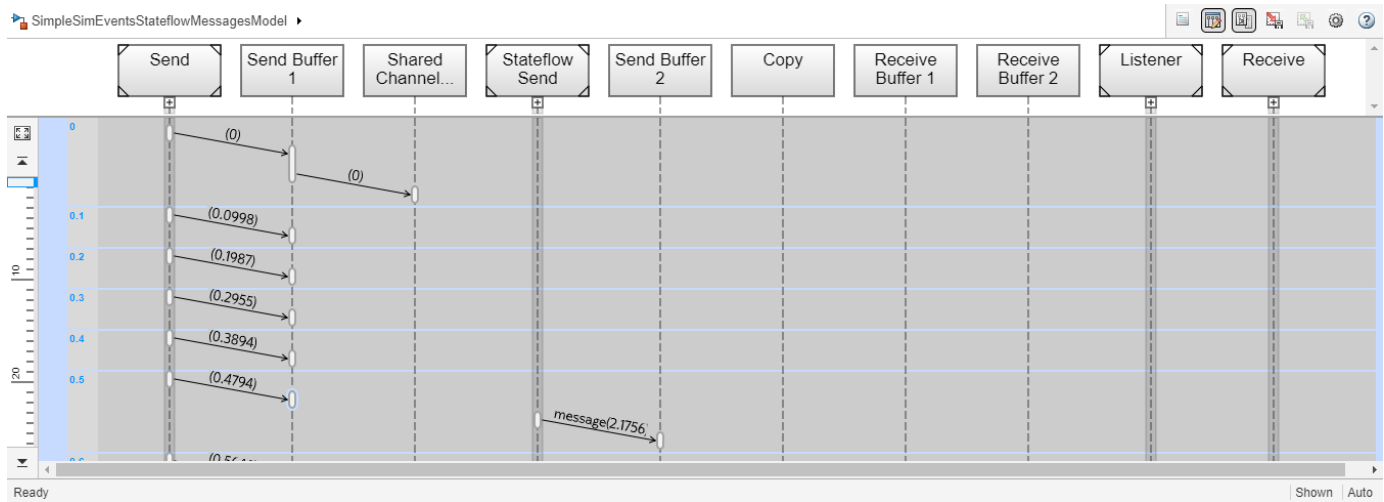

When you pause the animation, a magnifying glass appears on the blocks that store messages. If you point to the magnifying glass, you see the number of messages stored in the block.

To observe which messages are stored in the block, click the magnifying glass to open the Storage Inspector. For instance, the graphic below illustrates the messages stored in Send Buffer 1.

Turn the animation off and open the Sequence Viewer block to observe the Simulink Function calls and the flow of messages in the model.

For instance, observe the simulation time 0, during which a message carrying value 0 is sent from the Send component to Send Buffer 1. From simulation time 0.1 to 0.5, the Send component keeps sending messages to Send Buffer 1 with different data values. At time 0.5, the StateflowSend component sends a message to Send Buffer 2. For more information about using the Sequence Viewer block, see "Use the Sequence Viewer to Visualize Messages, Events, and Entities" on page 11-76.

# Model Wireless Message Communication with Packet Loss and Channel Failure

This example shows how to model wireless message communication with packet loss and channel failure by using Simulink® messages, Stateflow®, and SimEvents®.

In this model, there are two components that send messages and two components that receive messages. The messages are transmitted using a shared wireless channel with a transmission delay. A Stateflow® chart models message-sending logic in a wireless component and SimEvents® blocks model wireless message transmission, channel failure, and packet loss.

Copyright 2020 The MathWorks, Inc.

For an overview about messages, see “Simulink Messages Overview” on page 11-2.

## Create Components to Send and Receive Messages

In the model, there are two software components that output messages, WirelessSend and WirelessStateflowSend.

In the WirelessSend component, the Sine Wave block is the signal source. The Sine Wave block generates a sine wave with an amplitude of 1. The block **Sample time** is set to 0.1. The Send block converts the signal to a message that carries the data of the signal value. The WirelessSendComponent is connected to Send Buffer 1.

In the WirelessStateflowSend component, another Sine Wave block generates a sine wave signal and a Noise block is used to inject noise into the signal. The Noise block outputs a signal whose values are generated from a Gaussian distribution with mean of 0 and variance of 1. The Stateflow® chart represents a simple logic that filters a signal and decides whether to send messages. The StateflowSend component sends messages to Send Buffer 2.

In the model, there are two software components that receive messages, WirelessReceive and WirelessListener.

In the WirelessReceive component, a Receive block receives messages and converts message data to signal values. The component is connected to Receive Buffer 1.

In the WirelessListener component, there is a Simulink Function block that runs the `onOneMessage(data)` function. When a message arrives at Receive Buffer 3, the Simulink Function block takes the argument `data`, which is the value from message data, as the input signal. In the block, the `data` values are multiplied by 2. The block outputs the new data value.

To learn more about creating these components, see “Build a Shared Communication Channel with Multiple Senders and Receivers” on page 11-31.

### Model Wireless Message Communication Using Multicasting

The WirelessSend and WirelessStateflowSend components send messages to Send Buffer 1 and Send Buffer 2, which are SimEvents® Entity Multicast blocks that can wirelessly transmit messages. The Transmission Buffer block is a SimEvents® multicast receive queue that can receive messages sent by Send Buffer 1 and Send Buffer 2.

To achieve this wireless communication between Send Buffer 1, Send Buffer 2, and the Transmission Buffer block that is inside the Wireless Channel block:

- 1 In the Send Buffer 1 and Send Buffer 2 blocks, set the **Multicast tag** parameter to A.
- 2 In the Transmission Buffer block, set the **Multicast tag** parameter to A.

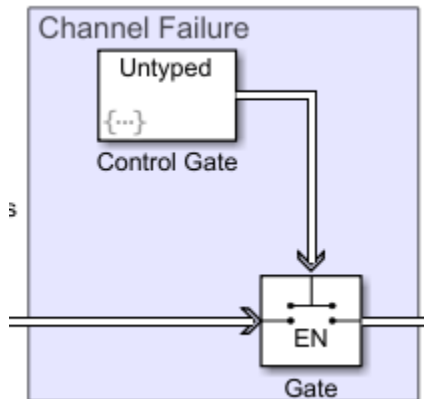

The **Multicast tag** parameter defines from which Entity Multicast blocks the messages are received.

## Model Channel Failure

A SimEvents® Entity Gate block is used to model channel failure. The block has two input ports. One input port is for incoming messages from Transmission Buffer. The second input port is a control port to decide when to open the gate.

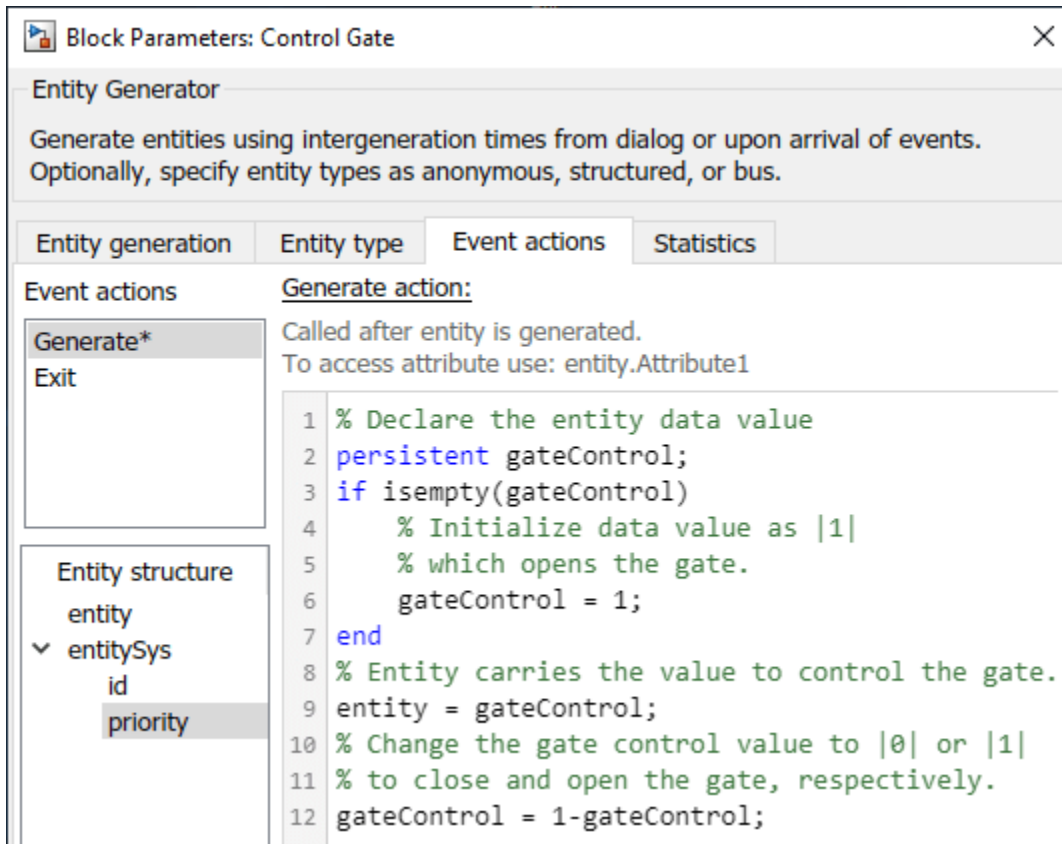

Set the **Operating mode** parameter for the Gate block to **Enable gate**. In this mode:

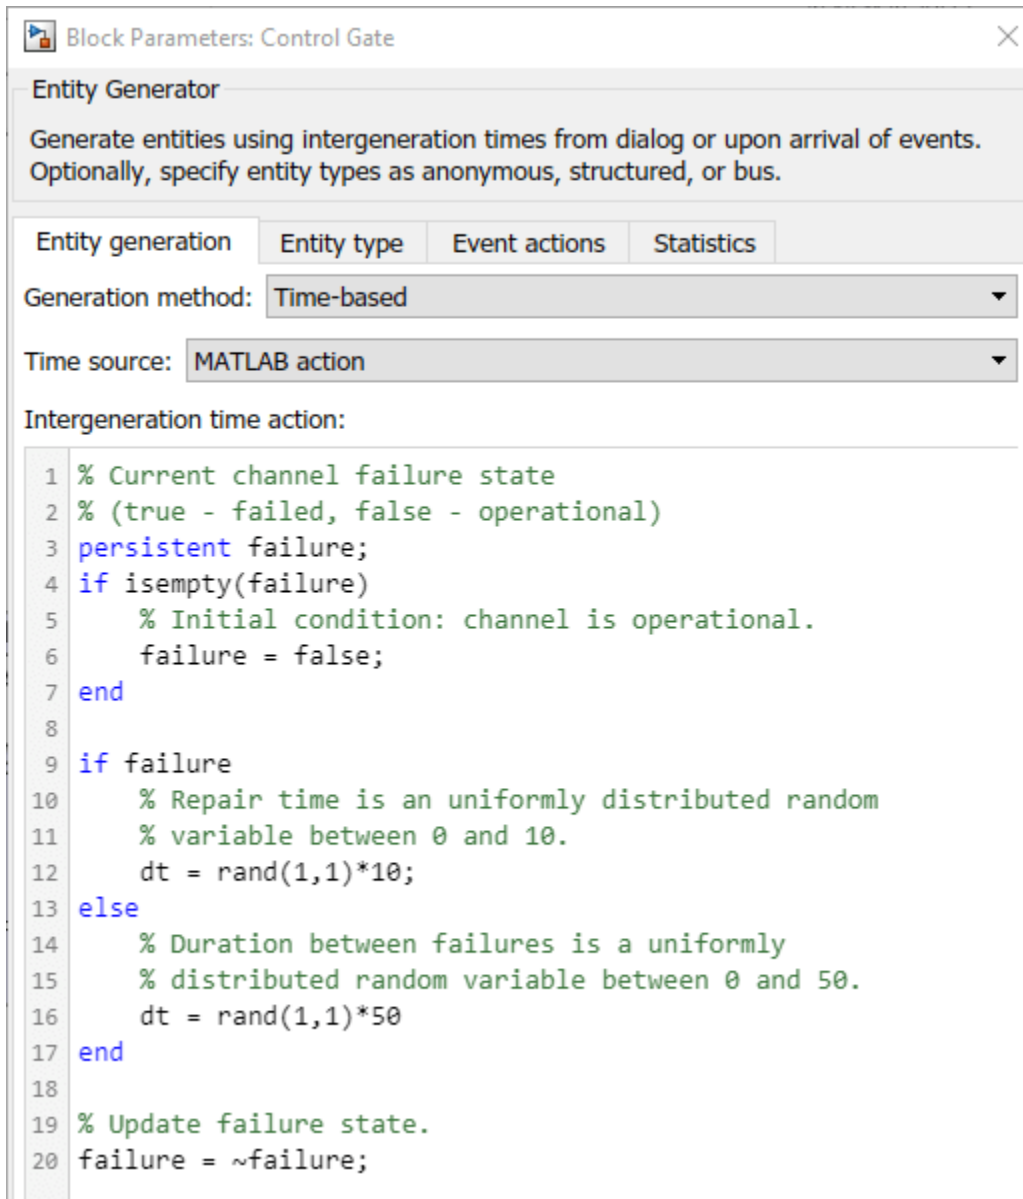

- The block opens the gate and permits messages to advance when it receives an entity carrying a value that is greater than 0 from its control port. This represents an operational channel.
- The block closes the gate and blocks messages passing if an entity carries data whose value is less than or equal to 0. This represents a channel failure.

To control the Gate block, you can use the SimEvents® Entity Generator block, which is labeled Control Gate in this example, to generate entities carrying different data values.

In the Control Gate block, in **Event actions**, in the **Generate action** field, the code below is used to generate entities to open and close the Gate block. Initially, entity data is 1 and the gate is open and the channel is in operational state. When a new entity is generated, its value changes to 0, which closes the gate. Every generated entity changes the status of the gate from open to closed or from closed to open.

In the Control Gate block, in the **Intergeneration time action** field, the code below is used to represent the operational and failed state of the channel. The code initializes the channel as operational. `dt` is the entity intergeneration time and is used to change the status of channel because each generated entity changes the status of the Gate block.

In the code, the repair time is generated from a uniform distribution that takes values between 0 and 10. The time interval between the failures is generated from another uniform distribution that takes values between 0 and 50.

### Model Packet Loss

To model the packet loss, a SimEvents® Entity Output Switch block is used.

The block has two input ports. One input port accepts messages. The other input port accepts entities that determine the output port selection. If the entity is set to 1, the block selects output port 1 to forward messages to the Wirelessly Share Messages block. If the entity is set to 2, the block selects output port 2, which is connected to an Entity Terminator block that represents packet loss.

In the Output Switch block:

- The **Number of output ports** is set to 2.
- To determine which output is selected, the **Switching criterion** is set to From control port and **Initial port selection** is set to 1.

To model a 0.1 probability of packet loss, in the Probabilistic Packet Loss block, select the **Event actions** tab, and in the **Generate action** field includes this code:

```

persistent rngInit;
if isempty(rngInit)
    seed = 12345;
    rng(seed);
    rngInit = true;
end

% Pattern: Uniform distribution
% m: Minimum, M: Maximum
m = 0; M = 1;
x = m + (M - m) * rand;

% x is generated from uniform distribution and
% takes values between |0| and |1|.
if x > 0.1
    % Entity carries data |1| and this forces Output switch to select
    % output |1| to forward entities to receive components.
    entity = 1;
else
    % Entity carries data |2| and this forces Output switch to select
    % output |2| and this represents a packet loss.
    entity = 1;
end

```

This means that entities entering the control port have a 0.9 probability of being set to 1, which makes the block output messages to the Wirelessly Share Messages block.

### Simulate the Model and Review results

Simulate the model.

- Open the Scope block connected top the Transmission Buffer block. The block displays the total number of messages transmitted through the shared channel.

4255 messages are transmitted through the channel.

The plot also displays the channel failures. For example, zoom into the first 100 seconds. Observer that the channel failure occurs between 40 and 49 during which message transmission is blocked.

Open the Data Inspector to visualize the entities that control the Gate. Entity data changes from 1 to 0 for each generated entity.

To see the number of lost messages, open the Scope block connected to the Packet Loss block.

409 messages are lost during transmission. This is 9.6 percent of the messages.

# Model an Ethernet Communication Network with CSMA/CD Protocol

This example shows how to model an Ethernet communication network with CSMA/CD protocol using Simulink® messages and SimEvents®. In the example, there are three computers that communicate through an Ethernet communication network. Each computer has a software component that generates data and an Ethernet interface for communication. Each computer attempts to send the data to another computer with a unique MAC address. An Ethernet interface controls the interaction between a computer and the network by using a CSMA/CD communication protocol. The protocol is used to respond to collisions that occur when multiple computers send data simultaneously. The Ethernet component represents the network and the connection between the computers.

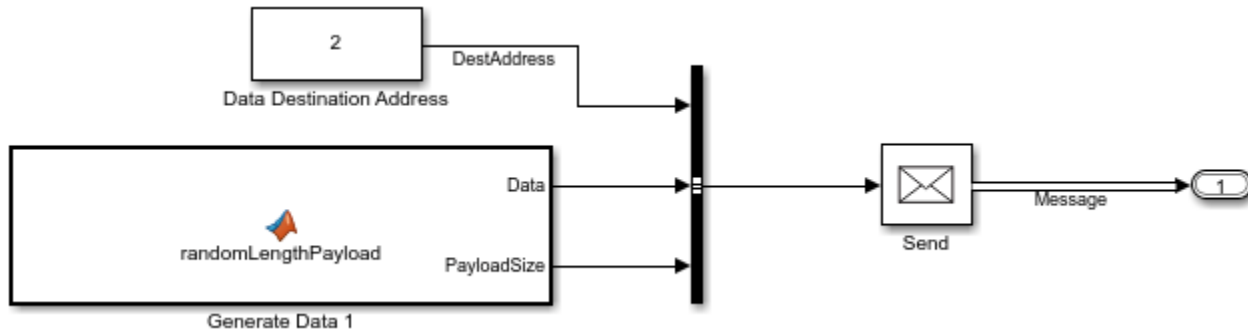

Copyright 2020 The MathWorks, Inc.

## Software Components

In the model, each software component generates data (payload) and combines the data, its size, and its destination into a message. Then, the message is sent to the Ethernet interface for communication.

In each Software Component subsystem:

- A MATLAB Function block generates data with a size between 46 and 1500 bytes [ 1 ].
- A Constant block assigns destination addresses to data.
- A Bus Creator block converts the Data, PayloadSize, and DestAddress signals to a nonvirtual bus object called dataPacket.
- A Send block converts dataPacket to a message.
- An Outport block sends the message to the Ethernet interface for communication.

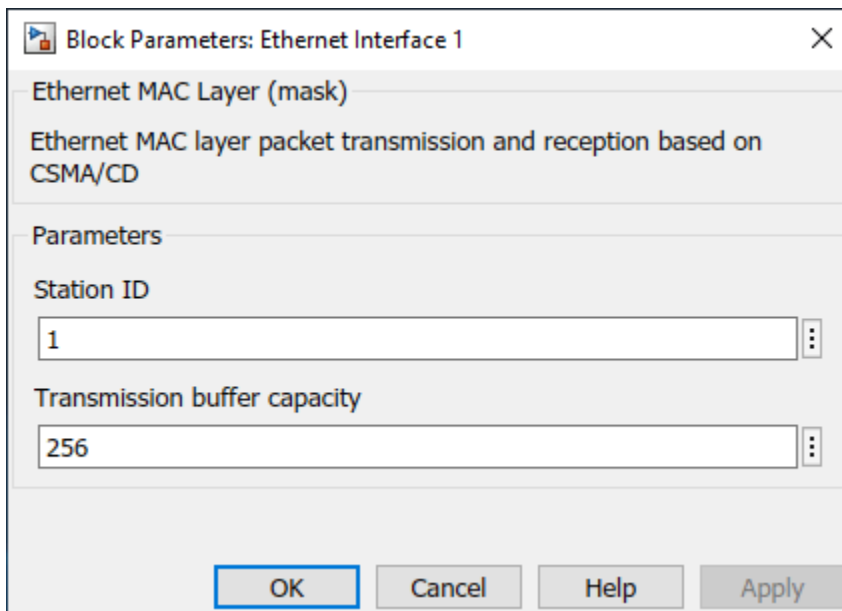

Each computer generates data with a different rate. You can change the data generation rate from the sample time of the MATLAB Function block.

To learn the basics of creating message send and receive interfaces, see “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22.

### Ethernet Interface

Double-click Ethernet Interface 1. Observe that you can specify the **Station ID** and **Transmission buffer capacity**.

The Ethernet Interface subsystems have three main parts:

- 1 Assemble Ethernet Frame — Converts an incoming message to an Ethernet (MAC) frame.
- 2 Transmission Buffer — Stores Ethernet frames for transmission.
- 3 Medium Access Control — Implements a CSMA/CD protocol for packet transmission [ 2 ].

### Assemble Ethernet Frame

The Assemble Ethernet Frame blocks convert messages to Ethernet frames by attaching Ethernet-specific attributes to the message [ 1 ].

In the packet assembly process:

- A SimEvents® Entity Replicator block labeled Copy Message copies an incoming message. The original message is forwarded to a SimEvents® Entity Generator block labeled Assemble MAC Frame. Because the Entity Generator block **Generation method** parameter is set to Event-based, it immediately produces an entity when the original message arrives at the block. A copy of the message is forwarded to a Simulink Function block with the `initPacket()` function. The terms *message* and *entity* are used interchangeably between Simulink® and SimEvents®.
- The Simulink Function block transfers the data, its size, and its destination address to the Assemble MAC Frame block for frame assembly.

- The Assemble MAC Frame block generates the Ethernet frames that carry both Ethernet-specific attributes and values transferred from the Simulink Function block.

Assemble MAC Frame block calls the `initPacket()` function as an action that is invoked by each frame generation event.

These are the attributes of the generated Ethernet frame:

- `entity.TxAddress` is `StationID`.
- `entity.RxAddress`, `entity.Data`, and `entity.PayloadSize` are assigned the values from the Simulink Function block.
- `entity.TxDelay` is the transmission delay. It is defined by the payload size and the bitrate. The Bit rate parameter is specified by an initialization function in the Model Properties.
- `entity.CRC` is the cyclic redundancy check for error detection.

### Transmission Buffer

The transmission buffer stores entities before transmission by using a first-in-first-out (FIFO) policy. The buffer is modeled by a Queue block.

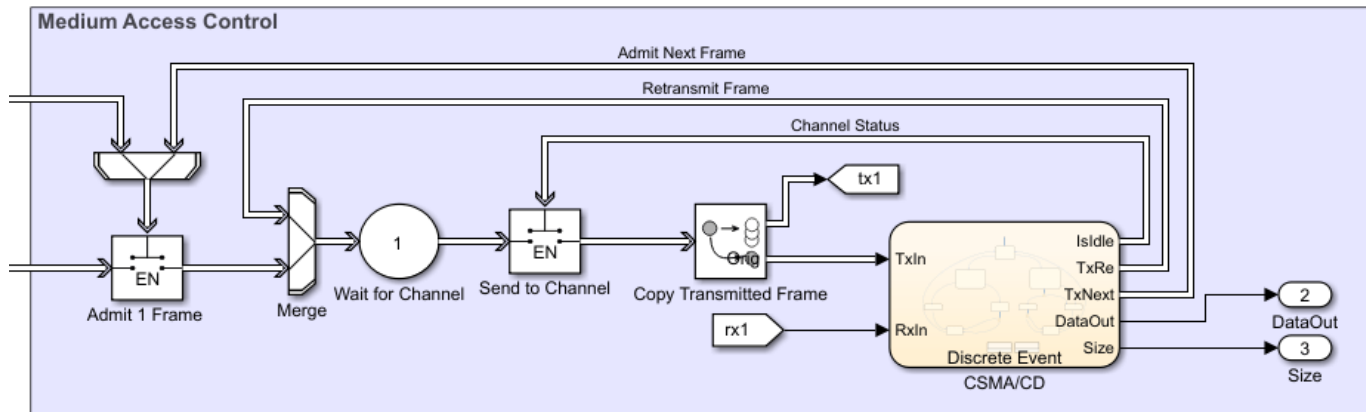

The capacity of the queue is determined by the **Transmission buffer capacity** parameter.

### Medium Access Control

The Medium Access Control blocks are modeled by using six SimEvents® blocks.

- An Entity Gate block labeled Admit 1 Frame is configured as an enabled gate with two input ports. One input port allows frames from the Transmission Buffer block. The other input port is called the control port, which accepts messages from the CSMA/CD block. The block allows one frame to advance when it receives a message with a positive value from CSMA/CD block.
- An Entity Input Switch block labeled Merge merges two paths. One input port accepts new frames admitted by the Admit 1 frame block and the other input port accepts frames for retransmission that are sent by the CSMA/CD block.
- An Entity Server block labeled Wait for Channel models the back off time of a frame before its retransmission through the channel.

- Another Entity Gate block labeled Send to Channel opens the gate to accept frames when the channel is idle. The channel status is communicated by the CSMA/CD chart.
- An Entity Replicator block labeled Copy Transmitted Frame generates a copy of the frame. One frame is forwarded to the Ethernet network, and the other is forwarded to the CSMA/CD chart.
- A Discrete-Event Chart block labeled CSMA/CD represents the state machine that models the CSMA/CD protocol.

### CSMA/CD Protocol

The CSMA/CD protocol [ 2 ] is modeled by a Discrete-Event Chart block that has two inputs:

- TxIn — Copy of the transmitted frame.
- RxIn — Received frame from the Ethernet network.

The chart has five outputs:

- IsIdle — Opens the Send to Channel gate to accept frames when the value is 1, and closes the gate when the value is 0.
- TxRe — Retransmitted frame that is forwarded to the Merge block if there is a collision detected during its transmission.
- TxNext — Opens the Admit 1 Frame gate to accept new frames when the value is 1.
- DataOut — Received data.
- Size — Size of the received data.

### Transmitting and Receiving Messages

The block is initially in the Standby state and the channel is idle.

If the block is transmitting, after a delay, the block attempts to transmit the message and `IsIdle.data` is set to 0 to declare that the channel is in use.

If the transmission is successful, the block sets `TxNext.data` to 1 to allow a new message into the channel and resets to the Standby state.

If there is a collision, the block resends the message after delaying it for a random back off time.  $n$  is the counter for retransmissions. The block retransmits a message a maximum of 16 times. If all of the retransmission attempts are unsuccessful, then the block terminates the message and allows the entry of a new message. Then it resets to StandBy.

Similarly, the block can receive messages from other computers. If there is no error, the messages are successfully received and the block outputs the received data and its size.

### Ethernet Hub

The Ethernet component represents the communication network and the cabled connections of the computers to the network.

Double-click the Ethernet block to see its parameters.

- **Connected stations** — These values are assigned to `Stations`, which is a vector with the station IDs as elements.
- **Length of cables (m)** — These values are assigned to `CableLength` and represent the length of the cables, in meters, for each computer connected to the hub.
- **Packet error rate (PER)** — These values are assigned to `PER` and represent the rate of error in message transmission for each computer.
- **Processing time (s)** — These values are assigned to `ProcessingTime` and it represents the channel transmission delay.

Three SimEvents® blocks are used to model the Ethernet network. The three computer connections are merged by using an Entity Input Switch block. An Entity Server block is used to model the channel transmission delay based on the cable length. An Entity Replicator block copies the transmitted message and forwards it to the three computers.

### Simulate the Model and Review the Results

Simulate the model and open the Scope block that displays the average channel utilization. The channel utilization converges to approximately 0.12.

Open Software Component 1 as a top model and change the data generation rate by setting the **Sample time** of the Generate Data 1 block to 0.01. Run the simulation again and observe that the channel utilization increases to 0.2.

### Connect New Computers to the Network

You can connect more computers to the network.

To add a new computer to the network:

- Copy an existing computer and assign a new ID by double-clicking the Ethernet Interface block. In this example, new computer has ID 4.

Copyright 2019 The MathWorks, Inc.

- Double-click the Ethernet block and add a station ID, cable length, and packet error rate for the new computer.

## Send and Receive Messages Carrying Bus Data

This example shows how to send and receive messages carrying bus data between model components.

In the model, there are two components, Send Component and Receive Component that send and receive messages, respectively. This example builds on another example, “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22, where two software components communicate using messages. The model is modified to send messages carrying bus data.

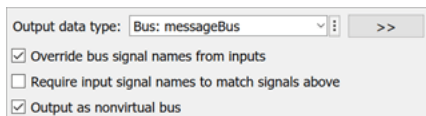

Copyright 2020 The MathWorks, Inc.

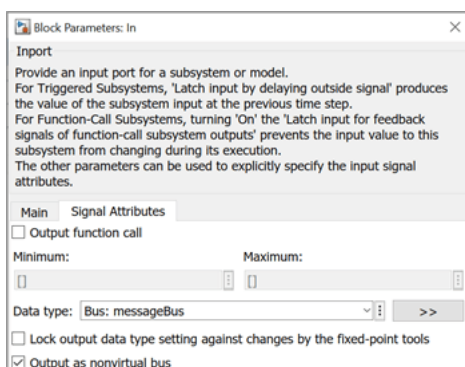

### Prepare the Model for Messages with Bus Data

The following steps are used to prepare the model for messages carrying bus data type.

- To create messages carrying non-virtual buses, in the Send Component, in the Bus Creator block, set the **Output data type** to messageBus and select the **Output as nonvirtual bus** check box.

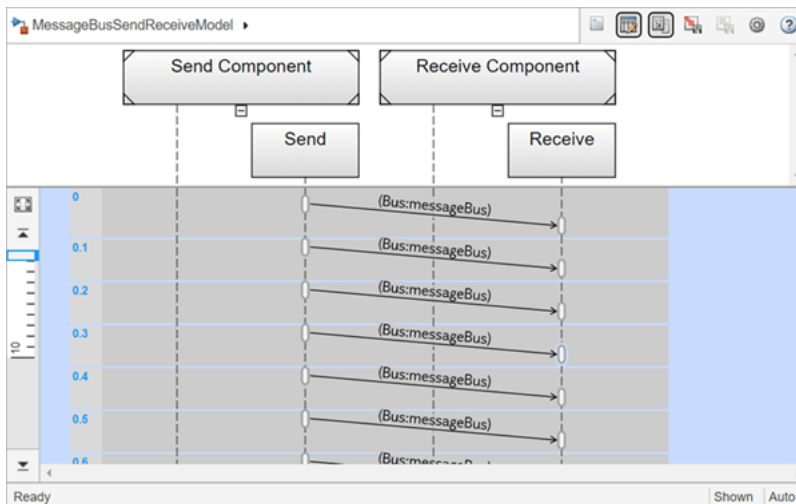

- To send messages carrying bus data, in the Send Component, in the Output block, under the **Signal Attributes** tab, set the **Data type** to messageBus and select the **Output as nonvirtual bus** check box.

- To receive messages carrying bus data, in the Receive Component, in the Inport block, under the **Signal Attributes** tab, set the **Data type** to messageBus and select the **Output as nonvirtual bus** check box.

### Simulate the Model and Visualize the Results

Simulate the model and open the Sequence Viewer block. Observe the transmission of messages carrying bus data.

## Use Virtual Buses with Message Elements for Component Communication

This example shows how to model message-based communication between software components that communicate using virtual buses with message elements.

The model in this example is a flat non-holonomic robot that can move or rotate with the help of two wheels, similar to a home vacuuming robot. This model assumes that the robot moves in one of two ways:

- Linear — Both wheels turn in the same direction with the same speed, and the robot moves linearly.
- Rotational — The wheels turn in opposite directions with the same speed, and the robot rotates in place.

Copyright 2021 The MathWorks, Inc.

To learn how to create the model for the robot, see “System Definition and Layout”.

In this example, the robot sends its velocity in x- and y- directions to the base station and its relative angle (direction of motion) values to a base station. The station's data consumption rate is slower than the data sent by the robot. A Queue block is used as a message buffer.

### Send Virtual Bus Message Elements with Nonvirtual Bus Payload

In this model, components that represent the mobile robot and the station communicate using virtual buses with message elements. `XVelocity` and `YVelocity` represent x and y components of the robot's velocity, respectively. `Angle` represents the robot's relative angle to the x-axis.

In the Mobile Robot Sending Data component, `XVelocity` and `YVelocity` signals are combined into the nonvirtual bus `Velocity`. The Send 1 block creates messages with velocity data as the payload. In this framework, messages provide asynchronous event-based communication between components. Using messages with a nonvirtual bus payload allows the software to treat `Velocity` as a data package with `XVelocity` and `YVelocity` as its fields. Therefore, each package includes `XVelocity` and `YVelocity` data.

The Send 2 block creates messages with `Angle` data as the payload. The Out Bus Element blocks labeled `SendVirtualBus.Velocity` and `SendVirtualBus.Angle` specify `Velocity` and `Angle` as elements of the virtual bus `SendVirtualBus`. You can combine messages into a virtual bus to

create message send interfaces. In the message receive interfaces, you can access the bus as a whole or select specific messages from the bus. For more information about message send and receive interfaces, see “Simulink Messages Overview” on page 11-2.

The components communicate via the following:

- The model pre-load function `load('Velocity.mat')` loads the `Velocity` bus object to the workspace.
- A Bus Creator block groups `XVelocity` and `YVelocity` into a nonvirtual bus defined by the `Velocity` bus object.
- The Send 1 block creates messages with `Velocity` as the payload.
- The Out Bus Element block labeled `SendVirtualBus.Velocity` creates the virtual bus `SendVirtualBus` with the `Velocity` element. In the block, **Data Type** is set to `Bus :` `Velocity`, and **Data mode** is set to `message`.

**Attributes of 'SendVirtualBus.Velocity'**

Data type:

Bus virtuality:

Data mode:

Dimensions:

Dims mode:

Unit:

Sample time:

Complexity:

Minimum:

Maximum:

- The Out Bus Element block labeled `SendVirtualBus.Angle` specifies `Angle` as a message element of `SendVirtualBus`.

The Station Receiving Data component receives virtual buses and selects the message elements using the In Bus Element block. Receive blocks convert messages to signals for processing and visualization.

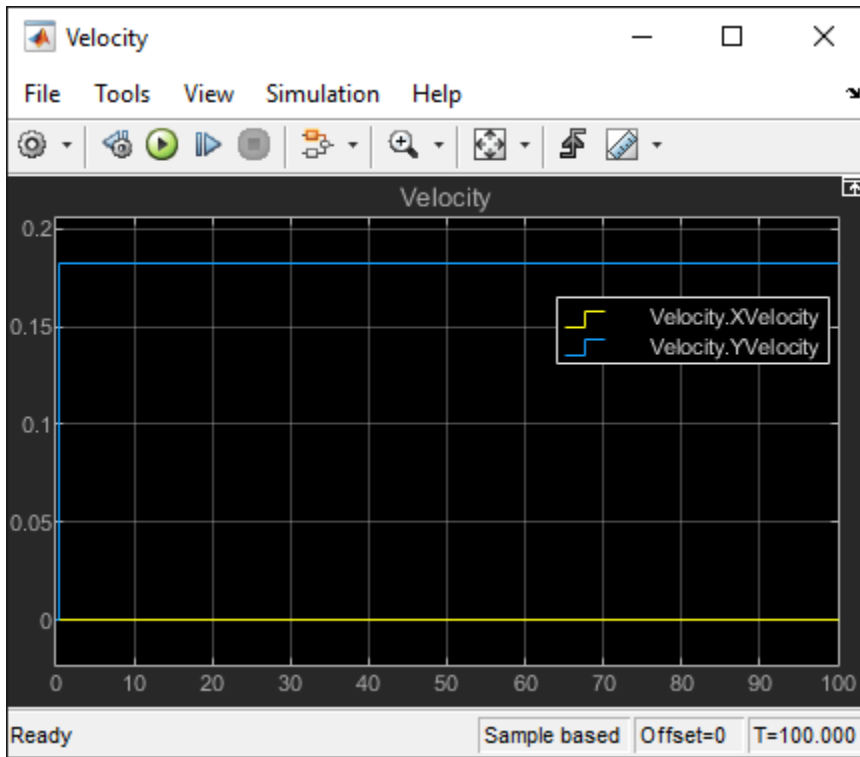

For more information about creating send and receive interfaces for messages with a nonvirtual bus payload, see “Send and Receive Messages Carrying Bus Data” on page 11-58.

You can simulate the model or generate code for both Mobile Robot Sending Data component and Station Receiving Data component. For more information, see “Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware” (Embedded Coder).

### Simulate the Model and Review Results

Simulate the model. Observe the communicated velocity of the robot in x and y directions. The robot moves in y direction because its velocity in x direction is constant and 0.

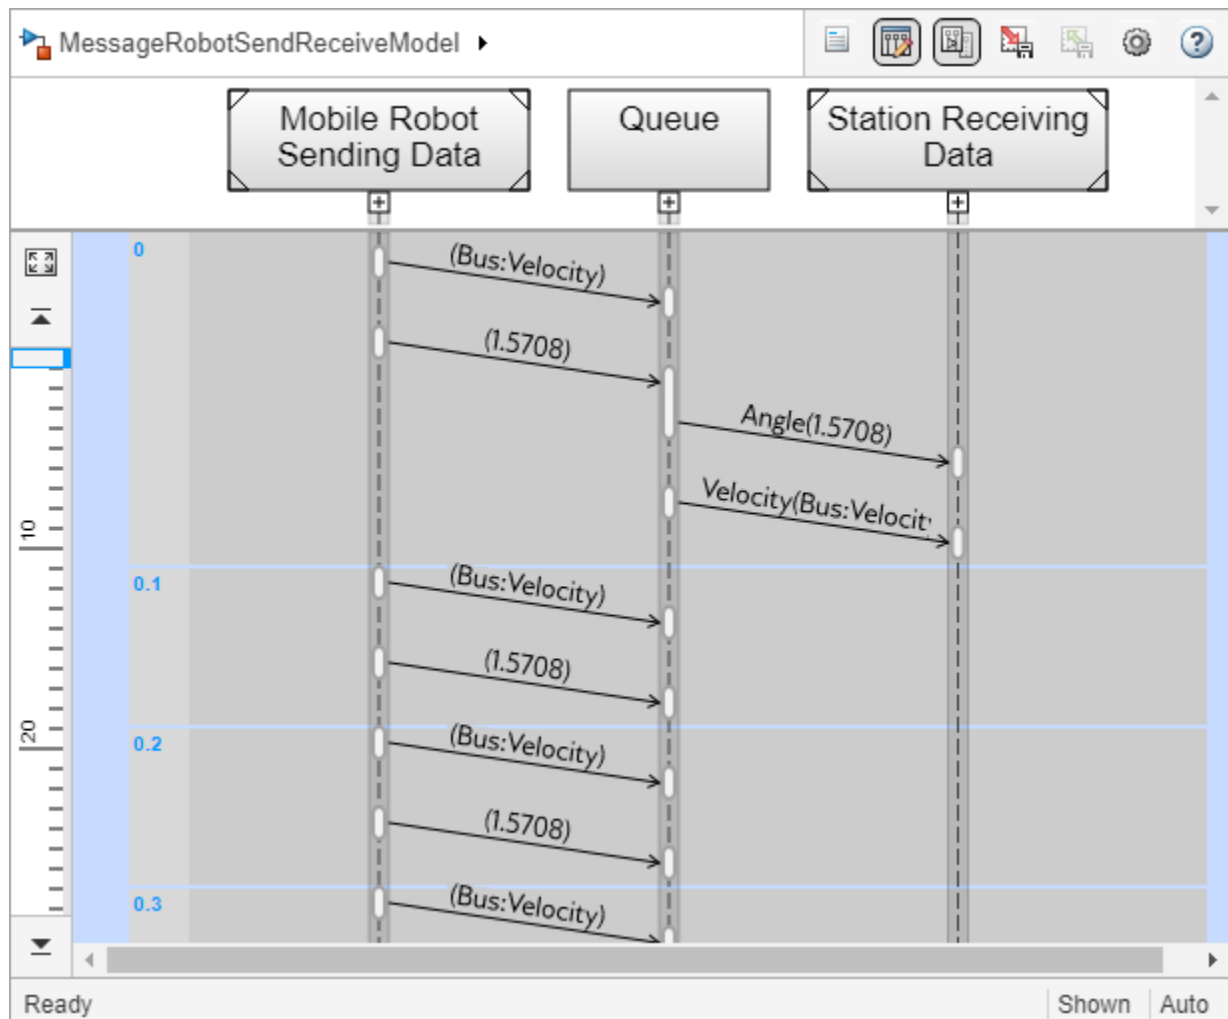

Observe the robot's constant relative angle in radians. The angle  $\pi/2$  confirms the motion in the y direction.

Use the Sequence Viewer tool to display the virtual buses communicated between the robot and the station. To open the Sequence Viewer tool, in the Simulink® toolstrip, on the **Simulation** tab, under **Review Results**, select **Sequence Viewer**.

The Sequence Viewer window displays the virtual bus transitions from the Mobile Robot Sending Data component to the Queue block and from the Queue block to the Station Receiving Data component.

### Queue Expansion

Expand the Queue lifeline in the Sequence Viewer window. Observe that the Queue block expands to two Queue blocks that provide storage for two virtual bus message elements, *Velocity* and *Angle*. The additional Queue block has the same configuration and capacity as the original Queue block. For more information about the Queue block, see “Use a Queue Block to Manage Messages” on page 11-12.

### Visualize Virtual Buses with Message Elements

Animation allows you to observe the virtual buses communicated between the robot and the station during the simulation. To turn on animation, from the toolbar, on the **Debug** tab, in the **Event Animation** section, select the **Animation Speed**.

You can specify **Slow**, **Medium**, or **Fast** animation speed. Select **None** to turn off the animation. For more information about animation and message visualizations, see “Animate and Understand Sending and Receiving Messages” on page 11-5.

The animation highlights virtual buses sent from the robot to the Queue block and from the Queue block to the station.

Pause the animation and point to the magnifying glass on the Queue block to open the Storage Inspector. The Storage Inspector displays the bus elements and message data.

### Virtual Buses with Message Elements in Architecture Models

You can model message-based communication between software components by first designing your system from the architecture level using System Composer™. The architecture models in System Composer support Simulink models with message input and output as component behavior.

Below is an example illustration that shows the design of architecture components to represent the mobile robot and the station. The Simulink models used in the example above, `MessageSendRobotModel` and `MessageReceiveRobotModel`, are attached to these components as component behaviors. When you compile the model, a LIFO queue of capacity 1 is automatically inserted to the architectural model for simulation. Designing message interfaces from the architecture level requires a System Composer license.

- “Simulink Messages Overview” on page 11-2
- “Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware” (Embedded Coder)

## Merge Message Lines Using a Message Merge Block

This example shows how to use a Message Merge block to route messages. In this example, message-based communication is constructed between two components: a Send component creates messages and sends them to a Receive component. A Queue block is used as a message buffer between the components and is configured as a FIFO queue with capacity 100. For information about how to create message communication between components, see “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22.

Copyright 2021 The MathWorks, Inc.

In this example, the Send component has two algorithms that generate data that is converted to messages using two Send blocks. The Message Merge block combines two message lines into a single message line.

You can prepare this model to generate C++ code for each component. The generated code contains necessary software interfaces that allow you to connect with an operating system or message middleware. For more information, see “Generate C++ Messages to Communicate Data Between Simulink and an Operating System or Middleware” (Embedded Coder).

### Simulate the Model and Review Results

Simulate the model. Observe the Scope block that displays the output. The value changes between 1 and 8 based on the two Constant blocks in the Send components.

## Specify Queue Properties for Message Interface

This topic explains how to specify queue properties for a message receive interface when you model message-based communication with Simulink between software components that run in different applications. In message-based communication, a send component sends messages, and a receive component accepts messages based on the logic it represents. For more information about creating message send and receive interfaces, see “Establish Message Send and Receive Interfaces Between Software Components” on page 11-22.

In your model with message-based communication, a queue stores and sorts messages between send and receive components. If you do not specify queue properties manually, a LIFO overwriting queue of capacity 1 is automatically inserted between send and receive components. For more information on message queue configurations, see “Use a Queue Block to Manage Messages” on page 11-12.

The topic shows you how to customize queue properties for your message receive interface and summarizes their use in architecture and AUTOSAR applications.

### Specify Queue Properties

Based on your application, specify queue properties for one of these three cases:

- Specify message queue properties for your composition. A composition represents components and their integration. For more information, see “Simulink Messages Overview” on page 11-2.
- Specify message queue properties for individual components in your model.
- Specify message queue properties for both individual components and your composition.

#### Customize Message Queue Properties for Compositions

You can customize queue properties for your composition by manually adding a Queue block from the Simulink Messages & Events library, or blocks from the SimEvents library.

In this example, a Queue block is manually placed to configure message queue properties when the receive interface is modeled using an Inport block and a Receive block. In this case, use Queue block parameters to specify the queue capacity, message sorting policy (FIFO or LIFO queue), and message overwriting policy.

#### Customize Message Queue Properties for Individual Components

You can specify queue properties for the message receive interface of an individual component using an In Bus Element block. These properties are then used by AUTOSAR to help generate target

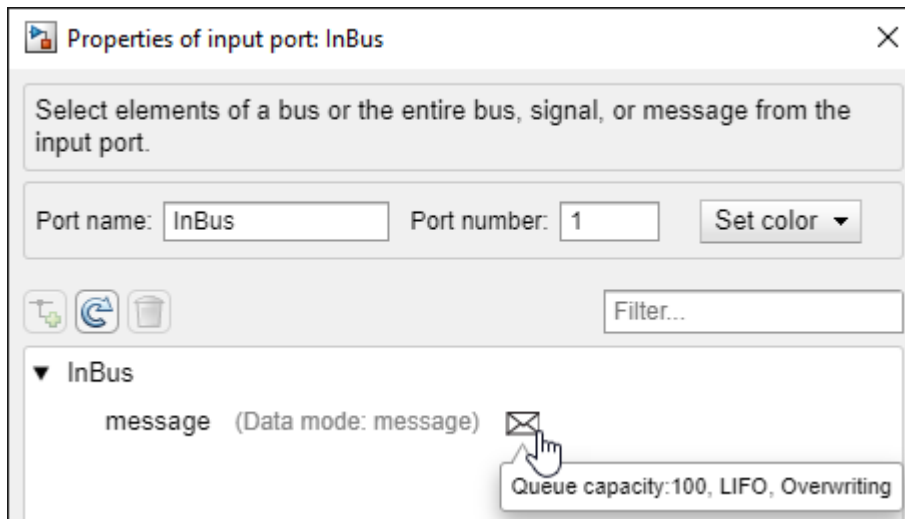

specific code for components. For more information, see “Configure AUTOSAR Queued Sender-Receiver Communication” (AUTOSAR Blockset).

- 1 Open the In Bus Element block. Select the bus element and specify its data mode using the **Data mode** parameter.

- 2 Select the message icon to configure queue properties for the selected message element.

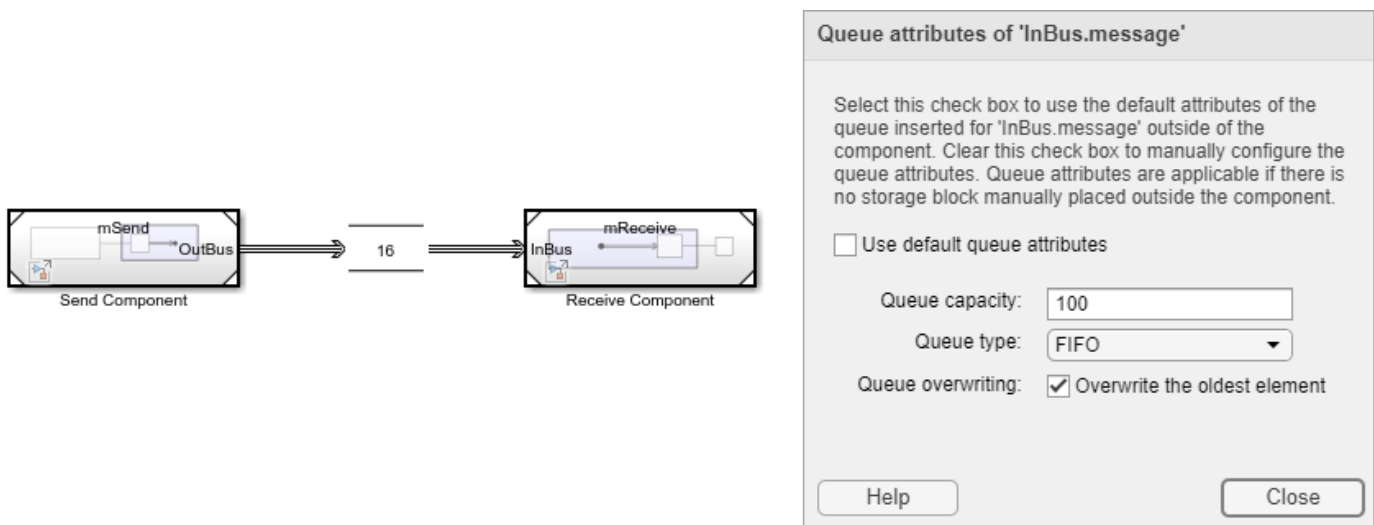

- 3 Clear the **Use default queue attributes** check box to specify queue attributes for the message element.

### Customize Message Queue Properties for Components and Compositions

In this scenario, you combine components with queue receive interface specifications and explicit queues. When you use both of these queue specifications, the explicit queue configuration will overwrite other queue specifications.

If you choose both configurations at the same time, you will receive this warning, which indicates that the configuration of the Queue block overwrites other queue configurations.

The queue attributes set for 'message' inside the component 'mReceive' are not applicable because there is a Queue block 'MessageSendReceiverModel/Queue' manually placed outside the component. To resolve this warning, remove the Queue block or select the "Use default queue attributes" checkbox inside the component.

Component: Simulink | Category: Block diagram warning

## Queue Expansion

If you use an automatically inserted Queue block or manually place a Queue block between send and receive components, for all of the queue specification methods, the queue expands to multiple queues to provide storage for each virtual bus message element. In this case, all of the queues have the same configuration and capacity as the original queue. For an example, see “Use Virtual Buses with Message Elements for Component Communication” on page 11-60.

If you use an In Bus Element block to model the receive interface, you can use multiple In Bus Element blocks to insert a different message queue for each received message element. The queue icon displays queue specifications for each message element.

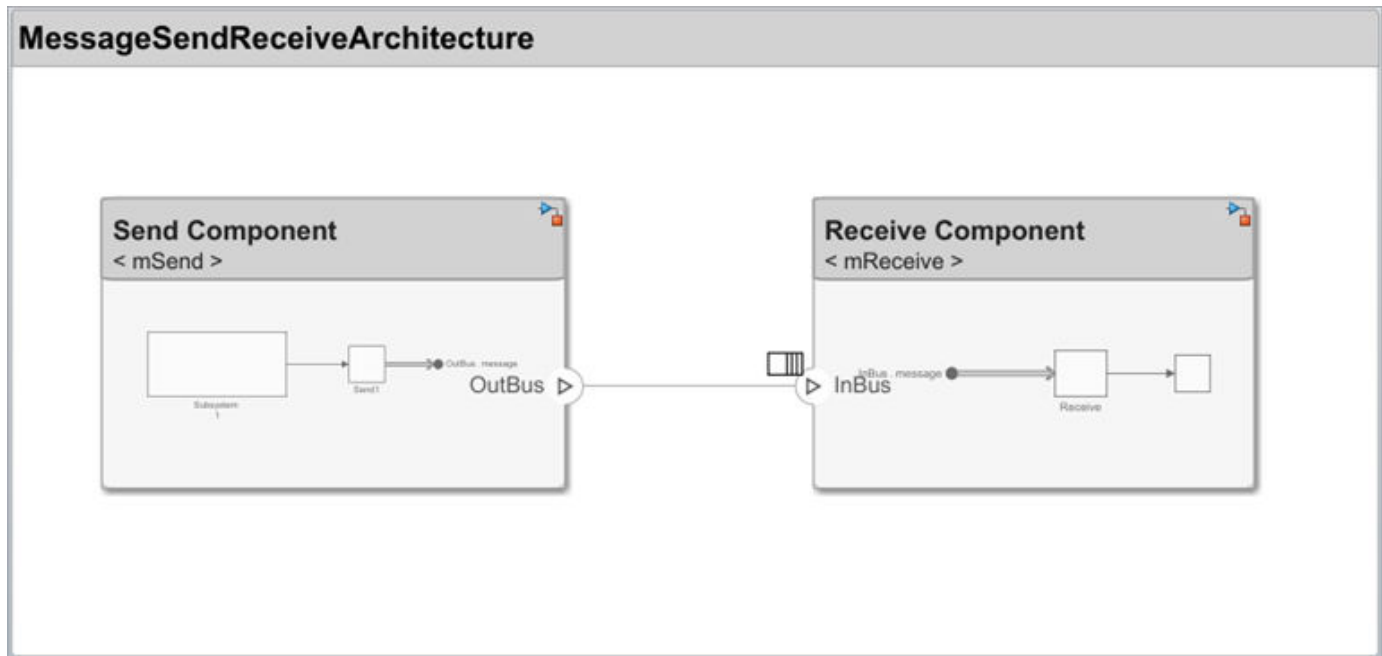

## Virtual Buses with Message Elements in Architecture Models

You can model message-based communication between software components by first designing your system from the architecture level using System Composer. The architecture models in System Composer support Simulink models with message input and output as component behaviors. Designing message interfaces from the architecture level requires a System Composer license.

This illustration shows the design of the architecture with send and receive components. The Simulink models used in the example above, mSend and mReceive, are attached to these components

as component behaviors. When you compile the model, a LIFO queue of capacity 1 is automatically inserted to the architecture model for simulation.

You can also use the In Bus Element block to manually specify queue properties for the receive interface behavior of your architecture component. After you update your model, you can point to the queue icon to view the queue configurations for each bus element in the component behavior.

## Use the Sequence Viewer to Visualize Messages, Events, and Entities

To see the interchange of messages and events between the blocks from the Simulink Messages & Events library, Stateflow charts in Simulink models, and SimEvents blocks, you can:

- Use the **Sequence Viewer** tool from the Simulink toolstrip.
- Add a Sequence Viewer block to your Simulink model.

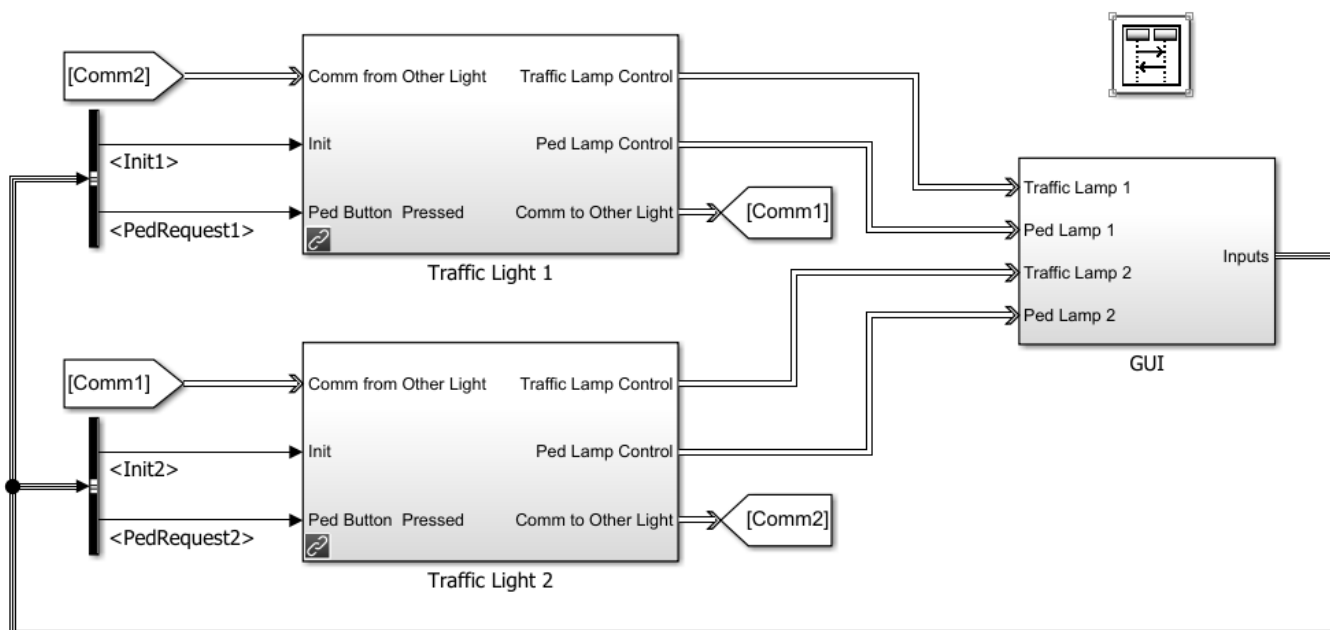

The Sequence Viewer allows you to visualize message transition events and the data that the messages carry. In the Sequence Viewer, you can view event data related to Stateflow chart execution and the exchange of messages between Stateflow charts. The Sequence Viewer window shows messages as they are created, sent, forwarded, received, and destroyed at different times during model execution. The Sequence Viewer window also displays state activity, transitions, and function calls to Stateflow graphical functions, Simulink functions, and MATLAB functions.

With the Sequence Viewer, you can also visualize the movement of entities between blocks when simulating SimEvents models. All SimEvents blocks that can store entities appear as lifelines in the Sequence Viewer window. Entities moving between these blocks appear as lines with arrows. You can view calls to Simulink Function blocks and to MATLAB Function blocks.

You can add a Sequence Viewer block to the top level of a model or any subsystem. If you place a Sequence Viewer block in a subsystem that does not have messages, events, or state activity, the Sequence Viewer window informs you that there is nothing to display.

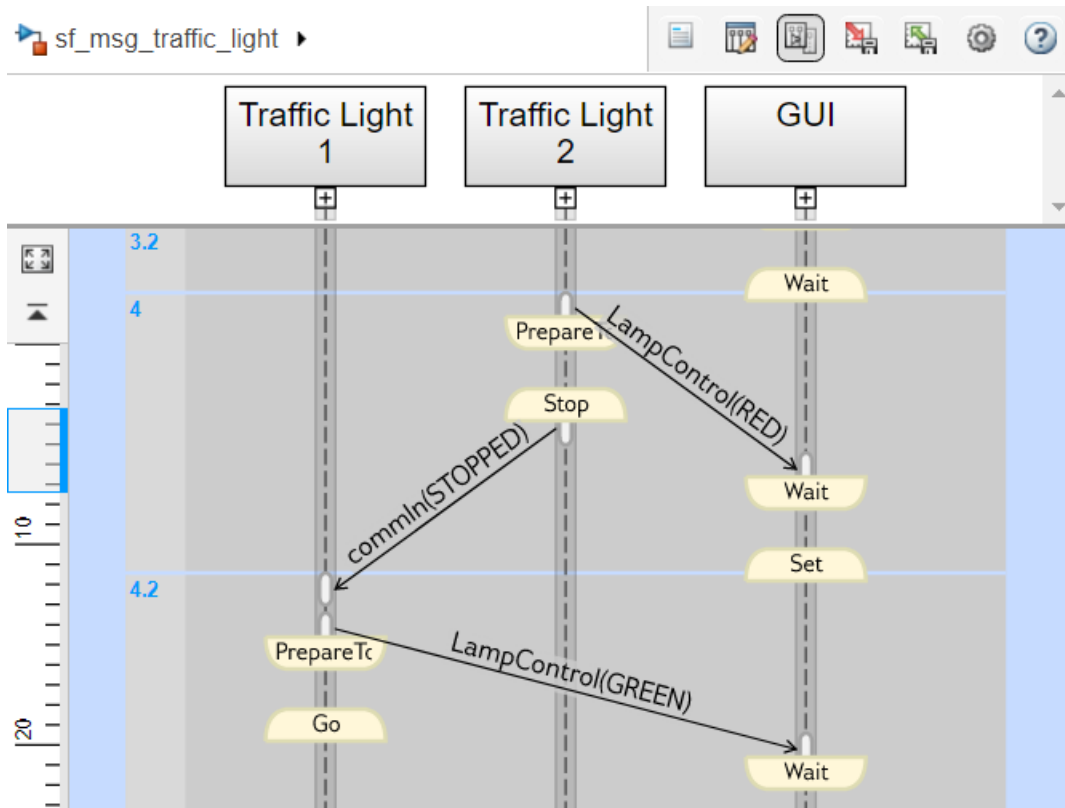

For instance, open the Stateflow example `sf_msg_traffic_light`.

```
openExample("stateflow/ModelingADistributedTrafficControlSystemUsingMessageExample")
```

Copyright 2015, The MathWorks, Inc.

This model has three Simulink subsystems: Traffic Light 1, Traffic Light 2, and GUI. During simulation, the Stateflow charts in these subsystems exchange data by sending messages. As messages pass through the system, you can view them in the Sequence Viewer window. The Sequence Viewer window represents each block in the model as a vertical lifeline with simulation time progressing downward.

## Components of the Sequence Viewer Window

### Navigation Toolbar

At the top of the Sequence Viewer window, a navigation toolbar displays the model hierarchy path. Using the toolbar buttons, you can:

-  Show or hide the **Property Inspector**.
-  Select an automatic or manual layout.
-  Show or hide inactive lifelines.
-  Save Sequence Viewer settings.
-  Restore Sequence Viewer settings.
-  Configure Sequence Viewer parameters.
-  Access the Sequence Viewer documentation.

## Property Inspector

In the **Property Inspector**, you can choose filters to show or hide:

- Events
- Messages
- Function Calls
- State Changes and Transitions

## Header Pane

The header pane below the Sequence Viewer toolbar shows lifeline headers containing the names of the corresponding blocks in a model.

- Gray rectangular headers correspond to subsystems.
- White rectangular headers correspond to masked subsystems.
- Yellow headers with rounded corners correspond to Stateflow charts.

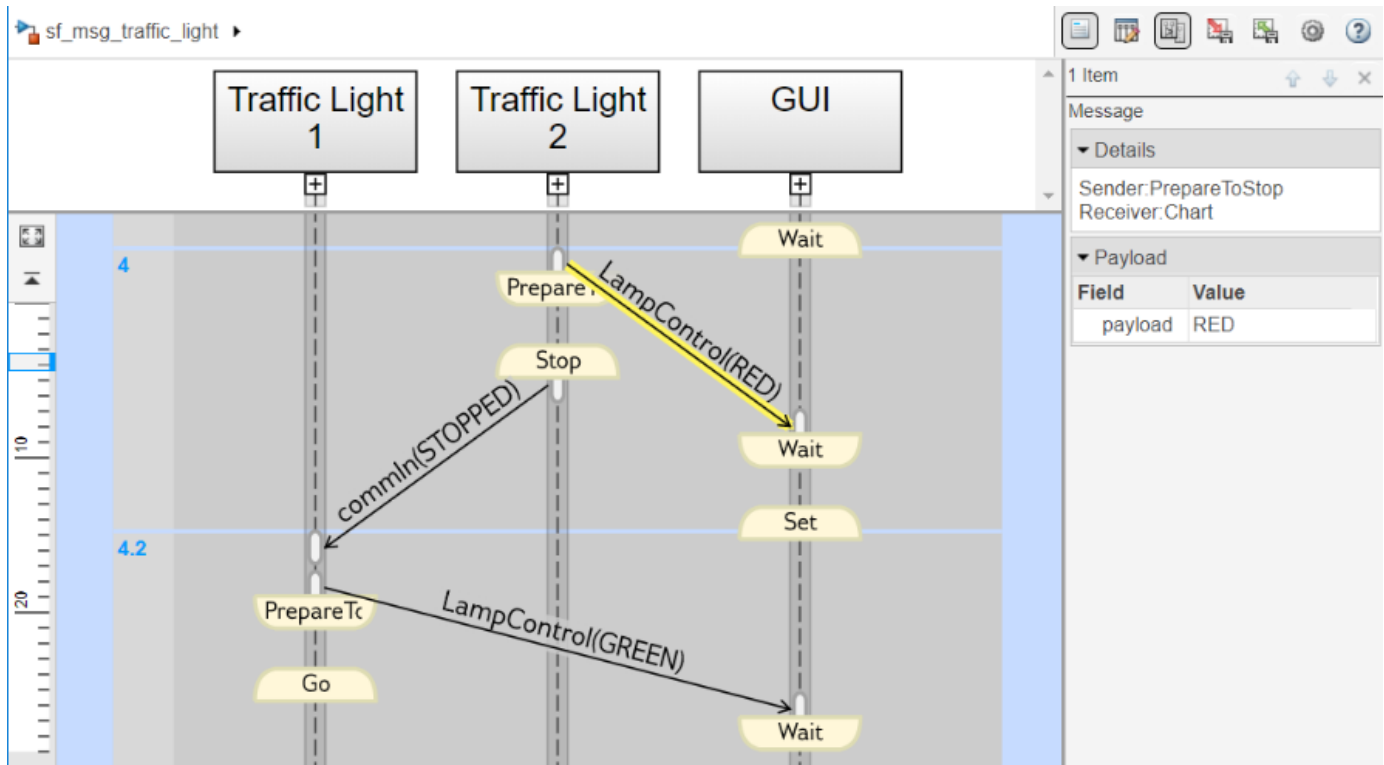

To open a block in the model, click the name in the corresponding lifeline header. To show or hide a lifeline, double-click the corresponding header. To resize a lifeline header, click and drag its right-hand side. To fit all lifeline headers in the Sequence Viewer window, press the space bar.

## Message Pane

Below the header pane is the message pane. The message pane displays messages, events, and function calls between lifelines as arrows from the sender to the receiver. To display sender, receiver, and payload information in the **Property Inspector**, click the arrow corresponding to the message, event, or function call.

## Navigate the Lifeline Hierarchy

In the Sequence Viewer window, the hierarchy of lifelines corresponds to the model hierarchy. When you pause or stop the model, you can expand or contract lifelines and change the root of focus for the viewer.

### Expand a Parent Lifeline

In the message pane, a thick, gray lifeline indicates that you can expand the lifeline to see its children. To show the children of a lifeline, click the expander icon  below the header or double-click the parent lifeline.

For example, expanding the lifeline for the Traffic Light 1 block reveals two new lifelines corresponding to the Stateflow charts Ped Button Sensor and Controller.

### Expand a Masked Subsystem Lifeline

The Sequence Viewer window displays masked subsystems as white blocks. To show the children of a masked subsystem, point over the bottom left corner of the lifeline header and click the arrow.

For example, the GUI subsystem contains four masked subsystems: Traffic Lamp 1, Traffic Lamp 2, Ped Lamp 1, and Ped Lamp 2.

You can display the child lifelines in these masked subsystems by clicking the arrow in the parent lifeline header.

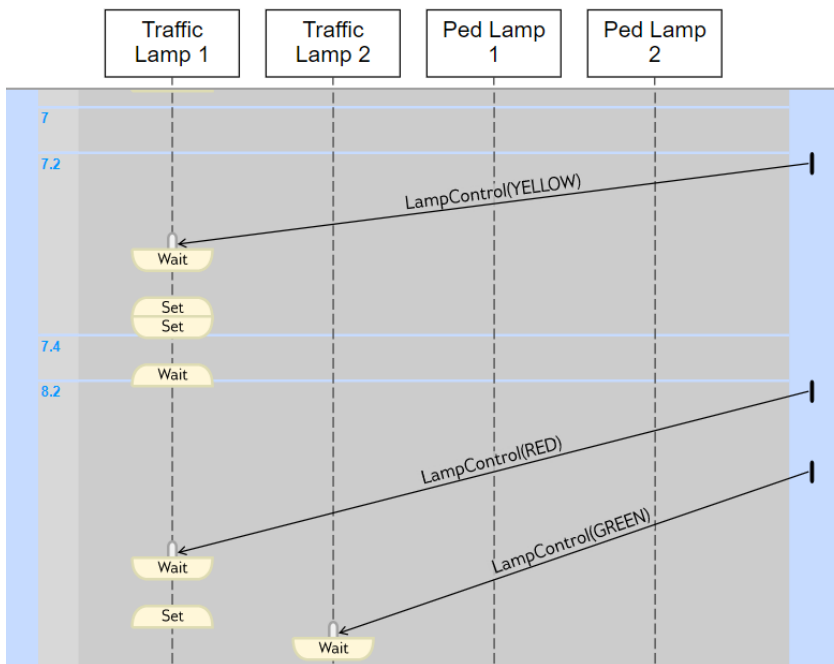

## Change Root of Focus

To make a lifeline the root of focus for the viewer, point over the bottom left corner of the lifeline header and click the arrow. Alternatively, you can use the navigation toolbar at the top of the Sequence Viewer window to move the current root up and down the lifeline hierarchy. To move the current root up one level, press the **Esc** key.

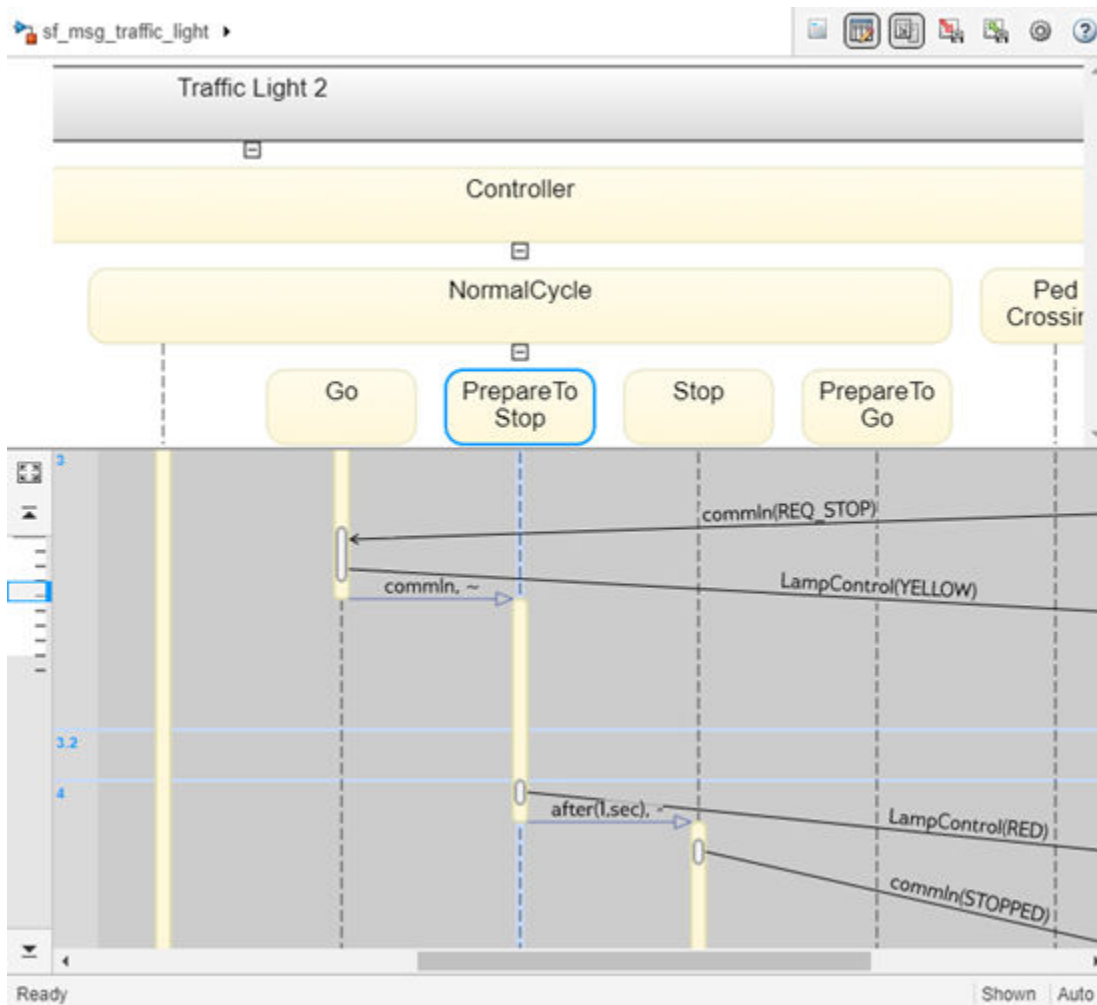

The Sequence Viewer window displays the current root lifeline path and shows its child lifelines. Any external events and messages are displayed as entering or exiting through vertical slots in the diagram gutter. When you point to a slot in the diagram gutter, a tooltip displays the name of the sending or receiving block.

## View State Activity and Transitions

To see state activity and transitions in the Sequence Viewer window, expand the state hierarchy until you have reached the lowest child state. Vertical yellow bars show which state is active. Blue horizontal arrows denote the transitions between states.

In this example, you can see a transition from Go to PrepareToStop followed, after 1 second, by a transition to Stop.

To display the start state, end state, and full transition label in the **Property Inspector**, click the arrow corresponding to the transition.

To display information about the interactions that occur while a state is active, click the yellow bar corresponding to the state. In the **Property Inspector**, use the **Search Up** and **Search Down** buttons to move through the transitions, messages, events, and function calls that take place while the state is active.

### View Function Calls

The Sequence Viewer displays function calls and replies. This table lists the type of support for each type of function call.

Function Call Type	Support
Calls to Simulink Function blocks	Fully supported.

Function Call Type	Support
Calls to Stateflow graphical or Stateflow MATLAB functions	<ul style="list-style-type: none"> <li>• Scoped — Select the <b>Export chart level functions</b> chart option. Use the <i>chartName.functionName</i> dot notation.</li> <li>• Global — Select the <b>Treat exported functions as globally visible</b> chart option. You do not need the dot notation.</li> </ul>
Calls to function-call subsystems	Fully supported and displayed.
Calls from MATLAB Function block	Supports displaying function call events with the limitation of calls crossing model reference boundaries.

The Sequence Viewer window displays function calls as solid arrows labeled with the format *function\_name(argument\_list)*. Replies to function calls are displayed as dashed arrows labeled with the format *[argument\_list]=function\_name*.

For example, in the model `slexPrinterExample`, a subsystem calls the Simulink Function block `addPrinterJob`. The function block replies with an output value of `false`.

To open this example, enter:

```
openExample("stateflow/ShareFcnsAcrossSLandSFExample")
```

## Simulation Time in the Sequence Viewer Window

The Sequence Viewer window shows events vertically, ordered in time. Multiple events in Simulink can happen at the same time. Conversely, there can be long periods of time during simulation with no events. As a consequence, the Sequence Viewer window shows time by using a combination of linear and nonlinear displays. The time ruler shows linear simulation time. The time grid shows time in a nonlinear fashion. Each time grid row, bordered by two blue lines, contains events that occur at the same simulation time. The time strip provides the times of the events in that grid row.

To show events in a specific simulation time range, use the scroll wheel or drag the time slider up and down the time ruler. To navigate to the beginning or end of the simulation, click the **Go to first event** or **Go to last event** buttons. To see the entire simulation duration on the time ruler, click the **Fit to view** button .

When using a variable step solver, you can adjust the precision of the time ruler. In the Model Explorer, on the **Main** tab of the Sequence Viewer Block Parameters pane, adjust the value of the **Time Precision for Variable Step** field.

## Redisplay of Information in the Sequence Viewer Window

The Sequence Viewer saves the order and states of lifelines between simulation runs. When you close and reopen the Sequence Viewer window, it preserves the last open lifeline state. To save a particular viewer state, click the **Save Settings** button  in the toolbar. Saving the model then saves that state information across sessions. To load the saved settings, click the **Restore Settings** button .

You can modify the **Time Precision for Variable Step** and **History** parameters only between simulations. You can access the buttons in the toolbar before simulation or when the simulation is paused. During a simulation, the buttons in the toolbar are disabled.

## Using Message Polling and Message Triggered Subsystems

This example shows how Message Polling Subsystem and Message Triggered Subsystem blocks operate and demonstrates the differences between them. Both Message Polling Subsystem and Message Triggered Subsystem blocks contain a Trigger block. Based on the configuration of the Trigger block, you can create these behaviors:

- Message Polling Subsystem block — The subsystem pulls messages from a queue periodically based on the sample time of the subsystem.
- Message Triggered Subsystem block in immediate mode — The message sender and the Message Triggered Subsystem are synchronized. The message sender invokes the subsystem by pushing messages.
- Message Triggered Subsystem block in scheduled mode — The execution order of the subsystem can be scheduled in the Schedule Editor to model an asynchronous behavior.

This example shows differences between these three modes and explains use cases for each mode.

Copyright 2021 The MathWorks, Inc.

### Overview

This model contains three identical message sources: Sender1, Sender2, and Sender3. Each source generates messages with payload values from two Repeating Stair Sequence blocks.

Sender1, Sender2, and Sender3 all have sample time of 1 and generate two messages at each time step. This figure shows the payload values of generated messages. The sequence repeats starting at time step 6.

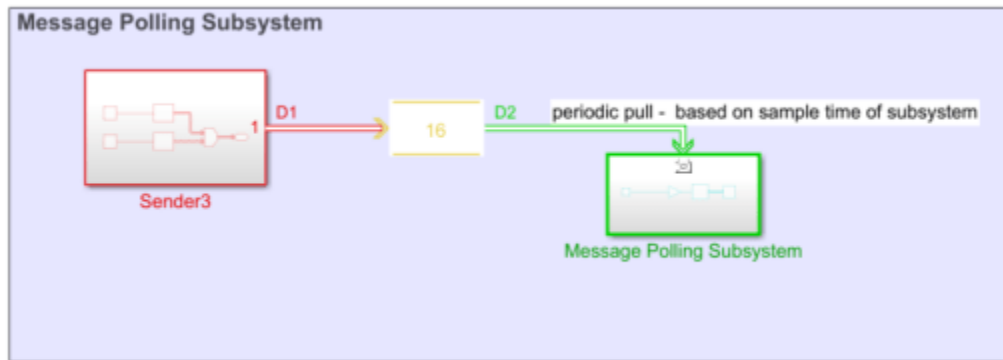

Inside each message receiving subsystem, the message payload is read, multiplied by 2 using a Gain block, and used as the payload for a message.

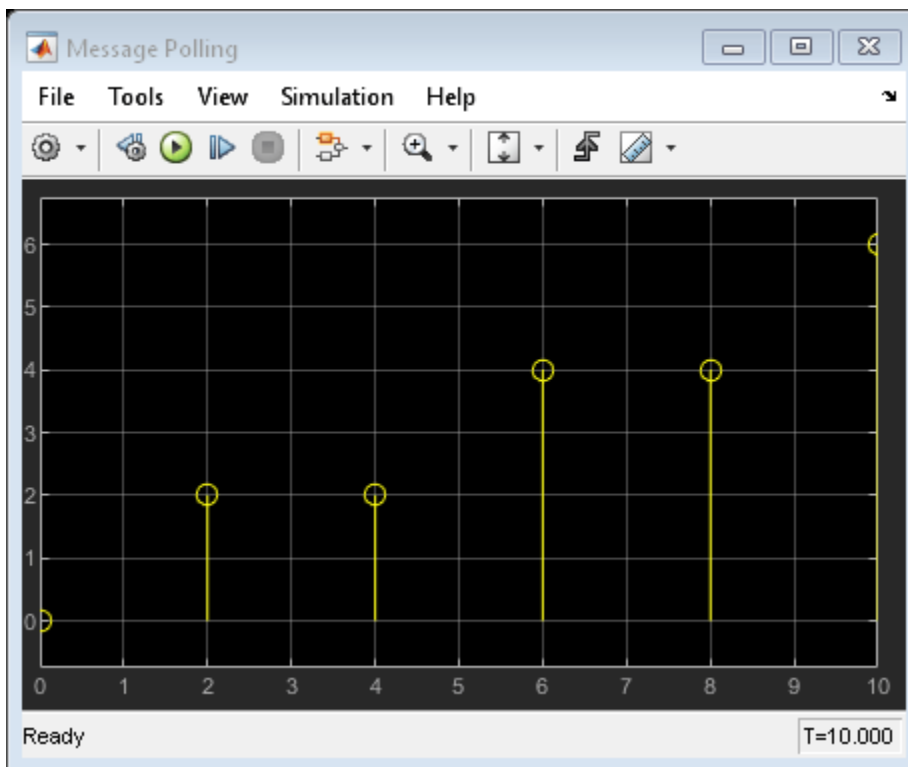

### Message Polling Subsystem

Use a Message Polling Subsystem block when you want to define the rate of the subsystem block when pulling messages. The block pulls a message from a queue based on its sample time, and the sample time can be specified on the subsystem block parameter. The block can pull only one message at each time step. You can configure the block to pull messages with a slower or faster rate.

In this example, the Message Polling Subsystem block has a sample time of 2. In each time step, the block checks for available messages at the Queue block. If a message is available, the Message Polling Subsystem block pulls one message and executes. A Queue block operating in FIFO mode with a capacity of 16 stands between the message sender and the Message Polling Subsystem block. This figure shows that the subsystem pulls messages with a slower rate using the sample times.

The scope output shows that the subsystem pulls and processes only one message every 2 time units, whereas two messages are sent to the Queue block at each time unit. During simulation, the Queue block fills up, and some messages are lost.

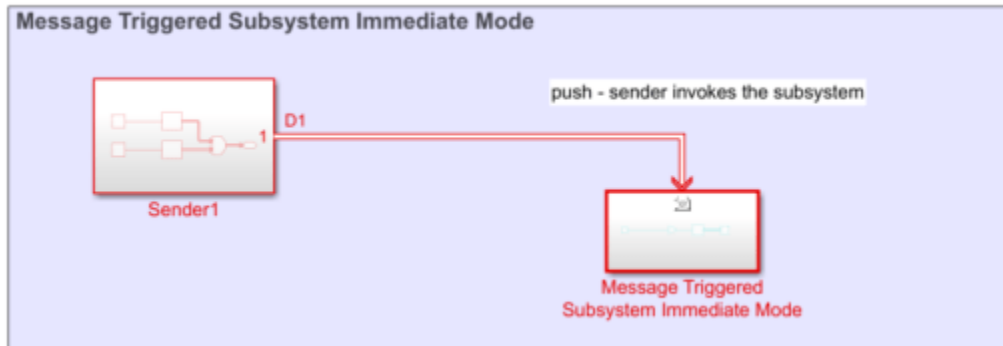

### Message Triggered Subsystem in Immediate Mode

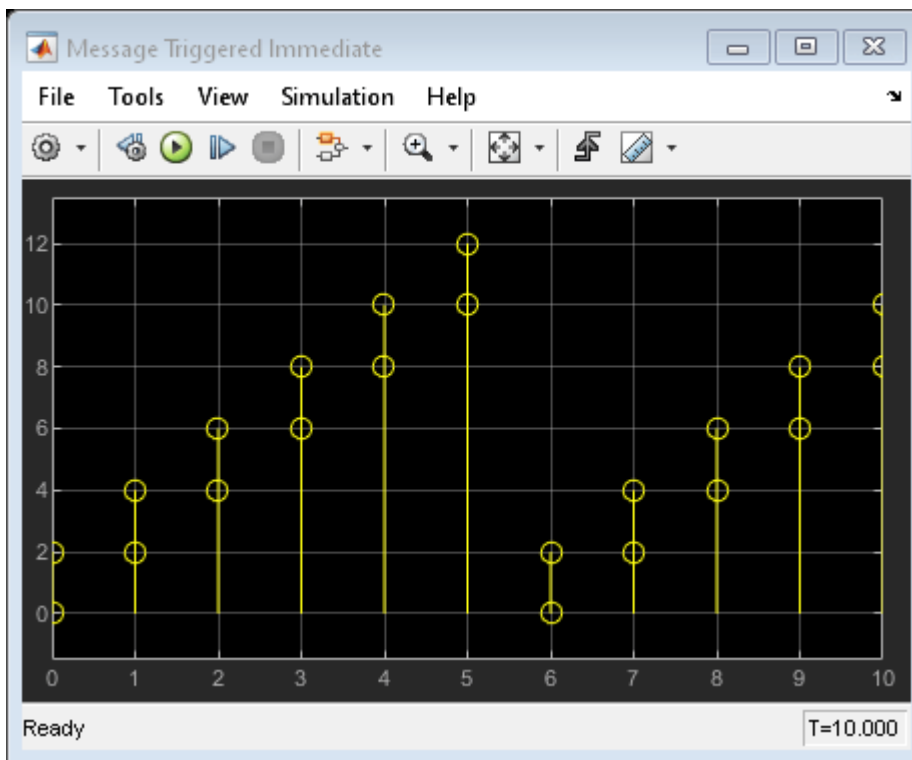

The first Message Triggered Subsystem block operates in immediate mode. That is, in the Trigger block inside the subsystem, the **Schedule as aperiodic partition** check box is not selected. Use this mode to represent the simple cases when you do not have to schedule the subsystem execution. In this configuration, the message sender invokes the Message Triggered Subsystem block for execution by pushing the available messages to the subsystem. The subsystem executes as soon as a message is pushed by the sender. If you use a Message Triggered Subsystem block in immediate mode, you do not have to use a Queue block between the message sender block and the subsystem. This mode supports code generation for the top model and its components. In the generated code, the

subsystem acts as a function that takes the message payload as an argument and is called by the sender.

This figure shows that the sample times are synchronized because the sender invokes the subsystem.

The scope output shows that the subsystem receives and processes two messages at each time unit.

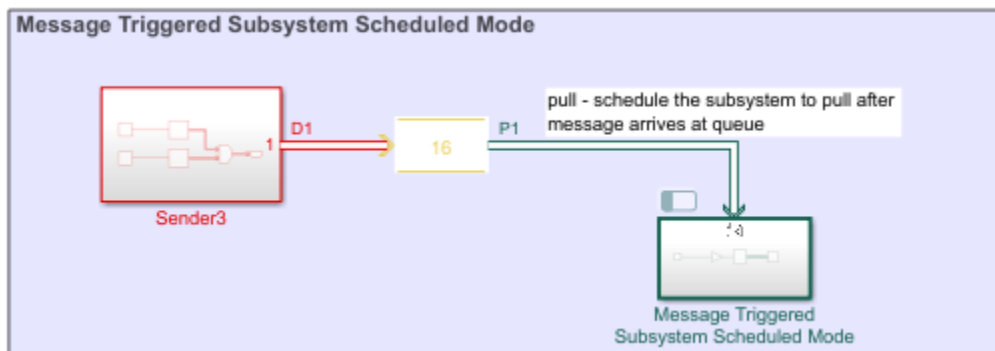

### Message Triggered Subsystem in Scheduled Mode

The second Message Triggered Subsystem block operates in scheduled mode. That is, in the Trigger block inside the subsystem, the **Schedule as aperiodic partition** check box is selected, which is the default configuration. Aperiodic partitions are partitions that are not necessarily periodically triggered or bound to a periodic time trigger and can be bound to an event. This mode allows you to schedule the execution of the subsystem using the Schedule Editor. For more information, see “Using the Schedule Editor” on page 25-11. In this case, the top model does not support code generation

because scheduling does not support code generation. However, you can move the Message Triggered Subsystem block inside a referenced model and connect to the root Inport and generate code for that component alone, which can then be integrated with the message middleware.

In this example, a Queue block operating in FIFO mode stands between the message source and the Message Triggered Subsystem block. When a message arrives at the Queue block, the message raises an event that triggers the Message Triggered Subsystem block to pull the message from the Queue block. Then, the subsystem pulls the message based on the message availability and the schedule. This figure shows the sample times of the message sender and the Message Triggered Subsystem block.

For example, this figure shows the Schedule Editor displaying the Message Triggered Subsystem block that is scheduled to execute first. In this case, a message arrives at the Queue block based on D1, and this event triggers the Message Triggered Subsystem to pull the message. The Message Triggered Subsystem pulls the message as soon as it arrives at the Queue block because it is scheduled first in the order. In this case, the Message Triggered Subsystem in scheduled mode behaves identically to a Message Triggered Subsystem in immediate mode. However, scheduled mode allows you change the order and schedule the execution of the subsystem based on your modeling requirements.

Simulate the model. The scope output shows that the Message Triggered Subsystem receives and processes two messages at each sample time hit.

## Asynchronous Message Handling in Adaptive Cruise Control

This example shows how to model an event-based adaptive cruise control (ACC) system using messages and message-triggered subsystems to reduce communication traffic and increase system efficiency. Components representing the physical system and control logic are simplified to show how sensory events can asynchronously trigger the ACC system. The model includes a front radar. The radar detects the distance between the vehicle and the vehicle ahead and identifies events for braking and acceleration. Then, the radar sends messages (in adaptive AUTOSAR this corresponds to adaptive events) to the ACC system. The ACC system converts messages to control signals and sends them to the brake actuator and powertrain to control the braking and acceleration of the vehicle. The model allows you how to manually brake or accelerate and observe the vehicle speed and engine rpm. For more information about messages, see “Simulink Messages Overview” on page 11-2.

Using this model, you can generate adaptive AUTOSAR code for the ACCModule component when you open the component as a top model. The DistanceSensorModule (inside FrontRadarSensor), BrakeControlModule (inside BrakeActuator), and PowertrainControlModule (inside Powertrain) components can generate classic AUTOSAR code when you open them as the top model. These reference models are highlighted with blue.

For more information about modeling adaptive cruise control logic, see “Collision Avoidance Assistance” (Automated Driving Toolbox).

Simplified Event-Based Adaptive Cruise Control System Using Messages

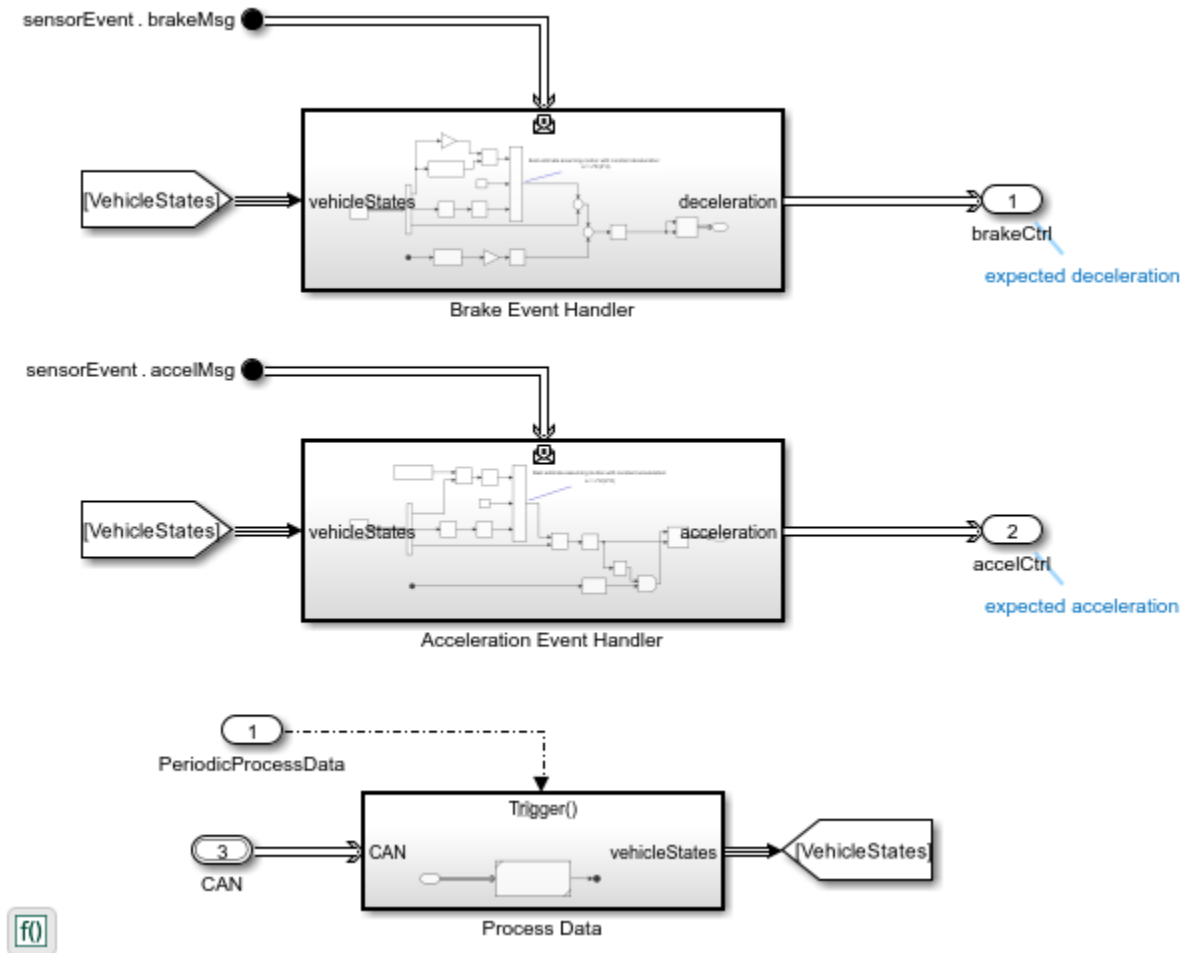

Copyright 2022 The MathWorks, Inc.

### Adaptive Cruise Control Module

In the model, the ACCModule component is subscribed to sensor (radar) events. The ACCModule has two Message Triggered Subsystem blocks, Brake Event Handler and Acceleration Event Handler. The subsystems respond to the braking and acceleration events asynchronously. In real applications, invoking event handlers is usually done by message middleware, and the order of execution can be random depending on the environment. However, in simulations, you can schedule the execution of your model partitions and generate deterministic results. To test the behavior of your model for various simulation scenarios, change the order of execution of your model partitions. To

create such model partitions in this model, Message Triggered Subsystem blocks are used in scheduled mode. In scheduled mode, you can schedule the execution of the subsystems as aperiodic partitions using the Schedule Editor. The subsystems pull and process the data based on a schedule instead of periodic execution, which reduces communication traffic and increases system efficiency.

In the ACCModule component, the Function-Call Subsystem Process Data periodically reads the CAN bus and generates the data of vehicle states. The data is used by the two Message Triggered Subsystems Brake Event Handler and Acceleration Event Handler. You can set the period of the Process Data component by using the **Sample time** parameter of the root Inport block.

The ACCModule component is an export-function model. This modeling pattern also allows you to generate code for independent functions that can be integrated with an external environment and scheduler. For more information about export-function models, see “Export-Function Models Overview” on page 10-96. Because the ACCModule component is an AUTOSAR adaptive software component, it acts as message middleware and can generate code to be asynchronously triggered via the AUTOSAR adaptive platform.

## Schedule Message-Triggered Subsystem Execution Using Schedule Editor

Open the Schedule Editor to observe the partitions of the model, including the message-triggered subsystems `ACCMModule.AccelerationEventHandler` and `ACCMModule.BrakeEventHandler`. For more information about the **Schedule Editor** tool, see “Using the Schedule Editor” on page 25-11.

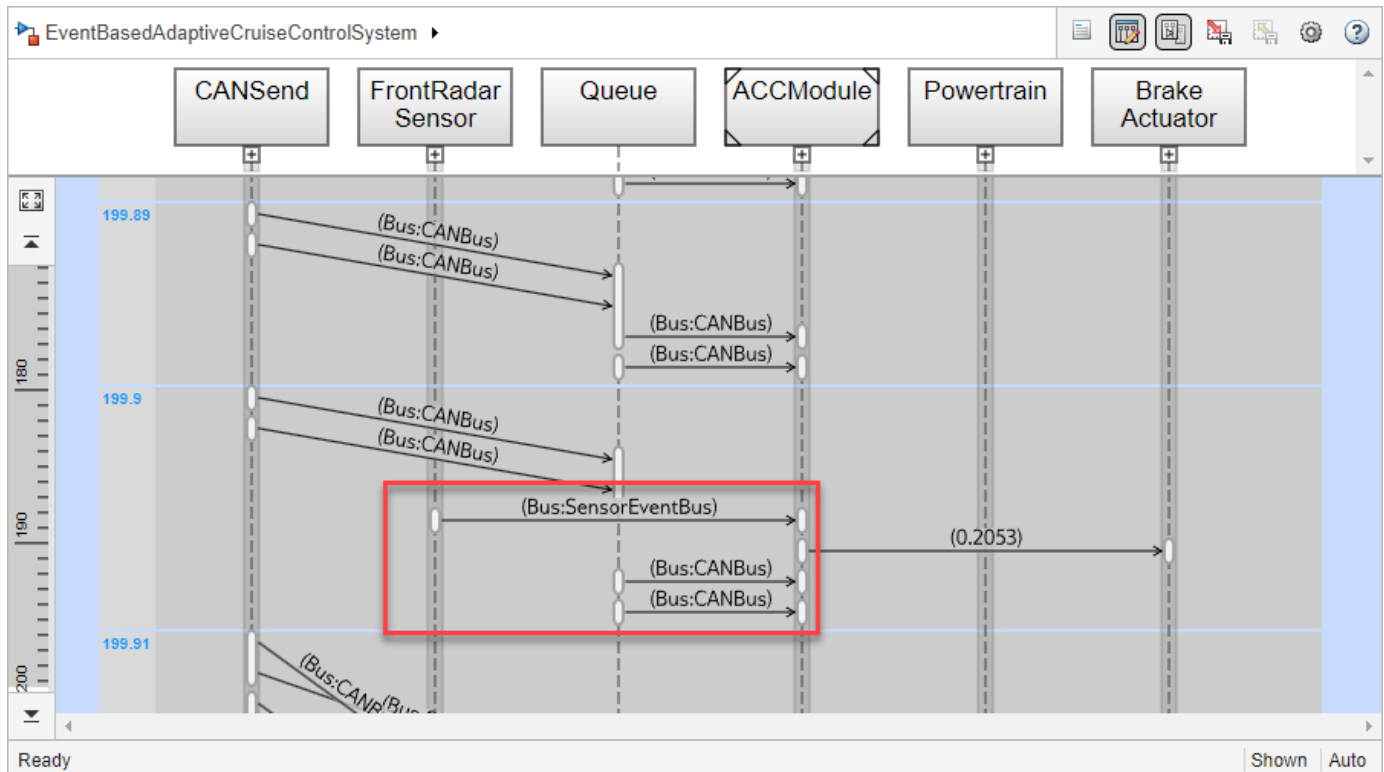

You can use the **Schedule Editor** tool to change the order of the execution of the partitions so that when multiple partitions (tasks) are scheduled to be executed at the same time, the higher priority task is executed first. If a lower priority task is already running, the higher priority task preempts the lower priority one.

## Simulate Model and Review Results

Simulate the model. Open the **Sequence Viewer** tool to observe the interchange of messages and event triggering between the blocks and components in your model. Also, you can see the order of the interchanges based on the current order of execution priority. In the current order, the `ACCMModule.AccelerationEventHandler` and the `ACCMModule.BrakeEventHandler` partitions have higher priority. The message from `FrontRadarSensor` with the `SensorEventBus` payload is transitioned to the `ACCMModule` component and triggers the corresponding Message Triggered Subsystem prior to the `CANBus` messages as shown in the red box. For more information about the **Sequence Viewer** tool, see “Use the Sequence Viewer to Visualize Messages, Events, and Entities” on page 11-76.

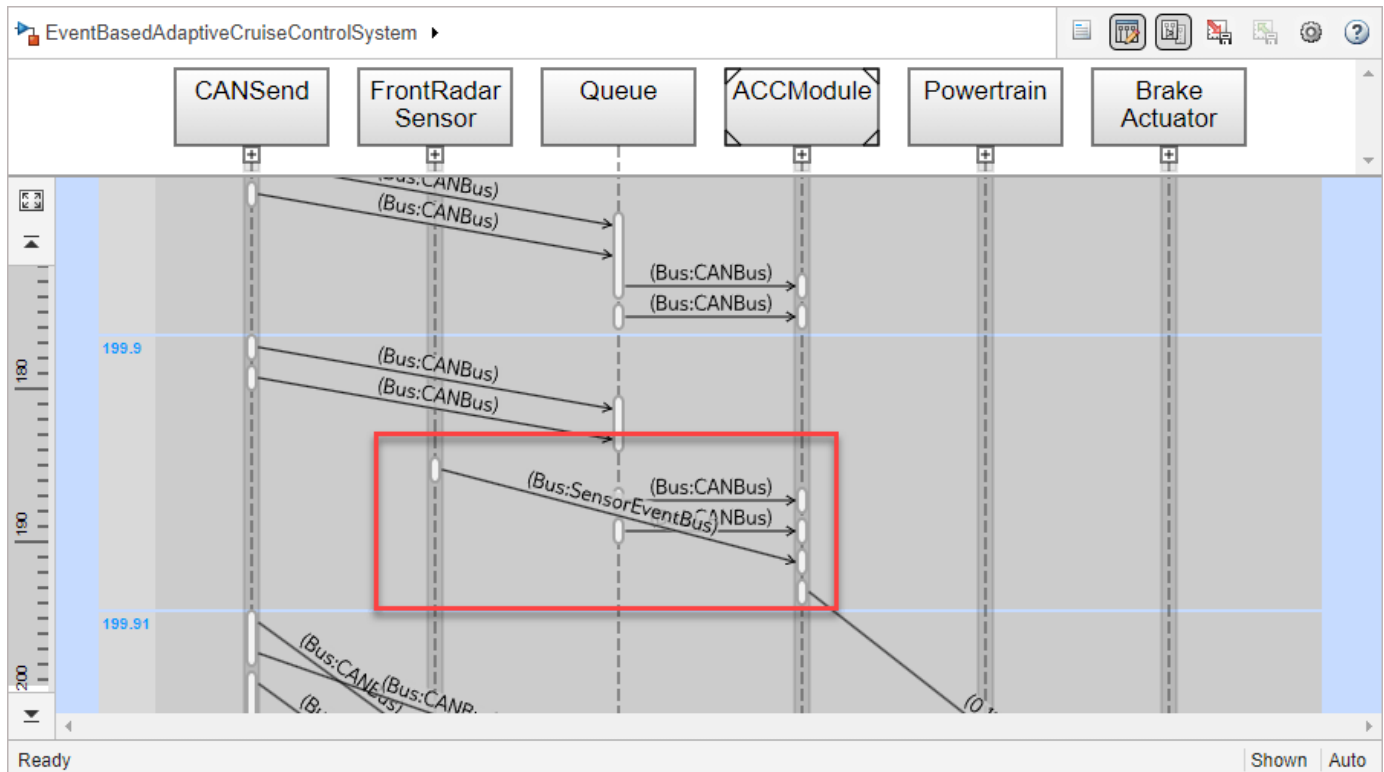

You can change the order of priority so that the asynchronous event handlers have lower priority. In this order, Process Data subsystem executes first and provides the latest vehicle state to the message triggered subsystems.

Order	Name	Trigger
1	Cont <i>implicit</i>	0
	FiM <i>implicit</i>	[0, 1]
	D1 <i>implicit</i>	0.01
	D2 <i>implicit</i>	0.1
	V1 <i>implicit, empty</i>	-2
	V2 <i>implicit, empty</i>	[-2, 1]
	V3 <i>implicit, empty</i>	[-2, 2]
2	V4 <i>implicit, empty</i>	[-2, 3]
	V5 <i>implicit, empty</i>	[-2, 4]
2	ACCModule.PeriodicProcessData	0.01
3	ACCModule.AccelerationEventHandler	ACCMo
4	ACCModule.BrakeEventHandler	ACCMo

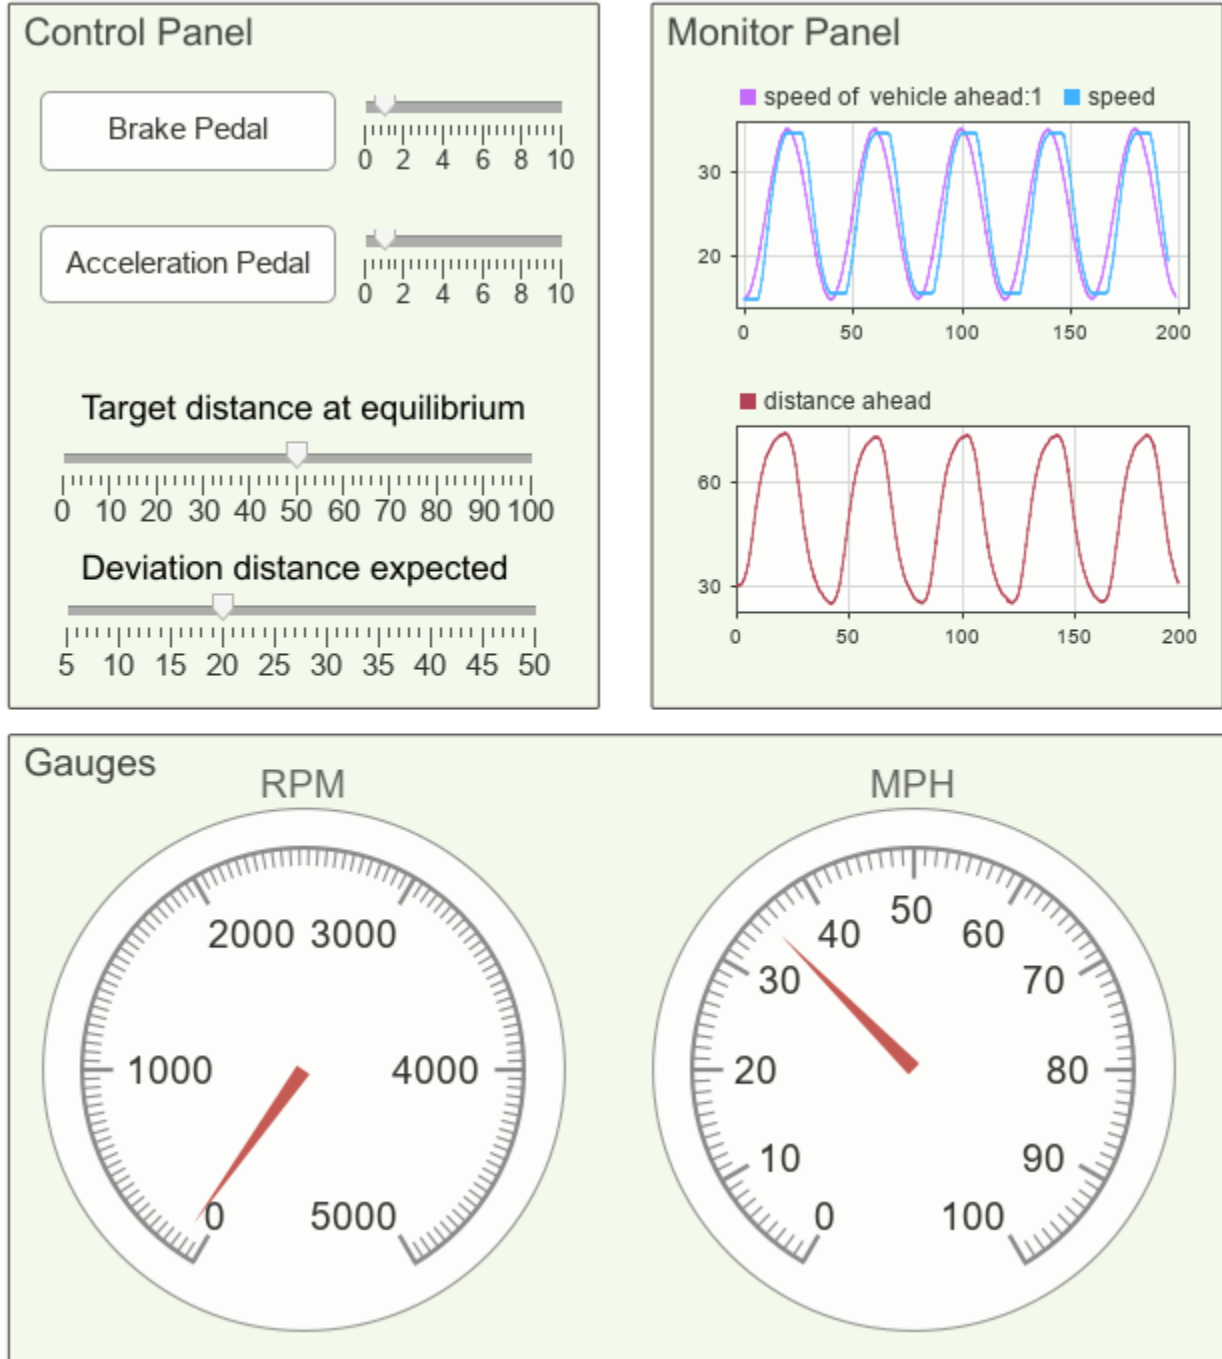

If you simulate the model again, you can observe that the transition from FrontRadarSensor to ACCModule occurs after the CANBus messages.

**Review Results of Simulation**

Open the Dashboard component to manually control the vehicle and review the results.

- The Monitor Panel shows the speed of the vehicle and the speed of the vehicle ahead. It also displays the distance between the vehicles.
- The Control Panel allows you to manually stop or accelerate the vehicle. You can also specify the target distance between the vehicles at the equilibrium along with the expected deviation.
- Gauges display the engine rpm and the vehicle speed in mph.

### Use Manual Break Pedal

Simulate the model again. Press the **Brake Pedal** in the Control Panel after 50 seconds. Release the pedal around 150 seconds. Observe the vehicle speed and distance between the vehicles during and after your manual brake.

“Working with Variants” on page 12-11

### What Are Variants?

In Model-Based Design workflows, creating multiple design variations for system components is essential to meet different sets of requirements. These requirements can cater to diverse market needs, customer preferences, or geographical features. Throughout the development lifecycle, from requirements to deployment, you may need to switch between these design choices.

Simulink variant capabilities allow you to represent all design alternatives of a system in a single model. Each design choice is incorporated into the model as a variant choice. Such models have a fixed common structure and a finite set of variable components that are activated depending on the variant choice. This model shows how Variant Source blocks help you implement variant choices for the input signals to a system. The inactive choice appears faded.

For an example, see “Use Variants to Create One Model for Many Systems” on page 12-9.

### Advantages of Using Variants

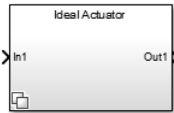

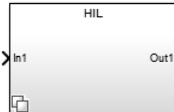

Using variants in Model-Based Design provides several advantages:

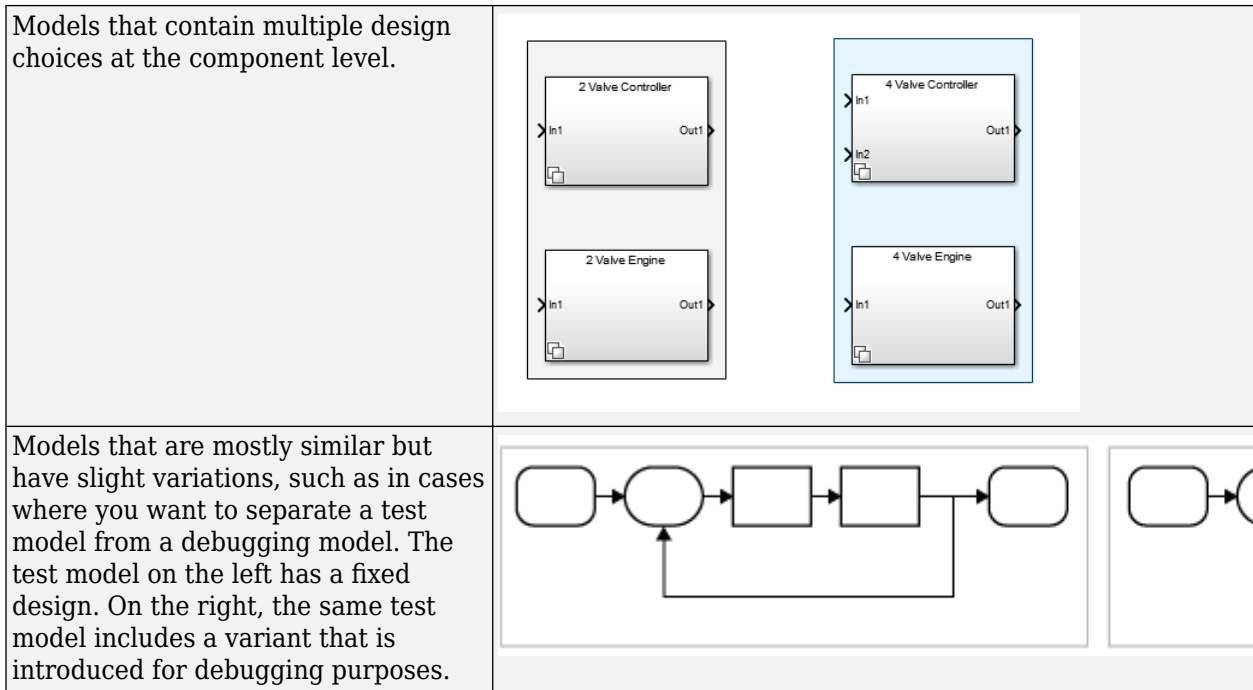

- Variants allow you to design one model for many systems.
- You can rapidly prototype design possibilities as variants without having to comment out sections of your model.
- Variants help you develop modular design platforms for reuse and customization. This approach improves workflow speed by reducing complexity.
- If a model component has several alternative configurations, you can explore the alternatives without altering the fixed components.
- You can use different variant configurations for simulation or code generation from the same model.
- You can simulate every design possibility for a given test suite.
- If you are working with large-scale designs, you can distribute the process of testing these designs on a cluster of multicore computers. Alternatively, you can map different test suites to design alternatives for efficient management of design-specific tests.
- You can generate a reduced model for a subset of variant configurations from a model with many variants.

## When to Use Variants

Here are three scenarios where you can use variants.

<p>Models that represent multiple simulation, code generation, or testing workflows.</p>	<div style="text-align: center;">  <p><b>Figure 1.</b> Model of an ideal actuator for basic simulation.</p> </div> <div style="text-align: center;">  <p><b>Figure 2.</b> Detailed actuator for simulating customizations.</p> </div> <div style="text-align: center;">  <p><b>Figure 3.</b> Model that is configured for Hardware-in-the-Loop simulation.</p> </div>
--	---

## Types of Variants in Simulink

Variant blocks help you represent multiple structural or algorithmic implementations of a system component in a single model and allow you to switch between them as per requirements. For an overview of the types of variant blocks in Simulink, see “Variant Blocks in Simulink” on page 12-7.

Variant parameters help you implement design variations that require varying values for block parameters. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 12-175.

Variant transitions allow you to transition to multiple design configurations within the same Stateflow chart. For more information, see “Create Variant Configurations in Stateflow Charts” (Stateflow).

Dimension variants allow you to specify symbolic dimensions that vary based on variant conditions. See “Implement Symbolic Dimensions for Array Sizes in Generated Code” (Embedded Coder).

AUTOSAR variants enable you to use variant blocks to implement AUTOSAR software components with variation points. See “Model AUTOSAR Variants” (AUTOSAR Blockset).

---

**Tip** For a list of examples that show variant capabilities in Simulink, see “V-Model for System Development with Simulink Variants” on page 12-151.

To see definitions for key terms and parameters used with variants, see “Variant Terminology” on page 12-21.

For examples that show variant code generation capabilities, see “Variant Systems” (Embedded Coder).

---

## Variant Blocks in Simulink

Use these variant blocks depending on the model design:

- Hierarchical variant blocks to create multiple implementations of a component in a separate hierarchy in the model.
- Inline variant blocks to represent all variant implementations at the same level in the model.
- Event-based variants to use variants to model context-dependent system behaviors.

Type of Variant	Variant Block	Use
Hierarchical variant blocks	Variant Subsystem	<p>The Variant Subsystem block is a template preconfigured with Subsystem blocks to represent the variant choices.</p> <p>The Variant Subsystem block allows a combination of Subsystem blocks, Model blocks, or Subsystem Reference blocks as variant choices.</p>
	Variant Model	<p>The Variant Model block is a template preconfigured with two Model blocks to represent the variant choices.</p> <p>The Variant Model block allows a combination of Subsystem blocks, Model blocks, or Subsystem Reference blocks as variant choices.</p>
	Variant Assembly Subsystem	<p>The Variant Assembly Subsystem block enables you to add or remove its variant choices from external files.</p> <p>The Variant Assembly Subsystem allows a combination of Model blocks, or Subsystem Reference blocks as variant choices.</p>
Inline variant blocks	Variant Source	The Variant Source block allows you to define variant choices as block regions connected to each of its inports. The block provides variation on the source of a signal.
	Variant Sink	The Variant Sink block allows you to define variant choices as block regions connected to each of its outports. The block provides variation on the destination of a signal.
	Manual Variant Source	The Manual Variant Source block is a toggle switch that allows you to define multiple variant choices at its inports.

Type of Variant	Variant Block	Use
	Manual Variant Sink	The Manual Variant Sink block is a toggle switch that allows you to define multiple variant choices at its outputs.
	Variant Connector	The Variant Connector block lets you define variant choices in a physical network. You can switch between components in the network during simulation without having to physically remove the components or exclude them from simulation.
Event-based variants	Simulink Function	The variant functionality in the Simulink Function block allows the block to be conditionally available. You can specify variant conditions on the function call port block or the block can inherit the condition from its function caller blocks.
	Initialize Function, Reset Function, and Terminate Function blocks	The variant functionality in Initialize, Reset, and Terminate blocks allow the blocks to be conditionally available. You can specify variant conditions on the event listener block.

### Compare Variant Blocks

This table presents a comparison between hierarchical and inline variant blocks.

Feature	Variant Source and Variant Sink blocks	Variant Subsystem and Variant Model blocks
Variant choice representation	Number of ports	Subsystem, Model, or Subsystem Reference blocks
Allows to implement variant choices in a separate hierarchy	No	Yes
Supports flexible number of inputs and outputs among variant choices (the choices do not have similar interface)	No	Yes, if the <b>Propagate conditions outside of variant subsystem</b> parameter is set to on.
Option to specify default variant	Yes	Yes
Supports control ports	No	Yes
Can be saved as standalone file	No	No
Supports Connection Port used for modeling physical connection lines	No	Only when the <b>Variant activation time</b> parameter is set to update diagram.

Feature	Variant Source and Variant Sink blocks	Variant Subsystem and Variant Model blocks
Comment a variant choice (by adding the % symbol before the variant control in the Block Parameters dialog box)	No	Yes

## Use Variants to Create One Model for Many Systems

This example shows variant design in a Simulink model. Consider the requirement to model a system that represents an automobile with several configurations. These configurations, although similar in several aspects, can differ in properties such as fuel consumption, motor type, or emission standard.

Instead of designing separate models for each configuration, you can represent the configurations as variant choices in a single model. You can choose to activate any one of the variant choices based on your requirements. This approach keeps the common components fixed.

This model contains a Variant Subsystem block, `Motor Variant Subsystem`, that represents the motor of the vehicle. The motor has two possible configurations, `Gas` and `Electric`, that are represented as variant choices within the Variant Subsystem block. A Variant Subsystem block adapts its interface according to the state of the underlying blocks. Here, the `Electric` motor does not have an `exhaust temperature` input. When you activate the `Electric` variant, Simulink automatically disables the corresponding port on the `Motor Variant Subsystem` and any other model components associated with that input.

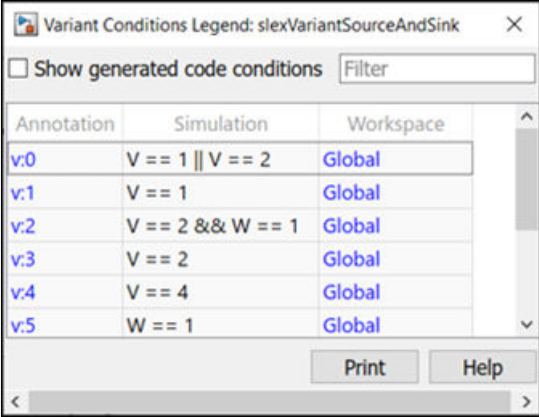

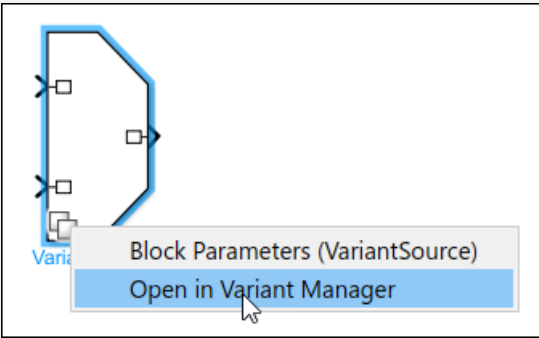

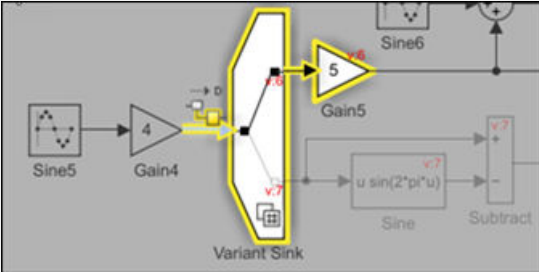

For the exhaust temperature sensor for this model, consider the need to switch between five different sensors provided by two vendors. You can use Variant Source blocks to represent all the choices in the same model and activate only one choice at a time.

## Working with Variants

### Visual Elements in Variant Models

Visual Element	Use																					
Variant Condition Legend	<p>The Variant Condition Legend dialog box helps you visualize the variant conditions applied on the model. Simulink annotates model components that have variant conditions, and the Variant Condition Legend displays the conditions for each annotation. See “Visualize Propagated Variant Conditions Using Variant Conditions Legend” on page 12-256.</p>  <table border="1" data-bbox="678 743 1149 974"> <thead> <tr> <th>Annotation</th> <th>Simulation</th> <th>Workspace</th> </tr> </thead> <tbody> <tr> <td>v:0</td> <td>V == 1    V == 2</td> <td>Global</td> </tr> <tr> <td>v:1</td> <td>V == 1</td> <td>Global</td> </tr> <tr> <td>v:2</td> <td>V == 2 &amp;&amp; W == 1</td> <td>Global</td> </tr> <tr> <td>v:3</td> <td>V == 2</td> <td>Global</td> </tr> <tr> <td>v:4</td> <td>V == 4</td> <td>Global</td> </tr> <tr> <td>v:5</td> <td>W == 1</td> <td>Global</td> </tr> </tbody> </table>	Annotation	Simulation	Workspace	v:0	V == 1    V == 2	Global	v:1	V == 1	Global	v:2	V == 2 && W == 1	Global	v:3	V == 2	Global	v:4	V == 4	Global	v:5	W == 1	Global
Annotation	Simulation	Workspace																				
v:0	V == 1    V == 2	Global																				
v:1	V == 1	Global																				
v:2	V == 2 && W == 1	Global																				
v:3	V == 2	Global																				
v:4	V == 4	Global																				
v:5	W == 1	Global																				
Variant Badges	<p>Each variant block displays a badge that changes with different parameter values set on the block. See “Variant Badges” on page 12-12.</p> 																					

Visual Element	Use
<p>Variant Fading and Signal Highlighting</p>	<p>The color of inactive variant choices fades by default. You can choose to disable the fading effect by using the <b>Variant Fading</b> option in the <b>Information Overlays</b> menu on the <b>Debug</b> tab of the Simulink Editor.</p> <p>Highlighting a signal that passes through variant blocks highlights the path of the active variant choice. See “Signal Highlighting in Variant Systems” on page 80-31.</p> 

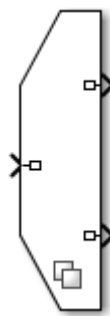

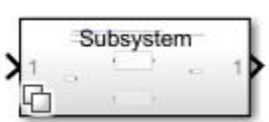

### Variant Badges

Each variant block displays a badge. The color and icon of the variant badge changes according to values of these parameters set on the block:

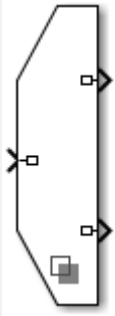

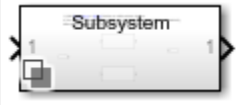

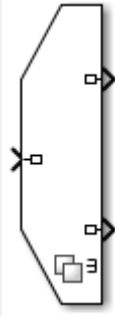

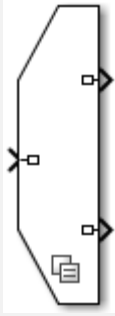

- **Variant activation time**
- **Variant control mode**
- **Allow zero active variant controls** (for Variant Source and Variant Sink blocks)
- **Propagate conditions outside of variant subsystem** (for Variant Subsystem block)

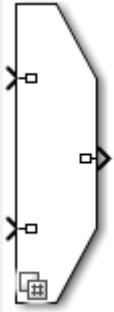

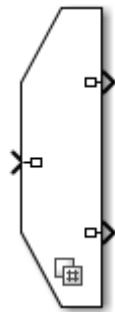

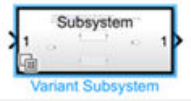

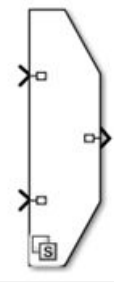

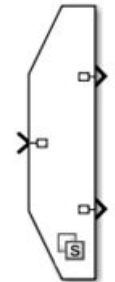

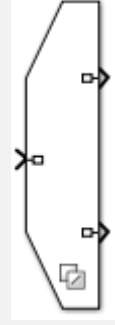

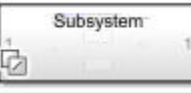

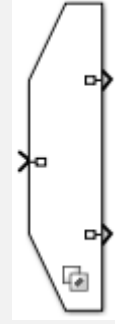

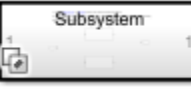

Variant Badges also provide quick access to some variant commands. Right-click the variant badge to access these commands.

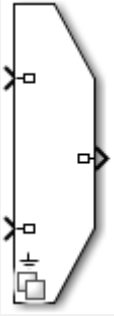

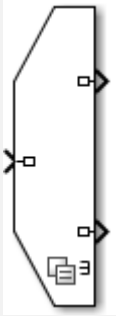

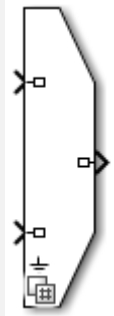

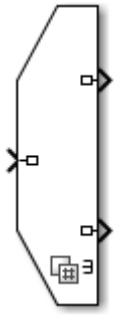

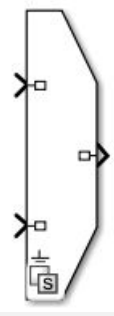

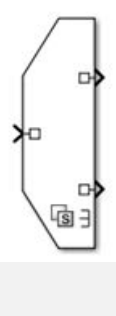

### Variant Badge Icons for Different Settings on Variant Blocks

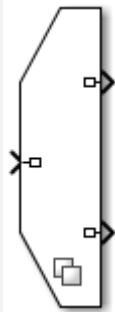

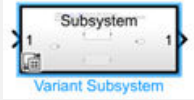

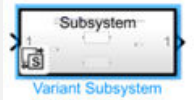

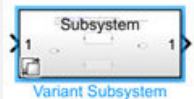

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
<p>Default Variant badge when no option is selected.</p>			

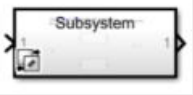

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
<p>Variant block with Label selected as <b>Variant control mode</b> and an active variant choice is selected from <b>Label mode active choice</b> option.</p>			
<p>Variant block with <b>Allow zero active variant controls</b> option selected.</p>			
<p>Variant block with expression selected as <b>Variant control mode</b> and update diagram selected as <b>Variant activation time</b>.</p>			
<p>Variant block with expression selected as <b>Variant control mode</b> and update diagram analyze all choices selected as <b>Variant activation time</b>.</p>			

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
<p>Variant block with expression selected as <b>Variant control mode</b> and code compile selected as <b>Variant activation time</b>.</p>			
<p>Variant block with expression selected as <b>Variant control mode</b> and startup selected as <b>Variant activation time</b>.</p>			
<p>Variant block with sim codegen switching selected as <b>Variant control mode</b> and update diagram selected as <b>Variant activation time</b>.</p>			
<p>Variant block with sim codegen switching selected as <b>Variant control mode</b> and update diagram analyze all choices selected as <b>Variant activation time</b>.</p>			
<p>Variant block with <b>Propagate conditions outside of variant subsystem</b> option selected.</p>	<p>Not applicable</p>	<p>Not applicable</p>	

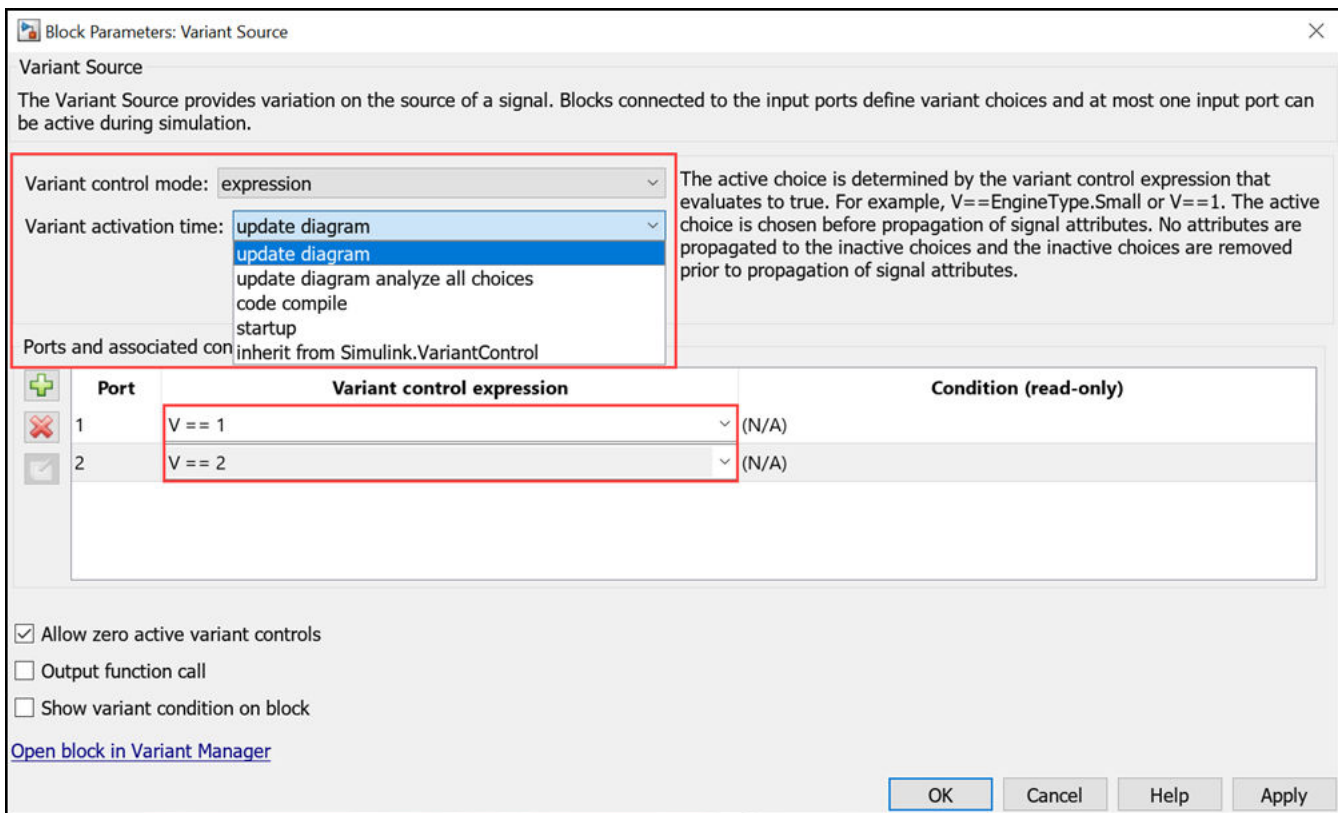

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
<p>Variant block with update diagram selected as <b>Variant activation time</b> and <b>Allow zero active variant controls</b> option selected.</p>			
<p>Variant block with update diagram analyze all choices selected as <b>Variant activation time</b> and <b>Allow zero active variant controls</b> option selected.</p>			
<p>Variant block with code compile selected as <b>Variant activation time</b> and <b>Allow zero active variant controls</b> option selected.</p>			
<p>Variant block with startup selected as <b>Variant activation time</b> and <b>Allow zero active variant controls</b> option selected.</p>			

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
<p>Variant block with inherit from Simulink.VariantControl selected as <b>Variant activation time</b> before model compile.</p>			
<p>Variant block with update diagram selected as <b>Variant activation time</b> and <b>Propagate conditions outside of variant subsystem</b> option selected.</p>	<p>Not applicable</p>	<p>Not applicable</p>	
<p>Variant block with update diagram analyze all choices selected as <b>Variant activation time</b> and <b>Propagate conditions outside of variant subsystem</b> option selected.</p>	<p>Not applicable</p>	<p>Not applicable</p>	
<p>Variant block with code compile selected as <b>Variant activation time</b> and <b>Propagate conditions outside of variant subsystem</b> option selected.</p>	<p>Not applicable</p>	<p>Not applicable</p>	
<p>Variant block with startup selected as <b>Variant activation time</b> and <b>Propagate conditions outside of variant subsystem</b> option selected.</p>	<p>Not applicable</p>	<p>Not applicable</p>

Variant block with sim codegen switching selected as <b>Variant control mode</b> and <b>Propagate conditions outside of variant subsystem</b> option selected.	Not applicable	Not applicable	

### Define and Control Variant Choices

You must associate each variant choice in a model with a variant control that is used to determine if the choice is active or inactive. For variant blocks, you can choose the mode in which you want to specify the variant controls using the **Variant control mode** parameter. For more information, see “Introduction to Variant Controls” on page 12-36.

### Automatically Identify Variant Regions Using Variant Condition Propagation

Simulink determines the model components that are active during simulation by the process of variant condition propagation. This process evaluates the variant controls specified on the variant blocks and automatically propagates the variant conditions to the connecting blocks. Variant conditions can propagate through signal lines, buses, and function calls. The process deactivates the model components associated with the inactive choices and they are not included in simulation. You can stop condition propagation to define variant regions in the model. See “Variant Condition Propagation Overview” on page 12-256.

### Choose a Variant Activation Time

You can also choose when the active variant choice is determined using the **Variant activation time** parameter. This parameter also determines how the active and inactive choices participate in the simulation and code generation workflows. See “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

---

**Note** You can choose the variant activation time for a variant block only when **Variant control mode** is set to expression.

Manual Variant Source and Manual Variant Sink blocks do not support variant controls and variant activation time. They determine the active variant choice based on the active inports and outports, respectively.

Variant Connector blocks do not support variant activation time.

---

### Manage All Variants Using Variant Manager

Variant Manager is a tool that allows you to visualize the model hierarchy and centrally manage the usage of variant elements across the hierarchy.

The tool is available as a support package named Variant Manager for Simulink with these main capabilities:

- Variant Manager — Visualize the model hierarchy, manage the usage of variant elements across the hierarchy, create and manage variant configurations.
- Variant Reducer — Generate a reduced model that contains only selected variant configurations.
- Variant Analyzer — Compare and contrast variant configurations to identify errors or inconsistencies.

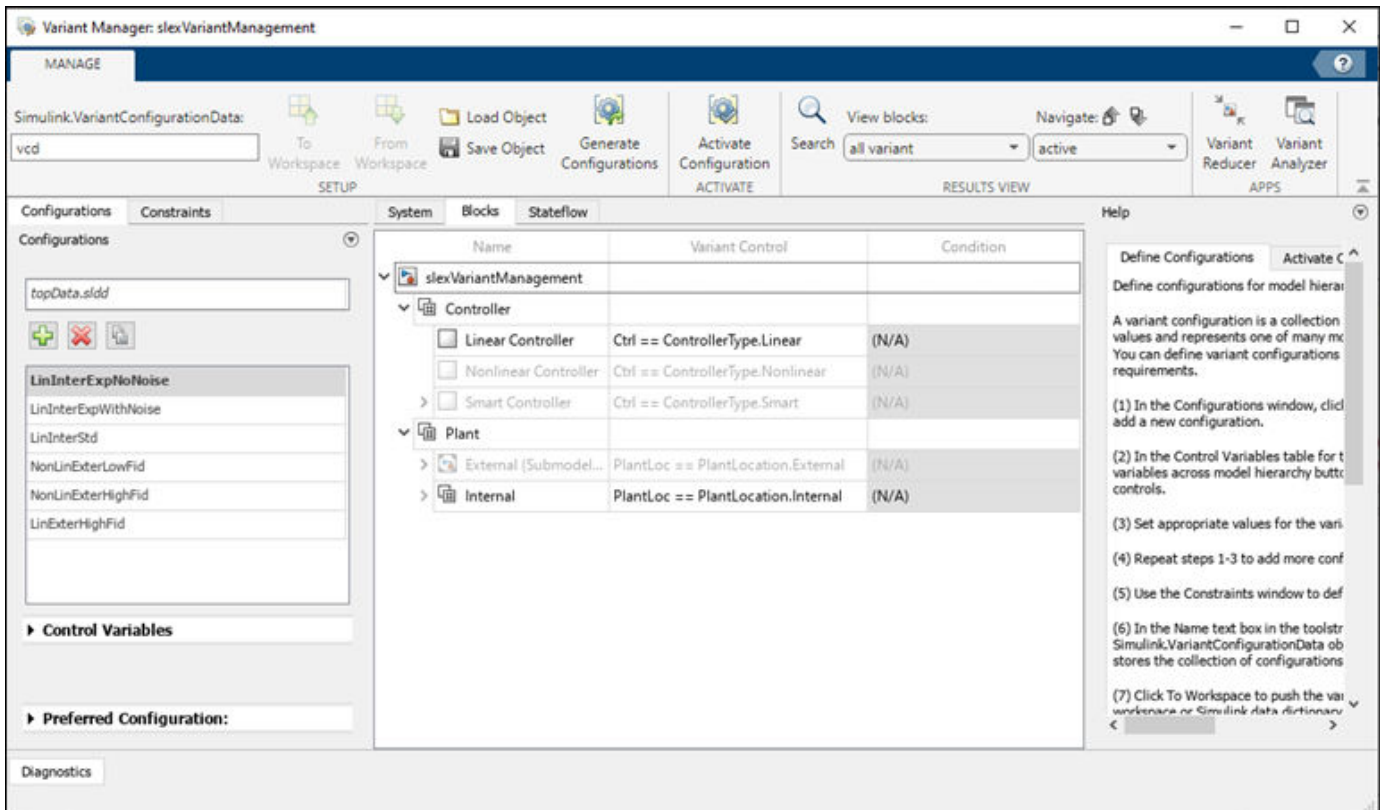

Create and Activate Variant Configurations:

A model hierarchy may contain several variant blocks, each with many variant choices. Combinations of these variant choices correspond to specific configurations of the system. Switching between these configurations and validating them manually can be complicated and can introduce errors. You can use the Variant Manager to create and save variant configurations for a model and run the model under any of the configurations. You can also validate the configurations against a set of constraints.

### Analyze and Reduce Variant Configurations:

You can use the Variant Analyzer tool in the Variant Manager to compare variant configurations for a model and to determine which blocks are used in each configuration. The tool helps in model verification and validation workflows because it can identify unused regions in the model.

You can use the Variant Reducer tool in the Variant Manager to automatically generate a reduced model for a subset of variant configurations and analyze the reduced model in a detailed report. The reduction process removes inactive components for the specified variant configurations. Variant Reducer reduces associated model references, subsystem references, and libraries in the model. The tool also reduces any dependent artifacts, such as MAT or .sldd files, and packages all the reduced artifacts in a specified output folder.

See “Variant Manager for Simulink”.

### Generate Code from Variant Models

You can use Simulink Coder or Embedded Coder to generate code from variant models. See “Prepare Variant-Containing Model for Code Generation” on page 12-103.

For examples that show variant code generation capabilities, see “Variant Systems” (Embedded Coder).

## Variant Terminology

Simulink variant terminology helps you to understand various parameters and terms.

Variant Terminology	Description
Variant Subsystem, Variant Model, Variant Assembly Subsystem	Contains one or more choices where each choice is a Subsystem or Model block.
Variant Source	Provides variation on the source of a signal.
Variant Sink	Provides variation on the sink (destination) of a signal.
Variant Model	Variant Subsystem block containing Model block as variant choices. See Variant Subsystem, Variant Model, Variant Assembly Subsystem.
Active choice on page 12-34	Variant choice associated with a variant control that evaluates to <code>true</code> .
Variant control mode on page 12-38	<code>expression</code> , <code>label</code> or <code>sim_codegen</code> switching for modeling variant blocks and variant parameters.
Variant control variable	MATLAB variable, <code>Simulink.Variant</code> object, or a <code>Simulink.Parameter</code> object. See “Types of Variant Control Variables (Operands) in Variant Blocks” on page 12-41.
Variant object	Container of variant control expression. See <code>Simulink.Variant</code> .
Variant Manager	Central tool that allows you to manage various variation points that are modeled using variant blocks in a system model.
Variant Reducer on page 89-32	Reduces variant models to simplified, standalone model depending on the selected variant configurations.

Variant Terminology	Description
<p>Variant Configuration, Variant Configuration data object</p>	<p>A variant configuration consists of a named set of variant control variables, their values, and configurations to be used by referenced models. It can be used to activate a variation of a Simulink model.</p> <p>A variant configuration data object (instance of the <code>Simulink.VariantConfigurationData</code> class) associated with a model stores:</p> <ul style="list-style-type: none"> <li>• Collection of all variant configurations for the model.</li> <li>• Set of constraints that must be satisfied by the model for all variant configurations.</li> <li>• Default configuration for the model.</li> </ul> <p>You can create new variant configurations and group them into a variant configuration data object from Variant Manager or programmatically using the <code>Simulink.VariantConfigurationData</code> class.</p> <p>To associate the variant configuration data object to a model, use the Export variant configuration data object functionality in Variant Manager, or use the <code>VariantConfigurationObject</code> parameter. Example:</p> <pre>variantConfig = Simulink.VariantConfigurationData; set_param(model, 'VariantConfigurationObject', ... 'variantConfig');</pre>

## Command Line Parameters

### Variant Subsystem Parameters

Parameter name	Description
Variant	<p>Used to check if the subsystem is a Variant Subsystem block. Returns on if the subsystem is a Variant Subsystem block, else it returns off. Example: <code>get_param(gcb, 'Variant')</code></p> <p>This is a read-only parameter.</p>
VariantChoices	<p>Gets the list of variant choices in a Variant Subsystem block. Example: <code>get_param(gcb, 'VariantChoices');</code></p> <p>Returns a 1-by-<i>N</i> struct array with fields:</p> <p>Name: Name of the variant control</p> <p>BlockName: Block path name</p> <p>This is a read-only parameter.</p>
VariantControl	<p>Subsystem block and Model block parameter, which applies to a choice block of a Variant Subsystem block and returns the variant control for the choice block.</p> <ul style="list-style-type: none"> <li>• <code>get_param</code> behavior: Returns variant controls for choice block of a Variant Subsystem block. Example: <code>get_param(gcb, 'VariantControl')</code></li> <li>• <code>set_param</code> behavior: Sets variant control for current block. Example: <code>set_param(gcb, 'VariantControl', 'A==1')</code></li> </ul>
VariantControlMode	<p>Specifies the mode for modeling Variant blocks, which can be either expression or label or sim codegen switching.</p> <ul style="list-style-type: none"> <li>• <code>get_param</code> behavior: Returns the mode set for modeling Variant blocks. Example: <code>get_param(gcb, 'VariantControlMode')</code></li> <li>• <code>set_param</code> behavior: Sets the mode for modeling Variant blocks. Example: <code>set_param(gcb, 'VariantControlMode', 'Label')</code></li> </ul> <p>See “Variant control mode”.</p>

Parameter name	Description
LabelModeActiveChoice	<p>Returns the variant control label of the selected choice for the Variant Subsystem block when VariantControlMode is specified as label . If VariantControlMode is specified as expression, this parameter returns empty ( '' ).</p> <ul style="list-style-type: none"> <li> <p><b>get_param behavior:</b></p> <p>Returns the variant control label of the selected choice for the Variant Subsystem when VariantControlMode is set to label. If VariantControlMode is set to expression, this parameter returns empty ( '' ).</p> </li> <li> <p><b>set_param behavior:</b></p> <p>When VariantControlMode is specified as expression, set_param makes the label selected as the active choice. When VariantControlMode is label, set_param switches between specified labels.</p> </li> </ul> <p>See "Label mode active choice".</p>
TreatAsGroupedWhenPropagatingVariantConditions	<p>Returns on if the Subsystem is treated as a group when propagating variant conditions else returns off.</p> <ul style="list-style-type: none"> <li> <p><b>get_param behavior:</b></p> <p>Indicates if the subsystem is treated as a group when propagating Variant conditions or not by returning on or off. Example:  get_param(gcb, 'TreatAsGroupedWhenPropagatingVariantConditions')</p> </li> <li> <p><b>set_param behavior:</b></p> <p>Enables or disables treating subsystem as a group when propagating variant conditions. Example: set_param(gcb, 'TreatAsGroupedWhenPropagatingVariantConditions', 'on')</p> </li> </ul> <p>See "Propagate Variant Conditions from Variant Source Blocks to Subsystem Blocks" on page 12-180.</p>

Parameter name	Description
GeneratePreprocessorConditionals	<p>Indicates if all the choices are to be analyzed and preprocessor conditionals to be generated by returning on or off.</p> <ul style="list-style-type: none"> <li>• <code>get_param</code> behavior: Indicates if all the choices are to be analyzed and preprocessor conditionals be generated by returning on or off. Example: <code>get_param(gcb, 'GeneratePreprocessorConditionals')</code></li> <li>• <code>set_param</code> behavior: Enables or disables analyzing all the choices and generating preprocessor conditionals. Example: <code>set_param(gcb, 'GeneratePreprocessorConditionals', 'on')</code></li> </ul> <p><b>Note</b> Use the “Variant activation time” parameter instead.</p>
CompiledActiveChoiceControl	<p>Returns the variant control corresponding to the active choice of the Variant Subsystem block and returns empty ( ' ' ) when no choice is active. When the block is commented or is inside a commented subsystem, this parameter returns empty( ' ' ). Example: <code>get_param(gcb, 'CompiledActiveChoiceControl')</code>.</p> <p>This is a read-only parameter.</p>
CompiledActiveChoiceBlock	<p>Returns the full block path name of the active Variant Subsystem block choice and returns empty ( ' ' ) when no choice is active. When the block is commented or is inside a commented Subsystem, the value is returned as empty( ' ' ). Example: <code>get_param(gcb, 'CompiledActiveChoiceBlock')</code>.</p> <p>This is a read-only parameter.</p>

Parameter name	Description
CompiledVariantInfo	<p>Block parameter that indicates the variant activeness of a block <i>after model compilation</i>. Returns a structure with three fields, with values set to on or off:</p> <ul style="list-style-type: none"> <li>• <b>IsActive</b>: Value is on if the block is active in simulation.</li> <li>• <b>IsInCodegen</b>: Value is on if the block is part of generated code.</li> <li>• <b>IsInStartup</b>: Value is on if the block is active or can become active in simulation (the propagated value of <b>Variant activation time</b> on the block is <b>startup</b>) after model compilation.</li> </ul> <p>For an example, see “Identify Variant Activeness of a Block After Model Compilation” on page 12-240.</p> <p>This is a read-only parameter.</p>
CompiledVariantActivationTime	<p>Returns the variant activation time of the block after model compilation. Before the model is compiled, this parameter returns update diagram activation time. Example:  <code>get_param(gcb, 'CompiledVariantActivationTime')</code></p> <p>This is a read-only parameter.</p>
PropagateVariantConditions	<p>Indicates if conditions on ports inside the Variant Subsystem block are to be propagated outside the block.</p> <ul style="list-style-type: none"> <li>• <b>get_param</b> behavior:  Indicates if conditions on ports inside the Variant Subsystem block are to be propagated outside the block.</li> <li>• <b>set_param</b> behavior:  Enables or disables propagating conditions outside Variant Subsystem block. Example:  <code>set_param(gcb, 'PropagateVariantConditions', 'on')</code></li> </ul> <p>See “Propagate conditions outside of variant subsystem”.</p>

Parameter name	Description
AllowZeroVariantControls	<p data-bbox="865 300 1385 363">Indicates if the Variant Subsystem block is allowed to have no active choices.</p> <ul data-bbox="865 394 1170 426" style="list-style-type: none"><li data-bbox="865 394 1170 426">• <code>get_param</code> behavior:</li></ul> <p data-bbox="906 447 1425 510">Indicates if the Variant Subsystem block is allowed to have no active choices.</p> <ul data-bbox="865 531 1170 562" style="list-style-type: none"><li data-bbox="865 531 1170 562">• <code>set_param</code> behavior:</li></ul> <p data-bbox="906 583 1442 646">Enables or disables having active choices in Variant Subsystem block. Example:</p> <pre data-bbox="906 646 1417 709">set_param(gcb, 'AllowZeroVariantControls', 'on')</pre> <p data-bbox="865 730 1352 762">See "Allow zero active variant controls".</p>

Parameter name	Description
VariantActivationTime	<p>Determines if Simulink sets the active choice of a Variant Subsystem block during update diagram or code compile.</p> <ul style="list-style-type: none"> <li>• <b>get_param</b> behavior: <p>Returns the Variant Activation Time of a Variant Subsystem block. This parameter can be set to update diagram, update diagram analyze all choices, or code compile.</p> <p>Example: <code>get_param(gcb, 'VariantActivationTime')</code></p> </li> <li>• <b>set_param</b> behavior: <ul style="list-style-type: none"> <li>• When you set the <b>Variant control mode</b> to <b>expression</b>, this parameter can be set to update diagram, update diagram analyze all choices, or code compile.</li> <li>• When you set the <b>Variant control mode</b> to <b>sim codegen switching</b>, this parameter can be set to either update diagram or update diagram analyze all choices. The code compile option becomes unavailable.</li> </ul> <p>Example:  <code>set_param(gcb, 'VariantActivationTime', 'update diagram')</code></p> </li> </ul> <hr/> <p><b>Note</b> The <code>get_param</code> and <code>set_param</code> behavior of <code>VariantActivationTime</code> parameter with the code compile option is equivalent to that of the parameter <code>GeneratePreprocessorConditionals</code>.</p> <hr/> <p>See “Variant activation time”.</p>

### Variant Source and Variant Sink Parameters

Parameter name	Description
VariantControls	<p>Returns a 1-by-N cell array of variant control expressions corresponding to each of the N ports of the Variant Source or Variant Sink blocks.</p> <ul style="list-style-type: none"> <li>• <b>get_param</b> behavior: Returns a cell array of variant control expressions corresponding to each ports of the Variant Source or Variant Sink blocks. Example: <code>get_param(gcb, 'VariantControls')</code></li> <li>• <b>set_param</b> behavior: Sets the cell array of Variant control expressions corresponding to each of ports of Variant Source or Variant Sink blocks. Example: <code>set_param(gcb, 'VariantControls', ({A==1}, '4'))</code></li> </ul>
VariantControlMode	<p>Specifies the mode for modeling variant blocks, which can be either Expression or Label.</p> <ul style="list-style-type: none"> <li>• <b>get_param</b> behavior: Returns the mode set for modeling Variant blocks. Example: <code>get_param(gcb, 'VariantControlMode')</code></li> <li>• <b>set_param</b> behavior: Sets the mode for modeling Variant blocks. Example: <code>set_param(gcb, 'VariantControlMode', 'Label')</code></li> </ul> <p>See "Variant control mode".</p>

Parameter name	Description
LabelModeActiveChoice	<p>Returns the variant control label of the selected choice for Variant Source or Variant Sink block when VariantControlMode is specified as Label. If VariantControlMode is specified as Expression, this parameter returns empty ('').</p> <ul style="list-style-type: none"> <li>• <b>get_param behavior:</b> Returns the variant control label of the selected choice for the Variant Subsystem when VariantControlMode is set to Label. If VariantControlMode is set to Expression, this parameter returns empty ('').</li> <li>• <b>set_param behavior:</b> When VariantControlMode is specified as Expression, set_param makes the label selected as the active choice. When VariantControlMode is Label, set_param switches between specified labels.</li> </ul> <p>See “Label mode active choice”.</p>
GeneratePreprocessorConditionals	<p>Indicates if all the choices are to be analyzed and preprocessor conditionals to be generated by returning on or off.</p> <ul style="list-style-type: none"> <li>• <b>get_param behavior:</b> Indicates if all the choices are to be analyzed and preprocessor conditionals to be generated by returning on or off. Example: get_param(gcb, 'GeneratePreprocessorConditionals')</li> <li>• <b>set_param behavior:</b> Enables or disables analyzing all the choices and generating preprocessor conditionals. Example: set_param(gcb, 'GeneratePreprocessorConditionals', 'on')</li> </ul> <p><b>Note</b> Use the “Variant activation time” parameter instead.</p>

Parameter name	Description
ShowConditionOnBlock	<p>Indicates if the VariantControlExpression is to be displayed on the block by returning on or off.</p> <ul style="list-style-type: none"> <li>• <code>get_param</code> behavior: Indicates if the VariantControlExpression is to be displayed on the block or not.</li> <li>• <code>set_param</code> behavior: Enables or disables the displaying of VariantControlExpression on the block. Example: <code>set_param(gcb, 'ShowConditionOnBlock', 'on')</code></li> </ul> <p>See “Show variant condition on block”.</p>
AllowZeroVariantControls	<p>Indicates if the block is allowed to have no active ports by returning on or off.</p> <ul style="list-style-type: none"> <li>• <code>get_param</code> behavior: Indicates if the Variant Source or Variant Sink block is allowed to have no active choices.</li> <li>• <code>set_param</code> behavior: Enables or disables having active choices in Variant Source or Variant Sink block. Example: <code>set_param(gcb, 'AllowZeroVariantControls', 'on')</code></li> </ul> <p>See “Allow zero active variant controls”.</p>
CompiledActiveVariantControl	<p>Returns the variant control corresponding to the active port from the last compilation instance. If no port is active, returns empty ( ' '). If the block is commented or inside a commented Subsystem or inside an inactive choice of a Variant Subsystem block, the value is not computed and returns empty ( ' '). Example: <code>get_param(gcb, 'CompiledActiveVariantControl')</code></p> <p>This is a read-only parameter.</p>

Parameter name	Description
CompiledActiveVariantPort	<p>Returns the "index" of the active port from the last compilation instance or returns -1 when no port is active. If the block is commented or inside a commented Subsystem or inside an inactive choice of a Variant Subsystem block (with generate preprocessor conditionals Off), the value is not computed, and returns empty ( ' ' ). Example: <code>get_param(gcb, 'CompiledActiveVariantPort')</code></p> <p>This is a read-only parameter.</p>
CompiledVariantActivationTime	<p>Returns the variant activation time of the block after model compilation. Before the model is compiled, this parameter returns update diagram activation time. Example: <code>get_param(gcb, 'CompiledVariantActivationTime')</code></p> <p>This is a read-only parameter.</p>

## Working with Variant Choices

### In this section...

“Default Variant Choice” on page 12-34  
 “Active Variant Choice” on page 12-34  
 “Inactive Variant Choice” on page 12-34  
 “Empty Variant Choice” on page 12-34  
 “List of Variant Choices” on page 12-35  
 “Open Active Variant” on page 12-35

Each variant choice in your model is associated with a conditional expression called variant control. The way you specify your variant controls determines the active variant choice. **Variant control mode** parameter available in the block parameters dialog box allows you to select **Expression** or **Label** mode for modeling Variant blocks.

This image shows the block parameters dialog box of a Variant Subsystem block that contains four variant choices:

- The first choice is commented out by adding the % symbol before the variant control.
- The second choice is the (default) and is activated when no variant control evaluates to true.
- The third choice is activated when the expression `mode==3 && version==2` evaluates to true.
- The fourth choice is activated when the expression `mode==2 && version==1` evaluates to true.

## Default Variant Choice

You can specify at most one variant choice as the default for the model. As shown in the image above, the `Linear Controller` subsystem is defined as the default variant choice. During model compilation, if Simulink finds that no variant control evaluates to `true`, it uses the default choice.

In the dialog box, select the variant choice and change its **Variant control** property to `(default)`.

## Active Variant Choice

While each variant choice is associated with a variant control, only one variant control can evaluate to `true` at a time. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control. At most one variant choice can be active. The active variant cannot be changed once model is compiled.

In this example, you can activate either the `Model` variant choice or the `Nonlinear Controller` variant choice by specifying appropriate values for `mode` and `version`.

Value of mode	Value of version	Active variant choice
2	1	Nonlinear Controller
3	2	Model

You can specify the values of `mode` and `version` at the MATLAB Command Window.

## Inactive Variant Choice

When a variant control activates one variant choice, Simulink considers the other variant choices to be inactive. Simulink ignores inactive variant choices during simulation. However, Simulink continues to execute block callbacks inside the inactive variant choices.

The color of inactive choices fades by default. You can choose to disable the fading effect by using the **Variant Fading** option. The **Variant Fading** option is available in the **Information Overlays** menu on the **Debug** tab of the Simulink Editor. You can use `get_param` and `set_param` commands to view or change the fading state of inactive choices programmatically. For example,

- `get_param('bdroot','VariantFading')` % To view the fading state of inactive choices
- `set_param('bdroot','VariantFading','on')` % To turn on the fading effect of inactive choices

## Empty Variant Choice

When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

For an empty variant choice, you can either specify a variant activation condition or comment out the variant condition by placing a `%` symbol before the condition.

If this variant choice is active during simulation, Simulink ignores the empty variant choice. However, Simulink continues to execute block callbacks inside the empty variant choices.

## List of Variant Choices

You can get a list of variant choices in a Variant Subsystem block using the read-only parameter `VariantChoices`.

```
varchoices = get_param(gcb, 'VariantChoices');
```

In this example, the `VariantChoices` parameter returns the following:

Fields	Name	BlockName
1	'%mode==2&&version==2'	'sldemo_variant_varchoices/Controller/Empty'
2	'(default)'	'sldemo_variant_varchoices/Controller/Linear Controller'
3	'mode==3&&version==2'	'sldemo_variant_varchoices/Controller/Model'
4	'mode==2&&version==1'	'sldemo_variant_varchoices/Controller/Nonlinear Controller'

## Open Active Variant

When you open a model, variant blocks display the name of the variant that was active the last time that you saved your model. Use the **Variant** menu to open the active variant. Right-click the block and select **Variant > Open**. Then select the active variant.

Use this command to find the current active choice:

```
get_param(gcb, 'CompiledActiveChoiceControl')
```

Use this command to find the path to the current active choice:

```
get_param(gcb, 'CompiledActiveChoiceBlock')
```

---

### Note

- The `CompiledActiveChoiceBlock` parameter is supported only for the Variant Subsystem block.
  - Active variant cannot be changed once the model is compiled.

## Introduction to Variant Controls

The components of a Simulink model that contain variants are activated or deactivated based on the variant choice that you select.

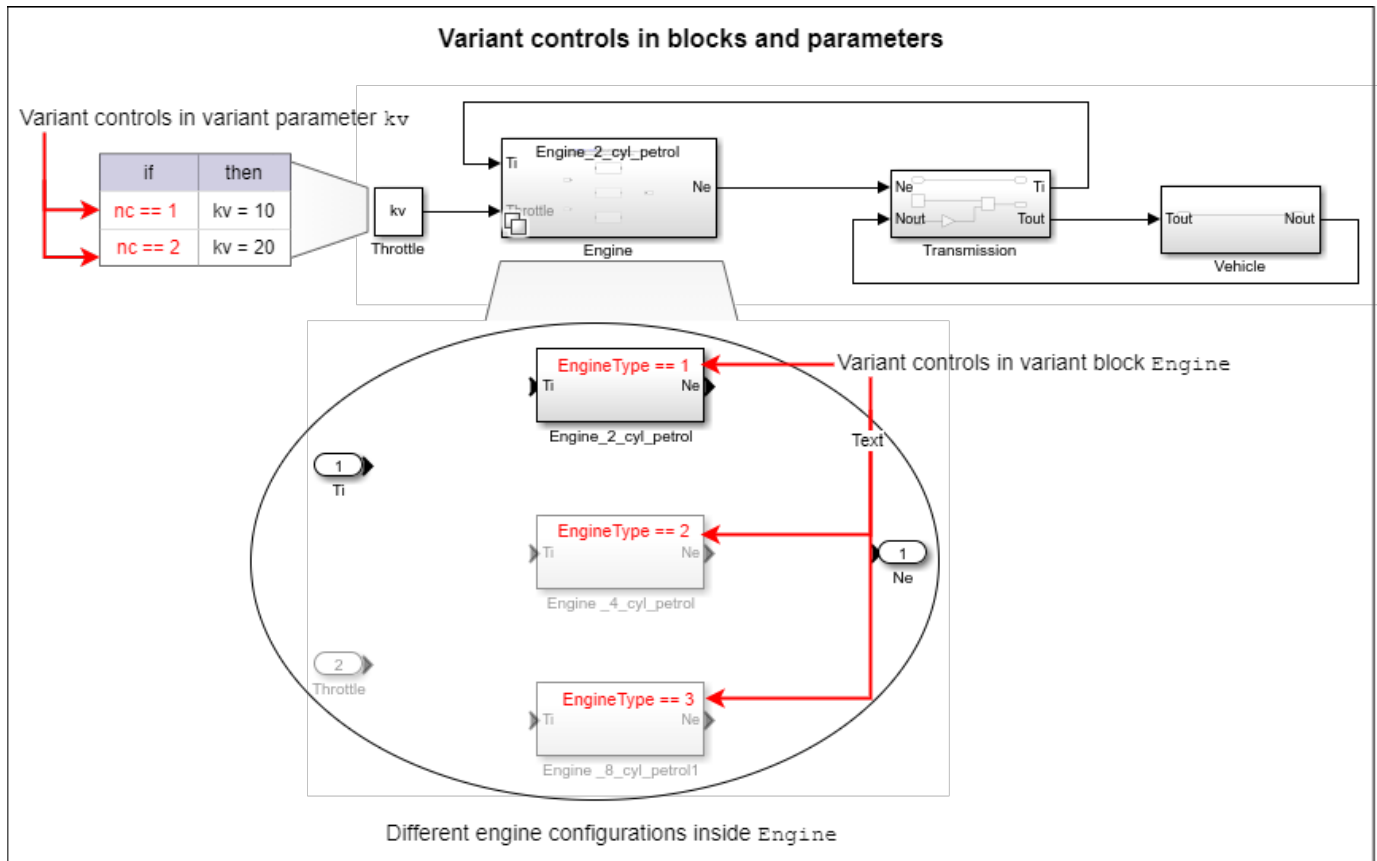

Each variant choice in your model is associated with a variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice. While each variant choice is associated with a variant control, only one variant control can evaluate to `true`. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control.

Suppose you want to simulate a model that represents a vehicle with three possible engine configurations: 4-cylinder gas, 6-cylinder gas, and 8-cylinder gas. In this scenario, the value of throttle is an input to the engine that differs for different configurations. You could implement each engine configuration as a separate subsystem inside the Variant Subsystem block named `Engine` and then switch between the subsystems based on the value of `EngineType`. Similarly, you could use a variant parameter `kv` to store multiple values of throttle and then switch between the values based on the value of `nc`. For example, if the value of `EngineType` is 1 and the value of `nc` is 2, a throttle value of 20 is provided as an input to the `Engine_2_cyl_petrol` subsystem during simulation.

In this example:

- Structural variations are controlled by using the variant controls `EngineType == 1`, `EngineType == 2`, and `EngineType == 3` in the Variant Subsystem block named `Engine`. For more information on how to control structural variations, see “Variant Control Modes in Variant Blocks” on page 12-38.
- Value variations are controlled by using the variant controls `nc == 1` and `nc == 2` in the variant parameter `kv`. For more information on how to control value variations, see “Variant Control Mode in Variant Parameters” on page 12-52.

## Variant Control Modes in Variant Blocks

The components of a Simulink model that contain variants are activated or deactivated based on the variant choice that you select.

Each variant choice in your model is associated with a variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice. While each variant choice is associated with a variant control, only one variant control can evaluate to `true`. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control. For a simple example, see “Introduction to Variant Controls” on page 12-36.

### Types of Variant Control Modes in Variant Blocks

These are types of variant control modes in Simulink:

- `expression` — In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive. See “Switch Between Choices Using Condition Expressions in Variant Blocks” on page 12-39.
- `label` — In `label` mode, Simulink chooses the active variant based on the name of the variant. The variant control is a string and does not require you to create any variable in any workspaces. See “Switch Between Choices Using Labels in Variant Blocks” on page 12-45.
- `sim_codegen_switching` — To automatically switch between the variants for simulation and code generation workflows without creating any workspace variable, use `sim_codegen_switching` mode. When you simulate a model, Simulink automatically chooses the `sim` branch as the active choice. Similarly, when you do a software-in-the-loop (SIL) or processor-In-Loop (PIL) simulation, generate code, or use external mode, Simulink automatically chooses the `codegen` branch. This mode is not supported for models configured with an ERT-based system target file and service code interface. See “Switch Between Choices for Simulation and Code Generation Workflows Without Using Control Variables in Variant Blocks” on page 12-47.

## Switch Between Choices Using Condition Expressions in Variant Blocks

In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive.

You can use the `expression` type of variant controls in variant blocks and in variant parameters.

---

**Note** You can simulate and generate code from the model containing a variant block with **Variant control mode** set to `expression` mode. The generated code can contain active and inactive choices that are enclosed in preprocessor conditionals `#if` and `#elif`, or regular `if` conditions.

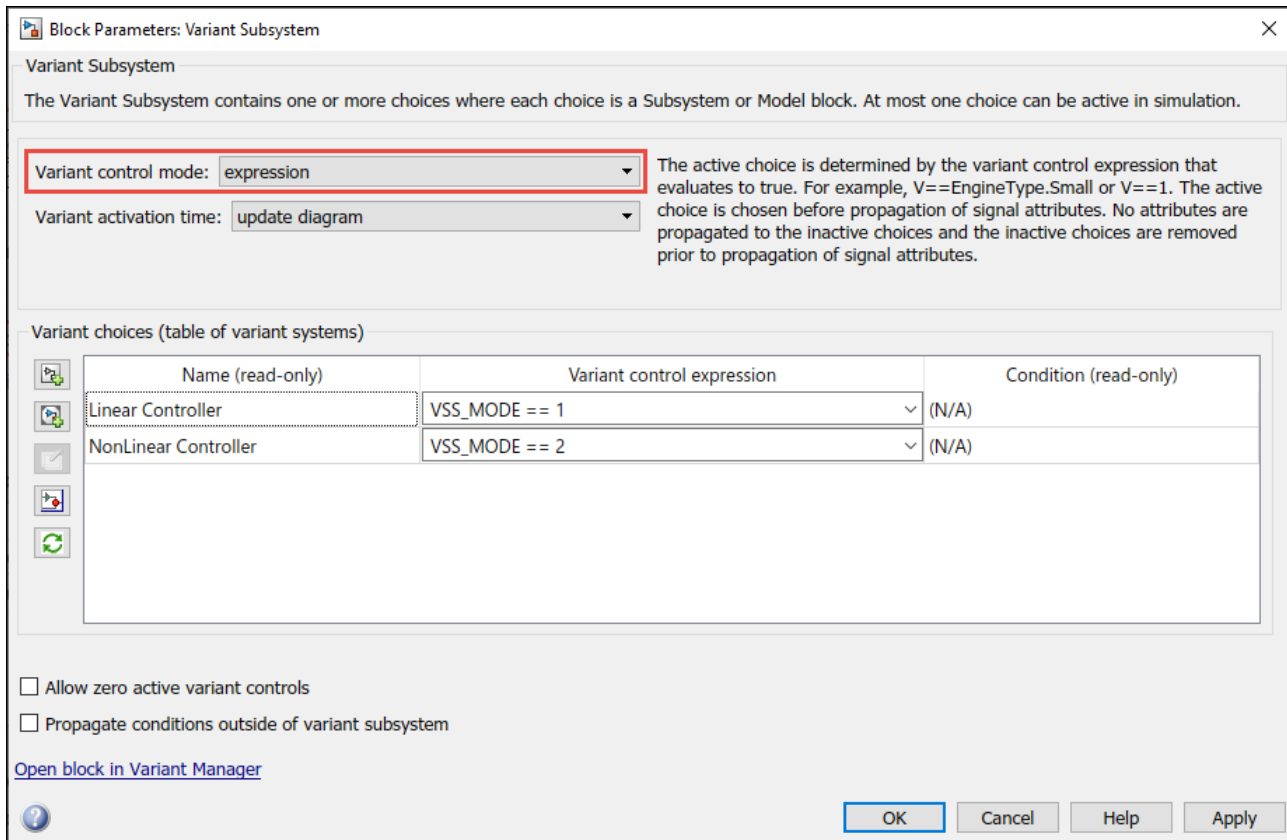

---

### Use expression Type of Variant Control in Variant Blocks

To specify the variant condition expressions in variant blocks:

- Right-click the badge on the variant block, select **Block Parameters**, and then specify the variant condition expression in the **Variant control expression** parameter of the block parameter dialog box.

## Variant control mode: expression

- Use this command.

```
set_param('Model/Controller/Linear Controller', 'VariantControl', 'VSS_MODE == 1')
```

In this command, *Model/Controller/Linear Controller* is the full path of the variant choice, and  $VSS\_MODE == 1$  is the expression associated with the variant choice.

### Types of Variant Controls in expression Mode

The variant controls can be:

- Boolean condition expression for rapid prototyping. For example,  $A == 1$ ,  $A ~= B$ ,  $A \&\& B == 1$ , and so on.
- A `Simulink.Variant` object that contains condition expressions for condition reuse. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks” on page 12-64.
- A default variant control if none of the choices evaluates to `true`. You can specify at most one variant choice as the default for the block. During simulation, if none of the variant controls evaluate to `true`, Simulink uses the default variant as the active variant choice. To set a variant choice as the default, select the `(default)` keyword in the **Variant control expression** column for that choice.

Here, *A* and *B* are operands called as variant control variables. `+`, `==`, and `&&` are operators in the condition expression. The condition expression can contain one or more such variant control variables and operators. For information on supported types and storage location of variant control

variables, see “Types of Variant Control Variables (Operands) in Variant Blocks” on page 12-41 and “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42. For information on operators, see “Types of Operators in Variant Blocks for Different Activation Times” on page 12-43.

**Note** You can comment out the variant controls by placing a % symbol before the control expressions. During simulation, if the corresponding variant choice is active, Simulink ignores the variant choice. However, Simulink continues to execute block callbacks inside the variant choice.

### Types of Variant Control Variables (Operands) in Variant Blocks

In expression mode, you can specify the variant control variables as any of these types, from options to use while prototyping to options required for generating code from your model.

Specification	Purpose	Example
<code>Simulink.VariantControl</code>	Associate a variant activation time to switch choices coherently	<code>A == 1</code> , where A is a <code>Simulink.VariantControl</code> object. See “Simulink.VariantControl Variables for Coherent Switching of Choices in Variant Blocks” on page 12-57.
Scalar variable	Rapid prototyping	<code>A == 1</code> , where A is a scalar variable. See “Scalar Variant Control Variables for Rapid Prototyping in Variant Blocks” on page 12-59.
<code>Simulink.Parameter</code> object	Generate preprocessor conditionals for code generation	<code>Vssmode == 1</code> , where <code>Vssmode</code> is a <code>Simulink.Parameter</code> object. See “Simulink.Parameter Type of Variant Control Variables for Code Generation in Variant Blocks” on page 12-60.
“Simulink Enumerations” on page 73-2	Improved code readability because condition values are represented as meaningful names instead of integers	<code>LEVEL == Level.Advanced</code> , where <code>Level</code> is an integer-based enumeration class and <code>Advanced</code> is the enumerated value. See “Enumerated Types To Improve Code Readability of Variant Control Variables of Variant Blocks” on page 12-62.

Specification	Purpose	Example
Simulink.Variant object	Reuse variant conditions	LinearController == 1, where LinearController is a Simulink.Variant object that encapsulates the condition expression FUEL==2 && EMIS==1. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks” on page 12-64.
struct	Group related variant control variables	Controller.Linear == 1, where Controller is a struct and Linear is its field. See “Structures to Group Related Variant Control Variables of Variant Blocks” on page 12-65.

For list of all examples, see “Use Variant Control Variables in Variant Blocks” on page 12-57.

### Storage Locations for Variant Control Variables (Operands) in Variant Blocks

You can define the variant control variables in different storage locations based on your requirement.

**Note** All the variant control variables in a variant block must originate from the same storage location.

Storage Location	Use for Storage Location	Supported Types of Variant Control Variables (See “Types of Variant Control Variables (Operands) in Variant Blocks” on page 12-41)	For More Information
Base workspace	Store variables while you experiment with temporary models	Scalar variables, Simulink.Variant, Simulink.Parameter, enumerated type, Simulink.VariantControl, and struct	“Temporary Data: Base Workspace” on page 72-105
Mask workspace	Permanently store data that is local to the mask of a block.	Scalar variables, enumerated type, and Simulink.VariantControl	“Approaches to Control Active Variant Choice of a Variant Block Using Mask or Model Workspace” on page 12-166

Storage Location	Use for Storage Location	Supported Types of Variant Control Variables (See “Types of Variant Control Variables (Operands) in Variant Blocks” on page 12-41)	For More Information
Model workspace	Permanently store data that is local to a model	Scalar variables, enumerated type, and Simulink.VariantControl	“Approaches to Control Active Variant Choice of a Variant Block Using Mask or Model Workspace” on page 12-166
Data dictionary	Permanently store global data, share data between models, and track changes made to data.	Scalar variables, Simulink.Variant, Simulink.Parameter, enumerated type, Simulink.VariantControl, and struct	“What Is a Data Dictionary?” on page 79-2

For capabilities and advantages of each storage location, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-102

### Types of Operators in Variant Blocks for Different Activation Times

Variant condition expressions can contain MATLAB operators, provided the expression evaluates to a Boolean value.

In variant blocks, the operators that you can use to form a variant condition expression depends on the **Variant activation time**.

When you specify the **Variant activation time** as:

- `update diagram` — Any condition expression that evaluates to `true` or `false`.
- `update diagram analyze all choices` or `code compile` — The supported operators are:
  - Parentheses for grouping
  - “Arithmetic Operators”, “Relational Operators”, “Logical Operators”, and “Bit-Wise Operations”, as listed in this table.

This table lists the MATLAB operators and their representation in the generated code. In these examples, A and B are expressions that evaluate to an integer, and x is a constant integer literal.

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional of Generated Code
<b>Arithmetic</b>	
<ul style="list-style-type: none"> <li>• <code>A + B</code></li> <li>• <code>+A</code></li> </ul>	<ul style="list-style-type: none"> <li>• <code>A + B</code></li> <li>• <code>A</code></li> </ul>

<b>MATLAB Expressions That Support Generation of Preprocessor Conditionals</b>	<b>Equivalent Expression in C Preprocessor Conditional of Generated Code</b>
<ul style="list-style-type: none"> <li>• A - B</li> <li>• -A</li> </ul>	<ul style="list-style-type: none"> <li>• A - B</li> <li>• -A</li> </ul>
A * B	A * B
idivide(A,B)	A / B If the value of the second operand (B) is 0, the behavior is undefined.
rem(A,B)	A % B If the value of the second operand (B) is 0, the behavior is undefined.
<b>Relational</b>	
A == B	A == B
A ~= B	A != B
A < B	A < B
A > B	A > B
A <= B	A <= B
A >= B	A >= B
<b>Logical</b>	
~A	!A, where A is not an integer
A && B	A && B
A    B	A    B
<b>Bitwise (A and B cannot both be constant integer literals)</b>	
bitand(A,B)	A & B
bitor(A,B)	A   B
bitxor(A,B)	A ^ B
bitcmp(A)	~A
bitshift(A,x)	A << x
bitshift(A,-x)	A >> x

- startup — The supported operators are:
  - Parentheses for grouping
  - “Relational Operators” and “Logical Operators”, as listed in this table.

This table lists the MATLAB operators and their representation in the generated code. In these examples, A and B are expressions that evaluate to an integer.

Supported Operators in Variant Condition Expression	Equivalent Expression in Regular if of Generated Code
<b>Relational</b>	
A == B	A == B
A ~= B	A != B
<b>Logical</b>	
~A	!A, where A is not an integer
A && B	A && B
A    B	A    B

**Note** In variant blocks with startup activation time:

- The variant control variables that originate from the mask or the model workspace cannot be used in the function-call operators such as `idivide`, `bitand`, and so on to form expressions.
- AUTOSAR post-build variants support only `==` and `&&` operators. For more information, see “Configure Postbuild Variant Conditions for AUTOSAR Software Components” (AUTOSAR Blockset).

### Evaluate Variant Condition Expressions at Different Variant Activation Times

In `expression` mode, you can specify if Simulink must evaluate condition expressions during model compile, simulation-loop, code compile, or model start up stage of simulation and code generation workflow using variant activation times. For information on stages of simulation and code generation and supported variant activation times in `expression` mode, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

### Automatically Identify Variant Regions Using Variant Condition Propagation

Simulink determines the model components that are active during simulation by the process of variant condition propagation. This process evaluates the variant controls specified on the variant blocks and automatically propagates the variant conditions to the connecting blocks. Variant conditions can propagate through signal lines, buses, and function calls to reach other blocks in the model. The process deactivates the model components associated with the inactive choices and they do not participate in simulation. You can stop condition propagation to define variant regions in the model.

You can use the Variant Conditions Legend to visualize the propagated variant conditions that activate each variant choice. Simulink annotates model components if there are variant conditions on them, and the Variant Conditions Legend displays the condition that corresponds to each annotation.

For more information, see “Variant Condition Propagation Overview” on page 12-256.

### Switch Between Choices Using Labels in Variant Blocks

In `label` mode, Simulink chooses the active variant based on the name of the variant. The variant control is a `string` and does not require you to create variable in any workspaces.

**Note** In `label` mode, the activation time of the variant block is set to `update diagram` by default. In other words, when you simulate a model or generate code from a model, Simulink determines the active choice in the model compilation stage and generates code only for the active choice. See “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

## Use label Mode in Variant Blocks

To specify the labels for choices in variant blocks, right-click the badge on the variant block, select **Block Parameters**, and then specify the labels in the **Variant control label** parameter of the block parameter dialog box.

### Variant control mode: label

## Set Active Choices Using Variant Control Labels

You can follow any of these approaches to set active choices in `label` mode:

- Specify a name for each variant choice in the **Variant control label** parameter of the variant block dialog box. All the names that you specify are listed in the **Label mode active choice** drop-down. The label that you select from the list becomes the active choice.
- Right-click the badge on the variant block and select **Label Mode Active Choice**.
- From the mask workspace using the initialization code. Using the mask initialization code, you can specify the active choice from variant block or any subsystem in the hierarchy. The active choice you specify in the mask initialization code overrides the active choice you specify using the **Label**

**mode active choice** drop-down or the **Label Mode Active Choice** menu item. For more information, see “Mask a Variant Subsystem” on page 42-86.

- Use this command:

```
set_param(blockName,'LabelModeActiveChoice', 'variantChoiceLabel')
```

where *blockName* is the name of the variant block and *variantChoiceLabel* is the label associated with the variant choice.

## Switch Between Choices for Simulation and Code Generation Workflows Without Using Control Variables in Variant Blocks

To automatically switch between the choices for simulation and code generation workflows without creating any workspace variable, use the `sim codegen` switching variant control mode.

---

**Note** In `sim codegen` switching mode, only the `update diagram` and the `update diagram analyze all choices` activation times are supported. In other words, when you simulate or generate code from a model, Simulink determines the active choice in the model compilation stage and generates the code only for the choice. See, “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

---

### Use `sim codegen` switching Mode in Variant Blocks

To specify simulation and code generation branches for variant choices, right-click the badge on the variant block, select **Block Parameters**, and then specify the (`sim`) and (`codegen`) keywords in the **Variant control switch** parameter of the block parameter dialog box.

When you simulate a model in normal, accelerator, or rapid Accelerator mode, Simulink automatically chooses the (`sim`) branch as the active choice. Similarly, when you do a software-in-the-loop (SIL), processor-In-Loop (PIL) simulation or generate code or use external mode, Simulink automatically chooses the (`codegen`) branch. The code is generated only for the active choice. Inactive choices are not included in the generated code. In this mode, you can at most have only two choices in the variant block.

## Variant control mode: sim codegen switching

Block Parameters: Variant Subsystem

Variant Subsystem

The Variant Subsystem contains one or more choices where each choice is a Subsystem or Model block. At most one choice can be active in simulation.

Variant control mode: **sim codegen switching** ▼ There must be two choices, "**(sim)**" and "**(codegen)**". The active choice, "**(sim)**" when simulating or "**(codegen)**" when generating code, is chosen before propagation of signal attributes. No attributes are propagated to the inactive choices and the inactive choices are removed prior to propagation of signal attributes.

## Variant Control Mode in Variant Parameters

### In this section...

“Switch Between Choices Using Condition Expressions in Variant Parameters” on page 12-52

“Variant Activation Times for Different Variant Control Modes in Variant Parameters” on page 12-55

The components of a Simulink model that contain variants are activated or deactivated based on the variant choice that you select.

Each variant choice in your model is associated with a variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice. While each variant choice is associated with a variant control, only one variant control can evaluate to `true`. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control. For a simple example, see “Introduction to Variant Controls” on page 12-36.

### Switch Between Choices Using Condition Expressions in Variant Parameters

In `expression` mode, Simulink chooses the active variant based on the evaluation of the variant conditions. When a condition expression evaluates to `true`, the corresponding variant choice becomes active. When a condition expression evaluates to `false`, the corresponding variant choice becomes inactive. See “Switch Between Choices Using Condition Expressions in Variant Parameters” on page 12-52.

---

**Note** You can simulate and generate code from the model containing a variant parameter with **Variant control mode** set to `expression` mode. The generated code can contain active and inactive choices that are enclosed in preprocessor conditionals `#if` and `#elif`, or regular `if` conditions.

---

With `expression` type of variant control mode:

- Use “`code compile`” on page 12-82 activation time to generate a code that contains active and inactive choices of the model in C preprocessor conditionals `#if` and `#elif`. The preprocessor conditionals are conditionally compiled for the active choice that you provide as an input to the compiler. For more information, see “Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211.
- Use “`startup`” on page 12-82 activation time to:
  - Improve the speed of iterative simulations and Simulink Test™ workflows using fast restart. For more information, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-244.
  - Generate a code that contains active and inactive choices of the model in regular `if` conditions. The `if` condition is evaluated and conditionally executed for the active choice that you provide as an input to the executable. For more information, see “Run Executable for Different Variant Parameter Values Without Recompiling Code” on page 12-274.

### Use expression Type of Variant Controls in Variant Parameters

To specify the variant condition expressions in variant parameters, use the `Simulink.VariantVariable` object. Once you successfully create the

`Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box. For more information, see “Create a Simple Variant Parameter Model” on page 12-178.

```
K1 = Simulink.VariantVariable('Choices', {'VSS_MODE == 1', 3.5, 'VSS_MODE == 2', 8.5})
```

## Types of Variant Controls in expression Mode

In variant parameters, the expression type of variant controls can be:

- Boolean condition expression for rapid prototyping. For example, `A == 1`, `A ~= B`, `A && B == 1`, and so on.
- A `Simulink.Variant` object that contains a condition expression for condition reuse. See “`Simulink.Variant` Objects for Variant Condition Reuse of Variant Parameters” on page 12-76.

Here, `A` and `B` are operands called as variant control variables. `==`, `~=`, and `&&` are operators in the condition expression. The condition expression can contain one or more such variant control variables and operators. For information on supported types and storage location of variant control variables, see “Types of Variant Control Variables (Operands) in Variant Parameters” on page 12-53 and “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 12-54. For information on operators, see “Types of Operators in Variant Parameters” on page 12-54.

## Types of Variant Control Variables (Operands) in Variant Parameters

In expression mode, you can specify the variant control variables as any of these types, from options to use while prototyping to options required for generating code from your model.

Specification	Purpose	Example
<code>Simulink.VariantControl</code> object	Associate a variant activation time	<code>A == 1</code> , where <code>A</code> is a <code>Simulink.VariantControl</code> object. See “Numeric Variant Control Values for Rapid Prototyping of Variant Parameters” on page 12-68.
<code>Simulink.Parameter</code> object	Generate preprocessor conditionals for code generation	<code>Vssmode == 1</code> , where <code>Vssmode</code> is a <code>Simulink.Parameter</code> object. See “ <code>Simulink.Parameter</code> Type of Variant Control Variables for Code Generation of Variant Parameters” on page 12-70.
“ <code>Simulink Enumerations</code> ” on page 73-2	Improved code readability because condition values are represented as meaningful names instead of integers	<code>LEVEL == Level.Advanced</code> , where <code>Level</code> is an integer-based enumeration class and <code>Advanced</code> is the enumerated value. See “Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters” on page 12-73.

Specification	Purpose	Example
Simulink.Variant object	Reuse variant conditions	LinearController == 1, where LinearController is a Simulink.Variant object that encapsulates the condition expression FUEL==2 && EMIS==1. See “Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters” on page 12-76.

For list of all examples, see “Use Variant Control Variables in Variant Parameters” on page 12-68.

### Storage Locations for Variant Control Variables (Operands) in Variant Parameters

You can define the variant control variables in different storage locations based on your requirement.

**Note** All the variant control variables in a variant parameter must originate from the same storage location.

Storage Location	Use for Storage Location	Supported Types of Variant Control Variables (See “Types of Variant Control Variables (Operands) in Variant Parameters” on page 12-53)	For More Information
Base workspace	Store variables while you experiment with temporary models	Simulink.Variant, Simulink.Parameter, enumerated type, and Simulink.VariantControl	“Temporary Data: Base Workspace” on page 72-105
Data dictionary	Permanently store global data, share data between models, and track changes made to data.	Simulink.Variant, Simulink.Parameter, enumerated type, and Simulink.VariantControl	“What Is a Data Dictionary?” on page 79-2

For capabilities and advantages of each storage location, see “Determine Where to Store Variables and Objects for Simulink Models” on page 72-102

### Types of Operators in Variant Parameters

Variant condition expressions can contain MATLAB operators, provided the expression evaluates to a boolean value. In variant parameters, the operators that you can use to form a variant condition expression are:

- Parentheses for grouping

- “Relational Operators” and “Logical Operators” as listed in this table.

This table lists the supported MATLAB operators and their equivalent in the generated code. In these examples, A and B are expressions that evaluate to an integer.

Supported MATLAB Expressions	Equivalent Expression in Generated C Code
<b>Relational</b>	
A == B	A == B
A ~= B	A != B
<b>Logical</b>	
~A	!A, where A is not an integer
A && B	A && B
A    B	A    B

### Evaluate Variant Condition Expressions at Different Variant Activation Times

In expression mode, you can specify if Simulink must evaluate condition expressions during model compile, simulation-loop, code compile, or model start up stage of simulation and code generation workflow using variant activation times. For information on stages of simulation and code generation, and supported variant activation times in expression mode, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

### Variant Activation Times for Different Variant Control Modes in Variant Parameters

This table explains the variant activation time supported for different variant control modes in variant parameters. For information on variant activation times, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

Variant control mode	Variant activation time			
	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	not supported			
sim codegen switching	not supported

## Use Variant Control Variables in Variant Blocks

This topic explains how to use different types of variant control variables in variant blocks.

Consider the `slexVariantSubsystems` model.

The Controller subsystem block dialog specifies two potential variants `Linear Controller` and `Nonlinear Controller`. `Linear Controller` and `Nonlinear Controller` blocks are associated with variant condition expressions  $V == 1$  and  $V == 2$ . Here,  $V$  is the variant control variable that determines the active choice. You can change  $V$  to any of these types based on your requirement.

### In this section...

“Simulink.VariantControl Variables for Coherent Switching of Choices in Variant Blocks” on page 12-57

“Scalar Variant Control Variables for Rapid Prototyping in Variant Blocks” on page 12-59

“Simulink.Parameter Type of Variant Control Variables for Code Generation in Variant Blocks” on page 12-60

“Enumerated Types To Improve Code Readability of Variant Control Variables of Variant Blocks” on page 12-62

“Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks” on page 12-64

“Structures to Group Related Variant Control Variables of Variant Blocks” on page 12-65

## Simulink.VariantControl Variables for Coherent Switching of Choices in Variant Blocks

You can associate a variant control variable of type `Simulink.VariantControl` with a variant activation time. `Simulink.VariantControl` variant control variables help you switch variant elements such as blocks and parameters coherently.

Consider a group of blocks that represents a design choice, with each block having the same variant control variable of type `Simulink.VariantControl`. If you set the variant activation time of these blocks to `inherit` from `Simulink.VariantControl`, the blocks inherit the activation time from the variant control variable. As a result, all the blocks have the same activation time and are activated simultaneously to generate rational simulation results and valid code.

You can define `Simulink.VariantControl` type of control variables in storage locations as listed in “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.

Open the `slexVariantSubsystems` model.

```
open_system('slexVariantSubsystems');
```

```
VSS_MODE = 2
```

In the block parameters dialog box of the Controller block:

1. Specify the variant controls, `V == 1` and `V == 2`.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'VariantControl', 'V==1')
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'VariantControl', 'V==2')
```

2. Set **Variant activation time** to inherit from `Simulink.VariantControl` to inherit the activation time from V.

```
set_param('slexVariantSubsystems/Controller', 'VariantActivationTime', 'inherit from Simulink.Va
```

In the base workspace, define a `Simulink.VariantControl` object, V. Set its value to 1, variant activation time to `update diagram`, and then simulate the model.

```
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'update diagram')
```

```
V =
  VariantControl with properties:
      Value: 1
  ActivationTime: 'update diagram'
```

During simulation, the Controller block inherits the `update diagram` activation time from V and the `Linear Controller` block becomes active.

Double-click the Controller block to see the active choice.

```
sim('slexVariantSubsystems');
```

If you change the value of V to 2, the Nonlinear Controller block becomes active during simulation. You can change the value of V using this command or from Simulink.VariantControl dialog box.

```
V.Value = 2;
sim ('slexVariantSubsystems');
```

If you change the variant activation time of V to update diagram analyze all choices, the Controller block inherits the update diagram analyze all choices activation time from V. You can observe the inherited activation time using CompiledVariantActivationTime.

```
V.ActivationTime = 'update diagram analyze all choices';
sim ('slexVariantSubsystems');
get_param('slexVariantSubsystems/Controller', 'CompiledVariantActivationTime')

ans =
'update diagram analyze all choices'
```

## Scalar Variant Control Variables for Rapid Prototyping in Variant Blocks

Scalar MATLAB® variant control variables allow you to rapidly prototype variant choices when you are still building your model. Scalar MATLAB variant control variables help you focus more on building your variant choices than on developing the expressions that activate those choices.

You can define scalar control variables in storage locations as listed in “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.

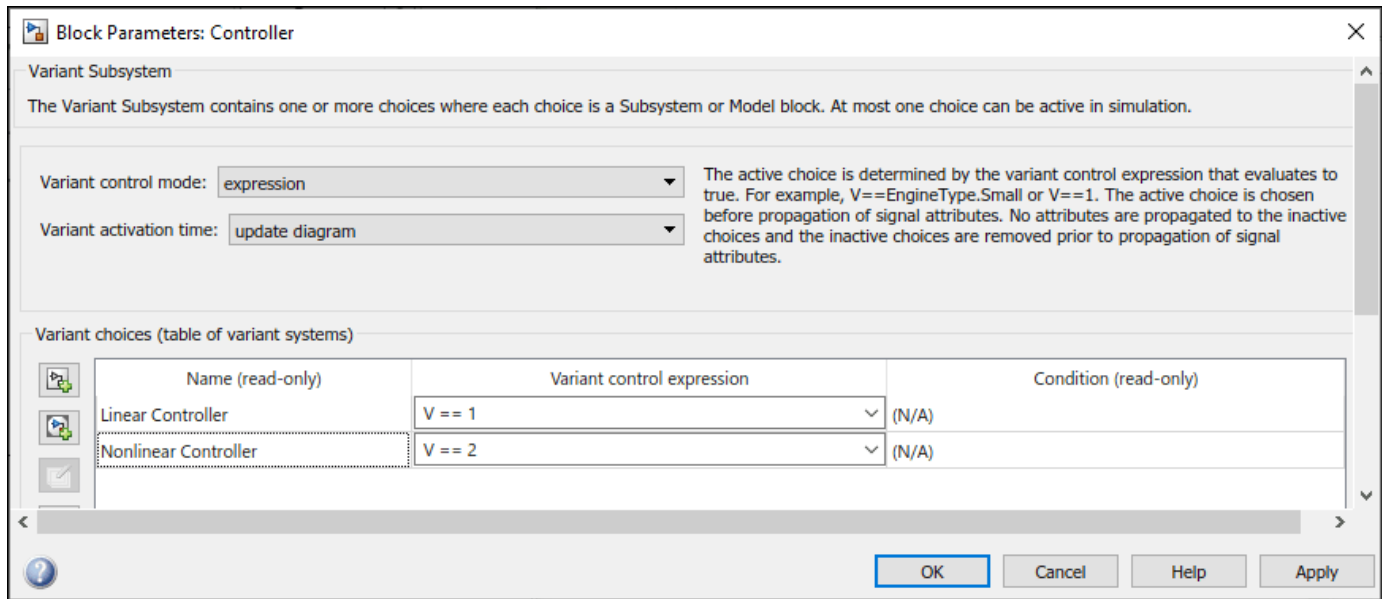

Open the slexVariantSubsystems model.

```
open_system('slexVariantSubsystems');

VSS_MODE = 2
```

In the block parameters dialog box of the Controller block, specify variant controls in their simplest form as scalar variables, V == 1 and V == 2.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'VariantControl', 'V==1')
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'VariantControl', 'V==2')
```

In the base workspace, define a variant control variable,  $V$ , set its value to 1, and then simulate the model.

```
V = 1;
```

During simulation, the Linear Controller block becomes active. Double-click the Controller block to see the active choice.

```
sim('slexVariantSubsystems');
```

Similarly, if you change the value of  $V$  to 2, the Nonlinear Controller block becomes active during simulation.

```
V = 2;
sim('slexVariantSubsystems');
```

## Simulink.Parameter Type of Variant Control Variables for Code Generation in Variant Blocks

If you intend to generate code for a model containing variant blocks, specify variant control variables as `Simulink.Parameter` objects. `Simulink.Parameter` objects allow you to specify other attributes, such as data type and storage class, and control the appearance and placement of variant control variables in generated code.

- You can define a variant control variable of type `Simulink.Parameter` only in the base workspace or in a data dictionary. Defining `Simulink.Parameter` type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.
- `Simulink.Parameter` objects within structures and that have data types other than `Simulink.Bus` objects are not supported.

Open the `slexVariantSubsystems` model.

```
open_system('slexVariantSubsystems');
VSS_MODE = 2
```

In the MATLAB Editor, define a `Simulink.Parameter` object, `V`.

```
V = Simulink.Parameter;
V.Value = 1;
V.DataType = 'int32';
V.CoderInfo.StorageClass = 'Custom';
V.CoderInfo.CustomStorageClass = 'ImportedDefine';
V.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

### Note:

Variant control variables defined as `Simulink.Parameter` objects can have any of the storage classes listed in “Storage Classes for Different Variant Activation Times” on page 12-88.

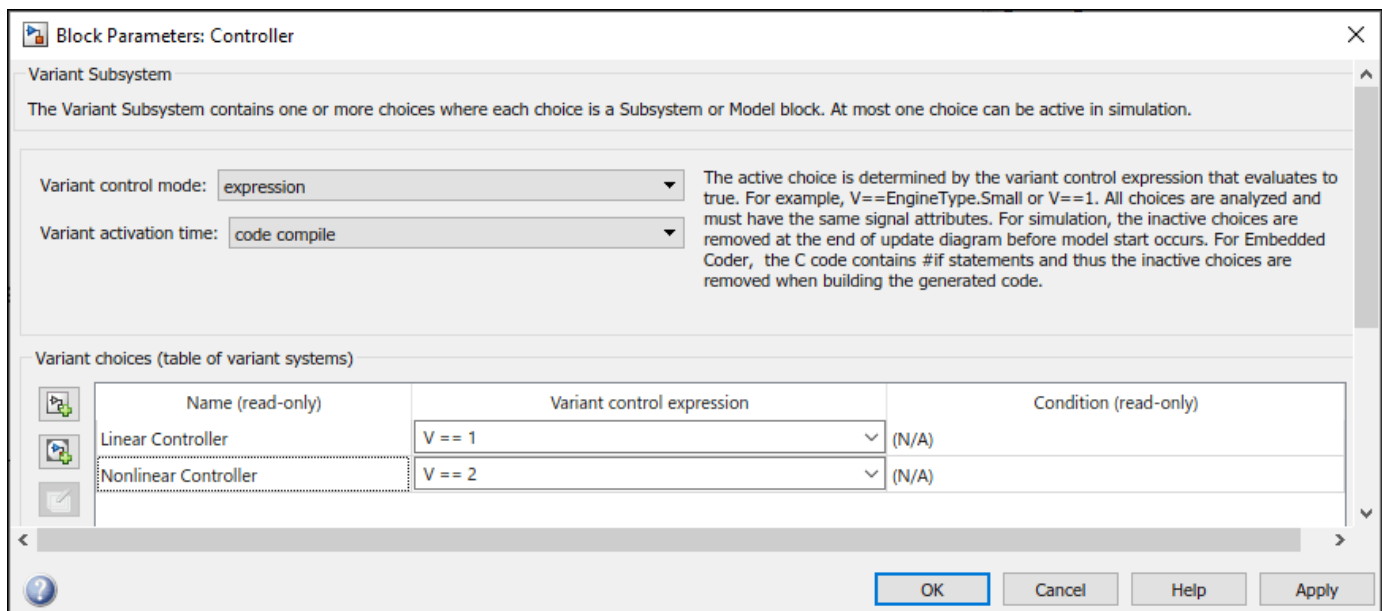

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. For more information, see “Convert Variant Control Variables into `Simulink.Parameter` Objects” on page 12-103.

Specify the `Simulink.Parameter` object as the variant control variable in the block parameters dialog box of the Controller block. Also, change the **Variant activation time** to `code compile`.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'VariantControl', 'V==1')
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'VariantControl', 'V==2')
set_param('slexVariantSubsystems/Controller', 'VariantActivationTime', 'code compile')
```

Ensure that the Linear Controller and NonLinear Controller blocks are atomic.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'TreatAsAtomicUnit', 'on');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'TreatAsAtomicUnit', 'on');
```

During simulation, the `Linear Controller` block becomes active. Double-click the `Controller` block to see the active choice.

```
sim ('slexVariantSubsystems');
```

Similarly, if you change the value of `V` to 2, the `Nonlinear Controller` block becomes active during simulation.

```
V .Value = 2;
sim ('slexVariantSubsystems');
```

Generate code from the model. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder).

The generated code contains both `Linear` and `Nonlinear` choices in preprocessor conditionals `#if` and `#elif` because of the code compile activation time. The variant control variable `V` is defined using a macro — `#define` directive — in the header file `demos_macro.h`. You can control the appearance and placement of `V` in the generated code and prevent optimizations from eliminating storage for `V` using the storage class property. For more information, see “Storage Classes for Different Variant Activation Times” on page 12-88.

```
% demos_macro.h
% /* Exported data define */
%
% /* Definition for custom storage class: Define */
% #define V          1          /* Referenced by:
%                               * '<S1>/Linear Controller'
%                               * '<S1>/Nonlinear Controller'
%                               */
% #endif                    /* RTW_HEADER_demo_macros_h_ */
```

## Enumerated Types To Improve Code Readability of Variant Control Variables of Variant Blocks

Use enumerated types to give meaningful names to integers used as variant control values. For more information on enumerated type data, see “Use Enumerated Data in Simulink Models” on page 73-6.

In the MATLAB® Editor, define the classes that map enumerated values to meaningful names.

Open the `slexVariantSubsystems` model.

```
open_system('slexVariantSubsystems');
```

```
VSS_MODE = 2
```

In the base workspace, define the classes that map enumerated values to meaningful names.

Here, `EngType` is an integer-based enumeration class that is derived from the built-in data type, `int32`. The class has two enumeration values, `Linear` and `NonLinear`. These enumerated values have underlying integer values 0 and 1.

```
type EngType
```

```

classdef EngType < Simulink.IntEnumType
    enumeration
        Small (1)
        Big (2)
    end
end

```

Specify the enumeration names as variant control variables in the block parameters dialog box of the Controller block. Also, change the **Variant activation time** to code compile.

```

set_param('slexVariantSubsystems/Controller/Linear Controller', 'VariantControl', 'V==EngType.Small');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'VariantControl', 'V==EngType.Big');
set_param('slexVariantSubsystems/Controller', 'VariantActivationTime', 'code compile')

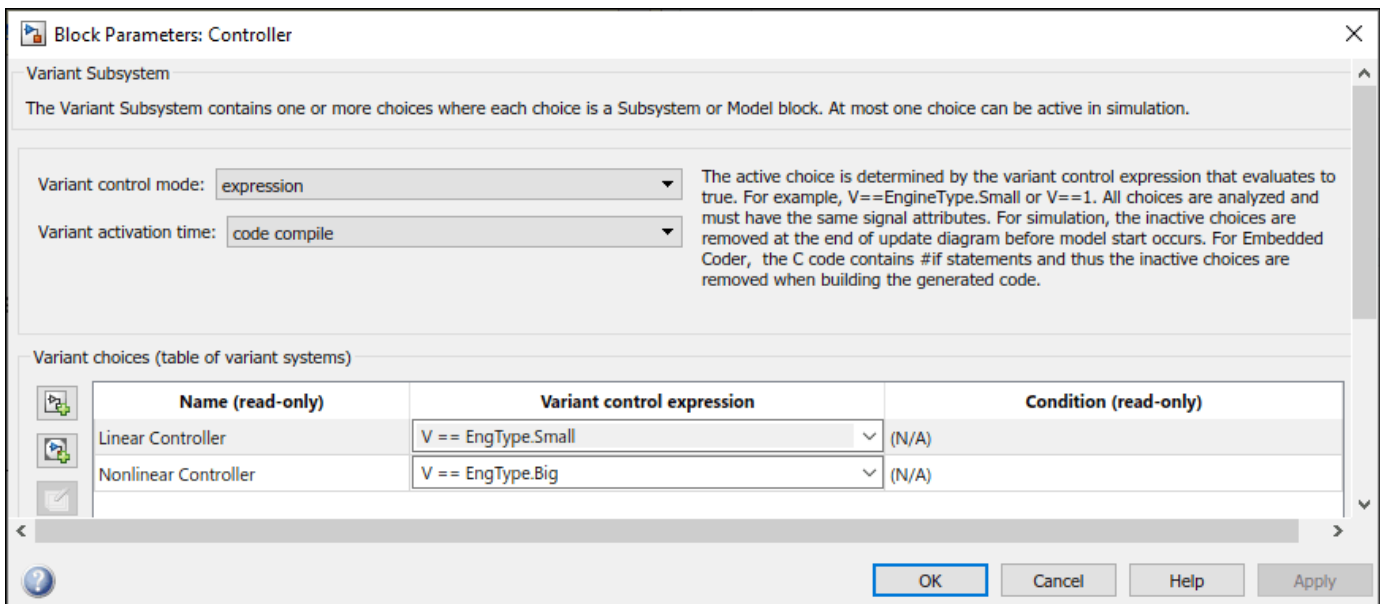

```

Ensure that the Linear Controller and NonLinear Controller blocks are atomic.

```

set_param('slexVariantSubsystems/Controller/Linear Controller', 'TreatAsAtomicUnit', 'on');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'TreatAsAtomicUnit', 'on');

```

Define the variant control variable, `V` in the base workspace, specify its value as `EngType.Small` and then simulate the model.

```
V = EngType.Small;
```

During simulation, the Linear Controller block becomes active. Double-click the Controller block to see the active choice.

```
sim('slexVariantSubsystems');
```

The code that you generate using enumerated types contains the names of the values rather than integers. Here, values 1 and 2 are represented as `EngType_Small` and `EngType_Big`.

```

% slexVariantSubsystems_types.h
% #ifndef V
% #define V                               EngType_Small
% #endif

```

```

%
% #ifndef DEFINED_TYPEDEF_FOR_EngType_
% #define DEFINED_TYPEDEF_FOR_EngType_
%
% typedef int32_T EngType;
%
% /* enum EngType */
% #define EngType_Small          (1)      /* Default value */
% #define EngType_Big           (2)
% #endif

% slexVariantSubsystems.c
% void slexVariantSubsystems_step(void)
% {
%     #if V == EngType_Small
%         logic of Linear Controller
%     #elif V == EngType_Big
%         logic of Nonlinear Controller
%     #endif
% }

```

Note that for variant blocks with “startup” on page 12-82 activation time, only enumerations that are defined using these techniques are supported:

- Using the function `Simulink.defineIntEnumType`
- By subclassing built-in integer data types `int8`, `int16`, `int32`, `uint8`, or `uint16`, or by subclassing `Simulink.IntEnumType`

These enumerations are also supported when permanently stored in a Simulink® data dictionary. See “Enumerations in Data Dictionary” on page 79-14.

## Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks

After identifying the variant values that your model requires, you can construct complex variant conditions to control the activation of your variant parameter values by defining variant conditions as `Simulink.Variant` objects. `Simulink.Variant` objects enable you to reuse common variant conditions across models and help you encapsulate complex variant condition expressions.

You can specify the whole of a variant condition expression or only the variant control variable inside the condition expression of type `Simulink.Variant`.

### Note:

- You can define a variant control variable of type `Simulink.Variant` only in the base workspace or in a data dictionary. Defining `Simulink.Variant` type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.
- `Simulink.Variant` within structures are not supported.

Open the `slexVariantSubsystems` model.

```
open_system('slexVariantSubsystems');
```

```
VSS_MODE = 2
```

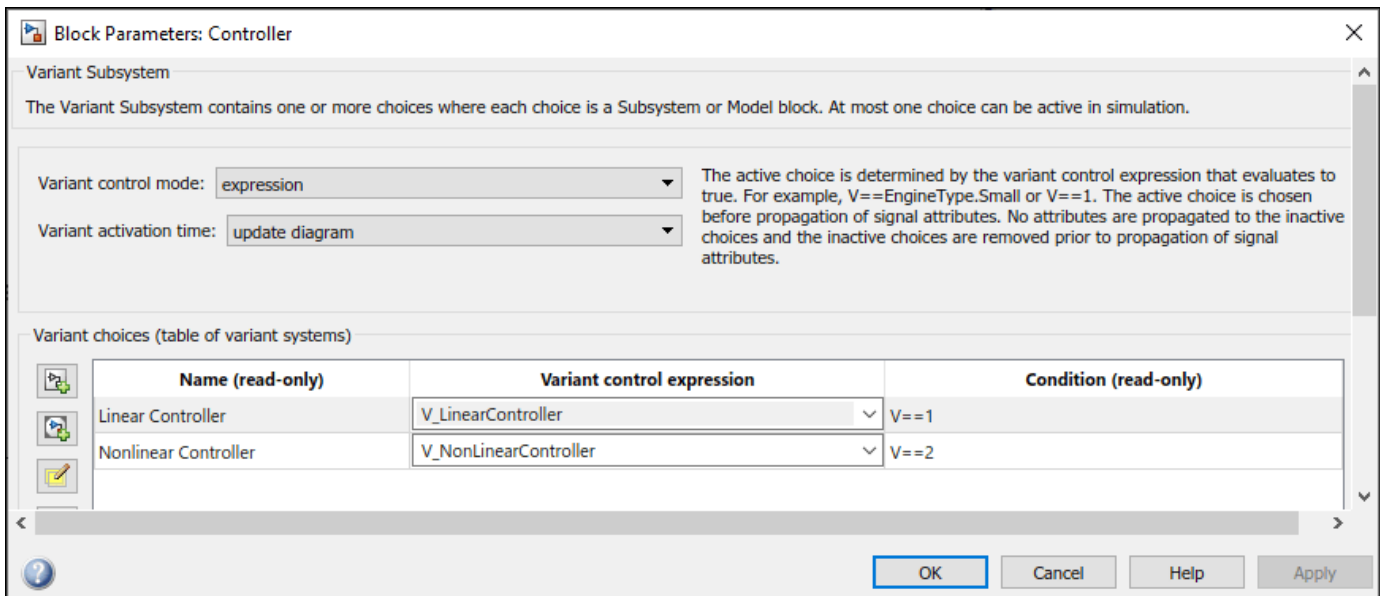

In the MATLAB® Editor, encapsulate variant control expressions as `Simulink.Variant` objects.

```
V_LinearController=Simulink.Variant('V==1');
V_NonLinearController=Simulink.Variant('V==2');
```

Specify the `Simulink.Variant` objects as the variant control variables in the block parameters dialog box of the Controller block.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'VariantControl', 'V_LinearController');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'VariantControl', 'V_NonLinearController');
```

The **Condition** column automatically shows the boolean condition that the `Simulink.Variant` object represents.

Define the variant control variable,  $V$ , specify its value as 1 and then simulate the model.

```
V = 1;
```

During simulation, the Linear Controller block becomes active. Double-click the Controller block to see the active choice.

```
sim('slexVariantSubsystems');
```

Using this approach, you can develop complex variant condition expressions that are reusable.

## Structures to Group Related Variant Control Variables of Variant Blocks

Use MATLAB® structure elements to group related variant control variables. You can control the characteristics of structures in the generated code and the placement of structures in memory. For more information, see `struct`.

Note that you can define a variant control variable of type structure only in the base workspace or in a data dictionary. Defining the structure type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.

Open the `slexVariantSubsystems` model.

```
open_system('slexVariantSubsystems');
```

```
VSS_MODE = 2
```

In the base workspace, define a structure to store related variant control variables. Add fields to the structure using dot notation.

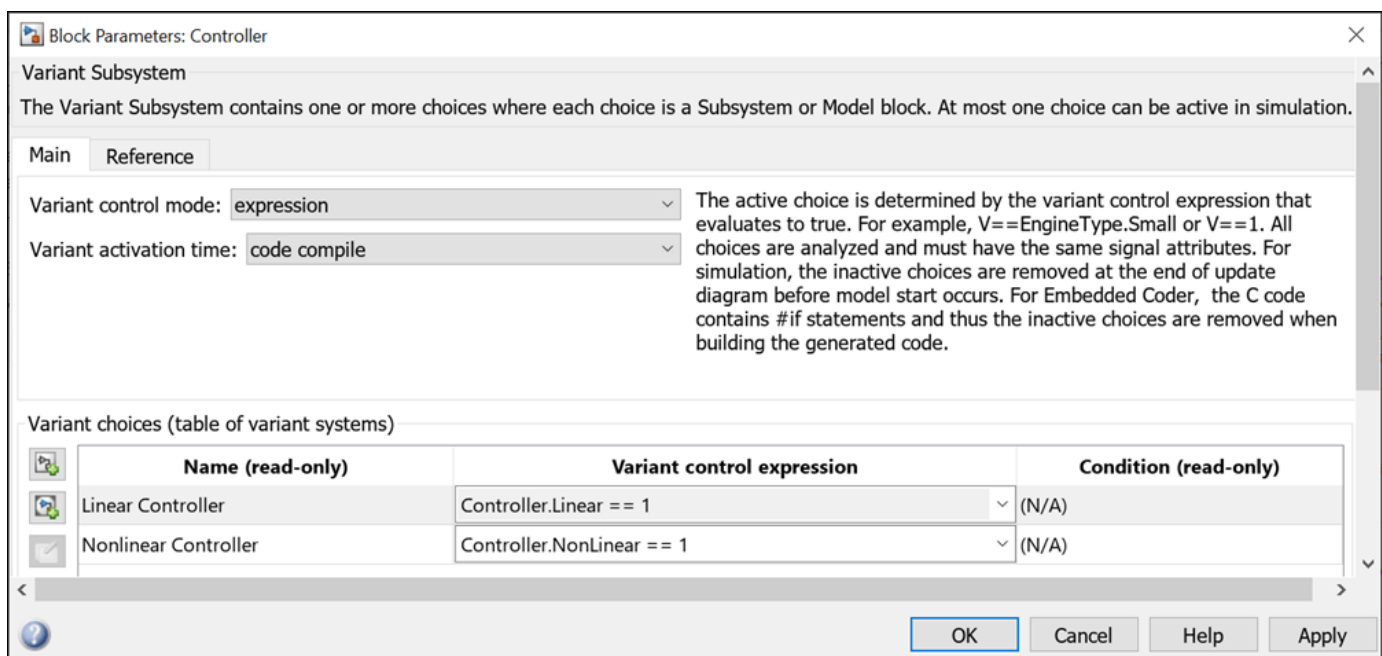

```
Controller.Linear = 1;
Controller.NonLinear = 0;
```

In the block parameters dialog box of the Controller block, specify variant controls using dot notation. Also, change the **Variant activation time** to `code compile`.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'VariantControl', 'Controller.Linear');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'VariantControl', 'Controller.NonLinear');
set_param('slexVariantSubsystems/Controller', 'VariantActivationTime', 'code compile');
```

Ensure that the Linear Controller and NonLinear Controller blocks are atomic.

```
set_param('slexVariantSubsystems/Controller/Linear Controller', 'TreatAsAtomicUnit', 'on');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller', 'TreatAsAtomicUnit', 'on');
```

Simulate the model. During simulation, the Linear Controller block becomes active.

```
sim('slexVariantSubsystems');
```

Double-click the Controller block to see the active choice.

Now, generate code from the model. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder).

The generated code contains both Linear and Nonlinear choices in the preprocessor conditionals `#if` and `#elif` because of the code compile activation time.

The generated header file `slexVariantSubsystems_types.h` defines a structure type that has a random name and initializes the variables `Controller_Linear` and `Controller_NonLinear`.

```
% #ifndef Controller_Linear
% #define Controller_Linear          1
% #endif
%
% #ifndef Controller_NonLinear
% #define Controller_NonLinear      0
% #endif
%
% #ifndef DEFINED_TYPEDEF_FOR_struct_XfS20q0AY2qBc3cwjMQEtF_
% #define DEFINED_TYPEDEF_FOR_struct_XfS20q0AY2qBc3cwjMQEtF_
%
% typedef struct {
%     real_T Linear;
%     real_T NonLinear;
% } struct_XfS20q0AY2qBc3cwjMQEtF;
```

The source file `slexVariantSubsystems.c` defines the logic for `Controller_Linear` and `Controller_NonLinear` choices.

```
% void slexVariantSubsystems_step(void)
% {
%     #if Controller_Linear == 1
%         logic of Linear Controller
%     #elif Controller_NonLinear == 1
%         logic of Nonlinear Controller
%     #endif
% }
```

For more information, see “Organize Data into Structures in Generated Code” (Embedded Coder).

## Use Variant Control Variables in Variant Parameters

This topic explains how to use different types of variant control variables in variant parameters.

Consider the `slexVariantParameters` model.

The **Gain** parameter of the Gain blocks are variant parameters that are specified as `Simulink.VariantVariable` objects, K1 and K2. K1 and K2 have multiple values associated with variant condition expressions  $V == 1$  and  $V == 2$ . Here, the variant control variable  $V$  that determines the active value of K1 and K2 is a `Simulink.VariantControl` object. You can change  $V$  to any of these types based on your requirement.

**Note** Before you start with these examples, we recommend you complete “Create a Simple Variant Parameter Model” on page 12-178.

### In this section...

“Numeric Variant Control Values for Rapid Prototyping of Variant Parameters” on page 12-68

“Simulink.Parameter Type of Variant Control Variables for Code Generation of Variant Parameters” on page 12-70

“Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters” on page 12-73

“Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters” on page 12-76

## Numeric Variant Control Values for Rapid Prototyping of Variant Parameters

Numeric values allow you to rapidly prototype variant values when you are still building your model. Numeric values help you focus more on building your variant values than on developing the expressions that activate those choices.

You can define numeric control values in locations listed in “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

In the MATLAB Editor, specify variant choices in their simplest form as numeric values in `Simulink.VariantVariable` objects K1 and K2.

```
K1 = Simulink.VariantVariable('Choices',{ 'V==1', 3.5, 'V==2', 8.5})
```

```
K1 =  
VariantVariable with 2 choices:
```

Condition	Value
V == 1	3.5000
V == 2	8.5000

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices',{ 'V==1', 4.5, 'V==2', 9.5})
```

```
K2 =  
VariantVariable with 2 choices:
```

Condition	Value
V == 1	4.5000
V == 2	9.5000

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining a control variable, *V*, and setting its value to 1 in a `Simulink.VariantControl` object.

```
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'update diagram')
```

```
V =
  VariantControl with properties:
      Value: 1
  ActivationTime: 'update diagram'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. *K1* is assigned a value of 3.5 and *K2* is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of *V* to 2, Simulink® sets the value of *K1* and *K2* to 4.5 and 9.5 during simulation. You can change the value of *V* using this command or from `Simulink.VariantControl` dialog box.

```
V.Value = 2;
sim('slexVariantParameters')
```

## Simulink.Parameter Type of Variant Control Variables for Code Generation of Variant Parameters

If you intend to generate code for a model containing variant parameters, specify variant control variables as `Simulink.Parameter` objects. `Simulink.Parameter` objects allow you to specify other attributes, such as data type and storage class, and control the appearance and placement of variant control variables in generated code.

- You can define a variant control variable of type `Simulink.Parameter` only in the base workspace or in a data dictionary. Defining `Simulink.Parameter` type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.
- `Simulink.Parameter` objects within structures and that have data types other than `Simulink.Bus` objects are not supported.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

In the MATLAB Editor, define a `Simulink.Parameter` object.

```
VSS_MODE = Simulink.Parameter;
VSS_MODE.Value = 1;
VSS_MODE.DataType = 'int32';
VSS_MODE.CoderInfo.StorageClass = 'Custom';
VSS_MODE.CoderInfo.CustomStorageClass = 'Define';
VSS_MODE.CoderInfo.CustomAttributes.HeaderFile = 'demo_macros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have any of the storage classes listed in “Storage Classes for Different Variant Activation Times” (Embedded Coder).

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. For more information, see “Convert Variant Control Variables into `Simulink.Parameter` Objects” on page 12-103.

Specify the object as a variant control in `Simulink.VariantVariable` objects K1 and K2.

```
K1 = Simulink.VariantVariable('Choices',{'V == 1', 3.5, 'V == 2', 8.5})
```

```
K1 =
VariantVariable with 2 choices:
```

Condition	Value
V == 1	3.5000
V == 2	8.5000

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices',{'V == 1', 4.5, 'V == 2', 9.5})
```

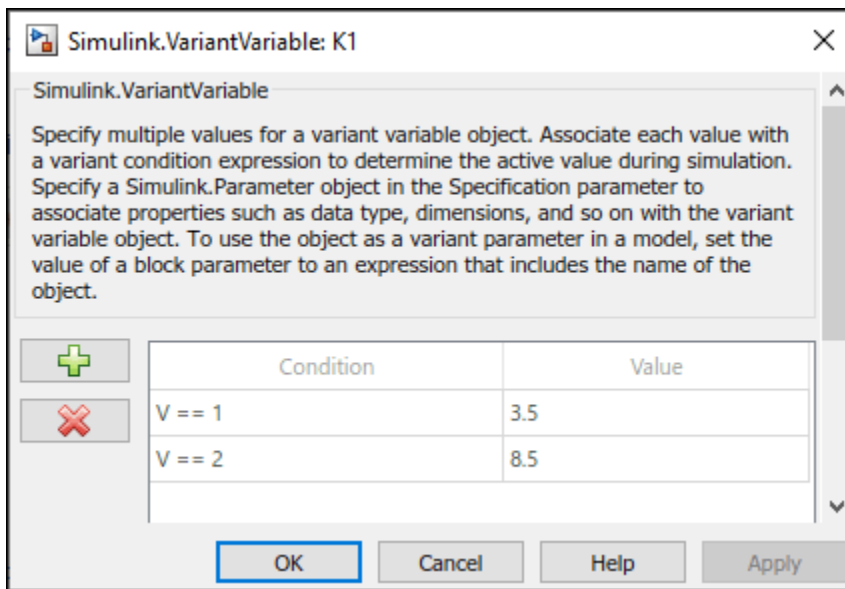

```
K2 =
VariantVariable with 2 choices:
```

Condition	Value
V == 1	4.5000
V == 2	9.5000

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining a control variable `V` and setting its value to `VSS_MODE` in a `Simulink.VariantControl` object.

```
V = Simulink.VariantControl('Value',VSS_MODE,'ActivationTime','code compile')
```

```
V =
  VariantControl with properties:
      Value: [1x1 Simulink.Parameter]
  ActivationTime: 'code compile'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. `K1` is assigned a value of 3.5, and `K2` is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of `VSS_MODE` to 2, Simulink® sets the value of `K1` and `K2` to 4.5 and 9.5 during simulation. You can change the value of `V` using this command or from `Simulink.VariantControl` dialog box.

```
VSS_MODE.Value = 2;
V.Value = VSS_MODE;
sim('slexVariantParameters')
```

Generate code from the model. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder)

The generated code contains both `Linear` and `Nonlinear` choices in preprocessor conditionals `#if` and `#elif` because of the code compile activation time. The variant control variable `V` is defined using a macro — `#define` directive — in the header file `demo_macros.h`. You can control the appearance and placement of `V` in the generated code and prevent optimizations from eliminating storage for `V` using the storage class property. For more information, see “Storage Classes for Different Variant Activation Times” (Embedded Coder).

```
% demo_macros.h
% /* Exported data define */
%
% /* Definition for custom storage class: Define */
% #define V      2          /* Referenced by:
%                          * '<Root>/Gain'
%                          * '<Root>/Gain1'
%                          */
% #endif                  /* RTW_HEADER_demo_macros_h_ */
%
% /*
```

## Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters

Use enumerated types to give meaningful names to integers used as variant control values. For more information on enumerated type data, see “Use Enumerated Data in Simulink Models” on page 73-6.

In the MATLAB® Editor, define the classes that map enumerated values to meaningful names.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

Specify the variant condition expressions `V == EngType.Small` and `V == EngType.Big` in Simulink.VariantVariable objects `K1` and `K2`.

```
K1 = Simulink.VariantVariable('Choices', {'V == EngType.Small',3.5,'V == EngType.Big',8.5})
```

```
K1 =
VariantVariable with 2 choices:
```

Condition	Value
<u>V == EngType.Big</u>	<u>8.5000</u>
V == EngType.Small	3.5000

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices', {'V == EngType.Small',4.5,'V == EngType.Big',9.5})
```

```
K2 =
VariantVariable with 2 choices:
```

Condition	Value
V == EngType.Big	9.5000
V == EngType.Small	4.5000

Specification: ''

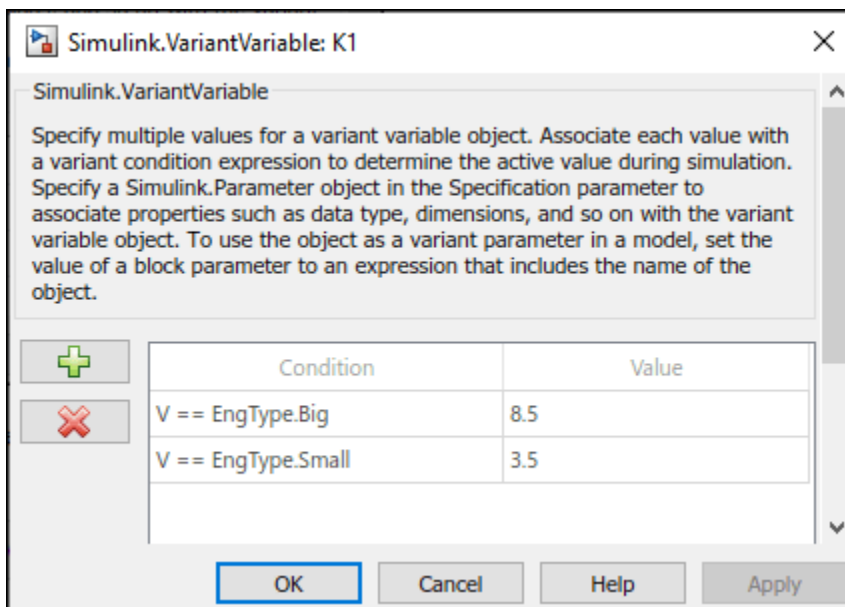

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Here, `EngType` is an integer-based enumeration class that is derived from the built-in data type, `int32`. The class has two enumeration values, `Small` and `Big`. These enumerated values have underlying integer values 1 and 2. In this example, the enumeration class is defined in the base workspace. You can choose to define the class in other storage locations as listed in “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.

type `EngType.m`

```
classdef EngType < Simulink.IntEnumType
    enumeration
        Small (1)
        Big (2)
    end
end
```

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining the control variable `V` and setting its value to `EngType.Small` in `Simulink.VariantControl` object `V`.

```
V = Simulink.VariantControl('Value', EngType.Small, 'ActivationTime', 'code compile')
```

```
V =
  VariantControl with properties:

      Value: Small
  ActivationTime: 'code compile'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. `K1` is assigned a value of 3.5, and `K2` is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of `V` to 2, Simulink® sets the value of `K1` and `K2` to 4.5 and 9.5 during simulation. You can change the value of `V` using this command or from `Simulink.VariantControl` dialog box.

```
V.Value = 2
```

```
V =
  VariantControl with properties:

      Value: 2
  ActivationTime: 'code compile'
```

```
sim('slexVariantParameters')
```

The code that you generate using enumerated types contains the names of the values rather than integers.

```
% slexVariantParameters_private.h
% #if V == EngType_Big || V == EngType_Small
%   /* Variable: K1 Referenced by: '<Root>/Gain' */
%   #if V == EngType_Big
%     #define rtCP_Gain_K1                (8.5)
%   #elif V == EngType_Small
%     #define rtCP_Gain_K1                (3.5)
%   #endif
% #endif
%
% #if V == EngType_Big || V == EngType_Small
%   /* Variable: K2 Referenced by: '<Root>/Gain1' */
%   #if V == EngType_Big
%     #define rtCP_Gain1_K2              (9.5)
%   #elif V == EngType_Small
%     #define rtCP_Gain1_K2              (4.5)
%   #endif
% #endif
% #endif
% #endif                                     /* RTW_HEADER_slexVariantParameters_private_h_ */
```

Note that for variant parameters with “startup” on page 12-82 activation time, only enumerations that are defined using these techniques are supported:

- Using the function `Simulink.defineIntEnumType`
- By subclassing built-in integer data types `int8`, `int16`, `int32`, `uint8`, or `uint16`, or by subclassing `Simulink.IntEnumType`

These enumerations are also supported when permanently stored in a Simulink® data dictionary. See “Enumerations in Data Dictionary” on page 79-14.

## Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters

After identifying the variant values that your model requires, you can construct complex variant conditions to control the activation of your variant parameter values by defining variant conditions as `Simulink.Variant` objects. `Simulink.Variant` objects enable you to reuse common variant conditions across models and help you encapsulate complex variant condition expressions.

- You can define a variant control variable of type `Simulink.Variant` only in the base workspace or in a data dictionary. Defining `Simulink.Variant` type of variant control variables in the mask or model workspace is not supported. For more information on storage locations for variant control variables, see “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.
- `Simulink.Variant` within structures are not supported.

Open the `slexVariantParameters` model.

```
open_system('slexVariantParameters')
```

In the MATLAB® Editor, encapsulate variant control expressions as `Simulink.Variant` objects.

```
LinearController=Simulink.Variant('V==1');
NonLinearController=Simulink.Variant('V==2');
```

Specify the `Simulink.Variant` objects as the variant controls in a `Simulink.VariantVariable` objects K1 and K2.

```
K1 = Simulink.VariantVariable('Choices',{'LinearController',3.5,'NonLinearController',8.5})
```

```
K1 =
VariantVariable with 2 choices:
```

Condition	Value
LinearController	3.5000
NonLinearController	8.5000

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

```
K2 = Simulink.VariantVariable('Choices',{'LinearController',4.5,'NonLinearController',9.5})
```

```
K2 =
VariantVariable with 2 choices:
```

Condition	Value
LinearController	4.5000

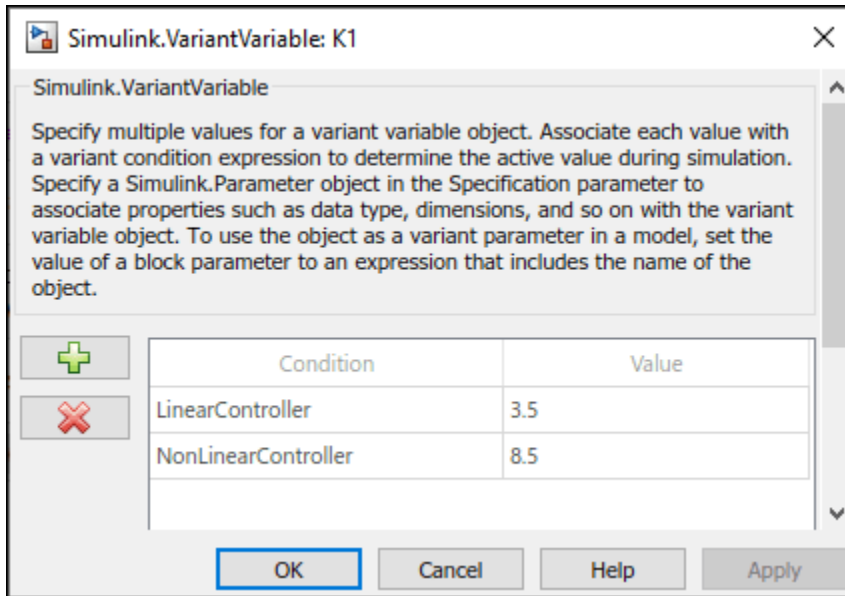

```
NonLinearController    9.5000
```

```
Specification: ''
```

Use `getChoice`, `setChoice`, `addChoice`, `removeChoice` to access, modify, add or remove choices

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the `VariantVariable` dialog box.

Activate one of the variant values by defining a `Simulink.VariantControl` object `V` and setting its value to 1.

```
V = Simulink.VariantControl('Value',1,'ActivationTime','update diagram')
```

```
V =
  VariantControl with properties:
      Value: 1
  ActivationTime: 'update diagram'
```

When you simulate the model, the condition `V == 1` evaluates to `true`. `K1` is assigned a value of 3.5, and `K2` is assigned a value of 8.5.

```
sim('slexVariantParameters')
```

If you change the value of `V` to 2, Simulink® sets the value of `K1` and `K2` to 4.5 and 9.5 during simulation. You can change the value of `V` using this command or from `Simulink.VariantControl` dialog box.

```
V.Value = 2;
sim('slexVariantParameters')
```

Using this approach, you can develop complex variant condition expressions that are reusable.

## Activate Variant During Different Stages of Simulation and Code Generation Workflow

Using variant activation time, Simulink sets active choices in variant blocks and variant parameters during different stages of simulation and code generation workflows.

The active choice is set:

- During the model compile stage, or the simulation-loop stage of the simulation workflow.
- During the model compile stage, the code compile stage, or the model startup stage of the code generation workflow.

See “Stages to Set Active Choices in Variant Blocks and Variant Parameters” on page 12-80.

To set the active choice, Simulink evaluates the variant controls that you specify in the workspace browser, at the command line, or in the callbacks, such as `InitFcn`, `PreLoadFcn`, and `PostLoadFcn`. For more information on callbacks, see “Model Callbacks” on page 4-54.

Setting the active choice at intermediate stages improves the speed of simulation and code generation workflows by enabling you to reuse the artifacts from the previous run. It also enables you to analyze variant choices for incompatibilities, such as datatype and dimension mismatches, prior to simulation and code generation.

For example, the code that you generate with `code compile` activation time contains all the choices. Prior to the code compilation, you can specify the value of the variant control variable. Based on the value of the variant control variable, Simulink sets the active choice, and the code is conditionally compiled only for the active choice. You can reuse the same code every time you change the value of the variant control variable. The code conditionally compiles for the given active choice.

Similarly, the code that you generate with `startup` activation time also contains all the choices. Prior to running the executable of the code, you can specify the active choice by changing the value of the variant control variable. You can reuse the same executable every time you change the value of the variant control variable. The executable conditionally runs for the given active choice. Additionally, `startup` activation time enables you to skip recompilation and directly start simulating the model. Recompiling the model is not required for accurate results.

---

**Note** Only one choice can be active any given stage of the simulation and code generation workflow.

---

### Stages to Set Active Choices in Variant Blocks and Variant Parameters

These tables describe the stages at which Simulink sets the active choice of variant blocks and variant parameters during simulation and code generation workflow.

Stages of Simulation Workflow	Description	Variant Activation Time
model compile	This is the first stage of the simulation workflow. In this stage, the block parameter expressions and callback functions of the model are evaluated, signal attributes, sample time attributes, and block execution order is determined, and the block is optimized to improve the simulation speed.	<ul style="list-style-type: none"> <li>• “update diagram” on page 12-81</li> <li>• “update diagram analyze all choices” on page 12-81</li> </ul>
simulation-loop	The Simulink successively computes the states and outputs of the system at intervals from the simulation start time to the finish time.	“startup” on page 12-82

For more information on stages in the simulation workflow, see “Simulation Phases in Dynamic Systems” on page 3-2.

Stages of Code Generation Workflow	Description	Variant Activation Time
model compile	This is the first stage of the simulation workflow. In this stage, the block parameter expressions and callback functions of the model are evaluated, signal attributes, sample time attributes, and block execution order is determined, and the block is optimized to improve the simulation speed.	<ul style="list-style-type: none"> <li>• “update diagram” on page 12-81</li> <li>• “update diagram analyze all choices” on page 12-81</li> </ul>
code compile	The C code is translated to machine code.	“code compile” on page 12-82
model startup	The central processing unit executes the model’s machine code instructions.	“startup” on page 12-82

## Types of Variant Activation Time in Variants Blocks and Variant Parameters

Simulink sets the active choice of variant blocks and variant parameters during different stages of simulation and code generation workflow using these variant activation times:

### update diagram

During simulation, Simulink sets and retains the active choice at the start of the model compilation stage before the signal attributes are propagated to the blocks. The inactive choices are removed from the simulation workflow. Signal attributes are then propagated only to the active choice, so only the active choice participates in the subsequent stages of simulation. The signal attributes are not analyzed for consistency across the model.

The code generation workflow is same as the simulation workflow. Since only active choices are retained and inactive choices are removed in the model compilation stage, the code that is generated in the codegen stage contains only the active choice.

For information on how to use the `update diagram` activation time in variant blocks and in variant parameters, see “Variant activation time” and “ActivationTime”.

### update diagram analyze all choices

During simulation, Simulink propagates signal attributes to all variant choices. The signal attributes in the choices are analyzed to check if each block can accept the signals connected to its inputs. Simulink then sets and retains the active choice late in the model compilation stage. The inactive choices are removed from the simulation workflow, so only active choice participates in the subsequent stages of simulation.

The code generation workflow is same as the simulation workflow. Since only active choices are retained and inactive choices are removed in the model compilation stage, the code that is generated in the codegen stage contains only the active choice.

For information on how to use the `update diagram analyze all choices` activation time in variant blocks and in variant parameters, see “Variant activation time” and “ActivationTime”.

### **code compile**

The simulation workflow is same as `update diagram analyze all choices`.

During code generation, Simulink propagates signal attributes to all variant choices. The signal attributes in all the choices are analyzed to check if each block can accept the signals connected to its inputs. All the choices participate in the codegen stage of the workflow. Thus, the generated code includes all the choices. In the code, the choices are enclosed in the C preprocessor conditionals `#if` and `#else`.

Simulink sets the active choice only when you compile the code to generate an executable from it. In other words, when you compile the code, the compiler accepts the active choice as input. The compiler compiles the preprocessor conditionals for the active choice and generates an executable for only the active choice. This option does not require you to regenerate the code next time you specify a different active choice. You generate the code only once, and you can then specify a different active choice prior to code compile and build the executable for that active choice.

---

**Note** In code compile:

- You must install Simulink Coder to generate code for only active choices in the model.
  - You must install Embedded Coder to generate code for active and inactive choices in the model.
- 

For information on how to use the `code compile` activation time in variant blocks and in variant parameters, see “Variant activation time” and “Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211.

### **startup**

During simulation, Simulink propagates signal attributes to all variant choices. The signal attributes in all the choices are analyzed to check if each block can accept the signals connected to its inputs. Simulink then sets and retains the active choice and removes the inactive choices in the simulation-loop stage. Only the active choice participates in the simulation-loop stage. This option does not require you to compile the model next time you change the active choice. You compile the model only once, and you can then specify a different active choice prior to the simulation-loop stage and simulate the model. Simulink successively computes the states and outputs of the model for that active choice.

During code generation, Simulink propagates signal attributes to all the variants choices. The signal attributes in all the choices are analyzed to check if each block can accept the signals connected to its inputs. All the choices participate in the codegen stage of the workflow and hence, the generated code includes all the choices. In the code, the choices are enclosed in regular `if` conditions.

Simulink sets the active choice only when you run the executable that is built from the generated code. In other words, when you run the executable, the central processing unit accepts the active

choice as input. The processor executes the `if` conditions for the active choice and generates the output for only the active choice. The advantage of using this option is that you are not required to regenerate the executable the next time you specify a different active choice. You generate the executable only once. You can then specify a different active choice prior to the running the executable and then generate the output for that active choice.

---

**Note** In `startup`, you must install either Simulink Coder or Embedded Coder to generate code for active and inactive choices in the model.

---

With `startup` activation time, you can:

- Perform a fast restart simulation on your model and change the active choice prior to the simulation-loop stage without the need to recompile the model each time. This improves the Simulink Test workflow with fast restart. For more information, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-244, “Simulate Variant Subsystem with Startup Activation Using `parsim`” on page 12-261, and “Verify and Validate Variant Models with Startup Activation Time” on page 12-267.
- Perform an accelerator or rapid accelerator simulation on your models. You can simulate a model incrementally with different variant configurations by changing the active variant each time without the need to regenerate code when there is no structural changes in the model. For more information, see “Simulate Variant Blocks in Accelerator and Rapid Accelerator Modes with Startup Activation Time” on page 12-272 and “Run Executable for Different Variant Parameter Values Without Recompiling Code” on page 12-274.
- Collect and aggregate coverage results from multiple simulations of Variant Subsystem, Variant Source, and Variant Sink blocks. With activation time set to `startup`, the coverage report displays all variant choices, regardless of whether they activate during the simulation. If a variant is not active during a simulation, the coverage analysis reports 0% coverage for that variant choice. For more information, see “Model Coverage for Variant Blocks” (Simulink Coverage).
- Simulate and create real-time applications from Simulink models with Variant blocks and run them on Speedgoat target computer hardware connected to your physical systems. To create real time models, you must change the Variants to `atomic` and set the variant parameter as `Simulink.Parameter`. For more information, see “Create Real-Time Applications Using Variants and Simulink Real-Time” on page 12-301
- Create standalone executables outside of Simulink with different variant configurations and simulate the standalone executable by changing the active variant via an input to the executable. For more information see, “Create Standalone Executables with Variants Using Simulink Compiler” on page 12-293.
- Generate HDL code that contains both active and inactive choices of a Variant Subsystem block. In the generated HDL code, the variant control variable is a tunable port. You can set the active choice by providing the value of the variant control variable at the model startup. For more information, see “Variant Subsystem: Using Variant Subsystems for HDL Code Generation” (HDL Coder).
- Export and import models with inline variant blocks, and variant subsystems to a standalone Functional Mock-up Unit (FMU). The Variant activation time of the variant blocks must be set to `startup`. You can also import an existing FMU by using the FMU block. For more information, see “Export and Import Function Mockup Unit (FMU) from Model with Variant Subsystem Blocks” on page 12-311.

For information on limitations with the `startup` activation time, see “Known Limitations of startup variant activation time” on page 12-264.

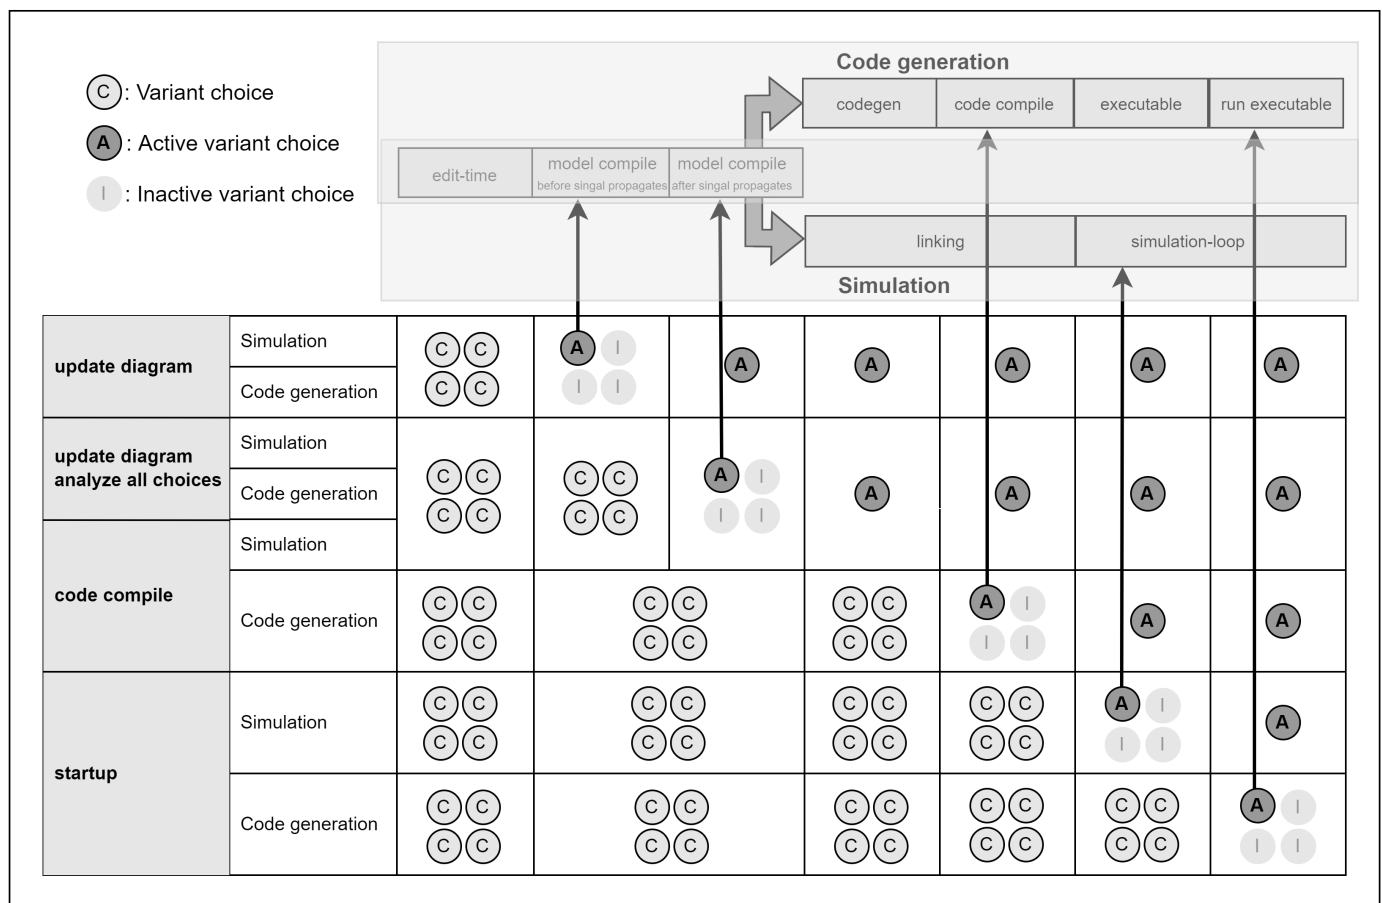

**inherit from Simulink.VariantControl**

The variant block inherits the activation time from its variant control variable of type `Simulink.VariantControl`. Inheriting the activation time from variant control variables help you switch variant elements such as blocks and parameters coherently. If a variant block has multiple variant control variables of type `Simulink.VariantControl`, then all those variables must have the same activation time.

For information on how to use the `inherit from Simulink.VariantControl` activation time in variant blocks, see “Variant activation time”. For an example, see “Simulink.VariantControl Variables for Coherent Switching of Choices in Variant Blocks” on page 12-57.

**Illustration of Different Variant Activation Times**

This figure shows the stages at which Simulink sets the active choice for different variant activation times.

**Variant Activation Time for Variant Blocks**

This section explains how to specify the variant activation time, the supported variant control modes, and the variant condition propagation for different activation times in variant blocks.

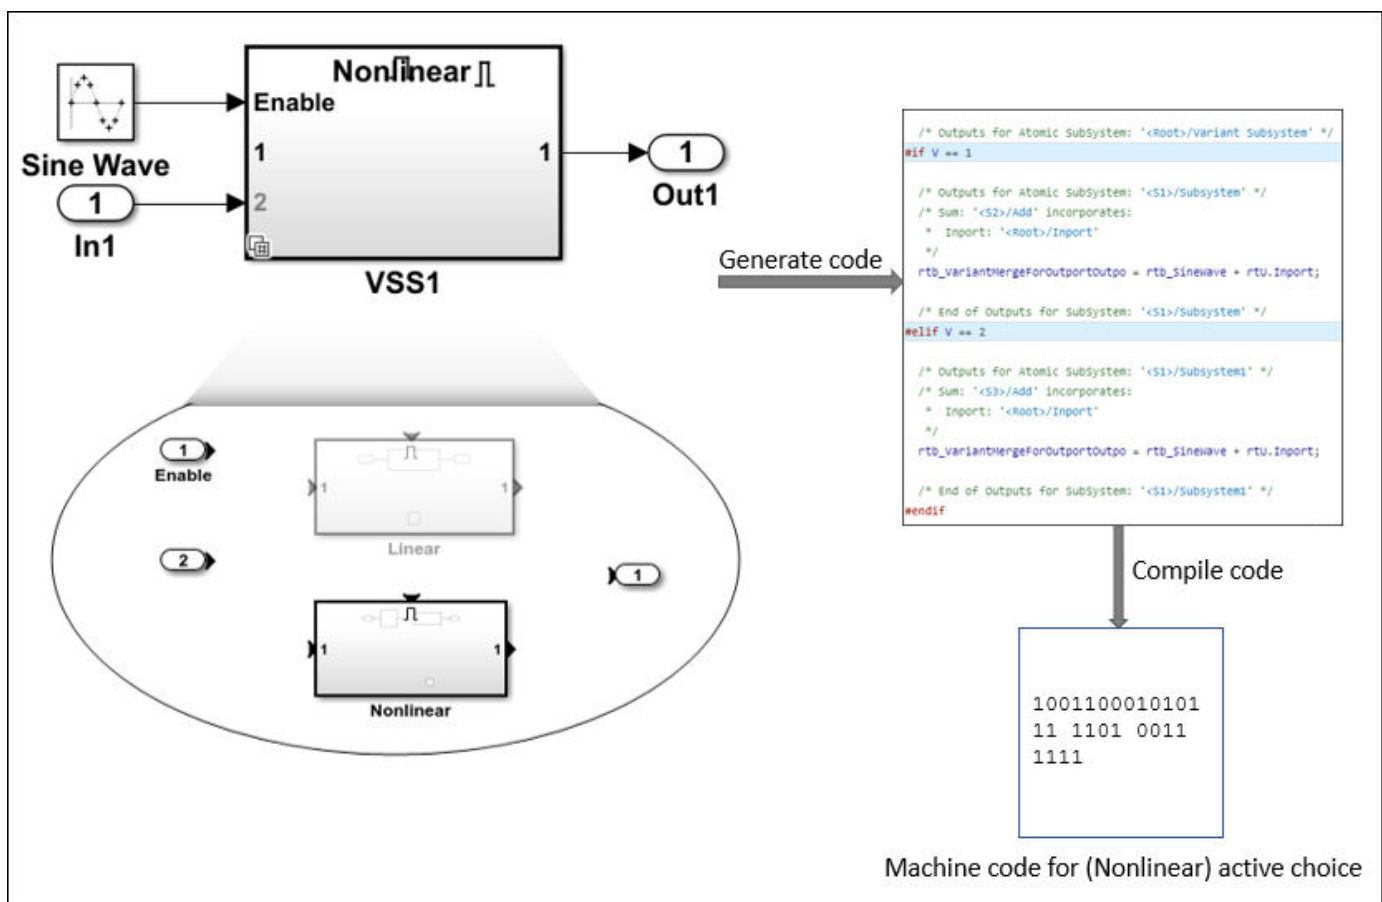

### Use Variant Activation Time in Variant Blocks

This example explains how to specify active choice using variant activation time in variant blocks.

Consider this model. The Variant Subsystem VSS1 has two potential variants, Linear and Nonlinear. The variant condition expression associated with the Linear is  $V == 1$ . The variant condition expression associated with the Nonlinear is  $V == 2$ . On the dialog box of VSS1, the **Variant activation time** parameter is specified as code compile.

When you generate code from this model, the generated code contains all variant choices of VSS1. In the code, the choices are enclosed in the C preprocessor conditional statements `#if` and `#elif`. Before you compile the code to generate an executable, you can specify a value for  $V$  as an input to the compiler. Upon compiling the code, the compiler accepts the value of  $V$  to evaluate each preprocessor conditional statement. Based on the condition that evaluates to `true`, the compiler sets the active choice and then generates the executable only for the active choice. For example, if you provide the input to the compiler as 1, the executable contains only the Linear variant choice.

To generate an executable for Nonlinear variant choice, change the input value to compiler to 2 and recompile the generated code.

### Supported Variant Activation Time in Variant Blocks

This section lists the variant activation time supported by each type of variant blocks:

- Hierarchical variant blocks and inline variant blocks
  - Variant Subsystem, Variant Model, Variant Source, Variant Sink— The availability of activation times depends on the type of the variant control mode that you specify for the block. For information on variant control modes, see “Introduction to Variant Controls” on page 12-36.
  - Variant Connector, Manual Variant Source, Manual Variant Sink— The variant activation time is by default set to `update diagram`. You cannot set it to any other activation time.
- Event-based variant blocks
  - Simulink Function— The block by default inherits the variant activation time from the corresponding Function Caller block. You can overwrite the inherited activation time to `code compile` or to `update diagram` by selecting or clearing the **Generate preprocessor conditionals** parameter on its block parameter dialog box, respectively.
  - Initialize Function, Reset Function, and Terminate Function— The variant activation time is by default set to `update diagram`. You can change it to `code compile` by selecting the **Generate preprocessor conditionals** parameter on its block parameter box.

This table lists the variant activation time supported by variant blocks in different control modes.

Variant activation time					
Variant blocks	Variant control mode	update diagram	update diagram analyze all choices	code compile	startup
Variant Subsystem, Variant Model, Variant Source, Variant Sink	expression	✓	✓	✓	✓
	label	✓	x	x	x
	sim codegen switching	✓	✓	x	x
Variant Connector, Manual Variant Source, Manual Variant Sink	expression	✓	x	x	x
	label	not supported			
	sim codegen switching	not supported			
Simulink Function, Initialize Function, Reset Function, and Terminate Function	expression	✓	✓	✓	x
	label	not supported			
	sim codegen switching	not supported			

**Note** The operators that you can use to form a variant condition expression in variant blocks depend on its variant activation time. See “Types of Operators in Variant Blocks for Different Activation Times” on page 12-43.

## Variant Condition Propagation for Different Activation Times in Variant Blocks

Variant condition propagation allows you to assign condition expressions outside the variant blocks to the connecting blocks to improve performance. When you propagate conditions outside the Variant block, the inactive choices do not run during simulation, which can improve performance, particularly in large models. The propagation of variant condition outside the variant block varies for different activation times. For information, see “Propagate Variant Conditions Outside Variant Subsystems” on page 12-125.

Propagating conditions through cascading blocks results in compounding conditions. Simulink does not support compounding conditions from variant blocks with `startup` and `code compile` variant activation times. For more information, see “Considerations and Limitations for startup Variant Activation Time” on page 12-241.

## Variant Activation Time in Variant Parameters

This section explains how to specify the variant activation time, and the supported variant control modes in variant parameters.

### Use Variant Activation Time in Variant parameters

This example explains how to specify active choice using variant activation time in variant parameters.

Consider this model. The **Gain** parameter of the Gain block is a variant parameter with its value set to K. The variable K has two values: 3.5 and 8.5. The Variant activation time of K is specified as `code compile` using the `Simulink.VariantControl`. This setting means that you can specify the active choice before code compilation starts.

```
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'code compile')
K = Simulink.VariantVariable('Choices', {'V==1', 3.5, 'V==2', 8.5})
```

When you generate code from this model, the generated code contains both active and inactive choices of K. In the code, the choices are enclosed in the C preprocessor conditional statements `#if` and `#elif`. When you compile this code to generate an executable, the compiler accepts the value of V as input to evaluate each preprocessor conditional statement. Based on the condition that evaluates to true, the compiler sets the active choice and then generates the executable only for the active choice. For example, if you provide the input to the compiler as 1, the executable is built for K set to 3.5.

To generate an executable with K set to 8.5, change the input value to compiler to 2 and compile the generated code again. You do not need to regenerate the code to generate an executable for different variant values.

**Supported Variant Activation Time in Variant Parameters**

This table lists the variant activation times available for variant parameters.

**Note** The operators that you can use to form a variant condition expression in variant parameters are listed in “Types of Operators in Variant Parameters” on page 12-54.

Variant control mode	Variant activation time			
	update diagram	update diagram analyze all choices	code compile	startup
expression	✓	✓	✓	✓
label	not supported			
sim codegen switching	not supported			

**Storage Classes for Different Variant Activation Times**

When you specify a condition expression to determine the active choice, each variant control variable of the expression has a storage class associated with it. Use storage classes to control the appearance and placement of the variant control variables in the generated code. Storage classes also prevent the optimizations such as elimination of the storage for variant control variables in the generated code. For more information, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

The variables used in the variant condition expressions must satisfy these criteria to generate code with Simulink Coder or Embedded Coder.

- The variant control variables in variant condition expressions must have these storage classes.
- This table lists the built-in storage classes supported for different activation times to generate code using Simulink Coder and Embedded Coder.

Built-in Storage Class	Variant activation time	
	code compile	startup
“ExportedGlobal” (Simulink Coder)	x	✓
“Model Default” (Simulink Coder)	x	✓
“ImportedExtern, ImportedExternPointer” (Simulink Coder)	x	✓

Built-in Storage Class	Variant activation time	
"Auto" (Simulink Coder)	x	x

- This table lists the custom storage classes supported for different activation times to generate code using Embedded Coder.

Custom Storage Class	Variant activation time	
	code compile	startup
"GetSet" (Embedded Coder)	x	✓
"Define, ImportedDefine" (Embedded Coder)	✓	x
"CompilerFlag" (Embedded Coder)	✓	x
Const and ConstVolatile. See, "Const, Volatile, and ConstVolatile" (Embedded Coder)	x	x
"Bitfield" (Embedded Coder)	x	✓
"Struct" (Embedded Coder)	x	✓
"ExportToFile" (Embedded Coder)	x	✓
"ImportFromFile" (Embedded Coder)	x	✓
Volatile. See, "Const, Volatile, and ConstVolatile" (Embedded Coder)	x	✓

- If the activation time of a variant control variable is set to **startup**, then specifying its storage class to any of these is not supported:
  - Storage classes such as **Define** that generates macros in the code.
  - Storage classes such as **Const** that generates constant qualified variables in the code.
- To use scalar MATLAB variables as variant control variables in variant blocks without any storage class for code generation, select **Tunable** as the **Default parameter behavior** from the **Model Settings** under **Code Generation > Optimization**. This criteria is not applicable to AUTOSAR post build variants.

## See Also

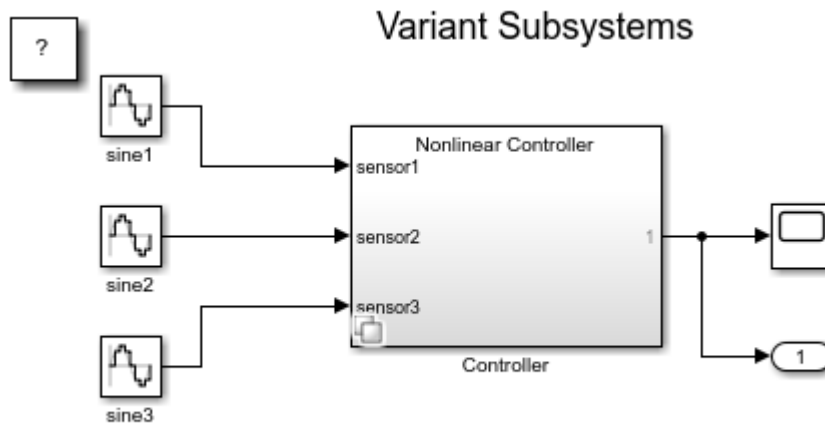

### More About

- "Options to Represent Variant Parameters in Generated Code" (Embedded Coder)
- "Simulate a Protected Model with Code Compile or Startup Activation Time" on page 12-265

## Create a Simple Variant Model

1. Open this model that contains variant blocks. For example, see “Implement Variations in Separate Hierarchy Using Variant Subsystems” on page 12-184 that contains a Variant Subsystem block (Controller).

```
open_system('slexVariantSubsystems')
```

Copyright 2010-2013 The MathWorks, Inc.

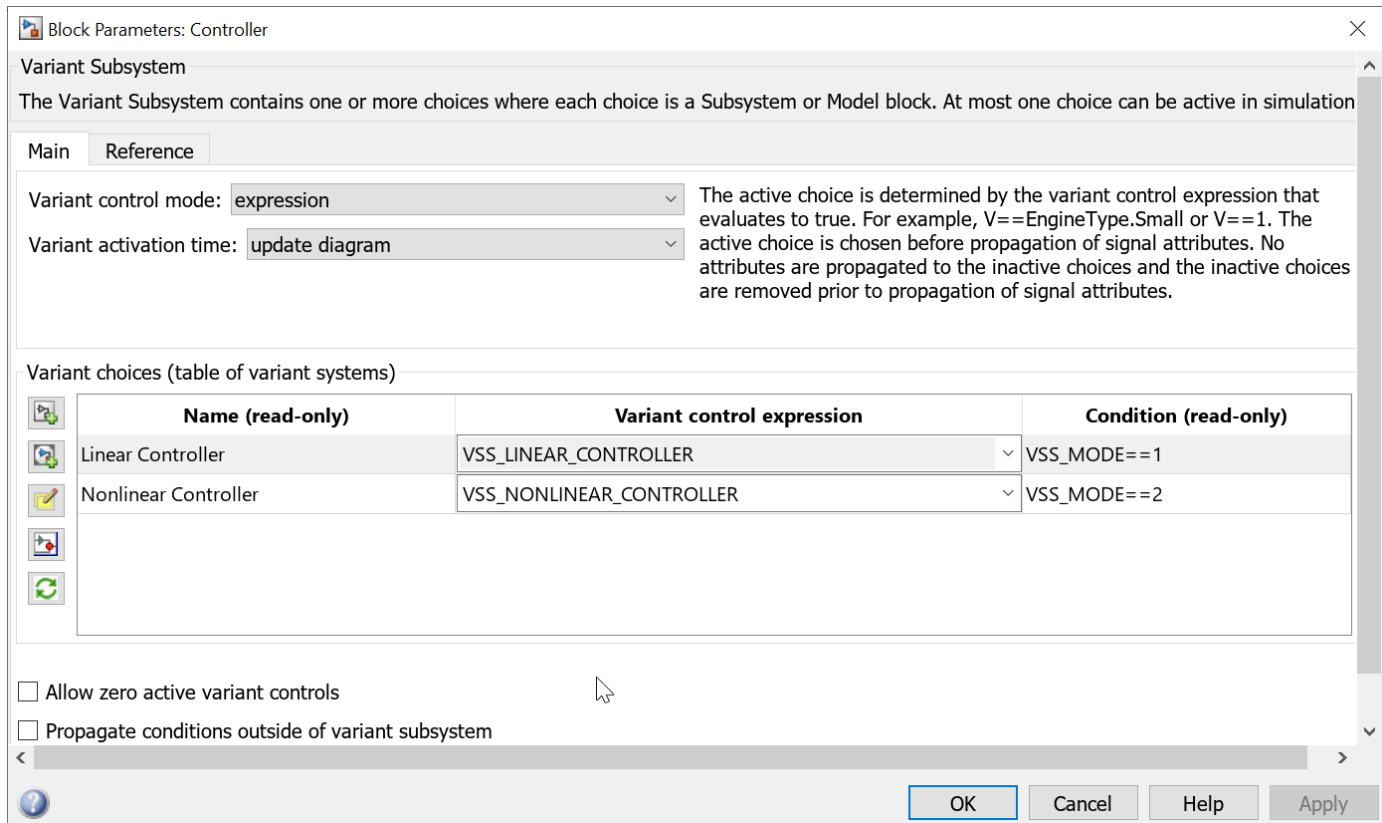

2. Define variant control variables that determine the condition under which a variant choice is active.

a. Right-click the variant block and click **Block Parameters**. The Block Parameters dialog box for the variant block opens.

b. To choose the active Variant based on the evaluation of the Variant conditions, use the expression mode else select label mode. When you select the Variant control mode as label, the **Label mode active choice** option is available. In label mode, Variant control need not be created in the global workspace. You can select an active Variant choice from **Label mode active choice** options.

c. Use the options available on the **Block Parameter** dialog box to add variant controls and its corresponding variant condition.

A sample screenshot for expression mode:

**Note:** The variables used to specify the variant control and variant condition must be defined in the global workspace, model workspace, mask workspace or data dictionary for the model.

3. Specify a default variant condition to be used when there is no active variant choice. Use the **Variant control** list to specify the default.

4. To activate a variant choice, type the variant choice in MATLAB® command window. For example, type `VSS_MODE = 2`.

5. To simulate the model, on the toolstrip, click **Run**. The model simulates for the specified active choice.

```
sim('slexVariantSubsystems');
```

6. Modify the active choice and simulate the model again, if necessary.

7. Generate code for the variants model with preprocessor conditionals.

**Note:** You must have an Embedded Coder® license to generate code.

a. In the Block Parameters dialog box, from the **Variant activation time** list, select `code compile`.

b. Open the Subsystem Block Parameters dialog boxes. Select the **Treat as atomic unit** parameter.

c. In the **Code Generation** section of Configuration Parameters dialog box, specify the **System target file** as `ert.tlc`.

d. In Model Explorer, define the variables used to specify the variant choice as a MATLAB variable or as a `Simulink.Parameter`. The data type of the `Simulink.Parameter` can be of type `Integer`, `Boolean`, or `Enumerated` and the storage class can be either `importedDefine(Custom)`, `Define(Custom)`, or `CompilerFlag`.

8. For the variants that are defined in the global workspace, export the control variables to a MAT-file. For example, type the following in the MATLAB command window:

a. `save <MAT-File Name> <Variable Name>`

b. `PostLoadCallback > load <MAT-File Name>`

**Note:** To update or refresh active models that contain Variant Subsystem blocks, on the **Modeling** tab, click **Update Model (Ctrl + D)** in Simulink.

### **Related Examples**

- “Define, Configure, and Activate Variant Choices in a Variant Subsystem Block” on page 12-95
- “Create and Activate Variant Configurations” on page 89-10
- “Create Variant Controls Programmatically” on page 12-93
- “Export Workspace Variables” on page 72-118

## Create Variant Controls Programmatically

### In this section...

“Create and Export Variant Controls” on page 12-93

“Reuse Variant Conditions” on page 12-93

“Enumerated Types as Variant Controls” on page 12-93

### Create and Export Variant Controls

Create control variables, define variant conditions, and export control variables.

- 1 Create control variables in the global workspace or a data dictionary.

```
FUEL=2;
EMIS=1;
```

- 2 Use the control variables to define the control condition using a `Simulink.Variant` object.

```
LinearController=Simulink.Variant('FUEL==2 && EMIS==1');
```

---

**Note** Before each simulation, define `Simulink.Variant` objects representing the variant conditions.

---

- 3 If you saved the variables in the global workspace, select the control variables to export. Right-click and click **Save As** to specify the name of a MAT-file.

### Reuse Variant Conditions

If you want to reuse common variant conditions across models, specify variant control conditions using `Simulink.Variant` objects.

Reuse `Simulink.Variant` objects to change the model hierarchy dynamically to reflect variant conditions by changing the values of the control variables that define the condition expression.

The example model `AutoSSVar` shows the use of `Simulink.Variant` objects to define variant control conditions.

---

**Note** You must use `Simulink.Variant` objects to define variant control conditions for AUTOSAR workflows.

---

### Enumerated Types as Variant Controls

Use enumerated types to give meaningful names to integers used as variant control values.

- 1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
    enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
```

```
end
end

classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
    enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
    end
end
```

- 2 Define `Simulink.Variant` objects for these classes in the global workspace.

```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
VE_SECOND_ORDER_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

## Define, Configure, and Activate Variant Choices in a Variant Subsystem Block

### In this section...

“Represent Variant Choices in a Variant Subsystem” on page 12-95

“Include Subsystem Block as Variant Choice” on page 12-97

“Include Simulink Model as Variant Choice” on page 12-98

“Configure Variant Controls” on page 12-100

“Map Inports and Outports of Variant Choices in Variant Subsystem” on page 12-101

“Convert to Variant Subsystem Block” on page 12-102

### Represent Variant Choices in a Variant Subsystem

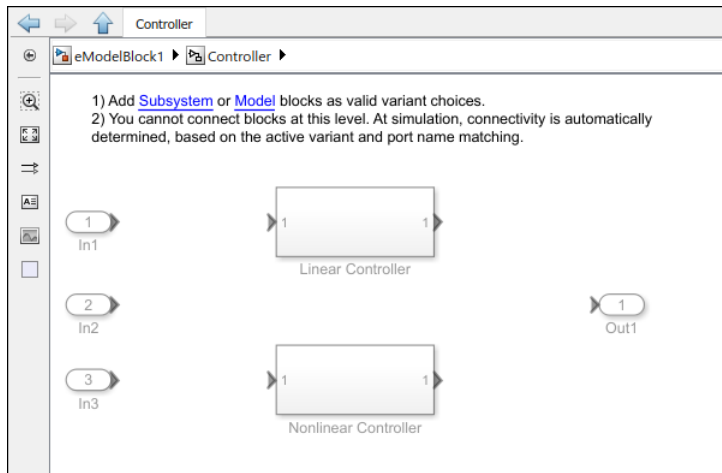

Variant choices are two or more configurations of a component in your model. This example shows how to represent variant choices inside a Variant Subsystem block. A Variant Subsystem block allows you to use a combination of Subsystem, Model, or Subsystem Reference blocks as variant choices. For other ways to represent design variants, see “Types of Variants in Simulink” on page 12-6.

- 1 Add a Variant Subsystem block to your model and name the block.

This block serves as the container for the variant choices.

- 2 Double-click the Variant Subsystem block. Add Inport and Outport blocks so that they match the inputs into and outputs from the Variant Subsystem block.

- 3 Open the block parameter dialog box. Right-click the badge on the Variant Subsystem block and select **Block Parameters (Subsystem)**.

**Tip** For information on all parameters on the Variant Subsystem block, see Variant Subsystem, Variant Model.

The **Variant choices** table in the block parameter dialog box shows the variant choices contained in the Variant Subsystem. You can use buttons to the left of the table to add or modify elements in the table.

Action	Button
<b>Create and add a new subsystem choice:</b> Create a new Subsystem block as a variant choice and add an entry for the new choice in the table.	
<b>Create and add a new model variant choice:</b> Create a new Model block as a variant choice and add an entry for the new choice in the table.	
<b>Create/Edit selected variant object:</b> Create or edit a Simulink.Variant object in the global workspace and specify the variant condition using the Simulink.Variant object parameter dialog box.	
<b>Note</b> For a model that uses the base workspace, this operation creates the Simulink.Variant object in the base workspace, and the object is available only for the current MATLAB session. To permanently store the data, save the object in a MAT file or MATLAB script.	
<b>Open selected variant choice block:</b> Open the Subsystem block for the selected row.	
<b>Refresh dialog information from Variant Subsystem contents:</b> Update the <b>Variant choices</b> table according to the variant choices and values of the variant control in the global workspace.	

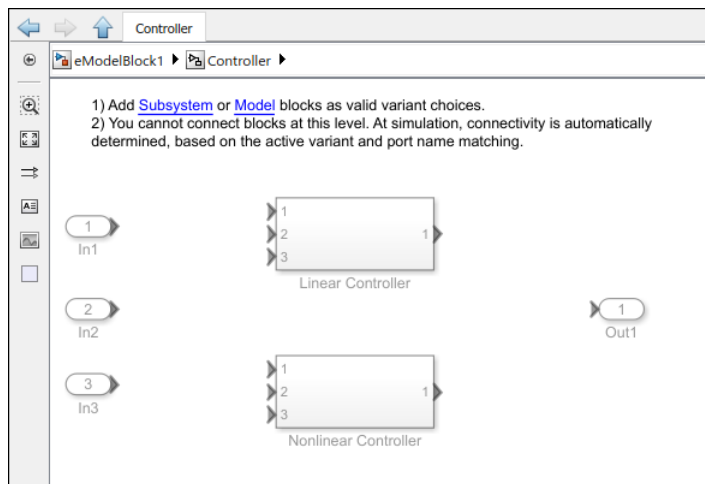

## Include Subsystem Block as Variant Choice

To include Subsystem block as a variant choice inside the Variant Subsystem:

- 1 In the block parameters dialog box, click the  button for each variant subsystem choice you want to add.

Simulink creates empty Subsystem blocks inside the Variant Subsystem block. The new blocks have the same number of input and output ports as the containing Variant Subsystem block.

**Tip** If your variant choices have different numbers of input and output ports, see “Map Inports and Outports of Variant Choices in Variant Subsystem” on page 12-101.

- 2 Open each Subsystem block and create the model that represents a variant choice.

- 3 When you prototype variants, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which a

subsystem is inactive without the need for completely modeling the variant. For an empty variant choice, either specify a variant activation condition or comment out the variant condition by placing a % symbol before the condition.

If the empty variant choice is active during compilation, Simulink ignores it.

## Include Simulink Model as Variant Choice

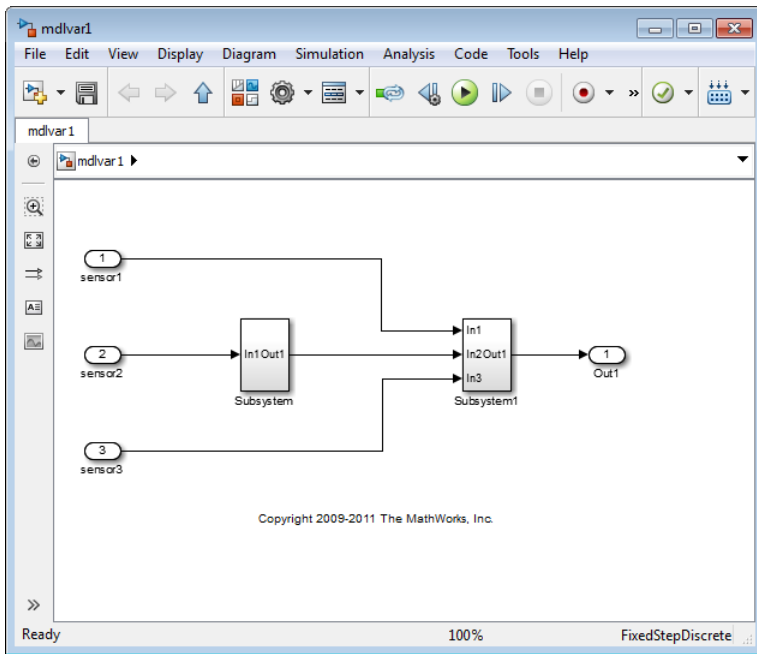

You can include a Simulink model as a variant choice inside a Variant Subsystem block.

- 1 Create a model that you want to include as a variant choice. Make sure that it has the same number of input and output ports as the containing Variant Subsystem block.

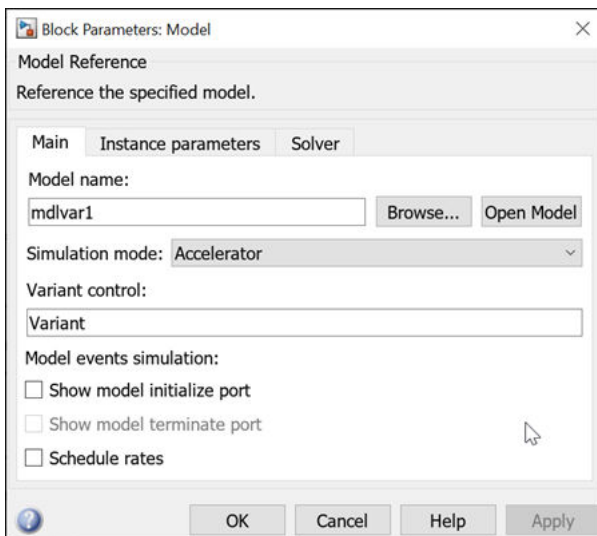

---

**Note** If your model has different numbers of input and output ports, see “Map Inports and Outports of Variant Choices in Variant Subsystem” on page 12-101.

---

- 2 In your model, right-click the Variant Subsystem block that contains variant choices and select **Block Parameters (Subsystem)**.
- 3 In the block parameters dialog box, click the  button to add a Model block as a variant choice.  
Simulink creates an unresolved Model block in the Variant Subsystem block.
- 4 Double-click the unresolved Model block. In the **Model name** box, enter the name of the model you want to use as a model variant choice and click **OK**.

## Configure Variant Controls

You can specify the conditions for activating a variant choice using variant controls. While each variant choice in a model is associated with a variant control, only one variant control can evaluate to `true`. You can also specify at most one variant choice as the default.

You can choose the mode in which you want to specify the variant controls using the **Variant control mode** parameter. This example uses the `expression` mode. Here, we specify the variant controls as Boolean condition expressions that contain normal MATLAB variables defined in the base workspace of the model.

---

**Tip** For information on different variant control modes, see “Introduction to Variant Controls” on page 12-36.

For information on the types of variant control variables supported in variant condition expressions, see “Types of Variant Control Variables (Operands) in Variant Blocks” on page 12-41 and “Types of Variant Control Variables (Operands) in Variant Parameters” on page 12-53.

---

- 1 In the MATLAB Command Window, specify the variant control variables that create an activation condition when combined.

```
mode = 3;  
version = 2;
```

- 2 Right-click the Variant Subsystem block that is the container for variant choices in your model and select **Block Parameters (Subsystem)**.
- 3 In the block parameters dialog box, in the **Variant control** column, select `(default)` for one choice.
- 4 Specify a variant condition for each of the other choices. If you are using an empty variant choice, specify a variant condition for the choice or comment out an existing activation condition by placing a `%` symbol before the condition.

Simulink evaluates the variant controls and verifies that only one variant choice is active during simulation. If none of the variant controls evaluate to `true`, Simulink uses the `(default)` variant for simulation and code generation.

If **Allow zero active variant controls** is selected, you can have zero active variant choices in the Variant Subsystem. When you select this option and there is no active variant choice, Simulink simulates the model without any active variant choice in the Variant Subsystem. This parameter is available only if there are no `(default)` variant choices in the Variant Subsystem and if you set **Variant control mode** to `expression`.

- 5 Click **Apply** to save the changes.

## Map Inports and Outports of Variant Choices in Variant Subsystem

A Variant Subsystem block allows you to use a combination of Subsystem, Model, or Subsystem Reference blocks as variant choices. The inputs that the Variant Subsystem block receives from upstream model components map to the input and output ports of the variant choices.

The blocks that represent variant choices can have input and output ports that differ in number from the input and output ports in the parent Variant Subsystem block. However, the following conditions must be met:

- The variant choices must have same set of inports as the Variant Subsystem container block or it must be a subset of ports on the container block.
- The variant choices must have same set of outports as the Variant Subsystem container block or it must be a subset of ports on the container block.
- If the Variant Subsystem container block has control ports:
  - The type of control port blocks in all the variant choices must be same as the Variant Subsystem block. For example, you cannot use Enabled Subsystem and Function-Call Subsystem blocks as choices within a Variant Subsystem block.
  - The control port on the Variant Subsystem block and the corresponding control ports on its variant choices must have the same name. For example, if the name of the control port on the Variant Subsystem is `fcn`, then the name of the corresponding control ports on all its variant choices must also be `fcn`.

During simulation, Simulink disables the inactive ports in a Variant Subsystem block.

## Convert to Variant Subsystem Block

In the Simulink Editor, you can convert these blocks to a Variant Subsystem block:

- Subsystem block
- Model block
- Variant Model block (for models created in versions earlier than R2017b)
- Conditionally executed subsystems

To do so, right-click the block. Then, in the context menu, click **Subsystem & Model Reference > Convert to > Variant Subsystem**.

You can also convert these block to Variant Subsystem block programmatically. To do so, use any of these syntaxes:

- `Simulink.VariantManager.convertToVariant(gcf)`
- `Simulink.VariantManager.convertToVariant(gcfh)`

For example:

```
addpath(fullfile(matlabroot,'examples','simulink_variants','main'));
open_system('sldemo_variant_subsystems');
Simulink.VariantManager.convertToVariant('sldemo_variant_subsystems/Controller');
```

If you convert variant models to variant subsystem, note that the behavior of the Model block parameter **Generate preprocessor conditionals** is different than the Variant Subsystem block parameter **Variant activation time**. For variant models, enabling the **Generate preprocessor conditionals** parameter causes simulation and update diagram to compile the active variant only. For variant subsystems, enabling the parameter compiles all the variants, which can slow down simulation and updates.

Converting variant models to variant subsystems can require that you update scripts that use the `Variants` command-line parameter.

## Prepare Variant-Containing Model for Code Generation

### In this section...

“Convert Variant Control Variables into Simulink.Parameter Objects” on page 12-103

“Configure Model for Generating Preprocessor Conditionals” on page 12-105

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

**Note** Simulink supports using multi-instance referenced models with variant Simulink Functions for code generation.

For information on using `STF_make_rtw_hook` file to customize build process, see “Customize Build Process with `STF_make_rtw_hook` File” (Simulink Coder).

### Convert Variant Control Variables into Simulink.Parameter Objects

MATLAB variables allow you to rapidly prototype variant control expressions when you are building your model and generate preprocessor conditionals for code generation. However, if you want to specify other code generation attributes (such as data type), you can convert MATLAB variables into `Simulink.Parameter` objects.

- 1 Specify the model in which you want to replace MATLAB variant control variables with `Simulink.Parameter` objects.

```
model = 'my_model_containing_variant_choices';
open_system(model);
```

- 2 Get the variables that are referenced in variant control expressions.

```
vars = Simulink.VariantManager.findVariantControlVars(model)
```

```
vars =
```

```
4x1 struct array with fields:
```

```
    Name
    Value
    Exists
    Source
    SourceType
```

- 3 Create an external header file for specifying variant control values so that the variable definitions are imported when the code runs.

```
headerFileName = [model '_importedDefines.h'];
headerPreamble = strrep(upper(headerFileName), '.', '_');

fid = fopen(headerFileName, 'w+');
fidErr = (fid == -1);
if (fidErr)
    fprintf('There was an error creating header file %s:...\n', headerFileName);
```

```
else
    fprintf('+++ Creating header file '%s' with variant control...
           variable definitions.\n\n', headerFileName);
    fprintf(fid, '#ifndef %s\n', headerPreamble);
    fprintf(fid, '#define %s\n', headerPreamble);
end
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- Define or ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- Your own storage class that defines data as a macro

---

**Note** If you generate code with startup activation time, specify the supported custom storage class for the objects. For more information on built-in and custom storage classes supported with startup activation time see “Storage Classes for Different Variant Activation Times” on page 12-88.

---

- 4 Loop through all the MATLAB variables to convert them into `Simulink.Parameter` objects.

```
count = 0;
for countVars = 1:length(vars)
    var = vars(countVars).Name;
    val = vars(countVars).Value;
    if isa(val, 'Simulink.Parameter')
        % Do nothing
        continue;
    end
    count = count+1;

% Create and configure Simulink.Parameter objects
% corresponding to the control variable names.
% Specify the storage class as Define (Custom).
newVal = Simulink.Parameter(val);
newVal.DataType = 'int16';
newVal.CoderInfo.StorageClass = 'Custom';
newVal.CoderInfo.CustomStorageClass = 'Define (Custom)';
newVal.CoderInfo.CustomAttributes.HeaderFile = headerFileName;

    Simulink.data.assigninGlobal(model, var, newVal);

    if ~fidErr
        fprintf(fid, '#endif\n');
        fclose(fid);
    end
end
```

---

**Note** The header file can be empty for the Define storage class.

---

## Configure Model for Generating Preprocessor Conditionals

If you represent variant choices inside a Variant Subsystem block or a Variant Model block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`.

If you represent variant choices using a Variant Source block or a Variant Sink block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`.

Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

---

**Note** You must have an Embedded Coder® license to generate code.

---

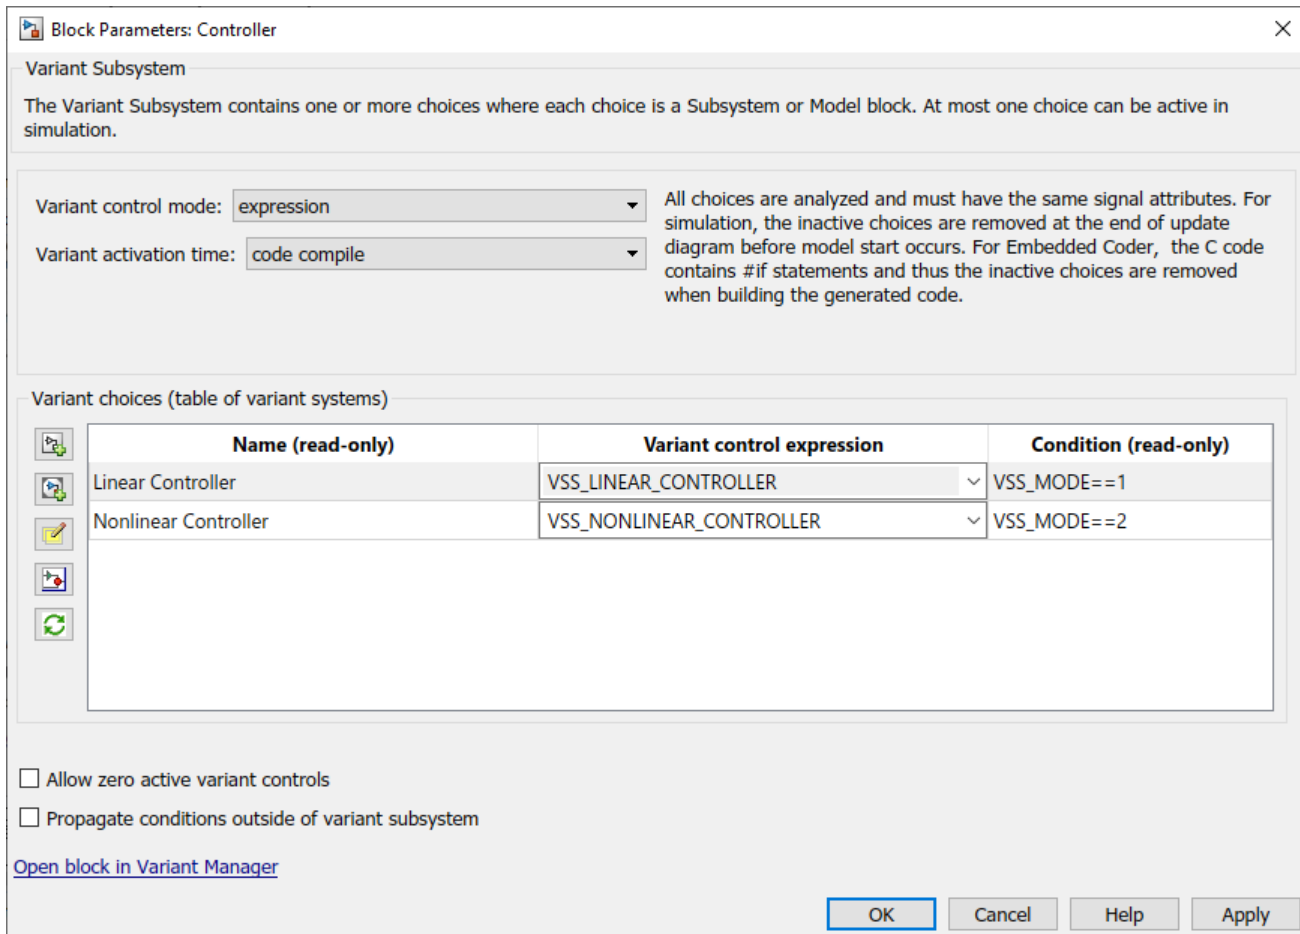

- 1 In the **Modeling** tab of the Simulink toolstrip, click **Model Settings**.
- 2 Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.

---

**Note** In the **Code Placement** pane, if **Compact** option is selected from **File packaging format** drop-down list, `model_types.h` file is not generated and contents of `model_types.h` file are moved to `model.h` file.

---

- 4 Select the **Code Generation** pane, and clear **Ignore custom storage classes** and **Apply**.
- 5 In your model, right-click the block containing the variant choices (Variant Subsystem, Variant Source, Variant Sink, or Variant Model block) and select **Block Parameters**.
- 6 Ensure that **Expression** (default option) is selected for **Variant control mode** parameter.
- 7 From the **Variant activation time** list, select `code compile`.

Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness for all variant choices.

## 8 Build the model.

## Visualize Variant Implementations in a Single Layer

Simulink provides two blocks that you can use to propagate conditions throughout the model and visualize all possible implementations of variant choices in a model. These blocks are called Variant Source and Variant Sink.

When you compile the model, Simulink determines which variant control evaluates to `true`. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

### How Variant Sources and Sinks Work

The Variant Source block has one or more input ports and one output port. You can define variant choices as blocks that are connected to the input port so that, at most, one choice is active. The active choice is connected directly to the output port of the Variant Source and the inactive choices are eliminated during simulation.

The Variant Sink block has one input port and one or more output ports. You can define variant choices as blocks that are connected to the output port so that, at most, one choice is active. The active choice is connected directly to the input port of the Variant Sink, and the inactive choices are eliminated during simulation.

Connect one or more blocks to the input port of the Variant Source block or the output port of the Variant Sink block. Then, you define variant controls for each variant choice entering the Variant Source block and exiting the Variant Sink block. For more information, see “Variant Condition Propagation with Variant Sources and Sinks” on page 12-116.

### Advantages of Using Variant Sources and Sinks

Using Variant Source and Variant Sink blocks in Model-Based Design provides these advantages:

- The blocks enable the propagation of variant conditions throughout the model and allow you to visualize variant choices in a single layer of your model.
- By visualizing all possible implementations of variant choices, you can improve the readability of your model.

- During model compilation, Simulink eliminates inactive blocks throughout the model, improving the runtime performance of your model.
- Variant sources and sinks provide variant component interfaces that you can use to quickly model variant choices.

### **Limitations of Using Variant Sources and Sinks**

- Variant Source and Variant Sink blocks work with time-based, function-call, or action signals. You cannot use SimEvents, Simscape Multibody, or other non-time-based signals with these blocks.
- The code generation variant report does not contain Variant Source and Variant Sink blocks.

## Define and Configure Variant Sources and Sinks

Simulink provides two blocks, Variant Source and Variant Sink, that you can use to visualize all possible implementations of variant choices in a model graphically. This example shows how to configure variant choices using the Variant Source and Variant Sink blocks.

### Represent Variant Choices in Variant Source and Variant Sink Blocks

The variant conditions at the inports and outports of Variant Source and Variant Sink blocks, respectively, determine the activation and deactivation of the blocks connected to them. You can specify the conditions for activating a variant choice using a *variant control*. While each variant choice is associated with a variant control, only one variant control can evaluate to true. When a variant control evaluates to true, Simulink activates the corresponding variant choice. You can also specify at most one variant choice as the default choice.

You can choose the mode in which you want to specify the variant controls using the **Variant control mode** parameter. This example uses the **expression** mode. Here, we specify the variant controls as Boolean condition expressions that contain Simulink.Parameter objects defined in the base workspace of the model.

---

**Tip** For information on different variant control modes, see “Introduction to Variant Controls” on page 12-36.

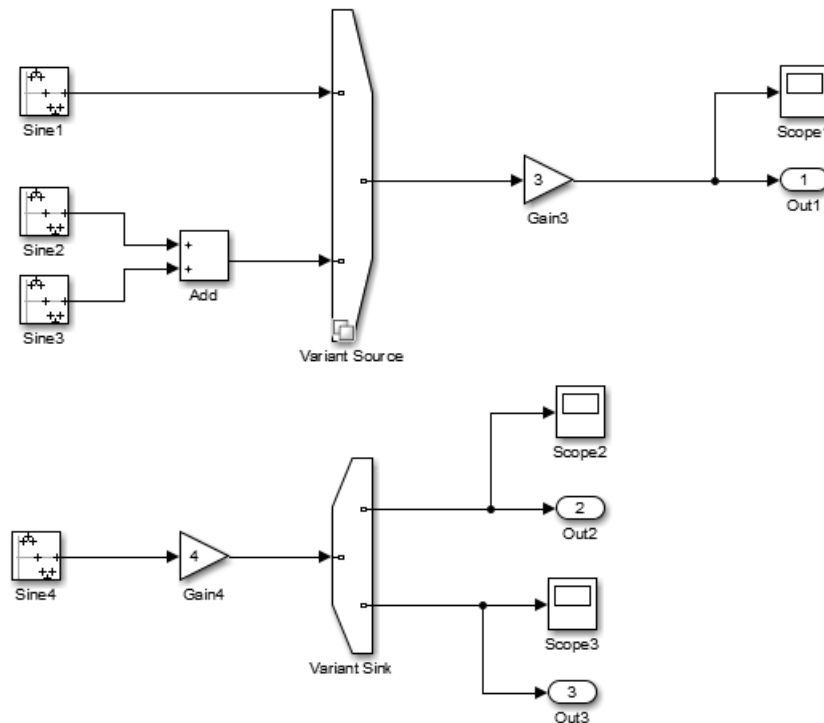

For information on the types of variant control variables supported in variant condition expressions, see “Types of Variant Control Modes in Variant Blocks” on page 12-38.

---

- 1 Add Variant Source and Variant Sink blocks to your model.

- 2 Using blocks from the Simulink Library Browser, create sources and sinks that represent variant choices. Connect choices to the input and output ports of the Variant Source and Variant Sink blocks.

- 3 In the MATLAB Command Window, run these commands to create the variant control variables.
 

```
V = Simulink.Parameter(1);
W = Simulink.Parameter(2);
```
- 4 Open the block parameter dialog box of the Variant Source block. Double-click the block or right-click the block and select **Block Parameters (Variant Source)**.

---

**Tip** For information on all block parameters, see Variant Source and Variant Sink.

---

The **Ports and associated conditions** table in the block parameter dialog box has a row for each variant choice connected to the input port of the Variant Source block. If there are no variant choices, the table is empty.

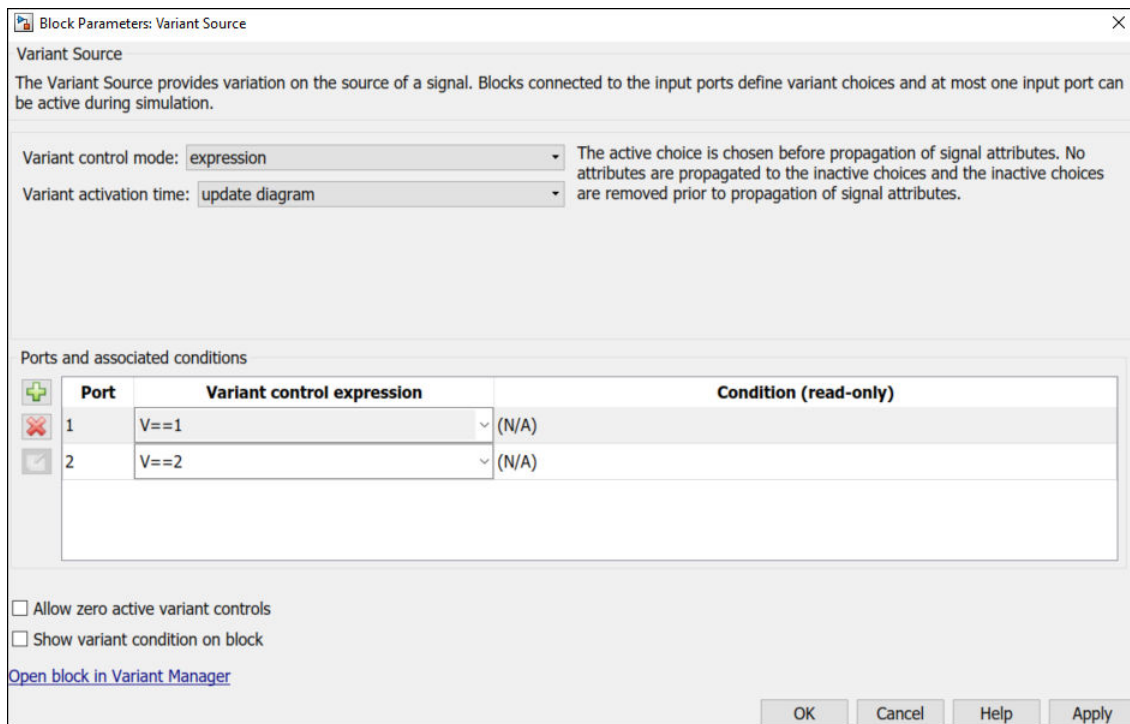

You can use buttons to the left of the table to modify the elements in the table.

Action	Button
<b>Add a new input port:</b> Create a new input port as a variant choice and add an entry for the new choice in the table.	
<b>Delete selected port:</b> Delete the selected variant choice from the block and the variant choice entry from the table.	

Action	Button
<p><b>Create/Edit selected variant object:</b> Create or edit a Simulink.Variant object for the selected variant choice in the global workspace and specify the variant condition using the Simulink.Variant object parameter dialog box.</p> <hr/> <p><b>Note</b> For a model that uses the base workspace, this operation creates the Simulink.Variant object in the base workspace, and the object is available only for the current MATLAB session. To permanently store the data, save the object in a MAT file or MATLAB script.</p>	

- 5 In the block parameters dialog box, in the **Variant control expression** column, type  $V==1$  for one choice and  $V==2$  for the other.

To specify one choice as the default variant, select (default) from the **Variant control expression** list. If none of the variant controls evaluate to true, Simulink uses the default variant for simulation and code generation.

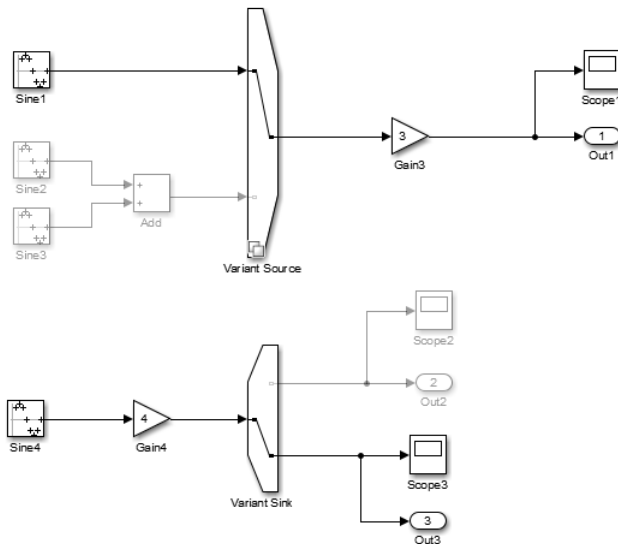

- 6 Click **Apply**.
- 7 Double-click the Variant Sink block. In the block parameters dialog box, in the **Variant control expression** column, type  $W==1$  for one choice and  $W==2$  for the other.

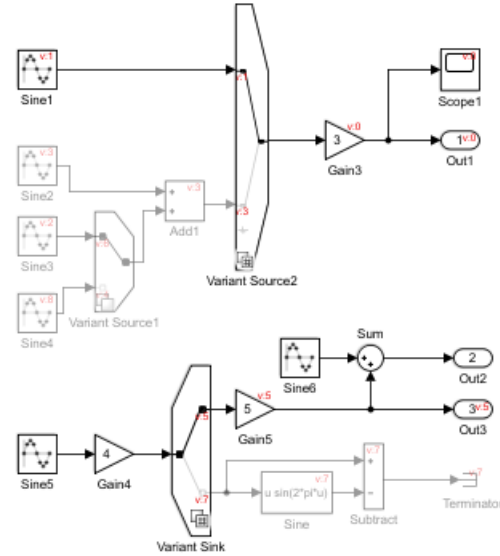

8 Click **Apply**.

9 Simulate the model. Simulink propagates the variant conditions to identify which model components to activate.

10 You can visualize the conditions that activate each variant choice. In the **Debug** tab of toolstrip, select **Information Overlays > Variant Conditions**.

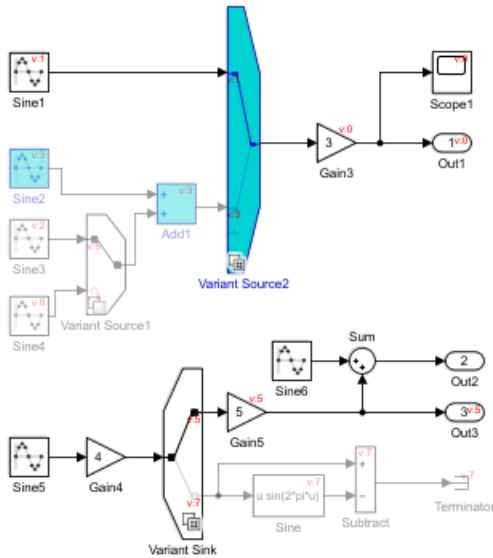

Variant Conditions Legend: slxVariantSourceAndSink

Show generated code conditions

Annotation	Simulation	Workspace	Code Generation
v:0	V == 1    V ...	Global	V == 1    V == 2
v:1	V == 1	Global	V == 1
v:2	V == 2 && ...	Global	V == 2

## Variant Condition Propagation with Variant Sources and Sinks

### How Variant Condition Propagation Works

When you specify variant conditions in models containing Variant Source and Variant Sink blocks, Simulink evaluates the variant controls specified on the variant blocks and automatically propagates the variant conditions to the connecting blocks to determine which components of the model are active during simulation. Simulink then deactivates the model components associated with the inactive choices and visualizes the active connections. Simulink uses the **Variant activation time** block parameter to determine the time frame when it chooses the active variant choice. For more information on variant activation time, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

**Note** The variant condition annotations displayed on model components help you visualize the propagated conditions.

To view the variant condition annotations, on the **Debug** tab, select **Information Overlays > Variant Legend**.

If **Variant Legend** is not available, on the **Debug** tab, select **Information Overlays > Variant Conditions**.

### Cross-Coupling of Inputs and Outputs

In this model, the Variant Source block has two inputs with variant conditions  $\text{Var} == 1$  and  $\text{Var} == 2$ , respectively. The first input to the Variant Source block branches into its second input before connecting to the block. The second input with variant condition  $\text{Var} == 2$  is the default variant choice.

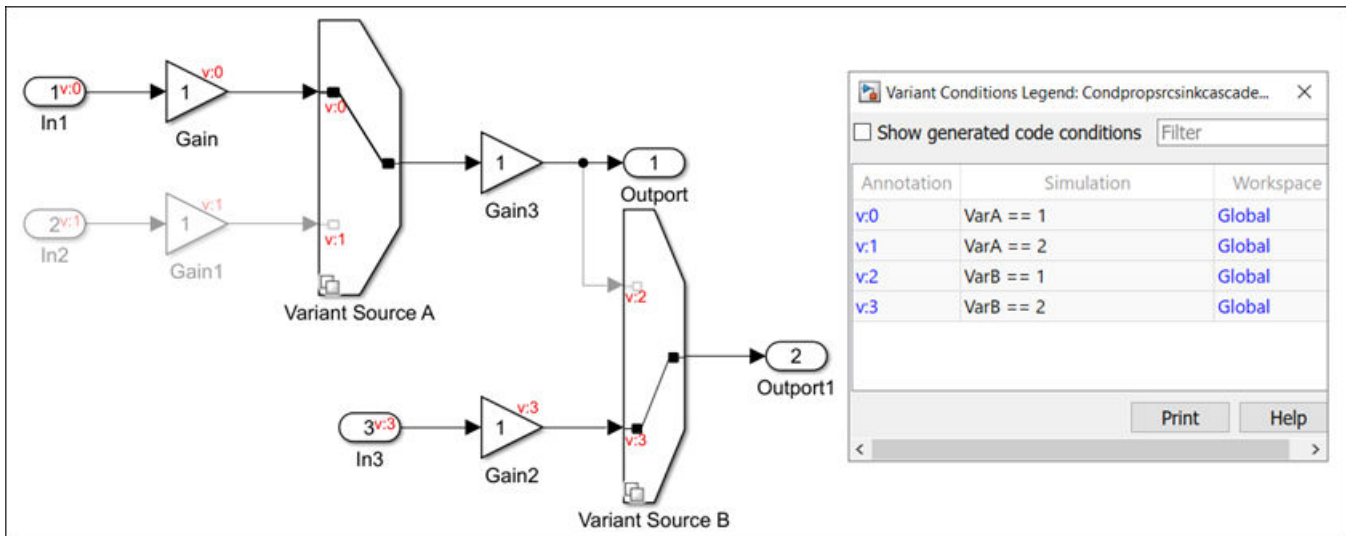

During simulation, this model exhibits three modes of operation:

Variant Condition	Active Choice
Var == 1	First input of Variant Source.
Var == 1    Var == 2	Second input of Variant Source and the branch of the first input.
Var == 2	Second input of Variant Source.

### Cascading Blocks and Compounding Conditions

In this model, Variant Source A and Variant Source B are two Variant Source blocks, each fed by two input ports, and connected in a cascading manner. The inputs to Variant Source A are active when  $VarA == 1$  or  $VarA == 2$ . The output of Variant Source A branches into one of the inputs of Variant Source B. The inputs to Variant Source B are active when  $VarB == 1$  or  $VarB == 2$ .

During simulation, this model exhibits eight modes of operation:

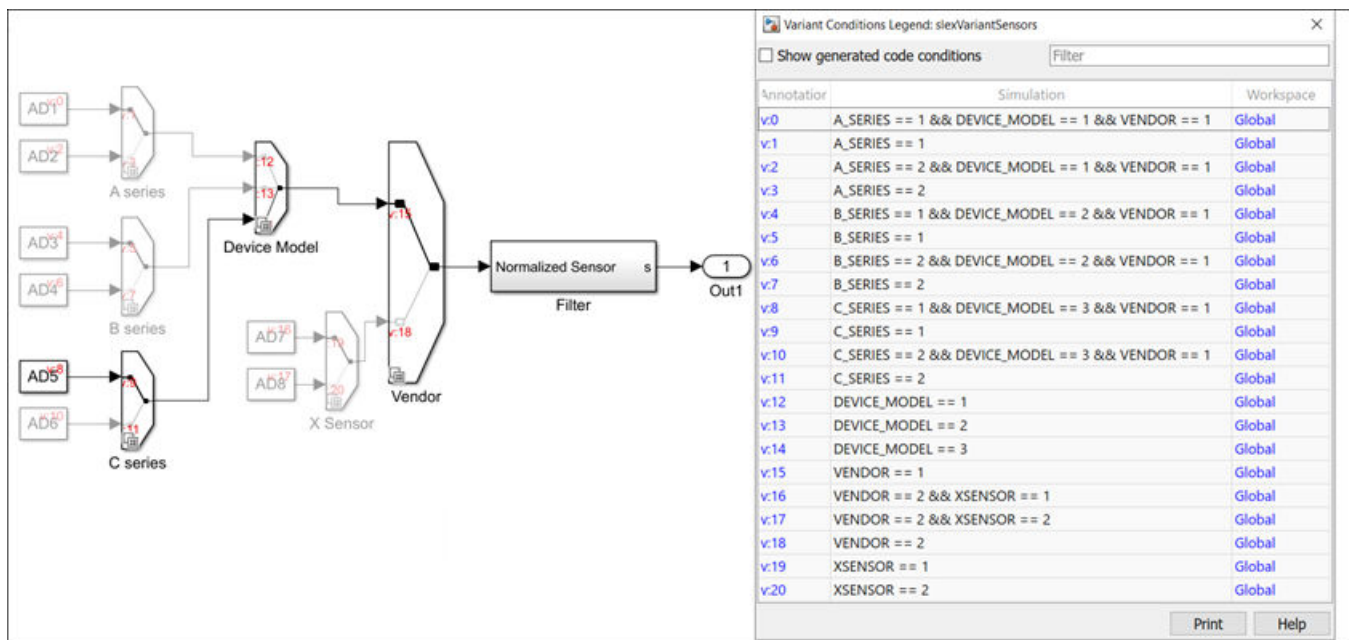

Variant Condition	Active Choice
$VarA == 1 \ \&\& \ VarB == 1$	First inputs of Variant Source A and Variant Source B.
$VarA == 1 \ \&\& \ VarB == 2$	First input of Variant Source A and the second input of Variant Source B.
$VarA == 2 \ \&\& \ VarB == 1$	Second input of Variant Source A and the first input of Variant Source B.
$VarA == 2 \ \&\& \ VarB == 2$	Second inputs of Variant Source A and Variant Source B.
$VarA == 1 \ \&\& \ VarB \neq (1,2)$	First input of Variant Source A.
$VarA == 2 \ \&\& \ VarB \neq (1,2)$	Second input of Variant Source B.
$VarA \neq (1,2) \ \&\& \ VarB == 1$	None
$VarA \neq (1,2) \ \&\& \ VarB == 2$	Second input of Variant Source B.

Variant Condition	Active Choice
VarA != (1,2) && VarB != (1,2)	None

### Hierarchical Nesting of Sources or Sinks

In this model, multiple Variant Source blocks are used to create hierarchical nesting of variant choices and provides variation on sensor inputs . Multiple choices for sensors are first grouped by series: A Series, B Series, and C Series. The Variant Source block, Device Model, selects a sensor from one of the series. The Vendor then chooses amongst the sensor choices provided by Device Model and XSensor .

Simulink propagates complex variant control conditions to determine which model components are active during compilation.

For more information, see “Hierarchical Nesting of Variant Sources and Variant Sinks” on page 12-202.

### Net Variant Condition

The net variant condition is the total of the local condition and its ancestral condition.

In this model, Variant Source and Variant Source1 are two single-input/single-output Variant Source blocks with the variant conditions  $V==1$  and  $W==1$ , respectively. The **Allow zero active variant controls** parameter is set to on for both the variant blocks. When this option is selected and there is no active variant choice, Simulink disables all the blocks connected to the input and output stream of the Variant Source block.

When you simulate this model, the Variant Source1 block and other blocks within the Subsystem block receive a local condition  $W==1$  propagated from the Variant Source1 block. The ancestral condition  $V==1$  is propagated from the Variant Source block onto the Subsystem block. Therefore, the net variant condition on the Variant Source1 block and other blocks within the Subsystem block is  $V==1 \ \&\& \ W==1$ . If the **Allow zero active variant controls** parameter is set to off for the Variant Source block, then condition on the Subsystem block is  $W==1$ .

## Condition Propagation with Subsystems

A variant condition can activate or deactivate a Subsystem block, but variant conditions cannot propagate into the subsystem. A Subsystem block can propagate variant conditions from its output port if that variant condition originates at a port inside the subsystem.

A subsystem can either be a virtual (grouped or ungrouped) or an atomic subsystem depending on the selections made in its Block Parameters dialog box.

- Grouped Virtual: Select the **Treat as grouped when propagating variant conditions** check box. A grouped virtual subsystem has a continuous line.
- Ungrouped Virtual: Clear the **Treat as grouped when propagating variant conditions** check box. An ungrouped virtual subsystem has a dotted line.
- Atomic: Select the **Treat as atomic unit** check box. An atomic virtual subsystem has a solid line.

Simulink propagates variant conditions differently to these subsystem types.

In this model, three types of subsystems are provided as input to the block Variant Source2.

- The grouped virtual subsystem is activated when  $V == 1$ . Simulink propagates the variant activation condition to all the blocks in the subsystem.
- The ungrouped virtual subsystem is activated when  $V == 2$ . Simulink propagates the variant activation condition to the blocks that were available in the subsystem while marking the subsystem virtual.
- The atomic subsystem is activated when  $V == 3$ . Simulink does not propagate the variant activation condition into this subsystem.

For more information, see “Propagate Variant Conditions from Variant Source Blocks to Subsystem Blocks” on page 12-180.

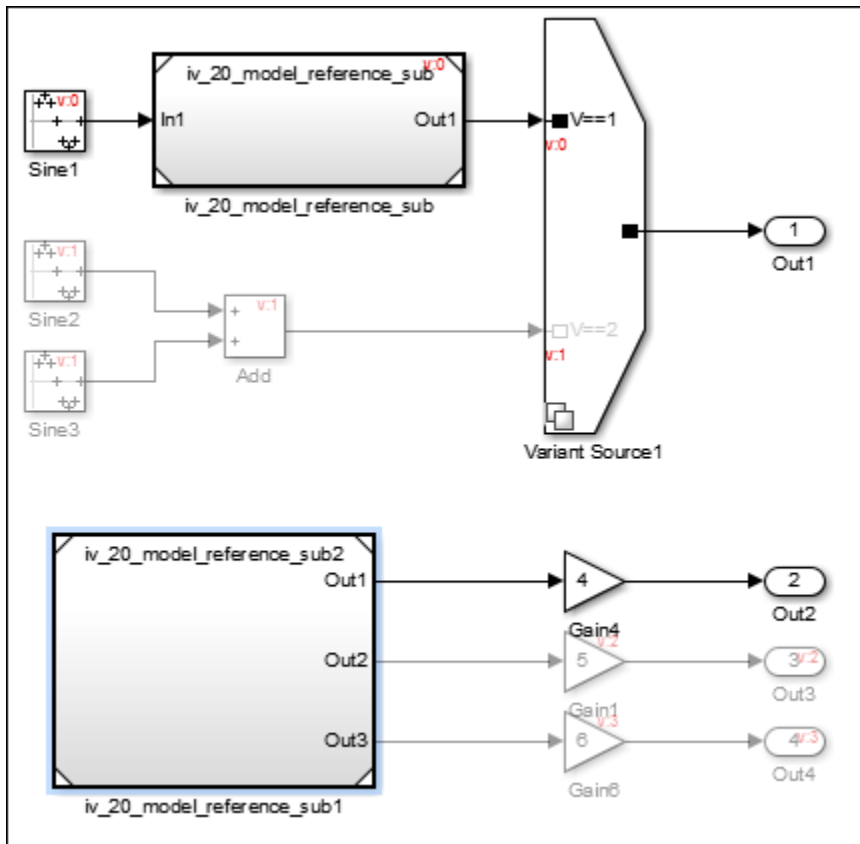

## Condition Propagation with Other Simulink Blocks

### Variant Condition Propagation with Model Block

Simulink compiles referenced models before propagating variant conditions. A variant condition can activate or deactivate a Model block, but variant conditions cannot propagate into the referenced model. A Model block can propagate variant conditions from its interface (input, output, or control port), if that variant condition originates at a port inside the model.

In this example, variant condition  $V==1$  activates the Model block `iv_20_model_reference_sub`. However, the condition does not propagate into the model referenced by the block. Model block `iv_20_model_reference_sub2` propagates the same variant condition from its output port.

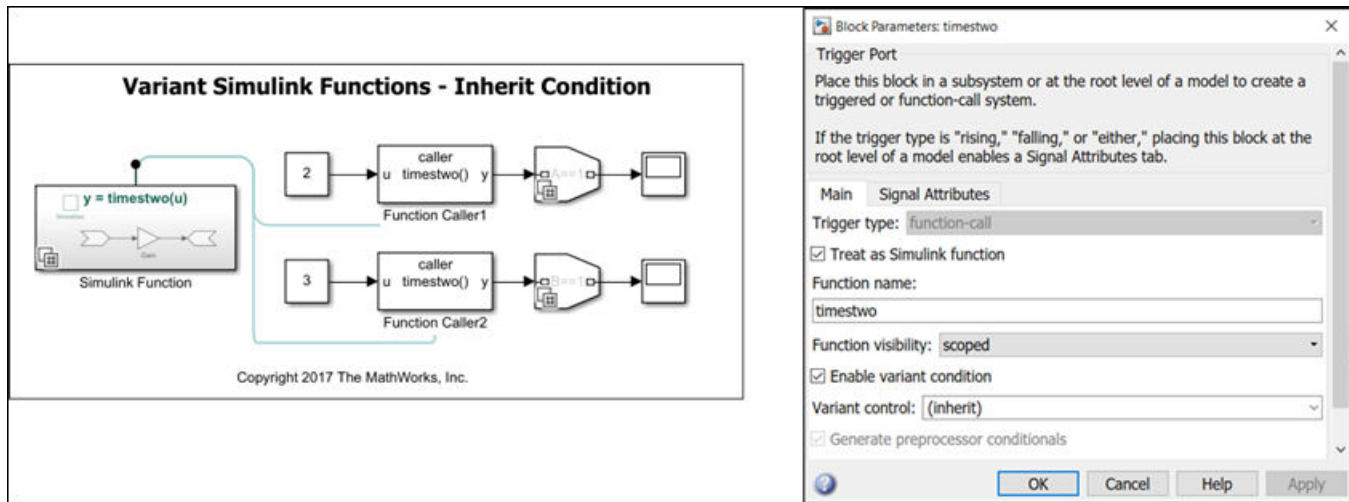

### Variant Condition Propagation with Simulink Function block

Argument Inport and Argument Outport blocks interfacing with Simulink Function blocks cannot be connected to Variant Source or Variant Sink blocks. One variant condition must control the entire Simulink Function.

Consider the model `slexVariantSimulinkFunctionInherit`.

In this example, the function-call port block within the Simulink Function block has the **Enable variant condition** option selected. The `(inherit)` keyword is used to specify the value for the **Variant control** parameter. As a result, the Simulink Function block inherits the variant condition from the corresponding Function Caller blocks in the model. The **Generate preprocessor conditionals** parameter value is also inherited.

**Note** Use the Configure C Step Function Interface dialog box to customize the generated C entry-point step function interface for a model. If input and output ports share an argument name and have propagated variant conditions, this level of interface control is not supported.

### Variant Condition Propagation with Initialize, Reset, and Terminate Blocks

The Initialize, Reset, and Terminate function blocks are pre-configured subsystem blocks that execute during model initialize, reset, and terminate events. Similar to a Simulink Function block these blocks support variant condition propagation. You can propagate variant conditions in Model blocks that have Reset Event ports. This results in optimized existence of blocks connected to the Reset Event ports. Models with inactive Variant Reset Event functions (in referenced models) also supports variant condition propagation.

#### Note

- Initialize and Terminate event ports are always unconditional because they control both the model default and block-specific initialize and terminate events of the referenced model. If you define an Initialize Function or Terminate Function block in the referenced model, it corresponds to an explicit initialize or terminate event.
- If you enable variants and define a variant condition on the Initialize Function or Terminate Function block in the referenced model, the variant condition will not contribute to the variant condition of the Model block instance.

In this example, the Event Listener block within the Init, Reset, and Term blocks have the **Enable variant condition** option selected. The **Variant control** parameter of the Event Listener block is specified as  $V==0$ . If you change the value of  $V$  to any value other than  $0$ , the Init, Reset, and Term blocks become inactive.

### Variant Condition Propagation with Bus

A Variant Source block can accept either virtual or nonvirtual bus inputs. When generating code with preprocessor conditionals, the bus types and hierarchies of all bus inputs must be the same.

However, all elements of a Mux, Demux, or a Vector Concatenate block signal must have the same variant condition.

For more information, see “Variant Condition Propagation with Bus” on page 12-147.

### Variant Condition Propagation with Variant Connector block

A Variant Connector block propagates variant conditions to all the connected components within the physical network. See, Variant Connector.

### Limitations

- Variant condition propagation from Simulink Function inside Stateflow block is not supported.
- The Variant Connector block does not propagate the variant condition across the boundary between the Simscape physical network and the Simulink blocks connected to it.

## Propagate Variant Conditions Outside Variant Subsystems

During simulation and code generation, Simulink propagates the variant conditions to determine which components of the model remain active. By default, these conditions do not propagate outside the Variant Subsystem. To allow the conditions to propagate to the connecting blocks, you can use the **Propagate conditions outside of variant subsystem** parameter on the Variant Subsystem block. For more information about the Variant Subsystem block, see Variant Subsystem, Variant Model.

The propagation of variant conditions outside of the Variant Subsystem block ensures that the components outside of the block are aware of the active and inactive state of the underlying blocks in the Variant Subsystem.

---

**Tip** Variant condition annotations on model components help you visualize the propagated conditions.

To view the annotations, on the **Debug** tab, select **Information Overlays > Variant Legend**.

If **Variant Legend** is not available, on the **Debug** tab, select **Information Overlays > Variant Conditions**.

---

### Factors That Affect Propagation of Variant Conditions

The propagation of variant conditions outside of a Variant Subsystem depends on the variant activation time of the block and the interface of the underlying variant choices. The “Variant activation time” determines if Simulink must analyze only the active choice or both active and inactive choices of the block when simulating or generating code from the model. If the interface of the analyzed variant choices matches the interface of the Variant Subsystem block, the variant conditions do not propagate outside the Variant Subsystem. In other words, if the analyzed variant choices use all the input and the output signals of the Variant Subsystem block, the variant conditions do not propagate outside of the block. The variant conditions do propagate outside of the Variant Subsystem block only if the interfaces do not match.

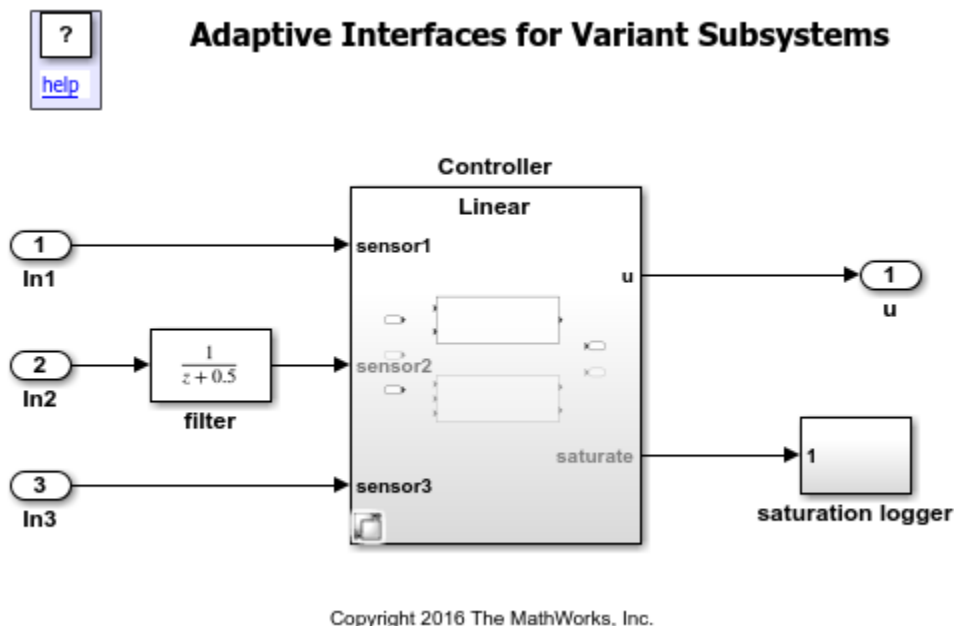

### Adaptive Interface for Variant Subsystems

This example shows how propagating variant conditions outside a Variant Subsystem block enables the block to adapt its interface according to the state of the underlying blocks for different activation

times. Also, the code that is generated for different activation times are explained. For information on factors that affect the propagation, see “Factors That Affect Propagation of Variant Conditions” on page 12-125.

Consider the `slexVariantSubsystemsAdaptiveInterface` model containing a Variant Subsystem block named `Controller` with two variant choices, `Linear` and `Nonlinear`. The `Linear` controller is active when  $V = 1$ , and the `Nonlinear` controller is active when  $V = 2$ .  $V$  is a variant control variable and is defined in the `PreLoadFcn` callback of the model.

To change the value of the variant control variable, in the MATLAB™ Command Window, type  $V = 1$  or  $V = 2$ .

Copyright 2016 The MathWorks, Inc.

Double-click the `Controller` block to view its contents. The `Linear` and `Nonlinear` controller blocks do not have the same interface. The inports `sensor1` and `sensor3` are used in `Linear` controller and `Nonlinear` controller blocks, but `sensor2` is used only in `Linear` controller block. Hence, the `sensor2` block is active only when `Linear` controller is active and is not executed for the other choice. To make the model components outside the Variant Subsystem (`Controller`) aware of the active or inactive state of blocks within the Variant Subsystem block, the block conditions must propagate outside the boundaries of the block. To propagate conditions outside of the `Controller` block, select **Propagate conditions outside of variant subsystem** in the Block Parameters dialog box of the block. By default, this parameter is set to off.

The propagation of variant conditions outside of Variant Subsystem depends on the **Variant activation time** of the block and the interface of its underlying variant choices. For more information, see “Propagation with Different Activation Times” on page 12-126.

## Propagation with Different Activation Times

Next, simulate the model and generate code for `Linear` and `Nonlinear` controllers with different activation times.

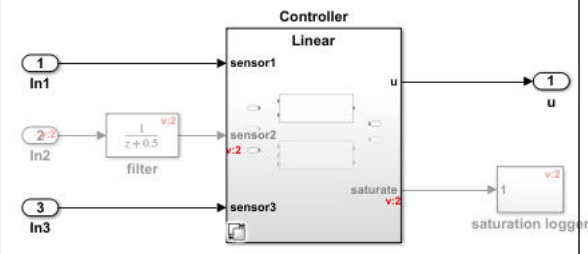

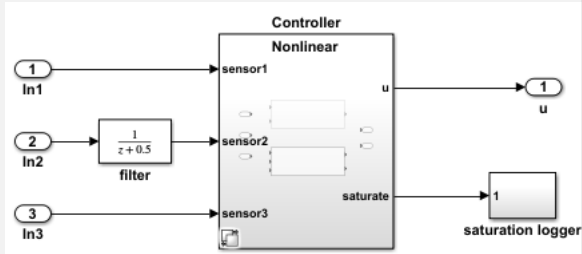

**Note** In the model, the `saturate` port is an unconnected output port and so it is not included in the generated code for any variant activation times.

---

### **Propagate Conditions for update diagram**

- 1** In the Block Parameters dialog box of the `Controller` block, set **Variant activation time** to “update diagram” on page 12-81.
- 2** To activate the `Linear` controller and its connected blocks, change the value of `V` to 1 and simulate the model.
- 3** Generate code from the model by using Embedded Coder and observe the results. The generated code contains only the `Linear` controller. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder).
- 4** Similarly, to activate the `Nonlinear` controller and its connected blocks, change the value of `V` to 2 and simulate the model. Generate code from the model and observe the results.

This table compares the propagation of variant conditions and the generated code for the `Linear` and `Nonlinear` controller choices for `update diagram` activation time.

When V = 1 Linear controller is active	When V = 2 Nonlinear controller is active
<ul style="list-style-type: none"> <li>Only the Linear controller is analyzed.</li> <li>The Linear controller uses only sensor1, sensor3 and u ports, so these ports and its connected blocks are active. The Linear controller does not use sensor2 and saturate ports, so these ports and its connected blocks are inactive. Since the interface of the Linear controller is different than the Controller subsystem, the variant conditions are propagated outside of the subsystem. The condition is propagated only to the ports that are not used by at least one of the variant choices. In this example, the variant annotation v:2 with condition set to false is displayed on sensor2, saturate, and all the connected blocks. In the variant conditions legend, a condition is set to false if the blocks associated with that condition are never active.</li> </ul>  <ul style="list-style-type: none"> <li>The code that you generate contains only the active ports. In this example, the input port In2 is inactive, so it is not part of the generated code.</li> </ul> <pre data-bbox="284 1369 857 1684"> //slexVariantSubsystemsAdaptiveInterface.h /* External inputs (root inport signals with default storage) */ typedef struct {     real_T In1;     real_T In3; } ExternalInputs;  /* External outputs (root outputs with default storage) */ typedef struct {     real_T u; } ExternalOutputs; </pre> <p>The active choice is unconditional. The unconditional statements are not enclosed in any conditional statements and are compiled or executed irrespective of the state of the variant choices.</p>	<ul style="list-style-type: none"> <li>Only the Nonlinear controller is analyzed.</li> <li>The Nonlinear controller uses all the input and output ports of the Controller subsystem, so all the input ports sensor1, sensor2, sensor3, and all its connected blocks are active. Also, all the output ports u, saturate, and all its connected blocks are active. Because of the matching interfaces, the variant conditions are not propagated outside of the Controller subsystem.</li> </ul>  <ul style="list-style-type: none"> <li>The code that you generate contains only the active ports. In this example, all the input and the output ports are active and so they are part of the generated code.</li> </ul> <pre data-bbox="901 1096 1479 1898"> //slexVariantSubsystemsAdaptiveInterface.h /* External inputs (root inport signals with default storage) */ typedef struct {     real_T In1;     real_T In2;     real_T In3; } ExternalInputs;  /* External outputs (root outputs with default storage) */ typedef struct {     real_T u; } ExternalOutputs;  /* '&lt;Root&gt;/In1' */ /* '&lt;Root&gt;/In2' */ /* '&lt;Root&gt;/In3' */  The active choice is unconditional. The unconditional statements are not enclosed in any conditional statements and are compiled or executed irrespective of the state of the variant choices.  /* '&lt;Root&gt;/u' */ /* Model step function */ void step(void) {     // Logic for Nonlinear choice } /* Model initialize function */ void initialize(void) {     /* (no initialization code required) */ } </pre>

When V = 1 Linear controller is active	When V = 2 Nonlinear controller is active
<pre>//slexVariantSubsystemsAdaptiveInterface.c /* Model step function */ void step(void) { // Logic for Linear choice } /* Model initialize function */ void initialize(void) { /* (no initialization code required) */</pre>	

**Note** When propagating variant conditions outside of a Variant Subsystem with `update diagram` activation time:

- If you set **Allow zero active variant controls** to on, the variant condition is displayed on all other active ports and its connected blocks to distinguish between the active blocks that belong to the variant region and the blocks that belong to the fixed region during simulation.
- The code that you generate with and without **Allow zero active variant controls** is the same.

### Propagate Conditions for `update diagram` analyze all choices

- 1 In the Block Parameters dialog box of the Controller block, set **Variant activation time** to “`update diagram analyze all choices`” on page 12-81.
- 2 To activate the Linear controller and its connected blocks, change the value of V to 1 and simulate the model.
- 3 Generate code from the model by using Embedded Coder and observe the results. The generated code contains only the Linear controller. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder).
- 4 Similarly, to activate Nonlinear controller and its connected blocks, change the value of V to 2 and simulate the model. Generate code from the model and observe the results.

This table compares the propagation of variant conditions for the Linear and Nonlinear controller choices with `update diagram analyze all choices` activation time. The generated code is the same as `update diagram`.

When V = 1 Linear controller is active	When V = 2 Nonlinear controller is active
<ul style="list-style-type: none"> <li>Linear controller and Nonlinear controller choices are analyzed.</li> <li>The Linear controller uses only sensor1, sensor3 and u ports, so these ports and its connected blocks are active. The Linear controller does not use sensor2 and saturate ports and so, these ports and its connected blocks are inactive.</li> <li>Since only the interface of the Nonlinear controller matches that of the Controller subsystem, and the interface of Linear controller does not match the interface of the Controller subsystem, the variant conditions are propagated outside of the Controller subsystem. The condition is propagated only to the ports that are not used by at least one of the variant choices. In this example, the variant annotation <math>v:1</math> with condition set to <math>V == 2</math> is displayed on the sensor2, saturate, and its connected blocks.</li> </ul>	<ul style="list-style-type: none"> <li>Linear controller and Nonlinear controller choices are analyzed.</li> <li>The Nonlinear controller uses all the input and output ports of the Controller subsystem, so all the input ports sensor1, sensor2, sensor3, and all its connected blocks are active. Also, all the output ports u, saturate, and all its connected blocks are active.</li> <li>Since only the interface of the Nonlinear controller matches that of the Controller subsystem, and the interface of the Linear controller does not match the interface of the Controller subsystem, the variant conditions are propagated outside of the Controller subsystem. The condition is propagated only to the ports that are not used by at least one of the variant choices. In this example, the variant annotation <math>v:1</math> with condition set to <math>V == 2</math> is displayed on the sensor2, saturate, and its connected blocks.</li> </ul>

**Note** When propagating variant conditions outside of a Variant Subsystem with update diagram analyze all choices activation time:

- If you set **Allow zero active variant controls** to on, the variant condition is displayed on all other active ports and its connected blocks to distinguish between the active blocks that belong to the variant region and the blocks that belong to the fixed region during simulation.
- The code that you generate with and without **Allow zero active variant controls** is the same.

### Propagate Conditions for code compile

- In the Block Parameters dialog box of the Controller block, set the **Variant activation time** to "code compile" on page 12-82.
- To activate the Linear controller and its connected blocks, change the value of V to 1 and simulate the model.

- 3 Generate code from the model by using Embedded Coder and observe the results. The generated code contains only the `Linear` controller. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder).
- 4 Similarly, to activate the `Nonlinear` controller and its connected blocks, change the value of `V` to 2 and simulate the model. Generate code from the model and observe the results.

The propagation of variant conditions for `Linear` and `Nonlinear` controller choices is the same as `update diagram analyze all choices`. The code that is generated for the `Linear` and `Nonlinear` controllers is as shown.

The code contains active and inactive ports. The ports that are not used by at least any of the variant choices are enclosed in necessary preprocessor conditionals `#if` and `#elif`. In this example, the input port `sensor2` is enclosed in condition `V == 2`.

```
//slexVariantSubsystemsAdaptiveInterface.h
External inputs (root inport signals with default storage)*/
typedef struct {
    real_T In1;                /* '<Root>/In1' */

#if V == 2
    real_T In2;                /* '<Root>/In2' */

#define EXTERNALINPUTS_VARIANT_EXISTS
#endif

    real_T In3;                /* '<Root>/In3' */
} ExternalInputs;
// External outputs (root outports fed by
// signals with default storage)
typedef struct {
    real_T u;
```

The active and inactive choices are enclosed in preprocessor conditionals `#if` and `#elif`.

```
//slexVariantSubsystemsAdaptiveInterface.c
/* Model step function */
void step(void)
{
#if V == 1
    // Logic for Linear choice
#elif V == 2
    // Logic for Nonlinear choice
}
/* Model initialize function */
void initialize(void)
{
    /* (no initialization code required) */
}
```

---

**Note** When propagating variant conditions outside of a Variant Subsystem with code compile activation time, if you set **Allow zero active variant controls** to on, the choices are enclosed in an additional conditional statement `#if V == 1 || V == 2`. This skips the compilation of both the choices if none of the choice evaluates to `true`.

---

### Propagate Conditions for startup

- 1 In the Block Parameters dialog box of the Controller block, set **Variant activation time** to “startup” on page 12-82.
- 2 To activate the Linear controller and its connected blocks, change the value of V to 1 and simulate the model.
- 3 Generate code from the model by using Embedded Coder and observe the results. The generated code contains only the Linear controller. For information on how to generate code, see “Generate Code Using Embedded Coder” (Embedded Coder).
- 4 Similarly, to activate Nonlinear controller and its connected blocks, change the value of V to 2 and simulate the model. Generate code from the model and observe the results.

The propagation of variant conditions for the Linear and Nonlinear controller choices is the same as `update diagram analyze all choices`.

The code that is generated for the Linear and Nonlinear controllers is as shown.

The code contains active and inactive ports.

```
//slexVariantSubsystemsAdaptiveInterface.h
/* External inputs (root inport signals with default storage) */
typedef struct {
    real_T In1;                /* '<Root>/In1' */
    real_T In2;                /* '<Root>/In2' */
    real_T In3;                /* '<Root>/In3' */
} ExternalInputs;

// External outputs (root outputs fed by signals
// with default storage) */
typedef struct {
    real_T u;                  /* '<Root>/u' */
} ExternalOutputs;
```

The active and inactive choices are enclosed in regular `if` and `else if` conditions.

```
//slexVariantSubsystemsAdaptiveInterface.c
/* Model step function */
void step(void)
{
    if (V == 1)
        // Logic for Linear choice
    else if (V == 2)
        // Logic for Nonlinear choice
    }
/* Model initialize function */
void initialize(void)
{
    /* InitializeConditions for VariantControlBlock: '<Root>/V' */
    utAssert((V == 1) + (V == 2) == 1);
}
}
```

---

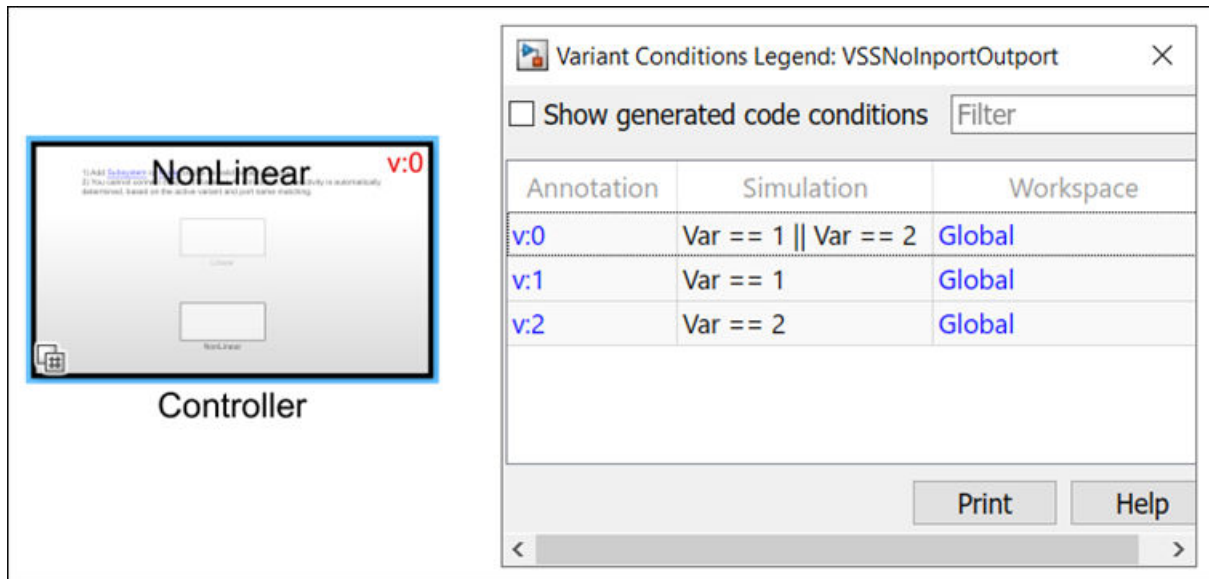

**Note** When propagating variant conditions outside of a Variant Subsystem with `startup` activation time, if you set **Allow zero active variant controls** to on, the choices are enclosed in an additional conditional statement `if V == 1 || V == 2`. This skips the compilation of both the choices if none of the choice evaluates to true.

---

## Propagation Without Inport and Output Blocks

Consider this model with a Variant Subsystem block that has two variant choices. There are no inports or outports on the block. The two variant choices have the conditions  $\text{Var}==1$  and  $\text{Var}==2$ , respectively. When the **Propagate conditions outside of variant subsystem** parameter of the Variant Subsystem block is set to off, a logical OR of the variant conditions,  $\text{Var}==1 \ || \ \text{Var}==2$ , is set on the Variant Subsystem block. When the parameter is set to on, no conditions are applied on the Variant Subsystem block.

## Propagate Conditions Programmatically

To propagate conditions outside of a Variant Subsystem block programmatically, use one of these syntaxes:

- Propagate conditions:

```
set_param(VariantSubsystemName, 'PropagateVariantConditions', 'on')
```

For example,

```
set_param('sldemo_variant_subsystems/Controller', 'PropagateVariantConditions', 'on')
```

- Propagate conditions and generate preprocessor conditionals in code:

```
set_param(VariantSubsystemName, 'PropagateVariantConditions', ...
'on', 'VariantActivationTime', 'code compile')
```

For example,

```
set_param('slexVariantSubsystems/Controller', 'PropagateVariantConditions', ...
'on', 'VariantActivationTime', 'code compile')
```

## Limitations

Propagated variant conditions from variant subsystems can be set on Simscape or Stateflow blocks only for the update diagram variant activation time.

---

**Note** All elements of a Mux, Demux, or a Vector Concatenate block signal must have the same variant condition.

---

## Use Variant Subsystem Blocks with Conditionally Executed Subsystems

You can use conditionally executed subsystems that use control input ports such as Enabled, Triggered, Reset, and the Function-Call subsystems as variant choices within the Variant Subsystem block. For more information on conditionally executed systems, see “Conditionally Executed Subsystems Overview” on page 10-3.

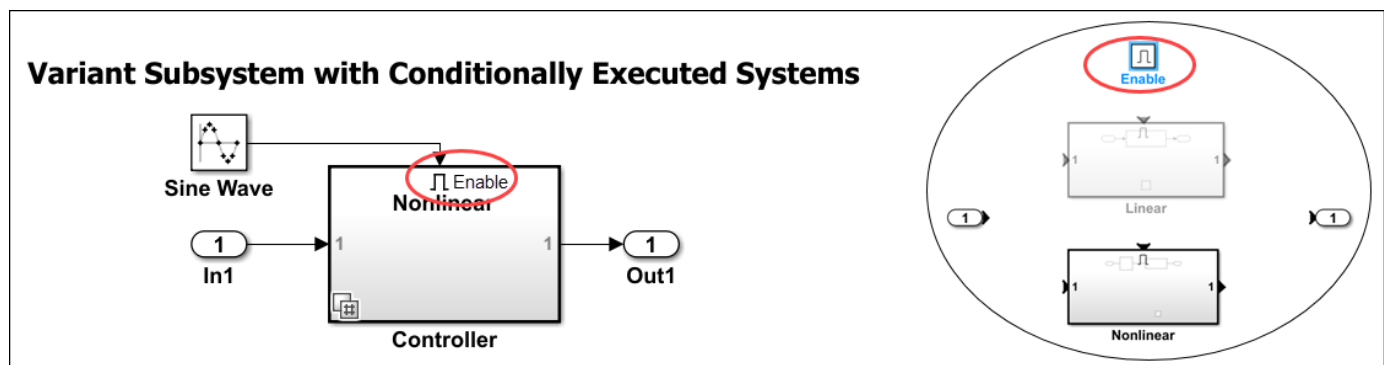

When you use conditionally executed subsystems as variant choices:

- The type of control port blocks in all the variant choices must be same as the Variant Subsystem block. For example, you cannot use Enabled Subsystem and Function-Call Subsystem blocks as choices within a Variant Subsystem block.
- The control port on the Variant Subsystem block and the corresponding control ports on its variant choices must have the same name. For example, if the name of the control port on the Variant Subsystem is `fcn`, then the name of the corresponding control ports on all its variant choices must also be `fcn`.

**Note** The properties set on the control ports that are inside the Variant Subsystem block are ignored during simulation and code generation.

### Create a Variant Subsystem with Enabled Subsystem as Choice

Consider this model with a Variant Subsystem block named `Controller` and two Enabled Subsystem blocks, `Linear` and `Nonlinear`, as variant choices. The variant conditions on the `Linear` and `Nonlinear` blocks are `VSSMODE==0` and `VSSMODE==1`, respectively. If you use an Enabled Subsystem block for the `Linear` choice, then the `Nonlinear` choice must also be an Enabled Subsystem.

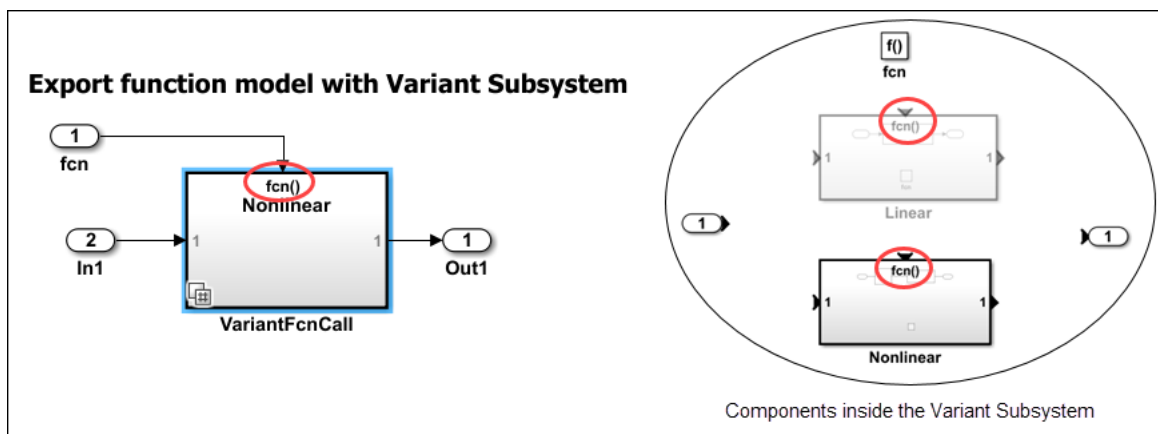

When you generate code from this model, the `Linear` and `Nonlinear` choices are guarded by the corresponding variant conditions.

```
step() {
#if VSSMODE==0
// code for Linear choice
.....
#elif VSSMODE==1
// code for Nonlinear choice
.....
#endif
}
```

## Use Variant Subsystem Block to Create an Export-Function Model

Export-function models are Simulink models that generate code for independent functions that can be integrated with an external environment and scheduler. You can use a Variant Subsystem block with Function-Call Subsystem blocks as variant choices to create an export-function model. For more information on export-function models, see “Export-Function Models Overview” on page 10-96.

Consider a model containing a Variant Subsystem block named `VariantFcnCall` with two Function-Call Subsystem blocks, `Linear` and `Nonlinear`, as variant choices. The variant conditions set on `Linear` and `Nonlinear` choices are `VSS_MODE==0` and `VSS_MODE==1`, respectively. The `VariantFcnCall` block has a root level function-call inport block, `fcn`, and the same name is given to the control ports on the `Linear` and `Nonlinear` choice blocks. The **Variant activation time** parameter of `VariantFcnCall` is set to `code compile`. If you use a Function-Call Subsystem block for the `Linear` choice, then the `Nonlinear` choice must also be a Function-Call Subsystem.

You can also have a similar modeling pattern with a multi-point entry function using Model blocks.

In this example, the inputs `fcn1`, `fcn2`, and `fcn3` are routed through a Variant Subsystem block, `Model`, that uses Model blocks as variant choices.

### Code Generation for Export-Function Model

When you generate code from this model with **Variant activation time** of `VariantFcnCall` set to `code compile`, the definition of the export function `fcn` contains the C preprocessor conditionals `#if` and `#endif`. The code for `Linear` and `NonLinear` choices are guarded by the corresponding variant conditions. When you generate code from this model with **Variant activation time** of `VariantFcnCall` set to `startup`, the definition of the export function, `fcn`, contains the regular `if` conditions. The code for `Linear` and `NonLinear` choices are guarded by the corresponding variant conditions.

This is the code generated with the activation time set to `code compile`. For more information on configuring the model to generate code, see “Prepare Variant-Containing Model for Code Generation” on page 12-103.

```
void fcn(void)
{
```

```
/* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor_fcn_at_outport_1' */
#if VSSMODE == 0

    rtDWork.Linear.DiscreteFilter = rtU.In1 - 0.5 *
    rtDWork.Linear.DiscreteFilter_states;
    rtDWork.Linear.DiscreteFilter_states = rtDWork.Linear.DiscreteFilter;

#endif                                     /* VSSMODE == 0 */

#if VSSMODE == 1

    rtDWork.Nonlinear.DiscreteFilter = look1_binlxpw(rtU.In1,
    rtCP_LookupTable_bp01Data, rtCP_LookupTable_tableData, 4U) - 0.5 *
    rtDWork.Nonlinear.DiscreteFilter_states;
    rtDWork.Nonlinear.DiscreteFilter_states = rtDWork.Nonlinear.DiscreteFilter;

#endif                                     /* VSSMODE == 1 */

#if VSSMODE == 0

    rtY.Out1 = rtDWork.Linear.DiscreteFilter;

#endif                                     /* VSSMODE == 0 */

#if VSSMODE == 1

    rtY.Out1 = rtDWork.Nonlinear.DiscreteFilter;

#endif                                     /* VSSMODE == 1 */

}
```

### Guard Export Function Definition in Generated Code

To guard the whole definition of the export function, fcn, using a variant condition, use a Variant Source block with the **Variant activation time** set to code compile as shown in this example.

---

**Note** The function definition is guarded only when the activation time is set to code compile. The function definition is not guarded for blocks with startup activation time.

---

In the generated code, the definition of the export function, `fcn()`, is guarded with `A==1`.

```
#if A == 1
void fcn(void)
{
...
}
#endif
```

This function can be referred using a code snippet similar to this one.

```
...
#if A==1
fcn()
#endif
.....
```

## Propagate Variant Conditions from Variant Subsystem Blocks to Conditional Subsystems

When you propagate a variant condition to a conditional subsystem, the same condition is set to all ports.

Consider this model. The Variant Subsystem block, `VariantFcnCall`, has conditional subsystem blocks as choices. The inport `fcn` on `VariantFcnCall` corresponds to the control input ports on the variant choice blocks. A single-input, single-output Variant Source block with the condition `A==1` is connected to the `fcn` port. The `VariantFcnCall` block gets the variant condition of the signal connected to the `fcn` port. The condition assigned to the block then propagates to the blocks connected to its input and output ports. When you simulate this model after setting `A=1`, the variant condition `A==1` propagates to the `VariantFcnCall` block and to the `In1` and `Out1` blocks connected to it, as shown in the Variant Conditions Legend.

## Limitations

These conditions are not supported when using conditionally executed systems as variant choices within a Variant Subsystem block:

- Action Port blocks in the variant choices.
- Iterator Port blocks in the variant choices of a Variant Subsystem with **Variant activation time** set to `code compile`.
- Configuring a model as an AUTOSAR component with runnable as a variant subsystem choice.
- Initialize Function, Reset Function, Terminate Function, and Simulink Function blocks.

---

**Note** Initialize and Terminate event ports are always unconditional because they control both the model default and block-specific initialize and terminate events of the referenced model. If you define an Initialize function block in the referenced model, it corresponds to an explicit initialize event.

---

## Convert Configurable Subsystem to Variant Subsystem

**Note** Configurable Subsystem will be removed in a future release. The Configurable Subsystem blocks in existing models must be converted to Variant Subsystem blocks.

Variant Subsystems offer more capabilities than Configurable Subsystems, with these advantages:

Feature	Configurable Subsystem	Variant Subsystem
Library	You need a Simulink library to create a template block in library to create instance of a configurable subsystem.	You do not need to create a library to create an instance of the variant subsystem.
Variant Control	You do not need variant controls to control Configurable subsystem blocks.	You can control variant blocks through label modes and other modes. Variant subsystem is a superset.
Code Generation	The generated code contains only the block choice.	The generated code can contain either the active choice of all the variants.
Model blocks and Subsystem blocks as choices.	You cannot mix Model blocks and Subsystem blocks as choices.	You can mix Model blocks and Subsystem blocks as variant choices.
Nested Workflows	It is not easy to control block choices in nested configurable subsystem hierarchy	Nested variant subsystem workflow is easy and not problematic.
Variant Manager	No centralized system to manage configurable subsystem blocks	Advanced variant management capabilities through the variant manager

You can convert Configurable Subsystem block to a Variant Subsystem block in one of the four ways:

### Convert Configurable Subsystem Blocks to Variant Subsystem Blocks Using Upgrade Advisor Programmatically

Configurable Subsystem blocks in a model can be converted to Variant Subsystem blocks programmatically using `upgradeadvisor`.

Perform these steps to convert Configurable Subsystem blocks in a model to Variant Subsystem blocks:

- 1 Open a model containing Configurable Subsystem block.

- Convert the library template blocks to Variant Subsystem blocks using `upgradeadvisor`. Create an object for `upgradeadvisor`, and run the method `upgrade` with the `upgrader` object output.

```
upgrader = upgradeadvisor(bdroot);
upgrader.upgrade
```

For information on using this method, see `upgradeadvisor`. A report with the status of the block conversion is generated.

## Convert Configurable Subsystem Blocks to Variant Subsystem Blocks Using Upgrade Advisor

Convert Configurable Subsystem blocks in a model to Variant Subsystem blocks using **Upgrade Advisor**.

When you compile a model containing Configurable Subsystem blocks, a warning is displayed which will instruct you to convert the Configurable Subsystem block to a Variant Subsystem block.

- Consider a model with Configurable Subsystem block. When you compile this model, a warning is displayed in the **Diagnostic Viewer**.

---

**Note** When you create a new Configurable Subsystem block, an upgrade advisor alert is displayed to convert the Configurable Subsystem block to Variant Subsystem block.

---

- In the **Diagnostic Viewer**, click **Open** in the **Suggested Actions** section.
- In the **Upgrade Advisor**, select **Identify configurable subsystem blocks for converting to variant subsystem blocks** and then click **Run This Check**. A list of all the Configurable Subsystem blocks in the model and recommended action to be performed is displayed.

---

**Note** To upgrade Configurable Subsystem instances created by Model discretizer in the model or subsystem level, perform the **Recommended Action**. The recommended action ensures that the information regarding discretization is retained.

---

To convert to Variant Subsystem, right click on each of the Configurable Subsystem instances provided in the list and select **Subsystem and Model Reference >Convert to>Variant Subsystem**.

---

- 4 In the model, perform the **Recommended Action** of running the **Analyze model hierarchy and continue upgrade sequence** to convert the configurable subsystem template blocks to update the listed configurable subsystem blocks. **Upgrade Advisor** guides you through the recommended sequence of steps to upgrade your models. Click **Continue Upgrade Sequence** to open the libraries in a sequence.
- 5 In the library, run the **Identify configurable subsystem blocks for converting to variant subsystem blocks** again. Click the **Convert All** button to convert all the configurable subsystem blocks in the libraries in the sequence. You must run the **Identify configurable subsystem blocks for converting to variant subsystem blocks** check as many times as the number of libraries.

## Convert Configurable Subsystem Blocks to Variant Subsystem Blocks Programmatically Using `convertToVariant`

Configurable Subsystem blocks in a model can be converted to Variant Subsystem blocks programmatically using `convertToVariant` method.

When a Configurable Subsystem is converted to a Variant Subsystem block, the Block choice of Configurable Subsystem block is changed to `LabelModeActiveChoice` in the Variant Subsystem block.

If the Block choice of the Configurable Subsystem template block is linked, then the block is copied to the Variant Subsystem graph and the copied blocks will have its links retained. If the Block choice of the Configurable Subsystem template block is not linked, then the block is copied to the Variant Subsystem graph and the block in the Configurable Subsystem library is linked to it.

Perform these steps to convert Configurable Subsystem blocks in a model to Variant Subsystem blocks:

- 1 Open a model containing Configurable Subsystem block.

- 2 In the command-line, enter the `find_system` command to find all the Configurable Subsystem blocks in the model:

```
find_system(bdroot, 'Regexp', 'on', 'LookUnderMasks', 'on', 'FollowLinks', 'on', 'Variants', '')
```

The Configurable Subsystem blocks present in the model are listed:

```
{'mconfigsub/config_sub'}
{'mconfigsub/nested config'}
```

- 3 Find the library template blocks from the list using `get_param` command.

```
get_param('mconfigsub/nested config','TemplateBlock')
ans =
    'mconfiglib/nested config'
```

```
get_param('mconfigsub/config_sub','TemplateBlock')
ans =
    'mconfiglib/Subsystem/config_sub'
```

- 4 Convert the library template blocks to Variant Subsystem blocks using `convertToVariant`.

```
Simulink.VariantManager.convertToVariant('mconfiglib/nested config')
```

```
Simulink.VariantManager.convertToVariant('mconfiglib/Subsystem/config_sub')
```

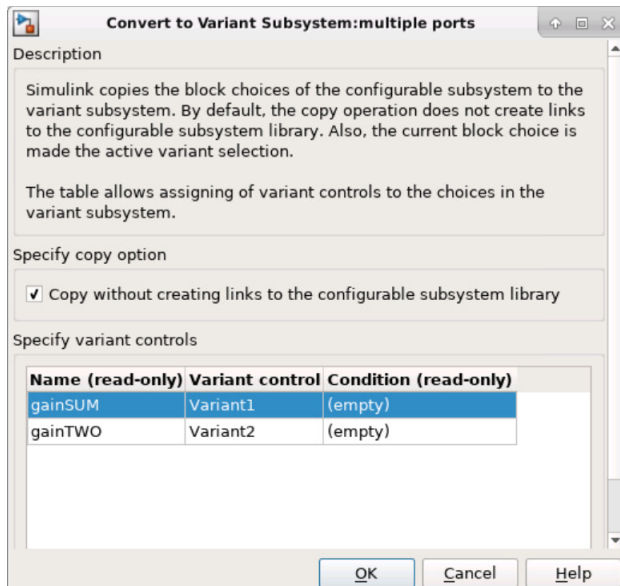

- 5 Save the libraries. You can use `save_system` command to save the libraries.
- 6 Close and open the model again. The Configurable Subsystem blocks in the model will be converted to Variant Subsystem blocks.

## Convert Configurable Subsystem Blocks to Variant Subsystem Blocks Through the Dialog

- 1 Open a model containing Configurable Subsystem block.

- 2 Right-click the Configurable Subsystem block and in the context menu, select **Subsystem & Model Reference > Convert to > Variant Subsystem**.
- 3 By default, the **Copy without creating links to the configurable subsystem library** check box is selected. This creates variant choices without creating links to library.

- 4 Click **OK**. The Configurable Subsystem block is converted to Variant Subsystem block and is displayed in a new window.

**Note** When Configurable Subsystem block is converted to a Variant Subsystem block, the Block choice of Configurable Subsystem block is changed to `LabelModeActiveChoice` in Variant Subsystem block.

- 5 Manually replace the Configurable Subsystem block with the converted Variant Subsystem block in the original model.

## Changing Active Variant

When Configurable Subsystem block is converted to a Variant Subsystem block, the Block Choice of Configurable Subsystem block is changed to Label mode active choice in Variant Subsystem block.

To change the active variant, perform one of these steps:

- Right-click the badge on the Variant Subsystem block and select **Block Parameters (Subsystem)**. In the block parameters dialog box, select the active variant from Label mode active choice drop-down list.
- Right-click the badge on the Variant Subsystem block and select **Label Mode Active Choice**.

---

**Note** When a Configurable Subsystem block with a mask is converted to Variant Subsystem block, the Label mode active choice option and all other parameters in block parameters dialog box is disabled. To change the active variant, right-click the badge on the Variant Subsystem block and select **Label Mode Active Choice**.

---

## Variant Elements Within Buses

### Create Buses with Variant Conditions

This example shows how to create bus signals with elements having different variant conditions. This model has two signals ('a', 'b') that are merged to create a bus signal. These two signals have different variant conditions,  $V==1$  and  $W==1$ .

The bus selector is fed by two signals having two different variant conditions ( $V==1$  and  $W==1$ ). When this bus signal is fed into a bus selector and when you select the individual signals from the bus, the variant condition is also selected.

---

**Note** Variant bus supports using Composite ports as input and output ports.

---

To see the completed model, open the `slexVariantBus` model.

### Variant Condition Propagation with Bus

A Variant Source block can accept either virtual or nonvirtual bus inputs.

Consider this model.

Same signal selected across a bus selector.

Annotation	Simulation	Workspace
v:0	V == 1    W == 1	Global
v:1	V == 1	Global
v:2	W == 1	Global

Bus is created with variant conditions  $V = 1$  and  $W = 1$ . When conditions  $V$  and  $W$  are propagated through the bus and when individual elements are selected from the bus, conditions are also selected.

## Code Generation

You can generate code for the model. To do so, on the **Apps** tab of toolstrip, click **Embedded Coder**, then on the **C Code** tab, click **Build**. For more information on configuring model to generate code, see “Prepare Variant-Containing Model for Code Generation” on page 12-103.

When generating code with preprocessor conditionals, the bus types and hierarchies of all bus inputs must be the same.

## Virtual and Nonvirtual Bus Behavior

Virtual buses provide the simplest approach for using buses to reduce signal clutter in a block diagram. Nonvirtual buses support modeling components (such as S-functions or MATLAB Function blocks) that require explicitly specified interfaces. There is no change in the propagation behavior of variant conditions when variant conditions are propagated through a virtual or nonvirtual bus.

Code generated for a virtual bus is as shown below.

```

/* Block states (default storage) for system '<Root>' */
typedef struct {

#if V == 1

    real_T UnitDelay_1_DSTATE;          /* '<Root>/Unit Delay' */

#define D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
#endif
    /* V == 1 */
#if W == 1

    int32_T UnitDelay_2_DSTATE;        /* '<Root>/Unit Delay' */

#define D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
#endif
    /* W == 1 */

```

```
#ifndef D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
```

```
char _rt_unused;
```

```
#endif
```

```
} D_Work_ex_bus_var_cond;
```

Code generated for a nonvirtual bus is as shown below.

```
/* Block states (default storage) for system '<Root>' */
typedef struct {
```

```
#if V == 1 || W == 1
```

```
myBus UnitDelay_DSTATE;          /* '<Root>/Unit Delay' */
```

```
#define D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
```

```
#endif          /* V == 1 || W == 1 */
```

```
#ifndef D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
```

```
char _rt_unused;
```

```
#endif
```

```
} D_Work_ex_bus_var_cond;
```

You must have an associated bus object in the bus, which provides properties that Simulink uses to validate the bus signal. For more information on bus objects, see “Specify Bus Properties with Simulink.Bus Object Data Types” on page 81-58. The bus object used in the bus is unconditional and it generates unguarded code as shown below.

```
typedef struct {
real_T a;
int32_T b;
} myBus;
```

## Variant Bus with Model Block

Consider this model containing a Model block.

This model has two signals ('a', 'b') which have different variant conditions,  $V==1$  and  $V==2$ .

From the Model block, the bus selector is fed two signals having two different variant conditions ( $V=1$  and  $V=2$ ). When you select the individual signals from the bus, the variant conditions are also selected.

### Known Limitations

- State logging is not supported for a block (for example, Unit Delay) that takes in a bus in which some elements are removed.

## V-Model for System Development with Simulink Variants

Simulink is often used to model systems that represent a product line. The systems in a product line, although based on the same definition, can differ in several aspects. For example, consider a product line of passenger cars where each variant has different set of features. Instead of designing multiple models to represent all possible variants, you can use Simulink variants to model all the variations in a product line in a single model. Simulink variant capabilities allow you to create flexible models with built-in variabilities to more efficiently manage, configure, and reuse your designs. For information on Simulink variants basics, see “What Are Variants and When to Use Them” on page 12-4.

The V-model represents a development process. The model demonstrates the relationship between each phase of the development cycle on the left side and its associated validation phase on the right side. Simulink variants supports the V-model development process by providing variant capabilities from the System Level Model phase, down to Code Generation, and up to the Interaction and Test phase. In the System Level Model and Component phases, you can use variant blocks and variant parameters to capture structural and data variations. You can use the Variant Manager for Simulink to prevent invalid variant combinations and reduce the variant model to contain only the selected variants. The generated code contains the variations defined in the model and the components. In the Test phases, you can use the Simulink Design Verifier to generate test cases to identify hidden design errors and use Simulink Test to execute user-defined tests. Also, you can use Simulink Coverage to get coverage for all variants.

Depending on your application and its role in the process, you might focus on one or more of the steps called out in the V-model or repeat steps at several stages of the V-model.

These tables list goals that you might have as you apply variations in your model and guides you on how to meet those goals. You can open and run the examples linked below to apply variants and generate code. For a list of models that show variant capabilities in Simulink, see “Simulink Variant Examples” on page 12-228.

- “System-Level Model” on page 12-152

## System-Level Model

You can model variations for any component in a system architecture model. A component may have two or more than two variant options that represent alternate structural decompositions. You can also define a mix of behaviors (defined in a Simulink model) and architectures (defined in a System Composer architecture model) as variant choices. For more information on System Composer architecture models, see “Compose Architectures Visually” (System Composer).

Goal	Capability	Example
Add components with alternative structural designs in architecture model.	Variant Component	“Create Variants” (System Composer)
Manage systems with variations in structural components.	“Variant Manager for Simulink”	“Create and Activate Variant Configurations” on page 89-10

## Components — Create Models with Structural Variations

Once you understand your modeling requirements, you can begin to identify the varying components of the system. Identifying components and their relationships within a top-level structure help build a potentially complex model systematically. With variant blocks in Simulink you can design multiple design alternatives of a system in a single model. Each design choice is incorporated into the model as a variant choice. You can choose to activate or deactivate the variant choices as per your requirement during simulation. For more information, see “What Are Variants and When to Use Them” on page 12-4.

This section covers:

- “Implement Structural Variabilities for Components” on page 12-152
- “Propagate Conditions from Variant Blocks Upstream and Downstream” on page 12-155
- “Control Visibility of Variant Regions” on page 12-155
- “Variant Controls in Structurally Varying Systems” on page 12-156
- “Control Variant Activation Times of Structurally Varying Systems” on page 12-157

### Implement Structural Variabilities for Components

You can implement structural variabilities in all domains, including controls logic, state machines, flow charts, and physical plants by using variant blocks in your model. For more information on variant blocks, see “Variant Blocks in Simulink” on page 12-7.

Goal	Capability	Example
Encapsulate variations of a component in a separate in your model. You can encapsulate subsystem (virtual and non-virtual) blocks, model blocks, and subsystem reference blocks to conditionally execute them.	Variant Subsystem, Variant Model	"Implement Variations in Separate Hierarchy Using Variant Subsystems" on page 12-184
<ul style="list-style-type: none"> <li>• Represent all variations of a component at the same level in your model.</li> <li>• Represent components with variations in source or destination signals.</li> </ul>	Variant Source and Variant Sink	<ul style="list-style-type: none"> <li>• Variant Source and Variant Sink Blocks in Car Wiper Motor Skeleton (Model)</li> <li>• "Variant Source and Variant Sink Blocks" on page 12-193</li> </ul>
Represent components that have a fixed common structure, but varying input and output interfaces.	Variant Subsystem, Variant Model	"Adaptive Interface for Variant Subsystems" on page 12-125
Represent variations at the same level in your model and toggle between the variant choices using a simple toggle switch mechanism.	Manual Variant Source and Manual Variant Sink	"Provide Variation at Source and Destination of a Signal Using Manual Variant Source and Manual Variant Sink Blocks" on page 12-226
Conditionally execute event-driven functions on a model initialize, reset, and terminate events.	Initialize Function, Reset Function, and Terminate Function	"Variant Condition Propagation with Initialize, Reset, and Terminate Blocks" on page 12-122
Conditionally execute trigger-driven functions (execution is controlled by external signal).	Enabled Subsystem, Triggered Subsystem, and Enabled and Triggered Subsystem	<ul style="list-style-type: none"> <li>• Variant Condition Propagation to Conditionally Executed Subsystems (Model)</li> <li>• "Create a Variant Subsystem with Enabled Subsystem as Choice" on page 12-135</li> <li>• "Propagate Variant Conditions from Variant Source Blocks to Conditionally Executed Subsystems" on page 12-199</li> </ul>

Goal	Capability	Example
	<p>“Using Function-Call Subsystems” on page 10-34</p>	<ul style="list-style-type: none"> <li>• “Use Variant Source Block to Receive or Output Function-Call Signals for Simulation and Code Generation” on page 12-229</li> <li>• “Use Variant Subsystem Block to Create an Export-Function Model” on page 12-136</li> </ul>
<p>Conditionally execute Simulink functions (analogous to a function in procedural programming language).</p>	<p>Simulink Function</p>	<ul style="list-style-type: none"> <li>• Variant Simulink Functions - Inherit Condition (Model)</li> <li>• Variant Simulink Functions - Specified Condition (Model)</li> <li>• “Variant Condition Propagation with Simulink Function block” on page 12-121</li> </ul>
<p>Merge output signals of conditionally executed Simulink functions.</p>	<p>“Using Function-Call Subsystems” on page 10-34</p>	<p>“Variant Function-Call Signals on Variant Subsystem Output” on page 12-232</p>
<p>Encapsulate Simulink models as variant choices and execute them conditionally.</p>	<p>Variant Subsystem, Variant Model</p>	<p>“Model Reference Variants”</p>
<p>Add or remove variant choices without modifying the model.</p>	<p>Variant Assembly Subsystem</p>	<p>“Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files” on page 12-316</p>
<p>Implement variations in real physical components.</p>	<p>Variant Connector</p>	<ul style="list-style-type: none"> <li>• “Model Variants in a Mechanical System Using Variant Connector Blocks” (Simscape)</li> <li>• “Model Variants in an Electrical Circuit Using Variant Connector Blocks” (Simscape)</li> </ul>
<ul style="list-style-type: none"> <li>• Active variant is fixed before the simulation starts and does not change during intermediate stage of simulation.</li> <li>• Switch between active variants using strings with minimal data management.</li> </ul>	<p>“Use label Mode in Variant Blocks” on page 12-46</p>	<p>“Switch Between Choices Using Labels in Variant Blocks” on page 12-45</p>

Goal	Capability	Example
Create branches in your model that apply only to simulation or only to code generation.	“Use sim codegen switching Mode in Variant Blocks” on page 12-47	“Switch Between Choices for Simulation and Code Generation Workflows Without Using Control Variables in Variant Blocks” on page 12-47

### Propagate Conditions from Variant Blocks Upstream and Downstream

You can expand the variability control to any region of your model by automatically propagating variant conditions from variant blocks to other blocks upstream and downstream. Variant conditions can propagate through signal lines, buses, and function calls to reach blocks in a model affected by variant selection. For more information, see “Variant Condition Propagation Overview” on page 12-256.

Goal	Capability	Example
Improve accuracy of the model and avoid manual computation of variant conditions to assign to the dependent blocks by propagating the state of the underlying blocks outside of the parent variant block.	Variant Subsystem, Variant Model	“Propagate Variant Conditions Outside Variant Subsystems” on page 12-125
Improve accuracy of the model and avoid manual computation of variant conditions to assign to the dependent blocks by propagating the state of the variant blocks to all its connected blocks.	<ul style="list-style-type: none"> <li>• Variant Source</li> <li>• Variant Sink</li> </ul>	“Variant Condition Propagation with Variant Sources and Sinks” on page 12-116
Remove variant region completely from model execution when no variant is active.	“Allow zero active variant controls”	“Propagate Variant Conditions Outside Variant Subsystems” on page 12-125
Stop propagating the state of variants upstream and downstream.	Ground and Terminator	“Control Variant Condition Propagation” on page 12-196
Reduce visual complexity by propagating variant elements in composite signals.	<ul style="list-style-type: none"> <li>• Group Signal Lines into Virtual Buses</li> <li>• Simscape Bus</li> </ul>	<ul style="list-style-type: none"> <li>• “Variant Elements Within Buses” on page 12-147</li> <li>• “Variant Connector Block with Simscape Bus Block” (Simscape)</li> </ul>

### Control Visibility of Variant Regions

You can control the visibility of variant regions by defining the variant control in appropriate workspaces as per your requirement. Limiting the scope helps avoid name conflicts and establish clear ownership of the variant controls between the blocks. It also enables you to use same names for variant controls in different scopes. For more information, see “Storage Locations for Variant Control

Variables (Operands) in Variant Blocks” on page 12-42 and “Types of Operators in Variant Blocks for Different Activation Times” on page 12-43.

Goal	Capability	Example
<ul style="list-style-type: none"> <li>• Create custom user interface for variants.</li> <li>• Prevent unintended modification of variant controls by encapsulating it behind a mask.</li> <li>• Use same names for variant controls in different masks by limiting the scope of controls.</li> </ul>	<p>“Masking Fundamentals” on page 42-2</p>	<ul style="list-style-type: none"> <li>• “Approaches to Control Active Variant Choice of a Variant Block Using Mask or Model Workspace” on page 12-166</li> <li>• “Mask Workspace Variable in Variant Connector Block” (Simscape)</li> <li>• “Control Variant Choices in Masked Variant Assembly Subsystem Block Using Mask Parameter Object” on page 12-325</li> </ul>
<ul style="list-style-type: none"> <li>• Improve model portability by permanently storing variant controls that is local to the model.</li> <li>• Use same names for variant controls in different models by limiting the scope of controls.</li> </ul>	<p>“Local Data: Model Workspace” on page 72-105</p>	<p>“Approaches to Control Active Variant Choice of a Variant Block Using Mask or Model Workspace” on page 12-166</p>
<p>Store global variant controls.</p>	<ul style="list-style-type: none"> <li>• “What Is a Data Dictionary?” on page 79-2</li> <li>• “Temporary Data: Base Workspace” on page 72-105</li> </ul>	<p>“Create a Simple Variant Model” on page 12-90</p>
<p>Set different active variants for multiple instances of custom locked library block.</p>	<p>“Approaches to Control Active Variant Choice of a Variant Block Using Mask or Model Workspace” on page 12-166</p>	<p>“Control Active Choice of Locked Custom Library Variant Subsystem Using Mask Parameter” on page 12-172</p>
<p>Define global variant controls for multiple variant regions at different levels of a model.</p>	<p>Data Store Memory</p>	<p>Variant Conditions and Data Stores (Model)</p>

**Variant Controls in Structurally Varying Systems**

Each variant choice in your model is associated with a variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice. You can use different types of variant controls variables while implementing variant regions in your model. For more information, see “Types of Variant Control Variables (Operands) in Variant Blocks” on page 12-41 and “Storage Locations for Variant Control Variables (Operands) in Variant Blocks” on page 12-42.

Goal	Capability	Example
Switch variant choices in related blocks and parameters coherently.	<code>Simulink.VariantControl</code>	"Simulink.VariantControl Variables for Coherent Switching of Choices in Variant Blocks" on page 12-57
Rapidly prototype variant controls when you are still building your model.	Scalar variable	"Scalar Variant Control Variables for Rapid Prototyping in Variant Blocks" on page 12-59
Reduce complexity of variant controls by encapsulating them.	<code>Simulink.Variant</code>	"Simulink.Variant Objects for Variant Condition Reuse of Variant Blocks" on page 12-64
Improve readability by representing variant controls as meaningful names instead of integers.	"Simulink Enumerations" on page 73-2	<ul style="list-style-type: none"> <li>• "Create Variant Controls Using an In-Memory Enumeration Class" on page 12-220</li> <li>• "Create Variant Controls Using MATLAB Enumeration Class" on page 12-223</li> </ul>
Improve readability by grouping related variant controls in a structure.	<code>struct</code>	"Structures to Group Related Variant Control Variables of Variant Blocks" on page 12-65

### Control Variant Activation Times of Structurally Varying Systems

Prior to simulation or code generation, you can check for incompatibilities, such as datatype and dimension mismatches in variants. You can design variants that can be activated in different stages of simulation and code generation workflows. During code generation, you can choose which variabilities to include in the generated code and activate them at different stages based on the requirements and the target platform. You can also check for incompatibilities, such as datatype and dimension mismatches in variants. For more information, see "Activate Variant During Different Stages of Simulation and Code Generation Workflow" on page 12-79.

Goal	Capability	Example
Retain active variant and remove inactive variant early in the model compilation stage, so that, the variants with incompatible signal attributes coexist in the simulation workflow.	"update diagram" on page 12-81	Consider a scenario where you want to simulate only the active variant. You have installed all the products required to simulate the active variant, but you do not have licenses that are required to simulate inactive variants. In this case, you can use <code>update diagram</code> activation time to remove inactive variants from execution at the beginning of the simulation workflow.

Goal	Capability	Example
Analyze active and inactive variants for incompatibilities in signal attributes such as dimension and data type prior to the simulation-loop stage.	“update diagram analyze all choices” on page 12-81	“Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79
Perform iterative simulations and enhance simulation speed without having to recompile the model or terminating the simulation each time you change the active variant.	“startup” on page 12-82	<ul style="list-style-type: none"> <li>• “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-244</li> <li>• “Simulate Variant Blocks in Accelerator and Rapid Accelerator Modes with Startup Activation Time” on page 12-272</li> </ul>

## Components — Create Models with Parameter Value Variations

You may have a set of requirements where the structure of the model remains the same, but the values of the parameters for each requirement are different. You can create a single model with fixed structure and create parameters with a finite set of values where each value corresponds to different requirements. You can then choose to activate or deactivate the variant choices during simulation. For more information on value variations, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 12-175.

This section covers:

- “Implement Variabilities in Parameter Values” on page 12-158
- “Variant Controls for Varying Parameter Values” on page 12-158
- “Control Variant Activation Times of Varying Parameter Values” on page 12-159

### Implement Variabilities in Parameter Values

You can implement value variabilities in all domains, including controls logic, state machines, flow charts, and physical plants by using variant parameters in your model.

Goal	Capability	Example
Design variants in block parameter values	“Use Variant Parameters to Reuse Block Parameters with Different Values” on page 12-175	“Create a Simple Variant Parameter Model” on page 12-178
Create parameters with variants having different dimensions.	“Allow symbolic dimension specification”	“Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211

### Variant Controls for Varying Parameter Values

Variant controls are `Simulink.VariantControl` objects that associates the `Value` of a variant control with an `ActivationTime`. Use the variant control objects to determine the active value of a

variant parameter during different stages of simulation and code generation workflow. You can specify different types of values for variant control objects while implementing variant regions in your model. For more information, see “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 12-54 and “Types of Variant Control Variables (Operands) in Variant Parameters” on page 12-53.

Goal	Capability	Example
Rapidly prototype variant controls when you are still building your model.	Numeric values	“Numeric Variant Control Values for Rapid Prototyping of Variant Parameters” on page 12-68
<ul style="list-style-type: none"> <li>• Reuse common variant controls across models.</li> <li>• Reduce complexity of variant controls by encapsulating them.</li> </ul>	<code>Simulink.Variant</code>	“Simulink.Variant Objects for Variant Condition Reuse of Variant Parameters” on page 12-76
Improve readability by representing variant controls as meaningful names instead of integers.	“Simulink Enumerations” on page 73-2	“Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters” on page 12-73
Improve readability by representing variant parameter values as meaningful names instead of integers.	“Simulink Enumerations” on page 73-2	“Improve Code Readability of Variant Parameters Using Enumerated Types” on page 12-281

### Control Variant Activation Times of Varying Parameter Values

Prior to simulation or code generation, you can check for incompatibilities, such as datatype and dimension mismatches in variants. You can design variants that can be activated in different stages of simulation and code generation workflows. During code generation, you can choose which variabilities to include in the generated code and activate them at different stages based on the requirements and the target platform. You can also check for incompatibilities, such as datatype and dimension mismatches in variants. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

Goal	Capability	Example
Retain active variant and remove inactive variant early in the model compilation stage, so that, the variants with incompatible signal attributes coexist in the simulation workflow.	“update diagram” on page 12-81	“Change Active Values and Activation Time of Variant Parameters” on page 12-208
Analyze active and inactive variants for incompatibilities in signal attributes such as dimension and data type prior to the simulation-loop stage.	“update diagram analyze all choices” on page 12-81	

Goal	Capability	Example
Perform iterative simulations without having to recompile the model or terminating the simulation each time you change the active variant.	“startup” on page 12-82	“Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-244

## Components — Create Models with Variations in Transition Paths

You can control the transition to multiple design configurations within the Stateflow charts using variant transitions.

Goal	Capability	Example
Conditionally execute transition path from source object to destination object.	“Conditions” (Stateflow) and “Condition Actions” (Stateflow)	“Create Variant Configurations in Stateflow Charts” (Stateflow)

## Components — Create Models with Variations in Dimensions

You can use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. These symbols propagate throughout the model during simulation, and then go into the generated code.

Goal	Capability	Example
Store dimensions in symbols to flexibly switch between variant choices.	“Allow symbolic dimension specification”	“Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions” (Embedded Coder)
Create parameters with variants having different dimensions.	“Symbolic Dimensions in Generated Code” (Embedded Coder)	“Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211

## Components — Create Models with Variations in AUTOSAR Interfaces

You can enable or disable AUTOSAR interfaces or implementations in the execution path using variation points in AUTOSAR software components. In Simulink, AUTOSAR system constants serve as inputs to control component variation points. Variation points present a choice between two or more variants. For more information, see “Model AUTOSAR Variants” (AUTOSAR Blockset).

Goal	Capability	Example
Enable or disable AUTOSAR ports and runnables.	“Variants for Ports and Runnables” (AUTOSAR Blockset)	“Configure Variants for AUTOSAR Ports and Runnables” (AUTOSAR Blockset)

Goal	Capability	Example
Vary implementation of AUTOSAR runnable by specifying variant conditions inside the runnable.	“Variants for Runnable Implementations” (AUTOSAR Blockset)	“Configure Variants for AUTOSAR Runnable Implementations” (AUTOSAR Blockset)
Model AUTOSAR calibration data in combination with different types of variant conditions.	“Export Variation Points for AUTOSAR Calibration Data” (AUTOSAR Blockset)	
Import variation points in AUTOSAR software components.	“Predefined Variants and System Constant Value Sets” (AUTOSAR Blockset)	“Control AUTOSAR Variants with Predefined Value Combinations” (AUTOSAR Blockset)
Store dimensions of AUTOSAR elements, such as a ports, in symbols to flexibly switch between variation points during code compilation.	“Variants for Array Sizes” (AUTOSAR Blockset)	“Configure Dimension Variants for AUTOSAR Array Sizes” (AUTOSAR Blockset)
Flexibly switch between AUTOSAR components after the code is compiled and deployed on an electronic control unit (ECU).	“Configure Postbuild Variant Conditions for AUTOSAR Software Components” (AUTOSAR Blockset)	
Flexibly switch between value combinations for AUTOSAR elements prior to code compile, or after the code is compiled and deployed on an ECU.	“Configure Variant Parameter Values for AUTOSAR Elements” (AUTOSAR Blockset)	

## Components — Manage Structural Variations in a Model

Variant Manager enables you to visually trace variations, manage variabilities simultaneously, and prevent invalid variant combinations in a system model or variant transitions in a Stateflow chart. You can also simplify a variant model by automatically reducing it to contain only the selected variants. For more information, see “Variant Manager for Simulink”.

Goal	Capability	Example
Visualize a tree view of a variant model hierarchy and edit properties of variant elements.	“Manage Variant Elements”	
Create Variant Configurations to represent combinations of variant choices across a model hierarchy.	“Variant Manager for Simulink”	“Create and Activate Variant Configurations” on page 89-10
Define constraints for variant configurations to prevent invalid variant combinations.	“Constraints on Variant Configurations” on page 89-3	“Define Constraints for Variant Configurations” on page 89-16

Goal	Capability	Example
Create a variant configuration data object to store, distribute, and reuse variant configurations for a model.	“Variant Configuration Data Object” on page 89-3	“Save and Reuse Variant Configurations Using Variant Configuration Data Object” on page 89-20
Validate and apply a variant configuration to a model early in the update diagram stage.	“Activate a Variant Configuration” on page 89-5	“Create and Activate Variant Configurations” on page 89-10
Automatically generate a reduced model that contains only selected variant configurations from a parent model with many variants.	“Reduce Variant Models Using Variant Reducer” on page 89-32	“Reduce Model Containing Variant Blocks” on page 89-52
Visualize and compare variant configurations to locate and diagnose potential faults or inconsistencies in the configurations.	“Analyze Variant Configurations in Models Containing Variant Blocks” on page 89-44	

## Generated Code

You can include variabilities in generated code to reuse and configure the code for different stages of development, such as testing different implementations or providing multifunctional code to third parties.

### Generate Code for Structurally Varying Systems

You can specify the variabilities of the variant blocks to be included in the generated code. You can also control the appearance, placement, definition, and declaration of variant controls in the generated code.

Goal	Capability	Example
Generate a code that contains active and inactive variants, and enables you to switch between the variants prior to code compile.	“code compile” on page 12-82	<ul style="list-style-type: none"> <li>• “Generate Preprocessor Conditionals for Variant Systems” (Embedded Coder)</li> <li>• “Use Variant Subsystem to Generate Code That Uses C Preprocessor Conditionals” (Embedded Coder)</li> </ul>

Goal	Capability	Example
Generate an executable that contains active and inactive variants, and enables you to switch between the variants at model startup.	“startup” on page 12-82	<ul style="list-style-type: none"> <li>• “Generate Code from Variant Blocks with Startup Activation Time” on page 12-289</li> <li>• “Create Standalone Executables with Variants Using Simulink Compiler” on page 12-293</li> <li>• “Variant Subsystem: Using Variant Subsystems for HDL Code Generation” (HDL Coder)</li> </ul>
Share variant controls among multiple blocks, separate values from their data types and other properties, control the appearance, placement, definition, and declaration of variant controls in the generated code.	Simulink.Parameter	“Simulink.Parameter Type of Variant Control Variables for Code Generation in Variant Blocks” on page 12-60
Improve code readability by representing variant controls as meaningful names instead of integers in generated code.	“Simulink Enumerations” on page 73-2	<ul style="list-style-type: none"> <li>• “Create Variant Controls Using an In-Memory Enumeration Class” on page 12-220</li> <li>• “Create Variant Controls Using MATLAB Enumeration Class” on page 12-223</li> <li>• Variant Subsystems - Enumerations (Model)</li> </ul>

### Generate Code for Varying Parameter Values

You can specify the variabilities of the variant parameters to be included in the generated code. You can also control the appearance, placement, definition, and declaration of variant controls and variant parameters in the generated code. For more information, see “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

Goal	Capability	Example
Generate a code that contains all variants and enables you to switch between the variants prior to code compile.	“code compile” on page 12-82	“Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211
Generate an executable that contains all variants and enables you to switch between the variants at model startup.	“startup” on page 12-82	“Run Executable for Different Variant Parameter Values Without Recompiling Code” on page 12-274

Goal	Capability	Example
Share variant controls among multiple blocks, separate values from their data types and other properties, control the appearance, placement, definition, and declaration of variant controls in the generated code.	<ul style="list-style-type: none"> <li>• Simulink.Parameter</li> <li>• “Storage Classes for Different Variant Activation Times” on page 12-88</li> </ul>	“Simulink.Parameter Type of Variant Control Variables for Code Generation of Variant Parameters” on page 12-70
Improve code readability by representing variant controls as meaningful names instead of integers.	“Simulink Enumerations” on page 73-2	“Enumerated Types to Improve Code Readability of Variant Control Variables of Variant Parameters” on page 12-73
Improve code readability by representing variant parameter values as meaningful names instead of integers.	“Simulink Enumerations” on page 73-2	“Improve Code Readability of Variant Parameters Using Enumerated Types” on page 12-281

### Generate Code for Varying Transition Paths

You can use variant transitions to create Stateflow charts in Simulink models that generate code to be used in a variety of different software situations. Variant transitions allow you to model a full subset of variations within one Stateflow chart so that you can choose which variation you want when you generate code or when you compile the generated code.

Goal	Capability	Example
Generate code that only contains the data members needed to execute the currently selected software configuration.	“Generate C or C++ Code from Stateflow Blocks” (Stateflow)	“Create Variant Configurations in Stateflow Charts” (Stateflow)

### Generate Code for Varying Dimensions

You can use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. These symbols propagate throughout the model during simulation, and then go into the generated code.

Goal	Capability	Example
Store dimensions in symbols to flexibly switch between variants during code compilation.	“Allow symbolic dimension specification”	“Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions” (Embedded Coder)
Store dimensions in automatically generated symbols to flexibly switch between variant parameter values during code compilation.	“Symbolic Dimensions in Generated Code” (Embedded Coder)	“Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211

Goal	Capability	Example
Store dimensions of AUTOSAR elements, such as a ports, in symbols to flexibly switch between variation points during code compilation.	“Variants for Array Sizes” (AUTOSAR Blockset)	“Configure Dimension Variants for AUTOSAR Array Sizes” (AUTOSAR Blockset)

## Component Tests and System-Level Tests

You can identify hidden design errors and detect model constructs in variants that result in integer overflow, dead logic, array access violations, and division by zero by generating test cases using Simulink Design Verifier. For more information, see “About Systematic Model Verification Using Simulink Design Verifier” (Simulink Design Verifier).

You can further execute user-defined tests on both active and inactive variants in a model by using Simulink Test.

Goal	Capability	Example
Analyze active variant to detect design errors and requirement violations by generating test cases for debugging.	“code compile” on page 12-82	See <b>SLDV Run</b> workflow in “Verify and Validate Variant Models with Code Compile Activation Time” on page 12-235
Analyze active and inactive variants to detect design errors and requirement violations by generating test cases for debugging.	“startup” on page 12-82	See <b>SLDV Run</b> workflow in “Verify and Validate Variant Models with Startup Activation Time” on page 12-267
Analyze only active variant and re-run the tests to analyze all variants.	“code compile” on page 12-82	See <b>Simulink Test Manager</b> workflow in “Verify and Validate Variant Models with Code Compile Activation Time” on page 12-235
Run iterative tests on active and inactive variants without recompiling the model for each variant.	“startup” on page 12-82	See <b>Simulink Test Manager</b> workflow in “Verify and Validate Variant Models with Startup Activation Time” on page 12-267

# Approaches to Control Active Variant Choice of a Variant Block Using Mask or Model Workspace

This example shows different approaches to control the active choice of inline variant and Variant Subsystem blocks from a mask or a model workspace. For more information on Variant blocks, see “What Are Variants and When to Use Them” on page 12-4.

## Model

In this example, four Simulink® models are highlighted in green, and one model is highlighted in red. The models in green represent the recommended approaches to control the active choice of Variant blocks. These approaches let you limit the scope of the variant control variable, avoid name conflicts, and establish a clear ownership of the variable between Variant blocks. They also allow you to use the same names for variables in different scopes.

### Variant Control variables from Mask/Model workspace

The Variant Subsystem, VSS1, contains a mask with the mask parameter, 'B', defined on it. 'B' is an edit box. This mask parameter is used as a Variant control variable for the Variant Subsystem. You can control the active Variant by changing the values on the mask dialog of VSS1.

The Variant Subsystem, VSS2, contains a mask on it. In the mask Initialization tab, a variable, 'A', is defined. You can use this variable as a Variant control variable for the Variant Subsystem.

The Variant Subsystem, VSS4, contains a mask parameter, VChoice. You can select the value of VChoice from the mask dialog. During simulation, the script in the mask Initialization tab reads this value and sets the active choice of the Variants. This is how you could control the Variant choices from the mask in earlier releases of Simulink. This is no longer a recommended approach.

The Variant Subsystem, VSS3, has a Variant control variable, 'C'. This variable is defined in the model workspace. You can view and edit this model workspace variable from the Model Explorer.

The Subsystem SS1, has a mask defined on it. This mask has a mask parameter VC that is used as a variant control variable for the Variant Source block Vsrc.

### Limitations in Recommended Approaches

- Work only if the **Variant control mode** parameter is set to **Expression** and the **Variant activation time** parameter is set to **update diagram**. So, when you simulate or generate code for models with the recommended approaches, Simulink do not analyze signal attributes for consistency and also the generates code only for active choice.
- Do not support using `Simulink.Variant` objects or `Simulink.Parameter` as variant control variables.
- Do not support using model arguments variables as variant control variables.
- The number of characters in the variant control variable must not exceed 40.
- The variant control variable originating from a mask workspace must not start with `SLMASK`.

### Approach 1: Use Mask Parameter as a Variant Control Variable

This section explains how to control the active variant choice of Variant Subsystem blocks and inline variant blocks by using a mask parameter.

#### Control Active Choice of a Variant Subsystem Block using Mask Parameter

Consider the model with Variant Subsystem block VSS1. The VSS1 subsystem specifies two potential variants, x2 and x3. The control expression for x2 is `B == 1` and for x3 is `B == 2`. The variable B is a mask parameter. To view the properties of B:

1. Right-click the VSS1 subsystem.
2. Select **Mask > Edit Mask**. In the **Parameters & Dialog** pane, under **Parameters**, the **Prompt** column specifies the label of the parameter on the mask dialog box, and the **Name** column specifies the name of the mask parameter. In this example, **Prompt** is specified as **Enter the choice**, and **Name** is specified as B.
3. To open the mask dialog box, double-click the VSS1 subsystem. During simulation, the index of the value that you specify here is mapped to the underlying variable B, which is then used to evaluate the variant condition expressions associated with the block. In this example, the default value of **Enter the choice** is 2. When you simulate this model, the variant condition `B == 2` evaluates to `true`. The x2 subsystem becomes inactive, and the x3 subsystem becomes active.
4. To modify the active choice, specify the value as 1 in the mask dialog box, then simulate the model again. During simulation, the value of the B is set to 1 which in turn evaluates the Variant condition, `B == 1` to `true`. The x2 subsystem becomes active, and the x3 subsystem becomes inactive.

### Control Active Choice of Inline Variant Blocks using Mask Parameter

Consider the model with masked Subsystem block SS1. The SS1 subsystem has a mask parameter VC that is used as a variant control variable in the underlying Variant Source block Vsrc. The first input port is associated with the control expression  $VC == 1$  and the second input port is associated with the control expression  $VC == 2$ . To view the properties of VC:

1. Right-click the SS1 subsystem.
2. Select **Edit Mask**. In the **Parameters & Dialog** pane, under **Parameters**, the **Prompt** column specifies the label of the parameter on the mask dialog box, and the **Name** column specifies the name of the mask parameter. In this example, **Prompt** is specified as **Choose the signal**, and **Name** is specified as **VC**.
3. To open the mask dialog box, double-click the SS1 subsystem. During simulation, the index of the value that you select here is mapped to the underlying variable VC, which is then used to evaluate the variant condition expressions associated with the Vsrc block. In this example, the default value of **Choose the signal** is **Sine Wave**. When you simulate this model, the index of the **Sine Wave**, 2, is mapped to VC. The variant condition  $VC == 2$  evaluates to **true**. As a result, the first input port of the Vsrc block that is associated with  $VC == 1$  becomes inactive and the second input port that is associated with  $VC == 2$  becomes active.
4. To modify the active choice, select the value as **Constant** in the mask dialog box, then simulate the model again. During simulation, the value of the VC is set to 1 which in turn evaluates the variant condition,  $VC == 1$  to **true**. The first input port of the Vsrc block becomes active and the second input port becomes inactive.

## Approach 2: Use Mask Initialization Variable as a Variant Control Variable

This section explains how to control the active variant choice of Variant Subsystem blocks using a mask initialization variable. You can follow this approach to control the active variant choice of inline variant blocks as well.

Consider the model with Variant Subsystem block VSS2. 1. In the VSS2 subsystem, the control expression for x2 is  $A == 1$  and for x3 is  $A == 2$ . The variable  $A$  used in the control expression is a regular MATLAB® variable that is defined in the **Initialization** tab of the mask workspace. To view the properties of  $A$ :

- a. Right-click the VSS2 subsystem.
- b. Select **Mask > Edit Mask**. In the **Initialization** tab, under **Initialization commands**, the value of  $A$  is set to 1.

During simulation, this value is used to evaluate the variant condition expressions associated with the block. When you simulate this model, the variant condition  $A == 1$  evaluates to `true`. The x2 subsystem becomes active, and the x3 subsystem becomes inactive.

3. To modify the active choice, specify the value of  $A$  as 2 in the **Initialization** tab, then simulate the model again. During simulation,  $A == 2$  evaluates to `true`. The x2 subsystem becomes active, and the x3 subsystem becomes inactive.

### Approach 3: Use Model Workspace Variable as a Variant Control Variable in a Variant Subsystem Block

This section explains how to control the active variant choice of Variant Subsystem blocks using a model workspace variable. You can follow this approach to control the active variant choice of inline variant blocks as well.

Consider the model with Variant Subsystem block VSS3. 1. In the VSS3 subsystem, the control expression for `x2` is `C == 1` and for `x3` is `C == 2`. The variable `C` used in the condition expression is a regular MATLAB® variable that is defined in the model workspace. To view the properties of `C`:

- On the **Modeling** tab, click **Model Explorer**.
- In the **Model Hierarchy** pane, click **Model Workspace**. The value of `C` is set to 1.

During simulation, this value is used to evaluate the variant condition expressions associated with the block. When you simulate this model, the variant condition `C == 1` evaluates to `true`. The `x2` subsystem becomes active, and the `x3` subsystem becomes inactive. To modify the active choice, specify the value of `C` as 2, then simulate the model again. During simulation, the Variant condition `C == 2` evaluates to `true`. The `x2` subsystem becomes active, and the `x3` subsystem becomes inactive.

#### Approach 4: Use Mask Initialization Script to Control Active Variant Choices of a Variant Subsystem Block

This approach is not recommended for controlling the active variant choice of Variant Subsystems. However, if the **Variant control mode** of the subsystem is set to **Label** mode, you can follow this approach. For more information, see “Mask a Variant Subsystem” on page 42-86.

## Control Active Choice of Locked Custom Library Variant Subsystem Using Mask Parameter

### In this section...

“Model” on page 12-172

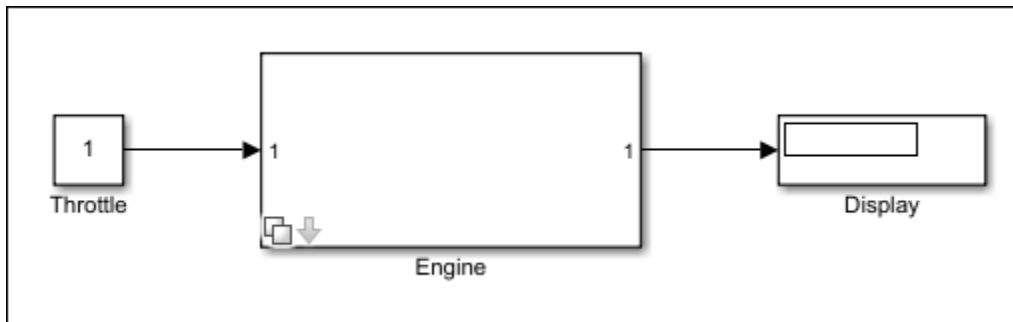

“Switch Between Active Choices” on page 12-173

This example shows how to control the active choice of a Variant Subsystem that belongs to a locked custom library by using a mask parameter as Variant control variable. Mask parameters limit the scope of the variable, which allows you to use the same names for control variables in different scopes. This example includes promoted parameters and control expressions with enumeration classes to simplify the interface of the mask dialog and control expressions with enumeration classes to improve the readability of the variant condition expressions. For more information on Variant Subsystems, see “Implement Variations in Separate Hierarchy Using Variant Subsystems” on page 12-184.

### Model

To open the Simulink model, type `slexVariantSubsystemUsingMaskAndEnums` in the MATLAB Command Window.

Consider the Engine subsystem block in the locked custom library, `slexVarEngineLibrary`.

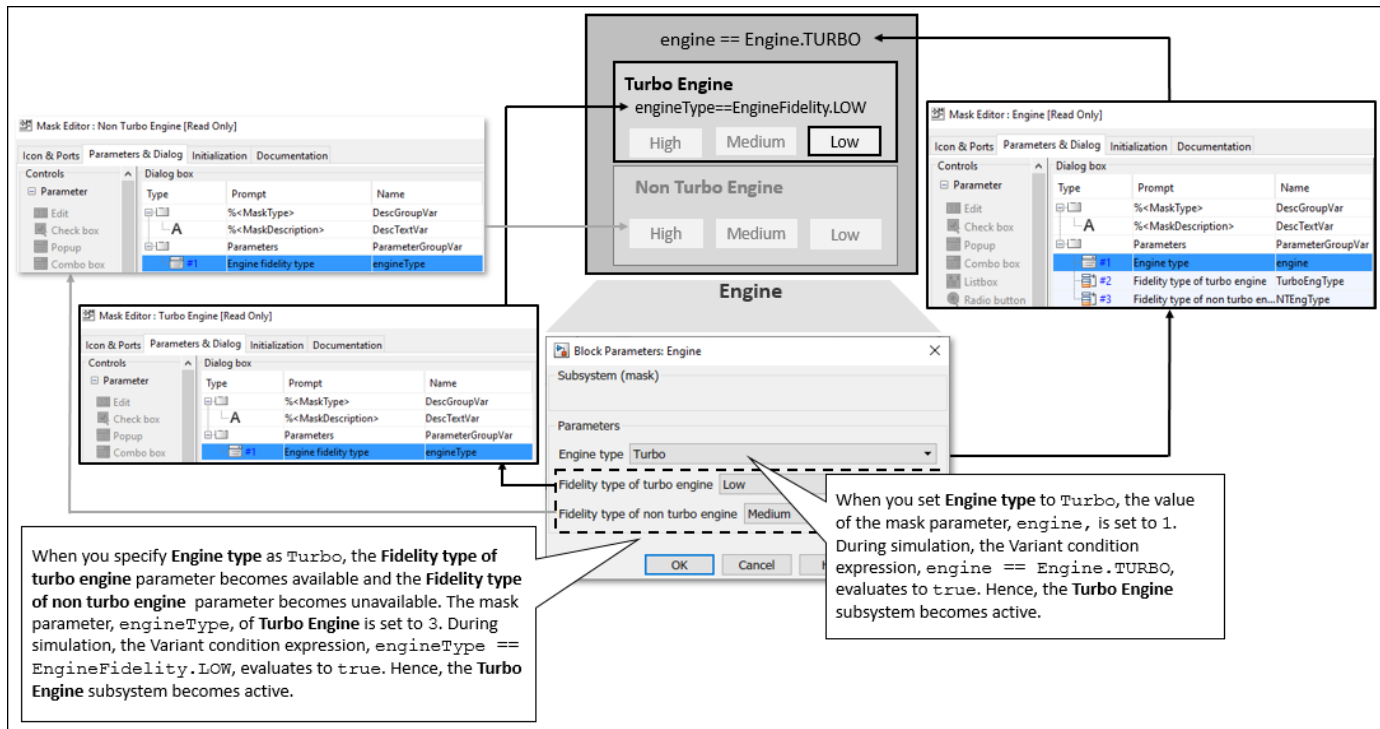

The mask dialog box of the subsystem contains these parameters:

- **Engine type:** When you select a value for this parameter, Simulink assigns the index of that value to the mask parameter `engine`. During simulation, the value of `engine` is used to evaluate the variant condition expressions to activate or deactivate the underlying Turbo Engine and Non Turbo Engine subsystems.
- **Fidelity type for turbo engine:** This parameter becomes available only if the **Engine type** parameter is set to Turbo. This parameter is promoted on to the mask dialog of the Engine subsystem from the underlying layer of the Turbo Engine subsystem. When you select a value for this parameter, Simulink assigns the index of that value to the mask parameter `enginetype` of the Turbo Engine subsystem. During simulation, the value of `enginetype` is used to evaluate the variant condition expression to activate or deactivate the underlying High, Medium, and Low subsystems.
- **Fidelity type for non turbo engine:** This parameter becomes available only if the **Engine type** parameter is set to Non Turbo. This parameter is promoted on to the mask dialog of the Engine subsystem from the underlying layer of the Non Turbo Engine subsystem. When you select a value

for this parameter, Simulink assigns the index of that value to the mask parameter `enginetype` of the Non Turbo Engine subsystem. During simulation, the value of `enginetype` is used to evaluate the variant condition expression to activate or deactivate the underlying High, Medium, and Low subsystems.

The scope of `enginetype` in the Turbo Engine subsystem is different from the scope of `enginetype` in the Non Turbo Engine subsystem. `enginetype` of Turbo Engine is visible only to the underlying layers of the Turbo Engine subsystem. Similarly, `enginetype` of Non Turbo Engine is visible only to the underlying layers of the Non Turbo Engine subsystem. Limiting the scope by using mask parameters as Variant control variables allows you to use the same name for variables with holding different values in the Turbo Engine and the Non Turbo Engine subsystems.

## Switch Between Active Choices

- 1 To simulate the model, on the **Simulation** tab, click Run. On the mask dialog of the Engine subsystem, the **Engine type** parameter is set to Non Turbo, and the **Fidelity type for non turbo engine** is set to Medium. As these parameters are mapped to the index of the mask parameters `engine` and `engineType`, the value of `engine` is set to 2, and the value of `engineType` is set to 1. Here, 2 specifies the index of the Non Turbo option, and 1 specifies the index of the High option. For more information on how the parameters on the mask dialog box are mapped to the underlying mask parameters, see "Create a Simple Mask" on page 42-6.

During simulation, the condition expressions `engine == Engine.NONTURBO` and `engineType == EngineFidelity.MEDIUM` evaluate to true. Here, `Engine` and `EngineFidelity` are integer-based enumeration classes defined in `Engine.m` and `EngineFidelity.m` files with values for `Engine.TURBO` and `Engine.NONTURBO` specified as 1 and 2, and the values for `EngineFidelity.HIGH`, `EngineFidelity.MEDIUM`, and `EngineFidelity.LOW` specified as 1, 2, and 3.

The NonTurbo Engine subsystem becomes active and the Turbo Engine subsystem becomes inactive.

- 2 To modify the active choice, select **Turbo** in the mask dialog box, then simulate the model again. During simulation, the value of `engine` is set to `1`, which evaluates the variant condition `engine == Engine.TURBO` to `true`. The Turbo Engine subsystem becomes active, and the Non Turbo Engine subsystem becomes inactive.

## Use Variant Parameters to Reuse Block Parameters with Different Values

You may have a set of requirements where the structure of the model remains the same, but the values of the parameters for each requirement are different. In this scenario, you can create a single model with fixed structure and create parameters with a finite set of values where each value corresponds to different requirements. Parameters that have multiple values are called variant parameters. Variant parameters can be defined in a MATLAB base workspace or a data dictionary.

Each value of a variant parameter must be associated with a variant condition expression. You can have multiple variant parameters associated with a variant condition, provided no two values belong to the same parameter. When a condition expression evaluates to `true`, all the values associated with that condition become active and are assigned to the corresponding parameters. If you change the value of the variant control variable, a different set of values is assigned to the parameters. This way, variant parameters allow you to logically bind a set of values across different parameters to a condition expression, and the values are assigned to the parameter based on the variant condition that evaluates to `true`.

Simulink selects the active value of a variant parameter during update diagram time, during code compile time, or during the model startup time. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

Consider this model. The **Gain** parameter of the Gain block is a variant parameter with its value set to  $K$ . The variable  $K$  has two values: 3.5 and 8.5. Simulink chooses active value of  $K$  based on the value of the variant control variable  $V$ . If  $V==1$  evaluates to `true`, the value of  $K$  is set to 3.5. If  $V==2$  evaluates to `true`, the value of  $K$  is set to 8.5.

### When to Create Variant Parameters

Variant parameters provide a way to design one model for many systems that differ in block parameter values. You can group different sets of values based on the system to simulate. Each set of values is associated with a variant condition expression. During simulation, if a variant condition evaluates to `true`, then all the values associated with that condition become active. To change the set of active values, change the value of the variant control variable and run the simulation again.

Consider this model that represents an automobile system with several configurations. These configurations, although similar in several aspects, can differ in values such as fuel consumption, engine size, or number of cylinders in the engine. Instead of designing multiple blocks that together represent all possible values, you can use variant parameters to model the varying values.

## Variant Parameter with Varying Values

In this model, the Fuel consumption, Engine size, and Number of cylinders have variant parameters  $fc$ ,  $es$ , and  $nc$ . The values of the variant parameters are based on the value of the variant control variable  $V$ . For example, if  $V==1$  evaluates to `true`, then the value of  $fc$  is set to 30,  $es$  is set to 1000, and  $nc$  is set to 4.

### Advantages of Using Variant Parameters

Using variant parameters in Model-Based Design provides several advantages:

- Variant parameters provide you a way to design one model for many systems.
- Variant parameters facilitate reuse of blocks. This approach improves workflow speed by reducing complexity.
- Variant parameters help you switch among different block parameter values for multiple simulation, code generation, or testing workflows.
- You are not required to regenerate the code for different values of a variant parameter because the generated code has preprocessor conditionals for each variant value of the parameter.

### Limitations of Using Variant Parameters

Using variant parameters in Model-Based Design also has limitations:

- The value of the variant control variable that determines the active value of a variant parameter must be a numeric value, an enumerated value, or a `Simulink.Parameter` object.
- Only the values of the variant parameters change based on the variant condition that evaluates to `true`. Other properties, such as storage class, data types, and so forth, remain the same irrespective of the variant condition.
- Variant parameters can only be defined in a base workspace or a data dictionary.

## Create a Simple Variant Parameter Model

This example shows you how to create a simple model with variant parameters.

Variant parameters provide you a way to design one model for many systems that differ in values. You can group different sets of values based on the system to simulate. Each set of values is associated with a variant condition expression. During simulation, if a variant condition evaluates to true, all the values associated with that condition become active. Use variant parameters to switch among different block parameter values for multiple simulation, code generation, or testing workflows.

Consider this model.

```
open_system('slexVariantParameters')
```

### Variant Parameters with Different Activation Times

Copyright 2020-2021 The MathWorks, Inc.

To specify the **Gain** parameters of the Gain1 and Gain2 blocks as variant parameters:

1. Define a `Simulink.VariantControl` object `V` in the base workspace of the model. The variant control variable object determines the active value of the variant parameter **Gain** of the Gain1 and Gain2 blocks. The object also associates the value with a variant activation time. For more information on activation time, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

```
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'update diagram')
```

```
V =
```

```
VariantControl with properties:
```

```
    Value: 1
  ActivationTime: 'update diagram'
```

2. Create `Simulink.VariantVariable` objects to define multiple values for the **Gain** parameter of the Gain blocks and associate each value with a variant condition expression. You can specify

properties such as dimension, data type, and so on for each object. In this example, K1 and K2 are variant parameter objects of `Simulink.Parameter` type. K1 specifies multiple values for the **Gain** parameter of the Gain1 block, and K2 specifies multiple values for the **Gain** parameter of the Gain2 block. During simulation, when a condition evaluates to `true`, all the values associated with that condition become active. The active values are then assigned to the corresponding **Gain** parameter.

```
Pspec = Simulink.Parameter(0);
Pspec.CoderInfo.StorageClass = 'ExportedGlobal';
K1 = Simulink.VariantVariable('Specification', 'Pspec', 'Choices', {'V==1', 3.5, 'V==2', 8.5});
K2 = Simulink.VariantVariable('Specification', 'Pspec', 'Choices', {'V==1', 4.5, 'V==2', 9.5});
```

Once you successfully create the `Simulink.VariantVariable` objects, you can modify them by using the methods described in “Public Methods” or from the VariantVariable dialog box.

3. Open the block parameter dialog box of the Gain blocks. Specify the **Gain** parameter of Gain1 as K1 and the **Gain** parameter of Gain2 as K2.

4. To simulate the model, on the **Simulation** tab, click **Run**. During simulation, as `V == 1` evaluates to `true`, the value of the **Gain** parameter of the Gain1 block is set to 3.5, and the value of the **Gain** parameter of Gain2 block is set to 8.5.

```
sim('slexVariantParameters');
```

5. To change the value of the **Gain** parameters, set the value of V to 2 and run the simulation again. You can change the value of V by performing any of these steps:

- Double-click the variant control variable created in the base workspace. In the VariantControl dialog box, specify the value of V as 2.
- In the MATLAB® Editor, execute this command:

```
V.Value = 2;
```

During simulation, as `V == 2` evaluates to `true`, the value of the **Gain** parameter of the Gain1 block is set to 4.5, and the value of the **Gain** parameter of the Gain2 block is set to 9.5.

```
sim('slexVariantParameters');
```

## Propagate Variant Conditions from Variant Source Blocks to Subsystem Blocks

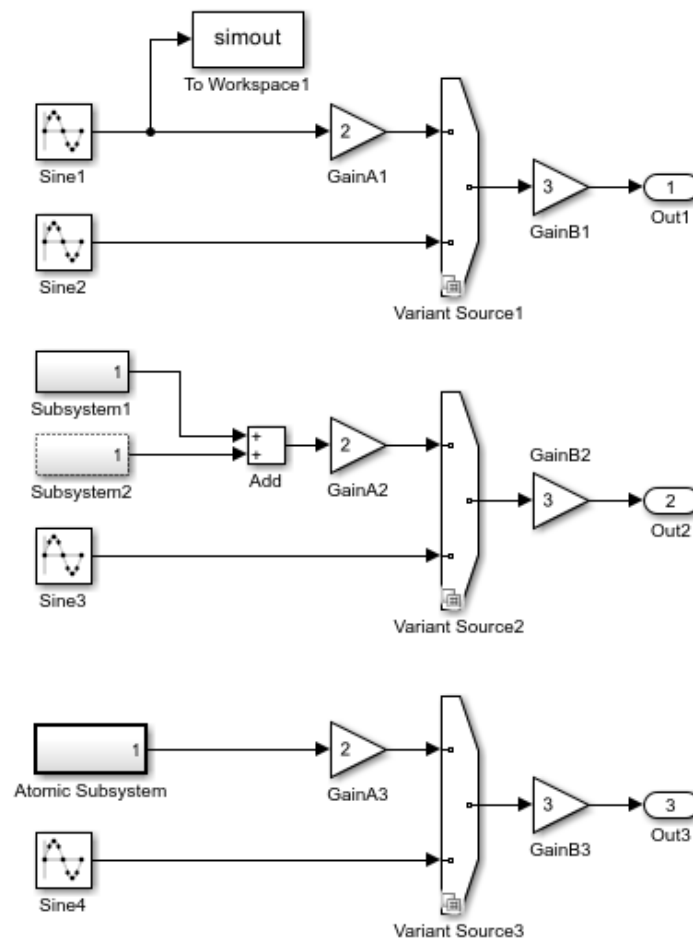

A Subsystem block can represent a virtual subsystem or a nonvirtual subsystem. A virtual subsystem provides graphical hierarchy in a model and does not impact the execution of a model. A nonvirtual subsystem executes as a single unit within a model. Simulink propagates variant conditions differently to these subsystems. This example shows the propagation of variant conditions from a Variant Source block to Subsystem blocks.

### Explore the Model

Open the model, `slexVariantCondPropToSubsystems`.

### Variant Condition Propagation to Subsystems

Copyright 2016 The MathWorks, Inc.

Click **Simulation > Run** to simulate this model and see the variant conditions being propagated from the Variant Source blocks to the blocks connected to it.

The variant condition annotation helps you visualize the propagated conditions. To be able to view the variant condition annotation, click **Display > Blocks > Variant Condition Legend**.

The model contains three Variant Source blocks: Variant Source1, Variant Source2, and Variant Source3, respectively.

Variant Source1 contains conditions  $V = 1$  and  $V = 2$  at inport. The variant condition  $V = 1$  propagates to GainA1 while  $V = 2$  propagates to Sine2. The Sine1 block does not get any propagated variant conditions because it is connected to a block, which is always consumed irrespective of the variant condition. If the To Workspace block1 did not exist or was commented-out before simulating the model, variant condition  $V = 1$  propagates to Sine1.

Variant Source2 is connected to virtual subsystems Subsystem1 and Subsystem2 that have identical contents, a Sine Wave block connected to a To Workspace and an Output blocks. Subsystem1 is a grouped virtual subsystem (**Treat as grouped when propagating variant conditions** is selected) while Subsystem2 (**Treat as grouped when propagating variant conditions** is clear) is an ungrouped virtual subsystem.

A Subsystem block becomes a grouped virtual subsystem when you select the **Treat as grouped when propagating variant conditions** check box in the block parameters dialog box. When the **Treat as grouped when propagating variant conditions** check box is clear, the subsystem is an ungrouped virtual subsystem.

A grouped subsystem represents a system of equation and hence the propagated conditions also apply to the blocks within this system. A grouped subsystem has a continuous boundary line. An ungrouped subsystem does not represent a system of equation and the blocks within it have ungrouped semantics. An ungrouped subsystem has a dotted boundary line and the conditions are propagated into the subsystem.

The variant condition  $V = 1$  propagates to Subsystem1 and further to the blocks within it as Subsystem1 is a grouped virtual subsystem (represents a system of equation). Since Subsystem1 is a system, the condition also applies the blocks within the system.

Subsystem2 that is an ungrouped virtual subsystem (does not represent a system of equation) also receives  $V = 1$  as the propagated condition, and the propagated variant condition  $V = 1$  propagates into Subsystem 2 as if the subsystem were expanded. The dotted lines on the Subsystem 2 icon indicates that it is flattened during Simulink compilation and hence you can see variant condition for those blocks inside it.

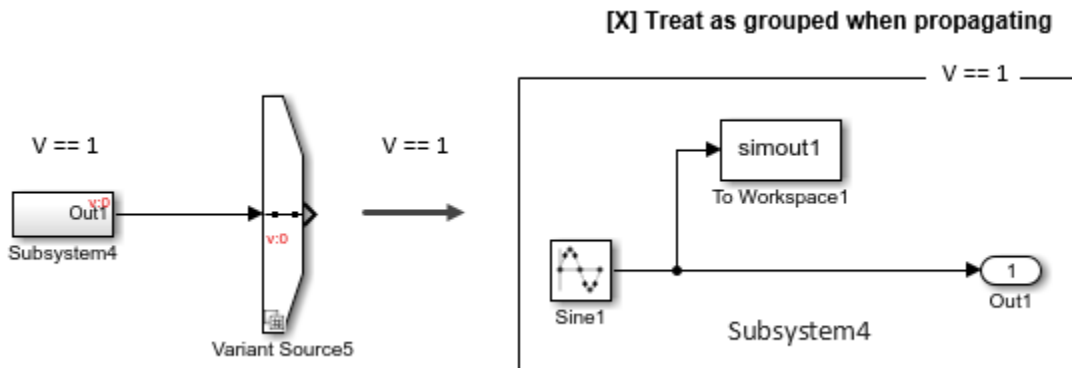

Variant Source3 is connected to a nonvirtual (atomic) subsystem with  $V = 1$  as the propagated variant condition. A nonvirtual (atomic) subsystem always represents a system of equations. An atomic subsystem has a continuous solid boundary line. The variant condition does not propagate inside the nonvirtual subsystem. Instead, it stays on the boundary. However, all blocks inside that subsystem get same variant condition as the Subsystem. The nonvirtual subsystem behaves as an entity.

Virtual subsystems by default works like a grouped collection of blocks where all the blocks contained inside the subsystem have the same variant condition. This is true when the **Treat as grouped when propagating variant conditions** parameter is selected. Virtual subsystems behave like an ungrouped collection of blocks when the **Treat as grouped when propagating variant conditions** parameter is cleared. In this example, the behavior of the Subsystem2 (Ungrouped) may not be as

expected as the block never becomes conditional. Nonvirtual subsystems always behave like an entity and the contents only execute when the condition assigned to the subsystem is satisfied. Nonvirtual subsystems, Model blocks, and grouped virtual subsystems behave the same.

**Virtual Subsystems with Treat as Grouped when Propagating Variant Conditions**

**Treat as grouped when propagating variant conditions** option is On: Consider an example with Variant Source block: Variant Source5 and a virtual subsystem Subsystem4. The Variant Source5 has a condition  $V = 1$ . Subsystem4 has a Sine Wave connected to a To Workspace1 and Output blocks.

Subsystem4 gets condition  $V = 1$  as  $V = 1$  is propagated from Variant Source5. The blocks inside Subsystem4 indirectly inherits the condition from Subsystem4. Subsystem4 is conditional as its inputs/outputs are conditional. To make the Subsystem4 as unconditional, add a new outport or clear the **Treat as grouped when propagating variant conditions** option.

**Treat as grouped when propagating variant conditions** option is Off: Consider an example with Variant Source block: Variant Source4 and a virtual subsystem Subsystem3. The Variant Source4 has condition  $V = 1$ . Subsystem3 has a Sine Wave connected to a To Workspace and Output blocks.

Subsystem3 gets the condition  $V = 1$  as  $V = 1$  propagates from Variant Source4. However due to unconditional block To Workspace1, the propagation stops and the condition  $V = 1$  is set only to the Out1 port. Now the Subsystem3 is also unconditional due to presence of unconditional blocks within.

## Implement Variations in Separate Hierarchy Using Variant Subsystems

This example shows the use of a Variant Subsystem, Variant Model, Variant Assembly Subsystem block in Simulink®. The Variant Subsystem block is a hierarchical variant block. The block allows you to encapsulate multiple implementations or variations of a system component in a separate hierarchy in the model. Each variation of the component present within the block is referred to as a choice. Only one of the variant choices within the Variant subsystem block can be active during model execution. You can use a combination of Subsystem blocks, Model blocks, or “Subsystem Reference” on page 4-32 blocks to represent the choices within the Variant Subsystem block.

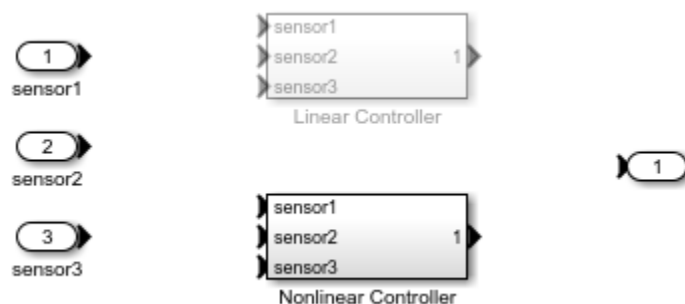

### Explore the Model

- Open the model `sldemo_variant_subsystems`. A variant subsystem block, `Controller`, encapsulates two different implementations of the controller component in the system.

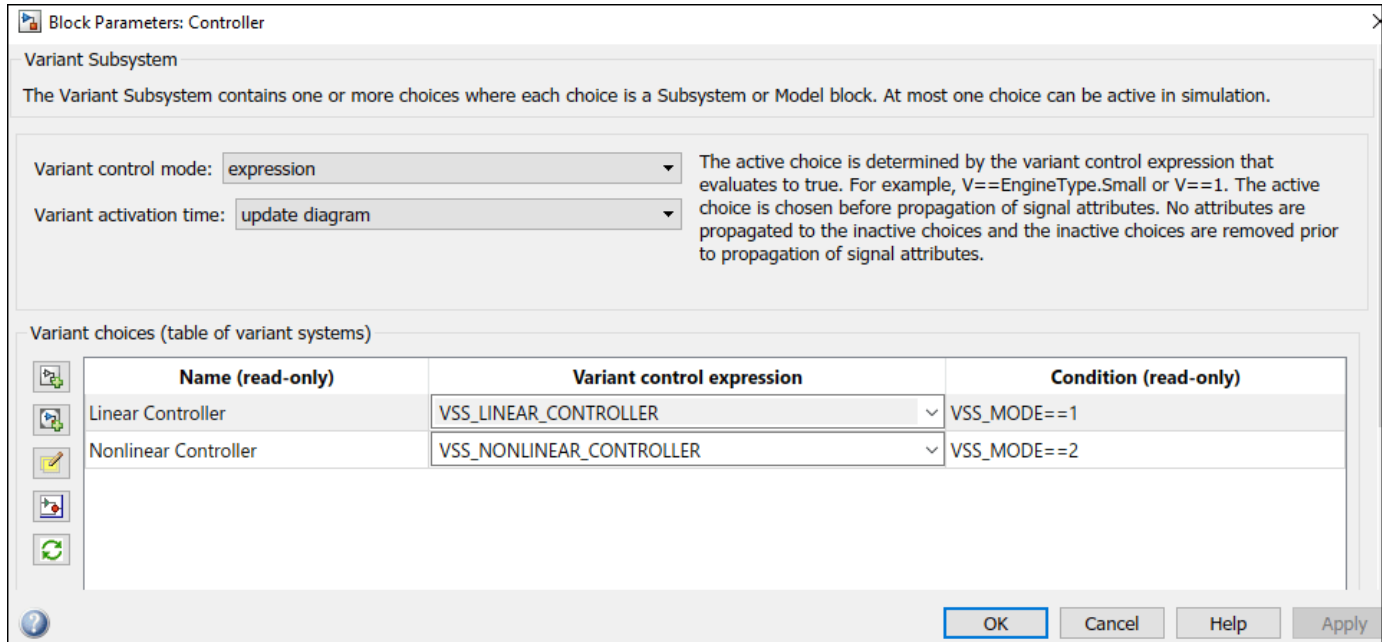

Copyright 2010-2013 The MathWorks, Inc.

- Open the variant subsystem block, `Controller`. Two Subsystem blocks represent the two possible variations of the `Controller` component. The first choice is a `Linear Controller` and the second choice is a `Nonlinear Controller`. Note that there are no drawn connections between the blocks inside the Variant Subsystem block. Simulink automatically wires the active variant to the Inport and Outport blocks of the Variant Subsystem block during simulation and disables the inactive ports.

- Open the Block Parameters dialog box for the Controller block. The **Variant choices** table lists the choices of the variant subsystem. Each variant choice in the Controller block is associated with a variant control. Simulink determines the active choice of the variant subsystem by evaluating the variant controls of all the choices. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control and disables the inactive choices. So, while each variant choice is associated with a variant control, only one variant control must evaluate to `true`. This allows you to swap the active and inactive choice in the Variant Subsystem without modifying the model structure.

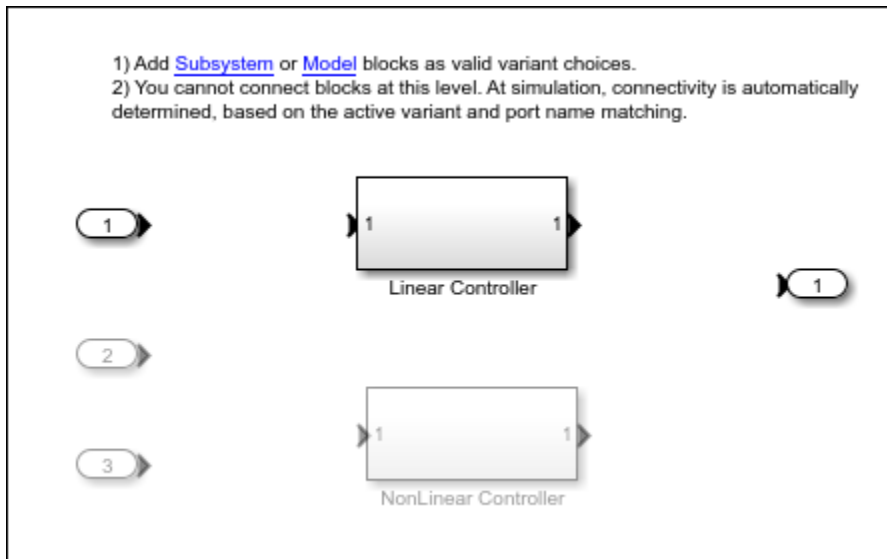

### Configure a Variant Subsystem Block

In this model, the Controller Variant Subsystem is preconfigured with two subsystems, Linear Controller and Nonlinear Controller, as variant choices. To add more Variant Subsystem blocks to this model and configure the blocks, perform these steps:

- 1 Add a Variant Subsystem block to your model using the Simulink Library Browser or the Quick Block Insert menu and name the block. This block serves as the container for the variant choices.
- 2 To open the Variant Subsystem, double-click the block. The Variant Subsystem block, by default, is a template preconfigured with two Subsystem blocks to represent the variant choices.
- 3 Inside the Variant Subsystem block, add Inport and Outport blocks so that they match the inputs into and outputs from the Variant Subsystem block.
- 4 Name the variant choice blocks.

#### NOTE:

- You can add only Inport, Outport, Subsystem, Model, and Subsystem Reference blocks inside a Variant Subsystem block. You can pass control signals through data ports.
- When you add a Variant Subsystem block to your model, the **Variant activation time** parameter is set to `update diagram` and the **Propagate conditions outside of variant subsystem** parameter is set to `off` by default.

### Types of Variant Choices in Variant Subsystem

You can add Subsystems, Simulink models, and Subsystem References as variant choices in a Variant Subsystem.

#### Include Subsystem Block as Variant Choice

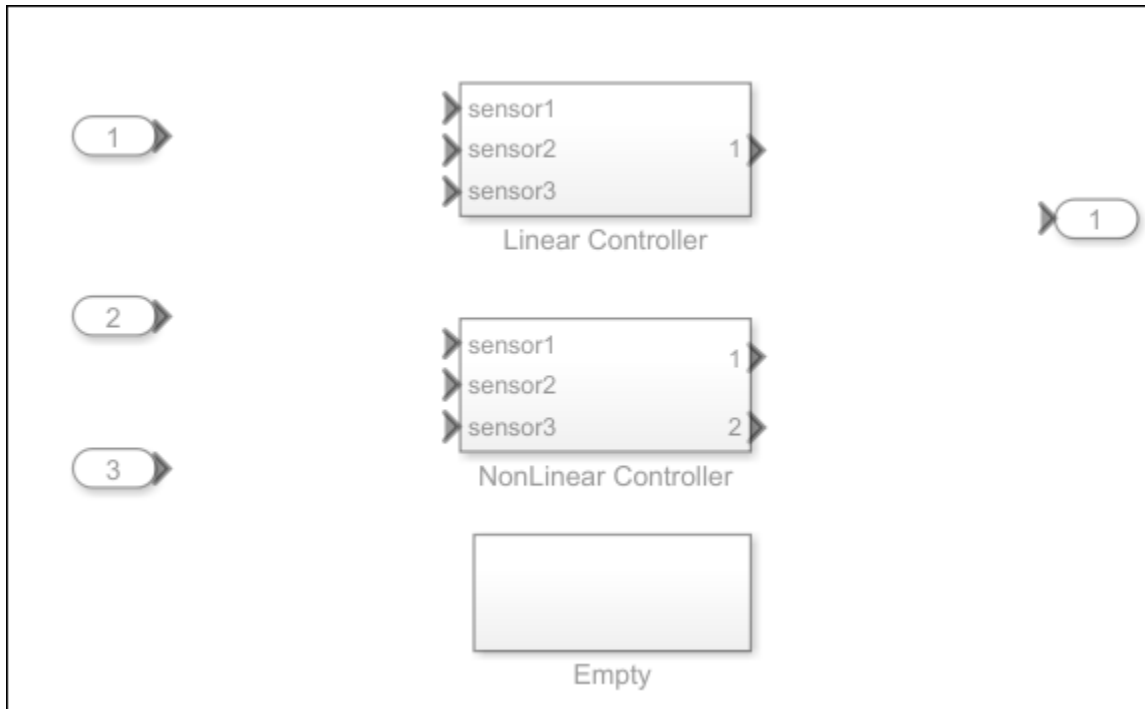

- 1 Open the block parameter dialog box of the Variant Subsystem block. Right-click the badge on the Variant Subsystem block and select **Block Parameters (Subsystem)**.
- 2 The “Variant choices (table of variant systems)” in the block parameter dialog box shows the variant choices that you added. You can use buttons to the left of the table to add or modify elements in the table.
- 3 To include a Subsystem block as a new variant choice inside the Variant Subsystem, click the Create and add a new subsystem variant choice button to the left of the Variant choices table. Simulink creates an empty Subsystem block inside the Variant Subsystem block. The new block has the same number of input and output ports as the containing Variant Subsystem block.
- 4 Open the Subsystem block and add the model elements that represent a variant choice.

Variant choices (table of variant systems)			
	Name (read-only)	Variant control expression	Condition (read-only)
	Linear Controller	true	(N/A)
	NonLinear Controller	false	(N/A)

#### NOTE:

- You can use conditionally executed subsystems such as Enabled, Triggered, Reset, and the Function-Call subsystems as variant choices within the Variant Subsystem block. For more information, see “Use Variant Subsystem Blocks with Conditionally Executed Subsystems” on page 12-135.

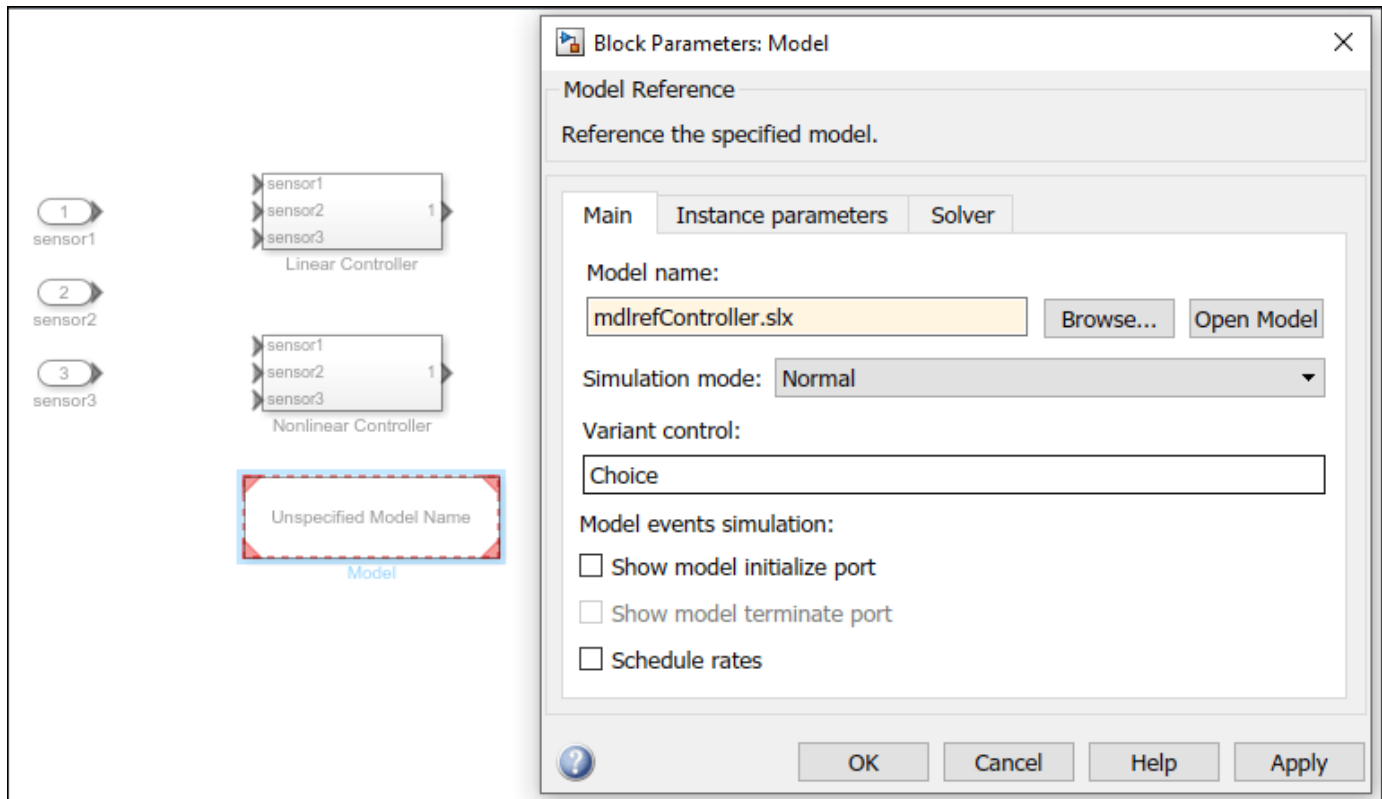

- When you prototype variants, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

### Include Simulink Model as Variant Choice

- To include a Simulink model (Model block) as a new variant choice inside the Variant Subsystem, click the Create and add a new model variant choice button to the left of the Variant choices table. Simulink creates an unresolved Model block in the Variant Subsystem block.
- Double-click the unresolved Model block. In the Model name box, enter the name of the model you want to use as a model variant choice and click OK.

**NOTE:** The referenced model must have the same number of input and output ports as the containing Variant Subsystem block.

### Include Subsystem Reference as Variant Choice

- 1 To include a Subsystem Reference as a new variant choice inside the Variant Subsystem, add a Subsystem Reference block using the Simulink Library Browser or the Quick Block Insert menu. Simulink creates an empty Subsystem Reference block in the Variant Subsystem block.
- 2 Double-click the Subsystem Reference block. In the Block Parameters dialog box, specify the subsystem block diagram file and click OK.

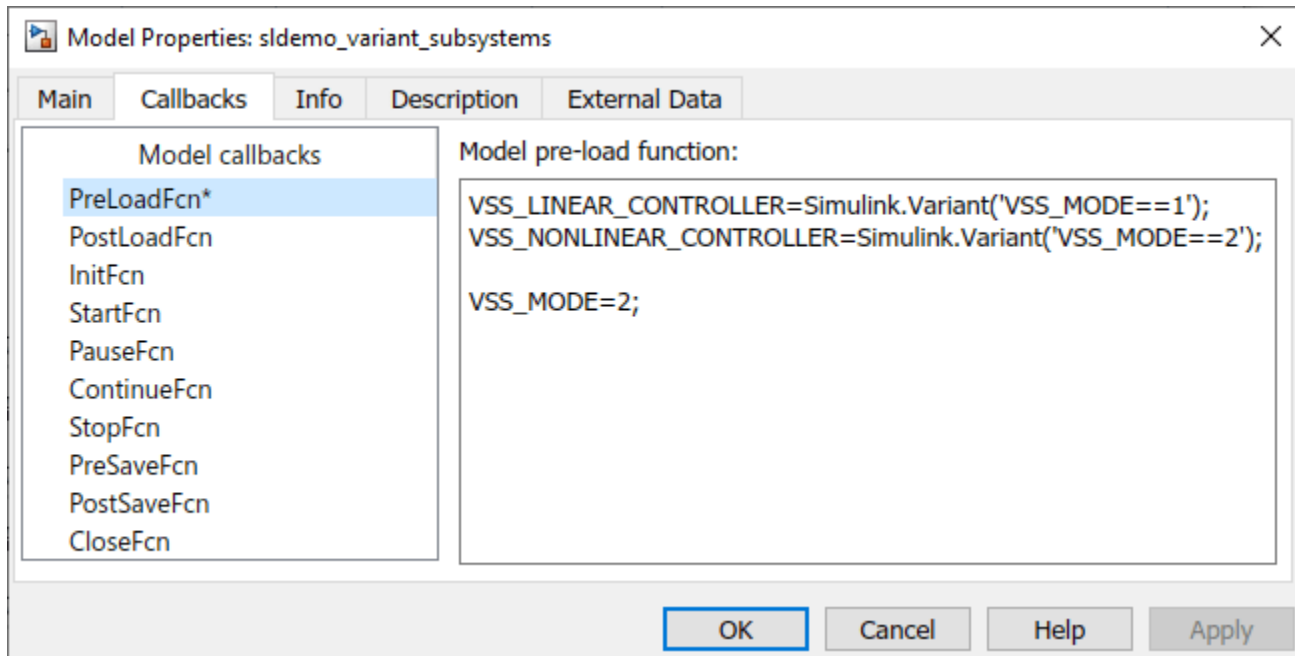

### Choose a Variant Control Mode

The **Variant control mode** parameter for the Controller block is set to **expression**. In this mode, you can specify the variant control for a choice as a Boolean condition expression, a `Simulink.Variant` object, the default variant choice, or an empty choice. For information on the different types of variant control modes, see “Variant Control Modes in Variant Blocks” on page 12-38.

### Use Variant Controls to Activate and Switch Between Variant Choices

In this model, the variant control for each choice is defined using two `Simulink.Variant` objects, `VSS_LINEAR_CONTROLLER` and `VSS_NONLINEAR_CONTROLLER`. To see the definitions of the `Simulink.Variant` objects used in this model, click **Model Settings > Model Properties > PreLoadFcn** callback. When you open the model, the `PreLoadFcn` callback runs and creates the objects in the base workspace of the model.

A `Simulink.Variant` object allows you to encapsulate a Boolean condition expression that activates a specific variant choice when it evaluates to `true`. You can build the condition expression using one or more variant control variables, which are defined as MATLAB® variables or `Simulink.Parameter` objects in the global workspace. In this example, a normal MATLAB variable, `VSS_MODE`, is used to build the condition expression for the `Simulink.Variant` objects.

To associate the Simulink.Variant objects, `VSS_LINEAR_CONTROLLER` and `VSS_NONLINEAR_CONTROLLER`, with the variant choices of the Controller block:

- In the Block Parameters dialog box, enter the name of the object in the **Variant control expression** column for each choice.
- The **Condition** column automatically shows the boolean condition that the Simulink.Variant object represents.

Since `VSS_MODE` is set to 2, the NonLinear Controller gets activated by default. To switch the active choice to Linear Controller, set `VSS_MODE = 1` in the base workspace and simulate the model.

**Specify Default Variant Choice:** When the variant control mode is set to `expression`, you can specify at most one variant choice as the default for the model. Simulink evaluates the variant controls and verifies that only one variant choice is active during simulation. If none of the variant controls evaluate to true, Simulink uses the default variant for simulation and code generation. To set a variant choice as the default, select the (default) keyword in the **Variant control expression** column for that choice.

**Specify Empty Variant Choice:** If you added an empty variant choice, you can either specify a variant activation condition for the choice or comment out the existing variant condition by placing a % symbol before the condition. If this variant choice is active during simulation, Simulink ignores the empty variant choice. However, Simulink continues to execute block callbacks inside the empty variant choices.

Variant choices (table of variant systems)		
Name (read-only)	Variant control expression	Condition (read-only)
Empty	%VSS_EMPTY_CONTROLLER	(Ignored)
Linear Controller	(default)	(N/A)
Nonlinear Controller	VSS_NONLINEAR_CONTROLLER	VSS_MODE==2

For information on other ways to define variant controls, see “Use Variant Control Variables in Variant Blocks” on page 12-57.

### Choose a Variant Activation Time

The **Variant activation time** that you specify for the Variant Subsystem block determines the stage when Simulink sets the active choice for the block. This parameter also determines how the active and inactive choices participate in the simulation and code generation workflows.

For the **Controller** block, this parameter is set to `update diagram`. So, Simulink sets the active choice at the start of the model compilation stage and the inactive choices are removed. When you execute the model, only the active choice is analyzed for consistency. Generated code contains only the active choice. For information on other variant activation times, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

### Represent Variant Choices That Have Different Interfaces

In this example, the two variant choices, `Linear Controller` and `NonLinear Controller`, have the same number of input and output ports as the `Controller` variant subsystem block. You can also have different number of inports and outports for variant choices inside a Variant Subsystem block. The Variant Subsystem block can adapt its interface based on the activeness of the underlying blocks. This allows you to model component variations that do not have a similar interface. These conditions must be satisfied by the variant choices:

- The variant choices must have same set of inports as the Variant Subsystem container block or it must be a subset of ports on the container block.
- The variant choices must have same set of outports as the Variant Subsystem container block or it must be a subset of ports on the container block.
- The variant choices must have same set of control port as the Variant Subsystem container block.

For an example, see “Adaptive Interface for Variant Subsystems” on page 12-125.

### Allow Zero Active Variant Controls for Variant Subsystem

The **Allow zero active variant controls** parameter on the Variant Subsystem block determines whether the block allows simulation even if none of the variant choices are active. When you select this option and if there is no active variant choice, Simulink simulates the model without any active variant choice in the Variant Subsystem. When you clear the option, Simulink generates an error when there is no active variant choice. This parameter is available only if there are no (`default`) variant choices in the Variant Subsystem and if you set **Variant control mode** to `expression`.

### Propagate Variant Conditions Outside Variant Subsystem

During simulation, Simulink automatically propagates variant conditions from variant blocks to connecting blocks to determine which components of the model remain active. For a variant

subsystem, the variant conditions defined on the choices do not propagate outside the Variant Subsystem block by default. To enable this, you can set the **Propagate conditions outside of variant subsystem** parameter on the Variant Subsystem block.

When you select the Propagate conditions outside of variant subsystem parameter, Simulink propagates the variant condition of the underlying blocks to the Variant Subsystem container block so that the subsystem can adapt its interface to the state of the underlying blocks. Ports that are mapped to the ports on the active choice becomes active. Ports that are mapped to the ports on the inactive choice becomes inactive. Selecting this option ensures that the components outside of the Variant Subsystem are aware of the active and inactive state of blocks within the Variant Subsystem block. For more information, see “Propagate Variant Conditions Outside Variant Subsystems” on page 12-125.

## Variant Source and Variant Sink Blocks

Define variant choice regions in the Variant Source and Sink blocks based on the block connectivity. The variant choice regions are computed by Simulink when you update diagram (**Simulation > Prepare > Update Model**).

The process of computing the variant choice regions is called **variant condition propagation**. The Variant Source block provides variation on the source of a signal, and the Variant Sink blocks provides variation on the destination (sink) of a signal.

Consider a model containing two Variant Source blocks (Variant Source1, Variant Source2) and a Sink block (Variant Sink).

Copyright 2016-2020 The MathWorks, Inc.

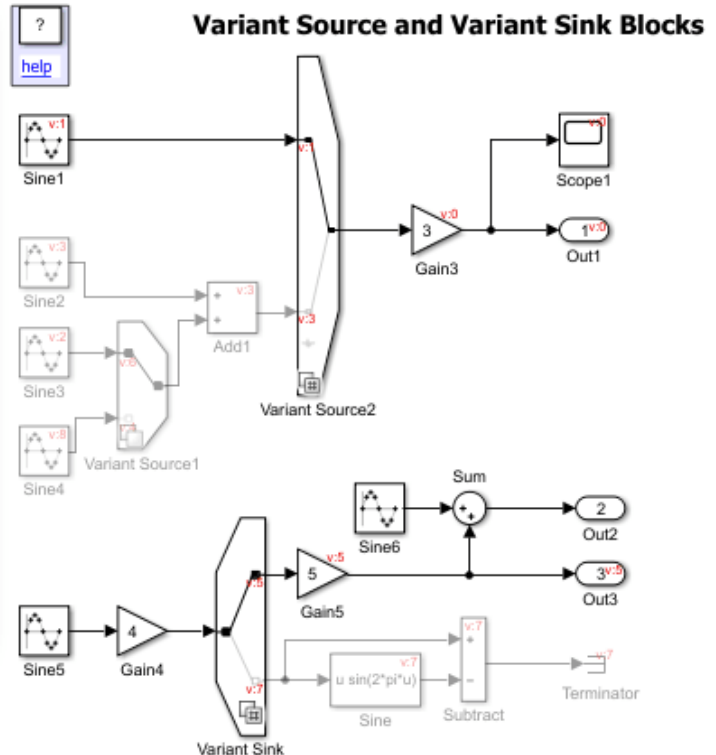

The variant conditions at the inports and outports of Variant Source and Sink blocks, respectively, determine the activation and deactivation of the blocks connected to them. To view the annotations and the variant conditions, in the **Debug** tab of the toolstrip, click **Information Overlays > Variant Conditions**.

Variant Conditions Legend: slxVariantSourceAndSi... X

Show generated code conditions Filter

Annotation	Simulation	Workspace
v:0	$V == 1 \parallel V == 2$	Global
v:1	$V == 1$	Global
v:2	$V == 2 \ \&\& \ W = \dots$	Global
v:3	$V == 2$	Global
v:4	$V == 4$	Global
v:5	$W == 1$	Global
v:6	$W == 1$	Global
v:7	$W == 2$	Global
v:8	false	Global

Print Help

Let us analyze the variant conditions and the block activation state.

- In **Variant Source1**, when  $W==1$ , the **Sine3** block is active, and when  $V==4$ , the **Sine4** block is active.
- In **Variant Source2**, when  $V==1$ , the **Sine1** block is active, and when  $V==2$ , the **Add1** block is active.
- At **Add1** block the condition propagation continues making **Variant Source1** block to be active only when the  $V==2$ . This further propagates to **Sine3** block and **Sine4** block, making the **Sine3** block active at  $V==2 \ \&\& \ W==1$  and the **Sine4** block active at  $V==2 \ \&\& \ W==2$ , respectively.
- The **Gain3** block is active when either  $V==1$  or  $V==2$ , and hence the condition  $V==2 \parallel V==1$ . The variant condition is further propagated to **Scope1** and **Out1**.
- The blocks connected to the outport of **Variant Sink** are active when  $W==1$  (**Gain5**), or  $W==2$  (**Sine**, **Subtract**, **Terminator**).
- The **Sum** block illustrates two key concepts in variant condition propagation: Signals are only variant if explicitly marked or when all paths can be proven to be variant. To make the **Sine6**, **Sum**, **Out2** variant, place a Single-Input Single-Output Variant Source before **Out2** (or after the **Sine6**). Reading an inactive signal is equivalent to reading ground. When  $W \neq 1$ , then the bottom input to the **Sum** block is inactive and  $Out2 = Sine6 + ground$ .

If you set the **Variant activation time** parameter to `code compile` for the Variant Source and Variant Sink block, the generated code contains the code for the active and the inactive (`#if COND`). If this parameter is not selected, then code is generated only for the active choices.

If you select the **Allow zero active variant controls** parameter for the Variant Source and Variant Sink block, you can simulate the variant model without an active variant. In such cases, Simulink

disables the blocks connected to the input and output stream of Variant Source and Variant Sink. These disabled blocks are ignored from update diagram or simulation.

## Control Variant Condition Propagation

During variant condition propagation, Simulink automatically assigns conditions to blocks. You can control how the variant condition propagates upstream and downstream in a model.

Consider this model.

Copyright 2016-2020 The MathWorks, Inc.

In Simulink, click **Simulation** > **Run** to view the variant condition propagation to blocks.

The Variant Source1 block has the  $A==1$  condition, which propagates backward and forward to the blocks connected to Variant Source1 block. The variant condition propagates to Gain4 block but does not propagate to the Sine Wave1 block.

The Scope block is unconditional and receives its inputs from the Sine Wave1 block. Therefore, the Sine Wave1 block is unconditional. If you remove the Scope block, the variant condition propagates to the Sine Wave1 block.

If you replace the Scope block with any other block (including the Terminator block), the Sine Wave1 block remains unconditional.

A block is unconditional if at least one of its inputs is unconditional. The input side of the Sum block is connected to Gain5 (conditional) block and to the Sine Wave2 (unconditional) block. Therefore, the Sum block is unconditional.

You can use these concepts to create a Subsystem block that controls the propagation of variant conditions to both sides or to one side.

### Stop Propagation of Variant Condition Upstream and Downstream

Consider the section of the model that is connected to the Variant Source2 and Variant Source3 blocks. When you simulate the model, the Variant condition from the Variant Source2 block and the Variant Source3 blocks propagates upstream and downstream.

The Stop on both sides block between Gain6 and the Gain7 block prevents the Variant condition from propagating upstream or downstream. Double-click the Stop on both sides block to view its components.

The Stop on both sides block uses a Terminator to stop the variant condition propagation on upstream of the Subsystem block. To stop the condition propagation on the downstream side of the Subsystem block, one of the inports is connected to Ground (unconditional). Therefore, this arrangement stops the variant condition propagation upstream and downstream. Similarly, you can selectively stop the condition propagation of variant condition upstream or downstream for a model. For example, if you remove the Terminator block, variant condition propagates upstream but is stopped downstream.

### Stop Propagation of Variant Condition Downstream

Here, one input port of the Subsystem block is unconditional making the Subsystem block unconditional at input side and thus stopping the propagation of variant condition downstream.

## Propagate Variant Conditions from Variant Source Blocks to Conditionally Executed Subsystems

A conditionally executed subsystem is a nonvirtual subsystem that allows you to control its execution with an external signal. Enabled, Triggered, and Function-Call Subsystems are examples of conditional subsystems. The external signal that controls a conditional subsystem is called the control signal and the port through which the signal enters the block is called the control port. For more information on conditional subsystems, see “Conditionally Executed Subsystems Overview” on page 10-3.

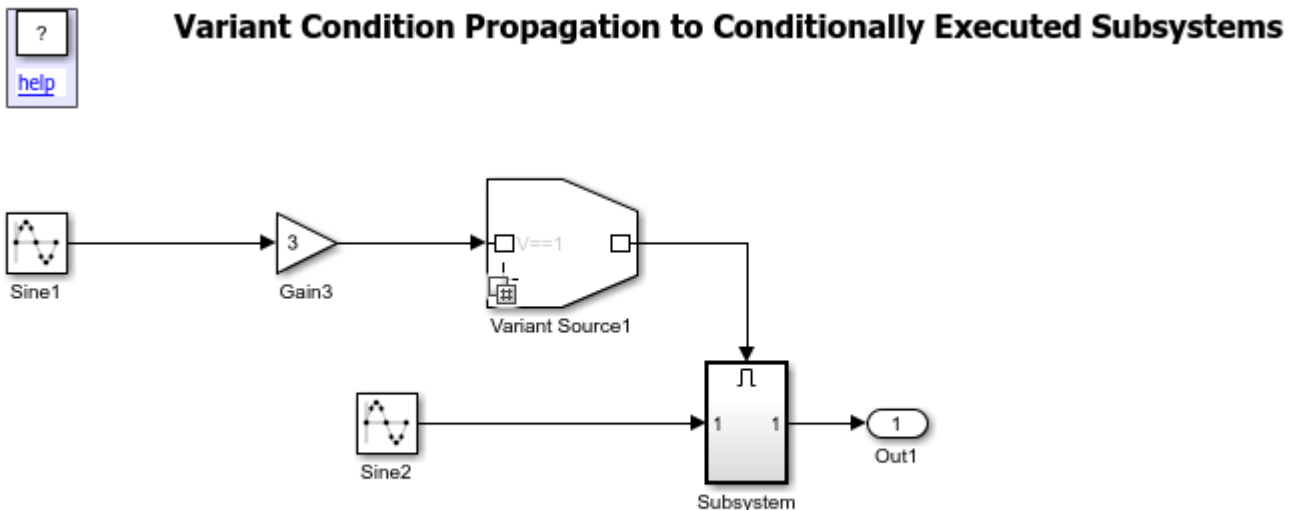

You can use a single-input/single-output or a multi-input Variant Source block to control the execution of conditional subsystems based on the active variant conditions at the inports of the Variant Source block.

### Use Variant Source Block to Control Execution of Conditional Subsystem Blocks

This example shows how to use a single-input/single-output Variant Source block to control the execution of a conditional subsystem block.

#### Explore the Model

Open the model `slexVariantControlPorts`.

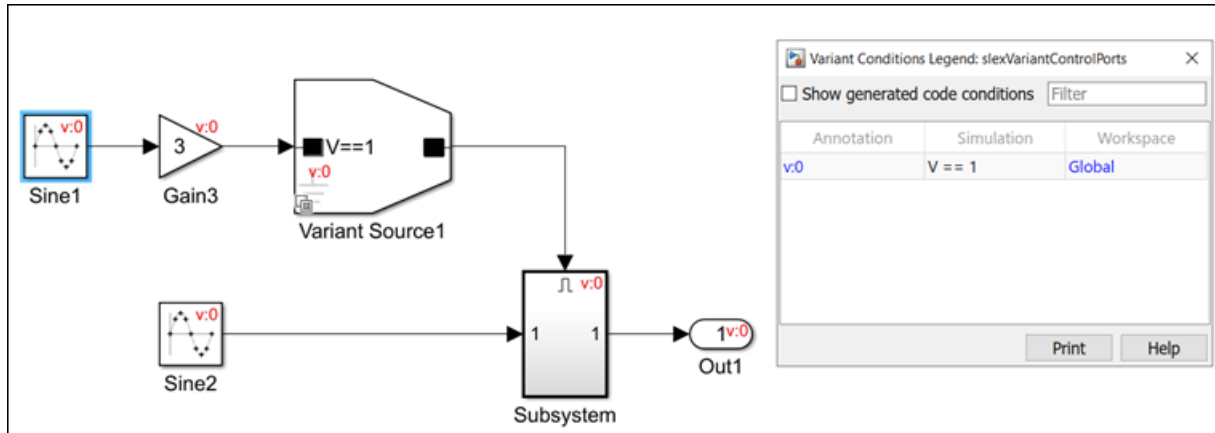

Copyright 2016 The MathWorks, Inc.

The model contains a single-input/single-output Variant Source block, `Variant Source1`, with variant condition set as  $V==1$ . The output from `Variant Source1` block is connected to the control port of the Enabled Subsystem `Subsystem`.

The **Allow zero active variant controls** parameter on the `Variant Source1` block is set to on. When this option is selected and there is no active variant choice, Simulink® disables all the blocks connected to the input and output stream of the Variant Source block.

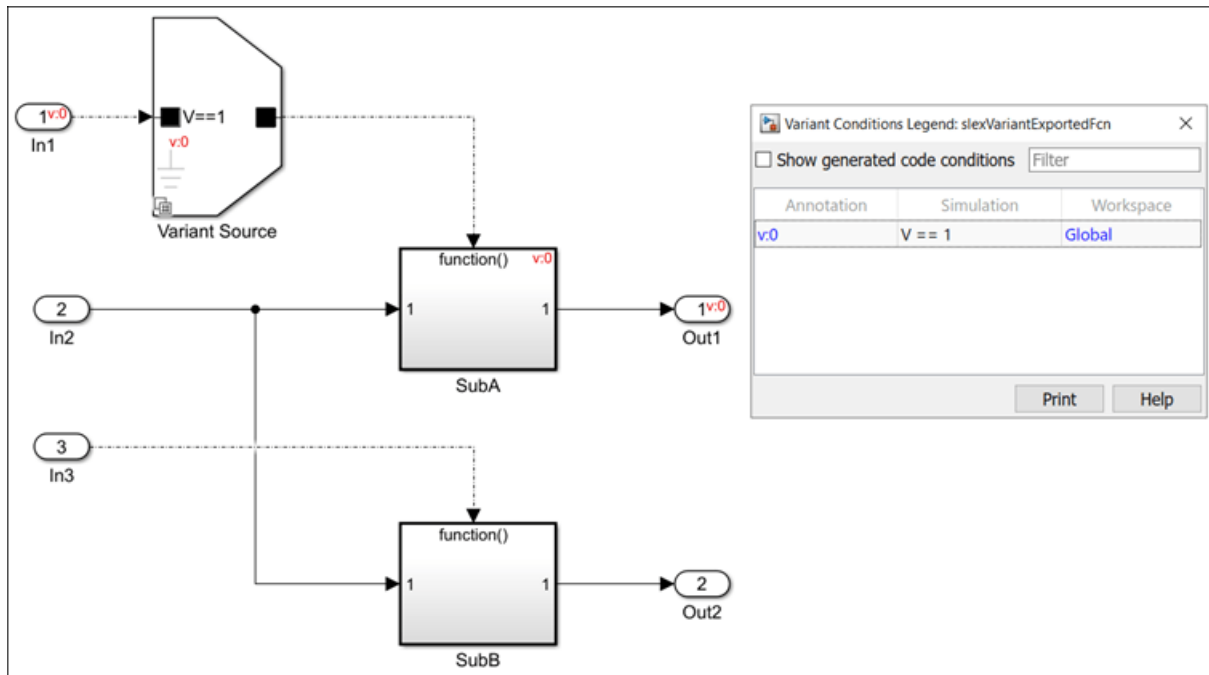

When you simulate the model after setting  $V=1$ , the condition  $V==1$  propagates to the output of `Variant Source1` and then to the control port of `Subsystem`. The condition assigned to the subsystem block then propagates to the blocks named `Sine2` and `Out1` connected to its input and output ports. If you set  $V$  to a value other than 1, Simulink disables all the blocks connected to the input and output of `Variant Source1`.

### Propagate Variant Conditions to Function-Call Subsystems

A Function-Call Subsystem block is a subsystem that another block can invoke directly during simulation. The Function-Call Subsystem block is analogous to a function in procedural programming language. For more information, see “Using Function-Call Subsystems” on page 10-34.

You can use a Variant Source block to make the Function-Call Subsystem block conditional.

The Variant Source block has condition `V==1`, where `V` is a `Simulink.Parameter`.

The **Output function call** parameter on the Variant Source block is set to on. This enables the block to output function-call signals.

The **Allow zero active variant controls** parameter on the Variant Source block is set to on.

When you simulate this model, the variant condition from the Variant Source block propagates to the control port of the SubA subsystem block and further propagates to the blocks connected to its inports and outports.

- When `V=1`, the SubA block is active and the variant condition propagates backward and forward to the blocks connected to the input (In1) and output (Out1) ports.
- When `V~=1` (for example, `V=0`), SubA becomes inactive, which makes Out1 inactive. In2 remains active because it is connected to SubB, which is active.
- If In2 is not connected to SubB, In2 becomes inactive when `V~=1`.

**Note:** If the Function-Call Subsystem is placed inside a virtual grouped subsystem, the variant condition triggering the Function-Call Subsystem must match the corresponding condition on the input of the higher level subsystem block.

## Hierarchical Nesting of Variant Sources and Variant Sinks

This example shows how to use Variant Source blocks to provide Variant selection on sensors.

This model illustrates how you can use multiple Variant Source blocks to provide variant selection on sensors. In this model, multiple Variant Source blocks are used to create hierarchical nesting of variant choices. Choices are first grouped by series: A Series, B Series, and C Series. A combination of one or more series is provided as input for a device model. The resulting device model is provided as input to the vendor by including or excluding a sensor selection. In this model, a constant block is masked as a place holder for analog-to-digital converter (A/D) blocks. This model shows variation of sensor inputs. Alternatively, you may use Variant Sink blocks to create variation of actuator outputs. The variant control variables that parameterize the Variant Source blocks are defined in the `PostLoadFcn` callback.

Consider this model with Variant Source blocks.

In this model, the Variant Source block "Vendor" gets inputs from Variant Source blocks "X Sensor" and "Device Model" blocks. The "X Sensor" block gets inputs from constants AD7 and AD8. The "Device Model" block gets inputs from Variant Source blocks "A Series", "B Series", and "C Series". The Variant Source blocks "A Series", "B Series", and "C Series" get inputs from Constant blocks.

Now simulate the model.

When you simulate the model, the constant block AD5 is active. The Variant Source block "Vendor" selects between two vendors, `VENDOR==1` or `VENDOR==2` and in the base workspace, `VENDOR` is a Simulink.Parameter with `VENDOR.Value=1`. The Variant Source block "Device Model" selects between `DEVICE_MODEL==1`, `DEVICE_MODEL==2`, or `DEVICE_MODEL==3` and in the base workspace, `DEVICE_MODEL.Value=3`. The Variant Source block "C Series" selects between `C_SERIES==1` and `C_SERIES==2` and in the base workspace, `C_SERIES.Value=2`.

### Code Generation

You can use Simulink Coder to generate code from a model containing Variant Subsystem blocks. By default, the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder.

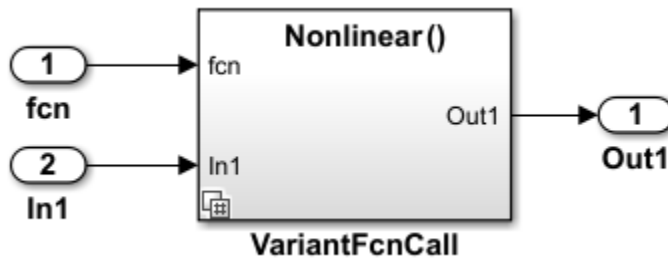

### More about

## Export-Function model with Variant Subsystem

This example shows how to use Variant Subsystem model with Function-Call blocks as choice.

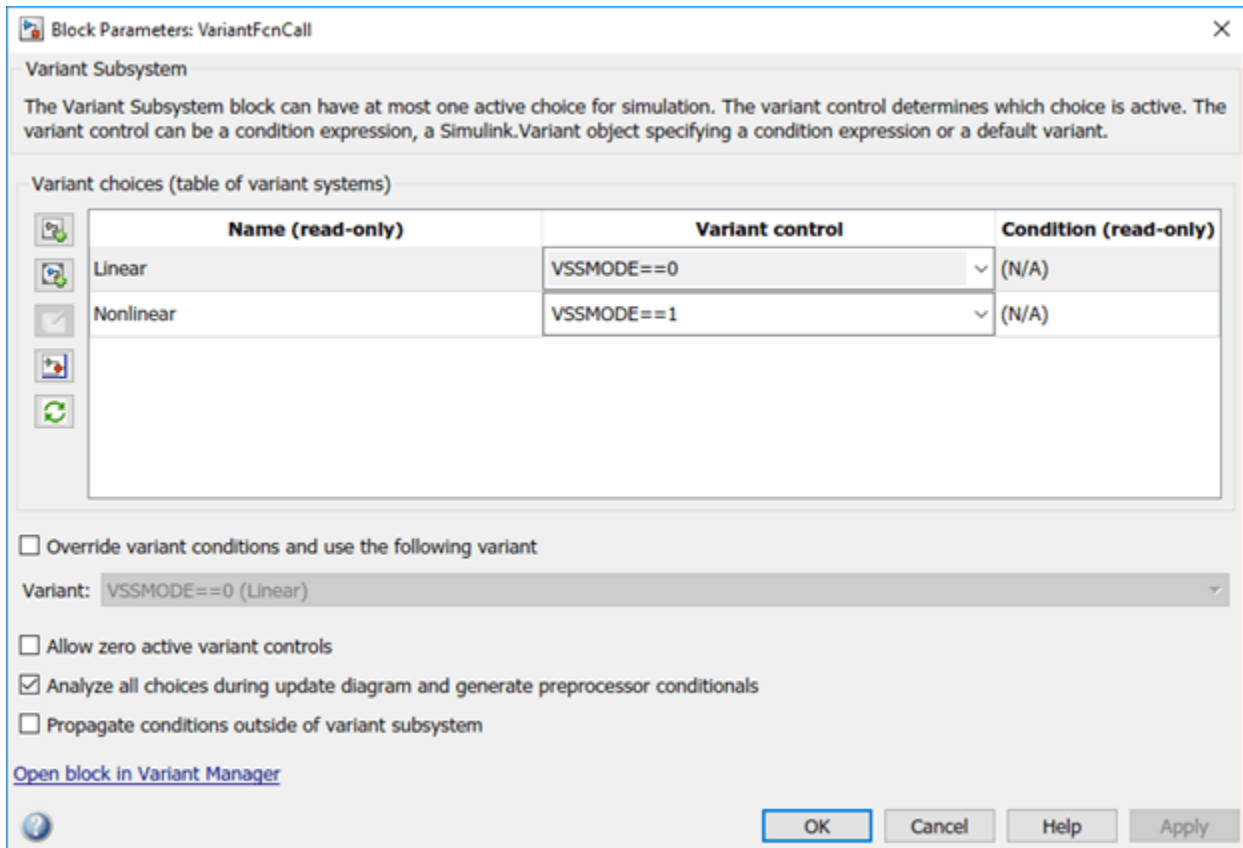

Consider this model containing a Variant Subsystem block.

**Note:** If you use Function-Call system as a variant choice for the Linear Subsystem block, then the other Subsystem block (Nonlinear) within the Variant Subsystem must also be Function-Call system. Additionally, the control ports in Linear and Nonlinear blocks and the corresponding inport block must have the same name (fcn).

The Variant Subsystem "VariantFcnCall" gets the inputs from two inport blocks. The "VariantFcnCall" block has two variant choices, Linear and Nonlinear governed by conditions  $VSSMODE==0$  and  $VSSMODE==1$ . Root inport(fcn) is a function-call inport connecting variant subsystem making this model as export function model.

You can simulate the model `slexVariantSubsystemEnableChoice` and verify the behavior of the counters by examining the results.

### Code Generation

You can use the Simulink Coder to generate code from a model containing Variant Subsystem blocks. By default the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder. In the generated code, the code inside `fcn` definition is guarded by C preprocessor conditionals inside export function.

```
% fcn() {
% #if VSSMODE==0
% // code for Linear choice
% .....
% #endif
% #if VSSMODE==1
% // code for Nonlinear choice
% .....
% #endif
```

### More about

- “Use Variant Subsystem Blocks with Conditionally Executed Subsystems” on page 12-135

## Variant Subsystem with Enable Subsystem as Choice

This example shows how to use Variant Subsystem model with Enable Subsystem as choice.

Consider this model with a Variant Subsystem block.

**Note:** If you use Enable Subsystem as a variant choice for the Linear Subsystem block then the other Subsystem block (Nonlinear) within the Variant Subsystem must also be Enable Subsystem.

```
open_system('slexVariantSubsystemEnableChoice')
```

### Variant Subsystem with Conditionally Executed Systems

Copyright 2017-2022 The MathWorks, Inc.

The Variant Subsystem block "Controller" gets the input from Sine Wave and Inport blocks. The "Controller" block has two Variant choices, Linear and Nonlinear. The Variant choices are governed by conditions  $VSSMODE==0$  and  $VSSMODE==1$ . This model can simulate and generate code based on  $VSSMODE$  value.

You can simulate the model `slexVariantSubsystemEnableChoice` and verify the behavior of the counters by examining the results.

### Code Generation

You can use the Simulink Coder to generate code from a model containing Variant Subsystem blocks. By default the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder. In the generated code, the code inside `fcn` definition is guarded by C preprocessor conditionals inside `export` function.

```
%step() {
% #if VSSMODE==0
% // code for Linear choice
% .....
% #elif VSSMODE==1
% // code for Nonlinear choice
% .....
% #endif
```

**More about**

- “Use Variant Subsystem Blocks with Conditionally Executed Subsystems” on page 12-135

## Change Active Values and Activation Time of Variant Parameters

This example shows how to change the active values and activation time of variant parameters in a Simulink® model.

In this example, you will learn how to:

- Change active values of variant parameters using variant condition expressions.
- Change the time of determining active values using variant activation time.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant control expression. During simulation, the value of a variant parameter associated with the condition that evaluates to `true` is the active value of the variant parameter. The value associated with the condition that evaluates to `false` is the inactive value of the parameter. To switch between the active values, change the value of the variant control variable. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 12-175.

### Prerequisite

Before you start with this example, we recommend you complete “Create a Simple Variant Parameter Model” on page 12-178.

### Explore the Model

1. Open the model.

```
open_system('slexVariantParameters')
```

### Variant Parameters with Different Activation Times

Copyright 2020-2021 The MathWorks, Inc.

In this model, the **Gain** parameter of the Gain blocks are variant parameters that are specified as `Simulink.VariantVariable` objects K1 and K2. The objects are defined in the `slexVariantParameterData.m` file.

2. Open the `slexVariantParameterData.m` file. The file is loaded in the **PostLoadFcn** callback of **Modeling > Model Settings > Model Properties**.

In the file, the objects K1 and K2 have multiple values associated with variant control expressions `V==1` and `V==2`. In addition to the value, you can specify attributes such as dimension, data type, and so on for each object using the “**Specification**” parameter of the object.

- **Variant control variable:** The value of the `Simulink.VariantControl` object `V` determines which values of K1 and K2 are active during simulation. If `V==1` evaluates to `true`, the values associated with `V==1` become active, and all the values associated with `V==2` become inactive. The active value of K1 is assigned to the **Gain** parameter of the Gain1 block, and the active value of K2 is assigned to the **Gain** parameter of the Gain2 block. Similarly, when `V==2` evaluates to `true`, all the values associated with `V==1` become inactive, and all the values associated with `V==2` become active. For more information on variant controls, see “Introduction to Variant Controls” on page 12-36.
- **Variant activation time:** Simulink can set active value of the variant parameter **Gain** at different stages of the simulation and code generation workflow. Based on the stage you specify as the variant activation time, Simulink determines if the generated code must contain only the active values or both active and inactive values of K1 and K2. The variant activation time also determines whether to analyze all the values of K1 and K2 for incompatibilities in signal attributes.

In this example, the value of `V` is specified as `1`, and the variant activation time is specified as `update diagram`. When you simulate this model, `V==1` evaluates to `true`. The value of K1 is set to `3.5` and the value of K2 is set to `4.5`. Simulink determines the active values during update diagram. When you generate a code from this model, the code contains only the active values of K1 and K2.

### Set Active Choice of Variant Parameters

The value of the variant control variable determines the active value of variant parameters during simulation. To switch the active values, change the value of variant control variable.

1. On the Simulink toolstrip, click **Run**. During simulation, `V==1` evaluates to `true`. As the values `3.5` and `4.5` are associated with `V==1`, these values are assigned to K1 and K2, respectively. Subsequently, the values are assigned to the **Gain** parameters of the Gain blocks.
2. To change the value of the **Gain** parameters, change the value of `V` to `2`, then simulate the model again.

```
V.Value = 2;
```

During simulation, all the values associated with `V==2` are assigned to K1 and K2. Subsequently, the values are assigned to the **Gain** parameters of the Gain blocks.

### Set Time to Determine Active Value of Variant Parameters

Simulink can set active value of the variant parameters at different stages of the simulation and code generation workflow. Based on the stage you specify as the variant activation time, Simulink determines if the generated code must contain only the active values or both active and inactive values of variant parameters. The variant activation time also determines whether to analyze all the values the variant parameters for incompatibilities in signal attributes.

For example, to specify the activation time of `V` as `update diagram`, type this command in the MATLAB® Command Window. Then, simulate the model again.

```
V.ActivationTime = 'update diagram';
```

Simulink sets the active values of K1 and K2 during update diagram before the propagation of signal attributes. The signal attributes such as dimension and data type are not analyzed for consistency across the model. The generated code contains only the active value of K1 and K2. For information on other activation times, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

### **See Also**

- “Options to Represent Variant Parameters in Generated Code” (Embedded Coder)
- “Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions” on page 12-211

## Compile Code Conditionally for all Values of Variant Parameters with Same and Different Dimensions

This example shows how to generate a C code that contains all the active and inactive values of variant parameters. The values are enclosed in preprocessor conditionals `#if` and `#elif` that enables you to compile the code conditionally based on the condition that evaluates to `true`.

In this example, you will learn how to:

- Use storage classes to control the appearance, placement, definition, and declaration of variant parameter variables in the generated code.
- Use symbolic dimensions to propagate varying dimensions of variant parameters as symbols in the generated code. Representing dimensions as symbols enables the code to flexibly switch between dimension values for the given active choice without regenerating code every time you change the value of the variant control variable.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant condition expression. During simulation, the value of the variant parameter associated with the condition that evaluates to `true` is the active value of that parameter. The value associated with the condition that evaluates to `false` is the inactive value of that variant parameter. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 12-175.

In the generated code, the active and inactive values of the variant parameters are enclosed in C preprocessor conditionals `#if` and `#elif`. The preprocessor conditionals enable you to conditionally compile the code for a given active value. You generate the code only once. You can then choose the active choice of variant parameters by changing the value of the variant control variable before running the code. You do not need to regenerate the code for different variant parameter choices.

- **Representation of variant parameter variables:** The values are represented as inline or tunable variables in the generated code. The representation is determined by the storage class that you specify for the variant parameters in the model. The variant parameters with default storage class `Auto` are represented as inline variables. The variant parameters with storage class other than `Auto` are represented as tunable variables in the generated code. For more information on how different storage classes are represented in the generated code, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).
- **Representation of variant parameter dimensions:** If the values of a variant parameter have different dimensions, then the dimensions are represented as symbols. These symbols propagate throughout the model during simulation and then go into the generated code. To represent dimensions as symbols, you must set **Modeling > Model Settings > Diagnostics > Advanced Parameters > Allow symbolic dimension specification** to on. For more information on symbolic dimensions, see “Allow symbolic dimension specification”.

### Prerequisite

Before you start this example, we recommend you complete “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

### Explore the model

1. Open the model.

```
open_system('slexVariantParametersCC')
```

Copyright 2020 The MathWorks, Inc.

The model contains blocks that have variant parameters that are specified as `Simulink.VariantVariable` objects. The objects are defined in the `slexVariantParameterCCData.m` file.

- **Constant:** The **Constant** parameters of the Constant blocks are variant parameters. The parameters are specified as variant variable objects `MAX_LIFT` and `SLIDER_POS`.
- **Table data** and **Breakpoint sets:** The **Table data** and **Breakpoint sets** of the n-D Lookup Table blocks are variant parameters. The parameters are specified as variant variable objects `T1Break1`, `T1Data`, `T2Break`, and `T2Data`.

2. Open the `slexVariantParameterData.m`. Observe these settings in the file:

- In this file, `VCtrl` is the `Simulink.VariantControl` object that determines the active value of the variant parameter objects `MAX_LIFT`, `SLIDER_POS`, `T1Break1`, `T1Data`, `T2Break`, and `T2Data`. The value of `VCtrl` is set to 1, and its activation time is specified as `code compile`. During simulation, the condition `VCtrl==1` evaluates to true. All the values associated with `VCtrl==1` become active, and the values associated with `VCtrl==2` become inactive. When you generate a code from this model, all the active and inactive values are enclosed in preprocessor conditionals `#if` and `#elif`.
- The variant parameter objects `MAX_LIFT` and `SLIDER_POS` have scalar numeric values with a default storage class `Auto`. When you generate the code, the values of the **Constant** parameters are inlined as macros. The variant parameter objects `T1Break1`, `T1Data`, `T2Break`, and `T2Data` are of `Simulink.Parameter` type with storage class specified as `ExportedGlobal`. When you generate the code, the values are represented by symbolic names as tunable variables in the generated code.

- The variant parameter objects T1Break1 and T1Data have values with different dimensions. When you generate the code, the dimensions of these parameters are represented as symbols.

### Set Active Choice of Variant Parameters

1. On the Simulink® toolstrip, click **Run**. During simulation, `VCtrl==1` evaluates to `true`. All the values associated with `VCtrl==1` are assigned to the corresponding variant variable objects and, subsequently, to the variant parameters that use these objects. For example, when `VCtrl==1` evaluates to `true`, the value of `MAX_LIFT` is set to `10`. As the **Constant** parameter of the `Constant1` block is set to `MAX_LIFT`, the value of the **Constant** parameter is also set to `10`.

2. To change the active values, change the value of `VCtrl` to `2`, then simulate the model again.

```
VCtrl.Value = 2;
```

During simulation, all the values associated with `VCtrl==2` are assigned to the variant variable objects, and those values are then assigned to the variant parameters using those objects.

### Generate Code Using Embedded Coder

To generate code for variant parameters that have values with different dimensions, use Embedded Coder.

Before you generate code from the model, make sure that you have write permission in your current folder. To generate code, in the **Apps** gallery of the model toolstrip, click **Embedded Coder**. On the **C Code** tab, click **Build**. For more information, see “Generate Code Using Embedded Coder” (Embedded Coder).

### Review Inline and Tunable Parameters in Generated Code

1. In the **C Code** tab, select **Open Report**.

2. Select the `slexVariantParametersCC_types.h` file from the **Generated Code** pane of the report. This file defines the value of the variant control variable `VCtrl` as `1`. The variant control variable determines the active value of variant parameters.

```
#ifndef VCtrl
#define VCtrl          1
#endif
```

3. Select the `slexVariantParametersCC_private.h` file. This file includes macros (`#define`) corresponding to all the values of the variant parameters with default storage class `Auto`. The active values of variant parameters `MAX_LIFT` and `SLIDER_POS` are enclosed in the C preprocessor conditional statement (`#if`) on the macros `rtCP_Constant_MAX_LIFT` and `rtCP_Constant1_SLIDER_POS`.

```
#if VCtrl == 1 || VCtrl == 2
/* Variable: MAX_LIFT
 * Referenced by: '<Root>/Constant'
 */
#if VCtrl == 1
#define rtCP_Constant_MAX_LIFT          (10.0)
#elif VCtrl == 2
#define rtCP_Constant_MAX_LIFT          (20.0)
#endif
#endif
```

```

#if VCtrl == 1 || VCtrl == 2
/* Variable: SLIDER_POS
 * Referenced by: '<Root>/Constant1'
 */
#if VCtrl == 1
#define rtCP_Constant1_SLIDER_POS      (0.0)
#elif VCtrl == 2
#define rtCP_Constant1_SLIDER_POS      (0.5)
#endif
#endif

```

4. Select the `slexVariantParametersCC.h` file. This file includes symbolic names for all the values of the variant parameters with storage class set to `ExportGlobal`. The variables are defined as extern variables.

```

/* Exported Global Parameters
#if VCtrl == 1 || VCtrl == 2
extern real_T T1Break[T1Break_dim0]; /* Variable: T1Break
 * Referenced by: '<Root>/1D Lookup'
 */

#endif

#if VCtrl == 1 || VCtrl == 2
extern real_T T1Data[T1Data_dim0]; /* Variable: T1Data
 * Referenced by: '<Root>/1D Lookup'
 */

#endif

#if VCtrl == 1 || VCtrl == 2
extern real_T T2Break[3]; /* Variable: T2Break
 * Referenced by: '<Root>/2D Lookup'
 */

#endif

#if VCtrl == 1 || VCtrl == 2
extern real_T T2Data[9]; /* Variable: T2Data
 * Referenced by: '<Root>/2D Lookup'
 */

#endif

```

5. Select the `slexVariantParametersCC.c` file. All the values of variant parameters are enclosed in C preprocessor conditional statements `#if` and `#elif`. When you compile this code, Simulink evaluates the preprocessor conditionals and compiles the code only for the active values of variant parameters. You can then specify a different value for `VCtrl` and recompile the same code for any other active values of variant parameters.

```

/* Exported block parameters */
#if VCtrl == 1

real_T T1Break[T1Break_dim0] = { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0,
2.0, 3.0, 4.0, 5.0 }; /* Variable: T1Break
 * Referenced by: '<Root>/1D Lookup'
 */

real_T T1Data[T1Data_dim0] = { -0.99990920426259511, -0.999329299739067,
-0.99505475368673046, -0.9640275800758169, -0.76159415595576485, 0.0,
0.76159415595576485, 0.9640275800758169, 0.99505475368673046,
0.999329299739067, 0.99990920426259511 };

```

```

        /* Variable: T1Data
        * Referenced by: '<Root>/1D Lookup'
        */

real_T T2Break[3] = { -10.0, 0.0, 10.0 } ;
        /* Variable: T2Break
        * Referenced by: '<Root>/2D Lookup'
        */

real_T T2Data[9] = { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0,
20.0, 23.0 } ;
        /* Variable: T2Data
        * Referenced by: '<Root>/2D Lookup'
        */

#elif VCtrl == 2

real_T T1Break[T1Break_dim0] = { -10.0, -9.0, -8.0, -7.0, -6.0, -5.0,
-4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0,
9.0, 10.0 } ;
        /* Variable: T1Break
        * Referenced by: '<Root>/1D Lookup'
        */

real_T T1Data[T1Data_dim0] = { -0.9999999587769273, -0.999999969540041,
-0.99999977492967584, -0.99999833694394469, -0.99998771165079559,
-0.99990920426259511, -0.999329299739067, -0.99505475368673046,
-0.9640275800758169, -0.76159415595576485, 0.0, 0.76159415595576485,
0.9640275800758169, 0.99505475368673046, 0.999329299739067,
0.99990920426259511, 0.99998771165079559, 0.9999833694394469,
0.99999977492967584, 0.999999969540041, 0.9999999587769273 } ;
        /* Variable: T1Data
        * Referenced by: '<Root>/1D Lookup'
        */

real_T T2Break[3] = { -20.0, 0.0, 20.0 } ;
        /* Variable: T2Break
        * Referenced by: '<Root>/2D Lookup'
        */

real_T T2Data[9] = { 8.0, 32.0, 20.0, 10.0, 38.0, 36.0, 12.0,
40.0, 46.0 } ;
        /* Variable: T2Data
        * Referenced by: '<Root>/2D Lookup'
        */

#endif

```

In this file, calls to the step function of each variant are conditionally compiled. In the step function, the macros and symbol names of variant parameters are used to form the equation.

```

/* Model step function */

void slxVariantParameters_step(void)
{
    slxVariantParametersCC_Y.Out1 = look2_binlx(rtCP_Constant_MAX_LIFT,
look1_binlx(rtCP_Constant1_SLIDER_POS, T1Break, T1Data, T1Data_dim0
- 1U), T2Break, T2Break, T2Data,
slxVariantParametersCC_ConstP.udLookup_maxIndex, 3U) * -2.0 + 2.0 *
slxVariantParametersCC_U.In1;
}

```

### **Review Dimension Symbol in Generated Code**

Select the `slexVariantParametersCC.c` file from the **Generated Code** pane of the report. In this file, the dimensions of variant parameters `T1Break` and `T1Data` are represented as symbols `T1Break_dim0` and `T1Data_dim0` and are enclosed in C preprocessor conditional statements `#if` and `#elif`. When you compile this code, Simulink evaluates the preprocessor conditionals and preserves the code only for the active values of variant parameters. If you specify the value of `VCtrl` as 1, the condition `VCtrl == 1` evaluates to `true`, and the values enclosed in `V == 1` becomes active during code compilation. You can then specify a different value for `VCtrl` and recompile the same code for any other active values of `T1Break` and `T1Data`.

## Automatic Mask Icon Promotion in Variant Subsystems

This example demonstrates how Simulink® automatically displays the mask icon of the active variant block on the parent Variant Subsystem block. The example shows mask icon promotion for these types of icons:

- Plain text
- Plot
- Built-in icon
- Image

### Explore the Model

Open the example model `slexVariantSubsystemMaskIconPromotion`.

### Variant Subsystem - Automatic mask icon promotion

Copyright 2020-2022 The MathWorks, Inc.

- VSS 1: The mask icon on the active variant block is plain text.

- VSS 2: The mask icon on the active variant block is a plot.

- VSS 3: The mask icon on the active variant block is a built-in icon.

- VSS 4: The mask icon on the active variant block is an image.

### Simulate the Model to View Mask Icon Promotion

On the **Simulation** tab, click **Run** to see how the mask icon of the active choice gets promoted to the parent subsystem.

### Variant Subsystem - Automatic mask icon promotion

## Create Variant Controls Using an In-Memory Enumeration Class

Each variant choice in a Simulink® model is associated with a conditional expression called a *variant control*. The variant control that evaluates to true determines the active variant choice in the model. This example shows how to create variant controls in your model using an in-memory enumeration class. The enumeration is created using the `Simulink.defineIntEnumType` function. You do not need to save the enumeration in a MATLAB® file. In code generation, enumerated types improve readability because condition values are represented as meaningful names instead of literal values.

### Explore the Model

Open the model `slexVariantSetupUsingInMemoryEnums`. It contains two variant choices, `Linear controller` and `Nonlinear controller`. Variant Sink and Variant Source blocks are used to implement the variant regions.

```
open_system('slexVariantSetupUsingInMemoryEnums');
```

Copyright 2020 The MathWorks, Inc.

### Specify the Enumeration Class in the PreLoad Callback of the Model

In this example, the enumeration class `Controller` is defined in the model PreLoad callback function. The enumeration class defines two enumeration members, `Linear` and `Nonlinear`, with underlying integer values 0 and 1. The enumeration definition is exported to a header file named `Controller.h` during code generation. The MATLAB variable `V` is used as the variant control variable to store the currently active variant choice.

```
Simulink.defineIntEnumType('Controller',...
    {'Linear', 'Nonlinear'}, [0;1], 'Description', 'Controller',...
```

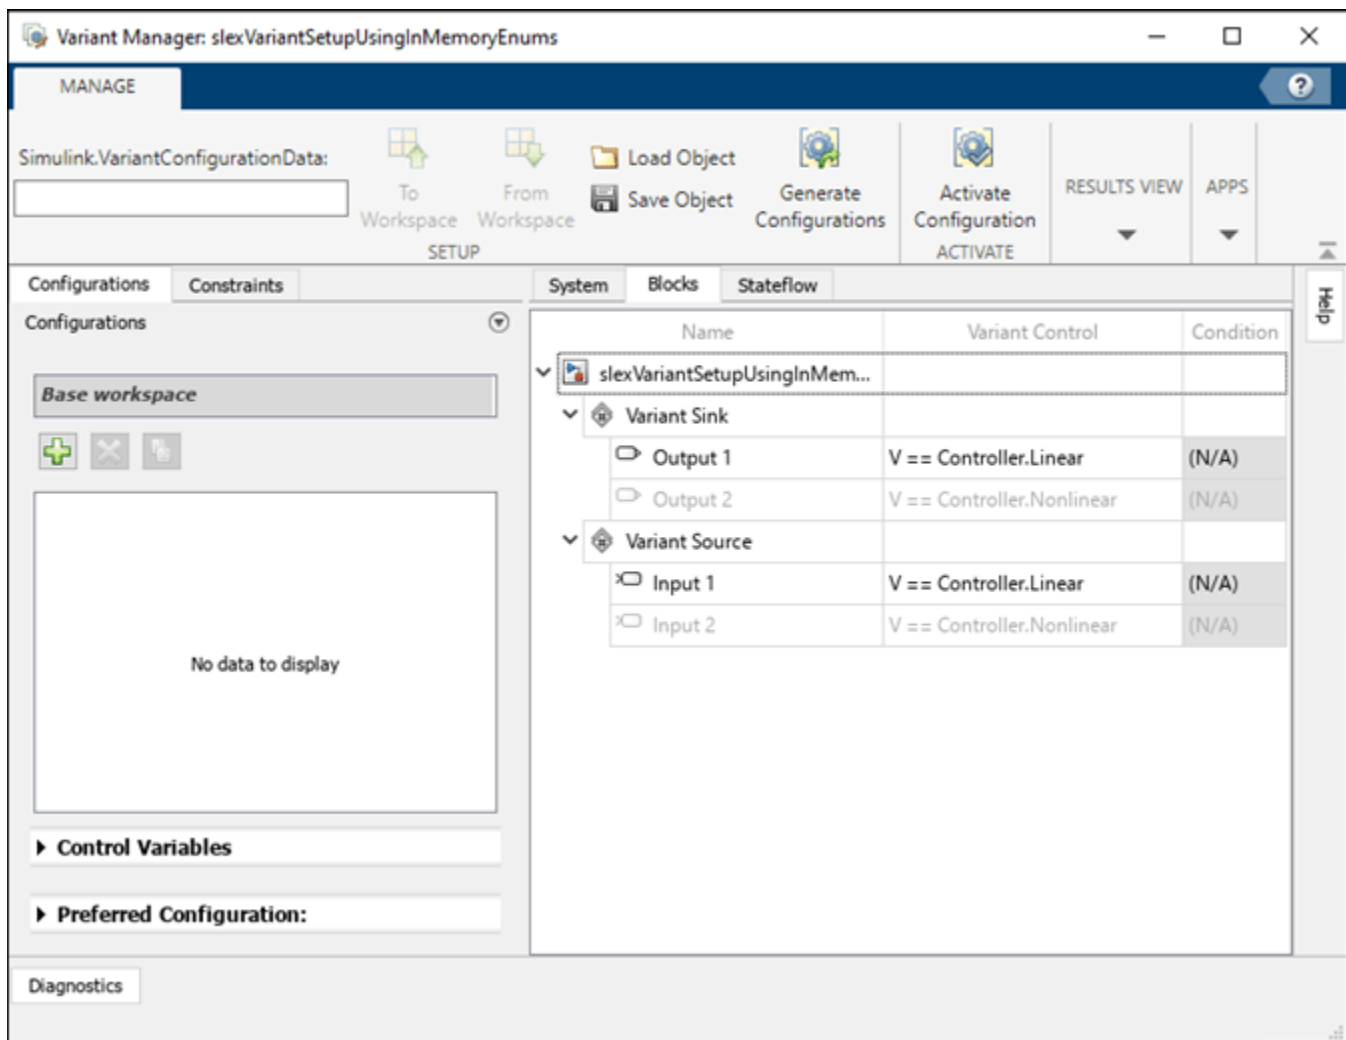

```
'DefaultValue', 'Linear', 'HeaderFile', 'Controller.h', 'DataScope',...
'Exported');
V = Controller.Linear;
```

### Build the Variant Condition Expression

You can set the variant controls from the Variant Manager. To open the Variant Manager, right-click the variant badge on the Variant Sink or Variant Source block and select **Open in Variant Manager**.

You can see how the enumeration members and the control variable is used to create the condition expressions `V == ControllerChoice.Linear` and `V == ControllerChoice.Nonlinear`. All supported Simulink enumerations can be used to build the condition expression. For information on enumerations in Simulink, see “Simulink Enumerations” on page 73-2.

## Create Variant Controls Using MATLAB Enumeration Class

Each variant choice in a Simulink® model is associated with a conditional expression called a *variant control*. The variant control which evaluates to true determines the active variant choice in the model. This example shows how to create variant controls in your model using a MATLAB® enumeration in the variant condition expressions. In code generation, enumerated types improve readability because condition values are represented as meaningful names instead of literal values.

### Explore the Model

Open the model `slexVariantSetupUsingIntEnums`. It contains two variant choices, `Linear controller` and `Nonlinear controller`. Variant Sink and Variant Source blocks are used to implement the variant regions.

Copyright 2020 The MathWorks, Inc.

### Specify the Enumeration Class in a MATLAB® File

You can create an enumeration class by adding an enumeration block to a class definition and saving it in a MATLAB file. In this example, the enumeration `ControllerChoice` (saved in `ControllerChoice.m`) derives from the built-in numeric type `int32`. It defines two enumeration members, `Linear` and `Nonlinear`.

```
classdef ControllerChoice < int32
    enumeration
        Linear (0),
        Nonlinear (1),
    end
end
```

```
%All the methods below can be optionally used to configure
%the enumeration in the generated code
methods (Static = true)
    %% Description of the enumeration
    function retVal = getDescription()
        retVal = 'Controller...';
    end
    %% Default value of the enumeration
    function retVal = getDefaultValue()
        retVal = ControllerChoice.Linear;
    end
    %% Specify whether the generated code imports/exports the definition
    %% of the enum used in the variant control expression
    function retVal = getDataScope()
        retVal = 'Exported';
    end

    %% Get the header file to import from/export to the definition of the
    %% enumeration in the generated code
    function retVal = getHeaderFile()
        retVal = 'Controller.h';
    end
end
end
```

### Create a Variant Control Variable

This example uses the MATLAB variable `V` as the variant control variable to store the variant choice that is currently active.

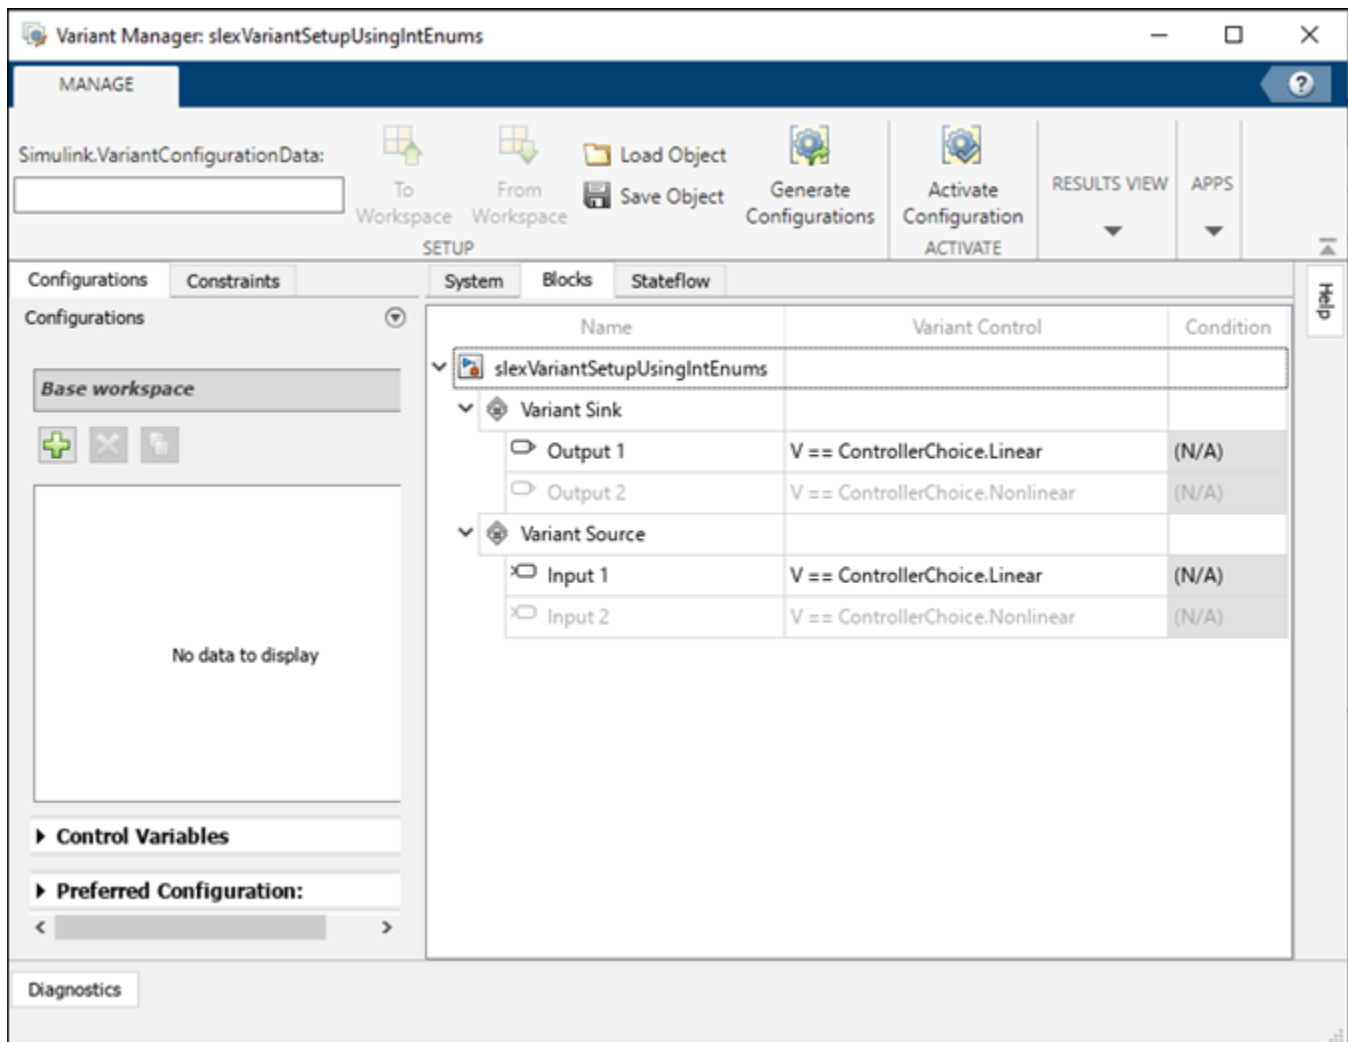

In the MATLAB Command Window, type:

```
V = ControllerChoice.Linear;
```

### Build the Variant Condition Expression

You can set the variant controls from the Variant Manager. To open the Variant Manager, right-click the variant badge on the Variant Sink or Variant Source block and select **Open in Variant Manager**.

You can see how the enumeration members and the control variable is used to create the condition expressions `V == ControllerChoice.Linear` and `V == ControllerChoice.Nonlinear`. All supported Simulink enumerations can be used to build the condition expression. For information on enumerations in Simulink, see “Simulink Enumerations” on page 73-2.

## Provide Variation at Source and Destination of a Signal Using Manual Variant Source and Manual Variant Sink Blocks

This example shows how to use the inline variant blocks — Manual Variant Source and Manual Variant Sink. The Manual Variant Source Block provides variation on the source of a signal. The block is a toggle switch that can have two or more input ports and one output port. Each input port is associated with a variant choice. Only one input port can be active during simulation, which in turn determines the active variant region. Similarly, the Manual Variant Sink block provides variation on the destination of a signal. The block can have two or more output ports and one input port. Only one output port can be active during simulation, and the blocks connected to that port determine the active variant.

### Explore the Model

Open the model `slexVariantManualBlocks`.

```
open_system('slexVariantManualBlocks');
```

Copyright 2016 The MathWorks, Inc.

The model has two inline variant blocks, Manual Variant Source and Manual Variant Sink. Both blocks have two variant regions at their input and output ports, respectively. The blocks indicate the currently active variant using a line that connects the input to the output.

### Switch the Active Variant

To toggle the variant choices in the Manual Variant Source or Manual Variant Sink block, double-click the block. You can also toggle the choices programmatically:

In the MATLAB® Command Window, type:

```
open_system([bdroot, '/Manual Variant Source']);
open_system([bdroot, '/Manual Variant Sink']);
```

### **Access Block Parameters**

To access the block parameters on a Manual Variant Source or Manual Variant Sink block, right-click the block and select **Mask > Mask Parameters**. You can change the number of input ports on a Manual Variant Source block or the number of output ports on a Manual Variant Sink block using the **Number of Choices** parameter.

### **Code Generation Behavior**

Simulink® determines the active variant during model compilation, and the generated code contains only the active choices.

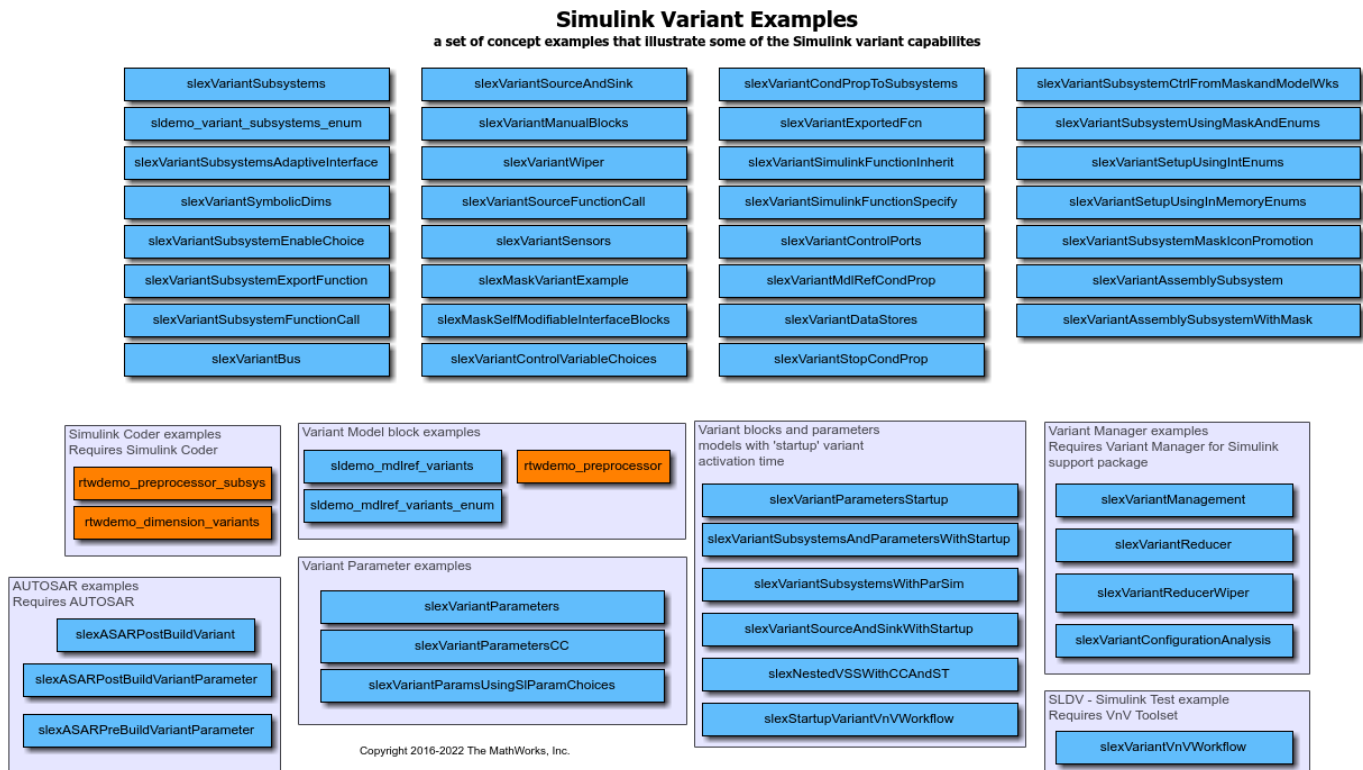

### **See Also**

- Manual Variant Sink
- Manual Variant Source

## Simulink Variant Examples

The `slexVariantExamples` model contains a set of conceptual examples that demonstrate capabilities of Simulink® variants.

```
open_system('slexVariantExamples');
```

## Use Variant Source Block to Receive or Output Function-Call Signals for Simulation and Code Generation

This example shows how a Variant Source block receives function-call signals at its input ports and conditionally merges the signals at its output port. You can use such variant signals to control the execution of conditionally executed subsystems.

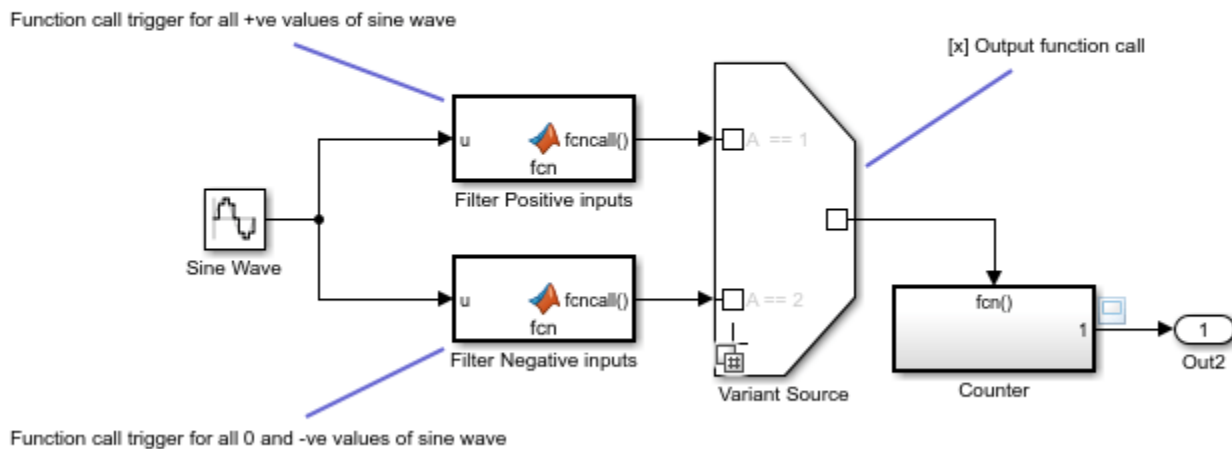

### Explore the Model

Open the model `slexVariantSourceFunctionCall.slx`.

```
open_system('slexVariantSourceFunctionCall.slx');
```

### Variant Source and Function call signal joining

Copyright 2020 The MathWorks, Inc.

The model contains a Variant Source block with the conditions  $A==1$  and  $A==2$  at its input ports.  $A$  is the variant control variable defined in the `PreLoadFcn` model callback. The variant conditions at the input and output ports of the Variant Source block determine the activation and deactivation of the blocks connected to it.

A Sine Wave block is connected to two MATLAB® Function blocks, `Filter Positive inputs` and `Filter Negative inputs`. The `Filter Positive inputs` block generates a function call when the value of the Sine Wave block is positive. The `Filter Negative inputs` block generates a function call when the Sine Wave block value is 0 or negative. The Variant Source block receives these function-call signals at its input ports. The output port of the Variant Source block is connected to a Function-Call Subsystem block named `Counter`. The subsystem is triggered when  $A==1$  and the Sine Wave block outputs positive values, and when  $A==2$  and the Sine Wave block outputs negative values.

The **Output function call** parameter on the `Variant Source1` block is set to `on`. This enables the block to receive and output function-call signals. To enable this option programmatically, use this command:

```
set_param('slexVariantSourceFunctionCall/Variant Source','OutputFunctionCall','on')
```

The **Allow zero active variant controls** parameter on the `Variant Source1` block is set to `on`. When this option is selected and there is no active variant choice, Simulink disables all the blocks connected to the input and output stream of the Variant Source block.

### Simulate the Model

To simulate the model, on the **Simulation** tab, click **Run**. Variant condition propagation determines the active and inactive variant choices.

- When  $A==1$ , `Filter Positive inputs` is active.
- When  $A==2$ , `Filter Negative inputs` is active.

In both cases, the count value in the Function-Call Subsystem, Counter, is incremented. If  $A \sim 1$  and  $A \sim 2$ , then Counter does not execute because the Sine Wave block is inactive.

## Variant Function-Call Signals on Variant Subsystem Output

This example shows how the Variant Subsystem block allows function-call signals from its choice blocks to be merged on its outputs.

**NOTE:** A Variant Subsystem block with more than one variant choice does not support function-call signals on its outputs when the variant activation time is set to `startup`.

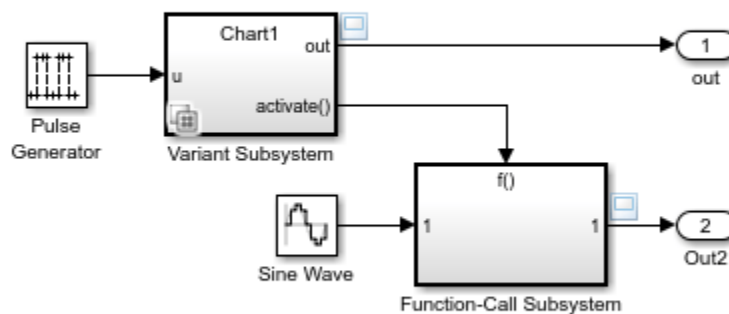

### Explore the Model

Open the model `slexVariantSubsystemFunctionCall`.

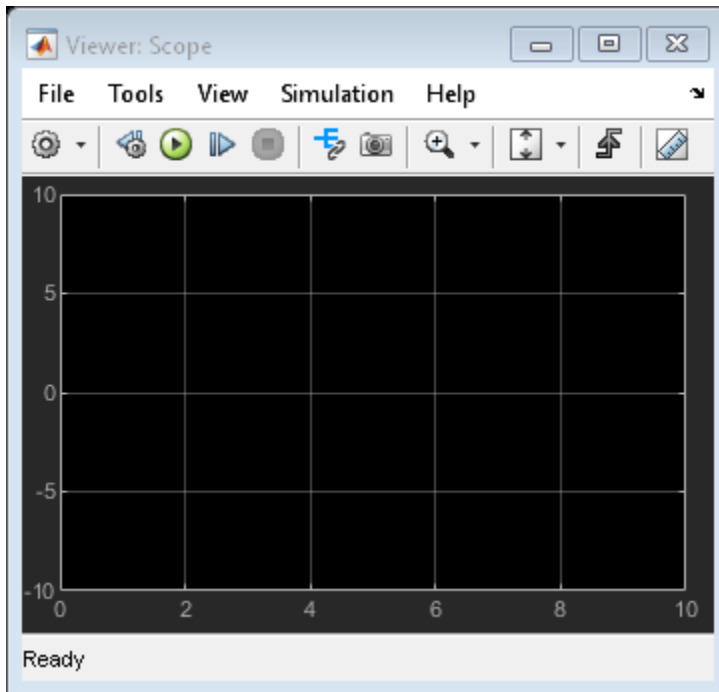

```
open_system('slexVariantSubsystemFunctionCall.slx');
```

### Variant Subsystem with function call signal on outputs

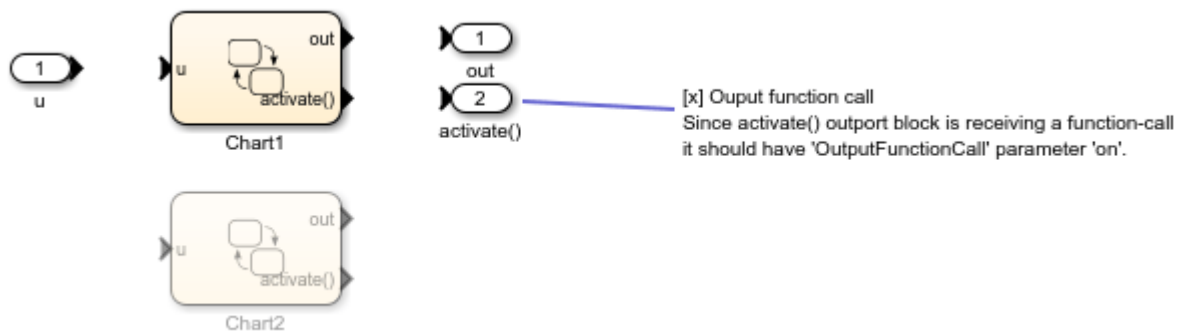

Copyright 2020-2022 The MathWorks, Inc.

The model contains a Variant Subsystem block with two Chart blocks, Chart1 and Chart2, as variant choices. The variant control variable A is defined in the PreLoadFcn model callback. The variant conditions on Chart1 and Chart2 are  $A==1$  and  $A==2$  respectively. A Pulse Generator block is connected to the Variant Subsystem block and all its choices. Chart1 and Chart2 are configured with port names that match the corresponding port names of the Variant Subsystem block.

```
open_system('slexVariantSubsystemFunctionCall/Variant Subsystem');
```

The **Output function call** parameter is selected on the **Signal Attributes** tab of the Block Parameters dialog box of the Outport block named `activate()`. This allows the Outport block of the variant subsystem to emit function-call signals. To enable this option programmatically, use this command:

```
set_param('slexVariantSubsystemFunctionCall/Variant Subsystem/activate()','OutputFunctionCall','on');
```

### Simulate the Model

To simulate the model, on the **Simulation** tab, click **Run**. Variant condition propagation determines the active and inactive variant choices.

- When  $A==1$ , Chart1 is active.
- When  $A==2$ , Chart2 is active.

The output `activate()` gets function-call signal from the choices Chart1 and Chart2. When the Function-Call Subsystem block is triggered, there is a sine wave output at Out2.

```
sim('slexVariantSubsystemFunctionCall.slx');
```

## Verify and Validate Variant Models with Code Compile Activation Time

This example shows how to verify and validate variant models with code compile variant activation time using Simulink® Design Verifier™ and Simulink Test™.

### Overview of Simulink Design Verifier and Simulink Test

Simulink Design Verifier identifies hidden design errors and detects model constructs that result in integer overflow, dead logic, array access violations, and division by zero. It also generates test cases for model coverage. For more information, see “About Systematic Model Verification Using Simulink Design Verifier” (Simulink Design Verifier).

Simulink Test provides tools for authoring, managing, and executing systematic, simulation-based tests of models, generated code, and simulated or physical hardware. You can create nonintrusive test harnesses to isolate the component under test and use the Test Manager to manage and execute user-defined tests. For more information, see “Functional Testing for Verification” (Simulink Test).

**NOTE:** The variant model `slexVariantVnVWorkflow` used in this example uses the code compile variant activation time. For such models, Simulink Test analyzes only the active variant choice by default. You must switch the active variant choice and re-run the tests to analyze all choices. To make the Simulink Test workflow iterative, you can use the `startup` variant activation time and run the test iterations in fast restart. The `startup` variant with the fast restart workflow allows you to switch the active variant choice in each iteration without the need to recompile the model to change the active variant. For an example that shows the Simulink Test workflow with startup variants and fast restart, see “Verify and Validate Variant Models with Startup Activation Time” on page 12-267.

### Explore the Model

Open the model, `slexVariantVnVWorkflow`.

```
open_system('slexVariantVnVWorkflow');
```

### V&V workflow on Variant Subsystems with code compile activation time

Access V&V Workflows	
<p><b>SLDV Run</b> (Double Click)</p>	<p>This button, will invoke SLDV and would generate test cases on different variant subsystems present in this model.</p>
<p><b>Open Simulink Test Manager</b> (Double Click)</p>	<p>This button, will launch the Simulink Test Manager (STM) Window. The Test Manager consists of various functional test cases. The variant choices are selected in the "Parameters" section of the STM. (To run the tests, double click on "Run Tests from STM" button in the Harness model or directly run the test suites through Test Manager).</p>

The model contains a Variant Subsystem block, `ComputeTargetSpeed`, with two variant choices, `ComputeTargetSpeed_Config1` and `ComputeTargetSpeed_Config2`. In this example, we use Simulink Design Verifier to generate test cases that satisfy condition and decision coverage objectives. The model uses a test harness, `slexVariantVnVWorkflow_mdIHarness`, created using Simulink Test and contains requirements based tests for each variant choice. The harness is saved with the model.

- To launch Simulink Design Verifier and automatically generate test cases for the variant choices in the model, double-click the **SLDV Run** button.
- To launch Simulink Test Manager and to view the test suites in the test harness, `slexVariantVnVWorkflow_mdIHarness`, double-click the **Open Simulink Test Manager** button.

### Use Simulink Design Verifier to Generate Test Cases

Simulink Design Verifier analyzes only the active variant choice in a variant model by default. You can write a MATLAB® script to generate test cases for all variant choices.

To view the configuration parameters associated with Simulink Design Verifier for this model:

- In the Simulink Editor, on the **Modeling** tab, click **Model Settings**.
- In the Configuration Parameters dialog box, click **Design Verifier** in the left side pane. In the **Analysis options** section, **Mode** is set to Test Generation. In the **Test Generation** category, **Model coverage objectives** is set to Condition Decision.

In the MATLAB Command Window, run the script corresponding to each of these steps. The **SLDV Run** button in the model automates the same script.

**Step 1:** Set the required Simulink Design Verifier options. For information on the options, see `sldvoptions` (Simulink Design Verifier).

```
modelName='slexVariantVnVWorkflow';
open_system(modelName);
%Create a design verification options object for the model.
opts = sldvoptions(modelName);
%Specify the optimization strategy to use when generating test cases.
opts.TestSuiteOptimization = 'Auto';
%Generate and save a Simulink Design Verifier report.
opts.SaveReport='on';
%Create unique reports for each variant choice.
opts.MakeOutputFilesUnique = 'on';
%Create a harness model generated by the Simulink Design Verifier analysis.
opts.SaveHarnessModel = 'off';
%Specify the analysis mode.
opts.Mode = 'TestGeneration';
```

**Step 2:** Set the variant choice for which tests need to be generated, then analyze the model.

```
%Set the active variant choice to ComputeTargetSpeed_Config1 in the base workspace.
assignin('base','speedConfig',1);
%Specify a file name for the analysis report to indicate the variant choice being analyzed.
opts.ReportFileName = ([modelName 'report_speedConfig1']);
%Track the execution progress from MATLAB command prompt.
disp([newline 'Performing SLDV Run for Model ' modelName ' with variant choice : SpeedConfig 1'])
%Invoke the model update command to activate the variant choice.
set_param(modelName, 'SimulationCommand', 'Update');
%Analyze the model to generate test cases and display messages in the log window.
[status,fileNames] = sldvrun(modelName, opts, true);
```

**Step 3:** Repeat **Step 2** for the variant choice `ComputeTargetSpeed_Config2`.

```
assignin('base','speedConfig',2);
opts.ReportFileName = ([modelName 'report_speedConfig2']);
disp([newline 'Performing SLDV Run for Model ' modelName ' with variant choice : SpeedConfig 2']
set_param(modelName, 'SimulationCommand', 'Update');
[status1,fileNames] = sldvrun(modelName, opts, true);
```

**Step 4:** Display the test generation status.

```
if status & status1
disp('Simulink Design Verifier test generation completed.');
```

After the analysis is complete, the Simulink Design Verifier Results Summary window opens and shows different ways you can use the results. See “Review Analysis Results” (Simulink Design Verifier). To export the generated tests to Simulink Test, click **Export test cases to Simulink Test**.

### Use Simulink Test to Execute Tests

You can use Simulink Test to execute user-defined tests or tests imported from Simulink Design Verifier. To execute the tests and analyze the results, use the Test Manager. Simulink Test analyzes only the active variant choice by default for variant models that use the code `compile` variant activation time. To analyze all variant choices in such models:

1. On the **Apps** tab, in the **Model Verification, Validation, and Test** section, click **Simulink Test**.
2. On the **Tests** tab, click **Simulink Test Manager**.
3. Create a test harness with the required test cases and select the harness model in the Test Manager.
4. Add the variant control variables to a parameter set in the **Parameter Overrides** section.
5. For each test case, change the value of the variant control variables in the parameter set according to each variant choice, then re-run the tests.

### Explore the test harness model

To see the test suites in the harness model, `slexVariantVnVWorkflow_mdIHarness`, double-click the **Open Simulink Test Manager** button in the model.

- In the test suite `CruiseControl_SpeedConfig_1`, the active variant choice is set to `ComputeTargetSpeed_Config1`. In `CruiseControl_SpeedConfig_2`, the active choice is set to `ComputeTargetSpeed_Config2`.

- Select a test suite and click **Run** in the Simulink toolstrip to run the tests. When the test finishes, click the **Results and Artifacts** tab in the Test Manager to review the aggregated results and coverage metrics. See “Perform Functional Testing and Analyze Test Coverage” (Simulink Test).

## Identify Variant Activeness of a Block After Model Compilation

Consider a model with two Variant Subsystem blocks, StartupVSS and UDVSS, with the **Variant activation time** parameter set to `startup` and `update diagram`, respectively. The result of **CompiledVariantInfo** parameter after model compilation is shown for each variant choice.

- The active choice in both StartupVSS and UDVSS has `IsInStartup` set to `on` because the blocks are active in simulation.
- The inactive choice in StartupVSS gets the propagated startup variant activation time from its parent, so `IsInStartup` is `on`.
- The inactive choice in UDVSS has the `update diagram` variant activation time, so `IsInStartup` is `off`.

# Considerations and Limitations for startup Variant Activation Time

## Combining startup and code compile Variant Activation Times in Variant Conditions

Simulink does not support combining variant conditions with startup and code compile variant activation times in a model.

### Case 1: Variant Source Block with startup Activation Time Connected to a Variant Source Block with code compile Activation Time

Consider a model with two Variant Source blocks, VS\_CC and VS\_ST, with the **Variant activation time** parameter set to code compile and startup, respectively.

During model compilation, the VS\_ST block propagates the variant condition, B==2 to the VS\_CC block. So, the propagated variant condition on the VS\_CC block is  $(A == 1 \ \&\& \ B == 2) \ || \ (A == 2 \ \&\& \ B == 2)$ , which combines conditions with startup and code compile activation times. This combination results in a compilation error.

### Case 2: Variant Source Block with startup Activation Time Connected to a Variant Subsystem Block with code compile Activation Time

In this model, a Variant Source block with the **Variant activation time** parameter set to startup is connected to a Variant Subsystem block with the **Variant activation time** parameter set to code compile. The **Propagate conditions outside of variant subsystem** parameter on the Variant Subsystem block is set to on. These settings result in propagation of conditions that combines startup and code compile activation times and produces a compilation error.

**Note** This constraint is applicable to any Simulink block that supports variant condition propagation. For example, you cannot combine `startup` variant conditions with Simulink Function blocks or Initialize, Reset, and Terminate blocks that have the **Generate preprocessor conditionals** parameter set to on. This parameter works similarly to the `code compile` variant activation time. For information on condition propagation with different blocks, see “Condition Propagation Scenarios” on page 12-259.

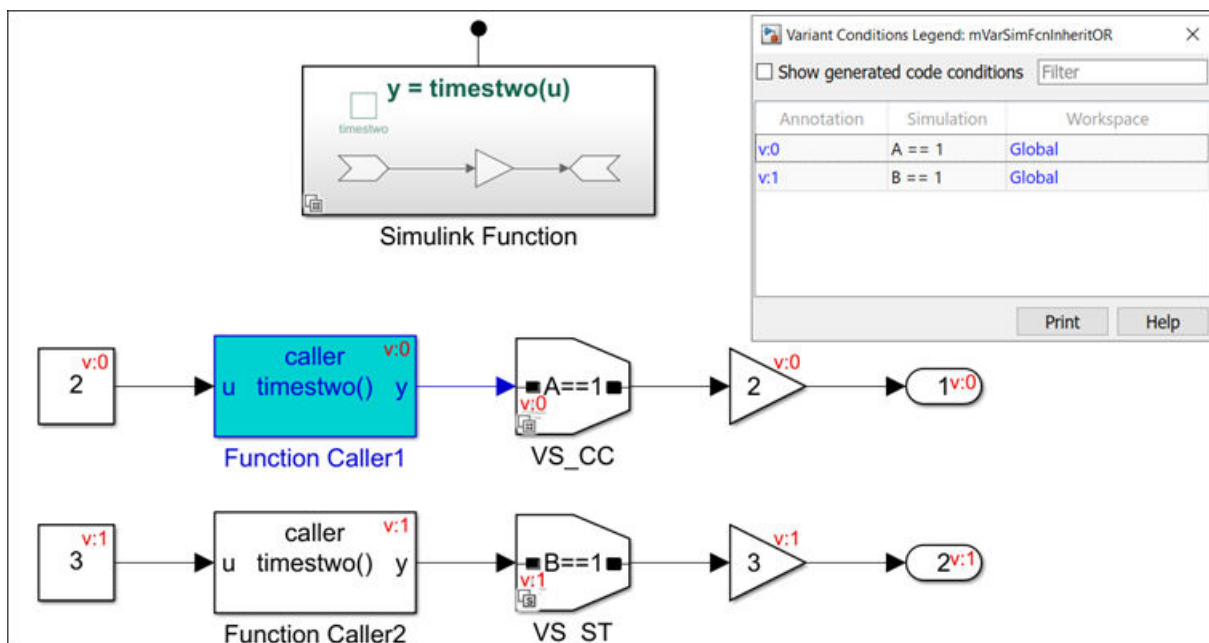

The compilation error for this scenario normally indicates the block that caused the error. If the error message does not indicate the block, then the variant condition that combined `startup` and `code compile` activation times could have propagated to a hidden block that Simulink inserted for internal use. Such blocks are not visible in the model.

### Exception Scenarios That Support Combining Variant Conditions with `startup` and `code compile` Variant Activation Times

These modeling scenarios support combining variant conditions with `startup` and `code compile` activation times:

- Simulink Function blocks that inherit variant conditions from Function Caller blocks in a model. The variant condition assigned to the Simulink Function block is a logical *OR* of the variant conditions propagated to the Function Caller blocks. In such cases, the Function Caller blocks can have `startup` and `code compile` activation times.
- Data Store Memory blocks in a model. These blocks receive a logical *OR* of the variant conditions propagated to the corresponding Data Store Read and Data Store Write blocks in the model. The reader and writer blocks in such models can have `startup` and `code compile` activation times.

In this model, the **Variant control** parameter on the function-call port block in the Simulink Function block is set to (*inherit*). The Function Caller blocks, Function Caller A and Function Caller B, receive variant conditions with `code compile` and `startup` activation times from the connected Variant Source blocks. The Simulink Function block inherits a combination of these variant conditions. This case does not result in a compilation error.

## Use of Variant Control Variables with startup Variant Activation Time in Another Variant Block

You cannot use a variant control variable used in a block with startup activation time in another variant block with a different activation time.

Consider a model with two variant blocks, *VSrc* and *VSink*, with the **Variant activation time** parameter set to **startup** and **update diagram**, respectively. Both the blocks use the same variant control variable, *A*. This results in a compile-time error.

## Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart

This example shows how to run iterative simulations on a fog lamp controller system using fast restart. The fog lamp controller system can operate in Driver Switch mode or in Sensor Connected mode. In Driver Switch mode, the driver controls the intensity of the fog lamps. In Sensor Connected mode, a sensor adjusts the intensity of the fog lamps based on the intensity of ambient light in the external environment.

When you run iterative simulations on the fog lamp controller system with fast restart enabled, Simulink does not need to recompile the model each time you simulate the model. Using fast restart, you compile a model only once. You can then change the control modes or type of fog lamps and simulate the model again without recompiling the model. For more information on fast restart, see “How Fast Restart Improves Iterative Simulations” on page 86-2.

### Model

Open the model `slexVariantSubsystemsAndParametersWithStartup`.

The Variant Subsystem block named `Controller` represents the structural variation. The variant parameter `lightVolt` represents the parameter variation in the model.

The `Controller` subsystem enables you to switch between `Sensors Connected` and `Driver Switch` modes by using the variant control variable `CTRL_MODE`. `Sensors Connected` mode is a sensor-based mode that automatically adjusts the intensity of fog lamps based on the sensor voltage for the varying intensity of ambient light. The `Drivers Switch` mode represents driver manually switching the fog lamps on and off.

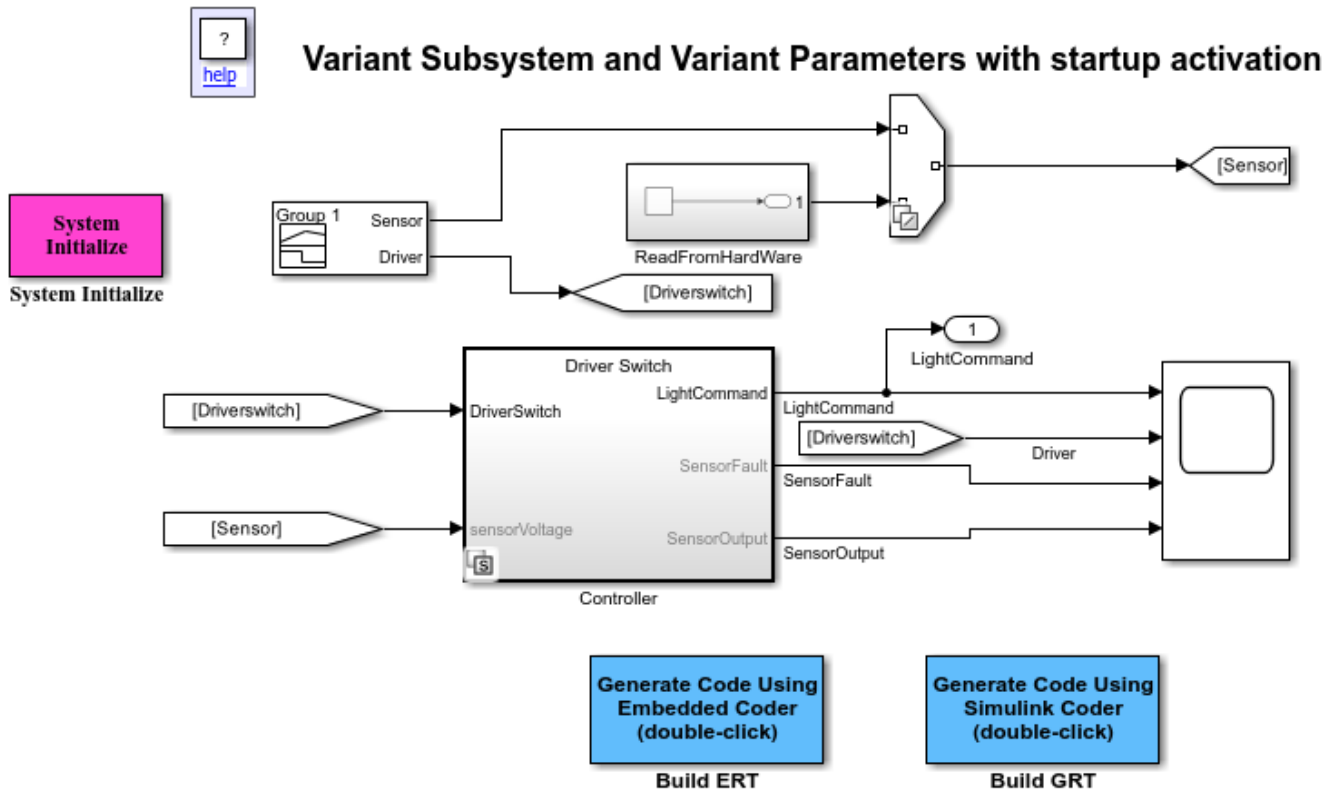

The `lightVolt` parameter contains fog lamp intensities for different types of fog lamps, `LIGHT_TYPE`, in `Sensor Connected` mode. The fog lamp intensities are mapped to the sensor voltage using the 1-D Lookup Table block.

In this example, the variables `CTRL_MODE`, `LIGHT_TYPE`, and `lightVolt` are defined in the `PreLoadFcn` callback. To view or modify the value of these variables, on the **Modeling** tab, select **Model Settings > Model Properties**. On the **Callbacks** tab, in the **Model callback** pane, select `PreLoadFcn`.

To run iterative simulations using fast restart, the activation time of the `Controller` block and `lightVolt` is set to `startup`.

```
open_system('slexVariantSubsystemsAndParametersWithStartup')
```

Copyright 2021-2022 The MathWorks, Inc.

### Explore Model Inputs and Outputs

The Signal Builder block generates two signal groups Sensor and Driver that are provided as inputs to the Controller subsystem block.

- In the Sensor signal group, the x-axis represents time in seconds. The y-axis represents the sensor voltages for varying ambient light intensities in external environment.
- In the Driver signal group, the x-axis represents time in seconds. The y-axis represents the driver action. 1 indicates that the driver has turned on the fog lamps and 0 indicates that the driver has turned off the fog lamps.

In this example, the driver turns on the fog lamps for first two seconds. During this time, the output is a delayed driver switch signal. From two seconds onward, the sensor generates voltages based on the intensity of the ambient light. The sensor voltage is then provided as an input to the 1-D Lookup Table block in the Sensor Connected mode. The lookup table then maps the sensor voltages to the fog lamp intensities in `lightVolt`. `lightVolt` has multiple values of fog lamp intensities that vary for different types of fog lamps, which are represented by `LIGHT_TYPE`.

The Scope block outputs these parameter values. The time axis is in seconds.

- **LightCommand:** In the Driver Switch mode, **LightCommand** is a delayed driver switch signal. The **LightCommand** signal is high if the **Driver** signal is high, and **LightCommand** is low if the **Driver** signal is low. In other words, when the driver turns on the fog lamps, the fog lamps are illuminated. When the driver turns off the fog lamps, the fog lamps turn dim.

In the Sensor Connected mode, **LightCommand** is same as **SensorOutput**, provided the sensor is working. **LightCommand** is high if **SensorOutput** output is high, and **LightCommand** is low if **SensorOutput** is low. **LightCommand** is independent of the **Driver** signal. However, **LightCommand** honors the **Driver** signal if the sensor is faulty.

- **Driver:** 0 indicates that the driver has turned off the fog lamps. 1 indicates that the driver has turned on the fog lamps.
- **SensorFault:** A sensor voltage between 0.5 and 5 indicates that the sensor is working correctly and the **SensorFault** is 0.
- **SensorOutput:** Fog lamp intensities correspond to the sensor voltages specified in the 1-D Lookup Table block.

### Iteratively Simulate Fog Lamp Controller System in Driver Switch and Sensor Connected Modes

To simulate the model in Driver Switch mode, perform these settings:

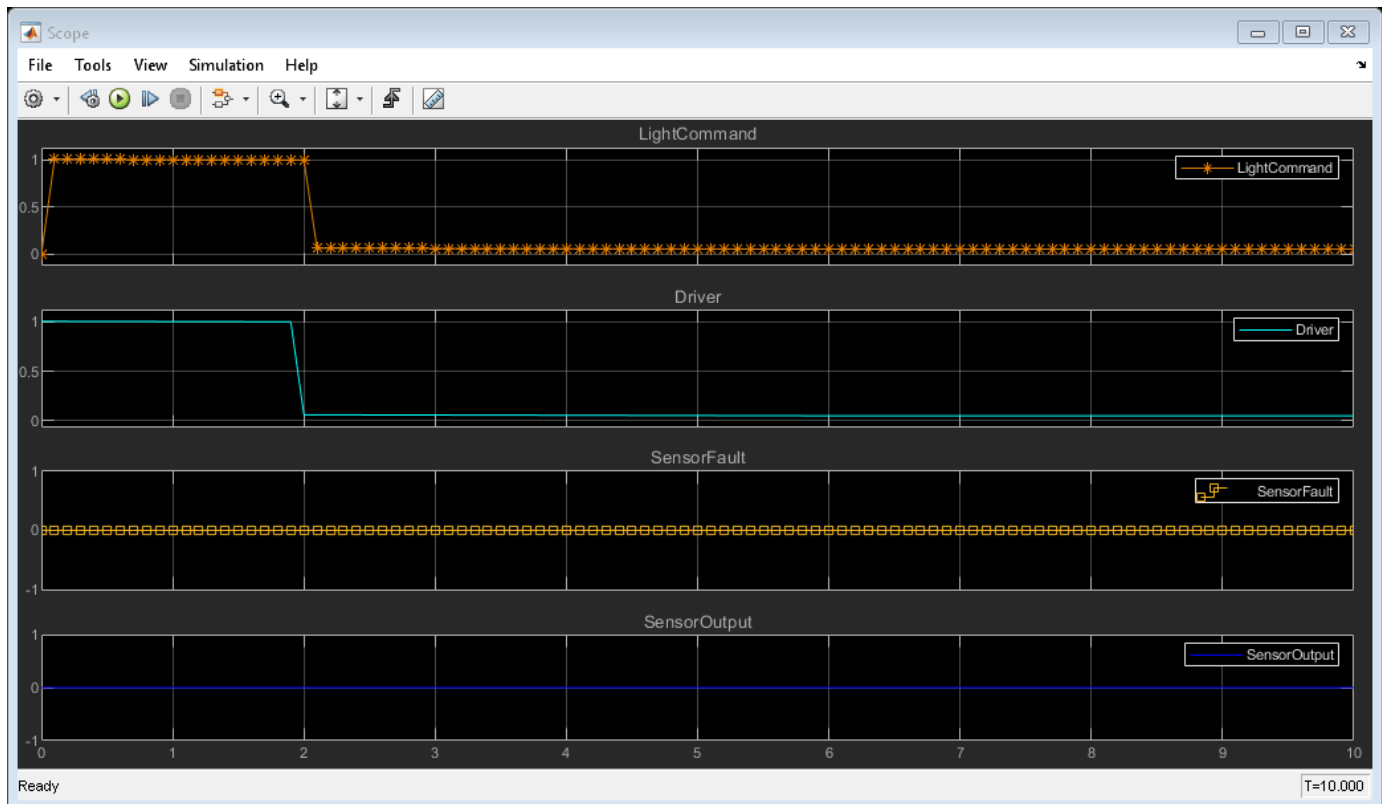

1. To enable fast restart, on the **Simulation** tab, in the **Simulate** section, click **Fast Restart**.
2. In the MATLAB® Command Window, set **CTRL\_MODE** to 2 to activate the Driver Switch mode. Check that the activation time of the Controller subsystem is set to **startup**.

```
CTRL_MODE.Value = int32(2);
```

3. Run the simulation. Use the Scope block to visualize the results.

In the Driver Switch mode, the fog lamps are turned on and off based on the action performed by the driver. So, the `LightCommand` is high when the Driver signal is high and the `LightCommand` is low when the Driver signal is low. The sensors are not active in this mode and hence the value of `SensorFault` and `SensorOutput` is 0. For more information, see Model Inputs and Outputs.

```
sim('slexVariantSubsystemsAndParametersWithStartup');
open_system('slexVariantSubsystemsAndParametersWithStartup/Scope')
```

4. Now, simulate the model in Sensor Connected mode by changing the value of `CTRL_MODE` to 1. The type of fog lamp, `LIGHT_TYPE`, is set to `LightType.Type1`.

```
CTRL_MODE.Value = int32(1);
```

5. Run the simulation again. Because fast restart is enabled, Simulink skips compilation and directly starts simulating the model. With fast restart enabled, recompiling is not required for accurate results when there is no structural change in the model. Use the Scope block to visualize the results.

`LightCommand` is high until `SensorOutput` is high and is independent of the `Driver` signal. For more information, see Model Inputs and Outputs.

```
sim('slexVariantSubsystemsAndParametersWithStartup');
open_system('slexVariantSubsystemsAndParametersWithStartup/Scope')
```

### Iteratively Simulate Fog Lamp Controller System with Varying Ambient Light in Sensor Connected Mode

1. To enable fast restart, on the **Simulation** tab, in the **Simulate** section, click **Fast Restart**.
2. In the MATLAB Command Window, set CTRL\_MODE to 1 to activate the Sensors Connected mode and set the value of LIGHT\_TYPE to LightType.Type1.

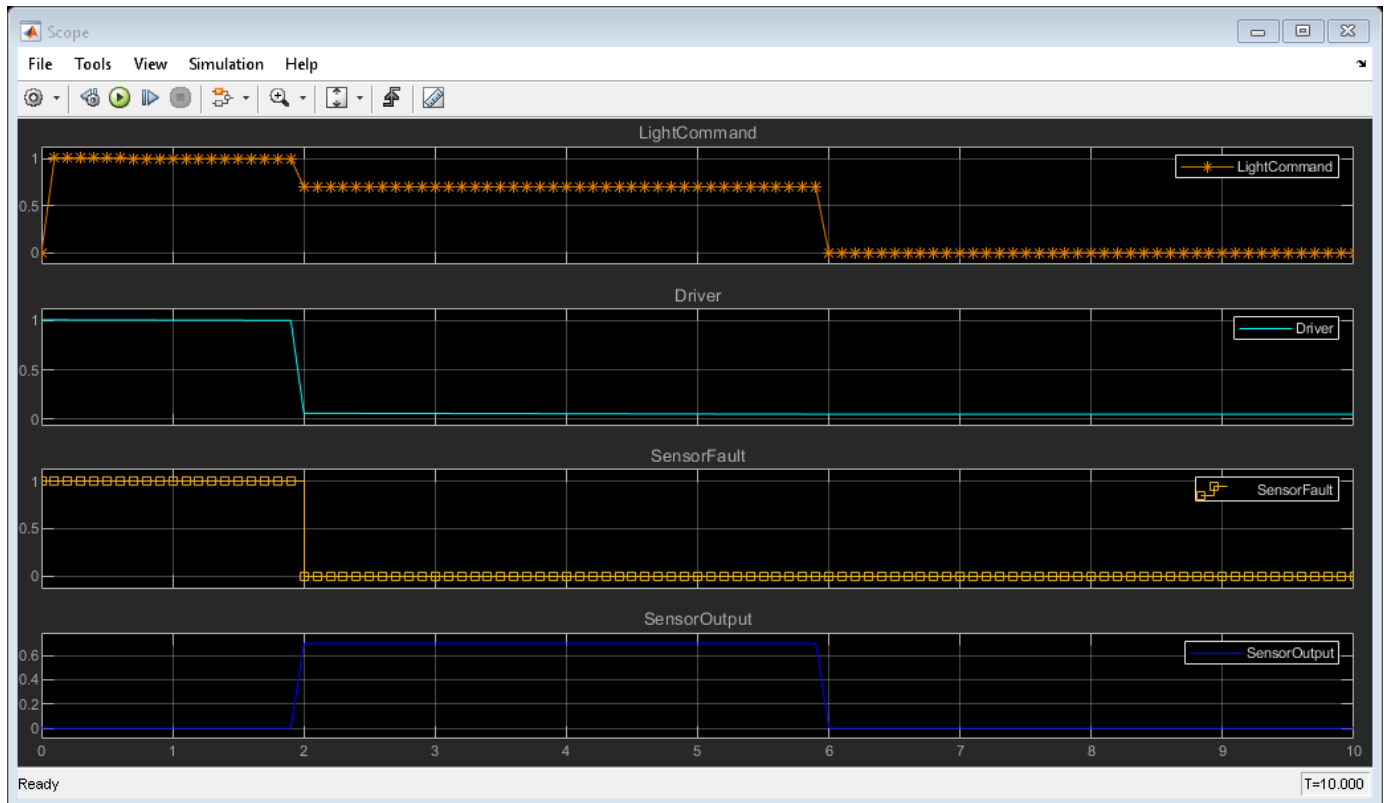

Check that the activation time of lightVolt is set to startup.

```
CTRL_MODE.Value = int32(1);
LIGHT_TYPE.Value = LightType.Type1;
```

3. Run the simulation. Use the Scope block to visualize the results.

For the first two seconds, the Driver signal from the Signal Builder block is high, so the LightCommand signal is also high. From two seconds onward, the sensor is working and generates SensorOutput based on the sensor voltages from the Signal Builder block. LightCommand is high until SensorOutput is high and is independent of the Driver signal. For information on how sensor voltages are mapped to SensorOutput, see Model Inputs and Outputs.

```
sim('slexVariantSubsystemsAndParametersWithStartup');
open_system('slexVariantSubsystemsAndParametersWithStartup/Scope')
```

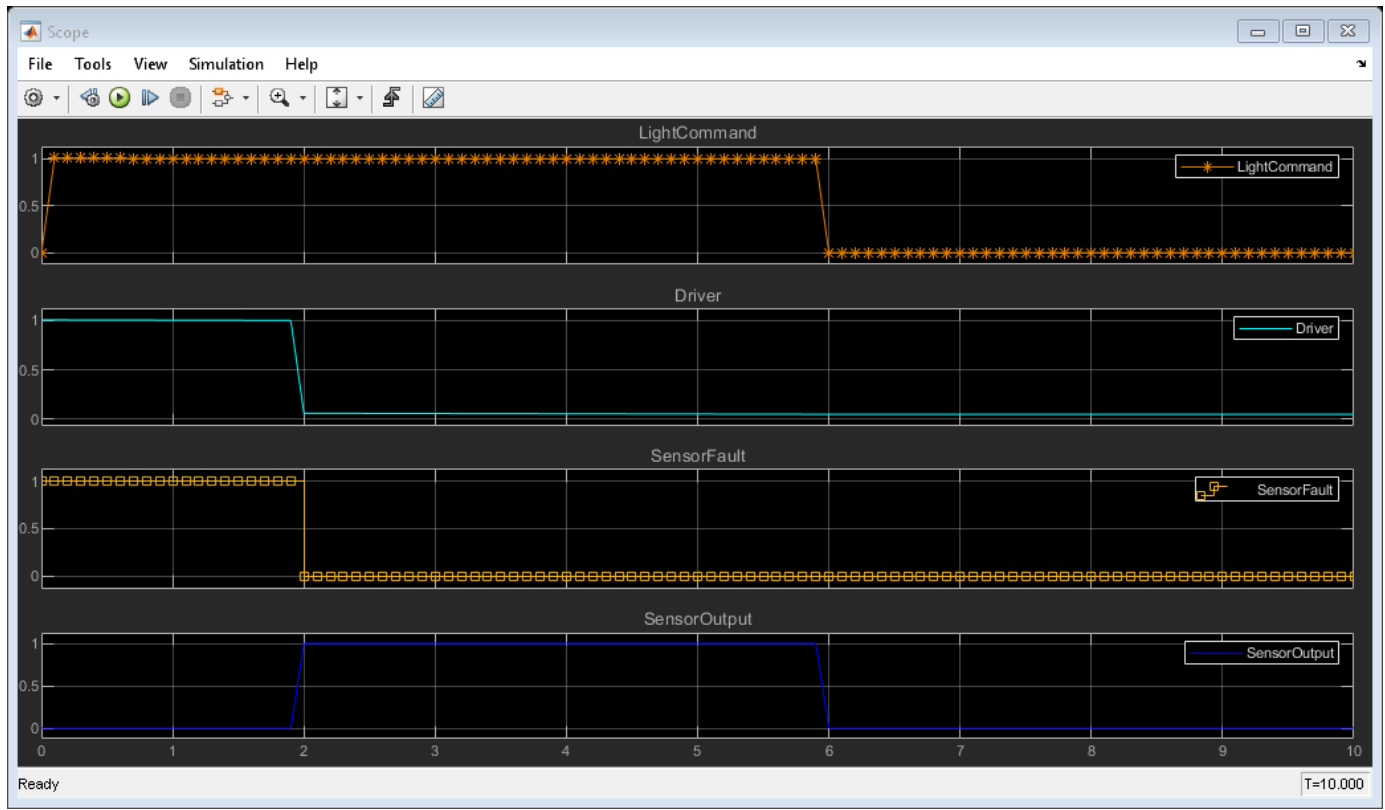

4. Change the value of `LIGHT_TYPE` to `LightType.Type2` and run the simulation again. Because fast restart is enabled, Simulink skips compilation and immediately starts simulating the model. Recompiling is not required for accurate results when no structural changes occur in the model.

```
LIGHT_TYPE.Value = LightType.Type2;
```

Use the Scope block to visualize the results. For more information, see Model Inputs and Outputs.

```
sim('slexVariantSubsystemsAndParametersWithStartup');
open_system('slexVariantSubsystemsAndParametersWithStartup/Scope')
```

## Generate Code from an Export Function Model

This example shows how to simulate and generate code for an export function model.

### Model

Open the model `slxVariantExportedFcn.slx`. The model contains a Variant Source block with the condition  $V == 1$ , where  $V$  is a `Simulink.Parameter` object which is defined in the `PostLoadFcn` in **File > Model Properties > Callbacks**. The value of  $V$  is set to 1.

The condition on the function call-signal specifies the condition for **SubA**. This condition is propagated to the blocks connected to the input ports of **SubA** and to the blocks connected to the output ports of **SubA**.

Copyright 2016 The MathWorks, Inc.

### Simulate the Model

When you simulate the model, the **SubA** will be inactive because  $V == 1$ . You will notice that **Out1** is also inactive. However **In2** remains active because **SubB** is active and **In2** is also connected to **SubB**. If you disconnect the line between **In2** and **SubB**, then **In2** will be inactive.

**Generate Code with code compile and startup**

Generate code with the Variant activation time set to code compile.

```
rtwbuild('slexVariantExportedFcn');
```

View the code generation report. The report includes links to model files such as `slexVariantExportedFcn.c` and associated utility and header files.

The figure contains a portion of the generated code, `slexVariantExportedFcn.c`. You will notice that `In1` is guarded, internally and externally, by the preprocessor conditionals(`#if`). `In3` is void because it does not receive any condition.

```

Code
slexVariantExportedFcn.c Search
29 static RT_MODEL_slexVariantExportedF_T slexVariantExportedFcn_M_;
30 RT_MODEL_slexVariantExportedF_T *const slexVariantExportedFcn_M =
31     &slexVariantExportedFcn_M_;
32
33 /* Model step function */
34 #if V == 1
35
36 void In1(void)
37 {
38
39 #if V == 1
40
41     /* RootInportFunctionCallGenerator generated from: '<Root>/In1' */
42     /* Outputs for Function Call SubSystem: '<Root>/SubA' */
43     /* Output: '<Root>/Out1' incorporates:
44      * Constant: '<S1>/Constant'
45      * Gain: '<S1>/Gain3'
46      * Inport: '<Root>/In2'
47      * Sum: '<S1>/Add'
48      */
49     slexVariantExportedFcn_Y.Out1 = (slexVariantExportedFcn_U.In2 + 2.0) * 3.0;
50
51     /* End of Outputs for SubSystem: '<Root>/SubA' */
52     /* End of Outputs for RootInportFunctionCallGenerator generated from: '<Root>/In1' */
53 #endif
54
55 }
56
57 #endif
58
59 /* Model step function */
60 void In3(void)
61 {
62     /* RootInportFunctionCallGenerator generated from: '<Root>/In3' incorporates:
63      * SubSystem: '<Root>/SubB'
64      */
65     /* Output: '<Root>/Out2' incorporates:
66      * Constant: '<S2>/Constant'
67      * Gain: '<S2>/Gain3'
68      * Inport: '<Root>/In2'
69      * Sum: '<S2>/Add'

```

When you change the Variant activation time from code compile to startup, you must change the storage class specification of V to 'ExportedGlobal'.

```
V.CoderInfo.StorageClass = 'ExportedGlobal';  
rtwbuild('slexVariantExportedFcn')
```

View the code generation report. The figure contains a portion of the generated code, `slexVariantExportedFcn.c`. You will notice that the generated code contains the regular `if` statements.

```

Code
slexVariantExportedFcn.c Search
34 ExtY_slexVariantExportedFcn_T slexVariantExportedFcn_Y;
35
36 /* Real-time model */
37 static RT_MODEL_slexVariantExportedF_T slexVariantExportedFcn_M;
38 RT_MODEL_slexVariantExportedF_T *const slexVariantExportedFcn_M =
39     &slexVariantExportedFcn_M;
40
41 /* Model step function */
42 void In1(void)
43 {
44     if (V == 1) {
45         /* RootInportFunctionCallGenerator generated from: '<Root>/In1' */
46         /* Outputs for Function Call SubSystem: '<Root>/SubA' */
47         /* Output: '<Root>/Out1' incorporates:
48          * Constant: '<S1>/Constant'
49          * Gain: '<S1>/Gain3'
50          * Inport: '<Root>/In2'
51          * Sum: '<S1>/Add'
52          */
53         slexVariantExportedFcn_Y.Out1 = (slexVariantExportedFcn_U.In2 + 2.0) * 3.0;
54
55         /* End of Outputs for SubSystem: '<Root>/SubA' */
56         /* End of Outputs for RootInportFunctionCallGenerator generated from: '<Root>/In1' */
57     }
58 }
59
60 /* Model step function */
61 void In3(void)
62 {
63     /* RootInportFunctionCallGenerator generated from: '<Root>/In3' incorporates:
64      * SubSystem: '<Root>/SubB'
65      */
66     /* Output: '<Root>/Out2' incorporates:
67      * Constant: '<S2>/Constant'
68      * Gain: '<S2>/Gain3'
69      * Inport: '<Root>/In2'
70      * Sum: '<S2>/Add'
71      */
72     slexVariantExportedFcn_Y.Out2 = (slexVariantExportedFcn_U.In2 + 1.0) * 3.0;

```

## Variant Condition Propagation Overview

### Automatically Identify Variant Regions Using Variant Condition Propagation

Simulink determines the model components that are active during simulation by the process of variant condition propagation. This process evaluates the variant controls specified on the variant blocks and automatically propagates the variant conditions to the connecting blocks. Variant conditions can propagate through signal lines, buses, and function calls to reach other blocks in the model. The process deactivates the model components associated with the inactive choices, and they are not included in simulation. You can control condition propagation to define variant regions in the model.

### Visualize Propagated Variant Conditions Using Variant Conditions Legend

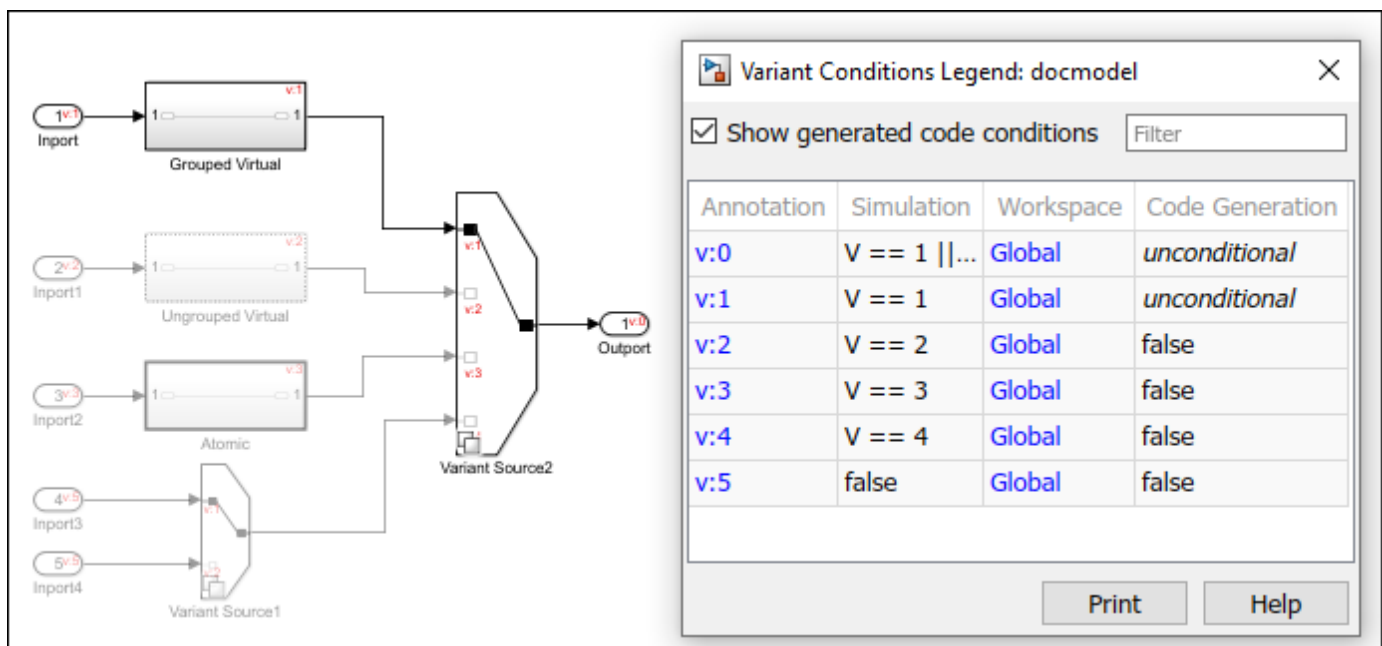

You can use the Variant Conditions Legend to visualize the propagated variant conditions that activate each variant choice. Simulink annotates model components if there are variant conditions on them, and the Variant Conditions Legend displays the condition that corresponds to each annotation.

Consider this model containing multiple variant choices feeding into Variant Source blocks. A specific variant condition activates each variant choice.

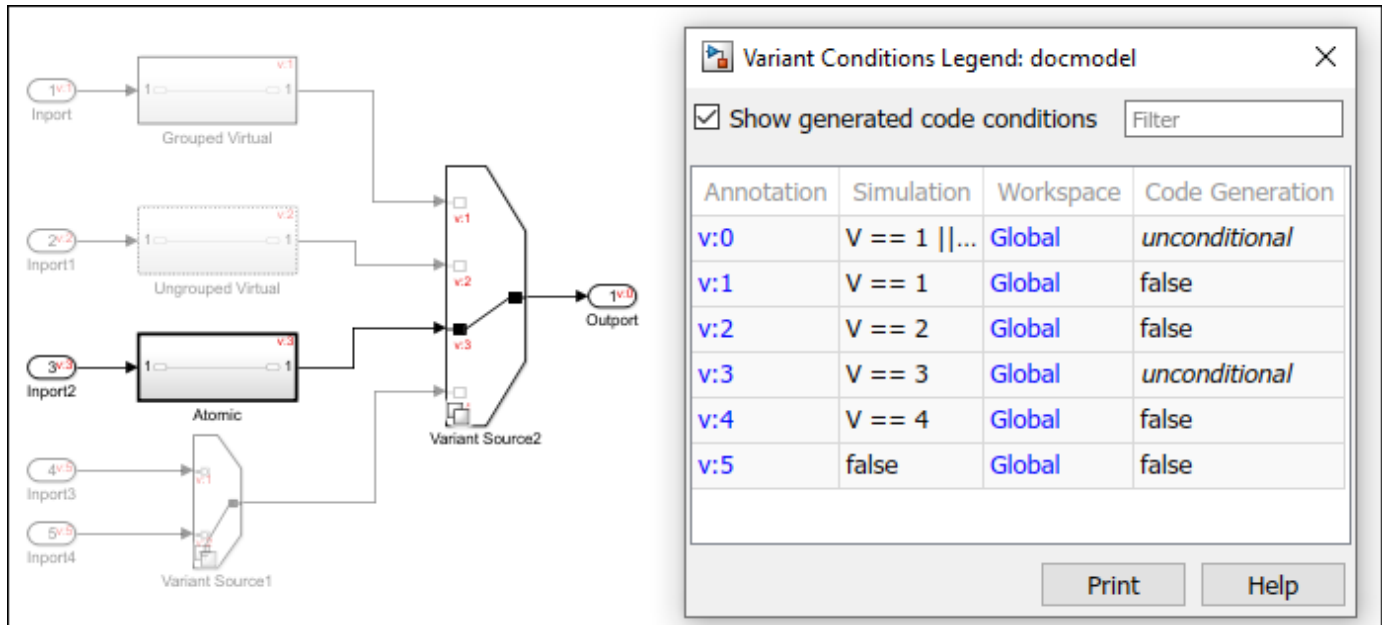

To view the Variant Conditions Legend, on the **Debug** tab, select **Information Overlays > Variant Legend**.

**Note** If **Variant Legend** is not available, on the **Debug** tab, select **Information Overlays > Variant Conditions**.

The Variant Conditions Legend dialog box appears. By default, the Variant Conditions Legend displays the variant condition annotation, the variant condition during simulation, and the source of the variant condition variables. To view the variant condition in the generated code, select **Show generated code conditions**.

The variant conditions on the blocks are annotated as  $v:C$ , where  $v$  is the variant semantic indicator and  $C$  represents the variant condition index. You can click through the hyperlinked variant annotations to observe which parts of the model the condition corresponds to. For example, if you click  $v:3$ , the parts of the model that have the condition  $V==3$  are highlighted as shown in this image.

When you pause on a block that has a variant condition, the tooltip displays the variant annotation and the related variant condition for the block. To view the variant condition annotation tooltip, the **Variant Condition** option must be selected.

In the legend, the source of the variant condition variables are also displayed. The variables can originate from a mask, a model, or a base workspace. All the variables used in a block must originate from the same source. In a model, the variables originating from different mask workspaces can have the same name and have different values. To observe the source of the variables, click the hyperlinked workspaces.

**Note** With the **Variant activation time** parameter set to `update diagram`, the source of variables displayed for inactive choices may be incorrect. The inactive choices are removed prior to propagation of signal attributes and are therefore not evaluated.

To view the **Variant Condition Legend** programmatically, use the `variantLegend` function in the MATLAB Command Window.

Variant condition annotations have these properties:

- There are no annotations on unconditional blocks.
- To reduce clutter, the legend only displays the final computed conditions. For example, if you enter a variant condition in a Variant Source block, that condition appears in the annotations only when you apply your changes.
- The conditions in the legend are sorted during display.

- In the legend, a condition is set to `false` if the blocks associated with that condition are never active.

For example, the `Inport4` block is connected to the `Variant Source1` block, whose condition is `V==1`. `Variant Source1` is connected to the `Variant Source2` block, which activates `Variant Source1` only when `V==4`. Therefore, `Inport4` can only be active when `V==1 && V==4`, a condition that is always `false`.

- In the legend, the `(default)` keyword is displayed as negated condition.

## Condition Propagation Scenarios

This table lists the topics that explain how condition propagation works with different model components.

Block	Scenario	Topic
Variant Subsystem block	Propagate conditions outside a Variant Subsystem block.	"Propagate Variant Conditions Outside Variant Subsystems" on page 12-125
	Adaptive interface capability of a Variant Subsystem block.	
	Propagate conditions to conditionally executed subsystem blocks such as Enable, Trigger, Reset, and Function-Call Subsystem when they are used as variant choices within a Variant Subsystem block.	"Use Variant Subsystem Blocks with Conditionally Executed Subsystems" on page 12-135
	Use Variant Subsystem block to create an export-function model.	
	Output variant function-call signals at the outports of a Variant Subsystem.	"Variant Function-Call Signals on Variant Subsystem Outport" on page 12-232
Variant Source and Variant Sink blocks	Propagate conditions from Variant Source and Variant Sink blocks.	"Variant Condition Propagation with Variant Sources and Sinks" on page 12-116
Variant Source block	Propagate conditions to conditionally executed subsystem blocks such as Enable, Trigger, Reset, and Function-Call Subsystem .	"Propagate Variant Conditions from Variant Source Blocks to Conditionally Executed Subsystems" on page 12-199
	Output variant function-call signals at the outport of a Variant Source.	"Use Variant Source Block to Receive or Output Function-Call Signals for Simulation and Code Generation" on page 12-229

Block	Scenario	Topic
	Propagate conditions to virtual and nonvirtual subsystems.	"Propagate Variant Conditions from Variant Source Blocks to Subsystem Blocks" on page 12-180
	Propagate conditions to Model blocks.	"Variant Condition Propagation with Model Block" on page 12-120
	Propagate conditions to bus element blocks.	"Variant Condition Propagation with Bus" on page 12-123
Variant Connector block	Propagate conditions to components within a physical network.	Variant Connector (Simscape)
Simulink Function blocks	Specify or inherit variant conditions on Simulink Function blocks.	"Variant Condition Propagation with Simulink Function block" on page 12-121
Initialize, Reset, and Terminate blocks	Propagate conditions to Initialize, Reset, and Terminate blocks.	"Variant Condition Propagation with Initialize, Reset, and Terminate Blocks" on page 12-122
Variant models	Stop propagation of variant conditions in a model.	"Control Variant Condition Propagation" on page 12-196

## Simulate Variant Subsystem with Startup Activation Using parsim

This example shows how you can simulate a Variant Subsystem with startup activation time using parsim. You can simulate multiple configurations in parallel with the **Variant activation time** set to startup using parsim. Each configuration will have one active variant.

### Model

Open the model `slexVariantSubsystemsWithParSim`. The model contains a variant subsystem block **Controller** with two choices **Linear Controller** and **Nonlinear Controller** with the conditions `VSS_MODE == 1` and `VSS_MODE == 2` respectively. Set the Variant activation time to startup in the **Block Parameters** dialog.

```
open_system('slexVariantSubsystemsWithParSim.slx');
```

Copyright 2021 The MathWorks, Inc.

### Step 1 - Setup the active variant selection for each variant choice

Setup the active variant selection for each variant choice and set the number of simulations to be equal to the number of variant choices. In this example model, we have two variant choices.

```
mdl = 'slexVariantSubsystemsWithParSim';
numSims = 2;
varControl = [1,2];
```

### Step 2 - Create the SimulationInput object

Create the `SimulationInput` object for each simulation run and set the variant control value for each run.

```
in(1:numSims) = Simulink.SimulationInput(mdl);
for idx = 1:numSims
    in(idx) = in(idx).setModelParameter('SimulationMode', 'rapid', ...
```

```
        'RapidAcceleratorUpToDateCheck', 'on', ...  
        'SaveTime', 'on', ...  
        'SaveOutput', 'on');  
    in(idx) = in(idx).setVariable('VSS_MODE',varControl(idx));  
end
```

### Step 3 - Use `parsim` to simulate the model

Use `parsim` to simulate the model in parallel for each variant control value.

```
out = parsim(in, 'ShowProgress', 'on');  
  
[31-Aug-2022 06:37:12] Checking for availability of parallel pool...  
Starting parallel pool (parpool) using the 'Processes' profile ...  
Connected to the parallel pool (number of workers: 12).  
[31-Aug-2022 06:40:44] Starting Simulink on parallel workers...  
[31-Aug-2022 06:41:12] Configuring simulation cache folder on parallel workers...  
[31-Aug-2022 06:41:14] Loading model on parallel workers...  
[31-Aug-2022 06:41:24] Running simulations...  
[31-Aug-2022 06:42:56] Completed 1 of 2 simulation runs  
[31-Aug-2022 06:42:56] Completed 2 of 2 simulation runs  
[31-Aug-2022 06:42:56] Cleaning up parallel workers...
```

You can simulate the model using `parsim` with `SetupFcn`. This is optional. If you run `parsim` without `SetupFcn`, set the `RapidAcceleratorUpToDateCheck` to `on`.

```
    out = parsim(in, 'ShowProgress', 'on', 'SetupFcn', @() slxVariantSubsystemsWithParSim_script_
```

The setup script, `slxVariantSubsystemsWithParSim_script_setup.m` builds the rapid acceleration target for the model.

### Step 4 - Plot the output values

Now plot the results from each run.

```
for i = 1:numSims  
    simOut = out(i);  
    t = simOut.tout;  
    y = simOut.yout;  
    plot(t, y)  
    hold all  
end
```

## Known Limitations of startup variant activation time

The following are currently not supported with `startup` variant activation time:

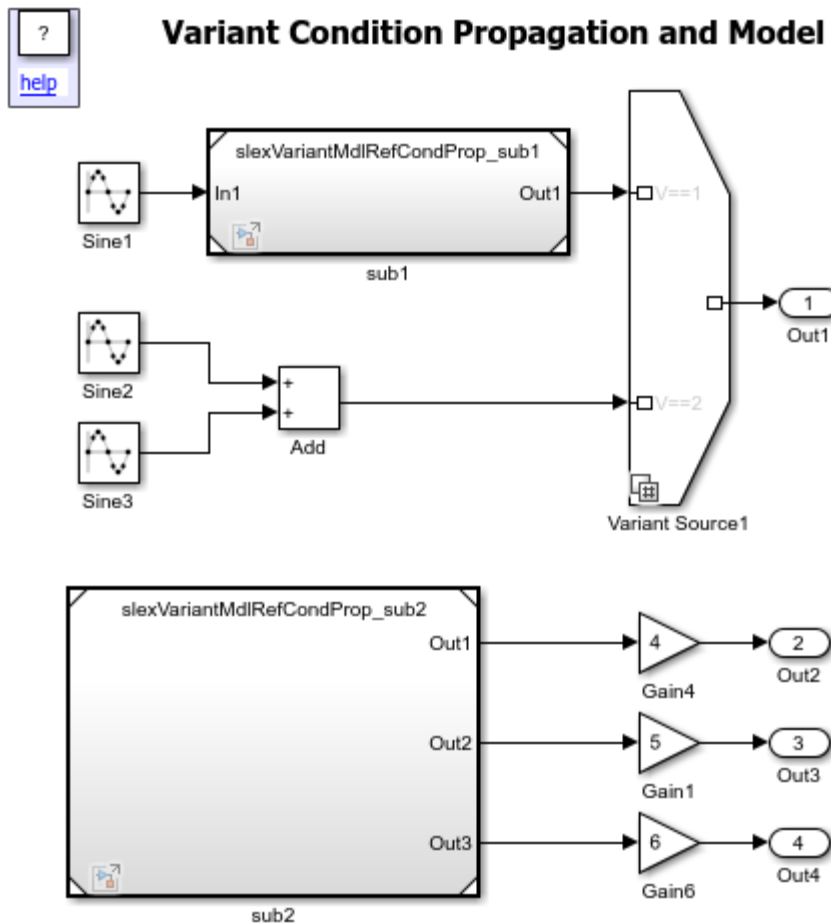

- Blocks with continuous states when they receive the `startup` variant condition.
- Blocks with Simscape physical connection ports.
- The variant condition expression can contain only "=", "~=", "&&", "||" and "~" operators.
- `Simulink.Parameter` with custom storage classes having `const` and `macro` types are not supported for ERT based code generation.
- Variant conditions with mix of code compile and startup gets combined during variant activation during propagation. Variant condition propagation with mix of code compile (`#if`) and startup (`if`) is not supported. Whenever code compile and startup gets combined it results in update diagram error. For more information, see "Considerations and Limitations for startup Variant Activation Time" on page 12-241.
- Multi-input variant source with '**Output function call**' selected to merge function-call signals is not supported.
- A Variant Subsystem block with `startup` activation time and more than one variant choice does not support function-call signals on its outports.
- Variant Manager constraints are not validated when variant control variable values are changed as part of fast restart workflows for variant blocks with `startup` activation time. For information on constraints, see "Define Constraints for Variant Configurations" on page 89-16.

## Simulate a Protected Model with Code Compile or Startup Activation Time

This example shows you how to simulate a protected model in the code compile and startup variant activation times.

### Model

Open the model `slexVariantMdlRefCondProp.slx`. The model contains two Model blocks, `sub1` and `sub2`. The variant condition  $V == 1$  is propagated to the Model Block `sub1`. However, the condition is not propagated to the blocks within `sub1`. The blocks within `sub1` implicitly inherit the condition. The Model block `sub2` propagates the Out variant conditions.

Copyright 2016 The MathWorks, Inc.

### Simulate with code compile Activation Time

Before you simulate, protect the Model block sub2. To protect the model reference of sub2, select the block sub2 and enter this command in the MATLAB Command Window. For more information on protecting models, see “Protect Models to Conceal Contents” (Simulink Coder).

```
Simulink.ModelReference.protect(gcb);
```

When the **Variant activation time** is set to `code compile`, changing the active variant for variant blocks in a protected model is not supported.

### Simulate with startup Activation Time

Before you simulate the model with `startup` activation time, delete the protected model.

```
delete('slexVariantMdlRefCondProp_sub2.slxp');
```

Set the **Variant activation time** of the Variant Sink block in the Model Block sub2 to `startup`. Change the variant control to 'W' and change the storage class specification of W to 'ExportedGlobal'.

```
W = copy(V);  
W.CoderInfo.StorageClass = 'ExportedGlobal';
```

Protect the model and change the active variant to simulate the model. To tune W in the protected model during simulation,

```
Simulink.ModelReference.protect(gcb, 'TunableParameters', {'W'})  
W.Value = int32(3);
```

The condition `W == 3` is propagated to the Gain6 and Out4.

# Verify and Validate Variant Models with Startup Activation Time

This example shows how to verify and validate variant models with startup variant activation time using Simulink® Design Verifier™ and test it using Simulink Test™.

## Model

Open the model `slexStartupVariantVnVWorkflow`. The model contains a Variant Subsystem block, `ComputeTargetSpeed`, with two variant choices, `ComputeTargetSpeed_Config1` and `ComputeTargetSpeed_Config2`. In this example, we use Simulink Design Verifier to generate test cases for models that contain startup variants and run predefined tests cases for the model using Simulink Test Manager.

- To launch Simulink Design Verifier and automatically generate test cases for the variant choices in the model, double-click the **SLDV Run** button.
- To launch the **Simulink Test Manager**, click the **Open Simulink Test Manager** button in the model. The **Simulink Test Manager** is launched with predefined tests cases for the `slexStartupVariantVnVWorkflow` model. To run each parameter set iteratively across the selected baseline, click **Run**. Once the test runs successfully, you will notice that the model output matches the expected output.

## Simulink Test Workflow with Startup Variants and Fast Restart

Access Simulink Test Workflow with Fast Restart and Startup Variants

**SLDV Run**  
(Double Click)

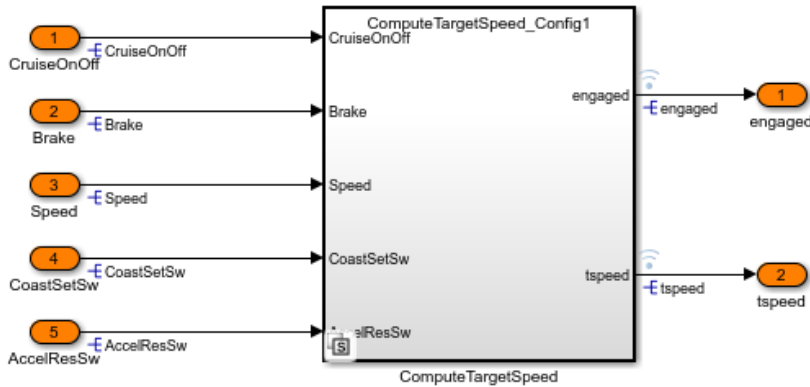

This button, will invoke SLDV and would generate test cases across all choices of variant subsystems present in this model in a single analysis run.

**Open Simulink Test Manager**  
(Double Click)

This button launches the Simulink Test Manager (STM) Window with predefined tests with Startup Variants. Please refer help for more information.

### Simulink Test Workflow with Startup Variants and Fast Restart

Access Simulink Test Workflow with Fast Restart and Startup Variants

SLDV Run  
(Double Click)

This button, will invoke SLDV and would generate test cases across all choices of variant subsystems present in this model in a single analysis run.

Open Simulink Test Manager  
(Double Click)

This button launches the Simulink Test Manager (STM) Window with predefined tests with Startup Variants. Please refer help for more information.

### Use Simulink Design Verifier to Generate Test Cases

Simulink Design Verifier can analyze all variant choices in single analysis run if the activation time is set to startup. To analyze all variant choices in a single run, the **Analyze all Startup Variants** configuration parameter must be enabled. To enable the configuration parameter:

- In the Simulink Editor, on the **Modeling** tab, click **Model Settings**.
- In the Configuration Parameters dialog box, click **Design Verifier** in the left side pane and select **Parameters and Variants**. In the **Parameters and Variants** pane, the **Analyze all Startup Variants** parameter is selected by default. If you de-select this parameter, Simulink Design Verifier analyzes only the active variant of the variant blocks with **Variant activation time** parameter set to startup.

In the MATLAB Command Window, run the script corresponding to each of these steps. The **SLDV Run** button in the model automates the same script.

**Step 1:** Set the required Simulink Design Verifier options. For information on the options, see `sldvoptions` (Simulink Design Verifier).

```
modelName='slexStartupVariantVnVWorkflow';
open_system(modelName);
%Create a design verification options object for the model.
opts = sldvoptions(modelName);
%Specify the optimization strategy to use when generating test cases.
opts.TestSuiteOptimization = 'Auto';
%Generate and save a Simulink Design Verifier report.
opts.SaveReport = 'on';
%Create unique reports for each variant choice.
opts.MakeOutputFilesUnique = 'on';
%Create a harness model generated by the Simulink Design Verifier analysis.
opts.SaveHarnessModel = 'off';
%Specify the analysis mode.
opts.Mode = 'TestGeneration';
%Display Simulink Design Verifier report.
opts.DisplayReport = 'off';
%Analyze the models for startup Variant.
opts.AnalyzeAllStartupVariants = on ;
```

**Step 2:** Analyze the model.

```
%Track the execution progress from MATLAB command prompt.
disp([newline 'Performing SLDV Run for Model ' modelName ' for all variant choices']);
disp(newline);
```

```
%Analyze the model to generate test cases and display messages in the log window.  
[status,fileNames] = sldvrun(modelName, opts, true);
```

**Step 3:** Display the test generation status.

```
if status & status1  
disp('Simulink Design Verifier test generation completed.');
```

After the analysis is complete, the Simulink Design Verifier Results Summary window opens and shows different ways you can use the results. See “Review Analysis Results” (Simulink Design Verifier). For more information about analyzing models with variants using Simulink Design Verifier, see Analyze all Startup Variants in “Design Verifier Pane: Parameters and Variants” (Simulink Design Verifier)

### Use Simulink Test to Execute Tests

The startup variant with the fast restart workflow allows you to switch the active variant choice in each iteration without the need to recompile the model to change the active variant. You can create parameter sets with different variant configurations in fast restart mode to test your systems without needing to recompile the model. To make the Simulink Test workflow iterative, use the startup variant activation time and run the test iterations in fast restart.

### Start Test Manager

To setup and run the test iterations in **Fast restart** and compare the model output with the expected output, follow the steps in this tutorial.

**1** Open the model, `slexStartupVariantVnVWorkflow`.

```
open_system('slexStartupVariantVnVWorkflow');
```

**2** To start Test manager, on the **Apps** tab, under **Model Verification Validation, and Test** click on **Simulink Test**. On the **Tests** tab, click **Simulink Test Manager**.

### Associate Model and Test Harness

Test suites contain one or more test cases and the default test case is a baseline test. Create a test suite and a new baseline test.

**1** From the Test Manager toolstrip, select **New > Test Suite**. Right click on **Test Suite** to create a new **Baseline Test**.

**2** Set the test case to use the model. In the above example, the model in use is `slexStartupVariantVnVWorkflow`. In Test Manager, under **System Under Test**, click the **Use current model** button.

**3** Select the `slexStartupVariantVnVWorkflow_md1Harness` from the **Harness** drop down under **Test Harness**.

### Create Parameter Sets

Create parameter sets and add the variant control variable with the respective value. Each parameter set aligns with a specific variant control value. In the above example, there are two parameter sets corresponding to the variant control expressions `speedConfig = 1` and `speedConfig = 2`. To override a model parameter,

- 1 Expand the **Parameter Overrides** section in the test case and click **Add**.
- 2 Click on **update diagram** to get model parameters.
- 3 Select the variant control parameter from the list. In the above example, it is `speedConfig`.

Simulink Test Manager allows iterations in the **Iterations** section of the test case. The **Table Iterations** provide a quick way to add iterations based items in your model or test case. Click on **Auto-generate** the iterations. Select the **Parameter Set** option from the list.

### **Capture Baseline**

When a baseline test case executes, the Test Manager captures signal data from signals in the model marked for logging and compares them to the baseline data. You can capture the baseline test outputs in Test Manager as an Excel® file or a MAT-file. Alternatively, you can add an external file to the test case as the baseline. In the test case under **Baseline Criteria**, click **Capture** and select the option **Capture Baselines for Iterations**. Specify the path to the iterations. In the above example, the path to `DisengageWithDisable` has been specified. Notice that the **Baseline** gets populated in the **Table Iterations** corresponding to each parameter set.

### **Run the Baseline Test**

Baseline tests compare the outputs from a simulation against the expected outputs. Ensure you have selected the **Run Test Iterations in Fast Restart** in the **Table Iterations** section. To run each parameter set iteratively across the selected baseline, click **Run**.

## Simulate Variant Blocks in Accelerator and Rapid Accelerator Modes with Startup Activation Time

This example shows how to simulate Variant Source and Variant Sink blocks in accelerator and rapid accelerator mode with startup variant activation time.

Both modes enable faster simulation without changing the model itself. The accelerator and rapid accelerator modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where runtime is long compared to the time associated with compilation and checking to see if the target is up to date. For more information on accelerator modes, see “How Acceleration Modes Work” on page 38-3.

Combined with the `startup` variant activation time, simulating in accelerator or rapid accelerator mode retains all variant choices. Thus incremental simulation does not regenerate code when there are no structural changes in the model and you only change the variant control value.

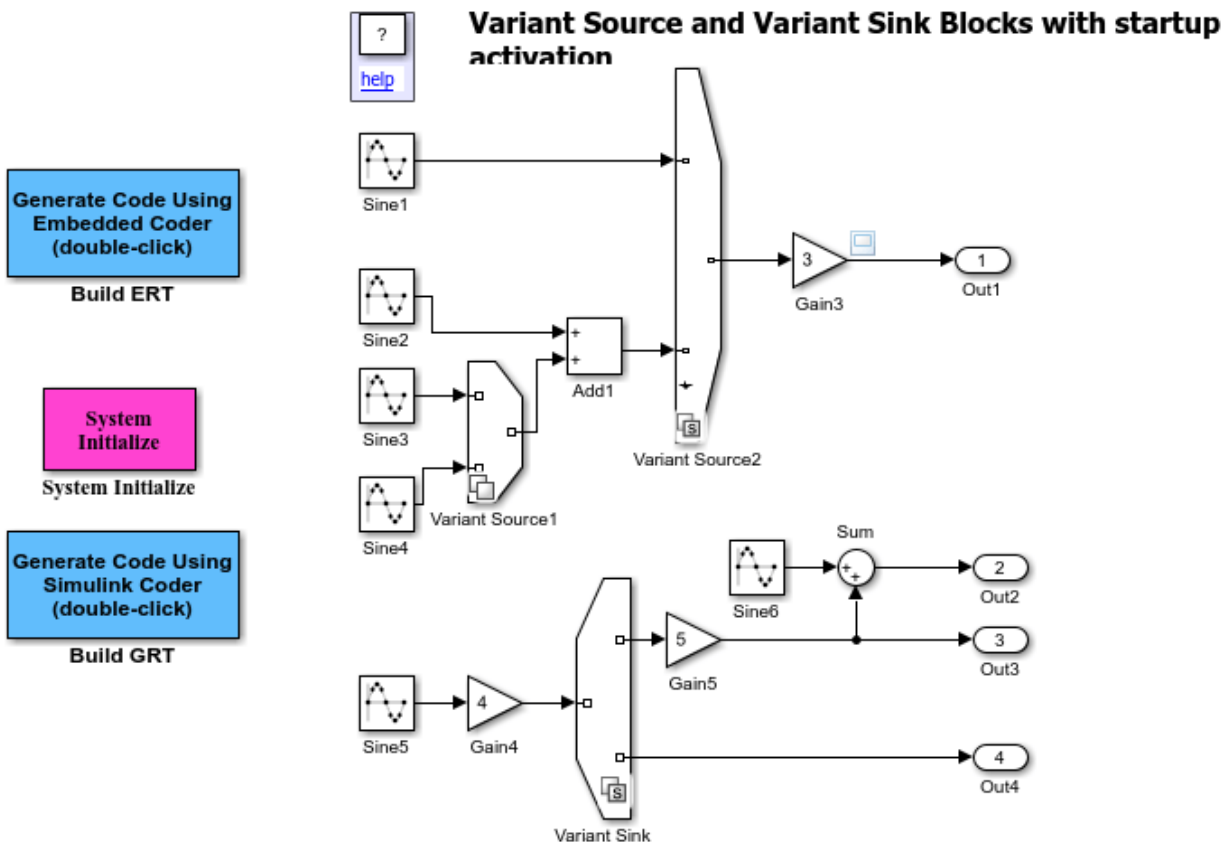

### Model

Open the model `slexVariantSourceAndSinkWithStartup.slx`. The Variant Source1 has conditions `X==1` and `X==2` for its input ports. The block named Variant Source1 has an update diagram activation time. `X` is a variant control variable and is defined in the `PostLoadFcn` of **File -> Model Properties -> Callbacks**. The Sine3 block is active when `X==1` is true, and the Sine4 block is active when `X==2` is true.

In the block named Variant Source2 block, the first input port is active when `V==1` is true. The second input port is active when `V==2` is true. The Variant Source2 has a startup activation time.

The block named Variant Sink has the conditions `W==1` and `W==2` on its output ports. These conditions are propagated to the connected blocks. The Gain5 block is assigned the condition `W==1`. The second output port of the Variant Sink block has the condition `W==2`. This condition is propagated to the Out4 block.

Since the Variant Source2 and Variant Sink blocks have a startup activation time, all the choices are available. You can toggle the active or inactive branch just before simulation.

Copyright 2021 The MathWorks, Inc.

### Simulate the Model

Before you run the simulation, set the mode to be either **Accelerator** or **Rapid Accelerator**.

```
sim(slexVariantSourceAndSinkWithStartup);
```

You can generate code by clicking on **Build ERT** or **Build GRT**. The generated code from Embedded Coder (ERT) or Simulink Coder (GRT) will have regular `if` conditions. For more information on generating code with startup activation time, see “Generate Code from Variant Blocks with Startup Activation Time” on page 12-289.

## Run Executable for Different Variant Parameter Values Without Recompiling Code

This example shows how to generate an executable that runs for different set of variant parameter values without needing to recompile the code for each set of values.

In this example, you build an executable that represents the step response of a linear system with PID controller. In the executable, the PID parameters, proportional gain and integral gain, are specified as variant parameters that have multiple values to cater to multiple requirements. Each value is associated with a variant control expression. When you run the executable, Simulink® evaluates the condition expressions. Based on the condition expression that evaluates to `true`, all the gain parameter values associated with that condition expression becomes active and the executable runs only for that set of gain values. You can then change the value of the variant control variable to run the executable for different set of gain parameter values. You are not required to recompile the code to build the executable for a different set of gain parameter values.

### Overview of Variant Parameters

Variant parameters can have multiple values. Each value of the variant parameter is associated with a variant condition expression. During simulation, the value of the variant parameter associated with the condition that evaluates to `true` is the active value of that parameter. The value associated with the condition that evaluates to `false` is the inactive value of that variant parameter. For more information, see “Use Variant Parameters to Reuse Block Parameters with Different Values” on page 12-175.

The variability and the representation of variant parameters in the generated code depends on the “ActivationTime” and the “Specification” property you specify. The activation time determines whether to include only active choice or both active and inactive choices in the code. The storage class determines whether to represent the parameters as inline or tunable variables. For more information, see “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

If you specify the activation time as `startup`, the generated code includes both active and inactive values of variant parameters. The values are enclosed in regular `if` conditions of the model initialize function of the code. When you run an executable that is built from the code, the `if` conditions are conditionally executed at the start of the execution. Based on the condition that evaluates to `true`, the executable determines the active values of the variant parameters. If you include all the values in the executable, then you do not need to recompile the code every time you change the value of the variant control variable. You build the executable only once. You can then change the value of the variant control variable and then run the executable for a different set of active values.

### Prerequisite

Before you start this example, we recommend you complete “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

### Explore the model

Open the model.

```
mdl = 'slexVariantParametersStartup';  
open_system(mdl)
```

## Variant Parameters with startup Activation Time (if in generated code)

Copyright 2021 The MathWorks, Inc.

The PID Controller block has two variant parameters, **Proportional(P)** and **Integral(I)**. The parameters are specified as `Simulink.VariantVariable` objects `Kp` and `Ki`. `Kp` and `Ki` have multiple values and are associated with a `Simulink.VariantControl` object `VCtrl`, as specified in the `slexVariantParameterGain.m` file. In this file, the activation time of `VCtrl` is specified as `startup`. So, the executable that you build from this model determines the active value of `Kp` and `Ki` at the start of its execution by reading the value of `VCtrl` from the `slexVariantParametersStartup_VCtrl.txt` file. Since, the value of `VCtrl` is specified as 1, the executable calculates the step response for the values associated with `VCtrl == 1`. To calculate the step response for a different value of `VCtrl`, change the value of `VCtrl` in the `slexVariantParametersStartup_VCtrl.txt` file and run the executable again.

### Build and Review the Generated Code With Regular `if` Conditions and `utAssert` Function

Before you generate code and build executable from the model, you first check that you have write permission in your current folder.

1. On the Simulink toolstrip, on the **Apps** tab, click **Embedded Coder**. On the **C Code** tab, click **Build**. For more information, see “Generate Code Using Embedded Coder” (Embedded Coder).

The code generator builds the executable, generates the **Code Generation Report**, and places the executable in the working folder. On Windows®, the executable is `slexVariantParametersStartup.exe`. On Linux®, the executable is `slexVariantParameterStartup`. Alternatively, enter this command in the MATLAB® Command Window to build the executable file.

```
slbuild mdl;

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
slxVariantParametersStartup	Code generated and compiled.	Code generation information file does

1 of 1 models built (0 models already up to date)  
Build duration: 0h 0m 19.667s

2. On the **C Code** tab, select **Open Report**.

3. Select the `slxVariantParametersStartup.c` file. In this file, the model initialize function includes:

a. Symbolic names for all the values of `Kp` and `Ki` enclosed in regular `if` conditions. These `if` conditions are evaluated when you run the executable.

```
if (get_VCtrl() == 1)
{
    Ki = 4.5;
    Kp = 0.15;
}
else if (get_VCtrl() == 2)
{
    Ki = 4.0;
    Kp = 0.5;
}
else if (get_VCtrl() == 3)
{
    Ki = 3.5;
    Kp = 0.75;
}
else if (get_VCtrl() == 4)
{
    Ki = 3.0;
    Kp = 1.0;
}
```

b. The `utAssert` function to ensure that at least one variant condition evaluates to `true` when running the executable.

```
utAssert((get_VCtrl() == 1) || (get_VCtrl() == 2) || (get_VCtrl() == 3) || (get_VCtrl() == 4));
```

4. In the `model_step` function, the symbol names of `Kp` and `Ki` are used to form the equation.

```
void slxVariantParameters_step(void)
{
    ...
    slxVariantParametersStartup_Y.Out1 = 0.5 *
    slxVariantParametersStartup_DW.DiscreteTransferFcn_states[1];
```

```
Add = (real_T)!(slxVariantParametersStartup_M->Timing.t[0] < 1.0) -slxVariantParametersStartup
```

```
rtb_FilterCoefficient = (0.0 * Add -
slexVariantParametersStartup_DW.Filter_DSTATE) * 100.0;

slexVariantParametersStartup_B.Sum = (Kp * Add +
slexVariantParametersStartup_DW.Integrator_DSTATE) + rtb_FilterCoefficient;

rtb_IntegralGain = Ki * Add;
...
}
```

### Set Active Values of Variant Parameters at Model Startup Stage

Identify the version of MATLAB® software on your machine. `ispc` returns logical 1 (true) if the version of MATLAB® software is for the Microsoft® Windows® platform. Otherwise, it returns logical 0 (false). On Windows®, the executable is `slexVariantParametersStartup.exe`. On Linux®, the executable is `slexVariantParameterStartup`. To run the generated executable, enter this command in the MATLAB Command Window.

```
if ispc
exeName = [mdl, '.exe'];
else
exeName = ['./', mdl];
end
system(exeName);

** created slexVariantParametersStartup.mat **
```

At the start of the execution, the executable invokes the model initialize function. The executable reads the value of `VCtrl` from the `slexVariantParametersStartup_VCtrl.txt` file to evaluate the `if` conditions in the function. Since the value of `VCtrl` is set to 1 in the `slexVariantParametersStartup_VCtrl.txt` file, the `if` condition for `VCtrl == 1` evaluates to true. The generated executable is conditionally run for the PID gain parameter values that are associated with `VCtrl == 1` and creates a `slexVariantParametersStartup.mat` MAT-file as an output. The MAT-file contains values for the variables `rt_tout` and `rt_yout`, where `rt_yout` represents the linear step response at the output block `Out1` for each time step `rt_tout`.

You can load the variables from the MAT-file by typing this command:

```
load slexVariantParametersStartup.mat;
```

To plot the linear step response, use this function:

```
plot(rt_tout, rt_yout.signals.values, 'x-');
```

Now, change the value of `VCtrl` in the `slexVariantParametersStartup_VCtrl.txt` file to 2. Run the executable again to observe the change in the step response.

### Set Different Active Values for Variant Parameters Without Recompiling Code

The `slexVariantStartup_script.m` script implements the logic to plot the linear step response for different values of proportional gain and integral gain parameters by changing the value of the `VCtrl` using a `for` loop.

When you run the script:

In the first iteration, the executable runs and the model initialize function is invoked. The executable reads the value of `VCtrl` as 1 from the `slexVariantParametersStartup_VCtrl.txt` file to evaluate the `if` conditions in the model initialize function. The condition `VCtrl == 1` evaluates to `true`, the proportional and integral gain values that are associated with `VCtrl == 1` becomes active. The executable calculates the step response for those values and creates a `slexVariantParametersStartup.mat` MAT-file that contains the step response calculated for each time step.

In the next iteration, the value of `VCtrl` is increased to 2. The executable calculates the step response for the associated values and appends the newly calculated step response to the MAT-file.

Similarly, the executable calculates the step response for values associated with conditions `VCtrl == 3` and `VCtrl == 4`.

The script plots the linear step response as shown.

```
run slexVariantParameters_script.m;
```

```

## Improve Code Readability of Variant Parameters Using Enumerated Types

You can use enumerated types to improve code readability of variant control values in variant parameters. “Simulink Enumerations” on page 73-2 improve readability because enumerated types of variant controls values are represented as meaningful names instead of integers in the generated code.

You can define enumerated types of variant control values in the storage locations listed in “Storage Locations for Variant Control Variables (Operands) in Variant Parameters” on page 12-54.

For variant parameters with `startup` activation time, only enumerations that are defined using these techniques are supported:

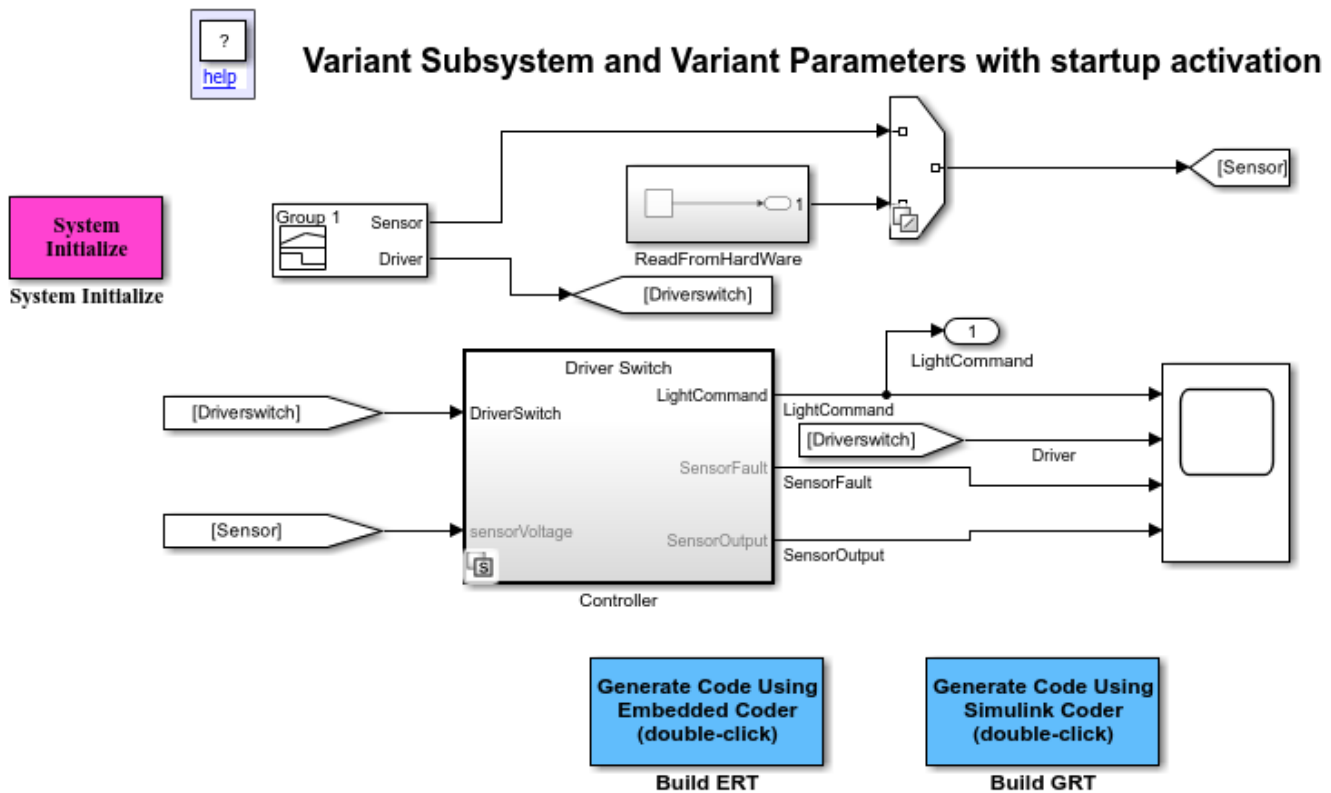

- Using the function `Simulink.defineIntEnumType`
- By subclassing built-in integer data types `int8`, `int16`, `int32`, `uint8`, or `uint16`, or by subclassing `Simulink.IntEnumType`

These enumerations are also supported when permanently stored in a Simulink® data dictionary. See “Enumerations in Data Dictionary” on page 79-14.

### Model

Open the model `slexVariantSubsystemsAndParametersWithStartup`.

```
open_system('slexVariantSubsystemsAndParametersWithStartup')
```

Copyright 2021-2022 The MathWorks, Inc.

This model represents a fog lamp controller system that operates in driver control mode and in sensor connected mode. In driver control mode, the intensity of the fog lamps is controlled by the driver. In sensor connected mode, the sensor adjusts the intensity of different types of fog lamps based on the intensity of ambient light in the external environment.

In this example, `lightVolt` is a variant parameter that represents fog lamp intensities. The sensor voltage from Signal Builder block is the intensity of ambient light in the external environment. The `LIGHT_TYPE` is the variant control variable that represents different types of fog lamps. `LIGHT_TYPE` enables you to switch between fog lamp intensities, `lightVolt`, for the given intensity of ambient light. `LIGHT_TYPE` can have two values, `LightType.Type1` and `LightType.Type2`.

When `LIGHT_TYPE == LightType.Type1` evaluates to `true`, a fog lamp intensity from `[0 0 0 0.7 0.7]` that corresponds to the given ambient light becomes active. When `LIGHT_TYPE == LightType.Type2` evaluates to `true`, a fog lamp intensity from `[0 0 0 1 1]` that corresponds to the given ambient light becomes active. For example, if the ambient light has an intensity 4 and the type of the fog lamp is `Type1`, the fog lamp is illuminated with intensity 0.7. Similarly, if the ambient light has an intensity 4 and the type of the fog lamp is `Type2`, the fog lamp is illuminated with intensity 1. For more information on this fog lamp controller system, see “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-244.

### Fog Lamp Types in a Enumeration Class

In this example, the enumeration `LightType`, saved in `LightType.m`, derives from the built-in class `Simulink.IntEnumType`. It defines two enumeration members, `Type1` and `Type2`, with underlying integer values 1 and 2.

type `LightType.m`

```
classdef LightType < Simulink.IntEnumType
% ControllerType - enumeration class used by
% slexVariantSubsystemsAndParametersWithStartup

% Copyright 2021-2022 The MathWorks, Inc.

    enumeration
        Type1 (1)
        Type2 (2)
    end

    methods (Static)
        function val = getDataScope()
            val = 'Imported';
        end

        function val = getHeaderFile()
            val = 'LightType.h';
        end
    end
end
```

### Simulate Fog Lamp Controller for Different Types of Fog Lamps in Sensor Connected Mode

1. In the MATLAB® Command Window:

a. Set `CTRL_MODE` to 1 to activate the Sensors Connected.

```
CTRL_MODE.Value = int32(1)
```

```
CTRL_MODE =
```

```
Parameter with properties:
```

```
Value: 1
CoderInfo: [1x1 Simulink.CoderInfo]
Description: ''
DataType: 'int32'
Min: []
Max: []
Unit: ''
Complexity: 'real'
Dimensions: [1 1]
```

b. Set `LIGHT_TYPE` to `LightType.Type1` to represent `Type1` type of fog lamps.

```
LIGHT_TYPE.Value = LightType.Type1
```

```

LIGHT_TYPE =
  VariantControl with properties:
      Value: Type1
      ActivationTime: 'startup'

```

Check that the activation time of the LIGHT\_TYPE is set to startup.

2. Run the simulation. Use the Scope block to visualize the results. For details about the signals that the Scope block plots, see the **Model Inputs and Outputs** section of “Run Iterative Simulations Without Recompiling Model for Variant Systems Using Fast Restart” on page 12-244.

3. Change the value of LIGHT\_TYPE to LightType.Type2 and run the simulation again. Use the Scope to visualize the results.

```

LIGHT_TYPE.Value = LightType.Type2

```

```

LIGHT_TYPE =
  VariantControl with properties:
      Value: Type2
      ActivationTime: 'startup'

```

### Generate Code for Enumerated Type of fog lamps

Before you generate code from the model, make sure that you have write permission in your current folder.

To generate code using Simulink® Coder™, the configuration parameters in **Model Settings > Code Generation** are set as:

1. The **System target file** is specified as grt.
2. On the **Custom Code** pane, the header file is specified as ReadLightControllerValues.h and the source file is specified as ReadLightControllerValues.c. This setting inserts the ReadLightControllerValues() function in the model source file, slxVariantSubsystemsAndParametersWithStartup.c, of the generated code.
3. In the **Apps** gallery of the model toolstrip, click **Simulink Coder**. On the **C Code** tab, click **Generate Code**. For more information, see “Generate Code Using Simulink Coder” (Simulink Coder).

```

slbuild('slxVariantSubsystemsAndParametersWithStartup')

### Starting build procedure for: slxVariantSubsystemsAndParametersWithStartup
### Successful completion of build procedure for: slxVariantSubsystemsAndParametersWithStartup

Build Summary

Top model targets built:

Model                                     Action                                     Rebuild Reason

```

```
=====
slxVariantSubsystemsAndParametersWithStartup Code generated and compiled. Code generation info
```

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 49.544s
```

### Review Generated Code

1. In the **C Code** tab, select **Open Report**.

2. From the **Generated Code** pane of the report, select the `slxVariantSubsystemsAndParametersWithStartup.c` file. The `slxVariantSubsystemsAndParametersWithStartup_initialize` function contains the `ReadLightControllerValues()` function to read the values of `CTRL_MODE` and `LIGHT_TYPE` for determining the mode of operation and the type of the fog lamp. The value of `LIGHT_TYPE` read using the function is compared to the enumerated names `Type1` and `Type2` that maps to the values 1 and 2 of the enumeration `LightType`. Based on the condition that evaluates to `true`, the set of fog lamp intensities to activate is determined.

```
void slxVariantSubsystemsAndParametersWithStartup_initialize(void)
{
...
/* user code (Initialize function Body) */

/* System '<Root>' */
ReadValueOfVariantControls();

/* Variant Parameters startup activation time */
if (LIGHT_TYPE == Type1) {
    for (i = 0; i < 5; i++) {
        slxVariantSubsystemsAndParam_P.lightVolt[i] = (real_T)tmp[i];
    }
} else if (LIGHT_TYPE == Type2) {
    for (i = 0; i < 5; i++) {
        slxVariantSubsystemsAndParam_P.lightVolt[i] = tmp_0[i];
    }
}
...
}
```

## Reuse Variant Parameter Values from Handwritten Code Using Simulink.Parameter Variables

This example shows how to use `Simulink.Parameter` variables to generate a code that imports variant parameter values from your existing code. Importing variant parameter values allows you to reuse the values that your existing code defines. You can then integrate and compile the generated and existing code into a single executable. You can choose to generate a code that imports variant parameter values at the beginning of code compile, simulation-loop, or model startup phases of simulation and code generation workflows based on the activation time you specify. For more information, see “Activate Variant During Different Stages of Simulation and Code Generation Workflow” on page 12-79.

### Limitations

- When you use `Simulink.Parameter` variables as values in a variant parameter, corresponding properties of all the `Simulink.Parameter` variables must be the same. Only the values of `Simulink.Parameter` variables can vary.
- `Simulink.Parameter` variables as values in a variant parameter can be defined only in the base workspace and data dictionary. Defining `Simulink.Parameter` variables in the mask or model workspace is not supported.
- `Simulink.Parameter` variables as values in a variant parameter within structures and that have data types other than `Simulink.Bus` objects are not supported.
- `Simulink.Parameter` variables as values in a variant parameter must have storage classes listed in “Storage Classes for Different Variant Activation Times” (Embedded Coder).

### Prerequisite

Before you start this example, we recommend you complete “Options to Represent Variant Parameters in Generated Code” (Embedded Coder).

### Explore the Model

Open the `slexVariantParamsUsingSlParamChoices` model.

```
open_system('slexVariantParamsUsingSlParamChoices')
```

### Variant Parameters using Simulink.Parameter choice variables

Copyright 2021 The MathWorks, Inc.

In this model, the **Gain** parameter of the Gain block is set to the variant parameter `kv`.

Open the `slexVariantParameterSlParamData.m` file. This file contains the definition of `kv`. `kv` has the two values `kp1` and `kp2` of `Simulink.Parameter` type. The storage class of `kp1` and `kp2` is set to “ImportedExtern, ImportedExternPointer” (Embedded Coder). The value of variant control variable `V` is set to 1, and its activation time is specified as “startup” on page 12-82.

During simulation, the condition `V == 1` evaluates to `true`. Since, `kp1` is associated with `V == 1`, `kp1` becomes active and `kp2` becomes inactive. The code that you generate from this model, imports values of `kp1` and `kp2` from the handwritten code that is provided in **Modeling > Model Settings > Code Generation > Custom Code > Additional Source Code > Additional Code**. You can then compile the code into a single executable that switches the active values based on the value of variant control variable `V`.

type `slexVariantParameterSlParamData.m`

```
% This file defines variant parameters using Simulink.Parameter variables
% as choice values for slexVariantParamsUsingSlParamChoices example. The
% variant parameter value is determined using the Simulink.Parameter values
% in simulation and code generation.

% Copyright 2021 The MathWorks, Inc.

% Variant control variable
V = Simulink.VariantControl('Value', 1, 'ActivationTime', 'startup');

% Simulink.Parameter choice variables
kp1 = Simulink.Parameter(3);
kp1.CoderInfo.StorageClass = 'ImportedExtern';

kp2 = Simulink.Parameter(6);
kp2.CoderInfo.StorageClass = 'ImportedExtern';

% Variant parameter
kv = Simulink.VariantVariable('Choices', {'V == 1', 'kp1', 'V == 2', 'kp2'});
```

### Generate Code Using Embedded Coder

Before you generate code from the model, make sure that you have write permission in your current folder.

In the **Apps** gallery of the model toolstrip, click **Embedded Coder**. On the **C Code** tab, click **Generate Code**. For more information, see “Generate Code Using Embedded Coder” (Embedded Coder).

```
slbuild('slexVariantParamsUsingSlParamChoices')
```

```
### Starting build procedure for: slexVariantParamsUsingSlParamChoices
### Successful completion of build procedure for: slexVariantParamsUsingSlParamChoices
```

Build Summary

Top model targets built:

Model	Action	Rebuild Reason
slexVariantParamsUsingSlParamChoices	Code generated and compiled.	Code generation information

```
1 of 1 models built (0 models already up to date)
Build duration: 0h 0m 27.332s
```

### Review Generated Code

1. In the **C Code** tab, in the **Results** section, click **Open Report**.
2. From the **Generated Code** pane of the report, select the `slexVariantParamsUsingSlParamChoices_private.h` file. `kp1` and `kp2` are declared as extern variables to use values from your handwritten code.

```
/* Imported (extern) block parameters */
extern real_T kp1;                               /* Variable: kp1
                                                * Referenced by: '<Root>/Gain'
                                                */
extern real_T kp2;                               /* Variable: kp2
                                                * Referenced by: '<Root>/Gain'
```

Your handwritten code is imported in `slexVariantParamsUsingSlParamChoices.c` file.

```
User code, define parameter choice values outside the generated code */
double kp1 = 3.0;
double kp2 = 6.0;
```

During code compile, the generated and your handwritten code is integrated into a single executable. At model startup, that is, prior to running the executable, the value of the variant parameter `kv` is determined based on the condition that evaluates to `true`.

```
/* Model initialize function */
void slexVariantParamsUsingSlParamChoices_initialize(void)
{
    /* Variant Parameters using Simulink.Parameter variables for choice values */
    if (V == 1) {
        slexVariantParamsUsingSlParam_P.kv = kp1;
    } else if (V == 2) {
        slexVariantParamsUsingSlParam_P.kv = kp2;
    }

    /* startup variant condition checks */
    utAssert((V == 1) + (V == 2) == 1);
}
```

## Generate Code from Variant Blocks with Startup Activation Time

This example shows you how to generate code with startup variant activation time. The generated code contains all variant choices with regular if statements.

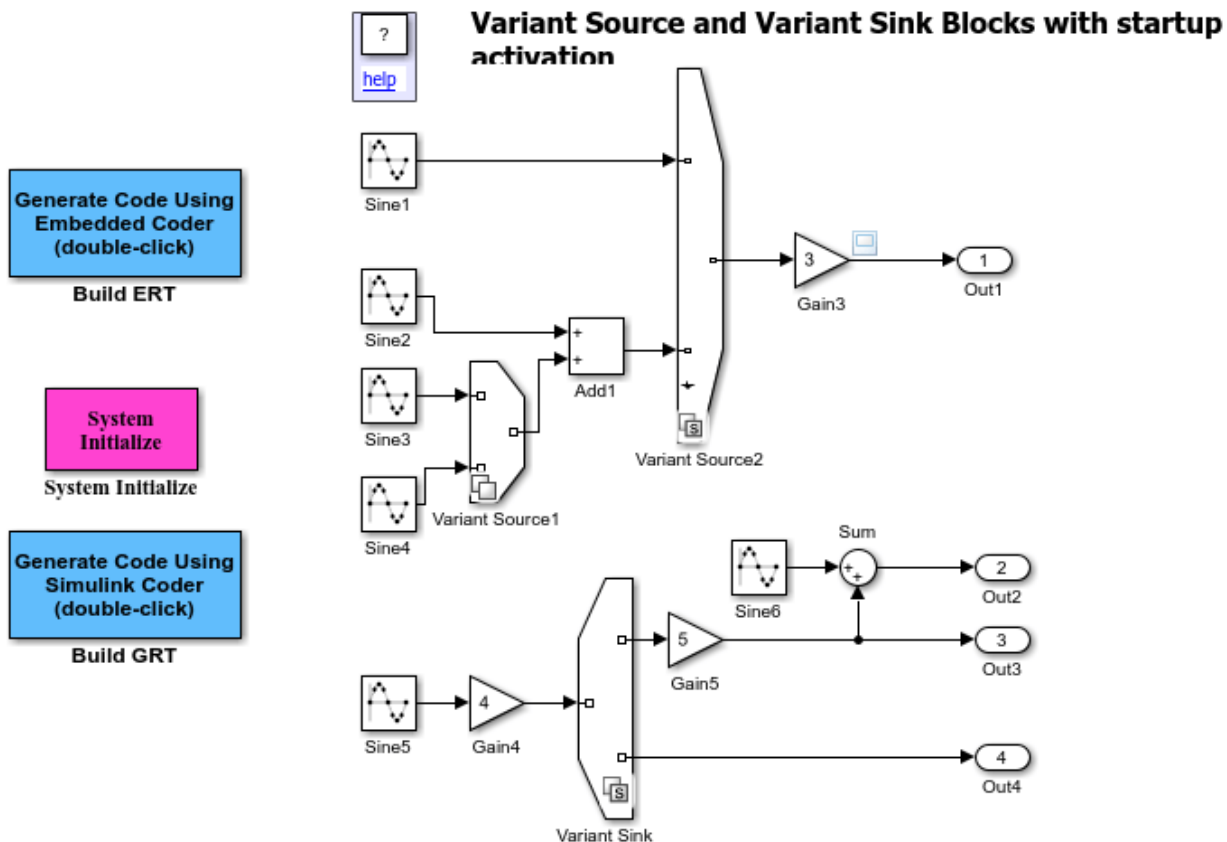

### Model

Open the model `slexVariantSourceAndSinkWithStartup.slx`. The Variant Source1 has conditions  $X==1$  and  $X==2$  for its input ports. The block named Variant Source1 has an update diagram activation time.  $X$  is a variant control variable and is defined in the PostLoadFcn of **File -> Model Properties -> Callbacks**. The Sine3 block is active when  $X==1$  is true, and the Sine4 block is active when  $X==2$  is true.

In the block named Variant Source2 block, the first input port is active when  $V==1$  is true. The second input port is active when  $V==2$  is true. The Variant Source2 has a startup activation time.

The block named Variant Sink has the conditions  $W==1$  and  $W==2$  on its output ports. These conditions are propagated to the connected blocks. The Gain5 block is assigned the condition  $W==1$ . The second output port of the Variant Sink block has the condition  $W==2$ . This condition is propagated to the Out4 block. If you select **Allow zero active variant controls** on the Variant Sink block, then the Sine5 and Gain4 blocks will be assigned the variant condition  $W==1|W==2$ .

```
open_system('slexVariantSourceAndSinkWithStartup.slx');
```

## Generate Code

You can generate code by clicking on **Build ERT** or **Build GRT**. The inline variant blocks **Variant Source2** and **Variant Sink** use the variant condition expression with parameters  $V$  and  $W$ . These parameters have an 'ExportedGlobal' storage class specification. When you specify a condition expression to determine the active choice, each variant control variable of the expression has a storage class associated with it. By using storage classes, you can control the appearance and placement of the variant control variables in the generated code. Storage classes also prevent the optimizations such as elimination of the storage for variant control variables in the generated code. The variables used in the variant condition expressions must satisfy certain criteria to generate code with Simulink Coder or Embedded Coder. For more information on the storage class specifications with startup activation time, see "Storage Classes for Different Variant Activation Times" on page 12-88.

Since the **Variant Source2** and **Variant Sink** blocks have startup activation time, all choices are available, and the generated code from Embedded Coder (ERT) or Simulink Coder (GRT) will have regular `if` conditions.

The code generated with Embedded Coder runs the selected variant.

```

if(V == 2) {
    rtb_Gain5 = sin((real_T)slexVariantSourceAndSinkWith_DW.counter * 2.0 *
        3.1415926535897931 / 10.0);
    rtb_Gain4 = sin((real_T)slexVariantSourceAndSinkWith_DW.counter_h * 2.0 *
        3.1415926535897931 / 10.0);
    rtb_Sine6 = rtb_Gain5 + rtb_Gain4;
} else if(V == 1) {
    /* Sin: '<Root>/Sine1' */
    rtb_Sine6 = sin((real_T)slexVariantSourceAndSinkWith_DW.counter_c * 2.0 *
        3.1415926535897931 / 10.0);
}

if((V == 1) || (V == 2)) {
    sllexVariantSourceAndSinkWithS_Y.Out1 = 3.0 * rtb_Sine6;
}

```

You can select the active variant using custom code via the System Initialize block. To change the value of V and W using custom code, navigate to **Model Settings > Code Generation > Custom Code**. Specify `#include "ReadVarControl.h"` under **Header file** and `ReadVarControl.c` under **Source file**.

The source file `ReadVarControl.c` should contain some code to read the value of V or W based on the requirement and set the active variant values.

```

#include "rtwtypes.h"
extern int32_T V;
extern int32_T W;
void SetValueOfVarControls()
{
    // The values of V and W can be read from a sensor or hardware
    // for simplicity it is hardcoded.
    V = 2;
    W = 2;
}

```

In the model initialize function, you may find code that sets the values for desired V and W, as shown below.

```

void sllexVarinatSourceAndSinkWithStartup_initialize(void)
{
    SetValueOfVarControls();
    utAssert((W == 1) + (W == 2) == 1);
    utAssert((V == 1) + (V == 2) <= 1);
}

```

#### NOTE -

- 1 The model initialize functions are not guarded in the generated code.
- 2 The `SetUpRuntimeResources`, `Start`, and `Initialize` methods of blocks are called irrespective of startup variant activation. The methods are not guarded conditionally in code generation.
- 3 Parameters used as variant control variables in startup activation will not appear in the generated CAPI or ASAP2 interfaces.

Once the model is initialized, the values of V and W do not change in the step method. If you have a requirement to ensure that value of variant control does not change in step, then you must add a check to the generated code to ensure that the variant control value does not change in step.

The `utAssert` statements in the model initialize function ensure that the generated code behavior for variant blocks matches with simulation. For example, `utAssert((V == 1) + (V == 2) <= 1)` ensures that you cannot have more than one active variant for Variant Source2.

If **Allow zero active variant control** is not selected, the `utAssert` statement checks that at least one variant choice is active for such variant blocks. If **Allow zero active variant control** is selected, it generates code to ensure that you cannot have more than one active variant.

## Create Standalone Executables with Variants Using Simulink Compiler

This example shows you how to create a standalone executable with a Variant Subsystem using the Simulink® Compiler™ workflow. You can use the same workflow for the Variant Source and Sink blocks as well.

Simulink Compiler enables you to share Simulink simulations as standalone executables. You can build the executables by packaging the compiled Simulink model and the MATLAB® code used to set up, run, and analyze a simulation.

In this example you will:

- 1 Create and Deploy a Script with Simulink Compiler.
- 2 Write MATLAB app which can tune the variant control value externally.

### Model

Open the model `sldemo_variant_subsystems`. The model contains a variant subsystem block **Controller** with two choices **Linear Controller** and **Nonlinear Controller** with the conditions `VSS_MODE == 1` and `VSS_MODE == 2` respectively. Set the Variant activation time to startup in the **Block Parameters** dialog.

Copyright 2010-2022 The MathWorks, Inc.

### Create and Deploy a Script with Simulink Compiler

1 Write the script to deploy - Create a function called `deployedScript`. This code creates a `Simulink.SimulationInput` object for the model. `variantControl` is the value that we pass through the `setVariable` method for the tunable parameter `VSS_MODE`.

To configure the `Simulink.SimulationInput` object for deployment, use the function `simulink.compiler.configureForDeployment`. This sets the simulation mode to Rapid Accelerator.

```
function deployedScript(variantControl)
    in = Simulink.SimulationInput('sldemo_variant_subsystems');
```

```
in = in.setVariable('VSS_MODE',variantControl);
in = simulink.compiler.configureForDeployment(in);
out = sim(in);
plot(out.yout);
end
```

**2 Compile Script for Deployment** - Before compiling the script that you want to deploy, ensure that the files for the model and script, in this case `sldemo_variant_subsystems` and the `deployedScript.m`, are included on the MATLAB search path.

To compile the script, use the `mcc` command with the script name. For more information, see `mcc` (MATLAB Compiler). This generates the stand alone application, `deployedScript.exe` which you can execute outside of MATLAB or Simulink.

```
mcc -m deployedScript.m
```

**\*3\*Run the Deployed Script** - To run the deployed executable, you need an appropriate runtime environment. To install the MATLAB Runtime, see <https://www.mathworks.com/products/compiler/matlab-runtime.html>. You can run the deployed application only on the platform that the deployed application was developed on. Run the deployed application, `deployedScript.exe`, from the Windows command prompt.

To see the output for when the active variant choice is `VSS_MODE = 1`,

```
./run_deployedScript.exe 1
```

To see the output for when the active variant choice is `VSS_MODE = 2`,

```
./run_deployedScript.exe 2
```

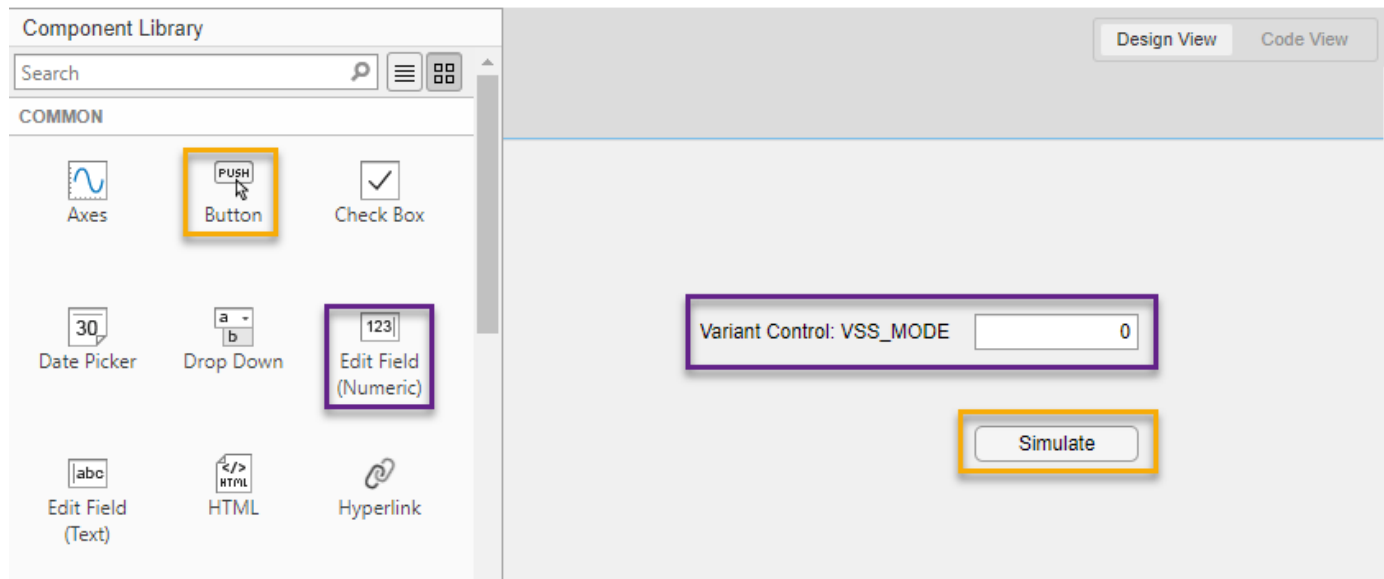

### Create the App in App Designer

You can write MATLAB app which can tune the variant control value externally. To learn more about how to create an app using the App Designer, see `appdesigner` and “Create and Run a Simple App Using App Designer”.

**1** Launch the MATLAB app from the App Designer

```
appdesigner
```

**2** Drag and drop a Edit Field and a push Button as shown below.

**3** Write a callback function for the Simulate button.

```
Callback function: SimulateButton, VariantControlVSS_MODEEditField
function SimpleButtonPushed(app, event)
    in = Simulink.SimulationInput('sldemo_variant_subsystems');
    in = in.setVariable('VSS_MODE',app.VariantControlVSS_MODEEditField.Value);
    in = simulink.compiler.configureForDeployment(in);
    out = sim(in);
    ax = uiaxes;
    plot(ax, out.yout);
end
```

4 Launch the app to tune the value of the variant control. Simulate with different values to see the result.

## Generate Code from Nested Variant Subsystem with Code Compile and Startup Activation

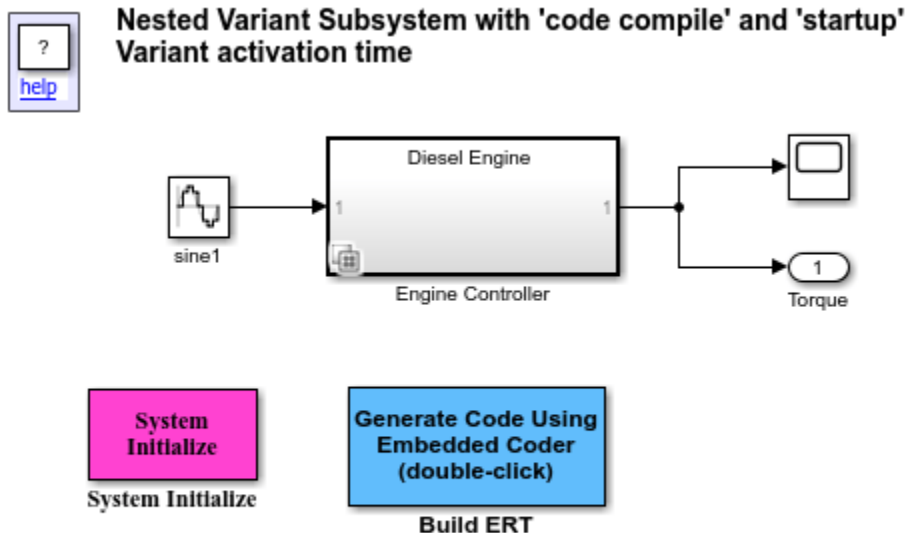

This example illustrates how `code compile` and `startup` variant activation time can be used together in two nested variant subsystems.

### Model

Open the model `slexNestedVSSWithCCAndST.slx`. The model contains a Variant Subsystem block `Engine Controller` with two choices `Diesel Engine` and `Petrol Engine` with the conditions `ENGINE_TYPE == 1` and `ENGINE_TYPE == 2` respectively. The Variant activation time parameter of the `Engine Controller` block is set to `code compile`. The two variants `Diesel Engine` and `Petrol Engine` have `startup` as the Variant activation time parameter. Each engine type has two choices `Efficient Mode` and `Normal Mode`. The `Petrol Engine` has the conditions `PMODE == 1` and `PMODE == 2`, and the `Diesel Engine` has the conditions `DMODE == 1` and `DMODE == 2`. One of the engine types can be selected while building the generated code and one of the controller modes can be selected before the start of execution of the code.

Both the variant subsystems have **Propagate conditions outside of variant subsystem** and **Allow zero active variant controls** turned off. When these flags are turned on, this model will error out during compilation as the conditions with `code compile` and `startup` variant activation time will get mixed for the `Inport` and `Outport` blocks. For more information, see “Considerations and Limitations for startup Variant Activation Time” on page 12-241

```
open_system('slexNestedVSSWithCCAndST.slx');
```

Copyright 2021 The MathWorks, Inc.

### **Generate Code**

Click on **Generate Code Using Embedded Coder** to generate code with ERT target. In the generated code, you can see the variant conditions related to **Engine Controller** appear with the preprocessor `#if` conditions and the conditions related to the mode appear as regular `if`.

```

slexNestedVSSWithCCAndST.c Search
59 slexNestedVSSWithCCAndST_B.sine1 = ((slexNestedVSSWithCCAndST_DW.lastSin *
60 0.99994516936551214 + slexNestedVSSWithCCAndST_DW.lastCos *
61 -0.010471784116245792) * 0.99994516936551214 +
62 (slexNestedVSSWithCCAndST_DW.lastCos * 0.99994516936551214 -

71             slexNestedVSSWithCCAndST_ConstP.udLookupTable_tableData, 4U);
72     } else if (DMODE == 2) {
73         HoldSine = slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e[0];
74         HoldSine += 0.5 * slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e[1];
75         slexNestedVSSWithCCAndST_B.VariantMergeForOutputOut1 = HoldSine;
76         HoldSine = slexNestedVSSWithCCAndST_B.sine1;
77         HoldSine -= 0.06 * slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e
78             [0];
79         HoldSine -= 0.3 * slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e[1];
80         slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e[1] =
81             slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e[0];
82         slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states_e[0] = HoldSine;
83     }
84
85 #elif ENGINE_TYPE == 2
86
87     if (PMODE == 1) {
88         slexNestedVSSWithCCAndST_B.VariantMergeForOutputOut1 = look1_binlpxw
89             (slexNestedVSSWithCCAndST_B.sine1, slexNestedVSSWithCCAndST_ConstP.pooled1,
90             slexNestedVSSWithCCAndST_ConstP.udLookupTable_tableData_k, 4U);
91     } else if (PMODE == 2) {
92         HoldSine = slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[0];
93         HoldSine += 0.7 * slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[1];
94         slexNestedVSSWithCCAndST_B.VariantMergeForOutputOut1 = HoldSine;
95         HoldSine = slexNestedVSSWithCCAndST_B.sine1;
96         HoldSine -= 0.09 * slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[0];
97         HoldSine -= 0.5 * slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[1];
98         slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[1] =
99             slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[0];
100        slexNestedVSSWithCCAndST_DW.DiscreteTransferFcn_states[0] = HoldSine;
101    }
102
103 #endif

```

The mix of `compile` and `startup` variant activation times enables you to fine tune the variant selection. In the generated executable, you can have either the `Petrol Engine` controller or the `Diesel Engine` controller. At startup, you can decide if you want the `Efficient Mode` or the `Normal Mode` of either `Petrol Engine` or `Diesel Engine` controllers. To do this, write a custom code which can help to select different variants at `startup` activation time in the `System Initialize` block. To select different variants, navigate to **Model Settings > Code Generation > Custom Code**. Specify the `Header file` and `Source file` as `#include "ChangeDieselController.h"` and `ChangeDieselController.c` respectively.

The `ChangeDieselController.c` is responsible for selecting the `startup` variant in the `initialize` function.

```
#include "rtwtypes.h"
extern int32_T DMODE;
void ChangeDieselEngineController()
{
    // select the diesel controller at startup.
    // This is just an example, so the value is hard coded.
    // In practical scenario, this can read value from sensor and
    // decide which controller you want at startup.
    DMODE = 1;
}
```

With the help of this code, you can select the `startup` variant in the `model_initialize` function and generate code.

```
void slxNestedVSSWithCCAndST_initialize(void)
{
    ChangeDieselEngineController();
    utAssert((DMODE == 1) + (DMODE == 2) == 1);
    utAssert((PMODE == 1) + (PMODE == 2) <= 1);
    slxNestedVSSWithCCAndST_DW.systemEnable = 1;
}
```

# Create Real-Time Applications Using Variants and Simulink Real-Time

This example shows you how to a real-time application with a variant subsystem by using the Simulink® Real-Time™ workflow. Simulink Real-Time lets you create real-time applications from Simulink models and run them on Speedgoat® target computer hardware connected to your physical system.

To run a Simulink Real-Time model on a target computer, connect the development and target computers in a network. For the steps, see “Set Up and Configure Simulink Real-Time” (Simulink Real-Time).

## Explore and Set Up Model

Open the model `sldemo_variant_subsystems`. The model contains a variant subsystem block `Controller` with two choices, `Linear Controller` and `Nonlinear Controller`, and has the conditions `VSS_MODE == 1` and `VSS_MODE == 2` respectively.

To create a real-time application:

**1** In the **Block Parameters** dialog box, set the **Variant activation time** to **startup**.

**2** Check that the **Variant control expression** is set to `VSS_MODE == 1` for `Linear Controller*` and `VSS_MODE == 2` for `NonLinear Controller`.

**3** Create the variant parameter `VSS_MODE` as a `Simulink.Parameter` with a value of 1 and data type of `int32`.

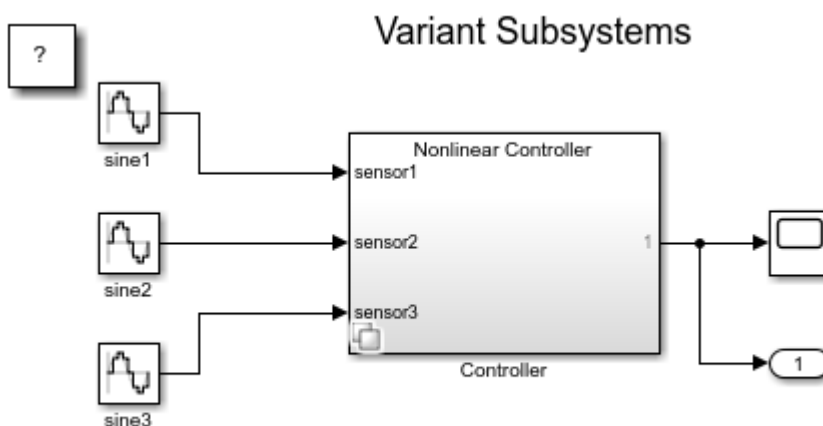

```
VSS_MODE = Simulink.Parameter(int32(1));
```

**4** Set the storage class of `VSS_MODE` to `ExportedGlobal`.

```
VSS_MODE.CoderInfo.StorageClass = 'ExportedGlobal';
```

**5** Change the variant choices to `atomic`.

```
open_system('sldemo_variant_subsystems');
```

Copyright 2010-2013 The MathWorks, Inc.

To provide information to Simulink Coder on how to build a real-time application from the model, set the simulation and real-time run parameters in the Configuration Parameters dialog box. To open the Configuration Parameters dialog box, on the **Modeling** tab, click **Model Settings**.

- 1** On the **Solver** pane, under **Solver selection**, from the **Type** list, select **Fixed-step**.
- 2** On the **Code Generation** pane, in the **Target selection** section, from the **System target file** list, select `slrealtime.tlc`. This selection is required to build a real-time application.
- 3** In the **Optimization** pane, select the **Default parameter behaviour** to **Tunable**.
- 4** On the **Interface** pane, under the **Data exchange interface**, clear the **External mode** check box.

The model is now ready to be used to build a standalone real-time application using the current configuration parameter settings.

### **Create and Run Real-Time Application**

Create the real-time application using the `slbuild` command. This generates the real-time application MLDATX file.

```
slbuild('sldemo_variant_subsystems');
```

Open the Simulink Real-Time Explorer, using the `slrtExplorer` (Simulink Real-Time) command.

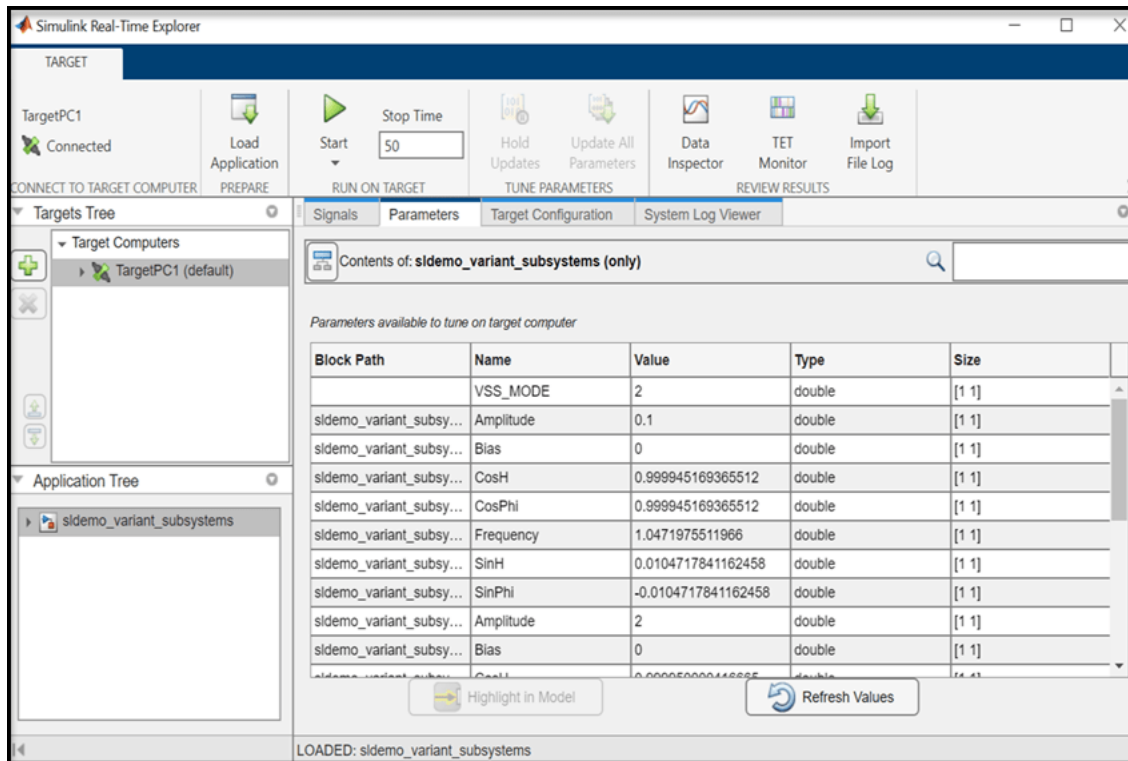

```
slrtExplorer
```

Load the real-time application `sldemo_variant_subsystems.mldatx` by clicking **Load Application**. In `slrtExplorer`, you can:

- 1** View a hierarchical display of signals in the **Signals** tab. You can see all the signals available under **Signals available on target computer**. Select the signal that you want to observe and add it to **Signals in Instrument**.

**2** Tune parameters in the **Parameters** tab. The value of the variant control variable `VSS_MODE` is set to 2 by default, as this was the value specified at compile-time. Before starting the simulation, you can choose to change the value to 1. This variable is set back to the default value at the end of the simulation.

3 Stream data to the Simulation Data Inspector. Run the real-time simulation. Open the Simulation Data Inspector and observe the different results for  $VSS\_MODE == 1$  and  $VSS\_MODE == 2$ .

**NOTE:** Check that you do not change the variant control value  $VSS\_MODE$  while the simulation is running. Simulink does not issue an error in case you change the variant control in between steps.

Output when  $VSS\_MODE == 1$

Output when VSS\_MODE == 2

## Use find\_system with Built-In MatchFilter Options for Variant Blocks

This example compares the pre-compile and post-compile time results when using the `find_system` function with the built-in “MatchFilter” functions. These filters help to find variant blocks that are active in simulation or part of the generated code:

- `Simulink.match.activeVariants`
- `Simulink.match.codeCompileVariants`

Open the model `sldemo_variant_subsystems`.

```
model='sldemo_variant_subsystems';
open_system(model);
```

### Before Model Compilation

Using the built-in match filters before compiling the model returns all blocks in the model, irrespective of their variant activeness.

```
find_system(model, 'MatchFilter', @Simulink.match.activeVariants)
```

```
ans = 26x1 cell
    {'sldemo_variant_subsystems' }
    {'sldemo_variant_subsystems/Controller' }
    {'sldemo_variant_subsystems/Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Linear Controller' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/Add' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/Discrete...' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/Out1' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
    {'sldemo_variant_subsystems/Controller/Out1' }
    {'sldemo_variant_subsystems/More Info' }
    {'sldemo_variant_subsystems/Scope' }
    {'sldemo_variant_subsystems/sine1' }
    {'sldemo_variant_subsystems/sine2' }
    {'sldemo_variant_subsystems/sine3' }
    {'sldemo_variant_subsystems/Out1' }
```

```
find_system(model, 'MatchFilter', @Simulink.match.codeCompileVariants)
```

```
ans = 26x1 cell
    {'sldemo_variant_subsystems' }
```

```

{'sldemo_variant_subsystems/Controller' }
{'sldemo_variant_subsystems/Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Linear Controller' }
{'sldemo_variant_subsystems/Controller/Linear Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/Linear Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/Linear Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Linear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Linear Controller/Discrete...' }
{'sldemo_variant_subsystems/Controller/Linear Controller/Out1' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
{'sldemo_variant_subsystems/Controller/Out1' }
{'sldemo_variant_subsystems/More Info' }
{'sldemo_variant_subsystems/Scope' }
{'sldemo_variant_subsystems/sine1' }
{'sldemo_variant_subsystems/sine2' }
{'sldemo_variant_subsystems/sine3' }
{'sldemo_variant_subsystems/Out1' }

```

### After Model Compilation

Compile the model.

```
set_param(model, 'SimulationCommand', 'update');
```

Using the `Simulink.match.activeVariants` filter returns the blocks that are active in simulation.

```
find_system(model, 'MatchFilter', @Simulink.match.activeVariants)
```

```

ans = 19x1 cell
{'sldemo_variant_subsystems' }
{'sldemo_variant_subsystems/Controller' }
{'sldemo_variant_subsystems/Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
{'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
{'sldemo_variant_subsystems/Controller/Out1' }
{'sldemo_variant_subsystems/More Info' }
{'sldemo_variant_subsystems/Scope' }
{'sldemo_variant_subsystems/sine1' }
{'sldemo_variant_subsystems/sine2' }
{'sldemo_variant_subsystems/sine3' }
{'sldemo_variant_subsystems/Out1' }

```

Using the `Simulink.match.codeCompileVariants` filter returns the blocks that are part of the generated C code.

```
sldemo_variant_subsystems([], [], [], 'compileForCodegen');
sldemo_variant_subsystems([], [], [], 'term');
find_system('sldemo_variant_subsystems', 'MatchFilter', @Simulink.match.codeCompileVariants)

ans = 19x1 cell
    {'sldemo_variant_subsystems' }
    {'sldemo_variant_subsystems/Controller' }
    {'sldemo_variant_subsystems/Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
    {'sldemo_variant_subsystems/Controller/Out1' }
    {'sldemo_variant_subsystems/More Info' }
    {'sldemo_variant_subsystems/Scope' }
    {'sldemo_variant_subsystems/sine1' }
    {'sldemo_variant_subsystems/sine2' }
    {'sldemo_variant_subsystems/sine3' }
    {'sldemo_variant_subsystems/Out1' }
```

### Find All Blocks Irrespective of Block Activeness

Use the `Simulink.match.allVariants()` filter to find all blocks irrespective of whether the block is active or inactive due to variants.

```
find_system(model, 'MatchFilter', @Simulink.match.allVariants)

ans = 26x1 cell
    {'sldemo_variant_subsystems' }
    {'sldemo_variant_subsystems/Controller' }
    {'sldemo_variant_subsystems/Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Linear Controller' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/Add' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/Discrete...' }
    {'sldemo_variant_subsystems/Controller/Linear Controller/Out1' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor1' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor2' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/sensor3' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/1-D Lookup Table' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Add' }
    {'sldemo_variant_subsystems/Controller/Nonlinear Controller/Out1' }
    {'sldemo_variant_subsystems/Controller/Out1' }
    {'sldemo_variant_subsystems/More Info' }
```

```
{'sldemo_variant_subsystems/Scope'           }  
{'sldemo_variant_subsystems/sine1'          }  
{'sldemo_variant_subsystems/sine2'          }  
{'sldemo_variant_subsystems/sine3'          }  
{'sldemo_variant_subsystems/Out1'           }
```

## Export and Import Function Mockup Unit (FMU) from Model with Variant Subsystem Blocks

This example shows you how to export a standalone Functional Mock-up Unit (FMU) from a model containing a Variant Subsystem block, then import it into a new model.

### Explore and Export Model to Standalone FMU

1. Open the model `slexVariantSubsystems`. The model contains a variant subsystem block `Controller` with two choices `Linear Controller` and `Nonlinear Controller` with the conditions `VSS_MODE == 1` and `VSS_MODE == 2` respectively.

```
open_system('slexVariantSubsystems')
```

Copyright 2010-2013 The MathWorks, Inc.

2. Set **Variant activation time** to `startup` in the Block Parameters dialog box of the `Controller` block. Also, set the `Linear Controller` and `Nonlinear Controller` choices as `atomic`.

```
set_param('slexVariantSubsystems/Controller','VariantActivationTime','startup');
set_param('slexVariantSubsystems/Controller/Linear Controller','TreatAsAtomicUnit','on');
set_param('slexVariantSubsystems/Controller/Nonlinear Controller','TreatAsAtomicUnit','on');
```

3. Set the active choice to `Nonlinear Controller` by setting `VSS_MODE` to `2`, then simulate the model.

```
VSS_MODE = 2;
sim('slexVariantSubsystems');
```

4. To export the model to an FMU:

- a. In the **Simulation** tab, click the **Save** drop-down.
- b. In the **Export Model To** section, click **Standalone FMU....**
- c. In FMU Export dialog, specify the location to save the FMU to be generated.
- d. Click **Create** to export to FMU.

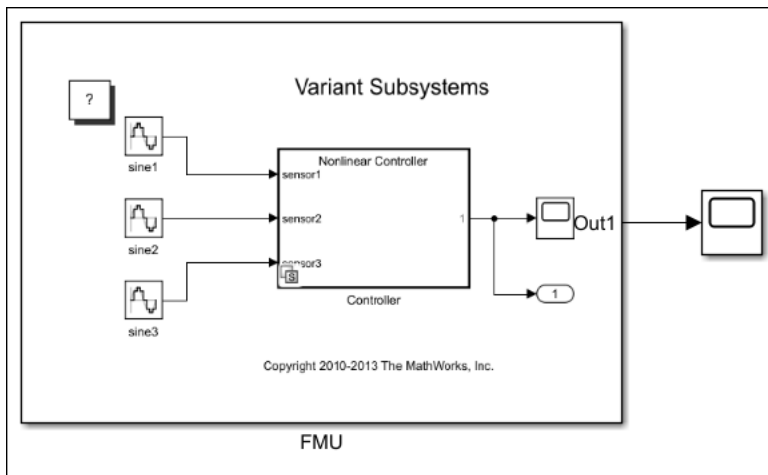

The generated FMU file, with the extension `.fmu` is at your specified location. You can now use this FMU file in the FMU block.

### Create Model with Standalone FMU

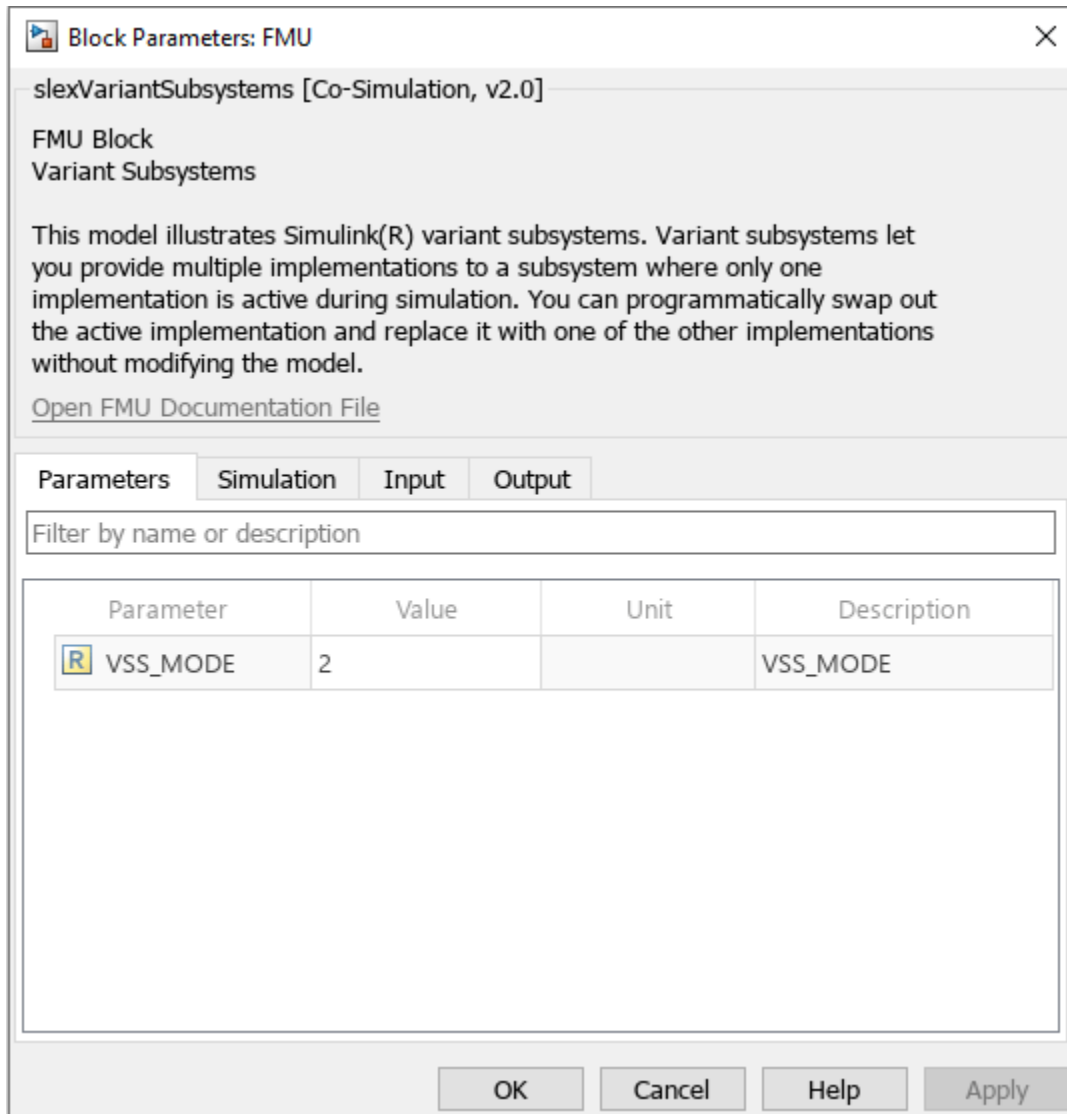

The FMU block lets you import your applications, contained in FMUs, into Simulink® to create a model with a standalone FMU.

To create a standalone FMU:

1. Create a model and add an FMU block from the Simulink Extras/FMU Import library.
2. Specify the name of the generated FMU file in the **FMU name** parameter in the Block Parameters dialog of the FMU block. The FMU block icon and port labels update to the labels of the corresponding FMU. You now have a standalone FMU.

When you double-click the FMU block, the **Parameters** tab of the **Block Parameters** has the same active choice as when you export the FMU, as the parameter `VSS_MODE` is equal to 2. You can change the value of the active choice by changing `VSS_MODE` to 1.

## Post-Build Support for AUTOSAR Variants

AUTOSAR software components use variants to enable or disable AUTOSAR interfaces or implementations in the execution path based on defined conditions. Variation points in a component present a choice between two or more variants. With post-build variant binding support, as defined in the AUOSAR standard, the AUTOSAR variation point workflows are enhanced. Previously, AUTOSAR Blockset supported pre-compile variant binding. With post-build variant binding, you can configure variants modeled in Simulink to activate at or after AUTOSAR software component startup by using an AUTOSAR RTE function call.

You can now:

- Import AUTOSAR software components containing post-build variation points from ARXML files into Simulink.
- Model AUTOSAR post-build variation points in software component models.
- Export ARXML variant descriptions that define `PostBuildVariantCriteria` criteria and `PostBuildVariantConditions` conditions and generate C code with AUTOSAR `Rte_PbCon` function calls.
- Import shared `PostBuildVariantCriterion` and `PostBuildVariantCondition` definitions from ARXML files into software component models.

For more information, see “Model AUTOSAR Variants” (AUTOSAR Blockset).

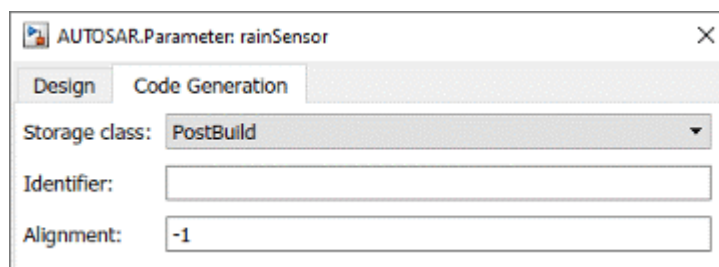

### Configure Post-Build for AUTOSAR Variants

AUTOSAR software components can use `VariationPoint` elements to enable or disable AUTOSAR elements such as ports and runnables based on defined conditions. In Simulink, to configure post-build binding for AUTOSAR:

- 1 Open an AUTOSAR component model in which Simulink variant blocks model AUTOSAR variants. For example, open the model `mAutosarVariantSubsystem.slx`, which is located in `matlabroot/help/toolbox/autosar/examples`.
- 2 Open the variant blocks and set the **Variant activation time** to startup. Click **Apply**.

- 3 Define post-build variant criteria and conditions for the AUTOSAR variants.
  - a For each post-build variant criterion, in the base workspace, create an `AUTOSAR.Parameter` object and set the storage class to `PostBuild`. Click **Apply**.

- b To construct a post-build variant condition, in a variant block, reference one or more criterion objects. For example, set `rainSensor == 1`. Click **Apply**.

Variant choices (table of variant systems)	
Name (read-only)	Variant control expression
VAR1	rainSensor == 1
VAR2	rainSensor == 2

**Note** To adhere to the AUTOSAR specification, construct the conditions in a specific format using equivalence to integer checks and && combinatorials. For example, `PBCrit1 == 1 && PBCrit2 == 2`.

- 4 Build the AUTOSAR component model. In the build folder:
- The exported ARXML file includes `PostBuildVariantCriterion` and `PostBuildVariantCondition` descriptions for the post-build variant criteria and conditions you defined.

```
<POST-BUILD-VARIANT-CONDITIONS>
  <POST-BUILD-VARIANT-CONDITION>
    <MATCHING-CRITERION-REF DEST="POST-BUILD-VARIANT-CRITERION">
      /vss_pkg/vss_dt/PostBuildCriteria/rainSensor
    </MATCHING-CRITERION-REF>
    <VALUE>1</VALUE>
  </POST-BUILD-VARIANT-CONDITION>
</POST-BUILD-VARIANT-CONDITIONS>
```

- The generated AUTOSAR C code includes `Rte_PbCon` function calls to resolve post-build conditions for variant binding.

```
void Runnable_Step(void)
{
  ...
  /* Outputs for Atomic SubSystem: '<Root>/Variant Subsystem' */
  if (Rte_PbCon_mAutosarVariantSubsystem_c0) {
    ...
  } else if (Rte_PbCon_mAutosarVariantSubsystem_c1) {
    ...
  }
  /* End of Outputs for SubSystem: '<Root>/Variant Subsystem' */
  ...
}
```

- For software-in-the-loop (SIL) simulation, in the stub folder, the model build generates stub implementations of the `Rte_PbCon` functions used to resolve the post-build conditions.

The ARXML file containing `PostBuild` conditions can now be imported. Parameter objects will be generated for each `PostBuildVariantCriterion` criterion and the relevant `Variant Source` and `Variant Sink` blocks will be created with `startup` variant activation time.

## Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files

This example shows how to add or remove the variant choices of a Variant Assembly Subsystem block without modifying the model. You can use external sources to manage the variant choices of the Variant Assembly Subsystem. For more information, see “Variant Assembly Subsystem”.

### Maintain Variant Choices of Variant Assembly Subsystem Block in Model and Subsystem Files

A Variant Assembly Subsystem block can contain Model blocks, “Subsystem Reference” blocks, or both as its variant choices. The variant choices are maintained in separate model and subsystem files that are on the MATLAB® path.

1. Open the `slexVariantAssemblySubsystem` model. The model contains a Variant Assembly Subsystem block Controller.

Copyright 2022 The MathWorks, Inc.

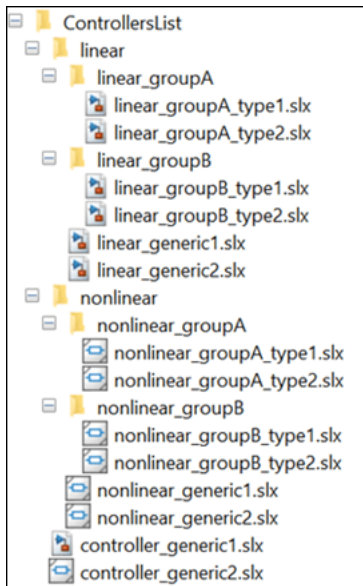

2. To add variant choices to the Controller block, open the Block Parameters dialog box and specify this MATLAB expression in the “**Variant choices specifier**” parameter.

```
{'linear_generic1','linear_generic2','nonlinear_generic1','nonlinear_generic2'}
```

In this example, the `linear_generic1` and the `linear_generic2` choices are Model blocks. The `nonlinear_generic1` and `nonlinear_generic2` blocks are Subsystem Reference blocks. These variant choices are maintained in their respective files inside the `ControllersList` folder.

Ensure that the `ControllersList` folder and all its subfolders are added to the search path of your current MATLAB session by using the `addpath` function.

3. After you specify an expression in the **Variant choices specifier** parameter, click the **Validate** button. The expression is evaluated to ensure that it is a valid MATLAB expression that returns a one-dimensional cell array of model or subsystem file names or file name patterns that are on the MATLAB path. On successful validation, the variant choices are added to the Controller block. Any errors encountered during the validation are displayed in the block dialog.

4. Double-click the Controller block to observe the four variant choices `linear_generic1`, `linear_generic2`, `nonlinear_generic1`, and `nonlinear_generic2` that are added to the Controller block. The file name and the path of the newly added variant choices are displayed in the **Variant Choices** table in the **Reference** tab.

5. From **Label mode active choice**, select `linear_generic1` and simulate the model. Observe that the `linear_generic1` choice becomes active.

6. You can modify the expression in the **Variant choices specifier** parameter as described in “Specify Variant Choices of Variant Assembly Subsystem Block in Variant Choices Specifier Parameter” on page 12-317, then simulate the model again.

## Specify Variant Choices of Variant Assembly Subsystem Block in Variant Choices Specifier Parameter

To add Model or Subsystem Reference blocks as variant choices to a Variant Assembly Subsystem block, specify the names of the files to be referenced. The file names must be specified as a MATLAB expression that returns a one-dimensional cell array of character vectors when evaluated. You can then validate the expression using the **Validate** button. On a successful validation, the blocks are added as variant choices to the Variant Assembly Subsystem block. The file names of the newly added variant choices and their corresponding absolute paths are displayed in the **Variant Choices** table.

The MATLAB expression that you specify must contain either of these:

- Model or subsystem file names that are on the search path of your current MATLAB session. For example, if you specify `{'modell.slx', 'subsystemRef1.slx'}` as a specifier, the blocks that reference the `modell.slx` and `subsystemRef1.slx` files are added as variant choices of the Variant Assembly Subsystem block.

- File name patterns which match the model or subsystem file names on the MATLAB path. The paths in the pattern can be absolute or relative to the parent folder of the model that contains the Variant Assembly Subsystem block. For example, if you specify {'folder\_1/\*.slx', 'folder\_2/\*.slx'} as a specifier, Simulink passes the character vectors folder\_1/\* and folder2/\* to the dir function. The function then returns the model and the subsystem files that are located inside the folder1 and folder2 folders. The blocks that reference the returned files are added as variant choices of the Variant Assembly Subsystem block.

For information on how to add files or folders to the search path, see `addpath`.

The following table shows different ways in which you can specify the **Variant choices specifier** parameter in the Controller block. Specify these expressions in the **Variant choices specifier** parameter and validate them by clicking the **Validate** button. On successful validation, the variant choices are added to the Controller block.

Variant Choices Specifier	Added Variant Choices
<p><b>Description</b> — Specify a relative path to a folder that contains model or subsystem files.</p> <p><b>Value</b> — {'ControllersList/*'}</p>	<p>The model or subsystem files that are located inside the ControllersList folder are added as variant choices. Files inside the subfolders of ControllersList are not added. The added choices are:</p> <ul style="list-style-type: none"> <li>• controller_generic1</li> <li>• controller_generic2</li> </ul>
<p><b>Description</b> — Specify relative path to a folder and its subfolders that contain model or subsystem files.</p> <p><b>Value</b> — {'ControllersList/**'}</p>	<p>The model or subsystem files that are located inside the ControllersList folder are added as variant choices. Files inside the subfolders of ControllersList are also added. The added choices are:</p> <ul style="list-style-type: none"> <li>• linear_groupA_type1</li> <li>• linear_groupA_type2</li> <li>• linear_groupB_type1</li> <li>• linear_groupB_type2</li> <li>• linear_generic1</li> <li>• linear_generic2</li> <li>• nonlinear_groupA_type1</li> <li>• nonlinear_groupA_type2</li> <li>• nonlinear_groupB_type1</li> <li>• nonlinear_groupB_type2</li> <li>• nonlinear_generic1</li> <li>• nonlinear_generic2</li> <li>• controller_generic1</li> <li>• controller_generic2</li> </ul>

Variant Choices Specifier	Added Variant Choices
<p><b>Description</b> — Specify relative path to a folder and its subfolders one level down that contain model or subsystem files.</p> <p><b>Value</b> — {'ControllersList/*', 'ControllersList/*/*'}</p>	<p>The model or subsystem files that are located inside the ControllersList folder are added as variant choices. Files inside the subfolders linear and nonlinear are also added. The added choices are:</p> <ul style="list-style-type: none"> <li>• linear_generic1</li> <li>• linear_generic2</li> <li>• nonlinear_generic1</li> <li>• nonlinear_generic2</li> <li>• controller_generic1</li> <li>• controller_generic2</li> </ul>
<p><b>Description</b> — Specify relative path to a folder that contain model or subsystem files and has subfolder names with a certain ending.</p> <p><b>Value</b> — {'ControllersList/**/*groupA/*'}</p>	<p>The model or subsystem files that are located inside the linear_groupA and nonlinear_groupA subfolders are added as variant choices. The added choices are:</p> <ul style="list-style-type: none"> <li>• linear_groupA_type1</li> <li>• linear_groupA_type2</li> <li>• nonlinear_groupA_type1</li> <li>• nonlinear_groupA_type2</li> </ul>
<p><b>Description</b> — Specify an absolute path to a folder that contains model or subsystem files</p> <p><b>Value</b> — In Windows systems, {'C:\VAS\ControllersList\*'}</p> <p>In UNIX systems, {'/VAS/ControllersList/*'}</p>	<p>The model or subsystem files that are located inside the ControllersList folder are added as variant choices. Files inside the subfolders of ControllersList are not added. The added choices are:</p> <ul style="list-style-type: none"> <li>• controller_generic1</li> <li>• controller_generic2</li> </ul>
<p><b>Description</b> — Specify the model or subsystem file names in a cell array</p> <p><b>Value</b> — {'linear_groupA_type1', 'linear_groupB_type2', 'nonlinear_generic1', 'controller_generic2'}</p>	<p>The specified model and subsystem files are added as variant choices. The added choices are:</p> <ul style="list-style-type: none"> <li>• linear_groupA_type1</li> <li>• linear_groupB_type2</li> <li>• nonlinear_generic1</li> <li>• controller_generic2</li> </ul>

Variant Choices Specifier	Added Variant Choices
<p><b>Description</b> — Create a MATLAB workspace variable that returns a cell array of models or subsystem file names. You can then specify the variable name as a variant choices specifier.</p> <p>For example, controllers:</p> <pre>controllers = {'linear_groupA_type1', 'linear_groupB_type2', 'nonlinear_generic1', 'controller_generic2'}</pre> <p><b>Value</b> — controllers</p>	<p>The model or subsystem files specified in <code>controllers</code> are added as variant choices. The added choices are:</p> <ul style="list-style-type: none"> <li>• linear_groupA_type1</li> <li>• linear_groupB_type2</li> <li>• nonlinear_generic1</li> <li>• controller_generic2</li> </ul>
<p><b>Description</b> — Create a MATLAB function that returns a cell array of models or subsystem file names. You can then specify the function name as a variant choices specifier.</p> <p>For example, the <code>getMyListOfControllerChoices</code> function is available for you to use.</p> <pre>function choices = getMyListOfControllerChoices     choices = {'linear_groupA_type1', 'linear_groupB_type2', ...         'nonlinear_generic1', 'controller_generic2'}; end</pre> <p><b>Value</b> — getMyListOfControllerChoices</p>	<p>The model or the subsystem files returned by <code>getMyListOfControllerChoices</code> are added as variant choices. The added choices are:</p> <ul style="list-style-type: none"> <li>• linear_groupA_type1</li> <li>• linear_groupB_type2</li> <li>• nonlinear_generic1</li> <li>• controller_generic2</li> </ul>
<p><b>Description</b> — Create a MATLAB function that returns a cell array of models or subsystem file names, and a file name pattern. You can then specify the function name as a variant choices specifier.</p> <p>For example, <code>getMyListOfControllers</code>.</p> <pre>function choices = getMyListOfControllers     choices = {'controller_generic1', 'ControllersList/nonlinear/**'}; end</pre> <p><b>Value</b> — getMyListOfControllers</p>	<p>The model and subsystem files returned by <code>getMyListOfControllers</code> are added as a variant choices. The added choices are:</p> <ul style="list-style-type: none"> <li>• nonlinear_groupA_type1</li> <li>• nonlinear_groupA_type2</li> <li>• nonlinear_groupB_type1</li> <li>• nonlinear_groupB_type2</li> <li>• nonlinear_generic1</li> <li>• nonlinear_generic2</li> <li>• controller_generic1</li> </ul>

Variant Choices Specifier	Added Variant Choices
<p><b>Description</b> — Create a MATLAB function to exclude certain files or folders from the selection. You can then specify the function name as a variant choices specifier.</p> <p>For example, the <code>getMyFilteredListOfControllerChoices</code> function is available for you to use.</p> <pre>function choices = getMyFilteredListOfControllerChoices % Pattern to include all the files inside 'ControllersList/' patternToInclude = 'ControllersList/**';  % Pattern to exclude all the files inside 'ControllersList/linear/linear_groupA/' patternToExclude = 'ControllersList/linear/linear_groupA/**';  % Set difference of files to include and exclude choices = setdiff(getSLXFileNames(patternToInclude), getSLXFileNames(patternToExclude));  function fileNames = getSLXFileNames(pattern) [~, fileNames, fileExts] = fileparts({dir(pattern).name}); fileNames = fileNames(strcmp(fileExts, '.slx')); end end</pre> <p><b>Value</b> — <code>getMyFilteredListOfControllerChoices</code></p>	<p>The model or subsystem files of <code>ControllersList</code> except those in <code>ControllersList/linear/linear_groupA</code> are added as variant choices. The added choices are:</p> <ul style="list-style-type: none"> <li>• <code>linear_groupB_type1</code></li> <li>• <code>linear_groupB_type2</code></li> <li>• <code>linear_generic1</code></li> <li>• <code>linear_generic2</code></li> <li>• <code>nonlinear_groupA_type1</code></li> <li>• <code>nonlinear_groupA_type2</code></li> <li>• <code>nonlinear_groupB_type1</code></li> <li>• <code>nonlinear_groupB_type2</code></li> <li>• <code>nonlinear_generic1</code></li> <li>• <code>nonlinear_generic2</code></li> <li>• <code>controller_generic1</code></li> <li>• <code>controller_generic2</code></li> </ul>

**See Also**

“Control Variant Choices in Masked Variant Assembly Subsystem Block Using Mask Parameter Object” on page 12-325 | “Convert Variant Subsystem to Variant Assembly Subsystem” on page 12-322

## Convert Variant Subsystem to Variant Assembly Subsystem

A “Variant Assembly Subsystem” block enables you to add or remove its variant choices from external sources without modifying the model. The Variant Assembly Subsystem block can contain Model blocks, “Subsystem Reference” blocks, or both as its variant choices. The choices are maintained in corresponding model or subsystem files that are on the MATLAB path.

During the conversion, the Variant Assembly Subsystem block:

- Validates the current configuration of Variant Subsystem for conversion
- Converts all the Subsystem choices (if any) to Subsystem Reference choices with the same name as the block
- Constructs a variant choice specifier of the form { '<file\_1>', '<file\_2>', ..., '<file\_N>' }, where `file_k` is the model or subsystem file name that contains the choice blocks
- Overwrites the values of the parameters “Name (read-only)” and “Variant control label” with the name of the model or subsystem files
- Displays the “File” and the “Path” of the newly added variant choices in the **Variant Choices** table

### Convert Variant Subsystem to Variant Assembly Subsystem Through Block Dialog

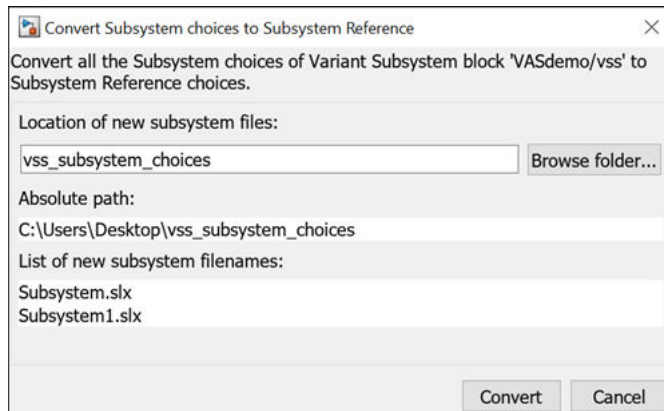

- 1 Open a model containing a Variant Subsystem block.
- 2 Set the **Variant control mode** parameter to `label` in the block dialog.
- 3 On the **Reference** tab, click the **Convert to Variant Assembly...** button.

If the Variant Subsystem block has at least one **Subsystem** block as its variant choice then a **Convert Subsystem choices to Subsystem Reference** dialog is displayed. Specify these details in the dialog:

- a In the **Location of new subsystem reference** parameter, specify a path to the folder where all the new Subsystem Reference blocks are to be saved in subsystem files. The folder path can be either a relative path to the model that contains the Variant Subsystem block or an absolute path. You can also select a folder from the file system by clicking the **Browse folder...** button.

By default, the relative folder path is generated with `_subsystem_choices` appended to the Variant Subsystem block name. The absolute path of that folder is displayed in the **Absolute path** parameter.

- b The **List of new subsystem filenames** lists the names of the subsystem files that correspond to the newly created Subsystem Reference blocks after the conversion. The names of the subsystem files are the same as the Subsystem blocks to be converted.

- c To validate the current configuration of the Variant Subsystem block, click **Convert**. If these validations pass, the Variant Subsystem block is converted to a Variant Assembly Subsystem block:
  - If the specified folder exists in the file system but not on the MATLAB path, you must resolve the issue by clicking **Add to path** from the dialog or using the `addpath` function.
  - If the specified folder does not exist in the file system, Simulink attempts to create the folder by using `mkdir` command and then add it to the MATLAB path.
  - If the specified folder contains a file whose name matches with one of the new subsystem file names, you must determine if you want to replace them.

## Convert Variant Subsystem Block to Variant Assembly Subsystem Programmatically

This example explains how to convert the Variant Subsystem block in a Simulink® model to a Variant Assembly Subsystem using the `Simulink.VariantManager.convertToVariantAssemblySubsystem` method.

1. Consider the `Controller` block in the `slexVariantSubsystems` model. The `Controller` block is a Variant Subsystem block that is to be converted to a Variant Assembly Subsystem block.

```
modelName = 'slexVariantSubsystems';
open_system(modelName);
```

```
VSS_MODE = 2
```

```
vssBlockPath = [modelName, '/Controller'];
```

2. Set the variant control mode of the `Controller` block to `label`.

```
set_param(vssBlockPath, 'VariantControlMode', 'label');
```

3. To convert the `Controller` block to a Variant Assembly Subsystem block, use the `convertToVariantAssemblySubsystem` method. After the conversion, the Subsystem choices `Linear_Controller` and `Nonlinear_Controller` are converted to Subsystem Reference blocks with the same name as the Subsystem blocks. The Subsystem Reference blocks are saved in the newly created subsystem files `Linear_Controller.slx` and `Nonlinear_Controller.slx` in your current working folder.

```
Simulink.VariantManager.convertToVariantAssemblySubsystem(vssBlockPath, pwd);
```

### Limitations

Only the Variant Subsystem block with the **Variant control mode** set to `label` can be converted to a Variant Assembly Subsystem block.

“Add or Remove Variant Choices of Variant Assembly Subsystem Blocks Using External Files” on page 12-316

## Control Variant Choices in Masked Variant Assembly Subsystem Block Using Mask Parameter Object

This example shows how to specify variant choices and set an active choice in a masked “Variant Assembly Subsystem” block using a mask parameter object.

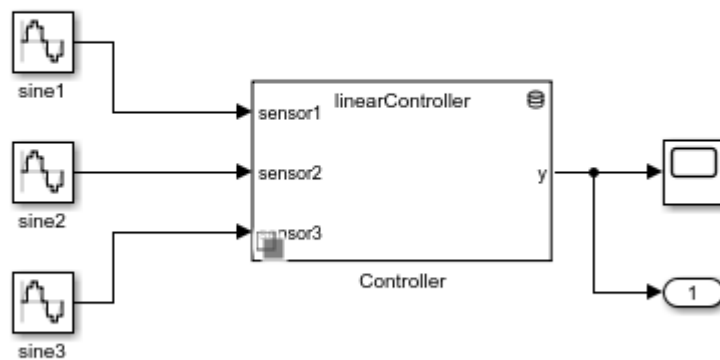

### Explore Model

Open the model `slexVariantAssemblySubsystemWithMask`, which contains a masked Variant Assembly Subsystem block, Controller.

```
open_system('slexVariantAssemblySubsystemWithMask')
```

### Masked Variant Assembly Subsystem

Copyright 2022 The MathWorks, Inc.

### Define Classes for Reference Models

In this example, the `vas_controller` class is a superclass that includes a property and two methods. The `getVariantChoices` method returns a cell array of variant choices to be added to the Variant Assembly Subsystem block. From the list of choices, the `setActiveVariant` method sets the choice, specified as `subsystemFile`, to be active.

```
type vas_controller.m
```

```
classdef (Abstract) vas_controller
    properties
        subsystemFile char
    end
    methods (Static)
        function list = getVariantChoices()
            list = {'linearController','nonlinearController'};
        end
    end
end
```

```
        methods
            function setActiveVariant(obj,blk)
                set_param(blk,'LabelModeActiveChoice',obj.subsystemFile)
            end
        end
    end
end
```

The two classes `vas_linearController` and `vas_nonlinearController` inherit from the `vas_controller` superclass. The `vas_linearController` class stores the name of the active choice as `linearController` in the inherited property `subsystemFile`. The class also stores numerator and denominator values used in the Discrete Transfer Fcn block of the `linearController` model.

type `vas_linearController.m`

```
classdef vas_linearController < vas_controller
    properties
        numerator
        denominator
    end

    methods
        function obj = vas_linearController()
            obj.numerator = [1 .7];
            obj.denominator = [1 .09 0.5];
            obj.subsystemFile = 'linearController';
        end
    end
end
```

Similarly, the `vas_nonlinearController` class stores the name of the active choice as `nonlinearController` in `subsystemFile`. The class also stores breakpoint and table values used in the 1-D Lookup Table of the `nonLinearController` model.

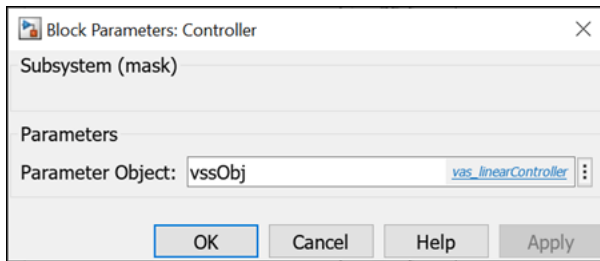

type `vas_nonlinearController.m`

```
classdef vas_nonlinearController < vas_controller
    properties
        breakpoints
        table
    end

    methods
        function obj = vas_nonlinearController()
            obj.breakpoints = -5:5;
            obj.table = tanh(-5:5);
            obj.subsystemFile = 'nonlinearController';
        end
    end
end
```

### Set Parameter Object Value in Parent Model

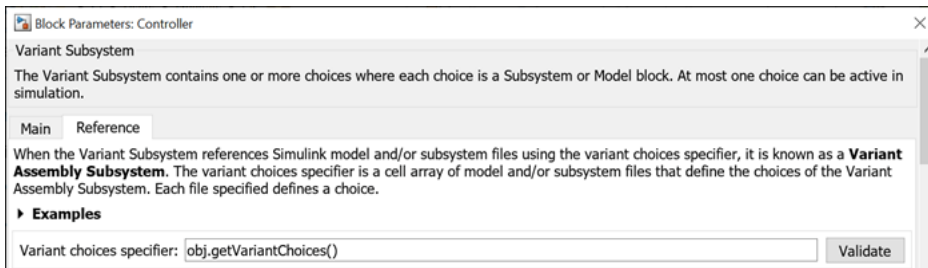

Double-click the Controller block to open the mask dialog box.

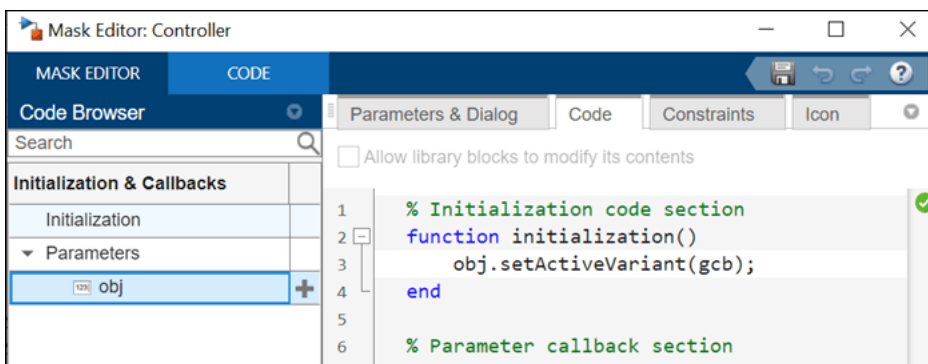

The value that you specify for `vssObj` in the mask dialog box is mapped to the mask parameter object `obj`.

Using `obj`, you can instantiate the class `vas_linearController` or `vas_nonlinearController`. You can then call its methods, `getVariantChoices` and `setActiveVariant`.

For example, to specify the variant choices of the Controller block, the “**Variant choices specifier**” parameter in the **Reference** tab of the Block Parameters dialog box is set to `obj.getVariantChoices()`.

To set an active choice in the Variant Assembly Subsystem block, the `obj.setActiveVariant()` method is used in its mask initialization code.

## Set Active Choice by Instantiating Classes Using Mask Parameter Object

### Case 1: linearController Is Active and nonlinearController Is Inactive

When you specify `vssObj` as `vas_linearController`, the value `vas_linearController` is mapped to the mask parameter object `obj`. The **Variant choices specifier** parameter value `obj.getVariantChoices()` evaluates to a cell array that contains the filenames `linearController` and `nonlinearController` to be added as variant choices to the Controller block. `obj.setActiveVariant(gcb)` in the mask initialization code sets the `linearController` subsystem to be active.

```
vssObj = vas_linearController;  
out = sim('slexVariantAssemblySubsystemWithMask');  
plot(out.tout, out.yout);  
xlabel('Time (seconds)')  
ylabel('data')
```

### Case 2: linearController Is Inactive and nonlinearController Is Active

When you specify `vssObj` as `vas_nonlinearController`, the value `vas_nonlinearController` is mapped to the mask parameter object `obj`. The **Variant choices specifier** parameter value `obj.getVariantChoices()` evaluates to a cell array that contains the filenames `linearController` and `nonlinearController` to be added as variant choices to the Controller block. `obj.setActiveVariant(gcb)` in the mask initialization code sets the `nonlinearController` subsystem to be active.

```
vssObj = vas_nonlinearController;  
out = sim('slexVariantAssemblySubsystemWithMask');  
plot(out.tout, out.yout);  
xlabel('Time (seconds)')  
ylabel('data')
```

# Managing Model Configurations

---

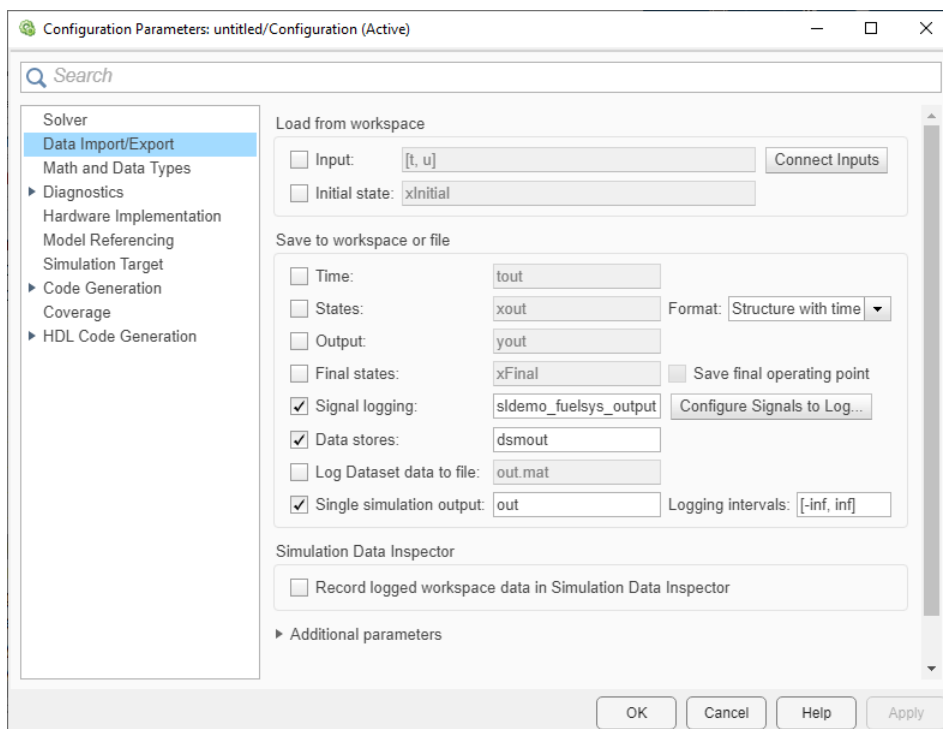

- “Set Model Configuration Parameters for a Model” on page 13-2
- “Manage Configuration Sets for a Model” on page 13-5
- “Share a Configuration with Multiple Models” on page 13-10
- “Share a Configuration Across Referenced Models” on page 13-18
- “Automate Model Configuration by Using a Script” on page 13-22
- “Configuration Object Functions” on page 13-25

## Set Model Configuration Parameters for a Model

Model configuration parameters determine how your model runs by specifying the type of solver used, import and export settings, and other settings that control model behavior. Every model has a *configuration set* that contains the model configuration parameters and their specified values. When you create a new model, it contains the default configuration set, called *Configuration*, that specifies the default values for the model configuration parameters.

To view and set the configuration parameters for your model, open the Configuration Parameters

dialog box. In the Simulink Editor, on the **Modeling** tab, click **Model Settings** .

Right-click a parameter name and select **What's This?** to see:

- A short parameter description.
- The parameter name that you can use in scripts.
- Parameter dependencies.

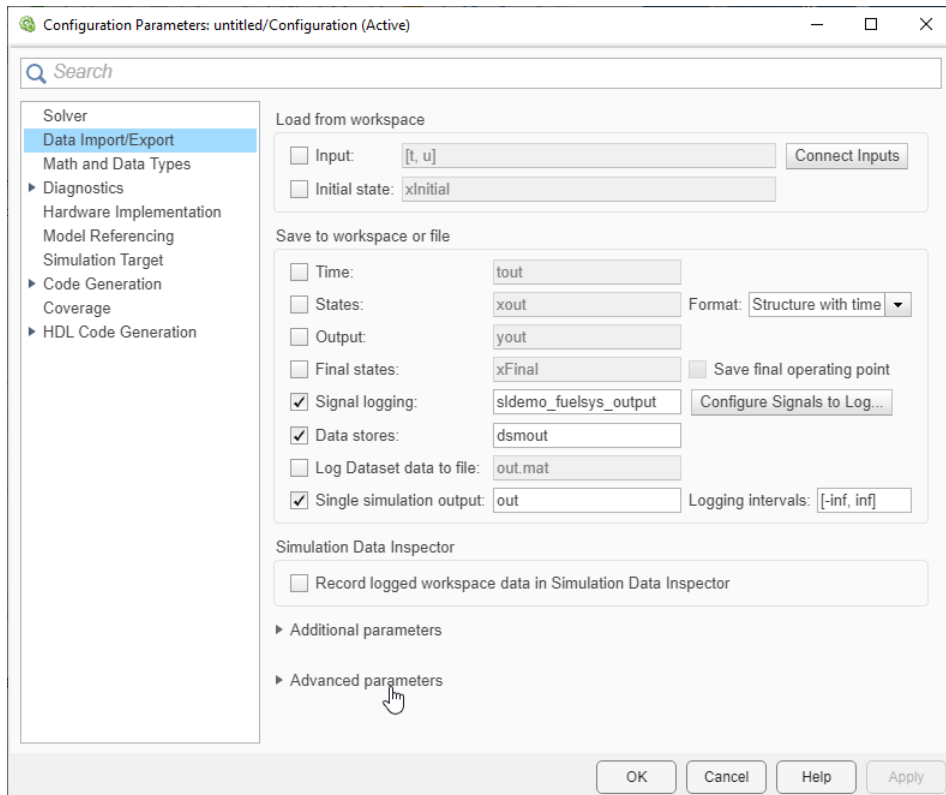

From the **What's This?** dialog box, click **Show more information** for the complete parameter documentation.

To find a parameter by using its name, command-line name, value, or description, use the **Search** box at the top of the dialog box. The search tool supports regular expressions. Type `.` in the search box to see a list of all parameters.

## Configuration Panes

The configuration set is organized in panes that contain parameters related to that category. To display the parameters for a specific category, click the associated pane in the tree on the left side of the dialog box. You can access the advanced parameters for each pane by mousing over the ellipsis toward the bottom of the dialog box and clicking **Advanced parameters**.

For more information about the parameters on each of the panes, see:

- “Solver Pane”
- “Model Configuration Parameters: Data Import/Export”
- “Math and Data Types Pane”
- “Model Configuration Parameters: Diagnostics”
- “Hardware Implementation Pane”
- “Model Configuration Parameters: Model Referencing”
- “Model Configuration Parameters: Simulation Target”

Some MathWorks products that work with Simulink define additional parameters. For example, parameters related to Simulink Coder are located on the “Model Configuration Parameters: Code Generation” (Simulink Coder) pane. If such a product is installed on your system, the configuration set also contains the associated configuration parameters and panes.

## Manage Configuration Sets for a Model

### In this section...

- “Create a Configuration Set in a Model” on page 13-5
- “Change Configuration Parameter Values in a Configuration Set” on page 13-6
- “Activate a Configuration Set” on page 13-7
- “Copy, Delete, and Move a Configuration Set” on page 13-7
- “Save a Configuration Set” on page 13-8
- “Load a Saved Configuration Set” on page 13-9
- “Compare Configuration Sets” on page 13-9

A model configuration set is a named collection of values for the parameters of a model.

You can associate multiple sets of parameter values with your model. The configuration sets associated with a model can specify different values for any or all configuration parameters. The model uses the parameter values of the *active* configuration. You can quickly change the active configuration to any of the configuration sets that are attached to the model.

Use multiple configuration sets in a model when you want to:

- Compare the difference in model execution after changing the values of several parameters.
- Use different configurations for your model when you use the model in different contexts.

For this example, you set up the model `sldemo_fuelsys_dd` to have two configuration sets that specify different solvers. You then copy one of the configurations to the model `vdp` and compare it with the default configuration set of `vdp`.

### Create a Configuration Set in a Model

The model `sldemo_fuelsys_dd` contains one configuration set, which uses a variable-step solver. Add another configuration to use a fixed-step solver.

- 1 Open the model. At the command line, type `sldemo_fuelsys_dd`.
- 2 Open the Model Explorer. On the **Modeling** tab, click **Design > Model Explorer**.
- 3 In the **Model Hierarchy** pane, expand the model node and select the model name `sldemo_fuelsys_dd`.
- 4 You can create a new configuration set in any of these ways:
  - From the **Add** menu, select **Configuration**.
  - On the toolbar, click the **Add Configuration** button .
  - Select the **Configurations** node below the model node. In the **Contents** pane, right-click an existing configuration set and copy and paste the configuration set.
- 5 Select the **Configurations** node below the model node. The new configuration set, `Configuration1`, appears in the **Contents** pane. The default configuration, `Configuration`, is still the active configuration for the model.

- 6 On the **Contents** pane, double-click the name Configuration1 and rename the configuration to FixedStepConfig. You specify the fixed-step solver in the following section.
- 7 Rename the configuration Configuration to VariableStepConfig.

## Change Configuration Parameter Values in a Configuration Set

To change the parameter values of a configuration set, open the Configuration Parameters dialog box for that configuration. You can open and change any configuration set, whether or not it is active.

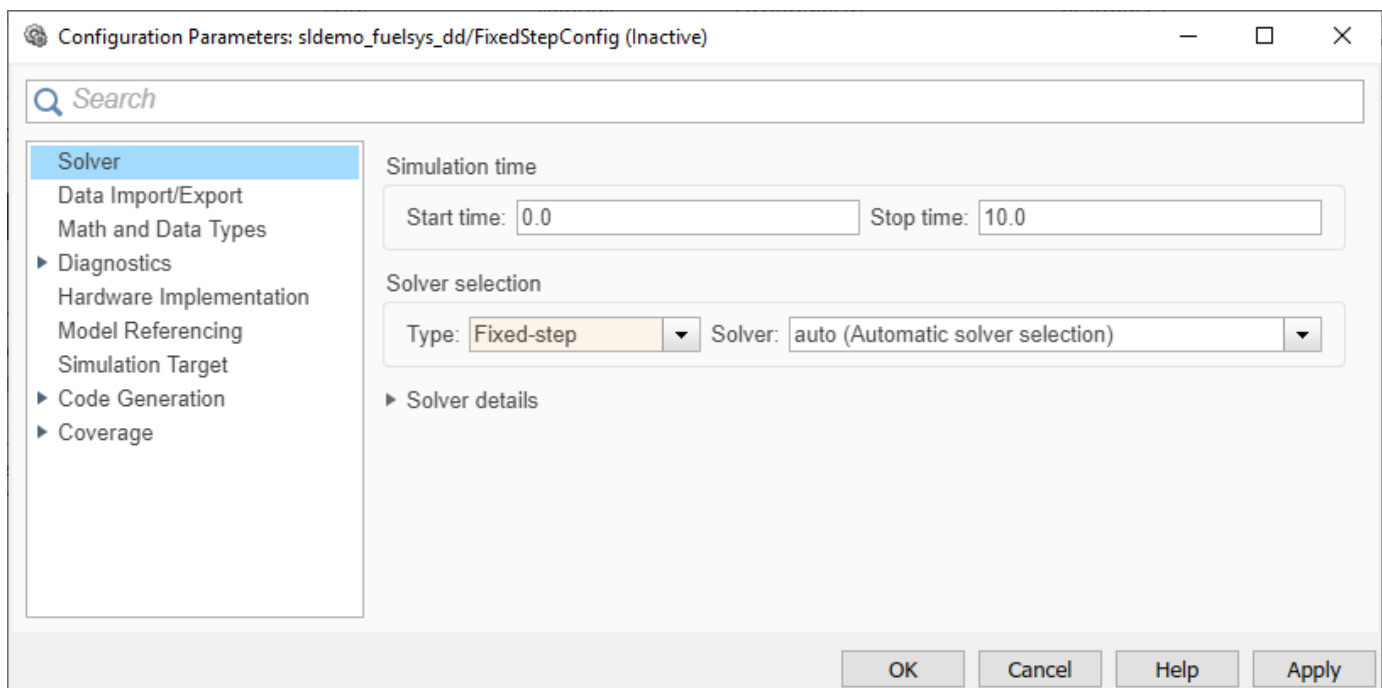

For this example, change the configuration FixedStepConfig to specify a fixed-step solver instead of the default variable-step solver.

- 1 Open the Model Explorer.
- 2 Expand the model node and select the **Configurations** node below it.
- 3 In the **Contents** pane, right-click the configuration set FixedStepConfig and click **Open**.

The configuration set opens in the Configuration Parameters dialog box.

**Note** Every configuration set has its own Configuration Parameters dialog box. As you change the state of a configuration set, the title bar of the dialog box changes to reflect the state.

- 4 On the **Solver** pane, set the **Type** parameter to Fixed-step. Click **OK**.

The model now contains two configurations, VariableStepConfig and FixedStepConfig, which use different solver types. You can compare how the solver settings affect simulation by changing the active configuration and simulating the model.

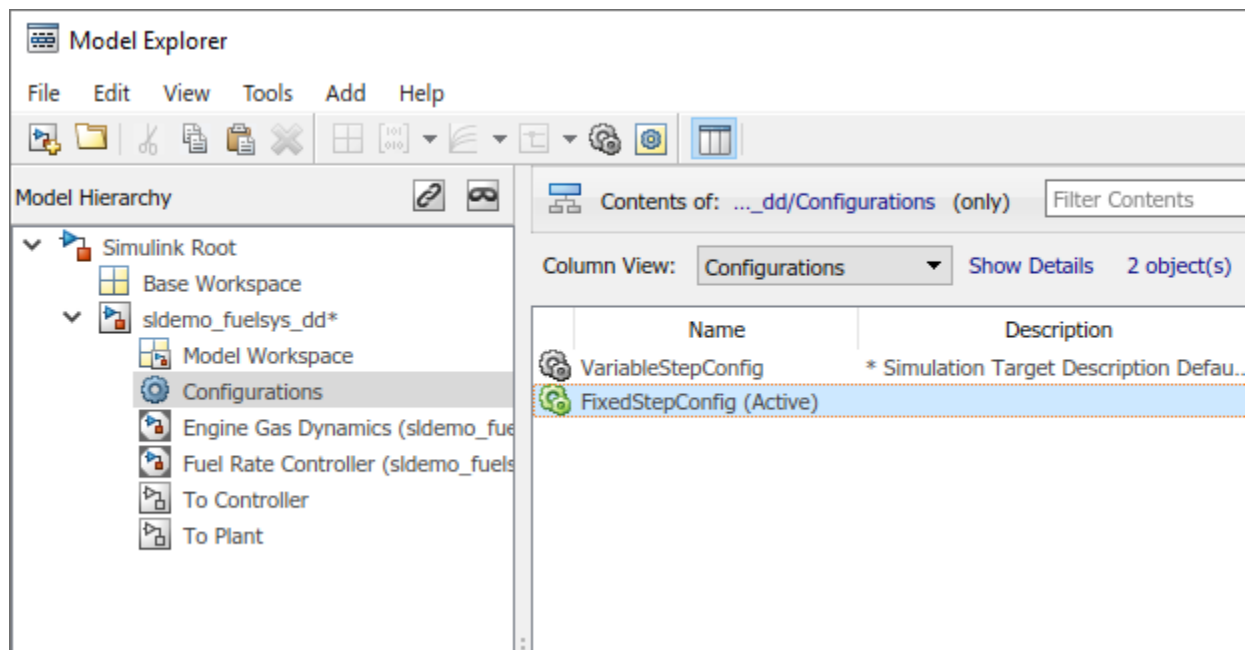

## Activate a Configuration Set

Only one configuration set associated with a model is active at any given time. The active set determines the current values of the model parameters. You can change parameter values in the active or inactive set at any time (except when executing the model). In this way, you can quickly reconfigure a model for different purposes, such as testing and production.

To activate the fixed-step configuration that you created in the previous section:

- 1 Open the Model Explorer.
- 2 Expand the model node and select the **Configurations** node below it.
- 3 In the **Contents** pane, right-click the configuration set `FixedStepConfig` and click **Activate**.

The active configuration displays (Active) to the right of the configuration name.

## Copy, Delete, and Move a Configuration Set

You can use the Model Explorer **Edit** or context menus to delete, copy, and move configuration sets among models displayed in the **Model Hierarchy** pane.

For this example, copy your configuration `FixedStepConfig` to the model `vdp`.

- 1 Open the model `vdp` and open the Model Explorer.
- 2 In the **Model Hierarchy** pane, expand the node of the model `sldemo_fuelsys_dd` and select the **Configurations** node below it.
- 3 In the **Contents** pane, right-click `FixedStepConfig` and click **Copy** in the context menu.
- 4 In the **Model Hierarchy** pane, right-click the model node `vdp` and click **Paste**.
- 5 Activate the configuration `FixedStepConfig` for the model `vdp`.

To copy the configuration set using drag-and-drop, hold down the right mouse button and drag the configuration set to the Configurations node of the model in which you want to create the copy.

To move a configuration set from one model to another using drag-and-drop, hold the left mouse button down and drag the configuration set to the Configurations node of the destination model.

---

**Note** You cannot move or delete an active configuration set from a model.

---

## Save a Configuration Set

When you store a configuration set in a model, the configuration set is saved when you save the model. Alternatively, you can store the configuration set outside of the model as a freestanding configuration set to share the configuration with other models. You can save the configuration set in a Simulink data dictionary, or export the configuration set to a MAT-file or to a script. If you store a freestanding configuration set in the base workspace, to save it, you must export it to a MAT-file or script.

### Simulink Data Dictionary

To save your configuration set outside of the model, store the configuration in a Simulink data dictionary. You can share and archive the configuration by using the data dictionary. To use the configuration in a model, use a configuration reference. For more information, see “Share a Configuration with Multiple Models” on page 13-10.

### Exported File

You can also save the settings of a configuration set as a `Simulink.ConfigSet` object in a MAT-file or as a MATLAB function or script. Export the configuration set to a MATLAB function or script when you want to compare the settings in different configuration sets. However, when you want to preserve a freestanding configuration set, exporting the configuration to a file is not recommended because you must manually load the configuration set when you want to use it. Save the configuration set in a Simulink data dictionary instead.

For this example, use the Model Explorer to save the configuration set `FixedStepConfig`, which you copied to the model `vdp`.

- 1 Open the Model Explorer.
- 2 In the **Model Hierarchy** pane, expand the model node `vdp` and select the Configurations node below it.
- 3 In the **Contents** pane, right-click the configuration `FixedStepConfig` and select **Export**.
- 4 In the Export Configuration to File dialog box, specify the name of the file and the file type. For this example, save the configuration as `FixedStepConfig.m`.

If you specify a `.m` extension, the file contains a MATLAB function that creates a configuration set object. If you specify a `.mat` extension, the file contains a configuration set object.

---

### Note

- Do not specify the name of the file to be the same as a model name. If the file and model have the same name, the software cannot determine which file contains the configuration set object when loading the file.

- To use the configuration set in a later release, specify a `.mat` extension. If you specify a `.m` extension, in rare cases, parameter values might change due to changing dependencies.

- 5 Click **Save**. The Simulink software saves the configuration set.

## Load a Saved Configuration Set

To load the configuration set that you saved from the model `vdp`:

- 1 Open the model `vdp`.
- 2 Open the Model Explorer.
- 3 In the **Model Hierarchy** pane, right-click the model and select **Configuration > Import**.
- 4 In the Import Configuration From File dialog box, select the M file that contains the function to create the configuration set object, or the MAT-file that contains the configuration set object. For this example, select `FixedStepConfig.m`.
- 5 Click **Open**. The Simulink software loads the configuration set.

---

### Note

- If you load a configuration set object that contains an invalid custom target, the software sets the System target file (Simulink Coder) parameter to `ert.tlc`.
  - If you load a configuration set that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.
- 

## Compare Configuration Sets

When you save two configuration sets as M files or as MAT-files, you can visually compare them by using the `visdiff` function. This function opens the Comparison Tool and presents the differences between the two files. For more information about the Comparison Tool, see “Compare Simulink Models” on page 21-6.

For this example, compare the default configuration `Configuration` to the configuration `FixedStepConfig`, which you copied to the model `vdp`.

- 1 Save the configuration `FixedStepConfig` to the file `FixedStepConfig.m`, as shown in “Save a Configuration Set” on page 13-8.
- 2 Save the second configuration, `Configuration`, to the file `DefaultConfig.m` by following the same procedure.
- 3 Compare the files.

```
visdiff('FixedStepConfig.m','DefaultConfig.m');
```

- “Set Model Configuration Parameters for a Model” on page 13-2

## Share a Configuration with Multiple Models

### In this section...

- “Create a Configuration Set in the Data Dictionary” on page 13-11
- “Create and Attach a Configuration Reference” on page 13-11
- “Resolve a Configuration Reference” on page 13-12
- “Activate a Configuration Reference” on page 13-13
- “Create a Configuration Reference in Another Model” on page 13-13
- “Change Parameter Values in a Referenced Configuration Set” on page 13-14
- “Change Parameter Value in a Configuration Reference” on page 13-14
- “Save a Referenced Configuration Set” on page 13-16
- “Load a Saved Referenced Configuration Set” on page 13-16
- “Configuration Reference Limitations” on page 13-16

To share a configuration set with multiple models, store it as a *freestanding configuration set* in a Simulink data dictionary or in the base workspace. By default, a configuration set resides within a single model so that only that model can use it. A freestanding configuration set is a `Simulink.ConfigSet` object that you store outside of your models so that multiple models can use it.

To use a freestanding configuration set in a model, create a *configuration reference* in the model that points to the freestanding configuration set. You can then activate the configuration reference in the same way as a standard configuration set. Multiple models can reference the same freestanding configuration set.

Use configuration references when you want to:

- Use the same configuration parameters in multiple models. When you change parameter values in the freestanding configuration, the changes apply to each model that references the configuration.

To share a configuration set across a model hierarchy, you can propagate the reference from the top model to its referenced models. For more information, see “Share a Configuration Across Referenced Models” on page 13-18.

- Change configuration parameters for any number of models without changing the model files. When you store a configuration set in a Simulink data dictionary, changing parameter values in the configuration changes the data dictionary file. Models that are linked to the data dictionary and reference the configuration set use the new values, but their model files are not changed.
- Quickly replace the configuration sets of any number of models without changing the model files. When you store a configuration set in a Simulink data dictionary, you can point to that configuration from a reference that is also stored in the data dictionary. Your models can then reference the data dictionary's configuration reference. When you change the data dictionary's reference to point to a different configuration set, the models use the new configuration.

When a configuration reference references a configuration in the base workspace, it points to a variable that represents the `Simulink.ConfigSet` object. Assigning a different configuration set to the variable assigns that configuration set to each model that references the variable.

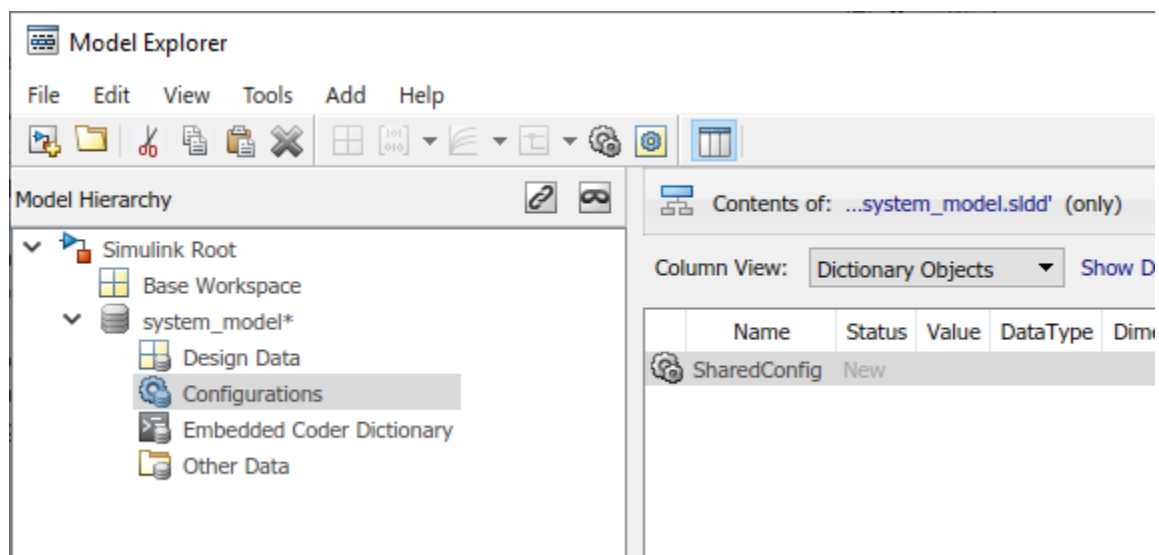

For this example, you store a configuration set in a Simulink data dictionary and reference the configuration set from models that are linked to the data dictionary. To create and link a Simulink data dictionary, see “Migrate Models to Use Simulink Data Dictionary” on page 79-7. To share a configuration set that is already saved in a model, convert the configuration to a referenced freestanding configuration, as shown in “Share a Configuration Across Referenced Models” on page 13-18.

## Create a Configuration Set in the Data Dictionary

Before you reference a freestanding configuration set from your models, create the configuration in a Simulink data dictionary and link it to your models. For this example, use the Simulink project `sldemo_slproject_airframe`. The project contains the Simulink data dictionary `system_model` and multiple models that are linked to the data dictionary.

- 1 Open the project. At the command line, type `sldemo_slproject_airframe`.
- 2 In the project folder, in the folder `data`, double-click the Simulink data dictionary `system_model.sldd`. The data dictionary opens in the Model Explorer.
- 3 In the **Model Hierarchy** pane, expand the data dictionary node for `system_model`. Right-click the node and click **Show Empty Sections**.
- 4 Select the **Configurations** node and click the **Add Configuration** button . The configuration set object appears in the **Contents** pane, with the default name, `Configuration`.
- 5 Name the new configuration `SharedConfig`.

Models that have access to the data dictionary `system_model.sldd` can reference the new configuration.

## Create and Attach a Configuration Reference

To use your freestanding configuration set in a model, attach a configuration reference that points to the configuration set. For this example, use the model `LinearActuator`. The model is linked to the Simulink data dictionary `system_model.sldd`, which contains your new configuration `SharedConfig`.

- 1 Open the model. At the command line, type `LinearActuator`.
- 2 In the Model Explorer, in the **Model Hierarchy** pane, select the model node.
- 3 Select **Add > Configuration Reference** or click the **Add Configuration Reference** button .
- 4 Under the model node, click **Configurations**. A new configuration reference named Reference is listed.
- 5 Name the configuration reference `LinActuatorRef`.

The new configuration reference is attached to the model, but it does not point to a freestanding configuration yet and it is not active. To complete the setup, resolve and activate the configuration reference.

## Resolve a Configuration Reference

An unresolved configuration reference is a configuration reference that is not pointing to a valid configuration set object. When you create a configuration reference by using the preceding steps, the reference is unresolved.

To resolve the configuration reference that you created:

- 1 In the **Model Hierarchy** pane, under the model node for the `LinearActuator` model, select the **Configurations** node. In the **Contents** pane, select the unresolved configuration reference, `LinActuatorRef`.

The right pane shows that the configuration reference is unresolved.

**Configuration Reference: LinearActuator/LinActuatorRef (Inactive)**

Configuration Reference

A configuration reference allows multiple models to use the same externally stored configuration set.

In a data dictionary or the base workspace, a configuration reference can be used to select the configuration for multiple models without modifying the models.

External configuration set referenced by 'LinearActuator'

Name: 

Select or specify configuration name

Location: system\_model.sidd

Description:

- 2 Use the **Name** drop-down menu to select SharedConfig, which you created in the data dictionary.

---

**Tip** You can specify the name of a configuration reference instead of a configuration set. However, nesting a configuration reference beyond this depth results in an error.

---

- 3 Click **Apply**. The warning icon disappears and the reference points to your freestanding configuration set.

If your configuration reference is already resolved, you can follow these steps to change which configuration set it references.

## Activate a Configuration Reference

After you create the configuration reference and attach it to the model, activate the reference to use the referenced configuration in the model.

- 1 In the **Model Hierarchy** pane, under the model node for the LinearActuator model, select the Configurations node. In the **Contents** pane, select the configuration reference LinActuatorRef.
- 2 Right-click the configuration reference LinActuatorRef and select **Activate**.

When the configuration reference is active, the Model Explorer shows the name of the reference with the suffix (Active). The freestanding configuration set now provides the configuration parameters for the model.

## Create a Configuration Reference in Another Model

For this example, you will update the configuration set and see how it affects its associated models. Repeat the process above to associate SharedConfig with a second model:

- 1 Open the model NonLinearActuator. This model is also linked to the data dictionary that contains the freestanding configuration set.

- 2 In Model Explorer, add a configuration reference to the model `NonLinearActuator`.
- 3 Name the configuration reference `NonLinActuatorRef`.
- 4 Point the reference to the freestanding configuration set `SharedConfig`.
- 5 Activate the configuration reference.

Both models now contain a configuration reference that points to the same configuration set object in the Simulink data dictionary.

## Change Parameter Values in a Referenced Configuration Set

You can edit a freestanding configuration set by opening it from the Configuration Reference dialog box of a reference that points to the configuration set. Changing the freestanding configuration set affects the configuration references that refer to it, except for parameters that are overridden in those references. To edit the configuration set that you reference from the models:

- 1 Open one of the models that references the configuration set. For this example, open the model `LinearActuator`.
- 2 To open the Configuration Reference dialog box, on the **Modeling** tab, click the **Model Settings** button . The Configuration Reference dialog box displays a read-only view of the referenced configuration `SharedConfig`. In the dialog box you can browse, search, and get context-sensitive help for the parameters in the same way you do in the Configuration Parameters dialog box.
- 3 At the top of the Configuration Reference dialog box, click the Model Configuration Parameters icon . The Configuration Parameters dialog box opens. You can now change and apply parameter values as you would for any configuration set.

---

**Note** Some options in the configuration set cannot be used in a freestanding configuration because they perform actions on one specific model. For example, the **Data Import/Export > Connect Inputs** button is not supported in freestanding configuration sets because it opens the Root Inport Mapper for the model that uses the configuration.

---

- 4 On the **Solver** pane, set the **Type** parameter to `Fixed-step`. Click **Apply**, then **OK**.
- 5 Your applied changes appear in the Configuration Reference dialog box. The models that reference the freestanding configuration `SharedConfig` use the new solver type.

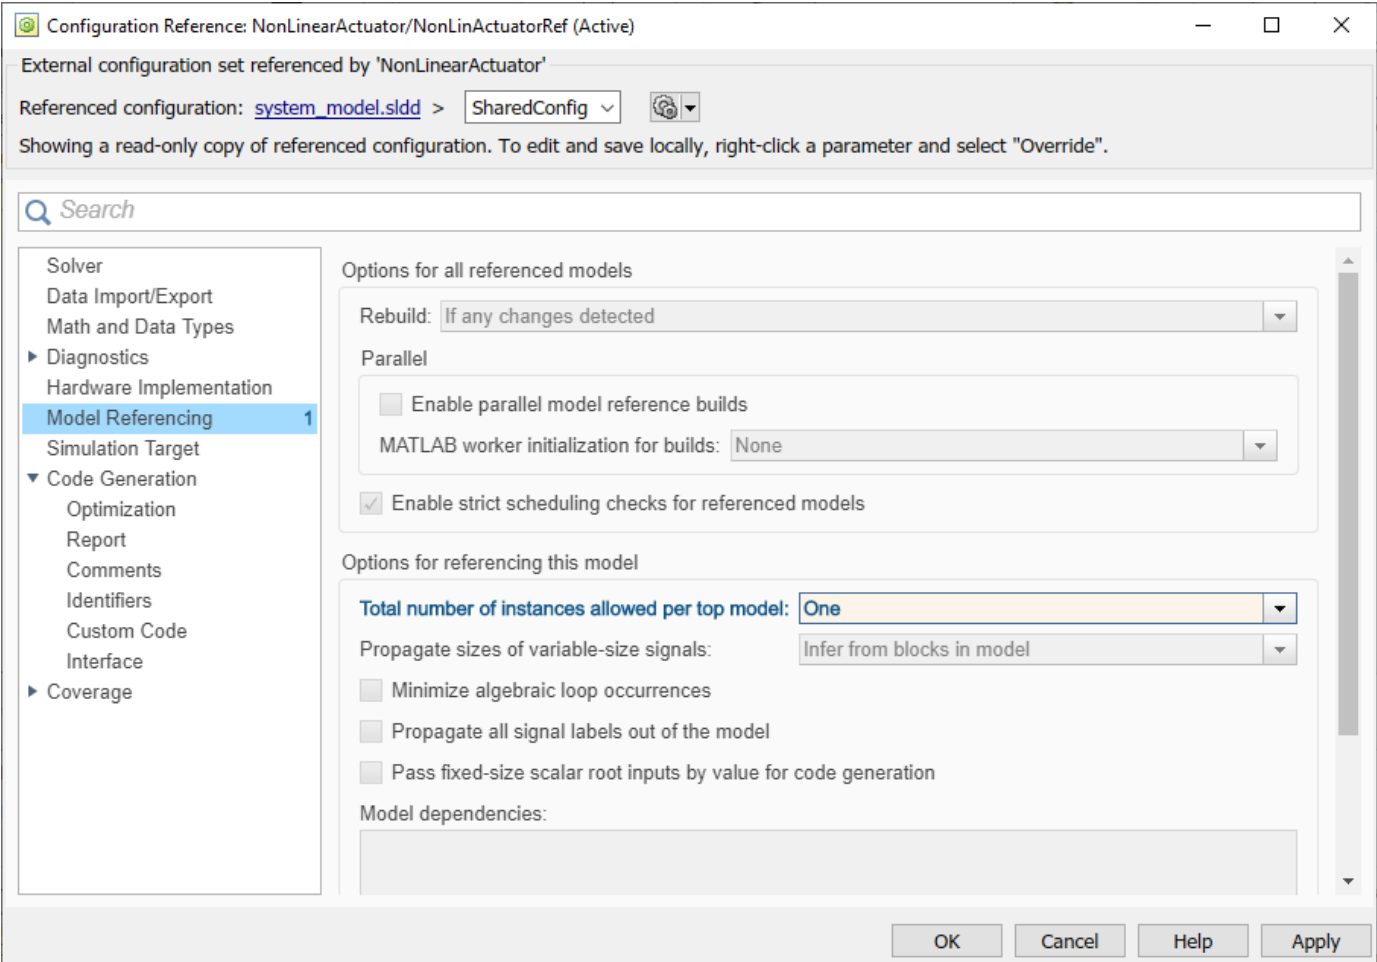

## Change Parameter Value in a Configuration Reference

You can override individual parameter values for models that reference freestanding configuration sets without changing the freestanding configuration. For an overridden parameter, the reference uses the value you assign locally instead of the value in the referenced configuration set. For example, suppose that `LinearActuator` and `NonLinearActuator` are both in the same model hierarchy. You want `LinearActuator` to be referenced as many times as it needs to be, but want Simulink to return an error if `NonLinearActuator` is referenced more than one time. In this example, you can override the **Model Referencing > Total number of instances allowed per top model** parameter for only the `NonLinearActuator` model.

For this example, override the parameter in the configuration reference for the model `NonLinearActuator`.

- 1 Open the model NonLinearActuator.
- 2 To open the Configuration Reference dialog box, on the **Modeling** tab, click the **Model Settings** button . The active configuration reference displays a read-only view of the referenced configuration.
- 3 Right-click the parameter you want to change and select **Override** from the context menu. You can now change the parameter value as you would for any configuration set. For this example, override the parameter **Model Referencing > Total number of instances allowed per top model** and set the value to One.

In the left pane, each pane displays the number of overridden parameters it contains.

- 4 Click **Apply** to keep the changes or **Cancel** to restore the parameter to the referenced value.

Changes you make to a parameter value apply only to the configuration reference in which you override and edit the parameter. They do not affect other references to the referenced configuration set. For this example, the model NonLinearActuator allows a top model to reference it once, while the model LinearActuator allows a top model to reference it multiple times.

To restore an overridden parameter to its value from the referenced configuration set, right-click the overridden parameter and select **Restore** from the context menu. The overridden parameter resets to the value in the referenced configuration and becomes read-only again.

## Save a Referenced Configuration Set

If you store your freestanding configuration set in a Simulink data dictionary, you can save changes to the configuration by saving the data dictionary.

If your model references a configuration set that you store in the base workspace, before you exit MATLAB, you need to save the referenced configuration set to a MAT-file or MATLAB script.

- 1 In the Model Explorer, in the Model Hierarchy, select **Base Workspace**.
- 2 In the **Contents** pane, right-click the name of the referenced configuration set object.
- 3 From the context menu, select **Export Selected**.
- 4 Specify the filename for saving the configuration set as either a MAT-file or a MATLAB script.

---

**Tip** When you reopen the model you must load the saved configuration set, otherwise the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Customize Model Behavior with Callbacks” on page 4-52.

---

## Load a Saved Referenced Configuration Set

If your configuration reference uses a configuration set that you exported to a MAT-file or MATLAB script, you need to load the referenced configuration set from the file to the base workspace.

- 1 In the Model Explorer, in the Model Hierarchy, right-click **Base Workspace**.
- 2 From the context menu, select **Import**.
- 3 Specify the filename for the saved configuration set and select OK. The configuration set object appears in the base workspace.

## Configuration Reference Limitations

- A configuration reference can point to another configuration reference, but you cannot nest a configuration reference beyond the second reference.
- If you activate a configuration reference when using a custom target, the `ActivateCallback` function does not trigger to notify the corresponding freestanding configuration set. Likewise, if a freestanding configuration set switches from one target to another, the `ActivateCallback` function does not trigger to notify the new target. This behavior occurs even if an active configuration reference points to that target. For more information about `ActivateCallback` functions, see “rtwgensettings Structure” (Simulink Coder).
- Not all parameters in a reference can be overridden, for example, parameters that must be consistent in a model reference hierarchy cannot be overridden.

### **Related Examples**

- “Share a Configuration Across Referenced Models” on page 13-18
- “Create Template from Model” on page 4-2

## Share a Configuration Across Referenced Models

This example shows how to share the same configuration set for the top model and referenced models in a model reference hierarchy. You can use a configuration reference in each of the models to reference the same configuration set object in a Simulink data dictionary that the models are linked to.

In the diagram, each model shown in the Dependency Analyzer specifies a configuration reference as its active configuration set. Each reference points to the freestanding configuration set, `my_configuration`. Therefore, the parameter values in `my_configuration` apply to all four models. Any parameter change in `my_configuration` applies to all four models. For more information about configuration references, see “Share a Configuration with Multiple Models” on page 13-10.

### Link Models to Simulink Data Dictionary

Create a Simulink data dictionary to store the configuration set. When you link the models in the hierarchy to the data dictionary, they can reference the configuration set.

- 1 Open the `sldemo_mdref_depgraph` model. At the command line, type `sldemo_mdref_depgraph`. Verify that your current folder is a writable folder.
- 2 On the **Modeling** tab, under **Design**, click **Link to Data Dictionary**.
- 3 In the Model Properties dialog box, click **New**. Name the new Simulink data dictionary `SharedDataDictionary` and click **Save**.

- 4 Click **OK**. Because this model includes referenced models, a pop-up window asks you if `SharedDataDictionary.sldd` should be used for all referenced models that do not already use a dictionary. Click **Change all models**. The current model and all of its referenced models are linked to the new data dictionary. When the data dictionary is linked, click **OK**.

The models are now linked to the Simulink data dictionary, `SharedDataDictionary.sldd`. When you store a configuration set in this data dictionary, the models that are linked to it can reference the configuration set.

### Convert Configuration Set to Configuration Reference

In the top model, you must convert the active configuration set to a configuration reference:

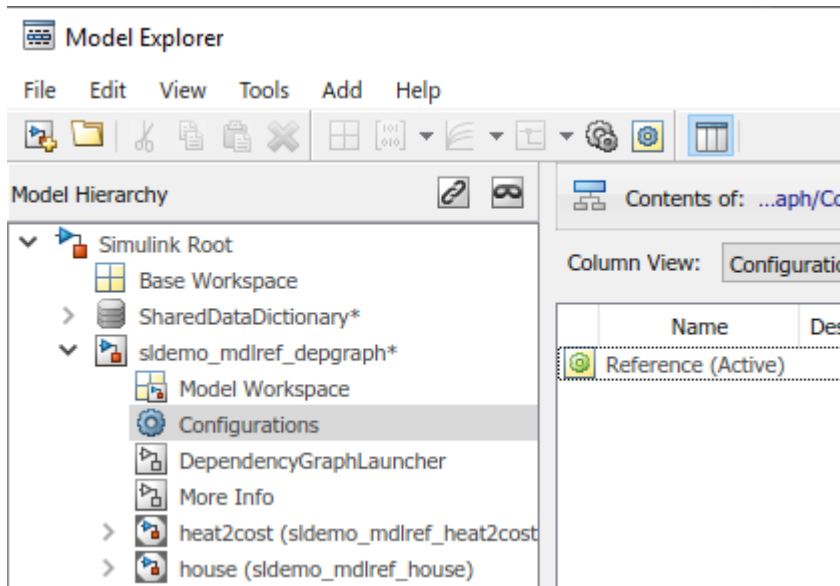

- 1 Open the Model Explorer.
- 2 In the **Model Hierarchy** pane, expand the top model, `sldemo_mdref_depgraph`. In the list, select the **Configurations** node, and right-click `Configuration (Active)` in the **Contents** pane. In the context menu, select **Convert to Configuration Reference**.
- 3 In the **Name** field, use the default name, `Configuration`. This configuration set object is stored in the data dictionary `SharedDataDictionary.sldd`.
- 4 Click **OK**.

The original configuration set is now stored as a configuration set object, `Configuration`, in the Simulink data dictionary. The active configuration for the top model is now a configuration reference that points to the configuration set object in the data dictionary.

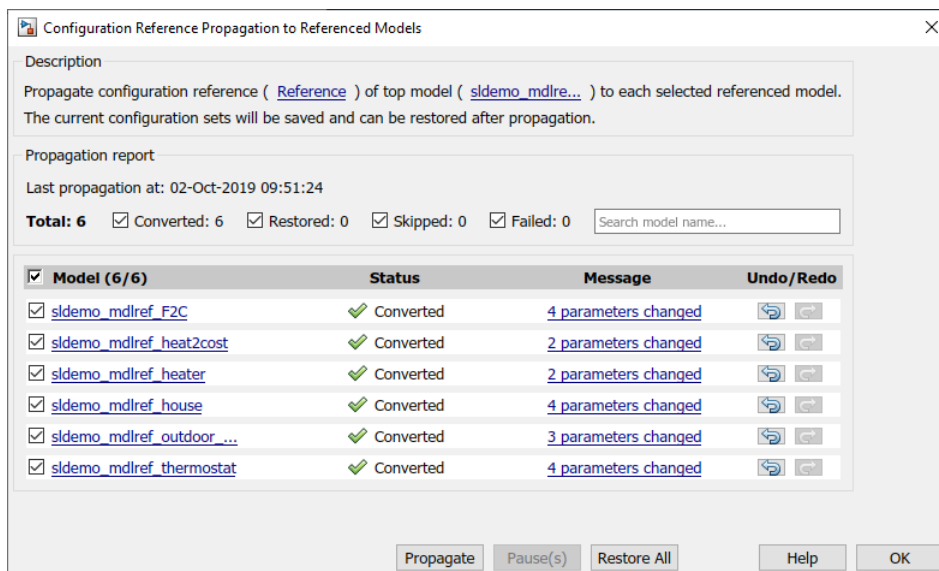

### Propagate a Configuration Reference

Now that the top model contains an active configuration reference, you can propagate this configuration reference to all of the child models. Propagation creates a copy of the top model configuration reference in each referenced model and makes it the active configuration. The configuration references point to the configuration set object in the data dictionary.

- 1 In the Model Explorer, in the **Model Hierarchy** pane, expand the `sldemo_mdref_depgraph` node and select the **Configurations** node.

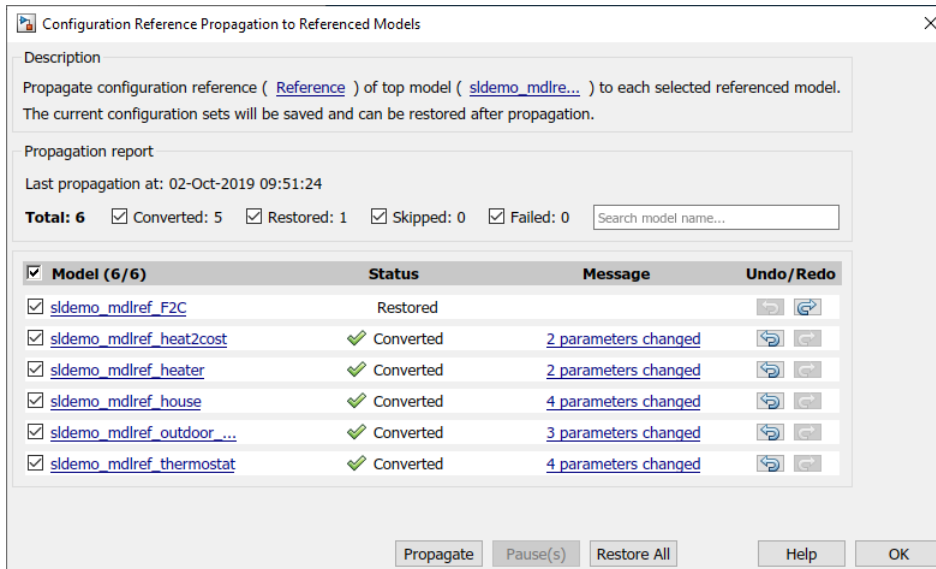

- 2 In the **Contents** pane, right-click the active configuration reference, **Reference (Active)**. In the context menu, select **Propagate to Referenced Models**.
- 3 In the Configuration Reference Propagation dialog box, select the check box for each referenced model. In this example, they are already selected.
- 4 The propagation mechanism saves the original configuration parameters for each referenced model so that you can undo the propagation. Click **Propagate**.
- 5 In the Propagation Confirmation dialog box, click **OK**.
- 6 In the Configuration Reference Propagation dialog box, the Propagation Report is updated and the **Status** for each referenced model is marked as **Converted**.

Now, each model in the hierarchy references the freestanding configuration Configuration. If you want one model to use a different value for a parameter, you can override individual parameters within the reference that the model uses. For more information, see “Change Parameter Value in a Configuration Reference” on page 13-14.

## Undo a Configuration Reference Propagation

After propagating a configuration reference from a top model to the referenced models, you can undo the propagation for all referenced models by clicking **Restore All**. If you want to undo the propagation for individual referenced models, in the **Undo/Redo** column, click the **Undo** button. The Propagation Report is updated and the **Status** for the referenced model is set to Restored.

### Related Examples

- “Share a Configuration with Multiple Models” on page 13-10

## Automate Model Configuration by Using a Script

If you want to use the same configuration setup for many models, you can write a script to programmatically configure each model in the same way. You can use the script to archive and compare the configuration settings that your models use.

This example shows three different ways to programmatically set up your model's configuration:

- Edit the model's existing active configuration set
- Create and edit a new configuration set in the model
- Create a configuration reference that points to a freestanding configuration set

For this example, use the model `sldemo_mdhref_depgraph`.

```
model = 'sldemo_mdhref_depgraph';
open_system(model)
```

### Edit the Active Configuration Set

To manipulate a configuration set that is associated with a model, use the `ConfigSet` object that represents the configuration set. For this example, use the configuration that is active for the model.

```
activeConfigObj = getActiveConfigSet(model);
get_param(activeConfigObj, 'Name')
```

```
ans =
'Configuration'
```

The active configuration for the model is `Configuration`. To see the current values of parameters in the configuration, use the `get_param` function and the `ConfigSet` object.

```
get_param(activeConfigObj, 'StopTime')
```

```
ans =
'2*24*60*60'
```

Rename the configuration set to `UpdatedConfig`.

```
set_param(activeConfigObj, 'Name', 'UpdatedConfig');
```

For this example, set a stop time of 200 and change the solver type to a variable-step solver.

```
set_param(activeConfigObj, 'StopTime', '200');
set_param(activeConfigObj, 'SolverType', 'Variable-step');
```

### Create and Activate a Configuration Set

When you want to change the model's configuration and preserve the original parameter values of its active configuration, create and activate a new configuration set in the model. To create another configuration set, copy an existing configuration set and attach the copy to the model. To avoid naming conflicts when you attach the copy, either rename the copy before attaching it or set `allowRename`, the optional third argument of `attachConfigSet`, to `true`.

For this example, copy the active configuration set. Rename the copy to `ConfigCopy` and attach it to the model.

```
newConfigObj = copy(activeConfigObj);
set_param(newConfigObj, 'Name', 'ConfigCopy');
attachConfigSet(model, newConfigObj);
```

When you attach a configuration set to a model, it is inactive. You can manipulate inactive configurations in the same way that you manipulate the active configuration set. To use the new configuration, activate it for the model.

```
set_param(newConfigObj, 'SolverType', 'Fixed-step');

setActiveConfigSet(model, 'ConfigCopy');
activeConfigSet = getActiveConfigSet(model);
get_param(activeConfigSet, 'Name')

ans =
'ConfigCopy'
```

Now, ConfigCopy is the active configuration set.

### Set Up a Configuration Reference

If you want to store the configuration set outside of your model, create a script that sets up a configuration reference in the model. The reference is stored in the model and it points to a freestanding configuration set, which is stored in either a Simulink data dictionary or in the base workspace. Use a freestanding configuration set and configuration references to share one configuration with multiple models. You can also use a freestanding configuration set when you want to edit the configuration without changing the model file.

For this example, configure the model `vdp` to use a configuration reference. First, create a freestanding configuration set in the base workspace by copying the model's active configuration set. The freestanding configuration is a `ConfigSet` object represented by the variable `freeConfigSet`. You can skip this step if you want to reference an existing freestanding configuration set.

```
model = 'vdp';
open_system(model)

freeConfigSet = copy(getActiveConfigSet(model));
```

Create a configuration reference. To point the reference to your freestanding configuration, set the `SourceName` property to `freeConfigSet`, the variable that represents your configuration. The new reference is a `ConfigSetRef` object represented by the variable `configRef`. Name the reference `vdpConfigRef`.

```
configRef = Simulink.ConfigSetRef;
set_param(configRef, 'SourceName', 'freeConfigSet')
set_param(configRef, 'Name', 'VdpConfigRef')
```

Attach the configuration reference to the model `vdp` by using the `ConfigSetRef` object. You can attach the reference to only one model. To use the configuration reference in the model, activate it.

```
attachConfigSet('vdp', configRef);
setActiveConfigSet('vdp', 'VdpConfigRef');
```

Now, when you change the configuration set that the object `freeConfigSet` represents, the changes apply to the model.

You can obtain parameter values in a configuration reference by using `get_param`. However, you cannot change parameter values directly in the configuration reference. To change the values, you

must use the `ConfigSet` object that represents the referenced freestanding configuration set. Get the freestanding configuration set from a configuration reference by using the `getRefConfigSet` method.

```
referencedConfigObj = getRefConfigSet(configRef);
```

Now, `referencedConfigObj` represents the same freestanding configuration set that your models reference. `freeConfigSet` represents that configuration set as well. Use the configuration set object to change parameter values in the referenced configuration set. These changes apply to each model that references the configuration.

```
set_param(referencedConfigObj, 'SignalLogging', 'off');  
set_param(referencedConfigObj, 'StartTime', '10');
```

## Configuration Object Functions

To interact with a configuration, programmatically, use a `Simulink.ConfigSet` object or a `Simulink.ConfigSetRef` object. You can use the following functions to get information about the configuration. For more information about using configurations, see “Manage Configuration Sets for a Model” on page 13-5.

Function	Purpose
<code>getFullName</code>	Return the full path name of a configuration set or configuration reference as a character vector.
<code>getModel</code>	Return the model that owns the configuration set or configuration reference as a handle to the model.
<code>getRefConfigSet</code>	Return the configuration set that a configuration reference points to.
<code>isActive</code>	Determine if the configuration set or configuration reference is the active configuration of the model, returned as a boolean value.
<code>isValidParam</code>	Determine if a specified parameter is a valid parameter of a configuration set.
<code>refresh</code>	Update a configuration reference after using the API to change any property of the reference, or after providing a configuration set that did not exist at the time the set was originally specified in <code>SourceName</code> . If you omit executing <code>refresh</code> after any such change, the configuration reference handle will be stale, and using it will give incorrect results.
<code>saveAs</code>	Save a configuration set to a MATLAB file.

## Concepts in Multicore Programming

### In this section...

- “Basics of Multicore Programming” on page 14-2
- “Types of Parallelism” on page 14-2
- “System Partitioning for Parallelism” on page 14-5
- “Challenges in Multicore Programming” on page 14-6

### Basics of Multicore Programming

Multicore programming helps you create concurrent systems for deployment on multicore processor and multiprocessor systems. A *multicore processor system* is a single processor with multiple execution cores in one chip. By contrast, a *multiprocessor system* has multiple processors on the motherboard or chip. A multiprocessor system might include a Field-Programmable Gate Array (FPGA). An FPGA is an integrated circuit containing an array of programmable logic blocks and a hierarchy of reconfigurable interconnects. A *processing node* processes input data to produce outputs. It can be a processor in a multicore or multiprocessor system, or an FPGA.

The multicore programming approach can help when:

- You want to take advantage of multicore and FPGA processing to increase the performance of an embedded system.
- You want to achieve scalability so your deployed system can take advantage of increasing numbers of cores and FPGA processing power over time.

Concurrent systems that you create using multicore programming have multiple tasks executing in parallel. This is known as *concurrent execution*. When a processor executes multiple parallel tasks, it is known as *multitasking*. A CPU has firmware called a scheduler, which handles the tasks that execute in parallel. The CPU implements tasks using operating system threads. Your tasks can execute independently but have some data transfer between them, such as data transfer between a data acquisition module and controller for the system. Data transfer between tasks means that there is a *data dependency*.

Multicore programming is commonly used in signal processing and plant-control systems. In signal processing, you can have a concurrent system that processes multiple frames in parallel. In plant-control systems, the controller and the plant can execute as two separate tasks. Using multicore programming helps to split your system into multiple parallel tasks, which run simultaneously, speeding up the overall execution time.

To model a concurrently executing system, see “Partitioning Guidelines” on page 14-31.

### Types of Parallelism

The concept of multicore programming is to have multiple system tasks executing in parallel. Types of parallelism include:

- Data parallelism
- Task parallelism

- Pipelining

## Data Parallelism

Data parallelism involves processing multiple pieces of data independently in parallel. The processor performs the same operation on each piece of data. You achieve parallelism by feeding the data in parallel.

The figure shows the timing diagram for this parallelism. The input is divided into four chunks, A, B, C, and D. The same operation  $F()$  is applied to each of these pieces and the output is  $O_A$ ,  $O_B$ ,  $O_C$ , and  $O_D$  respectively. All four tasks are identical, and they run in parallel.

The time taken per processor cycle, known as cycle time, is  $t = tF$ .

The total processing time is also  $tF$ , since all four tasks run simultaneously. In the absence of parallelism, all four pieces of data are processed by one processing node. The cycle time is  $tF$  for each task but the total processing time is  $4 \cdot tF$ , since the pieces are processed in succession.

You can use data parallelism in scenarios where it is possible to process each piece of input data independently. For example, a web database with independent data sets for processing or processing frames of a video independently are good candidates for data parallelism.

## Task Parallelism

In contrast to data parallelism, task parallelism doesn't split up the input data. Instead, it achieves parallelism by splitting up an application into multiple tasks. Task parallelism involves distributing tasks within an application across multiple processing nodes. Some tasks can have data dependency on others, so all tasks do not run at exactly the same time.

Consider a system that involves four functions. Functions  $F2a()$  and  $F2b()$  are in parallel, that is, they can run simultaneously. In task parallelism, you can divide your computation into two tasks. Function  $F2b()$  runs on a separate processing node after it gets data  $Out1$  from Task 1, and it outputs back to  $F3()$  in Task 1.

The figure shows the timing diagram for this parallelism. Task 2 does not run until it gets data Out1 from Task 1. Hence, these tasks do not run completely in parallel. The time taken per processor cycle, known as cycle time, is

$$t = t_{F1} + \max(t_{F2a}, t_{F2b}) + t_{F3}$$

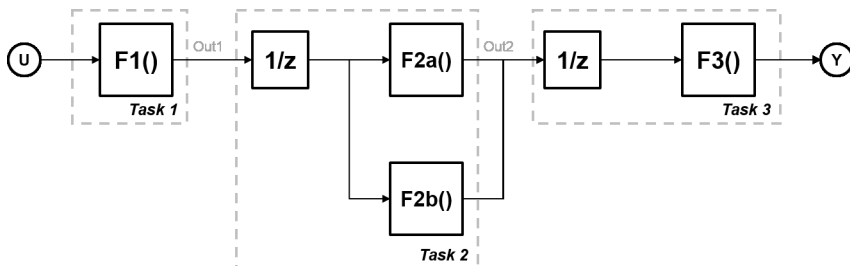

You can use task parallelism in scenarios such as a factory where the plant and controller run in parallel.

**Model Pipeline Execution (Pipelining)**

Use model pipeline execution, or pipelining, to work around the problem of task parallelism where threads do not run completely in parallel. This approach involves modifying your system model to introduce delays between tasks where there is a data dependency.

In this figure, the system is divided into three tasks to run on three different processing nodes, with delays introduced between functions. At each time step, each task takes in the value from the previous time step by way of the delay.

Each task can start processing at the same time, as this timing diagram shows. These tasks are truly parallel and they are no longer serially dependent on each other in one processor cycle. The cycle time does not have any additions but is the maximum processing time of all the tasks.

$$t = \max(\text{Task1}, \text{Task2}, \text{Task3}) = \max(t_{F1}, t_{F2a}, t_{F2b}, t_{F3})$$

You can use pipelining wherever you can introduce delays artificially in your concurrently executing system. The resulting overhead due to this introduction must not exceed the time saved by pipelining.

### System Partitioning for Parallelism

Partitioning methods help you to designate areas of your system for concurrent execution. Partitioning allows you to create tasks independently of the specifics of the target system on which the application is deployed.

Consider this system. F1-F6 are functions of the system that can be executed independently. An arrow between two functions indicates a data dependency. For example, the execution of F5 has a data dependency on F3.

Execution of these functions is assigned to the different processor nodes in the target system. The gray arrows indicate assignment of the functions to be deployed on the CPU or the FPGA. The CPU scheduler determines when individual tasks run. The CPU and FPGA communicate via a common communication bus.

The figure shows one possible configuration for partitioning. In general, you test different configurations and iteratively improve until you get the optimal distribution of tasks for your application.

## Challenges in Multicore Programming

Manually coding your application onto a multicore processor or an FPGA poses challenges beyond the problems caused by manual coding. In concurrent execution, you must track:

- Scheduling of the tasks that execute on the embedded processing system multicore processor
- Data transfers to and from the different processing nodes

Simulink manages the implementation of tasks and data transfer between tasks. It also generates the code that is deployed for the application. For more information, see “Multicore Programming with Simulink” on page 14-8.

In addition to these challenges, there are challenges when you want to deploy your application to different architectures and when you want to improve the performance of the deployed application.

### Portability: Deployment to Different Architectures

The hardware configuration that runs the deployed application is known as the architecture. It can contain multicore processors, multiprocessor systems, FPGAs, or a combination of these. Deployment of the same application to different architectures can require effort due to:

- Different number and types of processor nodes on the architecture
- Communication and data transfer standards for the architecture
- Standards for certain events, synchronization, and data protection in each architecture

To deploy the application manually, you must reassign tasks to different processing nodes for each architecture. You might also need to reimplement your application if each architecture uses different standards.

Simulink helps overcome these problems by offering portability across architectures. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-9.

### Deployment Efficiency

You can improve the performance of your deployed application by balancing the load of the different processing nodes in the multicore processing environment. You must iterate and improve upon your distribution of tasks during partitioning, as mentioned in “System Partitioning for Parallelism” on page 14-5. This process involves moving tasks between different processing nodes and testing the resulting performance. Since it is an iterative process, it takes time to find the most efficient distribution.

Simulink helps you to overcome these problems using profiling. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-9.

### Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*.

Simulink identifies loops in your system before deployment. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-9.

## **See Also**

### **Related Examples**

### **More About**

- “Multicore Programming with Simulink” on page 14-8

## Multicore Programming with Simulink

<b>In this section...</b>
---------------------------

“Basic Workflow” on page 14-8
-------------------------------

“How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-9
---

Using the process of partitioning, mapping, and profiling in Simulink, you can address common challenges of designing systems for concurrent execution.

Partitioning enables you to designate regions of your model as tasks, independent of the details of the embedded multicore processing hardware. This independence enables you to arrange the content and hierarchy of your model to best suit the needs of your application.

In a partitioned system, mapping enables you to assign partitions to processing elements in your embedded processing system. Use the Simulink mapping tool to represent and manage the details of executing threads, HDL code on FPGAs, and the work that these threads or FPGAs perform. While creating your model, you do not need to track the partitions or data transfer between them because the tool does this work. Also, you can reuse your model across multiple architectures.

Profiling simulates deployment of your application under typical computational loads. It enables you to determine the partitioning and mapping for your model that gives the best performance, before you deploy to your hardware.

### Basic Workflow

To deploy your model to the target.

- 1 Set up your model for concurrent execution.

For more information about configuring your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-20. With these settings, Simulink partitions your model based on the sample time of blocks at the root level, with each sample time in your model corresponding to a partition, and all blocks of a single rate or sample time belonging to the same partition.

If you want to specify how to partition your model, use explicit partitioning. With explicit partitioning, you must specify a target architecture, and then explicitly partition your model. For more information, see “Specify a Target Architecture” on page 14-21, and “Partition Your Model Using Explicit Partitioning” on page 14-26.

- 2 Generate code and deploy it to your target. You can choose to deploy onto multiple targets.

- To build and deploy on a desktop target, see “Build on Desktop” on page 14-37.
- To deploy onto embedded targets using Embedded Coder, see “Deploy Generated Software” (Embedded Coder).
- To build and deploy on a real-time target using Simulink Real-Time™, see “Standalone Operation” (Simulink Real-Time).
- To deploy onto FPGAs using HDL Coder, see “Deployment” (HDL Coder).

---

**Note** Deployment onto FPGAs is supported only for explicitly partitioned models.

---

- 3 Optimize your design. This step is optional, and includes iterating over the design of your model and mapping to get the best performance, based on your metrics. One way to evaluate your model is to profile it and get execution times.

Product	Information
Desktop target	“Profile and Evaluate Explicitly Partitioned Models on a Desktop” on page 14-38
Simulink Real-Time	“Execution Profiling for Real-Time Applications” (Simulink Real-Time)
Embedded Coder	“Code Execution Profiling” (Embedded Coder)
HDL Coder	“Speed and Area Optimization” (HDL Coder)

## How Simulink Helps You to Overcome Challenges in Multicore Programming

Manually programming your application for concurrent execution poses challenges beyond the typical challenges with manual coding. With Simulink, you can overcome the challenges of portability across multiple architectures, efficiency of deployment for an architecture, and cyclic data dependencies between application components. For more information on these challenges, see “Challenges in Multicore Programming” on page 14-6.

### Portability

Simulink enables you to determine the content and hierarchical needs of the modeled system without considering the target system. While creating model content, you do not need to keep track of the number of cores in your target system. Instead, you select the partitioning methods that enable you to create model content. Simulink generates code for the architecture you specify.

You can select an architecture from the available supported architectures or add a custom architecture. When you change your architecture, Simulink generates only the code that needs to change for the second architecture. The new architecture reuses blocks and functions. For more information, see “Supported Targets For Multicore Programming” on page 14-44 and “Specify a Target Architecture” on page 14-21.

### Deployment Efficiency

To improve the performance of the deployed application, Simulink allows you to simulate it under typical computational loads and try multiple configurations of partitioning and mapping the application. Simulink compares the performance of each of these configurations to provide the optimal configuration for deployment. This is known as profiling. Profiling helps you to determine the optimum partition configuration before you deploy your system to the desired hardware.

You can create a mapping for your application in which Simulink maps the application components across different processing nodes. You can also manually assign components to processing nodes. For any mapping, you can see the data dependencies between components and remap accordingly. You can also introduce and remove data dependencies between different components.

### Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle

creates a data dependency loop, also known as an *algebraic loop*. Simulink does not allow algebraic loops to occur across potentially parallel partitions because of the high cost of solving the loop using parallel algorithms.

In some cases, the algebraic loop is artificial. For example, you can have an artificial algebraic loop because of Model-block-based partitioning. An algebraic loop involving Model blocks is artificial if removing the use of Model partitioning eliminates the loop. You can minimize the occurrence of artificial loops. In the Configuration Parameter dialog boxes for the models involved in the algebraic loop, select **Model Referencing > Minimize algebraic loop occurrences**.

Additionally, if the model is configured for the Generic Real-Time target (`grt.tlc`) or the Embedded Real-Time target (`ert.tlc`) in the Configuration Parameters dialog box, clear the **Single output/update function** check box.

If the algebraic loop is a true algebraic condition, you must either contain all the blocks in the loop in one Model partition, or eliminate the loop by introducing a delay element in the loop.

The following examples show how to implement different types of parallelism in Simulink. These examples contain models that are partitioned and mapped to a simple architecture with one CPU and one FPGA.

## Implement Data Parallelism in Simulink

This example shows how to model data parallelism for a system to be deployed on a multicore processor. The model consists of an input, a functional component that applies to each input, and a concatenated output. For more information on data parallelism, see “Types of Parallelism” on page 14-2.

Set up this model for concurrent execution. To see the completed model, open `ex_data_parallelism_top`.

- 1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.

- 2 Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.

- 3 On the **Solver** pane, set **Type** to Fixed-step and click **Apply**. Also ensure that the **Periodic sample time constraint** is set to Unconstrained. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.
- 4 In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
- 5 In the selection pane, select **CPU**. Click **Add task**  four times to add four new tasks.
- 6 In the selection pane, select **Tasks and Mapping**. On the **Map block to tasks** pane:
  - Under **Block: Input**, click select task and select Periodic: Task.
  - Under **Block: Function 1**, select Periodic: Task1.
  - Under **Block: Function 2**, select Periodic: Task2.
  - Under **Block: Function 3**, select Periodic: Task3.
  - Under **Block: Output**, select Periodic: Task.

This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

- 7 In the selection pane, select **Data transfer**. In the **Data Transfer Options** pane, set the parameter **Periodic signals** to Ensure deterministic transfer (minimum delay). Click **Apply** and close the Concurrent Execution dialog box.
- 8 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration with Multiple Models” on page 13-10.

Update your model to see the tasks mapped to individual model blocks.

## Implement Task Parallelism in Simulink

This example shows how to implement task parallelism for a system in a Simulink model. The model consists of an input, functional components applied to the same input, and a concatenated output. For more information on Task Parallelism, see “Types of Parallelism” on page 14-2.

Set up the model for concurrent execution. To see the completed model, open `ex_task_parallelism_top`.

- 1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.

- 2 Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.

- 3 On the **Solver** pane, set **Type** to Fixed-step and click **Apply**. Also ensure that the **Periodic sample time constraint** is set to Unconstrained. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.
- 4 In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
- 5 In the selection pane, select **CPU**. Click **Add task**  three times to add new tasks.
- 6 In the selection pane, select **Tasks and Mapping**. To map partitions to the tasks you created, on the **Map block to tasks** pane:
  - Under **Block: Input**, click **select task** and select **Periodic: Task**.
  - Under **Block: Function 1**, select **Periodic: Task1**.
  - Under **Block: Function 2**, select **Periodic: Task2**.
  - Under **Block: Output**, select **Periodic: Task**.

The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

- 7 In the selection pane, select **Data transfer**. In the **Data Transfer Options** pane, set the parameter **Periodic signals** to **Ensure deterministic transfer (minimum delay)**. Click **Apply** and close the Concurrent Execution dialog box.
- 8 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration with Multiple Models” on page 13-10.

Update your model to see the tasks mapped to individual model blocks.

## Implement Pipelining in Simulink

This example shows how to implement pipelining for a system in a Simulink model. The model consists of an input, functional components applied to the same input, and a concatenated output. For more information on pipelining, see “Types of Parallelism” on page 14-2.

Setup this model for concurrent execution. To see the completed model, open `ex_pipelining_top`.

- 1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.

- 2 Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.

- 3 On the **Solver** pane, set **Type** to Fixed-step and click **Apply**. Also ensure that the **Periodic sample time constraint** is set to Unconstrained. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.
- 4 In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
- 5 In the selection pane, select **CPU**. Click **Add task**  three times to add three new tasks.
- 6 In the selection pane, select **Tasks and Mapping**. On the **Map block to tasks** pane:
  - Under **Block: Input**, click select task and select Periodic: Task.
  - Under **Block: Function 1**, select Periodic: Task1.
  - Under **Block: Function 2**, select Periodic: Task2.
  - Under **Block: Output**, select Periodic: Task.

This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

- 7 Close the Concurrent Execution dialog box.
- 8 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration with Multiple Models” on page 13-10.

Update your model to see the tasks mapped to individual model blocks.

**Note** Notice that delays are introduced between different tasks, indicated by the  $z^{-1}$  badge. Introducing these delays may cause different model outputs in Simulink. Ensure that your model has an expected output on simulating the parallelized model.

## Configure Your Model for Concurrent Execution

Follow these steps to configure your Simulink model to take advantage of concurrent execution.

- 1 Open your model.
- 2 On the **Modeling** tab, click **Model Settings**.
- 3 Select **Solver**, then in the **Solver selection** section, choose **Fixed-step** for the **Type** and **auto** (Automatic solver selection) for the **Solver**.
- 4 Under **Solver details**, select **Allow tasks to execute concurrently on target**. Selecting this check box is optional for models referenced in the model hierarchy. When you select this option for a referenced model, Simulink allows each rate in the referenced model to execute as an independent concurrent task on the target processor.
- 5 Select **Code Generation > Interface > Advanced parameters**, clear the **MAT-file logging** check box.

Once you have a model that executes concurrently on your computer, you can further configure your model in the following ways:

- “Specify a Target Architecture” on page 14-21
- “Partition Your Model Using Explicit Partitioning” on page 14-26.
- “Configure Data Transfer Settings Between Concurrent Tasks” on page 14-33

### See Also

#### More About

## Specify a Target Architecture

### In this section...

“Choose from Predefined Architectures” on page 14-21

“Define a Custom Architecture File” on page 14-22

For models configured for concurrent execution, you can choose the architecture to which you want to deploy your model. Choose from a set of predefined architectures in Simulink, or you can create an interface for a custom architecture. After selecting your architecture, you can use explicit partitioning to specify which tasks run on it. For more information, see “Partition Your Model Using Explicit Partitioning” on page 14-26.

### Choose from Predefined Architectures

You can choose from the predefined architectures available in Simulink, or you can download support packages for different available architectures.

- 1 In the Concurrent Execution dialog box, in the **Concurrent Execution** pane, click **Select**. The concurrent execution target architecture selector appears.

- 2 Select your target.

Property	Description
Multicore	Single CPU with multiple cores.
Sample Architecture	Single CPU with multiple cores and two FPGAs.
Simulink Real-Time	Simulink Real-Time target.
Get more ...	Click <b>OK</b> to start the Support Package Installer. From the list, select the target and follow the instructions.

- 3 In the Target architecture window, clear the **Preserve compatible properties** check box to reset existing target property settings to their default. Alternatively, select the **Preserve compatible properties** check box to preserve existing target property settings.
- 4 Click **OK**.

Simulink adds the corresponding software and hardware nodes to the configuration tree hierarchy. For example, the following illustrates one software node and two hardware nodes added to the configuration tree when you select Sample architecture as the target architecture.

## Define a Custom Architecture File

A custom architecture file is an XML file that allows you to define custom target properties for tasks and triggers. For example, you may want to define custom properties to represent threading APIs. Threading APIs are necessary to take advantage of concurrency on your target processor.

The following is an example custom architecture file:

```
<architecture brief="Multicore with custom threading API"
  format="1.1" revision="1.1"
  uuid="MulticoreCustomAPI" name="MulticoreCustomAPI">
  <configurationSet>
    <parameter name="SystemTargetFile" value="ert.tlc"/>
    <parameter name="SystemTargetFile" value="grt.tlc"/>
  </configurationSet>
  <node name="MulticoreProcessor" type="SoftwareNode" uuid="MulticoreProcessor"/>
</architecture>
```

```

<template name="CustomTask" type="Task" uuid="CustomTask">
  <property name="affinity" prompt="Affinity:" value="1" evaluate="true"/>
  <property name="schedulingPolicy" prompt="Scheduling policy:" value="Rate-monotonic">
    <allowedValue>Rate-monotonic</allowedValue>
    <allowedValue>Round-robin</allowedValue>
  </property>
</template>
</architecture>

```

An architecture file must contain:

- The architecture element that defines basic information used by Simulink to identify the architecture.
- A `configurationSet` element that lists the system target files for which this architecture is valid.
- One node element that Simulink uses to identify the multicore processing element.

---

**Note** The architecture must contain exactly one node element that identifies a multicore processing element. You cannot create multiple nodes identifying multiple processing elements or an architecture with no multicore processing element.

---

- One or more template elements that list custom properties for tasks and triggers.
  - The type attribute can be `Task`, `PeriodicTrigger`, or `AperiodicTrigger`.
  - Each property is editable and has the default value specified in the `value` attribute.
  - Each property can be a text box, check box, or combo box. A check box is one where you can set the `value` attribute to on or off. A combo box is one where you can optionally list `allowedValue` elements as part of the property.
  - Each text box property can also optionally define an `evaluate` attribute. This lets you place MATLAB variable names as the value of the property.

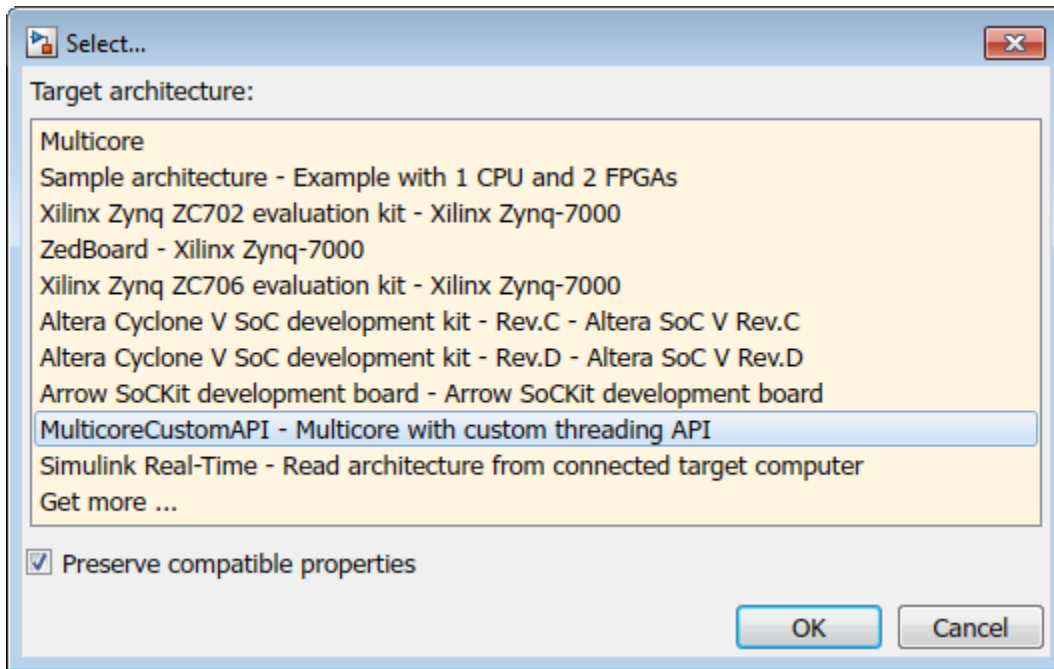

Assuming that you have saved the custom target architecture file in `C:\custom_arch.xml`, register this file with Simulink using the `Simulink.architecture.register` function.

For example:

- 1 Save the contents of the listed XML file in `custom_arch.xml`.
- 2 In the MATLAB Command Window, type:
 

```
Simulink.architecture.register('custom_arch.xml')
```
- 3 In the MATLAB Command Window, type:
 

```
openExample('slexMulticoreSolverExample')
```
- 4 In the Simulink editor, open the **Configuration Parameters** > **Solver** pane and click **Configure Tasks**. The Concurrent Execution dialog box displays.
- 5 In the **Concurrent Execution** pane, click **Select...** under **Target Architecture**. The Target architecture window displays.
- 6 Select `MulticoreCustomAPI` and click **OK**.

Your Concurrent Execution dialog box updates to contain Code Generation properties for the tasks as shown. These are the properties defined in the XML file.

- “Partition Your Model Using Explicit Partitioning” on page 14-26
- “Implicit and Explicit Partitioning of Models” on page 14-31

## Partition Your Model Using Explicit Partitioning

When you have a model that is configured for concurrent execution, you can add tasks, create partitions, and map individual tasks to partitions using explicit partitioning. This enables you to execute different parts of your model to different parts of your architecture. For more information, see “Implicit and Explicit Partitioning of Models” on page 14-31.

### Prerequisites for Explicit Partitioning

To use explicit partitioning, you must meet the following prerequisites:

- 1 Set up your model for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-20.
- 2 Convert all blocks at the root level of your model into one of the following types of blocks.
  - Models that are referenced using Model blocks
  - Subsystem blocks
  - MATLAB System blocks
  - MATLAB Function blocks
  - Stateflow charts

For more information, see “Implicit and Explicit Partitioning of Models” on page 14-31.

---

**Note** When using referenced models, replicate the model configuration parameters of the top model to the referenced models. Consider using a single configuration reference to use for all of your referenced models. For more information, see “Model Configuration Sets”.

---

- 3 Select the target architecture on which to deploy your model. For more information, see “Specify a Target Architecture” on page 14-21.

### Add Periodic Triggers and Tasks

Add periodic tasks for components in your model that you want to execute periodically. To add aperiodic tasks whose execution is trigger based, see “Add Aperiodic Triggers and Tasks” on page 14-27.

If you want to explore the effects of increasing the concurrency on your model execution, you can create additional periodic tasks in your model.

- 1 In the Concurrent Execution dialog box, right-click the **Periodic** node and select **Add task**.

A task node appears in the Configuration Execution hierarchy.

- 2 Select the task node and enter a name and period for the task, then click **Apply**.

The task node is renamed to the name you enter.

- 3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color. If you enable sample time colors for your model, the software honors the setting.

- 4 Click **Apply** as necessary.

To create more periodic triggers, click the **Add periodic trigger** symbol. You can also create multiple periodic triggers with their own trigger sources.

---

**Note** Periodic triggers let you represent multiple periodic interrupt sources such as multiple timers. The periodicity of the trigger is either the base rate of the tasks that the trigger schedules, or the period of the trigger. Data transfers between triggers can only be **Ensure Data Integrity Only** types. With blocks mapped to periodic triggers, you can only generate code for `ert.tlc` and `grt.tlc` system target files.

---

To delete tasks and triggers, right-click them in the pane and select **Delete**.

When the periodic tasks and trigger configurations are complete, configure the aperiodic (interrupt) tasks as necessary. If you do not need aperiodic tasks, continue to “Map Blocks to Tasks, Triggers, and Nodes” on page 14-28.

## Add Aperiodic Triggers and Tasks

Add aperiodic tasks for components in your model whose execution is interrupt-based. To add periodic tasks whose execution is periodic, see “Add Periodic Triggers and Tasks” on page 14-26.

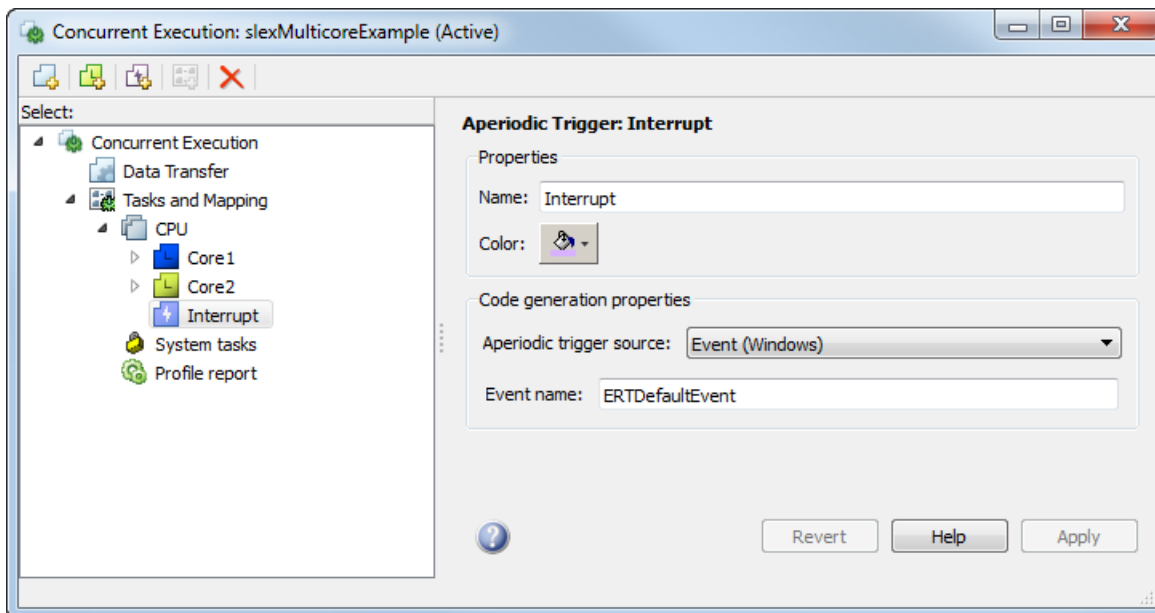

- 1 To create an aperiodic trigger, in the Concurrent Execution dialog box, right-click the **Concurrent Execution** node and click the **Add aperiodic trigger** symbol.

A node named **Interrupt $N$**  appears in the configuration tree hierarchy, where  $N$  is an integer.

- 2 Select **Interrupt**.

This node represents an aperiodic trigger for your system.

- 3 Specify the name of the trigger and configure the aperiodic trigger source. Depending on your deployment target, choose either **Posix Signal (Linux/VxWorks 6.x)** or **Event (Windows)**. For POSIX® signals, specify the signal number to use for delivering the aperiodic event. For Windows events, specify the name of the event.

- 4 Click **Apply**.

The software services aperiodic triggers as soon as possible. If you want to process the trigger response using a task:

- 1 Right-click the **Interrupt** node and select **Add task**.  
A new task node appears under the **Interrupt** node.
- 2 Specify the name of the new task node.
- 3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color.
- 4 Click **Apply**.

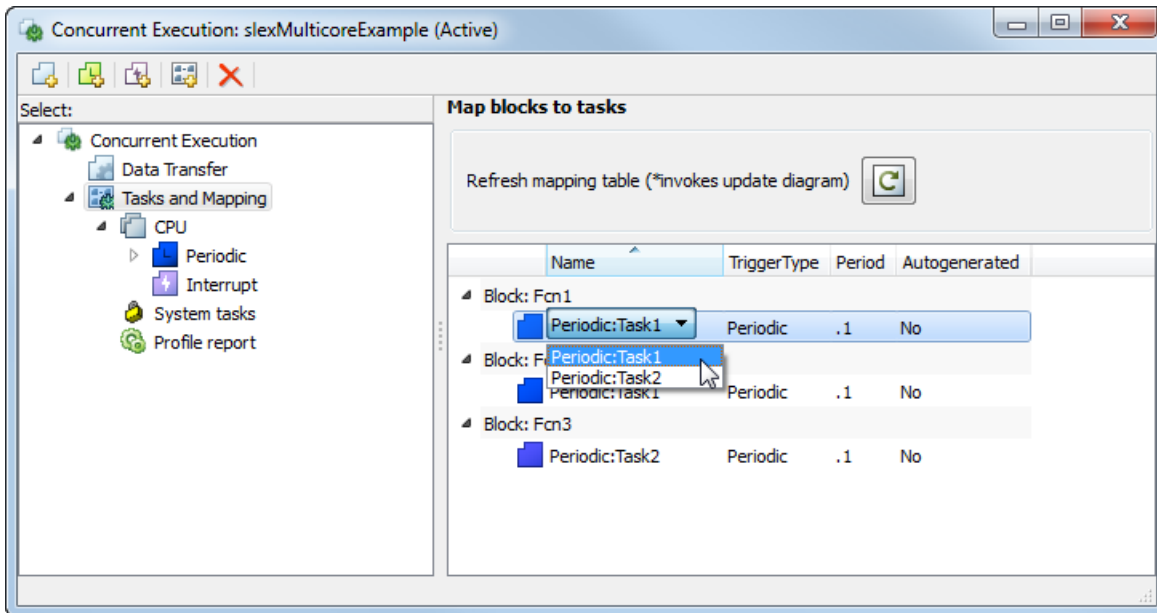

To delete tasks and triggers, right-click them in the pane and select **Delete**.

Once you have created your tasks and triggers, map your execution components to these tasks. For more information, see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-28.

## Map Blocks to Tasks, Triggers, and Nodes

After you create the tasks and triggers, you can explicitly assign partitions to these execution elements.

- 1 In the Concurrent Execution dialog box, click the **Tasks and Mapping** node.  
The **Tasks and Mapping** pane appears. If you add a Model block to your model, the new block appears in the table with a **select task** entry under it.
- 2 If you want to add a task to a block, in the **Name** column, right-click a task under the block and select **Add new entry**.
- 3 To assign a task for the entry, click the box in the **Name** column and select an entry from the list. For example:

The block-to-task mapping symbol appears on the top-left corner of the Model block. For example:

If you assign a Model block to multiple tasks, multiple task symbols are displayed in the top-left corner.

To display the Concurrent Execution dialog box from the block, click the block-to-task mapping symbol.

- 4 Click **Apply**.

### Note

- System tasks allow you to perform mapping incrementally. This means that if there is only one periodic trigger, Simulink assigns any Model blocks, subsystem blocks, or MATLAB System blocks that you have not explicitly mapped to a task, trigger, or hardware node to a task created by the system. Simulink creates at most one system task for each rate in the model. If there are multiple periodic triggers created, explicitly map the Model block partitions, subsystems, or MATLAB System blocks to a task, trigger, or hardware node.
- Map Model block partitions that contain continuous blocks to the same periodic trigger.

- You can map only Model blocks to hardware nodes. Also, if you map the Model block to a hardware node, and the Model block contains multiple periodic sample times, clear the **Allow tasks to execute concurrently on target** check box in the **Solver** pane of the Configuration Parameters dialog box.
- 

When the mapping is complete, simulate the model again.

## Implicit and Explicit Partitioning of Models

When implementing multicore programming for your application in Simulink, there are two ways to partition your model for running on individual processing nodes. If you are new to multicore programming in Simulink, use the default (implicit partitioning) for your first iteration of implementing multicore programming.

The automated way of creating tasks and mapping them to your processing nodes is called implicit partitioning. Simulink partitions your model based on the sample time of blocks at the root level. Each sample time in your model corresponds to a partition, and all blocks of a single rate or sample time belong to the same partition. Simulink maps these partitions to tasks that run on your processor. Implicit partitioning assumes your architecture to be a single multicore CPU. The CPU task scheduler handles all the partitioned tasks.

If you want to specify how to partition your model, use explicit partitioning. In explicit partitioning, you create partitions in the root-level model by using referenced models, MATLAB system blocks, MATLAB Function blocks, Stateflow charts, and Simulink subsystems. For example, if your model has data acquisition and a controller, partition your model by putting these components in two referenced models at the model root-level. Each sample time of the blocks in the model corresponds to a partition. You can add tasks to run on processing nodes in the Concurrent Execution dialog box and assign your partitions to these tasks. If some partitions are left unassigned, Simulink automatically assigns them to tasks.

In explicit partitioning, you can specify your own architecture. The default architecture is a multicore CPU, the same as the assumed architecture in implicit partitioning. Explicit partitioning has more restrictions on your root-level model than implicit partitioning. For more information, see “Limitations with Multicore Programming in Simulink” on page 14-46.

### Partitioning Guidelines

There are multiple ways to partition your model for concurrent execution in Simulink. Rate-based and model-based approaches give you primarily graphical means to represent concurrency for systems that are represented using Simulink and Stateflow blocks. You can partition MATLAB code using the MATLAB System block and the MATLAB Function block. You can also partition models of physical systems using multisolver methods.

Each method has additional considerations to help you decide which to use.

Goal	Valid Partitioning Methods	Considerations
Increase the performance of a simulation on the host computer.	No partitioning method	Simulink tries to optimize the host computer performance regardless of the modeling method you use. For more information on the ways that Simulink helps you to improve performance, see “Optimize Performance”.

Goal	Valid Partitioning Methods	Considerations
Increase the performance of a plant simulation in a multicore HIL (hardware-in-the-loop) system.	You can use any of the partitioning methods and their combinations.	The processing characteristics of the HIL system and the embedded processing system can vary greatly. Consider partitioning your system into more units of work than there are number of processing elements in the HIL or embedded system. This convention allows flexibility in the mapping process.
Create a valid model of a multirate concurrent system to take advantage of a multicore processing system.	You can use any of the partitioning methods and their combinations.	Partitioning can introduce signal delays to represent the data transfer requirements for concurrent execution. For more information, see “Configure Data Transfer Settings Between Concurrent Tasks” on page 14-33.
Create a valid model of a heterogeneous system to take advantage of multicore and FPGA processing.	<ul style="list-style-type: none"> <li>• Multicore processing: Use any of the partitioning methods.</li> <li>• FPGA processing: Partition your model using Model blocks.</li> </ul>	Consider partitioning for FPGA processing where your computations have bottlenecks that could be reduced using fine-grained hardware parallelism.

## Configure Data Transfer Settings Between Concurrent Tasks

Data dependencies arise when a signal originates from one block in one partition and is connected to a block in another partition. To create opportunities for parallelism, Simulink provides multiple options for handling data transfers between concurrently executing partitions. These options help you trade off computational latency for numerical signal delays.

Use the **Data Transfer Options** pane to define communications between tasks. Set the values for the `Use global setting` option of the Data Transfer tab in the Signal Properties dialog box. The table provides the model-level options that you can apply to each signal that requires data transfer in the system.

### Data Transfer Options

Goal	Data Transfer Type	Simulation	Deployment
<ul style="list-style-type: none"> <li>• Create opportunity for parallelism.</li> <li>• Reduce signal latency.</li> </ul>	Ensure data integrity only.	Data transfer is simulated using a one-step delay.	<p>Simulink Coder ensures data integrity during data transfer. Simulink generates code to operate with maximum responsiveness and data integrity. However, the implementation is interruptible, which can lead to loss of data during data transfer.</p> <p>Use a deterministic execution schedule to achieve determinism in the deployment environment.</p>
<ul style="list-style-type: none"> <li>• Create opportunity for parallelism.</li> <li>• Produce numeric results that are repeatable with each run of the generated code.</li> </ul>	Ensure deterministic transfer (maximum delay).	Data transfer is simulated using a one-step delay, which can have impact on the numeric results. To compensate, you might need to specify an initial condition for these delay elements.	Simulink Coder ensures data integrity during data transfer. In addition, Simulink Coder ensures that data transfer is identical with simulation.
<ul style="list-style-type: none"> <li>• Enforce data dependency.</li> <li>• Produce numeric results that are repeatable with each run of the generated code.</li> </ul>	Ensure deterministic transfer (minimum delay).	Data transfer occurs within the same step.	

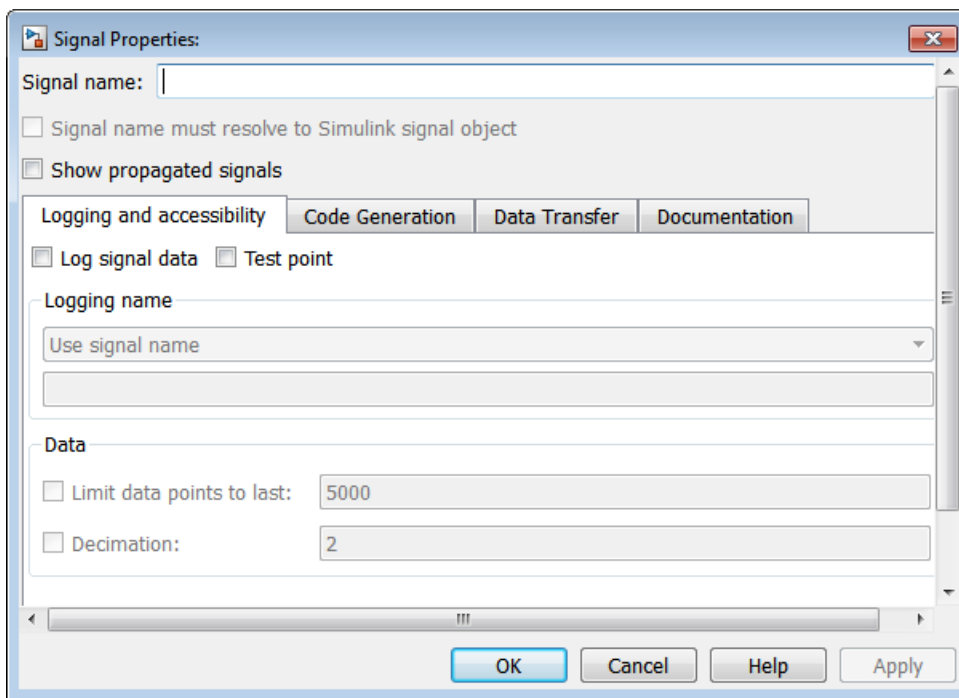

You can also override these options for each signal from the **Data Transfer** pane of the Signal Properties dialog box. For more information, see “Data Transfer Options for Concurrent Execution”.

For example, consider a control application in which a controller that reads sensory data at time  $T$  must produce the control signals to the actuator at time  $T+\Delta$ .

- If the sequential algorithm meets the timing deadlines, consider using option 3.
- If the embedded system provides deterministic scheduling, consider using option 2.
- Otherwise, use option 1 to create opportunities for parallelism by introducing signal delays.

For continuous signals, Simulink uses extrapolation methods to compensate for numerical errors that were introduced due to delays and discontinuities in data transfer.

To avoid numerical errors in signals configured for **Ensure Data Integrity Only** and **Ensure deterministic transfer (maximum delay)** data transfers, you may need to provide an initial condition. You can specify this initial condition in the **Data Transfer** tab of the Signal Properties dialog box. To access this dialog box, right-click the signal line and select **Properties** from the context menu. A dialog box like the following is displayed.

- 1 From the Data Transfer Options table, determine how you want your tasks to communicate.
- 2 In the Concurrent Execution dialog box, select Data Transfer defaults and apply the settings from step 1.

3 Apply your changes.

## Optimize and Deploy on a Multicore Target

### In this section...

“Generate Code” on page 14-36

“Build on Desktop” on page 14-37

“Profile and Evaluate Explicitly Partitioned Models on a Desktop” on page 14-38

“Customize the Generated C Code” on page 14-42

This topic shows how to use a model that is configured for concurrent execution using explicit partitioning and deploy it onto a target. To set up your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-20. To specify the target architecture, see “Specify a Target Architecture” on page 14-21. To use explicit partitioning in a model that is set up for concurrent execution, see “Partition Your Model Using Explicit Partitioning” on page 14-26.

### Generate Code

To generate code for a model that is configured for concurrent execution, on the **Apps** tab of the Simulink editor, select **Simulink Coder**. On the **C Code** tab, select **Build**. The resulting code includes:

- C code for parts of the model that are mapped to tasks and triggers in the Concurrent Execution dialog box. C code generation requires a Simulink Coder license. For more information, see “Code Generation” (Simulink Coder) and “Code Generation” (Embedded Coder).
- HDL code for parts of the model that are mapped to hardware nodes in the Concurrent Execution dialog box. HDL code generation requires an HDL Coder license. For more information, see “HDL Code Generation from Simulink” (HDL Coder).
- Code to handle data transfer between the concurrent tasks and triggers and to interface with the hardware and software components.

The generated C code contains one function for each task or trigger defined in the system. The task and trigger determines the name of the function:

```
void <TriggerName>_TaskName(void);
```

The content for each such function consists of target-independent C code, except for:

- Code corresponding to blocks that implement target-specific functionality
- Customizations, including those derived from custom storage classes (see “Organize Parameter Data into a Structure by Using Struct Storage Class” (Embedded Coder)) or “Code Replacement Libraries” (Simulink Coder)
- Code that is generated to handle how data is transferred between tasks. In particular, Simulink Coder uses target-specific implementations of mutual exclusion primitives and data synchronization semaphores to implement the data transfer as described in the following table of pseudocode.

Data Transfer	Initialization	Reader	Writer
Data Integrity Only	BufferIndex = 0; Initialize Buffer[1] with IC	Begin mutual exclusion Tmp = 1 - BufferIndex; End mutual exclusion Read Buffer[ Tmp ];	Write Buffer[ BufferIndex ]; Begin mutual exclusion BufferIndex = 1 - BufferIndex; End mutual exclusion
Ensure Determinism (Maximum Delay)	WriterIndex = 0; ReaderIndex = 1; Initialize Buffer[1] with IC	Read Buffer[ ReaderIndex ]; ReaderIndex = 1 - ReaderIndex;	Write Buffer[ WriterIndex ] WriterIndex = 1 - WriterIndex;
Ensure Determinism (Minimum Delay)	N/A	Wait dataReady; Read data; Post readDone;	Wait readDone; Write data; Post dataReady;
Data Integrity Only C-HDL interface	The Simulink Coder and HDL Coder products both take advantage of target-specific communication implementations and devices to handle the data transfer between hardware and software components.		

The generated HDL code contains one HDL project for each hardware node.

## Build on Desktop

Simulink Coder and Embedded Coder targets provide an example target to generate code for Windows, Linux and Mac OS operating systems. It is known as the native threads example, which is used to deploy your model to a desktop target. The desktop may not be your final target, but can help to profile and optimize your model before you deploy it on another target.

If you have specified an Embedded Coder target, make the following changes in the Configuration Parameters dialog box.

- 1 Select the **Code Generation > Templates > Generate an example main program** check box.
- 2 From the **Code Generation > Templates > Target Operating System** list, select **NativeThreadsExample**.
- 3 Click **OK** to save your changes and close the Configuration Parameters dialog box.
- 4 Apply these settings to all referenced models in your model.

Once you have set up your model, press **Ctrl-B** to build and deploy it to your desktop. The native threads example illustrates how Simulink Coder and Embedded Coder use target-specific threading APIs and data management primitives, as shown in “Threading APIs Used by Native Threads Example” on page 14-37. The data transfer between concurrently executing tasks behaves as described in Data Transfer Options. The coder products use the APIs on supported targets for this behavior, as described in “Data Protection and Synchronization APIs Used by Native Threads Example” on page 14-38.

### Threading APIs Used by Native Threads Example

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Periodic triggering event	POSIX timer	Windows timer	Not applicable

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Aperiodic triggering event	POSIX real-time signal	Windows event	POSIX non-real-time signal
Aperiodic trigger	For blocks mapped to an aperiodic task: thread waiting for a signal  For blocks mapped to an aperiodic trigger: signal action	Thread waiting for an event	For blocks mapped to an aperiodic task: thread waiting for a signal  For blocks mapped to an aperiodic trigger: signal action
Threads	POSIX	Windows	POSIX
Threads priority	Assigned based on sample time: fastest task has highest priority	Priority class inherited from the parent process.  Assigned based on sample time: fastest task has highest priority for the first three fastest tasks. The rest of the tasks share the lowest priority.	Assigned based on sample time: fastest task has highest priority
Example of overrun detection	Yes	Yes	No

### Data Protection and Synchronization APIs Used by Native Threads Example

API	Linux Implementation	Windows Implementation	Mac OS Implementation
Data protection API	<ul style="list-style-type: none"> <li>• pthread_mutex_init</li> <li>• pthread_mutex_ - destroy</li> <li>• pthread_mutex_lock</li> <li>• pthread_mutex_unlock</li> </ul>	<ul style="list-style-type: none"> <li>• CreateMutex</li> <li>• CloseHandle</li> <li>• WaitForSingleObject</li> <li>• ReleaseMutex</li> </ul>	<ul style="list-style-type: none"> <li>• pthread_mutex_init</li> <li>• pthread_mutex_ - destroy</li> <li>• pthread_mutex_lock</li> <li>• pthread_mutex_unlock</li> </ul>
Synchronization API	<ul style="list-style-type: none"> <li>• sem_init</li> <li>• sem_destroy</li> <li>• sem_wait</li> <li>• sem_post</li> </ul>	<ul style="list-style-type: none"> <li>• CreateSemaphore</li> <li>• CloseHandle</li> <li>• WaitForSingleObject</li> <li>• ReleaseSemaphore</li> </ul>	<ul style="list-style-type: none"> <li>• sem_open</li> <li>• sem_unlink</li> <li>• sem_wait</li> <li>• sem_post</li> </ul>

### Profile and Evaluate Explicitly Partitioned Models on a Desktop

Profile the execution of your code on the multicore target using the **Profile Report** pane of the Concurrent Execution dialog box. You can profile using Simulink Coder (GRT) and Embedded Coder (ERT) targets. Profiling helps you identify the areas in your model that are execution bottlenecks. You can analyze the execution time of each task and find the task that takes most of the execution time. For example, you can compare the average execution times of the tasks. If a task is computation

intensive, or does not satisfy real-time requirements and overruns, you can break it into tasks that are less computation intensive and that can run concurrently.

When you generate a profile report, the software:

- 1 Builds the model.
- 2 Generates code for the model.
- 3 Adds tooling to the generated code to collect data.
- 4 Executes the generated code on the target and collects data.
- 5 Collates the data, generates an HTML file (*model\_name\_ProfileReport.html*) in the current folder, and displays that HTML file in the **Profile Report** pane of the Concurrent Execution dialog box.

**Note** If an HTML profile report exists for the model, the **Profile Report** pane displays that file.

To generate a new profile report, click .

Section	Description
Summary	Summarizes model execution statistics, such as total execution time and profile report creation time. It also lists the total number of cores on the host machine.
Task Execution Time	Displays the execution time, in microseconds, for each task in a pie chart color coded by task.  Visible for Windows, Linux, and Mac OS platforms.
Task Affinitization to Processor Cores	Platform-dependent. For each time step and task, Simulink displays the processor core number the task started executing on at that time step, color coded by processor.  If there is no task scheduled for a particular time step, NR is displayed.  Visible for Windows and Linux platforms.

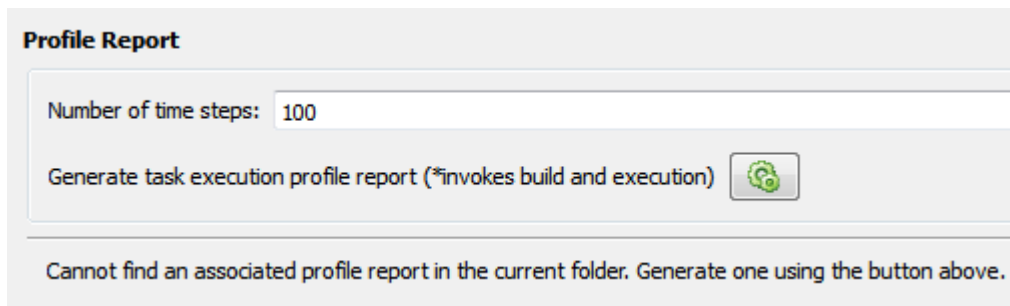

After you analyze the profile report, consider changing the mapping of Model blocks to efficiently use the concurrency available on your multicore system (see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-28).

### Generate Profile Report

This topic assumes a previously configured model ready to be profiled for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-20.

- 1 In the Concurrent Execution dialog box, click the **Profile report** node.

The profile tool looks for a file named *model\_name\_ProfileReport.html*. If such a file does not exist for the current model, the **Profile Report** pane displays the following.

---

**Note** If an HTML profile report exists for the model, the **Profile Report** pane displays that file.

To generate a new profile report, click .

---

- 2 Enter the number of time steps for which you want the profiler to collect data for the model execution.
- 3 Click the **Generate task execution profile report** button.

This action builds the model, generates code, adds data collection tooling to the code, and executes it on the target, which also generates an HTML profile report. This process can take several minutes. When the process is complete, the contents of the profile report appear in the **Profile Report** pane. For example:

## Task Execution Profiling Report for sllexMulticoreExample

### 1. Summary

Total simulation time [seconds]	9.9
Profile data created	Thu Nov 12 16:47:52 2015
Model name	sllexMulticoreExample
Number of processor cores on the host machine	12

### 2. Task Execution Time

Average Turnaround Time [microseconds]

Maximum Turnaround Time [microseconds]

### 3. Task Affinitization to Processor Cores

Clock Tick / Task	0	10	20	30	40
Task1	0	0	0	0	0
Task2	0	0	0	0	0
Task3	1	NR	1	NR	1
Task4	1	NR	NR	NR	NR

#### Legend

NR - Not scheduled to run

The profiling report shows the summary, execution time for each task, and the mapping of each task to processor cores. We see that tasks 1 and 2 run on core 0, where tasks 3 and 4 run on core 1. The **Task Execution Time** section of the report indicates that task 1 and task 3 take the most amount of time to run. Note that the period of task 3 is twice that of tasks 1 and 2, and the period of task 4 is twice that of task 3.

- Analyze the profile report. Create and modify your model or task mapping if needed, and regenerate the profile report.

#### Generate Profile Report at Command Line

Alternatively, you can generate a profile report for a model configured for concurrent execution at the command line. Use the `Simulink.architecture.profile` function.

For example, to create a profile report for the model `sllexMulticoreSolverExample`:

```
openExample('sllexMulticoreSolverExample');
Simulink.architecture.profile('sllexMulticoreSolverExample');
```

To create a profile report with a specific number of samples (100) for the model `sllexMulticoreSolverExample`:

```
Simulink.architecture.profile('sllexMulticoreSolverExample',120);
```

The function creates a profile report named `slxMulticoreSolverExample_ProfileReport.html` in your current folder.

## **Customize the Generated C Code**

The generated code is suitable for many different applications and development environments. To meet your needs, you can customize the generated C code as described in “Code and Tool Customization” (Embedded Coder). In addition to those customization capabilities, for multicore and heterogeneous targets you can further customize the generated code as follows:

- You can register your preferred implementation of mutual exclusion and data synchronization primitives using the code replacement library.
- You can define a custom target architecture file that allows you to specify target specific properties for tasks and triggers in the Concurrent Execution dialog box. For more information, see “Define a Custom Architecture File” on page 14-22.

## **See Also**

## Programmatic Interface for Concurrent Execution

Use these functions to configure models for concurrent execution.

To	Use
Create or convert configuration for concurrent execution.	<code>Simulink.architecture.config</code>
Add triggers to the software node or add tasks to triggers.	<code>Simulink.architecture.add</code>
Delete triggers or tasks.	<code>Simulink.architecture.delete</code>
Find objects with specified parameter values.	<code>Simulink.architecture.find_system</code>
Get configuration parameters for target architecture.	<code>Simulink.architecture.get_param</code>
Import and select architecture.	<code>Simulink.architecture.importAndSelect</code>
Generate profile report for model configured for concurrent execution.	<code>Simulink.architecture.profile</code>
Add custom target architecture.	<code>Simulink.architecture.register</code>
Set properties for a concurrent execution object (such as task, trigger, or hardware node).	<code>Simulink.architecture.set_param</code>
Configure concurrent execution data transfers.	<code>Simulink.GlobalDataTransfer</code>

### Map Blocks to Tasks

To map blocks to tasks, use the `set_param` function.

Map a block to one task:

```
set_param(block, 'TargetArchitectureMapping', [bdroot 'CPU/PeriodicTrigger1/Task1']);
```

Map a block to multiple tasks:

```
set_param(block, 'TargetArchitectureMapping', ...
  {[bdroot 'CPU/PeriodicTrigger1/Task1']; ...
  [bdroot 'CPU/PeriodicTrigger1/Task2']});
```

Get the current mapping of a block:

```
get_param(block, 'TargetArchitectureMapping');
```

- “Multicore Programming with Simulink” on page 14-8
- “Supported Targets For Multicore Programming” on page 14-44

## Supported Targets For Multicore Programming

### Supported Multicore Targets

You can build and download models that are implicitly or explicitly partitioned for the following multicore targets using system target files:

- Linux, Windows, and Mac OS using `ert.tlc` and `grt.tlc`.
- Simulink Real-Time using `slrealtime.tlc`.

---

#### Note

- To build and download your model, you must have Simulink Coder software installed.
  - To build and download your model to a Simulink Real-Time system, you must have Simulink Real-Time software installed. You must also have a multicore target system supported by the Simulink Real-Time product.
  - Deploying to an embedded processor that runs Linux and VxWorks® operating systems requires the Embedded Coder product.
- 

### Supported Heterogeneous Targets

In addition to multicore targets, Simulink also supports building and downloading partitions of an explicitly partitioned model to heterogeneous targets that contain a multicore target and one or more field-programmable gate arrays (FPGAs).

Select the heterogeneous architecture using the Target architecture option in the Concurrent Execution dialog box **Concurrent Execution** pane:

Item	Description
Sample Architecture	Example architecture consisting of single CPU with multiple cores and two FPGAs. You can use this architecture to model for concurrent execution.
Simulink Real-Time	Simulink Real-Time target containing FPGA boards.
Xilinx Zynq ZC702 evaluation kit	Xilinx® Zynq® ZC702 evaluation kit target.
Xilinx Zynq ZC706 evaluation kit	Xilinx Zynq ZC706 evaluation kit target.
Xilinx Zynq Zedboard	Xilinx Zynq ZedBoard™ target.
Altera Cyclone V SoC development kit Rev. C	Altera® Cyclone® SoC Rev. C development kit target.
Altera Cyclone V SoC development kit Rev. D	Altera Cyclone SoC Rev. D development kit target.
Arrow SoCKit development board	Arrow® SoCKit development board target.

---

**Note** Building HDL code and downloading it to FPGAs requires the HDL Coder product. You can generate HDL code if:

- You have an HDL Coder license
- You are building on Windows or Linux operating systems

You cannot generate HDL code on Macintosh systems.

---

## Limitations with Multicore Programming in Simulink

The following limitations apply when partitioning a model for concurrent execution.

- Configure the model to use the fixed-step solver.
- Do not use the following modes of simulation for models in the concurrent execution environment:
  - External mode for Mac desktop targets.
  - Logging to MAT-files (**MAT-file logging** check box selected). However, you can use the To Workspace and To File blocks.
  - If you are simulating your model using Rapid Accelerator mode, the top-level model cannot contain a root level Inport block that outputs function calls.
  - In the Configuration Parameters dialog box, set the **Diagnostics > Sample Time > Multitask conditionally executed subsystem** and **Diagnostics > Data Validity > Multitask data store** parameters to error.
- If you want to use explicit partitioning, at the root level of your model, the model must consist entirely of
  - Models that are referenced using Model blocks
  - Subsystem blocks
  - MATLAB System blocks
  - MATLAB Function blocks
  - Stateflow charts
  - Rate Transition blocks
  - Virtual connectivity blocks

The following are valid virtual connectivity blocks:

- Goto and From blocks
- Ground and Terminator blocks
- Inport and Outport blocks
- Virtual subsystem blocks that contain permitted blocks

## General Considerations when Building Simulink Models

In this section...
“Avoiding Invalid Loops” on page 15-2
“Shadowed Files” on page 15-3
“Model Building Tips” on page 15-5

### Avoiding Invalid Loops

You can connect the output of a block directly or indirectly (i.e., via other blocks) to its input, thereby, creating a loop. Loops can be very useful. For example, you can use loops to solve differential equations diagrammatically (see “Model a Continuous System” on page 15-6) or model feedback control systems. However, it is also possible to create loops that cannot be simulated. Common types of invalid loops include:

- Loops that create invalid function-call connections or an attempt to modify the input/output arguments of a function call (see “Using Function-Call Subsystems” on page 10-34 for a description of function-call subsystems)
- Self-triggering subsystems and loops containing non-latched triggered subsystems (see “Using Triggered Subsystems” on page 10-17 in the Using Simulink documentation for a description of triggered subsystems and Inport in the Simulink reference documentation for a description of latched input)
- Loops containing action subsystems

For triggered and function-call subsystem examples, see “Simulink Subsystem Semantics”.

You might find it useful to study these examples to avoid creating invalid loops in your own models.

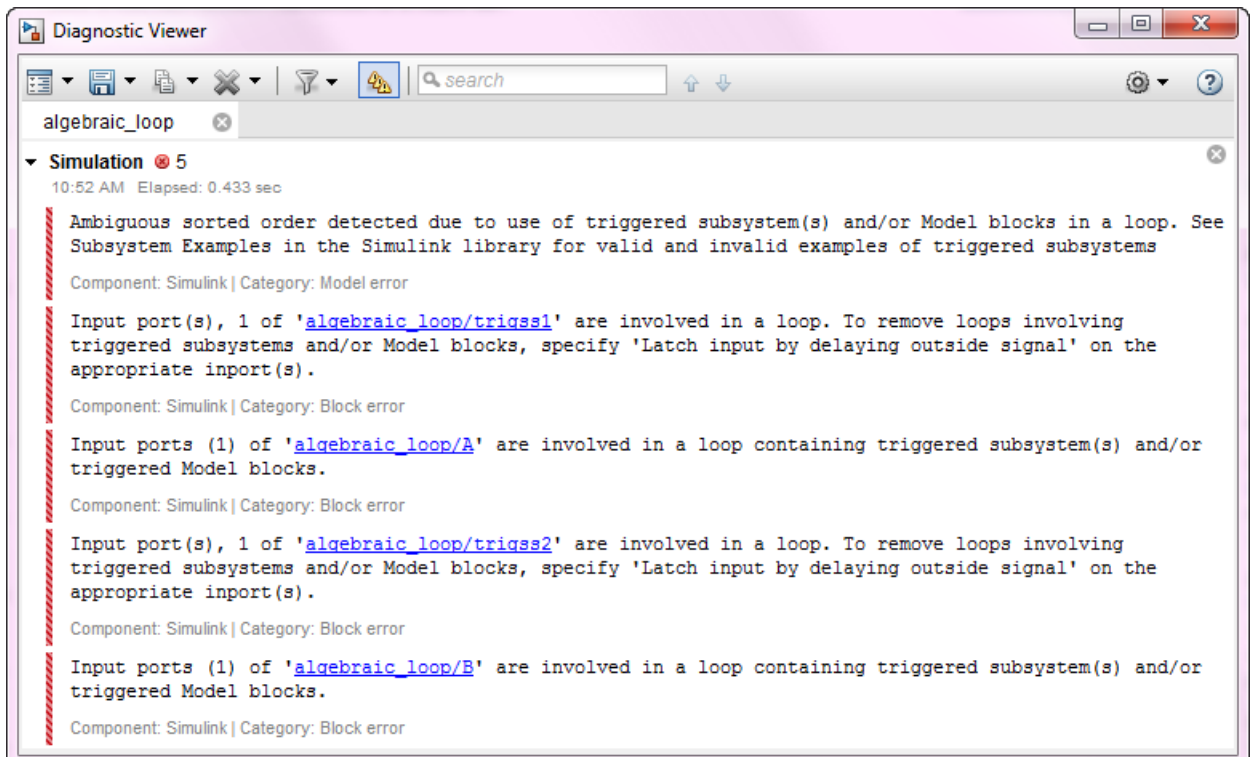

### Detecting Invalid Loops

To detect whether your model contains invalid loops, select **Update Model** from the **Modeling** tab of the toolstrip. If the model contains invalid loops, the invalid loops are highlighted. This is illustrated in the following model ,

and displays an error message in the Diagnostic Viewer.

## Shadowed Files

If there are two Model files with the same name (e.g. `mylibrary.slx`) on the MATLAB path, the one higher on the path is loaded, and the one lower on the path is said to be "shadowed".

---

**Tip** To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

---

The rules Simulink software uses to find Model files are similar to those used by MATLAB software. See “What Is the MATLAB Search Path?”. However, there is an important difference between how Simulink block diagrams and MATLAB functions are handled: a loaded block diagram takes precedence over any unloaded ones, regardless of its position on the MATLAB path. This is done for performance reasons, as part of the Simulink software's incremental loading methodology.

The precedence of a loaded block diagram over any others can have important implications, particularly since a block diagram can be loaded without the corresponding Simulink window being visible.

### **Making Sure the Correct Block Diagram Is Loaded**

When using libraries and referenced models, you can load a block diagram without showing its window. If the MATLAB path or the current MATLAB folder changes while block diagrams are in memory, these block diagrams can interfere with the use of other files of the same name.

For example, open a model with a library called `mylib`, change to another folder, and then open another model with a library also called `mylib`. When you run the first model, it uses the library associated with the second model.

This can lead to problems including:

- Simulation errors
- "Unresolved Link" icons on blocks that are library links
- Wrong results

### **Detecting and Fixing Problems**

To help avoid problems with shadowed files, you can turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

When updating a block diagram, the Simulink software checks the position of its file on the MATLAB path and will issue a warning if it detects that another file of the same name exists and is higher on the MATLAB path. The warning reads:

```
The file containing block diagram 'mylibrary' is shadowed  
by a file of the same name higher on the MATLAB path.
```

This may indicate that the wrong file called `mylibrary.slx` is being used. To see which file called `mylibrary.slx` is loaded into memory, enter:

```
which mylibrary  
  
C:\work\Modell\mylibrary.slx
```

To see all the files called `mylibrary` which are on the MATLAB path, including MATLAB scripts, enter:

```
which -all mylibrary
```

```
C:\work\Modell\mylibrary.slx  
C:\work\Model2\mylibrary.slx % Shadowed
```

To close the block diagram called `mylibrary` and let the Simulink software load the file which is highest on the MATLAB path, enter:

```
close_system('mylibrary')
```

## Model Building Tips

Here are some model-building hints you might find useful:

- Memory issues

In general, more memory will increase performance.

- Using hierarchy

More complex models often benefit from adding the hierarchy of subsystems to the model. Grouping blocks simplifies the top level of the model and can make it easier to read and understand the model. For more information, see “Create Subsystems” on page 4-17. The Model Browser provides useful information about complex models (see **Simulink Editor**).

- Cleaning up models

Well organized and documented models are easier to read and understand. Signal labels and model annotations can help describe what is happening in a model. For more information, see “Signal Names and Labels” on page 80-4 and “Describe Models Using Notes and Annotations” on page 4-4.

- Modeling strategies

If several of your models use the same blocks, you can save these blocks for easy reuse. For example, you can save a collection of blocks in a custom library. Then, when you build new models, you can copy these blocks from the library.

Generally, when building a model, design it first on paper, then build it using the computer. Then, when you start putting the blocks together into a model, add the blocks to the model window before adding the lines that connect them. This way, you can reduce how often you need to open block libraries.

- “Component-Based Modeling Guidelines” on page 23-2

## Model a Continuous System

To model the differential equation

$$\dot{x} = -2x(t) + u(t),$$

where  $u(t)$  is a square wave with an amplitude of 1 and a frequency of 1 rad/sec, use an integrator block and a gain block. The Integrator block integrates its input  $\dot{x}$  to produce  $x$ . Other blocks needed in this model include a Gain block and a Sum block. To generate a square wave, use a Signal Generator block and select the Square Wave form but change the default units to radians/sec. Again, view the output using a Scope block. Gather the blocks and define the gain.

In this model, to reverse the direction of the Gain block, select the block, then on the **Format** tab, click Flip left-right . To create the branch line from the output of the Integrator block to the Gain block, hold down the **Ctrl** key while drawing the line. For more information, see “Branch a Connection” on page 1-18.

Now you can connect all the blocks.

An important concept in this model is the loop that includes the Sum block, the Integrator block, and the Gain block. In this equation,  $x$  is the output of the Integrator block. It is also the input to the blocks that compute  $\dot{x}$ , on which it is based. This relationship is implemented using a loop.

The Scope displays  $x$  at each time step. For a simulation lasting 10 seconds, the output looks like this:

The equation you modeled in this example can also be expressed as a transfer function. The model uses the Transfer Fcn block, which accepts  $u$  as input and outputs  $x$ . So, the block implements  $x/u$ . If you substitute  $sx$  for  $x'$  in the above equation, you get

$$sx = -2x + u.$$

Solving for  $x$  gives

$$x = u/(s + 2)$$

or,

$$x/u = 1/(s + 2).$$

The Transfer Fcn block uses parameters to specify the numerator and denominator coefficients. In this case, the numerator is 1 and the denominator is  $s+2$ . Specify both terms as vectors of coefficients of successively decreasing powers of  $s$ .

In this case the numerator is [1] (or just 1) and the denominator is [1 2].

The results of this simulation are identical to those of the previous model.

## Best-Form Mathematical Models

### In this section...

“Series RLC Example” on page 15-9

“Solving Series RLC Using Resistor Voltage” on page 15-9

“Solving Series RLC Using Inductor Voltage” on page 15-10

### Series RLC Example

You can often formulate the mathematical system you are modeling in several ways. Choosing the best-form mathematical model allows the simulation to execute faster and more accurately. For example, consider a simple series RLC circuit.

According to Kirchoff's voltage law, the voltage drop across this circuit is equal to the sum of the voltage drop across each element of the circuit.

$$V_{AC} = V_R + V_L + V_C$$

Using Ohm's law to solve for the voltage across each element of the circuit, the equation for this circuit can be written as

$$V_{AC} = Ri + L \frac{di}{dt} + \frac{1}{C} \int_{-\infty}^t i(t) dt$$

You can model this system in Simulink by solving for either the resistor voltage or inductor voltage. Which you choose to solve for affects the structure of the model and its performance.

### Solving Series RLC Using Resistor Voltage

Solving the RLC circuit for the resistor voltage yields

$$V_R = Ri$$

$$Ri = V_{AC} - L \frac{di}{dt} - \frac{1}{C} \int_{-\infty}^t i(t) dt$$

#### Circuit Model

The following diagram shows this equation modeled in Simulink where  $R$  is 70,  $C$  is 0.00003, and  $L$  is 0.04. The resistor voltage is the sum of the voltage source, the capacitor voltage, and the inductor voltage. You need the current in the circuit to calculate the capacitor and inductor voltages. To calculate the current, multiply the resistor voltage by a gain of  $1/R$ . Calculate the capacitor voltage by integrating the current and multiplying by a gain of  $1/C$ . Calculate the inductor voltage by taking the derivative of the current and multiplying by a gain of  $L$ .

Series RLC Circuit: Formulated to solve for resistor current

This formulation contains a Derivative block associated with the inductor. Whenever possible, you should avoid mathematical formulations that require Derivative blocks as they introduce discontinuities into your system. Numerical integration is used to solve the model dynamics through time. These integration solvers take small steps through time to satisfy an accuracy constraint on the solution. If the discontinuity introduced by the Derivative block is too large, it is not possible for the solver to step across it.

In addition, in this model the Derivative, Sum, and two Gain blocks create an algebraic loop. Algebraic loops slow down the model's execution and can produce less accurate simulation results. See "Algebraic Loop Concepts" on page 3-39 for more information.

## Solving Series RLC Using Inductor Voltage

To avoid using a Derivative block, formulate the equation to solve for the inductor voltage.

$$V_L = L \frac{di}{dt}$$

$$L \frac{di}{dt} = V_{AC} - Ri - \frac{1}{C} \int_{-\infty}^t i(t) dt$$

### Circuit Model

The following diagram shows this equation modeled in Simulink. The inductor voltage is the sum of the voltage source, the resistor voltage, and the capacitor voltage. You need the current in the circuit to calculate the resistor and capacitor voltages. To calculate the current, integrate the inductor voltage and divide by  $L$ . Calculate the capacitor voltage by integrating the current and dividing by  $C$ . Calculate the resistor voltage by multiplying the current by a gain of  $R$ .

This model contains only integrator blocks and no algebraic loops. As a result, the model simulates faster and more accurately.

## Model a Simple Equation

To model the equation that converts Celsius temperature to Fahrenheit

$$T_F = 9/5(T_C) + 32$$

First, consider the blocks needed to build the model:

- A Ramp block to input the temperature signal, from the Sources library
- A Constant block to define a constant of 32, also from the Sources library
- A Gain block to multiply the input signal by 9/5, from the Math Operations library
- A Sum block to add the two quantities, also from the Math Operations library
- A Scope block to display the output, from the Sinks library

Next, gather the blocks into your model window.

Assign parameter values to the Gain and Constant blocks by opening (double-clicking) each block and entering the appropriate value. Then, click the **OK** button to apply the value and close the dialog box.

Now, connect the blocks.

The Ramp block inputs Celsius temperature. Open that block and change the **Initial output** parameter to 0. The Gain block multiplies that temperature by the constant 9/5. The Sum block adds the value 32 to the result and outputs the Fahrenheit temperature.

Open the Scope block to view the output. Now, choose **Run** from the **Simulation** menu to run the simulation. The simulation runs for 10 seconds.

## Model Differential Algebraic Equations

### In this section...

“Overview of Robertson Reaction Example” on page 15-14

“Simulink Model from ODE Equations” on page 15-14

“Simulink Model from DAE Equations” on page 15-16

“Simulink Model from DAE Equations Using Algebraic Constraint Block” on page 15-18

### Overview of Robertson Reaction Example

Robertson [1] on page 15-21 created a system of autocatalytic chemical reactions to test and compare numerical solvers for stiff systems. The reactions, rate constants ( $k$ ), and reaction rates ( $V$ ) for the system are given as follows:

Because there are large differences between the reaction rates, the numerical solvers see the differential equations as stiff. For stiff differential equations, some numerical solvers cannot converge on a solution unless the step size is extremely small. If the step size is extremely small, the simulation time can be unacceptably long. In this case, you need to use a numerical solver designed to solve stiff equations.

### Simulink Model from ODE Equations

A system of ordinary differential equations (ODE) has the following characteristics:

- All of the equations are ordinary differential equations.
- Each equation is the derivative of a dependent variable with respect to one independent variable, usually time.
- The number of equations is equal to the number of dependent variables in the system.

Using the reaction rates, you can create a set of differential equations describing the rate of change for each chemical species. Since there are three species, there are three differential equations in the mathematical model.

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

$$C' = 3 \cdot 10^7 B^2$$

Initial conditions:  $A = 1$ ,  $B = 0$ , and  $C = 0$ .

### Build the Model

Create a model, or open the model ex\_hb1ode.

- 1 Add three Integrator blocks to your model. Label the inputs  $A'$ ,  $B'$ , and  $C'$ , and the outputs  $A$ ,  $B$ , and  $C$  respectively.
- 2 Add Sum, Product, and Gain blocks to solve each differential variable. For example, to model the signal  $C'$ ,
  - a Add a Math Function block and connect the input to signal  $B$ . Set the **Function** parameter to square.
  - b Connect the output from the Math Function block to a Gain block. Set the **Gain** parameter to  $3e7$ .
  - c Continue to add the remaining differential equation terms to your model.
- 3 Model the initial condition of  $A$  by setting the **Initial condition** parameter for the  $A$  Integrator block to 1.
- 4 Add Out blocks to save the signals  $A$ ,  $B$ , and  $C$  to the MATLAB variable `yout`.

## Simulate the Model

Create a script that uses the `sim` command to simulate your model. This script saves the simulation results in the MATLAB variable `yout`. Since the simulation has a long time interval and `B` initially changes very fast, plotting values on a logarithmic scale helps to visually compare the results. Also, since the value of `B` is small relative to the values of `A` and `C`, multiply `B` by  $1 \cdot 10^4$  before plotting the values.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hblode` with the name of your model.

```
sim('ex_hblode')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with ODEs')
```

- 2 From the Simulink Editor, on the **Modeling** tab, click **Model Settings**.
  - In the Solver pane, set the **Stop time** to  $4e5$  and the **Solver** to `ode15s (stiff/NDF)`.
  - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3 Run the script. Observe that all of `A` is converted to `C`.

## Simulink Model from DAE Equations

A system of differential algebraic equations (DAE) has the following characteristics:

- It contains both ordinary differential equations and algebraic equations. Algebraic equations do not have any derivatives.
- Only some of the equations are differential equations defining the derivatives of some of the dependent variables. The other dependent variables are defined with algebraic equations.

- The number of equations is equal to the number of dependent variables in the system.

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to  $A = 1$ ,  $B = 0$ , and  $C = 0$ , the total concentration of the three species is always equal to 1 since  $A + B + C = 1$ . You can replace the differential equation for  $C$  with the following algebraic equation to create a set of differential algebraic equations (DAEs).

$$C = 1 - A - B$$

The differential variables  $A$  and  $B$  uniquely determine the algebraic variable  $C$ .

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

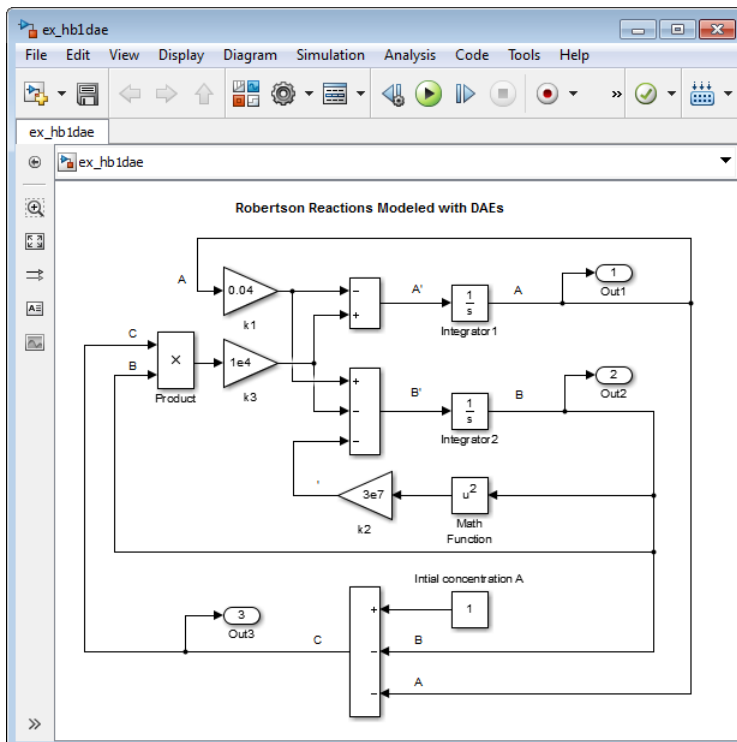

$$C = 1 - A - B$$

Initial conditions:  $A = 1$  and  $B = 0$ .

### Build the Model

Make these changes to your model or to the model `ex_hb1dae`, or open the model `ex_hb1dae`.

- Delete the Integrator block for calculating  $C$ .
- Add a Sum block and set the **List of signs** parameter to  $+ - -$ .
- Connect the signals  $A$  and  $B$  to the minus inputs of the Sum block.
- Model the initial concentration of  $A$  with a Constant block connected to the plus input of the Sum block. Set the **Constant value** parameter to  $1$ .
- Connect the output of the Sum block to the branched line connected to the Product and Out blocks.

## Simulate the Model

Create a script that uses the `sim` command to simulate your model.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1dae` with the name of your model.

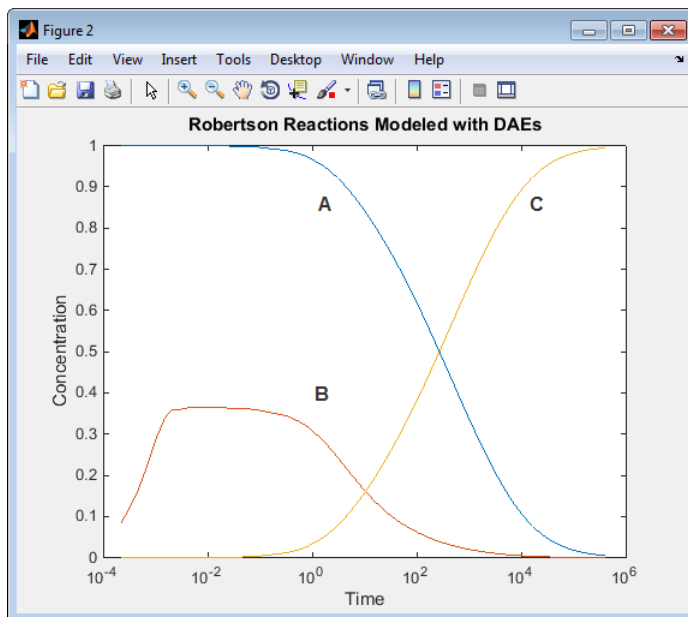

```
sim('ex_hb1dae')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs')
```

- 2 From the Simulink Editor, on the **Modeling** tab, click **Model Settings**.

— In the Solver pane, set the **Stop time** to  $4e5$  and the **Solver** to `ode15s (stiff/NDF)`.

— In the Data Import pane, select the **Time** and **Output** check boxes.

- 3 Run the script. The simulation results when you use an algebraic equation are the same as for the model simulation using only differential equations.

## Simulink Model from DAE Equations Using Algebraic Constraint Block

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to  $A = 1$ ,  $B = 0$ , and  $C = 0$ , the total concentration of the three species is always equal to 1 since  $A + B + C = 1$ .

You can replace the differential equation for  $C$  with an algebraic equation modeled using an Algebraic Constraint block and a Sum block. The Algebraic Constraint block constrains its input signal  $F(z)$  to zero and outputs an algebraic state  $z$ . In other words, the block output is a value needed to produce a zero at the input. Use the following algebraic equation for input to the block.

$$0 = A + B + C - 1$$

The differential variables  $A$  and  $B$  uniquely determine the algebraic variable  $C$ .

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

$$C = 1 - A - B$$

Initial conditions:  $A = 1$ ,  $B = 0$ , and  $C = 1 \cdot 10^{-3}$ .

### Build the Model

Make these changes to your model or to the model `ex_hb1dae`, or open the model `ex_hb1dae_acb`.

- 1 Delete the Integrator block for calculating  $C$ .
- 2 Add an Algebraic Constraint block. Set the **Initial guess** parameter to  $1e-3$ .
- 3 Add a Sum block. Set the **List of signs** parameter to  $-+++$ .
- 4 Connect the signals  $A$  and  $B$  to plus inputs of the Sum block.
- 5 Model the initial concentration of  $A$  with a Constant block connected to the minus input of the Sum block. Set the **Constant value** parameter to  $1$ .
- 6 Connect the output of the Algebraic Constraint block to the branched line connected to the Product and Out block inputs.
- 7 Create a branch line from the output of the Algebraic Constraint block to the final plus input of the Sum block.

## Simulate the Model

Create a script that uses the `sim` command to simulate your model.

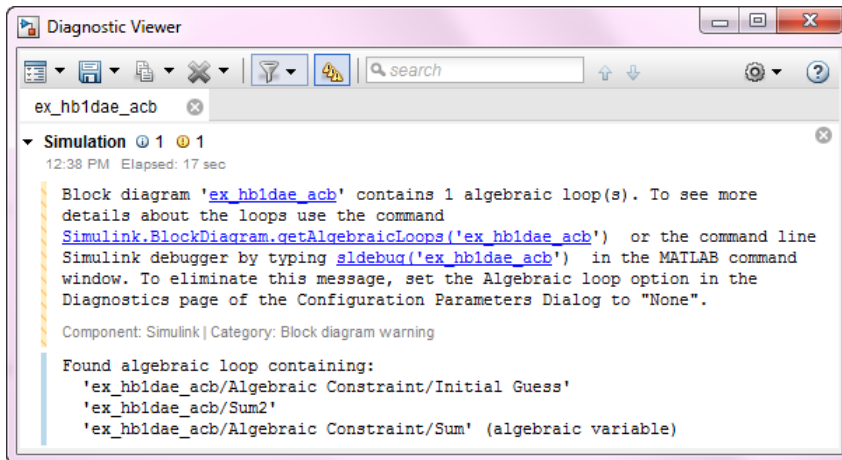

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hbl_acb` with the name of your model.

```
sim('ex_hbldae_acb')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs and Algebraic Constraint Block')
```

- 2 From the Simulink Editor, on the **Modeling** tab, click **Model Settings**.
  - In the Solver pane, set the **Stop time** to  $4e5$  and the **Solver** to `ode15s (stiff/NDF)`.
  - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3 Run the script. The simulation results when you use an Algebraic Constraint block are the same as for the model simulation using only differential equations.

Using an Algebraic Constraint block creates an algebraic loop in a model. If you set the **Algebraic Loop** parameter to `warning` (on the **Modeling** tab, click **Model Settings**, then select **Diagnostics**), the following message displays in the Diagnostic Viewer during simulation.

For this model, the algebraic loop solver was able to find a solution for the simulation, but algebraic loops don't always have a solution, and they are not supported for code generation. For more information about algebraic loops in Simulink models and how to remove them, see "Algebraic Loop Concepts" on page 3-39.

## Basic Modeling Workflow

In large, well-defined projects, you define file management and model architecture upfront. Your predefined requirements drive components and interfaces.

To understand how to create such projects, you must know how to create scalable models that represent system equations. This example shows how file storage and model architecture change to satisfy evolving project requirements as model size and complexity increases.

The example starts with a simple model that represents an algorithm.

The model grows and evolves into a simple project that manages the model, subsystem, and supporting files required by the model hierarchy.

Project - ModelingProjectExample			
Views	All	Project (8)	
Files			
Dependency Analyzer			
Name	Status	Type	
ex_modeling_mechanical_system.slx	✓	Simulink Subsystem	
ex_modeling_controller.slx	✓	Simulink Model	
ex_modeling_operator_variant.slx	✓	Simulink Model	
ex_modeling_variants.slx	✓	Simulink Model	
ex_modeling_variant_choice.m	✓	Script	
ex_modeling_data_controller.m	✓	Script	
ex_modeling_data_mechanical_system.m	✓	Script	
ex_modeling_bus_objects.m	✓	Function	

Walk through these steps to follow along with the modeling decisions as the model hierarchy evolves.

- 6** "Create Interchangeable Variations of Model Components" on page 15-39
- 7** "Set Up a File Management System" on page 15-41

You can use the files provided at any of these steps as starting points for your design. The final example helps you create a project that contains the model components and supporting files developed in this example set.

## Model a System Algorithm

When incomplete system requirements and a developing system design prevent you from defining file management and model architecture upfront, you can still model fundamental system algorithms. By organizing the model into inputs, outputs, and systems, you create a general framework for model components as the model grows.

To show the first stage of a modeling workflow that begins with limited information, this example uses a simple mechanical system composed of a mass, spring, and damper.

This second-order differential equation characterizes the system:

$$m\ddot{x} + c\dot{x} + kx = F$$

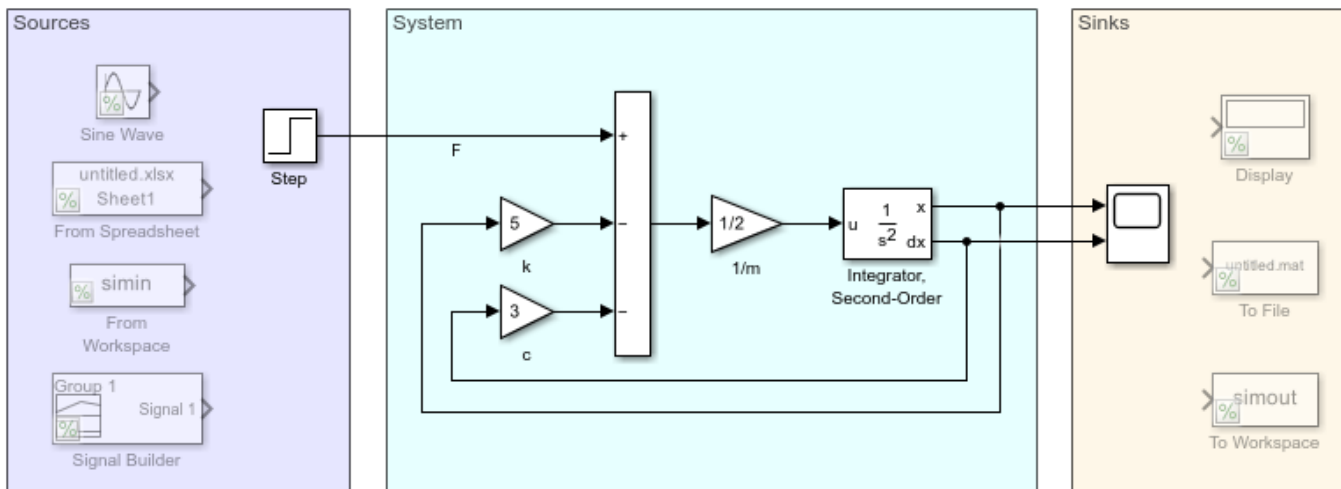

where

- $m$  is mass
- $c$  is the damping coefficient
- $k$  is the spring constant
- $\ddot{x}$  is acceleration
- $\dot{x}$  is velocity
- $x$  is displacement
- $F$  is force

Solving for  $\ddot{x}$  provides a form of this equation that maps more clearly to a Simulink® model.

$$\ddot{x} = \frac{1}{m}(F - c\dot{x} - kx)$$

In model `ex_modeling_simple_system`, a Sum block computes the forces applied to the mass, the Gain block labeled `1/m` computes the acceleration of the mass, and the Second-Order Integrator block solves for the velocity and position of the mass.

Copyright 2018-2019 The MathWorks, Inc.

These blocks, which represent the system, are grouped in an area. The two other areas contain system inputs and outputs. By organizing the model upfront, you create a general framework for model components as the model grows.

Since this example shows a model in the preliminary stages of development, the actual input force is unknown and can be represented by a variety of standard source blocks. Model `ex_modeling_simple_system` uses a Step block connected as input to the system. Some alternative source blocks are shown, but commented out. For example, you can use the From Spreadsheet block to load empirical data if it were available.

Similarly, a variety of sink blocks can accept the output displacement. To check whether simulation results meet expectations, model `ex_modeling_simple_system` uses a Scope block to visualize the signals.

## Create Model Components

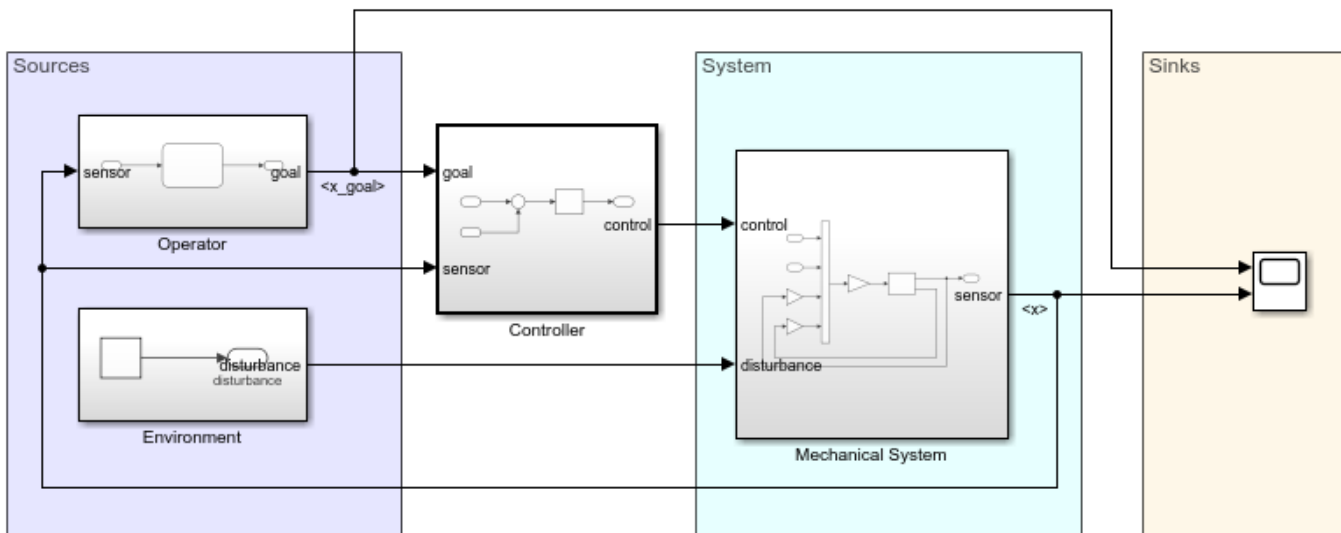

As you gather requirements for a system, you identify model components. You can identify where component interfaces exist even with incomplete specifications.

To define model components without affecting simulation results and specifying an interface that may change, you can create subsystems and visually organize the model.

Some components, such as digital controllers, should execute as a single unit within the model. For these standalone components with known boundaries, you can use an atomic subsystem. Defining atomic components upfront prevents costly refactoring when you want to generate standalone code.

Model `ex_modeling_components` contains four common model components.

- Mechanical System — A mass separated from a surface by a spring and damper
- Controller — Algorithm that controls the motion of the mechanical system
- Operator — Logic that defines the commands sent to the controller
- Environment — External disturbances that affect the mechanical system

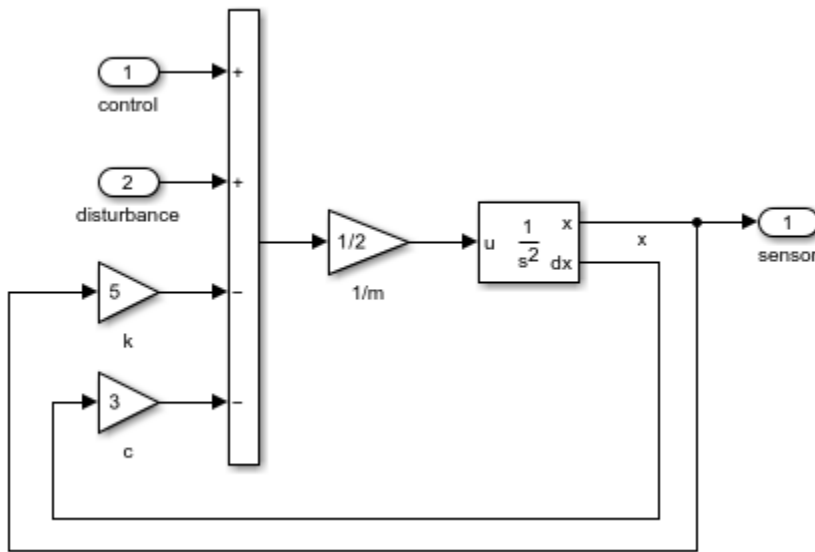

Copyright 2018-2019 The MathWorks, Inc.

The thicker line weight on the Controller block indicates that the controller is an atomic subsystem.

The ports on each of the Subsystem blocks correspond to input and output blocks within the subsystem. The block label shows the name of the corresponding port. For example, the Inport block labeled `disturbance` corresponds with the `disturbance` port of the Mechanical System block.

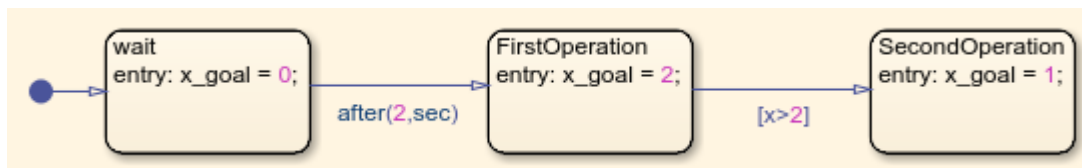

The four model components interact to determine the position of the mass.

The controller computes the force required to move the mechanical system to its goal position.

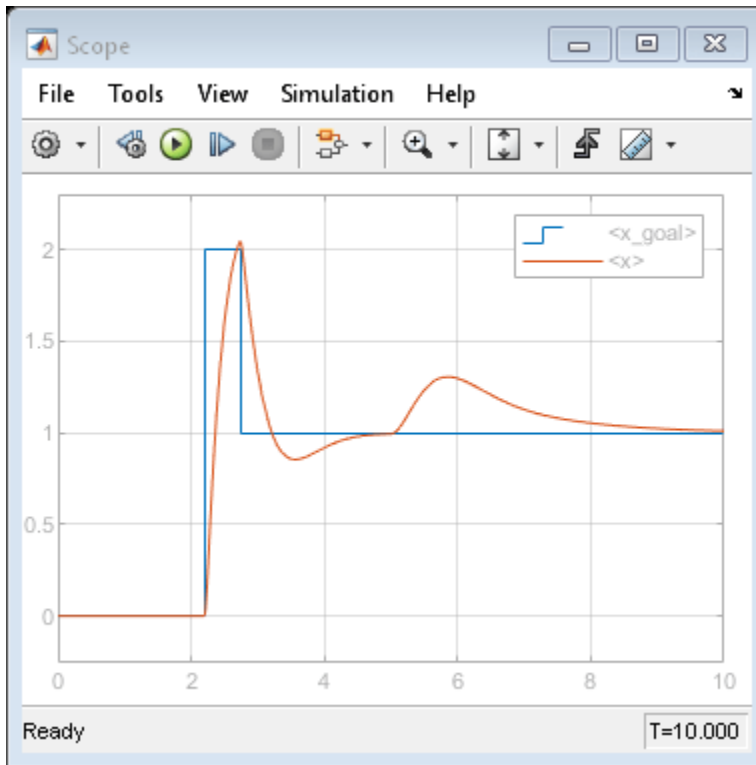

The operator determines the goal position of the mass and implements the related procedural logic with a Stateflow® chart.

The environment generates a disturbance force that affects the mechanical system.

During simulation, the operator tells the controller to wait 2 seconds, then move the mass up 2 meters. When the mass overshoots the goal position, the operator tells the controller to position the mass 1 meter above its original position. After 5 seconds, an environmental disturbance applies a steady force to the physical system and the controller reacts to stabilize the mass at the goal position.

## Manage Signal Lines

As a model grows, model components help functionally and visually organize blocks in the model. To similarly organize signal lines in the model, you can apply a variety of strategies, such as grouping signals into buses.

To demonstrate how to reduce signal line clutter, this example implements a model with multiple sensors and actuators. The system has two springs, dampers, and masses. A beam connects the two masses, as shown in this image.

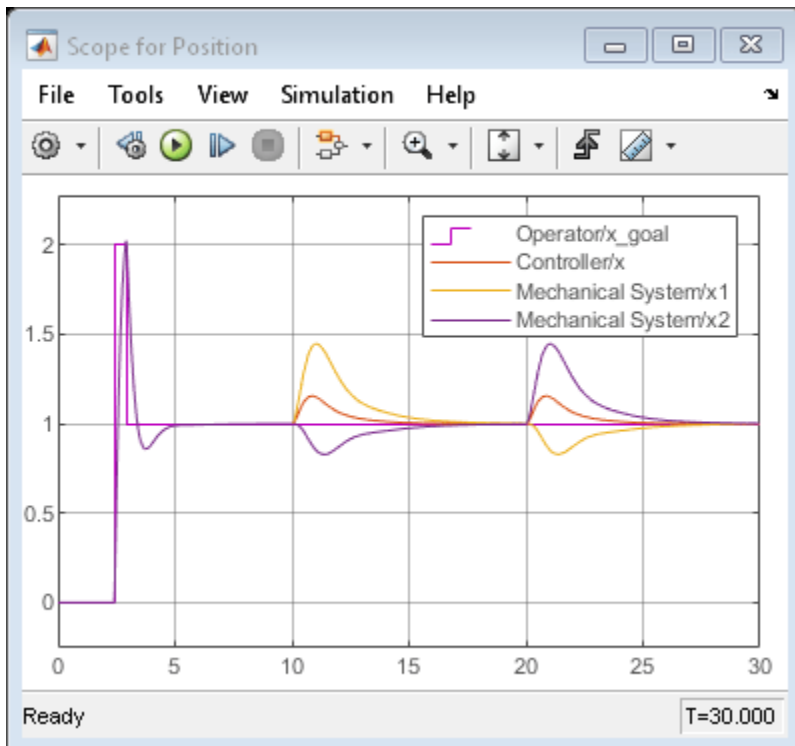

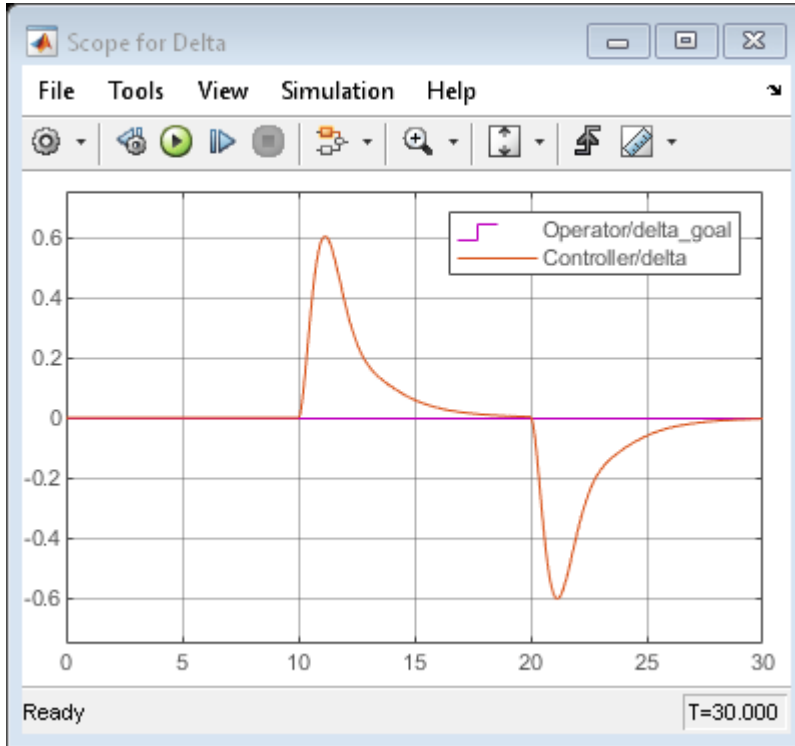

Sensors read the displacement of the masses. The controller regulates the height at the center of the beam  $x$  and levels the beam by computing the force the actuators must apply to the masses. The controller uses the height difference between the beam ends, *delta*, to level the beam.

Model `ex_modeling_signals` represents the system.

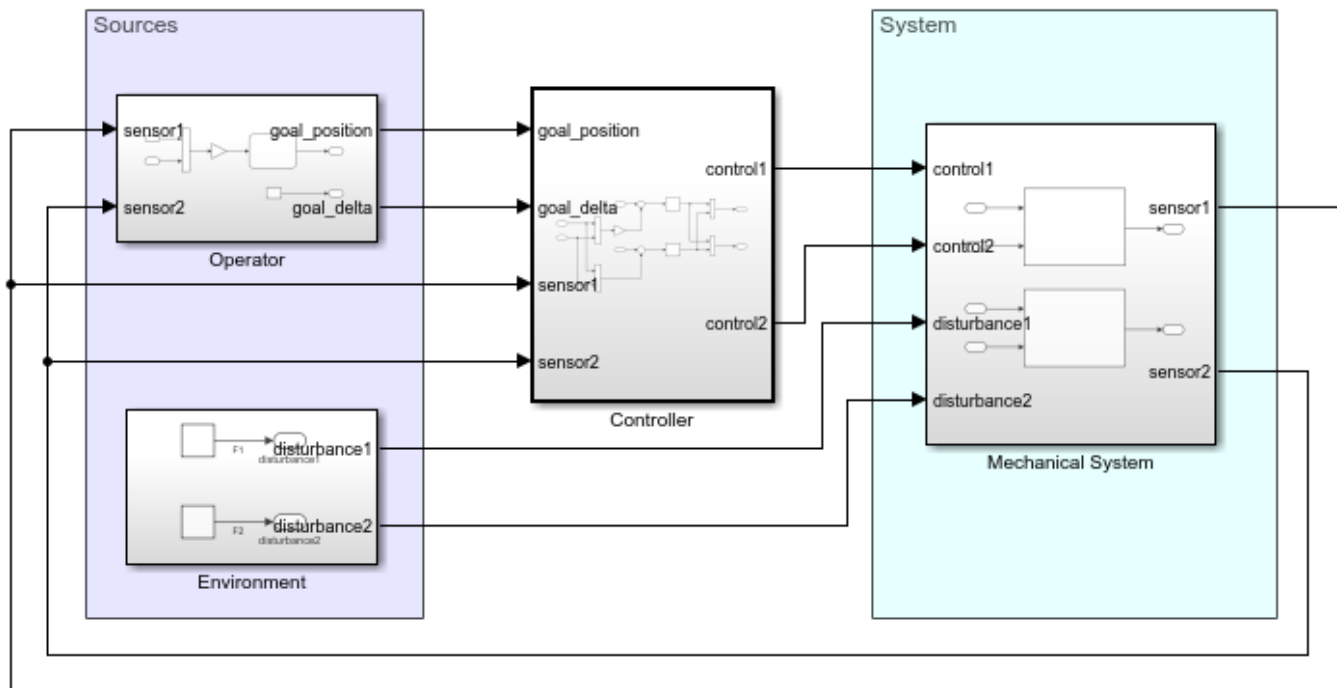

To display signals after simulation, the model uses two Scope blocks. One Scope block shows the goal and actual beam levelness. The other Scope block shows the goal and actual position of the beam at its center, along with the actual beam position at both ends.

To reduce the number of signal lines, you can connect a viewer directly to signal lines or enable data logging for signal lines. By choosing a way to visualize simulation data without using a sink block, you can avoid extra signal lines.

Model `ex_modeling_simulation_data_inspector` removes the Scope blocks and related signal lines, then enables data logging for those signals.

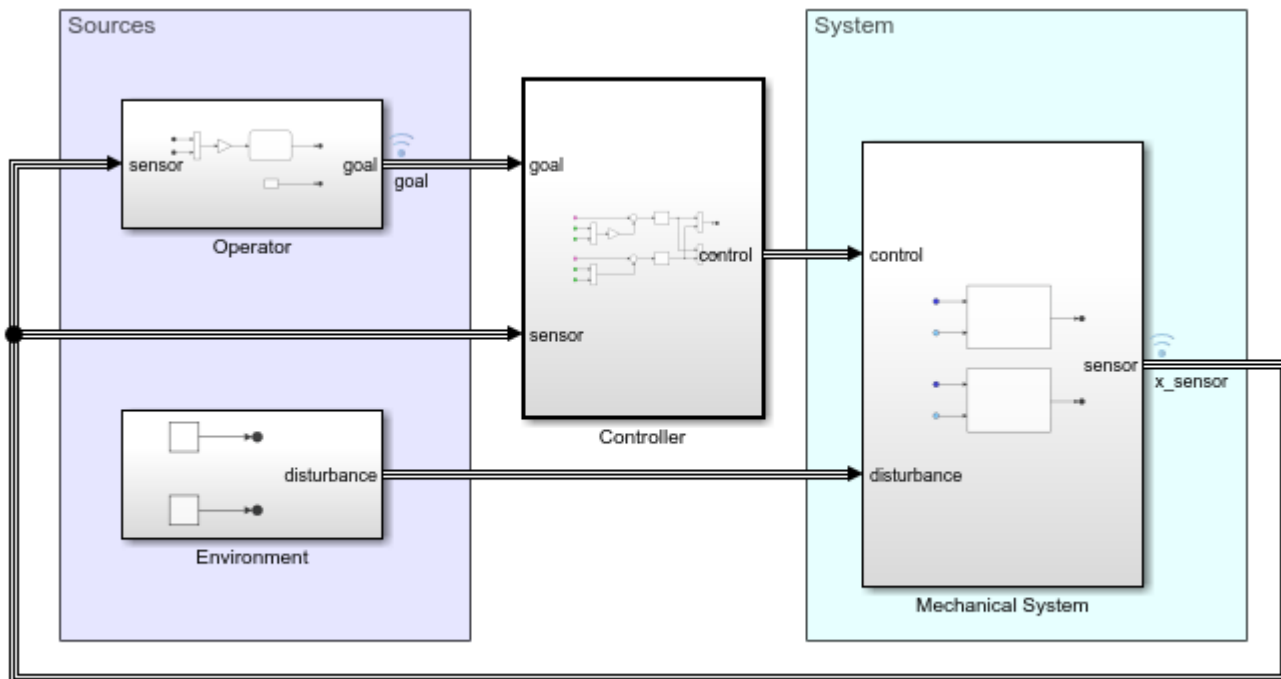

Copyright 2018-2019 The MathWorks, Inc.

To view the logged signals after simulation, open the Simulation Data Inspector by clicking the highlighted **Simulation Data Inspector** button.

To further reduce the number of signal lines, you can group signal lines into a bus by using a Bus Creator or Out Bus Element block. All signal lines retain their identities when grouped in a bus and can be separated downstream from the bus.

By creating buses, model `ex_modeling_composite_signals` provides an even more readable system representation.

Copyright 2018-2019 The MathWorks, Inc.

The simulation results remain the same after signals are grouped in buses. This example enables data logging for signal lines associated with buses `x_sensor` and `goal` instead of logging data individually for each of the signals in these buses.

## Manage Model Data

To define a parameter value that multiple blocks or models use, you can use variables. Separately updating numerical parameter values at each instance of the parameter can be inefficient and error prone. You can update the value of a variable in the workspace or source file that defines it. Having a single source for this information facilitates scalability and reusability of model components.

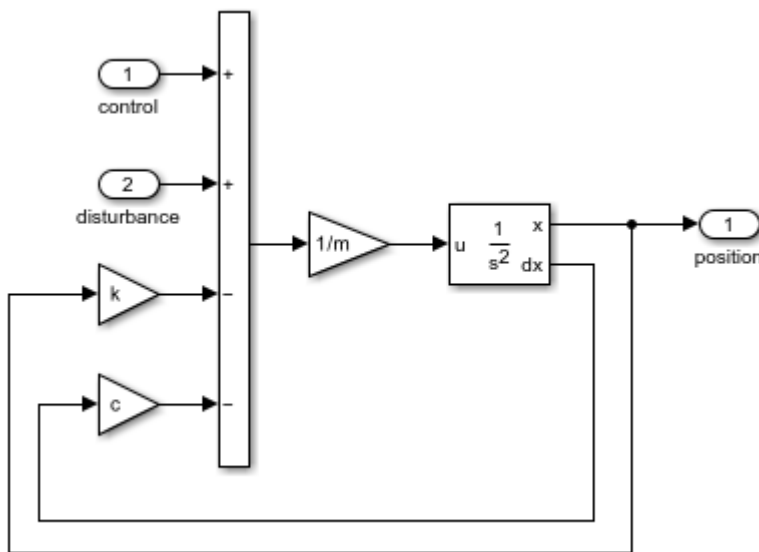

To specify value ranges, data types, tunability, and other characteristics of signals, states, and block parameters, you can use the `Simulink.Parameter` and `Simulink.Signal` objects. While you can use variables or objects to specify parameter values, this example uses variables for simplicity.

You can define variables by using these supporting file types:

- MAT-file
- MATLAB file
- Data dictionary

To load data for small models, you can use model callbacks. For large model hierarchies, different loading methods are more efficient.

In model `ex_modeling_data`, a `PreLoadFcn` model callback evaluates MATLAB file `ex_modeling_data_variables.m`, which defines variables  $k$ ,  $c$ , and  $m$  in the base workspace. Gain blocks in the mechanical system and PID Controller blocks in the controller use these variables.

You can interactively change variable values at the MATLAB® command prompt. You can also use tools like the Model Data Editor to edit values.

## Reuse Model Components from Files

When working on a large model, you can separate it into multiple files so that team members can develop different model components at the same time. You can reuse these components multiple times in a model and in other models.

Model, library, and subsystem files provide a single source for multiple instances of the same model component. To learn when you should use each of these componentization methods, see “Component-Based Modeling Guidelines” on page 23-2.

### Subsystems

Model `ex_modeling_component_reuse` references the contents of subsystem file `ex_modeling_mechanical_system.slx` twice to represent identical mechanical subsystems.

While you can define a subsystem for reuse in either a library or subsystem file, subsystem files allow for easier editing. When you edit a referenced subsystem, the changes apply to the subsystem file and all instances of the referenced subsystem.

Copyright 2019 The MathWorks, Inc.

## Models

Model `ex_modeling_component_reuse` references the contents of model file `ex_modeling_controller.slx`. Controller code is often deployed on embedded systems, so having a standalone controller model is useful.

Copyright 2018-2019 The MathWorks, Inc.

An embedded processor might not support default properties for the controller. Since a controller model might be used to generate code for an embedded processor, these constraints apply to the referenced controller model and the interface with its parent model:

- **Fixed Signal Attributes** — To require that buses at model interfaces share the same signal attributes, bus objects specify signal attributes at the three sets of input and output ports.

- Discrete Sample Time — To specify a discrete sample time, model `ex_modeling_controller` specifies a discrete execution domain and script `ex_modeling_data_controller.m` specifies discrete PID controller values.
- Fixed Data Type — To apply the single-precision data type required by the embedded processor, Data Type Conversion blocks convert the bus element data types before they reach the model interface.

## Create Interchangeable Variations of Model Components

To add flexibility to a model so that it can cater to different requirements, you can use variant subsystems and models. Variants allow you to choose among multiple variations of a component within a single model. You can change the active variant without modifying the model by changing the values of variant control variables at the MATLAB® command prompt.

Model `ex_modeling_variants` includes three variant choices for the operator subsystem.

Operator 1 is the active variant, which is defined by script `ex_modeling_variant_choice.m`. To determine the goal position for the mechanical system, this operator implements procedural logic with a Stateflow® chart.

Inactive variants and their contents are grayed out. To define the goal position for the mechanical system position, inactive variant subsystem Operator 2 uses a Waveform Generator block.

Variant choice Operator 3 is an inactive variant model. Variant Subsystem blocks allow both subsystems and models as variant choices.

## Set Up a File Management System

As a model grows, managing referenced files and dependencies becomes more complicated. To reduce the complexity of managing large models, you can use projects. Projects in Simulink help to organize large model hierarchies by finding required files, managing and sharing files and settings, and interacting with source control.

MATLAB® script `ex_modeling_project_setup.m` creates a project that contains these files:

- Subsystem file `ex_modeling_mechanical_system.slx`
- Model file `ex_modeling_variants.slx`
- Model file `ex_modeling_controller.slx`
- Model file `ex_modeling_operator_variant.slx`
- MATLAB script `ex_modeling_data_mechanical_system.m`
- MATLAB script `ex_modeling_data_controller.m`
- MATLAB script `ex_modeling_variant_choice.m`
- MATLAB function `ex_modeling_bus_objects.m`

Run the script to create the project.

Project - ModelingProjectExample			
Views	All	Project (8)	
Files			
Dependency Analyzer			
Name	Status	Type	
ex_modeling_mechanical_system.slx	✓	Simulink Subsystem	
ex_modeling_controller.slx	✓	Simulink Model	
ex_modeling_operator_variant.slx	✓	Simulink Model	
ex_modeling_variants.slx	✓	Simulink Model	
ex_modeling_variant_choice.m	✓	Script	
ex_modeling_data_controller.m	✓	Script	
ex_modeling_data_mechanical_system.m	✓	Script	
ex_modeling_bus_objects.m	✓	Function	

The MATLAB scripts and function are configured to **Run at Startup**.

Using this project, you can explore project capabilities, such as these capabilities:

- Automate tasks
- Create shortcuts for common actions
- Analyze file dependencies
- Analyze the impact of changing files
- Compare model files

In the Project **Views**, select **Dependency Analyzer** and click **Analyze** to run a dependency analysis on all the files in your project. In the dependency graph, hover over the dependency arrows to find the dependency type. It shows that the MATLAB scripts and functions are being run by model callbacks.

Since these files now run at startup, the model callbacks are redundant and can be removed.

The dependency graph also shows the two-level model hierarchy, in which the top model depends on a library and referenced model.

## What Are Projects?

You can use projects to help you organize your work. Find all your required files; manage and share files, settings, and user-defined tasks; and interact with source control.

If your work involves any of the following:

- More than one model file
- More than one model developer
- More than one model version

— then a project can help you organize your work. You can manage all the files you need in one place — all MATLAB and Simulink files, and any other file types you need such as data, requirements, reports, spreadsheets, tests, or generated files.

Projects can promote more efficient team work and individual productivity by helping you:

- Find all the files that belong with your project.
- Create standard ways to initialize and shut down a project.
- Create, store, and easily access common operations.
- View and label modified files for peer review workflows.
- Share projects using built-in integration with Subversion® (SVN) or Git, external source control tools.

Starting in R2019a, you can use projects in MATLAB, with or without Simulink. You can share projects with users who do not have Simulink.

For information on basic project workflows in MATLAB, see “Projects”.

Projects provide additional tools to help with Simulink workflows. For example:

- Opening models and running customizations on startup
- Checking for shadowed model files
- Dependency analysis of models, subsystems, libraries and library blocks, data files, requirements, and generated code
- Automatic refactoring help for models, libraries, library links, model references, model callbacks, S-functions, buses and bus elements
- Comparing and merging differences in models.

For help on project workflows in Simulink, see “Project Management”.

See the Web page <https://www.mathworks.com/products/simulink/projects.html> for the latest information, downloads, and videos.

To get started with managing your files in a project:

- 1** Try an example project to see how the tools can help you organize your work. See “Explore Project Tools with the Airframe Project” on page 16-5.
- 2** Create a new project. See “Create a New Project from a Folder” on page 16-17.
- 3** Analyze your project and check required files by using the Dependency Analyzer. See “Run a Dependency Analysis” on page 18-7.

- 4 Explore views of your files. See “Work with Project Files” on page 17-7.
- 5 Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-34.
- 6 Run custom task operations on batches of files. See “Run a Project Custom Task and Publish Report” on page 17-29.
- 7 If you use a source control integration, you can use the **Modified** files view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

### Explore the Airframe Project

Try an example project to see how the tools can help you organize your work. Projects can help you manage:

- Your design (model and library files, `.m`, `.mat`, and other files, source code for S-functions, and data)
- A set of actions to use with your project (run setup code, open models, simulate, build, and run shutdown code)
- Working with files under source control (check out, compare revisions, tag or label, and check in)

The Airframe example shows how to:

- 1 Set up and browse some example project files under source control.
- 2 Examine project shortcuts to access frequently used files and tasks.
- 3 Analyze dependencies in the example project and locate required files that are not yet in the project.
- 4 Modify some project files, find and review modified files, compare to an ancestor version, and commit modified files to source control.
- 5 Explore views of project files only, modified files, and all files under the project root folder.

### Set Up Project Files and Open the Project

Run this command to create a working copy of the project files and open the project:

```
sldemo_slproject_airframe
```

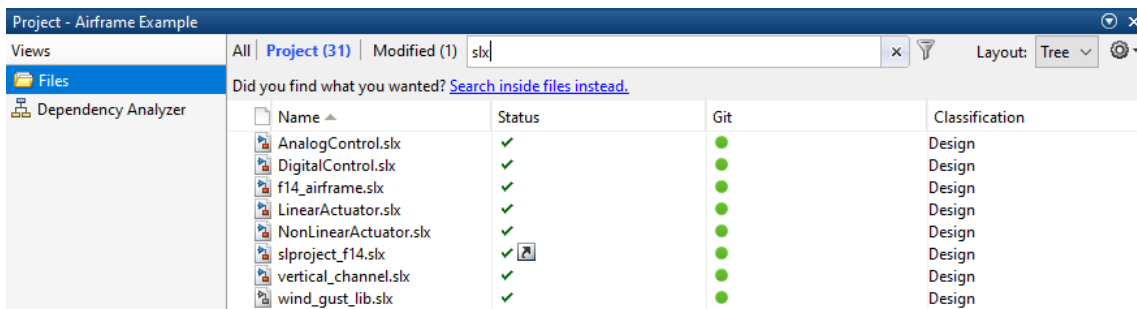

The project example copies files to your temporary folder so that you can edit them and put them under Git source control.

The Project window opens and loads the project. The project is configured to run some startup tasks, including changing the current working folder to the project root folder.

**Note** Alternatively, you can try this example project using SVN source control, by specifying `sldemo_slproject_airframe_svn`. The following example shows the options when using Git.

## View, Search, and Sort Project Files

- 1 In a Project, examine the **Files** view to manage the files within your project. When the **Project (number of files)** view is selected, only the files in your project are shown.
- 2 To see all the files in your sandbox, click **All**. This view shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to the project from your sandbox.
- 3 To find particular files or file types, in any file view, type in the search box or click the Filter button. You can also search inside files.

Click the **x** to clear the search.

- 4 To view files as a list instead of a tree, use the Layout control.
- 5 To sort files and to customize the columns, click the Organize view button at the far right of the search box.
- 6 You can dock and undock the Project into the MATLAB Desktop. If you want to maximize space for viewing your project files, undock the Project. Drag the title bar to undock it.

## Open and Run Frequently Used Files

You can use shortcuts to make scripts easier to find in a large project. View and run shortcuts on the Project Shortcuts toolstrip. You can organize the shortcuts into groups.

In this example, the script that regenerates S-functions is set as a shortcut so that a new user of the project can easily find it. You can also make the top-level model, or models, within a project easier to find. In this example, the top-level model, `slproject_f14.slx`, is a shortcut.

Regenerate the S-functions.

- 1 On the Project Shortcuts tab in the toolstrip, click the shortcut **Rebuild Project's S-functions**.

The shortcut file builds a MEX-file. If you do not have a compiler set up, follow the instructions to choose a compiler.

- 2 Open the `rebuild_s_functions.m` file to explore how it works.

Open the top model.

- On the Project Shortcuts tab, click the shortcut **F14 Model** to open the root model for this project.
- To create shortcuts to access frequently used files, select the **Files** view, right-click a file, and select **Create Shortcut**.

You can also specify files to run at startup and shutdown. See “Automate Startup Tasks” on page 16-29.

## Review Changes in Modified Files

Open and make changes to files and review changes.

- 1 Select the Files view. View folders using the tree layout, and then expand the `utilities` folder.
- 2 Either double-click to open the `find_top_model` file for editing from the project, or right-click and select **Open**.
- 3 Make a change in the Editor, such as adding a comment, and save the file.
- 4 In the project Files view, select the tab **Modified (number of files)**. After editing the file, you see **Modified (2)**. The files you changed appear in the list. You edited a file in the `utilities` folder. Observe that the Modified files list also includes a `resources` folder. The files stored in the `resources` folder are internal project definition files generated by your changes. The project definition files allow you to add metadata to files, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project. You can review changes in revisions of project definition files like any other project files. See “Project Definition Files” on page 19-41.
- 5 To review changes, right-click the `find_top_model` file in the **Modified** files view and select **Compare > Compare to Ancestor**.

The MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox against its ancestor stored in the version control tool. The comparison report type can differ depending on the file you select. If you select a Simulink model to **Compare > Compare to Ancestor**, this command runs a Simulink model comparison.

To compare models, try the following example.

- 1 In the Files view, select the **Project (number of files)** tab, and expand the models folder.
- 2 Either double-click to open the AnalogControl file for editing from the project, or right-click and select **Open**.
- 3 Make a change in the model, such as opening a block and changing some parameters, and then save the model.
- 4 To review changes, select the **Modified (number of files)** tab. Right-click the modified model file and select **Compare > Compare to Ancestor**.

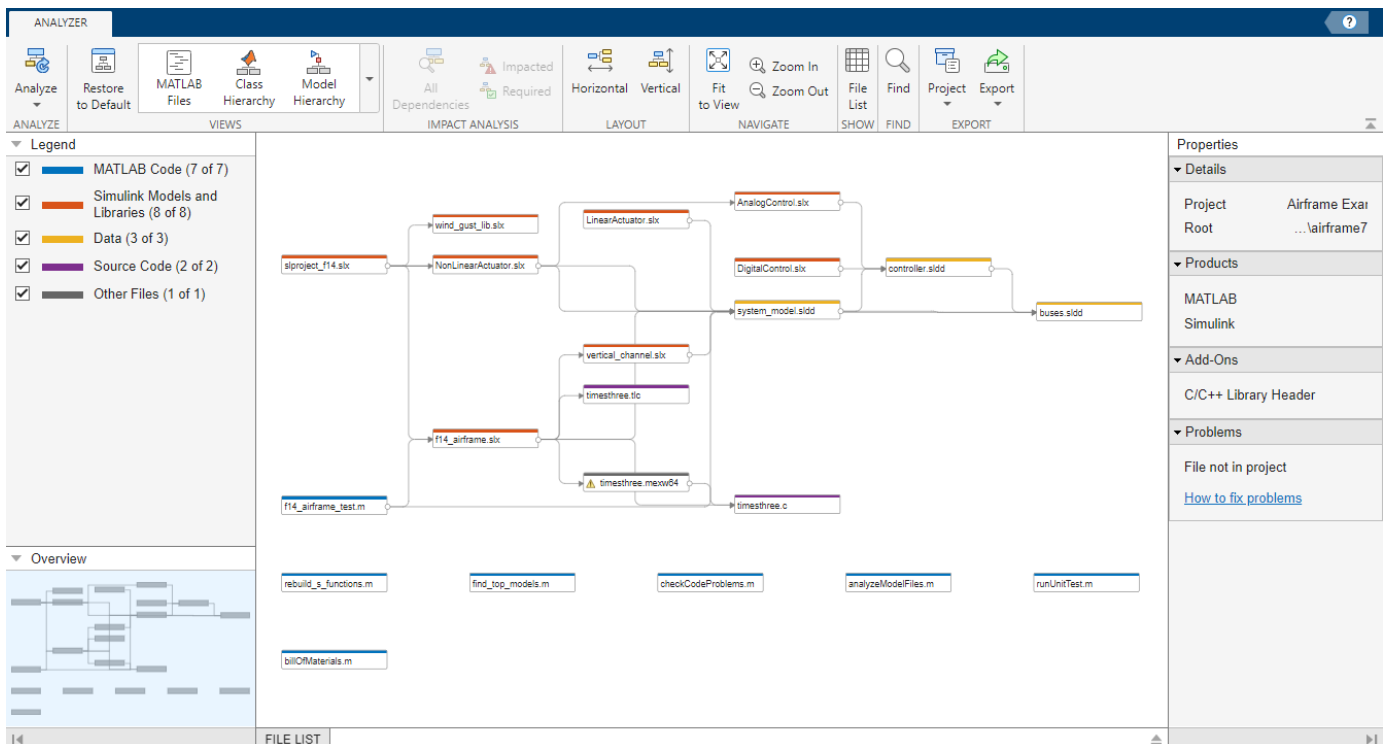

The Comparison Tool opens a report.

## Run Dependency Analysis

To check that all required files are in the project, run a file dependency analysis on the modified files in your project.

- 1 On the **Project** tab, click on the down arrow to expand the **Tools** gallery. Under **Apps**, click **Dependency Analyzer**.

The dependency graph displays the structure of all analyzed dependencies in the project. The **Properties** pane lists required products, add-ons, and any problem files.

- 2 To highlight the problem files, in the **Properties** pane, in the **Problems** section, point to the message **File not in Project** and click the magnifying glass icon .
- 3 Select the dependency arrow to examine the dependency type. `timesthree.mexw64` is an S-function binary file required by `f14_airframe.slx`. You can add binary files to your project or, as in this project, provide a utility script that regenerates them from the source code that is part of the project.

- 4 To remove the file from the problem files list, right-click the file and select **Hide Warnings**. The next time you run a dependency analysis, the file does not appear as a problem file.

In this example, you do not want to add the binary file to the project, but instead use the script to regenerate the binary file from the source code in the project. Use **Hide Warnings** to stop such files being marked as problems.

- 5 View dependencies of the modified files.
  - a In the Dependency Analyzer toolstrip, in the **Views** section, click **Source Control**. The color of each file in the graph now represents its source control status.
  - b In the dependency graph, select the modified files. To select multiple files, press **Shift** and click the files.
  - c In the Dependency Analyzer toolstrip, in the **Impact Analysis** section, click **All Dependencies**.

## Run Project Integrity Checks

To make sure that your changes are ready to commit, check your project. To run the project integrity checks, on the **Project** tab, click the down arrow to expand the **Tools** gallery. Under **Project Checks**, click **Check Project**. The checks look for missing files, files to add to source control or retrieve from source control, and other issues. The checks dialog box can offer automatic fixes to problems found. When you click a **Details** button in the Checks dialog box, you can view recommended actions and decide whether to make the changes.

## Commit Modified Files

After you modify files and you are satisfied with the results of the checks, you can commit your changes to the source control repository.

- 1 In the Files view, select the **Modified (number of files)** tab. The files you changed appear in the list.
- 2 To commit your changes to source control, on the Project tab, in the Source Control section, click **Commit**.
- 3 Enter a comment for your submission, and click **Submit**.

Watch the messages in the status bar as the source control commits your changes. Git commits to your local repository. To commit to the remote repository, use **Push** in the Source Control section. See “Pull, Push, and Fetch Files with Git” on page 19-51

## View Project and Source Control Information

- To view and edit project details, on the **Project** tab, in the **Environment** section, click **Details**. View and edit details such as the name, description, project root, startup folder, and generated files folders such as the `slprj` folder.
- To view details about the source control integration and repository location, on the Project tab, in the Source Control section, click **Git Details**. This Airframe example project uses Git source control.

Alternatively, use the project API to get the current project:

```
project = currentProject;
```

You can use the project API to get all the project details and manipulate the project at the command line. See `currentProject`.

For next steps, see “Project Management”.

## Create a Project from a Model

Create a project to organize your model and any dependent files. Use **Create Project from Model** to run a dependency analysis on your top model to identify required files.

---

**Tip** For a simpler option that automates more steps for you, see instead “Create a New Project from a Folder” on page 16-17.

---

Projects can help you organize your work and collaborate in teams. The project can help you to:

- Find all your required files
- Manage and share files, settings, and user-defined tasks
- Interact with source control.

- 1 In a Simulink model, on the **Simulation** tab, select **New > Project > New Project from this Model**.

Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies.

- 2 In the Create Project dialog box, edit any settings you want to change:

- **Name** — By default, the name of the suggested project root folder. Edit if desired.
- **Folder** — A folder that dependency analysis identified to contain all dependencies. If you want, click to select a different folder in the file system hierarchy between the file system root and the model folder.

All file dependencies in the project root folder are included in the project. All external dependencies are listed under **Dependencies**. If required files are outside your project root folder, then you cannot add these files to your project. An external dependency might not indicate a problem if the file is on your path and is a utility or other resource that is not part of your project.

- 3 Click **OK** to create the project containing your model and any other specified files.

For an example showing what you can do with projects, see “Explore Project Tools with the Airframe Project” on page 16-5.

## Set MATLAB Projects Preferences

You can set MATLAB projects preferences to specify project definition files type, detect project files shadowed by open models, and detect project-wide references when renaming, removing and deleting files.

On the **Home** tab, in the **Environment** section, click **Preferences**. Select **MATLAB > Project**. Then, adjust preference options as described in this table. Not all project preferences are available in MATLAB Online.

Preference	Usage
<b>New Projects</b>	To specify where to create new projects, in <b>Default folder</b> , browse to a folder on your system.
	To specify the <b>Project definition files</b> type for new projects, select an option based on your use case: <ul style="list-style-type: none"> <li>• <b>Use multiple project files (fixed path length)</b> is preferable if you need to work with long paths (default).</li> <li>• <b>Use multiple project files</b> helps to avoid file conflicts when performing merge on shared projects.</li> <li>• <b>Use a single project file (not recommended for source control)</b> is fast but likely causes merge issues when two users submit changes in the same project to a source control tool.</li> </ul>
	For details, see “Project Definition Files”.
	The <b>Project definition folder</b> , relative to the project root, is used to store the project metadata files. Select one of the available options to specify the folder name.
	To open the project welcome page after you create a new project, select <b>Show the welcome dialog after new project creation</b> .
<b>Project Startup</b>	To receive a warning about files shadowed by open models when opening a project, select <b>Detect project files shadowed by open models</b> .
	For details, see “Manage Shadowed and Dirty Models and Other Project Files” on page 17-8.
<b>Project Shutdown</b>	To receive a warning about files with unsaved changes when closing a project, select <b>Interrupt project close if there are dirty project files</b> .
	To automatically close project models when closing a project unless the project models contain unsaved changes, select <b>Check for open project models and close them, unless they are dirty</b> .
<b>File Management</b>	To disable the message that lists which files have changed after calling update to get the latest revisions from your SVN repository, clear <b>Show changes on source control updates</b> .

Preference	Usage
